Document Version: 1.1 – 2022-04-01

# SAP HANA Administration Guide for SAP HANA Platform

# Content

- 1     **SAP HANA Administration Guide.** . . . . . **9****
- 2     **Administration Information Map.** . . . . . **10****
- 3     **Database Administration Tasks at a Glance.** . . . . . **14****
- 4     **SAP HANA System Architecture Overview.** . . . . . **16****
- 4.1 Server Architecture of Tenant Databases. . . . . 16
  - Tenant Databases. . . . . 18
  - The System Database. . . . . 18
  - Administration of Tenant Databases. . . . . 19
- 4.2 Server Architecture of SAP HANA XS Advanced Runtime Platform. . . . . 21
- 4.3 Multiple-Host (Distributed) Systems. . . . . 24
  - Scale-Out Architecture of Tenant Databases. . . . . 25
  - Scale-Out Architecture of SAP HANA XS Advanced Runtime Platform. . . . . 27
- 4.4 Server Components of the SAP HANA Database. . . . . 30
- 4.5 System Limitations. . . . . 34
- 5     **SAP HANA Administration Tools.** . . . . . **39****
- 5.1 SAP HANA Cockpit. . . . . 42
  - Set Up SAP HANA Cockpit for the First Time. . . . . 43
  - Open the SAP HANA Cockpit. . . . . 45
  - Authorizations Needed for Monitoring and Administration. . . . . 46
  - Open the SAP HANA Database Explorer (SAP HANA Cockpit). . . . . 54
  - Setup and Administration with the Cockpit Manager. . . . . 61
  - Security Considerations for SAP HANA Cockpit. . . . . 110
  - Personalizing the Database Overview Page. . . . . 123
- 5.2 SAP HANA Studio. . . . . 123
  - Open the SAP HANA Administration Console. . . . . 124
  - Execute SQL Statements in SAP HANA Studio. . . . . 128
  - Managing SAP HANA Systems in SAP HANA Studio. . . . . 130
  - SAP HANA Studio Administration Preferences. . . . . 148
- 5.3 SAP HANA Hardware and Cloud Measurement Tools for Tailored Data Center Integration. . . . . 152
- 5.4 SAP Solution Manager for SAP HANA Administration. . . . . 153
  - Connecting SAP Solution Manager to SAP HANA. . . . . 154
  - Central Monitoring and Administration with SAP Solution Manager. . . . . 167
  - Analyzing the Root Cause of Problems. . . . . 168
  - Controlling Change. . . . . 168

<b>6</b>	<b>System Administration</b>	<b>170</b>
6.1	Aggregate Monitoring and Administration	170
	Landscape Monitoring and Administration	171
	Monitoring Multiple Systems in SAP HANA Studio	187
6.2	Starting and Stopping SAP HANA Systems	189
	Starting and Stopping Systems in SAP HANA Cockpit	190

# 1 SAP HANA Administration Guide

The SAP HANA Administration Guide is the central operations documentation for the on-premise deployment of the SAP HANA platform.

## Scope of this Document

The *SAP HANA Administration Guide* is the central administration guide which aims to provide background information and details of procedures to operate SAP HANA. However, there are several administration resources and tools available to administrators including cockpit applications and command line utilities; some of these tools have their own detailed documentation (see SAP HANA Administration Tools for a graphical overview of the tools available). This *SAP HANA Administration Guide* provides links to other documentation sets wherever necessary, in particular, the *SAP HANA SQL Reference Guide* and the *SAP HANA cockpit Administration Guide* are very closely integrated by linking.

The *SAP HANA Administration Guide* does not cover administration tasks related to some additional capabilities that may be installed in the SAP HANA system such as SAP HANA dynamic tiering and SAP HANA streaming analytics. For more information about the administration of these capabilities, see the relevant documentation on SAP Help Portal.

## Related Information

[SAP HANA Administration Tools \[page 39\]](#)

## 2 Administration Information Map

In addition to the SAP HANA Administration Guide, several other documents in the SAP HANA platform documentation set provide administrators with important information.

### SAP HANA Administration Guide

This guide is the entry point for all information related to the ongoing operation and maintenance of an on-premise deployment of the SAP HANA platform. It contains information about various administration tasks related to the following main areas:

- Administration and monitoring at the landscape, system, and database level
- Monitoring and configuration of security-related settings
- Landscape management and network administration
- Administration of the SAP HANA XS runtime environment
- Setup and management of the SAP HANA Deployment Infrastructure (HDI)
- High availability (including backup and recovery) and scalability
- Data access and integration with SAP HANA data provisioning tools and technologies

The *SAP HANA Administration Guide* also includes information on using the following native SAP HANA administration tools:

- SAP HANA cockpit

#### → Tip

For the documentation of the latest SAP HANA cockpit support package (SP), see [https://help.sap.com/viewer/p/SAP\\_HANA\\_COCKPIT](https://help.sap.com/viewer/p/SAP_HANA_COCKPIT)

- SAP HANA studio
- SAP HANA database lifecycle manager (HDBLCM)
- SAP HANA `hdsq1` command line
- SAP HANA XS administration tools
- SAP HANA application lifecycle management

### SAP HANA Troubleshooting and Performance Analysis Guide

This guide describes what steps you can take to identify and resolve specific performance issues and what you can do to enhance the performance of your SAP HANA database in areas such as:

- Host resources (CPU, memory, disk)
- Size and growth of data structures
- Transactional problems
- SQL statement performance
- Security, authorization, and licensing
- Configuration

Open the [SAP HANA Troubleshooting and Performance Analysis Guide](#)

## SAP HANA Tenant Databases Operations Guide

This guide brings together all the information required for the operation of an SAP HANA multitenant system, including:

- Overview of architecture and concepts of multitenant systems
- Creating and configuring tenant databases
- Monitoring and managing tenant databases
- Copying and moving tenant databases

Open the [SAP HANA Tenant Databases Operations Guide](#)

## SAP HANA Master Guide

This guide is the entry point for planning the installation of your SAP HANA system landscape. It provides you with overview information on the aspects such as:

- Use cases and scenarios that SAP HANA can be used in from an application point of view
- Deployment options for SAP HANA on-premise or in the cloud
- Implementation and operation activities during the lifecycle of SAP HANA

Open the [SAP HANA Master Guide](#)

## SAP HANA SQL and System Views Reference

The *SAP HANA SQL Reference* describes all SQL data types, predicates, operators, expressions, functions, statements, and error codes. The *SAP HANA System Views Reference* describes all system views. You can use the information in this guide to perform the following typical tasks:

- Monitor the current status of the SAP HANA system and database by querying monitoring views
- Analyze and diagnose historical monitoring data by querying statistics views
- Configure the database using SQL commands

Open the [SAP HANA SQL and System Views Reference](#)

## Administration Guides for Additional SAP HANA Capabilities

Separate administration information is available for the following additional capabilities that may be installed in your SAP HANA system:

- SAP HANA accelerator for SAP ASE
- SAP HANA data warehousing foundation
- SAP HANA dynamic tiering
- SAP HANA smart data integration and SAP HANA smart data quality
- SAP HANA streaming analytics
- SAP HANA real-time replication with SAP Landscape Transformation Replication Server

For more information, see the relevant documentation on SAP Help Portal.

### i Note

The topics listed above for each guide are not intended to be exhaustive but representative.

## Target Audiences

Document	Target Audience	Content Type
SAP HANA Administration Guide	Technology consultants, system administrators	Task- and role-oriented
SAP HANA Tenant Databases Operations Guide	Technology consultants, system administrators	Concept, task- and role-oriented
SAP HANA Troubleshooting and Performance Analysis Guide	Technology consultants, system administrators	Troubleshooting, root-cause analysis
SAP HANA Master Guide	Technology consultants, security consultants, system administrators	Concept and overview
SAP HANA SQL and System Views Reference	Technology consultants, security consultants, system administrators	Reference

## Additional Documentation Resources

### Product Documentation

For more information about the SAP HANA landscape, including installation and security, see [https://help.sap.com/viewer/p/SAP\\_HANA\\_PLATFORM](https://help.sap.com/viewer/p/SAP_HANA_PLATFORM).

# 3 Database Administration Tasks at a Glance

Overview of key tasks for the ongoing operation and maintenance of the SAP HANA database

## Initial Administration Tasks

After the initial setup and initial data load, it is strongly recommended that you perform a full data and file-system backup (including configuration backup). For more information, see the section on database backup and recovery.

### **i** Note

In replication scenarios with SAP Landscape Transformation Replication Server, do not switch off log writing during the initial data load from SAP ERP into the SAP HANA database. There is no system table or log file that records the information that log writing has been switched off, so it is not possible to check whether log writing has been switched on or off.

## Regular Administration Tasks

- Monitor the health of your SAP HANA system using, for example, the SAP HANA cockpit. The most important system information to review is:
  - Overall system status
  - Status of database services, for example, name server and index server
  - General system information (software versions and so on)
  - Alerts generated by the statistics service
  - Usage of important system resources: memory, CPU and disk

For more information, see *Monitoring the SAP HANA Database*. The SAP Note 2400024 - *How-To: SAP HANA Administration and Monitoring* also gives details of recommended tasks in the area of administration, monitoring and housekeeping.

- Perform regular data backups, including configuration backups. There are no specific guidelines for backup frequency, which depends on the usage scenario, but for general guidelines, see *Planning Your Backup and Recovery Strategy*.
- Avoid the log backup area becoming full by archiving old log backups to a different location.

### **⚠** Caution

Do not delete log segments at the operating system level, as the log area will become unusable and the database may stop working.

For more information, see *Housekeeping for Backup Catalog and Backup Storage*.

- Monitor disk space used for diagnosis files and delete files that are no longer needed.
- Check for the latest configuration parameter recommendations  
The SAP Note 2600030 - *Parameter Recommendations in SAP HANA Environments* is updated regularly with version-specific information covering cases where configuration parameter settings other than the default values are recommended.

## On-Demand Administration Tasks

- In the event of problems with the SAP HANA database, you can check log and trace files for errors. You can also activate and configure several trace types.  
For more information, see *Diagnosis Files* and *Configure Traces*.
- Before updating SAP HANA, perform a data backup including configuration files. This allows for the recovery of the system in the event the software update fails.

## Recurring Administration Tasks

Both SAP HANA Extended Services classic model and advanced model provide job-scheduling features so that you can run routine administration tasks in the background at planned intervals.

The following job-scheduling features are available:

- SAP HANA XS classic: Use the .xsjob file to run XS JavaScript functions or call an SQLScript procedure
- SAP HANA XS advanced: Use the Job Scheduler service and Job Scheduler Dashboard for administrators

# 4 SAP HANA System Architecture Overview

An SAP HANA system comprises multiple isolated databases and may consist of one host or a cluster of several hosts.

An **SAP HANA system** is identified by a single system ID (SID) and contains one or more tenant databases and one system database. Databases are identified by a SID and a database name. From the administration perspective, there is a distinction between tasks performed at system level and those performed at database level. Database clients, such as the SAP HANA cockpit, connect to specific databases.

The **SAP HANA XS advanced application server** is a layer on top of SAP HANA that provides the platform for running SAP HANA-based Web applications. It is an integral part of the SAP HANA system.

A system may consist of one host or a cluster of several hosts. This is referred to as a **multiple-host, distributed system, or scale-out system** and supports scalability and availability.

The following sections provide overview information about these aspects of system architecture.

## Related Information

[Server Architecture of Tenant Databases \[page 16\]](#)

[Server Architecture of SAP HANA XS Advanced Runtime Platform \[page 21\]](#)

[Multiple-Host \(Distributed\) Systems \[page 24\]](#)

[Server Components of the SAP HANA Database \[page 30\]](#)

## 4.1 Server Architecture of Tenant Databases

An SAP HANA database consists of multiple servers, for example, name server, index server, preprocessor server, and so on. The databases in an SAP HANA system run different combinations of these servers. The most important server is the index server. It contains the actual data stores and the engines for processing the data and runs in every tenant database.

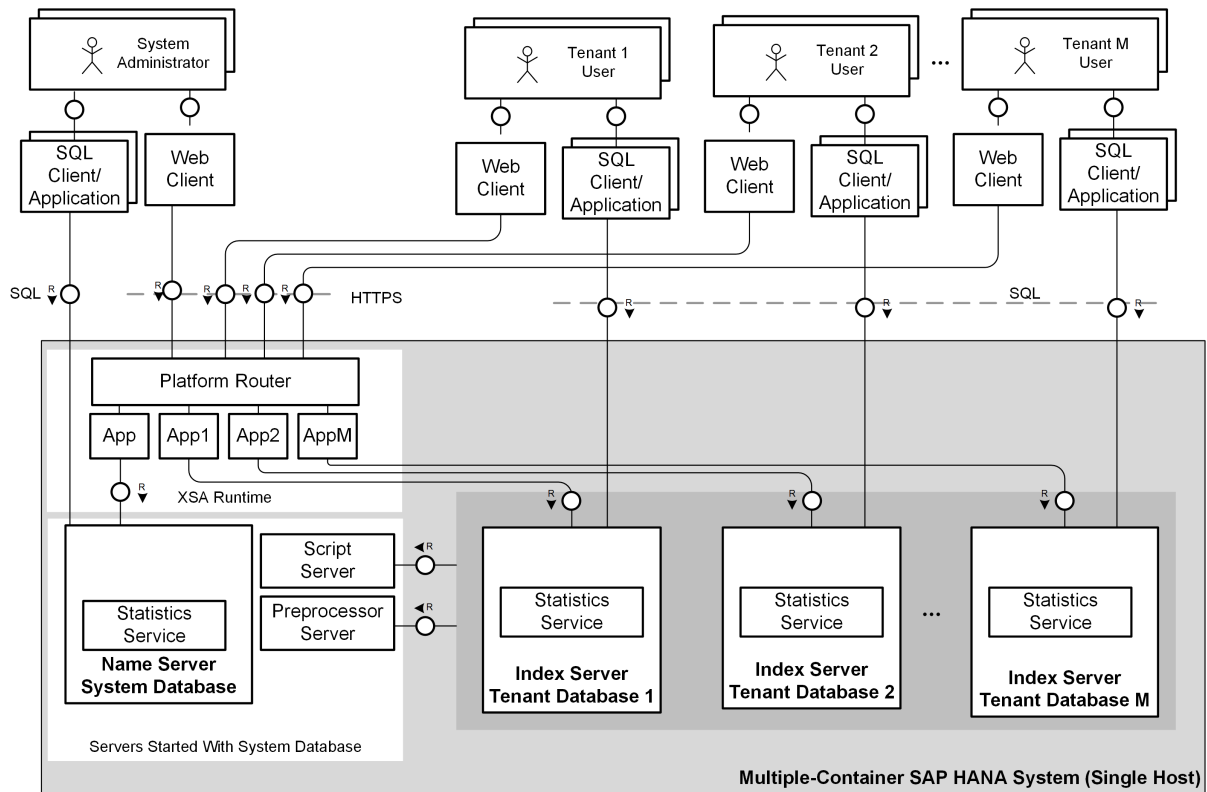

Only the **system database** runs the name server. The name server contains landscape information about the system as a whole, including which tenant databases exist. It also provides index server functionality for the system database. The name server does not own information about the location of tables and table partitions in tenant databases. Database-related information is stored in the relevant tenant database catalog.

**Tenant databases** require only an own index server. Servers that do not persist data, such as the compile server and the preprocessor server, run on the system database and serve all databases.

### i Note

For a full list and description of all SAP HANA servers, see *Server Components of the SAP HANA Database*.

The following figure shows a sample system with three databases (system database and three tenant databases) on a single host.

Single-Host SAP HANA System with Tenant Databases

### Note

If the SAP HANA XS classic server is available, it runs embedded in the (master) index server of the tenant database by default, although it can be added as a separate service if necessary. The **SAP Web Dispatcher**, which runs as a separate database service on the host of the system database, is used to route incoming HTTP requests from clients to the correct XS classic server based on virtual host names. This is part of network configuration. In addition to the system-internal Web Dispatcher, you can implement an external Web Dispatcher for load distribution. See the section on using the SAP Web Dispatcher for load balancing with tenant databases.

## 4.1.1 Tenant Databases

SAP HANA supports multiple isolated databases in a single SAP HANA system. These are referred to as tenant databases.

An SAP HANA system is capable of containing more than one tenant database.

A system always has exactly one system database, used for central system administration, and any number of tenant databases (including zero). An SAP HANA system is identified by a single system ID (SID). Databases are identified by a SID and a database name. From the administration perspective, there is a distinction between tasks performed at system level and those performed at database level. Database clients, such as the SAP HANA cockpit, connect to specific databases.

All the databases share the same installation of database system software, the same computing resources, and the same system administration. However, each database is self-contained and fully isolated with its own:

- Set of database users
- Database catalog
- Repository
- Persistence
- Backups
- Traces and logs

Although database objects such as schemas, tables, views, procedures, and so on are local to the database, cross-database SELECT queries are possible. This supports cross-application reporting, for example.

[Administration of Tenant Databases \[page 19\]](#)

## 4.1.2 The System Database

The system database is created during either installation or conversion from a single-container system to a tenant database system. The system database contains information about the system as a whole, as well as all its tenant databases. It is used for central system administration.

A system has exactly one system database. It contains the data and users for system administration. System administration tools, such as the SAP HANA cockpit, can connect to this database. The system database stores overall system landscape information, including knowledge of the tenant databases that exist in the system. However, it doesn't own database-related topology information, that is, information about the location of tables and table partitions in databases. Database-related topology information is stored in the relevant tenant database catalog.

Administration tasks performed in the system database apply to the system as a whole and all of its databases (for example, system-level configuration settings), or can target specific tenant databases (for example, backup of a tenant database). For more information, see *Administration of Tenant Databases*.

## Things to Remember About the System Database

- The system database does not have the same functionality as a tenant database.
- The system database is not a database with full SQL support.
- The system database cannot be distributed across multiple hosts, in other words, scale-out is not possible.
- If you need a full-featured SAP HANA database, you always have to create at least one tenant database.
- The system database does not support Application Function Libraries (AFL) and SAP liveCache applications.
- Cross-database access between the system database and a tenant database is not possible. The system database can show monitoring data from tenant databases (views in the schema SYS\_DATABASES) but can never show actual content from tenant databases.
- The system database cannot be copied or moved to another host.
- SAP HANA options can only run in tenant databases.
- Tenant-specific configurations cannot be set in the system database. Only global settings are allowed.
- Features can only be restricted or disabled at high level for tenant databases.

## Related Information

[Cross-Database Authorization in Tenant Databases](#)

[Restricted Features in Tenant Databases](#)

## 4.1.3 Administration of Tenant Databases

In SAP HANA systems there is a distinction between administration tasks performed at system level and those performed at database level.

### System Versus Database Administration

Tenant database systems have two levels of administration.

Some administration tasks are performed in the system database and apply globally to the system and all its databases. They include for example:

- Starting and stopping the whole system
- Monitoring the system
- Configuring parameters in configuration (\*.ini) files at system level
- Setting up and configuring tenant databases, for example:
  - Creating and dropping tenant databases
  - Disabling features on tenant databases
  - Configuring system- and database-specific parameters in configuration (\*.ini) files
  - Scaling out tenant databases by adding services
- Backing up tenant databases
- Recovering tenant databases

Some administration tasks are performed in the tenant database and apply only to that database. They include for example:

- Monitoring the database
- Provisioning database users
- Creating and deleting schemas, tables, and indexes in the database
- Backing up the database
- Configuring database-specific parameters in configuration (\*.ini) files

## Administration Tools

Several tools are available for the administration of SAP HANA. While all tools support database-level administration, system-level administration of tenant databases requires the SAP HANA cockpit (for example, monitoring availability of tenant databases, creating and deleting tenant databases).

For more information about the SAP HANA cockpit and other administration tools, see the section on administration tools in the *SAP HANA Administration Guide*.

## 4.2 Server Architecture of SAP HANA XS Advanced Runtime Platform

SAP HANA extended application services, advanced model (XS advanced for short) provides a comprehensive platform for the development and execution of micro-service oriented applications, taking advantage of SAP HANA's in-memory architecture and parallel execution capabilities.

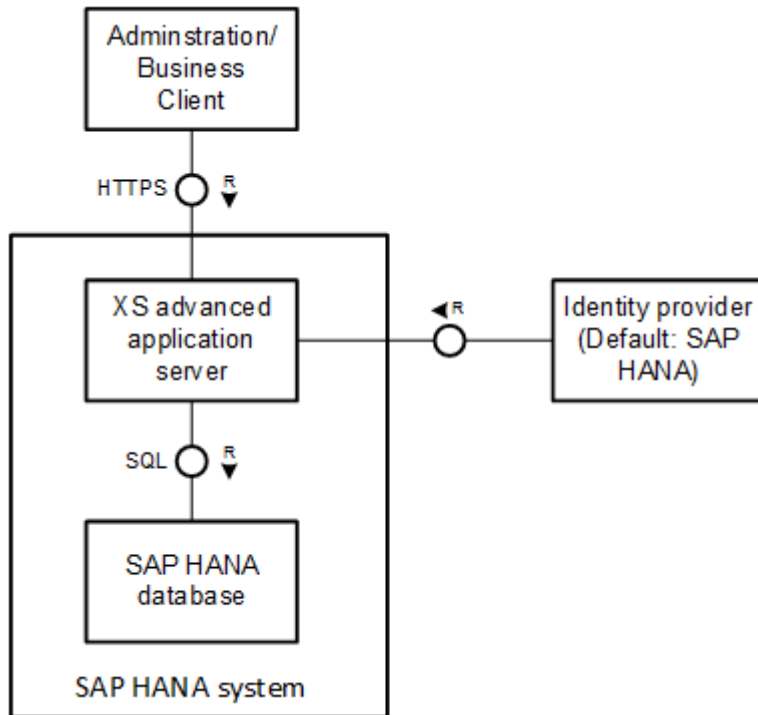

### About SAP HANA XS Advanced

SAP HANA XS advanced offers a rich set of embedded services that enable an end-to-end support for web-based applications including lightweight web servers, persistency services, and a configurable identity provider. Furthermore, the platform supports polyglot application development with a core set of pre-deployed runtimes that are accepted as industry standard, for example, node.js or JavaEE.

Although the built-in runtimes come with first-class development and monitoring support, the platform has an open architecture that allows you to add custom runtimes. This high flexibility makes it essential that you put a strong focus on security concepts, not only when configuring and setting up the infrastructure, but also throughout operating the system.

## Architecture Overview

As illustrated in the following diagram, the basic system architecture has a classic 3-tier approach:

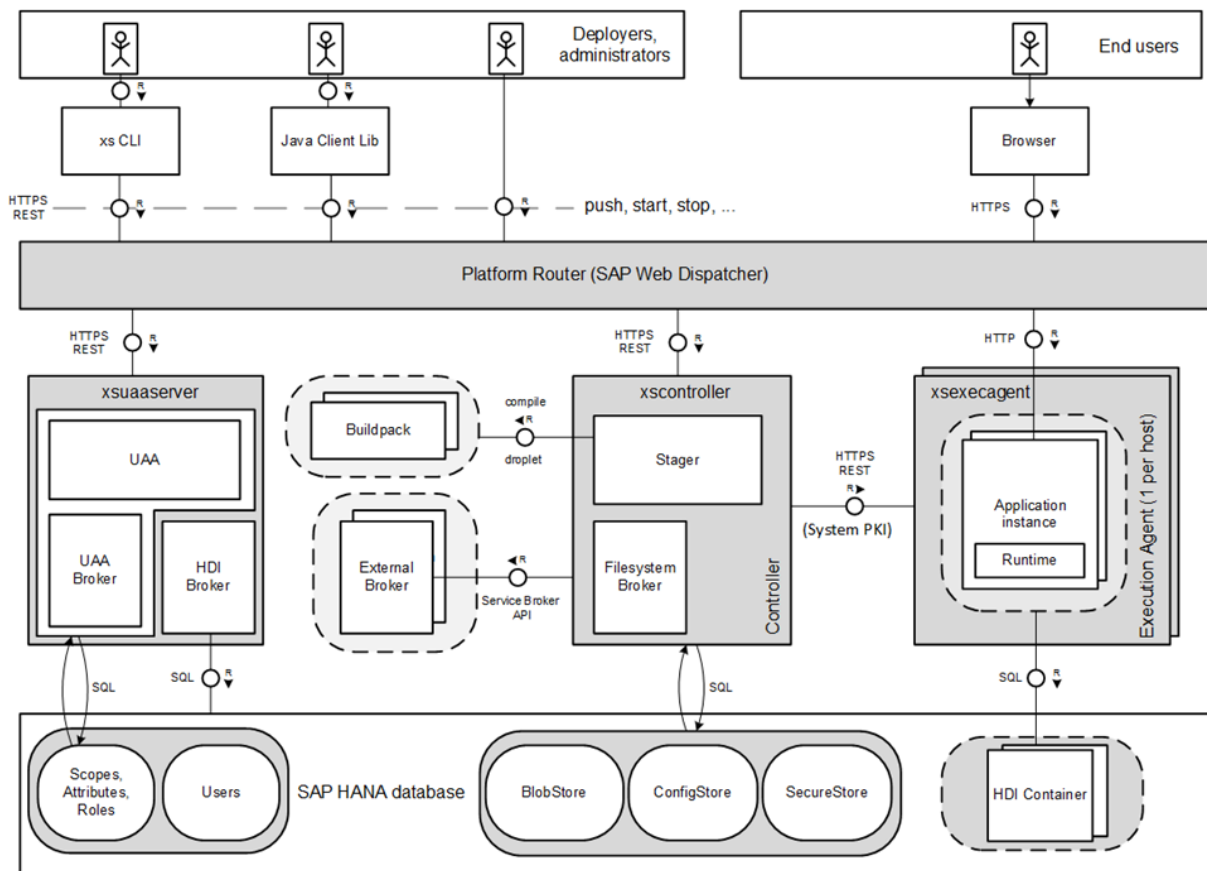

3-Tier Architecture of SAP HANA with XS Advanced

There is a distinction between the overall SAP HANA system and the SAP HANA XS advanced application server. The SAP HANA system refers to the entire SAP HANA platform part of the integrated solution. The SAP HANA XS advanced application server describes only the runtime platform as an integral part of the solution. All services of the SAP HANA system share the same system identifiers (that is, instance number and SID) and are controlled by the `hdbdaemon` service.

The third tier, represented by an SAP HANA database, provides persistency services, that is, data storage. In contrast, the application server components in the middle tier are responsible for deploying, running, and monitoring the applications. Most security-related features such as authentication, authorization, and auditing are primarily enforced in this layer. End users interact on the client layer with system or business users that are authenticated by an identity provider (IdP), which is SAP HANA user management by default. However, both the server components and the applications themselves access the SAP HANA database only through technical database users that the platform generates implicitly. Direct access to the database is only intended for database administration and monitoring purposes.

The following diagram provides a more detailed overview of the technical system landscape of the XS advanced application server. All relevant components and storages used by the application server layer are highlighted with a gray background.

Technical System Landscape of XS Advanced Application Server

The XS advanced application server relies on the following SAP HANA services contributing to the integrated platform solution:

1. `xscontroller` (Controller, FileSystem Broker, Platform Router)
2. `xsexecagent` (Execution Agent)
3. `xsuaaserver` (UAA, UAA Broker and SAP HANA Service Broker)

## Administration of the XS Advanced Runtime

A number of administration tools are available to enable you to maintain and manage the various components of the XS advanced runtime environment. For more information, see the section on maintaining the SAP HANA XS advanced model run time.

## 4.3 Multiple-Host (Distributed) Systems

An SAP HANA system can be distributed across multiple hosts for reasons of scalability and availability.

A multiple-host or distributed SAP HANA system is a system that is installed on more than one host. Otherwise, it is a single-host system.

An SAP HANA system installed on multiple hosts is identified by a single system ID (SID). It is perceived as one unit from the perspective of the administrator, who can install, update, start up, or shut down the system as a whole. The different databases of the system share the same metadata and requests from client applications can be transparently dispatched.

The main reason for distributing a system across multiple hosts is **scale-out**. A multiple-host system can overcome hardware limitations of a single physical server, and it can distribute the load between multiple servers. Distributing a system also supports **failover**. One or more hosts can be configured to work in standby mode, so that if an active hosts fails, a standby host automatically takes its place. The index servers on standby hosts do not contain any data and do not receive any requests.

For more information about hosts, including host roles, fail-over configuration, and storage options, see the *SAP HANA Server Installation and Update Guide*.

### Distributing Data

In a multiple-host system each index server is usually assigned to its own host for maximum performance. SAP HANA supports different ways of distributing data across the hosts:

- Different tables can be assigned to different index servers.
- A table can be split, or partitioned, in a way that different rows of the table are stored on different index servers
- A table can be replicated to multiple index servers, for better query and join performance.

When you create new tables or partitions, data is distributed to the available hosts by the system. By default a 'round-robin' distribution method is used, but tables can also be positioned by using table placement rules or by specifying a host and port number with the SQL CREATE TABLE statement in the location clause; this gives complete control over the positioning of individual tables.

Specific applications may have predefined table distribution rules and in some cases configuration files and documentation are available in SAP Notes to help you to set up the necessary partitioning and table placement rules.

For more information, see the sections on table placement, table partitioning, and table replication.

## Distributed Execution

Database clients may send their requests to any index server on any host in a distributed system. If the contacted index server does not own all of the data involved, it delegates the execution of some operations to other index servers, collects the result, and returns it to the database client. The SAP HANA client library supports load balancing and minimizes communication overhead by selecting connections based on load data and routing statements based on information about the location of data.

For more information, see the sections on connecting to SAP HANA databases and servers and statement routing in the *SAP HANA Client Interface Programming Reference*.

### 4.3.1 Scale-Out Architecture of Tenant Databases

Tenant databases can be distributed across several hosts in a multiple-host system.

To ensure system availability, an instance of the system database runs on all hosts (worker and standby) in a single master and multiple workers configuration. Tenant databases can be created on worker hosts and existing databases can be scaled out through the addition of services. If a host fails, the standby instance will fail over all active databases and their services. Like in a single-host system, the master candidate for a failing host is determined. On that host the system database is restarted, if necessary. Up to three hosts can be configured to act as the master host of a system. These three hosts can be set up in the clients with the database name to be reconnected to a tenant database even in the case of a host auto-failover of the master host with the system database.

The following figure shows a tenant database system with three tenant databases distributed across three hosts. Tenant database DB1 has only one index server on host 1, while DB2 and DB3 are distributed across several hosts. Tenant database DB2, for example, is divided into three database shards, each of them with its own index server on a different host. In this context, a database shard is the union of all tables, partitions and replicas of one database that reside on one index server. Tenant database DB3 consists of two shards, one on host 2 and one on host 3. System administrators can specify the host when they create the tenant database, or they can let SAP HANA choose an appropriate host based on load-balancing algorithms.

## Scale-Out Recommendations

When planning your SAP HANA deployment with tenant databases, various options exist with regard to scale-up versus scale-out.

In general, scaling up offers some performance advantages over scaling out, as memory access is local and minor overhead associated with inter-node network communication is avoided.

Note the following with regard to scale-out:

- It is possible to distribute tenant databases across several hosts in a scale-out system.
- The primary reason to distribute tenant databases generally is when their size is larger than the capacity of a single host. However, other reasons for distributing tenant database may exist, for example, a large SAP Business Warehouse (BW) system requires a scale-out configuration in accordance with its sizing rules.
- If tenant databases are distributed in a scale-out configuration due to sizing requirements, caution is advised when deploying additional tenant databases on the same host as a distributed tenant database

shard. The rationale is this: Workload in distributed scenarios can be somewhat volatile and less predictable. Therefore in many cases, it can be advantageous to dedicate maximum resources of the host to the distributed tenant database shard in order to maintain expected performance.

- In certain cases, more than one distributed tenant database shard may share the same host. In these cases, in order to dedicate maximum resources for a master node (for performance reasons), it is advisable to avoid deploying other tenant databases on the master node. For example, the following deployment should offer performance advantages:
  - Host 1: Master for tenant database 1
  - Host 2: Worker for tenant database 1 and worker for tenant database 2
  - Host 3: Master for tenant database 2
  - Host 4: Standby host for failover

## Related Information

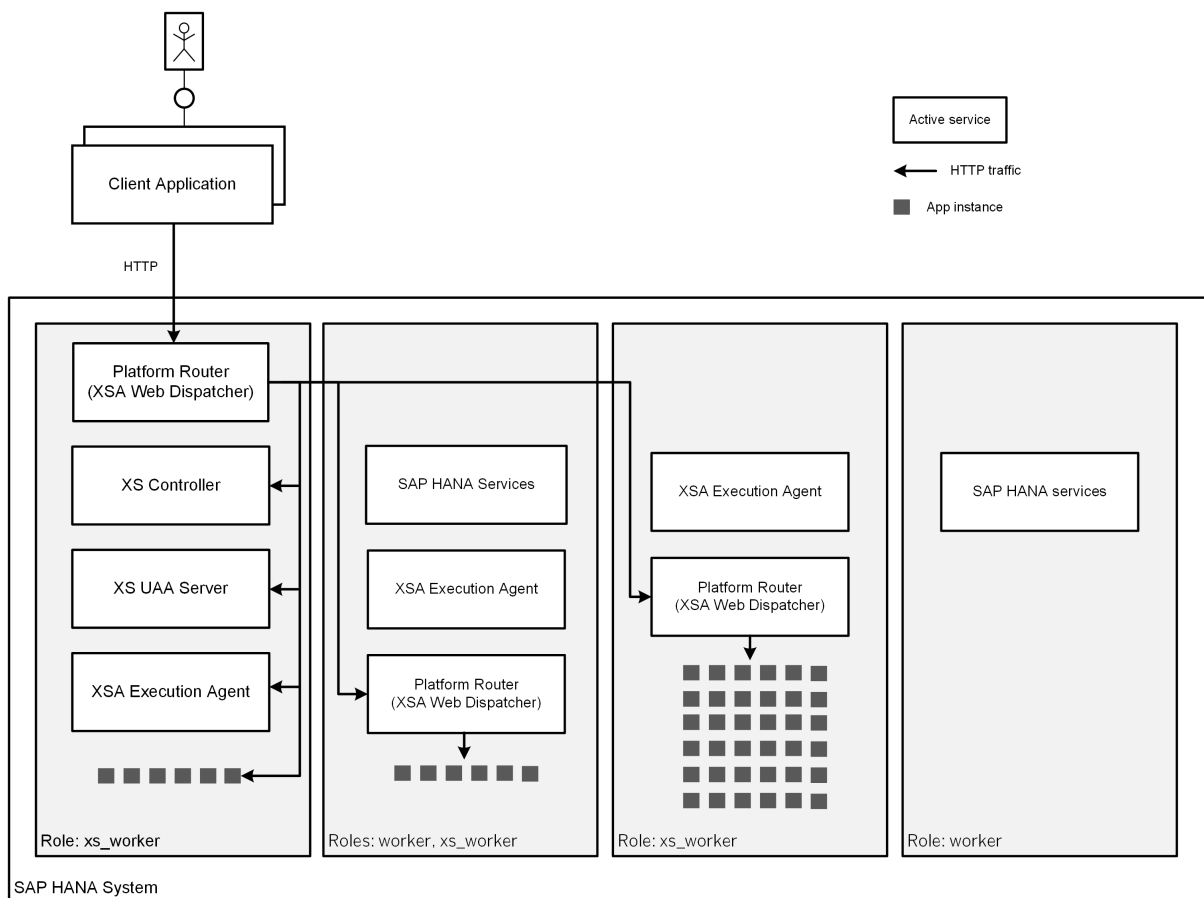

[Scaling SAP HANA \[page 1609\]](#)

### 4.3.2 Scale-Out Architecture of SAP HANA XS Advanced Runtime Platform

A multiple-host system that includes the SAP HANA XS advanced runtime can be flexibly configured to optimize load balancing and support failover.

During the installation of a multiple-host system with SAP HANA XS advanced, additional host roles are assigned for XS advanced. By default all worker hosts are configured to act as XS worker hosts; that is, they are additionally assigned the role `xs_worker`. However, it is also possible to configure dedicated hosts for XS advanced during installation.

The following figure shows a multiple-host system with two dedicated XS hosts and one shared host.

Multiple-Host System with Dedicated XS Worker Hosts and Shared Hosts

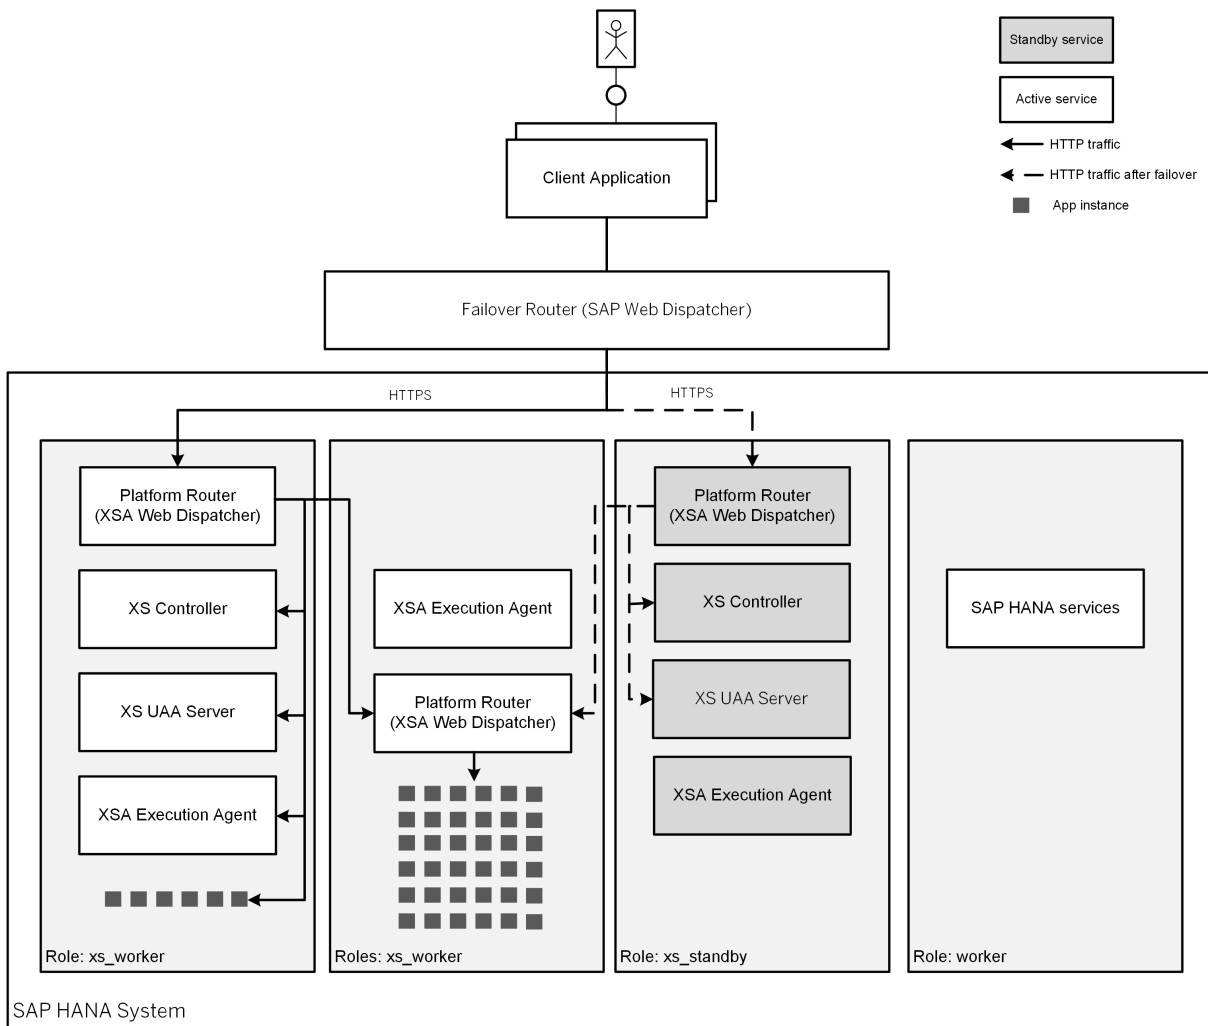

Additionally, the XS advanced runtime can be set up behind a reverse proxy (for example, a load balancer). For more information, see the section on installing the XS advanced runtime in the *SAP HANA Server Installation and Update Guide*.

## Failover Configuration

SAP HANA XS advanced integrates into the standard failover mechanisms of SAP HANA: If a worker host fails, a standby host takes over. If a host is both a worker and an XS worker, then the regular standby host takes over. However, a dedicated XS worker host must have a dedicated XS standby host, that is a host with the role `xs_standby`.

In addition, to support failover an external router (for example, SAP Web Dispatcher) must be set up to route requests to the XS advanced hosts active after failover. For more information, see the section on high availability for the XS advanced runtime.

The following figure shows a multiple-host system with two dedicated XS worker hosts, one dedicated XS standby host and SAP Web Dispatcher as failover router.

Multiple-host System Configured for XS Advanced Failover

## 4.4 Server Components of the SAP HANA Database

Overview of the most important server components of the SAP HANA database and the corresponding OS processes and services

### → Tip

For more information about the ports used by the components listed here, see the section on ports and connections.

### Core Servers

Server Component	OS Process	Service Name	Description
Name server	<code>hdbnameserver</code>	<code>nameserver</code>	The name server, which runs in the system database only, owns the information about the topology of the SAP HANA system, including knowledge of the tenant databases that exist in the system. Information about the location of tables and table partitions is stored in the relevant tenant database catalog.
Index server	<code>hdbindexserver</code>	<code>indexserver</code>	The index server, which runs in every tenant database (but not the system database), contains the actual data stores and the engines for processing the data.
Compile server	<code>hdbcompileserver</code>	<code>compileserver</code>	The compile server performs the compilation of stored procedures and programs, for example, SQLScript procedures. It runs on every host and does not persist data. It runs in the system database and serves all tenant databases.
Preprocessor server	<code>hdbpreprocessor</code>	<code>preprocessor</code>	The preprocessor server is used by the index server to analyze text data and extract the information on which the text search capabilities are based. It runs in the system database and serves all tenant databases.
SAP Web Dispatcher	<code>hdbwebdispatcher</code>	<code>webdispatcher</code>	The Web Dispatcher processes inbound HTTP and HTTPS connections to XS classic services.
SAP start service	<code>sapstartsrv</code>	<code>sapstartsrv</code>	The SAP start service is responsible for starting and stopping the other services in the correct order. It also performs other functions, such as monitoring their runtime state.

### Optional Servers

In addition to the core servers mentioned above, the following optional servers may also be running.

Server Component	OS Process	Service Name	Description
Script server	hdbscriptserver	scriptserver	<p>The script server is used to execute application function libraries written in C++.</p> <p>The script server is optional and must be added manually to the database that requires it. For more information, see the section on adding a service to a tenant database.</p>
Document store server	hdbdocstore	docstore	<p>This server is required for the document store repository. The document store allows native operations on JSON documents and joins with other column or row store tables.</p> <p>The document store is optional and must be added manually to the database that requires it. For more information, see the section on adding a service to a tenant database.</p>
XS advanced runtime	<ul style="list-style-type: none"> <li>• hdbxscontroller</li> <li>• hdbxsexeagent</li> <li>• hdixsuaaserver</li> </ul>	<ul style="list-style-type: none"> <li>• xscontroller</li> <li>• xsexeagent</li> <li>• hdixsuaaserver</li> </ul>	<p>SAP HANA includes a run-time environment for application development: <b>SAP HANA extended application services, advanced model</b> (XS advanced). The SAP HANA XS advanced model represents an evolution of the application server architecture within SAP HANA by building upon the strengths (and expanding the scope) of previous SAP HANA extended application services, classic model (XS classic).</p> <p>The SAP HANA XS advanced runtime consists of several processes for platform services and for executing applications. For more information about the individual services, see the table below.</p> <p>The SAP HANA XS advanced runtime runs either on dedicated hosts or together with other SAP HANA components on the same host.</p>
SAP HANA Deployment Infrastructure (HDI) server	hdbdiserver	diserver	<p>HDI handles the deployment of design-time artifacts into the SAP HANA database. If XS advanced is installed in the system, HDI is already enabled. Otherwise, you must enable it manually.</p> <p>For more information, see the section on enabling HDI in the database.</p>

Server Component	OS Process	Service Name	Description
XS classic server	hdbxsengine	xsengine	<p>SAP HANA Extended Application Services, classic model (XS, classic) is the application server for native SAP HANA-based web applications. It is installed with the SAP HANA database and allows developers to write and run SAP HANA-based applications without the need to run an additional application server. SAP HANA XS is also used to run web-based tools that come with SAP HANA, for instance for administration, lifecycle management and development.</p> <p>XS classic is the original implementation of SAP HANA XS.</p> <p>The XS classic server can run as a separate server process or embedded within the index server.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>SAP HANA XS, classic and the SAP HANA repository are deprecated as of SAP HANA 2.0 SPS 02. For more information, see SAP Note 2465027.</p> </div>
Extended store server	hdbesserver	esserver	<p>The extended store server is part of SAP HANA dynamic tiering. It provides a high-performance disk-based column store for very big data up to the petabyte range.</p> <p>For more information, see the documentation for SAP HANA dynamic tiering on SAP Help Portal.</p>
Data provisioning server	hdbdpserver	dpserver	<p>The data provisioning server is part of SAP HANA smart data integration. It provides capabilities such as data provisioning in real time and batch mode, real-time data transformations, data quality functions, adapters for various types of remote sources, and an adapter SDK for developing additional adapters.</p> <p>For more information, see the documentation for SAP HANA smart data integration on SAP HANA Portal.</p>
Streaming cluster	hdbstreamingserver	streamingserver	<p>The streaming cluster is part of SAP HANA streaming analytics. Streaming analytics extends SAP HANA with capabilities of SAP Event Stream Processor for consuming data streams and complex event processing.</p> <p>For more information, see the documentation for streaming analytics on SAP Help Portal.</p>

Server Component	OS Process	Service Name	Description
Accelerator for SAP ASE	hdbetsserver	etsserver	<p>The SAP ASE server is part of SAP HANA accelerator for SAP ASE. It provides SAP Adaptive Server Enterprise (ASE) users the ability to use SAP HANA on SAP ASE data for real-time analytics.</p> <p>For more information, see the documentation for SAP HANA accelerator for SAP ASE on SAP Help Portal.</p>

## SAP HANA XS Advanced Services

SAP HANA includes a run-time environment for application development: **SAP HANA extended application services, advanced model** (XS advanced). The SAP HANA XS advanced model represents an evolution of the application server architecture within SAP HANA by building upon the strengths (and expanding the scope) of previous SAP HANA extended application services, classic model (XS classic).

The SAP HANA XS advanced runtime runs either on dedicated hosts or together with other SAP HANA components on the same host. If the runtime platform of SAP HANA XS advanced is installed in your system, the following additional services run in the system database for platform services and for executing applications:

Server Component	OS Process	Service Name	Description
SAP HANA XS Controller	hdbxscontroller	xscontroller	<p>The Controller is the central management component of SAP HANA XS advanced. For example, it has a view on all deployed and/or running applications, and persists configuration and status information in the database.</p> <p>The Platform Router instance is managed by the <code>xscontroller</code> service. The Platform Router, which is realized by an SAP Web Dispatcher instance, exposes the public endpoint for the entire system.</p>
SAP HANA XS Execution Agent	hdbxsxexeagent	xsxecagent	The Execution Agent is responsible for managing processes, that is starting, keeping alive, and stopping tasks.
SAP HANA XS User Authentication and Authorization (UAA)	hdixsuaaserver	hdixsuaaserver	The UAA service manages user logon and logoff requests in SAP HANA XS advanced.

### → Recommendation

SAP recommends that customers and partners who want to develop new applications use SAP HANA XS advanced model. If you want to migrate existing SAP HANA XS classic applications to run in the new SAP HANA XS advanced run-time environment, SAP recommends that you first check the features available with the installed version of SAP HANA XS advanced; if the SAP HANA XS advanced features match the

requirements of the SAP HANA XS classic application you want to migrate, then you can start the migration process. For more information, see the *SAP HANA XS Advanced Migration Guide*.

## 4.5 System Limitations

Limitations to take into consideration when administering an SAP HANA database.

Aside from the table below, most system limits can also be viewed by querying the M\_SYSTEM\_LIMITS system view (`SELECT * FROM M_SYSTEM_LIMITS;`). However, your values might differ depending on the hardware and software configuration your system uses.

For details of sizing and limitations regarding HDI containers, refer to the topic SAP HDI Sizing and Limitations in the guide *SAP HANA Deployment Infrastructure (HDI) Reference for SAP HANA Platform* (see Related Information below).

Limitation Area	Limit	M_SYSTEM_LIMITS view name for the limitation
Database size limit	Row Store: 1,945 GB Column Store: Dependent on size of physical memory	MAXIMUM_SIZE_OF_ROW_STORE
Number of locks	Unlimited for record locks, 16,383 for table locks	MAXIMUM_NUMBER_OF_TABLE_LOCKS
Number of sessions	65,536	MAXIMUM_NUMBER_OF_SESSIONS

## Schema Limitations

Number of schemas per SAP HANA instance	Maximum value of BIGINT data type	
Identifier length	127 characters	MAXIMUM_LENGTH_OF_IDENTIFIER
Length of an alias name	128 characters	MAXIMUM_LENGTH_OF_ALIAS_NAME
Table name length	Same as Identifier length	MAXIMUM_LENGTH_OF_IDENTIFIER
Column name length	Same as Identifier length	MAXIMUM_LENGTH_OF_IDENTIFIER
Length of a string literal	8 MB	MAXIMUM_LENGTH_OF_STRING_LITERAL
Number of hex characters in a binary literal	8,192 Bytes	MAXIMUM_LENGTH_OF_BINARY_LITERAL

## Tables and View Limitations

Number of columns in a table	64,000  This limit can vary based on context, for example, in the context of virtual tables, SAP HANA may be limited by the capabilities of the remote system and the limit of the other DBMS may apply instead. In cases such as this, the limit that is met first becomes the actual limit.	MAXIMUM_NUMBER_OF_COLUMNS_IN_TABLE
Number of columns in a row table	1,000	MAXIMUM_NUMBER_OF_COLUMNS_IN_ROW_TABLE
Number of columns in a view	64,000	MAXIMUM_NUMBER_OF_COLUMNS_IN_VIEW
Number of rows in each table	Limited by storage size RS: 1,945 GB/sizeof(row),  CS: $2^{31}$ * number of partitions	
Length of a row	Limited by RS storage size (1,945 GB per index server)	
Size of a non-partitioned table	Limited by RS storage size (1,945 GB per index server)	
Number of partitions in a CS table	16,000	MAXIMUM_NUMBER_OF_PARTITIONS_IN_CSTABLE

Number of triggers per table per DML statement	1,024	MAXIMUM_NUMBER_OF_TRIGGERS_PER_TABLE_PER_DML
--	-------	--

Number of records per (non-partitioned) table	2 <sup>31</sup> (i.e. 2,147,384,648, or ~2 billion)	
---	---	--

---

### Indexes and Constraints

Number of indexes for a table	1,023	MAXIMUM_NUMBER_OF_INDEXES_IN_TABLE
-------------------------------	-------	------------------------------------

Number of primary key columns in each table	16	MAXIMUM_NUMBER_OF_COLUMNS_IN_PRIMARY_KEY
---	----	--

Number of primary key columns in each column store table	1,000	MAXIMUM_NUMBER_OF_COLUMNS_IN_PRIMARY_KEY_IN_COLUMN_TABLE
--	-------	--

Number of columns in an index	16	MAXIMUM_NUMBER_OF_COLUMNS_IN_INDEX
-------------------------------	----	------------------------------------

Number of columns in a UNIQUE constraint	16	MAXIMUM_NUMBER_OF_COLUMNS_IN_UNIQUE_CONSTRAINT
--	----	--

Size of sum of primary key, index, UNIQUE constraint	16,384 Bytes	MAXIMUM_SIZE_OF_KEY_IN_INDEX
--	--------------	------------------------------

Number of indexes in row store	256,000	
--------------------------------	---------	--

---

### SQL

Length of an SQL statement	2,147,483,648 Bytes	MAXIMUM_LENGTH_OF_SQL_STATEMENT
----------------------------	---------------------	---------------------------------

Depth of SQL view nesting	128	MAXIMUM_DEPTH_OF_SQL_VIEW_NESTING
---------------------------	-----	-----------------------------------

Maximum depth of SQL parse tree	0	MAXIMUM_DEPTH_OF_SQL_PARSE_TREE
---------------------------------	---	---------------------------------

This limitation does not show in M\_SYSTEM\_LIMITS unless a limit is configured to something other than 0 (no limit) using the `max_parse_tree_depth` parameter in `indexserver.ini`.

Maximum depth of joins in a statement.	0	MAXIMUM_DEPTH_OF_JOINS
<p>This limitation does not show in M_SYSTEM_LIMITS unless a limit is configured to something other than 0 (no limit) using the max_join_depth parameter in indexerver.ini.</p>		
Number of columns in an ORDER BY	65,535	MAXIMUM_NUMBER_OF_COLUMNS_IN_ORDER_BY
Number of columns in a GROUP BY	65,535	MAXIMUM_NUMBER_OF_COLUMNS_IN_GROUP_BY
Number of elements in IN predicates	65,535	MAXIMUM_NUMBER_OF_COLUMNS_IN_IN_PREDICATE
Number of elements in SELECT clause	65,535	MAXIMUM_NUMBER_OF_OUTPUT_COLUMNS_IN_STATEMENT
Number of tables in a statement.	0	MAXIMUM_NUMBER_OF_TABLES_IN_STATEMENT
<p>This limitation does not show in M_SYSTEM_LIMITS unless a limit is configured to something other than 0 (no limit) using the max_table_count_in_statement parameter in indexerver.ini.</p>		

### LOB Limitations

Maximum size of an in-memory LOB for a column store table	2 GB	MAXIMUM_SIZE_OF_MEMORY_LOB_IN_COLUMN_STORE
Maximum size of an in-memory LOB for a row store table	2 GB	MAXIMUM_SIZE_OF_MEMORY_LOB_IN_ROW_STORE
Maximum size of a packed LOB	1,013,760 bytes	MAXIMUM_SIZE_OF_PACKED_LOB
Maximum size of a LOB on disk	4,294,967,295 bytes	MAXIMUM_SIZE_OF_DISK_LOB

# 5 SAP HANA Administration Tools

Several tools can be used for the administration of SAP HANA.

## Native Tools for SAP HANA Administration

### SAP HANA Cockpit

The SAP HANA cockpit provides a single point of access to a range of tools for the administration and detailed monitoring of SAP HANA databases. For example, you can use the cockpit to start and stop systems and databases, monitor databases, configure system settings, manage users and authorizations, and do backups.

The cockpit also integrates the SAP HANA database explorer and the SAP HANA SQL analyzer. The database explorer allows you to query information about the database and view information about catalog objects, while the SQL analyzer helps you to understand and analyze the execution plans of queries.

The SAP HANA cockpit is a Web-based HTML5 user interface that you access through a browser. It runs on SAP HANA extended application services, advanced model (XS advanced). It can be used to administer and monitor SAP HANA databases running SAP HANA 1.0 SPS 12 or higher.

#### i Note

An SAP HANA cockpit support pack (SP) is released with every SAP HANA platform support package stack (SPS), but additional cockpit SPs may be released between platform SPSs. The *SAP HANA Administration Guide* contains information only about the cockpit SP delivered with the corresponding platform SPS. If you have a more recent cockpit SP, refer to the documentation available at [https://help.sap.com/viewer/p/SAP\\_HANA\\_COCKPIT](https://help.sap.com/viewer/p/SAP_HANA_COCKPIT). For more information about the revision and maintenance strategy of the cockpit, see SAP Note [2433181](#).

#### More information

[SAP HANA Cockpit \[page 42\]](#)

[SAP HANA Cockpit Installation and Update Guide](#)

### SAP HANA Studio

As an administrator, you use the SAP HANA studio, for example, to start and stop systems, monitor the system, configure system settings, and manage users and authorizations. Developers can use the SAP HANA studio to create content such as modeled views and stored procedures in the SAP HANA repository.

The SAP HANA studio is the legacy development environment and administration tool for SAP HANA, based on the Eclipse platform.

#### More information

[SAP HANA Studio \[page 123\]](#)

## SAP HANA hdbsql

SAP HANA hdbsql allows you to execute SQL statements and database procedures, as well as query information about the database and catalog objects, from the command line.

SAP HANA hdbsql is a command line tool installed on the SAP HANA server. It is available at `/usr/sap/<SID>/HDB<instance>/exe`. It can be used to access databases on both local and remote computers.

### More information

<https://help.sap.com/viewer/f1b440ded6144a54ada97ff95dac7adf/LATEST/en-US/c22c67c3bb571014afebeb4a76c3d95d.html>

## SAP HANA XS Administration Tools

Both the SAP HANA XS classic model and the SAP HANA XS advanced model include Web-based applications to configure and maintain the basic administration-related elements of the application-development process.

The SAP HANA XS advanced cockpit can be accessed from the SAP HANA cockpit.

In addition, the SAP HANA XS advanced model provides command-line tools (`xsa` and `xs CLI`) that you can use to maintain the applications that are deployed to the XS advanced run-time environment, as well as specific elements of the run-time environment itself, for example, the components that enable it, and the users who access and use it.

### More information

[Maintaining the SAP HANA XS Classic Model Run Time \[page 1665\]](#)

[Maintaining the SAP HANA XS Advanced Model Run Time \[page 1786\]](#)

## SAP HANA Application Lifecycle Management

Separate graphical user interfaces are available to install, update, and uninstall products and software components in the SAP HANA XS advanced and the SAP HANA XS classic environments.

The XS Advanced Application Lifecycle Management GUI can be accessed from the SAP HANA cockpit, while the XS Classic Application Lifecycle Management GUI can be accessed from the SAP HANA studio.

In addition, the `hdbalrm` command line tool can be used in the SAP HANA XS classic environment, while the `xs CLI` can be used in the SAP HANA XS advanced environment.

### More information

[Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model \[page 1085\]](#)

[Installing and Updating Products and Software Components in SAP HANA XS Advanced Model \[page 1092\]](#)

## SAP HANA Lifecycle Manager

The SAP HANA database lifecycle manager (HDBLCM) is used to perform SAP HANA platform lifecycle management (LCM) tasks, including installing, updating, and configuring an SAP HANA system.

The SAP HANA HDBLCM program can be run as a graphical user interface, a command-line interface, or as Web user interface in a Web browser.

### More information

[About the SAP HANA Database Lifecycle Manager \(HDBLCM\) \[page 1052\]](#)

## **SAP HANA Hardware and Cloud Measurement Tools**

The SAP HANA hardware and cloud measurement tools provide tests and reports for new single host and scale out systems to determine if the hardware you intend to use meets the minimum performance criteria required to run SAP HANA in production use.

### **More information**

[SAP HANA Hardware and Cloud Measurement Tools for Tailored Data Center Integration \[page 152\]](#)

## **SAP Tools for SAP HANA Administration**

### **SAP Solution Manager**

Use SAP Solution Manager to perform end-to-end root cause analysis and unified alert inbox for entire landscape and business process reporting.

SAP Solution Manager is a central alerting and monitoring infrastructure running on SAP NetWeaver AS for ABAP.

### **More information**

[SAP Solution Manager for SAP HANA Administration \[page 153\]](#)

### **SAP Landscape Manager**

SAP Landscape Manager allows you to automate advanced SAP HANA operations and avoiding business downtime during maintenance activities.

It is a central landscape management solution running SAP NetWeaver AS for Java.

### **More information**

[SAP Landscape Virtualization Management, enterprise edition](#)

### **SAP IT Operations Management**

SAP IT Operations Analytics (ITOA) lets you get and maintain a holistic, real-time overview of complex datacenter landscapes. You can collect, process, and analyze large volumes of data to find the root causes of datacenter issues and resolve them swiftly, or to predict issues and prevent them from happening in the first place.

ITOA is an SAP HANA XSC application that runs on the SAP HANA platform with the SAP HANA Predictive Analysis Library (SAP HANA PAL).

### **More information**

[SAP IT Operations Analytics](#)

## 5.1 SAP HANA Cockpit

Use the Web-based administration tool SAP HANA cockpit for the administration, monitoring and maintenance of SAP HANA systems.

The SAP HANA cockpit provides tools for the administration and monitoring of SAP HANA databases (databases), and for development capabilities through the SAP HANA database explorer. You can manage multiple databases, each running version SAP HANA 1.0 SPS 12, or later. databases running version SAP HANA 2.0 SPS 01 or later run in multi-container mode, but you can also monitor single-container systems running earlier versions of SAP HANA.

### i Note

An SAP HANA cockpit support pack (SP) is released with every SAP HANA platform support package stack (SPS), but additional cockpit SPs may be released between platform SPSs. The *SAP HANA Administration Guide* contains information only about the cockpit SP delivered with the corresponding platform SPS. If you have a more recent cockpit SP, refer to the documentation available at [https://help.sap.com/viewer/p/SAP\\_HANA\\_COCKPIT](https://help.sap.com/viewer/p/SAP_HANA_COCKPIT). For more information about the revision and maintenance strategy of the cockpit, see SAP Note [2433181](#).

### What can I do with the cockpit?

The SAP HANA cockpit provides aggregate, system and database administration features, such as database monitoring, user management, and data backup. You can use the SAP HANA cockpit to start and stop systems or services, monitor the system, configure system settings, and manage users and authorizations.

Cockpit apps that allow you to manage SAP HANA options and capabilities (for example, SAP HANA dynamic tiering) are only available if the option or capability has been installed.

### How can I keep an eye on the big picture?

When you first launch the cockpit, you can see system and tenant databases. (The cockpit refers to these as databases). A database is an SAP HANA system (identified by a host name and instance number) which may be a system or tenant database in a tenant (database) container, or a system in a single database container. These databases are organized into database groups - you'll only see databases belonging to the groups to which your cockpit user has been granted access. At a glance, you can see top alerts from more than one database, compare database configurations and monitor the health of multiple databases.

Whenever you like, you can drill down to perform in-depth monitoring on an individual system or tenant. In order to see alerts and other data for this individual database you need to enter database user credentials. These database user credentials must pre-exist (that is, they're already created on the database you're drilling into), and must have the system privilege CATALOG READ and SELECT on \_SYS\_STATISTICS. For any systems running version SAP HANA 2.0 SPS 01, or later, the cockpit database administrator has the option to enable or enforce single sign-on (SSO).

## How do I get access to groups of databases?

A single `COCKPIT_ADMIN` user is created through the cockpit installation process. This user creates other cockpit users through the Cockpit Manager configuration tool, which is launched through a separate URL provided during installation.

The cockpit administrator assigns the role of `Cockpit database Administrator` to at least one cockpit user. The `Cockpit database Administrator` registers databases, again through the Cockpit Manager. When databases are registered, they're added to auto-generated database groups, based on system usage type.

Since the `Cockpit database Administrator` can't grant cockpit users access to an auto-generated database group, they must also create one or more custom database groups. They add registered databases to each group, and grant access to one or more of the cockpit users that were created by the `COCKPIT_ADMIN`. When you launch the cockpit, you're able to see all the registered databases that belong to each of the database groups to which the `Cockpit database Administrator` has granted you access.

Integrated into the cockpit is the SAP HANA database explorer. The database explorer provides the ability to query information about the database using SQL statements, as well as the ability view information about your database's catalog objects.

## Related Information

[SAP Note 2380291](#) 

### 5.1.1 Set Up SAP HANA Cockpit for the First Time

After installation and before other users are able to access the SAP HANA cockpit, you need to perform several steps.

#### Prerequisites

- You have access to the cockpit administrator (`COCKPIT_ADMIN`) user, created during the installation process
- You have access to the master password that you were prompted to enter during the installation process.
- You know the URL for the cockpit created during the installation process.

#### Procedure

1. Connect to the Cockpit Manager and sign in as the `COCKPIT_ADMIN` user. The `COCKPIT_ADMIN` user and corresponding master password were established during cockpit installation.

Access the Cockpit Manager by clicking [Manage Cockpit](#) on the cockpit home page.

2. Create other cockpit users, keeping in mind what cockpit actions you want them to be able to perform.
3. Register databases.
4. Create database groups and add registered databases to each group.
5. Assign cockpit users access to one or more groups of databases.
6. Determine whether you would like to configure single sign-on authentication to the cockpit and/or the registered databases.
7. Share the credentials of the newly created cockpit users with the appropriate people, and instruct them to sign in to the SAP HANA cockpit.

In the cockpit, the [Database Directory](#) displays all the registered databases to which this cockpit user has access.

### 5.1.1.1 Determine Ports for SAP HANA Cockpit and Cockpit Manager

The ports for SAP HANA cockpit and the Cockpit Manager can be determined in the XS console after the cockpit installation.

#### Prerequisites

- You are logged in as `<sid>adm` user.
- You know the XS organization manager user password. The password matches the master password, which is set during installation.

#### Context

Ports, through which the SAP HANA cockpit and the Cockpit Manager can be accessed, are assigned automatically by the installer. Once the cockpit installation has successfully completed, information about host

and ports is displayed. If this information is no longer available, you can execute the following commands in the XS console to determine ports.

You can also assign free ports to SAP HANA cockpit during installation. For more information, see *SAP Note 2389709* in the Related Links section.

## Procedure

1. Change to the directory that contains the XS Advanced installation:

```
cd <sapmnt>/<SID>/xs/bin
```

By default, <sapmnt> is /hana/shared.

2. Log on to the SAP HANA XS advanced runtime by using the following command:

```
./xs-admin-login
```

3. Enter the password for the XSA admin user.
4. Display a list of the applications running in the current space. In the command shell, run the following command:

```
xs apps
```

A list of all running apps is displayed. Information on host and ports is displayed in the `urls` column. The SAP HANA cockpit is listed as `cockpit-web-app`. The Cockpit Manager is listed as `cockpit-admin-web-app`.

## Related Information

[SAP Note 2389709 - Specifying the port for SAP HANA Cockpit before installation](#)

### 5.1.2 Open the SAP HANA Cockpit

Access the SAP HANA cockpit from a web browser.

## Prerequisites

- You know the URL for the cockpit that was created during the cockpit installation process.
- You have a cockpit user name and password.
- Your Web browser supports the SAPUI5 library `sap.m`. For more information about SAPUI5 browser support, see SAP Note 1716423. See also the *Product Availability Matrix (PAM) for SAPUI5*.

## Procedure

1. Enter the SAP HANA cockpit URL in your browser.
2. Enter your cockpit user name and password.  
SAP HANA cockpit opens.

## Related Information

[Product Availability Matrix \(PAM\) for SAPUI5](#)

### 5.1.3 Authorizations Needed for Monitoring and Administration

To view information about the SAP HANA database and access the various applications for administration and monitoring, you need to connect to the database with a database user with appropriate database privileges. If you don't have the required privileges, specific tiles, features, or actions aren't available to you.

#### i Note

To be able to connect to a database and see minimum monitoring information, the connecting database user must have system privilege CATALOG READ and the SELECT privilege on the schema `_SYS_STATISTICS`.

## Database Monitoring and Administration

These tables list the database privileges required to view information about an SAP HANA database on the [Database Overview](#) page and to access monitoring and administration functions on subsequent pages.

## Monitoring

To Access...	You Need These SAP HANA Privileges...
<i>Services</i>	<ul style="list-style-type: none"> <li>• CATALOG READ system privilege</li> <li>• SELECT privileges on: <ul style="list-style-type: none"> <li>◦ SYS_DATABASES.m_services</li> <li>◦ SYS_DATABASES.m_service_memory</li> <li>◦ SYS_DATABASES.m_service_statistics</li> <li>◦ SYS_DATABASES.m_heap_memory_reset</li> <li>◦ SYS.m_services</li> <li>◦ SYS.m_service_memory</li> <li>◦ SYS.m_service_statistics</li> <li>◦ SYS.m_heap_memory_reset</li> <li>◦ _SYS_STATISTICS.STATISTICS_SCHEDULE</li> <li>◦ _SYS_STATISTICS.HELPER_ALERT_CHECK_INACTIVE_SERVICES_AGE</li> </ul> </li> </ul>
<i>Alerts</i>	SELECT privileges on _SYS_STATISTICS
<i>Memory Usage</i>	CATALOG READ system privilege
<i>Memory Analysis</i>	<ul style="list-style-type: none"> <li>• CATALOG READ system privilege</li> <li>• SELECT on _SYS_STATISTICS object privileges</li> </ul>
<i>CPU Usage</i>	CATALOG READ system privilege
<i>Disk Usage</i>	CATALOG READ system privilege
<i>Performance Monitor</i>	CATALOG READ system privilege
<i>Monitor Statements</i>	<p>To enable or disable memory tracking, you need the INIFILE ADMIN privilege.</p> <p>To cancel the session, you need the SESSIONS ADMIN privilege.</p>
<i>Sessions</i>	To cancel sessions or operations, you need the SESSION ADMIN privilege.
<i>Threads</i>	To cancel sessions or operations, you need the SESSION ADMIN privilege.
<i>Monitor expensive statements</i>	To configure expensive statements, you need the INIFILE ADMIN privilege.
<i>Open SQL plan cache</i>	To configure SQL plan cache, you need the INIFILE ADMIN privilege.
<i>Open blocked transactions</i>	No additional authorization required
<i>Smart Data Access</i>	No additional authorization required

## Alerting and Diagnostics

To Access...	You Need These SAP HANA Privileges...
<i>Configure alerts</i>	INSERT, EXECUTE, DELETE, and UPDATE privileges on _SYS_STATISTICS

To Access...	You Need These SAP HANA Privileges...
<a href="#">Plan trace</a>	<ul style="list-style-type: none"> <li>To turn plan trace on or off, you need the TRACE ADMIN privilege.</li> <li>To retrieve the results, you need the SELECT privilege on SYS schema. The SYSTEM user or a user with the SAP_INTERNAL_HANA_SUPPORT_ROLE has this authorization.</li> </ul>
System Replication	
To Access...	You Need These SAP HANA Privileges...
<a href="#">System Replication</a>	No additional authorization required
Other Administration	
To Access...	You Need These SAP HANA Privileges...

<a href="#">Security checklists</a>	No additional authorization required

## Backup and Recovery (SAP HANA Cockpit)

Authorizations for Backup and Recovery (SAP HANA Cockpit)

To Perform This Task...	You Need These SAP HANA System Privileges...		
	System Database	Tenant Database	Tenant Database (Through the System Database)
View, create, and cancel database backups	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	DATABASE BACKUP OPERATOR or DATABASE BACKUP ADMIN or DATABASE ADMIN
Delete database backups and backups of the backup catalog	BACKUP ADMIN	BACKUP ADMIN	DATABASE BACKUP ADMIN or DATABASE ADMIN
Recover or copy a database	Operating system user <sid>adm	(not possible)	DATABASE RECOVERY OPERATOR or DATABASE ADMIN
Schedule backups	BACKUP ADMIN  SELECT, UPDATE, and DELETE privileges for the following tables: <ul style="list-style-type: none"><li>• <code>_SYS_XS.JOB_SCHEDULES</code></li><li>• <code>_SYS_XS.JOBS</code></li></ul>	BACKUP ADMIN  SELECT, UPDATE, and DELETE privileges for the following tables: <ul style="list-style-type: none"><li>• <code>_SYS_XS.JOB_SCHEDULES</code></li><li>• <code>_SYS_XS.JOBS</code></li></ul>	DATABASE BACKUP OPERATOR or DATABASE BACKUP ADMIN or DATABASE ADMIN and SELECT, UPDATE, and DELETE privileges for the following tables: <ul style="list-style-type: none"><li>• <code>_SYS_XS.JOB_SCHEDULES</code></li><li>• <code>_SYS_XS.JOBS</code></li></ul>

To Perform This Task...	You Need These SAP HANA System Privileges...		
	System Database	Tenant Database	Tenant Database (Through the System Database)
Configure backups	<p>To display the backup configuration settings, <code>BACKUP ADMIN</code>.</p> <p>To configure <b>backup retention</b>, you also need:</p> <ul style="list-style-type: none"> <li><code>SELECT</code>, <code>UPDATE</code>, and <code>DELETE</code> privileges for table <code>_SYS_XS.JOB_SCHEDULES</code></li> <li><code>SELECT</code> privileges for table <code>_SYS_XS.JOBS</code></li> </ul>	<p>To display the backup configuration settings, <code>BACKUP ADMIN</code>.</p> <p>To configure <b>backup retention</b>, you also need:</p> <ul style="list-style-type: none"> <li><code>SELECT</code>, <code>UPDATE</code>, and <code>DELETE</code> privileges for table <code>_SYS_XS.JOB_SCHEDULES</code></li> <li><code>SELECT</code> privileges for table <code>_SYS_XS.JOBS</code></li> </ul>	<code>DATABASE BACKUP ADMIN</code>

## System-wide Backup Configuration

To change default configuration settings for all the tenant databases, you need `DATABASE ADMIN`.

For more information, see *Authorizations Needed for Backup and Recovery* in the *SAP HANA Database Backup and Recovery* section of the *SAP HANA Administration Guide*.

## Performance Management

Workload Management

To Access...	You Need These SAP HANA Privileges...
<a href="#">Analyze Workload (Based on Thread Samples)</a>	System privileges <code>CATALOG READ</code> and <code>INIFILE ADMIN</code> .
<a href="#">Analyze Workload (Based on Engine Instrumentation)</a>	System privilege <code>WORKLOAD ANALYZE ADMIN</code> .

To Access...	You Need These SAP HANA Privileges...
<a href="#">Capture Workload</a>	<p>Workload Capture Admin used to start captures, trigger backups, and collect Abstract SQL Plans in the source system.</p> <p>Privileges:</p> <ul style="list-style-type: none"> <li>• Requires the WORKLOAD CAPTURE ADMIN privilege to capture workloads</li> <li>• It can have the BACKUP OPERATOR privilege to trigger backups</li> <li>• It can have the INIFILE ADMIN privilege to see the previously used optional filters on the capture configuration page</li> </ul>
<a href="#">Replay Workload</a>	<p>The Control Replay Admin used for preprocessing and replaying in the control system.</p> <p>Privileges:</p> <ul style="list-style-type: none"> <li>• Requires the WORKLOAD REPLAY ADMIN privilege for preprocessing and replaying workloads, as well as generating replay reports</li> <li>• Requires the WORKLOAD ANALYZE ADMIN privilege for loading and analyzing workloads</li> <li>• Requires the CATALOG READ privilege for generating replay reports</li> </ul> <p>The Target Replay Admin used to execute replays and reset user passwords in the target system.</p> <p>Privileges:</p> <ul style="list-style-type: none"> <li>• Requires the WORKLOAD REPLAY ADMIN privilege to execute replays</li> </ul>

## Related Information

[Authorizations Needed for Backup and Recovery](#)

## 5.1.4 Open the SAP HANA Database Explorer (SAP HANA Cockpit)

Open the SAP HANA database explorer to view information about your database's catalog objects and execute queries.

### Prerequisites

You must be a user of the SAP HANA cockpit.

### Context

The database explorer displays your database objects, grouped by schema. It also contains an SQL console for executing SQL statements and an SQL analyzer for analyzing them, an SQL debugger for debugging procedures, as well as an MDX console for executing MDX queries.

### Procedure

1. In the SAP HANA cockpit, navigate to the *Overview* page of a database that you want to explore, and then click the *Browse Database* link on that page.

The database explorer opens and the catalog browser lists your database in its tree.

You can add other databases by clicking *Add a database to the Database Explorer* (+) at the top of the catalog browser.

2. From the catalog browser, choose your database to view the object types available, and then choose an object type to view its individual objects.
3. Choose an object to view the object's definition in the right pane, or right-click the object to choose a different action.

### Related Information

[Add a Database to the SAP HANA Database Explorer \[page 55\]](#)

[Execute MDX Queries in the SAP HANA Database Explorer](#)

[Execute SQL Statements \(SAP HANA Database Explorer\)](#)

## 5.1.4.1 Add a Database to the SAP HANA Database Explorer

Add a database to the SAP HANA database explorer so that you can browse its catalog and execute SQL statements against it.

### Context

Adding a database to the database explorer is similar to registering a database in the cockpit. Once a database is added, it is listed in the catalog browser pane on the left.

You cannot add a database to the database explorer that uses LDAP authentication.

### Procedure

1. Open the database explorer from the SAP HANA cockpit.
2. Add a database by clicking the [Add a Database to the Database Explorer](#) icon ( + ) at the top of the catalog browser pane on the left.
3. From the [Database Type](#) dropdown list, choose the type of database to add:

Database Type	Action
<b>Add a database that has been registered in the cockpit</b>	<ol style="list-style-type: none"><li>1. Choose <a href="#">Cockpit Database</a>.</li><li>2. Choose a resource from the list.</li><li>3. Choose to either use the credentials supplied in the cockpit, or to enter a different user name or password.</li></ol>
<b>An SAP HANA database</b>	<ol style="list-style-type: none"><li>1. Choose <a href="#">SAP HANA database</a>.</li><li>2. Specify the fully qualified domain name (FQDN) of the host on which the system is installed. Specify the instance number or port of the database you are adding. When adding a database that is part of a multi-host system, specify the master host. You do not have to enter all host names explicitly as they are determined automatically. If the master host becomes unavailable, then the connection is automatically established through one of the other hosts. Hosts that are added to the system later are also detected automatically.</li></ol>
<b>A tenant or the system database that is part of a multitenant database container system</b>	<ol style="list-style-type: none"><li>1. Choose <a href="#">SAP HANA database (Multitenant)</a>.</li><li>2. Specify the host and instance number or port of the system database.</li><li>3. Specify whether you are adding the system database or a tenant database. If you are adding a tenant database, then specify the name of the tenant database.</li></ol>

4. (Optional) If you are adding an SAP HANA database, a tenant database, or a system database that is part of a multi-tenant database container system, then specify encryption information and advanced connection properties as required.

Choose from the following encryption options:

Option	Description
<a href="#">Save user and password (stored in the SAP HANA secure store.)</a>	<p>By default, your database credentials are not saved. Each time you need to connect to an added database, you must provide your user credentials.</p> <p>Choose this option to save these user credentials so that you do not have to re-enter them each time you connect. These credentials are saved to the SAP HANA secure store.</p>
<a href="#">Connect to the database securely using TLS/SSL. (Prevents data eavesdropping.)</a>	<p>Choose this option to encrypt communication between the database explorer and the SAP HANA database using the Transport Security Layer (TLS)/Secure Sockets Layer (SSL) protocol.</p>
<a href="#">Verify the server's certificate using the trusted certificate below.</a>	<p>Choose the <a href="#">Verify the server's certificate using the trusted certificate below</a> option and provide a trusted certificate, if you want to verify the server's certificate when connecting. This prevents server impersonation. The certificate field must contain the contents of a certificate, and not a file name. For more information, see the <i>SAP HANA Security Guide</i>.</p>

**i Note**

You can only choose this option if you have also chosen the [Connect to the database securely using TLS/SSL. \(Prevents data eavesdropping.\)](#) option.

Choose from the following advanced options.

In the *Advanced Options* field, specify the advanced options as semi-colon-separated name=value pairs. For example: `locale=en-US, isolationLevel=READ COMMITTED`.

Option	Description
isolationLevel	The isolation level for the connection. The supported values are: READ COMMITTED, REPEATABLE READ, and SERIALIZABLE. The default is to specify no isolation level.
locale	The locale to use for the connection. If you do not set this option, then the database explorer looks for a locale setting in your user parameter, and then in your browser. If no locale setting is found, then the locale is set to en-US.
schema	The name of the schema that you want to use

Option	Description
CLIENT	Sets the session client for the connection. The value is a three character string. For example, CLIENT=100.

- (Optional) Choose a display name that is used to identify your database in the database explorer. Each database must have a unique display name. If you do not choose a display name, then one is generated for you.
- Click *OK*.

## Results

The database is added to the database browser.

## Next Steps

After adding a cockpit database, you can always go back and re-add the database with different user credentials. Just right-click the cockpit database and click *Add Database with Different User*.

## Related Information

[Securing the SAP HANA Database Explorer](#)

[Open Catalog Objects \[page 57\]](#)

[Execute SQL Statements \(SAP HANA Database Explorer\)](#)

## 5.1.4.2 Open Catalog Objects

Browse your database's catalog using the SAP HANA database explorer.

## Prerequisites

You must be a user of the database that you want to explore and you must have the required privileges to view the catalog items.

## Context

Some monitoring and problem analysis may require you to examine individual tables and views, for example, system views provided by the SAP HANA database. Use the catalog browser, which is located in the left pane, to find and open these catalog objects.

## Procedure

1. In the catalog browser, choose the database that you want to explore.

If your database is not listed in the catalog browser, then click [Add a database to the Database Explorer \(+\)](#) to add the database.

The catalog browser lists the catalog objects, grouped by schema.

2. Choose an object type to view its objects.

For example, choose [Tables](#) to list the tables in the database.

3. Choose an object to view its definition in an editor in the right pane, or right-click the object to choose a different action.

For example, right-click a table and choose [Open Data](#) to view the table's data.

## Related Information

[View Database Procedures in the SAP HANA Database Explorer](#)

### 5.1.4.3 Search for Database Objects in the SAP HANA Database Explorer

Search for database objects across all databases that the SAP HANA database explorer is connected to.

## Prerequisites

In the database explorer, connect to each database that you want to search.

## Context

Use the catalog browser to find your object when you know the type of object and the database that it exists in.

If you are unsure of the object type or the database that it exists in, then use the database object search. This search looks for matches in either a specified database or all of the connected databases in the database explorer and it can search across more than one object type. For example, use this search to find all tables and procedures that contain the word **production** in their names.

## Procedure

From the right sidebar of the database explorer, click [Object Search](#) (Q).

- a. Specify a search term that is longer than one character.
  - Specify \* to return all results.
- b. Optionally, restrict your search to a specific database.
- c. Target your search to specific object types by selecting them at the bottom of the pane.

## Results

The search results appear in the [Search for Database Objects](#) pane.

## Related Information

[Create URL Shortcuts to Database Objects in the SAP HANA Database Explorer \[page 59\]](#)

[Open Catalog Objects \[page 57\]](#)

### 5.1.4.4 Create URL Shortcuts to Database Objects in the SAP HANA Database Explorer

Use the SAP HANA database explorer to create a URL shortcut, and then use it to create a bookmark or favorite in your browser.

## Procedure

1. In the catalog browser, right-click a database object and choose [Create Shortcut](#).

2. Click [Copy URL](#) to copy the shortcut to your clipboard.
3. Paste the URL into your browser.
4. Use your browser to create a bookmark or favorite for the copied URL.

## Results

The shortcut is created. Use it to open the database explorer and quickly navigate to the database object.

## Related Information

[Search for Database Objects in the SAP HANA Database Explorer \[page 58\]](#)

### 5.1.4.5 Getting Started With the SAP HANA Database Explorer

Use the SAP HANA database explorer to query information about the database, as well as view information about your database's catalog objects.

The database explorer is integrated into both the SAP Web IDE for SAP HANA and in the SAP HANA cockpit. The database explorer contains features and functions required by both database administrators and developers.

#### What can I do with the SAP HANA database explorer?

The SAP HANA database explorer allows you to query your database and view information about your catalog objects, by providing the following functionality:

- A catalog browser** View the definitions of all types of catalog objects, for example: tables, views, stored procedures, functions, and synonyms. Also, view the content (data) of your tables and views.
- An SQL console** Create SQLScript procedures and queries, and then execute them or analyze their performance using the SQL analyzer.
- An SQL analyzer** View detailed information on your queries and evaluate potential bottlenecks and optimizations for these queries. The SQL analyzer is accessible from the SQL console, as well as from the plan trace and expensive statement features in the SAP HANA cockpit.
- An SQL debugger** View the call stack, set break points, view and evaluate expressions and variables.

[SAP Note 2373065](#)

### 5.1.5 Setup and Administration with the Cockpit Manager

The Cockpit Manager configuration tool is an application separate from the SAP HANA cockpit itself. Launch the Cockpit Manager using the URL that was provided during cockpit installation.

The functionality visible in the Cockpit Manager depends on the roles assigned to the user accessing the Cockpit Manager. The administrator roles of cockpit administrator, cockpit user administrator and cockpit database administrator can perform the tasks necessary to enable users of SAP HANA cockpit to manage and monitor databases. These roles can be assigned together to one user, or to separate individuals.

Before other cockpit users can make full use of SAP HANA cockpit, the cockpit user administrator needs to use the Cockpit Manager to:

- Create and manage cockpit users

Then, the cockpit database administrator needs to use the Cockpit Manager to:

- Register databases
- Create database groups
- Add databases to database groups
- Grant cockpit users access to database groups

Optionally, the cockpit administrator can use the Cockpit Manager to:

- Modify settings related to the configuration of the cockpit.

#### **i** Note

During cockpit installation, a master user, COCKPIT\_ADMIN, is automatically created. Its password corresponds to the master password, which you were prompted to enter during the installation process. This master user is assigned all three administrator roles, and can therefore access all aspects of the Cockpit Manager, and can create users, register databases, and assign users and databases to database groups. However, you can assign administrator roles to other users.

[Registered Databases \[page 73\]](#)

[Cockpit Settings \[page 69\]](#)

[Security Considerations for SAP HANA Cockpit \[page 110\]](#)

## 5.1.5.1 SAP HANA Cockpit User Management

Manage SAP HANA cockpit user credentials and the database groups they can access.

### SAP HANA Cockpit Users vs. Database Users

SAP HANA cockpit users and database users are two distinct users. Though they share similar concepts and terminology, such as roles and groups, they each have their own distinct meaning and function.

You use a cockpit user to log on to SAP HANA Cockpit or Cockpit Manager. They are created and managed in Cockpit Manager. Cockpit users are assigned cockpit roles, which dictate what tasks they can perform in SAP HANA cockpit or Cockpit Manager. A cockpit user that has been assigned the role to manage cockpit users can add and remove roles from any cockpit user except themselves. They can change the password of any user, including themselves. Cockpit users are assigned to database groups, which contain the registered databases that will be available in SAP HANA cockpit. Once logged in to cockpit, to access one of the registered databases, you must supply the credentials of a database user.

Each registered database has its own set of database users. A database user can monitor and manage a database in SAP HANA cockpit. Database users are managed in each registered database, using roles and privileges to control the tasks each can perform within the database. Just as you can't use cockpit credentials to access a registered database, you can't log on to cockpit or Cockpit Manager using database credentials.

### SAP HANA Cockpit Master User

During cockpit installation, a master user, `COCKPIT_ADMIN`, is automatically created. Its password is the master password specified during the installation process. This master user is assigned all administrator roles, and can perform all tasks in the Cockpit Manager.

Cockpit roles were introduced as of SAP HANA 2.0 SPS 01. If your `COCKPIT_ADMIN` user was created during the installation of an earlier version, then you may wish to assign it additional roles if you want to continue to access all aspects of the cockpit and the Cockpit Manager. You must log out and then back on again to have these new roles take effect for the `COCKPIT_ADMIN`.

### Business Users

Business users are users created outside of cockpit to access other applications, such as SAP HANA Client or XSA. If these users now need to access cockpit, rather than create a new user in cockpit, you can add the existing user to Cockpit Manager.

## 5.1.5.1.1 Create or Enable an SAP HANA Cockpit User

You can create new SAP HANA cockpit users, enable an existing cockpit user whose cockpit access has been revoked, or allow existing business users to access the SAP HANA cockpit.

### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit User Administrator Role`.

### Context

A new cockpit user can't see any databases in SAP HANA cockpit until someone with the `Cockpit Database Administrator` role assigns them to at least one database group that contains at least one registered database. An existing cockpit user whose access to cockpit was revoked must be re-enabled before it's visible in the Cockpit Users list in Cockpit Manager.

### Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Users](#).
2. Select [Create User](#).
3. Do one of the following:
  - Enter a user name, password, and e-mail address for the user.
  - Select the checkbox to enable an existing cockpit or business user to access the cockpit, then select the user from the dropdown list. The password and email-address for the user are that last set for the user in the outside application for a business user, or in Cockpit Manager for a cockpit user.
4. If the user is to use Kerberos single sign-on with SAP HANA Cockpit, select [SSO with Kerberos](#) and specify the external Kerberos credentials.
5. Assign one or more cockpit roles to the user. There's no single, all encompassing, administration role. Access to specific sections within Cockpit Manager requires specific roles. For example, to manage databases, groups, and users would require both the `Cockpit Database Administration Role` and the `Cockpit User Administration Role`. If a cockpit user is never expected to log in to SAP HANA cockpit, then there's no need to grant them the `Cockpit User Role`.

Role	Permits access to
<b>Cockpit Administrator Role</b>	The <a href="#">Cockpit Settings</a> section of the Cockpit Manager, where they can configure cockpit settings.
<b>Cockpit Database Administrator Role</b>	The <a href="#">Issues with Technical Users</a> , <a href="#">Registered Databases</a> , and <a href="#">Database Groups</a> sections of the Cockpit Manager, where they can

Role	Permits access to
	register databases, create database groups, and assign cockpit users to database groups.
<b>Cockpit User Administrator Role</b>	The <i>Cockpit Users</i> section of the Cockpit Manager, where they can create and manage cockpit users.
<b>Cockpit User Role</b>	The SAP HANA cockpit, where they can view and monitor all databases in any assigned database groups.
<b>Cockpit User Role and allow this user to register databases</b>	The SAP HANA cockpit and the <i>Registered Database</i> section of the Cockpit Manager.
<b>Cockpit User Role and Cockpit Configuration Template Administrator Role</b>	The SAP HANA cockpit and the <i>Configuration Templates</i> section on the SAP HANA cockpit <i>Home</i> page.
<b>Cockpit Troubleshooting Role</b>	The <i>XSA Logs</i> section of the Cockpit Manager.

**i Note**

To view XSA Logs, you also need to assign the XSA role of Space Auditor.

6. (Optional) Click  and select one or more database groups to which this user is a member. You can add the user to database groups later if needed, but a cockpit user is unable to access any registered database until this designation is done.
7. Select *Create User* or *Enable User*, depending on your action from step 3.

## Next Steps

- If you didn't assign the user to an existing database group, do it now.
- If the database group didn't already exist, create it now and add the user.

## Related Information

## 5.1.5.1.2 Add or Remove Database Groups for Cockpit Users

Add or remove the database groups that cockpit users are a member of.

### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit User Administrator Role`.
- The database groups the cockpit user belongs to already exist. See *Create a Database Group*.

### Context

In order for cockpit users to monitor and manage a registered database, you need to assign them to the database group to which the database belongs.

This task can also be done in the *Database Groups* section of the Cockpit Manager. See *Add or Remove Cockpit Users in Database Groups*.

### Procedure

1. In SAP HANA Cockpit Manager, select *Cockpit Users*.
2. Select the user whose access you want to add or remove from a group.
3. If necessary, then click *Database Groups* to display the list of the database groups the user is already a member of.
4. To add a group, select *Grant Access to Database Groups*, select one or more groups, and then click *OK*.
5. To remove a user's membership in a group, click the  (*Delete*) icon beside the group.

### Related Information

[Adding or Removing Cockpit Users in Database Groups \[page 87\]](#)

[Creating a Database Group \[page 85\]](#)

## 5.1.5.1.3 Editing Settings for a Cockpit User

You can modify some settings for an SAP HANA cockpit user.

### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit User Administrator Role`.

### Context

Except for deactivating or activating a cockpit user, you can't edit multiple cockpit users at the same time.

### Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Users](#).
2. Select the user whose access you want to modify.
3. To see the roles assigned to the user, click [Roles](#).
4. To change the password, single-sign-on credentials, or assigned roles for the user, click [Edit](#), make any changes, and then click [Save](#).

You can't change the roles assigned to the active cockpit user.

Role	Permits access to
<b>Cockpit Administrator Role</b>	The <a href="#">Cockpit Settings</a> section of the Cockpit Manager, where they can configure cockpit settings.
<b>Cockpit Database Administrator Role</b>	The <a href="#">Issues with Technical Users</a> , <a href="#">Registered Databases</a> , and <a href="#">Database Groups</a> sections of the Cockpit Manager, where they can register databases, create database groups, and assign cockpit users to database groups.
<b>Cockpit User Administrator Role</b>	The <a href="#">Cockpit Users</a> section of the Cockpit Manager, where they can create and manage cockpit users.
<b>Cockpit User Role</b>	The SAP HANA cockpit, where they can view and monitor all databases in any assigned database groups.
<b>Cockpit User Role and allow this user to register databases</b>	The SAP HANA cockpit and the <a href="#">Registered Database</a> section of the Cockpit Manager.
<b>Cockpit User Role and Cockpit Configuration Template Administrator Role</b>	The SAP HANA cockpit and the <a href="#">Configuration Templates</a> section on the SAP HANA cockpit <a href="#">Home</a> page.
<b>Cockpit Troubleshooting Role</b>	The <a href="#">XSA Logs</a> section of the Cockpit Manager.

Role	Permits access to
	<div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>i Note</b></p> <p>To view XSA Logs, you also need to assign the XSA role of Space Auditor.</p> </div>

5. To see the database group assignments for the user, click [Database Groups](#).
  - a. To add a group, select [Grant Access to Database Groups](#), select one or more groups, and then click *OK*.
  - b. To remove a user's membership in a group, click the  (*Delete*) button beside the group.

## Related Information

### 5.1.5.1.4 Delete a Cockpit User or Revoke Cockpit Access

You can delete cockpit users or just revoke their access to cockpit.

#### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit User Administrator Role`.

#### Context

Some cockpit users may have been created outside of the cockpit manager; their original purpose could have been to access other applications. Other cockpit users have been created through the cockpit manager for the sole purpose of accessing the cockpit. When you delete a cockpit user, you can choose to:

- Allow the underlying business user to remain (so that it can be used to access other applications), and only revoke the access to the cockpit.
- Completely delete the user.

Once a user's access to the cockpit is revoked, they don't appear in the Cockpit Users list. However, if you try to create a new user with the same user's name, a message appears warning that the user name already exists. To

completely delete a cockpit user whose cockpit access has been revoked, you must first re-create the user and then completely delete them.

## Procedure

1. In SAP HANA Cockpit Manager, select *Cockpit Users*.
2. Select the user whose access you want to delete or revoke.
3. Select *Delete*.
4. In the *Confirm Request* dialog:

Choose...	In order to...
<i>Remove Access Only</i>	Allow the business user to continue to exist outside the cockpit, but without cockpit access.
<i>Delete User</i>	Delete the business user from the cockpit and from any additional applications.
<i>Cancel</i>	Don't delete the user nor the cockpit access.

## Results

The cockpit user disappears from the list. If you only revoked access for the user, to restore access, see *Create or Enable a SAP HANA Cockpit User*.

## Related Information

[Security Considerations for SAP HANA Cockpit \[page 110\]](#)

[Create or Enable an SAP HANA Cockpit User \[page 63\]](#)

## 5.1.5.2 Cockpit Settings

In the Cockpit Manager, as a cockpit administrator, you can select [Settings](#) to configure data collection, proxy server settings, and the connection timeout period, and to control whether or not SAP HANA Cockpit displays auto-created groups.

### 5.1.5.2.1 Setting Data Collection

You can reconfigure the default, SAP HANA cockpit global settings for collecting monitoring data. This data includes database status, alert counts, and other data from registered databases.

#### Prerequisites

You're logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role`.

#### Context

Changes to SAP HANA cockpit settings are global and apply to the SAP HANA cockpit it manages.

You can change the defaults to specify:

- How many worker threads the collection service can use. Increasing threads can improve response time but uses more memory. The default is 5 threads.
- Whether and how often the cockpit collects database status and alert counts. The default is 60 seconds.
- Whether and how often the cockpit collects key performance area monitoring data from each managed database. The default is 5 minutes.

There could be a brief lag before your changes in values take effect.

#### **i** Note

You can also modify the collection settings for a specific database by editing the details of that database. Doing so overrides the global settings for that particular database. See *Override Data Collection for a Database*.

#### **→** Tip

The cockpit can support 1000s of registered databases. If the Multi-Host Health Monitor displays 'Not Collected' for specific databases, you can investigate the collection service log for rejected collections and reconfigure the worker threads accordingly.

## Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Settings](#).
2. Select [Data Collection](#) and then [Edit](#).
3. Make the necessary changes and then save them.

## Related Information

[Using XS CLI Commands to Troubleshoot the Cockpit \[page 109\]](#)

### 5.1.5.2.2 Set Up a Proxy Server

As a cockpit administrator, you can optionally set up a proxy server to use with SAP HANA cockpit.

## Prerequisites

You're logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role`.

## Context

Changes to SAP HANA cockpit settings are global and apply to the SAP HANA cockpit it manages.

There are two types of proxies available: the Network proxy and the HTTP(S) proxy. In both cases, you need to specify the host and port number.

For an HTTP(S) proxy, you can also specify exceptions that don't use the proxy host. Use the [No Proxy Host](#) field to enter the exceptions (addresses beginning with the strings you enter, separated by semicolons).

#### → Tip

After setting up a proxy server, be sure to check [Enable](#) before selecting [Save](#).

## Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Settings](#).
2. Select [Proxy](#) and then [Edit](#).

3. Make the necessary changes and then save them.

### 5.1.5.2.3 Setting Connection Timeout

You can specify the length of time that the SAP HANA cockpit waits for a connection before initiating a timeout.

#### Prerequisites

You're logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role`.

#### Context

Changes to SAP HANA cockpit settings are global and apply to the SAP HANA cockpit it manages.

If a server connection is unresponsive, you may want to ensure that the cockpit doesn't wait for a response indefinitely. You can configure the following timeout periods:

Timeout period	Default
Standard database connect timeout	30 seconds
Long running tasks database connect timeout	48 hours
SAP Control connect timeout	15 seconds
SAP Control read timeout	30 minutes

#### Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Settings](#).
2. Select [Connections](#) and then [Edit](#).
3. Make the necessary changes and then save them.

## 5.1.5.2.4 Displaying Auto-Generated Database Groups

You can choose whether or not SAP HANA cockpit displays databases as part of auto-created database groups.

### Prerequisites

You're logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role`.

### Context

Changes to SAP HANA cockpit settings are global and apply to the SAP HANA cockpit it manages.

Auto-generated groups contain databases that are based on the system usage type of each database (Production, Test, Development). System usage type is configured during system installation, or later using the `global.ini` file with the `usage` parameter in the `system_information` section.

You can choose to hide one or more of the auto-created groups. Opting to hide the auto-created groups doesn't affect the system usage type associated with the database. It simply prevents the cockpit from organizing the display of databases by auto-created group.

### Procedure

1. In SAP HANA Cockpit Manager, select [Cockpit Settings](#).
2. Select [Display](#) and then [Edit](#).
3. Clear the check mark from the groups to hide.
4. Save your changes.

### Related Information

[Personalizing the Home Page Database Groups \[page 84\]](#)

## 5.1.5.3 Registered Databases

A cockpit user with the `Cockpit Database Administrator` role can register and manage databases.

### 5.1.5.3.1 Register a Database

Add a database so that cockpit users can monitor and manage it with SAP HANA cockpit.

#### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role` or the `Cockpit User Role` with the option to register databases.
- A `technical` user account with the required privileges already exists, or you can provide the credentials of a database user with user creation privileges.
- If you plan to encrypt the SAP Control or database connection, in SAP HANA XS advanced, then you have:
  1. Manually imported the server root certificates
  2. Trusted the certificates by using the command syntax `xs trust-certificate <ALIAS> -c <CERT_FILE>`
  3. Exported the certificates to the cockpit by using the commands `xs restage cockpit-hdb-svc` followed by `xs restart cockpit-hdb-svc`  
See *Importing a Certificate for Encrypted Communication*.
- If you plan to add the database to a group during the registration process, then the group already exists.  
See *Create a Database Group*.

#### Context

To make a database available to a cockpit user, the registered database must be a member of at least one database group of which the cockpit user is a member.

#### Procedure

1. Click [Register a Database](#).
2. In the [Database](#) section:
  - a. Indicate whether the database name is system-generated (default) or user-defined.
  - b. Enter the host name for the database to register. Use a fully qualified host name if possible.

If you register a database and its statistics server is unreachable, then some cockpit features will be unavailable until the statistic server is reachable.

- c. Specify an identifier for the database — the instance number or a port number (of the SAP HANA nameserver).
  - d. (For Instance Number only) Select *Single container* or *Multiple containers* and then specify the type of database. If you selected *Tenant database*, then enter the tenant database name.
  - e. (Optional) Enter a description of the database.
3. In the *Connection* section, choose whether to encrypt the cockpit's connections to SAP Control (for starting and stopping) and to the database. For information about obtaining certificates, see *Certificate Management in SAP HANA* in the *SAP HANA Security Guide*.
- If you encrypt the SAP Control connection, then you're allowing a secure connection (HTTPS) to SAP Control (provided that you've met the prerequisite of importing the trusted certificates to the cockpit).
  - If you encrypt the database connection using a secure JDBC connection, then choose whether to validate the certificate. This option lets you stipulate whether to verify that the remote server is trusted by the cockpit. Deselect the checkbox if the SAP HANA database has a certificate that differs from the one currently imported, or if you haven't imported the certificate from the SAP HANA database into XS advanced. However, the recommendation is that you instead import a certificate for encrypted connections.
  - Optionally, you can enter a hostname to override the one in the certificate. Entering a hostname avoids the validation failure that could result from the certificate's hostname differing from the hostname that cockpit uses to connect. For example, if there's a host alias, or a short hostname instead of a fully qualified domain name.
4. In the `technical user` section:

Option	Description
<b>If the <i>Technical User</i> already exists</b>	Enter its user name and password. Cockpit Manager doesn't verify the specified technical user at this point. That happens later in the registration process.
<p><b>i Note</b></p> <p>The technical user must be unique for for each instance within a database. For example, if you've already registered the SYSTEMDB and are now registering the tenant , then the technical user for the tenant must be different from the SYSTEMDB.</p>	
<b>If the technical user doesn't already exist</b>	<p>Click <i>Create New Technical User</i> and specify the following:</p> <ol style="list-style-type: none"> <li>1. The user name and password of an administrator user with user creation privileges.</li> <li>2. The user name and password for the new technical user.</li> <li>3. (Optional) Select <i>Grant EarlyWatch Alert permission</i>.</li> <li>4. Click <i>Create</i>.</li> </ol> <p>You get a message regarding the success or failure of the user creation.</p>

- 5. (Optional) In the *Groups* section, select the database groups that you want to add your database to. You can also add a database group to a group after registration is complete.
- 6. (Optional) In the *Contact* section, enter contact information for the user responsible for the database.
- 7. Select *Review*.
- 8. Go over the details on the *Register Review* page and use *Edit* to make changes.
- 9. When you're satisfied with the information on the database, select *Register*.

## Results

- If registration is successful, then the newly registered appears in the registered list, and displays the software version.
- If you're prompted to register the system using the SAP HANA Agent, then click [Yes](#). Enter the instance number, select [Multiple containers](#), and then specify the type of database. If you selected Tenant database, then enter the tenant database name. Click [Register](#).
- If registration is successful, but Cockpit Manger is unable to establish a connection to the database, the newly registered database appears on the Registered list with a software version of 0.00.000.00.0 (UNKNOWN). Before you can access the database, resolve the connection issue. See [Troubleshooting Registration Issues](#).
- If the registration request fails because the specified information is invalid, then select [OK](#) to acknowledge the error. Select [Edit](#) in the section with the error, fix it, and scroll to the bottom of the page. Select [Review](#) and try registering the database again. See [Troubleshooting Registration Issues](#).

## Next Steps

- If Cockpit Manger is unable to connect to the database, but is able to register the database, then warning messages regarding failed statuses and privileges relating to the technical user appear. These messages appear because the system is unable to validate the related information. Acknowledge the messages. The newly registered database appears in the registered list, but the software version appears as 0.00.000.00.0 (UNKNOWN). Before you can use the database, you must resolve the connection issues. See [Troubleshooting Registration Issues](#).
- Verify that there are no issues with the technical user. See [The Technical User](#).
- If you didn't assign the database to a group during registration because the group didn't already exist, then create it now and add the new registered database to the group.
- If the group exists but you didn't assign the database to a group during registration, then assign it now.

## Related Information

[Troubleshoot Registration Issues](#)

[Creating a Database Group \[page 85\]](#)

[Importing a Certificate for Encrypted Communication \[page 118\]](#)

[Adding or Removing Databases in a Database Group \[page 86\]](#)

[Deactivate a Database User \[page 927\]](#)

[Delete a Database User \[page 929\]](#)

[The Technical User \[page 76\]](#)

### 5.1.5.3.1.1 The Technical User

The technical user is a dedicated database user that the cockpit uses to collect health data for monitoring the database (such as information on alerts and system performance).

The technical user must be unique for each instance within the database. If you reuse the technical user, then registration fails with a message that the system can't authenticate the user credentials.

Create the technical user during database registration by specifying the credentials of an administrator on that database with the ability to create user accounts. You can also create a technical user by using the [User and Role Management](#) card on the database [Database Overview](#) page, as long as you have the USER CREATION privilege.

The technical user should be exempt from password expiration policies and should be a dedicated account. Human users should never log in using the technical user account. At a minimum, the technical user requires the CATALOG READ system privilege and the SELECT privilege on the \_SYS\_STATISTICS schema. Additional privileges may be required, as additional optional permissions are enabled to enhance data collection. See *Security Considerations of SAP HANA Cockpit*. If you change the technical user of a registered database, then you must create the new user first by using [User and Role Management](#) in SAP HANA cockpit, and then edit the registered database in SAP HANA Cockpit Manager, specifying the new technical user credentials. You can't create a technical user when editing a registered database. Once the new technical user is assigned, if you don't need the old technical user, then deactivate it on the [User and Role Management](#) page.

### Resources with an Invalid Technical User

If there are issues with your database's technical user credentials, then you're notified via a message strip on your database in the [Database Directory](#) or [Cockpit Manager](#).

This message persists until you provide the correct credentials by clicking [Investigate](#) on the message strip, or by clicking on the [Issues With Technical Users](#) option on the [Cockpit Manager](#).

If all technical users are valid, then the [Issues With Technical Users](#) option no longer appears on the [Cockpit Manager](#).

### Related Information

[Create a Database User \[page 915\]](#)

## 5.1.5.3.2 Edit Database Settings

Once a database has been registered, you can modify some settings, including `technical user`, encryption, and single sign-on (SSO).

### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role` or the `Cockpit User Role` with the option to register databases.

### Context

When you log in to Cockpit Manager, if the credentials for this database's `technical user` (the logon the cockpit uses to collect system health and version information) need to be updated, then an indicator in the *Database Directory* alerts you. This behavior happens because the `technical user`'s password has changed, or the `technical user` has been deleted. You can't monitor the database until you fix the technical user's credentials.

### Procedure

1. Click *Register a Database*.
2. Select the database you want to modify.
3. On the *Database Details* tab, click *Edit*.
4. Modify the settings as needed.
  - Technical user
    - To change the technical user, you must supply a database user with user creation privileges.
    - You can:
      - Enter a new technical user as long as it already exists in the database. The new technical user must already exist; you can't create a new user while editing a registered database. Each database within the same instance must be assigned a unique technical user. If you try to assign the same technical user to multiple databases, then you get a `Request Failed` message.
      - Grant and remove access to other services used by the technical user. Granting access automatically grants any additional privileges required for the feature. However, removing access doesn't remove the granted privileges from the user.
      - Change the password for the technical user. The technical user passwords entered for the database in cockpit manager and in cockpit are stored in different locations, and must always match. Changing the password in one location doesn't automatically update the other location.
  - Connection

- If you encrypt the SAP Control connection, then you're allowing a secure connection (HTTPS) to SAP Control (provided that you've met the prerequisite of importing the trusted certificates to the cockpit).
  - If you encrypt the database connection using a secure JDBC connection, then choose whether to validate the certificate. This option lets you stipulate whether to check that the remote server is trusted by the cockpit. You can use this option if you haven't imported the certificate from the SAP HANA database into XS advanced, or if the SAP HANA database has a certificate that differs from the one currently imported.
  - Optionally, you can enter a hostname to override the one in the certificate. Providing a hostname avoids the validation failure that results from the hostname in a certificate differing from the hostname that cockpit uses to connect. For example, if there's a host alias, or a short hostname instead of a fully qualified domain name.  
For information about obtaining certificates, see *Certificate Management in SAP HANA* in the *SAP HANA Security Guide*.
  - Single Sign-on (SSO)
    - To enable SSO, supply a database user with the TRUST ADMIN, CERTIFICATE ADMIN, and USER ADMIN privileges. Before enabling SSO, consider migrating the Personal Security Environment (PSE) file to an in-database store. When SSO is enabled, a new PSE file may be created, which may prevent cockpit access to stored certificates. See SAP Note 265666.
    - To enforce SSO, you must supply a database user with the TRUST ADMIN, CERTIFICATE ADMIN, and USER ADMIN privileges. When enforced, cockpit users must use SSO to access the database in SAP HANA cockpit. Otherwise, on the [Database Directory](#) page, cockpit users can choose whether to access this database with SSO or enter alternate database user credentials. Enforce SSO only after you have configured SSO on the database. See *Enforce Single Sign-On on the Database*.
  - Data Collection (Status and Alert Counts, and Feature Data, EarlyWatch Alert Transmission and Collection)
    - You can modify the collection settings for a specific database by editing the details of that database. Doing so overrides the global settings for that particular database. Only perform changes if necessary.
    - To revert to the global setting, in database edit mode, select [Global Settings](#) (instead of [Database Override](#)).
5. When done, click [Save](#).

## Related Information

## 5.1.5.3.2.1 Enforce Single Sign-On on the Database

Before you can enforce SSO through cockpit only, you must configure SSO on the database.

### Prerequisites

- The cockpit users who access this database have been created.

### Context

You can enforce single sign-on (SSO) user authentication on database running SAP HANA 2.0 SPS 01 or later.

### Procedure

1. As a cockpit user who is a member of the registered database's database group, log in to SAP HANA cockpit.
2. Click the *Database Directory* tile.
3. Connect to the database as an existing database user with the TRUST ADMIN, USER ADMIN, and CERTIFICATE ADMIN privileges.
4. On the *Database Overview* page, on the *User & Role Management* card, select *Manage Users*.
5. Select a user to use SSO and click *Edit*.
6. Set the JWT mappings.
7. Return to the *Database Directory* page and connect to the database as the newly configured database user.
8. Return to the Cockpit Manager, edit the database and enforce SSO.

### Next Steps

Repeat this process for each managed database on which you want to configure SSO.

### 5.1.5.3.3 Unregister a Database

Remove one or more database from SAP HANA cockpit.

#### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role` or the `Cockpit User Role` with the option to register databases.

#### Context

Removing a database also removes it from any associated database groups.

#### Procedure

1. Click [Register a Database](#).
2. Select the database to remove and click [Unregister](#).

#### Related Information

[Register a Database \[page 73\]](#)

### 5.1.5.3.4 Export Databases

Export registration information about databases to a JSON file, which you can then import into other systems.

#### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role` or the `Cockpit User Role` with the option to register databases.
- The databases you're exporting are running and available on the network.

## Context

You can export multiple databases at the same time. Optionally, you can include the `technical user` and contact information in the export file. When you include the technical user, the password is not included.

## Procedure

1. Click [Register a Database](#).
2. Click the **⋮** (*More*) button, then click [Export Databases](#).
3. Select the databases you want to export.
4. (Optional) Click to [Save technical user login names](#) in the export file.
5. (Optional) Click to [Save contact settings](#) in the export file.
6. Click [Save export file](#).

## Next Steps

By default, the export file is saved to the Downloads folder and named `ResourceList.json`. Copy the export file to a location accessible by the importing system, then use the file to import the databases to the new system. If you included the `technical user` in the file, you can:

- Edit the export file and add the corresponding password before initiating the import. The `technical user` and password values then automatically populate the fields during the import. See [Add the Technical User Password to the Export Json File](#).
- Manually enter the `technical user` and password during the import.

## Related Information

[Import Databases \[page 82\]](#)

[Add the Technical User Password to the Export JSON File](#)

## 5.1.5.3.5 Import Databases

Add databases exported from other systems to the current system.

### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Administrator Role` or the `Cockpit User Role` with the option to register databases.
- You've created a `.json` or `.xml` export file on another SAP HANA system that specifies the databases to be imported, and you've copied that file to a location accessible to the importing system.
- If you plan to encrypt the SAP Control or database connection, in SAP HANA XS advanced, then you have:
  1. Manually imported the server root certificates
  2. Trusted the certificates using the command syntax `xs trust-certificate <ALIAS> -c <CERT_FILE>`
  3. Exported the certificates to the cockpit using the commands `xs restage cockpit-hdb-service` followed by `xs restart service cockpit-hdb-svc`.  
See *Import a Certificate for Encrypted Communication*.
- The databases you're importing are running and available on the network.

### Context

The export file may contain the `technical user` and or the password for each database. See *Add the Technical User Password to the Export JSON File*. If included, the information automatically populates the fields on the *Authenticate* page. You can override the information, if needed, but if specified, the user name and password must exist in the database.

The specification of a `technical user` and password during import is optional, so you can leave the fields empty, but if the `technical user` is specified, you must either enter a password or clear the `technical user` before you can proceed with the import.

If you don't specify a `technical user`, once the database is registered, you will see warning messages in SAP HANA Cockpit Manager and SAP HANA Cockpit that the `technical user` is missing and you are prompted to add it.

Validation of the `technical user` information doesn't occur until the actual import begins. If the `technical user` is invalid, an error message appears. You can edit the import details and try the import again.

### Procedure

1. Click *Register a Database*.
2. Click the `⋮` (*More*) icon, then click *Import Databases*.

3. On the Import page:
  - a. Choose the file type to be imported.
  - b. Click [Browse](#) and choose the file.
  - c. Specify whether to include collection settings.

The [Include collection settings](#) option appears for export files created from a cockpit version SP 10 or later. It includes settings for statuses, alerts, databases, and so on, which could override your global cockpit settings. Don't select this option if you don't want to override your global cockpit settings.

4. Select the databases you want to register.
5. On the [Authenticate](#) page,

Option	Action
To use the displayed technical user and password information from the export file	Go to step 6 <a href="#">[page 83]</a> .
To specify a technical user and password for a database	Manually enter the value. You can override any value displayed, but the credentials must be valid in the database being imported.
To assign the same technical user and password to each database	Click <a href="#">Use the same credentials for all selected database</a> . Enter a single technical user and password when prompted. The credentials must be valid in every database being imported.
To clear credentials and import all selected databases without a technical user defined	Click <a href="#">Clear credentials and register without providing a technical user for all selected databases</a> .

When importing multiple databases, you can use different options for the databases. For example, if you are importing three databases, you could leave the displayed user and password for the first database, override the values from the import file for the second database, and clear the technical user and password completely for the third database.

6. Click the [Step 4](#) button.
 

The [Step 4](#) button does not appear until both the technical user and password fields for each database either have values defined or are empty.
7. (Optional) If you included contact information in the export file, the values automatically appear. You can override any value displayed.
8. (Optional) Select a database group. All of the selected databases will be assigned to the same group.
9. Click [Review](#). Click [Edit](#) to make any changes.
10. Click [Import Databases](#).

A message appears to indicate the status of each database's import. If the import failed for a database, you can edit the values and try again.

## Next Steps

- (Optional) If you didn't specify a database group during the import, then specify one now.
- If you imported databases without specifying a technical user, the health data for monitoring databases will not be collected until a valid technical user is specified for the database. Add the technical user now.

[Add the Technical User Password to the Export JSON File](#)

### 5.1.5.3.6 Database Groups

You can create, populate, or remove the groups used to grant cockpit users access to registered databases.

A database group—a named set of one or more registered databases—controls management and monitoring privileges. You assign cockpit users and registered databases to a database group, enabling the user to monitor and manage the group's databases through the cockpit. A cockpit user can only access registered databases that are assigned to the same database group.

Database groups let you:

- View and administer similar databases together.
- Control which cockpit users can see and use particular databases.

You can create database groups whatever way you want—for example, by groups based on databases' geographic location, ownership, or purpose.

Each database also belongs to an auto-generated group. These auto-generated groups of databases (Production, Test, Development) are based on the system usage type of each database. System usage type is configured during system installation, or later using the `global.ini` file with the `usage` parameter in the `system_information` section.

You can hide the auto-generated groups if you don't want to use them. See *Displaying Auto-Generated Database Groups*.

You can't assign cockpit users to an auto-generated group, or to individual databases.

## Related Information

[Displaying Auto-Generated Database Groups \[page 72\]](#)

## 5.1.5.3.6.1 Creating a Database Group

Set up a group you can use to display, manage, and control access to related databases.

### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Database Administrator Role`.

### Context

When you create a database group, you can add both databases and cockpit users. Only users assigned to the group can see and access the group's databases.

### Procedure

1. In SAP HANA Cockpit Manager, select *database Groups*.
2. Click *Create Group*.
3. Enter a name for the group.  
The name can contain uppercase and lowercase letters, the digits 0 through 9, underscores, hyphens, periods, and spaces and must be unique.
4. (Optional) Enter a description for the group.
5. (Optional) Click  and select the registered databases to add to the new group. You can add registered databases to a group later if needed.
6. (Optional) Select *Register other databases after the group is created* so that as soon as the group is created, you can begin registering a new database. The new database is automatically added to the new group, but you can override this behavior if needed.
7. (Optional) Click  and select cockpit users who access the new group. You can add cockpit users to a group later if needed.
8. Click *Create Group*.

If you selected *Register other databases after the group is created* during creation, then the group is created and then the *Register Database* page opens. Otherwise, the new group appears in the Database Groups list.

### Next Steps

- If the registered databases or cockpit users didn't already exist when creating the database group, then create them now and add them to the new group.

- If you didn't assign existing users or registered databases to the new group during registration, then do it now.

## Related Information

[Register a Database \[page 73\]](#)

[Adding or Removing Cockpit Users in Database Groups \[page 87\]](#)

### 5.1.5.3.6.2 Adding or Removing Databases in a Database Group

Add a database to a database group or remove a database from a database group.

## Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Database Administrator Role`.
- The database to be added is already registered. See *Register a Database*.

## Context

Auto-generated groups don't appear on the *Database Group* page and you can't modify or delete them. Register a database to add it to a group.

## Procedure

1. In SAP HANA Cockpit Manager, select *database Groups*.
2. Select the group you want to add or remove a database from.
3. If necessary, then click *Database* to display the list of the group's databases.
4. To add a database, click *Add Database*, select one or more databases, and then click *OK*.
5. To remove a database, click the  (*Delete*) icon beside the database.

## Related Information

[Register a Database \[page 73\]](#)

### 5.1.5.3.6.3 Deleting a Database Group

Remove a database group from the SAP HANA cockpit.

#### Prerequisites

You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Database Administrator Role`.

#### Context

Any cockpit users who had access to databases solely through the delete database group will no longer be able to access them.

#### Procedure

1. In SAP HANA Cockpit Manager, select *database Groups*.
2. Select the group you want to remove.
3. Click *Delete* and confirm the deletion.

### 5.1.5.3.6.4 Adding or Removing Cockpit Users in Database Groups

Add a cockpit user to a database group or remove a user from a database group.

#### Prerequisites

- You are logged on to SAP HANA Cockpit Manager as a cockpit user that has been assigned the `Cockpit Database Administrator Role`.

- The cockpit users to be added to the group already exist. See *Create or Enable a Cockpit User*.

## Context

Auto-generated groups don't appear on the *Database Group* page and you can't modify or delete them.

## Procedure

1. In SAP HANA Cockpit Manager, select *database Groups*.
2. Select the group you want to add or remove a database from.
3. If necessary, then click *Cockpit Users* to display the list of the group's users.
4. To add a user, click *Add User*, select one or more users, and then click *OK*.
5. To remove a user, click the  (*Delete*) icon beside the user.

## Related Information

[Create or Enable an SAP HANA Cockpit User \[page 63\]](#)

### 5.1.5.4 Managing Databases, Users, and Groups with the Cockpit APIs

SAP HANA cockpit provides modifying (POST) and nonmodifying (GET) REST APIs. You access the APIs differently depending on whether you're calling a POST or a GET API and whether you're calling it programmatically or from a browser.

#### Using Cockpit APIs from an External Program

The external tool you use to invoke SAP HANA cockpit APIs must be capable of sending complex REST calls. The tool could be a custom program or a browser with a REST console plug-in. A browser with a REST plug-in is useful for testing.

To access cockpit POST and GET APIs from an external program, you must:

1. Obtain a service key for the external tool. (You obtain this key only once.)
2. Obtain an OAuth token using information in the service key, plus a cockpit user with the appropriate role. (You can use the OAuth token until it expires—usually in 30 minutes.)
3. Using the OAuth token, invoke one or more cockpit APIs.

## Obtaining a Service Key

The cockpit runs on SAP HANA extended application services, advanced model (XS advanced), which provides authentication and authorization to external tools via service keys to the User Authentication and Authorization component (cockpit-UAA). You use `xs` commands in SAP HANA XS advanced to generate a service key for your external tool. The service key is a block of Javascript Object Notation (JSON) code; you store it in a file that your application can load and use.

Run the `xs create-service-key cockpit-uaa <tool-name>-cockpit-uaa`

```
xs create-service-key cockpit-uaa <tool-name>-cockpit-uaa
```

Next, store the service key in a `.json` file:

```
xs service-key cockpit-uaa <tool-name>-cockpit-uaa > <tool-name>-service-key.json
```

Finally, edit the `.json` file to remove the lines before and after the curly brackets. The original file takes this form:

```
Getting service key "foo-cockpit-uaa" for service instance "cockpit-uaa" ...
{
  "tenantmode" : "dedicated",
  "clientid" : "sb-cockpit!i1",
  "verificationkey" : "<REDACTED>",
  "xsappname" : "cockpit!i1",
  "identityzone" : "uaa",
  "identityzoneid" : "uaa",
  "clientsecret" : "<REDACTED>",
  "url" : https://host:30032/uaa-security
}
OK
```

Change it to look similar to this:

```
{
  "tenantmode" : "dedicated",
  "clientid" : "sb-cockpit!i1",
  "verificationkey" : "<REDACTED>",
  "xsappname" : "cockpit!i1",
  "identityzone" : "uaa",
  "identityzoneid" : "uaa",
  "clientsecret" : "<REDACTED>",
  "url" : https://host:30032/uaa-security
}
```

## Obtaining an OAuth Token

OAuth tokens are granted to cockpit users, so you must identify a cockpit user you can employ to run the cockpit APIs. To find the role needed for the API you want to run, see [Using Cockpit POST APIs \[page 90\]](#) or [Using Cockpit GET APIs \[page 93\]](#).

Using your external tool along with the UAA URL provided in the service key and the cockpit user you've identified, invoke the UAA API `POST /oauth/token` with a `grant_type` of `password`. The `clientid` and `clientsecret` come from the service key (previous). For example:

```
POST https://host:30032/uaa-security/oauth/token HTTP/1.1
Host: localhost:8080
Accept: application/json
Authorization: Basic YXBwOmFwcGNsaWVudHNlY3JldA==
"grant_type=password&username=marissa&password=koala&clientid=<clientid>
&clientsecret=<clientsecret>"
```

Expect a response code of 200 with a body similar to this:

```
{
  "access_token": "2YotnFZFEjrlzCsicMWpAA",
  "token_type": "bearer",
  "expires_in": 3600
}
```

#### → Tip

Notice the value of `expires_in`, which tells you how long (in seconds) you can use the token before getting a new one.

For more on the `POST /oauth/token` API, see <https://github.com/cloudfoundry/uaa/blob/master/docs/UAA-APIs.rst>.

## Invoking Cockpit APIs

To obtain the URL for the `cockpit-adminui-svc`, which you use to access the cockpit APIs programmatically as described previously, issue this command to SAP HANA XS advanced:

```
$ xs apps | grep cockpit-adminui-svc
cockpit-adminui-svc          STARTED          1/1          128 MB
<unlimited> https://host:51025
```

## Related Information

[Using Cockpit POST APIs \[page 90\]](#)

[Using Cockpit GET APIs \[page 93\]](#)

### 5.1.5.4.1 Using Cockpit POST APIs

Details on the SAP HANA cockpit APIs that create, delete, or change objects in the cockpit.

For instructions on setting up programmatic access to the cockpit APIs, see [Managing Databases, Users, and Groups with the Cockpit APIs \[page 88\]](#).

The APIs described in the following table accept HTTP POST operations with arguments passed in the body in JSON format. Each API returns data in JSON format.

## Success

If an API succeeds, it returns:

- Status 200
- A JSON response in this form:

### Sample Code

```
{
  result: {
    <some data>
  }
}
```

## Failure

If an API fails, it returns:

- One of these statuses:
  - 401 – Unauthorized (the token provided isn't accepted)
  - 403 – Forbidden (the token doesn't include appropriate scopes to execute this API)
  - 400 – Bad request (an input argument is missing or invalid)
  - 500 – Server error (something else went wrong)
- A JSON response in this form:

### Sample Code

```
{
  message: {
    <error message with properties such as resource key, default text,
    etc.>
  }
}
```

## SAP HANA Cockpit POST APIs

Each API listed in the POST APIs table accepts HTTP POST operations with arguments passed in the body in JSON format. Each API returns data in JSON format. These POST APIs require you to use an authentication token as described in [Managing Databases, Users, and Groups with the Cockpit APIs \[page 88\]](#). Because out-of-the-box web browsers don't support POST operations, you need a suitable plug-in to use or test the cockpit's POST APIs with a browser.

POST APIs

API	What It Does	Input Parameters	Response <sup>1</sup>	Required Role
/registration/ SystemRegister	Registers an SAP HANA resource with the cockpit using JDBC. Post to the API with parameters in the body in JSON format (Content-Type=application/json; charset=UTF-8).	<p>hostName</p> <p>instanceNumber or port</p> <p>techUser</p> <p>techUserCredentials</p> <p>isMultiTenant – can be omitted if you specify port instead of instanceNumber</p> <p>databaseName – can be omitted if you specify port instead of instanceNumber</p> <p>security (encryptJDBC, validateServerCertificate, hostNameInCertificate)</p>	resid – resource ID of newly registered resource	Cockpit Resource Administrator or Cockpit Power User
/registration/ SystemUnregister	Unregisters an SAP HANA resource. Post to the API with parameters in the body in JSON format (Content-Type=application/json; charset=UTF-8).	resid – integer, required. The unique resource ID previously returned by a registration API.		Cockpit Resource Administrator or Cockpit Power User
/registration/ ResourceUnregister	Unregisters an SAP HANA resource.  Deprecated—use SystemUnregister instead.	resid		Cockpit Resource Administrator
/group/ GroupCreate	Creates a new resource group	<p>groupName</p> <p>groupDescription</p>	groupId	Cockpit Resource Administrator
/group/ GroupDelete	Deletes a resource group	groupId		Cockpit Resource Administrator

<sup>1</sup> See also the general responses described under Success and Failure.

API	What It Does	Input Parameters	Response <sup>1</sup>	Required Role
/user/ CockpitUserCreate	Creates a new cockpit user	username password email roleCollections []	cockpitId – ID of newly created user	Cockpit Administrator
/user/ CockpitUserDelete	Deletes a cockpit user	deleteFromUAA userId username		Cockpit Administrator
/group/ GroupResourceAdd	Adds a resource to a group	groupId resourceId		Cockpit Resource Administrator
/group/ GroupResourceRemove	Removes a resource from a group	groupId resourceId		Cockpit Resource Administrator
/group/ GroupUserAdd	Adds a user to a group	groupId userId		Cockpit Resource Administrator
/group/ GroupUserRemove	Removes a user from a group	groupId userId		Cockpit Resource Administrator

## 5.1.5.4.2 Using Cockpit GET APIs

The SAP HANA cockpit APIs provide information about registered databases, cockpit users and database groups. The GET APIs don't create, delete, or change anything in the cockpit.

### Prerequisites

- You must be authenticated as a SAP HANA cockpit user to invoke the APIs. Each API with "Get" in its name (RegisteredResourcesGet, for example) is protected with both authentication and authorization checks.
- You must have an OAuth token to invoke API calls against the cockpit-landscape-svc. To obtain a token, follow the instructions in [Managing Databases, Users, and Groups with the Cockpit APIs \[page 88\]](#).
- If you're using a browser to test a GET API, you must go through the app-router, using either the cockpit-admin-web-app or cockpit-web-app URL.

<sup>1</sup> See also the general responses described under Success and Failure.

## RegisteredResourcesGet

Returns information about the databases registered in SAP HANA cockpit.

**Prerequisites** You must have the COCKPIT\_RESOURCE\_ADMIN role or the COCKPIT\_POWER\_USER role. The information returned depends on your role:

- If you have the COCKPIT\_RESOURCE\_ADMIN role, then RegisteredResourcesGet returns information on all databases registered with this cockpit.
- If you have the COCKPIT\_POWER\_USER role, then RegisteredResourcesGet returns information on all databases registered by you with this cockpit.

**Returns** When it succeeds, RegisteredResourcesGet returns HTTP status 200 and the result data. Otherwise, it returns an HTTP response code and text describing why the request failed – for example, 403, "Permission Denied."

**Syntax** You can invoke GET APIs in two ways:

- Through the cockpit-web-app port via the app-router. The call is redirected to the XSA sign-in page if it doesn't present an app-router cookie indicating authentication status. This form of invocation through the app-router is ideal for testing with a web browser, but not ideal for programmatic calls.
- Against the cockpit-landscape-svc endpoint. Calls using this method must present a valid authentication token.

API Endpoints for RegisteredResourcesGet

cockpit-admin-web-app	/cp/admin/resource/RegisteredResourcesGet
cockpit-adminui-svc	/resource/RegisteredResourcesGet

RegisteredResourcesGet supports query parameters in OData format, for example, \$count, \$top=, \$skip=, \$orderby=.

RegisteredResourcesGet supports pagination and therefore returns a maximum of 100 rows for one page. If you have more than 100 registered databases, call /cp/admin/RegisteredResourcesGet or /resource/RegisteredResourcesGet to get the top 100 registered databases, then use the OData token \$top and \$skip to get the next 100 registered databases, for example:

```
/cp/admin/resource/RegisteredResourcesGet?$skip=100&$top=100
```

A successful response is a JSON object in this format:

```
{
  "result": [
    {
      "BuildNumber": "1522210459",
      "CertificateHostName": "",
      "CollectionConfigurations": [],
      "Connections": [
        {
          "Host": "host.domain.com",
          "IsSAPControlAuthenticated": false,
          "PortType": "INSTANCE",
          "PortValue": 1,

```

```

        "Role": "MASTER",
        "SAPControlUserName": null
    }
],
"CreatedBy": "COCKPIT_ADMIN",
"DatabaseName": "DBNAME",
"Designation": "CUSTOM",
"EncryptedJDBC": false,

"VersionMajor": 2,
"VersionMinor": 0
}
]
}

```

Each object in the array represents a registered database. The object returned has the following properties:

Property	Description
ResourceId	The internal ID the cockpit uses to identify this database. Other cockpit APIs require this ID as a parameter.
ResourceUniqueId	The unique internal identifier of the database. This value is either specified at registration time or read from the system being registered where possible. If not supplied by the caller or the database, a random value is generated but it isn't guaranteed to be unique.
ResourceName	The name of the database. For SAP HANA systems, the default name takes the form <DB>@<SID> – for example, DB1@HA0.
ResourceDescription	The description of the database optionally provided at registration time.
CreatedBy	The cockpit user who registered the database. (CreatedBy isn't the same as the database owner, following).The description of the database optionally provided by the registering user at registration time.
SystemName	The system name. For SAP HANA systems, it's the SID (HA0, for example).

Property	Description
DatabaseName	The database name, for example, DB1.
Designation	The designation or usage type of the database. For SAP HANA systems it can be PRODUCTION, DEVELOPMENT, TESTING, or CUSTOM.
Version	The database's full version string.
VersionMajor	The major version of the database as an integer (for example, 2)
VersionMinor	The minor version of the database as an integer (for example, 0)
ServicePack	The service pack of the database as an integer (for example, 20)
PatchLevel	The patch level of the database as an integer.
BuildNumber	The build number of the database.
ResKey	The description of the database optionally provided by the database key for the type of the database (for example "RESKEY_HANA_MDB_SYSTEM").
ResValue	The type of the database (for example, HANA_SYSTEM).
ResIcon	A path to an icon used to render the database type (not currently used)
OSVersion	The version of the operating system where the database is running
HardwarePlatform	The platform where the database is running (for example, VMware Virtual Platform).
ResourceOwnerName	Optional owner name. The owner isn't necessarily the same person who registered the system and doesn't have to be a cockpit user. This person the contact for questions or problems.
ResourceOwnerEmail	Optional. The e-mail address of the owner.
ResourceOwnerDetail	Optional. Additional details on the database owner. Details could include work hours, location, or phone number.
SSOSupported	If this value is true, this database supports single sign-on from the cockpit.
SSOEnabled	If this value is true, single sign-on from the cockpit is turned on.
SSOEnforced	If this value is true, single sign-on is the only available authentication method from the cockpit.
EncryptedJDBC	If this value is true, communication with this database uses an encrypted database connection.
EncryptedSAPControl	If this value is true, communication with the host agent managing this database uses TLS.
ValidateServerCertificate	If this value and EncryptedJDBC are both true, the client validates the server (database) using pre-installed certificates.
CertificateHostName	If set, the connection uses this value instead of the host name provided in the server certificate for encrypted database connections
TechnicalUser	The name of the <code>technical</code> user the cockpit uses for this database.
Host (& HostName)	The main host name of the database. Duplicated in both fields for compatibility.

Property	Description														
PortType	The type of the main connection to the database. Set to either "INSTANCE" or "SQL". If INSTANCE the port is an instance number. If SQL the port is a SQL port.														
Port	The instance number or SQL port (for example, the indexserver SQL port) of the main connection to the database.														
GroupCount	The number of groups this database belongs to.														
Connections	<p>All possible connections to the database (for scale-out systems or those systems with host aliases, for example). The main connection as dictated by Role is copied into the previous properties.</p> <p>An array of connection objects in this form:</p> <table border="1"> <thead> <tr> <th>Property</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>Role</td> <td>The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.</td> </tr> <tr> <td>PortType</td> <td>INSTANCE or SQL.</td> </tr> <tr> <td>PortValue</td> <td>Instance number or SQL port number.</td> </tr> <tr> <td>Host</td> <td>Host name for this connection.</td> </tr> <tr> <td>IsSAPControlAuthenticated</td> <td>If true, authenticated has been set (by the current user) for the SAP Control functionality.</td> </tr> <tr> <td>SAPControlUserName</td> <td>The name of the SAP Control user, if set.</td> </tr> </tbody> </table>	Property	Description	Role	The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.	PortType	INSTANCE or SQL.	PortValue	Instance number or SQL port number.	Host	Host name for this connection.	IsSAPControlAuthenticated	If true, authenticated has been set (by the current user) for the SAP Control functionality.	SAPControlUserName	The name of the SAP Control user, if set.
Property	Description														
Role	The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.														
PortType	INSTANCE or SQL.														
PortValue	Instance number or SQL port number.														
Host	Host name for this connection.														
IsSAPControlAuthenticated	If true, authenticated has been set (by the current user) for the SAP Control functionality.														
SAPControlUserName	The name of the SAP Control user, if set.														

## CockpitUsersGet

Returns information about cockpit users.

**Returns** When it succeeds, CockpitUsersGet returns HTTP status 200 and the result data. Otherwise, it returns an HTTP response code and text describing why the request failed – for example, 403, "Permission Denied."

**Syntax** You can invoke GET APIs in two ways:

- Through the cockpit-web-app port via the app-router. The call is redirected to the XSA sign-in page if it doesn't present an app-router cookie indicating authentication status. This form of invocation through the app-router is ideal for testing with a web browser, but not ideal for programmatic calls.

- Against the cockpit-landscape-svc endpoint. Calls using this method must present a valid authentication token.

API Endpoints for CockpitUsersGet

cockpit-admin-web-app	/cp/admin/user/CockpitUsersGet
cockpit-adminui-svc	/user/CockpitUsersGet

CockpitUsersGet supports the following query parameters in OData format. For example, \$orderBy= \$count, \$top=, and \$skip=. For example:

```
/cp/admin/user/CockpitUsersGet?$orderby=Name&$top=2
```

Note that only the Name field can be filtered with equal relation.

A successful response is a JSON object in this format:

```
{
  "result": [
    {
      "Id": "26",
      "Name": "COCKPIT ADMIN",
      "LastLogin": "2021-04-08 06:36:39 (UTC)",
      "ProviderId": null,
      "Email": "test@sap.com",
      "active": true,
      "uaaId": "156013"
    },
    {
      "Id": "474461",
      "Name": "COCKPIT USER",
      "LastLogin": "2021-02-08 09:58:31 (UTC)",
      "ProviderId": null,
      "Email": "test1@sap.com",
      "active": true,
      "uaaId": "170319"
    }
  ]
}
```

Each object in the array represents a database group. The object returned has these properties:

Property	Description
ID	Numerical ID
Name	The login name
LastLogin	Timestamp of the last login
ProviderID	(Optionally if the user has been created locally) The ID of the identity provider, if the user has been created by SSO; otherwise, null
Email	The email address of the user
Active	True/False
UaaID	The internal ID used by the UAA

## GroupsForUserGet

Returns information about the database groups (including the default groups Development, Production, Test, and automatic groups) that are visible to you.

**Returns** When it succeeds, GroupsForUserGet returns HTTP status 200 and the result data. Otherwise, it returns an HTTP response code and text describing why the request failed – for example, 403, "Permission Denied."

- Syntax**
- Through the cockpit-web-app port via the app-router. The call is redirected to the XSA sign-in page if it doesn't present an app-router cookie indicating authentication status. This form of invocation through the app-router is ideal for testing with a web browser, but not ideal for programmatic calls.
  - Against the cockpit-landscape-svc endpoint. Calls using this method must present a valid authentication token.

API Endpoints for GroupsForUserGet

cockpit-web-app	/cp/ls/group/GroupsForUserGet
cockpit-landscape-svc	/group/GroupsForUserGet

A successful response is a JSON object in this format:

```
{
  result: [
    {
      Type: 1,
      Name: "GROUPNAME",
      Description: "Description",
      RunWithAlert: 1,
      NotRunning: 0,
      ResourceCount: 5
    }
  ]
}
```

Each object in the array represents a database group. The object returned has these properties:

Property	Description
Type	An integer representing the type of the group: 1 = ALL group 2 = AUTO group (Production, Development, or Test) 3 = Group created by a user
Name	The name of the group.
Description	Optional. The description of the group provided by the user who created it.
CreatedBy	For Type 3 groups only. The cockpit user who created this database group.
Id	For Type 3 groups only. The groupId of this group.
ResourceCount	The number of databases in this group.
RunWithAlert	The number of databases in this group that have active alerts.

Property	Description
NotRunning	The number of databases in this group that aren't in the state RUNNING.

## GroupResourcesGet

Returns information about the databases in a specified group that's visible to you. Only groups returned by `GroupsForUserGet` can be used as arguments for `GroupResourcesGet`.

**Returns** When it succeeds, `GroupsForUserGet` returns HTTP status 200 and the result data. Otherwise, it returns an HTTP response code and text describing why the request failed – for example, 403, "Permission Denied."

**Syntax** You can invoke `GroupResourcesGet` in two ways:

- Through the cockpit-web-app port via the app-router. The call is redirected to the XSA sign-in page if it doesn't present an app-router cookie indicating authentication status. This form of invocation through the app-router is ideal for testing with a web browser, but not ideal for programmatic calls.
- Against the cockpit-landscape-svc endpoint. Calls using this method must present a valid authentication token.

API Endpoints for `GroupResourcesGet`

cockpit-web-app	<code>/cp/ls/group/GroupResourcesGet</code>
cockpit-landscape-svc	<code>/group/GroupResourcesGet</code>

`GroupResourcesGet` supports query parameters in OData format, for example, `$count`, `$top=`, `$skip=`, `$orderby=`.

`GroupResourcesGet` supports pagination and therefore returns a maximum of 100 rows for one page. If you have more than 100 registered databases included in the specified group that is visible to the current user, call `/cp/ls/group/GroupResourcesGet` or `/group/GroupResourcesGet` (with mandatory query parameters as either `?groupId=<id>` or `?groupDesignation=<string>`) to get the top 100 registered databases. Then, use the OData tokens `$top` and `$skip` to get next top 100 registered databases, for example:

```
/cp/ls/group/GroupResourcesGet?$skip=100&$top=100 (with mandatory query parameters as either &groupId=<id> or &groupDesignation=<string>)
```

**Parameters** `GroupResourcesGet` supports two forms of parameters: either a `groupId` obtained with `GroupsForUserGet`, or the `groupDesignation` of an automatic group. These are either PRODUCTION, DEVELOPMENT, TEST, CUSTOM, or ALL. The ALL group represents every database that you're authorized to see; it's a useful way for a non-admin user to get the list of all visible databases. If you specify a `groupId` you don't have access to, an error occurs.

`GroupResourcesGet` requires one of these query parameters:

- `?groupId=<id>` or
- `?groupDesignation=<string>`

A successful response is a JSON object in this format:

```
{
  "result": [
    {
      "AlertCountHigh": 2,
      "AlertCountMedium": 0,
      "Availability": 3,
      "AvailableGroups": {
        "__deferred": {
          "uri": "https://host.domain.com:port/pd/
ResourceOverviews(123L)"
        }
      },
      "BuildNumber": "1493036600",
      "Capacity": -1,
      "Connections": [
        {
          "Host": "host",
          "IsSAPControlAuthenticated": false,
          "PortType": "INSTANCE",
          "PortValue": 0,
          "Role": "MASTER",
          "SAPControlUserName": null
        }
      ],
      "DatabaseName": "",
      "Designation": "PRODUCTION",
      "GroupCount": 1,
      "Host": "host.domain.com",
      "HostName": "host.domain.com",
      "IsAuthenticated": false,
      "IsAuthenticatedWithSSO": false,
      "PatchLevel": 9,
      "Performance": -1,
      "Port": 0,
      "PortType": "INSTANCE",
      "RemoteUserName": null,
      "ResValue": "HANA_SYSTEM",
      "ResourceDescription": "",
      "ResourceId": "123",
      "ResourceName": "ResourceName",
      "SAPControlAuthenticated": false,
      "SAPControlUser": "",
      "SSOEnabled": false,
      "SSOEnforced": false,
      "SSOSupported": null,
      "ServicePack": 122,
      "State": "UNKNOWN",
      "SystemName": "SystemName",
      "UserGroupCount": 1,
      "Version": "1.00.122.09.1493036600 (fa/hana1sp12)",
      "VersionMajor": 1,
      "VersionMinor": 0,
      "XSASupported": null
    }
  ]
}
```

Each object in the array represents a database group. The object returned has these properties:

Property	Description
ResourceId	The internal ID the cockpit uses to identify this database. Other cockpit APIs require this ID as a parameter.

Property	Description
ResourceName	The name of the database. For SAP HANA systems, the default name takes the form <DB>@<SID> – for example, DB1@HA0.
ResourceDescription	The description of the database optionally provided by the registering user at registration time.
DatabaseName	The database name, for example, DB1.
SystemName	The system name. For SAP HANA systems it's the SID (HA0, for example).
Designation	The designation or usage type of the database. For SAP HANA systems, these designations can be PRODUCTION, DEVELOPMENT, TESTING, or CUSTOM.
Version	The database's full version string.
VersionMajor	The major version of the database as an integer (for example, 2)
VersionMinor	The minor version of the database as an integer (for example, 0)
ServicePack	The service pack of the database as an integer (for example, 20)
PatchLevel	The patch level of the database as an integer.
BuildNumber	The build number of the database.
ResValue	The type of the database (for example, HANA_SYSTEM).
SSOSupported	If this value is true, this database supports single sign-on from the cockpit.
XSASupported	If this value is true, this database has a running XS advanced server.
SSOEnabled	If this value is true, single sign-on from the cockpit is turned on.
SSOEnforced	If this value is true, single sign-on is the only available authentication method from the cockpit.
IsAuthenticated	If this value is true, the current user is authenticated with this database.
IsAuthenticatedWithSSO	If this value is true, the current user is authenticated with this database using single sign-on.
RemoteUserName	The database user currently used to authenticate with the database.
Host (& HostName)	The main host name of the database. Duplicated in both fields for compatibility.
State	The state of the database (RUNNING or STOPPED, for example).
Availability	A score describing the availability of the database.
Performance	A score describing the performance of the database.
Capacity	A score describing the capacity of the database.
AlertCountHigh	The number of high-level alerts currently active.
AlertCountMedium	The number of medium-level alerts currently active.
PortType	The type of the main connection to the database. Set to either "INSTANCE" or "SQL". If INSTANCE the port is an instance number. If SQL the port is a SQL port.

Property	Description														
Port	The instance number or SQL port (for example, the indexserver SQL port) of the main connection to the database.														
GroupCount	The number of groups this database belongs to.														
Connections	<p>All possible connections to the database (for scale-out systems or those systems with host aliases, for example). The main connection as dictated by Role is copied into the previous properties.</p> <p>An array of connection objects in this form:</p> <table border="1"> <thead> <tr> <th>Property</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>Role</td> <td>The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.</td> </tr> <tr> <td>PortType</td> <td>INSTANCE or SQL.</td> </tr> <tr> <td>PortValue</td> <td>Instance number or SQL port number.</td> </tr> <tr> <td>Host</td> <td>Host name for this connection.</td> </tr> <tr> <td>IsSAPControlAuthenticated</td> <td>If this value is true, authenticated has been set (by the current user) for the SAP Control functionality.</td> </tr> <tr> <td>SAPControlUserName</td> <td>The name of the SAP Control user, if set.</td> </tr> </tbody> </table>	Property	Description	Role	The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.	PortType	INSTANCE or SQL.	PortValue	Instance number or SQL port number.	Host	Host name for this connection.	IsSAPControlAuthenticated	If this value is true, authenticated has been set (by the current user) for the SAP Control functionality.	SAPControlUserName	The name of the SAP Control user, if set.
Property	Description														
Role	The role of the connection: MASTER, MASTER_ALIAS, TENANT_MASTER, SLAVE, or STANDBY.														
PortType	INSTANCE or SQL.														
PortValue	Instance number or SQL port number.														
Host	Host name for this connection.														
IsSAPControlAuthenticated	If this value is true, authenticated has been set (by the current user) for the SAP Control functionality.														
SAPControlUserName	The name of the SAP Control user, if set.														

## GroupUsersGet

Returns information about the cockpit users in SAP HANA cockpit Database Group.

**Returns** When it succeeds, GroupUsersGet returns HTTP status 200 and the result data. Otherwise, it returns an HTTP response code and text describing why the request failed – for example, 403, "Permission Denied."

**Syntax** You can invoke GET APIs in two ways:

- Through the cockpit-admin-web-app port via the app-router. The call is redirected to the XSA sign-in page if it doesn't present an app-router cookie indicating authentication status. This form of invocation through the app-router is ideal for testing with a web browser, but not ideal for programmatic calls.
- Against the cockpit-adminui-svc endpoint. Calls using this method must present a valid authentication token.

## API Endpoints for GroupUsersGet

cockpit-admin-web-app	/cp/admin/group/GroupUsersGet?groupID=<GroupID>
cockpit-adminui-svc	/group/GroupUsersGet?groupId=<GroupId>

For example:

```
/cp/admin/group/GroupUsersGet?groupId=334116
```

A successful response is a JSON object in this format:

```
{
  "d": {
    "results": [
      {
        "__metadata": {
          "id": "https://mo-8d26c58aa.mo.sap.corp:51033/od/
CockpitUsers(504110L)",
          "uri": "https://mo-8d26c58aa.mo.sap.corp:51033/od/
CockpitUsers(504110L)",
          "type": "com.sap.hana.cockpit.persistence.odata.CockpitUser"
        },
        "Id": "504110",
        "Name": "USER1",
        "LastLogin": null,
        "ProviderId": null,
        "Groups": {
          "__deferred": {
            "uri": "https://mo-8d26c58aa.mo.sap.corp:51033/od/
CockpitUsers(504110L)/Groups"
          }
        },
        "AvailableGroups": {
          "__deferred": {
            "uri": "https://mo-8d26c58aa.mo.sap.corp:51033/od/
CockpitUsers(504110L)/AvailableGroups"
          }
        }
      }
    ]
  }
}
```

Each object in the array represents a cockpit user. The object returned has these properties:

Property	Description
ID	The ID of the cockpit user.
Name	The name of the cockpit user.
LastLogin	The last login time of the cockpit user.
ProviderID	The provider ID of the cockpit user.
Groups	All groups for the user.
AvailableGroups	All available groups for the user.

## 5.1.5.5 User Notifications and Session Monitoring

Use Active Sessions to send pop-up notifications to SAP HANA cockpit users in real time and to monitor browser sessions.

### Related Information

[Monitoring Active Browser Sessions \[page 105\]](#)

[Sending a Notification to Logged-In Users \[page 106\]](#)

### 5.1.5.5.1 Monitoring Active Browser Sessions

Learn how many users are connected to SAP HANA cockpit, what response time they're experiencing, and which part of the cockpit they're looking at.

### Prerequisites

Your cockpit user has one of these roles:

- Cockpit Administrator
- Cockpit User Administrator

### Context

Each active browser session represents a user. The Cockpit Manager's main screen lists the number of browser sessions next to the Active Sessions option.

On the Active Sessions screen, you can see:

- Which users are logged in to the cockpit. (Users logged in to the Cockpit Manager aren't included.)
- Each user's recent response time (latency) measured in milliseconds. Delays become noticeable at 150–200 ms.
- Each user's location in the cockpit. For example, `#Shell-home` is the Home screen and `#resourcedirectory-show` is the *Database Directory*.

## Procedure

1. Connect to the Cockpit Manager and sign in as a cockpit administrator or cockpit user administrator. You can reach the Cockpit Manager by entering the Cockpit Manager URL created during cockpit installation. The URL takes this form:

```
https://<cockpit-host>:<port-number>
```

2. In the Cockpit Manager, select *Active Sessions*.
3. (Optional.) Enter a user's name in the Search Sessions field to filter the list of users.

## Related Information

[Sending a Notification to Logged-In Users \[page 106\]](#)

### 5.1.5.5.2 Sending a Notification to Logged-In Users

Send a pop-up alert to all users logged in to SAP HANA cockpit.

## Prerequisites

Your cockpit user has one of these roles:

- Cockpit Administrator
- Cockpit User Administrator

## Context

To alert users to upcoming service disruptions or similar events, you can use Active Sessions to send two types of user notifications:

- *Inform*. These messages appear in the browser window for five seconds. Users don't need to react to them.
- *Interrupt*. These messages remain in the browser window until the user clicks to dismiss them.

## Procedure

1. Connect to the Cockpit Manager and sign in as a cockpit administrator or cockpit user administrator.

You can reach the Cockpit Manager by entering the Cockpit Manager URL created during cockpit installation. The URL takes this form:

```
https://<cockpit-host>:<port-number>
```

2. In the Cockpit Manager, select *Active Sessions*.
3. To send an inform message to all logged-in users:
  - a. Click *Inform* (upper right).
  - b. Enter your message.
  - c. Click *Send Message*.
4. To send an interrupt message to all logged-in users:
  - a. Click *Interrupt* (upper right).
  - b. Select a type: *Information* or *Warning*.  
An information message displays an info symbol. A warning message displays an orange warning symbol.
  - c. Enter a title.
  - d. Enter your message.
  - e. Choose text to appear on the button users must click to dismiss your message.
  - f. Click *Send Message*.

## Related Information

[Monitoring Active Browser Sessions \[page 105\]](#)

## 5.1.5.6 View Logs to Troubleshoot the Cockpit

Find entries in the SAP HANA cockpit operational logs.

### Prerequisites

Your cockpit user has these roles:

- Troubleshooting (a cockpit role)
- Space Auditor (an XSA role - if you don't have the Space Auditor role, you can add it as described in [step 2 \[page 108\]](#).)

### Context

View log entries to troubleshoot problems like missing monitoring data on cockpit pages, database registration failure, and connection timeouts.

## Procedure

1. Connect to the Cockpit Manager and sign in as a user with the Troubleshooting role.

You can reach the Cockpit Manager by entering the Cockpit Manager URL created during cockpit installation. The URL takes this form:

```
https://<cockpit-host>:<port-number>
```

2. In the Cockpit Manager, select *XSA Logs*.

If you don't have Space Auditor, an XS advanced role, a notification about the role appears. You can add Space Auditor with this `xs` command:

```
xs set-space-role COCKPIT_ADMIN HANACockpit SAP SpaceAuditor
Adding role 'SpaceAuditor' to user COCKPIT_ADMIN in space "SAP" of org
"HANACockpit" ...
OK
```

3. In the log viewer, there are two required fields for selecting and filtering log entries: *Application* and *Lines*.

- a. From the *Application* list, select a service—for example, `cockpit-landscape-svc`.
- b. From the *Lines* list:
  - Select *All* to display all the entries in the log.
  - Select *Last* to specify the number of entries from the end of the log to display. For example, if you select *Last* and enter 10, the cockpit displays the last 10 entries in the log.
  - Select *Recent* to see the 25 most recent entries.
  - Select *Time Interval* to specify a range of time from which to display log entries. For example, to see log entries for the last four hours, select *Time Interval*. In the *Since* field, select today's date and set the time to four hours ago. In the *Until* field, select today's date and current time.

4. The log viewer has three optional fields: *Cockpit Area*, *Type*, and *Source*.

- a. (Optional) From the *Cockpit Area* list, select a component. Your selection here reduces the number of options in the *Application* list.
- b. (Optional) Select one or more log types from the *Type* list. To remove a log type, click the cancel icon (⊗) next to its name.
- c. (Optional) Select one or more log sources from the *Source* list. To remove a log source, click the (⊗) (*Cancel*) icon next to its name.

5. When you're satisfied with the settings in the filtering fields, click *Go*.

The cockpit displays any log entries that meet your specifications.

6. (Optional) You can use the tools in the Log Lines row to search, download, sort, and customize the display of the log entries.

- Search: Enter a full or partial search term in the *Search* field to display only log entries that contain your term.
- Download: Click the  (*Download*) icon to download a .txt file containing the displayed log entries.
- Sort: Click the  (*Sort*) icon to choose sorting criteria for the log entries.
- Customize display: Click the  *Table Personalization* icon to remove and reorganize the columns of the log entry table.

## 5.1.5.7 Using XS CLI Commands to Troubleshoot the Cockpit

If you encounter issues with SAP HANA cockpit, you can use XS CLI commands to view services logs and application status.

You can execute the XS CLI commands on the machine where the cockpit is installed, using the `<sid>adm` account, or remotely using the XSA Client. For complete details on logging into the SAP HANA XS advanced runtime console and on the XS CLI: Application Management commands, see *SAP HANA Developer Guide for SAP HANA XS Advanced Model*.

### Viewing Logs of Various Services

You can investigate potential issues by viewing the log file of a specific service with the command `xs logs <APP>`, where `<APP>` is the name of the application whose log-file details you want to display.

If you encounter issues with...	View the application log for...
Database registration, database group management, cockpit user management, or other Cockpit Manager issues	<ul style="list-style-type: none"><li>cockpit-admin-web-app</li><li>cockpit-admin-ui-svc</li><li>cockpit-persistence-svc</li></ul>
Displaying or retrieving data, or issues related to specific SAP HANA cockpit applications	<ul style="list-style-type: none"><li>cockpit-web-app</li><li>cockpit-hdbui-svc</li><li>cockpit-hdb-svc</li><li>cockpit-landscape-svc</li><li>cockpit-persistence-svc</li></ul>
Collections	<ul style="list-style-type: none"><li>cockpit-collection-svc</li><li>cockpit-hdb-svc</li><li>cockpit-persistence-svc</li></ul>

#### → Tip

In the log of `cockpit-collection-svc`, if you see: `A collection could not be submitted for execution because the worker thread pool is exhausted`, then consider increasing the collection worker thread pool in the data collection settings through the cockpit manager. Increase the threads incrementally, rechecking the log each time, until the issue is resolved.

### Viewing Application Status

After viewing log files, you can also look at application status with the `xs apps` command. Ensure that the following services are in the STARTED state, and that instances are up and running:

- hrtt-service

- sqlanz-svc
- sqlanz-ui hrft-core
- sapui5\_fesv2
- cockpit-persistence-svc
- cockpit-hdb-svc
- cockpit-collection-svc
- cockpit-hdbui-svc
- cockpit-landscape-svc
- cockpit-web-app
- cockpit-adminui-svc
- cockpit-admin-web-app

## 5.1.6 Security Considerations for SAP HANA Cockpit

Security considerations for SAP HANA cockpit include user management, single sign-on and certificate management.

### User Authentication

Several types of credentials are used within SAP HANA cockpit:

Credential	Details
COCKPIT_ADMIN	The master user for the cockpit created during the installation process. The password for the cockpit administrator user is the master password established during the installation process. This master user is assigned all three administrator roles, and can therefore access all aspects of the Cockpit Manager, and can create users, register databases, and assign users and databases to database groups.

Credential	Details
Cockpit Users	<p>The business users with access to the cockpit.</p> <p>Each is assigned one or more roles. For details, see <i>Managing Cockpit Users</i> in Related Information.</p>
Technical User	<p>An application global per-database set of database credentials for access to remote databases and necessary to regularly gather information such as state, status, and other generalized KPIs.</p> <p>The technical user is a dedicated database user. It's required to register a database and can be created during database registration if it doesn't already exist. At a minimum, the technical user requires <code>CATALOG READ</code> system privilege and <code>SELECT</code> permission on <code>_SYS_STATISTICS</code> catalog. Human users should never log in using the technical user account.</p>
Database User (User Remote Logon)	<p>The per database/per user set of database credentials for a remote database. This user is used by the cockpit user to view more sensitive information, and to make changes within their roles as defined on that database.</p> <p>Each cockpit user needs to provide database user credentials with the system privilege <code>CATALOG READ</code> and <code>SELECT</code> on <code>_SYS_STATISTICS</code> in order to drill down in the cockpit to the overview information for a specific database. The cockpit securely encrypts and stores separate database credentials for each cockpit user, but you can clear and re-enter the credentials through the <i>Database Directory</i> when you desire to do so. We recommend that each cockpit user connects with different database user credentials.</p>
Single Sign-On (SSO)	<p>For any systems running version SAP HANA 2.0 SPS 01, or later, the cockpit database administrator has the option to enable or enforce SSO. See <i>Setting Up Single Sign-On</i> in Related Information.</p>
Operating System User	<p>A per database set of credentials for accessing the SAP Control process (starting and stopping the database, and restoring features). This user is usually the <code>&lt;sid&gt;adm</code> account. The cockpit securely encrypts and stores these credentials, but you can clear and re-enter the credentials through the <i>Database Directory</i> when you desire to do so.</p>
Internal Communication	Service-to-service authentication
SAP HANA Service Broker User	For application persistence using the application's SAP HANA express database

## Network and Communication Security

The cockpit uses secure protocols on all client browser connections to HTTPS ports. Communication to SAP HANA databases uses JDBC, and can be secured by importing certificates into the cockpit. Additional communication is made to the remote hosts using a restful interface, which also can be secured. You can use properly signed certificates for the cockpit's external ports as well. For more information about obtaining certificates, see *Certificate Management in SAP HANA* in the *SAP HANA Security Guide*.

In a large enterprise, it's likely that you generate internal certificates that are signed by an internal certificate signing authority. In this case, you could insert the single (root) certificate from the signing authority. Any certificates signed by that authority (such as HTTPS or JDBC certificates) are automatically trusted. However, in a default installation, the SAP HANA system generates a self-signed certificate. In this situation, if the certificate isn't replaced by a correctly signed one, then that specific certificate can be imported in order to enable trust.

[Monitoring Your Databases in the Database Directory \[page 171\]](#)

[User and Role Management](#)

[Importing a Certificate for Encrypted Communication \[page 118\]](#)

[Setting Up Single Sign-On \[page 112\]](#)

### 5.1.6.1 Setting Up Single Sign-On

Single sign-on (SSO) is a form of authentication that allows user access without requiring that the user to enter credentials every time.

The SAP HANA cockpit offers the option to configure SSO to access cockpit itself (including the cockpit manager), and to connect to a registered database.

Configuring SSO access to the cockpit itself means that you don't need to provide cockpit user credentials in order to access the cockpit or the cockpit manager.

The option to enable or enforce single-sign on (SSO) for a specific database removes the need for providing database user credentials each time you connect to the database. If you enforce SSO, cockpit users must use SSO to access the database. If you enable SSO, but don't enforce it, cockpit users can choose whether to access this database with SSO or to enter alternate database user credentials.

#### **i** Note

Before enabling SSO, consider migrating the Personal Security Environment (PSE) file to an in-database store. When SSO is enabled, a new PSE file may be created, which may prevent cockpit access to stored certificates. See *SAP Note 2656666*.

## Related Information

[Edit Database Settings \[page 77\]](#)

[SAP Note 2656666](#) 

### 5.1.6.1.1 Configuring SSO Access to the SAP HANA Cockpit

To configure single-sign on authentication to the SAP HANA cockpit, use the cockpit for SAP HANA extended application services, advanced model (XS advanced cockpit), and the SAP Cloud Platform Identity Authentication Administration Console. These applications are external tools and not part of the SAP HANA cockpit itself.

#### Context

Authentication standard supported for SSO to SAP HANA cockpit: SAML

For more information about the XS advanced cockpit, including standards supported for SSO, refer to *Maintaining the XS Advanced Runtime Environment with SAP HANA XS Advanced Cockpit* or *Managing SAML Identity Providers in XS Advanced* in the *SAP HANA Administration Guide*.

#### **i** Note

The steps in these instructions detail how to configure SSO access using the SAP Cloud Platform Identity Authentication Administration Console. If you're using another identity provider (IDP), the steps or details vary.

#### Procedure

1. Log in to the SAP Cloud Platform Identity Authentication Administration Console and create named groups.
  - a. Navigate to  
`https://<IDP_URL>/admin`
  - b. Select *User Groups*.
  - c. Use *Add +* to provide a name for each group. For example:
    - HANA\_COCKPIT\_ADMIN
    - HANA\_COCKPIT\_RESOURCE\_ADMIN
    - HANA\_COCKPIT\_USER\_ADMIN
    - HANA\_COCKPIT\_USER

- HANA\_COCKPIT\_POWER\_USER

In the example above, we use cockpit roles for group names; you can choose your own group names.

- Select [Save](#).
  - Exit the SAP Cloud Platform Identity Authentication Administration Console.
- Use the XS advanced cockpit to add a new SAML identity provider.
    - Retrieve SAML2 metadata from your IDP.  
For example, using the SAP IDP, navigate to  
`https://<IDP_URL>/saml2/metadata`
    - Use the `xs a` command to access the xsa-cockpit URL.
    - In the left pane, select **Security > Trust Configuration**.
    - Select [New Trust Configuration](#) to add a new provider.
    - In the metadata text box, enter XML based on the SAML metadata you retrieved from the IDP in step [2.a \[page 114\]](#).
    - Select [Parse](#) to fill in the remaining fields.
    - Select [Save](#).
  - In the XS advanced cockpit, map the role collections. (For more information, see SAP Note 2569903).
    - Select **Security > Trust Configuration**.
    - Select the trust configuration you created in step [2 \[page 114\]](#).
    - Select [Role Collection Mappings](#).
    - Select [New Role Collection Mapping](#) to map each of the role collections to a group within the IDP. If you use the sample group names in step [1.c \[page 113\]](#), the mappings are:

Role Collection	Group Name
COCKPIT_ADMIN	HANA_COCKPIT_ADMIN
COCKPIT_RESOURCE_ADMIN	HANA_COCKPIT_RESOURCE_ADMIN
COCKPIT_USER_ADMIN, XS_USER_ADMIN	HANA_COCKPIT_USER_ADMIN
COCKPIT_USER	HANA_COCKPIT_USER
COCKPIT_POWER_USER	HANA_COCKPIT_POWER_USER

### **i** Note

If you're using the COCKPIT\_USER\_ADMIN role collection, you must map both COCKPIT\_USER\_ADMIN and XS\_USER\_ADMIN to the IDP group representing the cockpit user administrator, in this case HANA\_COCKPIT\_USER\_ADMIN.

- Select [Save](#).
- Retrieve spring SAML metadata from  
`https://<cockpit_FQDN>3<instance#>32/uaa-security/saml/metadata`  
For example, if the cockpit is running on yourserver.company.com instance 03, the URL is  
`https://yourserver.company.com:30332/uaa-security/saml/metadata`
  - The file for use in the IDP configuration downloads automatically.

6. Log in to the SAP Cloud Platform Identity Authentication Administration Console and create a new application to represent the SAP HANA cockpit.
  - a. Select [Applications and Resources](#).
  - b. Select [Add Application](#).
  - c. Enter an application name.
  - d. Select [Save](#).
7. In the SAP Cloud Platform Identity Authentication Administration Console, configure SAML.
  - a. Select the new application.
  - b. Select [SAML 2.0 Configuration](#).
  - c. Select the browse button to locate and select the downloaded metadata file (~/Downloads/spring\_saml\_metadata.xml).

### **i** Note

Only one application can be configured with the SAML provider. An error occurs if you introduce a duplicate, even with a different name.

8. In the SAP Cloud Platform Identity Authentication Administration Console, configure the application Name ID attribute.
  - a. Select [Name ID Attribute](#).
  - b. Select [Email](#).
  - c. Select [Save](#).
9. In the SAP Cloud Platform Identity Authentication Administration Console, provide assertion attributes.
  - a. Select [Assertion Attributes](#).
  - b. Add a groups attribute.
  - c. Modify the [groups](#) attribute (lowercase) to Groups (title case).
  - d. Accept the default assertion attribute for [First name](#), [Last name](#), and [E-mail](#).
10. In the SAP Cloud Platform Identity Authentication Administration Console, add the user.
  - a. Select [User Management](#).
  - b. Select [Add User](#).
  - c. Provide last name, email and user type, and account activation options.
  - d. Press [Save](#).
11. In the SAP Cloud Platform Identity Authentication Administration Console, edit the user.
  - a. Select [Applications](#).
  - b. Add the application you created in the XSA Admin tools.
  - c. Select [User Groups](#) and add the groups appropriate for this user (corresponding to the cockpit role).
12. Log in to the SAP HANA cockpit. You see the link on the sign-in page, and don't need to enter cockpit user credentials. (Selecting the link brings up the IDP authentication page.)

## Related Information

[Setting Up Single Sign-On \[page 112\]](#)

[SAP Note 2569903](#) 

## 5.1.6.1.2 Configuring SSO Access to a Database

Enabling single sign-on (SSO) allows a cockpit user to log on to a database without being prompted for database user credentials.

### Prerequisites

- The database has been registered in the cockpit. It meets these version restrictions:
  - SAP HANA 1.0 SPS 12 revision 14 or later, or
  - SAP HANA 2.0 SPS 01 or later
- You have a database user with the CATALOG READ, TRUST ADMIN, CERTIFICATE ADMIN, and USER ADMIN privileges.

The database user we use in the following steps is SSO\_USER.

To assign the necessary system privileges to an existing user called SSO\_USER, execute these SQL statements:

```
GRANT TRUST ADMIN TO SSO_USER;  
GRANT CERTIFICATE ADMIN TO SSO_USER;  
GRANT USER ADMIN TO SSO_USER;  
GRANT CATALOG READ TO SSO_USER;
```

- You have a second database user with the USER ADMIN system privilege.  
The second database user we use in the following steps is USER\_ADMIN.
- A user with the Cockpit Administrator or Cockpit User Administrator role has created one or more cockpit users who are accessing this database and assigned them the role `Cockpit User`.  
The cockpit user we use in the following steps is COCKPIT\_USER.
- For step 1 [page 117], you have a cockpit user with the Cockpit Administrator or Cockpit Database Administrator role.  
The cockpit administrator we use in the following steps is COCKPIT\_ADMIN.

### Context

Authentication standard supported for SSO to a managed database: JSON Web Token (JWT).

#### i Note

Before enabling SSO, consider migrating the Personal Security Environment (PSE) file to an in-database store. When SSO is enabled, a new PSE file may be created, which may prevent cockpit access to stored certificates. See SAP Note 265666.

The following steps configure SSO for a single managed SAP HANA database. Perform them for each database where SSO is needed. There's a separate set of steps for configuring SSO for the cockpit itself—see Related Information.

The result of this process is to link the cockpit account we're calling COCKPIT\_USER with the database account we're calling SSO\_USER. When SSO is enabled, you're able to sign in to the cockpit as COCKPIT\_USER by entering the password, and then signing in to a database as SSO\_USER without providing credentials. You can

also sign in to the database using different database credentials. If you choose to enforce SSO, you'll be able to sign in to the database from the cockpit **only** as SSO\_USER.

## Procedure

1. Enable SSO in the Cockpit Manager:
  - a. In the *Database Directory*, click *Manage Databases*.
  - b. Log in to the Cockpit Manager as COCKPIT\_ADMIN.
  - c. Select *Registered Databases*.
  - d. In the left column, choose the database for which you want to enable SSO.
  - e. Click *Edit* (bottom of screen).
  - f. Scroll down to the Single Sign On section and select *Enable SSO: Yes*.
  - g. In the Authorize SSO Setting Change dialog, enter the credentials of a cockpit user that has the CATALOG READ, TRUST ADMIN, CERTIFICATE ADMIN, and USER ADMIN privileges. We're using SSO\_USER here, as described in the Prerequisites.
  - h. Click *Save*.
2. Sign in to the database as a user with the USER ADMIN system privilege—we're using USER\_ADMIN here.
3. On the *Database Overview* page for the database, click *Manage users* (under User & Role Management).
4. Select the user with the CATALOG READ, TRUST ADMIN, CERTIFICATE ADMIN, and USER ADMIN privileges—SSO\_USER for purposes of this procedure.
5. To set the JWT mappings:
  - a. Under *Authentication*, select *JWT - You must add at least one identity provider*.
  - b. Click *Add JWT Identity*.
  - c. Select XS\_APPLICATIONUSER from the *Identity Provider* dropdown.
  - d. Turn off the *Automatic Mapping by Provider*.
  - e. Enter the user name of an existing cockpit user in *External Identity*—we're using COCKPIT\_USER here—and click *Save*.
6. Log out of the cockpit and log in as COCKPIT\_USER (the cockpit user for which you just set up JWT).
7. Go to the *Database Directory* and click the *Choose Authentication* link for the database you're configuring.
8. Make sure *Log on via single sign on* is selected and click *OK*.
9. Click the database name to log in.

The database signs you in as SSO\_USER, though you logged in to the cockpit as COCKPIT\_USER.

10. (Optional) Enforce SSO through the Cockpit Manager:
  - a. On the Home page, under Manage Landscape, click *Manage Cockpit* to return to the Cockpit Manager.
  - b. Click *Registered Databases*.
  - c. Choose the database for which you want to enforce SSO and click *Edit* (lower right).
  - d. Under Single Sign On, select *Enforce SSO: Yes* and click *Save*.
  - e. In the Authorize SSO Setting Change dialog, enter the credentials of SSO\_USER.
  - f. Click *Go to SAP HANA Cockpit* (lower right) to return to the cockpit.
  - g. Open the Database Directory and find the database for which you've configured SSO.

The database's Credentials column now says `SSO enforced`. You can access the database only as COCKPIT\_USER's mapped database user, SSO\_USER—the cockpit doesn't allow you to enter other credentials.

## Next Steps

Repeat these steps as needed to enable SSO for other databases.

## Related Information

[Create or Enable an SAP HANA Cockpit User \[page 63\]](#)

[Configuring SSO Access to the SAP HANA Cockpit \[page 113\]](#)

[SAP Note 2656666](#) 

### 5.1.6.2 Importing a Certificate for Encrypted Communication

You can import a certificate to enable an encrypted HTTP connection from the cockpit to SAP Control, or an encrypted JDBC connection from the cockpit to an SAP HANA database.

#### Procedure

1. Sign on as `<sid>adm` to the remote system with which you want the cockpit to establish a connection.
2. On the remote system, run the `sapgenpse` tool to export certificates from the in-memory certificate collection, or from the file-system PSE (`$SECUDIR/sapgenpse export_own_cert`).  
The location of required certificates depends on how you manage certificates in your system. For instance, point to SAP Control from a browser, and obtain the certificate.
3. Sign on as `<sid>adm` to the system hosting the cockpit.
4. Run the command `xs login`, and provide the name and password of the `COCKPIT_ADMIN` so that the `<sid>adm` can execute the `xs` command-line tool in the user context of `COCKPIT_ADMIN`.
5. In SAP HANA XS advanced model (XSA), trust the certificates using the command syntax `xs trust-certificate <ALIAS> -c <CERT_FILE>`, where `<ALIAS>` is a unique alias for the certificate within XSA, for example. `BZ1_SAPCONTROL` and `<CERT_FILE>` is the certificate you exported from the remote system.
6. Run the commands `xs restage cockpit-hdb-service cockpit-hdb-svc` followed by `xs restart service cockpit-hdb-svc` to refresh the certificates for the cockpit.

See *XS CLI: Certificates* in the *SAP HANA Developer Guide (For SAP HANA XS Advanced Model)*. For information about obtaining certificates, see *Certificate Management in SAP HANA* in the *SAP HANA Security Guide*.

## Related Information

[SAP Note 2300943](#)

[Register a Database \[page 73\]](#)

### 5.1.6.3 Ensuring a Secure Browser Connection

After you've installed the SAP HANA cockpit, ensure that communication with your web browser is encrypted.

#### Context

Unencrypted communication with a browser could pose a security risk. To secure the connection, provide the XSA server with a certificate that is signed by a certificate authority, or use your own self-signed certificate.

##### **i** Note

The steps outlined here are deliberately generic so as to apply to all configuration scenarios. For a detailed, specific example, see SAP Note 2631903.

#### Procedure

1. To use a certificate from a certificate authority:
  - a. Obtain a signed certificate from the certificate authority.
  - b. In SAP HANA XS advanced model (XSA), verify the domain using the command `xs domains`.
  - c. Set the XS domain certificate using the command `xs set-certificate <domain> -c <CERT_FILE> -k <CERT_KEY>`.
  - d. Restart XSA using the command `XSA restart`.
2. To use your own certificate:
  - a. Create a self-signed root certificate.
  - b. Create a second certificate that is signed by the root certificate
  - c. In SAP HANA XS advanced model (XSA), verify the domain using the command `xs domains`.
  - d. Set the XS domain certificate using the command `xs set-certificate <domain> -c <CERT_FILE> -k <CERT_KEY>`.
  - e. Restart XSA using the command `XSA restart`.
  - f. Update your browser's list of trusted root certificates to include the newly created root certificate file.

##### **i** Note

The XS domain name is tied to the certificate request. If the domain name starts out basically as the host name, you can change the domain name to a virtual host name so it's easy to remember and easy to redirect. The certificate for the domain needs to contain both the actual and virtual host names.

[SAP Note 2300936](#)

## 5.1.6.4 Data Protection and Privacy in SAP HANA Cockpit

SAP HANA cockpit provides tools you can use to conform to legal and business requirements for protecting system-stored personal data.

### Introduction

Data protection is associated with numerous legal requirements and privacy concerns. In addition to compliance with general data privacy regulation, it's necessary to consider compliance with industry-specific legislation in different countries/regions. SAP provides specific features and functions to support compliance with regard to relevant legal requirements, including data protection. SAP doesn't give any advice on whether these features and functions are the best method to support company, industry, regional, or country-specific requirements. Furthermore, don't take this information as advice or a recommendation regarding additional features that would be required in specific IT environments. Decisions related to data protection must be made on a case-by-case basis, considering the given system landscape and the applicable legal requirements.

#### i Note

SAP doesn't provide legal advice in any form. SAP software supports data protection compliance by providing security features and specific data protection-relevant functions, such as simplified blocking and deletion of personal data. In many cases, compliance with applicable data protection and privacy laws aren't be covered by a product feature. Definitions and other terms used in this document aren't taken from a particular legal source.

### Glossary

Term	Definition
Consent	The action of the data subject confirming that the usage of personal data can be allowed for a given purpose. A consent functionality allows the storage of a consent record in relation to a specific purpose and shows if a data subject has granted, withdrawn, or denied consent.
Deletion	The irreversible destruction of personal data.

Term	Definition
Personal data	Any information relating to an identified or identifiable natural person ("data subject"). An identifiable natural person is one who can be directly or indirectly identified. This identification can be by reference to an identifier such as a name, an identification number, location data, or online identifier. Personal data can also refer to physical, physiological, genetic, mental, economic, cultural, or social factors of that natural person.
Purpose	A legal, contractual, or in other form justified reason for the processing of personal data. The assumption is that any purpose has an end that is already defined when the purpose starts.

## User Consent

SAP HANA cockpit stores only personal data entered by users; it only collects personal data with a user's knowledge.

## Logging Read Access and Changes

SAP HANA cockpit provides tools for auditing access and changes to personal data stored in SAP HANA databases. For details, see *Auditing Database Activity*.

## Information Report

SAP HANA cockpit doesn't store any personal data except what is entered (if anything) in the optional contact information for databases. This information typically includes the name and e-mail address of the contact person, and you can see it in the database registration.

## Deletion of Personal Data

You can remove unneeded user accounts and database contact information. See:

- *Edit Database Settings*
- *Delete a Cockpit User or Revoke Cockpit Access*

## Related Information

[Auditing Database Activity](#)

[Edit Database Settings \[page 77\]](#)

[Delete a Cockpit User or Revoke Cockpit Access \[page 67\]](#)

## 5.1.6.5 Auditing in SAP HANA Cockpit

Audit logging lets you track events like logins and creation and deletion of user accounts.

### Prerequisites

- You have the password for the `COCKPIT_ADMIN` user, or
- If you want to use the Audit Log as a user other than `COCKPIT_ADMIN`, you've created an appropriate role collection and assigned it to that user. Give the role collection the application role `AuditLogViewer`, which is part of application `auditlog-ui` and role template `AuditLogViewer`. For details on building role collections, see *Maintain Roles for XS Advanced Applications* in the *SAP HANA Administration Guide*.

### Context

You can use the Audit Log to identify log entries for events that you want to track.

### Procedure

1. Log in to SAP HANA express edition or XS advanced:

```
xs login [-a <API_URL>] [-u <username>] [-p <password>] [-o <organization>] [-s <space>]
```

where `<API_URL>` is the API endpoint (for example, `https://api.example.com`)

2. To list applications, enter:

```
xs a
```

3. In the results, find the entry for the `auditlog-ui` service, which includes a URL.
4. Enter the `auditlog-ui` URL in a browser to open the *Audit Log*.
5. Use the Audit Log sorting and filtering tools to find logged events of interest to you.

### Related Information

[SAP HANA Administration Guide for SAP HANA Platform](#)

## 5.1.7 Personalizing the Database Overview Page

You can customize the *Database Overview* page of each system or tenant database.

When you access the *Database Overview* page of a tenant or system database, you have access to many cards, each representing a specific SAP HANA cockpit application. (If you don't have the required privileges, specific cards, features, or actions aren't available to you.) You can drag and drop to arrange these cards in your preferred order. You can filter the cards using one of four default views or hide cards that aren't relevant to you.

To hide cards, on the *Database Overview* page, select the view that contains the cards to be hidden. Click the  (<cockpit\_user>) icon, then *Manage Cards*. Only the cards for the select view are listed. Hide or display cards as desired. Click *OK* to save the settings.

While most actions in the  (<cockpit\_user>) area are available independently of the current context, some of the actions are directly tied to the content shown in the main content area, including:

- Settings
- Tools to personalize the current content
- Recently used and frequently visited apps

In the  (<cockpit\_user>) area, if Single Sign-On authentication is not enabled for your SAP HANA cockpit user, you can also change your SAP HANA cockpit password by selecting *User Account* and *Change Password* within *Settings*.

### Related Information

[Using the Database Overview Page to Manage a Database \[page 340\]](#)

[Monitoring Your Databases in the Database Directory \[page 171\]](#)

## 5.2 SAP HANA Studio

The SAP HANA studio runs on the Eclipse platform and is both a development environment and administration tool for SAP HANA.

Administrators can use the SAP HANA studio, for example, to start and stop services, to monitor the system, to configure system settings, and to manage users and authorizations. The SAP HANA studio accesses the servers of the SAP HANA database by SQL. Developers can use the SAP HANA studio to create content such as modeled views and stored procedures. These development artifacts are stored in the repository, which is part of the SAP HANA database. The SAP HANA studio is developed in Java and based on the Eclipse platform.

The SAP HANA studio presents its various tools in the form of perspectives. Database administration and monitoring features are available primarily within the SAP HANA Administration Console perspective. Additional perspectives include the SAP HANA Modeler perspective and the SAP HANA Development perspective. For more information about these perspectives, see the *SAP HANA Developer Guide (For SAP HANA Studio)* and the *SAP HANA Modeling Guide for HANA Studio*.

## i Note

Depending on how you installed the studio, all features may not be available. During installation, you can specify which features you require depending on your role. For system administration, only the feature SAP HANA Studio Administration is necessary. For more information, see *SAP HANA Studio Features* in the *SAP HANA Studio Installation and Update Guide*.

## Updating the SAP HANA Studio

To ensure that you are working with the most recent version of the SAP HANA studio, you need to check regularly for updates. You can update the SAP HANA studio using several methods. For example, you can use SAP HANA Software Lifecycle Manager, or you can set up a central update site.

For more information, see the *SAP HANA Studio Installation and Update Guide*.

## 5.2.1 Open the SAP HANA Administration Console

To access the database administration and monitoring features of the SAP HANA studio, you open the SAP HANA Administration Console perspective.

### Procedure

1. From your file explorer, start `hdbstudio.exe`.
2. On the *Welcome* page, choose *Open SAP HANA Administration Console*.

### Results

The SAP HANA Administration Console opens. The *Systems* view is open by default. This view is the central access point for performing system-specific administration and monitoring activities. From this view, you can access the other views and editors used for administration.

## i Note

Once you have closed the *Welcome* page, you can always change from another perspective to the SAP HANA Administration Console perspective by choosing **Window > Open Perspective > SAP HANA Administration Console** or by choosing the **SAP HANA Administration Console** button in the perspective switcher in the upper-right corner of the screen.

## Related Information

Systems View [page 131]

## 5.2.1.1 Screen Areas of the SAP HANA Administration Console

The database administration and monitoring features of the SAP HANA studio are presented in the SAP HANA Administration Console perspective according to a default screen layout.

The following figure shows the screen areas of the SAP HANA studio with the SAP HANA Administration Console perspective open:

Screen Areas of the SAP HANA Administration Console

The following is a brief overview of the various screen areas:

Screen Area	Description
Main menu and main toolbar	<p>The main menu contains standard Eclipse functions.</p> <p>The main toolbar is located beneath the main menu. The contents of this toolbar change based on the active perspective. Items in the toolbar might be enabled or disabled based on the state of either the active view or editor. The perspective switcher is an additional toolbar normally located on the top-right of the screen, next to the main toolbar. It allows quick access to perspectives that are currently open. It also has a button that can open new perspectives.</p>
Editor area	<p>Each perspective has editors for editing and browsing resources. Editors are displayed as tabs in the editor area. Several editors can be open at the same time.</p> <p>Important editors available in the SAP HANA Administration Console include:</p> <ul style="list-style-type: none"><li>• The System Monitor</li><li>• The Administration editor</li><li>• The Backup editor</li><li>• The Security editor</li><li>• The SQL console</li></ul>
Views	<p>Views support editors and provide alternative presentations as well as ways to navigate the information in the SAP HANA studio. Important views available in the SAP HANA Administration Console include:</p> <ul style="list-style-type: none"><li>• <a href="#">Systems</a>, which is the central access point for performing system administration and monitoring activities</li><li>• <a href="#">Error Log</a>, which contains error and information messages</li><li>• <a href="#">Properties</a>, which shows the detailed properties of the active resource (for example, the SAP HANA system selected in the <a href="#">Systems</a> view)</li></ul> <p>To open a view, from the main menu, choose <b>▶ Window ▶ Show View ▶</b>.</p>

For more information about the Eclipse platform, see the Eclipse documentation.

## 5.2.1.2 Editors and Views of the SAP HANA Administration Console

Several editors and views are available in the Administration Console for the administration and monitoring of SAP HANA databases.

The following table describes the main system-level editors and views available in the [Administration Console](#) and how to access them. Other editors are available for specific resources (for example users, roles, tables and so on).

View/Editor	Description	How to Open
<a href="#">Systems</a>	The <a href="#">Systems</a> view provides you with a hierarchical view of all the SAP HANA systems managed in the SAP HANA studio and their contents. It is the central access point for performing system-specific administration and monitoring activities using the other available editors.	The <a href="#">Systems</a> view is open by default when you open the Administration Console. If it is closed, you can open it from the main menu by choosing <b>Window &gt; Show View &gt; Systems</b> .
<a href="#">System Monitor</a>	The <a href="#">System Monitor</a> is an editor that provides you with an overview of all your SAP HANA systems at a glance. From the <a href="#">System Monitor</a> , you can drill down into the details of an individual system in the <a href="#">Administration</a> editor.	In the toolbar of the <a href="#">Systems</a> view, choose the  button.
<a href="#">Administration</a>	The Administration editor the main tool for performing administration and monitoring activities.	You can access the <a href="#">Administration</a> editor in several ways: <ul style="list-style-type: none"> <li>From the <a href="#">Systems</a> view toolbar, choose the  <a href="#">Open Default Administration</a> button.</li> <li>In the <a href="#">Systems</a> view, double-click the system.</li> <li>In the context menu of the <a href="#">Systems</a> view, choose <b>Configuration and Monitoring &gt; Open Administration</b>.</li> </ul>
<a href="#">Administration Diagnosis Mode</a>	The <a href="#">Administration</a> editor diagnosis mode allows you to monitor and perform emergency operations on systems to which either no SQL connection is available or the SQL connection is overloaded.	The <a href="#">Administration</a> editor opens automatically in diagnosis mode in the following situations: <ul style="list-style-type: none"> <li>When you open the <a href="#">Administration</a> editor for a system that cannot be reached by SQL</li> <li>When you initiate the start, stop, or restart of a system</li> </ul> <p>You can also open the <a href="#">Administration</a> editor in diagnosis mode from the <a href="#">Systems</a> view toolbar by choosing the  <a href="#">Open Diagnosis Mode</a> button.</p>
<a href="#">Backup</a>	The <a href="#">Backup</a> editor is the main tool for performing administration and monitoring activities related to backup.	You can access the <a href="#">Backup</a> editor in several ways: <ul style="list-style-type: none"> <li>Expand the system in the <a href="#">Systems</a> view and choose the  <a href="#">Backup</a> entry</li> <li>In the context menu of the <a href="#">Systems</a> view, choose <b>Backup and Recovery &gt; Open Backup Console</b>.</li> </ul>

View/Editor	Description	How to Open
<a href="#">Security</a>	<p>The <a href="#">Security</a> editor is the main tool for managing the following aspects of security administration:</p> <ul style="list-style-type: none"> <li>• Password policy</li> <li>• Auditing</li> <li>• Data volume encryption</li> </ul>	<p>You can access the <a href="#">Security</a> editor in several ways:</p> <ul style="list-style-type: none"> <li>• Expand the system in the <a href="#">Systems</a> view and choose the  <a href="#">Security</a> entry</li> <li>• In the context menu of the <a href="#">Systems</a> view, choose  <a href="#">Security</a>  <a href="#">Open Security Console</a> .</li> </ul>
<a href="#">SQL Console</a>	<p>Some tasks may require you to work with SQL statements, for example, certain administration tasks can only be performed using SQL. You can enter, execute, and analyze SQL statements in the SQL console.</p>	<p>You can access the SQL console in several ways:</p> <ul style="list-style-type: none"> <li>• From the <a href="#">Systems</a> view toolbar, choose the  button.</li> <li>• In the context menu of the <a href="#">Systems</a> view, choose <a href="#">Open SQL Console</a>.</li> </ul>

## Related Information

[System Monitor \[page 187\]](#)

[Administration Editor \[page 384\]](#)

[Execute SQL Statements in SAP HANA Studio \[page 128\]](#)

## 5.2.2 Execute SQL Statements in SAP HANA Studio

You can execute SQL statements in the SAP HANA studio using the SQL console.

### Prerequisites

- You have added the system in the [Systems](#) view. For more information, see [Add an SAP HANA System](#).
- You have the required privileges to perform the operation. For more information about privileges, see the [User Authorization](#).
- (Optional) You have customized the behavior of SQL statement execution in the SQL console. You can do this in the SAP HANA studio preferences ( [SAP HANA](#)  [Runtime](#)  [SQL](#) ). For more information, see [SAP HANA Studio Administration Preferences](#).

## Procedure

1. Open the SQL console:
  - a. Select the system in the *Systems* view.
  - b. From the toolbar, choose the  (*Open SQL console for selected system*) button.

The SQL console displays the connected system and user in the header. If you opened the SQL console from a specific catalog object, the schema is also displayed.

To connect to a different system from within the SQL console, choose the  (*Choose Connection*) button in the toolbar in the top-right of the editor and choose another system.

2. Enter the SQL statement or statements.

The following rules apply:

- You can write SQL syntax elements in either upper or lower case.
- You can add any number of spaces and line breaks.
- To force the system to distinguish between upper/lower-case letters in database object names (such as table names), enter the name between double quotation marks: "My\_Table"
- To comment out a line, use - - (double hyphens) at the start of the line.
- To use name completion, press the key combination `CTRL` + `SPACE`.  
This opens a list from which you can choose schema and table names, SQL keywords, and user-defined templates.

### Note

You define templates in the preferences (▶ *SAP HANA* ▶ *Runtime* ▶ *Templates* ▶).

- Enter multiple SQL statements, separated by the configured separator character, semicolon (;) by default.
3. Execute the statement(s) in one of the following ways:
    - In the context menu, choose *Execute*.
    - Choose the  *Execute* button in the toolbar.
    - Press `F8`.

If you have entered several statements, you can execute them individually by simply highlighting the statement and executing. If you do not highlight an individual statement, all statements are executed.

By default, statements are prepared before execution. You can disable statement preparation in the preferences.

## Results

The *Result* tab appears with the statement's results. Multiple *Result* editors may open depending on the statement(s) executed.

### Note

To prevent performance issues with the SAP HANA studio, by default only 50 *Result* editors can open. Once this number is reached, statement execution stops.

Information about statement execution is displayed in the lower part of the screen, for example:

```
Started: 2013-11-27 14:22:16
Statement 'SELECT * FROM "PUBLIC"."M_CS_TABLES"'
Successfully executed in 260 ms 932 µs (server processing time: 258 ms 868 µs)
Fetched 583 row(s) in 16 ms 602 µs (server processing time: 11 ms 278 µs)
```

### **i Note**

SAP HANA implements a prefetch mechanism that returns the head of the result together with the execute command. By default, 32 rows are prefetched. This means that if the result set is smaller than the number of rows prefetched, the subsequent fetch command can simply take the rows from the prefetch buffer in the client library without any further processing on the server.

## 5.2.3.1 Systems View

The *Systems* view provides you with a hierarchical view of all the SAP HANA systems managed in the SAP HANA studio and their contents. It is the central access point for performing system-specific administration and monitoring activities.

You can use the SAP HANA studio to manage both SAP HANA systems with and without tenant databases. In the *Systems* view, systems that do not support tenant databases are identified solely by their SID. Tenant databases are identified by their database name and SID (<database\_name>@<SID>). The system database can also be registered in the *Systems* view; it is identified by database name and SID (SYSTEMDB@<SID>). For more information about adding systems and tenant databases, see *Add an SAP HANA System*.

The *Systems* view comprises the following elements:

- A hierarchical view of all your systems/databases and their contents. For administration and monitoring purposes, the following are the most important elements:
  - The *Catalog* folder, which contains all activated database objects, grouped by schema
  - The *Security* folder, which contains all database users and activated roles

Double-clicking the top-level system entry in the hierarchical view opens it in the Administration editor.

From the hierarchical view, you can also access the Backup (📁) and Security (🔑) editors.

- A toolbar that provides you with quick access to several editors and functions.
- A context menu that provides you quick access to a range of system-specific functions.

### 5.2.3.1.1 Toolbar Options in the Systems View

The *Systems* view toolbar provides you with quick access to several editors and functions.

Icon	Option	Description
	<i>Add System...</i>	Opens the <i>Add System</i> dialog in which you can create and configure a connection to a system
	<i>Add System Archive Link...</i>	Opens the <i>Add System Archive Link</i> dialog in which you can add a link to a centrally-stored archive of SAP HANA systems

Icon	Option	Description
	<i>Open System Monitor</i>	Opens the System Monitor to see an overview of all systems in the Systems view
	<i>Open Default Administration</i>	Opens the Administration editor for the selected system
	<i>Open Diagnosis Mode</i>	Opens the Administration editor for the selected system in diagnosis mode
	<i>Open SQL Console</i>	Opens the SQL console for the selected system
	<i>Find System</i>	Opens the <i>Find System</i> dialog in which you can search for a system in the Systems view
	<i>Collapse All</i>	Collapses the tree expansion state of all systems in the Systems view
	<i>Link with Editor</i>	Toggles whether the entry selected in the <i>Systems</i> view is linked to the active editor. When this option is selected, changing the active editor will automatically update the selected system.
	<i>View Menu</i>	Provides menu items that allow you to sort or filter the contents of the <i>Systems</i> view

### 5.2.3.2 Add an SAP HANA System

To work with and manage an SAP HANA system using the SAP HANA studio, you must create and configure a connection to it.

#### Prerequisites

- The relevant ports in your firewall are open.
- If you want to secure communication between the SAP HANA server and the SAP HANA studio using the Secure Sockets Layer (SSL) protocol, you have configured the server for SSL and imported the trust store file that contains the server root certificate into either the Java keystore or your user keystore on the client.
- You must have a database user, or the necessary infrastructure for Kerberos-based user authentication must be in place.

## Procedure

1. From the *Systems* view toolbar, choose  (*Add System...*).  
The *System* wizard opens.
2. Enter the required system information:
  - System connection properties (required)
    - Host name
    - Instance
    - Mode

For more information about what to enter for these properties, see *System Connection Properties*.
  - Description (optional)  
This is the description of the system that you want to appear next to the system name in the *Systems* view.
  - Folder (optional)  
If you are organizing your systems in the *Systems* view using folders and have already created folders, choose the folder to which you want to add the system.
  - Locale (optional)  
This setting specifies the language of objects created in the SAP HANA repository.
3. Choose *Next*.
4. Choose the authentication type for user logon to the database:
  - If you are integrating the SAP HANA studio into a Kerberos-based single sign-on environment, choose *Authentication by current operating system user*.
  - If you are implementing user name/password authentication, choose *Authentication by database user* and enter the database user name and password. You can choose to have your password stored in the Eclipse secure storage so that you do not have re-enter it every time you open the studio.
5. Indicate whether you want to use a secure connection to the system by choosing *Connect using SSL*.

### i Note

You must select this option to be able to modify the SSL connection properties (step 9).

6. Configure the connection of the SAP start service (`sapstartsrv`) to the system.  
An HTTP connection to the system using the SAP start service is automatically enabled. You can choose to disable this connection if it is not required.

### i Note

If you disable this connection, administrative actions that require operating system access are not possible in the SAP HANA studio (for example, stopping and starting the system, performing a recovery, or opening the Administration editor in diagnosis mode).

If you want the SAP start service to communicate with the system via a secure connection, choose *Use HTTPS*.

7. Choose *Next*.
8. Optional: Modify the following advanced connection properties for your system:

Option	Description
<b>Option</b>	JDBC connection parameter(s)
<b>Auto-Reconnect</b>	Auto-reconnect option  If you select this option, the SAP HANA studio automatically reconnects if the connection to the system fails.

9. Optional: Configure SSL communication:

- To have the identity of the server validated during connection, choose [Validate SSL Certificate](#). The server's public-key certificate is validated against the root certificate stored in the trust store. If you want to override the system host name specified in the server certificate, enter a host name with a defined certificate.
- [Use user key store as trust store](#)  
The Java SSL property `trustStore` specifies the trust store containing the certificate used to validate that the server certificate is issued by a trusted entity. Each user can import certificates into a user keystore in Java using the `keytool` command line tool (part of the JRE installation). The user keystore is located in the home directory of the current operating system user. The file name is `.keystore`. The set of root certificates delivered with the JRE from well-known issuers (for example, Verisign, Thawte, Deutsche Telekom) is used when this option is not selected.

10. Choose [Finish](#).

The system is added in the [Systems](#) view. The system entry displays the following information:

- SID  
In the case of a multitenant database container, the database name is indicated before the SID, either `SYSTEMDB@<SID>` or `<database>@<SID>`
- Connected user
- System usage if it is a production system
- System or database description if available

Information about system availability and user connection status are indicated by icons.

## Results

You can now access the system or database in the SAP HANA studio.

## 5.2.3.2.1 System Connection Properties

To connect to an SAP HANA system or database in the SAP HANA studio, you must specify its connection properties (host, instance, and mode).

Property	Description
Host name	<p>Fully qualified domain name (FQDN) of the host on which the system is installed</p> <ul style="list-style-type: none"><li>Multi-host system If you are adding a multi-host system, specify the <b>master host</b>. You do not have to enter all host names explicitly as they are determined automatically. If the master host becomes unavailable, the connection is automatically established through one of the other hosts. Hosts that are added to the system later are also detected automatically.</li></ul> <div data-bbox="667 786 1394 987"><p>→ Tip</p><p>Once you have finished adding the system, you can see all available hosts in the system properties. Right-click the system in the <i>Systems</i> view and choose <i>Properties</i>. All hosts are listed on the <i>Hosts Used to Connect</i> tab of the <i>Database User Logon</i> page.</p></div> <div data-bbox="667 1003 1394 1173"><p>i Note</p><p>The host name of the server that hosts the database must be accessible from the client on which the SAP HANA studio is running, even if you add the system using its IP address.</p></div> <ul style="list-style-type: none"><li>Tenant databases If you are adding a tenant database in a tenant database system, specify the FQDN of the system host.</li></ul>
Instance	Instance number of the system
Mode	<p>Whether the system you are connecting to is a <b>single-container system</b> or <b>multiple-container system</b></p> <p>If you are connecting to a system with tenant databases, then you must further specify the specific database that you want to connect to:</p> <ul style="list-style-type: none"><li>The system database</li><li>A tenant database</li></ul>

### 5.2.3.3 Add an SAP HANA System with a Different User

If you want to work with an SAP HANA system using several database users, you can create a connection to the system or database in the SAP HANA studio with the credentials of different users.

#### Prerequisites

- The system has already been added once in the *Systems* view.
- If you want to secure communication between the SAP HANA server and the SAP HANA studio using the Secure Sockets Layer (SSL) protocol, you have configured the server for SSL and imported the trust store file that contains the server root certificate into either the Java keystore or your user keystore on the client.
- The relevant ports in your firewall are open.
- You must have a database user, or the necessary infrastructure for Kerberos-based user authentication must be in place.

#### Procedure

1. In the *Systems* view, right-click the system and choose *Add System with Different User*.
2. Choose the authentication type for user logon to the system:
  - If you are integrating the SAP HANA studio into a Kerberos-based single sign-on environment, choose *Authentication by current operating system user*.
  - If you are implementing user name/password authentication, choose *Authentication by database user* and enter the database user name and password. You can choose to have your password stored in the Eclipse secure storage so that you do not have re-enter it every time you open the studio.
3. Indicate whether you want to use a secure connection to the system by choosing *Connect using SSL*.

#### i Note

You must select this option to be able to modify the SSL connection properties (step 7).

4. Configure the connection of the SAP start service `sapstartsrv` to the system.  
An HTTP connection to the system using the SAP start service is automatically enabled. You can choose to disable this connection if it is not required.

#### i Note

If you disable this connection, administrative actions that require operating system access are not possible in the SAP HANA studio (for example, stopping and starting the system, performing a recovery, or opening the Administration editor in diagnosis mode).

If you want the SAP start service to communicate with the system via a secure connection, choose *Use HTTPS*.

5. Choose *Next*.

6. Optional: Modify the following advanced connection properties for your system:

Option	Description
<b>Option</b>	JDBC connection parameter(s)
<b>Auto-Reconnect</b>	Auto-reconnect option  If you select this option, the SAP HANA studio automatically reconnects if the connection to the system fails.

7. Optional: Configure SSL communication:

- To have the identity of the server validated during connection, choose [Validate SSL Certificate](#). The server's public-key certificate is validated against the root certificate stored in the trust store. If you want to override the system host name specified in the server certificate, enter a host name with a defined certificate.
- [Use user key store as trust store](#)  
The Java SSL property `trustStore` specifies the trust store containing the certificate used to validate that the server certificate is issued by a trusted entity. Each user can import certificates into a user keystore in Java using the `keytool` command line tool (part of the JRE installation). The user keystore is located in the home directory of the current operating system user. The file name is `.keystore`. The set of root certificates delivered with the JRE from well-known issuers (for example, Verisign, Thawte, Deutsche Telekom) is used when this option is not selected.

8. Choose [Finish](#).

The system is added in the [Systems](#) view. The system entry displays the following information:

- SID  
In the case of a tenant database system, the database name is indicated before the SID, either `SYSTEMDB@<SID>` or `<database>@<SID>`
- Connected user
- System usage if it is a production system
- System description if available

Information about system availability and user connection status are indicated by icons.

## Results

You can now access the system or database in the SAP HANA studio.

## Related Information

[User Authentication and Single Sign-On \[page 822\]](#)

[Provisioning Users \[page 889\]](#)

[Configure System Usage Type \[page 327\]](#)

[Configure TLS/SSL for SAP HANA Studio Connections \[page 146\]](#)

## 5.2.3.4 Link a Centrally-Stored Archive of SAP HANA Systems

To allow users who work in the SAP HANA studio to connect to multiple SAP HANA systems, you can manage a list of all systems in a centrally-accessible archive. Users can then simply link to this archive.

### Prerequisites

An XML file containing a list of all SAP HANA systems and their connection information exists at a centrally-accessible location, for example, a network file server.

You can create this file by exporting a list of systems from your installation of the SAP HANA studio to the required location.

### Context

A centrally-stored archive of SAP HANA systems allows you to deploy system information to all users of the SAP HANA studio, for example, developers, content modelers, and other administrators. It avoids users having to obtain the connection details of all systems individually and then having to add them all individually. In addition, if you change the central file, for example to add new systems or change the host of an existing system, you can ensure that users always have up-to-date system access.

### Procedure

1. From the *Systems* view toolbar, choose  (*Add System Archive Link...*).
2. Specify the following link details:
  - Link name
  - Path to the system archive containing the system information
  - Optional: A folder in the *Systems* view
3. Choose *Finish*.

### Results

The system archive appears in the *Systems* view as a link node (). By expanding the link node, you can see all the systems contained within.

To be able to access a system in the system archive, the password of the connecting user specified in the system properties must be available in the user's local Eclipse secure storage. If this is not the case, you must log on to the system.

### i Note

The system archive file does **not** contain user passwords.

As the system archive is only linked, note the following:

- Systems are not added to the user's local workspace.
- Users cannot edit the connection properties of systems in the system archive.
- Users cannot change the order or hierarchical structure of systems in the system archive.

## Related Information

[Export a List of SAP HANA Systems \[page 142\]](#)

### 5.2.3.5 Log Off From/Log On To an SAP HANA System

In the SAP HANA studio, you can log off from an SAP HANA system and close all connections to the system. To be able to connect to system again, you must log on.

## Procedure

- To log off from a system right-click it in the *Systems* view and choose *Log Off*. All open connections to the system are closed, and in the *Systems* view, the system appears disabled. No information regarding its operational status is available; you cannot expand it and browse its contents.

### i Note

Editors connected to the system at the time of log-off may close as a result. If an editor contains any unsaved work, you will be prompted to save it first.

- To log on to a system, simply double click it in the *Systems* view or from the context menu, choose *Log On*. If your password is saved in the Eclipse secure store, you are logged on to the system immediately and can connect to it again. If have disabled the storing of passwords in the Eclipse secure store, you must re-enter your password.

