A certificate collection is a database object created in runtime. It is therefore owned by the database user who creates it. If a certificate collection is in use, in other words it has been assigned one of the above purposes, it is not possible to change it (for example, add or remove certificates) or to delete it. However, if the owner of the certificate collection is deleted, the certificate collection will be deleted **even if it currently in use**.

### ⚠ Caution

The deletion of a certificate collection that is assigned a purpose could render the database unusable. For example, if TLS/SSL is being enforced for all client connections and the certificate collection used for TLS/SSL is deleted, no new client connections to the database can be opened.

## 7.5.3 View Certificates in the Certificate Store

You can view certificates stored in the database on the [Certificate Store](#) page of the SAP HANA cockpit.

### Prerequisites

- You have the system privilege `CERTIFICATE ADMIN` or `TRUST ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to the [Security Related Links](#) card and choose the link [Certificate Store](#).

The [Certificate Store](#) page opens. All certificates in the certificate store are listed. If you want to view the full details of a certificate, simply click it. For more information, see [Certificate Details](#).

If the certificate is used in one or more certificate collections, you can navigate to the [Certificate Collections](#) page by clicking the collection name in the [Used In](#) column.

#### i Note

You will only see the certificate collection if you have the object privilege `ALTER`, `DROP`, or `REFERENCES` on the collection.

### Related Information

[Certificate Details \[page 1030\]](#)

## 7.5.3.1 Certificate Details

On the [Certificate Store](#) page of the SAP HANA cockpit you can view the details of all certificates in the certificate store of the SAP HANA database.

Field	Description
<i>Issued To (CN)</i>	Common name of the person or entity identified by the certificate
<i>Issued To (DN)</i>	Distinguished name of the person or entity identified by the certificate
<i>Issued By (CN)</i>	Common name of the entity that verified the information and issued the certificate
<i>Issued By (DN)</i>	Distinguished name of the entity that verified the information and issued the certificate
<i>Issued On</i>	Date on which the certificate was issued
<i>Expires On</i>	End of certificate's validity
<i>Used In</i>	The certificate collections to which the certificate has been assigned
<i>Version</i>	X.509 version (as specified in the corresponding RFC)
<i>Public Key Algorithm</i>	Public key algorithm
<i>Public Key Length</i>	Public key length
<i>Signature Algorithm</i>	The cryptographic algorithm used to sign the certificate
<i>Basic Constraints</i>	Whether the certificate belongs to a certification authority (CA)
<i>Fingerprint</i>	The hash of the entire certificate, used as a unique identifier in the certificate store
<i>Serial Number</i>	Serial number assigned by the certificate issuer

### Related Information

[Certificate Collection Details \[page 1032\]](#)

## 7.5.4 View Certificate Collections

You can view the certificate collections available in the database on the [Certificate Collections](#) page of the SAP HANA cockpit.

### Prerequisites

- You have the system privilege `CATALOG READ` and either `TRUST ADMIN`, `USER ADMIN`, or `SSL ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, click the [Certificate Collections](#) link.

The [Certificate Collections](#) page opens. All existing collections are listed on the left. To see more detailed information about a specific collection on the right, simply select it. For more information, see [Certificate Collection Details](#).

#### i Note

Certificate collections are also referred to as personal security environments (PSEs).

### Related Information

[Certificate Collections \[page 1025\]](#)

## 7.5.4.1 Certificate Collection Details

On the [Certificate Collections](#) page of the SAP HANA cockpit, you can view the details of all certificate collections in the SAP HANA database.

Field	Description
<a href="#">Purpose</a>	<p>Purpose of the collection</p> <ul style="list-style-type: none"><li>• <a href="#">DATABASE REPLICATION</a> Database replication for the purposes of copying or moving a tenant database to another system</li><li>• <a href="#">JWT</a> User authentication based on JSON Web Tokens</li><li>• <a href="#">LDAP</a> Communication between SAP HANA and an LDAP server being used for user authentication and authorization</li><li>• <a href="#">SAML</a> User authentication based on SAML assertions</li><li>• <a href="#">SAP LOGON</a> User authentication based on logon and assertion tickets</li><li>• <a href="#">SSL/TLS</a> Communication between SAP HANA and an LDAP server being used for user authentication and authorization</li><li>• <a href="#">X509</a> User authentication based on X.509 certificates</li></ul>
<a href="#">Provider</a>	SAML or JWT identity provider if the collection purpose is <a href="#">SAML</a> or <a href="#">JWT</a>
<a href="#">Private Key</a>	<p>Indicates whether or not a private key has been set for the collection</p> <p>Only a collection with the purpose <a href="#">SSL/TLS</a> requires a private key. This is the key that the SAP HANA server uses to identify itself to connecting clients. While possible, there is no need to set a private key for certificate collections used for trust validation.</p>
<a href="#">Created By</a>	Database user who created the collection
<a href="#">Comment</a>	Optional comment

Field	Description
<a href="#">Certificates</a>	<p>Certificates assigned to the collection</p> <p>The function of each certificate in the certificate collection is indicated. The following functions are possible:</p> <ul style="list-style-type: none"> <li>• <b>TRUST</b> The certificate is the public-key certificate of a trusted communication partner.</li> <li>• <b>PERSONAL</b> The certificate is a server certificate belonging to the SAP HANA system and contains a private key.</li> <li>• <b>CHAIN</b> The certificate is an intermediate certificate that is part of the trust chain from the server certificate to the root certificate that the communication partner (client) trusts.</li> </ul> <p>For more information about the other certificate fields, see <a href="#">Certificate Details</a>.</p>

## Related Information

[Certificate Details \[page 1030\]](#)

## 7.5.5 Import a Trusted Certificate into the Certificate Store

You can store the public-key certificates of trusted communication partners, as well and the root certificates of trusted Certification Authorities directly in the SAP HANA database. You do this on the [Certificate Store](#) page of the SAP HANA cockpit.

### Prerequisites

- You have the system privilege System privilege `CERTIFICATE ADMIN`.
- The certificate that you want to add is available on your client in PEM format.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to the *Security Related Links* card and choose the link *Certificate Store*.  
The *Certificate Store* page opens, listing all certificates already in the certificate store.
2. Import the certificate:
  - a. Click *Import*.
  - b. Specify the location of the certificate file on your client or paste the content of the file.
  - c. Click *OK*.

The certificate is imported into the database and appears in the list of certificates in the certificate store. You can see the content of the certificate by navigating to its details view. For more information, see *Certificate Details*.

## Results

The certificate is available for assignment to one or more certificate collections.

## Related Information

[Certificate Details \[page 1030\]](#)

## 7.5.6 Create a Certificate Collection

You can create a certificate collection on the *Certificate Collections* page. Then, you add the relevant trusted certificates and if necessary, the server certificate.

## Prerequisites

- You have the system privilege `TRUST ADMIN`.
- The certificates you want to add to the collection are in the certificate store. For more information, see *Add a Certificate to the Certificate Store*.
- If you plan to add a server certificate to the collection, it is available on your client in PEM format.
- You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to the *Security Related Links* card and choose the link *Certificate Collections*.

The *Certificate Collections* page opens. All existing collections are listed on the left.

2. Create a new collection by clicking the **+** (*Add*) icon in the footer toolbar and entering the name of the collection.

The collection is created and appears in the list of collections on the left.

### Caution

You are the owner of the certificate collection. If your database user is deleted, the collection will also be deleted even if it currently in use. This could render the database unusable, for example, if SSL is being enforced for all client connections.

3. Add a trusted certificate by clicking *Add Certificate* and then selecting the certificate.

All certificates in the certificate store are available for selection. You can select more than one.

The trusted certificate is added to the collection. It has the function *TRUST*.

4. Optional: Add the server certificate.

In addition to the public-key certificates of trusted communication partners, you can add the certificate of the SAP HANA server. This certificate contains the server's private key, as well as the intermediate certificates that complete the trust chain from the server certificate to the root certificate that the communication partner (client) trusts. The server certificate is necessary if the collection will be used for a purpose that includes server authentication (for example, purpose *SSL*). To add a server certificate, proceed as follows:

- a. Click *Set Own Certificate*.
- b. Specify the location of the certificate file on your client or paste the content of the file.
- c. Click *OK*.

As a result:

- The server certificate is added to the collection. It has the function *PERSONAL*.
- Any intermediate certificates that are part of the trust chain from the server certificate to the root certificate are also added. They have the function *CHAIN*.
- The *Private Key* attribute changes from *Absent* to *Present*.

## Next Steps

Set the purpose of the collection.

## Related Information

[Server-Side Data Encryption Services](#)

[Set the Purpose of a Certificate Collection \[page 1036\]](#)

## 7.5.7 Set the Purpose of a Certificate Collection

You specify the purpose of a collection on the [Certificate Collections](#) page, for example SAML user authentication. A collection may have only one purpose and a purpose may only be served by one collection.

### Prerequisites

- If you are not the owner of the certificate collection, you need the object privilege `REFERENCES` on the certificate collection.
- You have the necessary system privilege to set the purpose:

Purpose	Privilege
User authentication	USER ADMIN
SSL/TLS (secure client-server communication over JDBC/ODBC)	SSL ADMIN
DATABASE REPLICATION	DATABASE ADMIN
LDAP	LDAP ADMIN
REMOTE SOURCE	CREATE REMOTE SOURCE

#### i Note

In addition, the server certificate containing the server's private key must be part of the collection.

- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#) page, with the [Security and User Management](#) or [All](#) view selected, navigate to the [Security Related Links](#) card and choose the link [Certificate Collections](#).
2. Find and select the collection that you want to set the purpose for.
3. Open the collection for editing by choosing [Edit Purpose](#).
4. In the dialog box, select the purpose:

Option	Description
<a href="#">DATABASE REPLICATION</a>	Communication between two systems via external SQL connections for the purposes of copying or moving a tenant database
<a href="#">JWT</a>	User authentication based on JSON Web Token (JWT)
<a href="#">LDAP</a>	Communication between the SAP HANA database and an LDAP server being used for user authentication and authorization

Option	Description
<i>SAML</i>	User authentication based on SAML assertions
<i>SAP LOGON</i>	User authentication based on logon and assertion tickets
<i>SSL/TLS</i>	Client-server communication over JDBC/ODBC secured using SSL/TLS
<i>X509</i>	User authentication based on X.509 client certificates
<i>REMOTE SOURCE</i>	Access data stored in a remote data source. For example, using Smart Data Access or Rserve.

### i Note

Only the purposes that have been enabled by the system administrator are visible, and only those you are authorized for are enabled.

5. Select a provider.

### i Note

Only the providers that have been enabled by the system administrator are visible, and only those you are authorized for are enabled.

6. Specify a host.  
You need to manually specify the host name to be used.
7. Save the collection.

## Results

The collection starts being used for the selected purpose immediately. If another collection had been assigned the purpose before, it will no longer be used.

## 7.5.8 Export a Client Certificate

You can export the contents of a client certificate available in the certificate store. For example, you may need to export the SAP HANA server certificate to set up a trust relationship with trusted clients.

### Prerequisites

- You have the system privilege `CERTIFICATE ADMIN` or `TRUST ADMIN`.
- You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### i Note

For information on how to set up the database client so that it accepts the server's certificate (or root certificate), including the use of the `openssl` or `sapgenpse` commands to extract and import these

certificates, refer to the section *Implement Mutual Authentication in the SAP HANA Client Interface Programming Reference*.

## Procedure

1. On the *Database Overview* page, with the *Security and User Management* or *All* view selected, navigate to the *Security Related Links* card and choose the link *Certificate Store*.

The *Certificate Store* page opens. All certificates in the certificate store are listed.

### i Note

You can also navigate to certificates through the certificate collection to which they are assigned.

2. Find the certificate you want to export and navigate to the detailed view.
3. Click *Show PEM Representation* in the footer.
4. Export the certificate contents using copy and paste.

## Related Information

[Implement Mutual Authentication](#)

## 7.5.9 SQL Statements and Authorization for In-Database Certificate Management (Reference)

All administration tasks related to in-database certificate management can be performed using SQL.

The following table lists the SQL statements for creating and managing certificates and certificate collections in the SAP HANA database, including the required authorization for each task. For more detailed information about the syntax of the statements mentioned, see the *SAP HANA SQL and System Views Reference*.

### i Note

Certificate collections are referred to as personal security environments (PSEs) in back-end terminology.

To...	Execute the Statement...	With the Authorization...
See certificates in the in-database certificate store	<pre>SELECT * FROM CERTIFICATES</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>You can also view certificates on the <a href="#">Certificate Store</a> app of the SAP HANA cockpit.</p> </div>	<p>System privilege CERTIFICATE ADMIN or TRUST ADMIN</p> <p>If you have object privilege ALTER on a certificate collection, you'll also be able to see the certificates used in this collection.</p>
See certificate collections	<pre>SELECT * FROM PSES</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>You can also view certificate collections in the <a href="#">Certificate Store</a> app of the SAP HANA cockpit.</p> </div>	<p>System privilege TRUST ADMIN</p> <p>If you have object privilege ALTER, DROP, or REFERENCES on a certificate collection, you'll also be able to see this collection.</p>
See which certificates are used in a certificate collection	<pre>SELECT * FROM PSE_CERTIFICATES</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>You can also see this information on the <a href="#">Certificate Store</a> app of the SAP HANA cockpit.</p> </div>	<p>Object privilege ALTER, DROP, or REFERENCES on the certificate collection</p>
Add a certificate to the in-database certificate store	<pre>CREATE CERTIFICATE FROM &lt;certificate_content&gt; [ COMMENT &lt;comment&gt; ]</pre>	<p>System privilege CERTIFICATE ADMIN</p>
Delete a certificate from the in-database certificate	<pre>DROP CERTIFICATE &lt;certificate_id&gt;</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>If the certificate has already been added to a certificate collection, it can't be deleted.</p> </div>	<p>System privilege CERTIFICATE ADMIN</p>
View certificate collections in the database, including the certificates they contain	<pre>SELECT * FROM PSE_CERTIFICATES</pre> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>You can also view certificate collections on the <a href="#">Certificate Collection</a> app of the SAP HANA cockpit.</p> </div>	<p>System privilege CATALOG READ and either TRUST ADMIN, USER ADMIN, or SSL ADMIN</p> <div style="border: 1px solid #ccc; padding: 5px; margin-top: 10px;"> <p><b>i Note</b></p> <p>If you own a certificate collection or you have the object privilege ALTER, DROP, or REFERENCES on a certificate collection, you'll be able to see it without the above privileges.</p> </div>
Create a certificate collection	<pre>CREATE PSE &lt;PSE_name&gt;</pre>	<p>System privilege TRUST ADMIN</p>

To...	Execute the Statement...	With the Authorization...
Add a public-key certificate to a certificate collection	<pre>ALTER PSE &lt;PSE_name&gt; ADD CERTIFICATE &lt;certificate_id&gt;</pre>	<ul style="list-style-type: none"> <li>• Nothing if you're the owner of the certificate collection</li> <li>• Object privilege ALTER on the certificate collection if you're not the owner</li> </ul>
Remove a public-key certificate from a certificate collection	<pre>ALTER PSE &lt;PSE_name&gt; DROP CERTIFICATE &lt;certificate_id&gt;</pre>	<div style="border: 1px solid #0070C0; padding: 5px;"> <p><b>i Note</b></p> <p>If the purpose of the certificate collection has already been set, then purpose-specific system privilege is additionally required (for example, USER ADMIN for user authentication purposes)</p> </div>
Add a private key to a certificate collection	<pre>ALTER PSE &lt;PSE_name&gt; SET OWN CERTIFICATE &lt;certificate_content&gt;</pre>	<ul style="list-style-type: none"> <li>• Nothing if you're the owner of the certificate collection</li> <li>• Object privilege ALTER on the certificate collection if you're not the owner</li> </ul>
Set the purpose of a certificate collection and qualify it if necessary	<pre>SET PSE &lt;PSE_name&gt; PURPOSE &lt;purpose&gt;</pre> <p>The following PSE purposes are possible:</p> <p><b>SAML</b></p> <p>You can qualify the purpose SAML for specific identity providers as follows:</p> <pre>SET PSE &lt;PSE_name&gt; PURPOSE SAML FOR PROVIDER &lt;provider, ...&gt;</pre> <div style="border: 1px solid #0070C0; padding: 5px;"> <p><b>i Note</b></p> <p>A provider can only be used to qualify the purpose of one collection. If you use SET PSE to assign a provider that is already assigned to another collection, the provider is removed from the other collection. If this was the only provider assigned to the other collection, the purpose is also removed.</p> </div>	<p>System privilege USER ADMIN</p>

To...	Execute the Statement...	With the Authorization...
	<p><b>JWT</b></p> <p>You can qualify the purpose JWT for specific identity providers as follows:</p> <pre>SET PSE &lt;PSE_name&gt; PURPOSE JWT FOR PROVIDER &lt;provider, ...&gt;</pre>	System privilege USER ADMIN
	<p><b>i Note</b></p> <p>A provider can only be used to qualify the purpose of one collection. If you use SET PSE to assign a provider that is already assigned to another collection, the provider is removed from the other collection. If this was the only provider assigned to the other collection, the purpose is also removed.</p>	
	<p><b>X509</b></p> <p>If the collection will be used for authenticating users accessing SAP HANA via JDBC/ODBC clients, you can qualify the purpose X509 for specific identity providers as follows: SET PSE</p> <pre>&lt;PSE_name&gt; PURPOSE X509 FOR PROVIDER &lt;provider, ...&gt;</pre>	System privilege USER ADMIN
	<p><b>i Note</b></p> <p>A provider can only be used to qualify the purpose of one collection. If you use SET PSE to assign a provider that is already assigned to another collection, the provider is removed from the other collection. If this was the only provider assigned to the other collection, the purpose is also removed.</p>	
	<p>If the collection will be used for authenticating users accessing via the SAP HANA XS classic server, do not add an identity provider.</p>	
	<b>SAP LOGON</b>	System privilege USER ADMIN

To...	Execute the Statement...	With the Authorization...
	<b>SSL</b>  <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>i Note</b></p> <p>You can only assign the purpose SSL if a private key has already been added.</p> </div>	System privilege SSL ADMIN
	<b>DATABASE REPLICATION</b>	System privilege DATABASE ADMIN
	<b>LDAP</b>	System privilege LDAP ADMIN
	<b>REMOTE SOURCE</b>  You can qualify the purpose REMOTE SOURCE for specific remote sources as follows: SET PSE <PSE_name> PURPOSE REMOTE SOURCE FOR REMOTE SOURCE <remote_source, ...>	System privilege CREATE REMOTE SOURCE
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>i Note</b></p> <p>A remote source can only be used to qualify the purpose of one collection. If you use SET PSE to assign a remote source that is already assigned to another collection, the remote source is removed from the other collection. If this was the only remote source assigned to the other collection, the purpose is also removed.</p> </div>	
Unset the purpose of a certificate collection	UNSET PSE <PSE_name> PURPOSE <PSE_purpose>	Purpose-specific system privilege
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>i Note</b></p> <p>If the collection has identity providers, remote sources or host names assigned, these are also removed from the collection.</p> </div>	

To...	Execute the Statement...	With the Authorization...
Add an identity provider, remote source or host name to a certificate collection	<ul style="list-style-type: none"> <li>ALTER PSE &lt;PSE_name&gt; ADD PROVIDER &lt;identity_provider&gt;</li> <li>ALTER PSE &lt;PSE_name&gt; ADD REMOTE SOURCE &lt;remote_source&gt;</li> <li>ALTER PSE &lt;PSE_name&gt; ADD HOST &lt;host_name&gt;</li> </ul>	Purpose-specific system privilege
<div style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>You can only use this statement to add further providers, remote sources or host names to a collection. In other words, the collection must have at least one provider, remote source or host name already added. To add the first provider, remote source or host name, use the SET PSE statement.</p> </div>		
Remove an identity provider, remote source or host name from a certificate collection	<ul style="list-style-type: none"> <li>ALTER PSE &lt;PSE_name&gt; DROP PROVIDER &lt;identity_provider&gt;</li> <li>ALTER PSE &lt;PSE_name&gt; DROP REMOTE SOURCE &lt;remote_source&gt;</li> <li>ALTER PSE &lt;PSE_name&gt; DROP HOST &lt;host_name&gt;</li> </ul>	Purpose-specific system privilege
<div style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>You cannot use this statement to remove the last provider, remote source or host name assigned to a collection. To remove the last provider, remote source or host name, use the UNSET PSE statement.</p> </div>		
See which certificate collections have qualified purposes	SELECT * FROM PSE_PURPOSE_OBJECTS	System privilege TRUST ADMIN  If you have object privilege ALTER or REFERENCES on a certificate collection or are the owner of the collection, you'll also be able to see information about that collection.

To...	Execute the Statement...	With the Authorization...
Delete a certificate collection	DROP PSE <PSE_name>	<ul style="list-style-type: none"> <li>Nothing, if you're the owner of the certificate collection</li> <li>Object privilege DROP on the certificate collection, if you're not the owner</li> </ul>

**i Note**  
 If the certificate collection has already been assigned a purpose, it can't be deleted.

## 8 SAP HANA Data Anonymization

Ensure the anonymization of data displayed in SQL and calculation views.

To enable data analysis while still protecting the privacy of individuals, data anonymization capabilities are available in SAP HANA in the form of anonymization views in the case of SQL, and as anonymization nodes in the case of calculation views.

### Note

SAP HANA provides only features and tools that help customers to implement data protection requirements and facilitate the required discussions between data scientists and data protection officers.

For more information about maintaining and using data anonymization in the context of SAP HANA, see the *SAP HANA Data Anonymization Guide*.

This section includes high-level information about the following aspects of data anonymization in SAP HANA:

- [Data-anonymization Views \[page 1045\]](#)
- [Data-anonymization Methods \[page 1046\]](#)
- [Generalization Hierarchies \[page 1046\]](#)
- [Data Change Strategies \[page 1046\]](#)
- [System and Monitoring Views \[page 1047\]](#)
- [Data Anonymization Monitoring \[page 1047\]](#)
- [Data Anonymization Report \[page 1047\]](#)

### Data-anonymization Views

Data anonymization can be applied to SQL views by specifying an anonymization method, for example, k-anonymity, l-diversity, or differential privacy and configuring the parameters of the selected data-anonymization method to meet the privacy level required.

You define anonymization views using the SQL CREATE VIEW statement and a WITH ANONYMIZATION clause which specifies an anonymization method and includes corresponding parameters for each column in the view to meet the required privacy level. There are three types of parameter:

- Static parameters - used to configure the view as a whole, such as defining the method ('algorithm') to use
- Column parameters - used to apply configuration values to individual columns of the view
- Hierarchy parameters - used for columns which are 'quasi identifiers' to create generalization hierarchies which determine how specific values can be replaced by more generic values.

The following example shows an anonymization clause including configuration properties for three columns of a table (ID, GENDER, LOCATION):

```
WITH ANONYMIZATION ( ALGORITHM 'K-ANONYMITY'  
PARAMETERS '{"k": 5}'  
COLUMN ID PARAMETERS '{"is_sequence": true}'  
COLUMN GENDER PARAMETERS '{"is_quasi_identifier":true, "hierarchy":{"embedded":  
[["F"], ["M"]]} }'
```

```
COLUMN LOCATION PARAMETERS '{"is_quasi_identifier":true, "hierarchy":
{"embedded": [{"Paris", "France"}, {"Munich", "Germany"}, {"Nice",
"France"}]}'');
```

Note that two of the columns are quasi identifiers and include the required hierarchy parameters to define appropriate generalization hierarchies.

### i Note

Anonymization nodes can be created for calculation views in the modeling environment of the SAP Web IDE. For more information, see *Anonymize Data Using Calculation Views* in the *SAP HANA Modeling Guide*.

## Data-anonymization Methods

Data anonymization methods provide a structured approach to modifying data for privacy protection. SAP HANA supports the following data-anonymization methods:

- k-anonymity  
Anonymizes data by hiding the individual record in a group of similar records, thus significantly reducing the possibility that the individual can be identified
- l-diversity  
For use in addition to k-anonymity if there is a risk that too much homogeneity in a sensitive attribute's values, in combination with other quasi-identifying attributes, might lead to loss of privacy
- Differential privacy  
Anonymizes data by randomizing sensitive information but in a way that regardless of whether an individual record is included in the data set or not, the outcome of statistical queries remains approximately the same. Differential privacy provides formal statistical privacy guarantees.

## Generalization Hierarchies

A hierarchy describes a generalization scheme for the values in a quasi-identifying column. The scheme allows the values in each row to be replaced by a higher-level group until each group in the data set contains a specified minimum number of members. Hierarchies are required for the data anonymization methods k-anonymity and l-diversity.

## Data Change Strategies

A data change strategy is applied to an anonymization view and determines how changes in the underlying source table should be handled when SQL `SELECT` statements are run.

## System and Monitoring Views

Information about all anonymized views is available in the following system and monitoring views:

- `ANONYMIZATION_VIEWS`
- `ANONYMIZATION_VIEW_COLUMNS`
- `M_ANONYMIZATION_VIEWS`

### i Note

In SAP HANA cockpit, you can display a report that lists all anonymized views as well as all calculation views that include one or more anonymization nodes. The anonymization report is available to users with the system privilege `CATALOG READ`. For more details about the anonymization report, see the section below.

## Data Anonymization Monitoring

Data anonymization statistics (key performance indicators) allow you to assess the quality of the anonymized data in an anonymization view. The key performance indicators (KPIs) display details of the information loss that is needed to render the data anonymous. The KPIs can be used to gain a better understanding of the effects of the applied anonymization methods and their respective parameters. This helps to achieve a balance between the goals of protecting data privacy while at the same time ensuring that the anonymized data remains useful. Most of the KPIs are available only for the anonymization methods k-anonymity and l-diversity.

Data anonymization KPIs can be retrieved with the procedure `GET_ANONYMIZATION_VIEW_STATISTICS`.

### i Note

Only the data controller who defined the view (with `CREATE VIEW`) or a user with `CATALOG READ` privileges can currently obtain results using the procedure `GET_ANONYMIZATION_VIEW_STATISTICS`.

The hierarchy KPIs and the `result.groups` KPIs (for anonymization results) are restricted to the owner of the view (that is, the user that issued the `CREATE VIEW` statement).

## Data Anonymization Report

In SAP HANA cockpit, you can display a report that lists all anonymized views as well as all calculation views that include one or more anonymization nodes. The anonymization report is available to users with the system privilege `CATALOG READ` and includes the following information:

- The name of the anonymized view or calculation view
- The name of the anonymization nodes (for calculation views only)
- The anonymization method used, for example: k-anonymity, l-diversity, or differential privacy
- Configuration values used by the specified anonymization method
- Columns in the view, including anonymization information

- KPI values for anonymized views

For more information about how to access anonymization reports, see the SAP HANA cockpit documentation.

# 9 SAP HANA Lifecycle Management

SAP HANA lifecycle management covers two aspects: platform lifecycle management for customizing and updating your SAP HANA platform and application lifecycle management for managing SAP HANA content products and transports.

## Platform Lifecycle Management Aspects

You can customize platform lifecycle management aspects of your SAP HANA system by accessing the SAP HANA database lifecycle manager from three user interfaces: the graphical user interface, the command-line interface, or the Web user interface in a stand-alone Web browser, in the SAP HANA studio, or via the SAP HANA cockpit.

SAP HANA platform lifecycle management encompasses the installation and update of an SAP HANA server, mandatory components, and additional components, as well as the post-installation configuration. The concepts and procedures for SAP HANA platform installation and update are described in the *SAP HANA Server Installation and Update Guide* on SAP Help Portal.

A number of system configuration features are integrated into the SAP HANA database lifecycle manager, such as:

- The initial configuration of your SAP HANA platform to integrate it into your landscape. For example, by registering it in a system landscape directory, or configuring the inter-service communication.
- Adapting the topology of your SAP HANA platform by adding or removing additional SAP HANA hosts.
- Reconfiguring the system.

System configuration as it pertains to SAP HANA lifecycle management is described in the *SAP HANA Platform Lifecycle Management* section of this *SAP HANA Administration Guide*.

## Application Lifecycle Management Aspects

SAP HANA application lifecycle management aspects can be accessed in different user interfaces: an interface that runs as an SAP HANA XS application in a web browser, a command-line tool hdbalm, integrated in SAP HANA studio, or via the SAP HANA cockpit.

SAP HANA application lifecycle management supports you in all phases of the lifecycle of an SAP HANA application or add-on product, from modelling your product structure, through application development, transport, assembly, to installing and updating products that you have downloaded from SAP Support Portal or which you have assembled yourself.

All application lifecycle management tasks are documented in the guide *SAP HANA Application Lifecycle Management* on SAP Help Portal.

System administrators use SAP HANA application lifecycle management mainly to install and update SAP HANA applications or add-on products. Therefore, these tasks are documented in this *SAP HANA Administration Guide*. Tasks related to SAP HANA development are documented in the *SAP HANA Developer Guide - For SAP HANA Studio* ( on SAP Help Portal) under *SAP HANA Application Lifecycle Management*.

## Related Information

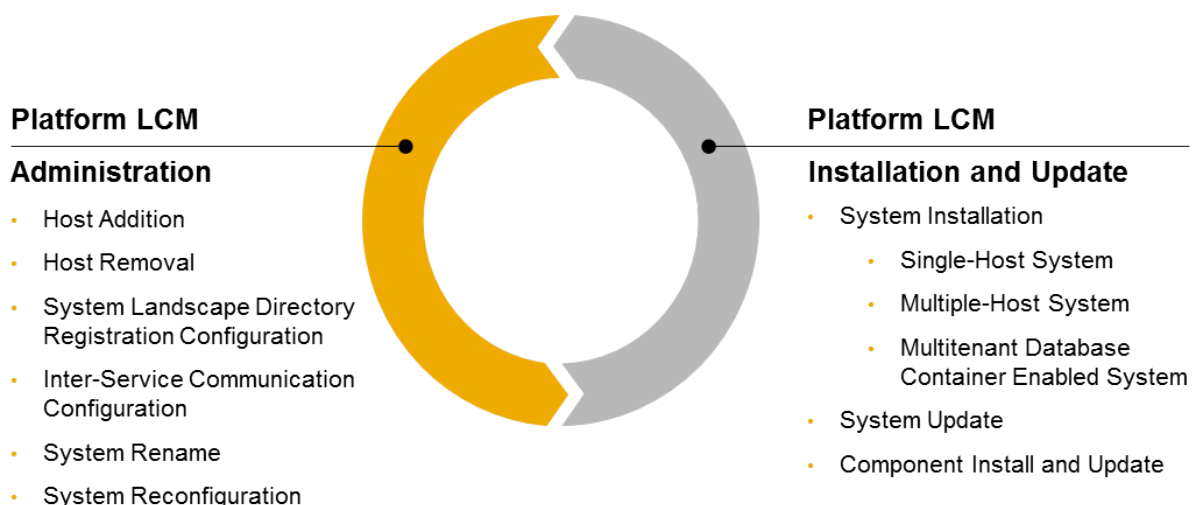

[SAP HANA Platform Lifecycle Management \[page 1050\]](#)

[SAP HANA Application Lifecycle Management \[page 1083\]](#)

## 9.1 SAP HANA Platform Lifecycle Management

After the SAP HANA system is installed, it can be configured on the system level.

The SAP HANA platform lifecycle management (LCM) information in this *SAP HANA Administration Guide* details platform administration and configuration. For information about installing and updating the SAP HANA system, see the *SAP HANA Server Installation and Update Guide* on SAP Help Portal.

The SAP HANA database lifecycle manager provides flexibility to accommodate all types of administrators. Before performing administration tasks using the SAP HANA database lifecycle manager, consider reviewing the topic *Using the SAP HANA Platform LCM Tools* to understand the available user interfaces, interaction modes, and parameter entry methods.

You can use the SAP HANA database lifecycle manager to perform the following administration tasks:

- Configure the system
  - Configure a multiple-host system
    - Add one or more hosts to a system
    - Remove one or more hosts from a system
  - Configure a connection to the System Landscape Directory (SLD)
  - Configure inter-service communication
- Change the existing system
  - Change the system identifiers
    - Rename system hosts
    - Change the SID
    - Change the instance number
  - Reconfigure the system
    - Relocate the system to new hardware
    - Copy or clone the system
    - Convert the system to a multitenant database container enabled system

## 9.1.1 About the SAP HANA Database Lifecycle Manager (HDBLCM)

The SAP HANA database lifecycle manager (HDBLCM) is used to install, update, or configure an SAP HANA system. You can use the SAP HANA database lifecycle manager in graphical user, command-line, or Web user interface.

### 9.1.1.1 Using the SAP HANA Platform LCM Tools

The SAP HANA database lifecycle manager (HDBLCM) is used to perform SAP HANA platform lifecycle management (LCM) tasks, including installing, updating, and configuring an SAP HANA system. The SAP HANA database lifecycle manager is designed to accommodate hardware partners and administrators, and so it offers a variety of usage techniques.

The SAP HANA database lifecycle manager is used by means of program interface type, program interaction mode, and parameter entry mode. Before using the SAP HANA database lifecycle manager, you should choose which user interface you prefer to use and how you want to modify the platform LCM task to achieve your desired result. You modify the actions of the platform LCM tools using parameters. Parameters can be modified in a number of ways, for example, in the entry field of a graphical interface, as a call option with the program call, or in a configuration file. These options can be mixed and matched depending on the parameters you need to use and the program interaction mode you choose.

Platform LCM Tools and Program Interaction Modes

	Interactive Mode	Advanced Interactive Mode	Batch Mode
Graphical User Interface	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input type="checkbox"/>
Command-Line Interface	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
Web User Interface	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

The first choice to make is which SAP HANA database lifecycle manager (HDBLCM) interface type you prefer to use. The SAP HANA HDBLCM program can be run as a graphical user interface, a command-line interface, or as Web user interface in a Web browser (the Web user interface is not available for all platform LCM tasks).

Once you've chosen the graphical user, command-line, or Web user interface, you can decide if you prefer to interactively enter parameter values, or give all required parameters with the call to the platform LCM tool, and let it run unattended to completion. Interactive mode is available for all user interfaces, and is the default mode for program interaction. To use interactive mode, you simply call the SAP HANA HDBLCM user interface, and enter parameter values as they are requested by the program. Advanced interactive mode involves entering some parameter values interactively and providing some parameter values as call options or in a configuration file. This is the recommended interaction mode if you'd like to modify parameter default values which are not requested in interactive mode. Batch mode is an advanced platform LCM interaction method because all required parameters must be provided with the call to the LCM program on the command line. Batch mode is designed for large-scale platform LCM tasks, which would be time consuming to perform interactively.

Platform LCM parameters can be entered interactively (only available for interactive mode or advanced interactive mode), as a call option on the command line, or via a configuration file. If you are performing platform LCM tasks in advanced interactive mode, you can choose any of the three parameter entry methods

(or use more than one). If you are using batch mode, you must enter parameter values either as call options to the SAP HANA database lifecycle manager or from a configuration file. The syntax for the parameters as call options can be found in the *Parameter Reference*. The configuration file is generated as a blank template, then edited, and called as a call option.

## Related Information

[Use Interactive Mode to Perform Platform LCM Tasks \[page 1061\]](#)

[Use Advanced Interactive Mode to Perform Platform LCM Tasks \[page 1062\]](#)

[Use Batch Mode to Perform Platform LCM Tasks \[page 1064\]](#)

### 9.1.1.1.1 Choosing the Correct SAP HANA HDBLCM for Your Task

It is important to distinguish between the version of the SAP HANA database lifecycle manager (HDBLCM) that is available on the installation medium and the version that is unpacked during installation, and subsequently used to perform administration and configuration tasks after the SAP HANA system has been installed.

The SAP HANA database lifecycle manager is available in two varieties - an installation medium version to perform installation and update, and a resident version for update and configuration that is unpacked on the SAP HANA host during installation or update. The SAP HANA resident HDBLCM has been designed to be version-compatible. That means, every time you install or update an SAP HANA system, you can be sure that any subsequent configuration tasks performed with the SAP HANA database lifecycle manager will work as expected because the installation or update tool and the configuration tool are of the same version and have been tested together. The SAP HANA resident HDBLCM is located at `<sapmnt>/<SID>/hdb1cm`.

### 9.1.1.1.2 Performing LCM Tasks by Program Interface

SAP HANA platform lifecycle management tasks can be performed from a graphical, command-line and Web user interface.

## Related Information

[Use the Graphical User Interface to Perform Platform LCM Tasks \[page 1054\]](#)

[Use the Command-Line Interface to Perform Platform LCM Tasks \[page 1055\]](#)

[Using the Web User Interface \[page 1056\]](#)

## 9.1.1.1.2.1 Use the Graphical User Interface to Perform Platform LCM Tasks

SAP HANA platform lifecycle management tasks can be performed from a graphical interface.

### Procedure

1. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
Installation Medium (Intel-Based Hardware Platforms)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_X86_64</pre>
Installation Medium (IBM Power Systems)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_PPC64</pre>
SAP HANA resident HDBLCM	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdblcmm</pre>

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the two SAP HANA database lifecycle manager types, see Related Information.

2. Start the SAP HANA platform lifecycle management tool:

```
./hdblcmmgui
```

3. Enter parameter values in the requested fields. In addition, you can specify parameter key-value pairs as call options or in the configuration file template.

#### **i** Note

If parameter key-value pairs are specified as command-line options, they override the corresponding parameters in the configuration file. Parameters in the configuration file override default settings.

#### **Order of parameter precedence:**

Command Line > Configuration File > Default

For more information about program interaction modes and parameter values entry methods, see Related Information.

### Related Information

[Choosing the Correct SAP HANA HDBLCM for Your Task \[page 1053\]](#)

[Entering Platform LCM Parameters as Call Options from the Command Line \[page 1068\]](#)

## 9.1.1.1.2.2 Use the Command-Line Interface to Perform Platform LCM Tasks

SAP HANA platform lifecycle management tasks can be performed from the command line.

### Procedure

1. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
Installation Medium (Intel-Based Hardware Platforms)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_X86_64</pre>
Installation Medium (IBM Power Systems)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_PPC64</pre>
SAP HANA resident HDBLCM	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdbldcm</pre>

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the two SAP HANA database lifecycle manager types, see Related Information.

2. Start the SAP HANA platform lifecycle management tool:

```
./hdbldcm
```

3. Enter parameter values in one of the following ways.
  - **Interactive parameter entry** - If you call the SAP HANA platform LCM tool only, the program runs in interactive mode. Parameter default values are suggested in brackets, and can be accepted with *Enter*. Otherwise, enter a non-default value, then select *Enter*.
  - **Command-line parameter entry as call options** - If you enter parameter key-value pairs as call options with the call to the SAP HANA platform LCM tool, the program runs in advanced interactive mode and requests values for any parameter values which you didn't specify in the original input. If you entered the batch mode call option, the program runs to completion without any further requests, unless a mandatory parameter was left out of the original input, in which case, the program fails to perform the platform LCM task.
  - **Configuration file parameter entry** - If you enter parameter key-value pairs in the configuration file template, and enter the configuration file path as a call option with the call to the SAP HANA platform LCM tool, the program runs in advanced interactive mode and requests values for any parameter values which you didn't specify in the original input. If you entered the batch mode call option, the program runs to completion without any further requests, unless a mandatory parameter was left out of the original input, in which case, the program fails to perform the platform LCM task.

#### Note

If parameter key-value pairs are specified as command-line options, they override the corresponding parameters in the configuration file. Parameters in the configuration file override default settings.

#### Order of parameter precedence:

Command Line > Configuration File > Default

For more information about program interaction modes and parameter values entry methods, see [Related Information](#).

## Related Information

[Performing LCM Tasks by Parameter Entry Method \[page 1065\]](#)

[Performing LCM Tasks by Program Interaction Mode \[page 1061\]](#)

[Entering Platform LCM Parameters as Call Options from the Command Line \[page 1068\]](#)

### 9.1.1.1.2.3 Using the Web User Interface

SAP HANA platform lifecycle management tasks can be performed using the SAP HANA database lifecycle manager (HDBLCM) Web user interface.

#### 9.1.1.1.2.3.1 About the Web User Interface

The SAP HANA database lifecycle manager (HDBLCM) Web user interface is hosted by the SAP Host Agent, which is installed on the SAP HANA host. When installing or updating the SAP HANA system, as part of the SAP HANA resident HDBLCM configuration, the SAP HANA system deploys its artifacts on the SAP Host Agent, thus enabling the Web user interface.

All Web user interface actions are always performed in the context of an already installed and registered SAP HANA system. In order to access the SAP HANA database lifecycle manager Web user interface you need to log on as the system administrator user `<sid>adm`.

The communication between the Web browser and the SAP Host Agent is always done over HTTPS, which requires that the SAP Host Agent has a secure sockets layer (SSL) certificate (PSE) in its security directory. For more information about SSL certificate handling, see [Related Information](#).

The backend is provided by the special executable `hdb1cmweb`, which is started automatically by the SAP Host Agent as soon as an action is triggered from the Web user interface and terminates after the action completes.

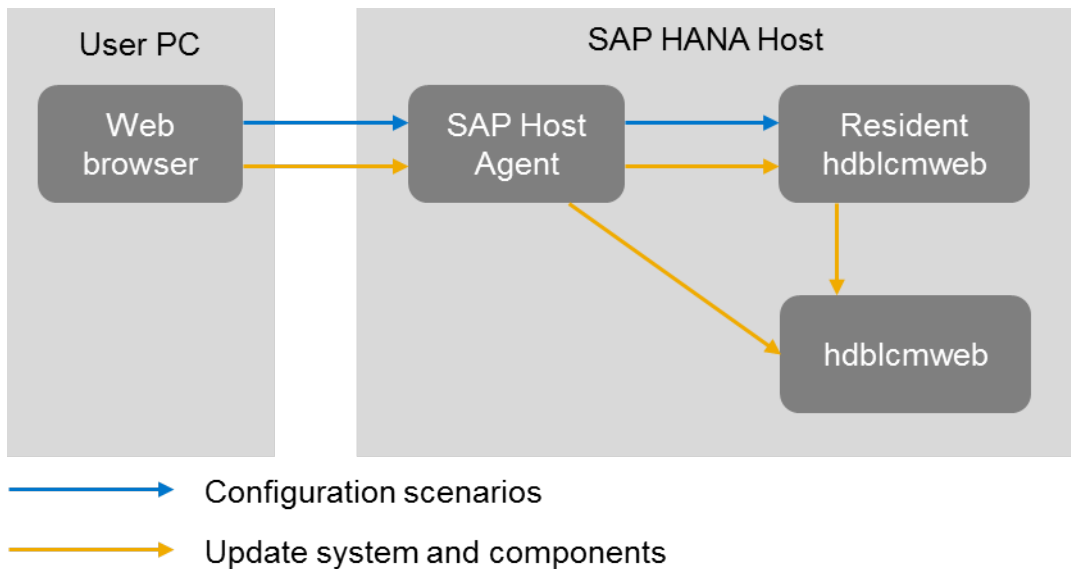

#### i Note

You should never start `hdb1cmweb` manually. For security reasons, `hdb1cmweb` is always started with system administrator user `<sid>adm` privileges. If you require logging with individual users (to ensure personalized logging), use the SAP HANA database lifecycle manager graphical user or command-line interface.

## i Note

Make sure that the system administrator user `<sid>adm` has permissions to read the paths, passed as parameters in the Web user interface (for example, the SAP HANA database installation kit or locations with SAP HANA components).

One platform LCM task, which is worth special attention is the update of the SAP HANA system and components. The SAP HANA system updates are always performed by the installation kit SAP HANA database lifecycle manager in the graphical user and command-line interfaces, (and not the SAP HANA resident HDBLCM). This is because the SAP HANA database lifecycle manager, in the graphical user and command-line interfaces, is not forward compatible. Meaning that only the new version of the tool knows how to update an older system.

On the other hand, all scenarios in the Web user interface are handled by the SAP HANA resident HDBLCM, which is part of the system. For this reason, as a first step before even starting the update process, you are required to enter a location of an SAP HANA database installation kit. After detecting the kit, the update Web user interface is loaded from the installation kit and the installation kit SAP HANA database lifecycle manager starts serving as backend until the update process finishes. It is as if you start the SAP HANA database lifecycle manager directly from the installation kit in graphical user or command-line interface.

## Related Information

[Secure Sockets Layer \(SSL\) Certificate Handling \[page 1071\]](#)

## 9.1.1.1.2.3.2 Use the Web User Interface to Perform Platform LCM Tasks

The SAP HANA database lifecycle manager (HDBLCM) can be accessed as a Web user interface in either a standalone browser or in the SAP HANA cockpit.

### Prerequisites

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing **Tools > Compatibility View Settings**.
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release
    - Google Chrome - Latest version
  - SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
  - Mac OS - Safari 5.1 or higher

#### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

### Context

The Web user interface supports only the following SAP HANA platform lifecycle management tasks:

- View system information
- Update system and components
- Install or update additional components
- Configure System Landscape Directory (SLD) registration
- Configure inter-service communication

When performing installation and update tasks, various parameters can be set in the [Advanced Parameters Configuration](#) dialog. To access the [Advanced Parameters Configuration](#) dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

## Procedure

Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser: <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>  <b>i Note</b> The URL is case sensitive. Make sure you enter upper and lower case letters correctly.
<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"><li>1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code>  <b>i Note</b> FQDN = fully qualified domain name</li><li>2. Drill down on the name of the system from <a href="#">My Resources</a> or from a group.</li><li>3. The links in <a href="#">Platform Lifecycle Management</a> each launch additional functionality, giving you expanded capabilities for managing the resource.</li></ol>

## Results

The SAP HANA database lifecycle manager is displayed as a Web user interface in either a standalone browser or in the SAP HANA cockpit.

## Related Information

[SAPUI5 Developer Guide](#)

[Add an SAP HANA System \[page 132\]](#)

### 9.1.1.1.2.3.3 Log Off From an SAP HANA System

In the SAP HANA database lifecycle manager (HDBLCM) Web user interface, you can log off from an SAP HANA system and close all connections to the system. To be able to connect to system again, you must log on.

#### Procedure

- To log off from a system click the *Log out* button.  
All open connections to the system are closed.

#### i Note

Currently, this feature is not available for browsers on mobile devices.

### 9.1.1.1.2.3.4 Troubleshooting the Web User Interface

If you have problems with the Web user interface, see SAP Note 2078425 for steps you can take to troubleshoot and resolve them.

#### i Note

The Web browser used to render the platform lifecycle management Web user interface in the SAP HANA studio **cannot** be changed via ► *Windows* ► *Preferences* ► *General* ► *Web Browser* ►.

#### Related Information

[SAP Note 2078425 - Troubleshooting note for SAP HANA Platform Management tool hdbclm](#) 

## 9.1.1.1.3 Performing LCM Tasks by Program Interaction Mode

SAP HANA platform lifecycle management tasks can be performed in interactive mode, advanced interactive mode and batch mode.

### 9.1.1.1.3.1 Use Interactive Mode to Perform Platform LCM Tasks

Interactive mode is a method for running SAP HANA platform lifecycle management (LCM) tools which starts the program and requires you to enter parameter values successively before the program is run. Interactive mode is the default mode for the SAP HANA platform LCM tools.

#### Context

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the different SAP HANA database lifecycle manager types, see Related Information.

The SAP HANA platform LCM tools offer a wide variety of parameters which can modify the platform LCM task you are performing. Some parameters can be modified in interactive mode when the graphical user, command-line, or Web user interface requests a value for a given parameter.

#### Procedure

1. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
Installation Medium (Intel-Based Hardware Platforms)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_X86_64</pre>
Installation Medium (IBM Power Systems)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_PPC64</pre>
SAP HANA resident HDBLCM	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdb1cm</pre>

To access the SAP HANA database lifecycle manager Web user interface, see Related Information.

2. Start the SAP HANA platform lifecycle management tool:

Option	Description
Graphical Interface	<code>./hdblcmgui</code>
Command-line Interface	<code>./hdb lcm</code>

To start the SAP HANA platform LCM tools in interactive mode, simply **do not** enter the parameter for batch mode (`--batch` or `-b`) as a call option. You can enter any other required parameters as call options or load a configuration file. The program runs in interactive mode and requests any missing parameters values, which must be verified or changed. You are provided with a summary of parameter values, which you can accept to run the program to completion, or reject to exit the program.

## Related Information

[Choosing the Correct SAP HANA HDBLCM for Your Task \[page 1053\]](#)

[Use the Web User Interface to Perform Platform LCM Tasks \[page 1058\]](#)

### 9.1.1.1.3.2 Use Advanced Interactive Mode to Perform Platform LCM Tasks

Interactive mode is a method for running SAP HANA platform lifecycle management (LCM) tools which starts the program and requires you to enter parameter values successively before the program is run. If you would like to enter call options not available in interactive mode, or make use of the configuration file, you can use a combination of interactive mode and advanced parameter entry methods.

## Context

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the different SAP HANA database lifecycle manager types, see Related Information.

The SAP HANA platform LCM tools offer a wide variety of parameters which can modify the platform LCM task you are performing. Some parameters can be modified in interactive mode when the graphical user, command-line, or Web user interface requests a value for a given parameter. However, some parameters are not available in interactive mode, and must be specified either as a call option with the call to the platform LCM tool, or from within a configuration file.

## Procedure

1. Review which parameters are offered in interactive mode.

If the parameter you want to configure is not available in interactive mode, you have two options. You can either enter the parameter key-value pair as a call option with the call to the platform LCM tool. Alternatively, you can generate a configuration file template, and edit the parameters value in the configuration file. Then call the configuration file as a call option with the call to the platform LCM tool.

Using the configuration file for interactive mode is recommended if you plan to perform the exact same platform LCM task multiple times.

2. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
Installation Medium (Intel-Based Hardware Platforms)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/HDB_LCM_LINUX_X86_64</pre>
Installation Medium (IBM Power Systems)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/HDB_LCM_LINUX_PPC64</pre>
SAP HANA resident HDBLCM	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdblcmm</pre>

3. If you plan to use a configuration file, prepare it with the following steps:

- a. Generate the configuration file template using the SAP HANA platform lifecycle management tool:

Run the SAP HANA platform LCM tool using the parameter `dump_configfile_template` as a call option. Specify an action and a file path for the template. A configuration file template and a password file template are created.

```
./hdblcmm --action=<LCM action> --dump_configfile_template=<file path>
```

- b. Edit the configuration file parameters. Save the file.
- c. Edit the password file. Save the file.

4. Start the SAP HANA platform lifecycle management tool:

Start the SAP HANA database lifecycle manager in either the graphical user interface or in the command-line interface, with a call option:

```
./hdblcmmgui --<parameter key>=<parameter value>
```

or

```
./hdblcmm --<parameter key>=<parameter value>
```

If you are using a configuration file, you must use the call option `--configfile=<file path>`.

## Related Information

[Choosing the Correct SAP HANA HDBLCM for Your Task \[page 1053\]](#)

### 9.1.1.1.3.3 Use Batch Mode to Perform Platform LCM Tasks

Batch mode is a method for running the SAP HANA database lifecycle manager which starts the program and runs it to completion without requiring you to interact with it any further. All required parameter values must be passed as call options or from a configuration file.

#### Prerequisites

- When using batch mode, passwords must either be defined in the configuration file, or passed to the installer using an XML password file and streamed in via standard input. In both cases, it is necessary to prepare the passwords. For more information, see *Specifying Passwords*.

#### Context

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the different SAP HANA database lifecycle manager types, see Related Information.

If you are new to performing the desired SAP HANA platform LCM task in batch mode, it is recommended to run some tests before using batch mode in a production environment.

#### Procedure

1. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
Installation Medium (Intel-Based Hardware Platforms)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_X86_64</pre>
Installation Medium (IBM Power Systems)	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_PPC64</pre>
SAP HANA resident HDBLCM	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdblcmlcm</pre>

2. Start the SAP HANA platform lifecycle management tool:

```
./hdblcmlcm --batch <additional parameters>
```

or

```
./hdblcmlcm -b <additional parameters>
```

It is mandatory to provide an SAP HANA system ID (SID) and user passwords during installation. In batch mode, you are restricted to providing these parameter values as call options on the command line (for passwords, by means of an XML file) or in a configuration file. If you don't provide parameter values for the other required parameters, you implicitly accept the default values.

## Example

The following example installs the SAP HANA server and client as a single-host system. The SAP system ID and instance number are also specified from the command line. The system passwords are read from a standard input stream by the installer. All other parameter defaults are automatically accepted and no other input is requested in order to complete the installation.

```
cat ~/hdb_passwords.xml | ./hdblcm --batch --action=install --
components=client,server --sid=DB1 --number=42 --read_password_from_stdin=xml
```

If a configuration file is used in combination with batch mode, an identical system can be installed with a simplified call from the command line. In the following example, passwords are defined in the configuration file, in addition to the action, components, SAP system ID, and instance number.

```
./hdblcm --batch --configfile=/var/tmp/H01_configfile
```

## Related Information

[Choosing the Correct SAP HANA HDBLCM for Your Task \[page 1053\]](#)

[Specifying Passwords](#)

[Use LCM Configuration Files to Enter Parameters \[page 1066\]](#)

[Entering Platform LCM Parameters as Call Options from the Command Line \[page 1068\]](#)

### 9.1.1.1.4 Performing LCM Tasks by Parameter Entry Method

SAP HANA platform lifecycle management (LCM) parameter values can be entered in a variety of methods: interactively by iteratively providing values in either the graphical interface or command prompt, as command-line options with the call to the platform LCM tool, or in a configuration file.

SAP HANA platform lifecycle management parameter values allow you to customize your SAP HANA installation, update, or configuration. Parameter values can be entered by **one or more** of the following methods:

<b>Interactively (Default)</b>	Using either command line interface, the graphical interface or the Web user interface, most parameters are requested interactively. Default parameter values are proposed in brackets and can be changed or confirmed. Parameters that are not requested (or specified via another method) accept the default value.
--------------------------------	---

**Command Line Options** Parameters are given in their accepted syntax as a space delimited list after the program call (for example, `hdblcm` or `hdblcmgui`). The specified parameters replace the defaults. If any mandatory parameters are excluded, they are requested interactively (unless batch mode is specified). All parameters can be entered from the command line. For more details about the accepted parameter syntax, see the inline help output (`--help`) for the individual SAP HANA lifecycle management tool.

**Configuration File** The configuration file is a plain text file, for which a template of parameter key-value pairs can be generated, edited, and saved to be called in combination with the program call. If any mandatory parameters are not specified, they are requested interactively (unless batch mode is used). All parameters can be entered in the configuration file. For more information about the configuration file, see Related Information.

### i Note

If parameters are specified in the command line, they override the corresponding parameters in the configuration file. Parameters in the configuration file override default settings.

#### **Order of parameter precedence:**

Command Line > Configuration File > Default

## 9.1.1.1.4.1 Entering Platform LCM Parameters Interactively

SAP HANA platform LCM interactive mode is default interaction mode for all platform LCM programs and interfaces.

You can run the graphical, command-line, or Web user interface in interactive mode by simply starting the program, and entering parameter values as they are requested by the program. In interactive mode, parameter default values are suggested in brackets and can be accepted with `[Enter]`.

Not all parameters are requested in interactive mode. If you would like to configure a parameter not offered in interactive mode, you must enter it as a call option with the call to the platform LCM program, or use corresponding configuration file for the platform LCM task.

## 9.1.1.1.4.2 Use LCM Configuration Files to Enter Parameters

By defining a prepared configuration file during installation, specified parameter values are used by the SAP HANA platform lifecycle management (LCM) tools to build a customized SAP HANA system.

### Context

The configuration file is a plain text file of specified parameters, written in the same syntax as in the command line (except without the leading two dashes `--`). A configuration file template can be generated, edited, and saved to be called with the call to the SAP HANA database lifecycle manager (HDBLCM).

The configuration file template provides a brief, commented-out summary of each parameter. Each parameter is set to its default value.

## Procedure

1. Change to the directory where the SAP HANA database lifecycle manager is located:

Option	Description
<b>Installation Medium (Intel-Based Hardware Platforms)</b>	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_X86_64</pre>
<b>Installation Medium (IBM Power Systems)</b>	<pre>cd &lt;installation medium&gt;/DATA_UNITS/ HDB_LCM_LINUX_PPC64</pre>
<b>SAP HANA resident HDBLCM</b>	<pre>cd &lt;sapmnt&gt;/&lt;SID&gt;/hdblcmm</pre>

In general, installation and update is carried out from the installation medium. Configuration tasks are performed using the SAP HANA resident HDBLCM. For more information about the two SAP HANA database lifecycle manager types, see Related Information.

2. Generate the configuration file template using the SAP HANA platform lifecycle management tool:

Run the SAP HANA platform LCM tool using the parameter `dump_configfile_template` as a call option. Specify an action and a file path for the template. A configuration file template and a password file template are created.

```
./hdblcmm --action=<LCM action> --dump_configfile_template=<file path>
```

3. Edit the configuration file parameters. Save the file.

It is recommended that at least the SAP system ID (`sid`) and the instance number (`number`) are uniquely defined. There are several required parameters, that are provided default values in case they are not customized. For more information, refer to the default values.

Some file path parameters have automatic substitution values as part of the default file path, using the `sid` (SAP HANA system ID) and `sapmnt` (installation path) parameters, so that the substituted values create file paths that are unique and system-specific. For example, the default for the data file path is: `datapath=/hana/data/${sid}`, where `sid` is automatically replaced by the unique SAP HANA system ID.

4. Start the SAP HANA platform lifecycle management tool:

Run the SAP HANA platform LCM tool using the parameter `configfile` as a call option. Specify the file path of the edited template.

```
./hdblcmm --configfile=<file path>
```

You can specify the path to a directory in which custom configuration files are saved using the parameter `custom_cfg` as a call option.

## Related Information

[custom\\_cfg](#)

[Choosing the Correct SAP HANA HDBLCM for Your Task \[page 1053\]](#)

### 9.1.1.1.4.3 Entering Platform LCM Parameters as Call Options from the Command Line

Call options are available for every SAP HANA platform LCM program.

You can use call options for a number of reasons:

- The parameter is not available in interactive mode, but can be entered as a call option.
- You are using batch mode.
- You are using a configuration file, but would like to override a parameter in the configuration file with a new value.
- You are installing an SAP HANA multiple-host system from the command line.

A call option is entered with the following notation:

```
./<program call> --<parameter1 key>=<parameter1 value> --<parameter2 key>=<parameter2 value>
```

Call options start with a double dash (--) if they are written in long-form syntax. Some parameters also have short-form syntax, in which they are preceded with a single dash (-). For more information about call option syntax, see the *Parameter Reference* topics.

## Related Information

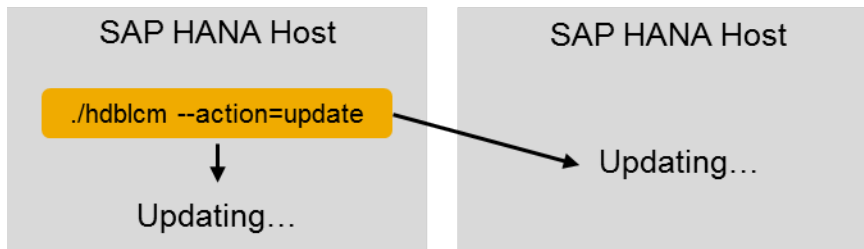

[Parameter Reference](#)

### 9.1.1.1.5 Executing Platform LCM Tasks

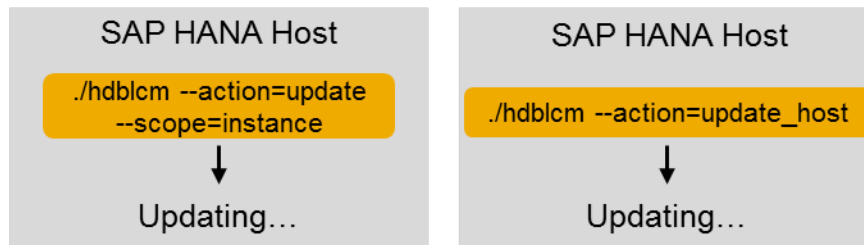

SAP HANA platform lifecycle management tasks can be performed on multiple-host systems centrally, by running the SAP HANA database lifecycle manager (HDBLCM) from any worker host and using remote execution to replicate the call on all remaining system hosts. Otherwise, the platform LCM tasks can be executed first on a worker host, and then re-executed manually on each remaining host. This method is considered decentralized execution.

The following is an example of an SAP HANA system update performed centrally and decentrally.

### Centralized Execution

### Decentralized Execution

## Related Information

[Centralized Execution of Platform LCM Tasks \[page 1069\]](#)

[Decentralized Execution of Platform LCM Tasks \[page 1074\]](#)

### 9.1.1.1.5.1 Centralized Execution of Platform LCM Tasks

SAP HANA platform lifecycle management (LCM) tasks can be performed centrally on multiple-host SAP HANA systems in a number of ways depending on the available certificate keys and the remote execution configuration.

#### 9.1.1.1.5.1.1 Using Secure Shell (SSH) to Execute Platform LCM Tasks

An SAP HANA system must be installed with root user credentials. During installation a secure shell (SSH) key is configured so that future platform LCM tasks can be performed remotely on multiple-host SAP HANA systems without requiring the root user password.

By default, the SAP HANA database lifecycle manager (HDBLCM) uses SSH during SAP HANA system installation or update. In order to use SSH, the SFTP subsystem must be active. Install the SAP Host Agent on

all system hosts to perform platform LCM tasks without root credentials. Once the SAP Host Agent is installed, it is used to perform any platform LCM tasks executed from the Web user interface or as the system administrator user `<sid>adm`.

### **i** Note

Platform LCM tasks cannot be executed remotely via SSH as the system administrator user `<sid>adm`.

The root user name must be the same for all hosts in a multiple-host system. The password of the root user must be identical on all hosts. If the passwords are not identical on all hosts or if you do not want to pass the passwords to the SAP HANA database lifecycle manager (HDBLCM), SSH keys can be distributed between the hosts in advance. Alternatively, platform LCM tasks can be executed without root credentials by using the SAP Host Agent.

## Related Information

[SAP Note 1944799 - SAP HANA Guidelines for SLES Operating System Installation](#)

[SAP Note 2009879 - SAP HANA Guidelines for Red Hat Enterprise Linux \(RHEL\) Operating System](#)

[Using SAP Host Agent to Execute Platform LCM Tasks \[page 1070\]](#)

## 9.1.1.1.5.1.2 Using SAP Host Agent to Execute Platform LCM Tasks

Platform LCM tasks can be executed without root credentials by using the SAP Host Agent. The SAP Host Agent is installed and updated by default during SAP HANA system installation and update.

The SAP HANA database lifecycle manager (HDBLCM) relies on the SAP Host Agent for the following functionality to work:

- Execution as the system administrator user `<sid>adm`
- Connectivity to remote hosts via HTTPS (when no SSH or root user credentials are available)
- Execution from the SAP HANA database lifecycle manager Web user interface

### **i** Note

The SAP HANA cockpit uses the SAP Host Agent to execute tasks as the system administrator user `<sid>adm`, for example, stopping and starting the system, or troubleshooting a system experiencing performance problems.

If execution on the remote hosts is done via SSH (default, `--remote_execution=ssh`), the SAP HANA database lifecycle manager is able to connect to a remote host via SSH and install and configure the SAP Host Agent. In contrast, the remote execution via SAP Host Agent (`--remote_execution=saphostagent`) requires that the SAP Host Agent is installed and configured on all involved hosts in advance, which includes:

- Install SAP Host Agent
- Configure a Secure Sockets Layer (SSL) certificate for the SAP Host Agent, so that the HTTPS port 1129 is accessible. If you don't want to configure HTTPS, it is also possible to use the call option `--use_http`. It

tells the SAP HANA database lifecycle manager to communicate with the SAP Host Agent via HTTP. During the addition of new hosts to an SAP HANA system (also during the installation of a multiple-host system), the HTTPS of the SAP Host Agent is automatically configured by the SAP HANA database lifecycle manager.

### ⚠ Caution

Use the call option `--use_http` with caution, because passwords are also transferred in plain text via HTTP.

## Related Information

[SAP Host Agent](#)

[Configuring SSL for SAP Host Agent on UNIX](#)

### 9.1.1.1.5.1.2.1 Secure Sockets Layer (SSL) Certificate Handling

To enable secure communication with the SAP Host Agent over HTTPS, the SAP Host Agent needs a secure sockets layer (SSL) certificate in its security directory. This certificate is also used by the SAP HANA database lifecycle manager (HDBLCM) Web-based user interface because the Web pages are served by the SAP Host Agent.

The SAP HANA database lifecycle manager handles certificate management during system installation, update, or rename, as well as during the addition of new hosts as follows:

- If there is no certificate in the SAP Host Agent security directory, the SAP HANA database lifecycle manager generates one. The SAP HANA host name is used as the default certificate owner. The certificate owner can be changed by using the call option `--certificates_hostmap=<fully_qualified_domain_name>`.
- If there is an existing certificate, the following applies:
  - If the certificate host name is not passed to the SAP HANA database lifecycle manager, or if the certificate host name is the same as the owner of the current certificate, the current certificate is preserved.
  - If the certificate host name is passed via the call option `--certificates_hostmap` and it differs from the owner of the current certificate, a new certificate is generated.
  - During update of an SAP HANA system, if the certificates on all hosts are in place, the call option `--certificates_hostmap` is ignored and the current certificates are preserved.

If you want to use your own SSL certificates, see the SAP Host Agent documentation in Related Information.

## Related Information

[certificates\\_hostmap](#)

[SAP Note 1907566 - Accessing the Latest SAP Host Agent Documentation](#) 

[SSL Configuration for the SAP Host Agent](#)

### 9.1.1.1.5.1.2.2 Starting Platform LCM Tasks as the System Administrator User <sid>adm

When starting platform LCM tasks as the system administrator user <sid>adm, the SAP HANA database lifecycle manager (HDBLCM) requires the usage of SAP Host Agent for execution of remote and local operations.

The following tasks in the SAP HANA database lifecycle manager can be performed as the system administrator user <sid>adm:

- System update from the installation medium
- Installation or update of additional components from the SAP HANA resident HDBLCM
- Host addition and host removal
- System Landscape Directory (SLD) registration configuration
- Inter-service communication configuration

Make sure that SAP Host Agent is installed and configured (HTTPS-enabled) on all hosts of the SAP HANA system.

#### i Note

Platform LCM tasks cannot be executed remotely via SSH as the system administrator user <sid>adm.

#### i Note

Make sure that the system administrator user <sid>adm has permissions to read the paths passed as parameters (for example, the locations of the SAP HANA components).

### 9.1.1.1.5.1.2.3 Add Hosts Using SAP Host Agent

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in combination with the SAP Host Agent in the command-line interface.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).

- The host which is to be added has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP Host Agent is installed on the host which is to be added. The SAP Host Agent will create the `<sapsys>` group, if it does not exist prior to installation. Make sure that the group ID of the `<sapsys>` group is the same on all hosts. For information about installing or updating the SAP Host Agent individually, see *Installing SAP Host Agent Manually* and *Upgrading SAP Host Agent Manually*.
- A Secure Sockets Layer (SSL) certificate is configured for the SAP Host Agent, so that the HTTPS port 1129 is accessible and the Personal Security Environment (PSE) for the server is prepared. For more information about SSL configuration for the SAP Host Agent, see *Configuring SSL for SAP Host Agent on UNIX*.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcmlcm
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcmlcm --remote_execution=saphostagent
```

3. Select the index for the `add_hosts` action.
4. Enter the names of the hosts to be added.
5. Enter the SAP Host Agent administrator (`sapadm`) password.
6. Define additional system properties.
7. Review the summary, and select `y` to finalize the configuration.

## Results

You have added one or more new hosts to an SAP HANA system. The SAP HANA system you have configured is a multiple-host system.

The new hosts have been added to the SAP HANA landscape information. The new hosts have been added to the landscape information of the system database.

This configuration task can also be performed in batch mode and using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

### 9.1.1.1.5.2 Decentralized Execution of Platform LCM Tasks

In some circumstances platform LCM actions must be executed on each individual host of the multiple-host system. This is referred to as **decentralized execution**.

Typically, SAP HANA platform lifecycle management actions, such as update, rename, and inter-service communication configuration, can be performed on a multiple-host system from one host. This is referred to as **centralized execution** and requires SSH or root credentials. For more information, see Centralized Execution of Platform LCM Tasks in Related Information.

In some circumstances, a secure shell (SSH) key may not be installed or root credentials are not available. In this case, the platform LCM actions must be executed on each individual host of the multiple-host system, which is also known as **decentralized execution**. For more information about decentralized execution, see SAP Note 2048681 in Related Information.

## Related Information

[SAP Note 2048681 - Performing SAP HANA platform lifecycle management administration tasks on multiple-host systems without SSH or root credentials](#)

## 9.1.1.1.6 Additional Information About Using the SAP HANA Platform LCM Tools

If you have already familiarized yourself with the way the SAP HANA database lifecycle manager (HDBLCM) works, you may be interested in additional information like log and trace files, Linux kernel parameter settings, or troubleshooting.

### Related Information

[Logging \[page 1075\]](#)

[Linux Kernel Parameters \[page 1076\]](#)

[General Troubleshooting for the SAP HANA Platform LCM Tools \[page 1077\]](#)

### 9.1.1.1.6.1 Logging

SAP HANA platform lifecycle management processes are logged by the system. The log files are stored in the following path:

```
/var/tmp/hdb_<SID>_<action>_<time stamp>
```

where <action> ::= install | update | addhost | uninstall | and so on.

The following log files are written while performing the action:

- <hdbcommand>.log: can be read using a text editor
- <hdbcommand>.msg: XML format for display in the installation tool with the GUI
- <hostname>\_tracediff.tgz: provides a delta analysis of the original trace files, makes a detailed analysis easier

You can also view diagnostic files in the SAP HANA database explorer using the administration function. For more information, see *View Diagnostic Files in the SAP HANA Database Explorer* in the *SAP HANA Administration Guide*.

#### Instant Logging

If an LCM action crashes or hangs before the execution is finished, even if no LCM action trace is enabled, HDBLCM writes a trace, which has the function of a preliminary (unformatted) log file. Upon program completion, this preliminary logfile is removed and replaced by the real, formatted log file.

The environment variable `HDB_INSTALLER_TRACE_FILE=<file>` enables the trace.

The environment variable `HDBLCM_LOGDIR_COPY=<target directory>` creates a copy of the log directory.

#### Log Collection

If you perform platform LCM actions on multiple-host SAP HANA systems, all log files are collected to a local folder to make error analysis more convenient.

To collect log files for multiple-host SAP HANA systems, an HDBLCM action ID is passed to each sub-program (underlying LCM tool) working on a remote host. Each sub-program writes a copy of the log file in to the following directory: `<installation path>/<SID>/HDB<instance number>/<host name>/trace`

## Related Information

### 9.1.1.1.6.2 Linux Kernel Parameters

The following table describes the parameters and limits that are set by the SAP HANA database lifecycle manager (HDBLCM) during the installation or update of an SAP HANA database. The actual values may differ, depending on your system configuration.

#### i Note

The SAP HANA database lifecycle manager (HDBLCM) will only change existing values if they are lower than the default values.

The SAP Host Agent can automatically optimize the following Linux Kernel Parameters:

- `net.ipv4.ip_local_port_range`
- `net.ipv4.ip_local_reserved_ports`

To configure the SAP Host Agent, make sure that the `/etc/sysctl.conf` configuration does not contain any of these two parameters. Afterwards, configure the SAP Host Agent profile parameters as described in *SAP Note 401162*.

Parameter	Description	Value	Location
<code>nofile</code>	Open file descriptors per user	1048576	<code>/etc/security/limits.conf</code>
<code>fs.file-max</code>	Open file descriptors per host	20000000	<code>/etc/sysctl.conf</code>
<code>fs.aio-max-nr</code>	Maximum number of asynchronous I/O requests	18446744073709551615 (= $2^{64}-1$ ) = <code>ULONG_MAX</code>	<code>/etc/sysctl.conf</code>
<code>vm.memory_failures_early_kill</code>	Method for killing processes when an uncorrected memory error occurs	1	<code>/etc/sysctl.conf</code>
<code>kernel.shmmax</code>	Maximum shared memory segment size (the default minimum value is 1 GB)	1073741824	<code>/etc/sysctl.conf</code>

Parameter	Description	Value	Location
kernel.shmmni	Maximum number of shared memory segments	32768	/etc/ sysctl.conf
kernel.shmall	System-wide limit of total shared memory, in 4k pages	<ul style="list-style-type: none"> <li>RAM &gt;= 35.5 TB: (shmmax * shmmni) / 65536</li> <li>RAM &lt; 35.5 TB: (0.9 * &lt;RAM in bytes&gt;) / 4096</li> </ul>	/etc/ sysctl.conf
net.ipv4.ip_local_port_range	Lower limit of ephemeral port range	40000	/etc/ sysctl.conf
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>No changes are applied if the SAP HANA database lifecycle manager (HDBLCM) detects or installs SAP Host Agent version 7.20.162 or greater.</p> </div>			
vm.max_map_count	Maximum number of Virtual Memory Areas (VMAs) that a process can own	2147483647	/etc/ sysctl.conf

## Related Information

### 9.1.1.1.6.3 General Troubleshooting for the SAP HANA Platform LCM Tools

The SAP HANA database lifecycle manager (HDBLCM) is a wrapper tool that calls the underlying HDB tools to perform the platform LCM action. If something unexpected happens when using HDBLCM, and the LCM action cannot be completed, you can check the logs and separately run the affected underlying tools.

#### ⚠ Caution

We only recommend the following underlying tools to be used for troubleshooting purposes.

Program Name	Description	Location
hdbinst	Command-line tool for installing the software	Installation media
hdbsetup	Installation tool with a graphical interface for installing or updating the software	Installation media
hdbuninst	Command-line tool for uninstalling the software and removing a host	Installation media and <installation path>/ <SID>/global/hdb/ install/bin
hdbaddhost	Command-line tool for adding a host to a system	<installation path>/ <SID>/global/hdb/ install/bin
hdbupd	Command-line tool for updating the software	Installation media
hdbrename	Command-line tool for renaming a system	<installation path>/ <SID>/global/hdb/ install/bin  and  /usr/sap/<SID>/SYS/ global/hdb/ install/bin
hdbreg	Command-line tool for registering an SAP HANA system	<installation path>/ <SID>/global/hdb/ install/bin  and  /usr/sap/<SID>/SYS/ global/hdb/ install/bin
hdbremovehost	Command-line tool for removing a host	<installation path>/ <SID>/global/hdb/ install/bin  and  /usr/sap/<SID>/SYS/ global/hdb/ install/bin

Program Name	Description	Location
hdbmodify	This command line tool removes and adds remote hosts.  Furthermore, the listen interface can be changed ('local', 'global', 'internal').	<installation path>/ <SID>/global/hdb/ install/bin  and  <installation path>/ <SID>/global/hdb/ install/bin
hdbupprep	Command-line tool for upgrading a repository by loading delivery units into the database	<installation path>/ <SID>/global/hdb/ install/bin  and  <installation path>/ <SID>/global/hdb/ install/bin

## 9.1.1.1.6.4 Managing SAP HANA System Components

SAP HANA system components can be installed, updated, or uninstalled using the SAP HANA database lifecycle manager (HDBLCM).

The SAP HANA system is made up of the following components:

- SAP HANA mandatory components
  - SAP HANA server
  - SAP HANA client
- SAP HANA additional components
  - SAP HANA studio
  - Application Function Libraries (AFL and the product-specific AFLs IBP, RTL, TRP, VCH, XRP)
  - SAP liveCache applications (SAP LCA or LCAPPS-Plugin)
  - SAP HANA smart data access (SDA)

### i Note

To install or uninstall the Solution Manager Diagnostics Agent, use Software Provisioning Manager (SWPM). For more information about the setting up the Solution Manager Diagnostics Agent using SWPM, see SAP Note 1858920 in Related Information.

### i Note

SAP LT replication configuration is a part of SL Toolset 1.0. For more information about configuring SAP LT replication, see SAP Note 1891393 in Related Information.

- SAP HANA options
  - SAP HANA dynamic tiering
  - SAP HANA streaming analytics
  - SAP HANA accelerator for SAP ASE

For more information about installing, updating, and uninstalling the SAP HANA mandatory components and SAP HANA additional components, see the *SAP HANA Server Installation and Update Guide*. For more information about installing, updating, and uninstalling the SAP HANA options, see SAP HANA option documentation in Related Information.

### ⚠ Caution

Be aware that you need additional licenses for SAP HANA options. For more information, see *Important Disclaimer for Features in SAP HANA Platform, Options and Capabilities* in Related Information.

## 9.1.1.1.6.5 Check the Installation Using the Command-Line Interface

You can check the installation of an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface for troubleshooting.

### Prerequisites

- You are logged in as root user.
- Any user has read and execute permissions for the directory that contains the installation medium.
- Depending on the storage solution, set the export options `rw,no_root_squash` for the installation directory.
- The operating system administrator (`<sid>adm`) user and other operating system users may exist prior to installation. Make sure that you have the passwords of the existing users, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) will not modify the properties of any existing user or group. The `<sid>adm` user passwords must be identical on all hosts.
- The SAP HANA system has been installed with its server software on a shared file system (export options `rw,no_root_squash`).

- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcmm
```

By default, <sapmnt> is /hana/shared.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcmm --action=check_installation
```

3. Enter the required credentials.
4. Review the summary, and select **y** to finalize the configuration.

## Results

The check tool outputs basic information about the configuration of the file system, system settings, permission settings, and network configuration. The checks are based on the property file stored in the following path:

```
<sapmnt>/<SID>/global/hdb/install/support/hdbcheck.xml
```

Use the generated log files as a reference in the case of troubleshooting. The log file is stored in the following path:

```
/var/tmp/hdb_<SID>_hdblcmm_check_installation_<time stamp>/hdblcmm.log
```

## Related Information

[check\\_installation](#)

## 9.1.1.2 Users Created During Installation

The following users are automatically created during the installation: `<sid>adm`, `sapadm`, `SYSTEM`, and `<sid>crypt`.

User	Description
<code>&lt;sid&gt;adm</code>	<p>The operating system administrator.</p> <ul style="list-style-type: none"><li>• The user <code>&lt;sid&gt;adm</code> is the operating system user required for administrative tasks such as starting and stopping the system.</li><li>• The user identifier (UID) of the <code>&lt;sid&gt;adm</code> user is defined during the system installation.</li><li>• The password of the <code>&lt;sid&gt;adm</code> user is set during installation with the <code>password</code> parameter.</li><li>• If you do not want the operating system user <code>&lt;sid&gt;adm</code> and its primary group to be created automatically, you can create it before installation. This might be the case if you use central user management such as Lightweight Directory Access Protocol (LDAP) or Network Information System (NIS). The SAP HANA database lifecycle manager (HDBLCM) will not modify the properties of any existing user or group.</li></ul> <p>The following requirements apply:</p> <ul style="list-style-type: none"><li>◦ The name of the user must follow the schema <code>&lt;sid&gt;adm</code>. All letters must be lower-case.</li><li>◦ The user should have a UID greater than 999.</li><li>◦ The primary group of the user must be <code>sapsys</code>. The default GID of the <code>sapsys</code> group is 79.</li><li>◦ The UID of this operating system user and GID of its primary group must be unique and identical on each host of a multiple-host system.</li></ul>
<code>sapadm</code>	<p>The SAP Host Agent administrator.</p> <ul style="list-style-type: none"><li>• If there is no SAP Host Agent available on the installation host, it is created during the installation along with the user <code>sapadm</code>.</li><li>• If the SAP Host Agent is already available on the installation host, it is not modified by the installer. The <code>sapadm</code> user and password are also not modified.</li><li>• The password of the <code>sapadm</code> user is set during installation with the <code>sapadm_password</code> parameter.</li><li>• If you do not want the user <code>sapadm</code> and its primary group to be created automatically, you can create it before installation.</li></ul> <p>The following requirements apply:</p> <ul style="list-style-type: none"><li>◦ The primary group of the user must be <code>sapsys</code>. The default GID of the <code>sapsys</code> group is 79.</li><li>◦ The GID of the primary group of the <code>sapadm</code> user must be unique and identical on each host of a multiple-host system.</li></ul>

User	Description
SYSTEM	<p>The database superuser.</p> <ul style="list-style-type: none"> <li>Initially, the SYSTEM user has all system permissions. Additional permissions can be granted and revoked again, however the initial permissions can never be revoked.</li> <li>Two SYSTEM users are created: one for the system database and one for the tenant database.</li> <li>The password of the SYSTEM user is set during installation with the <code>system_user_password</code> parameter.</li> </ul>
<sid>crypt	<p>The trusted local secure store (LSS) user.</p> <ul style="list-style-type: none"> <li>The user &lt;sid&gt;crypt owns the storage of the encryption keys and other similarly sensitive data.</li> <li>The user &lt;sid&gt;crypt is the only trusted user of the local secure store. Only processes called by a trusted user are accepted by the LSS right away.</li> </ul>

## 9.2 SAP HANA Application Lifecycle Management

SAP HANA Application Lifecycle Management supports you in all phases of an SAP HANA application lifecycle, from modelling your product structure, through application development, transport, assemble, and install.

## Phases of SAP HANA Application Lifecycle Management

The following are phases of SAP HANA application lifecycle management. Some phases are designed for developers only, while others, such as the installation of add-on products and software components, are designed for both.

- **Model**  
You define your product structure to provide a framework for efficient software development. This includes creating the following metadata: creating Repository packages for development, defining a package hierarchy and assigning packages to delivery units. The delivery units are then bundled in products.
- **Develop**  
You perform software developments in Repository packages. SAP HANA application lifecycle management supports you with change tracking functions which allow you to transport only changed objects.
- **Transport**  
You can transport your developed content in different ways according to your needs. You can choose between transporting products or delivery units, based on changelists or complete entities. The transport type can be native SAP HANA transport or transport using Change and Transport System (CTS). You can also export delivery units, and import them into another system.
- **Assemble**  
The developed software plus the metadata defined when modelling your product structure as well as possible translation delivery units are the basis for assembling your add-on product. You can also build Support Packages and patches for your product.
- **Install**  
You can install add-on products or software components that you downloaded from SAP Support Portal or assembled yourself.

All tasks related to the **Install** and **Configure** phases of SAP HANA application lifecycle management are documented in this *SAP HANA Administration Guide*. The tasks related to software development are documented in the *SAP HANA Developer Guide (For SAP HANA Studio)*. **All** phases of SAP HANA application lifecycle management are documented in the *SAP HANA Application Lifecycle Management Guide*.

## Related Information

[Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model \[page 1085\]](#)

## 9.2.1 Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model

SAP HANA application lifecycle management provides functions for installing and updating SAP HANA products or individual software components of SAP HANA XS classic model that you have downloaded from the SAP Support Portal, or that you have assembled yourself.

### Context

SAP HANA products consist of software components which are deployed to the SAP HANA repository. You have the following options to install and update SAP HANA products and software components:

- Using a **SAP Fiori application** integrated in the **SAP HANA Application Lifecycle Management XS application**. This application can be started in the following ways:
  - Start the SAP HANA Application Lifecycle Management on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/lm`. Afterwards, choose the **INSTALLATION** tab or tile.
  - Using a link in SAP HANA Web-based Development Workbench.  
In the SAP HANA Web-based Development Workbench Editor tool, choose **Navigation Links > Lifecycle Management >**. The SAP HANA Application Lifecycle Management home screen opens, where you can choose the **INSTALLATION** tab or tile..
  - Using the context menu in SAP HANA studio.  
Choose **Lifecycle Management > Application Lifecycle Management > Installation >** from the context menu for a particular system in the **SAP HANA Administration Console** perspective in SAP HANA studio.

The documentation about using SAP HANA Application Lifecycle Management to install and update SAP HANA products and software components describes the following use cases:

- *Installing and Updating SAP HANA Products*
- *Installing and Updating SAP HANA Software Components*
- Using the **hdbalm commandline tool**.  
To start **hdbalm**, start a command line client and navigate to the directory where **hdbalm** is located. You can also add this directory to your path.  
For more information about using **hdbalm** to install and update SAP HANA products and software components, see the following topics in the *SAP HANA Application Lifecycle Management Guide*:
  - *Using hdbalm*
  - *hdbalm install Command*

#### Note

SAP HANA system components like the SAP HANA client, SAP HANA studio, and additional system components like Application Function Libraries (AFL and the product-specific AFLs POS, SAL, SCA, SOP, UDF), SAP liveCache applications (SAP LCA or LCAPPS-Plugin), XS advanced runtime applications, or SAP HANA smart data access (SDA) are installed and updated using the SAP HANA database lifecycle manager (HDBLCM). For more information, refer to the *SAP HANA Server Installation and Update Guide*.

## Related Information

[Installing and Updating SAP HANA Software Components \[page 1088\]](#)

[Installation and Update Options \[page 1090\]](#)

[Using hdbalm](#)

[hdbalm install Command](#)

[SAP HANA Server Installation and Update Guide](#)

### 9.2.1.1 Installing and Updating SAP HANA Products

You can install and update SAP HANA products using SAP HANA application lifecycle management.

#### Prerequisites

- You have a product archive of an SAP HANA product that you want to install or update, or you have a directory location that contains the extracted product archive files.

#### i Note

An SAP HANA product archive is a \*.zip file that contains one or more software component archives as well as metadata files. For more information about the archive types that are used to deliver SAP HANA content, read the information about *SAP HANA content* in the *SAP HANA Administration Guide*.

- You have the privileges granted by a role based on the SAP HANA Application Lifecycle Management `sap.hana.xs.lm.roles::Administrator` role template.

#### Procedure

1. Open the SAP HANA Application Lifecycle Management.

The SAP HANA Application Lifecycle Management is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/lm`.

2. Choose the *INSTALLATION* tab.
3. Click in the *Archives* selection field to select a product archive, or the extracted product archive files, from your file directory that you want to install or update.

The files of the product archive are uploaded. The header area contains information about the product version, including the action that is to be performed: Installation or Update.

4. The *Product Instances* tab lists all product instances that are part of the archive.

For each product instance, the result of a software component check is displayed.

The following results can occur:

- *OK*  
The product instance can be installed.
- *Downgrade*  
The product instance contains one or more software components that are already installed in newer versions than the ones to be installed. The installation of this product instance would lead to a downgrade of these software components. Downgrades are not allowed. To continue the installation of the product, you have to set the installation/update option *Keep newer version of software component*. In this case, the downgrading software components will be skipped during the installation of the product instance.

### **i** Note

If it is required that you install the software component that causes the downgrade, for example, if the newer version has errors and you want to revert to the previous version, you can use the `install` command of `hdbadm` with the option `ALLOW_DU_DOWNGRADE` to enable the downgrade. However, use this option with care, since this may affect other installed products which require the newer version of this software component.

- *Some software components are installed already*  
If software components are already installed in the same version, by default, the system skips their installation during the installation/update of the product instance. If you want to reinstall the same version, you can set the option *Overwrite the same version of software component* in the installation and update options.

Click in the line of the product instance to display more information about the software components that are part of the product instance. For each software component, a status is displayed, as well as the installed version and the new version. If you click on the status icon, you get more information about the status.

5. If required, set installation or update options.

The options allow you to override the default behavior of the installation or update for specific situations. Use them with care. For more information about the options, see *Installation and Update Options*.

6. Select product instances for installation.

You can individually select single product instances. To install all instances, select the *Instance* check box in the header row.

All instances of the product, that are already installed on your system will automatically be checked for updates. If the archive that you uploaded contains newer versions for one or several software components, they will automatically be updated. It doesn't matter whether you selected the respective instance for installation.

7. To start the installation, choose *Install*.

The system displays the progress of the individual installation steps. You can click on each step to expand the log of the step.

## Results

If errors occur during the installation or update, an error message indicates the reason for the error and the system provides a log with more detailed information. If you cannot solve the problem and you need to open a

customer message, ensure that you assign it to the message component of the SAP HANA software component or product instance that caused the error. The [Support Information](#) tab contains the relevant information. Do **not** assign the message to the component of SAP HANA application lifecycle management since this may slow down the problem solving process.

If the installation or update finished successfully, you can start another installation using [New Installation](#).

## Related Information

[Installation and Update Options \[page 1090\]](#)

[Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model \[page 1085\]](#)

[SAP HANA Administration Guide \[page 9\]](#)

### 9.2.1.2 Installing and Updating SAP HANA Software Components

You can install and update SAP HANA software components using SAP HANA application lifecycle management.

#### Prerequisites

- You have one or multiple archives of SAP HANA software components that you want to install or update.

##### i Note

An SAP HANA software component archive is a \*.zip file that contains one delivery unit archive (\*.tgz) as well as metadata files. For more information about the archive types that are used to deliver SAP HANA content, read the information about *SAP HANA content* in this *SAP HANA Administration Guide*.

Software components which need to be installed at the operating system level, such as Application Function Libraries (AFLs), are **not** installed using SAP HANA application lifecycle management.

- You have the privileges granted by the SAP HANA Application Lifecycle Management `sap.hana.xs.lm.roles::Administrator` role.

#### Procedure

1. Open the SAP HANA Application Lifecycle Management.

The SAP HANA Application Lifecycle Management is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/lm`.

2. Choose the *INSTALLATION* tab.
3. Click in the *Archives* selection field to select one or multiple software component archives from your file directory that you want to install or update.

The software component archives are uploaded. For each software component the following information is displayed:

- o *Status*

The following status values exist:

- o *New*

The software component is not yet installed and can be installed.

- o *Update*

The software component is already installed and can be updated to a higher version.

- o *Downgrade*

The software component is already installed in a newer version than the one that is to be installed.

The installation of this software component would lead to a downgrade. Downgrades are not allowed. You cannot continue to install the software component.

### **i** Note

If it is required that you install the software component that causes the downgrade, you can use the `install` command of `hdbalm` with the option `ALLOW_DU_DOWNGRADE` to enable the downgrade. However, use this option with care, since this may affect already installed products which require the newer version of this software component.

- o *Already installed*

If software components are already installed in the same version, by default, the system skips their installation during the installation/update. If you want to reinstall the same version, you can set the option *Overwrite the same version of software component* in the installation and update options.

- o *Version* that is already *installed* in the system

- o *New version* that is to be installed

- o Whether the software component is part of a product that is already installed.

- o *Information* relevant for the *support*

4. If required, set installation or update options.

The options allow you to override the default behavior of the installation or update for specific situations. Use them with care. For more information about the options, see *Installation and Update Options*.

5. To start the installation, choose *Install*.

The system displays the progress of the individual installation steps. You can click on each step to expand the log of the step.

## Results

If errors occur during the installation or update, an error message indicates the reason for the error and the system provides a log with more detailed information. If you cannot solve the problem and you need to open a customer message, ensure that you assign it to the message component of the SAP HANA software component that caused the error. You can find this information in the support information of the component.

Do **not** assign the message to the component of SAP HANA application lifecycle management since this may slow down the problem solving process.

If the installation or update finished successfully, you can start another installation using [New Installation](#).

## Related Information

[SAP HANA Content \[page 1126\]](#)

### 9.2.1.3 Installation and Update Options

Installation and update options are available that allow you to influence the installation and update behavior, if required.

Installation and Update Options

Option	Corresponding Installation Option in hdbalm	Description
Overwrite the same version of software component	ALLOW_DU_SAME_VERSION	<p>By default, the system does not install a software component if the same version is already installed. It is possible to override this behavior in the following situations:</p> <ul style="list-style-type: none"><li>• If a previous installation operation failed, for example, because of activation errors.</li><li>• If you run continuous integration scenarios in which the same version of a software component is installed regularly.</li></ul>

Option	Corresponding Installation Option in hdbalm	Description
Keep newer version of software component	ALLOW_KEEP_DU_NEWER_VERSION	<p>If the product instance to be installed contains software components with lower versions than the installed ones, installing the software component in the lower version would lead to a downgrade of this software component. This is not allowed. You cannot install a downgrading software component. If you want to install the product instance without the downgrading software components, you can use this option. This option is useful if a software component is part of several products. If the product to be installed contains the software component in a version which is lower than the one already installed, you can choose to retain the newer version. In this case, the installation of the software component is skipped.</p>
Allow version update	ALLOW_DU_VERSION_UPDATE	<p>Allows version updates of software components.</p> <p>In some cases, for example, if a software component is part of several products, a version update of a software component could render one product inoperable. If the system detects an inconsistency, it aborts the operation. You can use this option to turn off this behavior.</p>
Roll back installation if activation errors occur (default)	This is the default behavior in hdbalm.	<p>By default, the installation is canceled if any activation errors occur and the complete installation is rolled back.</p> <p>Installation is also rolled back if you modified objects in your system and a modified object cannot be activated because it references an object that is part of the installation archive. This can occur, for example, if a procedure or view references a table in the archive.</p>

Option	Corresponding Installation Option in hdbalm	Description
Ignore activation errors of referencing objects	USE_TWO_COMMIT_ACTIVATION	<p>If an installation fails since an object outside of the archive cannot be activated due to references to an object in the archive, you can repeat the installation with this activation option. In this case, the object remains broken in the system after the installation, but the installation itself finishes successfully. You must correct the errors manually after the installation.</p> <p>You can check the transport log after performing the installation without this option to find out whether the activation errors were caused by objects in the archive or outside of the archive. After repeating the installation with this option, check the transport log to find out which objects must be repaired afterwards.</p>

## Related Information

[hdbalm install Command](#)

[Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model \[page 1085\]](#)

## 9.2.2 Installing and Updating Products and Software Components in SAP HANA XS Advanced Model

Application lifecycle management for SAP HANA XS advanced model provides functions for installing and updating products as well as individual software components of SAP HANA XS advanced that you have downloaded from the SAP Support Portal.

### Prerequisites

- The prerequisites described under *Prerequisites and Authorizations* are fulfilled. The link to the topic is in the *Related Information*.
- You have an SAP HANA XS advanced product or software component archive that you want to install or update.

### i Note

An SAP HANA XS advanced software component archive is a \*.zip file that consists of a multitarget application archive (MTA archive = \*.mtar file) and an `SL_MANIFEST.xml` file that contains metadata, such as version, vendor, support package, and patch level for the MTA archive.

An SAP HANA XS advanced product archive is a \*.zip file that consists of one or multiple software component archives plus a `pd.xml` and a `stack.xml` file. Both files contain metadata for the product, such as version, support package level, and vendor.

## Context

### i Note

From SPS 11, SAP HANA includes an additional run-time environment for application development: SAP HANA extended application services (XS), advanced model. SAP HANA XS advanced model represents an evolution of the application server architecture within SAP HANA by building upon the strengths (and expanding the scope) of SAP HANA extended application services (XS), classic model. SAP recommends that customers and partners who want to develop new applications use SAP HANA XS advanced model. If you want to migrate existing XS classic applications to run in the new XS advanced run-time environment, SAP recommends that you first check the features available with the installed version of XS advanced; if the XS advanced features match the requirements of the XS classic application you want to migrate, then you can start the migration process.

You have the following options to install and update SAP HANA products and software components in SAP HANA XS advanced:

- Using the XS advanced command line interface (CLI)
- Using the XS Advanced Application Lifecycle Management graphical user interface

The links to the corresponding topics are in the *Related Information*.

### i Note

SAP HANA system components like the SAP HANA client, SAP HANA studio, and additional system components like Application Function Libraries (AFL and the product-specific AFLs POS, SAL, SCA, SOP, UDF), SAP liveCache applications (SAP LCA or LCAPPS-Plugin), XS advanced runtime applications, or SAP HANA smart data access (SDA) are installed and updated using the SAP HANA database lifecycle manager (HDBLCM). For more information, refer to the *SAP HANA Server Installation and Update Guide*.

## Related Information

[Prerequisites and Authorizations \[page 1094\]](#)

[Installing and Updating Using the Command Line Interface \[page 1095\]](#)

[Installing and Updating Using the XS Advanced Application Lifecycle Management Graphical User Interface \[page 1113\]](#)

## 9.2.2.1 Prerequisites and Authorizations

The following prerequisites have to be fulfilled when you use functions required for installing and updating SAP HANA products and software components in SAP HANA XS advanced model.

- The XS advanced run time is installed and available on the SAP HANA server.  
For more information, see *Installing XS Advanced Runtime* in the *SAP HANA Server Installation and Update Guide*.
- When using the XS Advanced Application Lifecycle Management Graphical User Interface, the following software components are installed in addition to the XS advanced run time:
  - SAP UI5 component: XSACUI5FESV344P in version 1.44.8 or higher
  - SAP HANA XS Advanced Application Lifecycle Management Product Installer UI:  
XSAC\_ALM\_PRODUCT\_INSTALLER\_UI1

You can download the components from the Software Download Center at <https://support.sap.com/swdc> and install them using the `xs install` command in the command line interface.

For more information, see the *SAP HANA Server Installation and Update Guide*.

### i Note

If you have performed the default SAP HANA medium installation, both the SAP UI5 component and the SAP HANA XS Advanced Application Lifecycle Management Product Installer UI are already installed.

- Optional when using the XS advanced command line interface (XS CLI) for installation and update: The XS advanced command line client is installed on your local machine.  
The XS CLI client tools are installed by default on the SAP HANA server. You can log on to the server and execute the installation command there. However, if you want to connect to SAP HANA from your local machine, you must download and install the client tools locally. The XS CLI client tools (`xs.onpremise.runtime.client_<platform>-<version>.zip`) can be downloaded from the SAP HANA server, from the installation DVD, or from the SAP support portal.
- The SAP HANA database user that is used to perform the installation or update has one of the following permissions assigned:
  - The user has the `XS_CONTROLLER_USER` parameter assigned as well as the *SpaceDeveloper* role for each space in which the user wants to perform an installation or update.
  - The user has the `XS_CONTROLLER_ADMIN` parameter assigned.  
This scope allows the installation in all spaces.

For more information on assigning roles in SAP HANA XS advanced, see *Setting Up Security Artifacts* in the *SAP HANA Administration Guide*.

## Related Information

[SAP HANA Administration Guide \[page 9\]](#)

[SAP HANA Server Installation and Update Guide](#)

[Installing an SAP HANA System Including the XS Advanced Runtime](#)

## 9.2.2.2 Installing and Updating Using the Command Line Interface

To install and update products and software components in SAP HANA XS advanced, the `xs install` command is available in the XS advanced command line interface (CLI). Using this command you can install or update one product archive or one software component archive at a time.

### Procedure

1. Start the XS advanced command line interface (CLI).
2. Log on to the SAP HANA XS advanced runtime in the organization and space in which you want to install or update the product or software component.

To do this, use the `xs login` command with the following arguments and options:

Argument/Option	Description
<code>-u</code>	SAP HANA database user with the permissions as described in the <i>Prerequisites</i> section
<code>-p</code>	password
<code>-o</code>	organization in which the installation or update takes place
<code>-s</code>	space in which the installation or update takes place

#### Sample Code

```
xs login - u demo -p test -o demoorg -s demospace
```

For more information, see the *XS CLI: Logon and Setup* topic in *SAP HANA Developer Guide (for SAP HANA XS Advanced Model)*.

3. If you want that the archives to be installed are checked with antivirus software before the installation or update process, proceed as described under *Set Up a Virus Scan for Installation Archives*. The link to the topic is in the *Related Information* section.
4. Start the installation or update of the product or software component.

The `xs install` command is available in the XS advanced CLI both for installing product and software component archives in XS advanced and updating these. The `xs install` command detects whether the archive is a product archive or a software component archive. It also detects whether the product or software component is installed already and subsequently executes either an installation or update operation.

Enter the `xs install` command and specify the path to the archive. If required, enter any additional options. For example, to install a specific instance of a product, you can use the `-i` option and specify the

product instance. Or to make sure that the entity you are about to install is a product, you can add the `-pv` option. In this case, the installation is only performed if you specify a product archive for the `xs install` command. If you specify a software component archive, the installation is not performed.

### Sample Code

```
xs install ../sap_demo/target/XSASAMPLEPRODUCT1.0.zip
```

Instead of `xs install` you can also use the `xs ins` alias. For more information on the options, see *Installation and Update Options in XS Advanced Model*. For installation examples, see *Examples: Installing and Updating Products and Software Components in XS Advanced Model*. The links are in the *Related Information* section.

## Results

Before installing or updating the product or software component, the system performs different checks. If no errors are found, the system performs the installation or update with the arguments and options that you specified. During the process, the product installer calls the deploy service that performs the actual deployment. Afterwards, the product installer registers the product or software component as installed.

If the installation or update cannot be performed, it is possible, in some situations, to use additional options to override the default behavior of the system. For more information, see *Checks Before Installing or Updating Products or Software Components in XS Advanced Model* and *Installation and Update Options in XS Advanced Model*.

If errors occur during the installation or update, an error message indicates the reason for the error and the system provides a log with more detailed information. If you cannot solve the problem and you need to open a customer message, ensure that you assign it to the message component of the SAP HANA product or software component that caused the error. Do **not** assign the message to the component of SAP HANA application lifecycle management since this may slow down the problem solving process.

To display the correct log file, use one of the following commands with the process ID that you find in the result of the installation or update process.

- To display the log of a product installation, use the `display-installation-logs` command with the `--pv` option.

```
xs display-installation-logs <process ID> --pv
```

- To display the log of a software component installation, use the `display-installation-logs` command with the `--scv` option.

```
xs display-installation-logs <process ID> --scv
```

To display the history of installation or uninstallation processes, you can use the `display-installation-history` command.

```
xs display-installation-history
```

For more information on the commands used for installation, use `xs help <command>` in the XS advanced CLI, or see *The XS Command-Line Interface Reference* section in the *SAP HANA Developer Guide for XS Advanced Model*.

## Related Information

[Checks Before Installing or Updating Products or Software Components in SAP HANA XS Advanced Model \[page 1098\]](#)

[Set Up a Virus Scan for Installation Archives \[page 1097\]](#)

### 9.2.2.2.1 Set Up a Virus Scan for Installation Archives

You can set an environment variable in your system to enable a default virus scan for all software component archives that you want to install or update.

## Prerequisites

You have installed and configured the SAP virus scan interface as described in SAP Note [786179](#).

## Context

If the antivirus software that you are using does not check the software component archives that you want to install or update, you can use the SAP virus scan interface and set the environment variable `SCAN_UPLOADS` to the value `true`. This way, the system checks all archives that you want to install or update.

By default, no antivirus protection is set for the product installer.

## Procedure

1. In the commandline tool, set the XS advanced environment variable `SCAN_UPLOADS` to `true`.

#### Sample Code

```
xs set-env product-installer SCAN_UPLOADS true
```

For more information about setting environment variables in XS advanced, see *XS CLI: Application Management* in the *SAP HANA Developer Guide For SAP HANA XS Advanced Model*.

2. Restart the product installer.

The restart is required to ensure that the change to the environment variable takes effect.

#### Sample Code

```
xs restart product-installer
```

For more information about restarting applications in XS advanced, see *XS CLI: Application Management* in the *SAP HANA Developer Guide For SAP HANA XS Advanced Model*.

## Related Information

[Installing and Updating Products and Software Components in SAP HANA XS Advanced Model \[page 1092\]](#)  
[SAP HANA Developer Guide for XS Advanced Model](#)  
[XS CLI: Application Management](#)

### 9.2.2.2.2 Checks Before Installing or Updating Products or Software Components in SAP HANA XS Advanced Model

To ensure consistency of SAP HANA products, the system executes different checks before installing or updating a product or a software component in SAP HANA XS advanced.

#### Product installations only: Check whether the product to be installed is already installed and in which version

If the product to be installed is not yet installed, the installation will be performed. If it is already installed, the system checks the installed version. If it is already installed in the same version, or in a lower support package level, the installation or update will be performed.

- Product is already installed in higher version  
If the version of the product to be installed is lower than the installed version, the system terminates the process because installing the lower version would lead to a downgrade of the product.  
You can override this behavior and allow a downgrade of the product. To do this, you can use the `ALLOW_PV_DOWNGRADE` option with the `xs install` command.

- Product is already installed in lower version  
If the version of the product to be installed is higher than the installed version, the system updates the installed version automatically.

### i Note

The version of a product usually consists of one or more numbers in an ascending order. In addition to the version number, a support package level is provided for the product.

### Example

The version number is 1.0. In this case, the following versions are considered version updates: 1.1, 2.0, or 2.

## Check whether the software component is already installed and in which version

If the software component to be installed was not yet installed, the installation will be performed. If it was already installed, the system checks the installed version. If it is installed in a lower support package or patch level, the update will be performed.

### i Note

The version of a software component has the following form: "#.#.#", for example 1.0.3, where

- 1 = the version
  - 0 = the support package level
  - 3 = the patch level
- Software component is already installed in higher version  
If a version of a software component to be installed is lower than an installed version, the system terminates the installation.  
You have the following options to override this behavior:
    - You can allow a downgrade of the software component. To do this, use the `ALLOW_SC_DOWNGRADE` option.
    - For product installation only: You can skip the installation of all software components that are part of the archive and that are already installed in higher versions. To do this, use the `ALLOW_KEEP_SC_NEWER_VERSION` option.
  - Software component is already installed in same version  
If a version of a software component to be installed is the same as the installed version, the system proceeds as follows:
    - Product installation: The system does not install this software component. The installation of this software component is skipped during the installation of the product.
    - Software component installation: The system terminates the installation.
 You can override this behavior and allow the reinstallation of the same version. To do this, use the `ALLOW_SC_SAME_VERSION` option for this software component.

### i Note

If the software component is installed in the system in the same version with the status *BROKEN*, it is automatically reinstalled.

- Software component is already installed in lower version  
If a version of a software component to be installed is higher than an installed version, the system updates the installed version automatically.

## Check for dependencies on SAP HANA platform components or other XS advanced components

If the software component has dependencies on SAP HANA platform components or other XS advanced components that are not installed, the system terminates the process and displays the missing software components. You must install or update the missing software components before you can restart the current installation or update.

For more information on the options to override the default behavior, see *Installation and Update Options in XS Advanced Model*. The link is in the *Related Information* section.

## Check whether extension descriptor is valid, if an extension descriptor is used

If an extension descriptor is used for the installation process, the system checks that the extension descriptor file does not exceed a specific file size and that the syntax of the extension descriptor file is correct. If the file is too big or if the syntax is incorrect, the system will not start the installation process.

For more information on extension descriptors, see the *The MTA Deployment Extension Description* topic in the *SAP HANA Developer Guide for SAP HANA XS Advanced Model*.

## 9.2.2.2.3 Installation and Update Options in XS Advanced Model

Installation and update options are available in SAP HANA XS advanced that allow you to influence the installation and update behavior, if required.

The following is the default syntax for the `xs install` command in the XS advanced CLI:

```
xs install <ARCHIVE> [-p <TARGET_PLATFORM>] [-pv | --PRODUCT_VERSION] [-scv | --
SOFTWARE_COMPONENT_VERSION] [-t <TIMEOUT>] [-e
<EXT_DESCRIPTOR_1>[,<EXT_DESCRIPTOR_2>]] [-o
<VERSION_OPTION_1>[,<VERSION_OPTION_2>]] [-i | --INSTANCES
<INSTANCE_1[,INSTANCE_2]>] [--delete-services] [--delete-service-brokers] [--no-
start] [--ignore-lock]
```

The following is an example of a product installation:

```
xs install /sap_demo/target/XSASAMPLEPRODUCT1.0.zip -pv -o ALLOW_SC_SAME_VERSION
```

For more installation examples, see *Examples: Installing and Updating Products and Software Components in XS Advanced Model*. The link is in the *Related Information* section.

Installation and Update Arguments

Argument	Description
<ARCHIVE>	The path to (and name of) the archive containing the product or software component (SCV) to install, update, or downgrade

Installation and Update Options

Option	Description
-p <TARGET_PLATFORM>	Specify the target platform where the product or software component will be installed. If not specified explicitly, a target platform is created implicitly as ' <code>&lt;ORG&gt; &lt;SPACE&gt;</code> '.
-pv   --PRODUCT_VERSION	Install a product. The installation is performed only if the given archive is a product archive. Otherwise, the installation will fail.
-scv   -- SOFTWARE_COMPONENT_VERSION	Install a software component. The installation is performed only if the given archive is a software component archive. Otherwise, the installation will fail.
-e <EXT_DESCRIPTOR_1>[,<EXT_DESCRIPTOR_2>]	Define one or more extensions to the installation/deployment descriptors; multiple extension descriptors must be separated by commas. For more information on extension descriptors, see the <i>The MTA Deployment Extension Description</i> topic in the <i>SAP HANA Developer Guide for SAP HANA XS Advanced Model</i> and <i>The Multitarget Application Model</i> guide.

Option	Description
-t <TIMEOUT>	Specify the maximum amount of time (in seconds) that the installation service must wait for the installation operation to complete
-o <VERSION_OPTION_1>[,<VERSION_OPTION_2>]	Specify options which can be used to <b>override</b> the default behavior of the <code>install</code> command. The following options are available: <ul style="list-style-type: none"> <li data-bbox="679 555 1394 819"> <p>• <b>ALLOW_PV_DOWNGRADE</b> Allows a downgrade of the product. By default, the system does not install a product if the product is already installed in a higher product version or support package stack since this would lead to a downgrade of the product. It is possible to override this behavior, for example, if the newer version has errors and you want to revert to the previous version. This option is available for product installations only.</p> </li> <li data-bbox="679 837 1394 1240"> <p>• <b>ALLOW_KEEP_SC_NEWER_VERSION</b> Skips the installation of a software component if a newer version is already installed in the system. By default, the system does not install a product if a newer version of one of the software components contained in the product archive is already installed. It is possible to override this behavior. This option is useful, for example, if a software component is part of several products. If the product to be installed contains the software component in a lower version than the one already installed, you can choose to retain the newer version. If you use this option, the installation of this software component is skipped. This option is available for product installations only.</p> </li> <li data-bbox="679 1258 1394 1451"> <p>• <b>ALLOW_SC_DOWNGRADE</b> Allows a downgrade of the software component. By default, the system does not install a software component if this leads to a downgrade of the software component. It is possible to override this behavior, for example, if the newer version has errors and you want to revert to the previous version.</p> </li> </ul> <div data-bbox="719 1473 1394 1581" style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 5px; margin: 10px 0;"> <p><b>⚠ Caution</b> Use this option carefully.</p> </div> <ul style="list-style-type: none"> <li data-bbox="679 1599 1394 1787"> <p>• <b>ALLOW_SC_SAME_VERSION</b> Reinstalls the same version of the software component. By default, the system does not install a software component, if the same version is already installed. It is possible to override this behavior, for example, if you run continuous integration scenarios in which the same version of a software component is installed regularly.</p> </li> </ul>
-i, --INSTANCES <INSTANCE_1>[,<INSTANCE_2>]	By default all instances are installed; a comma-separated list of instances can be specified to limit the number of instances installed
--delete-services	Recreate changed services and/or delete discontinued services

Option	Description
<code>--delete-service-brokers</code>	Delete discontinued service brokers
<code>--no-start</code>	Do not start applications that are updated during the installation
<code>--ignore-lock</code>	Force installation even if the space targeted for installation is locked
<code>--deploy-passthrough</code> <{"<key>" : "<value>", ...}>	Option for the deploy service

See also the `xs install` command reference in the *XS CLI: Plugins* topic in the *SAP HANA Developer Guide for SAP HANA XS Advanced Model*.

### 9.2.2.2.4 Examples: Installing and Updating Products and Software Components in XS Advanced Model

The examples show how you can use the `xs install` command.

In the following examples you must be logged on to the XS command line interface (XS CLI) with a user with the authorizations required for installation and in the organization and space in which you want to perform the installation.

## Installation of New Product

The following example installs the product *XSA Sample Product* in version 1.0, SPS 0 (initial shipment stack) contained in the file `XSASAMPLEPRODUCT_1.0.zip`:

```
XSA Sample Product (sap.com) 1.0 SPS 0
Product Instance 1
SCV_A 1.0.0
SCV_B 1.0.0
```

No version of this product is currently installed. The following command is used:

```
xs install XSASAMPLEPRODUCT_1.0.zip
```

After the installation, the `xs list-products` command displays the product as follows:

```
name                vendor    version  SPS   instance ids
-----
XSA Sample Product  sap.com  1.0     0     1
```

The detail display for *XSA Sample Product* looks as follows:

```
xs list-products "XSA Sample Product"
-----
name                XSA Sample Product
vendor              sap.com
version             1.0
support package stack 0
-----
instance id        software component    version  state
-----
1                  -                    -        INSTALLED
                  SCV_A                1.0.0    INSTALLED
                  SCV_B                1.0.0    INSTALLED
-----
```

## Update with Support Package Stack

The following example installs the product *XSA Sample Product* in version 1.0, SPS 5 contained in the file `XSASAMPLEPRODUCT_1.0.5.zip` in the system:

```
XSA Sample Product (sap.com) 1.0 SPS 5
Product Instance 1
SCV_A 1.5.0
SCV_B 1.5.0
```

Version 1.0, SPS 0 (initial shipment stack) of *XSA Sample Product* containing software components `SCV_A` in version 1.0.0 and `SCV_B` in version 1.0.0 is currently installed. To ensure that the archive to be installed is a product archive, the `-pv` option is used.

```
xs install XSASAMPLEPRODUCT_1.0.5.zip -pv
```

After the update, the `xs list-products` command displays the product as follows:

```
xs list-products "XSA Sample Product"
-----
name                XSA Sample Product
vendor              sap.com
version             1.0
support package stack 5
-----
instance id        software component    version  state
-----
1                  -                    -        INSTALLED
                  SCV_A                1.5.0    INSTALLED
                  SCV_B                1.5.0    INSTALLED
-----
```

## Installation of Lower Support Package Version

The following example installs the product *XSA Sample Product* in version 1.0, SPS 3 contained in the file `XSASAMPLEPRODUCT_1.0.3.zip` in the system:

```
XSA Sample Product (sap.com) 1.0 SPS 3
Product Instance 1
SCV_A 1.3.0
SCV_B 1.3.0
```

Version 1.0, SPS 5 of *XSA Sample Product* containing software components `SCV_A` in version 1.5.0 and `SCV_B` in version 1.5.0 is currently installed. If the installation was started without any options, it would fail. To allow the downgrade of the support package version, you must use the `ALLOW_PV_DOWNGRADE` option. In addition, to allow a downgrade of the software components, you must use the `ALLOW_SC_DOWNGRADE` option.

```
xs install XSASAMPLEPRODUCT_1.0.3.zip -o ALLOW_PV_DOWNGRADE, ALLOW_SC_DOWNGRADE
```

After the installation, the `xs list-products` command displays the product as follows:

```
xs list-products "XSA Sample Product"
-----
name                XSA Sample Product
vendor              sap.com
version            1.0
support package stack 3
-----
instance id      software component      version      state
-----
1                -                            -            INSTALLED
                SCV_A                        1.3.0       INSTALLED
                SCV_B                        1.3.0       INSTALLED
-----
```

## Installation of Higher Product Version

The following example installs the product *XSA Sample Product* in version 2.0, SPS 1 contained in the file `XSASAMPLEPRODUCT_2.0.1.zip` in the system:

```
XSA Sample Product (sap.com) 2.0 SPS 1
Product Instance 1
SCV_A 2.1.0
SCV_B 2.1.0
```

Version 1.0, SPS 3 of *XSA Sample Product* containing software components `SCV_A` in version 1.3.0 and `SCV_B` in version 1.3.0 is currently installed. The installation of version 2.0, SPS 1 of the *XSA Sample Product* updates both the product version and the software component versions automatically.

```
xs install XSASAMPLEPRODUCT_2.0.1.zip -pv
```

After the installation, the `xs list-products` command displays the product as follows:

```
xs list-products "XSA Sample Product"
-----
name                XSA Sample Product
vendor              sap.com
version             2.0
support package stack 1
-----
instance id        software component    version    state
-----
1                  -                    -          INSTALLED
                  SCV_A                2.1.0     INSTALLED
                  SCV_B                2.1.0     INSTALLED
-----
```

## Installation of Lower Product Version

The following example installs the product *XSA Sample Product* in version 1.5, SPS 3 contained in the file `XSASAMPLEPRODUCT_1.5.3.zip` in the system:

```
XSA Sample Product (sap.com) 1.5 SPS 3
Product Instance 1
SCV_A 1.3.5
SCV_B 1.3.5
```

Version 2.0, SPS 1 of *XSA Sample Product* containing software components `SCV_A` in version 2.1.0 and `SCV_B` in version 2.1.0 is currently installed. To allow a downgrade of the product version, you must use the `ALLOW_PV_DOWNGRADE` option with the command. In addition, to allow a downgrade of the software components, you must use the `ALLOW_SC_DOWNGRADE` option.

```
xs install XSASAMPLEPRODUCT_1.5.3.zip -o ALLOW_PV_DOWNGRADE, ALLOW_SC_DOWNGRADE
```

After the installation, the `xs list-products` command displays the product as follows:

```
xs list-products "XSA Sample Product"
-----
name                XSA Sample Product
vendor              sap.com
version             1.5
support package stack 3
-----
instance id        software component    version    state
-----
1                  -                    -          INSTALLED
                  SCV_A                1.3.5     INSTALLED
                  SCV_B                1.3.5     INSTALLED
-----
```

## Installation of Software Component

The following example installs the software component *SCV\_A* in version 1.2.3 contained in the file *SCV\_A\_123.zip*. No version of this software component is currently installed. The `-scv` option is used to make sure that the archive to be installed is a software component archive.

```
xs install SCV_A_123.zip -scv
```

After the installation, the `xs list-components` command displays the software component as follows:

```
xs list-components
software component          version
-----
SCV_A (sap.com)            1.2.3
```

## Installation of Product with Lower Version of Software Component

The following example installs the product *XSA Test Product* in version 1.0, `SPS 3` contained in the file *XSATESTPRODUCT\_1.0.3.zip*. No version of the product is currently installed. However, the product contains the software component *SCV\_A* in version 1.0.3 which was already installed individually in version 1.2.3.

You have the following options to proceed with the installation:

- To allow a downgrade of the software component, you can use the `ALLOW_SC_DOWNGRADE` option with the command.

```
xs install XSATESTPRODUCT_1.0.3.zip -o ALLOW_SC_DOWNGRADE
```

After the installation, the `xs list-components` command displays the software component as follows:

```
xs list-components
software component          version
-----
SCV_A (sap.com)            1.0.3
```

- To keep the newer version of the software component, you can use the `ALLOW_KEEP_SC_NEWER_VERSION` option with the command.

```
xs install XSATESTPRODUCT_1.0.3.zip -o ALLOW_KEEP_SC_NEWER_VERSION
```

After the installation, the `xs list-components` command displays the software component as follows:

```
xs list-components
software component          version
-----
SCV_A (sap.com)            1.2.3
```

## 9.2.2.2.5 Display installed Products and Software Components in XS Advanced Model

To display products and software components of SAP HANA XS advanced that are already installed, the `xs list-products` and `xs list-components` commands are available.

### Prerequisites

The prerequisites are fulfilled as described in the *Prerequisites and Authorizations* topic. The link is in the *Related Information* section.

### Context

Instead of `xs list-products` you can also use the `xs lp` alias. Instead of `xs list-components` you can also use the `xs lc` alias.

For more information, see the *XS CLI: Plugins* topic in *SAP HANA Developer Guide (for SAP HANA XS Advanced Model)*.

### Procedure

1. Start the XS advanced command-line interface (CLI).
2. Log on to the SAP HANA XS advanced runtime in the organization and space where you want to display installed products or software components.
3. You have the following options:
  - To display all products that are installed in the current organization and space, use the `xs list-products` command without any arguments.

```
xs list-products
```

The system lists all installed products with information about vendor, version, support package level and installed instances.

- To display all software components that are installed in the current organization and space, use the `xs list-components` command.

```
xs list-components [--all]
```

The system lists all installed software components with information about vendor and version. The version is displayed in the format `<software component version>.<support package level>.<patch level>`.

If you use the `--all` option with the `list-components` command, the system also displays software components for which installations have failed and which are in status *BROKEN*.

- To display detailed information for a specific installed product, use the `xs list-products` command and add the name of the product `<PRODUCT NAME>` as argument. Optionally, or if another product with the same name and different vendor exists, add the `<VENDOR>`.

### ❁ Example

```
xs list-products XSASAMPLEPRODUCT sap.com
```

### i Note

If the product name contains a space, enter the product name in quotation marks: `xs list-products "SAMPLE PRODUCT" sap.com`

The system lists the specified product with information about vendor, version, and support package level. In addition, it lists all installed product instances and the software components that are assigned to the instances. For these, it lists the version and the state in which the software component exists in the system. They can have the following states:

- **INSTALLED**: The software component or product instance is successfully installed.
- **BROKEN**: The software component is installed in a broken state. This status can occur, for example, if there was an error in the deploy step during installation.
- **INSTALLING**: The installation of this software component is currently running.
- **INCOMPLETE**: The installation of this product instance is incomplete.
- **MISSING**: This software component is missing.

## Example

The output for the `xs list-products` command can look as follows:

### ≡ Sample Code

```
name          vendor    version  SPS   instance ids
-----
XSA Sample Product  sap.com  1.0     0     1,3
```

The output for the `xs list-products "XSA Sample Product"` command can look as follows:

### ≡ Sample Code

```
-----
name          XSA Sample Product
vendor        sap.com
version       1.0
SP            0
-----
instance id   software component    version  state
-----
1             -                     1.0     INSTALLED
             JAVA_HELLO_XSA_B     1.0.0   INSTALLED
             JAVA_HELLO_XSA_A     1.0.0   INSTALLED
3             -                     1.0     INSTALLED
             JAVA_HELLO_XSA_C     1.1.0   INSTALLED
```

## Related Information

[SAP HANA Developer Guide for XS Advanced Model](#)  
[XS CLI: Plug-ins](#)

### 9.2.2.2.6 Uninstall Products and Software Components in SAP HANA XS Advanced Model

Application lifecycle management for SAP HANA XS advanced model provides functions for uninstalling products as well as individual software components of SAP HANA XS advanced.

#### Prerequisites

- The prerequisites described under *Prerequisites and Authorizations* are fulfilled. The link to the topic is in the *Related Information*.
- You have a product or software component of SAP HANA XS advanced that you want to remove.

#### Context

You can uninstall products and software components of SAP HANA XS advanced that were installed using the `xs install` command.

#### Procedure

1. Start the XS advanced command-line interface (CLI).
2. Log on to the SAP HANA XS advanced runtime in the organization and space where you want to uninstall an installed product or software component.
3. Optional: Display the product or software component using the `xs list-products` or `xs list-components` command.
4. Start the uninstallation of the product or software component.

Enter the `xs uninstall` command and specify the name of the product or software component to be uninstalled, as well as the vendor, if required. In addition, you can enter options as required. The following is the default syntax for the `xs uninstall` command in the XS advanced CLI:

```
xs uninstall <NAME> [<VENDOR>] [-pv | --PRODUCT_VERSION] [-scv | --
SOFTWARE_COMPONENT_VERSION] [-f] [--ignore-scv-reuse] [--delete-services] [--
delete-service-brokers] [--ignore-lock]
```

The following arguments are available:

#### Uninstallation Arguments

Uninstallation Argument	Description
<NAME>	The name of an installed product version (PV) or software component version (SCV)
[<VENDOR>]	The name of the vendor of the specified product or software component version; <b>optional</b> : only needed when the same product or software component name exists with different vendors

The following options are available:

#### Uninstallation Options

Uninstallation Option	Description
-pv   --PRODUCT_VERSION	Remove the specified product.  To make sure that the entity you are about to uninstall is a product, you can add the <code>-pv</code> option. In this case, the uninstallation is only performed if you specify a product name as <NAME>. If you specify a software component name, the uninstallation will fail.
-scv   --SOFTWARE_COMPONENT_VERSION	Remove the specified software component.  To make sure that the entity you are about to uninstall is a software component, you can add the <code>-scv</code> option. In this case, the uninstallation is only performed if you specify a software component name as <NAME>. If you specify a product name, the uninstallation will fail.

Uninstallation Option	Description
<code>--ignore-scv-reuse</code>	Remove the specified software component even if it is used in other installed products.  <b>Note</b> You can use this option for uninstalling software components only.  By default, a software component will not be uninstalled if it is also part of another installed product. You can override this behavior by using the <code>--ignore-scv-reuse</code> option.
<code>-f</code>	Remove the specified product or software component without any system prompts or confirmation
<code>-i, --INSTANCES</code> <code>&lt;INSTANCE_1&gt;[, &lt;INSTANCE_2&gt;]</code>	By default all instances are uninstalled; a comma-separated list of instances can be specified to limit the number of instances to be uninstalled
<code>--delete-services</code>	Recreate changed services and/or delete discontinued services
<code>--delete-service-brokers</code>	Delete discontinued service brokers
<code>--ignore-lock</code>	Force removal of the product or software component even if the target space is locked

### Sample Code

```
xs uninstall 'XSA SAMPLE PRODUCT' -pv
```

Instead of `xs uninstall` you can also use the `xs uninst` alias. For more information on the `xs uninstall` command, use the `xs help uninstall` command.

## Results

The system undeploys and unregisters the specified product or software component from the SAP HANA server in the organization and space to which you are logged on.

If errors occur during the uninstallation, an error message indicates the reason for the error and the system provides a log with more detailed information. If you cannot solve the problem and you need to open a customer message, ensure that you assign it to the message component of the SAP HANA product or software component that caused the error. Do **not** assign the message to the component of SAP HANA application lifecycle management since this may slow down the problem solving process.

To display the correct log file, use the `xs display-installation-logs` command with the log ID that you find in the result of the uninstallation process and one of the `--unins_scv` or `--unins_pv` options.

```
xs display-installation-logs <log ID> --unins_scv
```

### 9.2.2.3 Installing and Updating Using the XS Advanced Application Lifecycle Management Graphical User Interface

You can use the XS Advanced Application Lifecycle Management graphical user interface to install, update, and uninstall products and software components in SAP HANA XS advanced model.

An SAP HANA product consists of one or several software components and can have one or several instances. Some SAP HANA software components require an MTA extension descriptor when they are installed. If this is the case for your product or software component, you can upload one or more MTA extension descriptor files together with the installation file. For more information on MTA extension descriptors, see *The MTA Deployment Extension Description* in the *SAP HANA Developer Guide for XS Advanced Model* and *The Multitarget Application Model* guide. The links can be found in the *Related Information* section.

1 Product : n Product Instances : m Software Components

1 Software Component: n Packages

1 Package : n Objects

1 Object : 1 Package

1 Package : 1 Software Component

1 Software Component: 1 Product Instance : 1 Product

Structure of an SAP HANA Product in XS Advanced

## Accessing the XS Advanced Application Lifecycle Management Graphical User Interface

1. To access the XS Advanced Application Lifecycle Management, choose one of the following options:
  - Use the following URL: `https://<server>:53280/index.html`  
53280 is the default port for the XS Advanced Application Lifecycle Management graphical user interface when port-based routing is used.  
If the routing configuration was changed to hostname routing during the installation, the URL can look different. For more information on routing configuration, see the *SAP HANA Server Installation and Update Guide* and SAP Note [2245631](#). In this case, you can check for the URL to access XS Advanced Application Lifecycle Management in the following places:
    - Using the XS advanced command line interface (CLI):  
Use the `xs version (xs -v)` command. Below the information about the installed server version, under *Registered Service URLs*, it shows the *product-installer* URL.
    - Using the SAP HANA XS Advanced Cockpit:  
In the tile catalog, choose the *Application Monitor* tile. In the list of applications (opening may take some time), locate the *product-installer-ui* and choose the *URL* link.
    - In SAP HANA Cockpit, for a specific resource, choose one of the links available in the *Application Lifecycle Management* section:
      - For software components: *Install, update and uninstall XS advanced components*
      - For products: *Install, update and uninstall XS advanced products*
      - To display installed software components and products: *Show history*
    - In the XS Advanced Cockpit, from the *Spaces* in the *Organizations* section, choose the *SAP* space. In the *SAP* space, locate the link to the *product-installer-ui* and start the UI by clicking on the link displayed under *Application Routes*.  
The *SAP* space is only visible if the user is assigned to it as Space Manager.
2. Log in with your user credentials.  
For more information, see [Prerequisites and Authorizations \[page 1094\]](#).
3. Select the space in which you would like to work by choosing *Switch Space* under *Additional Functionality*.

### i Note

When you use the XS Advanced Application Lifecycle Management graphical user interface for the first time, you are asked to select a space in which you would like to work. Select one from the list of spaces or use the search functionality on top of the list of spaces. This list displays only those spaces that you are authorized for. You can change the space that you are working in later on at any time.

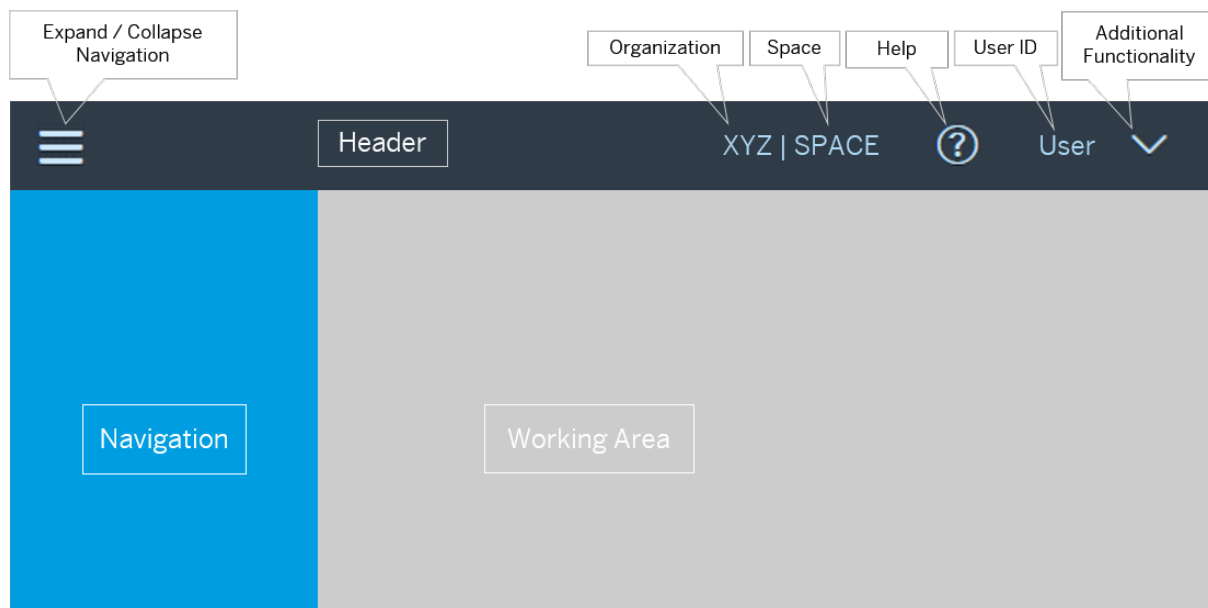

## Elements of the XS Advanced Application Lifecycle Management Graphical User Interface

In the header of the graphical user interface on the right, you can find the name of the space and the SID of the system that you are currently working with. The questionmark leads you to detailed information about how to use the XS Advanced Application Lifecycle Management graphical user interface. By clicking on your user ID, additional functions like switching spaces and logging out are offered.

On the left side, you can decide whether you would like to work on software components or products or would like to take a look into the installation history. In the working area, you can see details for the topic that you chose:

- **Software Components**  
A list of the software components that are already installed in the selected space is shown. There are several options to manage the installed software components. If no software components are installed in the selected space, the list is empty.
- **Products**  
On the left, a list of products that are already installed in the selected space is shown. On the right, details for the product selected in the list are provided. If no products are installed in the selected space, the list is empty.
- **Installation History**  
The installation history provides an overview of all installation, update and uninstallation activities for both software components and products in the selected space. It comprises detailed information about the activities, for example, type and status of the activity, name of the product or software component, version before and after the activity was executed. For a detailed installation, update or uninstallation screen with all actions that were executed, you can click on an activity. You can also download the log if you need it for further analysis, go to the product concerned or to the screen of software components to see the current state.  
To find activities for a certain user or to search for a process ID, you can use the search above the list. The menu to the right of the search field offers different sorting options.

The following figure shows the elements of the XS Advanced Application Lifecycle Management graphical user interface:

Elements of the XS Advanced Application Lifecycle Management Graphical User Interface

## 9.2.2.3.1 Install SAP HANA Software Components

You can use the XS Advanced Application Lifecycle Management graphical user interface to easily install new software components on your SAP HANA system.

### Prerequisites

- The required installation file is available at a file location that you can reach from your computer.
- Make sure that you have selected the correct space.

### Procedure

1. In the navigation area on the left, choose *Software Components* and then *Install/Update* in the working area.
2. Browse for the installation archive and, if required, enter one or more extension descriptors.
3. To upload the selected file, choose *Continue*.

#### i Note

If you want to clear the file selection, choose *Reset*. If you want to cancel the installation process, choose *Cancel*.

A list of the uploaded software components with some detailed information (for example, currently installed version, uploaded version, status) is displayed. The status for the software component that you uploaded is *Installation*.

4. Start the installation.

In the working area, you can now find information about the software component, its version, installation time and so on. You can also follow the installation progress which is done in the three steps *Validation*, *Deployment* and *Registration*. The icons for the different steps will change after a step is completed. You can click on the respective step for detailed information.

As soon as a green hook is shown for each step, the installation is successfully done.

### Results

The new software component is successfully installed on your SAP HANA system. You can check this by refreshing the list of installed software components.

## 9.2.2.3.2 Update SAP HANA Software Components

You can use the XS Advanced Application Lifecycle Management graphical user interface to easily update software components that are already installed on your SAP HANA system.

### Prerequisites

- Make sure that the installation file is available at a file location that you can reach from your computer.
- Make sure that you have selected the correct space.
- A previous version of the software component has already been installed to the selected space on your SAP HANA system.
- The software component is not part of a product.

#### i Note

A software component can only be updated if it is not part of a product. If it is part of a product, you need to update the complete product.

### Procedure

1. In the navigation area on the left, choose *Software Components*.

A list of the software components that are already installed in the selected space is shown.

#### i Note

If the list is empty, there are no software components installed in the selected space and you cannot update any software component. Make sure that you selected the correct space.

2. In the working area, choose *Install/Update*.
3. Browse for the installation archive and, if required, enter an extension descriptor.
4. To upload the selected file, choose *Continue*.

#### i Note

If you want to clear the file selection, choose *Reset*. If you want to cancel the update process, choose *Cancel*.

A list of the uploaded software components with detailed information (for example, currently installed version, uploaded version, status) is displayed. Depending on the installed and uploaded versions of the software component, the following situations are possible:

- If the version of the software component that you uploaded is higher than the one that is already installed, the status displayed in the list is *Update*. You can start the update directly.
- If the version that is already installed is the same as the one that you uploaded, you cannot start the installation directly. The status for the selected software component is *Already installed, to overwrite*

*set the corresponding option*. To do so, choose *Options* in the upper right side of the working area and select *Overwrite the same version of software component*. This can be helpful if you would like to repair the installed version. In the list of uploaded software components, the status is changed to *Overwrite*. You can now start the update process.

- If the version of the software component that is already installed is higher than the one that you just uploaded, you cannot proceed. You cannot downgrade software components during the update process.

5. To start the update process, choose *Start Installation*.

In the working area, you can now find information about the software component, its version, installation time and so on. You can also follow the installation progress which is done in the three steps *Validation*, *Deployment* and *Registration*. The icons for the different steps will change after a step is completed. You can click on the respective step for detailed information.

As soon as a green hook is shown for each step, the installation is successfully done.

## Results

The new version of the software component is successfully installed on your SAP HANA system. You can check this by refreshing the list of installed software components.

### 9.2.2.3.3 Install SAP HANA Products

You can use the XS Advanced Application Lifecycle Management graphical user interface to easily install new products on your SAP HANA system.

## Prerequisites

- The required installation file is available at a file location that you can reach from your computer.
- Make sure that you have selected the correct space.

## Procedure

1. In the navigation area on the left, choose *Products* and then *Install/Update* below the list of installed products in the working area.
2. Browse for the installation archive and, if required, enter an extension descriptor.
3. To upload the selected file, choose *Continue*.

### i Note

If you want to clear the file selection, choose *Reset*. If you want to cancel the installation process, choose *Cancel*.

Details about the uploaded product installation file (for example, vendor, version) are displayed. In addition, you can find information about the product instances that are part of the installation file. You can either decide to install the complete product with all instances or you can select one or several instances for installation.

#### **i** Note

It might happen that software components that are part of the product to be installed are already installed on your system. In this case you have to decide on how to proceed with these software components before you can start the installation. To do so, choose *Options* in the upper right side of the working area and maintain the settings.

#### 4. Start the installation.

In the working area, you can now find information about the product, its version, installation time and so on. You can also follow the installation progress which is done in the three steps *Validation*, *Deployment* and *Registration*. The icons for the different steps will change after a step is completed. You can click on the respective step for detailed information.

As soon as a green hook is shown for each step, the installation is successfully done. You can now download the installation log.

## Results

The new product is successfully installed on your SAP HANA system. You can check this by refreshing the list of installed products.

### 9.2.2.3.4 Update SAP HANA Products

You can use the XS Advanced Application Lifecycle Management graphical user interface to easily update products that are already installed on your SAP HANA system.

## Prerequisites

- Make sure that the installation file is available at a file location that you can reach from your computer.
- Make sure that you have selected the correct space.
- The product has already been installed to the selected space on your SAP HANA system.

## Procedure

1. In the navigation area on the left, choose *Products*.

A list of the products that are already installed in the selected space is shown.

### **i** Note

If the list is empty, there are no products installed in the selected space and you cannot update any product. Make sure that you selected the correct space.

2. In the working area below the list of installed products, choose *Install/Update*.
3. Browse for the installation archive and, if required, enter an extension descriptor.
4. To upload the selected file, choose *Continue*.

### **i** Note

If you want to clear the file selection, choose *Reset*. If you want to cancel the update process, choose *Cancel*.

A preview shows detailed information (for example, vendor, currently installed version, uploaded version) about the uploaded product and a list of product instances that are part of the uploaded installation file. You can either decide to update the complete product with all instances or you can select one or several instances for the update. The overview of instances also shows if software components of the respective instance are already installed. By default, instances that are already installed are selected for update. You cannot deselect them. To find out more about the software components concerned, you can click on the name of the instance.

Depending on the installed and uploaded versions of the product and its software components, the following situations are possible:

- If the versions of the product and all its instances and software components that you uploaded are higher than the versions of those that are already installed, you can start the update directly.
  - If an instance or some software components are already installed with the same version that is part of the uploaded file, these software components are not reinstalled automatically. To install them, choose *Options* in the upper right side of the working area and select *Overwrite the same version of software component*. This can be helpful if you would like to repair installed versions. In the list of instances, the *Prerequisite Check* is changed to *Same version will be overwritten*.
  - If the version of the software component that is already installed is higher than the one that you just uploaded, you would downgrade the already installed software components which is not possible during the update process. In this case, choose *Options* in the upper right side of the working area and select *Keep newer version of software component*.
  - You can select additional instances of the product for installation during the update process.
5. To start the update process, choose *Start Installation*.

In the working area, you can now find information about the software component, its version, installation time etc. You can also follow the installation progress which is done in the three steps *Validation*, *Deployment* and *Registration*. The icons for the different steps will change after a step is completed. You can click on the respective step for detailed information.

As soon as a green hook is shown for each step, the installation is successfully done.

## Results

The new version of the software component is successfully installed on your SAP HANA system. You can check this by refreshing the list of installed software components.

## 9.2.2.3.5 Uninstall SAP HANA Products or Software Components

You can use the XS Advanced Application Lifecycle Management graphical user interface to easily uninstall products or software components from your SAP HANA system.

### Prerequisites

The software component that you want to delete must not be part of an installed product.

#### i Note

If the software component that you want to delete is part of an installed product, you cannot uninstall it unless you uninstall the complete product or the product instance that contains the software component.

### Procedure

1. In the navigation area on the left, choose *Software Component* or *Product* according to your needs.

A list of installed software components or products is shown. If you want to uninstall an individual instance of a product, you can select it in the details of the selected product.

2. Choose *Uninstall* for the software component or product that you would like to uninstall.

You are prompted to confirm the uninstallation of the selected software component or product and to decide whether or not to delete services that were created during the previous deployment. These services might contain important user data, for example database content, that cannot be recovered after it is removed. If you choose to keep the services but want to delete them later, you can use the `xs delete-service` command in the command line client. For an overview of all existing services in a given space and their bound applications, use the `xs services` command.

3. To uninstall the software component or product and the related services if selected, choose *Uninstall*.

In the working area, you can now find information about the software component or product, its version, installation time and so on. You can also follow the uninstallation progress which is done in the three steps *Validation*, *Undeployment* and *Deregistration*. The icons for the different steps will change after a step is completed. You can click on the respective step for detailed information.

As soon as a green hook is shown for each step, the uninstallation is successfully done.

### Results

The software component or product is successfully uninstalled from your SAP HANA system. You can check this by refreshing the list of installed software components or products.

## 9.2.3 Configuring SAP HANA Applications with the Process Engine

The Process Engine (PE) is a framework available with SAP HANA application lifecycle management to enable automated technical configuration.

After the installation of a product or a delivery unit, an application typically must be configured before it can be used. The configuration tasks are described in the installation guides that are provided on the SAP Help Portal ([help.sap.com](http://help.sap.com)). Instead of performing cumbersome and error-prone manual activities, you can use the Process Engine to automate application configuration completely or partially. As a prerequisite, your application must provide content for the automated technical configuration.

The Process Engine (PE) framework is installed with SAP HANA application lifecycle management as automated content. It is available from the following locations:

- On the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/lm/pe/ui/`
- Using the *Configuration Services (Process Engine)* tile in SAP HANA Application Lifecycle Management XS user interface
- Using the *Manage Configuration Services* tile in SAP HANA cockpit

### Related Information

[Tutorial: Execute a Configuration Service with Process Engine \[page 1123\]](#)

[Process Engine Roles \[page 1122\]](#)

[Troubleshooting \[page 1126\]](#)

### 9.2.3.1 Process Engine Roles

To grant users the privileges they require to perform tasks with the Process Engine, you must assign them the relevant Process Engine roles.

The following table lists the roles that are available for tasks related to the Process Engine. The roles are hierarchical and interlinked. The `sap.hana.xs.lm.roles:Administrator` role is the *Administrator* role of SAP HANA application lifecycle management and grants the privileges of all other Process Engine-related roles as well as application lifecycle management roles. For more information, see *SAP HANA Application Lifecycle Management Roles* in the *SAP HANA Application Lifecycle Management Guide*.

#### → Recommendation

As repository roles delivered with SAP HANA can change when a new version of the package is deployed, either do not use them directly but instead as a template for creating your own roles, or have a regular review process in place to verify that they still contain only privileges that are in line with your organization's security policy. Furthermore, if repository package privileges are granted by a role, we recommend that these privileges be restricted to your organization's packages rather than the complete repository. To do this, for each package privilege (`REPO.*`) that occurs in a role template and is granted

on `.REPO_PACKAGE_ROOT`, check whether the privilege can and should be granted to a single package or a small number of specific packages rather than the full repository.

Roles available for the Process Engine

Role	Description
<code>sap.hana.xs.lm.pe.roles::PE_Display</code>	The user can monitor processes and display services.
<code>sap.hana.xs.lm.pe.roles::PE_Execute</code>	In addition to the previous role, the user can start, stop, skip, and resume processes.
<code>sap.hana.xs.lm.pe.roles::PE_Activate</code>	In addition to the previous roles, the user can activate services from repository files.
<code>sap.hana.xs.lm.roles::Administrator</code>	The user can install products. This role includes all previous roles.

## Related Information

[SAP HANA Application Lifecycle Management Roles](#)

### 9.2.3.2 Tutorial: Execute a Configuration Service with Process Engine

In this tutorial, you use the demo content delivered with the Process Engine to execute a configuration service.

## Prerequisites

- An SAP HANA system is available.
- SAP HANA XS is up and running on the SAP HANA system.
- Depending on the task you want to perform with the Process Engine, you must have the privileges based on a role granted by one of the Process Engine role templates described in *Process Engine Roles*. The link to the topic is in the *Related Information* section. The privileges of the `sap.hana.xs.lm.pe.roles::PE_Activation` role allows you to perform all Process Engine tasks.

## Context

The Process Engine uses different terms for identifying design time or runtime artifacts. The *service* is the core entity at design time. It has multiple attributes describing its purpose and steps representing the executable

entities. They perform the actual work during execution. An executable can be a JavaScript function in an XS JavaScript library or an SQL stored procedure. When starting a service, the Process Engine creates a *process* based on a service. It copies all steps associated with the service as tasks, and it copies the parameters of the selected variant to the parameters of the process. Furthermore, the Process Engine associates a *status* with the process.

You execute the following steps to configure the demo service:

- Activate the demo service.  
Services are delivered as repository objects. The services required by the administrator need to be enabled once before use. This activity is called *activation*.
- Prepare the demo service parameters.  
The demo service needs parameters during execution. The set of required parameters is stored under a common key, the *variant*. Before you can start a service you need to prepare variants. Since you are about to start the service for the first time, you do not have any variants prepared. If you repeat an execution, you can use an existing variant. For the demo service, you enter *user* and *password*. Since this is a demo example, the user does not need to exist and the password can be any set of characters.
- Start the demo service.  
The demo service consists of the following steps:
  - JS\_APPVAR by JavaScript  
This step executes a JavaScript function that shows how to consume and return parameters in JavaScript.
  - SQL\_APPVAR by SQL Script  
This step executes a SQL script function that shows how to consume and return parameters in SQL script.

### **i** Note

The demo content does not perform any configuration of the system. It only writes messages into the log of the Process Engine. It provides you with a hands-on experience for using the Process Engine.

## Procedure

1. Open SAP HANA Application Lifecycle Management.

SAP HANA Application Lifecycle Management is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/lm`

2. Choose *Configuration Services (Process Engine)*.

The process engine opens in a new browser window or a tab.

3. Select *Services* on the left-hand side of the screen.

A list of services available for configuration appears. Active services are indicated by a green status icon, inactive services have a grey status icon. Inactive services must be activated before they can be started.

You find the demo service *DEMO\_VarCont* as inactive in the list.

4. Select *DEMO\_VarCont* and choose *Activate*.

Note that the activation process can take some time. After the service was activated successfully, you can start it.

If the activation were not successful, you can find the error messages in a detailed log.

5. To display the service after the activation, choose *Go To Service*.

The details of the active service *Demo Service with Process Engine Variant Container* appear.

6. To prepare the parameters for the demo service, choose *Maintain Variants*.

A new screen for variant maintenance appears.

7. Enter a *user* name and a *password* as parameters and choose *Save As*.
8. Enter a *variant ID* and, optionally, a *description*, and then choose *Create*.
9. Return to the previous screen to view the variant that you just created.

If you open the *Steps* tab on screen, two executable steps are displayed.

10. To start the service, select your variant and choose *Start Variant*.

The *Process* tab opens and a new process appears at the top of the list.

11. Select the process to navigate to the process details.

A list of tasks appears.

12. Choose *Refresh* to observe the progress of the process.

The overall process status is displayed on top of the progress bar. It is a cumulation of the statuses of the individual tasks.

The status icons allow you to intervene in the process execution if errors occur. You can click on an icon to display the task log.

13. When the process completion reaches 100%, choose the *Parameters* tab.

You see an overview on the scalar parameters and their changes during execution.

Entries for the step *NA* show the parameter values after the variant container is copied and before the process execution starts. The other entries show the values after the step was executed.

14. To view the log of the *Consuming and returning parameters via SQL* task, select this task at the bottom of the screen.
  - a. Search for a message with a green status that starts with *JavaScript function sends*. At the end of the message, you see the parameter value of your **user**.
  - b. Search for a message with a green or orange status that contains the text *... password received*.

The step compares the received value of the parameter you entered as **password** with a value set by the demo service. If you entered the password as set by the demo service, the Process Engine issues the message *Correct password received*. If you entered a different password, the Process Engine writes *Incorrect password received* in the log.

## Results

You have used the demo configuration service of the Process Engine. You have activated the demo service, prepared the parameters, and executed the service. Afterward, you have checked the logs of the Process Engine.

## Related Information

[Process Engine Roles \[page 1122\]](#)

[Troubleshooting \[page 1126\]](#)

### 9.2.3.3 Troubleshooting

If a process stops with errors, you should first analyze the logs to find out why an error occurred. Afterward, you have various options to respond to the error situation.

The Process Engine provides a process log and a task log. If a single task has an error you can start with the task log to analyze if an error message is due to a specific step. If this does not help, you can open the process log and search or filter for error messages.

- **Process Log**

This is a collection of all task logs and additional entries related to the process. This log contains all messages with technical details, including the log of the internal activities of the Process Engine. You can find this log when you open the [Log](#) tab in the single process view.

- **Task Log**

This is the log of the execution of a single task. Messages with technical details about the Process Engine usually are not displayed here. You get this log when you navigate to a task view by clicking on a task in the single process view.

You have the following options to respond to an error:

- If the error is only temporary or you solved the error already, you can execute the step again by choosing [Resume](#).
- You can decide to perform the task manually and skip the execution of the task by choosing [Skip](#).
- You can cancel the current process and start a new one. To do this, choose [Cancel](#).
- If you cannot resolve the error, and you need to contact SAP, open an incident and assign it to the support component of the application that provides the configuration content or, alternatively, to component HAN-LM-APP. Make sure that you attach the diagnosis information that you can download for each process using the link on the [Diagnosis Information](#) tab.

## 9.3 SAP HANA Content

SAP HANA content is structured in the way that delivery units (DUs) are used to group SAP HANA content artifacts (such as analytic, attribute or calculation views, and SQLScript procedures).

DUs are grouped to SAP HANA products in order to ship and install SAP HANA applications with all dependent artifacts (grouped in DUs). To distribute SAP HANA content, a product archive (\*.ZIP file) or a delivery unit archive (\*.tgz file) is used. There are various ways of acquiring and deploying these archive types.

SAP HANA content, which is developed on SAP HANA Extended Application Services (SAP HANA XS), classic model, can also be grouped in a DU.

For more information about SAP HANA content deployed automatically during platform installation or upgrade, see *Components Delivered as SAP HANA Content* in the *SAP HANA Security Guide*.

## Related Information

[Components Delivered as SAP HANA Content](#)

### 9.3.1 SAP HANA Archive Types

The difference between the various archive types is their method of deployment, and when the content is deployed.

The following archive types are available:

- **Product archive file** (\*.ZIP)

A product version archive is a \*.ZIP file containing 1-n software component archive files and the following metadata files: `stack.xml`, `pd.xml`. A software component archive file is created for each DU containing its archive file (\*.tgz).

A product is usually the entity that delivers SAP HANA applications, but it can also be used for transports. SAP HANA content that can be downloaded independently is shipped as SAP HANA products in SAP HANA product archives. SAP HANA content that is not part of the SAP HANA database is called SAP HANA content add-on (or SAP HANA product). SAP HANA content add-ons are developed as part of the SAP HANA platform or as part of an application that runs on top of SAP HANA.

For information about how to deploy a product archive, see *Deploy a Product Archive (\*.ZIP)*.

- **Software Component Archive** (\*.ZIP)

A software component archive is a \*.ZIP file (in previous versions also \*.SAR files were delivered as software component archives) containing one delivery unit archive file (\*.tgz) and (optionally) a corresponding translation DU and the metadata file `SL_MANIFEST.XML`. A software component archive can be deployed with the same tool as product archives.

For information about how to deploy a software component archive, see *Deploy a Product Archive (\*.ZIP)*.

- **Delivery unit archive file** (\*.tgz)

A delivery unit archive is a \*.tgz file containing the SAP HANA content artifacts that are created in the SAP HANA repository. A DU is used to deliver one or more software components from SAP (or a partner) to a customer.

For distribution using export/import and deployment, a DU is contained in a delivery unit archive (\*.tgz file). It contains the objects and packages of a DU together with the metadata file `manifest.txt`. The transport is also offered at DU level.

The following types of delivery unit archive files are available:

- **Delivery unit archives as part of the SAP HANA database**

The following types of delivery unit archive files that are part of the SAP HANA database are available:

- **Automated content** is installed together with SAP HANA and imported into the SAP HANA repository during installation. This is an integral part of the SAP HANA database and is used by every SAP HANA database customer.

Automated content is located on the SAP HANA system in the following folder:

```
/usr/sap/<SID>/SYS/global/hdb/auto_content.
```

- **Non-automated content** is installed with SAP HANA, but needs to be imported into the SAP HANA repository manually by the system administrator. It is used for integral parts of the SAP HANA database, but is only used by a small number of customers.  
Non-automated content is located on the SAP HANA system in the following folder:  
`/usr/sap/<SID>/SYS/global/hdb/content.`  
Delivery unit archives that are non-automated content of the SAP HANA database need to be deployed manually.
  - **Independent delivery unit archives that are not part of the SAP HANA database**  
Delivery unit archives that are not installed together with the SAP HANA database and are not part of the SAP HANA database need to be deployed manually.
- For information about how to deploy or activate a delivery unit archive, see *Deploy a Delivery Unit Archive (\*.tgz)*.

## Related Information

[Deploy a Product Archive \(\\*.ZIP\) \[page 1128\]](#)

[Deploy a Delivery Unit Archive \(\\*.tgz\) \[page 1128\]](#)

### 9.3.2 Deploy a Product Archive (\*.ZIP)

SAP HANA application lifecycle management provides a method of deploying a product archive file (\*.ZIP file containing a product) or software component archive files (\*.ZIP).

For more information, see *Installing and Updating SAP HANA Products and Software Components* in the *SAP HANA Application Lifecycle Management Guide*.

## Related Information

[Installing and Updating SAP HANA Products and Software Components in SAP HANA XS Classic Model \[page 1085\]](#)

### 9.3.3 Deploy a Delivery Unit Archive (\*.tgz)

The following deployment methods for deploying a delivery unit archive file (\*.tgz file containing a DU) are provided:

- SAP HANA Application Lifecycle Management  
Choose ► *Products* ► *Delivery Units* ► *Import* .  
This tool runs on the SAP HANA XS Web server.  
For more information, see *Import a Delivery Unit* in the *SAP HANA Developer Guide (For SAP HANA Studio)*.

- SAP HANA Application Lifecycle Management  
SAP HANA application lifecycle management provides functions for installing and updating SAP HANA products:
  - SAP Fiori application integrated in the SAP HANA Application Lifecycle Management XS application
  - `hdbalim` command line toolFor more information, see *Installing and Updating SAP HANA Products and Software Components* in the *SAP HANA Application Lifecycle Management Guide*.
- SAP HANA studio  
Import function of the SAP HANA Modeler  
Choose ► *File* ► *Import* ► *SAP HANA Content* ► *Delivery Unit* ►.

For more information, see *SAP HANA Modeling Guide*.

## Related Information

[Import a Delivery Unit](#)

## 10.1 Landscape Management

Manage your SAP HANA system landscape efficiently and respond flexibly to changing resource requirements.

Depending on your SAP HANA deployment model and landscape architecture, you can reconfigure and reorganize your system in a number of ways.

### SAP HANA Tools

#### Copy and Move Operations

The following SAP HANA mechanisms allow you to copy and move systems and databases:

- **Platform LCM Tools:**  
An SAP HANA system can be safely and efficiently reconfigured by decoupling the system hosts from the installation path through unregistration, and re-coupling them in a different configuration through registration. System reconfiguration tasks can be performed with the SAP HANA database lifecycle manager (HDBLCM).
- **SAP HANA System Replication:**  
SAP HANA system replication can be used to create a copy of an SAP HANA system in a quick and simple way.  
System replication mechanisms can also be used to copy and move tenant databases securely and conveniently from one SAP HANA system to another with near-zero downtime.
- **Backup and Recovery:**  
You can create a homogeneous copy of an SAP HANA database by recovering an existing database to a different database. A homogenous database copy is a quick way to set up a cloned database, for example, for training, testing, or development.

## System Rename

An SAP HANA system can be renamed by changing the system identifiers, like host names, SID, and instance number. Changing system identifiers can be performed with the SAP HANA database lifecycle manager (HDBLCM).

## SAP Landscape Management

SAP Landscape Management is an add-on to SAP NetWeaver installed as an application with the SAP NetWeaver Application Server for Java (SAP NetWeaver AS for Java).

The enterprise edition of SAP Landscape Management software helps you to simplify and automate the efforts required to configure, provision, deploy, monitor, and manage your systems in both physical and virtualized infrastructures.

With SAP Landscape Management you can prepare, relocate, restart, start, stop, and unprepare single-host and multiple-host SAP HANA systems, and perform system replication operations.

## 10.1.1 Copying and Moving a System Using Platform LCM Tools

An SAP HANA system can be safely and efficiently reconfigured by decoupling the system hosts from the installation path through unregistration, and re-coupling them in a different configuration through registration. System reconfiguration tasks can be performed with the SAP HANA database lifecycle manager (HDBLCM).

### 10.1.1.1 Relocate the SAP HANA System

It may become necessary to move the SAP HANA system to different hardware. If so, you need to unregister the SAP HANA system and re-register it on the new hardware. System relocation can be performed with the SAP HANA database lifecycle manager (HDBLCM).

#### Context

Relocation can be performed on both the entire SAP HANA system or on an individual SAP HANA instance. So, you can flexibly decide if you want to relocate only one host (for example, in the case of host outage) or relocate all hosts in the system (for example, in a system scale up).

#### i Note

An SAP HANA system can only be relocated to a target system that runs on the same hardware platform as the source system.

#### Procedure

1. Unregister the SAP HANA instance or the SAP HANA system.

- a. Log on to the SAP HANA source host.

If you are unregistering a SAP HANA multiple-host system, you can log on to any system host. If you are unregistering a multiple-host system and would like to unregister one instance at a time, perform the unregistration of each local host.

- b. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdb1cm
```

By default, <sapmnt> is /hana/shared.

- c. Start the unregister task:

- o To unregister hosts using the SAP HANA database lifecycle manager command-line interface:
    - o Start the command-line tool interactively:

```
./hdb1cm
```

and enter the index of the `unregister_instance` action, if you only want to unregister the local host from the SAP HANA system. Enter the index of the `unregister_system` action, if you want to unregister all hosts in the SAP HANA system. Or,

- To unregister hosts using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdblcmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose *Unregister SAP HANA System*.

- d. To continue with the task proceed as follows:

- In the command line interface: Enter *y*.
- In the graphical interface:
  1. To display the summary of the configuration data, choose *Next*.
  2. To execute the configuration task, choose *Run*. The system displays the configuration progress.
  3. After the configuration task has finished, you can:
    - View the log. To do so, choose *View Log*.
    - Exit the graphical user interface. To do so, choose *Finish*.

2. Mount the installation path (`sapmnt`), the datapath, and the logpath on the target hosts.

3. Register the new host.

- a. Log on to the SAP HANA target host.

If you are registering an SAP HANA multiple-host system, you can log on to any system host. If you are registering a multiple-host system and would like to register one instance at a time, perform the registration on the local host before the remote hosts.

- b. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcm
```

By default, `<sapmnt>` is `/hana/shared`.

- c. Start the register task:

- To register hosts using the SAP HANA database lifecycle manager command-line interface:
  - Start the command-line tool interactively:

```
./hdblcm
```

and enter the index of the `register` and `rename` action, or

- To register hosts using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdblcmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose *Register and Rename SAP HANA System*.

- d. To continue with the task proceed as follows:

- In the command line interface: Enter *y*.
- In the graphical interface:
  1. To display the summary of the configuration data, choose *Next*.

2. To execute the configuration task, choose *Rename*. The system displays the configuration progress.
3. After the configuration task has finished, you can:
  - View the log. To do so, choose *View Log*.
  - Exit the graphical user interface. To do so, choose *Finish*.

### Note

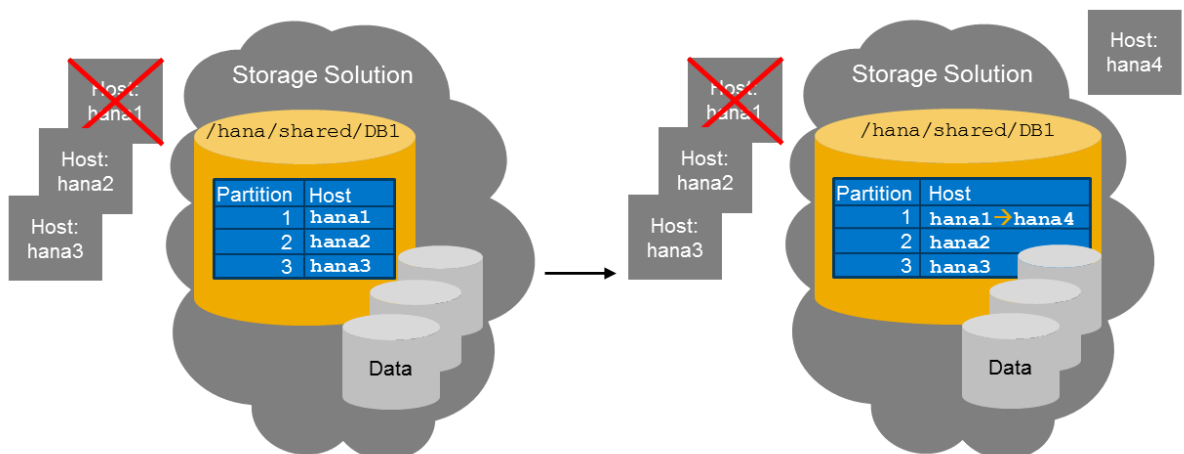

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdbclm --action=unregister_instance --help
./hdbclm --action=unregister_system --help
./hdbclm --action=register_rename_system --help
```

## Example

The following is an example of SAP HANA instance relocation from one host to another:

### SAP HANA Instance Relocation

1. Unregister SAP HANA host hana1 using `--action=unregister_instance`

2. Mount `/hana/shared` on host hana4.  
 3. Register SAP HANA host hana4 on the hana1 partition using `--action=register_rename_system` with host1 mapped to host4.

## Related Information

[SAP HANA Server Installation and Update Guide](#)

## 10.1.1.2 Copy or Clone an SAP HANA System

You can use the SAP HANA database lifecycle manager (HDBLCM) to make a copy or a clone of an SAP HANA system by copying the file system containing the SAP HANA database installation from an old storage solution to a new storage solution, and registering the copied SAP HANA system on new hosts.

### Prerequisites

Before cloning the SAP HANA system, you must create a physical copy of the SAP HANA system (storage snapshot, file systems copy). The source system must be offline or a database snapshot must have been taken on the source system before the physical copy of the SAP HANA system is created.

#### **i** Note

An SAP HANA system can only be cloned or copied to a target system that runs on the same hardware platform as the source system.

### Context

Cloning an SAP HANA system produces a new SAP HANA system, identical to the existing one. Copying an SAP HANA system produces a new SAP HANA system with the same landscape as the existing one, but slightly different parameter settings. If the interactive parameter defaults are accepted during host registration, the system is effectively cloned. If the new system parameters are set to different values, the new system is similar, but not identical to the source system.

You could, for example, copy an existing production system, and accept all parameter defaults during host registration except `system_usage`, which would be specified as "test". This configuration would allow you to have an almost identical copy of the existing system for test or quality assurance purposes.

#### **⚠** Caution

Keep in mind that in a system copy refresh scenario all users and roles are overwritten in the target system.

### Procedure

1. Copy the file system containing the SAP HANA database installation from the old storage solution to the new storage solution.
2. Mount the installation path (`sapmnt`), the data path, and the log path on the target hosts.
3. Register the new SAP HANA system on the target hosts.
  - a. Log on to the SAP HANA target host.

- b. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblc
```

By default, <sapmnt> is /hana/shared.

- c. Start the register task:

- To register hosts using the SAP HANA database lifecycle manager command-line interface:
  - Start the command-line tool interactively:

```
./hdblc
```

and enter the index of the `register` and `rename` action, or

- To register hosts using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdblcgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose *Register and Rename SAP HANA System*.

- d. To continue with the task proceed as follows:

- In the command line interface: Enter *y*.
- In the graphical interface:
  1. To display the summary of the configuration data, choose *Next*.
  2. To execute the configuration task, choose *Run*. The system displays the configuration progress.
  3. After the configuration task has finished, you can:
    - View the log. To do so, choose *View Log*.
    - Exit the graphical user interface. To do so, choose *Finish*.

### Note

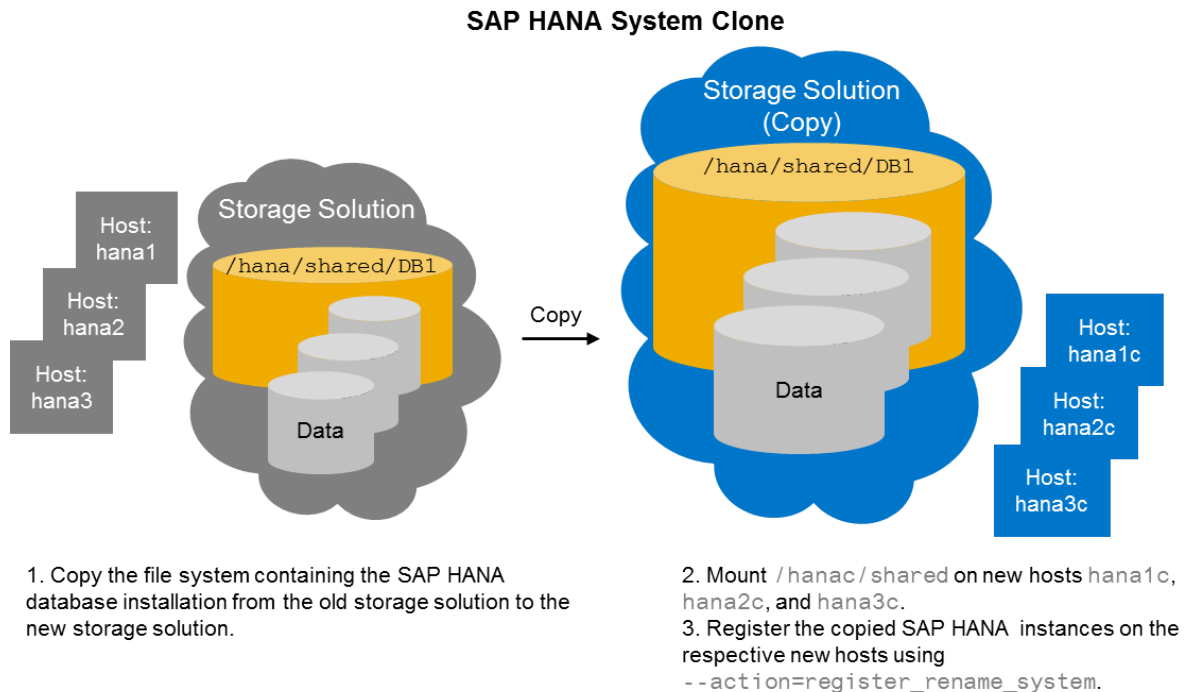

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdblc --action=register_rename_system --help
```

## Example

The following is an example of an SAP HANA being cloned:

[SAP HANA Server Installation and Update Guide](#)

### 10.1.2 Copying and Moving Tenant Databases

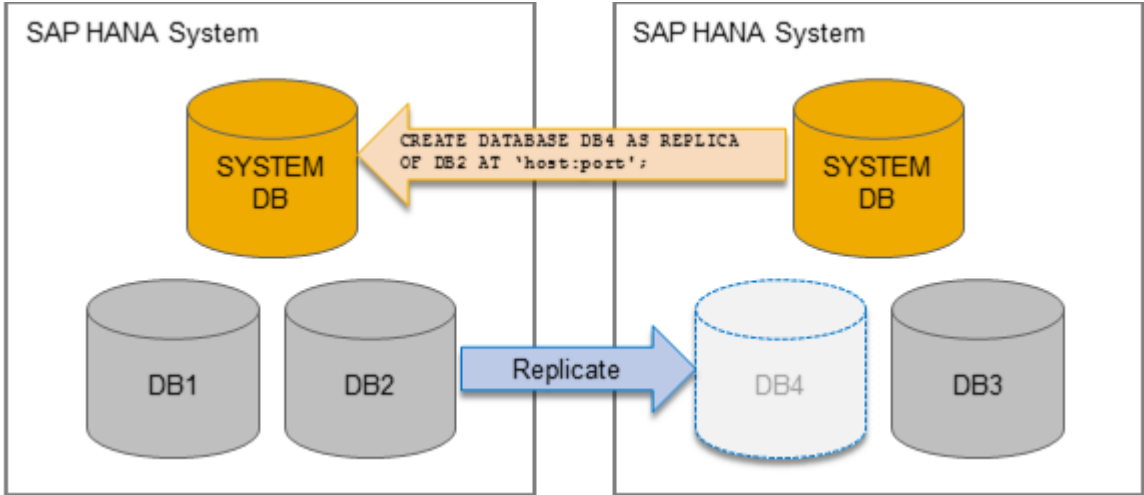

Using SAP HANA system replication mechanisms, SAP HANA tenant databases can be copied and moved securely and conveniently from one SAP HANA system to another with near-zero downtime. This allows you to respond flexibly to changing resource requirements and to manage your system landscape efficiently.

The following sections provide an overview of copying or moving a tenant database using system replication.

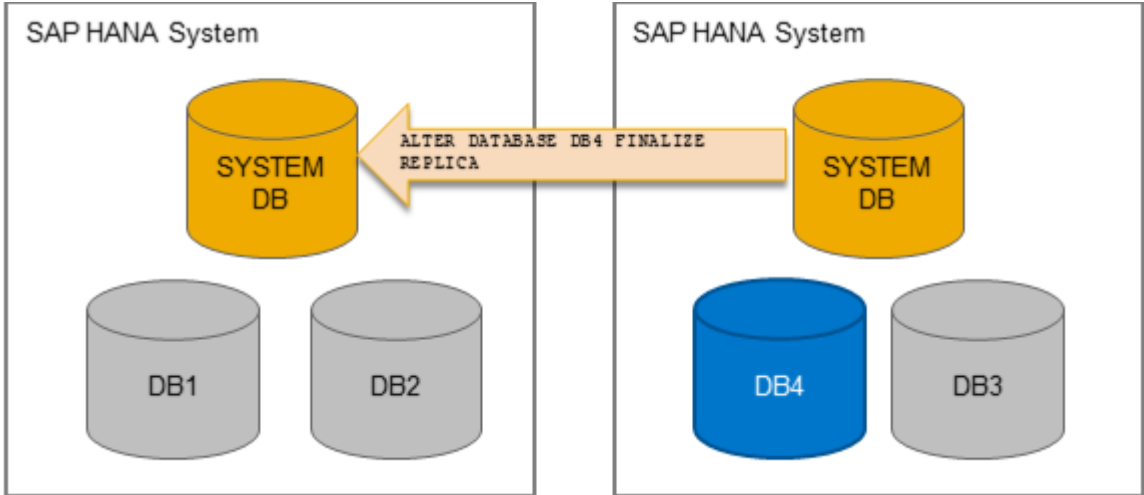

- [Process Overview \[page 1138\]](#)
- [Use Cases \[page 1139\]](#)
- [Which Data Is Copied or Moved? \[page 1140\]](#)
- [Recoverability After Copy or Move \[page 1140\]](#)
- [Client Communication After Move \[page 1141\]](#)
- [Prerequisites and Implementation Considerations \[page 1141\]](#)
- [Other Copy and Move Methods \[page 1142\]](#)

### Process Overview

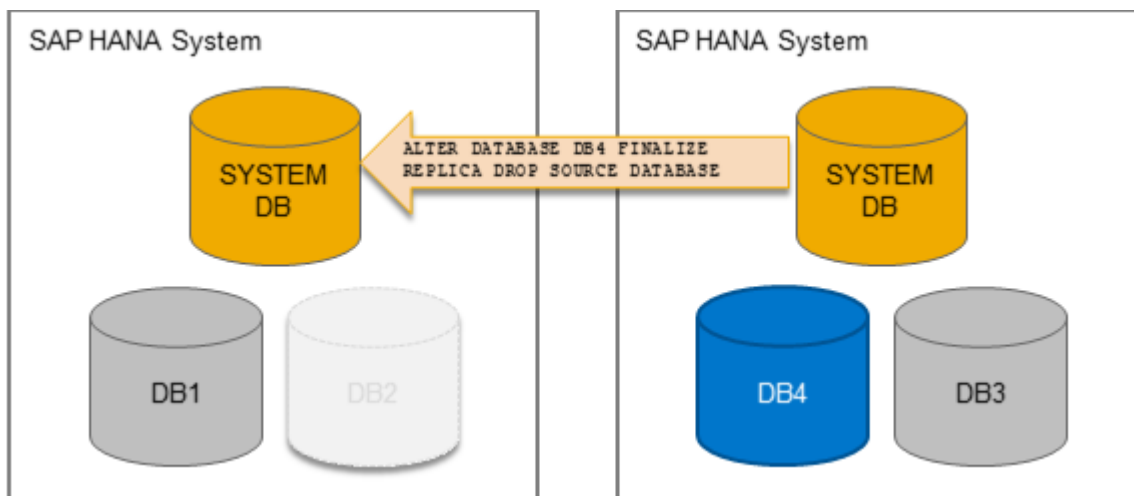

Copying and moving a tenant database are essentially the same process. First, the tenant database is copied through the replication of all of its data to a newly created tenant database in a target system:

Once all data has been successfully transferred, the new tenant database is started as a separate, independent database:

If the aim is to move the tenant database to the new system, the original tenant database is deleted and the new tenant database takes over:

The only difference between copying and moving a tenant database therefore is what happens to the original tenant database after all data has been transferred to the new tenant database in the target system.

In both cases, the new tenant database starts running as a fully separate, independent database.

Several tenant databases can be copied or moved to a system at the same time. It is also possible to copy or move a tenant database to a system with a different isolation level than the source system.

You can also use this mechanism to create a copy of a tenant database on the same host or to copy/move a tenant database to another host that is part of the same system.

## Use Cases

Copying and moving a tenant database from one system to another in this way has several applications, including:

- Load balancing between systems  
For example, a tenant database is running a more demanding workload than anticipated, so you move it to a system running on a host with more CPU resources.
- Management of deployment environment  
For example, you want to copy a tenant database running in your test system to the live production system.
- Tenant-database-specific upgrades  
For example, you want to upgrade a single tenant database but not the entire system, so you move the tenant database to a system already running the higher version.
- Template databases  
For example, you create a tenant database with a default configuration that you want to reuse as the basis for new tenant databases in other systems. You can simply copy the tenant database as a template to other systems.

## Which Data Is Copied or Moved?

When a tenant database is copied or moved, data is replicated from the original tenant database to the new tenant database in the target system.

The following table indicates which types of data are replicated and which are not.

Type of Data	Replicated?
Data and logs of the tenant database	Yes
Trace and log files	No
Data backups	No
Configuration (*.ini) files with tenant-database-specific values This refers to files in the directory <code>\$DIR_INSTANCE/.. /SYS/global/hdb/custom/config/&lt;database_name&gt;</code>	No
Certificates and certificate collections stored in the tenant database This refers to the digital certificates and certificate stores used for certificate-based user authentication and secure communication between SAP HANA and JDBC/ODBC clients.	Yes
<p><b>i Note</b></p> <p>If these certificates are stored in the file system in personal security environments (PSEs), they will not be replicated. To ensure that they are replicated, migrate the file-system-based PSEs to in-database certificate collections before copying or moving the tenant database. For more information about how to do this, see SAP Note 2175664.</p>	
Encryption root keys (for data and log volume encryption, backup encryption and the internal data encryption service)	Copy: No Move: Partially
<p><b>i Note</b></p> <p>The root key used for data volume encryption is not replicated during the move process.</p>	
Key management configurations if the local secure store (LSS) is used with an external key management system (KMS)	Yes
Application function libraries	No

## Recoverability After Copy or Move

When you copy a tenant database, the new tenant database does not have a backup history and cannot be recovered immediately after being copied. For this reason, it is important to perform a full data backup after you copy.

When you move a tenant database, the backup history of the original tenant database is retained in the new tenant database. As long as data and log backups of the source system are at a location accessible to the target system, the new tenant database is recoverable immediately after the move.

### ⚠ Caution

If you subsequently create a tenant database in the source system with the same name as the moved tenant database, the backup files of the original database are overwritten.

## Client Communication After Move

We recommend that you do not specify physical host names in the SQL client connect string. Otherwise, you would have to reconfigure all of your applications after a move. Instead, configure virtual host names or virtual IP addresses. For more information on virtual IP addresses, see *Configure Host-Independent Tenant Addresses*.

## Prerequisites and Implementation Considerations

- The copy and move process involves the creation of a new tenant database in the target system. Therefore, the target tenant database must not already exist in the target system.
- The target system must have a software version equal to or higher than the source system.
- If the source system is using the LSS in conjunction with an external KMS, then the target system must also use the LSS and a key management configuration ID (other than `DEFAULT`) must be provided to initiate the copy or move. Only a key administrator (user with `ENCRYPTION_ROOT_KEY_ADMIN`) system privilege can obtain this information from the system view `SYS.KEY_MANAGEMENT_CONFIGURATIONS`. The key administrator may add a dedicated configuration for the target system in the source system before the copy or move.  
If the source system is not using the LSS with a KMS, then the target system may use either the LSS or the SSFS secure store in the system. For more information, see *Server-Side Secure Stores* and *Using the LSS with an External Key Management System*.
- If data volume encryption is enabled in the original system, data is decrypted before replication and then re-encrypted (with a new root key) in the new database. However, during the copy and move process, data must be replicated via a secure (SSL/TLS) network connection by default.
- In a running system replication, it is possible to copy or move tenant databases into a primary system or from a primary system into another target system different than the secondary system.
- There can be no changes to the topology of the original tenant database while the move or copy is in progress. In other words, until the copy or move has been finalized, it is not possible to add services to or remove services from the source tenant database.
- If the source system is configured for host auto-failover, the copy or move process will fail in the event of failover to a standby host. If this happens, the simple solution is to delete the new tenant database on the target system, which will interrupt and clean up the copy or move process on the source and target side. Afterwards, the copy or move process has to be restarted. Alternatively, if restarting the process is not feasible, altering the network settings to make the standby host accessible through the same IP address as the failed host will resume the copy or move process.
- The following components must not be configured in the source tenant database:
  - Rserve server
  - SAP HANA dynamic tiering (extended storage server)
  - SAP HANA accelerator for SAP ASE (extended transaction service)

- SAP HANA streaming analytics (streaming host)

## Other Copy and Move Methods

### Backup and Recovery

It is possible to use backup and recovery to copy or move tenant databases between two systems. However, we recommend using SAP HANA system replication as described here. The main advantage of using system replication over backup and recovery is the absence of downtime. Using backup and recovery, you would have to shut down the original database after backing it up until the new database is successfully recovered. This is particularly critical if you are moving a tenant database. System replication is also a more convenient method because you don't need to move files between the different systems.

To copy or move a tenant database within the same system, we recommend using backup and recovery.

### SAP HANA Database Lifecycle Manager (HDBLCM)

To copy or clone an entire system, use the SAP HANA database lifecycle manager (HDBLCM) as described in the *SAP HANA Platform Lifecycle Management* section of the *SAP HANA Administration Guide*.

## 10.1.2.1 Copy and Move Process

Understand the stages and steps involved in copying and moving a tenant database from a source system to a target system using SAP HANA system replication.

### Overview

The process of copying or moving a tenant database is driven entirely by the target system.

The following figure shows the stages involved, as well as who performs the individual steps in each stage: the system administrator or the target system. Each step is then described in more detail.

Tenant Move/Copy Process Flow

## Prepare

Who?	Does What?	Where?
System administrator	Verifies that TLS/SSL is enabled on internal communication channels	System database of source and target system
	Configures secure connection from target system to source system by: <ol style="list-style-type: none"> <li>Creating a certificate collection with the purpose <code>DATABASE_REPLICATION</code> and adding the root certificate of the source system to the new collection This will allow trust to be established between the system databases of the target and source system for external communication via SQL.</li> <li>Creating a credential in the target system to enable authenticated access from the target system to the source system</li> </ol>	System database of target system
	Opens communication from the target system to the source system by enabling source system services to listen on all network interfaces	System database of source system
	Creates a credential to enable authenticated access to the source system for the purpose of copying or moving a tenant database	System database of target system

Who?	Does What?	Where?
	<p>If necessary, obtains a valid key management configuration ID (other than <code>DEFAULT</code>) from the key administrator (that is a user with system privilege <code>ENCRYPTION ROOT KEY ADMIN</code>).</p> <p>The key administrator may create a dedicated configuration for the new database in the source system before the copy or move and provide the ID of this configuration to the system administrator.</p>	System database of source system
	<div style="background-color: #f0f0f0; padding: 10px;"> <p><b>i Note</b></p> <p>This step is only relevant if the local secure store (LSS) is being used in conjunction with an external key management system (KMS).</p> </div>	
System administrator	Backs up the source tenant database	System database of source system

For more information, see *Preparing to Copy or Move a Tenant Database*.

## Copy and Move

Who?	Does What?	Where?
System administrator	Triggers the creation of the tenant database as a replica of the source tenant database by executing the SQL statement <code>CREATE DATABASE AS REPLICA</code>	System database of target system
System database of target system	<p>Establishes a secure connection to the system database using the stored credentials created above</p> <p>For subsequent secure communication between the systems, a set of public and private key pairs and public-key certificates is generated in the source system database. These will be used to secure communication from the target system database to the source system database, and from the target tenant database to the source tenant database.</p> <p>The generated key pairs and certificates are imported into two newly created certificate collections in the target system database.</p>	From target system to source system
	Creates a new tenant database with the same topology as the tenant database in the source system	Target system
	Initiates replication of data between the services in the source tenant database and the corresponding services in the target database	From source tenant database to target tenant database

Who?	Does What?	Where?
System administrator	Monitors the progress of data replication in system view <code>SYS_DATABASES.M_DATABASE_REPLICAS</code>	System database of target system or source system
	Once the replication status is <code>ACTIVE</code> (indicating that all data has been transferred), commits the copy by executing the SQL statement <code>ALTER DATABASE FINALIZE REPLICA</code>	System database of the target system
	In the case of a move, the administrator indicates that the source tenant database is to be dropped: <code>DROP SOURCE DATABASE.</code>	

For more information, see *Copy a Tenant Database to Another System* and *Move a Tenant Database to Another System*.

## Finalize

Who?	Does What?	Where?
System database in target system	Starts the target tenant database	Target system
	If the source tenant database is being moved to the target system, stops and drops the source tenant database	Source system
	Performs clean-up operations: <ul style="list-style-type: none"> <li>Deletes any cross-database dependencies to the original tenant database in other tenant databases of the source system (<b>move only</b>)</li> <li>Deletes any remote identity dependencies of users in the new tenant database in the target tenant database (<b>copy and move</b>)</li> <li>Generates a new root key used for data volume encryption and re-encrypts data if data volume encryption is enabled (<b>copy and move</b>)</li> </ul>	Source system and tenant database in target system
System administrator	Performs manual post-copy or post-move steps: <ul style="list-style-type: none"> <li>Back up the target tenant database This is only necessary after a copy since the new tenant database does not have a backup history and cannot be recovered. After a move, the new tenant database has the backup history of the original tenant database and can be recovered if data and log backups of the source system are at a location accessible to the target system.</li> <li>Reverse preparatory steps required to secure the copy process</li> <li>If necessary, reconfigure parameters in *.ini files with tenant-database-specific values</li> <li>If necessary, reconfigure cross-database access</li> </ul>	System database of the target system

Who?	Does What?	Where?
Key administrator	If necessary, changes the key management configuration.	System database of the target system
	<b>i Note</b> This step is only relevant if the local secure store (LSS) is being used in conjunction with an external key management system (KMS).	

## Cancel

Who?	Does What?	Where?
System administrator	Cancels the creation of the tenant database as a replica of the source tenant database by executing the SQL statement <code>DROP DATABASE &lt;database_name&gt;</code>	System database of target system
System database of target system	Drops the target tenant database	Target system
	Performs clean-up operations	Target system

- [Create and Manage a Key Management Configuration \[page 988\]](#)

## 10.1.2.2 Security of the Copy and Move Process

Copying or moving a tenant database from one system to another is a secure end-to-end process.

### Secure Network Communication

The copy and move process ensures end-to-end data encryption and host authentication on the basis of X.509 client certificates. Dedicated certificates and trust stores (referred to as certificate collections) are created as part of the copy or move process for the purpose of that specific copy or move. Certificates and certificate collections are stored directly in the system databases as database objects.

## i Note

If secure network communication is not required, it can be disabled. As a result, a copy or move of a tenant database can be initiated without the exchange of certificates. For more information, see *Disable Secure Network Communication*.

For more information about in-database certificate management, see the *SAP HANA Security Guide*.

## Authorization and Authentication

The copy and move process is triggered from the system database of the target system by a system administrator. To be able to execute the copy or move statements, the administrator user requires the system privilege `DATABASE ADMIN`.

To be able to establish a connection to the system database of the source system, the target system must be authenticated on the source system. This is achieved through the creation of a credential in the secure internal credential store of the system database of the target system. The required credential must be created manually by an administrator in the system database of the target system before the copy or move is started. For more information about the secure internal credential store, see the *SAP HANA Security Guide*.

## Encryption Key Handling

To protect data saved to disk from unauthorized access at operating system level, the SAP HANA database supports data encryption in the persistence layer for data and log volumes, and data and log backups. An internal data encryption service is also available to applications requiring data encryption. The instance secure store in the file system (SSFS) or the local secure store (LSS) is used to protect the root keys for these encryption services.

When a tenant database is **copied**, all encryption root keys in the tenant database in the target system are different to those in the tenant database of the source system.

When a tenant database is **moved**, all encryption root keys in the tenant database in the target system – with the exception of the root key used for data volume encryption – are the same as those in the source tenant database.

If the source system is using the LSS to protect root keys and the LSS is connected to an external key management system, then the target system must also use the LSS and the configuration ID of a key management configuration must be provided to initiate the copy or move process. Only the key administrator in the source system (user with `ENCRYPTION_ROOT_KEY_ADMIN` system privilege) can obtain this information from the system view `SYS.KEY_MANAGEMENT_CONFIGURATIONS`. This key management configuration is replicated to the target system and is initially used in the copied or moved database. The key administrator of the source system may prepare a dedicated configuration for the new database before the copy or move, or the key administrator of the target system can change the replicated configuration after the copy or move.

## Cross-Database Dependencies

If cross-database access is enabled in the original tenant database, some configured dependencies are automatically deleted to ensure no unauthorized communication paths or user mappings can be exploited in the copied or moved tenant database.

### Permitted Communication Paths

Part of the configuration of cross-database access involves specifying which tenant databases may communicate with each other and in which direction.

After a tenant database is moved to another system, it is deleted in the source system. However, communication paths referencing it will still exist in one or more of the other tenant databases in the source system. When the move operation is finalized, all such references to the original database are **automatically** deleted in other tenant databases of the source system.

Communication paths configured in the tenant database in the target system must manually be reconfigured after a move or copy.

### User Mappings

Another aspect of cross-database access configuration is the mapping of users in one tenant database to users in another tenant database using remote identities.

After a tenant database is moved or copied to another system, some of its database users may still be associated as remote identities for users in other databases in the source system. When the move or copy operation is finalized, all remote identity information of users in the new tenant database is **automatically** deleted.

New user mappings must be manually configured in the tenant database in the target system.

## Related Information

[Disable Secure Network Communication \[page 1148\]](#)

[Using the LSS with an External Key Management System \[page 986\]](#)

### 10.1.2.2.1 Disable Secure Network Communication

During the copy and move process, data is replicated via a secure (TLS/SSL) network connection by default. If this is not necessary in your scenario, you can disable this requirement.

### Prerequisites

- You have the system privilege INIFILE ADMIN.

- Neither the source system or target system is configured for high isolation (the value of the `database_isolation` in the `[multidb]` section of the `global.ini` file is **low**).
- The value of parameter `ssl` in the `[communication]` section of the `global.ini` file is set to **off**.
- External communication is not configured for TLS/SSL in either the source system or target system.

## Procedure

Using for example the SAP HANA cockpit or `ALTER SYSTEM ALTER CONFIGURATION` statement, set the parameter `[multidb]enforce_ssl_database_replication` in the `global.ini` file to **false**.

## Related Information

[Configuring SAP HANA System Properties \(INI Files\) \[page 301\]](#)

[Modify a System Property in SAP HANA Cockpit \[page 311\]](#)

## 10.1.2.3 Preparing to Copy or Move a Tenant Database

Before you copy or move a tenant database to another system, you must perform several steps. These are primarily to enable the systems to communicate with each other securely.

## Context

### i Note

During the copy and move process, data is replicated via a secure (TLS/SSL) network connection by default. If you do not require a secure network connection and have disabled this feature, you can skip the first two steps: *Verify TLS/SSL Configuration of Internal Communication Channels* and *Set Up Trust Relationship Between Target and Source Systems*. For more information, see *Disable Secure Network Communication*.

1. [Verify TLS/SSL Configuration of Internal Communication Channels \[page 1150\]](#)  
In both the source system and the target system, verify that TLS/SSL is enabled on internal communication channels on the basis of the system public key infrastructure (system PKI).
2. [Set Up Trust Relationship Between Target and Source Systems \[page 1151\]](#)  
Create a certificate collection in the system database of the target system and add either the public-key certificate of the system database of source system, or the root certificate of the source system. This certificate is used to secure communication between the systems via external SQL connections.
3. [Open Communication From Target to Source System \[page 1154\]](#)

Open communication from the target system to the source system by enabling services in the source system to listen on all network interfaces.

4. [Create Credential for Authenticated Access to Source System \[page 1155\]](#)  
Create a credential to enable authenticated access to the source system for the purpose of copying or moving a tenant database.
5. [Obtain Key Management Configuration ID \[page 1157\]](#)  
In the system database of the source system, obtain the ID of key management configuration to be replicated to the target system.
6. [Back Up Tenant Database \[page 1158\]](#)  
Back up the tenant database that will be copied or moved.

## Related Information

### 10.1.2.3.1 Verify TLS/SSL Configuration of Internal Communication Channels

In both the source system and the target system, verify that TLS/SSL is enabled on internal communication channels on the basis of the system public key infrastructure (system PKI).

## Prerequisites

You have a user in the system database of both systems with the system privilege `INIFILE ADMIN`.

## Context

During the copy and move process, data is replicated via a secure (TLS/SSL) network connection by default. If you do not require a secure network connection and have disabled this feature, you can skip this step. For more information, see *Disable Secure Network Communication*.

## Procedure

### → Remember

This step must be performed in both the source system and the target system.

1. Verify the `SYSTEM` layer values of the following parameters in the `global.ini` file:

- `[communication] ssl` must be set to **systempki**
- `[system_replication_communication] enable_ssl` must be set to **on**

You can verify (and change) these settings using the SAP HANA cockpit or alternatively, you can configure them by executing the following SQL statements:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'SYSTEM') SET
( 'communication', 'ssl') = 'systempki' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'SYSTEM') SET
( 'system_replication_communication', 'enable_ssl') = 'on' WITH RECONFIGURE;
```

2. Restart the system.

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Next task:** [Set Up Trust Relationship Between Target and Source Systems \[page 1151\]](#)

## Related Information

### 10.1.2.3.2 Set Up Trust Relationship Between Target and Source Systems

Create a certificate collection in the system database of the target system and add either the public-key certificate of the system database of source system, or the root certificate of the source system. This certificate is used to secure communication between the systems via external SQL connections.

## Prerequisites

- You have a user in the system database of the target system with the system privileges `CERTIFICATE ADMIN`, `TRUST ADMIN`, and `DATABASE ADMIN`.
- You have a copy of the `extract_certificates.py` python script. The python script file must be accessible to the `<sid>adm` user. You can find the script attached to *SAP Note 2175664*.
- You have the public-key certificate of the system database of the source system (or the root certificate of the source system) used for external communication.

If this certificate does not already exist, you can create it using the SAPGENPSE tool or the SAP Web Dispatcher administration tool, both of which are delivered with SAP HANA. The certificate must be imported into the source system.

### ⚠ Caution

By default, SAP HANA allows encrypted communication for all exposed interfaces leveraging self-signed certificates. Although self-signed certificates allow communication encryption, full communication security can only be reached leveraging certificates signed by a Certificate Authority (CA).

If the certificate does exist, its location depends on how you manage certificates in your system. Certificates stored in database (recommended) are contained in the certificate store. The required certificate is assigned to the collection with purpose [SSL](#). Certificates stored in the file system are contained in tenant database-specific personal security environments or PSEs (default `$SECUDIR/sapsrv.pse`).

For more information, see *TLS/SSL Configuration on the SAP HANA Server* in the SAP HANA Security Guide and *Managing Client Certificates* in the SAP HANA Administration Guide.

## Context

During the copy and move process, data is replicated via a secure (TLS/SSL) network connection by default. If you do not require a secure network connection and have disabled this feature, you can skip this step. For more information, see *Disable Secure Network Communication*.

### i Note

If you already have a CA-signed certificate, you can skip steps 1 through 3.

## Procedure

1. Create a personal security environment (PSE) file using the SAPGENPSE tool.

```
sapgenpse gen_pse -p <path>/<file name>.pse -x "" -noreq "CN=<FQDN of source host>"
```

### ❖ Example

```
sapgenpse gen_pse -p foo.pse -x "" -noreq "CN=sourcehost.domain"
```

2. Extract the generated private key and the self-signed certificate from the PSE file using the `extract_certificates.py` script.

```
python <path to script>/extract_certificates.py -p <file name>.pse
```

The script will print a list of one or more SQL statements that can be transferred to an SQL console using copy and paste.

3. In the system database of the source system, create a certificate collection and set its purpose to `SSL`. You can choose any name for the certificate collection.

You can do this using the *Certificate Collections* app of the SAP HANA cockpit or by executing the following SQL statements:

```
CREATE PSE <collection name>;
ALTER PSE <collection name> SET OWN CERTIFICATE '<private key and
certificate>';
SET PSE <collection name> PURPOSE SSL;
```

#### → Tip

You can generate the `ALTER PSE` SQL statement using the `extract_certificates.py` script.

4. In the system database of the target system, create a certificate collection and set its purpose to `DATABASE REPLICATION`. You can choose any name for the certificate collection.

You can do this using the *Certificate Collections* app of the SAP HANA cockpit or by executing the following SQL statements:

```
CREATE PSE <collection name>;
SET PSE <collection name> PURPOSE DATABASE REPLICATION;
```

5. If not already in the certificate store, import the public-key certificate of the system database of the source system (or the root certificate of the source system) into the certificate store of the target system.

You can do this using the *Certificate Store* app of the SAP HANA cockpit or by executing the following SQL statement:

```
CREATE CERTIFICATE FROM '<certificate content>';
```

6. Add the system database certificate (or root certificate) to the new collection.

You can do this using the *Certificate Collections* app of the SAP HANA cockpit or by executing the following SQL statement:

```
ALTER PSE <collection name> ADD CERTIFICATE <certificate id>;
```

#### → Tip

You will find the certificate ID in the system view `SYS.CERTIFICATES`.

```
SELECT * FROM SYS.CERTIFICATES;
```

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Previous task:** [Verify TLS/SSL Configuration of Internal Communication Channels \[page 1150\]](#)

**Next task:** [Open Communication From Target to Source System \[page 1154\]](#)

## Related Information

### 10.1.2.3.3 Open Communication From Target to Source System

Open communication from the target system to the source system by enabling services in the source system to listen on all network interfaces.

#### Prerequisites

You have the credentials of operating system administrator `<sid>adm` for the source system.

#### Context

Use the SAP HANA database lifecycle manager (HDBLCM) to configure inter-service communication so that the services of the target system can listen on all available network interfaces.

##### i Note

It is only necessary to perform this step in the source system. However, if you later want to be able to monitor the progress of the copy or move operation from the source system, you can also do it in the target system.

#### Procedure

##### i Note

The following procedure describes how to do this using the Web user interface. For more information about using the command-line interface or graphical user interface of the SAP HANA database lifecycle manager, see the *SAP HANA Administration Guide*.

Instead of using the SAP HANA database lifecycle manager (HDBLCM), you can execute the following SQL statement:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'SYSTEM') SET ( 'communication',  
'listeninterface') = '.global' WITH RECONFIGURE;
```

1. Open the SAP HANA database lifecycle manager by entering the following URL in a browser:  
`https://<host>:1129/lms1/HDBLCM/<sid>/index.html`
2. Click the tile *Configure Inter-Service Communication*.
3. When prompted, enter the password of the <sid>adm user.
4. Select the setting *global*.
5. Click *Run* to apply the new setting.
6. Close the application and log out.
7. Restart the SAP HANA database.

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Previous task:** [Set Up Trust Relationship Between Target and Source Systems \[page 1151\]](#)

**Next task:** [Create Credential for Authenticated Access to Source System \[page 1155\]](#)

## Related Information

[Internal Host Name Resolution \[page 1213\]](#)

### 10.1.2.3.4 Create Credential for Authenticated Access to Source System

Create a credential to enable authenticated access to the source system for the purpose of copying or moving a tenant database.

#### Prerequisites

- You have a user in the system database of the target system with the system privilege `CREDENTIAL ADMIN`.

#### Context

You create a credential in the secure internal credential store of the system database of target system.

The credential store is used in SAP HANA to securely store credentials required for outbound connections. For more information about the secure internal credential store, see the *SAP HANA Security Guide*.

## Procedure

In the system database of the target system, create a credential by executing the following SQL statement:

```
CREATE CREDENTIAL FOR COMPONENT 'DATABASE_REPLICATION' PURPOSE
'<host:internal_port_of_system_DB_of_source_system>'
TYPE 'PASSWORD' USING
'user="<user_in_system_DB_of_source_system_with_DATABASE_ADMIN>";password="<password>"'
```

The values required for each parameter are as follows:

Parameter	Required Value
COMPONENT	DATABASE_REPLICATION
PURPOSE	Host name and internal port number of the system database of the source system
TYPE	PASSWORD
USING	User name of a user in the system database of the source system with the system privilege DATABASE ADMIN

### Sample Code

```
CREATE CREDENTIAL FOR COMPONENT 'DATABASE_REPLICATION' PURPOSE
'host123456.acme.corp:30001' TYPE 'PASSWORD' USING
'user="DATABASE_ADMINISTRATOR";password="<password>"'
```

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Previous task:** [Open Communication From Target to Source System \[page 1154\]](#)

**Next task:** [Obtain Key Management Configuration ID \[page 1157\]](#)

## Related Information

[SAP HANA Security Guide](#)

## 10.1.2.3.5 Obtain Key Management Configuration ID

In the system database of the source system, obtain the ID of key management configuration to be replicated to the target system.

### Prerequisites

- The source system uses the local secure store (LSS) in conjunction with an external key management system (KMS) to protect encryption root keys.
- You have the system privilege `ENCRYPTION_ROOT_KEY_ADMIN`.

### Context

When moving or copying a tenant database, a key management configuration ID (other than `DEFAULT`) must be provided if the source system uses the LSS with a KMS. Since only a key administrator can obtain the key management configuration ID, this means that the key administrator must permit the transfer of a key management configuration to the target system.

This key management configuration is replicated to the target system and is initially used in the copied or moved database. The key administrator of the source system may create a dedicated configuration for the new database already before the copy or move, or the key administrator of the target system can change the replicated configuration after the copy or move.

### Procedure

Get the required configuration ID by querying system view `SYS.KEY_MANAGEMENT_CONFIGURATIONS`.

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Previous task:** [Create Credential for Authenticated Access to Source System \[page 1155\]](#)

**Next task:** [Back Up Tenant Database \[page 1158\]](#)

### Related Information

## 10.1.2.3.6 Back Up Tenant Database

Back up the tenant database that will be copied or moved.

### Context

You can back up the tenant database from the system database or from the tenant database directly. For more information, see *Creating Backups* in the *SAP HANA Administration Guide*.

**Task overview:** [Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

**Previous task:** [Obtain Key Management Configuration ID \[page 1157\]](#)

### Related Information

[Creating Backups \[page 1498\]](#)

## 10.1.2.4 Copy a Tenant Database to Another System

Copy a tenant database from one SAP HANA system to another. The new copied tenant database runs as a separate, independent database.

### Prerequisites

- All general system prerequisites are fulfilled. For more information, see *Copying and Moving Tenant Databases Between Systems*.
- All preparatory steps have been completed. For more information, see *Preparing to Copy or Move a Tenant Database*.
- You have a user in the system database of the target system with the system privilege `DATABASE ADMIN` and `CATALOG READ`.

### Procedure

1. Create a tenant database in the target system as a copy of the original tenant database in the source system.

You do this by executing the CREATE DATABASE statement:

### Code Syntax

```
CREATE DATABASE <target_database_name> [ AT [ LOCATION ]
'<target_hostname>[:<port_number_master_indexserver> ] ' ]
{ ADD '<servicetype>' [ AT [ LOCATION ]
'<target_hostname>[:<port_number_service> ]@<source_hostname>:<port_number_
service>' ] }...
{ AS REPLICA OF [ <source_database_name> ] AT [ LOCATION ]
'<source_hostname>[:<port_number_systemdb> ]' KEY MANAGEMENT CONFIGURATION
<id> }
[ OS USER '<username>' OS GROUP '<groupname>' ]
[ NO START ]
[ <restart_mode> RESTART ]
```

### Note

- As the location of the source tenant database, you specify the host name and port number for internal communication of the **system database** of the source system.
- If you enabled SSL, the host name must match the common name (CN) specified in the public-key certificate of the system database of source system.
- If you specify a service list, the number and type of services must match the source database.
- If your systems are configured for high isolation, you specify a valid OS user or OS group of the tenant database.
- Fallback snapshots are not copied to the target system.

### Sample Code

```
CREATE DATABASE TARGET_DATABASE AS REPLICA OF SOURCE_DATABASE AT
'host123456.acme.corp:30001';
```

With the execution of this statement, the system database of the target system does the following:

- Establishes a secure connection to the system database of the source system
  - Creates a tenant database with the same topology as the tenant database in the source system
  - Starts replicating data between the services in the source tenant database and the corresponding services in the target database
2. Monitor replication progress of data replication from the original tenant database to the new tenant database.

Use the system view `SYS_DATABASES.M_DATABASE_REPLICAS` to monitor the status of data replication in the system database of the target system or `SYS.M_DATABASES` to monitor directly in the new tenant database.

The current status of replication is shown in the field `REPLICATION_STATUS`. The value is aggregated across all individual services of the system, e.g. the system global status is only `ACTIVE`, if all individual services have replication status `ACTIVE`.

The following replication statuses are possible:

Status	Description
UNKNOWN	The secondary system did not connect to the primary system since the last restart of the primary system.
INITIALIZING	Data transfer is initialized. In this state, the secondary system cannot be used.
SYNCING	The secondary system is syncing again (e.g. after a temporary connection loss or restart of the secondary system).
ACTIVE	Initialization or sync with the primary system is complete and the secondary system is continuously replicating. If a crash occurs, no data is lost in SYNC mode.
ERROR	A connection error occurred (details can be found in REPLICATION_STATUS_DETAILS).

The view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` provides detailed information about the replication process at the service level.

#### → Tip

If the replication status is `ERROR`, use system view

`SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` to investigate further.

If you cannot create a replica because the source database is still in status "REPLICATING" even though the target database is already dropped, execute the statement `ALTER DATABASE <database_name> CANCEL REPLICA` on the source system to clean up the system before reattempting replication.

#### i Note

You can also monitor from the source system if you opened communication between the systems in both directions. For more information, see *Open Communication From Target to Source System*.

- When replication status is `ACTIVE` (indicating that the new tenant database is in sync with the original tenant database), stop replication and finalize the copy by executing the following statement in the system database of the target system:

```
ALTER DATABASE <new_database_name> FINALIZE REPLICA
```

With the execution of the above statement, the system database of the target system performs the following actions in the new tenant database:

- Starts the new tenant database
- Changes the root key for data volume encryption and re-encrypts data in the new database if data volume encryption is enabled
- Deletes remote identities of database users if the original tenant database was configured for cross-database access

## Next Steps

Perform the required manual post-move tasks.

[M\\_DATABASE\\_REPLICAS System View](#)

### 10.1.2.5 Move a Tenant Database to Another System

Move a tenant database in one SAP HANA system to another. After a move, the original tenant database is deleted and the new tenant database takes over.

#### Prerequisites

- All general system prerequisites are fulfilled. For more information, see *Copying and Moving Tenant Databases Between Systems*.
- All preparatory steps have been completed. For more information, see *Preparing to Copy or Move a Tenant Database*.
- You have a user in the system database of the target system with the system privilege `DATABASE ADMIN` and `CATALOG READ`.

#### Procedure

1. Create a tenant database in the target system as a copy of the original tenant database in the source system.

You do this by executing the `CREATE DATABASE` statement:

#### Code Syntax

```
CREATE DATABASE <target_database_name> [ AT [ LOCATION ]
'<target_hostname>[:<port_number_master_indexserver> ] ' ]
{ ADD '<servicetype>' [ AT [ LOCATION ]
'<target_hostname>[:<port_number_service> ]@<source_hostname>:<port_number_
service>' ] }...
{ AS REPLICA OF [ <source_database_name> ] AT [ LOCATION ]
'<source_hostname>[:<port_number_systemdb> ]' KEY MANAGEMENT CONFIGURATION
<id> }
[ OS USER '<username>' OS GROUP '<groupname>' ]
[ NO START ]
[ <restart_mode> RESTART ]
```

## Note

- As the location of the source tenant database, you specify the host name and port number for internal communication of the **system database** of the source system.
- If you enabled SSL, the host name must match the common name (CN) specified in the public-key certificate of the system database of source system.
- If you specify a service list, the number and type of services must match the source database.
- If your systems are configured for high isolation, you specify a valid OS user or OS group of the tenant database.
- Fallback snapshots are not moved to the target system.

## Sample Code

```
CREATE DATABASE TARGET_DATABASE AS REPLICA OF SOURCE_DATABASE AT
'host123456.acme.corp:30001';
```

With the execution of this statement, the system database of the target system does the following:

- Establishes a secure connection to the system database of the source system
- Creates a tenant database with the same topology as the tenant database in the source system
- Starts replicating data between the services in the source tenant database and the corresponding services in the target database

2. Monitor replication progress of data replication from the original tenant database to the new tenant database.

Use the system view `SYS_DATABASES.M_DATABASE_REPLICAS` to monitor the status of data replication in the system database of the target system or `SYS.M_DATABASES` to monitor directly in the new tenant database.

The current status of replication is shown in the field `REPLICATION_STATUS`. The value is aggregated across all individual services of the system, e.g. the system global status is only `ACTIVE`, if all individual services have replication status `ACTIVE`.

The following replication statuses are possible:

Status	Description
UNKNOWN	The secondary system did not connect to the primary system since the last restart of the primary system.
INITIALIZING	Data transfer is initialized. In this state, the secondary system cannot be used.
SYNCING	The secondary system is syncing again (e.g. after a temporary connection loss or restart of the secondary system).
ACTIVE	Initialization or sync with the primary system is complete and the secondary system is continuously replicating. If a crash occurs, no data is lost in <code>SYNC</code> mode.
ERROR	A connection error occurred (details can be found in <code>REPLICATION_STATUS_DETAILS</code> ).

The view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` provides detailed information about the replication process at the service level.

### → Tip

If the replication status is `ERROR`, use system view

`SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` to investigate further.

If you cannot create a replica because the source database is still in status "REPLICATING" even though the target database is already dropped, execute the statement `ALTER DATABASE <database_name> CANCEL REPLICA` on the source system to clean up the system before reattempting replication.

### i Note

You can also monitor from the source system if you opened communication between the systems in both directions. For more information, see *Open Communication From Target to Source System*.

3. When replication status is `ACTIVE` (indicating that the new tenant database is in sync with the original tenant database), stop replication and finalize the move by executing the following statement in the system database of the target system:

```
ALTER DATABASE <new_database_name> FINALIZE REPLICA DROP SOURCE DATABASE
```

With the execution of the above statement, the system database of the target system performs the following actions:

- Starts the new tenant database
- Changes the root key for data volume encryption and re-encrypts data in the new database if data volume encryption is enabled
- Drops the original tenant database in the source system

### i Note

To ensure that the new tenant database can be recovered to the most recent consistent state after the move, data backups are not deleted as part of the move process. This is important in the event that a backup is created in the original tenant database after replication has finished but before the original database is finally deleted.

- Deletes any communication paths configured for cross-database access that reference the original tenant database in the other tenant databases of the source system

## Next Steps

Perform the required manual post-move tasks.

## Related Information

[Copying and Moving Tenant Databases \[page 1137\]](#)

[Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

[Perform Manual Post-Copy/Move Tasks \[page 1169\]](#)

## 10.1.2.6 Copy a Tenant Database to Another Host within the same System

Copy a tenant database from one host to another within the same system.

### Prerequisites

- All general system prerequisites are fulfilled. For more information, see *Copying and Moving Tenant Databases Between Systems*.
- All preparatory steps have been completed. For more information, see *Preparing to Copy or Move a Tenant Database*.
- You have a user in the system database with the system privilege `DATABASE ADMIN` and `CATALOG READ`.

### Procedure

1. Create a tenant database as a copy of the original tenant database.

You do this by executing the `CREATE DATABASE` statement:

#### Code Syntax

```
CREATE DATABASE <target_database_name> [ AT [ LOCATION ]  
'<target_hostname>[:<port_number_master_indexserver> ] ' ]  
{ ADD '<servicetype>' [ AT [ LOCATION ]  
'<target_hostname>[:<port_number_service> ]@<source_hostname>:<port_number_<br>service>' ] }...  
{ AS REPLICAS OF [ <source_database_name> ] AT [ LOCATION ]  
'<source_hostname>[:<port_number_systemdb> ]' KEY MANAGEMENT CONFIGURATION  
<id> }  
[ OS USER '<username>' OS GROUP '<groupname>' ]  
[ NO START ]  
[ <restart_mode> RESTART ]
```

#### Note

- As the location of the source tenant database, you specify the host name and port number for internal communication of the **system database**.
- If you do not specify a target host name, the host with the lowest number of services will be used.
- If you enabled SSL, the host name must match the common name (CN) specified in the public-key certificate of the system database.
- If you specify a service list, the number and type of services must match the source database.

- If your systems are configured for high isolation, you specify a valid OS user or OS group of the tenant database.
- Fallback snapshots are not copied.

### ⇐ Sample Code

```
CREATE DATABASE TARGET_DATABASE AS REPLICA OF SOURCE_DATABASE AT
'host123456.acme.corp:30101';
```

With the execution of this statement, the system database does the following:

- Creates a tenant database with the same topology as the source tenant database
  - Starts replicating data between the services in the source tenant database and the corresponding services in the target database
2. Monitor replication progress of data replication from the original tenant database to the new tenant database.

Use the system view `SYS_DATABASES.M_DATABASE_REPLICAS` to monitor the status of data replication in the system database or `SYS.M_DATABASES` to monitor directly in the new tenant database.

The current status of replication is shown in the field `REPLICATION_STATUS`. The value is aggregated across all individual services of the system, e.g. the system global status is only `ACTIVE`, if all individual services have replication status `ACTIVE`.

The following replication statuses are possible:

Status	Description
UNKNOWN	The secondary system did not connect to the primary system since the last restart of the primary system.
INITIALIZING	Data transfer is initialized. In this state, the secondary system cannot be used.
SYNCING	The secondary system is syncing again (e.g. after a temporary connection loss or restart of the secondary system).
ACTIVE	Initialization or sync with the primary system is complete and the secondary system is continuously replicating. If a crash occurs, no data is lost in <code>SYNC</code> mode.
ERROR	A connection error occurred (details can be found in <code>REPLICATION_STATUS_DETAILS</code> ).

The view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` provides detailed information about the replication process at the service level.

### → Tip

If the replication status is `ERROR`, use system view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` to investigate further.

If you cannot create a replica because the source database is still in status "REPLICATING" even though the target database is already dropped, execute the statement `ALTER DATABASE <database_name> CANCEL REPLICA` on the source system to clean up the system before reattempting replication.

3. When replication status is `ACTIVE` (indicating that the new tenant database is in sync with the original tenant database), stop replication and finalize the copy by executing the following statement in the system database:

```
ALTER DATABASE <new_database_name> FINALIZE REPLICA
```

With the execution of the above statement, the system database performs the following actions in the new tenant database:

- Starts the new tenant database
- Changes the root key for data volume encryption and re-encrypts data in the new database if data volume encryption is enabled
- Deletes remote identities of database users if the original tenant database was configured for cross-database access

## Next Steps

## 10.1.2.7 Create a Copy of a Tenant Database on the Same Host

Create a copy of a tenant database on the same host.

## Prerequisites

- All general system prerequisites are fulfilled. For more information, see *Copying and Moving Tenant Databases Between Systems*.
- All preparatory steps have been completed. For more information, see *Preparing to Copy or Move a Tenant Database*.
- You have a user in the system database with the system privilege `DATABASE ADMIN` and `CATALOG READ`.

## Procedure

1. Create a tenant database as a copy of the original tenant database.

You do this by executing the `CREATE DATABASE` statement:

### Code Syntax

```
CREATE DATABASE <target_database_name>
{ ADD '<servicetype>' [ AT [ LOCATION ]
'<hostname>[:<port_number_service> ]@<hostname>:<port_number_service>' ] }.
. .
{ AS REPLICA OF [ <source_database_name> ] KEY MANAGEMENT CONFIGURATION
<id> }
[ OS USER '<username>' OS GROUP '<groupname>' ]
[ NO START ]
[ <restart_mode> RESTART ]
```

### Note

- If you enabled SSL, the host name must match the common name (CN) specified in the public-key certificate of the system database.
- If you specify a service list, the number and type of services must match the source database.
- If your systems are configured for high isolation, you specify a valid OS user or OS group of the tenant database.
- Fallback snapshots are not copied.

### Sample Code

```
CREATE DATABASE TARGET_DATABASE AS REPLICA OF SOURCE_DATABASE;
```

With the execution of this statement, the system database does the following:

- Creates a tenant database with the same topology as the source tenant database
  - Starts replicating data between the services in the source tenant database and the corresponding services in the target database
2. Monitor replication progress of data replication from the original tenant database to the new tenant database.

Use the system view `SYS_DATABASES.M_DATABASE_REPLICAS` to monitor the status of data replication in the system database or `SYS.M_DATABASES` to monitor directly in the new tenant database.

The current status of replication is shown in the field `REPLICATION_STATUS`. The value is aggregated across all individual services of the system, e.g. the system global status is only `ACTIVE`, if all individual services have replication status `ACTIVE`.

The following replication statuses are possible:

Status	Description
UNKNOWN	The secondary system did not connect to the primary system since the last restart of the primary system.

Status	Description
INITIALIZING	Data transfer is initialized. In this state, the secondary system cannot be used.
SYNCING	The secondary system is syncing again (e.g. after a temporary connection loss or restart of the secondary system).
ACTIVE	Initialization or sync with the primary system is complete and the secondary system is continuously replicating. If a crash occurs, no data is lost in SYNC mode.
ERROR	A connection error occurred (details can be found in REPLICATION_STATUS_DETAILS).

The view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` provides detailed information about the replication process at the service level.

#### → Tip

If the replication status is `ERROR`, use system view `SYS_DATABASES.M_DATABASE_REPLICA_STATISTICS` to investigate further.

If you cannot create a replica because the source database is still in status "REPLICATING" even though the target database is already dropped, execute the statement `ALTER DATABASE <database_name> CANCEL REPLICA` on the source system to clean up the system before reattempting replication.

- When replication status is `ACTIVE` (indicating that the new tenant database is in sync with the original tenant database), stop replication and finalize the copy by executing the following statement in the system database:

```
ALTER DATABASE <new_database_name> FINALIZE REPLICA
```

With the execution of the above statement, the system database performs the following actions in the new tenant database:

- Starts the new tenant database
- Changes the root key for data volume encryption and re-encrypts data in the new database if data volume encryption is enabled
- Deletes remote identities of database users if the original tenant database was configured for cross-database access

## Next Steps

Perform the required manual post-move tasks.

## Related Information

[Copying and Moving Tenant Databases \[page 1137\]](#)

[Preparing to Copy or Move a Tenant Database \[page 1149\]](#)

[Perform Manual Post-Copy/Move Tasks \[page 1169\]](#)

[CREATE DATABASE Statement \(Tenant Database Management\)](#)

## 10.1.2.8 Perform Manual Post-Copy/Move Tasks

After you have committed the copy or move and the new tenant database is up and running, you must perform several manual tasks.

### Procedure

1. Back up the new root keys to a root key backup file (\*.rkb) in a secure location.

#### ⚠ Caution

Store the root key backup file in a safe location. Losing this file may result in the database being unrecoverable.

2. Perform a full data backup of the new tenant database (copy only).
3. Reverse the preparatory steps required to secure the copy or move process:
  - Close network communication from the target system to the source system. See *Open Communication From Target to Source System*.
  - Delete the credential used by the system database of the target system to access the source system. See *Create Credential for Authenticated Access to Source System*.
  - Delete the certificate collection with purpose DATA REPLICATION created to secure external communication between the systems. See *Set Up Trust Relationship Between Target and Source Systems*.
  - If you created and signed the certificate yourself, delete the PSE file from the file system.
4. If necessary, reconfigure parameters in \*.ini files with tenant-database-specific values. See *Configuration Parameters in Tenant Database Systems*.
5. Reconfigure cross-database access, if required. See *Enable and Configure Cross-Database Access*.
6. After configuring cross-database access, rebuild or repair cross-database objects, if required. For improved performance, SAP HANA stores object IDs of remote objects in the catalog persistence. If a tenant database is copied or moved, these remote object IDs are likely to change and must be rebuilt by executing the CHECK\_CATALOG procedure. The following objects are supported: functions, procedures, synonyms, SQL views, and calculation views.

#### i Note

Only rebuild and repair cross-database objects if you want the original settings to be fully restored. For security reasons, you may not want cross-database objects to be restored on a copied or moved system.

#### ❖ Example

Rebuild all objects with remote dependencies by executing the following procedure:

```
CALL CHECK_CATALOG ('REBUILD_REMOTE_DEPENDENCY', null, null, null)
```

Repair all objects in `<schema>` by executing the following procedure:

```
CALL CHECK_CATALOG ('REPAIR_REMOTE_DEPENDENCY', '<schema>', null, null)
```

Repair the object `<schema>.<view>` by executing the following procedure:

```
CALL CHECK_CATALOG ('REPAIR_REMOTE_DEPENDENCY', '<schema>', '<view>', null)
```

## 10.1.3 Copying a System Using System Replication

SAP HANA system replication can be used to create a copy of an SAP HANA database in a quick and simple way.

You can register another SAP HANA database for replication in one of the following two system replication scenarios:

- As a secondary for a standalone SAP HANA database
- As a tier 3 secondary in a tier 2 system replication landscape

System Replication Scenarios

Original Setup	Source Database	Target Database
Standalone SAP HANA Database	Primary	Secondary
Tier 2 System Replication	Tier 2 Secondary	Tier 3 Secondary

After the replication is active and in sync, a takeover to the newly added tier makes the target SAP HANA database runnable with identical data to the source database.

## 10.1.3.1 Copy a System Using System Replication

You can use SAP HANA system replication to create a copy of an SAP HANA database.

### Prerequisites

- This process requires a source SAP HANA database which is to be copied.
- The target host(s) can also be virtual machines, but the installed SAP HANA version on the target must be either the same or higher than the version on the source.

### Procedure

1. Prepare the source database for replication with the following command:

```
hdbnsutil -sr_enable [--name=<siteName>]
```

2. Register the target database either as a secondary or tier 3 secondary depending on your original setup:

```
hdbnsutil -sr_register --remoteHost=<primary master host> --  
remoteInstance=<primary instance id>  
--replicationMode=[sync|syncmem|async] --name=<sitename>  
--operationMode=[delta_datashipping|logreplay|logreplay_readaccess]
```

The default operation mode is logreplay but you can specify a different mode in the command.

3. Start the newly registered target database.
4. When the system replication is active and in sync, perform a takeover on the target database.
5. After the takeover is done, the target database is running as a copy of the source database.
6. To avoid confusion with the source databases, rename the <SID> and change the instance number using the tool hdblocm.

## 10.1.4 Renaming a System

An SAP HANA system can be renamed by changing the system identifiers, like host names, SID, and instance number. Changing system identifiers can be performed with the SAP HANA database lifecycle manager (HDBLCM).

### System Identifiers

System identifiers are required parameters set during SAP HANA system installation. In some cases, it is necessary to change the originally configured system identifiers. All three system identifiers - host name, SID,

and instance number - can be changed together or individually from the SAP HANA database lifecycle manager graphical user or command-line interface.

### **i** Note

System replication must be disabled before renaming the SAP HANA system. If you need to change system identifiers for a system that is set up for system replication, you must first disable system replication, then change the system identifiers on each host and finally re-enable system replication.

The following options are available for SAP HANA database lifecycle manager in graphical user and command-line interfaces:

Task	Graphical User Interface	Command-Line Interface
Rename an SAP HANA System Host	▶ <i>Rename the SAP HANA Database System</i> ▶ <i>Define Host Properties</i> ▶ <i>Edit Host</i> ▶	<pre>--action=rename_system -- hostmap=&lt;old host&gt;=&lt;new host&gt;</pre>
Change the SID of an SAP HANA System	▶ <i>Rename the SAP HANA Database System</i> ▶ <i>Define System Properties</i> ▶ <i>Target System ID</i> ▶	<pre>--action=rename_system -- target_sid=&lt;new sid&gt;</pre>
Change the Instance Number of an SAP HANA System	▶ <i>Rename the SAP HANA Database System</i> ▶ <i>Define System Properties</i> ▶ <i>Target Instance Number</i> ▶	<pre>--action=rename_system -- number=&lt;new instance number&gt;</pre>

## Mounted SID Preparation

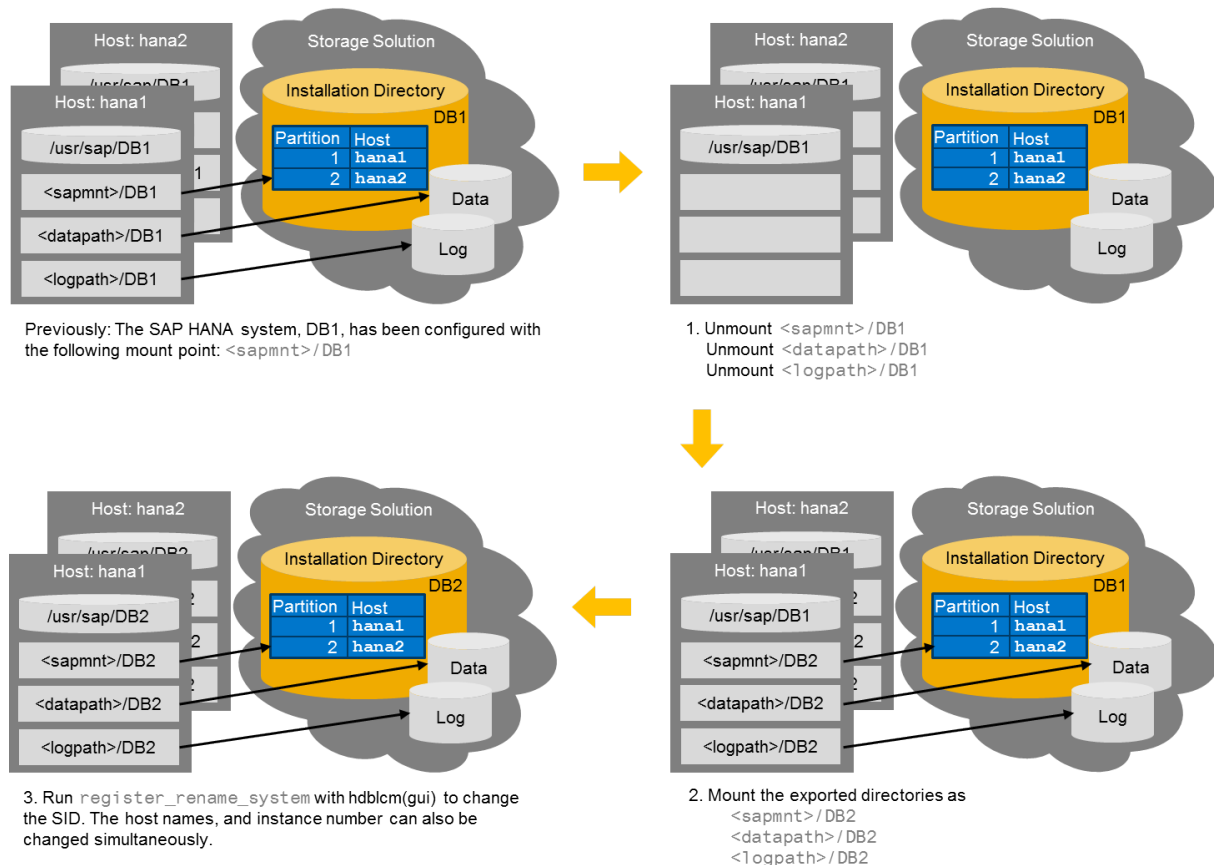

If the SID is included in the mount point, and you want to change the SID, you have to take extra preparation steps.