## Related Information

[Disable Password Storage in Eclipse Secure Store \[page 140\]](#)

## 5.2.3.5.1 User Logon Behavior on SAP HANA Studio Startup

Whether or not you are logged on to your SAP HANA systems when you start the SAP HANA studio depends on whether or not you were logged on when you closed the studio.

If you logged off from a system before closing the studio, you are still logged off and must log on explicitly. If you were logged on when you closed the studio, you are logged on automatically. This is the default behavior.

However, you can change this behavior so that no automatic logon takes place when the studio is started: explicit logon is always required.

To do so, choose **► Preferences ► SAP HANA ► Global Settings ►** and deselect the option *Restore logged-on/ logged-off status of systems on startup*.

### i Note

Automatic logon on studio startup can only take place if the connecting user's password is stored in the Eclipse secure store. If it is not, explicit logon is always required.

## 5.2.3.6 Disable Password Storage in Eclipse Secure Store

When an SAP HANA system is added in the SAP HANA studio, the user can choose to store his or her password in the Eclipse secure storage. To improve security, you can disable this password storage. Users must then log on to the system every time they open the studio.

### Prerequisites

You are logged on to the computer on which the SAP HANA studio is installed as either the root user (Linux) or local administrator (Windows).

### Context

The Eclipse secure storage stores user passwords securely to disk on the SAP HANA studio client. To connect to a system in the SAP HANA studio, the user does not have to enter his or her password; the stored password is used. This behavior may not be desired for security reasons in some cases, for example:

- To prevent individuals from being able to access systems using another user's credentials  
This is possible if several users share the computer on which the SAP HANA studio is installed.
- To prevent users from locking their accounts  
This is possible if a user's password for a system has expired but the old password is stored in the secure store. The user may lock their account due to too many failed logon attempts.

## Procedure

Disable password storage by specifying the command `-noPwdStore` in one of the following ways:

- As a start-up parameter of `hdbstudio.exe` (for example, in the program shortcut properties of a Windows installation)
- As a parameter in the `hdbstudio.ini` configuration file

## Results

User passwords cannot be stored in the Eclipse secure storage. When the SAP HANA studio is opened, systems appear in a logged-off state in the *Systems* view.

To connect to the system, the user must log on to it by choosing *Log On* from the context menu and then entering his or her password. The password is stored temporarily for the duration of the session only. The session ends when the user closes either the SAP HANA studio or the individual system by choosing *Log Off* from the context menu.

### 5.2.3.7 Organize the Systems View Using Folders

If you add several SAP HANA systems in the *Systems* view, you can define a folder structure to organize them.

## Procedure

1. From the main menu, choose **► New > Folder ◄**.
2. Enter a folder name.
3. In the *Systems* view, move your system to the new folder using drag and drop.
4. Repeat this procedure until you have added all your systems.

## Results

Once folders have been created, you can assign any new systems to a folder when you add them.

## 5.2.3.8 Search for SAP HANA Systems

If you have a large number of systems registered in the *Systems* view, you can search for a specific system to access it more quickly.

### Procedure

1. From the *Systems* view toolbar, choose the  (*Find System*) button.
2. Enter a search string.  
You can also use \* or ? as wildcards.  
Matching systems are displayed.
3. Select the system you were searching for.  
You can select several systems in the search results by pressing the `CTRL` key while selecting. You can use this, for example, to mark duplicate systems.
4. Choose whether you want to open the selected system in the Administration editor and/or the SQL console.

### Results

The system opens in the Administration editor and/or SQL console. If you did not select either of these options, the system is only highlighted in the *Systems* view.

## 5.2.3.9 Export a List of SAP HANA Systems

You can export a list of your SAP HANA systems from the SAP HANA studio as an XML file and then import it into another instance of the SAP HANA studio or use it as system archive to which other users can link.

### Procedure

1. From the main menu, choose `File > Export... >`.
2. Expand the *SAP HANA* folder and choose *Landscape*.
3. Choose *Next*.
4. Select the systems you want to export and enter a target file location.
5. Choose *Finish*.

## Results

The list of systems and their properties (name, description, host name, instance, and so on) is exported as an XML file to the specified location.

## Related Information

[Link a Centrally-Stored Archive of SAP HANA Systems \[page 138\]](#)

### 5.2.3.10 Import a List of SAP HANA Systems

You can import a list of SAP HANA systems that you previously exported from another instance of the SAP HANA studio.

## Procedure

1. From the main menu, choose **File** > **Import...**
2. Expand the **SAP HANA** folder and then choose **Landscape**.
3. Choose **Next**.
4. Choose **Browse...** and select the file containing the list of systems that you want to import.
5. Select the folder into which you want to import the file.
6. Choose **Finish**.

## Results

The systems are added in the **Systems** view of the SAP HANA studio.

To be able to access the systems, the password of the connecting user specified in the system properties must be available in the user's local Eclipse secure storage. If this is not the case, you must log on to the system.

### **i** Note

The file containing the list of systems does **not** contain user passwords.

## 5.2.3.11 Disable Default Filtering of Schemas

Users with the system privilege DATA ADMIN and/or CATALOG READ, for example database administrators, may not see all schemas in the [Systems](#) view of the SAP HANA studio since a default filter is applied.

### Context

In the [Systems](#) view of the SAP HANA studio, users only see those schemas for which at least one of the following criterion applies:

- The user has at least one object privilege on the schema.
- The user has at least one object privilege on at least one object in the schema.
- The user owns at least one object in the schema.

#### i Note

For all privilege checks, not only privileges directly granted to the user but also privileges granted to one of his or her roles (or to roles in these roles) are considered.

As a result, users with the system privilege DATA ADMIN and/or CATALOG READ cannot see all available schemas.

If, as a database administrator, you need to see all available schemas, you must disable this default schema filter.

### Procedure

1. In the [Systems](#) view, right-click [Catalog](#) and choose [Filters...](#)  
The [Filter for Schema](#) dialog box opens.
2. Select [Display all schemas](#).
3. Optional: Specify a filter pattern to reduce the number of schemas displayed.  
This is useful if the total number of schemas exceeds the number of displayable items in the tree (configured under [► Preferences > Catalog >](#)). If this is the case, then you will not see all schemas at once and will have to browse.
4. Save and apply the filter by choosing [OK](#).

### Results

Schemas are displayed filtered according the specified filter pattern.

## 5.2.3.12 Start the SAP HANA Studio with Immediate System Logon

The SAP HANA studio program accepts command line parameters that allow you to specify the system to be connected to immediately on startup. This can be useful to system administrators, as well as to other programs that call the SAP HANA studio.

### Prerequisites

You have a database user in the SAP HANA system that you want to log on to.

### Procedure

1. Launch the SAP HANA studio from its installation directory passing the following start parameters:

Option	Description
-h	Host name
-n	Instance number
-u	User name
-d	Tenant database

#### **i** Note

User names containing special characters that represent conjunction or redirection characters in the command line program must be enclosed in double quotation marks ("..."), regardless of where the special character appears in the user name.

#### **•** Example

Windows:

- o `hdbstudio.exe -h hana1 -n 02 -u DBADMIN -d Tenant01`
- o `hdbstudio.exe -h hana1 -n 02 -u "&test" -d Tenant01`

Linux

- o `hdbstudio -h hana1 -n 02 -u DBADMIN -d Tenant01`
- o `hdbstudio -h hana1 -n 02 -u "&test" -d Tenant01`

Mac OS:

- o `open -a /Applications/sap/hdbstudio.app --args -h hana1 -n 02 -u DBADMIN -d Tenant01`
- o `open -a /Applications/sap/hdbstudio.app --args -h hana1 -n 02 -u "&test" -d Tenant01`

The SAP HANA studio opens.

2. If prompted, enter your user password.

## Results

The system is added in the [Systems](#) view (if it is not already there), and you are logged on.

### 5.2.3.13 Configure TLS/SSL for SAP HANA Studio Connections

Secure communication between the SAP HANA studio and the SAP HANA database using the Transport Security Layer (TLS)/Secure Sockets Layer (SSL) protocol.

## Prerequisites

- You have configured the SAP HANA database for secure client-server communication over JDBC/ODBC. For more information, see *SSL Configuration on the SAP HANA Server* in the *SAP HANA Security Guide*.
- You have added the SAP HANA system in the SAP HANA studio.

## Context

The SAP HANA studio communicates with the SAP HANA database via the JDBC client interface. The client-side configuration of the SAP HANA studio uses Java TLS/SSL properties.

## Procedure

1. Using the keytool command line tool, import the truststore file that contains the server root certificate into either the Java keystore or your personal user keystore.

By default, the SAP HANA studio client validates server certificate(s) against the root certificate stored in the Java keystore of the running VM (virtual machine). This keystore is part of the Java installation and is located in the Java home directory under `${JAVA_HOME}/lib/security/cacerts` (Linux) or `%JAVA_HOME%/lib/security/cacerts` (Windows).

However, it is not recommended that you store the root certificate in this keystore, but in your personal user keystore instead. The user keystore is located in the home directory of the current operating system user. The file name is `.keystore`.

2. Enable and configure TLS/SSL secure communication between the SAP HANA studio and the server:

In the SAP HANA studio, open the system's properties and choose [Connect Using SSL](#).

This corresponds to setting the Java SSL property `encrypt` to **true**.

3. Configure how the identity of the server is to be validated during connection (server-side authentication):
  - a. In the system's properties dialog, choose the [Additional Properties](#) tab.
  - b. If you want server certificate(s) to be validated using the default truststore, choose [Validate SSL Certificate](#).

This corresponds to setting the Java SSL property `validateCertificate` to **true**.

When an TLS/SSL connection is established, the host name in the certificate being connected to and the host name in the server certificate must match. This may not always be the case. For example, in a single-host system, if a connection is established from the SAP HANA studio on the same host as the SAP HANA server, a mismatch would arise between the host named in the certificate (fully qualified host name) and the host used to establish the connection (`localhost`)\*.

You can override the host name specified in the server certificate by entering a host name with a defined certificate in the [Override Host Name Certificate](#) field. This corresponds to setting the Java SSL property `hostNameInCertificate`.

- c. If you want the server certificate to be validated using the user's keystore and not the default Java keystore, choose [Use user keystore as trust store](#).

This corresponds to changing the value of the Java SSL property `trustStore`.

### Note

If you do not have a working public key infrastructure (PKI), you can also suppress server certificate validation entirely by selecting neither of these options ([Validate SSL Certificate](#) or [Use user keystore as trust store](#)). However, this is not recommended.

4. Optional: If the identity of the client is to be validated by the SAP HANA server (client certificate validation), perform the following additional steps:
  - a. In the [Additional Properties](#) tab of the system properties, specify the path to the user keystore that contains your private key, as well as the pass phrase required to access this file.
  - b. Enable validation of the client's identity on the server by changing the parameter `[communication] sslValidateCertificate` in the `global.ini` file to **true**.

You can do this on the [Configuration](#) tab of the Administration editor.

- c. Import the client root certificate into the server truststore used for client-server communication.

If you manage client certificates directly in the database (recommended), this means importing the certificate into the certificate store and adding it to the certificate collection with the purpose [SSL](#).

## Results

In the [Systems](#) view, a lock icon appears next to the system name () , indicating that SSL communication is active.

## Related Information

[Add an SAP HANA System \[page 132\]](#)

## 5.2.4 SAP HANA Studio Administration Preferences

The preferences of the SAP HANA studio include many options for customizing the features of the SAP HANA Administration Console.

To open the preferences of the SAP HANA studio, choose **Window > Preferences**. The preferences related to SAP HANA perspectives are all available under *SAP HANA*.

The following preferences pages contain administration-related settings:

- [Administration \[page 148\]](#)
- [Global Settings \[page 149\]](#)
- [Runtime \[page 149\]](#)
- [Table Viewer \[page 152\]](#)

## Administration

Administration

Option	Description
Show user-defined SQL statements on the <i>System Information</i> tab	If you select this option, user-defined SQL statements contained in the specified XML file are displayed on the <i>System Information</i> tab of the Administration editor. You can also change the default location and name of the XML file.

Backup Editor

Option	Description
Number of SQL objects to retrieve	This setting determines the number of backups displayed on the <i>Backup Catalog</i> tab of the Backup editor.
Refresh interval in seconds	This setting determines the refresh interval of the <i>Overview</i> tab of the Backup editor.
Connection timeout in seconds	This setting sets a timeout for the connection to the backup editor.  If the specified timeout is exceeded, no further attempt is made to establish a connection to the Backup editor. As a consequence, the Backup editor is not displayed in the <i>Systems</i> view. The other information about the SAP HANA database is still shown in SAP HANA studio.

## Global Settings

### Global Settings

Option	Description
Restore logged-on/logged-off status of systems on startup	<p>This option determines whether or not you are automatically logged on to systems registered in the <a href="#">Systems</a> view. By default, if you were logged on when you closed the studio (and your password is saved in the Eclipse secure store), you are logged on automatically on restart. Similarly, if you logged off before closing the studio, you are not logged on restart and you must actively log on.</p> <p>If you deselect this option, you must always log on after restart.</p>
Request confirmation before a user is deleted	<p>When a user is deleted, all dependent objects are also deleted. Select this option if you want a confirmation message to appear before a user is deleted.</p>
Show Management Console for <code>hdbcons</code>	<p>If you select this option, an additional tab <a href="#">Console</a> is available in the Administration editor. You can execute <code>hdbcons</code> commands directly in this console.</p> <div style="border: 1px solid #ccc; padding: 5px;"><p><b>⚠ Caution</b></p><p>Technical expertise is required to use <code>hdbcons</code>. To avoid incorrect usage, use <code>hdbcons</code> only with the guidance of SAP HANA development support.</p></div>

## Runtime

### Catalog

Option	Description
Fetch all database catalog objects	<p>By default the SAP HANA studio fetches a limited number of catalog objects when folders in the <a href="#">Systems</a> view such as <a href="#">Tables</a> and <a href="#">Views</a> are opened.</p> <p>If you select this option, <b>all</b> catalog objects are loaded in the corresponding folder. This may affect system performance as it may take some time to fetch all database catalog objects.</p>
Number of database catalog objects to display	<p>If you do not select the <a href="#">Fetch all database catalog objects</a> option, you can specify the maximum number of catalog objects to be fetched. If the number of available objects exceeds the number specified here, the message <a href="#">Object limit reached</a> appears.</p> <p>The default number is 1,000.</p>
Show table comment before table name (Modeler)	<p>If you select this option, a table's description appears before its name in the <a href="#">Systems</a> view if the SAP HANA Modeler perspective is active.</p>

### Common

Option	Description
Confirm saving editors	<p>If you select this option, the system displays a confirmation dialog when an editor is closed with content that was not saved.</p>

Option	Description
Autosaving of SQL Console Content	If you select this option, the content of SQL console sessions is saved automatically when the SAP HANA studio is closed. No dialog requesting the user to save is displayed.
<ul style="list-style-type: none"> <li>Save content when SAP HANA Studio is closed</li> <li>Content save interval ... minutes</li> </ul>	Additionally, it is possible to have the content saved at a specified interval. If the SAP HANA studio is closed unexpectedly, the last version can be recovered.
Copy options:	These are formatting options for copying content from the table editor.
<ul style="list-style-type: none"> <li>Data separator</li> <li>Tab separated</li> <li>Align copied values with space</li> <li>Copy cell in editor by using <code>[CTRL] C</code></li> <li>Copy editor content with column header</li> </ul>	
Representation of null value	This option specifies the character used to display NULL values
Database identifier upper case	This option specifies that the IDs of database objects can be entered only in uppercase letters.
Default action for database tables:	This setting specifies which view of a table is opened when it is double-clicked in the <i>Systems</i> view: its definition or its content.
<ul style="list-style-type: none"> <li>Show content</li> <li>Show definition</li> </ul>	
Table Distribution Editor	This setting specifies the maximum number of tables that are displayed when you show table distribution.
Maximum Number of Tables Displayed	
Result	
Option	Description
Limit for LOB columns (bytes)	This option specifies the maximum number of bytes that are loaded from the database for one large object (LOB) column.
Limit for zoom (bytes)	This option specifies the maximum number of bytes that the SAP HANA studio displays when you zoom the LOB column in the result table in the <i>Result</i> tab of the SQL console.
Append exported data to file	If you select this option, then when you export the result table to a file, the system attaches the content of the current result table to the existing file content.
Display character byte value as hex	If you select this option, data of the data type CHAR BYTE is displayed as hexadecimal digits. If you do not select this option, this data is displayed in binary format.
Format values	If you select this option, country-specific formatting is applied (for example, numeric values or dates).
Display duration result row fetch	If you select this option, you can see in the SQL console how long it took to fetch one row of a result set.
Maximum number of rows displayed in result	This option specifies the maximum number of rows fetched from the database and displayed in the result table of the <i>Result</i> tab.

Option	Description
Enable zoom of LOB columns	<p>You must select this option if you want to be able to zoom LOB columns in the result table of the Result tab. You can zoom an LOB column by right-clicking and choosing .</p> <p>Note that if you zoom an LOB column, it is automatically closed after 15 minutes or when the <i>Result</i> tab is closed.</p>

### Note

The options available under *Result* relate to the display of results following execution of a SELECT statement the SQL console.

### SQL

Option	Description
Stop batch SQL statement execution if an error occurs	If you select this option, then when you execute a series of SQL statements separated by comment characters, the system stops the execution when an error occurs.
Clear SQL console log before SQL statement execution	If you select this option, the log from the last SQL statement is deleted before the next SQL statement is executed.
Close results before SQL statement execution	If you select this option, then when you execute an SQL statement in the SQL console, all old results tabs in the same SQL console session are closed.
Display time of statement execution start	If you select this option, you can see in the SQL console the time at which statement was executed.
Display duration of failed statements	If you select this option, you can see in the SQL console how long a statement took to execute in the SAP HANA studio even if the statement failed.
Connection parameters for SQL console: <ul style="list-style-type: none"> <li>• Auto-commit mode</li> <li>• Isolation level</li> <li>• Confirm change of connection</li> </ul>	<ul style="list-style-type: none"> <li>• Auto-commit mode:               <ul style="list-style-type: none"> <li>○ If on, the system performs all COMMIT actions automatically</li> <li>○ If off, you have to enter COMMIT statements explicitly.</li> </ul> </li> <li>• The isolation level determines how the system implicitly controls locking and versioning of database objects.</li> <li>• Confirm change of connection In the SQL console, you can change the SQL connection you are working on. When you change a connection, cursors may be closed or transactions may be rolled back. If you select this option, a change of SQL connection must first be confirmed.</li> </ul>

### SQL console settings

Command separator	This option specifies the separator for SQL statements in the SQL console.
Maximum number of characters for multiple statement execution	When you enter multiple statements in the SQL console for execution, the content must be parsed and the individual statements for execution recognized. However, if there is too much content, out-of-memory situations or a long parse time may result. When the number of characters specified with this option is reached, parsing does not take place and the content is executed as a single statement.
Number of tables for table name completion	This option specifies the number of tables that are displayed in the list when you use name completion in the SQL console.

Option	Description
Number of open <i>Result</i> editors	The results of statement execution may be returned in multiple <i>Result</i> editors. Once the number of open <i>Result</i> editors specified with this option is reached (by default 50), statement execution stops. We recommend that you do not increase the default value of this option as it may cause performance issues in the studio.

#### Templates

Option	Description
Name	Word to be completed when you press the key combination <code>CTRL</code> + <code>SPACE</code> .  You can create more than one template with the same name. If more than one template exists for one word, the system displays a list.
Context	Editor in which you can use the template.
Description	Template description
Auto insert	If on, the code assist automatically inserts the template if it is the only proposal available at the cursor position.

#### **i** Note

The options available under *Templates* always refer to the editor that is currently open.

## Table Viewer

#### Table Viewer

Option	Description
Show gridlines	Use these options to customize the appearance of list displays in the Administration editor, for example, the list of files on the <i>Diagnosis Files</i> tab.
Alternating colored rows	

## 5.3 SAP HANA Hardware and Cloud Measurement Tools for Tailored Data Center Integration

The SAP HANA hardware and cloud measurement tools allow you to check the interoperability of SAP HANA with your existing enterprise storage, network and server in production environments.

In addition to SAP HANA as standardized and highly optimized appliance, SAP offers the opportunity to run the SAP HANA server with a customer's preferred storage and network solutions. This option enables you to reduce hardware and operational costs through the reuse of existing hardware components and operational processes. Here an SAP HANA server means the exact same bill of material as the certified SAP HANA appliance but without storage. Certified SAP HANA servers that can be used in a TDI deployment are listed in the PAM and the SAP HANA Hardware Directory.

The SAP HANA hardware and cloud measurement tools provide tests and reports for new single host and scale out systems to determine if the hardware you intend to use meets the minimum performance criteria required

to run SAP HANA in production use. The tools consist of the SAP HANA hardware and cloud measurement tool, which can be downloaded from the SAP Support Portal, and the SAP HANA hardware and cloud measurement analysis, which is available online. For more information about installing and using the tools, see the *Related Links* section.

#### Caution

The test should only be used before going into production. Because the tests stress the system to the maximum it is not possible to use the tools in production systems.

## 5.4 SAP Solution Manager for SAP HANA Administration

SAP Solution Manager allows you to manage your business applications throughout their entire lifecycle. You can integrate SAP HANA into an overall operations concept supported through SAP Solution Manager, as of release 7.1, SP05.

SAP HANA is often used in conjunction with other SAP business applications. For example, an SAP ERP system might call accelerators on SAP HANA to speed up business processes, or a product such as SAP Business Warehouse is deployed on the SAP HANA database. If you are using SAP HANA in such a context, then you must manage your business application in addition to administering the in-memory database. This is best done using an integrated approach.

SAP provides you with the SAP Solution Manager application management platform as part of your maintenance agreement. You can use it to manage your business applications throughout their entire lifecycle. As of release 7.1, SP05, SAP Solution Manager supports integration with SAP HANA. You can optimize your operational processes using this combined approach. One example is root cause analysis. Let's assume you have detected a problem in an application that is deployed on SAP HANA or calls an SAP HANA accelerator. In this case, you first have to find out whether the problem is caused by the application or by the SAP HANA database. SAP Solution Manager allows you to trace a process across all included components (from the user interface to the database) to locate the source of the problem. Then, detailed analysis speeds up your resolution process.

Other examples of how SAP HANA and SAP Solution Manager can be valuably integrated in the area of system operation are the processes for monitoring and change control. If your business application is still running on a traditional database, even integrated database administration might be relevant.

### 5.4.1 Connecting SAP Solution Manager to SAP HANA

Configure a connection to SAP HANA in SAP Solution Manager.

If you want to use capabilities of SAP Solution Manager, you have to make sure that the two systems know each other. Prerequisite for this is the registration of the SAP HANA system in the System Landscape Directory (SLD). From there, SAP Solution Manager gets the information that the SAP HANA system exists. The communication between the systems is based on a central agent infrastructure. The pre-configured agents are delivered by SAP and deployed on the SAP HANA appliance by the hardware partner.

The configuration of the connection itself is done as part of the basic configuration of SAP Solution Manager. In the guided procedure for Managed Systems Configuration you just need to set up the correct connection, assign the right agents, enter some parameters, create required users, and do a few more configurations. After this, you can start the collaboration of SAP HANA and SAP Solution Manager.

Some of the processes in SAP Solution Manager require additional configuration to specify how they should handle the SAP HANA database. For example, you have to specify in system monitoring which metrics you want to control, or you have to define your transport landscape (development system to quality assurance system to production system) for change control.

## 5.4.1.1 Configuring an SAP HANA System to Connect to the System Landscape Directory (SLD)

You can use the SAP HANA database lifecycle manager to configure the connection parameters for the central System Landscape Directory (SLD) system.

The System Landscape Directory (SLD) serves as a central information repository for your system landscape. Data suppliers collect and send system data to SLD on a regular basis. The SLD data supplier for SAP HANA systems is implemented within the name server of the SAP HANA system. However, to enable the data collection process for your SAP HANA system, you must first configure the system's connection to the SLD. Note that the SAP HANA database lifecycle manager provides only the functionality to configure the connection to the SLD, the actual registration is performed automatically by the SLD data supplier afterward.

### Related Information

[Configure SLD Registration Using the Graphical User Interface \[page 155\]](#)

[Configure SLD Registration Using the Command-Line Interface \[page 157\]](#)

[Configure SLD Registration Using the Web User Interface \[page 159\]](#)

[Using the SAP HANA Platform LCM Tools \[page 1052\]](#)

### 5.4.1.1.1 Configure SLD Registration Using the Graphical User Interface

You can configure an SAP HANA system to connect to the System Landscape Directory (SLD) using the SAP HANA database lifecycle manager (HDBLCM) resident program in the graphical user interface.

### Prerequisites

- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on with the required root user or system administrator user `<sid>adm` credentials.

### Context

When an SAP HANA system is connected to the SLD, it can report its status and provide details and information about the system itself. For more information, see SAP Note 1673424 and SAP Note 1649323.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdb lcm
```

By default, <sapmnt> is /hana/shared.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdb lcmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

### i Note

To activate the local secure (LSS) store during installation, run `hdb lcmgui` with the parameter `secure_store=localsecurestore`.

3. Select *Configure System Landscape Directory Registration* from the activity options. Then select *Next*.
4. Define the required parameters. Then select *Next*.

Field Name	Description
<i>SLD Host Name</i>	Specifies the name of the host where the SLD system is installed.
<i>SLD Port</i>	Specifies the standard HTTP access port of the SLD.
<i>SLD User Name</i>	Specifies the user of the SLD system. It must be a user that already exists on the host where the SLD system is running.
<i>SLD Password</i>	Specifies the password for the SLD system.
<i>Use HTTPS</i>	Specifies whether or not to use HTTPS.

5. Review the summary, and select *Run* to finalize the configuration.

## Related Information

## 5.4.1.1.2 Configure SLD Registration Using the Command-Line Interface

You can configure an SAP HANA system to connect to the System Landscape Directory (SLD) using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface.

### Prerequisites

- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on with the required root user or system administrator user `<sid>adm` credentials.

### Context

When an SAP HANA system is connected to the SLD, it can report its status and provide details and information about the system itself. For more information, see SAP Note 1673424 and SAP Note 1649323.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblc
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
o ./hdblc
```

and enter the index of the `configure_sld` action, or

- o Start the tool with the `configure_sld` action specified:

```
./hdblc --action=configure_sld
```

3. Define the required parameters.

Field Name	Description
<i>SLD Host Name</i>	Specifies the name of the host where the SLD system is installed.
<i>SLD Port</i>	Specifies the standard HTTP access port of the SLD.

Field Name	Description
<i>SLD User Name</i>	Specifies the user of the SLD system. It must be a user that already exists on the host where the SLD system is running.
<i>SLD Password</i>	Specifies the password for the SLD system.
<i>Use HTTPS</i>	Specifies whether or not to use HTTPS.

For more information about parameters for SLD configuration, see [Related Information](#).

4. Review the summary, and select **y** to finalize the configuration.

## Results

You have configured the SAP HANA system to connect to the System Landscape Directory (SLD). The registration itself is performed by the SLD data supplier service.

This configuration task can also be performed in batch mode and using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

### i Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the `hdblcm` directory of the SAP HANA system, execute the following command:

```
./hdblcm --action=configure_sld --help
```

## Example

The following example configures the registration in an SLD system interactively. The connection from the SLD Data Supplier service to the SLD is over HTTPS.

```
./hdblcm --action=configure_sld --sld_hostname=mysap --sld_port=50000 --sld_username=SLDuser --sld_password=SLDpassword -https
```

### 5.4.1.1.3 Configure SLD Registration Using the Web User Interface

A connection to the System Landscape Directory (SLD) can be configured using the SAP HANA database lifecycle manager Web user interface.

#### Prerequisites

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing [Tools > Compatibility View Settings](#).
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release
    - Google Chrome - Latest version
  - SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
  - Mac OS - Safari 5.1 or higher

#### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

#### Context

When an SAP HANA system is connected to the SLD, it can report its status and provide details and information about the system itself. For more information, see SAP Note 1673424 and SAP Note 1649323.

## Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser: <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

### i Note

The URL is case sensitive. Make sure you enter upper and lower case letters correctly.

<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"><li>1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code></li></ol>
-------------------------	---

### i Note

FQDN = fully qualified domain name

2. Drill down on the name of the system from *My Resources* or from a group.
3. The links in *Platform Lifecycle Management* each launch additional functionality, giving you expanded capabilities for managing the resource.

2. Select the *Configure System Landscape Directory Registration* tile.
3. Specify values for the following fields:

Field Name	Description
<i>SLD Host Name</i>	Specifies the name of the host where the SLD system is installed.
<i>SLD Port</i>	Specifies the standard HTTP access port of the SLD.
<i>SLD User Name</i>	Specifies the user of the SLD system. It must be a user that already exists on the host where the SLD system is running.
<i>SLD Password</i>	Specifies the password for the SLD system.
<i>Use HTTPS Connection</i>	Specifies whether or not to use HTTPS.

4. Review the summary, and select *Run* to finalize the configuration.

## 5.4.1.2 Change the Default SLD Data Supplier Configuration

The System Landscape Directory (SLD) is the central directory of system landscape information relevant for the management of your software lifecycle. Data suppliers collect and send system data to SLD on a regular basis. The SLD data supplier for SAP HANA systems is implemented within the name server.

### Prerequisites

- The SLD is configured.  
For more information, see SAP Note 1018839 and the introductory section *Configuring an SAP HANA System to Connect to the System Landscape Directory*.
- You have the system privilege INIFILE ADMIN.

### Context

For SAP HANA systems, the name server contains the SLD data supplier. It is configured by default to automatically transfer data to the SLD on a regular basis using the `sldreg` executable. Data is transferred in XML format in a file named `sldreg.xml`. You can change the default settings if required by modifying the `nameserver.ini` configuration file; for example, it may not be necessary to send data to the SLD frequently if your landscape is stable, or you may need to change the default save locations of the configuration and log files.

You can edit configuration files in the SAP HANA cockpit or SAP HANA studio.

#### i Note

Links to additional resources related to SAP Solution Manager are listed under Related Links.

### Procedure

1. Navigate to the `nameserver.ini`.
2. Add a new section `sld` and add those parameters whose default value you want to change.

The following table lists the possible parameters and their default values.

#### i Note

Under normal circumstances, you will not need to change the default values. It should only be necessary, for example, for testing purposes or if requested as part of a support inquiry.

Key	Meaning	Default Value	Note
enable	Activates or deactivates the SLD data supplier	true	Allowed values are true, false. Re-enabling this parameter triggers a new generation of <code>sldreg.xml</code> and sending to the SLD system.
enable_virtddbhome	In a system replication landscape, enables the SAP_IdenticalDatabaseSystem association in SLD between the virtual database and the physical database configured with the parameters <code>sldvirtddbhome</code> and <code>sldsystemhome</code> in the <code>system_landscape_hostname_virtualization</code> section of the <code>global.ini</code> file	Undefined	<p>Allowed values are true and false.</p> <p>This parameter facilitates the registration of an SAP HANA system replication landscape in SAP Solution Manager.</p> <p>With the <code>sr_register</code> command, this parameter is set to <b>true</b> in the primary system and to <b>false</b> in the secondary system(s).</p> <p>In the event of a takeover (<code>sr_takeover</code>), the value of this parameter is set to <b>true</b> in the new primary system and to <b>false</b> in the original primary system, thus changing the association of virtual databases to the physical databases in the new primary.</p> <p>For more information, see <i>Configuring SAP HANA for System Replication Technical Scenario in SAP Solution Manager</i>.</p>
Interval	Specifies the frequency (in seconds) with which the <code>sldreg.xml</code> file is generated. If a newly-generated document is the same as the previous one, it is not sent to the SLD.	300	<p>It does not make sense to enter small positive values or negative values.</p> <p>If you enter 0 or a negative value, data is transferred to the SLD only once.</p> <p>Enter a value without a "1000 separator" (for example, 1899, not 1,899 or 1.899), otherwise it is interpreted as 0.</p>
force_interval	Specifies how often (in seconds) the <code>sldreg.xml</code> file must be sent to the SLD, even if the file has not changed.	43200	
configpath	Specifies the location of the folder that contains the configuration file <code>slddest.cfg</code>	<code>/usr/sap/&lt;sid&gt;/SYS/global</code>	Example: <code>/usr/sap/MPW/SYS/global</code>
	This file is a parameter for the call to <code>sldreg</code> .		

Key	Meaning	Default Value	Note
xmlpath	Specifies where the file <code>sldreg.xml</code> is generated and where the <code>sldreg.log</code> log file is written  <code>sldreg.log</code> is the log file of <code>sldreg</code> , and both files are parameters for the call to <code>sldreg</code> .	<code>/usr/sap/ &lt;sid&gt;/ HDB&lt;id&gt;/ &lt;currenthost &gt;/trace</code>	Example: <code>/usr/sap/LRH/HDB42/ velber1cm1/trace</code>
profilepath	Specifies the location of the folder that contains the <code>sldreg</code> profile <code>SLDREG.PFL</code> . This file is a parameter for the call to <code>sldreg</code> .	Undefined	Example: <code>/usr/sap/HGB/ profile</code>

## Results

The transfer of data will take place in line with your new settings.

### i Note

If errors occur in the transfer of data to the SLD, you can check the log file `sldreg.log` and the database trace for the name server with trace components `SLDCollect`, `SLDConfig`, and `SLDSend`.

### 5.4.1.3 Configuring SAP HANA for System Replication Technical Scenario in SAP Solution Manager

To model an SAP HANA system replication landscape in SAP Solution Manager as a technical scenario, you must configure SAP HANA to send the correct landscape data to the Landscape Management Database (LMDB) via the System Landscape Directory (SLD). SAP Solution Manager uses the system information managed in the LMDB.

System replication is a mechanism for ensuring the high availability of SAP HANA systems, as well as disaster recovery. Through the continuous replication of data from a primary to a secondary system, system replication

facilitates rapid failover in the event of a disaster. Production operations can be resumed with minimal downtime. With multitier system replication, a third system is attached to the first secondary making it a replication chain of three systems. For more information about system replication, see the section on availability and scalability in this guide.

Such a system replication landscape can be modeled as a technical scenario in SAP Solution Manager. The SAP HANA SLD supplier sends the required system landscape information to the LMDB based on the following landscape configuration settings in SAP HANA.

### **i Note**

The following configuration must be in place before you enable system replication on the primary system and register secondary systems.

## **Landscape Configuration Settings**

### **Define Virtual Databases (sldvirtdbhome)**

A virtual database is the logical host name under which an SAP HANA database can always be reached for the purposes of **takeover**. This ensures that application systems remain associated with the correct database in SLD when a secondary system takes over from the primary system.

In each SAP HANA system in the system replication landscape, configure a virtual database at the system level, or if desired for each individual tenant database, by setting the parameter

[system\_landscape\_hostname\_virtualization] sldvirtdbhome in the `global.ini` file of the system database. This will result in each virtual database being registered in SLD as an `SAP_HDBSystem` object (`<database_name>.DBTypeForSAP.HDB.SystemHome.<sldvirtdbhome>`).

Note the following:

- If you don't configure a value in the `global.ini` of each tenant database, the value configured in the `global.ini` of the SYSTEMDB applies. If you don't configure a value in the `global.ini` of the SYSTEMDB, the value of the `SLDVIRTDATABASEHOME` parameter in the default system profile (`hana/shared/<sid>/profile/DEFAULT.PFL`) is used; or if this value hasn't been set, the host name from the landscape properties file (`hana/shared/<sid>/lm_structure/landscapeVariables.properties`).
- Important: Configure a virtual database name for either all tenants or none. If some tenants are configured and some are not, the fallback values mentioned above are not used for those tenants without a configured value. In this case, the data supplier does not deliver this tenant completely and an error is written to the indexserver trace: "e SLDCollect logical database hostname = `<empty>`".
- Changing the `sldvirtdbhome` parameter in the `global.ini` file does not require a restart, whereas changing the default profile does.

### **Define Physical Databases (sldsystemhome)**

A physical database is the logical host name used to identify an SAP HANA database independently of internal host names for the purposes of **auto-host failover**. Since the host names of master and standby hosts are different, configuring a single physical database ensures that the same database is registered in SLD after a failover as before.

In each SAP HANA system in the system replication landscape, you configure a unique physical database at the system level, or if desired for each individual tenant database, by setting the parameter

[system\_landscape\_hostname\_virtualization] sldsystemhome in the `global.ini` file of the system database. This will result in each physical database being registered in SLD as an `SAP_HDBSystem` object (`<database_name>.DBTypeForSAP.HDB.SystemHome.<sldsystemhome>`).

Note the following:

- The LMDB does not support fully qualified domain names (FQDNs). We therefore recommend specifying physical databases without domain names. The data supplier will remove domains before sending physical databases to SLD.
- If you don't configure a value in the `global.ini` of each tenant database, the value configured the `global.ini` of the SYSTEMDB applies. If you don't configure a value in the `global.ini` of the SYSTEMDB, the value of the `SLDSYSTEMHOME` parameter in the default system profile (`hana/shared/<sid>/profile/DEFAULT.PFL`) is used; or if this value hasn't been set, the host name from the landscape properties file (`hana/shared/<sid>/lm_structure/landscapeVariables.properties`).
- Important: Configure a physical database for either all tenants or none. If some tenants are configured and some are not, the fallback values mentioned above are not used for those tenants without a configured value. In this case, the data supplier does not deliver this tenant completely and an error is written to the indexserver trace: "e SLDCollect logical computer hostname = `<empty>`".
- Changing the `sldsystemhome` parameter in the `global.ini` file does not require a restart, whereas changing the default profile does.

## Configure the Dependency Chain

In a system replication landscape, communication between primary and secondary systems is based on internal host names. This ensures that each site can resolve the host name of other sites and that the replication chain can switch seamlessly in the event of a takeover. To model the dependency relationship between databases in the replication chain in SLD, the physical databases must be mapped to the internal host names of the systems to which they belong.

In the `system_landscape_hostname_resolution` section of the `global.ini` file of the system database, create an entry for all internal host names in the system replication landscape and as the value, set the physical database available on the host. We recommend you do this in all systems.

The dependency relationship between databases will be modeled in SLD with the association `SAP_DatabaseReplicationDependency`.

### Note

For more information about mapping internal host names between primary and secondary systems, see the section on host name resolution for system replication.

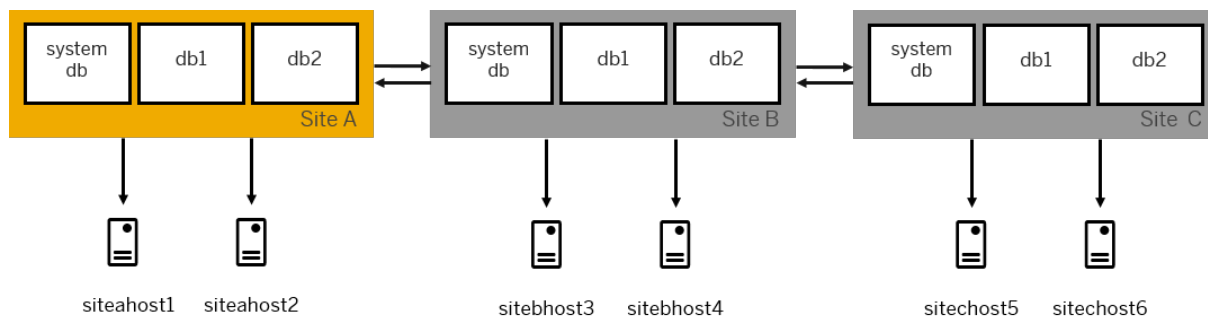

## Association of Virtual and Physical Names (`enable_virtdbhome`)

Once the above configuration is in place, the virtual and physical databases must be associated. This takes place implicitly when the secondary system is registered with the primary system. With the `sr_register` command, the parameter [sld] `enable_virtdbhome` in the `nameserver.ini` file is set to **true** in the primary system and to **false** in the secondary system(s). This results in the virtual databases being associated with the physical databases of the primary system in SLD with the association `SAP_IdenticalDatabaseSystem`.

In the event of a takeover (`sr_takeover`), the value of this parameter is set to **true** in the new primary system and to **false** in the original primary system, thus changing the association of virtual databases to the physical databases in the new primary.

## Example Configuration

The following figure shows a multitier system replication landscape. Each system in the chained setup is installed on two hosts for auto-host failover.

To send the required system landscape information to SLD, make the following landscape configuration settings in SAP HANA:

In all systems, configure virtual databases in the system database `global.ini` (section `system_landscape_hostname_virtualization`) as follows:

System	sldvirtdbhome Value for System	sldvirtdbhome Value for Tenant 1	sldvirtdbhome Value for Tenant 2
Primary system	systemDB	db1	db2
Tier 1 secondary system	systemDB	db1	db2
Tier 2 secondary system	systemDB	db1	db2

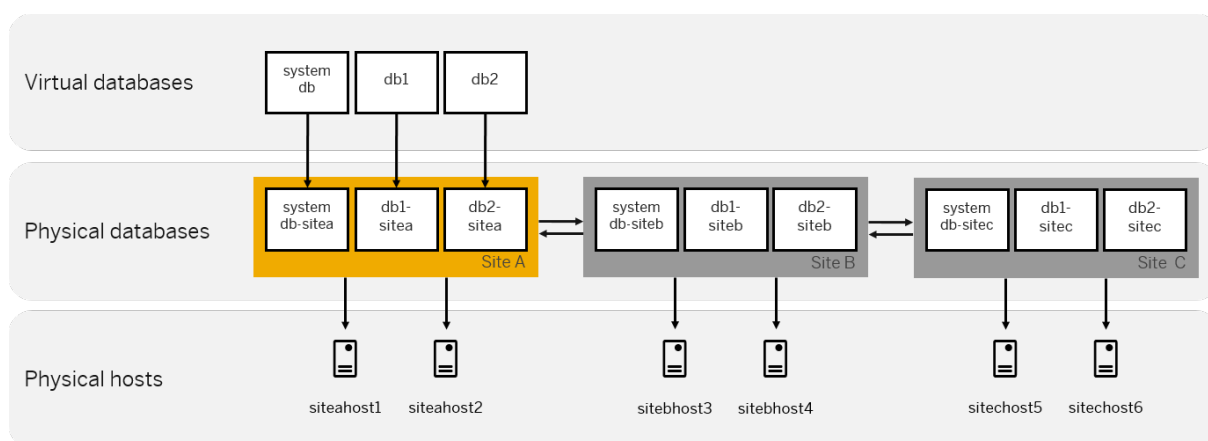

In all systems, configure the physical databases in the system database `global.ini` (section `system_landscape_hostname_virtualization`) as follows:

System	sldsystemhome Value for System	sldsystemhome Value for Tenant 1	sldsystemhome Value for Tenant 2
Primary system	systemDB-sitea	db1-sitea	db2-sitea
Tier 1 secondary system	systemDB-siteb	db1-siteb	db2-siteb
Tier 2 secondary system	systemDB-sitec	db1-sitec	db2-sitec

In all systems, configure the same host name resolution information in the system database `global.ini` (section `system_landscape_hostname_resolution`) as follows:

Parameter Name	Value for System	Value for Tenant 1	Value for Tenant 2
siteahost1	systemDB-sitea	db1-sitea	db2-sitea
siteahost2	systemDB-sitea	db1-sitea	db2-sitea

Parameter Name	Value for System	Value for Tenant 1	Value for Tenant 2
sitebhost3	systemDB-siteb	db1-siteb	db2-siteb
sitebhost4	systemDB-siteb	db1-siteb	db2-siteb
sitec host5	systemDB-sitec	db1-sitec	db2-sitec
sitec host6	systemDB-sitec	db1-sitec	db2-sitec

## 5.4.2 Central Monitoring and Administration with SAP Solution Manager

The monitoring and alerting infrastructure of SAP Solution Manager is based on a central agent infrastructure.

SAP delivers pre-configured agents for SAP HANA. If these agents have been deployed on SAP HANA and have been connected to SAP Solution Manager, SAP Solution Manager receives all alerts from the SAP HANA database. These alerts are displayed in the unified alert inbox.

SAP Solution Manager also provides an automated regular status check of your SAP solutions: SAP Early Watch Alert (EWA). This tool monitors the essential administrative areas of SAP components and keeps you up to date on their performance and stability. If you have any ABAP-based system in addition or running on SAP HANA, you can include the SAP HANA database information in the EWA report of this system: availability of services; size and growth; performance; important alerts; and correct setting of configuration parameters.

In addition to basic administration tasks, SAP provides specific task lists for SAP HANA, SAP Business Warehouse (BW) on SAP HANA, and SAP LT (Landscape Transformation) Replication Server. These lists

describe additional activities for administering these components and provide best practices for individual tasks.

### 5.4.3 Analyzing the Root Cause of Problems

You can use SAP Solution Manager to analyze the root cause of problems in your system landscape.

Often, SAP HANA systems are integrated with business applications that either call application accelerators in the SAP HANA database or are deployed on the database. If a problem occurs in this setup, you have to take a systematic approach to identify the precise cause of the fault. This standardized process must first broadly identify the components concerned and then analyze them more closely to arrive at the cause of the fault by process of elimination (top-down approach).

**End-to-end root cause analysis** in SAP Solution Manager provides your support organization with tools and methods that reliably identify the affected component while minimizing the time needed to solve the problem. In addition to your business applications, it supports also your SAP HANA database. This is the foundation for resolving problems in a holistic way. The DBA Cockpit is used in SAP Solution Manager to get a detailed insight into the status of the database. This is the same data that you can see in the SAP HANA cockpit for the SAP HANA database. But the DBA Cockpit supports other databases as well. If you have heterogeneous databases in your environment because your business applications still run on traditional databases, the DBA Cockpit enables you to use the same tool for the different databases.

**Trace analysis** records performance-related and functional faults in a specific user activity from the user's browser to the data stored in memory or on a storage sub-system. The measurement is triggered in the user interface and automatically activates recording of the relevant traces on every component processed by the user query.

After the root cause of a problem has been located, you can use detailed analysis to find a resolution. **Workload analysis** comprises server-related workload statistics for the connected systems. **Exception analysis** allows you to centrally analyze all exceptions from connected systems, such as serious error messages in logs or dumps. From here, you can start component-specific tools. And change analysis creates transparency for all changes (technical configuration, code, content) that have been made in the connected system landscape. This is particularly useful in the event of faults that occur once changes have been made to the production landscape.

#### Related Information

[DBA Cockpit for SAP HANA](#)

### 5.4.4 Controlling Change

In integrated system landscapes, SAP Solution Manager allows you to manage all changes centrally.

It is important to manage all changes in system landscapes using a central system. This is the only way to execute changes that affect more than one production system at the same time. For example, if you use SAP

HANA application-specific accelerators (for example, CO-PA) in combination with your SAP ERP back-end, you might need to synchronize changes of the data models on SAP HANA with changes for accessing the changed models from the transactions on SAP ERP. SAP Solution Manager provides central transport functions for the entire system landscape as well as additional support for quality management.

The process for transporting changes from a SAP HANA development system to a quality assurance and further on to the production system starts in the SAP HANA studio. There, you retrieve content from the SAP HANA source system and export it to enhanced Change and Transport System (CTS+) in SAP Solution Manager. The exported delivery units are attached automatically to a transport request of CTS+. After you have released this transport request, CTS+ triggers the automatic activation of the change in the SAP HANA repository on the target system (quality assurance or production).

In addition to supporting the transport and activation of new or changed data models, views, stored procedures, or analytic privileges, SAP Solution Manager offers additional possibilities to improve the quality of changes. You can use change analysis and reporting for getting information about the current status and history of changes. Configuration validation checks whether the systems of your system landscape (for example, development, quality assurance, and production) are configured consistently and according to the requirements. Quality Gate Management provides an additional quality inspection for projects and ensures changes are transported correctly and synchronously to the production systems. And Change Request Management within SAP Solution Manager controls the entire change execution with detailed process and workflow control. Out of these options, you can select those for controlling changes on SAP HANA that fit best to the quality strategy of your organization.

- [Managing Tables \[page 567\]](#)
- [Workload Management \[page 721\]](#)
- [Getting Support \[page 758\]](#)

## 6.1 Aggregate Monitoring and Administration

Use the SAP HANA cockpit or SAP HANA studio to view high-level information about the status, availability, performance, capacity, and alert counts of all resources in your SAP HANA landscape before drilling down for database-level monitoring and administration.

## Related Information

- [Landscape Monitoring and Administration \[page 171\]](#)
- [Monitoring Multiple Systems in SAP HANA Studio \[page 187\]](#)

## 6.1.1 Landscape Monitoring and Administration

For database groups to which you have access, you can monitor aggregated information representing each of the group's individual databases.

A database is an SAP HANA system, identified by a host and instance number. You can see data from multiple databases simultaneously—you can check the overall health of systems located within a data center or across your enterprise. You can drill down into status indicators for more detailed information.

### Additional Functionality

The tiles each launch additional functionality. If you're the cockpit administrator user or a cockpit database administrator user, *Manage Cockpit* gives you access to the *Cockpit Manager*. Developers and administrators can also visually browse database objects (tables and schemas) and execute SQL statements.

### Related Information

[Monitoring Your Databases in the Database Directory \[page 171\]](#)

[Configurations and Configuration Templates \[page 177\]](#)

### 6.1.1.1 Monitoring Your Databases in the Database Directory

Starting with an aggregate view of your registered databases in SAP HANA cockpit allows you to quickly discover any databases in your environment that have issues.

#### About the Database Directory

Use the *Database Directory* to view version and health information for all the databases in your landscape or to find a specific database instance. For each database, you can drill down for more information. Through the *Database Directory*, you can also specify the database user credentials required to access an individual database, which is necessary unless single sign-on is in effect for that instance.

When you first access the cockpit, the landscape level page displays important high-level information about all the SAP HANA databases to which you have been granted access. A database is identified by a host and instance number, and can be a single- or multi-host system. If you don't see any databases when you open the cockpit, either there are no databases registered in the cockpit, or your cockpit database administrator hasn't assigned databases to you. See *Setting Up Cockpit with the Cockpit Manager* and *Setup and Administration with the Cockpit Manager*.

You can use the cockpit to monitor and manage more than one database, each running version SAP HANA 1.0 SPS 12 or later. Any database running version SAP HANA 2.0 SPS 01 or later is set in multiple-container mode by default. The cockpit can also monitor single-container systems running earlier versions of SAP HANA. When you access the *Manage Services* application, the operations you have the option to perform depend on whether you are displaying a tenant or a system database.

## Database Groups

Each database belongs to a usage type group (Production, Test, Custom, or Development) depending on how it has been configured. Databases can also belong to one or more groups created by the cockpit database administrator.

You can also pay attention to the groups of databases and decide whether you need to navigate into a group to investigate potential issues, or you can click drill down to an individual database to obtain more details by clicking tabs, tiles, links, and numbers.

### → Tip

Unless your administrator has enabled single sign-on, you need to connect to the database with a database user that has the system privilege CATALOG READ and SELECT on `_SYS_STATISTICS`.

## Monitoring and Managing Database Health

The *Database Directory* provides a quick way to view essential health statistics for all the databases in your landscape. Clicking on a health statistic also provides a gateway to the application for that health component - for example, CPU usage - where you can view more information and manage configurations, and so on.

## Default Database Directory View

Column	Description
Status	<p>The status of the database. Can be one of:</p> <p><b>Error</b> The database cannot be accessed.</p> <p><b>Stopped</b> The database isn't running.</p> <p><b>No SQL access</b> The database is running but isn't responding to SQL queries.</p> <p><b>License Expired</b> The database is running but its software license has expired.</p> <p>If there's a license problem, click the database name. The <a href="#">Database Overview</a> offers a link to the license manager.</p> <p><b>Transitioning</b> The database is starting or stopping.</p> <p><b>Running with issues</b> The database is running but has one or more high-severity alerts such as missed backups or an SSL certificate that's expired or about to expire.</p> <p><b>Invalid technical user</b> The database is running, but SAP HANA cockpit is unable to monitor it because the credentials for the user that the cockpit employs to collect health data are incorrect or expired.</p> <p>If the technical user is invalid, click the database name. The <a href="#">Database Overview</a> offers a link to the Cockpit Manager, where you (or an administrator with Cockpit Manager privileges) can update the technical user credentials.</p> <p><b>Running</b> The database is running.</p> <p>Clicking on the status prompts you for the database credentials and then takes you to the <a href="#">Manage Services</a> page.</p>
Usage Type	<p>Indicates what the database is used for. Can be one of: <a href="#">Production</a>, <a href="#">Custom</a>, <a href="#">Test</a>, and <a href="#">Development</a>.</p>
Database	<p>Your database's name and the host it is located on. Clicking on the database name takes you to the <a href="#">Database Overview</a>.</p>
Alerts	<p>High and medium alerts for your database. Clicking on an alert icon takes you to the <a href="#">Alerts</a> page.</p>
Memory	<p>Shows values for <a href="#">Current</a> and <a href="#">Peak</a> memory; the <a href="#">Memory Allocation Limit</a>, and the <a href="#">Threshold</a> for high and medium memory usage alerts. Clicking the memory graph takes you to the <a href="#">Performance Monitor</a> where KPIs for your database's memory usage are displayed.</p>

Column	Description
CPU	Shows values for <i>Current</i> CPU usage, the <i>Threshold</i> for high CPU usage alerts, and the <i>Start Time</i> and <i>End Time</i> of the 12 hour time range that is shown. Clicking the CPU graph takes you to the <i>Performance Monitor</i> where KPIs for your database's CPU usage are displayed.
Disk	Shows the <i>Current</i> percentage of disk usage, the <i>Threshold</i> for high and medium disk usage alerts, and the <i>Severity Level</i> , which can be one of <i>normal</i> , <i>warning</i> , or <i>critical</i> . Clicking the disk graph takes you to the <i>Performance Monitor</i> where KPIs for your database's disk usage are displayed.
Expensive Statements	The number of expensive statements executed by the database. Clicking on the number takes you to the <i>Expensive Statements</i> tab on the <i>Monitor Statements</i> page.
Group	The number of database groups the database belongs to. Click the number to display a list of database groups..
Type/Version	Indicates whether the database is a tenant or system database and displays the SAP HANA version. Clicking the version brings you to the <i>System Information</i> .
Credentials	<p>When you click the link in the <i>Credentials</i> column, you can enter your SAP HANA database user name and password (unless single sign-on is enforced for this database). The cockpit securely encrypts and stores separate database credentials for each cockpit user; the database user name and password you enter can't be used by other cockpit users. See <i>Connect to a Database using Database Credentials</i>. You must be a user with the SYSTEM privilege to manage credentials.</p> <p>To save credentials for SAP Control to use for starting and stopping the database and restoring features, click <i>Manage Credentials</i> and enter the name and password of the database's &lt;sid&gt; adm OS user.</p> <p>If you wish to clear the credentials, click <i>Manage Credentials</i> and select <i>Delete the stored credentials for this database</i>.</p> <p>The cockpit securely encrypts and stores the credentials.</p> <p>You must be a user with the SYSTEM privilege to manage credentials.</p>
SAP Control Credentials	Enter SAP Control logon credentials.
Database Management/SQL Console	<p>If the database is a system database, then you can click <i>Database Management</i> to manage its tenant databases.</p> <p>If the database is a tenant database, then click on <i>SQL Console</i> to open a SQL console in the SAP HANA database explorer.</p>

You can enable the following additional filters by clicking  [Table Personalization](#):

#### Additional Database Directory Columns

Column	Description
Name	The name of the database instance. If you have chosen to use a system-generated name, then the name is comprised of the tenant or system database name along with the system name. For example, if your tenant name is TestDB and your system name is TestSystem, then your instance name is TestDB@TestSystem. If you are registering a system database for TestSystem, then your instance name is SYSTEDB@TestSystem.
Host	The host your database is located on.
System ID	The name of your database system.
Description	Any description that you've added to the database when you register it.
Availability / Performance / Capacity	High and medium alerts according to their corresponding Key Performance Area (KPA).
XSA Version	The XSA version, if installed, and any additional information, such as detailed information about version errors.
System ID@Host	The name of your database system and the host it is located on.
OS Version	The operating system version.
OS Kernel Version	The operating system kernel version.

[Getting to the Database Overview Page](#)

## 6.1.1.1.1 Connect to a Database With SSO or SAP HANA Credentials

Provide the credentials necessary to connect to a specific database using SAP HANA cockpit.

### Context

The cockpit database administrator user may have used the Cockpit Manager configuration tool to enable cockpit to use the database's single sign-on (SSO) user authentication for a particular database (running SAP HANA 2.0 SPS 01 or later). If not, each cockpit user needs to provide the SAP HANA user credentials for their database to connect directly to the database. Each cockpit user should connect with different database user credentials. You can also connect using the `<sid>adm` user if you want the database to be able to access the SAP Control process (which involves starting and stopping the database, and restoring features).

#### → Tip

Unless your administrator has enabled single sign-on, you must connect to the database with a database user that has the CATALOG READ system privilege and the SELECT privilege on `_SYS_STATISTICS`.

#### → Tip

To improve system security, and to more effectively audit system activity, it is strongly recommended to set up a named database user account for each SAP HANA cockpit user in each registered system.

### Procedure

On the *Database Directory* page, in the row displaying the database you want to connect to, choose one of the following:

- (Available for system databases only) Select the link in the *SAP Control Credentials* column, and enter the name and password of the database's `<sid>adm` user.
- Select the link in the *Credentials* column. The wording on the link and in the subsequent dialog depends on how the cockpit database administrator user has configured this database in the Cockpit Manager:

Database Configuration	Credentials Column displays...	Action
SSO has been enforced	<i>SSO Enforced</i>	Connect to the database through SSO. You don't need to enter database credentials.
SSO has been allowed	<i>SSO Enabled</i> , or the most recently used database user name, with a link to <i>Choose Authentication</i>	In the <i>Choose Authentication</i> dialog, you can choose to connect to the database through SSO or enter a different database user name and password.

Database Configuration	Credentials Column displays...	Action
SSO hasn't been allowed and you haven't previously connected to the database	The <a href="#">Enter Credentials</a> link	In the <a href="#">Enter Credentials</a> dialog, enter a database user name and password. The cockpit securely stores and encrypts the credentials for next time.
SSO hasn't been allowed but you've previously connected to the database	The most recently used database user name, with a link to <a href="#">Manage Credentials</a>	In the <a href="#">Manage Credentials</a> dialog, you can choose to enter a database user name and password, or simply clear the previously used database credentials.

The cockpit encrypts and stores the credentials, and allows you to connect to the database.

## 6.1.1.2 Configurations and Configuration Templates

Compare the configuration parameters for managed databases or use a configuration template to capture a set of parameter values and apply them to other databases, systems, or hosts.

## Related Information

[Taking a Snapshot of a Database's Configuration \[page 178\]](#)

[Comparing Database Configurations \[page 178\]](#)

[Applying a Configuration Template \[page 180\]](#)

[Creating a Configuration Template \[page 179\]](#)

[Modifying a Configuration Template \[page 182\]](#)

[Deleting a Configuration Template \[page 182\]](#)

## 6.1.1.2.1 Taking a Snapshot of a Database's Configuration

Save a configuration snapshot: a timestamped copy of a managed database's full set of configuration parameters.

### Prerequisites

- Register the database whose configuration you want to capture.

### Context

Snapshots let you capture an accurate record of each database's configuration, track configuration changes, and provide context to the historical data SAP HANA cockpit collects.

### Procedure

1. On your database's *Database Overview* page, click the *Manage system configuration* link on the *Database Administration* card.
2. Click *Take Snapshot*.
3. (Optional) Enter a description for the snapshot. The cockpit automatically associates the snapshot with its database.
4. To see previous snapshots, click the *Snapshots* tab.

The cockpit lists any previous snapshots of this database's configuration.

5. (Optional) To delete a snapshot, select it in the snapshots list and click  *Delete Snapshot*.

## 6.1.1.2.2 Comparing Database Configurations

Compare the current configurations of two databases, compare two snapshots, or compare a current database configuration to a snapshot.

### Prerequisites

- Add the databases whose configuration you want to compare.
- Ensure that the database or databases whose configurations you want to compare support configuration management. SAP HANA databases support configuration management in version SAP HANA 1.0 SPS 12 and later.

## Context

To run a comparison, you select a source and a target to compare.

- When you compare two current configurations, the source and target databases must be of the same type (two SAP HANA databases, for example) and must be running the same software version.
- When you compare a current configuration to a snapshot, they must belong to the same database. That is, you can't compare a current configuration to a snapshot of another database.
- When you compare two snapshots, they must belong to the same databases. That is, you can't compare a snapshot of one database to a snapshot of another database.

## Procedure

1. On your database's *Database Overview* page, click the *Manage database configuration* link on the *Database Administration* card.
2. Click *Compare*.
3. Choose a *Source*, choose the type of a target to compare it to (a *Snapshot* or a *Tenant Database*), and choose the *Target*.

Snapshots are listed by timestamp. Hover your mouse over the timestamp in the list to see that snapshot's description (if it has one).

4. (Optional) To display in the results only parameters whose values are different in the source and the target, select the *Show differences only* checkbox.

The cockpit filters out of the results those parameters whose values are the same in the source and the target. If there are no differences between the source and the target in the current configuration file, the cockpit displays `No differences found` in the parameter table.

5. To compare two snapshots:
  - a. With the database selected in the left pane, click the *Snapshots* tab in the middle of the screen.
  - b. Select the source snapshot from the list.
  - c. Click *Compare*.
  - d. On the *Database Configuration* screen, select the target snapshot from the *Target* dropdown list.

Snapshots are shown by timestamp. Hover your mouse over the timestamp in the list to see that snapshot's description (if it has one).

### 6.1.1.2.3 Creating a Configuration Template

Set up a configuration template you can use to set parameter values on selected databases.

## Prerequisites

You have the `Cockpit Template Administrator` role.

## Context

Every configuration template has a layer: database, host, or system. When you apply a database-layer template, it affects only the database you select. When you apply a host-layer template, it affects all the databases on that host, and when you apply a system-layer template, it affects all the associated tenant databases.

Templates are created by setting the configuration parameters on one of your databases, then using that database to create the template.

## Procedure

1. On the SAP HANA Cockpit *Home* page, click *Configuration Templates*.
2. Click *Create Template*.
3. Enter a name for your new template and a description. The description is optional.
4. Select the layer at which you want to create the template: database, host, or system.
5. Select the database, host, or system whose parameters serve as the model for the template. (You can add, remove, and reset the parameters later.)
6. Do one of:
  - Click the box at the top of the list to select all the parameters.
  - Click boxes to select one or more parameters individually.
7. Click *Review*.
8. Check the template and use the *Edit* links to correct it as needed.
9. Click *Create Template*.
10. (Optional) You can create a template from the *System Configuration* page of your cockpit database, but your template can only be created based on the host, system, or database that you're currently connected to. The steps are similar to the previous steps.

### 6.1.1.2.4 Applying a Configuration Template

Use a configuration template to set parameter values for databases, systems, or hosts.

## Prerequisites

- You have the system privilege INIFILE ADMIN on the database to which you're applying a configuration template.
- You have permission to set configuration parameters on the target systems.

## Context

Every configuration template has a layer: database, system, or host. When you apply a database-layer template, it affects only the database you select. When you apply a system-layer template, it affects all the associated tenant databases, and when you apply a host-layer template, it affects all the databases on that host.

## Procedure

1. On your database's [Database Overview](#) page, click the [Manage database configuration](#) link on the [Database Administration](#) card.
2. Click [Configuration Templates](#).
3. Select a configuration template from the list.  
Select the template's row in the list (not its radio button) to display its parameters and their values.
4. Click [Apply to Databases](#).
5. (Optional) In the [Select Databases](#) window, enter a full or partial database or host name in the Search field to filter the list of databases.
6. Do one of:
  - Click the [Database](#). A user with the Cockpit Template Administrator role has created at least one box at the top of the list to select all the database.
  - Click the boxes to select one or more databases individually.

### Note

The template application fails if you select a database for which you lack either the privileges needed to change the configuration or valid credentials. You can enter credentials in the [Database Directory](#).

7. Click [Apply Template](#).

## Results

A pop-up tells you whether the template was applied successfully and to how many databases it was applied.

## Related Information

[Creating a Configuration Template \[page 179\]](#)

## 6.1.1.2.5 Modifying a Configuration Template

Rename a configuration template, change its description, add or remove parameters, or change parameter values.

### Prerequisites

You have the `Cockpit Template Administrator` role.

### Procedure

1. On the SAP HANA Cockpit *Home* page, click *Configuration Templates*.
2. Select the row (not the radio button) of the template you want to modify.
3. To change the template's name or description, click *Rename* and enter the changes.
4. To change a parameter's value, click its *Edit Specific Value* link, then:
  - Enter a new value and click *Save*, or
  - Click *Assign Default* and click *Save*, or
  - Click *Cancel*.
5. To remove a parameter from the template, click its  (*Delete Parameter*) icon.
6. To add a parameter, click *Include More Parameters* and select from the list.

The parameters shown are parameters of the same layer as the one specified in the template and are from the database that was originally used to create the template.

## 6.1.1.2.6 Deleting a Configuration Template

Delete a configuration template from SAP HANA cockpit.

### Prerequisites

You have the `Cockpit Template Administrator` role.

### Context

## Procedure

1. On the SAP HANA Cockpit [Home](#) page, click [Configuration Templates](#).
2. Select the row (not the radio button) of the template you want to delete.
3. Click [Delete](#) and confirm that you want to delete the template.

### 6.1.1.3 SAP EarlyWatch Alert Service

Cockpit users with Support Hub user credentials and the required authorizations can configure [SAP EarlyWatch Alert](#) (EWA) in the Cockpit Manager to use the Solution Finder for SAP EarlyWatch Alert and the Alerts card inside SAP HANA cockpit.

The EWA functionality inside the SAP HANA cockpit collects diagnostic information from your cockpit system and sends it to SAP; SAP then sends back alerts and recommendations for the connected HANA databases in your cockpit system.

The Solution Finder for SAP EarlyWatch Alert offers a full text search of all SAP EarlyWatch Alert reports for any affected system. The search results display related alerts (sorted by severity), recommendations by SAP, and additional information. Alerts and recommendations sent back by SAP can also be viewed by all SAP HANA cockpit users from the [Alerts](#) card of your cockpit database.

#### 6.1.1.3.1 Specifying Authorization for the Technical User

In order for the SAP HANA cockpit to collect and send information to the SAP EarlyWatch Alert service, each database registered through the cockpit requires a technical user with specific privileges.

### Prerequisites

You must have the USER\_ADMIN system privilege.

### Context

SAP recommends that you set up a dedicated user account for each technical user. This user account shouldn't be used by people, but rather allocated for the purpose of connecting the database and the cockpit.

Set up SAP EarlyWatch Alert service for a specific HANA database in your SAP HANA cockpit. Set up the service by granting the following authorizations to the technical user of that database.

## Procedure

1. For each of the SAP HANA database you want to register through the cockpit, create a technical user account or modify the existing user account that the cockpit uses to collect monitoring data.

### i Note

Use SQL to create the technical user required to register a database through the SAP HANA cockpit and grant the minimum necessary authorizations:

```
CREATE USER <username> PASSWORD <password> NO FORCE_FIRST_PASSWORD_CHANGE
VALID UNTIL FOREVER;
GRANT CATALOG READ to <username>;
GRANT SELECT on SCHEMA _SYS_STATISTICS to <username>
```

2. For the technical user on each registered database for which the cockpit collects data for the SAP EarlyWatch Alert service, assign the SELECT object privilege on the following views:
  - change\_entries
  - package\_catalog
  - changes
  - active\_object
  - inactive\_object
3. Ensure that the technical user has the following:
  - Role: PUBLIC to access the Monitoring views.
  - Role: MONITORING to access the Statistics server views.

## 6.1.1.3.2 Managing SAP EarlyWatch Alert Global and Database-Specific Settings

In order for the SAP HANA cockpit to collect and receive data for the SAP EarlyWatch Alert service, you need to enter credentials for a valid global or specific S-User and configure transmission and collection settings.

### Context

You can set a global S-User, whose credentials are used for all the databases in your cockpit. However, if you have multiple S-Users and want to use a specific S-User for a specific cockpit database, you can override the global S-User settings for that database. Overriding the global S-User can be helpful, for example, if you have a specific S-User attached to a specific customer and want to use those credentials for that customer's cockpit database.

### i Note

SAP recommends setting the SAP EarlyWatch Alert service per cockpit database, rather than globally, specifically if your cockpit contains both development and production systems. The SAP EarlyWatch Alert service intended only for production systems.

## Procedure

1. Connect to the Cockpit Manager and sign in as a cockpit administrator.  
Access the Cockpit Manager by following the [Manage Cockpit](#) link in the cockpit.
2. Choose one of the following options:

Option	Action
Manage global EWA settings	<ol style="list-style-type: none"><li>1. Select ► <a href="#">Cockpit Settings</a> ► <a href="#">SAP EarlyWatch Alert</a> </li><li>2. Click <a href="#">Edit</a>.</li><li>3. Enter the S-User credentials that you want to use for all databases in the cockpit. For instructions on how to create an S-User, see <i>SAP Note 2174416: Creation and activation of users in the Technical Users application - SAP ONE Support Launchpad</i>.</li><li>4. Select the check box to receive SAP EarlyWatch Alerts and send any collected data to the SAP EarlyWatch Alert service.<div data-bbox="874 1037 1398 1388" style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px;"><p><b>i Note</b></p><p>If this SAP HANA database is connected to an SAP Solution Manager or any other ABAP stack, you can receive an SAP EarlyWatch Alert even if you deselect the check box. However, if you deselect the check box labeled <a href="#">Gather data to send to SAP EarlyWatch Alert service for analysis</a> and the database doesn't have a connection with an SAP Solution Manager or other ABAP stack, you don't receive an SAP EarlyWatch Alert.</p></div></li><li>5. Specify time of day at which data is transmitted daily from the cockpit to the SAP EarlyWatch Alert service.</li><li>6. Specify the day of the week and time at which data is collected from the registered database in the cockpit, and sent to the SAP EarlyWatch Alert service.</li><li>7. (Optional) Change the URL location where data is stored for transmission by both the SAP HANA cockpit and the SAP EarlyWatch Alert service. SAP recommends that you keep the default URL unless otherwise advised by an SAP representative.</li><li>8. (Optional) Add information for one or more SAP router instances. If more than one SAProuter instance is specified, multiple hops are used to transmit the data from the cockpit to SAP.</li><li>9. Click <a href="#">Save</a>.</li></ol>

Option	Action
Manage database-specific settings	<ol style="list-style-type: none"> <li>1. In the <i>Database Directory</i>, click <i>Manage Databases</i>.</li> <li>2. Select the database that you want to set a database-specific S-User for and click <i>Edit</i>.</li> <li>3. Enter your technical user credentials and click <i>Grant SAP EarlyWatch Alert permission</i>.</li> <li>4. Scroll down to the <i>EarlyWatch Alert Support Hub User</i> section.</li> <li>5. Enter the credentials of the S-User that you want to use for this specific database.</li> </ol> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin: 10px 0;"> <p><b>i Note</b></p> <p>Setting a database-specific S-User overrides the global S-User settings.</p> </div> <ol style="list-style-type: none"> <li>6. (Optional) Override the global EarlyWatch Alert transmission and collection settings.</li> </ol>

## Related Information

[SAP Note 2174416](#) 

### 6.1.1.3.3 Viewing SAP EarlyWatch Alerts

Cockpit users with Support Hub user credentials and the required authorizations can select the *SAP EarlyWatch Alert* tile to launch the Solution Finder for SAP EarlyWatch Alert in the SAP ONE Support Launchpad. Cockpit users without Support Hub user credentials can also view alerts and recommendations generated by SAP EarlyWatch Alert if it has been configured for their cockpit database using the *Alerts* card in the SAP HANA cockpit.

## Prerequisites

SAP EarlyWatch Alert (EWA) has been configured for your cockpit database.

## Context

The Solution Finder for SAP EarlyWatch Alert offers a full text search of all SAP EarlyWatch Alert reports for any affected system. The search results display related alerts (sorted by severity), recommendations by SAP and

additional information. You can select specific systems to see the complete corresponding paragraph from the relevant SAP EarlyWatch Alert report.

## Procedure

1. Log on to the SAP HANA cockpit.
2. If you have Support Hub user credentials, you can view alerts, critical info, and recommendations generated by the SAP EarlyWatch Alert for all configured cockpit databases. View the information by selecting the [SAP EarlyWatch Alert](#) tile on the cockpit home page.
3. If you don't have Support Hub user credentials, you can view alerts and critical info generated by the SAP EarlyWatch Alert service for your cockpit database by clicking the [Alerts](#) card on your database's [Database Overview](#).

If a displayed alert is an EWA alert, the [Source](#) entry is [SAP EarlyWatch Alert service](#). Only a selected subset of EWA alerts shown in the Solution Finder are forwarded to the SAP HANA cockpit.

## 6.1.2 Monitoring Multiple Systems in SAP HANA Studio

Using the [System Monitor](#) view of the SAP HANA studio, you can monitor the status of all registered systems.

### Related Information

[System Monitor \[page 187\]](#)

[Options for Customizing the System Monitor \[page 189\]](#)

### 6.1.2.1 System Monitor

The [System Monitor](#) provides you with an overview of all your SAP HANA systems at a glance, including operational status, resource usage, and current alerts. From the [System Monitor](#), you can drill down into the details of an individual system in the Administration editor.

#### i Note

To see all information for all systems, you must have either the MONITORING role or the system privilege CATALOG READ and the object privilege SELECT on the schema \_SYS\_STATISTICS.

System ID	Operational State	Alerts	Data Disk (GB)	Log Disk (GB)	Trace Disk (GB)	Database Resident Memory (G...	System Resident Memory (G...	Used Memory (GB)	CPU (%)

The System Monitor

## Related Information

[Systems View \[page 131\]](#)

[Options for Customizing the System Monitor \[page 189\]](#)

## Information Available in the System Monitor

The following information is available in the *System Monitor*.

Column	Description
System ID	ID assigned to system when added
Operational State	Overall system status
Alerts	The system issues alerts when resource usage and statistical thresholds are violated. These alerts are categorized as low, medium, or high priority. There are also information alerts. The number of alerts and their status is shown here.
Data Disk (GB)	Size of the data volume on disk
Log Disk (GB)	Size of the log volume on disk
Trace Disk (GB)	Size of trace files on disk
Database Resident Memory (GB)	Size of resident memory at operating system level owing to SAP HANA database processes
System Resident Memory (GB)	Total size of resident memory in the operating system
Used Memory (GB)	Amount of physical memory used by the SAP HANA database
CPU (%)	Percentage of CPU used by the SAP HANA database
Hostname	Name of the server hosting the SAP HANA database
Instance Number	Instance number is the administrative unit that comprises the server software components
System Data Disk (GB)	Total disk space occupied on disk(s) containing data
System Log Disk (GB)	Total disk space occupied on disk(s) containing log files
System Trace Disk (GB)	Total disk space occupied on disk(s) containing trace files
System Physical Memory (GB)	Total amount of physical memory used

Column	Description
System CPU (%)	Overall CPU usage
Distributed	Indicates whether the system is running on a single host or it is a distributed system running on more than one host
Start Time First	Time that the first service started  This value is updated when system is restarted for any reason.
Start Time Latest	Time that the last service was started, if, for example, one of the services was re-started individually
Version	Software version number of the SAP HANA studio
Platform	Operating system on which the SAP HANA studio is running
Number of Crash Dump Files	The number of crash dump files in the trace directory of the system

## 6.1.2.2 Options for Customizing the System Monitor

The toolbar of the *System Monitor* provides options for customizing the view.

Toolbar Option	Description
 (Filter)	Allows you to select a sub-set of systems to display in the <i>System Monitor</i> , if for example you have a very large number of systems
 (Properties)	Allows you to configure properties of the <i>System Monitor</i> , such as the refresh interval and whether or not you want it to open automatically when you open the SAP HANA studio
 (Configure Viewer)	Allows you to configure which information is displayed, that is, which columns are visible

## 6.2 Starting and Stopping SAP HANA Systems

As the operating system administrator (<sid>adm user), you can stop, start, and restart an SAP HANA system using the SAP HANA cockpit or the SAP HANA studio. You can also stop and start a system from the command line using the SAPControl program.

### Related Information

[Starting and Stopping Distributed SAP HANA Systems Using SAPControl \[page 1654\]](#)

## 6.2.1 Starting and Stopping Systems in SAP HANA Cockpit

You can use the SAP HANA cockpit to stop or start an SAP HANA system.

### Related Information

[Open the SAP HANA Cockpit \[page 45\]](#)

### 6.2.1.1 Start a Database

Use SAP HANA cockpit to start a database.

#### Prerequisites

- You are connected to the SYSTEMDB.
- You have the credentials of the operating system user (<sid>adm user) that was created when the system was installed.

#### Procedure

On the [Database Directory](#), click the [Start System](#) button at the top of the page.

#### Results

The database services start one by one, including those of any tenant databases. For details on starting an individual tenant database, see [Start a Tenant Database](#).

When all services have started, the system has the status [Running](#).

#### → Tip

To analyze any problems that may occur during startup, you can access the system's diagnosis files from the homepage of the SAP HANA cockpit.

If you're unable to start a database that was registered while it was unreachable, check the information entered during registration. The cockpit can't check the registration information for an unreachable database, and thus can't tell the difference between a host or database that's unreachable and one that doesn't exist. In particular, make sure these are correct:

- Host name
- Instance number
- Technical user name and password
- SAP HANA system ID

If you find an error, unregister the database and register it again.

## Related Information

[Register a Database \[page 73\]](#)

[Unregister a Database \[page 80\]](#)

## 6.2.1.2 Stop a Database

Use SAP HANA cockpit to stop a database.

### Prerequisites

- You are connected to the SYSTEMDB.
- You have the credentials of the operating system user (<sid>adm user) that was created when the system was installed.

### Procedure

1. On the *Database Directory*, click the *Stop System* button at the top of the page.
2. Specify how you want to stop the system:

Option	Description
<b>Softly</b>	The system is stopped after all running statements have finished. If the system doesn't stop before the specified timeout, it is stopped immediately. The default timeout is 5 minutes.
<b>Immediately</b>	The system is stopped immediately. Open transactions are aborted and rolled back.

## Results

The database services stop one by one. The services of tenant databases are stopped. For more information about how to stop an individual tenant database, see *Stop a Tenant Database* in the *SAP HANA Administration Guide*.

When all services have stopped, the system has the status *Stopped*.

### → Tip

To analyze problems even when the system is stopped, you can access the system's diagnosis files from the homepage of the SAP HANA cockpit.

## Related Information

[Restart Sequence \[page 199\]](#)

## 6.2.2.1 Start a System

Use the SAP HANA studio to start an SAP HANA system. All tenant databases will be started except those that were individually stopped.

### Prerequisites

You have the credentials of the operating system user (<sid>adm user) that was created when the system was installed.

### Procedure

1. In the *Systems* view, right-click the system you want to start and choose ► *Configuration and Monitoring* ► *Start System...* ▾

#### i Note

Execute the start command from the system database. The *Start System...* command is not available from tenant databases. For more information about how to stop an individual tenant database, see *Stop and Start a Tenant Database*.

2. Enter the user name and password of the operating system administrator that was created when the system was installed (that is, <sid>adm user).

### Results

- The Administration editor opens in diagnosis mode and the database services start one by one. When all services have started, the system appears as operational (  ) in the *Systems* view.
- All tenant databases are started. However, if a tenant database was previously stopped individually, it is not started with the system. For more information about how to stop an individual tenant database, see *Stop and Start a Tenant Database*.

#### → Tip

Refresh the *Systems* view to update the status of other instances of the system or tenant databases registered in the SAP HANA studio.

For more information about starting a distributed SAP HANA system using the `sapcontrol` program, see *Starting and Stopping a Distributed SAP HANA System Using sapcontrol*.

## Related Information

## 6.2.2.2 Stop a System

In certain situations, you may have to stop your system, for example after changing certain system parameters. Use the SAP HANA studio to stop an SAP HANA system.

### Prerequisites

You have the credentials of the operating system user (<sid>adm user) that was created when the system was installed.

### Procedure

1. In the *Systems* view, right-click the system you want to stop and choose ► *Configuration and Monitoring* ► *Stop System...* ►

#### i Note

Execute the stop command from the system database. The *Stop System...* command is not available from tenant databases. For more information about how to stop an individual tenant database, see *Stop and Start a Tenant Database*.

2. Specify how you want to stop the system:

Option	Description
<b>Soft</b>	The system is stopped after all running statements have finished or the specified timeout is reached.
<b>Hard</b>	The system is stopped immediately. Open transactions are aborted and rolled back.

3. Optional: Specify a stop wait timeout (date and time).  
If the system does not shut down before the specified timeout, it is shut down forcefully.
4. Enter the user name and password of the operating system user that was created when the system was installed (that is, <sid>adm user).

## Results

- The Administration editor opens in diagnosis mode and the database services stop one by one. When all services have stopped, the system appears as non-operational (  ) in the *Systems* view.
- All tenant databases are stopped. For more information about how to stop an individual tenant database, see *Stop and Start a Tenant Database*.

### → Tip

Refresh the *Systems* view to update the status of other instances of the system or tenant databases registered in the SAP HANA studio.

For more information about stopping a distributed SAP HANA system using the `sapcontrol` program, see *Starting and Stopping a Distributed SAP HANA System with sapcontrol*.

## Related Information

## 6.2.2.3 Restart a System

In certain situations, you may have to restart the system, for example, after a power failure. Use the SAP HANA studio to restart an SAP HANA system.

## Prerequisites

You have the credentials of the operating system user (<sid>adm user) that was created when the system was installed.

## Procedure

1. In the *Systems* view, right-click the system you want to start and choose ► *Configuration and Monitoring* ► *Restart System...* ►

### i Note

Execute the restart command from the system database. The *Restart System...* command is not available from tenant databases. For more information about how to stop a tenant database, see *Stop and Start a Tenant Database*.

2. Specify how you want to stop the system:

Option	Description
<b>Soft</b>	The system is stopped after all running statements have finished or the specified timeout is reached.
<b>Hard</b>	The system is stopped immediately. Open transactions are aborted and rolled back.

3. Optional: Specify a stop wait timeout (date and time).
4. Enter the user name and password of the operating system user that was created when the system was installed (that is, <sid>adm user).

## Results

- The Administration editor opens in diagnosis mode. The database services first stop one by one and then restart one by one. The icon displayed for the system in the *Systems* view changes as the status of the services changes.
- All tenant databases are stopped and restarted. However, if a tenant database was previously stopped individually, it is not restarted with the system. For more information about how to stop an individual tenant database, see *Stop and Start a Tenant Database*.

### → Tip

Refresh the *Systems* view to update the status of other instances of the system or tenant databases registered in the SAP HANA studio.

## Related Information

[Restart Sequence \[page 199\]](#)

[Operating System User sidadm \[page 822\]](#)

[Start a Tenant Database \[page 228\]](#)

## 6.2.2.4 Stop and Start a Database Service

You can stop and start individual database services (`nameserver`, `indexserver`, `xsengine` and so on) running on an SAP HANA host or hosts.

### Prerequisites

You have the system privilege `SERVICE ADMIN`.

### Context

You may need to stop and (re)start services in the following situations, for example:

- A host in a distributed system failed and a standby host took over. However, the services of the failed host remain inactive even after the host is reachable again. In this case, you need to restart the services manually.
- After an update of SAP HANA extended application services (SAP HANA XS), the `xsengine` service needs to be restarted.

#### i Note

The SAP HANA database provides several features in support of high availability, one of which is service auto-restart. In the event of a failure or an intentional intervention by an administrator that disables one of the SAP HANA services, the SAP HANA service auto-restart function automatically detects the failure and restarts the stopped service process.

### Procedure

1. In the Administration editor open the **► Landscape ► Services ►** tab.
2. Right-click the service and choose the required option:

Option	Description
Stop...	The service is stopped normally and then typically restarted.
Kill...	The service is stopped immediately and then typically restarted  To have the system create a crash dump file, select the option <i>Create Core File</i> . You can access the generated crash dump file on the <i>Diagnosis Files</i> tab.
Reconfigure Service...	The service is reconfigured. This means that any changes made to parameters in the system's configuration files are applied.
Start Missing Services...	Any inactive services are started.

## Related Information

[Monitoring Status and Resource Usage of System Components \[page 389\]](#)

[High Availability for SAP HANA \[page 1222\]](#)

[View Diagnosis Files in SAP HANA Studio \[page 762\]](#)

### 6.2.2.5 Monitoring SAP HANA Systems During Stop and Start

You can access the diagnosis files of a system that is starting up or has stopped by opening the Administration editor in the diagnosis mode.

The SAP HANA studio normally collects information about the system using SQL. However, when the system has not yet started, no SQL connection is available. Therefore, while the system is starting up or is stopped, the SAP HANA studio collects information about the database using the connection of the SAP start service (`sapstartsrv`). If you have the credentials of the operating system administrator (user `<sid>adm`), you can view this information in the Administration editor in diagnosis mode.

In this way, you can analyze any problems that may occur during startup or while the system is stopped. You can also read diagnosis files even when the system is stopped.

The Administration editor opens automatically in diagnosis mode in the following situations:

- When you open the Administration editor for a system without an SQL connection
- When you initiate the start, stop, or restart of a system

You can manually open a system in diagnosis mode by choosing the  (*Open Diagnosis Mode*) button from the drop-down menu of the  (*Administration*) button in the *Systems* view.

## Related Information

[Operating System User sidadm \[page 822\]](#)

[Monitoring Overall System Status and Resource Usage \[page 387\]](#)

[Troubleshooting an Inaccessible or Unresponsive SAP HANA System \[page 787\]](#)

### 6.2.3 Starting and Stopping Systems with SAPControl

You can use the SAPControl program to start or stop SAP HANA system from the command line.

#### i Note

You must be logged on to the SAP system host as user `<sid>adm` or as a user with root permissions.

Action	Command
Start the system	<code>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function StartSystem HDB</code>
Stop the system	<code>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function StopSystem HDB</code>
Query current status of all hosts in the system	<code>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function GetSystemInstanceList</code>

## 6.2.4 Restart Sequence

The SAP HANA system restart sequence restores the system to a fully operational state quickly.

When you restart an SAP HANA system, the following activities are executed by the restart agent of the persistence layer.

1. The data volume of each service is accessed in order to read and load the restart record.
2. The list of open transactions is read into memory.
3. Row tables are loaded into memory.
4. Open transactions are processed using the redo log:
  1. Write transactions that were open when the database was stopped are rolled back.
  2. Changes of committed transactions that were not written to the data area are rolled forward.

The first column tables start being reloaded into memory as they are accessed for roll forward.

### i Note

Since a regular or "soft" shutdown writes a savepoint, there are no replay log entries to be processed in this case.

After this step, the database is technically available and logon is possible.

5. Aborted transactions are determined and rolled back.
6. A savepoint is performed with the restored consistent state of the database.
7. Column tables that are marked for preload and their attributes are asynchronously loaded in the background (if they have not already been loaded as part of log replay).  
The preload parameter is configured in the metadata of the table. This feature is useful for example to make certain tables and columns used by important business processes available more quickly.
8. Column tables that were loaded before restart and their attributes start reloading asynchronously in the background (if they have not already been loaded as part of log replay or because they are marked for preload).  
During normal operation, the system tracks the tables currently in use. This list is used as basis for reloading tables after a restart.

Reloading column tables as described in steps 7 and 8 restores the database to a fully operational state more quickly. However, it does create performance overhead and may not be necessary in non-production systems. You can deactivate the reload feature in the `indexserver.ini` file by setting the `reload_tables` parameter in the `sql` section to **false**. In addition, you can configure the number of tables whose attributes are loaded in parallel using the `tables_preloaded_in_parallel` parameter in the `parallel` section of `indexserver.ini`. This parameter also determines the number of tables that are preloaded in parallel.

## Further Information

An SAP Community blog *SAP HANA Startup* gives further details of the restart sequence with example trace file entries.

## Related Information

[SAP Community Blog: SAP HANA Startup](#) 

## 6.3 Managing Tenant Databases

As the administrator of a tenant database system, you are responsible for creating and configuring new tenant databases, subsequently monitoring the availability and performance of databases, as well as performing certain database administration tasks.

### i Note

Administration of tenant databases is possible using the SAP HANA cockpit. However, command-line tools are required for some tasks.

### i Note

If you have SAP HANA options installed, review the section about tenant databases in the administration guide of the corresponding option for additional information before proceeding. Be aware that you need additional licenses for SAP HANA options and capabilities. For more information, see *Important Disclaimer for Features in SAP HANA Platform, Options and Capabilities*.

## Managing Audit Policies

You can change or delete audit policies for one or more tenant databases.

For more information, see *Manage Audit Policies for Tenant Databases in Security Administration and User Management*.

## Related Information

[Important Disclaimer for Features in SAP HANA \[page 2139\]](#)  
[Manage Audit Policies for Tenant Databases \[page 958\]](#)

## 6.3.1 Creating and Configuring Tenant Databases

You create tenant databases after installation if no initial tenant was created, after conversion from a single-container system to a multiple-container system, or anytime a new database is needed.

As a system administrator, you create tenant databases from the system database. You can then configure the new databases as required:

- Increase the database isolation level
- Disable certain features that are not required in tenant databases (for example, backup operations). Disabled features in tenant databases can still be accessed through the system database.
- Enable and configure cross-database access if read-only queries between tenant databases is required
- Edit the configuration change blacklist so that critical system properties cannot be changed by tenant database administrators
- Configure the SAP Web Dispatcher if tenant databases will be accessed by HTTP clients via the SAP HANA XS classic server

### i Note

Administration of tenant databases is possible using the SAP HANA cockpit. However, command-line tools are required for some tasks.

## Related Information

[Administration of Tenant Databases \[page 19\]](#)

### 6.3.1.1 Converting an SAP HANA System to Support Tenant Databases

You can convert an SAP HANA system to support tenant databases using the SAP HANA database lifecycle manager (HDBLCM) resident program. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

If your system was installed in single-container mode, you can still implement tenant databases by converting the system to a tenant database system. During the conversion process, the system database and one tenant database are created. The tenant database contains all the data of the original system, including users, system configuration, connection properties (port configuration), and system license. However, it does **not** contain the backup history.

After conversion, you can create and configure further tenant databases as needed.

#### **i Note**

After conversion, a port offset value of 100 is used to reserve ports for system replication communication. A port offset that you defined before the conversion is not changed.

## **Related Information**

[Convert to Tenant Databases Using the Graphical User Interface \[page 202\]](#)

[Convert to Tenant Databases Using the Command-Line Interface \[page 204\]](#)

[Convert to Tenant Databases Using the Web User Interface \[page 206\]](#)

### **6.3.1.1.1 Convert to Tenant Databases Using the Graphical User Interface**

You can convert an SAP HANA system to support tenant databases using the SAP HANA database lifecycle manager (HDBLCM) resident program in the graphical user interface. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

#### **Prerequisites**

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.

#### **Procedure**

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblc
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

### i Note

To activate the local secure (LSS) store during installation, run `hdblcmgui` with the parameter `secure_store=localsecurestore`.

3. Select *Convert to Tenant Databases* from the activity options. Then select *Next*.
4. Provide the password of the `<sid>adm` user and the `SYSTEM` user of `SYSTEMDB`, then select *Next*.
5. Review the summary, and select *Run* to finalize the configuration.

## Results

Your SAP HANA system is a tenant database system with one system database and one tenant database, both of which are running. You can verify this by adding both databases to SAP HANA cockpit and querying the public view `M_DATABASES` from the system database. The result will look like this:

DATABASE_NAME	DESCRIPTION	ACTIVE_STATUS
SYSTEMDB	SystemDB-<SID>-<INSTANCE>	YES
<SID>	SingleDB-<SID>-<INSTANCE>	YES

Note the following about the tenant database:

- It contains all the data (including users, configuration, and connection properties) of the original system (but not the original backup history).
- Configuration files that are tenant-specific (e.g. `indexserver.ini`, `xsengine.ini`, etc.) are now stored at the following location: `/usr/sap/<SID>/SYS/global/hdb/custom/config/DB_<database_name>`.
- Its trace files are now stored at the following location: `/usr/sap/<SID>/HDB<instance>/<host>/trace/DB_<database_name>`.

### i Note

Any trace files that were in the trace directory before the system was converted are not moved.

## Next Steps

- Create and configure any additionally required tenant databases. For more information, see *Create a Tenant Database*.

### i Note

If you configured the properties of the index server, script server, or xsengine server in your original system, these settings initially apply to **all** new tenant databases. You must explicitly configure tenant database if required. For more information, see *System Properties in Tenant Database Systems* in the *SAP HANA Administration Guide*.

- If HTTP access via the SAP HANA XS classic server is required, update the configuration of the Web Dispatcher. For more information, see *Configure HTTP Access to Tenant Databases* in the *SAP HANA Administration Guide*.

### 6.3.1.1.2 Convert to Tenant Databases Using the Command-Line Interface

You can convert an SAP HANA system to support tenant databases using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblc
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcm --action=convert_to_multidb
```

3. Provide the password of the `<sid>adm` user and `SYSTEM` user of `SYSTEMDB` user.
4. Review the summary, and select `y` to finalize the configuration.

## Results

Your SAP HANA system is a tenant database system with one system database and one tenant database, both of which are running. You can verify this by adding both databases to SAP HANA cockpit and querying the public view `M_DATABASES` from the system database. The result will look like this:

DATABASE_NAME	DESCRIPTION	ACTIVE_STATUS
SYSTEMDB	SystemDB-<SID>-<INSTANCE>	YES
<SID>	SingleDB-<SID>-<INSTANCE>	YES

Note the following about the tenant database:

- It contains all the data (including users, configuration, and connection properties) of the original system (but not the original backup history).
- Configuration files that are tenant-specific (e.g. `indexserver.ini`, `xsengine.ini`, etc.) are now stored at the following location: `/usr/sap/<SID>/SYS/global/hdb/custom/config/DB_<database_name>`.
- Its trace files are now stored at the following location: `/usr/sap/<SID>/HDB<instance>/<host>/trace/DB_<database_name>`.

### i Note

Any trace files that were in the trace directory before the system was converted are not moved.

## Next Steps

- Create and configure any additionally required tenant databases. For more information, see *Create a Tenant Database*.

### i Note

If you configured the properties of the index server, script server, or xsengine server in your original system, these settings initially apply to **all** new tenant databases. You must explicitly configure tenant database if required. For more information, see *System Properties in Tenant Database Systems* in the *SAP HANA Administration Guide*.

- If HTTP access via the SAP HANA XS classic server is required, update the configuration of the Web Dispatcher. For more information, see *Configure HTTP Access to Tenant Databases* in the *SAP HANA Administration Guide*.

### 6.3.1.1.3 Convert to Tenant Databases Using the Web User Interface

You can convert an SAP HANA system to support tenant databases using the SAP HANA database lifecycle manager Web user interface. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

#### Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing  *Tools*  *Compatibility View Settings* .

- Microsoft Edge
- Mozilla Firefox - Latest version and Extended Support Release
- Google Chrome - Latest version
- SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
- Mac OS - Safari 5.1 or higher

### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

## Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser:  <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

### i Note

The URL is case sensitive. Make sure you enter upper and lower case letters correctly.

<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"> <li>1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code></li> </ol>
-------------------------	---

### i Note

FQDN = fully qualified domain name

2. Drill down on the name of the system from *My Resources* or from a group.
3. The links in *Platform Lifecycle Management* each launch additional functionality, giving you expanded capabilities for managing the resource.

2. Select the *Convert to Tenant Databases* tile.
3. Optional: Modify the following parameters in the *Advanced Parameters Configuration* dialog. To access the *Advanced Parameters Configuration* dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Import Delivery Units In The System Database</b>	Import Delivery Units In The System Database
<b>Do Not Start Instance After Reconfiguration</b>	Do Not Start Instance After Reconfiguration
<b>Do Not Start Tenant Database After Reconfiguration</b>	Do Not Start Tenant Database After Reconfiguration

Option	Description
Timeouts	Sets customized timeouts ( <code>start_instance</code> , <code>stop_instance</code> ).

4. Provide the password of the `<sid>adm` user and `SYSTEM` user of `SYSTEMDB` user, then select *Next*.
5. Review the summary, and select *Run* to finalize the configuration.

## Results

Your SAP HANA system is a tenant database system with one system database and one tenant database, both of which are running. You can verify this by adding both databases to SAP HANA cockpit and querying the public view `M_DATABASES` from the system database. The result will look like this:

DATABASE_NAME	DESCRIPTION	ACTIVE_STATUS
SYSTEMDB	SystemDB-<SID>-<INSTANCE>	YES
<SID>	SingleDB-<SID>-<INSTANCE>	YES

Note the following about the tenant database:

- It contains all the data (including users, configuration, and connection properties) of the original system (but not the original backup history).
- Configuration files that are tenant-specific (e.g. `indexserver.ini`, `xsengine.ini`, etc.) are now stored at the following location: `/usr/sap/<SID>/SYS/global/hdb/custom/config/DB_<database_name>`.
- Its trace files are now stored at the following location: `/usr/sap/<SID>/HDB<instance>/<host>/trace/DB_<database_name>`.

### i Note

Any trace files that were in the trace directory before the system was converted are not moved.

## Next Steps

- Create and configure any additionally required tenant databases. For more information, see *Create a Tenant Database*.

### i Note

If you configured the properties of the index server, script server, or xsengine server in your original system, these settings initially apply to **all** new tenant databases. You must explicitly configure tenant database if required. For more information, see *System Properties in Tenant Database Systems* in the *SAP HANA Administration Guide*.

- If HTTP access via the SAP HANA XS classic server is required, update the configuration of the Web Dispatcher. For more information, see *Configure HTTP Access to Tenant Databases* in the *SAP HANA Administration Guide*.

### 6.3.1.1.4 Parameter Reference: Converting an SAP HANA System to Support Tenant Databases

Parameters can be specified when converting an SAP HANA system to tenant databases in order to customize the configuration task.

The SAP HANA database lifecycle manager convert to multodb action also supports the following parameters:

- `batch`
- `configfile`
- `dump_configfile_template`
- `help`
- `list_systems`
- `read_password_from_stdin`
- `version`

For more information about these parameters, see the *SAP HANA Server Installation and Update Guide*

For a complete list of the parameters, call the help of the convert to multodb task with the following command:

```
./hdblcm --action=convert_to_multodb --help
```

## Related Information

[batch](#)

[configfile](#)

[dump\\_configfile\\_template](#)

[help](#)

[list\\_systems](#)

[read\\_password\\_from\\_stdin](#)

[version](#)

[Specifying Passwords](#)

### 6.3.1.1.4.1 `import_content`

Imports delivery units.

#### Syntax

In the command line, the following syntax is used:

```
--import_content [=off]
```

#### Remarks

The default for this parameter is `--import_content`.

## Related Information

[SAP HANA Content \[page 1126\]](#)

### 6.3.1.1.4.2 `nostart`

Prevents the SAP HANA system from being started.

#### Syntax

In the command line, the following syntax is used:

```
--nostart
```

### 6.3.1.1.4.3 `nostart_tenant_db`

Prevents the SAP HANA tenant databases from being started.

#### Syntax

In the command line, the following syntax is used:

```
--nostart_tenant_db
```

## 6.3.1.1.5 Convert a System Replication Landscape to Support Tenant Databases

An SAP HANA system replication landscape can be converted to support tenant databases in an offline or near-zero downtime approach.

You can convert an SAP HANA single database container system that is part of a system replication configuration to support tenant databases. You have the choice to convert your SAP HANA system after taking all sites offline, or to convert in a near-zero downtime approach to minimize system downtime.

### Offline Conversion

To perform an offline conversion all systems at all sites must first be stopped. Then, starting with the primary site, execute the conversion script. Once the primary site is converted and online again, continue the conversion procedure with the next site, following the replication chain.

### Near-Zero Downtime Conversion

In order to carry out a near-zero downtime conversion, execute the conversion script on the secondary site. Once the conversion of this site is complete, perform a takeover. After stopping all other systems, execute the conversion script on the primary site and reregister the primary system.

### Related Information

[Perform an Offline Conversion \[page 212\]](#)

[Perform a Near-Zero Downtime Conversion \[page 213\]](#)

## 6.3.1.1.5.1 Perform an Offline Conversion

You can perform an offline conversion of an SAP HANA system replication landscape to support tenant databases. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

### Prerequisites

- The statistics server is **not** running as a separate server process (`statisticsserver`), but instead as an embedded service in the master index server. If this is not the case, migrate the statistics server to the embedded statistics service as described in SAP Note 1917938.
- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- You are logged on as the system administrator user `<sid>adm`.

### Procedure

1. Stop all SAP HANA systems on all sites.
2. Run the following command on the master host of the primary system:  

```
<sapmnt>/<SID>/hdb lcm/hdb lcm --action=convert_to_multidb
```

By default, `<sapmnt>` is `/hana/shared`.
3. Specify a new system user password.
4. Wait until the conversion has finished and the system is active again.
5. Create a data backup of the system database.
6. Repeat steps 2 through 4 on all remaining secondary systems, following the replication chain.

### Related Information

[SAP Note 1917938](#) 

[Configuring SAP HANA System Replication \[page 1255\]](#)

## 6.3.1.1.5.2 Perform a Near-Zero Downtime Conversion

You can perform a near-zero downtime conversion of an SAP HANA system replication landscape to support tenant databases. Converting an SAP HANA system to a tenant database system is permanent and cannot be reversed.

### Prerequisites

- The statistics server is **not** running as a separate server process (`statisticsserver`), but instead as an embedded service in the master index server. If this is not the case, migrate the statistics server to the embedded statistics service as described in SAP Note 1917938.
- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- You are logged on as the system administrator user `<sid>adm`.

### Procedure

1. Run the following command on master host of the secondary system:

```
<sapmnt>/<SID>/hdb lcm/hdb lcm --action=convert_to_multidb
```

By default, `<sapmnt>` is `/hana/shared`.

2. Specify a new system user password.
3. Wait until the conversion has finished and all systems are in sync again.
4. Stop all systems except the one you just converted.
5. Perform a takeover by the converted system.
6. Run the following command on master host of the primary system:  

```
<sapmnt>/<SID>/hdb lcm/hdb lcm --action=convert_to_multidb --nostart
```
7. Reregister the original primary system as the new secondary system.

### Related Information

[SAP Note 1917938](#) 

[Configuring SAP HANA System Replication \[page 1255\]](#)

## 6.3.1.2 Increase the System Isolation Level

You can increase the isolation level of an existing system from low (default) to high. With high isolation, the processes of individual tenant databases run under dedicated operating system (OS) users belonging to dedicated (OS) groups and internal communication is secured.

### Prerequisites

- You have root access to the SAP HANA system.
- You're logged on to the system database.
- You have the system privilege `DATABASE ADMIN`.
- Internal SAP HANA communication has been appropriately configured for TLS/SSL. `[communication] ssl` in the `global.ini` file must have the value `false` (default) or `systemPKI`.

#### ⚠ Caution

If you're using a manually configured public key infrastructure (PKI) to secure internal communication between hosts, the property `[communication] ssl` must be `true`. You can switch to system PKI by changing setting the parameter to `systemPKI`.

For more information, see *Secure Internal Communication and Server-Side TLS/SSL Configuration Properties for Internal Communication* in the *SAP HANA Security Guide*.

- If the system is running in an SAP HANA system replication configuration, the system PKI SSFS data file and key file have been copied from the primary system to the same location on the secondary systems:
  - `$DIR_INSTANCE/./global/security/rsecssfs/data/SSFS_<SID>.DAT`
  - `$DIR_INSTANCE/./global/security/rsecssfs/key/SSFS_<SID>.KEY`
- You have granted read permissions to the `sapsys` group by executing `chmod 640 $SECUDIR/sapsrv.pse`.

### Procedure

1. For every tenant database, create a dedicated OS user and group:
  - a. As root user, log on to the server on which the name server of the system database is running.
  - b. Create new groups for every tenant database:

```
groupadd <groupname>
```
  - c. Create new users for every tenant database, specifying `sapsys` as the primary group:

```
useradd -g sapsys <username>
```
  - d. Add every new user to the `sidshm` group and their own group as secondary groups:

```
usermod -G <sid>shm,<usergroup> <username>
```

#### i Note

If the system is distributed across multiple hosts, you must create identical users and groups on every host. Users and groups must have the same names and IDs on all hosts.

2. Stop all tenant databases in the system.

In the system database, in an SQL console, execute:

```
ALTER SYSTEM STOP DATABASE <databasename>;
```

→ Tip

You can also stop tenant databases in the *Database Management* app in SAP HANA cockpit.

3. Configure the system for high isolation.

As the operating system user <sid>adm, log on to the server on which the master index server is running and run the following command:

```
python /usr/sap/<SID>/HDB<instance>/exe/python_support/convertMDC.py --  
change=databaseIsolation --isolation=high
```

This command runs the following actions:

- Stops the system
  - Changes the value of the [multidb] database\_isolation property in the global.ini file to high
  - Starts the system
4. Assign every database to their respective OS user and group.

In the system database, in an SQL console, execute:

```
ALTER DATABASE <databasename> OS USER '<username>' OS GROUP '<groupname>'
```

→ Tip

You can also assign OS users and groups in the *Database Management* app of the SAP HANA cockpit.

5. Start all tenant databases.

In the system database, in an SQL console, execute:

```
ALTER SYSTEM START DATABASE <database_name>
```

→ Tip

You can also start tenant databases in the *Database Management* app of the SAP HANA cockpit.

## Results

The system is now running in high isolation mode. As a result:

- The processes of individual tenant databases run under dedicated OS users belonging to dedicated OS groups, and the processes of the system database run under the <sid>adm user.
- Internal database communication is authenticated using X.509 client certificates. Depending on how SSL for internal communication is configured, data communication within databases may also be encrypted. For more information about secure internal communication, see the *SAP HANA Security Guide*.

- Operations that require operating system access are restricted to users with the correct permissions. For more information, see the section on file and directory permissions with high isolation.
- New tenant databases can only be created if a dedicated OS user and group exist.

## Related Information

[Database Isolation \[page 216\]](#)

[Start a Tenant Database \[page 228\]](#)

[Create a Tenant Database \[page 224\]](#)

[Assign the OS User and Group for High Isolation \[page 219\]](#)

[Secure Internal Communication](#)

[File and Directory Permissions with High Isolation \[page 218\]](#)

[Isolation Level High for Backups and Third-Party Backup Tools](#)

[Server-Side TLS/SSL Configuration Properties for Internal Communication](#)

[SAP HANA Security Guide](#)

### 6.3.1.2.1 Database Isolation

Every tenant database is self-contained and isolated in terms of users, database catalog, repository, logs, and so on. However, to protect against unauthorized access at the operating system (OS) level, it's possible to increase isolation further through OS user separation and authenticated communication within databases.

## OS User Separation

By default, all database processes run under the default OS user `<sid>adm`. If it's important to mitigate against cross-database attacks through OS mechanisms, you can configure the system for high isolation. In this way, the processes of individual tenant databases must run under dedicated OS users belonging to dedicated OS groups, instead of all database processes running under `<sid>adm`. Database-specific data on the file system is then protected using standard OS file and directory permissions.

### i Note

`<sid>adm` is the OS user for the system database.

## Authenticated Communication

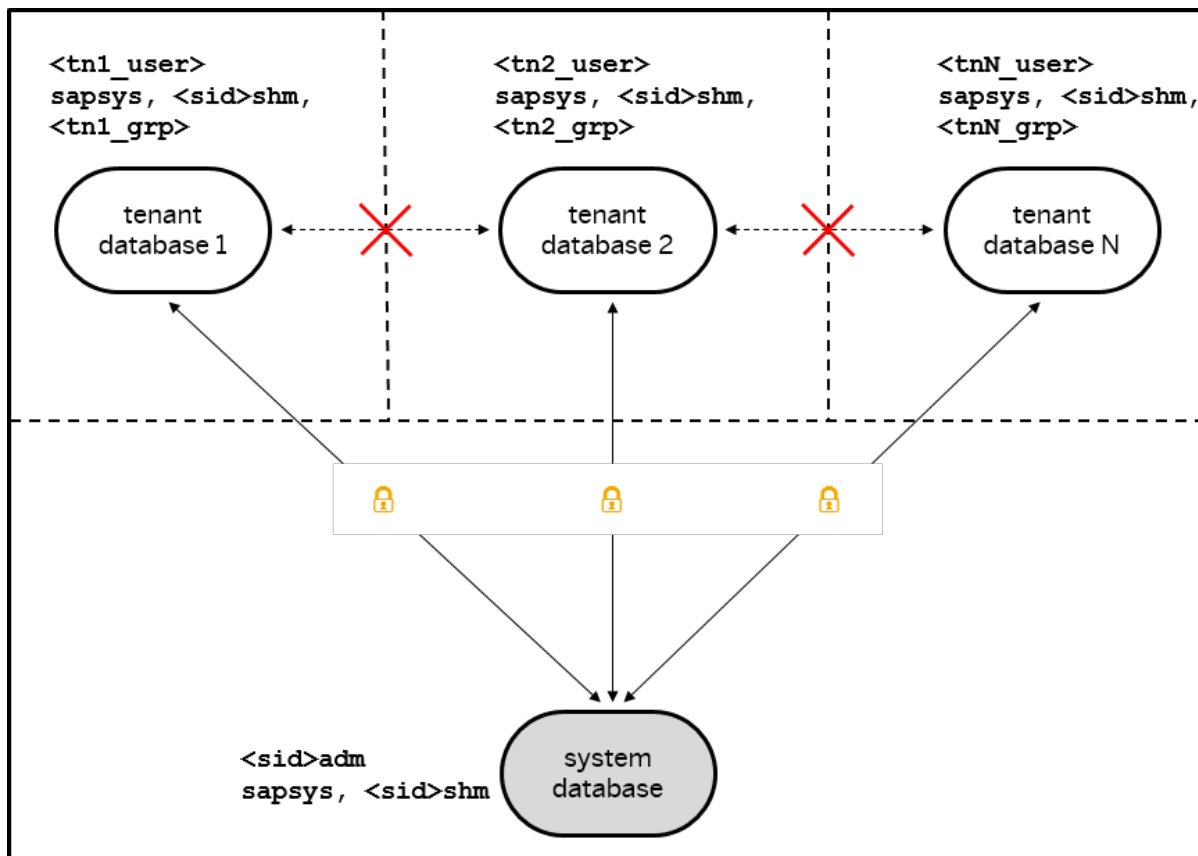

In addition, once high isolation has been configured, internal database communication is secured using the Transport Layer Security (TLS)/Secure Sockets Layer (SSL) protocol. Certificate-based authentication is used

to ensure that only the processes belonging to the same database can communicate with each other. It's also possible to configure internal communication so that all data communication within databases is encrypted.

### i Note

If cross-database access is enabled, communication between configured tenant databases is allowed.

High Database Isolation

## Configuration

You can specify the isolation level of the system during installation. The default isolation level is low. It's also possible to change the isolation level of an existing system (from low to high or from high to low) at any time. For more information, see *Increase the System Isolation Level* in the *SAP HANA Administration Guide*. Once high isolation has been configured, a dedicated OS user and group must exist for every tenant database. Otherwise, it's not possible to create or start a tenant database.

Internal database communication is secured with the same mechanism used for securing other internal SAP HANA communication channels. Once high isolation has been configured, authenticated communication within databases is enabled without any change required to the default TLS/SSL configuration for internal communication. However, encryption of data communication may need to be configured explicitly.

## Related Information

[File and Directory Permissions with High Isolation \[page 218\]](#)

[Secure Internal Communication](#)

[Increase the System Isolation Level \[page 214\]](#)

[SAP HANA Administration Guide](#)

### 6.3.1.2.2 File and Directory Permissions with High Isolation

In an SAP HANA system configured for high isolation, database-specific data on the file system is protected using standard file and directory permissions. All file and directory permissions are managed by the SAP HANA system and don't need to be set by the administrator.

#### System Database

The following table shows who has access to which data on the file system:

Files and Directories	Tenant OS User in Tenant OS Group	<sid>adm User
Files in directory containing system configuration files	Read permission (644)	Read permission (644)
Files in trace directory of the system database		Read and write permissions (600)
Directory containing Backint parameter file	Read permission (700)	Read permission (700)
Backint parameter file	Read and write permissions (660)	Read and write permissions (600)

#### Tenant Database

The following table shows who has access to which data on the file system:

##### i Note

If you want to grant the system administrator access to the tenant database backup files and directories, you need to add the <sid>adm user to each tenant's operating system group.

Files and Directories	Tenant OS User in Tenant OS Group	<sid>adm User
Database-specific directories containing: <ul style="list-style-type: none"> <li>• Data volumes</li> <li>• Log volumes</li> <li>• Log mirror volumes</li> <li>• Backups</li> </ul>	Read, write, and execute permissions (770)	
Database-specific directories containing: <ul style="list-style-type: none"> <li>• Configuration (*.ini) files</li> <li>• Trace files</li> </ul>	Read, write, and execute permissions (770)	Read, write, and execute permissions (770)
Files in database-specific directory containing: <ul style="list-style-type: none"> <li>• Configuration (*.ini) files</li> <li>• Trace files</li> </ul>	Read and write permissions (666)	Read and write permissions (666)
Directory containing Backint parameter file	Read, write, and execute permissions (750)	Read, write, and execute permissions (750)
Backint parameter file	Read and write permissions (640)	Read and write permissions (640)

## Related Information

[SAP HANA Security Guide](#)

### 6.3.1.2.3 Assign the OS User and Group for High Isolation

Specify the appropriate operating system (OS) user and group when moving a tenant database from a low to a high isolation level.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- The operating system user and operating system group exist.

## Context

When you change the isolation level to high, the entire system is automatically restarted. Any tenant that doesn't have a specified OS user and OS group isn't able to restart.

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database to which you want to assign an OS user and group. When the system is running in high isolation mode, any tenant without an OS user and OS group displays a status of Not Running.
3. Click the **⋮** (*More*) icon, and select [Assign OS user & group](#).
4. Enter the name of the OS user and OS group you want the tenant to use, and click *OK*.

## Next Steps

Start the tenant database.

## Related Information

[Clear the OS User and Group When Decreasing Isolation \[page 222\]](#)

[Start a Tenant Database \[page 228\]](#)

### 6.3.1.3 Decrease the System Isolation Level

If you configured a system for high isolation during installation or later, you can decrease it back to the default low level if necessary. With low isolation, the processes of all databases run under the default operating system (OS) user `<sid>adm`.

## Prerequisites

- You have root access to the SAP HANA system.
- You're logged on to the system database.
- You have the system privilege DATABASE ADMIN.

## Procedure

1. Stop all tenant databases in the system.

In the system database, execute the SQL statement `ALTER SYSTEM STOP DATABASE <database_name>`.

### → Tip

You can also stop tenant databases in the *Manage Databases* app of the SAP HANA cockpit.

2. Configure the system for low isolation.

As the operating system user `<sid>adm`, log on to the server on which the master index server is running and run the following command:

```
python /usr/sap/<SID>/HDB<instance>/exe/python_support/convertMDC.py --
change=databaseIsolation --isolation=low
```

This command runs the following actions:

- Stops the system
  - Changes the value of the `[multidb] database_isolation` property in the `global.ini` file to `low`
  - Starts the system
3. Clear the assignment of OS users and groups to tenant databases.

In the system database, in an SQL console, execute

```
ALTER DATABASE <database_name> OS USER '' OS GROUP ''
```

for every tenant database.

### → Tip

You can also clear the OS users and groups in the *Manage Databases* app of the SAP HANA cockpit.

4. Start all tenant databases.

In the system database, in an SQL console, execute

```
ALTER SYSTEM START DATABASE <database_name>
```

### → Tip

You can also start tenant databases in the *Database Management* app of the SAP HANA cockpit.

## Results

The system is now running in low isolation mode again.

- The processes of all databases run under `<sid>adm`.
- Internal database communication isn't authenticated.

## Related Information

[Start a Tenant Database \[page 228\]](#)

[Stop a Tenant Database \[page 229\]](#)

### 6.3.1.3.1 Clear the OS User and Group When Decreasing Isolation

If you've modified the isolation level from high to low, you can clear the previously assigned operating system user and operating system group.

#### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).

#### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database from which you want to clear the OS user and group.
3. Click the  (*More*) icon, and select [Assign OS user & group](#).
4. Delete the name of the existing OS user and OS group, and click *OK*.

#### Next Steps

Start the tenant database.

## Related Information

[Assign the OS User and Group for High Isolation \[page 219\]](#)

[Start a Tenant Database \[page 228\]](#)

## 6.3.1.4 Configure Tenant Replication

Before tenants can be replicated between systems, tenant replication must be configured.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the system database of the source or target system. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the system privilege `DATABASE ADMIN`, `INIFILE ADMIN`, and `CREDENTIAL ADMIN`.
- If encryption is required, you also must have the system privileges `CERTIFICATE ADMIN` and `TRUST ADMIN` for the target database.
- You are logged in to the system database (SYSTEMDB).

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Click the **\*\*\* (More)** icon, then [Configure Tenant Replication](#).
3. Choose [Replicate Tenant](#) if you are configuring replication on the source system. Choose [Create Tenant Using Replication](#) if you are configuring replication on the target system.
4. If you chose [Replicate Tenant](#) in Step 3, select the system database of the target system. If you chose [Create Tenant Using Replication](#) in Step 3, select the system database of the source system.
5. Warnings appear to indicate configuration changes required for replication. Select [Approve](#) to proceed.
6. If prompted, enter the SAP Control credentials required for the restart of the source and target system.
7. If a trust relationship has not yet been established between the source system and the target system, select an existing public key certificate or upload a certificate.
8. Review the summary, then choose [Prepare for Copy/Move](#) to finalize the preparation.

### Related Information

[Create a Tenant Database Using Replication \[page 226\]](#)

[Copy or Move a Tenant Database Using Replication \[page 256\]](#)

## 6.3.1.5 Create a Tenant Database

You create tenant databases after installation of a multiple-container system, after conversion from a single-container system to a single-tenant system, or anytime a new database is needed

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege `DATABASE ADMIN`.
- If the system is configured for high isolation, the operating system (OS) user and group required for the new tenant database already exist. For more information, see *Database Isolation* in the *SAP HANA Administration Guide*.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select **► Create Tenant ► Create Empty Tenant ▾**.
3. Enter the name of the new database and the password of the SYSTEM user.

Restrictions apply to tenant names. Alphanumerical string of lowercase alpha characters [a-z], uppercase alpha characters [A-Z], digits [0-9] are permitted. Depending on the file system, tenant names with up to 253 characters are supported.

#### **i** Note

The password must initially comply with the password policy configured in the system database. Once the database is created, you can change the password policy for the tenant database if you want.

4. (For high isolation only) Specify the OS user and group of the tenant database.

If the system in which you're creating the tenant database is configured for high isolation, the processes of individual tenant databases **must** run under dedicated OS users in dedicated OS groups. If the system is configured for low isolation (default), all tenant database processes run under the default OS user `<sid>adm`.

5. (Optional) Deselect [Start Automatically](#) to prevent the database from automatically starting.
6. (For multihost systems only) (Optional) Specify the host on which the database is to be created.

Under [Advanced Settings](#), specify the host you want the master index server to start. If you don't select a host, load-balancing algorithms determine optimal host placement.

7. (Optional) Specify the number of the internal communication port of the master index server.

Under [Advanced Settings](#), specify the port number for the default service. If you don't enter a port, it's assigned automatically based on port number availability. For more information about port number assignment, see *Connections for Tenant Databases* in the *SAP HANA Master Guide*.

8. (Optional) Add additional services required.
  - a. In the *Advanced Settings* section, choose *Add Service*.
  - b. Select the service you want to add.
  - c. (For multihost systems only) (Optional) Select the host and enter the port number of the new service.

If you don't select a host or enter a port number, they're automatically determined.

9. Click *Create Tenant Database*. If the host doesn't have at least three available ports, a dialog prompts you with the option to reserve additional instance numbers.

The system starts creating the database, which can take a few moments to complete.

Technically, the creation process runs in the background as follows:

- The database is assigned a unique system local ID.
- If you didn't specify host information, load-balancing algorithms determine optimal host placement.
- If you didn't specify the number of the internal communication port, it's assigned automatically based on port number availability.
- The necessary data and log volumes are created on the affected hosts.
- The new database is entered in the M\_DATABASES system view of the system database.
- The `daemon.ini` file is updated and the daemon process is triggered to start the index server service and any additionally added services on each configured host.
- The specified password is set for the user SYSTEM in the new database.

## Results

The new tenant database is created and possibly started, and appears in *Database Management*. It's now also in the M\_DATABASES view (`SELECT * FROM "PUBLIC"."M_DATABASES"`).

Delivery units (DUs) containing automated content start to be deployed in the background. If the system is online, you can monitor the progress of deployment by executing the following statement:

```
SELECT * FROM "PUBLIC"."M_SERVICE_THREADS" WHERE THREAD_TYPE = 'ImportOrUpdateContent';
```

For more information about automated content, see *SAP HANA Content* in the *SAP HANA Security Guide*.

## Next Steps

- Perform a full data backup. For more information, see *Performing Backups* in the *SAP HANA Administration Guide*.
- Adjust the value for the maximum number of asynchronous I/O requests by updating the value of the `fs.aio-max-nr` parameter in `/etc/sysctl.conf`. For more information, see *Linux Kernel Parameters* in the *SAP HANA Administration Guide*.
- Configure the new tenant database as required. For more information, see the section on managing Tenant Databases in the *SAP HANA Administration Guide*.

### 6.3.1.6 Create a Tenant Database Using Replication

You can create tenant databases by replicating from existing tenant databases.

#### Prerequisites

- You have configured tenant replication.
- You've navigated to the [Database Overview](#) page of the system database of the source or target system. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the system privilege `DATABASE ADMIN`.
- You have created a complete system backup for the source tenant database.

#### ⚠ Caution

When you use the cockpit to move a tenant, the source database is deleted as part of the process. If the source is running SAP HANA 2.0 SP01 or earlier, its backups are also deleted as part of the process—you can't roll back! Before moving, SAP recommends that you run a backup, then replicate the backup to a new location.

- For the target (the database where you're putting the moved or copied database):
  - You must have the system privileges `DATABASE ADMIN`.
- If the system is configured for high isolation, the operating system (OS) user and group required for the new tenant database already exist. For more information, see *Database Isolation* in the *SAP HANA Administration Guide*.
- You are logged in to the system database (SYSTEMDB).

#### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. To create a new tenant based on an existing tenant, choose ► [Create Tenant](#) ► [Create Tenant Using Replication](#) ►.

3. To create a copy of an existing tenant database, select *Copy using replication*. To remove the original tenant after the copy has been created, select *Move using replication*.
4. Select the source database and tenant.
5. Enter a name for the new tenant.

Restrictions apply to tenant names. Alphanumeric string of uppercase alpha characters [A-Z], digits [0-9] are permitted, starting with a letter. Depending on the file system, tenant names with up to 253 characters are supported.

6. (Optional) Specify the number of the internal communication port of the listed services.  
  
Under *Advanced Settings*, specify the port number for each service. If you don't enter a port, it's assigned automatically based on port number availability. In multihost systems enter host and port of a service. For more information about port number assignment, see *Connections for Tenant Databases* in the *SAP HANA Master Guide*.
7. (For high isolation system only) Enter a dedicated OS user and group for the source.
8. If configuration changes are required for the replication, warnings appear to indicate the required changes. Select *Approve* to proceed.  
  
You may see a warning that you do not have the privilege required to check if the databases are fully configured for tenant replication. Please contact your system administrator to make sure that tenant replication has been properly configured.
9. If prompted, enter the SAP Control credentials required for the restart of the system.
10. If a trust relationship has not yet been established between the source system and the target system, select an existing public key certificate or upload a certificate.
11. Review the summary, then choose *Copy Tenant Database* or *Move Tenant Database* to start replicating the tenant database.

## Next Steps

Register the new tenant in SAP HANA Cockpit Manager so it can be managed by SAP HANA Cockpit.

## Related Information

## 6.3.1.7 Start a Tenant Database

You can start tenant databases either individually, or all at once by starting the whole system.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege DATABASE ADMIN or DATABASE START.

### Context

For more information about how to start the whole system, see the sections on stopping and starting a database.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Click the [Start](#) button for the tenant you want to start.

### Related Information

## 6.3.1.8 Stop a Tenant Database

You can stop tenant databases either individually, or all at once by stopping the whole system.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege DATABASE ADMIN or DATABASE STOP.

### Context

Consider backing up the database before stopping it. For more information about how to stop the whole system, see the sections on stopping and starting a database.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database that you want to stop.
3. Click [Stop](#).

### Results

- The database is stopped.

#### **i** Note

This stop is a hard stop, which means that the database is stopped immediately even if users are connected. Open transactions are aborted and rolled back; no savepoint operation is forced. It isn't possible to back up a stopped database.

- The status of database changes accordingly.

### Related Information

## 6.3.1.9 Rename a Tenant Database

You can use the cockpit to rename a tenant database.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege DATABASE ADMIN:
- The database to be renamed:
  - Isn't running.
  - Isn't part of a copy or move operation.
  - Doesn't have system replication active.
  - Doesn't have the SAP HANA dynamic tiering option.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database that you want to rename.
3. Click [Stop](#) if the tenant is running.
4. Click the [Tenant Actions](#) dropdown menu and select [Rename Tenant](#).
5. Enter the new name, and select [Rename](#).

Restrictions apply to tenant names. Alphanumerical string of lowercase alpha characters [a-z], uppercase alpha characters [A-Z], digits [0-9], the hyphen (or minus) character "-", and the underscore character "\_" are permitted. Depending on the file system, tenant names with up to 253 characters are supported.

### Results

The database is renamed. On-disk directories that contain the tenant name are also renamed. Existing backups aren't renamed but backup history remains continuous.

## Related Information

[Create a Tenant Database \[page 224\]](#)

[Delete a Tenant Database \[page 231\]](#)

[RENAME DATABASE Statement \(Tenant Database Management\)](#)

### 6.3.1.10 Delete a Tenant Database

You can delete tenant databases that are no longer required.

#### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege `DATABASE ADMIN`.

#### Context

If you delete a tenant database that is running SAP HANA 2.0 SPS 01 or later, you have the option to keep the backup directories of the deleted tenant. Backups can then only be removed by deleting them from the file system. If you delete a tenant database that is running an earlier version of SAP HANA, the backup directories are deleted automatically. It's therefore recommended that if you want to preserve these backup directories, you relocate them before deleting the database.

#### i Note

If a tenant SAP HANA database is enabled for usage with XS advanced and mapped to an organization/ space in XS advanced, then it is recommended not to use cockpit (or the SQL command line interface) to delete the tenant database but to use the XS advanced xs command line interface. This is necessary so that XS advanced is aware that the tenant database is no longer available. Note, too, that if you use the XS advanced xs CLI to delete a tenant database used by XS advanced, all data in the tenant database is lost. See also 'Maintaining Tenant Databases in XS Advanced'.

#### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant to delete and click [Stop](#).

Once stopped, its status changes to *Stopped*.

3. Click the  (*Delete*) icon for the tenant.
4. If this database is running SAP HANA 2.0 SPS 01 or later, choose whether to *Keep Backup Directories* or *Delete Directories* and proceed with the database deletion, or *Cancel* the database deletion. If the database is running an earlier version of SAP HANA, choose whether to *Delete Tenant* or *Cancel* the database deletion.

## Results

The system commences the process to delete the database. Once deleted, the database disappears from the list. Volumes and trace files are removed.

## Next Steps

If you configured the SAP Web Dispatcher to route HTTP requests to the deleted database, you need to update the configuration.

### 6.3.1.11 Disable Features on a Tenant Database

To safeguard and/or customize your system, certain features of the SAP HANA database can be disabled in tenant databases. You can do this in the SAP HANA cockpit.

## Prerequisites

- The system database is registered in the SAP HANA cockpit.
- You have the system privilege INIFILE ADMIN.

## Context

Some features of the SAP HANA database are not required or desirable in certain environments, in particular features that provide direct access to the file system, the network, or other resources. To maximize your control over the security of your system, you can disable these features in tenant databases, for example import and export operations or the ability to back up the database.

The system view `M_CUSTOMIZABLE_FUNCTIONALITIES` provides information about those features that can be disabled and their status. This view exists in both the `SYS` schema of every database, where it contains database-specific information, and in the `SYS_DATABASES` schema of the system database, where it contains information about the enablement of features in all databases.

For more information about the features that can be disabled and why, see *Restricted Features in SAP HANA Tenant Databases* in the *SAP HANA Security Guide*.

You disable features in tenant databases in the `customizable_functionalities` section of the `global.ini` file.

### i Note

All features are enabled in the system database and cannot be disabled.

## Procedure

1. Determine which feature(s) you want to disable by referring to the view `M_CUSTOMIZABLE_FUNCTIONALITIES` (`SYS`) of the system database.
2. On the [Overview](#) page of the system database in the SAP HANA cockpit, open [Configuration of System Properties](#) by clicking the corresponding administration link.
3. Select the configuration file `global.ini` file and the section `customizable_functionalities`.
4. Add a new parameter for the feature that you want to disable:
  - a. Specify the database on which you want to blacklist the properties.
  - b. In the [Key](#) field, enter the name of feature that you want to disable and set the value to `false`.

### i Note

If you want to disable the feature on all tenant databases (including any that will be created in the future), enter `false` as the system layer value.

5. Repeat for further features not required in the tenant database(s).
6. Restart the affected tenant database(s).

## Results

The feature is disabled. You can verify this in the view `M_CUSTOMIZABLE_FUNCTIONALITIES` (`SYS_DATABASES`).

Tenant database administrators can see which features are enabled in their database using the view `M_CUSTOMIZABLE_FUNCTIONALITIES` (SYS).

[Restricted Features in Tenant Databases](#)

## 6.3.1.12 Enable and Configure Cross-Database Access

Read-only queries between tenant databases are supported but not enabled by default. You must first enable this feature for the system in the system database and then configure which databases may communicate with one another. You can do this in the SAP HANA cockpit.

### Prerequisites

- The system database is registered in the SAP HANA cockpit.
- You have the system privilege `INIFILE ADMIN`.

### Context

Every tenant database is self-contained with its own isolated set of database users and isolated database catalog. However, to support for example cross-application reporting, cross-database `SELECT` queries are possible. This means that database objects such as tables and views can be local to one database but be read by users from other databases in the same system.

So, for example, the following query would be possible:

```
SELECT *
FROM schema1.table1 AS tab1, db2.schema2.table2 as tab2
WHERE tab2.column2 = 'foobar'
```

For more information about which object types on remote databases can be accessed using this mechanism and which local object types can access remote database objects, see *Cross-Database Access*.

To allow queries between databases, you must first enable cross-database access and then specify which databases may communicate with one other. You can do this by configuring the `global.ini` configuration file in the SAP HANA cockpit.

## Procedure

1. On the [Overview](#) page of the system database in the SAP HANA cockpit, open [Manage System Configuration](#).
2. Locate the parameter `cross_database_access` in the configuration file `global.ini`.
3. Choose [Override Value](#) to change the parameter value to `true`.

Alternatively, enable cross-database access by executing the following statement in the system database:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'SYSTEM') set ('cross_database_access', 'enabled')='true' WITH RECONFIGURE;
```

4. Enable communication from one tenant database to one or more other tenant databases by executing the following statement in the system database:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'SYSTEM') set ('cross_database_access', 'targets_for_<source_db_name>')='<target_db1>[,<target_db2>...]' WITH RECONFIGURE;
```

### ❖ Example

You have two databases DB1 and DB2 and you want to be able to access DB1 from DB2. So you add the parameter with `targets_for_DB2` the value `DB1`.

### i Note

Cross-database access is configured only in one direction. If in the above example you also want DB2 to be able to access DB1, you would have to add the parameter `targets_for_DB1` with the value `DB2`.

## Results

Cross-database queries are now possible between the configured databases.

## Next Steps

Create remote identities for those users who require cross-database access. For more information, see *Cross-Database Authorization in Tenant Databases* in the *SAP HANA Security Guide*.

In order for a user in one database to be able to run a query or create an object that references objects in another database, the user must be mapped to a sufficiently privileged user in the remote database.

## Related Information

[Cross-Database Access \[page 236\]](#)

## 6.3.1.12.1 Cross-Database Access

Read-only queries between tenant databases in the same SAP HANA system are possible. This supports cross-application reporting. Cross-database access must be explicitly enabled.

Every tenant database is self-contained with its own isolated set of database users and isolated database catalog. However, to support for example cross-application reporting, cross-database SELECT queries are possible. This means that database objects such as tables and views can be local to one database but be read by users from other databases in the same system.

The following object types on remote databases can be accessed using cross-database access:

- Schemas
- Rowstore and columnstore tables (not including virtual tables)
- SQL views (not including monitoring views)
- Graphical calculation views
  - If they only use supported object types as data sources
  - If they don't use procedure-based analytic privileges
- Synonyms

The following object types on the local tenant database can access database objects on the remote tenant database:

- SQL views
- Scripted and graphical calculation views
- Procedures
- Synonyms

The SAP HANA modeler supports modeling of graphical calculation views using tables and other graphical calculation views as data sources from different tenant databases. For more information, see *Modeling Graphical Calculation Views With Tenant Databases* in the *SAP HANA Modeling Guide (For SAP HANA Studio)*.

For more information about how to enable and configure cross-database access, see *Enable and Configure Cross-Database Access*.

## 6.3.1.12.2 Workload Management and Cross-Database Queries

Cross-database queries are executed on one or more databases. The workload management settings of the tenant database executing the query or part of the query are applied.

To balance and manage different types of workload in SAP HANA (OLAP, OLTP, mixed, and internal), it is possible to classify workloads based on user and application context information and apply resource limitations (for example, a statement memory limit). Workload classes allow SAP HANA to influence dynamic resource consumption at the session or statement level.

The execution of any plan operations of a cross-database query in a remote tenant database is subject to the resource limitations of the workload classes and mappings defined in the remote database. If multiple remote tenant databases are involved in query execution, then different limitations may apply to different portions of the execution plan.

### i Note

For cross-database queries workload classes in the remote tenant database is the only way of applying resource limitations; in this case only the following set of workload class mapping properties is available:

- APPLICATION USER NAME
- CLIENT
- APPLICATION COMPONENT NAME
- APPLICATION COMPONENT TYPE
- APPLICATION NAME
- USER NAME

For cross-database queries it is not possible to control resource allocation by setting user parameters; normally, you can set values for the parameters STATEMENT MEMORY LIMIT, STATEMENT THREAD LIMIT and PRIORITY on user level, but this is not supported in this case. Also global ini file configurations (statement memory limit, statement thread limit) are not supported for cross-database queries.

For more information about workload management using workload classes and workload mappings, see *Workload Management* in the *SAP HANA Administration Guide*.

## Related Information

## 6.3.1.12.3 Troubleshooting Error Situations Related to Cross-Database Access

If you are using cross-database access to query data from other tenant databases in your system, some error situations may arise.

### Situation 1

You are creating views, procedures, or synonyms to access objects on other tenant databases in the same system. After dropping and re-creating an object on a remote tenant database, you can no longer access the view or procedure on the local tenant database. You get error messages such as `invalidated view` or `invalidated procedure`. You also notice that the `IS_VALID` column in the system views `VIEWS` and `PROCEDURES` do not accurately reflect the fact that the view or procedure is invalid. In addition, there are entries missing in the `OBJECT_DEPENDENCIES` system view for the affected views, procedures, or synonyms.

#### What's the problem?

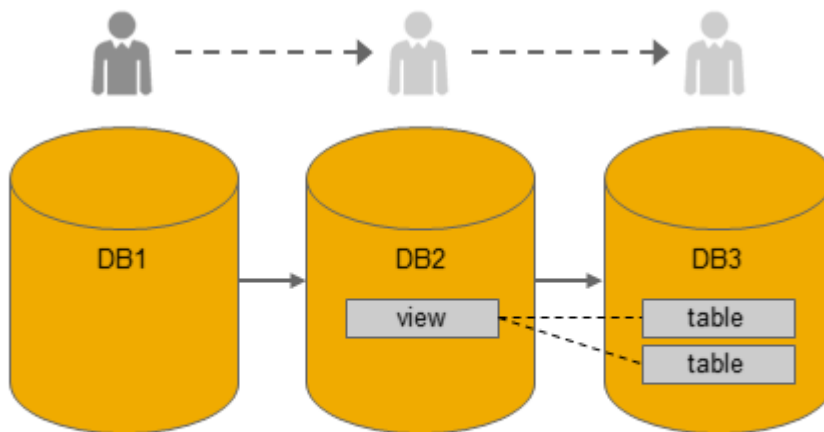

Cross-database access supports only read-only operations. Changes to an object on one tenant database cannot therefore be reflected accurately on other tenant databases that contain objects dependent on the changed object. This affects the validity flag in the relevant system views, as well as the object dependencies. Remote objects may stay valid if they retain their internal object identifier during re-creation and are re-created in a compatible way, but they will become invalid if their internal object identifier changes.

#### What can I do?

You need to re-create the dependent object in the local tenant database in order for it to become valid again.

### Situation 2

You are querying an SQL view or a calculation view on a remote tenant database and the view itself accesses objects on a third tenant database (multi-level cross-database access). You are getting error messages such as `insufficient privilege: not authorized`. Analytic privileges on the third tenant database may be evaluated based on the wrong database user.

Executed from DB1:

 `SELECT * FROM DB2.v2`

### What's the problem?

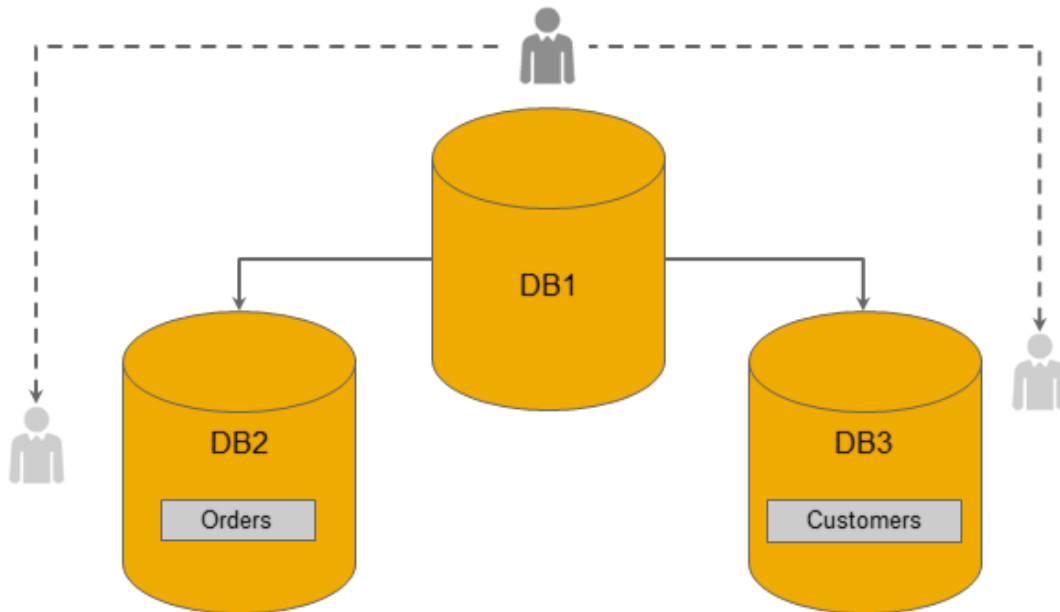

Cross-database queries do not support multiple tenant database levels as part of a view hierarchy, even if communication between databases is enabled (including the required authorized remote users).

### What can I do?

Nothing. The feature is not supported.

## Situation 3

Your system is running in high isolation mode. Queries that involve more than one remote tenant database run into timeouts. You are getting error messages such as `execution plan aborted` or `current operation canceled by request and transaction rolled back`. Accessing objects on remote tenant databases individually works fine.

Executed from DB1:

```

SELECT DB2.Orders.OrderID, DB3.Customers.CustomerName
FROM DB2.Orders
INNER JOIN DB3.Customers
ON DB2.Orders.CustomerID=DB3.Customers.CustomerID;

```

 A red prohibition sign is placed to the left of the SQL query, indicating that this query is not allowed or is problematic.

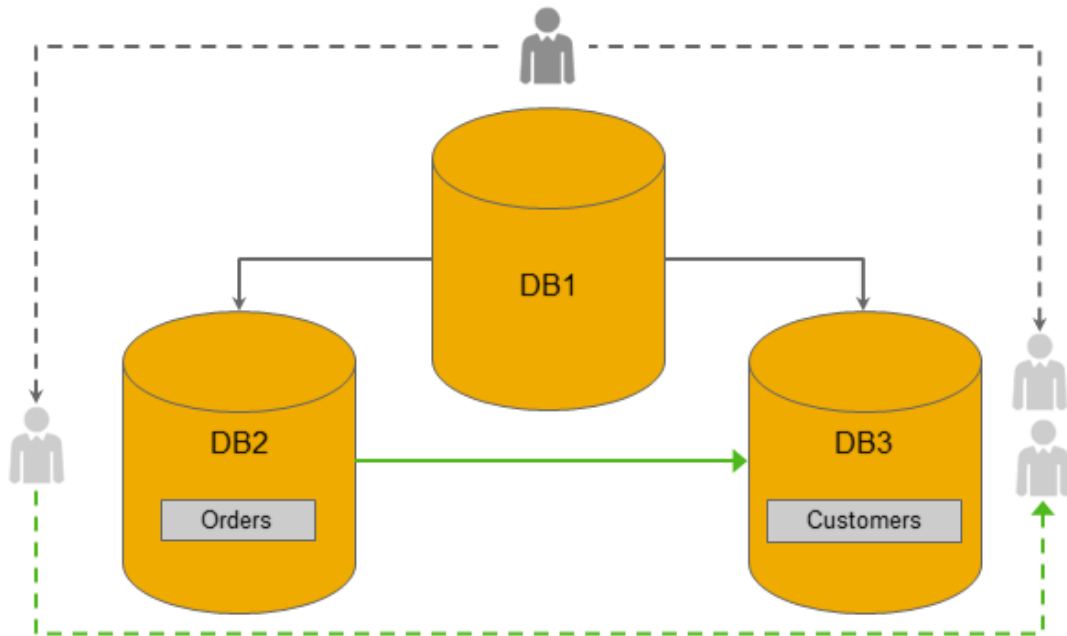

### What's the problem?

The communication channels that are enabled for cross-database queries are applied in a strict fashion to the underlying network channels as well. This means that one tenant database can only open a network connection to another tenant database if communication between these two databases has been explicitly enabled. The execution plan for a query that involves objects from multiple tenant databases could however lead to direct network connections between any of the tenant databases, even if communication between them has not been explicitly enabled. This specifically applies to joins between tables on two different remote tenant databases.

### What can I do?

You need to enable communication between all tenant database pairs that can potentially be involved in a query (including authorized remote users). For more information about how to do this, see *Enable and Configure Cross-Database Access*.

Executed from DB1:

```
SELECT DB2.Orders.OrderID, DB3.Customers.CustomerName
FROM DB2.Orders
INNER JOIN DB3.Customers
ON DB2.Orders.CustomerID=DB3.Customers.CustomerID;
```

## Related Information

[Enable and Configure Cross-Database Access \[page 234\]](#)

### 6.3.1.13 Prevent Changes to System Properties in Tenant Databases

To ensure the stability and performance of the overall system or for security reasons, you can prevent certain system properties from being changed by tenant database administrators, for example, properties related to resource management. A configuration change blacklist is available for this purpose. You configure the blacklist in the SAP HANA cockpit.

## Prerequisites

- The system database is registered in the SAP HANA cockpit.
- You have the system privileges INIFILE ADMIN.

## Context

System configuration (\*.ini) files have a database layer to facilitate the configuration of system properties for individual tenant databases. However, it may be desirable to prevent changes to certain properties being made directly in tenant databases because they could for example affect the performance of the system as a whole (CPU and memory management properties).

For this reason, a dedicated configuration change blacklist, `multidb.ini`, is available. This blacklist contains several critical properties by default. You can customize the default configuration, as well as add further properties by editing the file in the SAP HANA cockpit.

### i Note

Properties in the blacklist can still be configured at all levels in the system database. For more information about configuring system properties, see *Configuring SAP HANA System Properties (INI Files)*.

## Procedure

1. On the *Overview* page of the system database in the SAP HANA cockpit, open *Configuration of System Properties* by clicking the corresponding administration link.
2. Select the configuration file `multidb.ini` and the section `readonly_parameters`.
3. Add a new parameter to the blacklist:
  - a. Specify on which layer you want to blacklist the properties.

You can choose from the following layers:

Layer	Result
System	Configuration not possible in any tenant database.
Database	Configuration not possible in the specified tenant database(s)

### i Note

Layered configuration is possible. A lower-layer configuration overrides a higher-layer configuration. This also allows you to change the default configuration of the blacklist. The example below shows you how you could do this.

- b. In the *Key* field, enter the ini file section that contains the properties you want to blacklist.

If the section exists in more than one configuration file, you can specify the exact configuration file by entering `<file>/<section>`. If you do not specify a configuration file, the properties will be blacklisted in all files that contain the section.

For example, to specify the `communication` section in all configuration files, enter `communication`. But to specify the `communication` section in the `xsengine.ini` file only, enter `xsengine.ini/communication`.

- c. In the *Value* field, enter the properties that you want to blacklist.  
If you want to add all the properties in the section, enter `*`. If you want to add all the properties in all sections of a specific file, enter `<filename>/*` (for example, `xsengine.ini/*`).
- d. Choose *OK*.
- e. Add further parameters as required.

## Results

Tenant database administrators cannot change the properties in the configuration change blacklist. If they try, they will get the error message: `Change not allowed for tenant database`. System administrators can still change the properties in the system database in all layers.

## Example: Layered Configuration

The property `[sql] sql_executors` is blacklisted for all tenant databases in all configuration files by default. You could create a layered configuration for example as follows:

- You change the `sql` entry at the system layer and enter `plan_cache_size` as the value. This overrides the default configuration so that `[sql] plan_cache_size` is blacklisted instead of `[sql] sql_executors`.
- You change the `sql` entry at the system layer and enter `sql_executors` and `plan_cache_size` as the value. This overrides the default configuration so that both `[sql] plan_cache_size` and `[sql] sql_executors` are blacklisted.
- You add a new entry `indexserver.ini/sql` at the system layer with the value `plan_cache_size` as the value. This adds a specific configuration for the `indexserver.ini` file. Here, now only `[sql] plan_cache_size` is blacklisted.

## Related Information

[Configuring SAP HANA System Properties \(INI Files\) \[page 301\]](#)

## 6.3.1.13.1 Default Blocklisted System Properties in Tenant Databases

In systems that support tenant databases, there's configuration change blocklist `multidb.ini`, which is delivered with a default configuration.

The following table lists the system properties that are included in the `multidb.ini` file by default. So, tenant database administrators can't change these properties. System administrators can still change these properties in the system database in all layers.

You can customize the default configuration change blocklist by changing existing entries in the `multidb.ini` file and adding new ones. For more information about how to prevent changes to specific system properties in tenant databases, see *Prevent Changes to System Properties in Tenant Databases* in the *SAP HANA Administration Guide*.

File/Section	Properties	Description
auditing configuration	<ul style="list-style-type: none"> <li>default_audit_trail_type</li> <li>emergency_audit_trail_type</li> <li>alert_audit_trail_type</li> <li>critical_audit_trail_type</li> <li>audit_statement_length</li> </ul>	Prevents configuration of audit trail targets and the maximum audit statement length

[Unlock Blocklisted Parameters \[page 282\]](#)

[Copy Blocklisted Parameters \[page 283\]](#)

### 6.3.1.14 Configure HTTP(S) Access to Tenant Databases via SAP HANA XS Classic

To enable Web-based applications to send HTTP(S) requests to tenant databases via the SAP HANA XS classic server, the internal SAP Web Dispatcher must be configured so it knows which requests to dispatch to which database on the basis of DNS alias host names. You do this by specifying the public URL of every tenant database in the `xsengine.ini` configuration file.

## Prerequisites

- You are logged on to the system database.
- You have the system privilege INIFILE ADMIN.
- The network administrator has defined an alias hostname in your organization's Domain Name System (DNS) for every tenant database in the SAP HANA system. The alias hostname must refer to the hostname of the machine that is used for HTTP(S) access to the tenant database.
- You have a role based on the role template `sap.hana.xs.wdisp.admin::WebDispatcherAdmin`. This is required to access the SAP HANA Web Dispatcher Administration tool for configuring HTTPS.

## Context

The XS classic server allows Web-based applications to access SAP HANA via HTTP(S). The internal Web Dispatcher of the SAP HANA system manages these incoming HTTP(S) requests. To allow applications to send requests to specific databases, every tenant database needs an alias host name. Requests to the alias host name can then be forwarded to the XS server of the corresponding tenant database. Requests with the physical host name in the HTTP host header are forwarded to the XS server running on the system database.

The default HTTP ports are used in all cases, that is, 80<instance> (HTTP) and 43<instance> (HTTPS). Alias host names are mapped to internal HTTP(S) ports so that incoming requests can be routed to the correct database.

You configure HTTP(S) access to tenant databases by specifying in the `xsengine.ini` file the URLs by which each tenant database is publicly accessible. The system then automatically configures the Web Dispatcher by generating the required profile entries in the `webdispatcher.ini` configuration file. It is not necessary to specify the URL of the system database, this is done automatically.

### Note

This automatic configuration of the Web Dispatcher is controlled by the parameter `[profile] wdisp/system_auto_configuration` in the `webdispatcher.ini` configuration file. If this parameter is set to **false**, you need to configure the `webdispatcher.ini` file manually.

For HTTPS access, you must subsequently configure the required client certificates and trust stores using the SAP Web Dispatcher Administration tool. The following approaches are supported:

- Using a single "wildcard" server certificate in a single trust store that covers all databases in the system. Wildcard certificates are more flexible when tenant databases are frequently added and deleted. However, if you use a wildcard certificate, either the server requires its own sub-domain or you must ensure that the certificate cannot be abused from other servers.

### Caution

Do not use a wildcard server certificate if strict isolation between tenant databases is required. If authentication relies on a wildcard certificate and a shared trust store, users of one tenant database will be able to log on to other databases in the system.

- Using individual certificates in individual trust stores for each database

Individual certificates for each database are more suitable in a flat domain structure for individual servers. They also ensure strict isolation between tenant databases. However, they involve more administrative effort to maintain.

## Procedure

1. Specify the public URLs of all tenant databases in the `xsengine.ini` file in one of the following ways:

Option	Description
SAP HANA studio	<ol style="list-style-type: none"> <li>1. Open the Administration editor and choose the <i>Configuration</i> tab.</li> <li>2. Navigate to the <code>xsengine.ini</code> file and expand the <code>public_urls</code> section.</li> <li>3. For each tenant database in the system, add the new properties <code>http_url</code> and <code>https_url</code> at the <b>database layer</b> and enter its public URL as the value: <ul style="list-style-type: none"> <li>◦ <code>http://&lt;virtual_hostname&gt;:80&lt;instance&gt;</code></li> <li>◦ <code>https://&lt;virtual_hostname&gt;:43&lt;instance&gt;</code></li> </ul> </li> </ol>

### i Note

The scheme (`http/https`) must be included in the URL.

SQL	<p>For each tenant database, execute the statements:</p> <ul style="list-style-type: none"> <li>◦ <code>ALTER SYSTEM ALTER CONFIGURATION ('xsengine.ini', 'database', '&lt;tenant_DB_name&gt;') SET ('public_urls', 'http_url') = 'http://&lt;virtual_hostname&gt;:80&lt;instance&gt;' WITH RECONFIGURE;</code></li> <li>◦ <code>ALTER SYSTEM ALTER CONFIGURATION ('xsengine.ini', 'database', '&lt;tenant_DB_name&gt;') SET ('public_urls', 'https_url') = 'https://&lt;virtual_hostname&gt;:43&lt;instance&gt;' WITH RECONFIGURE;</code></li> </ul>
-----	---

### i Note

The following values are set at the **default layer** and represent the URLs of the system database:

- `http://$(SAPLOCALHOST):80$(SAPSYSTEM)`
- `https://$(SAPLOCALHOST):43$(SAPSYSTEM)`

By default, the system database initially retrieves any request with the port `80<instance_no>`. However, as soon as you configure the URLs of tenant databases, it is available under `http://<localhost>:80<instance>` only, and not the fully qualified domain name (FQDN). The local host is known to SAP HANA without the FQDN.

If you want to change this default behavior and configure a different URL for the system database, you can do so by executing the following statement:

```
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'system')
SET('public_urls', 'http_url') = 'http://<virtual_hostname>:80<instance>'
WITH RECONFIGURE;
```

New entries are now created in the `webdispatcher.ini` file at the host layer for every database. You can verify this by executing the following statement (from the system database):

```
SELECT KEY, VALUE, LAYER_NAME FROM SYS.M_INIFILE_CONTENTS WHERE FILE_NAME =
'webdispatcher.ini' AND SECTION = 'profile' AND KEY LIKE 'wdisp/system%'
```

This returns the following result for example:

```

KEY          | VALUE                                                                 | LAYER_NAME
wdisp/system_0 | GENERATED, SID=SYS, EXTSRV=http://localhost:30014, |
SRCVHOST='myhost' | DEFAULT
wdisp/system_1 | GENERATED, SID=MYD, EXTSRV=http://localhost:30042, |
SRCVHOST='mydatabase.example.com' | HOST
  
```

## 2. Optional: Secure incoming communication by configuring HTTPS.

Option	Description
<b>Single certificate for all databases</b>	<ol style="list-style-type: none"> <li>1. Start the SAP HANA Web Dispatcher Administration tool at <code>http://&lt;localhost&gt;:80&lt;instance&gt;/sap/hana/xs/wdisp/admin/</code>.</li> <li>2. For the default <code>SAPSSLS.pse</code> trust store, create a new SSL key pair and certificate request: <ol style="list-style-type: none"> <li>1. From the main menu, choose <b>SSL and Trust Configuration</b> <b>PSE Management</b>.</li> <li>2. From the <i>Manage PSE</i> menu, choose <i>SAPSSLS.pse</i>.</li> <li>3. Choose <i>Recreate PSE</i>.</li> <li>4. Enter a distinguished name that matches the host name of all tenant databases.</li> </ol> <div data-bbox="497 869 1394 1120" data-label="Complex-Block"> <p><b>❖ Example</b></p> <ul style="list-style-type: none"> <li>○ Physical host name: myhost.example.com</li> <li>○ Tenant host name 1: mydatabase1.example.com</li> <li>○ Tenant host name 2: mydatabase2.example.com</li> </ul> <p>In this case, you specify <code>CN=*.example.com</code> as the DN, thus creating a server certificate that matches all tenant databases and the system database.</p> </div> <ol style="list-style-type: none"> <li>5. Choose <i>Create</i>.</li> <li>6. Create a certificate request and submit to your certificate authority (CA) for signing (<i>Create CA Response</i>).</li> </ol> </li> <li>3. Import the signed certificate</li> </ol>

For more information, see *Configure HTTPS (SSL) for Client Application Access*.

<b>Individual certificates for each database</b>	<ol style="list-style-type: none"> <li>1. Start the SAP HANA Web Dispatcher Administration tool at <code>http://&lt;localhost&gt;:80&lt;instance&gt;/sap/hana/xs/wdisp/admin/</code>.</li> <li>2. For each tenant database and the system database, create a new trust store with a unique certificate: <ol style="list-style-type: none"> <li>1. From the main menu, choose <b>SSL and Trust Configuration</b> <b>PSE Management</b>.</li> <li>2. On the PSE management screen, choose <i>Create New PSE</i>.</li> <li>3. Enter a file name for the new PSE.</li> </ol> <div data-bbox="497 1552 1394 1659" data-label="Complex-Block"> <p><b>❖ Example</b></p> <p>example.pse</p> </div> <ol style="list-style-type: none"> <li>4. Enter the distinguished name: <p><b>CN=&lt;host name used for the tenant database in the public_urls section of the xsengine.ini file&gt;</b></p> </li> <li>5. Choose <i>Create</i>.</li> <li>6. For the new PSE, create a certificate request and submit to your CA for signing (<i>Create CA Response</i>).</li> <li>7. Import the signed certificate into the new PSE (<i>Import CA Response</i>).</li> </ol> </li> <li>3. Configure the Web Dispatcher to use multiple certificates:</li> </ol>
--	--

Option	Description
	<ol style="list-style-type: none"> <li>In the <code>webdispatcher.ini</code> file, create or change the parameter <code>[profile] icm/ssl_config_0</code>, specifying as the value:  <b>ID=ssl_config_main, CRED=SAPSSLS.pse, SNI_CREDS=&lt;semicolon (';') separated list of database PSE files&gt;</b></li> <li>Add <b>,SSLCONFIG=ssl_config_main</b> to the value of the <code>icm/server_port</code> parameter for the HTTPS port (by default <code>icm/server_port_1</code>).</li> </ol>
	<p><b>❖ Example</b></p> <pre>icm/server_port_1 = PROT=HTTPS,PORT=4443\$(SAPSYSTEM),PROCTIMEOUT=600, SSLCONFIG=ssl_config_main</pre>

## Results

You can access the XS server of tenant databases via the configured URLs.

### → Tip

If you experience slow response times when accessing the XS server of a tenant database (for example, Web-based applications running on the tenant database), this indicates that the server is not able to resolve the host name correctly using the DNS and retries repeatedly. If this is the case, contact your network administrator for a detailed problem analysis.

As a workaround, you can manually override virtual host name resolution on the machine where the browser is running by modifying the `/etc/hosts` file on the local machine. In this file, append a new line, starting with the static IP address of the server, followed by the virtual host name of your tenant database, for example, "10.20.30.40 mydatabase.example.com". To edit this file you need admin or root privileges.

## Next Steps

Optional: Enable access to Web-based applications from the SAP HANA studio.

Some Web-based tools are accessible from the SAP HANA studio, for example, the SAP HANA cockpit and SAP HANA Lifecycle Management tool. If you want to be able to access these tools from a tenant database registered in the studio, you must specify the alias hostname in the properties. You can do this as follows:

- In the *Systems* view, right-click the tenant database and choose *Properties*.
- Open the *XS Properties* page and enter the alias hostname in the *XS Host* field.

[Using SAP Web Dispatcher for Load Balancing with Tenant Databases \[page 290\]](#)

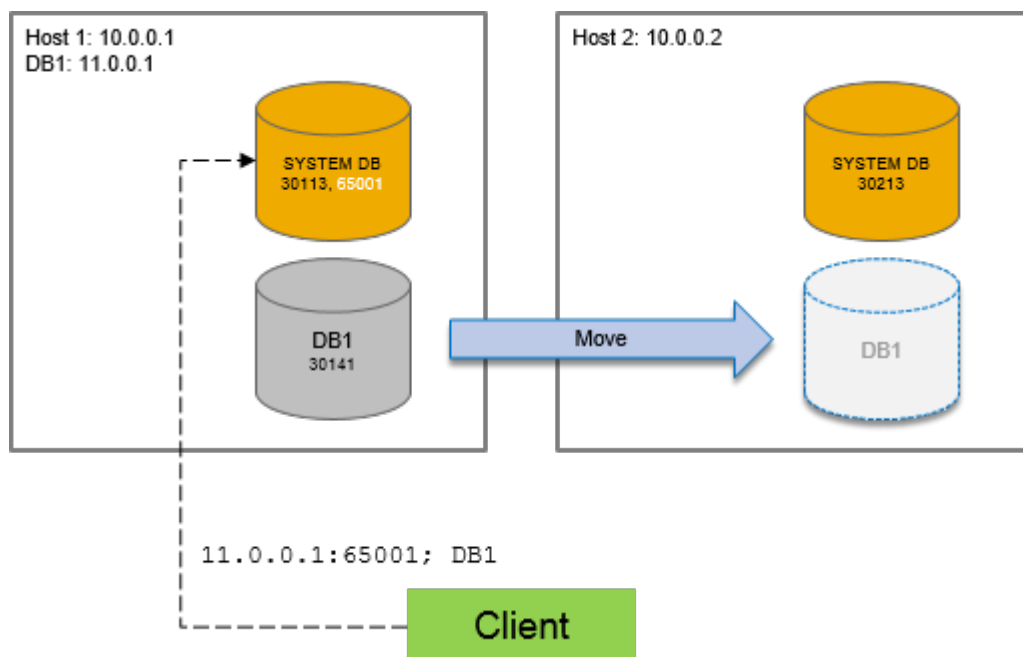

## 6.3.1.15 Configure Host-Independent Tenant Addresses

You can configure the access to tenant databases to be independent of the SAP HANA system ID number by mapping additional ports to a tenant database.

### Context

The client connection to a tenant database is established over port 3<instance\_no>13 of the system database. If a tenant database is moved to another system, the instance number of the system and consequently the connection port will change. To establish a connection independent of its current host, you can specify additional port numbers and map them to the tenants.

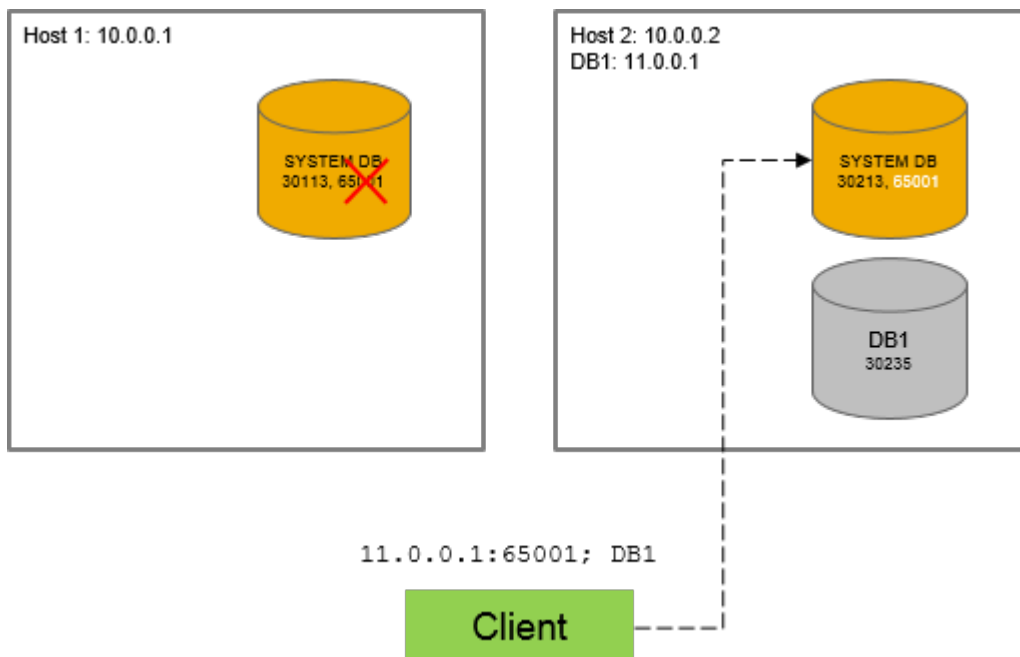

Configure a connection that is independent of the actual host IP address by mapping an IP address to each tenant database at operating system level. Add an additional port on which the system database listens for incoming connections. A client connection is then established by calling the IP address of the tenant, the name of the tenant database and the additional listen port.

### Sample Code

```
SERVERNODE=11.0.0.1:65001;UID=dbuser;PWD=Aa123456;DATABASENAME=DB1
```

Once the tenant was moved to the target system, the additional listen port has to be removed on the source system and added on the target system. The tenant-specific IP address must be added for the target host at operating system level. A client connection to the tenant database can still be established with the same information as before the move.

## Procedure

Configure additional ports on which the system database listens in addition to port 3<instance\_no>13. Any available port number except 0 is permitted.

You can do this by executing the following SQL statement:

```
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini' , 'system') SET ('multidb' , 'listenports' ) = '<port1>[,<port2>...]' WITH RECONFIGURE;
```

## Next Steps

To remove all additional ports for a tenant database, execute the following SQL statement:

```
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini' , 'system') UNSET ('multidb' , 'listenports' ) WITH RECONFIGURE;
```

## Related Information

[Copying and Moving Tenant Databases \[page 1137\]](#)

## 6.3.1.16 Create a Fallback Snapshot

Create a fallback snapshot of a tenant database. You can revert the state of a tenant database to a specific point in time if needed.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the privilege `DATABASE ADMIN`.
- You are connected to the system database.

### Context

You can create a fallback snapshot for a tenant database. It allows you to revert to a particular database state. If you no longer need the fallback snapshot, you can delete it.

A fallback snapshot can be useful if you perform changes to the contents of a database that you need to roll back quickly, for example, if you upgrade to a new version of an application.

Fallback snapshots can only be created for tenant databases. Configuration changes aren't included. You can only have one fallback snapshot per tenant database. You must delete the existing snapshot before creating a new one. A service can't be added or removed if a fallback snapshot already exists.

A fallback snapshot doesn't replace a database backup. A fallback snapshot isn't included in a database backup. You can create a fallback snapshot when the tenant database is running in the primary system of a system replication setup with the following restrictions:

- Delete any existing fallback snapshots on the primary system before configuring system replication.
- The operation mode for system replication must be `logreplay` or `logreplay_readaccess`.
- Fallback snapshots are propagated to the secondary system with the continuous log shipping. If a full data shipping is needed to resync the primary and the secondary, the fallback snapshot isn't available on the secondary afterwards.

You can also create a fallback snapshot by executing the `ALTER DATABASE` statement in the system database:

```
ALTER DATABASE <database name> CREATE FALLBACK SNAPSHOT;
```

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database for which you want to create a fallback snapshot.
3. Select **▶ Fallback Snapshot ▶ Create Fallback Snapshot ▶**.

## Results

A fallback snapshot is created. You can verify creation by querying the system view `SYS_DATABASES.M_SNAPSHOTS`.

## Related Information

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

[Delete a Fallback Snapshot \[page 254\]](#)

[Operation Modes for SAP HANA System Replication](#)

### 6.3.1.17 Reset to a Fallback Snapshot

Reset a tenant database to a fallback snapshot.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the privilege `DATABASE ADMIN`.
- You are connected to the system database.

## Context

Resetting can be useful if you performed changes to the contents of a database that you need to roll back quickly.

You can also start a tenant database from a fallback snapshot by executing the `ALTER DATABASE` statement in the system database:

```
ALTER SYSTEM START DATABASE <database name> FROM FALLBACK SNAPSHOT;
```

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database that you want to revert to the state captured in the fallback snapshot.
3. Select [▶ Fallback Snapshot ▶ Reset to Fallback Snapshot ▶](#).

The tenant database is reset to the state captured in the fallback snapshot.

## Results

The fallback snapshot will remain available after the reset. If you no longer need the fallback snapshot, delete it.

## Related Information

[Create a Fallback Snapshot \[page 252\]](#)

[Delete a Fallback Snapshot \[page 254\]](#)

### 6.3.1.18 Delete a Fallback Snapshot

Delete a fallback snapshot of a tenant database.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the privilege `DATABASE ADMIN`.
- You are connected to the system database.

## Context

You can only create one fallback snapshot per tenant database. If you need to create a new fallback snapshot, delete the existing one first.

You can also delete a fallback snapshot by executing the `ALTER DATABASE` statement in the system database:

```
ALTER DATABASE <database name> DROP FALLBACK SNAPSHOT;
```

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant database for which you want to delete a fallback snapshot.
3. Select ► [Fallback Snapshot](#) ► [Delete Fallback Snapshot](#) ►.

## Related Information

[Create a Fallback Snapshot \[page 252\]](#)

[Reset to a Fallback Snapshot \[page 253\]](#)

### 6.3.1.19 Prevent the Start of a Tenant Database at System Startup

Prevent the start of individual tenant databases.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege DATABASE ADMIN.

## Context

By default, all tenant databases that were running before the SAP HANA system was stopped are restarted upon system startup. For troubleshooting purposes, you may want to prevent a particular database from starting until the issue is resolved. You can also prevent startup using the ALTER DATABASE statement.

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant.
3. Click the [Tenant Actions](#) dropdown menu and select [Set Restart Mode](#) .

4. Select *No auto-restart*.
5. (Optional) To display the restart mode of all tenants through the  (*Setting*) icon and select *Restart Mode*.

## Results

Alternatively, you can prevent a tenant restart by executing the ALTER DATABASE statement:

```
ALTER DATABASE database_name NO RESTART
```

The tenant database isn't started after a system restart. You can verify the mode by querying the public view M\_DATABASES. The result looks like this:

DATABASE_NAME	DESCRIPTION	RESTART_MODE
SYSTEMDB	SystemDB-<SID>-<INSTANCE>	DEFAULT
<SID>	SingleDB-<SID>-<INSTANCE>	NO

To restore the default behavior, execute the following ALTER DATABASE statement:

```
ALTER DATABASE <database_name> DEFAULT RESTART
```

Then, start the tenant database manually. At the next system startup, the tenant database will be restarted.

## Related Information

[Start a Tenant Database \[page 228\]](#)

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

## 6.3.1.20 Copy or Move a Tenant Database Using Replication

Use system replication to copy or move a tenant database from one system to another.

### Prerequisites

- You have configured tenant replication.
- You've navigated to the *Database Overview* page of the system database of the source or target system. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the system privilege DATABASE ADMIN.
- You have created a complete system backup for the source tenant database.

### ⚠ Caution

When you use the cockpit to move a tenant, the source database is deleted as part of the process. If the source is running SAP HANA 2.0 SP01 or earlier, its backups are also deleted as part of the process—you can't roll back! Before moving, SAP recommends that you run a backup, then replicate the backup to a new location.

- For the target (the database where you're putting the moved or copied database):
  - You must have the system privileges `DATABASE ADMIN`.
- If the system is configured for high isolation, the operating system (OS) user and group required for the new tenant database already exist. For more information, see *Database Isolation* in the *SAP HANA Administration Guide*.
- You are logged in to the system database (SYSTEMDB).

## Context

For more information, see *Copying and Moving Tenant Databases Between Systems* in the *SAP HANA Administration Guide*.

## Procedure

1. At the top of the *Database Overview* page, click *Database Management*.
2. To copy or move a tenant to another system, choose ► *Tenant Actions* ► *Replicate Tenant* ▾. If you want to create a new tenant based on an existing tenant, choose ► *Create Tenant* ► *Create Tenant Using Replication* ▾. For more information, see *Create a Tenant Database Using Replication*.
3. To create a copy of an existing tenant database, select *Copy using replication*. To remove the original tenant after the copy has been created, select *Move using replication*.
4. Select the source database and tenant.
5. Enter a name for the new tenant.

Restrictions apply to tenant names. Alphanumeric string of uppercase alpha characters [A-Z], digits [0-9] are permitted, starting with a letter. Depending on the file system, tenant names with up to 253 characters are supported.

6. (Optional) Specify the number of the internal communication port of the listed services.

Under *Advanced Settings*, specify the port number for each service. If you don't enter a port, it's assigned automatically based on port number availability. In multihost systems enter host and port of a service. For more information about port number assignment, see *Connections for Tenant Databases* in the *SAP HANA Master Guide*.
7. (For high isolation system only) Enter a dedicated OS user and group for the source.
8. If configuration changes are required for the replication, warnings appear to indicate the required changes. Select *Approve* to proceed.

You may see a warning that you do not have the privilege required to check if the databases are fully configured for tenant replication. Please contact your system administrator to make sure that tenant replication has been properly configured.

9. If prompted, enter the SAP Control credentials required for the restart of the system.
10. If a trust relationship has not yet been established between the source system and the target system, select an existing public key certificate or upload a certificate.
11. Review the summary, then choose [Copy Tenant Database](#) or [Move Tenant Database](#) to start replicating the tenant database.

## Next Steps

Register the new tenant in SAP HANA Cockpit Manager so it can be managed by SAP HANA Cockpit.

## Related Information

### 6.3.1.21 Reset the SYSTEM Password of a Tenant Using the Cockpit

If the password of the SYSTEM user in a tenant database is unknown, you can reset it from the system database.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- There's no user available with the system privilege USER ADMIN that can reset the SYSTEM user password.

#### **i** Note

If you can log on as SYSTEM or another user with the system privilege USER ADMIN, don't use the procedure described here to change the password of the SYSTEM user. Instead, change the password using the [User](#) editor in SAP HANA cockpit

- You're connected to the system database and have the system privilege DATABASE ADMIN.

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Select the tenant and click [Stop](#).  
Once stopped, its status changes to [Not running](#).
3. Click [Tenant Actions](#) and then [Reset SYSTEM Password](#).
4. Enter and confirm a new temporary password for the SYSTEM user.
5. Select [Reset Password & Restart](#).

## Results

- The password for the SYSTEM user is reset and the tenant database is restarted.
- The next time you log on with the SYSTEM user, you will be prompted to change the password in line with the password policy of the tenant database
- If the SYSTEM user was previously deactivated, locked, or expired, it's now activated again. In this case, we recommend that you return it to its deactivated state.
- If auditing is enabled, the password change is automatically logged in both the system and tenant database audit trails.

## Related Information

## 6.3.2 Monitoring and Managing Tenant Databases

To ensure the overall performance and stability of an SAP HANA system, you as the system administrator can monitor all tenant databases in the system using the system database. You also can perform administration tasks such as stopping and starting tenant databases, or adding and removing services.

### i Note

Administration of tenant databases is possible using the SAP HANA cockpit. However, command-line tools are required for some tasks.

## Support Model

The following is the general approach for analyzing and resolving issues in tenant databases:

1. Tenant database administrators analyze issues in their tenant databases using the available diagnosis and trace files.
2. If tenant database administrators discover issues that they cannot analyze using diagnosis and trace files, they contact the system administrator.
3. The system administrator can first check the health of the tenant database in the system database by analyzing the monitoring data available in the SYS\_DATABASES schema.
4. If the system administrator cannot see what the problem is from the system database, the tenant database administrator needs to provide him with the necessary privileges to access the tenant database directly so that the system administrator can analyze the issue there.

## Related Information

### 6.3.2.1 Monitoring Tenant Databases in SAP HANA Cockpit

As the tenant database administrator, you can monitor the availability, resource usage, and performance of tenant databases in the SAP HANA cockpit from the system database.

Aggregate database information is available on the [Database Overview](#) page of the system database. Clicking the [Database Management](#) link displays information about all databases in your system and allows you to monitor and administer your tenant database. You can also create new tenant databases on this page.

You can use the cockpit to monitor and manage more than one database, each running version SAP HANA 1.0 SPS 12 or later. Any database running version SAP HANA 2.0 SPS 01 or later is set in multiple-container mode by default. The cockpit can also monitor single-container systems running earlier versions of SAP HANA. When you access the [Manage Services](#) application, the operations you have the option to perform depend on whether you are displaying a tenant or a system database.

#### i Note

To perform operations on a tenant database, you have the system privilege DATABASE ADMIN.

## Related Information

### 6.3.2.1.1 Database Details

The [Manage Databases](#) page provides you with detailed information about all databases, as well as several drill-down options for more detailed information about individual databases.

The following table lists the information available for databases, as well as the available drill-down option.

Column	Description	Drill-Down Option
<a href="#">Database Name</a>	Name of the tenant database	Click the database name to open the Overview, from which you can drill down to the <a href="#">Manage Services</a> page.  <a href="#">Manage Services</a> allows you to analyze the status and resource usage of the individual services of the database. For more information, see <a href="#">Service Details</a> . From <a href="#">Manage Services</a> , you can also stop and start services.
<a href="#">Status</a>	Status of the database: <ul style="list-style-type: none"><li>• Redistribution Running: A table redistribution plan has been executed</li><li>• Deleting: Database is being deleted</li><li>• Error: Database is in an error state</li><li>• Running with Issues: At least one service isn't running, or there is at least one high alert</li><li>• Maintenance: Database is in enforced maintenance mode</li><li>• Replicating: Database is undergoing replication</li><li>• Running: Database is running</li><li>• Starting: Database is starting</li><li>• Stopped: Database is stopped</li><li>• Stopping: Database is stopping</li><li>• Transitioning: Database is transitioning (starting or stopping)</li><li>• Unknown: Database is in an unknown state</li></ul>	No specific drill-down
<a href="#">Start Time</a>	The time of the most recent start of the database	No specific drill-down

Column	Description	Drill-Down Option
<a href="#">Alerts</a>	The number of high and medium priority alerts in the database	<p>Click the number of alerts to open them on the <a href="#">Alerts</a> page</p> <p><a href="#">Alerts</a> allows you to view and analyze alerts occurring in the database. You can view past occurrences of alerts. For more information, see <a href="#">Alert Details</a> and <a href="#">Alert Priorities</a>. You can also see how alerts are configured. For more information, see <a href="#">Alert Checker Details</a> and <a href="#">Alert Checker Statuses</a>.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Only those alerts that identify situations with a potentially system-wide impact are visible, for example, the physical memory on a host is running out. Alerts that expose data in the tenant database (for example, table names) are <b>not</b> visible to the system administrator in the system database.</p> </div>
<a href="#">Used Memory</a>	The used memory of the database in relation to the system	<p>Click the used memory bar to open the <a href="#">Performance Monitor</a> app</p> <p>The <a href="#">Performance Monitor</a> app allows you to visually analyze historical performance in the database across a range of related performance indicators. For more information, see <a href="#">Key Performance Indicators</a>.</p>
<a href="#">CPU Usage</a>	The CPU usage of the database in relation to the system	<p>Click the CPU usage bar to open the <a href="#">Performance Monitor</a> app</p> <p>The <a href="#">Performance Monitor</a> app allows you to visually analyze historical performance in the database across a range of related performance indicators. For more information, see <a href="#">Key Performance Indicators</a>.</p>
<a href="#">Disk Usage</a>	The disk usage of the database in relation to the system	<p>Click the disk usage bar to open the <a href="#">Performance Monitor</a> app</p> <p>The <a href="#">Performance Monitor</a> app allows you to visually analyze historical performance in the database across a range of related performance indicators. For more information, see <a href="#">Key Performance Indicators</a>.</p>
<a href="#">Fallback Snapshot</a>	Lists whether a fallback snapshot is available. A fallback snapshot can be useful if you perform changes to the contents of a database that you need to roll back quickly.	No specific drill-down

### 6.3.2.1.2 Service Details

*Manage Services* provides you with detailed information about database services for an individual database.

#### i Note

Not all of the columns listed below are visible by default. You can add and remove columns in the Columns dialog, which you open by clicking the  (*Settings*) icon in the table toolbar.

The following table lists the information available for services.

Column	Description
Host	Name of the host on which the service is running
Service	Service name, for example, indexserver, nameserver, xsengine, and so on
Status	<p>The status of the service</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"><li>• <i>Running</i></li><li>• <i>Running with Issues</i> (where at least one service isn't running, or there is at least one high alert)</li><li>• <i>Starting</i></li><li>• <i>Stopping</i></li><li>• <i>Stopped</i></li><li>• <i>Not Running</i></li></ul> <p>To investigate why the service isn't running, you can navigate to the crash dump file created when the service stopped.</p>

#### i Note

The crash dump file opens in the *Trace* tool of the SAP HANA Web-based Development Workbench. To see this information, you need the role `sap.hana.xs.ide.roles::TraceViewer` or the parent role `sap.hana.xs.ide.roles::Developer`.

Column	Description
Role	<p>Role of the service in a failover situation</p> <p>Automatic failover takes place when the service or the host on which the service is running fails.</p> <p>The following values are possible:</p> <ul style="list-style-type: none"> <li>• <i>Master</i> The service is the active master worker.</li> <li>• No entry The service is a slave worker.</li> <li>• <i>Standby</i> The service is in standby mode. It doesn't contain any data and doesn't receive any requests.</li> </ul>
Port	Port that the system uses for internal communication between services
Start Time	<p>Time at which the service started</p> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b> The time is given in the timezone of the SAP HANA server.</p> </div>
Service Alerts	Alerts triggered for the service.
Process ID	Process ID
CPU	<p>Mini chart visualizing the CPU usage of the service</p> <p>Clicking the mini chart opens the <i>Performance Monitor</i> for a more detailed breakdown of CPU usage.</p>
Memory	<p>Mini chart visualizing the memory usage of the service</p> <ul style="list-style-type: none"> <li>• Dark green shows the service's used memory.</li> <li>• Light green shows the service's peak memory.</li> <li>• The gray stroke represents the effective allocation limit.</li> <li>• The light gray background represents the physical memory.</li> </ul> <p>Clicking the mini chart opens the <i>Memory Analysis</i> app for a more detailed breakdown of memory usage.</p>
Used Memory (MB)	<p>Amount of memory currently used by the service</p> <p>Clicking the mini chart opens the <i>Memory Analysis</i> app for a more detailed breakdown of memory usage.</p>
Peak Memory (MB)	Highest amount of memory ever used by the service
Effective Allocation Limit (MB)	Effective maximum memory pool size that is available to the process considering the current memory pool sizes of other processes
Physical Memory on Host (MB)	Total memory available on the host
All Process Memory on Host (MB)	Total used physical memory and swap memory on the host
Allocated Heap Memory (MB)	Heap part of the allocated memory pool

Column	Description
Allocated Shared Memory (MB)	Shared memory part of the allocated memory pool
Allocation Limit (MB)	Maximum size of allocated memory pool
CPU Process Usage (%)	CPU usage of process
CPU Host (%)	CPU usage on host
Virtual Memory on Host (MB)	Virtual memory size on the host
Process Physical Memory (MB)	Process physical memory used
Process Virtual Memory (MB)	Process virtual memory
Shrinkable Size of Caches (MB)	Memory that can actually be freed in the event of a memory shortage
Size of Caches (MB)	Part of the allocated memory pool that can potentially be freed in the event of a memory shortage
Size of Shared Libraries (MB)	Code size, including shared libraries
Size of Thread Stacks (MB)	Size of service thread call stacks
Used Heap Memory (MB)	Process heap memory used
Used Shared Memory (MB)	Process shared memory used
SQL Port	SQL port number
Action	The available action for the service
<a href="#">Reset Memory Statistics</a>	Resets all memory statistics for all services.  Peak used memory is the highest recorded value for used memory since the last time the memory statistics were reset. This value is useful for understanding the behavior of used memory over time and under peak loads. Resetting peak used memory allows you, for example, to establish the impact of a certain workload on memory usage. If you reset peak used memory and run the workload, then you can then examine the new peak used memory value.
<a href="#">Go To Alerts</a>	Displays the alerts for this database.

[Monitoring Alerts](#)

## 6.3.2.1.3 Key Performance Indicators

The *Performance Monitor* allows you select a range of host-level and service-level KPIs to analyze historical performance data of the SAP HANA database.

### Host KPIs

KPI	Description
CPU	CPU used by all processes related to the operating system (OS)
Database resident memory	Physical memory used by all SAP HANA database processes
Total resident memory	Physical memory used by all OS processes
Physical memory size	Total physical memory
Database used memory	Memory used by all SAP HANA database processes
Database allocation limit	Memory allocation limit for all SAP HANA database processes
Disk used	Disk space used by data, log, and trace files belonging to the SAP HANA database
Disk size	Total disk size
Network in	Bytes read from the network by all processes
Network out	Bytes written to the network by all processes
Swap in	Bytes read from swap memory by all processes
Swap out	Bytes written to swap memory by all processes

### Services KPIs

KPI	Description
CPU	CPU used by the database process
System CPU	CPU used by the database process relative to the operating system
Memory used	Memory used by the database process
Memory allocation limit	Effective allocation limit of the database process
Handles	Number of open handles in the index server process
Ping time	Indexserver ping time including nsWatchdog request and collection of service-specific KPIs
Swap in	Bytes read from swap by the process
Open connections	Number of open SQL connections
Open transactions	Number of open SQL transactions

<b>KPI</b>	<b>Description</b>
Blocked transactions	Number of blocked SQL transactions
Statements	Number of finished SQL statements
Active commit ID range	Range between newest and oldest active commit ID
Pending session request count	Number of pending requests
Active versions	Number of active MVCC versions
Acquired record locks	Number of acquire record locks
Read requests	Number of read requests (selects)
Write requests	Number of write requests (insert, update, and delete)
Merge requests	Number of merge requests
Column unloads	Number of table and column unloads
Active threads	Number of active threads
Waiting threads	Number of waiting threads
Total threads	Total number of threads
Active SqlExecutors	Total number of active SqlExecutor threads
Waiting SqlExecutors	Total number of waiting SqlExecutor threads
Total SqlExecutors	Total number of SqlExecutor threads
Data write size	Bytes written to data area
Data write time	Time used for writing to data area
Log write size	Bytes written to log area
Log write time	Time used for writing to log area
Data read size	Bytes read from data area
Data read time	Time used for reading from data area
Log read size	Bytes read from log area
Log read time	Time used for reading from log area
Data backup write size	Bytes written to data backup
Data backup write time	Time used for writing to data backup
Log backup write size	Bytes written to log backup
Log backup write time	Time used for writing to log backup
Mutex Collisions	Number of collisions on mutexes
Read/Write Lock Collisions	Number of collisions on read/write locks

## Related Information

[Memory Usage in the SAP HANA Database](#)

## 6.3.2.1.4 Monitor Alerts for a Tenant Database

Alert situations in tenant databases can potentially impact the health of the overall system. For this reason, you as system administrator can monitor alerts occurring in individual tenant databases. You can monitor from the system database in the SAP HANA cockpit.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- To be able to drill down to the alert information of a tenant database, you must have registered it as a database in the cockpit.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Open the alerts of a particular database by clicking the number of alerts indicated for that database in the [Alerts](#) column.

#### → Tip

You can also access database-specific alerts from [Alerts](#) in the [Manage Databases](#) app.

### Next Steps

It can be helpful to see how alerts are configured in individual tenant databases. To navigate to the configuration of alert checkers from the [Alerts](#) app, click [Alert Definitions](#) on the top right-hand corner.

### Related Information

[Using the Database Overview Page to Manage a Database \[page 340\]](#)

[Services \[page 348\]](#)

[Alerts \(SAP HANA Cockpit\)](#)

## 6.3.2.1.4.1 Alert Details

When you select an alert, detailed information about the alert is displayed on the right.

The following detailed information about an alert is available:

Detail	Description
Category	<p>The category of the alert checker that issued the alert</p> <p>Alert checkers are grouped into categories, for example, those related to memory usage those related to transaction management and so on.</p>
Source	<p>Where the alert came from, whether the database itself, or a service such as SAP EarlyWatch Alert service.</p>
Next Scheduled Run	<p>When the related alert checker is next scheduled to run</p> <p>If the alert checker has been switched off (alert checker status <i>Switched Off</i>) or it failed the last time it ran (alert checker status <i>Failed</i>), this field is empty because the alert checker is no longer scheduled.</p>
Interval	<p>The frequency with which the related alert checker runs</p> <p>If the alert checker has been switched off (alert checker status <i>Switched Off</i>) or it failed the last time it ran (alert checker status <i>Failed</i>), this field is empty because the alert checker is no longer scheduled.</p>
Alerting Host & Port	<p>Name and port of the host that issued the alert</p> <p>In a system replication scenario, alerts issued by secondary system hosts can be identified here. This allows you to ensure availability of secondary systems by addressing issues before an actual failover.</p> <p>For more information about monitoring secondary systems in SAP HANA, see <i>Monitoring Secondary Sites</i> in the <i>SAP HANA Administration Guide</i>.</p>
Alert Checker	<p>Name and description of the related alert checker</p>
Proposed Solution	<p>Possible ways of resolving the problem identified in the alert, with a link to the supporting app, if available</p>
Past Occurrences of Alert	<p>Configurable graphical display indicating how often the alert occurred in the past</p>

## Related Information

[Monitoring Secondary Systems \[page 1342\]](#)

## 6.3.2.1.4.2 Alert Priorities

The priority of an alert indicates the severity of the problem and how quickly action needs to be taken.

Priority	Description
Information	Action recommended to improve system performance or stability
Low	Medium-term action required to mitigate the risk of downtime
Medium	Short-term action required (few hours, days) to mitigate the risk of downtime
High	Immediate action required to mitigate the risk of downtime, data loss, or data corruption

## 6.3.2.1.4.3 Alert Checker Details

When you select an alert checker [Alert Configuration](#), detailed information about the alert checker and its configuration is displayed on the right.

The following detailed information about an alert checker is available:

Detail	Description
Header information	The name of the alert checker, its status, and the last time it ran
Description	Description of what the alert checker does, for example what performance indicator it measures or what setting it verifies
Alert Checker ID	The unique ID of the alert checker
Category	The category of the alert checker  Alert checkers are grouped into categories, for example those related to memory usage, those related to transaction management, and so on.
Threshold Values for Prioritized Alerting	The values that trigger high, medium, low, and information alerts issued by the alert checker  The threshold values and the unit depend on what the alert checker does. For example, alert checker 2 measures what percentage of disk space is currently used so its thresholds are percentage values.
	<b>i Note</b>  Thresholds can be configured for any alert checker that measures variable values that should stay within certain ranges, for example, the percentage of physical memory used or the age of the most recent data backup. Many alert checkers verify only whether a certain situation exists or not. Threshold values <b>cannot</b> be configured for these alert checkers. For example, alert checker 4 detects services restarts. If a service was restarted, an alert is issued.
Interval	The frequency with which the alert checker runs

Detail	Description
Schedule Active	Indicator of whether the alert checker is running automatically at the configured interval
Proposed Solution	Possible ways of resolving the problem identified by the alert checker

## Related Information

[Alert Checker Statuses \[page 271\]](#)

[Configure Alert Thresholds \[page 375\]](#)

### 6.3.2.1.4.4 Alert Checker Statuses

The status of an alert checker indicates whether it is running on schedule, it has failed and been disabled by the system, or you switched it off.

Status	Description
Active	The alert checker is running on schedule.
Failed	<p>The alert checker failed the last time it ran (for example due to a shortage of system resources), so the system disabled it.</p> <p>The alert checker remains disabled for a specific length of time before it is automatically re-enabled. This length of time is calculated based on the values in the following columns of the table STATISTICS_SCHEDULE (_SYS_STATISTICS):</p> <ul style="list-style-type: none"> <li>• INTERVALLENGTH</li> <li>• SKIP_INTERVAL_ON_DISABLE</li> </ul> <p>Once <math>INTERVALLENGTH \times SKIP\_INTERVAL\_ON\_DISABLE</math> has elapsed, the alert checker is re-enabled. The default values for all alert checkers are such that failed checkers remain disabled for 1 hour. The system determines the status of every alert checker and/or whether the time to re-enablement has elapsed every 60 seconds.</p> <p>You can also re-enable the alert checker manually by switching it back on in <a href="#">Alert Configuration</a>.</p>
Switched Off	<p>You switched off the alert checker schedule.</p> <p>If you want the alert checker to run again automatically, you must manually switch it back on.</p>

## Related Information

[Switch Alerts Off/On \[page 376\]](#)

## 6.3.2.2 Add or Remove Services in a Tenant Database

Add or remove services in the tenant database.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Add a Service

### Prerequisites

- You are connected to the system database.
- You have:
  - The system privilege DATABASE ADMIN.
  - The EXECUTE privilege on the stored procedure SYS.UPDATE\_LANDSCAPE\_CONFIGURATION.

### Context

You can only add services when connected to the SYSTEMDB.

### Procedure

1. On the [Database Overview](#) of the system database, click [Databases Management](#).
2. In the [Status](#) column, click the status message of the tenant being managed.

The [Manage Services](#) page for the tenant opens.

#### Caution

If you click the database name instead of the status message, you are disconnected from SYSTEMDB and connected to the tenant. The [Database Overview](#) page for the tenant opens instead of the [Manage Services](#) page.

3. Click [▶ Manage Services ▶ Add Service ▶](#).
4. Select a service from the list.
5. Select a host and enter its port, or allow a host to be auto-assigned.

## Results

After database creation, the xsengine service automatically runs embedded in the (master) index server. If you add a separate xsengine service, the embedded service is stopped and removed.

You can't add a statisticsserver service. This service always runs embedded in the master index server of a tenant database.

There are other services available to add or remove if you've installed an SAP HANA capability (such as SAP dynamic tiering), and the host has been added to the SAP HANA SYSTEM DB.

### Results

- New data and log volumes are created on the host and the information is entered in the system landscape information of system database.
- The service is added to the M\_SERVICES system view.
- The service is started.

## Remove a Service

### Prerequisites

- You have the RESOURCE ADMIN and CATALOG READ system privileges.
- You have the SELECT privilege on \_SYS\_STATISTICS

### Context

You can remove a service from a tenant when connected to either the SYSTEMDB or the tenant. You access the [Manage Services](#) page for the tenant differently depending on your connection method.

### Procedure

1. Choose one of the following options:

Method	Action
Connected to SYSTEMDB	<ol style="list-style-type: none"> <li>At the top of the <i>Database Overview</i> page, click <i>Database Management</i>.</li> <li>In the <i>Status</i> column, click the status message of the tenant being managed.</li> </ol>
Connected to the tenant	<ol style="list-style-type: none"> <li>On the <i>Database Overview</i> with the <i>Monitoring</i> or <i>All</i> view selected, click <i>Manage Services</i> on the <i>Services</i> card.</li> </ol>

- Select the service to remove.

Not all services can be removed. You can't remove a global service, the master indexserver, or the primary indexserver on a host.

- Choose one of the following options:

Method	Action
Connected to SYSTEMDB	Click ► <i>Manage Services</i> ► <i>Remove Service</i> ►.
Connected to the tenant	Click <i>Remove Service</i> .

- Confirm the removal.

## Results

- Data volumes and traces files are removed. The data of the index server is distributed across the remaining index server instances.
- The service is removed from the M\_SERVICES system view.
- The service is stopped and removed from the system landscape information of system database.

## Related Information

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

## 6.3.2.3 Start and Stop Services in a Tenant Database

Start, stop, or kill services in the tenant database.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Start Missing Services

### Prerequisites

- You are be connected to the system database.
- You have the system privilege DATABASE ADMIN.

### Context

You can only start missing services when connected to the SYSTEMDB.

### Procedure

1. On the [Database Overview](#) of the system database, click [Databases Management](#).
2. In the [Status](#) column, click the status message of the tenant being managed

The [Manage Services](#) page for the tenant opens.

#### Caution

If you click the database name instead of the status message, you are disconnected from SYSTEMDB and connected to the tenant. The [Database Overview](#) page for the tenant opens instead of the [Manage Services](#) page.

3. Click [Stat Missing Services](#).

# Stop or Kill a Service

## Prerequisites

- You have the system privilege RESOURCE ADMIN.

## Context

You can stop or kill a service from a tenant when connected to either the SYSTEMDB or the tenant. You access the [Manage Services](#) page for the tenant differently depending on your connection method.

## Procedure

1. Choose one of the following options:

Method	Action
Connected to SYSTEMDB	<ol style="list-style-type: none"><li>1. At the top of the <a href="#">Database Overview</a> page, click <a href="#">Database Management</a>.</li><li>2. In the <a href="#">Status</a> column, click the status message of the tenant being managed.</li></ol>
Connected to the tenant	<ol style="list-style-type: none"><li>1. On the <a href="#">Database Overview</a> with the <a href="#">Monitoring</a> or <a href="#">All</a> view selected, click <a href="#">Manage Services</a> on the <a href="#">Services</a> card.</li></ol>

2. Select the service to stop or kill.
3. Click [Kill Service](#) or [Stop Service](#).
4. Confirm the stop or kill.

## 6.3.2.4 Change the Port of a Service in a Tenant Database

You can change the port of a service in the SAP HANA cockpit.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- The database user (with which you've connected to the database) must have the system privilege DATABASE ADMIN.

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. To change the port of a service, select [Manage Services](#) [Change Port](#).
3. In the [Change Port](#) dialog, select the [New Port](#) for the service.
4. Optional: If reserved instances are configured for the host, you can choose to select ports available on another instance.

### i Note

The default port number range for tenant databases is 3<instance>40—3<instance>99. This means that the maximum number of tenant databases that can be created per instance is 20. However, you can increase this by reserving the port numbers of further instances.

5. Optional: Start the service after changing the port.

By default, the service isn't started after the port is changed. If you want the service to be started after the port is changed, enable the [Start Automatically](#) option.

## Related Information

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

### 6.3.2.5 Restrict Features Available to a Tenant Database

To safeguard and/or customize your system, certain features of the SAP HANA database can be disabled in tenant databases.

## Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See [Getting to the Database Overview Page](#) in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege INIFILE ADMIN.

## Context

Some features of the SAP HANA database aren't required or desirable in certain environments, in particular features that provide direct access to the file system, the network, or other resources. To maximize your control

over the security of your system, you can disable these features in tenant databases, for example import and export operations or the ability to back up the database.

The system view `M_CUSTOMIZABLE_FUNCTIONALITIES` provides information about those features that can be disabled and their status. This view exists in both the `SYS` schema of every database, where it contains database-specific information, and in the `SYS_DATABASES` schema of the system database, where it contains information about the enablement of features in all databases.

For more information about the features that can be disabled and why, see *Restricted Features in Tenant Databases* in the *SAP HANA Tenant Databases*.

You can disable features in tenant databases in the `customizable_functionalities` section of the `global.ini` file, as well as in the SAP HANA cockpit as described here.

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Click [Restricted Features](#).
3. Click the tenant to restrict its features.
4. Select or clear the features to restrict.

### Note

The information in the [Layer](#) column indicates where the feature was defined. If a feature isn't defined at the database, then system-defined values are used. If there are no system-defined values, then default values are used. Thus, if you choose to restrict a system-defined value, it's restricted on all of the system's tenants.

5. (Optional) To delete a feature, you must be viewing the tenant or system in which it was defined. Select the delete icon at the end of the row.

### Note

If you delete a database-defined feature, the system-defined values are used. If there are no system-defined values, then default values are used.

6. Click [Save](#) to restrict the features you selected.

## Next Steps

Stop and restart the affected tenant database.

## Related Information

[Stop a Tenant Database \[page 229\]](#)

[Start a Tenant Database \[page 228\]](#)

[Lock Parameters Against Editing for a Tenant Database \[page 279\]](#)

## 6.3.2.6 Lock Parameters Against Editing for a Tenant Database

To ensure the stability and performance of the overall database or for security reasons, you can prevent certain system parameters from being changed by tenant database administrators, for example, parameters related to database management. A configuration change blacklist is available for this purpose.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are logged in to the system database (SYSTEMDB).
- You have the system privilege INIFILE ADMIN.

### Context

Database configuration (\*.ini) files have a database layer to facilitate the configuration of system parameters for individual tenant databases. However, it may be desirable to prevent changes to certain parameters being made directly in tenant databases because they could, for example, affect the performance of the database as a whole (CPU and memory management parameters).

You can use the cockpit to blacklist parameters for a particular database—that is, to lock them against editing. (The blacklist is stored in `multidb.ini`.) Several parameters are blacklisted by default, so you see them when you visit the [Blacklisted Parameters for Tenants](#) page for a tenant. You can remove default properties from that page—that is, make them editable by the tenant—and you can add parameters—lock them so they can't be edited.

#### **i** Note

Properties in the blacklist can still be configured at all levels in the system database. For more information about configuring system properties, see *Configuring SAP HANA System Properties (INI Files)*.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. On the [Manage Databases](#) screen, click [Manage Blacklisted Parameters](#) (upper right).

3. On the *Blacklisted Parameters for Tenants* page, the active tenant is highlighted in the left pane. Click the name of another tenant to manage its parameters.
4. To add a parameter to the blacklist, click *Add Parameter* at the top of the screen.
5. In the *Add Parameter to Blacklist* dialog, select the configuration file in which the parameter you want to add appears. To add a parameter that appears in more than one file, select *Any with the specified section*.
6. Enter or select your parameter's section in the configuration file. If you start to type the section name, the cockpit offers section names that match what you've entered—click to select one. If you prefer to select the section, click the double box at the end of the *Section* field to see a list. You can even combine the two methods: enter a few characters to narrow the number of choices offered when you click the double box.
7. Enter or select the parameter or parameters you want to add to the blacklist. If you start to type the parameter name, the cockpit offers section names that match what you've entered—click to select one. If you prefer to select the section, click the double box at the end of the *Parameters* field to see a list. You can even combine the two methods: enter a few characters to narrow the number of choices offered when you click the double box.

You can enter multiple parameters if they're all in the section you specified. You can also specify new parameters.

8. Click *OK* to save the new blacklist entries.

## Related Information

[Configuring SAP HANA System Properties \(INI Files\)](#)

[Restrict Features Available to a Tenant Database \[page 277\]](#)

### 6.3.2.6.1 Default Blacklisted System Properties in Tenant Databases

In systems that support tenant databases, there's configuration change blocklist `multidb.ini`, which is delivered with a default configuration.

The following table lists the system properties that are included in the `multidb.ini` file by default. So, tenant database administrators can't change these properties. System administrators can still change these properties in the system database in all layers.

You can customize the default configuration change blocklist by changing existing entries in the `multidb.ini` file and adding new ones. For more information about how to prevent changes to specific system properties in tenant databases, see *Prevent Changes to System Properties in Tenant Databases* in the *SAP HANA Administration Guide*.

File/Section	Properties	Description
auditing configuration	<ul style="list-style-type: none"> <li>default_audit_trail_type</li> <li>emergency_audit_trail_type</li> <li>alert_audit_trail_type</li> <li>critical_audit_trail_type</li> <li>audit_statement_length</li> </ul>	Prevents configuration of audit trail targets and the maximum audit statement length
auditing_csvtextfile	<ul style="list-style-type: none"> <li>max_file_size</li> <li>max_files</li> </ul>	Prevents configuration of the CSV text file audit trail files
communication	*	Prevents configuration of default key and trust stores, as well as other critical communication settings
global.ini/customizable_functionalities	*	Prevents disabling of restricted features
global.ini/extended_storage	*	Prevents configuration of extended storage (SAP HANA dynamic tiering)
global.ini/persistence	<ul style="list-style-type: none"> <li>basepath_datavolumes_es</li> <li>basepath_logvolumes_es</li> <li>basepath_databackup_es</li> <li>basepath_logbackup_es</li> </ul>	
global.ini/system_replication	<ul style="list-style-type: none"> <li>keep_old_style_alert</li> <li>enable_full_sync</li> <li>operation_mode</li> </ul>	Prevents configuration of certain system replication settings
global.ini/system_replication_communication	*	
global.ini/system_replication_hostname_resolution	*	
global.ini/xb_messaging	*	Prevents configuration of messaging
multidb.ini/readonly_parameters	*	Prevents configuration of the multidb.ini file itself
indexserver.ini/authentication	SapLogonTicketTrustStore	Prevents configuration of the trust store for user authentication with logon/assertion tickets
memorymanager	<ul style="list-style-type: none"> <li>allocationlimit</li> <li>minallocationlimit</li> <li>global_allocation_limit</li> <li>async_free_threshold</li> <li>async_free_target</li> </ul>	Prevents configuration of memory allocation parameters

File/Section	Properties	Description
execution	max_concurrency	Prevents configuration of threading and parallelization parameters
session	<ul style="list-style-type: none"> <li>maximum_connections</li> <li>maximum_external_connections</li> </ul>	
sql	sql_executors	

## Related Information

[Prevent Changes to System Properties in Tenant Databases](#)

[Unlock Blocklisted Parameters \[page 282\]](#)

[Copy Blocklisted Parameters \[page 283\]](#)

### 6.3.2.6.2 Unlock Blocklisted Parameters

Remove a parameter from the blocklist for a tenant database so that the parameter can be edited.

#### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the system privilege INIFILE ADMIN.
- You are connected to the system database.

#### Context

By removing a parameter from the blocklist, you can enable it to be edited. However, you can remove only parameters that you or other users have added to the blocklist—you can't remove parameters that are on the blocklist by default. Default parameters are displayed without delete or edit controls on the [Blocklisted Parameters for Tenants](#) page.

#### Procedure

- At the top of the [Database Overview](#) page, click [Database Management](#).

2. On the *Manage Databases* screen, click (upper right).

To see the *Manage Blocklisted Features* button, you might need to widen the window or click the three dots in the upper right corner of the screen. Manage Blocklisted Parameters

3. On the *Blocklisted Parameters for Tenants* page, the active tenant is highlighted in the left pane. Click the name of another tenant to manage its parameters.
4. To remove a parameter to the blocklist, click the red X to the right of the parameter to be deleted and confirm the deletion.

The cockpit displays the blocklist without the parameter you removed.

## Related Information

[Lock Parameters Against Editing for a Tenant Database \[page 279\]](#)

### 6.3.2.6.3 Copy Blocklisted Parameters

Copy parameters that have been added to another tenant's blocklist.

## Prerequisites

- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the system privilege INIFILE ADMIN.
- You are connected to the system database.

## Context

If you've added parameters to the target tenant before copying, you can choose whether to keep them. Parameters on the blocklist by default aren't copied.

## Procedure

1. At the top of the *Database Overview* page, click *Database Management*.
2. On the *Manage Databases* screen, click *Manage Blocklisted Parameters* (upper right).
3. On the *Blocklisted Parameters for Tenants* page, the active tenant is highlighted in the left pane. Click the name of another tenant to manage its parameters.

4. Click *Copy Parameters* at the top of the screen.
5. In the *Copy Parameters* dialog, select the tenant whose blocklist you want to copy (the source), and specify the tenant to which you want to copy the parameters (the target).
6. To make this tenant's blocklist an exact copy of the source tenant's blocklist, discarding any parameters you've added, select *Replace all parameters, making target and source identical*. To keep parameters you've added, select *Augment the target parameters with those from the source*.
7. Click *OK* to copy the blocklist.

## 6.3.2.7 View Diagnosis Files of an Unavailable Tenant Database

If a tenant database is unavailable, for example because it's stopped or experiencing major performance problems, the tenant database administrator can't access diagnosis files. In this case, you as the system administrator can access the diagnosis files of the tenant database from the system database using the SAP HANA database explorer.

### Procedure

Open the *Host Diagnostic Files* folder of your cockpit database, then click the diagnostic file that you want to examine to open it in an editor. The *Host Diagnostic Files* folder contains all diagnostic files that have been configured for the SAP Host Agent.

#### **i** Note

You cannot open binary trace files (marked with a binary icon) in the database explorer. You can only download binary trace files.

For more information about configuring the SAP Host Agent, see the *SAP Host Agent* documentation.

The cockpit database must have valid SAP Control Credentials set in the cockpit. If the user has not set valid SAP Control Credentials, then an error is returned.

The diagnosis files of the system database are displayed.

### Next Steps

If more detailed diagnosis information is required (for example for SAP Support), you can trigger the collection of a full system information dump for tenant databases. For more information, see *Collecting Diagnosis Information for SAP Support* in the *SAP HANA Administration Guide*.

## Related Information

[SAP Host Agent](#)

### 6.3.2.8 System and Statistics Views in Tenant Database Systems

Every database has its own SYS and \_SYS\_STATISTICS schemas that contain information about that database only. For system-level monitoring, additional views are accessible in the system database: the M\_DATABASES (SYS) view and the views in the SYS\_DATABASES schema.

- **M\_DATABASES**  
This view is available in the SYS schema of the system database of a multiple-container system. It provides an overview of all tenant databases in the system. Only users with the system privilege DATABASE ADMIN can see the contents of this view.
- **SYS\_DATABASES** schema  
The views in the SYS\_DATABASES schema provide aggregated information from a **subset** of the views available in the SYS and \_SYS\_STATISTICS schemas of all tenant databases in the system. These union views have the additional column DATABASE\_NAME to make it possible to identify from which database the information is coming refers. The system views in the SYS\_DATABASES schema are accessible only from the system database. To be able to view information in these views, you need the system privilege DATABASE ADMIN or CATALOG READ.

Tools such as the SAP HANA cockpit use these views to support system-level monitoring.

System and Statistics Views

### 6.3.3 Memory and CPU Usage for Tenant Databases

Manage and control the memory and CPU usage of your system by configuring limits for individual tenant databases. If necessary, you can also reserve memory for the system database.

#### Managing Resource Usage of Tenant Databases

Several system properties allow you to influence the allocation of memory and CPU resources in SAP HANA systems. System properties (INI) files have a database layer to facilitate the configuration of properties for individual tenant databases.

The following properties are useful for influencing the resource consumption of tenant databases.

- `[memorymanager] allocationlimit` in the `global.ini` file  
Use this property to limit the maximum amount of memory (in MB) that can be allocated individually to processes of a tenant database. Each process of a tenant database can allocate the specified value. Setting the allocation limit too low can cause the tenant database to become inaccessible until more memory can be allocated.

### ❖ Example

Executed from the system database:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'DATABASE', 'MYDB')
SET ('memorymanager','allocationlimit') = '8192' WITH RECONFIGURE;
```

### i Note

Memory alignment happens on the fly and can therefore take some time. To make it happen immediately, you can restart the database.

- [execution] `max_concurrency` in the `global.ini` file  
Use this property to influence the maximum number of CPU cores that can be used for each tenant database by limiting the number of concurrently running threads used by the JobExecutor subsystem. A reasonable default value is the number of cores divided by the number of tenant databases. Don't specify a value of 0. A change of this value takes effect immediately.

### ❖ Example

Executed from the system database:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'DATABASE', 'MYDB')
SET ('execution', 'max_concurrency') = '4' WITH RECONFIGURE;
```

### i Note

In NUMA architectures, setting the `max_concurrency` parameter isn't enough to achieve the desired performance gains, so also bind sockets that share memory using the affinity setting. For more information, see *Controlling CPU Consumption*.

## Managing Memory Usage of System Database

After installation, the system database contains only data required to monitor and manage the system, as well as statistics data related to itself. The system has an average memory consumption of 15 GB.

If the system database is experiencing performance problems, for example, out-of-memory situations, you can reserve a minimum amount of memory (MB) for the system database by configuring the parameter [multidb] `systemdb_reserved_memory` in the `global.ini` file.

## Related Information

[Configuring SAP HANA System Properties \(INI Files\)](#)

## 6.3.3.1 Define Memory Allocation Limits

As part of the provisioning process, you can ensure that memory is shared appropriately between tenant databases. By setting the memory allocation limits for each database on a host, you ensure appropriate memory sharing through setting the maximum amount of memory that can be allocated for a particular tenant database.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You are connected to the SYSTEMDB.

### Context

You can use the [Memory Allocation](#) tab of the [Configure Workload Allocation](#) app to view and modify memory allocation limits. These limits correspond to the settings of the `allocationlimit` parameter in the memory manager section of the `global.ini` file.

SAP HANA preallocates and manages its own memory pool, used for storing in-memory table data, thread stacks, temporary results, and other system data structures. When more memory is required for table growth or temporary computations, the SAP HANA memory manager obtains it from the pool. When the pool can't satisfy the request, the memory manager increases the pool size by requesting more memory from the operating system, up to a predefined allocation limit.

You can adjust the allocation limit for the services in the system at the following levels:

- System
- Tenant Database (these settings override the system settings)
- Host (these settings override the database and system settings)

For each database (or each database per host in a multi-host system), you can also refer to a mini-chart representing the memory usage of the `indexserver` in one day, where the vertical line shows the allocation limit setting for this specific database, dark green shows the actual used memory and light green shows the peak used memory.

The allocation limit value is applied to each service (for example, `indexserver`, `nameserver`, `compileserver`). However, when the [Configure Workload Allocation](#) app calculates the total memory available for allocation, only the `indexserver` is considered, since it requires much more memory than the other services.

### Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).

2. Select [Configure Workload Allocation](#) from the overflow menu in the header.
3. Select [Memory Allocation](#).
4. View the [Default allocation limit per service](#), or choose to edit the default by clicking the pencil icon. Changing the default causes each of the databases and hosts to inherit the value of the allocation limit (except those databases or hosts that have an allocation limit that already differs from the default).
5. View the [Allocation Limit](#) for each database or host, or choose to edit the value by clicking the pencil.
6. If you choose to edit the limit value, the [Edit Allocation Limit](#) dialog displays. Enter a value, or clear the allocation limit input field to revert to the allocation limit inherited from the default value.

The total memory available for allocation is equal to the sum of the allocation limits for each database (regardless of whether you've edited the limit or allowed the default value to be inherited). A warning displays if this sum exceeds the global allocation limit (the amount of available memory per host). However, SAP HANA does allow the sum of the allocation limits to exceed the global allocation limit.

## Related Information

[SAP HANA Used Memory](#)

[Memory Sizing](#)

[Allocated Memory Pools and Allocation Limits](#)

[SAP HANA Memory Usage and the Operating System](#)

### 6.3.3.2 Define CPU Cores Allocation Limits

As part of the provisioning process, you can ensure that CPU cores are shared appropriately between tenant databases. By setting the allocation limits, you ensure appropriate sharing of CPU cores, effectively specifying the maximum number of CPU cores that can be used by a particular tenant on a particular host.

## Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

In the SAP HANA cockpit, you can modify the CPU cores allocation limit. This limit corresponds to the settings of the `max_concurrency` parameter in the `global.ini` file.

Each host in an SAP HANA system has a physical set of CPU cores. You can adjust the maximum number of CPU cores available for allocation at each of the following levels:

- System
- Tenant database (these settings override the system settings)
- Host (these settings override the database and system settings)

## Procedure

1. At the top of the [Database Overview](#) page, click [Database Management](#).
2. Click [Global Allocation Limits](#) > [CPU Allocation](#) .

For each database (or each database per host in a multi-host system), you can also refer to its mini-chart representing the daily CPU usage of the indexserver, where dark green shows the peak CPU usage, and light green shows the average CPU usage.

3. View the [Default CPU cores allocation limit](#), or choose to edit the default by clicking the pencil icon. Changing the default causes each of the databases and hosts to inherit the value of the allocation limit (except those databases or hosts that have an allocation limit that already differs from the default).
4. View the [CPU Core Limit](#) for each of the databases, or choose to edit the value by clicking the pencil.
5. If you choose to edit the limit value, the [Edit Max CPU Cores](#) dialog displays. Enter a value, or clear the allocation limit input field to revert to the allocation limit inherited from the default value.

The total number of CPU cores available for allocation is equal to the sum of the allocation limits for each database (regardless of whether you've edited the limit or allowed the default value to be inherited). A warning displays if this sum exceeds the number of physical CPU cores.

## 6.3.4 Using SAP Web Dispatcher for Load Balancing with Tenant Databases

If an SAP HANA system has multiple instances of SAP HANA extended services, classic model (SAP HANA XS classic) and is distributed across multiple hosts, you can implement an external SAP Web Dispatcher to distribute the load of inbound HTTP requests and to ensure high availability.

The following section describes how to configure an external SAP Web Dispatcher for SAP HANA systems with tenant databases.

### Before You Start

Note the following points:

- The external SAP Web Dispatcher is a separate installation and does not form part of the SAP HANA system. It must have a minimum version of **745 Patch Level 21**.
- An SAP Web Dispatcher process also runs on all SAP HANA hosts on which an instance of SAP HANA XS is active. This internal SAP Web Dispatcher is a fixed part of the SAP HANA system. In a system with tenant

databases, this internal SAP Web Dispatcher must also be configured to enable HTTP access to individual databases. For more information, see *Configure HTTP(S) Access to Tenant Databases*.

- All information and configuration steps described in SAP Note [1855097](#) are still valid. In particular, the parameter `wdisp/filter_xs_internal_uri` has to be set to `false` in the `webdispatcher.ini` configuration file of your SAP HANA system.
- The configuration described in the following sections describes access to tenant databases. However, it is also valid for the system database. For the Web Dispatcher, there is no difference between tenant databases and the system database.
- The SAP Web Dispatcher handles only HTTP(S) access to SAP HANA.
- For more information about configuring secure HTTPS access, see *Configure HTTP(S) Access to Tenant Databases* (internal Web Dispatcher configuration) and *Configuring SAP Web Dispatcher to Support SSL* in the SAP HANA Web Dispatcher documentation.

[Configuring SAP Web Dispatcher to Support SSL](#)

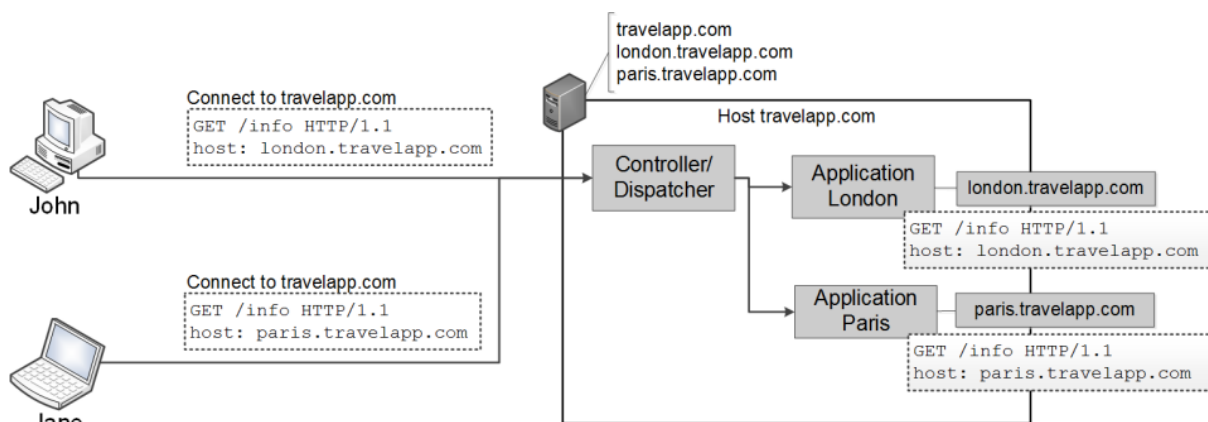

[Virtual-Host-Based Routing \[page 291\]](#)

[Configuring an External SAP Web Dispatcher for Tenant Databases \[page 293\]](#)

### 6.3.4.1 Virtual-Host-Based Routing

An example explains the basics of virtual-host-based routing.

The Website `travelapp.com` provides Web-based services for information about popular travel destinations. Services are implemented as separate applications, which run on separate Web servers on one host (`travelapp.com`). Virtual host names are used to distinguish between the available services: `london.travelapp.com` and `paris.travelapp.com`. Both virtual host names are aliases for `travelapp.com`. This can be illustrated as follows:

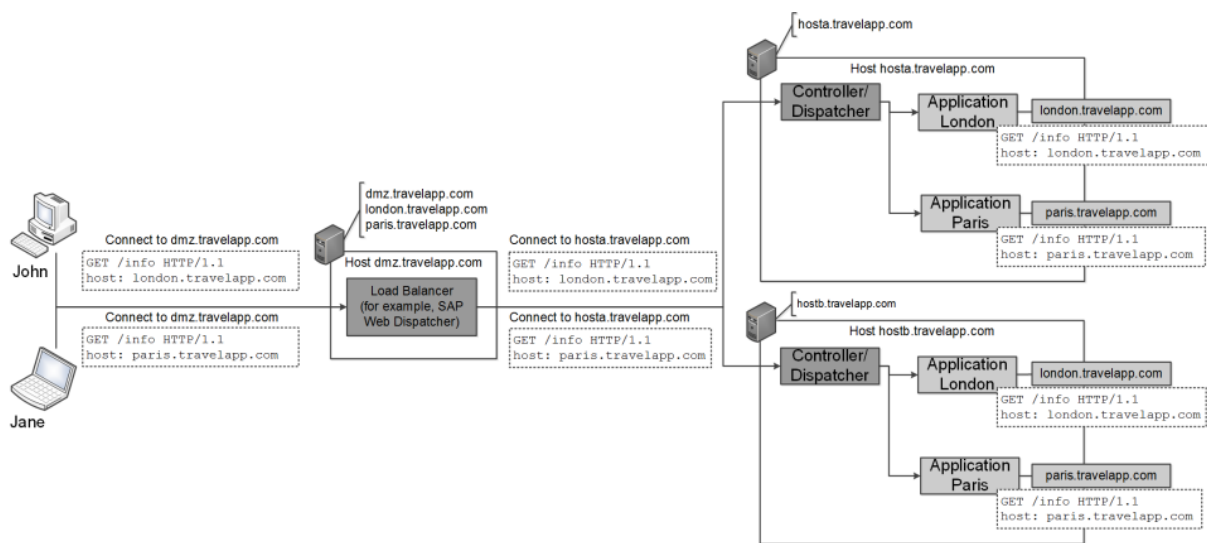

Virtual-Host-Based Routing

John wants to read information about London. Therefore, he enters `london.travelapp.com` into his browser. As `london.travelapp.com` is an alias for `travelapp.com`, the browser sends the HTTP request to `travelapp.com`, but it uses `london.travelapp.com` as the host header of this request. The request arrives at a controller or dispatcher process on `travelapp.com`. This dispatcher process decides whether to forward the request to the Web server responsible for displaying information about London or the Web server responsible for displaying information about Paris. This decision is made based on the host header, that is the host name that the user originally entered into the browser. `london.travelapp.com` is assigned to the application for London and `paris.travelapp.com` is assigned to the application for Paris.

Jane requires information about Paris and enters `paris.travelapp.com` into her browser. This request also arrives at the dispatcher process and is dispatched to the Paris application based on the host header of the request.

## Load Balancing

`travelapp.com` has proved to be a successful service with many users. As a result, one host is no longer sufficient, and the application has been installed on a second host. In addition, a load balancer is needed to distribute requests between the two hosts. The aliases `london.travelapp.com` and `paris.travelapp.com` have to be changed to point to the host of the load balancer to guarantee that all requests are handled by the load balancer (`dmz.travelapp.com`). This can be illustrated as follows:

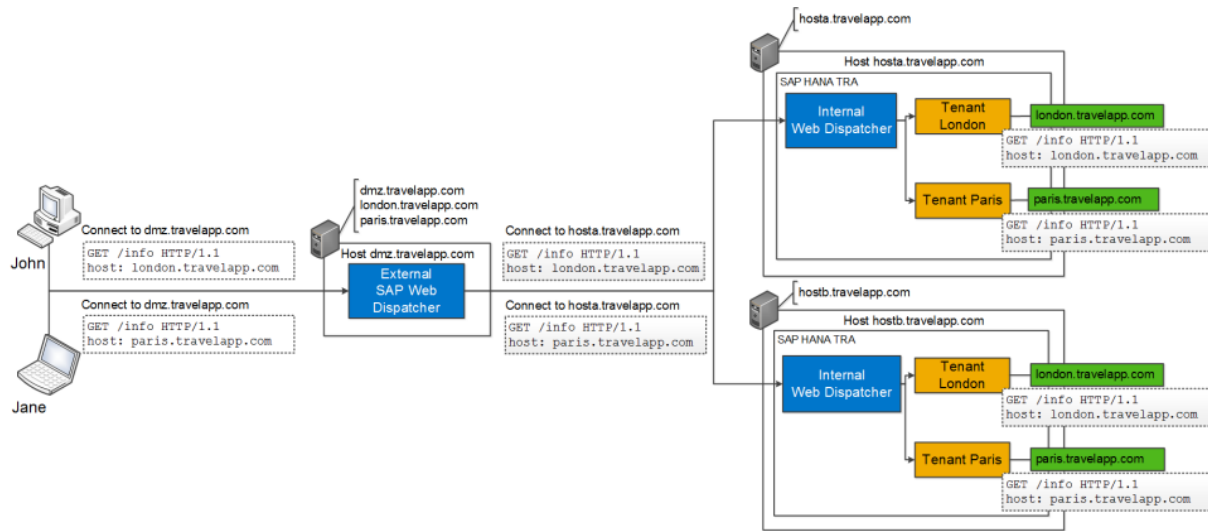

Virtual-Host-Based Routing with Load Balancing

John again wants to read information about London. Therefore, he enters `london.travelapp.com` into his browser. As `london.travelapp.com` is an alias for `dmz.travelapp.com`, the browser sends the HTTP request to `dmz.travelapp.com`, but it uses `london.travelapp.com` as the host header of this request. This request arrives at the load balancer, which simply forwards the request to `hosta.travelapp.com` or `hostb.travelapp.com` based on the current load. It must not change the host header of the request because this request is later necessary in the dispatcher. After that, the dispatcher handles the request as if no load balancer is involved, regardless of the fact that the host name in the host header actually points to another host.

## SAP HANA Tenant Databases

Translated to the context of SAP HANA tenant databases, the load balancer is an external SAP Web Dispatcher, and the dispatcher is the system-internal SAP Web Dispatcher, as illustrated in the following figure:

Virtual-Host-Based Routing for SAP HANA Tenant Databases

### 6.3.4.2 Configuring an External SAP Web Dispatcher for Tenant Databases

Virtual host names for differentiated HTTP access to tenant databases are configured in the system-internal SAP Web Dispatcher. If you're using an external SAP Web Dispatcher for load balancing, you must also configure the external Web Dispatcher. Otherwise, information about the selected virtual hosts can't be transported to the SAP HANA system.

#### → Remember

All of the configuration settings mentioned here are done in the **external** Web Dispatcher and not in the internal Web Dispatcher that is part of the SAP HANA system. The external Web Dispatcher is a separate installation and does not form part of the SAP HANA system. Before you can configure the external Web Dispatcher, the internal Web Dispatcher must already have been configured to enable HTTP access to individual databases. For more information, see *Configure HTTP(S) Access to Tenant Databases*.

### Single Versus Multiple Tenant Access via External Web Dispatcher

Every tenant database that needs to be accessed through the external Web Dispatcher requires a `wdisp/system_<xx>` parameter entry in the external Web Dispatcher profile (`sapwebdisp.pfl`). The `XSSRV` subparameter specifies the XS server to connect to, and the `XSVHOST` subparameter specifies the virtual host name of the tenant database.

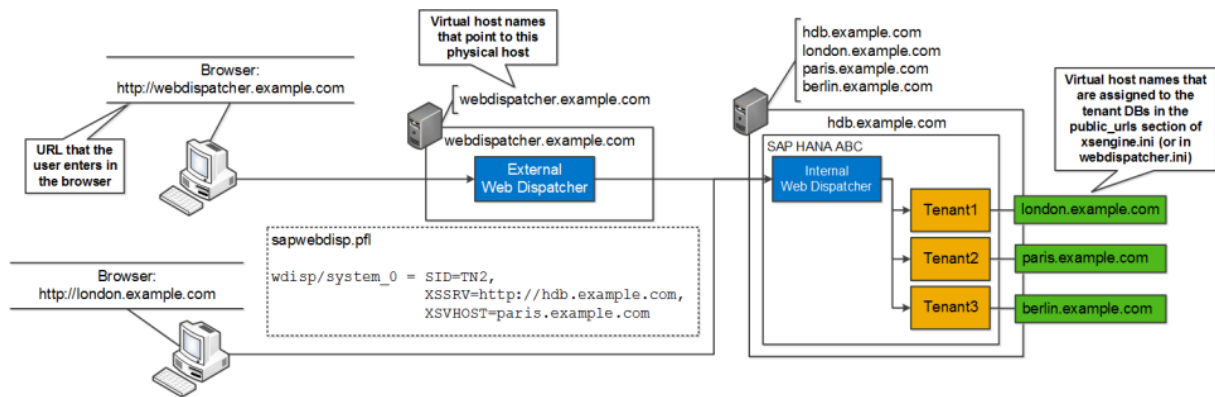

## ❁ Example

```
wdisp/system_<xx> = SID=<3-digit ID>, XSSRV=http://<physical host name of SAP HANA server>:<port>, XSVHOST=<virtual host name of the tenant>
```

## i Note

Virtual host names are configured in the `public_urls` section of the `xsengine.ini` configuration file (or in `webdispatcher.ini`). This is part of the **internal** Web Dispatcher configuration. For more information, see *Configure HTTP(S) Access to Tenant Databases*.

If only **one tenant database** needs to be accessed through the external Web Dispatcher, a single `wdisp/system_<XX>` entry for the tenant database with the above configuration is sufficient, as depicted in the following figure:

## i Note

The figure shows a simplified depiction of the Web Dispatcher profile (`sapwebdisp.pfl`). In the real configuration, the `XSSRV` subparameter requires port numbers, and line breaks are not allowed.

### Access to a Single Tenant Database

## i Note

An external Web Dispatcher is not mandatory to access a single tenant. But there are scenarios in which an external Web Dispatcher is required, for example sophisticated applications (for example, some SAP Fiori scenarios) or for security purposes. For more information, see the relevant application documentation and the SAP Web Dispatcher documentation.

Virtual host names are used to configure tenant differentiation. Two scenarios are possible:

- **Option 1:** Tenant databases are accessed via HTTP through the external Web Dispatcher only; there is no direct HTTP access to the tenant databases (recommended)
- **Option 2:** Tenants databases are accessed via HTTP both through the external Web Dispatcher and directly, bypassing the external Web Dispatcher  
This configuration requires additional virtual host names and is more complex than option 1. However, this option is useful if the external Web Dispatcher is being added to an existing landscape.

## Related Information

[SAP Web Dispatcher Documentation on SAP Help Portal](#)

[Configure HTTP\(S\) Access to Tenant Databases via SAP HANA XS Classic \[page 1718\]](#)

[Option 1: Configuring Access to Multiple \(or All\) Tenant Databases Through External Web Dispatcher Only \[page 295\]](#)

[Option 2: Configuring Access to Multiple \(or All\) Tenant Databases Through External Web Dispatcher and Directly \[page 298\]](#)

### 6.3.4.2.1 Option 1: Configuring Access to Multiple (or All) Tenant Databases Through External Web Dispatcher Only

Use this configuration if you want tenant databases to be accessed through the external Web Dispatcher only. With this configuration, there is no direct HTTP access to the tenant databases.

The main part of this configuration involves setting the virtual host names of tenant databases configured in the external Web Dispatcher profile to point to the host of the external Web Dispatcher, instead of the host of the SAP HANA system. As a result, all requests to the virtual host name of a tenant database first go to the external Web Dispatcher and are then forwarded to the internal Web Dispatcher in the SAP HANA system.

#### → Remember

Before you can configure the external Web Dispatcher, the internal Web Dispatcher must already have been configured to enable HTTP access to individual databases. For more information, see *Configure HTTP(S) Access to Tenant Databases*.

## Single-Host Systems

The `wdisp/system_<xx>` entry for each tenant database is configured in the external Web Dispatcher profile as follows:

- `XSSRV` specifies the actual physical SAP HANA host name and port to which requests are sent.
- `XSVHOST` specifies the virtual host name of the tenant database to which requests are sent.

#### i Note

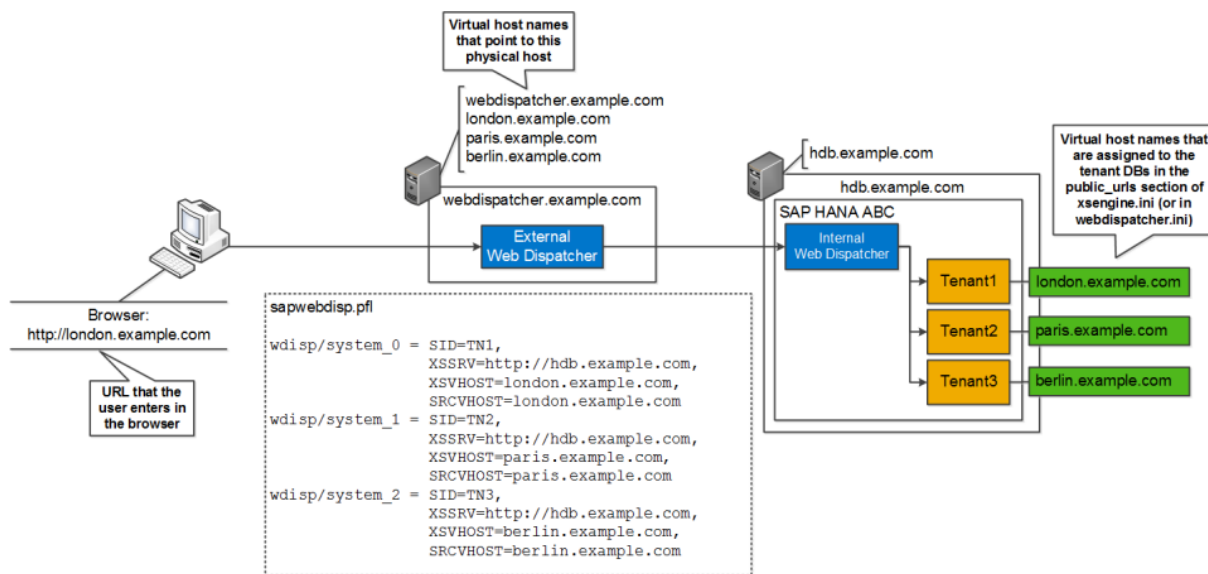

If a tenant database has multiple virtual host names assigned, only one needs to be entered in `XSVHOST`.

- `SRCVHOST` specifies the virtual host name that is used to map incoming HTTP requests to the `wdisp/system` entry that represents a particular tenant.

#### i Note

With this configuration option, `XSVHOST` and `SRCVHOST` are always identical.

The following figure depicts this configuration in a single-host system:

Access to Multiple Tenant Databases (Single Host)

## i Note

The figure shows a simplified depiction of the Web Dispatcher profile (`sapwebdisp.pfl`). In the real configuration, the `XSSRV` subparameter requires port numbers, and line breaks are not allowed.

In the example depicted above, what happens when the user enters `london.example.com` into her browser?

1. The browser opens a TCP/IP connection to `webdispatcher.example.com` because `london.example.com` is only an alias name for `webdispatcher.example.com`.
2. The browser sends an HTTP request over this connection. The host header of this HTTP request is `london.example.com`, which is the URL that the user entered.
3. The external Web Dispatcher receives the HTTP request, checks the host header and uses this to map the request to a `wdisp/system` entry. As `london.example.com` is the `SRCVHOST` value for `wdisp/system_0`, the request is associated with `wdisp/system_0`.
4. The external Web Dispatcher opens a TCP/IP connection to the `XSSRV` value of `wdisp/system_0` (`hdb.example.com`).
5. The external Web Dispatcher sets the destination of the request to the tenant database specified in the `XSVHOST` subparameter of `wdisp/system_0` (`london.example.com`) by injecting a proprietary HTTP header into the request.
6. The internal SAP HANA Web Dispatcher receives the request. Because of the injected HTTP header field, it identifies that the request is destined for tenant database 1 and forwards it to the XS server of tenant database 1.

## Multiple-Host Systems

In a multiple-host system, the external Web Dispatcher must be configured to connect to all hosts. This means that all hosts with a running XS server (or that may have an XS server in the future) have to be entered as the

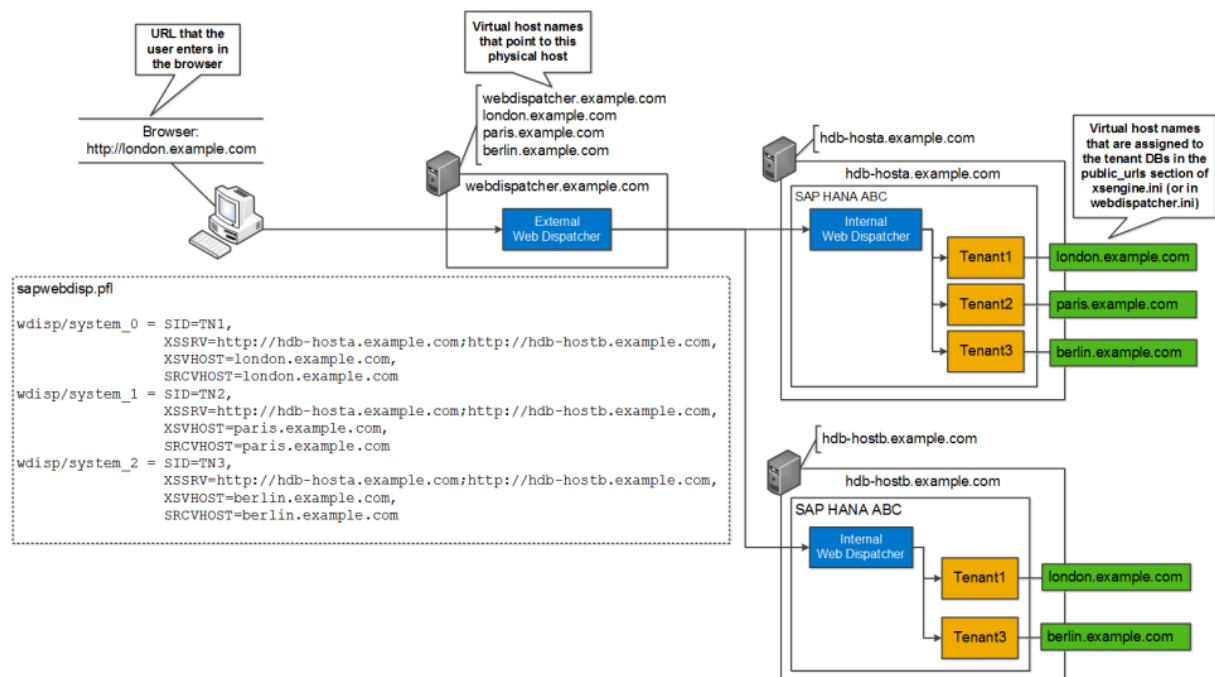

value for `XSSRV` as a semi-colon (;) separated list. Even if a tenant database is not running on a host, you should add the host to the list anyway. This will enable the smooth moving of tenant databases without the need to change the external Web Dispatcher configuration.

### → Remember

In the internal Web Dispatcher configuration, the virtual host name in the `XSVHOST` subparameter must be assigned to the tenant database on **all** hosts.

The following figure depicts the configuration in a multiple-host system:

### i Note

The figure shows a simplified depiction of the Web Dispatcher profile (`sapwebdisp.pfl`). In the real configuration, the `XSSRV` subparameter requires port numbers, and line breaks are not allowed.

## Access to Multiple Tenant Databases (Multiple Hosts)

Now what happens when the user enters `london.example.com` into her browser?

The process is identical to the single-host scenario with one exception: The external Web Dispatcher periodically checks which host(s) a tenant database is actually running on. If a tenant database is running on multiple hosts, the external Web Dispatcher performs load balancing between these hosts.

## Related Information

[Configure HTTP\(S\) Access to Tenant Databases via SAP HANA XS Classic \[page 1718\]](#)

## 6.3.4.2.2 Option 2: Configuring Access to Multiple (or All) Tenant Databases Through External Web Dispatcher and Directly

Use this configuration if you want tenant databases to be accessed both through the external Web Dispatcher and directly, bypassing the external Web Dispatcher.

With this configuration, additional virtual host names are required for each tenant database. These virtual host names point to the physical host name of the external Web Dispatcher. The virtual host names that are assigned to the tenant databases still point to the host of the SAP HANA system.

### → Remember

Before you can configure the external Web Dispatcher, the internal Web Dispatcher must already have been configured to enable HTTP access to individual databases. For more information, see *Configure HTTP(S) Access to Tenant Databases*.

## Single-Host Systems

The `wdisp/system_<xx>` entry for each tenant database is then configured in the external Web Dispatcher profile as follows:

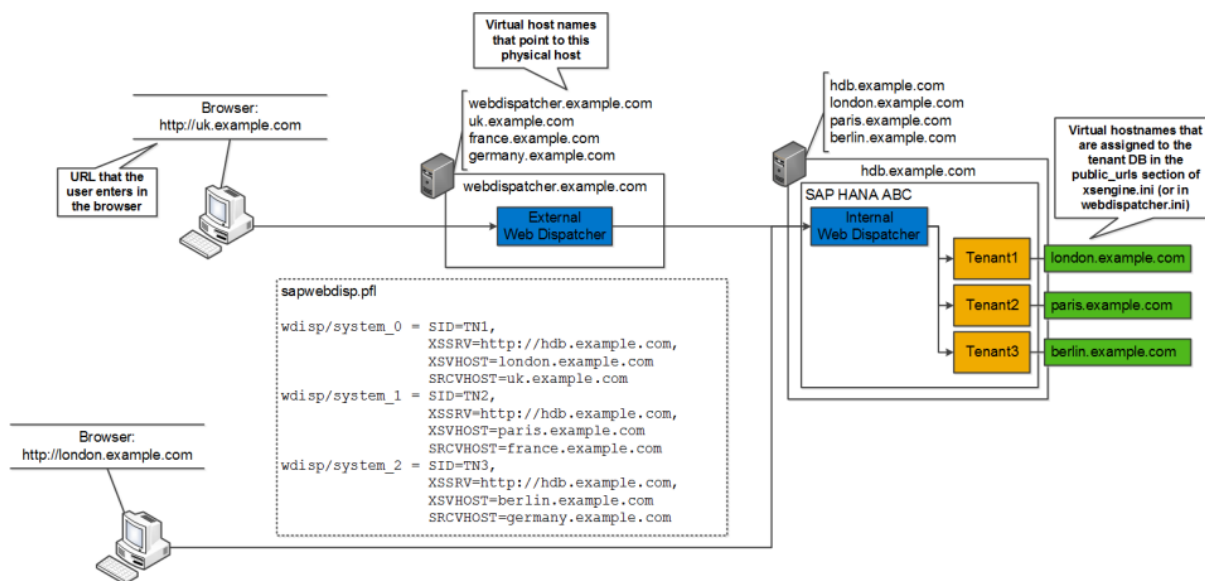

- `XSSRV` specifies the actual physical host name and port to which requests are sent.
- `XSVHOST` specifies the virtual host name of the tenant database to which requests are sent.

### i Note

If a tenant database has multiple virtual host names assigned, only one needs to be entered in `XSVHOST`.

- `SRCVHOST` specifies the virtual host name that is used to map incoming HTTP requests to the `wdisp/system_<xx>` that represents a particular tenant.

The following figure depicts this configuration in a single-host system:

Access to Multiple Tenant Databases in Single-Host System

## i Note

The figure shows a simplified depiction of the Web Dispatcher profile (`sapwebdisp.pfl`). In the real configuration, the `XSSRV` subparameter requires port numbers, and line breaks are not allowed.

In the example depicted above, what happens when the user enters `uk.example.com` into his browser?

1. The browser opens a TCP/IP connection to `webdispatcher.example.com` because `uk.example.com` is only an alias name for `webdispatcher.example.com`.
2. The browser sends an HTTP request over this connection. The host header of this HTTP request is `uk.example.com`, which is the URL that the user entered.
3. The external Web Dispatcher receives the HTTP request, checks the host header and uses it to map the request to a `wdisp/system` entry. As `uk.example.com` is the `SRCVHOST` value for `wdisp/system_0`, the request is associated with `wdisp/system_0`.
4. The external Web Dispatcher opens a TCP/IP connection to the `XSSRV` value of `wdisp/system_0` (`hdb.example.com`).
5. The external Web Dispatcher sets the destination of the request to the tenant database specified in the `XSVHOST` parameter of `wdisp/system_0` (`london.example.com`) by injecting a proprietary HTTP header into the request.
6. The internal SAP HANA Web Dispatcher receives the request. Because of the injected HTTP header field, it identifies that the request is destined for tenant database 1 and forwards it to the XS server of tenant database 1.

## Multiple-Host Systems

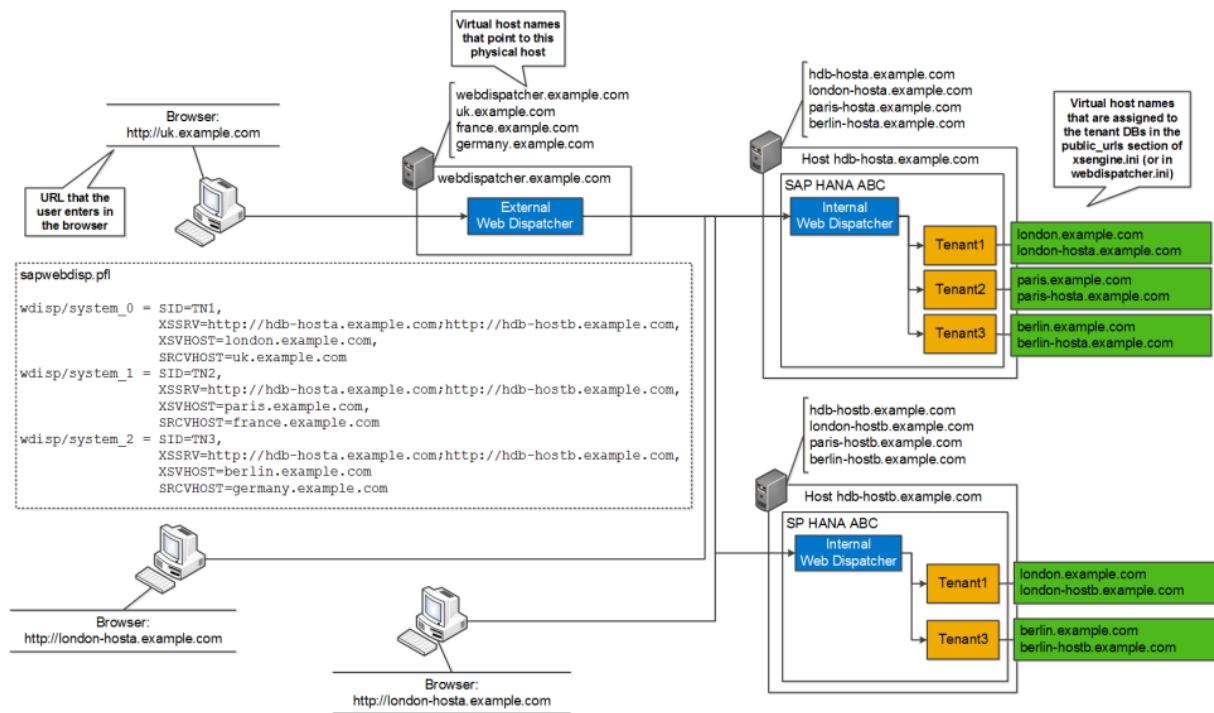

In a multiple-host system, the external Web Dispatcher must be configured to connect to all hosts. This means that all hosts with a running XS server (or that may have an XS server in the future) have to be entered as the

value for `XSSRV` as a semi-colon (;) separated list. Even if a tenant database is not running on a host, you should add the host to the list anyway. This will enable the smooth moving of tenant databases without the need to change the external Web Dispatcher configuration.

### → Remember

In the internal Web Dispatcher configuration, the virtual host name in the `XSVHOST` subparameter must be assigned to the tenant on **all** hosts.

The following figure depicts the configuration in a multiple-host system:

### i Note

The figure shows a simplified depiction of the Web Dispatcher profile (`sapwebdisp.pfl`). In the real configuration, the `XSSRV` subparameter requires port numbers, and line breaks are not allowed.

### Access to Multiple Tenant Databases in Multiple-Host System

What happens after the user enters `uk.example.com` into his browser?

The process is identical to the single-host scenario with one exception: The external Web Dispatcher periodically checks on which host(s) a tenant database is actually running. If a tenant database is running on multiple hosts, the external Web Dispatcher performs load balancing between these hosts.

## Related Information

[Configure HTTP\(S\) Access to Tenant Databases via SAP HANA XS Classic \[page 1718\]](#)

## 6.4 Configuring SAP HANA System Properties (INI Files)

An SAP HANA system has several configuration (`*.ini`) files that contain properties for configuring the system as a whole and individual tenant databases, as well as hosts and services.

### About Configuration Files

Every SAP HANA service has its own configuration file (for example, `indexserver.ini`, `compileserver.ini`, and so on). For service-independent properties, there is also a `global.ini`.

Configuration files are separated into sections; sections bundle properties of the same category.

SAP HANA uses a prioritized layered configuration framework. This means that properties can be configured at different levels or layers depending on the configuration file. The following layers are available; values from higher layers overwrite values of lower layers:

Layer	Description
Default	The default value for the property (read-only).
System	The system-specific value for the property (configurable in the system database). If a system-specific value is not configured for a property, the default value applies.
Database	The database-specific value for the property (configurable in the system or tenant database). For some properties, it is possible to set database-specific values. If a database-specific value is not configured, the system-specific or host-specific value applies. For detailed information see the section on database-specific configuration parameters.
Host	The host-specific value for the property (configurable in the system database). For some properties, it is possible to set host-specific values for multiple-host systems. If a host-specific value is not configured for a property that can be set at host level, the system-specific value applies.

Configuration files are stored on the SAP HANA server at the following locations according to layer:

- Default: `/usr/sap/<SID>/HDB<instance>/exe/config` (read only)
- System: `<sapmnt>/<SID>/SYS/global/hdb/custom/config`
- Database: `<sapmnt>/<SID>/SYS/global/hdb/custom/config/DB_<dbname>`
- Host: `/usr/sap/<SID>/HDB<instance>/<hostname>`

#### i Note

By default, `<sapmnt>` is `/hana/shared`.

## Changing Parameter Values

You can change configuration parameters using the SAP HANA cockpit, the SAP HANA studio, or the ALTER SYSTEM ALTER CONFIGURATION statement.

### i Note

In a system replication scenario, you cannot alter parameters of the secondary site using the SAP HANA cockpit or studio. Instead you must alter the parameters directly in the \*.ini files on the secondary site. Afterwards reconfigure the database using `hdbnsutil -reconfig`.

All public configuration parameters are defined in table CONFIGURATION\_PARAMETER\_PROPERTIES. In addition to basic properties such as data type, unit and a default value, the definition includes a flag to indicate if a system restart is required before a changed value becomes effective. You can look up parameter details using the system views listed below, using SAP HANA cockpit or by referring to the *Configuration Parameter Reference* in the SAP Help Portal.

### Validation

When you attempt to change a parameter value, the change is validated against the definition. Validation can be applied as follows:

- Value restrictions where a list of permitted values has been defined, either as a range (for example 0-100) or as a list of values ({default,on,off})
- Layer restrictions where a change is only permitted at a specified layer (either SYSTEM or HOST)
- Custom restrictions are additional restrictions where more detailed parsing of the value entered is required; this may be used, for example, to validate a value where a file path must be entered.

If the changed value is not valid for some reason, the new value is stored but a warning message is returned. You can prevent invalid values from being saved by setting the `unsupported_configuration_change` parameter to 'error', in which case the change is then rejected.

Because there is no hard validation of configuration values two alert checkers run in the background to monitor changes made to these settings: Alert 136 checks if any parameters are set to an unsupported value and Alert 137 triggers an information message if a configuration change has been made which requires a service restart in order to make it effective. The source of this information is system view `M_CONFIGURATION_PARAMETER_VALUES` which shows whether a value violates any restrictions (see System Views below).

In general, we do not recommend that you change the default values of parameters unless stated in the documentation or instructed to do so by SAP Support.

## Parameter Tracking

For traceability purposes changes to configuration values can be logged; optionally, a reason for the change can be entered in a comment value.

The tracking feature is enabled by default, but can be disabled by setting configuration parameter `write_log` in the `indexserver.ini` file to `false`. When it is enabled the SQL ALTER CONFIGURATION statement automatically updates the view `SYS.M_INIFILE_CONTENT_HISTORY`, this includes details of the time the change was made, the user name, the current and previous values and any comment text that was entered.

The following SQL example shows how the COMMENT keyword is used to include a reason for the change (refer to the *SAP HANA SQL Reference Guide* for more details):

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'DATABASE', 'C11')
SET ('memorymanager', 'allocationlimit') = '500000'
WITH RECONFIGURE
COMMENT 'Reverting to previous setting';
```

An SQL command CLEAR is also available to truncate the ini file history:

```
ALTER SYSTEM CLEAR INIFILE CONTENT HISTORY
```

This automatically adds a timestamp and comment to the history to indicate when the history was deleted.

Any changes made to configuration values at the level of the file system – by scripts or tools such as `hdbnsutil` are also tracked. This is done at system startup when the system recognizes that offline configuration changes have been made and writes an entry into the log history; this entry does not include details of the values which have been changed.

## System Views

The system view `M_INIFILES` contains information about the layers on which the properties of each configuration file can be configured and the view `M_INIFILE_CONTENTS` contains information about the values configured for the properties of each file and on which layers it has been defined.

The view `M_CONFIGURATION_PARAMETER_VALUES` shows more details about the value which has been applied. This includes the `RAW_VALUE` as it is cached in the service, if any parameter restrictions have been violated and also, if the value has been recently changed, whether a restart is still required to make the new value effective. This view can therefore be used to see the currently effective values.

This view may contain multiple entries for each key because a record is maintained for each key for each individual service (HOST / PORT). To query the table and filter the results for your own host and port you can refer to the `OWN` value maintained in `M_CONNECTIONS`. The following query shows this and selects, as an example, all keys in the 'expensive\_statement' section for the service executing your statement:

```
SELECT v.* FROM SYS.M_CONFIGURATION_PARAMETER_VALUES v, SYS.M_CONNECTIONS c
WHERE v.SECTION='olap' AND v.HOST=c.HOST AND v.PORT=c.PORT AND c.OWN='TRUE';
```

The view `M_INIFILE_CONTENT_HISTORY` is used by parameter tracking to show the history of changes as described above.

## Further Information

An SAP Community blog *Configuration Framework Improvements in SAP HANA 2* gives further details of this feature.

### 6.4.1 Database-Specific Configuration Parameters

In addition to the layers "default", "system", and "host", system configuration files also have a "database" layer to facilitate the configuration of properties for individual databases.

In general, you can configure database-specific properties both in the system database and in tenant databases themselves. Properties configured in the system database can be applied to all databases (if configured in the system layer) or to specific databases (if configured in database layer).

Properties configured in a tenant database apply to that tenant database only. Only properties in the following files can be configured in tenant databases:

- `attributes.ini`
- `docstore.ini`
- `dpserver.ini`
- `esserver.ini`
- `executor.ini`
- `extensions.ini`
- `global.ini`
- `indexserver.ini`
- `scriptserver.ini`
- `xsengine.ini`

The file `multidb.ini` is used as a blocklist to protect critical system settings from being changed in tenant databases. The list is delivered with a default configuration but this can be modified. The topic 'Lock Parameters Against Editing for a Tenant Database' describes how to do this from within SAP HANA cockpit.

## File Location

If properties are configured in the database layer, a database-specific configuration file is stored at the following location on the server: `/hana/shared/$SID/global/hdb/custom/config/DB_<dbname>`

### ❁ Example

The properties in the `nameserver.ini` file aren't database-specific. They can only be configured at system level. The `nameserver.ini` file is therefore stored at `/hana/shared/$SID/global/hdb/custom/config`.

However, the properties in the `indexserver.ini` can be database-specific. Properties that are configured in the system layer and apply to all databases are stored in the `indexserver.ini` at `/hana/shared/$SID/global/hdb/custom/config`. Properties configured for an individual database override the system-layer value and are stored in the `indexserver.ini` at `/hana/shared/$SID/global/hdb/custom/config/DB_<dbname>`.

## Layered Configuration

Many properties can be configured in the system, host, and database layer. Values configured in the database layer take precedence over system-layer values.

However, when you're connected to a tenant database, you see that the database-layer value of a property is also displayed as the system-layer value. This value occurs because, from the perspective of the tenant database, the database and the system are effectively the same. The true system-layer value (that is, the value configured for all databases in the system database) is displayed in the tenant database as the default-layer value.

Values configured in the host layer take precedence over database-layer values. Host values can only be configured in the system database.

You can see actual configuration values in SAP HANA cockpit, on the resources [Database Overview](#) page (select the [Manage System Configuration](#) link on the [Database Administration](#) card), or query the following system views:

- `M_INIFILE_CONTENTS (SYS_DATABASES)`  
This view can be accessed only from the system database. It contains the values configured for all properties on system, host, and database layer for **all** active databases.
- `M_INIFILE_CONTENTS (SYS)`  
This view is available in every database and contains the values that apply to the database in question. Values that were configured in the system layer in the system database are identified as default-layer values. Values that were configured in the database layer in the tenant database are identified as system- and database-layer values. Values configured at the host layer are shown only for hosts on which the database is running.

## Example

A system has 3 tenant databases DB1, DB2, and DB3, distributed across 2 hosts Host A and Host B:

The default value of the property `[execution] max_concurrency` in the `global.ini` file is 0. The system administrator changes the default configuration of this property in the `indexserver.ini` file as follows:

First, the system administrator creates a new system-layer value (**10**) in `indexserver.ini`. Since the system-layer value applies to all tenant databases and can't be changed by a tenant database user, users on all tenant databases initially see the value 10 as the default configuration:

Executed in DB1, DB2, and DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

Next, the system administrator sets a new value (**20**) for DB1, while leaving the configuration for DB2 and DB3 unchanged.

Executed in DB1:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	SYSTEM			execution	max_concurrency	20 ← Effective value
indexserver.ini	DATABASE			execution	max_concurrency	20 ← Effective value

Executed in DB2 and DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

## i Note

In DB1, the database-layer value is duplicated to the system layer because from the perspective of the tenant database, the database and the system are effectively the same.

Finally, the system administrator sets a new value (**15**) for host A. Since host values take precedence over database values, this value changes the effective value for DB1 and DB2.

Executed in DB1:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	HOST		HOST A	execution	max_concurrency	15 ← Effective value
indexserver.ini	SYSTEM			execution	max_concurrency	20
indexserver.ini	DATABASE			execution	max_concurrency	20

Executed in DB2:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	HOST		HOST A	execution	max_concurrency	15 ← Effective value
indexserver.ini	SYSTEM			execution	max_concurrency	20

Executed in DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

## Related Information

[SAP HANA Configuration Parameter Reference](#)

[Lock Parameters Against Editing for a Tenant Database \[page 279\]](#)

## 6.4.2 Database Configuration in SAP HANA Cockpit

From the [Database Overview](#), you can drill down to view and manage configuration (\*.ini) files.

To open the [Database Configuration](#) page, on the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.

Configuration files are separated into sections; sections bundle parameters of the same category. Parameters can be configured at different levels or layers depending on the configuration file. Layers control where parameter values apply and how parameters inherit default values. The following layers are available:

Layer	Description
Default	The default value for the parameter
System	The system-specific value for the parameter (configurable in the system database) If a system-specific value isn't configured for a parameter, then the default value applies.
Database	The database-specific value for the parameter (configurable in the system or tenant database) For some parameters, it's possible to set database-specific values. If a database-specific value isn't configured, then the host-specific value applies.
Host	The host-specific value for the parameter (configurable in the system database) For some parameters, it's possible to set host-specific values for multiple-host systems. If a host-specific value isn't configured for a parameter that can be set at host level, the system-specific value applies.

You can change configuration values ([Change Layer](#)) or quickly modify a value or assign a default.

You can filter by [Configuration File](#), [Section](#), and [Host](#) in order to display specific configuration file contents.

In general, SAP recommends that you don't change the default values of parameters unless the documentation suggests it or you're instructed to do so by SAP Support. While most parameters can be changed when the database is running, changes to some parameters require a database restart to take effect. To find out whether a restart is required for frequently used parameters, refer to the online reference in the SAP Help Portal.

## 6.4.2.1 System Properties

You can add new sections and parameters to configuration files, at one or more layers. You can also override the default value for existing properties.

### 6.4.2.1.1 Add a System Property Section

Sections in a configuration file bundle parameters of the same category.

#### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- You must have the system privilege DATABASE ADMIN to change the system property of a tenant database from the system database.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Procedure

1. On the [Database Overview](#) page, with the *Administration* or *All* view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Filter by [Configuration File](#) in order to display the file you want to add the new section to.
3. Select [Add Section](#).
4. Select a file from the dropdown list.
5. Enter the name of the new section.
6. Specify a parameter.
7. Specify the layer to which the parameter applies.
8. Specify:

Layer	Specify
<b>System Layer</b>	Specify the value for the system. The value is also inherited by tenants and hosts unless overridden.
<b>Database Layer</b>	Select one or more databases and specify the value for the parameter.
<b>Host Layer (Can only be used in SYSTEMDB)</b>	Select one or more hosts and specify the value.

9. (Optional) Add a comment about the new parameter.
10. Save the new section.

## 6.4.2.1.2 Add a System Property Parameter

In the configuration files of an SAP HANA system, you can add a parameter.

### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- You must have the system privilege DATABASE ADMIN to change the system property of a tenant database from the system database.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Filter by [Configuration File](#) and [Section](#) in order to display the section you want to add the new parameter to.
3. Click the **+** ([Add parameter to <section\\_name>](#)) icon beside the section name.
4. Specify a parameter.
5. Specify the layer to which the parameter applies.
6. Specify:

Layer	Specify
<b>System Layer</b>	Specify the value for the system. The value is also inherited by tenants and hosts unless overridden.
<b>Database Layer</b>	Select one or more databases and specify the value for the parameter.
<b>Host Layer (Can only be used in SYSTEMDB)</b>	Select one or more hosts and specify the value.

7. (Optional) Add comment about the new parameter.
8. Save the new parameter.

## 6.4.2.1.3 Modify a System Property in SAP HANA Cockpit

In the configuration files of an SAP HANA system, you can modify parameter values.

### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- You must have the system privilege DATABASE ADMIN to change the system property of a tenant database from the system database.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

You can change the value of a parameter or override its default value. You can't change the name of a section or parameter.

#### Note

In general, we don't recommend changing the default values of parameters unless stated in the documentation or instructed by SAP Support. For more information about configuration parameters, refer to the online reference in the SAP Help Portal.

### Procedure

1. On the [Database Overview](#) page, with the *Administration* or *All* view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Filter by [Configuration File](#) and [Section](#) in order to display the parameter you want to modify. All the parameters in the section are listed. [Override Value](#) appears for the default layer of each parameter. If the default value has been overridden at a level, then the [✎ \(Edit Parameter\)](#) and [⊗ \(Delete Parameter\)](#) icons appear on the layer.
3. To modify a user-defined value on a layer:
  - a. Click the [✎ \(Edit Parameter\)](#) icon.
  - b. Click in the value field and enter the new value.
  - c. Click [Save](#).
4. To override a default value, click [Override Value](#).
  - a. Select one or more layers to apply the new value to.
  - b. Enter the required details for the selected layers.
  - c. Click [OK](#) to apply the override.

## Related Information

[SAP HANA Configuration Parameter Reference](#)

### 6.4.2.1.4 Restore a System Property Default in SAP HANA Cockpit

You can reset changed parameters to their default values.

#### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- You must have the system privilege DATABASE ADMIN to change the system property of a tenant database from the system database.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Procedure

1. On the [Database Overview](#) page, with the *Administration* or *All* view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Filter by [Configuration File](#) and [Section](#) in order to display the parameter you want to restore to its default value.  
All the parameters in the section are listed. [Override Value](#) appears for the default layer of each parameter. If the default value has been overridden at a level, the [✎ \(Edit Parameter\)](#) and [⊗ \(Delete Parameter\)](#) icons appear on the layer.
3. Do one of:

To	Action
To restore the default value for a specific layer	Click the <a href="#">⊗ (Delete Parameter)</a> icon beside the layer. The user-defined value is cleared and the default value is reapplied.
To restore the default value for all layers	<ol style="list-style-type: none"><li>1. Click <a href="#">Override Value</a>.</li><li>2. Select the layers to restore.</li><li>3. Click <a href="#">Restore Default for All</a>. The value for each layer is restored to the default value.</li><li>4. Click <a href="#">OK</a>.</li></ol>

## 6.4.2.1.5 Database-Specific Configuration Parameters

In addition to the layers "default", "system", and "host", system configuration files also have a "database" layer to facilitate the configuration of properties for individual databases.

In general, you can configure database-specific properties both in the system database and in tenant databases themselves. Properties configured in the system database can be applied to all databases (if configured in the system layer) or to specific databases (if configured in database layer).

Properties configured in a tenant database apply to that tenant database only. Only properties in the following files can be configured in tenant databases:

- `attributes.ini`
- `docstore.ini`
- `dpserver.ini`
- `esserver.ini`
- `executor.ini`
- `extensions.ini`
- `global.ini`
- `indexserver.ini`
- `scriptserver.ini`
- `xsengine.ini`

The file `multidb.ini` is used as a blacklist to protect critical system settings from being changed in tenant databases. The list is delivered with a default configuration but this can be modified. The topic 'Lock Parameters Against Editing for a Tenant Database' describes how to do this from within SAP HANA cockpit.

### File Location

If properties are configured in the database layer, a database-specific configuration file is stored at the following location on the server: `/hana/shared/$SID/global/hdb/custom/config/DB_<dbname>`

#### ❁ Example

The properties in the `nameserver.ini` file aren't database-specific. They can only be configured at system level. The `nameserver.ini` file is therefore stored at `/hana/shared/$SID/global/hdb/custom/config`.

However, the properties in the `indexserver.ini` can be database-specific. Properties that are configured in the system layer and apply to all databases are stored in the `indexserver.ini` at `/hana/shared/$SID/global/hdb/custom/config`. Properties configured for an individual database override the system-layer value and are stored in the `indexserver.ini` at `/hana/shared/$SID/global/hdb/custom/config/DB_<dbname>`.

## Layered Configuration

Many properties can be configured in the system, host, and database layer. Values configured in the database layer take precedence over system-layer values.

However, when you're connected to a tenant database, you see that the database-layer value of a property is also displayed as the system-layer value. This value occurs because, from the perspective of the tenant database, the database and the system are effectively the same. The true system-layer value (that is, the value configured for all databases in the system database) is displayed in the tenant database as the default-layer value.

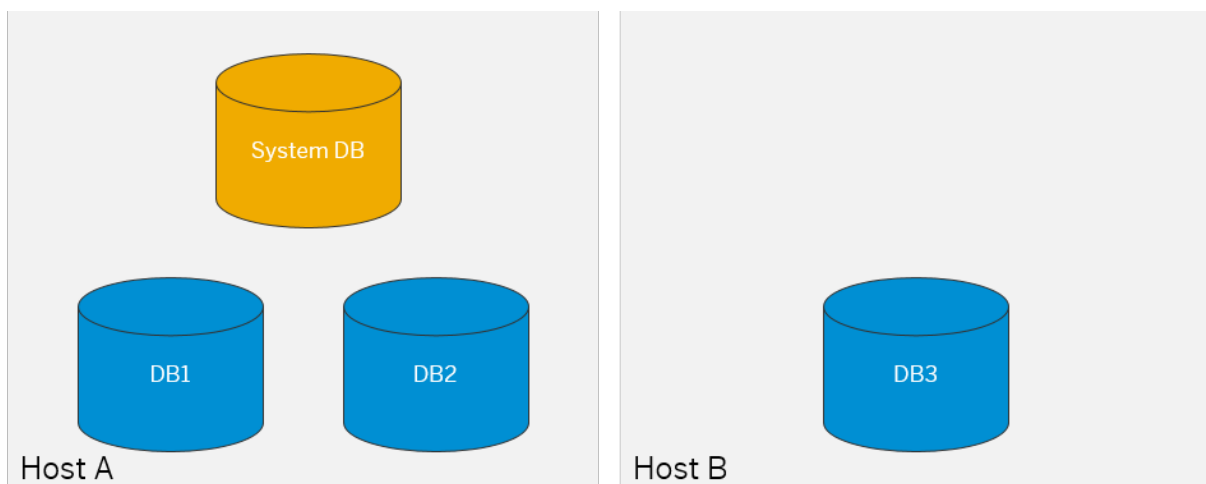

Values configured in the host layer take precedence over database-layer values. Host values can only be configured in the system database.

You can see actual configuration values in SAP HANA cockpit, on the resources [Database Overview](#) page (select the [Manage System Configuration](#) link on the [Database Administration](#) card), or query the following system views:

- `M_INIFILE_CONTENTS (SYS_DATABASES)`  
This view can be accessed only from the system database. It contains the values configured for all properties on system, host, and database layer for **all** active databases.
- `M_INIFILE_CONTENTS (SYS)`  
This view is available in every database and contains the values that apply to the database in question. Values that were configured in the system layer in the system database are identified as default-layer values. Values that were configured in the database layer in the tenant database are identified as system- and database-layer values. Values configured at the host layer are shown only for hosts on which the database is running.

## Example

A system has 3 tenant databases DB1, DB2, and DB3, distributed across 2 hosts Host A and Host B:

The default value of the property [execution] max\_concurrency in the global.ini file is 0. The system administrator changes the default configuration of this property in the indexserver.ini file as follows:

First, the system administrator creates a new system-layer value (10) in indexserver.ini. Since the system-layer value applies to all tenant databases and can't be changed by a tenant database user, users on all tenant databases initially see the value 10 as the default configuration:

Executed in DB1, DB2, and DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

Next, the system administrator sets a new value (20) for DB1, while leaving the configuration for DB2 and DB3 unchanged.

Executed in DB1:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	SYSTEM			execution	max_concurrency	20 ← Effective value
indexserver.ini	DATABASE			execution	max_concurrency	20 ← Effective value

Executed in DB2 and DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

## Note

In DB1, the database-layer value is duplicated to the system layer because from the perspective of the tenant database, the database and the system are effectively the same.

Finally, the system administrator sets a new value (15) for host A. Since host values take precedence over database values, this value changes the effective value for DB1 and DB2.

Executed in DB1:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	HOST		HOST A	execution	max_concurrency	15 ← Effective value
indexserver.ini	SYSTEM			execution	max_concurrency	20
indexserver.ini	DATABASE			execution	max_concurrency	20

Executed in DB2:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10
indexserver.ini	HOST		HOST A	execution	max_concurrency	15 ← Effective value
indexserver.ini	SYSTEM			execution	max_concurrency	20

Executed in DB3:

```
SELECT * FROM SYS.M_INIFILE_CONTENTS WHERE KEY='max_concurrency'
```

FILE_NAME	LAYER_NAME	TENANT_NAME	HOST	SECTION	KEY	VALUE
global.ini	DEFAULT			execution	max_concurrency	0
indexserver.ini	DEFAULT			execution	max_concurrency	10 ← Effective value

## Related Information

## 6.4.2.1.6 View Change History

You can view the change history of one or more values.

## Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

If a row in the table is selected when you click [View Change History](#), then the configuration file, section, and parameter are prefilled in the Change History screen and the screen automatically loads the data.

If a row isn't selected when this screen is launched, then only the filters set on the screen that launched it are set and the table is populated.

## Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. While the [Parameters](#) tab is active, select [View Change History](#).  
The change history table is displayed, sorted by time. You can personalize the table, including grouping, sorting, hiding columns, column order.

### 6.4.2.2 Create a Configuration Template

Set up a configuration template of parameter settings from one database that you can later apply to other databases.

## Prerequisites

You're familiar with the layers at which parameters can be configured. See *Database Configuration in SAP HANA Cockpit*.

## Procedure

1. On the SAP HANA cockpit [Home](#) page, click the [Configuration Templates](#) tile.
2. Select [Create Template](#).
3. Enter a name and description for the new template.
4. Specify the layer from which you select parameters for this template.
5. Select a database from which you select parameters for this template.
6. Select parameters for the template.
7. Select [Review](#). If necessary, click [Edit](#) to change your selections.
8. Select [Create Template](#)

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

### 6.4.2.3 Apply a Configuration Template

Use a configuration template to copy parameter settings from one database to another.

#### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- A configuration template has been created.

#### Procedure

1. On the SAP HANA cockpit *Home* page, click the *Configuration Templates* tile.
2. Choose a template.
3. Select *Apply to Databases*.
4. Choose a database to which to apply the template.
5. Click *Apply Template*.

#### Results

A message tells you whether the template was applied.

## Related Information

[Create a Configuration Template \[page 317\]](#)

## 6.4.2.4 Compare Configurations

You can compare the configuration of one database to that of another or compare the configuration of a database with a snapshot.

### Prerequisites

- Your database user has the system privilege INIFILE ADMIN.
- You must have the system privilege DATABASE ADMIN to change the system property of a tenant database from the system database.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Choose a type and a source.

Compare	Options
<b>System Database</b>	<ul style="list-style-type: none"><li>○ You can choose from any system database that you're authorized to view.</li><li>○ You can choose one or more databases as targets.</li></ul>
<b>Tenant Database</b>	<ul style="list-style-type: none"><li>○ You can choose from any tenant database that you're authorized to view.</li><li>○ You can choose one or more tenants as targets.</li></ul>
<b>Snapshots</b>	<ul style="list-style-type: none"><li>○ You can choose from snapshots that were created for this database.</li></ul>

3. Click [Compare](#).
4. Choose a target.

The target must be of the same type as the source.
5. (Optional) Click [Show Differences Only](#).
6. Enter a configuration file name, section, and layer, or leave them blank to have all the parameters included in the results.

The list is updated automatically.

## 6.4.2.5 Snapshots

You can take snapshots, view details, compare, and delete snapshots.

### 6.4.2.5.1 Take a Snapshot

At any time, you can create a new snapshot.

#### Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Select the [Snapshots](#) tab, if not active.
3. Click [Take Snapshot](#).
4. (Optional) Enter a descriptive name, and select [Take Snapshot](#).

#### Results

The new snapshot is added to the list.

### 6.4.2.5.2 View Snapshot Details

You can drill down from the list of snapshots to view parameter details of a particular snapshot.

#### Prerequisites

- You have the CATALOG READ system privilege.

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Select the [Snapshots](#) tab, if not active.
3. Click the > icon of the snapshot you want to view.

## Results

Details of the selected snapshot appear.

### 6.4.2.5.3 Delete a Snapshot

You can remove a snapshot from the list of snapshots.

## Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. While the [Snapshots](#) tab is active, select the snapshot you want to delete.
3. Select the ⊗ ([Delete Snapshot](#)) icon.
4. Confirm the deletion.

## 6.4.2.5.4 Compare Snapshots

You can compare different snapshots.

### Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Manage Database Configuration](#) link on the [Database Administration](#) card.
2. Select the [Snapshots](#) tab, if not active.
3. Select the source snapshot you want to compare.
4. Click [Compare](#).
5. Select a target snapshot to compare to.
6. Select [Compare](#).
7. Click the  icon in the [Snapshot](#) field, and select a target snapshot to compare to.

### Results

Only the differences between the two snapshots are listed. To show all values in both snapshots, clear the check mark from [Show Differences Only](#).

## 6.4.3 Configuring System Properties in SAP HANA Studio

Use the SAP HANA studio to configure SAP HANA system properties (INI files). You can access and edit configuration files on the [Configuration](#) tab of the Administration editor.

### Related Information

[Change a System Property in SAP HANA Studio \[page 323\]](#)

[Reset a System Property in SAP HANA Studio \[page 325\]](#)

## 6.4.3.1 Change a System Property in SAP HANA Studio

The properties of an SAP HANA system are defined in the parameters of its configuration files. Configuration files are separated into sections; sections bundle parameters of the same category.

### Prerequisites

- You have the system privilege INIFILE ADMIN.
- In multiple-container systems, you must have the system privilege DATABASE ADMIN if you are changing the system property of a tenant database from the system database.

### Procedure

1. In the Administration editor, choose the [Configuration](#) tab.  
A list of all configuration files appears.
2. Expand the configuration file that you want to change.  
All the sections of the configuration file are listed.
3. Expand the required section.  
All the parameters of the section are listed. For each parameter, you can see the default value.
4. In the context menu of the configuration parameter that you want to change, choose [Change...](#)  
The [Change Configuration Value](#) dialog box appears.
5. Enter the new value for the required layer.

Layer	Description
<b>System</b>	The value configured for the system applies to the system as whole, including all hosts of multi-host systems and all tenant databases of multi-DB systems.
<b>Host</b>	<p>For some properties, it is possible to set host-specific values if the system has multiple hosts.</p> <p>If host-specific values are possible, you can expand the <a href="#">Hosts</a> area of the <a href="#">Change Configuration Value</a> dialog box, select the relevant host(s), and enter the host-specific value(s).</p> <p>It is possible to enter both a value for the system as a whole and for individual hosts. In this case, the system-specific value only applies to those hosts that do not have a host-specific value.</p>
<b>Database</b>	<p>For some properties, it is possible to set database-specific values if the system has tenant databases.</p> <p>If database-specific values are possible for a given property, they can be configured both in the system database and the tenant database.</p>

Layer	Description
	<p>From the system database, you can configure database-specific values for all tenant databases in the system. From a tenant database, you can configure database-specific values only for that database.</p> <p>It is possible to enter a value for the system as a whole and individual databases. In this case, the system-specific value only applies to those databases that do not have a database-specific value.</p>

### Note

If it is not possible to enter a host-specific or a database-specific value, the disabled icon (⏏) is displayed in the host or database column of the list view, and there is no *Hosts/Databases* area in the *Change Configuration Value* dialog box.

## Results

- If you entered a new value for a parameter at system level, it is displayed in the *System* column with a green circle (●).
- If you entered a new value for a parameter at host level, a gray rhombus (◆) appears in the *Host* column. To show information about a specific host, select the host from the *Host* filter.
- If you entered a new value for a parameter at database level, a gray rhombus (◆) appears in the *Database(s)* column. If you are logged on to the system database, you can show information about a specific database by selecting the database from the *Database* filter. This is only possible in the system database.

## Next Steps

If necessary, restart the system.

## 6.4.3.2 Reset a System Property in SAP HANA Studio

You can restore changed parameters in the configuration files of an SAP HANA system back to their default values.

### Prerequisites

- You have the system privilege INIFILE ADMIN.
- In multiple-container systems, you must have the system privilege DATABASE ADMIN if you are resetting the system property of a tenant database from the system database.

### Procedure

1. In the Administration editor, choose the *Configuration* tab.  
A list of all configuration files appears.
2. Expand the configuration file that you want to change.  
All the sections of the configuration file are listed.
3. Expand the required section.  
All the parameters in the section are listed. You can identify parameters that have user-defined values at system level and/or host level and/or database level with a green circle (●) and gray rhombus (◆) respectively.
4. To delete a user-defined value and restore the default value, you can choose one of the following methods:

Procedure	Result
<p>Delete with automatic reset:</p> <ol style="list-style-type: none"><li>1. In the context menu of the configuration parameter, choose <i>Delete</i>. The <i>Delete Configuration Value</i> dialog box appears.</li><li>2. Choose the layer whose user-defined values you want to delete.</li><li>3. Choose <i>Delete</i>.</li></ol>	<p>The user-defined value(s) are cleared and the default value(s) are re-applied.</p> <div data-bbox="826 1541 1393 1675"><p><b>i Note</b></p><p>If you added a new parameter to a section, <i>Delete</i> deletes the parameter.</p></div>
<p>Manually restore default:</p> <ol style="list-style-type: none"><li>1. In the context menu of the configuration parameter, choose <i>Change...</i> The <i>Change Configuration Value</i> dialog box appears.</li><li>2. For the required layers, choose <i>Restore Default</i>, or if you want to reset all visible layers, choose <i>Restore Default for All</i>.</li><li>3. Choose <i>Save</i>.</li></ol>	<p>The user-defined value(s) are cleared and the default value(s) are re-applied.</p>

## 6.4.4 Console Tool setParameter.py

You can use the console tool `setParameter.py` to make changes to configuration parameter values, it can be run from the command line or integrated with other administration management tools and scripts.

### Using The Tool

The tool can be used either when the database is offline or online if for any reason it is not possible to make a configuration parameter change by executing an SQL statement. The tool can be run from the command line or integrated with other cluster management tools which may not have online access to the system. The tool ensures that if changes are made simultaneously to an ini file the changes are synchronized and applied correctly, this eliminates the need for administrators to directly edit ini files.

Using the tool when the system is online you can also enter a comment to provide transparency about why a change was made; comments are saved in table `M_INIFILE_CONTENT_HISTORY`. Also when the system is online you can make a parameter change and include a request to reconfigure the services at the same time.

When you identify the parameter value to change you also specify at which layer the change should be made (see example which follows):

- SYSTEM
- DATABASE:<DATABASENAME>
- HOST:<HOSTNAME>

Use the host layer to make a change to a parameter on a remote host. In this case the system must be online and the host must be reachable. If no host name is provided localhost is assumed.

### Syntax

The command supports both setting and unsetting parameters. No key value is required when unsetting a parameter:

```
python setParameter.py -set (or unset) =<LAYER>/<INIFILE_NAME>/<SECTION>/  
<KEY>=<VALUE>  
[-comment=comment] [-reconfigure] [-sapcontrol=1]
```

The tool also supports a 'help' argument (-h) which displays a page of help text. The help page is shown automatically if invalid syntax is entered.

## Example

You can use the tool as a script to set or unset multiple values at the same time. The following example sets the password length requirement and unsets the password layout parameter. This example uses the `reconfigure` argument (assuming the system is running) so the command will also attempt to reconfigure the service:

```
python setParameter.py -set="DATABASE:MyDatabase/indexserver.ini/password_policy/minimal_password_length=10"
-comment="Required Policy" -unset="DATABASE:MyDatabase/indexserver.ini/password_policy/password_layout"
-comment="layout not required" -reconfigure -sapcontrol=1
```

## Return Values

After submitting the command one of the following codes is returned indicating success or failure of the execution:

- 0 Successful execution
- 1 Could not be executed because of incorrect usage (unexpected parameter values)
- 2 Other error

If the `-sapcontrol=1` switch is set then one of the following is printed in the output:

- SAPCONTROL-OK
- SAPCONTROL-ERROR:<errorMsg>

## 6.4.5 Configure System Usage Type

You can configure the usage type of an SAP HANA system (for example, production, development) during installation with the `system_usage` parameter, or later by changing the system properties. Clients such as the SAP HANA cockpit and SAP HANA studio can use this property to alter behavior.

## Prerequisites

You have the system privilege INIFILE ADMIN.

## Context

The system usage type also governs to which resource group (production, test, development) the system is automatically assigned in SAP HANA cockpit when you register the system as a cockpit resource. During installation the `system_usage` parameter is available to set this value - refer to the *SAP HANA Server Installation and Update Guide* for details.

## Procedure

1. In the `global.ini` configuration file, change the value of the `usage` property in the `system_information` section.

You can enter any value, but the values listed below can be used by clients to alter behavior. This may trigger a warning to users when they are about to perform critical operations on systems with usage type **production** (for example, execute SQL statements, stop or restart the system, perform a data backup, and so on).

- production
- test
- development
- custom (default)

### **i** Note

If the system usage type is anything other than one of these values, you will not be able to register the SAP HANA system as a resource in the SAP HANA cockpit.

2. Restart the system.

## Related Information

[system\\_usage](#)

[Database Groups \[page 84\]](#)

## 6.4.6 Reserve Connections for Administrators

If the maximum number of connections has been reached in an SAP HANA system, it is not possible for anyone to log on, not even an administrator. For this reason, you can reserve a certain number of connections for administrative access only.

## Prerequisites

You have the system privilege INIFILE ADMIN and SESSION ADMIN.

## Procedure

1. In the `global.ini` configuration file, change the value of the `reserved_connections` property in the `session` section.

As the value, specify the number of connections you want to reserve. The default number of reserved connections is 10. The minimum number is 1.

2. Restart the system.

## Results

When the maximum number of connections minus the number reserved connections is reached, only an administrator with the system privilege SESSION ADMIN can log on to the system, for example, to resolve blocking situations by canceling sessions.

## 6.5 Managing SAP HANA Licenses

A valid license key is required to use the SAP HANA database. Additional license keys are required for certain applications running on SAP HANA, as well as for certain SAP HANA options and capabilities.

For most on premise SAP software, license keys are required to activate the product. You can request a license from the License Key Application of the SAP ONE Support Launchpad (specific credentials are required):

<https://support.sap.com/en/my-support/keys.html>

You will receive the license by email as a text file (the license key value is a single line in the file) which you can then upload and apply; this will license the usage of your system up to an allocated memory allowance.

You can apply a license key in SAP HANA cockpit (Upload System DB License). In cockpit you can also see which licenses are available in your database, you can install or remove license keys, and also view memory usage with respect to licensing.

You can also apply a license key from the SQL command line using the statement SET SYSTEM LICENSE where the license text is appended to the command.

Further details of licenses and license types are provided in this section.

## Related Information

[License Keys for SAP HANA Database \[page 330\]](#)

[Managing Licenses in SAP HANA Cockpit \[page 332\]](#)

[SET SYSTEM LICENSE Statement \(System Management\)](#)

[Important Disclaimer for Features in SAP HANA](#)

## 6.5.1 License Keys for SAP HANA Database

The SAP HANA database supports two kinds of license keys: temporary license keys and permanent license keys

SAP HANA licenses can be installed for the system database (global) or for a single tenant database (local). Global licenses are for the system database and all the tenant databases, but a license installed in a tenant database governs only that tenant database. If you remove a tenant-specific license key, that tenant database reverts to the global license key installed in the system database.

### Temporary License Keys

A temporary license key is automatically installed with a new SAP HANA system. A temporary license key is valid for 90 days. During this period, request and install a permanent license key.

### Permanent License Keys

#### Permanent License Keys: Expiration

Before a permanent license key expires, request and apply a new permanent license key. If a permanent license key expires, a (second) temporary license key is automatically installed. This temporary license key is valid for 28 days. During this time, you can request and install a new permanent license key.

You can request a permanent license key on SAP Support Portal (<http://support.sap.com>) under *Request Keys*. Permanent license keys are valid until the predefined expiration date. Furthermore, they specify the amount of memory licensed to an SAP HANA installation.

#### Permanent License Keys: Types

There are two types of permanent license key for SAP HANA: unenforced and enforced.

If an unenforced license key is installed, the operation of SAP HANA isn't affected if its memory consumption exceeds the licensed amount of memory. However, if an enforced license is installed, the system is locked down when the current memory consumption of SAP HANA exceeds the licensed amount of memory plus some tolerance. If lockdown occurs, either SAP HANA needs to be restarted, or a new license key that covers the amount of memory in use needs to be installed.

The two types of permanent license key differ from each other in the following line in the license key file:

License Key Type	License Key File Entry
Unenforced	SWPRODUCTNAME=SAP-HANA
Enforced	SWPRODUCTNAME=SAP-HANA-ENF
	SWPRODUCTNAME=SAP-HANA-DEV
	SWPRODUCTNAME=SAP-HANA-DIGITAL

## i Note

It's technically possible to install an enforced license in an SAP HANA instance with a regular, unenforced permanent license. In this case, the unenforced license key has priority. That is, if a valid unenforced license key is found, excessive memory consumption doesn't result in a system lockdown. However, if one license key expires and becomes invalid, the other license, if valid, becomes the valid license key of the instance. If the latter is an enforced license key, then the memory consumption is checked.

## License Keys for Tenant Databases

You can install permanent license keys in individual tenant databases. The license key installed in a tenant database is valid for that database only and takes precedence over the license key installed in the system database. If a tenant-specific license key isn't installed, the system database license key is effective in the tenant database.

## → Tip

The system view `SYS.M_LICENSE` provides tenant administrators with information on the license key effective in their tenant database, as well as where the license key is installed: in the tenant database itself or in the system database. System administrators can use the view `SYS_DATABASES.M_LICENSE` to see the same information for all tenant databases.

## System Lockdown

The system goes into lockdown mode in the following situations:

- The permanent license key has expired and either:
  - You didn't renew the temporary license key within 28 days, or
  - You did renew the temporary license key but the hardware key has changed
- The installed license key is an enforced license key and the current memory consumption exceeds the licensed amount plus the tolerance.
- You deleted all license keys installed in your database.

In lockdown mode, it isn't possible to query the database. Only a user with the system privilege `LICENSE ADMIN` can connect to the database and execute license-related queries, such as, obtain previous license data, install a new license key, and delete installed license keys.

In addition, the database can't be backed up in lockdown mode.

## Additional SAP HANA Licenses

Additional licenses are required for certain applications running on the SAP HANA database, as well as certain SAP HANA options and capabilities. For more information, see SAP Note 1644792 (License key/installation of SAP HANA).

## Related Information

[SAP Support Portal](#)

## 6.5.2 Managing Licenses in SAP HANA Cockpit

You can use the SAP HANA cockpit to see which licenses are available in your database, to install new license keys, and to view memory usage with respect to licensing.

### Related Information

[View Licenses \[page 332\]](#)

[Install a Permanent License \[page 335\]](#)

[Export Usage Data \[page 337\]](#)

[Delete Licenses \[page 338\]](#)

### 6.5.2.1 View Licenses

With SAP HANA cockpit, you can view licenses installed in your SAP HANA database.

#### Prerequisites

- You have the system privilege LICENSE ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Procedure

1. On the [Database Overview](#) page, navigate to the the [Database Administration](#) card, then choose [Database Licenses](#).

All licenses installed in the database are listed.

2. Choose an option:

Option	Description
<p>To view more information about a license</p>	<p>Select the license.</p> <p>License-specific information, and, if applicable, memory usage data, is displayed.</p> <p>For more information, see <i>License Details</i>.</p> <div data-bbox="826 521 1401 707" style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>If you're viewing license information in the system database, memory usage data is for the system as a whole. In a tenant database, only the usage data of the tenant database itself is shown.</p> </div>
<p>To view information about the licenses for one or more tenant databases</p>	<p>By default, the licenses for the system database are shown.</p> <p>To view a different database, select it from the <i>Database Name</i> menu.</p> <p>To view licenses for the system database and all tenant-specific licenses, remove all database names from the <i>Database Name</i> field.</p> <p>Here, you can see whether a tenant database is using the system database license, or whether it has its own license.</p> <p>If a license is uninstalled, it is no longer visible.</p>
<p>To request a new license</p>	<p>Select the database, then choose <i>Request New License</i>.</p> <p>The following information is displayed: Hardware key, System ID, installation number, and system number. This information is needed to apply for a new license.</p> <p>To apply for an SAP HANA license, choose <i>Go to the SAP Support Portal</i>.</p> <p>For more information, see <i>SAP Note 1644792 (License key/installation of SAP HANA)</i>.</p>

[License Keys for SAP HANA Database \[page 330\]](#)

[SAP Note 1644792](#)

## 6.5.2.1.1 License Details

The [Database Licenses](#) page provides you with detailed information about all licenses installed in the SAP HANA database.

### General Information for SAP HANA Database Licenses

Field	Description
Hardware Key	Unique hardware key
System ID	Unique SAP system identifier
License Type	License type, either permanent or temporary
Product Description	SAP HANA database
Starts On	Date as of which the license is valid
Expires On	Date on which the license expires
Licensed Memory Usage	Amount of memory usage licensed
Peak Memory Usage	Highest recorded value for main memory usage consumed by the SAP HANA database
GLAS ID	Unique product ID of SAP HANA required for license auditing

#### **i** Note

If you're viewing the information in the system database, memory usage data is for the system as a whole. In a tenant database, only the memory usage data of the tenant is shown.

The following additional fields are available if SAP Business Warehouse (SAP BW) is running on the SAP HANA database.

Field	Description
Peak Memory Usage of SAP BW	Highest recorded value for main memory usage consumed by SAP BW
GLAS ID of SAP BW	Unique product ID of SAP BW required for license auditing
Peak Memory Usage of Non-SAP BW Components	Highest recorded value for main memory usage consumed by SAP HANA
GLAS ID of Non-SAP BW Components	Unique product ID of SAP HANA required for license auditing

## General Information for Other SAP HANA Licenses

Field	Description
Hardware Key	Unique hardware key
System ID	Unique SAP system identifier
License Type	License type, either permanent or temporary
Product Description	Product for which the license is valid
Starts On	Date as of which the license is valid
Expires On	Date on which the license expires
Licensed <license_metric>	Amount of usage licensed  The unit of measurement varies from product to product. For example, SAP HANA dynamic tiering licensing is based on hard disk usage.
Peak <license_metric>	Highest recorded usage value consumed
GLAS ID	Unique product ID required for license auditing

## Memory Usage

The memory usage graph is available for SAP HANA database licenses and shows you the peak memory usage recorded every month for the previous twelve months.

### 6.5.2.2 Install a Permanent License

To use SAP HANA, you must request and install a permanent license key. You can do this in the SAP HANA cockpit.

## Prerequisites

- You have authorization to request permanent license keys on SAP Support Portal.
- You have the system privilege LICENSE ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

Request and install a permanent license key, for example, if the current license key of your SAP HANA system is about to expire, or you want to extend the amount of memory licensed for your system.

SAP HANA licenses can be installed for:

- The system database (global)  
Global licenses are for the system database and all the tenant databases.
- A single tenant database (local)  
A license installed in a tenant database governs only that tenant database.  
If you remove a tenant-specific license key, that tenant database reverts to the global license key installed in the system database.

### i Note

You can also request and install the license keys required for applications running on SAP HANA, as well as SAP HANA options and capabilities, using the procedure described here.

## Procedure

1. From the [Database Overview](#), navigate to the [Database Administration](#) card, then choose [Database Licenses](#).

### i Note

If the system is in lockdown, you're automatically prompted to navigate to the [License Details](#) page.

2. Request a permanent license key as follows:

- a. On the [Database Licenses](#) page, choose [Request New License](#).

If the system is currently running on a temporary license key, the hardware key and the system ID are displayed.

If the system already has a valid permanent license key, the installation number and system number are displayed. You need this information to fill out the request form for the license key.

- b. Choose [Go to SAP Support Portal](#).
- c. In SAP Support Portal, choose [Request Keys](#).

You're forwarded to the license key application of the SAP ONE Support Launchpad, where you can request a new key. When completing the request form, if you have the installation number and system number, then enter them first so that the other input fields are auto-completed. When you've finished, choose [Submit](#).

The permanent license is sent to you as an e-mail attachment.

3. To install the license key, choose [Upload System DB License](#), then upload the license file (\*.txt file) that you received by e-mail.

### i Note

If you're installing a second or subsequent permanent license key, it must have the same system-identification data as the permanent license key previously installed in the database. In particular, the

system ID (SID), hardware key, installation number, and system number must be the same. If any difference is detected in this data, the installation of the license key fails and no change is made to the license key in the database.

4. If required, specify the usage type for the system.

If a usage type has already been defined, you aren't prompted to specify a usage type.

The usage type can be:

- NONPRODUCTION  
Choose this type if your system isn't used for production.  
For example, for a system used for testing or quality assurance.
- RUNTIME  
Choose this type if you're using a RUNTIME license from SAP.
- FULL-USE  
Choose this type if you're using a FULL-USE license from SAP.
- ADMINISTRATION  
Choose this type if you're using your system as the basis to run SAP HANA Cockpit.

Optionally, use the following SQL statement to set the usage type when installing the license key:

```
SET SYSTEM LICENSE <license_key> [USAGE [NONPRODUCTION|RUNTIME|FULL|  
ADMINISTRATION] ]
```

### 6.5.2.3 Export Usage Data

SAP HANA licensing is based on the amount of memory used. The SAP HANA database tracks the highest value for memory used per calendar month for a one-year period. You may be requested by SAP to export this data for license audit purposes to verify the suitability of your license.

#### Prerequisites

- You have the system privilege LICENSE ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Procedure

1. From the [Database Overview](#), navigate to the [Database Administration](#) card, then choose [Database Licenses](#).
2. Choose [Export System DB System Measurement](#).
3. If a usage type is not already defined, specify a usage type.

For more information, see *Install a Permanent License*.

## Results

Usage data for all installed licenses is exported to the file `SAPHANASystemMeasurement.xml`, which is downloaded in line with your browser's file download settings.

### i Note

In Safari, the file isn't automatically downloaded. Instead, the content opens in a new tab or window and you must manually save the file by pressing `⌘` + `S`, choosing *page source*, and specifying a file name.

## Related Information

[SAP Note 1704499](#)

[Install a Permanent License \[page 335\]](#)

## 6.5.2.4 Delete Licenses

You can delete all existing license keys in the SAP HANA database, or you can delete licenses in the system database, leaving only tenant-specific licenses.

## Prerequisites

- You have the system privilege LICENSE ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, navigate to the the [Database Administration](#) card, then choose [Database Licenses](#).
2. Choose the option to delete all licenses.

If you are Connected To...	Option
A tenant database	<a href="#">Delete All Licenses</a> The license keys installed in the system database now take effect.

If you are Connected To...	Option
The system database	<p data-bbox="826 338 1197 365"><a href="#">Delete All System DB System Licenses</a></p> <p data-bbox="826 389 1190 416">The system database is locked down.</p> <p data-bbox="826 441 1374 501">Any tenant databases that do not have their own tenant-specific license key are also locked down.</p> <p data-bbox="826 526 1377 586">To unlock the databases, a new permanent license key is required.</p>

## Results

All permanent license keys are deleted.

## 6.6 Monitoring the SAP HANA Database

It's important that you monitor the operation of SAP HANA databases on a regular basis. Although SAP HANA actively alerts you of critical situations, keeping an eye on resource usage and performance will help you identify patterns, forecast requirements, and recognize when something is wrong. You can monitor SAP HANA using both the SAP HANA cockpit and the SAP HANA studio. These tools rely on the monitoring and alerting information provided by system views and the statistics service.

### Related Information

[Monitoring in SAP HANA Studio \[page 383\]](#)

[Monitoring in SAP HANA Cockpit \[page 339\]](#)

[System and Statistics Views \[page 413\]](#)

[The Statistics Service \[page 414\]](#)

### 6.6.1 Monitoring in SAP HANA Cockpit

You can perform several database monitoring tasks in the SAP HANA cockpit using a range of dedicated apps.

- Monitor overall database health
- Monitor status and resource usage of individual database services
- Analyze database performance across a range of key performance indicators related to memory, disk, and CPU usage

- Analyze the comparative memory utilization of column tables
- Analyze the memory statistics of the components of database services
- Monitor alerts occurring in the database and analyze patterns of occurrence
- Configure the alerting mechanism, for example, change alert threshold values, switch alert checkers on/off, and check for alerts out of schedule
- Monitor the status of system replication (if enabled)

If your system contains tenant databases and you are the overall system administrator, you can perform additional monitoring tasks at the system level.

### i Note

If your system does not support tenant databases (single-container system), system and database are perceived as a single unit and are monitored and administered as a single database.

## Related Information

[Open the SAP HANA Cockpit \[page 45\]](#)

[Managing Tenant Databases \[page 200\]](#)

[The Performance Monitor \[page 424\]](#)

[Alerts \[page 371\]](#)

[Alert Configuration \[page 375\]](#)

### 6.6.1.1 Using the Database Overview Page to Manage a Database

The *Database Overview* page displays important metrics and available functions, regardless of whether the database you're managing is a single-host or multi-host system, or a tenant database.

Through the *Database Overview* page, you can view key health indicators for this specific database, such as database status, alerts, and database utilization. You also have access to tools that allow you to perform database administration tasks, such as performance analysis, and executing SQL statements. Different parts of a single card can link to different views or applications. This way, you can see various components in a single view and decide whether to further examine issues by drilling down.

The *Database Overview* page is organized by cards, each of which represents a task or group of actions. You can search for a specific card, or filter by area to see related cards.

To launch the *Database Overview*, drill down on the name of the database from the *Database Directory*. Unless your administrator has enabled single sign-on, you'll need to connect to the database with a database user that has the system privilege CATALOG READ and SELECT on \_SYS\_STATISTICS.

### i Note

If you register an offline database and display its *Database Overview*, much of the information that appears on the *Database Overview* of an online database is missing. You can use the cockpit to start the database: click the *Stopped* icon, then click *Start System*.

The cards that appear on the [Database Overview](#) depend on whether you're connected to a tenant or system database and whether or not it's part of a multi-host system.

## Services

Your status can be running, running with issues, or stopped. Clicking on this status brings you to [Manage Services](#) where you can stop or kill a service, and start or stop a system.

## Alerts

Alert counts for the database are displayed for high- and medium-priority alerts, broken down by the nine alert categories defined in SAP HANA. (You can refresh the displayed data by using the manual or auto-refresh icons in the top-right corner). Clicking on the [Alerts](#) card brings you to the [Alert Monitor](#) for the database. In the bottom-right corner, there's a status message showing vital information about SAP HANA processes that collect data. By noting the status messages within the card, you can easily find out the validity of what you are seeing.

## Usage and Performance Metrics

You can monitor key database metrics through the [CPU Usage](#), [Memory Usage](#) and [Disk Usage](#) cards, as well as the [Threads](#), [Sessions](#), and [Monitor Statements](#) cards. In a multi-host system, each host is represented by a clickable bar, with the selected host having a time graph displayed to the right of the bar chart. Hover over the bars to see details for the selected host. If a bar is highlighted, there's an associated high (red) or medium (yellow) alert. With single-host databases, since there's only one host, no bar graphs are displayed. By viewing this high-level information, you can decide whether to drill down to the [Performance Monitor](#). See [Monitoring and Analyzing with the Performance Monitor](#).

## Smart Data Access

Without copying data directly into an SAP HANA database, you can use Smart Data Access to access remote data as if it were stored in local tables. Refer to the Smart Data Access section of the [SAP HANA Administration Guide](#).

## System Replication

If a database is part of a system replication configuration, you can monitor the status of replication between the primary system and one or more secondary systems. See [Monitoring SAP HANA System Replication with the SAP HANA Cockpit](#).

## Additional Functionality

You can launch additional functionality by selecting any of the links organized under the headings [Monitoring](#), [DB Administration](#), [User and Role Management](#), [Alerting and Diagnostics](#), [Other Administration](#), [Application Lifecycle Management](#), [Platform Lifecycle Management](#), and [Help](#). Specific links and related tasks are described in the subsequent topics of this guide.

## Security

The [Data Storage Security](#), [Auditing](#), [Authentication](#) blocks, and the [Security Related Links](#) help you to monitor many critical security settings. Additionally, you can perform administration tasks related to data and communication encryption, and audit logging. See [Monitoring Critical Security Settings](#).

## Performance Management

Use [Analyze Workload](#), [Capture Workload](#), and [Replay Workload](#) to manage performance. See [Capturing and Replaying Workloads](#).

Use [Analyze Workload](#) to analyze the database performance. See [Monitoring, Analyzing, and Improving Performance](#).

## Additionally Installed SAP HANA Contexts

Other cockpit features that allow you to manage additionally installed contexts (for example, SAP HANA dynamic tiering) are only visible and available if the specific context has been installed.

## 6.6.1.1.1 Cards Available on the Database Overview Page

The SAP HANA cockpit offers many pages to help you administer and monitor databases. These pages are accessible by selecting individual cards or links on the [Database Overview](#) page. If you don't have the required privileges, specific cards, features, or actions aren't available to you.

### Monitoring View

Card	Description
<a href="#">Services</a>	Monitors the status services. Opens the <a href="#">Manage Services</a> page where you can view database usage of individual database services, as well as perform other administration tasks such as stopping services. Indicates overall database health and the number of services running and not running are indicated. If the database is distributed across multiple hosts, it includes all services on worker hosts.
<a href="#">Alerts</a>	Monitors the status of the database and its services and the consumption of system databases. Indicates the number of high and medium alerts currently raised in the database. Opens the <a href="#">Alerts</a> page where you can view and analyze alert details.
<a href="#">Memory Usage</a>	<p>Monitors the total amount of memory currently used by the SAP HANA database in relation to the allocation limit.</p> <p><a href="#">Performance Monitor</a> page - Lets you visualize and explore the usage history of key system databases (CPU, memory, and disk). When accessed from the <a href="#">Memory Usage</a> card, memory-related KPIs are automatically selected.</p> <p><a href="#">Analyze Workloads</a> page - Monitors overall system health and lets you identify the root cause of potential performance issues.</p> <p>⋮ <a href="#">(More)</a> - Additional pages available for monitoring cache, memory, and load configuration.</p>
<a href="#">CPU Usage</a>	<p>Monitors the percentage of CPU used. If the database is distributed across multiple hosts, the CPU usage of all worker hosts is indicated. The host with the highest (most critical) CPU usage is shown in more detail.</p> <p><a href="#">Performance Monitor</a> - Lets you visualize and explore the usage history of key system databases (CPU, memory, and disk). When accessed from the <a href="#">CPU Usage</a> card, CPU-related KPIs are automatically selected.</p> <p><a href="#">Analyze Workloads</a> - Monitors overall database health and lets you identify the root cause of potential performance issues.</p>

Card	Description
<a href="#">Disk Usage</a>	<p>Monitors the <b>total</b> usage of all disks, including space used by non-SAP HANA data. The disk with the highest (most critical) disk usage is shown in more detail.</p> <p><a href="#">Performance Monitor</a> - Lets you visualize and explore the usage history of key system databases (CPU, memory, and disk). When accessed from the <a href="#">Disk Usage</a> card, disk-related KPIs are automatically selected.</p> <p><a href="#">Monitor Disk Volume</a> - Monitors disk statistics to ensure that there's enough space on disk for data volumes and log volumes.</p> <p><a href="#">Analyze Workloads</a> - Monitors overall database health and lets you identify the root cause of potential performance issues.</p>
<a href="#">SQL Statements</a>	<p>Monitors and analyzes different types of statements in your database, including active, SQL Plan cache, and expensive statements. Lets you enable statement memory tracking.</p>
<a href="#">Monitoring</a>	<p><a href="#">Performance Monitor</a> - Lets you visualize and explore the usage history of key system databases (CPU, memory, and disk).</p> <p><a href="#">Monitor Table Usage</a> - Monitors the number of hosts monitored and the name of the host with the highest memory usage. Opens <a href="#">Table Usage</a> page, where you can visualize tables by size, explore the usage history of tables, and move tables to warm storage.</p> <p><a href="#">Open blocked transactions</a> - Monitor transactionally blocked threads.</p> <p><a href="#">Profile memory</a> - Analyzes the memory consumption of the SAP HANA database over time can help you pinpoint bottlenecks, identify patterns, and forecast requirements.</p>
<a href="#">Threads</a>	<p>Monitors the number of currently active and blocked threads.</p>
<a href="#">Admission Control</a>	<p>Manages peak load by applying processing limits and determining how to handle new requests if the database is close to the point of saturation.</p>
<a href="#">Sessions</a>	<p>Analyzes the sessions connected to your SAP HANA database helps you identify which applications or which users are currently connected to your database, as well as what they are doing in terms of SQL execution.</p>
<a href="#">System Replication</a>	<p>Monitors status of system replication. On SYSTEMDB, the card lets you configure the system for replication</p>

## Security and User Management View

Card	Description
<a href="#">Data Encryption</a>	<p>Configures SAP HANA encryption services, including data volume and redo logs and data and log backups.</p>
<a href="#">Auditing</a>	<p>Monitors and configure audit policies, audit trails, and auditing-related alerts.</p>

Card	Description
<a href="#">Anonymization Report</a>	Monitors analytics on data while still protecting the privacy of individuals through anonymization views in the case of SQL, and as anonymization nodes in the case of calculation views.
<a href="#">User and Role Management</a>	<ul style="list-style-type: none"> <li>• <a href="#">User Management</a> - Monitors and manages database users.</li> <li>• <a href="#">Role Assignment</a> - Monitors and manages roles granted to database users.</li> <li>• <a href="#">Privilege Assignment</a> - Monitors and manages privileges granted to database users.</li> <li>• <a href="#">Role Management</a> - Monitors and manages roles to be granted to database users.</li> <li>• <a href="#">User Group Management</a> - Monitors and manages user groups for database users.</li> <li>• <a href="#">Authorization Dependency Viewer</a> - Analyzes database objects and their dependencies to help resolve object authorization errors..</li> </ul>
<a href="#">Security Related Links</a>	<ul style="list-style-type: none"> <li>• <a href="#">Certificate Store</a> - Monitors the in-database repository for X.509 client certificates.</li> <li>• <a href="#">Certificate Collections</a> - Monitors and manages certificate collections.</li> <li>• <a href="#">View network security information</a> - Monitors the cryptographic library in use in the database and the minimum accepted version of the transport layer security/secure sockets layer (TLS/SSL) protocol and lets you can see more detailed information about network configuration.</li> <li>• <a href="#">SAML Identity Providers</a> - Monitors and manages Security Assertion Markup Language (SAML) identity providers.</li> <li>• <a href="#">JWT Identity Providers</a> - Monitors and manages JSON Web Tokens (JWT) identity providers.</li> <li>• <a href="#">Security Checklist</a></li> <li>• <a href="#">Security Administration Help</a> - View documentation describing those security administration tasks that you can perform using the SAP HANA cockpit.</li> <li>• <a href="#">SAP HANA Security Website</a> - Link to the SAP HANA security website.</li> </ul>
<a href="#">Authentication</a>	Manages password policies (default or customized) and password blacklists.
<a href="#">Insufficient Privilege Details</a>	Displays information about an "insufficient privilege" error.

## Administration View

Card	Description
<a href="#">Capture Workload</a>	<p>Monitors captured workloads.</p> <p><a href="#">Start new Capture</a> - Opens the <a href="#">Capture Configuration</a> page, where you can configure new workloads for capture.</p>
<a href="#">Replay Workload</a>	<p>Monitors the number of replayed workloads. Opens the <a href="#">Replay Workload</a> page, where you can preprocess workloads, replay preprocessed workloads and monitor during workload replay.</p> <p><a href="#">Start New Replay</a> - Starts and stops any started replays.</p>

Card	Description
<a href="#">Database Backups</a>	<p>Manages backup and recovery of databases. Opens the <a href="#">Backup Catalog</a> page, where you can view a list of existing backups.</p> <p><a href="#">Backup Schedules</a> - Monitors and manages scheduled backups.</p> <p><a href="#">Recover Databases</a> - Recovers a database by selecting from a list of existing backups.</p> <p><a href="#">Copy Database</a> - Copies an SAP HANA database by recovering it to the same database or to a different database.</p> <p><a href="#">Backup Configuration</a> - Monitors and manages backup configurations.</p>
<a href="#">Smart Data Integration</a>	See Smart Data Integration Guide ( <a href="https://help.sap.com/viewer/p/HANA_SMART_DATA_INTEGRATION">https://help.sap.com/viewer/p/HANA_SMART_DATA_INTEGRATION</a> ).
<a href="#">Database Administration</a>	<p><a href="#">Manage database configuration</a> - Monitors and manages configuration (*.ini) files at the system, database, and host level.</p> <p><a href="#">Database Explorer</a> - Access the to query information about the database, view information about your database's catalog objects, and open the SQL console to execute SQL statements.</p> <p><a href="#">Manage workload classes</a> - Monitor and manage workload classes.</p> <p><a href="#">Manage database licenses</a> - Monitor and manage license keys for the database.</p>
<a href="#">Manage SQL Performance</a>	Analyzing statement performance to understand performance issues of a query execution and other query execution aspects of the SAP HANA database. Tools include Statement Hints, SQL Plan Stability, Plan Trace, Saved Plans, and Data Cache.
<a href="#">Recommendations</a>	Monitor recommendations to get suggestions for changes you can apply to the SAP HANA database to increase its performance and operation. Recommendation types include Ad Hoc, Physical Design, and SQL.
<a href="#">Alerting and Diagnostics</a>	<ul style="list-style-type: none"> <li>• <a href="#">Alerts Definitions</a> - Opens <a href="#">Alert Definitions</a> where you can configure alert schedules and thresholds and set up e-mail notification.</li> <li>• <a href="#">Configure Tracing</a></li> <li>• <a href="#">View trace and diagnostic files</a> - Opens the <a href="#">Trace</a> tool of the SAP HANA Database Explorer for SAP HANA cockpit.</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>The <a href="#">Trace</a> tool opens in a new window.</p> </div> <ul style="list-style-type: none"> <li>• Manage full system information dumps.</li> </ul>
<a href="#">Database Information</a>	View general information about the SAP HANA database, such as operational status and database version, can assist you to monitor your database.

Card	Description
<a href="#">Table Distribution</a> (Tenant only)	Monitor and save the current table distribution, automatically generate an optimized table distribution, re-run a previously executed plan, or restore a saved plan.  <a href="#">View Current Table Distribution</a> - View how tables are distributed across the hosts.
<a href="#">Other Administration</a>	<a href="#">Manage Hadoop Cluster</a> - Navigate to the Apache Ambari Web site and monitor Hadoop clusters.
<a href="#">Smart Data Access</a>	<ul style="list-style-type: none"> <li>• <a href="#">Running Statements</a> - Monitors the number of running remote statements. Opens the <a href="#">Remote Statements Monitor</a> page, where you can analyze remote statements in the database.</li> <li>• <a href="#">Active Connections</a> - Monitors the number of active remote connections. Opens the <a href="#">Remote Connections Monitor</a> page, where you can analyze remote connections in the database.</li> </ul>
<a href="#">Platform Lifecycle Management</a> (SYS-TEMDB only)	Specific links and related tasks that encompasses the installation and update of an SAP HANA server, mandatory components, and additional components, as well as the post-installation configuration.

## 6.6.1.1.2 Database Information

Accessing general information about the SAP HANA database, such as operational status and database version, can assist you to monitor your database.

In SAP HANA cockpit, you can access [Database Information](#) by drilling down in the [Database Overview](#) when the [Administration](#) or [All](#) view is selected. To do this, your database user needs the system privilege CATALOG READ.

Details include:

- Information such as operational status, database usage type, whether the database has multiple hosts, the number of hosts (if distributed), and database version
- The SAP HANA version history
- Information about the plug-ins that are installed
- The status of replication from your production database to a secondary database. This information is only available and applicable if you are operating a secondary instance of your database (for example, in a high availability scenario). If this is the case, then content from the primary or production instance of your database is replicated to the secondary instance.

## 6.6.1.2 Monitoring Database Health and Resource Usage

To identify problems early and avoid disruptions, you need to monitor your SAP HANA database continuously.

You can monitor the overall status and resource usage of the SAP HANA database at a glance on the homepage of the SAP HANA cockpit. Then, drill down for more detailed monitoring and analysis.

## 6.6.1.2.1 Services

To monitor the health of your SAP HANA database in more detail, for example, to troubleshoot performance bottlenecks, you can analyze the status and resource usage of individual database services. If necessary, you can perform follow-up operations, such as starting missing services, stopping a service, or killing a service. You can also start or stop a system.

You can use the cockpit to monitor and manage more than one database, each running version SAP HANA 1.0 SPS 12 or later. Any database running version SAP HANA 2.0 SPS 01 or later is set in multiple-container mode by default. The cockpit can also monitor single-container systems running earlier versions of SAP HANA. When you access the [Manage Services](#) application, the operations you have the option to perform depend on whether you are displaying a tenant or a system database.

Click [Manage Services](#) on the [Services](#) card. The [Services](#) card appears on the [Database Overview](#) page when the [Monitoring](#) or [All](#) view is selected.

You see the status of all the services in the database. For each service, detailed information about its memory consumption is available. For more information, see [Service Details](#).

Not all columns are visible by default. You can configure which columns are visible by clicking the  ([Settings](#)) icon. You can configure the sort order of the information by clicking the  ([Sort](#)) icon.

If there are any alerts in the system, you can see details by clicking the alert in the [Service Alerts](#) column or by clicking [Go to Alerts](#) at the top of the page.

If you want to investigate the memory usage history of a particular service, click the mini chart in the [Memory](#) column to open [Memory Analysis](#) for the service. You can also use [Reset Memory Statistics](#) link to clear the statistics history.

Depending on the situation, you may need to perform further operations on all or selected services (for example, start, stop, or kill a service). For more information about the available options, see [Operations on Services](#).

If necessary, you can also start or stop a system. See [Start a Database](#) and [Stop a Database](#).

### Related Information

[Alerts \[page 371\]](#)

[Add or Remove Services in a Tenant Database \[page 272\]](#)

## 6.6.1.2.1.1 Service Details

*Manage Services* provides you with detailed information about database services for an individual database.

### i Note

Not all of the columns listed below are visible by default. You can add and remove columns in the Columns dialog, which you open by clicking the  (*Settings*) icon in the table toolbar.

The following table lists the information available for services.

Column	Description
Host	Name of the host on which the service is running
Service	Service name, for example, indexserver, nameserver, xsengine, and so on
Status	<p>The status of the service</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"><li>• <i>Running</i></li><li>• <i>Running with Issues</i> (where at least one service isn't running, or there is at least one high alert)</li><li>• <i>Starting</i></li><li>• <i>Stopping</i></li><li>• <i>Stopped</i></li><li>• <i>Not Running</i></li></ul> <p>To investigate why the service isn't running, you can navigate to the crash dump file created when the service stopped.</p> <div data-bbox="558 1220 1394 1422"><h3>i Note</h3><p>The crash dump file opens in the <i>Trace</i> tool of the SAP HANA Web-based Development Workbench. To see this information, you need the role <code>sap.hana.xs.ide.roles::TraceViewer</code> or the parent role <code>sap.hana.xs.ide.roles::Developer</code>.</p></div>
Role	<p>Role of the service in a failover situation</p> <p>Automatic failover takes place when the service or the host on which the service is running fails.</p> <p>The following values are possible:</p> <ul style="list-style-type: none"><li>• <i>Master</i> The service is the active master worker.</li><li>• No entry The service is a slave worker.</li><li>• <i>Standby</i> The service is in standby mode. It doesn't contain any data and doesn't receive any requests.</li></ul>
Port	Port that the system uses for internal communication between services

Column	Description
Start Time	Time at which the service started
	<div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>The time is given in the timezone of the SAP HANA server.</p> </div>
Service Alerts	Alerts triggered for the service.
Process ID	Process ID
CPU	<p>Mini chart visualizing the CPU usage of the service</p> <p>Clicking the mini chart opens the <a href="#">Performance Monitor</a> for a more detailed breakdown of CPU usage.</p>
Memory	<p>Mini chart visualizing the memory usage of the service</p> <ul style="list-style-type: none"> <li>• Dark green shows the service's used memory.</li> <li>• Light green shows the service's peak memory.</li> <li>• The gray stroke represents the effective allocation limit.</li> <li>• The light gray background represents the physical memory.</li> </ul> <p>Clicking the mini chart opens the <a href="#">Memory Analysis</a> app for a more detailed breakdown of memory usage.</p>
Used Memory (MB)	<p>Amount of memory currently used by the service</p> <p>Clicking the mini chart opens the <a href="#">Memory Analysis</a> app for a more detailed breakdown of memory usage.</p>
Peak Memory (MB)	Highest amount of memory ever used by the service
Effective Allocation Limit (MB)	Effective maximum memory pool size that is available to the process considering the current memory pool sizes of other processes
Physical Memory on Host (MB)	Total memory available on the host
All Process Memory on Host (MB)	Total used physical memory and swap memory on the host
Allocated Heap Memory (MB)	Heap part of the allocated memory pool
Allocated Shared Memory (MB)	Shared memory part of the allocated memory pool
Allocation Limit (MB)	Maximum size of allocated memory pool
CPU Process Usage (%)	CPU usage of process
CPU Host (%)	CPU usage on host
Virtual Memory on Host (MB)	Virtual memory size on the host
Process Physical Memory (MB)	Process physical memory used
Process Virtual Memory (MB)	Process virtual memory
Shrinkable Size of Caches (MB)	Memory that can actually be freed in the event of a memory shortage

Column	Description
Size of Caches (MB)	Part of the allocated memory pool that can potentially be freed in the event of a memory shortage
Size of Shared Libraries (MB)	Code size, including shared libraries
Size of Thread Stacks (MB)	Size of service thread call stacks
Used Heap Memory (MB)	Process heap memory used
Used Shared Memory (MB)	Process shared memory used
SQL Port	SQL port number
Action	The available action for the service
<a href="#">Reset Memory Statistics</a>	Resets all memory statistics for all services.  Peak used memory is the highest recorded value for used memory since the last time the memory statistics were reset. This value is useful for understanding the behavior of used memory over time and under peak loads. Resetting peak used memory allows you, for example, to establish the impact of a certain workload on memory usage. If you reset peak used memory and run the workload, then you can then examine the new peak used memory value.
<a href="#">Go To Alerts</a>	Displays the alerts for this database.

[The Performance Monitor \[page 424\]](#)

[Monitoring Alerts](#)

### 6.6.1.2.1.2 Operations on Services

As an administrator, you may need to perform certain operations on all or selected services. For example, start missing services, or stop or kill a service.

Some tenant services, such as adding and starting missing services, can only be managed when connected to the SYSTEMDB, while other tenant services, such as killing a service or removing a service from a tenant can be managed when connected to either the SYSTEMDB or the tenant.

#### **i** Note

- Depending on the service, some options may not be available. You can use the cockpit to monitor and manage more than one database, each running version SAP HANA 1.0 SPS 12 or later. Any database running version SAP HANA 2.0 SPS 01 or later is set in multiple-container mode by default. The cockpit can also monitor single-container systems running earlier versions of SAP HANA.
- The SAP HANA database provides several features in support of high availability, one of which is service auto-restart. In the event of a failure or an intentional intervention by an administrator that

disables one of the SAP HANA services, the service auto-restart function automatically detects the failure and restarts the stopped service process. For more information about high availability, see *High Availability for SAP HANA* in the *SAP HANA Administration Guide*.

#### Start and Stop Services in a Tenant Database

Option	Description	Connected As	See
<a href="#">Start Missing Services</a>	Starts any inactive services.	SYSTEMDB only.	<a href="#">Start and Stop Services in a Tenant Database</a>
<a href="#">Stop Service</a>	Stops the selected service normally. The service then typically restarts automatically.	SYSTEMDB or tenant.	<a href="#">Start and Stop Services in a Tenant Database</a>
<a href="#">Kill Service</a>	Stops the selected service immediately, and if <i>Generate crash dump file</i> is selected, creates a crash dump file. The service then typically restarts automatically.	SYSTEMDB or tenant.	<a href="#">Start and Stop Services in a Tenant Database</a>
<a href="#">Add Service</a>	Adds the service you select from the list. Services can only be added to a tenant, not the system database itself.	SYSTEMDB only.	<a href="#">Add or Remove Services in a Tenant Database</a>
<a href="#">Remove Service</a>	Removes the selected service. You can only remove services that have their own persistence. If data is still stored in the service's persistence, it's redistributed to other services.  You can't remove the following services: <ul style="list-style-type: none"> <li>• Master name server</li> <li>• Master index server</li> <li>• Primary index server on a host</li> </ul>	SYSTEMDB or tenant.	<a href="#">Add or Remove Services in a Tenant Database</a>

**i Note**

To remove a service, you must have the EXECUTE privilege on the stored procedure SYS.UPDATE\_LANDSCAPE\_CONFIGURATION.

## 6.6.1.2.2 Memory Analysis

Analyzing the memory allocation of the SAP HANA database can help you understand and resolve unusual memory usage and out-of-memory incidents.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

The [Memory Analysis](#) app enables you to visualize and explore the memory allocation of every service of a selected host during a specified time range. If you notice an increase in overall memory usage, you can investigate whether it's due to a particular component, allocator, or table.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click the ► [Memory Usage](#) ► [More \(...\)](#) ► then click [Analyze Memory History](#).
2. Use the elements in the header to configure the display of memory statistics:

Dropdown	Description
<a href="#">Host and Services Selection</a>	Opt to display memory statistics from a different host and service combination.
<a href="#">Unit Selection</a>	Select a unit of measure in which to display all memory statistics
<a href="#">Last selected server time</a>	Select a time range for the memory allocation (upper) section, or select <a href="#">Custom</a> in order to edit the time range.
<a href="#">🔗 (Navigate Application)</a>	Opt to view the service you've selected through the Memory Analysis app in the Performance Monitor or the Workload Analyzer.
<a href="#">🕒 (Collection Frequency)</a>	View how often information is collected to populate the various charts and graphs. If it's necessary, you can use the <a href="#">Configuration of System Properties</a> app to modify the interval parameter of a statisticsserver component. Use caution because changes to the interval can affect performance.

Dropdown	Description
 ( <a href="#">Memory Alert Settings</a> )	Turn on or off the display of alerts and specify which priority level of alerts to display.
Threshold of Memory Usage	View the threshold of high priority memory usage alerts so you can determine what percentage of the effective allocation limit is being used by a service.

### Note

Data is collected and displayed only after the statistics server has been enabled. Ensure that you've configured the system properties (the .ini file) so that the statistics server's `active` parameter is set to `true`.

- Analyze the memory statistics by exploring the data in the upper chart.

Element	Description
Allocated Memory	The pool of memory preallocated by the host for storing in-memory table data, thread stacks, temporary results, and other system data structures.
Host Allocation Limit	The <code>global_allocation_limit</code> for the host (as set in the <code>global.ini</code> configuration file).
Service Allocation Limit	Each service running on the host has an allocation limit. Collectively, all services can't consume more memory than the global allocation limit.
Total Used Memory	The total amount of memory used by the selected service on the selected host, including program code and stack, all data and system tables, and the memory required for temporary computations.
Memory Alert Icon	Represents one or more alerts triggered by a memory event. You can click individual alert icons and scroll through details, or navigate to the <a href="#">Alerts</a> app.

- Move the vertical selection bar in the upper chart to populate the data in the lower chart. The vertical selection bar snaps to the closest time for which there's collected data for the components. You can control what is displayed in the lower chart by selecting one of its top tabs, as described in the next steps.
- Select the [Top Consumers](#) tab to have the lower chart display details about what is consuming the most memory for the host and service, in the given time period. Up to 50 top consumers are displayed. You can step through the collected data points by using the arrow buttons.

Element	Description
Name	Up to 50 allocators, objects, or other elements that have consumed the most memory during the specific time (chosen by the vertical selection bar in the upper chart).
Used Memory	The amount of memory consumed, displayed in the measurement units specified at the top of the page.
Component	The component with which the consumer is associated.

Element	Description
Top Consumers History	Expand <i>Top Consumers History</i> to see a chart of the top consumers (up to 10) for the time range selected at the top of the page.

6. Select the *Components* tab to have the lower chart display the *Used Memory by Component*.

Element	Description
Used Memory by Component	For the specific time (chosen by the vertical selection bar in the upper chart), the components of the selected service are listed in descending order of used memory.
Used Memory by Type	The donut chart displays a visual representation of the types of used memory for the specific time.
Components Used Memory History	Filling the checkbox of one or more components populates the <i>Used Memory History</i> chart.

7. Select the *Allocators* tab to display more detailed memory use in the lower chart. You can filter by component type. You can step through the collected data points by using the arrow buttons. (Allocators that have used less than 1 GB of memory aren't displayed.)

Element	Description
Used Memory by Allocator	For the specific time (chosen by the vertical selection bar in the upper chart), allocators of the selected component are listed in descending order of used inclusive memory. By clicking on an allocator, you can expand the list.
Filter by component name	To further refine the displayed allocator data, select the filter icon to specify one or more component names.
Allocators Used Memory History	Filling the checkbox of one or more allocators populates the Used Memory History chart.

8. Select the *Tables* tab to see statistics about tables' used memory or number of rows in the lower chart. Filter the display using the *Chart Value*, *Show Top (number)*, *Filter by Schema*, and *Time Range* filter options.

Element	Description
Top Tables by Size	When you select the <i>Used Memory Size</i> chart value, the chart displays the breakdown of memory usage of the highest consuming tables for the specified time.
Top Tables by Growth	When you select the <i>Used Memory Size</i> chart value, the chart displays the memory usage of the tables with the largest change in consumption for the selected time period. Hover over the data to see the <i>Previous Size</i> memory usage value from the beginning of the time period and the <i>Growth</i> during the time period (where the current size of the table is the sum of <i>Previous Size</i> and <i>Growth</i> ).

Element	Description
Top Tables by Rows	When you select the <i>Number of Rows</i> chart value, the chart displays the number of rows for each of the highest consuming tables for the specific time (chosen by the vertical selection bar in the upper chart).
Top Tables by Rows Growth	When you select the <i>Number of Rows</i> chart value, the chart displays the number or rows for each of the tables with the largest change in consumption for the selected time period.

- Select the *Out of Memory Events* tab to have the lower chart display the number of unique out-of-memory events that have occurred in the time range specified in the header. (The vertical selection bar doesn't influence the number of events displayed.)

Element	Description
Occurrences	The number of times a specific OOM event has been triggered.
Last Occurrence	The time and date of the most recent occurrence of the OOM event.
Last Reason	The parameter that triggered the most recent occurrence of the OOM event.
Statement	The SQL statement related to the OOM event.
Statement Hash	The unique identifier for the OOM event. Click the OOM identifier to open the Workload Analyzer and investigate the event.

#### → Tip

If an event has a corresponding OOM dump file, you can select *View Trace* to launch the Dump Viewer in the SAP Database Explorer.

In *Memory Statistics* charts, you can choose to display historical data for a time range between 24 hours and six weeks. In order to have a date range longer than six weeks (42 days), you can use SQL to update the `RETENTION_DAYS_CURRENT` value in the table `"_SYS_STATISTICS"."STATISTICS_SCHEDULE"`.

## 6.6.1.2.2.1 Types of Memory Alerts

The *Memory Statistics* chart can notify you about a variety of memory-related alerts.

Memory alerts related to the entire system

Alert	Description	Threshold Units	ALERT_ID
Licensed memory usage	Determines what percentage of licensed memory is used.	percent	44
Overflow of metadata version space	Determines the overflow ratio of the metadata version space.	ratio	74
Agent memory usage	Determines what percentage of total memory available on the agent is used.	percent	701

Memory alerts related to the host

Alert	Description	Threshold Units	ALERT_ID
Host physical memory usage	Determines what percentage of total physical memory available on the host is used. All processes that consume memory are considered, including non-SAP HANA processes.	percent	1
Streaming project physical memory usage	Determines what percentage of total physical memory available on the host is used for the streaming project.	percent	602
Plan cache hit ratio	Determines whether the plan cache hit ratio is too low.	ratio	91
Cached view size	Determines how much memory is occupied by the cached view.	percent	81

Memory alerts related to services

Alert	Description	Threshold Units	ALERT_ID
Memory usage of name server	Determines what percentage of allocated shared memory is being used by the name server on a host.	percent	12
Memory usage of services	Determines what percentage of its effective allocation limit is being used by a service.	percent	43
Plan cache hit ratio	Determines whether the plan cache hit ratio is too low.	ratio	91

Alert	Description	Threshold Units	ALERT_ID
Cached view size	Determines how much memory is occupied by the cached view.	percent	81
Memory alerts related to tables			
Alert	Description	Threshold Units	ALERT_ID
Record count of non-partitioned column-store tables	Determines the number of records in non-partitioned column-store tables, but ignores information stored in statistics_exclude_tables. Current table size isn't critical. Partitions need only be considered if tables are expected to grow rapidly. (A non-partitioned table can't contain more than 2,000,000,000 (2 billion) rows).	records	17
Alert_Mon_Column_Tables_Record_Count_Incl	Determines the number of records in non-partitioned column-store statistics_exclude_tables. This alert is inactive, unless you activate it.	records	117
Table growth of non-partitioned column-store tables	Determines the growth rate of non-partitioned column tables.	percent	20
Record count of column-store table partitions	Determines the number of records in the partitions of column-store tables, but ignores information stored in statistics_exclude_tables. A table partition can't contain more than 2,147,483,648 (2 billion) rows.	records	27
Alert_Partitioned_Table_Record_Count_Incl	Determines the number of records in the partitions of column-store statistics_exclude_tables. This alert is inactive, unless you activate it.	records	127
Size of delta storage of column-store tables	Determines the size of the delta storage of column tables.	MB	29

Alert	Description	Threshold Units	ALERT_ID
Total memory usage of column-store tables	Determines what percentage of the effective allocation limit is being consumed by individual column-store tables as a whole (that is, the cumulative size of all of a table's columns and internal structures).	percent	40
Memory usage of main storage of column-store tables	Determines what percentage of the effective allocation limit is being consumed by the main storage of individual column-store tables.	percent	45
Columnstore unloads	Determines how many columns in columnstore tables have been unloaded from memory. This alert can indicate performance issues.	tables	55
Total memory usage of table-based audit log	Determines what percentage of the effective memory allocation limit is being consumed by the database table used for table-based audit logging. If this table grows too large, the availability of the database could be impacted.	percent	64
Table growth of rowstore tables	Determines the growth rate of rowstore tables.	percent	67
Total memory usage of row store	Determines the current memory size of a row store used by a service.	percent	68
Row store fragmentation	Check for fragmentation of row store.		71
Overflow of rowstore version space	Determines the overflow ratio of the row store version space.	ratio	73
Rowstore version space skew	Determines whether the row store version chain is too long.	version	75
Auto merge of column-store tables	Determines whether the delta merge of a table was executed successfully.	records	88

## 6.6.1.2.2 System Views Used to Create Memory Alerts

The SAP HANA cockpit displays memory alerts in the *Memory Analysis* app based on SAP HANA system views.

The following system views provide the information with which values for current and historical memory allocation are calculated:

Views from the `_SYS` schema:

- `M_HOST_RESOURCE_UTILIZATION`
- `M_SERVICE_MEMORY`
- `M_SERVICE_COMPONENT_MEMORY`
- `M_RS_TABLES`
- `M_HEAP_MEMORY`
- `M_CS_COLUMNS`
- `M_OUT_OF_MEMORY_EVENTS`
- `M_SQL_PLAN_STATISTICS`

Views from the `_SYS_STATISTICS` schema:

- `HOST_RESOURCE_UTILIZATION_STATISTICS`
- `HOST_SERVICE_MEMORY`
- `HOST_SERVICE_COMPONENT_MEMORY`
- `HOST_HEAP_ALLOCATORS`
- `GLOBAL_ROWSTORE_TABLES_SIZE_BASE`
- `HOST_COLUMN_TABLES_PART_SIZE`
- `STATISTICS_OBJECTS`
- `STATISTICS_CURRENT_ALERTS`
- `STATISTICS_ALERT_INFORMATION`
- `STATISTICS_ALERT_THRESHOLDS`
- `GLOBAL_OUT_OF_MEMORY_EVENTS`

For more information about these views, see the *SAP HANA SQL Reference Guide*.

## 6.6.1.2.3 Monitor Table Usage

Monitor tables to optimize resource utilization and improve query performance.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

With [Table Usage](#) you can visualize tables by size, explore the usage history of tables, and move tables to warm storage.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click the [Monitor table usage](#) link on the [Monitoring](#) card.
2. To filter tables shown, adjust the [Total Access/Size/Display](#) values and click [Go](#). Click [Reset](#) to remove filters.

For the best display, select up to 50 tables. Two options for table analysis are available:

- For table format display, choose  ([Table Chart](#)).
- For graphical format display, choose  ([Bubble Chart](#)). Mouse over a bubble to show usage per column table.

### Next Steps

Monitor table operations to identify where you can improve performance and reduce memory utilization. Large in-memory tables that are accessed infrequently are good candidates for the SAP HANA dynamic tiering option. Note that tables moved into dynamic tiering disappear from table analysis displays.

## 6.6.1.2.4 Configure Host Failover

For multi-host systems, you can configure host auto-failover so that if an active host fails, standby hosts take over to ensure the continued availability of the database.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Host roles for failover are normally configured during installation. Using SAP HANA cockpit, you can monitor the status of individual hosts and switch the configured roles of hosts; you can't increase or decrease the number of worker hosts and standby hosts in relation to each other.

The primary reason for changing the configured roles is to prepare for the removal of a host. In this case, change the configured role of the name server host to SLAVE and the configured role of the index server host to STANDBY before stopping the database instance on the host and removing the host.

#### i Note

To change host configuration, your database user must have the system privilege RESOURCE ADMIN and the object privilege EXECUTE on the procedure UPDATE\_LANDSCAPE\_CONFIGURATION.

### Procedure

1. On the [Database Overview](#), with the [Administration](#) or [All](#) view selected, click the [Host Failover](#) link on the [Database Administration](#) card.  
All the hosts in the system are displayed, whether or not they're operational, as well as additional information about their auto-failover status and configuration.
2. Click the gear button to customize which columns to display.

Column	Description
Host	Host name

Column	Description
Active	<p>Indicates the status of services running on the host.</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li>○ YES All services are active.</li> <li>○ PARTIAL Some services are active.</li> <li>○ STARTING Some services are active, and some are starting.</li> <li>○ STOPPING Some services are active, and some are stopping.</li> <li>○ NO No services are active.</li> </ul>
Host Status	<p>Indicates the host's status and whether the system is operational.</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li>○ OK The system is operational and the host's actual role corresponds to its configured role.</li> <li>○ IGNORE The system is operational. The host is configured as a standby host and is available, but not in use.</li> <li>○ INFO The system is operational. The host's actual role is different from its configured role.</li> <li>○ WARNING The system isn't operational. The host will become available after start-up or failover.</li> <li>○ ERROR The system isn't operational. The host is missing.</li> </ul>
Failover Status	<p>Displays the failover status so you can see which hosts are active and which are on standby.</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li>○ &lt;Empty&gt; Failover isn't active or pending.</li> <li>○ WAITING ... SEC The host has failed. The system is waiting to fail over.</li> <li>○ WAITING The host has failed. The system is waiting for the host to restart to prevent unnecessary failover.</li> <li>○ FAILOVER TO &lt;host&gt; The host has failed and failover to a target host is in progress.</li> <li>○ FAILBACK TO &lt;host&gt; Failback to a worker host is in progress. Failback happens when the assigned standby host is stopped. However, there's no automatic failback while the standby host is still assigned since it would cause downtime.</li> <li>○ FAILED Failover isn't possible, for example, no further standby hosts available. For more information, see the nameserver trace.</li> </ul>

Column	Description
Nameserver Role (Configured)	<p>Specifies the host's configured role as name server.</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>○ MASTER 1, MASTER 2, MASTER 3 When you install a distributed system, up to three hosts are automatically configured as master name servers. The configured nameserver role of these hosts is MASTER 1, MASTER 2, and MASTER 3.</li> <li>○ SLAVE Additional hosts in your system are configured as slave name servers. The configured nameserver role of these hosts is SLAVE.</li> </ul>
Nameserver Role (Actual)	<p>Specifies the host's actual role as name server.</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>○ MASTER During system start-up, one of the hosts configured as master name servers (that is, those hosts with the configured name server role MASTER 1, MASTER 2, or MASTER 3) is designated to be the active master name server. The actual nameserver role of this host is MASTER. This master name server assigns one volume to each starting index server (with actual role MASTER or SLAVE), or no volume if it's a standby host (actual indexserver role STANDBY). If this active master nameserver host fails, one of the remaining hosts configured as a master nameserver becomes the active master name server.</li> <li>○ SLAVE The actual nameserver role of the remaining hosts configured as master and slave hosts is SLAVE.</li> </ul>
Indexserver Role (Configured)	<p>Specifies the host's configured role as index server.</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>○ WORKER</li> <li>○ STANDBY</li> </ul> <p>When you install a distributed system, you can configure hosts either as WORKER or STANDBY index servers. A host configured as a standby index server isn't used for database processing. All database processes run on the standby host, but they're idle and don't allow SQL connections.</p>

Column	Description
Indexserver Role (Actual)	<p>Specifies the host's actual role as index server.</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>○ MASTER The actual master indexserver is assigned on the same host as the name server with the actual role MASTER. The actual index server role of this host is MASTER. The master index server provides metadata for the other active index servers (with actual indexserver role SLAVE).</li> <li>○ SLAVE The actual index server role of remaining hosts (except hosts configured as standby hosts) is SLAVE. These hosts are active index servers and are assigned to one volume. If an active index server fails, the active master name server assigns its volume to one of the standby hosts.</li> <li>○ STANDBY The actual indexserver role of standby hosts is STANDBY. A standby host isn't assigned a volume by the active master name server and it doesn't open an SQL port.</li> </ul> <p>During normal operation when all hosts are available, a host with the configured role WORKER has the actual role MASTER or SLAVE, and a host with the configured role STANDBY has the actual role STANDBY. In the event of failover, the actual index server role of a host with the configured role STANDBY changes to SLAVE. The host status of the failed host changes from OK to INFO and the host status of the standby host changes from IGNORE to INFO.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>Failover is configured only for the name server and the index server on each host. The other components (for example, xsengine) aren't configured individually as they're always failed over together with the index server.</p> </div>
Failover Group (Configured/Actual)	<p>A failover group can be defined for each host. If there's a failover, the name server tries to fail over to a host within the same group.</p>
Worker Groups (Configured/Actual)	<p>The worker groups (also referred to as host subroles) for the host can be set here. The groups are required to support heterogeneous hardware in the landscape that is required, for example, for the extension node feature.</p> <p>Worker groups may also be relevant in a single-host installation. The worker group name is a free text value that is validated to trap illegal characters.</p>

Column	Description
Host Roles (Configured)	<p>Specifies the host's configured database role.</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>○ WORKER Worker host for database processing</li> <li>○ STANDBY Standby host for database processing</li> </ul> <p>Depending on your installation, the following additional host roles can be configured:</p> <ul style="list-style-type: none"> <li>○ EXTENDED_STORAGE_WORKER Worker host for SAP HANA dynamic tiering</li> <li>○ EXTENDED_STORAGE_STANDBY Standby host for SAP HANA dynamic tiering</li> <li>○ ETS_WORKER Worker host for SAP HANA accelerator for SAP ASE</li> <li>○ ETS_STANDBY Standby host for SAP HANA accelerator for SAP ASE</li> <li>○ STREAMING Host for SAP HANA Streaming Analytics</li> <li>○ XS_STANDBY Standby host for SAP HANA XS advanced runtime</li> <li>○ XS_WORKER Host for SAP HANA XS advanced runtime</li> </ul>
<p><b>i Note</b></p> <p>Multiple host roles aren't supported in production environments. However, if XS advanced runtime is installed, hosts can share multiple roles.</p>	
Host Roles (Actual)	Specifies the host's actual database role
Storage Partition	<p>Specifies the number of the <code>mnt000...</code> subdirectory used by the host for storing data and logs, for example, <code>1</code> if the subdirectory is <code>mnt00001</code>, <code>2</code> if it's <code>mnt00002</code>, and so on.</p> <p>During installation, volumes for storing data and log files are defined, which are the directories where data and logs are stored. The default directories are:</p> <ul style="list-style-type: none"> <li>○ <code>/hana/data/&lt;SID&gt;</code> for data</li> <li>○ <code>/hana/log/&lt;SID&gt;</code> for logs</li> </ul> <p>Each active host has exactly one subdirectory beneath these directories called <code>mnt00001</code>, <code>mnt00002</code>, and so on. The next level in the file hierarchy is the actual volume, with one subdirectory for each service called <code>hdb00001</code>, <code>hdb00002</code>, and so on.</p> <p>In the event of failover, the volumes of the failed host are reassigned to the standby host.</p>

Column	Description
Removal Status	<p>Indicates the status of the table redistribution operation used to move data off the index server of a host that you plan to remove.</p> <p>Before you can remove an active host from a single-container system, you must move the tables on the index server of this host to the index servers on the remaining hosts in the system. Once the value in the <i>Removal Status</i> column changes to REORG FINISHED or REORG NOT REQUIRED, you can physically remove the host using the SAP HANA lifecycle management tool hdblcm(gui).</p> <p>If your system is configured as a multiple-container system, you have to remove tenant-specific services first and then remove the host using the SAP HANA database lifecycle manager (HDBLCM). For more information, see <i>Remove a Service from a Tenant Database</i> in the <i>SAP HANA Administration Guide</i>.</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li>○ &lt;Empty&gt; Host hasn't been marked for removal.</li> <li>○ REORG PENDING A redistribution operation is required to move tables to other hosts.</li> <li>○ REORG ACTIVE A redistribution operation is in progress. For more information, you can query the system tables SYS.REORG_OVERVIEW and SYS.REORG_STEPS.</li> <li>○ REORG FAILED A redistribution operation was executed and failed. For more information, query the system table SYS.REORG_STEPS.</li> <li>○ REORG FINISHED A redistribution operation has completed. The host can be uninstalled.</li> <li>○ REORG NOT REQUIRED A redistribution operation isn't required. The host can be uninstalled.</li> </ul>

3. If you change a configured role or configured group, click *Apply* so that your changes take effect.

## Related Information

[Add or Remove Services in a Tenant Database \[page 272\]](#)

[Monitoring Tenant Databases in SAP HANA Cockpit \[page 260\]](#)

## 6.6.1.3 Disk Usage: Monitor Disk Volume

In order to ensure that the database can always be restored to its most recent committed state, you can use the SAP HANA cockpit to check disk statistics to check that there's enough space on disk for data volumes and log volumes.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

A disk has multiple volumes. Each volume has a data volume and a log volume. Data volumes have one file (datavolume\_0000.dat). Log volumes often have hundreds of files (multiple logsegment\_000\_0000003.dat; single logsegment\_000\_directory.dat). Log segment files have a state (Formatting, Preallocated, Writing, Closed, Truncated, BackedUp, RetainedFree, Free). Only log segment files with state Free can be reused. Log segment files have a fixed size although the size can vary per service. (For example, indexserver=1024MB; xsengine=8MB).

You may wish to monitor volume if, for example:

- You receive an alert about disk I/O read failure and want to see which volume has the issue and why.
- You're running out of disk space.
- You know that you're having a backup issue or a replication issue and want to understand how it's affecting disk usage.

### Procedure

1. In the [Monitoring](#) or [All](#) view, on the [Database Overview](#) page, click the **⋮** ([More](#)) icon on the [Disk Usage](#) card.
2. Select [Disk Volume Monitor](#).
3. (Optional) Filter the information displayed in the chart and the table:
  - Using the arrow beside the title (top left), select a predefined variant, or manage and save a custom variant.
  - Select from the dropdown lists to display a specific combination of host, tenant (if applicable), volume type (data volume or log volume), service, and volume ID.
4. View the information in the table:

Column	Description
Volume ID	The ID of the volume.
Service	The name of the service.
Type	Whether this volume is a data volume or log volume.
Size [MB]	Current size of the volume.
Used [MB]	Amount of disk space used on the host's hard disk.
Used [%]	Amount of disk space used on the host's hard disk as a percentage of the whole.
State	For log files, whether the state is Formatting, Preallocated, Writing, Closed, Truncated, BackedUp, RetainedFree or Free. The log segment file's state indicates its availability for reuse.
Files	Number of files of the same type and state for the particular host and service.
Path	Location of the service's data and log files in the file system.
Host	The name of the host.
Tenant	The name of the tenant.

5. Drill down on a row to see [Disk Volume Details](#) for a specific volume.
6. Select the various tabs to move to the corresponding section of the volume details.

Section	Description
Data Volume Files	Displays the data volume file names as well as the size of each file and how much of it's currently in use, both in MB and as a percentage of its total size. Used size is the amount of data in the file. As the size of the file is automatically increased with the payload but not automatically decreased, used size and total size can be different.
Log Files	Displays log file names, total size (which, for log files, is equivalent to used size), and state. When a file is full, log entries are written to the next log segment file available.
Volume I/O Statistics	Displays aggregated I/O statistics for the volume, and, for comparison, other volumes in the system, in your choice of time periods: <ul style="list-style-type: none"> <li>○ Since the service was restarted (default)</li> <li>○ Since the last manual reset</li> </ul> You can reset the statistics collection for all volumes by selecting <a href="#">Reset Volume I/O Total Statistics</a> .
Data Volume Page Statistics	Displays statistics on the data volume's pages (or blocks) broken down according to page size class. Superblocks are partitions of the data volume that contain pages of the same page size class. You can analyze how many superblocks are used for the specific size class and also how many pages/blocks are used. The fill ratio enables you to decide whether or not it makes sense to reorganize and release unnecessary superblocks, in other words, shrink the data volume.

7. In the [Volume I/O Statistics](#) section, use the left-most dropdown menu to display specific statistics associated with the volume:
  - Volume Size & Time
  - Volume Configuration
  - Advanced Write Statistics
  - Advanced Read Statistics

## Related Information

[Reclaim Space \[page 370\]](#)

[Persistent Data Storage in the SAP HANA Database](#)

[Monitoring Disk Space](#)

### 6.6.1.3.1 Reclaim Space

You can reclaim space by reclaiming freed log segments and unused space in data volumes.

#### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

Perform a backup before reclaiming space.

#### Context

The reclaim operation is across hosts & volumes per database & tenant. You can reclaim all log files in Free state but at least `log_preformat_segment_count` segments (by default, two) per database service aren't reclaimed. For data volumes, the reclaim is calculated by volume size – (used size \* specified `percentage_of_overload_size`).

#### Procedure

1. In the [Monitoring](#) or [All](#) view, on the [Database Overview](#) page, click the **⋮ (More)** icon on the [Disk Usage](#) card.
2. Select [Disk Volume Monitor](#).
3. Select [Reclaim Space](#) from the top toolbar.
4. In the dialog, select [Reclaim \(Free\) log segments](#) and/or [Reclaim data volume](#).
5. Select the [Reclaim Space](#) button.

## 6.6.1.4 Alerts

As an administrator, you actively monitor the status of the system and its services and the consumption of system resources. However, you are also alerted to critical situations, for example: a disk is becoming full, CPU usage is reaching a critical level, or a server has stopped.

The internal monitoring infrastructure of the SAP HANA database is continuously collecting and evaluating information about status, performance, and resource usage from all components of the SAP HANA database. In addition, it performs regular checks on the data in system tables and views and when configurable threshold values are exceeded, it issues alerts. In this way, you are warned of potential problems. The priority of the alert indicates the severity of the problem and depends on the nature of the check and the configured threshold values. For example, if 90% of available disk space has been used, a low priority alert is issued; if 98% has been used, a high priority alert is issued. For more information about the technical implementation of monitoring and alerting features in SAP HANA, see *The Statistics Service* in the *SAP HANA Administration Guide*.

For information on configuring alerts in SAP HANA cockpit, see *Configuring Alerts*.

Alerts are organized by category or KPAs (key performance areas), which is a predefined collection of the alert categories.

KPA	Alert Categories
Availability	<ul style="list-style-type: none"><li>• Availability</li><li>• Backup</li><li>• Diagnosis Files</li><li>• Security</li></ul>
Performance	<ul style="list-style-type: none"><li>• CPU</li><li>• Disk</li><li>• Memory</li></ul>
Capacity	<ul style="list-style-type: none"><li>• Configuration</li><li>• Sessions/Transactions</li></ul>

A summary of high and medium alerts in the database appears on the [Alert](#) card on the [Database Overview](#) page for a database. On the [Alerts](#) card, you can view alerts by category or KPA. The category or KPA with the most high alerts is listed first, followed by medium alerts. When two categories/KPAs have the same number of high and medium alerts, the categories/KPAs are listed alphabetically. Categories/KPAs with no medium or high alerts aren't listed. For alert details on a specific category or KPA, click the row. For alert details on all alerts, click the title of the [Alerts](#) card.

If you're using the KPA view and you display alerts for a specific KPA, the resulting list on the [Manage Alerts](#) page includes alerts for all categories within the specified KPA. You can't filter, sort, or group the list on the [Manage Alerts](#) by KPA.

To view alerts, you must have the CATALOG\_READ system privilege and the SELECT privilege on the \_SYS\_STATISTICS schema.

## Related Information

## 6.6.1.4.1 Alert Summary and Details

On the [Manage Alerts](#) page, the default summary list includes all current alerts with a priority of high, medium, and error. You can filter, sort, and view details, as needed.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the CATALOG\_READ system privilege and the SELECT privilege on the \_SYS\_STATISTICS schema.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, choose one of the following options:

Task	Action
Display alerts from a single category or KPA	Click the row of the category or KPA on the <a href="#">Alerts</a> card.
Display all high and medium alerts	Click in the title area of the <a href="#">Alerts</a> card.

A list of alerts appears on the [Manage Alerts](#) page.

Detail	Description
<a href="#">Priority</a>	Indicates the severity of the alert and how quickly action needs to be taken. <ul style="list-style-type: none"><li>○ Information - Action is recommended to improve system performance or stability.</li><li>○ Low - Medium-term action is required to mitigate the risk of downtime.</li><li>○ Medium - Short-term action is required (few hours, days) to mitigate the risk of downtime.</li><li>○ High - Immediate action is required to mitigate the risk of downtime, data loss, or data corruption.</li><li>○ Error - Immediate action is required to fix the issue. Use trace files to help track and resolve the issue.</li></ul>
<a href="#">Alert</a>	Provides a definition of the alert.
<a href="#">Time</a>	Indicates the time that the alert was triggered.

Detail	Description
<a href="#">Alerting Host &amp; Port</a>	<p>Provides the name and port of the host that issued the alert.</p> <p>In a system replication scenario, alerts issued by secondary system hosts can be identified here. This identification allows you to ensure the availability of secondary systems by addressing issues before an actual failover.</p> <p>For more information about monitoring secondary systems in SAP HANA, see <i>Monitoring Secondary Sites</i> in the <i>SAP HANA Administration Guide</i>.</p>
<a href="#">Source</a>	<p>Indicates where the alert originated from. The source could be the database itself, or a service such as the SAP EarlyWatch Alert service.</p>
<a href="#">Category</a>	<p>Indicates the category of the alert checker that issued the alert.</p> <p>Alert checkers are grouped into categories. The categories are:</p> <ul style="list-style-type: none"> <li>○ Availability</li> <li>○ Backup</li> <li>○ Configuration</li> <li>○ CPU</li> <li>○ Diagnosis Files</li> <li>○ Disk</li> <li>○ Memory</li> <li>○ Other</li> <li>○ Security</li> <li>○ Sessions/Transactions</li> </ul>

2. Click an alert to see its definition and more details, such as past occurrences, proposed solutions, and next scheduled runs.

## Related Information

[Alert Configuration \[page 375\]](#)  
[Monitoring Secondary Systems](#)  
[Search, Sort, and Filter Buttons](#)

## 6.6.1.4.2 View Past Alerts

Current alerts are alerts that were triggered by the last scheduled run of the alert definition. Past alerts are the historical record of past current alerts.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the CATALOG\_READ system privilege and the SELECT privilege on the \_SYS\_STATISTICS schema.

### Context

The [Manage Alerts](#) page always displays the most recently triggered (current) alerts. When a scheduled alert definition runs, current alerts on the [Manage Alerts](#) page for the scheduled definition become past alerts, disappearing from the list. New alerts for the definition triggered by the run appear as current alerts on the list.

When Deactivating an alert definition, doesn't remove its most recently triggered alert from the list. To remove these alerts, reactivate the alert definition and either resolve the issue or adjust the threshold so the alert is no longer triggered.

If you deactivate the schedule for an alert that appears on the current list, the triggered alerts remain on the list, even if the triggering issue is resolved. The current alerts become past alerts when you reactivate the alert definition and allow it to run for at least one interval.

Filter the list using the type [Past](#). To see the history of past alerts for a specific alert, display the alert details and select the frequency of the past occurrences.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click the [Alerts](#) card.
2. Choose one of the following:

Task	Action
<b>For a list of past alerts for the data-base,</b>	filter the list using the type <a href="#">Past</a> . Define additional filters to further refine the alert list.
<b>For a graphical display of past alerts for a single alert definition,</b>	click the alert to display its details. Click <a href="#">Occurrences</a> and set the past time frame.

## 6.6.1.4.3 Alert Configuration

Use the configuration options to tailor alerts in the SAP HANA database to your needs.

Alerts are based on predefined definitions, many of which are switched on by default. While you can't add new definitions, you can modify the predefined definitions by:

- Switching a specific alert definition on or off.
- Changing the threshold values that trigger alerts of different priorities, where applicable.
- Setting up e-mail notifications so that specific people are informed when alerts are issued.

### 6.6.1.4.3.1 Configure Alert Thresholds

In many cases, you can configure the thresholds that trigger an alert. An alert checker can have a low, medium, and high priority threshold.

#### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the CATALOG\_READ system privilege.
- You have SELECT, INSERT, DELETE, and UPDATE privileges on the \_SYS\_STATISTICS schema.

#### Context

Thresholds can be configured for any alert definition that measures variable values that stay within certain ranges. For example, the percentage of physical memory used or the age of the most recent data backup. Many alert definitions verify only whether a certain situation exists or not. Threshold values can't be configured for these alert definitions. For example, alert definitions 4 detects services restarts. If a service was restarted, an alert is issued.

You can set the threshold when creating a new alert or adjust the threshold of a triggered alert.

#### Procedure

1. To:

Task	Action
Adjust the threshold on a triggered alert.	<ol style="list-style-type: none"> <li>1. On the <i>Database Overview</i> page, with the <i>Monitoring</i> or <i>All</i> view selected, click the <i>Alerts</i> card.</li> <li>2. On the <i>Manage Alerts</i> page, click the triggered alert containing the thresholds you want to change.</li> <li>3. Click <i>Edit Alert Definition</i>.</li> </ol>
Configure the threshold on an alert definition.	<ol style="list-style-type: none"> <li>1. On the <i>Database Overview</i> page, with the <i>Monitoring</i> or <i>All</i> view selected, click <i>Alert Definitions</i> on the <i>Alerts</i> card.</li> <li>2. Click the alert definition containing the thresholds you want to change.</li> <li>3. Click <i>Edit</i>.</li> </ol>

2. Change the threshold values as required.
3. (Optional) To apply the alert definition to multiple databases, click *Apply to Other Databases*, select databases from the list, and click *OK*.
4. Save the alert definition.
5. (Optional) Click *Check Now* to run the alert definition immediately.

A message appears letting you now if the modified alert definition triggered an alert.

## Related Information

[Assign Roles to Database Users \[page 924\]](#)

[Alert Summary and Details \[page 372\]](#)

### 6.6.1.4.3.2 Switch Alerts Off/On

If you no longer want a particular alert to be issued, you can switch off the underlying alert definition. The system automatically switches off an alert definition when it fails to run, for example, due to a shortage of system resources.

## Prerequisites

- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the CATALOG\_READ system privilege.
- You have SELECT, INSERT, DELETE, and UPDATE privileges on the \_SYS\_STATISTICS schema.

## Context

In some situations, you may want to stop a particular alert from being issued, either because it's unnecessary (for example, alerts that notify you when there are other alerts in the system) or because it isn't relevant in your system (for example, backup-related alerts in test systems where no backups are performed).

### ⚠ Caution

If you switch off alerts, you may not be warned about potentially critical situations in your system.

You can switch an alert definition back on again at any time.

For a list of switched off alert definitions, see *Check Alert Definitions Status*.

## Procedure

1. To:

Task	Action
Turn on/off an alert definition that has triggered an alert.	<ol style="list-style-type: none"><li>1. On the <i>Database Overview</i> page, with the <i>Monitoring</i> or <i>All</i> view selected, click the <i>Alerts</i> card.</li><li>2. On the <i>Manage Alerts</i> page, click the triggered alert to be switched on/off.</li><li>3. Click <i>Edit Alert Definition</i>.</li></ol>
Turn on/off an alert definition.	<ol style="list-style-type: none"><li>1. On the <i>Database Overview</i> page, with the <i>Monitoring</i> or <i>All</i> view selected, click <i>Alert Definitions</i> on the <i>Alerts</i> card.</li><li>2. Click the alert definition to be turned on/off.</li><li>3. Click <i>Edit</i>.</li></ol>

2. Set the *Schedule Active* switch to *No* or *Yes*.
3. (Optional) To apply the change to multiple databases, click *Apply to Other Databases*, select databases from the list, and click *OK*.
4. Save the alert definition.

## Related Information

[Check Alert Definition Status \[page 378\]](#)

### 6.6.1.4.3.3 Check Alert Definition Status

Check the current status of an alert definition.

#### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- You have the CATALOG\_READ system privilege and the SELECT privilege on the \_SYS\_STATISTICS schema.

#### Context

By default, the [Define Alerts](#) page lists all alert definitions. Active definitions are green, and switched off definitions are yellow. Filter by status to focus the list.

#### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click [Alert Definitions](#) on the [Alerts](#) card.
2. Click [View Alerts](#).
3. (Optional) Set the Status filter.
4. (Optional) If the list is too long, filter by additional columns to further focus the list.

### 6.6.1.4.3.4 Set Up Email Notification Defaults

You can configure alert definitions so that you and other responsible administrators receive push notifications by email when alerts are issued.

You can configure one or more default recipients to be notified when any alert definition issues an alert. In addition, if different people need to be notified about different alerts, you can configure dedicated recipients for these alert definitions.

Note the following behavior:

- If you configure definition-specific recipients, default recipients are **not** notified.
- If you delete all definition-specific recipients, default recipients are notified again, if configured.
- You can configure definition-specific recipients regardless of whether or not default recipients are configured.

The configured recipients receive an email when an alert definition issues an alert. If the alert definition issues the same alert the next time it runs, no further email is sent. However, when the alert definition runs and it doesn't issue an alert, indicating that the issue is resolved or no longer occurring, a final email is sent

[Alert Checker Statuses](#)

### 6.6.1.5 Monitoring Multi-Host Health

For databases running on multiple hosts, SAP HANA cockpit provides status information on the health of database components on their respective hosts, and on resource utilization of hardware components, including CPU, memory, network, and storage on the respective hosts.

On a multi-host database, in the *Monitoring* or *All* view, click *Monitor Multi-Host Health* on the *Monitoring* card.

The *Multi-Host Health* charts display the most recent 10 minutes of data, organized by hosts within the system. The host types include: master, standby, dynamic tiering, streaming. The health metrics are:

Metric	Details
Host	Displays the host name(s).
Status	Displays the status for the given host.
Critical Alerts	Displays the number of high priority alerts for the given host.
CPU %	Displays the percentage of CPU usage for the given host.
Memory %	Displays the percentage of memory usage for the given host.
Out-of-Memory Events	Displays the number of out-of-memory events.
Unloads	Displays the number of columns unloaded due to low memory.
Disk Usage %	Displays the percentage of disk usage for the given host.
Network I/O	Displays the number of network input/output events.
Statements	Displays the changes in number of statements per second.
MVCC Versions	Displays the number of multi-version concurrency control versions.
Disk I/O	Displays the number of disk input/output events.

To reduce the number of hosts, or show particular hosts side by side, click *Filter by Host* on the top, right-hand corner of the screen, and select the desired host(s) from the list.

By clicking on specific multi-host health information, you can drill down to details about alerts when critical alerts are present.

When you click on a chart, instead of navigating directly to the Performance Monitor, Memory Analysis, or Workload Analysis pages, a dialog box appears that re-displays the chart, and offers multiple actions.

Clicking on...	Gives the option to...
CPU (%)	<ul style="list-style-type: none"> <li>• <a href="#">View CPU chart</a> displays the Performance Monitor with a CPU chart</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View CPU for all hosts</a> displays the Performance Monitor with a CPU chart for each host in the multi-host database</li> </ul>
Memory (%)	<ul style="list-style-type: none"> <li>• <a href="#">Analyze memory history</a> displays the Memory Analysis page</li> <li>• <a href="#">View memory chart</a> displays the Performance Monitor with a memory chart</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View memory for all hosts</a> displays the Performance Monitor with a memory chart for each host in the database.</li> </ul>
Out-of-Memory Events	View the number of out-of-memory events, per host, within a specified time range.
Unloads	<ul style="list-style-type: none"> <li>• <a href="#">View unloads chart</a> displays the Performance Monitor with a column unload chart</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View unloads for all hosts</a> displays the Performance Monitor with a column unload chart for each host in the scale-out system</li> </ul>
Disk Usage (%)	<ul style="list-style-type: none"> <li>• <a href="#">View disk usage chart</a> displays the Performance Monitor with a disk used chart</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View disk usage for all hosts</a> displays the Performance Monitor with a disk used chart for each host in the scale-out system</li> </ul>
Network I/O	<ul style="list-style-type: none"> <li>• <a href="#">View network I/O chart</a> displays the Performance Monitor with a single chart containing Network In, Network Out</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View network I/O for all hosts</a> displays the Performance Monitor with a chart containing Network In, Network Out for each host in the scale-out system</li> </ul>
Statements	<ul style="list-style-type: none"> <li>• <a href="#">Analyze workload</a> displays Workload Analysis</li> <li>• <a href="#">View statements chart</a> displays the Performance Monitor with a statements chart</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View statements for all hosts</a> displays the Performance Monitor with a statements chart for each host in the scale-out system</li> </ul>

Clicking on...	Gives the option to...
MVCC Versions	<ul style="list-style-type: none"> <li>• <a href="#">View MVCC versions chart</a> displays the Performance Monitor with a single chart containing: Acquired Record Locks, Active Commit ID Range, Active Versions</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with a shows all metrics</li> <li>• <a href="#">View MVCC versions for all hosts</a> displays the Performance Monitor with a chart (containing the same metrics as the preceding single chart) for each host in the scale-out system</li> </ul>
Disk I/O	<ul style="list-style-type: none"> <li>• <a href="#">View column unload chart</a> displays the Performance Monitor with a single chart containing: Data Write Size, Data Read Size, Log Write Size, Log Read Size, Data Backup Write Size, Data Backup Read Size</li> <li>• <a href="#">View all metrics for this host</a> displays the Performance Monitor with all metrics</li> <li>• <a href="#">View disk I/O for all hosts</a> displays the Performance Monitor with a chart (containing the same metrics as the preceding single chart) for each host in the scale-out system</li> </ul>

### 6.6.1.6 Use the Statement Library to Administer Your Database

The statement library in the SAP HANA database explorer contains default system statements and can also be used to store user-defined statements.

#### Prerequisites

The maximum size allowed per user for all stored statements is 10 MB, uncompressed.

Only user-defined statements can be accessed by HDI containers.

You cannot use forward slashes (/) in a statement name. Otherwise, there are no character restrictions.

## Context

Default system statements include all statements available in the `M_SYSTEM_INFORMATION_STATEMENTS` system view and all statements included in SAP Note 1969700.

You can edit statement contents and descriptions in the SQL console and then save them back to the statement library as a new statement, or by replacing the old version.

Create your own SQL statements for administration purposes directly in the SQL console and add them to the statement library. Alternatively, you can import statements saved as ZIP files, `.sql` files, or `.txt` files from your local computer or network file server.

The content of statements stored in the statement library is encrypted, except for the statement description; do not include sensitive information in your statement description.

The statement library is user-specific, therefore all stored statements are available for every database associated with a specific user.

Action	Description
Create a statement and add it to the statement library.	<ol style="list-style-type: none"><li>1. In the catalog browser, right-click your database and click <a href="#">Open SQL Console</a>.</li><li>2. Enter your SQL statement. Including a header is optional. However, a description for your SQL statement will not show up in the statement library unless you create one in your statement header. The format for your statement description is as follows:<pre>/* [DESCRIPTION] --Sample description */</pre>The statement description in the statement library shows the first line of the content after the <code>[DESCRIPTION]</code> section header.</li><li>3. Click  to add the statement to the statement library. You can change the statement name and see how the name and statement description will show up in the library.</li></ol>
Import a statement to your statement library	<ol style="list-style-type: none"><li>1. To import a SQL statement or set of statements to the statement library, right-click your database and click <a href="#">Show Statement Library</a>.</li><li>2. Click  <a href="#">Import</a>.</li></ol> <p>A file browser opens that allows you to import an individual statement in a <code>.sql</code>, <code>.txt</code>, or XML file, or a set of statements in a ZIP file.</p> <p>ZIP file hierarchies are flattened in the statement library.</p>

Action	Description
Export a file from the statement library	<div data-bbox="826 360 911 389" style="background-color: #e0e0e0; padding: 5px;"><b>i Note</b></div> <p data-bbox="826 416 1374 479">You can only export, delete, or rename statements with the type USER.</p> <ol data-bbox="810 519 1374 609" style="list-style-type: none"> <li>1. To export a USER-type statement from the statement library, select the statement and click <a href="#">↓ Export</a>, or right-click a statement and click <a href="#">Export</a>.</li> </ol> <p data-bbox="804 633 1267 656">Individual statements are exported as .sql files.</p>
Edit a statement in the library	<p data-bbox="804 696 1342 759">Edit a stored SQL statement by clicking its folder in the statement library and clicking <a href="#">Edit</a>.</p> <p data-bbox="804 786 1398 875">The statement opens in the SQL console where you can edit the syntax and description and add it back into the statement library under the same name or a different name.</p>

[System and Statistics Views \[page 413\]](#)

## 6.6.2.1 Administration Editor

To identify problems early and avoid disruptions, you need to monitor your systems continuously. While the System Monitor provides you with an overview of all systems at a glance, the Administration editor allows you to drill down into the details of resource usage and performance for each system.

In the Administration editor, you can monitor the following:

- Overall system state and resource usage by system and host
- Status and resource usage of all system components, for example, name server, index server, and so on
- Auto-failover status and configuration of hosts in distributed systems
- Alerts issued by the system in relation to its status, performance, and resource consumption
- Disk space consumed by system processes for the various storage types (data, log, and trace)
- System performance, for example, by analyzing performance indicators such as expensive statements, running threads, and load history

### **i** Note

To open the Administration editor with read-only access to the system views and alert information, you must have either the MONITORING role or the system privilege CATALOG READ and the object privilege SELECT on the schema `_SYS_STATISTICS`.

The screenshot displays the SAP HANA Administration Editor for instance 'SH2 (DBA)'. The interface includes a navigation bar with tabs for Overview, Landscape, Alerts, Performance, Volumes, Configuration, System Information, Diagnosis Files, and Trace Configuration. The 'Overview' tab is active, showing the following sections:

- General Information:** Operational Status: All services started; System Usage: Custom System; Start Time of First Started Service: 30.04.2014 07:58:12; Start Time of Latest Started Service: 30.04.2014 07:58:20; Distributed System: No; Version: 1.00.75.00.390872 (Stabilization\_COR); Build Time: 26.04.2014 00:13:22; Platform: SUSE Linux Enterprise Server 11.1; Linux Kernel Version: 2.6.32.12-0.7-default; Hardware Manufacturer: Hewlett-Packard.
- Current Alerts and Messages:** 1 alert with HIGH priority. A link to 'Show Alerts' is provided.
- SAP HANA Used Memory:** Used Memory/Peak Used Memory/Allocation Limit (GB) on Host lu306309: 15,99/16,74 / 21,10.
- Resident Memory:** Database Resident/Total Resident/Physical Memory (GB) on Host lu306309: 9,68/19,08 / 23,45.
- CPU Usage:** Database CPU Usage/Total CPU Usage/Maximum CPU Usage on Host lu306309: 3/5 / 100.
- Disk Usage:** Data Volume Size/Total Disk Usage/Total Disk Size (GB) on Host lu306309: 2,11/155,74 / 914,92; Log Volume Size/Total Disk Usage/Total Disk Size (GB) on Host lu306309: 2,30/155,74 / 914,92; Trace Volume Size/Total Disk Usage/Total Disk Size (GB) on Host lu306309: 0,01/155,74 / 914,92.

The Administration Editor

## Related Information

### 6.6.2.2 Monitoring System Availability

The availability of an SAP HANA system is indicated by its operational status, which you can see in the *Systems* view, in the *System Monitor*, and on the *Overview* tab of the Administration editor.

The availability of an SAP HANA system is indicated by its operational status, whereby the system assumes the status of the service (`nameserver`, `indexserver`, `preprocessor`, and so on) with the most critical status.

#### Note

Data and logs can only be backed up when all services that persist data are running.

The SAP HANA studio determines the status of services through an SQL connection and/or the SAP start service (`sapstartsrv`). For more information about the possible operational statuses, see *System Operational Statuses*.

You can see the operational status of a system in the SAP HANA studio in the following places:

- The *Systems* view
- The *Overview* tab of the Administration editor
- The *System Monitor*

An SAP HANA system consists of a number of services (including `indexserver`, `preprocessor`, `nameserver`, and `compileserver`).

## Error Situations

Error situations can interrupt the availability of the system regardless of its operational status. A system appears in the [Systems](#) view with an error icon (❌) in the following situations, for example:

- An SQL connection is not available.
- The connected user is invalid or their password has expired.
- The SAP HANA system was renamed.
- The SAP HANA license is invalid or has expired.
- The SAP HANA system is functioning as a secondary instance of your primary system, (for example, in a high availability scenario).

For more information about the nature of the error and how to resolve it, refer to the tooltip and the error log.

## SAP Start Service Unreachable

An error is also indicated if `sapstartsrv` cannot be reached. If this is the case but all other services are running (their status having been determined through an SQL connection), the system itself is operational and accessible.

There are several reasons why `sapstartsrv` is not reachable. You should first check whether or not it is running. You can do this by checking the connection to the Web service in a Web browser. Enter the following URL to get the Web service description (WSDL) from the `sapstartsrv` of an SAP HANA system:

```
http://<host>:5<instance_number>13/?wsdl
```

For a secure connection, enter:

```
https://<host>:5<instance_number>14/?wsdl
```

If you receive an XML output that starts with `definitions name="SAPControl"`, then the connection is working.

In many cases, `sapstartsrv` cannot be reached because the HTTP proxy is incorrectly configured in the SAP HANA studio. To resolve this, from the main menu, choose ► [Window](#) ► [Preferences](#) ► [Network Connections](#) ► and change the value for active provider from *Native* to *Direct*.

For more information, see SAP Note 1639568.

## Related Information

[Monitoring SAP HANA Systems During Stop and Start \[page 198\]](#)

[SAP Note 1639568](#) 

## 6.6.2.2.1 System Operational Statuses

An SAP HANA system can have several operational statuses. The system assumes the status of the service with the most critical status.

Status	Description
	The status of services (and therefore the system) is unknown because a connection to the database cannot be established either through an SQL connection or <code>sapstartsrv</code> . The system is not accessible.
	All services are started. The system is operational and accessible.
	One or more services are in the process of starting or <code>sapstartsrv</code> cannot be reached.
	One or more services are not started. The system is not operational and can be accessed in diagnosis mode only.

## 6.6.2.3 Monitoring Overall System Status and Resource Usage

When you open the Administration editor for a particular SAP HANA system, the [Overview](#) tab provides you with a summary of the overall status of the system, as well as an overview of resource usage.

Resource usage values are presented in such a way that you can compare the SAP HANA system with the operating system as a whole. If the system is distributed across several hosts, resource usage values are aggregated across all worker hosts. An additional bar shows the host with the highest (most critical) resource usage.

The bars indicating resource usage (memory, CPU, and disk) change color (green, yellow, and red) based on configurable check thresholds.

## Information Available on the Overview Tab

The following table lists the information available on the [Overview](#) tab:

Screen Area	Information Available
General Information	<ul style="list-style-type: none"> <li>• General information about the SAP HANA system, such as operational status, system usage type, whether the system has multiple hosts, the number of hosts (if distributed), and database version</li> <li>• The status of replication from your productive system to a secondary system This information is only available and applicable if you are operating a secondary instance of your database (for example, in a high availability scenario). If this is the case, then content from the primary or productive instance of your database is replicated to the secondary instance. More detailed information about this replication status is available on the <a href="#">Landscape &gt; Secondary System Status</a> tab.</li> </ul>
Alerts and Messages	Priority-rated alerts and messages reported by the system
Database Used Memory	<p>The following key indicators of memory usage are displayed:</p> <ul style="list-style-type: none"> <li>• <a href="#">Used Memory</a> The total amount of memory currently in use by SAP HANA is referred to as its used memory.</li> <li>• <a href="#">Peak Used Memory</a> The <a href="#">Used Memory</a> value is a current measurement. The <a href="#">Peak Used Memory</a> value is the highest used memory value recorded. This is useful for keeping track of the maximum value for used memory over time.</li> </ul> <div style="background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p><b>i Note</b></p> <p>Peak used memory is a resettable value. This can be useful if you want to establish the impact of a certain workload on memory usage. So for example, you can reset peak used memory, run the workload, and then examine the new peak used memory value. You can reset peak used memory on the <a href="#">Landscape &gt; Services</a> tab. From the context menu, choose <a href="#">Reset Memory Statistics</a>.</p> </div> <ul style="list-style-type: none"> <li>• <a href="#">Allocation Limit</a> The SAP HANA system, across its different processes, reserves a pool of memory before actual use. This pool of allocated memory is preallocated from the operating system over time, up to a predefined allocation limit, and is then efficiently used as needed by the SAP HANA database code. More memory is allocated to the pool as memory consumption increases. If the amount of memory used nears the allocation limit, SAP HANA may run out of memory if it cannot free memory.</li> </ul>
Resident Memory	<p>Resident memory is the amount of physical memory that is actually being used from the perspective of the operating system.</p> <p>It is possible that the <a href="#">Used Memory</a> value is lower than the <a href="#">Database Resident</a> value if SAP HANA returns memory back to its memory pool (for example, after a temporary computation) and does not inform the operating system. This is normal.</p>
CPU Usage	The information displayed here indicates the percentage of CPU used by the SAP HANA system compared with the operating system as a whole.
Disk Usage	The information displayed here indicates disk space occupied by data, log, and trace files belonging to the SAP HANA system compared with the operating system as a whole.

## Related Information

[Memory Usage in the SAP HANA Database \[page 510\]](#)

### 6.6.2.4 Monitoring Status and Resource Usage of System Components

To examine resource usage of an SAP HANA system in more detail, for example, to troubleshoot performance bottlenecks, you monitor its individual components or services.

On the **► Landscape ► Services ►** tab of the Administration editor, you can see the status of the services that start when the system is started. The initial connection to the system is established by the `sapstartsrv` service. If you have a multiple-host system, the services that start depend on which components are actually installed on the instance.

For each service, detailed information about its memory consumption is available. This allows you to get a more detailed breakdown of resource usage and troubleshoot performance bottlenecks.

The available filters allow you to show and hide the information according to host and/or service. This is generally only useful if you have a multiple-host system.

## Information Available on the Services Tab

The following information is displayed on [Services](#) sub-tab by default.

### → Tip

You can configure the view by choosing the  ([Configure Viewer](#)) button. For example, several additional columns are available.

Column	Description
Active	Indicates the status of the service The following statuses are possible: <ul style="list-style-type: none"><li>• The service is started ()</li><li>• The service is stopping or starting ()</li><li>• The service is stopped ()</li></ul> The daemon service displays the  icon while the host or any of its services are starting or stopping.
Host	Name of the host on which the service is running
Port	Port that the system uses for internal communication between services

Column	Description
Service	Service name, for example, <code>indexserver</code> , <code>nameserver</code> , <code>xsengine</code> , and so on
Detail	<p>Role of the host on which the service is running</p> <ul style="list-style-type: none"> <li>• Master The host is the active master host.</li> <li>• &lt;Empty&gt; The host is an active slave host.</li> <li>• Standby The host is a standby host.</li> </ul> <p>This is relevant only for distributed systems. For more detailed information, see the <a href="#">Hosts</a> sub-tab.</p>
Start Time	<p>Time at which the service started</p> <p>Two of the times in this column should match the <i>Start time of first started service</i> and <i>Start time of latest started service</i> shown on <a href="#">Overview</a> tab.</p>
Process ID	Process ID of the OS process
CPU	Bar view showing the CPU usage of the service
Memory	Bar view showing the used memory of the service in relation to physical memory available and the effective allocation limit of the service
Used Memory (MB)	Amount of memory currently used by the service
Peak Used Memory (MB)	Highest amount of memory ever used by the service
Effective Allocation Limit (MB)	Effective maximum memory pool size that is available to the process considering the current memory pool sizes of other processes
Memory Physical on Host (MB)	Total memory available on the host
SQL Port	Port through which the SQL connection to the specific service operates

## Related Information

[Memory Usage in the SAP HANA Database \[page 510\]](#)

### 6.6.2.4.1 Reset Peak Used Memory

Resetting peak used memory allows you for example to establish the impact of a certain workload on memory usage. You can reset peak used memory in the SAP HANA studio.

## Prerequisites

You have the system privilege RESOURCE ADMIN.

## Context

Peak used memory is the highest recorded value for used memory. This value is useful for understanding the behavior of used memory over time and under peak loads. If you reset peak used memory and run the workload, then you can then examine the new peak used memory value.

## Procedure

1. In the Administration editor, open the **▸ Landscape ▸ Services ▸** tab.
2. From the context menu, choose *Reset Memory Statistics*.  
All memory statistics for all services are reset.
3. Refresh the Administration editor to see new values.

### 6.6.2.4.2 Memory Indicators in the SAP HANA Studio

You can see the key indicators of memory usage in various editors of the SAP HANA studio.

What	Where
Current size of used memory	<i>Overview</i> tab of the <i>Administration</i> editor
Current memory usage of individual service	<b>▸ Landscape ▸ Services ▸</b> tab of the <i>Administration</i> editor
Overall peak used memory	<i>Overview</i> tab of the <i>Administration</i> editor
Peak used memory for an individual service	<b>▸ Landscape ▸ Services ▸</b> tab of the <i>Administration</i> editor
Memory usage of tables broken down by schema	Execute the predefined query <i>Schema Size of Loaded Tables</i> available on the <i>System Information</i> tab of the <i>Administration</i> editor
Current effective allocation limit of a service	<b>▸ Landscape ▸ Services ▸</b> tab of the <i>Administration</i> editor

[Monitoring Status and Resource Usage of System Components \[page 389\]](#)

## 6.6.2.5 Monitoring Host Status and Auto-Failover Configuration

The SAP HANA database supports high availability in a distributed system by providing for host auto-failover. If an active host fails, for example, because of a hardware failure, standby hosts can take over and thus ensure the continued availability of the database.

You can monitor the status of individual hosts on the [Landscape > Hosts](#) tab. Here, you can see all the hosts in the system, whether or not they are operational, as well as additional information about their auto-failover status and configuration.

Host roles for failover are normally configured during installation. The options available to you on the [Hosts](#) tab when you choose the  ([Configure Hosts for Failover Situation](#)) button are limited. You can only switch the configured roles of hosts; you cannot increase or decrease the number of worker hosts and standby hosts in relation to each other.

The primary reason for changing the configured roles in the [Configure Hosts for Failover Situation](#) dialog box is to prepare for the removal of a host. In this case, you would change the configured role of the name server host to SLAVE and the configured role of the index server host to STANDBY before stopping the database instance on the host and removing the host.

### Note

To change host configuration, you require the system privilege RESOURCE ADMIN and the object privilege EXECUTE on the procedure UPDATE\_LANDSCAPE\_CONFIGURATION.

### Example

Typical Configuration for a Multiple-Host System

Host	Name Server (Configured Role)	Name Server (Actual Role)	Index Server (Configured Role)	Index Server (Actual Role)
Initial host	Master 1	Master	Worker	Master
1st host added	Master 2	Slave	Worker	Slave
2nd host added	Slave	Slave	Worker	Slave
3rd host added	Slave	Slave	Worker	Slave
4th host added	Slave	Slave	Worker	Slave
5th host added	Slave	Slave	Worker	Slave
6th host added	Slave	Slave	Worker	Slave
7th host added	Master 3	Slave	Standby	Standby

## Information Available on the Hosts Tab

The table below lists the information available on the [Landscape > Hosts](#) tab.

## → Tip

You can configure the view by choosing the  (*Configure Viewer*) button. You can also call up information about the meaning of the various statuses by choosing the  (*Display Information*) button.

Column	Description
Host	Host name
Active	<p>Indicates the status of services running on the host</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"><li>• YES (  ) All services are active.</li><li>• PARTIAL (  ) Some services active.</li><li>• STARTING (  ) Some services are active, some are starting.</li><li>• STOPPING (  ) Some services are active, some are stopping</li><li>• NO (  ) No services active</li></ul>
Host Status	<p>Indicates whether or not the system is operational and the host's status</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"><li>• OK (  ) The system is operational and the host's actual role corresponds to its configured role.</li><li>• IGNORE (  ) The system is operational. The host is configured as a standby host and is available, but not in use.</li><li>• INFO (  ) The system is operational. The host's actual role is different from its configured role.</li><li>• WARNING (  ) The system is not operational. The host will become available after start-up or failover.</li><li>• ERROR (  ) The system is not operational. The host is missing.</li></ul>

Column	Description
Failover Status	<p>Displays the failover status so you can see which hosts are active and which are on standby</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li>• Empty Failover is neither active nor pending.</li> <li>• WAITING ... SEC The host has failed. The system is waiting to fail over.</li> <li>• WAITING The host has failed. The system is waiting for the host to restart to prevent unnecessary fail-over.</li> <li>• FAILOVER TO &lt;host&gt; The host has failed and failover to a target host is in progress.</li> <li>• FAILBACK TO &lt;host&gt; Failback to a worker host is in progress. This happens when the assigned standby host is stopped. However, there is no automatic failback while the standby host is still assigned since this would cause downtime.</li> <li>• FAILED Failover is not possible, for example, no further standby hosts available. For more information, see the nameserver trace.</li> </ul>
Nameserver Role (Configured)	<p>Specifies the host's configured role as name server</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>• MASTER 1, MASTER 2, MASTER 3 When you install a distributed system, up to three hosts are automatically configured as master name servers. The configured nameserver role of these hosts is MASTER 1, MASTER 2, and MASTER 3.</li> <li>• SLAVE Additional hosts in your system are configured as slave name servers. The configured nameserver role of these hosts is SLAVE.</li> </ul>
Nameserver Role (Actual)	<p>Specifies the host's actual role as name server</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>• MASTER During system start-up, one of the hosts configured as master name servers (that is, those hosts with configured name server role MASTER 1, MASTER 2, or MASTER 3) is designated to be the active master name server. The actual nameserver role of this host is MASTER. This master name server assigns one volume to each starting index server (those with actual role MASTER or SLAVE), or no volume if it is a standby host (actual indexserver role STANDBY). If this active master nameserver host fails, one of the remaining hosts configured as a master name server becomes the active master name server.</li> <li>• SLAVE The actual nameserver role of the remaining hosts configured as master and slave hosts is SLAVE.</li> </ul>

Column	Description
Indexserver Role (Configured)	<p>Specifies the host's configured role as index server</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>• WORKER</li> <li>• STANDBY</li> </ul> <p>When you install a distributed system, you can configure hosts either as WORKER or STANDBY index servers. A host configured as a standby index server is not used for database processing. All database processes run on the standby host, but they are idle and do not allow SQL connections.</p>
Indexserver Role (Actual)	<p>Specifies the host's actual role as index server</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>• MASTER The actual master index server is assigned on the same host as the name server with the actual role MASTER. The actual index server role of this host is MASTER. The master index server provides metadata for the other active index servers (that is, those with actual index-server role SLAVE).</li> <li>• SLAVE The actual index server role of remaining hosts (except those configured as standby hosts) is SLAVE. These are active index servers and are assigned to one volume. If an active index server fails, the active master name server assigns its volume to one of the standby hosts.</li> <li>• STANDBY The actual indexserver role of standby hosts is STANDBY. A standby host is not assigned a volume by the active master name server and it does not open an SQL port.</li> </ul> <p>During normal operation when all hosts are available, a host with the configured role WORKER has the actual role MASTER or SLAVE, and a host with the configured role STANDBY has the actual role STANDBY. In the event of failover, the actual index server role of a host with the configured role STANDBY changes to SLAVE. The host status of the failed host changes from OK to INFO and the host status of the standby host changes from IGNORE to INFO.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Failover is configured only for the name server and the index server on each host. The other components (for example, xsengine) are not configured individually as they are always failed over together with the index server.</p> </div>
Failover Group (Configured/Actual)	<p>A failover group can be defined for each host. In the event of failover, the name server tries to fail over to a host within the same group.</p>
Worker Groups (Configured/Actual)	<p>The worker groups (also referred to as a host sub-role) for the host can be set here. This is required to support heterogeneous hardware in the landscape which is required, for example, for the extension node feature.</p> <p>Worker groups may also be relevant in a single-host installation. The worker group name is a free text value, it is validated to trap illegal characters.</p>

Column	Description
Host Roles (Configured)	<p>Specifies the host's configured database or option role</p> <p>The following roles are possible:</p> <ul style="list-style-type: none"> <li>• WORKER Worker host for database processing</li> <li>• STANDBY Standby host for database processing</li> </ul> <p>Depending on your installation, the following additional host roles for SAP HANA options and capabilities may be configured:</p> <ul style="list-style-type: none"> <li>• EXTENDED_STORAGE_WORKER Worker host for SAP HANA dynamic tiering</li> <li>• EXTENDED_STORAGE_STANDBY Standby host for SAP HANA dynamic tiering</li> <li>• ETS_WORKER Worker host for SAP HANA accelerator for SAP ASE</li> <li>• ETS_STANDBY Standby host for SAP HANA accelerator for SAP ASE</li> <li>• STREAMING Host for SAP HANA streaming analytics</li> </ul> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>⚠ Caution</b></p> <p>Be aware that you need additional licenses for SAP HANA options and capabilities. For more information, see <a href="#">Important Disclaimer for Features in SAP HANA [page 2139]</a>.</p> </div> <p>SAP HANA SPS 11 includes an additional, new runtime environment for application development: SAP HANA extended application services (XS), advanced model. SAP HANA XS advanced represents an evolution of the application server architecture within SAP HANA by building upon the strengths (and expanding the scope) of SAP HANA extended application services, classic model. If the runtime platform of SAP HANA XS advanced is installed in your system, the following additional host roles are configured:</p> <ul style="list-style-type: none"> <li>• XS_STANDBY Standby host for SAP HANA XS advanced runtime</li> <li>• XS_WORKER Host for SAP HANA XS advanced runtime</li> </ul> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>Multiple host roles are <b>not</b> supported in production environments. However, if XS advanced runtime is installed, hosts can share multiple roles.</p> </div> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>SAP recommends that customers and partners begin to evaluate the new capabilities of SAP HANA extended application services, advanced model with this release (SPS 11). However, please note that it is not recommended to immediately start migrating existing applications to the new capabilities.</p> </div>
Host Roles (Actual)	Specifies the host's actual database or option role

Column	Description
Storage Partition	<p>Specifies the number of the <code>mnt000...</code> sub-directory used by the host for storing data and logs, for example, <code>1</code> if the sub-directory is <code>mnt00001</code>, <code>2</code> if it is <code>mnt00002</code>, and so on.</p> <p>During installation, volumes for storing data and log files are defined. These are the directories where data and logs are stored. The default directories are:</p> <ul style="list-style-type: none"> <li><code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/data</code> for data</li> <li><code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/log</code> for logs</li> </ul> <p>Each active host has exactly one sub-directory beneath these directories called <code>mnt00001</code>, <code>mnt00002</code>, and so on. The next level in the file hierarchy is the actual volume, with one sub-directory for each service called <code>hdb00001</code>, <code>hdb00002</code>, and so on.</p> <p>In the event of failover, the volumes of the failed host are re-assigned to the standby host.</p>
Removal Status	<p>Indicates the status of the table redistribution operation used to move data off the index server of a host that you plan to remove.</p> <p>Before you can remove an active host from a single-container system, you must move the tables on the index server of this host to the index servers on the remaining hosts in the system. You can do this by right-clicking the host and choosing <a href="#">Remove Host...</a> Once the value in the <a href="#">Removal Status</a> column changes to REORG FINISHED or REORG NOT REQUIRED, you can physically remove the host using the SAP HANA lifecycle management tool <code>hdblcm(gui)</code>.</p> <p>If your system is configured as a multiple-container system, you have to remove tenant-specific services first and then remove the host using the SAP HANA database lifecycle manager (HDBLCM). For more information, see <a href="#">Remove a Service from a Tenant Database</a> in the <i>SAP HANA Tenant Databases Operations Guide</i>.</p> <p>The following statuses are possible:</p> <ul style="list-style-type: none"> <li><code>&lt;Empty&gt;</code> Host has not been marked for removal.</li> <li>REORG PENDING A redistribution operation is required to move tables to other hosts.</li> <li>REORG ACTIVE A redistribution operation is in progress. For more information, you can query the system tables <code>SYS.REORG_OVERVIEW</code> and <code>SYS.REORG_STEPS</code>.</li> <li>REORG FAILED A redistribution operation was executed and failed. For more information, query the system table <code>SYS.REORG_STEPS</code>.</li> <li>REORG FINISHED A redistribution operation has completed. The host can be uninstalled.</li> <li>REORG NOT REQUIRED A redistribution operation not required. The host can be uninstalled.</li> </ul>

[Redistribute Tables Before Removing a Host \[page 707\]](#)

## 6.6.2.6 Monitoring Alerts

As an administrator, you actively monitor the status of the system and its services and the consumption of system resources. However, you are also alerted to critical situations, for example: a disk is becoming full, CPU usage is reaching a critical level, or a server has stopped.

The internal monitoring infrastructure of the SAP HANA database is continuously collecting and evaluating information about status, performance, and resource usage from all components of the SAP HANA database. In addition, it performs regular checks on the data in system tables and views and when configurable threshold values are exceeded, it issues alerts. In this way, you are warned of potential problems. The priority of the alert indicates the severity of the problem and depends on the nature of the check and the configured threshold values. For example, if 90% of available disk space has been used, a low priority alert is issued; if 98% has been used, a high priority alert is issued. For more information about the technical implementation of monitoring and alerting features in SAP HANA, see *The Statistics Service* in the *SAP HANA Administration Guide*.

All current unresolved alerts are summarized on the [Overview](#) tab of the Administration editor and displayed in detail on the [Alerts](#) tab. An alert remains current until the next time the relevant check is performed and the alert condition is not fulfilled, indicating that the problem situation has been resolved.

To see all alerts, on the [Alerts](#) tab, choose the corresponding entry from the [Show](#) drop-down list.

### i Note

To ensure that you are seeing the latest alerts, refresh the Administration editor regularly.

Alerts are displayed according to the following time periods:

Time Period	Alerts Displayed
Last 15 minutes, last 30 minutes, last hour, last 2 hours, and today	Alerts generated in the corresponding time period are shown. If an alert was generated 10 minutes ago, it appears under all these headings.
Yesterday	Only alerts that were generated yesterday are shown.
Last week	Only alerts generated during the previous week (Sunday to Saturday) are shown.
Two weeks ago, and so on	Only alerts generated during that week are displayed.

### i Note

Alerts are not rolled over into the following weeks. This enables you to compare the performance of the system over selected periods, as well as to view the alerts.

You can refine the list of displayed alerts further by specifying filters as follows:

- To filter according to a specific word in the check description, enter the word in the [Filter](#) field (for example, [license](#)).
- To filter according to additional attributes including priority and date of occurrence, choose the  [Filters](#) button in the toolbar on the top-right of the tab and select the required filter(s).

## Detailed Alert Information

You can view the detailed information about an alert by double-clicking it. The *Alert Details* dialog box appears with information including:

- A full description of the alert
- The time stamp for this occurrence of the alert
- Information about how to resolve the alert
- A list of previous occurrences of this alert

### i Note

The list is restricted to the most recent 1,000 occurrences or entries from the last 30 days.

The *Copy* button in the *Alert Details* dialog box allows you to copy the details of the alert to the clipboard, including its time(s) of occurrence. Note that only the 10 most recent occurrences are copied. Further occurrences are indicated by an ellipsis (...)

## Related Information

[Configure Check Thresholds \[page 402\]](#)

[The Statistics Service \[page 414\]](#)

[SAP HANA Troubleshooting and Performance Analysis Guide](#)

### 6.6.2.6.1 Alert Priorities

The priority of an alert indicates the severity of the problem and how quickly action needs to be taken.

Priority	Description
Information	Action recommended to improve system performance or stability
Low	Medium-term action required to mitigate the risk of downtime
Medium	Short-term action required (few hours, days) to mitigate the risk of downtime
High	Immediate action required to mitigate the risk of downtime, data loss, or data corruption

## 6.6.2.6.2 Check Information

Information about checks carried out by the system is available on the [Alerts](#) tab and in certain tables in the `_SYS_STATISTICS` schema.

### Information Available on the Alerts Tab

The [Check Information](#) area at the bottom of the [Alerts](#) tab provides a full list of all the checks carried out by the system. In addition to a description of what each check does and what you need to do in the event of an alert, you can see important scheduling information.

Column	Description
ID	Check ID
Description	Check description
User Action	What you can do in the event of an alert
Max Priority	The most severe alert that was generated the last time the check was carried out  For checks that consider only one object (for example, the check that determines how many days until your license expires), only one alert can be generated. This is automatically the most severe.  However, for checks that consider several objects (for example, the check that determines CPU utilization in a system with multiple hosts), several alerts can be generated for one check. The most severe is recorded here. For example, if in a distributed system with 5 hosts, the CPU utilization of 2 hosts was acceptable, 2 hosts exceeded the minimum threshold value, and 1 host exceeded the medium threshold, then <code>medium</code> would be the most severe alert generated.
Last Run	When the check was last carried out
On Schedule	Whether or not the check is on schedule  Even if a check is scheduled, that is there is a time and date in the <a href="#">Next Run</a> column, it is important to ensure that it is actually being carried out according to schedule. Otherwise, you will not be warned about critical situations, which could have serious consequences. You can see whether or not a check is being carried out on schedule in the <a href="#">On Schedule</a> column. If a check is not on schedule ( <i>No</i> in the <a href="#">On Schedule</a> column), then the system not performing checks as it should, and you must investigate further.
Next Run	When the check is scheduled to be carried out again
Interval	Interval at which the check is carried out in seconds

### Check Information Available in the `_SYS_STATISTICS` Schema

In addition to the above information available on the [Alerts](#) tab, the following tables in the `_SYS_STATISTICS` schema provide you with further information about the default checks, their configuration and scheduled execution.

Table	Description
STATISTICS_ALERT_INFORMATION	This table describes what each check does and what to do when an alert is issued.
STATISTICS_ALERT_THRESHOLDS	This table contains the threshold values for each check. The severity level indicates the type of alert that is issued when the threshold value is reached or exceeded as follows. Severity level 1 corresponds to an information alert and level 4 a high priority alert.
STATISTICS_SCHEDULE	This table contains the scheduling information for all checks.

**i Note**

It also contains the scheduling information for historical data collection.

## Related Information

[Embedded Statistics Service Views \(\\_SYS\\_STATISTICS schema\)](#)

### 6.6.2.6.3 Configure E-Mail Notifications for Alerts

You can configure the system in such a way that you receive an e-mail when an alert condition for all or specific checks is fulfilled.

#### Prerequisites

- You have the system privilege CATALOG READ and the SELECT privilege on the \_SYS\_STATISTICS schema.

#### i Note

Both of these privileges are included in the role MONITORING.

- You have the system privilege INIFILE ADMIN.

#### Procedure

- In the Administration editor, choose the *Alerts* tab.
- From the tab toolbar, choose the  (*Configure Check Settings*) button. The *Configure Check Settings* dialog box appears.

3. Enter the following information:
  - Sender's e-mail address  
E-mail address that is entered as the email's sender
  - SMTP server  
The mail server that the system sends the e-mails to

#### **i Note**

The statistics service does not support a mail server that requires additional authentication.

- Optional: SMTP Port  
The default SMTP port is 25. If the configured mailserver uses a different port, enter it.
4. Optional: Specify the recipient(s) to whom you want an e-mail notification to be sent when an alert is generated for any check.  
To do so, choose *Modify Recipients* and add the e-mail addresses of the users.

#### **i Note**

You can omit this step and only configure e-mail notification for specific checks (next step).

5. Specify the recipients to whom you want to an e-mail notification to be sent when an alert is generated for a specific check or checks.
  - a. Choose *Recipients Configuration for Specific Checks*.
  - b. Select the checks for which you want to configure e-mail notification and then choose *Add Recipients* to add the e-mail addresses of the users to be notified.
6. Choose *OK* to save the configuration.

## **Results**

The specified recipients are notified by e-mail when the system issues an alert for the relevant checks.

### **6.6.2.6.4 Configure Check Thresholds**

For some checks performed by the system, you can configure when an alert is issued, that is the alert condition. A check can have a low, medium, and high priority threshold.

## **Prerequisites**

You have the system privilege CATALOG READ and the SELECT and UPDATE privileges on the `_SYS_STATISTICS` schema.

## Procedure

1. In the Administration editor, choose the *Alerts* tab.
2. From the tab toolbar, choose the  (*Configure Check Settings*) button. The *Configure Check Settings* dialog box appears.
3. Choose the *Configure Check Thresholds* tab.
4. Choose the check that you want to change and enter the threshold values.  
The threshold value and unit depend on what is being measured. For example, for check 2 (disk usage), you could enter 90, 95 and 100 as the thresholds, where 90, 95 and 100 represent the percentage of disk space used.

### → Tip

Hover over a threshold value with the mouse to see information about the unit and the default value.

5. Choose *OK* when you have finished configuring the check thresholds.

## Results

Alerts are generated when the system records the configured threshold values. The color of the bar views on the *Overview* tab may also change when certain thresholds are changed. For example, you change the disk space threshold from 90, 95 and 100, to 85, 90 and 95. If the disk is at 95% usage, then the bar view would change from yellow to red.

### 6.6.2.7 Monitoring Disk Space

To ensure that the database can always be restored to its most recent committed state, you must ensure that there is enough space on disk for data and log volumes. You can monitor disk usage, volume size, and other disk activity statistics on the *Volumes* tab of the Administration editor.

There are two views available on the *Volumes* tab for monitoring the size of volumes on disk:

- Service
- Storage type (that is data, log, and trace)

### i Note

Although trace files are not stored in volumes, they are displayed on the *Volumes* tab in the *Storage* view as they consume disk space and therefore need to be monitored.

When you select a row in either view, detailed information is displayed in the lower part of the screen. In addition to size and usage information, statistics relating to the performance of read/write operations to disk are also available.

### i Note

Detailed information about nameserver volumes is currently not available.

# Information Available on the Volumes Tab

## Service/Storage Type View of Volumes

The following table displays the information available when you select the [Service](#) view. The information shown when you select the [Storage](#) view is the same. It is simply displayed according to storage type not service. Details about the size of trace files stored on disk are also available in this view.

### → Tip

You can configure the view by right-clicking the table and selecting [Configure Table...](#) For example, several additional columns are available.

Column	Description
Service/Volume	The service host and internal port You can expand the host/port to see the storage area for data and log.
Service	The name of the service that has a data and log volume
Total Volume Size [MB]	Total size of the service's data and log volumes If you expand the host/port, you can see the size of each volume.
Data Volume Size [MB]	Current size of the service's data volume
Log Volume Size [MB]	Current size of the service's log volume
Path	Location of the service's data and log files in the file system
Storage Device ID	ID of the device on which the data and log files are stored This can be useful for checking whether or not data and log files are on the same device.
Total Disk Size [MB]	Total size of the host's hard disk
Used Disk Size [MB]	Amount of disk space used on the host's hard disk as a whole
Available Disk Size [%]	Available disk space on the host's hard disk
Volume Subpath	The subpath of a volume
Storage ID/Service	The storage ID corresponding to the service using it
Volume ID	The ID of the volume

## Details View

When you select a row in either the [Storage](#) or [Service](#) view of volumes, detailed information is displayed in the lower part of the screen. In addition to size and usage information, statistics relating to the performance of read/write operations to disk are also available.

Tab Page	Description
Files	<p>This tab page displays the file name and type. It also shows the size of the file and how much of it is currently in use, both in MB and as a percentage of its total size. The relevance of used size depends on the file type as follows:</p> <ul style="list-style-type: none"> <li>• Data files Used size is the amount of data in the file. As the size of the file is automatically increased with the payload but not automatically decreased, used size and total size may be different.</li> <li>• Log segment files Used size equals total size. When a file is full, log entries are written to the next log segment file available. The log segment file's state indicates its availability for reuse. For more information, see the monitoring view <code>M_LOG_SEGMENTS</code>.</li> <li>• Trace files Used size is zero for unused trace files and equals total size for used trace files.</li> </ul>
Volume I/O Statistics	<p>This tab page shows aggregated I/O statistics for the volume since the service was started, for example, number of read/write requests, data throughput, total I/O time, and speed (MB/s). These figures can be useful when analyzing performance problems.</p> <p>For more information about the meaning of the individual fields, see the monitoring view <code>M_VOLUME_IO_TOTAL_STATISTICS</code>.</p>
Data Volume Superblock Statistics	<p>This tab page displays aggregated statistics on the data volume's superblocks since the service was started.</p> <p>Superblocks are partitions of the data volume that contain pages of the same page size class.</p> <p>For more information about the meaning of the individual fields, see monitoring view <code>M_DATA_VOLUME_SUPERBLOCK_STATISTICS</code>.</p>
Data Volume Page Statistics	<p>This tab page displays statistics on the data volume's pages (or blocks) broken down according to page size class. You can analyze how many superblocks are used for the specific size class and also how many pages/blocks are used. The fill ratio enables you to decide whether or not it makes sense to reorganize and release unnecessary superblocks, in other words, shrink the data volume.</p> <p>For more information about the meaning of the individual fields, see monitoring view <code>M_DATA_VOLUME_PAGE_STATISTICS</code>.</p>

## 6.6.2.8 Use User-Defined SQL Statements for System Monitoring

If you have your own SQL statements for monitoring purposes, you can save these on the *System Information* tab of the Administration editor for convenient repeated execution. Statements are saved in an XML file, which you can edit either directly in the studio or offline on your local file system.

### Prerequisites

- The display of user-defined SQL statements on the *System Information* tab is enabled in the SAP HANA studio preferences on the **► SAP HANA ► Administration ►** page.
- If necessary, you have changed the default name and location of the XML file to which user-defined statements are saved when you save them on the *System Information* tab.

#### i Note

It is possible to prepare your statements offline in an XML file and to specify this file here. The statements contained in the file then appear automatically on the *System Information* tab. However, to avoid errors, it is recommended that you create and edit statements on the *System Information* tab.

### Context

For customized monitoring, it is possible to save your own SQL statements on the *System Information* tab of the Administration editor for convenient repeated execution. You can create and save individual statements directly on the *System Information* tab. Alternatively, you can import multiple statements as text or ZIP archive files from a location on your local computer or network file server. To organize large numbers of statements meaningfully, you can define a folder structure.

When you save the Administration editor, all statements, together with the defined folder structure, are saved to a single XML file and are available on the *System Information* tab of the Administration editor for all systems registered in the SAP HANA studio.

#### i Note

The *System Information* tab does not support prepared SQL statements. You can execute prepared statements in the SQL console.

### Procedure

1. In the Administration editor, choose the *System Information* tab.  
The SQL statements delivered with SAP HANA are displayed in the *System* folder.

2. Create folders for organizing your statements as required:
  - a. From the context menu, choose *New Folder*.
  - b. Enter the name and description of the folder.
3. Add user-defined statements by creating them directly or importing them from file:

Option	Description
<b>Create a new user-defined statement</b>	<ol style="list-style-type: none"> <li>1. From the context menu, choose <i>New SQL Statement</i>.</li> <li>2. In the <i>User-Defined SQL Statement</i> dialog, specify a logical name and description for the statement, and then enter the statement in the space provided.</li> <li>3. Save the statement.</li> </ol>
<b>Import user-defined statements from file</b>	<ol style="list-style-type: none"> <li>1. From the context menu, choose <i>Import SQL Statements</i>.</li> <li>2. Navigate to the appropriate location and select the required file(s). You can select one or more plain text files (*.txt) or ZIP archive files (*.zip) containing multiple text files. Import only flat ZIP files. Sub-directories will be ignored during import.</li> </ol>

### **i** Note

Statements must begin with the keyword SELECT or WITH.

The statements are added to the list of statements on the *System Information* tab. If you did an import, the individual statements contained in the text or ZIP archive files are added to the list in a new folder named *Import <timestamp>*. The name of statement is extracted from the file.

4. Save the Administration editor.  
The list of statements on the *System Information* tab is saved to the XML file configured in the preferences.

## Results

Statements are now available for execution on the *System Information* tab of the Administration editor for all systems registered in the SAP HANA studio.

You can edit, delete, and rearrange user-defined statements and folders.

### **i** Note

You cannot edit or delete predefined system statements.

## Related Information

[XML File Structure for User-Defined SQL Statements \[page 408\]](#)

[Execute SQL Statements in SAP HANA Studio \[page 128\]](#)

## 6.6.2.8.1 XML File Structure for User-Defined SQL Statements

SQL statements created in or imported into the *System Information* tab of the Administration editor are saved to a single XML file according to a defined structure.

```
<systabs version="1.0">
  <systemtables>
    <folder name="Folder 1">
      <description>Folder 1 description</description>
      <systemtable name="Statement 1">
        <description>Statement 1 description</description>
        <sql>SELECT statement</sql>
      </systemtable>
      <systemtable name="Statement 2">
        <description>Statement 2 description</description>
        <sql>SELECT statement</sql>
      </systemtable>
    </folder>
    <folder name="Folder 2">
      <description>Folder Description</description>
      <systemtable name="Statement 3">
        <description>Statement 3 description</description>
        <sql>SELECT statement</sql>
      </systemtable>
    </folder>
  </systemtables>
</systabs>
```

## 6.6.2.9 Basic Monitoring Checklist for SAP HANA Systems

To ensure the smooth running of your SAP HANA systems, it is important to monitor regularly operational status and key performance indicators.