Normally, the installation path is exported and can be shared as `/<sapmnt>`. (The default for `<sapmnt>` is `/hana/shared`) so that several SAP HANA systems are located on the same physical device. However, if you exported a directory only for an individual SAP HANA system, the shared directory (the mount point) is `/<sapmnt>/<SID>`. In this case, you need to create a shared directory with the new target SID before changing the SID of the system.

## Example

In the following example, an SAP HANA system with a mounted SID is prepared for SID change:

### Changing the SID for an SAP HANA System with a Mounted SID

## 10.1.4.1 Rename an SAP HANA System Host

You can rename an SAP HANA system host using SAP HANA database lifecycle manager (HDBLCM) resident program on the system which you want to configure.

### Prerequisites

- You are logged in as root user.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- The host you want to rename is either reachable via both the old and new host names or the SAP HANA system is stopped.

## Context

### i Note

If you rename an SAP HANA system, this usually invalidates the permanent SAP license. A temporary license is installed, and must be replaced within 28 days. For more information, see [Related Information](#).

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdbclm
```

By default, <sapmnt> is /hana/shared.

2. Start the rename task:

- To rename a host using the SAP HANA database lifecycle manager command-line interface:
  - Start the command-line tool interactively:

```
./hdbclm
```

and enter the index of the `rename_system` action, or

- Start the tool with the `rename_system` action specified:

```
./hdbclm --action=rename_system --hostmap=<old host>=<new host>
```

- To rename a host using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdbclmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose *Rename the SAP HANA Database System*.
3. Select a host and choose *Edit Host...*
4. Enter the new host name in the *Target Host Name* field.

3. Define the required parameters.

For more information about parameters for the `rename_system` action, see the *SAP HANA Server Installation and Update Guide*.

### i Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdbclm --action=rename_system --help
```

4. To continue with the task proceed as follows:
  - In the command line interface: Enter *y*.
  - In the graphical interface:
    1. *Next*.
    2. To execute the configuration task, choose *Rename*. The system displays the configuration progress.
    3. After the configuration task has finished, you can:
      - View the log. To do so, choose *View Log*.
      - Exit the graphical user interface. To do so, choose *Finish*.

tenantmap](#)

## 10.1.4.2 Change the SID of an SAP HANA System

You can change the SID of an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program on the system which you want to configure.

### Prerequisites

- You are logged in as root user.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- The target SID must not exist. However, the target operating system administrator (<SID>adm) user may exist. Make sure that you have the password of the existing <SID>adm user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

### Context

#### **i** Note

If you rename an SAP HANA system, this usually invalidates the permanent SAP license. A temporary license is installed, and must be replaced within 28 days.

An SAP HANA system has one SID for the system database and all tenants. Renaming a system changes the SID for the system database and all tenants.

## Procedure

1. **In some cases**, the shared directory (mount point) includes the SID. If your mount point includes the SID, create a new shared directory before renaming the host.

Normally, the installation path (`<sapmnt>`), the data path (`<datapath>`), and the log path (`<logpath>`) are exported and can be shared. However, if you exported shared directories only for an individual SAP HANA system, the mount points are `<sapmnt>/<current SID>`, `<datapath>/<current SID>`, and `<logpath>/<current SID>`. In this case, you need to mount the exported directories as `<sapmnt>/<target SID>`, `<datapath>/<target SID>`, and `<logpath>/<target SID>` before changing the SID of the system.

- a. Stop the SAP HANA system.

To do this, in the SAP Host Agent perform the following operation:

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance number> -function StopSystem
```

- b. Stop the `sapstartsrv` service by using the following SAP Host Agent operation:

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance number> -function StopService
```

- c. Unmount `<sapmnt>/<current SID>`, `<datapath>/<current SID>`, `<logpath>/<current SID>`.
- d. Mount the exported directories as `<sapmnt>/<target SID>`, `<datapath>/<target SID>`, `<logpath>/<target SID>`.

2. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcmlcm
```

By default, `<sapmnt>` is `/hana/shared`.

### Note

If the mount point includes the SID, change to the SAP HANA resident HDBLCM directory of the **target SID**.

3. Start the SID change task:
  - o To change the SID using the SAP HANA database lifecycle manager command-line interface:
    - o Start the command-line tool interactively:

```
./hdblcmlcm
```

and enter the index of the `rename_system` action, or

- o Start the tool with the `rename_system` action specified:

```
./hdblcmlcm --action=rename_system --source_sid=<current SID> --target_sid=<new SID>
```

### i Note

If the mount point includes the SID, and you have completed the preparation in Step 1, select the [Register and Rename SAP HANA System](#) action in either the SAP HANA database lifecycle manager graphical user interface or command-line interface.

- To change the SID using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdblcmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose [Rename the SAP HANA Database System](#).
  3. Enter the new SID in the [Target System ID](#) field.
4. Define the required parameters.

For more information about parameters for the `rename_system` and `register_rename_system` actions, see the [SAP HANA Server Installation and Update Guide](#).

### i Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdblcm --action=rename_system --help
```

5. To continue with the task proceed as follows:
- In the command line interface: Enter `y`.
  - In the graphical interface:
    1. [Next](#).
    2. To execute the configuration task, choose [Rename](#). The system displays the configuration progress.
    3. After the configuration task has finished, you can:
      - View the log. To do so, choose [View Log](#).
      - Exit the graphical user interface. To do so, choose [Finish](#).

## 10.1.4.3 Change the Instance Number of an SAP HANA System

You can change the instance number of an SAP HANA system using SAP HANA database lifecycle manager (HDBLCM) resident program on the system which you want to configure.

### Prerequisites

- You are logged in as root user.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.

### Context

#### i Note

If you rename an SAP HANA system, this usually invalidates the permanent SAP license. A temporary license is installed, and must be replaced within 28 days. For more information, see Related Information.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblc
```

By default, <sapmnt> is /hana/shared.

2. Start the instance number change task:
  - To change an instance number using the SAP HANA database lifecycle manager command-line interface:
    - Start the command-line tool interactively:

```
./hdblc
```

and enter the index of the `rename_system` action, or

- Start the tool with the `rename_system` action specified:

```
./hdblc --action=rename_system --number=<new instance number>
```

- To rename a host using the SAP HANA database lifecycle manager graphical user interface:
  1. Start the graphical user interface tool:

```
./hdblcgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

2. Choose *Rename the SAP HANA Database System*.

3. Define the required parameters.

For more information about parameters for the `rename_system` action, see the *SAP HANA Server Installation and Update Guide*.

#### **i** Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdblcmm --action=rename_system --help
```

4. To continue with the task proceed as follows:

- In the command line interface: Enter *y*.
- In the graphical interface:
  1. *Next*.
  2. To execute the configuration task, choose *Rename*. The system displays the configuration progress.
  3. After the configuration task has finished, you can:
    - View the log. To do so, choose *View Log*.
    - Exit the graphical user interface. To do so, choose *Finish*.

[tenantmap](#)

## 10.2 Network Administration

Set up your SAP HANA system and the corresponding data center and network configuration in line with your organization's environment and implementation considerations.

An SAP HANA data center deployment can range from a database running on a single host to a complex distributed system with multiple hosts located at a primary and one or more secondary sites, and supporting a distributed multi-terabyte database with full high availability and disaster recovery.

How you configure your network depends on a number of considerations, including:

- Support for traditional database clients, Web-based clients, and administrative connections
- The number of hosts used for the SAP HANA system, ranging from a single-host system to a complex distributed system with multiple hosts

- Support for high availability through the use of standby hosts, and support for disaster recovery through the use of multiple data centers
- Security and performance

SAP HANA has different types of network communication channels to support the different SAP HANA scenarios and setups:

- Channels used for external access to SAP HANA functionality by end-user clients, administration clients, application servers, and for data provisioning via SQL or HTTP
- Channels used for SAP HANA internal communication within the database or, in a distributed scenario, for communication between hosts

Before you start configuring the network for SAP HANA, it's important that you understand the different types of connections to, from, and within SAP HANA and which ports to configure for them. In addition, you should be familiar with the mechanisms used for assigning and resolving host names in SAP HANA.

## Security

SAP HANA supports the isolation of internal communication from outside access. To separate external and internal communication, SAP HANA hosts use a separate network adapter with a separate IP address for each of the different networks. For IBM Power systems, this might be different.

SAP HANA supports IPv6. In a mixed IP environment both IPv4 and IPv6 are present. Communication with hosts that use IP addresses is possible as well. For further information, refer to *Configuration of SAP HANA in an IPv6 Environment*.

In addition, SAP HANA can be configured to use TLS/SSL for secure communication. For more information, see the *SAP HANA Security Guide*.

## Related Information

[Network Zones \[page 1182\]](#)

[Ports and Connections \[page 1183\]](#)

[Host Name Resolution \[page 1209\]](#)

[Configuring the Network for Multiple Hosts \[page 1644\]](#)

[Configuration of SAP HANA in an IPv6 Environment \[page 1181\]](#)

## 10.2.1 Configuration of SAP HANA in an IPv6 Environment

SAP HANA can be run in a dual-stack environment. In this mixed IP environment both IPv4 and IPv6 are present.

### Enabling IPv6 for an Existing Installation

If you already have IPv4 installed, you can activate IPv6 additionally to IPv4 by setting the environment variable in the file `hdbenv.sh`:

#### Sample Code

```
export SAP_IPv6_ACTIVE=1
```

After a restart, IPv6 is enabled for SAP HANA.

### Enabling IPv6 for a New Installation

#### Note

If IPv6 is the only available IP stack, the environment variables have to be set before the installation in `/etc/profile`.

For a new installation, set the environment variables in `/etc/profile`:

#### Sample Code

```
NI_USEIPv6=1
export NI_USEIPv6
SAP_IPv6_ACTIVE=1
export SAP_IPv6_ACTIVE
```

After a restart, IPv6 is enabled for SAP HANA.

### Handling Literal IPv6 Addresses

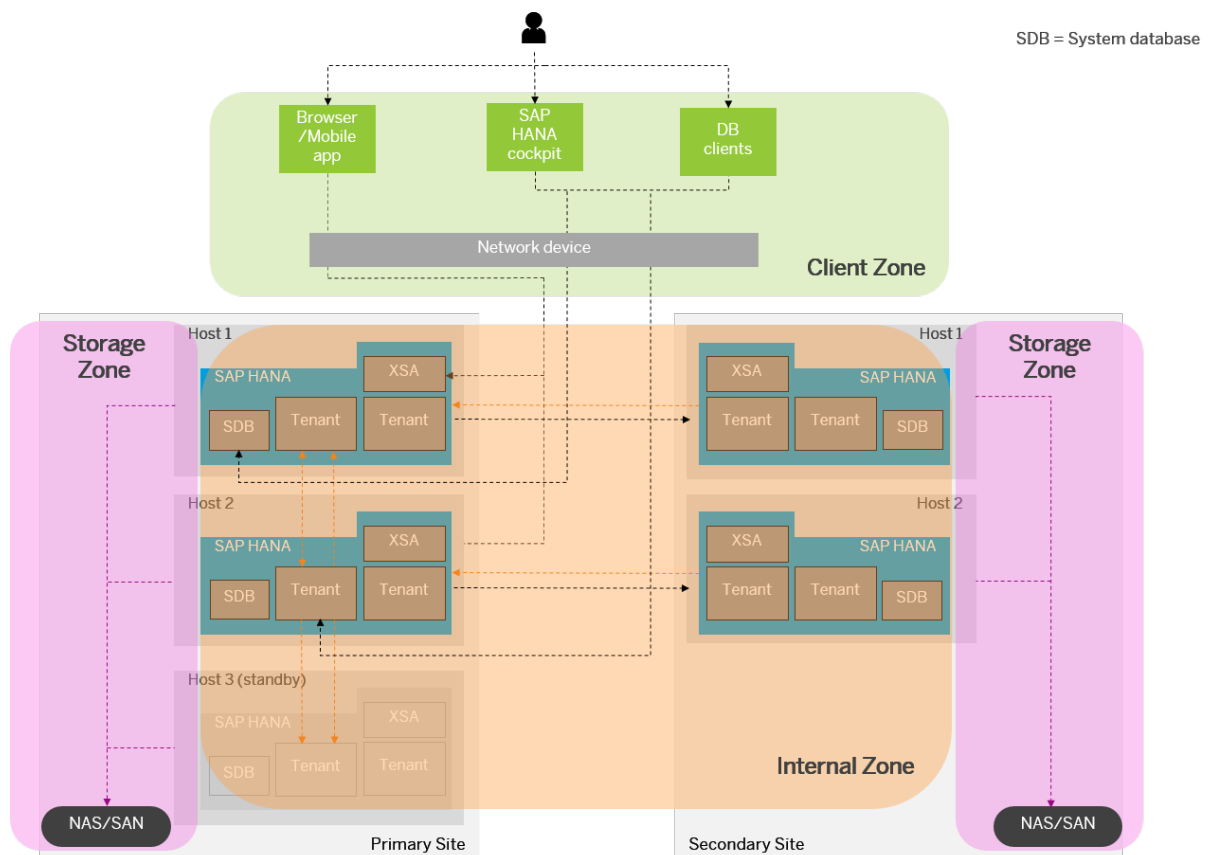

Whenever literal IPv6 addresses are involved, the host should be encapsulated with square brackets, for example `[2001:DB8::1234]`. This is necessary for SAP HANA to be able to distinguish the host from the port part of an address. With IPv4 this can be done by looking for the colon separator. The host part of an IPv6 address, however, contains colons instead of dots and therefore square brackets are used for distinction.

## 10.2.2 Network Zones

Separate network zones, each with its own configuration, allow you to control and limit network access to SAP HANA to only those channels required for your scenarios, while ensuring the required communication between all components in the SAP HANA network.

These network zones can be basically described as follows:

- **Client zone**  
The network in this zone is used by SAP application servers, by clients such as the SAP HANA studio or Web applications running against the SAP HANA XS server, and by other data sources such as SAP Business Warehouse.
- **Internal zone**  
This zone covers the interhost network between hosts in a distributed system as well as the SAP HANA system replication network.
- **Storage zone**  
This zone refers to the network connections for backup storage and enterprise storage. In most cases, the preferred storage solution involves separate, externally attached storage subsystem devices that are capable of providing dynamic mount-points for the different hosts, according to the overall landscape. A storage area network (SAN) can also be used for storage connectivity – for example, when running SAP HANA on IBM Power.

## 10.2.3 Ports and Connections

Before you start configuring the network for SAP HANA, you'll want to get an overview of the different types of connections to, from, and within SAP HANA and which ports to configure for them.

### Related Information

[Connections from Database Clients and Web Clients to SAP HANA \[page 1183\]](#)

[Connections for Distributed SAP HANA Systems \[page 1194\]](#)

[Connections for SAP HANA Extended Application Services, Advanced Model \[page 1202\]](#)

[Connections for Components in the Extended SAP HANA Landscape \[page 1205\]](#)

### 10.2.3.1 Connections from Database Clients and Web Clients to SAP HANA

Several types of connections between SAP HANA and external clients are possible.

The connections between SAP HANA and external components and applications can be classified as follows:

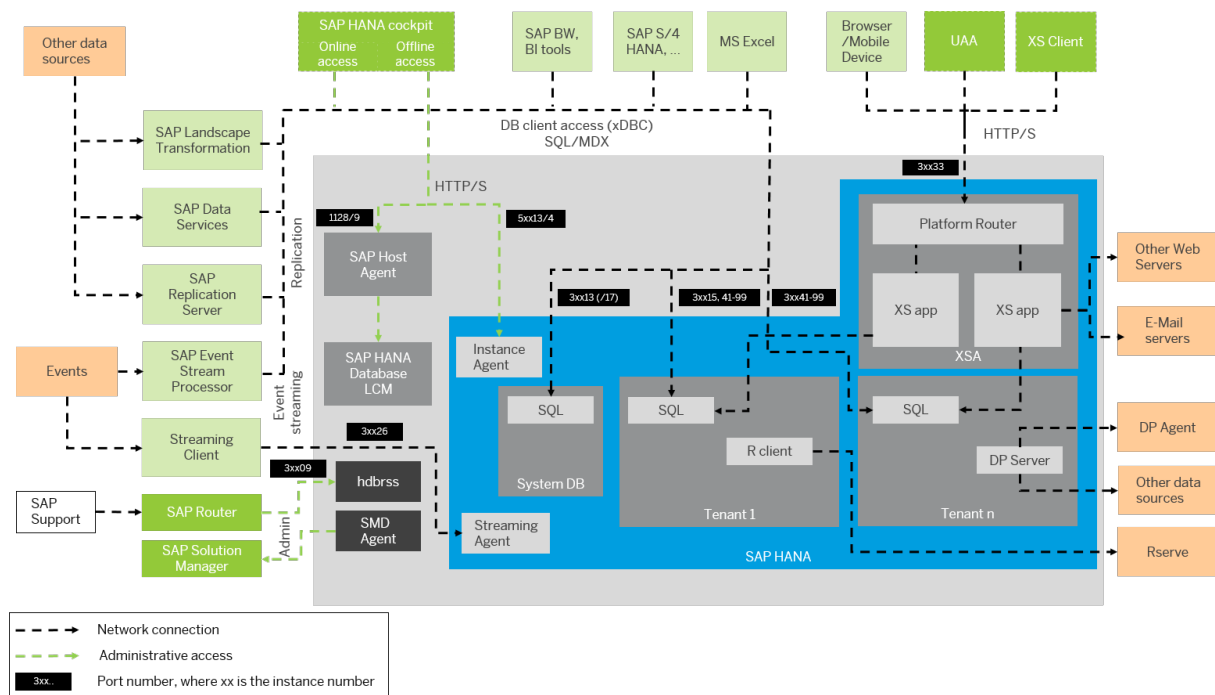

- Connections used for administrative purposes
- Connections used for data provisioning
- Connections from database clients that access the SQL/MDX interface of the SAP HANA database
- Connections from HTTP/S clients
- Outbound connections

You can see an example of what these connections look like in the diagram below. Network connections are depicted by dashed arrows. The direction of each arrow indicates which component is the initiator (start of arrow) and which component is the listener (end point of arrow). Administrative access to and from SAP HANA is depicted by the green dashed arrows. Port numbers are shown with a black background. The "xx" in the port numbers stands for the SAP HANA instance number.

The diagram shows all the network channels used by the SAP HANA software. For purposes of illustration, the diagram shows a single-host installation with two tenant databases. However, the connections shown apply equally to a distributed scenario.

## i Note

In distributed scenarios, you must also ensure that every database client can connect to every host (not shown in the diagram). Moreover, additional network channels are required in distributed scenarios for communication between the different hosts of an SAP HANA system or between the different sites. For more information, see the section on connections for distributed systems.

Connections from Database Clients and Web Clients to SAP HANA

The following tables explain the diagram and the different categories described above in more detail.

## Database Client Access via ODBC/JDBC (SQLDBC)

Client	Additional Information	TCP Port
Application servers that use SAP HANA as a database	You must enable SQL/MDX access for all database clients.	<ul style="list-style-type: none"> <li>System database: 3xx13</li> <li>First tenant database if automatically created during installation: 3xx15</li> <li>Tenant databases: 3xx41–3xx98</li> </ul>
Examples: SAP Business Warehouse and one or more components of SAP Business Suite	External and internal host names are mapped for the purposes of database client access. You can change the default mapping.	The port numbers of tenant databases are assigned automatically from the available port number

Client	Additional Information	TCP Port
<p>End-user clients that access the SAP HANA database directly</p> <p>Example: Microsoft Excel</p>		<p>range according to availability at the time the database is created. Administrators can also explicitly specify which port numbers to use when they create the tenant database. For more information, see the section on port assignment in tenant databases.</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>i Note</b></p> <p>In a new system created with one initial tenant database or an upgraded single-container system, the first tenant database is accessible on port 3xx15.</p> </div>

	<p><b>i Note</b></p> <p>SAP HANA XS, classic is deprecated as of SAP HANA 2.0 SPS 02. For more information, see SAP Note 2465027.</p>	<p><b>i Note</b></p> <p>This port is not depicted in the graphic above.</p>
SAP HANA Direct Extractor Connection (DXC)	This connection is used for ETL-based data acquisition. For more information, see the <i>SAP HANA Direct Extractor Connection Implementation Guide</i> .	
UI toolkit for SAP HANA Info Access	This connection is used for the SAP HANA Info Access HTTP search service. SAP HANA Info Access provides UI building blocks for developing browser-based search apps on SAP HANA. For more information, see the <i>SAP HANA Search Developer Guide</i> .	
SAP HANA cockpit, SAP HANA studio	This is the connection to the SAP HANA database lifecycle manager via SAP Host Agent. For more information about the SAP HANA database lifecycle manager, see the section on SAP HANA Platform Lifecycle Management.	1128 1129 (SSL)

### i Note

SAP HANA XS advanced server components and application instances also expose ports that are not designed for external communication. For more information about these, see *Connections for SAP HANA Extended Application Services, Advanced Model* and the *SAP HANA Security Guide*.

## Administrative Tasks

Client	Protocol	Additional Information	TCP Port
SAP support	Internal SAP protocol	The connection is not active by default because it is required only in certain support cases. To find out how to open a support connection, see the section on getting support.	3xx09
SAP HANA cockpit, SAP HANA studio	SQLDBC (ODBC/JDBC)	The connection to the instance agent acts as an administrative channel for low-level access to the SAP HANA instance to allow features such as starting or stopping of the SAP HANA database.	5xx13 5xx14 (SSL)

Other administrative tasks, mainly database administration, use the SQL/MDX channel of the database.

## Data Provisioning

Client	Protocol	Additional Information	TCP Port
Replication systems for external data sources	SQLDBC (ODBC/JDBC)	<p>The following replication technologies may be used:</p> <ul style="list-style-type: none"> <li>• SAP Landscape Transformation (SLT)</li> <li>• SAP Data Services (DS)</li> <li>• SAP Replication Server (not included with all licensed editions of SAP HANA)</li> </ul>	<ul style="list-style-type: none"> <li>• System database: 3xx13</li> <li>• Tenant databases: 3xx41–3xx98</li> </ul> <p>The port numbers of tenant databases are assigned automatically from the available port number range according to availability at the time the database is created. Administrators can also explicitly specify which port numbers to use when they create the tenant database. For more information, see the section on port assignment in tenant databases.</p> <div data-bbox="1077 996 1401 1254" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>In a new system created with one initial tenant database or an upgraded single-container system, the first tenant database is accessible on port 3xx15.</p> </div>
	HTTP/S	SAP HANA Direct Extractor Connection (DXC). This technology uses HTTP/S access via the SAP HANA XS classic server.	80xx/43xx
			<div data-bbox="1077 1332 1401 1478" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>This port is not depicted in the graphic above.</p> </div>

Client	Protocol	Additional Information	TCP Port
Streaming client	XML/RPC	This connection is used for SAP HANA Streaming Analytics (supported on Intel-based platforms only)	3xx26

**⚠ Caution**

SAP HANA Streaming Analytics is an SAP HANA option. Be aware that you need additional licenses for SAP HANA options. For more information, see [Important Disclaimer for Features in SAP HANA \[page 2139\]](#).

## Outbound Connections

Connection	Additional information
From the SAP Solution Manager diagnostics (SMD) agent to SAP Solution Manager	For information about how to install the SAP Solution Manager diagnostics agent, see SAP Note 1858920.
Calls from SAP HANA Extended Application Services to external servers	Examples: a Web server or an e-mail server (depends on what applications your company has deployed)
Smart data access from SAP HANA to external data sources for data federation purposes	For more information, see the section on smart data access.
From SAP HANA to the R environment	Only required for scenarios which use the R integration supported by SAP HANA. For more information, see the <i>SAP HANA R Integration Guide</i> .
From the data provisioning (DP) server of the SAP HANA database to the data provisioning agent and, depending on the type of adapter used, to the external data source(s)	<p>This connection is used for SAP HANA smart data integration in scenarios where SAP HANA is deployed on premise. For more information, see the <i>Installation and Configuration Guide for SAP HANA Smart Data Integration and SAP HANA Smart Data Quality</i>.</p> <p>SAP HANA with the DP server can run on IBM Power. However, the data provisioning agent needs to be hosted on an Intel machine. It is possible to connect between the two.</p>

**⚠ Caution**

SAP HANA smart data integration is an SAP HANA option. Be aware that you need additional licenses for SAP HANA options. For more information, see [Important Disclaimer for Features in SAP HANA \[page 2139\]](#).

### 10.2.3.1.1 Port Assignment in Tenant Databases

Every tenant database has its own ports and connections for internal and external communication.

Every tenant database has dedicated ports for SQL and internal communication. There is also a dedicated port for HTTP-based client communication via the SAP HANA XS classic server, which runs by default as an embedded service in the index server.

However, there are no standard port number assignments. Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.

The only exceptions to this are the tenant database that is automatically created when you **install** a single-tenant system and when you **convert** a single-container system to a tenant database system. This database retains the port numbers of the original single-container system: 3<instance>03 (internal communication), 3<instance>15 (SQL), and 3<instance>08 (HTTP via SAP HANA classic server). The ports of any subsequently added tenant database are automatically assigned according to availability at the time.

The default port number range for tenant databases is 3<instance>40–3<instance>99. This means that the maximum number of tenant databases that can be created per instance is 20. However, you can increase this by reserving the port numbers of further instances. In the cockpit, a dialog will prompt you to do this, or you can configure the property `[multidb] reserved_instance_numbers` in the `global.ini` file. The default value of this property is 0. If you change the value to 1, the port numbers of one further instance are available (for example, 30040–30199 if the first instance is 00). If you change it to 2, the port numbers of two further instances are available (for example, 30040–30299 if the first instance is 00). And so on.

#### i Note

The port number of the **system database** are fixed: 3<instance>01 (internal), 3<instance>13 (SQL), and 3<instance>14 (HTTP via XS classic server). If restricted SQL access is enabled, port 3<instance>17 is used for SQL requests to the system database.

Let's look at some simple examples.

## ❁ Example

### Example 1:

You perform a default SAP HANA system installation. This results in the automatic creation of a single tenant database. This tenant database has the following port numbers: 3<instance>03 (internal communication), 3<instance>15 (SQL), 3<instance>08 (HTTP via XS classic server).

Then, you create two additional tenant databases. Each of these tenant databases is automatically assigned port numbers for the following connection types:

- Internal communication
- SQL
- HTTP (This is the port of the XS classic server embedded in the index server.)

The second database is assigned ports 3<instance>40–42, and the third 3<instance>43–45.

### Example 2:

You install a new SAP HANA system without creating an initial tenant, by running the SAP HANA database lifecycle manager (HDBLCM) with the `create_initial_tenant` flag set to `off`. Then, you create three tenant databases. Each of these tenant databases is automatically assigned the following port numbers:

The first tenant database is assigned port numbers 3<instance>40–42, the second ports 3<instance>43–45, and the third 3<instance>46–48.

### Example 3:

You install a new SAP HANA system without creating an initial tenant, by running the SAP HANA database lifecycle manager (HDBLCM) with the `create_initial_tenant` flag set to `off`. Then, you create a tenant database. The same port numbers as above are assigned: 3<instance>40 (internal communication), 3<instance>41 (SQL), and 3<instance>42 (HTTP via XS classic server). Next, you add a separate xsengine service to the first database. This service is automatically assigned the next three available port numbers: 3<instance>43–45. Finally, you create a second tenant database. This tenant database is automatically assigned the next three available port numbers: 3<instance>46–48.

### Example 4:

You convert a single-container system to a tenant database system. This results in the automatic creation of one tenant database. This tenant database has the same port numbers as the original single-container system: 3<instance>03 (internal communication), 3<instance>15 (SQL), 3<instance>08 (HTTP via XS classic server). Then, you add a second index server to the tenant database. It is automatically assigned port numbers 3<instance>40–42. Finally, you create a second tenant database. It is automatically assigned ports the next three available port numbers: 3<instance>43–45.

### Example 5:

You can run multiple services of the same type in a single tenant on the same host. The service ports must be within the same port range and must not span across multiple port ranges. For example, you can assign port 30100 to index server A and port 30103 to index server B. You cannot assign port 30100 to index server A and port 30203 to index server B.

### i Note

All of the above examples refer to single-host systems and are based on automatic port number assignment.

You can determine the ports used by a particular tenant database by querying the M\_SERVICES system view, either from the tenant database itself or from the system database.

- From the tenant database: `SELECT SERVICE_NAME, PORT, SQL_PORT, (PORT + 2) HTTP_PORT FROM SYS.M_SERVICES WHERE ((SERVICE_NAME='indexserver' and COORDINATOR_TYPE='MASTER') or (SERVICE_NAME='xsengine'))`
- From the system database: `SELECT DATABASE_NAME, SERVICE_NAME, PORT, SQL_PORT, (PORT + 2) HTTP_PORT FROM SYS_DATABASES.M_SERVICES WHERE DATABASE_NAME='<DBNAME>' and ((SERVICE_NAME='indexserver' and COORDINATOR_TYPE= 'MASTER') or (SERVICE_NAME='xsengine'))`

### → Remember

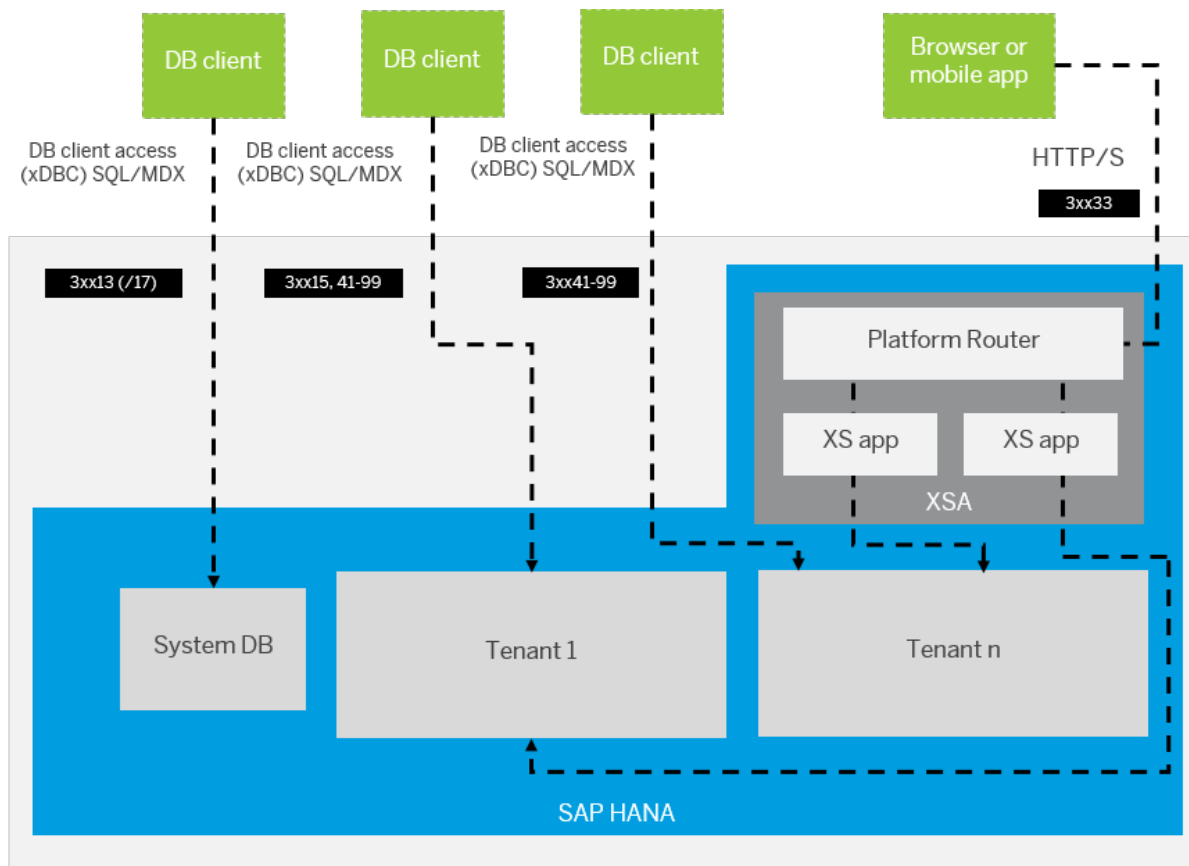

If your system was converted from single-container mode to a tenant database system, the HTTP port number of the first tenant database is **always** 3<instance>08 and not the port number returned using the above queries.

### i Note

System privilege DATABASE ADMIN or CATALOG READ is required to read the M\_SERVICES system view.

The following diagram shows an example of the connections and ports used in a system with two tenant databases, installed on a single host. The SAP HANA XS advanced runtime is used to run Web applications.

### Note

The SAP HANA XS advanced application server supports two routing modes: port routing and hostname routing. As URLs in the hostname routing scenario are user friendly and there is only a single public port, this mode is recommended for production usage and is depicted in the figure above. If port routing is configured, all public ports of the platform router are exposed: 51000 – 51500, 3xx30, and 3xx32. For more information, see SAP Note 2245631.

## Restricted SQL Access

If tenant databases need to be accessible from an external network, you can open an additional SQL port to prevent SQL access on port 3<instance>13. This prevents the exposure of the system database SQL administration port to the external network. You enable this feature by setting the property `[multidb] systemdb_separated_sql_port` to `true` in the `global.ini` file.

This opens port 17 for SQL requests to the system database and restricts access through port 3<instance>13 for database mapping. The connection through port 3<instance>13 is re-routed to 3<instance>17 if a connection to the system database is required. To connect to the system database, `DATABASENAME=SYSTEMDB` must be specified. Make sure that port 17 is not exposed to the external network.

### 10.2.3.2 Connections for Distributed SAP HANA Systems

SAP HANA systems can be distributed across multiple hosts for the purposes of scalability and availability.

An SAP HANA system is identified by a system ID (SID). Tenant databases are identified by the SID and their database name. Both are perceived as discrete units from the administration perspective. Some tasks are performed at system level (for example, installation, update, stop, and start) and others at database level (for example, database configuration, schema and table management). The system database is used for central system administration. The services of each database share the same metadata, and requests from client applications are transparently dispatched to the different services in the database. Servers that do not persist data, such as the compile server and the preprocessor server, run on the system database and serve all tenant databases.

A **distributed SAP HANA system** is a system that is installed on more than one host. An **SAP HANA instance** is a set of components of a distributed system that are installed on one host. Tenant databases can run individually on a single host or be distributed across several hosts.

### Connections for Internal Communication Between Hosts and Sites

In addition to external network connections, SAP HANA uses separate, dedicated connections exclusively for internal communication. There are two types of internal communication in distributed systems:

- Communication between hosts in a multiple-host system (scale-out)  
Internal network communication takes place between the hosts of a distributed system on one site. SAP HANA hosts contain a separate network interface card that is configured as part of a private network, using separate IP addresses and ports. For IBM Power systems, this might be different.

#### **i** Note

In single-host scenarios, the same communication channels are used for communication between the different processes on a single host and the internal IP addresses/ports are by default bound to the `localhost` interface.

There are a number of ways to isolate internal network ports from the client network. The preferred method depends on the data center configuration, on hardware vendor delivered options, and on the high availability implementation. Applying network separation for the internal communication prevents unauthorized access from outside networks. For additional security, it is possible to encrypt the internal communication using TLS/SSL. For more information, see the *SAP HANA Security Guide*.

## Ports for Multiple-Host System

Client	TCP Port	Service	Note
Hosts of a distributed system on one site	3xx00	daemon	
	3xx01	nameserver	System database port only
	3xx02	preprocessor	System database port only
	3xx03	indexserver	Port used by the indexserver of the initial tenant database created in a new installation or an upgraded single-container system.
	3xx40 - 3xx97	indexserver	Tenant database ports  Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.
	3xx04	scriptserver	Port used by the script server of the first tenant database created in a new installation or an upgraded single-container system (optional)
	3xx40 - 3xx97	scriptserver	Tenant database ports (optional)  Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.

Client	TCP Port	Service	Note
	3xx40 - 3xx97	docstore	<p>Tenant database ports (optional)</p> <p>Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.</p>
	3xx05	diserver	<p>Tenant database ports</p> <p>Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.</p>
	3xx25	diserver	<p>Port used by the diserver of the initial tenant database created in a new installation or an upgraded single-container system.</p>
	3xx40	diserver	<p>Tenant database ports</p> <p>Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.</p>

Client	TCP Port	Service	Note
	3xx06	webdispatcher	Port used by the webdispatcher of the initial tenant database created in a new installation or an upgraded single-container system.
	3xx07	xengine	Port used by the xengine of the initial tenant database created in a new installation or an upgraded single-container system.
	3xx08	xengine	Port used by the xengine of the initial tenant database created in a new installation or an upgraded single-container system.
	3xx42 - 3xx99	xengine	Tenant database ports Port numbers are assigned automatically from the available port number range according to availability at the time the database is created or a service is added. Administrators can also explicitly specify which port numbers to use when they create a tenant database or add a service.
	3xx10	compileserver	System database port only
	3xx11	dpserver	Port used by the dpserver of the initial tenant database created in a new installation or an upgraded single-container system.

Client	TCP Port	Service	Note
	3xx33	xscontroller	<p>System database port only, if hostname routing is configured</p> <p>The SAP HANA XS advanced application server supports two routing modes: port routing and hostname routing. As URLs in the hostname routing scenario are user friendly and there is only a single public port (3xx33), this mode is recommended for production usage and is depicted in the figure below. If port routing is configured, all public ports of the platform router are exposed: 51000 – 51500, 3xx30, and 3xx32.</p> <p>For more information, see SAP Note 2245631.</p>

### i Note

The "xx" in the port numbers is the SAP HANA instance number.

- Communication between sites in a system replication configuration (high availability)  
Internal network communication for system replication takes place between a primary site and a secondary site. In a multitier setup, this communication takes place between the tier-1 primary system and tier-2 secondary system as well as, asynchronously, between the tier-2 and tier-3 secondary systems. For more information about system replication and multitier setups, see the section on high availability. System replication is configured for the system as a whole. This means that the system database and all tenant databases are part of the system replication. System replication connections must be secured using TLS/SSL. In this case, landscape topology communication on the one hand, and data replication and log replication channels on the other, are secured in separate steps. For more information about configuring SSL for internal communication as well as securing communication between sites in system replication scenarios, see the *SAP HANA Security Guide*.

#### Ports for System Replication

Client	TCP Port	Service	Used For
Hosts on primary and secondary sites	4xx01	nameserver	Log and data shipping (system database)
	4xx02	nameserver	Unencrypted metadata communication (system database)

Client	TCP Port	Service	Used For
	4xx06	nameserver	TLS/SSL encrypted metadata communication (system database)
	4xx40 - 4xx97	indexserver	Log and data shipping (tenant databases)
	4xx40 - 4xx97	scriptserver	Log and data shipping (optional, tenant databases)
	4xx40 - 4xx97	docstore	Log and data shipping (optional, tenant databases)

#### i Note

A port offset value of 10,000 is used to reserve ports for system replication communication. This shifts the ports from the 3<instance number>00 to the 4<instance number>00 port range for services.

#### i Note

SAP HANA internal communication has sometimes been unofficially referred to as TREXNet communication. However, the term TREXNet is not valid in the context of SAP HANA.

## Example 1

The following diagram shows a multiple-host SAP HANA system with two active hosts and an extra standby host, fully system replicated to a secondary site to provide full disaster recovery support.

The vertical purple dashed lines show the communications between the services of a database; all instances communicate with all other instances of a multiple-host system on one site. The horizontal purple dashed lines show the initial connection for system replication communication between services on hosts on the primary site and the corresponding services on hosts of the secondary site (typically over a high-performance fiber network). The details of system replication configuration depend on the specific network setup of your company.

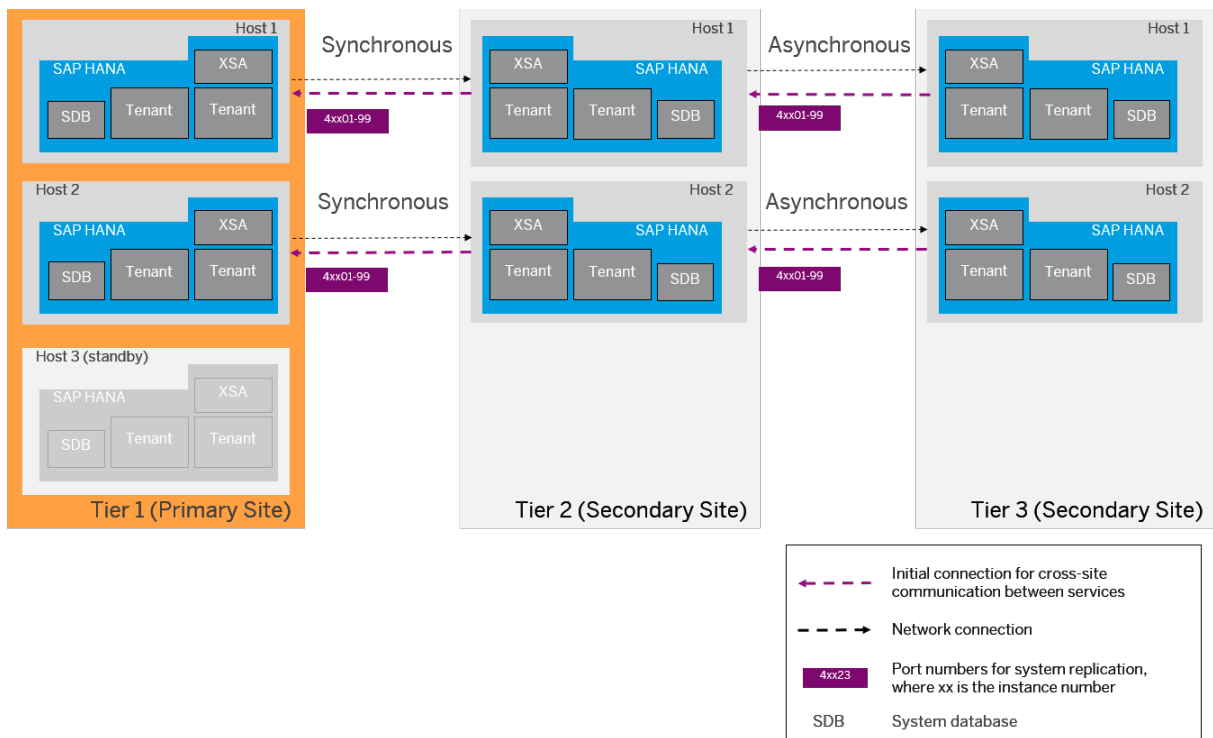

One of the most critical aspects of the network design of a highly available distributed system is the question of how the different clients manage to reconnect to the system when its topology changes due to the recovery operations following a failure or disaster. Two additional components can be used to handle client reconnection:

- A **network device** (router and/or switch), which can be used in conjunction with DNS or virtual IP redirection
- An **HTTP load balancer** (such as SAP Web Dispatcher) acts as a reverse proxy for HTTP connections and exposes a consistent external network address to the client network. The HTTP load balancer can also be used to provide load-balanced access to multiple distributed SAP HANA Extended Application Services (XS advanced) servers. For more information, see SAP Note 2300936.

## Example 2

The following diagram shows an example of multi-tier system replication:

## 10.2.3.3 Connections for SAP HANA Extended Application Services, Advanced Model

Additional ports and connections are required if you are using SAP HANA extended application services, advanced model (SAP HANA XS advanced).

Client	Service	TCP Port	Use
Platform Router	<code>xsuaaserver</code>	3xx31	Internal HTTP(S)  This port is used for the connection from the platform router to <code>xsuaaserver</code> for purposes of user authentication.
Platform Router	<code>xscontroller</code>	One dynamic port, in the range 51000-51500	Internal HTTP(S)  This port range is used for the connection from the platform router to the <code>xscontroller</code> for purposes of data access.
Application UI (browser, mobile, and so on)	Platform Router	Dynamic, in the range 51000-51500	Client HTTP(S)  This port range is used for the connection from the client to the platform router for access to the application instance.
Platform Router	Application Instances	Dynamic, in the range 50000-50999	Internal HTTP(S)  This port range is used in <b>single-host scenarios</b> for the connection from the platform router to the application instances.
Platform Router	Host-specific Web Dispatcher	Dynamic, in the range 50500-50999	Internal HTTP(S)  This port range is used in <b>multiple-host scenarios</b> for the connection from the platform router to the host-specific Web Dispatcher.

Client	Service	TCP Port	Use
Host-specific Web Dispatcher	Instances	Dynamic, in the range 50000-50499	Internal HTTP(S)  This port range is used in <b>multiple-host scenarios</b> for the connection from the host-specific Web Dispatcher to the application instance.
<code>xsexecagent</code>	<code>xscontroller</code>	3xx29	Internal HTTP(S)
<code>xscontroller</code>	<code>xsexecagent</code>	System	These ports are used for the connection between the xs execution agent and the <code>xscontroller</code> .

#### Port-Routing Mode

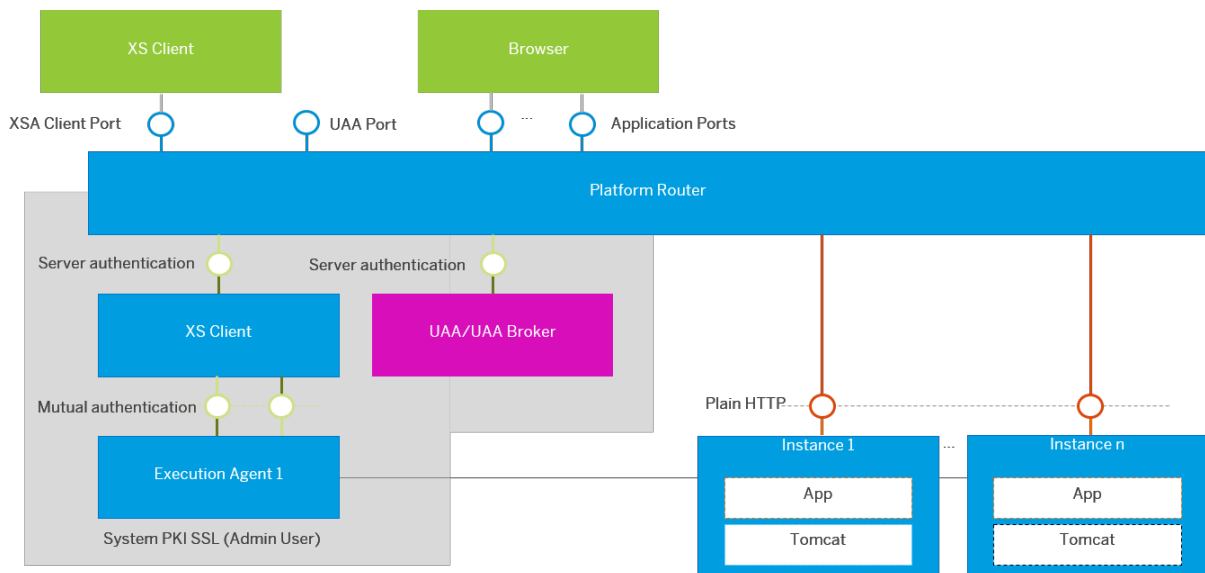

Client	Service	TCP Port	Use
Application UI (browser, mobile, and so on)	Platform Router	3xx32	Client HTTP(S)  This port is used for the connection from the client to the platform router for purposes of user authentication.
<ul style="list-style-type: none"> <li>• Command line client</li> <li>• SAP Web IDE</li> <li>• XSA Cockpit</li> <li>• Deploy Service</li> <li>• Monitoring applications</li> </ul>	Platform Router	3xx30	Client HTTP(S)  This port is used for the connection to the platform router for purposes of data access.

## Hostname-Routing Mode

Client	Service	TCP Port	Use
Application UI (browser, mobile, xs client, SAP Web IDE, XSA Cockpit, monitoring tools and so on)	Application instances	3xx33	<p>Web Dispatcher HTTP(S)</p> <p>This port is used for the platform router where routing is done by host names instead of ports. In this case, the <code>xscontroller</code> is available with URL <code>https://api.&lt;example.com&gt;:3xx33</code> and the <code>xsuaaserver</code> is available with URL <code>https://uaaserver.&lt;example.com&gt;:3xx33</code>.</p> <p>For more information, see SAP Note 2245631.</p>

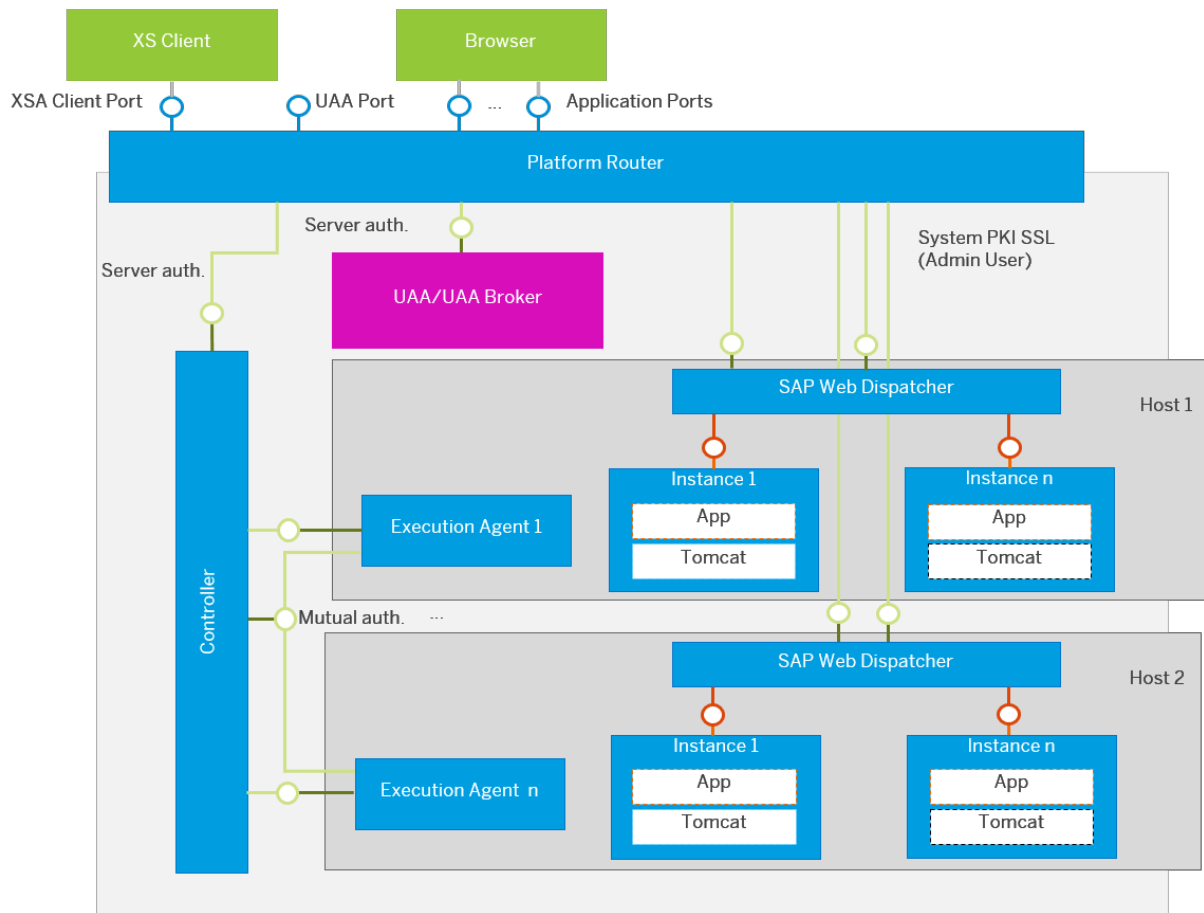

The following diagrams provide an overview of the ports and connections used by the SAP HANA XS advanced server infrastructure in single- and multiple-host scenarios. For more information about network and communication security, see the *SAP HANA Security Guide*.

### XS Advanced Ports and Connections (Single-Host Scenario)

## 10.2.3.4 Connections for Components in the Extended SAP HANA Landscape

Dedicated ports are used to connect components in the extended SAP HANA landscape.

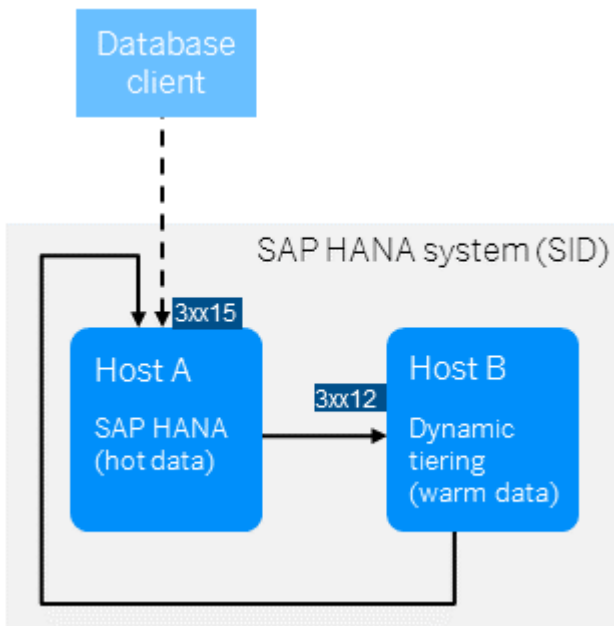

- [Connections for SAP HANA Dynamic Tiering \[page 1206\]](#)
- [Connections for SAP HANA Smart Data Integration \[page 1207\]](#)
- [Connections for SAP HANA Streaming Analytics \[page 1207\]](#)

- [Connections for SAP HANA Accelerator for SAP ASE \[page 1208\]](#)

### 10.2.3.4.1 Connections for SAP HANA Dynamic Tiering

No additional manual configuration of connections and ports is required in the SAP HANA software for SAP HANA dynamic tiering.

When an external client sends a request for warm data, it connects to the SAP HANA host which passes the request to the dynamic tiering host. The dynamic tiering host listens on internal port 3xx12. There is no direct connection between external components and the dynamic tiering host. The connection back from the dynamic tiering host to the SAP HANA host is through the SQL port of the SAP HANA host.

#### Related Information

[SAP HANA Dynamic Tiering](#)

[Important Disclaimer for Features in SAP HANA](#)

## 10.2.3.4.2 Connections for SAP HANA Smart Data Integration

The connections between the components for SAP HANA smart data integration may differ depending on whether SAP HANA is deployed on premise, in the cloud, or behind a firewall.

For more information, see the *Installation and Configuration Guide for SAP HANA Smart Data Integration and SAP HANA Smart Data Quality*.

### Related Information

[SAP HANA Smart Data Integration and SAP HANA Smart Data Quality](#)

## 10.2.3.4.3 Connections for SAP HANA Streaming Analytics

The internal connections and ports for SAP HANA streaming analytics are set up automatically. None of the ports are configurable.

#### **i** Note

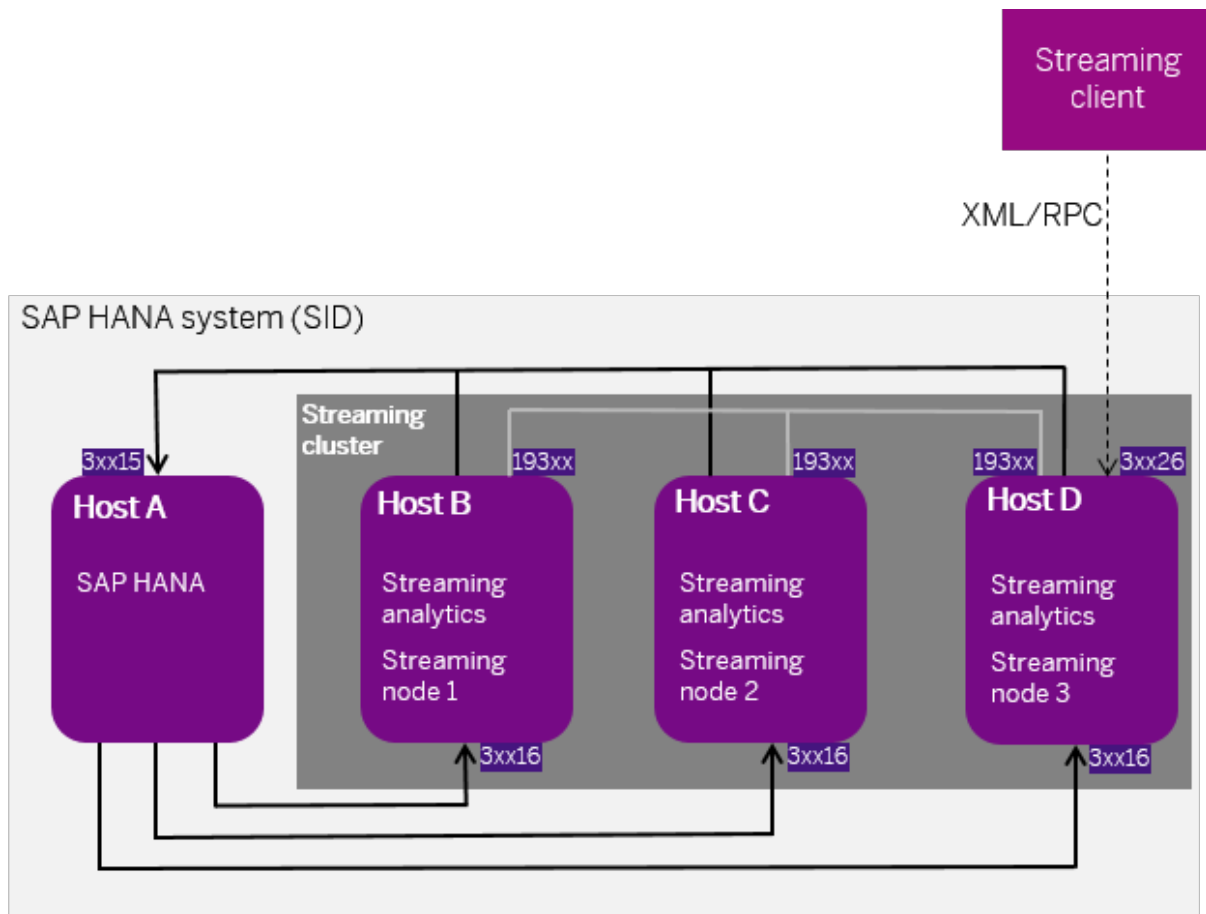

SAP HANA streaming analytics is supported on Intel-based platforms only.

The SAP HANA server connects to one or more streaming analytics servers on internal port 3xx16. Through this connection, SAP HANA gathers streaming analytics statistics. The connection is triggered by the SAP HANA cockpit monitoring views.

The streaming analytics hosts connect to the SAP HANA server on the SQL port of the tenant database. The streaming hosts retrieve the streaming license information and the streaming cluster configuration (which is stored on the SAP HANA database). If the streaming analytics project has an SAP HANA adapter or a generic database adapter that connects to SAP HANA, it also uses the SQL port connection.

Any streaming clients that run outside the SAP HANA system (such as custom-built external adapters) connect to a streaming node via the XML/RPC protocol on port 3xx26.

In a multi-node setup, the 193xx port is used for interserver communication between streaming hosts. This port is for internal use, but you may want to make a note of it for firewall settings.

## Related Information

[SAP HANA streaming analytics](#)

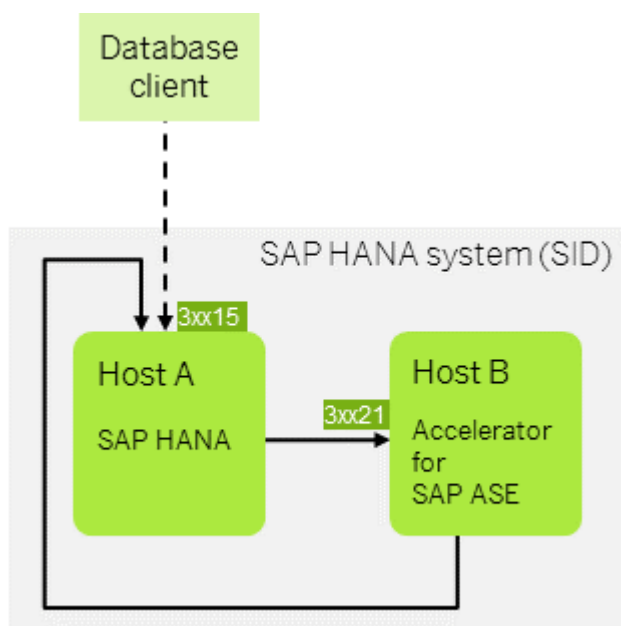

[Important Disclaimer for Features in SAP HANA](#)

### 10.2.3.4.4 Connections for SAP HANA Accelerator for SAP ASE

The internal connections and ports for SAP HANA accelerator for SAP ASE are set up automatically.

When an external client sends a request for warm data, it connects to the SAP HANA host which passes the request to the accelerator for SAP ASE host. The accelerator for SAP ASE host listens on internal port 3xx21. The connection back from the accelerator for SAP ASE host to the SAP HANA host is through the SQL port of the SAP HANA host. Any SAP ASE clients that run outside the SAP HANA system can connect to an accelerator for SAP ASE node on port 3xx21 directly.

## 10.2.4 Host Name Resolution

Understand the mechanisms used for assigning and resolving host names in SAP HANA.

## Related Information

[Default Host Names and Virtual Host Names \[page 1210\]](#)

[Internal Host Name Resolution \[page 1213\]](#)

[Host Name Resolution for System Replication \[page 1354\]](#)

[Host Name Resolution for SQL Client Communication \[page 1216\]](#)

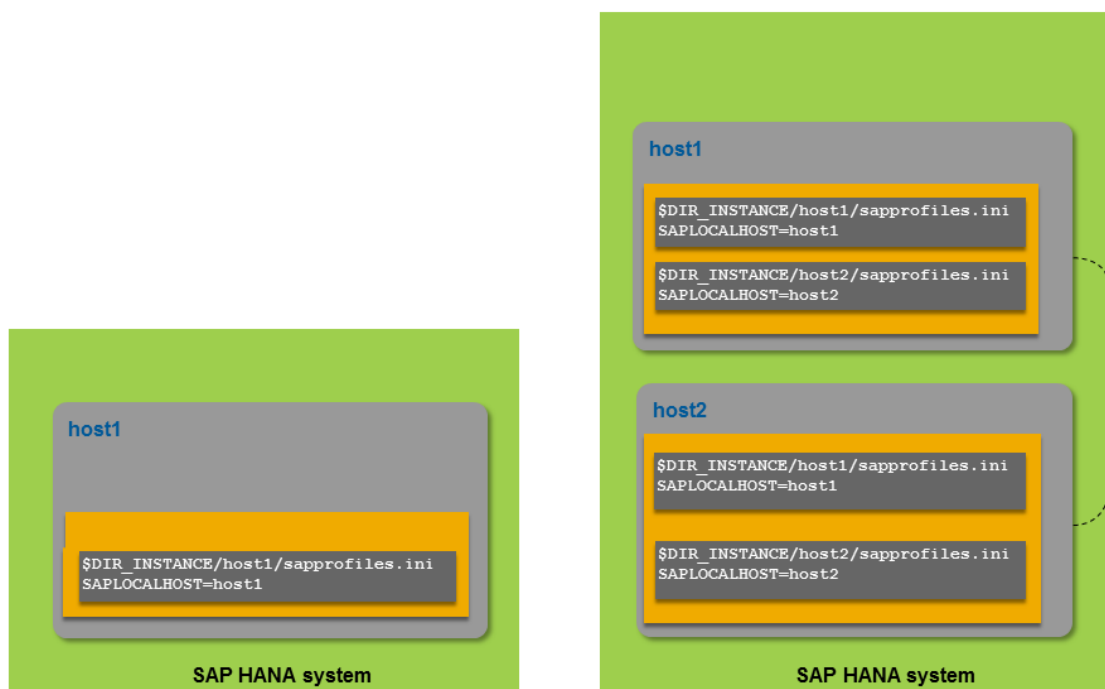

## 10.2.4.1 Default Host Names and Virtual Host Names

The assignment of multiple host names to the same host supports performance optimization as well as the security of your SAP HANA system. Moreover, some cluster managers and third-party backup tools as well as SAP Landscape Management work on the basis of virtual host names or IP aliases.

### Default Host Names

The default host names, if nothing else is configured during the installation of SAP HANA, are the host names defined at operating system level. The installation extracts the host names known to the operating system (that is, the names of the SAP HANA instances) and stores them in the sapstart service profiles, that is, in the following files:

```
/usr/sap/sapservices  
/usr/sap/<SID>/HDB<instance_number>/<hostname>/sapprofile.ini
```

Example of Default Host Names for SAP HANA

These host names are then used for all internal communication between SAP HANA services (`nameserver`, `indexserver`, and so on) and the SAP start service (`sapstartsrv`). In addition, SAP HANA system views with a `HOST` column show these host names.

## Virtual Host Names

Another approach is to specify alternative host names during installation. These are referred to as virtual host names. Virtual host names must also be unique across multiple SAP HANA systems if more than one data center or site is used.

Host names specified in this manner must be resolvable during installation time, as well as when SAP HANA is in operation. This is achieved, for example, by adding an `<ip> <hostname>` line to the operating system file `/etc/hosts` that contains the hostname-to-IP address mappings for the TCP/IP subsystem. Here is an example of what this might look like at operating system level for one host:

```
127.0.0.1      localhost
10.68.91.226   virtualhost1.wdf.sap.corp virtualhost1
```

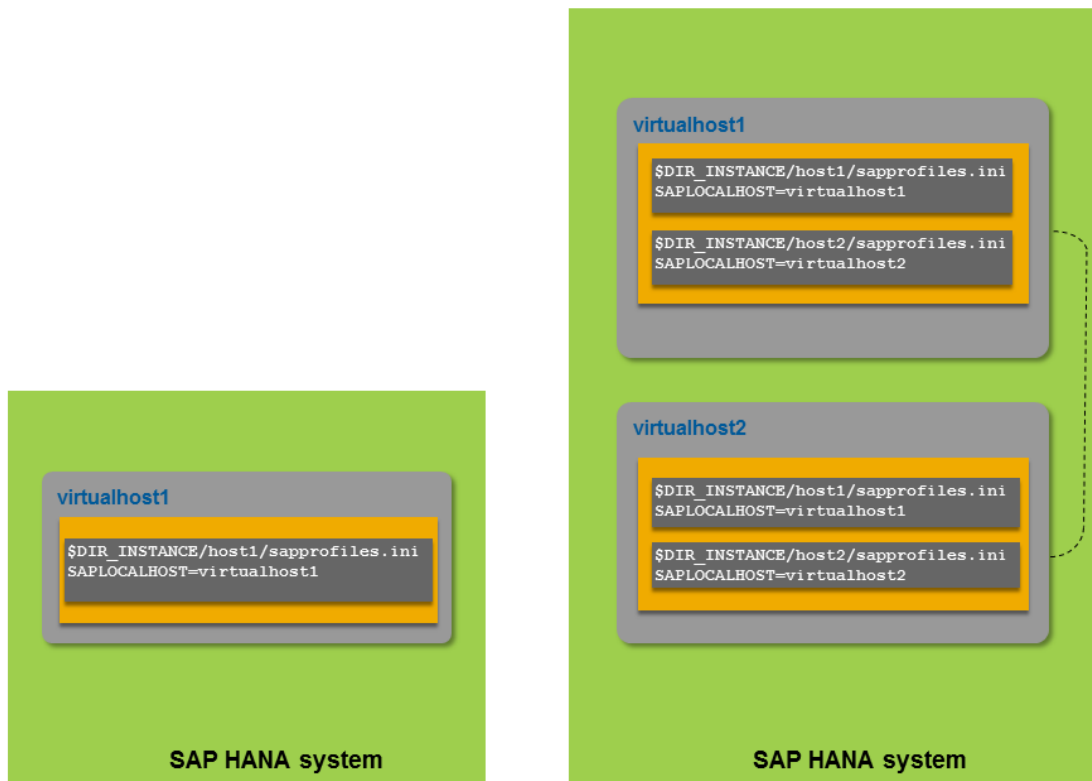

### i Note

The hosts file has a strictly defined structure. The three elements of each line are: IP address, fully qualified domain name, hostname. All lines and elements in the file must be unique. Modifications to the hosts file are effective after the next OS restart, or after a restart of the network service and the diagnostic agent.

Virtual host names are assigned as part of the installation process with the platform LCM command-line tool `hdblcm` using the `hostname` parameter. For more information about using the command-line tool or the `hostname` parameter, see the *SAP HANA Server Installation and Update Guide*.

The `<virtualhostname>` is then stored as the internal host name in the `sapstart` service profiles and shows up in the HOST column of any system view.

It is also possible to assign virtual host names once the system is up and running by using the platform LCM action `system_rename` with the `hostmap` parameter. For more information about mapping hosts, see *Rename an SAP HANA System Host*.

Example of Virtual (Internal) Host Names for SAP HANA

## Distributed Landscapes

In multiple-host systems used for scale-out, the host names of all hosts must be known to each SAP HANA host. The `/etc/hosts` file for each host must include the corresponding lines:

```

host1
127.0.0.1      localhost
10.68.91.226  virtualhost1.wdf.sap.corp virtualhost1
10.68.91.227  virtualhost2.wdf.sap.corp virtualhost2

```

```

host2
127.0.0.1      localhost
10.68.91.226  virtualhost1.wdf.sap.corp virtualhost1
10.68.91.227  virtualhost2.wdf.sap.corp virtualhost2

```

## Further Information

[SAP Community Blog: How to configure HANA network communication channels – Part 1: Public network](#)

## 10.2.4.2 Internal Host Name Resolution

SAP HANA services use IP addresses to communicate with each other. Host names are mapped to these IP addresses through internal host name resolution, a technique by which the use of specific and/or fast networks can be enforced and communication restricted to a specific network.

### Single Host Versus Multiple Hosts

For single-host systems, no additional configuration is required. The services listen on the loopback interface only (IP address 127.0.0.1). In the `global.ini` files, the `[communication] listeninterface` is set to `.local` as follows:

```
global.ini
[communication]
listeninterface=.local
```

In a distributed scenario with multiple hosts, the network needs to be configured so that interservice communication is operational throughout the entire landscape. In this setup, the host names (these could be virtual host names) of all hosts must be known to each other and thus to the SAP HANA system. This can be achieved by manually adding all hosts to each `/etc/hosts` file on the operating system of each host.

A distributed system can run with or without a separate network definition for interservice communication.

### Distributed System Without a Separate Internal Network

If no separate network is defined for internal communication, SAP HANA services listen on all available network interfaces. In the `global.ini` file, the listening interface is set to `.global` as follows:

```
global.ini
[communication]
listeninterface=.global
```

## ⚠ Caution

If the `listeninterface` parameter is set to `.global`, we strongly recommend that you secure the SAP HANA servers with additional measures such as a firewall and/or TLS/SSL. Otherwise, the internal service ports of the system are exposed and can be used to attack SAP HANA.

## Distributed System with a Separate Internal Network

A distributed system can be configured with a dedicated internal network in one of the following ways:

- At installation time, using the **HDBLCM command line option** as in the following example:

```
<installation medium>/DATA_UNITS/HDB_LCM_LINUX_X86_64/hdblcmm --  
internal_network=10.66.128.0/20
```

- Post installation, using the **resident HDBLCM** from the GUI, command-line, or Web user interface. The following example, in command-line mode, binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry:

```
<sapmnt>/<SID>/hdblcmm/hdblcmm --action=configure_internal_network --  
listen_interface=internal --internal_address=10.66.8/21
```

For more information, see *Configuring SAP HANA Inter-Service Communication*.

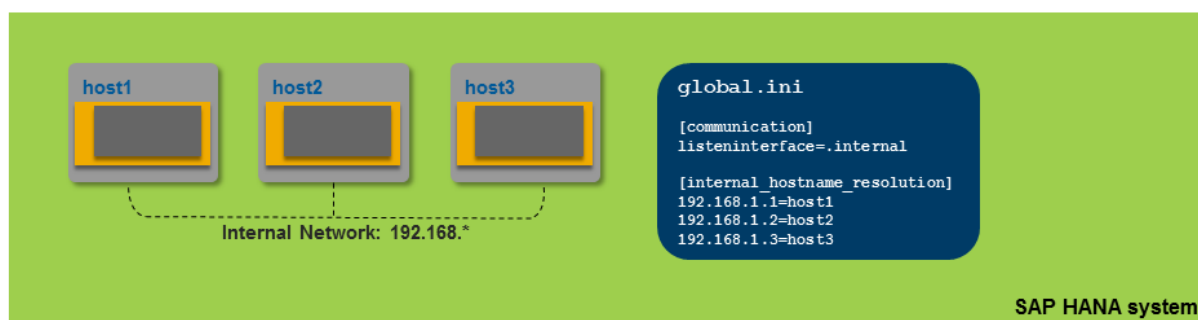

Post-installation configuration as described here is to be done by an SAP HANA system administrator with root credentials or on SAP HANA systems where SSH is configured. If root privileges or SSH are not available, you can still perform network configuration, but you need to use a host-by-host approach, also known as decentralized execution. In this case, see SAP Note 2048681.

SAP HANA automatically chooses on each host a network interface within the allowed network mask. If the network interface is defined as `.internal` in the `global.ini` file as described above, the SAP HANA services listen on this interface only:

```
global.ini  
[communication]  
listeninterface=.internal
```

Only the SAP start service (`sapstartsrv`) still listens on all interfaces, to accept start and stop commands, for example, from outside the SAP HANA system.

The following figure shows a simple example of how a separate internal network might be configured for an SAP HANA database with three hosts:

Simple Example of a Separate Internal Network for a Distributed SAP HANA System

For a more complex example, see *Host Name Resolution for System Replication*.

## Further Information

For more information about configuring the network for multiple hosts, see the section on scaling SAP HANA.

For information about the security of internal networks, see the *SAP HANA Security Guide*.

### i Note

SAP HANA internal communication has sometimes been unofficially referred to as TREXNet communication. However, the term TREXNet is not valid in the context of SAP HANA.

An SAP Community blog *How to configure HANA network communication channels – Part 2: Internal network* gives further details of these features.

## 10.2.4.3 Host Name Resolution for SQL Client Communication

Client applications communicate with SAP HANA servers from different platforms and types of clients via a client library (such as SQLDBC, JDBC, ODBC, DBSL, ODBO or ADO.NET) for SQL or MDX access.

In distributed systems, the application has a **logical connection** to the SAP HANA system: that is, the client library may in fact use multiple connections to different servers or change to a different underlying connection. The client library supports load balancing and minimizes communication overhead by:

- Selecting connections based on load data
- Routing statements based on information about the location of data

### i Note

Communication with SAP HANA hosts from a Web browser or a mobile application is requested using the HTTP protocol, which enables access to SAP HANA Extended Application Services, classic model (SAP HANA XS classic).

## Public Host Name Resolution

An SQL client library always connects to the first available host specified in the connect string. From this host, the client library then receives a list of all the hosts. During operations, statements may be sent to any of these hosts.

By default, the IP address of the primary network interface is returned to the clients, as configured in the following parameter:

```
global.ini
[public_hostname_resolution]
use_default_route=ip
```

This works as long as there is only one external network. If a hostname or IP address is unresolvable, the client library falls back on the host names in the connect string:

- In single-host systems, the user doesn't normally notice this. In rare cases, the connection attempt does not fail immediately but waits for a TCP timeout, making the first statement run very slowly.
- In distributed systems, performance is impaired because statements must first be sent to the initial host and then forwarded on the server side to the right host.

## Connect String with Multiple Host Names

In a distributed SAP HANA system consisting of more than one host, a list of hosts (host:port) is specified in the SQL client library connect string.

The connect string for JDBC, for example, could look like this:

```
jdbc:sap://host1:30015;host2:30015;host3:30015/
```

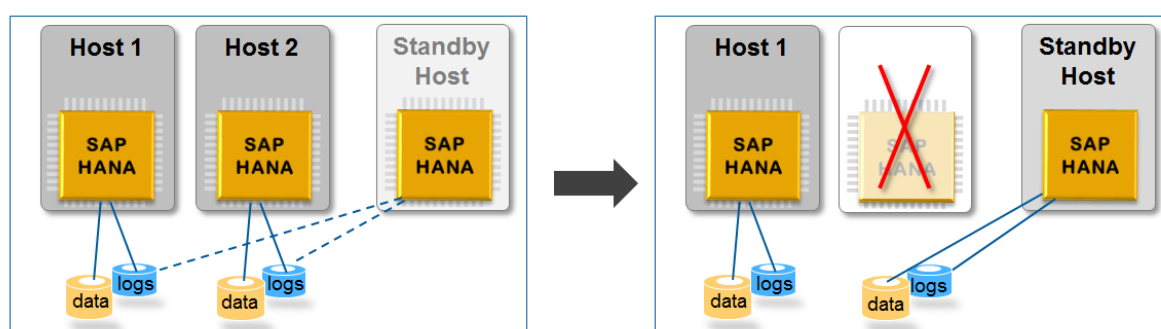

All hosts that could become the active master, because they are one of the three configured master candidates, must be listed in the connect string to allow an initial connection to any of them in the event of a host auto-failover. A host auto-failover is an automatic switch from a crashed host to a standby host in the same system. One (or more) standby hosts are added to a SAP HANA system and configured to work in standby mode. As long as they are in standby mode, these hosts do not contain any data and do not accept requests or queries. When an active (worker) host fails, a standby host automatically takes its place.

Inclusion of the standby hosts in the connect string is mandatory if they are master candidates, otherwise optional.

The client connection code (ODBC/JDBC) uses a "round-robin" approach to reconnection, ensuring that the clients can always access the SAP HANA database, even after failover.

The following figure illustrates how host auto-failover works. An active host fails (in this example, Host 2), and the standby host takes over its role by starting its database instance using the persisted data and log files of the failed host.

Example of Auto Host-Failover

One way to look up the master candidates in your distributed SAP HANA database is to use the following SQL statement:

```
select HOST
from SYS.M LANDSCAPE_HOST_CONFIGURATION
where NAMESERVER_CONFIG_ROLE like 'MASTER%'
order by NAMESERVER_CONFIG_ROLE
```

For more information, see the section on configuring clients for failover.

## Connect String for SAP HANA System Replication

If system replication is used, we recommend that you do **not** specify physical host names in the SQL client connect string. Otherwise, you would have to reconfigure all of your applications after a takeover. Instead, use a **virtual host name** or **virtual IP address**, and manage it using an external cluster manager. This virtual host name or IP address must point to the active master host on the active primary site.

## Further Information

System replication takeover hooks can be implemented to provide notification about the takeover. For more information about takeover hooks and client connection recovery, see the section on 'Implementing a HA/DR Provider' in System Replication.

An SAP Community blog *How to configure HANA network communication channels – Part 1: Public network* gives further details of these features.

### 10.2.4.3.1 Mapping Host Names for Database Client Access

Clients communicate with the database through external host names or external IP addresses. A default mapping of external host names to internal host names enables statement routing and automatic reconnection in the event of a failover.

By default, the IP address of the primary network interface is used but there may be situations where you need to change this configuration, such as for certain firewall configurations, network address translation (NAT) types, or multiple external networks. For this purpose, a `[public_hostname_resolution]` section in the `global.ini` file is used with:

```
use_default_route = ip # values: no,ip,name,fqdn
optional pattern mapping: map_<internal-prefix>* = <public-prefix>*<public-
suffix>
optional exact mapping: map_<internal-name> = <public-name>
```

If optional mappings exist, they are always considered regardless of the `use_default_route` parameter value. Exact mappings have higher priority than pattern mappings.

Each host identifies the network interface and thus the default route for the connection:

Description	Parameter	Example
IP address of the interface	<code>use_default_route = ip</code>	10.4.2.71

Description	Parameter	Example
Host name of the interface	<code>use_default_route = name</code>	lnd8520
Fully qualified name of the interface	<code>use_default_route = fqdn</code>	lnd8520.lnd.abc.corp
Disable feature and use internal host name	<code>use_default_route = no</code>	hananode01

#### ❖ Example

For connections to tenant databases, certificate validation may not work due to how SAP HANA handles host name resolution. If this is the case, setting the value of the parameter `use_default_route` to `fqdn` on the SYSTEM layer ensures that SAP HANA uses the FQDN and that certificate validation for secured JDBC/ODBC connections is allowed.

In most cases, you do not need to configure anything. If you do need to configure something, see if you can use one of the default route mechanisms. You need to specify your own mapping only if the default route mechanisms do not fit your network requirements.

#### ❖ Example

Here are some examples of how you might customize this parameter:

```
[public_hostname_resolution]
map_hananode* = myservername*
```

```
[public_hostname_resolution]
map_hananode* = hananode*.lnd.abc.corp
```

```
[public_hostname_resolution]
map_hananode01 = 10.4.2.71
map_hananode02 = 10.4.2.72
map_hananode03 = 10.4.2.73
map_hananode04 = 10.4.2.74
```

```
[public_hostname_resolution]
map_hananode0* = 10.4.2.7*
map_hananode1* = 10.4.2.8*
```

Changes to configuration and default routes are checked once a minute and become effective within a minute after the SQL system management statement `ALTER SYSTEM ALTER CONFIGURATION ... WITH RECONFIGURE .`

## Related Information

[Host Name Resolution for SQL Client Communication \[page 1216\]](#)

### 10.2.4.3.2 SQL Connection Information for New Clients

It can be convenient for new SQL clients to be able to query the connectivity information of an existing client.

The connect string of the existing client was stored in the secure store and cannot be accessed. However, you can use the `global.ini/[communication]/sql_connect_hosts` parameter to record the connectivity information in the SAP HANA server so that it is available for the database connection from new clients. This information is a list of host names or IP addresses, which could be virtual host name or IP addresses, separated by commas.

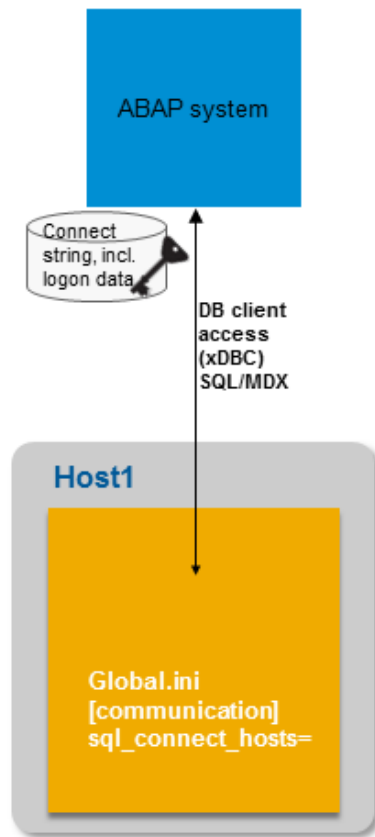

The SAP HANA server does not use this parameter. It is used by applications and components that connect to SAP HANA. If the parameter is not filled, the application needs to consume the host values as follows:

```
select HOST
from SYS.M_LANDSCAPE_HOST_CONFIGURATION
where NAMESERVER_CONFIG_ROLE like 'MASTER%'
order by NAMESERVER_CONFIG_ROLE
```

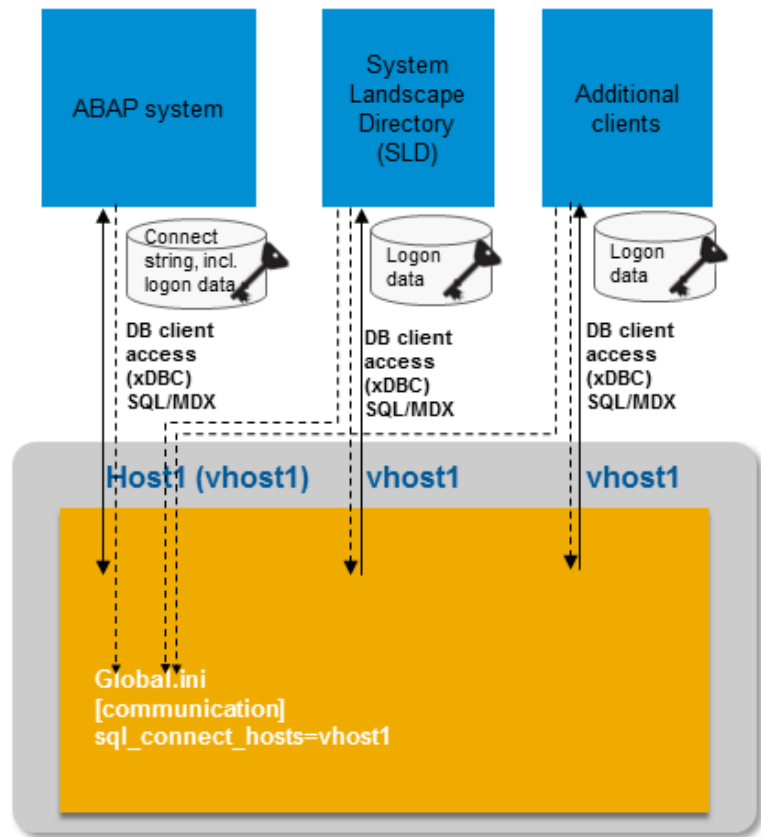

In the following example, an ABAP system is installed on SAP HANA and the connection information is stored on the client side in the connect string including the logon data. This is the standard case. The ABAP client then sets the `sql_connect_hosts` parameter on the SAP HANA server. A System Landscape Directory (SLD) is subsequently installed on the same SAP HANA system. The SLD agent is able to look up the parameter in SAP HANA to find out the connection information. If the parameter values are missing, SLD uses the above SQL statement. If more clients are added, they follow the same procedure.

The example shows a single host but the parameter can also be useful in scenarios with multiple hosts.

### With additional SQL connection

# 11 Availability and Scalability

SAP HANA provides comprehensive fault and disaster recovery support, as well as high availability for business continuity.

## Related Information

[High Availability for SAP HANA \[page 1222\]](#)

[SAP HANA Database Backup and Recovery \[page 1395\]](#)

[Scaling SAP HANA \[page 1609\]](#)

## 11.1 High Availability for SAP HANA

High availability is the name given to a set of techniques, engineering practices, and design principles that support the goal of business continuity and also ensure that data and services are available to authorized users when needed.

SAP HANA is fully designed for high availability. It supports recovery measures ranging from faults and software errors, to disasters that decommission an entire data center. High availability is achieved by eliminating single points of failure (fault tolerance), and providing the ability to rapidly resume operations after a system outage with minimal business loss (fault resilience). Fault recovery is the process of recovering and resuming operations after an outage due to a fault. Disaster recovery is the process of recovering operations after an outage due to a prolonged data center or site failure. Preparing for disasters may require backing up data across longer distances, and may thus be more complex and costly.

The key to achieving high availability is redundancy, including hardware redundancy, network redundancy and data center redundancy. SAP HANA provides several levels of defense against failure-related outages:

- **Hardware Redundancy:** SAP HANA appliance vendors offer multiple layers of redundant hardware, software and network components, such as redundant power supplies and fans, enterprise grade error-correcting memories, fully redundant network switches and routers, and uninterrupted power supply (UPS). Disk storage systems use batteries to guarantee writing even in the presence of power failure, and use striping and mirroring to provide redundancy for automatic recovery from disk failures. Generally speaking, all these redundancy solutions are transparent to SAP HANA's operation, but they form part of the defense against system outage due to single component failures.
- **Software:** Linux distributions certified for SAP HANA include security pre-configurations (for example, minimal network services). Additionally, the SAP HANA system software also includes a watchdog function, which automatically restarts configured services (index server, name server, and so on), in case of detected stoppage (killed or crashed).
- **Persistence:** SAP HANA persists transaction logs, savepoints and snapshots to support system restart and recovery from host failures, with minimal delay and without loss of data.

- Standby and Failover: Separate, dedicated standby hosts are used for failover, in case of failure of the primary, active hosts. This improves the availability by significantly reducing the recovery time from an outage.

[SAP HANA System Replication with Tenant Databases \[page 1235\]](#)

[Use SAP HANA System Replication for Near Zero Downtime Upgrades \[page 1360\]](#)

[Monitoring Secondary Systems \[page 1342\]](#)

### 11.1.1 SAP HANA High Availability Support

As an in-memory database, SAP HANA is not only concerned with maintaining the reliability of its data in the event of failures, but also with resuming operations with most of that data loaded back in memory as quickly as possible.

Downtime is the consequence of outages, which may be intentional (for example, for system upgrades) or caused by unplanned faults. A fault can be due to equipment malfunction, software or network failures, or due to a major disaster such as a fire, a regional power loss or a construction accident, which may decommission the entire data-center.

Fault Recovery is the process of recovering and resuming operations after an outage due to a fault. Disaster Recovery is the process of recovering operations after an outage due to a prolonged datacenter or site failure. Preparing for disasters may require backing up data across longer distances, and may thus be more complex and costly.

SAP HANA supports the following recovery measures from failures:

- Disaster recovery support:
  - Backups: Periodic saving of database copies in safe place.
  - Storage replication: Continuous replication (mirroring) between primary storage and backup storage over a network (may be synchronous).
  - System replication: Continuous update of secondary systems by primary system, including in-memory table loading.
- Fault recovery support:

- Service auto-restart: Automatic restart of stopped services on host (watchdog).
- Host auto-failover: Automatic failover from crashed host to standby host in the same system.
- System replication: Continuous update of secondary systems by primary system, including in-memory table loading and read-only access on the secondary.

System replication is flexible enough that it can also be used for both fault and disaster recovery to achieve high availability. The data pre-load option can be used for fault recovery to enable a quicker takeover than with Host Auto-Failover. You can build a solution with single node systems and do not need a scale out system and the additional storage and associated costs.

SAP HANA supports system replication for tenant databases on the system level, this means the tenant database system as a whole including all tenant databases. An SAP HANA system installed in multiple-container mode always has exactly one system database and any number of tenant databases (including zero). For more information on tenant databases see *Creating and Configuring Tenant Databases*.

## Using Secondary Servers for Non-Production systems

With SAP HANA system replication, you can use the servers on the secondary system for non-production SAP HANA systems under the following conditions:

- Table pre-load is turned off in the secondary system.
- The secondary system uses its own disk infrastructure. In the case of single node systems this means, the local disk infrastructure needs to be doubled.
- The non-production systems are stopped with the takeover to the production secondary.

[How to Perform System Replication for SAP HANA](#)

## 11.1.1.1 Backups

Backups are one of the key disaster recovery features offered by SAP HANA.

SAP HANA uses in-memory technology, but of course it fully persists any transaction that changes the data, such as row insertions, deletions and updates, so it can resume from a power-outage without loss of data. SAP HANA persists two types of data to storage: transaction redo logs, and data changes in the form of savepoints.

A transaction redo log is used to record a change. To make a transaction durable, it is not required to persist the complete data when the transaction is committed; instead it is sufficient to persist the redo log. Upon an outage, the most recent consistent state of the database can be restored by replaying the changes recorded in the log, redoing completed transactions and rolling back incomplete ones.

A savepoint is a periodic point in time, when all the changed data is written to storage, in the form of pages. One goal of performing savepoints is to speed up restart: when starting up the system, logs need not be processed from the beginning, but only from the last savepoint position. Savepoints are coordinated across all processes (called SAP HANA services) and instances of the database to ensure transaction consistency. By default, savepoints are performed every five minutes, but this can be configured.

Savepoints normally overwrite older savepoints, but it is possible to freeze a savepoint for future use; this is called a snapshot. Snapshots can be replicated in the form of full data backups, which can be used to restore a database to a specific point in time. This can be useful in the event of data corruption, for instance. In addition to data backups, smaller periodic log backups ensure the ability to recover from fatal storage faults with minimal loss of data.

Savepoints, can be saved to local storage, and the additional backups, can be additionally saved to backup storage. Local recovery from the crash uses the latest savepoint, and then replays the last logs, to recover the database without any data loss. If the local storage was corrupted by the crash, it is still possible to recover the database from the data and log backups, possibly with loss of some data. Regularly shipping backups to a remote location over a network or via couriers can be a simple and relatively inexpensive way to prepare for a disaster. Depending on the frequency and shipping method, this approach may have a recovery time ranging from hours to days.

## Related Information

[SAP HANA Database Backup and Recovery \[page 1395\]](#)

### 11.1.1.2 Storage Replication

SAP HANA offers disaster recovery support for storage replication solutions provided by hardware partners.

One drawback of backups is the potential loss of data between the time of the last backup and the time of the failure. A preferred solution therefore, is to provide continuous replication of all persisted data. Several SAP HANA hardware partners offer a storage-level replication solution, which delivers a backup of the volumes or file-system to a remote, networked storage system. In some of these vendor-specific solutions, which are certified by SAP, the SAP HANA transaction only completes when the locally persisted transaction log has been replicated remotely. This is called synchronous storage replication. Synchronous storage replication can be used only where the distance between the primary and backup site is relatively short (typically 100 kilometers or less), allowing for sub-millisecond round-trip latencies.

Due to its continuous nature, storage replication (sometimes also called remote storage mirroring) can be a more attractive option than backups, as it reduces the amount of time between the last backup and a failure. Another advantage of storage replication is that it also enables a much shorter recovery time. This solution requires a reliable, high bandwidth and low latency connection between the primary site and the secondary site.

See [SAP Note 1755396 Released DT solutions for SAP HANA with disk replication](#)

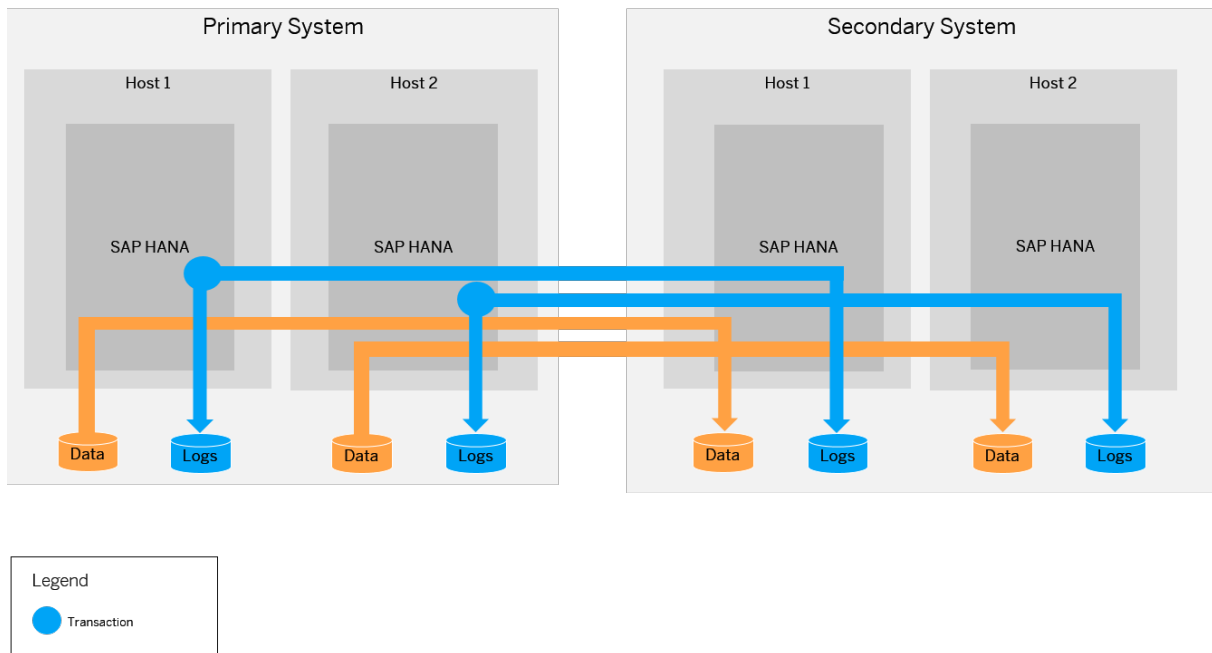

## Related Information

[SAP Note 1755396](#)

### 11.1.1.3 System Replication

System replication is available in every SAP HANA installation offering an inherent disaster recovery support.

System replication is set up so that a secondary system is configured as an exact copy of the active primary system, with the same number of active hosts in each system. The number of standby hosts need not be identical. With multitier system replication you can have a third system attached to the first secondary making it a replication chain of three systems. Each service instance of the primary SAP HANA system communicates with a counterpart in the secondary system. With multitarget system replication the primary system can replicate data changes to more than one secondary system.

The secondary system can be located near the primary system to serve as a rapid failover solution for planned downtime, or to handle storage corruption or other local faults, or, it can be installed in a remote site to be used in a disaster recovery scenario. Also both approaches can be chained together with multitier system replication. Like storage replication, this disaster recovery option requires a reliable connection channel between the primary and secondary sites. The instances in the secondary system operate in recovery mode. In this mode, all secondary system services constantly communicate with their primary counterparts, replicate and persist data and logs, and load data to memory. The main difference to primary systems is that the secondary systems do not accept requests or queries.

When the secondary system is started in recovery mode, each service component establishes a connection with its counterpart, and requests a snapshot of the data in the primary system. From then on, all logged changes in the primary system are replicated. Whenever logs are persisted in the primary system, they are also sent to the secondary system. A transaction in the primary system is not committed until the logs are replicated. What this means in detail, can be configured by choosing one of the log replication modes. For an overview of the replication modes, see *Replication Modes for SAP HANA*.

If the connection to the secondary system is lost, or the secondary system crashes, the primary system after a brief, configurable, timeout will resume replication. The secondary system persists, but does not immediately replay the received log. To avoid a growing list of logs, incremental data snapshots are transmitted asynchronously from time to time from the primary system to the secondary system. If the secondary system has to take over, only that part of the log needs to be replayed that represents changes that were made after the most recent data snapshot. In addition to snapshots, the primary system also transfers status information regarding which table columns are currently loaded into memory. The secondary system correspondingly preloads these columns. In the event of a failure that justifies full system takeover, an administrator instructs the secondary system to switch from recovery mode to full operation. The secondary system, which already preloaded the same column data as the primary system, becomes the primary system by replaying the last transaction logs, and then starts to accept queries.

### Note

To prevent unauthorized access to the SAP HANA database, the internal communication channels between the primary site and the secondary site in a system replication scenario need to be protected. This may

include filtering access to the relevant ports and channels by firewalls, implementing network separation, or applying additional protection at the network level (for example, VPN, IPSec). We recommend routing the connection between the two sites over a special site-to-site high-speed network, which typically already implements security measures such as separation from other network access and encryption or authentication between sites. The details of security measures and implementation of additional network security measures depend on your specific environment. For more information about network and security aspects, see the *SAP HANA Master Guide* and the *SAP HANA Security Guide*.

For a complete overview on system replication or for examples, see the *SAP HANA System Replication* guide.

## Related Information

[Overview of Steps \[page 1254\]](#)

[Recovery with System Replication \[page 1575\]](#)

[Replication Modes for SAP HANA System Replication \[page 1237\]](#)

### 11.1.1.4 Service Auto-Restart

Service auto-restart supports fault recovery for one service.

In the event of a software failure or an intentional intervention by an administrator that disables one of the configured SAP HANA services (Index Server, Name Server, and so on), the service will be restarted by the SAP HANA service auto-restart watchdog function, which automatically detects the failure and restarts the stopped service process. Upon restart, the service loads data into memory and resumes its function. While all data remains safe the service recovery takes some time.

### 11.1.1.5 Host Auto-Failover

Host auto-failover supports fault recovery for a failed host.

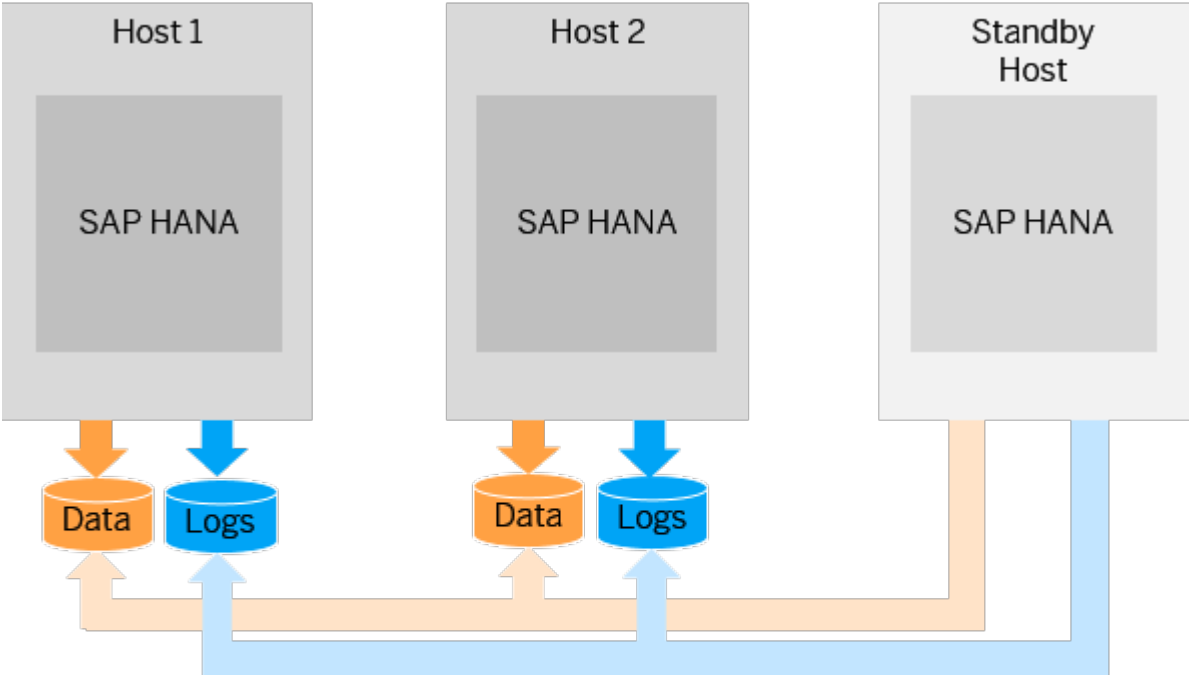

Host auto-failover is a local fault recovery solution that can be used in addition or as an alternative measure to system replication. One (or more) standby hosts are added to an SAP HANA system, and configured to work in standby mode. As long as they are in standby mode the databases on these hosts do not contain any data and do not accept requests or queries. This means they cannot be used for other purposes such as quality or test systems.

#### i Note

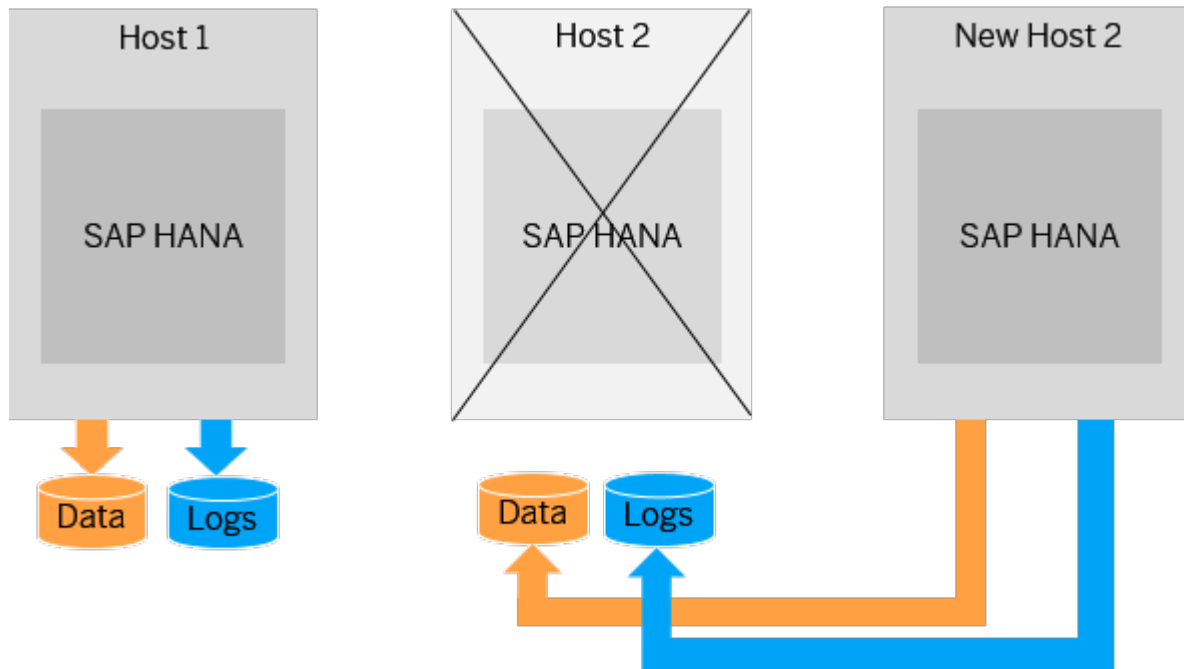

**Alternatives to Host Auto-Failover:** Host Auto-Failover requires shared network storage so that data and log files can be loaded from any server. However, Host Auto-Failover is not necessary in all systems (such as test systems or when other high availability solutions such as SAP HANA System Replication are used) and in these cases simpler storage options for the HANA data and log files can be used. Some alternative options, such as installing an NFS server on the master host, are described in a separate document in the SAP Community: *Storage alternatives for HANA scale-out without Host Auto-Failover*.

When an active (worker) host fails, a standby host automatically takes its place. If neither the name server process `hdbnameserver` nor `hdbdaemon` respond to network requests (because the instance is stopped, the OS has been shut down or powered off), a host is marked as inactive and an auto-failover is triggered. Since the standby host may take over operation from any of the primary hosts, it needs shared access to all the database volumes. This can be accomplished by a shared, networked storage server, by using a distributed file system, or with vendor-specific solutions that use an SAP HANA programmatic interface, the Storage Connector API, to dynamically detach and attach (mount) networked storage upon failover.

This scenario is illustrated in the graphic below:

Once repaired, the failed host can rejoin the system as the new standby host to reestablish the failure recovery capability:

In support of host auto-failover, database clients can be configured with the connection information of multiple hosts, optionally including the standby host. The client connection code (ODBC, JDBC, and so on) will try to connect to one of these, and upon successful connection receives the updated connection configurations. This ensures that clients can continue to reach the SAP HANA database, even after failover.

#### i Note

In a scale-out system, a failover from the failing master host is triggered automatically even if no standby host is configured. Then a worker host is attached to the volumes of the previous master.

#### i Note

It is not possible to do a seamless failover. A manual failover to a standby host can be triggered by stopping a worker host using the command `HDB stop`.

## 11.1.2 SAP HANA System Replication

SAP HANA system replication is a mechanism for ensuring the high availability of your SAP HANA system.

Through the continuous replication of data from a primary to a secondary system, including in-memory loading, system replication facilitates rapid failover in the event of a disaster. Productive operations can be resumed with minimal downtime.

The following administration activities are possible using the SAP HANA cockpit, using the SAP HANA studio, or using `hdbnsutil` on the command line:

- Performing the initial set-up, that is enabling system replication and establishing the connection between two identical systems
- Monitoring the status of system replication to ensure that both systems are in sync
- Triggering takeover by the secondary system in the event of a disaster and failback once the original system is available again
- Disabling system replication

System replication can also be set up or managed using SAP Landscape Management (SAP LaMa) - see related information links below.

For a complete overview of system replication including illustrations and examples, see the *SAP HANA System Replication* guide.

### 11.1.2.1 General Prerequisites for Configuring SAP HANA System Replication

Before you configure SAP HANA system replication, several prerequisites must be fulfilled.

#### System Requirements

- The primary and secondary systems must both be installed and correctly configured; verify that both systems are independently up and running.
- SAP HANA systems can only be replicated as the whole system, which means that the system database and all tenant databases are part of the system replication. A takeover can only be performed as a whole system. A takeover on the level of a single tenant database isn't possible.
- The configuration of active hosts in the primary and secondary system must be the same, which means that the number of active hosts, the names of the host roles, failover groups, and worker groups must be

identical in both systems. So, if there's a standby host on the primary system it need not be available on the secondary system and vice-versa.

- System replication between two systems on the same host isn't supported. Check that the host names in the primary system are different to the host names used in the secondary system. You can see the SAP HANA host name for each host in the environment variable `SAP_RETRIEVAL_PATH (/usr/sap/<SID>/HDB<InstNo>/<hostname>)` and with the python script `landscapeHostConfiguration.py`. For more information, see *Host Name Resolution for System Replication* and *Checking the Status with landscapeHostConfiguration.py* in the *SAP HANA Administration Guide*.  
If the host names of the primary and the secondary system are the same (for example, because two systems are used that have identical host names), change the host names used on the secondary system. For more information, see *Rename an SAP HANA System Host* in the *SAP HANA Administration Guide*.
- To secure the system replication communication channel between the primary and the secondary system, configure the ini parameters `[system_replication_communication] / listeninterface` and `allowed_sender` as described in *Host Name Resolution for System Replication*.
- For SAP HANA system replication, a port offset value of 10000 is configured to reserve ports for system replication communication.

### i Note

Note that values for port ranges do not need to be maintained manually. This can be done automatically by the SAP Host Agent which includes port reservation functionality and optimizes the relevant Linux kernel parameters. Refer to Linux Kernel Parameters in the Lifecycle Management section of the *SAP HANA Administration Guide* and the following SAP Notes:

- [401162 - Linux: Avoiding TCP/IP port conflicts and start problems](#), this describes setting up the SAP Host Agent.
  - [2382421 - Optimizing the Network Configuration on HANA- and OS-Level](#)
- If the local secure store (LSS) is being used as the secure store:
    - The primary and secondary systems require completely independent installations of the LSS with different file shares.
    - If the primary system has an active key management configuration with an external key management system (KMS), it is only possible to register secondary systems that use the LSS (and not the secure store in the file system (SSFS)). After successful replication, all secondary tenant databases are automatically connected to the same KMS account as the primary with the same key management configuration. For more information, see *Using the LSS with an External Key Management System*.
  - If a new tenant database is created in a running SAP HANA system replication, it must be backed up to participate in the replication. Afterward, the initial data shipping is started automatically for this tenant database. If a takeover is done while the initial data shipping is running and not finished, this new tenant database won't be operational after takeover and will have to be recovered with backup and recovery. See the *SAP HANA Database Backup and Recovery* section of the *SAP HANA Administration Guide*.
  - The secondary system must have the same SAP system ID (<SID>) and `instance number` as the primary system.

### i Note

The primary system replicates all relevant license information to the secondary system. An additional license isn't required. For more information, see [SAP Note 2211663 The license changes in an SAP HANA database after the deregistration of the secondary site](#).

- During an upgrade of the system replication landscape, the software version of the current secondary system must be equal or newer to the version of the current primary system.

### i Note

During a failback, the roles of your systems in the system replication landscape switch. Make sure in this case that your primary system doesn't have a newer software version than the secondary system.

### i Note

For Active/Active (read enabled) setups, the SAP HANA versions must be the same on the primary and the secondary system. Use this setup mainly during the upgrade process of the system replication landscape.

## Endianness

In a system replication landscape the systems on all sites must run on platforms with the same byte order. System replication is supported between Intel little-endian and IBM Power little-endian systems.

In SAP HANA the following byte order is supported in the corresponding SAP HANA and Linux versions:

Supported Byte Order

SAP HANA Version	Linux OS Version	Byte Order
SPS11 & SPS12	Linux Intel SLES 11	little-endian
	Linux Power SLES 11	big-endian
SAP HANA 2.0 SPS00	Linux Intel SLES 12	little-endian
	Linux Power SLES 12	

System replication is supported between Intel little-endian (SAP HANA SPS12 or SAP HANA 2.0 SPS 00) and IBM Power little-endian (SAP HANA 2.0 SPS 00).

## Configuration

- All configuration steps have to be executed on the coordinator nameserver node only.
- The .ini file configuration must be similar for both systems. Any changes made manually, or by SQL commands on one system should be manually duplicated on the other system. Automatic configuration parameter checks alert you to configuration differences between the two systems.

### i Note

To keep the ini file configuration similar on both systems, the INI parameter checker is per default configured to check for differences. Additionally, it can be configured to replicate parameter changes from the primary system to the secondary system.

- Ensure that `log_mode` is set to **normal** in the `persistence` section of the `global.ini` file. In log mode normal, the log segments are automatically backed up. This ensures that the database can be backed up to the most recent point in time.

## Authorization

- You must be logged on to both systems as the operating system user (user `<sid>adm`) or you have provided its credentials when prompted.
- You need the operating system user to set up a system replication landscape, to perform a takeover and a failback, as well as to disable system replication with the SAP HANA cockpit. For more information, see *Operating System User <sid>adm* and *Connect to a Database With SSO or SAP HANA Credentials*.
- Before you configure SAP HANA system replication, you must copy the system PKI SSFS .key and the .dat file from the primary system to the secondary system:

```
/usr/sap/<SID>/SYS/global/security/rsecssfs/data/SSFS_<SID>.DAT
/usr/sap/<SID>/SYS/global/security/rsecssfs/key/SSFS_<SID>.KEY
```

For more information, see *SAP Note 2369981 Required configuration steps for authentication with HANA System Replication*.

If you installed XS advanced, you must also copy the XSA SSFS .key and the .dat file from the primary system to the secondary system in the following directories:

```
/usr/sap/<SID>/SYS/global/xsa/security/ssfs/data/SSFS_<SID>.DAT
/usr/sap/<SID>/SYS/global/xsa/security/ssfs/key/SSFS_<SID>.KEY
```

For more information, see *SAP Note 2300936 Host Auto-Failover & System Replication Setup with SAP HANA extended application services, advanced model*.

The copied files become active during system restart. Therefore, it's recommended to copy them when the secondary system is offline (for example, before registration).

- In preparation for maintenance tasks (for example, near zero downtime upgrades), configure a user in the local userstore under the SRTAKEOVER key. For more information, see *Configure a User Under the SRTAKEOVER Key* in the *SAP HANA Administration Guide*.

## Dynamic Tiering

- If you plan to add SAP HANA dynamic tiering to your landscape in the future, see *SAP Note 2447994* before you enable HANA system replication. SAP HANA dynamic tiering requires certain communication ports, operation modes, and replication modes.
- SAP HANA dynamic tiering isn't supported with multitarget system replication. For more information about SAP HANA system replication with SAP HANA dynamic tiering, see *SAP Note 2447994*.

## 11.1.2.2 SAP HANA System Replication with Tenant Databases

The usual SAP HANA system replication principles apply for tenant database systems.

SAP HANA supports system replication for tenant databases on the system level, this means the tenant database system as a whole including all tenant databases. An SAP HANA system installed in multiple-container mode always has exactly one system database and any number of tenant databases (including zero).

Before you begin preparing a replication strategy for an SAP HANA system, you should be aware of the following important points:

- SAP HANA systems can only be replicated as the whole system. This means that the system database and all tenant databases are part of the system replication. A takeover can only be performed as a whole system. A takeover on the level of a single tenant database is not possible.
- Tenant management actions are synchronized over the whole replication topology so that an action (such as create, drop, start, stop) executed on a tenant on the primary is also performed on the secondary.
- If an active tenant database is stopped in a running SAP HANA system replication, it is stopped on the secondary site as well. If a takeover is done while tenant databases (which were part of the system replication) are stopped, they will be in the same state after takeover as they were on the primary site when they were stopped. The tenant databases must be started to complete the takeover.
- If a new tenant database is created in a configured SAP HANA system replication, it must be backed up to participate in the replication. Afterwards, the initial data shipping is started automatically for this tenant database. If a takeover is done while the initial data shipping is running and not finished, this new tenant database will not be operational after takeover and will have to be recovered with backup and recovery (see the *SAP HANA Database Backup and Recovery* section of the *SAP HANA Administration Guide*).
- If SAP HANA system replication runs in replication mode SYNC with the full sync option enabled, and if the connection to the secondary site is interrupted, no write operations on the primary site are possible. The operation of creating a tenant database, for example, will wait until the connection to the secondary is reestablished or the SQL statement times out.
- With SAP HANA systems, the services needed are generated automatically in the tenant databases.
- For SAP HANA system replication, a port offset value of 10000 is configured to reserve ports for system replication communication.

## i Note

Values for port ranges do not need to be maintained manually. This can be done automatically by the SAP Host Agent which includes port reservation functionality and optimizes the relevant Linux kernel parameters. Refer to 'Linux Kernel Parameters' in the Lifecycle Management section of the *SAP HANA Administration Guide* and the following SAP Notes:

- [401162 - Linux: Avoiding TCP/IP port conflicts and start problems](#), this describes setting up the SAP Host Agent.
  - [2382421 - Optimizing the Network Configuration on HANA- and OS-Level](#)
- For SAP HANA systems running with the HIGH isolation level, the system PKI SSFS data and key file must be copied from the primary system to the same location on the secondary system(s). For more information, see *Increase the System Isolation Level* in the *SAP HANA Administration Guide*.

For more information on the individual points, see the *Availability and Scalability* section of the *SAP HANA Administration Guide*.

## 11.1.2.3 Replication Modes for SAP HANA System Replication

While registering the secondary system, you need to decide which replication mode to use.

SAP HANA offers different modes for the replication of the redo log:

Replication modes

Log Replication Mode	Description
Synchronous in-memory (SYNCMEM)	<p>The primary system commits the transaction after it gets a reply that the log was received by the secondary system and stored in memory. The delay for the transaction in the primary system is smaller, because it only includes the time for transmitting the data. The disk I/O speed on the secondary system doesn't influence the primary's performance.</p> <p>When the connection to the secondary system is lost, the primary system continues the transaction processing and writes the changes only to the local disk.</p> <p>Data loss can occur in the following situations:</p> <ul style="list-style-type: none"><li>• When the primary and the secondary system fail at the same time while the secondary system is connected. The data is not written to disk – neither on the primary nor on the secondary system.</li><li>• When a takeover is executed while the secondary system is unavailable. The data that arrived on the secondary is outdated compared to the data on the primary.</li></ul> <p>This option provides better performance because it is not necessary to wait for disk I/O on the secondary system, but it is more vulnerable to data loss.</p>

Log Replication Mode	Description
Synchronous on disk (SYNC)	<p>The primary system waits with committing the transaction until it gets a reply that the log is persisted in the secondary system. This option guarantees immediate consistency between both systems, at a cost of delaying the transaction by the time for data transmission and persisting in the secondary system.</p> <p>When the connection to the secondary system is lost, the primary system continues the transaction processing and writes the changes only to the local disk. No data loss occurs in this scenario as long as the secondary system is connected. Data loss can occur, when a takeover is executed while the secondary system is disconnected.</p> <p>Additionally, this replication mode can run with a full sync option. This means that log write is successful when the log buffer has been written to the log file of the primary and the secondary system. When the secondary system is disconnected (for example, because of network failure), the primary system suspends the transaction processing until the connection to the secondary system is reestablished. No data loss occurs in this scenario. You can set the full sync option for system replication with the parameter <code>[system_replication]/enable_full_sync</code>.</p>
	<p><b>i Note</b></p> <p>If SAP HANA system replication runs in the SYNC replication mode with the full sync option enabled, and if the connection to the secondary site is interrupted, no write operations on the primary site are possible. The operation of creating a tenant database, for example, will wait until the connection to the secondary is reestablished or the SQL statement times out.</p> <p>For more information about how to enable the full sync option, see <i>Full Sync Option for System Replication</i>.</p>
Asynchronous (ASync)	<p>The primary system commits the transaction after sending the log without waiting for a response. Here we have no delay because the data transmission is asynchronous to the transaction in the primary system.</p> <p>This option provides better performance because it is not necessary to wait for log I/O on the secondary system. Database consistency across all services on the secondary system is guaranteed. However, it is more vulnerable to data loss. Data changes may be lost during takeover.</p>

### i Note

If you plan to add SAP HANA dynamic tiering to your landscape in the future, please check supported replication modes in *SAP Note 2447994* before you enable SAP HANA system replication.

The replication mode can be changed without going through a full data shipping from the primary system to the secondary system afterwards. For more information, see *Changing the Replication Mode*.

## Related Information

[Full Sync Option for SAP HANA System Replication \[page 1270\]](#)

[Changing the Replication Mode \[page 1267\]](#)

## 11.1.2.4 Operation Modes for SAP HANA System Replication

While registering the secondary system, you need to decide in which operation mode to run SAP HANA system replication.

System replication can be run in three operation modes: `delta_datashipping`, `logreplay` or `logreplay_readaccess`. Depending on the configured operation mode, the database sends different types of data packages to the secondary system. For more information, see *Data Transferred to the Secondary System*.

Operation Mode	Description
<code>delta_datashipping</code>	<p>This mode establishes a system replication where occasionally (per default every 10 minutes) a delta data shipping takes place in addition to the continuous log shipping.</p> <p>The secondary system persists the received log entries but it does not replay them until it has to take over. To shorten the log replay time, data snapshots are transmitted from time to time from the primary to the secondary system. The data snapshots are transferred asynchronously as differential backups (data backup deltas) triggered by the secondary system, which asks for a data backup delta with changes since the last one. During takeover the redo log needs to be replayed up to the last arrived delta data shipment.</p>
<code>logreplay</code>	<p>In this operation mode, a redo log shipping is done after system replication was initially configured with one full data shipping.</p> <p>The redo log is continuously replayed on the secondary system immediately after arrival making this step superfluous during takeover. Since the log is continuously replayed, the secondary system can take over immediately, if the primary system fails. With continuous log replay, the log entries are sent from the redo log buffers in memory. When the secondary system is temporarily disconnected, the primary system must not claim and overwrite the log segments that have not been replicated yet. This is achieved by retaining these log segments up to a configurable maximum retention size. When the maximum retention size is reached, the log segments are reclaimed and overwritten with new log to prevent a standstill of the primary system. After such a situation, a full data snapshot needs to be transferred again, when the secondary system is connected again.</p> <p>Because this operation mode does not require delta data shippings, the amount of data that needs to be transferred to the secondary system is reduced.</p>
<code>logreplay_readaccess</code>	<p>This mode is required for replication to an Active/Active (read enabled) secondary system.</p> <p>Using this operation mode while configuring your system replication, read access becomes possible on the secondary system by establishing a direct connection to the secondary system or by providing a SELECT statement from the primary system with a HINT. For more information, see also <i>Client Support for Active/Active (Read Enabled)</i> and SAP HANA SQL Reference Guide.</p> <p>This operation mode is similar to the <code>logreplay</code> operation mode regarding the continuous log shipping, the redo log replay on the secondary system, as well as the required initial full data shipping and the takeover. As with the <code>logreplay</code> operation mode, the redo log is replicated to the secondary system and continuously replayed to keep the secondary system synchronized.</p>

## Limitations

Before you begin preparing a replication strategy for an SAP HANA system, consider the following important aspects regarding the operation modes `logreplay` and `logreplay_readaccess`:

- Registering a secondary with operation mode `logreplay` against a primary running on an SAP HANA revision less than or equal to SPS10 will not work, because the primary does not yet support this feature. Furthermore, for operation mode `logreplay_readaccess` the primary must be running on a revision SAP HANA 2 SPS00 or higher.
- Only the operation mode `delta_datashipping` will work when registering the original primary (failback) after upgrade of the secondary during a near zero downtime upgrade from an SAP HANA revision less than or equal to SPS 10 to SPS 11, because the former primary's version does not yet support `logreplay`.
- If the connection to the secondary is not available, the primary system will keep writing the redo log segments in the online log area to be prepared for the delta log shipping after the connection is reestablished. These log segments are marked as *RetainedFree* until the secondary is in sync again. In this case there is a risk that the log volume may run full. To prevent this:
  - If a secondary is not used anymore, it must be unregistered (`sr_unregister`).
  - If a takeover to the secondary was done, the former primary should be disabled (`sr_disable`).For more information, see *How to Avoid Log Full Situations* in *LogReplay: Managing the Size of the Log File*.
- In a multitier or multitarget system replication it is not possible to combine the `logreplay` and `delta_datashipping` operation modes.
- For multitarget system replication only the `logreplay` and `logreplay_readaccess` modes are supported.
- The `logreplay` operation modes do not support history tables.

### i Note

If you plan to add SAP HANA dynamic tiering to your landscape in the future, please check supported operation modes in *SAP Note 2447994* before you enable SAP HANA system replication.

### i Note

When selecting an operation mode, keep in mind that the selected operation mode impacts the network throughput requirements of the communication channel used in SAP HANA system replication. For more information about this, see *Network Recommendations*.

For information about how to change the operation mode, see *Changing the Operation Mode*.

## Related Information

[Network Recommendations](#)

[Changing the Operation Mode \[page 1267\]](#)

## 11.1.2.4.1 Data Transferred to the Secondary System

The selected operation mode determines what types of data packages are sent to the secondary system.

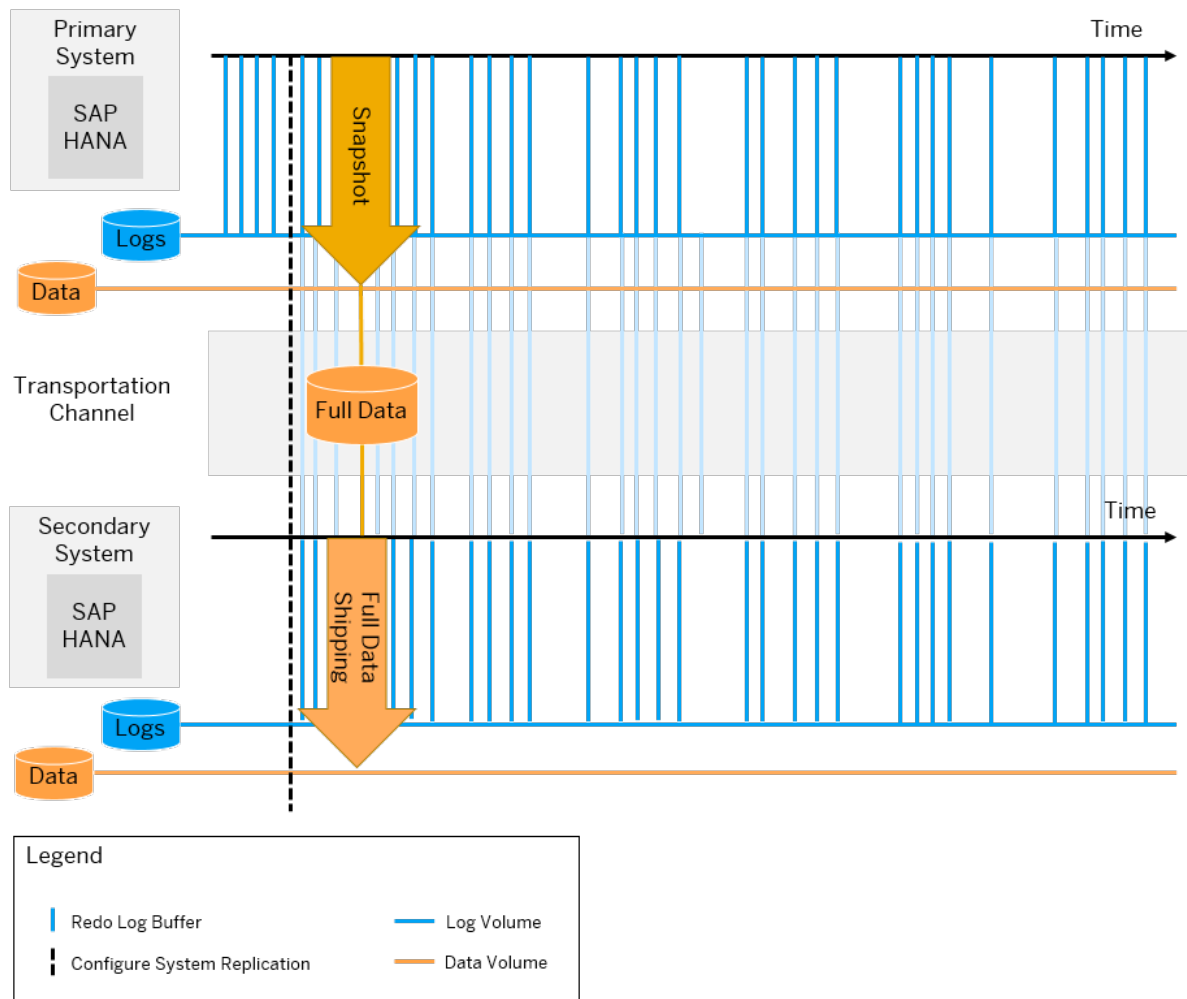

When system replication is configured, the following types of data packages can be sent to the secondary system:

- Initial full data shipping  
When system replication is configured, a full set of data created as an SAP HANA in-place snapshot on the disk of the primary system is initially sent.
- Delta data shipping  
When using the `delta_datashipping` operation mode, the data that has changed since the last full or the last delta data shipping is transported from the data area of the primary system to the data area of the secondary system. The default time is every 10 minutes.  
When using `logreplay` and `logreplay_readaccess`, delta data shippings are not required.
- Continuous redo log shipping  
Every committing write transaction on the primary system generates redo log buffers, which are continuously sent to the secondary system.

The following graphic illustrates this traffic on the transportation channel between the primary and the secondary system for the `delta_datashipping` operation mode:

The following graphic illustrates this traffic on the transportation channel between the primary and the secondary system for the `logreplay` and `logreplay_readaccess` operation modes:

## i Note

With the ini file parameter `datashipping_parallel_channels` (default 4), the full and the delta data shipping are done using parallel network channels. You can change it on the secondary system in the `global.ini` section `[system replication]`. For more information about configuration parameters, see *SAP HANA System Replication Configuration Parameters*.

## Related Information

[SAP HANA System Replication Configuration Parameters \[page 1271\]](#)

[Troubleshoot System Replication](#)

[System Replication Network Connection](#)

## 11.1.2.4.2 Data Volume Encryption with System Replication

Encryption for data volume, redo log, and data and log backups can be applied to all replicated systems.

### Enabling Encryption

You can enable (or disable) encryption in the primary system and the setting will be propagated to all secondary systems which are running and replicating. On replicated sites data volume encryption can be set either by parameter replication, or by directly applying manual settings.

In general, if you enable encryption in an operational database only the pages in use in the data volumes are encrypted. Pages in data volumes that are not in use may still contain old content, and are only overwritten and encrypted over time. In addition, only redo log entries that are created after encryption is enabled are encrypted. See also 'Enable Encryption' in the Security section.

From a replication perspective, using logreplay / logreplay\_readaccess operation modes, when you start encryption on the primary the complete persistence of all replicating systems is encrypted.

Using the delta\_datashipping mode only new sites are encrypted. In this case, if you want to ensure that previously created data pages are also encrypted it is necessary to re-register a site using the `force_full_replica` parameter to enable encryption. Carry out the following steps:

1. Stop the secondary site:

```
sapcontrol -nr <instance_number> -function StopSystem HDB
```

2. Re-register secondary site:

```
hdbnsutil -sr_register --force_full_replica
```

3. Start the secondary system to start replication:

```
sapcontrol -nr <instance_number> -function StartSystem HDB
```

See also SAP Note 2754379 *Data Volume Encryption is Only Propagated to Secondary Site for Newly Written Pages*.

### Checking the Encryption Status

On the primary site you can check whether that site is encrypted by running the following query:

```
select * from M_PERSISTENCE_ENCRYPTION_STATUS
```

On the secondary you can run the following hdbcons command to get information about the encryption status:

```
hdbcons "encryption status"
```

To identify a specific tenant, include the process ID of the tenant's indexserver:

```
hdbcons -p <PID> "encryption status"
```

Return values are: active: 0/1 or mayContainUnencryptedData: 0/1.

The same hdbcons command can be run on the replication site (SYSTEMDB logged in as <sid>adm) using the remote execution functionality to check the encryption status on the secondary or tertiary sites:

```
hdbcons -e hdbnameserver "distribute exec <hostname>:<port> encryption status"
```

See also SAP Note 2767023 *How to check the encryption status of a replication site in SAP HANA*.

## Related Information

[Enable Encryption \[page 1009\]](#)

[SAP Note 2754379 - Data Volume Encryption is Only Propagated to Secondary Site for Newly Written Pages](#)

[SAP Note 2767023 - How to check the encryption status of a replication site in SAP HANA](#)

### 11.1.2.5 Resync Optimization

Whenever the primary and the secondary system are disconnected, SAP HANA system replication is out of sync. To get in sync again, a shipping of the missing data is initiated.

The system tries to avoid a full data shipping and to achieve a resync with a delta data or a log shipping. To get the primary and the secondary system in sync again, their persistencies (that is, the data and log volumes) must be compatible. The system that is to be registered as the secondary system checks if its persistence is compatible with the primary system. If this check succeeds, a delta shipping can be carried out instead of requesting a full data shipping from the primary system.

A maximum of three checks are executed by the secondary system in the following order:

1. Check if the newest savepoint is compatible.  
The to-be secondary system checks if its newest savepoint is compatible. This check most likely succeeds if the secondary system has just been shut down for a short time.
2. Check if the newest replication snapshot is compatible:  
Replication snapshots are written on the system replication primary and secondary system while the replication is up and running. The replication snapshots are created on the secondary system each time a savepoint is written. On the primary system, the replication snapshots are created periodically (time and volume-based) to preserve a state that is known to be shipped to the secondary system. As the snapshot verification takes some time, a replication snapshot that is not yet verified to be shipped may have been created on the primary system.  
This check most likely succeeds after a test takeover on the secondary system because this state has to be available also on the primary system.
3. Check if the active replication snapshot is compatible:  
The active replication snapshot is a special replication snapshot created on the primary system and verified to be shipped to the secondary system. This check most likely succeeds during a failback operation because it's created on the old primary and the snapshot is verified to be shipped.

The first savepoint or snapshot that is compatible with the primary system will be used for delta data shipping. If none of the three savepoints or snapshots are compatible, then a full data shipping will automatically be carried out.

### **i Note**

If system replication is out of sync and you need to register again the initial secondary system, use the command `hdbnsutil -sr_register`. It is not needed to unregister the secondary system before registering it again. Unregistering the initial secondary system before registering it would hinder an optimized resync and would trigger a full data shipping.

Depending on the chosen operation mode, two different techniques are in place to achieve a resync: data retention and log retention. For more information, see *Data Retention* or *Log Retention*

## **Related Information**

[Data Retention \[page 1246\]](#)

[Log Retention \[page 1247\]](#)

### **11.1.2.5.1 Data Retention**

Data retention is the technique used to resync the disconnected systems when using the `delta_datashipping` operation mode.

With `delta_datashipping` the availability of the last snapshot that was successfully received by the secondary system, determines the type of the data shipping:

- If the last snapshot successfully received by the secondary system is still available on the secondary, the secondary system will request the incremental data to get in sync again.
- If it is no longer available, a full data shipping is necessary to get in sync again. The full data shipping is triggered automatically when the secondary reconnects with the primary and attempts to resynchronize.

To reduce the need for full data shipping after takeover, data snapshots are retained on the primary (or the new primary after takeover) for a given period of time. The `datashipping_snapshot_max_retention_time` parameter with a default of 300 minutes specifies for how long the primary system will keep the snapshot. Takeover takes place automatically but failback (registering the secondary) is a manual action which must be done within the snapshot retention period otherwise a full data shipping will be necessary.

#### **Scenarios where resynchronization is possible**

In many cases, when attempting to reconnect the secondary system after a takeover, the snapshot is available and resynchronization is possible via delta data or delta log shipping, as illustrated in the following scenarios:

- The failback scenario  
After a takeover the original primary system that was offline is registered as a new secondary. In this case a valid snapshot should be available on the new secondary from the time when this system was the primary and therefore resynchronization can be performed without the need for full data shipping.

- The re-register scenario (this is a non-standard case which could occur in a test environment)  
After a takeover the original secondary is again (without a long delay) registered as a secondary to the original primary. In this case the snapshots should still be available on the original secondary.
- Reconnection without takeover  
If the connection to an already initialized secondary system is temporarily lost but no takeover takes place then a valid snapshot will still be available on the secondary and replication can continue once the connection is restored.

### Actions which may necessitate full data shipping

These takeover scenarios might not apply if any of the following actions have been taken which would cause the snapshot to get lost. In these cases, if the snapshot is not available then full data shipping would be triggered:

- Disabling the primary system before registering it as secondary
- Running the system in the role of primary for more than the snapshot retention time.
- Unregistering a secondary so that it becomes a standalone system.

[SAP HANA System Replication Configuration Parameters \[page 1271\]](#)

## 11.1.2.5.2 Log Retention

With the `logreplay` and `logreplay_readaccess` operation modes, log segments can be marked as `retained` so that they can sync a secondary system after being disconnected.

With continuous log replay, delta data shipping cannot be used to sync a secondary system anymore. This is because although the primary's and secondary's persistence are logically compatible, they are no longer physically compatible. This means the data that is contained in the persistence is the same, but the layout of the data on pages can be different on the secondary system. Therefore, a secondary system can sync via delta log shipping only. This happens, for example, in the following use cases:

- The secondary system has been disconnected for some time (for example, because of a network problem or temporary shutdown of the secondary system).
- A former primary system has been registered for failback.

The secondary system only uses the log of the online log area of the primary system for re-syncing. The log must be retained for a longer time period than in the `delta_datashipping` mode to be able to sync the secondary system. If getting in sync again doesn't work with delta log shipping (for example, because the log has been reused), a full data shipping becomes necessary. To avoid this, the concept of log retention has been introduced.

For more information on log retention in different scenarios, see *Log Retention for Secondary Disconnect*, *Log Retention for Failback*, and *Log Retention and Multitarget System Replication*.

The following parameters are significant for log retention:

- Use the `enable_log_retention` parameter to enable or disable log retention.
- Use the `logshipping_max_retention_size` parameter to specify how the system behaves when many log segments of the type `RetainedFree` are created.

For a full description of the parameters, see *SAP HANA System Replication Configuration Parameters*.

[Log Retention for Failback \[page 1249\]](#)

[Estimating the Maximum Retention Time](#)

[Log Retention and Multitarget System Replication \[page 1250\]](#)

[SAP HANA System Replication Configuration Parameters \[page 1271\]](#)

### 11.1.2.5.2.1 Log Retention for Secondary Disconnect

When a secondary system configured with the operation mode `logreplay` or `logreplay_readaccess` is disconnected, the primary system will not reuse the log segments in the online log area that are required to sync the secondary system using delta log shipping.

These log segments are marked as `RetainedFree` until the secondary has successfully synced again. If a secondary system is stopped, the log volume will grow on the primary system until the log volume has filled up with log segments. Once the secondary system reconnects and has synced the missing log, these log segments are then set to `Free` and can be reused after that. This behavior is automatically turned on, if a secondary system with the operation mode `logreplay` or `logreplay_readaccess` is registered.

Log segments are retained on the primary as long as the secondary system is registered, but not connected to the primary system.

#### i Note

Therefore, if a secondary system is shut down and not used for a longer period of time, unregister it first, to prevent log volumes from accumulating on the primary system. However, in such a case a full data shipping will be necessary when the system reconnects.

#### i Note

Log full means that no more log segments can be created in the log volume, because the log segment directory is full. Currently the number of log segments is roughly 10000. Disk full means that the disk is full, which is not necessarily the case in the log full situation. Log retention usually deals with disk full situations, because with 10000 log segments having each a size of 1 GB you can create 10 TB of log segments.

To understand for how long the SAP HANA system replication landscape will survive before running into a log full situation, see *Estimating the Maximum Retention Time*.

The `logshipping_max_retention_size` parameter determines if a full log volume can be prevented at the price of a possibly necessary full data shipping when the system reconnects. The value of this parameter (default is 1 TB per log volume) should not exceed the size of the file system reserved for all log volumes.

## Related Information

[Estimating the Maximum Retention Time](#)

### 11.1.2.5.2 Log Retention for Failback

On the secondary system, log retention is required to do a failback with optimized data transport.

The primary system periodically creates persistence snapshots during replication and provides the log position information to the secondary system. After takeover, when the old primary is started again as a secondary, the most recent snapshot is opened on the old primary system and the missing log is requested from the new primary system.

Log retention can occur in two situations:

- While replication is active  
During replication, the secondary system keeps all log starting from the last snapshot position provided by the primary system. The old log is automatically released after a new snapshot has been created on the primary system. This behavior is turned on by default and it ensures that during replication only a few `RetainedFree` segments are kept online. They are needed to fill the gap between the primary snapshot and the current potential takeover log position.
- After a takeover  
After takeover, the new primary has to keep the log until a new secondary system is registered and has synced the missing log. Because syncing can take some time, this behavior has to be turned on explicitly on the new primary system as follows:

```
global.ini/[system_replication]/enable_log_retention = on
```

#### → Recommendation

If you have a setup in which there will be frequent failbacks between two systems, we recommend that you set the following parameter on both system to simplify the configuration: `global.ini/[system_replication]/enable_log_retention = on`

#### i Note

If the old primary system will not be reused as the new secondary system (failback), it should be disabled after the takeover using `hdbnsutil -sr_disable` to prevent log volumes from accumulating on the new primary system. You can disable it with SAP HANA cockpit, SAP HANA studio, or using the command line.

## 11.1.2.5.2.3 Log Retention and Multitarget System Replication

When the primary system replicates data changes to more than one secondary system, you should use force log retention and log retention propagation to reach an optimized re-sync and avoid a full data shipping after takeover or other disconnect situations.

### Force log retention

Force log retention is used on a system to retain log until it's actively disabled. To use force log retention, enter the value `force_on_takeover` for the `enable_log_retention` configuration parameter.

If `enable_log_retention = force_on_takeover` is configured, the log will be retained during replication for all direct secondaries until a takeover is executed. During takeover, the parameter is set to `force`. This means the log will be retained independently of any secondary system.

#### ❁ Example

A typical scenario is described in the following steps:

1. Configure all systems with `[system_replication]/enable_log_retention = force_on_takeover`
2. During takeover on a secondary system, if `force_on_takeover` is set, the value is changed to `enable_log_retention = force`. This means that starting from the takeover, the log is retained until it's explicitly disabled.
3. Re-register all required systems until the landscape is fully functional again.
4. Reset `[system_replication]/enable_log_retention = force_on_takeover` on the system on which takeover has been executed before re-establishing the original configuration.

The configuration must be done manually (for example, by the administrator or using setup scripts) because the SAP HANA system doesn't know when the system landscape has been completely reconfigured.

### Log retention propagation

Log retention propagation is used to retain the log based on the smallest savepoint log position in the whole system replication landscape. Log retention propagation should be enabled if you want to re-order your systems in a complex system replication setup.

This can be done by setting the following parameter in `global.ini`: `[system_replication]/propagate_log_retention = on`. If you want to propagate log retention in a system replication landscape between all systems, this parameter should be set on all systems in the landscape.

When you set this parameter on a system, it behaves as follows:

- The system sends to its source system the minimum log position of its own savepoint and the retained log position it gets from all direct secondaries as retained position.

- The system sends the minimum log position of its own savepoint and the retained log position it gets from all direct secondaries to the secondaries as retained log position.
- The system uses the minimum log position it gets from all direct secondaries and its source system (if not primary) as own retained log position.

## Example

To explain these concepts we are using the setup described in *Multitarget System Replication*. In this setup, primary system A replicates data changes to secondary system B located in the same data center. Primary system A also replicates data changes to the secondary system C located in another data center. Secondary system C is a source system for a further secondary system D located in the same data center with system C. For a quick overview, use the graphic below:

If there is a takeover on secondary system B, you must register system C to B and system A to B to recreate the original configuration. To avoid a full data shipping for both systems, system B must retain all the log until systems A and C have synced again. This can't be accomplished by setting `global.ini/[system_replication]/enable_log_retention = on` because system B doesn't know how many systems must be re-attached until the landscape is back in its functional state.

Force log retention should be used on system B until systems A and C are registered again and synced.

If you want to re-order your systems, enable log retention propagation. Log retention without propagation only affects the direct neighbors. For example, if system D is stopped in this setup, system C retains log for D, but not for A and B. If system D is re-attached to systems B or A and propagation is not turned on, log could be missing because systems A and B do not retain their log with respect to D.

### 11.1.2.5.3 Data and Log Compression

Data and log compression can be configured to reduce the amount of traffic between systems, especially over long distances (for example, when using the ASYNC replication mode).

Data and log compression can be used for the initial full data shipping, the sub sequential delta data shipping, as well as for the continuous log shipping. The following types of compression for log and data shipping are supported:

- Log
  - Log buffer tail compression
  - Log buffer content compression
- Data
  - Data page compression

#### Log Buffer Tail Compression

All log buffers are aligned to 4kb boundaries by a filler entry. With log buffer tail compression the filler entry is cut off from the buffer before sending it over the network and added again when the buffer has reached the secondary system. So, only the net buffer size is transferred to the secondary system.

The size of the filler entry is less than 4kb, this is the maximum size reduction per sent log buffer. If the size of the log buffers is large, the compression ratio is limited. Log buffer tail compression is turned on by default.

#### Log Buffer and Page Content Compression

Log buffers and data pages shipped to the secondary system can be compressed using a lossless compression algorithm (lz4). By default content compression is turned off. You can turn it on by setting the following configuration parameters on the secondary system in the `system_replication` section of the `global.ini` file:

- `enable_log_compression = true`
- `enable_data_compression = true`

Log buffer content compression works also in combination with log buffer tail compression. So, only the content part of the log buffer is compressed, without considering the filler entry.

### 11.1.2.6 SAP HANA System Replication Setup for XS Advanced Runtime

In a system replication setup, all the data – including XS advanced runtime system data and application data – is replicated to a secondary system.

XS advanced services and applications run only on the currently active system. On the secondary system, XS advanced services are in an idle state until the takeover takes place.

After the takeover, all XS advanced services are started which in turn brings up all XS advanced applications on the secondary system. Moreover, XS advanced services and applications use the same domains and certificates that were present in the primary system before the takeover started.

For this to work, the central point for XS advanced requests must be the same on the primary and the secondary systems. This is established by using a failover router similar to the host auto-failover setup. For more information about the host auto-failover setup, see *Host Auto-Failover Setup with XS Advanced Runtime*.

SAP HANA System Replication Setup for XS advanced

In case the failover router terminates SSL, the same rules apply as described in *Host Auto-Failover Setup with XS Advanced Runtime*.

For more information, see [SAP Note 2300936](#).

### 11.1.2.7 Overview of Steps

This topic provides an overview of the steps involved in setting up system replication between two systems, taking over to a secondary system, failing back to a primary system, and disabling system replication.

#### Procedure

1. Set up system replication on primary and secondary systems:
  - a. Start the primary system.
  - b. Create an initial data backup or storage snapshot on the primary system. The system database and all tenant databases must be backed up.
  - c. Enable system replication on the primary system (sr\_enable).
  - d. Prepare the secondary system for authentication by copying the system PKI SSFS .key and the .dat file from the primary system to the secondary system. For more information see *General Prerequisites for Configuring System Replication* and see SAP Note 2369981 *Required configuration steps for authentication with HANA System Replication*.
  - e. Register the secondary system with the primary system (sr\_register).
  - f. Start the secondary system.
2. During takeover, the secondary system takes over from the primary system:
  - a. Stop primary system in data center A.
  - b. Secondary system in data center B takes over from primary in data center A (sr\_takeover).
  - c. When the primary system is available again, register it with the secondary system (sr\_register).  
The roles are switched, the original primary is registered as a secondary system. The original secondary is the production system.
  - d. Start the system in data center A.

To avoid any risk of having multiple primary systems active at the same time you can also start a takeover with handshake. Using this option it is not necessary to stop the primary first and it also ensures that all the sent redo logs are written to disk on the secondary system before the takeover. For more information see *Takeover with Handshake*.
3. Restore the role of the original primary system:
  - a. Stop the system in data center B.
  - b. Send a takeover command from the system in data center A (sr\_takeover).

- c. Register the system in data center B as secondary again (sr\_register).
  - d. Start the system in data center B.
4. Disable system replication:
  - a. Unregister the secondary system.
  - b. Disable system replication on the primary system.

## 11.1.2.8 Configuring SAP HANA System Replication

You can configure system replication using SAP HANA cockpit, SAP HANA studio, or hdbnsutil.

You can configure system replication using the following tools:

- SAP HANA cockpit  
For more information, see the SAP HANA cockpit topic *Configure SAP HANA System Replication from the Primary System*.
- SAP HANA studio  
For more information, see *Configure System Replication with the SAP HANA Studio*.
- hdbnsutil  
For more information, see *Configure System Replication with hdbnsutil*.

## Related Information

## 11.1.2.8.1 Configure SAP HANA System Replication with the SAP HANA Cockpit

To configure SAP HANA system replication in the SAP HANA cockpit, first enable system replication on the primary system and then register the secondary system.

### Prerequisites

Access the [Database Overview](#) by clicking [Database Directory](#) and then clicking on your database name.

- You've considered all the general prerequisites needed to set up system replication. For more information, see *General Prerequisites for Setting Up SAP HANA System Replication*.
- You've registered the system database for both systems in the SAP HANA cockpit.
- You have the operating system user to set up a system replication landscape with the SAP HANA cockpit. For more information, see *Operating System User <sid>adm* in the *SAP HANA Administration Guide* and *Connect to a Database With SSO or SAP HANA Credentials*.

### Context

In the [Monitoring](#) or [All](#) view, on the [Database Overview](#) page, the [System Replication](#) card provides the possibility to configure system replication. Once the configuration is done, the card displays information on the operation mode, the replication mode, the configuration type, and the status of system replication.

The secondary system can be registered from the primary system or from the [Database Overview](#) page of the SAP HANA cockpit. You can register again a previously stopped secondary system when a full data shipping is needed or when you want to change the operation mode

### Related Information

[General Prerequisites for Configuring SAP HANA System Replication \[page 1231\]](#)

[Connect to a Database With SSO or SAP HANA Credentials \[page 176\]](#)

[Operating System User <sid>adm](#)

[SAP HANA System Replication](#)

## 11.1.2.8.1.1 Configure SAP HANA System Replication from the Primary System

To configure SAP HANA system replication, first enable system replication on the primary system and then register the secondary system. Use the SAP HANA cockpit to execute these separate steps in one configuration step from the primary system.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

- You've considered all the general prerequisites needed to set up system replication. For more information, see *General Prerequisites for Setting Up SAP HANA System Replication*.

### Context

This topic describes how to configure system replication from the primary system in SAP HANA cockpit in one configuration step. You can use this method for 2-tier and 3-tier setups.

#### i Note

If you plan to add SAP HANA dynamic tiering to your landscape in the future, see *SAP Note 2447994* before you enable HANA system replication. SAP HANA dynamic tiering requires certain communication ports, operation modes, and replication modes.

### Procedure

1. In the *Monitoring* or *All* view, on the [Database Overview](#) page of the system database (SYSTEMDB) of the future primary system, choose the [System Replication](#) card.

If you never configured system replication before, this card displays the message *System replication is not yet enabled for this system*.

The [System Replication](#) page opens. If you performed a data backup before enabling system replication, this page displays the last data backup on the top left and the [Configure System Replication](#) button on the top right.

2. Choose [Configure System Replication](#).  
The [System Replication Configuration](#) dialog opens, allowing you to run the configuration in background.
3. Enter the logical name used to represent the primary system in the [Tier 1 System Details](#) screen area.
4. Enter the logical name used to represent the secondary system in the [Tier 2 System Details](#) screen area.

Keep in mind that the secondary system must have the same SAP system ID (<SID>) and instance number as the primary system so that they're identified as secondaries.

5. Select the secondary system host and mark the checkbox below this area to stop the system.
6. Select a replication mode. For more information on the available replication modes, see *Replication Modes for SAP HANA System Replication* in the *SAP HANA Administration Guide*.
7. Select an operation mode. For more information on the available operation modes, see *Operation Modes for SAP HANA System Replication* in the *SAP HANA Administration Guide*.
8. Decide whether to initiate a full data shipping or not.
9. Check *Start Secondary after Registration*.
10. Optional: To add a third tier to your system replication landscape configuration, click *Add Tier 3 System* on the bottom left.
11. Choose *Configure*.

## Related Information

### 11.1.2.8.1.2 Configure SAP HANA System Replication from the Primary and the Secondary Systems

To set up SAP HANA system replication, first enable system replication on the primary system and then register the secondary system. Use the SAP HANA cockpit to execute these configuration steps on the primary system and separately on the secondary system.

## Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

- You've considered all the general prerequisites needed to set up system replication. For more information, see *General Prerequisites for Setting Up SAP HANA System Replication*.

## Context

This topic describes how to enable system replication on the primary system and then register the secondary system using the SAP HANA cockpit. You can use this method to configure any system replication setups you want.

### i Note

If you plan to add SAP HANA dynamic tiering to your landscape in the future, see *SAP Note 2447994* before you enable HANA system replication. SAP HANA dynamic tiering requires certain communication ports, operation modes, and replication modes.

## Procedure

1. In the *Monitoring* or *All* view, on the *Database Overview* page of the system database (SYSTEMDB) of the future primary system, choose the *System Replication* card.

If you never configured system replication before, this card displays the message *System replication is not yet enabled for this system*.

The *System Replication* page opens. If you performed a data backup before enabling system replication, this page displays overview information on the primary system on the top left and the *Enable This System as Primary* link on the top right.

2. Enter the logical name used to represent the primary system and choose *Configure* on the bottom right.
3. On the *Database Overview* page of the future secondary system, click on the *Services* card.
4. Choose *Stop System* on the bottom right, because the system has to be offline in order to be registered as a secondary system.

Back on the *Database Overview* page of the future secondary system, the *Services* card displays the status *Stopped*.

5. On the *Database Overview* page of the secondary system, choose the *System Replication* card.

The *System Replication* page opens, displaying overview information about the secondary system on the top left and the *Register Secondary System* button on the top right.

6. Choose *Register Secondary System*.

The *System Replication Configuration* page opens.

7. On the *System Replication Configuration* page, enter the logical name used to represent the secondary system.
8. On the *System Replication Configuration* page, select a replication mode. For more information on the available replication modes, see *Replication Modes for SAP HANA System Replication* in the *SAP HANA Administration Guide*.
9. Select an operation mode. For more information on the available operation modes, see *Operation Modes for SAP HANA System Replication* in the *SAP HANA Administration Guide*.
10. Enter the host of the source system.

### i Note

If you're operating a distributed system on multiple hosts, enter the name of the host on which the master name server is running.

11. Check *Start Secondary after Registration*.
12. Review the configured information and choose *Configure* on the bottom right.

The *System Replication Configuration* dialog opens. After the configuration is complete, the *System Replication Overview* page displays information on the configured systems.

## Related Information

### 11.1.2.8.1.3 Reinitialize the Secondary System

You can register again a previously stopped secondary system using the SAP HANA cockpit.

## Prerequisites

You've navigated to the *Database Overview* page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

## Context

You can register again a previously stopped secondary system. Reinitialize when a full data shipping is needed or when you want to change the operation mode.

### i Note

The *System Replication* card isn't available in the tenant database.

## Procedure

1. In the *Monitoring* or *All* view, on the *Database Overview* page of the system database (SYSTEMDB) of the stopped secondary system, choose the *System Replication* card.
2. On the *System Replication Overview*, choose *Reinitialize Secondary System* on the top right.
3. On the *System Replication Configuration* page, you can now change the configuration. Change the operation mode or resync the persistencies using the *Initiate full data shipping* option.  
The secondary system is up and running again.

## Related Information

[SAP HANA System Replication](#)

### 11.1.2.8.2 Configure SAP HANA System Replication with the SAP HANA Studio

To configure SAP HANA system replication between two identical SAP HANA systems, you must first enable system replication on the primary system and then register the secondary system.

## Prerequisites

- You have considered all the general prerequisites needed to set up system replication. For more information, see *General Prerequisites for Setting Up SAP HANA System Replication*.
- You have added both systems in the SAP HANA studio.

## Procedure

1. Enable system replication on the primary system, which has to be online, as follows:
  - a. In the *Systems* view, right-click the primary system and choose **► Configuration and Monitoring > Configure System Replication >**.  
The *Configure System Replication* dialog opens. The *Enable System Replication* option is selected by default.

### i Note

You can also access the *Configure System Replication* dialog from the **► Landscape > System Replication >** tab.

- b. Choose *Next*.
  - c. Enter the logical name used to represent the primary system and choose *Next*.
  - d. Review the configured information and choose *Finish*.
  - e. Stop the secondary with right-click on the secondary system and choosing ► *Configuration and Monitoring* ► *Stop System* ►.
2. Register the secondary system as follows:
    - a. Stop the secondary system if it is still running. Right-click the secondary system and choose ► *Configuration and Monitoring* ► *Stop System* ►
    - b. In the *Systems* view, right-click the secondary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ►. The *Configure System Replication* dialog opens.
    - c. Choose *Register Secondary System* and then *Next*.
    - d. Enter the required system information and the logical name used to represent the secondary system.

### **i** Note

If you are operating a distributed system on multiple hosts, you enter the name of the host on which the master name server is running.

- e. Specify the log replication mode. For more information on the available replication modes, see *Replication Modes for SAP HANA System Replication*.
  - f. Specify the operation mode. For more information, see *Operation Modes for SAP HANA System Replication*. The `logreplay_readaccess` operation mode is not available in SAP HANA studio.
  - g. Review the configured information and choose *Finish*.
3. Optional: Configure the parameters in the `system_replication` section of the `global.ini` file. These parameters determine for example the size and frequency of data and log shipping requests. All parameters have a default configuration.
  4. If necessary, start the secondary system.

### **i** Note

The secondary system is started automatically unless you deselected the corresponding option during configuration (step 2).

The secondary system requests an initial full data replica from the primary system.

## Results

You have enabled system replication and registered the secondary system with the primary system. The secondary system operates in recovery mode. All secondary system services constantly communicate with their primary counterparts, replicate and persist data and logs, and load data to memory. However, the secondary system does not accept SQL connections.

In the *Systems* view, the primary and secondary systems appear as operational (■). If the secondary system is not open for read access, it appears as operational (■) but with an error (✖) indicating that no connection to the database is available. For more information, see *Generic Conditions for Active/Active (Read Enabled)*.

### 11.1.2.8.3 Configure SAP HANA System Replication with hdbnsutil

You can configure SAP HANA system replication with the hdbnsutil command line tool.

#### Prerequisites

You have considered all the general prerequisites needed to configure system replication. For more information, see *General Prerequisites for Setting Up SAP HANA System Replication*.

##### Note

For SAP HANA tenant database systems all databases must be backed up using hdbnsutil via the database name option:

- for the system database `-d SystemDB`
- for the tenant databases `-d <tenantDBName>`

#### Procedure

1. Enable system replication on the primary system as follows:
  - a. Ensure that the configuration parameter `log_mode` is set to `normal` in the persistence section of the `global.ini` file.

Log mode `normal` means that log segments must be backed up. Log mode `overwrite` means that log segments are freed by the savepoint (therefore only useful for test installations without backup and recovery).

- b. Do an initial data backup or create a storage snapshot. In multiple-container systems, the system database and all tenant databases must be backed up. For more information, see *Creating Backups*.
- c. As `<sid>adm` on the command line enable the primary for system replication and give it a logical name with the following command. The primary system must be online at this time:

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_enable --name=<siteName>
```

Option Name	Value	Description
<code>--name</code>	<code>&lt;primary_alias&gt;</code>	Alias used to represent your primary system and assign it as the primary system for system replication

To check if the system has been successfully enabled for system replication with `hdbnsutil` run:

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_state
```

2. Stop the secondary system:

```
sapcontrol -nr <instance_number> -function StopSystem HDB
```

If you are running SAP HANA 2.0, you will need to copy the system PKI SSFS key and data file from the primary system to the secondary before registering the secondary system. The corresponding files can be found on the primary system in the following locations:

- `/usr/sap/<SID>/SYS/global/security/rsecssfs/data/SSFS_<SID>.DAT`
- `/usr/sap/<SID>/SYS/global/security/rsecssfs/key/SSFS_<SID>.KEY`

If you are running XS advanced, you will also need to copy both the SSFS key and data files for XS advanced from the primary system to the secondary system. The corresponding files can be found on the primary system in the following locations:

- `/usr/sap/<SID>/SYS/global/xsa/security/ssfs/data/SSFS_<SID>.DAT`
- `/usr/sap/<SID>/SYS/global/xsa/security/ssfs/key/SSFS_<SID>.KEY`

3. Register the secondary system as follows:

- a. Enable system replication on the secondary system as user `<sid>adm` with the following command:

```
hdbnsutil -sr_register --name=<secondarySiteName>
--remoteHost=<primary_host> --remoteInstance=<primary_systemnr>
--replicationMode=[sync|syncmem|async]--operationMode=[delta_datashipping|
logreplay|logreplay_readaccess]
```

#### hdbnsutil -sr\_register Call Options

Option Name	Value	Description
--name	<secondarySiteName>	Alias used to represent the secondary system
--remoteHost	<primary_host>	Name of the primary host that the secondary registers with
--remoteInstance	<primary_instancnr>	Instance number of primary
--replicationMode	[sync syncmem async]	Log replication modes
--operationMode	[delta_datashipping logreplay logreplay_readaccess]	Log operation mode
--online	N/A	If the system is running you can use this parameter to automatically perform a system restart. Not relevant if the system is shut down.
--force_full_replica	N/A	Use this parameter to initiate a full data shipping. Otherwise a delta data shipping is attempted
--withAllSecondaries	N/A	Use this option to re-attach existing secondaries to a new source system within an existing system replication setup

To check if the system has been successfully enabled for system replication with hdbnsutil run:

```
cd /usr/sap/<sid>/HDB<instancnr>/exe
```

```
./hdbnsutil -sr_state
```

- b. Start the secondary system to reinitialize it with the following command:

As <sid>adm:

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance_number> -function  
StartSystem HDB
```

Once the secondary system is started, the replication process will start automatically.

## 11.1.2.8.3.1 Example: Configure SAP HANA System Replication

This example shows you how to configure system replication with a single host system.

### Context

To configure system replication with two hosts, you may have to change the host names.

In this example a single host system is used. In multi-host systems all hosts have to be renamed.

#### i Note

To rename hosts in a production system replication landscape, system replication must be first deactivated. This means you have to first unregister and disable the secondary system before renaming any hosts. Once you have renamed the hosts then you can enable recovery mode again and register the secondary system with the primary system to re-activate system replication.

### Procedure

1. Enable system replication on the primary system, with the hostname ej11.

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_enable --name=dcsite1
```

2. Stop the secondary system. The primary system can stay online.

As <sid>adm

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance_number> -function StopSystem  
HDB
```

3. Register the secondary system with the following command:

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_register  
--name=dcsite2  
--remoteHost=ej11  
--remoteInstance=50  
--replicationMode=sync  
--operationMode=logreplay
```

Also see *SAP Note 611361 Hostnames of SAP servers*

4. Start the secondary system. This initiates the initial data transfer.

As <sid>adm

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance_number> -function StartSystem  
HDB
```

## Related Information

[Rename an SAP HANA System Host \[page 1173\]](#)

[SAP Note 611361](#)

### 11.1.2.8.4 Changing the Replication Mode

The replication mode can be changed without going through a full data shipping from the primary system to the secondary system afterwards.

To change the replication mode, use the following command on the online or offline secondary system:

```
hdbnsutil -sr_changemode --mode=sync|syncmem|async
```

In the M\_SERVICE\_REPLICATION view you can check whether the replication mode was changed correctly. The following command provides this information too:

```
hdbnsutil -sr_state --sapcontrol=1
```

## Related Information

[M\\_SERVICE\\_REPLICATION System View](#)

### 11.1.2.8.5 Changing the Operation Mode

The operation mode can only be changed by stopping and re-registering the secondary system with the desired operation mode.

You can change operation modes using the `hdbnsutil -sr_register` command and explicitly setting the new operation mode with the `-operationMode` option:

```
hdbnsutil -sr_register  
--remoteHost=<primary hostname>  
--remoteInstance=<instance number>  
--replicationMode=[sync|syncmem|async]  
--operationMode=[delta_datashipping|logreplay|logreplay_readaccess]  
--name=<siteName>
```

To start the replication with the new operation mode, start the secondary system:

```
sapcontrol -nr <instance_number> -function StartSystem HDB
```

### **i** Note

It is not necessary to unregister the secondary while changing the operation mode. The `hdbnsutil -sr_register` command overwrites the previous register configuration. To understand the scenarios in which you should unregister a secondary system, see *SAP Note 1945676*.

When changing the operation mode from `delta_datashipping` to `logreplay` or `logreplay_readaccess`, no full data shipping is necessary. Full data shipping is necessary, however, when switching from `logreplay` or `logreplay_readaccess` back to `delta_datashipping`.

## Related Information

[SAP Note 1945676](#)

### 11.1.2.8.6 Initializing the Secondary

Whenever the secondary is registered with the primary system, the goal is to get the persistence (that is, the data and log volumes) on the secondary system into a consistent state to the primary system.

After initially configuring system replication, a full data shipping takes place. This happens automatically, but it can also be done manually. For more information, see *Initialize the Secondary with Storage Copy from Primary*.

When initializing the secondary the following two situations can occur:

- The secondary system is completely unrelated to the primary system  
If the secondary system is unrelated to the primary system, a full data shipping is done. An in-place snapshot created on the disk of the primary system is initially sent to the secondary system. This initial full data shipping can be prevented by manual intervention and the secondary system can be initialized with a binary storage copy of the primary system's persistence. For more information, see *Initialize the Secondary with Storage Copy from Primary*.
- The secondary system is related to the primary system for one of the following reasons:
  - It was already registered before as a secondary system to this primary and probably shut down for a time.
  - It is a former primary system, which will become a secondary system through failback switching the replicating direction.

If the persistence (that is data and log volumes) of the secondary system is related to the primary system (it actually contains the persistence of the primary at a former time), the newly registered system can be synced with a delta data or log shipping avoiding a full data shipping.

After a new registration of the secondary system, a delta data or log shipping is always attempted. For more information, see *Resync Optimization*.

## Related Information

[Initialize the Secondary with Storage Copy from Primary \[page 1269\]](#)

[Resync Optimization \[page 1245\]](#)

### 11.1.2.8.6.1 Initialize the Secondary with Storage Copy from Primary

The secondary system can be initialized using a binary storage copy from the primary system.

#### Context

For this procedure copy only the data, not the log.

#### Procedure

1. Create a consistent binary storage copy from the primary system for the persistence of all services. You can use the snapshot technology to create an IO consistent persistence copy. Create a full copy of the persistence using the IO consistent storage snapshots.

If you can't use the method above, create a consistent OS copy of persistence while the primary system is stopped.

2. Shut down the secondary system.
3. Transfer or mount the full copy on the secondary system.
4. Replace the persistence of the secondary system with the storage copy from the primary system.
5. Register the secondary system without [--force\_full\_replica].
6. Start the secondary system.

#### Results

When the secondary system is started after the new registration, the initialization optimizations are carried out. The secondary system checks if its persistence is compatible with the persistence of the primary system. If this check succeeds, the secondary system requests only a delta data shipping.

## 11.1.2.8.7 Full Sync Option for SAP HANA System Replication

To reach a true Recovery Point Objective value of zero for synchronous system replication, the full sync option can be enabled for SYNC replication mode.

With the activated full sync option, the transaction processing on the primary system blocks when the secondary is currently not connected and newly created log buffers cannot be shipped to the secondary system. This behavior ensures that no transaction can be committed on the primary without shipping the log buffers to the secondary system.

The full sync option can be switched on and off using the command:

```
hdbnsutil -sr_fullsync --enable|--disable
```

This changes the setting of the parameter `enable_full_sync` in the `[system_replication]` section of the `global.ini` file accordingly.

### → Recommendation

When configuring the full sync option, proceed as follows:

1. Configure your system replication with the SYNC replication mode. This replication mode is the prerequisite for enabling the full sync option.
2. Check that the system replication status is active and in sync for all services.
3. Enable the full sync option with `hdbnsutil -sr_fullsync --enable`

In the `M_SERVICE_REPLICATION` system view, the setting of the full sync option can be viewed in the column `FULL_SYNC`. It can have the following values:

- **DISABLED:** Full sync is not configured at all.  
The parameter `enable_full_sync = false` in the `system_replication` section of the `global.ini` file.
- **ENABLED:** Full sync is configured, but it is not yet active.  
In this state transactions do not block. To become active, the secondary has to connect and the replication status has to be `ACTIVE`.
- **ACTIVE:** Full sync mode is configured and active.  
In this state if the network connection to a connected secondary is closed, the transactions on the primary system will block.

If full sync is enabled when an active secondary is currently connected, the `FULL_SYNC` column will be immediately set to `ACTIVE`.

If the secondary is stopped, disable the full sync option. Otherwise the primary blocks and it is not possible to stop it.

### i Note

Use the `hdbnsutil` command to resolve a blocking situation of the primary system caused by the enabled full sync option. This is important because a configuration changing command could also block in this state. You must do this also when you want to shut down the currently blocking primary system. Otherwise it is not possible to stop it.

The cluster manager that is used to operate SAP HANA system replication landscapes could provide a timeout after which the blocking situation is resolved automatically using the `hdbnsutil` command and deactivating

the full sync option. However, after the reason for the blocking situation disappears, you must activate the full sync option again (manually or automatically with the help of the cluster manager tool).

In a multitarget system replication setup, configure the full sync option on the primary system. Enter the site name used for the secondary system when registering it:

```
global.ini
[system_replication]
enable_full_sync[<secondary_site_name>] = true
```

### Note

In a multitarget system replication setup, you can use `hdbnsutil -sr_fullsync` to turn off the full sync option.

### 11.1.2.8.8 SAP HANA System Replication Configuration Parameters

Several configuration parameters are available for configuring SAP HANA system replication between the primary and secondary system.

The system replication parameters are defined in the `[system_replication]` section of the `global.ini` file and have the default values shown below. The *System* column defines whether the parameter can be set on the primary, the secondary, or both.

<b>Parameter</b>	<code>datashipping_min_time_interval</code>
Type	Integer
Unit	seconds
Default	600 (10 min)
System	Secondary
Description	Minimum time interval between two data shipping requests from the secondary system.  If <code>datashipping_logsize_threshold</code> (see next parameter) is reached first, the data shipping request will be sent before the time interval is elapsed when the log size threshold is reached.

<b>Parameter</b>	<code>datashipping_logsize_threshold</code>
Type	Integer
Unit	bytes
Default	5*1024*1024*1024 (5 GB)
System	Secondary
Description	<p>Minimum amount of log shipped between two data shipping requests from the secondary system.</p> <p>If the time defined by <code>datashipping_min_time_interval</code> (see previous parameter) has passed before reaching this threshold, the data shipping request will be sent before this threshold is reached when the time interval has elapsed.</p>

<b>Parameter</b>	<code>preload_column_tables</code>
Type	Boolean
Default	true
System	Primary and Secondary
Description	When this parameter is set, preloading of column table main parts is activated for the secondary according to the information in the loaded table information from the primary.

<b>Parameter</b>	<code>datashipping_snapshot_max_retention_time</code>
Type	Integer
Unit	minutes
Default	300
System	Primary

<b>Parameter</b>	<code>datashipping_snapshot_max_retention_time</code>
<b>Description</b>	<p>Maximum retention time (in minutes) of the last snapshot that has been completely shipped to the secondary system.</p> <p>Shipped snapshots older than <code>datashipping_snapshot_max_retention_time</code> will be dropped automatically. Snapshots currently used in data shipping are not affected and are not dropped, if data shipping takes longer than <code>datashipping_snapshot_max_retention_time</code>. They can be dropped if data shipping has been finished. If the parameter is set to 0, snapshots are immediately dropped after data replication finishes.</p> <p>When roles are switched between the primary and secondary systems preparing a failback later on, the secondary can be initialized with a delta replica between this snapshot and the current persistent state on the new primary after takeover. In order to do this:</p> <ul style="list-style-type: none"> <li>• A snapshot has to exist on the new secondary when it starts for the first time as secondary.</li> <li>• The snapshot has to be compatible with the persistence of the new primary.</li> </ul> <p>It is verified, if the snapshot has been the source of the primary system before takeover. It cannot be used, if the secondary is registered with an incompatible primary system. If both conditions are true, the secondary can be initialized with a delta replica.</p>

<b>Parameter</b>	<code>logshipping_timeout</code>
<b>Type</b>	Integer
<b>Unit</b>	seconds
<b>Default</b>	30
<b>System</b>	Primary
<b>Description</b>	<p>Number of seconds the primary waits for the acknowledgment after sending a log buffer to the secondary system.</p> <p>If the primary does not receive the acknowledgment for a sent log buffer within the time defined by <code>logshipping_timeout</code>, it closes the connection to the secondary system in order to continue data processing. This is done to prevent the primary system from blocking transaction processing if there is a hang situation on the connection to the secondary system.</p> <p>After the timeout period for a send operation has elapsed, transactions are written only on the primary system until the secondary has reconnected.</p> <p>The <code>logshipping_timeout</code> does not define a blocking period for logshipping on the primary system in general. It is used to close hanging connections on the primary system that are not getting automatically closed. If the redo log cannot be sent to the secondary system within this time, the connection is temporarily closed and the primary writes the redo log locally. This can happen any time, also when the primary is currently not waiting for acknowledgments from the secondary system.</p> <p>Use the <code>ful sync</code> option, if the primary system should block whenever the connection to the secondary system is lost. In this case the primary system will stop.</p>

<b>Parameter</b>	<code>logshipping_async_buffer_size</code>
Type	Integer
Unit	bytes
Default	67108864 (64MB)
System	Primary
Description	<p>In asynchronous replication mode, the log writer copies the log buffers into an intermediate memory buffer first and continues processing. A separate thread reads log buffers from this memory buffer and sends them to the secondary system asynchronously over the network.</p> <p>This parameter determines how much log can be intermediately buffered. This buffer is especially useful in peak times when log is generated faster than it can be sent to the secondary system. If the buffer is large, it can handle peaks for a longer period of time.</p> <p>The behavior of buffer full situations can be controlled by the parameter <code>logshipping_async_wait_on_buffer_full</code>.</p> <p>The parameter can be changed online, but will become active the next time the secondary system reconnects.</p>

<b>Parameter</b>	<code>logshipping_async_wait_on_buffer_full</code>
Type	Boolean
Default	true
System	Primary
Description	<p>This parameter controls the behavior of the primary system in asynchronous log shipping mode when the log shipping buffer is full.</p> <p>If set to true, the primary system potentially waits until there is enough space in the log shipping buffer, so that the log buffer can be copied into it. This can slow down the primary system if there is currently high load that cannot be handled by the network connection.</p> <p>If the parameter is set to false, the connection to the secondary system will be temporarily closed to not impact the primary system. Later, the secondary can reconnect and sync using delta shipping.</p>

<b>Parameter</b>	<code>reconnect_time_interval</code>
Type	Integer
Unit	seconds
Default	30
System	Secondary

---

**Parameter**    `reconnect_time_interval`

---

**Description**    If a secondary system is disconnected from the primary system because of network problems, the secondary system tries to reconnect periodically after the time interval specified in this parameter has passed.

---

---

**Parameter**    `enable_full_sync`

---

**Type**            Boolean

---

**Default**        false

---

**System**         Primary

---

**Description**    If set, system replication operates in full sync mode when the SYNC replication mode is set.

In full sync mode, transaction processing blocks when the secondary is currently not connected and newly created log buffers cannot be shipped to the secondary system. This behavior ensures that no transaction can be locally committed without shipping to the secondary system.

For more information, see *Full Sync Option for SAP HANA System Replication*.

---

---

**Parameter**    `enable_log_compression`

---

**Type**            Boolean

---

**Default**        false

---

**System**         Secondary

---

**Description**    If activated, log buffers will be compressed before sending them over the network to the secondary system. The secondary system decompresses the log buffers it receives and then writes them to disk. If the network bandwidth is the bottleneck in the system replication setup, log buffer compression can improve log shipping performance because less data is being sent over the network.

The drawback to sending a compressed log buffer to the secondary system is that it requires additional time and processing power for compression and decompression. This can result in worse log shipping performance if turned on in a configuration with a fast network.

The parameter has to be set on the secondary system. It can be changed online, but the secondary system has to re-connect to the primary system in order to activate the parameter change.

---

---

**Parameter**    `enable_data_compression`

---

**Type**            Boolean

---

**Default**        false

---

**System**         Secondary

---

---

**Parameter**    `enable_data_compression`

---

**Description**    If activated, data pages will be compressed before sending them over the network to the secondary system. The secondary system decompresses the data pages it receives and then writes them to disk. If the network bandwidth is the bottleneck in the system replication setup, data compression can improve log shipping performance because less data is being sent over the network.

                    The drawback to sending compressed data pages to the secondary system is that it requires additional time and processing power for compression and decompression. This can result in worse data shipping performance if turned on in a configuration with a fast network.

                    The parameter has to be set on the secondary system. It can be changed online, but the secondary system has to re-connect to the primary system in order to activate the parameter change.

---

**Parameter**    `keep_old_style_alert`

---

**Type**            Boolean

---

**Default**        false

---

**System**         Primary

---

**Description**    Before SPS 09 closed replication connections and configuration parameter mismatches were alerted with Alert 21.

                    With SPS 09 two dedicated alerts have been introduced for both error situations. By default old style alerting is still offered for backwards compatibility. When setting this parameter to false, the old behavior is turned off and only new alerts will be generated.

                    For more information, see *SAP HANA System Replication Alerts*.

---

**Parameter**    `operation_mode`

---

**Type**            enum

---

**Values**         delta\_datashipping/logreplay/logreplay\_readaccess

---

**Default**        logreplay

---

**System**         Secondary

---

---

<b>Parameter</b>	<code>operation_mode</code>
------------------	-----------------------------

---

Description	Operation mode of the secondary site during replication.
-------------	--

There are three different settings for this parameter:

- `delta_datashipping`  
System Replication uses data and log shipping for replication. Log buffers received by the secondary system are just saved to disk, savepoints after intermediate delta data shippings truncate the log. Column table merges are not executed on the secondary system, but merged tables on the primary system are transported via delta data shippings to the secondary system.
- `logreplay`  
System Replication uses an initial data shipping to initialize the secondary system. After that only log shipping is done and log buffers received by the secondary are replayed there. Savepoints are executed individually for each service and column table merges are executed on the secondary system.
- `logreplay_readaccess`  
System Replication uses an initial data shipping to initialize the secondary system. After that only log shipping is done and log buffers received by the secondary are replayed there. Savepoints are executed individually for each service and column table merges are executed on the secondary system. Furthermore, read only access via SQL is possible to the secondary system.

For more information, see *Operation Modes for SAP HANA System Replication*.

---

<b>Parameter</b>	<code>enable_log_retention</code>
------------------	-----------------------------------

---

Type	enum
------	------

---

Values	auto/off/on/force/force on takeover
--------	-------------------------------------

---

Default	auto
---------	------

---

System	Primary, Secondary
--------	--------------------

---

---

**Parameter**    `enable_log_retention`

---

**Description**    Enables or disables log retention on a system replication system. Log retention on the primary system is useful when the secondary should sync with the primary by re-shipping missing log after a network outage or downtime. If the missing log is not available anymore on the primary system, a data shipping is required (delta in operation mode `delta_datashipping`, full in all other operation modes). Log retention on the secondary system is needed to keep log for optimized re-sync during failback.

Configuration options:

- `auto`  
Log retention is automatically enabled if the secondary is in `logreplay` or `logreplay_readaccess` operation modes. For the `delta_datashipping` operation mode log retention is disabled.
- `on`  
Log retention is enabled.
- `off`  
Log retention is disabled.
- `force on takeover / force`  
In multitarget replication use this option to retain the log for all secondaries. The value `force` is set automatically during takeover. For a detailed example of this scenario see *Log Retention and Multitarget System Replication*.

When log retention is enabled and the system is configured as primary, the primary will not free log segments when the secondary system is disconnected, but keep them marked as `RetainedFree` for a potential optimized resync.

When setting log retention explicitly to `on` or `off`, it should also be set for `delta_datashipping` operation mode or for failback with delta log shipping optimization. In the latter case after takeover to the secondary, the old primary can re-sync via missing log with the new primary system and no full data shipping is required for initialization.

---

**Parameter**    `logshipping_max_retention_size`

---

**Type**    Integer

---

**Unit**    MB

---

**Default**    1048576 (1TB)

---

**System**    Primary

---

**Parameter** `logshipping_max_retention_size`

---

**Description** Sets the maximum amount of log that will be kept for syncing a secondary system. This value only has an effect if log retention is enabled.

Two situations have to be distinguished here:

If `logshipping_max_retention_size` has been set to a value other than 0, when no secondary is connected log segments are not reused even if they are truncated and backed up until the max size limit has been reached or the system runs into a log full situation.

If the maximum size limit is reached or in log full situations, the segments that are only kept for syncing the secondary system will be reused. This setting prevents the system from hanging on the primary system because of too many log segments that are held for syncing the secondary system. With this setting, the primary keeps running with the drawback that the secondary cannot sync anymore.

If `logshipping_max_retention_size` is configured to 0, log segments required for syncing the secondary are not reused and a log full results in a system standstill on the primary system until log writing can continue. This setting allows you to configure an upper limit up to which redo log segments are kept in `RetainedFree` state on the primary system before they are overwritten for syncing with a secondary system. When the reason for the log full has been resolved, the transaction processing can continue.

#### **i Note**

The default setting `logshipping_max_retention_size = 1048576` (MB) of 1 TB means that 1 TB of size is configured for every service, which replicates data to a secondary system. That is, every service owning a persistence in form of data and log volume.

#### **❖ Example**

If the services nameserver, two indexservers (for example, two tenant databases) and an xsengine are running in your SAP HANA system, the total configured log retention size will be 4 TB (4 x 1 TB). With this setting it can happen that the disk full is reached before the `RetainedFree` marked log segments are overwritten.

If you want to change the default value of 1 TB, you can do this in the `global.ini`. Another option is to set this parameter in the service ini files individually. For example, if the value is set in the `global.ini` of the system database, in the `global.ini` of a tenant database, and in the `indexserver.ini` of a tenant database, the `indexserver.ini` setting would win and will be taken for log retention of this indexserver.

---

**Parameter** `datashipping_parallel_channels`

---

**Type** Integer

**Default** 4

**System** Secondary

---

<b>Parameter</b>	<code>datashipping_parallel_channels</code>
Description	<p>The parameter defines the number of network channels used by full or delta datashipping. The actual number of channels for each shipping can be adjusted by the system to reduce overhead depending on the current amount of data to be shipped.</p> <p>Higher parallelism can be useful when large amounts of data (above several GB at least) needs to be shipped and the utilization of network bandwidth by single network stream is low. Please note that the overall bandwidth is still limited by the I/O bandwidth because the data needs to be read from the primary system.</p> <p>To deactivate the parameter, change the default to 0.</p>

<b>Parameter</b>	<code>datashipping_parallel_processing</code>
Type	Boolean
Default	True
System	Secondary
Description	<p>If activated, each data-shipping channel is assigned a separate job, therefore not only the network I/O but the processing steps are also done in parallel.</p> <p>This can be useful when the communication encryption and/or data compression are the limiting factor of the data-shipping performance.</p> <p>This would not be effective if the parameter <code>datashipping_parallel_channels</code> was set to 1 or 0.</p>

### 11.1.2.8.9 SAP HANA System Replication Command Line Reference

This topic provides details of the supported system replication options for the command line tool `hdbnsutil`.

<b>Command</b>	<code>-sr_enable</code>
Options	<code>[--name=&lt;site alias&gt;]</code>

<b>Command -sr_enable</b>	
System	Primary
Online/Offline	Online
Description	<p>Enables a system to serve as a system replication source system.</p> <p>In multitier and multitarget setups the --name= option is mandatory. Use <code>-sr_enable</code> to enable the source system for any further tier that is added to the system replication landscape.</p>

<b>Command -sr_disable</b>	
System	Primary
Online/Offline	Online
Description	Disables system replication capabilities on the primary system.

<b>Command -sr_register</b>	
System	Secondary
Online/Offline	Offline
Description	<ul style="list-style-type: none"> <li>• <code>--remoteHost=&lt;primary master host&gt;</code> Registers a system to a source system and creates the replication path for the system replication.</li> <li>• <code>--remoteInstance=&lt;primary instance id&gt;</code></li> <li>• <code>--replicationMode=sync syncmem async</code> Specifies the replication mode.</li> <li>• <code>--operationMode=delta_datashipping logreplay logreplay_readaccess</code> Specifies the operation mode.</li> <li>• <code>--name=&lt;unique site name&gt;</code> Specifies the system name.</li> <li>• <code>[--online]</code> If the system is running you can use this parameter to automatically perform a system restart. Not relevant if the system is shut down.</li> <li>• <code>[--force_full_replica]</code> If a parameter is given, a full data shipping is initiated. Otherwise a delta data shipping is attempted.</li> <li>• <code>[--withAllSecondaries]</code> This option helps to manage reconfiguration of sites in a multitarget replication landscape. You can use this to re-attach a secondary to another source system within the landscape; any existing subtrees will remain attached. All sites in the landscape must be online when you run the command.</li> </ul>

<b>Command -sr_unregister</b>	
Options	<code>[--id=&lt;site id&gt; --name=&lt;site name&gt;]</code>
System	Primary, Secondary
Online/Offline	<p>Secondary offline</p> <p>Primary online (to remove metadata)</p>

---

**Command**     **-sr\_unregister**

---

Description     Unregisters a secondary system from its source.

Use this command on the secondary that needs to be unregistered. When the secondary system is not available, this command can also run on the primary. In this case use either the `-id` option or the `-name` option to identify the secondary system.

**i Note**

There are three scenarios in which it is necessary to unregister system replication:

- When the secondary system is available, but should be de-coupled permanently  
You will be able to use the secondary system as a standard SAP HANA installation afterwards.
- When the secondary system is not available anymore and the primary system needs to be cleaned up in order to be able to register a new system  
This can occur when the secondary system was uninstalled or when it cannot be recovered after a disaster.
- When you want to re-establish the original setup after a takeover in a multitier system replication configuration  
For more information, see *Restore the Original SAP HANA Multitier System Replication Configuration*.

To understand how to use the `-sr_unregister` command correctly, see *SAP Note 1945676*.

---

**Command**     **-sr\_initialize**

---

Options     `--database=<tenantDB>|--volume=<volume id> [--force_full_replica]`

System     Primary

Online/Offline     Online

Description     Initializes a given database or specific volume for system replication. If parameter  `[--force_full_replica]` is given, a full data shipping is initiated, otherwise a delta data shipping is attempted. See also SAP Note 2980989 - *How-To: Performing a Full Data Shipment for a Single Volume / Service*.

This command is normally not required as initialization takes place automatically. It may be required in exceptional circumstances to reinitialize one specific tenant where replication needs to be restarted.

---

**Command**     **-sr\_fullsync**

---

Options     `--enable | --disable`

System     Primary

Online/Offline     Online and offline

Description     For use with the SYNC replication mode to ensure replication consistency. Full sync mode ensures that no transaction can be committed on the primary without shipping the log buffers to the secondary. See *Full Sync Option for SAP HANA System Replication*.

---

**Command**     **-sr\_changemode**

---

Options     `--mode=sync|syncmem|async`

System     Secondary

---

<b>Command</b> <b>-sr_changemode</b>	
Online/Offline	Online and offline
Description	Changes the replication mode of a secondary system.
<b>Command</b> <b>-sr_takeover</b>	
System	Secondary
Online/Offline	Online and offline
Description	Makes this secondary the new primary system.
<b>Command</b> <b>-sr_state</b>	
System	Primary and Secondary
Online/Offline	Online and offline
Description	Shows status information about a system replication system.

## 11.1.2.8.10 Add and Remove Hosts in SAP HANA System Replication

You can add a new host to a replicated system with the SAP HANA lifecycle manager.

### Context

#### **i** Note

Hosts must be added equally to both primary and secondary sites.

#### **i** Note

Do not turn off system replication when adding a host.

## → Recommendation

It is recommended that a host is added to the secondary site before adding it to the primary site. This avoids the situation where the new host saves data without first being in sync.

## Procedure

1. Add a host to the secondary site and start it.
2. Add a host to the primary site and start it.  
Replication begins automatically.
3. To remove a host, first remove it from the primary site and then remove the host from the secondary site.

## Related Information

[Add Hosts Using the Command-Line Interface \[page 1622\]](#)

[Remove Hosts Using the Command-Line Interface \[page 1630\]](#)

### 11.1.2.9 Performing a Takeover

The takeover process is the name for the task of switching your active system from the current primary system to the secondary system.

If your primary data center is not available, for example because of planned downtime or due to a disaster, and a decision has been made to fail over to the secondary data center, you can perform a takeover on your secondary system.

We recommend that you use third-party external tools to check if hosts, the network, and data center are still available.

To help you decide if a takeover is advisable with regard to system availability, downtime and the risk of data loss, see the decision tree in *SAP Note 2063657 SAP HANA System Replication Takeover Decision Guideline*. In addition, you can use python scripts such as `getTakeoverRecommendation.py` to help you decide when a takeover should be carried out. For a detailed description of the available python scripts, see 'Checking the SAP HANA System Replication Status' in the *SAP HANA System Replication Guide*.

The takeover does not include stopping the former primary system. If you are performing a takeover as part of a planned downtime, first make sure that the primary system has been fully stopped.

If you wish to avoid stopping the primary system you can also simply isolate it in the landscape by putting it behind a firewall. It is also not necessary to completely stop the primary if you use the command line option 'takeover with handshake' (`hdbnsutil -sr_takeover --suspendPrimary`), see *Takeover with Handshake* for details.

If necessary, you can verify that the primary is no longer available using the STONITH command which checks for the existence of a failed host. A scenario where this command is used is given in the section 'Example HA/DR Provider Implementation'.

Once the takeover command completes, the former secondary system becomes the new active primary system.

You can perform a takeover using the following tools:

- SAP HANA cockpit  
For more information, see *Perform a Takeover with the SAP HANA Cockpit*.
- SAP HANA studio  
For more information, see *Perform a Takeover with the SAP HANA Studio*.
- hdbnsutil  
For more information, see *Perform a Takeover with hdbnsutil*.

[SAP Note 2063657](#)

### 11.1.2.9.1 Perform a Takeover with SAP HANA Cockpit

You can perform a takeover on your secondary system using the SAP HANA cockpit.

## Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

- It's recommended to stop the primary system before starting a takeover.

#### i Note

If you're performing a takeover as part of a planned downtime, first make sure that the primary system has been fully stopped before performing a takeover to the secondary system.

- The secondary system must be fully initialized.

- You need the operating system user to perform a takeover with the SAP HANA cockpit. For more information, see *Operating System User <sid>adm* in the *SAP HANA Administration Guide* and *Connect to a Database With SSO or SAP HANA Credentials*.
- The takeover command can be executed both when the secondary system is offline or online.

## Procedure

1. In the *Monitoring* or *All* view, on the *Database Overview* page of the system database (SYSTEMDB) of the secondary system meant to perform the takeover, choose the *System Replication* card.

The *System Replication Overview* is displayed.

2. Choose *Take Over*.
3. To start the takeover, click *Start Takeover* in the *Takeover* dialog.

You can also start a takeover with handshake by choosing to fully synchronize the secondary system. For more information about the takeover with handshake, see *Takeover with Handshake* in the *SAP HANA Administration Guide*.

4. Stop the primary system from the *Services* card on the *Database Overview*.

## Related Information

[Connect to a Database With SSO or SAP HANA Credentials \[page 176\]](#)

[Operating System User <sid>adm](#)

[Takeover with Handshake](#)

[SAP HANA System Replication](#)

### 11.1.2.9.2 Perform a Takeover with the SAP HANA Studio

You can perform a takeover on your secondary system using the SAP HANA studio.

## Prerequisites

- The secondary system must be fully initialized.  
You can check this in SAP HANA studio: **Administration Console** > **Landscape** > **System Replication** **▾**.  
The secondary system is ready for takeover if all services display *REPLICATION\_STATUS ACTIVE*.
- The takeover command can be executed both when the secondary system is offline or online.
- You are logged on to the secondary system as the operating system user (user <sid>adm) or can enter these credentials when prompted.

## i Note

If you are performing a takeover as part of a planned downtime, you should first make sure that the primary system has been fully stopped before performing a takeover to the secondary system.

## Procedure

1. In the *Systems* view, right-click the secondary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾.
2. Choose *Perform Takeover* from the actions list.
3. Enter the required system information and choose *Next*.
4. Review the information and choose *Finish*.

## Results

The secondary system is now the production system. If the system is already running, it comes out of recovery mode and becomes fully operational immediately: it replays the last transaction logs and starts to accept queries. If the system is offline, it takes over production operation when you start it.

### 11.1.2.9.3 Perform a Takeover with hdbnsutil

You can perform a takeover on your secondary system with the `hdbnsutil` command line tool.

## Prerequisites

- The secondary system must be fully initialized.  
You can check this in M\_SERVICE\_REPLICATION or in the SAP HANA studio ► *Administration Console* ► *Landscape* ► *System Replication* ▾. The secondary system is ready for takeover if all services display *REPLICATION\_STATUS ACTIVE*.
- The takeover command can be executed both when the secondary system is offline or online.

## i Note

If you are performing a takeover as part of a planned downtime, you should first make sure that the primary system has been fully stopped before performing a takeover to the secondary system.

## Procedure

As <sid>adm enter the following command on the secondary system to enable the secondary system to take over and become the primary system:

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_takeover [--comment="Your Comment"]
```

Use the `--comment` to add a reason for the takeover (for example, to distinguish between a planned or unplanned takeover). This comment is displayed in the `M_SYSTEM_REPLICATION_TAKEOVER_HISTORY` monitoring view in the `COMMENTS` column.

If the system is offline, the takeover is actually carried out when the system is started again.

### 11.1.2.9.4 Client Connection Recovery After Takeover

Connection recovery after a takeover can be done with network-based IP redirection or network-based DNS redirection.

After a takeover, the client or the application server need to be able to continuously reach the SAP HANA system, no matter which system is currently the primary system after takeover.

After a takeover, the new primary database server is not aware of previous connections which existed between clients and the former primary server. If the client application does not issue a new request and keeps waiting for a reply from the server, it will not receive an explicit request to close these connections from either of the servers and will keep waiting indefinitely. To prevent this, the SAP HANA client library supports the TCP keepalive feature provided by the operating system. This feature will lead the client to abort the invalid connection on its end and to trigger a reconnect after a specified period during which the former primary server is not reachable.

However, the default keepalive settings for the operating system (2 hours) may lead the client processes to wait for a long time before they abort the connection on their end and trigger a reconnect with the new primary system. For example, the default Linux settings leave the clients waiting for more than two hours before aborting the connection. For more information on how to configure the keepalive settings to match your needs see *SAP Note 2053504 - System replication: Hanging client processes after a takeover* and the corresponding documentation for your operating system.

There are different possibilities for enabling client connection recovery:

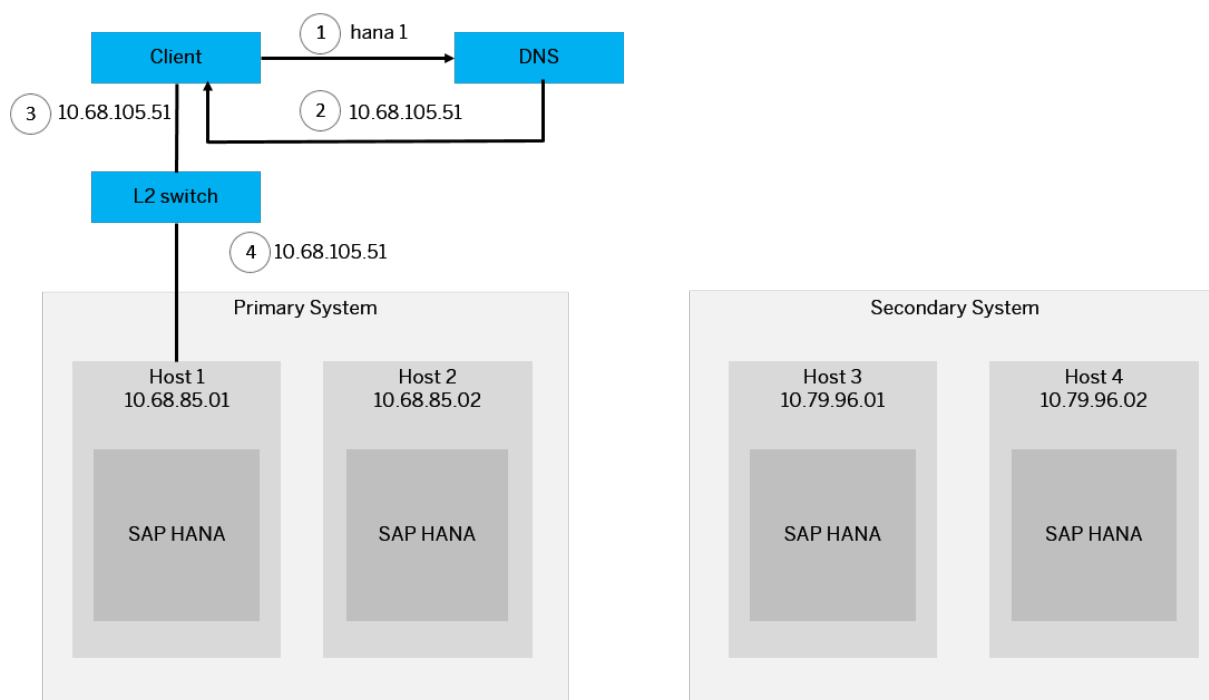

1. IP redirection  
A virtual IP address is assigned to the virtual host name. In case of a takeover, the virtual IP will unbind from the network adapter of the primary system and bind to the adapter on the secondary system.
2. DNS redirection  
In this scenario the IP for the host name in the DNS will be changed from the address of the primary to the address of the secondary system.

Both methods have their advantages. If there are no existing constraints, the IP redirection has the clear benefit of being faster to process in a script rather than synchronizing changes of DNS entries over a global network.

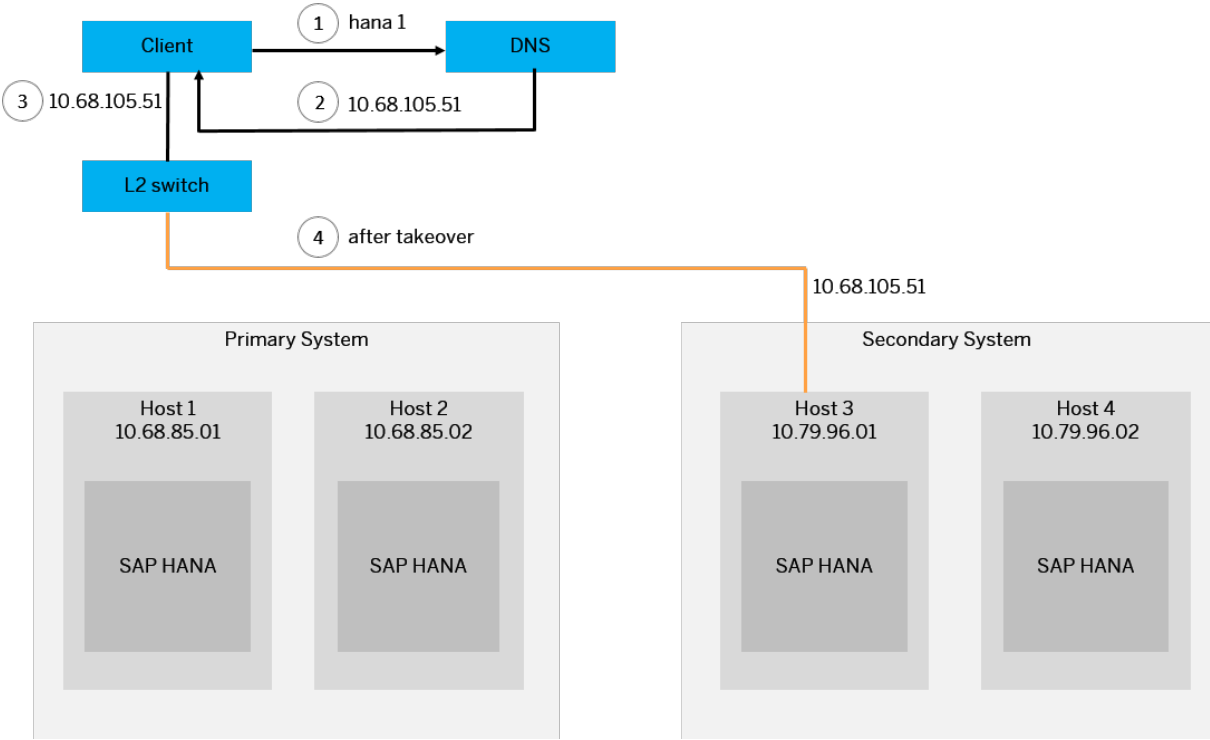

## 1. Network-based IP Redirection

The principle of IP redirection is to define an additional "logical" host name (hana1, in the diagram below) with its own separate logical IP address (10.68.105.51), and then map this initially to the MAC address of the original host in the primary system (by binding it to one of the host's interfaces):

As part of the takeover procedure, a script is executed which re-maps the unchanged logical IP address to the corresponding takeover host in the secondary system. This must be done pair-wise, for each host in the

primary system. The remapping affects the L2 (OSI layer 2: data link ) switching, as can be seen in step 4 of the following diagram:

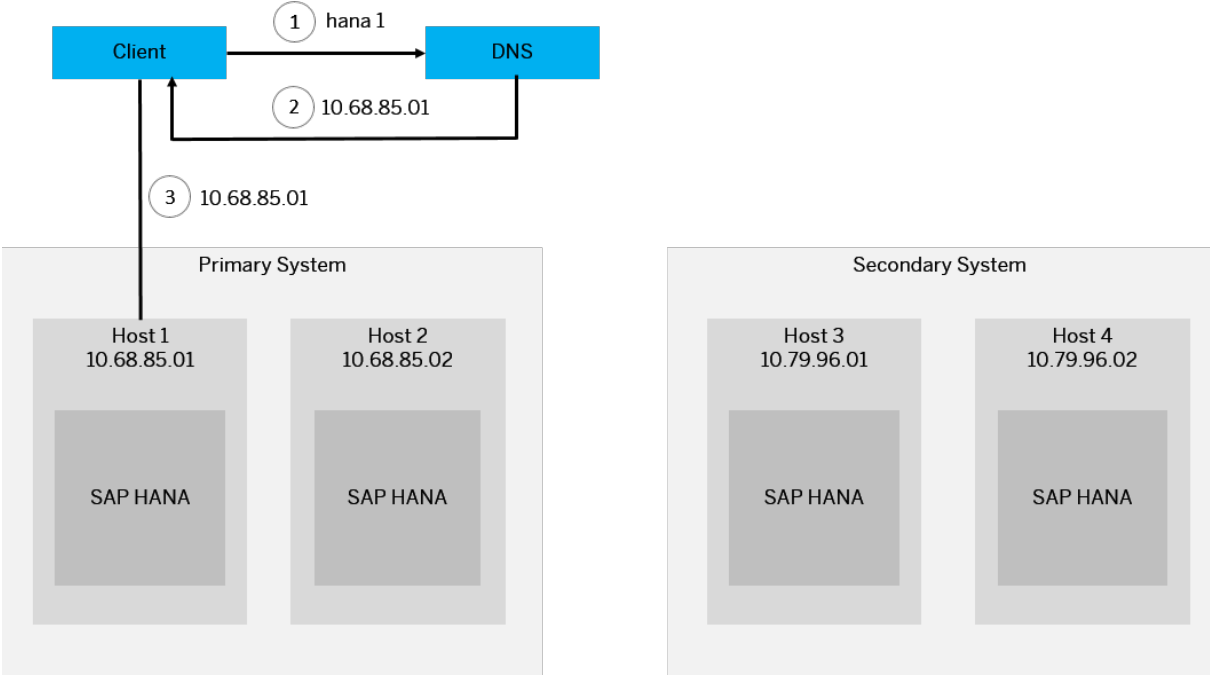

IP redirection can be implemented using a number of actual techniques, for example with the use of Linux commands which affect the network Address Resolution Protocol (ARP) tables (ip addr add/del...), by configuring L2 network switches directly, or by using cluster management software. Following the IP redirection configuration, the ARP caches should be flushed, to provide an almost instantaneous recovery experience to clients.

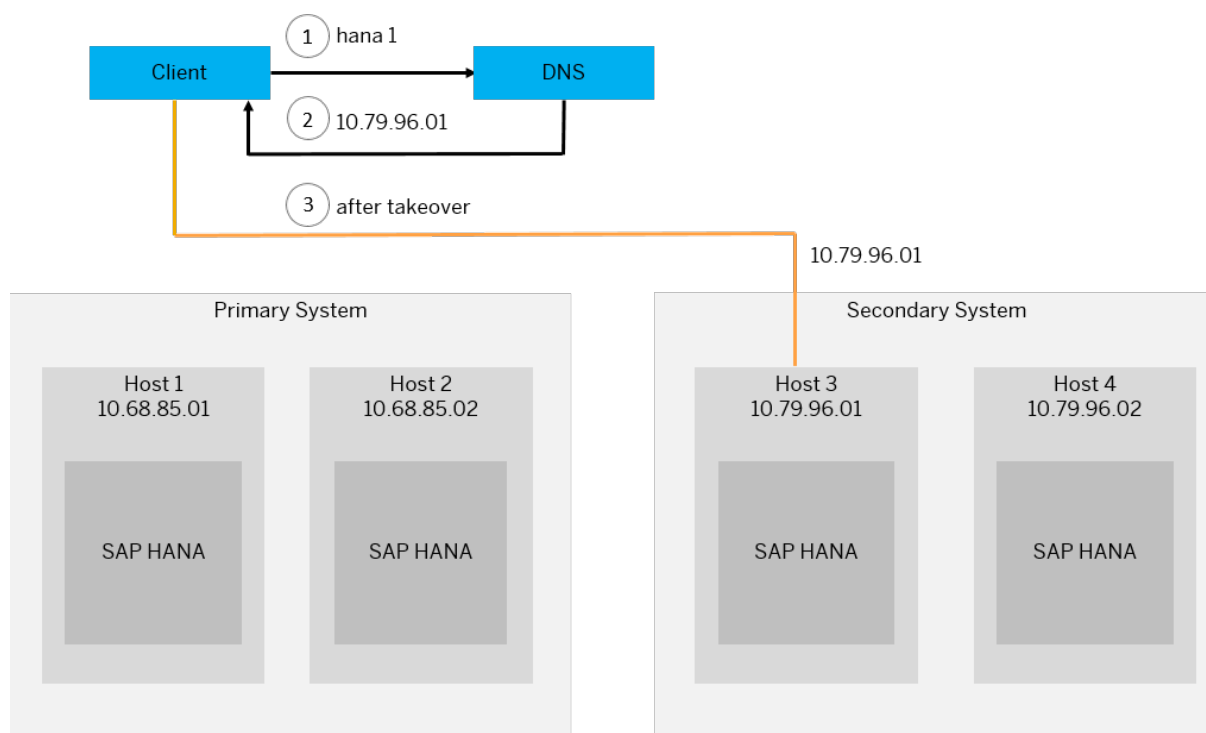

IP redirection requires that both the primary and failover host(s) are on the same L2 network. If the standby system is in a completely separate L3 network, then DNS redirection is the preferred alternative solution.

## 2. Network-based DNS Redirection

DNS redirection is an alternative to IP redirection. DNS is a binding from a logical domain name to an IP address. Clients contact a DNS server to obtain the IP address of the SAP HANA host (step 1 below) they wish to reach:

As part of the takeover procedure, a script is executed that changes the DNS name-to-IP mapping from the primary host to the corresponding host in the secondary system (pair-wise for all hosts in the system). From that point in time, clients are redirected to the failover hosts:

This solution shares the advantage with IP redirection that there are no client-specific configurations. Further, it supports disaster recovery configurations where the primary and secondary standby systems may be in two completely different network domains (separated by routers). One drawback of this solution is that modifying DNS mappings requires a vendor-proprietary solution. Further, due to DNS caching in nodes (both clients and intermediate network equipment), it may take a while (up to hours) until the DNS changes are propagated, causing clients to experience downtime despite the recovery of the system.

HA/DR providers can inform external entities about activities inside SAP HANA scale-out (such as Host Auto-Failover) and SAP HANA system replication setups. Actions can be defined in a Python script which should be executed before or after certain activities (such as, startup, shutdown, failover, takeover, connection changed, service state changed). One application of this is to move virtual IP addresses after takeover in SAP HANA system replication. Additionally, external cluster management software can be used to perform the client reconnect after takeover. For more information, see *Implementing HA/DR Providers*.

## Related Information

[SAP Note 2053504 - System replication: Hanging client processes after a takeover](#)

## 11.1.2.9.5 Invisible Takeover and Restart

During an invisible takeover or a restart, the session's state needs to be recovered and restored to the new primary system.

During a standard takeover you switch your active system from the current primary system to the secondary system. After a standard takeover, the primary system loses all connections to the client. Moreover, the secondary system is not aware of the previous connections, which existed between the client and the primary system. This is different in an invisible takeover.

You can perform an invisible takeover to achieve an automatic recovery of your sessions after takeover to your new primary system. For dedicated client applications this takeover will be invisible. Differently from a standard takeover, an invisible takeover ensures that the client reconnects to the primary system and the sessions are restored to the secondary system.

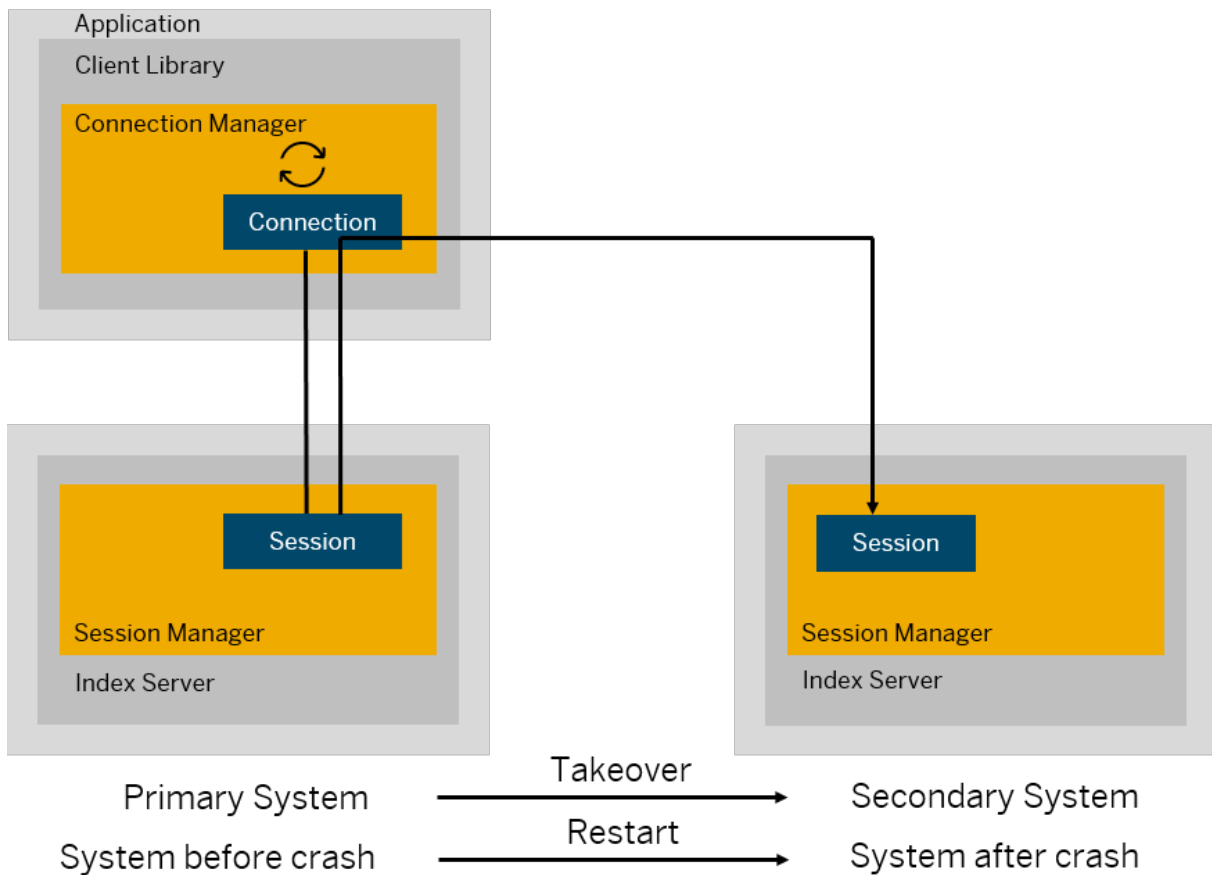

This seamless recovery is possible also when restarting the system (for example, after a system crashes).

The session's state needs to be recovered and restored to the new primary system in an invisible takeover scenario or to the new system in a restart scenario. The cross-layer between the session and the client library makes the seamless recovery possible. This cross-layer feature called *transparent session recovery* recovers the current session's state and the physical connection.

### i Note

The transparent session recovery is supported by SQLDBC for SAP HANA 2.0.

Use the graphic below to better understand this process in an invisible takeover or a restart scenario after the active system crashed:

## Configuration

The `enable_session_recovery` parameter in the session section of the ini file controls the session recovery. The default value is `true` recovering all session variables and restoring the client connections from the primary system to the secondary system. This parameter is configurable online, but the changes can be applied only to the connections established after making the changes.

## Limitations

- Sessions which have created or updated a global temporary table with any DDL or DML commands won't be recovered. However, sessions which have created a local temporary table will be recovered without the table recovery.
- Ongoing write transaction will be rolled back with an error and the session can be recovered when an application restarts the failed transaction with no explicit reconnect trial from the application
- Almost all session variables from the current session context are recovered.
- If the client has sent a request to the server but the server has not successfully responded back, the session is not recovered. However, sessions are still recovered when a SQL command is not sent from the client to the server.

## 11.1.2.9.6 Takeover with Handshake

The takeover with handshake ensures that all the sent redo log is written to disk on the secondary system.

During a planned takeover, it is important to ensure that no data gets lost (all primary updates must be available on the secondary system) and the former primary system is isolated to avoid a split-brain situation with multiple active primary systems.

The takeover with handshake is ideal for a safe planned takeover while the primary is still running. All new writing transactions on the primary system are suspended and the takeover is only executed when all redo log is available on the secondary system. When performing a takeover with handshake, it is not needed to check the replication status or to stop the old primary before the takeover.

In a nutshell, a takeover with handshake avoids:

- Data loss, because the log is available on the secondary system before the takeover is triggered.
- Split-brain situations, because the former primary will be suspended.

### i Note

The takeover with handshake will only be performed if the two previously mentioned conditions are guaranteed. Otherwise, the takeover will be aborted and the primary resumed.

Trigger a takeover with handshake using `hdbsutil -sr_takeover --suspendPrimary` on the secondary system.

If a primary service cannot be accessed or a service replication is not active or in sync, the takeover will be aborted and reported as an error. In this case, there is no impact on the system and the replication remains as it was. The suspended primary can be unblocked using the `-sr_register hdbsutil` command.

### i Note

The following limitations apply:

- It is supported only on the second tier.
- It is not supported with Dynamic Tiering services.

## Related Information

[Use SAP HANA System Replication for Near Zero Downtime Upgrades \[page 1360\]](#)

## 11.1.2.9.7 Automatic Registration After Takeover

In multi-target replication scenarios you can automate the process of registration after a takeover.

An option is available to automatically re-register the secondaries in the landscape which were previously registered before the takeover. This is particularly useful in multi-target replication scenarios and helps to avoid the normal procedure of having to shut down, register and restart each secondary.

To use this feature, set the parameter `register_secondaries_on_takeover` to TRUE (in the `[system_replication]` section of the `global.ini` file). The parameter must be set on the new primary. After connecting to the source all services are then automatically restarted and synchronized with the new primary.

This case is illustrated in the topic *Disaster Recovery Scenarios for Multitarget System Replication* where secondary sites in a different data center are registered to a new primary.

You can check the status of each server after a takeover by querying the view `M_SERVICE_REPLICATION` which has details of the status of all replication sites in the landscape.

## Related Information

[Disaster Recovery Scenarios for Multitarget System Replication \[page 1325\]](#)

### 11.1.2.10 Secondary Time Travel

You can start the secondary system or the log replay on the secondary system at a previous point in time.

Secondary time travel is a temporary takeover which is effective at a previous point in time. Once secondary time travel has been configured, snapshots and additional log data are retained on the secondary system for a defined period of time. These are then used to start the system at a selected point in the past by opening the appropriate snapshot and replaying the required log entries to reach the requested point. For this reason secondary time travel only works with the logreplay operation modes (`logreplay` or `logreplay_readaccess`). Secondary time travel is started using the command: `hdbnsutil -sr_timetravel` with additional options to specify the start time.

#### Note

You can safely use the SYNC replication mode with the full sync option; secondary time travel maintains a connection to the primary system and does not risk leading to a freeze of the primary (see Replication Modes).

Secondary time travel can be used in two ways:

1. To quickly access again data, which was deleted in the original system. For more information, see *Execute Secondary Time Travel*.
2. To intentionally keep the secondary system's log replay delayed. This can be used with Active/Active (Read Enabled) to read older data from the secondary system while the secondary keeps replicating. For more information, see *Execute Secondary Time Travel While Replication Continues*.

Using option one, the secondary system does a takeover up to the specified point in time so that data can be read. It is then necessary to resync with the primary so that the secondary is again available for a complete takeover. You can do this using the `-sr_register` command line option as described in *Configure SAP HANA System Replication with hdbnsutil*.

If time travel is configured in a multi-target replication scenario it would be possible, for example, to maintain a tier 3 disaster recovery host which is reserved for accessing data in time travel mode.

Option two uses an additional command line parameter: `startMode=replicate`. In this case, the secondary system is restarted but there is no takeover and replication of log data continues. The system restarts at the

specified point in time and log replay is stopped at this point. Commands are then available to manually advance the log replay or to resume automatic log replay. This option offers more flexibility; because there is no takeover you can restart the system repeatedly if necessary at any available snapshot. The earliest point in time is defined by the setting of the `timetravel_max_retention_time` parameter described below.

Using Active / Active in this scenario (that is, with operation mode `logreplay_readaccess` - a license is required) it is possible to then read data at the latest point of log replay. Operation mode `logreplay` does not provide read access to the delayed replay.

Note that using this option in a multi-target replication scenario it is only possible to read data at tier 2. Also, if data will be read using hint based statement routing, a specific server must be named; a configuration parameter is available for this: `hint_based_routing_site_name`.

## Preparation: Configuration Parameters

Configuration parameters for secondary time travel can be found in the `system_replication` section of the `global.ini` file, these must be configured on the secondary system. See *Configuration Parameters* for details.

To prepare the system for time travel, the `timetravel_max_retention_time` parameter must be set on the secondary system. This parameter defines the time period to which the secondary system can be brought back in the past. After setting this parameter, the secondary starts retaining log data and snapshots.

Optionally, the `timetravel_snapshot_creation_interval` parameter can be modified to adjust the frequency of snapshot creation. The default value of this parameter is 1440 minutes (1 day).

These parameters should be maintained in relation to each other, for example, the snapshot interval time will be less than or equal to the max retention time. The parameter with the greater value determines the length of time for which logs and snapshots must be retained on the system.

## Monitoring

Monitoring of time travel is possible using the system view `M_SYSTEM_REPLICATION_TIMETRAVEL` which includes details such as start times and redo log positions. Also `M_SYSTEM_REPLICATION_TAKEOVER_HISTORY` shows secondary time travel events. A time travel takeover is shown with the value 'TIMETRAVEL' in the `TAKEOVER_TYPE` column and any comments entered with the time travel commands are visible in the `COMMENTS` column.

## Security: Root Keys

Because of security requirements the active root keys (visible in view `ENCRYPTION_ROOT_KEYS`) in the restored secondary system may have timestamps which are more recent than the specified time travel date. The latest root keys are required because old root keys are only used for decryption.

## Related Information

[Execute Secondary Time Travel \[page 1298\]](#)

[Configuration Parameters \[page 1300\]](#)

[Execute Secondary Time Travel While Replication Continues \[page 1299\]](#)

[Monitoring Secondary Time Travel \[page 1301\]](#)

[Replication Modes for SAP HANA System Replication \[page 1237\]](#)

[Configure SAP HANA System Replication with `hdbnsutil` \[page 1263\]](#)

## 11.1.2.10.1 Execute Secondary Time Travel

You can start the secondary system in online mode at a previous point in time to access again data, which was deleted in the original system.

### Prerequisites

- Set the required parameters to define the point in time to which the secondary system can be brought back in the past. For a full list of available parameters for secondary time travel, see *Configuration Parameters*.

#### i Note

Set the parameters carefully to avoid log full or disk full situations. For time travel to work, log and snapshots are kept online in the data area. Because of this, log and data will grow on the secondary system when time travel is turned on. The system workload determines how much data is needed.

- Use the `logreplay` or the `logreplay_readaccess` operation mode in your system replication setup.

### Procedure

1. Stop the secondary system.
2. Execute `hdbnsutil -sr_timetravel --startTime=<startTime> [--callTakeoverHooks=on|off] [--comment="Your Comment"]`

For `startTime` use the following format specified in UTC: `dd.mm.yyyy-hh.mm.ss`

You can specify if takeover hooks should be called. If the `timetravel_call_takeover_hooks` parameter is not explicitly specified, takeover hooks won't be called. For more information on takeover hooks, see *Implementing a HA/DR Provider*.

Use the `--comment` to add a reason for the time travel. This comment is displayed in the `M_SYSTEM_REPLICATION_TAKEOVER_HISTORY` monitoring view in the `COMMENTS` column.

3. Start the secondary system.

The secondary system will enter in online mode at the specified point in time during restart. After restart, the other services read the requested point in time and open their persistence using this information. If the requested point in time cannot be reached, then time travel will be aborted. A check ensures that there are time travel snapshots older than the start time for each service.

### Related Information

[Configuration Parameters \[page 1300\]](#)

[M\\_SYSTEM\\_REPLICATION\\_TAKEOVER\\_HISTORY System View](#)

## 11.1.2.10.2 Execute Secondary Time Travel While Replication Continues

You can start the log replay at a previous point in time to read older data from the secondary system, while the secondary keeps replicating.

### Prerequisites

- Set the required parameters to define the point in time to which the secondary system can be brought back in the past. For a full list of available parameters for secondary time travel, see *Configuration Parameters*.

#### i Note

Set the parameters carefully to avoid log full or disk full situations. For time travel to work, log and snapshots are kept online in the data area. Because of this, log and data will grow on the secondary system when time travel is turned on. The system workload determines how much data is needed.

- The `logreplay` or `logreplay_readaccess` operation modes are supported but in order to read data from the secondary a license for Active / Active (Read Enabled) is required with operation mode `logreplay_readaccess`. Operation mode `logreplay` does not provide read access.

### Procedure

1. Stop the secondary system.
2. Execute `hdbnsutil -sr_timetravel --startTime=<startTime> --startMode=replicate`

For `startTime` use the following format specified in UTC: `dd.mm.yyyy-hh.mm.ss`

3. Start the secondary system.

After the system has started, the persistence has been opened on the specified point in time, it is replicating log, and log replay is not running.

4. Optional: Trigger the log replay manually with `hdbnsutil -sr_recoveruntil {--endTime=<timestamp>|max} [--nowait]`

For `<timestamp>` use the following format specified in UTC: `dd.mm.yyyy-hh.mm.ss`

Use `max` to trigger the log replay up to the newest possible point in time. In this case, the target timestamp is automatically determined by checking the valid time travel range for each service.

Use `--nowait` to specify if the command should be executed asynchronously.

5. Optional: Stop the manual replay mode by setting the `timetravel_logreplay_mode` parameter back to `auto` or using `hdbnsutil -sr_replaymode --mode={auto|manual}`

## Related Information

[Configuration Parameters \[page 1300\]](#)

### 11.1.2.10.3 Configuration Parameters

Use the following parameters to prepare your system for secondary time travel.

The parameters are defined in the `system_replication` section of the INI file. All parameters are set on the secondary system.

Parameter	<code>timetravel_max_retention_time</code>
Type	integer
Unit	minutes
Default	0
Description	If set to 0, secondary time travel is turned off. If this parameter is set to a value different from 0, the secondary system can be brought online up to the defined point in the past.

Parameter	<code>timetravel_snapshot_creation_interval</code>
Type	integer
Unit	minutes
Default	1440
Description	<p>Defines how frequently snapshots are created for secondary time travel. Time travel snapshots are kept until they get older than the defined <code>timetravel_max_retention_time</code> parameter. If time travel needs to be done on an older point in time, the snapshot that best fits the requested point in time will be opened and the remaining changes are applied via log replay.</p> <p>A new snapshot is created when the point in time defined in this parameter has passed since the last snapshot creation. Snapshots older than the point in time defined in <code>time_travel_max_retention_time</code> are dropped.</p>

Parameter	<code>timetravel_call_takeover_hooks</code>
Type	bool
Values	true, false
Default	false

<b>Parameter</b>	<b>timetravel_call_takeover_hooks</b>
Description	Indicates if takeover hooks should be called during secondary time travel.
<b>Parameter</b>	<b>timetravel_logreplay_mode</b>
Type	enum
Values	auto, manual
Default	auto
Description	<p>Defines how the log replay is executed on the secondary system.</p> <p>The following settings are allowed:</p> <ul style="list-style-type: none"> <li>• Auto The log replay is done automatically up to the newest possible log position.</li> <li>• Manual You must manually trigger the log replay up to the requested timestamp using the <code>-sr_recoveruntil hdbnsutil</code> command.</li> </ul>

## 11.1.2.10.4 Monitoring Secondary Time Travel

You can monitor the retaining log and the created snapshots.

To monitor secondary time travel, the secondary system must be online. The current time travel range cannot be determined, when the secondary is offline.

You can determine the valid range for which time travel can be executed in two ways:

- Using `hdbnsutil -sr_timetravel --printRange`  
This command provides a range for each service in which time travel can be executed:

Value	Description
START_TIME	<p>Contains the oldest possible point in time for which timetravel can be executed.</p> <p>As time travel is done for all services, the intersection of all ranges have to be checked to make sure, all services can reach the specified timestamp.</p>
END_TIME	<p>Contains the last possible point in time for which timetravel can be executed.</p> <p>For worker services, this timestamp can be some time back without being outdated, if there was no more activity on this worker for some time. To ignore the worker volumes, only the lines for transaction coordinating host can be considered. Those are marked as MASTER in the COORDINATOR_TYPE column.</p>

- Using SQL on the primary system via the `_SYS_DATABASES_SR_SITE_<sitename>.M_SYSTEM_REPLICATION_TIMETRAVEL` secondary proxy view.

The start time or the log position of the system can be monitored using `M_SYSTEM_REPLICATION_TAKEOVER_HISTORY`.

## 11.1.2.11 Performing a Failback

After a takeover has been carried out the roles between primary and secondary can be switched over.

In the case of a failover, the former primary has to be registered as the secondary with the now active primary system. The roles are switched compared to the original setup.

You can perform a failover using the following tools:

- SAP HANA cockpit  
For more information, see the SAP HANA cockpit topic *Perform a Failback*.
- SAP HANA studio  
For more information, see *Perform a Failback with the SAP HANA Studio*.
- `hdbnsutil`  
For more information, see *Perform a Failback with hdbnsutil*.

### Related Information

[Perform a Failback in SAP HANA Cockpit \[page 1302\]](#)

[Perform a Failback with the SAP HANA Studio \[page 1304\]](#)

[Perform a Failback with hdbnsutil \[page 1306\]](#)

### 11.1.2.11.1 Perform a Failback in SAP HANA Cockpit

To perform a failback in the SAP HANA cockpit, register the former primary system as secondary to the current primary.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

- You need the operating system user to perform a failback with the SAP HANA cockpit. For more information, see *Operating System User <sid>adm* in the *SAP HANA Administration Guide* and *Connect to a Database With SSO or SAP HANA Credentials*.
- The former primary system isn't running.
- The current primary system is running.

## Context

In the SAP HANA cockpit, you can perform a failback either from the current primary system or from the former primary system (the future secondary). The configuration steps are the same as described in *Configure System Replication from the Primary System* or *Configure System Replication from the Primary and the Secondary System*.

This procedure describes how to register the former primary as a new secondary. Use the *System Replication* card on the system *Database Overview* page of the former stopped primary to register this system as a new secondary.

## Procedure

1. Register the secondary system as follows:
  - a. In the *Monitoring* or *All* view, on the *Database Overview* page of the system database (SYSTEMDB) of the former primary system, choose the *System Replication* card.

The *System Replication* page opens.
  - b. Choose *Register as Secondary* on the top right.

The *Register Secondary System* page opens.
  - c. On the *Register Secondary System* page, enter the logical name used to represent the secondary system.
  - d. Select a replication mode. For more information on the available replication modes, see *Replication Modes for SAP HANA System Replication*.
  - e. Select an operation mode. For more information on the available operation modes, see *Operation Modes for SAP HANA System Replication*.
  - f. Enter the host of the source system.
- g. Check *Start Secondary after Registration*.
2. Review the configured information and choose *Configure* on the bottom right.

### i Note

If you're operating a distributed system on multiple hosts, enter the name of the host on which the master name server is running.

## Results

The original primary system is now registered as the secondary system with the current primary system (that is, the original secondary system). The secondary system is getting in sync again with the primary system. As such, it's attempting to avoid a full data shipping.

Verify that the secondary system replication status is `All services are active and in sync`.

## Related Information

[Operating System User <sid>adm](#)

[SAP HANA System Replication](#)

## 11.1.2.11.2 Perform a Failback with the SAP HANA Studio

You can perform a failback using the SAP HANA studio.

### Prerequisites

- You are logged on to both systems as the operating system user (user <sid>adm) or are able to enter these credentials when prompted.
- The former primary system is not running.
- The current primary system is running.

### Context

To fail back, you must attach your former primary system as new secondary system to the current primary system.

### Procedure

1. Register the former primary system as the new secondary system as follows:
  - a. In the *Systems* view, right-click the primary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾.  
The *Configure System Replication* dialog opens.

#### i Note

You can also access the *Configure System Replication* dialog from the ► *Landscape* ► *System Replication* ▾ tab.

- b. Choose *Register Secondary System* and then *Next*.
- c. Enter the required system information and the logical name used to represent the system.

#### **i Note**

If you are operating a distributed system on multiple hosts, you enter the name of the host on which the master name server is running.

- d. Specify the log replication mode. For more information on the available replication modes, see *Replication Modes for SAP HANA System Replication*.
- e. Specify the operation mode. For more information on the available operation modes, see *Operation Modes for SAP HANA System Replication*.
- f. Review the configured information and choose *Finish*.
- g. If necessary, start the former primary system.

#### **i Note**

The former primary system is started automatically unless you deselected the corresponding option during configuration.

The former primary system is now registered as the secondary system with the current primary system (that is, the former secondary system). As the data that is already available in the former primary system cannot be reused, a complete initialization is carried out. This means that a full data replication takes place until the former primary system is fully in sync.

2. Verify that the secondary system replication status is `All services are active and in sync`. You can see this status in the Administration editor on the *Overview* tab.

## **Results**

The former primary system and the former secondary system switched their roles.

## **Related Information**

[Operation Modes for SAP HANA System Replication \[page 1239\]](#)

## 11.1.2.11.3 Perform a Failback with hdbnsutil

You can perform a failback using the hdbnsutil command line tool.

### Prerequisites

- You need the operating system user to perform a failback. For more information, see *Operating System User <sid>adm*.
- The former primary system is not running.
- The current primary system is running.

### Context

This is the same procedure as is used for setting up a normal secondary described in steps 2 and 3 of *Configure SAP HANA System Replication with hdbnsutil*. To fail back, attach your original primary system as new secondary system to the current primary system. These are identified in the following parameters of the command: `--remoteHost=<new primary hostname>`, `--name=<new secondarySiteName>`. Refer also to the hdbnsutil example *Example: Configure SAP HANA System Replication* where the primary and secondary are identified as `dcsite1` and `dcsite2` respectively.

### Procedure

When the former primary is available again and offline, it can be registered as the new secondary.