Step	What to Check	What to Do
1	System availability (basic pulse check).	<p>You can verify the operational status of all your SAP HANA systems at a glance in the System Monitor and of individual systems on the <a href="#">Overview</a> tab of the Administration editor.</p> <p>For full system availability, the following services must be active for each system:</p> <ul style="list-style-type: none"><li>• <code>nameserver</code></li><li>• <code>indexserver</code></li><li>• <code>preprocessor</code></li></ul> <p>You can check the status of individual services of a system on the <a href="#">Landscape &gt; Services</a> tab.</p> <p>Normally, the <code>daemon</code> service automatically restarts inactive services, but you can also do so manually by choosing <a href="#">Restart Missing Services</a> from the context menu of the <a href="#">Landscape &gt; Services</a> tab.</p> <p>To investigate the reason for inactive services, consider the following actions:</p> <ul style="list-style-type: none"><li>• On the <a href="#">Diagnosis Files</a> tab, find and review the log file <code>available.log</code>, which shows whether or not the <code>daemon</code> and therefore the complete SAP HANA server was down.</li><li>• On the <a href="#">Diagnosis Files</a> tab, merge all diagnosis files and check the period before the service stopped (for example, the previous 30 minutes).</li><li>• Check any alerts generated in the period before the service stopped.</li></ul>

Step	What to Check	What to Do
2	New and past alerts	<p>SAP HANA self-monitors its own status and performance and alerts you of critical situations (that is, when defined threshold values are reached or exceeded).</p> <p>New alerts appear on the <a href="#">Overview</a> tab.</p> <div data-bbox="683 521 1398 674" style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>For all points in this checklist, an alert is generated if a critical situation arises.</p> </div> <p>To identify potential trends and to help you troubleshoot particular issues, you should also monitor past error and high-priority alerts for specific time periods (for example, yesterday, last week, last month), as well as the frequency with which they occurred daily and weekly.</p> <p>For more information about individual alerts, refer to the details on the <a href="#">Alerts</a> tab.</p>
3	Memory consumption of SAP HANA (in particular used memory and peak used memory) and memory consumption on host machines	<p>You can review the memory usage of all your systems at a glance in the System Monitor, of an individual system on the <a href="#">Overview</a> tab, and of individual services on the <a href="#">Landscape</a> &gt; <a href="#">Services</a> tab.</p> <p>If memory usage bars are yellow or red, consider the following actions:</p> <ul style="list-style-type: none"> <li>• Check the error log for application or technical errors and contact SAP Support if necessary.</li> </ul> <div data-bbox="683 1205 1398 1375" style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>To open the error log, from the main menu choose <a href="#">Window</a> &gt; <a href="#">Show View</a> &gt; <a href="#">General</a> &gt; <a href="#">Error Log</a>.</p> </div> <ul style="list-style-type: none"> <li>• If there are no errors, increase available memory or reorganize your data.</li> </ul>

Step	What to Check	What to Do
4	CPU usage	<p>You can review the CPU usage of all your systems at a glance in the System Monitor, of an individual system on the <a href="#">Overview</a> tab, and of individual services on the <a href="#">Landscape &gt; Services</a> tab.</p> <p>If the CPU usage bar is yellow or red, consider the following actions:</p> <ul style="list-style-type: none"> <li>• Check the error log for application or technical errors and contact SAP Support if necessary.</li> </ul> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p><b>i Note</b></p> <p>To open the error log, from the main menu choose <a href="#">Window &gt; Show View &gt; General &gt; Error Log</a>.</p> </div> <ul style="list-style-type: none"> <li>• If there are no errors, analyze the trace files of running services. You can access these on the <a href="#">Diagnosis Files</a> tab.</li> <li>• Increase available resources.</li> </ul>
5	Disk usage (data volume)	<p>You can review how much disk space is being consumed by the data volume in all your systems at a glance in the System Monitor and for an individual system on the <a href="#">Overview</a> tab.</p> <p>If the disk usage bar for data is yellow or red, consider the following actions:</p> <ul style="list-style-type: none"> <li>• Reorganize your data.</li> <li>• Increase disk space.</li> </ul>
6	Disk usage (log volume)	<p>You can review how much disk space is being consumed by the log volume in all your systems at a glance in the System Monitor and for an individual system on the <a href="#">Overview</a> tab.</p> <p>If the disk usage bar for log files is yellow or red, consider the following actions:</p> <ul style="list-style-type: none"> <li>• Reorganize unnecessary log files.</li> <li>• Verify that the last backup executed successfully.</li> </ul>
7	Disk usage (trace files)	<p>You can review how much disk space is being consumed by trace files in all your systems at a glance in the System Monitor and for an individual system on the <a href="#">Overview</a> tab.</p> <p>If the disk usage bar for trace files is yellow or red, consider the following actions:</p> <ul style="list-style-type: none"> <li>• Switch off traces.</li> <li>• Delete unnecessary trace files.</li> <li>• Review the configured trace file rotation.</li> </ul>

Step	What to Check	What to Do
8	Regular, successful execution of backups	<p>You can access the backup catalog, which provides information about the execution and history of data and log backups, on the <i>System Information</i> tab.</p> <p>To diagnose backup errors, refer to the files <code>backup.log</code> and <code>backint.log</code> files, which are accessible on the <i>Diagnosis Files</i> tab.</p>
9	Sufficient space for backups	Ensure that there is sufficient space at the chosen backup destination.
10	Existence of crash dump files	<p>You can check for crash dump files on the <i>Diagnosis Files</i> tab.</p> <p>If such files exist, investigate further. If necessary, contact SAP Support.</p>
11	Number of active threads and the duration of the top 5 threads	<p>You can review active threads on the <b>► Performance ► Threads ►</b> tab.</p> <p>If further investigation is required, refer to the other sub-tabs of the <i>Performance</i> tab. Here you can analyze the following:</p> <ul style="list-style-type: none"> <li>• Expensive SQL statements</li> <li>• Sessions</li> <li>• SQL performance history</li> <li>• Progress of long-running operations</li> <li>• System load history</li> </ul>
12	Active threads with the description "call..." and the duration of such threads	"Call..." threads have a huge impact on performance. They are created on import/export of catalog objects and during data replication with using the SAP Landscape Transformation Replication Server (SAP LT).

## 6.6.3 System and Statistics Views

The SYS schema of the SAP HANA database contains various information about the current state of the database in its many views. Historical data is collected and stored in the views of the `_SYS_STATISTICS` schema.

### System Views

The SAP HANA database provides many system views that contain important information about the database. Much of the information in these views is available in SAP HANA's administration tools. However, it can be necessary to examine the data directly as part of more detailed monitoring and performance analysis.

System views are located in the SYS schema. However, as public synonyms of all views exist, it is not necessary to specify the schema name when you query these views.

#### i Note

Many system views are available in two versions – one that shows the data gathered since a particular service was last started, and one that shows the data gathered since the time the view was last reset. For example, the view `M_VOLUME_IO_TOTAL_STATISTICS` shows the total read size and the total write size for each volume since a service was last started. The SQL command `ALTER SYSTEM RESET MONITORING VIEW SYS.M_VOLUME_IO_TOTAL_STATISTICS_RESET` initializes the statistics shown by this view. The view `M_VOLUME_IO_STATISTICS_RESET` now shows the statistics since the reset time.

You can access the information in a system view by querying the view directly using SQL, or opening it from the catalog using the SAP HANA database explorer or the SAP HANA studio.

#### → Tip

Several predefined SQL SELECT statements on system views are available in the SAP HANA studio on the *System Information* tab of the Administration editor or in the statement library of the SAP HANA database explorer. These statements provide you with easy access to important system information. Double-clicking an entry in this list executes the underlying statement.

If you have compiled your own SQL statements for monitoring purposes, you can save these statements for convenient repeated execution.

For more information about all available system views, see the *SAP HANA SQL and System Views Reference*.

### Statistics Views

The internal monitoring infrastructure of the SAP HANA database (statistics service) is continuously collecting and evaluating information about status, performance, and resource usage from all components of the SAP HANA database. This information is historicized to tables and views in the schema `_SYS_STATISTICS`. You can use these tables and views to analyze system behavior over time.

## Additional System Views in the System Database

Every database has its own SYS and \_SYS\_STATISTICS schemas that contain information about that database only. For system-level monitoring, additional views are accessible in the system database: the M\_DATABASES (SYS) view and the views in the SYS\_DATABASES schema.

### Related Information

[Embedded Statistics Service Views \(\\_SYS\\_STATISTICS schema\)](#)

[Use the Statement Library to Administer Your Database \[page 381\]](#)

[Use User-Defined SQL Statements for System Monitoring \[page 406\]](#)

[The Statistics Service \[page 414\]](#)

## 6.6.4 The Statistics Service

The statistics service is a central element of SAP HANA's internal monitoring infrastructure. It notifies you when critical situations arise in your systems and provides you with historical monitoring data for analysis.

- [Introduction \[page 414\]](#)
- [Technical Implementation \[page 415\]](#)
- [Data Management in the Statistics Service \[page 415\]](#)
- [The Statistics Service in Multitenant Database Containers \[page 416\]](#)

### Introduction

As an SAP HANA database administrator, you need to monitor the status of the system and its services and the consumption of system resources. When critical situations arise, you need to be notified so that you can take appropriate action in a timely manner. For data center operation and resource allocation planning, you need to analyze historical monitoring data. These requirements are met by SAP HANA's internal monitoring infrastructure. A central element of this infrastructure is the statistics service.

The statistics service collects and evaluates information about status, performance, and resource consumption from all components belonging to the system. In addition, it performs regular checks and when configurable threshold values are exceeded, issues alerts. For example, if 90% of available disk space is used, a low priority alert is issued; if 98% is used, a high priority alert is issued.

Monitoring and alert information are stored in database tables in a dedicated schema (\_SYS\_STATISTICS). From there, the information can be accessed by administration tools, such as SAP HANA cockpit, or SAP HANA studio.

## Technical Implementation

The monitoring and alerting features of the SAP HANA database are performed by the statistics service.

The **statistics service** is implemented by a set of tables and SQLScript procedures in the master index server and by the statistics scheduler thread that runs in the master name server. The SQLScript procedures either collect data (data collectors) or evaluate alert conditions (alert checkers). Procedures are invoked by the scheduler thread at regular intervals, which are specified in the configuration of the data collector or alert checker. Data collector procedures read system views and tables, process the data (for example, if the persisted values need to be calculated from the read values) and store the processed data in measurement tables for creating the measurement history.

Alert checker procedures are scheduled independently of the data collector procedures. They read current data from the original system tables and views, not from the measurement history tables. After reading the data, the alert checker procedures evaluate the configured alert conditions. If an alert condition is fulfilled, a corresponding alert is written to the alert tables. From there, it can be accessed by monitoring tools that display the alert. It is also possible to have e-mail notifications sent to administrators if an alert condition is fulfilled. Depending on the severity level of the alert, summary emails are sent with different frequency (hourly, every 6 hours, daily). You can also trigger alert checker procedures directly from monitoring tools (for example, SAP HANA cockpit).

## Data Management in the Statistics Service

The following mechanisms exist to manage the volume of data collected and generated by the statistics service:

- Configurable data retention period  
The data collected by the data collectors of the statistics service is deleted after a default number of days. The majority of collectors have a default retention period of 42 days. For a list of those collectors that have a different default retention period, execute the following statement:

```
SELECT o.name, s.retention_days_default FROM
  _SYS_STATISTICS.STATISTICS_SCHEDULE s, _SYS_STATISTICS.STATISTICS_OBJECTS o
WHERE s.id = o.id AND o.type = 'Collector'and s.retention_days_default !=
42 order by 1;
```

You can change the retention period of individual data collectors with the following SQL statement:

```
UPDATE _SYS_STATISTICS.STATISTICS_SCHEDULE set
RETENTION_DAYS_CURRENT=<retention_period_in_days> where
ID=<ID_of_data_collector>;
```

### → Tip

To determine the IDs of data collectors execute the statement:

```
SELECT * from _SYS_STATISTICS.STATISTICS_OBJECTS where type = 'Collector';
```

Alert data in the `_SYS_STATISTICS.STATISTICS_ALERTS` table is also deleted by default after a period of 42 days. You can change this retention period with the statement:

```
UPDATE _SYS_STATISTICS.STATISTICS_SCHEDULE set
RETENTION_DAYS_CURRENT=<retention_period_in_days> where ID=6002;
```

- Maximum number of alerts

By default, the number of alerts in the system (that is rows in the table `_SYS_STATISTICS.STATISTICS_ALERTS_BASE`) cannot exceed 1,000,000. If this number is exceeded, the system starts deleting rows in increments of 10 percent until the number of alerts is below the maximum. To change the maximum number of alerts permitted, add a row with the key `internal.alerts.maxrows` and the new maximum value to the table `_SYS_STATISTICS"."STATISTICS_PROPERTIES`.

#### ❖ Example

```
INSERT INTO _SYS_STATISTICS.STATISTICS_PROPERTIES VALUES
('internal.alerts.maxrows', 500000);
```

## The Statistics Service in Multitenant Database Containers

In multiple-container systems, the statistics service runs as an embedded process in the (master) index server of every tenant database. Every database has its own `_SYS_STATISTICS` schema.

Monitoring tools such as the SAP HANA cockpit allow administrators in the system database to access certain alerts occurring in individual tenant databases. However, this access is restricted to alerts that identify situations with a potentially system-wide impact, for example, the physical memory on a host is running out. Alerts that expose data in the tenant database (for example, table names) are **not** visible to the system administrator in the system database.

## Related Information

[Tenant Databases \[page 18\]](#)

[Using Alert and Collector Profiles \[page 416\]](#)

### 6.6.4.1 Using Alert and Collector Profiles

You can apply profiles to alert and collector values.

The internal monitoring infrastructure of the SAP HANA database is continuously collecting and evaluating information about status, performance, and resource usage from all components of the SAP HANA database. You can control the alert and collector behavior by applying profiles.

## Available Profiles

Each profile affects the system performance in a different way. Select the profile that suits your system best. All profiles change the value of the parameter `retention_days_default`, which controls for how many days collector data is stored. Additionally, the profiles `HXE` and `SYSTEMDB` reduce the number of enabled alerts and collectors.

The following profiles are available:

Profile	Description
S	This profile applies default values multiplied by 0.5. Resulting values are rounded up, if necessary.
M	No changes are applied to the default alert and collector values. This is the default profile.
L	This profile applies default values multiplied by 1.5. Resulting values are rounded up, if necessary.
HXE	This profile disables several alerts and collectors, and sets the default values for all collectors to 1. This is the default profile for SAP HANA Express systems.
SYSTEMDB	This profile disables several alerts and collectors, and applies default values multiplied by 0.5. Resulting values are rounded up, if necessary. This is the default profile for the system database.

## Switching Between Profiles

The following mechanisms exist to manage alert and collector profiles:

- View the currently enabled profile with the following statement:

```
SELECT VALUE FROM _SYS_STATISTICS.STATISTICS_PROPERTIES WHERE KEY =  
'internal.sizing.profile'
```

- Enable a profile with the following statement:

```
UPDATE _SYS_STATISTICS.STATISTICS_PROPERTIES SET VALUE = '<S, M, L, HXE,  
SYSTEMDB>' WHERE KEY = 'internal.sizing.profile'
```

Customized values for `DEFAULT_VALUE` in the table `_SYS_STATISTICS.STATISTICS_ALERT_THRESHOLDS` and `STATUS`, `INTERVALLENGTH`, `RETENTION_DAYS_DEFAULT` in the table `_SYS_STATISTICS.STATISTICS_SCHEDULE` are stored with each profile.

## SAP HANA Express Profile (HXE)

The SAP HANA Express profile disables a number of alerts and sets the default values for all collectors to 1.

The following alerts remain active after enabling the HXE profile:

- Alert\_Check\_Inactive\_Services
- Alert\_Check\_Restarted\_Services
- Alert\_Check\_Service\_Allocation\_Limit
- Alert\_CrashDump\_Files
- Alert\_Internal\_Disk\_Full\_Events
- Alert\_Internal\_Events
- Alert\_License\_Expiring
- Alert\_Lock\_Wait\_Time\_Out
- Alert\_Long\_Running\_Statements
- Alert\_Mon\_TraceFileSize
- Alert\_Password\_Expiration
- Alert\_RTE\_Dump\_Files
- Alert\_Summary\_Email\_All
- Alert\_Summary\_Email\_High
- Alert\_Summary\_Email\_Medium\_High

The following collectors remain active after enabling the HXE profile:

- Collector\_Global\_Internal\_Events
- Collector\_Host\_Column\_Tables\_Part\_Size
- Collector\_Host\_Heap\_Allocators
- Collector\_Host\_Service\_Memory
- Collector\_Tel\_Disk\_Usage
- Collector\_Tel\_Feature\_Usage
- Collector\_Tel\_Host\_Information
- Collector\_Tel\_Inifile\_Contents
- Collector\_Tel\_Licenses
- Collector\_Tel\_Out\_Of\_Memory\_Events
- Collector\_Tel\_System\_Overview

[Monitoring and Analyzing Performance in SAP HANA Studio \[page 489\]](#)

[SAP Note 2867960](#) 

## 6.6.4.2 Failing Checks

The alerting mechanism of the SAP HANA database relies on the regular execution of checks. If a check fails to execute, it is important to investigate the reason why. Otherwise, you may not be warned about potentially critical situations. Checks often fail due to a shortage of system resources.

If a check fails to execute, an alert is issued indicating that there is an internal statistics service problem. You can also see whether individual checks have stopped running on schedule on the [Alerts](#) page of the SAP HANA cockpit. As long as a check is not being executed, it cannot alert you about potentially critical situations.

Alerting Mechanism	Response
Statistics service	<p>A check is disabled the first time it fails to execute. It remains disabled for a specific length of time before it is automatically re-enabled. This length of time is calculated based on the values in the following columns of the table STATISTICS_SCHEDULE (_SYS_STATISTICS):</p> <ul style="list-style-type: none"><li>• INTERVALLENGTH</li><li>• SKIP_INTERVAL_ON_DISABLE</li></ul> <p>Once <math>INTERVALLENGTH \times SKIP\_INTERVAL\_ON\_DISABLE</math> has elapsed, the check is re-enabled. The default values for all checks are such that failed checks remain disabled for 1 hour.</p> <p>The system determines the status of every check and/or whether the time to re-enablement has elapsed every 60 seconds.</p> <p>You can control the time to re-enablement by changing the value in the column SKIP_INTERVAL_ON_DISABLE.</p> <p>You can also re-enable the check manually.</p>

### i Note

The behavior described above also applies to the data collectors of the statistics service.

## 6.7 Managing and Monitoring SAP HANA Performance

In addition to the administration tools in the SAP HANA cockpit, other resources are introduced here that are available to you to help improve the performance of your database.

### Monitoring

Monitoring past and current information about the performance of the SAP HANA database is important to prevent performance issues and for root-cause analysis of problems. The SAP HANA cockpit provides a number of monitoring tools; the Performance Monitor of the SAP HANA cockpit is particularly useful for analysis as it shows side-by-side visual displays of both system performance and the workload currently being applied.

### Caching

Caching is used widely in SAP HANA as a strategy to improve performance by re-using queried data rather than re-reading and processing the data every time it is requested. Administration and analysis tools for working with the Plan Cache for query optimization are available in the SAP HANA cockpit. In addition to this, the following configurable applications of caching query results in SAP HANA are available:

**The query result cache** applies to column store tables and views and offers most potential to improve performance in situations where data is predominantly read; this is because updates to the base tables invalidate this type of cache. Configuration options for this cache include defining a maximum memory budget for the cache and defining a white list of tables or views to which caching is applied. This is described in detail in SAP Note 2014148 *Guidelines for Using the Query Result Cache*.

**The static result cache (sometimes referred to as *cached views*) and the dynamic result cache** are further applications of caching. The static result cache is created for a specific view and remains valid for the duration of a user-defined retention period. The dynamic result cache is similar but does not have a retention period; it guarantees transactional consistency by maintaining delta records of all changes applied to the underlying table. Details of the static and dynamic result cache can be found in the *SAP HANA Troubleshooting and Performance Analysis Guide*.

### Hints

Hints are instructions for the SAP HANA database server which influence the way a database request is processed. They are typically used to optimize SAP HANA performance or memory consumption and have no effect on the result set of the request. Predefined hints for various purposes are delivered with SAP HANA, you can list these from the HINTS system view; refer to the *SAP HANA SQL and System Views Reference Guide* for more details. You can also create user-defined hints and apply these to a select statement. If a query has both a user-defined and a system-defined hint, the user hint is used in preference.

For convenience you can associate queries with specific hints so that the hint is always applied to the query at runtime. This can be done firstly in the Statement Hints app of SAP HANA cockpit (see also STATEMENT\_HINTS system view), and as an alternative to linking a hint to a select statement you can pin a hint to a specific execution plan in the SQL plan cache. Pinning is applied using the ALTER SYSTEM PIN SQL PLAN CACHE ENTRY instruction and uses the execution plan PLAN\_ID value to link to a hint. Refer to the *SAP HANA SQL and System Views Reference Guide* and to SAP Note 2400006 FAQ: *SAP HANA Statement Hints* for details.

Many hints are available for use with cached data or data replicas to provide 'hint-based routing' functionality so that administrators have control over exactly which source is used when a choice of data sources is

available. Here, in this Performance chapter of the *SAP HANA Administration Guide* we also include a section on the configurable hint classes which are available, see *Using Hints to Query Data Snapshots* for details.

## Capture and Replay

SAP HANA capture and replay allows you to capture the workload of a production system and to replay the captured workload on a target system. This can help you evaluate potential impacts on performance or stability after a change in hardware or software configuration.

[Improving Performance in SAP HANA Cockpit \[page 482\]](#)

## 6.7.1.1 Monitoring Performance in SAP HANA Cockpit

Monitoring past and current information about the performance of the SAP HANA database is important for root-cause analysis and the prevention of future performance issues.

You can use the following tools to monitor fine-grained aspects of system performance in the SAP HANA cockpit:

- Use the *Performance Monitor* to visually analyze historical performance data across a range of key performance indicators related to memory, disk, and CPU usage.
- Use *Threads* to monitor the longest-running threads active in your system. You can use it to see, for example, how long a thread is running, or if a thread is blocked for a prolonged period.
- Use the *Sessions* card to monitor all sessions in your landscape.
- Use the *Statements Monitor* to analyze the current most critical statements running in the database.
- Use *Expensive Statements* to analyze individual SQL queries whose execution time was above a configured threshold.
- Use the *SQL plan cache* to get an insight into the workload of the SAP HANA database as it lists all statements currently cached in the SAP HANA database.
- Use the *Blocked Transactions* to monitor the details of transactionally blocked threads.

### Related Information

[Blocked Transactions \[page 438\]](#)

## 6.7.1.1 The Performance Monitor

Analyzing the performance of the SAP HANA database over time can help you pinpoint bottlenecks, identify patterns, and forecast requirements. Use the [Performance Monitor](#) to visually analyze historical performance data across a range of key performance indicators related to memory, disk, and CPU usage.

### What is the Performance Monitor?

The [Performance Monitor](#) opens displaying the load graph for the selected resource: CPU, disk, or memory. The load graph initially visualizes resource usage of all hosts and services listed on the left according to the default KPI group of the selected resource.

Change the information displayed on the load graph by:

- Switching between a number of predefined views:
  - [Default](#)
  - [CPU](#)
  - [Disk](#)
  - [Memory](#)
- Defining the monitored time frame by entering your desired dates or selecting from [Presets](#).
- Setting the automatic refresh rate.
- Using the [Add Chart](#) button to create custom charts displaying the host and services selection, and selected KPIs. For a list of all available KPIs, see [Key Performance Indicators](#).
- Filtering the results you see in the chart by selecting only the KPIs you are interested in. The hierarchically sorted table legend displays the KPI unit, y-axis scale, as well as minimum, maximum, and average values.
- Zooming into a specific time on a graph by brushing across the desired selection on the load graph directly. Click on the zoom in button on upper right corner of the highlighted area. Select [Undo](#) in the header toolbar to zoom out again
- Comparing the performance of your selected KPIs at different times using the [Performance Comparison](#) page. For more information, see [Compare Performance](#).
- Clicking the  ([Settings](#)) icon, to customize your graphs by including hosts and services as well as additional KPIs in the [Charts](#) tab. In the [Alerts](#) tab, configure alerts according to category and priority status. You can then save the customizations as a view. See [Saved Views](#).

### How can I access the Performance Monitor?

On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, you access the [Performance Monitor](#) page by clicking the title, the graph, or [Monitor Performance](#) on the following cards:

- [Memory Usage](#)
- [CPU Usage](#)
- [Disk Usage](#)

You can also click the [Monitor Performance](#) link on the [Monitor](#) card.

## Related Information

[Analyze Workloads Based on Thread Samples \[page 471\]](#)

[Memory Analysis \[page 353\]](#)

### 6.7.1.1.1 Key Performance Indicators

The *Performance Monitor* allows you select a range of host-level and service-level KPIs to analyze historical performance data of the SAP HANA database.

#### Host KPIs

KPI	Description
CPU	CPU used by all processes related to the operating system (OS)
Database resident memory	Physical memory used by all SAP HANA database processes
Total resident memory	Physical memory used by all OS processes
Physical memory size	Total physical memory
Database used memory	Memory used by all SAP HANA database processes
Database allocation limit	Memory allocation limit for all SAP HANA database processes
Disk used	Disk space used by data, log, and trace files belonging to the SAP HANA database
Disk size	Total disk size
Network in	Bytes read from the network by all processes
Network out	Bytes written to the network by all processes
Swap in	Bytes read from swap memory by all processes
Swap out	Bytes written to swap memory by all processes

## Services KPIs

KPI	Description
CPU	CPU used by the database process
System CPU	CPU used by the database process relative to the operating system
Memory used	Memory used by the database process
Memory allocation limit	Effective allocation limit of the database process
Handles	Number of open handles in the index server process
Ping time	Indexserver ping time including nsWatchdog request and collection of service-specific KPIs
Swap in	Bytes read from swap by the process
Open connections	Number of open SQL connections
Open transactions	Number of open SQL transactions
Blocked transactions	Number of blocked SQL transactions
Statements	Number of finished SQL statements
Active commit ID range	Range between newest and oldest active commit ID
Pending session request count	Number of pending requests
Active versions	Number of active MVCC versions
Acquired record locks	Number of acquire record locks
Read requests	Number of read requests (selects)
Write requests	Number of write requests (insert, update, and delete)
Merge requests	Number of merge requests
Column unloads	Number of table and column unloads
Active threads	Number of active threads
Waiting threads	Number of waiting threads
Total threads	Total number of threads
Active SqlExecutors	Total number of active SqlExecutor threads
Waiting SqlExecutors	Total number of waiting SqlExecutor threads
Total SqlExecutors	Total number of SqlExecutor threads
Data write size	Bytes written to data area
Data write time	Time used for writing to data area
Log write size	Bytes written to log area
Log write time	Time used for writing to log area
Data read size	Bytes read from data area
Data read time	Time used for reading from data area
Log read size	Bytes read from log area

KPI	Description
Log read time	Time used for reading from log area
Data backup write size	Bytes written to data backup
Data backup write time	Time used for writing to data backup
Log backup write size	Bytes written to log backup
Log backup write time	Time used for writing to log backup
Mutex Collisions	Number of collisions on mutexes
Read/Write Lock Collisions	Number of collisions on read/write locks

## Related Information

[Memory Usage in the SAP HANA Database](#)

### 6.7.1.1.2 Compare Performance

Use [Performance Comparison](#) to examine the performance of your selected KPIs at different time intervals.

## Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click [Monitor Performance](#) on the [Memory Usage](#), [CPU Usage](#), [Disk Usage](#), or [Monitoring](#) card.  
The [Performance Monitor](#) opens displaying the load graph for the selected database: CPU, disk, or memory.
2. In the [Performance Monitor](#), select the KPIs you want to compare.
3. Click and drag your mouse within the graph to select a time duration.  
This selection will make up the main chart that you can contrast to any additional charts you create on the [Performance Comparison](#) page.
4. Click the  ([Compare](#)) icon in the highlighted area.
5. The [Performance Comparison](#) page opens, displaying the KPIs as well as hosts and services that were selected in the [Performance Monitor](#).

- Optional: You can add or remove KPIS by clicking the [Refine KPIS](#) button in the header toolbar and making your selection. You can also adjust hosts and services.

Optional: You can adjust the time range of the chart by selecting the desired start and end of the monitored time interval, or choosing from [Presets](#) in the header toolbar.

- Add an additional chart for comparing performance at different time intervals by selecting the [Add a chart to compare](#) link on the bottom of the screen or by clicking the [Add chart](#) button in the header toolbar.

A selection of preset time intervals to choose from opens. Once you have made your choice, the additional chart displaying that time range appears.

#### **i** Note

The [Add a chart to compare](#) link is only available for the first additional chart, any other chart must be added by using the [Add Chart](#) button in the header toolbar.

- Optional: Per default, the monitored time interval is defined via a range. To choose a time interval that is dynamically adjusted to the time interval of the main chart, click on the [Relational](#) button above the respective chart and make your time interval selection.
- Optional: Update the chart by pressing the [Update](#) button above the respective chart.
- Optional: You can bookmark a time range in a load chart to easily refer to it in the future.

Highlight a time range on the desired chart, click the navigation icon on the top right corner of the highlighted area, and choose [Bookmark Selection](#).

The highlighted area changes color to indicate that a bookmark has been set. Above the chart containing bookmarks, there is a link with the number of bookmarks contained in the chart. It lists the bookmarked time range as well as the bookmark selection date. Clicking it highlights and navigates to the bookmarked time range on the chart.

It is possible to name the bookmark by clicking the navigation icon on the highlighted area and selecting [Add Description](#). The description is displayed in the bookmark list above the chart.

To modify the description, click on the navigation icon. You can also delete the bookmark through the navigation icon or by clicking the trash bin.

- Navigate to the [Performance Monitor](#) or [Workload Analysis](#) page by highlighting a time range, clicking on the navigation icon and making your selection.

## 6.7.1.1.3 Performance Monitor Data for SAP Support

To help SAP Support analyze and diagnose problems with your system, you can collect a snapshot of the performance monitor data from your system into a zip file. You can trigger the collection of diagnosis information from the SAP HANA cockpit.

### Related Information

[Import Performance Monitor Data \[page 429\]](#)

[Export Performance Monitor Data \[page 430\]](#)

## 6.7.1.1.3.1 Import Performance Monitor Data

To analyze and diagnose problems with the SAP HANA database, you can import performance monitor data from a zip file into the SAP HANA cockpit.

### Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click [Monitor Performance](#) on the [Memory Usage](#), [CPU Usage](#), [Disk Usage](#), or [Monitoring](#) card.  
The [Performance Monitor](#) opens displaying the load graph for the selected database: CPU, disk, or memory.
2. Click the  ([Import](#)) icon.  
The [Support Tools](#) page opens, displaying a list of available performance monitor data sets.
3. If the desired data set is listed, click the data set name to open it.
4. If the desired data set is not listed, you can import it from a local or a remote file,
  - a. Select [Import](#) on the bottom of the page.
  - b. Enter a name for the data set.
  - c. Browse to the file containing the performance monitor data set that you want to import.
  - d. Click [Import](#).
  - e. The system imports the performance monitor data set from the zip file. This may take some time and runs in the background.

Once the performance monitor data is available, it is displayed in the list of [Performance Monitor Data Sets](#).

Click the data set name to open it.

## 6.7.1.1.3.2 Export Performance Monitor Data

To help SAP Support analyze and diagnose problems with the SAP HANA database, you can export performance monitor data into a zip file, which you can then download and, for example, attach to a support message.

### Prerequisites

- You have the CATALOG READ system privilege.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click [Monitor Performance](#) on the [Memory Usage](#), [CPU Usage](#), [Disk Usage](#), or [Monitoring](#) card.  
The [Performance Monitor](#) opens displaying the load graph for the selected database: CPU, disk, or memory.
2. Click the [↓ \(Export All\)](#) icon to export the CPU, disk, or memory KPI data.
3. Click [Export](#) in the [Export All](#) dialog.

The system collects the relevant information and saves it to a zip file. This may take some time and runs in the background.

Once the collection is available, you can download it by clicking the download button. It will be saved to the download directory of your browser on your client.

## 6.7.1.1.2 Threads

Use [Threads](#) to monitor the longest-running threads active in your system. You can use it to see, for example, how long a thread is running, or if a thread is blocked for a prolonged period.

Analyzing the threads running in the SAP HANA database can be helpful when analyzing the current system load.

You can identify which statements or procedures are being executed and at what stage they are, who else is connected to the system, and if there are any internal processes running as well.

The [Threads](#) card provides information about the number of currently active and blocked threads in the database.

On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, on the [Threads](#) card, click either the number of active or blocked threads on the card or the card title to open the [Threads](#) page.

The [Threads](#) page allows you to monitor the longest-running threads in your current system. You can retrieve more information or customize what is being displayed, for example:

- Filter threads by host, service, and thread type
- Choose the sorting order by checking the [Group and Sort](#) box and selecting the sorting parameters
- See the call stack information on your chosen thread
- Define columns and choose the parameters you want information on

When you have selected a thread, you can [Navigate To](#) the [Sessions](#) or [Blocked Transactions](#) page for the thread with the same connection ID.

If a thread is in a blocked transaction or is using an excessive amount of memory, you can cancel the operation executing the thread by clicking [Cancel Operations](#) in the footer toolbar.

## Related Information

[Thread Details \[page 431\]](#)

### 6.7.1.1.2.1 Thread Details

The [Threads](#) card provides you with detailed information about the 1000 longest-running threads currently active in the database.

#### **i** Note

Not all of the columns listed below are visible by default. You can add and remove columns in the Columns dialog, which you open by clicking the  ([Settings](#)) icon in the table toolbar.

## Thread Information

To open the [Threads](#) card, on the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click either the number of active or blocked threads on the card or the card title.

The table below lists the information available for threads.

Detail	Description
Blocking Transaction	Blocking transaction
Duration (ms)	Duration (ms)
Host	Host name
Port	Internal port
Service	Service name

<b>Detail</b>	<b>Description</b>
Hierarchy	Thread grouping information. Filled with Connection ID/ Update Transaction ID/Transaction ID or left empty for inactive threads
Connection ID	Connection ID
Thread ID	Thread ID
Calling	The thread or service which the thread calls
Caller	The thread or service which called this thread
Thread Type	Thread type
Thread Method	Thread method
Thread Detail	Thread detail
User	User
Application User	Application user name
CPU Time	CPU time of thread
Cumulative CPU Time	CPU time of thread and associated children
Transaction ID	Transaction ID
Update Transaction ID	Update transaction ID
Thread Status	Thread state
Connection Transaction ID	Transaction object ID
Connection Start Time	Connected Time
Connection Idle Time (ms)	Time that the connection is unused and idle
Connection Status	Connection Status: 'RUNNING' or 'IDLE'
Client Host	Host name of client machine
Client IP	IP of client machine
Client PID	Client Process ID
Connection Type	Connection type: Remote, Local, History (remote), History (local)
Own Connection	Own connection: TRUE if own connection, FALSE if not
Memory Size per Connection	Allocated memory size per connection
Auto Commit	Commit mode of the current transaction: TRUE if the current connection is in auto-commit mode, FALSE otherwise
Last Action	The last action done by the current connection: ExecuteGroup, CommitTrans, AbortTrans, PrepareStatement, CloseStatement, ExecutePrepared, ExecuteStatement, FetchCursor, CloseCursor, LobGetPiece, LogPutPiece, LobFind, Authenticate, Connect, Disconnect, ExecQidItab, CursorFetchItab, InsertIncompletItab, AbapStream, TxStartXA, TxJoinXA
Current Statement ID	Current statement ID

Detail	Description
Current Operator Name	Current operator name
Fetch Record Count	Sum of the record count fetched by select statements
Sent Message Size (Bytes)	Total size of messages sent by the current connection
Sent Message Count	Total message count sent by the current connection
Received Message Size (Byte)	Total size of messages/transactions received by the current connection
Received Message Count	Total message/transaction count received by the current connection
Creator Thread ID	Thread ID who created the current connection
Created By	Engine component that created the connections: Session, Planning, Repository, CalcEngine, Authentication, Table Exporter, Loader, LLVM, JSVM, IMS Search API, OLAP Engine, Mergedog, Ping Status, Name Server, Queue Server, SQL Stored Procedure, Authorization, TrexViaDbssl from ABAP, HybridTable Reorganizer, Session external
Is Encrypted	Encrypted: TRUE if the secure communication is enabled (SSL enabled), FALSE, otherwise
Connection End Time	The time when the connection is closed for history connections
Blocked Update Transaction ID	Write transaction ID of the write transaction waiting for the lock
Blocking Transaction ID	Transaction object ID of the transaction holding the lock
Thread ID of Lock Owner	Connection ID associated with the blocked write transaction
Blocking Update Transaction ID	Write transaction ID of the write transaction holding the lock
Transactional Lock Type	Transactional lock type
Transactional Lock Mode	Transactional lock mode
Lock Wait Component	Waiting for lock component
Lock Wait Name	Waiting for lock ID
Timestamp of Blocked Transaction	Timestamp of the blocked transaction
Waiting Record ID	ID of the record on which the lock is currently placed
Waiting Object Name	Name of the object on which the lock is currently placed
Waiting Object Type	Type of the object on which the lock is currently placed
Waiting Schema Name	Name of the schema on which the lock is currently placed

### 6.7.1.1.3 Session Monitoring

Use the [Sessions](#) card to monitor all sessions in your landscape.

Analyzing the sessions connected to your SAP HANA database helps you identify which applications or which users are currently connected to your system, as well as what they are doing in terms of SQL execution.

The [Sessions](#) card displays the number of active and total sessions.

On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, on the [Sessions](#) card, click either the number of active or blocked threads on the card or the title of the card to open the [Sessions](#) page.

The [Sessions](#) page allows you to monitor all sessions in the current landscape. You can see the following information:

- Active/inactive sessions and their relation to applications
- Whether a session is blocked and, if so, which session is blocking it
- The number of transactions that are blocked by a blocking session
- Statistics such as average query runtime and the number of DML and DDL statements in a session
- The operator currently being processed by an active session

To support monitoring and analysis, you can perform the following actions on the [Sessions](#) page:

- Cancel a session by choosing [Cancel Sessions](#)
- Save the data sets as a text or html file by choosing the [Save As...](#) button.

## 6.7.1.1.4 Statements

Use [Monitor Statements](#) to monitor and analyze different types of statements in your system.

On the [Database Overview](#), with the [Monitoring](#) or [All](#) view selected, click the [SQL Statements](#) card to open the [Monitor Statements](#) page.

There are four views available in the table on the [Monitor Statements](#) page:

Monitor Statements Table

View	Function
Overview	An overview and analysis of the most critical statements running in the database.
Active Statements	A list of all statements currently running in the system.
SQL Plan Cache	Insights into the workload of the SAP HANA database through a list of all statements currently cached in the SAP HANA database
Expensive Statement Trace	Analysis of individual SQL queries whose execution time is above a configured threshold.

You can use the search bar above the table to search for and display only the SQL statements you are interested in.

## Related Information

[Monitor and Analyze Active Statements \[page 435\]](#)

[Monitor and Analyze Statements with SQL Plan Cache \[page 436\]](#)

[Monitor and Analyze Expensive Statements \[page 437\]](#)

## 6.7.1.1.4.1 Monitor and Analyze Active Statements

On the [SQL Statements](#) page, use the [Overview](#) view to analyze the current most critical statements running in the database, and the [Active Statements](#) view to see all actively running statements.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Analyzing the current most critical statements running in the SAP HANA database can help you identify the root cause of poor performance, CPU bottlenecks, or out-of-memory situations. Enabling memory tracking ([Overview](#) view only) allows you to monitor the amount of memory used by single statement executions.

Statements are ranked based on a combination of the following criteria:

- Runtime of the current statement execution
- Lock wait time of the current statement execution
- Cursor duration of the current statement execution

### Procedure

1. On the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view open, click the title or [View all](#) on the [SQL Statements](#) card.

The [Overview](#) view opens. It allows you to analyze the most current statements running in the database. You can see:

- The 100 most critical statements, listed in order of the longest runtime
- The full statement string and ID of the session in which the statement is running
- Application, application user, and the database running the statement
- Whether a statement is related to a blocking transaction

2. Click the [Active Statements](#) tab.

The [Active Statements](#) view shows:

- The full statement string and ID of the session in which the statement is running
- The host and port, as well as the connection ID of the active statement

- The last executed time
- If the statement has a parent statement and its ID
- 3. To support monitoring, you can perform these actions on either view:
  - a. See the full SQL statement and open the statement with the *SQL analyzer* by clicking *More* in the *Statement String* column and selecting *Open in SQL Analyzer*.
  - b. Navigate to the *Sessions* page to analyze the session with the same ID as the statement by clicking on the  (*Navigate to Sessions*) icon next to the workload class column.
  - c. Set up or modify workload classes by clicking a statement's *Workload Class Name*. Choose *New* to create a new workload class or *Existing* to select a workload class from a list, then fill in the fields.
  - d. (*Overview* view only) Enable or disable memory tracking.
  - e. Personalize the columns displayed in the view using the  (*Settings*) icon.

## Related Information

[Create a Workload Class](#)

[Create a Workload Class Mapping](#)

### 6.7.1.1.4.2 Monitor and Analyze Statements with SQL Plan Cache

On the *SQL Statements* page, use the *SQL Plan Cache* view to get an insight into the workload of the database as it lists all statements currently cached in the SAP HANA database.

## Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

Analyzing all statements currently cached in the SAP HANA database can help you identify statement hashes, as well as if a statement has been correctly cached.

Technically, the plan cache stores compiled execution plans of SQL statements for reuse, which gives a performance advantage over recompilation at each invocation. For monitoring reasons, the plan cache keeps statistics about each plan, for instance number of executions, min/max/total/average runtime, and lock/wait statistics. Analyzing the plan cache is very helpful as one of the first steps in performance analysis because it gives an overview about what statements are executed in the system.

## i Note

Due to the nature of a cache, seldom-used entries are evicted from the plan cache.

The SQL plan cache is useful for observing overall SQL performance as it provides statistics on compiled queries. You can get insight into frequently executed queries and slow queries with a view to finding potential candidates for optimization.

## Procedure

1. On the *Database Overview* page, with the *Monitoring* or *All* view open, click the title or *View all* on the *SQL Statements* card to open the *SQL Statements* page.
2. Select the *SQL Plan Cache* tab.
3. To support monitoring and analysis, you can perform the following actions on the view:
  - a. Open the selected SQL statement with the SQL analyzer by clicking *More* next to the statement string and selecting Open in SQL Analyzer.
  - b. Open the selected SQL statement with SQL analyzer and save the executed plan statistics as a PLV file by clicking on *More* next to the statement string and selecting *Analyze and Save Plan*.
  - c. Save the data sets as a text or HTML file by choosing the *Save As...* button.
  - d. Configure the plan cache size by choosing *Configure*.
  - e. Clear all cached statements by choosing *Clear All Plan Cache*.
  - f. Personalize the columns displayed in the view using the  (*Settings*) icon.

## 6.7.1.1.4.3 Monitor and Analyze Expensive Statements

On the *SQL Statements* page, use the *Expensive Statements* view to analyze individual SQL queries whose execution time is above a configured threshold.

## Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

Analyzing expensive statements can help you understand why they exceed duration thresholds.

The expensive statements trace records information about the expensive statements for further analysis and displays it on the *Expensive Statements* page.

## Procedure

1. On the *Database Overview* page, with the *Monitoring* or *All* view selected, click the *SQL Statements* and then click the *Expensive Statements* tab.
2. To support monitoring and analysis, you can perform these actions on the view:
  - a. Define the monitored date.
  - b. Filter expensive statements, refresh the list, choose the sorting parameter, and filter by parameter.
  - c. Save the data sets as a text or HTML file by choosing the *Save As...* button.
  - d. Open an expensive statement with the SQL analyzer by clicking *More* in the *Statement String* and selecting *Open in SQL Analyzer*.
  - e. Set up or modify workload classes by clicking a statement's *Workload Class Name*. Choose *New* to create a new workload class or *Existing* to select a workload class from a list, then fill in the fields.
  - f. Access the *Current Table Distribution* page to view the current table distribution in detail.
  - g. Personalize the columns displayed in the view using the  (*Settings*) icon.

## Related Information

[Expensive Statements Trace](#)

[Create a Workload Class](#)

[Create a Workload Class Mapping](#)

### 6.7.1.1.5 Blocked Transactions

Use *Blocked Transactions* to monitor transactionally blocked threads. You can use it to see, for example, what transaction is blocking a thread, the type of lock held, and the owner of the lock.

Blocked transactions are transactions that are unable to be processed further because they need to acquire transactional locks (record or table locks) that are currently held by another transaction. Transactions can also be blocked while waiting for other resources such as network or a disk (database or metadata locks).

Analyzing the blocked transactions in SAP HANA database can be helpful when analyzing the current system load, as transactionally blocked threads can impact application responsiveness.

The *Blocked Transactions* feature provides information on the number of currently blocked threads in the database.

On the *Database Overview* page, with the *Monitor* or *All* view selected, click the *Open Blocked Transactions* link on the *Monitoring* card.

To support monitoring and analysis, you can perform the following actions on the *Blocked Transactions* page:

- Filter transactions with the help user-defined keywords
- Select to hide own or idle sessions
- Customize the blocked transaction columns to show only desired parameters
- Click on a blocked transaction and select *Navigate To...* on the bottom right of the screen to jump to *Threads* or *Sessions* with the same connection ID.

## 6.7.1.2 Analyzing Performance in SAP HANA Cockpit

You can analyze the performance of the database using the SAP HANA cockpit.

You can use the following tools to analyze fine-grained aspects of database performance in the SAP HANA cockpit:

- Use the capture and replay to detect, analyze, or verify any potential issues before applying changes or upgrades.
- Use the workload analyzer to analyze the database performance through data from thread samples. You can also use it to analyze the workload captured with the capture and replay tool, or any other workload occurring in a system.
- Use the SQL analyzer to understand performance issues of a query execution and other query execution aspects of the SAP HANA database.

### Related Information

[Capturing and Replaying Workloads \[page 439\]](#)

[Analyzing Workloads \[page 468\]](#)

[Analyzing Statement Performance \[page 475\]](#)

## 6.7.1.2.1 Capturing and Replaying Workloads

Capturing and replaying workloads from an SAP HANA database helps you evaluate potential impacts on performance or stability after a change in the hardware or software configuration.

The following sections provide an overview of SAP HANA capture and replay:

### What can I do with SAP HANA capture and replay?

This tool allows you to capture the workload of a source system and to replay the captured workload on a target system without applications.

Moreover, you can use the tool to analyze the captured workload and the reports generated after replaying the workload. Comparing the performance between the source and target systems can help you find the root cause of performance differences.

### What is a workload?

Workload in the context of SAP HANA can be described as a set of requests with common characteristics. For more information about workload, see *Workload in the Context of SAP HANA*.

In the context of SAP HANA capture and replay, workload can mean any change to the database via SQL statements that come from SAP HANA client interfaces such as JDBC, ODBC, or DBSL. The workload can be created by applications or clients (for example, SAP NetWeaver or Analytic).

## When should I use SAP HANA capture and replay?

Use SAP HANA capture and replay to detect, analyze, or verify any potential issues before applying changes or upgrades, such as:

- Hardware change
- SAP HANA revision upgrade
- SAP HANA ini file change
- Table partitioning change
- Index change
- Landscape reorganization for SAP HANA scale-out systems
- Apply HINT to queries

For more information on possible use cases, see *An overview of possible use cases for SAP HANA capture and replay*.

## How can I access SAP HANA capture and replay?

Open SAP HANA capture and replay from the SAP HANA cockpit. On the [Database Overview](#) page, search for the [Capture Workload](#) and [Replay Workload](#) tiles.

## How does SAP HANA capture and replay work?

The main steps involved in the capturing and replaying process are:

1. Capture  
In this step the tool automatically collects the execution context information together with the incoming requests to the database. The captured workload file stores the start times of the SQL statements. A database backup is recommended after starting capturing to ensure that the source and target systems are in a consistent state.
2. Preprocess  
In this step the tool reconstructs and optimizes the captured workload file to make it replayable on a target system. This process is a one-time operation and the stored preprocessed workload file can be replayed multiple times.
3. Replay  
The replayer is a service on operating system level that needs to be started before replaying. The tool replays the preprocessed file based on the SQL statement timestamp or on the transactional order. Together with the collected execution context it allows you to accurately simulate the database workload.

#### 4. Analyze

For a final analysis, you can generate comparison reports displaying a capture-replay or a replay-replay comparison. You can analyze the statements based on results or on performance.

[SAP Note 2362820](#)

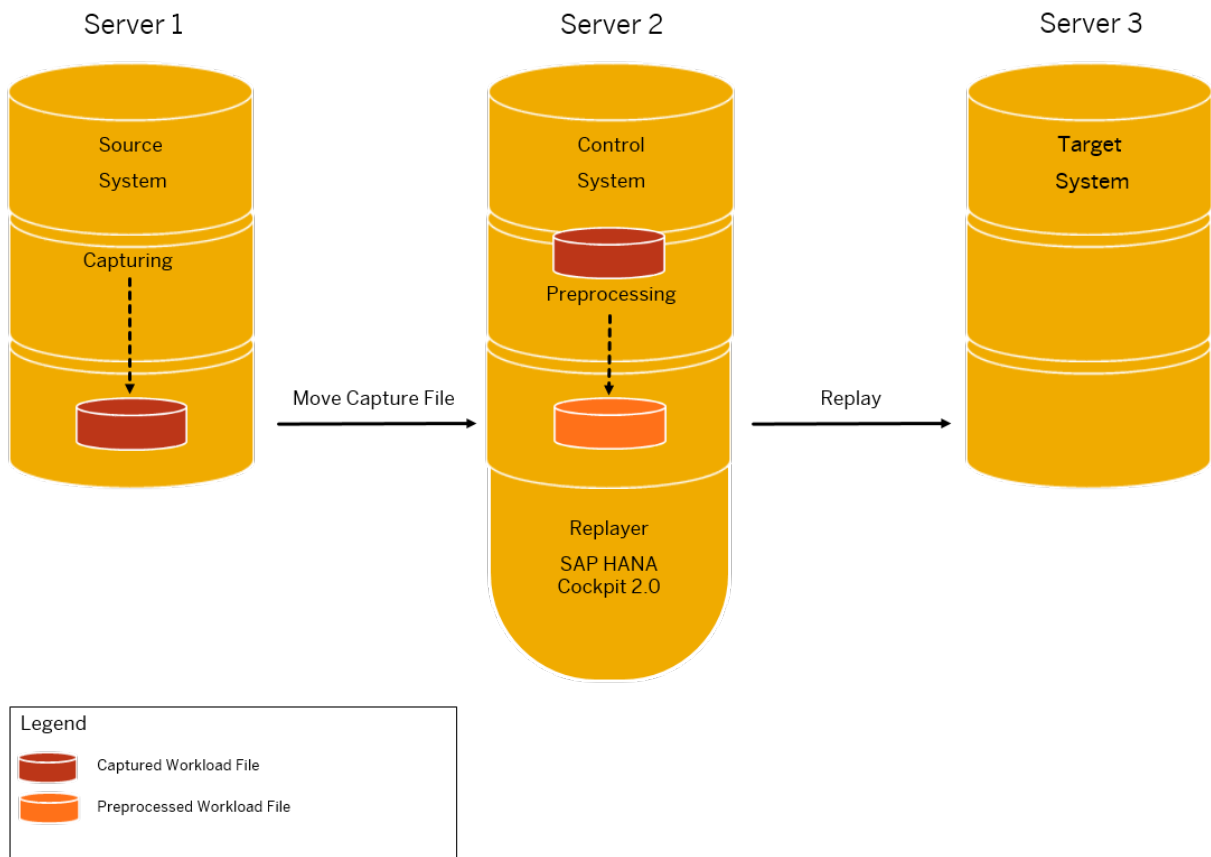

### 6.7.1.2.1.1 Landscape Considerations

A 3-tier setup is recommended.

The 3-tier setup has the following advantages:

- Three or more servers are possible depending on the number of dedicated replayer systems.
- The replay results will be stored in the separate control system when recovering the target system.
- This setup is recommended for replays with re-initialization of the target system.
- This setup is recommended for scenarios with multiple replayers.

The graphic below offers an example of a 3-tier setup. Keep in mind that the replayers and SAP HANA cockpit can run on the control system server or on individual servers.

### i Note

SAP HANA capture and replay can also be used with SAP HANA, Express Edition installations. For more information, see *Adjust the Global Allocation Limit* in the *Getting Started with SAP HANA 2.0, express edition (Virtual Machine Method)* or *Capture and replay with multiple distributed replayers on SAP HANA, Express Edition*.

## System types

These systems should be part of a 3-tier setup:

System Type	Description
Source System	<ul style="list-style-type: none"> <li>• The original workload is captured here</li> <li>• The captured workload file and the database backup are initially created here and stored on disk</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Running a capture will have an overhead on CPU utilization and disk I/O.</p> </div>
Control System	<ul style="list-style-type: none"> <li>• This can be a dedicated system or a shared system</li> <li>• Manages and directs replayers when running a replay</li> <li>• Stores replay results for analysis</li> <li>• Preprocessing is executed here</li> <li>• Serves as central monitoring system for the replay process</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Preprocessing and replaying require CPU and memory to execute.</p> </div>
Target System	<ul style="list-style-type: none"> <li>• This can be a dedicated system or a shared system</li> <li>• The replay is executed here, even though it's started from the control system</li> <li>• For meaningful replay results, the system should be in consistent state with the source system (recovered via database backup from the source system)</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>If the control system and target system are the same, the replay results are lost when the target system is recovered.</p> </div>
Replayer	<ul style="list-style-type: none"> <li>• Process running on the operating system</li> <li>• Is responsible for reading from preprocessed workload files and executing workload on the target system</li> <li>• Replayers can run on individual systems</li> <li>• Multiple replayers can be used to scale the workload during replay</li> <li>• Replayers can run on SAP HANA, express edition installations</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>→ Recommendation</b></p> <p>Run the replayers on the control system or a separate system because the replay requires CPU and memory to execute.</p> </div>

System Type	Description
SAP HANA cockpit 2.0	<ul style="list-style-type: none"> <li>Used to set up, configure, monitor, analyze while capturing, preprocessing and replaying</li> <li>SAP HANA cockpit 2.0 can run on SAP HANA, express edition installations</li> </ul>

**→ Recommendation**

Run SAP HANA cockpit 2.0 on the control system host.

### i Note

The replayers and SAP HANA cockpit can run on the control system server or on individual servers.

## Prerequisites

- Check the disk performance to ensure that there is sufficient bandwidth for capturing and preprocessing workloads without any performance bottlenecks. If disk performance is not sufficient, the active capture can impact the source system.
- Check the available disk space in combination with the characteristics of the workload that should be captured. The required disk space is highly dependent on the type of workload being captured. Use the disk space that is dedicated to the database instance itself.
- One replayer service is sufficient to execute a replay successfully. For a better scalability and performance in large workload scenarios, multiple replayers can be used for all replaying purposes. When using multiple replayers, distribute and divide all involved components (for example, target instance, control instance, one or more replayers) on different hosts and systems. Doing so will reflect the initial captured workload as realistic as possible. This will also reduce the effect which the resource consumption of the components might have on a replay.
- Use a separate control and target instance for replaying workloads. If a replayed statement causes a crash, it will be displayed in the replay report. When you use one and the same control and target instance, the replay report entry causing a crash will not be successfully sent to the control instance.
- Use the secure store for saving passwords and authenticating users. For more information, see *Secure User Store (hdbuserstore)* in the *SAP HANA Security Guide*.
- The target system should meet the same privacy and security prerequisites as the source system. Since the target system processes the same data as the source system, it should meet an appropriate security level depending on data criticality. Unnecessary network connections to the target system should not be allowed. Users registered on the source system might be able to access the target system after a replay has been completed.
- Regarding version dependencies, the following rules can be followed:
  - Target system  $\geq$  Control system & Replayers  $\geq$  Source system
  - The source system should be at least 122.14+ for captures with transactional replay enabled
- To trigger replays, the control system and target system must be registered in the same SAP HANA cockpit. The user in the SAP HANA cockpit should be able to access them both. When registering the target system, the cockpit does not store the credentials. For more information, see *Register a Database*.

For more information, see *SAP Note 2362820*.

[SAP HANA Security Guide](#)

[Registered Databases \[page 73\]](#)

### 6.71.2.1.2 System Privileges

You need the following system privileges when using SAP HANA capture and replay.

System and User	Description
Cockpit User for SAP HANA cockpit	<ul style="list-style-type: none"><li>• Requires the Cockpit Database Administrator role</li><li>• It is used for registering, managing and accessing databases</li></ul>
Workload Capture Admin for the source system	<ul style="list-style-type: none"><li>• Used to start captures and trigger backups in the source system</li><li>• Requires the WORKLOAD CAPTURE ADMIN privilege to capture workloads</li><li>• Optional: BACKUP OPERATOR privilege to trigger backups</li><li>• Optional: INIFILE ADMIN privilege to see the previously used optional filters on the capture configuration page</li><li>• This user needs to be used as the connecting user when registering the source system in the same SAP HANA cockpit</li></ul>
Control Replay Admin for the control system	<ul style="list-style-type: none"><li>• Used for preprocessing and replaying in the control system</li><li>• Requires the WORKLOAD REPLAY ADMIN privilege for preprocessing and replaying workloads, as well as generating replay reports</li><li>• Requires the WORKLOAD ANALYZE ADMIN privilege for loading and analyzing workloads</li><li>• Requires the CATALOG READ privilege for generating replay reports</li><li>• This user needs to be used as the connecting user when registering the control system in the same SAP HANA cockpit</li></ul>
Target Replay Admin for the target system	<ul style="list-style-type: none"><li>• Used to execute replays and reset user passwords in the target system</li><li>• Requires the WORKLOAD REPLAY ADMIN privilege to execute replays</li><li>• This user needs to be used as the connecting user when registering the target system in the same SAP HANA cockpit</li></ul>

### 6.7.1.2.1.3 Files and Sizing Guidelines

The files used in the process of capturing, preprocessing and replaying a workload can have different sizes depending on various factors.

#### Captured workload file

After capturing the workload from a source system, a captured workload file will be available for the replay. This captured workload file contains multiple captured workload segment files as indicated in the graphic below:

On a conceptual level, we will refer to the captured workload file using the shorter term "captured workload".

The size of the captured workload file depends on:

- Number of requests
- String size of captured statements
- Number and size of captured input parameters for statements
- If configured, the average size of the captured explain plans also needs to be considered

Activating a capture may cause:

- CPU overhead on the source system
- Memory overhead on the source system  
To configure the memory used, see the `compressionbuffersize` and `filebuffersize` parameters in *SAP Note 2362820*
- Increase in disk I/O  
The amount depends on the data that needs to be written to disk.

## Preprocessed workload file

To optimize the captured workload file before replaying it, you need to preprocess it first.

While preprocessing the captured workload file, the captured statement segment files are stored in a directory. After the preprocessing is completed, the output is a preprocessed workload file containing the directory with multiple files as indicated in the graphic below:

On a conceptual level, we will refer to the preprocessed workload file using the shorter term "preprocessed workload".

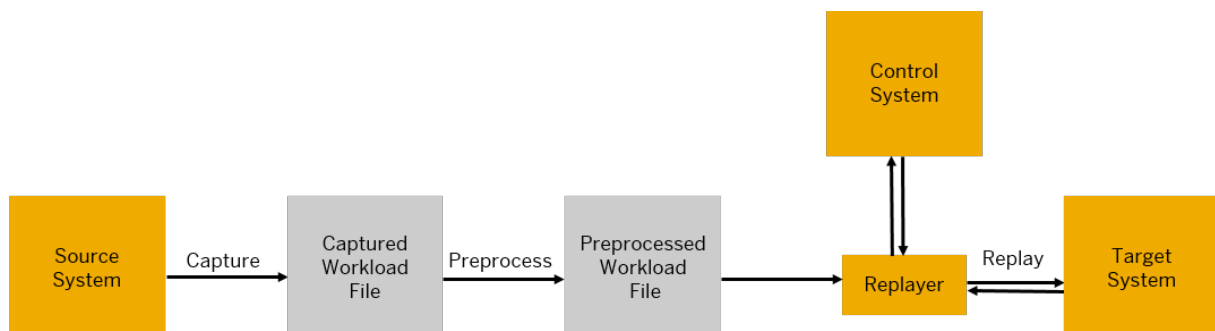

The size of the preprocessed workload file is larger than the captured workload file. The size varies depending on the compression and content of the captured workload file. Preprocessed workload files are always uncompressed.

Preprocessing a captured workload file may cause:

- CPU utilization  
The database will utilize the CPU as much as possible to achieve the best performance.
- Memory consumption
- Increase in disk I/O  
The amount depends on the data that needs to be read and written.

## Replay

The replay process is performed by the replayer, which should be running before starting the replay as indicated in the graphic below:

Running a replayer may cause:

- CPU utilization
- Memory consumption  
The amount of memory consumed depends on the size of the preprocessed workload file. However, even though the replayer is a separate process running on the operating system of a SAP HANA installation, its memory can be limited using the global allocation limit of its host database.
- Increase in disk I/O  
The amount depends on the data that needs to be read from disk.

The duration of the replay depends on the duration of the capture.

Running a replay may cause:

- CPU utilization  
The target system will use resources according to the workload being replayed.
- Memory consumption  
The amount of memory consumed depends on the content of the preprocessed workload file.
- Increase in disk I/O on the control system  
The amount depends on the data that needs to be written and read and is influenced by the replay result size.

The size of the replay result depends on:

- The total record count
- The memory allocated for each record
- If configured, the average size of the captured explain plans also needs to be considered

#### **i** Note

When using different servers, capturing, preprocessing, and replaying may cause network traffic.

## Related Information

[SAP Note 2362820](#) 

### 6.7.1.2.1.4 Capturing a Workload

You can capture the entire workload from a source system or only a part of this workload.

To capture the workload from a source system, use the *Capture Workload* card.

## Related Information

[Capture a Workload \[page 449\]](#)

[Monitoring a Captured Workload \[page 452\]](#)

[Capturing Configuration Settings \[page 450\]](#)

## 6.7.1.2.1.4.1 Capture a Workload

You can capture the workload from a source system.

### Prerequisites

You have the Workload Capture Admin user for the source system.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, you can choose the [Capture Workload](#) card or choose [Start New Capture](#) directly from the card.

If you choose the [Capture Workload](#) card, the [Capture Management](#) page opens. If you already captured workload with SAP HANA capture and replay, you see the captured workload located in the currently configured capture destination. You can also see information such as name, status, start time, size, duration, or capture usage.

If you choose [Start New Capture](#) directly from the card, the [Configure New Capture](#) page opens.

2. Optional: To change the capture destination, choose [Configure Capture](#) on the bottom right of the [Capture Management](#) page.

The captured workload file is stored by default in the \$SAP\_RETRIEVAL\_PATH/trace directory with a \*.cpt file extension. For tenant databases there is a subfolder in the trace directory for each tenant. Since the default trace directory generally resides in the same storage area with data and log volumes, capturing workloads may affect the performance across the entire system over time. If you enter a different destination for the captured workload file, you may have a better distribution of the disk I/O between the data and log volumes and the captured workload file.

3. To start configuring the new capture, choose [New Capture](#) on the [Capture Management](#) page on the bottom right.

On the [Configure New Capture](#) page it is mandatory to enter the name of the new capture.

You can customize other optional settings before you start the capture. For an overview of these settings, see [Capture Configuration Settings](#).

4. Choose [Start Capture](#) on the bottom right.

The new captured workload is displayed on the [Capture Management](#) page with the status [Capturing](#). You can stop the capture or you can let it run as long as you wish.

## Related Information

[Capturing Configuration Settings \[page 450\]](#)

[System Privileges \[page 445\]](#)

[Monitoring a Captured Workload \[page 452\]](#)

### 6.7.1.2.1.4.1.1 Capturing Configuration Settings

You can customize several optional settings before you start capturing a workload.

The tables provide an overview of the settings that can be customized.

#### General Information

Setting	Description
Usage	Select if you will use the captured workload for a replay, an analysis, or both.  Your selection in this field impacts the collected data. For example, when capturing a workload for analysis, the <i>Workload Details</i> option is automatically turned on in the <i>Data Collection</i> section.
Capture Name	Enter a name for the capture. This field is mandatory.
Description	Enter a description of the capture for future reference.
Schedule	You can schedule the capture to start at a specific point in time by specifying the start and end time. If you turn it on, the status of your captured workload changes to <i>Scheduled</i> . After setting a specific time, you can change it later. However, once you schedule a capture, you can't turn off the schedule setting anymore.

#### Capture Control

Setting	Description
Create Backup	<p>Turn it on to automatically create a database backup of the source system after starting the capture.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>→ Recommendation</b></p> <p>To ensure that the source system and the target system are in a consistent state for capture and replay, we recommend to perform a database backup after starting the capture. A database backup is required only for the first time, because incremental backups can be used once the system has been initialized for the first time. For more information about backups, see <i>SAP HANA Backup and Recovery</i> in the <i>SAP HANA Administration Guide</i>.</p> </div> <p>Use the <a href="#">Backup Settings</a> link to choose the backup type (for example, complete, differential, incremental), to select between Backint integration or file-based backups, to add a prefix to the file name, to define a path to store the backup file, or to enter parameters for the Backint.</p> <p>By creating a backup, you can ensure the ability to use the <a href="#">Synchronize with backup</a> option during replay. For more information, see <i>Replay Configuration Settings</i>.</p>

Overwrite Capture When Time Exceeds	<p>Turn it on and enter a time to remove the captured workload segment files that are older than the specified time you entered.</p> <p>Only closed segments are deleted. The currently active captured workload segment file is not affected.</p>
Overwrite Capture When Disk Usage Exceeds	<p>Turn it on and select a ratio to remove the old captured workload segment files when the disk usage exceeds the specified percentage.</p> <p>Only closed segments are deleted. The currently active captured workload segment file is not affected.</p>

## Data Collection

Setting	Description
Explain Plan	<p>Turn it on to collect the output of the EXPLAIN PLAN command for the captured statements.</p> <p>You can use this information for analysis after the replay.</p>
Workload Details	<p>Turn it on to collect additional information for the workload analyzer such as application source, involved threads, network statistics, or related objects.</p> <p>If this option is disabled, the captured workload file can still be viewed using the workload analyzer, but less information will be available for the review.</p>
SQL Input Parameters	<p>Turn it on to see the parameter values in the replay report. To do so, turn on the <a href="#">Workload Details</a> option first. This allows you to enable the <a href="#">SQL Input Parameters</a> option.</p> <p>This option is needed for replaying.</p>

## Optional Filter

Setting	Description
Optional Filter	<p>Use the additional filters to capture only desired aspects of the workload.</p> <p>Filters can include different aspects such as:</p> <ul style="list-style-type: none"> <li>• <i>Application Name</i> (for example, HDBStudio)</li> <li>• <i>Application User Name</i> is the name of the user logged in to the application.</li> <li>• <i>Database User Name</i> is the name of the database user (for example, SYSTEM).</li> <li>• <i>Client</i> is the ABAP client number (for example, 000).</li> </ul>

Replaying Configuration Settings \[page 458\]](#)

### 6.7.1.2.1.4.1.2 Monitoring a Captured Workload

You can monitor a captured workload.

To view monitoring information such as duration, the number of captured statements, or disk space, open the *Capture Monitor* by choosing the started capture from the *Capture Management* page. If you defined any filters, these can also be viewed in the *Capture Information* section.

If you didn't create a backup when starting the capture, you can also start a backup from the *Capture Monitor* page. If you do so, you can check any details about the backup by clicking the drop-down arrow next to *Capture Monitor* and opening the previously started backup from the *Related Apps* section.

Back on the *Capture Management* page, you can see the capture's name, status, duration, number of statements, size, or usage. You can filter captured workloads by the start time.

You can use the captured workload file for replay or analyzing. From the *Capture Management* page, you can open the workload analyzer. It is mandatory to load the captured workload before opening it with the workload analyzer. You can do this in two ways:

- You can load the captured workload by clicking *Start* in the *Workload Analysis* column. Then choose the captured workload to open the *Workload Analysis* page.
- Alternatively, you can choose a captured workload which was not loaded before. Load it after opening the *Workload Analysis* page using the *Load* button on the top right.

For more information, see *Analyze Workloads Based on Captured Workloads*.

You can monitor the captured workload in the M\_WORKLOAD\_CAPTURE system view. For more information, see *M\_WORKLOAD\_CAPTURES System View* in the *SAP HANA SQL Reference Guide* guide.

## Related Information

[Analyze Workloads Based on Captured Workloads \[page 473\]](#)

[M\\_WORKLOAD\\_CAPTURES System View](#)

### 6.71.2.1.5 Replaying a Workload

You can replay the preprocessed workload based on the SQL statement timestamp or on the transactional order.

Replaying a workload implies that the captured statements are executed again.

#### → Recommendation

Manually copy the captured workload files from the source system to the control system and the database backup from the source system to target system.

You can replay all captured workloads as often as necessary.

#### → Recommendation

When running consecutive replays, restore the target system back to a consistent state after a replay and before running another replay. This is necessary because after replaying a workload on a system, any changes applied during that replay will remain active in the system.

#### ❖ Example

Let's assume the captured workload file includes the statement `<INSERT INTO TABLE A VALUES (x) .` During a replay, value `x` will be inserted into table A. At the end of the replay, table A contains value `x`. If you run another replay without resetting the system to its initial state, table A will contain duplicate values `x, x` at the end of the replay or the statement will fail (for example, in the case of unique constraint errors). As `x, x` does not reflect the intended end result of the replay, it is recommended to restore the system after every replay when running multiple replays of the same captured workload.

The following two steps are necessary before replaying the captured workload:

1. Preprocess a captured workload  
The preprocessing step is required to optimize the captured workload file before replaying it. For more information, see *Preprocess a Captured Workload*.
2. Start the replayer  
The replay process is performed by the replayer, which should be running before starting the replay. The replayer is a service on operating system level that reads SQL commands from the preprocessed workload file and executes them one-by-one in timestamp-based order. For more information, see *Start and Stop the Replayer*.

You can preprocess a captured workload and replay the preprocessed workload using the [Replay Workload](#) card.

After replaying the preprocessed workload, you can generate replay reports. If you want to see the SQL statement parameters in the replay report, load the `.cpt` file after opening the workload analyzer.

## Related Information

- [Preprocess a Captured Workload \[page 454\]](#)

- [M\\_WORKLOAD\\_REPLAY\\_PREPROCESSES System View](#)

### 6.7.1.2.1.5.1 Preprocess a Captured Workload

The preprocessing step is necessary to optimize the captured workload file before replaying it.

#### Prerequisites

- You have the Control Replay Admin user for the control system.
- You have captured workloads using the *Capture Workload* card. For more information, see *Capture a Workload*.
- Copy the captured workload file from the source system to the target system in the trace directory. If you use a control system that is different from the target system, copy the captured workload file to the control system.  
You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### → Recommendation

Perform the pre-processing step in a separate system, not in the source system.

#### Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, choose the *Replay Workload* card.

The *Replay Management* page opens displaying an overview of the captured workload located on the current system in the *Replay Candidate* tab.

2. Choose *Start* in the *Preprocess Status* column to start preprocessing the captured workload. If the status is not available, open the *Details* link to understand why.

## Related Information

[Capture a Workload \[page 449\]](#)

[System Privileges \[page 445\]](#)

### 6.7.1.2.1.5.2 Start and Stop the Replayer

The replayer is a service on operating system level that should be running before starting the replay.

## Prerequisites

- You have a user with the WORKLOAD REPLAY ADMIN system privilege to control the replayer. Store the logon credentials in the secure store. For more information, see *Secure User Store (hdbuserstore)* in the *SAP HANA Security Guide*.
- When using multiple replayers distribute and divide all involved components (for example, target instance, control instance, one or more replayers) on different hosts and systems.

### i Note

The replayer is not a part of the SAP HANA database services that are running as daemon process. You must start and stop it yourself.

## Procedure

1. Configure a hdbuserstore entry to authenticate the replayer with the database using the following command on the operating system on which your SAP HANA database is installed:  

```
hdbuserstore SET <key name> <host name@tenant database name> <user name>  
<password>
```
2. Start the replayer using the following command on the Linux command line of the system that you want to start the replayer on:  

```
hdbwltreplayer -controlhost <controlHost> (-controlport <controlPort> | -  
controlinstnum <controlInstanceNumber> [-controldbname <controlDatabaseName>]) -  
controladminkey <userName,secureStoreKey> -port <listenPortNumber>
```

## i Note

Running the command on the target system does not trigger the replay, it only starts the replayer.

The `controlhost`, `controlinstnum`, `controladminkey`, and `controldbname` parameters indicate the location of the control system.

Parameter Description

Parameter	Description
<code>controlhost</code>	Specifies the database host name of the control or target system (without a <code>sqlport</code> ).
<code>controlinstnum</code>	Specifies the database instance number.
<code>controladminkey</code>	Specifies the user name and secure store key of the control management connection separated by a comma.
<code>controldbname</code>	Specifies the database name. When connected to a tenant, the tenant name should be used. When connected to a system database, the system database should be used as control database name.
<code>port</code>	Specifies the discretionary port number for internal communication. You can use every port which is currently free. This port is used as long as the replayer is running.
	<b>i Note</b> Do not to use any default ports or ports used by other processes (for example, 22 or 8080).
<code>controlport</code>	Specifies the control instance.

To start multiple instances of the replayer in parallel, define a specific port for each instance. The setup of the second instance fails when two instances run on the same port.

When running replays with a longer duration, you can add `&` at the end of the command line. This starts the process in the background and you can close the terminal connection immediately.

## ❁ Example

```
hdbwltreplayer -controlhost <controlHost> (-controlport <controlPort> | -controlinstnum <controlInstanceNumber> [-controldbname <controlDatabaseName>]) -controladminkey <userName,secureStoreKey> -port <listenPortNumber> &
```

## i Note

If you want to use SSL encryption with the replayer, navigate to the `wltreplayer.ini` file on the OS and edit or add the section `[replay_client]` as follows:

- Add the parameter `enable_target_ssl_connection = [true|false]` to enable SSL connections between the target system and the replayer

- Add the parameter `enable_control_ssl_connection = [true|false]` to enable SSL connections between the control system and the replayer

Only fully qualified domain names can be used for `<controlHost>` when starting the replayer.

3. If the console is still open, use Ctrl+C to stop the replayer. Alternatively, identify the OS process ID of the running replayer and shut it down using `kill<pid>`.

## Related Information

[Secure User Store \(hdbuserstore\)](#)

[SAP Note 2362820](#)

### 6.7.1.2.1.5.3 Replay a Preprocessed Workload

You can replay all preprocessed workloads as often as necessary.

## Prerequisites

- You have the privileges of a Target Replay Admin user. See *System Privileges* in the *SAP HANA Administration Guide for SAP HANA Platform*.
- The target system meets the same security and privacy prerequisites as the source system. Since the target system processes the same data as the source system, it should meet an appropriate security level depending on how critical your data is.

#### → Recommendation

Do not allow unnecessary network connections to the target system. Users registered on the source system could access the target system after the replay is completed.

- You have preprocessed the captured workloads using the [Replay Workload](#) card. For more information, see [Preprocess a Captured Workload](#).
- The replayer is running. For more information, see [Start and Stop the Replayer](#).

You've navigated to the [Database Overview](#) page of the database you want to manage. See [Getting to the Database Overview Page](#) in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the *Administration* or *All* view selected, click the [Replay Workload](#) card or click the [Start New Replay](#) link on the card.

The *Replay Management* page opens displaying the captured workload.

2. To change the preprocess destination, choose *Configure Replay* on the bottom right.

After the preprocessing is completed, the preprocessed workload file is stored by default in the `$SAP_RETRIEVAL_PATH/trace` directory. Since the default trace directory generally resides in the same storage area with data and log volumes, preprocessing workloads may affect the performance across the entire system. If you enter a different destination, you may have a better distribution of the disk I/O between the data and log volumes, and the preprocessed files.

3. Choose a preprocessed workload with the status *Preprocessed* to start configuring it for the replay.

The *Replay Configuration* page opens allowing you to configure various mandatory and optional settings. For more information about each setting, see *Replay Configuration Settings*.

#### **i** Note

If a database backup is available, restore the database before starting the replay in the target system. For more information, see *SAP HANA Backup and Recovery*. When running a replay on a target system that has been restored using a backup taken automatically during the capture process, activate the *Synchronize Replay with Backup*.

If no or only outdated database backups are available, you can still restore the database or manually export parts of the data before starting the replay in the target system. When running a replay on a target system that was restored using old backups or contains only smaller manual exports of data, deactivate the *Synchronize Replay with Backup* option.

4. After configuring the replay, choose *Review* to view the replay configuration.
5. To start the replay, choose *Confirm*.

The *Replay Management* opens displaying the workloads that are being replayed in the *Replay List* tab.

## Related Information

[Analyzing Replay Reports \[page 464\]](#)

[System Privileges](#)

### 6.7.1.2.1.5.3.1 Replaying Configuration Settings

The *Replay Configuration* allows you to configure several settings.

The *General Information* page allows you to customize the following mandatory and optional settings:

#### General Replay Information

---

**Setting      Replay Name**

---

Type      Mandatory

---

Description      Enter a name for the replay. By default this field has the same name as the initial captured file.

---

---

**Setting      Description**

---

Type      Optional

---

Description      Enter a description for the replay for your future reference. This information can be used when changing settings for different replays.

---

### Target System Information

---

**Setting      Host**

---

Type      Mandatory

---

Description      Select a host name from the list.

The information for the identifier, instance number, port number, and container will be filled automatically.

---

---

**Setting      Identifier, Instance Number, Port Number**

---

Type      Mandatory

---

Description      These fields are automatically filled when selecting the host.

---

---

**Setting      Container**

---

Type      Mandatory

---

Description      This field is automatically filled when selecting the host.

---

### Target Instance Options

---

**Setting      Synchronize Replay with Backup**

---

Type      Optional

---

---

**Setting      Synchronize Replay with Backup**

---

**Description**      This option allows you to synchronize the replay with an existing database backup. It compares the log position ID of each transaction with the restart log ID of the backup used for recovery of the target system

The option is turned on by default allowing the replayer to compare each statement with the database backup. This option makes it possible to check if there are no duplicate inserts and if the backup and replay are aligned. A backup is required for this option to work correctly. If it's tuned on without a recovery or with a wrong recovery, transactions might be rolled back.

If the option is turned off, the replayer will replay statements even if no backup is present. If turned off and no recovery from the backup created during capture has been made, it's possible that transactions are missed during replay. If turned off, but recovery from the backup created during capture has been made, it's possible that unexpected results can occur during replay.

---

**Setting      Collect Explain Plan**

---

**Type**              Optional

**Description**      Collect the output of the EXPLAIN PLAN command for captured statements. You can use this information for comparison after the replay.

---

**Setting      Transactional Replay**

---

**Type**              Optional

**Description**      This option enables guaranteed transactional consistency during a replay.

**i Note**

Enabling this option may cause overhead to query runtime as transactional consistency needs to be checked constantly.

---

**Optional Filter****Setting      Optional Filter**

---

**Type**              Optional

**Description**      Use the *Optional Filter* to selectively replay only desired aspects of workloads.

Filters can include different aspects such as *Application Name*, *Application User Name*, *Database User Name*, *Client*.

---

The *Replay Information* page allows you to customize the following mandatory settings:

**Setting      Replayer Authentication**

---

**Type**              Mandatory

---

---

**Setting    Replayer Authentication**

---

Description    Enter the database user who has the WORKLOAD REPLAY ADMIN privilege and will be used for the final preparation steps in the target instance.

                    Select the authentication method and enter the credentials.

---

**Setting    Replayer List**

---

Type            Mandatory

---

Description    Check the running [Replayer](#) that will be used to connect to the target system and facilitate the replay.

---

**Setting    User Authentication**

---

Type            Mandatory

---

Description    Enter the SYSTEM user and the technical user.

For a realistic replay, all users that are part of the workload, which has been chosen to be replayed, must be authenticated. For more information, see *Secure User Store (hdbuserstore)* in the *SAP HANA Security Guide*.

To conduct a stable replay, reset the passwords of the database users. To reset the password for the database users captured in the source system you have the following options:

- You can reset the passwords at once for all users not authenticated by external tools or created during the replay. As a result, these users will receive new passwords and get authenticated for the replay. Choose [Reset Password](#) to reset all passwords for all users except for the SYSTEM user and the technical user. This can be helpful when you don't know the actual password of each user. On the [Reset Password](#) window enable the confirmation box and choose [Confirm](#). All selected user passwords in the defined target system will be changed as defined in this step.
  - You can authenticate users manually using the secure user store keys. The [User List](#) provides details on the authentication method for each user.
- 

## Related Information

[Secure User Store \(hdbuserstore\)](#)

### 6.7.1.2.1.5.3.2 Monitoring a Replayed Workload

You can monitor a replayed workload.

The [Replay Management](#) shows the workloads that are being replayed in the [Replay List](#) tab. You can start multiple replays in parallel. For more information on each replay, open the [Details](#) link in the message field.

To stop a replay when it is in progress, choose [Stop](#) in the [Replay Status](#) column. The status of the replay changes then to [Stopped](#).

Import replay reports using the [Import Replay](#) button on the [Replay List](#) tab. For information on the security implications and configuration steps needed for importing replay reports, see [SAP Note 2109565](#).

To access the [Replay Monitor](#), choose the running replay. The monitoring view provides information such as duration, number of statements, size, and other details about the replay in progress. You can navigate away from the monitoring view using the arrow on the top right and can return anytime.

If you have already replayed preprocessed workloads, you can generate comparison reports for further analysis. For more information, see [Generating Replay Reports](#).

You can monitor the preprocessed workload in the `M_WORKLOAD_REPLAY_PREPROCESSES` system view and the replayed workload in the `M_WORKLOAD_REPLAYS` system view. For more information, see [M\\_WORKLOAD\\_REPLAY\\_PREPROCESSES System View](#) and [M\\_WORKLOAD\\_REPLAYS System View](#) in the [SAP HANA SQL Reference Guide](#).

## Related Information

[M\\_WORKLOAD\\_REPLAYS System View](#)

[M\\_WORKLOAD\\_REPLAY\\_PREPROCESSES System View](#)

[SAP Note 2109565](#) 

### 6.7.1.2.1.5.3.3 Generating Replay Reports

You can generate replay reports after successfully replaying a captured workload.

On the [Replay Management](#) page you can generate replay reports displaying:

- **Capture-Replay Comparison**  
You can open a capture-replay comparison choosing a replay from the [Replay List](#). When opening a comparison report directly from the [Replay List](#), the report shown always compares values from the original captured workload with values from the replay.
- **Replay-Replay Comparison**  
When using the [Compare Replays](#) button on the bottom right, the report shown always compares different replays with each other based on the same initial captured workload.

## 6.7.1.2.1.5.3.3.1 Generate a Replay-Replay Comparison Report

You can compare two or more replayed workloads with each other based on the same initial captured workload.

### Prerequisites

- You have a user with the WORKLOAD REPLAY ADMIN, CATALOG READ, and WORKLOAD ANALYZE ADMIN system privileges.
- You have replayed preprocessed workloads using the [Replay Workload](#) card. For more information, see [Replay a Preprocessed Workload](#).

You've navigated to the [Database Overview](#) page of the database you want to manage. See [Getting to the Database Overview Page](#) in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

You can start the comparison of the replayed workloads from the [Replay List](#) in the [Replay Management](#) page.

### Procedure

1. On the [Database Overview](#), with the [Administration](#) or [All](#) view selected, click the [Replay Workload](#) card.
2. Click the [Replay List](#) tab and then click [Compare Replays](#) on the bottom right.

The [Select Baseline Replay](#) dialog opens allowing you to select the replayed workload that you want to compare. Use the [Target SID](#) information to distinguish between the replays.

3. Select one entry from the displayed list and click [Close](#).

The [Select Target Replay](#) dialog opens allowing you to select the replayed workload that you want to compare with the previously selected workload. The list displays replayed workloads based on the same initial captured workload.

4. Select one or more entries from the displayed list and click [Compare Replays](#) on the bottom right.

The [Replay Report](#) opens displaying a comparison of the selected replayed workloads.

### Related Information

[System Privileges \[page 445\]](#)

[Replay a Preprocessed Workload \[page 457\]](#)

[Analyzing Replay Reports \[page 464\]](#)

## 6.7.1.2.1.5.3.4 Set a Breakpoint

When you identify a problem in the replay report, you can set a breakpoint to pause the replay exactly where the identified problem occurred.

### Prerequisites

### Context

You can start the replay a second time after setting breakpoints. When starting the replay again, this would allow you to look for example at system views before that statement is executed, or to look at the trace file.

You can set a breakpoint from the performance comparison or results comparison tabs on the [Replay Report](#) page.

### Procedure

1. Open the [Execution Details](#) by choosing a statement from the SQL statements list.
2. Choose [Set Breakpoints](#) on the top right.
3. Choose [Save](#) on the top right.
4. Go back to the [Replay Management](#) page to configure and start the replay again.
5. After starting the replay, open the [Replay Monitor](#) to view the breakpoints and a list of all statements.

On the bottom right you can use the [Resume Replay](#) button to execute the paused statement and continue to the next breakpoint. Or you can use the [Execute and Pause](#) button to execute the paused statement and then pause again.

## 6.7.1.2.1.5.3.5 Analyzing Replay Reports

You can use comparison reports to analyze the completed replay.

The information is displayed on four tabs:

- Overview
- Load
- Performance Comparison
- Result Comparison

On the performance and result comparison tabs you can perform the following actions:

- Download detailed information in JSON format by choosing the download button at the top of the statement detail table.  
In the *Download SQL Statements* dialog, you can select the category of statements as well as the number of statements. For the performance comparison, these categories are *All*, *Comparable*, *Faster*, *Slower*, *Replay Failed*. For the result comparison, these categories are *All*, *Identical*, *Verification Skipped*, *Replay Failed*.
- Export replay reports to store them outside the database using the *Export Replay* button.

On the performance and result comparison tabs you can open the execution details for a specific statement by selecting the statement from the list. You can use the detailed execution level of both report types to compare the EXPLAIN PLAN results between the initial captured and replayed workloads, or between the baseline and target workloads. Comparing the plans can provide guidance for further statement-level investigation. This is only possible if the *Collect Explain Plan* setting was activated for both the capture and the replay during the configuration steps. For more information about this setting, see *Capture Configuration Settings* and *Replay Configuration Settings*.

## Related Information

[Replaying Configuration Settings \[page 458\]](#)

[Capturing Configuration Settings \[page 450\]](#)

### 6.7.1.2.1.5.3.5.1 Overview

The *Overview* tab displays an overall comparison of the SQL statements involved in the capturing and replaying process.

#### i Note

When you turn off the *Transactional Replay* option on the *Replay Configuration* page, the result comparison does not include guaranteed transactional correctness. When running replays with this option turned on, the performance comparison can include a runtime overhead due to the transactional consistency.

Overview Information

Block Name	Description
Result Comparison	In a result-based comparison you get an overview of the statements with identical or different results. Click the block to open directly the <i>Result Comparison</i> tab.
Performance Comparison	In a performance-based comparison you get an overview of the statements based on a comparison of run-times.  You can change the tolerance ratio selecting a value from the drop-down list or entering a new value.  Click the block to open directly the <i>Performance Comparison</i> tab.

Block Name	Description
Different Statements	Displays the top SQL statements that have different results from the selected baseline in descending order. You can click each row to open the <a href="#">Execution Detail</a> page for the selected SQL statement. Use the drop-down arrow to filter the statements by time or by the number of records that have different results.
Slower Statements	Displays the top SQL statements that have a different performance ordered by the difference in execution time. Use the drop-down arrow to filter the statements by elapsed time, CPU time, or by execution time. You can click each row to open the <a href="#">Execution Detail</a> page for the selected SQL statement. To view KPI details for each statement, you can click the icon on the right at the end of the row.
Verification Skipped	Displays the distribution of reasons for statements with skipped result comparison.
Replay Failed	Displays the distribution of reasons for the statements, which failed during replay. Use the drop down arrow to filter the statements by time or error code.
Capture Information	Displays information on the capture system, capture options, and the properties of the capture file.
Replay Information	Displays information on the replay system and the replay options. If the comparison was made between two replays, the information is displayed in a <a href="#">Baseline Replay Information</a> block and in a <a href="#">Target Replay Information</a> block.

## Related Information

[Replay a Preprocessed Workload \[page 457\]](#)

### 6.71.2.15.3.5.2 Load

The load chart compares both the capture and the replay based on selected KPIs.

This tab includes load charts comparing both the captured and the replayed workloads after a capture-replay comparison, or the baseline and the target workloads after a replay-replay comparison. The capture values are represented by a solid line, the replay values are represented by a dotted line.

The KPIs can be toggled independently for both the capture and replay aspects making it easier to compare them with each other. Additional KPIs can be added using the [Show More KPIs](#) button on top right of the load chart.

## 6.71.2.15.3.5.3 Performance Comparison

The performance-based comparison provides an overview of statements compared by runtime.

Based on the selected tolerance ratio, the statements are classified as *Comparable* when they have a similar runtime within the defined tolerance ratio, *Faster*, *Slower*, or *Failed*.

You can sort the displayed statements by clicking directly the column header. You can sort them in ascending or descending order or you can filter the list. You can use the fields and buttons on top to:

- Search for a specific statement
- Change the tolerance ratio
- Display more statements
- Restore to default
- Refresh the displayed data
- Download detailed information in JSON format
- Change the sorting criteria
- Change filters
- Group
- Add more columns for analysis

To view a summary of how the execution time was spent, select the statistics symbol at the end of each statement line.

To open the execution details for a specific statement, select the statement from the list. On the *Execution Details* page, you can:

- Create a list of further statements, by choosing *Show More Statements* on the top right
- Search the list of individual executions
- View any parameters that might have been part of the query. To display the parameters, the associated captured workload file must be loaded in the workload analyzer.
- View the runtime *KPIs* for that execution
- Display the explain plan comparison for that statement

For failed executions you can see why the statement execution failed and what reasons can be investigated further by manual statement-level analysis.

## 6.71.2.15.3.5.4 Result Comparison

The result-based comparison provides an overview of statements with, for example, identical or different results.

The result-based replay report also includes a classification of statement types based on the content of those statements being either deterministic or non-deterministic. Deterministic statements should always deliver the same results during a replay. Non-deterministic statements are expected to deliver different results (for example, because they don't contain an explicit sorting of results).

Statements are classified as:

- Identical if their result sets have the same row count and the same result hash

- Different if any of these criteria differ between capture and replay
- Skipped if they are related to system calls, monitoring view accesses or other internal actions, which don't require a result-based check
- Failed if they returned an error code

You can sort the displayed statements by clicking directly the column header. You can sort them in ascending or descending order or you can filter the list. You can use the fields and buttons on top to:

- Search for a specific statement
- Display more statements
- Restore to default
- Refresh the displayed data
- Download detailed information in JSON format
- Change the sorting criteria
- Change filters
- Group
- Add more columns for analysis

To open the execution details for a specific statement, select the statement from the list.

On the *Execution Details* page, you can search the list of individual executions, bring up a list of other statements to choose from with the *Show More Statements* button, view runtime KPIs for that execution as well as the result-based values, view any parameters that might have been part of the query, or display an explain plan comparison for that statement.

For skipped executions you can see why the verification of an execution was skipped.

For executions with different results you can see why the results are classified as being different. This classification is based on the result set's row count and result hash.

For failed executions you can see why the statement execution failed and what reasons can be investigated further by manual statement-level analysis such as the performance comparison tab.

## 6.7.1.2.2 Analyzing Workloads

Analyzing workloads from an SAP HANA database with the workload analyzer can help you identify the root cause of performance issues.

The following sections provide an overview of the workload analyzer tool:

### What is the workload analyzer tool?

The workload analyzer is a tool that allows you to analyze the workload captured with the capture and replay tool, or any other workload occurring in a system.

The workload analyzer has two versions:

- The workload analyzer based on thread samples  
This version uses thread samples data to analyze the performance.

- The workload analyzer based on captured workloads  
This version of the tool performs the analysis using the captured workloads containing all the statistics of the query execution. Furthermore, it allows a deeper analysis with a full set of execution details.  
For more information on how to capture the workload of a system with the capture and replay tool, see *Capture a Workload*.

## What is the workload analyzer based on captured workloads?

The workload analyzer based on captured workloads is a solution for analyzing database performances based on the workload captured with the capture and replay tool.

The workload analyzer based on engine instrumentation offers you two analysis types:

- On the upper part of the screen, the chart displays the system resource usage.
- On the lower part of the screen, three sections are displayed with further analysis:
  - *Capture Information*  
This section offers a detailed overview of the information on the captured workload, such as a summary, capture overview, filter options, database, and more. Selecting the section description will allow you to jump to the information you are interested in.
  - *SQL Statements*  
In this section, the graph displays the top SQL statements of the captured workload, and allows you to select the dimension you are interested in for graphical representation.
  - *Timeline*  
This section offers a timeline analysis based on an application and statement level hierarchy enables you to evaluate anomalies in the timeline and identify potentially problematic statements.
  - *Threads*  
In this section the main stacked area chart displays a more detailed visualization of the chart on the upper part of the screen based on a selected dimension (for example, thread type) over a given period of time. The bar charts located at the bottom next to it display the top five statements consuming most of the threads during the given timeframe. Clicking a specific statement hash opens a dialog with detailed statement information and an option to analyze it further with the SQL analyzer tool.

In contrast to the workload analyzer based on thread samples, using this tool requires to capture and load the workload before analyzing the performance. Capturing all the workload by default is not recommended because it introduces an overhead to system performance.

For more information on how to use the workload analyzer based on engine instrumentation, see *Analyze Workloads Based on Engine Instrumentation*.

## What is the workload analyzer based on thread samples?

The workload analyzer based on thread samples is a solution for analyzing database performance using thread samples.

The workload analyzer based on thread samples provides a workload analysis using different KPIs, and it offers the following information sets:

- On the upper part of the screen, the chart displays the system resource usage. The chart displays both a real-time and a historical analysis. The information displayed on the grey background represents the historical analysis of the workload. Both analysis types are based on the sampling data. However, the historical analysis contains only aggregated data.
- On the lower part of the screen, the main analysis page offers the following four sections:
  - [SQL Statements](#)  
This section displays the analysis chart displaying the number of threads by lock wait time, and below, statement information and SQL statement. The option to navigate to the SQL analyzer tool for further investigation is provided by clicking on an entry on the chart.
  - [Background Jobs](#)  
This section displays in the main chart information on the job progress. The miniature chart shows the system load data within the time range specified in the upper load chart, and the table below displays information on the delta merge.
  - [Timeline](#)  
This section displays a timeline chart of the workloads, and a statements table containing thread-level information below. Clicking a block on the table will highlight the corresponding statement entry in the table.
  - [Threads](#)  
In this section the main stacked area chart displays a more detailed visualization of the chart on the upper part of the screen based on a selected dimension (for example, thread type) over a given period of time. The bar charts located at the bottom next to it display the top five statements consuming most of the threads during the given timeframe. Clicking a specific statement hash opens a dialog with detailed statement information and an option to analyze it further with the SQL analyzer tool.

For more information on how to use the workload analyzer based on thread samples, see *Analyze Workloads Based on Thread Samples*.

## Why should you use the workload analyzer tool?

The workload analyzer gives you an overview of the system's health at a glance. Moreover, the tool helps you identify the root cause of performance issues either by a real-time analysis or by reviewing historical data.

## How to access the workload analyzer tool?

You can access both versions of the workload analyzer from the SAP HANA cockpit as follows:

- To access the workload analyzer based on thread samples, use one of the following:
  - From the [Database Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click [Analyze Workloads](#) on the [CPU Usage](#), [Disk Usage](#), or [Memory Usage](#) cards.  
or
  - From the [Database Overview](#) page, with the [All](#) view selected, click [Monitor Performance](#) on the [CPU Usage](#), [Disk Usage](#), or [Memory Usage](#) cards. From the [Performance Monitor](#) page, click the [⌵ \(Navigation menu\)](#) icon and choose [Workload Analysis](#).

- or
- From the *Database Overview* page, with the *Monitoring* or *All* view selected, click *Analyze Memory History* on the *Memory Usage* cards.
  - On the *Memory Analysis* page, click the *Navigation menu* icon and choose *Workload Analysis*.
- To access the workload analyzer based on captured workloads, use one of the following:

#### i Note

Only workloads with the status *Loaded* can be analyzed. If the desired workload is *Not Loaded*, select *Start* next to the status to load the captured workload before proceeding.

- On the *Workload Analysis* page, click *Capture*.
- or
- From the *Database Overview* page, with the or *All* view selected, click the *Capture Workloads* card. The *Capture Management* page opens displaying a list of captured workloads.
- Click on a *Workload Analysis* status of the workload you wish to analyze. The *Capture Report* page opens where you can select to *Analyze Workload*.
- Open the workload analyzer based on thread samples. The chart on system resource usage on the top of the page displays areas highlighted in green when a workload has been captured. Drag across the highlighted area.

#### i Note

If a workload has not been loaded yet, you need to click on icon in the highlighted area and select *Load Capture*. The *Capture Report* page opens, allowing you to *Load Workload* on the top of the page.

## Related Information

[Capture a Workload \[page 449\]](#)

[Analyze Workloads Based on Thread Samples \[page 471\]](#)

[Analyze Workloads Based on Captured Workloads \[page 473\]](#)

[The Performance Monitor \[page 424\]](#)

[Memory Analysis \[page 353\]](#)

### 6.7.1.2.2.1 Analyze Workloads Based on Thread Samples

You can analyze database performance using the workload analyzer based on thread samples.

## Prerequisites

You have the system privileges `CATALOG READ` and `INIFILE ADMIN`.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. Open the [Workload Analysis](#) page. See *Analyzing Workloads*.

The workload analyzer opens displaying a chart on system database usage on the upper part of the screen and a more detailed visualization distributed in four sections:

View descriptions

View	Description
Top SQL Statements	A graphical representation of number of threads by lock wait time, and statement information and SQL statement.
Background Jobs	A chart displaying information on the jobs running in the background, and a delta merge table.
Timeline	A graph displaying the workloads by application name and statement hash, and a list of statements in a table.
Threads	Two graphs with customizable dimensions.

2. Analyze the displayed charts using the following features:
  - a. On the top part of the screen, set the observed time range by selecting from presets or entering a custom time range, or by using the navigation buttons.
  - b. In the settings menu, select desired KPIs. The selected KPIs appear in the legend area on the left-side of the chart. For a list of all available KPIs, see *Key Performance Indicators*.
  - c. Customize your chart by applying a number of filtering options to only analyze the workloads you are interested in.
  - d. Import and export datasets in order to store the data in an application and to analyze it in another system.
  - e. Click the  (*Navigate to other apps*) icon and choose *Performance Monitor* to monitor and analyze the performance of the SAP HANA database over time..
  - f. Navigate to the [Current Table Distribution](#) page to see how tables are distributed across the hosts using one of the following:
    - In the *Top SQL Statements* view, left-click or Ctrl+left-click one or more statements from a chart or table. In the dialog window, choose *Open in Current Table Distribution*.
    - In the *Timeline* view, left-click or Ctrl+left-click one or more statements from the chart. In the dialog window, choose *Open in Current Table Distribution*.
    - In the *Timeline* view, in the Threads table, click the  icon in the *Accessed Tables* column for a statement. In the dialog, choose *Open in Current Table Distribution*.
    - In the *Threads* view, left-click or Ctrl+left-click one or more bars from the secondary dimension chart. In the dialog, choose *Open in Current Table Distribution*.

- g. On the lower part of the screen in the *Top SQL Statements* view, select a SQL statement on the graph to see the statement hash, wait time, and number of waiting threads. Optional: To navigate to the *SQL Analyzer* page, click *Open in SQL Analyzer* to analyze query execution performance.
- h. On the lower part of the screen in the *Background Jobs* view, edit the granularity of the chart, and customize the delta merge table by setting the sorting order and defining the displayed columns.
- i. Customize the timeline chart in the *Timeline* view by adding new dimensions. Click *Edit* and select dimensions to add or remove from the chart.
- j. In the *Threads* view, see the workload analysis information you desire in the graphs by selecting from the primary and secondary dimensions on the left of each graph.

## 6.7.1.2.2 Analyze Workloads Based on Captured Workloads

You can analyze database performance using the workload analyzer based on captured workloads.

### Prerequisites

You have the `WORKLOAD ANALYZE ADMIN` system privilege.

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

In order to analyze the captured workload, the file has to be loaded into the database.

### Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, click the *Capture Workload* card.

The *Capture Management* page opens, displaying captured workloads that can be analyzed with the workload analyzer based on captured workload.

### i Note

Only workloads with the status *Loaded* can be analyzed. If the desired workload is *Not Loaded*, select *Start* next to the status to load the captured workload before proceeding. Please note that there is a 4 second delay in the initiation of the capturing process.

2. Click on the status of a loaded workload.

The *Workload Analysis* page opens.

It displays a load chart overview of the workload on the top of the screen and the following information sections below:

Sections

Description
A summary of informative data on the captured workload.
A graphic representation of number of threads by lock wait time, and statement information and SQL statement.
A graph displaying the workloads by application name and statement hash, and a list of statements in a table.
Two graphs with customizable dimensions.

### i Note

This view is only available if the workload was captured in the same system.

3. Analyze the captured workload using the following features:
  - a. Select the time range for the workload analysis by clicking on the date displayed on the top of the screen and selecting from a predefined set of time ranges or entering a custom range.
  - b. Navigate back to the *Capture Management* page by clicking Captures.
  - c. Customize the information displayed on the load graph on the upper part of the screen by selecting the host and services, filtering the results, or selecting the desired KPIs. The selected KPIs appear in the legend area on the left-side of the chart. For a list of all available KPIs, see *Key Performance Indicators*. Moreover, you can set specific filters (for example, statement hash, thread type, or application source) in order to analyze only the data you are interested in.
  - d. On the lower part of the screen in the *Top SQL Statements* view, select a workload on the graph to see the statement hash, wait time, and number of waiting threads. Navigate to the *SQL Analyzer* page by clicking *Open in SQL Analyzer* to analyze query execution performance.
  - e. Customize the timeline chart in the *Timeline* view by adding new dimensions. Click on *Edit* and select dimensions to add or remove from the chart.

## 6.7.1.2.3 Analyzing Statement Performance

Analyzing statement performance helps you understand performance issues of a query execution and other query execution aspects of the SAP HANA database.

The following sections provide an overview of the SQL analyzer tool:

### What is the SQL analyzer tool?

The SQL analyzer is a query performance analysis tool of SAP HANA. The tool can be used to view detailed information on each query execution and can help you evaluate potential bottlenecks and optimizations for these queries.

### How can you access the SQL analyzer?

You can open the SQL analyzer from the SAP HANA cockpit in one of the following ways:

- **Using the *SQL Statements* card**
  - From the *Database Overview* page, with the *Monitoring* or *All* view selected, click *View all* on the *SQL Statements* card.
  - Click the *Expensive Statements* tab.**
    - You can identify which SQL statements require a significant amount of time and resources. Each statement in the *Statement String* column has a *More* link, which opens the *Full SQL Statement* dialog.
    - Click *Open in SQL Analyzer* to open the selected query with the SQL analyzer tool.
    - Click *Open in SQL Analyzer* to open the selected query with the SQL analyzer tool.
  - Click the *SQL Plan Cache* tab.**
    - Click the *More* link to open the *Full SQL Statement* dialog.
    - Click *Open in SQL Analyzer*.
- **Using the *Manage SQL Performance* card**
  - From the *Database Overview* page, with the *Administration* or *All* view selected, on the *Manage SQL Performance* card click *Statement Hints*, *Plan Stability*, *Plan Trace*, or *Saved Plans*.
  - On each page, each statement string has a *More* link in the *Statement String* column, which opens the *Full SQL Statement* dialog.
  - Click *Open in SQL Analyzer* to open the selected query with the SQL analyzer tool.

Using the [Workload Analysis](#) (based on thread sampling) See [Analyzing Workloads Based on Thread Samples](#).

- Using [Database Explorer](#) On the [Database Overview](#) page, click [Open SQL Console](#). The SAP HANA database explorer opens.  
Click the [Analyze](#) button, and then click [Analyze SQL](#) to open the SQL analyzer.
- From the SAP Web IDE for SAP HANA you can open the SQL analyzer in a SQL Console by clicking [Analyze SQL](#) in the menu of the [Analyze](#) button.

## Which views are supported by the SQL analyzer?

The following views are supported by the SQL analyzer:

### SQL Analyzer Views

View	Description
Overview	This view provides an overview of the query execution including metadata for the analysis. It displays the following KPIs: <ul style="list-style-type: none"><li>• Time</li><li>• Dominant Operators</li><li>• Statistics</li><li>• SQL Performance Recommendations</li></ul> To get more information on the KPIs, see <a href="#">Key Performance Indicators</a> .
Plan Graph	This view provides graphical guidance to help you understand and analyze the execution plan of a SQL statement. In case of SQLScript, the SQLScript definition is also displayed.
SQL	This view displays the complete SQL string that is analyzed.
Operators	This view provides a list of operators used during query execution and includes additional details about each operator, which can be used for analysis.
Timeline	This view provides a complete overview of the execution plan based on the visualization of sequential time-stamps.
Tables in Use	This view provides a list of tables used during query execution and includes further details on tables, which can be used for further analysis. It can be used to understand which tables are needed to fulfill a given SQL statement execution.

View	Description
Table Accesses	This view provides details on the table accesses performed during the processing of a SQL statement, which can be used for analysis.
Compilation Summary	This view provides details on the query compilation process. It can be used to understand how much time was spent on which operation, which cost-based information was used, and what the plan properties are.
Recommendations	This view shows details on the provided recommendation allowing you to understand the reasoning for it.

### 6.7.1.2.3.1 Statement Performance

The SQL analyzer is used to analyze statement execution performance.

## Context

The *SQL Analyzer* can be opened from the SAP HANA cockpit or the SAP HANA database explorer. You can also open it from the SAP Web IDE for Full-Stack Development. For more information on how to open the SQL analyzer, see *How can you access the SQL analyzer?* in *Analyzing Statement Performance*.

## Procedure

1. Open the SQL analyzer.

The [SQL Analyzer](#) page opens, displaying the following views:

- Overview
- Plan Graph
- SQL
- Operators
- Tables in Use
- Table Accesses
- Compilation Summary
- Recommendations

2. Open the [Overview](#) tab to see important KPIs required to begin a performance analysis before going into the complex details.

KPI Description

KPI	Description
Statistics	<p>System version: The version of the system where the execution occurred</p> <p>Tables in use: Total number of tables touched by any operators during execution</p> <p>You can navigate to the <a href="#">Tables in Use</a> tab on the table below by clicking this line.</p> <p>Result Records: The final result record count</p> <p>Memory Allocated: Total memory allocated for executing the statement</p> <p>Distribution: Number of SAP HANA index servers that are related to the query execution</p> <p>The name of the host</p>
SQL Performance Recommendations	Recommendations on how you can improve the performance of SQL-related operations.

3. Open the [Plan Graph](#) tab to understand and analyze the execution plan of an SQL statement. It displays a visualization of a critical path based on inclusive execution time of operators and allows you to identify the most expensive path in a query execution plan.

In case of a SQLScript, the [Plan Graph](#) displays its complete definition. To retrieve the information in a text format, you can copy the definition by clicking the copy icon.

In the [Plan Graph](#) tab you can open the [Detail Properties](#) view by clicking one of the operators. This view offers detailed information on the operator such as name, location, ID, summary.

You can open the edge information detail by clicking one of the links between the operators. This view offers further information on the edge values, such as target, source, output cardinality, fetch call count, and estimated output cardinality.

Furthermore, you can configure plan graph settings. You can set the color of the nodes by type or location, and choose to show either physical or logical inner plans.

4. Open the [SQL](#) tab to get the complete view of the SQL statement string that is being analyzed.

5. Open the [Operators](#) tab to pinpoint specific operators of interest.

The view lists characteristics of all operators and supports:

- Display of various KPIs, for example physical (whether an operation is a real, physically executed one), offset, execution time, CPU time
  - Setting of filters along all the columns/KPIs
  - Display of the number of operators within the filtered set
  - Immediate aggregated information (max, min, sum, and so on) for the same KPIs on the filtered operator set
  - Detailed display of all operators within the filtered set
6. Open the [Tables in Use](#) tab for an overview of which tables have been used during the processing of a statement.

The view displays the following information:

- The name of the table
  - The host and port of the table's partition in the [Location](#) column
  - The partition number of the table's partition in the [Partition](#) column
  - The maximum possible amount of data processed for a given table during the execution of a statement, including the possibility of multiple accesses, in the [Max. Entries Processed](#) column
  - How often a table has been accessed during statement execution in the [Number of accesses](#) column
  - The maximum processing time across the possibly multiple table accesses in the [Maximum processing time](#) column
7. Open the [Table Accesses](#) tab to see the details on the table accesses performed during the processing of a statement.

The view displays the following information:

- The [Offset](#) time for accessing the table
- The name of the table
- The [Conditions](#) that affect the table accesses
- The [Processing Time](#)
- The amount of entries processed during an operation in the [Entries Processed](#) column
- The host and port of the table's partition in the [Location](#) column
- The operator's unique ID in a query execution result in the [Operator Id](#) column
- The name of the operator
- The detail information of an operator in the [Details](#) column
- The partition number of the table's partition in the [Partition](#) column

For cached plans, the table displays the following information: [Inclusive Estimated Cost](#), [Exclusive Estimated Cost](#), and the [Estimated Output Size](#).

Optional: To get aggregated information for each column, choose the aggregator functions in the drop-down menu under the column name. If an aggregator is chosen, you can see [More](#) information for your chosen query.

Optional: To refine results, click on [Filters](#) on the upper right corner. The [Filters](#) page appears, where you can choose the information type, operator, and enter values according to which you wish to filter the [Table Accesses](#). Choose [OK](#) to confirm. If you want to remove the filters you selected, go to the [Filters](#) page and choose to [Restore](#) to defaults.

Optional: To sort the results, click the sorting icon next to the [Filters](#) button and choose the sorting order.

Optional: To customize the columns displayed in the information list, click on the settings icon on the upper right corner and choose to hide or display the desired columns.

8. Open the [Compilation Summary](#) tab to view details on the query compilation process, including compilation time breakdown, cost-based optimization details, and plan properties.
9. Open the [Recommendations](#) tab to see the details for each provided recommendation. This allows you to easier understand the reasoning behind the recommendation for SQL query optimization.
10. Optional: Re-execute the SQL query by clicking the [Re-execute](#) button on the top right corner. If the query is parameterized, you can change the parameter values.

With a parameterized query, the [Input Parameters](#) appears, prompting you to enter your desired parameters in the [Parameter](#) tab. You can list the parameter values and separate them by a comma, or enter and edit them individually. Where applicable, you can check the [Empty value](#) box. The values you entered are reflected in the SQL string that you can see in the [SQL Statement](#) tab. Click on [Execute SQL](#) to analyze the SQL string according to the parameter values you entered and see the result on the [SQL Analyzer](#) page.

## Related Information

[Analyzing Statement Performance \[page 475\]](#)

### 6.7.1.2.3.2 Monitor and Analyze Statements with Plan Trace

Plan Trace is a trace feature for SQL analyzer.

## Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

Plan Trace enables you to collect SQL queries and their execution plans, executed in a given time frame. For each SQL query traced you can visualize the execution plan for performance analysis. Only 'SELECT' statements are traced with Plan Trace.

## Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, click *Plan Trace* on the *Manage SQL Performance* card.

The *Plan Trace* page opens, displaying a set of statistics for each SQL statement collected in a given time frame. To find the most expensive SQL statements use the displayed categories (for example, start and end time, schema, user, statement hash).

2. Click the *Configure Trace* button on the bottom right to configure the plan trace.

The *Configuration* dialog opens, allowing you to set options like maximum disk or memory usage.

3. Optional: Open the selected statement string with the SQL analyzer by clicking the *More* link in the *Full SQL Statement* dialog.

## 6.7.1.2.3.3 Manage Saved Plans

The SQL analyzer result page shows SQL plans saved from a previously executed query.

### Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

The saved plans feature allows you to revisit SQL statement queries that were executed with the SQL analyzer in a previous session without having to re-execute them in the current session.

## Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, click on the *Saved Plans* section on the *Manage SQL Performance* card.

The *SQL Analyzer result* page opens, displaying the *Saved Plans* table, containing the collected information on previously executed SQL queries. To find your desired SQL statements, use the displayed categories (for example, system version, statement string, plan type, user name, schema name, statement hash, and so on).

2. Optional: You can delete saved plans in two ways:
  - a. Mark the checkbox on the left of the listed statement, and select *Delete* on the top of the table.

The *Delete Plan* dialog opens, asking you if you want to delete both the plan and the corresponding PLV file, or just the plan.

- b. Select a statement and click on the trash bin icon next to the statement string.

The *Delete File* dialog opens, making sure if you want to delete the chosen PLV file.

#### **i Note**

This option does not get rid of the plan, just the PLV file. If you want to delete the plan as well, choose the former method.

3. Optional: You can search saved plans by entering a statement string keyword in the search field.
4. Optional: You can sort the order of the table and filter results by the desired parameter.
5. Optional: You can customize what columns are shown in the table in the settings menu.

[Statement Performance \[page 477\]](#)

### **6.7.1.3 Improving Performance in SAP HANA Cockpit**

You can improve the performance of the database using the SAP HANA cockpit.

You can use the following tools to analyze fine-grained aspects of system performance in the SAP HANA cockpit:

- Use the *Recommendations* card to get suggestions on how to improve and optimize your database.
- Use the *Data Cache* to monitor and manage different types of cached queries.
- *Manage plan stability* to restore performance speed from the previous to the current system.
- *Manage statement hints* to add statement hints to an SQL statement without modifying the actual statement in the application.

## **Related Information**

[Recommendations](#)

[Data Cache](#)

[SQL Plan Stability \[page 483\]](#)

[Statement Hints \[page 485\]](#)

## 6.7.1.3.1 SQL Plan Stability

SQL plan stability helps ensure the fast performance of queries by capturing query plans in a source system and reusing them in a target system to regenerate the original query plan.

In SAP HANA, the SQL query processor parses SQL statements and generates SQL query execution plans. As the query processor and the query optimizer continue to be developed (in, for example, the SAP HANA Execution Engine - HEX) the resultant execution plans for a given query may change from one SAP HANA revision to another. Although all developments are intended to improve performance of a query, it is possible it might not be equivalent after an upgrade.

In order to guarantee the performance of a query in new system upgrades, the plan stability feature offers the option to preserve a query's execution plan by capturing an abstraction of the plan and reusing it after the upgrade to regenerate the original plan and retain the original performance. In some cases, using statement hints may provide a solution to a loss of performance, see *Managing Statement Hints*.

Restrictions related to Plan Stability are documented in SAP Note 2639193: *SAP HANA SQL Plan Stability*.

### Related Information

[Manage SQL Plan Stability \[page 483\]](#)

[Statement Hints \[page 485\]](#)

[SQL Plan Stability](#)

[SAP Note 2639193](#)

### 6.7.1.3.1.1 Manage SQL Plan Stability

Use the *SQL Plan Stability* app to capture query plans in a source system and reuse them in a target system to regenerate the original query plan.

### Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, click on the *SQL Plan Stability* section of the *Manage SQL Performance* card.

The *SQL Plan Stability* page opens. If you have any captured abstract SQL plans from the source system, they are displayed in the table view.

2. To capture SQL query plans from the source system, turn the *Capture Abstract SQL Plans* on.

You are prompted to configure the capture options. Choose from registered filters or create your own, choose whether you want to include plans from the SQL Plan Cache, and select *Start Capture*.

The *Capture Status* appears on the top of the screen, displaying the progress of captured execution plans and plans from SQL Plan Cache.

Optional: Press the refresh button next to the *Capture Status* to see the captured plans in the table below.

After the process is turned off, the captured query plans are displayed in the *Captured Plans* table.

Optional: If you want to terminate the capture process prematurely, turn the *Capture Abstract SQL Plans* off.

3. Optional: See the full SQL statement string of a query by selecting *More* next to the visible statement string snippet in the table.
4. To apply the imported SQL query plans to the current system, turn the *Apply Abstract SQL Plans* on.

#### **i** Note

This will only apply to the SQL queries listed in the *Captured Plans* table.

Optional: Enable or disable the SQL query plans being applied to the current system by selecting them in the table and choosing *Enable* or *Disable* above the table. You can also *Select All ASP* query plans, or choose to *Delete* plans.

Optional: To see the progress of the query plan application, press the refresh button.

5. Optional: You can adjust the settings such as the maximum number of saved plans and maximum memory allocation in the *Configure Capture* dialog.
6. Optional: You can change the location details (host and port) of the server by selecting *Update Locations* from the *Advanced* options menu.

The *Update Locations* dialog opens where you can set the desired host and port.

7. A migration of abstract SQL plans is necessary after a system upgrade. If you are trying to use Plan Stability features with outdated data, you will be prompted to migrate the abstract SQL plans into the upgraded system. You can also do this actively by selecting *Migrate ASPs* from the *Advanced* options menu.

The *Migrate Abstract SQL Plans* dialog opens, prompting you to confirm your choice.

#### **i** Note

During the migration of abstract SQL plans to the upgraded system other Plan Stability functionalities are not available.

## 6.7.1.3.2 Statement Hints

Use [Statement Hints](#) to add statement hints to an SQL statement without modifying the actual statement in the application.

[Statement Hints](#) allow you to pair an SQL statement string with a string of hints to be used during execution. Whenever a particular SQL statement is then executed in SAP HANA, the assigned statement hints are automatically added to the statement for execution.

Open the [Statement Hints](#) page by clicking on the [Statement Hints](#) section of the [Manage SQL Performance](#) card.

## 6.7.1.3.3 Analyzing SQL and Saving Plans

This function of the SAP HANA cockpit allows you to save SQL plans, download them, and load a file from the SAP HANA database.

There are two ways in which you can record SQL plans for future reference with the SAP HANA cockpit:

- You can **save** them within the SAP HANA database filesystem, and
- **Download** the saved SQL plans as local PLV files on your personal computer.

Both of these options are available with this functionality.

Additionally, you can also **load** PLV files into the SQL Analyzer tool from the trace folder in the SAP HANA database.

### Related Information

[Save Plans as Files \[page 485\]](#)

[Load Files \[page 487\]](#)

[Download Files \[page 488\]](#)

### 6.7.1.3.3.1 Save Plans as Files

You can save SQL plans within the SAP HANA database.

### Prerequisites

- Since this functionality can be accessed from different performance management and monitoring tools within the SAP HANA cockpit, please check the privileges they might require respectively.

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

Saving SQL plans helps you record them as PLV files in the trace folder within the SAP HANA database.

You can save SQL plans from the following performance monitoring pages:

- Expensive Statements
- Plan Stability
- Statement Hints
- SQL Analyzer

## Procedure

1. On the [Database Overview](#) page, select the desired page.

Database Overview View	Card	Select
<a href="#">Administration or All</a>	<a href="#">Manage SQL Performance</a>	<ul style="list-style-type: none"> <li>○ <a href="#">Statement Hints</a></li> <li>○ <a href="#">Plan Stability</a></li> </ul>
<a href="#">Monitoring or All</a>	<a href="#">SQL Statements</a>	<ul style="list-style-type: none"> <li>○ <a href="#">SQL Plan Cache</a></li> <li>○ <a href="#">Expensive Statements</a></li> </ul>

- a. Click [More](#) beside the desired statement string.
- b. Choose [Analyze SQL and Save Plan](#).

or

On the [SQL Analyzer](#) page click [Execute and Save](#) option from the [Execute](#) menu. Choosing [Execute](#) only will not save the plan.

2. Enter a prefix for a file name.
3. Choose whether to run the analysis as a background activity.

## 6.7.1.3.3.2 Load Files

You can load saved files within the SAP HANA database.

### Prerequisites

- To load files, you have to have saved SQL plans in the SAP HANA database. For more information, see, *Save Plans*.
- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Loading saved SQL plans into the database will allow you to open the saved SQL plan with the *SQL Analyzer*.

You load saved SQL plans from the *Saved Plans* page.

### Procedure

1. On the *Database Overview* page, with the *Administration* or *All* view selected, click the *Saved Plans* section on the *Manage SQL Performance* card.
2. Click *Load PLV*.

A dialogue appears, prompting you to select files you want to load into the current system. The location of the files appears on the top of the file list.

3. Choose the desired files that you want to load into the SAP HANA database and confirm.

### Related Information

## 6.7.1.3.3 Download Files

You can download saved SQL plans as local files to your hard drive.

### Prerequisites

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.
- To download files, you have to have saved SQL plans in the SAP HANA database. For more information, see, *Save Plans*.
- Since this functionality can be accessed from different performance management and monitoring tools within the SAP HANA cockpit, please check the privileges they might require respectively.

### Context

Downloading SQL plans helps you share the SQL plans as a PLV file with others.

You can download SQL plans on the [Saved Plans](#) page and the [SQL Analyzer](#) page.

### Procedure

1. On the [Database Overview](#) page, with the *Administration* or *All* view selected, click [Saved Plans](#) on the [Manage SQL Performance](#) card.
2. Download SQL plans as local files to your hard drive from the [Saved Plans](#) tool by choosing the download icon next to the desired statement string.
3. Download SQL plans as local files to your hard drive from the [SQL Analyzer](#) tool by clicking the [Download](#) button on the upper right corner of the executed parameterized query.

A dialogue appears that allows you to [Download](#) the file to your hard drive.

## 6.7.2 Monitoring and Analyzing Performance in SAP HANA Studio

Gathering and analyzing data regarding the performance of your SAP HANA systems is important for root-cause analysis and the prevention of future performance issues. The SAP HANA studio provides a number of tools for this purpose.

General information about overall system performance is available in the System Monitor and on the [Overview](#) tab of the Administration editor. You can monitor the following fine-grained aspects of system performance on the [Performance](#) tab:

- Threads
- Sessions
- Blocked transactions
- Execution statistics of frequently-executed queries in the SQL plan cache
- Expensive statements
- Progress of long-running jobs
- System load

[SAP HANA Troubleshooting and Performance Analysis Guide](#)

### 6.7.2.1 Filters on the Performance Tab

As the information available on the [Performance](#) tab is very detailed, some useful filters are available with which you can customize the amount and type of information displayed.

Filter	Description	Sub-Tab
Table Viewer	Use the table viewer to show and hide columns.  To open the table viewer, choose  ( <a href="#">Configure Viewer</a> ) in the toolbar on the top-right of the screen.	All

Filter	Description	Sub-Tab
Hide Sessions	Use this filter to hide idle sessions, as well as sessions originating in the Administration editor or the SAP HANA studio.	<ul style="list-style-type: none"> <li>• <a href="#">Threads</a></li> <li>• <a href="#">Sessions</a></li> <li>• <a href="#">Blocked Transactions</a></li> </ul>
Column Filter	Use this filter to see information by distinct values in visible columns. To open the column filter, choose  <a href="#">Filters...</a> in the toolbar on the top-right of the screen.	<ul style="list-style-type: none"> <li>• <a href="#">Sessions</a></li> <li>• <a href="#">SQL Plan Cache</a></li> <li>• <a href="#">Expensive Statements</a></li> <li>• <a href="#">Job Progress</a></li> </ul>
Host/Service/Thread Type	Use these filters to show threads from a specific host or service, or of a specific type.	<a href="#">Threads</a>
Free-text filter	Use this filter to find a specific character string or expression in the displayed information.	<ul style="list-style-type: none"> <li>• <a href="#">Sessions</a></li> <li>• <a href="#">Blocked Transactions</a></li> <li>• <a href="#">SQL Plan Cache</a></li> <li>• <a href="#">Expensive Statements</a></li> <li>• <a href="#">Job Progress</a></li> </ul>

Any filters or layout configuration that you apply on the following sub-tabs are saved when you close the SAP HANA studio and applied the next time you open the tab. This is independent of which system you open.

- [Sessions](#)
- [Expensive Statements Trace](#)
- [SQL Plan Cache](#)
- [Job Progress](#)

## 6.7.2.2 Thread Monitoring

You can monitor all running threads in your system in the Administration editor on the [Performance](#) [Threads](#) sub-tab. It may be useful to see, for example, how long a thread is running, or if a thread is blocked for an inexplicable length of time.

### Thread Display

By default, the [Threads](#) sub-tab shows you a list of all currently active threads with the [Group and sort](#) filter applied. This arranges the information as follows:

- Threads with the same connection ID are grouped.
- Within each group, the call hierarchy is depicted (first the caller, then the callee).
- Groups are displayed in order of descending duration.

On big systems with a large number of threads, this arrangement provides you with a more meaningful and clear structure for analysis. To revert to an unstructured view, deselect the [Group and sort](#) checkbox or change the layout in some other way (for example, sort by a column).

## Thread Information

Detailed information available on the [Threads](#) sub-tab includes the following:

- The context in which a thread is used  
This is indicated by the thread type. Important thread types are `SqlExecutor` and `PlanExecutor`. `SqlExecutor` threads handle session requests such as statement compilation, statement execution, or result fetching issued by applications on top of SAP HANA. `PlanExecutor` threads are used to process column-store statements and have an `SqlExecutor` thread as their parent.

### i Note

With revision 56, `PlanExecutor` threads were replaced by `JobWorker` threads.

### i Note

The information in the [Thread Type](#) column is only useful to SAP Support for detailed analysis.

- What a thread is currently working on  
The information in [Thread Detail](#), [Thread Method](#), and [Thread Status](#) columns is helpful for analyzing what a thread is currently working on. In the case of `SqlExecutor` threads, for example, the SQL statement currently being processed is displayed. In the case of `PlanExecutor` threads (or `JobWorker` threads as of revision 56), details about the execution plan currently being processed are displayed.

### i Note

The information in the [Thread Detail](#), [Thread Method](#), and [Thread Status](#) columns is only useful to SAP Support for detailed analysis.

- Information about transactionally blocked threads  
A transactionally blocked thread is indicated by a warning icon (⚠) in the [Status](#) column. You can see detailed information about the blocking situation by hovering the cursor over this icon.  
A transactionally blocked thread cannot be processed because it needs to acquire a transactional lock that is currently held by another transaction. Transactional locks may be held on records or tables. Transactions can also be blocked waiting for other resources such as network or disk (database or metadata locks). The type of lock held by the blocking thread (record, table, or metadata) is indicated in the [Transactional Lock Type](#) column.  
The lock mode determines the level of access other transactions have to the locked record, table, or database. The lock mode is indicated in the [Transactional Lock Type](#) column.  
**Exclusive** row-level locks prevent concurrent write operations on the same record. They are acquired implicitly by update and delete operations or explicitly with the `SELECT FOR UPDATE` statement.  
Table-level locks prevent operations on the content of a table from interfering with changes to the table definition (such as drop table, alter table). DML operations on the table content require an **intentional exclusive** lock, while changes to the table definition (DDL operations) require an exclusive table lock. There is also a `LOCK TABLE` statement for explicitly locking a table. Intentional exclusive locks can be acquired if no other transaction holds an exclusive lock for the same object. Exclusive locks require that no other transaction holds a lock for the same object (neither intentional exclusive nor exclusive).  
For more detailed analysis of blocked threads, information about low-level locks is available in the columns [Lock Wait Name](#), [Lock Wait Component](#) and [Thread ID of Low-Level Lock Owner](#). Low-level locks are locks acquired at the thread level. They manage code-level access to a range of resources (for example, internal data structures, network, disk). Lock wait components group low-level locks by engine component or resource.

The *Blocked Transactions* sub-tab provides you with a filtered view of transactionally blocked threads.

## Monitoring and Analysis Features

To support monitoring and analysis, you can perform the following actions on the *Threads* sub-tab:

- See the full details of a thread by right-clicking the thread and choosing *Show Details*.
- End the operations associated with a thread by right-clicking the thread and choosing *Cancel Operations*.

### i Note

This option is not available for threads of external transactions, that is those with a connection ID of -1.

- Jump to the following related objects by right-clicking the thread and choosing *Navigate To > <related object>* 
  - Threads called by and calling the selected thread
  - Sessions with the same connection ID as the selected thread
  - Blocked transactions with the same connection ID as the selected thread
- View the call stack for a specific thread by selecting the *Create call stacks* checkbox, refreshing the page, and then selecting the thread in question.

### i Note

The information contained in call stacks is only useful to SAP Support for detailed analysis.

- Activate the expensive statements trace, SQL trace, or performance trace by choosing *Configure Trace >* *<required trace>* .  
The *Trace Configuration* dialog opens with information from the selected thread automatically entered (application and user).

### i Note

If the SQL trace or expensive statements trace is already running, the new settings overwrite the existing ones. If the performance trace is already running, you must stop it before you can start a new one.

[M\\_SERVICE\\_THREAD\\_SAMPLES System View](#)

[SQL Trace \[page 772\]](#)

[Performance Trace \[page 775\]](#)

[Expensive Statements Trace \[page 777\]](#)

## 6.7.2.3 Session Monitoring

You can monitor all sessions in your landscape in the Administration editor on the [Performance > Sessions](#) sub-tab.

### Session Information

The [Sessions](#) sub-tab allows you to monitor all sessions in the current landscape. You can see the following information:

- Active/inactive sessions and their relation to applications
- Whether a session is blocked and if so which session is blocking
- The number of transactions that are blocked by a blocking session
- Statistics like average query runtime and the number of DML and DDL statements in a session
- The operator currently being processed by an active session (*Current Operator* column).

#### i Note

In earlier revisions, you can get this information from the SYS.M\_CONNECTIONS monitoring view with the following statement:

```
SELECT CURRENT_OPERATOR_NAME FROM M_CONNECTIONS WHERE CONNECTION_STATUS =  
'RUNNING'
```

#### → Tip

To investigate sessions with the connection status RUNNING, you can analyze the SQL statements being processed in the session. To see the statements, ensure that the *Last Executed Statement* and *Current Statement* columns are visible. You can then copy the statement into the SQL console and analyze it using the *Explain Plan* and *Visualize Plan* features. It is also possible to use the SQL plan cache to understand and analyze SQL processing.

### Monitoring and Analysis Features

To support monitoring and analysis, you can perform the following actions on the [Sessions](#) sub-tab:

- Cancel a session by right-clicking the session and choosing *Cancel Session...*
- Jump to the following related objects by right-clicking the session and choosing [Navigate To > <related object>](#):
  - Threads with the same connection ID as the selected session
  - Blocked transactions with the same connection ID as the selected session
- Activate the performance trace, SQL trace, or expensive statements trace by choosing [Configure Trace > <required trace>](#).  
The *Trace Configuration* dialog opens with information from the selected session automatically entered (application and user).

### i Note

If the SQL trace or expensive statements trace is already running, the new settings overwrite the existing ones. If the performance trace is already running, you must stop it before you can start a new one.

## Related Information

[SQL Trace \[page 772\]](#)

[Performance Trace \[page 775\]](#)

[Expensive Statements Trace \[page 777\]](#)

[M\\_TRANSACTIONS System View](#)

## 6.7.2.4 Blocked Transaction Monitoring

Blocked transactions, or transactionally blocked threads, can impact application responsiveness. They are indicated in the Administration editor on the **► Performance ► Threads ►** tab. You can see another representation of the information about blocked and blocking transactions on the *Blocked Transactions* sub-tab.

### Information About Blocked Transactions

Blocked transactions are transactions that are unable to be processed further because they need to acquire transactional locks (record or table locks) that are currently held by another transaction. Transactions can also be blocked waiting for other resources such as network or disk (database or metadata locks).

The type of lock held by the blocking transaction (record, table, or metadata) is indicated in the *Transactional Lock Type* column.

The lock mode determines the level of access other transactions have to the locked record, table, or database. The lock mode is indicated in the *Transactional Lock Type* column.

**Exclusive** row-level locks prevent concurrent write operations on the same record. They are acquired implicitly by update and delete operations or explicitly with the SELECT FOR UPDATE statement.

Table-level locks prevent operations on the content of a table from interfering with changes to the table definition (such as drop table, alter table). DML operations on the table content require an **intentional exclusive** lock, while changes to the table definition (DDL operations) require an exclusive table lock. There is also a LOCK TABLE statement for explicitly locking a table. Intentional exclusive locks can be acquired if no other transaction holds an exclusive lock for the same object. Exclusive locks require that no other transaction holds a lock for the same object (neither intentional exclusive nor exclusive).

For more detailed analysis of blocked transactions, information about low-level locks is available in the columns *Lock Wait Name*, *Lock Wait Component* and *Thread ID of Low-Level Lock Owner*. Low-level locks are locks

acquired at the thread level. They manage code-level access to a range of resources (for example, internal data structures, network, disk). Lock wait components group low-level locks by engine component or resource.

## Monitoring and Analysis Features

To support monitoring and analysis, you can perform the following actions on the *Blocked Transactions* sub-tab:

- Jump to threads and sessions with the same connection ID as a blocked/blocking transaction by right-clicking the transaction and choosing **► Navigate To > <related object> ▾**.
- Activate the performance trace, SQL trace, or expensive statements trace for the blocking transaction (that is the lock holder) by choosing **► Configure Trace > <required trace> ▾**. The *Trace Configuration* dialog opens with information from the selected thread automatically entered (application and user).

### i Note

If the SQL trace or expensive statements trace is already running, the new settings overwrite the existing ones. If the performance trace is already running, you must stop it before you can start a new one.

### 6.7.2.5 Monitoring SQL Performance with the SQL Plan Cache

The SQL plan cache can provide you with an insight into the workload in the system as it lists frequently executed queries. You can view the plan cache in the Administration editor on the **► Performance > SQL Plan Cache ▾** sub-tab.

Technically, the plan cache stores compiled execution plans of SQL statements for reuse, which gives a performance advantage over recompilation at each invocation. For monitoring reasons, the plan cache keeps statistics about each plan, for instance number of executions, min/max/total/average runtime, and lock/wait statistics. Analyzing the plan cache is very helpful as one of the first steps in performance analysis because it gives an overview about what statements are executed in the system.

### i Note

Due to the nature of a cache, seldom-used entries are evicted from the plan cache.

The SQL plan cache is useful for observing overall SQL performance as it provides statistics on compiled queries. Here, you can get insight into frequently executed queries and slow queries with a view to finding potential candidates for optimization.

The following information may be useful:

- Dominant statements (TOTAL\_EXECUTION\_TIME)
- Long-running statements (AVG\_EXECUTION\_TIME)
- Frequently-executed plans (EXECUTION\_COUNT)
- Number of records returned (TOTAL\_RESULT\_RECORD\_COUNT)
- Statements with high lock contention (TOTAL\_LOCK\_WAIT\_COUNT)

### i Note

The collection of SQL plan cache statistics is enabled by default, but you can disable it on the [SQL Plan Cache](#) tab by choosing [Configure](#).

To help you understand and analyze the execution plan of an SQL statement further, you can generate a graphical view of its plan by right-clicking the statement and choosing [Visualize Plan](#).

The system views associated with the SQL plan cache are M\_SQL\_PLAN\_CACHE\_OVERVIEW and M\_SQL\_PLAN\_CACHE.

## Related Information

[M\\_SQL\\_PLAN\\_CACHE\\_OVERVIEW System View](#)

## 6.7.2.6 Expensive Statements Monitoring

Expensive statements are individual SQL queries whose execution time was above a configured threshold. The expensive statements trace records information about these statements for further analysis and displays them in the Administration editor on the [Performance > Expensive Statements Trace](#) sub-tab.

The individual steps of statement execution are displayed in a hierarchical tree structure underneath aggregated statement execution information.

The following information may be useful:

- When the query started (START\_TIME)
- How long the query took (DURATION\_MICROSEC)
- Name(s) of the objects accessed (OBJECT\_NAME)
- The SQL statement (STATEMENT\_STRING)

## i Note

The expensive statements trace is deactivated by default. You can activate and configure it either here on the [Expensive Statements Trace](#) sub-tab, or on the [Trace Configuration](#) tab.

To help you understand and analyze the execution plan of an expensive statement further, you can generate a graphical view of its plan by right-clicking the statement and choosing [Visualize Plan](#).

## Related Information

[Expensive Statements Trace \[page 777\]](#)

[M\\_EXPENSIVE\\_STATEMENTS System View](#)

## 6.7.2.7 Job Progress Monitoring

Certain operations in SAP HANA typically run for a long time and may consume a considerable amount of resources. You can monitor long-running jobs in the Administration editor on the [Performance > Job Progress](#) sub-tab.

By monitoring the progress of long-running operations, for example, delta merge operations and data compression, you can determine whether or not they are responsible for current high load, see how far along they are, and when they will finish.

The following information is available, for example:

- Connection that triggered the operation (CONNECTION\_ID)
- Start time of the operation (START\_TIME)
- Steps of the operation that have already finished (CURRENT\_PROGRESS)
- Maximum number of steps in the operation (MAX\_PROGRESS)

For more information about the operations that appear on the [Job Progress](#) sub-tab, see system view [M\\_JOB\\_PROGRESS](#).

## Related Information

[M\\_JOB\\_PROGRESS System View](#)

## 6.7.2.8 Load Monitoring

A graphical display of a range of system performance indicators is available in the Administration editor on the [► Performance ► Load](#) sub-tab.

You can use the load graph for performance monitoring and analysis. For example, you can use it to get a general idea about how many blocked transactions exist now and in the past, or troubleshoot the root cause of slow statement performance.

## 6.7.3 Performance: Using Hints to Query Data Snapshots

Several features in SAP HANA use data snapshots to improve performance. You can use configurable hint classes as a standard way of controlling at run time how the data is selected, either from the snapshot or from the database.

Several features in SAP HANA use data snapshots or replicated data to improve performance; this includes:

- Result Cache
- Asynchronous Table Replication
- System Replication (Active/Active Read Enabled).

Snapshots carry the risk of holding stale data and administrators need to be able to specify a maximum time value up to which the replicated data may lag behind the live data. The features listed above all use the `RESULT_LAG()` hint with a set of standard configurable hint classes as a common way of controlling how the data is selected at run time (also referred to as hint-based routing). Hint classes give the administrator a tool to balance a system in terms of query response time, query load, resource utilization and freshness of data. Moreover, they de-couple SAP HANA features from application development and administrator choices.

### Using the Hint `RESULT_LAG()`

The `RESULT_LAG()` hint takes two parameter values to determine:

- Which is the preferred data source (snapshot or live data)
- How much time the retrieved data may lag behind the live data.

The syntax for the `RESULT_LAG()` hint is as shown here:

```
WITH HINT (RESULT_LAG("<short_class_name>", [seconds]))
```

**Class name:** the following pre-defined hint classes are available for use with this hint, these, and options for configuring them, are described in detail below. Only the last two elements of the name are used in SQL statements, for example 'hana\_cache', 'hana\_short' and so on:

- `hint_result_lag_hana_cache` - for Result Cache, the default lag time value is the cache retention time

- `hint_result_lag_hana_atr` - for Asynchronous Table Replication, the default lag time value can be defined as a configuration parameter
- `hint_result_lag_hana_sr` - for System Replication (Active/Active), the default lag time value can be defined as a configuration parameter
- `hint_result_lag_hana_es_atr` - for the extended storage replica node, the default lag time value can be defined as a configuration parameter
- `hint_result_lag_hana_short`
- `hint_result_lag_hana_long`

Note that customers and developers may also add classes of their own (and corresponding configuration values) but these must not use the `hana_*` or `sap_*` naming convention.

**Seconds:** This parameter is an optional time value in seconds; this is the maximum time lag up to which the data is judged to be acceptable; if the snapshot or replica is older then it will not be used and the query is routed to the data source. If no seconds value is given the default value will be used. In some cases this feature can be disabled by setting a configuration option - see details below.

### Configuration of Routing

Each hint class has its own section in the `indexserver.ini` file (`[hint_result_lag_hana_short]` for example, sections must also be added for user-defined classes) where one or more parameters are available. All classes have the `enable_features` parameter; this is the 'routing' parameter which is used to define an order of preference for the data source used. The following table shows the default `enable_features` setting for each class, for example, the `hana_long` class is defined by default with the sequence, 'resultcache,atr,sr', meaning: data from the resultcache is preferred, if not then data from a replica table (asynchronous table replication), otherwise data from a secondary system (system replication). The same maximum lag time value defined is applied to the whole sequence of data sources (an example is given below):

Class	Parameter	Default Setting (Preferred Source Sequence)
<code>hana_cache</code>	<code>enable_features</code>	resultcache
<code>hana_atr</code>	<code>enable_features</code>	atr
<code>hana_sr</code>	<code>enable_features</code>	sr
<code>hana_es_atr</code>	<code>enable_features</code>	es,atr
<code>hana_short</code>	<code>enable_features</code>	atr, sr
<code>hana_long</code>	<code>enable_features</code>	resultcache,atr,sr

More detail of how these classes are used in each of the three application areas is described in the following subsections.

### Hint Class for Result Cache

Using the class `hana_cache` the result cache of the target view / table function is exploited if it is enabled and applicable. This is shown in the following example:

```
SELECT * FROM V1 WITH HINT( RESULT_LAG ( 'hana_cache', 30) );
```

If a value for the seconds (time) parameter of the hint is given it overrides any retention time value which has been defined for the view. For example, the 30 second time lag defined in the above example would override the hundred minute retention period defined when the cache was created:

```
ALTER VIEW v1 ADD CACHE RETENTION 100;
```

The result cache and dynamic result cache are described in detail in the *SAP HANA Troubleshooting and Performance Analysis Guide*.

## Hint Class for Asynchronous Table Replication

You can use the `hana_atr` class to access replicated tables.

```
SELECT * FROM T1 WITH HINT( RESULT_LAG ('hana_atr') , 10 );
```

If the current lag time for the data on the replica is less than the stated value for the [seconds] parameter (10 seconds in this example) then the query is executed on the replicated table, otherwise it would be executed on the source.

### More Configuration Options for Class `hana_atr`

Parameter:	<code>atr_default_lag_time</code>
Purpose	The default lag time value for this class. This value will be applied if no seconds value is entered with the hint on the SQL command line.
Default	-1 In this case if no seconds value is entered with the hint the query is always routed to the replica.
Unit	seconds
Parameter:	<code>atr_ignore_lag_time</code>
Purpose	Set this to true to disable the check for the specified lag time so that the query will always access replica tables regardless of the value entered with the hint and the default lag time setting.
Default	false

For more information refer to the *Asynchronous Table Replication* section of this guide.

## Hint Class for System Replication (Active/Active read enabled)

You can use the class `hana_sr` for system replication and select data from the secondary system. This is shown in the following example:

```
SELECT * FROM T1 WITH HINT( RESULT_LAG ('hana_sr', 60) );
```

If this is used in a situation where the result cache might also be available, the following table shows specifically which data source is used in either of the two possible cases (result cache available yes or no):

<b>enable_features</b>	<b>Result Cache Available?</b>	<b>Data Source</b>
sr,resultcache	Yes	Secondary (cache used)
sr,resultcache	No	Secondary
resultcache,sr	Yes	Primary (cache used)
resultcache,sr	No	Secondary
sr	Yes	Secondary
sr	No	Secondary
resultcache	Yes	Primary (cache used)
resultcache	No	Primary

This table shows the behavior on the primary system. If the application connects to the secondary system directly the result cache can be also used at secondary. For more information refer to the *Active/Active (Read Enabled)* section of this guide.

## More Configuration Options for Class hana\_sr

Other parameters are also available for the *hana\_sr* hint class:

<b>Parameter:</b>	<b>sr_default_lag_time</b>
Purpose	The default lag time value for this class. This value will be applied if no value is entered with the hint on the SQL command line.
Default	-1 In this case if no seconds value is entered with the hint the query is always routed to the secondary.
Unit	seconds

<b>Parameter:</b>	<b>sr_ignore_lag_time</b>
Purpose	Set this to true to disable the check for the specified lag time.
Default	false

<b>Parameter:</b>	<b>sr_enable_primary_redirection_for all errors</b>
Purpose	The routed statement will be redirected to primary for all errors.
Default	true

<b>Parameter:</b>	<b>sr_enable_primary_redirection</b>
Purpose	This parameter is used for error handling: if an out of memory error occurs on the secondary, or if the lag time is exceeded, then the routed statement will be redirected to the primary and executed.
Default	true

## Examples Using HANA\_SHORT and HANA\_LONG

You can use `hana_short` and `hana_long` classes in combination with other application-specific hint classes. Here, we give two examples; in the first a value for the `seconds` parameter is given, and in the second the default values for each data source as specified in the configuration file are used. The configuration file for `hana_long` for example, could be as follows:

### Sample Code

```
[hint_result_lag_hana_long]
enable_features = resultcache,atr,sr
atr_default_lag_time = 10
sr_default_lag_time = 20
```

The `enable_features` parameter specifies the sequence of data sources as: result cache preferred, secondly table replica, otherwise system replication secondary system.

**Example 1** In this example a `seconds` value is given in the query and this value is used in all three cases to evaluate whether the cached/replicated data is acceptable.

```
SELECT * FROM V1 WITH HINT( RESULT_LAG ('hana_long') , 10 );
```

First if the result cache data is less than the `seconds` parameter value (10 seconds) the query will read data from here. If the result cache is too stale then the age of the replicated table data will be evaluated against the `seconds` parameter value and if this data is too stale then the system replicated data will be evaluated to determine whether to execute the query on the primary or secondary system. If none of the cached sources is available (`seconds` value smaller than the current lag time) then the primary system is accessed.

**Example 2** In the following example (referring to the same sequence of three data sources) a time value is not given in the query, and the default lag values for each data source are used to evaluate whether the data source is acceptable:

```
SELECT * FROM V1 WITH HINT( RESULT_LAG ('hana_long') );
```

The default values are: for result cache the predefined retention period, for `atr` and `sr` the ini parameter values defined in the `[hint_result_lag_hana_long]` section apply, that is, `atr_default_lag_time` for asynchronous replication (10 seconds in the sample code above) and `sr_default_lag_time` for system replication (20 seconds in the sample code above).

## Related Information

[SAP HANA Troubleshooting and Performance Analysis Guide](#)

[Active/Active \(Read Enabled\) \[page 1328\]](#)

[Asynchronous Table Replication Operations \[page 694\]](#)

## 6.7.4 Plan Cache

The plan cache stores execution plans of frequently executed SQL statements so that they can be reused rather than having to recompile the plan each time the statement is run. Administrators can also use the plan cache for performance analysis to get an overview of what statements are executed in the system.

### Plan Cache for Administrators

For administrators, the SQL plan cache is useful for monitoring overall SQL performance as it provides statistics on compiled queries such as the number of executions, runtime details, and lock/wait statistics. You can use this information to get insights into frequently executed queries and slow queries and identify potential candidates for optimization.

You can view the plan cache in SAP HANA cockpit by clicking on the [Top SQL Statements](#) card in your resource's [Database Overview](#); then, on the [Monitor Statements](#) screen select the [SQL Plan Cache](#) page. See cockpit documentation ([Monitor and Analyze Statements with SQL Plan Cache](#)) for more information.

### Eager Eviction

SQL statements stay in the Plan Cache as long as they are required, but entries which are of little value are evicted from the cache. Eviction takes place automatically by default, but if you wish to manage this more carefully (or turn eviction off completely) configuration settings are available to manage the cache on the basis of usage frequency or a more balanced usefulness score which is automatically calculated. Configuration parameters for this are in the [SQL] section of the indexserver.ini file.

To manage eviction you must firstly activate the `plan_cache_eager_eviction_mode` parameter by changing its default value (auto) to 'custom'.

By default, cached plans that are not used for more than two days are automatically evicted. You can change this retention period and also the frequency with which the plan cache is scanned for old plans.

Parameters for Retention Period	Default	Usage
<code>plan_cache_eager_eviction_mode</code>	auto	Set this to 'custom' if you wish to change the default eviction settings. Set this to 'off' to disable plan cache eager eviction.

Parameters for Retention Period	Default	Usage
plan_cache_eager_eviction_time_based_retention_time	2880	Sets the minimum retention period in minutes for time-based eviction. Setting this to a negative number disables this feature.
plan_cache_eager_eviction_time_based_scan_period	120	Sets the frequency, in minutes, of how often time-based eviction occurs.

For score-based eviction, the plan cache periodically assigns a score to each plan to evaluate it in terms of a range of criteria such as: Frequency of execution, Time since last execution.

You can configure score-based eviction to evict a certain percentage of low-scoring plans. By default, the bottom 10 percent of plans are evicted each time the scan of the cache is run.

Parameters for Score-based Eviction	Default	Usage
plan_cache_eager_eviction_score_based_rate	10	Sets the percentage of low-score plans to be evicted. Setting this to a negative number disables this feature.
plan_cache_eager_eviction_score_based_scan_period	15	Sets the frequency, in minutes, of how often score-based eviction occurs.

## Monitoring Views

The following monitoring views have details of cached plans:

- M\_SQL\_PLAN\_CACHE\_OVERVIEW includes, for example, timestamp values of the last scans for time/score-based eviction.
- M\_SQL\_PLAN\_CACHE includes, for example, timestamp values of the last execution time of a plan and also score details of current plan cache entries.
- M\_SQL\_PLAN\_STATISTICS includes a value for last invalidation reason, such as, LOW\_SCORE or EXPIRED.

## Related Information

[Monitor and Analyze Statements with SQL Plan Cache \[page 436\]](#)

## 6.7.5 SQL Analyzer Extension

Analyzing statement performance helps you understand performance issues of a query execution and other query execution aspects. SQL analyzer is currently available as an extension for Visual Studio Code.

The following sections provide an overview of the SQL analyzer tool:

### What is the SQL analyzer?

The SAP HANA SQL analyzer is a query performance analysis tool of SAP HANA. The tool can be used to view detailed information on each query execution and can help you evaluate potential bottlenecks and optimizations for these queries.

You can view and analyze the following in the SQL analyzer:

SQL analyzer views

View	Description
Navigation panel	<p>The navigation panel offers access to the following:</p> <ul style="list-style-type: none"><li>• <i>Plan graphs</i> lists the added .PLV and .PLVX files and lets you add or remove files from this list</li><li>• <i>Top 5 dominant operators</i> lists the most time-consuming operators sorted by their execution time</li><li>• <i>Top 10 critical path operators</i> lists critical paths based on inclusive execution time of operators and allows you to identify the most expensive paths in a query execution plan</li><li>• <i>Last 10 visited</i> is a historic list of the operators selected in the <i>Graph</i> view</li><li>• <i>Bookmarks</i> lists operators bookmarked in the <i>Graph</i> view and lets you see their details or remove them</li><li>• <i>Exceptions</i> lists operators with the exception status</li></ul>

View	Description
Overview	<p>This view provides an overview of the query execution including metadata for the analysis. It displays the following KPIs that offer the following actions:</p> <ul style="list-style-type: none"> <li>• <a href="#">Execution summary</a> shows the total compilation and execution times of the query, its start time, peak memory usage, number of operators and edges, and lets you see the compilation summary or exception details when available</li> <li>• <a href="#">Dominant plan operators</a> shows the top 5 most time-consuming operators by their execution time</li> <li>• <a href="#">Audits</a> lists the audits stored in the operator details</li> <li>• <a href="#">Data Usage</a> shows the statistics on data usage for the query execution, where <a href="#">Virtual Tables</a> indicates the number of remote data sources and <a href="#">Cross DB Access</a> shows the number of tenant databases accessed during query execution; details can be accessed in the <a href="#">Table Access</a> view</li> <li>• <a href="#">Distribution</a> shows the number of SAP HANA index servers that are related to the query execution, and lets you see details of node distribution and network transfers</li> <li>• <a href="#">Context</a> shows the SQL query, user, schema, session variables and parameter values of the execution, the full details of which can be found in the <a href="#">SQL</a> tab</li> <li>• <a href="#">System Information</a> displays the accessed host and SAP HANA version of the system where the execution occurred</li> <li>• <a href="#">SQL Performance Recommendations</a> show recommendations on query execution improvement and lets you see more details in the <a href="#">Recommendation</a> view</li> </ul>
Statement Statistics	<p>This view is only available when SQLScript procedure call is executed for plan visualization. It shows the list of the inner statements being executed within the SQLScript and provides the execution statistics for each.</p> <p>You can support analysis in the following ways:</p> <ul style="list-style-type: none"> <li>• Filter statements you want to analyze</li> <li>• Navigate to the <a href="#">Plan Graph</a> tab by selecting an inner statement in the table where it the SQLScript plan will be highlighted</li> <li>• Open a specific inner plan in a separate tab with an overview, plan graph, timeline, and other information about the plan</li> </ul>

View	Description
Plan Graph	<p data-bbox="804 356 1390 555">This view provides graphical guidance to help you understand and analyze the execution plan of a SQL statement. It displays a top-down data flow visualization of a critical path based on inclusive execution time of operators and allows you to identify the most expensive path in a query execution plan.</p> <p data-bbox="804 580 1390 707">Plan operators are displayed as <i>nodes</i> in the plan graph, and information (like operation name, operator summary, schema, and execution time bar) on it is within. Its display depends on the zoom level.</p> <p data-bbox="804 732 1390 860">The cardinality or number of rows connecting two operators are visualized as lines – or <i>edges</i> – between the nodes. The thickness of the edge is proportional to the number of rows. Critical paths are displayed as red lines.</p> <p data-bbox="804 884 1318 907">You can interact with the graph in the following ways:</p> <ul data-bbox="804 931 1390 1417" style="list-style-type: none"><li>• Show the graph views horizontally or vertically</li><li>• Zoom in or out</li><li>• Reset graph to initial state</li><li>• Expand or collapse container operator</li><li>• Show property details in the <i>Property</i> view</li><li>• Show the logical plan of the selected inner plan as a dialog</li><li>• Choose to display or hide a minimap</li><li>• Export the current query execution as .PLVX</li><li>• Display, add, edit, or hide comments with captured images of the selected operator</li><li>• Create or remove bookmarks for an operator</li><li>• Show, adjust, or hide settings</li></ul>

View	Description
SQL Context	<p>This view provides SQL execution related information like the executed SQL query, as well as session context variables and parameter values assigned upon query execution.</p> <p>Each section provides common capability to enlarge view in the independent area, and copying data shown. User can click the related buttons as shown in the view below.</p> <p>The following SQL-related information on the query execution is available:</p> <ul style="list-style-type: none"> <li>• <a href="#">SQL Query</a> displays the complete analyzed SQL string and allows you to copy it</li> <li>• <a href="#">Session Context</a> lists session variables like database user and schema name with their values in table form and allows you to re-execute the query with the same session information, as well as copy it</li> <li>• <a href="#">Parameter Values</a> displays parameter values during query execution in table form, allows you to re-execute the query with the same parameter values, as well as copy them</li> </ul> <p>You can support analysis in the following ways:</p> <ul style="list-style-type: none"> <li>• Enlarge the view of the independent area</li> <li>• Copy data</li> </ul>
Operators	<p>This view provides a list of operators used during query execution and includes additional details about each operator, which can be used for analysis. Each operator is grouped in parent-child hierarchies and selecting an operator will highlight the corresponding node in the <a href="#">Plan Graph</a> view.</p>
Timeline	<p>The timeline view displays a complete overview of the execution plan based on the visualization of sequential time stamps. The operator tree table displays hierarchical parent-child relationships and container-inner plan relationships.</p> <p>Based on the operators, the time stamp chart shows the operations executed at different time intervals, with each operation visualized by a different color. You can retrieve more detailed information like operator name by selecting the time stamp.</p>
<div style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>Some .PLV files have compile time, and in their time stamp chart, it will denote the beginning, as other execution tasks can only start after that.</p> </div>	

View	Description
Table Access	The table access view shows details on the table accesses performed during the processing of a statement. To improve analysis, you can group operators or filter the results.
Recommendations	This view provides a list of suggestions you can apply to improve various aspects of the query execution, like query execution time.
Properties	The properties view a list of properties of the selected operator or edge. In case a property has sub-properties, these are displayed in a hierarchical tree structure.
Compilation Summary	This view provides details on the query compilation process, including compilation time breakdown, cost-based optimization details, and plan properties. In case the query is not executed, the compilation summary is not available.
Performance Trace	This view lists operators which contain performance trace. Performance trace is a tool built into SAP HANA database that records performance indicators for the individual query processing steps in the database kernel.
Function Profiler	This view lists operators which contain function profiler. The function profiler traces routines called during the database runtime.
Comments	<p>The commenting function provides you with an enriched collaborative analysis experience by allowing you to make comments on the query and share it as a single file.</p> <p>Comments can be added by the hover button next to the operator.</p> <p>In the comment view, you can support analysis by:</p> <ul style="list-style-type: none"> <li>• Editing you user identity</li> <li>• Reading and leaving new comments</li> <li>• Commenting specific areas on the plan graph</li> <li>• Searching comments</li> <li>• Adjusting comment view</li> <li>• Adding images of a selected operator in the plan graph</li> </ul>

## How can you install the SQL analyzer for Visual Studio Code?

The SQL analyzer is available at the Visual Studio Code Marketplace. Go to the website and download the SAP HANA SQL analyzer extension for Visual Studio Code.

## How can you access and set up the SQL analyzer for Visual Studio Code?

1. Open Visual Studio Code.
2. Open the SAP HANA SQL analyzer extension.
3. Select the *File* dialog and choose to open file or the plus icon on the *Plan Graph* view.
4. Select a .PLV file from the dialog.
5. Select the opened .PLV file to show the visualized plan.

## 6.8 Memory Usage in the SAP HANA Database

Memory is a fundamental resource of the SAP HANA database. Understanding how the SAP HANA database requests, uses, and manages this resource is crucial to the understanding of SAP HANA.

SAP HANA provides a variety of memory usage indicators that allow for monitoring, tracking, and alerting. The most important indicators are used memory and peak used memory. Since SAP HANA contains its own memory manager and memory pool, external indicators such as the size of resident memory at host level and the size of virtual and resident memory at process level can be misleading when you are estimating the real memory requirements of an SAP HANA deployment.

You can find detailed information about memory consumption of individual components and operations by looking into memory allocator statistics.

For more information about memory consumption with regards to SAP HANA licenses, see SAP Note 1704499 *System Measurement for License Audit*.

[SAP Note 1704499](#)

### 6.8.1 SAP HANA Used Memory

The total amount of memory used by SAP HANA is referred to as used memory. It includes program code and stack, all data and system tables, and the memory required for temporary computations.

SAP HANA consists of a number of processes running in the Linux operating environment. Under Linux, the operating system (OS) is responsible for reserving memory to all processes. When SAP HANA starts up, the OS

reserves memory for the program code (sometimes called the text), the program stack, and static data. It then dynamically reserves additional data memory when requested by the SAP HANA memory manager. Dynamically allocated memory consists of heap memory and shared memory.

The following figure shows used memory, consisting of code, stack, and table data:

Since the code and program stack size are about 6 GB, almost all of used memory is used for table storage, computations, and database management.

## Service Used Memory

An SAP HANA system consists of multiple services that all consume memory, in particular the `indexserver` service, the main database service. The index server holds all the data tables and temporary results, and therefore dominates SAP HANA used memory.

## Peak Used Memory

Ultimately, it's more important to understand the behavior of used memory over time and under peak loads. For this purpose, SAP HANA has a special used memory indicator called peak used memory. As the value for used memory is a current measurement, peak used memory allows you to track the maximum value for used memory over time.

You can also reset peak used memory. Resetting can be useful if you want to establish the impact of a certain workload on memory usage. So for example, you can reset peak used memory, run the workload, and then examine the new peak used memory value.

## Memory Usage of Tables

The dominant part of the used memory in the SAP HANA database is the space used by data tables. Separate measurements are available for column-store tables and row-store tables.

### i Note

The SAP HANA database loads column-store tables into memory column by column only upon use, which is sometimes called "lazy loading". This method means that columns that are unused aren't loaded and memory waste is avoided. When the SAP HANA database runs out of allocatable memory, it tries to free up some memory by unloading unimportant data (such as caches) and even table columns that haven't been used recently. Therefore, if it's important to measure precisely the total, or worst-case, amount of memory used for a particular table, it's important to ensure that you fully load the table into memory.

## Memory Usage of Expensive Statements

Every query and statement consumes memory, for the evaluation of the statement plan, caching, and, mainly the calculation of intermediate and final results. While many statement executions use only a moderate amount of memory, some queries, for instance using unfiltered cross joins, taxes even large systems.

Expensive statements are individual SQL statements whose execution time exceeded a configured threshold. The expensive statements trace records information about these statements for further analysis. If in addition to activating the expensive statements trace, you enable per-statement memory tracking, the expensive statements trace also shows the peak memory size used to execute expensive statements.

It's further possible to protect an SAP HANA system against excessive memory usage due to uncontrolled queries by limiting the amount of memory used by single statement executions per host.

## 6.8.2 Memory Allocator Statistics

Detailed information about memory consumption can be found by looking into allocator statistics.

Allocator statistics track the memory consumption of individual components and operations in SAP HANA and may help you to analyze issues related to memory consumption. Statistics are saved in the system views

M\_HEAP\_MEMORY (allocated memory by component) and M\_CONTEXT\_MEMORY (allocated memory that can be associated with a connection, a statement, or a user). Both views have a reset feature so that statistics can be captured for a specific period of time. The embedded statistics service also includes a view which tracks memory allocation per host: HOST\_HEAP\_ALLOCATORS.

Refer to the *SAP HANA SQL and System Views Reference* for full details of these views.

Allocator statistics are saved automatically for each core processor and in certain scenarios where systems have a large number of logical cores the statistics can consume a significant amount of memory. To save memory, statistics logging can be reduced to save statistics only for each node or only for each statistics object. An example of using the `lscpu` command to retrieve details of the physical and logical CPU architecture is given in the section *Controlling CPU Consumption*.

You can configure this feature by setting values for the following two configuration parameters in the `global.ini` file:

- The parameter `pool_statistics_striping` can reduce the amount of memory consumed by the component-specific allocator statistics (rows in M\_HEAP\_MEMORY with category *PoolAllocator*).
- The parameter `composite_statistics_striping` can reduce the amount of memory consumed by statement-specific allocator statistics (rows in M\_CONTEXT\_MEMORY).

The parameters can be set to one of the following values, the configuration can be changed online, but the change will only affect newly created statistic objects:

Value	Effect
auto (default value)	Let the system decide the statistics strategy. By default HANA will try to utilize as much memory as possible for maximum performance.
core	The system allocates one stripe per logical core.
numa	The system allocates only one stripe per NUMA node.
none	In this case, the system creates a single stripe per statistics object.

Controlling CPU Consumption \[page 728\]](#)

### 6.8.3 Memory Sizing

Memory sizing is the process of estimating in advance the amount of memory that is required to run a certain workload on an SAP HANA database. To understand memory sizing, several questions need to be answered.

- What is the size of the data tables that must be stored in the SAP HANA database?  
You may be able to estimate this based on the size of your existing data, but unless you precisely know the compression ratio of the existing data and the anticipated growth factor, this estimate may not be accurate.
- What is the expected compression ratio that SAP HANA applies to these tables?

The column store of the SAP HANA database automatically uses a combination of various advanced compression algorithms (dictionary, RLE, sparse, and so on) to compress each table column separately. The achieved compression ratio depends on many factors, such as the nature of the data, its organization and data types, the presence of repeated values, the number of indexes (SAP HANA requires fewer indexes), and so on.

- How much extra working memory is required for temporary computations?  
The amount of extra memory depends on the size of the tables (larger tables create larger intermediate result tables in operations such as joins), but even more on the expected workload in terms of the concurrency and complexity of analytical queries (each concurrent query needs its own workspace).

The following SAP Notes provide additional tools and information to help you size the required amount of memory:

- SAP Note 1514966 - SAP HANA 1.0: Sizing SAP In-Memory Database
- SAP Note 1637145 - SAP BW on HANA: Sizing SAP In-Memory Database
- SAP Note 2296290 - New Sizing Report for BW on HANA

However, the most accurate method is to import several representative tables into an SAP HANA system, measure the memory requirements, and extrapolate from the results.

## 6.8.4 Allocated Memory Pools and Allocation Limits

SAP HANA, across its different processes, reserves a pool of memory before actual use. This pool of allocated memory is preallocated from the operating system over time, up to a predefined global allocation limit, and is then efficiently used by SAP HANA as needed.

SAP HANA preallocates and manages its own memory pool, used for storing in-memory table data, thread stacks, temporary results, and other system data structures. When more memory is required for table growth or temporary computations, the SAP HANA memory manager obtains it from the pool. When the pool can't satisfy the request, the memory manager increases the pool size by requesting more memory from the operating system, up to a predefined allocation limit.

By default, the allocation limit is calculated as follows: 90% of the first 64 GB of available physical memory on the host, plus 97% of each further GB.

The limit can be changed by modifying the `global_allocation_limit` configuration parameter in the `global.ini` file. It can be defined either as a fixed value in MB or as a flexible percentage of the available main memory size. If you enter a percentage value, the precise value of the limit is calculated automatically by the system. Moreover, if you then change the size of the container where the system runs the allocation limit automatically adjusts to the correct percentage of the new container size.

There's normally no reason to change the value of this parameter. However, on development systems with more than one SAP HANA system installed on a single host you could limit the size of the memory pool to avoid resource contentions or conflicts.

A change may also be necessary to remain in compliance with the memory allowance of your license if you purchased a license for less than the total amount of physical memory available. This change is illustrated in the following examples:

#### ❖ Example

- You have a server with 512 GB, but purchased an SAP HANA license for only 384 GB. You therefore set the `global_allocation_limit` to 393216 (384 \* 1024 MB).
- You have a distributed HANA system on four hosts with 512 GB each, but purchased an SAP HANA license for only 768 GB. Set the `global_allocation_limit` to 196608 (192 \* 1024 MB on each host).

## Service Allocation Limit

In addition to the global allocation limit, each service running on the host has an allocation limit, the service allocation limit. Given that collectively, all services can't consume more memory than the global allocation limit, each service has what is called an effective allocation limit. The effective allocation limit of a service specifies how much physical memory a service can in reality consume given the current memory consumption of other services.

#### ❖ Example

A single-host system has 100-GB physical memory. Both the global allocation limit and the individual service allocation limits are 92.5% (default values). Therefore:

- Collectively, all services of the SAP HANA database can use a maximum of 92.5 GB.
- Individually, each service can use a maximum of 92.5 GB.

Therefore, if 2 services are running and the current memory pool of service 1 is 50 GB, then the effective allocation limit of service 2 is 42.5 GB. This allocation happens because service 1 is already using 50 GB and together they can't exceed the global allocation limit of 92.5 GB.

## What happens when the allocation limit is reached?

Memory is a finite resource. Once the allocation limit has been reached and the pool is exhausted, the memory manager only allocates memory for internal operations after first giving up something else. Buffers and caches are released, and column store tables are unloaded, column by column, based on a least-recently-used order, up to a preset lower limit. When tables are partitioned over several hosts, it's managed on a host-by-host basis; that is, column partitions are unloaded only on hosts with an acute memory shortage.

Avoid table (column or partition) unloading since it leads to performance degradation later when the table is queried and the data has to be reloaded. You can identify pool exhaustion by examining the `M_CS_UNLOADS` system view.

However, it's still possible that the memory manager needs more memory than is available leading to an out-of-memory failure. This may happen, for example, when too many concurrent transactions use up all memory, or when a complex query performs a cross join on large tables and creates a huge intermediate result that exceeds the available memory.

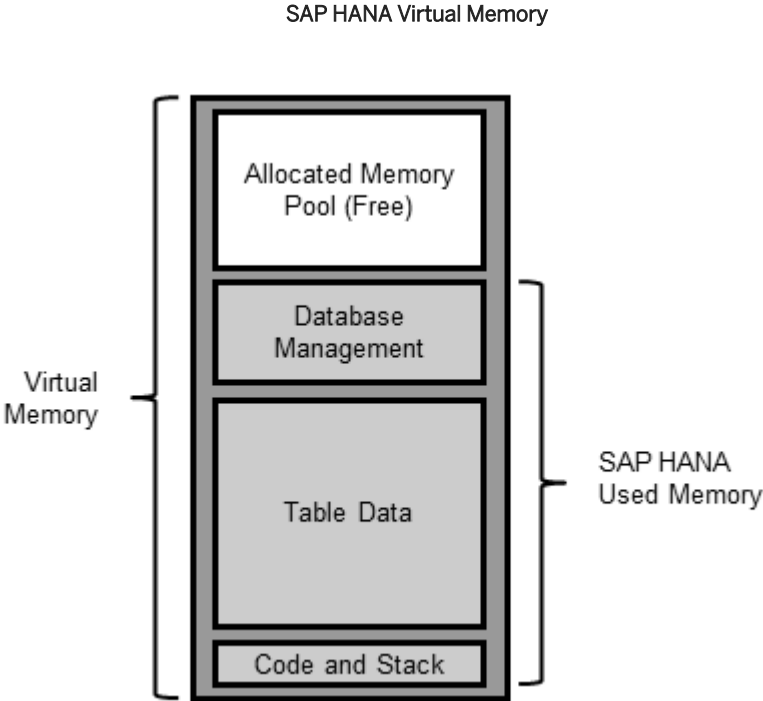

### Related Information

[Change the Global Memory Allocation Limit](#)

## 6.8.5 SAP HANA Memory Usage and the Operating System

Due to the way in which SAP HANA manages memory, the relationship between Linux memory indicators and SAP HANA's own memory indicators may not correlate as expected.

From the perspective of the Linux operating system, SAP HANA is a collection of separate processes. Linux programs reserve memory for their use from the Linux operating system. The entire reserved memory footprint of a program is referred to as its virtual memory. Each Linux process has its own virtual memory, which grows when the process requests more memory from the operating system, and shrinks when the process relinquishes unused memory. You can think of virtual memory size as the memory amount that the process has requested (or allocated) from the operating system, including reservations for its code, stack, data, and memory pools under program control. SAP HANA's virtual memory is logically shown in the following figure:

### i Note

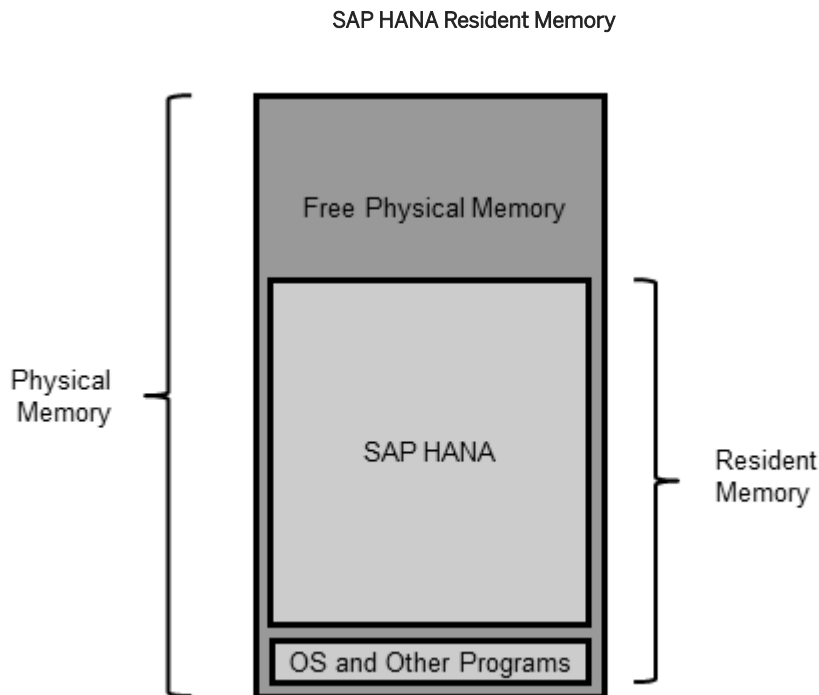

SAP HANA really consists of several separate processes, so the preceding figure shows all SAP HANA processes combined.

## Virtual, Physical, and Resident Memory

When part of the virtually allocated memory actually needs to be used, it's loaded or mapped to the real, physical memory of the host and becomes resident. Physical memory is the DRAM memory installed on the host. On most SAP HANA hosts, it ranges from 256 gigabytes (GB) to 1 terabyte (TB). It's used to run the Linux operating system, SAP HANA, and all other programs.

Resident memory is the physical memory actually in operational use by a process. Over time, the operating system may swap out some of a process's resident memory according to a least-recently-used algorithm to make room for other code or data. Thus, a process's resident memory size may fluctuate independently of its virtual memory size. In a properly sized SAP HANA appliance, there's enough physical memory so that swapping is disabled and isn't observed.

This memory usage can be illustrated as follows:

On a typical SAP HANA appliance, the resident memory part of the operating system and all other running programs usually doesn't exceed 2 GB. The rest of the memory is therefore dedicated for the use of SAP HANA.

When memory is required for table growth or for temporary computations, the SAP HANA code obtains it from the existing memory pool. When the pool can't satisfy the request, the SAP HANA memory manager requests and reserves more memory from the operating system. At this point, the virtual memory size of SAP HANA processes grows.

Once a temporary computation completes or a table is dropped, the freed memory is returned to the memory manager, which recycles it to its pool without informing the operating system. Therefore, from SAP HANA's perspective, the amount of used memory shrinks, but the processes' virtual and resident memory sizes aren't affected. This creates a situation where the used memory value can shrink to below the size of SAP HANA's resident memory, which is normal.

#### **i Note**

The memory manager can also choose to return memory back to the operating system, for example when the pool is close to the allocation limit and contains large unused parts.

## **Related Information**

[SAP HANA Used Memory \[page 510\]](#)

[Memory Sizing \[page 513\]](#)

[Allocated Memory Pools and Allocation Limits \[page 514\]](#)

## **6.8.6 Change the Global Memory Allocation Limit**

SAP HANA preallocates a pool of memory from the operating system over time, up to a predefined global allocation limit. You can change the default global allocation limit.

### **Prerequisites**

You have the system privilege INIFILE ADMIN.

### **Context**

The `global_allocation_limit` parameter is used to limit the amount of memory that can be used by SAP HANA. The unit for this parameter is MB. The default value is 0 in which case the global allocation limit is calculated as follows: 90% of the first 64 GB of available physical memory on the host plus 97% of each further GB. Or, in the case of small physical memory, physical memory minus 1 GB. Alternatively, you can define this limit as a flexible percentage of the available main memory size. If you enter a percentage value the precise value of the limit will be calculated automatically by the system. Moreover, if you then change the size of the container where the system runs the allocation limit will automatically adjust to the correct percentage of the new container size.

Changing this parameter does not require a restart.

## Procedure

In the `global.ini` configuration file change the value of the `global_allocation_limit` in the `memorymanager` section.

You can enter a value for the entire system and, for distributed multiple-host systems, for individual hosts. If you enter only a value for the system, it is used for all hosts. For example, if you have 5 hosts and you set the limit to 5 GB, the system can use up to 5 GB on each host (25 GB in total). If you enter a value for a specific host, then for that host, the specific value is used and the system value is only used for all other hosts.

Refer to the *Workload Management* section for details of other options for managing memory including setting a statement limit and admission control.

## 6.9 Persistent Data Storage in the SAP HANA Database

Persistent storage media are required for ongoing save operations for data and redo log files.

To protect data from the risk of memory failure SAP HANA persists in-memory data to storage media and flushes all changed data from memory to the data volumes. This operation takes place on the basis of savepoints which occur by default every 5 minutes.

Customers have a choice of storage media types: in addition to conventional hard disk storage, non-volatile RAM is also supported for data storage, specifically, for the MAIN fragment of column store tables. For more information about the MAIN and DELTA fragments of tables refer to Delta Merge.

The following subsections describe how these types of persistence work and how they must be configured for use. The two storage types operate in a similar way but there are some essential differences and a separate section is dedicated to each type.

## Related Information

[The Delta Merge Operation \[page 621\]](#)

## 6.9.1 Data and Log Volumes

To ensure that the database can always be restored to its most recent committed state, changes to data in the database are periodically copied to disk, logs containing data changes and certain transaction events are also saved regularly to disk. Data and logs of a system are stored in volumes.

SAP HANA persists in-memory data by using savepoints. Each SAP HANA service has its own separate savepoints. During a savepoint operation, the SAP HANA database flushes all changed data from memory to the data volumes. The data belonging to a savepoint represents a consistent state of the data on disk and remains so until the next savepoint operation has completed. Redo log entries are written to the log volumes for all changes to persistent data. In the event of a database restart (for example, after a crash), the data from the last completed savepoint can be read from the data volumes, and the redo log entries written to the log volumes since the last savepoint can be replayed.

The frequency at which savepoints are defined can be configured in the `persistence` section of the `global.ini` file (every 5 minutes by default). Savepoints are also triggered automatically by a number of other operations such as data backup, and database shutdown and restart. You can trigger a savepoint manually by executing the following statement `ALTER SYSTEM SAVEPOINT`.

You must always ensure that there is enough space on the disk to save data and logs. Otherwise, a disk-full event will occur and the database will stop working.

### Directory Hierarchy for Data and Log Storage

During the installation process, the following default directories are created as the storage locations for data and log volumes:

- `/usr/sap/<SID>/SYS/global/hdb/data`
- `/usr/sap/<SID>/SYS/global/hdb/log`

#### i Note

These default directories are defined in the parameters `basepath_datavolumes` and `basepath_logvolmes` in the `persistence` section of the `global.ini` file.

These directories contain a series of sub-directories to store data for each of the following:

Host	Named <code>mnt00001</code> , <code>mnt00002</code> , <code>mnt00003</code> ... by default.
Tenant database	"DB_" + <database name>
Database service	Named <code>hdb00001</code> , <code>hdb00002</code> , <code>hdb00003</code> ... by default.
Replica volume	A separate persistence for each replica volume; the subdirectory is the numerical Replica ID value.

Example of a data subdirectory for a tenant database named "M90" (see also the following illustration):

```
/usr/sap/DB1/SYS/global/hdb/data/mnt00001/DB_M90/hdb00002/00001/
```

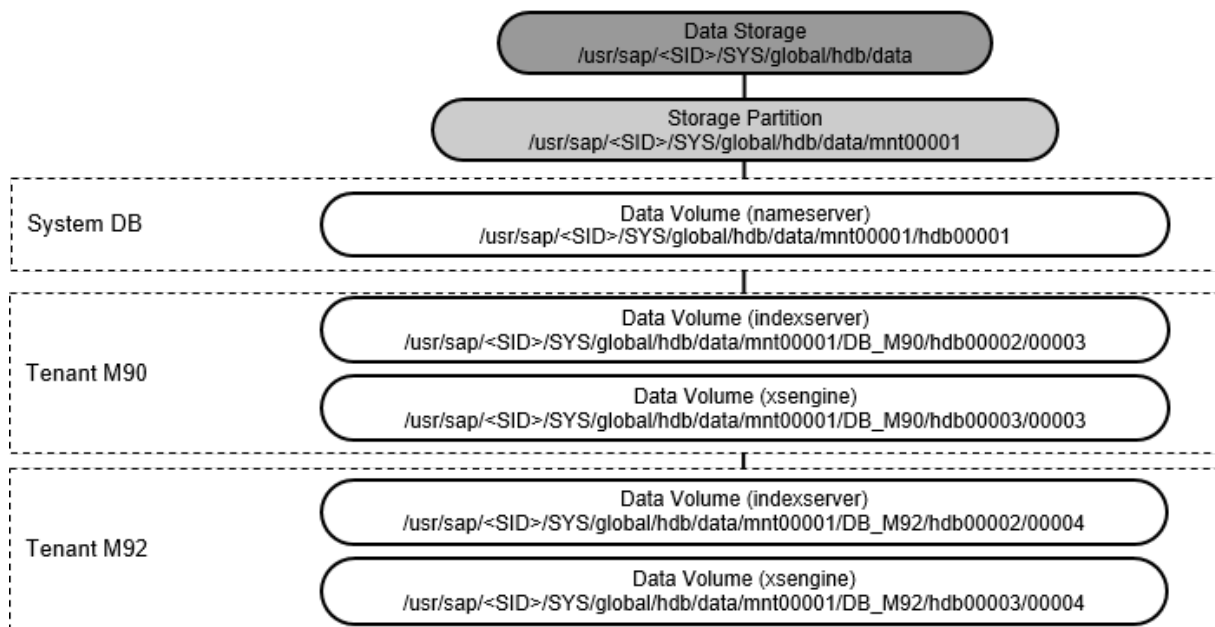

The services that persist data and therefore have volumes are the following:

Service	Note
nameserver	Only the nameserver service in the system database on the active master host persists data. Slave nameserver hosts communicate with the master, but do not persist data.
indexserver	The indexserver service in tenant databases on all hosts except standby hosts persists data. This data volume can be partitioned to improve performance when reading and writing to this server.
xsengine (if running as a separate service)	The xsengine service persists data on any host on which it is running.

The following figure illustrates the default storage hierarchy described above using the example of data storage. The system is a replication system with two tenant databases on a single host.

Directory Hierarchy for Persistent Data Storage

## Data and Log Volumes

### Data Volumes

By default each data volume contains one file (`datavolume_0000.dat`) in which data is organized into pages, ranging in size from 4KB to 16MB (page size class). Data is written to and loaded from the data volume page-wise. Over time, pages are created, changed, overwritten, and deleted. The size of the data file is automatically increased as more space is required. However, it is not automatically decreased when less space is required. This means that at any given time, the actual payload of a data volume (that is the cumulative size of the pages currently in use) may be less than its total size. This is not necessarily significant – it simply means that the amount of data in the file is currently less than at some point in the past (for example, after a large data load). The `Total Size` and the `Fill Ratio` values in the monitoring view `M_DATA_VOLUME_STATISTICS` give details about capacity.

If a data volume has a considerable amount of free space, it might be appropriate to shrink the data volume. However, a data file that is excessively large for its typical payload can also indicate a more serious problem with the database. SAP support can help you analyze your situation.

The indexserver data volume can be partitioned so that data can be segmented and distributed over several *stripes* on the disk to improve performance. SQL commands are available to create and drop partitions, a numeric partition ID value is assigned automatically by the system. In this case, the volume ID and an offset value to identify the stripe where the data is saved are included in the volume file name (datavolume\_nnnn\_<offset>.dat). See *Partitioning Data Volumes* for details.

## Log Volumes

Each log volume contains the file `logsegment_<partition_ID>_directory.dat` and one or more log segment files (`logsegment_<partition_ID>_<segment_number>.dat`). Currently only one log partition is supported for each service, so the default file names are `logsegment_000_directory.dat` and `logsegment_000_00000000.dat`, `logsegment_000_00000001.dat`, `logsegment_000_00000002.dat` and so on. Log segment files are cyclically overwritten depending on the log mode. The log mode determines how logs are backed up. Log volumes only grow if there are no more segment files available for overwriting. Log segment files that are available for overwriting have been backed up and are not required for a database restart. If necessary you can remove these files to free up space in your file system by executing the SQL statement `ALTER SYSTEM RECLAIM LOG`. Note that new log segment files will need to be created later and this will affect performance.

You can monitor disk usage in SAP HANA cockpit using the Disk Usage and Performance Monitor apps. See *Monitoring Disk Space* and *Monitoring in SAP HANA Cockpit* for details.

### ⚠ Caution

Do not remove either data files or log files using operating system tools as this will corrupt the database.

## Multiple Files in Data Volumes for Ext3 File Systems

The Ext3 file system has a file size limitation of 2TB. If the existing files in a data volume located in an Ext3 file system reach the 2 TB limit, SAP HANA automatically creates additional files. This allows the use of Ext3 file systems even with applications (in particular, single-host SAP ERP systems) that have a larger memory requirement per host.

For more information about splitting data backups into files of limited size, see the section on data backups.

## Related Information

## 6.9.2 Partitioning Data Volumes

Data volumes on the indexserver can be partitioned so that read and write operations can run in parallel with increased data throughput. Additionally, you can partition data volumes on remote system replication hosts.

### Creating Partitions

Each SAP HANA service has one data volume which by default stores its data in one single file. Administrators have the option to partition the data volume for the indexserver so that data files can be segmented and stored in different locations and can then be accessed in parallel threads. In the case of Network File Systems data can also be written in parallel across multiple connections. Partitioning data volumes in this way will therefore speed up all read/write operations on the volume including savepoints, merges, restart, table loading operations, and backups.

#### i Note

For EXT\* and XFS file systems the problem of excessively large file sizes in relation to large data volumes is overcome by striping. These file systems have a maximum size of 2TB for each physical file and the persistency layer automatically chooses appropriate striping sizes for these file systems. You can define a maximum file size for stripes using the striping configuration parameters in the persistence section of the indexserver.ini file: `datavolume_striping` (TRUE / FALSE), and `datavolume_striping_size_gb` (a value between 100 and 2000GB).

If you create a new partition on the index server it is added simultaneously to all indexservers in the topology. New partitions become active after the next savepoint on each indexserver, this is shown in the partition STATE value which changes from ACTIVATING to ACTIVE. By default all data volumes have a single partition with the numeric ID zero. A numeric partition ID is assigned automatically to new partitions by the HANA persistency layer. If the partition numbering is for any reason inconsistent across all indexservers then any attempt to add new partitions will fail.

By default the basepath for data volume partitions is `/usr/sap/<SID>/SYS/global/hdb/data`, however, you can also add partitions in a specified path of your own choice (see examples below using the ADD PARTITION PATH syntax). The path must be reachable by all nodes or services in the topology. Beneath the specified path the standard folder structure is created automatically with a numbered folder for each host. A user-defined path is required, for example, if you are using multiple NFS connections so that data can be written in parallel to different paths. This option must be explicitly enabled by setting the `PERSISTENCE_DATAVOLUME_PARTITION_MULTIPATH` parameter in the `customizable_functionalities` section of `global.ini` to TRUE.

The partition basepath is saved in the `indexserver.ini` configuration file in the `basepath_datavolume` key of the `partition ID` section.

**Data Volumes for System Replication** A further possibility is to specify the id of a host used for system replication; the site can be identified by name or numerical ID. This makes it possible to replicate data to a specific partition. Examples of these options using the SYSTEM REPLICATION SITE syntax are given below.

## Example SQL Statements

Details of the SQL statements to manage data volume partitions are given in the *SAP HANA SQL and System Views Reference*, the two main statements to add and drop partitions are shown here. If you execute the command to add a partition on the indexserver it will add a new partition to all indexservers in the topology:

```
ALTER SYSTEM ALTER DATAVOLUME ADD PARTITION
```

You can drop specific data volume partitions by specifying the partition ID number:

```
ALTER SYSTEM ALTER DATAVOLUME DROP PARTITION <id>
```

This command drops the identified partition from all indexservers in the topology. The default partition with ID zero cannot be dropped. If you drop a partition then all data stored in the partition is automatically moved to the remaining partitions and for this reason dropping a partition may take time. This operation also removes the partition entry from the configuration file.

In a running system replication setup, you may not be able to drop an active data volume partition as system replication uses data volume snapshot technology. You may see the following error: *Cannot move page inside/out of DataVolume*. In this case it may be necessary to disable system replication functionality, drop the partition, and then setup system replication again.

The following examples show usage of adding and dropping a replication site by using the SYSTEM REPLICATION SITE syntax:

```
ALTER SYSTEM ALTER DATAVOLUME ADD PARTITION [PATH '<path>'] [SYSTEM REPLICATION SITE <site>]
```

```
ALTER SYSTEM ALTER DATAVOLUME DROP PARTITION <id> [SYSTEM REPLICATION SITE <site>]
```

The value for <site> can be specified as either the site name as a string value or the numeric SAP HANA system replication site id value.

## Monitoring Views

You can see the current data volume configuration from the following two views:

- **M\_DATA\_VOLUME\_STATISTICS**: This provides statistics for the data volume partitions on the indexserver including the number of partitions and size.
- **M\_DATA\_VOLUME\_PARTITION\_STATISTICS**: This view provides statistics for the individual partitions, identified by **PARTITION\_ID**, and includes the partition **STATE** value.

In a replication scenario you can monitor the **M\_DATA\_VOLUME\_PARTITION\_STATISTICS** view on the secondary via proxy schema **SYS\_SR\_SITE<siteName>** (where <siteName> is the name of the secondary site).

## 6.9.3 Persistent Memory

Persistent memory (non-volatile RAM, also referred to as Storage Class Memory) is supported in SAP HANA as a persistent storage type.

Persistent memory (or NVRAM) is an emerging class of memory that combines the qualities of both DRAM and Flash storage and bridges the gap between disk storage and main memory. For the purposes of SAP HANA, its most important characteristics are that it's byte addressable like DRAM and can be treated by the CPU as RAM, offering fast read and write performance; its latency characteristics are also very close to DRAM.

The latest information about this feature, such as hardware availability and operating system support, is provided in SAP Note 2618154 *SAP HANA Persistent Memory (NVM)*.

The persistent storage functions as DRAM memory and is used specifically for MAIN data fragments of the column store where approximately 90% of the data of a table is held. In this way, DELTA data can continue to be stored in DRAM (a relatively small quantity of data requiring the fastest possible access) with the MAIN segment of a table in NVRAM. Note that if persistent memory storage is enabled, data is still written to the data volumes but is ignored. After a system restart, the main data fragments saved in persistent storage are still available in memory and don't have to be reloaded. This storage type has no impact on backup and recovery or high availability processes.

As with the data volume persistent storage feature, data is persisted on the basis of savepoints. In the case of non-volatile memory storage, NVM blocks are constructed whenever the in-memory MAIN fragment is created and are kept consistent according to HANA's savepoints.

The key performance benefit is in greatly accelerated start-up times so that data can be quickly reloaded into memory and any system downtime can be minimized. Other benefits can include higher memory capacities per server.

Performance differences of this storage type compared to DRAM due to higher latency are mitigated by features such as hardware prefetchers. It's also possible to enable persistent memory storage for selected tables or for specific columns of a table so that a selective implementation of this storage type is possible (see the Configuration section).

### Installation

The persistent memory feature can be set up during system installation using the SAP HANA database lifecycle manager (HDBLCM). The lifecycle manager uses two parameters to enable persistent memory (`use_pmem`) and the `pmempath` parameter to set the basepath (see the Configuration section). For more information on lifecycle manager, refer to the *SAP HANA Server Installation and Update Guide*.

At the level of the Linux operating system, SAP HANA only supports DAX enabled (Direct Access) file systems.

### Filesystem layout of persistent memory block storage

The directory specified as the basepath (see Configuration) is the root persistent memory storage directory beneath which data for each savepoint is stored. The structure beneath the basepath is maintained by HANA and no attempt should be made to modify this content. Multiple logical versions of blocks are saved and are organized in subdirectories named on the basis of, for example, service name, Volume ID and current savepoint version. There are two subdirectory systems, one for data and one for deletion requests: the memory storage persistence maintains a history of requests to delete blocks in a *tombstones* directory parallel to the *data* directory. In the case of tombstone blocks, the savepoint version relates to the savepoint when the data block was requested for deletion.

## Configuration

The default behavior for using persistent memory is determined automatically: the system tests for the DAX filesystem at the defined persistent memory basepath. If the hardware is installed and the basepath correctly configured pointing to the persistent memory mount, then alltables use persistent memory by default. The SAP HANA installer sets the persistent memory basepath parameter if it's able to identify the DAX filesystem and if the user of the installation tool confirms the usage; the basepath parameter can also be set manually if necessary.

This default behavior can be overridden at four levels in the sequence shown here:

4	Database	Can be enabled or disabled by configuration parameter.
3	Table	Can be enabled or disabled by SQL statement.
2	Partition	Can be enabled or disabled by SQL statement.
1	Column	Can be enabled or disabled by SQL statement.

This level of granularity offers a high degree of flexibility: if persistent memory is applied at a certain level it's automatically inherited at lower levels of the sequence but can also be overridden at lower levels.

At the highest configuration level (database), persistent memory is managed by setting the `table_default` configuration parameter for the database as a whole. You can switch `table_default` to OFF to enable more selective persistent memory storage at lower levels for particular tables and partitions.

At other levels, persistent memory is managed at the SQL command line using the `alter_persistent_memory_spec` clause with the CREATE / ALTER table commands. Here, we give examples to show how it can be applied at each level; refer to the SAP HANA SQL Reference Guide for full details of this clause.

### Configuration Parameter: Basepath

As with the other data and log persistent storage volumes and also the fast restart option (tmpfs), the storage location basepath for persistent memory storage must be defined as a configuration parameter in the `persistence` section of the `global.ini` file. Enter the basepath location in the following parameter:

Parameter	<code>basepath_persistent_memory_volumes</code>
Short Description	Location of NVRAM storage.
Full Description	Data for NVRAM-enabled tables or columns is stored at the location defined in this parameter. Multiple locations can be defined here using a semicolon as a separator (no spaces). Multiple paths correspond to NUMA nodes without any ordering restriction in terms of NUMA node mapping, for example, for a four-NUMA node system: <code>"/mnt/pm0;/mnt/pm1;/mnt/pm4;/mnt/pm2"</code>
Type	Text
Change	Restart required (offline changeable only)
Default	Blank

Parameter	basepath_persistent_memory_volumes
Layer Restriction	HOST - can only be set at the HOST level.

## Configuration Parameter: Enable persistent memory storage

The `table_default` parameter is in the `persistent_memory` section of the `indexserver.ini` file.

Parameter	table_default
Short Description	Enable or disable persistent memory storage for the database generally.
Full Description	This parameter can be set to ON or OFF or DEFAULT (no explicit preference, follow the existing default behavior). The setting applies for the complete database but can be overridden by settings applied at a lower level.
Change	Online
Default	DEFAULT

## SQL Alter Persistent Memory Clause

Persistent memory can be enabled by SQL command using the `alter_persistent_memory_spec` clause with CREATE and ALTER table. This command can be used at any of the three levels (table, partition, or column) to enable or disable persistent memory storage using the PERSISTENT MEMORY switch. The following examples illustrate this method using CREATE TABLE.

**Example 1:** Create table with persistent memory storage enabled for the new table.

```
CREATE COLUMN TABLE PMTABLE (C1 INT, C2 VARCHAR (10)) PERSISTENT MEMORY ON
```

PERSISTENT MEMORY can be set to ON, OFF, or DEFAULT meaning no preference.

**Example 2:** Create range-partitioned table with persistent memory storage for a selected partition (only valid for range partitions):

```
CREATE COLUMN TABLE PMTABLE (C1 INT) PARTITION BY RANGE (C1) (
    PARTITION '0' <= VALUES < '10' PERSISTENT MEMORY ON,
    PARTITION OTHERS PERSISTENT MEMORY OFF);
```

**Example 3:** Create table with persistent memory storage applied to selected columns of a table:

```
CREATE COLUMN TABLE PMTABLE (C1 INT PERSISTENT MEMORY ON, C2 VARCHAR (10), C3
INT PERSISTENT MEMORY OFF)
```

For ALTER TABLE, a preference value is also required (in addition to the ON/OFF switch) to determine how the change is applied. This clause is the `alter_persistent_memory_preference` clause that requires one (or more) of the following keywords:

- IMMEDIATE - the change is applied immediately and the specified storage is populated.
- DEFERRED - the specified storage will be populated at the time of the next delta merge or reload.
- CASCADE - this keyword can be used at table level in addition to IMMEDIATE and DEFERRED to apply the change to all lower levels of the hierarchy.

The following example shows this usage with ALTER TABLE and cascades the change immediately to partitions and columns of the named table:

```
ALTER TABLE MYTABLE PERSISTENT MEMORY ON IMMEDIATE CASCADE
```

## Unloading Tables from Memory

The standard UNLOAD statement, and also table unloads, executed implicitly by HANA services due to memory running low, don't by default free the memory but simply remove the mapping of relevant data structures from the HANA service process address space and the MAIN data fragment remains; this applies to both persistent memory and the fast restart option (tmpfs). The configuration parameter `table_unload_action` in the [persistent\_memory] section of the `indexserver.ini` file can be used to control this unload behavior. The default value of the parameter is RETAIN but this can be set to DELETE in which case MAIN data fragments are cleared from memory.

Regardless of the setting of this parameter, you can also use UNLOAD with the additional DELETE PERSISTENT MEMORY clause to free memory, for example:

```
UNLOAD FRAOTABLE DELETE PERSISTENT MEMORY;
```

## Monitoring Views

For full details of the monitoring views and values named here, refer to the *SAP HANA SQL and System Views Reference*.

The following monitoring views show information about persistent memory in the PERSISTENT\_MEMORY column: M\_CS\_TABLES, M\_CS\_COLUMNS and M\_CS\_ALL\_COLUMNS. This information shows either TRUE (persistent memory is enabled) or FALSE.

At the level of tables (M\_CS\_TABLES), usage information is shown as PERSISTENT\_MEMORY\_SIZE\_IN\_TOTAL.

At the level of columns (M\_CS\_COLUMNS and M\_CS\_ALL\_COLUMNS) usage information is shown in a series of columns named: MAIN\_PERSISTENT\_MEMORY\_SIZE\_IN\_\*. These columns show usage in the categories DATA, DICT, INDEX, MISC, and UNUSED. These column views also include STORED\_IN\_PERSISTENT\_MEMORY and LOADED\_FROM\_PERSISTENT\_MEMORY, both TRUE/FALSE values.

Three monitoring views show full statistical details of persistent memory usage:

- M\_PERSISTENT\_MEMORY\_VOLUMES - capacity, usage, and metadata of persistent memory volumes configured per NUMA Node.
- M\_PERSISTENT\_MEMORY\_VOLUME\_DATA\_FILES - metadata statistics about files created by SAP HANA services for data storage on the persistent memory volumes.
- M\_PERSISTENT\_MEMORY\_VOLUME\_STATISTICS - statistics of physical lifecycle events of blocks managed by SAP HANA services on the persistent memory volumes.

The view M\_TABLE\_PERSISTENT\_MEMORY\_FILES shows persistent memory file information for all of the tables, partitions, and columns in the database.

Statistics server collectors save historic information in the following statistics views:

- `_SYS_STATISTICS.HOST_PERSISTENT_MEMORY_VOLUMES` - reports the capacity, usage, and metadata of persistent memory volumes.
- `_SYS_STATISTICS.HOST_PERSISTENT_MEMORY_VOLUME_STATISTICS` - reports the statistics of physical lifecycle events of blocks managed by SAP HANA services on the persistent memory volumes.

[SAP HANA Fast Restart Option](#)

### 6.9.4 SAP HANA Fast Restart Option

The SAP HANA Fast Restart option uses storage in the file system to preserve and reuse MAIN data fragments to speed up SAP HANA restarts. This is effective in cases where the operating system is not restarted.

The SAP HANA Fast Restart option makes it possible to reuse MAIN data fragments after an SAP HANA service restart without the need to re-load the MAIN data from the persistent storage. It leverages the SAP HANA Persistent Memory implementation with the key performance benefit of greatly accelerated start-up times so that data can be quickly reloaded into memory and system downtimes can be minimized. In contrast to Persistent Memory which works with a DAX enabled file system, the Fast Restart option stores MAIN data fragments in tmpfs file systems with content in DRAM. Tmpfs file systems can grow and shrink dynamically.

The Fast Restart option can be used with all supported SAP HANA hardware platforms and all supported operating system versions. The HANA online performance and sizing KPIs are not impacted.

#### Comparison of Persistent Memory and File System Storage

The Fast Restart option is a bridge technology for environments where servers with Persistent Memory are not available. It provides less downtime but not the cost efficiency which can be gained with Persistent Memory. The following table compares the two features and indicates in which cases in-memory data of MAIN data fragments can be reused without reading the data from the persistent storage.

Scenario	Persistent Memory	Fast Restart Option
HANA restart	Yes	Yes
HANA service restart	Yes	Yes
HANA upgrade/service patch	Yes	Yes
Operating system update/service patch	Yes	No
Server reboot (planned)	Yes	No

Scenario	Persistent Memory	Fast Restart Option
Server reboot (HW failure)	Yes	No
Power outage	Yes	No
BIOS/firmware update	Yes	No
HW upgrade w/o Persistent Memory replacement	Yes	No

## Preparation

To use this feature you must create a mount on the tmpfs file system for each NUMA node and HANA instance and set the basepath parameter to identify these locations (see *Configuration* below).

Firstly, use the following command to determine the number of CPU sockets available in the HANA server:

```
> cat /sys/devices/system/node/node*/meminfo | grep MemTotal | awk 'BEGIN
{printf "%10s | %20s\n", "NUMA NODE", "MEMORY GB"; while (i++ < 33) printf "-";
printf "\n"} {printf "%10d | %20.3f\n", $2, $4/1048576}'
```

This returns the node details, for example, two nodes numbered zero and one:

```
NUMA NODE |          MEMORY GB
-----|-----
      0 |          376.638
      1 |          376.514
```

Make a directory and mount for each node equipped with memory making sure that all tmpfs mounts have preferred NUMA policy, for example:

```
> mkdir -p /hana/tmpfs0/<SID>
> mount tmpfs<SID>0 -t tmpfs -o mpol=prefer:0 /hana/tmpfs0/<SID>
> mkdir -p /hana/tmpfs1/<SID>
> mount tmpfs<SID>1 -t tmpfs -o mpol=prefer:1 /hana/tmpfs1/<SID>
```

Allow access to the directories:

```
> chown -R <SID>adm:sapsys /hana/tmpfs*/<SID>
> chmod 777 -R /hana/tmpfs*/<SID>
```

If you want to limit the size of these mounts you may use the SIZE option of the mount command, for example:

```
mount tmpfs<SID>0 -t tmpfs -o mpol=prefer:0,size=250G /hana/tmpfs0/<SID>
```

To ensure that the mount points are available after an operating system reboot you must also add entries into the file system table, for example: `/etc/fstab`:

```
> tmpfs<sid>0 /hana/tmpfs0/<sid> tmpfs rw,relatime,mpol=prefer:0 0 0
> tmpfs<sid>1 /hana/tmpfs1/<sid> tmpfs rw,relatime,mpol=prefer:1 0 0
```

## Configuration

**Basepath** As with the other existing data and log persistent storage volumes, for MAIN data fragments the in-memory storage location basepath must be defined as a configuration parameter in the [persistence] section of the global.ini file. Enter the basepath location in the `basepath_persistent_memory_volumes` parameter (this parameter can only be set at the level of HOST). All MAIN data fragments are stored at the location defined here. Multiple locations corresponding to NUMA nodes can be defined using a semi-colon as a separator (no spaces), for example:

```
/hana/tmpfs0/<SID>;/hana/tmpfs1/<SID>
```

See also the *Persistent Memory* topic where the same basepath parameter is used.

**Enablement for Partitions, Tables or Columns** You can determine storage preferences for Fast Restart in the same way as for Persistent Memory by using the SQL CREATE and ALTER table statements with the `alter_persistent_memory_spec` clause.

Refer to the examples in *Persistent Memory* for details.

**Global allocation limit** As an alternative to setting a limit on the size of each mount as described above, overall tmpfs memory usage for all NUMA nodes for a given HANA instance and a given server node can be limited by setting the `persistent_memory_global_allocation_limit` parameter in the [memorymanager] section of the global.ini file. By default, no limit is specified: enter a value in MB to set a limit on the size of the used tmpfs space for each host. Note that when decreasing this value NVM blocks are not automatically deleted, it is still necessary to actively manage how tables are unloaded from memory as described in the following paragraphs on Unloading Tables from Memory.

## Unloading Tables from Memory

The standard UNLOAD statement and also table unloads executed implicitly by HANA services due to memory running low, do not by default free the memory but simply remove the mapping of relevant data structures from the HANA service process address space and the MAIN data fragment remains - either in persistent memory or in tmpfs. The configuration parameter `table_unload_action` in the [persistent\_memory] section of the indexserver.ini file can be used to control this unload behavior. The default value of the parameter for tmpfs is DELETE in which case MAIN data fragments are cleared from tmpfs, but this can be set to RETAIN if required.

Regardless of the setting of this parameter, you can also use UNLOAD with the additional DELETE PERSISTENT MEMORY clause to completely free memory, for example:

```
UNLOAD MYTABLE01 DELETE PERSISTENT MEMORY;
```

If you wish to limit the size of this main memory storage you can decrease the tmpfs file system size or use the parameter `persistent_memory_global_allocation_limit` to restrict the used tmpfs size.

## Monitoring Views

The same monitoring views used by persistent memory are also used by the Fast Restart feature (see *Persistent Memory*). For example, the `PERSISTENT_MEMORY` column in `M_CS_TABLES`, `M_CS_COLUMNS` and `M_CS_ALL_COLUMNS` shows `TRUE` if real persistent memory or `tmpfs` is enabled.