```
hdbnsutil -sr_register --remoteHost=<new primary hostname>
--remoteInstance=<instance number>
--replicationMode=<sync/syncmem/async>
--operationMode=<delta_datashipping|logreplay|logreplay_readaccess>
--name=<new secondarySiteName>
```

### Related Information

## 11.1.2.12 Disabling SAP HANA System Replication

Remove a system replication configuration when you want to run the two systems separately or if you don't need this high availability and disaster recovery mechanism anymore.

To remove a system replication configuration, unregister the secondary and disable the primary system.

### ⚠ Caution

Keep in mind that after unregistering, the unregistered system is still active and applications may be connected to it. You must therefore ensure that applications are connected to the correct server. Potential problem situations, for example, are where replication with Smart Data Integration is active or where shared log backup locations are used. Refer to the following SAP notes for more information:

- 1945676 - Correct usage of `hdbnsutil -sr_unregister`. This note describes the use cases of the `sr_unregister` command
- 2904125 - Data loss can occur in split-brain state when/if system replication is disabled while SDI is active

You can disable system replication using the following tools:

- SAP HANA cockpit  
For more information, see *Disable SAP HANA System Replication with the SAP HANA Cockpit*.
- SAP HANA studio  
For more information, see *Disable SAP HANA System Replication with the SAP HANA Studio*.
- `hdbnsutil`  
For more information, see *Disable SAP HANA System Replication with hdbnsutil*.

### i Note

There are only two scenarios where it is necessary to unregister system replication:

- When the secondary system is available, but should be de-coupled permanently  
You will be able to use the secondary system as a standard SAP HANA installation afterwards.
- When the secondary system is not available anymore and the primary system needs to be cleaned up in order to be able to register a new system  
This can occur when the secondary system was uninstalled or when it cannot be recovered after a disaster.

## 11.1.2.12.1 Disable SAP HANA System Replication in SAP HANA Cockpit

You can disable SAP HANA system replication in an SAP HANA system using the SAP HANA cockpit.

### Prerequisites

- The secondary system must be offline.
- You need the operating system user to disable system replication with the SAP HANA cockpit. For more information, see *Operating System User <sid>adm* in the *SAP HANA Administration Guide* and *Connect to a Database using Database Credentials*.

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. In the *Monitoring* or *All* view, on the [Database Overview](#) page of the system database (SYSTEMDB), use the [Services](#) card .
2. Unregister the secondary system as follows:
  - a. In the *Monitoring* or *All* view, on the [Database Overview](#) page of the system database (SYSTEMDB) of the stopped secondary system, choose the [System Replication](#) card to stop the secondary system.

The [System Replication](#) card opens displaying the [System Replication Overview](#).

- b. Choose [Unregister this Secondary](#) on the top right.

Depending whether your system should be online or offline after unregistering it, check the [Start system after unregistration](#) option in the confirmation dialog and choose [OK](#). For more information, see [SAP Note 1945676](#).

3. Disable system replication on the primary system as follows:
  - a. In the *Monitoring* or *All* view, on the [Database Overview](#) page of the primary system, choose the [System Replication](#) card.

The [System Replication](#) card opens displaying the [System Replication Overview](#).

- b. Choose [Disable System Replication](#) on the top right and confirm that you want to disable system replication.

The [Ignore the secondary system](#) option allows you to disable the primary system even though the secondary is still attached. This could be relevant, if the secondary has been uninstalled in the meantime.

## Related Information

## 11.1.2.12.2 Disable SAP HANA System Replication with the SAP HANA Studio

You can disable SAP HANA system replication in an SAP HANA system using the SAP HANA studio.

### Prerequisites

- You are logged on to both systems as the operating system user (user <sid>adm) or are able to enter these credentials when prompted.
- The secondary system must be offline.

### Procedure

1. Unregister the secondary system as follows:
  - a. In the *Systems* view, right-click the primary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾.  
The *Configure System Replication* dialog opens.

#### i Note

You can also access the *Configure System Replication* dialog from the ► *Landscape* ► *System Replication* ▾ tab.

- b. Choose *Unregister secondary system* and then *Next*.
  - c. Enter the required system information and choose *Next*.
  - d. Review the configured information and choose *Finish*.
2. Disable system replication on the primary system as follows:
    - a. In the *Systems* view, right-click the primary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾.
    - b. Choose *Disable system replication* and choose *Next*.
    - c. Review the configured information and choose *Finish*.

## 11.1.2.12.3 Disable SAP HANA System Replication with hdbnsutil

You can disable SAP HANA system replication with `hdbnsutil`.

### Prerequisites

- You are logged on to both systems as the operating system user (user `<sid>adm`) or are able to enter these credentials when prompted.
- The secondary system must be offline.

### Procedure

1. Stop the secondary system:

```
sapcontrol -nr <instance_number> -function StopSystem HDB
```

2. On secondary system unregister the secondary system:

```
hdbnsutil -sr_unregister --id=<secondarySiteID>
```

#### **i** Note

If system replication is out of sync and you need to register again the initial secondary system, use the command `hdbnsutil -sr_register`. It is not necessary to unregister the secondary system before registering it again.

For an overview of `hdbnsutil -sr_unregister` use cases, see *SAP Note 1945676*.

3. Disable system replication on the primary system as follows:

```
hdbnsutil -sr_disable
```

## 11.1.2.13 SAP HANA Multitier System Replication

To offer higher levels of availability, you can link multiple systems in a SAP HANA multitier system replication landscape.

You can configure system replication to support geo-clustering, that is multitier system replication between a primary data center and other geographically remote data centers to form a single highly available system.

### Related Information

[Configuring SAP HANA Multitier System Replication \[page 1311\]](#)

[Performing a Takeover and a Failback in SAP HANA Multitier System Replication \[page 1319\]](#)

### 11.1.2.13.1 Configuring SAP HANA Multitier System Replication

With multitier system replication, a tier 2 system replication setup can be used as the source for replication in a chained setup of primary system, tier 2 secondary system, and tier 3 secondary system.

After configuring a basic system replication scenario, you must add a third system to provide another level of redundancy. In a multitier setup, the primary system is always on tier 1, a tier 2 secondary has a primary system as its replication source, and a tier 3 secondary has the tier 2 secondary as its replication source.

The operation mode must be the same for all systems. However, if `logreplay_readaccess` is used between tier 1 and tier 2, as an exception from this rule only the `logreplay` operation mode can be used between tier 2 and tier 3. Furthermore, it is not possible to combine the `logreplay` and `delta_datashipping` operation modes.

Multitier system replication supports various replication mode combinations. For more information, see *Supported Replication Modes Between Systems*.

You can configure multitier system replication using the following tools:

- SAP HANA cockpit  
For more information, see *Example: Configure SAP HANA Multitier System Replication with the SAP HANA Cockpit*.
- SAP HANA studio  
For more information, see *Example: Configure SAP HANA Multitier System Replication with the SAP HANA Studio*.
- `hdbnsutil`  
For more information, see *Example: Configure SAP HANA Multitier System Replication with hdbnsutil*.

### 11.1.2.13.1.1 Supported Replication Modes Between Systems

In a multitier system replication scenario, the following replication mode combinations are supported.

#### Replication Mode Combinations

Tier1 to Tier 2	Tier 2 to Tier 3	Description	Use Case
SYNC	SYNC	<p>In this setup, tier 1, tier 2, and tier 3 are coupled with SYNC replication mode.</p> <p>Tier 2 sends the acknowledgment to tier 1 after the log buffer has been received and written to disk, and after the log buffer has also been received and written by tier 3.</p> <p>When primary has received the acknowledge, the buffer has been persisted by all the tiers.</p>	<p>Tier 1 and tier 2 are located in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a second close data center.</p>
SYNC	SYNCMEM	<p>Tier 2 sends the acknowledge to tier 1 after the log buffer has been received, written to disk and it has been also received by tier 3.</p>	<p>Tier 1 and tier 2 are located in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a</p>

Tier1 to Tier 2	Tier 2 to Tier 3	Description	Use Case
		When the primary receives acknowledgment, it is not clear that also tier 3 has persisted the buffer to disk, but disk IO on tier 3 has been triggered.	second close data center.
SYNC	ASync	<p>Tier 1 and tier 2 are closely coupled with replication mode SYNC, while tier 3 is decoupled by using ASync.</p> <p>Tier 2 acknowledges the arrival of the redo log buffers in-memory and on disk to tier 1, while it only hands over the redo log buffer to the network without awaiting an acknowledgment from tier 3.</p> <p>If the connection to tier 3 is too slow and the ASync replication buffer (an intermediate memory buffer) is running full, ASync replication to tier 3 can have an impact on the primary.</p>	<p>Tier 1 and tier 2 are located in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a far distant data center.</p>
SYNcMEM	SYNc	<p>In this synchronous setup tier 1 and tier 2 are closely coupled with replication mode SYNcMEM, while tier 3 is closely coupled with SYNc.</p> <p>Tier 2 sends the acknowledgment to tier 1 after the log buffer has been received in memory. IO is triggered asynchronously. The</p>	<p>Tier 1 and tier 2 are located in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a second close data center.</p>

Tier1 to Tier 2	Tier 2 to Tier 3	Description	Use Case
		<p>asynchronous IOalso triggers the send operation to tier 3. The log write on tier 2 is confirmed, when also tier 3 has written the log buffer.</p> <p>When the primary receives the acknowledge, it is unclear, if tier 3 has already received and persisted the log buffer.</p>	
SYNCMEM	SYNCMEM	<p>In this setup tier 1, tier 2, and tier 3 are coupled with replication mode SYNCMEM.</p> <p>Tier 2 sends the acknowledgment to tier 1 after the log buffer has been received in memory. IO is triggered asynchronously. The asynchronous IO also triggers the send operation to tier 3. The log write on tier 2 is confirmed, when tier 3 has received the log buffer in memory.</p> <p>When the primary receives the acknowledge, it is unclear, if tier 3 has already received and persisted the log buffer.</p>	<p>Tier 1 and tier 2 are located in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a second close data center.</p>
SYNCMEM	ASync	<p>Tier 1 and tier 2 are closely coupled with replication mode SYNCMEM, while tier-3 is decoupled with ASync replication.</p>	<p>Primary and tier 2 are used in a local data center for fast takeover.</p> <p>Tier 3 is used for disaster recovery in a far distant data center.</p>

Tier1 to Tier 2	Tier 2 to Tier 3	Description	Use Case
		<p>Tier 2 acknowledges the arrival of the redo log buffers in-memory to tier 1, while it only hands over the redo log buffer to the network without awaiting an acknowledgment from tier 3.</p> <p>If the connection to tier 3 is too slow and the ASYNC replication buffer (an intermediate memory buffer) is running full, ASYNC replication can have an impact on the primary.</p>	
ASYNC	ASYNC	<p>With these asynchronous replication modes there is no wait for acknowledgments between tiers (no acknowledge propagation).</p> <p>A replication backlog for tier 2 and tier 3 is possible.</p> <p>Information about the replication status on tier 1 and tier 2 is available in the ASYNC replication buffer (an intermediate memory buffer). This buffer running full could cause a minimal impact on the performance of the primary.</p>	<p>Tier 1 performance is most important as well as a disaster recovery capability. For best performance of tier 1 decouple tier 2 and tier 3.</p> <p>Data loss on tier 2 and tier 3 is possible to some extent, but performance is more critical.</p>

## 11.1.2.13.1.2 Example: Configure SAP HANA Multitier System Replication with SAP HANA Studio

You can configure SAP HANA multitier system replication using the SAP HANA studio.

### Prerequisites

- You have considered all the general prerequisites needed to set up system replication. For more information, see *General Prerequisites for Configuring SAP HANA System Replication*.
- You have added the systems in the SAP HANA studio.
- You have verified that the `log_mode` parameter in the `persistence` section of the `global.ini` file is set to **normal** for the systems.  
You can do this in the Administration editor (*Configuration* tab) of the SAP HANA studio.
- You have stopped the tier 3 secondary system.

### Context

The following example describes how to add a tier 3 secondary with a synchronously running tier 2 system replication.

### Procedure

1. Enable system replication on the tier 2 secondary, which has to be online, as follows:
  - a. In the *Systems* view right click the tier 2 secondary system, choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾  
The *Configure System Replication* dialog opens. The *Enable System Replication* option is selected by default. The site name is already known from the topology metadata.
  - b. Choose *Next*.
  - c. Review the configured information and choose *Finish*.
2. Register the tier 3 secondary system as follows:
  - a. You have installed and configured three identical, independently operationalStop the tier 3 secondary system if it is still running. Right-click the tier 3 secondary system and choose ► *Configuration and Monitoring* ► *Stop System* ▾
  - b. In the *Systems* view, right-click the tier 3 secondary system and choose ► *Configuration and Monitoring* ► *Configure System Replication* ▾.  
The *Configure System Replication* dialog opens.
  - c. Choose *Register Secondary System* and then *Next*.
  - d. Enter the required system information and the logical name used to represent the tier 3 secondary system.

### i Note

If you are operating a distributed system on multiple hosts, you enter the name of the host on which the master name server is running.

- e. Specify the replication mode and enter the tier 2 secondary system's host name.

For more information, see *Supported Replication Modes Between Systems*.

- f. Review the configured information and choose *Finish*.

## Results

The secondary system is automatically started and the replication process to the tier 3 secondary then starts automatically.

## Related Information

[General Prerequisites for Configuring SAP HANA System Replication \[page 1231\]](#)

[Supported Replication Modes Between Systems \[page 1312\]](#)

## 11.1.2.13.1.3 Example: Configure SAP HANA Multitier System Replication with hdbnsutil

Learn how to configure SAP HANA multitier system replication with the hdbnsutil command line.

## Prerequisites

- You have considered all the general prerequisites needed to configure system replication. For more information, see *General Prerequisites for Configuring SAP HANA System Replication*.
- You have installed and configured three identical, independently operational SAP HANA systems – a primary system, a tier 2 secondary system, and a tier 3 secondary system.

## Context

The following steps show how to configure such a system. In this scenario there are three SAP HANA systems: A, B, and C, named SiteA, SiteB, and SiteC. Furthermore, in this scenario multitier system replication supports a tier 2 secondary with sync replication mode and a tier 3 secondary with async replication mode. The operation mode is `logreplay`.

## Procedure

1. [A] Start the SAP HANA database.
2. [A] Create a data backup or storage snapshot. In multiple-container systems, the system database and all tenant databases must be backed up.
3. [A] Enable system replication and give the system a logical name. As <sid>adm:

```
cd /usr/sap/<sid>/HDB<instancenr>/exe
```

```
./hdbnsutil -sr_enable --name=SiteA
```

4. Stop the tier 2 secondary.  
As <sid>adm run the SAPControl program to shut down the system:

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance_number> -function StopSystem  
HDB
```

5. [B] On the stopped tier 2 secondary, register site B with Site A as <sid>adm:

```
hdbnsutil -sr_register --replicationMode=sync --operationMode=logreplay --  
name=SiteB  
--remoteInstance=<instId> --remoteHost=<hostname_of_A>
```

6. [B] Start the tier 2 secondary system.  
As <sid>adm run the SAPControl program to start the system:

```
/usr/sap/hostctrl/exe/sapcontrol sapcontrol -nr <system number> -function  
StartSystem HDB
```

7. [B] Enable this site as the source for a tier 3 secondary system:  
As <sid>adm on the tier 2 secondary run `hdbnsutil -sr_enable`

8. [C] Stop the tier 3 secondary system.  
As <sid>adm run the SAPControl program to shut down the system:

```
/usr/sap/hostctrl/exe/sapcontrol -nr <instance_number> -function StopSystem  
HDB
```

9. [C] On the stopped system, register siteC as a tier 3 secondary system as <sid>adm:

```
hdbnsutil -sr_register --replicationMode=async --operationMode=logreplay --  
name=SiteC  
--remoteInstance=<instId> --remoteHost=<hostname_of_B>
```

10. [C] Start the SAP HANA database on the tier 3 secondary.  
As <sid>adm run the SAPControl program to start the system:

```
/usr/sap/hostctrl/exe/sapcontrol sapcontrol -nr <system number> -function  
StartSystem HDB
```

11. Check the replication status with `systemReplicationStatus.py` on command line or in the `M_SERVICE_REPLICATION` system view.

## Related Information

[Supported Replication Modes Between Systems \[page 1312\]](#)

[Operation Modes for SAP HANA System Replication \[page 1239\]](#)

### 11.1.2.13.2 Performing a Takeover and a Failback in SAP HANA Multitier System Replication

You can perform a takeover and a failback also in a SAP HANA multitier system replication.

If the primary system fails, you can perform a takeover to the tier 2 secondary system.

Once your failed system is operational again, you can attach it as a tier 3 secondary system or you can restore the original multitier system replication configuration. To learn how to perform these steps with the `hdbnsutil` command line, see *Attach the Original Primary System as a New Tier 3 Secondary System* and *Restore the Original SAP HANA Multitier System Replication Configuration*.

## Related Information

[Example: Attach the Original Primary System as a New Tier 3 Secondary System \[page 1319\]](#)

[Example: Restore the Original SAP HANA Multitier System Replication Configuration \[page 1320\]](#)

#### 11.1.2.13.2.1 Example: Attach the Original Primary System as a New Tier 3 Secondary System

Once your failed system is operational again, you can attach it as a tier 3 secondary system.

## Context

The steps below show how to set up multitier system replication again after a takeover. In these scenarios there are three SAP HANA systems A, B and C, named SiteA, SiteB, and SiteC. Furthermore, in this scenario multitier system replication supports a tier 2 secondary with sync replication mode and a tier 3 secondary with async replication mode.

## Procedure

SiteA failed, SiteB has taken over and now you attach SiteA as the tier 3 secondary.

1. [C] Change the replication mode of the new tier 2 secondary:

```
cd /usr/sap/<sid>/HDB<instance_number>/exe
./hdbnsutil -sr_changemode --replicationMode=sync
```

Multitier system replication supports various replication mode combinations. For more information, see *Supported Replication Modes between Sites*.

2. [C] Enable SiteC as the replication source:

```
hdbnsutil -sr_enable
```

3. [A] Make sure that the SAP HANA database is stopped. This should be the case as a takeover was already carried out otherwise you can stop it with the following command:

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StopSystem
HDB
```

4. [A] Register SiteA as a new tier 3 secondary.

```
hdbnsutil -sr_register --replicationMode=async --name=SiteA --
remoteInstance=<instId> --remoteHost=<hostname_of_C>
```

5. [A] Start the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StartSystem
HDB
```

6. [B] Check in M\_SERVICE\_REPLICATION that sync system replication is ACTIVE from SiteB to SiteC and that async replication is ACTIVE from SiteC to SiteA.

## Related Information

[Supported Replication Modes Between Systems \[page 1312\]](#)

### 11.1.2.13.2.2 Example: Restore the Original SAP HANA Multitier System Replication Configuration

Once your failed system is operational again, you can restore the original SAP HANA multitier system replication configuration.

## Context

The steps below show how to set up multitier system replication again after a takeover. In these scenarios there are three SAP HANA systems A, B and C, named SiteA, SiteB, and SiteC. Furthermore, in this scenario multitier

system replication supports a tier 2 secondary with sync replication mode and a tier 3 secondary with async replication mode.

## Procedure

You want to restore the original multitier setup:

1. [C] Stop the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StopSystem  
HDB
```

2. [A] Stop the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StopSystem  
HDB
```

3. [A] Register as secondary:

```
hdbnsutil -sr_register --replicationMode=sync --name=SiteA --  
remoteInstance=<instId> --remoteHost=<hostname_of_B>
```

4. [A] Start the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StartSystem  
HDB
```

5. [B] Check in M\_SERVICE\_REPLICATION that sync system replication is ACTIVE from SiteB to SiteA.

6. [A] SiteA takes over as the primary system:

```
hdbnsutil -sr_takeover
```

7. [B] Stop the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StopSystem  
HDB
```

8. [A] Enable system replication:

```
hdbnsutil -sr_enable --name=SiteA
```

9. [B] Register SiteB as the tier 2 secondary of SiteA.

```
hdbnsutil -sr_register --replicationMode=sync --name=SiteB --  
remoteInstance=<instId> --remoteHost=<hostname_of_A>
```

10. [B] Start the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StartSystem  
HDB
```

11. [B] Enable SiteB as a replication source system:

```
hdbnsutil -sr_enable
```

12. [C] Register SiteC as a tier 3 secondary in the multitier system replication scenario:

```
hdbnsutil -sr_register --replicationMode=async --name=SiteC --
remoteInstance=<instId> --remoteHost=<hostname_of_B>
```

13. [C] Start the SAP HANA database

```
/usr/sap/hostctrl/exe/sapcontrol -no <instance_number> -function StartSystem
HDB
```

14. [B] Check in M\_SERVICE\_REPLICATION that sync replication is ACTIVE from SiteA to SiteB and that async replication is ACTIVE from SiteB to SiteC.

## 11.1.2.14 SAP HANA Multitarget System Replication

In a multitarget system replication, primary and secondary systems can replicate data changes to more than one system.

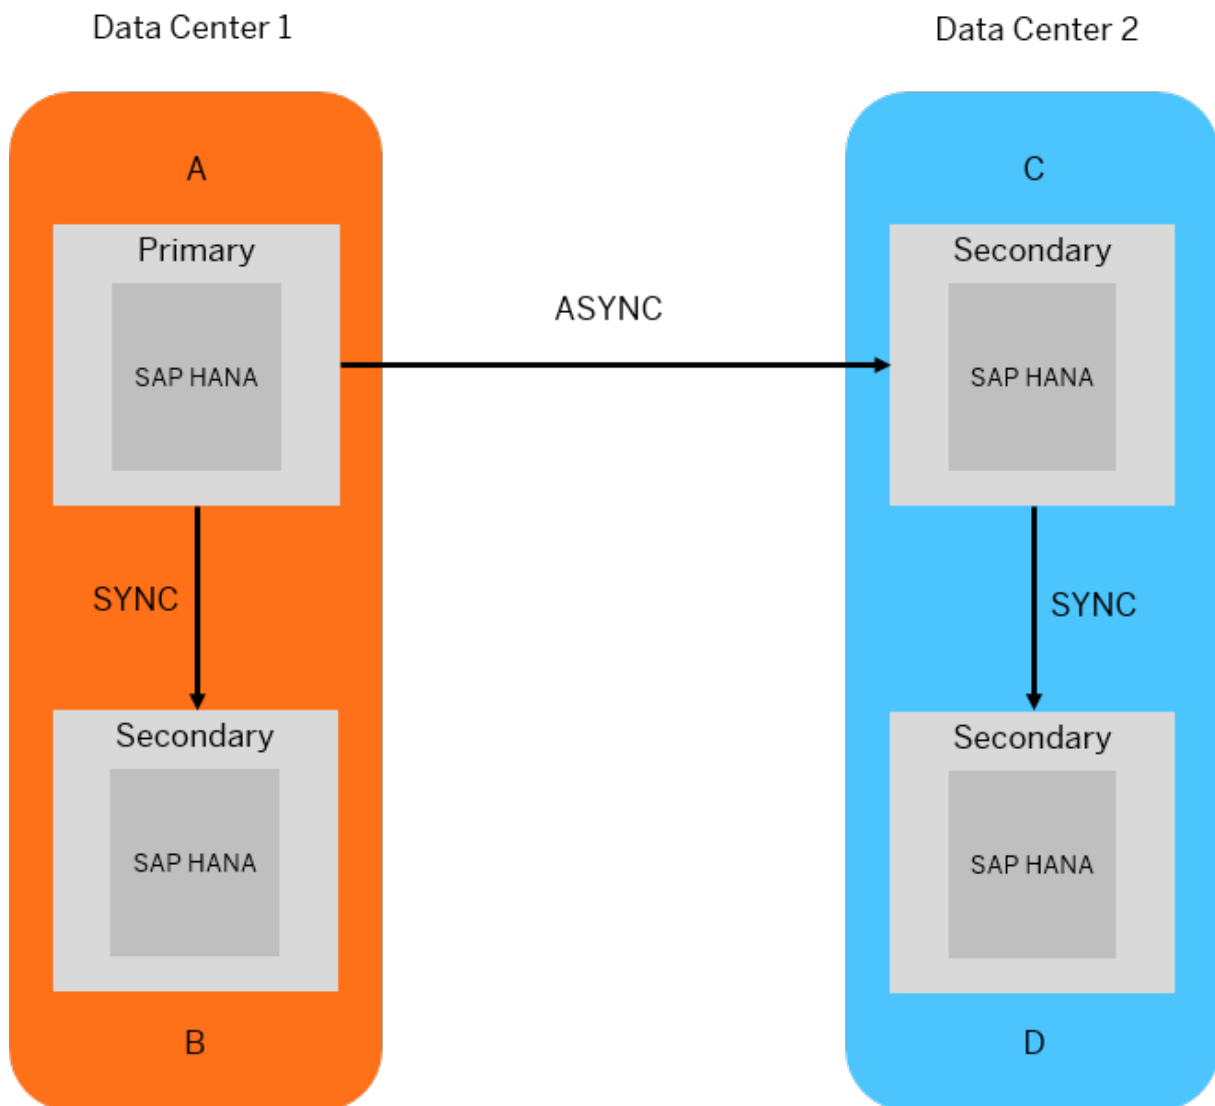

Multitarget system replication brings advantages for several use cases:

- Update scenarios
- Rearrangements of system replication multitier chains
- Reaching higher availability (before stopping existing structures, new structures can be built and established)

The graphic shows a possible setup for multitarget system replication.

Primary system A in data center 1 replicates data changes to secondary system B in the same data center.

Primary system A also replicates data changes to secondary system C in data center 2. Secondary system C is a source system for a further secondary system D located in the same data center with system C.

To understand how to handle different disaster recovery scenarios, see *Disaster Recovery Scenarios for Multitarget System Replication*. In a multitarget system replication, the secondary systems can be configured to automatically re-register to a new source system when the original source system is unavailable.

For multitarget system replication either the `logreplay` or `logreplay_readaccess` mode is required.

In a multitarget system replication setup, you can configure multiple secondaries as Active/Active (read enabled). Only one of these secondaries can be accessed via hint-based statement routing; the others must be accessed via direct connection. For more information on Active/Active (read enabled), see *Active/Active (Read Enabled)*.

[Active/Active \(Read Enabled\) \[page 1328\]](#)

## 11.1.2.14.1 Example: Configure a SAP HANA Multitarget System Replication

You can configure a multitarget system replication in which a primary system replicates data changes to more than one secondary system.

### Context

In this example, primary system A in data center 1 replicates data changes to secondary system B in the same data center. Primary system A also replicates data changes to secondary system C in data center 2. Secondary system C is a source system for a further secondary system D located in the same data center with system C.

### Procedure

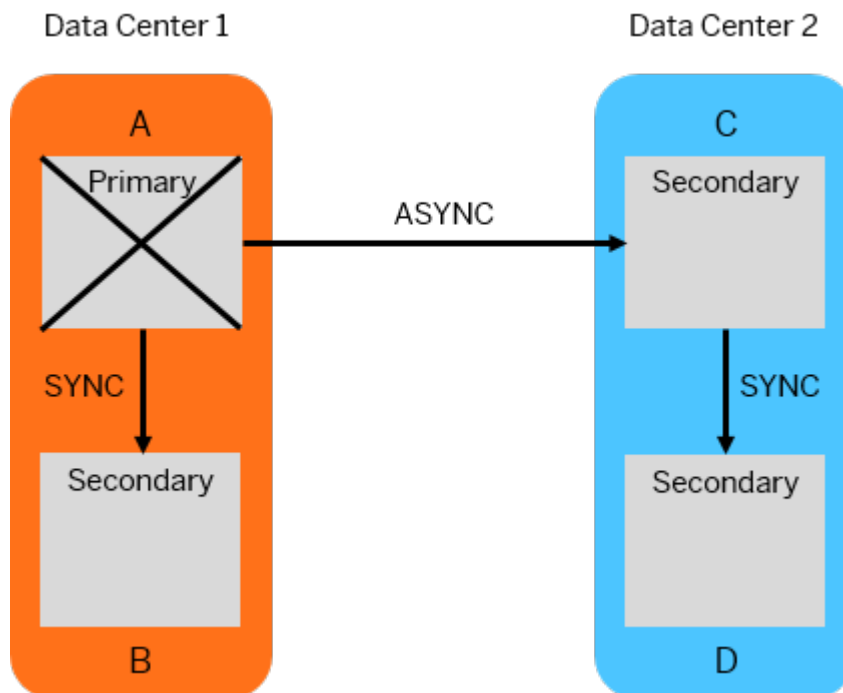

1. On primary system A in data center 1:
  - a. Create backups.
  - b. Enable system replication.
2. On the local secondary system B in data center 1:
  - a. Stop the system.
  - b. Register it to A.
  - c. Start the system.
3. On the remote secondary system C in data center 2:
  - a. Stop the system.
  - b. Register it to A.
  - c. Start the system.
4. On the remote secondary system D in data center 2:
  - a. Stop the system.
  - b. Register it to C.
  - c. Start the system.

## 11.1.2.14.2 Disaster Recovery Scenarios for Multitarget System Replication

Several solutions are available when the systems involved in a multitarget system replication configuration fail.

We are using the setup described in *Multitarget System Replication* to exemplify the procedure. In this setup, primary system A replicates data changes to secondary system B located in the same data center. Primary system A also replicates data changes to the secondary system C located in data center 2. Secondary system C is a source system for a further secondary system D located in the same data center with system C.

### Failure on Primary System A

When primary system A fails, proceed as follows:

1. Take over on secondary system B in data center 1.
2. Register secondary system C in data center 2 to the new primary system B in data center 1. Then, register secondary system D in data center 2 to secondary system C.
3. After the failure on the previous primary system A is solved, register it to the new primary system B in data center 1.

Alternatively, you can set the `global.ini/[system_replication]/register_secondaries_on_takeover` parameter to `true` and take over on secondary system B in data center 1. As a result, secondary system C in data center 2 will register automatically to the new primary system B in data center, while secondary system D in data center 2 will register automatically to secondary system C.

After the failure on the previous primary system A is solved, register it to the new primary system B in data center 1. See also the additional options described in *Automatic Registration After Takeover*.

## Failure of Data Center 1

When all the systems in data center 1 fail, proceed as follows:

1. Take over on secondary system C in data center 2.
2. After the failure on the previous primary system is solved, register system A to the new primary system C in data center 2.
3. Register secondary system B as tier 3 to system A in data center 1.

For more information about takeover and failback, see *Performing a Takeover* and *Performing a Failback*.

## Related Information

[Log Retention \[page 1247\]](#)

[Automatic Registration After Takeover \[page 1295\]](#)

### 11.1.2.14.3 Automated Search for Alternative Source Sites

You can maintain a list of alternative source sites to which a secondary can be registered in case the preferred site is not available for some reason.

To use the option of considering alternative system replication sites to register to, set up a list of site names in the parameter `alternative_sources` (in the `[system_replication]` section of the `global.ini` file). In the multi-target scenario illustrated here where site A is the main primary, this could be used, for example, for site D so that if a connection to site C is not possible then it will register to site B:

In the configuration parameter both site names are given in a comma-separated list. Optionally, you can also specify the replication mode for each site by appending it with a colon:

```
alternative_sources=SiteC:ASync,SiteB:SyncMem
```

Two further parameters in the `[system_replication]` section of the `global.ini` file are used to determine firstly, the number of times the system will try to connect before switching to the alternative list (default value 20), and also the time interval between each attempt to connect (default value 30 seconds):

```
retries_before_register_to_alternative_source  
reconnect_time_interval
```

## 11.1.2.15 Active/Active (Read Enabled)

Active/Active (read enabled) enables SAP HANA system replication to support read access on the secondary system.

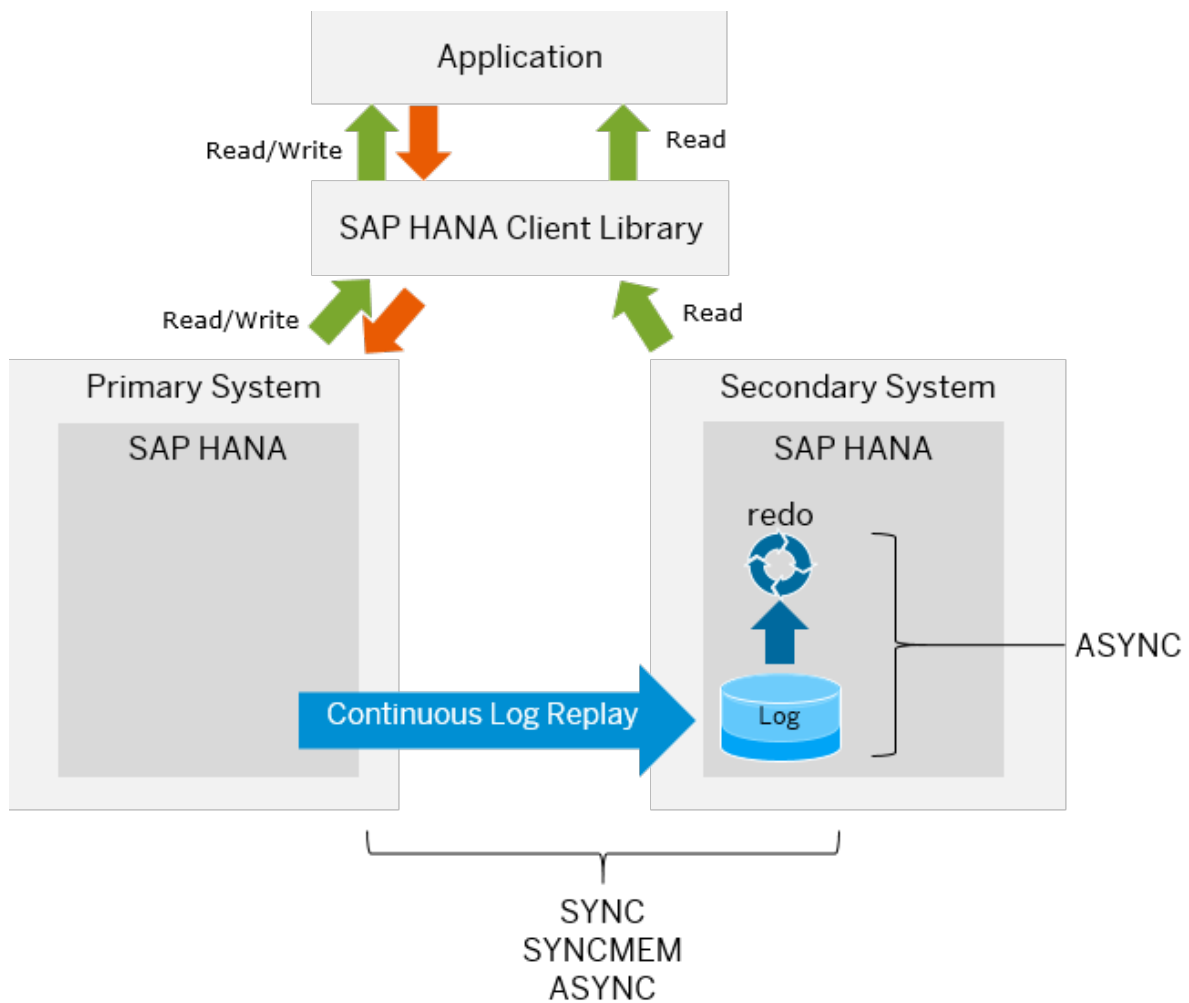

### Active/Active (Read Enabled)

Active/Active (read enabled) reduces the load on the primary system but does not double the capacity; it simply extends read capabilities. In a replication system that is configured for Active/Active (read enabled), the SQL ports on the secondary system are open for read access. This makes it possible to use the secondary system for read-intensive tasks and to have a better balance of workloads improving the overall performance of the SAP HANA database.

Active/Active (read enabled) is activated with the System Replication operation mode `logreplay_readaccess`, and uses the continuous logreplay mode. This operation mode provides fast takeovers, reduced need for bandwidth in continuous operation, and support for all replication modes: SYNC (with or without the full sync option), SYNCMEM, and ASYNC. For a detailed illustration of the general system replication processes, see *System Replication*.

The following graphic shows an Active/Active (read enabled) configuration: the primary system is fully active and supports reading and writing and the secondary system is enabled for read queries.

## Operation Mode

To enable read access on the secondary system use the operation mode `logreplay_readaccess` when configuring system replication. Two options are supported to connect to the secondary as described in the topic 'Connection Types'.

To use this operation mode, the primary and the secondary systems must have the same SAP HANA version. For this reason, read-only access to the secondary system is not possible during a rolling upgrade until both versions are the same again.

In a multitier setup, read access on the secondary is only supported for tier 2. In a 3-tier system using Active/Active (read enabled), the `logreplay_readaccess` mode is required between the primary and the active secondary systems, while the `logreplay` mode is required between the other (tier 2 and tier 3) secondary systems. In a multitarget setup, multiple secondary systems with `logreplay_readaccess` are supported.

## i Note

With the operation mode `logreplay_readaccess`, the secondary system allows read-only access on column tables via SQL providing a delayed view on the data compared to the primary system. There is no minimum delay guarantee. Read access on system and monitoring views is supported as well.

For more information about the operation mode `logreplay_readaccess`, see *Operation Modes for SAP HANA System Replication*. An SAP HANA Academy video on Active / Active (read enabled) is available on YouTube.

## License Key Management

Although Active/Active (read enabled) requires an additional add-on license it does not require an additional license key as the secondary system is operated automatically with the license key of the primary system. Changes of the license key are done on the primary system and replicated to the secondary system. The license for Active/Active (read enabled) also covers the multi-target replication scenario; the license requirement is related to setting the `logreplay_readaccess` operation mode. For more information about licenses, see *Managing SAP HANA Licenses*.

### 11.1.2.15.1 Generic Conditions for Active/Active (Read Enabled)

When using the secondary system for read access, several aspects need to be considered.

#### Points to Consider

- The processors in the primary and secondary systems must be both either Intel-based or IBM Power-based with the same byte ordering. A platform mixture is not supported.

- The secondary system allows read access if the primary system runs the same SAP HANA version (that is, the same build number, for example: 2.00.048.01.1593581573). A different version leads to prohibiting the read access until the same software version is used.
- The redo log replay runs as an asynchronous process on the secondary system. The secondary system provides statement level snapshot isolation with potentially delayed view on the data and no minimum delay guarantee.
- The secondary system gets its own virtual IP addresses or host names representing the secondary function.
- DML executions for table types that do not lead to redo log writing are possible on Active/Active (read enabled) secondary systems. This applies, for example, to global temporary tables, local temporary tables or row store no-logging retention tables. Explain Plan is also available on the secondary system. For more information, see *Data Manipulation Statements*.
- The query execution in the secondary system is rejected if it needs background migrations requiring redo log writes (for example, L2-Delta migration).

#### → Recommendation

Perform the migration in the primary system (for example, load table) and wait until it is replicated and replayed in the secondary system.

- Internal processes for operations like Column Store delta merges take place on the secondary system.

## Limitations

- Active/Active (read enabled) is supported in a multitier SAP HANA replication system. However, read access is limited to tier 2. The `logreplay` operation mode is required between tier 2 and the further tier level and no read access connections can be opened to the further tier level.
- If Active/Active (read enabled) is used with Dynamic Tiering services, there is no read access to Dynamic Tiering data on the secondary system.
- The export of tables is possible with CSV as target. However, binary exports on the secondary system are not supported.
- The use of workload classes is not supported on the secondary system.

## Support for Multiple SAP HANA Databases

It is possible to use the read-enabled secondary system for other SAP HANA systems such as development or QA environments. In this case the following sizing conditions apply:

- The secondary hardware must offer the same CPU and memory capacities as those offered by the primary system **plus** the resources for the additional system.
- After a takeover, the system must be capable of handling both the primary's writing load and the secondary's reporting load.

For more information about this scenario, see also SAP Note 1681092 *Multiple SAP HANA DBMSs (SIDs) on one SAP HANA system*.

[SAP Note 2447994](#)

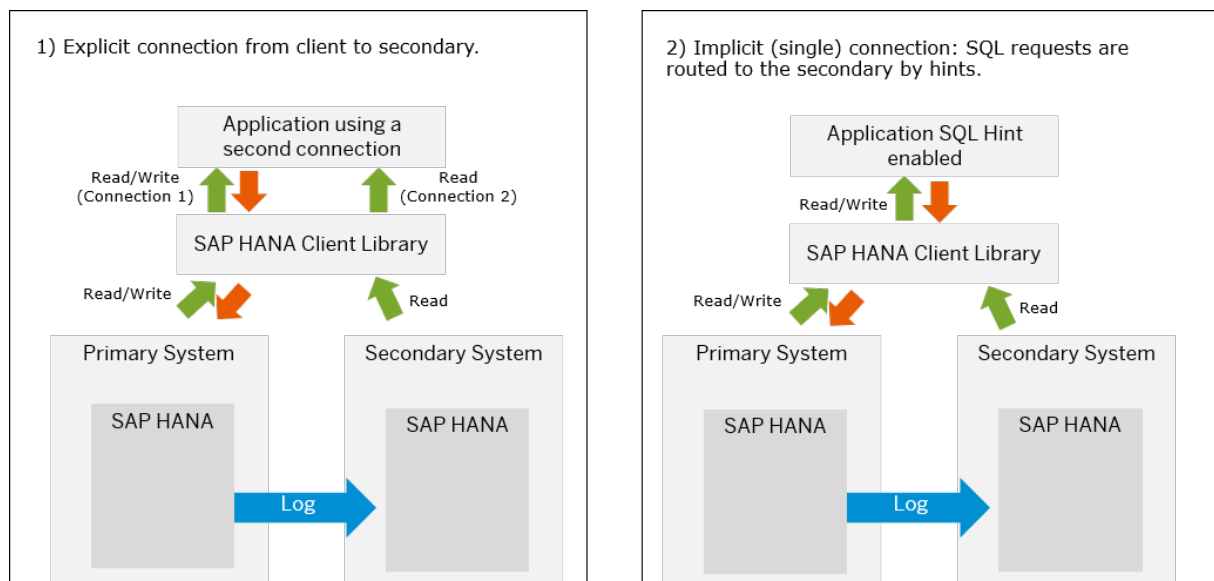

### 11.1.2.15.2 Connection Types

You can connect to an Active/Active (read enabled) secondary system either directly, or indirectly through the primary.

There are two ways to access the read-enabled secondary system:

1. Opening an explicit connection to the secondary system. In this case the application queries the read enabled secondary directly.
2. Executing an SQL statement on the primary system with a hint, the hint is evaluated and reroutes the query to the secondary system.

To provide access to the read enabled secondary it must have its own virtual IP address. The following illustration shows a comparison of these two methods:

When setting up Active/Active (read enabled) you should verify that the SQL ports on the secondary system are open and ready to take SQL commands. You can see the status of the port in the monitoring view `M_SYSTEM_REPLICATION` in column `SECONDARY_READ_ACCESS_STATUS`, the status should be 'Active'. In SAP HANA cockpit, the status of the port on the secondary is visible in the System Replication app on the primary; the status should show: 'Secondary Read Access: Enabled'.

For more details of the client connection refer to the *SAP HANA Client Interface Programming Reference for SAP HANA Platform* (link given below).

## Hint-based Statement Routing

In this case the application connects to the primary system and the query execution unfolds as follows:

1. The SAP HANA client sends the statement-prepare with hint to the primary system.
2. The primary system decides where to execute the statement and returns the result to the SAP HANA client.
3. The SAP HANA client opens an additional connection to the secondary system according to the host information returned by the primary system. The client sends the statement execution call to the secondary system. The session property changes are handed over to the secondary system via the SAP HANA client. If the secondary system cannot execute the statement, it returns an error and the SAP HANA client sends the statement to the primary system.

For more details and an example see the following topic *Hint-Based Routing for Active/Active (Read Enabled)*. All available hints for SAP HANA are described in the section *HINT Details* in the *SAP HANA SQL and System Views Reference Guide*.

To cancel long-running sessions on a read enabled secondary system, use: `ALTER SYSTEM CANCEL SESSION.`

### Limitations:

#### i Note

Hint-based statement routing is supported by SAP HANA ODBC, SQLDBC, ADO.Net, JDBC drivers for SAP HANA 2.0 and the SAP HANA Node.js.

- The SAP HANA client has an open working connection to the primary system.
- Hint-based statement routing is not supported for CALL procedures.
- Temporary tables are not supported.
- Hint-based statement routing is not supported for write transactions.

### Related Information

[HINT Details \(SAP HANA SQL and System Views Reference\)](#)

[M\\_SYSTEM\\_REPLICATION System View \(SAP HANA SQL and System Views Reference\)](#)

[Hint-Based Statement Routing for Active/Active \(Read Enabled\) \[page 1334\]](#)

[Client Support for Active/Active \(Read Enabled\) - Client Interface Programming Reference](#)

### 11.1.2.15.3 Hint-Based Statement Routing for Active/Active (Read Enabled)

Connections to a primary system can use hint-based statement routing statement execution to a secondary system on a per-statement basis. This reduces the load on the primary system and increases overall performance.

To indicate that a statement should be hint-based routed to the secondary system, add the hint text `WITH HINT (RESULT_LAG ('hana_sr'))` to the end of the SQL SELECT statement. For example:

```
SELECT C1, C2 FROM T1 WHERE C3 = 'constant value' WITH  
HINT (RESULT_LAG ('hana_sr'))
```

Queries that are executed directly (not prepared) are not hint-based routed even if they contain a hint. To take advantage of hint-based statement routing, there must be separate prepare and execute operations at the SQLDBC or JDBC level. In some cases, applications or interfaces that use SQLDBC or JDBC (such as SAP HANA Studio, SAP HANA Cockpit, ABAP, or PyDBAPI) can perform a separate prepare and execute without the user's knowledge.

#### Routing Conditions

In the following cases, the execution transparently falls back to the primary system, even if the statement contains a hint to route to the secondary system:

- The connection's isolation level is set to repeatable read or serializable.
- Connection to the secondary system is not possible (for example, there is a secondary system outage, a networking issue, and so on).
- The connection currently has a write transaction (uncommitted insert, update, or delete) in progress.
- The query references temporary tables.

If the routed connection is dropped while fetching from a hint-routed query result set, an error may be returned to the application.

#### i Note

Hint-based statement routing is only applied to SELECT statements.

#### Fallback Routing

In the following cases, a statement that has been routed to the secondary system gets re-routed to the primary system:

- The hint contains a maximum delay time parameter and the secondary system is delayed by more than that amount.
- The secondary system is near its maximum memory usage.
- The statement prepared in the primary system does not detect any access to the Dynamic Tiering data, but the statement execution in the secondary system requires Dynamic Tiering data.

## Timeout

If the previous hint-based routed statement execution falls back to the primary system due to a connection or communication error, then future hint-based statement routing does not attempt to re-connect to the secondary system for several seconds. This avoids the performance cost of retrying the connection to the secondary system frequently when it is likely to fail.

In this case, the time between reconnection attempts to the secondary system is between five seconds and five minutes from the last reconnection attempt. The time between reconnection attempts automatically increases if reconnection attempts continue to fail.

In a multitier system replication system, hint-based statement routing always routes from the primary to the secondary system.

[HINT Details](#)

[Connection Types \[page 1332\]](#)

### 11.1.2.15.4 Configuration Parameters

Several parameters are available for configuring Active/Active (read enabled).

**Parameter:** `operation_mode`

---

Values: `logreplay_readaccess`

---

System: `Secondary`

---

Description: System Replication uses an initial data shipping to initialize the secondary system. After that, only log shipping is done and the log buffers received by the secondary system are being replayed there. Savepoints are executed individually for each service. Column table merges are executed on the secondary system. Additionally, read access via SQL is provided to the secondary system.

---

Relevant for Active/Active (read enabled) are also `enable_log_retention` and `logshipping_max_retention_size`. For more information about these parameters, see *SAP HANA System Replication Configuration Parameters*.

## Related Information

[SAP HANA System Replication Configuration Parameters \[page 1271\]](#)

## 11.1.2.15.5 Checking the Active/Active (Read Enabled) Configuration

You can check if your system replication is configured as an Active/Active (read enabled) system.

### SAP HANA Cockpit

On the *System Replication* tile on the primary system, the `logreplay_readaccess` operation mode indicates that your system is an Active/Active (read enabled) system. Additionally, an enabled secondary read access informs you that the SQL ports are open for reading on the Active/Active (read enabled) secondary system.

On the system overview page of the secondary system, the *Mode: read-only* indicates that your system is an Active/Active (read enabled) system. Additionally, the *Delay* in ms is shown on top indicating how far behind is the consistent view on the data of this secondary system compared to the current data of the primary system.

For examples and more information, see *System Replication Tile* and *Example: Monitoring SAP HANA System Replication with SAP HANA Cockpit*.

### SAP HANA Studio

On the primary system, select `M_SYSTEM_REPLICATION` from the monitoring view. To find out if your system is an Active/Active (read enabled) system, verify the columns *OPERATION\_MODE* and *SECONDARY\_READ\_ACCESS\_STATUS*.

### Command Line

As `<sid>adm` run one of the following commands and then look for the operation mode `logreplay_readaccess`:

```
python $DIR_INSTANCE/exe/python_support/systemReplicationStatus.py --
sapcontrol=1 | grep OPERATION_MODE_
service/ld4144/30207/OPERATION_MODE=logreplay_readaccess
service/ld4144/30201/OPERATION_MODE=logreplay_readaccess
service/ld4144/30203/OPERATION_MODE=logreplay_readaccess
```

or

```
hdbnsutil -sr_state | grep "operation mode"
operation mode: logreplay_readaccess
```

## Related Information

[System Replication Tile](#)

[Example: Monitoring SAP HANA System Replication with the SAP HANA Cockpit](#)

### 11.1.2.15.6 Memory Management

Several parameters can be used to set the memory limit for read accesses on the secondary system.

The total statement memory is limited to 50 % of the global allocation limit, because 50% of the storage is reserved for log replay. Log replay should not fail because of memory limitations.

Use the parameters below to set the memory limit for read accesses on the secondary system:

**Parameter:** `sr_total_statement_memory_limit`

---

Type: int (GB)

---

Default: (empty)

---

Section: memorymanager

---

Description: Memory limit in GB:

- (empty): 50% of global allocation limit
- 0: disable the feature
- N: set the value as a limit

---

**Parameter:** `sr_enable_tracking`

---

Type: bool

---

Default: on

---

Section: resource\_tracking

---

Description: Main switch for resource tracking used on the system replication secondary system.

---

**Parameter:** `sr_memory_tracking`

---

Type: bool

---

Default: on

---

**Parameter:** `sr_memory_tracking`

---

Section `resource_tracking`

---

Description: Enables or disables memory tracking on the secondary system.

---

## 11.1.2.15.7 Authentication Methods

There are several authentication methods supported for an Active/Active (read enabled) system replication.

The following authentication methods are supported for the primary system:

- Basic (User Name/Password)
- Kerberos
- SAML
- Session Cookies

The secondary system delegates the authentication phase to the primary system using the existing communication channel from the secondary system to the primary system. Remote authentication tickets or credentials are sent over the data centers.

## 11.1.2.15.8 Virtual IP Address Handling

In an Active/Active (read enabled) configuration, a second virtual IP address for the read access on the secondary system is needed.

Since in an Active/Active (read enabled) configuration both systems are open for SQL access, a second virtual IP address for read access on the secondary system is needed.

During takeover you can keep the virtual IP address of the secondary system. This virtual IP address will be used for read access until a reconnect occurs. The former virtual IP address of the primary system is also rebound to access the former secondary system, which is the now active system. In this situation, two virtual IP addresses are available for accessing the former secondary system after takeover. For more information, see *Client Connection Recovery After Takeover*.

### **i** Note

Make sure that the now active system is capable to handle the workload of the former primary system and the read-access secondary system.

During failback the system replication systems switch their roles and the virtual IP addresses switch their locations too.

## Related Information

### 11.1.2.15.9 Monitoring Active/Active (Read Enabled)

You can monitor the Active/Active (read enabled) solution using proxy views or the SAP HANA Cockpit.

#### Proxy views

The embedded statistics server runs in the primary system and collects data from the secondary system providing them in the corresponding proxy schema. For more information, see *Monitoring Secondary Systems*.

#### SAP HANA Cockpit

The monitoring functionality in the SAP HANA cockpit supports access to the read-enabled system. Additionally, it provides information about the delay of the currently available consistent view. For more information, see *Monitoring SAP HANA System Replication with the SAP HANA Cockpit*.

### 11.1.2.16 Monitoring SAP HANA System Replication

You can monitor SAP HANA system replication with different tools.

You can monitor system replication using the following tools:

- SAP HANA cockpit  
For more information, see *Monitoring SAP HANA System Replication with the SAP HANA Cockpit* in the SAP HANA cockpit guide.
- SAP HANA studio  
For more information, see *Monitoring SAP HANA System Replication with the SAP HANA Studio* in the SAP HANA studio guide.

- `hdbnsutil`

For more information, see *Monitoring SAP HANA System Replication with hdbnsutil*.

[SAP HANA System Replication Alerts \[page 1340\]](#)

[Monitoring Secondary Systems \[page 1342\]](#)

### 11.1.2.16.1 SAP HANA System Replication Alerts

This is an overview of all alerts issued for the primary system.

<b>Alert ID 78</b>	<b>Connection Closed</b>
Description	Alert 78 is raised when a system replication connection is closed.
<b>Alert ID 79</b>	<b>Configuration Parameter Mismatch</b>
Description	Alert 79 is raised when there is a configuration parameter mismatch between the primary and the secondary system.
<b>Alert ID 94</b>	<b>Logreplay Backlog</b>
Description	<p>Alert 94 is raised when the system replication logreplay backlog increases. A delayed log replay on the secondary system causes a longer takeover time.</p> <p>The alert has a different priority based on the size of the redo log that was not yet replayed:</p> <ul style="list-style-type: none"> <li>• Low: 10 GB &lt; logreplay backlog &lt; 50 GB</li> <li>• Medium: 50 GB &lt;= logreplay backlog &lt; 500 GB</li> <li>• High: logreplay backlog &gt;= 500 GB</li> </ul> <p>To identify the reason for the increased system replication logreplay backlog, check the state of the services on the secondary system. To get more information, monitor the secondary system. Possible causes for the increased system replication logreplay backlog can be, for example, a slow or not functioning log replay, or a non-running service on the secondary system.</p>

**Alert ID 104****Increased Log Shipping Backlog**

---

## Description

Alert 104 is raised when the system replication log shipping is delayed or does not work properly causing data loss on the secondary system, if a takeover is done.

The alert has a different priority based on the threshold reached:

- Low: 1 GB < log shipping backlog < 10 GB
- Medium: 10 GB <= log shipping backlog < 50 GB
- High: log shipping backlog >= 50 GB

To identify the reason for the increased log shipping backlog, check the status of the secondary system. Possible causes for the increased backlog can be a slow network performance, connection problems, or other internal issues (for example, in SYNC or SYNCMEM replication modes).

**i Note**

The calculated log shipping backlog size is the total size of the data. If you are using data compression for data and log files then the real size kept in the log buffer will be smaller. Compression of the log buffer tail, for example, is enabled by default see Data and Log Compression for details.

---

**Alert ID 106****ASync Replication In-Memory Buffer Overflow**

---

## Description

Alert 106 is raised when the local in-memory buffer in the ASync replication mode is running full indicating possible network issues with the connection to the secondary system.

The alert has a different priority based on the threshold reached:

- Medium: if buffer runs full once within 24 hours
- High: if buffer runs full more than once within 24 hours

To identify the reason for the local in-memory buffer running full, check the buffer size, the network, the IO on the secondary system, or look for peak loads.

The alert depends on the setting of the

`logshipping_async_wait_on_buffer_full` parameter. For more information about this parameter, see *SAP HANA System Replication Configuration Parameters*.

---

**Alert ID 107****Inconsistent fallback snapshot**

---

## Description

Alert 107 is raised for the primary and the secondary systems when there are broken fallback snapshots. For more information about fallback snapshots, see *Create a Fallback Snapshot*.

---

**i Note**

Before SAP HANA 1.0 SPS 09 there was one alert categorized as "Internal Event" (Alert 21) which covered alerts 78 and 79. Both situations were covered by one event type and could only be distinguished by the information text provided. Since SAP HANA 1.0 SPS 11 old style alerts based on alert 21 are not created anymore as a default.

You can create them by setting the configuration parameter `keep_old_style_alert` to **true**. These alerts can be required to keep the existing monitoring infrastructure working. If activated, new alerts and old style alerts are created in parallel. Old alerting can be disabled by setting the `keep_old_style_alert` configuration parameter to **false** in global.ini file.

---

The new alerts require that you have migrated to the embedded statistics server. For more information, see [SAP Note 1917938](#).

## 11.1.2.16.2 Monitoring Secondary Systems

Remote SQL access on the primary system allows monitoring and reporting of the secondary system statistics.

There is a possibility to monitor the secondary system through proxy schemas and views. Proxy schemas and views are provided on the primary system. They extract the corresponding information from the monitoring views on the secondary system. The retrieval of statistics is unaffected by the replication or operation mode and is available for a two system replication setup as well as for multitier landscapes.

A new schema is created on the primary system for each registered secondary system. This schema follows the naming convention `_SYS_SR_SITE_<siteName>`, where `<siteName>` is the case-sensitive name given at the registration time of the secondary system. This schema contains a selected subset of monitoring views (for example, `M_VOLUME_IO_TOTAL_STATISTICS`), which proxies the statistics from the secondary system. These proxy views have the same column definitions as the equivalently named public synonyms already available for the primary system. When a secondary system is unregistered, the corresponding schema will be dropped.

### Note

If system replication is configured as an Active/Active (read enabled) system with the `logreplay_readaccess` operation mode, then more data is available from the secondary system in the `_SYS_SR_SITE_<siteName>` proxy schema and more monitoring views of the secondary system can be accessed using virtual tables.

Based on these views and tables available in the proxy schema, the statistics server is able to generate alerts on the secondary systems of a system replication landscape. Alerts issued by the secondary systems are displayed in the [Alerts](#) tile of the SAP HANA cockpit.

`SYS_DATABASES_SR_SITE <secondary_site_name>` is a second proxy schema containing proxy views, which can be queried to get information from the corresponding view in the `SYS_DATABASES` schema on the secondary system. These proxy views simplify the monitoring of secondary systems from the primary system.

## Limitations

- Monitoring view access is only possible if the primary and secondary systems run with exactly the same software version; that is, the same build number, for example: 2.00.048.01.1593581573.
- When such a proxy view is queried and the secondary system is not started, no results are shown without the report of an SQL error.
- Querying against multitenant landscapes is limited to single tenant databases or the system database, meaning there are no views unifying all tenants on the system database similar to the SYS\_DATABASES schema.

## Related Information

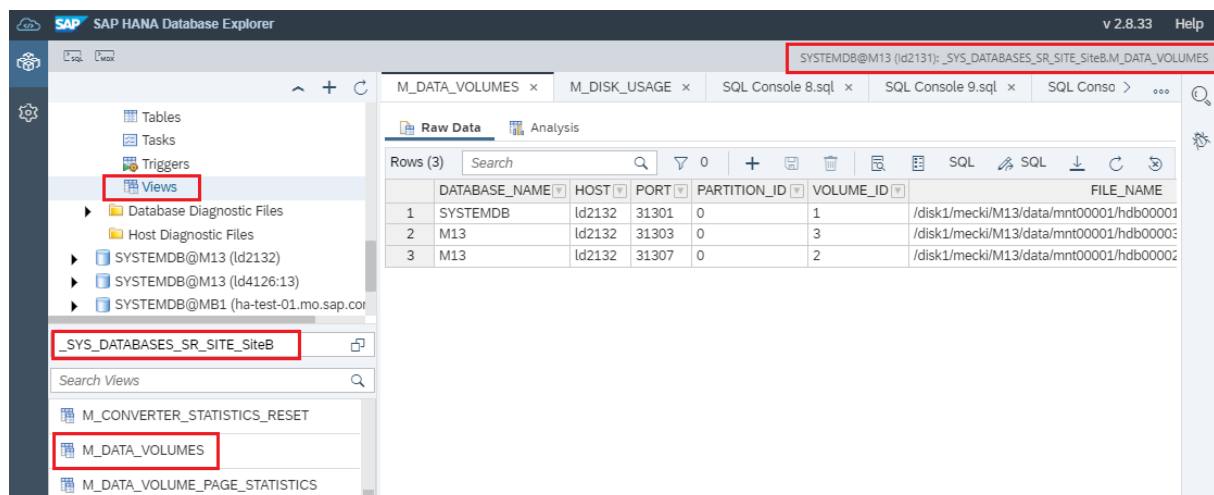

[Alert Details \[page 269\]](#)

[Proxy Schemas and Views \[page 1343\]](#)

### 11.1.2.16.2.1 Proxy Schemas and Views

You can monitor the secondary system through proxy schemas and views.

To see the proxy views of the secondary system's monitoring views, you can use the SAP HANA cockpit. On the system overview page of the primary system, choose *Execute SQL* to open the SAP HANA Database Explorer. Then open the primary's catalog and go to the corresponding schema. This is a schema example:

To see the virtual tables available in the proxy schema of the secondary system, open the proxy schema for the primary system in the SAP HANA Database Explorer for the primary system and choose *Tables*. A long list of accessible monitoring views from the secondary will be available.

## Example

The virtual tables can look as follows:

The screenshot shows the SAP HANA Database Explorer interface. The left sidebar displays a tree view of database objects, with 'Tables' selected and 'M\_DISK\_USAGE' highlighted. The main window shows the 'Raw Data' view of the 'M\_DISK\_USAGE' table. The table has 7 rows and 3 columns: 'HOST', 'USAGE\_TYPE', and 'USED\_SIZE'. The data is as follows:

HOST	USAGE_TYPE	USED_SIZE
ld2132	CATALOG_BACKUP	1154695168
ld2132	DATA	2176319524
ld2132	DATA_BACKUP	-1
ld2132	LOG	7114899492
ld2132	LOG_BACKUP	1154695168
ld2132	ROOTKEY_BACKUP	-1
ld2132	TRACE	250810308

Any of these proxy views or virtual tables can be accessed using SQL from the primary system by providing the correct secondary's schema name. For example:

```
select * from "_SYS_SR_SITE_SiteB"."M_HOST_INFORMATION";
```

### 11.1.2.16.3 Monitoring and Replicating INI File Parameter Changes

INI file parameters should be the same on each site of a system replication landscape and are checked automatically.

The configuration parameter checker reports any differences between primary, secondary, and further secondary systems.

Some parameters may have different settings on the primary and the secondary system on purpose. One example is the `global_allocation_limit` parameter where the secondary is used for other systems. By adding those parameters to the exclusion list below, they are excluded from checking and replication.

Activate ini parameter replication so that changes made on the primary are automatically replicated to the secondary systems. Otherwise, changes should be manually duplicated on the other systems.

The checks of the configuration parameter checker:

- Are done every hour by default.
- Generate alerts.
  - The alerts are visible in the SAP HANA cockpit, SAP HANA studio, and the `M_EVENTS` system view.
  - To view the alerts in the SAP HANA cockpit, look for the alerts tile on the system overview page of the SAP HANA cockpit and choose *Show All*. You can see all alerts including the ones created because of parameter mismatch.
- Are optimized for the most recently changed parameters.

Enable and disable the parameter check on the primary site with `[inifile_checker]/enable = true | false`. The parameter checker is on by default.

Enable and disable the parameter replication on the primary site with `[inifile_checker]/replicate = true | false`. The parameter replication is off by default.

The ini file parameter replication follows these rules:

Parameter set on		
Primary System	Secondary System	Activity
yes	no	Copy parameter to the secondary system.
no	yes	Delete parameter on the secondary system.
set to value x	set to value y	Copy value x to the secondary system.

The parameter changes on the secondary system are applied differently for each parameter:

- Online changeable parameters become active after the `ALTER SYSTEM` command or by editing the `.ini` file followed by the automatically triggered `hdbnsutil -reconfig` command.
- Offline changeable parameters become active after a restart. When changing such a parameter, it is necessary to restart the primary and secondary systems before a takeover. For more information about configuration parameters, see *Configuration Parameter Reference*.

To prevent parameters from generating alerts and eventually getting replicated, it is possible to create exclusions. In the following example, different global allocation limits (GAL) on primary and secondary systems can be set without being overwritten by the parameter replication.

### ❁ Example

If for example you intend to use your secondary system for DEV/QA systems and set the global allocation limit to its minimal value (as described above), you may exclude this `global_allocation_limit` parameter from these checks as follows:

```
[inifile_checker]
enable = true|false
interval = 3600
exclusion_global.ini/SYSTEM = memorymanager/global_allocation_limit
```

The exclusion rules are written in the following syntax (comma separated list) and take effect immediately:

```
exclusion_[inifile name|*][/<LAYER>] = [section with
wildcards|*][/parameter with wildcards|*], ...
<LAYER> := SYSTEM\|HOST\|DATABASE\|\"
```

## 11.1.2.16.4 Monitoring SAP HANA System Replication in SAP HANA Cockpit

To monitor SAP HANA system replication, you can use the [System Replication](#) card in the SAP HANA cockpit.

To open the [System Replication Overview](#) page, with the [Monitoring](#) or [All](#) view selected, click the [System Replication](#) card on the [Database Overview](#) page in the SAP HANA cockpit.

The [System Replication Overview](#) displays a graphical representation of the system replication landscape with the following information:

- The name and role of the system, as well as the selected operation mode  
For the operation modes `logreplay` and `logreplay_readaccess`, a retention time estimation is also displayed. The [Estimated log retention time](#) is an estimation of the time left before the primary system starts to overwrite the `RetainedFree` marked log segments and a full data shipping becomes necessary to get the primary and secondary systems back in sync after a disconnect situation. The [Estimated log full time](#) is an estimation of the time left before the primary system runs into a log full. The value shown in the header shows the situation into which the system could run first: log retention or log full.
- If the SQL ports of the secondary system are open for read access
- The replication mode used between the systems
- The current average redo log shipping time and the average size of shipped redo log buffers

Furthermore, detailed information on system replication is provided in the following tabs:

### i Note

These tabs are displayed only if you configured a system replication before.

Tabs on the System Replication Overview

Tab Name	Description
Graphical Overview	The <a href="#">Graphical Overview</a> tab provides information about each tier.
Related Alerts	The <a href="#">Related Alerts</a> tab provides a description of any existing alerts, as well as their priority. This tab is only displayed when system replication-related alerts are available.
Replicated Services	The <a href="#">Replicated Services</a> tab provides information on the replication status per site and service.
Network	The <a href="#">Network</a> tab provides information on the time it took to ship the redo log to the secondary system and to write the redo log to the local log volume on disk.  You can select the network connection that you want to analyze (for example, <a href="#">Network Site 1 to 2</a> or <a href="#">Network Site 2 to 3</a> ). The graph displayed compares the local write wait time with the remote write wait time monitored over the last 24 hours.
Log Shipping Backlog	The <a href="#">Log Shipping Backlog</a> tab provides a graphical representation on the history of the log shipping backlog.

Tab Name	Description
Log Replay	<p>The <i>Log Replay</i> tab provides a graphical representation on the delay of the secondary system. This tab is displayed if the chosen operation mode for the system replication landscape is <code>logreplay</code> or <code>logreplay_readaccess</code>.</p> <p>When this tab is activated for a secondary system the log replay delay is initially shown for the last 24 hours but a longer time period can be selected from a list.</p> <p>Furthermore, in this tab you can select to visualize the estimated log retention time as well as the estimated log full time for all system replication relevant services.</p>
Network Speed Check	<p>The <i>Network Speed Check</i> tab provides a way to measure the network speed of the system replication host-to-host network channel mappings.</p>
Time Travel	<p>The <i>Time Travel</i> tab provides an overview of the available snapshots, as well as the possibility to start a secondary time travel. This tab is only displayed on the overview of the secondary system.</p>
Takeover History	<p>The <i>Takeover History</i> tab provides an overview of the entire takeover and time travel history available.</p>
Parameter Settings	<p>The <i>Network Security Settings</i> option displays the specific network security details configured between the primary and the secondary systems.</p> <p>The <i>Invisible Takeover</i> option provides the possibility to turn on the invisible takeover. Differently from a standard takeover, an invisible takeover ensures that the client reconnects to the primary system and the sessions are restored to the secondary system.</p>

## 11.1.2.16.5 Monitoring SAP HANA System Replication with hdbnsutil

You can monitor SAP HANA system replication using `hdbnsutil`.

### Standard System Replication

To view the status of the system replication topology configuration on both systems, execute `hdbnsutil -sr_state` on the primary and the secondary:

```
tedadm@ld2131:/usr/sap/TED/HDB07> hdbnsutil -sr_state
checking for active or inactive nameserver ...
System Replication State
~~~~~
mode: primary
site id: 1
site name: SITEA
Host Mappings:
~~~~~
ld2131 ->
```

```
[SITEA] ld2131
ld2131 ->
[SITEB] ld2132
done.
```

## Multitier System Replication

For a multitier system replication the mappings of all three systems are displayed:

```
utladm@ld2131:/usr/sap/UT1/HDB01> hdbnsutil -sr_state
checking for active or inactive nameserver ...
System Replication State
~~~~~
mode: primary
site id: 1
site name: SITEA
Host Mappings:
~~~~~
ld2131 ->[SITEA] ld2131
ld2131 ->[SITEC] ld2133
ld2131 ->[SITEB] ld2132
done.
```

When using the additional option `--sapcontrol=1`, the key value pair output can be parsed by a script line by line.

Here is the output where the `-sr_state` command was executed on a primary system of a multitier system replication:

```
utladm@ld2131:/usr/sap/UT1/HDB01> hdbnsutil -sr_state --sapcontrol=1
checking for active or inactive nameserver ...
SAPCONTROL-OK: <begin>
mode=primary
site id=1
site name=SITEA
mapping/ld2131=SITEA/ld2131
mapping/ld2131=SITEC/ld2133
mapping/ld2131=SITEB/ld2132
SAPCONTROL-OK: <end>
Done
```

Here is the output where the `-sr_state` command was executed on a tier 2 secondary site of a multitier system replication:

```
utladm@ld2132:/usr/sap/UT1/HDB01> hdbnsutil -sr_state --sapcontrol=1
checking for active or inactive nameserver ...
SAPCONTROL-OK: <begin>
mode=sync
site id=2
site name=SITEB
active primary site=1
mapping/ld2132=SITEA/ld2131
mapping/ld2132=SiteC/ld2133
mapping/ld2132=SITEB/ld2132
primary masters=ld2131
SAPCONTROL-OK: <end>
done.
```

## Output Reference

Output	Description
Mode	Can have the values <code>primary</code> , <code>sync</code> , <code>async</code> , and <code>syncmem</code> to represent the mode relevant on the system where the command is executed.  For example, in a multitier system replication on the primary the mode would be <code>primary</code> , on the tier 2 secondary it could be either <code>sync</code> or <code>syncmem</code> , and on the tier 3 secondary it is <code>async</code> .
Site ID	A unique identifier of a system which is incremented for each system attached to a SAP HANA system replication. It is removed, when system replication is disabled.
Site Name	The name you give your systems during the enable and register steps of the system replication configuration.
Mapping/<currentHost>	Shows which hosts are involved in this SAP HANA system replication together with their system name. If the SAP HANA database is offline, this host mapping cannot be shown on the secondaries.
Active primary site	Shows the system ID of the currently active system.
Primary masters	Shows the host names of the currently active master candidates of the primary.

### i Note

When running `hdbnsutil -sr_state` on an offline SAP HANA, no host mapping will be available. For more information, see [SAP Note 2315257](#).

## Related Information

[SAP Note 2315257](#)

### 11.1.2.16.6 Monitoring SAP HANA System Replication with the SAP HANA Studio

You can monitor SAP HANA system replication using the SAP HANA studio.

You can monitor system replication in the administration editor of the primary system as follows:

- The general status is displayed on the [Overview](#) tab.  
This should be *All services are active and in sync*.
- Detailed information is available on the [Landscape](#) > [System Replication](#) tab.  
Here you can see the system replication status. For all services, the `REPLICATION_STATUS` should be `ACTIVE`. Detailed information about shipped sizes and shipping times are also available.  
Since the secondary instance does not accept SQL connections while data replication is active, basic information about the secondary system is also shown.

For more information about the meaning of the individual fields, see the `M_SERVICE_REPLICATION` system view. For more information on the system replication status, see *Checking the System Replication Status*.

## Related Information

[Checking the SAP HANA System Replication Status](#)

### 11.1.2.16.7 SAP HANA System Replication Details

Detailed information from the `M_SERVICE_REPLICATION` and the `M_SYSTEM_REPLICATION` monitoring views about system replication.

General Overview

Column	Description
Site ID 1	Generated ID of the primary site
Secondary Site ID 2	Generated ID of the secondary site
Service	Name of the service
Volume ID	Persistence volume ID
Operation Mode	<ul style="list-style-type: none"> <li>LOGREPLAY</li> <li>LOGREPLAY_READACCESS</li> <li>DELTA DATA SHIPPING</li> </ul>
Replication Mode	Configured replication mode: <ul style="list-style-type: none"> <li>SYNC: synchronous replication with acknowledgment when buffer has been written to disk on the secondary system</li> <li>SYNCMEM: synchronous replication with acknowledgment when buffer arrived in memory on the secondary system</li> <li>ASYNC: asynchronous replication where the primary doesn't wait for the acknowledgment</li> <li>UNKNOWN: is set if replication mode can't be determined (for example, if there are communication errors when getting status information from a service).</li> </ul>

Column	Description
Replication Status	<p>Current status of replication:</p> <ul style="list-style-type: none"> <li>UNKNOWN: secondary didn't connect to primary since last restart of the primary</li> <li>INITIALIZING: initial data transfer is running. In this state, the secondary is first usable when this is finished</li> <li>SYNCING: secondary is syncing again (for example, after a temporary connection loss or restart of the secondary)</li> <li>ACTIVE: initialization or sync with primary is complete and secondary is continuously replicating. If crash occurs, no data loss occurs in SYNC replication mode.</li> <li>ERROR: replication can't take place because the secondary system isn't accessible (details can be found in Replication Details)</li> </ul>
Replication Details	Additional information for Replication Status, for example, the error text if status is ERROR.
Full Sync	<p>Indicates if the service is currently operating in sync replication mode with the full sync option set.</p> <p>If full sync is enabled in a running system, full sync might not be active immediately. This is done to prevent the system from blocking transactions immediately when setting the parameter to true. Instead, in a first step, full sync has to be enabled. In a second step, it's internally activated when the secondary is connected and becomes ACTIVE.</p> <ul style="list-style-type: none"> <li>DISABLED: full sync isn't configured at all</li> <li>ENABLED: full sync is configured, but it isn't yet active, so transactions don't block in this state. To become active, the secondary has to connect and Replication Status has to be ACTIVE.</li> <li>ACTIVE: full sync mode is configured and active. If a connection of a connected secondary is getting closed, transactions on the primary side block in this state.</li> </ul> <p>If full sync is enabled when an active secondary is currently connected, the FULL_SYNC is immediately set to ACTIVE.</p>
Secondary Fully Recoverable	<p>TRUE: No full data backup is needed after takeover on secondary. Backups created on the primary and local log segments enable a full database recovery.</p> <p>FALSE: Log segments needed for a full database recovery are missing. After takeover, a full data backup has to be executed before a full recovery up to the most recent time point can be executed.</p>
Secondary Active	Status of the secondary node (also see ACTIVE_STATUS in M_SERVICES)
Secondary Connect Time	Timestamp the secondary connected to the primary. If there are reconnects from the secondary side, this field contains the last connect time.
Secondary Reconnect Count	Number of reconnects from secondary side for this service.

Column	Description
Secondary Failover Count	Number of failovers for this service on secondary side.
Buffer Full count	Number of times, the asynchronous replication buffer was full since last service restart (only relevant for replication mode async; 0 for replication modes sync/syncmem).

#### Log Positions

Column	Description
Last Log Position	Last known log position on primary
Last Log Position Time	Timestamp of last known log position
Replayed Log Position	Log end position of the last known replayed log buffer on secondary site
Replayed Log Position Time	Timestamp of the last known replayed log buffer on the secondary site
Last Shipped Log Position Time	Timestamp of last log position being shipped to secondary
Shipped Log Buffer Count	Number of log buffers shipped to secondary
Shipped Log Buffers Total Size (Bytes)	Size of all log buffers shipped to secondary
Shipped Log Buffers Total Time (µs)	Time taken to ship all the log buffers to the secondary. <ul style="list-style-type: none"> <li>• SYNC/SYNCMEM: total round-trip time to send the log buffers and receive the acknowledgment.</li> <li>• ASYNC: start time when sending the log buffers, and end time when the OS reports that the log buffers were sent (and the log shipping buffer space was freed). This time could be shorter than the SYNC/SYNCMEM duration</li> </ul>
Time delay (ms)	Time delay between the last shipped log position time and the replayed log position time on the secondary
Size delay (Bytes)	Size delay between the last shipped log position size and the replayed log position size on the secondary (1 log position = 64 bytes)

#### Savepoints

Column	Description
Last Savepoint Version	Last savepoint version on primary
Last Savepoint Log Position	Log position of current savepoint
Last Savepoint Start Time	Timestamp of current savepoint
Last Shipped Savepoint Version	Last savepoint version shipped to secondary
Last Shipped Savepoint Log Position	Log position of last shipped savepoint
Last Shipped Savepoint Time	Timestamp of last shipped savepoint

#### Full Data Replica

Column	Description
Full Data Replica Shipped Count	Number of full data replicas shipped to secondary
Full Data Replica Shipped Total Size (Bytes)	Total size of all full data replica shipped to secondary
Full Data Replica Shipping Total Time (µs)	Duration for shipping all full data replica
Last Full Data Replica Shipped Size (Bytes)	Size of last full data replica shipped to secondary
Start Time of Last Full Data Replica	Start time of last full data replica
End Time of Last Full Data Replica	End time of last full data replica

#### Delta Data Replica

This information is only displayed if the operation mode is `delta_datashipping`.

Column	Description
Delta Data Replica Shipped Count	Number of delta data replicas shipped to secondary
Delta Data Replica Shipped Total Size (Bytes)	Total size of all delta data replicas shipped to secondary
Delta Data Replica Shipped Total Time (µs)	Duration for shipping of all delta data replicas
Size of Last Delta Data Replica (Bytes)	Size of last delta data replica
Start Time of Last Delta Data Replica	Start time of last data delta replica
End Time of Last Delta Data Replica	End time of last data delta replica

#### Log Shipping Backlog

Column	Description
Current Replication Backlog Size (Bytes)	<p>Current replication backlog in bytes. The size of all log buffers that have been created on primary site, but not yet sent to the secondary site.</p> <p>Even in replication modes <code>sync/syncmem</code> this column can have a value different from 0.</p> <p>Here it represents the size of log buffers that are in the local send queue (max number of those buffers is the number configured log buffers on primary site).</p>
Max Replication Backlog Size (Bytes)	Max replication backlog in bytes (max value of <code>BACKLOG_SIZE</code> since system start).
Current Replication Backlog Time (µs)	<p>Current replication backlog in microseconds. This time is the difference between time of the last sent log buffer and the current log buffer.</p> <p>Even in replication modes <code>sync/syncmem</code> this column can have a value different from 0, because log buffers are still in the send queue (max number of these buffers is the number of log buffers configured on primary site).</p>
Max Replication Backlog Time (µs)	Max replication backlog in microseconds (max value of <code>BACKLOG_TIME</code> since system startup).

#### Log Replay

This information is only displayed if the operation mode is `logreplay` and `logreplay_readaccess`.

Column	Description
Replay Backlog Size (Bytes)	Specifies the size of all log buffers that have been shipped to the secondary site but haven't yet been replayed on the secondary site.
Max Replay Backlog Size (Bytes)	Specifies the maximum value of the REPLAY_BACKLOG_SIZE since the system startup.
Replay Backlog Time (µs)	Specifies the time difference between the time of the last shipped log buffer and the last replayed log buffer on the secondary site.
Max Replay Backlog Time (µs)	Specifies the maximum value of REPLAY_BACKLOG_TIME since the system startup.

## Related Information

[SQL and System View Reference](#)

### 11.1.2.17 Host Name Resolution for System Replication

The correct mapping of internal host names between primary and secondary systems is required for system replication.

With SAP HANA system replication, each SAP HANA instance communicates on the service level with a corresponding peer in the secondary system to persist the same data and logs as in the primary system. The replication of the transactional load can be configured to work in synchronous or asynchronous mode, depending mainly on the distance between the two sites.

Communication between the primary and the secondary system is based on internal ('virtual') host names. The host names of the other site must always be resolvable, either through configuration in SAP HANA or corresponding entries in the `/etc/hosts` file.

For system replication it is not necessary to edit the `/etc/hosts` file, internal host names must be mapped to IP addresses in the `global.ini` file to create a dedicated network for system replication. This is necessary to ensure that each site can resolve the host name of other replicating sites and that hosts can be switched seamlessly in the event of a takeover. These virtual host names must be set before registering the secondary system because the `-sr_register` command uses this mapping. Mappings are maintained in the `[system_replication_hostname_resolution]` section:

```
global.ini
[system_replication_hostname_resolution]
<ip-address_site>=<internal-host-name_site>
<...>
```

Virtual host names can also be used if the hostnames have a domain suffix, for example: the internal hostnames can be defined as `ab820*` and `ab830*`, but the public names have to include the domain, such as `ab820*.abc.xyz.com` and `ab830*.def.xyz.com`

### ⚠ Caution

Note that by default no mappings are specified and system replication communication uses the default network route (typically the public network). If you use a public network instead of a separate network, you **must** secure this connection with additional measures such as a firewall or a virtual private network and/or TLS/SSL.

The mappings are used in combination with the `listeninterface` parameter in the `[system_replication_communication]` section which in a replication scenario can be set to either `.global` or `.internal`. The following table shows two settings of the `listeninterface` parameter and the scope of the corresponding mapped host names. These are both illustrated in the following graphics showing a multi-node replication environment with a separate internal network for replication.

Another `listeninterface` parameter in the `[communication]` section is used for the communication between SAP HANA services (name server, index server, and so on) in a distributed system, but it has no impact on system replication.

<code>listeninterface</code>	Host Name Resolution Mappings	Additional Information
<code>.global</code>	IP addresses and host names of neighboring sites (minimum) or for all hosts of own site as well as for all hosts of neighboring sites. Also applies to multi-tier setups.	This establishes a separate network for system replication communication.  → Tip Also for multitier and multitarget setups, this is how you can use a dedicated network for system replication communication.
<code>.internal</code>	Entries for all hosts of own site as well as for all hosts of neighboring sites	A separate network is used for system replication communication. The primary hosts listen on the dedicated ports of the separate network only, and incoming requests on the public interfaces are rejected.  ⚠ Caution As of SAP HANA 1.0 SPS 11, network communication for system replication with <code>listeninterface=.internal</code> is supported for two-tier replication but <b>not for multitier and multitarget setups</b> .

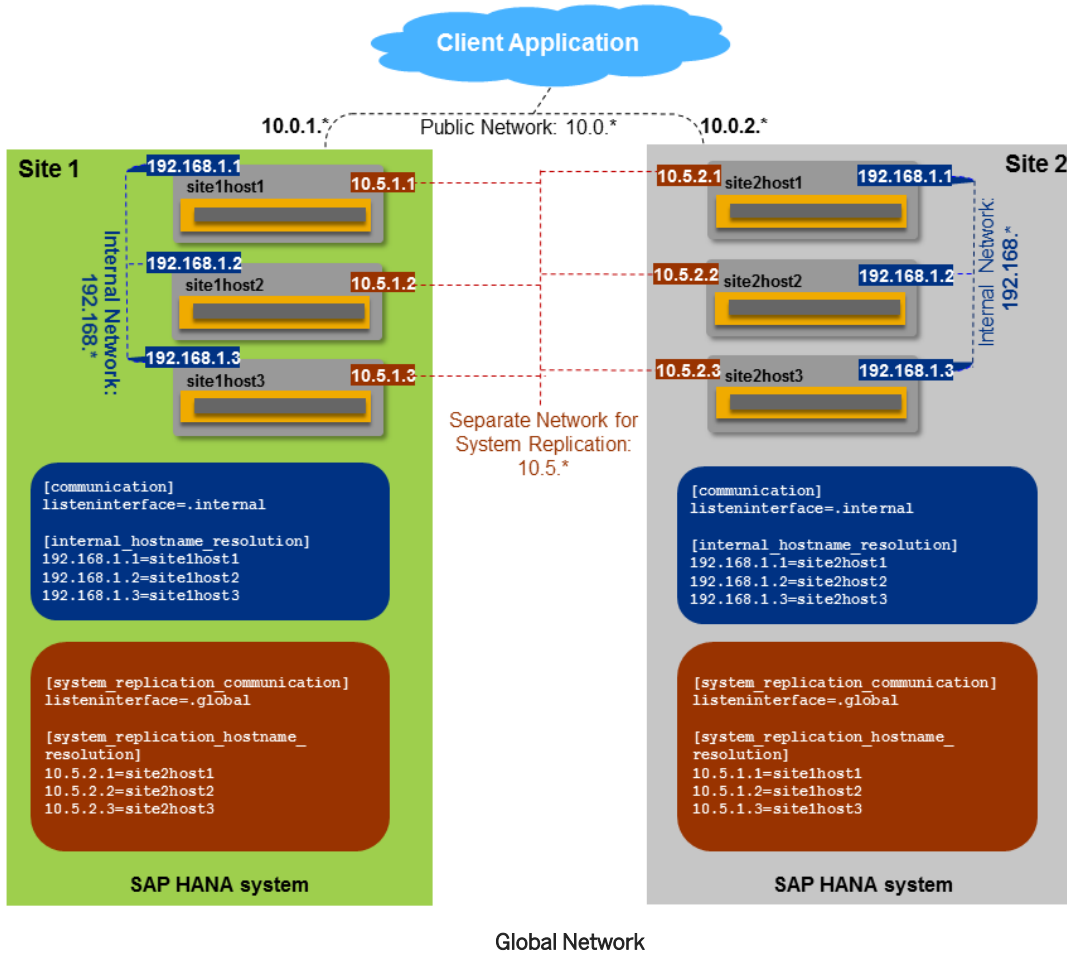

## Examples

The following examples show the host name resolution configuration for system replication to a secondary site. Three distinct networks can be identified:

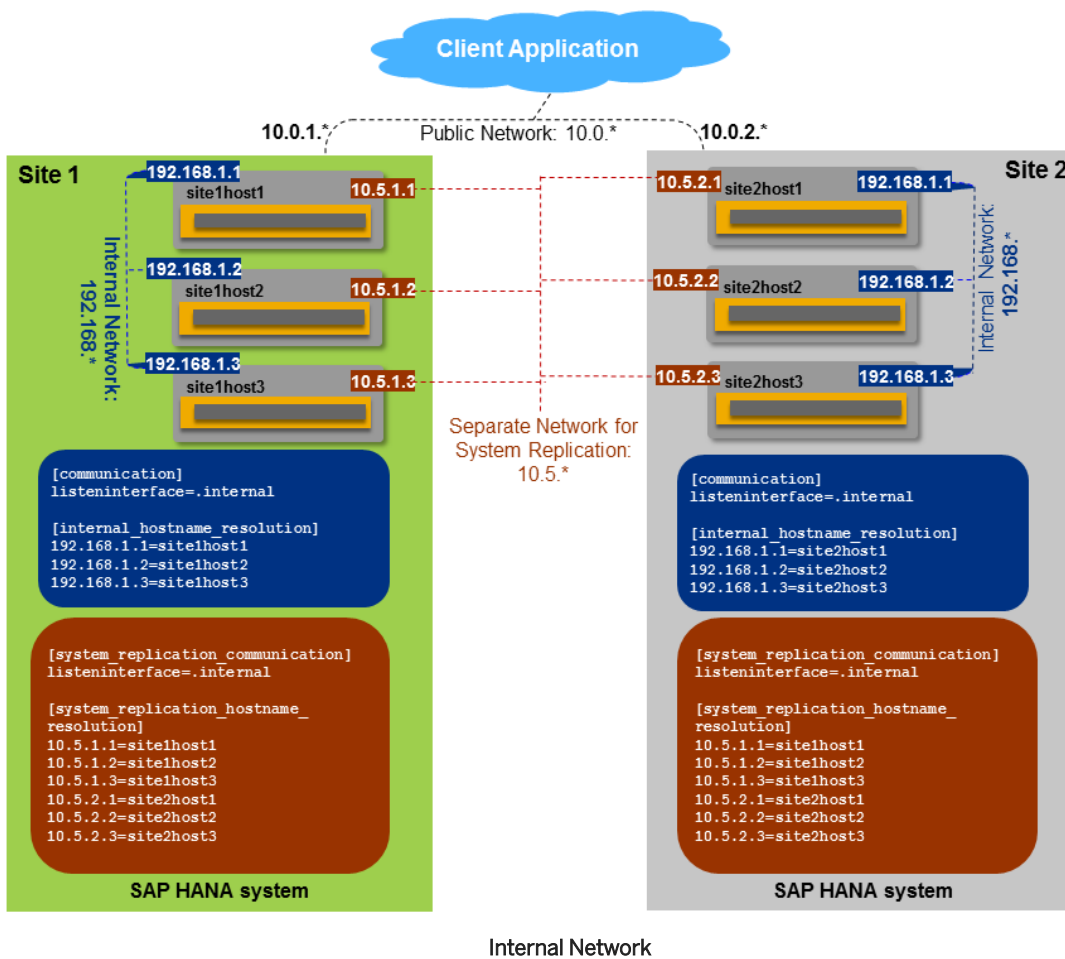

- Public network with addresses in the range of 10.0.1.\*
- Network for internal SAP HANA communication between hosts at each site: 192.168.1.\*

- Dedicated network for system replication: 10.5.1.\*

In the first example, the `[system_replication_communication]listeninterface` parameter has been set to `.global` and only the hosts of the neighboring replicating site are specified.

In the following example, the `[system_replication_communication]listeninterface` parameter has been set to `.internal` and all hosts (of both sites) are specified.

## Important Security Information

If you use a public network instead of a separate internal network and/or the parameter `listeninterface=.global`, you **must** secure this connection with additional measures such as a firewall or a virtual private network and/or TLS/SSL.

If no separate internal network channel is configured for SAP HANA system replication, the `allowed_sender` parameter can be used to restrict communication between the primary and secondary sites to certain hosts. For this purpose, the following settings are made in the `global.ini` file on the primary site:

```
global.ini
[system_replication_communication]
allowed_sender=<comma-separated list of IP-addresses of secondary or CIDR-
netmasks>
```

An example of this parameter value would be `10.0.1.0/30`. The default is no restriction.

## Further Information

For more security-related information, see the *SAP HANA Security Guide* and *SAP HANA Security Checklists and Recommendations*.

An SAP Community blog *How to configure HANA network communication channels – Part 2: Internal network* gives further details of these features.

The original white paper describing system replication provides further background information: *Introduction to High Availability for SAP HANA*.

## 11.1.2.18 Updating SAP HANA Systems with SAP HANA System Replication

You can update your SAP HANA systems running in a SAP HANA system replication.

If for some reason you have to stop and restart the primary or the secondary, once the systems are available they will automatically try to get in sync again. There are no manual steps necessary.

If the system is running with `logreplay` or `logreplay_readaccess`, see *Resync Optimization* to prevent your system from running full or having to do a full data shipping. This can happen when the time during which the primary could not replicate gets too long. An optimized resync with delta data or log shipping can be achieved avoiding a full data shipping, depending on the the time the upgrade is taking and the settings of the `logshipping_max_retention_size` and `datashipping_snapshot_max_retention_time` parameters.

You must update your SAP HANA systems running in a system replication setup by updating the secondary system first and then updating the primary system. For more information, see *Update an SAP HANA System Running in a System Replication Setup*.

The secondary system can run with a higher software version than the primary system. For more information, see *Use SAP HANA System Replication for Near Zero Downtime Upgrades*.

### Note

System Replication with SAP HANA 2.0 requires authentication for data and log shipping channels. The authentication is done using the certificates in the system PKI SSFS store. Thus, there is an additional manual setup step required to exchange certificates in the system PKI SSFS store between the primary and

the secondary system when upgrading from SAP HANA 1.0 to SAP HANA 2.0. For more information, see [SAP Note 2369981](#).

Hardware can also be exchanged with a minimal downtime using SAP HANA system replication. For more information, see [SAP Note 1984882: Using HANA system replication for Hardware Exchange with Minimum Downtime](#).

[SAP Note 1984882](#)

### 11.1.2.18.1 Configure a User Under the SRTAKEOVER Key

In preparation for maintenance tasks, you must configure a user in the local userstore under the SRTAKEOVER key.

## Context

The SRTAKEOVER user requires the necessary privileges to import the repository content of the new version of the software during the takeover process.

## Procedure

1. As `<sid>adm` configure a user in the local userstore under the SRTAKEOVER key. Use a public host name to access the corresponding SQL port of the System DB (`<SystemDBsqlport>`). Execute this command on the primary and secondary systems:

```
hdbuserstore SET SRTAKEOVER <publichostname>:<SystemDBsqlport> <myrepouser>  
<myrepouser_password>
```

### i Note

This configuration step should be performed only in the system database, not in every single tenant.

2. Create a `<myrepouser>` user with the necessary privileges to import the repository content as follows:

```
CREATE USER MY_REPO_IMPORT_USER PASSWORD MyRepoUserPW123;  
GRANT EXECUTE ON SYS.REPOSITORY_REST TO MY_REPO_IMPORT_USER;  
GRANT REPO.READ ON ".REPO_PACKAGE_ROOT" TO MY_REPO_IMPORT_USER;  
GRANT REPO.IMPORT TO MY_REPO_IMPORT_USER;  
GRANT SELECT ON SYS.REPO.DELIVERY_UNITS TO MY_REPO_IMPORT_USER;  
GRANT REPO.ACTIVATE_IMPORTED_OBJECTS ON ".REPO_PACKAGE_ROOT" TO  
MY_REPO_IMPORT_USER;
```

For example, for public host name "mypublichost" and system number "00", "MY\_REPO\_IMPORT\_USER", and "MyRepoUserPW123" :

```
hdbuserstore SET SRTAKEOVER mypublichost:30013 MY_REPO_IMPORT_USER  
MyRepoUserPW123
```

The host name has to be the public host name of the host on which the command is executed and the port is the SQL port number of the system database.

For more information, see the *Secure User Store (hdbuserstore)* section in the *SAP HANA Security Guide*.

#### Note

In a scale-out configuration, the command has to be executed on all hosts. If the password for the repository import user is changed, the password saved in the userstore also has to be changed.

## Related Information

[Secure User Store \(hdbuserstore\)](#)

## 11.1.2.18.2 Use SAP HANA System Replication for Near Zero Downtime Upgrades

You can use SAP HANA system replication to upgrade your SAP HANA systems as the secondary system can run with a higher software version than the primary system.

### Prerequisites

You configured a user in the local userstore under the SRTAKEOVER key. For more information, see *Configure a User Under the SRTAKEOVER Key*.

System replication is configured and active between two identical SAP HANA systems:

- The primary system is the production system.
- The secondary system will become the production system after the upgrade.

## Context

With system replication active, you can first upgrade the secondary system to a new revision and have it take over in the role of primary system. The takeover is carried out in only a few minutes and committed transactions or data are not lost. You can then do an upgrade on the primary system, which is now in the role of secondary.

### i Note

It is possible to reduce the time required to perform an update. For more information, see *Prepare an Update for Flexible System Downtime* in the *SAP HANA Server Installation and Update Guide*.

The secondary system can be initially installed with the new software version or upgraded to the new software version when the replication has already been configured. After the secondary has been upgraded, all data has to be replicated to the secondary system (already having the new software version). When the secondary system is ACTIVE (all services have synced), a takeover has to be executed on the secondary system. This step makes the secondary system the production system running with the new software version.

If the installed system version on the primary is HANA 2.0 SPS 04 or greater then you are recommended to use the 'takeover with handshake' option to ensure a consistent handover. Using this option the primary continues to run but the writing of transactions on the primary system is suspended. The takeover is only executed when all redo log is available on the secondary system. See step 3 in the following procedure.

If you are upgrading from SAP HANA 1.0 to SAP HANA 2.0 note that system replication with SAP HANA 2.0 requires authentication for data and log shipping channels, this is done using the certificates in the system PKI SSFS store. You must therefore copy the system PKI SSFS key and the data file from the current primary system to the new to-be secondary system. Copy the files before registration when the secondary system is offline; the files can be found here:

```
/usr/sap/<SID>/SYS/global/security/rsecssfs/data/SSFS_<SID>.DAT  
/usr/sap/<SID>/SYS/global/security/rsecssfs/key/SSFS_<SID>.KEY
```

For more information, see *SAP Note 2369981: Required configuration steps for authentication with HANA System Replication*.

In an Active/Active (read enabled) system replication setup, the version of the primary and the secondary systems must be identical. For the near zero downtime upgrade to work, the operation mode on the secondary system is automatically set to `logreplay`. Like this, the two systems can get back in sync before the takeover step. To establish again the Active/Active (read enabled) landscape at the end, the `logreplay_readaccess` operation mode must be explicitly specified during the former registration of the primary system as a new secondary system.

For more information about near zero downtime upgrades when using a multitarget system replication setup, see *Use Multitarget System Replication for Near Zero Downtime Upgrades*.

## Procedure

1. Upgrade the secondary system's SAP HANA server software and all other components.

From your installation directory execute as root:

```
./hdblcm --action=update
```

2. Verify that system replication is active and that all services are in sync.

You can check that the column REPLICATION\_STATUS in M\_SERVICE\_REPLICATION has the value ACTIVE for all services.

3. Depending on the version installed on the primary, perform a takeover by doing one of the following:
  - If the installed system version on the primary is HANA 2.0 SPS 04 or greater then you have the option to use the `--suspendPrimary` parameter for a 'takeover with handshake' which ensures that all redo logs are written to disk. In this case, execute the takeover as `<sid>adm` with the following command:

```
hdbnsutil -sr_takeover --suspendPrimary
```

- If the installed system version on the primary is less than HANA 2.0 SPS 04, then:
  - Stop the primary system.
  - Execute the takeover as `<sid>adm` with the following (default) command:

```
hdbnsutil -sr_takeover
```

You can then switch virtual IP addresses to the secondary system, and start using it productively.

4. If XS Advanced is being updated as well, update the XS Advanced applications.

```
./hdblcm --action=update
```

5. If the primary has not been stopped (takeover with handshake option), you can now stop the primary system.
6. Upgrade the original primary from the installation directory as root user using the 'nostart' option. This option is required because otherwise the primary has to be stopped again before it can be registered as the secondary:

```
./hdblcm --action=update --hdbupd_server_nostart
```

### Note

For a fast synchronization of the sites – after registering again the original primary system – perform this fallback within the time given by the `datashipping_snapshot_max_retention_time` parameter (default 300 minutes), otherwise, a full data shipping will be done. Furthermore, the optimized resync depends on the availability of the last snapshot.

For more information about near zero downtime upgrades in multitier system replication, see *SAP Note 2386973*.

7. Register the original primary as secondary as `<sid>adm`.

```
hdbnsutil -sr_register --name=<secondary_alias>  
--remoteHost=<primary_host> --remoteInstance=<primary_systemnr>  
--replicationMode=[sync|syncmem|async] --operationMode=[delta_datashipping|  
logreplay|logreplay_readaccess]
```

8. Start the original primary.

### 11.1.2.18.2.1 Use Multitarget System Replication for Near Zero Downtime Upgrades

You can upgrade your SAP HANA systems running in a multitarget system replication setup.

#### Prerequisites

Multitarget system replication is configured and active between identical SAP HANA systems.

#### Context

We are using the following setup to exemplify the procedure:

##### Example

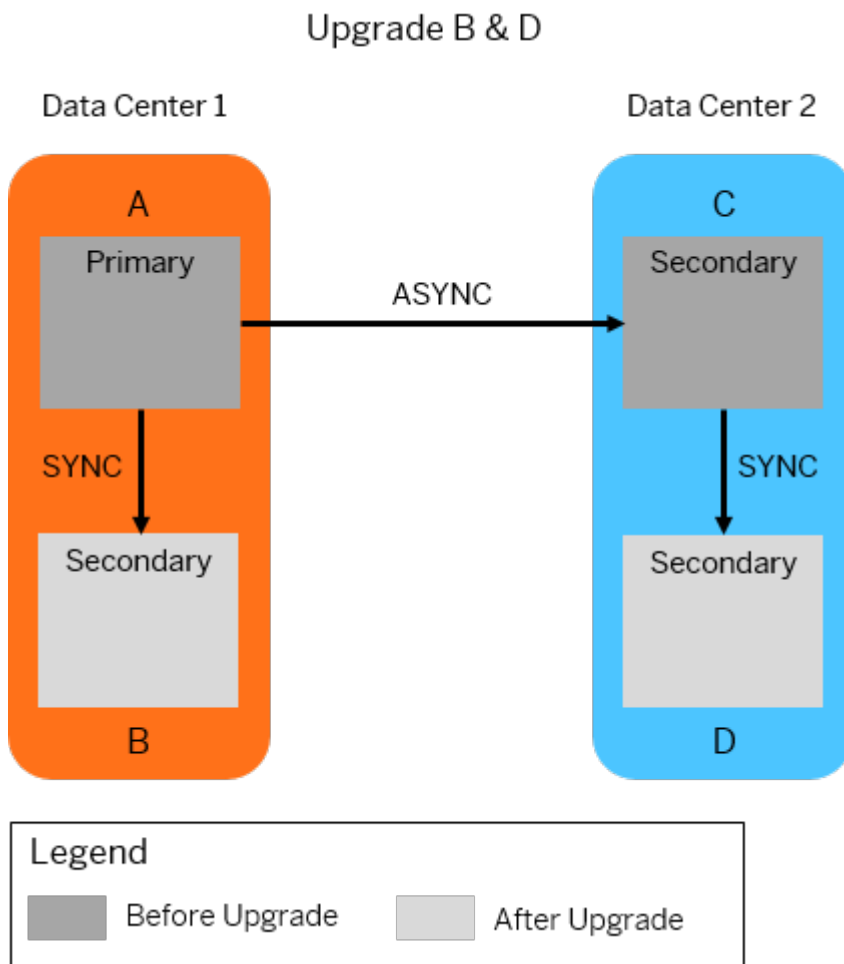

Primary system A replicates data changes to secondary system B located in the same data center. Primary system A also replicates data changes to the secondary system C located in data center 2. Secondary system C is a source system for a further secondary system D located in the same data center with system C.

In this setup:

- The primary system is the production system.
- The secondary system located in the same data center as the primary system will become the production system after the upgrade. Further secondary systems are located in a remote data center.
- There is no replication error.

## Procedure

1. Upgrade secondary system B in data center 1 and secondary system D in data center 2.

2. Register secondary system D in data center 2 to secondary system B in data center 1.

- Upgrade secondary system C in data center 2. Then, register secondary system C to secondary system D in data center 2.

Upgrade C  
Register C → D

4. Take over on secondary system B in data center 1.  
After takeover, secondary system B will be the new primary system.

### Takeover on B

- 5. Upgrade and register the previous primary system A to the new primary system B in data center 1.

## Related Information

### 11.1.2.18.3 Update SAP HANA Systems Running in a System Replication Setup

You can update your SAP HANA system with active system replication by updating the secondary and the primary system one after the other.

## Prerequisites

System replication is configured and active between two SAP HANA systems.

## Context

You must update your SAP HANA system running in a system replication setup by updating the secondary system first and then updating the primary system.

### → Remember

For system replication setups it is required that the secondary system has the same version as the primary system or a higher version. As such, the secondary system must always be updated before the primary system.

### i Note

Updating one system after the other results in some downtime. If you want to update your system with reduced downtime, see *Use SAP HANA System Replication for Near Zero Downtime Upgrades*.

It is possible to reduce the time required to perform an update. For more information, see *Prepare an Update for Flexible System Downtime*.

## Procedure

1. Upgrade the SAP HANA server software and all installed components on the secondary system.

From your installation directory execute as root or as `<sid>adm`:

```
./hdblcm --action=update
```

2. With the secondary system online, use the SAP HANA lifecycle management tools to upgrade all the other components to the same revision as the server software.
3. Verify that system replication is active and that all services are in sync.  
You can check that the REPLICATION\_STATUS column in M\_SERVICE\_REPLICATION has the value ACTIVE for all services.
4. Upgrade the SAP HANA server software and all installed components on the primary system.

From your installation directory, execute as root or as `<sid>adm`:

```
./hdblcm --action=update
```

5. With the primary system online, use the SAP HANA lifecycle management tools to upgrade all other components to the same revision as the server software.
6. Verify that system replication is active and that all services are in sync.

## Related Information

[Use SAP HANA System Replication for Near Zero Downtime Upgrades \[page 1360\]](#)

[Prepare an Update for Flexible System Downtime](#)

## 11.1.2.19 Configure Secure Communication (TLS/SSL) Between Primary and Secondary Sites

Configure TLS/SSL on communication channels between primary and secondary systems using the system public key infrastructure (PKI).

### Prerequisites

- You have the credentials of the operating system user, `<sid>adm`.
- You have the system privilege INIFILE ADMIN.

### Context

The following communication channels between primary and secondary systems can be secured using TLS/SSL:

- Metadata channel used to transmit metadata (for example, topology information) between the sites
- Data channel used to transmit data between the sites.

#### i Note

On SAP HANA systems with dynamic tiering, the following steps also enable the system PKI for internal system replication communication. No additional steps are required. Before you configure communication for dynamic tiering see SAP Note 2447994 - *SAP HANA Dynamic Tiering Support for SAP HANA System Replication*.

Be aware that you need additional licenses for SAP HANA options and capabilities. For more information, see *Important Disclaimer for Features in SAP HANA Platform, Options and Capabilities*.

### Procedure

1. Shut down all systems.

If you want to avoid downtime when enabling TLS/SSL, disable system replication. You can enable or disable TLS/SSL without downtime only if the primary system is not enabled.

2. In the primary and secondary system, enable TLS/SSL for the data channel.

In the `global.ini` file, configure the property `[system_replication_communication] enable_ssl`. The following values are possible:

Value	Description
off (default)	TLS/SSL is disabled for replication source and target systems
on	TLS/SSL is enabled for replication source and target systems

### Note

You must enable SSL for the whole system, that is, in the `global.ini` file of the system database. Setting this feature for single tenant databases is not supported.

For a simple system replication scenario involving two systems, it is sufficient to set the property to `on` in both systems.

For multitier and multitarget system replication scenarios involving three systems, you can apply `on` in all 3 systems to secure all system replication connections. Alternatively, you can use `site_name` as index to secure either only the communication to the tier 3 secondary system or only the communication to the primary system.

### Example

To exclude the communication between the primary and the secondary, and to secure the communication between all other systems, set the parameter as follows:

```

siteA      ----->      siteB      ----->      siteC
  enable_ssl=on              enable_ssl=on
enable_ssl=on
  enable_ssl[siteB]=off      enable_ssl[siteA]=off

```

### Note

To avoid communication failure between systems, TLS/SSL must be enabled on all systems at the same time. TLS/SSL won't be used unless the secondary system reconnects with the primary. To do this either restart the primary and secondary systems, or re-setup system replication .

3. As `<sid>adm`, restart the `sapstartsrv` service on the secondary system(s):
  - a. `sapcontrol -nr <instance_no> -function StopService`
  - b. `/usr/sap/<sid>/HDB<instance_no>/exe/sapstartsrv pf=/usr/sap/<sid>/SYS/profile/<sid>_HDB<instance_no>_<host> -D -u <sid>adm`
4. Restart all systems.

## Related Information

## 11.1.3 Setting Up Host Auto-Failover

Host auto-failover is a local fault-recovery solution that can be used as a supplemental or alternative measure to system replication. One (or more) standby hosts are added to an SAP HANA system, and configured to work in standby mode.

The databases on the standby hosts do not contain any data and do not accept requests or queries as long as they are in standby mode.

When an active worker host fails, a standby host automatically takes its place. Since the standby host may take over operation from any of the primary hosts, it needs access to all the database volumes. This can be accomplished by a shared networked storage server, by using a distributed file system, or with vendor-specific solutions that can dynamically mount networked storage upon failover.

For more information about how to add an additional standby host, see *Adding Hosts to an SAP HANA System*.

You can monitor the status of all active and standby hosts in the SAP HANA cockpit and the SAP HANA studio.

A HA/DR provider script is available to provide hooks that can be called in response to events during host auto-failover. For more information, see *Implementing a HA/DR Provider*.

### Related Information

[Implementing a HA/DR Provider \[page 1380\]](#)

[SAP HANA Host Auto-Failover !\[\]\(626ce8ac21792b9405bfddfea8e0c96a\_img.jpg\)](#)

[SAP HANA Storage Requirements !\[\]\(a8f9309f944226d1420f5fed22e2b6e6\_img.jpg\)](#)

### 11.1.3.1 Configuring Clients for Failover

You can configure failover support for clients so that they continue to work in a transparent way to the user in the event of a failover.

SAP HANA clients that were configured to reach the original host need to be sent to the standby host after host auto-failover.

One way to handle this is using a network-based (IP or DNS) approach. Alternatively, SQL/MDX database clients can be configured with the connection information of multiple hosts, optionally including the standby host, by providing a list of hosts in the connection string. The client connection code uses a "round-robin" approach to reconnect, thus ensuring that the client can reach the SAP HANA database, even after failover.

To support failover with client libraries, you have to specify a list of host names separated by a semicolon instead of a single host name. Only hosts that have the role master or standby should be used.

To determine which hosts to use, execute the following SQL statement:

```
SELECT HOST FROM M_LANDSCAPE_HOST_CONFIGURATION WHERE NAMESERVER_CONFIG_ROLE LIKE 'MASTER%' ORDER BY NAMESERVER_CONFIG_ROLE
```

Since one of these master candidates will be active, only they have to be added. When hosts are added to a system, the master list is extended to three hosts, meaning there is one host configured as the actual master and two worker hosts are configured as master candidates. When the first standby host is added to the system, a worker host is removed from this list and replaced by the standby host. This is done because it is faster to fail over to an idle standby host than to an active worker host.

The client will choose one of these hosts to connect to. If a host is not available, the next host from the list will be used. Only in the case that none of the hosts are available will you get a connection error.

If a connection gets lost when a host is not available any longer, the client will reconnect to one of the host specified in the host list.

#### Example Configurations

Client	Example
JDBC	<pre>Connect URL: jdbc:sap://host1:30015;host2:30015;host3:30015/</pre>
SQLDBC	<pre>SQLDBC_Connection *conn = env.createConnection(); SQLDBC_Retcode rc = conn-&gt;connect ("host1:30015;host2:30015;host3:30015", "", "user", "password");</pre>
ODBC	<pre>Connect URL: "DRIVER=HDBODBC32; UID=user; PWD=password; SERVERNODE=host1:30015,host2:30015,host3:30015";</pre>

## HTTP Client Access via SAP HANA Extended Application Services, Classic Model

To support HTTP (Web) clients accessing SAP HANA via the SAP HANA XS classic server, it is recommended to install an external, itself fault protected, HTTP load balancer (HLB), such as SAP Web Dispatcher, or a similar product from another vendor. The HLBs are configured to monitor the Web servers on all hosts on all sites. For more information see, *Configuring HTTP Load Balancing for SAP HANA Extended Application Services (XS)*.

If an SAP HANA instance fails, the HLB, which serves as a reverse web-proxy, redirects the HTTP clients to the running SAP HANA XS instance on an active host. HTTP clients are configured to use the IP address of the HLB itself, which is obtained via DNS, and remain unaware of any SAP HANA failover activity.

## Related Information

[Client Connection Recovery After Takeover \[page 1288\]](#)

### 11.1.3.2 Configuring Application Servers for Failover

You can configure failover support for application servers by using the secure user store of the SAP HANA client (`hdbuserstore`) to specify a list of host names that the server can connect to.

For the clients in a host auto-failover landscape, the use of virtual IP addresses is recommended. You can store user logon information, including passwords, in the secure user store of the SAP HANA client (`hdbuserstore`). This allows client programs to connect to the database without having to enter a password explicitly.

The `hdbuserstore` can also be used to configure failover support for application servers (for example, for SAP Business Warehouse) by storing a list of all (virtual) host names to which the application server can connect. All nodes that are master candidates must be added to the `hdbuserstore`.

#### → Tip

For more information about how to find out the three master candidates in a distributed system, see SAP Note 1930853.

The application server will choose one of these hosts to connect to from the list. If a host is not available, the next host from the list will be used. Only if none of the hosts are available will you get a connection error. If a connection gets lost when a host is no longer available, the application server will reconnect to one of the hosts specified in the host list.

You can specify a list of host names in the secure user store using the following `hdbuserstore`:

```
hdbuserstore SET default "<hostname_node1>:3<system_number>15; .... <hostname_node(n)>: 3<system_number>15" SAP<sid> <Password>
```

#### ≡ Sample Code

```
hdbuserstore SET default  
"1d9490:33315;1d9491:33315;1d9492:33315;1d9493:33315" SAPP20 <password>
```

KEY default

```
ENV : 1d9490:33315;1d9491:33315;1d9492:33315;1d9493:33315  
USER: SAPP20
```

For more information about `hdbuserstore`, see the *SAP HANA Security Guide*

## Related Information

[SAP Note SAP Note 1930853](#)

### 11.1.3.3 Configure HTTP Load Balancing for SAP HANA Extended Application Services, Classic Model

To enable load balancing for HTTP access to the SAP HANA XS classic sever, you need to set up a load balancer (for example, SAP Web Dispatcher).

#### Context

To support HTTP (Web) clients accessing SAP HANA via the SAP HANA XS classic server, it is recommended to install an external, itself fault protected, HTTP load balancer (HLB), such as SAP Web Dispatcher, or a similar product from another vendor. The HLBs are configured to monitor the Web servers on all hosts on all sites.

The SAP Web Dispatcher automatically reads the system topology from SAP HANA XS classic and is notified of changes to the topology, for example, when a host is no longer available or a standby host has taken over. The SAP Web Dispatcher then sends requests to a running XS instance on an active host. Third-party load balancers often use a static configuration with an additional server availability check.

The SAP Web Dispatcher can be configured with a list of the three master hosts. Once one of the master hosts is available the SAP Web Dispatcher acquires the topology information. HTTP clients can be configured to use the IP address of the HTTP load balancer itself, and remain unaware of any SAP HANA failover activity.

#### i Note

For more information about using and configuring the SAP Web Dispatcher for load balancing with SAP HANA multitenant database containers, see *Using SAP Web Dispatcher for Load Balancing with Tenant Databases*.

#### Procedure

1. Install SAP Web Dispatcher with a minimum release of 7.40 using the SAP NetWeaver Software Delivery Tool and update it to the latest version available on the SAP Software Download Center.
2. Log on to the SAP Web Dispatcher host as the <SID>adm user. Here the <SID> refers to the one of the SAP Web Dispatcher installation.
3. Open the instance profile of your SAP Web Dispatcher.

The SAP Web Dispatcher profile can be found in the following location:

```
usr/sap/<SID>/SYS/profile
```

4. Disable the ABAP system configuration, which is done automatically during the installation by commenting out the entries in this section of the profile:

```
# Accessibility of Message Servers
```

```
-----  
#rdisp/mshost = ldcialx  
#ms/http_port = 8110
```

5. Add a list of semicolon separated URLs and the base URL (without path) used for fetching topology information, to the XSSRV parameter in the profile.

An example could be:

```
wdisp/system_0 = SID=HDX, XSSRV=http://ld9490:8089;http://ld9491:8089,  
SRCSRV=*
```

## 11.1.3.4 Host Auto-Failover Parameters

This topic provides an overview of parameters available for Host Auto-Failover.

### Master Failover without Standby Hosts

Distributed landscapes without standby hosts may also perform a failover to ensure that the master host is always available.

<b>Parameter</b>	<code>nameserver.ini/[failover]/enable_master_failover</code>
------------------	---

---

<b>Description:</b>	When set to false, the masterize check of the nameserver master candidates is disabled. Furthermore, adding a new host does not modify the master candidates list.
---------------------	--

---

<b>Online</b>	Yes
---------------	-----

<b>Change:</b>	
----------------	--

---

<b>Default:</b>	True
-----------------	------

---

### Failover Groups

During installation a failover group can be configured per host. If a failover target host is available in the same group, it will be preferred over hosts from other groups. This can be used to achieve better "locality" in large

systems (for example, to use network or storage connection with less latency). It can also be used to separate differently sized hardware or storages.

**Parameter** `nameserver.ini/[failover]/cross_failover_group`

---

Description: When set to false, failover is restricted to the hosts in the same group.

---

Online Yes

Change:

---

Default: False

---

## Automatic Host Shutdown by Service Failures

For every service a fixed number of restarts can be defined after which the daemon stops. The nameserver is the only service that has the first parameter set to true as default. This means that any problem involving a constant nameserver crash will eventually stop the daemon.

**Parameter** `daemon.ini/[failover]/startup_error_shutdown_instance`

---

Description: When set to true, the daemon will shut down all services on the host if this service cannot start.

---

Online Yes

Change:

---

Default: True

---

**Parameter** `daemon.ini/[failover]/startup_error_restart_retries`

---

Description: The number of retries if a service fails in the startup procedure.

---

Online Yes

Change:

---

Default: 4

---

### 11.1.3.5 Host Auto-Failover Setup with XS Advanced Run Time

Understand the host auto-failover setup for the XS advanced run time.

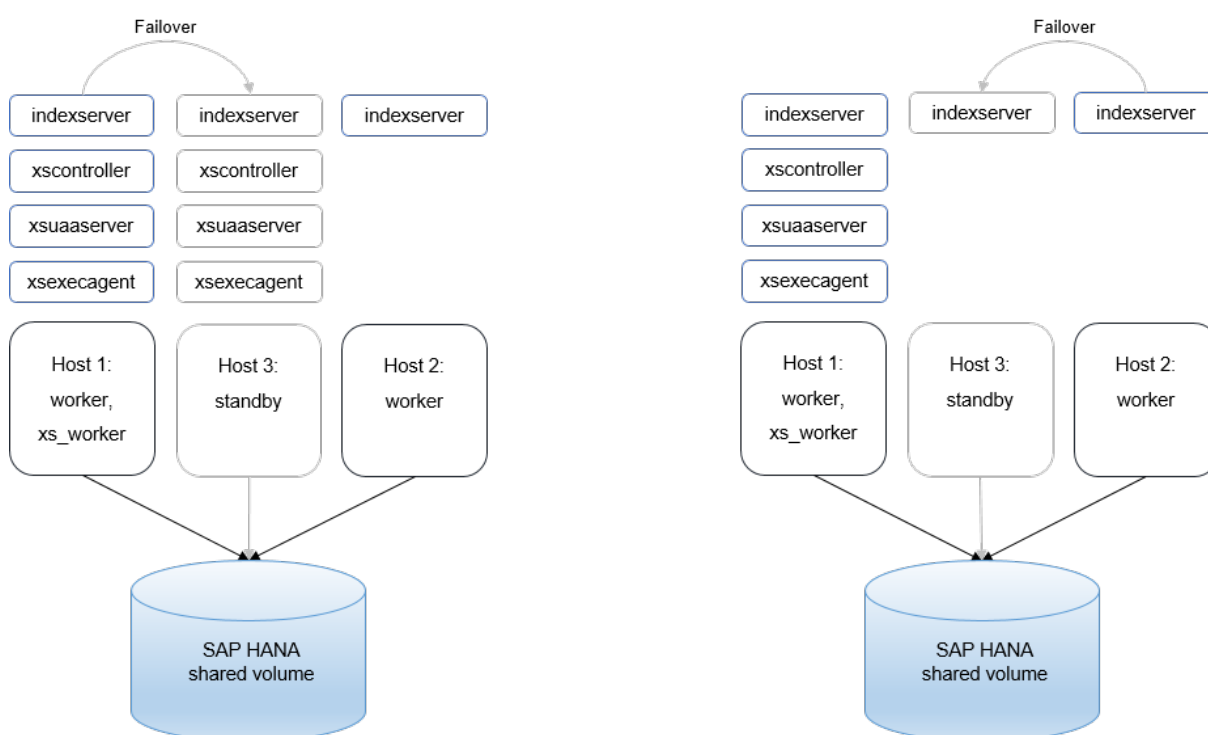

The host auto-failover setup for XS advanced integrates with failover mechanisms supported by SAP HANA. For more information, see *Setting Up Host Auto-Failover* in *Related Information*. Since host auto-failover always requires a multi-host setup, you have to fulfill all the prerequisites of a multi-host setup with XS advanced, as

described in *Multi-Host Setup with XS Advanced in Related Information*. The following new host roles have been introduced for use with the XS advanced run time:

- `xs_worker`
- `xs_standby`.

### Host Auto-Failover Without Separate `xs_worker` Hosts

A host with the role `standby` automatically takes over the load of a failing host with the role `worker`. At the same time, the standby host takes over any additional roles that were assigned to the failing worker host. That means that when the `xs_worker` role is assigned to a host with role `worker`, a host with role `standby` would automatically take over the role `xs_worker` from the worker host as well. One consequence of this is that it takes over the XS advanced processes as well, as illustrated in the scenario on the left-hand side of the following figure:

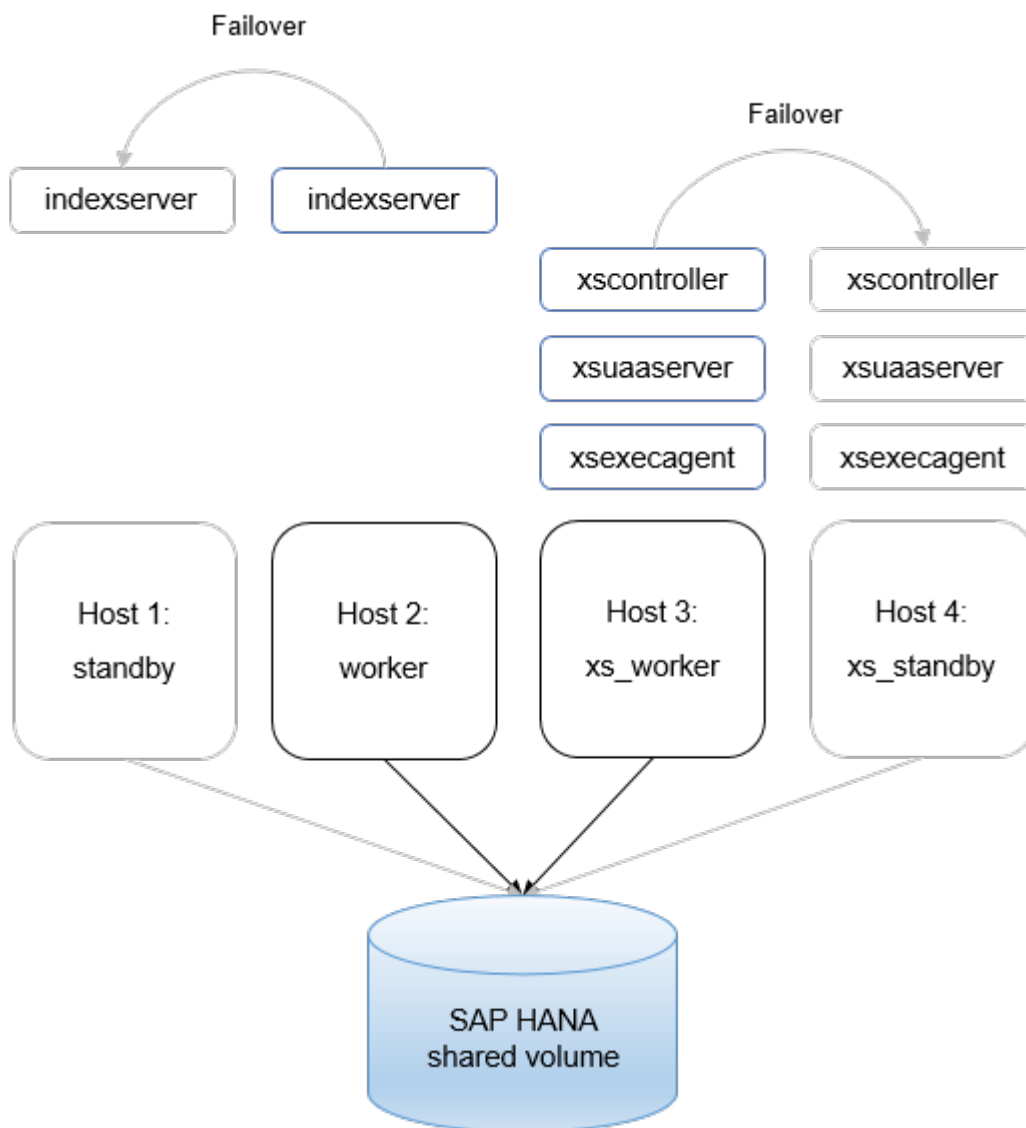

#### Note

A standby host only participates in the failover procedure once.

For example, in the scenario illustrated on the right-hand side of the figure above, the standby Host 3 takes over the roles from Host 2 as this host fails first. Since Host 3 is busy as a result of the failover, there is no standby host left to take over XS advanced processes if Host 1 also fails. So, in this example, if you want to have a failover host available to take over XS advanced processes after Host 2 fails, you need to specify an additional host with a standby role (for example, Host 4, which is not depicted in the figure above) to cope with this situation.

### Host Auto-Failover With Separate `xs_worker` Hosts

To set up failover hosts for separate hosts with the `xs_worker` role, hosts with the host role `xs_standby` are required. In the following example, separate hosts with the roles `standby` and `xs_standby` take over the load for either SAP HANA services (`worker`) or XS advanced services (`xs_worker`) and applications respectively.

It is only recommended to combine `standby` and `xs_standby` roles on one host if hosts with the `xs_worker` and `worker` role have the same hardware specifications. Otherwise, XS advanced processes could be assigned to hosts with SAP HANA database certified hardware after failover as shown by the following example:

- The host with the `worker` role uses SAP HANA database certified hardware.
- The host with the `xs_worker` role uses commodity hardware (but SAP HANA compliant).
- The host with the `xs_worker` role fails first.

In this scenario, the combined `standby` / `xs_standby` host takes over `xs_worker` only and cannot be used to take over the separate host with the `worker` role anymore. The XS advanced processes would then run on a standby host with over-sized hardware.

## 11.1.4 Implementing a HA/DR Provider

The SAP HANA nameserver provides a Python-based API, which is called at important points of the host auto-failover and system replication takeover process.

These so called "hooks" or HA/DR providers can be used for arbitrary operations that need to be executed. One of the most important uses of the failover hooks is moving around a virtual IP address (in conjunction with STONITH).

Nevertheless, there are other purposes like starting tools and applications on certain hosts after failover or even stopping DEV or QA SAP HANA instances on secondary sites before takeover. Multiple failover hooks can be installed and used in parallel with a defined execution order.

### i Note

When calling subprocesses within a HA/DR Provider implementation, please refrain from using the Python modules `subprocess` and `popen2`, as well as `os.popen()`, `os.popen2`, `os.popen3`, and `os.popen4`. Those methods allocate memory, which can cause a deadlock when forking the nameserver process. Use `os.system()` instead.

This section will describe the Python API in detail and gives an example how the hooks can be used. An implemented Python class is called a HA/DR provider. This script contains hook methods, which are called at certain events.

The failover hooks are included in SAP HANA. SAP HANA comes with its own Python interpreter, which is used for interpreting the user defined failover hooks. The failover hook API also has a version number.

## Running Python Version 3

In SAP HANA SPS 05 Python version 2 and Python 3 (the default) are supported. You can determine which Python version to use by running the following command in SAP HANA database lifecycle manager (with the value either 'python2' or 'python3'):

```
./hdblcm --configure_python=python3
```

Python version 2 will be superseded in a future release and you are recommended to test and update your own scripts to run in Python 3. You should also ensure that scripts included in third party software (such as cluster manager software) are compatible. Examples given in this documentation are compatible with Python version 3.

See also the SAP Note *Python 3 Migration Guide For SAP HANA* for more information.

[SAP Note 3070359](#)

### 11.1.4.1 Create a HA/DR Provider

You can adapt Python files delivered with SAP HANA to create your own HA/DR provider. This allows you to integrate, for example, SAP HANA failover mechanisms into your existing scripts.

#### Context

To create your own HA/DR provider, the following steps must be executed and then add the methods you want to use from those listed in *Hook Methods*:

#### Procedure

1. Create a new directory for the HA/DR provider

The directory should be within the shared storage of the SAP HANA installation, but outside the <SID> directory structure (otherwise it is likely to be deleted/overwritten during a SAP HANA update).

For example you could use the following location: `/hana/shared/myHooks`

2. Copy the `exe/python_support/hdb_ha_dr/HADRDummy.py` from an installed SAP HANA system to the new location.

For example, copy the file to: `/hana/shared/myHooks/myFirstHook.py`

#### i Note

Do not copy the `client.py`, otherwise updates and new features will be missed when updating SAP HANA. When using the import statement as described below the `client.py` from the SAP HANA installation will be used.

3. Adapt the contents of the new file by renaming the Python class to the name of the file, for an example see Code Listing 1
4. Fill out the Python dict in the `about()` method, for an example see Code Listing 1.

#### Sample Code

##### Code Listing 1

```
from hdb_ha_dr.client import HADRBase, Helper
import os, time
class myFirstHook(HADRBase):
    apiVersion = 1
    def __init__(self, *args, **kwargs):
```

```

# delegate construction to base class
super(myFirstHook, self).__init__(*args, **kwargs)
def about(self):
    return {"provider_company" :      "SAP",
           "provider_description" :   "Template Dummy Provider",
           "provider_version" :      "1.0"}

```

Within the SAP HANA environment, the path `exe/python_support` is part of the PYTHONPATH setting. Therefore, `hdb_ha_dr` can be used as module for the import of the base class in helper class (shown in the first line of Code Listing 1).

The attribute `apiVersion` defines which HA/DR provider API version will be used.

The `__init__()` method should always call the super method with the parameters `*args, **kwargs` in order to ensure the correct initialization of the tracer and configuration file wrapper. If required, additional initialization steps can be used here.

Finally, the `about()` method must return a Python dict with the keys as shown. The values will be used for monitoring in the `M_HA_DR_PROVIDERS` view.

There are three class attributes defined in the HA/DR provider base class::

- `tracer`: a tracer that is available to all derived classes tracing to the nameserver's trace file
- `config`: a wrapper for easy access of optional configuration parameters in the `global.ini`
- `apiVersion`: the definition of the API version

More details can be found in the sections `Additional Configuration Parameters` and `Tracing` (see `Related Information`).

## Next Steps

With the basic HA/DR provider now implemented you can continue by choosing and adding the methods listed in *Hook Methods* to your provider.

## Related Information

[Hook Methods \[page 1383\]](#)

[Install and Configure a HA/DR Provider Script \[page 1389\]](#)

## 11.1.4.1.1 Hook Methods

There are a number of pre takeover, post takeover and general hooks available for you to use.

The following hook methods are available:

Name	Trigger	Caller	Landscape	Error behavior
<b>startup()</b>	Beginning of name-server's start up phase	Starting nameserver	Each individual host	Nameserver aborts, start up is canceled
<b>shutdown()</b>	Just before the name-server exits	Stopping nameserver	Each individual host	Error trace is written
<b>failover()</b> [Host Auto-Failover]	As soon as the name-server made a decision about the new role	Host that takes over the role	Each host that gets a new role	Nameserver aborts, failover is canceled
<b>stonith()</b> [Host Auto-Failover]	As soon as the name-server made the decision about the new role	Master nameserver	For each failed host	Nameserver aborts, failover is canceled
<b>preTakeover()</b> [System Replication]	As soon as the hdbnsutil -sr_takeover command is issued	Master nameserver	Called only once on the master	Takeover is aborted
<b>postTakeover()</b> [System Replication]	As soon as all services with a volume return from their assign-call (open SQL port)	Master nameserver	Called only once on the master	Error trace is written
<b>srConnection-Changed()</b> [System Replication]	As soon as one of the replicating services loses or (re-)establishes the system replication connection	Master nameserver	Called only once on the master	Error trace is written
<b>srServiceState-Changed()</b>	As soon as the name-server made a decision about the new state	Host that detects a local service change	Each individual host	Error trace is written
<b>srReadAccessInitialized()</b> [System Replication]	As soon as a tenant database or the system database is ready to accept SQL read queries on a read enabled secondary system	Master node on the primary system	Called only once on the master node on the primary system	Error trace is written
<b>srSecondaryUnregistered()</b> [System Replication]	When the primary system is informed about a takeover or unregister of one of its secondary systems	Master node on the primary system	Called only once on the master node on the primary system	Error trace is written

All hook methods receive a set of parameters, which can be used to identify the state and configuration of the calling nameserver. The nameserver expects the return code 0 in case of successful execution and codes other than 0 for the error case.

The hook methods are shown in detail in the following sections.

## Startup hook method stub

Code Listing 3 shows the startup hook method stub.

```
def startup(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    """
    Hook description:

    * time of call: beginning of startup of the nameserver
    * caller: the starting host
    * landscape: each host calls it individually
    * behavior upon failure: nameserver aborts, startup is canceled
    @param hostname: the local hostname
    @type hostname: string
    @param storage_partition: the storage partition number, 0 for standby hosts
    @type storage_partition: int
    @param system_replication_mode: mode of system replication
    @type system_replication_mode: string
    @param **kwargs: place holder for later usage (new parameters) to
        keep the interface stable
    @type **kwargs: dict
    @return: information about success
    @rtype: int
    """
    return 0
```

## Shutdown hook method stub

Code Listing 4 shows the shutdown hook method stub.

### i Note

The invocation of the shutdown() method is not guaranteed. If the nameserver is terminated prematurely it cannot call the HA/DR provider, for example if a host fails or during SAP HANA shutdown, when the services have not had enough time to run through their shutdown routines. Therefore crucial tasks such as the deletion of virtual IPs need to be implemented in the startup() and failover() method.

```
def shutdown(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    """
    Hook description:

    * time of call: just before the nameserver exits
    * caller: the stopping host
    * landscape: each host calls it individually
    * behavior upon failure: error trace is written
    @param hostname: the local hostname
    @type hostname: string
    @param storage_partition: the storage partition number, 0 for standby hosts
    @type storage_partition: int
    @param system_replication_mode: mode of system replication
    @type system_replication_mode: string
```

```

@param **kwargs: place holder for later usage (new parameters) to
    keep the interface stable
@type **kwargs: dict
@return: information about success
@rtype: int
"""
return 0

```

## Failover hook method stub

Code Listing 5 shows the failover hook method stub.

```

def failover(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    """
    Hook description:

    * time of call: when the nameserver made the decision about the new role
    * caller: the host that takes over the role
    * landscape: called on each host that gets a new role
    * behavior upon failure: nameserver aborts, failover is canceled
    @param hostname: the local hostname
    @type hostname: string
    @param storage_partition: the storage partition number, 0 for standby hosts
    @type storage_partition: int
    @param system_replication_mode: mode of system replication
    @type system_replication_mode: string
    @param **kwargs: place holder for later usage (new parameters) to
        keep the interface stable
    @type **kwargs: dict
    @return: information about success
    @rtype: int
    """
    return 0

```

## stonith hook method stub

Code Listing 6 shows the stonith hook method stub.

```

def stonith(self, failing_host, **kwargs):
    """
    Hook description:

    * time of call: when the nameserver made the decision about the new role
    * caller: the master host
    * landscape: for each failed host
    * behavior upon failure: nameserver aborts, failover is canceled
    @param failing_host: the SAP HANA internal name of the failed host
    @type failing_host: string
    @param **kwargs: place holder for later usage (new parameters) to
        keep the interface stable
    @type **kwargs: dict
    @return: information about success
    @rtype: int
    """
    return 0

```

## preTakeover hook method stub

Code Listing 7 shows the preTakeover hook method stub.

```
def preTakeover(self, isForce, **kwargs):
    """
    Hook description:

    * time of call: as soon as the hdbnsutil -sr_takeover command is issued
    * caller: the master host
    * landscape: called only once on the master
    * behavior upon failure: nameserver aborts, takeover is canceled
    @param isForce: flag if it is a normal or forced takeover (as of today,
        takeover is always forced regardless of the value of the
        flag)
    @type isForce: bool
    @param **kwargs: place holder for later usage (new parameters) to
        keep the interface stable
    @type **kwargs: dict
    @return: information about success
    @rtype: int
    """
    return 0
```

## postTakeover hook method stub

Code Listing 8 shows the postTakeover hook method stub.

```
def postTakeover(self, rc, **kwargs):
    """
    Hook description:

    * time of call: as soon as all services with a volume return from their
        assign-call (open SQL port)
    * caller: the master host
    * landscape: called only once on the master
    * behavior upon failure: error trace is written
    @param rc: the return code of the actual takeover process; 0=success,
        1=waiting for forced takeover, 2=failure
    @type rc: int
    @param **kwargs: place holder for later usage (new parameters) to
        keep the interface stable
    @type **kwargs: dict
    @return: information about success
    @rtype: int
    """
    return 0
```

## srConnectionChanged hook method stub

Code Listing 9 shows the srConnectionChanged hook method stub.

```
def srConnectionChanged(self, parameters, **kwargs):
    """
```

```

Hook description:
* time of call: as soon as one of the replicating services loses or
  (re-)establishes the system replication connection
* caller: master node on primary site
* landscape: called only once on the master node on primary site
* behavior upon failure: error trace is written
* Possible return codes:
* 0: Ok - continue processing

* 1: Block - Further HANA processing is blocked if HANA lost sync (is_in_sync
= false).
  Every 5 sec. there will be a retry to call this hook.
* If an HA/DR Provider shall not block SAP HANA processing or if a blocking
  situation caused by an HA/DR Provider shall (temporarily) be
  resolved use 'hdbnsutil -sr_blockonconnectionchanged --disable'
@param parameters: dict of parameters {hostname:string, port:string,
  database:string, status:int, database_status:int,
  system_status:int, timestamp:string, is_in_sync:bool, reason:string}
@type parameters: dict
@param **kwargs: place holder for later usage (new parameters) to keep the
  interface stable
@type **kwargs: dict
@return: information about success (0 = continue transaction, 1 = halt
  further transactions)
@rtype: int
* parameters:
* -- hostname: host where the service is running
* -- port: service's port
* -- database: service's tenant database (MDC)
* -- status: service replication status (10: NoHSR, 11: Error, 12: Unknown,
13: Initializing, 14: Syncing, 15: Active)
* -- database_status: tenant database replicating status (10: NoHSR, 11:
Error, 12: Unknown, 13: Initializing, 14: Syncing, 15: Active)
* -- system_status: HANA database overall replicating status (10: NoHSR, 11:
Error, 12: Unknown, 13: Initializing, 14: Syncing, 15: Active)
* -- timestamp: date and time of the event
* -- is_in_sync: true if service is in sync
* -- reason: additional details (e.g. 'Starting', 'Stopping')
* -- siteName: name of the replicating secondary site
"""
return 0

```

## srServiceStateChanged hook method stub

Code Listing 10 shows the srServiceStateChanged hook method stub.

```

def srServiceStateChanged(self, parameters, **kwargs):
    """
    Hook description:
    * time of call: as soon as the nameserver made a decision about the new state
    * caller: host that detects a local service change
    * landscape: each individual host
    * behavior upon failure: error trace is written
    @param parameters: dict of parameters {hostname:string, service_name:string,
    service_port:string, service_status:string, timestamp:string}
    @type parameters: dict
    * parameters:
    * -- hostname: host where the service state has changed
    * -- service_name: name of the service
    * -- service_port: port of the service
    * -- service_status: (no, yes, unknown, starting, stopping)
    * -- timestamp: date and time of the service change event
    """

```

```
"""
return 0
```

## srReadAccessInitialized hook method stub

Code Listing 11 shows the srReadAccessInitialized hook method stub.

```
def srReadAccessInitialized(self, parameters, **kwargs):
    """
    Hook description:
    * time of call: when a tenant database or the SystemDB is ready to accept SQL
    read queries on a read enabled secondary system
    * caller: master node on primary site
    * landscape: called only once on the master node primary site
    * behavior upon failure: error trace is written
    @param parameters: dict of parameters {last_initialized_database:string,
    databases_with_read_access_initialized:list<string>,
    databases_without_read_access_initialized:list<string>, timestamp:string,
    all_databases_initialized:bool}
    @type parameters: dict
    @param **kwargs: place holder for later usage (new parameters) to keep the
    interface stable
    @type **kwargs: dict
    * parameters:
    * -- last_initialized_database: tenant database that has finished its read
    access initialization and is ready to accept SQL requests
    * -- databases_with_read_access_initialized: list of tenant databases that
    have finished their read access initialization
    * -- databases_without_read_access_initialized: list of tenant databases that
    have NOT finished their read access initialization
    * -- timestamp: date and time of the event
    * -- all_databases_initialized: true if all tenant databases have finished
    the read access initialization
    """
    return 0
```

## srSecondaryUnregistered hook method stub

Code Listing 12 shows the srSecondaryUnregistered hook method stub.

```
def srSecondaryUnregistered(self, parameters, **kwargs):
    """
    Hook description:

    * time of call: when a secondary sends an unregister request to the primary
    (e.g. -sr_unregister, -sr_takeover)
    * caller: master node on primary site
    * landscape: called only once on the master node primary site
    * behavior upon failure: error trace is written

    @param parameters: dict of parameters {site_name:string, site_id:int,
    reason:string}
    @type parameters: dict
    @param **kwargs: place holder for later usage (new parameters) to keep the
    interface stable
```

```

@type **kwargs: dict
@return: information about success
@rtype: int

* parameters:
* -- site_name: name of the secondary site that requests the unregister
* -- site_id: internal ID of the secondary site that requests the unregister
* -- reason: context in which the unregister happens (e.g. "unregister",
"takeover")
"""
return 0

```

## 11.1.4.2 Install and Configure a HA/DR Provider Script

You can add, configure, and monitor your custom provider scripts in the SAP HANA studio.

If the HA/DR provider script is created, it can easily be installed on a SAP HANA system by adding a section called [ha\_dr\_provider\_<classname>] to the global.ini with following parameters:

- provider : the class name
- path : location of the script
- execution\_order : the ordering of the HA/DR provider if there is more than one; this is a number between 1 and 99

An example is shown in Code Listing 9.

### Sample Code

#### Code Listing 9

```

[ha_dr_provider_myfirsthook]
provider = myFirstHook
path = /hana/shared/myHooks
execution_order = 50

```

It is possible to specify multiple HA/DR providers by adding multiple sections.

All scripts are loaded during the start up phase of the name server, alternatively, to avoid the need for a restart, run the following command to reload the scripts immediately:

```
hdbnsutil -reloadHADRProviders
```

## Additional Configuration Parameters

If the HA/DR provider requires additional configurations parameters, arbitrary key value pairs can be added to the configuration parameter section. An example is shown in Code Listing 10.

## Sample Code

Code Listing 10 - HA/DR Provider section and custom configuration parameters

```
[ha_dr_provider_myfirsthook]
provider = myFirstHook
path = /hana/shared/myHooks
execution_order = 50
myparameter1 = somevalue
myparameter2 = 42
```

To consume these parameters, the configuration parameter wrapper `HADRBBaseConfiguration` (initialized in base class of the HA/DR Provider) can be used with following methods:

- `self.config.hasKey(<name>)`
- `self.config.get(<name>)`

## Sample Code

Code Listing 11 - Using the configuration parameter wrapper

```
def startup(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    if self.config.hasKey("myparameter1"):
        self.tracer.debug("param2 is '%s'" %
self.config.get("myparameter2"))
    return 0
```

## Access Rights

In many cases, the HA/DR provider needs additional rights granted in order to run operating system command and programs that require root access. Usually those rights are granted by adding a line to the `/etc/sudoers` file similar to this:

```
<sid>adm ALL= NOPASSWD: /path/command, /path2/command2
```

For example: `mmtadm ALL= NOPASSWD: /sbin/arping, /sbin/ip`

## Execution Order

The order of execution is defined with the `execution_order` parameter in the `ha_dr_<classname>` section of the `global.ini` file by specifying a number between 1 and 99 – the lower the number, the higher the priority. For example:

## Sample Code

Code Listing 12 - Configuration for two HA/DR Providers

```
[ha_dr_provider_mySTONITH]
provider = mySTONITH
path = /hana/shared/myHooks
```

```

execution_order = 50
[ha_dr_provider vIPMover]
provider = vIPMover
path = /hana/shared/myHooks
execution_order = 51

```

With the `execution_order` parameter, you can ensure that the `mySTONITH` provider is always called before the `vIPMover` provider

## Monitoring with M\_HA\_DR\_PROVIDERS

The monitoring view `M_HA_DR_PROVIDERS` contains all information about installed HA/DR Providers.

	PROVIDER_NAME	PROVIDER_COMPANY	PROVIDER_DESCRIPTION	PROVIDER_VERSION	PROVIDER_TYPE	PROVIDER_PATH	EXECUTION_ORDER
1	vIPMover	SAP	vIP Mover	1.0	GENERIC	/hana/shared/myHooks	51

## Tracing

There are a number of methods provided with the HA/DR provider base class that allow you to implement trace levels:

- `self.tracer.debug(<text>)`
- `self.tracer.info(<text>)`
- `self.tracer.warning(<text>)`
- `self.tracer.error(<text>)`
- `self.tracer.fatal(<text>)`

Everything will be traced to the component `ha_dr_<classname>`, in this example it would be `ha_dr_myfirsthook`. The default trace level is "info". You can override the level used by setting the parameter `ha_dr_<classname>=<level>` in the trace section of the `global.ini` file.

Additionally, the name server itself traces general information about the HA/DR provider calls and return code to the trace component `ha_dr_provider`. The default trace level is "info" as well.

### 11.1.4.3 Example HA/DR Provider Implementation

A full example showing how two HA/DR providers can be implemented for a sample landscape consisting of two SAP HANA systems with system replication enabled.

#### i Note

This example does not make any statement or assumption about what kind of hardware and software set up is licensed and if it fulfills production SAP HANA requirements at all. This is only a showcase, based on

virtual machines, which was available during the development of this example and should not be considered for production use. Concepts such as virtual IPs are not always applicable since the network architecture within and across data centers needs to be considered.

The usage of virtual IPs to automatically reconnect to the master host after a failover or a system replication takeover only works if the virtual IP on the failing host is disabled through a controlled shut down. In a split brain situation (network problems separate parts of the landscape) or on host failures it cannot be guaranteed that the virtual IP is unique in the network causing severe routing issues. Therefore, for some use cases virtual hostnames or cluster manager software to control the assignment of virtual IPs might be an alternative.

The context of this example is based on two SAP HANA systems consisting of 16 virtual machines each. Two HA/DR providers are going to be implemented:

- A provider that sets up a virtual IP address on the master host of the primary system allowing all clients to use always the same IP address for connecting regardless of any HA or DR activities. This HA/DR provider will be called *vIPMover*.
- A provider that runs STONITH in order to ensure proper I/O fencing. STONITH will be called for host auto-failover (the failed host) and system replication takeover (all three master candidates of the other site). The latter one is usually the task of an external cluster manager, but for this simple example, we use the direct way (which is usually not possible in real data center set ups). This HA/DR provider will be called *mySTONITH*.

## vIPMover HA/DR Provider

The purpose of this provider is to set up a virtual IP address every time the active master host moves. This can either happen when host auto-failover occurs or by a system replication takeover. For the failover case, the IP address move will simplify the SQL client connect by just having one IP address/hostname to specify. And for the system replication case, the client is able to find seamlessly the new system. However, proper fencing is a crucial part of moving an IP address around in order to avoid split-brain situations, because two hosts listen on the same address. The solution for this problem in this example will be the *mySTONITH* HA/DR provider, which will reboot the virtual machine, which has failed.

The HA/DR provider will make use of the Linux operating system commands `/sbin/arping` and `/sbin/ip`, which need to be added to the `/etc/sudoers` file for SAP HANA's `<sid>adm` user.

Listing 13 shows the class definition, constructor and the `about()` method of the *vIPMover* class.

### Sample Code

Code Listing 13 - Class definition, constructor and `about()` method of the *vIPMover* class

```
from hdb_ha_dr.client import HADRBase
import os
class vIPMover(HADRBase):
    apiVersion = 1
    def __init__(self, *args, **kwargs):
        super(vIPMover, self).__init__(*args, **kwargs)
        self.vIP = self.config.get("vip")
        self.eth = self.config.get("eth")
        self.netMask = self.config.get("netmask")
    def about(self):
        return {"provider_company" : "SAP Documentation Example",
```

```
"provider_description" : "vIP Mover",
"provider_version" : "1.0"}
```

Using `apiVersion = 1`, the `__init__()` method calls its super method and additionally reads the three attributes `vIP`, `eth` and `netMask` from the configuration file. More details later. The next step is to define helper methods for the actual setup of the virtual IP address. This example uses the standard Linux command `ip` and `arping` to set up and shut down an IP address:

### Sample Code

Helper methods for virtual IP address setup and shut down

```
def setupIP(self):
    # setup IP
    command1 = "sudo /sbin/ip addr add %s/%s dev %s" % (self.vIP,
self.netMask, self.eth)
    rc1 = os.system(command1)
    self.tracer.info("command '%s' returned with rc=%s" % (command1, rc1))
    command2 = "sudo /sbin/arping -U -c 5 %s" % self.vIP
    rc2 = os.system(command2)
    self.tracer.info("command '%s' returned with rc=%s" % (command2, rc2))
    return rc1 + rc2
def shutdownIP(self):
    command = "sudo /sbin/ip addr del %s/%s dev %s" % (self.vIP,
self.netMask, self.eth)
    rc = os.system(command)
    self.tracer.info("comand '%s' returned with rc=%s" % (command, rc))
    return rc
```

The commands that will be executed in this example would be:

```
sudo /sbin/ip addr add 10.208.155.179/20 dev eth0
sudo /sbin/arping -U -c 5 10.208.155.179
```

Finally, Listing 15 shows the implementation of the hook methods.

### Sample Code

Code Listing 15 - The hook method implementation

```
def startup(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    self.shutdownIP()
    # only setup vIP on the primary system
    if system_replication_mode not in ["", "primary"]:
        return 0
    # only setup vIP on the master host
    if storage_partition == 1:
        return self.setupIP()

    return 0
def shutdown(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    if system_replication_mode not in ["", "primary"]:
        return 0
    if storage_partition == 1:
        return self.shutdownIP()
    return 0
def failover(self, hostname, storage_partition, system_replication_mode,
**kwargs):
    if system_replication_mode not in ["", "primary"]:
        return 0
```

```

    if storage_partition == 1:
        return self.setupIP()
    return 0
def preTakeover(self, isForce):
    """Pre takeover hook."""
    return self.setupIP()

```

The three methods `startup()`, `shutdown()` and `failover()` have the same structure. The condition `if system_replication_mode not in ["", "primary"]` checks if there is no system replication configured or if it is a system replication primary system.

In the `preTakeover()` method, the virtual IP address is started just before the internal takeover process begins.

The HA/DR provider is configured in the `global.ini` with the three user-defined parameters:

### Sample Code

Code Listing 16 - The vIPMover configuration in the SAP HANA system

```

[ha_dr_provider_vIPMover]
provider = vIPMover
path = /hana/shared/myHooks
execution_order = 51
vip = 10.208.155.179
eth = eth0
netmask = 20

```

## mySTONITH HA/DR Provider

The second HA/DR provider offers STONITH to the SAP HANA system. For this example the virtual machine sends a hard reboot command with a locally installed API to a management node outside the SAP HANA system. As the system is installed with virtual hostnames, but the API requires the public hostnames, a mapping of both is defined in the `global.ini`. Another option would be to resolve those names via naming convention if applicable.

Listing 17 shows the HA/DR Provider implementation.

### Sample Code

Code Listing 17 - Implementation of the mySTONITH HA/DR provider

```

from hdb_ha_dr.client import HADRBase
import os
class mySTONITH(HADRBase):
    apiVersion = 1
    def __init__(self, *args, **kwargs):
        super(mySTONITH, self).__init__(*args, **kwargs)
        self.hsrStonith = self.config.get("hsr_stonith").split()
    def about(self):
        return {"provider_company" : "SAP Documentation Example",
                "provider_description" : "Basic virtual machine STONITH",
                "provider_version" : "1.0"}

    def stonith(self, failingHost, **kwargs):
        vmName = self.config.get("map_%s" % failingHost)
        if vmName == "":
            raise Exception("hostname for virtual machine not configured")

```

```

        self.tracer.info("calling STONITH for %s (%s)" % (vmName,
failingHost))
        return os.system(("<script> <logon credentials> --name %s <hard
reboot> <servicing host>" % (vmName)))

def preTakeover(self, isForce):
    rc = 0
    for h in self.hsrStonith:
        rc = rc + self.stonith(h)
    return rc

```

The `__init__()` and `about()` methods are filled similar to the example above. The `stonith()` method looks up the SAP HANA internal hostname via configuration parameter and executes the STONITH command. This is specific to the type of the virtual environment. For bare metal servers, an IPMI-based call is a typical implementation.

The `preTakeover()` method sends a STONITH command to all master hosts of the other site defined via configuration parameter `hsr_stonith`, a space-separated list of host names.

As a result the configuration entries look like this:

### Sample Code

```

[ha_dr_provider_mySTONITH]
provider = mySTONITH
path = /hana/shared/myHooks
execution_order = 50
hsr_stonith = hananode17 hananode28 hananode32
map_hananode17 = DEWDFTVU3017
map_hananode28 = DEWDFTVU3028
map_hananode32 = DEWDFTVU3032
map_hananode01 = DEWDFTVU3001
map_hananode02 = DEWDFTVU3002
map_hananode03 = DEWDFTVU3003
map_hananode04 = DEWDFTVU3004
map_hananode05 = DEWDFTVU3005
map_hananode06 = DEWDFTVU3006
map_hananode07 = DEWDFTVU3007
map_hananode08 = DEWDFTVU3008
map_hananode09 = DEWDFTVU3009
map_hananode10 = DEWDFTVU3010
map_hananode11 = DEWDFTVU3011
map_hananode12 = DEWDFTVU3012
map_hananode13 = DEWDFTVU3013
map_hananode14 = DEWDFTVU3014
map_hananode15 = DEWDFTVU3015
map_hananode16 = DEWDFTVU3016

```

## 11.2 SAP HANA Database Backup and Recovery

SAP HANA offers comprehensive functionality to safeguard your database and ensure that it can be recovered speedily and with maximum business continuity.

SAP HANA supports the following backup and recovery capabilities:

- Manual and automated backups

- Extensive configuration options
- Integrity checks for backups
- Backup lifecycle management (housekeeping)
- Recovery to the most recent state or to a specific point-in-time
- Recovery to a specific data backup or data snapshot
- Database copy using backup and recovery
- Full integration with third-party backup tools

### i Note

This documentation only covers backup and recovery of an SAP HANA database. It does not describe how to back up and recover all the components that can be part of an SAP system.

## Related Information

[Working with Third-Party Backup Tools \[page 1442\]](#)

## 11.2.1 Planning Your Backup and Recovery Strategy

When you are planning a backup strategy, consider using a combination of backup types for different recovery scenarios to minimize the risk of data loss, and to ensure that, in the event of a fault, a recovery can be completed speedily and with minimal downtime.

### When to Create a Data Backup

It is recommended that you create a data backup in the following situations:

- After the initial load
- At regular intervals

You can schedule backups to run at specific times without additional user intervention.

#### → Tip

You can use less recent data backups for a recovery, provided that the subsequent log backups are available. If more log backups have to be replayed, the recovery takes longer to complete.

For this reason, we recommended that you use the most recent data backup and subsequent log backups to recover the database.

The more frequently a database is backed up, the faster the recovery will be.

- Before the database software is upgraded to a new version  
If a software upgrade fails, it is possible to use the backup to recover the database to its state before the upgrade.

#### **i Note**

After an SAP HANA upgrade, the backup history is not broken. A full backup is not necessary to ensure that the backup history is intact.

- After any situation that causes log writing to be interrupted  
For example, immediately after the log mode was changed.

## Scheduling Regular Backups

It is strongly recommended to schedule regular data backups from the data area of your SAP HANA database to a secure location.

A backup plan could look like this:

- Data snapshot: daily  
For more information, see *Points to Note: Backup with Data Snapshots*.

#### **i Note**

If you have a backup and recovery strategy that is based on **data snapshots**, you must ensure that all the data snapshots that you wish to use for a recovery are replicated outside of the SAP HANA storage system.

- Data backup (in the file system or using third-party backup tools): once a week
- Automatic log backups

For more information about scheduling backups using SAP HANA cockpit, see *Schedule Backups*.

## Lifecycle Management (Housekeeping)

It is recommended to regularly delete full backups and backup generations that are no longer needed to recover your SAP HANA database.

For more information, see *Housekeeping: Deleting and Archiving Backups*.

## 11.2.2 Points to Note About Backup and Recovery

Before you begin preparing a backup strategy for your SAP HANA installation, you should be aware of specific considerations that apply to backup and recovery.

### 11.2.2.1 Points to Note: SAP HANA Backups

When you plan your backup strategy, you should be aware of several important points concerning SAP HANA data backups, data snapshots, delta backups, and log backups.

- Backups can only be created when SAP HANA is online.  
All the configured SAP HANA services must be running.  
While full backups (data backups and data snapshots), delta backups (differential and incremental backups), and log backups are being created, the impact on system performance is negligible, and users can continue to work normally.  
For more information, see *SAP HANA Backup Types*.

#### Caution

Do not create a full backup after a database fault or other failure has occurred.

- With a data backup, only the actual data is backed up.  
Unused space in the database is not backed up.  
A full data backup contains all the data that is required to recover the database to a consistent state. This includes both business data and administrative data.

#### Note

A full data backup does not include the log area or customer-specific configuration settings (\*.ini files).

- The system database can initiate backups of both the system database itself and of individual tenant databases.  
A tenant database can create its own backups without needing to connect through the system database.
- A data backup reflects the consistent database state from the time at which the data backup was started.  
Changes made to the database after a data backup was started are not included in the data backup.  
If a data backup is recovered without any log backups, open transactions in the data backup are rolled back to the start time of the data backup.

- If a new full backup (data backup or data snapshot) is started before the previous full backup is finished, SAP HANA handles the situation as follows:
  - The first full backup continues as normal.
  - The second full backup does not start, and an error message is displayed.
- It is not possible to back up and recover individual database objects. Backup and recovery always apply to the whole database. For more information, see *Data Backups*.

## SAP HANA Dynamic Tiering and SAP HANA Backup

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

### i Note

`hdbbackupcheck` does not support SAP HANA Dynamic Tiering.

## Worker Groups

If you have defined worker group sub-roles, information about the worker groups for each volume is stored as part of SAP HANA full backups (complete data backups and data snapshots).

## SAP HANA Cockpit and Backup

From SAP HANA cockpit 2.0, to schedule backups for an SAP HANA 1.0 database, you must be logged onto that database. You cannot schedule backups for SAP HANA 1.0 databases through the system database.

## Related Information

[SAP HANA Backup Types \[page 1416\]](#)

[Data Backups \[page 1417\]](#)

[Tenant Databases \[page 18\]](#)

[Schedule Backups \[page 1507\]](#)

[SAP Note 2375865](#) 

## 11.2.2.1.1 Points to Note: File-Based Backups

When you plan your backup strategy, you should be aware of several important points concerning how SAP HANA handles backups to the file system.

- The configured destination for data and log backups must be valid throughout the whole system, not only for specific hosts.  
Backups of tenant databases are always created in subdirectories of this location.
- To make the backup area available to all the nodes in a database, it is strongly recommended to use shared backup storage.  
In addition, shared storage offers support for database copy.

### i Note

#### Shared Backup Storage

Shared backup storage allows the system database or the master index server of a tenant database to perform availability checks for file-based backups at the beginning of the recovery.

If you are working with file-based backups, and shared storage is not used for backups, the master name server has no access to the backup storage of the other servers. As a consequence, the master name server cannot check whether backups are available. This means that the availability checks cannot be performed at the beginning of the recovery. If you have started a recovery that cannot be completed because one or more of the required backups are not available, this will only be detected later, when each service checks the availability of its own backups.

If the complete recovery needs to be repeated because log backups or delta backups are missing, this may cause significant disruption to work with the database.

## Related Information

[Change the Backup Configuration Settings \[page 1455\]](#)

[Parameters for Data Backup Settings \[page 1467\]](#)

[Naming Conventions \[page 1436\]](#)

[Parameters for Backing Up the Backup Catalog \[page 1489\]](#)

## 11.2.2.1.2 Points to Note: Backup with Data Snapshots

If you are planning a backup strategy that makes use of data snapshots, you should be aware of several important points.

- You can create a data snapshot of an SAP HANA system (the system database and all its tenant databases).
- To **create** a data snapshot, you need to use native SQL.  
For more information, see *Create a Data Snapshot (Native SQL)*.
- If your backup and recovery strategy is based on data snapshots, you must ensure that all the data snapshots that you wish to use for a recovery are replicated outside of the SAP HANA storage system.

- Data snapshots using Backint are not supported by SAP HANA. If you are using a third-party backup tool, check with your vendor whether storage-level snapshot technologies are supported.

## Related Information

[Data Snapshots \[page 1420\]](#)

[Create a Data Snapshot \(Native SQL\) \[page 1502\]](#)

[Comparison of Data Backups and Data Snapshots \[page 1422\]](#)

[Points to Note: Recovery with Data Snapshots \[page 1406\]](#)

### 11.2.2.1.3 Points to Note: Log Modes

SAP HANA uses two log modes: `normal` and `overwrite`. By default, SAP HANA runs in log mode `normal`.

After installation, SAP HANA temporarily runs in log mode `overwrite`.

In log mode `overwrite`, the log segments are not backed up. When a log segment is full, it is closed. After a successful savepoint, that log segment can be reused. In this way, log mode `overwrite` ensures that the log area does not grow excessively.

After you create the first full data backup, SAP HANA automatically switches to the default log mode `normal`, and log backups are created.

#### → Tip

If you change the log mode from `overwrite` – where log backups are not created – to log mode `normal`, **you must create a full data backup** to ensure that log backups are created again, and that the database can be recovered to the most recent point in time.

## SAP HANA Dynamic Tiering and Log Mode Overwrite

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

## Related Information

[Log Modes \[page 1481\]](#)

[Change Log Modes \[page 1483\]](#)

[SAP Note 2375865](#) 

## 11.2.2.1.4 Points to Note: Third-Party Backup Tools

Third-party backup tools can be fully integrated with SAP HANA to enable you to perform backup and recovery operations.

- The implementation of the API of a third-party backup tool that uses the `Backint for SAP HANA` interface must be certified by SAP.  
For more information, see *Working with Third-Party Backup Tools*.
- To recover a database, it is possible to use a combination of backups from a third-party backup tool and backups from the file system, provided that the backups originate from the same SAP HANA database.
- SAP HANA supports high isolation scenarios for third-party backup tools.  
For more information, see *Isolation Level High for Backups and Third-Party Backup Tools*.

## SAP HANA Dynamic Tiering and Third-Party Backup Tools

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

### Related Information

[SAP Note 2375865](#)

## 11.2.2.1.5 Points to Note: Release Compatibility of SAP HANA Backups

In some situations, backups from earlier SAP HANA releases can be used for a recovery.

- SAP HANA backups created with release 1.0 SPS10 or newer can be used to recover or copy to SAP HANA 2.0.  
This applies to both SAP HANA single-container systems and tenant databases.  
For more information about using backups from SAP HANA 1.x to recover or copy to SAP HANA 2.x releases, see *SAP Note 2372809 (Mandatory Preparation Steps for Upgrading a SAP HANA 1 System to SAP HANA 2)*.  
For SAP HANA running on IBM Power systems, different release compatibilities apply.  
For more information, see *Points to Note: SAP HANA on IBM Power Systems*.
- A backup of an SAP HANA single-container system **cannot be recovered to a system database**.

## Related Information

[Points to Note: SAP HANA on IBM Power Systems \[page 1411\]](#)

[SAP Note 2372809](#) 

### 11.2.2.2 Points to Note: SAP HANA Recovery

Before you plan your backup and recovery strategy, you should be aware of several important points with regard to recovering an SAP HANA database.

- The SAP HANA version used for the recovery must always be the same or higher than the SAP HANA version used to create the data and log backup.  
Data and log backups cannot be used to recover to a lower SAP HANA version.  
If you are upgrade your SAP HANA from a maintenance revision to a support package, certain restrictions apply. For more information, see SAP Note 1948334 (*SAP HANA Database Update Paths for Maintenance Revisions*) and SAP Note 2378962 (*SAP HANA 2.0 Revision and Maintenance Strategy*).
- A system database only needs to be recovered if it is corrupted.  
If only a tenant database is corrupted, the system database does not need to be recovered.
- To perform a recovery, an SAP HANA database needs to be shut down.  
For this reason, during recovery, a database cannot be accessed by end users or applications.

The **system database** is shut down for recovery

All its tenant databases are automatically shut down as well.

The whole SAP HANA system is not available until the recovery of the system database has been completed.

#### i Note

When you recover and restart a system database, its tenant databases are not automatically restarted. You should first check that the system database was recovered successfully, then restart the tenant databases manually.

A **tenant database** is shut down for recovery

The system database and any other tenant databases remain online.

#### i Note

Recovery from a data snapshot:

Before you make the data snapshot available in the data area of the storage system, you must first shut down the database.

- To recover a complete SAP HANA system:  
A recovery of a tenant database is always initiated from the system database.  
You first need to recover the system database. After the system database has been recovered successfully, each tenant database is recovered separately. The tenant databases cannot be recovered together in one single operation.

- Before a SAP HANA is recovered, all target volumes are deleted and recreated with the recovered data. When you recover a tenant database that is being encrypted on the fly, recovery ensures that there are no unencrypted shadow pages in the recovered database. For this reason, it is not necessary to drop and recreate a tenant database before starting the recovery.
- Using SAP HANA cockpit, only a **tenant database** can be recovered to a point in time. Using SAP HANA cockpit, a **system database** can only be recovered to its most recent state. To recover a system database to a point in time, use the `recoverSys.py` tool. For more information, see *Recover a System Database to a Point in Time*.

## SAP HANA Dynamic Tiering

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

## Worker Groups

If you have defined worker group sub-roles, information about the worker groups for each volume is stored as part of SAP HANA full backups (complete data backups and data snapshots).

Ensure that the target system for a database recovery has the same number of worker groups as the source system.

### ⚠ Caution

If the target system is not configured correctly, SAP HANA cannot be recovered.

Before you start a recovery, you should normally ensure that the worker groups in the SAP HANA system and the backups have the same names. However, under certain circumstances, it is possible to override this restriction.

For more information, see the `<IGNORE WORKERGROUPS>` option for *RECOVER DATABASE Statement (Backup and Recovery)* in the SAP HANA SQL Reference Guide.

## SAP HANA Cockpit and Recovery

SAP HANA cockpit 2.0 SP05 can be used to recover only SAP HANA 2.0 databases.

*2616241 (Recovery of SAP HANA 1.0 with SAP HANA Cockpit 2.0)*.

## Related Information

[SAP Note 2616241](#)

## 11.2.2.2.1 Points to Note: Delta Backups and Recovery

SAP HANA supports both differential and incremental backups.

- You can recover an SAP HANA database using a full data backup (complete data backup or data snapshot) and a combination of a differential backup and one or more incremental backups.
- By default, when SAP HANA computes a recovery strategy, it gives preference to differential and incremental backups over log backups.  
To recover using only a full data backup and log backups, specify the appropriate options in the recovery dialog.
- If you recover an SAP HANA database, and do not immediately create a full data backup, the delta backups subsequently created are based on the data backup that was used for the recovery.

#### **i** Note

If you wish to recover SAP HANA using differential or incremental backups, you must also use log backups. If log backups are not available, you can only recover using a full data backup.

## Related Information

[Delta Backups \[page 1418\]](#)

## 11.2.2.2 Points to Note: Recovery with Data Snapshots

Data snapshots offer an additional option to safeguard and recover an SAP HANA database. If you are planning a backup strategy that makes use of data snapshots, you should be aware of several important points.

### ⚠ Caution

Unlike a database recovery from data backups and log backups, the process of recovering SAP HANA from a data snapshot is not entirely under the control of SAP HANA. Manual steps are necessary, for example, to restore the data snapshot to the correct location before the recovery can begin.

To ensure that it succeeds, recovering SAP HANA from a data snapshot requires expert knowledge.

If you are in doubt as to how to ensure that the prerequisites for a recovery from a data snapshot are met, we recommend that you instead consider recovering SAP HANA using a standard recovery from data backups and log backups.

- Using SAP HANA cockpit and storage system tools, you can recover a complete SAP HANA system (the system database and all its tenant databases) from a data snapshot.
- To recover SAP HANA from a data snapshot, you need to recover the system database, and then recover each tenant database separately.  
The tenant databases cannot be recovered together in one single operation.
- To recover a database from a data snapshot, you can optionally also use delta backups and log backups.
- While a data snapshot is being created, no further data integrity checks are performed (checksum calculation) on page or block level.  
If a data snapshot has been changed before it is used for a recovery, SAP HANA will only detect this when the database is started.
- It is **not possible** to use a data snapshot of an SAP HANA single-container system to recover an SAP HANA multitenant database system.

## Related Information

[Data Snapshots \[page 1420\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

## 11.2.2.3 Points to Note: License Keys and Recovery

When you recover an SAP HANA database, you should be aware of certain license key requirements.

The license key for an SAP HANA database is based on the system ID and the hardware ID. After a recovery, if the SID or hardware ID has changed, an SAP HANA license key becomes invalid.

SAP HANA licenses can be installed for the system database (global) or for a single tenant database (local). Global licenses are for the system database and all the tenant databases, but a license installed in a tenant database governs only that tenant database. If a local license key is removed, that tenant database reverts to the global license key installed in the system database.

During recovery, a temporary license key is installed automatically if the backup used for recovery had a permanent license that is still valid. You can work with the automatically installed temporary license for up to 90 days. During this time, you need to apply to SAP to have the license from the source database transferred to a new license key. You then need to install the new license key in the recovered SAP HANA database.

For more information, see *License Keys for SAP HANA Database* in *SAP HANA Administration Guide (Licensing)*.

## Lockdown

If SAP HANA is in lockdown immediately after a recovery or a database copy, this can be because:

- The SID or hardware key of the target SAP HANA system does not match the SID or hardware key of the source SAP HANA system, and
- The backup contains an invalid license key.  
This could be a permanent license key that expired more than 28 days ago (grace period), a temporary license key that expired, or a temporary license key that was already auto-generated during a previous recovery.

If the system is in lockdown, you need to request and install a new license key for the current SID or hardware key.

If the backup has a valid permanent license key, a new temporary license key is generated automatically when the target system is restarted after recovery, even if the SID and/or the hardware key have changed.

## Related Information

[License Keys for SAP HANA Database \[page 330\]](#)

[Recovering an SAP HANA Database \[page 1547\]](#)

[Prerequisites for Copying a Database Using Backup and Recovery \[page 1579\]](#)

### 11.2.2.2.4 Points to Note: Extension Nodes for SAP Business Warehouse

If you are using extension nodes for Business Warehouse, you need to consider some important points with regard to SAP HANA recovery.

## Data Temperature

Ensure that warm data is recovered to a service that is configured for warm data.

Likewise, hot data must be recovered to a service that is configured for hot data.

This means that you need to set up the same number and type of services for hot and warm data on the target host that were running on the source host.

For more information, see *Data Temperature: Extension Node for Business Warehouse* and SAP Note 2453736 (*How-To: Configuring SAP HANA for SAP BW Extension Node in SAP HANA 2.0*).

## Worker Groups

If you have defined worker group sub-roles, information about the worker groups for each volume is stored as part of SAP HANA full backups (complete data backups and data snapshots).

Ensure that the target system for a database recovery has the same number of worker groups as the source system.

### Caution

If the target system is not configured correctly, SAP HANA cannot be recovered.

Before you start a recovery, you should normally ensure that the worker groups in the SAP HANA system and the backups have the same names. However, under certain circumstances, it is possible to override this restriction.

For more information, see the `<IGNORE WORKERGROUPS>` option for *RECOVER DATABASE Statement (Backup and Recovery)* in the SAP HANA SQL Reference Guide.

## Related Information

[Extension Node \[page 566\]](#)

[SAP Note 2453736](#)

[SAP HANA SQL Reference Guide for SAP HANA Platform  
RECOVER DATABASE Statement \(Backup and Recovery\)](#)

### 11.2.2.3 Points to Note: Copying a Database Using Backup and Recovery

You can use backup and recovery to copy a tenant database to the same or a different SAP HANA system, or to copy a system database to a different SAP HANA system. When you copy an SAP HANA database, you should be aware of certain important considerations.

You can copy an SAP HANA database using file-based backups or backups created using third-party tools.

### Note

To create a database copy using differential or incremental backups, you must also use log backups. If log backups are not available, you can only create a database copy using a full data backup.

## Database Copy and Data Snapshots

- You can create a data snapshot of an SAP HANA database with one or more tenant databases.
- For a database copy using data snapshots, the number of hosts and the number and type of services assigned to each host must be the same for the source database and the target database. Also, the mountpoint IDs must be identical.
- When you copy SAP HANA from a data snapshot, you first need to recover the system database. After the system database has been recovered successfully, each tenant database is recovered separately. The tenant databases cannot be recovered together in one single operation.
- Before you make the data snapshot available in the data area of the storage system, you must first shut down the database.

## Database Copy and System Replication

If you have system replication configured, and require near-zero downtime, consider using system replication to copy a tenant database.

For more information, see *Copying and Moving Tenant Databases Between Systems* in the *SAP HANA Administration Guide*.

## Related Information

[Copying a Database Using Backup and Recovery \[page 1578\]](#)

[Copying and Moving Tenant Databases \[page 1137\]](#)

### 11.2.2.4 Points to Note: System Replication

Data backups and log backups can only be written on the primary system.

## After a Takeover

### i Note

After a takeover, it is **not** necessary to create a new full data backup (data backup or data snapshot) of the now active system. Backups of the former primary system can be used to recover the database, but not in combination with delta backups from the current primary.

Delta backups must be based on the complete data backup of the current primary. After a takeover, if you wish to create delta backups, you must first have created a complete data backup of the current primary.

If you wish to recover SAP HANA using differential or incremental backups, you must also use log backups. If log backups are not available, you can only recover using a full data backup.

After a takeover, ensure the following:

- Backups from the former primary system are not being written to the same location as backups from the now active system.

### ⚠ Caution

If backups from different systems are mixed up, it will not be possible to recover the database.

This can be achieved in either of the following ways:

- Disable automatic log backups and any scheduled data backups in the former primary system.
- Shut down the former primary system to ensure that it creates no new data backups and no new log backups.
- Any backups scheduled in the now active system are configured in accordance with your requirements. For more information, see *Schedule Backups*.

## Before a Recovery

Before a recovery, disable the FULL SYNC option.

If you are running system replication with replication mode `SYNC` and the `FULL SYNC` option enabled, the system will not start after a recovery, because no write operations are possible.

To prevent this from happening, before you perform a recovery, manually disable the `FULL SYNC` option in `global.ini`.

You can use the following command as `<sid>adm`:

```
hdbnsutil -sr_fullsync --disable
```

For more information, see SAP Note 2165547 (*FAQ: SAP HANA Database Backup & Recovery in an SAP HANA System Replication Landscape*) and *Recovery with System Replication*.

## System Replication and Third-Party Backup Tools

- If backups are managed using a third-party tool, the `Backint` for SAP HANA API must be accessed by both the active system and the original primary system.
- If SAP HANA is recovered from backups that were created with different UIDs, some third-party backup tools may prevent the recovery from being started.

For more information, contact your tool vendor or ensure that the same UID is used for all the backups used for a recovery.

## Related Information

[Schedule Backups \[page 1507\]](#)

[Recovery with System Replication \[page 1575\]](#)

[SAP Note 2165547](#)

### 11.2.2.5 Points to Note: SAP HANA on IBM Power Systems

If you are working with IBM Power systems, you should be aware of certain important points concerning SAP HANA.

- Backups created with SAP HANA 2.0 are compatible with the supported hardware platforms Intel and IBM Power. You can recover SAP HANA 2.0 using data backups and log backups created with SAP HANA 2.0 on either an Intel-based system or an IBM Power-based system. Data backups and log backups created with SAP HANA 1.0 SPS10 or newer running on an Intel-based system can be used to recover SAP HANA 2.0 to both Intel-based and IBM Power-based systems. Data backups and log backups created with SAP HANA 1.0 on an IBM Power-based system **cannot** be used to recover SAP HANA 2.0.

Compatibility of Backups of SAP HANA 1.0 for Recovery to SAP HANA 2.0 (IBM Power and Intel)

Backup Source (Data Backups and Log Backups)	Recovery to SAP HANA 2.0 (IBM Power)	Recovery to SAP HANA 2.0 (Intel)
SAP HANA 1.0 SPS9 and earlier	NO	NO
SAP HANA 1.0 (SPS10 and later) (IBM Power)	NO	NO
SAP HANA 1.0 (SPS10 and later) (Intel)	YES	YES
SAP HANA 2.0 (IBM Power and Intel)	YES	YES

- For third-party backup tools, separate certification processes are required for each platform and tool version. If a third-party backup tool is certified for Intel platforms, that tool is **not** automatically also certified for IBM Power Systems (and vice versa). Separate tool certification is required for IBM Power LE and IBM Power BE systems.

## 11.2.3 Authorizations Needed for Backup and Recovery

Backup and recovery operations can only be performed by users that have the appropriate authorizations. The authorization required depends on whether administrative tasks are performed at system level or at database level.

### → Tip

We recommend that you create your own dedicated database users with only the specific authorizations required for backup and recovery.

The following authorizations are required to administer SAP HANA:

### Backup and Recovery (SAP HANA Cockpit)

Authorizations for Backup and Recovery (SAP HANA Cockpit)

To Perform This Task...	You Need These SAP HANA System Privileges...		
	System Database	Tenant Database	Tenant Database (Through the System Database)
View, create, and cancel database backups	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	DATABASE BACKUP OPERATOR or DATABASE BACKUP ADMIN or DATABASE ADMIN
Delete database backups and backups of the backup catalog	BACKUP ADMIN	BACKUP ADMIN	DATABASE BACKUP ADMIN or DATABASE ADMIN
Recover or copy a database	Operating system user <sid>adm	(not possible)	DATABASE RECOVERY OPERATOR or DATABASE ADMIN

To Perform This Task...

You Need These SAP HANA System Privileges...

	System Database	Tenant Database	Tenant Database (Through the System Database)
Schedule backups	<p>BACKUP ADMIN</p> <p>SELECT, UPDATE, and DELETE privileges for the following tables:</p> <ul style="list-style-type: none"> <li>• <code>_SYS_XS.JOB_SCHEDULES</code></li> <li>• <code>_SYS_XS.JOBS</code></li> </ul>	<p>BACKUP ADMIN</p> <p>SELECT, UPDATE, and DELETE privileges for the following tables:</p> <ul style="list-style-type: none"> <li>• <code>_SYS_XS.JOB_SCHEDULES</code></li> <li>• <code>_SYS_XS.JOBS</code></li> </ul>	<p>DATABASE BACKUP OPERATOR or</p> <p>DATABASE BACKUP ADMIN or</p> <p>DATABASE ADMIN and SELECT, UPDATE, and DELETE privileges for the following tables:</p> <ul style="list-style-type: none"> <li>• <code>_SYS_XS.JOB_SCHEDULES</code></li> <li>• <code>_SYS_XS.JOBS</code></li> </ul>
Configure backups	<p>To display the backup configuration settings, BACKUP ADMIN.</p> <p>To configure <b>backup retention</b>, you also need:</p> <ul style="list-style-type: none"> <li>• SELECT, UPDATE, and DELETE privileges for table <code>_SYS_XS.JOB_SCHEDULES</code></li> <li>• SELECT privileges for table <code>_SYS_XS.JOBS</code></li> </ul>	<p>To display the backup configuration settings, BACKUP ADMIN.</p> <p>To configure <b>backup retention</b>, you also need:</p> <ul style="list-style-type: none"> <li>• SELECT, UPDATE, and DELETE privileges for table <code>_SYS_XS.JOB_SCHEDULES</code></li> <li>• SELECT privileges for table <code>_SYS_XS.JOBS</code></li> </ul>	<p>DATABASE BACKUP ADMIN</p>

### System-wide Backup Configuration

To change default configuration settings for all the tenant databases, you need DATABASE ADMIN.

## Native SQL

Authorizations for Backup and Recovery (Native SQL)

To Perform This Task...	You Need These SAP HANA System Privileges...		
	System Database	Tenant Database	Tenant Database (Through the System Database)
View, create, and cancel database backups	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	BACKUP ADMIN or BACKUP OPERATOR (recommended for batch users only)	DATABASE BACKUP OPERATOR DATABASE BACKUP ADMIN DATABASE ADMIN
Check that required disk space for a backup is available.	BACKUP OPERATOR, BACKUP ADMIN		DATABASE BACKUP OPERATOR, DATABASE BACKUP ADMIN
Recover or copy a database		(not possible)	DATABASE RECOVERY OPERATOR DATABASE ADMIN
Check whether backups are accessible			DATABASE RECOVERY OPERATOR
Create data snapshots	BACKUP OPERATOR, BACKUP ADMIN	(not possible)	(not possible)
Delete database backups and backups of the backup catalog	BACKUP ADMIN	BACKUP ADMIN	DATABASE BACKUP ADMIN DATABASE ADMIN

## Backup Encryption

Authorizations for Backup and Recovery (Backup Encryption)

	System Database	Tenant Database	Tenant Database (Through the System Database)
Enable or Disable Backup Encryption  (To encrypt backups, no additional authorization is required.)	ENCRYPTION ROOT KEY ADMIN	ENCRYPTION ROOT KEY ADMIN	ENCRYPTION ROOT KEY ADMIN

**i Note**  
Encryption for a tenant database can only be enabled or disabled from the system database if the system database has control.

For more information about backup encryption, see *Enable Encryption of Data and Log Backups* in the *SAP HANA Administration Guide (Encryption)* and *ALTER SYSTEM BACKUP ENCRYPTION Statement (System Management)* in the *SAP HANA SQL and System Views Reference*.

## BACKUP ADMIN Versus BACKUP OPERATOR

The system privileges `BACKUP ADMIN` and `BACKUP OPERATOR` allow you to implement a more specific separation of user roles.

System Privilege	Permitted Operations
<code>BACKUP ADMIN</code>	All backup-related operations, including deleting backups and backup configuration.
<code>BACKUP OPERATOR</code>	<ul style="list-style-type: none"> <li>• Create backups</li> <li>• Cancel backups</li> <li>• Check available space</li> <li>• Query views</li> </ul>

## SAP HANA Studio

Authorizations for Backup and Recovery (SAP HANA Studio)

To Perform This Task...	You Need These SAP HANA System Privileges...		
	System Database	Tenant Database	Tenant Database (Through the System Database)
View and create database backups	BACKUP ADMIN	BACKUP ADMIN	DATABASE ADMIN
	CATALOG READ	CATALOG READ	
Recovery	Operating system user <sid>adm	(not possible)	DATABASE ADMIN

For more information about SAP HANA authorization, see *SAP HANA Authorization* in the *SAP HANA Security Guide* and *GRANT Statement (Access Control)* in the *SAP HANA SQL Reference Guide for SAP HANA Platform*.

## 11.2.4 SAP HANA Backup Types

SAP HANA supports the following backup types:

- Full backups:
  - Complete data backups
  - Data snapshots

### Note

To make use of storage snapshot-based SAP HANA backups, first create an SAP HANA data snapshot.

For more information, see *Data Snapshots and Database Snapshots*

- Delta backups (incremental backups and differential backups)
- Redo log backups
- Native encryption of backups

- Backups created using third-party backup tools

## Related Information

[Backing Up Customer-Specific Configuration Settings \[page 1494\]](#)

[Naming Conventions \[page 1436\]](#)

[Diagnosis Files for Backup and Recovery \[page 1600\]](#)

### 11.2.4.1 Data Backups

A data backup includes all the data that is required to recover the database to a consistent state.

With a data backup, only the actual data is backed up. Unused space in the database is not backed up.

#### **i** Note

A data backup does not include the log area or customer-specific configuration settings (\*.ini files).

The data area is backed up in parallel for each of the SAP HANA services. If SAP HANA is running on multiple hosts, a data backup includes all the service-specific backup parts for all the hosts.

While a data backup is running, some data integrity checks are performed. These integrity checks are performed on block level (page level on disk) only, and do not analyze the content of each data block.

If these checks are successful, the data is written to the backup destination.

#### **i** Note

To ensure the safety of your data, data backups should be stored on multiple different backup destinations outside the SAP HANA database.

## Related Information

[Creating Backups \[page 1498\]](#)

[Backing Up Customer-Specific Configuration Settings \[page 1494\]](#)

## 11.2.4.2 Delta Backups

Delta backups contain only the data that has been changed since the last full data backup (complete data backup or data snapshot) or the last delta backup.

### i Note

Delta backups can only be created after a data backup has been created.

With a delta backup, changed data means changes to the physical representation of the data in the SAP HANA persistent storage. This is not always the data that was actually changed by an application. An internal reorganization can change the physical representation **without changing the actual data**.

### 🔗 Example

In a delta merge of a column store partition, only a small amount of the data may have been changed. Nevertheless, all the data is restructured and rewritten. This means that a delta merge can be as large as a full data backup. If a delta backup is created in this situation, the whole partition is backed up in the delta data backup, even if only a small amount of the actual data was changed.

## Benefits of Delta Backups

Delta backups allow you to reduce the amount of data that is backed up, compared to full data backups.

In turn, this means that delta backups are normally faster to create than full data backups.

In addition, a database recovery using delta backups is normally faster than a recovery using log backups. With delta backups, only the changed data is recovered, whereas with log backups, each log entry needs to be processed separately before it is recovered. Recovering many log backups is normally more CPU-intensive than recovering a small number of delta backups.

### → Tip

To keep data that is frequently changed separate from data that is not frequently changed, consider partitioning column store data. Partitioning column store data can reduce the size of delta backups.

## Related Information

[Delta Backup Types \[page 1419\]](#)

## 11.2.4.2.1 Delta Backup Types

SAP HANA supports both differential backups and incremental backups.

### i Note

Delta backups can only be created after a data backup has been created.

Comparison of Delta Backup Types

	Differential Backup	Incremental Backup
<b>What Data is Backed Up?</b>	The data changed since the last full data backup (complete data backup or data snapshot).	The data changed since the last full data backup or the last delta backup (incremental or differential).
<b>Backup Size</b>	The amount of data to be saved with each differential backup <b>increases</b> .	If data remains unchanged, it is not saved to more than one backup. For this reason, incremental backups are the smallest of the backup types.
<b>Backup and Recovery Strategy</b>	If your backup strategy is based on only full data backups and differential backups, only two backups are needed for a recovery: one full data backup and one differential backup.	If your backup strategy is based on only full data backups and incremental backups, to recover the database, SAP HANA needs the following backups: <ul style="list-style-type: none"><li>• The full data backup on which the incremental backups are based</li><li>• Each incremental backup made since the full data backup</li></ul> In some situations, many incremental backups may be needed for a recovery.

## Recovery Using Delta Backups

### i Note

A recovery can use multiple incremental backups, but only one differential backup.

If you wish to recover SAP HANA using differential or incremental backups, you must also use log backups. If log backups are not available, you can only recover using a full data backup.

**System replication:** Delta backups must be based on the complete data backup of the current primary. After a takeover, if you wish to create delta backups, you must first have created a complete data backup of the current primary.

To recover SAP HANA, you can combine a differential backup with one or more incremental backups.

### ❖ Example

You could recover SAP HANA to a specific point in time using the following sequence of backups:

1. Full data backup
2. Differential backup
3. Incremental backup 1
4. Incremental backup 2
5. Log backups

## Related Information

[Recover a Database \[page 1548\]](#)

[Recovery with System Replication \[page 1575\]](#)

## 11.2.4.3 Data Snapshots

A data snapshot captures the data persisted in the data area at a particular point in time. A data snapshot includes all the data that is required to recover each individual SAP HANA database to a consistent state.

### Benefits of Data Snapshots

Data snapshots offer an additional option to safeguard the SAP HANA data area and to recover an SAP HANA database.

Data snapshots have the following benefits:

- Data snapshots can be created with minimal impact on database performance. Data snapshots are created in the storage system and do not consume database resources.
- Recovery from a data snapshot is faster than a recovery from a data backup. The data snapshot only needs to be made available in the data area of the storage system.

For more information about the relative benefits of data snapshots, see *Comparison of Data Backups and Data Snapshots*.

### i Note

To make use of storage snapshot-based SAP HANA backups, first create an SAP HANA data snapshot.

For more information, see *Data Snapshots and Database Snapshots*

## Data Snapshots and External Storage Systems

The external storage system must copy each data volume in an atomic operation in order to ensure the I/O consistency of the data snapshot. Multiple data volumes do not need to be copied in parallel; data volumes can be copied one at a time.

## Data Snapshots and SAP HANA Dynamic Tiering

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

## Related Information

[Create a Data Snapshot \(Native SQL\) \[page 1502\]](#)

[Encryption of Data Snapshots \[page 1426\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

[SAP Note 2375865](#) 

### 11.2.4.3.1 Data Snapshots and Database Snapshots

A **data snapshot** is created by first creating an **internal database snapshot** of the file system of the data area. The internal database snapshot is then used to create a data snapshot.

The internal database snapshot captures the state of the SAP HANA database at the point in time that the snapshot was started. In this way, the internal database snapshot ensures that the state of the data snapshot is consistent.

#### **i** Note

While a **data snapshot** is being created, no further data integrity checks are performed (checksum calculation) on page or block level.

(With **data backups**, the block-level integrity of the data to be backed up is checked automatically while the backups are being created. The content of each data block is not checked.)

## Internal Database Snapshot and System Replication

An internal database snapshot used to create a data snapshot does not conflict with an internal database snapshot used for system replication. There is no relation between these two types of internal database snapshots.

### Related Information

[Create a Data Snapshot \(Native SQL\) \[page 1502\]](#)

[Encryption of Data Snapshots \[page 1426\]](#)

## 11.2.4.3.2 Comparison of Data Backups and Data Snapshots

You can use this overview to help assess the benefits of using data backups and data snapshots as part of your backup strategy.

Comparison of Data Backups and Data Snapshots

	Data Backup to File	Data Backup Using Backint	Data Snapshot
<b>Advantages</b>	<ul style="list-style-type: none"><li>• Integrity checks at block level For more information, see <i>Manually Checking Whether a Recovery is Possible</i>.</li><li>• Can be encrypted For more information, see <i>SAP HANA Backup Encryption</i>.</li></ul>	<ul style="list-style-type: none"><li>• Integrity checks at block level</li><li>• Integrated into existing data center infrastructure</li><li>• Third-party backup tool offers additional features. For example, deduplication.</li><li>• Backups are immediately available for recovery</li></ul>	<ul style="list-style-type: none"><li>• Fast</li><li>• Negligible impact on network</li><li>• Can be encrypted For more information, see <i>Encryption of Data Snapshots</i>.</li></ul>
<b>Disadvantages</b>	<ul style="list-style-type: none"><li>• Requires additional storage</li><li>• Generates additional network load</li><li>• File system needs to be monitored (fill level)</li><li>• More time is needed to make backups available for recovery</li></ul>	<ul style="list-style-type: none"><li>• Generates additional network load</li></ul>	<ul style="list-style-type: none"><li>• No integrity checks on page or block level (Checksum calculation)</li></ul>

	Data Backup to File	Data Backup Using Backint	Data Snapshot
<b>Backup Size</b>	<ul style="list-style-type: none"> <li>• Payload only</li> </ul>	<ul style="list-style-type: none"> <li>• Payload only</li> </ul>	<ul style="list-style-type: none"> <li>• Size of the data area (but is usually compressed or deduplicated by the storage tool)</li> </ul>
<b>Backup Duration</b>	<ul style="list-style-type: none"> <li>• IO-bound (reading from data volume, writing to target)</li> <li>• Network-bound (writing to target file system)</li> </ul>	<ul style="list-style-type: none"> <li>• IO-bound (reading from data volume)</li> <li>• Network-bound (writing to backup server)</li> </ul>	<ul style="list-style-type: none"> <li>• Negligible (depending on the storage tool)</li> </ul>

## Related Information

[Encryption of Data Snapshots \[page 1426\]](#)

[Working with Third-Party Backup Tools \[page 1442\]](#)

### 11.2.4.4 Log Backups

By default, SAP HANA log segments are backed up automatically.

Log segments are backed up for each service that has persistence. When a log backup is created, only the actual data (the "payload") of the log segments is written from the log area to service-specific log backups in the file system or to a third-party backup tool.

#### Interrupted Log Backups

If an SAP HANA service stops, log backups for that service also stop. The stopped service must be immediately restarted.

#### Caution

If a stopped service is not restarted, a database recovery will only be possible to a point in time before this service stopped. That is, only to a point in time for which log backups for **all services** exist.

If log backups for any service are missing, it will not be possible to recover the database to its most recent state.

#### Log Area Unavailable

If the log area becomes temporarily unavailable, once it is available again, SAP HANA automatically continues creating log backups for all the log segments that have not so far been backed up.

## Removing a Service

If you need to remove a service, use the procedure described in the section *Steps After Copying a Database*, as this ensures that the log area is backed up and can be used to recover the database.

### 11.2.4.4.1 Savepoints and Redo Logs

To maintain optimal performance, an SAP HANA database holds the bulk of its data in memory. However, SAP HANA also uses persistent storage to provide a fallback in the event of a fault or a failure.

During normal database operation, changed data is automatically saved from memory to disk at regular **savepoints**. By default, savepoints are created every five minutes, including during a backup.

With a system running on properly configured hardware, the impact on performance of savepoints is negligible. Savepoints do not affect the processing of transactions. During a savepoint, transactions continue to run as normal, and new transactions can be started as normal.

Additionally, all data changes are recorded in the **log segments in the redo log buffer**. When a database transaction is committed, these log segments are saved to disk. Also, if the redo log buffer fills at any time, the redo log buffer is written to disk anyway, even if no commit has been sent.

## Related Information

[Persistent Data Storage in the SAP HANA Database \[page 519\]](#)

[Database Restart and Savepoints \[page 1425\]](#)

[M\\_SAVEPOINTS System View](#)

## 11.2.4.4.2 Database Restart and Savepoints

An SAP HANA database can be restarted in the same way as a disk-based database, and returned to its most recent consistent state by replaying the redo logs from the log area (not the log backups).

The log records in the log area only need to be processed from the last savepoint position, rather than from the beginning of the log area. In this way, savepoints help to speed up database restarts.

While savepoints and logs can protect your data against some failures, these mechanisms offer no protection if the persistent storage itself is damaged or if a logical error occurs. To be able to react appropriately and quickly to a hardware failure, as well as to protect your data against logical errors and the possibility of corruption caused by software changes, it is essential to have a well-planned strategy for backup and recovery.

[Savepoints and Redo Logs \[page 1424\]](#)

## 11.2.4.5 SAP HANA Backup Encryption

SAP HANA supports native encryption of backups.

Backup encryption safeguards the privacy of the SAP HANA backup data by preventing unauthorized parties from reading the content of backups. A backup of an SAP HANA single-container system can only be recovered to a tenant database.

When backup encryption is enabled, the backup data is transferred encrypted to the backup location, both for file-based backups and for backups created using third-party backup tools.

SAP HANA backups are encrypted using AES 256-bit encryption.

### Which Backup Types Can Be Encrypted?

A backup of an SAP HANA single-container system can only be recovered if backup encryption is enabled, all backups are encrypted. It is not possible to enable encryption for an individual data backup.

#### i Note

The backup catalog is not encrypted.

#### i Note

To encrypt data snapshots, additional steps are necessary.

For more information, see *Encryption of Data Snapshots* in *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

## 11.2.4.5.1 Encryption of Data Snapshots

If backup encryption is enabled, data snapshots are not automatically encrypted. To encrypt data snapshots, additional steps are necessary.

A data snapshot can be encrypted if the following conditions are met:

- Backup encryption is enabled.
- Log encryption is enabled.
- Data volume encryption is enabled.

For more information, see the *SAP HANA Administration Guide (Encryption)* and the *SAP HANA Security Guide*.

- The data conversion status is **not active**.

The SAP HANA database must not be in the process of encrypting or decrypting data.

To check the data conversion status, execute the following SQL statement:

```
SELECT DATA_CONVERSION_ACTIVE FROM M_PERSISTENCE_ENCRYPTION_STATUS
```

To encrypt a data snapshot, `DATA_CONVERSION_ACTIVE` must be set to **false**.

For more information, see *M\_PERSISTENCE\_ENCRYPTION\_STATUS System View* in the SAP HANA SQL Reference Guide for SAP HANA Platform.

[SAP HANA Backup Encryption \[page 1425\]](#)

## 11.2.4.5.2 Resource Consumption With Backup Encryption

With backup encryption enabled, SAP HANA backups require additional main memory and CPU. Depending on how much main memory and CPU are available, you can offset an impact on backup performance by adjusting buffer sizes, enabling parallel encryption, or multistreaming (for third-party backup tools).

Typically, backup encryption does not impact the performance of backup and recovery, since the backup and recovery operations, such as encryption, checksum calculation, and I/O, run in parallel. However, with backup encryption, higher CPU usage is to be expected. Depending on the sizing of your SAP HANA system, you may notice a negative impact on overall system performance.

To create encrypted backups with optimal performance, SAP HANA consumes up to three times as much main memory and CPU than is needed to create unencrypted backups. Resource consumption is compared below:

Backup Type	Buffer Allocated
Unencrypted backups	<p>The memory consumed by backup is determined by the configured I/O buffer size to read/write backups.</p> <p>For an unencrypted data backup, this amount of memory is allocated twice, one buffer for reading data and one buffer for writing data. This is the case when multistreaming is not used.</p> <p>To configure I/O buffer size, you can use the parameter <code>data_backup_buffer_size</code> in the backup section of the <code>global.ini</code> parameter file.</p> <p>For more information, see <i>Change the I/O Buffer Size</i>.</p>
Multistreaming backups	<p>The configured I/O buffer size is also allocated to each channel.</p> <p>With multistreamed backups, SAP HANA allocates one additional I/O buffer for each additional channel. For this reason, the memory consumption is calculated as <math>\text{data\_backup\_buffer\_size} * (1 + \text{parallel\_data\_backup\_backint\_channels})</math>.</p> <p>To configure multistreaming backups, you can use the parameter <code>parallel_data_backup_backint_channels</code> in the backup section of the <code>global.ini</code> parameter file.</p> <p>For more information, see <i>Configure Multistreaming with Third-Party Backup Tools</i>.</p>

Backup Type	Buffer Allocated
Encrypted backups	<p>The configured I/O buffer size is also allocated to two additional I/O buffers for each channel for each persistent service. For this reason, the memory consumption is calculated as <math>\text{data\_backup\_buffer\_size} * (1 + 3 * \text{parallel\_data\_backup\_backint\_channels})</math></p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>i Note</b></p> <p>The size of encrypted SAP HANA backups is the same as unencrypted backups (except for the checksum).</p> </div>

### Considerations for Backup Encryption

Depending on how much main memory and CPU are available on an SAP HANA system, consider the following options:

- Configure SAP HANA to run backup (and recovery) with sub-optimal performance. You can configure SAP HANA to perform backup and recovery operations with encryption enabled, but with the same resource consumption as without encryption. As a consequence, backup and recovery operations will typically take longer to complete. Set the parameter `enable_parallel_backup_encryption` from **true** (default) to **false**.
- Install additional CPUs in your SAP HANA system.
- Reduce the backup I/O buffer size allocated by SAP HANA. If the I/O buffer size is reduced, backup will typically have a lower throughput, and, as a consequence, will take longer to complete. If no additional physical main memory is available, the backup I/O buffer size for a database can be reduced to approximately one third of the backup I/O buffer size configured for unencrypted backups. For more information, see *Change the I/O Buffer Size* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.
- If you are working with a third-party backup tool, it is not recommended to use data deduplication with encrypted backups, as this will increase backup times with no actual benefit.

### Calculating Backup Memory Consumption

The following examples illustrate how SAP HANA allocates main memory for data backup.

#### Example

##### Backup without Multistreaming

Criteria	Configuration	Memory Allocated for Data Backup
Configuration parameter setting:	<code>parallel_data_backup_backint_channels = 1</code>	

Criteria	Configuration	Memory Allocated for Data Backup
Backup encryption enabled?	No	1024 MB + 1024 MB = <b>2 GB</b>
Backup encryption enabled?	Yes	1024 MB + (3 * 1024 MB) = <b>4 GB</b>

### Example

#### Backup with Multistreaming

Criteria	Configuration	Memory Allocated for Data Backup
Configuration parameter setting:	<code>parallel_data_backup_back int_channels = 32</code>	
Backup encryption enabled?	No	1024 MB + (32 * 1024 MB) = <b>33 GB</b>
Backup encryption enabled?	Yes	1024 MB + (3 * 32 * 1024 MB) = <b>97 GB</b>

In this scenario, SAP HANA allocates approximately three times as much main memory with backup encryption enabled, compared with backup encryption disabled.

### 11.2.4.5.3 Backup Encryption Root Key

If you enable encryption (either for backup, log, or data volume), the SAP HANA backups are encrypted and decrypted using a backup encryption root key.

If you enable encryption (either for backup, log, or data volume), the SAP HANAThe same backup encryption root key is used for data backups and log backups.

#### i Note

Data snapshots are not encrypted using the backup encryption root key.

For more information, see *Encryption of Data Snapshots* in *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

The backup encryption root key is encrypted and stored in the secure store in the file system (instance SSFS) together with other encryption root keys. For example, application encryption root keys.

When a new tenant database is created, a new backup encryption root key is generated for that tenant database.

Other tenant databases retain their existing backup encryption root key.

#### Caution

If backup encryption is enabled, database administrators must ensure that the current backup encryption root key and older versions are backed up.

Whenever the backup encryption root key is changed, you must back it up. Without a current backup of the backup encryption root key, some data will be lost after a recovery.

There is always one active backup encryption root key. If (repeated) root key rotation is used, previously active keys can also exist, and may be needed to recovery SAP HANA from older encrypted backups.

For more information, see *Root Key Backup* in the *SAP HANA Security Guide*.

#### Note

The block-level integrity of encrypted backups can still be checked without access to the backup encryption root key.

For more information, see *Manually Checking Whether a Recovery is Possible* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

For more information about working with encryption root keys, see *Encryption Key Management* in the *SAP HANA Security Guide* and *Changing Encryption Root Keys* in the *SAP HANA Administration Guide (Encryption)*.

## 11.2.4.5.4 SAP HANA Dynamic Tiering and Backup Encryption

If you are planning a backup and recovery strategy for a landscape that makes use of SAP HANA dynamic tiering, see *SAP Note 2375865 (SAP HANA Dynamic Tiering 2.0: Backup and Restore Functional Restrictions)* for information about considerations for dynamic tiering.

### Related Information

[SAP Note 2375865](#) 

## 11.2.4.6 Backup Catalog

The backup catalog contains information about the backup history.

The backup catalog enables SAP HANA to determine the following:

- Whether a recovery is possible
- Which backups to use to recover a database
- Which backups are no longer needed for a recovery

The system database and each tenant database have their own backup catalog.

### **i** Note

Each time a backup of any type is created, the backup catalog is backed up and versioned. In this way, the latest version of the backup catalog always contains the entire backup history.

### Recovery Without the Backup Catalog

It is possible to recover SAP HANA without using a backup catalog, or using data backups that are not recorded in the backup catalog.

Without a backup catalog, a point-in-time recovery cannot be done. Without a backup catalog, it is only possible to recover SAP HANA to a specific data backup.

If you recover SAP HANA using a backup that is not recorded in the backup catalog, you need to manually specify the backup type (File or Backint), the location of the backup, and its prefix.

## 11.2.4.6.1 What Information is in the Backup Catalog?

The backup catalog contains information about the backup history.

In the Backup Catalog	Description
Backups created for a database	<p>This includes data backups, data snapshots, delta backups (differential and incremental backups), and log backups.</p> <p>Each recovery is recorded in the backup catalog, but not displayed in the monitoring views.</p> <p>For more information, see <i>Monitoring Views for the Backup Catalog</i>.</p>
Start and completion times of the backups	<p>The backup catalog records local server times and UTC times.</p> <p>The start and end times of a recovery are recorded in the backup catalog as local server time. Points in time for a recovery in the SQL statements are specified as UTC.</p> <p>The start time of a backup does not reflect the exact state of the database when the backup was created. The savepoint that determines the database state is always taken after the start time of a data backup.</p> <p>Changes made to the database after this savepoint are not included in a data backup.</p>
Whether a backup is still running	<p>The backup catalog does not show the progress of a backup. The progress of a backup is recorded in the <code>backup.log</code>, and can be seen using the view <code>M_BACKUP_PROGRESS</code>.</p> <p>For more information, see <i>backup.log</i> and <i>Monitoring Views for the Backup Catalog</i>.</p>
Status of a backup	<p>Records whether a backup was completed successfully or not.</p> <p>The status can be:</p> <ul style="list-style-type: none"><li>• successful</li><li>• failed</li><li>• running</li><li>• cancel pending</li><li>• canceled</li></ul>
Volumes that were backed up	<p>Backups are created in separate backup destinations for each volume.</p>

In the Backup Catalog	Description
Log backups and the log positions they contain	<p>For data backups, one exact redo log position is recorded. This redo log position corresponds to its savepoint. During a recovery, log replay starts at the redo position for the data backup.</p> <p>For log backups, a range of redo log positions is recorded, from the oldest log entry to the newest log entry.</p>
Backup destinations and their sizes	<p>Data backups can be written to different destinations. However, all the parts of the same data backup are written to the same destination.</p> <p>For file-based data backups, you can change the default destination.</p> <p>For backups created using third-party backup tools, a named pipe is created in the file system for the system database or tenant database. The default backup destination cannot be changed.</p>
Destination type	<p>The destination type can be:</p> <ul style="list-style-type: none"> <li>• file</li> <li>• Backint</li> <li>• data snapshot</li> </ul>
Backup ID	<p>ID of a data backup or a log backup.</p> <p>All backup files of a single data backup share the same BACKUP_ID.</p> <p>If you are working with a third-party backup tool, an external backup ID (EBID) is also included.</p>
Encryption Root Key	<p>If encryption is enabled, the key used for encrypting a backup.</p>
Comment	<p>Additional user-supplied information.</p> <p>A comment can help to identify a particular backup in the backup catalog.</p>

## Related Information

- [Monitoring Views for the Backup Catalog \[page 1434\]](#)
- [backup.log \[page 1600\]](#)
- [Savepoints and Redo Logs \[page 1424\]](#)

## 11.2.4.6.2 Monitoring Views for the Backup Catalog

You can use monitoring views to display information from the backup catalog. Monitoring views are stored in the SYS schema.

The monitoring views `M_BACKUP_CATALOG`, `M_BACKUP_CATALOG_FILES`, and `M_BACKUP_PROGRESS` provide different overviews of information from the backup catalog.

Monitoring View	Description
<code>M_BACKUP_CATALOG</code>	<p>Provides an overview of information about backup activities.</p> <p>Each row in the view provides information about a separate catalog entry identified by a backup ID. This information includes the type (for example, data backup), and start and completion times.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>The backup ID is used to reference the parts of a backup in the <code>M_BACKUP_CATALOG_FILES</code> monitoring view.</p> </div>
<code>M_BACKUP_CATALOG_FILES</code>	<p>Provides information about the backups created, and the backup destinations for data and log backups.</p> <p>Each row in the view has a corresponding entry in the <code>M_BACKUP_CATALOG</code> monitoring view. Each row is identified by a backup ID.</p> <p>The <code>M_BACKUP_CATALOG_FILES</code> monitoring view provides additional information about each database service that was involved in a backup. For example, with a data backup, each database service is listed with its specific backup information such as destination path and redo log position.</p>
<code>M_BACKUP_PROGRESS</code>	<p>Provides detailed information about the most recent data backup.</p> <p>Each row contains information about one service that is part of the data backup, identified by host name and port number.</p>

Comparison of the Monitoring Views for the Backup Catalog

<code>M_BACKUP_CATALOG</code>	<code>M_BACKUP_CATALOG_FILES</code>	<code>M_BACKUP_PROGRESS</code>
All types of backups (data backup, log backup, delta backups, and data snapshots, if available)	Only for data backups, differential backups, and incremental backups	
All completed and currently running backups since the database was created	Currently running and last finished backups only	
Persistent	Cleared at database restart	
Total amount of data for completed backups only	Total and already transferred amount of data for all backups	

For more information, see the *SAP HANA SQL Reference Guide for SAP HANA Platform*.

## Example: Search for a Data Snapshot Using M\_BACKUP\_CATALOG

To search for a data snapshot in the backup catalog, you can use either the backup ID or the comment.

To search for a backup ID, use the following command:

```
SELECT * FROM "SYS"."M_BACKUP_CATALOG" WHERE BACKUP_ID = backup_id
```

## Related Information

[M\\_BACKUP\\_CATALOG System View](#)

[M\\_BACKUP\\_CATALOG\\_FILES System View](#)

### 11.2.4.6.3 Rebuilding the Backup Catalog

In exceptional situations that are outside of the control of SAP HANA, the backup catalog may not be available at the time of a recovery. If the backup catalog is not available, it can be largely rebuilt using the existing data and log backups from the file system.

To rebuild the backup catalog, use the `hdbbackupdiag` tool.

For more information, see SAP Note 1812057 (*Reconstruction of the backup catalog using hdbbackupdiag*).

#### Caution

If the backup catalog is rebuilt:

- The backup catalog only contains information about the data backups and log backups that you provide through the `hdbbackupdiag` tool.  
Any parts of the database backup history that you do not specify are lost.
- The backup catalog no longer contains data snapshots or backups created using third-party tools.  
As a consequence, those backups cannot be used for a recovery.
- Data and log backup directories must contain **only SAP HANA data**.
- A log is generated and written to the SAP HANA working directories.  
If you rebuild the backup catalog **more than once**, this log will also be read, and an error will be caused.  
For this reason, if you need to rebuild the backup catalog a second time, remove the log from the first rebuild.
- Only the backup of the backup catalog is affected; the persistent SAP HANA backup catalog is not changed.  
The backup of the backup catalog is used to recover SAP HANA.

## Related Information

[Checking Whether a Recovery is Possible \[page 1531\]](#)

[Housekeeping: Deleting and Archiving Backups \[page 1517\]](#)

## 11.2.4.7 Naming Conventions

When you plan your backup strategy, you need to be familiar with the naming conventions and recommendations for file-based data backups, delta backups, and third-party backup tools.

### Related Information

[Naming Conventions for Data Backups \[page 1436\]](#)

[Naming Conventions for Delta Backups \[page 1440\]](#)

[Naming Conventions for Log Backups \[page 1441\]](#)

[Naming Conventions for the Backup Catalog \[page 1442\]](#)

[Temporary Names for File-Based Backups \[page 1442\]](#)

### 11.2.4.7.1 Naming Conventions for Data Backups

When you plan your backup strategy, you need to be familiar with the naming conventions and recommendations for data backups.

Each data backup name is comprised of the following elements:

```
<path><prefix>_<suffix>
```

#### **i** Note

The naming conventions apply to data backups created in the file system and data backups created using third-party tools. With third-party tools, you cannot change the backup path.

## Elements of Data Backup Names

Name Element	Description
<code>&lt;path&gt;</code> For example: <code>/backup/data/</code>	<p>Optional.</p> <p><b>For file-based backups:</b></p> <p>If no complete path is specified, the default backup destination is prepended to the backup name.</p> <p><b>For backups created using third-party tools:</b></p> <p>A named pipe is created in the file system for the system database or tenant database:</p> <ul style="list-style-type: none"><li>• <code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/backint/SYSTEM</code></li><li>• <code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/backint/DB_&lt;tenant_database_name&gt;</code></li></ul> <p>A third-party backup tool reads data to be backed up from the named pipe, and writes the backup data in accordance with the tool configuration.</p>

Name Element	Description
<prefix>	<p>Optional.</p> <p>You can use the prefix proposed by the system or you can specify a different prefix for the backup name.</p>
	<p><b>→ Tip</b></p> <p>To be able to more easily identify archived file-based backups, it is strongly recommended that you use a unique prefix for each data backup name. For example, a timestamp.</p> <p>By default, the name of each scheduled backup is prefixed with the timestamp of the start of the backup. The placeholders <b>[date]</b> and <b>[time]</b> are automatically converted to the current timestamp.</p> <p>If you use the same prefixes, it is recommended that you replicate a data backup to a new destination as soon as the backup is created. Otherwise, an existing complete data backup with the same name will be overwritten by the next data backup.</p> <p>For backups created using <b>third-party tools</b>, data backups are not overwritten. The Backint for SAP HANA interface is able to identify multiple versions of backups with the same name.</p> <p>Nevertheless, for easier identification and versioning, it is strongly recommended to assign unique backup names.</p>
	<p><b>i Note</b></p> <p>It is <b>not</b> possible to change the prefix of a backup after it has been created.</p>
<Suffix>	<p>The system adds a suffix to each backup name.</p> <p>For complete data backups, the suffix is unique only within a specific backup. For delta backups and log backups, the suffix is unique for a specific database.</p> <p>As a suffix is assigned for each service that is included in the backup, you only need to specify the name (&lt;path&gt;&lt;prefix&gt;) for all the backups on all the hosts in the system. The next time a service is backed up, the system assigns the same suffix to the backup to that service.</p>

### i Note

Once backups have been created, it is strongly recommended that you **do not change** their names.

When backups are created, their names are stored in the backup catalog. For a recovery, specific backup components are located using the names stored in the backup catalog. If the name of a backup was changed after it was recorded in the backup catalog, it will not be possible to locate it using the backup catalog, and it will not be possible to use it for a point-in-time recovery. A renamed backup can only be used to recover the database without replaying log backups (RECOVER DATA).

You can copy or move file-based backups to a different location. If you use a moved backup for a recovery, you need to specify its current location.

## Example: Names for Parts of a Data Backup

During backup, each service backs up its data to the specified backup destination.

Below is an example of a set of backups from one data backup.