For full details of the monitoring views refer to the *SAP HANA SQL and System Views Reference*.

## 6.9.5 Persistence Consistency Check

A command-line diagnosis tool is available to analyze physical corruptions of the persistent storage.

The persistence checking tool, `hdbpersdiag`, can be used to carry out page consistency checks on storage snapshot backups of SAP HANA data volumes. You can use the basic 'check all' option of the tool to verify the healthy state of data volumes. If problems occur, the tool may help to identify the cause so that an effective solution can be quickly adopted. Contact SAP Support if necessary; support staff may use the more advanced options of the tool to analyze problems in greater detail.

It is possible that although pages of data were correctly written to disk (which is guaranteed by SAP HANA verification using checksums) data is corrupted on the disk and errors occur as data from the storage snapshot backup is loaded. Errors may be related to an incorrect checksum value or to an incorrect savepoint version, for example:

```
Wrong checksum: Calculated <calc_checksum>, stored <act_checksum>.;  
$lpno$=<log_pageno>; $ppno$=<phys_pageno>
```

### Using the `hdbpersdiag` Tool

The tool, `hdbpersdiag`, is independent of the SAP HANA native backup process and is delivered as part of the standard installation in the following directory:

```
/usr/sap/<sid>/HDB<inst_id>/exe
```

You can run the tool and execute the 'check all' option which checks all pages for the given data volume path. Note that the data volume must not be currently in use by HANA:

```
hdbpersdiag  
check all <data_volume_path>
```

From the output, it may be possible to determine the name of the table(s) which are affected. Possible actions to restore the table include recovering the corrupt page from the trace directory, merging with the data still in memory, deleting a corrupted table or deleting corrupted rows. In a high availability scenario where system replication is in place it may be possible to simply perform a takeover to a secondary or tertiary site to avoid the need to restore data from a corrupt data volume.

Full details of using the tool and examples are given in SAP Note 2272121 – *How-To: Analyzing Physical Corruptions with the SAP HANA Persistence Diagnosis Tool*.

## 6.10 Data Tiering

SAP HANA offers various software solutions to intelligently manage multi-temperature data which brings advantages for performance, economy, and security.

Data tiering is the assignment of data to different storage and processing tiers based on the aging characteristics of the data. The tiered storage options available in SAP HANA to manage multi-temperature data (hot, warm, and cold) are introduced briefly here.

For hot data, non-volatile memory (persistent memory) can be used. This has a lower TCO than DRAM memory and can be added to SAP HANA to expand overall memory capacity and increase the volume of hot data that can be stored in-memory. Data in persistent memory is saved after a system shutdown so database startup times are faster since data does not need to be loaded into memory from disk.

For warm data SAP HANA native storage extension is a general-purpose, built-in warm data store in SAP HANA that lets you manage less-frequently accessed data without fully loading it into memory.

SAP HANA dynamic tiering is an optional add-on to the SAP HANA database. It extends SAP HANA memory by providing the ability to create, query, and load warm data into disk-based, columnar database tables (called extended tables and multistore tables).

An Extension Node is a dedicated HANA in-memory node for warm data processing that allows the SAP HANA database system to scale out at a lower cost and is appropriate for both SAP BW and native SAP HANA applications. The Extension Node is an additional SAP HANA node with relaxed memory and CPU requirements but with the same functionality as a pure SAP HANA node.

Cold data can be stored on the lowest cost storage tiers but still remain accessible to SAP HANA via SQL on request. The cold data tier for native SAP HANA applications and SAP Business Warehouse (SAP BW) applications is managed by SAP Data Hub or the SAP HANA Spark Controller, for storage in Data Hub or Hadoop. For more information on cold data tiering in SAP HANA refer to:

- [SAP HANA Data Warehousing Foundation - Data Lifecycle Manager Guide for XSC](#)
- [SAP HANA Data Warehousing Foundation Data Lifecycle Manager Guide for XSA](#)

## Related Information

[Extension Node \[page 566\]](#)

[Persistent Memory \[page 525\]](#)

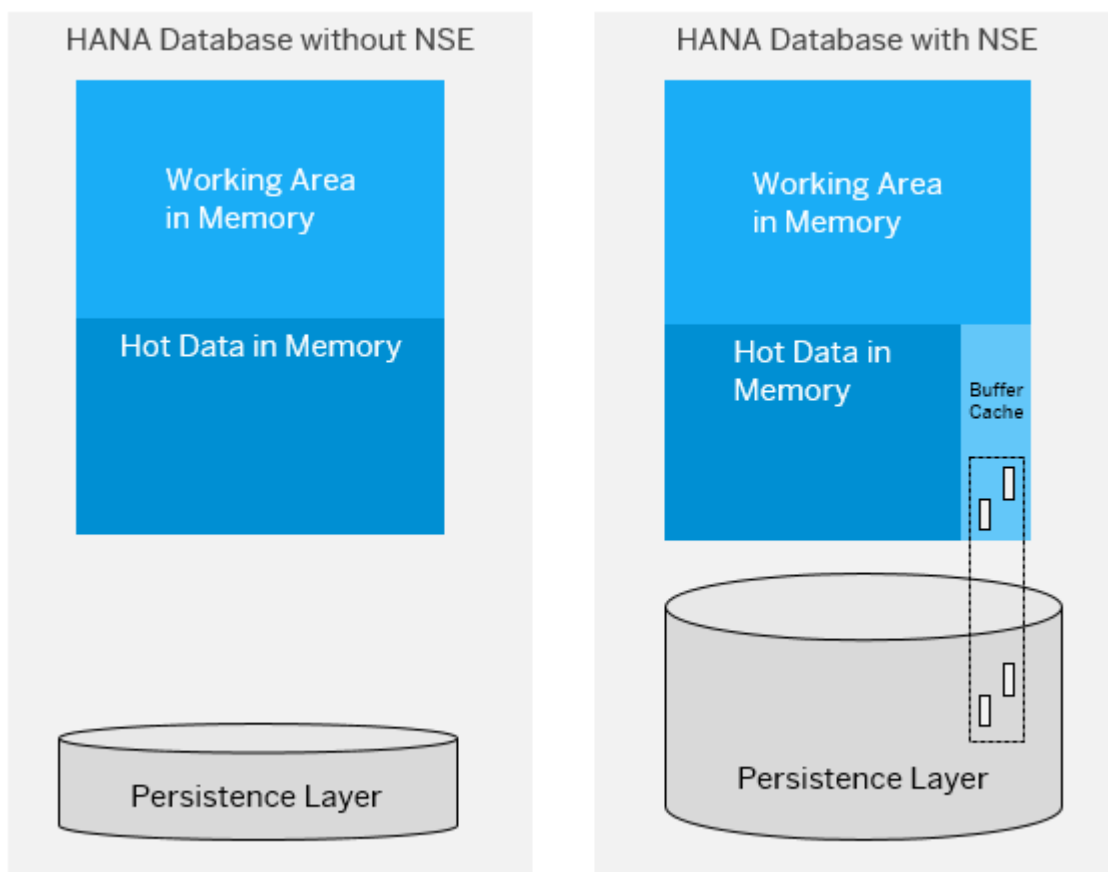

## 6.10.1 SAP HANA Native Storage Extension

SAP HANA Native Storage Extension (NSE) is a general-purpose, built-in warm data store in SAP HANA that lets you manage less-frequently accessed data without fully loading it into memory. It integrates disk-based or flash-drive based database technology with the SAP HANA in-memory database for an improved price-performance ratio.

SAP HANA offers various software solutions to manage multi-temperature data (hot, warm, and cold), such as DRAMs for hot data and SAP HANA Extension Nodes, SAP HANA dynamic tiering for warm data, and SAP HANA Cold Data Tiering for cold data.

- Hot data is used to store mission-critical data for real-time processing and analytics. It is retained continuously in SAP HANA memory for fast performance, and is located in the highest performance (and highest TCO) storage.
- Warm data is primarily used to store mostly read-only data that need not be accessed frequently. The data need not reside continuously in SAP HANA memory, but is still managed as a unified part of the SAP HANA database — transactionally consistent with hot data, and participating in SAP HANA backup and system replication operations, and is stored in lower cost stores within SAP HANA.
- Cold data is used to store read-only data, with very infrequent access requirements. You manage cold data separately from the SAP HANA database, but you can still access it from SAP HANA using SAP HANA's data federation capabilities.

This image shows the difference between standard HANA in-memory storage and the storage offered with NSE:

The capacity of a standard SAP HANA database is equal to the amount of hot data in memory. However, the capacity of a SAP HANA database with NSE is the amount of hot data in memory plus the amount of warm data on disk.

Since growth in data volume results in increased hardware costs, the ability to decouple data location from a fixed storage location (layer) is one of the key themes of a multi-temperature data storage strategy.

NSE is integrated with other SAP HANA functional layers, such as query optimizer, query execution engine, column store, and persistence layers. Key highlights of NSE are:

- A substantial increase in SAP HANA data capacity, with good performance for high-data volumes.
- The ability to co-exist with the SAP HANA in-memory column store, preserving SAP HANA memory performance.
- An enhancement of existing in-market paging capabilities by supporting compression, dictionary support, and partitioning.
- An intelligent buffer cache that manages memory pages in SAP HANA native storage extension column store tables.
- The ability to monitor and manage buffer cache statistics via system views.
- The ability to support any SAP HANA application.
- A simple system landscape with high scalability that covers a large spectrum of data sizes.

- An advisor that collects object access statistics and provides column store object load unit recommendations.

#### → Remember

- The NSE feature in SAP HANA does not require you to modify your applications.
- Although SAP HANA 2.0 calculates 10% of memory for the buffer cache by default, this memory is only reserved and not allocated. SAP HANA accesses 100% of its memory (including the 10% reserved for the buffer cache) if you are not using NSE.
- If there are page loadable tables in your current version of SAP HANA and you move to another, later, version, only those tables that were designated as page-loadable in the earlier version use the buffer cache in the later version (up to the limit that was calculated in the original version of SAP HANA you were running).

### 6.10.1.1 How SAP HANA NSE Fits with other Data Tiering Solutions from SAP

SAP HANA Native Storage Extension (NSE) is deeply integrated with the SAP HANA database.

Data tiering is the assignment of data to different storage and processing tiers based on various characteristics of the data (hot, warm, and cold data for these tiering systems). Administrators perform this assignment because ever growing volumes of data demand that it be managed intelligently – for performance, for economy, and for security purposes.

SAP HANA handles hot data very well, using persistent memory (PMEM) to extend the in-memory storage capacity for hot data for on-premises, and using DRAM for on-premises and for SAP HANA-as-a-Service. SAP HANA manages cold data with the SAP HANA cold data tiering solution, which provides persistence capabilities for cold data in external data stores (for example HDFS, Google Cloud storage, S3, and the Azure Data Lake Store), and with Hadoop and Spark as low cost options for on-premise HANA.

SAP HANA NSE integrates disk-based database technology with the SAP HANA in-memory database for an improved cost-to-performance ratio, while complementing other warm data tiering solutions from SAP such as –

- SAP HANA Extension Node: An SAP HANA node dedicated to storing and processing warm data. It can manage a higher data volume than a normal HANA node because the data resides on disk most of the time.
- SAP HANA Dynamic Tiering: Extends SAP HANA memory by providing the ability to create, query, and load data into disk-based, columnar database tables called extended tables and multi-store tables.

NSE complements these other warm-data tiering solutions by adding a native warm data tier to a HANA database, managing page-loadable warm data in the HANA database with expanded disk capacity, and an intelligent buffer cache to transfer pages of data between memory and disk.

## 6.10.1.2 SAP HANA NSE Features

Key capabilities of the SAP HANA native storage extension (NSE) include page loadable objects (that is, data is stored so that individual pages can be loaded) with support for all general data types as well as large object and spatial data.

Additional capabilities of SAP HANA NSE are:

- Paging support: Specify which database tables, partitions, or columns are page loadable with the `CREATE TABLE` and `ALTER TABLE` commands. See [Reduce the Memory Footprint Using Page-Loadable Columns \[page 539\]](#).
- Paging support for inverted indexes: Inverted indexes on column tables (or on constraints that create these indexes) reduce the memory footprint by removing the redundant storage for strings and improve performance by providing faster unique checks. See [Changing the Load Units for Indexes Using ALTER INDEX \[page 546\]](#).
- Paging for dictionaries for columns having any fixed size data type.
- Buffer cache: A portion of the main memory that lets you temporarily store pages and move them between main memory and SAP HANA's persistence layer. The SAP HANA NSE buffer cache replaces the SAP HANA default page replacement model and memory limit mechanism for the memory pages. The buffer cache works with the existing SAP HANA resource and memory manager to implement page management policy. NSE is designed to reduce memory usage for specific columns, partitions, and tables by not requiring those columns to be fully memory-resident. See [SAP HANA NSE Buffer Cache \[page 556\]](#).

### i Note

As a native feature, SAP HANA NSE supports any SAP HANA application. However, existing applications do not automatically use its capabilities, and thus application developers are responsible for making database configuration changes to leverage the NSE feature (such as specifying a load unit in configuration parameters) while creating or altering database tables.

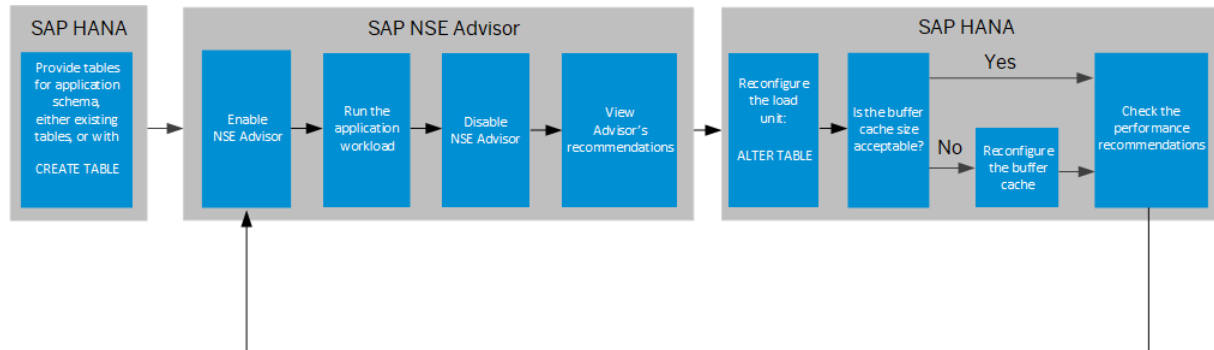

## 6.10.1.3 SAP HANA NSE Functional Restrictions

SAP HANA native storage extension is subject to certain functional restrictions. For details, see the SAP note [2927591](#) – *SAP HANA Native Storage Extension 2.0 SPS 05 Functional Restrictions*.

## 6.10.1.4 Getting Started With SAP HANA NSE

Use the command line or the SAP Cockpit to use SAP HANA NSE.

The steps for configuring SAP HANA for NSE are:

Use this syntax to perform SAP HANA NSE tasks:

Task	Syntax	For more information see:
Set the load unit for columns, tables, and partitions.	<pre>CREATE [ &lt;table_type&gt; ] { &lt;table_name&gt;   &lt;replica_name&gt; } ... &lt;load_unit&gt;</pre> <p>Where:</p> <pre>&lt;load_unit&gt; ::= PAGE LOADABLE   COLUMN LOADABLE</pre>	<ul style="list-style-type: none"> <li>• <a href="#">Setting the Load Unit using CREATE TABLE</a></li> <li>• <a href="#">CREATE TABLE Statement (Data Definition)</a></li> </ul>
Alter the load unit for existing tables, partitions, primary keys, unique constraints, and indexes.	<pre>ALTER TABLE &lt;table_name&gt; ... &lt;load_unit&gt;</pre> <p>Where:</p> <pre>&lt;load_unit&gt; ::= PAGE LOADABLE   COLUMN LOADABLE   DEFAULT LOADABLE</pre>	<ul style="list-style-type: none"> <li>• <a href="#">Changing the Load Unit using ALTER TABLE</a></li> <li>• <a href="#">ALTER TABLE Statement (Data Definition)</a></li> </ul>

### → Remember

The only difference between normal tables and tables in NSE is that in the latter the table is of a paged load unit. To the outside (e.g., to query engines), there is no functional difference, the only difference is in how certain operations perform; for instance, point queries on cold (unloaded columns) may be faster on paged data because only a few pages are brought into memory.

[SAP HANA NSE Buffer Cache \[page 556\]](#)

### 6.10.1.5 Using Indexes in SAP HANA NSE

Indexes are stored on individual columns in a column store in SAP HANA Native Storage Extension (NSE), and contain the same data that is stored in the column, but sorted differently.

Create your indexes using either a PRIMARY KEY or using the CREATE INDEX command. Regardless of the method used, you can create an index on a single column or on multiple columns.

Indexes created on a single column add an inverted index structure to the existing column, and if this column is configured with a paged load unit, the index structure is also paged.

Indexes created over multiple columns include an internal column that materializes the index values, and is paged according to:

- The load unit configuration of the table and partition on which the column resides.
- The load unit explicitly specified by the ALTER INDEX commands used to alter the index. See [ALTER INDEX Statement \(Data Definition\)](#).

This means the sizes of column-store indexes are comparable to the size of the data, so if the data size is larger and needs to be paged, you can page the indexes as well.

If there is sufficient memory available, keeping all indexes in memory does not hurt — and in some cases, improves — performance. However, you may not need to keep all indexes in memory to get the desired performance.

Indexes in memory are useful if the column is in memory and the index lookups and range queries are frequently accessed.

You can use inverted hash indexes on column tables. See [Changing the Load Units for Indexes Using ALTER INDEX \[page 546\]](#).

### 6.10.1.6 Reduce the Memory Footprint Using Page-Loadable Columns

SAP HANA native storage extension (NSE) uses techniques to load only the pages into memory that include data that is relevant to your search. Pages containing data that is not accessed by your query are not loaded from disk.

NSE supports column store tables, which support page-loadable columns and designate a column, partition, or an entire table as either page loadable or column loadable. Use the ALTER TABLE and CREATE TABLE commands to specify the `<load_unit>` preferences for column, table, or partition. Setting `<load_unit>` to PAGE enables the columns to load its structures in a pagewise manner into main memory. Specifying the `<load_unit>` as COLUMN loads the entire database object into the memory (the load unit designation only defines the behavior of the column load; it does not perform the load itself).

Page-loadable columns provide benefits in these situations for tables, partitions, or columns that are less frequently accessed:

- Using a fully qualified primary key – allows for a smaller working memory footprint for the page-loadable columns when this OLTP-style data access (during which all columns of a row are accessed, usually qualified by primary key) is compared to the standard column table behavior. NSE uses a smaller memory footprint for OLTP-style access because only a portion of the index columns are needed to locate the row, and only a portion of each column must be loaded to extract the row, as opposed to the entire set of columns that are required for a typical in-memory access.  
For a page loadable column, the read performance may vary depending on whether the page is in the buffer cache or if it must be read from disk. Internal primary key and index columns are implicitly paged in partitions with a load unit of PAGE (see [Using Indexes in SAP HANA NSE \[page 539\]](#)).
- Without a fully qualified primary key – page-loadable columns need a small memory footprint for processing with this OLAP-style data access (which scans all data of a single column), unlike standard column table behavior. NSE uses a smaller memory footprint for OLAP-style data access because only one portion at a time is required to scan the column instead of requiring the whole column to be in memory. This comes at a cost of slightly slower column scan performance due to reads from persistent storage during the query execution. SAP HANA uses an intelligent prefetch mechanism to read columns up front so it need not wait for I/O to complete, and optimizes OLAP performance for column scans.

Typically, SAP HANA keeps all column-loadable data completely in memory for fast processing. For NSE, SAP HANA chooses an in-memory or paged-loadable representation based on the size of the column, access pattern, and so on, using the buffer cache to reduce the memory footprint for warm data.

The query performance on warm data may be somewhat reduced compared to the performance on hot data. You can convert data from column-loadable to page-loadable and vice versa.

Depending on the compression and data type, the page-loadable columns choose whether to page the main store data and the main store dictionary when you issue ALTER TABLE or CREATE TABLE with the `<load_unit>` parameter. The columns make the decision of whether to page their components based on internal heuristics – this decision is therefore not user-configurable.

SAP HANA uses a smart paging algorithm, so for smaller-sized, NSE-enabled columns, it may decide not to use page-wise access and instead load the columns fully in-memory. In some cases, when there are few rows or very efficient compression, the fully in-memory representation is smaller than a single page, so the column does not use page loading because doing so increases the memory overhead. However, these in-memory representations may transition to paged representations (or vice versa) when the size of the structure changes.

### **i** Note

Paging is supported for the main store portion of the NSE-enabled columns. The delta store portion remains fully memory resident and is unaffected by the page loadable feature. Index structures on main store page-loadable columns are pageable.

Page-loadable columns provide a paged persistence for data and manage the pages in a buffer-cache, similar to traditional database systems. Use the ALTER TABLE and CREATE TABLE commands with the `<load_unit>` value (COLUMN, PAGE, or DEFAULT) to specify which columns, tables, and table partitions are page loadable and which are column loadable.

### **i** Note

To move a portion of an unpartitioned table to SAP HANA NSE, you must first partition the table.

## Related Information

[Changing the Load Unit Using ALTER TABLE \[page 544\]](#)

[Understanding Load Unit Behavior in SAP HANA NSE Column Store Tables \[page 541\]](#)

### 6.10.1.6.1 Configure SAP HANA to Use Page-Loadable Column Storage

You can configure columns, partitions, tables, and indexes by configuring the `<load_unit>` parameter in DDL statements.

The DDL statements you can use to configure load units for column store storage are:

- CREATE TABLE
- ALTER TABLE
- ALTER INDEX

#### 6.10.1.6.1.1 Understanding Load Unit Behavior in SAP HANA NSE Column Store Tables

The loading behavior is determined by the load unit (one of PAGE, COLUMN, and DEFAULT) specified for the column, partition, and table in SAP HANA native storage extension (NSE) column-store tables.

A column can be an in-memory column (which has a load unit of COLUMN) or a paged-attribute column (which has a load unit of PAGE), depending on its specified load unit. When you run a DDL (for example, ALTER TABLE), SAP HANA determines the effective load unit for a column based on load unit precedence as described below.

To determine whether a column is fully in-memory or is paged, SAP HANA checks the load unit that is being set at the column level, described in the table below:

<b>Load unit is set to:</b>	<b>The effective load unit is:</b>
If the column-level load unit is configured as either PAGE LOADABLE or COLUMN LOADABLE	The configured load unit.
If the column-level load unit is configured as DEFAULT LOADABLE	SAP HANA checks, and uses, the partition-level load unit.
If the partition-level load unit is configured as PAGE LOADABLE or COLUMN LOADABLE	The configured load unit.
If the partition-level load unit is configured as DEFAULT LOADABLE	SAP HANA checks, and uses, the table-level load unit.

Load unit is set to:	The effective load unit is:
If the table load unit is configured as PAGE LOADABLE or COLUMN LOADABLE	The configured load unit.
If the table load unit is configured as DEFAULT LOADABLE	The COLUMN LOADABLE load unit.

The effective load unit also depends on factors such as whether the column is pageable or not. For example, text columns cannot be paged.

### i Note

DEFAULT indicates that the user does not have any explicit load unit preference for a database object. A database object with the tag as DEFAULT LOADABLE inherits the load unit preference of its parent object. For example, a column inherits its partition's preference and a partition inherits its table's load unit preference. The system default load unit is COLUMN LOADABLE.

Keep in mind the following points while using DEFAULT load unit in the CREATE TABLE and ALTER TABLE commands:

- For CREATE TABLE: If you do not provide any explicit load unit preference, the system uses load unit as DEFAULT.
- For ALTER TABLE – If you want to reset the existing load unit preference, you must specify DEFAULT LOADABLE. If you do not specify any load unit tag in the ALTER TABLE command (for instance, if you are changing the default value of a column but do not want to change the load unit), the existing load unit is retained.

## 6.10.1.6.1.2 Setting the Load Unit Using CREATE TABLE

Use the CREATE TABLE statement with the load\_unit parameter to set the load unit for tables, any heterogeneous RANGE partition, and columns. Note that you can't use NSE load unit syntax for time selection tables.

See [CREATE TABLE](#).

### i Note

Persistent memory (NVRAM) is supported in SAP HANA as a persistent storage type, and is enabled using DDL statements (such as CREATE and ALTER TABLE) using the PERSISTENT MEMORY switch at the table, partition, or column level. Although you can specify both paging (by using PAGE LOADABLE as the load unit) and persistent memory (by using the PERSISTENT MEMORY ON switch) on the same column, partition, or table, the load unit is given higher precedence over persistent memory. This means that if a column has both PAGE LOADABLE and PERSISTENT MEMORY ON, data is not persisted into NVRAM because page-loadable columns are not supported on persistent memory.

## Creating NSE-Enabled Tables at the Table Level

This example sets the load unit to page loadable for the entire table:

```
CREATE COLUMN TABLE T1 (C1 INT) PAGE LOADABLE
```

This example sets the load unit to page loadable for the C2 column:

```
CREATE COLUMN TABLE T (C1 INT, C2 VARCHAR (10) PAGE LOADABLE)
```

This example creates a table with the load units set for column and tables:

```
CREATE TABLE T2 (COL1 INT COLUMN LOADABLE, COL2 INT) PAGE LOADABLE;
```

Viewing the load unit on table T2 shows that it includes both page- and column-loadable columns:

```
SELECT TABLE_NAME, COLUMN_NAME, LOAD_UNIT FROM M_CS_COLUMNS WHERE TABLE_NAME='T2';
```

TABLE_NAME	COLUMN_NAME	LOAD_UNIT
T2	COL1	COLUMN
T2	COL2	PAGE

## Creating NSE-Enabled Tables with Partitions

See [NSE-Enabled Partitioned Tables \[page 547\]](#) for information about changing the load unit for partitioned tables.

## Creating NSE-Enabled HDBtables

Use this syntax to create NSE-enabled HDBtables:

```
COLUMN TABLE <TABLE_NAME> (  
  <COLUMN_NAME> [, <COLUMN_NAME>] PAGE LOADABLE,  
)
```

For example, this creates the T3 HDBtable, which includes the page loadable column, COL1:

```
COLUMN TABLE T3 (  
  COL1 INT PAGE LOADABLE,  
  COL2 INT  
)
```

This creates the T4 HDBtable, which includes a page-loadable partition:

### **i** Note

The double parenthesis surrounding the partition declaration are syntactically required.

```
COLUMN T4 (COL1 INT, COL2 INT)
```

```
PARTITION BY RANGE (COL1) ((PARTITION 0 <= VALUES < 10 PAGE LOADABLE, PARTITION OTHERS))
```

This creates a page-loadable HDBtable, T1:

```
COLUMN T1 (COL1 INT, COL2 CHAR) PAGE LOADABLE
```

### 6.10.1.6.1.3 Changing the Load Unit Using ALTER TABLE

Specify the `load_unit` parameter to change the load unit at a table, partition, or column level. The NSE syntax for ALTER TABLE offers improved performance and is non-blocking.

The syntax is:

```
ALTER TABLE <TABLE_NAME> ... <LOAD_UNIT_WITH_CASCADE>;  
ALTER TABLE <TABLE_NAME> <PARTITION_ID> | <RANGE> <LOAD_UNIT_WITHOUT_CASCADE>
```

Where:

```
<LOAD_UNIT> ::= { COLUMN | PAGE | DEFAULT } LOADABLE
```

#### Changing the Load Unit for a Table

This example alters the load unit for a table:

```
ALTER TABLE T PAGE LOADABLE CASCADE
```

Use of `CASCADE` removes any existing partition or column-level load unit preferences.

#### Changing the Load Unit for a Column

This example alters a load unit of column to be `DEFAULT LOADABLE`, which means there is no explicit preference for the paging attribute that is used when the results are loaded from the table:

```
ALTER TABLE T1 ALTER (C1 INT DEFAULT LOADABLE)
```

## Changing the Load Unit for a Partition

### Example

This example alters a partition's load unit specification (for range partition only):

```
ALTER TABLE T4 ALTER PARTITION 5 PAGE LOADABLE
```

Viewing the load unit on table T4 shows that columns in partition 5 are now page-loadable:

```
SELECT TABLE_NAME, PART_ID, COLUMN_NAME, LOAD_UNIT FROM M_CS_COLUMNS WHERE  
TABLE_NAME='T4';
```

TABLE_NAME	PART_ID	COLUMN_NAME	LOAD_UNIT
T4	1	C1	COLUMN
T4	1	C2	COLUMN
T4	2	C1	PAGE
T4	2	C2	PAGE
T4	3	C1	COLUMN
T4	3	C2	COLUMN
T4	4	C1	COLUMN
T4	4	C2	COLUMN
T4	5	C1	PAGE
T4	5	C2	PAGE

### Example

This example alters a partition's load unit by specifying the RANGE clause:

```
ALTER TABLE TAB ALTER PARTITION RANGE (A)  
((PARTITION 0<= VALUES <10)) PAGE LOADABLE
```

## Using ALTER TABLE to Change Load Units with a Reduced Blocking Window

Changing the loadable property of a column requires that the column data is re-written in the new format. However, ALTER TABLE supports parallel DMLs that run until the next savepoint is triggered. If you specify multiple columns in the same DDL, all columns are converted in parallel according to the availability of the CPUs, greatly improving the performance of this task.

The syntax is:

```
ALTER TABLE <TABLE_NAME> ALTER (<COLUMN_NAME> ALTER [COLUMN | PAGE] LOADABLE)
```

To run ALTER TABLE with a reduced window for blocking:

- The DDL AUTOCOMMIT property must be enabled:

```
SET TRANSACTION AUTOCOMMIT DDL ON
```

- You cannot specify other ALTER clauses with the LOAD UNIT conversion clause.

### i Note

DDLs that are not online typically do not allow parallel DMLs to run.

For example:

- This alters columns C1 and C2 in parallel to be page- and column-loadable, respectively:

```
ALTER TABLE T1 ALTER (C1 ALTER PAGE LOADABLE, C2 ALTER COLUMN LOADABLE)
```

## Using ALTER TABLE Command for Compressed and Uncompressed Columns

- If you execute the following ALTER TABLE command on a compressed column, the C1 column remains compressed with the new load unit specified:

```
ALTER TABLE T ALTER (C1 ALTER <LOAD_UNIT>)
```

- If you execute the following ALTER TABLE command on a compressed column, the C1 column is uncompressed with the new load unit specified:

```
ALTER TABLE T ALTER (C1 INT <LOAD_UNIT>)
```

Where:

```
<LOAD_UNIT> = {PAGE|COLUMN|DEFAULT} LOADABLE
```

### i Note

The uncompressed columns will remain uncompressed after you execute the above commands.

## 6.10.1.6.1.4 Changing the Load Units for Indexes Using ALTER INDEX

Using paged value indexes on column tables reduces the memory footprint. This example creates a unique inverted value index named `idx` on columns `col1` and `col2` on table `COLUMN_TABLE`.

```
CREATE UNIQUE INVERTED VALUE INDEX idx ON COLUMN_TABLE(col1, col2);
```

This example converts an index named `idx`, to page loadable.

```
ALTER INDEX idx PAGE LOADABLE;
```

### i Note

Paging is supported for inverted value indexes, which are defined on multiple columns.

## 6.10.1.6.1.5 Viewing Load Unit Information for Column Store Tables in SAP HANA NSE

Several system and monitoring views provide information on load unit preferences (PAGE loadable, COLUMN loadable, or DEFAULT loadable) set for the SAP HANA NSE column-store table.

- System views
  - TABLES
  - TABLE\_PARTITIONS
  - TABLE\_COLUMNS
  - INDEXES – shows index load unit for supported index types.

### i Note

DEFAULT indicates that the user does not have any explicit load unit preference for a database object. A database object with the tag `DEFAULT LOADABLE` inherits the load unit preference of its parent object. For example, a column inherits its partition's load unit preference and a partition inherits its table's. The system default load unit is `COLUMN LOADABLE`.

- Monitoring views: The `LOAD_UNIT` column is added to display the derived load unit at a given granularity level, following the precedence logic.
  - M\_CS\_TABLES
  - M\_TABLE\_PARTITIONS
  - M\_CS\_COLUMNS
  - M\_CS\_ALL\_COLUMNS

## 6.10.1.6.1.6 NSE-Enabled Partitioned Tables

For SAP HANA NSE tables, partitioning can be heterogeneous or non-heterogeneous. However, partition load unit can be set only for heterogeneous partitioning. This scenario describes a sequence of steps creating a page-loadable, partitioned table and then altering its load unit.

NSE supports only the RANGE and RANGE-RANGE HETEROGENEOUS partitioning schemes. If you have a RANGE or RANGE-RANGE partition, you can define the load unit at any level of the partitions.

### i Note

For multistore tables in heterogeneous partitioning, you cannot specify an `ENABLE DELTA` clause in the `CREATE TABLE` statement. First create a non-delta-enabled heterogeneous multistore table and then use the `ALTER TABLE` command to enable delta for the table.

## Creating and Altering Single-Level NSE-Enabled Partitions

These examples show how to convert a single-level partitioned table from non-heterogeneous to heterogeneous. The example creates a single-level non-heterogeneous partitioned table:

```
CREATE COLUMN TABLE T (C1 INT) PARTITION BY RANGE (C1)
(PARTITION 0 <= VALUES < 1000, PARTITION 1000 <= VALUES < 2000, PARTITION
OTHERS );
```

This statement alters table T with heterogeneous partitioning:

```
ALTER TABLE T PARTITION BY RANGE (C1)
((PARTITION 0 <= VALUES < 1000 , PARTITION 1000 <= VALUES < 2000 , PARTITION
OTHERS));
```

This example uses the NSE syntax to create an NSE-enabled, single-level heterogeneous partitioned table. Note that the double parenthesis surrounding the partition declaration are syntactically required by CREATE TABLE.

```
CREATE COLUMN TABLE T (C1 INT) PARTITION BY RANGE (C1)
((PARTITION 0 <= VALUES < 1000 PAGE LOADABLE, PARTITION 1000 <= VALUES < 2000
COLUMN LOADABLE, PARTITION OTHERS COLUMN LOADABLE));
```

View the load units to verify the change:

```
SELECT P.schema_name,P.table_name,P.partition,P.range,P.subpartition,P.subrange,
TP.part_id,TP.load_unit,TP.loaded,TP.record_count FROM M_CS_PARTITIONS P INNER
JOIN M_TABLE_PARTITIONS TP
ON P.part_id = TP.part_id AND P.schema_name = TP.schema_name AND P.table_name =
TP.table_name
WHERE P.table_name = 'T';
```

	SCHEMA_NAME	TABLE_NAME	PARTITION	RANGE	SUBPARTITION	SUBRANGE	PART_ID
	LOAD_UNIT	LOADED	RECORD_COUNT				
1	SYSTEM	T	1	0-1000			
	PAGE	FULL	0				
2	SYSTEM	T	2	1000-2000			
	COLUMN	FULL	0				
3	SYSTEM	T	3				
	COLUMN	FULL	0				

This changes the load unit for partition 2 to be page loadable:

```
ALTER TABLE T ALTER PARTITION RANGE (C1) ((PARTITION 1000 <= VALUES < 2000))
PAGE LOADABLE;
```

## Creating and Altering Second-Level NSE-Enabled Partitions

These examples show altering second level partitions.

Create table T2, which includes this first and second-level heterogeneous partitioning:

```
CREATE COLUMN TABLE T ( C1 INT, C2 INT)
PARTITION BY RANGE (C1)
((PARTITION 0 <= VALUES < 1000, PARTITION 1000 <= VALUES < 2000 PAGE LOADABLE,
PARTITION OTHERS)
```

```

SUBPARTITION BY RANGE (C2)
(PARTITION 0 <= VALUES < 100,
PARTITION 100 <= VALUES < 200, PARTITION 200 <= VALUES < 300 , PARTITION
OTHERS));

```

View the load unit on table T to verify the changes

```

SELECT P.schema_name,P.table_name,P.partition,P.range,P.subpartition,P.subrange,
TP.part_id,TP.load_unit,TP.loaded,TP.record_count FROM M_CS_PARTITIONS P INNER
JOIN M_TABLE_PARTITIONS TP
ON P.part_id = TP.part_id AND P.schema_name = TP.schema_name AND P.table_name =
TP.table_name
WHERE P.table_name = 'T';

```

	SCHEMA_NAME	TABLE_NAME	PARTITION	RANGE	SUBPARTITION	SUBRANGE	PART_ID
			LOAD_UNIT				
			LOADED				
			RECORD_COUNT				
1	SYSTEM	T	1	0-1000	1	0-100	
	COLUMN	FULL	0				
2	SYSTEM	T	1	0-1000	2	100-200	
	COLUMN	FULL	0				
3	SYSTEM	T	1	0-1000	3	200-300	
	COLUMN	FULL	0				
4	SYSTEM	T	1	0-1000	4		
	COLUMN	FULL	0				
5	SYSTEM	T	2	1000-2000	1	0-100	
	PAGE	FULL	0				
6	SYSTEM	T	2	1000-2000	2	100-200	
	PAGE	FULL	0				
7	SYSTEM	T	2	1000-2000	3	200-300	
	PAGE	FULL	0				
8	SYSTEM	T	2	1000-2000	4		
	PAGE	FULL	0				
9	SYSTEM	T	3		1	0-100	
	COLUMN	FULL	0				
10	SYSTEM	T	3		2	100-200	
	COLUMN	FULL	0				
11	SYSTEM	T	3		3	200-300	
	COLUMN	FULL	0				
12	SYSTEM	T	3		4		
	COLUMN	FULL	0				

This example changes the load unit for a second-level partition corresponding to a first-level partition. To change the second-level partition for other first-level partitions, you must use the command multiple times on this specific first-level partition:

```

ALTER TABLE T ALTER PARTITION
RANGE (C1) ((PARTITION 0 <= VALUES < 1000)
SUBPARTITION BY RANGE(C2) (PARTITION 200 <= VALUES < 300)) PAGE LOADABLE;

```

Changing the load unit for the first-level partition on T:

```

ALTER TABLE T ALTER PARTITION RANGE (C1) ((PARTITION 1000 <= VALUES < 2000))
COLUMN LOADABLE;

```

View the load unit on table T. The second-level partitions, 4 – 12 now show as column-loadable:

```

SELECT P.schema_name,P.table_name,P.partition,P.range,P.subpartition,P.subrange,
TP.part_id,TP.load_unit,TP.loaded,TP.record_count FROM M_CS_PARTITIONS P INNER
JOIN M_TABLE_PARTITIONS TP
ON P.part_id = TP.part_id AND P.schema_name = TP.schema_name AND P.table_name =
TP.table_name
WHERE P.table_name = 'T';

```

	SCHEMA_NAME	TABLE_NAME	PARTITION	RANGE	SUBPARTITION	SUBRANGE	PART_ID
	LOAD_UNIT	LOADED	RECORD_COUNT				
1	SYSTEM	COLUMN	T	0-1000	1	0-100	
2	SYSTEM	COLUMN	T	0-1000	2	100-200	
3	SYSTEM	<b>PAGE</b>	T	0-1000	3	200-300	
4	SYSTEM	COLUMN	T	0-1000	4		
5	SYSTEM	COLUMN	T	1000-2000	1	0-100	
6	SYSTEM	COLUMN	T	1000-2000	2	100-200	
7	SYSTEM	COLUMN	T	1000-2000	3	200-300	
8	SYSTEM	COLUMN	T	1000-2000	4		
9	SYSTEM	COLUMN	T		1	0-100	
10	SYSTEM	COLUMN	T		2	100-200	
11	SYSTEM	COLUMN	T		3	200-300	
12	SYSTEM	COLUMN	T		4		

## 6.10.1.6.1.7 SAP HANA NSE Support for the Statistics Server

The column tables of SAP HANA statistics server don't use SAP HANA NSE by default. Thus, if you're using NSE in your SAP HANA 2.0 environment, SAP recommends you to activate NSE for the column tables of the SAP HANA statistics server. Use the information here for the required guidance.

### Check the NSE Setting for Statistics Server

To check the current NSE setting for SAP HANA statistics server, execute the following SQL query:

```
SELECT DISTINCT LOAD_UNIT FROM SYS.TABLES WHERE SCHEMA_NAME = '_SYS_STATISTICS'
AND IS_COLUMN_TABLE = 'TRUE' AND IS_USER_DEFINED_TYPE = 'FALSE';
```

On analysing the query result and the current NSE setting through the output, you may need to activate or deactivate the SAP HANA statistics server based on whether it uses the PAGE LOADABLE or DEFAULT LOADABLE clause. See the following sections for details on doing the needful.

## Activate NSE for Column Tables of SAP HANA Statistics Server by Using the 'PAGE LOADABLE' Clause

Configure all statistics server column tables to use **PAGE LOADABLE** by executing the following DDL statement:

```
CREATE PROCEDURE ESS_ALTER_PAGE_LOADABLE LANGUAGE SQLSCRIPT SQL SECURITY INVOKER
AUTOCOMMIT DDL ON AS
l_idx int;
BEGIN
    table_names = SELECT TABLE_NAME FROM SYS.TABLES WHERE SCHEMA_NAME =
' _SYS_STATISTICS' AND IS_COLUMN_TABLE = 'TRUE' AND IS_USER_DEFINED_TYPE =
'FALSE' AND LOAD_UNIT != 'PAGE' ORDER BY 1;
    FOR l_idx IN 1..RECORD_COUNT(:table_names) DO
        EXEC 'SELECT COUNT(*) FROM _SYS_STATISTICS.'
    || :table_names.TABLE_NAME[:l_idx];
        EXEC 'MERGE DELTA OF _SYS_STATISTICS.' || :table_names.TABLE_NAME[:l_idx]
    || ' FORCE REBUILD';
        EXEC 'ALTER TABLE _SYS_STATISTICS.' || :table_names.TABLE_NAME[:l_idx] ||
PAGE LOADABLE CASCADE';
    END FOR;
END;
CALL ESS_ALTER_PAGE_LOADABLE;
DROP PROCEDURE ESS_ALTER_PAGE_LOADABLE;
```

## Deactivate NSE for Column Tables of SAP HANA Statistics Server by Using the 'DEFAULT LOADABLE' Clause

Configure statistics server column tables to use **DEFAULT LOADABLE** by executing the following DDL statement:

```
CREATE PROCEDURE ESS_ALTER_DEFAULT_LOADABLE LANGUAGE SQLSCRIPT SQL SECURITY
INVOKER AUTOCOMMIT DDL ON AS
l_idx int;
BEGIN
    table_names = SELECT TABLE_NAME FROM SYS.TABLES WHERE SCHEMA_NAME =
' _SYS_STATISTICS' AND IS_COLUMN_TABLE = 'TRUE' AND IS_USER_DEFINED_TYPE =
'FALSE' AND LOAD_UNIT != 'DEFAULT' ORDER BY 1;
    FOR l_idx IN 1..RECORD_COUNT(:table_names) DO
        EXEC 'ALTER TABLE _SYS_STATISTICS.' || :table_names.TABLE_NAME[:l_idx] ||
DEFAULT LOADABLE CASCADE';
    END FOR;
END;
CALL ESS_ALTER_DEFAULT_LOADABLE;
DROP PROCEDURE ESS_ALTER_DEFAULT_LOADABLE;
```

## Related Information

[Understanding Load Unit Behavior in SAP HANA NSE Column Store Tables \[page 541\]](#)

## 6.10.1.6.2 Monitoring View Extensions for Column Store Paged Data Size

A number of monitoring views provide information about the in-memory and on-disk size of the page-loadable data in relation to the in-memory and on-disk size of non-paged (column-loadable) data, helping you understand the effectiveness of page-loadable storage.

### 6.10.1.6.2.1 Configuring Paged Large Object Data Types

To designate an LOB column as page loadable, define it with the PAGE LOADABLE load unit in the CREATE TABLE and ALTER TABLE commands.

LOB data columns can be configured as either page loadable or column loadable by setting the LOAD UNIT value in the commands CREATE TABLE and ALTER TABLE. However, memory usage for LOB data types is controlled by the Hybrid LOB configuration parameters independent of the LOAD UNIT configuration. While the LOAD UNIT can be configured to either COLUMN LOADABLE or PAGE LOADABLE for a LOB data column, it does not determine the memory usage for LOB data types.

The M\_CS\_ALL\_COLUMNS system view provides the information regarding on-disk and in-memory size of paged data, and also includes the information on LOB supported columns, designated as PAGE LOADABLE. Use the following system views to review the reduction in memory footprint as a result of paged LOBs:

- Main memory – with paged LOB, the main memory size for data and dictionary is zero.
  - MAIN\_MEMORY\_SIZE\_IN\_DATA
  - MAIN\_MEMORY\_SIZE\_IN\_DICT
- Main page loadable memory – depending on the amount of LOB column being loaded into the memory, the system displays values for the main page loadable memory for data and dictionary.
  - MAIN\_PAGE\_LOADABLE\_MEMORY\_SIZE\_IN\_DATA
  - MAIN\_PAGE\_LOADABLE\_MEMORY\_SIZE\_IN\_DICT

As an example, run the following command to view the main and page loadable memories:

```
SELECT
MAIN_MEMORY_SIZE_IN_DATA,
MAIN_MEMORY_SIZE_IN_DICT,
MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DATA,
MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DICT
FROM M_CS_ALL_COLUMNS
WHERE TABLE_NAME = <table_name>
AND COLUMN_NAME = <column_name>
```

For example, for a table named TEST\_MST\_TABLE in the SAPQM7 schema:

```
SELECT
MAIN_MEMORY_SIZE_IN_DATA,
MAIN_MEMORY_SIZE_IN_DICT,
MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DATA,
MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DICT
FROM M_CS_ALL_COLUMNS
where schema_name='SAPQM7' and table_name='TEST_MST_TABLE'
```

## Related Information

[Hybrid LOBs \(Large Objects\) \[page 618\]](#)

### 6.10.1.6.2.2 Statistics for Page-Loadable Storage

A number of monitoring views report information at the partition, column, and column sub-object level, along with the existing non-paged memory size statistics.

These views include page-loadable memory size statistics and non-paged memory statistics, so the total memory size reported is the sum of the page loadable and non-paged memory sizes, and the storage distribution is clearly understandable. This example from M\_CS\_ALL\_COLUMNS shows that the value of MEMORY\_SIZE\_IN\_TOTAL results from the MEMORY\_SIZE\_IN\_MAIN plus the value of MEMORY\_SIZE\_IN\_DELTA:

	HOST	PORT	SCHEMA_NAME	TABLE_NAME	COLUMN_NAME
MEMORY_SIZE_IN_TOTAL			MEMORY_SIZE_IN_MAIN		MEMORY_SIZE_IN_DELTA
1	lsvxc0115	30,703	TPCH_PL	LINEITEM	L_ORDERKEY
37,029,428			37,025,152		4,276
2	lsvxc0115	30,703	TPCH_PL	LINEITEM	L_PARTKEY
34,354,952			34,350,676		4,276
3	lsvxc0115	30,703	TPCH_PL	LINEITEM	L_SUPPKEY
11,091,296			11,087,020		4,276

The number reported for paged memory footprint is the size of the resident memory in the resource within the buffer cache. This is not the size of the memory in use – which is typically very small or zero, consisting only of pages currently being read or written by a client – and not the total data size on disk.

The monitoring views that include information about the size of in-memory and on-disk page-loadable data are listed below.

Monitoring View	Description
M_CS_ALL_COLUMNS	<p>M_CS_ALL_COLUMNS includes these columns to provide statistics for page-loadable and non-paged memory footprints:</p> <ul style="list-style-type: none"> <li>• MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN</li> <li>• MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DATA</li> <li>• MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DICT</li> <li>• MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_INDEX</li> <li>• MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_MISC</li> </ul> <p>Other columns in M_CS_ALL_COLUMNS also include information about the page-loadable columns; use them to determine the effectiveness of your page loadable data:</p> <ul style="list-style-type: none"> <li>• The value of MEMORY_SIZE_IN_TOTAL = the sum of MEMORY_SIZE_IN_MAIN + MEMORY_SIZE_IN_DELTA</li> <li>• The value of MEMORY_SIZE_IN_MAIN includes the value of MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN</li> <li>• The value of MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN is compiled by adding: <pre> MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DATA + MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DICT + MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_INDEX + MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_MISC ----- MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN = &lt;sum&gt; </pre> </li> <li>• MAIN_PAGE_LOADABLE_MEMORY_SIZE_IN_DICT may have a value of 0 for data types that do not support paged dictionaries. In this situation, M_CS_ALL_COLUMNS reports the in-memory dictionary size in the MAIN_MEMORY_SIZE_IN_DICT column.</li> <li>• PAGED_MEMORY_SIZE_IN_INDEX may have a value of 0 for columns without indexes defined or loaded, and for columns that have inverted indexes (light-weight data structures that map column dictionary value IDs to the corresponding row IDs) that are not yet converted to paged indexes — this can occur in older tables that have not yet gone through a delta merge.</li> </ul>
M_CS_COLUMNS	<p>Includes the MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN column to provide page-loadable information about the total resident paged memory size of columns.</p>
M_CS_TABLES	<p>Contains memory statistics for tables. These are aggregates of the column memory statistics in M_CS_ALL_COLUMNS, which includes the MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN column to provide the total resident paged-memory size of a table.</p> <p>Other columns in M_CS_TABLES also include information about the page-loadable columns; use them to determine the effectiveness of your page loadable data:</p> <ul style="list-style-type: none"> <li>• The value for MEMORY_SIZE_IN_PAGE_LOADABLE is the same as its value in M_CS_ALL_COLUMNS.</li> <li>• The value for MEMORY_SIZE_IN_TOTAL = the sum of MEMORY_SIZE_IN_MAIN + MEMORY_SIZE_IN_DELTA.</li> <li>• The value for MEMORY_SIZE_IN_MAIN includes the value of MEMORY_SIZE_IN_PAGE_LOADABLE_MAIN.</li> </ul>

Monitoring View	Description
M_TABLE_PARTITIONS	<p>A number of columns in M_TABLE_PARTITIONS include information about the page-loadable columns; use them to determine the effectiveness of your page loadable data:</p> <ul style="list-style-type: none"> <li>• The value for MEMORY_SIZE_IN_PAGE_LOADABLE is the same as its value in M_CS_ALL_COLUMNS.</li> <li>• The value for MEMORY_SIZE_IN_TOTAL = the sum of MEMORY_SIZE_IN_MAIN + MEMORY_SIZE_IN_DELTA.</li> <li>• DISK_SIZE_IN_PAGE_LOADABLE provides the total disk size, in bytes, of page-loadable storage.</li> </ul>

### 6.10.1.6.2.3 Persistent Size of Page Loadable Data

A number of monitoring views include column and column dictionary, data, and index sub-structure information about the disk size of page-loadable data (this is the size on disk, not the disk size itself).

Monitoring View	Description
M_TABLE_PERSISTENCE_STATISTICS	<p>M_TABLE_PERSISTENCE_STATISTICS includes the DISK_SIZE of column, which describes the total on-disk size of the column.</p> <p>The value for DISK_SIZE also includes the size of page loadable data for the table.</p>
M_CS_COLUMNS_PERSISTENCE	<p>M_CS_COLUMNS_PERSISTENCE includes the MAIN_PHYSICAL_SIZE_IN_PAGE_LOADABLE column, which reports the total on-disk size stored in page-loadable format for this table.</p> <p>The value for MAIN_PHYSICAL_SIZE includes the value for MAIN_PHYSICAL_SIZE_PAGE_LOADABLE.</p>
M_TABLE_PARTITIONS	<p>M_TABLE_PARTITIONS includes the MEMORY_SIZE_IN_PAGE_LOADABLE column, which reports the size of the total resident-paged memory of the partition, and the DISK_SIZE_IN_PAGE_LOADABLE column, which reports the total disk size of the page-loadable storage for this partition.</p> <p>M_TABLE_PARTITIONS includes these columns to provide statistics for page-loadable and non-paged memory footprints:</p> <ul style="list-style-type: none"> <li>• The aggregate value of MEMORY_SIZE_IN_PAGE_LOADABLE for the partition.</li> <li>• The value of DISK_SIZE is the same as its value in M_TABLE_PERSISTENCE_STATISTICS.</li> <li>• The value of DISK_SIZE includes the value of DISK_SIZE_IN_PAGE_LOADABLE.</li> </ul>

## 6.10.1.7 SAP HANA NSE Buffer Cache

The SAP HANA Native Storage Extension (NSE) buffer cache replaces the SAP HANA default page replacement and memory limit mechanism for the memory pages.

### i Note

The buffer cache is enabled by default. You need not perform any tasks to enable the buffer cache.

The buffer cache works with the existing SAP HANA memory manager to implement a page management policy. The buffer cache provides page memory from the dynamically managed memory pools. SAP HANA supports multiple page sizes, ranging from 4 KB to 16 MB. The buffer cache divides its memory into multiple buffer pools, with each pool for one supported page size.

### i Note

The default size of the buffer cache is 10% of the HANA memory.

### 6.10.1.7.1 Buffer Cache Sizing Guidelines

Both hot and warm data in an SAP HANA system exist on disk in the data volume. SAP HANA loads hot data column-wise into memory, where it resides until the system has to handle memory pressure. SAP HANA loads warm data stored in NSE page-wise into the buffer cache, and recently-used data resides in the buffer cache.

Consequently, depending on the usage pattern and buffer cache size, SAP HANA must read data from disk, which impacts the performance of queries according to the disk bandwidth.

You should allocate enough buffer cache to avoid accessing the disk for most queries. An application's performance varies based on the amount of data that is available in the buffer cache and how much data the application must read from disk. Although the size of the buffer cache with respect to warm data size varies from application to application, as a starting point the ratio of the buffer cache to the warm data on disk should not be smaller than 1 to 8. For example, if you have 8 GB of warm storage, you should allocate at least 1 GB of buffer cache. If your frequently-accessed NSE data set is small, you can experiment with a larger ratio of warm storage to buffer cache.

### 6.10.1.7.2 Adjusting the Buffer Cache Size

The command `ALTER SYSTEM ALTER CONFIGURATION` offers two parameters that enable you to set the upper limit permitted for the buffer cache in SAP HANA NSE-enabled tables. The limits are set in megabytes.

Use these parameters to dynamically expand or shrink the buffer cache size. Ensure that your buffer cache is large enough to manage your warm data set. The parameters are:

- `max_size`: Explicitly specifies the upper limit of the buffer cache, in MBs.
- `max_size_rel`: Specifies the upper limit of the buffer cache as a percentage of the SAP HANA memory.

## i Note

When both `max_size` and `max_size_rel` are set, the system uses the smallest value. When applying the values to a scale-out system at the DATABASE layer, `max_size_rel` will be relative to the allocation for each host, which can be different for each. In this case, the values can be interpreted as:

`max_size_rel` = 15% of allocation limit (for the given host), but capped to `max_size` = 20GB.

Therefore for smaller hosts, the relative setting (`max_size_rel`) is used. For larger hosts, the absolute cap (`max_size`) is applied.

The following statement configures the buffer cache capacity for SAP HANA tables:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system')
SET ('<cache_name>', 'max_size') = '<cache_size>' [with reconfigure]
```

In the statement above, `<cache_name>` is `buffer_cache_cs`, and `<cache_size>` is the size of the buffer cache, in MBs.

## i Note

- The command `ALTER SYSTEM ALTER CONFIGURATION` is executed on the tenant database.
- Only users with `INIFILE ADMIN` permissions can change the configuration.

SAP HANA does not allocate `max_size` on an immediate basis, only as needed. If both the parameters are set to non-zero values, the most restrictive value is chosen for the buffer cache.

After the reduction in buffer cache, if the current data size is lower than the new and reduced upper limit, the state of the buffer cache remains unchanged; that is, it still remains in an `ENABLED` state. However, if the current memory usage is more than the new upper limit, the buffer cache starts to shrink, and the free or used buffers are released to the SAP HANA Memory Manager until the current usage is less than or equal to the new upper limit. The buffer cache state then changes to `shrinking`.

Let us look at two examples that illustrate how you can configure the buffer cache to 1500 MB for the SAP HANA NSE column store table using the `max_size` and `max_size_rel` parameters.

- Example 1: Use the `max_size` parameter to set the buffer cache capacity to 1500 MB –

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system')
SET ('buffer_cache_cs', 'max_size') = '1500'
```

- Example 2: Use the `max_size_rel` parameter to set the buffer cache capacity to 15 percent of the SAP HANA memory, which in this case is 10000 MBs (which means the buffer cache capacity gets set to 1500 MB) –

```
'ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system')
SET ('buffer_cache_cs', 'max_size_rel') = '15'
[with reconfigure]
```

The following table lists various scenarios on how to calculate buffer cache capacity based on `max_size` and `max_size_rel`:

#### Calculating the Maximum Storage Capacity of Native Storage Extension Buffer Cache

<code>max_size</code> , in MBs	<code>max_size_rel</code> – Percentage of SAP HANA Memory	Maximum Cache Capacity	Description
Not user-configured	Not user-configured	<ul style="list-style-type: none"> <li>In the absence of <code>max_size</code> or <code>max_size_rel</code> configuration parameters, if <code>page_loadable_columns_limit</code> is configured in <code>global.ini</code>, its value is used as the maximum cache capacity.</li> <li>If cache is not specified in either <code>max_size</code> or <code>max_size_rel</code>, or <code>page_loadable_columns_limit</code>, then the system uses 10% of the SAP HANA server memory as the maximum cache capacity for the column store table.</li> </ul>	Buffer cache maximum values, with the SAP HANA memory limit set to 10000 MB: <ul style="list-style-type: none"> <li>Column store buffer cache – 1000 MB</li> </ul>
Not user-configured	A non-zero value	Maximum size of the buffer cache = <code>max_size_rel</code> .  The value of <code>page_loadable_columns_limit</code> is ignored.	The non-zero value of <code>max_size</code> or <code>max_size_rel</code> determines the effective buffer cache size. For example, if the <code>max_size_rel</code> is set to zero and <code>max_size</code> is set to any non-zero value, the system uses <code>max_size</code> as the buffer cache size.
A non-zero value	Not user-configured	Maximum size of the buffer cache = <code>max_size</code> .  The value of <code>page_loadable_columns_limit</code> is ignored.	If both the parameters are set to non-zero values, the lowest value is chosen for the buffer cache.
A non-zero value	A non-zero value	The value of <code>page_loadable_columns_limit</code> is ignored.	If both the parameters are set to non-zero values, the lowest value is chosen for the buffer cache.

### Note

Configuring `max_size` or `max_size_rel` to 0 (zero) determines effective buffer cache size to be the default value which is 10% of SAP HANA memory.

### 6.10.1.7.3 Monitoring the Buffer Cache

Two SAP HANA views — `M_BUFFER_CACHE_STATISTICS` and `M_BUFFER_CACHE_POOL_STATISTICS` — provide information on the buffer cache for SAP HANA NSE column store tables.

- `M_BUFFER_CACHE_STATISTICS` – provides information on cache configuration, cache status, and current memory usage. For example, cache name, the name of the cache replacement policy, the maximum and used (allocated) cache capacities, current state of the cache — enabled, disabling, disabled, shrinking — and the number of times a buffer has been released for reuse by the cache. See [M\\_BUFFER\\_CACHE\\_STATISTICS](#).
- `M_BUFFER_CACHE_POOL_STATISTICS` – provides statistics on each pool in a buffer cache, such as pool size, pool's growth percentage (the memory size calculated as the percentage of the `max_size` parameter, to which the buffer pool will grow if the Free List is empty), the number of buffers currently allocated for this pool, the number of buffers in the LRU chain for the pool, and the number of buffers in the hot buffer list for the pool. See [M\\_BUFFER\\_CACHE\\_POOL\\_STATISTICS](#).

#### Note

The buffer cache maintains a buffer pool for each supported page size.

### 6.10.1.7.4 Handling Out-of-Buffer Errors

When your buffer cache is not large enough to handle your workload, SAP HANA generates an alert message.

During an out-of-buffer situation, regular user tasks may be rolled back, and critical tasks (for example, recovery) use the emergency buffer pool.

The following is an example of an out-of-buffers event:

```
9/5/18 3:09 PM At 2018-09-15 14:58:14 on lssjc0064:30003;
Buffer Cache 'CS(buffer_cache_CS)' with max_size 1 MB ran out of buffers
```

The event, called "OutOfBuffersEvent," leaves a trace in the indexserver trace file. For example:

```
EventManagerImpl.cpp(00689) : New event reported:
'OutOfBuffersEvent[id= 1, "Buffer Cache 'CS(buffer_cache_cs)'
with max_size 1 MB ran out of buffers", state= NEW, acknowledged= false]'
```

You can also view this event by querying the `SYS.M_EVENTS` system catalog.

The `OutOfBuffersEvent` event is triggered when a task requesting for a page to be loaded or allocated finds that the buffer cache has run out of buffers, causing SAP HANA to throw this error:

```
Error ID : 3020054
Error Text : CS cannot provide requested memory as its limit of <N> MByte is
exceeded.
```

This example shows the error message added to the indexserver trace file:

```
Sample trace in the indexserver trace file:
[55451]{-1}[723/295150499] 2018-08-29 00:41:12.077284 e attributes
PagedAttributeDef.h(03645) : mergeOldIntoNew : merge exception for paged
attribute
SAPBS4:ACDOCA.MAT_PSPNR: exception 1: no.3020054
(NDS/BufferCache/impl/BufferCache.cpp:314)
```

**CS cannot provide requested memory as its limit of 10240 MByte is exceeded**

Resolve out-of-buffer events by increasing the maximum size for the corresponding buffer cache.

To do this, use ALTER SYSTEM ALTER CONFIGURATION, such as in this example, which configures the maximum size of the buffer cache to 1000000 MB:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system')
  SET ('buffer_cache_cs', 'max_size') = '1000000'
  [with reconfigure]
```

### **i Note**

After the last out-of-buffers error is reported, if the server notices that a number of subsequent buffer requests have been successfully fulfilled by the buffer cache without raising another error, the server then auto-resolves the out-of-buffers event.

## **Related Information**

[Adjusting the Buffer Cache Size \[page 556\]](#)

## **6.10.1.8 SAP HANA NSE and Paged Large Object Data Types**

The large object data types (LOBs) such as binary large object (BLOB), character large object (CLOB), and national character large object (NCLOB) are used to store large amounts of data.

The data vector and the portion of LOBs stored in the LOB dictionary are paged. LOB data columns can be configured as either page loadable or column loadable by setting the LOAD UNIT value in the commands CREATE TABLE and ALTER TABLE. However, memory usage for LOB data types is controlled by the Hybrid LOB configuration parameters independent of the LOAD UNIT configuration. While the LOAD UNIT can be configured to either COLUMN LOADABLE or PAGE LOADABLE for a LOB data column, it does not determine the memory usage for LOB data types.

## **Related Information**

[Hybrid LOBs \(Large Objects\) \[page 618\]](#)

## 6.10.1.9 Data Compression in SAP HANA Native Storage Extension

SAP HANA NSE supports all types of columnar compression techniques, including dictionary and advanced compression.

### Related Information

[Data Compression in the Column Store \[page 633\]](#)

## 6.10.1.10 Understanding the SAP HANA NSE Advisor

Use the SAP HANA Native Storage Extension Advisor (NSE Advisor) to get suggestions about load units for tables, partitions, or columns according to how frequently they are accessed. The NSE Advisor provides a flexible interface to act on individual recommended objects to convert from column loadable to page loadable, or vice versa.

### i Note

You must have the `CATALOG READ` or `DATA ADMIN` role in order to get recommendations from the NSE Advisor.

The NSE Advisor determines the temperature of the data based on how frequently it is accessed at the query level for each column, and uses rule-based heuristics to identify hot and warm objects (that is, columns, partitions, and tables) as candidates to be page- or column-loadable. The NSE Advisor allows you to provide adjustable thresholds for warm (rarely accessed, stored on disk) and hot (frequently accessed, stored in-memory) objects.

Generally, the NSE Advisor recommends that you change the load unit of a table, partition, or a column to:

- Page-loadable to reduce memory footprint without much performance impact.
- Column-loadable to improve performance by keeping hot objects in memory.

The NSE Advisor runs a rule-based algorithm on statistical information that provides recommendations based on the counters it collects during the scan.

Running the NSE Advisor results in a list of tables, partitions, and columns with suggestions of whether they should be page- or column-loadable.

You can run the NSE Advisor in the following ways:

- Using the SQL interface on SAP HANA Platform. See [Using the NSE Advisor with SQL Commands for Warm Data Recommendations \[page 563\]](#) and the [SAP HANA SQL Reference Guide](#).
- Using the SAP HANA Cockpit. See [Using the NSE Advisor for Warm Data Recommendations](#) in the *SAP HANA Administration with SAP HANA Cockpit Guide*.

## 6.10.1.10.1 How the NSE Advisor Uses the Statement Cache for Recommendations

SAP HANA uses heuristics to determine which objects (tables, partitions, or columns) are suitable for conversion to page loadable - to save memory space - or column loadable - to improve performance by keeping hot objects in memory.

Achieving the best cost and performance ratio requires that you know which objects can be made page loadable, reducing the in-memory foot print without significantly affecting performance.

Each workload has its own data access pattern:

- Objects that are small and accessed frequently should be kept in memory to improve performance.
- Objects that are large and rarely accessed are better kept on disk to reduce memory usage. These objects are brought in memory only when needed, and only for the pages that are accessed.

SAP HANA performs this task in two phases: the first phase builds the data access pattern given a specific workload, and the second phase applies a heuristic rule on the data access statistics to generate the recommendations for which objects should be converted to which load unit.

To build the data access pattern for a workload, each physical access to a column fragment is counted and updated at query level in an internal cache called the access statistics cache. Because only the main fragment is paged for a page loadable column, the access count is recorded only for access to the main fragment. The access count for the original main fragment is retained when the delta fragment is merged to the main fragment. When a column is unloaded from memory during the workload, its access count is also retained in the access statistics cache and continues to be updated after the column is loaded again in memory.

DDLs that drop an object clean up the corresponding statistics entries related to the dropped objects. Building the data access statistics has a small impact to the ongoing workload performance, so it is only enabled through a configuration option. Contents of the statistics cache can be viewed through a monitor view. The cache can be cleared when not needed or when a new cache needs to be built for a different workload.

SAP HANA uses heuristics to generate load unit recommendations from the access statistics cache, including:

- Scan density – the object access scan count and object memory size ratio (the object can be a table, a partition or a column).
- Hot object threshold – the minimum scan density for an object to be considered a hot object. This is derived from a parameter for percentage of objects to be considered hot.
- Cold object threshold – the maximum scan density for an object to be considered a cold object. This is derived from a parameter for percentage of objects to be considered cold.
- Object size threshold – the minimum object size to be considered for recommendation. This is derived from a parameter for minimum object size.

A list of objects is compiled with recommendations to convert their load unit based on their scan density values. The object can be either a table, or a partition, or a column.

SAP HANA recommends that the object be page loadable if the object's:

```
Scan_Density < Cold Object Threshold and Object Memory Size > Object Size  
Threshold
```

SAP HANA recommends that the object be column loadable if the object's:

```
Scan_Density > Hot Object Threshold
```

SAP HANA may recommend that a table be page loadable due to an overall low scan density while a column within the table is recommended to be column loadable due to a high scan density for that particular column. In that case, the column level recommendation takes precedence over the table level recommendation. Similarly, partition level recommendation takes precedence over the table level recommendation.

Use the NSE Advisor to view the recommendations.

## 6.10.1.10.2 Using the NSE Advisor with SQL Commands for Warm Data Recommendations

Get column, partition and table load-unit recommendations through SQL commands for SAP HANA Native Storage Extension (NSE). The SAP HANA NSE Advisor tool (NSE Advisor) determines the temperature of data, and uses rule-based (data temperature threshold, access pattern/frequency, data density) algorithms to derive these recommendations, in particular to identify hot and warm objects as candidates to be either page-loadable or column-loadable.

### Prerequisites

You need either the `CATALOG READ` or `DATA ADMIN` system privilege to execute the SQL statements used in this task.

Additionally, refer to the table below for information on executing specific SQL statements in this task:

SQL Statement	Privilege Required	Applicable SAP HANA Version and Revision
<code>ALTER SYSTEM CLEAR CACHE</code>	<code>DEVELOPMENT</code>	SAP HANA 2.0 SPS 05, Rev 2.00.052 and lower
	<code>RESOURCE ADMIN</code>	SAP HANA 2.0 SPS 05, Rev 2.00.053 and higher
<code>ALTER SYSTEM ALTER CONFIGURATION</code>	<code>INIFILE ADMIN</code>	<i>No specific version/revision recommendation</i>

The recommendations monitor view applicable for this task is `M_CS_NSE_ADVISOR`.

## Context

To get load unit recommendations for NSE from the NSE Advisor, do the following:

## Procedure

1. Clean up all the cache entries in the Access Stats Cache. This step ensures that `cs_access_statistics` cache does not contain any junk information in its last sample.

```
ALTER SYSTEM CLEAR CACHE ('cs_access_statistics');
```

2. (Optional) (Applies to SAP HANA 2.0 SPS 05, Revisions greater than or equal to **2.00.053**)

Enlarge the configuration for `'cs_access_statistics', 'min_row_count'` to limit the cache entry count in the Access Stats Cache as follows if you see a timeout error while querying `M_CS_NSE_ADVISOR` in Step 4:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini','system') SET ('cs_access_statistics','min_row_count') = '10000' WITH RECONFIGURE;
```

### Note

`min_row_count` controls the minimum row count for a table to be considered for warm recommendations. This means small tables with a lower row count than `min_row_count` will not insert cache entries into the Access Stats Cache and thus, will not be advised by the NSE Advisor. The default value for `min_row_count` is 10,000. Also, if you see a timeout error while querying `M_CS_NSE_ADVISOR` in Step 4, follow the instructions in Step 6 to do a clean-up, then reuse NSE Advisor from Step 1.

3. Enable CS Access Stats Collection and run the workload:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini','system') SET ('cs_access_statistics','collection_enabled') = 'true' WITH RECONFIGURE;
```

4. When the workload has been running for a couple of hours, you can then get the recommendations from the `M_CS_NSE_ADVISOR` view. Run the following command:

```
SELECT * FROM M_CS_NSE_ADVISOR
```

5. Review the recommendations and modify corresponding tables, columns, and partitions to page-loadable or column-loadable. If the output is empty, you might need to fine-tune threshold values as explained below, and then again check the recommendations on the `M_CS_NSE_ADVISOR` view. The hot and cold object threshold values (10) and the minimum object size (999) in the following commands are used as examples:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system') SET ('cs_nse_advisor','hot_object_threshold_rel') = '10' WITH RECONFIGURE;
```

The default threshold value is 10% for hot objects.

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system') SET ('cs_nse_advisor','cold_object_threshold_rel') = '10' WITH RECONFIGURE;
```

The default threshold value is 10% for cold objects.

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'SYSTEM') SET
('cs_nse_advisor', 'min_object_size') = '999' WITH RECONFIGURE;
```

The default minimum object size is 1048576 bytes.

Where:

- `hot_object_threshold_rel`: Controls the percentage of objects, according to row scan count and size, to consider when calculating hot object threshold.
- `cold_object_threshold_rel`: Controls the percentage of objects, according to row scan count and size, to consider when calculating cold object threshold.
- `min_object_size`: Controls the minimum object size for an object to be considered for the recommendations.

### Note

The syntax does not currently support setting the load unit for individual internal columns. Thus, if the recommendation of the NSE Advisor is to change an internal column (for example, `$trexexternalkey$`) from column-loadable to page-loadable, the workaround is:

- Change the load unit of the entire table to page-loadable using the command `ALTER TABLE <table_name> page loadable`, and then
- Modify the load unit for individual columns in the table to explicitly set them back to column-loadable using the command `ALTER TABLE ALTER ( ( <column_name> ALTER column loadable [ , <column_name> ALTER column loadable [ ,... ] ] )`

The command `ALTER TABLE ALTER ( $trexexternalkey$ page loadable )` is not supported. This workaround can be time-consuming.

6. Disable CS Access Stats Collection. By default, an enabled CS Access Stats Collection might affect SAP HANA performance and consume some memory. It is recommended that you disable CS Access Stats Collection and clear CS Access Stats cache to save memory. Run the following command:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'system') SET
('cs_access_statistics', 'collection_enabled') = 'false' [with reconfigure]
ALTER SYSTEM CLEAR CACHE ('cs_access_statistics');
```

## 6.10.2 Extension Node

For scaled-out systems (SAP HANA native systems or in a SAP Business Warehouse) where a multi-temperature storage strategy is required, you can use the extension node feature to deploy a different type of host in the server landscape which is used exclusively for warm data.

### Overview

The hardware sizing guidelines for data storage depend upon the type of data being stored. Hot data must be stored in SAP HANA memory for fast access, and the normal ratio of RAM to data storage in this case is 2:1, for example, a system with 8TB of RAM can store up to 4TB of hot data.

However, if the frequency of usage of data slows down, the data temperature can be classified as warm. Warm data cannot be removed from the primary database as it may still need to be changed, but the performance of select statements is less crucial than for hot data.

Consequently, the sizing requirements for nodes which exclusively contain warm data can be relaxed. For example, it is possible to double the amount of data on such a node, or even quadruple it as long as the sizing of the data volume allows this. Extension nodes still use the column store and need dynamic memory for query processing, so overloading the node in this way is only possible, if the amount of data which is used at any point in time, and the amount of required memory for query processing is within the level of available DRAM on this node. When considering to what extent an extension node can be overloaded, query and model design are extremely important to minimize the amount of warm data that has to be loaded into memory and avoid wasting valuable DRAM unnecessarily.

You can create an extension node in SAP HANA native systems or in SAP Business Warehouse. SAP BW offers powerful data modeling features which make it possible to separate warm data from hot data. An extension node can be implemented by purchasing new hardware or by reconfiguring an existing node in the SAP HANA landscape. After configuring the extension node and modeling the data correctly to categorize the data according to temperature you can redistribute data using landscape management or data distribution optimizer so that objects that are classified for warm data will be moved to the extension node.

### Configuration

The extension node is configured as a slave node and has a host sub role (*worker* group value *worker\_dt*) which identifies the special function of the node. Table placement settings and locations are stored in metadata table `SYS.TABLE_PLACEMENT_LOCATIONS`.

The configuration procedure is described in the following two SAP Notes:

- 2741690 - *How-To: Configuring SAP HANA Extension Nodes* (specific to HANA 2.0 SPS 04)
- 2415279 - *How-To: Configuring SAP HANA for the SAP HANA Extension Node* (relevant for HANA native scenarios)

These notes include example commands that are required to set up table placement in a SAP BW on HANA scenario, a SAP BW/4HANA scenario and also for HANA Native scenarios. After completing the configuration procedure you can verify the location of the extension node in the view `M_LANDSCAPE_HOST_CONFIGURATION` and the locations for table placement can be seen in `SYS:TABLE_PLACEMENT_LOCATIONS`.

Note that the worker group name given to the extension node is also used by the following processes where it is important that the warm data is handled correctly:

- Backup and recovery to ensure that the right data is restored to this server
- SAP HANA system replication
- Standby nodes.

The use of sub roles and placing data in this way is not restricted to extension nodes, it can also be used more generically, for example, to pin schemas or applications to specific nodes of the landscape.

## Tools Available for Redistribution

Data objects which already exist in SAP Business Warehouse can be reclassified and moved to the extension node using either the landscape redistribution tool in SAP HANA or the data distribution optimizer (DDO).

In SAP Business Warehouse data objects for warm data are mainly write-optimized data store objects (DSO), advanced DSOs (aDSO) or persistent staging area (PSA) tables. In the case of advanced DSOs which contain hot and warm data and are split by partitions, use the data distribution optimizer tool to redistribute the data.

## 6.11 Managing Tables

The SAP HANA database stores data in memory in tables, organized in columns, and partitions, distributed among multiple servers.

In addition to the row and column data storage types, the Document Store for JSON artifacts is fully integrated into the SAP HANA database architecture. The document collections of the Document Store are also classified as a type of table and they can be created, updated and read by SQL. The Document Store allows native operation on JSON, for example, filtering, aggregation, and joining JSON documents with HANA column or row store tables.

The default table type is column-type tables. If the table type in a CREATE TABLE statement is not explicitly stated then the table will automatically be a column table. It is possible to override this behavior by setting the configuration parameter `default_table_type` in the `sql` section of the `indexserver.ini` file. The default table type for temporary tables is row-type.

### 6.11.1 Columnar and Row-Based Data Storage

The SAP HANA database supports two types of table: those that store data either column-wise (column tables) or row-wise (row tables). SAP HANA is optimized for column storage and this is the default table type.

Conceptually, a database table is a two dimensional data structure with cells organized in rows and columns. Computer memory however is organized as a linear sequence. For storing a table in linear memory, two options can be chosen as shown below. A row store stores a sequence of records that contains the fields of one row in the table. In a column store, the entries of a column are stored in contiguous memory locations.

**Principle of Row- and Column-Based Storage for a Table**

In the SAP HANA database, tables that are organized in columns are optimized for high-performing read operations while still providing good performance for write operations. Efficient data compression is applied to save memory and speed up searches and calculations. Furthermore, some features of the SAP HANA database, such as partitioning, are available only for column tables. Column-based storage is typically suitable for big tables with bulk updates. However, update and insert performance is better on row tables. Row-based storage is typically suitable for small tables with frequent single updates.

The following table outlines the criteria that you can use to decide whether to store your data tables as column tables or row tables:

Storage Type	When to Use
Column store	<ul style="list-style-type: none"> <li>Calculations are typically executed on individual or a small number of columns.</li> <li>The table is searched based on the values of a few columns.</li> <li>The table has a large number of columns.</li> <li>The table has a large number of rows and columnar operations are required (aggregate, scan, and so on)</li> <li>High compression rates can be achieved because the majority of the columns contain only a few distinct values (compared to the number of rows).</li> </ul>

Storage Type	When to Use
Row store	<ul style="list-style-type: none"> <li>• The application needs to process only one single record at one time (many selects and /or updates of single records).</li> <li>• The application typically needs to access the complete record.</li> <li>• The columns contain mainly distinct values so compression rate would be low.</li> <li>• Neither aggregations nor fast searching are required.</li> <li>• The table has a small number of rows (for example, configuration tables).</li> </ul>

### i Note

- The SAP HANA database allows row tables to be joined with column tables. However, it is more efficient to join tables of the same storage type.
- It is possible to change an existing table from one storage type to the other (`ALTER TABLE ALTER TYPE`).

## Advantages of Column-Based Storage

Column tables have several advantages:

- **Higher data compression rates**  
Columnar data storage allows for highly efficient compression. Especially if the column is sorted, there will be ranges of the same values in contiguous memory, so compression methods such as run length encoding or cluster encoding can be used more effectively.
- **Higher performance for column operations**  
With columnar data organization, operations on single columns, such as searching or aggregations, can be implemented as loops over an array stored in contiguous memory locations. Such an operation has high spatial locality and efficiently utilizes the CPU caches.  
In addition, highly efficient data compression not only saves memory but also increases speed.
- **Elimination of additional indexes**  
In many cases, columnar data storage eliminates the need for additional index structures since storing data in columns already works like having a built-in index for each column: The column-scanning speed of the in-memory column store and the compression mechanisms (especially dictionary compression) already allow read operations with very high performance. In many cases, it will not be required to have additional index structures. Eliminating indexes reduces memory size, can improve write performance, and reduces development efforts. However, this does not mean that indexes are not used at all in SAP HANA. Primary key fields always have an index and it is possible to create additional indexes, if required. In addition, full text indexes are used to support full-text search.
- **Elimination of materialized aggregates**  
Thanks to its column-scanning speed, the column store makes it possible to calculate aggregates on large amounts of data on the fly with high performance. This eliminates the need for materialized aggregates in many cases. Eliminating materialized aggregates has several advantages. It simplifies data model and aggregation logic, which makes development and maintenance more efficient; it allows for a higher level of concurrency because write operations do not require exclusive locks for updating aggregated values; and it ensures that the aggregated values are always up-to-date (materialized aggregates are sometimes updated only at scheduled times).
- **Parallelization**

Column-based storage also simplifies parallel execution using multiple processor cores. In a column store data is already vertically partitioned. That means operations on different columns can easily be processed in parallel.

### 6.11.2 Temporal Tables

Temporal tables is a general term for tables which provide functionality to manage historical data: that is, to maintain a set of current values which are valid for a predefined period and also maintain an auditable continuous history of changes.

History Tables were introduced in SAP HANA 1.0 to maintain a history of previous versions of each record and to support time-based queries. SAP History Tables, however, are limited principally because the validity periods are based on system values such as database commit IDs which cannot be maintained or managed by applications.

System-Versioned Tables were introduced in SAP HANA 2.0 SPS 03 to address this, making the validity periods accessible to SQL. For system-versioned tables the data is split across two tables: a current data table and a corresponding history table. They support the tracking of changes on column store tables by capturing the validity period of each record, it is then possible to read ranges of historical data and to query in 'time-travel' mode using the AS OF + <time-stamp> syntax.

Many applications, however, need to be able to manage and manipulate historical business data independent of system time-stamps, for example, to define the validity period of a stock unit or the duration of a customer contract. Application-Time Period Tables have been introduced in SAP HANA 2.0 SPS 04 for this purpose so that records in the database can also have an application-specific validity period and applications can perform time-based queries on business data with optimized access paths.

#### **i** Note

SAP history tables are still available in the SAP HANA product but you are recommended to use system-versioned and application-time period tables in preference to history tables.

#### 6.11.2.1 SAP HANA History Tables

SAP HANA supports column-based history tables which allow queries on historical data (also known as time-based queries).

History tables are special database tables that only allow inserts. Write operations on history tables do not physically overwrite existing records, instead, they always insert new versions of the data record into the database. The most recent versions in history tables are called current data. All other versions of the same data object contain historical data. Each row in a history table has timestamp-like system attributes that indicate

the time period when the record version in this row was the current one. Historical data can be read from history tables by requesting the execution of a time-based query against a historical view of the database (`SELECT ... AS OF time`). Alternatively, you can put a database session in history mode, so that all subsequent queries are processed against the historical view.

The history tables in SAP HANA correspond to system-versioned temporary data in SQL. For system-versioned temporal data the timestamps are automatically set and indicate the transaction time when the data was current. New versions are automatically created by the system during updates.

System-versioned tables and application-time period tables have been introduced in more recent versions of SAP HANA and these should now be used in preference to history tables. Refer to the *SAP HANA SQL and System Views Reference* for more details.

## Related Information

[CREATE TABLE](#)

[System-Versioned Tables \[page 572\]](#)

[Application-Time Period Tables \[page 574\]](#)

### 6.11.2.2 System-Versioned Tables

System-versioned tables are part of the SQL standard. They support the tracking of changes on column store tables by capturing the validity period of each record.

Specifically in SAP HANA, each record has a *Valid from* and *Valid to* value; these values are maintained by the system so that the mechanism is invisible to the user.

System-versioned tables always consist of two physical tables:

1. The main table of records that are currently valid.
2. A corresponding history table (a one-to-one correspondence) of archived records. A naming convention is not required but may be helpful, for example, to append "\_history" to the name of the main table.

#### Note

Note that the *history table* in this context is not the same as SAP HANA history tables in versions before HANA 2 SPS 03.

When you execute DML commands (insert, delete, update) on a system-versioned table, any records which are deleted or updated (and where the *Valid from* and *Valid to* columns are populated) are archived in the history table. Internal triggers are executed to manage the archiving process.

Full details of system-versioned tables are given in the *SAP HANA SQL and System Views Reference* (see, for example `CREATE TABLE <system_versioning_spec>`).

Some introductory examples are given here.

## Creating System-Versioned Tables

You can either create new system-versioned tables (using `CREATE`) or you can modify an existing table with the `ALTER` keyword so that it becomes a system-versioned table. The key syntax elements are shown here using `CREATE`:

```
CREATE COLUMN TABLE my_table
(
  <data columns>
  <validfrom_columnname> TIMESTAMP NOT NULL GENERATED ALWAYS AS ROW START,
  <validto_columnname> TIMESTAMP NOT NULL GENERATED ALWAYS AS ROW END,
  PERIOD FOR SYSTEM_TIME (valid_from, valid_to)
)
WITH SYSTEM VERSIONING HISTORY TABLE my_table_history [[NOT]VALIDATED];
```

- The `valid_from` and `valid_to` columns are timestamps and are maintained by the system; they have a special generation type: *generated always as row start* and *generated always as row end*. The *Valid to* value of the current record is always set to `MAX_TIMESTAMP`. These valid from and valid to timestamp columns are then identified as *period for system\_time* values.
- The `WITH` clause specifies the corresponding history table for the archived data.
- An optional validation keyword is also supported.

## History Tables

The history table has essentially the same structure as the main table but must also meet a number of consistency requirements, specifically: the history table does not have the primary key constraint of the current table, and the `valid_from` and `valid_to` columns are defined without generation clause. If you convert an existing table to a history table you must ensure that all requirements for consistency are met.

Only delete operations on history tables are allowed, this is permitted in order to support housekeeping. Inserts and updates are not allowed and generate a 'feature-not-supported' error. As a workaround to this it would be possible to temporarily drop the system versioning on the table and history table and reapply it later.

Archived records in the history table can still be accessed by referring to their timestamp values. To query a history table one or more timestamp values must be provided with one of the following time operators:

- to select data which was valid at a single point in time you can specify a timestamp with the 'timetravel' operator `AS OF`
- to define time ranges you can use the `FROM - TO` syntax or `BETWEEN - AND`

This example gives basic syntax using `AS OF`.

```
SELECT * FROM <system_versioned_table> FOR SYSTEM_TIME AS OF '<utc-timestamp>'
```

A timetravel period can also be defined for the current session using a session variable so that the `AS OF` is no longer necessary with each command:

```
SET [SESSION] 'TEMPORAL_APPLICATION_TIME_AS_OF' = '2018-01-01';
SELECT * FROM My_sys_time_table;
```

## Deleting Data

To permanently delete data from a system-versioned table it is necessary to delete data from both main and history tables in the following sequence:

1. Issue a delete statement referencing the main table - this will delete the data in the main table and move the deleted versions into the history table.
2. Issue a delete statement referencing the history table – this will then delete the data permanently.

## System Views

Temporal tables can be identified in the following system views:

- In the `SYS.TABLES` view `TEMPORAL_TYPE` is used to identify temporal tables. Possible values are: *Temporal* for the current table of a system-versioned table or an application-time period table, *History* or *NULL* for any other table type.
- Details of system-versioned tables and their corresponding history table are available in the view `SYS.TEMPORAL_TABLES` (`TABLE_NAME` and `HISTORY_TABLE_NAME`). Temporal tables are further categorized in `SYS.TEMPORAL_TABLES.PERIOD_NAME` where the value is either `SYSTEM_TIME` for the current table of a system-versioned table or `APPLICATION_TIME` for application-time period tables.
- In the `SYS.TABLE_COLUMNS` view `GENERATION_TYPE` indicates either: *ALWAYS AS ROW START* or *ALWAYS AS ROW END*.

## Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.2.3 Application-Time Period Tables

Application-Time Period Tables allow you to manage and manipulate historical business data based on application-specific time periods which are independent of system time-stamps.

Application-time period tables capture the time in which a record is valid in the business world rather than on the basis of the time it was entered in the database. Using these tables, time periods can reflect the past, present or future as determined by business needs and can be updated and managed from within the application. These tables are only available in the column store.

Some applications may require a history based on both system time stamps and business orientated time stamps. For these scenarios application-time period tables can be combined with system-versioned tables to form bi-temporal tables.

## Creating and Updating Application-Time Period Tables

Full details of the SQL commands available for working with application-time period tables are given in the *SAP HANA SQL Reference Guide* (see, for example CREATE TABLE <application\_time\_period\_configuration> and <bi\_temporal\_table\_spec>).

Here we give a brief introduction to the essential commands with examples.

You can create an application-time period table with either CREATE or ALTER table commands using the clause PERIOD FOR APPLICATION\_TIME (valid\_from, valid\_to).

To select records which have been valid at a certain point in time ('timetravel'), use the AS OF operator:

```
select * from <app_time_table> for application_time as of '<timestamp>'
```

A timetravel period can also be defined for the current session so that the AS OF is no longer necessary with each command:

```
SET [SESSION] 'TEMPORAL_APPLICATION_TIME_AS_OF' = '2018-01-01';  
SELECT * FROM My_app_time_table;
```

You can update historical records within a specified time frame using the UPDATE FOR PORTION OF syntax. The following example sets the value of customer\_email for the period January 2018:

```
UPDATE customers FOR PORTION OF application_time FROM '2018-01-01' TO  
'2018-01-31'  
SET customer_email='new_email@acmecompany.de' WHERE customer_id=1;
```

This updates records where the ValidFrom and ValidTo dates overlap with the given portion dates. These records will be updated and the validity periods will be adjusted as follows: the valid to date of the existing record is closed, a new record is inserted for the month of January and a new record is inserted from the end of January:

CUSTOMER_ID	CUSTOMER_NAME	CUSTOMER_EMAIL	VALIDFROM	VALIDTO
1	ACME Company	info@acmecompany.de	2017-10-01	2018-01-01
1	ACME Company	new_email@acmecompany.de	2018-01-01	2018-01-31
1	ACME Company	info@acmecompany.de	2018-01-31	9999-12-31

## System Views

The difference between the current table of a system versioned table and an application-time period table can be seen in the database in SYS.TEMPORAL\_TABLES.PERIOD\_NAME. The value is either SYSTEM\_TIME for the current table of a system-versioned table or APPLICATION\_TIME for application-time period tables. Bi-temporal tables have two entries in this view for both SYSTEM\_TIME and APPLICATION\_TIME.

The column SYS.TABLES.TEMPORAL\_TYPE shows the value TEMPORAL if the table is an application-time period table or HISTORY for history tables of a system-versioned table.

## Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.3 The JSON Document Store

The SAP HANA Document Store is a store for JSON artifacts and allows native operations on JSON including filtering, aggregation, and joining JSON documents with HANA column or row store tables.

JSON documents (JavaScript Object Notation) are stored in so-called collections. The content of a JSON document may be deeply structured but unlike XML it does not have a schema. This means that any valid JSON data may be inserted without first declaring its structure.

Collections appear to users like tables and users can work with them in SQL in a similar fashion. For example, data can be inserted with the regular INSERT statement and read via SELECT. You can read data from tables and collections in a single statement and you can combine tables and collections by joining as with any other column or row store table.

SAP HANA transactions span all three storage types (Column, Row and Document stores) in a single database which conforms to all the principles of data management: atomicity, consistency, isolation and durability.

Technically, collections are stored in a dedicated binary format; in SQL however, they are defined as tables with their own sub-type. You can see this by selecting collections on the basis of the table type value 'COLLECTION':

```
SELECT * FROM tables WHERE table_type = 'COLLECTION'
```

Full technical details of the Document Store are given in the *SAP HANA Developer Guide for XS Advanced*.

Details of Document Store-specific SQL statements are given in the *SAP HANA JSON Document Store Guide* and the *SAP HANA SQL Reference and System Views Guide*. The following example is included here to illustrate how a collection of customer details can be created, updated and read. The INSERT statement illustrates the syntax and structure of nested JSON data and the corresponding SELECT statements show the use of path expressions to navigate the content of the JSON document:

```
create collection Customers;
```

```
insert into Customers values('{"name": "Paul",  
    "address": {  
        "street": "Main Street 10",  
        "city": "Heidelberg"  
    }  
}');
```

```
select * from Customers where "address"."city" = 'Heidelberg';
```

```
select "address"."city", count(*) from Customers group by "address"."city";
```

Because there is no schema to enforce consistent use of data types, you may need to implement your own policy to ensure that data is inserted consistently.

## Enabling the JSON Document Store

The JSON Document Store is an optional feature of the SAP HANA database which you have to create for each tenant database. Only a single Document Store process per tenant is possible. Create the Document Store using the ALTER DATABASE statement:

```
ALTER DATABASE <database name> ADD 'docstore'
```

Note that once you have created the Document Store and added collections to it, it can only be removed from the landscape by first removing all collections. The JSON Document Store runs only in the *docstore* server process and collections cannot be moved to any other server (such as the *indexserver*).

The Document Store does not have a pre-determined SQL port, all communication is routed through ordinary index servers.

The Document Store is available for the SAP HANA Express Edition.

## 6.11.4 Basic Table Management in SAP HANA Cockpit

Using SAP HANA database explorer, you can for example execute SQL statements and database procedures, as well as query information about the database and database objects. SAP HANA database explorer is available from the SAP HANA cockpit.

### Related Information

[Open the SAP HANA Database Explorer \(SAP HANA Cockpit\) \[page 54\]](#)

## 6.11.4.1 Create Tables and Views (SQL)

Create a row-store or column-store table by executing the CREATE TABLE or a CREATE VIEW statement.

### Prerequisites

To create a table, you must be authorized to create tables in the selected schema.

To create a view, you must be authorized to create views in the selected schema.

### Context

A view is a combination or selection of data from tables modeled to serve a particular purpose. Views appear like readable tables, in other words, database operations that read from tables can also be used to read data from views. For example, you can create a view that simply selects some columns from a table, or a view that selects some columns and some rows according to a filter pattern.

#### i Note

The following procedure describes how to create a simple table and view. Database and application developers use SAP HANA development tools to create database objects such as tables and views as design-time objects in the repository of the SAP HANA database. For more information, see the *SAP HANA Developer Guide*.

### Procedure

Choose one of the following options:

Option	Action
Create a table	<p>Execute a CREATE TABLE statement.</p> <p>The following example creates a Table named A that has two INTEGER columns A and B. Column A the primary key.</p> <pre>CREATE TABLE A (A INT PRIMARY KEY, B INT);</pre>
Create a view	Execute a CREATE VIEW statement.

Option	Action
	<p>The following example creates a view named v that selects all records from table A.</p> <pre>CREATE VIEW v AS SELECT * FROM A;</pre>

## 6.11.4.2 Export Schemas, Tables, and Other Catalog Objects

Export catalog objects, including schemas, from your database by using the SAP HANA database explorer.

### Prerequisites

- You must have the SELECT privilege for the catalog objects that you want to export.
- You must have the EXPORT system privilege.

### Context

You cannot export a database object larger than 2 GB. If you are exporting a database object larger than 1 GB, then export the object to the SAP HANA computer rather than to the local computer.

### Procedure

1. In the catalog browser, right-click the object that you want to export, and then choose *Export Catalog Objects*.
2. Specify a file name for the object being exported and choose whether to export the object to your local computer or an SAP HANA server.

Option	Description
<i>Local Computer</i>	<p>Choose this option to save the export as a compressed file to a directory on your local machine.</p> <p>To avoid sending large amounts of data across the network, do not use this option when exporting large amounts of table data. Instead choose to export to the same computer as the SAP HANA server. An export (as well as an import) will fail if the resulting compressed file is larger than 2GB.</p> <p>The contents of the compressed file are not encrypted, so do not use this option if your local machine is not secure.</p>
<i>SAP HANA Server</i>	<p>Choose this option to save the export to a directory in the database server's file system.</p> <p>If you specify a different directory from the default, then:</p> <ul style="list-style-type: none"> <li>○ The directory path must exist.</li> <li>○ The directory path cannot contain symbolic links.</li> <li>○ When the database is part of a distributed system, specify a directory on a shared disk.</li> <li>○ You can specify the <i>backup</i> or the <i>work</i> directory of the database instance, but you cannot specify any other database instance directory. For example, if the database instance is located in the <code>/usr/sap/HDB/HDB00</code> directory, then you could specify: <code>/usr/sap/HDB/HDB00/backup</code> or <code>/usr/sap/HDB/HDB00/work</code> as a directory for the export.</li> </ul> <p>The contents of the export are not encrypted.</p>

3. Specify the scope of the export with the following options:

Export option	Description
<i>Include dependencies</i>	Select this option to export the objects as well as any objects that depend on them. For example, if a table has any triggers or indexes associated with it, then their definitions are exported.
<i>Include table data</i>	<p>When exporting tables, select this option to export the data, in addition to the definitions.</p> <p>Clear this option to export only the table object definitions.</p>
<i>Number of parallel threads</i>	<p>Increasing the number of threads can speed up the export and affect database performance. Consider the following guidelines when choosing the number of threads to use:</p> <ul style="list-style-type: none"> <li>○ For a view or procedure, use two or more threads, up to the number of dependent objects.</li> <li>○ For a whole schema, consider using more than ten threads, up to the number of CPU cores in the system.</li> <li>○ For an SAP BW or SAP ERP system with tens of thousands of tables, using many threads is reasonable (up to 256).</li> </ul>
<i>Column table format</i>	<p>Specify the format to use when exporting tables:</p> <ul style="list-style-type: none"> <li>○ Choose <i>CSV</i> when you are exporting row-store tables or when you must read the contents of the export.</li> <li>○ Choose <i>Binary</i> to speed up the export time when you are exporting column-store tables.</li> </ul>

4. Click *Export*.

## Results

The catalog objects are exported to the specified location. The length of time that the export process takes depends on number of objects being exported and the scope of the export.

Monitor the progress of a running export by using the M\_EXPORT\_BINARY\_STATUS monitoring view.

## Related Information

[Import Schemas, Tables, and Other Catalog Objects \[page 581\]](#)

[M\\_EXPORT\\_BINARY\\_STATUS System View](#)

### 6.11.4.3 Import Schemas, Tables, and Other Catalog Objects

Import catalog objects, including schemas, into your database by using the SAP HANA database explorer.

#### Prerequisites

- Import data must be compressed in `.tar.gz` format, which is provided during the database explorer export. Data exported by the SAP HANA studio must be compressed to `.tar.gz` before it can be imported.
- The database objects being imported must have been exported by using the export feature in the database explorer.
- In the destination database you must have the INSERT/UPDATE, DROP, or CREATE object privileges for the destination catalog objects and you must have the IMPORT system privilege. By default, these privileges are not granted to an HDI container user; they must be granted.
- If you are importing binary files, then those files must have been generated on an SAP HANA system that has the same endianness as the destination system.

#### Context

You cannot import a database object larger than 2 GB. If you are importing a database object larger than 1 GB, then import the object to the SAP HANA computer rather than to the local computer.

#### Procedure

1. In the SAP HANA database explorer, right-click the schema that you want to import the objects to, and choose *Import Catalog Objects*.
2. Specify the directory you're importing the file from and whether you're importing the object from your local computer or an SAP HANA server. If this file is greater than 1 GB, then it must be imported from the same

computer as the SAP HANA server to avoid sending large amounts of data across the network. The import fails if the file exceeds 2 GB.

3. Specify the scope of the import by choosing the relevant options:

Option	Description
<i>Include dependencies</i>	Dependent objects of the selected objects are also imported. For example, if a table has any triggers or indexes associated with it, then these definitions are imported.
<i>Include table data</i>	Import the table data along with the table definitions.  If you deselect this option, then only the table definitions are imported.
<i>Replace existing objects</i>	If objects with the same names already exist in the destination database, then they are overwritten by the objects being imported.
<i>Fail import if it contains invalid data</i>	If you are including object data when importing a catalog object, then selecting this checkbox ensures that your import is canceled if any of the object data is incomplete or corrupt.
<i>Number of parallel threads</i>	Increasing the number of threads can speed up the import and affect database performance. Consider the following guidelines when choosing the number of threads to use: <ul style="list-style-type: none"><li>○ For a view or procedure, use two or more threads, up to the number of dependent objects.</li><li>○ For a whole schema, consider using more than ten threads, up to the number of CPU cores in the system.</li><li>○ For an SAP BW or SAP ERP system with tens of thousands of tables, using many threads is reasonable (up to 256).</li></ul>

4. Click *Import*.

## Results

The catalog objects are imported. The length of time that the export process takes depends on the number of objects being imported and the scope of the import.

You can monitor the progress of a running import with the M\_IMPORT\_BINARY\_STATUS monitoring view.

## Related Information

## 6.11.4.4 Import Data Into a New or Existing Table

Import data from your local system into a new or existing database table.

### Prerequisites

You cannot import CSV files larger than 200 MB.

The file content must follow the data type format supported by SAP HANA as documented in the *SAP HANA SQL and System Views Reference* guide.

### Context

Import data from a comma-separated value (CSV) file.

Unlike using the IMPORT statement, which only allows you to import data if you are creating or replacing a table, this feature allows you to add rows of data to an existing table.

### Procedure

1. Right-click on one of the following to access the context menu: your database, your database's *Tables* icon, or the table you want to import the data to.
2. In the context menu, click *Import Data*.

The import wizard opens.

3. Configure your *Import Properties*.
  - a. If the first row of your file contains a header, then leave *File has header in first row* checked (the default). If the first row of your file contains data, then un-check the box.

#### i Note

If you un-check the *File has header in first row* option, then the first row of your file is considered data content and must contain data in every column.

- b. Choose a file to import your data from.
- c. Choose a schema to import your data to.
- d. Choose a new or existing table to import your data to.

#### i Note

If you are importing the data into an HDI container or an Application Managed Service Instance, then you can only import your data into an existing table.

If you are importing your data into an SAP HANA single or multitenant database, then you can import your data into a new table or add data to an existing table.

4. Click [Step 2](#).
5. Configure the mapping for the new table.
  - a. If you are creating a new table, then specify your table type and column names and properties, such as data type and column order.
  - b. If you are importing your data to an existing table, then configure the source column names for the target columns.

When dragging a column into the table, you must drag it either directly above or below another column.

6. Specify the type of error handling for the server during the import process.
7. Click [Show Import Summary](#) to view a preview of your import.
8. Click [Import Into Database](#).

## Results

The data is imported into the specified table and the import progress is displayed on the [Import Status](#) page. Press [Cancel](#) at any time to roll back the import operation.

## 6.11.4.5 Open Catalog Objects

Browse your database's catalog using the SAP HANA database explorer.

### Prerequisites

You must be a user of the database that you want to explore and you must have the required privileges to view the catalog items.

### Context

Some monitoring and problem analysis may require you to examine individual tables and views, for example, system views provided by the SAP HANA database. Use the catalog browser, which is located in the left pane, to find and open these catalog objects.

### Procedure

1. In the catalog browser, choose the database that you want to explore.  
If your database is not listed in the catalog browser, then click [Add a database to the Database Explorer](#) (+) to add the database.

The catalog browser lists the catalog objects, grouped by schema.

2. Choose an object type to view its objects.

For example, choose [Tables](#) to list the tables in the database.

3. Choose an object to view its definition in an editor in the right pane, or right-click the object to choose a different action.

For example, right-click a table and choose [Open Data](#) to view the table's data.

[Create a Table in Runtime \[page 590\]](#)

[Create a View in Runtime \[page 592\]](#)

## 6.11.5.1 Opening Tables and Views

Some monitoring and problem analysis may require you to examine individual tables and views, for example, system views provided by the SAP HANA database. You can open tables and views in the SAP HANA studio in different ways. Several viewing options are available depending on what you want to do.

### 6.11.5.1.1 Navigate to a Table or View

Navigate to the table or view in the *Systems* view.

#### Procedure

1. In the *Systems* view, navigate to the table or view you want to open.
2. From the context menu, choose how you want to view the table or view:
  - Definition
  - Content
  - Data preview

#### **i** Note

By default, double-clicking the table or view in the *Systems* view opens its definition. You can configure this setting in the preferences of the SAP HANA studio.

#### Results

The table or view is displayed using the selected viewing option.

#### Related Information

[Table Definition \[page 588\]](#)

[Table/View Content \[page 590\]](#)

[Data Preview \[page 590\]](#)

## 6.11.5.1.2 Search for a Table or View

Search for the table or view.

### Procedure

1. From the *Systems* view toolbar, choose the  (*Find Table*) button.
2. Enter a search string (at least two characters, case insensitive).  
Matching tables and views are displayed immediately.
3. Select the required table or view.
4. Choose whether you want to display the content and/or the definition of the table or view.

### Results

The table or view is displayed using the selected viewing option.

### Related Information

[Table Definition \[page 588\]](#)

[Table/View Content \[page 590\]](#)

[Data Preview \[page 590\]](#)

## 6.11.5.2 Viewing Options for Tables and Views

You can open tables and views in different ways in the SAP HANA studio depending on what you want to do.

Open a table or view using one of the following viewing options:

- [Table Definition \[page 588\]](#)
- [Table/View Content \[page 590\]](#)
- [Data Preview \[page 590\]](#)

## 6.11.5.2.1 Table Definition

The definition view of a table provides you with information about the table's structure and properties (for example, schema, type, column properties, and indexes).

Detailed information relating to the table's memory usage and size is available on the *Runtime Information* sub-tab. This information can be useful in the following cases, for example:

- You want to examine the memory usage of an individual table in detail as part of performance analysis or optimization.
- You want to review the partitioning of a table.

Due to the different memory management concepts for row store and column store tables, the information displayed varies according to table type.

### i Note

For views, only the create statement is available.

## Runtime Information of Column-Store Tables

For column-store tables, you can review the following information:

- Overall memory usage information for the table, including total size of the table in memory, size of main and delta storages in memory, number of records, and size on disk

### i Note

It is not possible to accurately determine the memory consumption of a table from its size on disk. This is because not all data structures that represent a table are stored on disk, they are only created when the table is loaded into memory.

- Detailed memory usage information at the level of partition and individual column

### i Note

If the table is not partitioned, the information for the single item on the *Parts* tab is for the table.

The following information may be useful:

Column	Description
Total size	The cumulative in-memory size of all columns and internal structures in the partition, or of the individual column
Main size	The cumulative in-memory size of all columns in the partition in main storage, or of the individual column in main storage
Delta size	The cumulative in-memory size of all columns in the partition in delta storage, or of the individual column in delta storage

Column	Description
Estimated maximum size	The estimated maximum size of the table when loaded into memory, including main and delta storages
Time of last delta merge operation	Time of last delta merge operation
Load status	Partitions can be fully, partially, or not loaded. Individual columns can be either loaded or not.
Main storage compression ratio (%)	The current compression ratio of the column in main storage

### i Note

If you want to analyze the compression ratio of a table, it must be fully loaded into memory.

## Runtime Information of Row-Store Tables

For row-store tables, you can review the following information:

- Overall memory usage information for the table, including total size of the table in memory, number of records, and size on disk
- Memory usage of fixed and variable parts of the table  
Row tables are permanently stored in memory using a linked list of pages. The values displayed here indicate the occupancy level of available pages.

### i Note

The memory usage information of column and row store information displayed on the *Runtime Information* tab is retrieved from the following monitoring views:

- M\_TABLES
- M\_RS\_TABLES
- M\_CS\_TABLES
- M\_CS\_COLUMNS
- M\_CS\_PARTITIONS

## Related Information

[Memory Sizing \[page 513\]](#)

[M\\_RS\\_TABLES System View](#)

[M\\_TABLES System View](#)

[M\\_CS\\_TABLES System View](#)

[M\\_CS\\_COLUMNS System View](#)

[M\\_CS\\_PARTITIONS System View - Deprecated](#)

## 6.11.5.2 Table/View Content

Opening the content view of a table or view executes a SELECT statement on the table/view. The results set shows the actual records in the table/view. This is useful, for example, if you want to view the content of a system view to help you understand what is happening in the database.

When you open the content view, by default, only the first 1,000 rows of the table or view are displayed. You can change this setting in the preferences of the SAP HANA studio under ► [SAP HANA](#) ► [Runtime](#) ► [Catalog](#) ⌵.

To view the full content of a table cell, for example a large object (LOB) value, in the context menu of the cell, choose ► [Export Cell to...](#) ► [Zoom...](#) ⌵

### i Note

LOB values are not formatted. Any LOB data that cannot be visualized is not changed.

## 6.11.5.2.3 Data Preview

Opening the data preview of a table or view allows you to analyze its content in different ways. Similarly to the content view, this is particularly useful for analyzing system views.

### ♣ Example

You want to check the global memory consumption of the database over the last 30 days.

1. Open the data preview of the table `HOST_RESOURCE_UTILIZATION_STATISTICS` (`_SYS_STATISTICS` schema).
2. Choose the *Data Analysis* tab.
3. Move the column `SERVER_TIMESTAMP` from the *Available Objects* area to the *Labels Axis* area.
4. Move the column `INSTANCE_TOTAL_MEMORY_USED_SIZE` from the *Available Objects* area to the *Values Axis* area.
5. Choose your preferred graphical output.

## 6.11.5.3 Create a Table in Runtime

A table is a two dimensional data structure with cells organized in rows and columns. Tables can be created as row-store or column-store tables depending on the use case.

### Prerequisites

To create a table, you must be authorized to create objects in the selected schema.

## Context

### i Note

The following procedure describes how to create a simple table in runtime. Database and application developers use SAP HANA development tools to create database objects such as tables as design-time objects in the repository of the SAP HANA database. For more information, see the *SAP HANA Developer Guide*.

## Procedure

1. In the *Systems* view, open the catalog and navigate to the schema in which you want to create the new table.
2. In the context menu of the schema in which you want to create the table, choose *New Table*
3. Enter the following information:
  - Table name
  - Table type (column store or row store)
4. Define the columns of your table as follows:
  - a. Enter the name and properties of the first column.
  - b. To add further columns, choose the  button.
5. If necessary, add indexes.
  - a. On the *Indexes* tab, choose the  button.
  - b. Specify the name and the index type (standard index or full-text index).  
A full-text index enables full-text search.
  - c. In the lower part of the screen, define the index for the required column(s), together with any other necessary parameters.

### i Note

You can create an index for a table any time either by right-clicking the table in the *Systems* view and choosing *New Index*, or opening the table definition for editing.

Indexes are added to the table definition and in the schema's *Indexes* folder.

6. To create the table, choose  (*Create Table*).

## Results

The table appears in the *Tables* folder of the relevant schema.

## Related Information

[Setting up the Data Persistence Model in SAP HANA](#)  
[Creating Full-Text Indexes Using SQL](#)

### 6.11.5.4 Create a View in Runtime

A view is a combination or selection of data from tables modeled to serve a particular purpose.

#### Prerequisites

You are authorized to create objects in the selected schema and to select data from the tables to be included in the view.

#### Context

A view is a combination or selection of data from tables modeled to serve a particular purpose. Views appear like readable tables, in other words, database operations that read from tables can also be used to read data from views. For example, you can create a view that simply selects some columns from a table, or a view that selects some columns and some rows according to a filter pattern.

#### i Note

The following procedure describes how to create a simple SQL view in runtime. Database and application developers use SAP HANA modeling tools to create database objects such as modeled views as design-time objects in the repository of the SAP HANA database. For more information, see the *SAP HANA Developer Guide*.

#### Procedure

1. In the *Systems* view, open the catalog and navigate to the *Views* folder in the relevant schema.
2. In the context menu, choose *New View*.  
The editor for creating a new view opens.
3. Specify the view name.
4. Select the relevant tables by dragging them from the *Systems* view into the editor area, or by choosing the  (*Insert*) button.
5. To create a join, proceed as follows:
  - a. Drag a column from one table to the column of another table.

- b. Choose the join type in the *Join Order* area.

If you define more than one join, you can define the order in which the joins are executed using drag and drop.

6. Drag and drop the columns to be contained in the result set into the *Columns* area.  
You can specify additional constraints or create synonyms for column names here.
7. To preview the data, choose *Data Preview* in the context menu of the editor.
8. To show the equivalent SQL statement, choose *Export SQL* in the context menu of the editor.
9. To create the view, choose the  (*Execute*) button.

## Results

The view appears in the *Views* folder of the relevant schema.

## Related Information

[Setting Up the Analytic Model](#)

### 6.11.5.5 Export Tables and Other Catalog Objects

Using the SAP HANA studio, you can export all catalog objects to a file system and then import them back into another database. This may be necessary, for example, to move data from a test system to a production system, clone your system, or provide the data to SAP Support so they can replicate a scenario.

## Prerequisites

- You have SQL object privilege SELECT for the catalog objects in question.
- To browse server directories the SAP HANA studio and server have to be installed on one machine.

## Procedure

1. Select the objects you want to export in one of the following ways:

Option	Description
Find objects for export	1. From the main menu, choose  <i>File</i>  <i>Export</i>  .

Option	Description
	<ol style="list-style-type: none"> <li>2. Select the export destination ► <i>SAP HANA</i> ► <i>Catalog Objects</i> ► and choose <i>Next</i>. The <i>Export</i> dialog box appears.</li> <li>3. Search for the objects you want to export and add them to list of objects to be exported on the right.</li> </ol>
<b>Select object for export</b>	<ol style="list-style-type: none"> <li>1. In the <i>Systems</i> view, select the objects that you want to export.</li> <li>2. From the context menu, choose <i>Export</i>. The <i>Export</i> dialog box appears. The selected objects are displayed on the right of the dialog box.</li> <li>3. Optional: Search for additional objects to be exported and add them to list of objects to be exported on the right.</li> </ol>

2. Choose *Next*.
3. Specify the scope of the export by choosing the relevant options:

Option	Description
<b>Column Table Format</b>	The file format used for export can be either CSV or binary. Exports in binary format are faster and more compact. However, CSV format is better if you need to use the data in a non-SAP HANA system. It also has the advantage of being human readable. Binary is selected by default.

#### i Note

Column-store tables, procedures, and sequences can be exported in either binary or CSV format. However, row-store tables can be exported only in CSV format. If you trigger an export of catalog objects that includes row-store tables but you select binary as the format, the row-store tables will be exported but in CSV format.

<b>Export Catalog Objects</b>	<p>Using the following options, you can configure the scope of the export:</p> <ul style="list-style-type: none"> <li>○ Select <i>Including Data</i> to export both object definitions and data are exported. This option is selected by default.</li> </ul> <p>If you deselect this option, only object definitions are exported. This may be useful, for example, if want to copy only the table definition in order to create a new table with the same structure.</p> <ul style="list-style-type: none"> <li>○ Select <i>Including Dependencies</i> to export dependent objects of selected objects, that is triggers and indexes. This option is selected by default.</li> </ul>
-------------------------------	---

4. Specify the location to which the file is to be exported:

Option	Description
<b>Export Catalog Objects on Server</b>	The selected catalog objects are saved to a directory on the database server file system. The default directory is <code>/usr/sap/&lt;SID&gt;&lt;instance&gt;/work</code> .

#### i Note

If you want to specify a different directory in the server's file system, it must already exist and the database must be authorized to access it.

<b>Export Catalog Objects to Current Client</b>	The selected catalog objects are saved in the specified directory on the client file system.
---	--

#### i Note

The specified directory must be empty. You can specify a directory that does not exist; it will be created when you start the export.

### → Recommendation

For the export of small tables or catalog-only exports, a CSV export to the client file system is appropriate. However, keep the maximum file size of your operating system in mind. A binary export on the server is recommended for large exports (for example, exports over 2 GB).

5. Enter the number of parallel threads to be used for the export.

The more threads you use, the faster the export will be. This does however impact the performance of the database as more threads use more resources.

### → Recommendation

The following guidelines apply:

- For a view or procedure, use two or more threads, up to the number of dependent objects.
- For a whole schema, consider using more than 10 threads, up to the number of CPU cores in the system.
- For a whole SAP BW or SAP ERP system with tens of thousands of tables, using a large number of threads is reasonable (up to 256).

6. Choose *Finish*.

## Results

The catalog objects are exported to the specified location. Depending on the number of objects being exported and the scope of the export, this may take some time.

You can monitor the progress of a running export in the monitoring view M\_EXPORT\_BINARY\_STATUS.

Information messages and errors are recorded in the *Error Log* view ( [Window](#)  [Show View](#)  [Error Log](#) .

## Related Information

[M\\_EXPORT\\_BINARY\\_STATUS System View](#)

## 6.11.5.6 Import Tables and Other Catalog Objects

Using the SAP HANA studio, you can import previously exported catalog objects into another database. This may be necessary, for example, to move data from a test system to a production system, clone your system, or provide the data to SAP Support so they can replicate a scenario.

### Prerequisites

- Depending on the import, you have the SQL object privilege INSERT/UPDATE, DROP, or CREATE for the catalog objects in question.
- If you are importing binary files, then those files must have been generated on an SAP HANA system that has the same endianness as the destination system.
- To browse server directories, the SAP HANA studio and server have to be installed on one machine.

### Context

You can import previously exported catalog objects into an another database. This may be necessary, for example, if you want to move data from a test system to a production system, if you want to clone your system, or if you want to provide the data to SAP Support so they can replicate a certain scenario.

### Procedure

1. Select the objects you want to import in one of the following ways:

Option	Description
Find objects for import	<ol style="list-style-type: none"><li>1. From the main menu, choose <b>File &gt; Import</b>.</li><li>2. Select the import source <b>SAP HANA &gt; Catalog Objects</b> and choose <i>Next</i>. The <i>Import</i> dialog box appears.</li><li>3. Specify the location of previously exported objects:<ul style="list-style-type: none"><li>○ For objects exported on the database server file system, choose <i>Import Catalog Objects on Server</i> and enter the directory. The default export directory is entered by default.</li><li>○ For objects exported to a location on the client file system, choose <i>Import Catalog Objects from Current Client</i> and browse to the directory.</li></ul></li><li>4. Choose <i>Next</i>.</li><li>5. Search for the objects that you want to import and add them to list of objects to be imported on the right. You can filter the search results by format type (CSV or binary).</li></ol>

Option	Description
<b>Select objects for import</b>	<ol style="list-style-type: none"> <li>In the <i>Systems</i> view, select the objects that you want to import.</li> <li>From the context menu, choose <i>Import</i>. The <i>Import</i> dialog box appears.</li> <li>Specify the location of previously exported objects: <ul style="list-style-type: none"> <li>For objects exported on the database server file system, choose <i>Import Catalog Objects on Server</i> and enter the directory. The default directory for export is entered by default.</li> <li>For objects exported to a location on the client file system, choose <i>Import Catalog Objects from Current Client</i> and browse to the directory.</li> </ul> </li> <li>Choose <i>Next</i>.</li> <li>Optional: Select any additional objects found at the specified export location that you want to import and add them to list of objects to be imported on the right. For objects exported to a location on the client file system, you can filter the search results by format type (CSV or binary).</li> </ol>

- Choose *Next*.
- Specify the scope of the import by choosing the relevant options:

Option	Description
<b>Including Data</b>	<p>Object definitions and data are imported.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>This option is selected by default. However, the export must have included both definition and data.</p> </div> <p>If you deselect this option, only object definitions are imported. For example, you may want to copy only the table definition in order to create a new table with the same structure.</p>
<b>Including Dependencies</b>	<p>Dependent objects of selected objects are also imported, that is triggers and indexes. This option is selected by default.</p>
<b>Replace Existing Catalog Objects</b>	<p>If the objects already exist, they are overwritten.</p>

- Enter the number of parallel threads to be used for the import.

The more threads you use, the faster the import will be. This does however impact the speed of the database as more threads uses more resources.

#### → Recommendation

The following guidelines apply:

- For a view or procedure, use two or more threads, up to the number of dependent objects.
- For a whole schema, consider using more than 10 threads, up to the number of CPU cores in the system.
- For a whole SAP BW or SAP ERP system with tens of thousands of tables, using a large number of threads is reasonable (up to 256).

- Choose *Finish*.

## Results

The catalog objects are imported from the specified location. Depending on the number of objects being imported and the scope of the import, this may take some time.

You can monitor the progress of a running import in the monitoring view `M_IMPORT_BINARY_STATUS`.

Information messages and errors are recorded in the *Error Log* view ().

### 6.11.5.7 Import ESRI Shapefiles

SAP HANA supports the Environmental System Research Institute, Inc. (ESRI) shapefile format. ESRI shapefiles are used to store geometry data and attribute information for the spatial features in a data set. You can import ESRI shapefiles into SAP HANA column-store tables using the SAP HANA studio.

## Prerequisites

You have the required privileges for creating and updating objects in the target schema (INSERT/UPDATE or CREATE ANY) or for creating schemas (CREATE SCHEMA).

## Context

Spatial data is data that describes the position, shape, and orientation of objects in a defined space. SAP HANA supports spatial data processing, which for example allows application developers to associate spatial information with their data.

The ESRI shapefile format is a popular geospatial vector data format for representing spatial objects in the form of shapefiles (several files that are used together to define the shape). An ESRI shapefile includes at least three different files: `.shp`, `.shx`, and `.dbf`. The suffix for the main file is `.shp`, the suffix for the index file is `.shx`, and the suffix for the attribute columns is `.dbf`. All files share the same base name and are frequently combined in a single compressed file.

You can import ESRI shapefiles into dedicated column-store tables using the import feature of SAP HANA studio.

## Procedure

1. From the main menu, choose **File > Import**.
2. Select import source **SAP HANA > ERSI Shapefiles** and choose *Next*.
3. Select the system that you want to import the shapefiles into and choose *Next*.  
Only shapefiles are available for selection.
4. Enter the schema into which you want to import the shape data.  
If the schema does not exist and you have the required privileges, the schema is created.  
If the table with the same name as the shapefile already exists, you can choose to overwrite it.
5. Enter the number of parallel threads to be used for the import.  
The more threads you use, the faster the import will be. This does however impact the speed of the database as more thread uses more resources.
6. To start the import, choose *Finish*.

## Results

The shapefiles are imported into column-store tables in the specified schema. Each shapefile corresponds to one table. Depending on the number of shapefiles being imported, this may take some time.

Information messages and errors are recorded in the *Error Log* view (**Window > Show View > Error Log**).

## Related Information

[Import ESRI Shapefiles Using SQL Commands](#)

### 6.11.6 Importing Data from External Sources

A number of options are available for importing external data to tables in the SAP HANA database.

You can import data from external sources to the SAP HANA database; this can be either a complete table or data which is appended to an existing table. Typically the data is in CSV format although binary, GZIP and other formats are supported (refer to the *SAP HANA SQL and System Views Reference* for full syntax details). Importing Microsoft Excel formats is possible within the Database Explorer in SAP HANA cockpit which provides a step-by-step wizard for this.

The two SQL commands for importing data are IMPORT and IMPORT FROM:

- IMPORT is used to import catalog objects (tables, views, synonyms, sequences, and procedures) that have previously been exported with the EXPORT statement.
- IMPORT FROM is used to import external data and append it to an existing table.

## Using IMPORT FROM with Network Sources

The basic syntax for using IMPORT FROM is shown in this example:

```
IMPORT FROM CSV FILE '/data/data.csv' INTO "MYTABLE"  
WITH ERROR LOG '/data/data.err'
```

The file type can be either a CSV file or, for statistics objects, a control file. The file path and the target object are required and a number of options are supported in the WITH <import\_from\_option\_list> clause, these include the location of the error log.

For full details of the options and examples of this command refer to the *SAP HANA SQL Reference Guide*.

## Security

Users need the IMPORT privilege to access files on the file server, this is not granted by default to any user. Access is limited to files which can be read by the <sid>adm of the HANA system.

By default, only three locations can be used for the CSV source data and the error log:

- \$DIR\_INSTANCE/work
- \$DIR\_INSTANCE/backup
- \$SAP\_RETRIEVAL\_PATH/trace

If you use a different location in the command it will generate a warning message that the path is invalid. If you wish to use a different location it must be specified in the configuration parameter *csv\_import\_path\_filter* in the *import\_export* section of the *indexserver.ini* configuration file.

For more information on Security see the following SAP Notes:

- 2109565 - Potential information disclosure relating to IMPORT FROM statement in SAP HANA
- 2876090 - Security Restriction on Setting Error Log Option of IMPORT/EXPORT FROM Command.

## Named Pipes

Typically, the data must be copied to the specified file path on the HANA server, however, the <file path> clause of this command also supports named pipes. A persistent pipe, also referred to in Linux as 'FIFO', transfers data in memory either from a local or network source and makes it unnecessary to manually copy the CSV file to a local disk. The performance for this type of import is also significantly faster.

In the following example, the HANA server is set up to listen (steps 1-3) and an external node on the network is set up to send data (step 4). This example uses netcat (nc) to set up the named pipe but appropriate security precautions must be taken - see following note.

### ⚠ Caution

You must take responsibility for security implications if using tools such as netcat which provides no encryption and no authentication.

1. Create the named pipe on the HANA server:

```
$ mkfifo /tmp/myfifo
```

2. Start the netcat listener and redirect its output to the named pipe:

```
$ nc -l 8080 > /tmp/myfifo
```

3. Execute the IMPORT FROM command specifying the named pipe as the file path:

```
IMPORT FROM CSV FILE '/tmp/myfifo' INTO "SYSTEM"."TBL_A";
```

4. On the external host start netcat to send the CSV data, specifying the target server and port number and the source of the data:

```
$ nc MyHANAServer:8080 < /path/to/csvfile
```

Once this has been set up it remains open and HANA polls the pipe continuously until either the end of the data stream is reached or until the session is canceled.

The named pipe can also be used for local data and the following example shows a command to redirect local text data to the pipe:

```
$ cat /path/to/csvfile > /tmp/myfifo
```

## 6.11.7 Table and Catalog Consistency Checks

Using stored procedures and commands available in the SAP HANA database, you can perform a range of consistency checks on the database catalog and on database tables.

You are recommended to integrate consistency checks into your routine maintenance schedule so that any problems can be detected as soon as they occur.

Two command line procedures are available to check table consistency and the database catalog:

```
CALL CHECK_TABLE_CONSISTENCY ()
```

```
CALL CHECK_CATALOG ()
```

Optionally, the table consistency check can be scheduled within the embedded statistics service.

For each procedure a list of checking actions is available, for example, CHECK\_COLUMN\_TABLES, CHECK\_ROW\_TABLES, CHECK\_PARTITIONING\_DATA, and so on; these can all be individually activated or

omitted from the check as required. For some of these checks a repair option is supported, for example REPAIR\_PARTITIONING\_DATA. Additional privileges are required for repair actions, these actions must be explicitly specified and must be run separately from check actions. A complete list of all check and repair actions for the two procedures is available by running `GET_CHECK_ACTIONS()`. Details of these commands, configuration options and the statistics features for table consistency checks are given in the sections which follow.

#### → Recommendation

Running database checks affects system performance therefore the checks should be run in a timeframe when the system is not at high load. If you are running an active/active (read enabled) system you can run the checks on the read enabled secondary system, or possibly on a system copy.

[Configuration Parameters for the Table Consistency Check \[page 607\]](#)

[Active/Active \(Read Enabled\) \[page 1328\]](#)

[The Statistics Service \[page 414\]](#)

### 6.11.7.1 Table Consistency Check

The table consistency check is a procedure available in the SAP HANA database that performs a range of consistency check actions on database tables. It can be run from the command line or scheduled within the statistics service.

## Manual Execution

To execute the procedure manually, you must have the following system privileges:

- CATALOG READ for check actions
- DATA ADMIN for repair actions

## Input Parameters

To see details of all check actions which relate to table consistency, including a description of what they do, call the procedure `GET_CHECK_ACTIONS`:

```
CALL GET_CHECK_ACTIONS('CHECK_TABLE_CONSISTENCY')
```

## Syntax

The syntax of the table consistency check procedure is as follows:

```
CALL CHECK_TABLE_CONSISTENCY ('<check_action1>[,<check_action2>]',  
'<schema_name>', '<table_name>')
```

This procedure is also available for the Dynamic Tiering option but the syntax and options supported are different. Refer to the SAP HANA SQL Reference Guide for details.

Use the parameter `check_action` to define one or more specific check actions, or enter **CHECK** as the value to execute all default check actions. Use the parameters `schema_name` and `table_name` to define specific schemas and tables to check, or enter **NULL** as the value for these parameters to check all tables in all schemas.

### ❖ Example

The first example performs all default check actions on all tables. The second example performs only two specific checks (primary key and column tables) on two named tables:

```
CALL CHECK_TABLE_CONSISTENCY ('CHECK', NULL, NULL)  
  
CALL CHECK_TABLE_CONSISTENCY('CHECK, CHECK_PRIMARY_KEY, CHECK_COLUMN_TABLES',  
'MYSHEMA', 'MYTABLE01, MYTABLE02');
```

Check actions can be excluded by using a minus character before the action name. This command for example, executes all checks which are included in the summary action 'CHECK' except for CHECK\_PRIMARY\_KEY:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK, -CHECK_PRIMARY_KEY', NULL, NULL);
```

The following three actions cannot be excluded: 'CHECK', 'CHECK\_COLUMN\_TABLES', 'CHECK\_ROW\_TABLES'.

It is also possible to use the minus character to exclude specific tables from the consistency check. This command for example, executes all checks on all tables except for tables 'T1' and 'T2':

```
CALL CHECK_TABLE_CONSISTENCY('CHECK', 'SYSTEM', '-T1, -T2');
```

Note that you cannot mix excluding tables and naming specific tables in the same command; this would generate an error.

The results returned are available in two monitoring views as described below under Statistics Service - Results.

### i Note

Some check actions are contained within others and are therefore not explicitly executed when you execute the CHECK action. Repair actions make changes to the data and are excluded from the CHECK action.

Lower case characters and special characters in schema and table names must be enclosed in double quotes. The syntax, for example, for a table named "ABC/abc" in the SYSTEM schema must be as follows:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK', 'SYSTEM', '"ABC/abc"');
```

## Results

Results of all consistency checks, whether executed manually or scheduled in the statistics service, are available in two monitoring views:

- `M_CONSISTENCY_CHECK_HISTORY`
- `M_CONSISTENCY_CHECK_HISTORY_ERRORS`

The first view gives high level information about parameters used for the check, runtime duration and the total number of tables with errors; each run is identified by a `CHECK_EXECUTION_ID` value. The errors table lists and gives details of all errors found within each check run. If errors are found you may wish to contact SAP Support to analyze the results and advise on any required action.

In order to avoid storing redundant data, if a manually executed run is repeated by the same user and returns the same results the existing entry in the history table is updated with statistical information instead of creating a new entry for each run. The history table contains statistical information of all related runs, including minimum/maximum/average runtime, number of invocations, timestamp of first/last invocation.

To save disk space you can also clear these tables by executing the following statement:

```
ALTER SYSTEM CLEAR CONSISTENCY CHECK HISTORY [UNTIL <timestamp>]
```

This statement cleans up all entries in the `SYS.CONSISTENCY_CHECK_RUNS_` and `SYS.CONSISTENCY_CHECK_HISTORY_ERRORS_` tables up to the specified point in time.

## Configuration

A set of ini parameters in the `indexserver.ini` file is available to control the command line table consistency check. These include, for example: startup behavior, timeout values, and 'smart' job scheduling parameters to skip large jobs which may severely impact performance. These are described in detail in a separate subsection.

Two SAP Notes on consistency checks are available: 1977584 and an FAQ Note 2116157.

## Table Consistency Checks in the Statistics Service

You are recommended to schedule the table consistency check so that it runs automatically at regular intervals. The frequency depends on your scenario.

Table consistency checking can be scheduled in the embedded statistics service using collector `_SYS_STATISTICS.Collector_Global_Table_Consistency`. Run-time parameters are maintained as key-value pairs in the `_SYS_STATISTICS.STATISTICS_PROPERTIES` table and the results of the check (details of any errors which are found) are available in the statistics view `GLOBAL_TABLE_CONSISTENCY`. The statistics server also includes a configurable Table Consistency alert (#83) which checks the number of errors and affected tables detected by the consistency check.

The following property values (run-time parameters) can be defined:

Key	Default Value
<code>internal.table_consistency.check_actions</code>	<code>check_variable_part_sanity, check_data_container, check_variable_part_double_reference_global, check_partitioning, check_replication, check_table_container_no_load</code>

Key	Default Value
internal.table_consistency.target_schema	NULL (all schemas)
internal.table_consistency.target_table	NULL (all tables)
internal.table_consistency.max_duration	0 (no maximum duration)

Note that by default a relatively small number of check actions is carried out to avoid overloading the system, however, the keyword 'check' is available here which acts as a wildcard to execute all check actions. To activate all check actions update this value as shown here.

```
update _SYS_STATISTICS.STATISTICS_PROPERTIES set value = 'check' where key =
'internal.table_consistency.check_actions'
```

The processing sequence for column store tables (row store tables are typically much smaller) is done in strict rotation based on the value of a last check timestamp (oldest first). This ensures that even if the check is canceled before it completes, all tables will eventually be checked over a number of procedure runs.

## Result

Results of all consistency checks, whether executed manually or scheduled in the statistics service, are available in two monitoring views as described above.

## Disabling Automatic Checks

You can temporarily disable the statistics collector and alert by executing the following statements:

```
CALL CHECK_TABLE_CONSISTENCY('SET_COLLECTOR_SCHEDULE', 'status', 'inactive')
CALL CHECK_TABLE_CONSISTENCY('SET_ALERT_SCHEDULE', 'status', 'inactive')
```

You can re-enable the statistics collector and alert by repeating these calls and setting the 'inactive' value to 'idle'.

[SAP Note 2116157](#)

[CALL CHECK\\_TABLE\\_CONSISTENCY Statement \(Multistore Table\) \[Dynamic Tiering\]](#)

[Configuration Parameters for the Table Consistency Check \[page 607\]](#)

## 6.11.7.2 Catalog Consistency Check

The catalog consistency check can be run from the command line or be scheduled at the operating system level to perform a range of consistency check actions on the database catalog. The frequency with which you do this depends on your scenario.

### → Recommendation

Do not simultaneously run the catalog check and perform DDL operations (for example, dropping users) since this may cause the check to return multiple errors. Either run the catalog check on the system copy

or wait until other operations have completed. Only if you continue to receive errors should you contact SAP Support.

## Manual Execution

To execute this procedure, you must have the system privilege CATALOG READ (or DATA ADMIN).

The syntax of the table consistency check call is as follows:

```
CALL CHECK_CATALOG  
( '<action>', '<schema_name>', '<object_name>', '<catalog_object_type>' )
```

The `action` parameter specifies the check action(s) to be performed.

To see details of all check actions which relate to catalog consistency, including a description of what they do, call the procedure `GET_CHECK_ACTIONS`:

```
CALL GET_CHECK_ACTIONS ('CHECK_CATALOG' )
```

Use the parameter `action` to define one or more specific check actions, or enter `CHECK` as the value to execute all available actions. Use the parameters `schema_name` and `object_name` to define specific schemas and objects to check, or enter `NULL` as the value for these parameters to check all objects in all schemas.

Specify `NULL` as the value for the parameter `catalog_object_type`. This parameter is not currently effective and is reserved for future use.

### ❖ Example

To perform all check actions on all objects of all types, execute the statement:

```
CALL CHECK_CATALOG ('CHECK', NULL, NULL, NULL)
```

Object names are case sensitive and this example shows the use of quotation marks to submit a lower-case table name:

```
CALL CHECK_CATALOG ('CHECK', 'SYSTEM', '"mytest"', 'TABLE');
```

## Result

If errors are found the procedure returns a set of results with the following columns: SCHEMA, NAME, OBJECT\_TYPE, ERROR\_CODE, ERROR\_MESSAGE.

If errors are found, you may wish to contact SAP Support to analyze the results and advise on the required action.

## 6.11.7.3 Configuration Parameters for the Table Consistency Check

A set of configuration parameters in the `indexserver.ini` file is available to control the manual table consistency check.

The configuration parameters that control startup behavior are in the `metadata` and `row_engine` sections of the configuration file. Other parameters for timeout values and parameters to skip large jobs which may severely impact performance are available in the `table_consistency_check` section.

### [metadata]

Parameter	<code>enable_startup_consistency_check</code>
Short Description	Enable/disable metadata consistency check during SAP HANA startup
Full Description	The metadata consistency check during startup includes CHECK_CATALOG is executed with check action CHECK_OBJECT_REFERENTIAL_INTEGRITY.
Type	Boolean
Change	Offline
Default	True

### [row\_engine]

Parameter	<code>consistency_check_at_startup</code>
Short Description	Configure row store consistency check during SAP HANA startup.
Full Description	This parameter is used to configure a row store consistency check via CHECK_TABLE_CONSISTENCY during SAP HANA startup. It's a list parameter and the allowed values are 'table', 'page' and 'index', which perform consistency checks on 'table', 'page' and 'index' respectively. This consistency check can be disabled by setting the parameter value to 'none'.
Type	List of strings
Change	Offline
Default	table,page,index

Parameter	<code>startup_consistency_check_timeout</code>
Short Description	Maximum duration of consistency check at SAP HANA startup
Full Description	This parameter controls the maximum duration of the row store consistency check executed during SAP HANA startup (see <code>consistency_check_at_startup</code> ).
Type	Integer

Parameter	startup_consistency_check_timeout
Unit	Second
Change	Offline
Default	600

### [table\_consistency\_check]

Parameter	check_max_concurrency_percent
Short Description	Maximum concurrency for table consistency check
Full Description	This parameter controls the overall CPU and thread resource consumption of CHECK_TABLE_CONSISTENCY, defined as a percentage of <code>max_concurrency_hint</code> in the <code>global.ini</code> file which is the general limit for the number of concurrently running threads.
Type	Integer
Range	1-100
Change	Online
Default	80

Parameter	enable_table_consistency_check_trace
Short Description	Enable/disable table consistency check tracing
Full Description	This parameter controls if the output of CHECK_TABLE_CONSISTENCY is dumped to trace files with the following naming convention: <code>&lt;service&gt;_&lt;host&gt;.&lt;port&gt;.table_consistency_check.&lt;timestamp&gt;.trc</code>
Type	Boolean
Change	Online
Default	True

Parameter	large_job_threshold
Short Description	Threshold for large jobs
Full Description	The parameters <code>large_job_threshold</code> and <code>max_num_large_jobs</code> can be used to make sure that not too many large tables are checked in parallel. Tables exceeding the defined number of rows (default: 100 million) are considered as large tables.
Type	Integer

Parameter	large_job_threshold
Unit	Number of rows
Change	Online
Default	100000000

Parameter	max_duration
Short Description	Define the maximum duration of a CHECK_TABLE_CONSISTENCY call
Full Description	This parameter controls the maximum duration of a CHECK_TABLE_CONSISTENCY call. After the specified time the CHECK_TABLE_CONSISTENCY call is implicitly canceled. The default value 0 refers to unlimited duration.
Type	Integer
Unit	Seconds
Change	Online
Default	0

Parameter	max_num_large_jobs
Short Description	Maximum number of large jobs running in parallel
Full Description	The parameters large_job_threshold and max_num_large_jobs can be used to make sure that not too many large tables are checked in parallel. This parameter controls the maximum number of large tables being checked at the same time.
Type	Integer
Change	Online
Default	4

Parameter	max_result_entry
Short Description	Maximum number of generated errors per node
Full Description	Maximum number of generated errors per SAP HANA node; if more errors are found, the following information is provided: <error_count> errors were found in total. <error_count - max_result_entry> errors are suppressed.
Type	Integer
Change	Online

Parameter	max_result_entry
Default	1000000

Parameter	max_result_entry_per_entity
Short Description	Maximum number of generated error per table
Full Description	Maximum number of generated error per table (partition). If more errors are found, the following information is provided: <error_count> errors were found in this table(partition). <error_count - max_result_entry_per_entity> errors are suppressed
Type	Integer
Change	Online
Default	1000

Parameter	remote_check_timeout
Short Description	Maximum wait time for remote checks
Full Description	CHECK_TABLE_CONSISTENCY terminates if checks on remote tables on secondary node aren't finished within the specified time range. The default value of 86400000 milliseconds refers to a maximum duration of one day.
Type	Integer
Unit	Millisecond
Change	Online
Default	86400000

## 6.11.8 Row Store Reorganization

Row store reorganization may be required from time to time to recover data fragments in memory; you can carry out reorganization either online or offline.

Row store reorganization recovers data fragments in memory that result from the way in which memory segments and pages are allocated. During reorganization fragmented pages are moved to other segments and the resultant empty segments are freed.

You can run the process online when the database is running or offline when the database is restarted:

- The offline process is run by setting the values of a series of 'row\_engine' configuration file parameters in the indexserver.ini file and then restarting the database. Generally, a better compaction ratio is achieved by running reorganization offline as there is no transaction update activity.

- The online process can be executed either by using the SQL system management statement RECLAIM DATA SPACE, or by executing the stored procedure REORGANIZE\_ROWSTORE(). These processes do not require exclusive access to tables, this means that tables can be updated while the reorganization process is running.

The stored procedure REORGANIZE\_ROWSTORE() can also be used to estimate the benefit of offline row store reorganization as described below.

SAP Note 1813245 - *SAP HANA DB: Row Store Reorganization* gives details of all prerequisites and the preparation steps required before running either online or offline reorganization and gives details of the configuration changes required for the offline process.

### ⚠ Caution

If you have not yet installed the SPS 05 update 052.00, then you must not run row-store reorganization on tables in the 'SYS' schema; in earlier versions this can cause corruption in the database. Details of this program error are given in SAP Note 2964340 - *Indexserver Crashes After Executing an Online Rowstore Reorganization for Tables in SYS Schema*.

## SQL RECLAIM DATA SPACE

The syntax for the SQL statement is as follows:

```
ALTER SYSTEM RECLAIM [ROW] DATA SPACE [IMMEDIATE] [<host_port>]
```

For reorganization on a remote node optional parameter values can be provided to specify the host and the port of the server where reorganization is to be carried out. If these are omitted reorganization is carried out on the server where the current connection is made.

Refer to the *SAP HANA SQL and System Views Reference* for further details of the RECLAIM DATA SPACE statement.

## Stored Procedure REORGANIZE\_ROWSTORE()

An advantage of using the stored procedure in preference to the SQL statement is that the stored procedure automatically distributes the command to all running nodes. The basic syntax of the stored procedure is:

```
CALL REORGANIZE_ROWSTORE ('REORGANIZE')
```

With the offline mode you can firstly estimate the benefit of row store reorganization and assess how much memory might be recovered; use the syntax illustrated in the following examples.

### Offline Mode Estimate

The syntax for the estimate option is as follows:

```
CALL REORGANIZE_ROWSTORE ('ESTIMATE_MEMORY_SAVING', 'OFFLINE');
```

The procedure returns the estimated saved memory size in MB, the estimated moved page size in MB and the estimated moved page count.

### Reorganize a Schema / Table / Segments

The syntax for the reorganize function is given here, the procedure can also be run for a specific named schema and table or for a specific segment:

```
CALL REORGANIZE_ROWSTORE ('REORGANIZE', 'TABLE', 'MySchema', ['<TABLE_NAME>'])
```

If the optional parameter TABLE\_NAME is not given, all row store tables in the specified schema will be reorganized.

Use the SEGMENTS key word to identify one or more segments to reorganize. In this case a json string is required to specify the segments as shown in the following example:

```
CALL REORGANIZE_ROWSTORE('REORGANIZE', 'SEGMENT', '[{"location": "host1:port1", "segments": [3, 4]}, {"location": "host2:port2", "segments": [5, 6, 7]}]')
```

This reorganizes segment 3, 4 on 'host1:port1' and segment 5, 6, 7 on 'host2:port2'

The procedure also includes a documentation parameter: REORGANIZE\_ROWSTORE ('HELP')

## Related Information

[SAP Note 1813245](#)

[SAP Note 2964340](#)

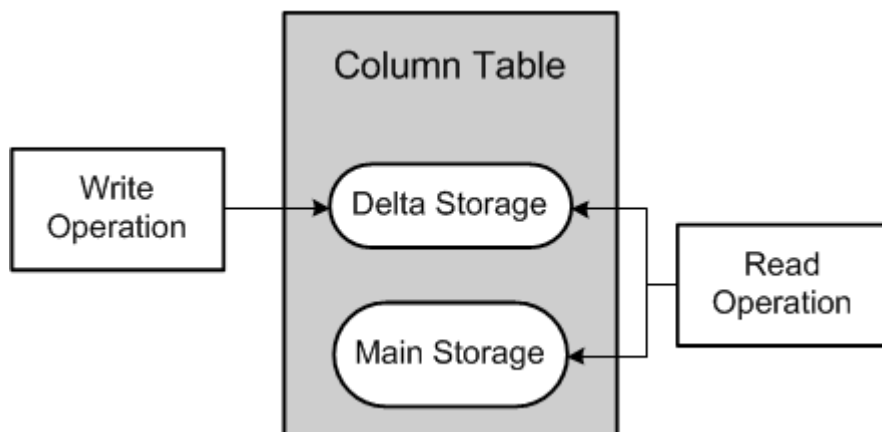

## 6.11.9 Memory Management in the Column Store

The column store is the part of the SAP HANA database that manages data organized in columns in memory. Tables created as column tables are stored here.

The column store is optimized for read operations but also provides good performance for write operations. This is achieved through 2 data structures: main storage and delta storage.

The main storage contains the main part of the data. Here, efficient data compression is applied to save memory and speed up searches and calculations. Write operations on compressed data in the main storage would however be costly. Therefore, write operations do not directly modify compressed data in the main storage. Instead, all changes are written to a separate data structure called the delta storage. The delta storage uses only basic compression and is optimized for write access. Read operations are performed on both structures, while write operations only affect the delta.

### Main Storage and Delta Storage

The purpose of the delta merge operation is to move changes collected in the delta storage to the read-optimized main storage. After the delta merge operation, the content of the main storage is persisted to disk and its compression recalculated and optimized if necessary.

A further result of the delta merge operation is truncation of the delta log. The delta storage structure itself exists only in memory and is not persisted to disk. The column store creates its logical redo log entries for all operations executed on the delta storage. This log is called the delta log. In the event of a system restart, the delta log entries are replayed to rebuild the in-memory delta storages. After the changes in the delta storage have been merged into the main storage, the delta log file is truncated by removing those entries that were written before the merge operation.

#### i Note

As only data in memory is relevant, the load status of tables is significant. A table can have one of the following load statuses:

- Unloaded, that is, none of the data in the table is loaded to main memory
- Partly loaded, that is, some of the data in the table is loaded to main memory, for example, a few columns recently used in a query
- Fully loaded, that is, all the data in the table is loaded into main memory

However, data that is in the delta storage can only be fully loaded or unloaded. Partial loading is not possible. Therefore, if a delta merge has not been performed and the table's entire data is in the delta storage, the table is either fully loaded or unloaded.

## Loading and Unloading of Data in the Column Store

The SAP HANA database aims to keep all relevant data in memory. Standard row tables are loaded into memory when the database is started and remain there as long as it is running. They are not unloaded. Column tables, on the other hand, are loaded on demand, column by column when they are first accessed. This is sometimes called lazy loading. This means that columns that are never used are not loaded and memory waste is avoided.

#### i Note

This is the **default** behavior of column tables. In the metadata of the table, it is possible to specify that individual columns or the entire table are loaded into memory when the database is started.

The database may actively unload tables or individual columns from memory, for example, if a query or other processes in the database require more memory than is currently available. It does this based on a least recently used algorithm. This unload mechanism can be combined with manually-applied unload priority values. The priority value is applied to a table as a number between 0 and 9; tables with a higher priority are unloaded earlier than other tables.

For more information you can also refer to SAP Note 2127458 *FAQ: SAP HANA Loads and Unloads*

You can also configure columns to allow access to the main storage one page at a time instead of requiring the whole column to be in memory. This enables you to save memory and query a single value in the main storage when certain individual columns or the entire table reside on disk. To enable this feature, specify column description clauses PAGE LOADABLE or COLUMN LOADABLE in the <column\_desc> of a CREATE TABLE or ALTER TABLE statement.

### 6.11.9.1 Load/Unload a Column Table into/from Memory

Under normal circumstances, the SAP HANA database manages the loading and unloading of tables into and from memory automatically, the aim being to keep all relevant data in memory. However, you can manually load and unload individual tables, as well as load table columns if necessary.

## Prerequisites

You have one of the following privileges:

- System privilege TABLE ADMIN
- SQL object privilege UPDATE for the table or the schema in which the table is located

## Context

As the SAP HANA database automatically manages the loading and unloading of tables it is not normally necessary to manually load and unload individual tables and table columns. However, this may be necessary for example:

- To precisely measure the total or “worst case” amount of memory used by a particular table (load)
- To actively free up memory (unload)

# Load and Unload a Table Using Administration Tools

## Context

The procedure is the same in both SAP HANA studio and database explorer using the context menu options available for a selected table in the catalog. In SAP HANA studio you can see detailed information about a table's current memory usage and load status on the *Runtime Information* tab of the table definition. See also monitoring view M\_CS\_TABLES below.

## Procedure

1. In the *Systems* view, navigate to the table in the catalog.
2. In the context menu of the table, choose *Load into Memory* or *Unload from Memory* as required.
3. To start the operation accept the confirmation prompt which is displayed.

## Results

If you loaded a table, the complete data of the table, including the data in its delta storage, is loaded into main memory. Depending on the size of the table, this may take some time. The table's load status is FULL.

If you unloaded a table, the complete data of the table, including the data in its delta storage, is unloaded from main memory. Subsequent access to this table will be slower as the data has to be reloaded into memory. The table's load status is NO.

# Load and Unload a Table Using SQL

## Procedure

1. Open the SQL console and execute the required statement. The LOAD statement supports options to specify one or more table columns, just delta data or all data. You can query the monitoring view M\_CS\_TABLES for full details of the table (example below).
  - Load MyTable into memory: `LOAD MyTable ALL;`
  - Load columns A and B of MyTable into memory: `LOAD MyTable (A, B);`
  - Unload MyTable from memory: `UNLOAD MyTable;`
2. Query the load status of MyTable: `SELECT loaded FROM m_cs_tables WHERE table_name = 'MyTable';`

## Results

If you load only selected columns then the table's load status is PARTIALLY. If you unload a table, the complete data of the table, including the data in its delta storage, is unloaded from main memory.

### 6.11.9.2 Managing Memory by Object Usage

You can use the Unused Retention Period feature to automatically unload objects from memory which are not being used.

SAP HANA has a built-in memory management system which automatically unloads swappable resources from memory if the level of available memory gets too low. An additional method for managing memory is the Unused Retention Period, this automatically unloads objects from memory which are not being used.

#### **i** Note

You can check the total number of objects and the usage of swappable and non-swappable size using the view M\_MEMORY\_OBJECTS.

#### Unused Retention Period

To proactively manage memory, even if no low memory situation is present, you can automatically unload swappable objects from memory on the basis of how frequently objects are used. The time-based parameter `unused_retention_period` is available for this in the `global.ini` file.

To use this feature change the default value (initially set to 0) to a number of seconds, for example 7200 (2 hours). Objects which are not used within this time period are flagged as being eligible to unload.

Objects which have exceeded the retention period are not immediately unloaded from memory, an additional checking process which runs at a pre-defined interval initiates the unload. The frequency of the check is controlled by the `unused_retention_period_check_interval` configuration parameter. This is set by default to 7200 seconds (2 hours).

## Retention Times and Priorities for Objects

In addition to the general configuration parameter you can apply a retention period and an unload priority value to the table or partition definition itself (see the *SAP HANA SQL and System Views Reference* for details). The following example applies an unload retention period of 60 seconds to table `myTable`.

```
ALTER TABLE "myTable" WITH PARAMETERS ('UNUSED_RETENTION_PERIOD'='60')
```

Note that retention period values can only be applied to tables if a configuration value has been set for `unused_retention_period` in the `global.ini` file.

The unload priority value is a number from 0 to 9 where 0 means the object can never be automatically unloaded and 9 means the earliest unload. The following example reduces the default value of 5 to 2:

```
ALTER TABLE "myTable" UNLOAD PRIORITY 2
```

The unload priority of a table is saved in the `TABLES` table:

```
SELECT UNLOAD_PRIORITY FROM TABLES WHERE TABLE_NAME = "myTable"
```

### Note

Note that changes in unload priority are not immediately effective; the change only takes effect the next time the table is loaded into memory. Therefore if you want to apply the change immediately you should unload and reload the table with the following two statements:

```
UNLOAD "myTable";  
  
LOAD "myTable" ALL;
```

As these operations may take a long time for large tables, consider running these jobs at a suitable time outside business hours.

Resources have a retention disposition weighting value which also influences the sequence in which objects are unloaded from memory. The weighting is used with the time value since the last access of a resource to calculate a disposition value. Priorities 6-9 correspond to 'early unload' disposition, priorities 1-5 correspond to a 'long term' disposition, and tables with a priority of zero are 'non swappable'. Disposition values are configurable by a set of parameters in the `memoryobjects` section of the `global.ini` file although this is not normally necessary. See also SAP Note 1999997 - FAQ: SAP HANA Memory.

## Related Information

[SAP Note 1999997](#) 

### 6.11.9.3 Hybrid LOBs (Large Objects)

To save memory you can store LOB data on disk, in this case the data is only loaded into memory when it is needed. Alternatively, you can use the configurable Hybrid LOB feature which is flexible and stores LOBs either on disk or in memory depending on their size.

SAP HANA can store large binary objects (LOBs) such as images or videos on disk and not inside column or row structures in main memory. This influences the size of the row store loaded into memory and therefore affects start up and takeover times. An LOB saved on disk is referenced only by an ID in the corresponding table column and is loaded into memory on demand.

This significantly reduces main memory consumption especially when LOB data is not actually requested. LOB data has a short-term disposition setting and if there are memory shortages it is removed from memory before column or table data needs to be unloaded (see Cache Consumption below).

The basic options for managing storage of LOBs are:

- Save all LOBs in memory (LOB size of up to 1GB supported)
- Save all LOBs on disk (a virtual file is created per LOB)
- Use the configurable Hybrid feature which uses three storage types for LOBs depending on their size: the smallest LOBs are stored in memory, the largest LOBs are stored on disk, and medium-sized LOBs are stored together in LOB containers.

Large object data columns can be configured as either page loadable or column loadable by setting the LOAD UNIT value in the CREATE TABLE and ALTER TABLE commands. However, memory usage for large object data types is controlled by the Hybrid LOB configuration parameters independent of the LOAD UNIT configuration. While the LOAD UNIT can be configured to either COLUMN LOADABLE or PAGE LOADABLE for a large object data column, the LOAD UNIT does not determine the memory usage for large object data types. Refer also to the Native Storage Extension topic *SAP HANA NSE and Paged Large Object Data Types*.

## Configuration for Hybrid LOBs

Three configuration file settings in the indexserver.ini are used to implement and manage the hybrid LOB feature.

The `default_lob_storage_type` setting (section SQL) can be set to `memory` or `hybrid` (default). If Hybrid is activated the following two parameters are also used.

For hybrid LOBs the `lob_memory_threshold` setting (section SQL) must be set to a numeric value of bytes (default 1000). This defines an initial size threshold for the smallest LOBs.

The `midsizelob_threshold` setting (section Persistence) defines the upper threshold for mid-size LOBs. It is set to 4000 (bytes) by default and should not be set any lower than this.

LOBs are then categorized on the basis of the following types:

- Small LOBs (type *Inplace*) are always completely loaded into main memory when the attribute is loaded.
- Medium-sized LOBs where the size is between the two thresholds have the storage type *Packed*. These LOBs share a single LobContainer per attribute and are only loaded into main memory when required.
- Large LOBs (type *File*) are stored in their own virtual file on disk and are loaded individually into main memory on demand.

## i Note

The need to load and initialize many LOBs during a system restart may have a considerable negative impact on the restart time. Type *Packed* reduces the number of small LOBs being represented as single files, and may, therefore, be the most efficient in terms of optimizing restart times. This may be particularly advantageous for scenarios using persistent memory and the fast restart option.

The hybrid LOB feature is available in the row and column store but type *Packed* is only implemented for column store tables.

Once the hybrid LOB feature is activated, all newly created LOB values are stored based on the new rules. Existing LOB values remain untouched. If necessary, the feature can be applied to tables retrospectively using the ALTER or CREATE TABLE commands with the <lob\_type\_name> clause (blob, clob and so on) and an optional memory\_threshold\_value. This will apply the value of the *lob\_memory\_threshold* setting. Values applied from the SQL command line take precedence over system settings.

The following examples apply values to a newly-created table.

```
-- no value for memory threshold, the system setting is applied
create column table <table> (id int, data blob);
```

The effects of applying values of 0 (all LOBs saved on disk) and null (all LOBs saved in memory) are also shown here.

```
-- all lobs are on disk:
create column table <table> (id int, data blob memory threshold 0);
-- all lobs <= 1000 bytes are in memory, larger lobs are on
disk:
create column table <table> (id int, data clob memory threshold 1000);
-- all lobs are in memory:
create column table <table> (id int, data nclob memory threshold null);
```

Note that *memory threshold* is always referenced as smaller or equal (<=).

Alternatively, you can apply the value of the *midsizelob\_threshold* system property to convert a column or table to use a hybrid LOB, using the LOB REORGANIZE clause with ALTER TABLE. The following example does this for two specified columns of a table:

```
ALTER TABLE 'MyTable' LOB REORGANIZE 'Attachments', 'Pictures'
```

If no columns are specified the thresholds are applied to all LOB columns in the table. The LOB REORGANIZE clause also supports an ONLINE mode (or ONLINE PREFERRED) which does not require an exclusive lock on tables so that data updates can still be applied. See the ALTER TABLE <lob\_reorganize\_clause> in the *SAP HANA SQL Reference Guide* for more information.

## Memory Consumption per Table

Even when LOB data is stored on disk you still need to store some information in memory. This information can be retrieved by querying M\_TABLES, M\_CS\_TABLES or M\_CS\_COLUMNS:

```
SELECT * FROM M_CS_TABLES WHERE SCHEMA_NAME = '<schema>' ORDER BY
MEMORY_SIZE_IN_TOTAL DESC;
SELECT * FROM M_CS_COLUMNS WHERE SCHEMA_NAME = '<schema>' AND TABLE_NAME =
'<table>' ORDER BY MEMORY_SIZE_IN_TOTAL DESC;
```

---

## System HEAP\_MEMORY

To see how much main memory is consumed by hybrid LOB data stored on disk that is actually loaded into main memory use M\_HEAP\_MEMORY:

```
SELECT * FROM M_HEAP_MEMORY WHERE CATEGORY = 'Pool/PersistenceManager/  
LOBContainerDirectory';
```

## Cache Consumption

To speed up access when LOBs are stored on disk, LOB data is cached inside SAP HANA page cache with short term disposition.

### **i** Note

Do not change this as it will cause performance issues.

During high load HEAP\_MEMORY might increase significantly (until SAP HANA's general memory limit is reached). This is no problem as LOB data is unloaded first from the page cache as it uses short term disposition.

For memory analysis the cache may be cleaned or SAP HANA is restarted in order to free caches. Both options should be used carefully as this unloads all tables and reload might be expensive (meaning it may require a downtime).

For an overview of the cache use: `SELECT * FROM M_MEMORY_OBJECT_DISPOSITIONS`

M\_MEMORY\_OBJECT\_DISPOSITIONS shows which component holds which kind of disposition resource (whether the memory objects are short, mid, long-term or non-swappable). It does not tell you what data is stored in cached pages.

## 6.11.10 The Delta Merge Operation

Write operations are only performed on the delta storage. In order to transform the data into a format that is optimized in terms of memory consumption and read performance, it must be transferred to the main storage. This is accomplished by the delta merge operation.

The following figure shows the different steps in the merge process, which objects are involved, and how they are accessed:

The Delta Merge Process

1. Before the merge operation, all write operations go to Delta 1 storage and all read operations read from Main 1 and Delta 1 storages.
2. While the merge operation is running, the following happens:
  1. All write operations go to the second delta storage, Delta 2.
  2. Read operations read from the original main storage, Main 1, and from both delta storages, Delta 1 and Delta 2.
  3. The content of Main 1 and Delta 1 are merged into the new main storage, Main 2.
3. After the merge operation has completed, the following happens:
  1. Main1 and Delta1 storages are deleted.
  2. The content of the complete main storage is persisted to disk.

### i Note

With this double buffer concept, the table only needs to be locked for a short time: at the beginning of the process when open transactions are moved to Delta2, and at the end of the process when the storages are “switched”.

### ⚠ Caution

The minimum memory requirement for the delta merge operation includes the current size of main storage plus future size of main storage plus current size of delta storage plus some additional memory. It is important to understand that even if a column store table is unloaded or partly loaded, the whole table is loaded into memory to perform the delta merge.

The delta merge operation can therefore be expensive for the following main reasons:

- The complete main storages of all columns of the table are re-written in memory. This consumes some CPU resources and at least temporarily duplicates the memory needed for the main storages (while Main 1 and Main 2 exist in parallel).

- The complete main storages are persisted to disk, even if only a relatively small number of records were changed. This creates disk I/O load.

This potentially negative impact on performance can be mitigated by splitting tables. The size of the main storage can be reduced by splitting the table into multiple partitions, each with its own main and delta storages. The delta merge operation is performed at partition level and only for partitions that actually require it. This means that less data needs to be merged and persisted. Note that there are disadvantages to partitioning tables that should also be considered.

## Delta Merge on Partitioned Tables

During the delta merge operation, every partition of a partitioned table is treated internally as a standalone table with its own data and delta store. Only the affected partitions are subject to the merge operation. As described above, the whole table has to be duplicated during the merge operation, so for partitioned tables, the amount of needed main memory during the merge operation is reduced, depending on the size of the partition.

A table can be repartitioned independently of whether it has data in main or delta storage. However, repartitioning can be faster if the delta is small.

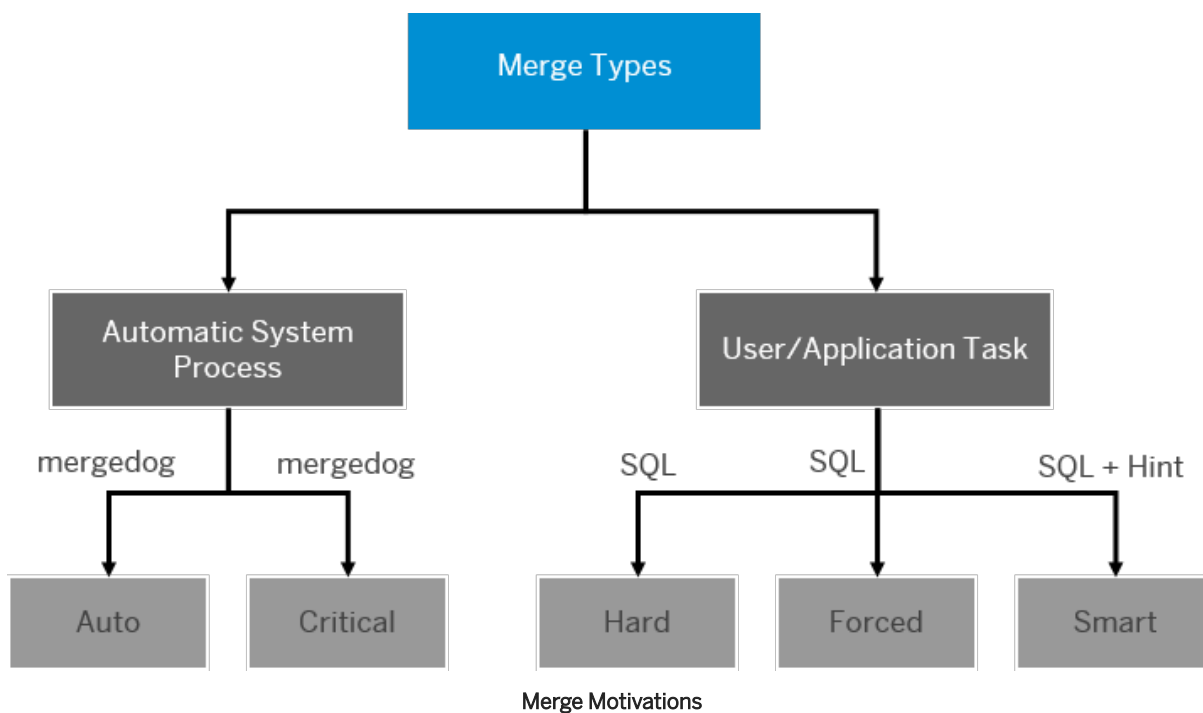

## Related Information

[Table Partitioning \[page 637\]](#)

### 6.11.10.1 Merge Motivations

The request to merge the delta storage of a table into its main storage can be triggered in several ways. These are called merge motivations.

The following figure illustrates the different merge motivations and how they are triggered.

## Auto Merge

The standard method for initiating a merge in SAP HANA is the auto merge. A system process called `mergedog` periodically checks the column store tables that are loaded locally and determines for each individual table (or single partition of a split table) whether or not a merge is necessary based on configurable criteria (for example, size of delta storage, available memory, time since last merge, and others).

Auto merge is active if the `active` parameter in the `mergedog` section of the `indexserver.ini` file is set to `yes`.

### i Note

Auto merge can be activated and deactivated for an individual table in the system view `TABLES (SYS)`. The value in the column `AUTO_MERGE_ON` can be changed to `TRUE` or `FALSE`.

### i Note

Deactivating auto merge for a table implicitly disables automatic compression optimization as well (column `AUTO_OPTIMIZE_COMPRESSION_ON` set to `FALSE`). This is the case even if the `AUTO_OPTIMIZE_COMPRESSION_ON` column is set to `TRUE` in the system view `TABLES`. For tables with auto merge disabled, compression optimization must be triggered manually.

## Smart Merge

If an application powered by SAP HANA requires more direct control over the merge process, SAP HANA supports a function that enables the application to request the system to check whether or not a delta merge

makes sense now. This function is called smart merge. For example, if an application starts loading relatively large data volumes, a delta merge during the load may have a negative impact both on the load performance and on other system users. Therefore, the application can disable the auto merge for those tables being loaded and send a "hint" to the database to do a merge once the load has completed.

When the application issues a smart merge hint to the database to trigger a merge, the database evaluates the criteria that determine whether or not a merge is necessary. If the criteria are met, the merge is executed. If the criteria are not met, the database takes no further action and only a subsequent hint from the application will trigger another evaluation of the criteria.

Smart merge is active if the `smart_merge_enabled` parameter in the `mergedog` section of the `indexserver.ini` file is set to `yes`.

### ⚠ Caution

For tables that you want to merge with the smart merge, you should disable the auto merge. Otherwise, the auto merge and smart merge may interfere with each other.

## Hard Merges

You can trigger the delta merge operation for a table manually by executing the SQL statement `MERGE DELTA OF "<table_name>"`. This is called a hard merge and results in the database executing the delta merge for the table either immediately if sufficient system resources are available, or as soon as sufficient system resources become available. The hard merge is therefore subject to the merge token control mechanism.

### i Note

Unlike system-triggered delta merge operations, all of the manually-executed delta merge operations listed here do not subsequently trigger an optimization of the compression of the table's new main storage. If the table was compressed before the delta merge operation, it remains compressed with the same compression strategy afterward. If it was not compressed before the delta merge operation, it remains uncompressed afterward. After a manual delta merge, you must therefore trigger compression optimization manually.

## Critical Merge

The database can trigger a critical merge in order to keep the system stable. For example, in a situation where auto merge has been disabled and no smart merge hints are sent to the system, the size of the delta storage could grow too large for a successful delta merge to be possible. The system initiates a critical merge automatically when a certain threshold is passed.

## Related Information

[Perform a Manual Delta Merge Operation \[page 631\]](#)

## 6.11.10.2 The Merge Monitor

The delta merge operation for column tables is a potentially expensive operation and must be managed according to available resources and priority. This is the responsibility of the merge monitor.

The system uses cost functions to decide which table to merge, when, and in which order. There are also cost functions that control how many tables are merged at the same time and how many threads are used to merge a single table.

The merge monitor is responsible for controlling all merge requests for all column tables on a single host. In a distributed system, every index server has its own merge monitor.

All merge requests must acquire a merge token from the merge monitor. A merge token represents an allocation of system resources and "entitles" the merge to actually start. The merge monitor blocks merge requests if there are not enough system resources available or if the same table is already being merged by another thread. This avoids long waits and delays for other threads for inserting or just reading data.

Depending on current system resource consumption, merge motivation, and the evaluation of the various cost functions, the merge monitor lets single requesting merge threads pass and releases waiting threads.

### i Note

There is no option or need to disable, stop, or even kill the merge monitor. The merge monitor is not a thread.

## 6.11.10.3 Cost Functions

The SAP HANA database decides whether or not to execute a requested delta merge and the order in which to execute multiple requests based on configurable merge criteria or cost functions.

Cost functions can be configured depending on the merge motivation, that is whether the merge is being requested by the automatic system process mergedog (auto merge), by a hint from the application (smart merge), by SQL statement (hard merge), and so on.

Cost functions are evaluated in runtime and configured in the mergedog section of the `indexserver.ini` file. The following cost functions are available:

- `auto_merge_decision_func` and `smart_merge_decision_func`  
These cost functions determine whether or not a requested delta merge is executed.
- `auto_merge_priority_func` and `smart_merge_priority_func`  
These cost functions determine the priority that is assigned to the delta merge request.
- `critical_merge_decision_func`  
This cost function determines whether or not a delta merge is executed. It will run a delta merge to avoid situations that could lead to an out of memory or system crash even if other cost functions have been turned off or fail to run.

- `hard_merge_priority_func`  
This cost function determines the priority of hard merges.
- `load_balancing_func`  
This cost function determines the allocation of system resources to merge processing.

### Note

The decision cost function is evaluated only once for each merge request. In the case of a merge request triggered by a smart merge hint, if the cost function returns a result of false (that is, the system decides that a delta merge is not required), the request is logged but no further evaluation takes place. Only a new hint can potentially initiate a new delta merge.

The following parameters are available for configuring the cost functions. You can use them to build cost functions for all delta merge configurations.

### Caution

It is not recommended that you change the default settings for delta merge unless instructed to do so by SAP Support.

Parameter	Meaning
DMS	Delta memory size [MB]  This refers to the size of the table's delta storage.
TMD	Table merge delay [sec]  This refers to the time since the last merge of table
MRC	Main row count [million]  This refers to the current number of rows in the main storage of the table.
DMR	Deleted main rows [million]  This refers to the number of deleted records not in delta storage, but marked as deleted in main storage. Merging makes sense if there are many deleted rows.
DLS	Delta log size [MB]
DCC	Delta cell count [million]  This refers to the current number of cells in the delta storage of the table. For example, if the delta storage contains 3 records, each with 4 columns, then the delta cell count is 12.
DRC	Delta row count [million]  This refers to the current number of rows in the delta storage of the table.
QDW	Queuing delay wait [sec]  This refers to the time that a merge thread has been waiting for the merge monitor to allocate it merge tokens. This parameter can be useful if you want to implement a first come first served scheduling strategy.
NAME	Table name [string]
SCHEMA	Schema name [string]

Parameter	Meaning
CLA	CPU load average [percentage]
LCC	Logical CPU count
THM	Total heap memory [MB]
AHM	Available heap memory, including memory that could be freed [MB]
DUC	Delta uncommitted row count [million] This refers to the number of uncommitted rows in the delta storage of the table.
MMS	Main memory size [MB]
UPT	Index server uptime [sec]
MMU	Main max udiv [million]
OCRC	(Last) optimize compression row count [million]
CRCSOC	Change row count since (last) optimize compression [million]
RP	Table is range partitioned [boolean]
PAL	Process allocation limit [MB]

## Cost Functions Examples

Cost Function Configuration	Meaning
<pre>auto_merge_decision_func = DMS&gt;1000 or TMD&gt;3601 or DCC&gt;800 or DMR&gt;0.2*MRC or DLS&gt;5000</pre>	<p>An automatic delta merge of a table is executed if :</p> <ul style="list-style-type: none"> <li>• The size of its delta storage exceeds 1000 MB, or</li> <li>• It has not been merged in over 60 minutes, or</li> <li>• Its delta cell count exceeds 800 million, or</li> <li>• More than 20% of the records in its main storage were deleted, or</li> <li>• The size of its delta log is greater than 5000 MB</li> </ul>
<pre>auto_merge_decision_func = DMS &gt; 1000 or DMS &gt; 42 and weekday(now())=6 and secondtime(now())&gt;secondtime('01:00') and secondtime(now())&lt;secondtime('02:00')</pre>	<p>An automatic delta merge of a table is executed if:</p> <ul style="list-style-type: none"> <li>• The size of its delta storage exceeds 1000 MB, unless</li> <li>• It is Saturday between 1.00 and 2.00, in which case it will be merged if delta storage exceeds 42MB</li> </ul> <p>Note the week starts with Monday as day 0.</p>

Cost Function Configuration	Meaning
<ul style="list-style-type: none"> <li>• <code>smart_merge_decision_func = DMS&gt;1000 or DCC&gt;800 or DLS&gt;5000</code></li> <li>• <code>smart_merge_priority_func = DMS/1000</code></li> </ul>	<p>A delta merge request of a table triggered by a smart merge hint is executed if:</p> <ul style="list-style-type: none"> <li>• The delta storage size exceed 1000 MB, or</li> <li>• The delta cell count in the delta storage is greater than 800 million, or</li> <li>• The size of the delta log is greater than 5000 MB</li> </ul> <p>The system prioritizes smart merge requests based on the size of the delta storage, that is, tables with the bigger deltas are merged first.</p>
<code>hard_merge_priority_func = QDW</code>	Delta merges triggered by hard merge are prioritized only by queuing delay wait, in other words, on a first in first out basis.
<code>hard_merge_priority_function = 1/(7+MMS)</code>	Delta merges triggered by hard merge are prioritized by table size. Smaller tables are merged first, the idea being to free some memory first before bigger tables start merging.

[Data Compression in the Column Store \[page 633\]](#)

[SAP Note 2057046](#)

### 6.11.10.4 Merge Tokens

The delta merge operation can create a heavy load on the system. Therefore, controls need to be applied to ensure that merge operations do not consume all system resources. The control mechanism is based on the allocation of merge tokens to each merge operation.

With the exception of the forced merge, a merge operation cannot start unless it has been allocated tokens. If all merge tokens are taken, merge requests have to wait either until the system releases new merge tokens because more resources are available, or until merge tokens have been released by completed merge requests.

The number of merge tokens available for allocation is adjusted based on current system resource availability. This number is recalculated periodically by the system based on a cost function configured in the `load_balancing_func` parameter in the `mergedog` section of the `indexserver.ini` file. The default configuration is `load_balancing_func = 1 + LCC * (100-CLA)/100`. If a hard maximum is required for the amount of tokens available, you can configure a constant value configured or a constant parameter (for example, LCC). Each merge token represents a single CPU.

For every merge request, the number of tokens required to perform the merge is calculated by the system. If the system is not able to determine a value, a default value is returned. This default value can be configured in the `token_per_table` parameter in the `mergedog` section of the `indexserver.ini` file. However, it is not recommended that you change this value.

### i Note

It is not possible to check the number of merge tokens available for allocation at any given time, but it is logged in the indexserver trace file if you activate the indexserver component `mergemonitor` with trace level INFO.

## Related Information

[Database Trace \(Basic, User-Specific, and End-to-End\) \[page 766\]](#)

### 6.11.10.5 Monitoring Delta Merge History

Information about all delta merge operations since the last system start are logged in the monitoring view `M_DELTA_MERGE_STATISTICS`. In addition to completed merge operations, information is available on merge hints received by applications and post-merge compression optimization.

You can access a predefined view of these merge statistics in the statement library of the SAP HANA database explorer or in the SAP HANA studio on the [System Information](#) tab of the Administration editor.

The following columns contain potentially useful information:

Column	Description
TYPE	Here you can see the type of merge history entry. The following values are possible: <ul style="list-style-type: none"><li>• MERGE for an actual delta merge operation</li><li>• HINT for a merge hint sent to SAP HANA by an application</li><li>• SPARSE for the post-merge optimization of main storage compression</li></ul>
MOTIVATION	This column identifies the underlying merge motivation: AUTO, SMART, HARD, or FORCE
SUCCESS	This column depends on the entry in the TYPE column. <ul style="list-style-type: none"><li>• For MERGE or SPARSE entries, it indicates whether or not the merge or compression optimization operation was successful.</li><li>• For HINT entries, it indicates whether or not the hint from the application to merge was accepted.</li></ul> If the hint was accepted (SUCCESS=TRUE), then there is an associated entry of type MERGE. If the hint was rejected (SUCCESS=FALSE), then no merge is triggered, so there is no associated MERGE entry.
LAST_ERROR	This column provides information about error codes of the last errors that occurred (most often 2048). Details are provided in ERROR_DESCRIPTION.

### i Note

Even if the hint was accepted (SUCCESS=TRUE), this does not necessarily mean that the subsequent merge was successful. You must check the SUCCESS column of the merge entry.

Column	Description
ERROR_DESCRIPTION	<p>The following error codes are possible:</p> <ul style="list-style-type: none"> <li>• Error 2480: The table in question is already being merged.</li> <li>• Error 2481: There are already other smart merge requests for this table in the queue.</li> <li>• Error 2482: The delta storage is empty or the evaluation of the smart merge cost function indicated that a merge is not necessary.</li> <li>• Error 2483: Smart merge is not active (parameter <code>smart_merge_enabled=no</code>).</li> <li>• Error 2484: Memory required to optimize table exceeds heap limit (for failed compression optimization operations (TYPE=SPARSE, SUCCESS=FALSE)).</li> </ul>
PASSPORT	For entries with the merge motivation SMART, this column identifies the application that sent the hint to merge (for example, SAP BW powered by SAP HANA)

### Note

If the index server is restarted, the delta merge history will initially be empty. The system also collects delta merge statistics in the table `HOST_DELTA_MERGE_STATISTICS (_SYS_STATISTICS)` independent of system restarts. However, as the system only collects statistical data periodically, this table may not have the most recent delta merge operations.

### Example

The following is an example of how to use the merge history to find a merge you were expecting to happen based on the settings for triggering smart merge hints in your application.

1. Look for merges triggered by smart merge in the merge history by executing the following SQL statement:

```
SELECT * FROM M_DELTA_MERGE_STATISTICS WHERE table_name = '<your_table>' AND motivation = 'SMART'
```
2. If no results are returned, check to see if the application actually sent any hints by executing the following statement:

```
SELECT * FROM M_DELTA_MERGE_STATISTICS WHERE type = 'HINT' AND table_name = '<your_table>'
```

If the application did not send a hint, then the system will not initiate a delta merge. However, if the application did send a hint, the system only executes the merge if the criteria for smart merge are fulfilled. The information is available in the SUCCESS column. The system decides whether or not to accept the hint and execute the merge by evaluating the smart merge decision cost function.
3. If you still have not found the smart merge, check the long-term history by executing the following statement:

```
SELECT * FROM _SYS_STATISTICS.HOST_DELTA_MERGE_STATISTICS WHERE table_name = '<your_table>'
```

## Tracing

You can activate the logging of merge-related information in the database trace for the indexserver component. The relevant trace components are `mergemonitor` and `mergedog`. We recommend the trace level INFO.

## 6.11.10.6 Perform a Manual Delta Merge Operation

You can trigger the delta merge operation for a column table manually, for example, if you need to free up memory.

### Prerequisites

You have one of the following privileges:

- System privilege TABLE ADMIN
- SQL object privilege UPDATE for the table or the schema in which the table is located

### Context

It may be necessary or useful to trigger a merge operation manually in some situations, for example:

- An alert has been issued because a table is exceeding the threshold for the maximum size of delta storage.
- You need to free up memory. Executing a delta merge operation on tables with large delta storages is one strategy for freeing up memory. The delta storage does not compress data well and it may hold old versions of records that are no longer required for consistent reads. For example, you can use the following SQL statement to retrieve the top 100 largest delta storages in memory:

```
SELECT TOP 100 * from M_CS_TABLES ORDER BY MEMORY_SIZE_IN_DELTA DESC
```

You can trigger the delta merge operation for a column table manually in the SAP HANA studio by menu command or SQL statement. A manually-executed delta merge operation corresponds to a hard merge. However, if you use SQL, you can also pass additional parameters that trigger forced merges and memory-only merges.

## Procedure

1. Execute the required merge in one of the following ways:

Option	Description
SAP HANA studio	<ol style="list-style-type: none"><li>1. In the <i>Systems</i> view, navigate to the table.</li><li>2. In the context menu of the table, choose <i>Perform Delta Merge</i>.</li><li>3. Choose <i>OK</i>.</li></ol>
SQL	<p>Open the SQL console and execute the required statement. The first command is for a hard merge, the FORCE REBUILD option executes a hard merge even if no rows from old delta can be merged and no rows from old main can be deleted:</p> <ul style="list-style-type: none"><li>○ <code>MERGE DELTA OF '&lt;table_name&gt;'</code></li><li>○ <code>MERGE DELTA OF '&lt;table_name&gt;' FORCE REBUILD</code></li></ul>

2. Optional: Confirm the delta merge operation in one of the following ways (SAP HANA studio):
  - Open the table definition from the *Systems* view and on the *Runtime Information* tab, check the relevant values.

### i Note

Even though the delta merge operation moves data from the delta storage to the main storage, the size of the delta storage will not be zero. This could be because while the delta merge operation was taking place, records written by open transactions were moved to the new delta storage. Furthermore, even if the data containers of the delta storage are empty, they still need some space in memory.

- Check the merge history by opening the *Merge Statistics* table on the *System Information* tab. The SUCCESS column indicates whether or not the merge operation was executed.

### → Tip

The delta merge operation can take a long time. You can see the progress of delta merge operations currently running in the Administration editor on the ► *Performance* ► *Job Progress* ▾ tab.

## Results

The delta merge operation is executed.

### i Note

Unlike system-triggered delta merge operations, manually-executed delta merge operations do not subsequently trigger an optimization of the compression of the table's new main storage. If the table was compressed before the delta merge operation, it remains compressed with the same compression strategy afterward. If it was not compressed before the delta merge operation, it remains uncompressed afterward. After a manual delta merge, you must therefore trigger compression optimization manually.

## Related Information

[MERGE DELTA Statement \(Data Manipulation\)](#)

### 6.11.11 Data Compression in the Column Store

The column store allows for the efficient compression of data. This makes it less costly for the SAP HANA database to keep data in main memory. It also speeds up searches and calculations.

Data in column tables can have a two-fold compression:

- Dictionary compression  
This default method of compression is applied to all columns. It involves the mapping of distinct column values to consecutive numbers, so that instead of the actual value being stored, the typically much smaller consecutive number is stored.
- Advanced compression  
Each column can be further compressed using different compression methods, namely prefix encoding, run length encoding (RLE), cluster encoding, sparse encoding, and indirect encoding. The SAP HANA database uses compression algorithms to determine which type of compression is most appropriate for a column. Columns with the PAGE LOADABLE attribute are compressed with the NBit algorithm only.

#### i Note

Advanced compression is applied only to the main storage of column tables. As the delta storage is optimized for write operations, it has only dictionary compression applied.

Compression is automatically calculated and optimized as part of the delta merge operation. If you create an empty column table, no compression is applied initially as the database cannot know which method is most appropriate. As you start to insert data into the table and the delta merge operation starts being executed at regular intervals, data compression is automatically (re)evaluated and optimized.

Automatic compression optimization is ensured by the parameter `active` in the `optimize_compression` section of the `indexserver.ini` configuration file. This parameter must have the value `yes`.

#### i Note

If the standard method for initiating a delta merge of the table is disabled (`AUTO_MERGE_ON` column in the system view `TABLES` is set to `FALSE`), automatic compression optimization is implicitly disabled as well. This is the case even if the `AUTO_OPTIMIZE_COMPRESSION_ON` column is set to `TRUE` in the system view `TABLES`. It is necessary to disable auto merge if the delta merge operation of the table is being controlled by a smart merge triggered by the application. For more information, see the section on merge motivations.

## Compression Factor

The compression factor refers to the ratio of the uncompressed data size to the compressed data size in SAP HANA.

The uncompressed data volume is a database-independent value that is defined as follows: the nominal record size multiplied by the number of records in the table. The nominal record size is the sum of the sizes of the data types of all columns.

The compressed data volume in SAP HANA is the total size that the table occupies in the main memory of SAP HANA.

### ❁ Example

You can retrieve this information for a fully-loaded column table from the monitoring view M\_CS\_TABLES by executing the statement: `select SCHEMA_NAME, TABLE_NAME, MEMORY_SIZE_IN_TOTAL from PUBLIC.M_CS_TABLES where SCHEMA_NAME='<schema>' and TABLE_NAME='<table>'`

The compression factor achieved by the database depends on your SAP HANA implementation and the data involved.

For more information see *Cost Functions*

## Cost Functions for Optimize Compression

The cost functions for optimize compression are in the optimize\_compression section of the service configuration (e.g. indexserver.ini)

- **auto\_decision\_func** - if triggered by MergeDog
- **smart\_decision\_func** - if triggered by SmartMerge

Default Cost Function Configuration	Meaning
MMU > 0.010240 and if(OCRC, max(MRC, OCRC) / min(MRC, OCRC) >= 1.75, 1) and (not RP or (RP and TMD > 86400))	Optimize compression runs if <ul style="list-style-type: none"> <li>• The table contains more than 10240 rows AND</li> <li>• (Optimize compression was never run before OR</li> <li>• The number of rows increase or decrease by factor of 1.75)</li> <li>• AND - if range partitioned, the last delta merge happened more than 24 hours ago.</li> </ul>

## 6.11.11.1 Check the Compression of a Column Table

For column-store tables, you can check the type of compression applied to table columns, as well as the compression ratio.

### Prerequisites

To check the compression status of a table accurately, ensure that it is first fully loaded into main memory.

### Procedure

1. To check the type of compression applied to table columns, execute the following SQL statement:

```
SELECT SCHEMA_NAME, TABLE_NAME, COLUMN_NAME, COMPRESSION_TYPE, LOADED from
PUBLIC.M_CS_COLUMNS where SCHEMA_NAME='<your_schema>' and
TABLE_NAME='<your_table>'
```

The columns of the selected table are listed with the type of compression applied. The following values are possible:

- DEFAULT
- SPARSE
- PREFIXED
- CLUSTERED
- INDIRECT
- RLE

#### **i** Note

Even if the column is not loaded into memory, the compression type is indicated as DEFAULT. This is because there will always be some level of dictionary compression. However, unless the column is loaded, the database cannot determine the type of compression actually applied. The LOADED column indicates whether or not the column is loaded into memory.

2. Check the compression ratio of table columns, that is, the ratio of the column's uncompressed data size to its compressed data size in memory.

You can do this in the SAP HANA studio:

- a. In the Administration editor, open the table definition in the table editor.
- b. Choose the *Runtime Information* tab.
- c. In the *Details for Table* area, choose the *Columns* tab.

The compression ratio is specified in the *Main Size Compression Ratio [%]* column.

## Related Information

### 6.11.11.2 Compress a Column Table Manually

The SAP HANA database decides which columns in a column table to compress and which compression algorithm to apply for each column. It does this as part of the delta merge operation. It is normally not necessary that you interfere with this process. However, you can trigger compression manually.

#### Prerequisites

You have the UPDATE privilege for the table.

#### Context

We do not recommend that you interfere with the way in which the SAP HANA database applies compression. However, if a table is not compressed and you think it should be, you can request the database to reevaluate the situation.

Before you do this, consider the reasons why the table may not be compressed, for example:

- The table is very small.
- The table's delta storage has never been merged with its main storage.
- The table was created and filled using an old version of the SAP HANA database that did not compress data automatically. No further data loads, and consequently no delta merge operations, have taken place.
- The auto merge function has been disabled for the table (AUTO\_MERGE\_ON column in the system view TABLES is set to FALSE). Deactivating auto merge for a columnstore table implicitly disables the automatic compression optimization as well. This is the case even if the AUTO\_OPTIMIZE\_COMPRESSION\_ON column is set to TRUE in the system view TABLES.

#### Procedure

1. Request the database to reevaluate compression by executing the SQL statement:

```
UPDATE "<your_table>" WITH PARAMETERS ('OPTIMIZE_COMPRESSION'='YES')
```

The database checks all of the table's columns and determines whether or not they need to be compressed, or whether or not existing compression can be optimized. If this is the case, it compresses the data using the most appropriate compression algorithm. However, note the following:

- The database will only reevaluate compression if the contents of the table have changed significantly since the last time compression was evaluated.
  - Even if the database does reevaluate the situation, it may determine that compression is not necessary or cannot be optimized and so changes nothing.
2. Check the compression status of the table.
  3. Optional: If compression has not changed, force the database to reevaluate compression by executing the following SQL statement `UPDATE "<your_table>" WITH PARAMETERS ('OPTIMIZE_COMPRESSION'='FORCE')`.  
The database checks all of the table's columns and determines whether or not they need to be compressed, or whether or not existing compression can be optimized. If this is the case, it compresses the data using the most appropriate compression algorithm. Note that the database may still determine that compression is not necessary or cannot be optimized and so changes nothing.
  4. Check the compression status of the table.

## 6.11.12 Table Partitioning

The partitioning feature of the SAP HANA database splits column-store tables horizontally into disjunctive sub-tables or partitions. In this way, large tables can be broken down into smaller, more manageable parts. Partitioning is typically used in multiple-host systems, but it may also be beneficial in single-host systems.

Partitioning can be done either in SAP HANA cockpit (refer to *SAP HANA Administration with SAP HANA Cockpit*) or at the SQL command line. Partitioning is transparent for SQL queries and data manipulation language (DML) statements. There are additional data definition statements (DDL) for partitioning itself:

- Create table partitions
- Re-partition tables
- Merge partitions to one table
- Add/delete partitions
- Move partitions to other hosts
- Perform the delta merge operation on certain partitions

When a table is partitioned, the split is done in such a way that each partition contains a different set of rows of the table. There are several alternatives available for specifying how the rows are assigned to the partitions of a table, for example, hash partitioning or partitioning by range.

The following are the typical advantages of partitioning:

- Load balancing in a distributed system  
Individual partitions can be distributed across multiple hosts. This means that a query on a table is not processed by a single server but by all the servers that host partitions.

- Overcoming the size limitation of column-store tables  
A non-partitioned table cannot store more than 2 billion rows. It is possible to overcome this limit by distributing the rows across several partitions. Each partition must not contain more than 2 billion rows.
- Parallelization  
Partitioning allows operations to be parallelized by using several execution threads for each table.
- Partition pruning  
Queries are analyzed to determine whether or not they match the given partitioning specification of a table (static partition pruning) or match the content of specific columns in aging tables (dynamic partition pruning). If a match is found, it is possible to determine the specific partitions that hold the data being queried and avoid accessing and loading into memory partitions which are not required. See *Static and Dynamic Partition Pruning* for details.
- Improved performance of the delta merge operation  
The performance of the delta merge operation depends on the size of the main index. If data is only being modified on some partitions, fewer partitions will need to be delta merged and therefore performance will be better.
- Explicit partition handling  
Applications may actively control partitions, for example, by adding partitions to store the data for an upcoming month.

The following figure illustrates how a table can be distributed over three hosts with dedicated partitions for individual months.

Example of Table Partitioning

### i Note

After adding or removing hosts, it is recommended that you execute a redistribution operation. Based on its configuration, the redistribution operation will suggest a new placement for tables and partitions in the system. If you confirm the redistribution plan, the redistribution operation will re-distribute the tables and partitions accordingly.

For more detailed information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

[Partition a Table \(in SAP HANA Administration with SAP HANA Cockpit\)](#)

## 6.11.12.1 Single-Level Partitioning

When a table is partitioned, its rows are distributed to partitions according to different criteria known as partitioning specifications.

The SAP HANA database supports the following single-level partitioning specifications:

- Round robin
- Hash
- Range

For advanced use cases, these specifications can be nested using multi-level partitioning.

### Related Information

[Multi-Level Partitioning \[page 644\]](#)

#### 6.11.12.1.1 Hash Partitioning

Hash partitioning is used to distribute rows to partitions equally for load balancing and to overcome the 2 billion row limitation. The number of the assigned partition is computed by applying a hash function to the value of a specified column. Hash partitioning does not require an in-depth knowledge of the actual content of the table.

For each hash partitioning specification, columns must be specified as partitioning columns. The actual values of these columns are used when the hash value is determined. If the table has a primary key, these partitioning columns must be part of the key (note, however, that a hash partitioning that creates only 1 partition does not impose any primary key restriction on the partitioning key columns). The advantage of this restriction is that a uniqueness check of the key can be performed on the local server. You can use as many partitioning columns as required to achieve a good variety of values for an equal distribution.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

## Example: Creating a Hash-Partitioned Table Using SQL

SQL Command	Result
<pre>CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b)) PARTITION BY HASH (a, b) PARTITIONS 4</pre>	<ul style="list-style-type: none"><li>• 4 partitions on columns a and b are created.</li><li>• The target partition is determined based on the actual values in columns a and b.</li><li>• At least one column has to be specified.</li><li>• If a table has a primary key, all partitioning columns must be part of that key.</li></ul>
<pre>CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b)) PARTITION BY HASH (a, b) PARTITIONS GET_NUM_SERVERS ()</pre>	The number of partitions is determined by the database at runtime according to its configuration. It is recommended to use this function in scripts, and so on.

## Data Types

The following data types are allowed for the partitioning column:

Date time Types	DATE, TIME, SECONDDATE, TIMESTAMP
Numeric Types	TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL, DECIMAL(p,s)
Boolean Type	BOOLEAN
Character String Types	VARCHAR, NVARCHAR
Binary Types	VARBINARY
Large Object Types	BLOB, CLOB, NCLOB using the ST_MEMORY_LOB option
Text Types	SHORTTEXT

### **i** Note

For balanced partitioning `TIMESTAMP` values using hours are supported, but for heterogeneous partitioning the smallest time unit possible is the whole day - see example in Range Partitioning.

## Creating Partitions at Specific Locations

You can specify at which location (index server) the partition should be created using the `AT LOCATION` clause as shown in the following examples. Note that this can be used with all partitioning types: hash, round robin and range.

In this first example, the specific number of partitions to create is given (3) with a corresponding list in the location clause of three hosts (name and port number) so that one partition will be created on each host:

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT) PARTITION BY HASH (a, b)
PARTITIONS 3 AT LOCATION 'myHost01:30001', 'myHost02:30003', 'myHost03:30003';
```

If the number of partitions doesn't match with the number of hosts a best fit is applied automatically: extra locations are ignored if too many are named and locations are reused in round robin fashion if there are more partitions than locations. If no location is specified then the partitions are automatically assigned to hosts at random.

In this second example the number of partitions is returned from the GET\_NUM\_SERVERS() function:

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT) PARTITION BY HASH (a, b)
PARTITIONS GET_NUM_SERVERS() AT LOCATION 'myHost01:30001';
```

Similarly, in this case, if the number of partitions doesn't match with the number of hosts a best fit is applied automatically. Note that the number of servers returned by GET\_NUM\_SERVERS() is based on table placement rules and ignores the number of servers specified by the AT LOCATION clause.

## Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

[Range Partitioning \[page 642\]](#)

### 6.11.12.1.2 Round-Robin Partitioning

Round-robin partitioning is used to achieve an equal distribution of rows to partitions. However, unlike hash partitioning, you do not have to specify partitioning columns. With round-robin partitioning, new rows are assigned to partitions on a rotation basis. The table must not have primary keys.

Hash partitioning is usually more beneficial than round-robin partitioning for the following reasons:

- The partitioning columns cannot be evaluated in a pruning step. Therefore, all partitions are considered in searches and other database operations.
- Depending on the scenario, it is possible that the data within semantically-related tables resides on the same server. Some internal operations may then operate locally instead of retrieving data from a different server.

For Round-Robin and Round-Robin-Range partitioning schemas there is validation of the following DML statements to ensure that the data remains consistent: INSERT, UPDATE, DELETE and UPSERT. For these statements the partition id passed is checked to ensure that the values are consistent with the original round-robin partitioning specification.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

## Example: Creating a Round-Robin Partitioned Table Using SQL

SQL Command	Result
<pre>CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT) PARTITION BY ROUNDROBIN PARTITIONS 4</pre>	4 partitions are created. Note: The table must not have primary keys.
<pre>CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT) PARTITION BY ROUNDROBIN PARTITIONS GET_NUM_SERVERS ()</pre>	The number of partitions is determined by the database at runtime according to its configuration. It is recommended to use this function in scripts or clients that may operate in various landscapes.

### Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.12.1.3 Range Partitioning

Range partitioning creates dedicated partitions for certain values or value ranges in a table. For example, a range partitioning scheme can be chosen to create a partition for each calendar month. Partitioning requires an in-depth knowledge of the values that are used or are valid for the chosen partitioning column.

Partitions may be created or dropped as needed and applications may choose to use range partitioning to manage data at a fine level of detail, for example, an application may create a partition for an upcoming month so that new data is inserted into that new partition.

#### **i** Note

Range partitioning is not well suited for load distribution. Multi-level partitioning specifications address this issue.

The range partitioning specification usually takes ranges of values to determine one partition (the integers 1 to 10 for example) but it is also possible to define a partition for a single value. In this way, a list partitioning known in other database systems can be emulated and combined with range partitioning.

When rows are inserted or modified, the target partition is determined by the defined ranges. If a value does not fit into one of these ranges, an error is raised. To prevent this you can also define an 'others' partition for any values that do not match any of the defined ranges. 'Others' partitions can be created or dropped on-the-fly as required.

Range partitioning is similar to hash partitioning in that if the table has a primary key on it, the partitioning columns must be part of the key. Many data types are supported for range partitioning, see the list below.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

## Example: Creating a Range-Partitioned Table Using SQL

The following example creates three columns for integers and divides the first column into four partitions. Ranges are defined using this semantic: `<= VALUES <`, ranges for single values use `=`.

- 1 partition for values greater than or equal to 1 and less than 5
- 1 partition for values greater than or equal to 5 and less than 20
- 1 partition for values of 44
- 1 others partition for all other values which do not match the specified ranges

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b))
PARTITION BY RANGE (a)
(PARTITION 1 <= VALUES < 5,
PARTITION 5 <= VALUES < 20,
PARTITION VALUE = 44, PARTITION OTHERS)
```

The partitioning column (a in this example) has to be part of the primary key.

## Data Types

The following data types are allowed for the partitioning column:

Date time Types	DATE, SECONDDATE, TIMESTAMP
Numeric Types	TINYINT, SMALLINT, INTEGER, BIGINT, DECIMAL(p,s)
Boolean Type	BOOLEAN
Character String Types	VARCHAR, NVARCHAR
Binary Types	VARBINARY
Large Object Types	BLOB, CLOB, NCLOB using the ST_MEMORY_LOB option
Text Types	SHORTTEXT

For heterogeneous range partitioning the numeric data types support negative and positive numbers, so that the use case shown in the following example (where the column TESTRESULT is defined as an integer) is possible:

```
PARTITION BY RANGE ("TESTRESULT") ((PARTITION VALUES = 0), (PARTITION VALUES =
-1), (PARTITION VALUES = -10), (PARTITION OTHERS));
```

This option is supported for the following multi-level range partitioning types: RANGE-RANGE, RANGE-HASH and also HASH-RANGE. It is not supported for multi-store (dynamic tiering) tables.

For the VARBINARY type the partition definition entered in the SQL code must specify the boundaries of the conditions using the HEX representation of the binary value. This is shown in the following example which creates a 2-column table, the first column is for integers and the second column for 16 byte varbinary data. In this case, partition boundaries for the varbinary data must be specified with 32 hexadecimal digits (2 hex characters required for each binary byte):

```

create column table DEMO_RAW (a int, b varbinary(16))
partition by range (b)
(
partition '00000000000000000000000000000000' <= values < '01000000000000000000000000000000',
partition '01000000000000000000000000000000' <= values < '02000000000000000000000000000000',
partition '02000000000000000000000000000000' <= values < '03000000000000000000000000000000',
partition '03000000000000000000000000000000' <= values < 'FFFFFFFFFFFFFFFFFFFFFFFFFFFFFFFF'
)

```

When using a balanced partitioning schema and defining ranges for partitioned tables on `TIMESTAMP` columns, the precision of `TIMESTAMP` values can be specified in units up to the level of hour (does not apply to heterogeneous partitioning). The hour value can be either appended to a date separated by a space or included in a single string of digits as shown in the following examples:

```
PARTITION '2010-01-01 00' <= VALUES < '2010-02-01 00', PARTITION OTHERS
```

```
PARTITION 2016031400 <= VALUES < 2016031500, PARTITION OTHERS
```

## Related Information

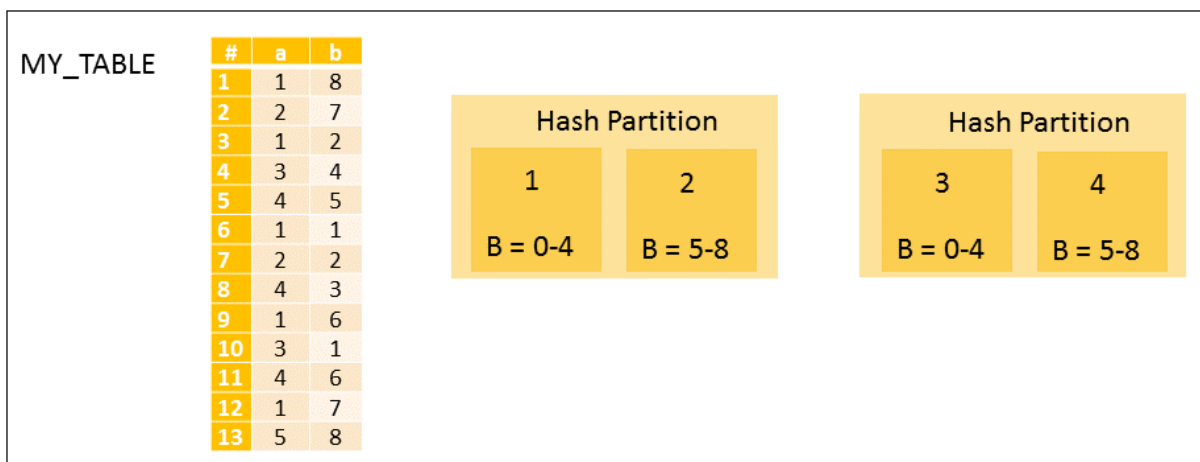

[Partitioning Limits \[page 669\]](#)

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.12.2 Multi-Level Partitioning

Multi-level partitioning can be used to overcome the limitation of single-level hash partitioning and range partitioning, that is, if the table has a primary key this column must be used as a partitioning column. Multi-level partitioning makes it possible to partition by a column that is not part of the primary key.

The following code example and illustration show how multi-level partitioning can be applied using hash partitioning at the first level and range partitioning at the second level. Data in the second level partitions is grouped on the basis of the value of a selected column 'b': rows where the value is below 5 and rows where the value is 5 or greater but less than 9.