```
/backup/data/COMPLETE_DATA_BACKUP_databackup_0_1
```

```
/backup/data/COMPLETE_DATA_BACKUP_databackup_1_1
```

```
/backup/data/COMPLETE_DATA_BACKUP_databackup_2_1
```

...

In the above example:

Element	In Example
<path>	/backup/data/
<prefix>	COMPLETE_DATA_BACKUP
<suffix>	databackup_0_1
	The suffix is automatically added by SAP HANA.
	0 is the volume ID.
	1 is the partition ID.

## 11.2.4.7.2 Naming Conventions for Delta Backups

When you plan your backup strategy, you need to be familiar with the naming conventions and recommendations for differential and incremental backups.

Structure of File Names for Delta Backups

	Differential Backups	Incremental Backups
<b>Prefix</b>	User-defined. A timestamp is recommended. For example: <b>2018-01-23</b>	User-defined. A timestamp is recommended. For example: <b>2018-01-23</b>
<b>String</b>	<code>datbackup_differential</code>	<code>datbackup_incremental</code>
<b>Backup ID</b>	The backup ID of the <b>full data backup</b> on which the differential backup is based	The backup ID of the <b>full data backup or the delta backup</b> on which the incremental backup is based
<b>Delta Backup ID</b>	ID of the differential backup	ID of the incremental backup
<b>Volume ID</b>	Volume ID as with complete data backups	Volume ID as with complete data backups
<b>Partition ID</b>	Partition ID as with complete data backups	Partition ID as with complete data backups

### Example: File Names for Differential Backups

The SQL statement `BACKUP DATA DIFFERENTIAL USING FILE ('2018-01-23')` creates a differential backup based on the previously created full data backup.

Example names of incremental backup files:

`2018-01-23_datbackup_differential_1426237023821_1426237780534_0_1`

`2018-01-23_datbackup_differential_1426237023821_1426237780534_1_1`

`2018-01-23_datbackup_differential_1426237023821_1426237780534_2_1`

`2018-01-23_datbackup_differential_1426237023821_1426237780534_3_1`

### Example: File Names for Incremental Backups

The SQL statement `BACKUP DATA INCREMENTAL USING FILE ('2018-01-23')` creates an incremental backup based on the previously created full data backup or differential backup.

Example names of incremental backup files:

```
2018-01-23_databackup_incremental_1426237023821_1426237028496_0_1
2018-01-23_databackup_incremental_1426237023821_1426237028496_1_1
2018-01-23_databackup_incremental_1426237023821_1426237028496_2_1
2018-01-23_databackup_incremental_1426237023821_1426237028496_3_1
```

### 11.2.4.7.3 Naming Conventions for Log Backups

Log backup names are generated automatically. Unlike the data backup names, no parts of the log backup names are user-defined.

The names of log backups are assigned in accordance with specific naming conventions.

Each log backup name comprises the following elements:

```
<log_backup>_<volume ID>_<log partition ID>_<first redo log position>_<last redo log position>.<backup_ID>
```

The elements of log backup names are separated by an underscore. A period ('.') separates the appended backup ID from the log name.

Elements of Log Backup Names

Name Element	Description
<log_backup>	All log backups begin with the string <log_backup>.
<volume ID>	The volume ID for the SAP HANA service. For example, name server, index server, script server, or XS engine.
<log partition ID>	Only one log partition is supported for each service.
<first redo log position>	The oldest entry in log backup
<last redo log position>	The most recent entry in the log backup
<backup_ID>	Uniquely identifies the log backup

#### i Note

<backup\_ID> is calculated automatically by SAP HANA. <backup\_ID> is only used for file-based backups, not for backups with third-party backup tools.

## Example

A log backup name could look like this:

```
log_backup_1_0_1234567_1238567.1380740407446
```

### 11.2.4.7.4 Naming Conventions for the Backup Catalog

Different names are assigned to the backup catalog with file-based backups and when using a third-party backup tool.

The backup catalog is assigned a name in the following format:

```
log_backup_0_0_0_0.<Backup_ID>
```

With a third-party tool, the backup catalog is assigned a name in the following format:

```
log_backup_0_0_0_0
```

### 11.2.4.7.5 Temporary Names for File-Based Backups

When file-based backups are written, they are first written using a temporary name.

After a part of a backup has been written successfully, it is renamed to the final name used for the SAP HANA service. Existing backups with the same name are only overwritten after the backup for the service was completed successfully.

#### **i** Note

If existing backups are overwritten by backups with the same names, at least **twice the space** in the backup location is needed, because the old backup and the new backup exist for a time in parallel.

## 11.2.5 Working with Third-Party Backup Tools

Third-party backup tools can be fully integrated with SAP HANA to enable you to perform backup and recovery operations from SAP HANA cockpit and using native SQL.

### Backint for SAP HANA Interface

In addition to the file system, you can back up and recover an SAP HANA database using an SAP-certified third-party tool that supports the `Backint for SAP HANA interface`, which is used to communicate with an SAP HANA database.

Each active host in a distributed SAP HANA system may have one or more volumes to be backed up. When `Backint for SAP HANA` is used to back up a database, several communication processes are started, one for each volume. Backint-based data backups and log backups can be created in parallel.

A third-party backup tool reads data to be backed up from named pipes, and writes the data in accordance with the tool configuration. For a third-party backup tool, the only objects created in the file system are named pipes. Named pipes occupy no space in the file system.

## Prerequisites for Using Third-Party Backup Tools

- The implementation of the API of a third-party backup tool that uses the `Backint for SAP HANA` interface must be certified by SAP.
- You have a support contract with the tool vendor that permits you to use the third-party backup tool with SAP HANA.

More information:

- [SAP Note 1730932 \(Using Backup Tools with Backint for SAP HANA\)](#)
- For a current overview of certified third-party backup tools, go to the [SAP Certified Solutions Directory](#). Use the search term `HANA-BRINT` and select a partner name to display more details.
- [SAP Note 1730998 \(Unrecommended versions of backup tools\)](#) contains a list of backup tool versions that should **not** be installed or activated in an SAP HANA appliance.
- For more information about installing and configuring a third-party backup tool, consult the documentation provided by the tool vendor.

## Related Information

[SAP Note 2031547](#) 

[SAP Note 1730932](#) 

[SAP Note 1730998](#) 

[SAP Certified Solutions Directory](#) 

## 11.2.5.1 Configuring a Third-Party Backup Tool

After a third-party backup tool has been installed, you can back up and recover an SAP HANA database without making any further changes to the default configuration. However, you have the option to specify a Backint parameter file, and to change some of the tool configuration settings.

### Directories for Third-Party Backup Tools

For third-party backup tools, the following directories are used for all types of backups (including delta backups and backups of the backup catalog):

- System database: `/usr/sap/<SID>/SYS/global/hdb/backint/SYSTEMDB`
- Tenant database: `/usr/sap/<SID>/SYS/global/hdb/backint/DB_<tenant_database_name>`

The content of the backups is not necessarily written to these directories. The backup tool decides where the content of the backups is written to.

A third-party backup tool reads data to be backed up from named pipes, and writes the data in accordance with the tool configuration. For a third-party backup tool, the only objects created in the file system are named pipes. Named pipes occupy no space in the file system.

#### i Note

For third-party backup tools, the backup destinations cannot be changed. During a recovery, SAP HANA retrieves the backup content from the locations provided by the third-party backup tool.

### Backint Parameter File

If required by the third-party backup tool, you can specify Backint parameter files for data backup, log backups, and the backup catalog. The content and syntax of the parameter files is tool-specific and defined by the tool vendor.

For more information, see the vendor documentation for the third-party backup tool.

To specify Backint parameter files for SAP HANA, use SAP HANA cockpit.

For more information, see *Change the Backup Configuration Settings*.

### SAP HANA Parameters for a Third-Party Backup Tool

SAP HANA offers several parameters for configuring a third-party backup tool.

For more information, see *Configure SAP HANA Parameters for a Third-Party Backup Tool*

## Related Information

[Change the Backup Configuration Settings \[page 1455\]](#)

[Configure SAP HANA Parameters for a Third-Party Backup Tool \[page 1445\]](#)

### 11.2.5.1.1 Configure SAP HANA Parameters for a Third-Party Backup Tool

SAP HANA offers several parameters for configuring a third-party backup tool.

#### Prerequisites

The Backint agent has been installed.

If the Backint agent is not installed, you cannot change the Backint parameter files.

SAP HANA expects the Backint agent executable (`hdbbackint`) to be in the following path:

```
/usr/sap/<SID>/SYS/global/hdb/opt/hdbbackint
```

If the Backint agent executable is not installed in this path, a symbolic link must be created during the installation of a third-party backup tool. This symbolic link points from `/usr/sap/<SID>/SYS/global/hdb/opt/hdbbackint` to the actual location of the Backint agent executable.

#### **i** Note

You cannot change the `Backint` agent using SAP HANA cockpit or SAP HANA studio.

#### Procedure

You can display and change configuration parameters using SAP HANA cockpit and SAP HANA studio.

For more information, see *Configuring System Properties in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

To display all the parameters for third-party backup tools, search for `backint` from the system properties overview.

The following parameters are available for third-party backup tools:

Option	Parameter
Specify a timeout for log backups for third-party tools.	<code>backint_response_timeout</code>  For more information, see <i>Timeout for Log Backups (Backint)</i> .
Write backups of the backup catalog using a third-party backup tool.	<code>catalog_backup_using_backint</code>  For more information, see <i>Destination for Backups of the Backup Catalog</i> .
Enable or disable log backup using a third-party tool.	<code>log_backup_using_backint</code>  For more information, see <i>Change the Log Backup Destination Type</i> .
Specify the number of channels to be used for multistreaming.	<code>parallel_data_backup_backint_channels</code>  This parameter applies to complete data backups and delta backups.  For more information, see <i>Configure Multistreaming with Third-Party Backup Tools</i> and <i>Prerequisites: Recovery Using Multistreamed Backups</i> .
Specify the Backint protocol version used by SAP HANA to communicate with the third-party backup tools.	<code>backint_protocol_version</code>  Depending on the Backint protocol version, SAP HANA uses different parameters and flags. This parameter must be set to the protocol version supported by the third-party backup tool.  Default:  <code>backint_protocol_version = 1.0</code>  Possible values: <b>1.0, 1.5</b>

## Related Information

[Change the Backup Configuration Settings \[page 1455\]](#)

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

## 11.2.5.1.2 Configure Multistreaming with Third-Party Backup Tools

Multistreaming allows backup data to be distributed in parallel to multiple devices. When creating complete data backups and delta backups, a third-party backup tool can use multiple channels to write the backup data for each service.

### Context

By default, multistreaming is disabled, which means that SAP HANA uses a single channel for data backups and delta backups. If required, you can configure SAP HANA to use additional channels. When multiple channels are used, SAP HANA distributes the data equally across the available channels. All the parts of a multistreamed backup are approximately the same size.

Multistreamed data backups are configured individually for each database.

#### i Note

To create multistreamed data backups and delta backups of an SAP HANA database, the third-party backup tool must also be configured to use multiple channels. To get optimal performance, ensure that the third-party backup tool is configured correctly.

For more information about the configuration of the backup tool, consult the vendor documentation.

### Procedure

1. To enable multistreaming for data backups and delta backups, configure the parameters `parallel_data_backup_backint_channels` and `parallel_data_backup_backint_data_threshold` for each database.

The parameters are in the `backup` section of `global.ini`.

For more information, see *Configuring System Properties in SAP HANA Cockpit*.

2. Specify the appropriate values for each service.

Parameter	Possible Values
<code>parallel_data_backup_backint_channels</code>	<p>Specify the number of channels to be used for multistreaming.</p> <p>You can specify a value between 1 and 32. The maximum number of channels permitted for each service is 32.</p> <p>The default value is <b>1</b>.</p>

Parameter	Possible Values
	<p>A value of 1 means that data backups with third-party backup tools are created through a single channel. This disables multistreaming. To enable multistreaming, specify a value greater than 1.</p> <div data-bbox="813 488 1402 840" style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>i Note</b></p> <p>Each additional channel requires an additional IO buffer (by default, 512 MB). Ensure that increasing the number of channels does not have a negative impact on memory consumption.</p> <p>If backup encryption is enabled, three additional IO buffers are needed for each channel. For more information, see <i>SAP HANA Backup Encryption</i>.</p> </div>
<code>parallel_data_backup_backint_data_threshold</code>	<p>Specify the minimum data backup size for multistreaming to be enabled. The value is specified in GB.</p> <p>You can specify a value of 1 GB or more.</p> <p>The default value is <b>128 GB</b>.</p> <p>The threshold applies to each service individually. If the data backup size for a service is below the threshold, that service will not be multistreamed, even if multistreaming is enabled</p> <p>(<code>parallel_data_backup_backint_channels &gt; 1</code>).</p>

3. (Optional) Ensure that all buffers fit into memory.

You can optimize the configuration of the following parameters:

- Reduce the backup buffer size.  
Reconfigure `data_backup_buffer_size`.  
For more information, see *Change the Backup Buffer Size*.
- Reduce the number of channels.  
Reconfigure `parallel_data_backup_backint_channels`.

4. Save.

The changes take effect immediately.

[Change the I/O Buffer Size \[page 1469\]](#)

[SAP HANA Backup Encryption \[page 1425\]](#)

### 11.2.5.1.3 Timeout for Log Backups (Backint)

If the Backint agent does not respond for a user-specified time when writing log backups, SAP HANA cancels the Backint process.

The timeout for log backups for third-party tools is specified using the following parameter:

```
backint_response_timeout=<seconds>
```

The parameter is set on the tenant database coordinator node in the backup section of the `indexserver.ini` parameter file.

The default timeout is 600 s.

#### i Note

This parameter is used for log backups and backups of the backup catalog.

If the Backint process terminates as the result of a timeout, it may be recorded in the `backint.log` as having terminated with an error.

The following error message is written to the trace file for the service:

```
Backint did not respond for 600 seconds, killing pid
```

## Related Information

[Set the Interval Mode for Log Backups \[page 1484\]](#)

[SAP Note 2571163](#)

### 11.2.5.1.4 Isolation Level High for Backups and Third-Party Backup Tools

SAP HANA supports high isolation for third-party backup tools.

In an SAP HANA database, it is necessary to ensure that a tenant database cannot access the backups of other tenant databases. If your third-party backup tool does not support high isolation, you can set up separate Backint parameter files for each tenant database. These Backint parameter files are owned and managed by the operating system user (`<sid>adm`), which has read and write access. The tenant databases have only read access to the Backint parameter file through the tenant-specific group.

For more information about the access permissions required for system and tenant databases, see *Set the Isolation Level to High for Backups with Third-Party Backup Tools*.

#### i Note

To ensure high isolation in an SAP HANA database with many tenant databases, many Backint parameter files may be needed.

## → Tip

Check with your third-party backup tool vendor whether any tool-specific restrictions apply.

## Related Information

[Set the Isolation Level to High for Backups with Third-Party Backup Tools \[page 1450\]](#)

[Increase the System Isolation Level \[page 214\]](#)

[Database Isolation \[page 216\]](#)

[Overview of SAP HANA Security Functions](#)

### 11.2.5.1.4.1 Set the Isolation Level to High for Backups with Third-Party Backup Tools

By default, an SAP HANA tenant database has isolation level low. You can increase the isolation level to high to ensure that one tenant database cannot access the backups of other tenant databases.

## For the System Database

### Procedure

1. On operating system level, create a database-specific directory for the Backint parameter files.  
The database-specific directory must be owned by the operating system user `<sid>adm` and the group `sapsys`.
2. Assign the access permissions 700 to the directory.  
700 allows user `<sid>adm` read, write, and execute access to the directory; the group has no access permission; others have no access permission.
3. In the database-specific directory, create a Backint parameter file for backups.  
If required, also create a database-specific Backint parameter file for log backups.  
The parameter file must be owned by the operating system user `<sid>adm` and group `sapsys`.
4. Assign the access permissions 600 to the parameter file.  
600 allows user `<sid>adm` read and write access to the file; the group has no access permission; others have no access permission.
5. Use the parameters `data_backup_parameter_file`, `log_backup_parameter_file`, and `catalog_backup_parameter_file` to specify the Backint parameter files.

# For Each Tenant Database

## Context

To grant the system administrator access to the tenant database backup files and directories, you need to add the `<sid>adm` user to the operating system group of each tenant. For more information, see *File and Directory Permissions with High Isolation* in the *SAP HANA Administration Guide*.

## Procedure

1. On operating system level, create a database-specific directory for the Backint parameter files.  
The database-specific directory must be owned by the operating system user `<sid>adm` and by the group of the tenant database.
2. Assign the access permissions 750 to the directory.  
750 allows user `<sid>adm` read, write, and execute access to the directory; the group has read and execute permission; others have no access permission.
3. In each tenant-specific directory, create a tenant-specific Backint parameter file for backups.  
If required, also create a tenant-specific Backint parameter file for log backups and backups of the backup catalog.  
The parameter file must be owned by the operating system user `<sid>adm` and group of the tenant database.
4. Assign the access permissions 640 to the parameter file.  
640 allows user `<sid>adm` read and write access to the file; the group has read permission; others have no access permission.
5. Assign the tenant-specific Backint parameter file(s) in the SAP HANA system.
  - a. Locate the parameter `data_backup_parameter_file` in the `backup` section of `global.ini`.  
For more information, see *Configuring System Properties in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.
  - b. Open the change dialog.
  - c. Specify the new path to the parameter file.
  - d. Save.  
When you save, the change takes effect immediately.  
To change the Backint parameter file for log backups, repeat this procedure for the parameter `log_backup_parameter_file`.  
To change the Backint parameter file for backups of the backup catalog, repeat this procedure for the parameter `catalog_backup_parameter_file`.

Alternatively, to change the Backint parameter file setting, you can execute the following SQL statement:

### Sample Code

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'DATABASE',
'<database_name>') SET ('backup', '<backup_parameter_file>') =
'<absolute_path_and_name>' WITH RECONFIGURE
```

This statement changes one parameter. If you need to assign a tenant-specific Backint parameter file for both data backups and log backups, you need to execute the statement once for each Backint parameter file.

### Example

Assume that you want to assign new Backint parameter files for a tenant database called `<TENANT1>` in an SAP HANA database called `<PR2>`.

With the following statement, you can assign a new parameter file for data backups:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'DATABASE', 'TENANT1') SET
('backup', 'data_backup_parameter_file') = '/usr/sap/PR2/SYS/
global/hdb/opt/config/DB_TENANT1/PR2_TENANT1_data.utl' WITH RECONFIGURE
```

With the following statement, you can assign a new parameter file for log backups:

```
ALTER SYSTEM ALTER CONFIGURATION ('global.ini', 'DATABASE', 'TENANT1') SET
('backup', 'log_backup_parameter_file') = '/usr/sap/PR2/SYS/global/hdb/opt/
config/DB_TENANT1/PR2_TENANT1_log.utl' WITH RECONFIGURE
```

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

[File and Directory Permissions with High Isolation \[page 218\]](#)

## 11.2.5.2 Delta Backups and Third-Party Backup Tools

SAP HANA supports seamless integration of SAP-certified third-party backup tools.

Normally, delta backups will work using the default configuration settings. In some situations, additional steps may be required to create delta backups with a third-party backup tool.

If you are using a third-party tool to create delta backups, consider the following points:

### Configuring the Backint Agent

Ensure that the Backint agent executable (`hdbbackint`) is configured correctly.

For more information about configuring your third-party backup tool, see *Configuring a Third-Party Backup Tool* and consult the tool vendor documentation.

## –l LOG Option

For delta backups, SAP HANA uses the `hdbbackint` level log (option `–l LOG`) in combination with the `hdbbackint` parameter file for data backups. This `hdbbackint` call is sent internally by SAP HANA and is recorded in the `backint.log` file.

### ⚠ Caution

If a third-party tool uses the option `–l LOG` to specify the log backup container, the log backup container could unintentionally be used for delta backups as well as for log backups. This can potentially cause an error situation.

For this reason, we recommend that you set up two dedicated `hdbbackint` parameter files: one for data backups and one for log backups

If you are in doubt, check with your tool vendor for more details **before** you use delta backups as part of your backup strategy.

## Related Information

[Configuring a Third-Party Backup Tool \[page 1444\]](#)

[Configure SAP HANA Parameters for a Third-Party Backup Tool \[page 1445\]](#)

### 11.2.5.3 Upgrading a Third-Party Backup Tool

When you upgrade third-party backup software, the following procedure is strongly recommended.

1. Before you start a software upgrade in your production system:
  - Test the upgrade in a test system.
  - Disable automatic log backups through Backint.  
Disabling automatic log backup ensures that the backup history is not disrupted.  
For more information, see *Log Settings: Log Backup: Create Log Backups in Backup Configuration Settings*, and *SAP Note 2009486 (Disable SAP HANA log backups during upgrade of third-party backup tool that supports the Backint for SAP HANA interface)*.
2. While you are upgrading the third-party backup software:
  - Do **not** perform a data backup of the SAP HANA system.
  - Do not make any changes to the backup catalog.
3. After you have upgraded the third-party backup software, enable automatic log backups again.

→ Tip

Monitor the log area to ensure that enough space is available.

If your third-party backup tool is unavailable for an extended period, consider writing the log backups to the file system.

## Related Information

[Backup Configuration Settings \[page 1457\]](#)

## 11.2.6 SAP HANA Backup

There are different options to configure and create backups of an SAP HANA database.

The following sections describe how to:

- Display SAP HANA backup configuration settings
- Configure SAP HANA backups
- Back up your SAP HANA database
- Schedule SAP HANA backups
- Audit the creation and cancelation of a backup
- Delete old full backups and backup generations (housekeeping)

## Related Information

[Display the Backup Configuration Settings \[page 1455\]](#)

[Change the Backup Configuration Settings \[page 1455\]](#)

[Creating Backups \[page 1498\]](#)

[SAP HANA Backup Types \[page 1416\]](#)

[Backup Audit Actions for Security \[page 1516\]](#)

[Housekeeping: Deleting and Archiving Backups \[page 1517\]](#)

[Persistent Data Storage in the SAP HANA Database \[page 519\]](#)

## 11.2.6.1 Display the Backup Configuration Settings

Using SAP HANA cockpit, you can display an overview of the active backup configuration settings for a specific database.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#), with the [Administration](#) or [All](#) view selected, click the [Database Backups](#) card.
2. On the card, click [Backup Configuration](#).

The configuration settings for the database are displayed.

#### i Note

On this page, most configuration settings are only displayed. For the **current database**, you can **edit** the configuration settings for the Backup Scheduler and the backup retention policy.

### Related Information

[Change the Backup Configuration Settings \[page 1455\]](#)

## 11.2.6.2 Change the Backup Configuration Settings

Using SAP HANA cockpit, you can change the default backup configuration settings for the system database and all the tenant databases in the SAP HANA system.

### Prerequisites

You have the authorization DATABASE ADMIN.

## Context

To change the default configuration settings for all the databases in an SAP HANA system, you need to work through the system database.

## Procedure

1. From the [Database Directory](#), select a system database, then choose [Database Management](#).

An overview of the databases in the SAP HANA system is displayed.

2. Choose [Backup Configuration](#).

An overview of the current systemwide default backup configuration settings is displayed.

The backup encryption status for the SAP HANA system is displayed. For more information, see *SAP HANA Backup Encryption* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

3. To change a group of configuration settings, navigate to that group and choose [Edit](#).

When you edit a settings group, SAP HANA cockpit checks whether the configuration settings are within the recommended range. If a setting has been changed to a non-recommended setting, a setting within the recommended range is proposed. You then have the option to save or discard the recommended setting.

4. Save or discard your changes.

To reset a group of configuration settings to the default values, choose [Reset to Default](#).

When you save, the changes take effect immediately for the system database and all the tenant databases.

## Related Information

[Backup Configuration Settings \[page 1457\]](#)

[Display the Backup Configuration Settings \[page 1455\]](#)

[Authorizations Needed for Backup and Recovery](#)

[Log Modes](#)

[SAP HANA Backup Encryption](#)

[Schedule Backups \[page 1507\]](#)

## 11.2.6.2.1 Backup Configuration Settings

Using SAP HANA Cockpit, you can configure the behavior of data and log backups, the backup catalog, backup retention, and third-party backup tools. You can also specify whether to allow users of tenant databases to create backups.

### Backint Settings

The options for third-party backup tools are only visible if the `Backint` agent is installed.

#### Backint Parameter Files

If required by the third-party backup tool, you can specify `Backint` parameter files for data backup, log backups, and the backup catalog. The content and syntax of the parameter files is tool-specific and defined by the tool vendor.

For more information, see the vendor documentation for the third-party backup tool.

#### → Remember

If you disable `Backint`, also check that the destination used for file-based backups is correct.

Setting	Description
<i>Use the Same Parameter File for All</i>	You can use the same <code>Backint</code> parameter file for data backups, log backups, and for backups of the backup catalog.
<i>Data Backup, Log Backup, Catalog Backup</i>	You can specify a different <code>Backint</code> parameter file for data backups, log backups, and for backups of the backup catalog.

#### i Note

To use a parameter file, there needs to be a symbolic link pointing from `/usr/sap/<SID>/SYS/global/hdb/opt/hdbconfig/` to the actual parameter file in the directory.

If a new host is added, ensure that the database services have access to the `Backint` agent and the parameter file.

#### i Note

To specify parameter files for the databases in a **high isolation** system, you need to work from the system database.

With high isolation, the settings are configured separately for the system database and the tenant databases. For each database, you can use a different `Backint` parameter file for data backups, log backups, and for backups of the backup catalog.

To ensure high isolation in an SAP HANA database with many tenant databases, many `Backint` parameter files may be needed.

For more information, see *Isolation Level High for Backups and Third-Party Backup Tools* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

## Backint Response Timeout

Setting	Description
<i>Set Timeout (Catalog and Log Backups)</i>	<p>Enable a timeout for the connection to the third-party backup tool.</p> <p>The timeout is measured from the time of the first request to the Backint for SAP HANA agent.</p> <div data-bbox="820 698 1402 808"><p><b>i Note</b> This timeout is reset when data is transferred.</p></div>
<i>Timeout After (Minutes)</i>	<p>Specify the timeout.</p> <p>The default timeout is 10 minutes. If you do not specify a timeout, the default value is used.</p> <p>You can change the setting in increments of 5 minutes up to a maximum of 30 minutes.</p> <p>For more information, see <i>Timeout for Log Backups (Backint)</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p> <p>If the Backint process terminates as the result of a timeout, it may be recorded in the <code>backint.log</code> as having terminated with an error.</p> <p>For more information, see <i>backint.log</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

## Catalog Settings

Setting	Description
<i>Destination Type</i>	The destination type can be the file system or a third-party backup tool.

Setting	Description
<i>Location</i>	<p><b>For file system backups:</b></p> <p>By default, the backup catalog is backed up to the same location as the log backups: <code>\$(DIR_INSTANCE) / backup/log</code></p> <p>You can specify an alternative location for backups of the backup catalog.</p> <p><b>For Backint:</b></p> <p>The backup data is written through the third-party backup tool. You cannot change the location.</p> <p>For more information, see <i>Destination for Backups of the Backup Catalog</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

## Log Settings

### Log Mode

Setting	Description
<i>Log Mode</i>	<p>SAP HANA uses two log modes: <code>normal</code> and <code>overwrite</code></p> <p>By default, SAP HANA runs in log mode <code>normal</code>.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p>→ <b>Tip</b></p> <p>If you change the log mode from <code>overwrite</code> – where log backups are not created – to log mode <code>normal</code>, <b>you must create a full data backup</b> to ensure that log backups are created again, and that the database can be recovered to the most recent point in time.</p> </div> <p>For more information, see <i>Change Log Modes</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

## Log Backup

Setting	Description
<a href="#">Create Log Backups</a>	<p>Enable or disable automatic log backups.</p> <p>If <a href="#">Create Log Backups</a> is disabled, the other settings in the parameter group cannot be changed.</p> <p>To enable log backups, the log mode must be set to <code>normal</code>. In log mode <code>overwrite</code>, you cannot change the log backup settings.</p> <p>For more information, see <a href="#">Log Modes</a> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p> <div style="border: 1px solid #ccc; padding: 10px; background-color: #f9f9f9;"><p><b>⚠ Caution</b></p><p>During normal system operation (log mode <code>normal</code>), it is strongly recommended that you enable automatic log backups. When log segments are backed up, the space they occupied in the log area can be freed. SAP HANA can overwrite the newly freed space in the log area with new log entries. In this way, automatic log backups can prevent the log area from filling. If automatic log backups are disabled, the log area grows until the file system is full. If the file system is full, and no more log segments can be created, the database freezes.</p></div>
<a href="#">Use Consolidated Backups</a>	<p>To improve the performance of log backups, SAP HANA can write multiple log segments of a service to a single consolidated log backup.</p> <p>If you do not use consolidated log backups, each log segment is backed up to its own backup.</p> <p>For more information, see <a href="#">Consolidated Log Backups</a> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

Setting	Description
<i>Maximum Size</i>	<p>For consolidated log backups:</p> <p>You can configure the maximum size of consolidated log backups in increments of 8 GB.</p> <p>The default value is 16 GB.</p> <p>This means that one backup operation creates consolidated log backups with a maximum size of 16 GB.</p> <p>The minimum size is 8 GB. The maximum size allowed is 64 GB.</p> <p>For more information, see <i>Consolidated Log Backups</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>
<i>Destination Type</i>	<p>The destination type can be the file system or a third-party backup tool.</p>
<i>Location</i>	<p><b>For file system backups:</b></p> <p>By default, SAP HANA log segments in the log area are backed up to: <code>\$(DIR_INSTANCE)/backup/log</code></p> <p>You can specify an alternative location.</p> <p><b>For Backint:</b></p> <p>The backup data is written through a third-party backup tool.</p> <p>You cannot change the location.</p>
<i>Back Up Logs</i>	<p>Specify when to back up the log segments.</p> <p><b>At latest after specified time limit:</b> If log segments become full, they are backed up immediately, even if the log backup time limit has not been reached.</p> <p>(This is the same as log backup interval mode: immediate)</p> <p><b>Only after specified time limit:</b> Log segments are backed up after the time limit you specify. This means that log segments are <b>not automatically backed up</b> if the log segments become full.</p> <p>(This is the same as log backup interval mode: service)</p> <p>For more information, see <i>Set the Interval Mode for Log Backups</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i></p>

Setting	Description
<i>Time Limit</i>	<p>Specify the time limit for log backups.</p> <p>By default, the time limit is 15 minutes.</p> <p>The maximum permitted time limit is 1440 minutes (24 hours).</p>

## Data Backup Settings

### Data Backup

Setting	Description
<i>Destination Type</i>	The destination type can be the file system or a third-party backup tool (Backint).
<i>Location</i>	<p><b>File system backups:</b></p> <p>By default, the backups are written to the following location:  <code>\$(DIR_INSTANCE)/backup/data</code></p> <p>You can specify an alternative location to which to write data backups.</p> <p><b>Backint:</b></p> <p>The backup data is written through a third-party backup tool.</p> <p>You cannot change the location.</p> <p>For more information, see <i>Parameters for Data Backup Settings</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>
<i>Limit Maximum Size (File System Backups)</i>	<p>For file system backups, you can specify a maximum file size.</p> <p>The maximum file size applies to the data backups of all services.</p> <p>If the size of a data backup file for a service exceeds the specified limit, SAP HANA splits the file into multiple smaller files.</p>
<i>Maximum Size (GB)</i>	<p>You can specify the maximum file size of data backups in increments of 50 GB up to 2000 GB.</p> <p>The actual size of data backups may be smaller than the specified maximum size.</p>

Setting	Description
<a href="#">Enable Multistreaming of Backint Backups</a>	<p>When a third-party backup tool creates a data backup, it can use multiple streams in parallel for each service.</p> <p>Default: 1 stream (Multistreaming is disabled; SAP HANA uses one stream for data backups.)</p> <p>To enable multistreaming for third-party backup tools, set the toggle switch to <b>Yes</b>. You can use between 2 and 32 parallel streams.</p> <p>When multiple streams are used, all the parts of a backup are approximately the same size.</p> <p><i>Threshold Triggering Multistreaming (GB)</i>: When multistreaming is enabled, you can specify a threshold backup size. If a backup size is greater than the threshold, the backup uses multiple streams. If a backup is less than the specified size, only one stream is used.</p>

**i Note**

To create multistreamed data backups, the third-party backup tool must also be configured to use multiple streams with good performance.

For more information about the configuration of the backup tool, consult the vendor documentation.

For more information, see *Configure Multistreaming with Third-Party Backup Tools* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

### Data Backup Scheduler

To be able to create scheduled data backups, the data backup scheduler must be enabled. (If the scheduler is not enabled, you can still schedule backups, but the schedule will not run and they will not be created.)

Setting	Description
<i>Enable Scheduler for Tenant Databases</i>	<p>Enable or disable the backup scheduler for all tenant databases.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>i Note</b></p> <p>A backup of a tenant database can be scheduled through the system database. If the assigned tenant database user is permitted, a backup of a tenant database can be also scheduled through the tenant database itself.</p> <p>For more information, see <i>Restrictions for Tenant Database Users</i>.</p> </div>
<i>Enable Scheduler for the SYSTEMDB</i>	Enable or disable the backup scheduler for the system database.
<i>Assigned Database User</i>	The user that activates the backup schedules is also used to execute the backups. If the backup scheduler is running, the associated user is displayed.

## Retention Policy

You can configure the settings for the system database and each tenant database.

Setting	Description
<i>Delete Backup Generations Automatically</i>	Automatically schedule jobs to delete backup generations.
<i>Retain Backup Generations Younger Than</i>	Specify a number of days. Backup generations will be retained for at least that number of days.
<i>Minimum No. of Retained Backup Generations</i>	<p>You can retain between 1 and 14 backup generations.</p> <p>By default, two backup generations are retained.</p>
<i>Options for Backup Deletion</i>	You can delete the records of the unwanted data backup(s) from the backup catalog only, or you can delete both the records in the backup catalog and the physical backups from the file system or third-party backup tool, if you are using one.

Setting	Description
<a href="#">Start Daily Automatic Deletion (UTC)</a>	<p>You can define a point in time at which to begin automatically deleting unwanted backups. Alternatively, you can configure SAP HANA to start deleting unwanted backups at any time of the day.</p> <p>Alternatively, you can ask SAP HANA cockpit to select a random start time at which to delete backups every day.</p> <p>The time you specify is interpreted as UTC.</p>
<a href="#">Assigned Database User</a>	<p>The user that activates the retention policy schedules is also used to perform retention actions. If the retention policy scheduler is running, the associated user is displayed.</p>

## Restrictions for Tenant Database Users

Setting	Description
<a href="#">Users Can Create Backups</a>	<p>You can prevent all users of a tenant database from creating backups.</p> <p>By default, no restrictions are enforced. Tenant database users can create backups.</p> <p>For more information about authorizations, see <i>Authorizations Needed for Backup and Recovery</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>
<a href="#">Users Have Free Choice of Backup Destination</a>	<div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b> For file-system backups only.</p> </div> <p>For tenant database users with authorization to create backups.</p> <p>You can permit tenant database users to create backups:</p> <ul style="list-style-type: none"> <li>• In any directory</li> <li>• Only in the default backup destination or a subpath of the default backup destination. Users can create new subdirectories for backups below the default backup destination.</li> </ul> <div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b> Changes take effect immediately.</p> </div>

### 11.2.6.2.2 Backup Configuration Parameters

In addition to displaying and changing backup configuration settings using SAP HANA cockpit and SAP HANA studio, you can also configure the underlying parameters.

For more information about changing parameter values, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Backing Up Customer-Specific Configuration Settings \[page 1494\]](#)

## 11.2.6.2.2.1 Parameters for Data Backup Settings

Data backups can be written to different destinations. However, all the parts of the same data backup are written to the same destination.

For file-based data backups, you can change the default destination.

For backups created using third-party backup tools, the default backup destination cannot be changed.

### Related Information

[Change the Default Destination for File-Based Data Backups \[page 1467\]](#)

[Naming Conventions \[page 1436\]](#)

[Configure SAP HANA Parameters for a Third-Party Backup Tool \[page 1445\]](#)

[Change the Backup Configuration Settings \[page 1455\]](#)

### 11.2.6.2.2.1.1 Change the Default Destination for File-Based Data Backups

Each time you start a file-based data backup, you have the option to change the default backup destination or to specify a different destination for the current backup only.

### Context

By default, file-based data backups are written to `$DIR_INSTANCE/backup/data`.

#### → Tip

For file-based backups, it is recommended that you create the destination directory structures **before the backup is started**.

### Procedure

1. Locate the parameter `basepath_databackup` in the `persistence` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

### → Tip

For improved data safety, it is recommended that you specify a path to a secure backup destination. The data area, log area, and backups should never be on the same physical storage devices.

2. Open the change dialog.
3. Specify the new default destination.
4. Save.

## Results

The change takes effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

### 11.2.6.2.2.1.2 Set the Maximum File Size for File-Based Backups

For file-based data backups, you may need to limit the maximum size of a single backup file. For example, due to file system limitations.

## Context

If the size of a data backup file for a service exceeds the specified limit, SAP HANA splits the file into multiple smaller files.

## Procedure

1. Locate the parameter `data_backup_max_chunk_size` in the `backup` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.

3. Specify the new maximum size (in MB).

You can specify the maximum file size of data backups up to 2048000 MB (2000 GB).

The actual size of data backups may be smaller than the specified maximum size.

#### **i Note**

If existing backups are overwritten by backups with the same names, at least **twice the space** in the backup location is needed, because the old backup and the new backup exist for a time in parallel.

4. Save.

#### **i Note**

Changes take effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

[Backup Configuration Settings \[page 1457\]](#)

### 11.2.6.2.2.1.3 Change the I/O Buffer Size

To increase or decrease the memory consumption of SAP HANA backup and recovery, you can change the I/O buffer size that is allocated by SAP HANA for data backups and log backups.

## Context

To back up the data from main memory, SAP HANA allocates different numbers of buffers to data backups, depending on whether the data backups are singlestreamed or multistreamed:

<b>Data Backup Streaming</b>	<b>Buffer Allocation</b>
Singlestreamed data backups:	Allocates two I/O buffers for each persistent service
Multistreamed data backups:	Allocates $n+1$ I/O buffers for each persistent service.  $n$ is the number of streams defined by the parameter <code>parallel_data_backup_backint_channels</code> .  For more information, see <i>Configure Multistreaming with Third-Party Backup Tools</i> .

## i Note

Changing the I/O buffer memory consumption affects each persistent service for the database that is being backed up.

If you change the size of the backup I/O buffer, check to see if the change has any effect on backup runtime. If you do not notice an improvement in backup runtime, consider restoring the SAP HANA default size.

## Procedure

1. In the `backup` section of the `global.ini` parameter file, locate the parameter `data_backup_buffer_size`.
2. Open the change dialog.
3. Specify the new I/O buffer size for data backups.

Possible values:	128 - 4096 MB
------------------	---------------

---

Default:	512 MB for each buffer
----------	------------------------

---

4. Save.

## Results

The change takes effect immediately.

## Related Information

## 11.2.6.2.2.1.4 Set Parallel Backup Encryption

You can enable or disable parallel backup encryption.

### Context

When backup encryption is enabled, additional operations have to be performed for each backup buffer (encryption, checksum). These can be executed either serially, or in parallel for maximum throughput (default).

If parallel backup encryption is enabled, backup and recovery with encryption is executed with maximum throughput. This requires higher CPU and memory consumption.

If parallel backup encryption is disabled, backup and recovery with encryption enabled is executed with the same resource consumption as without encryption. Typically, backup and recovery operations will take longer to complete.

### Procedure

1. In the `backup` section of the `global.ini` parameter file, locate the parameter `enable_parallel_backup_encryption`.
2. Open the change dialog.
3. Specify the new setting.

Enable parallel backup encryption:	<code>enable_parallel_backup_encryption = true</code>
	(Default)

---

Disable parallel backup encryption:	<code>enable_parallel_backup_encryption = false</code>
-------------------------------------	--

---

4. Save.

### Related Information

[Change the Log Backup Destination Type \[page 1487\]](#)

[Change the Log Backup Destination \[page 1488\]](#)

[Consolidated Log Backups \[page 1474\]](#)

### 11.2.6.2.2.2.1 Find the Optimal Log Backup Configuration

To ensure that there is an optimal balance between log backup performance and the safety of your production data, you can adjust the log backup configuration.

### Log Backup Configuration

The following configuration options influence log backup behavior:

Log Backup Option	See...
Log backup interval	<i>Change the Log Backup Interval</i>
Log backup interval mode	<i>Set the Interval Mode for Log Backups</i> Parameter <code>log_backup_interval_mode</code>
Consolidated log backups	<i>Consolidated Log Backups</i> Use the parameter <code>max_log_backup_size</code> in combination with the log backup interval mode (parameter <code>log_backup_interval_mode</code> ).
Log segment size	Parameter <code>log_segment_size_mb</code> in the <i>SAP HANA Configuration Parameter Reference</i> .

## Considerations for an Optimal Log Backup Interval

Issue	Consider...
Does a large number of small log backup files cause performance issues?	<p>Reducing the frequency of log backups could enhance log backup performance.</p> <p>To reduce the number of log backup files, consider:</p> <ul style="list-style-type: none"><li>• Setting the log backup interval mode to service. service offers maximum benefit when using consolidated log backups. With service, each log backup is created only after a service-specific timeout has been reached.</li><li>• Increasing the log segment size and leaving the log backup interval mode immediate. A log backup is created immediately after a log segment becomes full, or when the service-specific timeout for a log segment has been reached.</li></ul>
If log backups are created infrequently, and the log area fails, many log segments may be irretrievably lost. How much data loss is acceptable to your recovery point objective?	<p>A lower frequency of creating log backups can negatively impact your recovery point objective if the log area fails.</p> <p>To ensure minimum data loss, consider keeping <code>log_backup_interval_mode</code> set to the default value immediate.</p>
If the log area is corrupted, can your recovery point objective still be met?	<p>Consolidated log backups, with a small number of relatively large log backups, can enhance log backup performance.</p> <p>However, as a consequence, if the log area fails, a lot of data may be irretrievably lost.</p> <p>For example, collecting 10 GB of log segments in one log backup will mean that fewer log backup are created and less frequently. If the log area is corrupted, it may mean that 10 GB of log data is irretrievably lost.</p> <p>If it is acceptable to have a small number of large backup files, consider setting <code>log_backup_interval_mode</code> to service.</p> <p>With log backup interval mode service, each log backup is created only after a service-specific timeout has been reached.</p>
What file size can be handled with the highest I/O throughput in your landscape?	<p>To keep the overhead low, you can reduce the number of log segments. Consider increasing the log segment size (parameter <code>log_segment_size_mb</code>).</p>

## Related Information

[Change the Log Backup Interval \[page 1486\]](#)

[Set the Interval Mode for Log Backups \[page 1484\]](#)

[Consolidated Log Backups \[page 1474\]](#)

[log\\_segment\\_size\\_mb in the SAP HANA Configuration Parameter Reference](#)

### 11.2.6.2.2.1.1 Consolidated Log Backups

To improve the performance of log backups, SAP HANA can write multiple log segments of a service to a single consolidated log backup. You can configure the maximum size of a consolidated log backup to be processed by a single backup operation.

## Context

### Why Consolidate Log Backups?

Log segments in the log area are only released after a log backup was completed successfully. After log segments have been released, the space they occupy can then be overwritten with new log segments.

If a single log backup operation takes a long time, during that time, several other log segments may be queued for backup. During periods of high load, log segments may be closed and queued for backup faster than a single backup operation can be completed.

If many log segments are waiting to be backed up, there can be a delay in releasing them. As a result of this delay, the log area may grow.

If the log segments cannot be backed up and released faster than the log area is growing, the log area could become full.

To remedy this issue, SAP HANA can write all the log segments of a service that are ready to be backed up at a particular time to a single consolidated log backup. A consolidated log backup contains multiple log segments.

#### **i** Note

The option to consolidate log backups is primarily intended for use with third-party backup tools that create a large number of small backups in a short time. However, consolidated log backups are supported for both third-party backup tools and file system backups.

### Log Backup Interval Mode

The behavior of the log backup process is also influenced by the log backup interval mode, which can be immediate (default) or service.

immediate means that a log backup is created immediately when a log segment becomes full, or when the service-specific timeout for a log segment has been reached. With log backup interval mode immediate, there are typically only a few log segments within one log backup.

In the SAP HANA log area, the log segments that are part of a log backup are only released after the last of the queued log segments has been backed up and if they are no longer needed to restart the database.

For more information, see *Set the Interval Mode for Log Backups*.

## Procedure

Configure the maximum size of a consolidated log backup to be processed by a single backup operation.

1. Locate the parameter `max_log_backup_size` in the `backup` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.
3. Select the database or the host.

You can configure the size of a consolidated log backup for one or more tenant databases and for one or more hosts.

4. Set the size in GB.

The default value is **16** GB.

This means that one (consolidated) log backup is filled with log segments up to a maximum size of 16 GB.

The maximum size allowed is 64 GB.

To reset to the default value, choose *Restore Default*.

5. Save.

## Results

The backup catalog is written and backed up **once** for each log backup.

To check that consolidated log backups are enabled, you can use the `hdbbackupdiag` tool or the `M_BACKUP_CATALOG_FILES` system view.

For more information, see *Verify That Log Backups are Being Consolidated (hdbbackupdiag)* or *Verify That Log Backups are Being Consolidated (M\_BACKUP\_CATALOG\_FILES)*.

### **i** Note

In the backup catalog, separate entries are maintained for the log segments in a log backup. However, if you subsequently want to remove log backups from a consolidated log backup, you can only remove all the consolidated log backups together, and then only if none of them is still needed for recovery.

[Find the Optimal Log Backup Configuration \[page 1472\]](#)

### 11.2.6.2.2.1.1.1 Verify That Log Backups are Being Consolidated (hdbbackupdiag)

You can check whether log backup consolidation is enabled or disabled.

## Context

If a log backup contains multiple log segments, log backup consolidation is enabled.

To check log whether a log backup contain more than one log segment, you can use the `hdbbackupdiag` tool.

## Procedure

```
Execute hdbbackupdiag -d <log_backup_directory> -b <log_backup_name>.
```

`<log_backup_directory>` is the directory where the log backups are located.

## Results

Information is displayed about the log segments in the log backup.

If the log backup contains more than one log segment, log backup consolidation is enabled.

### ❖ Example

In this example, `hdbbackupdiag` is used to check the content of a log backup.

```
hdbbackupdiag -d /usr/sap/HD2/HDB02/backup/log/DB_HD2 -b  
log_backup_2_0_7246592_7267136.1613127042627
```

Returns the following results:

#### ⇌ Output Code

```
Backup file: /usr/sap/HD2/HDB02/backup/log/DB_HD2/  
log_backup_2_0_7246592_7267136.1613127042627  
Backup time: 2021-02-12T10:50:42+00:00  
LogSegmentBackupInfo:  
StartPosition: 7246592  
EndPosition: 7266816  
LogSegmentBackupInfo:  
StartPosition: 7266816  
EndPosition: 7267136
```

Here, the log backup contains two log segments. This indicates that log backup consolidation is enabled and working correctly.

## Related Information

[Check the Backups Required for a Recovery \(hdbbackupdiag\) \[page 1537\]](#)

[Verify That Log Backups are Being Consolidated \(M\\_BACKUP\\_CATALOG\\_FILES\) \[page 1477\]](#)

### 11.2.6.2.2.1.1.2 Verify That Log Backups are Being Consolidated (M\_BACKUP\_CATALOG\_FILES)

You can check whether log backup consolidation is enabled or disabled.

## Context

If a log backup contains multiple log segments, log backup consolidation is enabled.

To check whether log backup consolidation is enabled, you can use the system view `M_BACKUP_CATALOG_FILES`.

If the `LOG_SEGMENT_COUNT` is greater than 1, log backup consolidation is enabled.

For more information, see *M\_BACKUP\_CATALOG\_FILES System View*.

## Procedure

To check the log segment count in `M_BACKUP_CATALOG_FILES`, use the following SQL statement:

```
SELECT * from M_BACKUP_CATALOG_FILES WHERE LOG_SEGMENT_COUNT > 1
```

## Results

If more than one row is returned, log backup consolidation is enabled.

### ❖ Example

The SQL statement could return the following results:

#### ⇐ Output Code

```
ENTRY_ID, BACKUP_ID, SOURCE_ID, SOURCE_TYPE_NAME, HOST, SERVICE_TYPE_NAME, REDO_L  
OG_POSITION, FIRST_REDO_LOG_POSITION, LAST_REDO_LOG_POSITION, BACKUP_SIZE, DEST  
INATION_PATH, DESTINATION_TYPE_NAME, EXTERNAL_BACKUP_ID, LOG_SEGMENT_COUNT, BAC  
KUP_CATALOG_BACKUP_ID, UTC_LAST_COMMIT_TIME, BACKINT_FALLBACK_USED, COMPRESSED  
_SIZE, COMPRESSION_ALGORITHM  
1613126753637, 1613126753637, 2, "volume", "cc-hostd2-v", "indexserver", ? ,  
7228096, 7246592, 1183744, "/usr/sap/HD2/HDB02/backup/log/DB_HD2/  
log_backup_2_0_7228096_7246592.1613126753637", "file", "",  
2, 1613126754280, "2021-02-12 10:45:53.423639000", "FALSE", ? , ?  
1613127042627, 1613127042627, 2, "volume", "cc-hostd2-v", "indexserver", ? ,  
7246592, 7267136, 1314816, "/usr/sap/HD2/HDB02/backup/log/DB_HD2/  
log_backup_2_0_7246592_7267136.1613127042627", "file", "",  
2, 1613127042929, "2021-02-12 10:50:42.373881000", "FALSE", ? , ?  
2 rows selected (overall time 3090 usec; server time 2096 usec)
```

Here, the log backup contains two log segments. This indicates that log backup consolidation is enabled and working correctly.

## Related Information

[Check the Backups Required for a Recovery \(hdbbackupdiag\) \[page 1537\]](#)

[M\\_BACKUP\\_CATALOG\\_FILES System View](#)

[Verify That Log Backups are Being Consolidated \(hdbbackupdiag\) \[page 1476\]](#)

## 11.2.6.2.2.2.1.2 Troubleshooting: Slow Log Backups

If log backups are delayed or interrupted, as a consequence, space will not be freed up in the log area fast enough to accommodate new log segments.

## Context

If logs are being backed up too slowly, over time, the log area can grow until the file system is full. If a disk full error occurs, no more log segments can be created, and the database freezes.

## → Tip

It is recommended that you proactively check the performance of log backups.

## Procedure

To check the performance of log backups:

1. Locate the SQL statement `LogBackupDelays` in the [Statement Library](#).

For more information, see *Use the Statement Library to Administer Your Database*.

2. Check the values returned for log backups.

Performance Indicator	Description
<code>NOT_BACKED_UP</code>	<p>A value greater than 2 indicates that logs are being backed up slowly.</p> <p>For more information, see <i>SAP Note 1835075 (Analyze backup and recovery performance issues)</i>.</p>
<code>TIME_SINCE_BACKUP_H</code>	<p>If the time continues to increase, this indicates a delay in logs being backed up.</p> <p>If automatic log backups are disabled, ensure that they are enabled.</p> <p>For more information, see <i>Enable and Disable Automatic Log Backup</i>.</p> <p>If the log backup thread is blocked, contact SAP HANA support.</p>

## Related Information

[Find the Optimal Log Backup Configuration \[page 1472\]](#)

[Parameters for Log Backup Settings \[page 1472\]](#)

[SAP Note 1835075](#)

## 11.2.6.2.2.2 Enable and Disable Automatic Log Backup

By default, SAP HANA creates redo log backups automatically at regular intervals. You can disable and enable automatic log backups.

### Prerequisites

To enable automatic log backups, the log mode must be set to `normal`.

For more information, see *Log Modes*.

#### ⚠ Caution

During normal system operation (log mode `normal`), it is strongly recommended that you enable automatic log backups. When log segments are backed up, the space they occupied in the log area can be freed. SAP HANA can overwrite the newly freed space in the log area with new log entries. In this way, automatic log backups can prevent the log area from filling. If automatic log backups are disabled, the log area grows until the file system is full. If the file system is full, and no more log segments can be created, the database freezes.

### Procedure

1. Locate the parameter `enable_auto_log_backup` in the `persistence` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.
3. Specify whether to enable or disable automatic log backups.

The default setting is `yes` (automatic log backup is active).

You can specify either `yes` or `no` to enable or disable automatic log backups.

To reset to enable automatic log backups, choose [Restore Default](#).

4. Save.

### Results

The change takes effect immediately.

If any log backups are running, they will first be completed before automatic log backups are disabled.

## Related Information

[Log Modes \[page 1481\]](#)

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

[Change the Backup Configuration Settings \[page 1455\]](#)

### 11.2.6.2.2.2.3 Log Modes

SAP HANA can run either in log mode `normal` or `overwrite`.

After installation, SAP HANA temporarily runs in log mode `overwrite`.

In log mode `overwrite`, the log segments are not backed up. When a log segment is full, it is closed. After a successful savepoint, that log segment can be reused. In this way, log mode `overwrite` ensures that the log area does not grow excessively.

After you create the first full data backup, SAP HANA automatically switches to the default log mode `normal`, and log backups are created.

#### → Tip

If you change the log mode from `overwrite` – where log backups are not created – to log mode `normal`, **you must create a full data backup** to ensure that log backups are created again, and that the database can be recovered to the most recent point in time.

Log Mode	Description
normal (Default)	<p>In log mode <code>normal</code>, log segments are backed up automatically if automatic log backups are enabled.</p> <p>For more information, see <i>Enable and Disable Automatic Log Backup</i> and <i>Changing the Backup Configuration Settings</i>.</p> <div data-bbox="616 544 1399 685" style="background-color: #f0f0f0; padding: 5px;"> <p>→ <b>Tip</b></p> <p>Log mode <code>normal</code> is recommended to provide support for point-in-time recovery.</p> </div> <p>After a log segment has been backed up, closed, and a savepoint has been written, the space it occupied can be freed. SAP HANA can then overwrite the newly freed space in the log area with new log entries. In this way, automatic log backups can prevent the log area from filling.</p> <div data-bbox="616 853 1399 1055" style="background-color: #f0f0f0; padding: 5px;"> <p>⚠ <b>Caution</b></p> <p>If the log area becomes full and no more log segments can be created in the file system, the database freezes. No more log entries can be written until a log backup has been completed, and the log segments are no longer needed to restart the database.</p> </div>
overwrite	<p>No log backups are created. When savepoints are written, log segments are immediately freed to be overwritten by new log entries.</p> <p>When log mode <code>overwrite</code> is active, the <i>Log Backup Settings</i> in the Backup Console cannot be changed.</p> <p>Log mode <code>overwrite</code> can be useful for installations that do not need to be backed up or recovered. For example, for test installations.</p> <div data-bbox="616 1346 1399 1585" style="background-color: #f0f0f0; padding: 5px;"> <p>⚠ <b>Caution</b></p> <p>Log mode <code>overwrite</code> is not recommended for production systems.</p> <p>With log mode <code>overwrite</code>, a point-in-time recovery is not possible. Delta backups created in log mode <code>overwrite</code> cannot be used for a point-in-time recovery.</p> </div> <div data-bbox="616 1608 1399 1742" style="background-color: #f0f0f0; padding: 5px;"> <p>i <b>Note</b></p> <p>Even if no log backups are written, with each data backup, the <b>backup catalog</b> is still backed up.</p> </div>

⚠ **Caution**

Do not delete log segments at operating system level, as this makes the log area unusable. As a consequence, the database may stop working immediately, and it will not be possible to restart the database.

For more information about switching log modes, see *Backup Configuration Settings* or *Change Log Modes*.

## Related Information

[Change the Log Backup Interval \[page 1486\]](#)

[Set the Interval Mode for Log Backups \[page 1484\]](#)

## 11.2.6.2.2.3.1 Change Log Modes

You can switch between the SAP HANA log modes `normal` and `overwrite`.

### Context

#### → Tip

If you change the log mode from `overwrite` – where log backups are not created – to log mode `normal`, **you must create a full data backup** to ensure that log backups are created again, and that the database can be recovered to the most recent point in time.

### System Replication

If you are using system replication, ensure that the log mode is `normal`. If the log mode is `overwrite`, log segments will not be backed up.

For more information, see *General Prerequisites for Configuring SAP HANA System Replication*.

### Procedure

1. Locate the parameter `log_mode` in the `persistence` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.

3. Specify the new log mode.

The log mode can be either `normal` or `overwrite`.

For more information, see *Log Modes*.

To reset SAP HANA to the default log mode `normal`, choose [Restore Default](#).

4. Save.

The change takes effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

[Log Modes \[page 1481\]](#)

[General Prerequisites for Configuring SAP HANA System Replication \[page 1231\]](#)

## 11.2.6.2.2.2.4 Set the Interval Mode for Log Backups

You can specify an interval mode for log backups.

### Context

#### → Tip

You can also specify the log backup interval mode using the Backup Configuration App in SAP HANA cockpit.

### Procedure

1. Locate the parameter `log_backup_interval_mode` in the `backup` section of the `global.ini` parameter file.

For more information about how to change parameter settings, see *Database Configuration in SAP HANA Cockpit*.

`log_backup_interval_mode` controls the use of the log backup timeout.

For more information, see *Change the Log Backup Interval*.

2. Specify the desired log backup interval mode.

You can set the following interval modes:

Log Backup Interval Mode	Description
<i>immediate</i> (Default)	<p>A log backup is created immediately after a log segment becomes full, or when the service-specific timeout for a log segment has been reached.</p> <p>If you have configured consolidated log backups (parameter <code>max_log_backup_size</code>), the log backup process does not wait for the configured size of log backups to be queued. If fewer log backups are queued, all the queued log backups are processed.</p> <p>For more information, see <i>Consolidated Log Backups</i>.</p>
<i>service</i>	<p>A log backup is created only after a service-specific timeout has been reached.</p> <p>This backup includes all the log segments in states <b>writing</b>, <b>closed</b>, and <b>truncated</b>.</p>

### 3. Save.

Changes take effect immediately.

#### **i** Note

The log interval mode and timeout are included in the system view `M_BACKUP_CONFIGURATION`.

For more information, see `M_BACKUP_CONFIGURATION`.

## Related Information

[Consolidated Log Backups \[page 1474\]](#)  
[M\\_BACKUP\\_CONFIGURATION System View](#)

## 11.2.6.2.2.2.5 Change the Log Backup Interval

You can change the interval at which log backups are created.

### Prerequisites

The log backup interval takes effect only if **automatic log backups** are enabled.

To enable automatic log backups, the log mode must be `normal`.

For more information, see *Log Modes*.

### Context

Specifying an appropriate interval for log backups enables you to recover an SAP HANA database with a good Recovery Point Objective (RPO). In the event of database failure, the RPO is the maximum time span from which data will be lost if the log area cannot be used for recovery, and if only data backups, delta backups, and log backups are available.

#### i Note

If the log segments become full before the log backup interval, the logs are backed up automatically.

#### → Tip

You can specify the log backup interval using the Backup Configuration App in SAP HANA cockpit or the Backup Console in SAP HANA studio.

### Procedure

Change the log backup interval.

1. Locate the parameter `log_backup_timeout_s` in the `persistence` section of the `global.ini` parameter file.

For more information about how to change parameter settings, see *Database Configuration in SAP HANA Cockpit*.

2. Specify the desired log backup interval.

By default, the log backup interval is 15 minutes (900 s).

A log backup interval of 15 minutes (or less) is recommended for production systems.

For test systems, you can set a longer log backup interval, depending on what data loss is acceptable to you if a fault occurs.

### **i** Note

If you specify a timeout of 0, log backups are created only when a log segment is full and when services are restarted.

3. Save.

### **i** Note

If log segments become full, they are backed up immediately, even if the log backup interval has not been reached.

## Results

The change takes effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Log Modes \[page 1481\]](#)

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Set the Interval Mode for Log Backups \[page 1484\]](#)

## 11.2.6.2.2.2.6 Change the Log Backup Destination Type

You can change parameters to the destination type for file-based log backups.

### Procedure

1. Locate the parameter `log_backup_using_backint` in the `backup` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.
3. Specify the destination type.

Possible values:

- true (back up using Backint)

- false (back up to the file system)

By default, log backups are written to the file system.

#### **i** Note

The destination type *Backint* is only available if the Backint agent is installed.

4. Save.

The change takes effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

[Destination for Backups of the Backup Catalog \[page 1491\]](#)

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

## 11.2.6.2.2.2.7 Change the Log Backup Destination

You can change parameters to the default destination for file-based log backups.

### Context

#### **i** Note

The log backup destination can only be changed for file-based backups.

It is not possible to change the backup destinations for third-party backup tools.

Backups created using third-party backup tools always use the destination: `/usr/sap/<SID>/SYS/global/hdb/backint`

A third-party backup tool reads data to be backed up from named pipes, and writes the data in accordance with the tool configuration. For a third-party backup tool, the only objects created in the file system are named pipes. Named pipes occupy no space in the file system.

### Procedure

1. Locate the parameter `basepath_logbackup` in the `persistence` section of the `global.ini` parameter file.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

2. Open the change dialog.
3. Specify the destination for log backups.

By default, file-based log backups are written to: `$DIR_INSTANCE/backup/log`

#### → Tip

For improved data safety, it is recommended that you specify a path to a secure backup destination.

The data area, log area, data backups, and log backups should never be on the same physical storage devices.

- 4.

## Results

The change takes effect immediately.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

### 11.2.6.2.2.3 Parameters for Backing Up the Backup Catalog

Each time a backup of any type is created, the backup catalog is backed up and versioned. In this way, the latest version of the backup catalog always contains the entire backup history.

Even in situations such as when `log_mode = overwrite` is set, where log backups are not created, the backup catalog is still backed up.

If the backup catalog is backed up using a third-party tool, the tool also handles the versioning of the backup catalog.

You can manually change the following settings for the backup catalog:

- The destination type  
The destination type can be the file system or a third-party backup tool.  
For more information, see *Destination Type for Backups of the Backup Catalog*.
- Where the backup catalog is backed up  
For more information, see *Destination for Backups of the Backup Catalog*.
- Whether backups of the backup catalog are accumulated  
For more information, see *Accumulated Backups of the Backup Catalog*.

## Related Information

[Destination Type for Backups of the Backup Catalog \[page 1490\]](#)

[Destination for Backups of the Backup Catalog \[page 1491\]](#)

[Accumulated Backups of the Backup Catalog \[page 1493\]](#)

[Change the Backup Configuration Settings \[page 1455\]](#)

[Configure SAP HANA Parameters for a Third-Party Backup Tool \[page 1445\]](#)

[Log Modes \[page 1481\]](#)

### 11.2.6.2.2.3.1 Destination Type for Backups of the Backup Catalog

For backups of the backup catalog, you can configure the backup destination type.

#### Parameter to Configure the Destination Type for Backups of the Backup Catalog

Task	Parameter
Destination Type:	<p>Write backups of the backup catalog to the file system or using a third-party backup tool.</p> <p><code>catalog_backup_using_backint</code></p> <p><code>in global.ini/[backup]/</code></p> <p>Values:</p> <ul style="list-style-type: none"><li>• true (back up using Backint)</li><li>• false (back up to the file system)</li></ul> <p>Default value: false (Backups of the backup catalog are written to the file system.)</p>

For more information about changing parameter settings, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

## Related Information

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

## 11.2.6.2.3.2 Destination for Backups of the Backup Catalog

You can change the default destination for backups of the backup catalog.

By default, the backup catalog is backed up to the same destination as the **log backups**. If required, you can configure a separate destination for backups of the backup catalog.

### ⚠ Caution

If you change the default destination for the log backups, the backup catalog is **not automatically backed up to the same location**.

For this reason, if you change the default destination for the log backups, you must also check that the backup catalog is being backed up to the desired destination.

For more information about changing parameter settings, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

## Parameters to Configure the Destination for Backups of the Backup Catalog

Task	Parameter
File-based Backups:	<p>Specify the directory to which to write backups of the backup catalog.</p> <p><code>basepath_catalogbackup</code></p> <p><code>in global.ini/[persistence]/</code></p> <p>Default value: empty (Backups of the backup catalog are written to the default directory for log backups: <code>\$DIR_INSTANCE/backup/log</code>)</p>
Backint:	<p>Specify a Backint parameter file for the backup catalog.</p> <p><code>catalog_backup_parameter_file</code></p> <p><code>in global.ini/[backup]/</code></p> <p>Default value: empty (No Backint parameter file is used.)</p>

## Considerations for the Backup Catalog and Recovery

When you recover SAP HANA, you are prompted to select a directory or destination type for the backup catalog, regardless of the location of the backup catalog that is currently configured. SAP HANA then only searches the specified directory (not the subdirectories) or Backint, and selects the most recent backup catalog available there.

## Recovery and the Backup Catalog Using SQL

To recover SAP HANA using native SQL, the location of the backup catalog in the file system can be specified in the syntax for `RECOVER DATABASE` and `RECOVER DATA` using the following clause:

- File-based backups:  
`USING CATALOG PATH ('<path>')`
- Third-party backup tools:  
`USING CATALOG BACKINT`

If no location is specified, the location specified in the .ini files is used.

For more information, see *RECOVER DATABASE Statement (Backup and Recovery)* and *RECOVER DATA Statement (Backup and Recovery)* in the *SAP HANA SQL and System Views Reference*.

## Considerations for System Copy

When you recover SAP HANA to create a system copy, it is not necessary to move old log backups and old backups of the backup catalog. The location of the backup catalog is specified explicitly.

## Considerations for an SAP HANA Upgrade

During an upgrade from SAP HANA 1.0 to SAP HANA 2.0, customer-specific configuration settings are automatically retained.

### → Tip

Before an upgrade, if the destination for log backups was changed, you should check that the backup catalog is being backed up to the desired destination. Check the parameters `catalog_backup_using_backint`, `catalog_backup_parameter_file`, and `basepath_catalogbackup`.

## Consideration for a New SAP HANA Installation

When you install a new SAP HANA system, ensure that the log backups and the backup catalog are BOTH backed up to the desired destination.

## Related Information

### 11.2.6.2.2.3.3 Accumulated Backups of the Backup Catalog

Each time a backup is created, the operation is recorded in the backup catalog, which is itself then backed up. If many data and log backups are created within a short time, the backup catalog would need to be backed up just as frequently.

If many backups of the backup catalog are queued to run, the most recently completed backup of the backup catalog will not reflect the most recent database backups. If many backups are waiting to be processed, this can cause increased backup times, as a backup is only completed when it has been recorded in the backup catalog and the backup catalog has been backed up.

To address this issue, SAP HANA can accumulate changes to the backup catalog, and back them up together in one operation.

A new backup of the backup catalog would then include all the changes to the backup catalog that were made since the last backup of the backup catalog. Accumulating multiple backups of the backup catalog in this way has the advantage that fewer backups of the backup catalog are created.

Accumulated backups of the backup catalog are supported for both file system backups and third-party backup tools.

#### 11.2.6.2.2.3.3.1 Disable Writing Accumulated Backups of the Backup Catalog

By default, writing accumulated backups of the backup catalog is enabled. You can disable writing accumulated backups of the backup catalog.

#### Procedure

1. Locate the parameter `enable_accumulated_catalog_backup` in the `backup` section of `global.ini`.  
For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.
2. Open the change dialog.
3. Disable (or enable) writing accumulated backups of the backup catalog.

To back up the backup catalog after each log backup, set the parameter to `false`.

The default setting is `true` (multiple log backups are accumulated to one backup of the backup catalog).

To reset to the default behavior, choose *Restore Default*.

4. Save.

#### **i Note**

Changes take effect immediately.

## **Related Information**

[Database Configuration in SAP HANA Cockpit \[page 307\]](#)

[Configuring System Properties in SAP HANA Studio \[page 322\]](#)

### **11.2.6.3 Backing Up Customer-Specific Configuration Settings**

Customer-specific configuration settings are not backed up automatically as part of a full backup. The configuration settings are not essential to perform a database recovery.

When you recover or copy an SAP HANA database, a backup of the configuration settings can be helpful to more easily identify and restore customer-specific changes to the default settings. If you want to use customer-specific configuration settings after a recovery, you need to reconfigure the recovered system in a separate step.

For more information, see *Back Up Customer-Specific Configuration Settings*.

You can display and change configuration parameters using SAP HANA cockpit and SAP HANA studio.

For more information, see *Database Configuration in SAP HANA Cockpit* or *Configuring System Properties in SAP HANA Studio*.

## **Locations of the SAP HANA Configuration Files**

By default, configuration files for SAP HANA are written to specific directories.

Locations of the SAP HANA Configuration Files

<b>Configuration Settings</b>	<b>Location</b>
Global configuration settings	<code>/usr/sap/\$SID/global/hdb/custom/config/</code>

Configuration Settings	Location
Configuration settings for a tenant database	<pre>/usr/sap/\$SID/global/hdb/custom/config/DB_&lt;database_name&gt;</pre> <p>For more information, see <i>Database-Specific Configuration Parameters</i> in the <i>SAP HANA Administration Guide</i>.</p>
Host-specific configuration settings	<pre>/usr/sap/&lt;SID&gt;/HDB&lt;instance no.&gt;/&lt;host&gt;/</pre>

### i Note

Configuration files (\*.ini files) are only created if customer-specific changes are made to them after installation. If no customer-specific changes have been made, the directories may be empty.

## Default SAP HANA Configuration Files

During installation of SAP HANA database, the following configuration files are created:

Content of the Main SAP HANA Configuration Files

Configuration File	Description
sapprofile.ini	<p>Contains system identification information, such as the system name (SID) or the instance number.</p> <p>After installation, <code>sapprofile.ini</code> is not changed again.</p> <div data-bbox="821 1288 1401 1523" style="border: 1px solid orange; padding: 5px;"> <p><b>⚠ Caution</b></p> <p><code>sapprofile.ini</code> contains information that is specific to each host. For this reason, in a recovery situation, the <code>sapprofile.ini</code> file must not be copied manually to a different host, as it will not be compatible with a new landscape.</p> </div> <p>The <code>sapprofile.ini</code> file can be found in the following directory:</p> <pre>/usr/sap/&lt;SID&gt;/HDB&lt;instance no.&gt;/&lt;host&gt;/</pre> <div data-bbox="821 1668 1401 1881" style="border: 1px solid blue; padding: 5px;"> <p><b>i Note</b></p> <p><code>sapprofile.ini</code> is not displayed in the <i>Configuration of System Properties</i> overview in SAP HANA cockpit or in the <i>Configuration</i> tab in SAP HANA studio.</p> </div>

Configuration File	Description
<code>daemon.ini</code>	<p>Contains information about which database services to start.</p> <p>The <code>daemon.ini</code> file can be found in the following directory:</p> <pre>/usr/sap/&lt;SID&gt;/HDB&lt;instance no.&gt;/&lt;host&gt;/</pre>
<code>nameserver.ini</code>	<p>The <code>nameserver.ini</code> file contains global configuration settings for each SAP HANA installation.</p> <p>The landscape section contains the system-specific landscape ID and assignments of hosts to roles MASTER, WORKER, and STANDBY. It also contains configuration settings for system replication and for the SAP HANA Storage Connector API.</p> <p>If the system landscape is changed, for example, hosts are added or removed, the landscape section of the <code>nameserver.ini</code> is also changed.</p>

[Change the Backup Configuration Settings \[page 1455\]](#)

### 11.2.6.3.1 Back Up Customer-Specific Configuration Settings

You can generate an overview of customer-specific changes to SAP HANA configuration, and use this information to restore the configuration settings after a recovery or a database copy.

## Context

When you recover or copy an SAP HANA database, a backup of the configuration settings can be helpful to more easily identify and restore customer-specific changes to the default settings. If you want to use customer-

specific configuration settings after a recovery, you need to reconfigure the recovered system in a separate step. You can do this using an SQL script.

## Procedure

1. To generate a list of customer-specific configuration settings, execute the following SQL script on the system database:

### Code Syntax

```
select 'ALTER SYSTEM ALTER CONFIGURATION ('''|| file_name ||''', '''|
      case layer_name
        when 'SYSTEM' then layer_name
        when 'DATABASE' then layer_name ||''', '''| database_name
        when 'HOST' then layer_name ||''', '''| host
      end ||
      '''') SET ('''|| section ||''', '''| key ||''') = '''|value ||''
WITH RECONFIGURE;'
      as "Configuration File Backup"
from sys_databases.m_inifile_contents
where layer_name != 'DEFAULT';
```

2. The SQL script generates a list of configuration settings that have been changed from the SAP HANA default settings.

Each parameter change is output as an ALTER SYSTEM ALTER CONFIGURATION statement.

For example:

### Output Code

```
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('execution', 'max_concurrency') = '20' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('execution', 'single_thread_group') = '1' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('httpserver', 'embedded') = 'true' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('httpserver', 'listenport') = '3$(SAPSYSTEM)14' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('httpserver', 'maxthreads') = '10' WITH RECONFIGURE;
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'SYSTEM') SET
('httpserver', 'workerpoolsize') = '5' WITH RECONFIGURE;
```

3. Check which of the parameters you want to restore to your new SAP HANA database.

### Caution

Before you restore the parameter changes, ensure that the parameter changes are compatible with a different system.

For example, if a landscape ID is used, ensure that it is the landscape ID of the new system.

4. Copy the SQL statements for the parameter changes that you want to restore to the new system.
5. Execute the desired SQL statements on the new system.

The configuration settings are now updated in the new system.

## Related Information

[ALTER SYSTEM ALTER CONFIGURATION Statement \(System Management\)](#)

### 11.2.6.4 Creating Backups

The sections that follow describe how to create backups.

You can create backups using the following tools:

- SAP HANA cockpit
- SAP HANA studio
- Native SQL

#### ⚠ Caution

Do not create a full backup after a database fault or other failure has occurred.

#### Scheduling Backups

You can schedule backups using SAP HANA cockpit.

You can also schedule regular backups using an external scheduler, such as cron.

## Related Information

[Schedule Backups \[page 1507\]](#)

### 11.2.6.4.1 Estimate the Space Needed in the File System for a Data Backup

If there is not enough space in the file system for backups, a backup will fail. To ensure that sufficient free space is available, before you back up the database, you should estimate the amount of space that will be needed.

#### Context

When you back up an SAP HANA database, the estimated backup size is displayed in the backup dialog in SAP HANA cockpit and SAP HANA studio.

This information is read from table `M_BACKUP_SIZE_ESTIMATIONS`.

For more information, see *M\_BACKUP\_SIZE\_ESTIMATIONS System View* in *SAP HANA SQL and System Views Reference*.

To estimate the space required for a backup, make a note of the space requirement from table *M\_BACKUP\_SIZE\_ESTIMATIONS*, and use the SQL statement `BACKUP CHECK` to check that this amount of space is available in the backup destination.

For more information, see *BACKUP CHECK Statement (Backup and Recovery)* in *SAP HANA SQL and System Views Reference*.

### **i** Note

The actual size of a data backup can be larger or smaller than the estimated size.

For example, if data is changed in the database after the size has been estimated and before the backup is created, the actual backup size may be different from the estimated size.

If existing backups are overwritten by backups with the same names, at least **twice the space** in the backup location is needed, because the old backup and the new backup exist for a time in parallel.

It is therefore recommended to keep some additional free space in reserve.

## Related Information

[M\\_BACKUP\\_SIZE\\_ESTIMATIONS System View](#)

[BACKUP CHECK Statement \(Backup and Recovery\)](#)

[Create Data Backups \[page 1499\]](#)

[Temporary Names for File-Based Backups \[page 1442\]](#)

## 11.2.6.4.2 Create Data Backups

Using SAP HANA cockpit, you can create complete data backups and delta backups (differential backups and incremental backups).

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Procedure

1. On the [Database Overview](#), with the [Administration](#) or [All](#) view and click the [Database Backups](#) card.

The backup catalog is displayed.

- (Optional) You can display more information or delete complete data backups:

To...	Steps
<b>Display more details about a backup.</b>	Click its row.
<b>Display an overview of backup generations.</b>	<p>Choose the chart icon.</p> <p>The chart shows the start time of the backup generation, its total size, and the sizes of the full data backup and the associated delta backups and log backups that can be used in combination for a recovery.</p> <p>From the overview of backup generations, you can delete backup generations.</p> <p>For more information, see <i>Delete Backup Generations</i>.</p>
<b>Change the order in which the columns are displayed.</b>	<p>Choose <i>Settings</i>, and use the arrow buttons.</p> <p>In the same way, you can also customize the backup details pages for each database.</p>
<b>Delete a complete data backup.</b>	<p>Scroll down to the row and choose <i>Delete</i>.</p> <p>You can remove the backup from the catalog only, or also physically delete the backup.</p>

- (Optional) To restrict the information displayed, choose *Filter*.

Filter By...	Description
<i>Backup Type</i>	Displays the backup types that were selected in the previous session.
<i>Status</i>	<p>You can display backups with the status:</p> <ul style="list-style-type: none"> <li>○ Canceled</li> <li>○ Failed</li> <li>○ Prepared           <p>A data snapshot has been prepared, but has not been confirmed or abandoned.</p> </li> <li>○ Running           <p>If a backup is running, click to display its progress.</p> </li> <li>○ Successful</li> </ul>
<i>Start Time</i>	Display backups from a specific time range.

If you change the filter settings, your changes are retained.

- Choose *Create Backup*.
- Specify the backup type:

Backup Type	Description
<b>Complete</b>	A complete data backup includes all the data structures that are required to recover the database.
<b>Incremental</b>	An incremental backup stores the data changed since the last data backup - either the last data backup or the last delta backup (incremental or differential).
<b>Differential</b>	Differential backups store all the data changed since the last full data backup.

The estimated size of the backup is displayed. This information is read from the system view `M_BACKUP_SIZE_ESTIMATIONS`.

For more information, see *M\_BACKUP\_SIZE\_ESTIMATIONS System View* in the *SAP HANA SQL Reference Guide for SAP HANA Platform*.

- Specify the backup destination type.

Option	Description
<b>File</b>	Writes the backup data to the file system.
<b>Backint</b>	Writes the backup data through a third-party backup tool.

#### Note

This option is only available if a third-party backup tool is installed.

The Backint parameters have no effect on the behavior of SAP HANA. For information about the Backint parameters, contact your tool vendor.

- Specify the backup prefix.

By default, the current date and time is proposed.

#### → Tip

It is strongly recommended to use the default prefix, as a unique timestamp makes it easier to identify archived backups.

- Specify the backup destination.

Option	Description
<b>For file-based backups:</b>	Ensure that there is sufficient space at the specified backup destination. For more information, see <i>Estimate the Space Needed for a Data Backup</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i> .
<b>For third-party backup tools:</b>	For third-party backup tools, the destination is always: <ul style="list-style-type: none"> <li>System database: <code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/backint/SYSTEMDB</code></li> </ul>

Option	Description
	<ul style="list-style-type: none"> <li>Tenant database: <code>/usr/sap/&lt;SID&gt;/SYS/global/hdb/backup/DB_&lt;tenant_database_name&gt;</code></li> </ul> <p>You can only change the backup prefix.</p>

9. To start the backup, choose [Back Up](#).

The progress of the backup is displayed.

When all volumes have been backed up, the backup catalog overview is displayed again. Here, you can verify that the backup was completed successfully.

## Related Information

[Estimate the Space Needed in the File System for a Data Backup](#)

[M\\_BACKUP\\_SIZE\\_ESTIMATIONS System View](#)

### 11.2.6.4.3 Create a Data Snapshot (Native SQL)

You can create a data snapshot of an SAP HANA database system with one or more tenant databases. You create a data snapshot using SQL.

## Prerequisites

- A data snapshot can only be created through the system database. It is not possible to create a data snapshot for a tenant database separately.
- The SAP HANA database (the system database and all the tenant databases) is online, and all the configured services are running. The system status for the system database and the tenant database is `System Running`. This is shown on the [Services](#) card in the [Database Overview](#).

## Context

A data snapshot is created in three steps that are performed in the SAP HANA database and at storage system level.

## Step to Create a Data Snapshot

## Description

*Prepare* the database for the data snapshot.

An **internal database snapshot** is created that reflects a consistent database state at the point in time it is created in the file system.

### i Note

If an internal database snapshot exists, no new data backups or new data snapshots can be created.

Conversely, while a data backup is running, you cannot create a data snapshot.

Create the data snapshot.

The data snapshot is created based on the previously created internal database snapshot.

### i Note

To ensure its consistent state, the **data snapshot** relies on the previously created **internal database snapshot**. If the database or a database service is restarted, the **internal database snapshot** is lost.

At this stage, the data snapshot is in the SAP HANA data area. To be able to create further data snapshots or data backups, you need to manually make all the content of the data area available in a separate storage location, and then confirm the data snapshot.

### → Remember

Data snapshots only offer increased data safety if they are moved or replicated to a separate storage medium. The files and directories under the mountpoint of the data area must all be stored together. The data volumes themselves must not be moved.

## Step to Create a Data Snapshot

## Description

[Confirm](#) or [Abandon](#) the data snapshot.

When the data snapshot was successfully created, you must confirm or abandon it to be able to create further data snapshots or data backups.

When a data snapshot is confirmed, it is recorded in the backup catalog as successful. When a data snapshot is abandoned, it is recorded in the backup catalog as unsuccessful.

The data snapshot is always **recorded in the backup catalog** - even if the internal database snapshot is lost before the data snapshot is confirmed. When the data snapshot is confirmed, you are notified whether the data snapshot can be used for a recovery.

### i Note

If the confirm fails, the database snapshot is marked as unsuccessful. You should physically delete the data snapshot because it may not be possible to use it for recovery.

## Procedure

To execute SQL statements, you can use the SQL console in SAP HANA cockpit. (Choose [Open SQL Console](#) from the [Database Overview](#).)

1. Create a new internal database snapshot.

From the system database, execute the following SQL statement:

```
BACKUP DATA FOR FULL SYSTEM CREATE SNAPSHOT [COMMENT <STRING>];
```

Optionally, add a comment. This comment can help to identify the data snapshot in the backup catalog.

### i Note

`FOR FULL SYSTEM` is mandatory to create a snapshot.

### Sample Code

```
BACKUP DATA FOR FULL SYSTEM CREATE SNAPSHOT COMMENT 'SNAPSHOT-2019-10-22';
```

For more information, see *BACKUP DATA CREATE SNAPSHOT Statement (Backup and Recovery)* in the *SAP HANA SQL and System Views Reference*.

An **internal database snapshot** is now created ('prepared').

### i Note

The snapshot will be created for the entire SAP HANA database, that is, the system database and all the tenant databases. It is not possible to create snapshots for an individual tenant database or only for the system database.

2. Find out the backup ID of the **internal database snapshot** in the state `PREPARED`.

### i Note

SAP HANA cannot ensure that the backup ID of the data snapshot of the system database and the backup ID of the tenant database are the same. As data snapshots are administered by the system database, you must use the backup ID of the **system database** to create the data snapshot.

Use the following SQL statement:

```
SELECT * FROM M_BACKUP_CATALOG WHERE ENTRY_TYPE_NAME = 'data snapshot';
```

### Sample Code

```
SELECT BACKUP_ID, COMMENT FROM M_BACKUP_CATALOG WHERE ENTRY_TYPE_NAME =  
'data snapshot' AND STATE_NAME = 'prepared' AND COMMENT =  
'SNAPSHOT-2019-10-22';
```

Make a note of the backup ID.

### i Note

Older internal database snapshots may exist in the state `successful` or `unsuccessful`.

The database is now prepared for the data snapshot.

An **internal database snapshot** is created, reflecting a consistent database state at the point in time it is created.

### i Note

If an internal database snapshot exists, no new data backups or new data snapshots can be created. Conversely, while a data backup is running, you cannot create a data snapshot.

At this stage, all the snapshot-relevant data is only stored in the data area. To be able to use the data snapshot for a recovery later on, this data needs to be stored in a separate location.

3. In the storage system, make all the content of the data area available together in a separate storage location.

To create the data snapshot, you can use the tool provided by your storage vendor. For more information, consult the tool documentation.

### i Note

A data snapshot contains all the persisted data in the data area. For this reason, the files and directories under the mountpoint of the data area must all be stored together.

### → Tip

For a recovery using a data snapshot, only the data area must be restored from the storage tool. You still can use the log area for the recovery.

### i Note

The directory name of the data area is defined by configuration parameter `basepath_datavolumes` in the `global.ini` configuration file, in the `persistence` section.

After the data snapshot has been created in a separate storage location, it needs to be confirmed.

4. [Confirm](#) or [Abandon](#) the data snapshot.

Use the following SQL statement:

Option	Description
<b>Confirm</b>	<pre>BACKUP DATA FOR FULL SYSTEM CLOSE SNAPSHOT BACKUP_ID &lt;BACKUP_ID&gt; SUCCESSFUL &lt;STRING&gt;;</pre> <p>Confirm that the data snapshot has been successfully saved to a new storage location.</p> <p>You can specify an external ID to identify the data snapshot later in the storage system.</p> <pre>☞ Sample Code</pre> <pre>BACKUP DATA FOR FULL SYSTEM CLOSE SNAPSHOT BACKUP_ID 1489592445498 SUCCESSFUL 'SNAPSHOT-2019-10-22';</pre>
<b>Abandon</b>	<pre>BACKUP DATA FOR FULL SYSTEM CLOSE SNAPSHOT BACKUP_ID &lt;BACKUP_ID&gt; UNSUCCESSFUL [&lt;STRING&gt;;</pre> <p>If the data snapshot cannot be created, or if confirmation fails, choose <a href="#">Abandon</a>.</p> <p>Optionally, you can add a comment to explain why the data snapshot was not successful.</p> <pre>☞ Sample Code</pre> <pre>BACKUP DATA FOR FULL SYSTEM CLOSE SNAPSHOT BACKUP_ID 1489592445498 UNSUCCESSFUL 'SNAPSHOT-2019-10-22 FAILED';</pre>

For more information, see *BACKUP DATA CLOSE SNAPSHOT Statement (Backup and Recovery)* in the *SAP HANA SQL and System Views Reference*.

### → Tip

It is strongly recommended to confirm or abandon a data snapshot **as soon as possible after it has been created**.

While the data snapshot is being prepared or created, the snapshot-relevant data is frozen. While the snapshot-relevant data remains frozen, changes can still be made in the database. Such changes will not cause the frozen snapshot-relevant data to be changed. Instead, the changes are written to

positions in the data area that are separate from the data snapshot. Changes are also written to the log.

However, the longer the snapshot-relevant data is kept frozen, the more the data volume can grow.

#### **i** Note

If the database or an individual database service is restarted, the **internal database snapshot** is lost. If the database snapshot is lost before the data snapshot is confirmed, the data snapshot is still written. During confirmation, the database notifies you that the data snapshot cannot be used.

After you have confirmed or abandoned a data snapshot, it is recorded in the backup catalog as either successful or unsuccessful.

#### **i** Note

A data snapshot now exists for both the system database and the tenant database.

The internal database snapshot that was used to create the data snapshot is discarded.

It is now possible to create further data snapshots or data backups.

## Related Information

[Data Snapshots](#)

[BACKUP DATA CREATE SNAPSHOT Statement \(Backup and Recovery\)](#)

[BACKUP DATA CLOSE SNAPSHOT Statement \(Backup and Recovery\)](#)

### 11.2.6.4.4 Schedule Backups

Using SAP HANA cockpit, you can schedule data backups or delta backups to run without supervision at specific intervals. You can schedule individual backups or series of recurring backups.

## Prerequisites

### Authorizations

You require the following authorizations:

Authorization	Purpose
BACKUP ADMIN	Schedule backups for the current database (system database or a tenant database).

## Authorization

## Purpose

### → Tip

To schedule backups, you can set up a user on each tenant database with the `BACKUP ADMIN` authorization or a user in the system database with the required privileges.

One of the following privileges:

- `DATABASE BACKUP OPERATOR`
- `DATABASE BACKUP ADMIN`
- `DATABASE ADMIN`

Schedule backups for tenant databases through the system database. (Not backups of the system database itself)

For more information, see *SAP Note 2699762 (Backup and Recovery: Software Requirements for Scheduling Backups in SAP HANA Cockpit)*.

`SELECT`, `UPDATE`, and `DELETE` privileges for the following tables:

- `_SYS_XS.JOB_SCHEDULES`
- `_SYS_XS.JOBS`

For more information, see *Authorizations Needed for Backup and Recovery* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

## Backup Scheduler

The data backup scheduler must be enabled.

The data backup scheduler is normally enabled automatically. Under certain circumstances, you may need to manually enable the data backup scheduler, which requires the XS classic engine to be running.

For more information, see *Manually Enabling the Data Backup Scheduler*.

Backup schedules are enabled globally.

If the data backup scheduler is not enabled, SAP HANA cockpit displays a warning, and a link to [Backup Configuration](#) page where you can enable the data backup scheduler.

For more information, see *Changing the Backup Configuration Settings*.

### i Note

The user that activates the backup schedules is also used to create the backups.

Backup schedules run for the database for which they are scheduled. Backup schedules do not run in the SAP HANA cockpit that administers the schedules.

## Compatibility With SAP HANA 1.0

Backup schedules created with SAP HANA cockpit 1.0 are not compatible with SAP HANA cockpit 2.0.

### ⚠ Caution

Before you upgrade from SAP HANA 1.0 to SAP HANA 2.0, you must use SAP HANA cockpit 1.0 to delete all the backup schedules created with SAP HANA 1.0.

After the upgrade to SAP HANA 2.0, you need to create new backup schedules.

From SAP HANA cockpit 2.0, to schedule backups for an SAP HANA 1.0 database, you must be logged onto that database. You cannot schedule backups for SAP HANA 1.0 databases through the system database.

## Procedure

1. From the *Database Directory*:

To Schedule Backups For...	Perform the Following Steps...
<b>A tenant database</b> (through the system database)	<ol style="list-style-type: none"> <li>1. Log onto the <b>system database</b>. The <i>Database Overview</i> page is displayed.</li> <li>2. From the <i>Database Overview</i>, choose <i>Database Management</i>.</li> <li>3. Choose <i>Backup Schedules</i>. The scheduling calendar is displayed for all the databases in the SAP HANA system.</li> </ol>
<b>The current database</b>	<ol style="list-style-type: none"> <li>1. Log onto the database for which you want to schedule backups (the system database or a tenant database).</li> <li>2. From the <i>Database Backups</i> card, choose <i>Backup Schedules</i>. The scheduling calendar is displayed for the current database only.</li> </ol>

2. To create a new backup schedule, choose + (Create Schedule).

Alternatively, click the calendar on the day for which you want to create the schedule.

3. Specify whether to schedule a series of recurring backups or a one-off backup.
4. If you are working through the system database, select a database for which to create the schedule.
5. If you are scheduling a series of backups, specify a name for the schedule.

It is recommended to choose a schedule name that enables you to easily identify the schedule.

6. Specify the backup type.

Option	Description
<b>Complete</b>	A complete data backup includes all the data that is required to recover the database to a consistent state.
<b>Differential</b>	Backs up all the data changed since the last full data backup (complete data backup or data snapshot).
<b>Incremental</b>	Backs up the data changed since the last full data backup (complete data backup or data snapshot) or the last incremental or differential backup.

### i Note

Currently, scheduling data snapshots is not supported.

7. Specify the *Destination Type*.

Option	Description
<i>File</i>	To write the backups to the file system, select <i>File</i> .  If necessary, you can specify a new destination or change the default destination.  For more information, see <i>Parameters for Data Backup Settings</i> .
<i>Backint</i>	This option is only displayed if you are working with a third-party backup tool.  To create backups using a third-party backup tool, select the destination type <i>Backint</i> . If needed, specify the <i>Backint Parameters</i> .  For more information, see <i>Working with Third-Party Backup Tools</i> .

8. Specify a *Backup Prefix*.

→ Tip

By default, the name of each scheduled backup is prefixed with the timestamp of the start of the backup. The placeholder `<[date]_[time]>` is automatically converted to the current timestamp.

To be able to more easily identify archived backups, it is strongly recommended to use the default, as it provides a unique prefix for each backup.

9. Specify a *Backup Destination*.

By default, file-based data backups are written to the following subdirectories:

- System database: `$DIR_INSTANCE/backup/data/SYSTEMDB`
- Tenant database: `$DIR_INSTANCE/backup/data/DB_<tenant_database>`

For file-based data backups, you have the option to change the default backup destination.

The default backup destination for third-party backup tools cannot be changed.

10. (Optional) Add a comment.

A comment helps you to later identify the backups in the backup catalog.

11. If you are scheduling a series of backups, specify the recurrence pattern.

You can schedule the backup to run each week, once each month, every two months, quarterly, twice a year, or once a year.

12. Specify the recurrence options for the backup schedule.

The recurrence options depend on whether you specified a weekly or month-based recurrence pattern.

Recurrence Setting	Description
<i>Time Zone</i>	Select the time zone in which you want to specify the backup time.  You can select any time zone that is convenient for you.
<i>Create Backups At</i>	Specify a time to run the scheduled backups in the selected time zone.

Recurrence Setting	Description
	You can specify a time manually or choose the clock icon to select a time from the list.
<b>(Weekly)</b> <i>Create Backups On</i>	Specify on which days of the week you want the backups to be created.  You can select one or more days.
<b>(Month-based)</b> <i>Create Backups On (UTC)</i>	Specify a day or a week of the month.  <i>Day of Month:</i> You can select the first day, the 15th day, or the last day in the month.  <i>Week of Month:</i> Specify which day of the month to create the backup. For example, the last Sunday in the month or the first Monday in the month.
<i>Activate Schedule On</i>	Specify a day in the selected time zone.  The first backup scheduled will be created on this day or as soon as possible afterwards when the schedule criteria are fulfilled.

When you have specified the recurrence options, SAP HANA cockpit displays when the first backup will be created. The time is shown in both the time in the specified time zone and UTC.

If you specified a month-based recurrence pattern, the months in which the backups will be created are also shown. For example, October or Monthly.

#### **i** Note

All times specified are interpreted as UTC. If the local time changes due to daylight saving time, the UTC time for the scheduled backup does not change.

13. Choose *Review*.

A summary of the schedule options is displayed.

To make changes, choose *Edit* for an option group.

14. When the schedule settings are complete, choose *Save Schedule*.

The new schedule is saved and is active immediately.

The next backup scheduled will be created at the time displayed.

#### **⚠** Caution

If SAP HANA is **offline** at a time for which backups are scheduled, scheduled backups will not run.

When SAP HANA is running again, skipped backups are **not automatically rescheduled**.

### 11.2.6.4.4.1 Manually Enable the Data Backup Scheduler

When backup schedules are created, they are activated automatically. Under certain circumstances, you may need to manually enable the data backup scheduler, which requires the XS classic engine to be running.

#### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

#### Context

##### Note

The user that activates the backup schedules is also used to execute the backups.

#### Procedure

1. On the [Database Overview](#), with the [Administration](#) or [All](#) view selected, click the [Backup Configuration](#) link on the [Database Backups](#) card.
2. Go to  [Data Backup Settings](#)  [Data Backup Scheduler](#) .
3. Choose [Edit](#).
4. Set Enable Data Backup Scheduler to YES.

5. [Save](#).

The data backup scheduler and the XS Job Scheduler are enabled.

#### **i Note**

If it is not possible to enable the data backup scheduler, you may need to manually enable the XS Job Scheduler, and possibly also the XS Engine.

For more information, see *Enable the XS Job Scheduler (XS Classic)* and *Enable the XS Engine (XS Classic)*.

## **Related Information**

[Enable the XS Job Scheduler \(XS Classic\) \[page 1513\]](#)

[Enable the XS Engine \(XS Classic\) \[page 1514\]](#)

[Schedule Backups \[page 1507\]](#)

### **11.2.6.4.4.1.1 Enable the XS Job Scheduler (XS Classic)**

To schedule data backups or delta backups using SAP HANA cockpit, the XS Job Scheduler (XS Classic) must be enabled.

## **Prerequisites**

The XS Job Scheduler requires the XS Engine to be enabled.

## **Context**

Normally, the XS Engine is enabled by default. In some cases, you may need to activate the XS Engine manually.

The XS Job Scheduler is enabled separately for the system database and for each tenant database.

## **Procedure**

1. For the **system database**, the XS Job Scheduler must be enabled in the `nameserver.ini` file.

To enable the XS Job Scheduler, use the following SQL statement:

```
ALTER SYSTEM ALTER configuration ('nameserver.ini','SYSTEM') SET
('scheduler','enabled')= 'true' WITH reconfigure;
```

2. For each **tenant database**, the XS Job Scheduler must be enabled in the `xsengine.ini` file.

To enable the XS Job Scheduler, use the following SQL statement:

```
ALTER SYSTEM ALTER configuration ('xsengine.ini','SYSTEM') SET
('scheduler','enabled')= 'true' WITH reconfigure;
```

## Related Information

[Schedule Backups \[page 1507\]](#)

[Enable the XS Engine \(XS Classic\) \[page 1514\]](#)

### 11.2.6.4.4.1.2 Enable the XS Engine (XS Classic)

To schedule backups using SAP HANA cockpit, the XS scheduler must be enabled. The XS scheduler requires the XS engine to be running.

## Context

Normally, the XS engine is enabled by default in an SAP HANA system. In some cases, you may need to activate the XS engine manually.

The XS engine is enabled separately for the system database and for each tenant database.

## Procedure

1. For the **system database**, the XS engine must be enabled in the `nameserver.ini` file.

To enable the XS engine, you can use the following SQL statement:

```
ALTER SYSTEM ALTER configuration ('nameserver.ini','SYSTEM') SET
('httpserver','embedded')= 'true' WITH reconfigure;
```

2. For each **tenant database**, the XS engine must be enabled in the `xsengine.ini` file.

To enable the XS engine, you can use the following SQL statement:

```
ALTER SYSTEM ALTER configuration ('xsengine.ini','SYSTEM') SET
('httpserver','embedded')= 'true' WITH reconfigure;
```

## Related Information

[Schedule Backups \[page 1507\]](#)

[Enable the XS Job Scheduler \(XS Classic\) \[page 1513\]](#)

### 11.2.6.4.4.2 Manage and Delete Backup Schedules

Using SAP HANA cockpit, you can display an overview of backup schedules, pause or reactivate schedules, and delete schedules.

#### Context

Backup schedules run for the database for which they are scheduled. Backup schedules do not run in the SAP HANA cockpit that administers the schedules.

#### Procedure

1. From the system database, on the [Database Overview](#), choose [Database Management](#).

A status overview of the system database and the tenant databases is displayed.

2. Choose [Backup Schedules](#).

An overview of the backups scheduled for the system database and the tenant databases is displayed.

- a. You can display the schedules for a week or for a whole month. Choose [1 Month](#) or [1 Week](#).

If a schedule is set to be executed at a future date, scroll forward in the schedule calendar to see that schedule.

- b. Choose a task.

To...	Steps
Display the details of a backup schedule.	Click the backup in the calendar.
Change a backup schedule.	<ol style="list-style-type: none"><li>1. Select a backup schedule and choose <a href="#">More Details</a>.</li><li>2. Choose <a href="#">Edit Schedule</a>.</li><li>3. Make the desired changes.</li></ol>

#### i Note

It is not possible to change the recurrence of a schedule between weekly and monthly. For a schedule with weekly recurrence, you can change

To...	Steps
	<p>the days of the week on which the schedule is executed.</p> <p>4. Choose <i>Save</i>.</p>
Pause or reactivate a backup schedule.	<p>1. Select a backup schedule and choose <i>More Details</i>.</p> <p>2. Choose <i>Pause Schedule</i>.</p> <p>To reactivate a paused schedule, choose <i>Activate Schedule</i>.</p>
Delete a backup schedule.	<p>1. Select a backup schedule and choose <i>More Details</i>.</p> <p>2. Choose <i>Delete</i>, then confirm.</p> <p>The backup schedule is deleted permanently.</p>

## Related Information

[Schedule Backups \[page 1507\]](#)

### 11.2.6.5 Backup Audit Actions for Security

You can audit the creation and cancelation of a backup.

When an action occurs, the audit policy is triggered and an audit event is written to the audit trail. Audit policies are database-specific.

For more information, see the SAP HANA Security Guide.

## Related Information

[Audit Policies](#)

[Create an Audit Policy \[page 969\]](#)

[CREATE AUDIT POLICY Statement \(Access Control\)](#)

## 11.2.6.6 Cancel a Backup

You can cancel a running data backup or a delta backup (differential or incremental).

### Context

The option to cancel a backup is only available while the backup is running.

#### i Note

In some situations, it may **not** be possible to cancel a running backup. For example, if it is not possible to access internal locks, or if a file cannot be written to an NFS mount.

### Procedure

1. From the backup dialog, choose *Cancel Backup*.
2. Confirm your decision.

The backup is canceled and you are notified.

### Results

After you have canceled a backup, you can start a new data backup.

#### → Tip

If you canceled a running backup performed by a **third-party backup tool**, it is recommended to ensure that any incomplete backups are physically deleted.

## 11.2.6.7 Housekeeping: Deleting and Archiving Backups

It is recommended to regularly check whether old full backups or backup generations can be deleted.

You can delete full backups and backup generations if they are no longer needed for a recovery, or to keep your backup storage space at an optimum level.

For more information, see *Deleting Backup Generations*.

## Archiving Backups

Full backups that need to be retained for an extended period can be archived in a secure location and then removed from the backup catalog. Ensure that archived backups cannot be accessed directly by SAP HANA and cannot be deleted.

### → Tip

It is important to regularly truncate the backup catalog because, as it increases in size, it can consume a lot of storage space and also take longer to write each new backup.

An archived **full data backup** can still be used to recover SAP HANA, even if it is not recorded in the backup catalog.

If you need to ensure that you can recover SAP HANA from older log backups and delta backups, you need to retain backups of the backup catalog.

## Related Information

[Delete Backup Generations \[page 1519\]](#)

[Delete Backups \[page 1522\]](#)

[Backup Catalog](#)

### 11.2.6.7.1 Prerequisites for Deleting Old Backups

Before you delete old backup generations or individual full backups, some prerequisites must be met.

- You have the appropriate system privilege:

BACKUP ADMIN

Connect directly to a system database or a tenant database and delete backup and backup generations of that database.

For more information, see *BACKUP CATALOG DELETE Statement (Backup and Recovery)*.

DATABASE ADMIN

Connect to a system database and delete backup generations or individual full backups of a tenant database.

- To delete backups and backup generations of a tenant database, the tenant database must be online.
- To delete backup generations, you need to decide from which time onwards you want to retain data backups.
- Before you physically delete backup generations or individual full backups, ensure that the backups retained are accessible and consistent, so that, if needed, they can be used to recover the database.
- At least one full data backup must remain in the backup catalog.

## Deleting Data Snapshots

When you delete a data snapshot from SAP HANA cockpit, **only its record is removed from the backup catalog**.

SAP HANA does not physically delete a data snapshot. To physically delete a data snapshot, you must delete it manually in the repository where it is stored.

## Deleting File System Backups

SAP HANA searches for a backup only in the physical location recorded in the backup catalog. If a backup has been moved from the location recorded in the backup catalog, SAP HANA cannot delete it.

## Related Information

[Delete Backups \[page 1522\]](#)

[Rebuilding the Backup Catalog](#)

[Data Snapshots](#)

## 11.2.6.7.2 Delete Backup Generations

Using SAP HANA cockpit, you can delete backup generations that are no longer needed for a recovery.

### Context

You can delete the backup catalog records of backup generations, but retain the associated physical backups. Optionally, you can delete the records from the backup catalog and also the associated physical backups.

#### i Note

You can automate the deletion of backup generations by configuring the retention policy.

For more information, see *Change the Backup Configuration Settings*.

A backup generation comprises the following backups:

<b>A Backup Generation Consists Of...</b>	<b>...Backups</b>
Successfully created full backup:	<ul style="list-style-type: none"><li>• Complete data backup</li></ul> <b>OR</b> <ul style="list-style-type: none"><li>• Data snapshot</li></ul>
<b>AND</b>	<ul style="list-style-type: none"><li>• Delta backups (differential or incremental backups)</li><li>• Log backups</li></ul>

## A Backup Generation Consists Of...

Backups that were created after the full backup and up to the start time of the next successful full backup:

## ...Backups

- Backups of the backup catalog

## Procedure

1. From the *Database Directory*, select a database.

Option	Description
To access a system database	<p>From the <i>Database Overview</i> of the system database, locate the <i>Database Backups</i> card and click it.</p> <p>An overview of information from the backup catalog is displayed for the system database.</p>
To access a tenant database from its system database	<p>From the <i>Database Overview</i> of the system database:</p> <ol style="list-style-type: none"><li>1. Choose <i>Database Management</i>.</li><li>2. Click the backup entry.</li></ol> <p>The backup catalog overview for the tenant database is displayed.</p>
To access a tenant database directly	<p>From the <i>Database Overview</i> of the tenant database, locate the <i>Database Backups</i> card and click it.</p> <p>An overview of information from the backup catalog is displayed for the tenant database.</p>

### i Note

To delete backups directly from a tenant database, you need the BACKUP ADMIN privilege for the tenant database, and the *Restrictions for Tenant Database Users* permit the tenant database user to make changes.

For more information, see *Authorizations Needed for Backup and Recovery* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)* and *Backup Configuration Settings*.

2. To display an overview of backup generations, choose the chart icon.

The chart shows the start time and end time of the backup generation, its total size, and the sizes of the full data backup and the associated delta backups, log backups, and backups of the backup catalog that can be used for a recovery.

### i Note

The end time of a backup generation is the start time of the next backup generation.

To customize the information displayed, choose [Filter](#).

In the dialog box, you can specify a time range from which to display the backup generations.

3. Click the row of the most recent backup generation that you want to retain.

A summary of information about the backup generation is displayed.

4. To delete one or more backup generations, choose [Delete Backup Generations](#).

#### Caution

When you select one backup generation, **all the backup generations** that are **older than the selected backup generation** will be deleted.

This includes the backup generations that are displayed, and also the backup generations that are outside of the time filter, and therefore not currently displayed.

5. In the dialog box, select an option:

Option	Description
<a href="#">Remove from backup catalog only</a>	Delete only the backup catalog records of backup generations, but retain the associated physical backups.
<a href="#">Also delete physically</a>	Delete the records from the backup catalog and also the associated physical backups. You can delete the physical backups in either the file system or a third-party backup tool, or both.

#### Caution

When you confirm, the records of the backups are deleted from the backup catalog immediately, even though it may take some more time for the physical backups to be deleted.

#### Note

SAP HANA can only physically delete backups that are in the location recorded in the backup catalog. SAP HANA cannot physically delete backups that have been moved to a different location.

6. To confirm, choose [Delete](#).

The backup generations are deleted in accordance with the options you specified.

## Related Information

[Change the Backup Configuration Settings \[page 1455\]](#)

[Manage and Delete Backup Schedules \[page 1515\]](#)

## 11.2.6.7.3 Delete Backups

Using SAP HANA cockpit, you can display an overview of complete data backups (and delta backups), and also delete individual full data backups.

### Context

#### i Note

To ensure that no backups are deleted that would prevent SAP HANA from being recovered, it is not possible to delete delta backups and log backups individually.

You can delete the backup catalog records of individual full backups, but retain the associated physical backups. Optionally, you can delete the records in the backup catalog and also the associated physical backups.

For example, to comply with legal requirements for data retention, you may wish to retain specific historical data backups, but without the intention of using them for a production database recovery.

#### i Note

If a full backup is physically available, but not recorded in the backup catalog, that full backup can still be used to recover the database.

To be able to recover SAP HANA using **third-party data backups** that are not recorded in the backup catalog, the data backups must have a unique prefix.

### Procedure

1. From the [Database Directory](#), select a database.

Option	Description
To access a system database	<p>From the <a href="#">Database Overview</a> of the system database, locate the <a href="#">Database Backups</a> card and click its title.</p> <p>An overview of information from the backup catalog is displayed for the system database.</p>
To access a tenant database from its system database	<ol style="list-style-type: none"><li>1. From the <a href="#">Database Overview</a> of the system database, choose <a href="#">Database Management</a>.</li><li>2. Select the tenant database. The backup catalog overview for the tenant database is displayed.</li></ol>

Option	Description						
<p><b>To access a tenant database directly</b></p>	<p>From the <i>Database Overview</i> of the tenant database:</p> <ol style="list-style-type: none"> <li>1. Choose <i>Database Management</i>.</li> <li>2. From the overview of the databases in the SAP HANA system, select the tenant database. The backup catalog overview for the tenant database is displayed.</li> </ol> <div data-bbox="831 577 1402 981" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>To delete backups directly from a tenant database, you need the BACKUP ADMIN privilege for the tenant database, and the <i>Restrictions for Tenant Database Users</i> permit the tenant database user to make changes.</p> <p>For more information, see <i>Authorizations Needed for Backup and Recovery</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i> and <i>Backup Configuration Settings</i>.</p> </div>						
<p>a. To customize the information displayed, choose <i>Filter</i>.</p> <p>From the dialog box, you can filter the following information:</p> <table border="1" data-bbox="279 1108 1402 1877"> <tbody> <tr> <td data-bbox="279 1108 790 1332"> <p><i>Backup Type</i></p> </td> <td data-bbox="790 1108 1402 1332"> <p>By default, <i>Complete Data Backup</i> and <i>Data Snapshot</i> are selected.</p> <p>To display information about delta backups, select <i>Differential Backup</i> and <i>Incremental Backup</i> and confirm.</p> </td> </tr> <tr> <td data-bbox="279 1332 790 1814"> <p><i>Status</i></p> </td> <td data-bbox="790 1332 1402 1814"> <p>You can display backups with the status:</p> <ul style="list-style-type: none"> <li>○ Canceled</li> <li>○ Failed</li> <li>○ Prepared</li> </ul> <p>A data snapshot has been prepared, but has not been confirmed or abandoned.</p> <div data-bbox="895 1592 1402 1731" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>To create a data snapshot, you need to use native SQL.</p> </div> <ul style="list-style-type: none"> <li>○ Running</li> <li>○ Successful</li> </ul> </td> </tr> <tr> <td data-bbox="279 1814 790 1877"> <p><i>Start Time</i></p> </td> <td data-bbox="790 1814 1402 1877"> <p>You can display backups from a specific time range.</p> </td> </tr> </tbody> </table>	<p><i>Backup Type</i></p>	<p>By default, <i>Complete Data Backup</i> and <i>Data Snapshot</i> are selected.</p> <p>To display information about delta backups, select <i>Differential Backup</i> and <i>Incremental Backup</i> and confirm.</p>	<p><i>Status</i></p>	<p>You can display backups with the status:</p> <ul style="list-style-type: none"> <li>○ Canceled</li> <li>○ Failed</li> <li>○ Prepared</li> </ul> <p>A data snapshot has been prepared, but has not been confirmed or abandoned.</p> <div data-bbox="895 1592 1402 1731" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>To create a data snapshot, you need to use native SQL.</p> </div> <ul style="list-style-type: none"> <li>○ Running</li> <li>○ Successful</li> </ul>	<p><i>Start Time</i></p>	<p>You can display backups from a specific time range.</p>	
<p><i>Backup Type</i></p>	<p>By default, <i>Complete Data Backup</i> and <i>Data Snapshot</i> are selected.</p> <p>To display information about delta backups, select <i>Differential Backup</i> and <i>Incremental Backup</i> and confirm.</p>						
<p><i>Status</i></p>	<p>You can display backups with the status:</p> <ul style="list-style-type: none"> <li>○ Canceled</li> <li>○ Failed</li> <li>○ Prepared</li> </ul> <p>A data snapshot has been prepared, but has not been confirmed or abandoned.</p> <div data-bbox="895 1592 1402 1731" style="border: 1px solid #ccc; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>To create a data snapshot, you need to use native SQL.</p> </div> <ul style="list-style-type: none"> <li>○ Running</li> <li>○ Successful</li> </ul>						
<p><i>Start Time</i></p>	<p>You can display backups from a specific time range.</p>						

- b. To change the order in which the columns are displayed, choose *Settings*, and use the arrow buttons.

- To delete a full backup (complete data backup or data snapshot), choose the *Delete* icon for that backup.

In the dialog box, specify whether to:

*Remove from backup catalog only*

Delete only the backup catalog record of a full backup, but retain the associated physical backup.

*Also delete physically*

Remove the record of the backup from the backup catalog and delete the associated physical backup.

You can delete the physical full backup in either the file system or a third-party backup tool.

#### ⚠ Caution

When you confirm, the record of the backup is deleted from the backup catalog immediately, even though it may take some more time for the physical backup to be deleted.

#### i Note

SAP HANA can only physically delete backups that are in the location recorded in the backup catalog. SAP HANA cannot physically delete backups that have been moved to a different location.

- To confirm, choose *Delete*.

Before a backup is physically deleted, the following plausibility checks are performed:

- **For a file-based backup:** The system checks the backup ID.
- **For third-party backup tools:** The system checks the external backup ID (EBID) and whether the path to the backup is identical to the backup location of the current database.

If the plausibility check is successful, the system starts deleting the physical backup in the background.

#### i Note

The delete operation continues until all the parts of the selected backup have been deleted.

If the system or a service is stopped and restarted, the delete operation is automatically resumed.

You can monitor the progress of the deletion operation in the `backup.log` file.

## Related Information

[Delete Backup Generations \[page 1519\]](#)

[Create Data Backups \[page 1499\]](#)

[Backup Configuration Settings \[page 1457\]](#)

## 11.2.6.7.3.1 Delete Old Backups (SAP HANA Studio)

You can delete records of backups from the backup catalog. Alternatively, you can delete records of backups from the backup catalog and also delete the associated physical backups.

### Context

#### ⚠ Caution

Deleting backups is a critical operation. To keep a record of all backup deletions, use the auditing feature in the SAP HANA database. The action to be audited is BACKUP CATALOG DELETE.

For more information about auditing, see *Auditing Activity in the SAP HANA Database and Create an Audit Policy* in the *SAP HANA Administration Guide*.

### Procedure

#### i Note

The steps described here ensure that no backups are deleted that would prevent SAP HANA from being recovered. For this reason, it is not possible to delete delta backups and log backups individually.

1. In SAP HANA studio, choose **► Backup and Recovery ► Open Backup Console ▾**.
2. In the Backup Console for the system database, go to the **Backup Catalog** tab.
3. Select the database.
4. Select a data backup and right-click to open the context menu.

Option	Description
<a href="#">Delete Data Backup...</a>	Delete the selected data backup.
<a href="#">Delete Older Backups...</a>	Retain the selected data backup and delete all older data backups, delta backups, and log backups.

A dialog box appears.

5. Specify what you want to delete:

Option	Description
<a href="#">Catalog</a>	Delete the records of the selected data backup(s) from the backup catalog only.

Option	Description
<i>Catalog and Backup Location</i>	<p>Delete the selected data backup(s) from the backup catalog and also delete the physical backups.</p> <p>Specify the location of the physical data backup(s) to be deleted.</p> <p>If you have physical backups in both the file system and a third-party backup tool, you can choose to delete data backups in only one location.</p>

**i Note**

SAP HANA can only physically delete backups that are in the location recorded in the backup catalog. SAP HANA cannot physically delete backups that have been moved to a different location.

6. Choose *Next* and review the information about the data backup(s) that will be deleted.
 

Optionally, you can download a list of the deleted backups to a plain text file.
7. If you are sure that you want to delete the data backup(s), choose *Finish*.

## Results

The system deletes the selected data backup(s).

If you chose to delete from the backup catalog only, the system deletes the backup records, and refreshes the backup catalog in the Backup Console.

### i Note

If you chose to delete records from the backup catalog **and also the associated physical backups**, the truncated backup catalog is displayed immediately, even though it may take some more time for the physical backups to be deleted.

Before the backup(s) are physically deleted, the following plausibility checks are performed:

- **For file-based backups:**  
The system checks the backup ID.
- **For third-party backup tools:**  
The system checks the external backup ID (EBID) and whether the path to the backup is identical to the backup location of the current database.

If the plausibility check is successful, the system starts deleting the physical backup(s).

Depending on the size and number of the backups, this can take some time.

You can monitor the progress of the deletion operation in the `backup.log` file.

### i Note

The delete operation continues until all the selected backups have been deleted.

If the system or a service is stopped and restarted, the delete operation is automatically resumed.

If the oldest data backup is deleted, the delta backups and the log backups for the period up to the next oldest data backup are **not** automatically deleted.

## 11.2.7 SAP HANA Recovery

It may be necessary to recover an SAP HANA database due to a number of different reasons.

- Data is unusable (disaster recovery)
  - The data area is unusable.  
For more information, see *Data Area is Unusable (Disaster Recovery)*.
  - The log area is unusable.  
For more information, see *Log Area is Unusable (Disaster Recovery)*.
- A logical error has been detected (fault recovery)  
If a logical error occurs, the database needs to be recovered to its state at a particular point in time.  
For more information, see *Logical Error - Point-in-Time Recovery (Fault Recovery)*.
- You want to create a copy of the database.  
For more information, see *Copying a Database Using Backup and Recovery*.

## Related Information

### SAP HANA Recovery Scenarios

[Recovery Scenarios \[page 1572\]](#)

[Data Area is Unusable \(Disaster Recovery\) \[page 1572\]](#)

[Logical Error - Point-in-Time Recovery \(Fault Recovery\) \[page 1574\]](#)

### SAP HANA Recovery

[Prerequisites for Database Recovery \[page 1528\]](#)

[Recover a Database \[page 1548\]](#)

[Recover a Database \(SAP HANA Studio\) \[page 1551\]](#)

[Copying a Database Using Backup and Recovery \[page 1578\]](#)

[Recover a System Database to a Point in Time \(recoverSys.py\) \[page 1559\]](#)

## 11.2.7.1 Prerequisites for Database Recovery

Before you start a database recovery, certain preparations are needed.

- The SAP HANA database software is installed on the target system.  
For more information, see the *SAP HANA Server Installation and Update Guide*.
- You need the following logon credentials:

To Recover...	Log On As...
System database	The operating system user <sid>adm in the target system
Tenant database	The database user

The SAP control credentials are required for the SAP HANA recovery and also to shut down the database. For more information, see *Setup and Administration with the Cockpit Manager in SAP HANA Administration with SAP HANA Cockpit*.

- To perform a recovery, an SAP HANA database needs to be shut down.

System database	If the system database is shut down for recovery, all its tenant databases are automatically shut down as well. The whole SAP HANA system is not available until the recovery of the system database has been completed.
Tenant database	While a tenant database is being recovered, it cannot be accessed by end users or applications. The other tenant databases in the SAP HANA system continue working as normal.

### i Note

If you recover SAP HANA from a data snapshot, you must shut down the database **before** you make the data snapshot available in the data area of the storage system.

For more information, see *Recover SAP HANA From a Data Snapshot*.

- At the beginning of a recovery, the data backup, the delta backups, and the log backups to be used must be either accessible in the file system or available through a third-party backup tool.

The following backups must be available:

- At least one full backup (complete data backup or data snapshot)
- If required, delta backups created since the full backup to be used
- If required, log backups created since the full backup to be used  
(Covering changes not already contained in the delta backups)
- If required, the log area

### i Note

If a full backup is physically available, but not recorded in the backup catalog, that backup can still be used to recover the database. However, it is not possible to recover SAP HANA to a point in time if the log backups or delta backups are not recorded in the backup catalog.

- If you are recovering the database from a data snapshot, the data snapshot must be replicated to the data area.  
For more information, see *Recover SAP HANA From a Data Snapshot*.
- To recover **customer-specific configuration settings** (\*.ini files), it is recommended that you first configure the customer-specific settings before you recover the database and the replay log backups.  
For more information, see *Backing Up Customer-Specific Configuration Files*.

## Disk Sizing

When you recover an SAP HANA database, disk space requirements can temporarily increase. As a general rule, ensure that you are working with enough disk space to contain at least either the complete data backup and the delta backups or the data snapshot that you are using for the recovery.

## Multiple Host Systems

If you are working with file-based backups on multiple hosts, shared backup storage is needed to perform the availability checks. If recovery-relevant data is not available at the beginning of the recovery, this may not be detected until after the recovery has started. In this situation, the recovery can be started, but will fail.

For this reason, for systems with multiple hosts, we recommend that you manually check whether a recovery is possible before you start the recovery.

For more information, see *Checking Whether a Recovery is Possible*.

## Related Information

[SAP HANA Server Installation and Update Guide](#)

[Setup and Administration with the Cockpit Manager](#)

[Prerequisites: Recovering an Encrypted SAP HANA Database \[page 1529\]](#)

[Prerequisites: Recovery Using Multistreamed Backups \[page 1530\]](#)

[Checking Whether a Recovery is Possible \[page 1531\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

[Backing Up Customer-Specific Configuration Settings \[page 1494\]](#)

### 11.2.7.1.1 Prerequisites: Recovering an Encrypted SAP HANA Database

Before you recover an encrypted SAP HANA database, you should consider several important points.

- If you are recovering SAP HANA from encrypted backups, import the latest encryption root key backup. If needed, backed up older versions of the backup encryption root key must also be imported.  
For more information, see *Import Backed-up Root Keys* in the *SAP HANA Administration Guide (Encryption)*.
- Data volume encryption must be enabled **before the recovery is started**.  
This ensures that all the data is encrypted as it is recovered. During a recovery, all data from data backups and log backups is encrypted, even if some or all of the backups are not encrypted.

### i Note

When you recover a tenant database that is being encrypted on the fly, recovery ensures that there are no unencrypted shadow pages in the recovered database. For this reason, it is not necessary to drop and recreate a tenant database before starting the recovery.

For more information, see *Enable and Disable Encryption of Data and Log Volumes* in the SAP HANA Administration Guide (Encryption).

## Related Information

[SAP HANA Backup Encryption \[page 1425\]](#)

[Import Backed-Up Root Keys Before Database Recovery \[page 1015\]](#)

[Enabling Encryption of Data and Log Volumes](#)

## 11.2.7.1.2 Prerequisites: Recovery Using Multistreamed Backups

For a recovery using multistreamed backups, there needs to be the same number of channels that were used for the backup.

When you prepare a recovery from multistreamed backups, you do not need to take any special steps to adjust the number of channels used. During a recovery, SAP HANA is able to recognize how many channels were used for a backup, and automatically uses this number of channels for the recovery.

SAP HANA does **not** check the value of parameter `parallel_data_backup_backint_channels`, which defines the number of channels used for multistreaming for both data backups and delta backups.

The backup catalog shows all the parts of a multistreamed backup. For a recovery, the order of the backup parts is not important. SAP HANA can recover the parts of a multistreamed backup in any order.

## Related Information

[Configure Multistreaming with Third-Party Backup Tools \[page 1447\]](#)

[Configure SAP HANA Parameters for a Third-Party Backup Tool \[page 1445\]](#)

## 11.2.7.2 Checking Whether a Recovery is Possible

The success of a database recovery can only be ensured if the required backups are available and have not been changed since they were created. For this reason, it is recommended that you check backups periodically, or if you suspect that they have been changed in some way since they were created.

### Automatic Checks for Backups

When SAP HANA data backups, delta backups, or log backups are created, the integrity of the data to be backed up is automatically checked while the backups are being written. These integrity checks are performed on block level. However, the actual content of the data blocks is not analyzed. The backup is written only if the integrity check was successful.

When a recovery is started, the block-level integrity of the backups to be used is automatically checked. If an error is detected, the recovery is stopped, and will need to be repeated.

### Manual Checks for Recovery

In addition to the automatic backup checks performed by SAP HANA, you can manually check data backups and log backups **without performing a recovery**.

You can check the following:

Check...	Using...
Can a database can be recovered to a specific point in time?	Before you start a recovery, you can use <code>hdbrecovercheck</code> .  For more information, see <i>Check Recoverability (hdbrecovercheck)</i> .
Which backups are required?	<code>hdbbackupdiag</code> determines: <ul style="list-style-type: none"><li>• Which data backups and log backups are required to recover the database to a specified point in time</li><li>• Whether these backups are available and can be accessed</li></ul> For more information, see <i>Check the Backups Required for a Recovery (hdbbackupdiag)</i> .  <code>hdbbackupdiag</code> can also be used to rebuild the backup catalog. For more information, see <i>Rebuilding the Backup Catalog</i> .

## Check...

Were individual data backups or log backups changed since they were created?

## Using...

Use `hdbbackupcheck`

For more information, see *Checking Individual Backups (hdbbackupcheck)*.

For more information, see SAP Note [1869119](#) (Checking backups with "hdbbackupcheck")

### ! Restriction

`hdbbackupcheck` does not support SAP HANA Dynamic Tiering.

## i Note

`hdbrecovercheck`, `hdbbackupdiag`, and `hdbbackupcheck` can all be used with file system backups and third-party backup tools.

`hdbbackupdiag` and `hdbbackupcheck` cannot be used with data snapshots.

With third-party backup tools, `hdbbackupdiag` and `hdbbackupcheck` must run in a system with the same SID to which the backups were written.

## Isolation Level High for Backups and Third-Party Tools

To grant the system administrator access to the tenant database backup files and directories, you need to add the `<sid>adm` user to the operating system group of each tenant. For more information, see *File and Directory Permissions with High Isolation* in the *SAP HANA Administration Guide*.

## Related Information

[Isolation Level High for Backups and Third-Party Backup Tools \[page 1449\]](#)

[Rebuilding the Backup Catalog \[page 1435\]](#)

## 11.2.7.2.1 Check Recoverability (hdbrecovercheck)

Before you start a recovery, you can use the Python script `hdbrecovercheck.py` to verify that a database can be recovered to a specific point in time.

### Prerequisites

- Python support  
In a standard SAP HANA installation, `hdbrecovercheck.py` is installed in `$DIR_EXECUTABLE/python_support`.
- For file-based backups, if the directories that you want to use are different from the directories specified in the backup catalog, you need to manually specify the directories containing the backup catalog, the data backups, and the log backups.  
You can opt to ignore the log area (log segments that have not been backed up) or delta backups.  
If no backup paths are specified, `hdbrecovercheck.py` uses the paths specified in the backup catalog.

#### ! Restriction

`hdbrecovercheck.py` does not support system copy or system replication.

### Context

`hdbrecovercheck.py` checks all the resources required (backups and log area) for a recovery to a specific point in time to verify whether they:

- Exist
- Can be accessed

`hdbrecovercheck.py` also gives you the option to check the consistency of the backups on:

- Volume level
- Page level
- All hosts for all services

You can check the consistency of the backups up to a point in time without actually verifying that a recovery to that point in time is possible.

### Procedure

1. Use the following command to call `hdbrecovercheck.py`:

Option	Description
<b>Backup Catalog is in the File System:</b>	<code>python python_support/hdbrecovercheck &lt;option&gt; -c &lt;backup catalog path&gt; --database &lt;name&gt;</code>
<b>Backup Catalog is in Backint:</b>	<code>python python_support/hdbrecovercheck &lt;option&gt; -b --database &lt;name&gt;</code>

To display all the options, use the command: `python python_support/hdbrecovercheck.py -h`

- (Optional) To check the consistency of the backups, use the following command: `hdbrecovercheck.py checkBackupConsistency [-h]`.

Select the following options:

Option	Description
<code>-D DATABASE</code>	Specify the name of the database
<code>-c BACKUPCATALOGPATH</code>	Specify the path to backup catalog in the file system
<code>-b</code>	Use the backup catalog from the third-party backup tool (Backint)
<code>-t TIMESTAMP</code>	Timestamp to be reached, in UTC Default: now
<code>-l LOGBACKUPPATHS</code>	Specify the log backup paths as a comma-separated list
<code>-d DATABACKUPPATHS</code>	Specify the data backup paths as a comma-separated list
<code>-v, --verbose</code>	Verbose output
<code>--json</code>	json output

#### ❁ Example