### Multi-Level Partitioning

The syntax of the SQL code to create these partitions is as follows:

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, PRIMARY KEY (a,b))
PARTITION BY
HASH (a,b) PARTITIONS 2,
RANGE (b) (PARTITION 0 <= VALUES < 5, PARTITION 5 <= VALUES < 9)
```

The primary key column restriction only applies at the first partitioning level. When a row is inserted or updated, the unique constraint of the key must be checked. If the primary key has to be checked on all partitions across the landscape, this would involve expensive remote calls. Second-level partition groups, however, allow inserts to occur whilst only requiring primary key checks on local partitions.

Related second level partitions form a partition group; the figure above shows two groups (partitions 1 and 2 are a group and partitions 3 and 4). When a row is inserted into partition 1, it is only required to check for uniqueness on partitions 1 and 2. All partitions of a partition group must reside on the same host. SQL commands are available to move partitions but it is not possible to move individual partitions of a group, only partition groups as a whole.

## Using Date Functions to Partition

You can use multi-level partitioning to implement time-based partitioning to leverage a date column and build partitions according to month or year. This could be used for example to minimize the run-time of the delta merge operation. The performance of the delta merge operation depends on the size of the main index of a table. If data is inserted into a table over time and it also contains a date in its structure, then multi-level partitioning on the date could be very effective. Partitions containing old data are typically only modified infrequently, there is therefore no need for a delta merge on these partitions; the merge is only required on partitions where new data is inserted.

If a table needs to be partitioned by month or by year and it contains only a date column or a timestamp column, you can use the date functions shown below to restrict your query results by year or by year and month.

## Example: Partitioning Using Date Functions

This example partitions by hash using the year() function:

```
CREATE COLUMN TABLE MY_TABLE (a DATE, b INT, PRIMARY KEY (a,b)) PARTITION BY HASH  
(year(a)) PARTITIONS 4
```

If a value takes the format "2018-12-08", the hash function is only applied to "2018". This function can also be used for pruning.

This example partitions by range using the year() function:

```
CREATE COLUMN TABLE MY_TABLE (a DATE, b INT, PRIMARY KEY (a,b)) PARTITION BY RANGE  
(year(a)) (PARTITION '2010' <= values < '2013', PARTITION '2013' <= values <  
'2016')
```

This example partitions by range using the year and month value using the month() function:

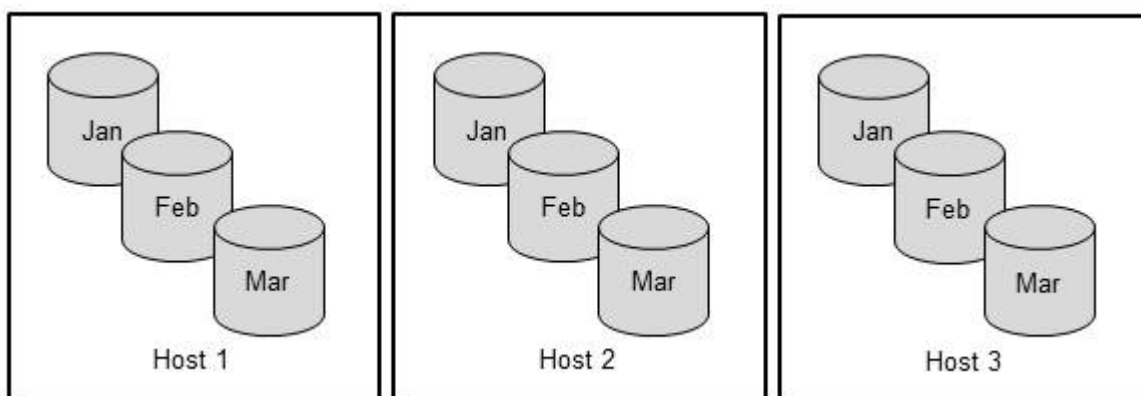

```
CREATE COLUMN TABLE MY_TABLE (a DATE, b INT, PRIMARY KEY (a,b)) PARTITION BY RANGE  
(month(a)) (PARTITION '2005-01' <= values < '2005-07', PARTITION '2005-07' <=  
values < '2006-01')
```

### 6.11.12.2.1 Hash-Range Partitioning

Hash-range partitioning is the most common type of multi-level partitioning. Hash partitioning is implemented at the first level for load balancing and range partitioning at the second level for time-based partitioning.

The following figure shows a typical usage scenario. The load is distributed to three hosts using hash partitioning. Range partitioning is used at the second level to distribute the data to individual partitions according to month.

Hash-Range Partitioning

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

## Example: Creating a Table with Hash-Range Multi-Level Partitioning Using SQL

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b))
  PARTITION BY
    HASH (a, b) PARTITIONS 4,
    RANGE (c)
      (PARTITION 1 <= VALUES < 5,
       PARTITION 5 <= VALUES < 20)
```

### Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

## 6.11.12.2 Round-Robin-Range Partitioning

Round-robin-range multi-level partitioning is the same as hash-range multi-level partitioning but with round-robin partitioning at the first level.

For Round-Robin and Round-Robin-Range partitioning schemas there is validation of the following DML statements to ensure that the data remains consistent: INSERT, UPDATE, DELETE and UPSERT. For these statements the partition id passed is checked to ensure that the values are consistent with the original round-robin partitioning specification.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

## Example: Creating a Table with Round-Robin-Range Partitioning Using SQL

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT)
  PARTITION BY
    ROUNDROBIN PARTITIONS 4,
    RANGE (c)
      (PARTITION 1 <= VALUES < 5,
       PARTITION 5 <= VALUES < 20)
```

### Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.12.2.3 Hash-Hash Partitioning

Hash-hash multi-level partitioning is implemented with hash partitioning at both levels. The advantage of this is that the hash partitioning at the second level may be defined on a non-key column.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

#### Example: Creating a Table with Hash-Hash Partitioning Using SQL

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b))
  PARTITION BY
    HASH (a, b) PARTITIONS 4,
    HASH (c) PARTITIONS 7
```

#### Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

### 6.11.12.2.4 Range-Range Partitioning

Range-range multi-level partitioning is implemented with range partitioning at both levels. The advantage of this is that the range partitioning at the second level may be defined on a non-key column.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

#### Example: Creating a Table with Range-Range Partitioning Using SQL

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT, c INT, PRIMARY KEY (a,b))
  PARTITION BY
    RANGE (a)
      (PARTITION 1 <= VALUES < 5,
       PARTITION 5 <= VALUES < 20),
    RANGE (c)
      (PARTITION 1 <= VALUES < 5,
       PARTITION 5 <= VALUES < 20)
```

#### Related Information

[CREATE TABLE Statement \(Data Definition\)](#)

## 6.11.12.3 Heterogeneous Partitioning

Heterogeneous partitioning offers more flexibility for range-range and range-hash two-level partitioning schemas.

The normal (*balanced*) second-level range partitioning schema applies the same second level specification to all first level partitions. But for some scenarios a flexible *heterogeneous* second-level range partitioning schema may be required with different second-level range specifications for each first level partition. This is possible for both column-store tables and Dynamic Tiering multi-store tables using the special heterogeneous partitioning clauses for the CREATE TABLE and ALTER TABLE PARTITION BY statements.

For heterogeneous partitioning the first level partitioning type must be range (single level heterogeneous partitioning is also possible) however, unlike balanced partitioning there is no requirement to partition on a primary key column. For range-range and range-hash partitioning all partitions at the second level must be based on the same columns.

Heterogeneous partitioning supports the following features:

- Properties (metadata) for partitions; these are defined simply as a value with a boolean state (see section *Partition Properties*)
- Placement of first-level and second-level partitions so that partitions can be placed (or moved) directly on a specified host supporting HANA scale-out or Dynamic Tiering solution (placement is also supported for normal balanced partitioning).

The following set of range-range examples illustrate this feature.

**Example 1:** Heterogeneous 2-level range-range partitions. The SUBPARTITION BY keyword is required to specify the second-level heterogeneous partitions. The syntax in this example shows partitions one and two bracketed together; this is possible if the same subpartition definition applies to both first level partitions.

```
CREATE COLUMN TABLE T(N INT, C CHAR) PARTITION BY RANGE(N) (
(PARTITION VALUE = 1, PARTITION VALUE = 2) SUBPARTITION BY RANGE(C) (PARTITION VALUE = 'A', PARTITION VALUE = 'B'),
(PARTITION VALUE = 3) SUBPARTITION BY RANGE(C) (PARTITION VALUE = 'E', PARTITION VALUE = 'F'),
(PARTITION VALUE = 4) SUBPARTITION BY RANGE(C) (PARTITION VALUE = 'G')
)
```

#	N	C
1	1	A
2	2	A
3	1	B
4	3	E
5	4	G
6	1	A
7	2	B
8	4	G
9	1	B
10	3	F
11	4	A
12	1	C
13	5	A

**Example 2:** AT LOCATION can be used at first or second level to specify where the partition(s) should be created, this can be either on an indexserver or the extended store server for Dynamic Tiering. The INSERT switch is available to create read-only partitions and can be used to prevent insert statements from being executed on the partition.

```
CREATE COLUMN TABLE T3(XSO_GROUP INT, BELNR BIGINT) PARTITION BY RANGE(XSO_GROUP) (
(PARTITION 000 <= VALUES < 002 AT LOCATION 'indexserver_host:port',
PARTITION VALUE = 999 AT LOCATION 'indexserver_host:port')
SUBPARTITION BY RANGE(BELNR) (PARTITION 000000000000 <= VALUES < 999999999999 INSERT OFF ),
(PARTITION 002 <= VALUES < 004 AT LOCATION 'DT_host:port')
SUBPARTITION BY RANGE(BELNR) (PARTITION 000000000000 <= VALUES < 610000000001 INSERT OFF));
```

Table 'T3'

#	XSO_GROUP	BELNR
1	001	610000000001
2	000	999999999999
3	002	610000000001
4	999	610000000001
5	001	610000000001
6	999	610000000001
7	002	610000000001
8	001	610000000001
9	999	610000000001

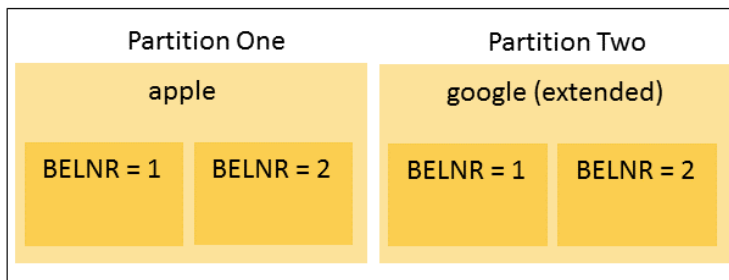

**Example 3:** This example shows the storage type option which is available: either **USING DEFAULT STORAGE** or **USING EXTENDED STORAGE** for Dynamic Tiering.

```
CREATE COLUMN TABLE T_Unbalanced ( BELNR INT, COLGRP NVARCHAR(20) ) PARTITION BY RANGE(COLGRP) (
( PARTITION VALUE = 'apple' USING DEFAULT STORAGE,
PARTITION VALUE = 'google' USING EXTENDED STORAGE )
SUBPARTITION BY RANGE(BELNR) ( PARTITION VALUE=1, PARTITION VALUE=2 ) )
```

Table 'T\_Unbalanced'

#	BELNR	COLGRP
1	1	apple
2	2	google
3	2	google
4	2	apple
5	1	google
6	1	apple
7	2	google
8	2	google
9	1	apple
10	1	google

An additional option which is available with the create table statement is the PRIMARY KEY UPDATE property, this determines if UPDATE statements are allowed on primary key columns. SQL statements are also available to drop heterogeneous subpartitions, redefine heterogeneous first-level partitions, and move heterogeneous first-level partitions (and their subpartitions) to a new location. Full details of these options are given in the *SAP HANA SQL and System Views Reference*.

## Related Information

[Partition Properties \[page 651\]](#)

## 6.11.12.4 Partition Properties

A set of configurable properties is available for partitions which can be applied using the ALTER PARTITION command.

The following properties are supported for partitions, values for these are saved in the TABLE\_PARTITIONS system view:

Property	Value	Scope
Load Unit	DEFAULT, COLUMN, PAGE	Heterogeneous partitioning only
Persistent memory	TRUE / FALSE	Balanced partitioning only
NUMA Node	List of preferred NUMA Nodes	Balanced partitioning only
Insert	TRUE / FALSE	Heterogeneous partitioning only
Storage type	DEFAULT / EXTENDED (for multi-store tables)	Heterogeneous partitioning only
GROUP_NAME	Group properties from table placement	Heterogeneous partitioning only
GROUP_TYPE		Heterogeneous partitioning only
SUBTYPE		Heterogeneous partitioning only

These properties can be modified for a partition using the ALTER PARTITION command:

```
ALTER TABLE <table_ref> ALTER PARTITION <partition_ref> INSERT <ON / OFF>
```

The storage type property only applies at the first level location and can only be modified by using the MOVE PARTITION command:

```
MOVE PARTITION <partition_number> TO <move_location>
```

Persistent memory can be enabled or disabled at the level of partitions using the CREATE and ALTER table commands with the alter\_persistent\_memory\_spec clause. Refer to the section Persistent Memory for more details and refer to the sections of the *SAP HANA SQL Reference Guide* for details of the heterogeneous and non-heterogeneous alter partition clauses.

### Related Information

[Non-heterogeneous Alter Partition Clauses](#)

## 6.11.12.5 Range Partitioning: More Options

Some special features are available for range partitioning: adding additional ranges, deleting ranges, and using dynamic 'others' partitions.

### 6.11.12.5.1 Explicit Partition Handling for Range Partitioning

For all partitioning specifications involving range, it is possible to have additional ranges added and removed as necessary. This means that partitions are created and dropped as required by the ranges in use. In the case of multi-level partitioning, the desired operation is applied to all relevant nodes.

#### **i** Note

If a partition is created and an others partition exists, the rows in the others partition that match the newly-added range are moved to the new partition. If the others partition is large, this operation may take a long time. If an others partition does not exist, this operation is fast as only a new partition is added to the catalog.

Range partitioning requires at least one range to be specified regardless of whether or not there is an others partition. When partitions are dropped, the last partition created cannot be dropped even if an others partition exists.

For range-range partitioning you have to specify whether a partition has to be added or dropped on the first or second level by specifying the partitioning column.

#### **⚠** Caution

The DROP PARTITION command deletes data. It does not move data to the others partition.

For more information about the SQL syntax for partitioning, see *SAP HANA SQL and System Views Reference*.

#### **⚙** Example

Changing a Table to Add/Drop Partitions

```
ALTER TABLE MY_TABLE ADD PARTITION 100 <= VALUES < 200
ALTER TABLE MY_TABLE DROP PARTITION 100 <= VALUES < 200
```

#### **⚙** Example

Changing a Table to Add/Drop an Others Partition

```
ALTER TABLE MY_TABLE ADD PARTITION OTHERS
ALTER TABLE MY_TABLE DROP PARTITION OTHERS
```

You can add a range to the first and second level respectively as follows;

#### **⚙** Example

```
CREATE COLUMN TABLE MY_TABLE (a INT, b INT)
```

```
PARTITION BY
  RANGE (a) (PARTITION 1 <= VALUES < 5),
  RANGE (b) (PARTITION 100 <= VALUES < 500)
```

### ❖ Example

```
ALTER TABLE MY_TABLE ADD PARTITION (a) 5 <= VALUES < 10
ALTER TABLE MY_TABLE ADD PARTITION (b) 500 <= VALUES < 1000
```

### ❖ Example

```
ALTER TABLE MY_TABLE DROP PARTITION (a) 5 <= VALUES < 10
ALTER TABLE MY_TABLE DROP PARTITION (b) 500 <= VALUES < 1000
```

## Related Information

[ALTER TABLE Statement \(Data Definition\)](#)

### 6.11.12.5.2 Dynamic Range Partitioning

Dynamic Range Partitioning is available to support the automatic maintenance of the others partition.

When you create an *others* partition there is a risk that over time it could overflow and require further maintenance. Using the dynamic range feature the *others* partition is monitored by a background job and will be automatically split into an additional range partition when it reaches a predefined size threshold. The background job also checks for empty partitions and if a range partition is found to be empty it is automatically deleted (the *others* partition is never automatically deleted).

You can create partitions with a dynamic *others* partition by including the **DYNAMIC** keyword in the command when you create the partition. This can be either a single level or a second level **RANGE** partition and dynamic ranges can be used with both balanced and heterogeneous partitioning scenarios.

There are three possible ways of setting the row count threshold for dynamic range partitions:

- Using the **THRESHOLD** keyword in the SQL command (see example below); in this case the value is saved in the table meta data.
- In the **DYNAMIC\_RANGE\_THRESHOLD** field of the **TABLE\_PLACEMENT** table which also includes an option to trigger dynamic partitioning.
- A third option is define a threshold value as a system configuration parameter (see *Configuration* below).

### ❖ Example

This example creates an *others* partition for table T and then uses the optional keywords **DYNAMIC** and a `<threshold_count>` value to specify a maximum size for the partition of 3 million rows. When this threshold is reached a new partition will be created:

```
CREATE COLUMN TABLE T (A VARCHAR(5) NOT NULL, NUM INTEGER NOT NULL)
```

```
PARTITION BY RANGE (A AS INT) (PARTITION OTHERS DYNAMIC THRESHOLD 3000000)
```

Not all data types are suitable for dynamic partitioning, the range partitioning column must be a not-nullable column and must be a consistently incrementing numerical sequence such as a timestamp or an integer. The following types are supported:

Datetime Types	DATE, SECONDDATE, TIMESTAMP
Numeric Types	TINYINT, SMALLINT, INTEGER, BIGINT
Character String Types	VARCHAR, NVARCHAR
Text Types	SHORTTEXT

You can change the threshold value for an existing dynamic partition or disable dynamic partitioning using the ALTER TABLE command:

### ❖ Example

The first example here redefines the threshold for the table (using the value defined in the DYNAMIC\_RANGE\_THRESHOLD field of the TABLE\_PLACEMENT table) and the second command turns dynamic range partitioning off:

```
ALTER TABLE T PARTITION OTHERS DYNAMIC THRESHOLD 1000000;
```

```
ALTER TABLE T PARTITION OTHERS NO DYNAMIC;
```

## Thresholds and Processing

Tables with a dynamic others partition are monitored by a configurable background job which checks the current size of the partition in comparison to the defined threshold and makes adjustments (either adding a new partition or removing obsolete partitions) as required. If the others partition has exceeded the threshold then all records in the others partition at the time the job runs are added to the new partition. Corresponding SQL instructions for these actions are the ADD PARTITION FROM OTHERS (to add a new partition) and DROP EMPTY PARTITIONS (to delete a partition), see `dynamic_range_clause` in the *SAP HANA SQL and System Views Reference* for more details.

The background job runs at a predefined interval and searches for a threshold value in the sequence of options given above starting with the table meta data. Similarly an ALTER TABLE instruction for dynamic partitioning where a threshold is not specified in the SQL command will apply whichever threshold value it finds first.

## Configuration

In the [partitioning] section of indexserver.ini file the following configuration parameters are available for dynamic partitioning:

- `dynamic_range_default_threshold` - enter the value you require, the default value is 10,000,000 rows. If no other value has been specified then this parameter value is used.
- `dynamic_range_check_time_interval_sec` - the background job runs at a predefined interval defined as a number of seconds. By default this is 900 but this can be changed here if required. You can deactivate this background job by setting the parameter to -1.

## 6.11.12.6 Partitioning Operations

How a table is partitioned can be determined on creation or at a later point in time. You can change how a table is partitioned in several ways.

You can change partitioning in the following ways:

- Change a partitioned table into a non-partitioned table by merging all of its partitions
- Partition a non-partitioned table
- Re-partition an already-partitioned table, for example:
  - Change the partitioning specification, for example, from hash to round-robin
  - Change the partitioning columns
  - Increase or decrease the number of partitions

Performing a partitioning operation on a table in the above ways can be costly for the following reasons:

- It takes a long time to run, up to several hours for huge tables.
- It has relatively high memory consumption.
- It writes everything to the log (required for backup and recovery).

The re-partitioning operation is a non-blocking process. Apart from a short period at the start as the partitioning process is prepared it does not require an exclusive lock on the database. This means that you can execute SQL DML commands while repartitioning is running, however, DDL operations (table manipulations such as create or drop) are still blocked. At the end of the partitioning process an exclusive lock is again required to apply repartitioning to delta contents.

### → Recommendation

(Re-)partition tables before inserting mass data or while they are still small. If a table is not partitioned and its size reaches configurable absolute thresholds, or if a table grows by a certain percentage per day, the system issues an alert.

### → Recommendation

Although it is possible to (re-)partition tables and merge partitions manually, in some situations it may be more effective to use the redistribution operation available for optimizing table partitioning (for example, if a change of partition specification is **not** required). Redistribution operations use complex algorithms to evaluate the current distribution and determine a better distribution depending on the situation.

### i Note

When you change the partitioning of tables the table creation time of the affected tables will be updated to the time you performed the action.

## Related Information

[Optimize Table Partitioning \[page 710\]](#)

[ALTER TABLE Statement \(Data Definition\)](#)

## 6.11.12.6.1 Partition a Non-Partitioned Table

You can partition an existing non-partitioned column-store table in the Table Distribution editor of the SAP HANA studio.

### Prerequisites

- You have system privilege CATALOG READ and object privileges SELECT and UPDATE either for the table being modified or the schema it is in. If you are the owner of the table, then you can also partition the table without object privileges.
- You have considered the performance impact of partitioning the table.

### Procedure

1. Open the *Table Distribution* editor by right-clicking any of the following entries in the *Systems* view and then choosing *Show Table Distribution*:
  - Catalog
  - Schema
  - Tables

A list of all tables is displayed.

#### i Note

For performance reasons, not all tables are displayed, but only the first 1,000. You can change this setting in the preferences of the SAP HANA studio under **▮ SAP HANA > Runtime > Catalog ▮**. If more tables exist in the selected schema, a message is displayed.

2. Right-click the table that you want to partition and choose *Partition Table*.
3. Specify the first-level partitioning specification:
  - Hash
  - Round robin
  - Range

#### i Note

Round robin is only available as an option if the table does not have a primary key.

4. Optional: If you want a second level of partitioning, choose *Additional level of partitioning* followed by the required partitioning specification.

The available options depend on the selected first-level specification. The following combinations are possible:

- Hash-range
- Round-robin-range

- Hash-hash

5. Enter the information required for the selected partitioning specification(s):

Option	Description
<b>Hash</b>	<ol style="list-style-type: none"> <li>1. Specify the number of partitions. If the system is distributed, you can enter the number of partitions or choose to have the same number of partitions as the number of hosts.</li> <li>2. Select the partitioning column(s). For first-level hash partitioning, only primary key columns are available for selection. For second-level hash partitioning, all columns are available.</li> <li>3. Optional: For date or timestamp columns, specify a date function to partition by year or month.</li> </ol>
<b>Round robin</b>	<p>Specify the number of partitions.</p> <p>If the system is distributed, you can enter the number of partitions or choose to have the same number of partitions as the number of hosts.</p>
<b>Range</b>	<ol style="list-style-type: none"> <li>1. Select the partitioning column. For first-level range partitioning, only primary key columns that have the data type string, integer, and date are available for selection. For second-level range partitioning, all columns with string, integer, and date data types are available.</li> <li>2. Optional: For date or timestamp columns, specify a date function to partition by year or month.</li> <li>3. Add the required partitions. For each partition, you must specify the value range, that is the start value and the end value. You can also add partitions for single values. An 'others' partition is created automatically.</li> <li>4. Choose <i>Validate Input</i> to ensure that the values you have entered are consistent.</li> </ol>

### i Note

The following general restrictions apply when using the hash and range partitioning specifications:

- The maximum number of partitions supported is 1,000.
- Partitioning columns specified for hash and range must not contain commas (,), dollar signs (\$), or round opening braces (()).
- Ranges must not contain commas (,), semi-colons (;), minus signs (-), asterisks (\*), and the pipe character (|).

6. Choose *Finish*.

## Results

The system partitions the table as specified. The progress of the operation is displayed in the *Progress* view. When partitioning has completed, the information in the *Partition Details for <schema.table>* area is updated accordingly.

### i Note

The partitioning operation may take a long time depending on the size of table, available system resources, and so on.

## Next Steps

In a multiple-host system, you can now distribute the table partitions to the available hosts. Although you can do this manually, it is recommended that you execute the table redistribution operation [Optimize Table Distribution](#).

## Related Information

[Optimize Table Distribution \[page 710\]](#)

[Modify Table Distribution Manually \[page 712\]](#)

## 6.11.12.6.2 Change a Partitioned Table into a Non-Partitioned Table

You can change a partitioned table into a non-partitioned table by merging all of its partitions. You do this in the Table Distribution editor of the SAP HANA studio.

## Prerequisites

- You have system privilege CATALOG READ and the object privilege ALTER for the table being modified or the schema it is in.
- If the merge process involves moving some partitions to a single host, the target host must have sufficient memory.
- You have considered the performance impact of merging the table.

## Procedure

1. Open the [Table Distribution](#) editor by right-clicking one of the following entries in the [Systems](#) view and choosing [Show Table Distribution](#):
  - Catalog
  - Schema
  - Tables

### i Note

For performance reasons, not all tables of the selected schema are displayed, but only the first 1,000 tables. You can change this setting in the preferences of the SAP HANA studio. If more tables exist in the selected schema, a message is displayed.

2. Right-click the partitioned table that you want to convert to a non-partitioned table and choose [Merge Partitions](#).

#### i Note

When you choose this action the table creation time will be updated to the time you performed the action.

## Results

In a single-host system, the system starts to merge the partitions into a non-partitioned table immediately.

In a multiple-host system, the system first checks that all partitions reside on the same host. If this is not the case, you are prompted to select the host to which you want to move them all. Before moving the partitions to the selected host, the system checks that the host has sufficient memory. If this is the case, the system first moves the partitions before merging them.

The progress of the operation is displayed in the [Progress](#) view. When the partitions have been completely merged, or moved and merged, the information in the [Partition Details for <schema.table>](#) area is updated accordingly.

#### i Note

Merge operations may take a long time depending on the size of the partitions, whether or not the partitions have to be moved first, available system resources, and so on.

## 6.11.12.7 Time Selection Partitioning (Aging)

The SAP HANA database offers a special time selection partitioning scheme, also called aging. Time selection or aging allows SAP Business Suite application data to be horizontally partitioned into different temperatures like hot and cold.

SAP Business Suite ABAP applications can use aging, which must not be used for customer or partner applications, to separate hot (current) data from cold (old) data by using time selection partitioning to:

- Create partitions and re-partition
- Add partitions
- Allocate rows to partitions
- Set the scope of Data Manipulation Language (DML) and Data Query Language (DQL) statements.

Setting the DML and DQL scope is the most important aspect of time selection partitioning. It uses a date to control how many partitions are considered during SELECT, CALL, UPDATE, UPSERT and DELETE. This date may be provided by the application with a syntax clause and it restricts the number of partitions that are considered.

For example a SELECT statement may be issued that retrieves all data having a date greater or equal to May 1st, 2009. It shall also include the current/hot partition. On the other hand, UPDATE operations can also be restricted in the same way. If a date is provided, the current partition is also always included.

## i Note

Tables with time selection partitioning cannot be converted into any other kind of tables using `ALTER TABLE`.

## Unique Constraints for Cold Partitions

By default SAP HANA enforces unique constraints on all partitions. The application may actively overrule this behavior for cold partitions though. This requires that the applications enforce uniqueness for cold partitions by themselves. Duplicate keys are then considered to be application errors.

The reason is that typical OLTP workload in SAP Business Suite for SAP HANA is executed on the current/hot partition and its performance shall not be affected by unique checks for cold partitions that are not relevant for typical OLTP processing.

If the application overrules the uniqueness constraints:

- A row of the current/hot partition may be in conflict with a row of a cold partition,
- A row of a cold partition may be in conflict with a row of another cold partition, and
- A row within a cold partition may be in conflict with another row within the same cold partition.

Partitioning is transparent from an SQL perspective. If a table has a unique index or a primary key and if it has duplicates in cold partitions, a `SELECT` may return duplicates for a unique index or primary key. This behavior is correct from a database perspective, but this is considered an application error. The database will return an undefined result set. The only kind of statement that will return a correct result set if duplicate primary keys exist is a `SELECT` statement, which does nothing but select data with a `WHERE` clause on the full key (no joins, aggregations, aggregate functions or the like and not complex `WHERE` conditions). There is no guarantee with respect to the result set for further unique constraints if duplicates exist.

## Paged Attributes

Cold partitions may optionally be created as paged attributes. This reduces memory consumption. Memory for resident pages are included in the system views `M_CS_TABLES`, `M_CS_COLUMNS` and `M_CS_ALL_COLUMNS`. The field `MEMORY_SIZE_IN_MAIN` and related statistics include both the paged and non-paged memory for tables or columns.

Global statistics for resident pages can be found in the `M_MEMORY_OBJECT_DISPOSITIONS` view. The number and size of pages used by paged attributes are tracked in `PAGE_LOADABLE_COLUMNS_OBJECT_COUNT` and `PAGE_LOADABLE_COLUMNS_OBJECT_SIZE`, respectively.

## Converting Aging tables to Column Store Tables

In some specific cases it is possible to convert time selection partitioned tables to column store tables.

- Single-level aging partitioned table can be converted to non-partitioned table
- Two-level aging partitioned table can be converted to one-level partitioned table with second-level time selection partitions merged
- Single-level or two-level aging multistore tables can be converted to regular column store partitioned tables by firstly moving partitions from extended storage to the column store and then converting. Refer to the topic *Convert a Multistore Table to a Partitioned Column Store Table* in the SAP HANA Dynamic Tiering documentation set for more details.

Examples to illustrate this are given here showing firstly the command to create the table and then alter it:

### ❖ Example

1) Convert single-level aging table and merge the partitions to an unpartitioned column store table

```
CREATE COLUMN TABLE TAB (A INT, B INT PRIMARY KEY, _DATAAGING NVARCHAR(8))
PARTITION BY RANGE (_DATAAGING)
(USING DEFAULT STORAGE (PARTITION value = '00000000' IS CURRENT,
PARTITION '20100101' <= VALUES < '20110101', PARTITION OTHERS))
WITH PARTITIONING ON ANY COLUMNS ON
FOR NON CURRENT PARTITIONS UNIQUE CONSTRAINTS OFF
FOR DEFAULT STORAGE NON CURRENT PARTITIONS PAGE LOADABLE;
```

```
ALTER TABLE TAB MERGE PARTITIONS;
```

2) Convert two-level aging-partitioned table to a single-level column store partitioned table (HASH-RANGE to HASH)

```
CREATE COLUMN TABLE TAB (A INT, B INT PRIMARY KEY, _DATAAGING NVARCHAR(8))
PARTITION BY HASH(B) PARTITIONS 2, RANGE (_DATAAGING)
(USING DEFAULT STORAGE (PARTITION value = '00000000' IS CURRENT,
PARTITION '20100101' <= VALUES < '20110101', PARTITION OTHERS))
WITH PARTITIONING ON ANY COLUMNS ON
FOR NON CURRENT PARTITIONS UNIQUE CONSTRAINTS OFF
FOR DEFAULT STORAGE NON CURRENT PARTITIONS PAGE LOADABLE;
```

```
ALTER TABLE TAB PARTITION BY HASH (B) PARTITIONS 2;
```

Note that in this case the partition number must be 2.

3) Convert two-level aging-partitioned table to single-level column store partitioned table (RANGE-RANGE to RANGE)

```
CREATE COLUMN TABLE TAB (A INT PRIMARY KEY, B INT, _DATAAGING NVARCHAR(8))
PARTITION BY RANGE(A) (PARTITION VALUE = 1, PARTITION 10 <= VALUES < 20,
PARTITION OTHERS), RANGE (_DATAAGING)
(USING DEFAULT STORAGE (PARTITION value = '00000000' IS CURRENT,
PARTITION '20100101' <= VALUES < '20110101', PARTITION OTHERS))
WITH PARTITIONING ON ANY COLUMNS ON
FOR NON CURRENT PARTITIONS UNIQUE CONSTRAINTS OFF
FOR DEFAULT STORAGE NON CURRENT PARTITIONS PAGE LOADABLE;
```

```
ALTER TABLE TAB PARTITION BY RANGE(A) (PARTITION VALUE = 1, PARTITION 10 <=
VALUES < 20, PARTITION OTHERS);
```

Note that in this case the partition spec must be the same as the first-level spec of the aging table.

More information on data aging is available in the following SAP Note: 2416490 - FAQ: *SAP HANA Data Aging in SAP S/4HANA*.

### 6.11.12.8 Partitioning Consistency Check

You can call general and data consistency checks for partitioned tables to check, for example, that the partition specification, metadata and topology are correct.

There are two types of consistency checks available for partitioned tables:

1. General check  
Checks the consistency among partition specification, metadata and topology.
2. Data check  
Performs the general check and additionally checks whether all rows are located in the correct parts.

To perform the general check, execute the following statement:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK_PARTITIONING', '<schema>', '<table>')
```

To perform the extended data check, execute:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK_PARTITIONING_DATA', '<schema>', '<table>')
```

If any of the tests encounter an issue with a table, the statement returns a row with details on the error. If the result set is empty (no rows returned), no issues were detected.

If the extended data check detects, that rows are located in incorrect parts, this may be repaired by executing:

```
CALL CHECK_TABLE_CONSISTENCY('REPAIR_PARTITIONING_DATA', '<schema>', '<table>')
```

#### **i** Note

The data checks can take a long time to run depending on the data volume.

## Related Information

[Table Consistency Check \[page 602\]](#)

### 6.11.12.9 Designing Partitions

There are a number of factors to consider to optimize the design of your data partitioning strategy including how it will affect select and insert performance and how it will adjust to data changes over time.

Different partitioning strategies need to be tested to determine the best one for your particular scenario. Based on your tests you should choose the partitioning strategy that shows the best performance for your scenario.

The design principals listed here are aids to help you decide on the correct partitioning strategy for your scenario.

### **i Note**

SAP Business Warehouse on SAP HANA handles partitioning itself. Do not interfere with its partition management unless this has been recommended by SAP.

## **Query Performance**

- For replicated dimension tables the database tries to use replicas that are local to the fact table partitions.
- Partition pruning analyzes the WHERE clauses and seeks to reduce the number of partitions. Try to use partitioning columns that are often used in WHERE clauses. This reduces run time and load.
- Usually hash partitioning is the best partitioning scheme for the first level, especially in scale out scenarios. This is because the client may already use pruning on the client machine and send the query directly to the host that holds the data, where possible. This is called “client-side statement routing”. This is especially important for single select statements.
- Use as many columns in the hash partitioning as required for good load balancing, but try to use only those columns that are typically used in requests. In the worst case only single select statements may leverage pruning.
- If tables are joined with each other, it is beneficial if the tables are partitioned over the same columns and have the same number of partitions. This way the join may be executed locally in scale out scenarios and the network overhead is reduced.
  - This guarantees that the matching values are in a partition with the same part ID. You have to put all parts with the same ID on the same host.
- Queries do not necessarily become faster when smaller partitions are searched. Often queries make use of indexes and the table or partition size is not significant. If the search criterion is not selective though, partition size does matter.

## **Data Manipulation Language (DML) Performance**

- If insert performance is key to your scenario, a larger number of partitions might show better results. On the other hand, a higher number of partitions may reduce query performance.
- Partition pruning is used during DML operations.
- For replicated column store tables, all DML operations are routed through the host with the master partition (where the replica with Part ID 1 is located).
- If there is a unique constraint on a non-key column, the performance will suffer exponentially with the number of partitions on other servers. This is because the uniqueness on all partitions has to be checked. Therefore, if partitioning is required, consider a low number of partitions and ideally put all partitions on the same host. This way the number of remote calls is reduced.

## Data Lifecycle

If time-based partitioning is suitable for the dataset being partitioned, it should always be used as it has a number of advantages:

- The runtime of a delta merge is dependent on the size of the main index. This concept leverages the fact that new data is inserted into new partitions whereas data in old partitions is infrequently updated. Over time, the formerly new partitions become old and new partitions are being created. Delta merges on old partitions are not required anymore. This way the overall runtime of delta merges does not increase with the table size, but remains at a constant level. Using time-based partitioning often involves the use of hash-range partitioning with range on a date column. This requires knowledge of the actual values for range partitioning.
- By using explicit partition management, new partitions can be created, for example, one partition per calendar week and old partitions may be dropped entirely rather than deleting individual rows.
- If you split an index, always use a multiple of the source parts (for example 2 to 4 partitions). This way the split will be executed in parallel mode and also does not require parts to be moved to a single server first.
- Do not split/merge a table unless necessary. These operations write all data into the log which consumes a high amount of disk space. Moreover, the operations take a long time and locks the table exclusively (only selects are allowed during partitioning operations). ADD PARTITION can be used to add additional partitions. If there is no 'others' partition, this call only creates a new partition which is fast and happens in real time after an exclusive lock of the table was acquired. On the other hand, if the table has an others partition, a call to ADD PARTITION causes the existing others partition to be split into a new others partition and newly requested range. This is a costly operation. Therefore it is recommended, that if ADD PARTITION is used frequently in a scenario, the table shall not have an others partition.

## Partition Size

- Due to the high number of factors to be considered when evaluating a partitioning scheme a recommendation for partition sizes cannot be provided. If you do not know if you will partition a table at all or with how many partitions you need to start with measurements. Here are some suggested starting points:
  - If a table has less than 500 million rows, do not partition it at all unless:
    - The corresponding tables in joins are partitioned. If they are try to find mutual partitioning columns.
    - Table growth is expected. Since re-partitioning is time consuming, it is recommended to split a table while it is still small.
  - If your table has more than 500 million rows, choose 300 million per partition.
  - Keep in mind that a partition must not exceed 2 billion rows.
- Be aware that a higher number of partitions might lead to higher memory consumption as each partition has its own exclusive dictionary, which is not shared. If each partition stores disjunctive values, this is not an issue. On the other hand, if each partition has similar or the same values this means that the dictionaries have similar data which is stored redundantly. In this case consider using fewer partitions

## Table Design

- If the data is replicated into the SAP HANA database, it might be fair from a data consistency perspective to remove a primary key or to extend the key (since the key constraint is enforced in the source database). This way you might be able to have multiple tables with the same partitioning columns even though the original database design would not have allowed it. Having the same partitioning columns is ideal as related data may reside on the same physical host and therefore join operations may be executed locally with no or hardly any communication costs.
- When designing database schemas for dependent hosts, for example, a database structure for business objects with header and leaf nodes, do not use a single GUID column as the primary key. In such a case it is hardly possible to have all related data (for example, a business object instance) on the same host. One option might be to have a GUID as the primary key in the header table and each host, irrespective of its level, could have that GUID as the first primary key column.
- Do not define a unique constraint on a partitioned table unless absolutely necessary.
- On the second partitioning level, a non-primary key column may be used. Still, the unique constraint has to be enforced on all parts of the respective first-level partition. Since all parts of one first-level partition are moved as a whole, this unique check is always local.
- In case the database table is replicated from another database, an others partition for range is generally recommended. If a proper range is not defined, the insert statement will fail and the data will not get replicated properly.
- Ideally tables have a time criterion in the primary key. This can then be used for time-based partitioning. Number ranges and so on can also be used. The advantage of number ranges is that it is easy to form equally sized partitions, but on the other hand it introduces an administrative burden the amount of data that is loaded needs to be closely monitored and new partitions need to be created in advance. In case of actual dates, you only need to periodically create new partitions, for example, before a new quarter starts.

## Other Considerations

- Use `GET_NUM_SERVERS()` in scripts for hash and round-robin partition specifications. This way Table Placement is used to calculate the number of partitions that will be used in the given landscape.
- If it is likely that a table has to be re-split in future and range partitioning is used, define an others partition. (If it is not defined upon table creation, it can be created afterward and if required dropped after the split operation).
- To check whether a table is partitioned, do not consider the existence of a partition specification in the metadata. Instead check `IS_PARTITIONED` in `M_TABLES` or for the existence of parts, for example in `M_CS_TABLES`. It is allowed that a partition specification is defined which does not immediately lead to a partitioned table.

### 6.11.12.9.1 Static and Dynamic Partition Pruning

An important partitioning strategy to improve performance is to match partitions wherever possible with the most frequently queried data so that data pruning is possible.

Pruning takes place automatically in the background and tries to eliminate any unnecessary partition from the selection which is not essential for the query result. If your partitions are designed to support this, pruning can

avoid accessing and loading into memory partitions which are not required which reduces the overall load on the system. The classic use case for effective pruning is where date-based partitions are used. For example, if a table is partitioned by year, a query restricted to the data of a single year is executed only on the partition with data for the selected year.

Two forms of partition pruning are possible: static and dynamic.

- **Static partition pruning** is based on the partition definition. The query optimizer analyzes the WHERE clause of queries to determine whether or not the filters match the given partitioning specification of a table. If a match is found, it may be possible to target only the specific partitions that hold the data and thus reduce the number of partitions being queried.
- **Dynamic partition pruning** is content-based and can be applied to historical partitions of a HANA aging table. This type of pruning takes place at run time but the decision about which partitions to load is based on pre-calculated column statistics of the data in selected columns. Based on the existence of statistics valid for partition pruning (which must be up to date at the time the query is processed), query evaluation can determine if it is necessary to read the partitioned column of data and load it into memory.

## Statistics for Dynamic Partition Pruning

Statistics for dynamic partition pruning are created and maintained as part of the SAP HANA data statistics functionality and are maintained and used only in the indexserver instance where the partition resides. Statistics are explicitly created and refreshed through SQL statements (such as CREATE STATISTICS) and to use dynamic pruning you must first run CREATE STATISTICS for a specified table, partition and column (see following *Enabling* subsection). Any column other than the partition key can be used. The statistics for dynamic partition pruning are persisted with other statistic values in the system catalogs (this takes place asynchronously in the background), however, the pruning statistics values are also cached in memory for the pruning process.

Statistics for pruning have a limited life-span: as new data is added to the column the content of these statistics becomes stale. It is therefore necessary to periodically refresh the pruning statistics. This is done automatically each time delta merge runs and can also be done on demand (see DDL statements below). The statistics are considered to be invalid as soon as new data is added to the column and pruning is then no longer applied to the column until the pruning statistics have been refreshed.

With historically aged data partitions, it is likely that the greatest number of inserts and deletions occurs in the current time period. The older time partitions will be more stable, and for this reason dynamic pruning is only applied to time-based selections on historical data not the current time period.

## Enabling Dynamic Partition Pruning

Static and dynamic pruning are designed as integral features of the query optimizer and execution processes. However, not all query engines are currently able to take full advantage of dynamic pruning and the setting **use\_dynamic\_pruning** in the query\_mediator section of the indexserver.ini file must be set to **True** to enable dynamic pruning for the HANA OLAP engine plan.

Statistics for dynamic partition pruning must be explicitly created for a specific table using the CREATE STATISTICS command as shown in the following example (also applies to ALTER STATISTICS). This creates statistics for all partitions:

```
CREATE STATISTICS test_dynPruning_tabl_coll
ON tabl (coll)
TYPE SIMPLE VALID FOR DATA DEPENDENCY;
```

For dynamic partition pruning the statistics object type 'SIMPLE' is required with the property set 'VALID FOR DATA DEPENDENCY' as shown here. It is only applicable to partitioned column store tables and multistore tables using time selection partitioning. Only the following datatypes are supported for the statistics columns: VARCHAR (strings with numerical content), INTEGER, DECIMAL, DATE.

Executing the CREATE STATISTICS statement in this way initializes the column for dynamic pruning and populates the pruning statistics. The pruning statistics values are recalculated either by delta merge or, additionally, an explicit refresh statement is available to recalculate the statistics on demand:

```
REFRESH STATISTICS test_dynPruning_tabl_coll
```

Similarly, a DROP STATISTICS command is available and can be used in the same way to drop pruning statistics for a table.

Refer to the *SAP HANA SQL and System Views Reference* for full details.

## Monitoring Views and Tracing

Information about statistics for dynamic partition pruning is available in the M\_DATA\_STATISTICS view.

Diagnostics information is also available. You can see debug details of the pruning process by setting the trace level of the `part_pruning` configuration parameter (in the trace section of the `indexserver.ini` file) to **debug**.

See also *Configure Traces* for more information.

### 6.11.12.9.2 Creating an Effective Partitioning Scheme

This checklist demonstrates how to choose a good partitioning scheme for given tables.

- Tables of above 500 million rows are good candidates for partitioning. This also applies to small tables that are often joined with tables of above 500 million rows.
- If the table has a unique index (other than the primary key), the table may be partitioned, but the additional unique checks introduce a performance penalty.

- Check the primary key.
  - If none exists, any columns may be used for Hash partitioning.
  - If one is present, identify the minimal set of columns that are required to have equally balanced partitions; a sufficiently high number of distinct values is required. Keep in mind that if these columns are all in the WHERE clause of a query, partition pruning may be leveraged.
  - In the case of tables that are replicated into SAP HANA, it may be legitimate to drop the primary key since it is checked in the source database.
- Take other tables into consideration that are often used in joins with the current table. Ideally they have the same number of partitions and partitioning columns.
- Identify time-based attributes; this may be a date, year or at least a sequence. Use them for time-based partitioning. Ideally this column is part of the primary key.
- If you define range partitioning, decide whether or not you require an others partition. Ideally, no others partition is required.
- Decide on the number of partitions. Use Table Placement rules, if applicable.
- In case of a scale out system, move all corresponding partitions to the respective hosts.
- Run extensive performance tests with the most-prominent queries and/or DML load. Try to use analytical views. Vary partitioning columns, partitioning schemes and the number of partitions.

## 6.11.12.9.2.1 Partitioning Example

This example describes an initial and subsequently improved partitioning schema for a database storing test results.

Assume that for each make various tests run. So many rows have to be stored for a TEST\_CASE and MAKE\_ID.

### Original Table Design

- The original table design suggested having a sequence number as the only primary key column. There are time columns marking the start and end of the test run.
- The table was partitioned by Hash over the sequence number and by range over the start date.

### Access Pattern

There are two prominent ways how the data is accessed:

1. Select all test results for a make (“Did my make pass the tests?”)
2. Select results of a single test for all makes within the last month (“How is the history of my test? Has an error happened before?”)

So typically either the TEST\_CASE or the MAKE\_ID is in the WHERE clause, sometimes both when investigating details of a test run.

## Problems with this Original Table Design and Partitioning

- The sequence number is not often part of the WHERE clause and hence all partitions are considered in the query. This is especially an issue in scale-out landscapes where OLTP-like queries are ideally only executed on a single node.
- There is a hash-range partitioning with range on a date column. This allows time-based partitioning to be used. But the date column is not part of the primary key. Therefore the unique constraint on the primary key has to be ensured by checks with the parts of the first-level partition.

## Suggested Table Design

- Have TEST\_CASE, MAKE\_ID and SEQ\_NUMBER as the primary key. The actual requirement that there are uniquely identifiable rows for a combination of TEST\_CASE and MAKE\_ID is met.
- Partition by hash-range with hash over TEST\_CASE and range over MAKE\_ID. The MAKE\_ID increases over time and therefore is also a good column to use for time-based partitioning.

## Reasoning

- No primary key checks with other partitions (using range on primary key column).
- Good pruning since partitioning columns match the typical access pattern.
  - If the query has the MAKE\_ID in the WHERE clause (compare query type 1), all servers that hold partitions have to be considered, but only a single partition per server.
  - If the query has the TEST\_CASE in the WHERE clause (compare type 2), only one server has to be considered (compare Client-Side Statement Routing), but all partitions on that server.
  - If MAKE\_ID and TEST\_CASE are in the WHERE clause, only a single partition on one server has to be considered.

In this scenario there is one type of query which has the effect that all servers that hold partitions are considered. This is not ideal, but cannot always be prevented depending on the nature of the data and access patterns.

## 6.11.12.9.3 Partitioning Limits

General restrictions that apply to the use of partitioning are explained here.

### General Limitations

- The maximum number of partitions for one table is 16000. A table may be re-partitioned as often as required. The limit of 16000 partitions is independent from the location of the partitions in a distributed (scale-out) landscape.

- Column names containing spaces are not supported for partitioning.
- Partitioning columns specified for hash and range partitioning must not contain commas (","), dollar signs ("\$\$") or round opening parentheses ("(").
- Range partition values must not contain commas (","), minus signs ("-"), asterisks ("\*") or the space character.
- When using an equidistant series and table partitioning, for efficient compression ROUND ROBIN partitioning should not be used. HASH or RANGE partitioning should be used so that records with the same series key are in the same partition.

## History Tables

Tables with history tables can also be partitioned. A history table is always partitioned with the same partitioning type as the main table.

- The 2 billion rows barrier is also valid for the history tables and in case of partitioned history tables this will be also hold true on a per partition basis.
- If a table uses multi-level partitioning, it is possible to use partitioning columns which are not part of the primary key. This feature cannot be used in conjunction with history tables.
- Tables with history cannot be replicated.

## Partitioning Columns

The supported data types for partitioning columns for hash and range partitioning are listed in the corresponding subsections.

- The data type of columns used as partitioning columns must not be changed.
- If a table has a primary key, a column must not be removed from the primary key if it is being used as partitioning column. In the case of a multi-level partitioning, this applies to the first level. It is always possible to remove the entire primary key.
- Currently, partitioning does not support a generated column as a partitioning key.

[Hash Partitioning \[page 639\]](#)

## 6.11.12.10 System Views for Monitoring Partitions

A number of system views allow you to monitor your partitions.

System View	Description
TABLE_PARTITIONS	Contains partition-specific information for partitioned tables including details of level 1 and level 2 ranges. This also includes table placement grouping properties GROUP NAME, GROUP TYPE, SUBTYPE. For heterogeneous partitioning the properties NODE_ID and PARENT_NODE_ID are shown so that the hierarchical relationships between partitions can be seen. In this view only values entered by the user are shown (not inherited values from the parent node).
M_TABLE_PARTITIONS	Contains column table information per partition. For heterogeneous partitioning the properties NODE_ID and PARENT_NODE_ID are shown so that the hierarchical relationships between partitions can be seen. In this view implicit inherited values from the parent node are shown.
PARTITIONED_TABLES	General partitioning information for all partitions of a table
TABLE_COLUMNS	Contains table column information.
M_CS_TABLES	Shows run time data per partition (the PART_ID value is the sequential number of the partition). Be aware that after a split/merge operation the memory size is not estimated and therefore the values show zero. A delta merge is required to update the values.
M_TABLES	Shows row counts and memory usage in an aggregated way for partitioned tables (IS_PARTITIONED set to TRUE). Information is based on M_CS_TABLES.
M_CS_PARTITIONS	Shows which partitions or sub-partitions in column store tables form a partition group. This information is for example required when partitions or groups of sub-partitions are to be moved to another host.
M_TABLE_PARTITION_STATISTICS	Shows selection statistics for each partition. In particular, it shows the number of times the partition is selected and includes the timestamp of the last time it was selected. This view is not populated by default and can be enabled through configuration parameter <code>partition_statistics_select_enabled</code> in the <code>partitioning</code> section of the <code>indexserver.ini</code> file.

## 6.11.12.11 Multistore Tables

A multistore table is a range partitioned SAP HANA column table that has at least one partition in SAP HANA and other partitions in different physical stores associated with SAP HANA.

Multistore capability is currently implemented through SAP HANA dynamic tiering, which provides extended storage as an alternate physical store for SAP HANA table partitions. Multistore tables are managed and monitored just like other columnar tables, but offer the advantages of disk-based storage for data aging through extended storage.

Multistore data management allows flexible administration, such as:

- Moving data between extended or default storage.
- Creating or dropping partitions directly in either extended or default storage.
- Repartitioning a table, if new partitioning does not move data between default and extended storage.

Data modification operations let you easily change the storage type for data. For example, you can change the storage type for a partition when you import data into a table or modify the data in a multistore table during an insert operation.

### i Note

Multistore functionality does not support all features of SAP HANA. For details of features supported, see *Multistore Tables* in the *SAP HANA Dynamic Tiering Administration Guide*.

## Related Information

[Manage a Multistore Table \(Dynamic Tiering Administration Guide\)](#)

## 6.11.13 Table Placement

Table classification and table placement configuration, enhanced by partitioning, build the foundation for controlling the data distribution in a SAP HANA scale-out environment.

## Table Classification and Placement

Application data is usually stored in a multitude of database tables, and data from several of these tables is combined via SQL operations like join or union when it is queried. As these relations between different tables are defined in the application code, this information is not available within SAP HANA. The table classification feature provides a possibility to push down this semantic information in the database by allowing administrators to define groups of tables. This information can be used, for example, when determining the number of partitions to be created, or, in the case of a scale-out landscape, the node where to locate the tables or partitions.

The classification is performed by providing each table with a group name, group type and subtype. Based on combinations of these elements as well as the table names and schema names, a set of configuration values can be defined as table placement rules, the rules are used to control, for example, the placement of partitions or the number of partitions during operations like table creation or redistribution. By doing this, associated or strongly related tables are placed in such a way that the required cross-node communication is minimized for SQL operations on tables within the group.

Table placement rules are applied during system migration or table creation, but it may also be necessary to adjust the location or the number of partitions on an ongoing basis for handling data growth. Table redistribution can therefore also be run on demand to optimize the landscape as the system evolves. Repartitioning is always necessary, for example, for any table or partition in the database which reaches the maximum count of 2 billion rows.

The following tools are available to perform table repartitioning and redistribution; these tools evaluate the current landscape and determine an optimized distribution:

- SAP HANA Table Redistribution (available in SAP HANA cockpit, SAP HANA studio, or executed from the command line)
- Data Distribution Optimizer (part of SAP HANA Data Warehousing Foundation)

Balancing a SAP HANA scale-out landscape with these tools is done in two stages:

1. Generation of a plan based on table placement rules (described in detail below). After generating the plan, you can review it and adjust the definition of the rules if required.
2. Execution of the plan which implements the partitioning and distribution changes.

Because split table and move table are operations that require table locks, the execution of the plan should not be performed during a period where there is heavy load on the database.

### **i** Note

Please refer to the corresponding documentation for details. In particular, the *SAP HANA SQL and System Views Reference* gives details of all SQL syntax for the operations described here.

## **Table Classification and Table Placement Rules**

Table placement rules are defined in the table SYS.TABLE\_PLACEMENT; system privilege TABLE ADMIN is required to maintain these settings. Placement rules basically address the following areas:

- Classification: related tables which must be located together are organized in groups
- Configuration settings to manage partitioning (number of initial partitions, split threshold and so on)
- Physical distribution or location of tables or partitions in the server landscape.

When creating a table, if the defined rules match with a table or a table group, SAP HANA will consider them while creating the table.

Please keep in mind that partition specifications still need to be defined by the application.

## **Related Information**

[Scaling SAP HANA \[page 1609\]](#)

[CREATE TABLE Statement \(Data Definition\)](#)

[ALTER TABLE Statement \(Data Definition\)](#)

## 6.11.13.1 Table Classification (Groups)

Associated tables can be classified by a common table group.

The SQL interface of SAP HANA provides three possible kinds of classifications: group name, group type and subtype. Tables which have been classified with group information are included in the SYS.TABLE\_GROUPS table and you can review classification details in the monitoring view SYS.TABLE\_GROUPS (details below). Tables with the same group name are kept on the same host, or, in the case of partitioned tables that are distributed over several hosts, corresponding first-level partitions are distributed for all tables the same way.

One table in the group is defined as the leading table and its table placement settings are applied to all other tables in the group. This can be, for example, the location, or in the case of partitioned tables (if SAME\_PARTITION\_COUNT is set in SYS.TABLE\_PLACEMENT, see below), the number of first-level partitions.

Note that specific applications, like SAP BW, classify objects automatically as they are created and must not be changed manually.

SYS.TABLE\_GROUPS

Column	Description
SCHEMA_NAME	The schema name.
TABLE_NAME	The table name.
GROUP_NAME	The group name
GROUP_TYPE	The group type. Example: in SAP BW there are predefined group types that classify the tables associated with a BW object, such as: sap.bw.cube (InfoCubes), sap.bw.dso (DataStore Objects), sap.bw.psa (PSA tables) and so on.
SUBTYPE	The subtype. This is required for some group types, for example in SAP BW: <ul style="list-style-type: none"><li>• a table belonging to an InfoCube (group type sap.bw.cube) can be a fact table (subtype FACT_IMO) or a dimension table (subtype DIM)</li><li>• a table belonging to a DataStore Object (group type sap.bw.dso) can be an active table (subtype ACTIVE), an activation queue (subtype QUEUE), or a ChangeLog (subtype CHANGE_LOG)</li></ul>
IS_GROUP_LEAD	Determines the leading table within a group. If none is set, the largest, partitioned, non-replicated column store table is used as leading table.

### Example

In this example the following three tables that belong to SAP Business Warehouse (BW) DataStore Object with technical name ZFIGL, all have the same group name value and form the group 'ZFIGL'.

Example Table Group

Table Name	Group Type (GROUP_TYPE)	Subtype (SUBTYPE)	Group Name (GROUP_NAME)
/BIC/AZFIGL00	sap.bw.dso	ACTIVE	ZFIGL
/BIC/AZFIGL40	sap.bw.dso	QUEUE	ZFIGL
/BIC/B0000197000	sap.bw.dso	CHANGE_LOG	ZFIGL

For native applications, the application developer can define a grouping manually, for example, by grouping tables together that are often joined. The following statements show examples of setting table group attributes using CREATE and ALTER table:

```
CREATE COLUMN TABLE "TEST".A1 (A INT) GROUP TYPE ABC GROUP SUBTYPE T
```

```
ALTER TABLE "SAPLG1"."/BIC/MUCSTR000000" SET GROUP NAME "ABC"
```

## Creating Groups Dynamically

There are a number of options for creating table groups dynamically based on the information available in the SQL Plan Cache.

- The Join Path Analysis tool is available within the Data Distribution Optimizer, or the ABAP grouping report for S/4HANA scale-out.
- Table Redistribution also includes an optional preparation step to integrate the Group Advisor tool into the plan generation process to create table groups dynamically.

## Related Information

[Configuration of Table Redistribution \[page 719\]](#)

## 6.11.13.2 Table Placement Rules

The TABLE\_PLACEMENT table provides a customizing interface which can be used for the dynamic management of partitions and locations.

### The TABLE\_PLACEMENT Table

The content of the table is shown here. Parameters 6-10 define how a table or a group of tables is partitioned; further information about usage is provided in the subsections and topics which follow.

## SYS.TABLE\_PLACEMENT

#	Column	Description
1	SCHEMA_NAME	The schema name (as for table groups).
2	TABLE_NAME	The table name.
3	GROUP_NAME	The group name.
4	GROUP_TYPE	The group type.
5	SUBTYPE	The subtype.
6	MIN_ROWS_FOR_PARTITIONING	Partitioning rule: the number of records that must exist in the table before the number of first-level partitions is increased above 1.
7	INITIAL_PARTITIONS	Partitioning rule: determines the number of initial partitions to create, for example, HASH 1, HASH 3,
8	REPARTITIONING_THRESHOLD	Partitioning rule: if the row count exceeds this value then further split iterations are considered.
9	DYNAMIC_RANGE_THRESHOLD	Applies to tables that use the dynamic range partitioning feature. Overwrites the system default value defined in <a href="#">indexserver.ini</a> <a href="#">[partitioning]</a> <a href="#">dynamic_range_default_threshold</a> (10,000,000) for that specific combination of schema / table / group characteristics.
10	SAME_PARTITION_COUNT	Specifies that all partitions of the tables in a group will contain the same number of partitions.  Globally maintained in <a href="#">global.ini</a> <a href="#">[table_placement]</a> <a href="#">same_num_partitions</a> but in case of several applications with deviating settings, it can be maintained on a more granular level.
11	LOCATION	Location rule: master, slave, all (see following topic on Locations).
12	PERSISTENT MEMORY	Whether or not the data is loaded in persistent memory.
13	PAGE LOADABLE	Whether or not the data is page loadable.
14	REPLICA COUNT	The required number of replicas.
15	NUMA_NODE_INDEXES	The allowed NUMA nodes.

## Partitioning Rules

The partitioning parameters are used to define how a table or a group of tables is partitioned if the table has a first-level partitioning specification of HASH or ROUNDROBIN. RANGE partitioning is not handled in this way.

If the number of rows is lower than `MIN_ROWS_FOR_PARTITIONING`, the table consists only of one partition. If this minimum row limit is exceeded, the table will be partitioned in as many partitions as are required to fulfill the following constraints:

- The number of partitions is larger or equal to the value of  $(\text{row count of the table}) / \text{REPARTITIONING\_THRESHOLD}$
- The number of partitions is a multiple of `INITIAL_PARTITIONS`
- The number of partitions is smaller or equal to the number of hosts in case parameter `max_partitions_limited_by_locations` is not set to false and the number of partitions is less than the value of parameter `max_partitions` (see Repartitioning below).

Therefore, if the table has more than one partition, there are at least `INITIAL_PARTITIONS` partitions, and each partition has less than `REPARTITIONING_THRESHOLD` records. Here partitions refer to first-level partitions (of type `HASH` or `ROUNDROBIN`).

Please note, when a partitioned table is created without an estimated row count (default behavior) a partitioned table is created with `INITIAL_PARTITIONS` first-level partitions, whereas in a redistribution it is targeted to have a single first-level partition (assuming `MIN_ROWS_FOR_PARTITIONING > 0`). In specific applications, creation is performed with an estimated row count, for example, BW with 1 million and therefore it will be created with only one first level-partition (assuming `MIN_ROWS_FOR_PARTITIONING > 1,000,000`).

## Repartitioning

There is no automatic repartitioning when threshold values are exceeded. Instead, this is proposed the next time the redistribution process is executed.

The values entered for partitioning must be consistent with the physical landscape, especially the number of server nodes available:

- If repartitioning is necessary, tables are only repartitioned by doubling the number of existing (initial) partitions. This is done for performance reasons. The maximum number of (first-level) partitions reached by that process is defined by parameter `global.ini > [table_placement] > max_partitions` (default 12).
- By default, the system does not create more partitions than the number of available hosts (or more specifically possible locations). For example, if `INITIAL_PARTITIONS` is set to 3 but the distributed SAP HANA database has five possible locations, repartitioning from three to six partitions would not take place. A table can have more than one partition per host if the parameter `global.ini > [table_placement] > max_partitions_limited_by_locations` is set to false (default true). This rule is disregarded if a higher number of first level partitions is required to partition groups with more than 2 billion records (`global.ini > [table_placement] > max_rows_per_partition`, default = 2,000,000,000).

## How Rules Are Applied

The `TABLE_PLACEMENT` table is read in such a way that a more specific rule supersedes a more generic one. A complete matrix of priorities is available in SAP Note 1908082 Table Placement Priorities.

For example, an entry with only schema applies to all tables of that schema; additional entries for that schema and specific group types overrule the more general rule.

## Monitoring View

You can see the actual table placement settings per table by querying the system view `M_EFFECTIVE_TABLE_PLACEMENT`. You can see the valid location(s) according to the configuration and for

each partitioning parameter the actual values and in the corresponding `_MATCH` columns the reason (matching rule) for those.

The information how a table is classified, can be reviewed in the monitoring view `SYS.TABLE_GROUPS`.

### 6.11.13.3 Table Placement Locations

A location is a text value that uses table placement rules at runtime to map to one or more specific volume IDs.

## Locations

Locations use table placement rules (specifically table group types) to map to a list of volume IDs; volume IDs are used in preference to a host:port combination because port numbers may change if a takeover occurs. Some predefined locations are available which are linked to hosts by the worker group value, these have a predefined relationship to specific volume IDs. You can also define your own locations in the `TABLE_PLACEMENT_LOCATIONS` table and for each location make an association to one or more volume IDs; example SQL commands for doing this are given below.

The following predefined locations are available:

Location	Description
default	'default' is the name of a worker group and it used as the default location for hosts if no other locations are defined. This value can be seen in the <code>WORKER_CONFIG_GROUPS</code> field in system view <code>M_LANDSCAPE_HOST_CONFIGURATION</code> .
master	This is the master location node. The value 'MASTER' is set as <code>coordinator_type</code> for the indexserver in system view <code>M_SERVICES</code> .
slave	Other pre-defined locations are slaves, that is, any <code>coordinator_type</code> value for the indexserver in system view <code>M_SERVICES</code> which is not MASTER.
all	The 'all' location includes both masters and slaves.

## Worker Groups as Locations

You can also add your own worker group location values for a host. To add custom locations as worker groups use the following 'SET' procedure and specify the host name; multiple worker group values must be separated by a space as shown:

```
call SYS.UPDATE_LANDSCAPE_CONFIGURATION( 'SET
WORKERGROUPS', '<hostname>', '<name1> <name2> <name3>' )
```

The worker group assignment for a host can be found in entry WORKER\_ACTUAL\_GROUPS of view M\_LANDSCAPE\_HOST\_CONFIGURATION and accessed by executing the following 'GET' procedure:

```
call SYS.UPDATE_LANDSCAPE_CONFIGURATION( 'GET WORKERGROUPS', '<hostname>' )
```

Note that the worker group `worker_dt` is a special worker group required for handling warm data in the extension node (see section on Extension Node and following example).

## Other User-defined Locations

Location definitions are stored in table TABLE\_PLACEMENT\_LOCATION where the location is associated with specific volumes. You can add locations to this table and use the keywords INCLUDE and EXCLUDE to specify which volumes the location can use. Locations are visible in system view TABLE\_PLACEMENT\_LOCATIONS:

LOCATION_NAME	INCLUDE	EXCLUDE
ALL		WORKER_DT
SLAVE		WORKER_DT
MY_GROUP	WORKER_DT, MASTER	
OLTP_PROCESSOR	2,3	
myLocation	5	

New locations and volume assignments are only effective after the next reconfiguration of the indexserver. The currently effective volume IDs for a location are visible in the view M\_TABLE\_PLACEMENT\_LOCATIONS, this is shown in the example which follows.

### Note

- In TABLE\_PLACEMENT, the value '#1' can be used as an affix to the location group name. This indicates that the partitions of all tables for which that rule apply will be located on a single host of that location group, that is, no distribution of several hosts takes place.
- If a location group (worker group) is not found in M\_LANDSCAPE\_HOST\_CONFIGURATION, the system checks whether the location group has been defined by the HANA 1.0 configuration. This means whether an entry with the custom location name exists in section [table\_placement] in the global.ini file, assigning a comma separated list of volume IDs as value to it.

## Example

This scenario creates a separate location for warm data so that tables intended for warm data can be created and correctly located on the warm data volume ID. It shows the three steps: creating new locations, creating corresponding table placement rules, and positioning of newly-created tables on specified volumes. Full details of these statements with further examples are given in the *SAP HANA SQL Reference Guide: ALTER SYSTEM ALTER TABLE PLACEMENT Statement*.

### 1) Create Two User-Defined Locations

Two user-defined locations are created and the INCLUDE/EXCLUDE keywords are used to manage the related volume IDs of each location:

```
ALTER SYSTEM ALTER TABLE PLACEMENT LOCATION worker_dt SET (INCLUDE => '5') ;
```

```
ALTER SYSTEM ALTER TABLE PLACEMENT LOCATION all_without_worker_dt SET (INCLUDE  
=> 'all', exclude=>'worker_dt') ;
```

The relationship between the location and the volume IDs can be seen in the system view `M_TABLE_PLACEMENT_LOCATIONS`. Here, the new user-defined locations have been added after the predefined locations with the result that one single volume ID (#5) is reserved for location `worker_dt`:

LOCATION_NAME	SYSTEM_DEFINED_VOLUME_IDS	INCLUDE	EXCLUDE	EFFECTIVE_VOLUME_IDS
all	2,3,4			2,3,4
default	2,3,4			2,3,4
master	2			2
slave		All	master	3,4
worker_dt		5		5
all_without_worker_dt		All	worker_dt	2,3,4

### 2) Create Table Placement Rules

Corresponding rules for these locations are created in the `TABLE PLACEMENT` table. The locations are added and the `worker_dt` location is associated with a group type for warm data:

```
ALTER SYSTEM ALTER TABLE PLACEMENT (SCHEMA_NAME => 'MY_APPLICATION') SET  
(LOCATION=>'all_without_worker_dt');
```

```
ALTER SYSTEM ALTER TABLE PLACEMENT (SCHEMA_NAME =>  
'MY_APPLICATION', GROUP_TYPE=>'WARM_DATA') SET (LOCATION=>'worker_dt');
```

### 3) Create and Locate Tables

When new tables are created they are positioned according to the placement rules and group type settings.

```
CREATE TABLE "MY_APPLICATION"."TABLE_A" (INT A);
```

```
CREATE TABLE "MY_APPLICATION"."TABLE_B" (INT A);
```

```
CREATE TABLE "MY_APPLICATION"."TABLE_C" (INT A) GROUP TYPE "WARM_DATA";
```

The result is that only TABLE\_C is created on the indexserver that is connected to volume ID 5. TABLE\_A and TABLE\_B are created on one of the other indexservers in the landscape.

## 6.11.13.4 Pre-defined Table Placement Scenarios

For specific applications, SAP provides recommendations regarding partitioning and table distribution configurations.

For the following scenarios SAP provides recommendations regarding table distribution configurations, for these scenarios SQL implementation scripts and detailed documentation is provided in SAP Notes.

### SAP BW powered by SAP HANA

All required steps and recommended settings for SAP BW on HANA 2 are described in SAP Note 1908075 *BW on SAP HANA: Table placement and landscape redistribution*. This includes a zip file with documentation and SQL code to configure various scenarios covering a range of TABLE\_PLACEMENT settings depending on the node size (TB per node) and the number of master and slave nodes.

### SAP BW/4 HANA

All required steps and recommended settings for SAP BW/4 on HANA 2 are described in SAP Note 2334091 *BW/4HANA: Table Placement and Landscape Redistribution*. This includes a zip file with documentation and SQL code to configure various scenarios covering a range of TABLE\_PLACEMENT settings depending on the node size (TB per node) and the number of master and slave nodes.

### SAP S/4HANA

For details of scale-out options for SAP S/4HANA refer to SAP Note 2408419 *SAP S/4HANA - Multi-Node Support*. This note includes scripts and configuration settings as well as detailed documentation about table groups and migration.

### SAP Business Suite Powered by SAP HANA and S/4HANA

SAP Note 1899817 *SAP Business Suite on SAP HANA database: table placement* includes configuration scripts to set up partitioning and distribution for Suite and S/4 HANA for various support package stack releases.

## Further Resources

An introductory Frequently-Asked-Questions document is available on the SCN Community portal: *SAP BW/4HANA and SAP BW-on-HANA with SAP HANA Extension Nodes*

A scenario for SAP BPC (HANA 1 release) is described in SAP Note 2003863 *Enable BPC HANA table distribution*, this note includes table placement settings for BPC systems.

## 6.11.14 Table Replication

In a scale-out system tables (or selected columns of column store tables) may be replicated to multiple hosts. This can help to reduce network traffic when, for example, slowly-changing master data often has to be joined with tables, or partitions of tables, that are located on other hosts.

### Synchronous and Asynchronous Replication

Both asynchronous table replication and synchronous table replication are supported. The following table summarizes the advantages and disadvantages of these two approaches.

With asynchronous table replication there can be differences between the source table and the replica table; the application developer must take this into account and decide for which queries and users the replica tables with a potentially out-dated snapshot are acceptable. Synchronous table replication offers most of the benefits of asynchronous table replication but is more transparent and no SQL or application changes are necessary.

Comparing the table replication types

<b>Optimistic Synchronous Table Replication (OSTR)</b>	<b>Asynchronous Table Replication (ATR)</b>
Pro: Symmetric and thus easy to use.	Pro: Little overhead at the source node.
	Replicating updates with less overhead at the source transactions.

### Optimistic Synchronous Table Replication (OSTR)

Con: There is a performance penalty but only to the write transactions commit operations (DML and read transactions are not affected).

### Asynchronous Table Replication (ATR)

Cons: not easy to use due to asymmetry between source and replica

Replicas have different (possibly outdated) state than their source tables. This incurs difficulty in its usage model. That is, the source and its replica are not symmetric or equivalent to each other and the application developers should explicitly hint which queries are fine with such staleness.

#### **i** Note

In SAP HANA 2.0 a new version of synchronous table replication was implemented: Optimistic Synchronous Table Replication (OSTR). Any replica tables that were created in earlier versions are no longer valid and must be recreated for the new SAP HANA release. Refer to the *Synchronous Table Replication* topic for details.

## Sub-Table Replication

Sub-table replication makes it possible to replicate just a selected set of columns of a table to a replica instead of the complete table. It may be only necessary to replicate the specific columns which are required by users who are querying the table; this is more efficient in terms of less memory consumed by the replica and an increase in replication performance.

Sub-table replication can be used for any column store table using either synchronous or asynchronous replication. Using sub-table replication a source table can be replicated to one or more nodes and can also be replicated to the same node as the source. Each replica can have a different column specification from the source; all replicas are treated like a normal table for query purposes.

A number of options are available to create sub-table replicas either at the same time as a new table is created or later by adding a replica to an existing table. Generally, data definition statements are not permitted on replica tables, with the exception of MOVE and DROP statements (see the examples in the topic which follows).

The monitoring view M\_TABLE\_REPLICAS contains information about replicated tables. In the system view TABLE\_REPLICAS the column HAS\_DIFFERENT\_COLUMNS is set to TRUE for sub-tables. More details about each column are available from the view M\_CS\_COLUMNS.

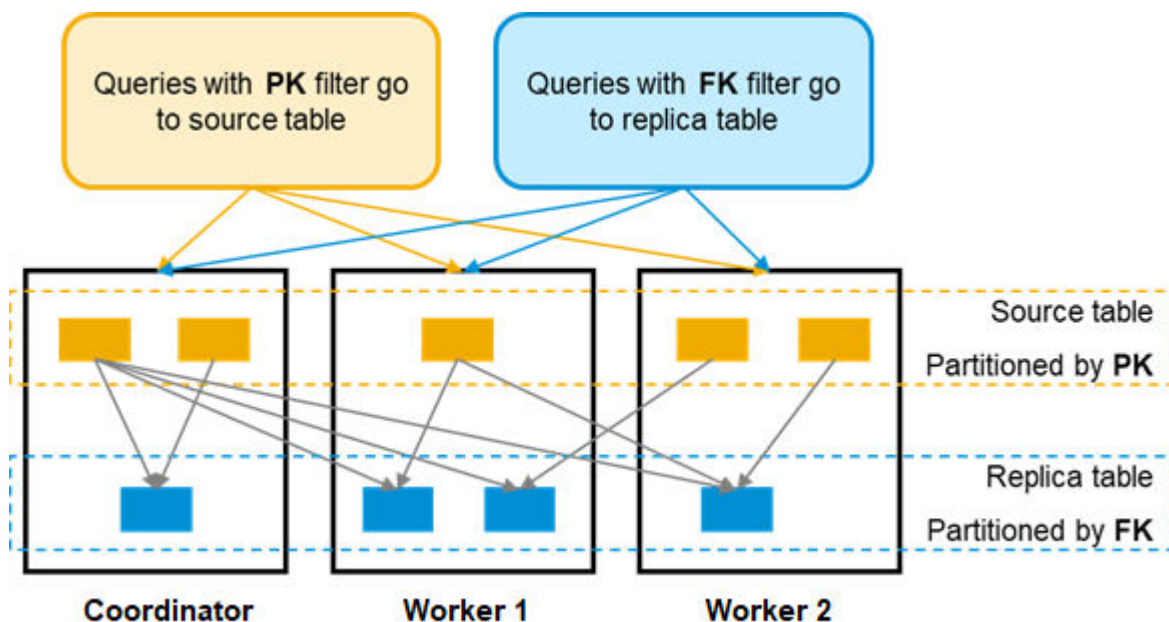

## Replicating Partitioned Tables

In order to provide flexibility in how replica tables are created, it is also possible to replicate partitioned tables in such a way that the replica has a different partitioning specification to the source table.

This is shown in the following illustration based on a scenario using three host servers. A table is partitioned at the first level by ranges on the basis of its primary key value - giving a result of five partitions which are located on the three servers.

The partitions are replicated to new replica tables by using hash partitioning on the basis of a foreign key value - which results in four 'replica' tables.

In a scenario like this you can then optimize your database queries to route them directly to the correct replica. There is no automatic routing of queries, but since the replica tables all have specific names queries can be directed to the appropriate replica by explicitly using the correct table name in the select statement:

This feature can be used with both synchronous and asynchronous replication modes.

In this scenario the source table and replicas can be located in the same node. You must give asymmetric replica tables and partitions a unique name, and queries to a replica must explicitly name the target replica, for example:

```
SELECT C1, C2, C3, CN FROM MyReplica_Partition3
```

In the current release, partitioning to a replica can only be done using HASH and RANGE partitioning (support for round robin and multi-level partitioning will be introduced later). Updates to source tables with asymmetric partitions are possible, but not all DDL statements are supported, see Table Replication Limitations for details.

Note that replica tables with an asymmetric-partition have two additional columns:

- \$reference\_rowid\$ stores the corresponding row ID in the source table without partition information
- \$reference\_partid\$ stores the logical partition ID of the corresponding record in the source table.

These are required because the row id of a record in the replica may be different to the row id in the source.

## Monitoring Views

The monitoring view M\_TABLE\_REPLICAS contains information about replicated tables. For asymmetric partitioned replicas the column HAS\_DIFFERENT\_PARTITIONS is set to TRUE.

## Examples

Refer to the *SAP HANA SQL and System Views Reference* for full details of syntax and all options supported. A number of examples to illustrate this feature are given in the Examples topic (see Related Links).

## Things to Consider

Before using table replication, consider the following aspects:

- Replicated tables consume main memory when they are loaded and disk space since each replica has its own independent persistence. Therefore an increased amount of main memory is needed. This needs to be considered for sizing. In OSTR, source and replica always have the same state. Therefore application developers do not need to be aware of existence of replicas. Queries can be routed to the source and replicas evenly and implicitly by the database.
- For replica creation, the configuration for table placement is taken into consideration.
- You cannot replicate column store tables that have history tables.

Table replication must only be used if these considerations are acceptable for your use case. Refer also to the topic which follows on general limitations.

## Status Aware Routing

Status aware routing applies to both synchronous and asynchronous replication. This feature ensures that in a situation where replica tables exist, if replication is disabled then queries are automatically routed to the source table. For asynchronous replication it may be necessary to query a specific replica table using hints or routing, to do this replication must be enabled. See topic *Asynchronous Table Replication Operations* for details.

## Table Replication Consistency Checks

The following consistency checks are available for replicated tables in the column store, though these cannot be run with sub-table replication and asymmetric partition replication.

To perform the general check, execute:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK_REPLICATION', '<schema>', '<table>')
```

In OSTR, source and replica always have the same state. Therefore application developers, to perform a lightweight data check which ensures that all rows are replicated, execute:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK_REPLICATION_DATA_LIGHTWEIGHT', '<schema>', '<table>')
```

To perform a full data check which ensures all replica hold the same data in all columns, execute:

```
CALL CHECK_TABLE_CONSISTENCY('CHECK_REPLICATION_DATA_FULL', '<schema>', '<table>')
```

The data checks can take a long time to run depending on the data volume.

## 6.11.14.1 Table Replication Examples

Here we give examples of the data definition statements used to create and manage replica tables.

### Examples of Locating Replica Tables

You can use the same syntax for both column store tables and row store tables.

#### Example: Creating Tables with Replicas on All Hosts

SQL Command	Result
<pre>CREATE COLUMN TABLE MY_TABLE (I INT PRIMARY KEY) REPLICA AT ALL LOCATIONS</pre>	Creates a column store table with a replica on each available host.
<pre>ALTER TABLE MY_TABLE ADD REPLICA AT ALL LOCATIONS</pre>	Replicates an existing table on each available host
<pre>ALTER TABLE MY_TABLE2 DROP REPLICA AT ALL LOCATIONS</pre>	Drops all replicas

#### Example: Creating Tables with Replicas on Specific Hosts

You can use the following commands to control the location of replicas.

SQL Command	Result
<code>CREATE ROW TABLE MY_TABLE5 (I INT PRIMARY KEY) AT LOCATION '&lt;master_node&gt;;</code>	Creates a new row store table with a replica on a specified host (for example, master)
<code>ALTER TABLE MY_TABLE5 ADD REPLICA AT LOCATION '&lt;first_slave_node&gt;;</code>	Replicates an existing row store table at the specified location
<code>ALTER TABLE MY_TABLE5 MOVE REPLICA FROM '&lt;first_slave_node&gt;' TO '&lt;second_slave_node&gt;;</code>	Moves an existing replica from one specified location to another
<code>ALTER TABLE MY_TABLE3 DROP REPLICA AT LOCATION '&lt;second_slave_node&gt;;</code>	Drops the replica from the specified host

## Examples Using Sub-Table Replication

The key words `SYNCHRONOUS REPLICA` are required to create sub-table replicas. Only `MOVE` and `DROP` data definition statements are permitted on sub-table replicas. You can create source and replica tables in any of three ways:

1. Create a replica from an existing table using `ALTER TABLE - ADD` to keep the same name as the source table.
2. Create a replica from an existing table using `CREATE TABLE - LIKE` to give the replica a new name.
3. Create a source and replica at the same time using `CREATE TABLE` syntax.

## Example

The following examples are based on a source table `SRC.TBL` which has columns A, B, C, D, E.

SQL Command	Result
<code>ALTER TABLE SRC.TBL ADD SYNCHRONOUS REPLICA (B, C, E) AT '&lt;host:port&gt;;</code>	Create a replica from an existing table keeping the name of the source table; this example creates a replica containing only columns B, C, E.
<code>CREATE COLUMN TABLE REP.TBL LIKE SRC.TBL SYNCHRONOUS REPLICA (A, C, D) AT '&lt;host:port&gt;;</code>	Create a replica with a new name (REP.TBL) from an existing table; this example creates a replica with columns A, C, D.
<code>CREATE COLUMN TABLE SRC.TBL (A INT, B INT, C NVARCHAR(10)) SYNCHRONOUS REPLICA (A, B) AT '&lt;host:port&gt;;</code>	Create a source and replica at the same time, in this case the data types are also required.
<code>ALTER TABLE REP.TBL MOVE TO '&lt;host:port&gt;;</code>	Move an explicitly named replica sub-table.
<code>ALTER TABLE REP._SYS_REP_TBL#1 MOVE TO '&lt;host:port&gt;;</code>	Move an explicitly named replica sub-table.

SQL Command	Result
<code>DROP TABLE REP.TBL;</code>	Drop an explicitly named replica sub-table.

## Examples Using Partitioned Tables

### Example

SQL Command	Result
<code>CREATE COLUMN TABLE SRC_TABLE (C1, C2, C3, ... CN, primary key (C1, C2, C3)) PARTITION BY HASH (C1) PARTITIONS 32;</code>	Create a source table (SRC_TABLE) with a number of columns. The table has 32 hash-partitioned partitions based on the values of column 1 (C1).
<code>CREATE COLUMN TABLE REP_TABLE1 LIKE SRC_TABLE REPLICAS PARTITION BY HASH (C2) PARTITIONS 8;</code>	Create a replica table (REP_TABLE1) which has an asymmetric partitioning scheme compared to its source table. All columns of the source table are replicated but the replica is partitioned on column 2 (C2) to create 8 partitions.
<code>CREATE COLUMN TABLE REP_TABLE2 LIKE SRC_TABLE REPLICAS (C1, C3) PARTITION BY RANGE (C3) (PARTITION '1' &lt;= VALUES &lt; '100', PARTITION OTHERS);</code>	Create another replica table (REP_TABLE2) which also has an asymmetric partitioning scheme compared to its source table. Only columns 1 and 3 of the source table are replicated and the replica is partitioned on column 3 (C3) by ranges (specifically one partition with all values between 1 and 100, and a partition for all other values).

## 6.11.14.2 Table Replication Limitations

General restrictions that apply to the use of table replication.

- Table replication works only within a single SAP HANA scale-out landscape. It cannot be used for replicating a table across two different SAP HANA landscapes or between SAP HANA and other DBMS instances.
- Source tables can be distributed to multiple nodes but (except for the case of sub-table replication) a source table and its replica cannot be located at the same node.
- Only one identical replica table (or table partition) can exist in a replica node (except for the case of sub-table replication).
- The following table types cannot be set as a replication table:
  - History table
  - Flexible table
  - Temporary table
  - Virtual table
  - Extended Storage table
  - Multistore table
  - System-versioned table

- Tables with masked columns, tables with associations, tables with series data.
- Tables with record commit timestamp column
- Write operations cannot be executed at the replica table. Such access will return an error.
- DDL operations cannot be executed directly at the replica table. Such access will return an error.
- DDL operations with online option are not allowed for a replication table.
- DDL operations on a replication source table cannot be executed with a 'DDL auto-commit off' transaction. Such access will return an error.
- It is not allowed for a 'DDL auto-commit off' transaction to execute a write operation on a replication source table after a DDL operation on any table in the same transaction boundary.
- It is not allowed for a 'DDL auto-commit off' transaction to execute a DDL operation on replicated table when its replication status is ENABLED.
- Updates to source tables with asymmetric partitions are possible, but not all DDL statements are supported (add partition, for example, is not supported). The DDLs in the following table are supported, other operations may also work but you should verify the results:

<b>Objects</b>	<b>Supported Actions</b>
Replica	add/drop/move/enable/disable
Source table	drop/move/truncate
Column	add drop/modify possible if the target column is not a partitioning key of replica tables
Primary key	drop add is possible if the target column is already a partitioning key of replica tables
Foreign key	add / drop
Unique constraint	add / drop
Constraint	drop
Check	add

- The binary import on the replicated table (source or replica table) is not allowed. You need to drop the replica tables and then import and re-create the replica tables again.
- Export from the replica table is not allowed. Export from the source table is allowed but the exported data contains only the source table's data. It does not contain any data of the replica.

### 6.11.14.3 Asynchronous Table Replication

Asynchronous table replication can help reduce workload on hosts by balancing load across replica tables on worker hosts in a distributed SAP HANA system.

Asynchronous replication has a number of key characteristics:

- Table replication

Only a selected list of tables can be set as replicated tables, this is different to system replication which replicates the entire database.

- **Asynchronous replication**  
Write operations on those replicated tables are propagated to their replica tables asynchronously with almost no impact to the response time of source write transactions. That is, the write transaction is committed without waiting for its propagation to the replica.
- **Transactional replication**  
Read queries routed to the replica may not see the up-to-date committed result by the nature of asynchronous replication. But, the cross-table transactional consistency is guaranteed by preserving the source transaction boundary and their commit order on log replay at the replica side.
- **Parallel log replay**  
Although the read queries routed to the replica may see outdated data, the propagation delay is minimized by using parallel log replay at the replica side.

### 6.11.14.3.1 Configure Asynchronous Table Replication

To set up asynchronous table replication you create a replica schema, create replica tables, handle large column store tables and activate replication on the system.

#### Context

In the steps listed here SRC\_SCHEMA, REP\_SCHEMA, TAB1 and PART\_TAB1 indicate source schema name, replica schema name, normal table name and partitioned table name respectively.

#### Procedure

1. Create a replica schema

```
CREATE SCHEMA REP_SCHEMA;
```

This creates the replica schema called REP\_SCHEMA.

2. Create replica tables

You can choose the location of your replica tables using *Table Placement Rules* or you can *Set an Explicit Table Location*.

3. Handle large column store source tables.

If you need to create a replica of a large column store table (more than 2 GB) see *Optimize Replication Activation Time for Large Column Store Tables*.

4. Activate replication.

```
ALTER SYSTEM ENABLE ALL ASYNCHRONOUS TABLE REPLICAS;
```

Even after creating replica tables, replay is not activated without this activation command. We recommend first creating all of your necessary replicas and then activating them once.

## Results

You have created and activated your table replicas.

You can check this with the following command:

```
SELECT * FROM M_ASYNCHRONOUS_TABLE_REPLICAS [WHERE SOURCE_SCHEMA_NAME = SRC_SCHEMA AND SOURCE_TABLE_NAME = TAB1];
```

This will show all replica tables created for SRC\_SCHEMA.TAB1.

### 6.11.14.3.1.1 Table Placement Rules for Replicas

The following SQL commands create table placement rules for replica schema, which can be used to create or add replica tables.

#### Example

Create table placement rules

SQL Command	Result
<pre>ALTER SYSTEM ALTER configuration ('global.ini', 'SYSTEM') SET ('table_placement', 'repl_volumes')='6,7,8' WITH RECONFIGURE;</pre>	<p>This command creates a configuration parameter called 'repl_volumes' which will be used for the table placement rule.</p> <p>'6,7,8' means multiple nodes for replica host and each of them indicates a volume ID.</p>

## SQL Command

```
ALTER SYSTEM ALTER TABLE PLACEMENT  
(SCHEMA_NAME => 'REP_SCHEMA') SET  
(LOCATION => 'repl_volumes');
```

## Result

This command will create a table placement rule for 'REP\_SCHEMA' which uses 'repl\_volumes' as the configuration parameter. With this table placement rule, any of tables in REP\_SCHEMA will be created at the locations mapped in 'repl\_volumes'.

Note that replica table cannot be created on a master index-server and it's not allowed to create multiple replicas of the same table on the same replica host.

## Example

Create or add a replica table using table placement rules

### SQL Command

```
CREATE TABLE REP_SCHEMA.TAB1 LIKE  
SRC_SCHEMA.TAB1 ASYNCHRONOUS REPLICA;
```

### Result

This command creates the first replica table without assigning its location. The replica table will be created on one of the available replica hosts.

```
ALTER TABLE SRC_SCHEMA.TAB1 ADD  
ASYNCHRONOUS REPLICA;
```

This creates more than one replica for SRC\_SCHEMA.TAB1

It creates the second replica table on another replica host without assigning its location. The second replica table will be created on one of the replica hosts which does not have the same replica table. If there are no more replica hosts to add a replica table to, an error will be returned. You can create the third, fourth, and so on, replica tables in the same manner.

```
CREATE TABLE REP_SCHEMA.PART_TAB1 LIKE  
SRC_SCHEMA.PART_TAB1 ASYNCHRONOUS  
REPLICA;
```

In this example there's no difference between the normal table and the partitioned table. Please note that by default, the replica's partitions will be created like the source partitions' host distribution. Therefore the number of used hosts by the replica is the same as the source table.

```
ALTER TABLE SRC_SCHEMA.PART_TAB1 ADD  
ASYNCHRONOUS REPLICA;
```

For partitioned table, this example creates additional replica tables using the same procedure as for the normal table. As a default, the additional replica partitions will be created on the replica hosts which don't already have the tables' replica partitions.

## 6.11.14.3.1.2 Set an Explicit Table Location

You can set an explicit table location with SQL commands.

### Example

SQL Command	Result
<pre>CREATE TABLE REP_SCHEMA.TAB1 LIKE SRC_SCHEMA.TAB1 ASYNCHRONOUS REPLICAS AT 'host1:port1';</pre>	<p>This creates the first replica table on the specified location 'host1:port1'.</p> <p>Note that replica table cannot be created on master index-server and it's not allowed to create multiple replica tables on the same replica node</p>
<pre>ALTER TABLE SRC_SCHEMA.TAB1 ADD ASYNCHRONOUS REPLICAS AT 'host2:port2'; ALTER TABLE SRC_SCHEMA.TAB1 ADD ASYNCHRONOUS REPLICAS AT 'host3:port3';</pre>	<p>Additional replica tables are created at the specified locations.</p>
<pre>CREATE TABLE REP_SCHEMA.PART_TAB1 LIKE SRC_SCHEMA.PART_TAB1 ASYNCHRONOUS REPLICAS AT ('host1:port1', 'host2:port2', ...);</pre>	<p>For partitioned table, this command creates the first replica table for a partitioned table. The replica partitions will be distributed on the specified nodes.</p>
<pre>ALTER TABLE SRC_SCHEMA.PART_TAB1 ADD ASYNCHRONOUS REPLICAS AT ('host3:port3', 'host4:port4', ...);</pre>	<p>For partitioned table, this command creates additional replica tables on other replica nodes. The replica partitions will be distributed on the specified nodes.</p>

## 6.11.14.3.2 Asynchronous Table Replication Operations

There are a number of operations you can perform on replica tables such as querying, adding, deactivating, dropping, and monitoring tables.

### Querying Replica Tables

With asynchronous replication it may be necessary to query a specific replica table. To do this replication must be enabled, if it is disabled, all queries on replica tables are automatically re-routed to the source host and tables (this is called status aware routing).

If you submit a simple query to select data from a table which has multiple replica tables then one of the replica tables is automatically selected to service the query. However, it is also possible to use query hints to select a specific replica (identified by volume id) or to use the `result_lag` hint which only selects replica data if it is within an acceptable (specified) lag time. The following examples illustrate these methods:

#### Query Distribution

Using the following type of query one of the replica tables will be automatically selected:

```
SELECT * FROM REP_SCHEMA.TAB1;
```

#### Explicit Connection (Schema Mapping)

To access one specific replica table you can use the `route_to` hint to make an explicit connection to the location of the replica by including the volume ID number:

```
SELECT * FROM REP_SCHEMA.TAB1 with hint(route_to(4));
```

In this example '4' in the `route_to` hint identifies the volume id of the indexserver. If the specified volume has the replica table, it is selected to service the query.

You can use the following query to retrieve the volume id of a specific replica:

```
SELECT V.VOLUME_ID, C.SCHEMA_NAME, C.TABLE_NAME, C.PART_ID, C.RECORD_COUNT FROM  
M_VOLUMES V, M_CS_TABLES C  
WHERE V.HOST = C.HOST and V.PORT = C.PORT AND SCHEMA_NAME = 'REP_SCHEMA' AND  
TABLE_NAME LIKE '%TAB1%';
```

This example uses `M_CS_TABLES` to select a column table. Replace this with `M_RS_TABLES` to check for row tables.

#### Using Hints to Avoid Stale Data

You can query replica tables with the `result_lag` hint as shown in the following example.

```
SELECT * FROM SRC_SCHEMA.TAB1 WITH HINT(RESULT_LAG('hana_atr', [seconds]));
```

A preconfigured hint class exists for Asynchronous Table replication, which is called `hint_result_lag_hana_atr`. If the current lag time of the data on the replica is within the acceptable delay period (that is, if the current lag time is smaller than the stated value for the `[seconds]` parameter), then the query is executed on the replica. Otherwise the query is routed to the source table.

The seconds parameter is optional and if no value is entered on the SQL command line, the default value defined in configuration parameter `atr_default_lag_time` will be applied (configuration details are given in section *Performance: Using Hints to Query Data Snapshots*).

### **i** Note

Note that if a query is submitted repeatedly and the staleness of the replica data in relation to the seconds parameter changes between query executions (from acceptable to unacceptable or from unacceptable to acceptable) a recompilation of the query would be triggered. Recompilation is triggered whenever the seconds parameter value of the hint is evaluated and the result causes a switch to a new data source.

It is important therefore in order to minimize the recompilation overhead to set an appropriate value for the seconds parameter in relation to how often the query is submitted and how frequently the data is refreshed.

## Add More Replica Tables to an Active Asynchronous Table Replication System

You can create more replica tables in your existing ATR system and activate replication. You can activate table replication globally or for a specific named table as shown in the following examples:

```
ALTER SYSTEM ENABLE ALL ASYNCHRONOUS TABLE REPLICAS
```

This approach incurs a high-cost job if your system already has many replica tables or is actively replicating. In this case you are recommended to use the following command which requires global replication to be turned on:

```
ALTER TABLE SRC_SCHEMA.TAB2 ENABLE ASYNCHRONOUS REPLICA;
```

This example activates the replication operation for `SRC_SCHEMA.TAB2`. You can use the `disable` parameter instead of `enable` to deactivate replication. Note that during the table level replication activation phase, transactional consistency of the target replica table is not guaranteed.

## Deactivate Replication

To deactivate the overall replication operation of all replication tables use:

```
ALTER SYSTEM DISABLE ALL ASYNCHRONOUS TABLE REPLICAS;
```

Its progress can be monitored by the following query:

```
SELECT * FROM M_TABLE_REPLICAS WHERE REPLICATION_STATUS != 'ENABLED'.
```

## Drop Replica Tables

The following examples show how to drop replica tables. Note that if a source table is dropped its corresponding replica table is dropped as well.

This example drops REP\_SCHEMA schema and all replica tables in the schema as well:

```
DROP SCHEMA REP_SCHEMA CASCADE;
```

These examples show dropping replica tables for SRC\_SCHEMA.TAB1. Firstly at a specific named host and secondly at all locations:

```
ALTER TABLE SRC_SCHEMA.TAB1 DROP REPLICA AT '<replica host>:<replica port>';
```

```
ALTER TABLE SRC_SCHEMA.TAB1 DROP REPLICA AT ALL LOCATIONS;
```

## Monitoring Replica Tables

Use the system view M\_TABLE\_REPLICAS to monitor replica tables. M\_ASYNCHRONOUS\_TABLE\_REPLICAS is deprecated in SPS 12.

The field LAST\_ERROR\_CODE displays error codes. More detailed information will be described in field LAST\_ERROR\_MESSAGE.

You can look up the meaning of an error code in the system view M\_ERROR\_CODES. The error codes 2, 4 and 1025 are typically shown during replication and those are categorized as "ERR\_GENERAL", "FATAL\_OUT\_OF\_MEMORY" and "ERR\_COM" respectively in M\_ERROR\_CODES.

[Performance: Using Hints to Query Data Snapshots \[page 498\]](#)

### 6.11.14.3.3 Row to Column Table Replication

You can replicate data from row store tables to column store replicas, for mixed data types this may give optimal performance.

In a scale-out environment you can replicate data asynchronously from a row store source table to a column store replica table. Row store tables typically provide better performance for transactional (OLTP) workload in comparison to column store tables. Similarly, column store tables offer the best performance for analytics workload. Row to column table replication may therefore be an optimal replication configuration for mixed workload types to get the best performance from both types of table.

## Row-to-Column Table Replication Operations

You can configure asynchronous Row-to-Column table replication with the following SQL commands:

- Create a row store source table:

```
CREATE ROW TABLE SRC_SCHEMA.TAB (A INT)
```

- Create a column store replica table. For the first replica creation you need to specify the 'COLUMN' keyword:

```
CREATE COLUMN TABLE REP_SCHEMA.TAB LIKE SRC.TBL ASYNCHRONOUS REPLICA AT '<host>:<port>'
```

or alter an existing table:

```
ALTER TABLE SRC_SCHEMA.TAB ADD ASYNCHRONOUS REPLICA AT '<host>:<port>'
```

All other operations are the same as general asynchronous table replication (such as table placement rule, activate replication, deactivate replication and drop replica tables).

## Limitations

The following limitations apply:

- Only asynchronous mode is supported for Row-to-Column table replication. Synchronous mode is not supported because the replay performance of the column store does not fully catch up with the throughput of the row store source table.
- Binary object data is not supported, a row store source table which has an LOB type field cannot have a column store replica table.

### 6.11.14.3.4 Replicate Aging Tables

You can selectively replicate only the hot (current) partitions of aging tables, which means you can have the same benefit of the hot (current) partitions without increasing memory used for cold (old) partitions.

## Procedure

1. Create an aging table; there are a number of possible ways to do this.
  - a. You can create an aging table with the following CREATE COLUMN TABLE command:

```
CREATE COLUMN TABLE SRC AGING_SCHEMA.AGING_TABLE (PK INT, TEMPERATURE  
VARCHAR(8) default '00000000', PRIMARY KEY (PK)  
PARTITION BY RANGE (TEMPERATURE)  
(PARTITION VALUE = '00000000' IS CURRENT, PARTITION OTHERS)  
WITH PARTITIONING ON ANY COLUMNS ON
```

```
at 'host:port', 'host:port'
```

- b. Promote a non-partitioned table into a hash-aging table:

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE partition by range (temperature)
(partition value = '00000000' IS CURRENT, PARTITION OTHERS) WITH
PARTITIONING ON ANY COLUMNS ON
```

- c. Promote a hash-partitioned table into an aging table

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE PARTITION BY
HASH(A) PARTITIONS 2,
RANGE(TEMPERATURE) (PARTITION VALUE = '00000000' IS CURRENT)
WITH PARTITIONING ON ANY COLUMNS ON
FOR DEFAULT STORAGE NON CURRENT PARTITIONS PAGE LOADABLE
FOR NON CURRENT PARTITIONS UNIQUE CONSTRAINTS OFF;
```

- d. If an Aging table exists, use ADD PARTITION to create further cold partitions, for example:

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE ADD PARTITION 20000101 <= VALUES
< 20020101
```

Partitioning parameter values:

- Use RANGE for Range partitioning
- TIME SELECTION is the internal name for this aging implementation
- PAGED ATTRIBUTES is an optional property that may be specified in order to use Paged Attributes for cold partitions
- NO UNIQUE CHECK is an optional property that disables the unique check on cold partitions
- TEMPERATURE is the VARCHAR(8) temperature column
- 00000000 is the identifier for the hot partition
- <ranges> shall be substituted with actual dates. For example, specify '20130101-20140101, 20140101-20150101'

2. Enable Actual Only Replication.

The configuration parameter `async_rep_actual_only_replication_enabled` in the `indexserver.ini` file must be enabled; it is enabled by default.

3. Create a replica schema.

```
CREATE SCHEMA REP_SCHEMA
```

4. Activate replication.

```
ALTER SYSTEM ENABLE ALL ASYNCHRONOUS TABLE REPLICAS;
```

This statement will activate all the other replicas except actual-only replication (actual-only replicas will be created in the next step). The actual-only replication should be enabled separately (in step 6) after all the other replicas are already enabled here.

5. Create replica tables.

- a. Create replica table with Table Placement rule.

The following commands create table placement rules for a replica schema:

```
ALTER SYSTEM ALTER configuration ('global.ini', 'SYSTEM') SET
('table_placement', 'repl_volumes')='6,7,8' WITH RECONFIGURE;
```

Here, *repl\_volumes* is an alias name used to apply the table placement rule. '6,7,8' means multiple nodes are used as replica hosts and each number indicates the volume ID.

```
ALTER SYSTEM ALTER TABLE PLACEMENT (SCHEMA_NAME => 'REP_SCHEMA') SET  
(LOCATION => 'repl_volumes');
```

With this table placement rule, any of tables in REP\_SCHEMA will be created at the locations mapped in "repl\_volumes".

### Note

Replica tables cannot be created on master indexserver and it is not allowed to create multiple replica tables on the same replica node.

To create the first replica table without assigning its location use the following SQL statement. The replica table will be created on one of replica nodes.

```
CREATE TABLE REP_AGING_SCHEMA.AGING_TABLE LIKE  
SRC_AGING_SCHEMA.AGING_TABLE ASYNCHRONOUS REPLICA;
```

If you want to create more than one replica for SRC\_SCHEMA, use:

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE ADD ASYNCHRONOUS REPLICA;
```

This creates the second replica table on other replica nodes without assigning its location. The second replica table will be created on one of replica nodes which does not have the same replica table. If there are no more replica nodes to add a replica table to, an error will be returned. You can create the third, the fourth, and more replica tables in the same manner.

- b. Create replica table with an explicit table location.

To create the first replica table on the specified location 'host:port'.

```
CREATE TABLE REP_AGING_SCHEMA.AGING_TABLE LIKE  
SRC_AGING_SCHEMA.AGING_TABLE ASYNCHRONOUS REPLICA AT 'host:port';
```

### Note

Replica tables cannot be created on master indexserver and it is not allowed to create multiple replica tables on the same replica node.

To create additional replica tables on the specified location. You can create partitioned tables on more than one host using a comma separated list enclosed in parentheses as in the following examples:

```
CREATE TABLE REP_AGING_SCHEMA.AGING_TABLE LIKE  
SRC_AGING_SCHEMA.AGING_TABLE ASYNCHRONOUS REPLICA AT ('host1:port1',  
'host2:port2', ...);
```

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE ADD ASYNCHRONOUS REPLICA AT  
( 'host1:port1', 'host2:port2', ... );
```

6. Turn a partition on or off.

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE [ENABLE/DISABLE] ASYNCHRONOUS  
REPLICA PARTITION [logical partition id];
```

Only hot partitions can be turned on/off. If only the hot partition is enabled, the others are not replicated.

## 7. Check Replica Tables

To view all replica tables created for SRC\_AGING\_SCHEMA.AGING\_TABLE use:

```
SELECT * FROM M_ASYNCHRONOUS_TABLE_REPLICAS WHERE SOURCE_SCHEMA_NAME = 'SRC_SCHEMA' AND SOURCE_TABLE_NAME = 'AGING_TABLE';
```

## 8. Query on aging tables with a hint

You can read hot or cold data from an aging table using the following SQL suffix. The RANGE\_RESTRICTION is a filter for the range partitioning.

```
WITH RANGE_RESTRICTION('CURRENT') or WITH RANGE_RESTRICTION('DATE');
```

Use DATE in the format “yyyy-mm-dd”. If you specify a date, it will always consider the hot partition as well. CURRENT is the hot partition.

```
SELECT * FROM SRC_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('CURRENT')
SELECT * FROM REP_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('CURRENT')
SELECT * FROM SRC_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('2000-01-01')
SELECT * FROM REP_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('2000-01-01')
```

## 9. Deactivate Replication

```
ALTER SYSTEM DISABLE ALL ASYNCHRONOUS TABLE REPLICAS;
```

This command deactivates the overall replication operation of all replication tables.

You can monitor its progress using:

```
SELECT * FROM M_TABLE_REPLICAS WHERE REPLICATION_STATUS != 'ENABLED';
```

You can turn off a specific table only using:

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE DISABLE ASYNCHRONOUS REPLICA;
```

## 10. Drop Replica Tables

### i Note

If a source table is dropped, its corresponding replica table is dropped as well.

```
DROP SCHEMA REP_SCHEMA CASCADE;
```

Drops REP\_SCHEMA schema and all replica tables in the schema as well.

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE DROP REPLICA AT ALL LOCATIONS;
```

Drops all replica tables of the specified source table SRC\_AGING\_SCHEMA.AGING\_TABLE.

```
ALTER TABLE SRC_AGING_SCHEMA.AGING_TABLE DROP REPLICA AT 'host:port' ;
```

Drops the replica located at '<replica host>:<replica port>'.

## 6.11.14.3.5 Query Aging Tables

An actual partition on a replica is only able to be accessed by using the CURRENT range restriction on a replica table. Otherwise, all queries are routed to a source table even though the queries are on a replica table.

### Procedure

1. Access to actual partition(hot data) on replica

You can get hot data from an actual partition by using the CURRENT range restriction on a replica table.

```
SELECT * FROM REP_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('CURRENT')
```

2. Access to both actual(hot data) and history partition(cold data) on replica

You can get hot and cold data from both actual and history partitions by using the DATE range restriction on a replica table. The query is routed to a source table. Even though the DATE range restriction indicates only hot data, the query is routed to a source table.

```
SELECT * FROM REP_AGING_SCHEMA.AGING_TABLE WITH RANGE_RESTRICTION('yyyy-mm-dd')
```

3. Access to replica without RANGE RESTRICTION

You can get data from all actual and historical partitions. The query is routed to a source table.

```
SELECT * FROM REP_AGING_SCHEMA.AGING_TABLE
```

## 6.11.14.4 Synchronous Table Replication

Synchronous table replication is a transparent solution which does not require any SQL or application changes. The table replication happens at commit time.

### Note

In SAP HANA 2.0 a new version of synchronous table replication has been implemented (OSTR) and replica tables which were created in earlier versions may no longer be valid. In this case an error message *Feature not supported* will be generated. If this error occurs the replica tables must be dropped and recreated using the ALTER TABLE commands for DROP and ADD:

```
ALTER TABLE {SCHEMA_NAME}.{TABLE_NAME} DROP REPLICA AT ALL LOCATIONS
```

```
ALTER TABLE {SCHEMA_NAME}.{TABLE_NAME} ADD [SYNCHRONOUS] REPLICA AT  
'replica_location'
```

### Related Information

[Configure Synchronous Table Replication \[page 702\]](#)

## 6.11.14.4.1 Configure Synchronous Table Replication

You can configure synchronous replication using the SQL editor simply by adding replica tables.

### Context

In the example commands below the following placeholders are used:

SRC_SCHEMA *	table schema name	REP_SCHEMA *	replica table schema name
SRC_TABLE *	table name	REP_TABLE	replica table name
SRC_PART_TABLE *	partitioned table name	REP_PART_TABLE	replica partitioned table name

\*We assume that SRC\_SCHEMA, REP\_SCHEMA and SRC\_TABLE and SRC\_PART\_TABLE already exist in your system.

Note that for synchronous replication no initial activation is necessary.

### Procedure

#### Add Replica Tables

Normal Table	Partitioned Table
<b>Explicit synchronous table creation</b> <pre>CREATE COLUMN TABLE REP_SCHEMA.REP_TABLE LIKE SRC_SCHEMA.SRC_TABLE SYNCHRONOUS REPLICA AT 'host:port'</pre>	<b>Explicit synchronous table creation</b> <pre>CREATE COLUMN TABLE REP_SCHEMA.REP_PART_TABLE LIKE SRC_SCHEMA.SRC_PART_TABLE SYNCHRONOUS REPLICA AT 'host:port'</pre>
<b>Implicit synchronous table creation</b> <pre>ALTER TABLE SRC_SCHEMA.SRC_TABLE ADD SYNCHRONOUS REPLICA AT 'host:port'</pre>	<b>Implicit synchronous table creation</b> <pre>ALTER TABLE SRC_SCHEMA.SRC_PART_TABLE ADD SYNCHRONOUS REPLICA AT 'host:port';</pre>
<p><b>This creates a replica table at the specified location 'host:port'. Note that it is not allowed to create multiple replica tables on the same replica node.</b></p>	<p>For a partitioned table, it creates a replica table for a partitioned table. The replica partitions cannot be distributed on the several nodes. They should be located on the same replica node.</p>

## Results

Activation is not necessary. You can check your replica tables by querying the M\_TABLE\_REPLICAS view.

This view shows general information on synchronous table replicas.

```
SELECT * FROM M_TABLE_REPLICAS WHERE SOURCE_TABLE_NAME = 'SRC_TABLE'
```

## Related Information

[Table Replication Limitations \[page 688\]](#)

### 6.11.14.4.2 Operations for Synchronous Replication

There are a number of operations you can perform for synchronous replication such as activating or deactivating replication, and dropping replica tables.

#### Activate and Deactivate Replication

The following command deactivates all synchronous replication:

```
ALTER SYSTEM DISABLE ALL SYNCHRONOUS TABLE REPLICAS
```

The following command deactivates a specific synchronous table replica:

```
ALTER TABLE SRC_SCHEMA.SRC_TABLE DISABLE SYNCHRONOUS REPLICA
```

Activate Replication for all or specific synchronous tables again.

The following command activates all synchronous replication:

```
ALTER SYSTEM ENABLE ALL SYNCHRONOUS TABLE REPLICAS
```

The following command activates a specific synchronous table replica:

```
ALTER TABLE SRC_SCHEMA.SRC_TABLE ENABLE SYNCHRONOUS REPLICA
```

You can check a table's current replication status; this is shown in M\_TABLE\_REPLICAS.

## Drop Replica Tables

Use the following commands to drop replica tables. Note that if a source table is dropped, its corresponding replica tables are all dropped as well.

The following command drops all replica tables of the specified source table "SRC\_TABLE":

```
ALTER TABLE SRC_SCHEMA.SRC_TABLE DROP REPLICA AT ALL LOCATIONS
```

The following command drops one of replica tables which is located at "<replica host>:<replica port>":

```
SRC_TABLE'. ALTER TABLE SRC_SCHEMA.SRC_TABLE DROP REPLICA AT '<replica host>:<replica port>
```

Using synchronous replication you do not have to modify queries in any way to access replica tables. When you access a source table, either the source table or the replica table is automatically selected and the query is routed to the selected table in a round robin manner. So, just by adding replica tables, the read-only query workload can be load balanced without any SQL string or application problem change.

## 6.11.15 Redistributing Tables in a Scaleout SAP HANA System

In a scaleout SAP HANA system, tables and table partitions are assigned to an index server on a particular host when they are created. As the system evolves over time you may need to optimize the location of tables and partitions by running automatic table redistribution.

There are several occasions when tables or partitions of tables need to be moved to other servers, for example, the tables and partitions which grow fastest in size may need to be split and redistributed. Table redistribution aims to balance the workload across all hosts and optimize the location of tables and partitions so that tables which are often used together are located on the same node. Table redistribution is based on the table placement rules, these determine, for example, table sizes, partitioning threshold values, and preferred partition locations.

Although it is possible to move tables and table partitions manually from one host to another, this is not practical for large-scale redistribution of data. The table redistribution function offers a range of options to perform balancing, optimization and housekeeping tasks. Redistribution is a two stage process: the first stage is to generate a redistribution plan, this can be done iteratively and the distribution configuration can be modified and tweaked until the desired result is achieved; secondly the plan is executed.

You can run table redistribution from the SAP HANA administration tools, studio and cockpit, or from the SQL command line.

## Related Information

[Table Distribution](#)

[Managing Table Redistribution in SAP HANA Studio \[page 705\]](#)

[Table Redistribution Commands \[page 714\]](#)

## 6.11.15.1 Table Distribution in SAP HANA Cockpit

Use the SAP HANA cockpit to manage table distribution. You can view and save the current table distribution, automatically generate an optimized table redistribution, re-run a previously executed plan, or restore a saved plan.

Many features related to Table Distribution are available within SAP HANA cockpit, including:

- Table placement rules
- Generating and executing table redistribution plans
- Modifying table distributions
- Table group advisor

All information related to these features is given in the *SAP HANA Cockpit Administration Guide*. Use the links on this page to go directly to the latest version of the cockpit documentation.

## 6.11.15.2 Managing Table Redistribution in SAP HANA Studio

Administrators can use the table redistribution feature in the SAP HANA studio to create a plan for redistributing and repartitioning tables. The administrator can review the plan and execute it.

SAP HANA supports several redistribution operations that use complex algorithms as well as configurable table placement rules and redistribution parameters to evaluate the current distribution and determine a better distribution depending on the situation.

Redistribution operations are available to support the following situations:

- You are planning to remove a host from your system
- You have added a new host to your system
- You want to optimize current table distribution
- You want to optimize table partitioning

## Data Distribution Optimizer

To plan, adjust and analyze landscape redistribution, you can also use the Data Distribution Optimizer. The Data Distribution Optimizer is an SAP HANA XS-based tool included in the SAP HANA Data Warehousing Foundation option. The Data Distribution Optimizer provides packaged tools for large scale SAP HANA use cases to support more efficient data management and distribution in an SAP HANA landscape. For more information, see the *SAP HANA Data Warehousing Foundation - Data Distribution Optimizer Administration Guide*.

### 6.11.15.2.1 Save Current Table Distribution

Changing how tables are distributed across the hosts of a distributed SAP HANA system is a critical operation. Therefore, before executing a redistribution operation, it is strongly recommended that you backup the landscape so that it can be restored if necessary.

## Prerequisites

To be able to save the current table distribution, you must have the system privilege RESOURCE ADMIN and at least the object privilege ALTER and UPDATE for all schemas involved.

## Procedure

1. In the Administration editor, choose  **Landscape** > **Redistribution** >

2. Save the current table distribution by choosing [Save](#).  
The [Table Redistribution](#) dialog box appears.
3. Choose [Next](#).  
The system generates a redistribution plan that shows the distribution that will be saved.

#### **i** Note

Saving the current table operation involves the execution of a redistribution operation even though an actual redistribution of data does not take place.

4. Choose [Execute](#).  
The system saves the current table distribution. The associated redistribution operation appears in the list of executed operations.

## Results

You can now restore the saved table distribution at later point in time if necessary.

## 6.11.15.2.2 Redistribute Tables Before Removing a Host

Before you can remove a host from your SAP HANA single-container system, you must move the tables on the index server of the host in question to the index servers on the remaining hosts in the system.

## Prerequisites

To be able to redistribute tables across the hosts in your system, you must have the system privilege RESOURCE ADMIN and at least the object privilege ALTER for all schemas involved. As redistributing data is a critical operation, it is also recommended that you have saved the current distribution so you can restore it if necessary.

This procedure applies to single-container systems only. In a tenant database system you can remove hosts from an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program or the SAP HANA database lifecycle manager (HDBLCM) Web user interface. For more information, see *Removing Hosts from an SAP HANA System*.

## Procedure

1. In the Administration editor, choose [► Landscape ► Hosts ▾](#).
2. From the context menu of the host that you plan to remove, choose [Remove Host...](#)
3. In the [Remove Host](#) dialog box, choose [Yes](#).

The system marks the host for removal and executes the required redistribution operation. This results in the data on the index server of the host being moved to the index servers of the remaining hosts in the system.

The redistribution operation appears in the list of executed operations on the *Redistribution* tab.

## Results

You can remove the host.

### ⚠ Caution

After you remove the host from your system, you must perform a data backup to ensure that you can recover the database to a point in time after you removed the host.

## Related Information

[Creating Backups \[page 1498\]](#)

[Removing Hosts from an SAP HANA System \[page 1628\]](#)

## 6.11.15.2.3 Redistribute Tables After Adding a Host

After you have added a new worker host to your SAP HANA system, you need to redistribute the tables in the system to balance the memory footprint of the tables and to improve performance (load balancing).

## Prerequisites

To be able redistribute tables across the hosts in your system, you must have the system privilege RESOURCE ADMIN and at least the object privilege ALTER and UPDATE for all schemas involved. As redistributing data is a critical operation, it is also recommended that you have saved the current distribution so you can restore it if necessary.

## Procedure

1. In the Administration editor, choose ► *Landscape* ► *Redistribution* ►.
2. In the *Redistribution Operations* area, select *Redistribute tables after adding host(s)* and choose *Execute*. The *Table Redistribution* dialog box appears.

3. Choose *Next*.  
The system evaluates the current distribution of tables and generates a redistribution plan. This plan specifies which tables will be moved where.
4. Review the redistribution plan to ensure that you want to proceed and choose *Execute*.  
The system redistributes the tables in your system across all available index servers. The associated redistribution operation appears in the list of executed operations.

## 6.11.15.2.4 Restore Previous Table Distribution

Changing how tables are distributed across the hosts of an SAP HANA system is a critical operation. You may need to restore the table distribution from a previous point in time.

### Prerequisites

To be able to restore a previous table distribution, you must have the system privilege RESOURCE ADMIN and at least the object privilege ALTER for all schemas involved.

### Procedure

1. In the Administration editor, choose **► Landscape ► Redistribution ►**.
2. In the *Executed Operations* area, identify the operation that corresponds to the table distribution that you want to restore.  
For example, you saved the table distribution at a particular point in time and you want to revert to this configuration.
3. Check the redistribution plan of the operation to ensure that you want to proceed.  
To do this, select the operation and choose *Show Plan...*
4. Select the operation and choose *Restore*.  
The system restores the selected table distribution. The associated redistribution operation appears in the list of executed operations.

## 6.11.15.2.5 Optimize Table Distribution

During production operation, you may discover that the initial assignment of tables and partitions to index servers is no longer optimal, for example, frequently joined tables are located on different servers. You can therefore trigger a redistribution operation that evaluates the current situation and determines how distribution can be improved.

### Prerequisites

You must have the system privileges RESOURCE ADMIN and CATALOG READ, and at least the object privilege ALTER for all schemas involved.

### Procedure

1. In the Administration editor, choose ► [Landscape](#) ► [Redistribution](#) ▾.
2. In the [Redistribution Operations](#) area, select [Optimize table distribution](#) and choose [Execute](#). The [Table Redistribution](#) dialog box appears.
3. Optional: Enter the parameter `NO_SPLIT` if you do not want the operation to repartition tables.
4. Choose [Next](#).  
The system evaluates the current distribution of tables and partitions, and whether or not partitioned tables need to be repartitioned. A redistribution plan is subsequently generated, specifying which tables and partitions will be moved where, and how partitioned tables will be repartitioned and new partitions distributed.

#### i Note

The redistribution operation evaluates whether or not a partitioned table needs repartitioning based on its partitioning specification (that is, hash, round robin, range and so on). This is only relevant for column-store tables. System tables, temporary tables, and row-store tables are not considered.

5. Review the redistribution plan to ensure that you want to proceed and choose [Execute](#).  
The system redistributes and repartitions the tables and partitions in your system.

#### i Note

Partitioning is a potentially expensive operation both in terms of time and memory consumption.

The associated redistribution operation appears in the list of executed operations.

## 6.11.15.2.6 Optimize Table Partitioning

In a distributed SAP HANA system, partitioned tables are distributed across different index servers. The location of the different partitions can be specified manually or determined by the database when the table is

initially partitioned. Over time, this initial partitioning may no longer be optimal, for example, if a partition has grown significantly.

## Prerequisites

To be able to optimize partitioning, you must have the system privilege `RESOURCE ADMIN` and at least the object privilege `ALTER` for all schemas involved. As redistributing data is a critical operation, it is also recommended that you have saved the current distribution so you can restore it if necessary.

## Procedure

1. In the Administration editor, choose **► Landscape ► Redistribution ►**.
2. In the *Redistribution Operations* area, select *Optimize table partitioning* and choose *Execute*. The *Table Redistribution* dialog box appears.
3. Choose *Next*.

The system evaluates whether or not partitioned tables need to be repartitioned. A redistribution plan is subsequently generated, specifying how partitioned tables will be repartitioned and how newly-created partitions will be distributed.

### i Note

The redistribution operation evaluates whether or not a partitioned table needs repartitioning based on its existing partitioning specification. This is only relevant for column-store tables. System tables, temporary tables, and row-store tables are not considered.

4. Review the redistribution plan to ensure that you want to proceed and choose *Execute*. The system re-partitions the required tables and distributes the new partitions in your system.

### i Note

Partitioning is a potentially expensive operation both in terms of time and memory consumption.

The associated redistribution operation appears in the list of executed operations.

## Related Information

[Save Current Table Distribution \[page 706\]](#)

## 6.11.15.2.7 Modify Table Distribution Manually

In a distributed SAP HANA system, you can move individual tables or table partitions from the index server of one host to the index server of another.

### Prerequisites

- You have the system privilege DATA ADMIN
- The target host has sufficient memory for the table(s) or partition(s).

### Procedure

#### → Recommendation

For a large-scale redistribution of data, it is recommended that you execute one of the available redistribution operations instead of modifying table distribution manually as described here. Redistribution operations use complex algorithms to evaluate the current distribution and determine a better distribution depending on the situation.

1. Open the table distribution editor by right-clicking the required entry in the *Systems* view and then choosing *Show Table Distribution*:
  - Catalog
  - Schema
  - Tables

A list of all tables is displayed.

#### i Note

For performance reasons, not all tables are displayed, but only the first 1,000. You can change this setting in the preferences of the SAP HANA studio under **▶ SAP HANA ▶ Runtime ▶ Catalog ▶**. If more tables exist in the selected schema, a message is displayed.

2. Optional: Use the filtering options to refine the list of tables displayed according to table name and/or schema. If you want to see only those tables on a specific host or specific hosts, proceed as follows:
  - a. Open the table viewer by choosing *Configure Table...* from the context menu.
  - b. Move the hosts that you do not want to see from the *Visible Columns* column to the *Available Columns* column.
  - c. Close the table viewer.
  - d. In the table distribution editor, select the *Show only tables on selected hosts* checkbox.
3. To view the detailed distribution information of a partitioned table, select the table in the overview list. The information appears in the *Partition Details for <schema.table>* area.

### **i** Note

You can only see table partition information for column-store tables as this is the only table type that can be partitioned.

4. To move a table to another host, proceed as follows:
  - a. Right-click the table in the overview list and choose *Move Table...*
  - b. Specify the host to which you want to move the table.If the target host has sufficient memory, the table is moved. The information in the table distribution editor is refreshed accordingly.
5. To move a table partition or sub-partition to another host, proceed as follows:
  - a. Right-click the partition or sub-partition in the *Table Partition Details* area and choose *Move Partitions...*  
Note that you can select multiple partitions.
  - b. Specify the host to which you want to move the partition(s).If the target host has sufficient memory, the partitions are moved. The information in the table distribution editor is refreshed accordingly.

## 6.11.15.2.8 Monitor Table Distribution

To support the analysis and monitoring of performance issues in a distributed SAP HANA system, a table distribution editor is available in which you can see how tables are distributed across the hosts.

## Context

In the case of partitioned tables, you can also see how the individual partitions and sub-partitions are distributed, as well as detailed information about the physical distribution, for example, part ID, partition size, and so on.

### **i** Note

You can also see the detailed distribution information of an individual table by viewing its table definition (select *Table Definition* from the context menu when pointing at a table in the *Systems* view; partitioning information is shown on the *Runtime Information* tab).

## Procedure

1. Open the *Table Distribution* editor by right-clicking any of the following entries in the *Systems* view and then choosing *Show Table Distribution*:
  - Catalog
  - Schema
  - Tables

A list of all tables is displayed.

### i Note

For performance reasons, not all tables are displayed, but only the first 1,000. You can change this setting in the preferences of the SAP HANA studio under **▶ SAP HANA > Runtime > Catalog ▶**. If more tables exist in the selected schema, a message is displayed.

2. Optional: Use the filtering options to refine the list of tables displayed according to table name and/or schema. If you want to see only those tables on a specific host or specific hosts, proceed as follows:
  - a. Open the table viewer by choosing *Configure Table...* from the context menu.
  - b. Move the hosts that you do not want to see from the *Visible Columns* column to the *Available Columns* column.
  - c. Close the table viewer.
  - d. In the table distribution editor, select the *Show only tables on selected hosts* checkbox.
3. To view the detailed distribution information of a table, select the table in the overview list. The information appears in the *Partition Details of <schema.table>* area.

### i Note

You can only see table partition information for column-store tables as this is the only table type that can be partitioned. A non-partitioned column-store table is considered a table with one partition.

### 6.11.15.3 Table Redistribution Commands

As an alternative to using Table Redistribution in SAP HANA Cockpit you can also run it from the command line; this approach offers additional functionality including the option to modify at run time some of the configuration parameters which control redistribution.

Table redistribution is based on the table placement rules defined in the table `TABLE_PLACEMENT`, these determine, for example, table sizes, partitioning threshold values and preferred partition locations. Tables which have been grouped using the properties `GROUP`, `GROUP NAME` and `SUBTYPE` are also distributed to

maximize colocation so that partitions with common properties are located together. Note that location preferences take precedence over grouping properties.

Redistribution is a two stage process: firstly to generate the plan and secondly to execute the plan; separate commands are used for each stage:

1. The plan generation command is a multi-purpose tool which requires an algorithm number as a parameter to determine which actions are executed. Depending on the algorithm selected, additional optional parameter values may also be available to give more control over the execution.
2. The plan execution command takes a single parameter which is the numeric plan id value. You can retrieve this value (REORG\_ID) from the REORG\_OVERVIEW system view - see System Views below.

The syntax for these commands is:

- `CALL REORG_GENERATE(<algorithm integer>, <optional parameter string>);`
- `CALL REORG_EXECUTE (<plan_id>)`

## Partitioning of Large Tables

The REORG\_GENERATE command includes a check on table sizes and large unpartitioned tables which are close to the maximum size limit of 2 billion records (or a lower value which can be set in configuration) will be identified as candidates for partitioning. A check is made to identify primary key columns which can be used for hash partitioning. If no suitable columns are found then any of the first five columns in the table are used as the basis for hash partitioning. If no suitable columns are found for hash partitioning then round-robin partitioning is used instead.

This feature can be enabled by setting the configuration parameter `enable_partition_spec_creator` to TRUE. Users should bear in mind that this feature can have a negative impact on performance as tables must be locked during the process.

The maximum table size at which partitioning takes place is defined in the parameter `max_rows_per_partition` in the `table_placement` section of the `global.ini` file (the default value is 2 billion).

## Pinning Tables

To prevent tables from being moved during distribution you can pin them to the current host. You can do this using the NOT MOVABLE clause of the CREATE/ALTER table command. Refer to the *SAP HANA SQL and System Views Reference* for full details.

## Required Privileges

RESOURCE ADMIN and CATALOG READ privileges are required to call REORG\_GENERATE(). The command only operates on tables and partitions which the executing user is allowed to see as catalog objects.

## Generating the Plan: Algorithms and Options

The following table gives an overview of the most commonly-required algorithms and a summary of the options available for each one - see examples and details of the options which follow.

## Table Redistribution Algorithms and Options

Num	Algorithm Name	Description
6	Balance landscape	<p>This function checks if tables in the landscape are placed on invalid servers according to the table placement rules, and checks if a split or merge is necessary in order to achieve optimal positions for the partitions and tables and to evenly distribute tables across the indexserver hosts.</p> <p><b>Options:</b> TOP   USE_GROUP_ADVISOR   SCHEMA_NAME   TABLE_NAME   GROUP_NAME   GROUP_TYPE   GROUP_SUBTYPE   RECALC   NO_PLAN   NO_SPLIT   SCOPE</p>
1	Add server	<p>Run this check after adding one or more index servers to the landscape. If new partitions can be created a plan will be generated to split the tables and move the new partitions to the newly added indexservers.</p> <p><b>Options:</b> TOP   USE_GROUP_ADVISOR   SCHEMA_NAME   TABLE_NAME   GROUP_NAME   GROUP_TYPE   GROUP_SUBTYPE   RECALC   NO_PLAN</p>
2	Clear server	<p>Moves all partitions from a named server to other servers in the landscape.</p> <p><b>Options:</b> USE_GROUP_ADVISOR</p>
4	Save	Save current landscape setup. No optional parameter.
5	Restore	Restore a saved landscape setup. Enter the plan ID value as the optional parameter value.
7	Check number of partitions	This function checks if partitioned tables need to be repartitioned and creates a plan to split tables if the partitions exceed a configured row count threshold. No optional parameter.
12	Execute Group Advisor	Calls the Group Advisor and creates an executable plan from its output. See Group Advisor in the following topic.
14	Check table placement	<p>Check current landscape against table placement rules and (if necessary) provide a plan to move tables and partitions to the correct hosts.</p> <p><b>Additional Options:</b> LEAVE_UNCHANGED_UNTOUCHED   KEEP_VALID   NO_SPLIT</p>
15	Rerun plan	<p>Rerun failed items from previously executed plans.</p> <p><b>Option:</b> RERUN_ALL</p>
16	Housekeeping	<p>Perform housekeeping tasks. Additional privileges may be required for specific actions.</p> <p><b>Housekeeping Options:</b> OPTIMIZE_COMPRESSION   DEFRAG   LOAD_TABLE   MERGE_DELTA   ALL</p>

## Optional Parameters

The following table gives more details of the optional parameters which are available.

Option	Type	Detail
TOP	String	Restrict redistribution to the top n items. Example: CALL REORG_GENERATE (6, 'TOP=>4 ') executes algorithm #6 and optimizes only the top four table groups.
USE_GROUP_ADV ISOR	String	Calls the Group Advisor and creates an executable plan from its output.
SCHEMA_NAME	String	Restrict redistribution to the named schema(s) - comma-separated list.
TABLE_NAME	String	Restrict redistribution to the named table(s) - comma-separated list.
GROUP_NAME	String	Restrict redistribution to the named group(s) - comma-separated list.
GROUP_TYPE	String	Restrict redistribution to the named group types(s) - comma-separated list.
GROUP_SUBTYPE	String	Restrict redistribution to the named sub types(s) - comma-separated list.
RECALC	True / False	If true then recalculate the landscape data of the last REORG_GENERATE run. This option works only if REORG_GENERATE has been called before within the same connection session. This parameter can be used to speed up plan generation with different parameters.
NO_PLAN	True / False	If true then the planning stage of generating the plan is skipped. This can be used with external tools when landscape data needs to be collected and a distribution must be calculated but might be modified.
SCOPE	Keyword	<p>Use one or more of the following values (see example which follows) to restrict the scope of the redistribution to include only the named items specified by these keywords. The default value is 'ALL' so that all tables visible to the user are included in the redistribution.</p> <p><b>LOADED</b> Tables which are loaded or partially loaded</p> <p><b>UNLOADED</b> Tables which are not loaded</p> <p><b>FILLED</b> Tables with a record count greater than 10</p> <p><b>EMPTY</b> Tables with a record count less than or equal to 10</p> <p><b>USED</b> Tables with a total execution count greater than 10</p> <p><b>UNUSED</b> Tables with a total execution count of less than or equal to 10</p> <p><b>LOB</b> Tables with LOB columns</p> <p><b>NOLOB</b> Tables without LOB columns</p>

## Examples

### Add server (algorithm 1)

With this algorithm you can use the optional filter parameters to, for example, restrict redistribution to specified schemas, tables, table groups and so on. The following example uses the SCHEMA\_NAME option to generate a plan for all tables in schema SAPBWP.

```
CALL REORG_GENERATE (1, 'SCHEMA_NAME => SAPBWP')
```

### Balance Landscape / Table (algorithm 6)

The following examples show the usage of optional parameters with this balancing algorithm:

If the options parameter string is left blank a plan is generated for all visible tables:

```
CALL REORG_GENERATE (6, '');
```

This example uses the GROUP\_NAME option to generate a plan for all tables in three specified groups:

```
CALL REORG_GENERATE (6, 'GROUP_NAME=>TABLEGROUP1, TABLEGROUP2, TABLEGROUP3');
```

This example uses the SCHEMA\_NAME option to generate a plan for all tables in schema SAPBWP:

```
CALL REORG_GENERATE (6, 'SCHEMA_NAME => SAPBWP');
```

This example show usage of the SCOPE option. The plan is restricted to only tables with a record count greater than 10 and which have no LOB columns.

```
CALL REORG_GENERATE (6, 'SCOPE=>FILLED,NOLOB');
```

## System Views

The following system views show details of table redistribution. The last two views in this list show information about the most recent distribution operation; the details are deleted when the current connection to the database is closed.

- REORG\_OVERVIEW Provides an overview of landscape redistributions.
- REORG\_STEPS Shows details of the individual steps (items) of each plan.
- REORG\_PLAN This view contains details of the last table redistribution plan generated with this database connection.
- REORG\_PLAN\_INFOS Showing details (as key-value pairs) of the last executed redistribution (algorithm value and parameters used).

## Related Information

[Configuration of Table Redistribution \[page 719\]](#)

## 6.11.15.3.1 Group Advisor

The Group Advisor tool can be executed from within table redistribution to make recommendation about creating table groups.

Table grouping identifies tables which are often used together so that during redistribution they can be located together on the same node in order to avoid cross-node communication in the landscape. The group advisor tool can be integrated into table redistribution to execute a preparation step which creates groups automatically. The tool determines which tables are often used together by analyzing the current statement cache to find relationships between tables and it then (internally) makes recommendations about which tables should be located together. Table redistribution evaluates these recommendations before generating the plan.

When the plan is executed the table grouping information is persisted in the table `SYS.TABLE_GROUP` by setting a group name and setting the group type 'sap.join'. Note that existing table groups which have been defined for other applications (Business Warehouse, for example) are not modified in any way by the Group Advisor.

From the command line you can execute Group Advisor in the `REORG_GENERATE` command (algorithm 12) which then creates an executable plan from its output. Group Advisor is configurable by submitting configuration values in JSON format either directly on the command line or by writing the JSON code to a configuration parameter. To submit JSON code as a configuration parameter use `group_advisor_parameter` in the `table_redist` section of the `indexserver.ini` file.

## 6.11.15.3.2 Configuration of Table Redistribution

The operation of table redistribution is managed by configuration parameters; some of these can be reconfigured for the current session at run-time.

### Configuration

The precise operation of table redistribution is managed by sets of configuration parameters located in the service configuration file (typically `indexserver.ini`) section `table_redist`. Firstly, there are parameters controlling common behavior of table redistribution and secondly a set of session parameters for fine tuning redistribution by applying weighting values.

These parameters can be defined by the administrator for the system generally, but for some values the system settings can be overridden by values submitted on the command line. This is done by entering the key-value pair as a parameter value as shown in the following example. These settings can be combined with other parameters in a comma-separated string.

```
CALL REORG_GENERATE (6, 'BALANCE_BY_EXECUTION_COUNT=>True');
```

Settings passed in this way are only valid for the current user session.

The following tables list the configuration parameters which can be set:

<b>Parameter</b>	<b>Data Type</b>
ALL_MOVES_PHYSICAL	BOOLEAN
ASYMETRIC_CORRECTION_BY	INTEGER
DEBUG_BALANCE_DETAIL	BOOLEAN
DEBUG_EXPORT_DETAIL	BOOLEAN
DEBUG_SCORECARD_DETAIL	BOOLEAN
ENABLE_CONSISTENCY_CHECK	BOOLEAN
ENABLE_CONTENT_TABLE_REDIST	BOOLEAN
ENABLE_ENSURE_MOVES	BOOLEAN
ENABLE_MERGE	BOOLEAN
ENABLE_MULTI_STORE_TABLES	BOOLEAN
ENABLE_OPTIMIZE_COMPRESSION	BOOLEAN
ENABLE_RELOAD_TABLES	BOOLEAN
ENABLE_REPARTITIONING_WITH_GCD	BOOLEAN
ENABLE_ROW_STORE_TABLES	BOOLEAN
ENABLE_SYS_TABLE_REDIST	BOOLEAN
EXPORT_DATA	BOOLEAN
FORCE_PARTNUM_TO_SPLITRULE	BOOLEAN
MAX_PARTITIONS	INTEGER
MAX_PARTITIONS_LIMITED_BY_LOCATIONS	BOOLEAN
MAX_PLAN_ITERATIONS	INTEGER
MAX_ROWS_PER_PARTITION	INTEGER
MEM_LOAD_TRESHOLD	INTEGER
MIN_PLAN_ITERATIONS	INTEGER
MOVE_ROW_STORE	STRING
USE_GROUPS_FOR_DEPENDENCY	BOOLEAN

Parameter	Data Type
WORK_SEQUENCE	STRING
WORK_SEQUENCE_ASC	BOOLEAN
WORK_SEQUENCE_SORT	STRING

The following parameters (can also be set from the command line) control the optimization process. They are in pairs: firstly a boolean parameter and a corresponding numeric 'weight' parameter with the suffix '\_WEIGHT', for example:

- BALANCE\_BY\_PARTNUM - boolean parameter: set to True to activate this pair
- BALANCE\_BY\_PARTNUM\_WEIGHT - numeric value used as a factor (default = 1)

The parameters can be activated by setting the first one to `true` and then setting a numeric value for the weight parameter, this operates as a multiplication factor to calculate a priority value for this aspect of redistribution.

Parameter	Optimize by...
BALANCE_BY_PARTNUM	- by the number of partitions placed on the indexserver
BALANCE_BY_MEMUSE	- by memory usage based on size of table / partition
BALANCE_BY_TABLE_SIZE_HOSTED	
BALANCE_BY_ROWS	- by the number of rows of the tables/partitions
BALANCE_BY_WORKLOAD	
BALANCE_BY_EXECUTION_COUNT	- by an external provided execution count
BALANCE_BY_EXECUTION_TIME	- by an external provided execution time
BALANCE_BY_RANDOMIZER	
BALANCE_BY_TABLE_CLASSIFICATION	

## 6.12 Workload Management

The load on an SAP HANA system can be managed by selectively applying limitations and priorities to how resources (such as the CPU, the number of active threads and memory) are used. Settings can be applied globally or at the level of individual user sessions by using workload classes.

On an SAP HANA system there are many different types of workload due to the capabilities of the platform, from simple or complex statements to potentially long-running data loading jobs. These workload types must be balanced with the system resources that are available to handle concurrent work. For simplicity we classify workload queries as transactional (OLTP) or analytic (OLAP). With a transactional query the typical response

time is measured in milliseconds and these queries tend to be executed in a single thread. Analytic queries on the other hand tend to feature more complex operations using multiple threads during execution, this can lead to higher CPU usage and memory consumption compared with transactional queries.

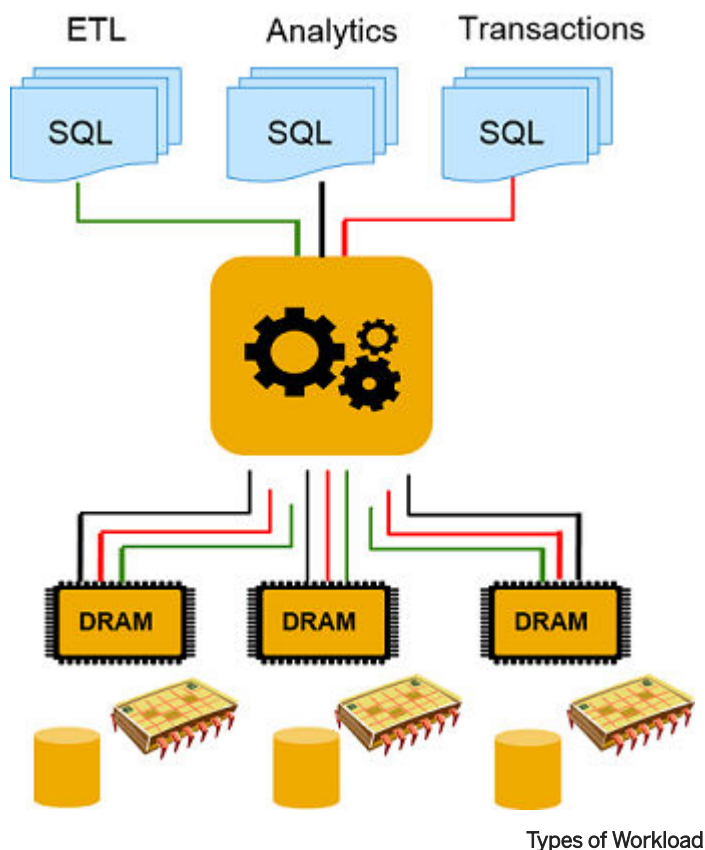

To manage the workload of your system aim to ensure that the database management system is running in an optimal way given the available resources. The goal is to maximize the overall system performance by balancing the demand for resources between the various workloads, not just to optimize for one particular type of operation. If you achieve this then requests will be carried out in a way that meets your performance expectations and you will be able to adapt to changing workloads over time. Besides optimizing for performance you can also optimize for robustness so that statement response times are more predictable.

## 6.12.1 Workload in the Context of SAP HANA

Workload in the context of SAP HANA can be described as a set of requests with common characteristics.

We can look at the details of a particular workload in a number of ways. We can look at the source of requests and determine if particular applications or application users generate a high workload for the system. We can examine what kinds of SQL statements are generated: are they simple or complex? Is there a prioritization of work done based on business importance, for example, does one part of the business need to have more access at peak times? We can also look at what kind of service level objectives the business has in terms of response times and throughput.

The following figure shows different types of workload such as Extract Transform and Load operations (used in data warehouses to load new data in batches from source system) as well as analytic and transactional operations:

When we discuss workload management we are really talking about stressing the system in terms of its resource utilization. The main resources we look at (shown in the above illustration) are CPU, memory, disk I/O, and network. In the context of SAP HANA, disk I/O comes into play for logging, for example, in an OLTP scenario many small transactions result in a high level of logging compared to analytic workloads (although SAP HANA tries to minimize this). With SAP HANA, network connections between nodes in a scale out system can be optimized as well, for example, statement routing is used to minimize network overhead as much as possible.

However, when we try to influence workload in a system, the main focus is on the available CPUs and memory being allocated and utilized. Mixed transactional and analytic workloads can, for example, compete for resources and at times require more resources than are readily available. If one request dominates there may be a queuing effect, meaning the next request may have to wait until the previous one is ready. Such situations need to be managed to minimize the impact on overall performance.

## 6.12.1.1 Options for Managing Workload

Workload management can be configured at multiple levels: at the operating system-level, by using global initialization settings, and at the session level.

There are a number of things you can do to influence how workload is handled:

- Outside the SAP HANA system on the operating system level you can set the affinity of the available cores.
- You can apply static settings using parameters to configure execution, memory management and peak load situations.
- You can influence workload dynamically at system runtime by defining workload classes.

All of these options have default settings which are applied during the HANA installation. These general-purpose settings may provide you with perfectly acceptable performance in which case the workload management features described in this chapter may not be necessary. Before you begin with workload management, you should ensure that the system generally is well configured: that SQL statements are tuned, that in a distributed environment tables are optimally distributed, and that indexes have been defined as needed.

If you have specific workload management requirements the following table outlines a process of looking at ever more fine-grained controls that can be applied with regard to CPU, memory and execution priority.

Options for Controlling Workload Management

Area	Possible Actions
<b>CPU</b> Configure CPU at Operating System level	Settings related to <i>affinity</i> are available to bind server processes to specific CPU cores. Processes must be restarted before these changes become effective. For more information, see <i>Controlling CPU Consumption</i> .
<b>CPU Thread Pools</b> Configure CPU at HANA System level	Global <i>execution</i> settings are available to manage CPU thread pools and manage parallel execution (concurrency). For more information, see <i>Controlling Parallel Execution of SQL Statements</i> .
<b>Memory</b> Apply settings for memory management	Global <i>memorymanager</i> settings are available to apply limits to the resources allocated to expensive SQL statements. For more information, see <i>Setting a Memory Limit for SQL Statements</i> .
<b>Admission Control</b> Configuration options for peak load situations	Global <i>admission control</i> settings can be used to apply system capacity thresholds above which SQL statements can be either rejected or queued. For more information, see <i>Managing Peak Load (Admission Control)</i> .

Area	Possible Actions
<b>Priority and Dynamic Workload Class Mapping</b> Manage workload and workload priority using classes	<p>A more targeted approach to workload management is possible by setting up pre-configured classes which can be mapped to individual user sessions. You can, for example, map an application name or an application user to a specific workload class. Classes include the option to apply a workload priority value.</p> <p>You can set up classes using:</p> <ul style="list-style-type: none"> <li>• SAP HANA cockpit</li> <li>• SQL commands</li> </ul> <p>For more information, see <i>Managing Workload with Workload Classes</i>.</p>

At the end of this section is a set of scenarios giving details of different hardware configurations and different usage situations. For each scenario, suggestions are made about appropriate workload management options which could be used.

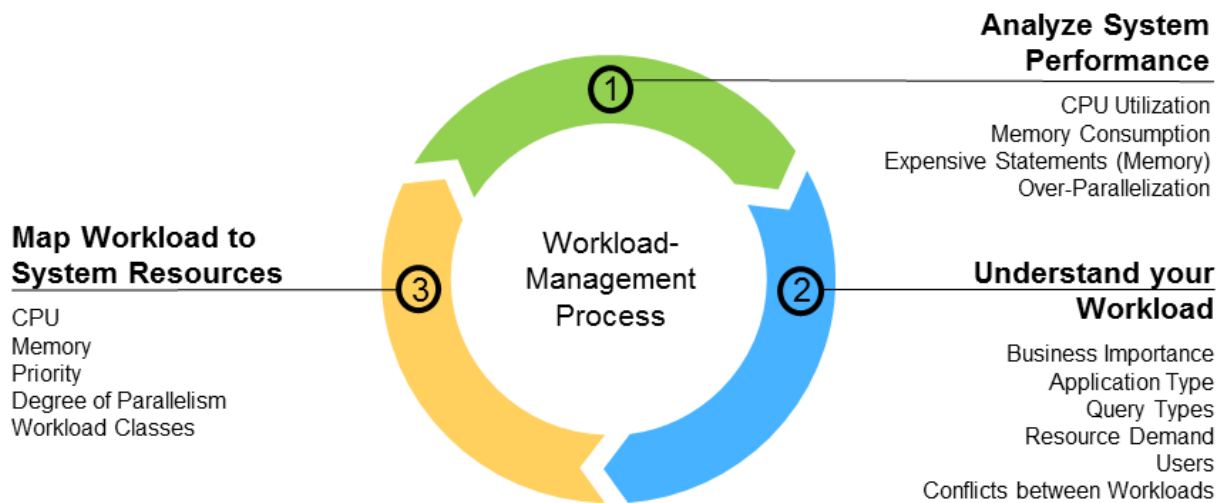

## Related Information

- [Controlling CPU Consumption \[page 728\]](#)
- [Controlling Parallel Execution of SQL Statements \[page 735\]](#)
- [Setting a Memory Limit for SQL Statements \[page 737\]](#)
- [Managing Peak Load \(Admission Control\) \[page 740\]](#)
- [Managing Workload with Workload Classes \[page 745\]](#)
- [Example Workload Management Scenarios \[page 755\]](#)

### 6.12.1.2 Understand your Workload

Managing workload can be seen as an iterative three-part process: Analyze the current system performance, understand the nature of your workload and map your workload to the system resources.

There is no one single workload management configuration that fits all scenarios. Because workload management settings are highly workload dependent you must first understand your workload. The following figure shows an iterative process that you can use to understand and optimize how the system handles workload.

1. First you look at how the system is currently performing in terms of CPU usage and memory consumption. What kinds of workloads are running on the system, are there complex, long running queries that require lots of memory?
2. When you have a broad understanding of the activity in the system you can drill down in to the details such as business importance. Are statements being run that are strategic or analytic in nature compared to standard reporting that may not be so time critical. Can those statements be optimized to run more efficiently?
3. Then, when you have a deeper understanding of the system you have a number of ways to influence how it handles the workload. You can start to map the operations to available resources such as CPU and memory and determine the priority that requests get by, for example, using workload classes.

### 6.12.1.3 Analyzing System Performance

You can use system views to analyze how effectively your system is handling the current workload.

This section lists some of the most useful views available which you can use to analyze your workload and gives suggestions about actions that you might take to improve performance. Refer also to the scenarios section for more details of how these analysis results can help you to decide about which workload management options to apply.

Other performance analysis issues are described in the *SAP HANA Troubleshooting and Performance Analysis Guide*.

### Analyzing SQL Statements

Use these views to analyze the performance of SQL statements:

- M\_ACTIVE\_STATEMENTS
- M\_PREPARED\_STATEMENTS

- M\_EXPENSIVE\_STATEMENTS

If these views indicate problems with statements you can use workload classes to tune the statements by limiting memory or parallelism.

Consider also the setting of any session variables (in M\_SESSION\_CONTEXT) which might have a negative impact on these statements. The following references provide more detailed information on this:

- SAP Note 2215929 *Using Client Info to set Session Variables and Workload Class settings* describes how client applications set session variables for dispatching workload classes.
- The *SAP HANA Developer Guide (Setting Session-Specific Client Information)*.

## Analyzing CPU Activity

Use these views to analyze CPU activity:

- M\_SERVICE\_THREADS
- M\_SERVICE\_THREAD\_SAMPLES
- M\_EXPENSIVE\_STATEMENTS.CPU\_TIME (column)
- M\_SERVICE\_THREAD\_CALLBACKS (stack frame information for service threads)
- M\_JOBEXECUTORS (job executor statistics)

These views provide detailed information on the threads that are active in the context of a particular service and information about locks held by threads.

If these views show many threads for a single statement, and the general system load is high you can adjust the settings for the set of 'execution' ini-parameters as described in the topic *Controlling Parallel Execution*.

## 6.12.2 Controlling CPU Consumption

SAP HANA can exploit the processor's NUMA architecture to optimize performance by applying NUMA core affinity settings to server processes and by specifying NUMA node location preferences for specific database objects.

Non-uniform memory access (NUMA) processors have their own local memory and have access to memory shared between processors. The memory access time depends on the memory location relative to the processor: processors can access their own local memory faster than non-local memory.

SAP HANA can exploit the processor's NUMA architecture to optimize performance by:

1. Applying NUMA core affinity settings to server processes. With this option you can use the affinity configuration parameter to restrict CPU usage of SAP HANA server processes to certain CPUs or ranges of CPUs. You can set restrictions for the following servers: nameserver, indexserver, compileserver, preprocessor, and xsengine.
2. Specifying NUMA node location preferences for specific database objects. With this option you can specify in SQL NUMA node location preferences for specific database objects using either the CREATE TABLE or ALTER TABLE statements. NUMA node location preferences can be applied at any of the following levels:
  - Table (column store)
  - Table Partition (range partitioning)
  - Column

Before making any changes, however, you must begin by analyzing the system topology using, for example, the Linux `lscpu` command or the SAP HANA monitoring views.

### → Tip

As an alternative to applying CPU affinity settings you can achieve similar performance gains by changing the parameter [execution] `max_concurrency` in the `global.ini` configuration file. Changing the configuration file may be more convenient and doesn't require the system to be offline.

This section gives details and examples of these procedures. Further information can also be found in KBA 2470289: *FAQ: SAP HANA Non-Uniform Memory Access (NUMA)*.

[SAP Note 2470289](#) 

## 6.12.2.1 Examining the System Topology

On systems with many CPU cores and NUMA nodes it is important to understand the system topology in order to optimize the system to achieve good performance and robust response times.

Firstly, to confirm the physical and logical details of your CPU architecture, analyze the system using operating system commands and / or system views.

For Xen and VMware, the users in the VM guest system see what is configured in the VM host. So, the quality of the reported information depends on the configuration of the VM guest. Therefore, SAP can't give any performance guarantees in this case.

### Operating System Commands

#### lscpu

The `lscpu` command returns a listing of details of the system architecture. The following table gives a commentary on the most useful values based on an example system with 2 physical chips (sockets), each containing 8 physical cores. These cores are hyperthreaded to give a total of 32 logical cores.

#	Feature	Example Value
1	Architecture	x86_64
2	CPU op-modes	32-bit, 64-bit
3	Byte Order	LittleEndian
4	CPUs	32
5	On-line CPUs list	0-31
6	Threads per core	2
7	Cores per socket	8
8	Sockets	2
9	NUMA nodes	2
21	NUMA node0 CPUs	0-7,16-23
22	NUMA node1 CPUs	8-15,24-31

- 4-5: This example server has 32 logical cores numbered 0-31
- 6-8: Logical cores ("threads") are assigned to physical cores. Hyperthreading is where multiple threads are assigned to a single physical core. In this example, there are 2 sockets, with each socket containing 8 physical cores (total 16). Two logical cores (#6) are assigned to each physical core, thus, each core exposes two execution contexts for the independent and concurrent execution of two threads.
- 9: In this example there are 2 NUMA nodes, one for each socket. Other systems may have multiple NUMA nodes per socket.

- 21–22: The 32 logical cores are numbered and assigned to one of the two NUMA nodes.

### i Note

Even on a system with 32 logical cores and two sockets the assignment of logical cores to physical CPUs and sockets can be different. It's important to collect the assignment in advance before making changes. A more detailed analysis is possible using the system commands described in the next step. These provide detailed information for each core including how CPU cores are grouped as siblings.

## Topology Commands

You can also use the set of CPU topology commands in the `/sys/devices/system/cpu/` directory tree. For each logical core, there is a corresponding numbered subdirectory (`/cpu12/` in the following examples). The examples show how to retrieve this CPU information and the table gives details of some of the most useful commands available:

### ❁ Example

```
cat /sys/devices/system/cpu/present
cat /sys/devices/system/cpu/cpu12/topology/thread_siblings_list
```

Command	Example Output	Commentary
<code>present</code>	0–15	The number of logical cores available for scheduling.
<code>cpu12/topology/core_siblings_list</code>	4–7, 12-15	The cores on the same socket.
<code>cpu12/topology/thread_siblings_list</code>	4, 12	The logical cores assigned to the same physical core (hyperthreading).
<code>cpu12/topology/physical_package_id</code>	1	The socket of the current core - in this case <code>cpu12</code> .

Other Linux commands that are relevant here are `sched_setaffinity` and `numactl`. `sched_setaffinity` limits the set of CPU cores available (by applying a CPU affinity mask) for execution of a specific process (this can be used, for example, to isolate tenants) and `numactl` controls NUMA policy for processes or shared memory.

## hdbcons

The database management client console `hdbcons` can also be used to retrieve topology information, using for example, the job executor information command. In this case the ID of the indexserver process is required as a parameter:

```
hdbcons -p <PID> "jexec info"
```

## SAP HANA Monitoring Views

Information about the system topology and the CPU configuration is available in system views. You can run the example queries given here on the tenant or system database.

**M\_HOST\_INFORMATION** provides host information such as machine and operating system configuration. Data in this view is stored in key-value pair format, the values are updated once per minute. For most keys the INIFILE ADMIN privilege is required to view the values. Select one or more key names for a specific host to retrieve the corresponding values:

```
select * from SYS.M_HOST_INFORMATION where key in
('cpu_sockets','cpu_cores','cpu_threads');
```

**M\_NUMA\_RESOURCES** provides information on overall resource availability for the system:

```
select MAX_NUMA_NODE_COUNT, MAX_LOGICAL_CORE_COUNT from SYS.M_NUMA_RESOURCES;
```

**M\_NUMA\_NODES** provides resource availability information on each NUMA node in the hardware topology, including inter-node distances and neighbor information, for example:

```
select HOST, NUMA_NODE_ID, NUMA_NODE_DISTANCES, MEMORY_SIZE from
SYS.M_NUMA_NODES;
```

**M\_CS\_COLUMNS** has details of tables, columns and partitions and the following example may be helpful to check the NUMA locations where tables are distributed across NUMA nodes. In this case CPU load is distributed across NUMA nodes by NUMA-local processing, but memory consumption is also better distributed to the memory attached to each NUMA node.

```
select table_name, column_name, part_id, string_agg( numa_node_index, ',' ) from
m_cs_columns
group by table_name, column_name, part_id
order by table_name, column_name, part_id;
```

Refer to the *SAP HANA SQL and System Views Reference Guide* for full details of these views.

## Related Information

### 6.12.2.2 Applying Affinity Configuration Changes

You can use the `affinity` configuration parameter to restrict CPU usage of SAP HANA server processes to certain CPUs or ranges of CPUs.

Based on the information returned from the examination of the topology, apply affinity settings in `daemon.ini` to bind specific processes to logical CPU cores. This approach applies primarily to the use cases of SAP HANA tenant databases and multiple SAP HANA instances on one server; you can use this approach, for example, to partition the CPU resources of the system by tenant database.

You can set restrictions for the following servers: `nameserver`, `indexserver`, `compileserver`, `preprocessor`, and `xsengine` (each server has a section in the `daemon.ini` file). The affinity setting is applied by the `TrexDaemon` when it starts the other HANA processes using the command `sched_setaffinity`. Changes to the affinity settings take effect only after restarting the HANA process.

To make the changes described here you require the privilege INIFILE ADMIN.

After making changes you can rerun the topology analysis queries and operating system commands to verify the changes you have made.

## Examples

The following examples and commentary show the syntax for the ALTER SYSTEM CONFIGURATION commands required.

### ❁ Example

To restrict the nameserver to two logical cores of the first CPU of socket 0, use the following affinity setting:

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini', 'SYSTEM') SET ('nameserver',  
'affinity') = '0,16'
```

### ❁ Example

To restrict the preprocessor and the compileserver to all remaining cores (that is, all except 0 and 16) on socket 0, use the following affinity settings:

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini', 'SYSTEM') SET  
( 'preprocessor', 'affinity') = '1-7,17-23'  
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini', 'SYSTEM') SET  
( 'compileserver', 'affinity') = '1-7,17-23'
```

### ❁ Example

To restrict the indexserver to all cores on socket 1, use the following affinity settings:

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini', 'SYSTEM') SET ('indexserver',  
'affinity') = '8-15,24-31'
```

## Multi-Tenant Database Examples

You can assign affinities to different tenants of a multi-tenant database on the same host as shown here. Run these SQL statements on the SYSTEMDB.

### ❁ Example

In this scenario tenant NM1 already exists, here we add another tenant NM2:

```
CREATE DATABASE NM2 ADD AT LOCATION 'host:30040' SYSTEM USER PASSWORD  
Manager1;
```

Set the configuration parameter to bind CPUs to specific NUMA nodes on each tenant. You can use the following notation with a dot to identify the specific tenant:

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini', 'SYSTEM') SET  
( 'indexserver.NM1', 'affinity') = '0-7,16-23';
```

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini','SYSTEM') SET
('indexserver.NM2', 'affinity') ='8-15,24-31';
```

To assign affinities to multiple indexservers of the same tenant on the same host, execute the following SQL statements on the SYSTEMDB to apply the `instance_affinity[port]` configuration parameter:

### ❁ Example

In this scenario, an indexserver is already running on tenant NM1 on port 30003. Here we add another indexserver on a different port:

```
ALTER DATABASE NM1 ADD 'indexserver' AT LOCATION 'host:30040';
```

Set the different instances of the `instance_affinity[port]` configuration parameter to bind CPUs to specific NUMA nodes on each indexserver. The configuration parameter has a 1–2 digit suffix to identify the final significant digits of the port number, in this example 3000**3** and 300**40**:

```
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini','SYSTEM') SET
('indexserver.NM1', 'instance_affinity[3]')='0-7,16-23';
ALTER SYSTEM ALTER CONFIGURATION ('daemon.ini','SYSTEM') SET
('indexserver.NM1', 'instance_affinity[40]')='8-15,24-31';
```

Restart the indexserver processes to make the affinity settings effective.

## 6.12.2.3 Applying NUMA Location Preferences to Tables

You can specify NUMA node location preferences for specific database objects in SQL using either the CREATE TABLE or ALTER TABLE statements.

### NUMA Node Preferences

To apply NUMA node location preferences in SQL for tables, columns or partitions, you can use the NUMA NODE clause followed by a list of one or more preferred node locations. Refer to the previous subsection for how to use the `lscpu` command to understand the system topology. Refer to the *SAP HANA SQL and System Views Reference* for full details of this feature.

You can specify either individual nodes or a range of nodes as shown in the following example:

```
CREATE COLUMN TABLE T1(A int, B varchar(10)) NUMA NODE ('1', '3 TO 5')
```

In this example table T1 will be processed by NUMA node 1 if possible and otherwise by any of NUMA nodes 3-5. Preferences are saved in system table `NUMA_NODE_PREFERENCE_`.

Use the following statement to remove any preferences for an object:

```
ALTER TABLE T1 NUMA NODE NULL
```

By default, preferences are only applied the next time the table is loaded. You can use the ALTER TABLE statement with the keyword IMMEDIATE to apply the preference immediately (the default value is DEFERRED):

```
ALTER TABLE T1 NUMA NODE ('3') IMMEDIATE
```

## Granularity

NUMA node location preferences can be applied at any of the following levels:

- Table (column store only)
- Table Partition (range partitioning only)
- Column

If multiple preferences for a column or partition have been defined then the column preference is applied first, then the partition preference, then the table.

The following example shows the statement being used to apply a preference for column A in table T1:

```
CREATE COLUMN TABLE T1(A int NUMA NODE ('2'), B varchar(10))
```

The following examples show statements to apply a preference for partition A in table T1:

```
CREATE COLUMN TABLE T1(A int , B varchar(10)) PARTITION BY RANGE(A) (PARTITION  
VALUE = 2 NUMA NODE ('4'))
```

```
ALTER TABLE T1 ADD PARTITION (A) VALUE = 3 NUMA NODE ('1') IMMEDIATE
```

It is also possible to identify a partition by its logical partition ID number and set a preference using ALTER TABLE as shown here:

```
ALTER TABLE T1 ALTER PARTITION 2 NUMA NODE ('3')
```

## Transferring Preferences

Using the CREATE TABLE LIKE statement the new table can be created with or without the NUMA preference. In the following example any preference which has been applied to T2 will (if possible) apply on new table T1. The system checks the topology of the target system to confirm if it has the required number of nodes, if not, then the preference is ignored:

```
CREATE TABLE T1 LIKE T2
```

The keyword WITHOUT can be used as shown in the following example to ignore any preference which has been applied to T2 when creating the new table T1:

```
CREATE TABLE T1 LIKE T2 WITHOUT NUMA NODE
```

A similar approach is used with the IMPORT and EXPORT Statements; any preference is saved in the exported table definition and applied, if possible, in the target environment when the table is imported. In this case you can use the IGNORE keyword to import a table and ignore any node preferences:

```
IMPORT SYSTEM."T14" FROM '/tmp/test/' WITH REPLACE THREADS 40 IGNORE NUMA NODE
```

[SAP HANA SQL Reference Guide for SAP HANA Platform](#)

### 6.12.3 Controlling Parallel Execution of SQL Statements

You can apply ini file settings to control the two thread pools `SqlExecutor` and `JobExecutor` that control the parallelism of statement execution.

#### ⚠ Caution

The settings described here should only be modified when other tuning techniques like remodeling, repartitioning, and query tuning have been applied. Modifying the parallelism settings requires a thorough understanding of the actual workload since they have impact on the overall system behavior. Modify the settings iteratively by testing each adjustment. For more information, see *Understand your Workload*.

On systems with highly concurrent workload, too much parallelism of single statements may lead to sub-optimal performance. Note also that partitioning tables influences the degree of parallelism for statement execution; in general, adding partitions tends to increase parallelism. You can use the parameters described in this section to adjust the CPU utilization in the system.

Two thread pools control the parallelism of the statement execution. Generally, target thread numbers applied to these pools are soft limits, meaning that additional available threads can be used if necessary and deleted when no longer required:

- **SqlExecutor**  
This thread pool handles incoming client requests and executes simple statements. For each statement execution, an `SqlExecutor` thread from a thread pool processes the statement. For simple OLTP-like statements against column store as well as for most statements against row store, this will be the only type of thread involved. With OLTP we mean short running statements that consume relatively little resources, however, even OLTP-systems like SAP Business Suite may generate complex statements.
- **JobExecutor**  
The `JobExecutor` is a job dispatching subsystem. Almost all remaining parallel tasks are dispatched to the `JobExecutor` and its associated `JobWorker` threads.  
In addition to OLAP workload the `JobExecutor` also executes operations like table updates, backups, memory garbage collection, and savepoint writes.

You can set a limit for both `SqlExecutor` and `JobExecutor` to define the maximum number of threads. You can use this for example on a system where OLAP workload would normally consume too many CPU resources to apply a maximum value to the `JobExecutor` to reserve resources for OLTP workload.

#### ⚠ Caution

Lowering the value of these parameters can have a drastic effect on the parallel processing of the servers and reduce the performance of the overall system. Adapt with caution by iteratively making modifications and testing. For more information, see *Understand your Workload* and *SAP Note 2222250 - FAQ SAP HANA Workload Management* which contains more details of the workload configuration parameters.

A further option to manage statement execution is to apply a limit to an individual user profile for all statements in the current connection using 'THREADLIMIT' parameter. This option is described in *Setting User Parameters*.

## Parameters for SqlExecutor

The following SqlExecutor parameters are in the `sql` section of the `indexserver.ini` file.

`sql_executors` - sets a soft limit on the target number of logical cores for the SqlExecutor pool.

- This parameter sets the target number of threads that are immediately available to accept incoming requests. Additional threads will be created if needed and deleted if not needed any more.
- The parameter is initially not set (0); the default value is the number of logical cores in a system. As each thread allocates a particular amount of main memory for the stack, reducing the value of this parameter can help to avoid memory footprint.

`max_sql_executors` - sets a hard limit on the maximum number of logical cores that can be used.

- In normal operation new threads are created to handle incoming requests. If a limit is applied here, SAP HANA will reject new incoming requests with an error message if the limit is exceeded.
- The parameter is initially not set (0) so no limit is applied.

### ⚠ Caution

SAP HANA will not accept new incoming requests if the limit is exceeded. Use this parameter with extreme care.

## Parameters for JobExecutor

The following JobExecutor parameters are in the `execution` section of the `global.ini` or `indexserver.ini`.

`max_concurrency` - sets the target number of logical cores for the JobExecutor pool.

- This parameter sets the size of the thread pool used by the JobExecutor used to parallelize execution of database operations. Additional threads will be created if needed and deleted if not needed any more. You can use this to limit resources available for JobExecutor threads, thereby saving capacity for SqlExecutors.
- The parameter is initially not set (0); the default value is the number of logical cores in a system. Especially on systems with at least 8 sockets consider setting this parameter to a reasonable value between the number of logical cores per CPU up to the overall number of logical cores in the system. In a system that supports tenant databases, a reasonable value is the number of cores divided by the number of tenant databases.

`max_concurrency_hint` - limits the number of logical cores for job workers even if more active job workers would be available.

- This parameter defines the number of jobs to create for an individual parallelized operation. The JobExecutor proposes the number of jobs to create for parallel processing based on the recent load on the

system. Multiple parallelization steps may result in far more jobs being created for a statement (and hence higher concurrency) than this parameter.

- The default is 0 (no limit is applied but the hint value is never greater than the value for `max_concurrency`). On large systems (that is more than 4 sockets) setting this parameter to the number of logical cores of one socket may result in better performance but testing is necessary to confirm this.

`default_statement_concurrency_limit` - restricts the actual degree of parallel execution per connection within a statement.

- This parameter controls the maximum overall parallelism for a single database request. Set this to a reasonable value (a number of logical cores) between 1 and `max_concurrency` but greater or equal to the value set for `max_concurrency_hint`.
- The default setting is 0; no limit is applied. Note, however, that a new default value for this parameter may also be set during installation using the SAP HANA database lifecycle manager (HDBLCM) tool. In this case, a limit may already be in force. See also SAP Note 3011356 - Default Value of global.ini [execution] `default_statement_concurrency_limit` Changed.

## 6.12.4 Setting a Memory Limit for SQL Statements

You can set a statement memory limit to prevent single statements from consuming too much memory.

### Prerequisites

To apply these settings you must have the system privilege `INIFILE ADMIN`.

For these options, `enable_tracking` and `memory_tracking` must first be enabled in the `global.ini` file. Additionally, `resource_tracking` must be enabled in this file if you wish to apply different settings for individual users (see Procedure below).

### Context

You can protect an SAP HANA system from uncontrolled queries consuming excessive memory by limiting the amount of memory used by single statement executions per host. By default, there is no limit set on statement

memory usage, but if a limit is applied, statement executions that require more memory will be aborted when they reach the limit. To avoid canceling statements unnecessarily you can also apply a percentage threshold value which considers the current statement allocation as a proportion of the global memory currently available. Using this parameter, statements which have exceeded the hard-coded limit may still be executed if the memory allocated for the statement is within the percentage threshold. The percentage threshold setting is also effective for workload classes where a statement memory limit can also be defined.

You can also create exceptions to these limits for individual users (for example, to ensure an administrator is not prevented from doing a backup) by setting a different statement memory limit for each individual.

These limits only apply to single SQL statements, not the system as a whole. Tables which require much more memory than the limit applied here may be loaded into memory. The parameter `global_allocation_limit` limits the maximum memory allocation limit for the system as a whole.

You can view the (peak) memory consumption of a statement in `M_EXPENSIVE_STATEMENTS.MEMORY_SIZE`.

## Procedure

1. Enable statement memory tracking.

In the `global.ini` file, expand the `resource_tracking` section and set the following parameters to **on**:

- `enable_tracking = on`
- `memory_tracking = on`

2. `statement_memory_limit` - defines the maximum memory allocation per statement in GB. The parameter is not set by default.

- In the `global.ini` file, expand the `memorymanager` section and locate the parameter. Set an integer value in GB between 0 (no limit) and the value of the global allocation limit. Values that are too small can block the system from performing critical tasks.
- When the statement memory limit is reached, a dump file is created with 'compositelimit\_oom' in the name. The statement is aborted, but otherwise the system is not affected. By default only one dump file is written every 24 hours. If a second limit hits in that interval, no dump file is written. The interval can be configured in the `memorymanager` section of the `global.ini` file using the `oom_dump_time_delta` parameter, which sets the minimum time difference (in seconds) between two dumps of the same kind (and the same process).
- The value defined for this parameter can be overridden by the corresponding workload class property `STATEMENT_MEMORY_LIMIT`.

After setting this parameter, statements that exceed the limit you have set on a host are stopped by running out of memory.

3. `statement_memory_limit_threshold` - defines a percentage of the global allocation limit. Parameter `statement_memory_limit` is respected only if total used memory exceeds the global allocation limit by this threshold percentage. The default value is 0% (of the `global_allocation_limit`) so `statement_memory_limit` is always respected.

- In the `global.ini` file, expand the `memorymanager` section and set the parameter as a percentage of the global allocation limit.
- This parameter provides a means of controlling when the `statement_memory_limit` is applied. If this parameter is set, when a statement is issued the system will determine if the amount of memory it consumes exceeds the defined percentage value of the overall `global_allocation_limit`

parameter setting. The statement memory limit is only applied if the current SAP HANA memory consumption exceeds this statement memory limit threshold as a percentage of the global allocation limit.

- This is a way of determining if a particular statement consumes an inordinate amount of memory compared to the overall system memory available. If so, to preserve memory for other tasks, the statement memory limit is applied and the statement fails with an exception.
  - Note that the value defined for this parameter also applies to the workload class property STATEMENT\_MEMORY\_LIMIT.
4. `total_statement_memory_limit` - a value in gigabytes to define the maximum memory available to all statements running on the system. The default value is 0 (no limit).
- This limit does not apply to users with the administrator role SESSION ADMIN or WORKLOAD ADMIN who need unrestricted access to the system. However, a check of the user's privileges allowing the administrator to by-pass the limit is only made for the first request when a connection is made. The privileged user would have to reconnect to be able to bypass the statement memory limit again (see also Admission Control).
  - The value defined for this parameter cannot be overridden by the corresponding workload class property TOTAL\_STATEMENT\_MEMORY\_LIMIT.
  - There is a corresponding parameter for use with system replication on an Active/Active (read enabled) secondary server. This is required to ensure that enough memory is always available for essential log shipping activity. See also `sr_total_statement_memory_limit` in section *Memory Management*.
5. User parameters can limit memory for statements. For further information, refer to *Setting User Parameters for Workload*.

## Results

The following example and scenarios show the effect of applying these settings:

Example showing statement memory parameters

Parameter	Value
Physical memory	128 GB
<code>global_allocation_limit</code>	The unit used by this parameter is MB. The default value is: 90% of the first 64 GB of available physical memory on the host plus 97% of each further GB; or, in the case of small physical memory, physical memory minus 1 GB.
<code>statement_memory_limit</code>	1 GB (the unit used by this parameter is GB.)
<code>statement_memory_limit_threshold</code>	60%

### Scenario 1:

A statement allocates 2GB of memory and the current used memory size in SAP HANA is 50GB.

- $0,9 * 128\text{GB} = 115,2$  (global allocation limit)
- $0,6 * 115,2 = 69,12$  (threshold in GB)
- $50\text{ GB} < 69,12\text{ GB}$  (threshold not reached)

The statement is executed, even though it exceeds the 1GB `statement_memory_limit`.

#### Scenario 2:

A statement allocates 2GB and the current used memory size in SAP HANA is 70GB

- 70 GB > 69,12 GB (threshold is exceeded)

The statement is cancelled, as the threshold is exceeded, the `statement_memory_limit` is applied.

## Related Information

[Change the Global Memory Allocation Limit \[page 518\]](#)

[Memory Management \[page 1337\]](#)

[Setting User Parameters for Workload \[page 744\]](#)

[Managing Peak Load \(Admission Control\) \[page 740\]](#)

## 6.12.5 Managing Peak Load (Admission Control)

Use the admission control feature to apply processing limits and to decide how to handle new requests if the system is close to the point of saturation.

You can apply thresholds using configuration parameters to define an acceptable limit of activity in terms of the percentage of memory usage or percentage of CPU capacity.

Admission Control can be maintained either from the SQL command line or in SAP HANA cockpit. For further specific details refer to *Manage Admission Control* in the SAP HANA cockpit documentation.

Limits can be applied at two levels so that firstly new requests will be queued until adequate processing capacity is available or a timeout is reached, and secondly, a higher threshold can be defined to determine the maximum workload level above which new requests will be rejected. If requests have been queued, items in the queue are processed when the load on the system reduces below the threshold levels. If the queue exceeds a specified size or if items are queued for longer than a specified period of time they are rejected.

If a request is rejected an error message is returned to the client that the server is temporarily overloaded:  
`1038, 'ERR_SES_SERVER_BUSY', 'rejected as server is temporarily overloaded',` in this case the connection is rolled back.

The load on the system is measured by background processes which gather a set of performance statistics covering available capacity for memory and CPU usage. The statistics are moderated by a configurable averaging factor (exponentially weighted moving average) to minimize volatility, and the moderated value is used in comparison with the threshold settings.

There are some situations where it is not recommended to enable admission control, for example, during planned maintenance events such as an upgrade or the migration of an application. In these cases it is expected that the load level is likely to be saturated for a long time and admission control could therefore result in the failure of important query executions.

**By-passing admission control** The admission control filtering process does not apply to all requests. In particular, requests that release resources will always be executed, for example, Commit, Rollback, Disconnect and so on.

The filtering also depends on user privileges: administration requests from SESSION\_ADMIN and WORKLOAD\_ADMIN are always executed. However, this is limited: the check on user privileges is only made for the first request when a connection is made. For subsequent requests no check is made and all users, regardless of privileges, are subject to the workload controls in place. The user with administrator privileges would have to reconnect to be able to bypass the controls again. This functionality was implemented to reduce the overhead incurred in checking privileges for routed connections. No privilege check takes place when admission control is disabled (see following section on Configuration).

**Admission control limitation with Active-Active (Read Only):** admission control evaluates requests at the session layer as part of statement preparation before decoding the request packet from the client, whereas the decision about routing the request is made later in the SQL engine. This means that in an active-active setup if the admission control load threshold is exceeded on the primary then the incoming request is queued on the primary system. Statements which have been prepared and a decision to route the request to the secondary has already been made would directly connect to the secondary.

## Related Information

[Manage Admission Control \(SAP HANA cockpit\)](#)

### 6.12.5.1 Configuring Admission Control

Threshold values for admission control to determine when requests are queued or rejected are defined as configuration parameters.

The admission control feature is enabled by default and the related threshold values and configurable parameters are available in the indexserver.ini file. A pair of settings is available for both memory (not active by default) and CPU which define firstly the queuing level and secondly the rejection level. Two parameters are available to manage the statistics collection process by defining how frequently statistics are collected and setting the averaging factor which is used to moderate volatility. A high-level alert will be raised if there are any session requests queued or rejected by admission control.

These parameters, in the *admission\_control* section of the ini file, are summarized in the following table (see also Queue Management below):

Parameter	Default	Detail
enable	True	Enables or disables the admission control feature.
queue_cpu_threshold	90	The percentage of CPU usage above which requests will be queued. Queue details are available in the view M_ADMISSION_CONTROL_QUEUES. The value 0 or 100 means that no requests are queued.
queue_memory_threshold	0	The percentage of memory usage above which requests will be queued. The value 0 or 100 means that no requests are queued.

Parameter	Default	Detail
reject_cpu_threshold	0	The percentage of CPU usage above which requests will be rejected. The default value 0 means that no requests are rejected, but may be queued.
reject_memory_threshold	0	The percentage of memory usage above which requests will be rejected. The default value 0 means that no requests are rejected, but may be queued.
averaging_factor	70	This percentage value gives a weighting to the statistic averaging process: a low value has a strong moderating effect (but may not adequately reflect real CPU usage) and a value of 100% means that no averaging is performed, that is, only the current value for memory and CPU consumption is considered.
averaging_factor_cpu	0	This parameter can be used specifically to smooth statistics on CPU usage. It is not set by default (value zero) but if it is set then it overrides the averaging_factor parameter and this CPU value is applied as a factor to average CPU statistics only.
averaging_factor_memory	0	This parameter can be used specifically to smooth statistics on memory usage. It is not set by default (value zero) but if it is set then it overrides the averaging_factor parameter and this memory value is applied as a factor to average memory statistics only.
statistics_collection_interval	1000	Unit milliseconds. The statistics collection interval is set by default to 1000ms (1 second) which has a negligible effect on performance. Values from 100ms are supported. Statistics details are visible in the view M_ADMISSION_CONTROL_STATISTICS.

## Events and Rejection Reasons

If statements are being rejected you may need to investigate why this is happening. Events related to admission control are logged and can be reviewed in the M\_ADMISSION\_CONTROL\_EVENTS view. The key information items here are the event type (such as a statement was rejected or a statement was queued or dequeued) and the event reason which gives an explanatory text related to the type. Other details in this view include the length of time the statement was queued and the measured values for memory and CPU usage.

Two parameters are available to manage the event log in the *admission\_control\_events* section of the ini file:

Parameter	Default	Detail
queue_wait_time_threshold	5000000	The length of time measured in microseconds for which a request must be queued above which it is included in the event log (default is 5 seconds). If the parameter is set to 0 then events are not logged.
record_limit	10000	The maximum record count permitted in the monitor of historical events.

## Queue Management

If requests have been queued, items in the queue are processed when capacity becomes available. A background job continues to evaluate the load on the system in comparison to the thresholds and when the load is reduced enough queued requests are submitted in batches on an oldest-first basis.

The queue status of a request is visible in the M\_CONNECTIONS view; the connection status value is set to *queuing* in column M\_CONNECTIONS.CONNECTION\_STATUS.

There are several configuration parameters (in the *admission\_control* section of the ini file) to manage the queue and how the requests in the queue are released. You can apply a maximum queue size or a queue timeout value; if either of these limits are exceeded then requests which would otherwise be queued will be rejected. An interval parameter is available to determine how frequently to check the server load so that de-queueing can start, and a de-queue batch size setting is also available.

Parameter	Default	Detail
max_queue_size	10000	The maximum number of requests which can be queued. Requests above this number will be rejected.
dequeue_interval	1000	Unit: milliseconds. Use this parameter to set the frequency of the check to reevaluate the load in comparison to the thresholds. The default is 1000ms (1 second). This value is recommended to avoid overloading the system, though values from 100ms are supported.
dequeue_size	50	Use this parameter to set the de-queue batch size, that is, the number of queued items which are released together once the load is sufficiently reduced. This value can be between 1 and 9999 queued requests.
queue_timeout	600	Unit: seconds. Use this parameter to set the maximum length of time for which items can be queued. The default is 10 minutes. The minimum value which can be applied is 60 seconds, there is no maximum limit. Requests queued for this length of time will be rejected.  Note that the timeout value applies to all entries in the queue. Any changes made to this configuration value will be applied to all entries in the existing queue.
queue_timeout_check_interval	10000	Unit: milliseconds. Use this parameter to determine how frequently to check if items have exceeded the queue timeout limit. The default is 10 seconds. The minimum value which can be applied is 100 milliseconds, there is no maximum limit.

### **i** Note

If Admission Control has been configured and is active it takes precedence over any other timeout value which might have been applied. This means other timeouts which apply to a query (such as a query timeout) would not be effective until the query has been dequeued or rejected by the queue time out.

## 6.12.6 Setting User Parameters for Workload

In workload management, there are three user parameters that you can use in order to control resource allocation.

It is possible to set values for the parameters STATEMENT MEMORY LIMIT, STATEMENT THREAD LIMIT and PRIORITY on user level. You can perform this from the SQL command line. Alternatively, you can set the parameters in the [Workload Classes](#) page of the SAP HANA cockpit as well, choosing the [User-Specific Parameters](#) tab. USER ADMIN privileges are required for setting these values. For further information, refer to [Create User-Specific Parameters](#).

The following examples show how to query the settings. The parameter settings currently applied for a selected user are shown in USER\_PARAMETERS:

```
SELECT * FROM USER_PARAMETERS WHERE USER_NAME = 'SYSTEM';
```

The values of the user parameters currently applied for the current session are shown in M\_CONNECTIONS. The following example shows the current connection for the PRIORITY user parameter:

```
SELECT PRIORITY FROM M_CONNECTIONS WHERE CONNECTION_ID = CURRENT_CONNECTION;
```

### STATEMENT MEMORY LIMIT

Set a value (in GB) for the statement memory limit with the following SQL statement:

```
ALTER USER MyUserId SET PARAMETER STATEMENT MEMORY LIMIT = '1';
```

This statement excludes a user from the global limit.

Note that this user parameter-based approach to limiting memory for statements is not supported for cross-database queries, nor is it effective in XSC developed applications. In these cases you can apply memory limits using workload classes in the remote tenant database. For further information on cross-database queries, refer to [Workload Management and Cross-Database Queries](#).

If both a global and a user statement memory limit are set, the user-specific limit takes precedence, regardless of whether it is higher or lower than the global statement memory limit. If the user-specific statement memory limit is removed, the global limit takes effect for the user.

#### **i** Note

Setting the statement memory limit to 0 will disable any statement memory limit for the user. Alternatively, to reset a user-specific limit use the CLEAR option:

```
ALTER USER MyUserId CLEAR PARAMETER STATEMENT MEMORY LIMIT
```

### STATEMENT THREAD LIMIT

Set a value to limit the concurrency of statements with the following SQL statement:

```
ALTER USER MyUserId SET PARAMETER STATEMENT THREAD LIMIT = '20';
```

## PRIORITY

You can set a user-level priority value for all statements in the current connection; the range of possible values is from 0 to 9 (the default is 5). Use the following statement:

```
ALTER USER MyUserId SET PARAMETER PRIORITY = '9';
```

Note that the user priority value is not effective in XSC developed applications. For XSC applications you can apply a priority value using workload classes.

[Setting a Memory Limit for SQL Statements \[page 737\]](#)

## 6.12.7 Managing Workload with Workload Classes

You can manage workload in SAP HANA by creating workload classes and workload class mappings. Appropriate workload parameters are then dynamically applied to each client session.

You can classify workloads based on user and application context information and apply configured resource limitations (related to statement memory or thread limits) or a priority value. Workload classes allow SAP HANA to influence dynamic resource consumption on the session or statement level.

Workload classes and workload class mappings can be maintained either from the SQL command line or in SAP HANA cockpit. For further specific details refer to *Workload Management Statements* in the *SAP HANA SQL and System Views Reference Guide* and to *Managing Workload Classes in SAP HANA cockpit* in the SAP HANA cockpit documentation.

Workload class settings override other configuration settings (ini file values) which have been applied. Workload class settings also override user parameter settings which have been applied by the SQL command ALTER USER, however, workload class settings only apply for the duration of the current session, whereas changes applied to the user persist. More detailed examples of precedence are given in a separate section.

To apply workload class settings client applications can submit client attribute values (session variables) in the interface connect string as one or more property-value pairs. The key values which can be used to work with workload classes are: database user, client, application name, application user and application type.

Based on this information the client is classified and mapped to a workload class. If it cannot be mapped it is assigned to the default workload class. The configuration parameters associated with the workload class are read and this sets the resource variable in the session or statement context.

The list of supported applications includes: HANA WebIDE (XS Classic), HANA Studio, ABAP applications, Lumira, and Crystal Reports. Full details of the session variables available in each supported client interface which can be passed in the connect string are given in SAP Note 2331857 *SAP HANA workload class support for SAP client applications*. Refer also to the *SAP HANA Client Interface Programming Reference*, 'Setting Session-Specific Client Information'. Session variables for workload classes are also supported for use with remote sources as described in the topic 'Session-Specific Information for Connections'.

Managing workload classes requires the 'WORKLOAD ADMIN' privilege. Any changes made to workload classes or mappings are effective almost immediately with only a minimal delay. In terms of the privileges of the executing user (DEFINER or INVOKER), the workload mapping is always determined on the basis of invoking user, regardless of if the user has definer or invoker privileges.

Users, classes and mappings are interrelated: if you drop a user in the SAP HANA database, all related workload classes are dropped and if you drop a workload class, the related mappings are also dropped.

### **i** Note

In a scale-out environment workload classes are created for the complete SAP HANA database and do not have to be created for each single node. However, restrictions defined in these workload classes are applied to each single node and not to the complete SAP HANA database.

Note also that workload classes cannot be used on an Active/Active (read only) secondary node.

## Creating a Workload Class

You can use workload classes to set values for the properties listed here. Each property also has a default value which is applied if no class can be mapped or if no other value is defined. For all of the following parameters, although you can enter values including decimal fractions (such as 1.5GB) these numbers are rounded down and the whole number value is the effective value which is applied.

Parameter	Value
PRIORITY	To support better job scheduling, this property prioritizes statements in the current execution. Priority values of 0 (lowest priority) to 9 (highest) are available; the default value is 5.
STATEMENT THREAD LIMIT	To avoid excessive concurrent processing due to too many small jobs this property sets a limit on the number of parallel JobWorker threads per statement and process. The value can be set to a number between 0 (no limit) and the number of logical cores. If the parameter is not set in a workload class definition then the thread limit is applied in the sequence of: user parameter value followed by the value of the <code>default_statement_concurrency_limit.ini</code> file setting, but both of these are overridden by any value (including the 0 setting) which is set for the statement thread limit workload class parameter.

Parameter	Value
STATEMENT MEMORY LIMIT	<p>To prevent a single statement execution from consuming too much memory this property sets a memory allocation limit in GB per statement. The value can be set to a number between 0 (no limit) and the value of the global allocation limit. If the parameter is not set in a workload class definition then the memory limit is applied in the sequence of: user parameter value followed by the value of the <code>statement_memory_limit</code> ini file setting, but both of these are overridden by any value (including the 0 setting) which is set for the statement memory limit workload class parameter.</p> <p>Note that if a percentage threshold value has been defined in the global <code>statement_memory_limit_threshold</code> parameter it is also effective for the workload class and may soften the effect of the statement memory limit.</p>
TOTAL STATEMENT THREAD LIMIT	<p>Similar to the STATEMENT THREAD LIMIT this property sets an aggregated thread limit which applies to all statements currently being executed within the workload class as a whole.</p>
TOTAL STATEMENT MEMORY LIMIT	<p>Similar to the STATEMENT MEMORY LIMIT this property sets an aggregated memory limit which applies to all statements currently being executed within the workload class as a whole.</p>
STATEMENT TIMEOUT	<p>This property applies a time limit (specified as a number of seconds) after which any query which has not completed execution will time out generating the following error: <code>ERR_API_TIMEOUT</code> .</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>Note</b></p> <p>There are three ways of applying a query timeout value:</p> <ul style="list-style-type: none"> <li>• At the command line (JDBC, SQLDBC) using a <code>querytimeout</code> instruction.</li> <li>• Applying a time value (in seconds) in the <code>statement_timeout</code> configuration parameter (indexserver.ini file, session section).</li> <li>• Applying a time value using workload classes.</li> </ul> <p>If multiple values have been defined using different methods, precedence rules apply: the workload class takes precedence over the ini file, and, if a <code>querytimeout</code> value has been applied then the smallest (strictest) value which has been defined applies. See examples which follow.</p> </div>
WRITE TRANSACTION LIFETIME	<p>This property sets a time value in minutes to limit the lifetime of long-running uncommitted write transactions. The property is not set by default (blank).</p> <p>There is a corresponding ini file configuration parameter for this property: <code>write_transaction_lifetime</code> in the transaction section of the <code>indexserver.ini</code> file, it is not set by default (0) but can be set to a number of minutes. If a workload class property has been defined it takes precedence over the configuration file value.</p>

Parameter	Value
IDLE CURSOR LIFETIME	<p>This property sets a time value in minutes to limit the lifetime of long-lived cursors. The property is not set by default (blank).</p> <p>There is a corresponding ini file configuration parameter for this property: <code>idle_cursor_lifetime</code> in the transaction section of the <code>indexserver.ini</code> file, it is set to 720 minutes by default. If a workload class property has been defined it takes precedence over the configuration file value.</p>

### i Note

Note the following points about workload class properties:

- The timeout period for the parameters WRITE TRANSACTION LIFETIME and IDLE CURSOR LIFETIME is not exact: there may be a delay for timeout values of less than 60 minutes.
- For thread and memory limits workload classes can contain either the statement-level properties or the aggregated total properties, not both. For the aggregated limits the full set of three properties must be defined: TOTAL STATEMENT THREAD LIMIT, TOTAL STATEMENT MEMORY LIMIT and PRIORITY.

## Example

You can set values for one or more resource properties in a single SQL statement. This example creates a workload class called `MyWorkloadClass` with values for all three properties:

```
CREATE WORKLOAD CLASS "MyWorkloadClass" SET 'PRIORITY' = '3', 'STATEMENT MEMORY LIMIT' = '2' , 'STATEMENT THREAD LIMIT' = '20'
```

## Examples of Precedence for Query Timeout

If multiple values have been defined using the different timeout methods available then precedence rules apply. Firstly, if a valid matching workload class value has been defined this takes precedence over the ini file setting. Secondly, if a querytimeout value has been applied then the smallest (strictest) valid value which has been defined applies. The following table shows some examples; in each case the values marked by an asterisk are the ones which apply.

QueryTimeout	25	25	25	<b>25*</b>
statement_timeout (ini)	10	<b>10*</b>	<b>10*</b>	10 (ignored)
STATEMENT TIMEOUT (Workload class)	<b>20*</b>	no match	no value	0 (disabled)

## Creating a Workload Mapping

Mappings link workload classes to client sessions depending on the value of a specific client information property. The class with the most specific match is mapped to the database client.

The SAP HANA application sends client context information in the 'ClientInfo object'. This is a list of property-value pairs that an application can set in the client interface. You can change the running session-context of a connected database client using the SQL command 'ALTER SYSTEM ALTER SESSION SET', see also *Setting Session-Specific Client Information* in the *SAP HANA Developer Guide*.

The properties supported are listed here; the workload class with the greatest number of matching properties to the session variables passed from the client is applied. If two workload classes have the same number of matching properties then they are matched in the following prioritized order:

Field Name	Description
OBJECT NAME	Object types PROCEDURE, PACKAGE and AREA are supported. This property only applies to procedures including AFLLANG procedure which is a standard execution method to execute the application function. Example: If a workload class is matched to an object with type AREA, then it will apply the workload class definition to all AFLLANG procedures which call application functions in the given AFL AREA. Object type PACKAGE works in a similar way. If more than one workload class is matched by the OBJECT NAME then the more specific object type has the higher priority: PROCEDURE > PACKAGE > AREA.
SCHEMA NAME	Schema name of object defined in the OBJECT NAME property.
XS APPLICATION USER NAME*	Name of the XS application user. For XSA applications which use the session variable XS_APPLICATIONUSER for the business user value.
APPLICATION USER NAME*	Name of the application user, usually the user logged into the application.
CLIENT*	The client number is usually applied by SAP ABAP applications like SAP Business Suite / Business Warehouse.
APPLICATION COMPONENT NAME*	Name of the application component. This value is used to identify sub-components of an application, such as CRM inside the SAP Business Suite.
APPLICATION COMPONENT TYPE*	This value is used to provide coarse-grained properties of the workload generated by application components.
APPLICATION NAME*	Name of the application
USER NAME USERGROUP NAME	The name of the SAP HANA database user, that is, the 'CURRENT_USER' of the session of the database the application is connected to. Alternatively, you can use the name of a user group; if both user name and group are provided a validation error is triggered. The user name has a higher priority than the user group in cases where these properties are required to determine the best match.

The properties marked with an asterisk support the use of wildcard characters, the default wildcard character is % - see the second example here.

## Example

This example creates a workload mapping called **MyWorkloadMapping** which applies the values of the **MyWorkloadClass** class to all sessions where the application name value is **HDBStudio**:

```
CREATE WORKLOAD MAPPING "MyWorkloadMapping" WORKLOAD CLASS "MyWorkloadClass" SET
'APPLICATION NAME' = 'HDBStudio';
```

This example creates the **MyWorkloadMapping1** workload mapping using the default wildcard character (does not need to be specified) to match any application name beginning with 'BW':

```
CREATE WORKLOAD MAPPING "MyWorkloadMapping1" WORKLOAD CLASS "MyWorkloadClass" SET
'APPLICATION NAME' = 'BW%' WITH WILDCARD;
```

This example specifies a different wildcard character '\_' to alter the **MyWorkloadMapping1** mapping:

```
ALTER WORKLOAD MAPPING "MyWorkloadMapping1" WORKLOAD CLASS "MyWorkloadClass" SET
'APPLICATION NAME' = 'BW_' WITH WILDCARD '_' ;
```

Refer also to Workload Management Statements in the *SAP HANA SQL and System Views Reference Guide*.

## Hints for Workload Classes

To give control over workload classes at run-time a `workload_class` hint is available. You can use this as the query is executed to apply alternative properties compared to the ones otherwise defined. For example, workload class 'YOUR\_WORKLOAD\_CLASS' applies the values: PRIORITY 5, THREAD 5, MEMORY 50GB. This is then overridden by the values defined in a new class, as a hint, to apply a higher priority value, a lower thread limit and a lower memory threshold:

```
SELECT * FROM T1 WITH HINT( WORKLOAD_CLASS("MY_WORKLOAD_CLASS") );
```

This example applies more restrictive limits than those already defined and by default workload class hints can only be used in this way; the hint is ignored if any of the new values weaken the restrictions or if any values are invalid. You can change this default behavior, however, by switching the following configuration parameter in the `session_workload_management` section of the `indexserver.ini` file: `allow_more_resources_by_hint`. If this parameter is set to **True** then any hint can be applied.

## When are Restrictions Applied?

Generally, limitations applied by configuration settings, user profile parameters and workload class settings are applied as queries are compiled. For workload classes, you can see this by querying the `M_EXEPENSIVE_STATEMENTS` monitoring view to see the operation value (COMPILE, SELECT, FETCH and so on) when the workload class was applied to a statement string. This is not true, however, if the workload class mapping was overridden by a hint, and also does not apply to the OBJECT NAME and SCHEMA NAME workload class properties. In these cases, the statement can only be evaluated after compiling.

## Importing and Exporting Class Details

If you need to import and export workload classes, the normal SQL command for IMPORT will not work because workload classes do not belong to a schema (you cannot import into the SYS schema because it is maintained by the system). A script is available to support this functionality if you need to import a class. The script is typically shipped in the `exe/python_support` directory.

To use this you must first export the monitor views `SYS.WORKLOAD_CLASSES` and `SYS.WORKLOAD_MAPPINGS` to text (csv) format. You can then use the script to reimport the class:

1. Execute SQL EXPORT command:  

```
EXPORT SYS.WORKLOAD_CLASSES, SYS.WORKLOAD_MAPPINGS AS CSV INTO '<PATH>' WITH REPLACE
```
2. Load CSV files using python script `importWorkloadClass.py` specifying the host as a parameter:  

```
python importWorkloadClass.py --host='<host>' --SID='<SID>' --user='<DB-user>' --password='<PW>' <PATH>
```

## Disabling and Enabling Workload Classes

After creating one or more workload classes it is also possible to disable them. This may be necessary, for example, for testing purposes.

1. Disable or enable a single named class:  

```
ALTER WORKLOAD CLASS '<Class Name>' {enable | disable}
```
2. Disable all workload classes using the 'all' switch:  

```
ALTER WORKLOAD CLASS all {enable | disable}
```

### 6.12.7.1 Monitoring Views for Workload Classes

You can use system views to monitor, export, disable and view details of workload classes.

The following system views allow you to monitor workload classes and workload mappings:

- WORKLOAD\_CLASSES
- WORKLOAD\_MAPPINGS

In these system views the field `WORKLOAD_CLASS_NAME` shows the effective workload class used for the last execution of that statement:

- M\_ACTIVE\_STATEMENTS
- M\_PREPARED\_STATEMENTS
- M\_EXPENSIVE\_STATEMENTS (enable\_tracking and memory\_tracking must first be enabled in the global.ini file for this view)
- M\_CONNECTIONS

If no workload class is applied then these views display the pseudo-workload class value `"_SYS_DEFAULT"`.

You can also use queries such as the following examples to read data from these views:

#### Sample Code

```
-- get overview of available workload classes and workload class mappings
select wc.*, wm.workload_mapping_name, user_name, application_user_name,
application_name, client
from workload_classes wc, workload_mappings wm where wc.workload_class_name =
wm.workload_class_name;
```

#### Sample Code

```
-- get sum of used memory of all prepared statements grouped by workload
class which are executed in the last 10 minutes; requires memory tracking
select workload_class_name, sum(memory_size), count(*) statement_count,
count(distinct connection_id) as distinct_connection_count,
count(distinct application_name) as distinct_application_count,
count(distinct app_user) as distinct_applicationuser_count
from sys.m_expensive_statements
where add_seconds(start_time, 600) >= now() and memory_size >= 0
group by workload_class_name;
```

#### Sample Code

```
-- get information about priorities assigned to prepared statements executed
in the last 10 minutes
select workload_class_name, min(priority) min_priority, max(priority)
max_priority, count(*) statement_count,
count(distinct connection_id) as distinct_connection_count,
count(distinct application_name) as distinct_application_count,
count(distinct app_user) as distinct_applicationuser_count
from sys.m_expensive_statements
where add_seconds(start_time, 600) >= now()
group by workload_class_name;
```

#### Sample Code

```
-- collect workload related information for active statements
with job_count_per_statement as (select statement_id, count(0) num_active_jobs
from sys.m_service_threads
where statement_hash <> '' and is_active = 'TRUE'
group by statement_id, statement_hash)
select s.statement_id, s.statement_string, s.memory_size, s.duration_microsec,
```

```
s.application_source, s.application_name, s.app_user, s.db_user,
s.priority, s.statement_thread_limit, s.statement_memory_limit,
s.workload_class_name, st.num_active_jobs
from sys.m_expensive_statements s, job_count_per_statement st
where st.statement_id = s.statement_id;
```

#### Sample Code

```
-- collect workload related information for active statements
select s.statement_id, s.statement_string, s.memory_size, s.cpu_time,
       s.application_source, s.application_name, s.app_user, s.db_user,
       s.workload_class_name
from sys.m_expensive_statements s;
```

#### Sample Code

```
-- get information from system views
select * from sys.m_prepared_statements;
select * from sys.m_active_statements;
select * from sys.m_expensive_statements;
select * from m_service_threads;
select * from m_service_thread_samples;
```

## 6.12.7.2 Workload Class Examples

Here we give examples to show how the workload management features interact together.

Workload class settings override other ini file configuration settings which have been applied and also override user parameter settings which have been applied by the SQL command ALTER USER, however, workload class settings only apply for the duration of the current session, whereas changes applied to the user persist. More detailed examples of this and also how hints are applied to invoke a workload class at run-time are given in this section. The SAP HANA SQL Reference Guide also includes examples of precedence including code samples.

### Note

For the examples shown in this section where memory limits are defined, the resource tracking parameters *enable\_tracking* and *memory\_tracking* in the global.ini file must be set to **true**.

## Precedence of Workload Management Properties

In general, workload management settings are applied in the sequence of: workload class settings followed by user parameters followed by other ini file settings.

### Precedence of Workload Class Values

The following table shows a scenario where a statement memory limit setting has been applied in the global ini file, restrictions have been applied at the level of the user profile and also in a workload class. In this basic example, if the workload class is mapped to a statement then the workload class settings take precedence and

so for the duration of the current session the following values are effective: thread limit 10, memory limit 50 GB, priority 7.

Basic Scenario: Precedence of Workload Management Properties

	Global.ini	User Profile	Workload Class
Concurrency (job executor threads)	N/A	Thread limit 5	Thread limit 10
Statement Memory limit	50 GB	30 GB	50 GB
Priority	N/A	Priority 5	Priority 7

The following two variations on this scenario show the chain of precedence:

1. If the workload class thread limit is undefined the user profile value is effective: 5
2. If the workload class memory limit is undefined and the user profile memory limit is undefined then the global value is effective: 50 GB
3. If the workload class memory limit is 0 then there is no limit on memory allocation per statement.

### Total Statement Values for Workload Classes

For workload classes using the aggregated properties (TOTAL STATEMENT THREAD LIMIT and TOTAL STATEMENT MEMORY LIMIT) the same principle of precedence applies as shown above. In this case all three values (thread limit, memory limit and priority) must all be defined and higher level settings would only be applied if the workload class was invalid for some reason. Note also that if a workload class with aggregated properties is used, memory and concurrency limits for single statements from ini parameters or user profile are not applied for statements running inside this class.

### Using Hints to specify a Workload Class

If a workload class is specified with an SQL statement as a hint at run-time then the settings of the matching hint class take precedence. In the following example, two workload classes are matched to the current execution request. The limitations specified by the hint class are successfully applied: thread limit 4, statement memory limit 30 GB, and priority 4.

Example showing use of hints

	Global.ini	User Profile	Workload Class	Hint Workload Class
Concurrency	N/A	Thread limit 5	Thread limit 5	Thread limit 4
Statement Memory limit	50 GB	30 GB	50 GB	30 GB
Priority	N/A	Priority 5	Priority 5	Priority 4

The following two variations on this scenario show the effects of additional conditions:

1. If, for example, the Concurrency (Thread limit) value of the hint workload class is left undefined then all values of the hint workload class would be ignored. In the above example, the workload class settings take precedence since hint workload class is ignored. And so for the duration of the current session the following values are effective: thread limit 5, memory limit 50 GB, priority 5. If the workload class memory limit is undefined the user profile value is effective: 30.
2. By default, the hint can only be used to specify more restrictive values; in this scenario if the hint workload class memory limit was 70 GB then all values of the hint workload class would be ignored. This behavior

can be reversed by setting the ini file parameter `allow_more_resources_by_hint` to True; in that case the more generous limit of 70 GB would then be applied.

## Related Information

[Managing Workload with Workload Classes \[page 745\]](#)  
[SAP HANA SQL Reference Guide for SAP HANA Platform](#)

## 6.12.8 Example Workload Management Scenarios

Here, we give a number of scenarios to illustrate how workload management settings can be applied for systems of different sizes, different workload types (analytics and transactional) and different usage scenarios (a system which is optimized for robustness as opposed to high performance).

### i Note

All settings are tuning parameters and must be tested and validated before being used in production. See the process description in *Understand Your Workload Management*.

## System Details

The scenarios which follow are based on the system specifications given here: firstly describing hardware resources and secondly the workload types which the system is expected to handle.

System Types 1: Small and Large Hardware Configurations

	Small (maximum 4 sockets)	Large
Sockets (processors)	2	16
Physical cores per socket	8	2 x 15 = 30
Logical cores (threads)	32	16 x 30 = 480
Memory	64 GB	256GB

Note that related to memory resources, the setting for global memory allocation limit is very important. By default, it is calculated as 90% of the first 64 GB of available physical memory on the host plus 97% of each further GB; or, in the case of small physical memory, physical memory minus 1 GB.

Secondly, we give details of two contrasting types of workload: pure analytics processing and mixed transactions, to show how the system can be configured to handle these different situations:

#### System Types 2: Workload and Processing Types

	<b>Analytics Workload</b>	<b>Mixed Workload</b>
Installed Applications	SAP Business Warehouse (or similar analytic application)	SAP Business Suite (OLTP) and Smart Business Apps (OLAP)
Workload type	Only OLAP.	Mixed OLAP and OLTP.
Processing characteristics	CPU and Memory intensive - long transaction times (+ 1 second)	Both applications have short-running statements (milliseconds or microseconds) where response time is critical as well as long-running CPU and memory-intensive OLAP statements.
Data	Bulk loading	
Concurrent queries, Concurrent users.	Few (10-100)	Many (> 1000)

## Scenario 1: Mixed Workload (OLAP and OLTP) Optimized for Robustness

In the first scenario, the focus is on achieving robust statement execution time and high availability of the system.

#### Small System with Mixed Workload Optimized for Robustness

<b>Tuning Option</b>	<b>Example Setting</b>
<code>statement_memory_limit</code>	Start testing with this parameter set to 25% of the global allocation limit.
<code>default_statement_concurrency_limit</code>	Assign 33% of the logical cores on the system.
<code>max_concurrency_hint</code>	For systems with at least 80 logical cores consider <code>max_concurrency_hint</code> equal to the number of logical cores per socket.
Workload Classes	Fine-grained control is possible with workload classes. In a mixed workload scenario, the OLTP load could be configured with a higher priority than OLAP.

## Scenario 2: Mixed Workload (OLAP and OLTP) Optimized for Performance

For the second scenario we take exactly the same system as scenario 1 but we optimize for performance instead of robustness by relaxing some of the settings:

Small System with Mixed Workload Optimized for Performance

Tuning Option	Example Setting
<code>max_concurrency_hint</code>	For systems with at least 80 logical cores consider <code>max_concurrency_hint</code> equal to the number of logical cores per socket.
Workload Classes	Consider assigning higher priority to OLTP statements than to OLAP statements by using workload classes based on the application.

## Scenario 3: Analytics

Pure OLAP scenarios tend to be more performance oriented, hence, we remove the limitations on concurrency here (leading to a best-effort approach). On the other hand, to avoid out-of-memory situations, we keep the memory limits.

Small Analytic System

Tuning Option	Example Setting
<code>statement_memory_limit</code>	Start testing with this parameter set to 25% of the global allocation limit.
<code>statement_memory_limit_threshold</code>	Start testing with this parameter set to 50% of the global allocation limit.

Check `M_EXPENSIVE_STATEMENTS.MEMORY_SIZE` for the typical memory usage of statements.

## Scenario 4: Large System with at least 4 Sockets - All Workload Types

Large systems usually need to handle many concurrent statements therefore it is usually reasonable to limit the concurrency of statements; but also, this may help to avoid cases where HANA over-parallelizes. Less parallelism per statement on these large systems tends to have better performance because statements run on one single NUMA node and we tend to avoid cross NUMA node communication.

Large System, All Workload Types

Tuning Option	Example Setting
<code>statement_memory_limit</code>	Start testing with this parameter set to 25% of the global allocation limit.
<code>default_statement_concurrency_limit</code>	Assign 33% of the logical cores on the system.

Tuning Option	Example Setting
<code>max_concurrency</code>	From SPS12, the default setting should give good performance in most cases. If necessary, consider reducing the value of this parameter. Start testing with the parameter set to 50% of the available logical cores.
<code>max_concurrency_hint</code>	Consider setting <code>max_concurrency_hint</code> equal to the number of logical cores per socket.
Workload Classes	In mixed scenarios fine-grained control is possible with workload classes.

## 6.13 Getting Support

There are many support resources available to help you work with SAP HANA and a range of tools and functions to help you (together with SAP Support) to analyze, diagnose, and resolve problems.

### Support Resources

The SAP Support Portal is the starting point for all support questions; an SAP user ID ('S-user') is required for access: <https://support.sap.com>. From here you have access to all resources including the One Support launchpad, support incidents, software downloads, license keys, documentation, SAP Notes and options for contacting Support.

#### Guided Answers

Guided Answers is an interactive online support tool to help you to diagnose and solve problems using decision trees. It covers many SAP products including SAP HANA and offers a set of step-by-step problem-solving documents each one designed to address a specific issue. Guided Answers is available in the SAP Support portal at the following address: <https://ga.support.sap.com/dtp/viewer/>

#### i Note

Two Guided Answers trees may be particularly helpful in making an initial assessment of any problem:

- The *SAP HANA Component Guide* tree will help you to troubleshoot an issue and determine the correct component reference (such as *HAN-DB-BAC* for SAP HANA Backup and Recovery). If you need to contact Support the component ID will enable Support analysts to immediately identify where the problem is located. [SAP HANA Component Guide](#)

- The *SAP HANA Troubleshooting and Problem Categorization* tree is a general high-level troubleshooting tree for SAP HANA. [SAP HANA Troubleshooting](#)

## SAP Community

In the SAP Community Network (SCN) you can find many support resources online including wikis, blogs, reference materials and so on. This SCN wiki page, for example, provides links to many specialist troubleshooting topics: [SAP HANA In-Memory Troubleshooting Guide](#).

The SAP Questions and Answers knowledge base may also provide quick answers to many common questions: [SAP Q&A](#).

## YouTube

Both SAP HANA Academy and SAP Support offer YouTube channels with a wide range of support materials in video format:

- <https://www.youtube.com/user/saphanaacademy>
- <https://www.youtube.com/user/SAPSupportInfo>

## Contacting Support

If you need personal interactive support for questions which are not covered by these resources then you may need to open a support incident. The Support team may require you to prepare analysis documents and provide diagnostic information (such as trace files) in order to efficiently analyze your scenario; tools and procedures for doing this are described in detail in this section.

Integrated into the online process of creating a support ticket is the **Support Log Assistant** tool. This tool automatically scans support related files (such as logs, traces and configuration files) for known issues and offers solutions, recommendations and documentation resources to solve or prevent problems. The Support Log Assistant is also available as a standalone tool; the following link is to a Support Portal getting started page with direct access to the tool: [Support Log Assistant](#).

### Incidents, Calls and Chat Sessions

In addition to incidents the *Expert Chat* and *Schedule an Expert* support options may be preferable alternatives. A chat session can be either a simple text chat within your browser or you can share screens with an expert to demonstrate a specific issue or question. If you can plan your support call in advance there is also the option of scheduling a 30-minute call with a support engineer. Full details of these options are available in the *My Support* area of the portal: [Product Support](#).

See also the following knowledge base articles:

- 2570790 - Expert Chat Frequently Asked Questions - SAP Product Support
- 2392095 - Requirements for a successful Expert Chat Session with SAP Product Support

[Diagnosis Files \[page 760\]](#)

[Traces \[page 764\]](#)

[Problem Analysis Using hdbcons \[page 802\]](#)

## 6.13.1 Diagnosis Files

Diagnosis files include log and trace files, as well as a mixture of other diagnosis, error, and information files. In the event of problems with the SAP HANA database, you can check these diagnosis files for errors. Traces generally need to be explicitly enabled and configured.

### Location of Diagnosis Files

Diagnosis files of the system database are stored at the following default location on the SAP HANA server: `/usr/sap/<SID>/HDB<instance>/<host>/trace`.

Trace files of tenant databases are stored in a sub-directory named `DB_<database_name>`.

#### → Recommendation

Monitor disk space that is used for diagnosis files and delete files that are no longer needed.

### Related Information

[Traces \[page 764\]](#)

[Monitoring Disk Space \[page 403\]](#)

[Tenant Databases \[page 18\]](#)

## 6.13.1.1 View Diagnostic Files in the SAP HANA Database Explorer

Diagnose and analyze errors in an SAP HANA database by viewing the relevant diagnostic files in the SAP HANA database explorer.

### Context

In the catalog browser, diagnostic files for online databases are grouped by host and then by service. In a multi-host system, check each host folder to view all diagnostic files associated with a particular service.

### Procedure

Choose one of the following options:

Option	Description
<b>View diagnostic files for a database that is online and available</b>	Open the <i>Database Diagnostic Files</i> folder of your database, then right-click the diagnostic file that you want to examine and click <i>Show Files</i> to open the file in an editor. If the trace file is binary, then it cannot be opened in the database explorer, but can be downloaded. The <i>Database Diagnostic Files</i> folder contains all diagnostic files that are available through the database's M_TRACEFILES system view.
<b>View diagnostic files for a cockpit database that is either online or offline</b>	Open the <i>Host Diagnostic Files</i> folder of your cockpit database, then right-click the diagnostic file that you want to examine and click <i>Show Files</i> to open the file in an editor. If the trace file is binary, then it cannot be opened in the database explorer, but can be downloaded. The <i>Host Diagnostic Files</i> folder contains all diagnostic files that have been configured for the SAP Host Agent.  For more information about configuring the SAP Host Agent, see the <i>SAP Host Agent</i> documentation.  The cockpit database must have valid SAP Control Credentials set in the cockpit. If the user has not set valid SAP Control Credentials, then an error is returned.
<b>View diagnostic files for tenant databases in an MDC system</b>	Under the <i>Database Diagnostic Files</i> folder of your database, right-click the folder of the tenant database that you want to view trace files for, and then click <i>Show Files</i> to open the file in an editor.

**i Note**  
You must be connected to the system database as the SYSTEM user.

### Related Information

[Collecting Diagnosis Information for SAP Support](#)

## 6.13.1.2 View Diagnosis Files in SAP HANA Studio

In the event of problems with the SAP HANA database, you can display the relevant diagnosis file(s) in the SAP HANA studio and analyze for errors.

### Prerequisites

You have the system privilege CATALOG READ.

### Procedure

In the Administration editor, choose the *Diagnosis Files* tab.

All available diagnosis files are displayed. Use the available options to filter the number of files.

#### i Note

If you are in the system database, you initially see the diagnosis files of the system database only.

For more information about other options for working with diagnosis files, see *Options for Diagnosis File Handling (SAP HANA Studio)*

### Related Information

[Options for Diagnosis File Handling \(SAP HANA Studio\) \[page 762\]](#)

[View Diagnosis Files of an Unavailable Tenant Database \[page 284\]](#)

### 6.13.1.2.1 Options for Diagnosis File Handling (SAP HANA Studio)

In the SAP HANA studio, you can filter, merge, delete, compress, and download diagnosis files.

The following options for working with diagnosis files are available on the *Diagnosis Files* tab of the Administration editor.

Option	Description
Filter files by text	To refine the list of diagnosis files, enter a filter text in the <i>Filter</i> field. For example, if you want to see only SQL trace files, enter <code>sqltrace</code> . You can also filter by host.

Option	Description
Filter files by tenant database (system database only)	To see the diagnosis files for a particular tenant database, select the database name. This filter is only available in the system database. If no tenant database is selected (default), the diagnosis files of the system database are displayed.
Display file contents	<p>To display the contents of a file, right-click it and choose <i>Open</i>, or double-click the file.</p> <p>The <i>Show Start of File</i> and <i>Show End of File</i> buttons help you to navigate particularly large files more easily. You can specify how many lines you want to see when you filter the file in this way.</p> <div data-bbox="603 651 1390 869" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>Depending on the type of data in the diagnosis file, the number of lines actually displayed may be less than or greater than specified. This is because the data in some diagnosis files is fetched in bytes and the number of bytes per line varies.</p> </div> <div data-bbox="603 891 1390 1039" style="background-color: #f0f0f0; padding: 5px;"> <p><b>→ Tip</b></p> <p>Crash dump files have a hyperlinked table of contents. To see the hyperlinks, press the <code>CTRL</code> key as you move your mouse over the entries.</p> </div>
Merge file contents	<p>You can merge the diagnosis files listed by choosing <i>Merge Diagnosis Files...</i></p> <p>This feature is helpful during troubleshooting as it allows you to review multiple diagnosis files of different file types at the same time.</p> <p>As merging diagnosis files can take a long time depending on the size and number of files to be merged, you can restrict the amount of data included by specifying a timeframe (for example, data from the last 24 hours only or from between certain dates and times). You can also restrict to data of trace level ERROR.</p> <p>If you select <i>Export to CSV file</i>, the merged trace file is exported to the specified location. If you do not select this option, the file is opened directly in the SAP HANA studio in the <i>Merged Diagnosis Files</i> editor. Here, you can use additional filtering options and the timeframe slider to drill down and analyze further.</p>

Option	Description
Delete files	<p>You delete one or more individual log files or other non-trace files (for example, *.log, *.tpt, *.py) from the list by selecting the file(s) in question and in the context menu, choosing <i>Delete</i>.</p> <p>You delete trace files in the following ways:</p> <ul style="list-style-type: none"> <li>You can delete trace files in the same way as other diagnosis files by right-clicking them and choosing <i>Delete</i>.</li> </ul> <div data-bbox="667 584 1390 869" style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>i Note</b></p> <p>The file may not actually be deleted. If a running service is currently writing to the file, it cannot be deleted. If this is the case, the file disappears from the list in the SAP HANA studio and is hidden in the file system at operating system level. As long as a service is still writing to the file, it still exists and consumes disk space. Once the file reaches its maximum size, the system stops writing to it and creates a new trace file. When the file is physically deleted depends on how trace file rotation is configured.</p> </div> <ul style="list-style-type: none"> <li>You can batch delete trace files, for example all the trace files of a specific service, by choosing <i>Delete Trace Files...</i> and making the required selection.</li> </ul> <div data-bbox="667 965 1390 1131" style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>i Note</b></p> <p>In this case, if it is not possible to delete trace files because they are open, the content of the file is cleared. The file still exists but its size is reduced.</p> </div>
Compress files	<p>If you need to download a diagnosis file (for example, to send it to SAP Support), you can compress it first on the server. This is useful for large diagnosis files and/or slow connections. To compress a file, right-click it and choose <i>Compress</i>. After compression, the file has the file format *.zip. You can select multiple files to compress.</p>
Download files	<p>To download a diagnosis file for offline analysis, right-click and choose <i>Download</i>. You can select multiple files to download.</p>

## 6.13.2 Traces

SAP HANA provides various traces for obtaining detailed information about the actions of the database system for troubleshooting and error analysis.

The following is an overview of the main traces available in SAP HANA:

Configure or Run...	To...	Using...
Database trace	Understand activity in the components of the SAP HANA database in general, or for a specific user or client operation	SAP HANA database explorer SAP HANA studio
	<p><b>i Note</b></p> <p>Database tracing is always active. Information about error situations is always recorded in alert trace files.</p>	
SQL trace	Collect information about all SQL statements executed on the index server	SAP HANA database explorer SAP HANA studio
Expensive statements	Record information about individual SQL statements whose execution time exceeded a configured threshold	SAP HANA cockpit SAP HANA database explorer SAP HANA studio
Plan trace	Visualize the execution plans of SQL SELECT statements for in-depth query performance analysis	SQL analyzer SAP HANA PlanViz perspective of the SAP HANA studio
	<p><b>i Note</b></p> <p>The plan trace is part of the SAP HANA tools for query execution analysis: the Web-based <b>SQL analyzer</b>, which is integrated into the SAP HANA cockpit and SAP Web IDE for SAP HANA, and the <b>SAP HANA PlanViz</b> perspective of the SAP HANA studio.</p>	
Deadlock Detection	Create a <i>waitgraph</i> file that contains thread information about deadlocks.	SAP HANA database explorer (SQL Statement)
Performance trace	Record performance indicators of individual query processing steps in the database kernel for detailed performance analysis by SAP Support	SAP HANA studio
Kernel profiler	Generate a profiler trace for detailed performance analysis by SAP Support	SAP HANA database explorer SAP HANA studio
Full system information dump	Create a runtime dump if requested by SAP support to understand the behavior of SAP HANA in a problem situation	SAP HANA cockpit or SAP HANA studio
SAP Web Dispatcher HTTP traces	Analyze HTTP requests	SAP HANA cockpit or SAP HANA studio

[Configure Tracing in the SAP HANA Database Explorer \[page 785\]](#)

## 6.13.2.1 Database Trace (Basic, User-Specific, and End-to-End)

The database trace records information about activity in the components of the SAP HANA database. You can use this information to analyze performance and to diagnose and debug errors.

### Database Trace Files

Each service of the SAP HANA database writes to its own trace file. The file names follow the default naming convention:

```
<service>_<host>.<port_number>.<3_digit_file_counter>.trc
```

#### ❖ Example

```
indexserver_veadm009.34203.000.trc
```

Information recorded by the `alert` trace component of the database trace is written to a separate file to ensure that critical information is easy to find. The file names follow the default naming convention:

```
<service>_alert_<host>.trc
```

#### i Note

The trace files generated for the Web Dispatcher service are different. For more information, see *Trace Configuration for Internal Web Dispatcher*.

You access database trace files with other diagnosis files.

## Basic Database Trace Configuration

Database tracing is always active. This means that information about error situations is always recorded. However, for more detailed analysis of a specific problem or component, you may need to configure a certain trace component to a trace level higher than the default value. For example, the `backup` trace component records information about backup operations, the `authorization` component records information about authorization operations, and so on.

### → Tip

For more information about which trace component to use for which situation, see SAP Note 2380176.

### Changing the trace level of a trace component

If a trace component is available in all services, the trace level can be configured for all services at once. It is also possible to configure the trace level of a component individually for a specific service. The trace level of a component configured at service level overrides the trace level configured for all services. Some components are only available in a particular service and cannot therefore be changed globally.

### 🔗 Example

You change the trace level of the `memory` component to `ERROR` for all services and for the `indexserver` service, you change it to `WARNING`. This means that the `memory` component of the `indexserver` service will trace up to level `WARNING` and the `memory` component of all other services will trace to the level `ERROR`.

You can configure the trace levels of database trace components in the SAP HANA database explorer or the SAP HANA studio. Alternatively, you can modify the parameters in the `trace` section of the `global.ini` configuration file (for all services) or service-specific files such as `indexserver.ini`. The individual parameters correspond to trace components and the parameter value is the trace level.

### 🔗 Example

Use the following statement to set the trace level of the `authentication` component to `DEBUG`:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'SYSTEM') SET ('trace',  
'authentication') = 'DEBUG' WITH RECONFIGURE
```

### i Note

In the SAP HANA database explorer and SAP HANA studio, a trace level that has been inherited from the global or `ALL SERVICES` configuration (either the default or system configuration) is shown in brackets.

### What trace levels are possible?

The higher the trace level, the more detailed the information recorded by the trace. The following trace levels exist:

- NONE (0)
- FATAL (1)
- ERROR (2)
- WARNING (3)
- INFO (4)

- DEBUG (5)

### Note

Even if you select trace level NONE, information about error situations is still recorded.

## Alert Trace Component

The `alert` trace component is used to ensure that critical information is easy to find by duplicating high-priority trace messages to separate alert trace files. By default, trace messages with trace level ERROR and higher are written to the alert trace file.

### Example

If the `alert` component is set to WARNING, the alert trace contains messages created with trace levels WARNING, FATAL and ERROR.

## User-Specific and End-to-End Database Traces

User-specific and end-to-end traces extend the configured database trace by allowing you to change the trace level of components in the context of a particular user or end-to-end analysis. The trace levels configured for components in these contexts override those configured in the database trace.

### Example

In the database trace, you changed the trace level of the `memory` component to ERROR for all services, and for the `indexserver` service you changed it to WARNING. Now, you create a user-specific trace for `User1` and increase the trace level for all services to WARNING. For the `indexserver` service, you increase it to DEBUG. This results in the following tracing behavior for the `memory` component:

- For all users except `User1`, all services except the `indexserver` will trace to ERROR
- For all users except `User1`, the `indexserver` will trace to WARNING
- For `User1`, all services except the `indexserver` will trace to WARNING
- For `User1`, the `indexserver` will trace to DEBUG

If you are connected to a database of version HANA 2.0 SPS 03, then you can use the [Statement Hash](#) option when configuring user-specific tracing in the SAP HANA database explorer. This option allows you to filter your tracing according to specific SQL statements.

To run tracing on a specific SQL statement, you must first find the unique identifier (statement hash) for that statement and enter it in the [Statement Hash](#) field when configuring your user-specific trace session.

For example, if you want to see trace information when running the statement `SELECT * FROM DUMMY;`, then execute the following statements to find its statement hash:

```
SELECT * FROM DUMMY;
SELECT statement_string, statement_hash FROM m_sql_plan_cache WHERE
statement_string = 'SELECT * FROM DUMMY;';
```

Enter the result of the second statement into the [Statement Hash](#) field of the [User-Specific Trace](#) configuration dialog to include tracing for the `SELECT * FROM DUMMY;` statement in your user-specific trace.

## End-to-End Traces

End-to-end traces are triggered by applications outside of the SAP HANA database. The default trace levels for the SAP HANA database components are normally sufficient and do not need to be changed. For more information about end-to-end analysis in your landscape, see the following link 'End-to-End Analysis Overview' in the SAP Library for Solution Manager .

## Further Information

An SAP Community blog *User-specific Database Traces filtered by connection\_id and statement\_hash* gives further details of this feature.

### 6.13.2.1.1 Database Trace Configuration in Tenant Databases

Tenant databases inherit the database trace level configured in the system database unless you change the trace level in the tenant database.

The trace level of trace components in a tenant database is inherited from the system database as the default value. If you want to configure a different trace level for a particular component in the tenant database, either globally for all services or for a specific service, you can do so by changing the trace level of the relevant component.

#### i Note

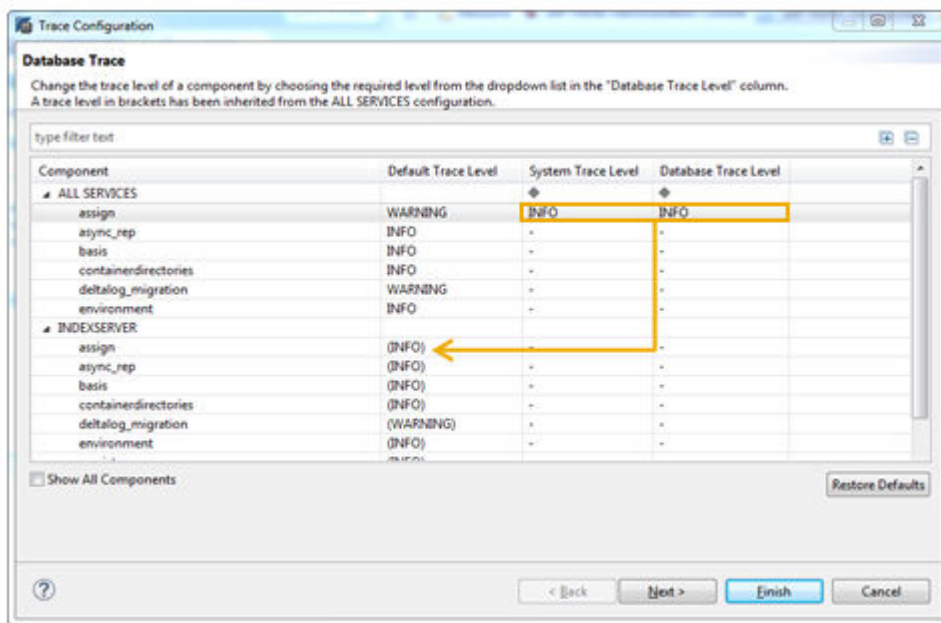

In the SAP HANA studio, the trace level of a component will also be displayed as the system trace level, and you cannot change the system trace level. This is because from the perspective of the tenant database, the database and the system are effectively the same. The true system trace level (that is, the value configured in the system database) appears as the default trace level for the tenant database.

#### i Note

A trace level that has been inherited from the ALL SERVICES configuration (either the default or database configuration) is shown in brackets.

## ❖ Example

In the following example, you can see that the default trace level for the component `assign` inherited from the system database is `WARNING`. The trace level was changed to `INFO` for all services in this database. The `indexserver` service therefore inherits this trace level. All the other components keep the default configuration.

Database Trace Configuration in a Tenant Database (Studio View)

## 6.13.2.1.2 Configure Database Trace File Rotation

Trace file rotation prevents trace files from growing indefinitely by limiting the size and number of trace files. You can configure trace file rotation globally for all services in the database and for individual services.

### Prerequisites

You have the system privilege `INIFILE ADMIN`.

### Context

You configure trace file rotation in the `global.ini` configuration file (all services) or the service-specific file (for example, `indexserver.ini`).

## Procedure

Depending on whether you are configuring trace file rotation for all system services or for an individual service, proceed as follows:

Option	Description
<b>All services</b>	<p>In the <code>trace</code> section of the <code>global.ini</code> file, configure the following parameters:</p> <ul style="list-style-type: none"><li>◦ <code>maxfiles</code> by specifying the maximum number of trace files that may exist</li><li>◦ <code>maxfilesize</code> by specifying in bytes the maximum size an individual trace file may reach</li></ul> <div data-bbox="331 640 1401 772"><p><b>i Note</b></p><p>The default configuration for trace file rotation in the <code>global.ini</code> file is <code>maxfiles=10</code> and <code>maxfilesize=10000000</code>.</p></div>
<b>Individual service</b>	<p>In the <code>trace</code> section of the <code>global.ini</code> file, configure the following parameters. If there is no <code>trace</code> section, add one.</p> <ul style="list-style-type: none"><li>◦ <code>maxfiles</code> by specifying the maximum number of trace files that may exist</li><li>◦ <code>maxfilesize</code> by specifying in bytes the maximum size an individual trace file may reach in bytes</li></ul> <div data-bbox="331 936 1401 1068"><p><b>i Note</b></p><p>If these two parameters do not exist in the <code>trace</code> section or if you created a new <code>trace</code> section, create them.</p></div>

## Results

When a trace file reaches the specified maximum file size, it is closed, and a new file created. When the specified maximum number of files is reached, the next time a new file is created, the first file is deleted, and so on.

### i Note

The system checks the size and number of diagnosis files regularly. The threshold values for these checks (check 50 and 51) should be in line with the configured trace file rotation.

[Configure Traces in SAP HANA Studio \[page 786\]](#)

[Configure Check Thresholds \[page 402\]](#)

## 6.13.2.2 SQL Trace

The SQL trace collects information about all SQL statements executed on the index server (tenant database) or name server (system database) and saves it in a trace file for further analysis. The SQL trace is inactive by default.

Information collected by the SQL trace includes overall execution time of each statement, the number of records affected, potential errors (for example, unique constraint violations) that were reported, the database connection being used, and so on. The SQL trace is a good starting point for understanding executed statements and their potential effect on the overall application and system performance, as well as for identifying potential performance bottlenecks at statement level.

### SQL Trace Files

SQL trace information is saved as an executable python program (by default `sqltrace_<...>.py`), which can be used to replay the traced database operations. You can also use the SQL Trace Analyzer tool to automate the analysis of the file.

### Enabling and Configuring the SQL Trace

You can enable and configure the SQL trace in the SAP HANA database explorer or SAP HANA studio. Alternatively, you can modify the parameters in the `sqltrace` section of the `indexserver.ini` (tenant database) or `nameserver.ini` (system database).

#### ❖ Example

Use the following statement to enable the SQL trace:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'SYSTEM') SET ('sqltrace', 'trace') = 'on' WITH RECONFIGURE
```

#### → Recommendation

Do not leave the SQL trace enabled all the time as writing trace files consumes storage space on the disk and can impact database performance significantly.

### Trace Levels

You can set the level for the SQL trace by changing the value of the configuration parameter `[sqltrace] level` in the `indexserver.ini` file (tenant database) or `nameserver.ini` file (system database). Trace information includes details such as executed timestamp, thread ID, connection ID, and statement ID.

Trace Level	Description
NORMAL	All statements that have finished successfully are traced.

Trace Level	Description
ERROR	All statements that returned errors are traced.
ERROR_ROLLBACK	All statements that are rolled back are traced.
ALL	All statements including status of normal, error, and rollback are traced.
ALL_WITH_RESULTS	In addition to the trace generated with trace level ALL, the result returned by select statements is also included in the trace file.

#### **i** Note

An SQL trace that includes results can quickly become very large.

#### **⚠** Caution

An SQL trace that includes results may expose security-relevant data, for example, query result sets.

## Trace Details

You can configure trace detail information by setting the parameter `[sqltrace] details`. You can select one or more categories of information to include in the trace, for example: `'basic,resource_consumption'`. Possible values are listed in the following table. Note that for resource consumption information (this is also included in the 'all' option) the following two parameters in the `global.ini` file `[resource_tracking]` section, must be set to 'on':

- `enable_tracking`
- `memory_tracking`

You may also wish to limit the maximum memory allocation per statement by setting a value for the `[memorymanager] statement_memory_limit` parameter in the `global.ini` file. Set this to 5, for example, to apply a limit of 5GB.

Trace Details	Description
basic	Connection information and statement information (default)
all	Include all comments of connection and statement
user_variables	User-defined variables in the session context
statement	Statement information such as executed timestamp, thread ID, connection ID, statement ID, statement hash and duration
session_variables	System-defined variables in the session context
resource_consumption	Statement resource consumption information such as local (+remote, if available) cpu-time and memory-size.
passport	Decoded passport contents

Trace Details	Description
connection	Connection information such as session ID, transaction ID, client PID, client IP, user name, schema name, and session variable:value pairs
"empty"	Trace without these comments

## Additional Configuration Options

Option	Configuration Parameter	Default	Description
Trace file name	<code>tracefile</code>	<code>sqltrace_</code> <code>\$HOST_</code> <code>{PORT}_</code> <code>{COUNT:</code> <code>3}.py</code>	<p>User-specific name for the trace file</p> <p>If you do not enter a user-specific file name, the file name is generated according to the following default pattern:</p> <p><code>DB_&lt;dbname&gt;/sqltrace_</code> <code>\$HOST_</code> <code>{PORT}_</code> <code>{COUNT:3}.py</code>, where:</p> <ul style="list-style-type: none"> <li>• <code>DB_&lt;dbname&gt;</code> is the sub-directory where the trace file is written if you are running on a tenant database</li> <li>• <code>\$HOST</code> is the host name of the service (for example, <code>indexserver</code>)</li> <li>• <code>\$PORT</code> is the port number of the service</li> <li>• <code>\$COUNT:3</code> is an automatically generated 3-digit number starting with 000 that increments by 1 and serves as a file counter when several files are created.</li> </ul>
User, application, object, and statement filters	<code>user</code> <code>application_user</code> <code>application</code> <code>object</code> <code>statement_type</code>	Empty string	<p>Filters to restrict traced statements to those of particular database or application users and applications, as well as to certain statement types and specific objects (tables, views, procedures).</p> <p>All statements matching the filter criteria are recorded and saved to the specified trace file.</p> <p>For <code>user</code>, <code>application_user</code>, and <code>application</code> the use of wildcards is supported (see following subsection <i>Using Wildcards</i>).</p>
Flush limit	<code>flush_interval</code>	16	<p>During tracing, the messages of a connection are buffered. As soon as the flush limit number of messages is buffered (or if the connection is closed), those messages are written to the trace file.</p> <p>When set to 0, every SQL trace statement is immediately written to the trace file</p>

## Using Wildcards

If you apply filters for the `user`, `application_user`, and `application` parameters, the use of wildcards and exceptions is also supported. The asterisk wildcard character denotes any number of characters and the exclamation mark denotes an exclusion. For example:

```
user=SM*, JONES, !GREEN, !BRO*
```

In this case all users starting with SM will be traced, JONES will be traced, user GREEN will not be traced and all users starting with BRO will not be traced. If terms in the string conflict with each other then the sequence in which the terms occur determines the result. In the following example user SMALL will be traced in spite of the exclusion; the exclusion is ignored because it occurs after the first wildcard.

```
user=SM*, JONES, !SMALL, !BRO*
```

## Trace File Rotation

The size and number of trace files are controlled by the following parameters.

Parameter	Default	Description
<code>max_files</code>	<b>1</b>	Sets the maximum number of trace files
<code>filesize_limit</code>	<b>1610612736</b> (or 1.5 GB)	Sets the maximum size of an individual trace file in bytes

### Caution

If both the maximum number of files and the maximum file size are reached, SQL tracing stops. If this happens, you can increase the values of `max_files` and `filesize_limit`. See SAP Note 2629103.

## SAP HANA SQL Trace Analyzer

SAP HANA SQL trace analyzer is a Python tool you can use to analyze the HANA SQL trace output. The tool gives you an overview of the top SQL statements, the tables accessed, statistical information on different statement types and on transactions executed.

For more information about the installation and usage of SAP HANA SQL trace analyzer, see SAP Knowledge Base Article 2412519 *FAQ: SAP HANA SQL Trace Analyzer*.

## Related Information

[Diagnosis Files \[page 760\]](#)

[SAP Note 2629103](#)

## 6.13.2.3 Performance Trace

The performance trace is a performance tracing tool built into the SAP HANA database. It records performance indicators for individual query processing steps in the database kernel. You may be requested by SAP Support to provide a performance trace.

Information collected includes the processing time required in a particular step, the data size read and written, network communication, and information specific to the operator or processing-step-specific (for example,

number of records used as input and output). The performance trace can be enabled in multiple tenant databases at the same time to analyze cross-database queries.

## Performance Trace Files

Performance trace results are saved to the trace files with file extension \*.tpt or \*.cpt, which you can access with other diagnosis files. To analyze these files, you need a tool capable of reading the output format (\*.tpt and \*.cpt). SAP Support has tools for evaluating performance traces.

## Enabling and Configuring the Performance Trace

You can enable and configure the performance trace in the SAP HANA studio or using the `ALTER SYSTEM * PERFTRACE` SQL statements.

### ❖ Example

To start the performance trace execute `ALTER SYSTEM START PERFTRACE`.

## Configuration Options

Option	Description
Trace file name	The name of the file to which the trace data is automatically saved after the performance trace is stopped
User and application filters	Filters to restrict the trace to a single specific database user, a single specific application user, and a single specific application
Trace execution plans	You can trace execution plans in addition to the default trace data.
Function profiler	The function profiler is a very fine-grained performance tracing tool based on source code instrumentation. It complements the performance trace by providing even more detailed information about the individual processing steps that are done in the database kernel.
Duration	How long you want tracing to run  If a certain scenario is to be traced, ensure that you enter a value greater than the time it takes the scenario to run. If there is no specific scenario to trace but instead general system performance, then enter a reasonable value. After the specified duration, the trace stops automatically.

Additional filter options are available in extended mode to restrict the trace data further.

For more information about how to configure the performance trace using SQL, see the *SAP HANA SQL and System Views Reference*.

### 6.13.2.4 Expensive Statements Trace

Expensive statements are individual SQL statements whose execution time exceeds a configured threshold. The expensive statements trace records information about these statements for further analysis and is inactive by default.

If, in addition to activating the expensive statements trace, you enable per-statement memory tracking, the expensive statements trace will also show the peak memory size used to execute the expensive statements.

#### Expensive Statements Trace Information

If you have the TRACE ADMIN privilege, then you can view expensive statements trace information in the following ways:

- In the *Expensive Statements* app of the SAP HANA cockpit
- In the *Statement Library* in SAP HANA database explorer by searching for *Expensive Statements Analysis*.
- In the M\_EXPENSIVE\_STATEMENTS system view

#### Enabling and Configuring the Expensive Statements Trace

You can enable and activate the expensive statements trace in the SAP HANA cockpit or the SAP HANA database explorer. Alternatively, you can modify the parameters in the `expensive_statement` section of the `global.ini` configuration file.

#### Configuration Options

##### i Note

The following table shows the configuration parameters which are available; not all of these may be available in the SAP HANA cockpit or the SAP HANA database explorer.

Option	Configuration Parameter	Default Value	Description
Trace status	<code>enable</code>	<code>off</code>	Specifies the activation status of the trace.

Option	Configuration Parameter	Default Value	Description
Threshold CPU time	<code>threshold_cpu_time</code>	<b>-1</b> (disabled)	<p>Specifies the threshold CPU time of statement execution in microseconds.</p> <p>When set to 0, all SQL statements are traced.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Resource tracking and CPU time tracking must also be enabled. You can do this by configuring the corresponding parameters in the <code>resource_tracking</code> section of the <code>global.ini</code> file.</p> </div>
Threshold memory	<code>threshold_memory</code>	<b>-1</b> (disabled)	<p>Specifies the threshold memory usage of statement execution in bytes.</p> <p>When set to 0, all SQL statements are traced.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Resource tracking and memory tracking must also be enabled. You can do this by configuring the corresponding parameters in the <code>resource_tracking</code> section of the <code>global.ini</code> file.</p> </div>
Threshold duration	<code>threshold_duration</code>	<b>1000000</b> (microseconds = 1 second)	<p>Specifies the threshold execution time in microseconds.</p> <p>When set to 0, all SQL statements are traced. In the SAP HANA database explorer, you can set the threshold duration to be measured in seconds or milliseconds.</p>
User, application, and object filters	<code>user</code> <hr/> <code>application_user</code> <hr/> <code>application</code> <hr/> <code>object</code>	Empty string	<p>Specifies filters to restrict traced statements to those of a particular database, application user, application, or tables/views. For <code>user</code>, <code>application_user</code>, and <code>application</code> the use of wildcards is supported (see following subsection <i>Using Wildcards</i>).</p>

Option	Configuration Parameter	Default Value	Description
Passport trace level	<code>passport_tracelevel</code>	Empty string	<p>If you are activating the expensive statements trace as part of an end-to-end trace scenario with the Process Monitoring Infrastructure (PMI), you can specify the passport trace level as an additional filter.</p> <p>This means that only requests that are marked with a passport of the specified level are traced.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Process tracing is possible only for components in the ABAP and Business Objects stacks.</p> </div>
Trace parameter values	<code>trace_parameter_values</code>	<b>true</b>	In SQL statements, field values may be specified as parameters (using a "?" in the syntax). If these parameter values are not required, then you can disable this setting to reduce the amount of data traced.
Trace flush interval	<code>trace_flush_interval</code>	10	Specifies the number of records after which a trace file is flushed.
Use in-memory tracing	<code>use_in_memory_tracing</code>	<b>true</b>	If in-memory tracing is active, then information is cached in memory. Otherwise, the data is written directly to file.
In-memory tracing records	<code>in_memory_tracing_records</code>	<b>30000</b>	<p>Specifies the maximum number of trace records (per service) stored in memory.</p> <p>This setting only takes effect when in memory tracing is active.</p>

## Using Wildcards

If you apply filters for the `user`, `application_user`, and `application` parameters, the use of wildcards and exceptions is also supported. The asterisk wildcard character denotes any number of characters and the exclamation mark denotes an exclusion. For example:

```
user=SM*, JONES, !GREEN, !BRO*
```

In this case all users starting with SM will be traced, JONES will be traced, user GREEN will not be traced and all users starting with BRO will not be traced. If terms in the string conflict with each other then the sequence in which the terms occur determines the result. In the following example user SMALL will be traced in spite of the exclusion; the exclusion is ignored because it occurs after the first wildcard.

```
user=SM*, JONES, !SMALL, !BRO*
```

## Trace File Rotation

To prevent expensive statement trace information from growing indefinitely, you can limit the size and number of trace files using the following parameters in `expensive_statement` of `global.ini`.

Parameter	Default	Description
<code>maxfiles</code>	<b>10</b>	<p>Specifies the maximum number of trace files.</p> <p>When the maximum number of trace files reached, the oldest trace file is deleted and a new one opened.</p> <p>When set to 0, trace file rotation is disabled.</p>
<code>maxfilesize</code>	<b>10000000</b> (or 9.5 megabytes)	<p>Specifies the maximum size of an individual trace file in bytes.</p> <p>When the maximum number of files is greater than 1 and the maximum file size is reached, a new trace file is opened.</p> <p>When the maximum number of files is 1, the maximum file size is greater than zero, and the maximum file size is reached, the trace file is deleted and a new one opened.</p>

### 6.13.2.5 Deadlock Detection Using SQL

To help with diagnosis of system issues you can create a `waitgraph` file that contains thread information about deadlocks.

From the SQL command line you can use the `ALTER SYSTEM CREATE WAITGRAPH` command to create a `waitgraph` file that contains thread information about deadlocks. Full details of the syntax are given in the SAP HANA SQL Reference Guide; here, the usage and optional configuration steps are explained with some examples to illustrate the essential functionality. `RESOURCE_ADMIN` privileges are required to run this command. You can monitor the progress of the job in the monitoring view `M_JOB_PROGRESS`.

The following command will write the current waitgraph on service myhost:30003 into the trace file named my\_waitgraph.trc.

```
ALTER SYSTEM CREATE WAITGRAPH AT LOCATION 'myhost:30003' INTO FILE  
'my_waitgraph.trc'
```

If a file name is not specified then the following default file name structure is used:

```
<servicename>_<hostname>.<port>.waitgraph.<YYYYMMDD-HHMMSS>.<pid>.trc
```

In the above example only threads that caused a deadlock are part of the waitgraph. To get more detail you can use the ALL THREADS syntax to include all threads even if they do not participate in the deadlock:

```
ALTER SYSTEM CREATE WAITGRAPH ALL THREADS INTO FILE 'my_waitgraph.trc'
```

## 6.13.2.6 Kernel Profiler

The kernel profiler is a sampling profiler built into the SAP HANA database. It can be used to analyze performance issues with systems on which third-party software cannot be installed, or parts of the database that are not accessible by the performance trace. It is inactive by default.

The kernel profile collects, for example, information about frequent and/or expensive execution paths during query processing.

It is recommended that you start kernel profiler tracing immediately before you execute the statements you want to analyze and stop it immediately after they have finished. This avoids the unnecessary recording of irrelevant statements. It is also advisable as this kind of tracing can negatively impact performance.

### Enabling and Configuring the Kernel Profiler

You can enable and configure the kernel profiler in the SAP HANA Database Explorer (Trace Configuration) or you can manage the kernel profiler from the SQL command line using the ALTER SYSTEM command. In both cases RESOURCE ADMIN or TRACE ADMIN privileges are required.

#### Enabling Kernel Profiler using SQL

The kernel profiler statement supports basic functions such as start, stop, save and clear, but also a number of options such as to run the profile for a specific location, for a specific user or within certain memory limits.

The following examples illustrate the basic usage of the ALTER SYSTEM command:

```
ALTER SYSTEM START KERNEL PROFILER
```

```
ALTER SYSTEM SAVE KERNEL PROFILER
```

The SAVE keyword stops the profiler, saves the data (to the trace directory) and clears allocated memory. The following statement starts profiling at host:port ab1234:30003 and filters for the user specific trace (database trace) profile MYTRACEPROFILE

```
ALTER SYSTEM START KERNEL PROFILER AT 'ab1234:30003' TRACEPROFILE
'MYTRACEPROFILE' ;
```

Refer to the SAP HANA SQL Reference Guide for further options and details of these commands.

## Configuration Options in Database Explorer

Option	Description
Service(s) to profile	The service(s) that you want to profile.
Sampling interval	The amount of time the kernel profiler is to wait between call stack retrievals.  When you activate the kernel profiler, it retrieves the call stacks of relevant threads several times. It waits between each sample for the length of time specified here minus the time the previous retrieval took.
Memory limit	Memory limit that will stop tracing.  The kernel profiler can potentially use a lot a memory. To prevent the SAP HANA database from running out of memory due to profiling, you can specify a memory limit that cannot be exceeded.
Optional filter	The specific database user or application user you want to profile.

## Kernel Profiler Traces

Profiling results are saved to two trace files. When started from SQL:

- kernel\_profiler\_cpu.dot
- kernel\_profiler\_wait.dot

When started from Database Explorer:

- CPU\_<service>\_<host>\_<port>\_<timestamp>.dot
- WAIT\_<service>\_<host>\_<port>\_<timestamp>.dot

To analyze these trace files you need a tool capable of reading the .dot output format, or you may be asked to send the files to SAP Support.

### View M\_KERNEL\_PROFILER

The view M\_KERNEL\_PROFILER displays the status of the profiler (started or stopped) and provides information about current kernel profilers. The view can also be accessed by users with RESOURCE ADMIN and/or TRACE ADMIN privileges.

## Further Information

An SAP Community blog *Kernel profiler filtered by connection ID and statement hash* gives further details of this feature.

## 6.13.2.7 Traces and Trace Configuration for Internal Web Dispatcher

Several traces and trace configuration options are available for the internal Web Dispatcher, which runs as a native SAP HANA service (`webdispatcher`).

The HANA internal web dispatcher is an implementation of the NetWeaver web dispatcher. The support component ID for the web dispatcher is: BC-CST-WDP. For more detailed information you can refer to the SAP Web Dispatcher documentation and the NetWeaver documentation using the links given below under Related Information.

### Developer Trace

The developer trace is the main trace for the Web Dispatcher and contains technical information for troubleshooting problems.

The developer trace file is `webdispatcher_<host>.<port>_dev_webdisp`.

You can configure the developer trace in the following ways:

- Changing the database trace level for the `dev_webdisp` component of the `webdispatcher` service  
The default trace level is ERROR.
- Changing (or adding) the property `rdisp/trace` in the `[profile]` section of the `webdispatcher.ini` configuration file.  
Possible values are 0, 1, 2, and 3.

## Database Trace

The database trace files for the Web Dispatcher contain secondary information related to the Web Dispatcher's integration into the SAP HANA integration system (start/stop, configuration changes, and so on).

The database trace files are:

- `webdispatcher_<host>.<port>.<3_digit_file_counter>.trc`
- `webdispatcher_alert.<host>.trc`

You can configure the database trace by changing the trace level for the `webdispatcher` component of the `webdispatcher` service.

## Header Trace

The header trace allows you to analyze HTTP requests and responses efficiently since it contains only the request data and no information about the internal workings of Web Dispatcher.

You can activate the header trace by adding the property `icm/http/trace_info` in the `[profile]` section of the `webdispatcher.ini` configuration file and setting the value to `true`. The trace level is `false` by default.

Header trace information is written to the `dev_webdisp` trace file.

## HTTP Access Log

To monitor all HTTP(s) requests processed in an SAP HANA system, you can set up the internal Web Dispatcher to write a standardized HTTP log for each request.

To configure the Web Dispatcher to log all HTTP(s) requests, you add the property `icm/http/logging_0` to the `[profile]` section of the `webdispatcher.ini` configuration file, specifying the following value:

```
PREFIX=/, LOGFILE=$(DIR_INSTANCE)/trace/access_log-%y-%m-%d, MAXSIZEKB=10000,  
SWITCHTF=day, LOGFORMAT=SAP
```

The access log file is `access_log-<timestamp>`.

### ❁ Example

```
Sample log file entry: [26/Nov/2014:13:42:04 +0200] 10.18.209.126 BOB - "GET /sap/xse/  
test/InsertComment.xsjs HTTP/1.1" 200 5 245
```

The last three numbers are the HTTP response code, the size in bytes, and the response time in milliseconds. For more information about logging and alternative log formats, see the Internet Communication Manager (ICM) documentation on SAP Help Portal.

## 6.13.2.8 Configure Tracing in the SAP HANA Database Explorer

Various types of tracing are available in the SAP HANA database explorer for obtaining detailed information about your database system operations.

### Prerequisites

To configure tracing, you must have the TRACE ADMIN system privilege.

You must be connected to an SAP HANA database. You cannot configure tracing for HDI containers or cockpit resources.

### Procedure

1. Right-click your database and click [Trace Configuration](#).
2. Click [Edit](#) on the type of tracing that you want to configure.
3. On the [Trace Configuration](#) editor, configure your trace settings and click [OK](#).

### Results

You have configured your tracing type and can now view and download tracing results from either your [Database Diagnostic Files](#) folder or your [Host Diagnostic Files](#) folder.

## Related Information

[Traces](#)

## 6.13.2.9 Configure Traces in SAP HANA Studio

Various traces are available for obtaining detailed information about the actions of the database system. You can activate and configure traces in the SAP HANA studio on the *Trace Configuration* tab of the Administration editor.

### Prerequisites

To configure traces, you must have the system privilege TRACE ADMIN. To configure the kernel profiler, you must have the `SAP_INTERNAL_HANA_SUPPORT` standard role.

### Context

You can configure the following traces:

- Database traces (basic, user, end-to-end)
- SQL trace
- Performance trace
- Expensive statements trace
- Kernel profiler
- Plan trace

### Procedure

1. In the Administration editor, choose the *Trace Configuration* tab.
2. Choose the  (*Edit Configuration*) button for the trace that you want to configure. The *Trace Configuration* dialog box appears.
3. Make the required settings.

The configuration options available in the *Trace Configuration* dialog box depend on the trace type.

#### i Note

To restore the default status or configuration of a trace, in the *Trace Configuration* dialog box choose *Restore Defaults*.

#### → Tip

If you are configuring the database trace, not all trace components are visible by default in the *Trace Configuration* dialog box. To view all additional components, select *Show All Components*.

## Results

Data recorded by traces is saved to trace files, which you can view on the [Diagnosis Files](#) tab.

## Related Information

### 6.13.3 Troubleshooting an Inaccessible or Unresponsive SAP HANA System

For situations when a system cannot be reached by SQL or is experiencing performance problems, both the SAP HANA studio and the SAP HANA cockpit provide mechanisms by which you or an SAP support engineer can access diagnosis information and perform emergency operations to resolve the situation.

## Related Information

[Troubleshooting an Unresponsive Database in SAP HANA Cockpit \[page 787\]](#)

[Troubleshoot Unresponsive System in SAP HANA Studio \[page 788\]](#)

#### 6.13.3.1 Troubleshooting an Unresponsive Database in SAP HANA Cockpit

Use SAP HANA cockpit to identify performance issues in a specific system or a tenant database by examining transactional information.

## Prerequisites

You've navigated to the [Database Overview](#) of your system database. See [Getting to the Database Overview Page](#).

You must have `<sid>adm` credentials to access the [Troubleshoot Unresponsive Database](#) page. These can be entered for the system or tenant database in the [Database Directory](#).

## Procedure

1. On the [Database Overview](#) page, with the [Administration](#) or [All](#) view selected, click the [Troubleshoot Unresponsive Systems](#) link on the [Alerting and Diagnostics](#) card.

[Troubleshoot Unresponsive System](#) organizes information about the system by tab. You can diagnose:

- Connections
  - Transactions
  - Blocked Transactions
  - Threads
2. (Optional)

You can select one connection or transaction to cancel, or choose to cancel all of them.

## Related Information

[Open the SAP HANA Cockpit \[page 45\]](#)

[Using the Database Overview Page to Manage a Database \[page 340\]](#)

[Monitoring Your Databases in the Database Directory \[page 171\]](#)

### 6.13.3.2 Troubleshoot Unresponsive System in SAP HANA Studio

When a system cannot be reached by SQL or is experiencing performance problems, you cannot use the Administration editor to troubleshoot and/or resolve issues. By opening the Administration editor in diagnosis mode you or an SAP support engineer can access diagnosis information and perform emergency operations to resolve the situation.

## Prerequisites

You have the credentials of the operating system user (`<sid>adm` user) that was created when the system was installed.

## Procedure

1. Open the Administration editor in diagnosis mode:
  - If the system is stopped or cannot be reached by SQL, double-click the system in the *Systems* view.
  - If the system is running, choose the  (*Open Diagnosis Mode*) button from the drop-down menu of the  (*Administration*) button in the *Systems* view.

### Note

The Administration editor is available in diagnosis mode only from the system database. If a tenant database is unavailable, you can view its diagnosis files in the standard Administrator editor of the system database on the *Diagnosis Files* tab.

2. If required, enter the <sid>adm user name and password.

## Results

The Administration editor opens in diagnosis mode.

Here, you see the operational status of all services in the system (*Processes* tab) and you have access to log and trace files (*Diagnosis Files* tab). It is also possible to trigger the collection of diagnosis information into a zip file, which you can then download and attach to a support message. For more information, see *Collect and Download Diagnosis Information in SAP HANA Studio*.

If transactional problems are the source of performance issues, you can analyze current activity in the system on the *Emergency Information* tab. Here you see all connections, transactions, blocked transactions, and threads in the system. If necessary, you can cancel individual connections and transactions, or even cancel all transactions.

## Related Information

[Collect and Download Diagnosis Information in SAP HANA Studio \[page 792\]](#)

## 6.13.4 Collecting Diagnosis Information for SAP Support

To help SAP Support analyze and diagnose problems with your system, you can collect a range of diagnosis information from your system into a zip file. You can trigger the collection of diagnosis information from the SAP HANA cockpit, the SAP HANA studio, and the command line.

[Diagnosis Information Collected \[page 798\]](#)

### 6.13.4.1 Collect and Download Diagnosis Information in SAP HANA Cockpit

To help SAP Support analyze and diagnose problems with the SAP HANA database, you can collect diagnosis information into a zip file, which you can then download and attach to a support message for example. With the SAP HANA cockpit, you can create and manage system information dumps.

#### Prerequisites

- If the database is online, you need the following privileges:

To...	You Need...
Collect diagnosis information	EXECUTE privilege on the procedure <code>SYS.FULL_SYSTEM_INFO_DUMP_CREATE</code>
List diagnosis information	SELECT privilege on the view <code>SYS.FULL_SYSTEM_INFO_DUMPS</code>  In the system database of a multiple-container system, you also need SELECT on <code>SYS_DATABASES.FULL_SYSTEM_INFO_DUMPS</code> so that you can see diagnosis information collected from tenant databases.
Download collected diagnosis information	EXECUTE privilege on the procedure <code>SYS.FULL_SYSTEM_INFO_DUMP_RETRIEVE</code>

To...	You Need...
Delete collected diagnosis information	EXECUTE privilege on the procedure SYS.FULL_SYSTEM_INFO_DUMP_DELETE

- If the system is online, but you want to switch it to offline before collecting information, you will be prompted to connect to the database using the SAP Control credentials.
- If the system is offline (including the system database in a multiple-container system), you must have credentials of the operating system administrator (user <sid>adm).
- If the database is a tenant database in a multiple-container system and it is offline, you must be logged on to the system database and have the privileges listed above. It is not possible to collect, list, download, or delete diagnosis information from an offline tenant database.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, select the [Administration](#) view and select [Manage full system information dumps](#) on the [Alerting & Diagnostics](#) card.
2. On the [Diagnosis Files](#) page, if the system is online, you can use the drop down list to switch to offline. You will be prompted to connect to the database with the SAP Control credentials. (If the system is offline, you cannot switch to online).
3. On the [Diagnosis Files](#) page, choose a zip file from the list or click [Collect Diagnostics](#) to create a new zip file.
4. When creating a new zip file, specify the scope of information to be collected:

Option	Description
<b>Collect from existing files</b>	Select this option if you want to collect diagnosis information for one or more file types, for a specific time period, by default the last 7 days. If you also want information from system views, then select <a href="#">Include system views</a> .

### i Note

If you are connected to the system database of a multiple-container system, only information from the system views of the system database will be collected. Information from the system views of tenant databases will **not** be collected regardless of this option.

Information from system views is collected through the execution of SQL statements, which may impact performance. In addition, the database must be online, so this option is not available in diagnosis mode.

<b>Create from runtime environment (RTE)</b>	<p>Select this option if you want to restrict the information collected to one or more RTE dump files. You can configure the creation and collection of dump files by specifying the following additional information:</p> <ul style="list-style-type: none"> <li>○ The number sets to be collected (that is, the number of points in time at which RTE dump files will be collected). Possible values are 1- 5.</li> <li>○ The interval (in minutes) at which RTE dump files are to be collected (possible values are 1, 5, 10, 15, and 30). The default value is 1.</li> <li>○ The host(s) from which RTE dump files are to be collected.</li> </ul>
--	--

Option	Description
	<ul style="list-style-type: none"> <li>○ The service(s) for each selected host from which RTE dump files are to be collected.</li> <li>○ The section(s) from each selected service from which RTE dump files are to be collected.</li> </ul>

5. If your system database is version HANA 2.0 SPS 04 revision 45 or later, then you have the option of choosing which database or databases to collect diagnosis for.

If the SYSTEM database is online, then you can choose to download diagnostic information for **only** the SYSTEM database, for specified tenant databases, or for all databases in the system.

If the SYSTEM database is offline, then you can choose to download diagnostic information for either the SYSTEM database or for specified tenant databases.

## Results

The system collects the relevant information and saves it to a zip file. This may take some time and can be allowed to run in the background.

If you are connected to the system database of a multiple-container system, information from all tenant databases is collected and saved to separate zip files.

### 6.13.4.2 Collect and Download Diagnosis Information in SAP HANA Studio

To help SAP Support analyze and diagnose problems with the SAP HANA database, you can collect diagnosis information into a zip file, which you can then download and attach to a support message for example. The SAP HANA studio uses either SQL or the SAP Host Agent to collect diagnosis information depending on whether SAP HANA is either online or offline.

#### Prerequisites

- If the database is online, you need the following privileges:

To...	You Need...
Collect diagnosis information	EXECUTE privilege on the procedure <code>SYS.FULL_SYSTEM_INFO_DUMP_CREATE</code>

To...	You Need...
List diagnosis information	<p>SELECT privilege on the view SYS.FULL_SYSTEM_INFO_DUMPS</p> <p>In the system database of a multiple-container system, you also need SELECT on SYS_DATABASES.FULL_SYSTEM_INFO_DUMPS so that you can see diagnosis information collected from tenant databases.</p>
Download collected diagnosis information	EXECUTE privilege on the procedure SYS.FULL_SYSTEM_INFO_DUMP_RETRIEVE
Delete collected diagnosis information	EXECUTE privilege on the procedure SYS.FULL_SYSTEM_INFO_DUMP_DELETE

- If the database is a tenant database in a multiple-container system and it is currently offline, you must be logged on to the system database and have the privileges listed above. It is not possible to collect, list, download, or delete diagnosis information from an offline tenant database.
- If the system is offline (including the system database in a multiple-container system), you must have credentials of the operating system administrator (user <sid>adm). It is not possible to collect, list, download, or delete diagnosis information via an SQL connection.

## Procedure

1. In the Administration editor, choose the *Diagnosis Files* tab.

### i Note

If there is no connection to the database, the Administration editor opens in diagnosis mode and you will be prompted to enter the credentials of the <sid>adm user. If you are a tenant database administrator and there is no connection to your tenant database, you cannot proceed. Only the system administrator can collect diagnosis information from the system database.

2. Choose ► *Diagnosis Information* ► *Collect* ▾.
3. Specify the scope of information to be collected:

Option	Description
<b>Collect all diagnosis information</b>	<p>Select this option if you want to collect all diagnosis information for a specific time period, by default the last 7 days. If you also want information from system views, then select <i>Include system views</i>.</p> <div data-bbox="427 1697 520 1733" data-label="Section-Header"> <h3>i Note</h3> </div> <div data-bbox="429 1744 1345 1832" data-label="Text"> <p>If you are connected to the system database of a multiple-container system, only information from the system views of the system database will be collected. Information from the system views of tenant databases will <b>not</b> be collected regardless of this option.</p> </div> <p>Information from system views is collected through the execution of SQL statements, which may impact performance. In addition, the database must be online, so this option is not available in diagnosis mode.</p>

Option	Description
<b>Create and collect one or multiple sets of runtime environment (RTE) dump files</b>	<p>Select this option if you want to restrict the information collected to one or more RTE dump files. You can configure the creation and collection of dump files by specifying the following additional information:</p> <ul style="list-style-type: none"> <li>○ The index server(s) from which RTE dump files are to be collected</li> <li>○ The number of RTE dump file sets to be collected (possible values are 1, 2, 3, 4, and 5)</li> <li>○ The interval (in minutes) at which RTE dump files are to be collected (possible values are 1, 5, 10, 15, and 30). The default value is 1.</li> </ul>

### i Note

Older systems do not support all of the above options. It may not be possible to exclude system views from collection or you may require operating system (<sid>adm) user access to do so.

The system collects the relevant information and saves it to a zip file. This may take some time and can be allowed to run in the background.

If you are connected to the system database of a multiple-container system, information from all tenant databases is collected and saved to separate zip files.

4. To download the zip file containing the collected diagnosis information, proceed as follows:
  - a. Choose **Diagnosis Files > List**.  
The *Diagnosis Information* dialog box opens. The zip file containing the collected diagnosis information is listed together with any other zip files of previously collected information.
  - b. Select the relevant zip file and choose *Download Collection*.
  - c. Specify the download location.
5. Optional: Delete any old collections that you no longer need by selecting them and choosing *Delete Collections*.

## Related Information

[Diagnosis Information Collected \[page 798\]](#)

### 6.13.4.3 Collect Diagnosis Information from the Command Line

The `fullSystemInfoDump.py` script allows you to collect information from your system, even when it is not accessible by SQL. You can then add this information to a support message, for example. The script is part of the SAP HANA server installation and can be executed directly from the command line.

## Prerequisites

You are logged on as the operating system user, <sid>adm.

## Context

The `fullSystemInfoDump.py` script is part of the server installation and can be run from the command line. It is located in the directory `$DIR_INSTANCE/exe/python_support`.

### i Note

In a multiple-container system, only the system administrator can collect diagnosis information from the command line since tenant database administrators do not have operating system access. Tenant database administrators must use the SAP HANA cockpit or studio to collect diagnosis information from their database.

## Procedure

Start the script from its location with the command:

```
python fullSystemInfoDump.py
```

You can modify the command with several command line options. To see the available options, specify the option `--help`.

If the system can be reached by SQL (and you have not specified the option `--nosql`), the script starts collecting diagnosis information. If the system cannot be reached by SQL, the script starts collecting support information but does not export data from system views.

## Results

The script creates a zip file containing the collected information and saves it to the directory `DIR_GLOBAL/sapcontrol/snapshots`. `DIR_GLOBAL` typically points to `/usr/sap/<sid>/SYS/global`.

The name of the zip file is structured as follows:

```
fullsysteminfodump_<SID>_<DBNAME>_<HOST>_<timestamp>.zip
```

The timestamp in the file name is UTC. The host and SID are taken from the `sapprofile.ini` file.

The output directory for the zip file is shown as console output when the script is running.

## Related Information

[Collect and Download Diagnosis Information in SAP HANA Cockpit \[page 790\]](#)

[Collect and Download Diagnosis Information in SAP HANA Studio \[page 792\]](#)

[fullSystemInfoDump.py Command Line Options \[page 796\]](#)

[Diagnosis Information Collected \[page 798\]](#)

## 6.13.4.3.1 fullSystemInfoDump.py Command Line Options

You can specify several command line options when executing the `fullSystemInfoDump.py` script from the command line.

Option	Description
<code>--version</code>	Displays script version number
<code>--help</code>	Shows help
<code>--nosql</code>	Excludes the collection of system views
	<b>i Note</b> If you are connected to the system database, only information from the system views of the system database will be collected. Information from the system views of tenant databases will <b>not</b> be collected regardless of this option.
<code>--file &lt;filename&gt;</code>	Zips the specified file in its source directory
	<b>i Note</b> This option only zips the file; it does not trigger the collection of any other information.
<code>--days &lt;no. of days&gt;</code>	Collects information from the specified number of past days The default value is 7.
	<b>i Note</b> You cannot use this option with the options <code>--fromDate</code> and <code>--toDate</code> .
<code>--fromDate &lt;YYYY-MM-DD&gt;</code>	Collects information starting from the specified date
<code>--toDate &lt;YYYY-MM-DD&gt;</code>	Collects information up to the specified date
<code>--rtedump</code>	Restricts the information collected to an RTE dump file or files You can configure the creation and collection of RTE dump files further with the remaining options.
<code>--indexservers &lt;comma-separated list of index servers&gt;</code>	Specifies the index server(s) from which RTE dump files are to be collected By default, dump files are created and collected for all index servers
<code>--interval &lt;interval in minutes&gt;</code>	Specifies the interval at which RTE dump files are to be collected Possible values are 1, 5, 10, 15, and 30. The default value is 1.

Option	Description
<code>--sets &lt;no. of RTE dump file sets&gt;</code>	Specifies the number of RTE dump file sets to be collected. Possible values are 1, 2, 3, 4, and 5.
<code>--tenant &lt;tenant database name&gt;</code>	Specifies which tenant database information is to be collected from  You must specify a database name.  To collect information from the system database, specify <b>SYSTEMDB</b> .

## 6.13.4.4 System Information Dump Files in SQL

You can obtain a run-time environment (RTE) dump file from the SQL command line.

In addition to the ways already described you can also obtain a run-time dump file using SQL. You can use the `ALTER SYSTEM CREATE RUNTIMEDUMP` command to create either a complete or a selective dump file about system activity. Full details of the syntax are given in the SAP HANA SQL Reference Guide; here, the usage and optional configuration steps are explained with some examples to illustrate the essential functionality. `RESOURCE_ADMIN` privileges are required to run this command. You can monitor the progress of the job in the monitoring view `M_JOB_PROGRESS`.

The basic syntax allows you to specify a host and an output file name. By default all sections of the dump file are written:

```
ALTER SYSTEM CREATE RUNTIMEDUMP AT LOCATION 'myhost:30003' INTO FILE
'my_rte_dump.trc'
```

If a file name is not specified then the following default file name structure is used:

```
<servicename>_<hostname>.<port>.rtedump.<YYYYMMDD-HHMMSS>.<pid>.trc
```

For example:

```
indexserver_myhost0001.30203.rtedump.20180627-104305.012220.trc
```

You can also name specific sections of the run time dump file to be included; for example, the following command prints only the `STACK_SHORT` section:

```
ALTER SYSTEM CREATE RUNTIMEDUMP AT LOCATION 'myhost:30003' SECTIONS
('STACK_SHORT') INTO FILE 'my_rte_dump.trc'
```

Alternatively, you can omit the `SECTIONS` argument and run the command based on a pre-defined profile which selects sections of the dump file to include. Profiles are defined as configuration file values in the `global.ini` file. The following command, for example, will write a runtime dump that contains all sections defined by profile `myRTEProfile`:

```
ALTER SYSTEM CREATE RUNTIMEDUMP PROFILE 'myRTEProfile' INTO FILE
'my_rte_dump.trc'
```

The profile myRTEProfile may have the following defined as default sections, which would print all sections except STACK\_FULL and MEMMAP.

```
!STACK_FULL, !MEMMAP, *
```

The profile is defined in the [runtimedump] section of the global.ini file with a name in the following format: <profileName>\_sections; the value for the parameter is a comma-separated list of section names to include in the run-time dump output if the SECTIONS argument is not specified in the SQL statement. You can use the asterisk as a wildcard character at the end of the string and the exclamation mark before a section name to explicitly exclude a section which would otherwise be selected, as shown in the following examples:

- Default\_sections = !STACK\_FULL,!MEMMAP,\*
- my\_sections = \*

Changes made to this configuration parameter are immediately effective, a restart is not necessary.

## 6.13.4.5 Diagnosis Information Collected

The Python support script fullSystemInfoDump.py script collects a range of information from your system for diagnosis purposes. It can be triggered from the SAP HANA cockpit, the SAP HANA studio, or directly from the command line.

### i Note

All of the following file types are collected unless the option --rtedump is specified, in which case only runtime environment (RTE) dump files are created and collected.

## Log File

All information about what has been collected is shown as console output and is written to a file named log.txt that is stored in the zip file.

## Trace Files

Each of the following trace files is put into a file with the same name as the trace file. For storage reasons, only the trace files from the last 7 days are collected unabridged. Older trace files are not collected. This behavior can be changed by using option --days or with the options --fromDate and --toDate.

Crashdump files and runtime dump files are always collected unabridged.

- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/compileserver\_alert\_<SAPLOCALHOST>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/compileserver\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/daemon\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/indexserver\_alert\_<SAPLOCALHOST>.trc

- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/indexserver\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/nameserver\_alert\_<SAPLOCALHOST>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/nameserver\_history.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/nameserver\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/preprocessor\_alert\_<SAPLOCALHOST>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/preprocessor\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/statisticsserver\_alert\_<SAPLOCALHOST>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/statisticsserver\_<SAPLOCALHOST>.<...>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/xsengine\_alert\_<SAPLOCALHOST>.trc
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/xsengine\_<SAPLOCALHOST>.<...>.trc

## Configuration Files

All configuration files are collected unabridged and stored in a file with the same name as the .ini file:

- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/attributes.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/compileserver.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/daemon.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/executor.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/extensions.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/filter.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/global.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/indexserver.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/inifiles.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/localclient.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/mimetypemapping.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/nameserver.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/preprocessor.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/scriptserver.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/statisticsserver.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/validmimetypes.ini
- \$DIR\_INSTANCE/<SAPLOCALHOST>/exe/config/xsengine.ini

## Database System Log Files

The following backup files are collected unabridged:

- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/backup.log
- \$DIR\_INSTANCE/<SAPLOCALHOST>/trace/backint.log

## RTE Dump Files

For each index server, an RTE dump file containing information about threads, stack contexts, and so on is created and stored in the file `indexserver_<SAPLOCALHOST>_<PORT>_runtimedump.trc`. These files are stored unabridged.

## Crashdump Information

Crashdump files for services are collected unabridged.

## Performance Trace Files

Performance trace files with the suffix `*.tpt` are collected unabridged.

## Kerberos Files

The following Kerberos files are collected:

- `/etc/krb5.conf`
- `/etc/krb5.keytab`

## System Views

If the collection of system views is not excluded (option `--nosql` specified), all rows of the following system views (with the exceptions mentioned below) are exported into a CSV file with the name of the table.

### i Note

If you are connected to the system database of a multiple-container system, only information from the system views of the system database will be collected. Information from the system views of tenant databases will **not** be collected regardless of this option.

- `SYS.M_CE_CALCSCENARIOS WHERE SCENARIO_NAME LIKE '%_SYS_PLE%'`
- `SYS.M_CONNECTIONS` with `CONNECTION_ID > 0`
- `SYS.M_DATABASE_HISTORY`
- `SYS.M_DEV_ALL_LICENSES`
- `SYS.M_DEV_PLE_SESSIONS_`
- `SYS.M_DEV_PLE_RUNTIME_OBJECTS_`
- `SYS.M_EPM_SESSIONS`

- SYS.M\_INIFILE\_CONTENTS
- SYS.M\_LANDSCAPE\_HOST\_CONFIGURATION
- SYS.M\_RECORD\_LOCKS
- SYS.M\_SERVICE\_STATISTICS
- SYS.M\_SERVICE\_THREADS
- SYS.M\_SYSTEM\_OVERVIEW
- SYS.M\_TABLE\_LOCATIONS
- SYS.M\_TABLE\_LOCKS
- SYS.M\_TABLE\_TRANSACTIONS
- \_SYS\_EPM.versions
- \_SYS\_EPM.TEMPORARY\_CONTAINERS
- \_SYS\_EPM.SAVED\_CONTAINERS
- \_SYS\_STATISTICS.STATISTICS\_ALERT\_INFORMATION
- \_SYS\_STATISTICS.STATISTICS\_ALERT\_LAST\_CHECK\_INFORMATION

### i Note

Only the first 2,000 rows are exported.

- \_SYS\_STATISTICS.STATISTICS\_ALERTS

### i Note

Only the first 2,000 rows are exported.

- \_SYS\_STATISTICS.STATISTICS\_INTERVAL\_INFORMATION
- \_SYS\_STATISTICS.STATISTICS\_LASTVALUES
- \_SYS\_STATISTICS.STATISTICS\_STATE
- \_SYS\_STATISTICS.STATISTICS\_VERSION

The first 2,000 rows of all remaining tables in schema \_SYS\_STATISTICS are exported ordered by column SNAPSHOT\_ID.

## Additional Information Collected If SQL Connection Is Not Available

All available topology information is exported to a file named `topology.txt`. It contains information about the host topology in a tree-like structure. The keys are grouped using brackets while the corresponding values are referenced by the symbol `==>`. For example:

```
[
  ['host']
    ['host', 'ld8521']
      ['host', 'ld8521', 'role']
        ==> worker
      ['host', 'ld8521', 'group']
        ==> default
      ['host', 'ld8521', 'nameserver']
        ['host', 'ld8521', 'nameserver', '30501']
          ['host', 'ld8521', 'nameserver', '30501', 'activated_at']
            ==> 2011-08-09 16:44:02.684
          ['host', 'ld8521', 'nameserver', '30501', 'active']

```

```

==> no
['host', 'ld8521', 'nameserver', '30501', 'info']
['host', 'ld8521', 'nameserver', '30501', 'info', 'cpu_manufacturer']
==> GenuineIntel
['host', 'ld8521', 'nameserver', '30501', 'info',
'topology_mem_type']
==> shared
['host', 'ld8521', 'nameserver', '30501', 'info',
'sap_retrieval_path_devid']
==> 29
['host', 'ld8521', 'nameserver', '30501', 'info', 'build_time']
==> 2011-07-26 17:15:05
['host', 'ld8521', 'nameserver', '30501', 'info', 'net_realhostname']
==> -
['host', 'ld8521', 'nameserver', '30501', 'info', 'build_branch']
==> orange_COR
['host', 'ld8521', 'nameserver', '30501', 'info', 'mem_swap']
==> 34359730176
['host', 'ld8521', 'nameserver', '30501', 'info', 'mem_phys']

```

## 6.13.5 Problem Analysis Using hdbcons

`hdbcons` is a command line tool with which commands can be executed against running processes using a separate communication channel. It is intended for problem analysis by SAP HANA development support.

### ⚠ Caution

Technical expertise is required to use `hdbcons`. To avoid incorrect usage, use `hdbcons` only with the guidance of SAP HANA development support.

`hdbcons` commands can be executed directly in the Administration editor on the *Console* tab. However, it is not visible by default. You can enable the display of the *Console* tab in the preferences of the SAP HANA studio under **SAP HANA > Global Settings**.

To see a list of available commands and display the help for a command, enter the command `help`.

Each command is subject to an individual authorization check. Operating system user (<sid>adm) access is not required.

## 6.13.6 Open a Support Connection

In some support situations, it may be necessary to allow an SAP support engineer to log into your system to analyze the situation.

### Procedure

1. To enable a support user to log on to your system, complete the following tasks:
  - a. Install the SAProuter as described on SAP Support Portal.

- b. Set up a support connection as described in SAP Note 1634848 (*SAP HANA database service connections*).
  - c. Configure a Telnet connection as described in SAP Note 37001 (*Telnet link to customer systems*)
  - d. Configure an SAP HANA database connection as described in SAP Note 1592925 (*SAP HANA studio service connection*).
  - e. Configure a TREX/BIA/HANA service connection as described in SAP Note 1058533 (*TREX/BIA/HANA service connection to customer systems*).
2. Create a database user and grant the MONITORING role.

The MONITORING role allows a database user to open the SAP HANA Administration Console perspective of the SAP HANA studio with read-only access to the system, system views, statistics views, trace files, and so on. However, this role does not provide any privileges for accessing application data. With the MONITORING role, it is also not possible to change the configuration of or start and stop a system. You can grant the MONITORING role to a support engineer if SAP support needs to connect to the system. Depending on the issue to be analyzed, further privileges may be needed to allow sufficient analysis (for example, to access application data or data models).

## 7.1 Monitoring Critical Security Settings in SAP HANA Cockpit

SAP HANA has many configuration settings that allow you to customize your system for your implementation scenario and system environment. Some of these settings are important for the security of your system. Misconfiguration could leave your system vulnerable. The SAP HANA cockpit allows you to monitor several critical security settings at a glance.

### i Note

In addition to using SAP HANA cockpit to monitor critical security settings, refer to *SAP HANA Security Checklists and Recommendations*. This document provides more detailed information as well as recommendations for many settings.

## Related Information

[SAP HANA Security Checklists and Recommendations](#)

## 7.1.1 View Status of Security Settings

You can view the status of critical security settings of the SAP HANA database in the SAP HANA cockpit on the [Database Overview](#) page.

### Prerequisites

- You have the authorization to see security-related information.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, review the status of the security settings.  
For more information, see *Overview of Security Options*.
2. To find more detailed information and functions, drill down.

### Related Information

[Overview of Security Options \[page 806\]](#)

## 7.1.2 Overview of Security Options

The [Database Overview](#) offers information about important security settings, and links to further information and configuration options.

### Cards

## 7.1.3 Network Security Details

You can view important configuration settings related to secure internal SAP HANA communication and secure external SQL client communication on the *View network security communication* page of SAP HANA cockpit.

### Note

For more information about how to configure secure communication, see the *SAP HANA Security Guide*.

General Settings

Field	Description
<a href="#">Cryptographic Provider</a>	The cryptographic service provider being used by the SAP HANA server
<a href="#">Maximum TLS/SSL Protocol Version Accepted</a>	The maximum TLS/SSL protocol version accepted
<a href="#">Minimum TLS/SSL Protocol Version Accepted</a>	The minimum TLS/SSL protocol version accepted

Field	Description
<a href="#">Allowed TLS/SSL Cipher Suites</a>	The encryption algorithms allowed for TLS/SSL connections  This value depends on the cryptographic service provider used. The default values are <a href="#">PFS:HIGH::EC_HIGH:+EC_OPT</a> (CommonCryptoLib) and <a href="#">ALL:!ADH:!LOW:!EXP:!NULL:@STRENGTH</a> (OpenSSL).

#### External JDBC/ODBC Communication

Field	Description
<a href="#">Enforce TLS/SSL for SQL Connections</a>	Indicates whether all clients communicating with the SAP HANA database via the SQL interface are required to use a secured connection  The database refuses SQL connection attempts that don't use TLS/SSL.
<a href="#">Key Store</a>	The key store file that contains the server's private key(s)
<a href="#">Trust Store</a>	The trust store file that contains the server's public certificate(s)
<a href="#">Validate Client Certificates</a>	Indicates whether or not the certificate of the communication partner is validated

#### Internal Communication

Field	Description
<a href="#">TLS/SSL Secured</a>	Indicates whether or not internal communication channels are secured using TLS/SSL  The following values are possible: <ul style="list-style-type: none"> <li>• <a href="#">Disabled</a> (default)</li> <li>• <a href="#">System PKI</a></li> <li>• <a href="#">Manual configuration</a></li> </ul> For more information about these values, see <a href="#">Server-Side TLS/SSL Configuration Properties for Internal Communication</a> in the <a href="#">SAP HANA Security Guide</a> .

Field	Description
<a href="#">Listening On</a>	<p>Indicates the listening interface for internal SAP HANA connections</p> <p>The following values are possible:</p> <ul style="list-style-type: none"> <li> <b>Local network</b>  SAP HANA services listen on the loopback interface only (IP address 127.0.0.1). Only connections from the local machine are possible. This value is only relevant for single-host systems and is the recommended configuration. </li> <li> <b>Global network</b>  In multiple-host systems without a separate internal network, SAP HANA services listen on all available network interfaces. Connections from remote machines are possible. </li> </ul> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>⚠ Caution</b></p> <p>This setting exposes the internal SAP HANA service ports. To avoid a vector for security attacks, it is strongly recommended that you secure SAP HANA internal ports with an additional firewall.</p> </div> <ul style="list-style-type: none"> <li> <b>Internal network</b>  In multiple-host systems with a separate internal network, SAP HANA services listen on a network interface within the allowed network mask. Only connections from machines (hosts) in the internal network are possible. </li> </ul> <p>For more information, see <i>Configuring the Network for Multiple Hosts</i> and <i>Configuring SAP HANA Inter-Service Communication</i> in the <i>SAP HANA Administration Guide</i>.</p>
<a href="#">Internal Host Name Resolution</a>	<p>The IP addresses of the network adapters used for SAP HANA internal communication</p> <p>This is relevant for multiple-host systems with a separate internal network (service communication: <a href="#">Internal network</a>).</p>
<a href="#">Key Store</a>	The key store file that contains the server's private key(s)
<a href="#">Trust Store</a>	The trust store file that contains the server's public certificate(s)
<a href="#">Validate Client Certificates</a>	Indicates whether or not the certificate of the communication partner is validated

## 7.2 Managing SAP HANA Users

Every user who wants to work with the SAP HANA database must have a database user. As a user administrator, you create and provision the required users, as well as perform other tasks related to user administration.

Managing users in SAP HANA includes the following tasks:

- Configuring SAP HANA for the required user authentication mechanisms
- Creating roles and users
- Granting users the roles and privileges they require for their duties
- Other user administration tasks such as resolving authorization or authentication issues, deactivating users, and so on.

### Note

Users of SAP HANA SAP HANA Extended Services (SAP HANA XS) advanced applications are managed independently of the SAP HANA database. Dedicated administration tools are available for managing application users and roles. For more information, see the section on maintaining the SAP HANA XS advanced model runtime in the *SAP HANA Administration Guide*.

[Maintaining the SAP HANA XS Advanced Model Run Time \[page 1786\]](#)

### 7.2.1 Database Users

Every user who wants to work with the SAP HANA database must have a database user.

Database users are created with either the `CREATE USER` or `CREATE RESTRICTED USER` statement, or using SAP HANA cockpit (*User Management*).

## Standard Users

Standard users correspond to users created with the `CREATE USER` statement. By default they can create objects in their own schema and read data in system views. Read access to system views is granted by the `PUBLIC` role, which is granted to every standard user.

## Restricted Users

Restricted users, which are created with the `CREATE RESTRICTED USER` statement, initially have no privileges. Restricted users are intended for provisioning users who access SAP HANA through client applications and who are not intended to have full SQL access via an SQL console. If the privileges required to use the application are encapsulated within an application-specific role, then it is necessary to grant the user only this role. In this way, it can be ensured that users have only those privileges that are essential to their work.

Compared to standard database users, restricted users are initially limited in the following ways:

- They cannot create objects in the database as they are not authorized to create objects in their own database schema.
- They cannot view any data in the database as they are not granted the standard `PUBLIC` role.
- They are only able to connect to the database using HTTP/HTTPS.

For restricted users to connect via ODBC or JDBC, access for client connections must be enabled by executing the SQL statement `ALTER USER <user_name> ENABLE CLIENT CONNECT` or enabling the corresponding option for the user in the SAP HANA cockpit.

For full access to ODBC or JDBC functionality, users also require the predefined role `RESTRICTED_USER_ODBC_ACCESS` or `RESTRICTED_USER_JDBC_ACCESS`.

### i Note

Disabling ODBC/JDBC access for a user, either a restricted user or a standard user, does not affect the user's authorizations or prevent the user from executing SQL commands via channels other than JDBC/ODBC. If the user has been granted SQL privileges (for example, system privileges and object privileges), he or she is still authorized to perform the corresponding database operations using, for example, a HTTP/HTTPS client.

A user administrator can convert a restricted user into a standard user (or vice versa) as follows:

- Granting (or revoking) the `PUBLIC` role  
You can do this by editing the user in the SAP HANA cockpit or with the SQL statement `ALTER USER <username> GRANT | REVOKE ROLE PUBLIC`.
- Granting (or revoking) authorization to create objects in the user's own schema  
You can do this by editing the user in the SAP HANA cockpit or with the SQL statement `ALTER USER <username> GRANT | REVOKE CREATE ANY ON OWN SCHEMA`.
- Enabling (or disabling) full SQL  
You can do this by editing the user in the SAP HANA cockpit or with the SQL statement `ALTER USER <user_name> ENABLE CLIENT CONNECT`.

### i Note

A user is only identified as a restricted user in system view `USERS` if he doesn't have the `PUBLIC` role or authorization for his own schema.

## Predefined Database Users

When an SAP HANA database is created, several database users are created by default. The most important of these is the `SYSTEM` database user, which should be deactivated in production systems.

Several technical database users (that is, database users that do not correspond to real people) are also created, for example, `SYS` and `_SYS_REPO`.

For more information about other predefined database users, see the *SAP HANA Security Guide*.

## Related Information

[Predefined Users](#)

### 7.2.1.1 The `SYSTEM` User

The `SYSTEM` database user is the initial user that is created during the creation of the SAP HANA database.

`SYSTEM` is the database superuser. It has irrevocable system privileges, such as the ability to create other database users, access system tables, and so on.

In the system database, the `SYSTEM` user has additional privileges for managing tenant databases, for example, creating and dropping databases, changing configuration (`*.ini`) files of databases, and performing database-specific data backups.

It is highly recommended that you do not use `SYSTEM` for day-to-day activities in production environments. Instead, use it to create database users with the minimum privilege set required for their duties (for example, user administration, system administration). Then deactivate `SYSTEM`. You may temporarily reactivate the `SYSTEM` user for emergency or bootstrapping tasks.

#### **i** Note

The `SYSTEM` user is not required to update the SAP HANA database system; a lesser-privileged user can be created for this purpose. However, to upgrade SAP support package stacks, SAP enhancement packages and SAP systems using the Software Update Manager (SUM) and to install, migrate, and provision SAP systems using the Software Provisioning Manager (SWPM), the `SYSTEM` user **is required** and needs to be temporarily reactivated for the duration of the upgrade, installation, migration or provisioning.

If the password of `SYSTEM` user of the system database is lost, it can be reset using the operating system user (`<sid>adm` user). The system administrator can reset the `SYSTEM` user password of a tenant database from the system database.

## Related Information

[Deactivate the `SYSTEM` User \[page 815\]](#)

[Create a Lesser-Privileged Database User for Update](#)  
[Resetting the SYSTEM User Password \[page 816\]](#)

## 7.2.1.2 Deactivate the SYSTEM User

As the most powerful database user, `SYSTEM` is not intended for use in production systems. Use it to create lesser privileged users for particular purposes and then deactivate it.

### Prerequisites

You have the system privilege `USER ADMIN`.

### Context

It is highly recommended that you do not use `SYSTEM` for day-to-day activities in production environments. Instead, use it to create database users with the minimum privilege set required for their duties (for example, user administration, system administration). Then deactivate `SYSTEM`. You may temporarily reactivate the `SYSTEM` user for emergency or bootstrapping tasks.

#### **i** Note

The `SYSTEM` user is not required to update the SAP HANA database system; a lesser-privileged user can be created for this purpose. However, to upgrade SAP support package stacks, SAP enhancement packages and SAP systems using the Software Update Manager (SUM) and to install, migrate, and provision SAP systems using the Software Provisioning Manager (SWPM), the `SYSTEM` user **is required** and needs to be temporarily reactivated for the duration of the upgrade, installation, migration or provisioning.

### Procedure

Execute the following statement:

#### Code Syntax

```
ALTER USER SYSTEM DEACTIVATE USER NOW;
```

## Results

The SYSTEM user is deactivated and can no longer **connect** to the SAP HANA database. However, it may appear as though SYSTEM is still active in the system (for example when a procedure that was created by SYSTEM with DEFINER MODE is called).

You can verify that user SYSTEM is in fact deactivated in the USERS system view. For user SYSTEM, check the values in the columns USER\_DEACTIVATED, DEACTIVATION\_TIME, and LAST\_SUCCESSFUL\_CONNECT.

### i Note

You can still use the SYSTEM user as an emergency user even if it has been deactivated. Any user with the system privilege USER ADMIN can reactivate SYSTEM with the statement `ALTER USER SYSTEM ACTIVATE USER NOW`. To ensure that an administrator does not do this surreptitiously, it is recommended that you create an audit policy monitoring ALTER USER statements. Also change the password of the SYSTEM user after reactivating it.

### 7.2.1.3 Resetting the SYSTEM User Password

The system database and all tenant databases each have their own SYSTEM user. The system administrator can reset the password of any SYSTEM user if it has been irretrievably lost.

## Related Information

[Reset the SYSTEM User Password in the System Database \[page 817\]](#)

[Reset the SYSTEM User Password in a Tenant Database \[page 820\]](#)

## 7.2.1.3.1 Reset the SYSTEM User Password in the System Database

A database administrator has a number of options to reset the password for the SYSTEM user in the system database.

### Prerequisites

Situation	Prerequisite
If you <b>can</b> log on as the SYSTEM user	Logon credentials for the SYSTEM user in the system database
If you <b>cannot</b> log on as the SYSTEM user	<ul style="list-style-type: none"><li>The system privilege USER ADMIN for a different user</li><li>To reset the SYSTEM user password in emergency mode, you need the credentials of the operating system administrator (&lt;sid&gt;adm).</li></ul>

### Context

If you <b>can</b> log on as the SYSTEM user	<ul style="list-style-type: none"><li>Change the password using SAP HANA cockpit. Log onto the system database, and choose <a href="#">User &amp; Role Management</a> &gt; <a href="#">Manage Users</a>.</li><li>Log onto the system database, and execute the ALTER USER SQL statement: <pre>ALTER USER SYSTEM PASSWORD &lt;new_password&gt;</pre></li></ul>
If you <b>cannot</b> log on as the SYSTEM user	<p>If the password of the SYSTEM user has been irretrievably lost, you cannot log on to the database as the SYSTEM user.</p> <p>A user with the system privilege USER ADMIN can set a new password for the SYSTEM user.</p> <p>Alternatively, you can reset the password as the operating system administrator by starting the name server in emergency mode. The steps to do this are described below.</p>

## Procedure

To reset the SYSTEM user password in emergency mode:

1. Log on to the server on which the name server of the system database is running as the operating system user (that is, `<sid>adm` user).
2. Open a command line interface.
3. Shut down the instance by executing the following command:

```
/usr/sap/<SID>/HDB<instance>/exe/sapcontrol -nr <instance> -function StopSystem  
HDB
```

4. In a new session, start the name server of the system database by executing the following commands:

- `/usr/sap/<SID>/HDB<instance>/hdbenv.sh`
- `/usr/sap/<SID>/HDB<instance>/exe/hdbnameserver -resetUserSystem`

After some start-up notifications, the prompt `resetting of user SYSTEM - new password` appears, followed by additional notifications:

```

: /usr/sap/ / > /usr/sap/ C/ /exe/hdbnameserver -resetUserSystem

HDB          HDBSettings.sh  hdbenv.csh      work/
HDBAdmin.sh  backup/         hdbenv.sh       xterms
HDBSettings.csh exe/           /

HDB          HDBSettings.sh  hdbenv.csh      work/
HDBAdmin.sh  backup/         hdbenv.sh       xterms
HDBSettings.csh exe/           /
NewPassword1
new pw accepted.
(Re)Activating user SYSTEM...
done

```

#### Reset SYSTEM User Password (System Database)

5. After the last notification appears, enter a new password for the SYSTEM user.  
You must enter a password that complies with the password policy configured for the system.  
The password for the SYSTEM user of the system database is reset and the name server stops.
6. In a new session, start the instance by executing the following command:  

```

/usr/sap/<SID>/HDB<instance>/exe/sapcontrol -nr <instance> -function StartSystem
HDB

```

## Results

- The password of the SYSTEM user in the system database is reset. The next time you log on with this user, you have to change the password in accordance with the password policy of the system database.
- If you previously deactivated the SYSTEM user, it is now also reactivated. This means you will need to deactivate it again.

### 7.2.1.3.2 Reset the SYSTEM User Password in a Tenant Database

A database administrator has a number of options to reset the password for the SYSTEM user in a tenant database.

## Prerequisites

Situation	Prerequisite
If you <b>can</b> log on as the SYSTEM user	Logon credentials for the SYSTEM user in the tenant database
If you <b>cannot</b> log on to the tenant database as the SYSTEM user	<ul style="list-style-type: none"><li>• The system privilege USER ADMIN for a different user in the tenant database</li><li>• You are connected to the system database and have the system privilege DATABASE ADMIN.</li></ul>

## Context

- |   |   |
|---|---|
| If you <b>can</b> log on as the SYSTEM user | <ul style="list-style-type: none"><li>• Change the password using SAP HANA cockpit. Log onto the tenant database, and choose <a href="#">User &amp; Role Management</a> &gt; <a href="#">Manage Users</a> .</li><li>• Log onto the tenant database, and execute the SQL statement ALTER USER:<br/>ALTER USER SYSTEM PASSWORD<br/>&lt;new_password&gt;</li></ul> |
|---|---|

If you **cannot** log on as the SYSTEM user

If the password of the SYSTEM user has been irretrievably lost, you cannot log on to the tenant database as the SYSTEM user.

A user with the system privilege USER ADMIN can set a new password for the SYSTEM user from the system database.

Alternatively, you can reset the password using the SQL statement ALTER DATABASE from the system database. The steps to do this are described below.

---

## Procedure

To reset the SYSTEM user password for a tenant database:

1. Stop the tenant database.

Execute the following statement:

```
ALTER SYSTEM STOP DATABASE <database_name>
```

2. Create a new password for the SYSTEM user by executing the following statement:

```
ALTER DATABASE <database_name> SYSTEM USER PASSWORD <new_password>
```

### **i** Note

The password must adhere to the password policy of the system database.

The password for the SYSTEM user is reset and the tenant database is started.

## Results

- The password of the SYSTEM user in the tenant database is reset. The next time you log on with this user, you have to change the password in accordance with the password policy of the tenant database.
- If the SYSTEM user was previously deactivated, locked, or expired, it is now activated again. We recommend that you deactivate it.
- If auditing is enabled, the password change is automatically logged in both the system and tenant database audit trails.

[Reset the SYSTEM Password of a Tenant Using the Cockpit \[page 258\]](#)

## 7.2.2 Operating System User <sid>adm

The <sid>adm user is not a database user but a user at the operating system level. Also referred to as the operating system administrator, this user has unlimited access to all local resources related to SAP systems.

As part of the installation process, an external operating system user (<sid>adm, for example, sp1adm or xyzadm) is created.

This operating system user exists to provide an operating system context. From the operating system perspective, the operating system administrator is the user that owns all SAP HANA files and all related operating system processes. Certain administration operations require the operating system user's credentials, for example, starting or stopping the system.

If the system is configured for high isolation, additional OS users must be created for each tenant database. As a result, the processes of individual tenant databases run under dedicated OS users belonging to dedicated OS groups, and not under <sid>adm. Database-specific data on the file system is subsequently protected using standard OS file and directory permissions.

### Related Information

[Database Isolation \[page 216\]](#)

## 7.2.3 User Authentication and Single Sign-On

The identity of database users accessing SAP HANA is verified through a process called authentication. SAP HANA supports several authentication mechanisms that can be used for the integration of SAP HANA into single sign-on environments (SSO). The mechanisms used to authenticate individual users are specified as part of the user definition.

### i Note

For JDBC and ODBC client connections, user passwords are always transmitted in encrypted hashed form during the user authentication process, never in plain text. For HTTP connections via SAP HANA XS classic, HTTPS must be configured. In SSO environments, we recommend using encrypted communication channels for **all** client connections.

## 7.2.3.1 User Authentication Mechanisms

SAP HANA supports several authentication mechanisms. Mechanisms that are not required can be disabled.

### Supported Authentication Mechanisms

Mechanism	Description	Can Be Used for SSO
SAP HANA user name and password	Users accessing the SAP HANA database authenticate themselves by entering their database user name and their local SAP HANA password.	No
Kerberos, SPNEGO	<p>A Kerberos authentication provider can be used to authenticate users accessing SAP HANA in the following ways:</p> <ul style="list-style-type: none"><li>• Directly from ODBC and JDBC database clients within a network (for example, the SAP HANA studio)</li><li>• Indirectly from front-end applications such as SAP BusinessObjects applications and other SAP HANA databases using Kerberos delegation</li><li>• Via HTTP/HTTPS access by means of SAP HANA Extended Services (SAP HANA XS), advanced model and classic model</li></ul> <p>In this case, Kerberos authentication is enabled with Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO).</p>	Yes
Security assertion markup language (SAML)	<p>A SAML bearer assertion can be used to authenticate users accessing SAP HANA directly from ODBC/JDBC database clients.</p> <p>SAP HANA can act as a service provider to authenticate users accessing via HTTP/HTTPS by means of SAP HANA XS classic.</p>	Yes

#### i Note

A user who connects to the database using an external authentication provider must also have a database user known to the database. The external identity is mapped to the identity of an internal database user.

#### i Note

A user who connects to the database using an external authentication provider must also have a database user known to the database. The external identity is mapped to the identity of an internal database user.

Mechanism	Description	Can Be Used for SSO
Logon and assertion tickets	<p>Users can be authenticated by SAP logon or assertion tickets issued to them when they log on to an SAP system that is configured to create tickets (for example, the SAP Web Application Server or Portal).</p> <p><b>i Note</b> To implement logon/assertion tickets, the user specified in the logon/assertion ticket must already exist in SAP HANA; there is no support for user mapping.</p>	Yes
X.509 client certificates	<p>Users can be authenticated by client certificates signed by a trusted Certification Authority (CA) for:</p> <ul style="list-style-type: none"> <li>• HTTP/HTTPS access by means of SAP HANA XS, advanced model and classic model</li> <li>• JDBC/ODBC client access</li> </ul> <p><b>i Note</b> To implement X.509 client certificates, the user specified in the certificate must already exist in SAP HANA; there is no support for user mapping.</p>	Yes
JSON Web Token (JWT)	<p>A JSON Web Token can be used to authenticate users accessing SAP HANA directly from ODBC/JDBC database clients or indirectly through SAP HANA extended application services, advanced model (SAP HANA XS, advanced).</p> <p><b>i Note</b> A user who connects to the database using an external authentication provider must also have a database user known to the database. The external identity is mapped to the identity of an internal database user.</p>	Yes
LDAP	<p>A password stored in an LDAP directory server can be used to authenticate users accessing SAP HANA directly from ODBC/JDBC database clients, if authentication using users' local SAP HANA authentication has been disabled.</p> <p><b>i Note</b> A user who connects to the database using an external authentication provider must also have a database user known to the database. The external identity and the database user name are the same. If the LDAP provider is enabled to create database users in SAP HANA, the required user is created automatically if it doesn't exist.</p>	No

Mechanism	Description	Can Be Used for SSO
Session cookies	Session cookies are not technically an authentication mechanism. However, they reconnect users who have already been authenticated by Kerberos, SAML or JWT and extend the validity period of logon and assertion tickets.	Yes

### Note

For ODBC/JDBC access, by default, the SAP HANA database and the client interfaces choose different authentication methods based on the credentials supplied. You can explicitly limit the authentication methods used by providing a set of allowed authentication methods in the `authenticationMethods` parameter as part of the connection string. For more information, see the *SAP HANA Client Interface Programming Reference*.

## Isolated Single Sign-On for Tenant Databases

Separate, database-specific authentication is possible for every certificate-based authentication mechanism since it is possible to create different certificate collections for individual purposes directly in every database, and every database can have its own key pair and public key certificate.

For SAML assertions, X.509 certificates (for HTTP access via SAP HANA XS classic model), and logon tickets, it is also possible to use certificate collections (or PSEs) located on the file system. It is still possible to configure different trust and key stores for every database in the `global.ini` file. However, bear the following points in mind:

- If different trust and key stores are not explicitly configured for tenant databases, the same ones will be used for all external communication channels (including HTTP) for all databases.

### Caution

If you have configured in tenant databases or the system database single sign-on mechanisms that rely on trust stores located in the file system (such as SAP logon and assertion tickets or SAML) and the trust stores are shared, users of one tenant database may be able to log on to other databases in the system.

- By default, only the system administrator can configure separate trust and key stores for tenant databases by changing the relevant properties in the `global.ini` file. This is because tenant database administrators are prevented from changing any communication properties. They are in the default configuration change blocklist (`multidb.ini`).

For more information about certificate collections in the database and PSEs in the file system, see the section on certificate management.

For Kerberos-based authentication, a per-database configuration is not possible – databases users in all databases must be mapped to users in the same Key Distribution Center.

## Disabling Authentication Mechanisms

By default all supported authentication mechanisms are enabled, but it is possible and recommended to disable those that are not used in your environment. You do this by configuring the parameter `[authentication] authentication_methods` in the `global.ini` configuration file. The value of this parameter specifies all enabled methods as a comma-separated list.

The default value is

`pbkdf2,password,kerberos,spnego,saml,saplogon,x509xs,jwt,sessioncookie,x509,ldap`.

### i Note

`pbkdf2` refers to password authentication using passwords hashed with PBKDF2 (Password-Based Key Derivation Function 2), while `password` refers to password authentication using passwords hashed with secure hash algorithm SHA-256. Even if `password` is listed as a supported authentication method here, a user will not be able to log on with a SHA-256 hashed password if this hash method has been disabled with the parameter `[authentication] password_hash_methods`.

### i Note

If you are using SAP HANA dynamic tiering, it is not possible to disable logon and assertion tickets (`saplogon`) as an authentication mechanism.

Changes to the parameter `authentication_methods` are audited by default if auditing is enabled.

## 7.2.3.2 Configuring SAP HANA for User Authentication and Single-Sign On

You can integrate SAP HANA into the user authentication infrastructure of your system landscape. To do so, you must configure SAP HANA for the required mechanisms.

SAP HANA supports several authentication mechanisms, several of which can be used for the integration of SAP HANA into single sign-on environments (SSO). Depending on which mechanisms you are implementing, you must configure SAP HANA accordingly.

## Configuration of Authentication of SAP HANA XS Classic Applications

To configure security-related aspects of SAP HANA XS classic applications, including SSO, use the SAP HANA XS Classic Administration Tools. For more information, see the section on maintaining the SAP HANA XS classic model run-time in the *SAP HANA Administration Guide*.

[Maintaining Single Sign-On for SAP HANA XS Applications \(Classic\) \[page 1722\]](#)

[Configuring LDAP Integration \[page 943\]](#)

### 7.2.3.2.1 Configure the Database Password Policy and Password Blacklist

The passwords of database users are subject to certain rules. These are defined in the password policy and the password exclude list. You can change the default password policy of the database and maintain entries in the password exclude list in line with your organization's security requirements.

#### Context

The password policy of the database is defined by parameters in the `password_policy` section of the `indexserver.ini` configuration file for tenant databases and the `nameserver.ini` configuration file for the system database. The database password policy is valid for all database users unless the user is in a user group with its own dedicated password policy. For more information about user group-specific password policies, see the section on user groups in the *SAP HANA Security Guide*.

#### → Tip

To determine which password policy a user is currently subject to, query the system view `M_EFFECTIVE_PASSWORD_POLICY`.

In addition to configuring the password policy parameters, you can also add words or partial words to the password exclude list. The password exclude list is implemented with the database table `_SYS_PASSWORD_BLACKLIST` in the schema `_SYS_SECURITY`. This table is empty when the database is first created.

You can change the database password policy and edit the password blacklist using the *Password Policy and Blacklist* app of the SAP HANA cockpit or the *Security* editor of the SAP HANA studio.

## Related Information

[Configure the Database Password Policy and Blacklist in SAP HANA Cockpit \[page 828\]](#)

[Password Policy Configuration Options \[page 830\]](#)

[User Groups](#)

### 7.2.3.2.1.1 Configure the Database Password Policy and Blacklist in SAP HANA Cockpit

Configure the password policy and password blacklist using the SAP HANA cockpit.

#### Prerequisites

- You have the system privilege INIFILE ADMIN.
- You have the object privileges SELECT, INSERT, and DELETE for the `_SYS_PASSWORD_BLACKLIST` table in the `_SYS_SECURITY` schema.

#### Procedure

1. In the SAP HANA cockpit, navigate to the *Overview* page and choose the *Authentication* block.  
The *Password Policy and Blacklist* page opens.
2. Click *Edit* in the footer bar.
3. In the *Password Policy* area, configure the options in line with your security requirements.  
All options have a default value. For more information about the individual parameters and their default values, see *Password Policy Configuration Options*.
4. In the *Password Exclude List* area, add the words or partial words that you want to prohibit in passwords.  
The following configuration options are available:

Option	Description
<b>Contained in Password</b>	If you select this option, passwords that contain the excluded word are excluded. If you do not select this option, only passwords that match the specified word exactly are excluded.
<b>Case-Sensitive</b>	If you select this option, the specified word is case sensitive.

#### ❁ Example

If you add the words **SAP**, **my\_sap\_pwd**, and **sap\_password** to the exclude list and select the *Contained in Password* checkbox, then passwords containing "SAP", "my\_sap\_pwd", and "sap\_password" are not allowed, regardless of how the password policy is configured.

5. Click [Save](#) to save the password policy and password exclude list.

## Results

The passwords of database users must be created and changed in line with the defined policy.

## Related Information

[Password Policy Configuration Options \[page 830\]](#)

### 7.2.3.2.1.2 Configure the Database Password Policy and Blacklist in SAP HANA Studio

Configure the password policy and password blacklist using the SAP HANA studio.

## Prerequisites

- You have the system privilege INIFILE ADMIN.
- You have the object privileges SELECT, INSERT, and DELETE for the `_SYS_PASSWORD_BLACKLIST` table (`_SYS_SECURITY`).

## Procedure

1. Open the SAP HANA studio.
2. Open the [Security](#) editor of the database whose password policy you want to configure and choose the [Password Policy](#) tab.
3. In the [Password Policy](#) area, configure the options in line with your security requirements.  
All options have a default value. For more information about the individual parameters and their default values, see [Password Policy Configuration Options](#).
4. In the [Password Blacklist](#) area, add words or partial words that you want to prohibit in passwords by choosing the  ([Add](#)) button and entering the word.  
The following configuration options are available:

Option	Description
<b>Contained in Password</b>	If you select this option, passwords that contain the excluded word are excluded. If you do not select this option, only passwords that match the specified word exactly are excluded.
<b>Case-Sensitive</b>	If you select this option, the specified word is case sensitive.

#### ❖ Example

If you add the words **SAP**, **my\_sap\_pwd**, and **sap\_password** to the exclude list and select the *Contained in Password* checkbox, then passwords containing "SAP", "my\_sap\_pwd", and "sap\_password" are not allowed, regardless of how the password policy is configured.

5. Choose the  (*Deploy*) button.

## Results

The passwords of database users must be created and changed in line with the defined policy.

## Related Information

[Password Policy Configuration Options \[page 830\]](#)

### 7.2.3.2.1.3 Password Policy Configuration Options

The password policy is defined by parameters in the `password_policy` section of the `indexserver.ini` configuration file (tenant databases) or `nameserver.ini` configuration file (system database). Password policy parameters may also be individually configured in the definition of a user group.

The following sections describe these parameters, which correspond to the configuration options available in the SAP HANA cockpit.

- [Minimum Password Length \[page 831\]](#)
- [Lowercase Letters/Uppercase Letters/Numerical Digits/Special Characters Required \[page 831\]](#)
- [Password Change Required on First Logon \[page 832\]](#)
- [Number of Last Used Passwords That Cannot Be Reused \[page 833\]](#)
- [Number of Allowed Failed Logon Attempts \[page 834\]](#)
- [User Lock Time \[page 835\]](#)
- [Minimum Password Lifetime \[page 835\]](#)
- [Maximum Password Lifetime \[page 835\]](#)
- [Lifetime of Initial Password \[page 836\]](#)
- [Maximum Duration of User Inactivity \[page 836\]](#)
- [Notification of Password Expiration \[page 837\]](#)

- [Exempt SYSTEM User from Locking \[page 837\]](#)
- [Detailed Error Information on Failed Logon \[page 838\]](#)

## Minimum Password Length

The minimum number of characters that the password must contain

<b>Parameter</b>	<code>minimal_password_length</code>
<b>Default Value</b>	8 (characters)
<b>Additional Information</b>	You must enter a value between 6 and 64.
<b>UI Label</b>	<i>Minimum Password Length</i>

## Lowercase Letters/Uppercase Letters/Numerical Digits/ Special Characters Required

The character types that the password must contain and how many

<b>Parameter</b>	<code>password_layout</code>
<b>Default Value</b>	Aa1, that is, at least one uppercase letter, at least one number, and at least one lowercase letter

## Additional Information

The following character types are possible:

- Lowercase letter (a-z)
- Uppercase letter (A-Z)
- Numerical digits (0-9)
- Special characters (underscore (\_), hyphen (-), and so on)  
Any character that is not an uppercase letter, a lowercase letter, or a numerical digit is considered a special character.

The following formats are supported for passwords:

```
<password> ::= {  
  <letter> [ { <letter_or_digit> | # | $ } [...] ]  
  | <digit> [ <letter_or_digit> [...] ]  
  | <any_quoted_string> }
```

If configuring this option in the `indexserver.ini` file using the `password_layout` parameter, you can use any specific letters, numbers and special characters, and the characters can be in any order. For example, the default value example could also be represented by **a1A**, **hQ5**, or **9fG**. To enforce the use of at least one of each character type including special characters, you specify **A1a\_** or **2Bg?**. To enforce the use of a specific number of a particular character type, specify the character type multiple times. For example, if passwords must contain at least 3 digits, you could specify the layout with **a123A** or **789fG**.

### Note

Passwords containing special characters other than underscore must be enclosed in double quotes ("). The SAP HANA studio does this automatically. When a password is enclosed in double quotes ("), any Unicode characters may be used.

### Caution

The use of passwords enclosed in double quotes (") may cause logon issues depending on the client used. The SAP HANA studio and `hdbsql` support passwords enclosed in double quotes (").

---

## UI Labels

*Lowercase Letters/Uppercase Letters/Numerical Digits/Special Characters Required*

---

## Password Change Required on First Logon

Defines whether users have to change their initial passwords immediately the first time they log on

Parameter	<code>force_first_password_change</code>
-----------	--

Default Value	True
---------------	------

---

### Additional Information

If this parameter is set to **true**, users can still log on with the initial password but every action they try to perform will return the error message that they must change their password.

If this parameter is set to **false**, users are not forced to change their initial password immediately the first time they log on. However, if a user does not change the password before the number of days specified in the parameter `maximum_unused_initial_password_lifetime`, then the password still expires and must be reset by a user administrator.

A user administrator (that is, a user with the system privilege USER ADMIN) can force a user to change his or her password at any time with the following SQL statement: `ALTER USER <user_name> FORCE PASSWORD CHANGE`

A user administrator can override this password policy setting for individual users (for example, technical users) with the following SQL statement:

- `CREATE USER <user_name> PASSWORD <password> [NO FORCE_FIRST_PASSWORD_CHANGE]`
- `ALTER USER <user_name> PASSWORD <password> [NO FORCE_FIRST_PASSWORD_CHANGE]`

#### i Note

This parameter is only valid for users connecting with their SAP HANA database user name and password. It is not valid for connections established through other authentication mechanisms.

---

UI Label

*Password Change Required on First Logon*

---

## Number of Last Used Passwords That Cannot Be Reused

The number of last used passwords that the user is not allowed to reuse when changing his or her current password

Parameter	<code>last_used_passwords</code>
Default Value	5 (previous passwords)
Additional Information	If you enter the value <b>0</b> , the user can reuse his or her old password.
UI Label	<i>Number of Last Used Passwords That Cannot Be Reused</i>

---

## Number of Allowed Failed Logon Attempts

The maximum number of failed logon attempts that are permitted; the user is locked as soon as this number is reached

<b>Parameter</b>	<code>maximum_invalid_connect_attempts</code>
<b>Default Value</b>	6 (failed logon attempts)
<b>Additional Information</b>	<p>You must enter a value of at least <b>1</b>.</p> <p>As long as the number of failed logon attempts does not exceed the permitted number of failed attempts, the timestamp of the last failed attempt is recorded in column <code>LAST_INVALID_CONNECT_ATTEMPT</code> of system view <code>SYS.USERS</code>. Once the user is locked (after having exceeded the permitted number of failed logon attempts), this timestamp is no longer updated. The timestamp is used as the starting time for calculating how long the user is locked (<code>password_lock_time</code>).</p> <p>A user administrator can reset the number of invalid logon attempts with the following SQL statement: <code>ALTER USER &lt;user_name&gt; RESET CONNECT ATTEMPTS</code></p> <p>The first time a user logs on successfully after an invalid logon attempt, an entry is made in the <code>INVALID_CONNECT_ATTEMPTS</code> system view containing the following information:</p> <ul style="list-style-type: none"><li>• The number of invalid logon attempts since the last successful logon</li><li>• The time of the last successful logon</li></ul> <p>A user administrator can delete information about invalid logon attempts with the following SQL statement: <code>ALTER USER &lt;user_name&gt; DROP CONNECT ATTEMPTS</code></p> <div data-bbox="603 1330 1394 1518"><p><b>→ Recommendation</b></p><p>Create an audit policy to log activity in the <code>INVALID_CONNECT_ATTEMPTS</code> system view. For example, create an audit policy that logs data query and manipulation statements executed on this view.</p></div> <div data-bbox="603 1532 1394 1675"><p><b>i Note</b></p><p>If <code>password_lock_for_system_user</code> is set to <b>false</b>, the <code>SYSTEM</code> user will not be locked regardless of the number of failed logon attempts.</p></div>
<b>UI Label</b>	<i>Number of Allowed Failed Logon Attempts</i>

## User Lock Time

The number of minutes for which a user is locked after the maximum number of failed logon attempts

<b>Parameter</b>	password_lock_time
<b>Default Value</b>	1440 (minutes)
<b>Additional Information</b>	<p>If you enter the value <b>0</b>, the user is unlocked immediately. This disables the functionality of parameter <code>maximum_invalid_connect_attempts</code>.</p> <p>The value in column <code>LAST_INVALID_CONNECT_ATTEMPT</code> of system view <code>SYS.USERS</code> is used as the start time for calculating how long the user is locked.</p> <p>A user administrator can reset the number of invalid logon attempts and reactivate the user account with the following SQL statement: <code>ALTER USER &lt;user_name&gt; RESET CONNECT ATTEMPTS</code>. It is also possible to reactivate the user in the user editor of the SAP HANA studio.</p> <p>To lock a user indefinitely, enter the value <b>-1</b>. On the <a href="#">Password Policy and Exclude List</a> page of the SAP HANA cockpit, this corresponds to selecting the <a href="#">Lock User Indefinitely</a> checkbox. The user remains locked until reactivated by a user administrator as described above.</p>
<b>UI Label</b>	<a href="#">User Lock Time</a>

## Minimum Password Lifetime

The minimum number of days that must elapse before a user can change his or her password

<b>Parameter</b>	minimum_password_lifetime
<b>Default Value</b>	1 (day)
<b>Additional Information</b>	If you enter the value <b>0</b> , the password has no minimum lifetime.
<b>UI Label</b>	<a href="#">Minimum Password Lifetime</a>

## Maximum Password Lifetime

The number of days after which a user's password expires

<b>Parameter</b>	maximum_password_lifetime
<b>Default Value</b>	182 (days)

**Additional Information**

You must enter a value of at least **1**.

A user administrator can exclude users from this password check with the following SQL statement: `ALTER USER <user_name> DISABLE PASSWORD LIFETIME`. However, this is recommended for technical users only, not database users that correspond to real people.

A user administrator can re-enable the password lifetime check for a user with the following SQL statement: `ALTER USER <user_name> ENABLE PASSWORD LIFETIME`.

---

<b>UI Label</b>	<i>Maximum Password Lifetime</i>
-----------------	----------------------------------

---

## Lifetime of Initial Password

The number of days for which the initial password or any password set by a user administrator for a user is valid

<b>Parameter</b>	<code>maximum_unused_initial_password_lifetime</code>
------------------	---

<b>Default Value</b>	7 (days)
----------------------	----------

**Additional Information**

You must enter a value of at least **1**.

If a user has not logged on using the initial password within the given period of time, the user will be deactivated until their password is reset.

### Note

In SAP HANA 1.0 SPS 12 and earlier, this parameter was misspelled as `maximum_unused_inital_password_lifetime`. If this parameter had a user-specified value before upgrade, this value will be set as the value of the parameter `maximum_unused_initial_password_lifetime`. The misspelled parameter is unset and disappears from the custom configuration file.

---

<b>UI Label</b>	<i>Lifetime of Initial Password</i>
-----------------	-------------------------------------

---

## Maximum Duration of User Inactivity

The number of days after which a password expires if the user has not logged on

<b>Parameter</b>	<code>maximum_unused_productive_password_lifetime</code>
------------------	--

<b>Default Value</b>	365 (days)
----------------------	------------

<b>Additional Information</b>	You must enter a value of at least <b>1</b> .  If a user has not logged on within the given period of time using any authentication method, the user will be deactivated until their password is reset.
<b>UI Label</b>	<i>Maximum Duration of User Inactivity</i>

## Notification of Password Expiration

The number of days before a password is due to expire that the user receives notification

<b>Parameter</b>	password_expire_warning_time
<b>Default Value</b>	14 (days)
<b>Additional Information</b>	Notification is transmitted via the database client (ODBC or JDBC) and it is up to the client application to provide this information to the user.  If you enter the value <b>0</b> , the user does not receive notification that his or her password is due to expire.  The system also monitors when user passwords are due to expire and issues a medium priority alert (check 62). This may be useful for technical database users since password expiration results in the user being locked, which may affect application availability. It is recommended that you disable the password lifetime check of technical users so that their password never expires ( <code>ALTER USER &lt;technical_username&gt; DISABLE PASSWORD LIFETIME</code> ).
<b>UI Label</b>	<i>Notification of Password Expiration</i>

## Exempt SYSTEM User from Locking

Indicates whether or not the user SYSTEM is locked for the specified lock time (password\_lock\_time) after the maximum number of failed logon attempts (maximum\_invalid\_connect\_attempts)

<b>Parameter</b>	password_lock_for_system_user
<b>Default Value</b>	true
<b>Additional Information</b>	This parameter cannot be configured for a user group.
<b>UI Label</b>	<i>Exempt SYSTEM User from Locking</i>

## Detailed Error Information on Failed Logon

Indicates the detail level of error information returned when a logon attempt fails

<b>Parameter</b>	<code>detailed_error_on_connect</code>
<b>Default Value</b>	false
<b>Additional Information</b>	<p>If set to <b>false</b>, only the information <code>authentication failed</code> is returned.</p> <p>If set to <b>true</b>, the specific reason for failed logon is returned:</p> <ul style="list-style-type: none"><li>• Invalid user or password</li><li>• User is locked</li><li>• Connect try is outside validity period</li><li>• User is deactivated</li></ul>
<b>UI Label</b>	<i>Detailed Error Information on Failed Logon</i>

### Related Information

[Configure the Database Password Policy and Blacklist in SAP HANA Studio \[page 829\]](#)

[Create an Audit Policy \[page 969\]](#)

## 7.2.3.2.2 Configure a Password Policy for a User Group

If the users of a user group have different password requirements, you can configure group-specific values for the individual options of the password policy on the *User Groups* page of the SAP HANA cockpit.

### Prerequisites

- You have the object privilege `USERGROUP OPERATOR` on the user group. If the user group is configured for shared administration (administration mode: *Group and user administrators*), system privilege `USER ADMIN` is also sufficient.
- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

The users of different user groups may have different requirements when it comes to passwords. For example, you may want the passwords of technical users to be very complex.

You configure group-specific values only for the required password policy options. You don't have to configure a value for all options. For those options without a group-specific value, the value from database password policy is simply copied. When you save and enable the password policy, it applies to users in the group until you enable the user group policy.

## Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, choose the [User Group Management](#) link.
2. Select the relevant user group.
3. In the [Password Policy](#) area, choose [Configure](#) and configure the options in line with the user group's requirements.

The initial values for all options are copied from the password policy configured for the database. If you do not configure a group-specific value for a particular parameter, the value from database password policy applies. Choosing [Reset Default](#) reapplies all values from the database password policy.

For more information about the password policy options, see [Password Policy Details](#).

4. To enable the group password policy, choose [Save and Enable](#).

## Results

The user group password policy is configured and effective for users in the user group.

### → Tip

To determine which password policy a user is currently subject to, query the system view `M_EFFECTIVE_PASSWORD_POLICY`.

## Related Information

[User Groups](#)

[Password Policy Details](#)

[M\\_EFFECTIVE\\_PASSWORD\\_POLICY System View](#)

[Create a User Group \[page 906\]](#)

## 7.2.3.2.3 Configure Kerberos for SAP HANA Database Hosts

If you are implementing Kerberos-based user authentication, you must configure Kerberos on the authentication server.

### Prerequisites

To allow users to log on to the SAP HANA database using Kerberos authentication, you have installed MIT Kerberos client libraries on the host(s) of the SAP HANA database.

### Context

SAP HANA supports Kerberos version 5 for single sign-on based on Active Directory (Microsoft Windows Server) or Kerberos authentication servers. For HTTP access via SAP HANA Extended Services (SAP HANA XS), advanced or classic model, Kerberos authentication is enabled with Simple and Protected GSSAPI Negotiation Mechanism (SPNEGO).

Once Kerberos client libraries have been installed, you must configure Kerberos on the authentication server by performing the following logical steps:

1. Register service principal names (SPN) for each host in the SAP HANA system using the following syntax:  
`<service>/<host domain name>@<Kerberos realm name>`, where
  - `<service>` is either **hdb** (for Kerberos via ODBC and JDBC) or **HTTP** (for SPNEGO via HTTP/SAP HANA XS)
  - `<host domain name>` is the fully qualified domain name of the host  
If the service is HTTP, you must register one SPN for each alias of the host name as well.
  - `<Kerberos realm name>` (Kerberos terminology) is identical to domain name in Active Directory terminology

This results in the generation of a service key table (keytab) for each host. This keytab contains the encrypted key for the host in question.

2. Export the keytab(s) to files.
3. Import each keytab file into the Kerberos installation on the respective host.

### Procedure

The concrete steps to be performed on the authentication server depend on whether you are using Kerberos or Active Directory as follows:

1. Register the SPNs.

### **i** Note

In Active Directory, before a SPN can be registered, you must create a plain user account that acts as the server principal on the domain controller. Afterward, you must map the SPN to the user account using a separate command.

2. Export the keytab(s) to files using a command line tool shipped with the authentication server.  
This is applicable for both Kerberos and Active Directory.
3. Import the keytab files.  
The files are transported to the file system path on the SAP HANA database hosts in line with how the Kerberos client is configured.

## Results

You can now map the users stored in the Kerberos Key Distribution Center (KDC) to database users in SAP HANA database. You can do this when you create database users. Alternatively, if database users already exist, you can change their authentication details.

### → Remember

A per-database configuration is not possible – databases users in all databases must be mapped to users in the same KDC.

For more information about how to set up SSO with SAP HANA using Kerberos and Microsoft Active Directory, see SAP Note 1837331.

## 7.2.3.2.4 Add a SAML Identity Provider in SAP HANA Studio

If you are implementing Security Assertion Markup Language (SAML) to authenticate users accessing SAP HANA via the SQL interface directly (that is using JDBC and ODBC clients), you must add the SAML identity providers for the required users. You can do this using the SAP HANA studio.

### Prerequisites

- You have created a certificate collection with the purpose **SAML** in the database and have imported the X.509 certificates that will be used to sign the SAML assertions from the identity provider. Ensure that the entire certificate chain of the X.509 certificate is available.

#### Caution

We recommend creating certificate collections for individual purposes in the database directly, rather than using trust stores (PSE) in the file system. By default, the same PSE in the file system is shared by all databases for all external communication channels (including HTTP) and certificate-based authentication. Different PSEs must be explicitly configured for tenant databases.

- You have the system privilege USER ADMIN.

### Procedure

#### Note

While you can configure SAML providers for ODBC/JDBC-based SAML authentication using the SAP HANA cockpit, SAP HANA studio or SQL, always use the SAP HANA XS Administration Tool to configure SAML providers that will be used for HTTP access via the XS classic server.

- In the *Security* editor, choose the *SAML Identity Providers* tab.
- Select the relevant cryptographic provider.
- Add a new identity provider as follows:

Option	Description
<b>Read from certificate</b>	<ol style="list-style-type: none"><li>Choose  (<i>Import SAML identity provider from certificate file</i>).</li><li>Enter the name of the identity provider. The following naming conventions apply: Spaces and special characters except underscore ( _ ) are not permitted. The name must start with a letter. The name cannot exceed 127 characters.</li></ol> <p>The system reads the X.509 certificate obtained from the identity provider and extracts the issuer and subject distinguished names (DNs). It then enters these in the corresponding fields.</p>

Option	Description
	<p><b>i Note</b></p> <p>If the certificate fails to read with an <code>IOException</code> or a <code>CertificateException</code>, try recoding the certificate from Base64 (*.pem) to DER (*.der) using OpenSSL or other tools.</p> <p>You can also enter the issuer and subject DNs manually.</p>
<b>Manually</b>	<ol style="list-style-type: none"> <li>1. Choose  (<i>Add SAML identity provider</i>)</li> <li>2. Enter the name of the identity provider (in line with the above naming conventions).</li> <li>3. Enter the issuer and subject DNs.</li> </ol>

4. Save the identity provider by choosing the  (*Deploy*) button.

## Results

The identity provider is now available for mapping to individual database users. You can do this when you create the database user. Alternatively, if the database user already exists, you can change their authentication details.

## Related Information

[Secure Communication Between SAP HANA and JDBC/ODBC Clients](#)  
[Single Sign-On Using SAML 2.0](#)  
[Maintaining SAML Providers \(HTTP Access via XS Classic Server\) \[page 1698\]](#)  
[Create a Database User \[page 915\]](#)

### 7.2.3.2.5 Add a SAML Identity Provider in SAP HANA Cockpit

If you are implementing Security Assertion Markup Language (SAML) to authenticate users accessing SAP HANA via the SQL interface directly (that is, using JDBC and ODBC clients), you must add the SAML identity providers for the required users.

## Prerequisites

- You have created a certificate collection with the purpose `SAML` in the database, and have imported the X.509 certificates that will be used to sign the `SAML` assertions from the identity provider. Ensure that the entire certificate chain of the X.509 certificate is available.

### ⚠ Caution

We recommend creating certificate collections for individual purposes in the database directly, rather than using trust stores (PSE) in the file system. By default, the same PSE in the file system is shared by all databases for all external communication channels (including HTTP) and certificate-based authentication. Different PSEs must be explicitly configured for tenant databases.

- You have configured the `[authentication] saml_service_provider_name` system property if necessary. This parameter determines whether or not an audience restriction will be validated. If the parameter is not set, an SAP HANA system ignores a possible audience restriction tag in a SAML assertion. By default, in SAP HANA tenant databases the parameter is set to the tenant name and the instance ID, for example, 'TENANT01'. For the system database, the parameter is empty by default.
- You have the system privilege USER ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

### i Note

While you can configure SAML providers for ODBC/JDBC-based SAML authentication using the SAP HANA cockpit, SAP HANA studio or SQL, always use the SAP HANA XS Administration Tool to configure SAML providers that will be used for **HTTP access via the XS classic server**.

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [Security Related Links](#) and choose [SAML Identity Providers](#).
2. Choose [Add Identity Provider](#).
  - a. Specify a name for the identity provider.

The following naming conventions apply:

- Spaces and special characters except underscore (\_) are not permitted.
- The name must start with a letter.
- The name cannot exceed 127 characters.

- b. Enter the entity ID.
- c. Select the appropriate certificate from the certificate store.

### i Note

It is not possible to enter the issuer and subject distinguished names (DNs) manually. If the certificate is not available, choose [Go to Certificate Store](#) and import it. Then, return to the [SAML Identity Providers](#) page and start again. For more information, see *Import a Trusted Certificate into the Certificate Store*.

- d. Choose [Add](#).

## Results

The identity provider can now be mapped to individual database users. You can map the identity provider when you create the database user. Alternatively, if the database user already exists, you can change their authentication details.

### 7.2.3.2.6 Add a JWT Identity Provider in SAP HANA Cockpit

If you are using JSON Web Tokens (JWT) to authenticate users accessing SAP HANA via the SQL interface directly (that is, using JDBC and ODBC clients) or clients that connect to SAP HANA through the SAP HANA XS advanced server, you must add the JWT identity providers for the required users.

## Prerequisites

- You have created a certificate collection with the purpose `JWT` in the database and have imported the X.509 certificates that will be used to validate incoming tokens from the identity provider. Ensure that the entire certificate chain of the X.509 certificate is available.
- You have the system privilege `USER ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [Security Related Links](#) and choose [JWT Identity Providers](#).
2. Choose [Add Identity Provider](#).
  - a. Specify a name for the identity provider.
  - b. Enter the issuer URL.

This is used to map the token to an identity provider. It corresponds to the name provided in the `iss` claim of the JWT tokens issued by this JWT provider

- c. Enter the JWT identity claim.

This is the claim in the JWT token used for mapping the SAP HANA user to an external user name.

- d. Choose [Add](#).

## Results

The identity provider can now be mapped to individual database users. You map the identity provider when you create the database user. Alternatively, if the database user already exists, you can change the user's authentication details.

## Related Information

### 7.2.3.2.7 Configure Authentication Using SAP Logon Tickets and Assertions

Configure SAP HANA to use SAP logon or assertion tickets to authenticate users accessing SAP HANA directly from ODBC/JDBC database clients.

## Prerequisites

- If you are using certificate collections and certificates stored directly in the database (recommended), you have all the necessary privileges. See *SQL Statements and Authorization for In-Database Certificate Management (Reference)* in the *SAP HANA Security Guide*.
- If you are using a trust store located in the file system, you have the system privilege INIFILE ADMIN.
- You have the system privilege USER ADMIN or for users in user groups configured for exclusive administration, the object privilege USERGROUP OPERATOR on the relevant user group(s).

## Context

SAP HANA validates incoming logon/assertion tickets against certificates signed by a trusted Certification Authority (CA) stored in a dedicated trust store. This trust store must contain all root certificate(s) used to validate logon/assertion tickets. We recommend creating a certificate collection with the purpose **SAP LOGON** and the required certificates directly in the database.

It is also possible to use a trust store located in the file system. The default location of the trust store in the file system depends on the cryptographic library configured for SSL:

- `$SECUDIR/saplogon.pse` (CommonCryptoLib)

### i Note

The `saplogon.pse` trust store is available automatically.

- `$HOME/.ssl/saplogon.pem` (OpenSSL)

### i Note

**Deprecated:** OpenSSL is deprecated. You must migrate to CommonCryptoLib. For more information, see SAP Note 2093286.

If necessary, you can change the location of this trust store in the `indexserver.ini` system properties file.

### ⚠ Caution

By default, the same trust store in the file system is shared by all databases. Different PSEs must be explicitly configured for tenant databases.

## Procedure

1. Configure the trust store:

Option	Description
<b>In-database certificate collection</b>	Create a certificate collection with the purpose <code>SAP LOGON</code> that contains the required certificates. You can import certificates, and create and configure certificate collections using the SAP HANA cockpit or the relevant SQL statements ( <code>CREATE CERTIFICATE</code> , <code>CREATE PSE</code> , <code>ALTER PSE</code> and <code>SET PSE</code> ).
<b>File-system based</b>	<ol style="list-style-type: none"><li>1. In the configuration file <code>indexserver.ini</code> file, change the value of the <code>[authentication] saplogontickettruststore</code> parameter.</li><li>2. Restart the system.</li></ol> <p>You can modify configuration files in the SAP HANA cockpit.</p>

2. Configure users for authentication using logon/assertion tickets.

You do this in the user definition using either the SAP HANA cockpit or the `CREATE | ALTER USER` statement.

## 7.2.4 User Authorization

After successful logon, the user's authorization to perform the requested operations on the requested objects is verified.

To perform operations in the SAP HANA database, a database user must have the necessary privileges. Users must have both the privilege(s) to perform the operation and to access the resources (such as schemas and tables) to which the operation applies. Privileges can be granted to database users either directly, or indirectly through roles that they have been granted. In this case, the privileges are inherited. Roles are the standard mechanism of granting privileges to users.

### **i** Note

For some administration tasks, such as start-up, the credentials of the SAP operating system user (<sid>adm) are also required.

## 7.2.4.1 Privileges

Several privilege types are used in SAP HANA (system, object, analytic, package, and application).

Privilege Type	Applicable To	Target User	Description
System privilege	System, database	Administrators, developers	<p>System privileges control general system activities. They are mainly used for administrative purposes, such as creating schemas, creating and changing users and roles, monitoring and tracing.</p> <p>System privileges are also used to authorize basic repository operations.</p> <p>System privileges granted to users in a particular tenant database authorize operations in that database only. The only exception is the system privileges DATABASE ADMIN, DATABASE STOP, DATABASE START, and DATABASE AUDIT ADMIN. These system privileges can only be granted to users of the system database. They authorize the execution of operations on individual tenant databases. For example, a user with DATABASE ADMIN can create and drop tenant databases, change the database-specific properties in configuration (*.ini) files, and perform database-specific backups.</p>

Privilege Type	Applicable To	Target User	Description
Object privilege	Database objects (schemas, tables, views, procedures and so on)	End users, technical users	<p>Object privileges are used to allow access to and modification of database objects, such as tables and views. Depending on the object type, different actions can be authorized (for example, SELECT, CREATE ANY, ALTER, DROP).</p> <p>Schema privileges are object privileges that are used to allow access to and modification of schemas and the objects that they contain.</p> <p>Source privileges are object privileges that are used to restrict access to and modification of remote data sources, which are connected through SAP HANA smart data access.</p> <p>Object privileges granted to users in a particular database authorize access to and modification of database objects in that database only. That is, unless cross-database access has been enabled for the user. This is made possible through the association of the requesting user with a remote identity on the remote database. For more information, see <i>Cross-Database Authorization in Tenant Databases</i> in the <i>SAP HANA Security Guide</i>.</p>
Analytic privilege	Analytic views	End users	<p>Analytic privileges are used to allow read access to data in SAP HANA information models (that is, analytic views, attribute views, and calculation views) depending on certain values or combinations of values. Analytic privileges are evaluated during query processing.</p> <p>Analytic privileges granted to users in a particular database authorize access to information models in that database only.</p>

Privilege Type	Applicable To	Target User	Description
Package privilege	Packages in the classic repository of the SAP HANA database	Application and content developers working in the classic SAP HANA repository	<p>Package privileges are used to allow access to and the ability to work in packages in the classic repository of the SAP HANA database.</p> <p>Packages contain design time versions of various objects, such as analytic views, attribute views, calculation views, and analytic privileges.</p> <p>Package privileges granted to users in a particular database authorize access to and the ability to work in packages in the repository of that database only.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>With SAP HANA XS advanced, source code and web content are not versioned and stored in the SAP HANA database, so package privileges are not used in this context. For more information, see <i>Authorization in SAP HANA XS Advanced</i>.</p> </div>
Package privilege	Packages in the classic repository of the SAP HANA database	Application and content developers working in the classic SAP HANA repository	Package privileges are not relevant in the SAP HANA service for SAP BTP context as the SAP HANA repository is not supported.
Application privilege	SAP HANA XS classic applications	Application end users, technical users (for SQL connection configurations)	<p>Developers of SAP HANA XS classic applications can create application privileges to authorize user and client access to their application. They apply in addition to other privileges, for example, object privileges on tables.</p> <p>Application privileges can be granted directly to users or roles in runtime in the SAP HANA studio. However, it is recommended that you grant application privileges to roles created in the repository in design time.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>With SAP HANA XS advanced, application privileges are not used. Application-level authorization is implemented using OAuth and authorization scopes and attributes. For more information, see <i>Authorization in SAP HANA XS Advanced</i>.</p> </div>
Application privilege	SAP HANA XS classic applications	Application end users, technical users (for SQL connection configurations)	Application privileges are not relevant in the SAP HANA service for SAP BTP context as SAP HANA XS classic is not supported.

## i Note

There are no HDI or XS advanced equivalents in the SAP HANA authorization concept for package privileges on repository packages and applications privileges on SAP HANA XS classic applications. For more information about the authorization concept of XS advanced, see the *SAP HANA Security Guide*.

### Privileges on Users

An additional privilege type, privileges on users, can be granted to users. Privileges on users are SQL privileges that users can grant on their user. ATTACH DEBUGGER is the only privilege that can be granted on a user.

For example, User A can grant User B the privilege ATTACH DEBUGGER to allow User B debug SQLScript code in User A's session. User A is only user who can grant this privilege. Note that User B also needs the object privilege DEBUG on the relevant SQLScript procedure.

For more information, see the section on debugging procedures in the *SAP HANA Developer Guide*.

## 7.2.4.2 System Privileges

System privileges control general system activities.

System privileges are mainly used to authorize users to perform administrative actions, including:

- Creating and deleting schemas
- Managing users and roles
- Performing data backups
- Monitoring and tracing
- Managing licenses

System privileges are also used to authorize basic repository operations, for example:

- Importing and exporting content
- Maintaining delivery units (DU)

System privileges granted to users in a particular database authorize operations in that database only. The only exception is the system privileges DATABASE ADMIN, DATABASE STOP, and DATABASE START, DATABASE AUDIT ADMIN. These system privileges can only be granted to users of the system database. They authorize the execution of operations on individual tenant databases. For example, a user with DATABASE ADMIN can create and drop tenant databases, change the database-specific properties in configuration (\*.ini) files, and perform database-specific or full-system data backups.

## i Note

System privileges should always be assigned with caution.

## Related Information

[System Privileges \(Reference\) \[page 853\]](#)

### 7.2.4.2.1 System Privileges (Reference)

System privileges control general system activities.

#### General System Privileges

System privileges restrict administrative tasks. The following table describes the supported system privileges in an SAP HANA database.

System Privilege	Description
ADAPTER ADMIN	Controls the execution of the following adapter-related statements: CREATE ADAPTER, DROP ADAPTER, and ALTER ADAPTER. It also allows access to the ADAPTERS and ADAPTER_LOCATIONS system views.
AGENT ADMIN	Controls the execution of the following agent-related statements: CREATE AGENT, DROP AGENT, and ALTER AGENT. It also allows access to the AGENTS and ADAPTER_LOCATIONS system views.
ALTER CLIENTSIDE ENCRYPTION KEYPAIR	Authorizes a user to add a new version of a client-side encryption key pair (CKP), or to drop all older versions of the CKP.
ATTACH DEBUGGER	Authorizes debugging across different user sessions. For example, userA can grant ATTACH DEBUGGER to userB to allow userB to debug a procedure in userA's session (userB still needs DEBUG privilege on the procedure, however).

System Privilege	Description
AUDIT ADMIN	Controls the execution of the following auditing-related statements: CREATE AUDIT POLICY, DROP AUDIT POLICY, and ALTER AUDIT POLICY, as well as changes to the auditing configuration. It also allows access to the AUDIT_LOG, XSA_AUDIT_LOG, and ALL_AUDIT_LOG system views.
AUDIT OPERATOR	Authorizes the execution of the following statement: ALTER SYSTEM CLEAR AUDIT LOG. It also allows access to the AUDIT_LOG system view.
AUDIT READ	Authorizes read-only access to the rows of the AUDIT_LOG, XSA_AUDIT_LOG, and ALL_AUDIT_LOG system views.
BACKUP ADMIN	Authorizes BACKUP and RECOVERY statements for defining and initiating backup and recovery procedures. It also authorizes changing system configuration options with respect to backup and recovery.
BACKUP OPERATOR	Authorizes the BACKUP statement to initiate a backup.
CATALOG READ	Authorizes unfiltered access to the data in the system views that a user has already been granted the SELECT privilege on. Normally, the content of these views is filtered based on the privileges of the user. CATALOG READ does not allow a user to view system views on which they have not been granted the SELECT privilege.
CERTIFICATE ADMIN	Authorizes the changing of certificates and certificate collections that are stored in the database.
CLIENT PARAMETER ADMIN	Authorizes a user to override the value of the CLIENT parameter for a database connection or to overwrite the value of the \$\$client\$\$ parameter in an SQL query.
CREATE CLIENTSIDE ENCRYPTION KEYPAIR	Authorizes a user to create client-side encryption key pairs.
CREATE R SCRIPT	Authorizes the creation of a procedure by using the language R.
CREATE REMOTE SOURCE	Authorizes the creation of remote data sources by using the CREATE REMOTE SOURCE statement. It also allows you to set the purpose of a certificate collection to REMOTE SOURCE.
CREATE SCENARIO	Controls the creation of calculation scenarios and cubes (calculation database).
CREATE SCHEMA	Authorizes the creation of database schemas using the CREATE SCHEMA statement.

System Privilege	Description
CREATE STRUCTURED PRIVILEGE	<p>Authorizes the creation of structured (analytic privileges).</p> <p>Only the owner of the privilege can further grant or revoke that privilege to other users or roles.</p>
CREDENTIAL ADMIN	<p>Authorizes the use of the statements CREATE CREDENTIAL, ALTER CREDENTIAL, and DROP CREDENTIAL.</p>
DATA ADMIN	<p>Authorizes reading all data in the system views. It also enables execution of Data Definition Language (DDL) statements in the SAP HANA database.</p> <p>A user with this privilege cannot select or change data in stored tables for which they do not have access privileges, but they can drop tables or modify table definitions.</p>
DATABASE ADMIN	<p>Authorizes all statements related to tenant databases, such as CREATE, DROP, ALTER, RENAME, BACKUP, and RECOVERY.</p>
DATABASE START	<p>Authorizes a user to start any database in the system and to select from the M_DATABASES view.</p>
DATABASE STOP	<p>Authorizes a user to stop any database in the system and to select from the M_DATABASES view.</p>
DROP CLIENTSIDE ENCRYPTION KEYPAIR	<p>Authorizes a user to drop other users' client-side encryption key pairs.</p>
ENCRYPTION ROOT KEY ADMIN	<p>Authorizes all statements related to management of root keys:</p> <p>Allows access to the system views pertaining to encryption (for example, ENCRYPTION_ROOT_KEYS, M_ENCRYPTION_OVERVIEW, M_PERSISTENCE_ENCRYPTION_STATUS, M_PERSISTENCE_ENCRYPTION_KEYS, and so on).</p>
EXPORT	<p>Authorizes EXPORT to a file on the SAP HANA server. The user must also have the SELECT privilege on the source tables to be exported.</p>
EXTENDED STORAGE ADMIN	<p>Authorizes the management of SAP HANA dynamic tiering and the creation of extended storage.</p>
IMPORT	<p>Authorizes the import activity in the database using the IMPORT statements. Additional privileges may also be required to be able to execute an IMPORT. See the IMPORT statement for more information.</p>
INIFILE ADMIN	<p>Authorizes making changes to system settings.</p>

System Privilege	Description
LDAP ADMIN	Authorizes the use of the CREATE   ALTER   DROP   VALIDATE LDAP PROVIDER statements.
LICENSE ADMIN	Authorizes the use of the SET SYSTEM LICENSE statement to install a new license.
LOG ADMIN	Authorizes the use of the ALTER SYSTEM LOGGING [ON   OFF] statements to enable or disable the log flush mechanism.
MONITOR ADMIN	Authorizes the use of the ALTER SYSTEM statements for events.
OPTIMIZER ADMIN	Authorizes the use of the ALTER SYSTEM statements concerning SQL PLAN CACHE and ALTER SYSTEM UPDATE STATISTICS statements, which influence the behavior of the query optimizer.
RESOURCE ADMIN	Authorizes statements concerning system resources (for example, the ALTER SYSTEM RECLAIM DATAVOLUME and ALTER SYSTEM RESET MONITORING VIEW statements). It also authorizes use of the Kernel Profiler statements, and many of the statements available in the Management Console.
ROLE ADMIN	<p>Authorizes the creation and deletion of roles by using the CREATE ROLE and DROP ROLE statements. It also authorizes the granting and revoking of roles by using the GRANT and REVOKE statements.</p> <p>Activated repository roles, meaning roles whose creator is the predefined user <code>_SYS_REPO</code>, can neither be granted to other roles or users nor dropped directly. Not even users with the ROLE ADMIN privilege can do so. Check the documentation concerning activated objects.</p>
SAVEPOINT ADMIN	Authorizes the execution of a savepoint using the ALTER SYSTEM SAVEPOINT statement.
SCENARIO ADMIN	Authorizes all calculation scenario-related activities (including creation).
SERVICE ADMIN	Authorizes the ALTER SYSTEM [START CANCEL RECONFIGURE] statements for administering system services of the database.
SESSION ADMIN	Authorizes the ALTER SYSTEM commands concerning sessions to stop or disconnect a user session or to change session variables.

System Privilege	Description
SSL ADMIN	Authorizes the use of the SET...PURPOSE SSL statement. It also allows access to the PSES system view.
STRUCTUREDPRIVILEGE ADMIN	Authorizes the creation, reactivation, and dropping of structured (analytic) privileges.
SYSTEM REPLICATION ADMIN	Authorizes the use of ALTER SYSTEM statements related to system replication.
TABLE ADMIN	Authorizes LOAD, UNLOAD and MERGE of tables and table placement.
TRACE ADMIN	Authorizes the use of the ALTER SYSTEM statements related to database tracing (including the Kernel Profiler feature) and the changing of trace system settings.
TRUST ADMIN	Authorizes the use of statements to update the trust store.
USER ADMIN	Authorizes the creation and modification of users by using the CREATE   ALTER   DROP USER statements.
VERSION ADMIN	Authorizes the use of the ALTER SYSTEM RECLAIM VERSION SPACE statement of the multi-version concurrency control (MVCC) feature.
WORKLOAD ADMIN	Authorizes execution of the workload class and mapping statements (for example, CREATE   ALTER   DROP WORKLOAD CLASS, and CREATE   ALTER   DROP WORKLOAD MAPPING).
WORKLOAD ANALYZE ADMIN	Used by the Analyze Workload, Capture Workload, and Replay Workload applications when performing workload analysis.
WORKLOAD CAPTURE ADMIN	Authorizes access to the monitoring view M_WORKLOAD_CAPTURES to see the current status of capturing and captured workloads, as well of execution of actions with the WORKLOAD_CAPTURE procedure.
WORKLOAD REPLAY ADMIN	Authorizes access to the monitoring views M_WORKLOAD_REPLAY_PREPROCESSES and M_WORKLOAD_REPLAYS to see current status of preprocessing, preprocessed, replaying, and replayed workloads, as well as the execution of actions with the WORKLOAD_REPLAY procedure.
<identifier>.<identifier>	Components of the SAP HANA database can create new system privileges. These privileges use the component-name as the first identifier of the system privilege and the component-privilege-name as the second identifier.

## Repository System Privileges

### Note

The following privileges authorize actions on individual packages in the SAP HANA repository, used in the SAP HANA Extended Services (SAP HANA XS) classic development model. With SAP HANA XS advanced, source code and web content are no longer versioned and stored in the repository of the SAP HANA database.

System Privilege	Description
REPO.EXPORT	Authorizes the export of delivery units for example
REPO.IMPORT	Authorizes the import of transport archives
REPO.MAINTAIN_DELIVERY_UNITS	Authorizes the maintenance of delivery units (DU, DU vendor and system vendor must be the same)
REPO.WORK_IN_FOREIGN_WORKSPACE	Authorizes work in a foreign inactive workspace
REPO.CONFIGURE	Authorize work with SAP HANA Change Recording, which is part of SAP HANA Application Lifecycle Management
REPO.MODIFY_CHANGE	
REPO.MODIFY_OWN_CONTRIBUTION	
REPO.MODIFY_FOREIGN_CONTRIBUTION	

## Related Information

### GRANT

[Developer Authorization in the Repository](#)

### 7.2.4.3 Object Privileges

Object privileges are SQL privileges that are used to allow access to and modification of database objects.

For each SQL statement type (for example, SELECT, UPDATE, or CALL), a corresponding object privilege exists. If a user wants to execute a particular statement on a simple database object (for example, a table), he or she must have the corresponding object privilege for either the actual object itself, or the schema in which the object is located. This is because the schema is an object type that contains other objects. A user who has object privileges for a schema automatically has the same privileges for all objects currently in the schema and any objects created there in the future.

Object privileges are not only grantable for database catalog objects such as tables, views and procedures. Object privileges can also be granted for non-catalog objects such as development objects in the repository of the SAP HANA database.

Initially, the owner of an object and the owner of the schema in which the object is located are the only users who can access the object and grant object privileges on it to other users.

An object can therefore be accessed only by the following users:

- The owner of the object
- The owner of the schema in which the object is located
- Users to whom the owner of the object has granted privileges
- Users to whom the owner of the parent schema has granted privileges

### ⚠ Caution

The database owner concept stipulates that when a database user is deleted, all objects created by that user and privileges granted to others by that user are also deleted. If the owner of a schema is deleted, all objects in the schema are also deleted even if they are owned by a different user. All privileges on these objects are also deleted.

### i Note

The owner of a table can change its ownership with the `ALTER TABLE` SQL statement. In this case, the new owner becomes the grantor of all privileges on the table granted by the original owner. The original owner is also automatically granted all privileges for the table with the new owner as grantor. This ensures that the original owner can continue to work with the table as before.

## Authorization Check on Objects with Dependencies

The authorization check for objects defined on other objects (that is, stored procedures and views) is more complex. In order to be able to access an object with dependencies, both of the following conditions must be met:

- The user trying to access the object must have the relevant object privilege on the object as described above.
- The user who created the object must have the required privilege on all underlying objects **and** be authorized to grant this privilege to others.

If this second condition is not met, only the owner of the object can access it. He cannot grant privileges on it to any other user. This cannot be circumvented by granting privileges on the parent schema instead. Even if a user has privileges on the schema, he will still not be able to access the object.

### i Note

This applies to procedures created in `DEFINER` mode only. This means that the authorization check is run against the privileges of the user who created the object, not the user accessing the object. For procedures created in `INVOKER` mode, the authorization check is run against the privileges of the accessing user. In this case, the user must have privileges not only on the object itself but on all objects that it uses.

### → Tip

The SAP HANA studio provides a graphical feature, the authorization dependency viewer, to help troubleshoot authorization errors for object types that typically have complex dependency structures: stored procedures and calculation views.

### 7.2.4.3.1 Object Privileges (Reference)

Object privileges are used to allow access to and modification of database objects, such as tables and views.

The following table describes the supported object privileges in an SAP HANA database.

Object Privilege	Command Types	Applies to	Privilege Description
ALL PRIVILEGES	DDL & DML	<ul style="list-style-type: none"><li>• Schemas</li><li>• Tables</li><li>• Views</li></ul>	<p>This privilege is a collection of all Data Definition Language (DDL) and Data Manipulation Language (DML) privileges that the grantor currently possesses and is allowed to grant further. The privilege it grants is specific to the particular object being acted upon.</p> <p>This privilege collection is dynamically evaluated for the given grantor and object.</p>
ALTER	DDL	<ul style="list-style-type: none"><li>• Schemas</li><li>• Tables</li><li>• Views</li><li>• Functions/procedures</li></ul>	Authorizes the ALTER statement for the object.
CREATE ANY	DDL	<ul style="list-style-type: none"><li>• Schemas</li><li>• Tables</li><li>• Views</li><li>• Sequences</li><li>• Functions/procedures</li><li>• Remote sources</li><li>• Graph workspaces</li><li>• Triggers</li></ul>	Authorizes all CREATE statements for the object.

Object Privilege	Command Types	Applies to	Privilege Description
CREATE OBJECT STRUCTURED PRIVILEGE	DDL	<ul style="list-style-type: none"> <li>Schemas</li> <li>Views</li> </ul>	Authorizes creation of structured privilege commands on the object even if the user does not need to have the CREATE STRUCTURED PRIVILEGE.
CREATE VIRTUAL FUNCTION	DDL	<ul style="list-style-type: none"> <li>Remote sources</li> </ul>	Authorizes creation of virtual functions (the REFERENCES privilege is also required).
CREATE VIRTUAL PROCEDURE	DDL	<ul style="list-style-type: none"> <li>Remote sources</li> </ul>	Authorizes creation of virtual procedure to create and run procedures on a remote source.
CREATE VIRTUAL PACKAGE	DDL	<ul style="list-style-type: none"> <li>Schemas</li> </ul>	Authorizes creation of virtual packages that can be run on remote sources.
CREATE VIRTUAL TABLE	DDL	<ul style="list-style-type: none"> <li>Remote sources</li> </ul>	Authorizes the creation of proxy tables pointing to remote tables from the source entry.
CREATE TEMPORARY TABLE	DDL	<ul style="list-style-type: none"> <li>Schemas</li> </ul>	Authorizes the creation of a temporary local table, which can be used as input for procedures, even if the user does not have the CREATE ANY privilege for the schema.
DEBUG	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Calculation Views</li> <li>Functions/procedures</li> </ul>	Authorizes debug functionality for the procedure or calculation view or for the procedures and calculation views of a schema.
DEBUG MODIFY	DDL	<ul style="list-style-type: none"> <li>Functions/procedures</li> </ul>	For internal use only.

Object Privilege	Command Types	Applies to	Privilege Description
DELETE	DML	<ul style="list-style-type: none"> <li>• Schemas</li> <li>• Tables</li> <li>• Views</li> <li>• Functions/procedures</li> </ul>	<p>Authorizes the DELETE and TRUNCATE statements for the object.</p> <p>While DELETE applies to views, it only applies to updatable views (that is, views that do not use a join, do not contain a UNION, and do not use aggregation).</p>
DROP	DDL	<ul style="list-style-type: none"> <li>• Schemas</li> <li>• Tables</li> <li>• Views</li> <li>• Sequences</li> <li>• Functions/procedures</li> <li>• Remote sources</li> <li>• Graph workspaces</li> </ul>	<p>Authorizes the DROP statements for the object.</p>
EXECUTE	DML	<ul style="list-style-type: none"> <li>• Schemas</li> <li>• Functions/procedures</li> </ul>	<p>Authorizes the execution of a SQLScript function or a database procedure by using the CALLS or CALL statement respectively. It also allows a user to execute a virtual function.</p>
INDEX	DDL	<ul style="list-style-type: none"> <li>• Schemas</li> <li>• Tables</li> </ul>	<p>Authorizes the creation, modification, or dropping of indexes for the object.</p>
INSERT	DML	<ul style="list-style-type: none"> <li>• Schemas</li> <li>• Tables</li> <li>• Views</li> </ul>	<p>Authorizes the INSERT statement for the object.</p> <p>The INSERT and UPDATE privilege are both required on the object to allow the REPLACE and UPSERT statements to be used.</p> <p>While INSERT applies to views, it only applies to updatable views (views that do not use a join, do not contain a UNION, and do not use aggregation).</p>

Object Privilege	Command Types	Applies to	Privilege Description
REFERENCES	DDL	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> </ul>	Authorizes the usage of all tables in this schema or this table in a foreign key definition, or the usage of a personal security environment (PSE). It also allows a user to reference a virtual function package.
REMOTE TABLE ADMIN	DDL	<ul style="list-style-type: none"> <li>Remote sources</li> </ul>	Authorizes the creation of tables on a remote source object.
SELECT	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> <li>Views</li> <li>Sequences</li> <li>Graph workspaces</li> </ul>	Authorizes the SELECT statement for the object or the usage of a sequence. When selection from system-versioned tables, users must have SELECT on both the table and its associated history table.
SELECT CDS METADATA	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> </ul>	Authorizes access to CDS metadata from the catalog.
SELECT METADATA	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> </ul>	Authorizes access to the complete metadata of all objects in a schema (including procedure and view definitions), including objects that may be located in other schemas.
TRIGGER	DDL	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> </ul>	Authorizes the CREATE/ALTER/DROP/ENABLE and DISABLE TRIGGER statements for the specified table or the tables in the specified schema.
UNMASKED	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Views</li> <li>Tables</li> </ul>	Authorizes access to masked data in user-defined views and tables. This privilege is required to view the original data in views and tables that are defined by using the WITH MASK clause.

Object Privilege	Command Types	Applies to	Privilege Description
UPDATE	DML	<ul style="list-style-type: none"> <li>Schemas</li> <li>Tables</li> <li>Views</li> </ul>	<p>While UPDATE applies to views, it only applies to updatable views (views that do not use a join, do not contain a UNION, and do not use aggregation).</p>
USERGROUP OPERATOR	DML	<ul style="list-style-type: none"> <li>User groups</li> </ul>	<p>Authorizes a user to change the settings for a user group, and to add and remove users to/from a user group.</p> <p>Users with the USERGROUP OPERATOR privilege can also create and drop users, but only within the user group they have the USERGROUP OPERATOR privilege on (CREATE USER &lt;user_name&gt; SET USERGROUP &lt;usergroup_name&gt;).</p> <p>A user can have the USERGROUP OPERATOR privilege on more than one user group, and a user group can have more than one user with the USERGROUP OPERATOR privilege on it.</p> <p>When granting USERGROUP OPERATOR to a user group, you must include the keyword USERGROUP before the name of the user group (for example: GRANT USERGROUP OPERATOR ON <b>USERGROUP</b> &lt;usergroup&gt; TO &lt;grantee&gt;). This is slightly different syntax than granting USERGROUP OPERATOR to a user.</p>

Object Privilege	Command Types	Applies to	Privilege Description
<code>&lt;identifier&gt;.&lt;identifier&gt;</code>	DDL		Components of the SAP HANA database can create new object privileges. These privileges use the component-name as first identifier of the system privilege and the component-privilege-name as the second identifier.

## Related Information

[GRANT](#)

### 7.2.4.4 Analytic Privileges

Analytic privileges grant different users access to different portions of data in the same view based on their business role. Within the definition of an analytic privilege, the conditions that control which data users see is either contained in an XML document or defined using SQL.

## Row-Level Access Control

Standard object privileges (`SELECT`, `ALTER`, `DROP`, and so on) implement coarse-grained authorization at object level only. Users either have access to an object, such as a table, view or procedure, or they don't. While this is often sufficient, there are cases when access to data in an object depends on certain values or combinations of values. Analytic privileges are used in the SAP HANA database to provide such fine-grained control at row level of which data individual users can see within the same view.

#### Example

Sales data for all regions are contained within one analytic view. However, regional sales managers should only see the data for their region. In this case, an analytic privilege could be modeled so that they can all query the view, but only the data that each user is authorized to see is returned.

## Creating Analytic Privileges

Although analytic privileges can be created directly as catalog objects in runtime, we recommend creating them as design-time objects that become catalog objects on deployment (database artifact with file suffix `.hdbanalyticprivilege`).

In an SAP HANA XS classic environment, analytic privileges are created in the built-in repository of the SAP HANA database using either the SAP HANA Web Workbench or the SAP HANA studio. In an SAP HANA XS advanced environment, they are created using the SAP Web IDE and deployed using the SAP HANA deployment infrastructure (SAP HANA DI).

### i Note

HDI supports only analytic privileges deployed using SQL (see below). Furthermore, due to the container-based model of HDI, where each container corresponds to a database schema, analytic privileges created in HDI are schema specific.

## XML- Versus SQL-Based Analytic Privileges

Before you implement row-level authorization using analytic privileges, you need to decide which type of analytic privilege is suitable for your scenario. In general, SQL-based analytic privileges allow you to more easily formulate complex filter conditions using sub-queries that might be cumbersome to model using XML-based analytic privileges.

### → Recommendation

SAP recommends the use of SQL-based analytic privileges. Using the *SAP HANA Modeler* perspective of the SAP HANA studio, you can migrate XML-based analytic privileges to SQL-based analytic privileges. For more information, see the *SAP HANA Modeling Guide for HANA Studio*.

### i Note

As objects created in the repository, XML-based analytic privileges are deprecated as of SAP HANA 2.0 SPS 02. For more information, see SAP Note 2465027.

The following are the main differences between XML-based and SQL-based analytic privileges:

Feature	SQL-Based Analytic Privileges	XML-Based Analytic Privileges
Control of read-only access to SAP HANA information models: <ul style="list-style-type: none"><li>• Attribute views</li><li>• Analytic views</li><li>• Calculation views</li></ul>	Yes	Yes
Control of read-only access to SQL views	Yes	No
Control of read-only access to database tables	No	No

Feature	SQL-Based Analytic Privileges	XML-Based Analytic Privileges
Design-time modeling using the SAP HANA Web-based Workbench or the <i>SAP HANA Modeler</i> perspective of the SAP HANA studio	Yes	Yes
<b>i Note</b> This corresponds to development in an SAP HANA XS classic environment using the SAP HANA repository.		
Design-time modeling using the SAP Web IDE for SAP HANA	Yes	No
<b>i Note</b> This corresponds to development in an SAP HANA XS advanced environment using HDI.		
Transportable	Yes	Yes
HDI support	Yes	No
Complex filtering	Yes	No

## Enabling an Authorization Check Based on Analytic Privileges

All column views modeled and activated in the SAP HANA modeler and the SAP HANA Web-based Development Workbench automatically enforce an authorization check based on analytic privileges. XML-based analytic privileges are selected by default, but you can switch to SQL-based analytic privileges.

Column views created using SQL must be explicitly registered for such a check by passing the relevant parameter:

- `REGISTerviewFORAPCHECK` for a check based on XML-based analytic privileges
- `STRUCTURED PRIVILEGE CHECK` for a check based on SQL-based analytic privileges

SQL views must always be explicitly registered for an authorization check based on analytic privileges by passing the `STRUCTURED PRIVILEGE CHECK` parameter.

### i Note

It is not possible to enforce an authorization check on the same view using both XML-based and SQL-based analytic privileges. However, it is possible to build views with different authorization checks on each other.

## 7.2.4.5 Package Privileges

Package privileges authorize actions on individual packages in the classic SAP HANA repository.

### Note

With SAP HANA XS advanced, source code and web content are not versioned and stored in the SAP HANA database, so package privileges are not used in this context.

Privileges granted on a repository package are implicitly assigned to the design-time objects in the package, as well as to all sub-packages. Users are only allowed to maintain objects in a repository package if they have the necessary privileges for the package in which they want to perform an operation, for example to read or write to an object in that package. To be able perform operations in all packages, a user must have privileges on the root package `.REPO_PACKAGE_ROOT`.

### → Recommendation

We recommend that package privileges be granted on a single package or a small number of specific packages belonging to your organization, rather than on the complete repository.

If the user authorization check establishes that a user does not have the necessary privileges to perform the requested operation in a specific package, the authorization check is repeated on the parent package and recursively up the package hierarchy to the root level of the repository. If the user does not have the necessary privileges for any of the packages in the hierarchy chain, the authorization check fails and the user is not permitted to perform the requested operation.

In the context of repository package authorizations, there is a distinction between native packages and imported packages.

## Privileges for Native Repository Packages

A native repository package is created in the current SAP HANA system and expected to be edited in the current system. To perform application-development tasks on **native** packages in the SAP HANA repository, developers typically need the privileges listed in the following table:

Package Privilege	Description
<code>REPO_READ</code>	Read access to the selected package and design-time objects (both native and imported)

Package Privilege	Description
REPO.EDIT_NATIVE_OBJECTS	Authorization to modify design-time objects in packages originating in the system the user is working in
REPO.ACTIVATE_NATIVE_OBJECTS	Authorization to activate/reactivate design-time objects in packages originating in the system the user is working in
REPO.MAINTAIN_NATIVE_PACKAGES	Authorization to update or delete native packages, or create sub-packages of packages originating in the system in which the user is working

## Privileges for Imported Repository Packages

An imported repository package is created in a remote SAP HANA system and imported into the current system. To perform application-development tasks on **imported** packages in the SAP HANA repository, developers need the privileges listed in the following table:

### i Note

It is not recommended to work on imported packages. Imported packages should only be modified in exceptional cases, for example, to carry out emergency repairs.

Package Privilege	Description
REPO.READ	Read access to the selected package and design-time objects (both native and imported)
REPO.EDIT_IMPORTED_OBJECTS	Authorization to modify design-time objects in packages originating in a system other than the one in which the user is currently working
REPO.ACTIVATE_IMPORTED_OBJECTS	Authorization to activate (or reactivate) design-time objects in packages originating in a system other than the one in which the user is currently working
REPO.MAINTAIN_IMPORTED_PACKAGES	Authorization to update or delete packages, or create sub-packages of packages, which originated in a system other than the one in which the user is currently working

## 7.2.4.6 Application Privileges

In SAP HANA XS classic, application privileges define the authorization level required for access to an SAP HANA XS classic application, for example, to start the application or view particular functions and screens.

### i Note

With SAP HANA XS advanced, application privileges are not used. Application-level authorization is implemented using OAuth and authorization scopes and attributes.

Application privileges can be assigned to an individual user or to a group of users, for example, in a role. The role can also be used to assign system, object, package, and analytic privileges. You can use application privileges to provide different levels of access to the same application, for example, to provide advanced maintenance functions for administrators and view-only capabilities to normal users.

If you want to define application-specific privileges, you need to understand and maintain the relevant sections in the following design-time artifacts:

- Application-privileges file (`.xsprivileges`)
- Application-access file (`.xsaccess`)
- Role-definition file (`<RoleName>.hdbrole`)

Application privileges can be assigned to users individually or by means of a user **role**, for example, with the *“application privilege”* keyword in a role-definition file (`<RoleName>.hdbrole`) as illustrated in the following code. You store the roles as design-time artifacts within the application package structure they are intended for, for example, `acme.com.hana.xs.appl.roles`.

```
role acme.com.hana.xs.appl.roles::Display
{
    application privilege: acme.com.hana.xs.appl::Display;
    application privilege: acme.com.hana.xs.appl::View;
    catalog schema "ACME_XS_APP1": SELECT;
    package acme.com.hana.xs.appl: REPO.READ;
    package ".REPO_PACKAGE_ROOT" : REPO.READ;
    catalog sql object "_SYS_REPO"."PRODUCTS": SELECT;
    catalog sql object "_SYS_REPO"."PRODUCT_INSTANCES": SELECT;
    catalog sql object "_SYS_REPO"."DELIVERY_UNITS": SELECT;
    catalog sql object "_SYS_REPO"."PACKAGE_CATALOG": SELECT;
    catalog sql object "ACME_XS_APPL"."acme.com.hana.xs.appl.db::SYSTEM_STATE":
    SELECT, INSERT, UPDATE, DELETE;
}
```

The application privileges referenced in the role definition (for example, `Display` and `View`) are actually defined in an application-specific `.xsprivileges` file, as illustrated in the following example, which also contains entries for additional privileges that are not explained here.

## Note

The `.xsprivileges` file must reside in the package of the application to which the privileges apply.

The package where the `.xsprivileges` resides defines the scope of the application privileges; the privileges specified in the `.xsprivileges` file can only be used in the package where the `.xsprivileges` resides (or any sub-packages). This is checked during activation of the `.xsaccess` file and at runtime in the by the XS JavaScript API `$.session.(has|assert)AppPrivilege()`.

```
{
  "privileges" : [
    { "name" : "View", "description" : "View Product Details" },
    { "name" : "Configure", "description" : "Configure Product Details" },
    { "name" : "Display", "description" : "View Transport Details" },
    { "name" : "Administrator", "description" : "Configure/Run Everything" },
    { "name" : "ExecuteTransport", "description" : "Run Transports" },
    { "name" : "Transport", "description" : "Transports" }
  ]
}
```

The privileges are **authorized** for use with an application by inserting the *authorization* keyword into the corresponding `.xsaccess` file, as illustrated in the following example. Like the `.xsprivileges` file,

the `.xsaccess` file must reside either in the root package of the application to which the privilege authorizations apply or the specific subpackage which requires the specified authorizations.

### i Note

If a privilege is inserted into the `.xsaccess` file as an authorization requirement, a user must have this privilege to access the application package where the `.xsaccess` file resides. If there is more than one privilege, the user must have at least one of these privileges to access the content of the package.

```
{
  "prevent_xsrp": true,
  "exposed": true,
  "authentication": {
    "method": "Form"
  },
  "authorization": [
    "acme.com.hana.xs.appl::Display",
    "acme.com.hana.xs.appl::Transport"
  ]
}
```

## 7.2.4.7 Database Roles

A database role is a collection of privileges that can be granted to either a database user or another role in runtime.

A role typically contains the privileges required for a particular function or task, for example:

- Business end users reading reports using client tools such as Microsoft Excel
- Modelers creating models and reports
- Database administrators operating and maintaining the database and its users

Privileges can be granted directly to users of the SAP HANA database. However, roles are the standard mechanism of granting privileges as they allow you to implement complex, reusable authorization concepts that can be modeled on business roles.

### Creation of Roles

Roles in the SAP HANA database can exist as runtime objects only (catalog roles), or as design-time objects that become catalog objects on deployment (database artifact with file suffix `.hdbrole`).

In an SAP HANA XS classic environment, database roles are created in the built-in repository of the SAP HANA database using either the SAP HANA Web Workbench or the SAP HANA studio. These are also referred to as repository roles. In an SAP HANA XS advanced environment, design-time roles are created using the SAP Web IDE and deployed using SAP HANA deployment infrastructure (SAP HANA DI, or HDI).

### i Note

Due to the container-based model of HDI where each container corresponds to a database schema, HDI roles, once deployed, are schema specific.

SAP HANA XS advanced has the additional concept of application roles and role collections. These are independent of database roles in SAP HANA itself. In the XS advanced context, SAP HANA database roles are used only to control access to database objects (for example, tables, views, and procedures) for XS advanced applications. For more information about the authorization concept of XS advanced, see the *SAP HANA Security Guide*.

## Role Structure

A role can contain any number of the following privileges:

- **System privileges** for general system authorization, in particular administration activities
- **Object privileges** (for example, SELECT, INSERT, UPDATE) on database objects (for example, schemas, tables, views, procedures, and sequences)
- **Analytic privileges** on SAP HANA information models
- **Package privileges** on repository packages (for example, REPO.READ, REPO.EDIT\_NATIVE\_OBJECTS, REPO.ACTIVATE\_NATIVE\_OBJECTS)
- **Application privileges** for enabling access to SAP HANA-based applications developed in an SAP HANA XS classic environment

### i Note

There are no HDI or XS advanced equivalents in the SAP HANA authorization concept for package privileges on repository packages and applications privileges on SAP HANA XS classic applications. For more information about the authorization concept of XS advanced, see the *SAP HANA Security Guide*.

A role can also contain other roles.

## Roles Best Practices

For best performance of role operations, in particular, granting and revoking, keep the following basic rules in mind:

- Create roles with the smallest possible set of privileges for the smallest possible group of users who can share a role (principle of least privilege).
- Avoid granting object privileges at the schema level to a role if only a few objects in the schema are relevant for intended users.
- Avoid creating and maintaining all roles as a single user. Use several role administrator users instead.

[Authorization in SAP HANA XS Advanced](#)

[Create a Design-Time Role](#)

## 7.2.4.7.1 Catalog Roles and Design-Time Roles Compared

It is possible to create roles as pure runtime objects that follow classic SQL principles or as design-time objects.

In SAP HANA XS classic, database roles are created in the built-in repository of the SAP HANA database using either the SAP HANA Web Workbench or the SAP HANA studio. In SAP HANA XS advanced, design-time roles are created using the SAP Web IDE and deployed using SAP HANA deployment infrastructure (SAP HANA DI, or HDI).

### i Note

SAP HANA XS classic and the SAP HANA repository are deprecated as of SAP HANA 2.0 SPS 02. For more information, see SAP Note 2465027.

Catalog roles make sense in scenarios where user and role provisioning is carried out solely using a higher-level application that connects to SAP HANA through a technical user such as SAP Identity Management.

The following table summarizes the differences between catalog roles and design-time roles:

Feature	Catalog Roles	Design-Time Repository Roles	Design-Time HDI Roles
Transportability	Roles cannot be transported between systems. They can only be created in runtime by users with the system privilege ROLE ADMIN.	Roles can be transported between systems using several transport options: <ul style="list-style-type: none"> <li>• SAP HANA Application Lifecycle Manager</li> <li>• The change and transport system (CTS+) of the SAP NetWeaver ABAP application server</li> <li>• SAP HANA Transport Container (HTC)</li> </ul>	Roles can be transported between systems using the following transport option: <ul style="list-style-type: none"> <li>• The change and transport system (CTS+) of the SAP NetWeaver ABAP application server</li> </ul>
Version management	No version management is possible.	The repository provides the basis for versioning. As repository objects, roles are stored in specific repository tables inside the database. This eliminates the need for an external version control system.	Roles are developed as design-time objects within a project stored in the GIT repository. The complete role history is therefore available in GIT.

Feature	Catalog Roles	Design-Time Repository Roles	Design-Time HDI Roles
Ownership	Roles are owned by the database user who creates them. If the creating user is dropped, any roles created in the user's own schema are also dropped.	The technical user <code>_SYS_REPO</code> is the owner of all roles created in the repository, not the database user who creates them. Therefore, roles are not directly associated with the creating user. To create a role, a database user needs only the privileges required to work in the repository.	<p>Roles are owned by the object owner of the container (technical user <code>&lt;container&gt;#00</code>) where role development is taking place.</p> <p>Roles are not directly associated with the creating user. To create a role, a developer needs only the authorization required to work in the relevant space using the SAP Web IDE for SAP HANA.</p> <p>If roles for different purposes are developed in different containers, then roles are not all owned by the same technical user (as is the case with repository roles).</p>

Feature	Catalog Roles	Design-Time Repository Roles	Design-Time HDI Roles
Grant and revoke process	<p>Roles created in runtime are <b>granted</b> directly by the database user using the SQL GRANT and REVOKE statements.</p> <p>To grant privileges to a role, a user requires either the system privilege ROLE ADMIN, or all the privileges being granted to the role. In the latter case, if any of these privileges are revoked from the granting user, they are automatically revoked from the role.</p> <p>Roles can be <b>revoked</b> by the granting user or any user with the system privilege ROLE ADMIN.</p> <div style="border: 1px solid #0070C0; padding: 5px; margin: 10px 0;"> <p><b>i Note</b></p> <p>With the exception of roles granted by technical user _SYS_REPO, a user with ROLE ADMIN <b>cannot</b> revoke roles granted by technical users SYS and _SYS*.</p> </div> <p>If the granting user is dropped (not necessarily the role creator), all roles that he or she granted are revoked.</p>	<p>Roles are granted and revoked using built-in procedures. Any administrator with the EXECUTE privilege on these can grant and revoke roles.</p>	<p>Roles are granted and revoked using database procedures provided in either the HDI container's or container group's API schema. Any container or container group administrator with the EXECUTE privilege on these procedures can grant and revoke roles.</p> <p>Any user with the system privilege ROLE ADMIN can also grant and revoke roles.</p>

In general, it is recommended that you model roles as design-time objects for the following reasons:

- Unlike roles created in runtime, roles created as design-time objects can be transported between systems. This is important for application development as it means that developers can model roles as part of their application's security concept and then ship these roles or role templates with the application. Being able to transport roles is also advantageous for modelers implementing complex access control on analytic content. They can model roles in a test system and then transport them into a production system. This avoids unnecessary duplication of effort.
- Roles created as design-time objects are not directly associated with a database user. They are created by technical users and granted through the execution of stored procedures. Any user with access to these procedures can grant and revoke a role. Roles created in runtime are granted directly by the database user and can be revoked only by the granting user or a user with the system privilege ROLE ADMIN. Additionally, if the database user is deleted, all roles that he or she granted are revoked. As database users correspond

to real people, this could impact the implementation of your authorization concept, for example, if an employee leaves the organization or is on vacation.

### 7.2.4.8 System Views for Verifying Users' Authorization

You can query several system views to get detailed information about exactly which privileges and roles users have and how they come to have them. This can help you to understand why a user is authorized to perform particular actions, access particular data, or not.

#### → Remember

You must have the system privilege CATALOG READ to query the following views.

System View	Query	Result
ACCESSIBLE_VIEWS	<pre>SELECT * from "PUBLIC"."ACCESSIBLE_VIEWS" where USER_NAME = '&lt;user_name&gt;';</pre>	All views that the user is authorized to access are returned.
EFFECTIVE_APPLICATION_PRIVILEGES	<pre>select * from "SYS"."EFFECTIVE_APPLICATION_PRIVILEGES" where USER_NAME='&lt;user_name&gt;;</pre>	All application privileges granted to the specified user both directly and indirectly through roles are returned separately.
EFFECTIVE_MASK_EXPRESSIONS	<pre>SELECT * FROM EFFECTIVE_MASK_EXPRESSIONS where ROOT_SCHEMA_NAME = '&lt;schema_name&gt;' and ROOT_OBJECT_NAME = '&lt;object_name&gt;' and ROOT_COLUMN_NAME = '&lt;column_name&gt;' and USER_NAME ='&lt;user_name&gt;;</pre>	All masked columns that the specified user can see in the specified view and the corresponding mask expressions

System View	Query	Result
EFFECTIVE_PRIVILEGE_GRANTEES	<p>Object privilege: SELECT * FROM EFFECTIVE_PRIVILEGE_GRANTEES WHERE OBJECT_TYPE = '&lt;object_type&gt;' AND SCHEMA_NAME = '&lt;schema_name&gt;' AND OBJECT_NAME = '&lt;object_name&gt;' AND PRIVILEGE = '&lt;privilege&gt;';</p> <p>System privilege: SELECT * FROM EFFECTIVE_PRIVILEGE_GRANTEES WHERE OBJECT_TYPE = 'SYSTEMPRIVILEGE' AND PRIVILEGE = '&lt;privilege&gt;';</p> <p>XML-based analytic privilege: SELECT * FROM EFFECTIVE_PRIVILEGE_GRANTEES WHERE OBJECT_TYPE = 'ANALYTICPRIVILEGE' AND SCHEMA_NAME = '&lt;schema_name&gt;' AND OBJECT_NAME = '&lt;privilege_object_name&gt;' AND PRIVILEGE = 'EXECUTE';</p> <p>SQL-based analytic privilege: SELECT * FROM EFFECTIVE_PRIVILEGE_GRANTEES WHERE OBJECT_TYPE = 'SQLANALYTICPRIVILEGE' AND SCHEMA_NAME = '&lt;schema_name&gt;' AND OBJECT_NAME = '&lt;privilege_object_name&gt;' AND PRIVILEGE = 'EXECUTE';</p>	All users or roles who have the specified privilege are returned.
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>For analytic privileges, schema name is optional.</p> </div>		
EFFECTIVE_PRIVILEGES	SELECT * FROM "PUBLIC"."EFFECTIVE_PRIVILEGES" where USER_NAME = '<user_name>';	All privileges granted to the specified user both directly and indirectly through roles are returned separately.
EFFECTIVE_ROLE_GRANTED	SELECT * FROM EFFECTIVE_ROLE_GRANTED WHERE ROLE_NAME = '<role_name>';	All users or roles who have the specified role are returned.

System View	Query	Result
EFFECTIVE_ROLES	<pre>SELECT * FROM "PUBLIC"."EFFECTIVE_ROLES" where USER_NAME = '&lt;user_name&gt;' AND ROLE_SCHEMA_NAME = '&lt;schema_name of role&gt;';</pre>	All roles granted to the specified user both directly and indirectly through other roles are returned separately.
<div style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>Schema name is optional.</p> </div>		
EFFECTIVE_STRUCTURED_PRIVILEGES	<pre>SELECT * from "PUBLIC"."EFFECTIVE_STRUCTURED_PRIVILEGES" where ROOT_SCHEMA_NAME = '&lt;schema&gt;' AND ROOT_OBJECT_NAME = '&lt;object_name&gt;' AND USER_NAME = '&lt;user_name&gt;'</pre>	The analytic privileges that are applicable to the specified view are returned, including dynamic filter conditions if relevant. It is also indicated whether or not the specified user is authorized to access the view.
GRANTED_PRIVILEGES	<pre>SELECT * FROM "PUBLIC"."GRANTED_PRIVILEGES" where GRANTEE = '&lt;user_name&gt;';</pre>	Privileges granted directly to the specified user (or role) are returned. Privileges contained within granted roles are not shown.
<div style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>It is possible to query the privileges directly granted to a role by replacing where GRANTEE = '&lt;USER&gt;' with where GRANTEE = '&lt;ROLE&gt;'</p> </div>		
GRANTED_ROLES	<pre>SELECT * FROM "PUBLIC"."GRANTED_ROLES" where GRANTEE = '&lt;user/role_name&gt;';</pre>	All roles granted directly to the specified user (or role) are returned. Roles contained within granted roles are not shown.
<div style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>It is possible to query the roles directly granted to a role by replacing where GRANTEE = '&lt;USER&gt;' with where GRANTEE = '&lt;ROLE&gt;'</p> </div>

## 7.2.4.9 Resolve Insufficient Privilege Errors

Use the built-in procedure `GET_INSUFFICIENT_PRIVILEGE_ERROR_DETAILS` to find out which privilege a user is missing when he or she gets an "insufficient privilege" error.

### Prerequisites

- You have the EXECUTE object privilege on `GET_INSUFFICIENT_PRIVILEGE_ERROR_DETAILS`.
- You have the GUID of the error received by the end user experiencing the authorization issue.

#### ❖ Example

```
insufficient privilege: Detailed info for this error can be found with guid  
'3DFFF7D0CA291F4CA69B327067947BEE'
```

### Context

When a user is not authorized to perform an operation and receives an "insufficient privilege" error, it is often difficult to know which privilege or privileges the user is in fact missing. Many "insufficient privilege" errors therefore also return a GUID that allows you as an administrator to identify the missing privilege. Then you can decide whether or not to grant the privilege to the user.

#### i Note

Not all "insufficient privilege" errors can be resolved by granting the user a missing privilege, for example, some operations can only be performed by the SYS user, or by a user in the system database. In these cases, the error message provides the explanation.

If the user is missing several privileges, only the first missing privilege determined by the authorization check is returned. You can find out what other privileges are missing by successively running `GET_INSUFFICIENT_PRIVILEGE_ERROR_DETAILS` with the GUID returned with each subsequent error message.

The details of every "insufficient privilege" error due missing user privileges are stored in an internal table for 144 hours by default. The number of entries in this table is limited to 10,000. This configuration is controlled by the following parameters in the `authorization` section of the `global.ini` file:

- `insufficient_privilege_error_details_retain_duration`
- `insufficient_privilege_error_details_retain_records`

## i Note

It is possible to disable this feature by setting the parameter `enable_insufficient_privilege_error_details_procedure` to `false`. However, then it is only possible to troubleshoot authorization errors using the database trace, which may not be feasible in all scenarios.

## Procedure

Execute the procedure `GET_INSUFFICIENT_PRIVILEGE_ERROR_DETAILS`:

```
call SYS.GET_INSUFFICIENT_PRIVILEGE_ERROR_DETAILS ('<GUID in "insufficient
privilege" error>', ?)
```

## Results

The result provides you with information about the first authorization check performed for the particular user connection.

## Next Steps

If you grant the end user the identified missing privilege and he or she gets another "insufficient privilege", then the user is missing another privilege. Call the procedure again with the GUID of the next error message to troubleshoot further.

[Database Trace \(Basic, User-Specific, and End-to-End\) \[page 766\]](#)

## 7.2.4.10 Resolve Errors Using the Authorization Dependency Viewer

You can use the authorization dependency viewer in the SAP HANA studio as a first step in troubleshooting authorization errors and invalid object errors for stored procedures and calculation views with complex dependency structures.

### Prerequisites

You have the system privilege CATALOG READ.

### Context

The authorization dependency viewer is a graphical tool that depicts the object dependency structure of stored procedures and calculation views together with the SQL authorization status of the object owner along the dependency paths.

You can use the authorization dependency viewer as a first step in troubleshooting the following authorization errors and invalid object errors for these object types:

- NOT AUTHORIZED (258)
- INVALIDATED VIEW (391)
- INVALIDATED PROCEDURE (430)

Authorization or invalid object errors occur if the object owner does not have all the required privileges on all underlying objects on which the object depends (for example, tables, views, and procedures). The object owner must have both the appropriate SQL object privilege (for example, EXECUTE, SELECT) and the authorization to grant the object privilege to others (that is, WITH GRANT OPTION is set).

The authorization dependency viewer helps you to identify where there are invalid authorization dependencies in the object structure. This is particularly useful for objects with large and complex dependency structures.

#### → Recommendation

Use the authorization dependency viewer only with procedures with security mode DEFINER. Procedures with security mode INVOKER are not validated correctly.

#### ⚠ Caution

The authorization dependency viewer simply shows you which privileges are missing. Grant missing privileges with due care.

## Procedure

1. Open the procedure or calculation view in the authorization dependency viewer:
  - a. Navigate to the object in the *Systems* view.
  - b. In the context menu, choose *Show Authorization*.

The object dependency structure is displayed as a hierarchical tree. Each node in the structure represents a database object. The same database object may appear multiple times if it is referenced at different levels of the tree. The lines connecting the nodes indicate the nature and status of the authorization dependency between the objects. For information, see *Classification of Authorization Dependencies Between Objects*.

Full information about the connection is also displayed in the *Properties* view when you select the connection.

### i Note

If the *Properties* view is not visible, from the main menu choose ► *Window* ► *Show View* ► *Properties* ►.

2. Isolate the object(s) with missing authorization by choosing the  *Show missing authorization only* button.
3. Optional: If necessary, manipulate the view to help your analysis using the available toolbar options.
4. Grant the missing privilege(s) to the user with the invalid dependency.

This might be your user if you are the object owner, but it might also be the owner of another object if you are facing a complex object hierarchy.
5. In the authorization dependency viewer, refresh () the view to verify the validity of previously invalid dependencies.

## Related Information

[Classification of Authorization Dependencies Between Objects \[page 886\]](#)

### 7.2.4.10.1 Example: Resolving an Invalidated Procedure Error

This example shows you how you identify the source of an invalidated procedure error using the authorization dependency viewer.

## Context

Assume the following:

User DEPVIEWER is the owner of the schema DEPVIEWER, which contains the objects DEPVIEW and DEPTABLE.

User BODOS creates the procedures PROC\_TO\_PROC\_HIER, PROC\_TO\_PROC, and PROC\_TO\_DEPVIEWER. The objects are dependent on each other as follows:

- PROC\_TO\_PROC\_HIER executes the procedures PROC\_TO\_DEPVIEWER and PROC\_TO\_PROC.
- PROC\_TO\_PROC executes PROC\_TO\_DEPVIEWER
- PROC\_TO\_PROC selects and deletes from DEPTVIEW.
- PROC\_TO\_DEPVIEWER selects from DEPTABLE and DEPTVIEW.
- DEPTVIEW selects from DEPTABLE.

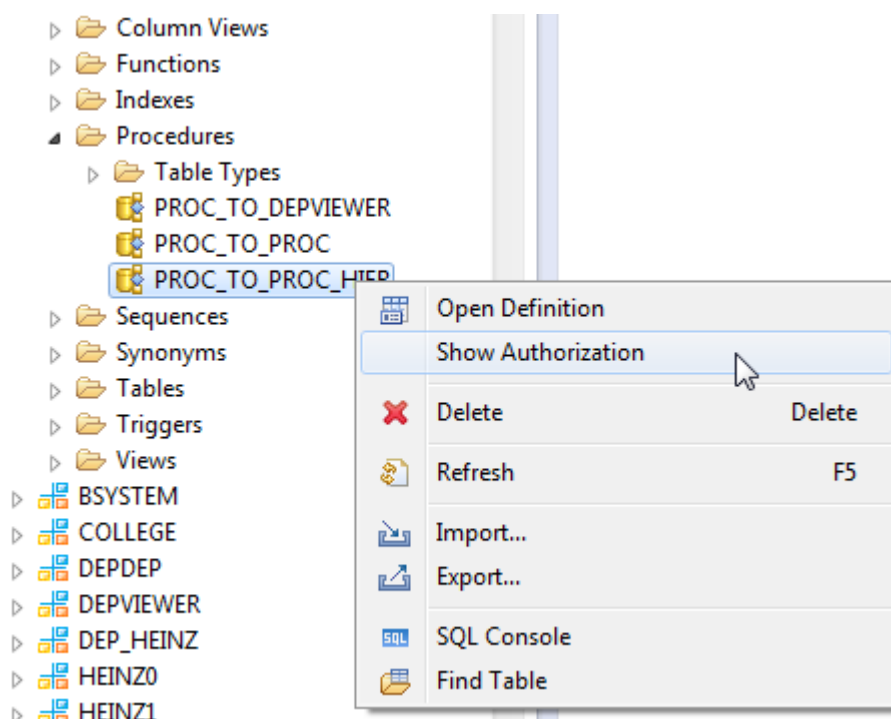

Other users are now granted EXECUTE privilege on PROC\_TO\_PROC\_HIER. However, when they execute the procedure, the following error appears:

```
Could not execute 'call PROC_TO_PROC_HIER' SAP DBTech JDBC: [430]: invalidated procedure: PROC_TO_PROC_HIER: line 1 col 6 (at pos 5)
```

You can use the authorization dependency viewer to isolate the source of the problem as follows:

## Procedure

1. In the *Systems* view, navigate to the procedure PROC\_TO\_PROC\_HIER and from the context menu, choose *Show Authorization*:

The full authorization dependency structure of the procedure is displayed as a hierarchical tree:

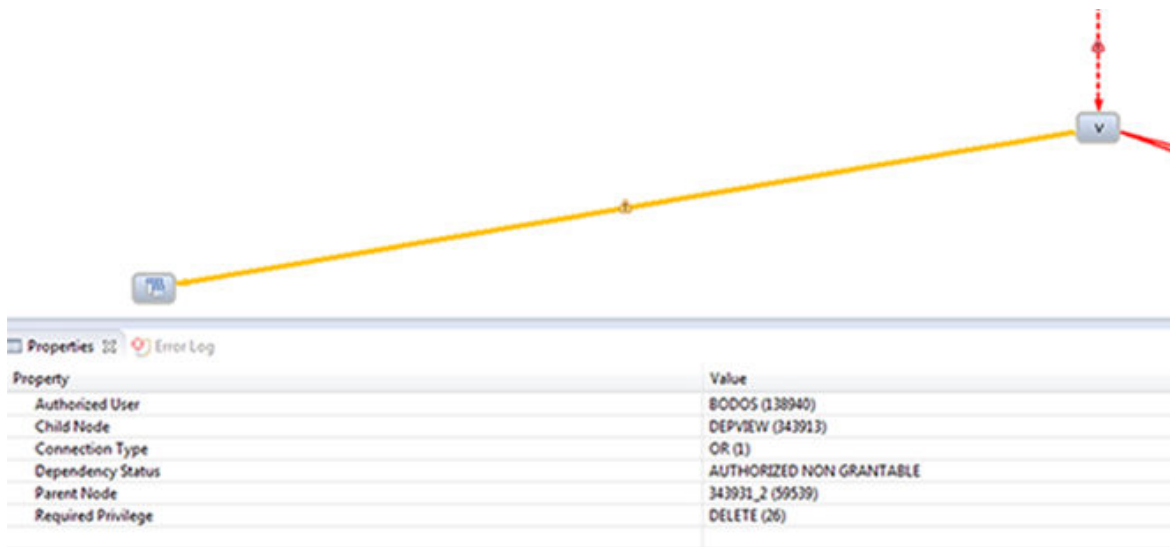

- From the toolbar, choose  (*Show missing authorization only*).

Only the invalid dependency path is shown. You can see that privileges are missing on either the view DEPVIEW or its parent schema DEPVIERER:

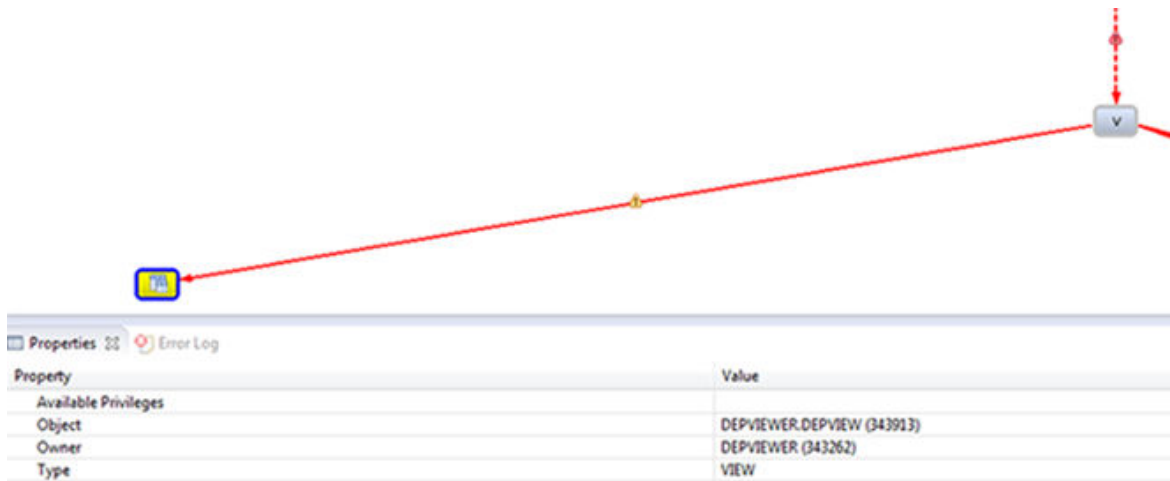

- To examine the invalid dependency path in more detail, select the connection to the view.

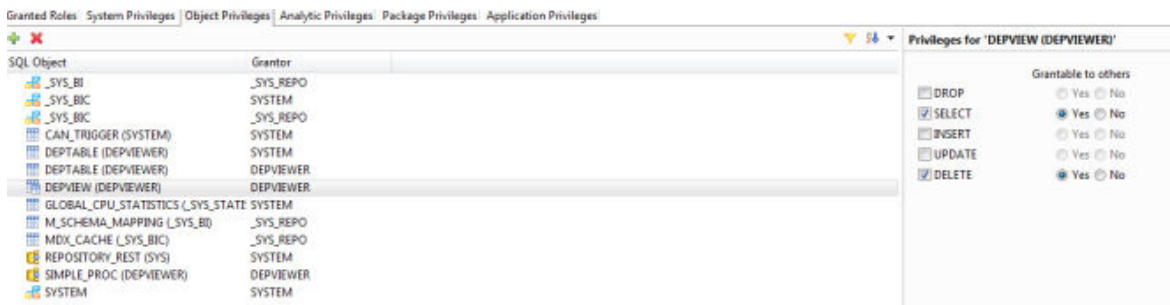

In the *Properties* view, you can see that the owner of the procedure has the required DELETE privilege on the underlying view, but is not authorized to grant this privilege further (dependency status is AUTHORIZED NON GRANTABLE). This invalidates the procedure that references the view.

- To see who owns the view (and therefore who needs to grant the missing authorization) select the object.

In the *Properties* view, you can see that the view DEPVIEW is owned by the user DEPVIEWER.

- As user DEPVIEWER, in the user definition of user BODOS, select *Grantable to others* for the EXECUTE privilege on the object DEPVIEW:

### i Note

Any user to whom user DEPVIEWER has granted the required privilege with authorization to grant further could also grant the missing authorization to user BODOS.

6. In the authorization dependency viewer, choose .

There are now no invalid authorization dependencies; the procedure is valid ():

## 7.2.4.10.2 Classification of Authorization Dependencies Between Objects

The authorization dependency viewer visualizes a root object's authorization dependency structure as a hierarchical tree. The lines connecting the nodes in the tree indicate the nature and status of the authorization dependency between the objects.

Connection	Description
Long dash line (----)	An AND connection exists between the parent node and the child nodes. Access to the parent node requires authorization to all child nodes.
Solid line (-----)	An OR connection exists between the parent node and the child nodes. Access to the parent node requires authorization to one of the child nodes.
Black line	The authorization dependency status is valid, that is, the user has the required privilege to the child object and is authorized to grant it further. This is additionally indicated by the  (AUTHORIZED GRANTABLE) icon.

Connection	Description
Red line	<p>The authorization dependency status is invalid in some way. The following icons indicate the exact status:</p> <ul style="list-style-type: none"> <li>  (NOT AUTHORIZED)            The user does not have the required privilege for the child object.         </li> <li>  (AUTHORIZED NON GRANTABLE)            The user has the required privilege for the child object but is not authorized to grant it further because he is missing WITH GRANT OPTION.         </li> <li>  (AUTHORIZED NON GRANTABLE_ENFORCED)            The user has the required privilege for the child object but is not able to grant it further because it itself is not grantable. This fact determines the dependency status of the parent object even if the parent object has an OR connection to another child object with valid authorization.         </li> <li>  (INVALID)            The user does not have the required privilege for the child object or the child object is invalidated. This fact determines the dependency status of the parent object even if the parent object has an OR connection to another child object with a valid dependency status.         </li> </ul>

### 7.2.4.10.3 Toolbar Options in the Authorization Dependency Viewer

Several options in the authorization dependency viewer allow you to manipulate the view to help your analysis of authorization errors.

Option	Description
 (Switch to the graph view)	<p>Opens the graph view</p> <p>This view shows the dependency structure as a graph. In the tree view, the same database object might appear multiple times if it is referenced at different levels of the tree. In the graph view, each database object is only one node. This feature might be helpful in identifying the single root cause of your problem.</p>
 (Switch to the object dependencies only view)	<p>Opens the object dependencies view</p> <p>This view shows the transitive closure of all objects on which the view or procedure depends. This tree does not contain duplicate nodes or meta nodes.</p>
 (Zoom in)/ (Zoom out)	<p>Zooms in or out of the dependency structure for the required level of detail</p>

Option	Description
 (Reset zoom)	Resets the view after zooming
 (Auto arrange)	Resets the view after rearranging

## 7.2.4.11 Restrict Use of the CLIENT User Parameter

Allow only authorized technical users to overwrite the value of the `CLIENT` parameter for a database connection or the value of the `$$client$$` parameter in an SQL query.

### Context

The `CLIENT` user parameter can be used to authorize named users in SAP HANA database. Only a user with the `USER ADMIN` system privilege can change the value of the `CLIENT` parameter already assigned to other users. However, at runtime, any user can assign an arbitrary value to the `CLIENT` parameter either by setting the corresponding session variable or passing the parameter via placeholder in a query.

While this is the desired behavior for technical users that work with multiple clients such as SAP Business Warehouse, S/4 HANA, or SAP Business Suite, it is problematic in named user scenarios if the `CLIENT` parameter is used to authorize access to data and not only to perform data filtering.

### Procedure

1. Grant the system privilege `CLIENT PARAMETER ADMIN` to database users or roles who are permitted to access to the `CLIENT` user parameter (for example, technical users).

#### Sample Code

```
GRANT CLIENT PARAMETER ADMIN TO <user or role>;
```

2. In the `global.ini` configuration file, see the value of the `[authorization]` `secure_client_parameter` to `true`.

### Results

Only users with the system privilege `CLIENT PARAMETER ADMIN` can overwrite the value of the `CLIENT` parameter for a database connection or the value of the `$$client$$` parameter in an SQL query.

## Related Information

[SAP Note 2582162](#)

## 7.2.5 Provisioning Users

As a user administrator, you create and configure database users, as well as authorize them to work with the SAP HANA database.

The recommended process for provisioning users is as follows:

1. Define and create roles.
2. Create users.
3. Grant roles to users.

Further tasks related to user provisioning include for example:

- Deleting users when they leave the organization
- Reactivating users after too many failed logon attempts
- Deactivating users if a security violation has been detected
- Resetting user passwords

### i Note

If you are using an Identity Management (IDM) system for user provisioning, it is highly recommended that you create a dedicated technical user for that system that has the system privileges USER ADMIN and ROLE ADMIN and object privilege EXECUTE on the procedure GRANT\_ACTIVATED\_ROLE. This database user should then be used exclusively by the IDM system for its user provisioning tasks.

## Related Information

[Catalog Roles and Design-Time Roles Compared \[page 873\]](#)

### 7.2.5.1 Provisioning Users in SAP HANA Cockpit

You can use the SAP HANA cockpit to create database users and grant them roles.

### i Note

Use SQL to create the technical user required to register a database through the SAP HANA cockpit and grant the minimum necessary authorizations:

```
CREATE USER <username> PASSWORD <password> NO FORCE_FIRST_PASSWORD_CHANGE  
VALID UNTIL FOREVER;  
GRANT CATALOG READ to <username>;
```

```
GRANT SELECT on SCHEMA _SYS_STATISTICS to <username>
```

## 7.2.5.1.1 View a Database User

You can view database users on the [User Management](#) page of the SAP HANA cockpit.

### Prerequisites

- You have the system privilege CATALOG READ. You don't require any additional privileges to view your own database user.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [User Management](#).

An overview of all existing database users is displayed.

2. To see more detailed information about a specific user, simply select it.

For more information, see [Database User Details](#).

### Related Information

[Database User Details \[page 891\]](#)

## 7.2.5.1.1.1 Database User Details

On the *User Management* page of the SAP HANA cockpit, you can view the details of all users in the SAP HANA database.

### General Information

Field	Description
<i>User Name</i>	Unique user name
<i>User Group</i>	A user can belong to only one user group, but a user does not have to be a member of any group.
<i>E-Mail</i>	User's e-mail address
<i>Valid From/To</i>	Validity period of the user  If the user account is not currently within its validity period, the user is inactive and cannot log on.  If no validity period is configured, the user is indefinitely valid.
<i>Last Successful Login</i>	The last time the user logged on successfully
<i>Deactivated Since</i>	Time the user was deactivated
<i>Creation of Objects in Own Schema</i>	Indicates whether or not the user can create objects in their database schema  Standard users can create objects in their schema. Restricted users cannot.  For more information about the difference between standard and restricted users, see <i>Database Users</i> .
<i>PUBLIC Role</i>	Indicates whether or not the user has the PUBLIC role  Standard users have this role by default. Restricted users do not.  For more information about the difference between standard and restricted users, see <i>Database Users</i> .
<i>Disable ODBC/JDBC Access</i>	Indicates whether or not the user can connect to the database via ODBC or JDBC  By default, ODBC/JDBC access is disabled for restricted users, meaning they can only connect via HTTP/HTTPS, and enabled for standard users.  For more information about the difference between standard and restricted users, see <i>Database Users</i> .
<i>Comment</i>	Free-text comment or description (if applicable)

## Authorization Mode

Field	Description
<a href="#">Authorization Mode</a>	<p>Indicates whether the user's authorization is based on LDAP group membership or local SAP HANA mechanisms</p> <p>A user with authorization mode <a href="#">LDAP</a> is granted roles exclusively based on their LDAP group membership. It is not possible to grant such a user other roles or privileges directly.</p> <p>The default user authorization mode is <a href="#">Local</a>. This means that the user must be granted roles and privileges directly.</p> <p>For more information about LDAP group authorization, see the <a href="#">SAP HANA Security Guide</a>.</p>
<a href="#">Assign Roles</a>	The <a href="#">Assign Roles</a> view is displayed on the right of the screen.
<a href="#">Assign Privileges</a>	Open the <a href="#">Assign Privileges</a> app where you can assign privileges to the user

## Authentication

Field	Description
<a href="#">Password</a>	<p>Indicates whether or not user name-password authentication is enabled</p> <p>Users accessing the SAP HANA database authenticate themselves by entering their database user name and either their local SAP HANA password or a password stored in an LDAP directory server.</p>
<a href="#">Force password change on next logon</a>	Indicates whether the user must change a password set by a user administrator the first time he or she logs on, regardless of how the password policy parameter <a href="#">Password Change Required on First Logon</a> is configured
<a href="#">Kerberos</a>	<p>Indicates whether or not Kerberos authentication is enabled</p> <p>If enabled, the external identity to which the database user is mapped must be specified.</p>
<a href="#">SAP Logon Ticket, SAP Assertion Ticket</a>	Indicates whether or not authentication using SAP logon or assertion tickets is enabled
<a href="#">SAML</a>	<p>Indicates whether or not SAML authentication is enabled</p> <p>If enabled, the external identity to which the database user is mapped can be explicitly specified. Alternatively, if the option <a href="#">Automatic Mapping by Provider</a> is selected, the identity provider is allowed to map its users to the database user.</p>

Field	Description
<i>JWT</i>	<p>Indicates whether or not JSON Web Token authentication is enabled</p> <p>If enabled, the external identity to which the database user is mapped can be explicitly specified. Alternatively, if the option <i>Automatic Mapping by Provider</i> is selected, the identity provider is allowed to map its users to the database user.</p>
<i>X509</i>	Indicates whether or not X.509 certificate authentication is enabled

### **i** Note

For more information about authentication mechanisms, see the *SAP HANA Security Guide*.

## Custom User Properties

Additional user properties can be configured for client applications. The following properties are available by default:

Property	Description
CLIENT	<p>The session client</p> <p>When you create SAP HANA calculation views, it is possible to filter the data according to the client specified in table fields such as MANDT or CLIENT.</p>
LOCALE	<p>The user's locale</p> <p>When you create SAP HANA information models (attribute views, analytic views, and calculation views), this parameter can be used to translate information according to the user's locale.</p>
PRIORITY	<p>The priority with which the thread scheduler handles statements executed by the user</p> <p>Priority values of 0 (lowest priority) to 9 (highest) are available; the default priority is 5.</p>

Property	Description
STATEMENT MEMORY LIMIT	<p>The maximum memory (in GB) that can be used by a statement executed by the user</p> <p>The properties <code>statement_memory_limit</code> and <code>statement_memory_limit_threshold</code> in the <code>memory_manager</code> section of the <code>global.ini</code> configuration file are used to limit the memory that can be allocated with respect to statement execution.</p> <p><code>statement_memory_limit_threshold</code> indicates what percentage of the global memory allocation limit must be in use before the specific value of <code>statement_memory_limit</code> is applied. If this memory limit is being applied and a statement execution exceeds it, then the statement is aborted.</p> <p>With this user parameter, you can set a user-specific limit that takes precedence over the global statement memory limit.</p> <p>For more information about memory usage, see <i>Setting a Memory Limit for SQL Statements</i> in the <i>SAP HANA Administration Guide</i>.</p>
STATEMENT THREAD LIMIT	<p>The maximum number of threads that can be used by a statement executed by the user</p>
TIME ZONE	<p>The user's timezone</p> <p>The standard database formats for locale and timezone are supported.</p>

## 7.2.5.1.2 View a Database Role

You can view database roles on the [Role](#) page of the SAP HANA cockpit.

### Prerequisites

- You have the system privilege CATALOG READ or ROLE ADMIN.

#### i Note

Even if ROLE ADMIN was revoked from your user, you can still view roles that you created yourself.

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [Role Management](#).

An overview of all existing database roles is displayed.

2. To see more detailed information about a specific role, simply select it.

For more information, see [Database Role Details](#).

### Related Information

[Database Role Details \[page 896\]](#)

## 7.2.5.1.2.1 Database Role Details

On the [Role Management](#) page of SAP HANA cockpit, you can view the details of all roles in the SAP HANA database.

### General Information

Field	Description
<a href="#">Schema</a>	<p>Schema in which the role exists (if applicable)</p> <p>The schema represents the role's runtime namespace, which allows it to be used in different contexts.</p> <p>A role without a schema is a global role.</p> <div style="border: 1px solid orange; padding: 5px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>A role with a namespace will be deleted if the schema is deleted.</p> </div>
<a href="#">Creator</a>	User who created the role
<a href="#">LDAP Groups</a>	<p>LDAP groups that have been mapped to the role (if applicable)</p> <p>Database users configured for LDAP authorization who belong to the specified group(s) are automatically granted the role in line with your LDAP configuration for SAP HANA. For more information, see the <i>SAP HANA Security Guide</i>.</p>
<a href="#">Comment</a>	Free-text comment or description (if applicable)
<a href="#">Type</a>	<p>The role type:</p> <ul style="list-style-type: none"> <li>• <a href="#">Catalog</a> A role created in run-time with the SQL statement <code>CREATE ROLE</code></li> <li>• <a href="#">Catalog (LDAP)</a> A catalog role with LDAP group mappings</li> <li>• <a href="#">HDI</a> A role created using the SAP Web IDE for SAP HANA and deployed using SAP HANA deployment infrastructure (SAP HANA DI)</li> <li>• <a href="#">HDI (LDAP)</a> A HDI role with LDAP group mappings LDAP groups are mapped to the activated catalog role.</li> <li>• <a href="#">Repository role</a> A role created in the built-in repository of the SAP HANA database using either the SAP HANA Web Workbench or the SAP HANA studio</li> </ul>

Field	Description
<i>Is Part of Roles</i>	Indicates whether the role is included in another role
<i>Roles</i>	Other roles granted to this role
<i>System Privileges</i>	<p>System privileges granted to the role</p> <p>System privileges control general system activities. They are mainly used for administrative purposes, such as creating schemas, creating and changing users and roles, performing data backups, managing licenses, and so on.</p> <p>For a list of all system privileges, see <i>System Privileges (Reference)</i> in the <i>SAP HANA Administration Guide</i>.</p>
<i>Object Privileges</i>	<p>Object privileges granted to the role</p> <p>Object privileges are used to allow access to and modification of database objects, such as tables and views. Depending on the object type, different actions can be authorized (for example, SELECT, CREATE ANY, ALTER, DROP, and so on).</p> <p>For a list of all object privileges, see <i>Object Privileges (Reference)</i> in the <i>SAP HANA Administration Guide</i>.</p>
<i>Analytic Privileges</i>	<p>Analytic privileges granted to the role</p> <p>Analytic privileges are used to control read access to data in SAP HANA information models (that is, analytic views, attribute views, and calculation views) depending on certain values or combinations of values.</p>
<i>Is Part of Roles</i>	Other roles to which this role has been granted
<i>Application Privileges</i>	<p>Application privileges granted to the role</p> <p>Application privileges are used to authorize user and client access to SAP HANA XS classic applications.</p>

**i Note**

Application privileges are not relevant in the context of SAP HANA XS advanced applications. For more information about the authorization concept of the SAP HANA XS advanced, see the *SAP HANA Security Guide*.

Field	Description
<i>Package Privileges</i>	<p>Package privileges granted to the role</p> <p>Package privileges are used to allow access to and the ability to work in packages in the repository of the SAP HANA database.</p> <div data-bbox="804 510 1394 680" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>With SAP HANA XS advanced, source code and web content are not versioned and stored in the repository, so package privileges are not relevant in this context.</p> </div>
<i>Privileges on Users</i>	<p>Privileges on users granted to the role</p> <p>ATTACH DEBUGGER is the only privilege that can be granted on a user.</p> <p>For example, User A can grant User B the privilege ATTACH DEBUGGER to allow User B debug SQLScript code in User A's session. User A is only user who can grant this privilege. Note that User B also needs the object privilege DEBUG on the relevant SQLScript procedure.</p>

## 7.2.5.1.3 Create a Role

You can create a new role and grant it privileges and roles on the [Role Management](#) page of the SAP HANA cockpit. You can also map roles to LDAP groups if you are implementing user authorization based on LDAP group membership.

### Prerequisites

- You have the system privilege `ROLE ADMIN`.
- You have the privileges required to grant privileges and roles to the new role.  
For more information, see [Prerequisites for Granting and Revoking Privileges and Roles](#).
- You've navigated to the [Database Overview](#) page of the database you want to manage. See [Getting to the Database Overview Page](#) in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [Role Management](#).

An overview of all existing database roles is displayed.

2. Create the role:
  - a. Click the **+** (*Add*) icon.
  - b. Specify a unique role name.
  - c. Optional: Enter a comment or text to describe the role.
  - d. Optional: Assign the role a runtime namespace by choosing the schema in which to create the role.

Role namespaces allow you to reuse role names in different contexts. If you do not select a schema, the role will be created as a global role.

#### Caution

A role with a namespace will be deleted if the schema is deleted.

3. Optional: If you are implementing user authorization based on LDAP group membership, map one or more LDAP group to the role:
  - a. Enable the assignment of LDAP groups to the role.
  - b. Add the required LDAP groups by specifying the unique distinguished name (DN).

Users configured for LDAP authorization who belong to the specified group(s) are automatically granted the role in line with your LDAP configuration for SAP HANA. For more information, see the *SAP HANA Security Guide*.

4. Choose [Create](#).

The role is created.

5. Assign the required roles to the role:

- a. In the *Roles* area, choose *Edit*.
  - b. Choose *Add* and select the roles you want to assign.
  - c. If you want users who have the new role to be able to grant the assigned role on to others, choose *Grantable to Others*.
  - d. Save the role assignment.
6. Assign the required privileges to the role:
- a. For the relevant privilege type, choose *Edit*.
  - b. Choose *Add* and select the privileges you want to assign.

#### **i Note**

For object and package privileges, you must first add the object or package and then add the required privilege to the object or package.

- c. If you want users who have the new role to be able to grant the assigned privilege on to others, choose *Grantable to Others*.
- d. Save the privilege assignment.
- e. Repeat for further privilege types.

## **Results**

The role is created and appears in the list of roles on the left.

## **Next Steps**

Assign the role to the required database users. You should only do this for users with authorization mode *Local*, not *LDAP*.

If you mapped LDAP groups to the role, configure the connection to the LDAP provider and configure the required database users for LDAP group authorization. For more information, see the *SAP HANA Administration Guide*.

## 7.2.5.1.3.1 Prerequisites for Granting and Revoking Privileges and Roles

To be able to grant and revoke privileges and roles to and from users and roles, several prerequisites must be met.

The following table lists the prerequisites that a user must meet to grant privileges and roles to another user (or role).

### Prerequisites for Granting Privileges

To grant...	The granting user needs...
A system privilege	The system/object privilege being granted and be authorized to grant it to other users and roles
An object privilege on an object that exists only in runtime	
An object privilege on objects deployed to an HDI container	One of the following: <ul style="list-style-type: none"> <li>• The privilege being granted and be authorized to grant it to other users and roles</li> <li>• Privileges to execute GRANT_CONTAINER_SCHEMA_PRIVILEGES in the container's API schema, or, if the user is a container group administrator, privileges to execute GRANT_CONTAINER_SCHEMA_PRIVILEGES in the container group's API schema.</li> </ul>
	<b>→ Recommendation</b> It is recommended that you grant and revoke privileges on objects deployed to an HDI container using a role deployed to the container.
An analytic privilege deployed to an HDI container	The privilege being granted and be authorized to grant it to other users and roles
	<b>→ Recommendation</b> It is recommended that you grant and revoke analytic privileges deployed to an HDI container using a role deployed to the container.
An object privilege on an activated object created in the repository, such as a calculation view (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure GRANT_PRIVILEGE_ON_ACTIVATED_CONTENT
An object privilege on a schema containing activated objects created in the repository, such as a calculation view (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure GRANT_SCHEMA_PRIVILEGE_ON_ACTIVATED_CONTENT
A package privilege (SAP HANA XS classic model)	The package privilege being granted and be authorized to grant it to other users and roles

To grant...	The granting user needs...
An analytic privilege created in the repository (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure GRANT_ACTIVATED_ANALYTICAL_PRIVILEGE
An application privilege (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure GRANT_APPLICATION_PRIVILEGE
Privilege on user ATTACH DEBUGGER	To be the user on which ATTACH DEBUGGER is granted
A role created in runtime	Either: <ul style="list-style-type: none"> <li>The role being granted and be authorized to grant it to other users and roles, or</li> <li>The system privilege ROLE ADMIN</li> </ul>
A role deployed to an HDI container	One of the following: <ul style="list-style-type: none"> <li>The role being granted and be authorized to grant it to other users and roles, or</li> <li>The system privilege ROLE ADMIN</li> <li>Privileges to execute GRANT_CONTAINER_SCHEMA_ROLES in the container's API schema, or, if the user is a container group administrator, privileges to execute GRANT_CONTAINER_SCHEMA_ROLES in the container group's API schema.</li> </ul>
A role created in the repository (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure GRANT_ACTIVATED_ROLE

#### Prerequisites for Revoking Privileges

To revoke ...	The revoking user needs...
A system privilege	To be the user who granted the privilege
An object privilege on an object that exists only in runtime	
An object privilege on objects deployed to an HDI container	One of the following: <ul style="list-style-type: none"> <li>Be the user who granted the privilege</li> <li>Privileges to execute REVOKE_CONTAINER_SCHEMA_PRIVILEGES in the container's API schema, or, if the user is a container group administrator, privileges to execute REVOKE_CONTAINER_SCHEMA_PRIVILEGES in the container group's API schema.</li> </ul>

#### → Recommendation

It is recommended that you grant and revoke privileges on objects deployed to an HDI container using a role deployed to the container.

An analytic privilege deployed to an HDI container	Be the user who granted the privilege
--	---------------------------------------

#### → Recommendation

It is recommended that you grant and revoke analytic privileges deployed to an HDI container using a role deployed to the container.

To revoke ...	The revoking user needs...
An object privilege on an activated object created in the repository, such as a calculation view (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure REVOKE_PRIVILEGE_ON_ACTIVATED_CONTENT
An object privilege on schema containing activated objects created in the repository, such as a calculation view (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure REVOKE_SCHEMA_PRIVILEGE_ON_ACTIVATED_CONTENT
A package privilege (SAP HANA XS classic model)	The user who granted the privilege
An analytic privilege created in the repository (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure REVOKE_ACTIVATED_ANALYTICAL_PRIVILEGE
An application privilege (SAP HANA XS classic model)	The object privilege EXECUTE on the procedure REVOKE_APPLICATION_PRIVILEGE
Privilege on user ATTACH DEBUGGER	To be the user on which ATTACH DEBUGGER is granted
A role created in runtime	<ul style="list-style-type: none"> <li>To be the user who granted the role, or</li> <li>The system privilege ROLE ADMIN</li> </ul>
<div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>With the exception of roles granted by technical user <code>_SYS_REPO</code>, a user with ROLE ADMIN <b>cannot</b> revoke roles granted by technical users <code>SYS</code> and <code>_SYS*</code>.</p> </div>	
A role created in the repository	The object privilege EXECUTE on the procedure REVOKE_ACTIVATED_ROLE
A role deployed to an HDI container	One of the following: <ul style="list-style-type: none"> <li>Be the user who granted the role</li> <li>The system privilege ROLE ADMIN</li> <li>Privileges to execute REVOKE_CONTAINER_SCHEMA_ROLES in the container's API schema, or, if the user is a container group administrator, privileges to execute REVOKE_CONTAINER_SCHEMA_ROLES in the container group's API schema.</li> </ul>

## Authorization of User `_SYS_REPO`

If you are implementing your authorization concept using roles and you are creating roles in the repository of the SAP HANA database, the technical user `_SYS_REPO` is the granting and revoking user. `_SYS_REPO` **automatically** meets all of the above prerequisites with the exception of those for granting/revoking objects privileges on objects that exist only in runtime. These privileges must be explicitly granted to `_SYS_REPO`. For more information about roles as repository objects, see the *SAP HANA Security Guide*.

## How are HDI roles granted and revoked?

In the SAP HANA deployment infrastructure (HDI), there are two types of user that can grant or revoke roles.

Roles created in an HDI container can be granted to (or revoked from) other roles and users either by an administrator of the container or an administrator of the container group that the container belongs to.

Preferably, roles created in an HDI container are granted or revoked by a container administrator.

For more information about granting and revoking access to objects deployed to an SAP HDI container, see the *SAP HANA Deployment Infrastructure (HDI) Reference*.

[SAP HANA Security Guide](#)

### 7.2.5.1.4 Change a Role

You can change the roles and privileges assigned to a role on the [Role Management](#) page of SAP HANA cockpit.

## Prerequisites

- You have the system privilege `ROLE ADMIN` or are the owner of the role.
- You have the privileges required to grant privileges and roles to the role. For more information, see *Prerequisites for Granting and Revoking Privileges and Roles*.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

It is possible to change a catalog role by revoking roles and privileges from the role or granting further roles and privileges.

### Caution

Do not change roles that were originally created in design time, that is, **HDI roles** or **repository roles**. If you change the runtime version of such a role, your changes will be overwritten the next time a new version of

the design-time role is deployed. For more information about creating roles in design time, see the SAP HANA developer documentation.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to *User & Role Management*, then choose *Role Management*.

An overview of all existing database roles is displayed.

2. Find the role you want to change.

### → Tip

Search for a role by entering the name or part of the name in the search box.

3. To change the role's LDAP group mapping or comment, choose the *Edit* button in the header area.
4. To change the roles or privileges assigned to the role, select the relevant tab page and choose *Edit*.
5. Make the required changes and save.

## Related Information

[Database Role Details \[page 896\]](#)

[Prerequisites for Granting and Revoking Privileges and Roles \[page 901\]](#)

### 7.2.5.1.5 Delete a Role

You can delete a role on the *Role Management* page of the SAP HANA cockpit.

## Prerequisites

- You have the system privilege `ROLE ADMIN`.
- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to *User & Role Management*, then choose *Role Management*.

An overview of all existing database roles is displayed.

2. Find the role you want to change.

→ Tip

Search for a role by entering the name or part of the name in the search box.

3. Choose *Delete*.

## Results

The role is deleted.

i Note

You can also use the above procedure to delete HDI and repository roles. However, these roles will be recreated when they are deployed again.

## 7.2.5.1.6 Create a User Group

To manage associated users together, you can create and configure a user group.

### Prerequisites

- You have the system privilege USER ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

User groups are an efficient way to manage users:

- Every user group can have its own dedicated administrator(s).  
In this way, user management tasks can be delegated to several people independently of each other.
- A user group can be configured for exclusive administration.  
This means that only the designated group administrator(s) can manage the users in the group. This could be useful, for example, to protect highly-privileged users or technical users from accidental deletion or manipulation.
- Group-specific user configuration is possible.  
By setting user properties at the group level, you can configure related users quickly and differently to users in other groups. For example, you could include the technical users required by connecting applications in their own user group with a customized password policy.

- To save time, you can use a wizard to quickly apply a basic configuration to user groups. For more information, see *Configure the Base Setup for User Groups*.

### i Note

User groups are intended to support a separation of user management duties. User groups do not control data access. Data access is controlled by a user's authorizations (roles and privileges).

For more information about user groups, see the *SAP HANA Security Guide*.

## Procedure

1. On the *Database Overview*, with the *Security and User Management* or *All* view selected, navigate to *User & Role Management*, then choose *User Group Management*.
2. Choose *New User Group*.
3. Specify the name of the user group.
4. Specify how the user group is to be managed.

Option	Description
<b>Group administration mode:</b>	<p><i>Both group administrators and user administrators can manage this user group</i> (shared administration)</p> <p>Not only designated group administrators can modify the group, but also any user administrator (that is, any user with system privilege USER ADMIN).</p> <p>This is the default administration mode.</p> <p><i>Only a group administrator can manage this user group</i> (exclusive administration)</p> <p>Only the designated group administrator(s) can modify the group, for example, adding new users to the group or removing users from the group. In this way, groups of users can be managed completely independently of each other.</p>
<b>(Optional) Group creator can manage group</b>	<p>You, as creator and owner of the group, are <b>automatically</b> a group administrator because you have the object privilege USERGROUP OPERATOR on the user group.</p>

### i Note

To add an existing user from the global pool of users to the user group, as well as remove a user from the group (and return it to the global pool of users), the group administrator also needs to be a user administrator, that is have system privilege USER ADMIN.

Option	Description
	To prevent yourself from being a group administrator, de-select <i>Group creator can manage group</i> . You will then not be granted the object privilege USERGROUP OPERATOR on the user group. However, you can still grant it to other users to authorize them to be group administrators.
(Optional) Comment	Enter a comment or text to describe the user group.

5. Choose *Add* to save the user group.

## Results

The user group is created.

## Next Steps

- Designate the user group administrators.  
You do this by granting the object privilege USERGROUP OPERATOR on the user group to the relevant users or roles.
- Add users to the user group.  
You can do this by choosing *Move Users to Group* or *Create User*, depending on whether you want to add an existing user or a new user.
- If required, configure a group-specific password policy.

### → Remember

If you configured the user group for exclusive administration, only a group administrator can add/remove users and configure the password policy. The group administrator may also need to be a user administrator, that is have system privilege USER ADMIN.

[Configure the Base Setup for User Groups \[page 909\]](#)

## 7.2.5.1.6.1 Configure the Base Setup for User Groups

You can use a wizard to quickly apply a basic configuration for user groups.

### Prerequisites

- You have the system privilege USER ADMIN.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Instead of manually configuring user groups, you can use a wizard to apply SAP's recommended configuration settings. This allows you to quickly start working with user groups.

For a registered database, the UI notifies you if user group configuration was not completed using the base setup wizards. You have the option to disable these notifications.

#### i Note

The base setup does not guarantee that the configuration is optimal for your particular system. To optimize the configuration, it may be advisable to manually configure specific settings.

### Procedure

1. On the [Database Overview](#), with the [Security and User Management](#) or *All* view selected, navigate to [User & Role Management](#), then choose [User Group Management](#).
2. Choose [Base Setup](#).

Specify the base settings for the user group.

Option	Description
<b>Display base setup notifications for User Group Management</b>	Enable or disable notifications for a user group type. You can change this setting at any time.

Option	Description
<b>Change Global Settings</b>	<p>To enable or disable all security-related notifications about the base setup, choose <a href="#">User Interface Notification &gt; Display base setup notifications &gt;</a>.</p> <p>You can enable or disable notifications at any time.</p> <p>For more information about SAP HANA cockpit user settings, see <a href="#">Personalizing the Database Overview Page</a>.</p>
<b>User groups</b>	<p>To complete the base setup, choose <a href="#">Complete Setup</a> for each user group type.</p> <p>Follow the on-screen instructions.</p> <p>If you do not wish to change the configuration, choose <a href="#">Set manually to completed</a> and choose <i>OK</i>. This disables notifications about the base setup.</p>

You can configure the following settings for user groups:

- The user group name
- The group administration mode
- Password policy.

For example, the permitted number of failed login attempts, when to enforce a password change.

The field border color alerts you to the status of a specified value:

- **Blue:** SAP-recommended value
- **Yellow:** Different from the SAP-recommended value
- **Red:** Not permitted

3. Choose [Review](#) to display an overview of the user group settings.

To make changes, choose [Edit](#).

4. Choose [Save](#).

## Results

The configuration settings are saved.

Notifications about the base setup are no longer displayed.

## Related Information

[Personalize the SAP HANA Cockpit](#)  
[Create a User Group \[page 906\]](#)

## 7.2.5.1.6.2 User Group Details

On the *User Group Management* page of the SAP HANA cockpit, you can view the details of a user group.

Field	Description
<i>Owner</i>	User who created the group
<i>Group Administration Mode</i>	<p>Specifies who can manage the group:</p> <ul style="list-style-type: none"><li>• Group administrators <b>and</b> user administrators (shared administration) Not only designated group administrators can modify the group but also any user administrator (that is, any user with system privilege USER ADMIN). This is the default administration mode.</li><li>• Group administrators only (exclusive administration) Only the designated group administrator(s) can modify the group, for example, adding new users to the group or removing users from the group. In this way, groups of users can be managed completely independently of each other.</li></ul> <div data-bbox="850 1003 1394 1263" style="border: 1px solid #ccc; padding: 10px;"><p><b>i Note</b></p><p>To add an existing user from the global pool of users to the user group, as well as remove a user from the group (and return it to the global pool of users), the group administrator also needs to be a user administrator, that is have system privilege USER ADMIN.</p></div> <p>The user administrator can configure the administration mode when creating the group, or later by editing the group.</p>
<i>Comment</i>	Free-text comment or description
<i>Users in Group</i>	<p>Database users in the group</p> <p>A user can belong to only one user group.</p> <div data-bbox="805 1512 1394 1680" style="border: 1px solid #ccc; padding: 10px;"><p><b>i Note</b></p><p>Users don't have to be a member of any group. Users who are not in any group are managed as normal by user administrators.</p></div>

Field	Description
<a href="#">Password Policy</a>	<p>Group-specific configuration of the password policy</p> <p>The user group password policy is effective if a group-specific value has been configured for at least one option and the group policy has been enabled. For those options with no group-specific value, the value from the database password policy is copied.</p> <p>If no group-specific values have been configured for any parameters or the group policy has not been enabled, the password policy configured for the database is the effective.</p>
<a href="#">Workload Classes</a>	<p>If a workload class is assigned to the user group, it is displayed.</p> <p>From here, you can:</p> <ul style="list-style-type: none"> <li>• Display more information about a workload class. Click its name.</li> <li>• Change the configuration of the workload class. For example, to restrict resource usage- Choose <a href="#">Edit</a>.</li> <li>• Create a new workload class and assign it to the user group. Choose <a href="#">Create</a>, and specify the configuration. Choose <a href="#">Add User Group</a>, then <a href="#">Create</a>.</li> </ul> <p>For more information, see <i>Managing Workload Classes</i> in the <i>SAP HANA Administration Guide</i>.</p>

## Related Information

[Managing Workload Classes](#)

### 7.2.5.1.6.3 SQL Statements and Authorization for User Group Administration (Reference)

Creating and configuring user groups, and subsequently managing the users in those groups requires different combinations of privileges.

## Creating and Configuring User Groups

User administrators create and configure user groups. Group administrators can change the configuration.

To...	You need...	For example...
Create a user group	System privilege USER ADMIN	<ul style="list-style-type: none"> <li>CREATE USERGROUP TechnicalUsers;</li> <li>CREATE USERGROUP Research DISABLE USER ADMIN;</li> </ul>
Change the administration mode of a user group	System privilege USER ADMIN	<ul style="list-style-type: none"> <li>ALTER USERGROUP TechnicalUsers DISABLE USER ADMIN;</li> <li>ALTER USERGROUP Research ENABLE USER ADMIN;</li> </ul>
Make another user the group administrator of a user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN, or</li> <li>Object privilege USERGROUP OPERATOR on the group with the option to grant it to others</li> </ul>	GRANT USERGROUP OPERATOR ON USERGROUP TechnicalUsers TO TechnicalUsersAdmin;
Configure user parameters and enable/disable usergroup parameter sets	<ul style="list-style-type: none"> <li>System privilege USER ADMIN, or</li> <li>Object privilege USERGROUP OPERATOR on the group</li> </ul> <div data-bbox="603 1025 991 1223" style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>If the user group has been configured for exclusive administration, USERGROUP OPERATOR on the group is required.</p> </div>	<ul style="list-style-type: none"> <li>CREATE USERGROUP Training SET PARAMETER 'password_layout' = 'Ala!', 'minimal_password_length' = '7' ENABLE PARAMETER SET 'password policy';</li> <li>ALTER USERGROUP TechnicalUsers SET PARAMETER 'force_first_password_change' = 'false';</li> <li>ALTER USERGROUP TechnicalUsers ENABLE PARAMETER SET 'password policy';</li> <li>ALTER USERGROUP TechnicalUsers DISABLE PARAMETER SET 'password policy';</li> </ul>
Delete a user group	System privilege USER ADMIN	DROP USERGROUP Training;
	<div data-bbox="603 1682 991 1821" style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>You cannot delete a user group if there are still users in the group.</p> </div>	

## Managing Users

### Managing users who are not in any user group

User administrators manage users who do not belong to a user group.

To...	You need...	For example...
Create, change, delete a user not in any user group	System privilege USER ADMIN	<code>CREATE USER Michael PASSWORD &lt;password&gt;;</code>

### Managing users in a user group configured for shared administration (default)

Group administrators and user administrators can manage users in user groups configured with the option `ENABLE USER ADMIN`.

To..	You need...	For example...
Create a user in the user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN, or</li> <li>Object privilege USERGROUP OPERATOR on the group</li> </ul>	<code>CREATE USER John PASSWORD &lt;password&gt; SET USERGROUP Research;</code>
Delete a user in the user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN, or</li> <li>Object privilege USERGROUP OPERATOR on the group</li> </ul>	<code>DROP USER John CASCADE;</code>
Add an existing user from the global pool of users to the user group	System privilege USER ADMIN	<code>ALTER USER Julie SET USERGROUP Research;</code>
Move a user from another user group to the user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN, or</li> <li>Object privilege USERGROUP OPERATOR on both groups</li> </ul>	<code>ALTER USER Julie SET USERGROUP Training;</code>
Remove a user from the user group (and return to the global pool of users)	System privilege USER ADMIN	<code>ALTER USER Julie UNSET USERGROUP;</code>

### Users in a user group configured for exclusive administration

Only group administrators can manage users in user groups configured with the option `DISABLE USER ADMIN`.

To..	You need...	For example...
Create a user in the user group	Object privilege USERGROUP OPERATOR on the user group	<code>CREATE USER sapsid PASSWORD &lt;password&gt; SET USERGROUP TechnicalUsers;</code>
Delete a user in the user group	Object privilege USERGROUP OPERATOR on the user group	<code>DROP USER sapsid CASCADE;</code>
Add an existing user from the global pool of users to the user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN <b>and</b></li> <li>Object privilege USERGROUP OPERATOR on the group</li> </ul>	<code>ALTER USER Thomas SET USERGROUP TechnicalUsers;</code>

To..	You need...	For example...
Move a user from another user group to the user group	<ul style="list-style-type: none"> <li>Object privilege USERGROUP OPERATOR on both groups</li> </ul>	ALTER USER Julie SET USERGROUP TechnicalUsers;
<div style="background-color: #f0f0f0; padding: 10px; border-left: 2px solid #0070c0;"> <p><b>i Note</b></p> <p>If the user's current group is not configured for exclusive administration, object privilege USERGROUP OPERATOR on this group is not required; system privilege USER ADMIN is sufficient.</p> </div>		
Remove a user from the user group	<ul style="list-style-type: none"> <li>System privilege USER ADMIN <b>and</b></li> <li>Object privilege USERGROUP OPERATOR on the group</li> </ul>	ALTER USER Thomas UNSET USERGROUP;

### 7.2.5.1.7 Create a Database User

You create a standard database user for every person who needs to work directly with the SAP HANA database. When you create a user, you also configure how the user will be authenticated and optionally add the user to a user group.

#### Prerequisites

- You have the system privilege `USER ADMIN`.
- If you are creating the user in a user group configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group. For more information about user groups, see the *SAP HANA Security Guide*
- If you are integrating SAP HANA database users into a single sign-on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured. For more information about SSO, see the *SAP HANA Security Guide*.

- If you are implementing LDAP group authorization or LDAP-based authentication, the necessary infrastructure must be in place and configured. For more information, see the section on configuring LDAP group authorization in the *SAP HANA Administration Guide*.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [User Management](#).

An overview of all existing database users is displayed.

2. Create a new user. Click the **+** (*Add*) icon, then choose [Create User](#).
3. Specify the new user name.  
You must give the user a unique name. User names can contain any CESU-8 characters except for a small subset. For more information, see *Unpermitted Characters in User Names*.
4. Optional: Select the user group to which you want to assign the user.

### → Remember

If the user group is configured for exclusive administration, you must have the privilege USERGROUP OPERATOR on the user group.

5. Optional: Specify the user's e-mail address.
6. Optional: Specify a validity period for the user, including the appropriate time zone.

For example, if you are creating a user for a new employee, you can enter their start date in the [Valid From](#) field.

If you do not enter any values, the user is immediately and indefinitely valid.

7. Optional: Prevent the user from being able to create objects in his own database schema by selecting [No](#) for the option [Creation of Objects in Own Schema](#).

### i Note

If you select [No](#) for both this option **and** the next option ([PUBLIC Role](#)), the user will be created as a restricted user, not a standard user.

8. Optional: Prevent the user from being granted the standard PUBLIC role by selecting [No](#) for the option [PUBLIC Role](#).

The PUBLIC role contains the privileges for filtered read-only access to the system views. To see data in a particular view, the user also needs the SELECT privilege on the view.

### i Note

If you select [No](#) for both this option **and** the previous option ([Creation of Objects in Own Schema](#)), the user will be created as a restricted user, not a standard user.

9. Optional: Prevent the user from being able to connect to the database via ODBC and JDBC clients by selecting the corresponding checkbox.

By default, standard users have access via ODBC and JDBC clients.

If you disable ODBC/JDBC client access, the user can still connect via HTTP. Furthermore, disabling ODBC/JDBC access does not affect the user's authorizations or prevent the user from executing SQL commands via channels other than JDBC/ODBC.

10. Optional: Enter a comment or text to describe the user.
11. Optional: Set the authorization mode to LDAP if the user's authorization is based on LDAP group membership.

A user with authorization mode *LDAP* is granted roles exclusively based on their LDAP group membership. It is not possible to grant such a user other roles or privileges directly.

The default user authorization mode is *Local*. This means that the user must be granted roles and privileges directly as normal.

### **i** Note

Setting the authorization mode of the user is only one step in the configuration of LDAP group authorization. For more information, see the section on configuring LDAP group authorization in the *SAP HANA Administration Guide*.

12. Specify how the user can be authenticated.

### **i** Note

You must specify at least one authentication mechanism. For more information about the supported mechanisms, see *Database User Details*.

<b>Authentication Mechanism</b>	<b>Required Configuration</b>
<b>User name and password</b>	Select the type of password.  The user can be authenticated by a password stored in the SAP HANA database (option: <i>Local</i> ) or a password stored in an LDAP directory server (option: <i>LDAP</i> ).  If you choose authentication by local password, enter and confirm the user's initial password. You can override the password policy setting ( <i>Password Change Required on First Logon</i> ) that forces users to change a password set by a user administrator the first time they log on. This is useful for technical users, for example.
<b>Kerberos</b>	Enter the user principal name (UPN) specified in the Microsoft Active Directory or the Kerberos Key Distribution Center as the external ID.
<b>SAP logon and assertion tickets</b>	No additional user configuration required in user definition
<b>SAML</b>	Choose <i>Add Identity Provider</i> , select the identity provider, and then enter the user ID known to the SAML identity provider.  Alternatively, you can allow the identify provider to map its users to the database user by enabling automatic mapping by provider.

Authentication Mechanism	Required Configuration
	<p><b>i Note</b></p> <p>The identity provider must already be created. You can do this on the <a href="#">SAML Identity Provider</a> page or using the SQL statement <code>CREATE SAML PROVIDER</code>.</p>
<p><b>JWT (JSON Web Token)</b></p>	<p>Choose <a href="#">Add Identity Provider</a>, select the identity provider, and then enter the user ID known to the JWT identity provider.</p> <p>Alternatively, you can allow the identify provider to map its users to the database user by enabling automatic mapping by provider.</p> <p><b>i Note</b></p> <p>The identity provider must already be created. You can do this on the <a href="#">JWT Identity Provider</a> page or using the SQL statement <code>CREATE JWT PROVIDER</code>.</p>
<p><b>X.509 certificate</b></p>	<p>Choose <a href="#">Add X509 Certificate Manually</a> and enter the user's public key certificate information.</p> <p><b>i Note</b></p> <p>X.509 certificates are supported only for HTTP access through the SAP HANA XS classic server.</p>

13. Optional: Specify additional user properties required by client applications.

You can select from the available properties (see *Database User Details*) or manually enter a property.

14. Save the user.

## Results

The user is created and appears in the list of users on the left. A new schema is created for the user in the catalog. It has the same name as the user.

## Next Steps

Assign roles or privileges to the user (authorization mode *Local* only).

## Related Information

[User Groups](#)

- [Create a User Group \[page 906\]](#)

## 7.2.5.1.7.1 Unpermitted Characters in User Names

User names can contain any CESU-8 characters except for a small subset.

The following characters are not allowed as user names:

Unicode Character	Character	Name
U+0021	!	Exclamation mark
U+0022	"	Quotation mark
U+0024	\$	Dollar sign
U+0025	%	Percent sign
U+0027	'	Apostrophe
U+0028	(	Left parenthesis
U+0029	)	Right parenthesis
U+002A	*	Asterisk
U+002B	+	Plus sign
U+002C	,	Comma
U+002E	.	Full stop
U+002F	/	Solidus
U+003A	:	Colon
U+003B	;	Semicolon
U+003C	<	Less-than sign
U+003D	=	Equals sign
U+003E	>	Greater-than sign
U+003F	?	Question mark
U+0040	@	Commercial at
U+005B	[	Left square bracket

Unicode Character	Character	Name
U+005C	\	Reverse solidus
U+005D	]	Right square bracket
U+005E	^	Circumflex accent
U+0060	`	Grave accent
U+007B	{	Left curly bracket
U+007C		Vertical line
U+007D	}	Right curly bracket
U+007E	~	Tilde

## 7.2.5.1.8 Create a Restricted Database User

You create a restricted user for users who access SAP HANA through client applications – full SQL access via an SQL console is not intended. When you create a restricted user, you also configure how the user will be authenticated and optionally add the user to a user group.

### Prerequisites

- You have the system privilege `USER ADMIN`.
- If you are creating the user in a user group configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group. For more information about user groups, see the *SAP HANA Security Guide*.
- If you are integrating SAP HANA database users into a single sign-on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured. For more information about SSO, see the *SAP HANA Security Guide*.
- If you are implementing LDAP group authorization or LDAP-based authentication, the necessary infrastructure must be in place and configured. For more information, see the section on configuring LDAP group authorization in the *SAP HANA Administration Guide*.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [User Management](#).

An overview of all existing database users is displayed.

2. Create a new restricted user. Click the **+** ([Add](#)) icon, then choose [Create Restricted User](#).

3. Specify the new user name.

You must give the user a unique name. User names can contain any CESU-8 characters except for a small subset. For more information, see *Unpermitted Characters in User Names*.

4. Optional: Select the user group to which you want to assign the user.

#### → Remember

If the user group is configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group.

5. Optional: Specify the user's e-mail address.

6. Optional: Specify a validity period for the user, including the appropriate time zone.

For example, if you are creating a user for a new employee, you can enter their start date in the *Valid From* field.

If you do not enter any values, the user is immediately and indefinitely valid.

7. Optional: Allow the user to create objects in her own database schema by selecting *Yes* for the option *Creation of Objects in Own Schema*.

#### i Note

If you select *Yes* for this option, the user will be created as a standard user, not a restricted user.

8. Optional: Grant the user the standard PUBLIC role by selecting *Yes* for the corresponding option.

The PUBLIC role contains the privileges for filtered read-only access to the system views. To see data in a particular view, the user also needs the SELECT privilege on the view.

#### i Note

If you select *Yes* for this option, the user will be created as a standard user, not a restricted user.

9. Optional: Allow the user to connect to the database via ODBC and JDBC clients by deselecting the corresponding checkbox.

By default, restricted users are only able to connect to the database using HTTP. You must explicitly allow access via ODBC and JDBC clients by changing this setting.

For full access to ODBC or JDBC functionality, you must grant restricted users the standard role `RESTRICTED_USER_ODBC_ACCESS` or `RESTRICTED_USER_JDBC_ACCESS`. You can do this on the *Assign Roles* page.

10. Optional: Enter a comment or text to describe the user.

11. Optional: Set the authorization mode to LDAP if the user's authorization is based on LDAP group membership.

A user with authorization mode *LDAP* is granted roles exclusively based on their LDAP group membership. It is not possible to grant such a user other roles or privileges directly.

The default user authorization mode is *Local*. This means that the user must be granted roles and privileges directly as normal.

### i Note

Setting the authorization mode of the user is only one step in the configuration of LDAP group authorization. For more information, see the section on configuring LDAP group authorization in the *SAP HANA Administration Guide*.

12. Specify how the user can be authenticated.

### i Note

You must specify at least one authentication mechanism. For more information about the supported mechanisms, see *Database User Details*.

Authentication Mechanism	Required Configuration
User name and password	<p>Select the type of password.</p> <p>The user can be authenticated by a password stored in the SAP HANA database (option: <i>Local</i>) or a password stored in an LDAP directory server (option: <i>LDAP</i>).</p> <p>If you choose authentication by local password, enter and confirm the user's initial password. You can override the password policy setting (<i>Password Change Required on First Logon</i>) that forces users to change a password set by a user administrator the first time they log on. This is useful for technical users, for example.</p>
Kerberos	<p>Enter the user principal name (UPN) specified in the Microsoft Active Directory or the Kerberos Key Distribution Center as the external ID.</p>
SAP logon and assertion tickets	<p>No additional user configuration required in user definition</p>
SAML	<p>Choose <i>Add Identity Provider</i>, select the identity provider, and then enter the user ID known to the SAML identity provider.</p> <p>Alternatively, you can allow the identify provider to map its users to the database user by enabling automatic mapping by provider.</p> <div data-bbox="829 1489 1396 1653" data-label="Text"><p><b>i Note</b></p><p>The identity provider must already be created. You can do this on the <i>SAML Identity Provider</i> page or using the SQL statement <code>CREATE SAML PROVIDER</code>.</p></div>
JWT (JSON Web Token)	<p>Choose <i>Add Identity Provider</i>, select the identity provider, and then enter the user ID known to the JWT identity provider.</p> <p>Alternatively, you can allow the identify provider to map its users to the database user by enabling automatic mapping by provider.</p>

Authentication Mechanism	Required Configuration
	<p><b>i Note</b></p> <p>The identity provider must already be created. You can do this on the <a href="#">JWT Identity Provider</a> page or using the SQL statement <code>CREATE JWT PROVIDER</code>.</p>
<p><b>X.509 certificate</b></p>	<p>Choose <a href="#">Add X509 Certificate Manually</a> and enter the user's public key certificate information.</p> <p><b>i Note</b></p> <p>X.509 certificates are supported only for HTTP access through the SAP HANA XS classic server.</p>

13. Optional: Specify additional user properties required by client applications.

You can select from the available properties (see *Database User Details*) or manually enter a property.

14. Save the user.

## Results

The user is created and appears in the list of users on the left. A new schema is also created for the user in the catalog. It has the same name as the user. However, as a restricted user, the user is not authorized to create objects in this schema. For more information about all restrictions, see *Database Users*.

## Next Steps

Assign roles to the user (authorization mode *Local* only).

## Related Information

[SAP HANA Administration Guide](#)

## 7.2.5.1.9 Assign Roles to Database Users

Roles are the preferred way to assign privileges to SAP HANA database users. It is recommended that you assign roles to users instead of granting privileges individually. You can grant (or remove) roles on the [Role Assignment](#) page of SAP HANA cockpit.

### Prerequisites

- You have the privileges required to grant or revoke roles.  
If you have the system privilege `ROLE ADMIN`, you can grant any role. Otherwise, the following applies:
  - To grant a catalog role, that is a role created in runtime using SQL, you need to have the role being granted yourself and be authorized to grant it to other users and roles.
  - To grant a HDI role, that is a schema-specific role deployed using SAP HANA deployment infrastructure, you need privileges to execute `GRANT_CONTAINER_SCHEMA_ROLES` in the container's API schema, or, if you are a container group administrator, privileges to execute `GRANT_CONTAINER_SCHEMA_ROLES` in the container group's API schema.
  - To grant a repository role, that is a role created in the repository of the SAP HANA database, you need the object privilege `EXECUTE` on the procedure `GRANT_ACTIVATED_ROLE`.For more information, see *Prerequisites for Granting and Revoking Privileges and Roles*.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Roles are the standard and recommended way of granting privileges to users. In the [Assign Roles](#) app of the SAP HANA cockpit, you can assign roles by either:

- Selecting the user you want to assign roles – this allows you to assign multiple roles to one user
- Selecting the role you want to assign to users – this allows you to assign one role to multiple users

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to the [User & Role Management](#) card and choose [Role Assignment](#).
2. In the [Assign Roles](#) app, choose how you want to assign roles, by user or by role, and proceed accordingly:

Option	Description
User	<ol style="list-style-type: none"><li>1. Find the user.</li><li>2. Choose <a href="#">Edit</a> and then <a href="#">Add</a>.</li></ol>

Option	Description
	<ol style="list-style-type: none"> <li>3. Find the role(s) you want to assign to the user and choose <i>Select</i>.</li> <li>4. If you want the user to be able to grant the role to other users, choose <i>Grantable to Others</i>.</li> <li>5. Choose <i>Save</i>.</li> </ol>
Role	<ol style="list-style-type: none"> <li>1. Find the role you want to assign.</li> <li>2. Choose <i>Edit</i> and then <i>Assign User</i>.</li> <li>3. Find the user(s) you want to assign the role to and choose <i>Assign</i>.</li> <li>4. If you want the user to be able to grant the role to other users, choose <i>Grantable to Others</i>.</li> <li>5. Choose <i>Save</i>.</li> </ol>

## Related Information

[Database Roles \[page 871\]](#)

[Prerequisites for Granting and Revoking Privileges and Roles \[page 901\]](#)

### 7.2.5.1.10 Assign Privileges to a User

It is recommended that you assign roles to users instead of granting privileges individually. However, you can still grant privileges directly to users on the [Privilege Assignment](#) page.

## Prerequisites

- You have the system privilege USER ADMIN.
- You have the privileges required to grant specific privileges to the user.  
To grant SQL privileges, you must have the privilege and/or role yourself and be authorized to grant it to someone else. To grant privileges on activated repository objects, you must be authorized to execute certain stored procedures. For more information, see [Prerequisites for Granting and Revoking Privileges and Roles](#).
- You've navigated to the [Database Overview](#) page of the database you want to manage. See [Getting to the Database Overview Page](#) in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to the [User & Role Management](#) area, then choose [Privilege Assignment](#).

2. On the [Assign Privileges](#) page, locate the user you want to edit.

The user's existing privileges are displayed, as well as the user that assigned them.

3. Assign the required privileges to the user:
  - a. For the relevant privilege type, choose [Edit](#).
  - b. Choose [Add](#), then select the privilege(s) you want to assign.

#### **i** Note

For object and package privileges, you must first add the object or package and then add the required privilege to the object or package.

- c. Choose [OK](#).
- d. Optional: If you want the user to be able to grant the new privilege on to other users, choose [Grantable to Others](#).
- e. Save the privilege assignment.
- f. Repeat for further privilege types.

## Related Information

### 7.2.5.1.11 Change a Database User

For an existing database user, you can change properties such as e-mail, user group, period of validity, or authorization.

#### Prerequisites

- You have the system privilege `USER ADMIN`.
- If the user is in a user group configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group. For more information about user groups, see the *SAP HANA Security Guide*.
- If you are integrating SAP HANA database users into a single sign-on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured. For more information about single sign-on integration, see the *SAP HANA Security Guide*.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to *User & Role Management*, then choose *User Management*.

An overview of all existing database users is displayed.

2. Locate the user you want to change.

### → Tip

Search for a user by entering the name or part of the name in the search box, or create a filter by clicking the  (*Filter*) icon.

3. Choose *Edit*.
4. Make the required changes.

For more information about the individual fields and settings, see *Database User Details*.

### → Remember

To change the user's authorization, open the *Role Assignment* or *Privilege Assignment* pages.

5. *Save*.

## Related Information

[Database User Details \[page 891\]](#)

[Assign Roles to Database Users \[page 924\]](#)

[Assign Privileges to a User \[page 925\]](#)

[Single Sign-On Integration](#)

[SAP HANA Security Guide](#)

## 7.2.5.112 Deactivate a Database User

Users can be automatically deactivated for security reasons, for example, if they violate password policy rules. As a user administrator, you may need to explicitly deactivate a user, for example, if an employee temporarily leaves the company or a security violation is detected.

## Prerequisites

- You have the system privilege `USER ADMIN`.
- If the user is in a user group configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group. For more information about user groups, see the *SAP HANA Security Guide*

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

### → Tip

As an administrator, you may want to temporarily deactivate all users in a system except certain administrative users so that these users can perform administration or maintenance tasks. For more information about how to do this without deactivating users individually as described here, see *SAP Note 1986645 (Allow only administration users to work on HANA database)*.

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to [User & Role Management](#), then choose [User Management](#).

An overview of all existing database users is displayed.

2. Locate the user you want to deactivate.

### → Tip

Search for a user by entering the name or part of the name in the search box, or create a filter by clicking the  ([Filter](#)) icon.

3. Choose [Deactivate](#).

## Results

The database user is now deactivated, and remains deactivated until you reactivate it. The user still exists in the database, but cannot connect to the database any more.

### i Note

It may still appear as though deactivated users are still active in the system (for example, when a procedure that was created by the user with DEFINER MODE is called).

To activate the user again, choose [Activate](#).

## Related Information

[SAP Note 1986645](#) 

[SAP HANA Security Guide](#)

## 7.2.5.1.13 Delete a Database User

You may need to delete a database user, for example, if an employee leaves your organization.

### Prerequisites

- You have the system privilege `USER ADMIN`.
- If the user is in a user group configured for exclusive administration, you must have the privilege `USERGROUP OPERATOR` on the user group. For more information about user groups, see the *SAP HANA Security Guide*

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to *User & Role Management*, then choose *User Management*.

An overview of all existing database users is displayed.

2. Locate the user you want to delete.

#### → Tip

Search for a user by entering the name or part of the name in the search box, or create a filter by clicking the  (*Filter*) icon.

3. Choose *Delete*.
4. Specify whether or not you also want to delete dependent objects.

Option	Description
<i>Restrict</i>	Which objects are deleted depends on which objects the user owns: <ul style="list-style-type: none"><li>○ If all objects owned by the user are in the user's home schema: The user, the schema, and all objects in the schema will be deleted.</li><li>○ If the user is the owner of any database objects in schemas outside their home schema: The user will <b>not</b> be deleted.</li></ul>
<i>Cascade</i>	Delete the user and also all objects owned by the user.

Option	Description
	<div style="border-left: 2px solid orange; padding-left: 10px;"> <p><b>⚠ Caution</b></p> <p>If you choose <i>Cascade</i>:</p> <ul style="list-style-type: none"> <li>○ All objects owned by the user will be deleted</li> <li>○ Privileges granted to others by the user will be re-voked</li> <li>○ All objects in the user's schema will be deleted, <b>even if they are owned by a different user</b>. All privileges on these objects will also be re-voked.</li> </ul> </div>

**Roles:** Local roles (in a user's schema) are always deleted when the schema is deleted.

Other (global) roles do not have an owner. When a user is deleted, users and other roles created by the user are NOT deleted. These global roles can only be deleted explicitly using the DROP ROLE statement.

5. Confirm.

## Results

The user is deleted.

## Related Information

[SAP HANA Security Guide](#)

## 7.2.5.2 Provisioning Users in SAP HANA Studio

You can use the *User* and *Role* editors of the SAP HANA studio to perform user-provisioning tasks.

### 7.2.5.2.1 Create a Role in Runtime

You can create a new role directly in runtime and grant it the privileges and roles necessary for the task or function that it represents. You can create a role with the *Role* editor of the SAP HANA studio.

#### Prerequisites

- You have the system privilege `ROLE ADMIN`.
- You have the privileges required to grant privileges and roles to the new role.

#### Procedure

##### → Recommendation

Creating roles in the repository of the SAP HANA database offers more flexibility than creating them in runtime as described here. The recommended approach is therefore to create roles as repository objects. For more information about roles as repository and how to model roles in design time, see the *SAP HANA Developer Guide (For SAP HANA Web Workbench)*.

1. Create a new role:
  - a. In the *Systems* view, choose **► Security ► Roles**.
  - b. From the context menu, choose *New Role*.The *New Role* editor opens.
2. Specify a unique role name.

The role name can contain all characters, except double quotation marks ("...").
3. Optional: Assign the role a runtime namespace by choosing the schema in which to create the role.

Role namespaces allow you to reuse roles in different contexts. If you do not select a schema, the role will be created as a global role.

##### ⚠ Caution

A role with a namespace will be deleted if the schema is deleted.

4. Grant the required roles and privileges.

To authorize a user who has been granted the role to pass on granted roles and privileges to other users, you can select *Grantable to other users and roles*. Note that this option is not available when granting the following:

- Roles created in the repository
  - Privileges on objects created in the repository
5. Save the role by choosing the  (*Deploy*) button to create the role.

## Results

The role is created and appears in the  *Security*  *Roles*  folder. It is automatically granted to your user.

## Related Information

[Prerequisites for Granting and Revoking Privileges and Roles \[page 901\]](#)

[Create a Design-Time Role](#)

### 7.2.5.2 Create and Authorize a User

You create a standard database user for every user who wants to work with the SAP HANA database. When you create a user, you can also configure how the user will be authenticated, as well as which roles and privileges they need. You can create a user with the *User* editor of the SAP HANA studio.

## Prerequisites

- You have the system privilege USER ADMIN.
- You have the privileges required to grant specific privileges and roles to the new user.  
To grant SQL privileges and roles, you must have the privilege and/or role yourself and be authorized to grant it to others. To grant privileges on activated repository objects, you must be authorized to execute certain stored procedures. For more information, see *Prerequisites for Granting and Revoking Privileges and Roles*.
- If you are integrating SAP HANA database users into a single-sign on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured.

## Procedure

1. Create the user:
  - a. In the *Systems* view, choose  *Security*  *Users* .
  - b. From the context menu, choose *New User*.  
The *New User* editor opens on the *User* tab.

- Specify the new user name.

You must give the user a unique name. User names can contain any CESU-8 characters except for a small subset. For more information, see *Unpermitted Characters in User Names*.

- Optional: Prevent the user from being able to connect to the database via ODBC and JDBC clients by selecting the corresponding checkbox.

#### **i Note**

By default, standard users have access via ODBC and JDBC clients. If ODBC/JDBC client access is disabled, the user can still connect via HTTP. Furthermore, disabling ODBC/JDBC access does not affect the user's authorizations or prevent the user from executing SQL commands via channels other than JDBC/ODBC.

- Specify the user's properties:

Option	Description
<b>Authenti- cation</b>	<p>You can set up one or more of the following types of user authentication:</p> <ul style="list-style-type: none"> <li><b>User name/password</b> authentication by a password You can override the password policy setting (<i>force_first_password_change</i>) that forces users to change a password set by a user administrator the first time they log on. This is useful for technical users, for example.</li> <li><b>Kerberos</b> authentication (external) by specifying the user principal name (UPN) specified in the Microsoft Active Directory or the Kerberos Key Distribution Center as the external ID</li> <li><b>SAML</b> authentication (external) by selecting the identity provider and then entering the user ID known by the SAML identity provider Alternatively, you can allow the identify provider to map users to the database user by selecting the checkbox in the <i>Any</i> column.</li> <li><b>X.509 certificates</b> by adding the user's public key certificate(s)</li> </ul>
	<div data-bbox="424 1211 512 1245" data-label="Section-Header"> <h4><b>i Note</b></h4> </div> <div data-bbox="424 1256 1187 1288" data-label="Text"> <p>X.509 certificates are supported only for HTTP access through SAP HANA XS</p> </div>
	<ul style="list-style-type: none"> <li>SAP logon and assertion tickets</li> </ul>
<b>Valid From/ Until</b>	<p>You can specify a validity period for the user. For example, if you are creating a user for a new employee, you can enter their start date in the <i>Valid From</i> field.</p> <p>If you do not enter any values, the user is immediately and indefinitely valid.</p>
<b>Session client</b>	<p>When you create SAP HANA information models (attribute views, analytic views, and calculation views), it is possible to filter the data according to the client specified in table fields such as MANDT or CLIENT. You can specify the client relevant for the user here.</p>

- Authorize the user by granting the required roles and privileges.

To authorize the user to pass on granted roles and privileges to other users, you can select *Grantable to other users and roles*. Note that this option is not available when granting the following:

- Roles created in the repository
- Privileges on objects created in the repository
- Privileges granted on your user

- Optional: Specify additional user information:

- Choose the *User Parameters* tab.
- Add the required parameters.

For more information about the available parameters, see *Custom User Properties*.

7. Save the user by choosing the  (*Deploy*) button.

The system verifies that the user's password complies with the configured password policy and that it is not on the password blacklist.

## Results

The user is created and appears in the *Users* folder. A new schema is also created for the user in the catalog. It has the same name as the user. The standard role PUBLIC is always and irrevocably granted. This role allows the user read-only access to system views.

### 7.2.5.2.3 Create and Authorize a Restricted User

You create a restricted user for users who access SAP HANA through client applications – full SQL access via an SQL console is not intended. When you create a restricted user, you can also configure how the user will be authenticated, as well as which roles and privileges they need. You can create a restricted user with the *User* editor of the SAP HANA studio.

## Prerequisites

- You have the system privilege USER ADMIN.
- You have the privileges required to grant specific privileges and roles to the new user.  
To grant SQL privileges and roles, you must have the privilege and/or role yourself and be authorized to grant it to others. To grant privileges on activated repository objects, you must be authorized to execute certain stored procedures. For more information, see *Prerequisites for Granting and Revoking Privileges and Roles*.
- If you are integrating SAP HANA database users into a single-sign on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured.

## Procedure

1. Create the user:
  - a. In the *Systems* view, choose **► Security ► Users ▾**.
  - b. From the context menu, choose *New Restricted User*.  
The *New Restricted User* editor opens.

2. Specify the new user name.

You must give the user a unique name. User names can contain any CESU-8 characters except for a small subset. For more information, see *Unpermitted Characters in User Names*.

3. Optional: Allow the user to connect to the database via ODBC and JDBC clients by deselecting the corresponding checkbox.

By default, restricted users are only able to connect to the database using HTTP. You must explicitly allow access via ODBC and JDBC clients by changing this setting.

For full access to ODBC or JDBC functionality, you must grant restricted users the standard role `RESTRICTED_USER_ODBC_ACCESS` or `RESTRICTED_USER_JDBC_ACCESS`.

4. Specify the user's properties:

Option	Description
<b>Authenti- cation</b>	<p>You can set up one or more of the following types of user authentication:</p> <ul style="list-style-type: none"> <li>○ <b>User name/password</b> authentication by a password You can override the password policy setting (<code>force_first_password_change</code>) that forces users to change a password set by a user administrator the first time they log on. This is useful for technical users, for example.</li> <li>○ <b>Kerberos</b> authentication (external) by specifying the user principal name (UPN) specified in the Microsoft Active Directory or the Kerberos Key Distribution Center as the external ID</li> <li>○ <b>SAML</b> authentication (external) by selecting the identity provider and then entering the user ID known by the SAML identity provider Alternatively, you can allow the identify provider to map users to the database user by selecting the checkbox in the <i>Any</i> column.</li> <li>○ <b>X.509 certificates</b> by adding the user's public key certificate(s)</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; margin-top: 10px;"> <p><b>i Note</b> X.509 certificates are supported only for HTTP access through SAP HANA XS</p> </div> <ul style="list-style-type: none"> <li>○ SAP logon and assertion tickets</li> </ul>
<b>Valid From/ Until</b>	<p>You can specify a validity period for the user. For example, if you are creating a user for a new employee, you can enter their start date in the <i>Valid From</i> field.</p> <p>If you do not enter any values, the user is immediately and indefinitely valid.</p>
<b>Session client</b>	<p>When you create SAP HANA information models (attribute views, analytic views, and calculation views), it is possible to filter the data according to the client specified in table fields such as <code>MANDT</code> or <code>CLIENT</code>. You can specify the client relevant for the user here.</p>

5. Authorize the user by granting the required roles and privileges.

To authorize the user to pass on granted roles and privileges to other users, you can select *Grantable to other users and roles*. Note that this option is not available when granting the following:

- Roles created in the repository
- Privileges on objects created in the repository

- Privileges granted on your user
6. Optional: Specify additional user information:
    - a. Choose the *User Parameters* tab.
    - b. Add the required parameters.

For more information about the available parameters, see *Custom User Properties*.
  7. Save the user by choosing the  (*Deploy*) button.

The system verifies that the user's password complies with the configured password policy and that it is not on the password blacklist.

## Results

The user is created and appears in the *Users* folder. A new schema is also created for the user in the catalog. It has the same name as the user. However, as a restricted user, the user is not authorized to create objects in this schema. For more information about all restrictions, see *Database Users*.

### 7.2.5.2.4 Copy a User Based on SAP HANA Repository Roles

If you are implementing user authorization through roles created in the SAP HANA repository, it is possible to create a new user by copying an existing user. The repository roles granted to the existing user are automatically granted to the new user. SQL roles and individual privileges are **not** granted. You can copy a role in this way using the SAP HANA studio.

## Prerequisites

You have the system privilege USER ADMIN and the object privilege EXECUTE on the GRANT\_ACTIVATED\_ROLE (SYS\_REPO) procedure.

## Context

Copying a user allows you to create a new user with the same repository roles as the source user automatically granted.

### i Note

Only roles created in the SAP HANA repository are granted. SQL roles, including the standard roles delivered with the SAP HANA database (MONITORING, MODELING, and so on) and individual privileges are **not** granted.

## Procedure

1. Copy an existing user:
  - a. In the *Systems* view, choose **► Security ► Users ▾**.
  - b. Right-click the user to be copied and choose *Copy User*.The *Copy User* editor opens. The repository roles granted to the source user automatically appear on the *Granted Roles* tab.
2. Enter the required user-specific information, that is, user name and authentication details.
3. Grant any additional roles and privileges required by the user.
4. Create the user by choosing the  (*Deploy*) button to create the user.

The system verifies that the user's password complies with the configured password policy and that it is not on the password blacklist.

## Results

The user is created and appears in the *Users* folder. A new schema is also created for the user in the catalog. It has the same name as the user.

## 7.2.5.2.5 Change a User

You can change a user's authentication information, grant them new privileges and roles, as well as revoke previously granted privileges and roles. You can change a user with the *User* editor of the SAP HANA studio.

### Prerequisites

- You have the system privilege USER ADMIN.

#### i Note

A user can change his or her own password without USER ADMIN.

- You have the privileges required to grant specific privileges and roles to the user. To grant SQL privileges and roles, you must have the privilege and/or role yourself and be authorized to grant it to others. To grant privileges on activated repository objects, you must be authorized to execute certain stored procedures. For more information, see *Prerequisites for Granting and Revoking Privileges and Roles*.
- If you are integrating SAP HANA database users into a single-sign on (SSO) environment using one or more of the supported mechanisms, the necessary infrastructure must be in place and configured.

### Procedure

1. Open the user for editing:
  - a. In the *Systems* view, choose **Security > Users**.
  - b. Open the relevant user.

2. Make the required changes.

You can change the following:

- Authentication methods supported for the user
- Password for user name/password authentication
- External ID for Kerberos authentication, that is the user principal name (UPN) specified in the Microsoft Active Directory or the Kerberos Key Distribution Center
- Identity provider and external user ID for SAML authentication
- User's public key certificate for X.509 certificate authentication (only supported for HTTP access through SAP HANA Extended Services (SAP HANA XS))
- SAP logon and assertion tickets
- Validity period
- Session client
- Granted roles and privileges
- Whether or not the user is allowed to pass on his or her privileges to other users (*Grantable to other users and roles* option)

### i Note

This option is **not** available when granting the following:

- Roles created in the repository
- Privileges on objects created in the repository
- Privileges granted on other users

3. Save the user by choosing the  (*Deploy*) button to save the changes.

If you changed the user's password, the system verifies that it complies with the configured password policy and that it is not on the password blacklist.

## 7.2.5.2.6 Delete a User

You may need to delete a database user if an employee leaves your organization for example. You can delete a user with the *User* editor of the SAP HANA studio.

### Prerequisites

You have the system privilege USER ADMIN.

### Procedure

1. In the *Systems* view, choose  *Security*  *Users* .
2. Right-click the user you want to delete and choose *Delete*.
3. Choose either *Restrict* or *Cascade* to determine how dependent objects are handled.

*Restrict* (default) With this option deletion depends upon which objects the user owns: the user is only dropped if they only have a home schema, don't own any objects in other schemas and have not created any schema local roles in their home schema. If the user is owner of any database objects in schemas

other than their home schema then the user will not be deleted. When the user is deleted, all objects in the schema are deleted and any granted privileges related to this schema and these objects are revoked.

**Cascade** This option is required if the user owns objects in other schemas. In this case the user is deleted and the following actions are carried out:

- The user's home schema and other schemas belonging to the user are dropped. All objects stored in them are also dropped regardless of which user created them; this also invalidates dependent objects.
- All objects owned by the user, even if they are part of another schema are dropped. This may invalidate objects that are dependent on deleted objects regardless of their owner or schema.
- Privileges on deleted objects and schemas are revoked and privileges granted by the deleted user are revoked; this may cause further revokes if the privileges have been granted further. Privileges granted to the deleted user are also revoked and potentially further revoked.
- Public synonyms that are owned by the user are dropped.

Notes on roles:

- Global roles are not dropped; global roles can only be dropped explicitly by running the DROP ROLE statement.
- Schema-local roles created by the user in other users' schemas are not dropped; they are only dropped when the schema owner is dropped or the schema itself is dropped.

## 7.2.5.2.7 Deactivate a User

Users can be automatically deactivated for security reasons, for example, if they violate password policy rules. However, as a user administrator, you may need to explicitly deactivate a user, for example, if an employee temporarily leaves the company or a security violation is detected. You can deactivate a user with the [User](#) editor of the SAP HANA studio.

### Prerequisites

You have the system privilege USER ADMIN.

### Procedure

#### → Tip

As an administrator you may want to temporarily deactivate all users in a system except certain administrative users so that these users can perform administration or maintenance tasks. For more information about how to do this without deactivating users individually as described here, see SAP Note 1986645.

1. In the *Systems* view, choose **► Security ► Users ►** and open the user that you want to deactivate.
2. From the editor toolbar, choose  (*Deactivate User...*)

## Results

The database user is now deactivated and remains so until you reactivate. The user still exists in the database, but cannot connect to the database any more. The reason (`explicitly deactivated`) and the time of deactivation are displayed in the user's details.

### Note

It may still appear as though deactivated users are still active in the system (for example when a procedure that was created by the user with DEFINER MODE is called).

## Related Information

[SAP Note 1986645](#)

## 7.2.5.2.8 Reactivate a User

As a user administrator, you may need to reactivate a user, for example, you explicitly deactivated the user or the user has made too many invalid log-on attempts. You can reactivate a user with the *User* editor of the SAP HANA studio.

## Prerequisites

You have the system privilege USER ADMIN.

## Procedure

1. In the *Systems* view, choose  *Security*  *Users*  and open the user that you want to reactivate.
2. From the editor toolbar, choose  (*Activate User...*)  
The user is now reactivated.

## 7.2.5.2.9 Additional User Parameters

Several additional user parameters allow you to add more information about a user, for example their e-mail address.

Parameter	Description
EMAIL ADDRESS	<p>The user's e-mail address</p> <p>The e-mail address must be unique to the user.</p>
LOCALE	<p>The user's locale</p> <p>When you create SAP HANA information models (attribute views, analytic views, and calculation views), this parameter can be used to translate information according to the user's locale.</p>
PRIORITY	<p>The priority with which the thread scheduler handles statements executed by the user</p> <p>The priority can be in the range 0-9 with 9 representing the highest priority. 5 is the default priority.</p>
STATEMENT MEMORY LIMIT	<p>The maximum memory (in GB) that can be used by a statement executed by the user</p> <p>The properties <code>statement_memory_limit</code> and <code>statement_memory_limit_threshold</code> in the <code>memory_manager</code> section of the <code>global.ini</code> configuration file are used to limit the memory that can be allocated with respect to statement execution.</p> <p><code>statement_memory_limit_threshold</code> indicates what percentage of the global memory allocation limit must be in use before the specific value of <code>statement_memory_limit</code> is applied. If this memory limit is being applied and a statement execution exceeds it, then the statement is aborted.</p> <p>With this user parameter, you can set a user-specific limit that takes precedence over the global statement memory limit.</p> <p>For more information about memory usage, see <i>Monitoring Memory Usage</i>.</p>
TIME ZONE	<p>The user's timezone</p> <p>The standard database formats for locale and timezone are supported.</p>

## 7.2.6 Configuring LDAP Integration

The Lightweight Directory Access Protocol (LDAP) is an application protocol for accessing directory services. If you use an LDAP-compliant directory server to manage users and their access to resources, you can leverage LDAP-based authentication to access SAP HANA and LDAP group membership to authorize users.

### Related Information

[LDAP User Authentication](#)

[LDAP Group Authorization for Existing Users](#)

[Secure Communication Between SAP HANA and an LDAP Directory Server](#)

### 7.2.6.1 Configure LDAP Authentication and Authorization

Set up a connection to an LDAP server by creating an LDAP provider in SAP HANA. Depending on your requirements, you can use the LDAP server to authenticate or authorize, or to authenticate and authorize users. For LDAP-authenticated users, you can also enable the automatic creation of users in SAP HANA.

#### Prerequisites

- An LDAP v3 compliant server
- Communication between SAP HANA and the LDAP server is secure.

#### ⚠ Caution

If the LDAP server is being used for user authentication, communication between SAP HANA and the LDAP server must be secured to protect the transmission of user passwords.

#### i Note

To protect data transmitted between the client and SAP HANA, as well as to ensure that the client is connecting to the expected SAP HANA (server authentication), you must secure communication between clients and SAP HANA.

- To create an LDAP provider in SAP HANA, you have the system privilege `LDAP ADMIN`.
- To configure SAP HANA users, system privilege `USER ADMIN` or users in user groups configured for exclusive administration, the object privilege `USERGROUP OPERATOR` on the relevant user group(s).
- To map LDAP groups to SAP HANA roles (authorization only), you have the system privilege `ROLE ADMIN`.

## Procedure

1. Create and configure an LDAP provider in the SAP HANA database.

You do this using the `CREATE LDAP PROVIDER` statement. For more information, see the section *LDAP Provider Configuration (Reference)* in this guide, as well as the documentation for `CREATE LDAP PROVIDER` in the *SAP HANA SQL Reference*.

### Sample Code

The following example creates an LDAP provider that can be used to authenticate users via a secure connection (LDAP with STARTTLS). The provider is enabled and set as the default LDAP provider.

```
CREATE LDAP PROVIDER my_ldap_provider
CREDENTIAL TYPE 'PASSWORD' USING
'user=cn=LookupAccount,cn=Users,dc=largebank,dc=como;password=<password>'
USER LOOKUP URL 'ldap://myhostname:389/cn=Users,dc=largebank,dc=com??sub?
(&(objectClass=user)(sAMAccountName=*))'
ATTRIBUTE DN 'distinguishedName'
SSL ON
DEFAULT ON
ENABLE PROVIDER;
```

### Sample Code

The following example creates an LDAP provider that can be used for authenticating and authorizing users via a secure connection (ldaps). The provider is enabled, permitted to create users in SAP HANA, and set as the default LDAP provider.

```
CREATE LDAP PROVIDER my_ldap_provider
CREDENTIAL TYPE 'PASSWORD' USING
'user=cn=LookupAccount,cn=Users,dc=largebank,dc=como;password=hUWe8ZTiQyG'
USER LOOKUP URL 'ldaps://myhostname:389/cn=Users,dc=largebank,dc=com??sub?
(&(objectClass=user)(sAMAccountName=*))'
ATTRIBUTE DN 'distinguishedName'
ATTRIBUTE MEMBER_OF 'memberOf'
SSL OFF
DEFAULT ON
ENABLE PROVIDER
ENABLE USER CREATION FOR LDAP;
```

2. For **LDAP authentication**, configure the SAP HANA users to be authenticated using their LDAP password.

### Note

This step is only necessary if you have **not** enabled the LDAP provider for automatic user creation

You can configure users for LDAP authentication using either the SAP HANA cockpit or the `CREATE USER` or `ALTER USER` statements.

### Sample Code

```
CREATE USER julie WITH IDENTITY FOR LDAP PROVIDER;
```

### Note

Users configured for LDAP authentication cannot simultaneously be configured for local password authentication. Local password authentication must be disabled before an existing user can be

```
configured for LDAP authentication, for example, using the statement ALTER USER <user_name>
DISABLE PASSWORD.
```

3. For **authorization based on LDAP group membership**, do the following:

- a. Map LDAP groups to roles in the SAP HANA database.

This allows SAP HANA to determine which roles to assign to users based on their membership in one or more LDAP groups, either directly or indirectly through nested groups. Users' access to requested resources is then determined by the privileges defined in the SAP HANA roles.

You map LDAP groups to roles in the role definition in SAP HANA using either the SAP HANA cockpit or the `CREATE ROLE` or `ALTER ROLE` statements. You must specify the unique distinguished name (DN) of an LDAP group.

#### Sample Code

```
CREATE ROLE Securities_DBA
LDAP GROUP
`cn=Securities_DBA,OU=Application,OU=Groups,ou=DatabaseAdmins,cn=Users,d
c=largebank,dc=com` ;
```

#### Note

It is not possible to include an LDAP group in the definition of design-time roles.

- b. Configure SAP HANA users for LDAP group authorization, if necessary.

#### Note

If you have configured LDAP authentication, this step is only necessary if you have not enabled the LDAP provider for automatic user creation

You can configure users for LDAP group authorization by specifying `LDAP` as the authorization mode using either the SAP HANA cockpit or the `CREATE USER` and `ALTER USER` statements.

#### Sample Code

```
CREATE USER USER1 PASSWORD <password> AUTHORIZATION LDAP ;
```

#### Note

If you change the authorization mode of an existing user, any roles and privileges already granted to the user are revoked. For more information, see the *SAP HANA Security Guide*.

#### Tip

To see which authorization mode is configured for a user, display the user in the SAP HANA cockpit or refer to the `AUTHORIZATION_MODE` column of the `USERS` system view.

4. Verify the configuration of the LDAP provider using the `VALIDATE LDAP PROVIDER` statement.

#### Example

##### Example 1:

This example verifies whether the specified SAP HANA user can be successfully authenticated using their LDAP password.

#### Sample Code

```
VALIDATE LDAP PROVIDER my_ldap_provider CHECK USER testuser1 PASSWORD '<LDAP_password>;'
```

#### Example 2:

This example verifies that based on the current LDAP configuration and role-to-group mappings in SAP HANA, the specified SAP HANA user will be granted SAP HANA roles:

#### Sample Code

```
VALIDATE LDAP PROVIDER my_ldap_provider CHECK USER 'john';
```

## 7.2.6.2 LDAP Provider Configuration (Reference)

To set up a connection to an LDAP server, you must create an LDAP provider in the SAP HANA database. Depending on your requirements, you can use the LDAP server to authenticate and/or authorize users. For LDAP-authenticated users, you can also enable the automatic creation of users in SAP HANA.

The following table describe the information needed to configure the LDAP provider. For the exact syntax of the element, see `CREATE LDAP PROVIDER` and `ALTER LDAP PROVIDER` statements *SAP HANA SQL and System Views Reference*.

Configuration Information	SQL Clause	Description/Example
Name	<code>&lt;ldap-provider-name&gt;</code>	Name of the LDAP server
How the LDAP server is accessed	<code>CREDENTIAL TYPE</code>	Access take places using an LDAP server user with permissions to perform searches as specified by the user look-up URL. You must specify the distinguished name (DN) and password of this user.

Configuration Information	SQL Clause	Description/Example
The LDAP URL used to locate a requested user entry on the LDAP server	USER LOOKUP URL	<p>Returns a unique user entry on the LDAP server that corresponds to current SAP HANA user</p> <p>The user look-up URL has the following format:</p> <pre>ldap[s]://&lt;hostname&gt;:&lt;port&gt;/&lt;base_dn&gt;?&lt;attributes&gt;?&lt;scope&gt;?&lt;filter&gt;</pre> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>❖ Example</b></p> <pre>USER LOOKUP URL 'ldaps://myhostname:389/cn=Users,dc=largebank,dc=com??sub?(&amp;(objectClass=user)(sAMAccountName=*))'</pre> </div> <p>The search for a user entry is based on the SAP HANA user name of the current user. The search filter must include a filter condition in the format '<code>&lt;attribute&gt;=*</code>', where <code>&lt;attribute&gt;</code> is an LDAP attribute whose value is matched against the name of the SAP HANA user.</p> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>i Note</b></p> <p>The search filter must contain a single asterisk (*). An error is returned if either no asterisk or more than one is present.</p> </div> <p>The asterisk (*) is replaced by the SAP HANA user name before the LDAP search query is sent to LDAP server.</p> <p>In the above example <code>(&amp;(objectClass=user)(sAMAccountName=*))</code> becomes</p> <pre>(&amp;(objectClass=user)(sAMAccountName=&lt;USER_NAME of the current HANA user&gt;))</pre> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>i Note</b></p> <p>The user look-up search query must return a single entry, that is a unique user entry corresponding to the current SAP HANA user. An error occurs if more than one entry is returned.</p> </div> <p>The <code>&lt;attributes&gt;</code> element must remain empty in the user look-up URL. Any <code>&lt;attributes&gt;</code> specified in the user look-up URL are ignored. SAP HANA internally constructs the <code>&lt;attributes&gt;</code> list before executing the user look-up URL as follows:</p> <ul style="list-style-type: none"> <li>• If a nested group URL is specified, <code>&lt;attributes&gt;</code> is replaced with the attribute specified by <code>ATTRIBUTE DN</code> clause.</li> </ul>

Configuration Information	SQL Clause	Description/Example
		<ul style="list-style-type: none"> <li>If a nested group URL is not specified, <code>&lt;attributes&gt;</code> is replaced with the attributes specified by <code>ATTRIBUTE DN</code> and <code>ATTRIBUTE MEMBER_OF</code> clauses.</li> </ul>

Configuration Information	SQL Clause	Description/Example
Optional: The LDAP URL used to obtain a user's group membership information, including nested groups, from the LDAP server	NESTED GROUP LOOKUP URL	The nested group look-up URL returns the complete list of groups of which the LDAP user identified by the user look-up URL is a member, including groups with indirect membership.

The nested group look-up URL has the following format:

```
ldap[s]://<hostname>:<port>/<base_dn>?<attributes>?<scope>?<filter>
```

#### ❖ Example

```
NESTED GROUP LOOKUP URL `ldaps://myhostname:389/ou=groupsOU,dc=x??sub?(member:1.2.840.113556.1.4.1941:=*)`
```

The asterisk (\*) in the search filter is replaced by the user DN before the nested group look-up URL search query is executed.

#### i Note

The search filter must contain a single asterisk (\*). An error is returned if either no asterisk or more than one is present.

SAP HANA obtains the list of groups from the NESTED GROUP LOOKUP URL query in the following manner:

- If no attributes are specified in the nested group look-up URL, the attribute specified by ATTRIBUTE DN clause is used.

#### ❖ Example

```
'ldap://myhostname:389/ou=groupsOU,dc=x??sub?(member:1.2.840.113556.1.4.1941:=*)'
```

In this case, before sending the above query to the LDAP server to obtain list of groups, SAP HANA replaces the empty attribute list with the attribute specified by the ATTRIBUTE DN clause. Also, '\*' in the search filter is replaced with the user DN that is obtained by executing USER LOOKUP URL query.

- If more than one attribute is specified in the nested group look-up URL, then SAP HANA only uses the first attribute from the <attributes> list. Other attributes are ignored.

If the nested group look-up URL query returns more than one entry, then the value of the first attribute from each entry is combined to obtain the complete list of groups for the user.

Configuration Information	SQL Clause	Description/Example
		This attribute is optional if the LDAP provider is being used for user authentication only.
The LDAP attribute that provides the distinguished name (DN) of the LDAP user entry	ATTRIBUTE DN	<p><b>❖ Example</b></p> <pre>ATTRIBUTE DN 'distinguishedName'</pre>
Optional: The LDAP attribute that provides a list of groups that a user is a member of	ATTRIBUTE MEMBER_OF	<p><b>❖ Example</b></p> <pre>ATTRIBUTE MEMBER_OF 'memberOf'</pre> <p>This attribute is not required if a nested group look-up URL is specified. If both <code>ATTRIBUTE MEMBER_OF</code> and <code>NESTED GROUP LOOKUP URL</code> are specified, <code>NESTED GROUP LOOKUP URL</code> takes precedence.</p> <p>This attribute is optional if the LDAP provider is being used for user authentication only.</p>
Whether or not connections between SAP HANA and the LDAP server are secured using TLS/SSL	SSL ON   SSL OFF	<p>This setting applies to both LDAP access authentication and queries, including user lookup and nested groups lookup.</p> <p>If TLS/SSL is enabled, the URL begins with "ldap://".</p> <p><b>→ Remember</b></p> <p>The root certificate of the LDAP server must be available in a certificate collection with purpose <i>LDAP</i>.</p> <p><b>i Note</b></p> <p>TLS/SSL-secured communication uses the SAP cryptographic library, CommonCryptoLib. For more information, see SAP Note 1848999.</p> <p>Connections to the LDAP server can also be secured using the secure LDAP protocol. In this case, the URL begins with <code>ldaps://</code> and TLS/SSL must be switched off.</p> <p><b>⚠ Caution</b></p> <p>Whether the LDAP provider is to be used for LDAP group authorization and/or authentication, you must secure communication between SAP HANA and the LDAP server using the TLS/SSL protocol to protect the transmission of user passwords between SAP HANA and the LDAP server.</p>

Configuration Information	SQL Clause	Description/Example
Whether the LDAP provider is to be used for LDAP group authorization and/or authentication	DEFAULT ON   DEFAULT OFF	You can create several LDAP providers but only one can be in use at any time.
Whether or not the LDAP provider is enabled	DISABLE PROVIDER   ENABLE PROVIDER	Whether or not the LDAP provider is enabled
Optional: Whether or not the LDAP provider can create a database user in SAP HANA if required	ENABLE USER CREATION FOR LDAP [USER TYPE {STANDARD   RESTRICTED}]	<p>The LDAP server creates a user in SAP HANA if all of the following are true:</p> <ul style="list-style-type: none"> <li>• LDAP authentication is enabled both in SAP HANA and for the user logging on.</li> <li>• The user is a member of at least one LDAP group mapped to an SAP HANA role.</li> <li>• A database user with this name does not already exist.</li> </ul> <p>By default, the user created is a standard user. If you want restricted users to be created, add the option USER TYPE RESTRICTED.</p> <p>The new database user is automatically configured for LDAP authentication and LDAP group authorization (authorization mode LDAP).</p>

### ⚠ Caution

If the default LDAP provider is disabled, users configured for LDAP authorization and/or authentication will not be able to log on after the configured role reuse duration has expired. For more information about the reuse duration, see the *SAP HANA Security Guide*.

## 🌱 Example

The following example creates an LDAP provider for obtaining the LDAP group membership of SAP HANA users via a secure connection (LDAP with STARTTLS). The provider is enabled and set as the default for LDAP group authorization.

### 📄 Sample Code

```
CREATE LDAP PROVIDER my_ldap_provider
CREDENTIAL TYPE 'PASSWORD' USING
'user=cn=LookupAccount,cn=Users,dc=largebank,dc=como;password=hUWe8ZTiQyG'
USER LOOKUP URL 'ldap://myhostname:389/cn=Users,dc=largebank,dc=com??sub?
(&(objectClass=user)(sAMAccountName=*))'
ATTRIBUTE DN 'distinguishedName'
ATTRIBUTE MEMBER_OF 'memberOf'
SSL ON
DEFAULT ON
ENABLE PROVIDER;
```

[Activate and Configure Auditing \[page 952\]](#)

[Create an Audit Policy \[page 954\]](#)

[Delete Audit Entries \[page 960\]](#)

#### 7.3.1.1 Activate and Configure Auditing

The auditing feature of the SAP HANA database allows you to monitor and record selected actions performed in your database. To be able to use this feature, it must first be activated for the database. It is then possible to create and activate the required audit policies. You can do this on the [Auditing](#) page of the SAP HANA cockpit.

## Prerequisites

- You have the system privileges `AUDIT ADMIN` and `INIFILE ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, click the [Auditing](#) card.

The [Auditing](#) page opens.

2. Enable auditing.
  - a. Open the [Configuration](#) tab and choose [Edit](#).
  - b. Set the auditing status to [Enable](#).

### i Note

You can also enable auditing directly on [Auditing](#) card with the on/off switch.

3. Optional: Configure the required audit trail targets.

By default, this is possible only in the **system database**.

You can configure multiple audit trail targets: one for the database ([Overall Audit Trail Target](#)), and optionally one or more for the severity of audited actions, that is the audit level of the corresponding audit entries. If you do not configure a specific target for an audit level, audit entries are written to the overall audit trail target. For more information about the available audit trail targets, see [Audit Trail Targets](#).

[Database table](#) is the default audit trail target for tenant databases and [syslog](#) for the system database.

### i Note

If you are configuring auditing in a tenant database, you cannot change the audit trail targets. This is because the underlying system properties (`[auditing configuration] *_audit_trail_type`) are in the configuration change blacklist `multidb.ini`. Audit trails are by default written to an internal database table of the tenant database. Although not recommended, it is possible to change the audit trail target of a tenant database in the following ways:

- The system administrator changes the audit trail targets for individual tenant databases directly by configuring the relevant system property (`[auditing configuration] *_audit_trail_type`) in the `global.ini` file.
- The system administrator removes the relevant system property (`[auditing configuration] *_audit_trail_type`) from the configuration change blacklist, thus enabling the tenant database administrator to change the audit trail target.

### ⚠ Caution

To ensure the privacy of tenant database audit trails, it is recommended that you do **not** change the default audit trail target (internal database table) of tenant databases.

4. Save your configuration.

## Results

Auditing is activated in your database and you can now create audit policies.

## Related Information

[Create an Audit Policy \[page 954\]](#)

[Audit Trail Targets \[page 973\]](#)

[System Properties for Configuring Auditing](#)

[Default Blocklisted System Properties in Tenant Databases \[page 280\]](#)

### 7.3.1.2 Create an Audit Policy

An audit policy defines the actions to be audited, as well as the conditions under which the action must be performed to be relevant for auditing. When an action occurs, the policy is triggered and an audit event is written to the audit trail. Audit policies are database specific. You can create audit policies on the [Auditing](#) page of the SAP HANA cockpit.

## Prerequisites

- You have the system privilege `AUDIT ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to the [Auditing](#) card, then click the card title.
2. On the [Audit Policies](#) tab of the [Auditing](#) page, click the [Create Audit Policy](#) button.
3. Enter the policy name.
4. Select the audited action status.

The action status specifies when the actions in the policy are to be audited.

The following values are possible:

Status	Description
All	All executions of the specified actions are audited, whether successful or unsuccessful.
Successful (default)	The action is audited only when the SQL statement is successfully executed.
Unsuccessful	The action is audited only when the SQL statement is unsuccessfully executed.

### **i** Note

An unsuccessful attempt to execute an action means that the user was not authorized to execute the action. If another error occurs (for example, misspellings in user or object names and syntax errors), the action is generally not audited. In the case of actions that involve data manipulation (that is, INSERT, SELECT, UPDATE, DELETE, and EXECUTE statements), additional errors (for example, invalidated views) are audited.

5. Specify the actions to be audited.

### **i** Note

Only actions belonging to the same category can be combined together in the same policy.

Selecting *All Actions* covers not only all actions that can be audited individually, but also actions that cannot otherwise be audited. Such a policy is referred to as a firefighter policy and is useful if you want to audit the actions of a particularly privileged user, for example.

### **⚠** Caution

The actions that are audited are limited to those that take place inside the database engine while it is running. Therefore, database restart and recovery will not be audited.

6. If necessary, select the target object(s) to be audited.

You must specify a target object if the actions to be audited involve data manipulation, for example, the actions SELECT, INSERT, UPDATE, DELETE, and EXECUTE. The actions in the policy will only be audited when they are performed on the specified object or objects.

When specifying target objects, note the following:

- You can only enter schemas, tables, views, procedures, and functions.
- The target object must be valid for **all actions** in the policy.

7. If necessary, select the user(s) to be audited.

It is possible to specify that the actions in the policy be audited only when performed by a particular user or users (*Only the selected users*). Alternatively, you can specify that the actions in the policy be audited when performed by all users **except** a particular user or users (*All users except those selected*).

The actions in the policy will only be audited when performed by the specified user(s). If you do not specify a user, the actions will be audited regardless of who performs them.

### **i** Note

You **must** specify a user if you chose to audit all actions.

- Optional: Select the audit level.

The audit level specifies the severity of the audit entry written to the audit trail when the actions in the policy occur and ranges from INFO to EMERGENCY. The default level is INFO.

- Optional: Select one or more policy-specific audit trail targets (system database only).

Audit entries triggered by this policy will be written to the specified audit trail target(s). If you do not specify a policy-specific target, entries will be written to the audit trail target for the audit level of the policy if configured, or the audit trail target configured for the system.

- Optional: Specify a retention period.

A retention period can only be specified for audit policies that have **database table** set **explicitly** as the audit trail target, not database table as the default target.

Set *Delete audit entries automatically* to *On*.

Specify a time period, after which audit entries will be deleted.

- Specify whether you want the audit policy to be immediately enabled (default) or initially disabled on creation.
- Choose *Review* to check the configuration of the new audit policy.
- Save the new audit policy.

## Results

The new policy appears in the list of audit policies. Unless you configured it otherwise, the new policy is automatically enabled. This means that when an action in the policy occurs under the conditions defined in the policy, an audit entry is created in the audit trail target(s) configured for the policy. If an action event is audited by multiple audit policies and these audit policies have different audit trail targets, the audit entry is written to all trail targets.

You can disable a policy at any time by changing the policy status. It is also possible to delete a policy.

### **i** Note

Audit policies are not owned by the database user who creates them and therefore will not be deleted if the corresponding database user is deleted.

## Related Information

[System Properties for Configuring Auditing](#)

## 7.3.1.2.1 Configure the Base Setup for Audit Policies

You can use a wizard to quickly apply a basic configuration for audit policies.

### Prerequisites

- You have the system privilege `AUDIT ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page*.

### Context

Instead of manually configuring audit policies, you can use a wizard to apply SAP's recommended configuration settings. This allows you to quickly start working with audit policies.

For a registered database, the UI notifies you if audit policy configuration was not completed using the base setup wizards. You have the option to disable these notifications.

#### i Note

The base setup does not guarantee that the configuration is optimal for your particular system. To optimize the configuration, it may be advisable to manually configure specific settings.

### Procedure

1. On the [Database Overview](#), with the [Security and User Management](#) or [All](#) view selected, navigate to the [Auditing](#) card, then click the card title.
2. Choose [Base Setup](#).

Specify the base settings for auditing.

Option	Description
<a href="#">Display base setup notifications for Auditing</a>	Enable or disable notifications for auditing. You can change this setting at any time.
<a href="#">Change Global Settings</a>	To enable or disable all security-related notifications about the base setup, choose <a href="#">User Interface Notification</a> <a href="#">Display base setup notifications</a> . You can enable or disable notifications at any time.

Option	Description
	For more information about SAP HANA cockpit user settings, see <i>Personalizing the Database Overview Page</i> .
<a href="#">Auditing Setup</a>	To complete the base setup, choose <i>Complete Setup</i> and follow the on-screen instructions.  If you do not wish to change the configuration, choose <i>Manually set to completed</i> and choose <i>OK</i> . This disables notifications about the base setup.

3. When you have finished, choose [Review](#) to display an overview of the auditing settings.
4. Choose [Save](#).

## Results

The configuration settings are saved.

Notifications about the base setup are no longer displayed.

## Related Information

### 7.3.1.3 Manage Audit Policies for Tenant Databases

You can change or delete audit policies for one or more tenant databases.

## Prerequisites

- Auditing is enabled.
- You have the system privilege `DATABASE AUDIT ADMIN` in the system database.

## Procedure

1. Connect to the system database.
2. On the [Database Overview](#) page, go to the [Auditing](#) card, and click its title.

An overview of the audit policies created on the system database for the tenant databases is displayed. (Audit policies that were created on the tenant databases are not displayed here.)

3. Select an action.

Option	Description
<b>To display the SQL statement for an audit policy...</b>	Select one or more audit policies, then choose <a href="#">Show SQL Statements</a> .  If you select multiple audit policies, the SQL statements for each audit policy are displayed together.
<b>To delete an audit policy...</b>	Select one or more audit policies, then choose <a href="#">Delete Audit Policies</a> .  When you confirm, the policies are deleted and no more data is collected for them.  To delete data that was collected by the audit policies, see <a href="#">Delete Audit Entries</a> .

4. To change an audit policy, click its row.

The configuration of the audit policy is displayed.

5. Choose [Edit](#).
6. Make the required changes.

For more information about configuration options for audit policies, see [Auditing Details](#).

7. Select the tenant database(s) to be audited.

In the [Audited Database](#) section, select one or more tenant databases in which to enable the policy.

8. Save.

## Results

The changed policy appears in the list of audit policies. If you set the audit policy status to [Enabled](#), the audit policy is automatically enabled in the tenant databases that you specified.

## Related Information

## 7.3.1.4 Delete Audit Entries

If the audit trail target is or was a database table, you can delete old audit entries, for example to prevent the audit table from growing indefinitely.

### Prerequisites

- The audit trail target is or was [Database Table](#).
- You have archived the audit entries that you plan to delete.
- You have the system privilege AUDIT OPERATOR.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

The database monitors the size of the table with respect to the memory allocation limit and issues an alert when it reaches defined values (by default 5%, 7%, 9%, and 11% of the allocation limit). This behavior can be configured with check 64.

#### i Note

If the table has grown so large that there is not enough memory available to delete old entries as described here, you can use the SQL command `ALTER SYSTEM CLEAR AUDIT LOG ALL` to completely empty the table. However, even if you archived the audit table beforehand (**recommended**), any new entries written between the time of archiving and the time of clearing may be lost.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, click the [Auditing](#) card.

An overview of the audit policies is displayed.

2. Choose the [Audit Trail](#) tab.
3. Choose [Delete Audit Entries](#) and select which audit entries you want to be deleted.
  - Entries older than a specific number of days
  - Entries created before a date

- All entries
4. Choose *Delete* to delete the specified audit entries from the audit table.

## Results

The audit entries that you selected are deleted.

## Related Information

[Configure Alert Thresholds \[page 375\]](#)

### 7.3.1.5 Auditing Details

On the *Auditing* page of the SAP HANA cockpit you can view and manage audit policies, audit trail targets, and the database table audit trail.

## Audit Policies

### → Tip

You can refine the list of audit policies by using the filtering options available in the table toolbar. Filter by policy name or audited action by entering the term directly in the search field, or click the  (*Filter Settings*) button and select the required filter options. To clear all filters, click  (*Clear All Filters*).

Field	Description
<i>Audit Policy</i>	Audit policy name
<i>Policy Status</i>	An audit policy can be either <i>Enabled</i> or <i>Disabled</i> .
<i>Audited Actions</i>	An audit policy can specify several related actions to be audited.  For a full list of all actions that can be audited, see the documentation for SQL access control statement CREATE AUDIT POLICY in the <i>SAP HANA SQL and Systems View Reference</i> .

Field	Description
<i>Audited Action Status</i>	<p>When the actions in the policy are to be audited:</p> <ul style="list-style-type: none"> <li>• On successful execution</li> <li>• On unsuccessful execution</li> <li>• All executions of the specified action are audited, whether successful or unsuccessful.</li> </ul>
<i>Audit Level</i>	<p>The severity of the audit entry written to the audit trail when the actions in the policy occur</p> <p>The following audit levels are possible</p> <ul style="list-style-type: none"> <li>• Emergency</li> <li>• Critical</li> <li>• Alert</li> <li>• Warning</li> <li>• Info</li> </ul>
<i>Users</i>	<p>User(s) included in the audit policy or excluded from the audit policy</p> <p>Actions in the policy are audited when performed by either the specified user(s) or any user except the specified user(s).</p>
<i>Audited Objects</i>	<p>The following audited object types are possible:</p> <ul style="list-style-type: none"> <li>• Schemas (and all objects contained within)</li> <li>• Tables</li> <li>• Views</li> <li>• Procedures</li> <li>• Sequences</li> </ul>
<i>Audit Trail Target</i>	<p>Policy-specific audit trail target(s)</p> <p>If there is no policy-specific audit trail target, audit entries generated by the policy are written to the audit trail target for the audit level of the policy if configured, or the audit trail target configured for the database. The applicable default audit trail target is always indicated in brackets.</p>
<i>Retention Period</i>	<p>Audit entries can be retained for a specified time, then deleted automatically.</p> <p>A retention period can only be specified for audit policies that explicitly have database table as the audit trail target.</p>
	<p><b>i Note</b></p> <p>If the retention period is changed, any audit entries that are no longer included are deleted immediately.</p>

## Configuration

Field	Description
<i>Auditing Status</i>	An audit policy can be either <i>Enabled</i> or <i>Disabled</i> .
<i>Overall Audit Trail Target</i>	The default audit trail target for the database  If you do not configure a specific target for an audit level or a specific target for an audit policy, audit entries are written to this audit trail target.
<i>Target for Audit Level Alert</i>	The audit trail target to which audit entries with audit level <code>ALERT</code> are written
<i>Target for Audit Level Emergency</i>	The audit trail target to which audit entries with audit level <code>EMERGENCY</code> are written
<i>Target for Audit Level Critical</i>	The audit trail target to which audit entries with audit level <code>CRITICAL</code> are written

### i Note

By default, it is not possible to configure audit trail targets in tenant databases. The audit trail target is *Database table*. For more information, see the section on audit trail targets.

## Audit Trail

If the audit trail target is or was database table, you can view and manage the audit logs here, including the audit logs of the XS advanced run-time environment if available.

For more information, see the section on the audit trail view.

## Related Information

[Auditing Activity in the SAP HANA Database](#)

[Audit Trail Targets \[page 973\]](#)

[Audit Trail View \[page 964\]](#)

[Delete Audit Entries \[page 960\]](#)

## 7.3.1.6 Audit Trail View

For each occurrence of an audited action, one or more audit entries are written to the audit trail. If the audit trail target is a database table, you can view the log on the [Auditing](#) page of the SAP HANA cockpit. It is also possible to view the audit logs of the XS advanced run-time environment.

To view the audit trail, on the [Database Overview](#) page, click the [Auditing](#) card.

On the [Audit Trail](#) tab, you can choose from the following log entries:

- [All Logs](#)  
Both database and XS advanced audit entries
- [SAP HANA Logs](#)  
Audit entries written by audit polices configured in the database
- [XSA Logs](#)  
Audit entries written by the audit log service of XS advanced

The following sections describe the layout of the audit trail and the options for configuring the layout.

### Audit Trail Columns: SAP HANA Logs

Default Columns

Field	Description
Time Stamp	Time of event occurrence (in system local time)
Policy Name	Name of the audit policy that was triggered
Level	Severity of audited action
Status	Execution status of the statement
Client Host	Name of the host where the action occurred
User Name	User who performed the action
Statement	Statement that was executed

Additional Columns

Field	Description
Action	Action that was audited and thus triggered the policy
Application User Name	Application user who performed the action
	<div style="border-left: 2px solid orange; padding-left: 10px;"><p><b>⚠ Caution</b></p><p>Treat this information with caution. It comes from the application and SAP HANA has no way of verifying its authenticity.</p></div>
Client Host	Name of the client machine
Client IP	IP address of the client application
Client PID	Process ID of the client process

Field	Description
Client Port	Port of the client process
Comment	Additional information about the audited event
	<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>Currently in case of failed logon attempts, the reason for failure appears in this field.</p> </div>
Connection ID	ID of the session in which the statement was executed
File Name	Configuration file name, for example global.ini
Grantable	Indication of whether the privilege or role was granted with or without GRANT/ADMIN OPTION
Grantee	Name of the target user of the action, for example, grantee in a GRANT statement
Grantee Schema	Name of the schema of a granted or revoked role
Key	Configuration parameter, for example global_auditing_state
Object Name	Name of the object on which an action was performed, for example, a privilege was granted
Original Database	Name of tenant database in which the query originated; relevant for cross-database queries between tenant databases
Original User	Name of database user who executed the query in the origin tenant database; relevant for cross-database queries between tenant databases
Port	Port number
Previous Value	Previous value of the parameter, for example CSVTEXTFILE
Privilege Name	Name of the privilege that was granted or revoked
Role Name	Name of the role that was granted or revoked
Role Schema Name	Name of the schema in which a role was created/dropped, or the schema of a granted/ revoked role
Schema Name	Name of the schema where the action occurred, for example, a privilege was granted on a schema, or a statement was executed on object in a schema
Section	Configuration section name, for example auditing configuration
Service	Name of the service where the action occurred
Value	New parameter value, for example CSTABLE
XS Application User Name	XS application user name, for example, XSA_ADMIN

## Audit Trail Columns: XSA Logs

### Default Columns

Field	Description
Time	Time that the event occurred
XSA Organization ID	Application organization GUID
XSA Space ID	Application space GUID
App	Name of the application
XSA Instance ID	GUID of the used audit log service instance
User	Name of the application user
Message	Unique audit log message ID generated by the audit service

### Additional Columns

Field	Description
Attachment Name	Name of the attachment that triggered the event.
Attachment ID	ID of the attachment that triggered the event
Attribute	Attribute that was changed
Attribute New Value	Old value of the attribute
Attribute Old Value	New value of the attribute
Binding ID	Application binding GUID in regards to the specific auditlog service instance that is being used
Category Type	
Client Host	IP of the client host
Client IP	IP of the client application
Client PID	PID of the client process
Client Port	Port of the client process
Connection ID	Connection ID
Created	Time of the event occurrence at the client side
Host	Name of the host where the event occurred
Level	Severity level of the event
Policy Name	Name of the audit policy triggered
Port	Port number
Service	Service name
Statement	SQL statement that caused the event
Statement User	Name of the user who executed the statement
Successful	Whether the event was successful or no
User Name	Name of the user connected to the database

Field	Description
XSA Channel	Communication protocol that was used when the audit event was triggered
XSA Data Subject	Owner of the accessed personal data
XSA Message IP	IP address of the event occurrence
XSA Object	Object containing the accessed personal data
XSA Tenant	XSA tenant GUID
XSA UUID	Unique audit log message ID generated by the audit service

## Audit Trail View Configuration

You can configure the audit trail view by clicking the  (*Settings*) icon. The following options are available.

### **i** Note

Your preferences are not saved when you log out of the cockpit.

Option	Description
<i>Columns</i>	Select the columns you want to see and the order in which they are displayed.
<i>Sort</i>	Sort the audit trail by one or more columns in ascending or descending order.
<i>Filter</i>	Filter the audit trail by creating complex include and exclude filters.
	<h3><b>i</b> Note</h3> <p>Values are case sensitive.</p>
<i>Group</i>	Organize the audit trail by grouping events according to a particular field (for example, audited action, policy and so on).

## Related Information

[Audit Trail Layout for Trail Target Database Table](#)

## 7.3.2 Managing Auditing in the SAP HANA Studio

Use the *Security* editor of the SAP HANA studio to enable auditing, configure audit trail targets, and create audit policies.

### 7.3.2.1 Activate and Configure Auditing

The auditing feature of the SAP HANA database allows you to monitor and record selected actions performed in your database. To be able to use this feature, it must first be activated for the database. It is then possible to create and activate the required audit policies. You can do this using the *Security* editor of the SAP HANA studio.

#### Prerequisites

You have the system privilege AUDIT ADMIN.

#### Procedure

1. Enable auditing:
  - a. In the Security editor of the system to be audited, choose the *Auditing* tab.
  - b. In the *System Settings for Auditing* area, set the global auditing status to *Enabled*.

#### i Note

In multiple-container systems, you enable auditing for the system database and each tenant database independently.

2. Configure the required audit trail targets.

You can configure multiple audit trail targets: one for the system, and optionally one or more for the severity of audited actions, that is the audit level of the corresponding audit entries. If you do not configure a specific target for an audit level, audit entries are written to the audit trail target configured for the system. For more information about the supported audit trail targets, see *Audit Trail Targets*.

#### i Note

If you are configuring auditing in a tenant database, you cannot change the audit trail targets. Audit trails are by default written to the internal database table. A system administrator may change the audit trail targets for tenant databases by changing the relevant system property ([auditing configuration] \*\_audit\_trail\_type) in the `global.ini` file. However, this is not recommended. For more information, see *System Properties for Configuring Auditing* in the *SAP HANA Security Guide*.

3. Save your configuration by choosing the  (*Deploy*) button.

## Results

Auditing is now activated in your system (or database) and you can create the required audit policies.

## Related Information

[Audit Trail Targets \[page 973\]](#)

[System Properties for Configuring Auditing](#)

### 7.3.2.2 Create an Audit Policy

An audit policy defines the actions to be audited, as well as the conditions under which the action must be performed to be relevant for auditing. When an action occurs, the policy is triggered and an audit event is written to the audit trail. Audit policies are database specific. You can create audit policies using the *Security* editor of the SAP HANA studio.

## Prerequisites

You have the system privilege AUDIT ADMIN.

## Procedure

1. Create a new policy:
  - a. In the Security editor of the system to be audited, choose the *Auditing* tab.
  - b. In the *Audit Policies* area, choose *Create New Policy*.

A new line is added to the list of policies.

2. Enter the policy name.
3. Specify the actions to be audited as follows:
  - a. In the *Audited Actions* column, choose the **...** button.  
The *Edit Actions Audited by policy\_name* dialog box appears.
  - b. Select the required actions.

Not all actions can be combined together in the same policy. When you select an action, those actions that are not compatible with the selected action become unavailable for selection.

Selecting *All Actions* covers not only all other actions that can be audited individually but also actions that cannot otherwise be audited. Such a policy is referred to as a firefighter policy and is useful if you want to audit the actions of a particularly privileged user.

### Caution

The actions that are audited are limited to those that take place inside the database engine while it is running. Therefore, system restart and system recovery will not be audited.

c. Choose *OK*.

#### 4. Specify the action status.

The action status specifies when the actions in the policy are to be audited. The following values are possible:

Status	Description
SUCCESSFUL	The action is audited only when the SQL statement is successfully executed.
UNSUCCESSFUL	The action is audited only when the SQL statement is unsuccessfully executed.
ALL	The action is audited when the SQL statement is both successfully and unsuccessfully executed.

### Note

An unsuccessful attempt to execute an action means that the user was not authorized to execute the action. If another error occurs (for example, misspellings in user or object names and syntax errors), the action is generally not audited. In the case of actions that involve data manipulation (that is, INSERT, SELECT, UPDATE, DELETE, and EXECUTE statements), additional errors (for example, invalidated views) are audited.

#### 5. Specify the audit level.

The audit level specifies the severity of the audit entry written to the audit trail when the actions in the policy occur.

#### 6. If necessary, specify the user(s) to be audited.

It is possible to specify that the actions in the policy be audited only when performed by a particular user or users. Alternatively, you can specify that the actions in the policy be audited when performed by all users **except** a particular user or users.

Users do not have to exist before they can be named in an audit policy. However, if a specified user does not exist, it cannot be audited by the audit policy. When the user is subsequently created, the audit policy will apply for the user.

The actions in the policy will only be audited when performed by the specified user(s). If you do not specify a user, the actions will be audited regardless of who performs them.

### Note

You **must** specify a user if you chose to audit all auditable actions.

#### 7. If necessary, specify the target object(s) to be audited.

You must specify a target object if the actions to be audited involve data manipulation, for example, the actions SELECT, INSERT, UPDATE, DELETE, and EXECUTE. The actions in the policy will only be audited when they are performed on the specified object or objects.

When specifying target objects, note the following:

- You can only enter schemas, tables, views, procedures, and functions.
- The target object must be valid for **all actions** in the policy.
- An object does not have to exist before it can be named as the target object of an audit policy. However, if the object does not exist, it cannot be audited by the audit policy. When an object with the specified name is subsequently created, the audit policy will apply for the object, assuming it is of a type that can be audited and the audited action applies to that object type. For example, if the audited action is EXECUTE, the subsequently created object must be a procedure.

8. Optional: Specify one or more policy-specific audit trail targets.

Audit entries triggered by this policy will be written to the specified audit trail target(s). If you do not specify an audit trail target, entries will be written to the audit trail target for the audit level of the policy if configured, or the audit trail target configured for the system. For more information about the supported audit trail targets, see *Audit Trail Targets*.

### i Note

If you are creating the audit policy in a tenant database, you cannot specify policy-specific audit trail targets. The audit trail targets configured for the system or audit level apply, by default internal database table. A system administrator may change the audit trail targets for tenant databases by changing the relevant system property (`[auditing configuration] *_audit_trail_type`) in the `global.ini` file. However, this is not recommended. For more information, see *System Properties for Configuring Auditing* in the *SAP HANA Security Guide*.

9. Save the new policy by choosing the  (*Deploy*) button.

## Results

The list of audit policies is saved together with the new policy. The new policy is automatically enabled. This means that when an action in the policy occurs under the conditions defined in the policy, an audit entry is created in the audit trail target(s) configured for the policy. If an action event is audited by multiple audit policies and these audit policies have different audit trail targets, the audit entry is written to all trail targets.

You can disable a policy at any time by changing the policy status. It is also possible to delete a policy.

### i Note

Audit policies are not owned by the database user who creates them and therefore will not be deleted if the corresponding database user is deleted.

## Related Information

## 7.3.2.3 Delete Audit Entries from the Audit Trail

If the audit trail target is or was a database table, you can delete old audit entries, for example to prevent the audit table from growing indefinitely. You can do this using the *Security* editor of the SAP HANA studio.

### Prerequisites

- The audit trail target is or was *Database Table* (CSTABLE).
- You have archived the audit entries that you plan to delete.
- You have the system privilege AUDIT OPERATOR.

### Context

To avoid the audit table growing indefinitely, it is possible to delete old audit entries by truncating the table. The system monitors the size of the table with respect to the memory allocation limit and issues an alert when it reaches defined values (by default 5%, 7%, 9%, and 11% of the allocation limit). This behavior can be configured with check 64.

#### i Note

If the table has grown so large that there is not enough memory available to delete old entries as described here, you can use the SQL command `ALTER SYSTEM CLEAR AUDIT LOG ALL` to completely empty the table. However, even if you archived the audit table beforehand (**recommended**), any new entries written between the time of archiving and the time of clearing may be lost.

### Procedure

1. In the Security editor of the relevant system, choose the *Auditing* tab.
2. Choose the  (*Truncate the database table audit trail*) and select the date and time until which you want audit entries to be deleted.

## Results

All entries in the table audit trail up until the specified date are deleted.

## Related Information

### 7.3.3 Audit Trail Targets

In production systems, SAP HANA supports internal database table, syslog, and SAP HANA kernel trace as audit trail targets.

Audit Trail Target	Description
Internal database table	<p>Using an SAP HANA database table as the target for the audit trail makes it possible to query and analyze auditing information quickly. It also provides a secure and tamper-proof storage location. Audit entries are only accessible through the public system views AUDIT_LOG, XSA_AUDIT_LOG, and the union of these two views ALL_AUDIT_LOG. Only SELECT operations can be performed on this view by users with the system privilege AUDIT OPERATOR, AUDIT ADMIN, or AUDIT READ.</p> <p>If a database table is explicitly configured as the audit trail target of an audit policy, you can define in the audit policy a retention period after which audit entries are automatically deleted. It is also possible to delete old audit entries by truncating the table. You can do this in SAP HANA cockpit or with the SQL statement ALTER SYSTEM CLEAR AUDIT LOG. The system monitors the size of the table with respect to the overall memory allocation limit of the system and issues an alert when it reaches defined values (by default 5%, 7%, 9%, and 11% of the allocation limit). This behavior can be configured with check 64 ("Total memory usage of table-based audit log"). Only users with the system privilege AUDIT OPERATOR can truncate the audit table.</p>

Audit Trail Target	Description
Logging system of the Linux operating system (syslog)	<p>The syslog is a secure storage location for the audit trail because not even the database administrator can access or change it. There are also numerous storage possibilities for the syslog, including storing it on other systems. In addition, the syslog is the default log daemon in UNIX systems. The syslog therefore provides a high degree of flexibility and security, as well as integration into a larger system landscape. For more information about how to configure syslog, refer to the documentation of your operating system.</p>
CSV text file	<p>A separate CSV file is created for every service that executes SQL.</p> <p>By default, CSV files are written to the same directory as trace files (<code>/usr/sap/&lt;sid&gt;/&lt;instance&gt;/&lt;host&gt;/trace</code>). This means that database users with the system privilege DATA ADMIN, CATALOG READ, TRACE ADMIN, or INIFILE ADMIN can access them. In the SAP HANA database explorer, they are listed under <i>Database Diagnostics Files</i>, and at operating system level, any user in the SAPSYS group can access them.</p> <p>CSV audit trail files are created for each server in a distributed database system. For a holistic view, you need to merge the individual files in a distributed setup.</p>

**⚠ Caution**

If the syslog daemon cannot write the audit trail to its destination, you will not be notified. To avoid a situation in which audited actions are occurring, but audit entries are not being written to the audit trail, ensure that the syslog is properly configured and that the audit trail target is accessible and has sufficient space available.

**i Note**

Additionally, the option exists to write the audit trail to a kernel trace file (`*.ltc`) in the trace directory (`/usr/sap/<sid>/<instance>/<host>/trace`).

The kernel trace output is not human-readable. It must be converted into a CSV files using the command-line tool `hdbltracediag` and then loaded into relational tables for SQL analysis.

`hdbltracediag` is available on the SAP HANA server at `/usr/sap/<sid>/HDB<instance>/exe`.

## Audit Trails for Tenant Databases

By default, tenant database administrators **cannot** configure audit trail targets independently for their database since the underlying system properties are in the default configuration change blacklist

(`multidb.ini`). For maximum isolation of audit trails between individual tenants, the default target for all audit trails in tenant databases is internal database table. It is possible to change the audit trail target of a tenant database in the following ways:

- The system administrator changes the audit trail targets for individual tenant databases directly by configuring the relevant system property (`[auditing configuration] *_audit_trail_type`) in the `global.ini` file.
- The system administrator removes the relevant system property (`[auditing configuration] *_audit_trail_type`) from the configuration change blocklist, thus enabling the tenant database administrator to change the audit trail target.

### ⚠ Caution

To ensure the privacy of tenant database audit trails, it is recommended that you do **not** change the default audit trail target (internal database table) of tenant databases.

## 7.3.4 Best Practices and Recommendations for Creating Audit Policies

Best practices and recommendations to help you create audit policies

### Principles and Best Practices

Create audit policies for the following purposes in the database:

- Intrusion detection
- Security change log and traceability
- Data protection and privacy
- System change log
- Monitoring

When creating audit policies, consider the following general principles:

- Define audit policies that avoid unnecessary events in the audit log as much as possible.
- Log all changes related to security configuration.

- Log all changes related to users and user authorization.
- Unexpected events often give the most information. The principle is to define auditing for everything and exclude the expected.

To reduce the performance impact of auditing, consider the following basic guidelines:

- Create as few audit policies as possible. It is usually better to have one complex policy than several simple ones.

#### → Remember

Some audit actions cannot be combined in the same policy.

- Use audit actions that combine other actions where possible.

#### ❖ Example

Audit the `GRANT ANY` action instead of the `GRANT PRIVILEGE` and the `GRANT STRUCTURED PRIVILEGE` actions.

- Create audit policies for DML actions only if required. Auditing DML actions impacts performance more than auditing DDL actions.
- Do not create audit policies for actions that are automatically audited, for example `CREATE AUDIT POLICY`. For a list of actions that are always audited, see *Actions Audited by Default Audit Policy*.
- Do not create audit policies for database-internal tables that are involved in administration actions. Create policies for the administration actions themselves.

#### ❖ Example

`P_USER_PASSWORD` is an internal database table that cannot be accessed by any user, not even the `SYSTEM`. Changes in these tables are carried out by internal mechanisms, and not by DML operations. Don't include these tables in an audit policy. Instead create an audit policy for changes to users (`ALTER USER` action) instead.

- Create a firefighter policy (that is, a policy that audits all actions for a user) only in exceptional circumstances, for example, to check whether a certain user is being used for everyday work or if a support user has been given access to the system. Firefighter policies may create large amounts of audit data and significantly impact performance if they are used for high-load users.

## Recommended Audit Policies

We recommend creating the basic set of audit policies detailed below in the SAP HANA database. All of these policies can be created using the basic setup wizard for auditing in the SAP HANA cockpit.

### i Note

As the audit log written by these audit policies will take up space in your database, all audit policies are defined with a suggested retention period. This retention period has been calculated based on SAP's assessment of how critical each individual audit policy is and the volume of audit entries each policy is expected to generate. We recommend that you closely monitor the size of the `AUDIT_LOG` table to ensure that its size does not affect your daily operations. Delete or export unnecessary entries in the `AUDIT_LOG` table as appropriate. For more information about the audit trail "database table", see *Audit Trails*.

All of the following policies can be created using the auditing configuration wizard of the SAP HANA cockpit.

## Intrusion detection

- Unsuccessful connection attempts:

```
CREATE AUDIT POLICY "_SAP_session connect" AUDITING UNSUCCESSFUL CONNECT
LEVEL ALERT TRAIL TYPE TABLE RETENTION 20;
ALTER AUDIT POLICY "_SAP_session connect" ENABLE;
```

- Attempts to validate user credentials

```
CREATE AUDIT POLICY "_SAP_session validate" AUDITING ALL VALIDATE USER LEVEL
ALERT TRAIL TYPE TABLE RETENTION 20;
ALTER AUDIT POLICY "_SAP_session validate" ENABLE;
```

## Security configuration

- Changes to authorization

```
CREATE AUDIT POLICY "_SAP_authorizations" AUDITING ALL GRANT ANY, REVOKE ANY
LEVEL INFO TRAIL TYPE TABLE RETENTION 180;
ALTER AUDIT POLICY "_SAP_authorizations" ENABLE;
```

- Changes to users

```
CREATE AUDIT POLICY "_SAP_user administration" AUDITING SUCCESSFUL ALTER
ROLE, ALTER USER, ALTER USERGROUP, CREATE ROLE, CREATE USER, CREATE
USERGROUP, DROP ROLE, DROP USER, DROP USERGROUP LEVEL INFO TRAIL TYPE TABLE
RETENTION 180;
ALTER AUDIT POLICY "_SAP_user administration" ENABLE;
```

- Changes to structured privileges in development systems

```
CREATE AUDIT POLICY "_SAP_structured privileges" AUDITING SUCCESSFUL ALTER
STRUCTURED PRIVILEGE, CREATE STRUCTURED PRIVILEGE, DROP STRUCTURED PRIVILEGE
LEVEL INFO TRAIL TYPE TABLE RETENTION 180;
ALTER AUDIT POLICY "_SAP_structured privileges" ENABLE;
```

## System configuration

- Changes to certificates and certificate collections

```
CREATE AUDIT POLICY "_SAP_certificates" AUDITING ALL ALTER PSE, CREATE
CERTIFICATE, CREATE PSE, DROP CERTIFICATE, DROP PSE LEVEL INFO TRAIL TYPE
TABLE RETENTION 180;
ALTER AUDIT POLICY "_SAP_certificates" ENABLE;
```

- Changes to authentication providers

```
CREATE AUDIT POLICY "_SAP_authentication provider" AUDITING ALL ALTER JWT
PROVIDER, ALTER LDAP PROVIDER, ALTER SAML PROVIDER, CREATE JWT PROVIDER,
CREATE LDAP PROVIDER, CREATE SAML PROVIDER, DROP JWT PROVIDER, DROP LDAP
PROVIDER, DROP SAML PROVIDER, VALIDATE LDAP PROVIDER LEVEL CRITICAL TRAIL
TYPE TABLE RETENTION 180;
ALTER AUDIT POLICY "_SAP_authentication provider" ENABLE;
```

- Changes to client-side encryption

```
CREATE AUDIT POLICY "_SAP_clientside encryption" AUDITING ALL ALTER
CLIENTSIDE ENCRYPTION COLUMN KEY, ALTER CLIENTSIDE ENCRYPTION KEYPAIR, CREATE
CLIENTSIDE ENCRYPTION COLUMN KEY, CREATE CLIENTSIDE ENCRYPTION KEYPAIR, DROP
CLIENTSIDE ENCRYPTION COLUMN KEY, DROP CLIENTSIDE ENCRYPTION KEYPAIR LEVEL
CRITICAL TRAIL TYPE TABLE RETENTION 180;
```

```
ALTER AUDIT POLICY "_SAP_clientside encryption" ENABLE;
```

- Changes to user `_SYS_REPO` authorization in development systems:

```
CREATE AUDIT POLICY "_SAP_designtime privileges"  
  AUDITING SUCCESSFUL  
  EXECUTE ON  
    "_SYS_REPO"."GRANT_ACTIVATED_ANALYTICAL_PRIVILEGE",  
    "_SYS_REPO"."GRANT_ACTIVATED_ROLE",  
    "_SYS_REPO"."GRANT_APPLICATION_PRIVILEGE",  
    "_SYS_REPO"."GRANT_PRIVILEGE_ON_ACTIVATED_CONTENT",  
    "_SYS_REPO"."GRANT_SCHEMA_PRIVILEGE_ON_ACTIVATED_CONTENT",  
    "_SYS_REPO"."REVOKE_ACTIVATED_ANALYTICAL_PRIVILEGE",  
    "_SYS_REPO"."REVOKE_ACTIVATED_ROLE",  
    "_SYS_REPO"."REVOKE_APPLICATION_PRIVILEGE",  
    "_SYS_REPO"."REVOKE_PRIVILEGE_ON_ACTIVATED_CONTENT",  
    "_SYS_REPO"."REVOKE_SCHEMA_PRIVILEGE_ON_ACTIVATED_CONTENT"  
  LEVEL INFO TRAIL TYPE TABLE RETENTION 180;  
ALTER AUDIT POLICY "_SAP_designtime privileges" ENABLE;
```

- Changes to SAP HANA configuration files (\*.ini files)

```
CREATE AUDIT POLICY "_SAP_configuration changes" AUDITING ALL STOP SERVICE,  
SYSTEM CONFIGURATION CHANGE LEVEL INFO TRAIL TYPE TABLE RETENTION 180;  
ALTER AUDIT POLICY "_SAP_configuration changes" ENABLE;
```

- Changes to the SAP HANA license key

```
CREATE AUDIT POLICY "_SAP_license addition" AUDITING ALL SET SYSTEM LICENSE  
LEVEL INFO TRAIL TYPE TABLE RETENTION 180;  
ALTER AUDIT POLICY "_SAP_license addition" ENABLE;  
CREATE AUDIT POLICY "_SAP_license deletion" AUDITING ALL UNSET SYSTEM LICENSE  
LEVEL INFO TRAIL TYPE TABLE RETENTION 180;  
ALTER AUDIT POLICY "_SAP_license deletion" ENABLE;
```

## Monitoring

- Backup and recovery of database

```
CREATE AUDIT POLICY "_SAP_recover database" AUDITING ALL BACKUP CATALOG  
DELETE, BACKUP DATA, RECOVER DATA LEVEL INFO TRAIL TYPE TABLE RETENTION 180;  
ALTER AUDIT POLICY "_SAP_recover database" ENABLE;
```

### i Note

This policy does not audit scheduled backups, only manually executed backups. You must audit the `CREATE SCHEDULER JOB`, `ALTER SCHEDULER JOB`, and `DROP SCHEDULER JOB` events to log backup schedule modifications.

## Additional policies in production systems

In production systems, additional audit policies are usually required to log further activities as defined by IT policy and to meet governance and legal requirements such as SOX compliance.

We also recommend auditing not only successful events but unsuccessful events by defining the audit action status `ALL`. Knowing about unsuccessful events might be a prerequisite to discovering an attack on your system.

### ⚠ Caution

SAP HANA audit policies are defined at the database level and cannot cover all requirements for data protection and privacy. The business semantics of data are part of the application definition and

implementation. It is therefore the application that "knows", for example, which tables in the database contain sensitive personal data, or how business level objects, such as sales orders, are mapped to technical objects in the database.

## 7.4 Managing Data Encryption in SAP HANA

SAP HANA supports data-at-rest encryption and application data encryption.

### i Note

For more information about encryption of network communication, see the *SAP HANA Security Guide*.

## Related Information

[Server-Side Data Encryption Services \[page 979\]](#)

[SAP HANA Client Secure User Store \(hdbuserstore\) \[page 1019\]](#)

[Client-Side Data Encryption \[page 1020\]](#)

[SAP HANA Network and Communication Security](#)

### 7.4.1 Server-Side Data Encryption Services

SAP HANA features encryption services for encrypting data at rest, as well as an internal encryption service available to applications with data encryption requirements.

## Passwords

On the SAP HANA database server, all passwords are stored securely:

- Operating system user passwords are protected by the standard operating system mechanism, `/etc/shadow` file.

- All database user passwords are stored in salted hash form using PBKDF2 (Password-Based Key Derivation Function 2) and, for downward compatibility, secure hash algorithm SHA-256. The SAP HANA implementation of PBKDF2 uses the SHA-256 secure hash algorithm and 15,000 iterations.

### **i Note**

The hash method SHA-256 can be disabled by setting the parameter `[authentication] password_hash_methods` in the `global.ini` configuration file to **pbkdf2**. The default value is **pbkdf2, sha256**.

- Credentials required by SAP HANA applications for outbound connections are securely stored in a database-internal credential store. This internal credential store is in turn secured using the internal application encryption service.

## **Data-at-Rest Encryption**

To protect data saved to disk from unauthorized access at operating system level, the SAP HANA database supports data encryption in the persistence layer for the following types of data:

- Data volumes
- Redo log volumes
- Data and log backups

## **Security-Relevant Application Data**

An internal encryption service is used to encrypt sensitive application data. This includes credentials required by SAP HANA for outbound connections, private keys of the SAP HANA server stored in the database, and data in secure stores defined by developers of SAP HANA XS applications (classic or advanced) or other applications (through SQL).

## **Secure Stores**

SAP HANA uses either the instance SSFS (secure store in the file system) or the local secure store (LSS), to protect the root keys used for all data-at-rest encryption services and the internal application encryption service. It uses the system PKI SSFS to protect the system-internal root certificates required for secure internal communication.

## **Related Information**

[Data and Log Volume Encryption](#)

[Backup Encryption](#)  
[Internal Application Encryption Service](#)  
[Server-Side Secure Stores \[page 981\]](#)  
[Local Secure Store \(LSS\)](#)  
[Encryption Key Management](#)

## 7.4.1.1 Server-Side Secure Stores

SAP HANA uses the configured secure store, that is, either the instance SSFS (secure store in the file system) or the local secure store (LSS), to protect the root keys used for all data-at-rest encryption services and the internal application encryption service. It uses the system PKI SSFS to protect the system-internal root certificates required for secure internal communication.

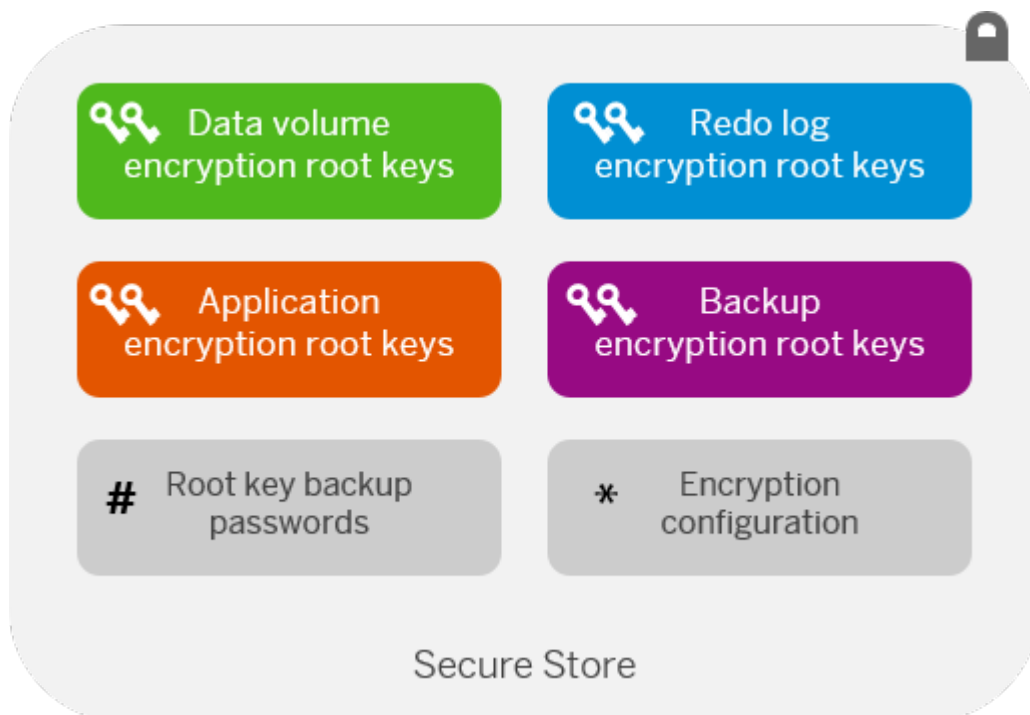

### Secure Store for Encryption Root Keys

SAP HANA uses the configured secure store to protect the following:

- The root keys used for:
  - Data volume encryption
  - Redo log encryption
  - Data and log backup encryption
  - Internal application encryption service of the database
- The password of the root key backup
- Encryption configuration information

These root keys protect all encryption keys (and data) used in the SAP HANA database from unauthorized access.

The system database and all tenant databases have their own encryption root keys.

Secure Store Contents

There are two variations of the encryption root key secure store:

- The **instance SSFS** (secure store in the file system) is a single file in the local file system which hosts the encryption keys for all tenants. It is the default secure store.

#### i Note

To prevent data encrypted in the SAP HANA database from becoming inaccessible, the content of the instance SSFS and key information in the database must remain consistent. The database detects if this is not case, for example if the instance SSFS becomes corrupted, and issues an alert (check 57). It is recommended that you contact SAP Support to resolve the issue.

- The **local secure store** (LSS) is a separate lightweight utility that runs as a separate service on the SAP HANA server under a different operating system user. It uses tenant-specific files. For more information about the LSS, see *Local Secure Store*.

## System PKI SSFS

The system PKI SSFS (secure store in the file system) protects the X.509 certificate infrastructure that is used to secure internal SSL/TLS-based communication between hosts in a multiple-host system or between processes of the individual databases in a system.

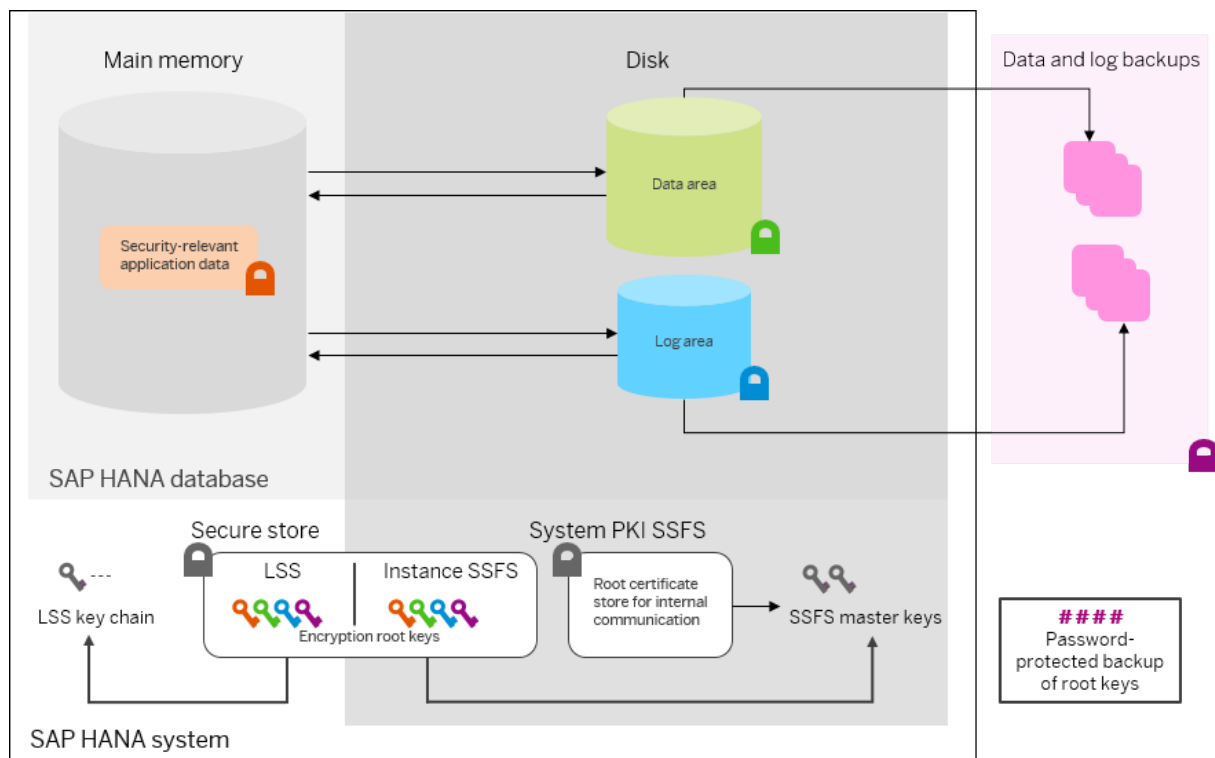

The master key of the system PKI SSFS encrypts all system-internal root certificates required for secure internal communication.

## Encryption Services and Keys

The following diagram provides an overview of which data in SAP HANA can be encrypted using a dedicated encryption service, and how all associated encryption root keys are stored in the configured secure store.

### i Note

The following diagram shows only one database. However, a system always has a system database and any number of tenant databases. Every database in the system has its own encryption root keys for each of the available encryption services. The root keys of all databases are stored in the configured secure store.

Encryption Services and Keys

## Master Key Change

The contents of both the instance SSFS and the system PKI SSFS are protected by individual master key files in the file system.

Unique master keys are generated for the instance SSFS, if used, and the system PKI SSFS during installation or update. However, if you received your system pre-installed from a hardware or hosting partner, we recommend that you change them immediately after handover to ensure that they are not known outside of your organization. You can also change the master keys any time later.

### i Note

The default path of the key file of the instance SSFS is `/usr/sap/<sid>/SYS/global/hdb/security/ssfs`. If you change the default path, you may need to reconfigure it in the event of a system rename.

## Related Information

[Local Secure Store \(LSS\)](#)

[Secure Internal Communication](#)

[Change the SSFS Master Keys \[page 984\]](#)

### 7.4.1.1.1 Change the SSFS Master Keys

The secure stores in the file system (SSFS) used by SAP HANA are protected by unique master keys, generated during installation or update. However, if you received your system pre-installed from a hardware or hosting partner, we recommend that you change these master keys immediately after handover to ensure that they are not known outside your organization.

#### **i** Note

If you have replaced the instance SSFS with the local secure store (LSS), you still have a master key for the system PKI SSFS.

## Prerequisites

- You have shut down the SAP HANA system.
- You have the credentials of the operating system user (<sid>adm) that was created when the system was installed.

## Context

You can change the SSFS master keys using the command line tool `rsecssfx`, which is installed with SAP HANA and available at `/usr/sap/<SID>/HDB<instance>/exe`.

Before changing the SSFS master keys, note the following:

- In a distributed SAP HANA system, every host must be able to access the file location of the instance SSFS master key.
- The SSFS master keys only have to be changed once for the whole instance and not per tenant database.
- If the instance SSFS is used in a system-replication configuration, you change the instance SSFS master key on the primary system. To trigger replication of the new key to the secondary system, you must subsequently restart the secondary system. In multi-tier system replication scenarios involving three systems, restart the tier-2 secondary system first, then the tier-3 secondary system. If a secondary system takes over from its replication source before the new master key has been replicated, all systems registered will use the old key from the former secondary system instead.

## Procedure

1. Log on to the SAP HANA system host as the operating system user, `<sid>adm`.
2. Change the master key of the **instance SSFS**, if used, as follows:
  - a. Re-encrypt the instance SSFS with a new key with the command:

```
export RSEC_SSFS_DATAPATH=/usr/sap/<SID>/SYS/global/hdb/security/ssfs
export RSEC_SSFS_KEYPATH=<path to current key file>
rsecssfx changekey $(rsecssfx generatekey -getPlainValueToConsole)
```

For script languages bash and csh the syntax is:

```
rsecssfx changekey `rsecssfx generatekey -getPlainValueToConsole`
```

### i Note

The command uses backticks.

- b. Configure the specified key file location in the `global.ini` configuration file at `/usr/sap/<SID>/SYS/global/hdb/custom/config/global.ini`.

If the file does not exist, create it. Add the following lines:

```
[cryptography]
ssfs_key_file_path = <path to key file>
```

### i Note

The default path of the key file is `/usr/sap/<sid>/SYS/global/hdb/security/ssfs`. If you change the default path, you may need to reconfigure it in the event of a system rename.

3. Re-encrypt the **system PKI SSFS** with a new key with the following command:

```
export RSEC_SSFS_DATAPATH=/usr/sap/<SID>/SYS/global/security/rsecssfs/data
export RSEC_SSFS_KEYPATH=<path to current key file>
rsecssfx changekey $(rsecssfx generatekey -getPlainValueToConsole)
```

### i Note

The default path of the key file is `/usr/sap/<sid>/SYS/global/security/rsecssfs/key`. If you change the default path, you may need to reconfigure it in the event of a system rename.

For script languages bash and csh the syntax is:

```
rsecssfx changekey `rsecssfx generatekey -getPlainValueToConsole`
```

### i Note

The command uses backticks.

4. Restart the SAP HANA system.

## Next Steps

In a system-replication setup, perform the following steps:

1. Configure the location of the instance SSFS master key file on the secondary system(s). The file itself will be automatically copied when you restart the secondary system(s)
2. Restart the secondary system(s) to trigger the replication of the key files.

### → Remember

In multi-tier system replication scenarios involving three systems, restart the tier-2 secondary system first, then the tier-3 secondary system.

For file system-based copies of SAP HANA database installations, you must manually save and restore the instance SSFS master key file. Otherwise data loss can occur.

In regular backup and recovery scenarios, the SSFS must always be restored from a recent root key backup before a database recovery, unless:

- You have never changed the redo log encryption key.
- You are performing a recovery into the same database from which the backup was taken, and the database's secure store is intact and contains the latest root key changes.

### i Note

It is not necessary to save the system PKI SSFS key file. The system will generate a new system PKI SSFS automatically if required.

## Related Information

[Stop a System](#)

[Configuring SAP HANA System Properties \(INI Files\)](#)

[Server-Side Data Encryption Services](#)

[Import Backed-Up Root Keys Before Database Recovery \[page 1015\]](#)

[SAP Note 2183624](#)

### 7.4.1.1.2 Using the LSS with an External Key Management System

The payloads stored in the local secure store (LSS) can be secured additionally by using an external key management service (KMS) or hardware security module (HSM). In this case, the LSS must be configured to use the KMS or HSM. The use of a KMS or HSM is optional.

### i Note

Only the SAP Data Custodian Key Management Service is supported.

When an external KMS or HSM is used with the LSS, the LSS payload database (DB) files, as well as the LSS backup of these files are encrypted with the public key of an asymmetric key pair whose private key is stored in the KMS or HSM. Consequently, to read and decrypt a payload DB file, access to the private key of the key pair is required.

To verify that the KMS is available and that there is an active key, SAP HANA regularly polls the network reachability of the KMS. This allows the LSS to respond to the following changes:

- If the KMS reports that the key has been **revoked** (disabled or deleted), the database is shut down and cannot be restarted or recovered from a backup (until the key is available again).

#### ⚠ Caution

Key revocation is not trivial and should never be used as a way to temporarily prevent access to applications. While a disabled key can be re-enabled, the cost (in terms of effort and time) of resuming application operation after a temporary key disablement may be high. Deleting a key is irreversible.

- If the KMS reports that the key has been **rotated** (a new primary version of the key has been created), the currently active key management configuration is updated and the LSS automatically re-encrypts payload DB files with the new key. This can be confirmed by querying the `KEY_MANAGEMENT_CONFIGURATION` system view: There will be a backup of the old configuration and the new active configuration has the new key version configured

If the KMS is unreachable for some reason, the polling rate is increased until it responds again. While the KMS is unreachable, read access remains possible if the LSS cache is full. If the cache is empty, read access will result in errors. Write access is not possible. The LSS writes error traces to its trace folder.

You can configure the polling interval using the `[cryptography] key_revocation_check_interval` in the `nameserver.ini`. The value must be between 1 and 3600 seconds. The default value is 60 seconds. If you set a value outside this range, it defaults to 60 seconds. Furthermore, if you set a value under 60 seconds, a warning is displayed that the polling rate might be too high and could lead to unnecessarily high network traffic.

## Second Access Key Pair

The LSS payload DB file contains the SAP HANA encryption root keys used for encrypting SAP HANA data and log volumes, as well as data and log backups of individual tenant databases (and the system database). Therefore, you need to keep the private key of this asymmetric key pair in a safe place. If the private key is lost, damaged, or becomes unusable for some reason, the database data, logs, and backups can no longer be used.

For this reason, a second access key pair can be used in LSS at the same time as the key pair of the KMS or HSM. You generate this second access key pair yourself. The second access key should only be used in the event of an emergency. It can be used to:

- Restore the LSS component using the `lssbackup` utility (`restoreWithSecondAccessKey`)
- Import backed-up SAP HANA encryption root keys as the first step in recovering an encrypted SAP HANA database (`RECOVER ENCRYPTION ROOT KEYS` statement)

The public key is provided to LSS as a self-signed certificate that is part of the external key management configuration passed to SAP HANA. SAP HANA forwards this certificate to the LSS, which then uses it to add a second header to the payload DB file. This allows the payload DB file to be decrypted with either the help of the KMS or HSM (using the first header), or in an emergency case, with the private key of the second access key pair (using the second header).

[SAP Note 2911896 - How to Configure an SAP HANA System to Use the SAP Data Custodian Key Management Service](#)

### 7.4.1.1.2.1 Create and Manage a Key Management Configuration

A key management configuration includes a JSON document containing the configuration information required to connect to the chosen external key management service (KMS) or hardware security module (HSM).

#### Prerequisites

You can log on to the system database and have the system privileges `ENCRYPTION ROOT KEY ADMIN` and `DATABASE ADMIN`.

#### Context

You create and manage the tenant-specific configurations required to use a KMS or HSM in the system database using the SQL statements described below. Every database has a `DEFAULT` configuration, which is active by default and corresponds to no connection to an external KMS.

##### Caution

After a key management configuration has been added, changed or activated, the LSS must be backed up. If automatic LSS backups are enabled (default), the required backup is always written and available for recovery. If automatic LSS backups are disabled (not recommended), this must be considered in your backup strategy. A missing backup could result in your database being unrecoverable. For more information, see *Automatic Content Backups* in the *SAP HANA Security Guide*.

For more information about the settings required by a specific KMS or HSM, see SAP Note 2917358.

## Procedure

- To **add a key management configuration** for a specific database (tenant database or system database), execute the following statement:

```
ALTER DATABASE <database_name>  
  ADD KEY MANAGEMENT CONFIGURATION <config_name> PROPERTIES '<settings>'
```

Parameter	Description
<database_name>	Name of the database
<config_name>	A unique name consisting of uppercase letters only, for example, 'AWS_HSM'. The name 'DEFAULT' is forbidden.
<settings>	A JSON document with key-value settings. The list of keys and their supported values depends on the chosen KMS or HSM. The command will fail if the specified settings do not work.

The new configuration for the specified database is stored in the LSS tenant-specific configuration database file (lssconfig.db).

- To **alter a key management configuration** for a specific tenant database, execute the following statement:

```
ALTER DATABASE <database_name>  
  ALTER KEY MANAGEMENT CONFIGURATION <config_name> PROPERTIES '<updates>'
```

Parameter	Description
<database_name>	Name of the tenant database
<config_name>	The name of the configuration to be modified, in uppercase letters
<updates>	A JSON document with the new key-value settings. The list of keys and their supported values depends on the chosen HSM or KMS. All settings not described in the update remain unchanged.

This command will fail if the changed settings do not work.

- To **activate a key management configuration** for a specific tenant database, execute the following statement.

By activating a configuration, you can switch between different configurations.

```
ALTER DATABASE <database_name>  
  ACTIVATE KEY MANAGEMENT CONFIGURATION <config_name>
```

Parameter	Description
<database_name>	Name of the database
<config_name>	The name of the configuration to be activated, in uppercase letters

The command will fail (leaving everything unchanged) if the newly activated configuration does not work.

- To **remove a key management configuration** for a specific tenant database, execute the following statement:

```
ALTER DATABASE <database_name>
  DROP KEY MANAGEMENT CONFIGURATION <config_name>
```

Parameter	Description
<database_name>	Name of the database
<config_name>	The name of the configuration to be deleted, in uppercase letters

The command will fail if the specified configuration is still active. You deactivate a configuration by activating another one.

### i Note

If you no longer want to use the LSS with a key management system at all, activate the `DEFAULT` key management configuration.

## Related Information

[Automatic Content Backups](#)

[SAP Note 2917358](#)

[ALTER SYSTEM {ADD | ACTIVATE | UPDATE | DROP} KEY MANAGEMENT CONFIGURATION Statement \(System Management\)](#)

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

## 7.4.1.1.2.2 Create a Second Access Key

The second access key is needed for recovering from disasters in the key management service (KMS) or hardware security module (HSM). You create a second access key by using the `SAPGENPSE` tool.

## Procedure

### i Note

For security reasons, we recommend that you do not enter the passwords (`-x` and `-z`) on the command line. By omitting these parameters, you will be interactively prompted to enter the passwords. In this way, you avoid unintentionally leaving the passwords in the command history.

1. Create an asymmetric key pair as follows:

```
sapgenpse get_pse -a RSA:2048:SHA256 -x <second_access_key_passphrase> -p
<second_access_key>.pse -noreq CN=<host_FQDN>">
```

Parameter	Description
<second_access_key_passphrase>	Password for the PSE file
<second_access_key>	Name of the PSE file

2. Export the certificate with the public key to the file <second\_access\_certificate>.pem:

```
sapgenpse export_own_cert -p <second_access_key>.pse -x
<second_access_key_passphrase> -o <second_access_certificate>.pem
```

Parameter	Description
<second_access_key>	Name of the PSE file
<second_access_key_passphrase>	Password for the PSE file
<second_access_certificate>	File name of the exported certificate

3. Export the private key file as follows and then store it in a safe place.

You can optionally add a passphrase for the exported private key interactively or by using the `-z` option. If you add a passphrase, it must be inserted whenever the private key is used. Make sure that you do not forget the passphrase, or store it in a safe place.

```
sapgenpse export_p8 -x <second_access_key_passphrase> -z
<private_key_passphrase> -p <second_access_key>
<second_access_private_key>.pem
```

Parameter	Description
<second_access_key_passphrase>	Password for the PSE file
<second_access_key>	Name of the PSE file
<second_access_private_key>	File name of the exported private key
<private_key_passphrase>	Password for the exported private key file

Once the private key and passphrase have been stored in a safe place, the PSE file can be deleted.

## Related Information

[Encryption Key Chain](#)

## 7.4.1.1.2.3 Add Second Access Certificates to the Key Management Configuration

The public key of the second access key is provided as a self-signed certificate that is part of the external key management configuration passed to SAP HANA.

### Prerequisites

You can log on to the system database and have the system privileges `ENCRYPTION ROOT KEY ADMIN` and `DATABASE ADMIN`.

### Procedure

1. In the JSON document with key-value settings, enhance an already existing external key management configuration by adding the second access certificate to a JSON object with the `SET` action. For example:

```
{
  "setup": {
    "configure_second_access": {
      "action": "SET",
      "certificates": [
        "-----BEGIN CERTIFICATE-----
<certificate content base64 encoded>
-----END CERTIFICATE-----"
      ]
    }
  }
  <KMS-specific configuration goes here>
}
```

- If you have already configured second access certificates for the active external key management configuration and want to add them to a new key management configuration, apply the `KEEP` action in the JSON document with key-value settings:

```
{
  "setup": {
    "configure_second_access": {
      "action": "KEEP"
    }
  }
  <KMS-specific configuration goes here>
}
```

- If you already have second access certificates for the active external key management configuration but do not want to use them in a new key management configuration, apply the `NONE` action in the JSON document with key-value settings:

```
{
  "setup": {
    "configure_second_access": {
      "action": "NONE"
    }
  }
}
```

```
}  
  <KMS-specific configuration goes here>  
}
```

2. Add, alter, or activate the key management configuration using the corresponding SQL statements. See *Create a Key Management Configuration*.

## Results

The LSS now encrypts the body encryption key of the payload DB file twice: first with the certificate obtained from the KMS or HSM, and second with the certificate of the second access key pair. Both results are stored in the header of the payload database file. In normal operations, the LSS opens the payload DB file with the help of the KMS or HSM. Use the second access key only to recover from disasters in the KMS or HSM.

## Related Information

[Create and Manage a Key Management Configuration \[page 988\]](#)

### 7.4.1.1.2.4 Restore a Payload Database File Backup with the Second Access Key

Use the private key file of the second access key to restore the payload database (DB) file of a tenant in an emergency. This is necessary in rare cases only.

## Prerequisites

- You have operating system-level access to the SAP HANA system as the `<sid>crypt` user.
- When the LSS backup was created, the active key management configuration contained a second access key. See *Create a Second Access Key and Add Second Access Certificates to the Key Management Configuration*.

## Procedure

1. Copy the private key file from its safe place to a directory that is readable and writable by `<sid>crypt`.

- Restore the tenant's payload DB file using the `lssbackup` utility:

```
lssbackup -t <tenant> restoreWithSecondAccessKey <backupfile> payload
<configbackup> <privatekeyfile>
```

Parameter	Description
<tenant>	Name of the tenant
<backupfile>	Backup file of the payload DB file
<configbackup>	Backup file of the config DB file
<privatekeyfile>	The file name of the PEM-encoded private key file of the second access key that was used in the LSS backup

#### i Note

The system database and tenant databases are both tenants in the LSS context.

#### i Note

The payload DB file cannot be restored from a single backup file that contains both the contents of the payload DB file and the config DB file.

- Enter the LSS backup password.
- Enter the passphrase for the private key if one has been set.

## Results

The restore operation uses the second access key provided as a private key file and the corresponding passphrase to decrypt and restore the contents of the payload DB file.

## Related Information

### 7.4.1.1.2.5 Monitoring Key Management Configurations

The monitoring view `KEY_MANAGEMENT_CONFIGURATIONS` provides information about the existing key management configurations.

It gives the following details:

Column	Description
DATABASE_NAME	Database name
CONFIGURATION_NAME	Name of the key management configuration
IS_ACTIVE	Indicates whether this configuration is used by the LSS to define access to SAP HANA's sensitive information
TYPE	Type of external key management
CLIENT_VERSION	Version of the driver software
PROPERTIES	Reduced version of the <code>properties</code> section of the <code>&lt;settings&gt;</code> JSON (the "credentials" object is omitted)
CONFIGURATION_ID	ID that uniquely identifies a key management configuration

The certificates configured for the second access key are shown as an additional object, "second\_access", of the `<settings>` JSON, as shown below:

```
{
  "second_access": {
    "certificates": [
      "-----BEGIN CERTIFICATE-----
<certificate content base64 encoded>
-----END CERTIFICATE-----"
    ]
  }
  <KMS-specific configuration goes here>
}
```

## Related Information

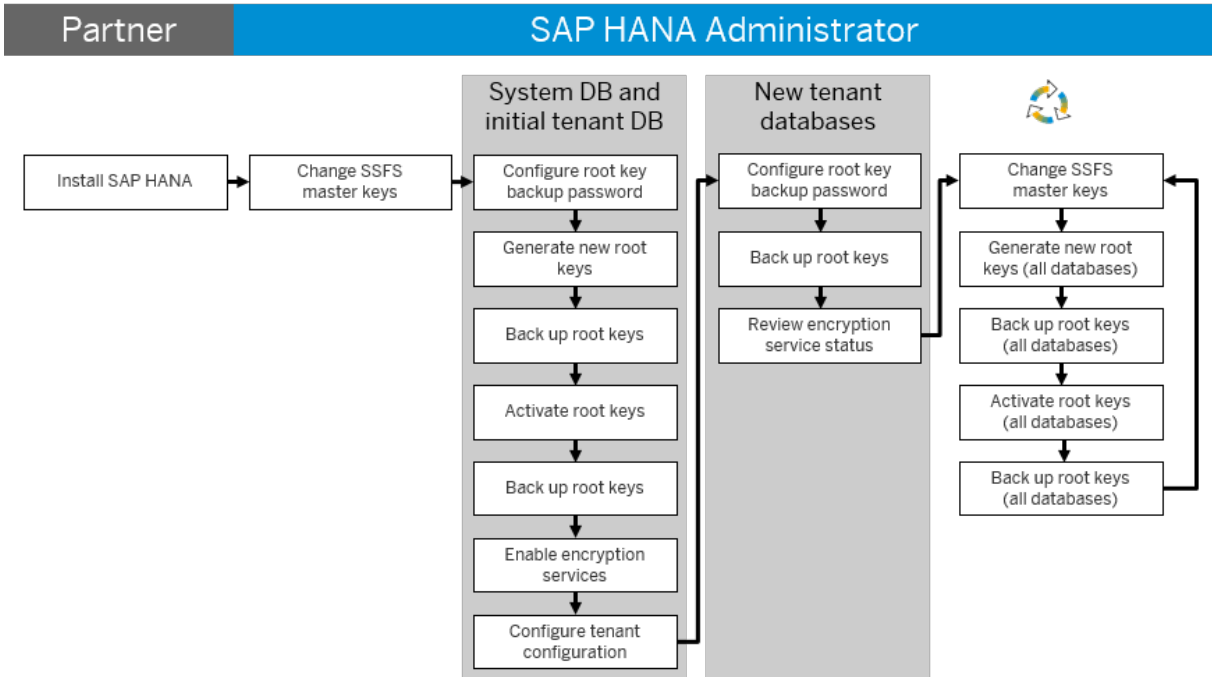

[KEY\\_MANAGEMENT\\_CONFIGURATIONS System View](#)

### 7.4.1.2 Encryption Configuration

We recommend that you configure data encryption immediately after handover of your system from a hardware or hosting partner.

#### First-Time Configuration

The following figure shows the recommended process for configuring encryption in your SAP HANA system for the first time.

Immediately after system handover from your hardware or hosting partner, perform the following high-level steps.

Location	Steps	More Information
On the SAP HANA server	Change the master keys of the instance SSFS, if used, and the system PKI SSFS. <sup>(1)</sup>	Unique master keys are generated for the instance SSFS, if used, and the system PKI SSFS during installation or update. However, if you received your system pre-installed from a hardware or hosting partner, we recommend that you change them immediately after handover to ensure that they are not known outside of your organization. You can also change the master keys any time later.
In the system database	1. Set the password for the root key backup for the system database. This password is required to securely back up root keys and subsequently restore backed-up root keys during data recovery. <sup>(2)</sup>	<p><b>⚠ Caution</b></p> <p>The password is stored in the secure store along with the other root keys and used whenever you create a backup of the encryption root keys. The password should also be stored in a separate safe location. You will need to enter it to restore the secure store content before a database recovery. Losing this password may result in the database being unrecoverable.</p>

Location	Steps	More Information
	<p>2. Change the encryption root keys for all encryption services (data volume encryption, redo log encryption, data and log backup encryption, and internal application encryption) in the system database.<sup>(3)</sup></p> <ol style="list-style-type: none"> <li>1. Generate new root keys.</li> <li>2. Back up all root keys to a root key backup file in a secure location.</li> <li>3. Activate the new root keys.</li> <li>4. Back up all root keys.</li> </ol>	<p>Unique root keys are generated during installation or database creation. However, if you received SAP HANA from a hardware or hosting partner, we recommend that you change them immediately after handover to ensure that they are not known outside of your organization. You can also change root keys any time later.</p> <p>You must back up all keys after you generate or activate a key of any type. This ensures that you always have an up-to-date backup of your root keys available for recovery.</p> <div data-bbox="1007 824 1396 1021" style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>⚠ Caution</b></p> <p>Store the root key backup file in a safe location. Losing this file may result in the database being unrecoverable.</p> </div>
	<p>3. Enable the required encryption services: Data volume encryption, redo log encryption, and data and log backup encryption in the system database.<sup>(4)</sup></p>	<p>Although SAP HANA provides you with the flexibility to encrypt data volumes, redo logs, and backups independently of each other, if you require full protection in the persistence layer, we recommend that you enable all services.</p> <p>It is not necessary to enable the internal application encryption service explicitly. It is available automatically to requesting applications.</p>
	<p>4. Configure how you want encryption to be handled in new tenant databases. You can do so with the following parameters in the <code>database_initial_encryption</code> section of the <code>global.ini</code> configuration file:</p> <ul style="list-style-type: none"> <li>• <code>persistence_encryption</code> (default: off)</li> <li>• <code>log_encryption</code> (default: off)</li> <li>• <code>backup_encryption</code> (default: off)</li> <li>• <code>encryption_config_control</code> (default: local_database)</li> </ul>	<p>By default, all encryption services are disabled in new tenant databases and only tenant database administrators can enable them. See <i>Encryption Configuration Control</i>.</p>

Location	Steps	More Information
In the first tenant database (if automatically created during installation)	1. Set the password for the root key backup for the first tenant database. <sup>(2)</sup>	The password is required to securely back up root keys and subsequently restore backed-up root keys during data recovery.
	2. Change the encryption root keys for all encryption services in the first tenant database. <sup>(3)</sup>	See step 2 above (system database).
	3. Enable the required encryption services in the first tenant database. <sup>(4)</sup>	By default, only the tenant database administrator can do this in the tenant database. See <i>Encryption Configuration Control</i> .
In subsequent tenant databases	1. Set the password for the root key backup for the tenant database. <sup>(2)</sup>	The password is required to securely back up root keys and subsequently restore backed-up root keys during data recovery.
	2. Back up all root keys to a root key backup file in a secure location.	It is not necessary to change the root keys in new tenant databases. Unique root keys are generated on database creation and cannot be known outside of your organization.
		<p><b>⚠ Caution</b></p> <p>Store the root key backup file in a safe location. Losing this file may result in the database being unrecoverable.</p>
	3. Change the status of encryption services in the tenant database if required. <sup>(4)</sup>	Who can enable or disable encryption services depends on how the parameter <code>encryption_config_control</code> is configured. See <i>Encryption Configuration Control</i> .
	Encryption services are configured in line with the parameters in the <code>database_initial_encryption</code> section of the <code>global.ini</code> configuration file as described above.	
During operation	<ul style="list-style-type: none"> <li>Periodically change the master keys of the instance SSFS, if used, and the system PKI SSFS in line with your security policy.</li> <li>Periodically change the encryption root keys in all databases in line with your security policy.</li> </ul>	

<sup>(1)</sup> If the instance SSFS is used in a system-replication configuration, you change the instance SSFS master key on the primary system. To trigger replication of the new key to the secondary system, you must subsequently restart the secondary system. In multi-tier system replication scenarios involving three systems, restart the tier-2 secondary system first, then the tier-3 secondary system. If a secondary system takes over from its replication source before the new master key has been replicated, all systems registered will use the old key from the former secondary system instead.

<sup>(2)</sup> In a system-replication configuration, set the root key backup password in the primary system only. The password will be propagated to all secondary systems. The secondary systems must be running and replicating.

<sup>(3)</sup> In a system-replication configuration, change root keys in the primary system only. New keys will be propagated to all secondary systems. The secondary systems must be running and replicating.

<sup>(4)</sup> In a system-replication configuration, enable (or disable) encryption in the primary system only. The setting will be propagated to all secondary systems. The secondary systems must be running and replicating.

---

## Configuration After Update from a Single-Container System

If you updated from a single-container system, your system has a system database and one tenant database. The existing data encryption configuration is retained. Note the following:

- The SSFS master keys for the system remain unchanged and the instance SSFS is still used.
- Existing encryption root keys are the encryption root keys of the tenant database. The update process generates new unique root keys for the system database.
- If a root key backup password existed before update, it is the root key backup password of the tenant database. The system database will not have a root key backup password set. You must set this password manually after the update.
- Encryption services that were enabled before update are enabled in both the system database and the tenant database.

[Encryption Key Management](#)

### 7.4.1.2.1 Encryption Configuration Control

You can enable or disable the encryption of data and log volumes, and data and log backups in a new SAP HANA database or in an existing operational database. For a tenant database, you need to know whether encryption configuration is controlled by the tenant database or the system database.

## Ownership of Encryption Control

By default, encryption configuration is controlled by the tenant database, but the control can be switched to the system database, or the system database can switch control back to the tenant database.

To see which database is controlling encryption configuration for a tenant database, you can query the system view `SYS.M_ENCRYPTION_OVERVIEW`. From the system database, you can query the system view `SYS_DATABASES.M_ENCRYPTION_OVERVIEW`.

## Encryption Control in New Tenant Databases

When a new tenant database is created, the `encryption_config_control` parameter in the `database_initial_encryption` section of the `global.ini` configuration file in the system database determines whether encryption configuration is controlled by the tenant database or the system database. You can use this parameter to configure encryption control for new tenant databases:

- If the value of this parameter is `local_database` (default), then only the tenant database administrator can enable or disable encryption from the tenant database.
- If the value is `system_database`, then only the system database administrator can enable or disable encryption from the system database.

## Switching Encryption Control in Existing Tenant Databases

If the tenant database controls encryption configuration, the tenant database administrator can hand over this control to the system administrator by executing the following `ALTER SYSTEM` statement:

```
ALTER SYSTEM ENCRYPTION CONFIGURATION CONTROLLED BY SYSTEM DATABASE
```

If the system database controls encryption configuration, the system database administrator can hand it over to the tenant database administrator by executing the following `ALTER DATABASE` statement:

```
ALTER DATABASE <database_name> ENCRYPTION CONFIGURATION CONTROLLED BY LOCAL DATABASE
```

For simplicity, the system database administrator can hand over control to all tenants at once by executing the following statement:

```
ALTER SYSTEM ENCRYPTION CONFIGURATION CONTROLLED BY LOCAL DATABASES
```

## Related Information

[ALTER SYSTEM ENCRYPTION CONFIGURATION Statement \(System Management\)](#)

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

[M\\_ENCRYPTION\\_OVERVIEW System View](#)

## 7.4.1.3 Set the Root Key Backup Password

The root key backup password is required to securely back up the root keys of the database and subsequently to restore the backed-up root keys during data recovery.

### Prerequisites

You have the system privilege `ENCRYPTION ROOT KEY ADMIN`.

### Procedure

Set the root key backup password with the following SQL statement.

```
ALTER SYSTEM SET ENCRYPTION ROOT KEYS BACKUP PASSWORD <passphrase>
```

The length and layout of the password must be in line with the database's password policy.

#### ⚠ Caution

If the root key backup already has a password, it will be overwritten.

#### i Note

In a system-replication configuration, set the root key backup password in the primary system only. The password will be propagated to all secondary systems. The secondary systems must be running and replicating.

### Results

The password is set and stored in the secure store together with the SAP HANA encryption root keys and encryption-related configuration. You must provide this password to import root keys from the backup into the database before starting a database recovery. All root key backups taken after the password is set use this password to protect the backup files.

For more information about root key backups, see the *SAP HANA Security Guide*. For more information about setting the root key backup password using the SAP HANA cockpit, see the SAP HANA cockpit documentation.

#### ⚠ Caution

The password should also be stored in a separate safe location. You will need to enter it to restore the secure store content before a database recovery. Losing this password may result in the database being unrecoverable.

### → Tip

To verify that the password you have is the same as the one that the system uses when creating new root key backups, use the statement `ALTER SYSTEM VALIDATE ENCRYPTION ROOT KEYS BACKUP PASSWORD <passphrase>`.

## Related Information

[Password Policy Configuration Options \[page 830\]](#)

[Root Key Backup](#)

[ALTER SYSTEM VALIDATE ENCRYPTION ROOT KEYS BACKUP PASSWORD Statement \(System Management\)](#)

[Set the Root Key Backup Password](#)

## 7.4.1.4 Changing Encryption Root Keys

Unique root keys are generated during installation or database creation. However, if you received SAP HANA from a hardware or hosting partner, we recommend that you change them immediately after handover to ensure that they are not known outside of your organization. You can also change root keys any time later.

Change the root keys for the following encryption services immediately after handover of your system and periodically during operation:

- Data volume encryption
- Redo log encryption
- Data and log backup encryption
- Internal application encryption

It is important to always change encryption root keys as follows:

1. Generate new root keys.
2. Back up all root keys.
3. Activate new root keys.
4. Back up all root keys

### ⚠ Caution

You must back up all keys after you generate or activate a key of any type. This ensures that you always have an up-to-date backup of your root keys available for recovery.

### i Note

In a system-replication configuration, change root keys in the primary system only. New keys will be propagated to all secondary systems. The secondary systems must be running and replicating.

## Related Information

[Encryption Key Management](#)

### 7.4.1.4.1 Generate New Root Keys

The first step in changing encryption root keys is to generate new root keys.

#### Prerequisites

- You are connected to the tenant database requiring the root key change.
- You have the system privilege `ENCRYPTION ROOT KEY ADMIN`.

#### Procedure

Generate new root keys for all encryption services using the following SQL statements:

Encryption Service	Statement
Data volume encryption	<pre>ALTER SYSTEM PERSISTENCE ENCRYPTION CREATE NEW ROOT KEY WITHOUT ACTIVATE</pre>
Redo log encryption	<pre>ALTER SYSTEM LOG ENCRYPTION CREATE NEW ROOT KEY WITHOUT ACTIVATE</pre>
Data and log backup encryption	<pre>ALTER SYSTEM BACKUP ENCRYPTION CREATE NEW ROOT KEY WITHOUT ACTIVATE</pre>
Internal application encryption	<pre>ALTER SYSTEM APPLICATION ENCRYPTION CREATE NEW ROOT KEY WITHOUT ACTIVATE</pre>

New root keys for all encryption services are generated. To verify the creation of new root keys, query the system view `ENCRYPTION_ROOT_KEYS` and check the status of the latest entries for each root key type.

## Related Information

[ENCRYPTION\\_ROOT\\_KEYS System View](#)

[ALTER SYSTEM PERSISTENCE ENCRYPTION Statement \(System Management\)](#)

[ALTER SYSTEM LOG ENCRYPTION Statement \(System Management\)](#)  
[ALTER SYSTEM BACKUP ENCRYPTION Statement \(System Management\)](#)  
[ALTER SYSTEM APPLICATION ENCRYPTION Statement \(System Management\)](#)

## 7.4.1.4.2 Back Up Root Keys

After you have generated or activated new encryption root keys or created a new tenant database with new root keys, you must back up all root keys.

### Prerequisites

- The external location to which you plan to save the backup is accessible.
- You have set the root key backup password.
- If using the SQL statement `BACKUP ENCRYPTION ROOT KEYS`:
  - The system database has encryption configuration control. See *Encryption Configuration Control*.
  - You have the system privilege `ENCRYPTION ROOT KEY ADMIN`
  - You have the system privilege `BACKUP ADMIN` or `BACKUP OPERATOR` if backing up the system database root keys, or the system privilege `DATABASE BACKUP ADMIN` or `DATABASE BACKUP OPERATOR` if backing up a tenant database's root keys.
- If using the SQL function `ENCRYPTION_ROOT_KEYS_EXTRACT_KEYS` or `ENCRYPTION_ROOT_KEYS_EXTRACT_ALL_KEYS_FOR_DATABASE`, you have the system privilege `ENCRYPTION ROOT KEY ADMIN`.
- If using `hdbnsutil`, you have the credentials of the operating system user (`<sid>adm`).
- If using `hdbnsutil`, you know the ID of the database whose root keys you want to back up. You can determine the IDs of all tenant databases by executing the following SQL command in the system database:

```
SELECT DATABASE_NAME,  
       CASE WHEN (DBID = '' AND  
                DATABASE_NAME = 'SYSTEMDB')  
            THEN 1  
            WHEN (DBID = '' AND  
                DATABASE_NAME <> 'SYSTEMDB')  
            THEN 3  
            ELSE TO_INT(DBID)  
            END DATABASE_ID  
FROM (SELECT DISTINCT DATABASE_NAME, SUBSTR_AFTER (SUBPATH, '.') AS DBID FROM  
SYS_DATABASES.M_VOLUMES)
```

### Context

A backup of encryption root keys must be available at an external location to ensure recovery is possible in certain scenarios.

## ⚠ Caution

Store both the root key backup and the password required to read it in a secure location. Losing the backup or the password may result in the database being unrecoverable.

You can back up root keys in a number of ways.

Option	Execution Location	Database Mode	Backup File Location
<b>SQL statement</b> <code>BACKUP ENCRYPTION_ROOT_KEYS</code>	System database	Tenant database can be online or offline; system database must be online	File system on the database server. The file needs to be manually copied to a secure external location.
<b>SQL extraction function</b> <code>ENCRYPTION_ROOT_KEY_S_EXTRACT_KEYS<sup>(1)</sup></code>	Applicable database	Database must be online	CLOB result. The result needs to be manually copied and saved to a file at a secure external location.
<b>SQL extraction function</b> <code>ENCRYPTION_ROOT_KEY_S_EXTRACT_ALL_KEYS_FOR_DATABASE</code>	Applicable database or system database	If executed from the tenant database: Database must be online  If executed from the system database: Database can be online or offline; system database must be online	CLOB result. The result needs to be manually copied and saved to a file at a secure external location.
<b>SAP HANA cockpit<sup>(2)</sup></b>	Applicable database	Database must be online	Local file system
<b>hdbnsutil tool<sup>(3)</sup></b>	SAP HANA server	Database can be online or offline	File system on the database server. The file needs to be manually copied to a secure external location.

## i Note

- <sup>(1)</sup>If the local secure store (LSS) is being used in conjunction with an external key management system, then you cannot back up the root keys using `ENCRYPTION_ROOT_KEYS_EXTRACT_KEYS` since it does not extract the keys in the required format. You must use `ENCRYPTION_ROOT_KEYS_EXTRACT_ALL_KEYS_FOR_DATABASE`.
- <sup>(2)</sup>The SAP HANA cockpit can only be used to back up root keys if the secure store in the file system (SSFS) is being used.
- <sup>(3)</sup>If the local secure store (LSS) is being used in conjunction with an external key management system, then you cannot back up the root keys using `hdbnsutil` since a separation of duties between operating system administrator and key administrator is not possible.

## Procedure

1. Back up the root keys of a tenant database using one of the following methods:

Option	Description
<p><b>SQL statement</b> <code>BACKUP ENCRYPTION ROOT KEYS</code></p>	<p>In the system database, execute the SQL statement:</p> <pre data-bbox="837 392 1396 548"> BACKUP ENCRYPTION ROOT KEYS [ &lt;root_keytype_list&gt; ] [ FOR &lt;database_name&gt; ] USING &lt;root_key_backup_definition_file&gt; </pre> <ul style="list-style-type: none"> <li>○ <code>&lt;database_name&gt;</code> is the name of the tenant database.</li> <li>○ The <code>&lt;root_keytype_list&gt;</code> option lists the root key types and accepts the values <code>PERSISTENCE</code>, <code>LOG</code>, <code>BACKUP</code>, and <code>APPLICATION</code>. If you do not specify any value for <code>&lt;root_keytype_list&gt;</code>, all root key types are backed up.</li> </ul> <div data-bbox="874 779 1396 1019" style="border: 1px solid #ccc; padding: 5px;"> <p><b>Note</b></p> <p>If the LSS is being used in conjunction with an external key management system, then you cannot back up individual root key types. A full LSS backup is required. Therefore, in this case you must not use the <code>&lt;root_keytype_list&gt;</code> option.</p> </div> <ul style="list-style-type: none"> <li>○ <code>&lt;root_key_backup_definition_file&gt;</code> specifies the backup file. The file is written to the file system on the database server.</li> </ul>
<p><b>SQL extraction function</b> <code>ENCRYPTION_ROOT_KEYS_EXTRACT_KEYS</code></p>	<ol style="list-style-type: none"> <li>1. <p><b>SQL extraction function</b> <code>ENCRYPTION_ROOT_KEYS_EXTRACT_ALL_KEYS_FOR_DATABASE</code></p>	<ol style="list-style-type: none"> <li>1. Depending on which database has encryption configuration control, execute the following SQL statement in either the tenant database or the system database: <pre data-bbox="874 1624 1396 1758"> SELECT ENCRYPTION_ROOT_KEYS_EXTRACT_ALL_KEYS_FOR_DATABASE ('&lt;database_name&gt;') FROM DUMMY </pre> <p>The result of this command is a character large object (CLOB).</p> </li> <li>2. Copy the CLOB result and save it to a file at a secure external location. We recommend the file extension <code>.rkb</code>.</li> </ol>

Option	Description
SAP HANA cockpit	You can back up root keys using the <a href="#">Data Encryption</a> app of the SAP HANA cockpit. For more information, see the SAP HANA cockpit documentation.

#### hdbnsutil tool

#### i Note

If the LSS is being used in conjunction with an external key management system, then you cannot back up the root keys using `hdbnsutil`.

1. Log on to the SAP HANA server as operating system user `<sid>adm`.
2. Back up the new keys with the following command:

```
cd /usr/sap/<sid>/
<HDBinstance_no>/exe
./hdbnsutil -backupRootKeys
<filename>.rkb --dbid=<dbid> --
type='ALL'
```

- o `<dbid>` is the tenant database ID.
- o The `<type>` option is the root key type and accepts the values PERSISTENCE, LOG, BACKUP, and APPLICATION. The value ALL specifies that root keys of all types are backed up. If you do not specify any value for `<type>`, all root key types are backed up.
- o `<filename>.rkb` specifies the root key backup definition file. The file is written to the file system on the database server.

2. Save the root key backup file to a secure location.

#### ⚠ Caution

Store the root key backup file in a safe location. If this file is lost, it may not be possible to recover the database.

3. Optional: To ensure that the backup file can be recovered, validate the password for the root key backup file.

#### i Note

Each root key backup file created is unique. You must validate it as described here and not through comparison with other files (if multiple backups have been done).

To validate the backup file log on to the SAP HANA server as operating system user `<sid>adm`, and use the following command in the `hdbnsutil` tool:

```
cd /usr/sap/<sid>/<HDBinstance_no>/exe
./hdbnsutil -validateRootKeysBackup <filename> [--password=<passphrase>]
```

### → Recommendation

We recommend that you do not enter the password on the command line. You will be interactively prompted to enter it. In this way, you avoid unintentionally leaving the password in the command history and making it visible in process monitoring tools provided by the operating system.

[Back Up Root Keys \(SAP HANA Cockpit\)](#)

### 7.4.1.4.3 Activate Root Keys

Activate new encryption root keys so that they can be used to encrypt new data.

## Prerequisites

- You are connected to the tenant database requiring the root key change.
- You have the system privilege `ENCRYPTION ROOT KEY ADMIN`.
- You have backed up the new encryption root keys. You can verify whether or not root keys are backed up by querying the system view `ENCRYPTION_ROOT_KEYS`.

## Procedure

Activate the new root keys by executing the following SQL statements:

Encryption Service	Statement
Data volume encryption	<pre>ALTER SYSTEM PERSISTENCE ENCRYPTION ACTIVATE NEW ROOT KEY</pre>
Redo log encryption	<pre>ALTER SYSTEM LOG ENCRYPTION ACTIVATE NEW ROOT KEY</pre>

Encryption Service	Statement
Data and log backup encryption	ALTER SYSTEM BACKUP ENCRYPTION ACTIVATE NEW ROOT KEY
Internal application encryption	ALTER SYSTEM APPLICATION ENCRYPTION ACTIVATE NEW ROOT KEY

If encryption is enabled, new data is encrypted with the new root keys.

### **i** Note

It is not necessary to enable the internal application encryption service explicitly. It is available automatically to requesting applications.

## Related Information

## 7.4.1.5 Enable Encryption

You can enable data volume encryption, redo log encryption, and encryption of data and log backups in a new SAP HANA database or in an existing operational database.

### Prerequisites

- To enable encryption for a tenant database, you know whether encryption configuration is controlled by the tenant database or the system database:
  - If the tenant database controls encryption configuration, encryption can only be enabled or disabled directly in the tenant database and not from the system database.
  - If the system database controls encryption configuration, encryption can only be enabled or disabled using SQL from the system database, with a user that has the system privilege `DATABASE ADMIN`.

See *Encryption Configuration Control*.
- You have the system privilege `ENCRYPTION ROOT KEY ADMIN`.
- If necessary, you have changed and backed up the encryption root keys. See *Changing Encryption Root Keys*.

## Context

It is recommended that you enable encryption in the system database and the tenant databases when they are created. In this way, you ensure that all the pages are encrypted. If you received SAP HANA from a hardware or hosting partner, you should enable encryption after handover and before importing your sensitive data.

If you enable encryption in an operational database, only the pages in use in the data volumes are encrypted. Pages in data volumes that are not in use may still contain old content, and are only overwritten and encrypted over time. This means that your data in data volumes will only be fully encrypted after some delay. In addition, only redo log entries that are created after encryption is enabled are encrypted. Redo log files that were created before encryption was enabled are not encrypted. Although encryption can be switched on at any point in time, unencrypted data can remain on disk. If this is not wanted, you will need to install a new database on a fresh hard drive, activate encryption, import a backup, and low-level erase the old disks.

You can enable encryption of full data backups, delta data backups, and log backups in the database at any time.

### → Recommendation

Although SAP HANA provides you with the flexibility to encrypt data volumes, redo logs, and backups independently of each other, if you require full protection in the persistence layer, we recommend that you enable all services.

## Procedure

### i Note

In a system-replication configuration, enable (or disable) encryption in the primary system only. The setting will be propagated to all secondary systems. The secondary systems must be running and replicating.

Enable the required encryption service using the SAP HANA cockpit (tenant database control only) or the following SQL statements:

If the tenant database has control

- Data volume encryption

```
ALTER SYSTEM PERSISTENCE  
ENCRYPTION ON
```

- Redo log encryption

```
ALTER SYSTEM LOG ENCRYPTION ON
```

- Backup encryption

```
ALTER SYSTEM BACKUP ENCRYPTION ON
```

If the system database has control

- Data volume encryption

```
ALTER DATABASE <database_name>  
PERSISTENCE ENCRYPTION ON
```

- Redo log encryption

```
ALTER DATABASE <database_name> LOG  
ENCRYPTION ON
```

- Backup encryption

```
ALTER DATABASE <database_name>  
BACKUP ENCRYPTION ON
```

---

## Results

### Data volume encryption and redo log encryption

All data persisted to data volumes is encrypted and all future redo log entries persisted to log volumes are encrypted.

### Backup encryption

Backup encryption is enabled. Subsequent log backups, as well as full backups and delta data backups will be encrypted.

#### **i** Note

If backup encryption is active, a data snapshot is **not automatically encrypted**. For more information, see *Backup Encryption*.

[SAP Note 2159014](#)

## 7.4.1.6 Disable Encryption

Disabling data volume encryption triggers the decryption of all encrypted data. Newly persisted data is not encrypted. Disabling redo log encryption makes sure that future redo log entries are not encrypted when they are written to disk.

### Prerequisites

- To disable encryption for a tenant database, you know whether encryption configuration is controlled by the tenant database or the system database:
  - If the tenant database controls encryption configuration, encryption can only be enabled or disabled directly in the tenant database and not from the system database.
  - If the system database controls encryption configuration, encryption can only be enabled or disabled using SQL from the system database, with a user that has the system privilege `DATABASE ADMIN`. See *Encryption Configuration Control*.
- You have the system privilege `ENCRYPTION ROOT KEY ADMIN`.

### Procedure

#### Note

In a system-replication configuration, enable (or disable) encryption in the primary system only. The setting will be propagated to all secondary systems. The secondary systems must be running and replicating.

Disable the required encryption service using the SAP HANA cockpit (tenant database control only) or the following SQL statements:

If the tenant database has control

- Data volume encryption

```
ALTER SYSTEM PERSISTENCE  
ENCRYPTION OFF
```

- Redo log encryption

```
ALTER SYSTEM LOG ENCRYPTION OFF
```

- Backup encryption

```
ALTER SYSTEM BACKUP ENCRYPTION OFF
```

If the system database has control

- Data volume encryption

```
ALTER DATABASE <database_name>  
PERSISTENCE ENCRYPTION OFF
```

- Redo log encryption

```
ALTER DATABASE <database_name> LOG  
ENCRYPTION OFF
```

- Backup encryption

```
ALTER DATABASE <database_name>  
BACKUP ENCRYPTION OFF
```

---

## Results

### Data volume encryption

Data starts being decrypted in the background. Depending on the size of the SAP HANA database, this process can be very time consuming. Only after this process has completed is all your data decrypted. Newly persisted data is not encrypted.

### Redo log encryption

New redo log entries are not encrypted. Existing redo log entries are not decrypted. Log entries will only be fully unencrypted when all encrypted entries have been overwritten.

### Backup encryption

New data backups, delta backups, and log backups are not encrypted. On an unencrypted data volume, data snapshots are also unencrypted.

[ALTER SYSTEM BACKUP ENCRYPTION Statement \(System Management\)](#)

[ALTER DATABASE Statement \(Tenant Database Management\)](#)

## 7.4.1.7 Change the Page Encryption Key Used for Data Volume Encryption

It is recommended that you periodically change the encryption key used to encrypt pages in the data area in line with your organization's security policy. If necessary, you can re-encrypt the entire data area with the new key. You can change the page encryption key in the SAP HANA studio.

### Prerequisites

You have the system privilege `RESOURCE ADMIN` or `ENCRYPTION_ROOT_KEY_ADMIN`.

### Context

Changing the encryption key used to encrypt pages in the data area limits the potential impact of a key being compromised. It is recommended that you do so periodically in line with your security policy. You can trigger the creation of a new (randomly generated) page encryption key at any time. This new key is used to encrypt pages as of the next savepoint operation. By default, pages that were previously written to disk are not re-encrypted. However, you may need or want to re-encrypt your entire data area with the new key. For example, you have a lot of encryption keys in your system, an encryption key was compromised, or your organization's security policy requires that all data be encrypted with keys not older than a certain age.

You can see all encryption keys in your system and their validity periods in the monitoring view `M_PERSISTENCE_ENCRYPTION_KEYS`.

#### i Note

Page encryption keys are not root keys. They are stored within an encrypted document that is part of the SAP HANA persistence and which is encrypted with the SAP HANA root key for data volumes.

### Procedure

1. In the Security editor, choose the *Data Volume Encryption* tab.
2. Choose the  (*Create new page encryption key*) button.

To have the entire data area re-encrypted with the new key in addition, choose *Force all data to be re-encrypted*.

After the next savepoint operation, a new random encryption key is generated. This key will be used to encrypt pages as of the next savepoint operation. Depending on the workload of the database, this may not happen for some time. Pages that were previously written to disk are only re-encrypted if you selected the corresponding option. If this is the case, old pages are first decrypted using the old key and then re-encrypted with the new key.

## Results

You can verify the result of a key change in the monitoring view `M_PERSISTENCE_ENCRYPTION_STATUS`. The column `KEY_CHANGE_WITH_NEXT_SAVEPOINT` contains the value `TRUE`.

### **i** Note

Encryption keys that are no longer in use are automatically removed the next time the database is restarted.

## Related Information

[M\\_PERSISTENCE\\_ENCRYPTION\\_KEYS System View](#)

## 7.4.1.8 Import Backed-Up Root Keys Before Database Recovery

Before performing a recovery from encrypted data and log backups, you must import the backed-up root keys.

## Prerequisites

- You have the credentials of the operating system user (`<sid>adm`).
- You can log on to the system database and have the system privilege `DATABASE STOP`.
- The location of the root key backup file is accessible.
- If using SQL to import keys: You have the system privilege `DATABASE RECOVERY OPERATOR` or `DATABASE ADMIN` and `ENCRYPTION ROOT KEY ADMIN` in the system database.
- If using `hdbnsutil` to import keys: You know the ID of the database whose root keys you want to import. You can determine the IDs of all tenant databases by executing the following SQL command in the system database:

```
SELECT DATABASE_NAME,  
       CASE WHEN (DBID = '' AND  
                 DATABASE_NAME = 'SYSTEMDB')  
             THEN 1  
             WHEN (DBID = '' AND  
                 DATABASE_NAME <> 'SYSTEMDB')  
             THEN 3  
             ELSE TO_INT(DBID)  
             END DATABASE_ID  
FROM (SELECT DISTINCT DATABASE_NAME, SUBSTR_AFTER (SUBPATH, '.') AS DBID FROM  
SYS_DATABASES.M_VOLUMES);
```

## Context

Before you recover an encrypted database, you must first import backed-up root keys to initialize the secure store. When the instance SSFS (secure store in the file system) is used as the secure store, the set of keys from the root key backup file replaces the set of keys in the instance SSFS. When the local secure store (LSS) is used, the key import ensures that only the missing keys are added to the secure store; no keys are deleted.

If the LSS is being used with an external key management system, backed-up root keys can also be recovered using a second access key pair in an emergency situation. This is only necessary if the private key stored in the KMS has been lost, damaged, or becomes unusable for some reason.

You can import root keys in the following ways:

Option	Execution Location	Database Mode	Scope
<b>SQL statement</b> <code>RECOVER ENCRYPTION ROOT KEYS</code>	System database	The tenant database must be offline.	Encryption root keys can only be recovered for tenant databases.
<b>hdbnsutil tool*</b>	SAP HANA server	The tenant database must be offline.	Encryption root keys can be recovered for tenant databases and system databases.

### i Note

\*If the local secure store (LSS) is being used in conjunction with an external key management system, then you cannot recover root keys using `hdbnsutil`.

## Procedure

1. Log on to the SAP HANA server as operating system user `<sid>adm`.
2. Validate that you have the password for the root key backup file:

```
cd /usr/sap/<sid>/<HDBinstance_no>/exe
./hdbnsutil -validateRootKeysBackup <filename> [--password=<password>]
```

### → Recommendation

We recommend that you do not enter the password on the command line (`--password`). By omitting this parameter, you will be interactively prompted to enter it.

3. In the system database, stop the tenant database to be recovered.

You can do this in the SAP HANA cockpit or by executing the statement `ALTER SYSTEM STOP <database_name>`.

4. Import backed-up root keys using one of the following methods:
  - Using the SQL statement `RECOVER ENCRYPTION ROOT KEYS`

- To recover keys from the **SSFS or LSS with no external key management configuration**, in the system database, execute:

```
RECOVER ENCRYPTION ROOT KEYS (<root_keytype_list>) FOR <database_name>
USING <root_key_backup_definition_file> PASSWORD <password>
```

- <database\_name> is the name of the tenant database.
- <root\_keytype\_list> (optional) specifies the root key types and accepts the values PERSISTENCE, LOG, BACKUP, and APPLICATION. If you do not specify any value for <root\_keytype\_list>, all root key types are imported.
- <root\_key\_backup\_definition\_file> specifies the root key backup file in the file system.
- <password> is the root key backup password
- To recover keys from the **LSS with an external key management configuration**, in the system database, execute:

```
RECOVER ENCRYPTION ROOT KEYS AND SETTINGS FOR <database_name> USING
<root_key_backup_definition_file> PASSWORD <password>
```

- <database\_name> is the name of the tenant database.
- <root\_key\_backup\_definition\_file> specifies the root key backup file in the file system.
- <password> is the root key backup password
- To recover keys from the **LSS with external key management configuration using a second access key pair**, in the system database, execute:

```
RECOVER ENCRYPTION ROOT KEYS AND SETTINGS FOR <database_name> USING
<root_key_backup_definition_file> PASSWORD <password> SECURE STORE
SECOND ACCESS (PRIVATE KEY <private_key> PASSWORD <passphrase>
CERTIFICATE '<CERT>')
```

- <database\_name> is the name of the tenant database.
- <root\_key\_backup\_definition\_file> specifies the root key backup file in the file system.
- <password> is the root key backup password
- <private\_key> <passphrase> is the PEM-encoded private key file of the second access key and its passphrase, if one was set.
- <cert> is the public-key certificate of the second access key.
- Using the hdbnsutil program

### Note

If the LSS is being used in conjunction with an external key management system, you cannot recover a root key backup using hdbnsutil.

Execute the following command:

```
cd /usr/sap/<sid>/<HDBinstance_no>/exe
./hdbnsutil -recoverRootKeys <filename> --dbid=<dbid> --
password=<password> --type=ALL
```

- <dbid> is the tenant database ID.

- The `<type>` Import the backed-up root keys using either the option is the root key type and also accepts the values `PERSISTENCE`, `LOG`, `BACKUP`, and `APPLICATION`. The value `ALL` specifies that root keys of all types are imported. If you do not specify any value for `<type>`, all key types are imported.

#### → Recommendation

We recommend that you do not enter the password on the command line (`--password`). By omitting this parameter, you will be interactively prompted to enter it.

#### i Note

If you have backed-up root keys to different files, for example according to root key type, you need to execute the command several times.

### 7.4.1.9 Use FIPS 140-2 Certified Cryptographic Kernel in CommonCryptoLib

The SAP Cryptographic Library, CommonCryptoLib, supports a FIPS 140-2 compliant cryptographic kernel module, which must be enabled if required.

#### Prerequisites

CommonCryptoLib patch level 8.4.37 or higher is in use. You can check the version with the following statement: `SELECT * FROM "SYS"."M_HOST_INFORMATION" WHERE KEY LIKE 'crypt%';`

#### i Note

This statement also shows current version information of your FIPS-compliant crypto kernel if already enabled. If FIPS mode is disabled, the version number is `none`.

## Procedure

1. In the database, set the value of the parameter `[cryptography] ccl_fips_enabled` in the `global.ini` configuration file to **true**.
2. Restart the database.

## Results

The FIPS 140-2 certified crypto kernel, `libslcryptokernel`, is used instead of the built-in crypto kernel, `libsapcrypto.so`.

If `libslcryptokernel` is not a FIPS 140-2 certified one, the initialization of the library will fail. This means that SAP HANA server processes will not start because of dependent errors in other security functions, for example license errors, SSL errors, and so on.

## 7.4.2 SAP HANA Client Secure User Store (hdbuserstore)

The secure user store (`hdbuserstore`) is a tool installed with the SAP HANA client. Use it to store connection information to SAP HANA systems securely on the client so that client applications can connect to SAP HANA without users having to enter this information. It is typically used by scripts connecting to SAP HANA.

The secure user store allows you to store SAP HANA connection information, including user passwords, securely on clients. In this way, client applications can connect to SAP HANA without the user having to enter host name or logon credentials. You can also use the secure store to configure failover support for application servers in a 3-tier scenario (for example, SAP Business Warehouse) by storing a list of all the hosts that the application server can connect to.

### i Note

The secure user store can be used for all supported clients. The SAP HANA Studio, however, does not use the SAP HANA secure user store, but the Eclipse secure storage. For more information, see the Eclipse documentation.

For more information about the secure user store, see the *SAP HANA Security Guide*.

## Related Information

[Secure User Store \(hdbuserstore\)](#)

### 7.4.2.1 Change the Secure User Store Encryption Key

If you are using the current version of the SAP HANA client, there is no need to change the encryption key of the secure user store. However, if you are using an older version of the SAP HANA client, we recommend changing the encryption key after installation of the SAP HANA client.

#### Procedure

1. Change the encryption key with the command:

```
hdbuserstore CHANGEKEY
```

The `hdbuserstore` program is available after installation of the SAP HANA client in the following directories:

- `/usr/sap/hdbclient` (Linux/Unix)
- `%SystemDrive%\Program Files\sap` (Microsoft Windows)

A new master encryption key is randomly generated and data in the secure store is re-encrypted with the new key.

2. Verify that the key has been changed with the command:

```
hdbuserstore LIST
```

If the key file `SSFS_HDB.KEY` exists, the time stamp of the file indicates when the key was last successfully changed.

## Related Information

[Secure User Store \(hdbuserstore\)](#)

### 7.4.3 Client-Side Data Encryption

Client-side data encryption is a column-level data encryption capability managed by the client driver.

It provides a separation between those who own the data (and can view it) and those who manage the data (but should have no access), and delivers a built-in protection of sensitive data from other third-party database

administrators and cloud administrators. With client-side encryption, table columns containing sensitive data (credit card numbers, for instance) are encrypted using an encryption key that is accessible only to the client. Column data is encrypted and decrypted only on the client-driver, allowing the applications to read and write data in cleartext form.

Client-side encryption uses both symmetric and asymmetric encryption. Sensitive column data is encrypted with a symmetric column encryption key (CEK) which is encrypted using an asymmetric client key pair (CKP). CEKs are encrypted and stored on the SAP HANA server. The public key of the CKP is stored on the SAP HANA server and in the `hdbkeystore` (a secure key store) on the client's local machine. The private key of the CKP is stored only in the `hdbkeystore` on the client's local machine. Key generation and data encryption and decryption happens on the client driver only; SAP HANA server only stores the encrypted keys and encrypted data.

To access the encrypted data, an application must use a client driver that supports client-side encryption and the client must have access to the CEK that encrypts the column. When writing or reading encrypted data to or from the server, the application must use a prepared statement.

Client-side data encryption supports two types of encryption – non-deterministic (or randomized) and deterministic. Choose the encryption algorithm based on the intended use of the data.

Client-side data encryption also supports key rotation for column encryption keys (CEKs) and client key pairs (CKPs). Keys rotation decreases the risk of keys being breached and ensures users' data confidentiality and security. SAP Common Crypto Library (`sapcrypto.dll`) provides data encryption capabilities for client-side encryption. Client-side encryption is supported on JDBC and ODBC (SQLDBC) client drivers available with the SAP HANA client.

#### **i Note**

Applications developed using SAP HANA Extended Applications Services, classic model (XS classic) do not use the SAP HANA client.

For more conceptual and procedural information about how to configure client-side data encryption, see the *SAP HANA Client-Side Data Encryption Guide*.

## **Related Information**

[SAP HANA Client-Side Data Encryption Guide](#)

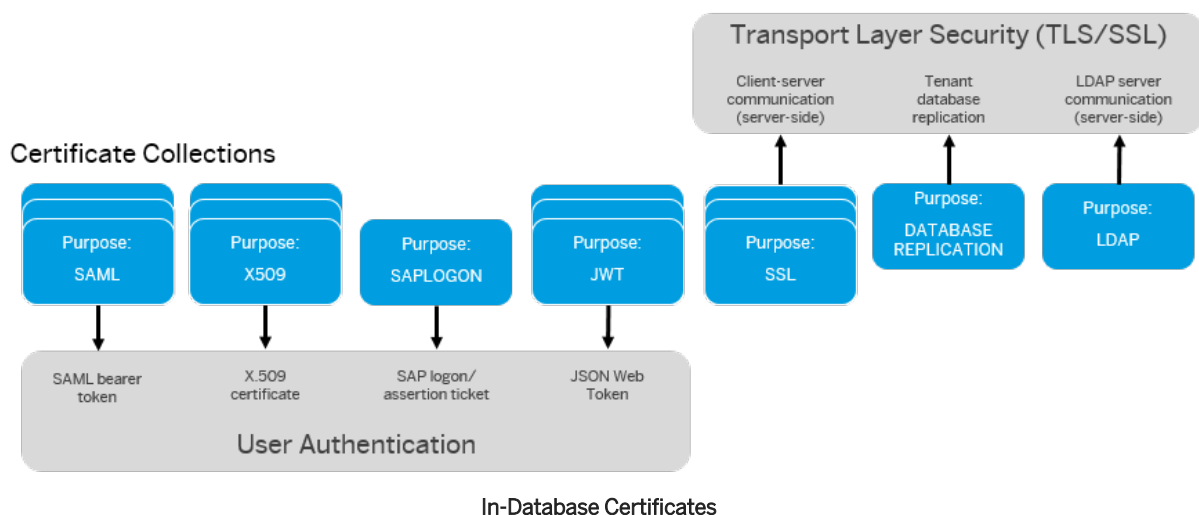

## 7.5 Managing Client Certificates

SAP HANA uses X.509 client certificates as the basis for securing internal and external communication channels, as well as for several user authentication mechanisms. Certificates can be stored and managed in files in the file system and in many cases directly in the SAP HANA database.

### Certificate Management in the Database

All certificate-based user authentication mechanisms in SAP HANA, as well as secure communication between SAP HANA and clients that access the SQL interface of the database rely on X.509 client certificates for authentication and verification of digital signatures. For ease of management, many of these certificates can be stored directly in the SAP HANA database, where they are grouped into collections that serve a unique purpose.

The following figure shows for which purposes certificates stored in the database are possible:

### Optional in-database storage

You may store and manage the certificates for the following purposes directly in the SAP HANA database:

- User authentication based on:
  - SAML assertions
  - Logon and assertion tickets
  - X.509 certificates for HTTP access via SAP HANA XS classic model

#### i Note

SAP HANA XS advanced also supports X.509 certificate-based user authentication, however, does not require a certification collection in the SAP HANA database. For more information, see the *SAP HANA Administration Guide*.

- Client-server communication over JDBC/ODBC secured using TLS/SSL

## i Note

Although we recommend storing and managing these certificates in the database, files containing certificates may also be stored in the file system for the above purposes. See below.

### Mandatory in-database storage

You **must** store and manage the certificates for the following purposes directly in the SAP HANA database:

- User authentication based on JSON Web Tokens (JWT)
- User authentication based:
  - JSON Web Tokens (JWT)
  - X.509 certificates for JDBC/ODBC client access
- Secure communication between the following components:
  - Two SAP HANA systems during the process of copying or moving a tenant database
  - SAP HANA and an LDAP server being used for user authentication and/or authorization
  - SAP HANA and remote data sources in an SAP HANA smart data access scenario

## Certificate Management in the File System

Although we recommend using in-database storage where possible, you can store and manage some certificates in trust and key stores located in the file system, in so-called personal security environments or PSEs.

### ⚠ Caution

By default, the same PSE in the file system is shared by all databases for all external communication channels (including HTTP) and certificate-based authentication. Different PSEs must be explicitly configured for tenant databases.

### → Recommendation

You can migrate certificates from file-system based storage to in-database storage. If you do migrate certificates in the file system to the database, delete all related files from the file system to avoid any potential conflicts. For more information, see SAP Note 2175664.

However, not all certificates can be stored in the database, in particular the certificates required to secure internal communication channels using the system public key infrastructure (system PKI), and HTTP client access using SAP Web Dispatcher. These certificates are contained in PSE files located in the file system.

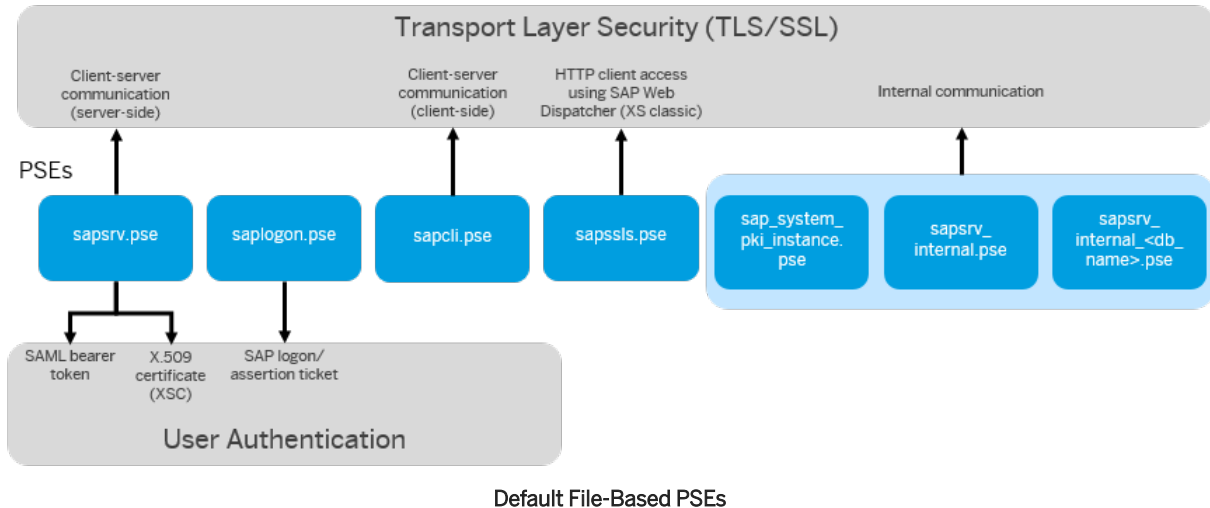

### ⚠ Caution

Do not delete these files from the file system.

The following figure shows for which purposes certificates stored in PSEs in the file system are possible. These PSEs are available by default and can be managed using for example the SAP Web Dispatcher administration tool or the SAPGENPSE tool, both of which are delivered with SAP HANA. If you are using OpenSSL, you can also use the tools provided with OpenSSL.

## i Note

OpenSSL is deprecated. If you are using OpenSSL, migrate to CommonCryptoLib. For more information, see SAP Note 2093286.

## 7.5.1 Client Certificates

X.509 client certificates required for certificate-based user authentication and secure communication between SAP HANA and clients that access the SQL interface of the database can be stored and managed directly in the SAP HANA database.

Certificates stored in the SAP HANA database can be used for:

- Trust validation  
Certificates used for trust validation are the public-key certificates of trusted communication partners or root certificates from trusted Certification Authorities. These certificates contain the public part of a user's or component's public and private key pair.
- Server authentication  
Certificates used for server authentication are the public-key certificates of the SAP HANA server used to identify the server to connecting clients. In addition to the public-key information of the server, these

certificates contain the server's private keys, as well as the intermediate certificates that complete the trust chain from the server certificate to the root certificate that the communication partner (client) trusts.

#### **i Note**

Private keys are stored securely using the internal application encryption service of the SAP HANA database. For more information, see the section on the internal application encryption service.

Once they have been imported into the database, certificates can be assigned to certificate collections. Certificate collections are also created and managed directly in the database, where they serve a unique purpose.

#### **i Note**

Although we recommend creating and managing both certificates and certificate collections in the database where possible, files containing certificates may also be stored in the file system in some cases.

## **7.5.2 Certificate Collections**

A certificate collection (or PSE) is a secure location where the public information (public-key certificates) and private information (private keys) of the SAP HANA server are stored. A certificate collection may also contain the public information (public-key certificates) of trusted communication partners or root certificates from trusted Certification Authorities. Certificate collections can be created and managed as database objects directly in the SAP HANA database.

### **Certificate Collection Purposes**

Certificate collections uniquely serve one of the following purposes in the database in which they exist.

<b>For...</b>	<b>Set the Purpose...</b>
User authentication based on SAML assertions	SAML
User authentication based on JSON Web Tokens	JWT
User authentication based on X.509 certificates	X509

For...	Set the Purpose...
User authentication based on logon and assertion tickets	SAP LOGON
Client-server communication over JDBC/ODBC secured using TLS/SSL	SSL
Database replication with the aim of copying or moving a tenant database to another system	DATABASE REPLICATION
Communication between SAP HANA and an LDAP server being used for user authentication and authorization	LDAP
Communication between SAP HANA and remote data sources in an SAP HANA smart data access scenario	REMOTE SOURCE

The client certificates required for each purpose are assigned to the corresponding certificate collection from the in-database certificate store. A certificate can be assigned to more than one certificate collection.

### i Note

You only need to set your own key or a private key in collections used for client-server communication, that is with purpose `SSL`. Although it is possible to do so, there is no need to set a private key for certificate collections used for trust validation.

### i Note

Although we recommend creating and managing both certificates and certificate collections in the database where possible, files containing certificates may also be stored in the file system in some cases.

## Certificate Collections with Qualified Purpose

Collections with the following purposes may be qualified further:

Purpose	Optional Qualification
SAML	Identity providers
JWT	Identity providers
X509	Identity providers
	<h3>i Note</h3> <p>For authenticating user access via the SAP HANA XS classic server, do not add an identity provider to the collection.</p>
REMOTE SOURCE	SAP HANA remote sources

Qualifying the purpose of a collections allows you to assign the same purpose to several collections. In this way, the assertions, tokens and certificates issued by different providers can be validated separately, and the

connections to different remote sources can be secured separately. Identity providers and remote sources must already exist in the database before they can be added to a collection, and each provider or remote source can only be assigned to one certificate collection.

If multiple collections with the same purpose exist, note the following behavior:

- Collections with qualified purposes take precedence over a collection with the same purpose that has not been qualified, that is a collection with the same purpose that has not been assigned any providers or remote sources.

#### **i** Note

Only one collection with an unqualified purpose may exist.

- If there is only one collection with a particular purpose and it is qualified, any unassigned providers or remote sources that may be configured cannot be validated.

#### **i** Note

In the case of collections with purpose SAML and SSL, the trust store located on the file system and configured with the `global.ini` parameter `[communication] sslTrustStore` is used instead (`sapsrv.pse` by default).

This behavior can be illustrated with the following example.

#### **❖** Example

Multiple SAML identity providers are configured in your database (providerA, providerB, and providerC). Initially, two certificate collections are used for SAML-based user authentication. The first collection (pse1) is assigned the purpose `SAML` but no specific identity providers have been added. The second collection (pse2) is also assigned the purpose `SAML` but is qualified for a specific identity provider (providerA). This is configured as follows:

```
SET PSE pse1 PURPOSE SAML;  
SET PSE pse2 PURPOSE SAML FOR PROVIDER providerA;
```

With this configuration, collection pse2 has a qualified purpose and is used to validate requests signed by providerA only. Collection pse1 is not qualified with any specific providers and so is used to validate requests from all other providers configured in the database.

If you now drop collection pse1, requests from providerB and providerC can no longer be validated. This is because there is no collection with the unqualified purpose `SAML`, and these providers have not been added to any other collection with purpose `SAML`. This means that it is no longer possible to log on or connect to the database using providerB and providerC (assuming that `sapsrv.pse` does not contain the necessary certificates).

In addition to creating a new collection with the unqualified purpose `SAML`, you could resolve the situation in a number of ways:

- Create one or more additional collections with the purpose `SAML` and assign the other providers to these:

#### **≡** Sample Code

```
CREATE PSE pse3;  
SET PSE pse3 PURPOSE SAML FOR PROVIDER providerB;
```

```
CREATE PSE pse4;  
SET PSE pse4 PURPOSE SAML FOR PROVIDER providerC;
```

Collections pse3 and pse4 are now used to validate requests signed by providerB and providerC respectively.

- Assign the other providers to the existing collection with qualified SAML purpose (pse2):

#### ≡, Sample Code

```
ALTER PSE pse2 ADD PROVIDER providerB, providerC;
```

pse2 is now used to validate requests signed by providerA, providerB, and providerC.

- Remove the provider assigned to the existing collection, thus making it applicable to all providers:

#### ≡, Sample Code

```
SET PSE pse2 PURPOSE SAML;
```

pse2 is now used to validate requests signed by all providers.

## Ownership of Certificate Collections