```
python python_support/hdbrecovercheck.py checkBackupConsistency -
c /usr/sap/HD3/HDB03/backup/log/DB_HD3 --database HD3
```

For the database named HD3, checks the consistency of the log backups specified in the file-based backup catalog needed for a recovery until now.

- To check whether the backups can be used to recover the database to the desired point in time, use the following command: `hdbrecovercheck.py checkPointInTimeReachable [-h]`.

Select the following options:

Option	Description
<code>-D DATABASE</code>	Specify the name of the database

Option	Description
-c BACKUPCATALOGPATH	Path to backup catalog in the file system
-b	Use the backup catalog from the third-party backup tool (Backint)
-t TIMESTAMP	Specify the timestamp to be reached, in UTC Default: now
-i	Ignore the log area
-I	Ignore delta backups
-l LOGBACKUPPATHS	Specify the log backup paths as a comma-separated list
-d DATABACKUPPATHS	Specify the data backup paths as a comma-separated list
-v	Verbose output
--json	json output

#### ❖ Example

```
python python_support/hdbrecovercheck.py checkPointInTimeReachable -
c /usr/sap/HD3/HDB03/backup/log/DB_HD3 --database HD3 -t "2020-09-02
10:10:30" -v
```

For the database named HD3, checks the backups specified in the file-based backup catalog to determine whether the backups can be used to recover to the desired point in time (2020-09-02 at 10:10:30 UTC), with verbose output.

## Results

The backups and the log area are checked.

Trace data (hdbrecovercheck.trc) is written to the SAP HANA trace directory.

For more information about viewing trace files, see *View Diagnostic Files in the SAP HANA Database Explorer*.

## Options for a Recovery

You are notified as to what options are available for the recovery:

Result	Option
The specified point in time is in the current backup history or log area.	You can proceed with the recovery.

<b>Result</b>	<b>Option</b>
The specified point in time is missing from the current backup history, but it is recorded in the backup log.	Action: Check the backup log. You may be able to recover to the point in time using the relevant log positions.
The point in time cannot be reached.	This could mean that a specified path is incorrect or that a backup is corrupt at the specified path, but backups at a different location may be still usable.  Action: <ul style="list-style-type: none"> <li>• Specify the correct backup paths.</li> <li>or</li> <li>• Recover to a different point in time.</li> </ul>
The backup history is lost.  If log mode overwrite was used, log segments may have been overwritten.	The database can be recovered without log replay.
(If there is no log backup)  The log area and the data backup are incompatible.	<ol style="list-style-type: none"> <li>1. Specify the path to a different backup catalog containing the correct data backup(s).</li> <li>2. You can recover the database without log replay. (Initialize the log area.)</li> </ol>
The log backups and the log area are incompatible.	<ol style="list-style-type: none"> <li>1. Specify the path to a different backup catalog containing the correct log backups.</li> <li>2. You can recover the database without log replay. (Initialize the log area.)</li> </ol>

## 11.2.7.2 Check the Backups Required for a Recovery (hdbbackupdiag)

The `hdbbackupdiag` tool determines which backups are required to complete a recovery to a specified point in time. It also checks whether these backups are available and whether they can be accessed.

### Context

With `hdbbackupdiag`, you can verify the following:

#### For file-based backups:

- The backup is available in the file system, either at the location to which it was written or at a location specified by a search path.  
The backups to be used can be in any directory in the file system.
- The current operating system user has read authorization for the file.
- The actual size of the backup file is the same as the size recorded in the backup file header.
- The backup ID is identical to the backup ID specified in the backup catalog.

#### For backups created using a third-party backup tool:

- The backup is available in the third-party backup tool.

#### → Tip

To maintain good recovery performance, and to allow the check to be completed quickly, `hdbbackupdiag` checks only the metadata of a backup. It does not check the integrity of the backup content on block level.

It is recommended that you use this tool periodically to check the consistency of the metadata of a backup.

### Procedure

1. Ensure that `hdbbackupdiag` can locate the backup catalog.

To do this, you can either execute `hdbbackupdiag` in the directory where the backup catalog is located (file-based only) or execute `hdbbackupdiag` with options that specify which directories to search for the latest backup catalog. By default, this is the directory where the last log backups were written before the recovery was started.

The default directory is `$DIR_INSTANCE/backup/log`.

For more information, see *Change the Log Backup Settings*.

2. Start `hdbbackupdiag`.

Use the following command:

```
hdbbackupdiag [options] [-d <directory>]
```

The options for `hdbbackupdiag` are described below.

Option	Description
<code>-h   --help</code>	Display the available options.
<code>--check</code>	<p>Check:</p> <ul style="list-style-type: none"> <li>Whether all the backups (including log backups and delta backups) required for a recovery exist and can be accessed</li> <li>The metadata is consistent</li> </ul> <p>The <code>hdbbackupdiag</code> tool first computes the recovery strategy in accordance with the input parameters and builds a list of backups that will be needed for the recovery. <code>hdbbackupdiag</code> then checks whether all the backups needed are available and can be accessed. To verify that all the backup metadata is consistent and has not changed since the backup was made, <code>hdbbackupdiag</code> then also checks that the backup headers are correct.</p> <div style="border: 1px solid #0070c0; padding: 5px; background-color: #e6e6e6;"> <p><b>i Note</b></p> <p>The <code>hdbbackupdiag</code> tool (and the SQL statement <code>BACKUP CHECK ACCESS</code>) does <b>not</b> check the persisted content of the backup. To check the backup content, you can use the <code>hdbbackupcheck</code> tool for each backup listed by <code>hdbbackupdiag</code>.</p> <p>For more information about <code>hdbbackupcheck</code>, see <i>Manually Checking Whether a Recovery is Possible</i>.</p> </div>
<code>-f</code>	<p>Display the names of the backups required for recovery as a simple list.</p> <p>From this list, the backup names can be easily included in shell scripts.</p>
<code>-B</code>	Display the names of backups with Backint information.
<code>-v</code>	<p>Display all available information.</p> <p>For example, the SAP HANA version that was used to create a backup.</p>
<code>-d &lt;directory&gt;</code>	<p>Specify the directory to search for the backup catalog.</p> <p>If you do not specify a directory, the current directory is searched for the latest version of the backup catalog. If specified, the directories indicated with <code>--logDirs</code> (see below) and the third-party backup tool are also searched.</p> <div style="border: 1px solid #0070c0; padding: 5px; background-color: #e6e6e6;"> <p><b>i Note</b></p> <p>All directories must be specified as absolute paths.</p> </div>
<code>-c &lt;catalog&gt;</code>	Specify the name of the backup catalog.
<code>-i &lt;BackupID&gt;</code>	<p>Specify a backup ID.</p> <p>If you do not specify a backup ID, the most recent usable data backup is used.</p>

Option	Description
<code>-u &lt;"YYYY-MM-DD hh:mm:ss"&gt;</code>	Specify a target time for the recovery (UTC time). If you do not specify a time, the most recent possible point in time is used.
<code>--dataDir &lt;directory&gt;</code>	Specify a directory to search for data backups or delta backups. If you do not specify a directory, only the paths specified in the backup catalog are searched.
<code>--logDirs &lt;directories&gt;</code>	Specify a comma-separated list of directories to search for log backup files. If you do not specify this option, only the paths specified in the backup catalog are searched.
<code>--useBackintForCatalog</code>	With this option, the third-party backup tool is searched for the most recent version of the backup catalog.
<code>--databaseName &lt;database&gt;</code>	Used only with SAP HANA and third-party backup tools. This option is used with <code>--useBackintForCatalog</code> to specify a tenant database or the system database:  <code>--databaseName &lt;name_of_tenant_database&gt;</code>  <code>--databaseName SYSTEMDB</code>
<code>--backintDataParamFile &lt;paramFileName&gt;</code>	Specify a parameter file to access data backups and delta backups through a third-party backup tool.
<code>--backintLogParamFile &lt;paramFileName&gt;</code>	Specify a parameter file to access log backups through a third-party backup tool. If you do not specify a parameter file, the parameter file used to access the data backups is used.
<code>--pickCatalog</code>	If you want to recover SAP HANA to a point in time (UNTIL timestamp) that is not available in the current timeline, a suitable catalog is selected for the recovery time.  More information: See SAP Note: <a href="#">2050606</a> (Recover database from not current backup history)
<code>--generate</code>	Generate a new backup catalog

### ⚠ Caution

The `--generate` option is intended for exceptional situations and **file-based backups only**. This option does not support data snapshots or backups created using third-party tools.

If you use the `--generate` option, any information about data backups or log backups created using third-party tools will be lost from the newly generated backup catalog. It will then no longer be possible to use this information for a recovery.

Option	Description
<code>--ignoreDeltaDataBackups</code>	Exclude delta backups.

## Results

The output of `hdbbackupdiag` contains the names of all the files required to recover the SAP HANA database.

## Related Information

### 11.2.7.2.1 Examples of Output From `hdbbackupdiag`

The output of `hdbbackupdiag` contains the names of all the files required to recover a SAP HANA database.

If you specify the `--check` option, the results of the metadata checks are also displayed.

#### ❖ Example

```
hdbbackupdiag --check --logDirs /usr/sap/HD2/HDB00/backup/log/ --
dataDir /usr/sap/HD2/HDB00/backup/data/
```

With this example command, the following steps are performed:

- `hdbbackupdiag` recursively searches the directory `/usr/sap/HD2/HDB00/backup/data/` for data backups and delta backups.  
If a data backup is not found, `hdbbackupdiag` attempts to check the original backup directory specified in the backup catalog.
- `hdbbackupdiag` recursively searches the directory `/usr/sap/HD2/HDB00/backup/log` for log backups.
- `hdbbackupdiag` checks whether a recovery is possible from the perspective of the backup component.  
The metadata of the backup files is checked to determine whether all the required backups are available and consistent.  
In addition, `hdbbackupdiag` checks whether a recovery to the desired time is possible. In this example, this is most recent point in time.

#### i Note

A recovery can still fail due to a persistent page corruption. This would be detected by the `hdbbackupcheck` tool. For more information, see *Manually Checking Whether a Recovery is Possible*.

- SAP HANA decides which data backup in the specified directory to use for the recovery.

This command returns the following output, including some errors:

### Sample Code

```
found backup catalog 1426152872410 from backint /usr/sap/HD2/SYS/
global/hdb/backint/log_backup_0_0_0_0

log_backup_2_0_273152_273792.1426152620143' successfully checked.
(...)
```

The first error occurs because a log backup is not available. The second error is because a log backup does not have the expected size.

### Example

Display all the backups required to recover the database until May 11, 2015, 01:05:00 p.m. The metadata of the backups is not checked.

From this list, the backup names can be easily included in shell scripts.

The time specified is UTC time, not local time.

```
hdbbackupdiag -f -d /usr/sap/MBY/HDB01/backup/log -u "2015-05-11 13:05:00"
```

```

## Related Information

[Checking Whether a Recovery is Possible \[page 1531\]](#)

### 11.2.7.2.3 Checking Individual Backups (hdbbackupcheck)

It is recommended that you check backups to verify that they have not been changed since they were created. For example, if backups have been transferred to a new storage medium.

## Context

You can use the `hdbbackupcheck` tool to check the integrity of individual data backups and log backups for both file-based backups and backups created using third-party backup tools.

`hdbbackupcheck` can be used either from inside an SAP HANA installation, or from outside an SAP HANA installation to check backups that are not accessed by an SAP HANA node.

### → Tip

Even if the metadata of a backup is correct, the backup may still have internal errors. For this reason, we recommend that you use `hdbbackupcheck` to check for corruption in individual data or log backups.

## Related Information

[Check Individual Backups Inside an SAP HANA Installation \(hdbbackupdiag, hdbbackupcheck\) \[page 1543\]](#)

[Check Individual Backups Outside an SAP HANA Installation \[page 1546\]](#)

[SAP Note 1869119](#)

### 11.2.7.2.3.1 Check Individual Backups Inside an SAP HANA Installation (hdbbackupdiag, hdbbackupcheck)

You can manually check the integrity of individual data backups and log backups.

#### Context

To find out which backup files are needed for a recovery, you can use `hdbbackupdiag`.

For more information, see *SAP Note 1821207 (Determining required recovery files)*.

To check a data backup, execute `hdbbackupcheck` for each individual part of the data backup. A data backup of an SAP HANA instance consists of multiple parts, each with the same prefix. A part of a backup is a backup file in the system storage or a backup object that has been transferred to an external backup tool.

#### i Note

If you are working with third-party backup tools, consult the tool documentation to learn more about the backup checks that these tools offer.

#### Procedure

1. Identify the data backups that you want to check.

Use the `hdbbackupdiag` tool.

2. To check the backups, you need the following information:

- File name (*Location*)  
For file-based data backups, the location is the file system path to the data backup. If the data backup is below the current directory, the relative path can be used.  
For data backups managed using a third-party backup tool, the location is the complete path and name, beginning with `/usr/sap/<SID>/SYS/global/hdb/backupint/`.
- External backup ID  
You need the external ID if you are using a third-party backup tool.
- Optionally, the backup ID assigned by the SAP HANA database when the backup was created.

3. Call `hdbbackupcheck` on the command line using the appropriate values for each part of a data backup.

`hdbbackupcheck` offers the following options:

```
hdbbackupcheck [parameters] <backup> [-i <backupid>] [-e <ebid>]
```

Options for `hdbbackupcheck`

Option	Description
<code>-v</code>	Display the header data of the backup.
<code>-p &lt;directory&gt;</code>	By default, the log files <code>backupcheck.log</code> and <code>backintcheck.log</code> are created in the trace directory.  To create the log files in a different directory, call <code>hdbbackupcheck</code> with option <code>-p &lt;directory&gt;</code> and specify the directory.
<code>&lt;backup&gt;</code>	Name of the backup file.
<code>--backintParamFile &lt;filename&gt;</code>	Specify the parameter file for the third-party backup tool.  If the working directory is not the directory where the file is located, specify the absolute path. To find out this path, consult the documentation provided by the tool vendor.
<code>-i &lt;backupid&gt;</code>	Specify the SAP HANA backup ID of the backup to be checked.  The backup ID is assigned to the backup when it is created.
<code>-e &lt;ebid&gt;</code>	External backup ID  If the part of the backup is in a third-party backup tool, you need to specify the external backup ID.
<code>--dump &lt;backupfile&gt;</code>	List the contents of the backup, if possible.

## Results

`hdbbackupcheck` notifies you if any errors were detected in the checked part of the backup.

## Related Information

[SAP Note 1821207](#) 

## 11.2.7.2.3.1.1 Examples of Output From hdbbackupcheck

hdbbackupcheck notifies you if any errors were detected in the checked part of the backup.

If no errors were detected, hdbbackupcheck returns 0.

If an error was detected, hdbbackupcheck returns 1.

Below are some examples of output from hdbbackupcheck:

### ❁ Example

```
hdbbackupcheck backup/data/BackupTestMaster_databackup_1_1
```

#### ≡ Output Code

```
Backup '/hana/shared/BNR/HDB00/backup/data/  
BackupTestMaster_databackup_1_1' successfully checked.
```

### ❁ Example

```
hdbbackupcheck -v backup/data/BackupTestMaster_databackup_1_1
```

#### ≡ Output Code

```
Check backup '/hana/shared/BNR/HDB00/backup/data/  
BackupTestMaster_databackup_1_1'  
Check backup '/hana/shared/BNR/HDB00/backup/data/  
BackupTestMaster_databackup_1_1'.  
Destination header information:  
DestVersion: 5  
DatabaseID: 51a3a622-1627-46c8-e100-00000a1d0eab  
InternalStartTime: 1370415876795  
CurrDestInformation: [FILE] [/usr/sap/BNR/HDB00/backup/data/  
BackupTestMaster_databackup_1_1]  
backupID: 1370415876776  
ServiceName: nameserver  
NumberOfVolumeFiles: 4  
HostName: berl30052174a  
VolumeID: 1  
DestID: 1  
MaxDestID: 1  
SrcPoolInformation[0]: [DATABASE_SNAPSHOT]@node[1]  
DstPoolInformation[0]: [FILE] [/usr/sap/BNR/HDB00/backup/data/  
BackupTestMaster_databackup_1_1]  
Source header information:  
SrcType: 1  
SourceInformation: [DATABASE_SNAPSHOT]@node[1]  
srcVersion: 5  
sourceSize: 70455296
```

### ❁ Example

Check a data backup that was written to the file system and at some stage was corrupted:

```
hdbbackupcheck backup/data/Hallo_databackup_2_1
```

### Output Code

```
ERROR: [110088] Error reading backup from 'FILE' '/hana/shared/BNR/HDB00/
backup/data/Hallo_databackup_2_1'
ERROR: [110059] The backup /hana/shared/BNR/HDB00/backup/data/
Hallo_databackup_2_1 is corrupt, size is 14807859
ERROR: Backup '/hana/shared/BNR/HDB00/backup/data/Hallo_databackup_2_1'
not successfully checked!
```

### Example

Check a log backup that was saved to a third-party backup tool using the configuration file /myBackupTool/backupint.cfg:

```
hdbbackupcheck --backintParamFile /myBackupTool/backupint.cfg /usr/sap/BNR/SYS/
global/hdb/backupint/log_backup_1_0_2177088_2177344 -e BCKINTk168Gc
```

### Output Code

```
Backup '/usr/sap/TG2/SYS/global/hdb/backupint/
log_backup_1_0_2177088_2177344' successfully checked.
```

## 11.2.7.2.3.2 Check Individual Backups Outside an SAP HANA Installation

You can use the `hdbbackupcheck` tool to manually check the integrity of backups **outside** an SAP HANA installation.

### Context

You can use `hdbbackupcheck` to check backups that are not accessed by an SAP HANA node, without generating additional load on the SAP HANA node.

#### Note

Using `hdbbackupcheck` **outside** an SAP HANA installation is recommended only for file-based backups.

### Procedure

1. In the SAP HANA installation, create an archive with the required files: `hdbbackupcheckpack <archive>`

### i Note

The archive created here contains only the test software and not the data backups to be tested.

2. Move the archive `<archive>` to the target system and unpack it:
  - a. Create a directory `<targetdir>` in the target system.
  - b. Copy the archive `<archive>` and the program `$DIR_INSTANCE/exe/SAPCAR` to the directory `<targetdir>` in the target system.
3. Unpack the archive, add the directory of `hdbbackupcheck` to the environment variable `<LD_LIBRARY_PATH>`, and call the program as described above:
  - a. `cd <targetdir>`
  - b. `./SAPCAR -xvf <archive>`
  - c. `export LD_LIBRARY_PATH=<targetdir>:$LD_LIBRARY_PATH`
  - d. `./hdbbackupcheck -v <backup>`

### i Note

By default, the files `backupcheck.log` and `backintcheck.log` are created in the current directory. To create these files in a different directory, start `hdbbackupcheck` with option `-p <directory>`.

## 11.2.7.3 Recovering an SAP HANA Database

SAP HANA supports different options for database recovery.

You can recover an SAP HANA database to its most recent consistent state or to an earlier state. You can recover an SAP HANA database to the same system, or to a different system to create a copy of the database.

### i Note

To recover a database, it is possible to use a combination of backups from a third-party backup tool and backups from the file system, provided that the backups originate from the same SAP HANA database.

## Related Information

[Recover a Database \[page 1548\]](#)

[Recover a Database \(SAP HANA Studio\) \[page 1551\]](#)

[Recover a Database from a Data Backup \(SAP HANA Studio\) \[page 1556\]](#)

[Recovery Scenarios \[page 1572\]](#)

[Copying a Database Using Backup and Recovery \[page 1578\]](#)

[Recover a System Database to a Point in Time \(recoverSys.py\) \[page 1559\]](#)

## 11.2.7.3.1 Recover a Database

Using SAP HANA cockpit, you can recover an SAP HANA database.

### Context

A tenant database is recovered through its system database.

A tenant database can be recovered to its most recent state or to a specific point in time.

Using SAP HANA cockpit, a system database can only be recovered to its most recent state.

#### i Note

A recovery to the most recent state or to a point in time is equivalent to the SQL statement `RECOVER DATABASE` (not `RECOVER DATA`).

For more information, see *RECOVER DATABASE Statement (Backup and Recovery)* and *RECOVER DATA Statement (Backup and Recovery)* in the *SAP HANA SQL Reference Guide*.

### Procedure

1. From the *Database Directory*, select the system database.

The *Database Overview* is displayed.

Option	Description
<b>To recover the system database</b>	<p>From the <i>Database Backups</i> card, choose <i>Recover database</i>.</p> <p>If the system database is still running, you are prompted to shut it down.</p> <p>If the system database is shut down for recovery, all its tenant databases are automatically shut down as well. The whole SAP HANA system is not available until the recovery of the system database has been completed.</p>
<b>To recover a tenant database</b>	<p>Choose <i>Database Management</i>.</p> <p>Select the row with the tenant database and choose <i>Recover</i>.</p> <p>If the database is not already shut down, you are prompted to shut it down.</p>

Follow the steps on the screen.

2. When the database is shut down, specify the state to which you want to recover the database.

Option	Description
<i>Recover to the most recent state</i>	<p>Recover the database to a state as close as possible to the current time.</p> <p>→ Tip Using the most recent complete data backup makes for a faster recovery.</p>
<i>Recover to a specific point in time</i>	<p>Specify a time zone and a point in time to which to recover the tenant database.</p> <p>i Note Any changes that were made <b>after</b> the specified point in time will not be in the recovered tenant database.</p> <p>i Note If you specify a point in time in the future, the effect will be the same as recovering the database to the most recent state.</p>

- Specify the location of the most recent backup catalog.

Option	Description
<i>Backint location only</i>	<p>If a third-party backup tool is selected, Backint is searched.</p>
<i>Default location</i>	<p>For file system backups, the location for the backups of the backup catalog is defined using the parameter <code>basepath_catalogbackup</code>.</p> <p>The default setting for <code>basepath_catalogbackup</code> is:</p> <pre>\$DIR_INSTANCE/backup/log</pre> <p>By default, log backups for tenant databases are written to a tenant-specific subdirectory.</p> <p>By default, backups of the backup catalog are written to the same tenant-specific subdirectory as the log backups.</p>
<i>Alternative location</i>	<p>If the backup catalog is not in the default location, specify its location.</p> <p>For more information, see <i>Destination for Backups of the Backup Catalog</i> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

An overview of available backups is displayed.

- Select the data backup to use for the recovery.
- Specify whether to use delta backups (differential and incremental backups).

#### ⚠ Caution

The complete data backups and the delta backups must be in the same location for the recovery to work correctly.

For more information about delta backups, see *Delta Backups*.

- If necessary, you can change the location to be searched for data backups and delta backups.

To specify additional locations for log backups, choose [Add more](#).

If you leave the locations empty, SAP HANA uses the backup locations specified in the backup catalog.

7. Check whether the backups are available.

Here, you can decide whether to check if all the backups needed are available and can be accessed **before the recovery starts**. The availability check is performed at the beginning of the recovery.

#### **i** Note

SAP HANA does not check the integrity of the backups content on block level.

For more information, see *Manually Checking Whether a Recovery is Possible* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

8. Specify whether to initialize the log area.

#### **⚠** Caution

If you initialize the log area, the content of the log area is lost.

No log records from the log area can then be replayed during the recovery. Only the log backups can be used.

In the following situations, you **must** initialize the log area:

- The log area is unusable.
- You are recovering the database to a different system.

9. Choose [Review](#).

An overview of the settings for the recovery is displayed.

To change any settings, choose [Edit](#).

All the settings that you specified are retained until you change them.

10. To display the SQL statement to be used for the recovery, choose [Display SQL Statement](#).

For more information, see *Recovering a Database Using Native SQL* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

11. To perform the recovery, choose [Start Recovery](#).

The progress of the recovery for each SAP HANA service is displayed.

## Results

When the recovery is completed, a message confirms this, and shows the point in time to which the database was recovered.

#### **i** Note

The SQL statement used for a recovery is recorded in `backup.log`. For a point-in-time recovery, the point in time is specified in the SQL statement as **UTC**.

The time at which the recovery was started and completed is recorded in `backup.log` as **local server time**, not UTC.

For more information, see *Diagnosis Files for Backup and Recovery* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

### i Note

The point in time that SAP HANA returns after a recovery may be **before** the point in time that you specified for the recovery. This is because the point in time that was actually reached in the recovery is that of the most recent global COMMIT to the database that was recovered.

### i Note

When you recover and restart a system database, its tenant databases are not automatically restarted. You should first check that the system database was recovered successfully, then restart the tenant databases manually.

The SAP HANA database is now online and can be used by applications.

[RECOVER DATABASE Statement \(Backup and Recovery\)](#)

[RECOVER DATA Statement \(Backup and Recovery\)](#)

### 11.2.7.3.1.1 Recover a Database (SAP HANA Studio)

Using SAP HANA studio, you can recover an SAP HANA database to its most recent consistent state or to a specific point in time.

## Prerequisites

- A data backup or a data snapshot.
- Delta backups and/or log backups

- The log area

For more information, see *Prerequisites for Database Recovery*.

### ⚠ Caution

From SAP HANA 2.0, it is possible to specify a separate Backint parameter file for data backups, log backups, and the backup catalog. SAP HANA studio does not support using a separate Backint parameter file for the backup catalog. If you have configured separate Backint parameter files for the log backups and the backups of the backup catalog, you should recover your database using SAP HANA cockpit or native SQL.

## Procedure

1. In SAP HANA studio, open the context menu and choose *Backup and Recovery*.  
Then choose either *Recover System Database...* or *Recover Tenant Database...*  
The Recovery Wizard opens.  
Follow the instructions in the wizard.
2. If prompted, enter the `<sid>adm` user and password and choose *OK*.

### i Note

`<sid>adm` is the OS user for the system database, and is not needed for tenant databases.

3. When prompted, confirm that the database can be shut down.
4. Specify the recovery type.

Option	Description
<i>Recover the database to its most recent state</i>	Recovers the database to as close as possible to the current time.  → Tip Using the most recent available full backup makes for a faster recovery.
<i>Recover the database to the following point in time</i>	Specify a point in time to which to recover the database.  i Note Any changes that were made after the most recent log backup will not be in the recovered database. In addition, all the transactions that were open during the log backup will be rolled back.  If you need to perform a point-in-time recovery, consider recovering the database to a different system.

This option uses the following data:

Option	Description
	<ul style="list-style-type: none"> <li>○ <b>Recommended:</b> The last available data backup (file-based or Backint) or data snapshot available before the specified point in time</li> <li>○ Log backups and delta backups made after the full backup and up to the desired point in time</li> <li>○ Log area</li> </ul>

**i Note**

If you specify a point in time in the future, the effect will be the same as recovering the database to the most recent state.

<p>▶ <i>Advanced</i> ▶  <i>Recover the database to the following log position</i> ▶</p>	<p><b>i Note</b></p> <p>This recovery type is an advanced option that can be used in exceptional cases where a previous recovery failed.</p> <p>This option uses the following data:</p> <ul style="list-style-type: none"> <li>○ The most recent data backup or data snapshot available before the specified log position</li> <li>○ Log backups or delta backups made since the data backup or data snapshot to be used</li> <li>○ The log area</li> </ul>
---	--

**i Note**

This option is not available for system databases.

5. Choose *Next*.
6. If the log backups are not in the original location, specify a new location, and choose *Add*.
7. Choose *Next*.

An overview of data backups is displayed.

8. From the backup catalog, you can select a complete data backup or a data snapshot. You can also resume an interrupted recovery.

Option	Description
<i>Refresh</i>	If you make available a new data snapshot in the data area, and it does not immediately appear, choose <i>Refresh</i> to update the overview.
<i>Show More</i>	To display additional backups from the backup catalog, choose <i>Show More</i> .
<i>Check Availability</i>	To ensure that a backup exists at the specified location, choose <i>Check Availability</i> . If the system indicates that the data backup is not available at the selected location, and you know that it has been moved, you can specify an alternative location to be checked.

**i Note**

The availability of Backint backups can be checked.

The availability of file-based backups can only be checked if shared backup storage is used.

A partially completed recovery that can be resumed is given the backup prefix *RESUME*.

### ⚠ Caution

The full backups and the delta backups must be in the same location for the recovery to work correctly.

### i Note

To recover a database from a data snapshot, the data snapshot must be made available in the data area of the database.

After the system database has been recovered from a data snapshot, the tenant database must then be recovered.

9. Choose *Next*.
10. Finalize the recovery settings.

Option	Description
<b>Check Availability of Delta and Log Backups</b>	<p>Check whether all the required log backups and delta backups are available before the recovery starts. If any log backups are missing, they are listed, and the recovery is stopped before any data is changed.</p> <p>You can check the availability of either file-based, third-party backups (Backint), or both.</p> <div data-bbox="421 974 1402 1585"><h3>⚠ Caution</h3><p>If you choose not to perform this check before the recovery starts, the check is still performed, but later in the recovery process.</p><p>If an error is not detected until after the recovery has been started, the recovery will be interrupted.</p><p>After a recovery has been interrupted, the database has an inconsistent state, and it will not be possible to start the database. If the database has an inconsistent state, SAP HANA automatically prevents the database from starting.</p><p>If you attempt to restart the database after a recovery has been interrupted, the following message is written to the nameserver trace file:</p><pre>Cannot start the service 'nameserver' at '&lt;host:SQL Port&gt;' responsible for the volume '&lt;volume number&gt;' because of an error during recovery.</pre><p>In this situation, you need to recover the database using a different recovery strategy.</p></div>
<b>Initialize Log Area</b>	<p>If you initialize the log area, the content of the log area is lost. No records from the log area can then be replayed. The records from the log backups are replayed if they are needed.</p> <div data-bbox="421 1704 1402 1944"><h3>⚠ Caution</h3><p>Disabling log backups may cause significant loss of data.</p><p>In the following situations, you <b>must</b> initialize the log area:</p><ul style="list-style-type: none"><li>○ The log area is unusable</li><li>○ You are recovering the database to a different system</li></ul></div>

Option	Description
<b>Use Delta Backups</b>	<p>By default, SAP HANA includes delta backups in its recovery strategy, and gives preference to delta backups over log backups.</p> <p>You can choose to not use delta backups for a recovery. If delta backups are not used, log backups will be used.</p>
<b>Install New License Key</b>	<p>If you already have a license key for the new SAP HANA database, you can import your existing license key.</p> <p>If you are recovering the database to a database with a new SID or landscape ID, a new license key is needed.</p> <p>For more information, see <i>Points to Note: License Keys and Recovery</i>.</p>

11. Choose *Next*.

Option	Description
<a href="#">Show SQL Statement</a>	Display the SQL statement to be used for the recovery.

A summary of the selected options is displayed. To make changes, choose *Back*.

12. If the settings are correct, choose *Finish*.

The recovery starts.

## Results

When the recovery is complete, a message confirms this, and shows the timestamp to which the recovery was completed.

### **i** Note

The timestamp that SAP HANA returns after a recovery is the timestamp of the last COMMIT to the database that has been recovered.

This timestamp may be before the point in time that you specified for the recovery.

The SAP HANA database is now online and can be used by applications.

## 11.2.7.3.1.2 Recover a Database from a Data Backup (SAP HANA Studio)

Using SAP HANA studio, you can recover an SAP HANA database from a specific data backup.

### Prerequisites

A data backup or a data snapshot.

For more information, see *Prerequisites for Database Recovery*.

### Context

#### i Note

For a recovery from a data backup, delta backups are not used.

Delta backups are only used to recover SAP HANA to a point in time.

#### i Note

If you are not using the backup catalog for the recovery, you need to know the backup type (File, Backint, or data snapshot), the location, and the prefix of the data backup.

### Procedure

1. In SAP HANA studio, open the context menu for a database.  
To recover a tenant database, open the context menu from its system database.
2. Choose *Backup and Recovery*.
3. Choose *Recover Tenant Database...* and specify the tenant database to recover.  
The Recovery Wizard opens.  
Follow the on-screen instructions.
4. Choose *Next*.
5. Specify the following recovery type: *Recover the database to a specific data backup*

### ⚠ Caution

With this option, the SAP HANA database is **initialized** with the specified data backup. This data backup begins a new database lifecycle. Older data backups are then no longer compatible with logs written after the recovery.

### ⚠ Caution

Log entries are not replayed from the log backups nor from the log area.

All the log entries that still exist in the log area are deleted.

All the changes made after the data backup or data snapshot will be lost.

If you recover a system database, all the changes to the information about its tenant databases that were made after the data backup or data snapshot will be lost.

6. Choose [Next](#).
7. Specify the location of the backup catalog(s).
  - [Recover using the backup catalog](#)  
If the backup catalog is not in the default location, specify the new location.
  - [Recover without the backup catalog](#)  
If you use a backup that is not recorded in the backup catalog, you will need to manually specify the backup type (File or Backint), the location of the backup, and its prefix.

### i Note

The SID of the source system is only relevant for database copy using third-party backup tools.

8. Choose [Next](#).
9. If prompted, confirm that the database can be shut down.

An overview of the relevant full backups is displayed.

10. Specify the data backup to use for the recovery.

Option	Description
<a href="#">Refresh</a>	If you make available a new data snapshot in the data area, and it does not immediately appear, choose <a href="#">Refresh</a> to update the overview.
<a href="#">Show More</a>	To display additional backups from the backup catalog, choose <a href="#">Show More</a> .
<a href="#">Check Availability</a>	To ensure that a backup exists at the specified location, choose <a href="#">Check Availability</a> . If the system indicates that the data backup is not available at the selected location, and you know that it has been moved, you can specify an alternative location to be checked.

### i Note

The availability of Backint backups can be checked.

The availability of file-based backups can only be checked if shared backup storage is used.

11. Choose [Next](#).

12. Finalize the recovery settings.

Option	Description
<b>Initialize Log Area</b>	<p>This option is selected by default.</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"><p><b>⚠ Caution</b></p><p>No log entries from the log area are replayed, and the log area is initialized. <b>The content of the log area is lost.</b></p></div>
<b>Install New License Key</b>	<p>If you already have a license key for the new SAP HANA database, you can import your existing license key.</p> <p>If you are recovering the database to a database with a new SID or landscape ID, a new license key is needed.</p> <p>For more information, see <i>Points to Note: License Keys and Recovery</i>.</p>

13. Choose [Next](#).

A summary of the selected options is displayed. To make changes, choose [Back](#).

To display the SQL statement to be used for the recovery, choose [Show SQL Statement](#).

14. If the settings are correct, choose [Finish](#) to start the recovery.

The progress of the recovery for each SAP HANA service is displayed in the dialog box.

## Results

When the recovery is complete, a message confirms this and shows the timestamp when the recovery was completed.

When the SAP HANA database has been restarted, it can be used again by applications.

## Related Information

[Cancel a Recovery \[page 1564\]](#)

## 11.2.7.3.2 Recover a System Database to a Point in Time (recoverSys.py)

To recover an SAP HANA database, it is strongly recommended that you use SAP HANA cockpit. Using SAP HANA cockpit, it is only possible to recover a system database to its most recent state. To recover a system database to a point in time, you can use the `recoverSys.py` tool.

### Prerequisites

#### i Note

The `recoverSys.py` tool can only be used to recover a system database. `recoverSys.py` cannot be used to recover a tenant database. To recover a tenant database, use SAP HANA cockpit or native SQL.

#### ⚠ Caution

If you recover a system database to a point in time, tenant databases that were registered after that point in time will be lost.

- The system database is offline.
- You are logged with the OS user `<sid>adm`.

### Context

To call `recoverSys.py`, enter the statement in the following format: `HDBSettings.sh recoverSys.py [<parameters>]`

If you run `HDBSettings.sh recoverSys.py` without any parameters, `recoverSys.py` performs a recovery to the most recent point in time.

#### i Note

Starting `recoverSys.py` on its own does not do anything.

### Procedure

To recover a system database:

1. Set the environment using `HDBSettings.sh`.
2. Execute the `recoverSys.py` tool: `HDBSettings.sh recoverSys.py [<parameters>]`.

`recoverSys.py` shuts down the database.

## Results

Once the system database has started, `recoverSys.py` terminates.

To check that the recovery was successful, see the `backup.log`.

For more information, see *Diagnosis Files for Backup and Recovery*.

### i Note

If `recoverSys.py` returns an exit code '0', this is not confirmation that the recovery was successful.

The recovery is not complete yet.

If you use the parameter `--wait`, the script waits until the recovery has completed.

If you do not use the `--wait` parameter, you need to manually check whether the recovery has completed by looking at the instance status or the logs.

## Related Information

[Options for Recovery with recoverSys.py \[page 1560\]](#)

[Diagnosis Files for Backup and Recovery \[page 1600\]](#)

[BACKUP LIST DATA Statement \(Backup and Recovery\)](#)

### 11.2.7.3.2.1 Options for Recovery with recoverSys.py

The default behavior of the `recoverSys.py` tool can be overridden using the options described below.

Options for `recoverSys.py`

<b>recoverSys.py Options</b>	<b>Description</b>
<code>--help</code>	Get help for the <code>recoverSys.py</code> script.

## recoverSys.py Options

## Description

--command="`<SQL command>`"

Use this option to specify an SQL recovery command.

### ≡, Sample Code

This statement performs a recovery to the database state of '2023-10-22 15:00:00'.

```
HDBSettings.sh recoverSys.py --
command="RECOVER DATABASE UNTIL
TIMESTAMP '2023-10-22 15:00:00'"
```

### i Note

If you specify a point in time in the future, the effect will be the same as recovering the database to the most recent state.

### ≡, Sample Code

This statement performs a recovery to the database state of '2018-10-22 15:00:00' based on the data backup identified by BACKUP ID '1380740407446', using the backup catalog located in '/remote/backup/CHH/catalog'.

```
HDBSettings.sh recoverSys.py --
command="RECOVER DATABASE UNTIL
TIMESTAMP '2018-10-22 15:00:00'
USING CATALOG PATH ('/remote/
backup/CHH/catalog') USING
BACKUP_ID 1380740407446 CHECK
ACCESS USING FILE"
```

The statement checks the availability of the backup files before performing the recovery.

### ≡, Sample Code

To perform a recovery on a remote host, pass the recovery command to a remote shell command.

```
ssh <sid>adm@<remoteHost>
"HDBSettings.sh recoverSys.py --
command=\"RECOVER DATABASE UNTIL
TIMESTAMP '2018-10-22 15:00:00'\""
```

### → Remember

The times specified are UTC times.

recoverSys.py Options	Description
--wait	<p>Causes the script to wait until the recovery has completed (either successfully or unsuccessfully).</p> <p>Default: The script <b>does not wait</b> for the recovery to complete. The recovery is started and runs in the background.</p> <p>If the script is terminated manually, the database recovery will not stop.</p> <p>For more information, see <i>Starting and Stopping Distributed SAP HANA Systems Using sapcontrol</i>.</p> <div data-bbox="826 701 1374 875" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>If <code>recoverSys.py</code> is called automatically, you should use the option <code>--wait</code> to wait for the recovery to complete before you send further commands to the database.</p> </div>
--password=<password>	<p>If authentication is necessary, you can supply a password for <code>&lt;sid&gt;adm</code>.</p> <p>If you do not specify the password, <code>recoverSys.py</code> prompts you to enter a password.</p> <div data-bbox="826 1111 1374 1234" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>If you use the <code>--password</code> option, the password can be displayed in the process list of the operating system.</p> </div>
--timeout=<time>	<p>Specify a timeout for database shutdown and start.</p> <p>Default: 120s</p>
--licenseFile=<file name>	<p>Specify a license key file to append to the recovery command as a <code>SET LICENSE</code> clause.</p> <p>If you specify a command using the <code>--command</code> option, <code>SET LICENSE</code> is automatically appended to the command.</p> <div data-bbox="826 1612 1374 1861" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>An SAP HANA license key becomes invalid if the <code>&lt;SID&gt;</code> or landscape ID is changed. The recovered system is assigned a temporary license that is valid for 90 days. You can apply to SAP to have the license from the source system transferred to a new license key for the recovered system.</p> </div>
--semaphoreOnly	<p>For use by SAP HANA cockpit only.</p>

recoverSys.py Options	Description
<code>--masterOnly</code>	For use by SAP HANA cockpit only.
<code>--forceMaster &lt;host&gt;</code>	<p><code>recoverSys.py</code> attempts to use the current host as the master host for the recovery. If this host cannot be used as a master, <code>recoverSys.py</code> fails. To use a different host, use <code>--forceMaster</code> to specify the master host for the recovery.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>At most, three hosts can be used as the master host. The roles of the hosts are defined through the <code>name-server.ini</code> file. For this reason, it is not possible to use any host as the master host.</p> </div>
<code>--feature</code>	For use by SAP HANA studio only.
<code>--silent</code>	Use this option to reduce diagnostics output.
<code>--cancel</code>	<p>Use this option to cancel a recovery after it has started.</p> <div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>Canceling a recovery makes the database state inconsistent. SAP HANA prevents an inconsistent database from being started.</p> <p>To be able to work with the database again after canceling a recovery, you would need to perform the recovery again.</p> <p>For more information, see <i>Cancel a Recovery</i>.</p> </div>

## Related Information

[Starting and Stopping Distributed SAP HANA Systems Using SAPControl \[page 1654\]](#)

[Cancel a Recovery \[page 1564\]](#)

## 11.2.7.3.3 Cancel a Recovery

You can cancel a recovery while it is in progress. After a recovery is canceled, it needs to be repeated or resumed before work can continue in the database.

### Context

While a recovery is in progress, the option to cancel it is displayed.

### Procedure

1. From the recovery progress view, choose *Cancel Recovery*.
2. Confirm your decision.

### Results

#### ⚠ Caution

After a recovery has been canceled, the database has an inconsistent state.

SAP HANA automatically prevents a database with an inconsistent state from being started.

For this reason, the only way to make the database available is to repeat or resume the recovery.

For more information about resuming a recovery, see *Resume a Canceled Recovery* in the *SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)*.

#### i Note

If you attempt to restart the database after a recovery is canceled, the following message is written to the nameserver trace file:

```
Cannot start the service 'nameserver' at '<host:SQL Port>' responsible for the volume '<volume number>' because of an error during recovery.
```

### Related Information

[Resume a Canceled Recovery \[page 1565\]](#)

## 11.2.7.3.4 Resume a Canceled Recovery

Instead of repeating an entire recovery, it is possible to resume a recovery that was canceled or aborted. It is normally only necessary to resume a recovery in exceptional circumstances.

### Prerequisites

#### i Note

After a recovery is canceled or aborted, the SAP HANA database cannot restart. Before work can continue in the database, the recovery must be completed.

- It is possible to resume a recovery that uses a full backup (a data backup or a data snapshot) with delta backups and log backups.  
A recovery can only be resumed after the recovery from the full backup is completed.  
If the recovery is canceled or fails during recovery from a data backup, the recovery cannot be resumed.

#### ! Restriction

A recovery from **only a full data backup** cannot be resumed.

If a recovery from only a full data backup is canceled or fails, the recovery needs to be repeated from the beginning.

- To resume a recovery from a data snapshot, you can use the same data snapshot that you used when you started the recovery.  
The data snapshot does not need to be replicated to the data area again. You only need to ensure that the required delta backups and log backups are available.
- It is possible to resume a recovery both with file-based backups and with third-party backup tools.
- A resumed recovery must use the same backup catalog as the recovery that was canceled or aborted.

### Disk Sizing

When you resume a recovery, disk space requirements can temporarily increase. If you resume a recovery, as a general rule, ensure that you are working with enough disk space to contain at least the data backup and the delta backups.

### Context

In many situations, a recovery can be repeated from the beginning in only a short time, and the database can be running again with only minimal loss of uptime. However, in some situations, having to repeat a recovery from the beginning may cause a significant delay. In such situations, the option to resume a recovery can save a considerable amount of time, both with a very large database or a relatively small database.

### Fallback Points

During a recovery, SAP HANA automatically defines fallback points, which mark the points after which it is possible to resume a recovery.

The first fallback point occurs after the recovery from the complete data backup. After recovery from a delta backup is completed, another fallback point is set. Fallback points are also written during log recovery.

A recovery can be resumed from the latest fallback point. The part of the recovery from before the fallback point does not need to be repeated.

### **i** Note

If you resume a recovery to an earlier point in time than for the canceled recovery, the log fallback points are not used. In this situation, only the fallback point for the recovery from the data backup (and, if used, also the delta backups) can be used; the log recovery needs to be repeated from the beginning.

After a recovery has been successfully completed, the fallback points are invalidated. It is then no longer possible to perform a new recovery based on those fallback points.

## **Configuring Fallback Points**

You can define how often fallback points are written during log recovery.

Configure the parameter `log_recovery_resume_point_interval` in the `global.ini` configuration file.

The time interval that you specify translates to the maximum acceptable database uptime lost while the log recovery is resumed after a recovery from the data backup (and possibly also the delta backups) has been completed.

## **Viewing Fallback Points**

Each SAP HANA service defines its own service-specific fallback point after recovery from a data backup or delta backups. Together, these service-specific fallback points make up the fallback point for the whole database. When a fallback point has been written for **all the services** in the database, the fallback point for the whole database is recorded in `backup.log`.

### **i** Note

No fallback points are written during log recovery.

### **❖** Example

The following example shows one fallback point in the `backup.log` file.

In this example, the fallback point is written to `fallback_databackup_0_1`:

```
2018-10-22T17:41:46+02:00 P012898 15c215ef3c7 INFO RECOVERY fallback point
written into /usr/sap/DB1/SYS/global/hdb/data/mnt00001/hdb00002.00004/
fallback_databackup_0_1
```

For more information, see `backup.log`.

## **Procedure**

Resume a Canceled Recovery

1. Re-start the recovery.

A partially completed recovery that can be resumed is displayed in the backup overview.

For more information, see *Recover a Database*.

2. In the recovery dialog, select the backup with which the recovery can be resumed.
3. Follow the steps described on-screen to complete the recovery.

## Results

When the recovery is complete, a message confirms this, and shows the time to which the database was recovered.

The SAP HANA database is now online and can be used by applications.

## Related Information

[backup.log](#)

[Recover a Database \[page 1548\]](#)

[RECOVER DATABASE Statement \(Backup and Recovery\)](#)

### 11.2.7.3.4.1 Resuming a Canceled Recovery Using Native SQL

You can resume a recovery by using the `recoverSys.py` tool and the SQL recovery command with `USING RESUME`.

For more information about `recoverSys.py`, see *Recover a System Database to a Point in Time*.

#### **i** Note

`USING RESUME` can only be used if a fallback point already exists.

If no fallback point exists, an error is returned.

For simple SQL statements, `USING RESUME` is appended.

For SQL statements with options such as `IGNORE DELTA DATA BACKUPS` or `CHECK ACCESS`, `USING RESUME` should be placed **after the path** and **before the option**.

#### Sample Code

```
RECOVER DATABASE UNTIL TIMESTAMP '2018-10-22 17:41:46' USING RESUME
```

```
RECOVER DATABASE FOR Tenant_1 UNTIL TIMESTAMP '2018-10-22 17:41:46' USING  
CATALOG PATH ('/hana/DB1/backup/catalog') USING LOG PATH ('/hana/DB1/backup/  
log') USING RESUME CHECK ACCESS ALL;
```

### 11.2.7.3.5 Recover SAP HANA From a Data Snapshot

Using SAP HANA cockpit and storage system tools, you can recover a complete SAP HANA system (the system database and all its tenant databases) from a data snapshot.

#### Prerequisites

##### ⚠ Caution

Unlike a database recovery from data backups and log backups, the process of recovering SAP HANA from a data snapshot is not entirely under the control of SAP HANA. Manual steps are necessary, for example, to make available the data snapshot in the correct location before the recovery can begin.

To ensure that it succeeds, recovering SAP HANA from a data snapshot requires expert knowledge.

If you are in doubt as to how to ensure that the prerequisites for a recovery from a data snapshot are met, we recommend that you instead consider recovering SAP HANA using a standard recovery from data backups and log backups.

#### Before you Start

- The SAP HANA version used to create the data snapshot must be the same or higher than the SAP HANA version used to create the database copy.  
A data snapshot cannot be used to create a copy of a lower SAP HANA version.
- While a data snapshot is being created, no data integrity checks are performed by SAP HANA (checksum calculation) on page or block level.  
This means that, if SAP HANA database blocks were corrupted when the data snapshot was created, SAP HANA will only detect this when the database is started. It may then not be possible to complete the recovery.

#### During the Recovery

- To recover SAP HANA from a data snapshot, you need to shut down the target SAP HANA database, then make available the data snapshot in the data area of the target database.
- Recover the system database first. When the system database has been recovered successfully, recover each tenant database separately.  
The tenant databases cannot be recovered together in one single operation.  
These steps are described in *Recover all Tenant Databases From a Data Snapshot*.
- To recover a database from a data snapshot, you can optionally also use delta backups and log backups.

## Procedure

First, recover the **system database** from the data snapshot.

1. From the [Database Directory](#), open the system database and shut down the database.
2. From the [Database Overview](#), then choose [Stop System](#).
3. Follow the on-screen instructions to shut down the database.

The database is shut down.

In [Manage Services](#), the system status is shown as [Stopped](#).

4. Go to the [Database Overview](#).
5. Outside of SAP HANA cockpit, make the data snapshot (the content of the data area) available in the data area of the storage system.

The data snapshot must be accessible by the `<SID>adm` user.

6. From SAP HANA cockpit, go to the [Database Overview](#), and choose [Recover database](#) from the [Database Backups](#) card.
7. Specify the recovery target.

You can recover the database to its most recent state or specify a point in time to which to recover the database.

8. Specify the location of the most recent backup catalog.

Option	Description
<a href="#">Backint location only</a>	If a third-party backup tool is selected, Backint is searched.
<a href="#">Default location</a>	<p>For file system backups, the location for the backups of the backup catalog for the system database is defined using the parameter <code>basepath_catalogbackup</code>.</p> <p>The default setting for <code>basepath_catalogbackup</code> is:</p> <pre>\$DIR_INSTANCE/backup/log</pre> <p>By default, log backups for tenant databases are written to a tenant-specific subdirectory.</p> <p>By default, backups of the backup catalog are written to the same tenant-specific subdirectory as the log backups.</p>
<a href="#">Alternative file system location</a>	<p>If the backup catalog is not in the default location, specify its location.</p> <p>For more information, see <a href="#">Destination for Backups of the Backup Catalog</a> in the <i>SAP HANA Administration Guide (SAP HANA Database Backup and Recovery)</i>.</p>

An overview of available backups is displayed.

9. Select the data snapshot.
10. Specify whether to use delta backups.

### Note

If you wish to recover SAP HANA using delta backups (differential or incremental backups), you must also use log backups. If log backups are not available, you can only recover using a full data backup.

11. Specify the location of the log backups, if available.
12. To ensure that a backup exists at the specified location, check the availability of the backups.
13. If necessary, initialize the log area.

### Caution

Initializing the log area may cause significant loss of data.

If you initialize the log area, the content of the log area is lost. No records from the log area can then be replayed. The records from the **log backups** are replayed if they are needed.

In the following situations, you **must** initialize the log area:

- The log area is unusable
- You are recovering the database to a different system

14. To recover the system database, choose [Start Recovery](#).

The progress of the recovery is displayed.

When the recovery is completed, a message confirms this, and shows the point in time to which the database was recovered.

The system database is now online, but cannot yet be used by applications.

You should now first check that the system database was recovered successfully, then restart the tenant databases manually.

For more information, see *Recover all Tenant Databases From a Data Snapshot*.

[SAP Note 2340161](#)

## 11.2.7.3.5.1 Recover all Tenant Databases From a Data Snapshot

When the system database has been recovered successfully from a data snapshot, you need to recover all the tenant databases from the same data snapshot.

### Prerequisites

- The system database has been successfully recovered.
- The data snapshot that was used to recover the system database remains available in the data area of the storage system.

### Context

When the system database has been recovered successfully from a data snapshot, only the system database is started automatically. When you have checked that the system database was recovered correctly, you need to then recover each tenant database separately.

### Procedure

1. From the [Database Directory](#), select the recovered system database and go to the [Database Overview](#).
2. Choose [Database Management](#).

An overview of the databases in the SAP HANA system is displayed.

3. Select a tenant database.
4. Choose [Recover Tenant](#).

Follow the on-screen instructions.

5. To recover the tenant database, choose [Start Recovery](#).

The progress of the recovery for each SAP HANA service is displayed.

When the recovery is completed, a message confirms this, and shows the point in time to which the database was recovered.

The SAP HANA tenant database is now online and can be used by applications.

To recover the remaining tenant databases, repeat the steps for each tenant database.

## Related Information

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

### 11.2.7.4 Recovery Scenarios

Depending on the cause of the database failure, a different recovery strategy and procedure may be appropriate.

The following sections describe the recommended steps to recover the database in different recovery scenarios.

#### 11.2.7.4.1 Data Area is Unusable (Disaster Recovery)

If the data area becomes unusable, you can recover an SAP HANA database.

If the data area is unusable, and all data changes since the last complete data backup are still available in the log backups and log area, you can still recover the data from committed transactions that was in the memory at the time of the failure. No committed data is lost.

##### ⚠ Caution

If you reinstall the SAP HANA software to recover the database, **do not first create a data backup**.

The first data backup in a newly installed SAP HANA system creates a new backup catalog. As a result, the backup catalog from the old database is hidden and cannot be used for the recovery without manual intervention. However, in this scenario, the old backup catalog is still needed to recover the old database.

Once the database has been recovered successfully from a data backup or a data snapshot, the log entries from the log backups and the log area are replayed.

It is also possible to recover the database using an older data backup or data snapshot in combination with delta backups and log backups. The log backups needed for the recovery include those created **after** the data backup or data snapshot.

For more information, see *SAP Note 1821207 (Determining required recovery files)*.

##### i Note

In the recovery dialog, ensure that the paths to the data and log backup files are correct.

### Used for Recovery

- Data backup  
Alternatively, data snapshot

- Delta backups
- Log backups
- Log area

## Steps for Recovery

Recover the database to its most recent state.

For more information, see *Recovering an SAP HANA Database*.

## Related Information

[Recovering an SAP HANA Database \[page 1547\]](#)

[SAP Note 1821207](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

### 11.2.7.4.2 Log Area is Unusable (Disaster Recovery)

If a log area becomes unusable, it is still possible to recover an SAP HANA database.

If the **log area** becomes unusable, it cannot be used for a recovery. It is only possible to recover the entries from the **log backups**. As a consequence, any changes that were made after the most recent log backup will be lost after a recovery. In addition, all the transactions that were open during the log backup will be rolled back.

It is still possible to recover the database to a point in time covered by the existing log backups.

#### Caution

If you reinstall the SAP HANA software to recover the database, **do not first create a data backup**.

The first data backup in a newly installed SAP HANA system creates a new backup catalog. As a result, the backup catalog from the old database is hidden and cannot be used for the recovery without manual intervention. However, in this scenario, the old backup catalog is still needed to recover the old database.

To prevent entries from the unusable log area from being replayed, in the recovery dialog, you must select the *Initialize log area* option. This option initializes the log area, and the old (unusable) content of the log area is lost.

## Used for Recovery

- Data backup  
Alternatively, data snapshot

- Delta backups
- Log backups

## Steps for Recovery

1. Recover the database to the most recent state.  
When the database has been successfully recovered from the data backup or data snapshot, the log entries from the log backups are replayed.
2. Select the *Initialize log area* option.

## Related Information

[Recovering an SAP HANA Database \[page 1547\]](#)

[Delta Backups \[page 1418\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

### 11.2.7.4.3 Logical Error - Point-in-Time Recovery (Fault Recovery)

If a logical database error occurs, you can recover an SAP HANA database to a point in time before the error occurred.

#### ⚠ Caution

All changes made after the point in time of the recovery will be lost in the recovered database.

For this reason, a point-in-time recovery is not recommended for production systems.

If you need to perform a point-in-time recovery of your production system, consider recovering the database to a different system and importing the missing data back into your production system. For example, if a specific table was lost, import that table from the recovered system to the new system.

## Used for Recovery

- Data backup from before the point in time to recover to.  
Alternatively, data snapshot
- Delta backups
- Log backups made after the data backup
- Log area

## Steps for Recovery

Recover the database to a point in time before the logical error occurred.

You need to specify a point in time to which to recover the database.

### **i** Note

If you specify a point in time in the future, the effect will be the same as recovering the database to the most recent state.

## Related Information

[Recovering an SAP HANA Database \[page 1547\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

## 11.2.7.4.4 Recovery with System Replication

If you are using a disaster-tolerant solution with system replication, some specific recovery scenarios apply.

## Related Information

[Points to Note: System Replication \[page 1409\]](#)

### 11.2.7.4.4.1 Point-In-Time Recovery of a Primary System

A primary system in a system replication scenario can be recovered to a specific point in time.

To recover the primary system to a specific point in time (not to the most recent database state), you need to stop the secondary system for the time that the primary system is being recovered.

If the secondary system continues to run while the primary system is being recovered, the secondary system starts replication again immediately after the primary system is online again. As a consequence, incompatible, outdated log segments are sent to the secondary system.

To reinitialize system replication after the recovery, the offline secondary system must be registered again to the primary system, and restarted.

## Used for Recovery

- Data backup  
Alternatively, data snapshot
- Delta backups

### i Note

Delta backups must be based on the complete data backup of the current primary. After a takeover, if you wish to create delta backups, you must first have created a complete data backup of the current primary.

- Log backups  
The log backups that are associated with the data backup and cover the desired point-in-time (including the log backups made **after** the desired point in time).

## Steps for Recovery

1. Stop the secondary system.
2. Recover the primary system.
3. Re-register the secondary system.  
For more information, see *Configure the Secondary System*.
4. Start the secondary system.

## Related Information

[Configure SAP HANA System Replication with hdbnsutil \[page 1263\]](#)

[Recovering an SAP HANA Database \[page 1547\]](#)

[Recovery with System Replication \[page 1575\]](#)

## 11.2.7.4.2 Recovery of a New Primary System After a Takeover

With system replication, during a takeover, you switch your active system from the current primary system to the secondary system. After a takeover, it may at some stage be necessary to recover the active system (the former secondary system).

### Used for Recovery

- Data backups  
The data backup can be created either from the original primary or the now active system. Alternatively, you can use a data snapshot.
- Log backups  
The log backups that belong to the data backup or the data snapshot. That is, if the data backup was made on the new primary system after takeover, only the log backups from the new primary system can be used.
- Log area of the new primary system
- Delta backups

#### Note

Delta backups must be based on the complete data backup of the current primary. After a takeover, if you wish to create delta backups, you must first have created a complete data backup of the current primary.

#### Caution

If SAP HANA is recovered from backups that were created with different UIDs, some third-party backup tools may prevent the recovery from being started.

For more information, contact your backup tool vendor or ensure that the same UID is used for all the backups used for a recovery.

### Steps for Recovery

1. Ensure that the original primary system is stopped and is not writing complete data backups and log backups.
2. Ensure that the required data backup (or data snapshot), the delta backups, and the log backups can be accessed by the now active system.
3. Recover the now active system.  
For more information, see *Recovering an SAP HANA Database*.  
When the database has been successfully recovered from the data backup or data snapshot, the log entries from the log backups are replayed.

### ⚠ Caution

After a takeover, ensure that the original primary system does not continue to write log backups to the same location as the now active system.

For more information, see *Recovery with System Replication*.

### i Note

After a takeover, it is not necessary to create a new full data backup of the now active system. Backups of the former primary system can be used to recover the database.

Delta backups must be based on the complete data backup of the current primary. After a takeover, if you wish to create delta backups, you must first have created a complete data backup of the current primary.

## Related Information

[Delta Backups \[page 1418\]](#)

## 11.2.8 Copying a Database Using Backup and Recovery

A database copy is a quick way to set up a cloned database, for example, for training, testing, or development.

You can use backup and recovery to copy a system database or a tenant database within the same system or to a different system. You can create a copy of a database using a complete data backup or a data snapshot.

Additionally, using delta backups (differential or incremental backups) and log backups allows you to copy the database to a specific point in time.

### i Note

To create a database copy using differential or incremental backups, you must also use log backups. If log backups are not available, you can only create a database copy using a full data backup.

You can create a database copy with the following combinations of source database and target database:

Source Database	Target Database
System database	The system database of a different system

Source Database	Target Database
Tenant database	<p>A different tenant database in the same system</p> <p>A tenant database in a different system</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>i Note</b></p> <p>A tenant database cannot be copied to a single-container system.</p> </div>
Single-container system	<p>Tenant database</p> <div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 5px;"> <p><b>i Note</b></p> <p>An SAP HANA backup created with SAP HANA 1.0 SPS10 (single-container system) or newer can be used to recover a tenant database.</p> </div>

## Database Copy and System Replication

If you have system replication configured, and require near-zero downtime, consider using system replication to copy a tenant database.

For more information, see *Copying and Moving Tenant Databases Between Systems* in the *SAP HANA Administration Guide*.

## Related Information

[Prerequisites for the Source Database \[page 1580\]](#)

[Prerequisites for the Target Database \[page 1581\]](#)

[Copying and Moving Tenant Databases \[page 1137\]](#)

[Copy a Database \[page 1584\]](#)

### 11.2.8.1 Prerequisites for Copying a Database Using Backup and Recovery

Before you create a copy of an SAP HANA database, you should consider some important points.

- You can copy a database to machines from different vendors and with different hardware configurations, provided that both the source and target machines are compliant with the SAP HANA appliance specifications. Special requirements may apply to ensure the compatibility of SAP HANA backups with IBM Power Systems.

For more information, see *Points to Note: SAP HANA on IBM Power Systems*.

- To copy a complete SAP HANA system, the system database needs to be recovered first. Then each tenant database is recovered separately.
- For the system database, you must have the logon credentials of the operating system user (<sid>adm). For a tenant database, the system database user must have the authorization DATABASE ADMIN.
- If you expect a different set of volumes to be recovered, before you start the recovery for a database copy, you should remove existing data and log volumes.  
After a recovery to create a database copy, the system may include different volumes, or volumes may be assigned to different hosts.  
Existing volumes that are not used for the new system will not be overwritten or removed. Any additional disk space is not released. This may lead to unexpected disk full situations.

### SAP Notes

[SAP Note 1821207](#)

[SAP Note 1812980](#)

[SAP Note 2378962](#)

## 11.2.8.1.1 Prerequisites for the Source Database

Before you prepare the database to copy from, consider some important points.

- You can copy an SAP HANA database using file-system backups or backups created using a third-party backup tool.

### i Note

To copy a database, it is also possible to use a backup catalog from a different source than the backups:

- Backups from a third-party backup tool with a backup catalog from the file system
  - Backups from the file system with a backup catalog from a third-party backup tool
- Make the data backups, the delta backups, and the log backup files from the source database available in the appropriate directory in the target database.  
For more information, see *SAP Note 1821207 (Determining required recovery files)*.

### i Note

To create a database copy using differential or incremental backups, you must also use log backups. If log backups are not available, you can only create a database copy using a full data backup.

- The content of the **log area** of the source database cannot be used for recovery.

#### Caution

With a database copy, the log area of the target system is always initialized. When the log area is initialized, the content of the log area is lost.

- If you are upgrading from SAP HANA 1.x to SAP HANA 2.x, some additional steps may be necessary. For more information about using backups from SAP HANA 1.x to recover or copy to SAP HANA 2.x releases, see *SAP Note 2372809 (Mandatory Preparation Steps for Upgrading a SAP HANA 1 System to SAP HANA 2)*.

## Related Information

[SAP Note 1821207](#) 

[SAP Note 2372809](#) 

### 11.2.8.1.2 Prerequisites for the Target Database

Before you prepare the database to copy to, consider some important points.

- The version of the SAP HANA target database is the same or newer than the SAP HANA source database. For a database copy using SAP HANA cockpit, the target database must be at least SAP HANA 2.0 SPS 01.
- The target database has sufficient disk space and memory. The target system should have at least the same amount of disk space as the source system.
- The target system can have any number of hosts. The number and type of services in tenant databases is set automatically during a copy from a complete data backup when a backup catalog is used. If desired, and if performance limitations are acceptable, a copy of a database can be set up on a platform with less memory and CPU capacity and a different number of hosts.
- A valid license key is available for the target database. For more information, see *Points to Note: License Keys and Recovery*.

## Related Information

[Points to Note: License Keys and Recovery \[page 1406\]](#)

### 11.2.8.1.3 Prerequisites for Copying a System Database

Before you copy a system database to a new SAP HANA system, consider some important constraints.

- The host roles of the hosts in the target system must contain the host roles of hosts in the source system. For this reason, there must be at least one host in the target system with at least the same number of host roles for each host in the source system.
- The number of hosts in the source and target systems does not need to be the same. This means that scale-down or scale-up scenarios are supported. However, scale-down or scale-up is not possible for hosts with only non-SAP HANA host roles. For example, `xs_worker`, or `streaming`. The number of hosts that have non-SAP HANA host roles must be the same in the target system and the source system. Alternatively, the non-SAP HANA roles are removed in the target system.
- During the database copy, services from the source system are moved to the hosts in the target system based on the host roles.  
If the number of hosts and their respective host roles is the same in the source and target systems, then the services are moved to the hosts with the same host roles. If the number of hosts is different, then the services in the source system are distributed evenly across the hosts in the target system.

### 11.2.8.1.4 Database Copy Using a Data Snapshot

Using SAP HANA cockpit and storage system tools, you can copy a complete SAP HANA database (the system database and all its tenant databases) from a data snapshot. Before you copy a database using a data snapshot, consider some important points.

#### Caution

Unlike creating a database copy from data backups and log backups, the process of creating a database copy from a data snapshot is not entirely under the control of SAP HANA. Manual steps are necessary, for example, to make available the data snapshot to the correct location before the database copy can begin.

To ensure that it succeeds, copying SAP HANA using a data snapshot requires expert knowledge.

If you are in doubt as to how to ensure that the prerequisites for a database copy from a data snapshot are met, we recommend that you instead consider creating a database copy using a standard recovery from data backups and log backups.

## SAP HANA Version

The SAP HANA version used to create the data snapshot must be the same or newer than the SAP HANA version used to create the database copy.

A data snapshot cannot be used to create a copy of an older SAP HANA version.

## Scenario 1: Copying a Complete SAP HANA System (Recommended)

A data snapshot includes the complete data areas for the system database and all the tenant databases, ensuring that the topology and directory structure will be identical in the target system.

Ensure that the following are identical in the source system and the target system:

- The number of hosts
- The host paths configured as the file system mountpoints for SAP HANA
- The directory name of the data area  
This is defined by configuration parameter `basepath_datavolumes` in the `global.ini` configuration file.

## Scenario 2: Other Database Copy Variants

Using a data snapshot, it is possible, for example, to copy a single tenant database, copy SAP HANA to different hosts, or a copy using a different service configuration.

For all copy procedures based on a data snapshot, the persisted source data snapshot must still contain the entire data area of the SAP HANA system.

While a data snapshot is being created, no further data integrity checks are performed (checksum calculation) on page or block level. This means that, if a data snapshot has been changed before it is used for a database copy, SAP HANA will only detect this when the database is started. It may then not be possible to complete the database copy.

For this reason, it is imperative that you ensure that the topology and directory structure of the data area is identical for the source database and the target system.

In addition to the points for Scenario 1, ensure that the following criteria are identical in the source system and the target system:

- The IDs of the tenant database(s)  
(A database ID is not the same as the database name.)  
The IDs are visible in the topology, which you can query. For more information about how to query the topology, see *SAP Note 2340161 (Backup and Recovery Fails with 'unnecessary' Hosts in Topology)*.
- The number and type of services persisting data  
This includes the volume IDs assigned to each tenant database and to each host.  
For example, if the source system has an indexserver with `volumeID = 2`, the target system must also have an indexserver with `volumeID = 2`; The target system cannot have a scriptserver with `volumeID = 2`.
- The distribution of the services across the hosts  
For example, if the source system has 1 service on 3 hosts, and the target system has 3 services on 1 host, this will not work. The number and type of services is still same, but the distribution is not the same. Here, the target system must also have 1 service on 3 hosts.

## Creating the Database Copy

- To copy SAP HANA from a data snapshot, you need to:
  1. Shut down the target SAP HANA database.
  2. Make available the data snapshot in the data area of the target database.

### i Note

If you intend to copy a single tenant database, make the data snapshot available in a separate location outside the SAP HANA data area.

- To create a database copy from a data snapshot, follow the steps described in *Recover SAP HANA From a Data Snapshot*.

[SAP Note 2340161](#)

## 11.2.8.2 Copy a Database

Using SAP HANA cockpit, you can create a copy of an SAP HANA database by recovering it to the same system or to a different system.

## Procedure

1. Locate the database to copy to.

### i Note

This database will be overwritten by the recovery.

Database to Copy To	Perform the Following Steps...
System database	<ol style="list-style-type: none"> <li>1. From the <i>Database Overview</i> for the system database, go to the <i>Database Backups</i> card, and choose <i>Copy Database</i>.</li> <li>2. Follow the instructions on the screen. The actual sequence of steps that you perform depends on the specific options that you choose.</li> </ol>
Tenant database	<ol style="list-style-type: none"> <li>1. From the <i>Database Overview</i>, choose <i>Database Management</i>.</li> <li>2. Select the tenant database that you want to copy, and choose <b>▶ Tenant Actions ▶ Copy Tenant Using Backup ▶</b>.</li> <li>3. Follow the instructions on the screen. The actual sequence of steps that you perform depends on the specific options that you choose.</li> </ol>

2. Specify the database copy type.

Database Copy Type	Description
<i>Full data backup only</i>	Create a copy of the database from the start time of the full data backup.
<i>Data and log backups</i>	Create a copy of the database to a specific point in time.  In the next step, you are prompted to specify the time zone, the date and the time.

3. Specify whether to use a backup catalog.

If you are copying a database using a full data backup only, you can either select the data backup from the backup catalog, or specify its location without using a backup catalog.

A copy to a point in time is not possible if the full data backup is not recorded in a backup catalog.

Use a Backup Catalog	What Happens?
<i>No</i>	Copy the database without using a backup catalog.  In the next steps, you are prompted to select the location of the data backup in the file system. The data backup to use is identified by its prefix.
<i>Yes</i>	Use a backup catalog to locate the data backup.  In the next step, you are prompted to specify the location of the backup catalog.

4. Specify the backup location.

Backup Location	Subsequent Steps
File system	<p>In the next step, specify the location and prefix of the data backup to be used.</p> <div style="border: 1px solid #ccc; padding: 5px; margin: 10px 0;"> <p><b>❖ Example</b></p> <p>For the tenant database PR1TENANT, the location to specify could look like this:</p> <pre>/usr/sap/PR1/HDB00/backup/data/ DB_PR1TENANT/</pre> </div> <p>For the system database, the location to specify could look like this.</p> <pre>/usr/sap/PR1/HDB00/backup/data/ SYSTEMDB/</pre>

<b>Backint</b>	If you are copying a database using a third-party backup tool, in the next step, specify the source system.
----------------	---

5. (Backint only) Specify the source database.

Source Database	Subsequent Steps
System database	Specify the SID of the source system.
Tenant database	<p>Specify whether to copy the tenant database from:</p> <ul style="list-style-type: none"> <li>○ A tenant database in the same SAP HANA system</li> <li>○ A tenant database in a different SAP HANA system</li> <li>○ A SAP HANA single-container system</li> </ul> <p>A SAP HANA single-container system can only be copied to a tenant database, not to a system database.</p>

6. (File system only) Specify the backup to be used.

Backup Catalog	Backup to be Used
<b>If you are using a backup catalog:</b>	An overview of the available backups is displayed, depending on whether the catalog is in the file system or a third-party backup tool.
<b>If you are not using a backup catalog:</b>	<p>In the next step, specify the location and the prefix of the backup.</p> <p>If required, specify alternative locations for the data and log backups.</p>

7. (Optional) Check the availability of the backups to be used for the database copy.

This check ensures that the backups exist at the location specified.

8. (Tenant Database Only) Decide whether to use worker groups.

By default, when you copy a database from an indexserver that has worker groups, the target system must have worker groups with the same names as in the source system. Otherwise the database copy fails.

If you choose to ignore worker groups, if worker groups with matching names are found in the target system, those worker groups are used. If no worker groups with matching names are found, the worker groups of the backup service are changed to the default to match those of the target system.

9. Review your settings.
  - a. Choose [Review](#) to display a summary of the settings you specified.
  - b. To display the SQL statement that will be used for the copy, choose [Display SQL Statement](#).
  - c. To change the settings, choose [Edit](#). All the settings that you specified are retained until you change them.
10. Start the database copy.
  - a. If the settings are correct, choose [Start Copy](#).

SAP HANA cockpit displays a warning that you are about to overwrite the target system.

- b. To start the database copy, choose [Start Copy](#) again.

The progress of the copy for each SAP HANA service is displayed.

While the database is being copied, it is possible to cancel the copy process.

## Results

When the database copy is completed, a message confirms this.

A copy of the SAP HANA database is created in the location you specified.

Database Copied	Next Steps
If you copied a system database	You now need to copy the tenant databases in the SAP HANA system.
If you copied a tenant database	The copy of the SAP HANA tenant database is now online and can be used by applications.

### Note

For a database copy to a point in time, SAP HANA cockpit shows the point in time to which the copy was made.

The point in time that SAP HANA returns after a copy is the point in time of the last COMMIT to the database that has been copied.

For this reason, this point in time may be before the point in time that you specified for the copy.

## Database Credentials

To allow SAP HANA cockpit to connect to the copied database, you may need to change the credentials of the user that is registered in SAP HANA cockpit.

### ⚠ Caution

Ensure that the correct passwords are used to connect to the copied SAP HANA database. If an incorrect password is used multiple times, SAP HANA may respond by locking that database user account.

[Cancel a Recovery \[page 1564\]](#)

[Recover SAP HANA From a Data Snapshot \[page 1568\]](#)

### 11.2.8.2.1 Copying a Database Using Third-Party Backup Tools (SAP HANA Studio)

Using third-party backup tools, you can create a homogeneous copy of an SAP HANA database.

#### i Note

To create a copy of a database, it is not possible to mix backups from the file system and a third-party tool. The backups must originate from the same system.

## Prerequisites

Before you can create a copy of a database, the following prerequisites must be met for the **target** database:

- The Backint agent is installed and configured.  
For more information, consult the documentation from your tool vendor.
- If Backint parameter files are required, you need to:
  1. On operating system level, create the required Backint parameter files in locations that are accessible by the Backint agent.  
One configured set of Backint parameter files is needed to access the backups from the source database.  
A second configured set of Backint parameter files is needed to create new backups for the target database.

#### ❖ Example

If a source database SID is **ABC**, its parameter file for Backint could be called `param_backint_ABC.utl`. If a target database SID is **DEF**, its parameter file for Backint could be called `param_backint_DEF.utl`.

## i Note

For database copy, the SID must be included in the Backint parameter file name.

Make a note of the path and the parameter file name. You will need this information to assign the parameter files to the database.

2. Assign the Backint parameter files to the database.

Using the following parameters, specify the path and name of the parameter files for the following backup types:

Data backups	<code>data_backup_parameter_file</code>
Backups of the backup catalog	<p>To write backups of the backup catalog using a third-party backup tool, configure the following parameter: <code>catalog_backup_using_backint = true</code></p> <p>To specify the location of parameter file for backups of the backup catalog, use the following parameter: <code>catalog_backup_parameter_file</code></p> <p>For more information, see <i>Destination for Backups of the Backup Catalog</i>.</p>
Log backups	<code>log_backup_parameter_file</code>
	<p>For more information, see <i>Change the Log Backup Destination</i>.</p>

## i Note

Using SAP HANA studio, you can specify a parameter file for data backups and log backups for a third-party backup tool. However, to specify a parameter file for backups of the backup catalog, you need to use the parameter `catalog_backup_parameter_file`.

While the target database is online, go to the [Backup Console](#) and choose ► [Configuration](#) ► [Backint Settings](#) ►.

Specify the path and name of the parameter file as follows:

```
/<path>/<user-defined>$(SAPSYSTEMNAME)<optional-extension>
```

## ❖ Example

If the source database is called **ABC** and you have named the parameter file `param_backint_ABC.utl`, the path and name to specify here could be:

```
/usr/sap/DEF/SYS/global/hdb/opt/hdbconfig/param_backint_$(SAPSYSTEMNAME).utl
```

Depending on the third-party backing tool used, it may also be necessary to include the name of the source tenant database in the name of the parameter file. To this end, use the variable `$(DBNAME)`.

### ❖ Example

If a source database SID is **ABC**, and the source database name is **DB1**, its parameter file for Backint could be called **param\_backint\_DB1\_ABC.utl**.

If a target database SID is **DEF**, and the target database name is **DB2**, its parameter file for Backint could be called **param\_backint\_DB2\_DEF.utl**.

The path to the parameter file would be:

```
/usr/sap/DEF/SYS/global/hdb/opt/hdbconfig/param_backint_$(DBNAME)_$(SAPSYSTEMNAME).utl
```

### ⚠ Caution

Ensure that the variable `$(SAPSYSTEMNAME)` appears exactly like this in the Backint parameter file name that you specify here. When you copy a database using Backint, `$(SAPSYSTEMNAME)` is dynamically replaced at runtime with the SID of the source database that you specify for database recovery.

The same applies to the optional variable `$(DBNAME)`.

### 3. [Save](#) your changes.

- Move or delete available data backups and log backups from the **target** database in order to make them inaccessible during the recovery.  
During a recovery, SAP HANA searches for the most recent backup catalog. If the backup catalog in the target database is newer than in the source database, SAP HANA may use an undesired backup for recovery.

## Related Information

[Destination for Backups of the Backup Catalog \[page 1491\]](#)

[Change the Log Backup Destination \[page 1488\]](#)

[SAP Note 2905510](#) 

## 11.2.8.2.1.1 Copy a Database to a Point in Time Using Third-Party Backup Tools (SAP HANA Studio)

Using third-party backup tools with a data backup and log backups, you can create a copy of an SAP HANA database to a specific point in time.

### Procedure

Start the recovery of the target database.

1. In SAP HANA studio, open the context menu and choose *Backup and Recovery*.
2. Choose *Recover Tenant Database...*

Specify the recovery type.

3. You can specify either *Recover the database to its most recent state* or *Recover the database to the following point in time*.

If you are recovering the database to a specific point in time, enter the required information.

4. Choose *Next*.
5. Specify the SID of the *Source System*.

By default, the source is set to the SID of the target system. To specify the name of a tenant database, use the form `<DBNAME@SID>`.

#### i Note

The SID that you specify here is used by SAP HANA to replace the variable `<$ (SAPSYSTEMNAME) >` in the *Backint Parameter File* displayed in the Backup Console.

To specify the name of the source tenant database, use the variable `<$ (DBNAME) >`.

6. Choose *Next*.

The available data backups for the specified source database are displayed.

7. Select a backup and choose *Next*.
8. For *Check Availability of Log Backups*, you can select *Third-Party Backup Tool (Backint)*.
9. Select *Initialize log area*.
10. You can select *Install new license key* and specify the license key file, or apply a license key file later.
11. Choose *Next*.
12. Review the recovery options and if correct, choose *Finish*.

The recovery is started.

### Results

When the recovery has been successfully completed, the target database is started.

The source database has now been recovered to the target database, and you can work with the target database.

#### → Tip

After the target database has been backed up, the source Backint parameter file is no longer needed. However, it is recommended that you retain the source Backint parameter file, as you will need it if you want to copy the source database again.

## Related Information

[Steps After Copying a Database \[page 1594\]](#)

### 11.2.8.2.1.2 Copy a Database Using a Data Backup Only and Third-Party Backup Tools (SAP HANA Studio)

Using third-party backup tools with a data backup only, you can create a homogeneous copy of an SAP HANA database.

## Procedure

Start the recovery of the target database.

1. In SAP HANA studio, open the context menu and choose *Backup and Recovery*.
2. Choose *Recover Tenant Database...*
3. Specify *Recover the database to a specific data backup*.
4. Choose *Next*.
5. Specify the location of the backup catalog.

You can select *Recover using the backup catalog* and specify the location of the backup catalog, or select *Recover without the backup catalog*.

If you copy SAP HANA using a third-party backup tool without a backup catalog, the parameter file(s) must still be configured.

Using the following parameters, specify the path and name of the parameter file for the following backup types:

Data backups	<code>data_backup_parameter_file</code>
--------------	---

---

Backups of the backup catalog

To write backups of the backup catalog using a third-party backup tool, configure the following parameter:  
`catalog_backup_using_backint = true`

To specify the location of parameter file for backups of the backup catalog, use the following parameter:  
`catalog_backup_parameter_file`

For more information, see *Destination for Backups of the Backup Catalog*.

### **i** Note

Using SAP HANA studio, you can specify a parameter file for data backups for a third-party backup tool. However, to specify a parameter file for backups of the backup catalog, you need to use the parameter `catalog_backup_parameter_file`.

6. Specify *Backint System Copy* and specify the SID of the *Source System* that you want to copy.

To specify the name of a tenant database, use `<DBNAME@SID>`.

7. Choose *Next*.

8. Supply the required information.

Select the data backup or data snapshot, or specify the location of the data backup and the backup prefix.

9. If the log backups are not in the original location, specify a new location, and choose *Add*.

10. Choose *Next*.

11. Select *Initialize log area*.

12. You can select *Install new license key* and specify the license key file, or apply a license key file later.

13. Choose *Next*.

14. Review the recovery options and if correct, choose *Finish*.

The recovery is started.

## Results

When the recovery has been successfully completed, the target database is started.

The source database has now been recovered to the target database, and you can work with the target database.

### **i** Note

After the target database has been backed up, the source Backint parameter file is no longer needed. However, if you need to copy the source database again, you will still need the source Backint parameter file.

## Related Information

[Steps After Copying a Database \[page 1594\]](#)

[Destination for Backups of the Backup Catalog \[page 1491\]](#)

[Change the Log Backup Destination \[page 1488\]](#)

### 11.2.8.3 Steps After Copying a Database

When you have completed a database copy, consider performing specific additional steps.

#### Backing up the Target Database

When the database copy is completed, it is **not imperative** to create a new backup of the target database.

Nevertheless, it is **recommended** to back up the target database.

If you need to recover the target database before you have created a full backup of it, you can still use backups from the source database.

For this reason, it is recommended to keep the old backups available, at least until a new data backup of the target system has been created.

#### Backup Catalog

When a database copy is created, a new backup catalog is created in the target database. This new backup catalog allows the target database to be recovered using backups of the source database and new backups of the target database.

SAP HANA automatically uses the source database backups that are recorded in the backup catalog. You do not need to specify the SID of the source database again.

The backup catalog in the target database records **only** the backups from the source database that were used to recover the target database. If it is necessary to recover the target database again, you can only use the same backups of the source system that are recorded in the backup catalog. In this situation, older backups and different data backups, delta backups, and log backups cannot be used to recover the target database.

#### Scheduled Backups

After a database copy, ensure that any backups scheduled in the target database are configured in accordance with your requirements.

If backups were scheduled in the source database, after a database copy, the backups are scheduled to run in the target database with the same configuration as in the source database.

For more information, see *Scheduling Backups*.

## Services

An SAP HANA database automatically generates the services that it requires. You do not need to take any special steps to change the number of services.

After a database copy, you can remove a service. You may wish to do this, for example, if the target database has fewer hosts and more services than the source database.

### i Note

If you use the SQL statement `ALTER DATABASE` to remove a service, the remaining services are not redistributed. After a service is removed, all the remaining services are where they were before.

For this reason, we strongly recommend that you use SAP HANA cockpit to remove a service.

For more information, see *Use the Cockpit to Add or Remove Services in a Tenant Database* in the *SAP HANA Administration Guide* and *ALTER DATABASE Statement (Tenant Database Management)* in the *SAP HANA SQL and System Views Reference*.

## Hosts

To remove a **host**, use SAP HANA database lifecycle manager (HDBLCM).

For more information about removing services, see *SAP HANA Administration - LCM Configuration* in the *SAP HANA Administration Guide*.

## SAP HANA Secure User Store

If you use the SAP HANA secure user store (`hdbuserstore`) to connect to the database, you need to update the account information in the secure user store to match the accounts in the target database.

SAP HANA cockpit checks whether the user's logon credentials permit the user to perform a task.

For more information, see *Secure User Store (hdbuserstore)* in the *SAP HANA Administration Guide (Encryption)*.

## Third-Party Backup Tools

### → Tip

After the target database has been backed up, the source Backint parameter file is no longer needed. However, it is recommended that you retain the source Backint parameter file, as you will need it if you want to copy the source database again.

## 11.2.8.4 Database Copy: Scenarios

The following examples illustrate common situations in which a database copy is created.

## Related Information

[Database Copy: Target Database has Fewer Hosts Than the Source Database \[page 1597\]](#)

[Database Copy: Target Database has More Hosts Than the Source Database \[page 1598\]](#)

[Database Copy: System Database \[page 1599\]](#)

## 11.2.8.4.1 Database Copy: Target Database has Fewer Hosts Than the Source Database

In this example scenario, we create a database copy where the target database has fewer hosts than the source database.

### Prerequisites

The same prerequisites apply as for an SAP HANA database recovery.

For more information, see *Prerequisites for Database Recovery*.

### Context

In the following example, the source database and the target database are both tenant databases.

The source database has two hosts, each with one index server.

The target database has only one host.

File-based backups are used.

### Procedure

1. Create a target database with one host.

Follow the steps described in *Create a Tenant Database*.

2. Copy the database.

Follow the steps described in *Copy a Database Using File-Based Data Backup or Data Snapshot Only*.

All content of the data backup is recovered to the target host.

The target database now holds the data of the two hosts from the source database, and there are two index servers on the single-host target database.

3. Remove the index server.

For more information, see *Use the Cockpit to Add or Remove Services in a Tenant Database*.

### Results

The source database with two hosts has been copied to the target database with one host.

## Related Information

[Prerequisites for Database Recovery \[page 1528\]](#)

[Create a Tenant Database \[page 224\]](#)

[Steps After Copying a Database \[page 1594\]](#)

[Add or Remove Services in a Tenant Database \[page 272\]](#)

### 11.2.8.4.2 Database Copy: Target Database has More Hosts Than the Source Database

In this example scenario, we use a third-party backup tool to copy a SAP HANA database where the target database has more hosts than the source database.

#### Prerequisites

The same prerequisites apply as for an SAP HANA database recovery.

For more information, see *Prerequisites for Database Recovery*.

#### Context

In the following example, the source database and the target database are both tenant databases.

The source database has **two** hosts, each with one index server.

The target database has **three** hosts.

You are using a third-party backup tool.

#### Procedure

1. Create a target database.

Follow the steps described in *Create a Tenant Database*.

You can use CREATE DATABASE to create the target database. SAP HANA automatically creates an additional index server on a second host. There is no need to remove or add a host.

2. Copy the database.

Follow the steps described in *Copy a Database Using Data Backup Only and Third-Party Backup Tools*.

All content of the backup is recovered to the two existing hosts.

At this stage, the third host in the target system remains unused.

For more information, see *Adding and Removing Hosts*.

3. Distribute all the data in the target database from the two hosts to the three hosts that are now available.

## Results

A database with three hosts has been created, containing the data from the previous two-host database.

## Related Information

[Prerequisites for Copying a Database Using Backup and Recovery \[page 1579\]](#)

[Create a Tenant Database \[page 224\]](#)

[Steps After Copying a Database \[page 1594\]](#)

[Adding and Removing Hosts \[page 1611\]](#)

### 11.2.8.4.3 Database Copy: System Database

In these example scenarios, a system database is copied to an SAP HANA system with different host roles.

#### Scenario 1

System 1	System 2
Host A: host_role = worker	Host C: host_role = worker, xs_worker
Host B: host_role = standby	Host D: host_role = standby, xs_standby

It is possible to copy (recover) the system database from a backup created in System 1 to System 2, because the host roles of the System 2 hosts contain same the roles as System 1.

The services from host A will be moved to host C; the services from host B will be moved to host D.

However, it will not be possible to recover the system database from a backup from System 2 to System 1, because the hosts in System 1 do not have the xs\_worker and xs\_standby roles.

## Scenario 2

System 1	System 2
Host A: host_role = worker	Host C: host_role = worker
Host B: host_role = xs_worker	

It is possible to copy (recover) the system database from System 1 to System 2. This is a scale-down scenario. Host B on System 1 with only the xs\_worker role is removed from the target system.

It is possible to copy (recover) the system database from System 2 to System 1. This is a scale-up scenario. Services from host C will be moved to host A; host B will be used for XSA-related services.

### 11.2.9 Diagnosis Files for Backup and Recovery

The `backup.log` and `backint.log` files record information about backups and recoveries. This information can be used to diagnose errors.

Each SAP HANA database writes its own `backup.log` and `backint.log` file. If log rotation is enabled, sequentially named files can also exist. For example `backup.001.log` or `backint.001.log`

#### Related Information

[backup.log \[page 1600\]](#)

[backint.log \[page 1601\]](#)

[Housekeeping for backup.log and backint.log \[page 1602\]](#)

[View Diagnostic Files in the SAP HANA Database Explorer](#)

[Configuring SAP HANA System Properties \(INI Files\)](#)

[SAP Note 2797078](#)

#### 11.2.9.1 backup.log

The `backup.log` file records information about data backups, log backups, and the backup catalog.

`backup.log` also records information about recovery operations.

##### i Note

The SQL statement used for a recovery is recorded in `backup.log`. For a point-in-time recovery, the point in time is specified in the SQL statement as **UTC**.

The time at which the recovery was started and completed is recorded in `backup.log` as **local server time**, not UTC.

### Note

For a point-in-time recovery, the point in time specified in the SQL statement may be different from the point in time that was actually reached in the recovery. This is because the point in time that was actually reached in the recovery is that of the most recent global COMMIT to the database that was recovered.

For example, a point in time of **13:15** was specified for a recovery. SAP HANA interprets this time as UTC. The point in time reached could be **13:28:56+01:00** (local server time), which would be **12:28:56** as UTC.

The point in time recorded for a point-in-time recovery is the same regardless of whether the backups are from the file system or from a third-party backup tool.

## Display the Content of backup.log

You can display the content of `backup.log` as follows:

SAP HANA cockpit

Choose **View trace and diagnostic files** > **<system database>** > **Database Diagnostic Files** > **<host>** > **other**.

SAP HANA studio

In the Backup Console on the **Overview** tab, choose **Open Log File**.

In the Administration editor, go to the **Diagnosis Files** tab.

## Related Information

[Automatic File Rotation for backup.log and backint.log \[page 1603\]](#)

[Deleting backup.log and backint.log Using SQL Statements \[page 1605\]](#)

### 11.2.9.2 backint.log

`backint.log` contains information about the activities of the `Backint` agent.

The `Backint` agent is part of a third-party backup tool.

`backint.log` records all the parameters used to call the `Backint` agent, and the values returned. Each time the `Backint` agent is called, the command parameters and the return code are appended to `backint.log`.

`backint.log` includes the content of the following files:

- `Backint` input file  
This file is created when the `Backint` agent is started.
- `Backint` output file  
The `Backint` agent writes its output to this file.

The contents of the command file and the output file are copied to `backint.log`.

## Display the Content of `backint.log`

You can display the content of `backint.log` as follows:

SAP HANA cockpit	Choose ► <a href="#">View trace and diagnostic files</a> ► <code>&lt;system database&gt;</code> ► <a href="#">Database Diagnostic Files</a> ► <code>&lt;host&gt;</code> ► <a href="#">other</a> ►.
SAP HANA studio	In the Administration editor, go to the <a href="#">Diagnosis Files</a> tab.

## Related Information

[Automatic File Rotation for `backup.log` and `backint.log` \[page 1603\]](#)

[Deleting `backup.log` and `backint.log` Using SQL Statements \[page 1605\]](#)

### 11.2.9.3 Housekeeping for `backup.log` and `backint.log`

As more data is written to `backup.log` and `backint.log`, the files grow. Their increased size will not impact database performance, but may possibly occupy a large amount of space on disk.

To prevent the files from growing excessively, you can:

- Enable automatic file rotation for `backup.log` and `backint.log`
- Use SQL statements to delete `backup.log` and `backint.log`

#### ⚠ Caution

`backup.log` and `backint.log` are managed by SAP HANA. For this reason, you **must not delete** these files on operating system level.

If it is necessary to manually delete log files, only delete them by using SQL.

## Related Information

[Automatic File Rotation for backup.log and backint.log \[page 1603\]](#)

[Deleting backup.log and backint.log Using SQL Statements \[page 1605\]](#)

### 11.2.9.3.1 Automatic File Rotation for backup.log and backint.log

Automatic file rotation can be configured individually for each database. For each database, the configuration settings always apply to both `backup.log` and `backint.log`.

#### ! Restriction

Rotation is not supported by SAP HANA studio.

For more information, see SAP Note 2797078 (How to configure the size of the HANA Backup files `backup.log` and `backint.log`).

By default, automatic file rotation is disabled.

To enable rotation, configure the following parameters for each database in `global.ini`, section `backup`:

Parameter	Description
<code>max_trace_file_size</code>	<p>Specify the maximum size of the <code>backup.log</code> and <code>backint.log</code> files.</p> <p>Default: <b>-1</b> (Rotation is disabled, and the files can grow indefinitely.)</p> <p>You can specify a file size of <b>10MB</b> or more. When you specify a file size, automatic file rotation is then enabled. To disable automatic file rotation, reset the parameter to its default value of <b>-1</b>.</p> <p>When automatic file rotation is enabled, a sequential 3-digit number from 000 to 999 is appended to the file name.</p> <p>For example: <code>backup.001.log</code>, <code>backint.010.log</code></p> <p>When a log file reaches the specified maximum size, it is rotated. When a log file is rotated, a new empty file is created and assigned the next sequential number.</p> <p>If there is no restriction on the maximum number of log files, or if <code>max_trace_files</code> <math>\geq</math> <b>999</b>, when <code>backup.999.log</code> reaches its maximum size, the file numbering starts from <code>backup.000.log</code> again. If, at this time, a log</p>

Parameter	Description
max_trace_files	<p>file named backup.000.log already exists, it is overwritten.</p> <div data-bbox="826 465 1372 604"> <p><b>i Note</b></p> <p>Diagnosis messages are never split across multiple log files. Consequently, the specified maximum file size may be exceeded slightly.</p> </div>
	<p>Specify the maximum number of rotation files to be retained for backup.log and backint.log.</p> <p>Default: <b>10</b> files</p> <p>(The minimum number of log files is <b>2</b>.)</p> <p>When the specified number of rotation files is exceeded, the oldest rotation file is automatically deleted.</p> <div data-bbox="826 945 1340 1052"> <p><b>i Note</b></p> <p>When automatic file rotation is enabled or disabled, existing log files are <b>not</b> automatically deleted.</p> </div>

### i Note

If automatic file rotation for backup diagnosis files is enabled, multiple backup.log or backint.log files can exist. The file names are numbered sequentially, in the same way as SAP HANA trace files. For example, backup.001.log.

For more information about how to configure parameters, see *Configuring System Properties in SAP HANA Cockpit* in *SAP HANA Administration with SAP HANA Cockpit*.

## Related Information

[backup.log \[page 1600\]](#)

[backint.log \[page 1601\]](#)

## 11.2.9.3.2 Deleting backup.log and backint.log Using SQL Statements

If it is necessary to manually delete log files, only delete them by using SQL statements.

### ⚠ Caution

`backup.log` and `backint.log` are managed by SAP HANA. For this reason, you **must not delete** these files on operating system level.

Use the following SQL statements:

- To delete `backup.log` files:  
ALTER SYSTEM CLEAR TRACES ('BACKUP')
- To delete `backint.log` files:  
ALTER SYSTEM CLEAR TRACES ('BACKINT')

With both SQL statements, you can optionally specify WITH BACKUP to compress a log file instead of deleting it.

### → Tip

You can use these SQL statements regardless of whether automatic file rotation is enabled or disabled.

For more information, see *ALTER SYSTEM CLEAR TRACES Statement (System Management)* in the *SAP HANA SQL and System Views Reference*.

## 11.2.10 Reference

Reference and legacy information about SAP HANA backup and recovery.

## Related Information

[Backup Alerts \[page 1606\]](#)

## 11.2.10.1 Backup Alerts

SAP HANA raises alerts that warn you of errors related to backups.

<b>Alert:</b>	<b>Check availability of volumes for backup</b>
Alert ID:	34
Description:	<p>This check warns you if a backup cannot be created because a volume or a service is unavailable.</p> <p>This alert can be triggered in combination with the alerts NOT_ASSIGNED_VOLUMES and CHECK_INACTIVE_SERVICES.</p>
Alert Text:	<no> (<service>) is not available. A backup cannot be created.
User Action:	Find out why the volume or service is not available.
Default Interval:	1 hour
<b>Alert:</b>	<b>Check whether a data backup exists</b>
Alert ID:	35
Description:	<p>Checks whether at least one data backup exists, and warns you if no successful data backup is available for the instance. You are warned before any actual data loss occurs.</p>
Alert Text:	No data backup exists.
User Action:	To ensure that your database can be recovered, create a data backup as soon as possible.
Default Interval:	6 hours
	This check is also performed when the database is started.
<b>Alert:</b>	<b>Check last data backup</b>
Alert ID:	36
Description:	<p>Checks whether the last data backup was successful, and warns you if the last data backup failed.</p> <p>If a scheduled backup fails, this check can help you prevent a situation from arising where no current backups are available.</p>
Alert Text:	The last data backup was not successful.

<b>Alert: Check last data backup</b>	
User Action:	Find out why the last data backup was not successful, resolve the problem, and create a new data backup as soon as possible.
Default Interval:	1 hour

<b>Alert: Check the age of the last data backup</b>	
Alert ID:	37
Description:	<p>Checks the age of the last successful backup.</p> <p>This includes complete data backups, data snapshots, and delta backups (differential data backups and incremental data backups).</p> <p>If the last successful backup is too old, the following alert levels are generated:</p> <ul style="list-style-type: none"> <li>• 20 days: High</li> <li>• 7 days: Medium</li> <li>• 5 days: Low</li> </ul>
Alert Text:	The last data backup is <days> days old.
User Action:	To reduce your downtime in a recovery situation, create a data backup as soon as possible.
Default Interval:	24 hours

<b>Alert: Check last log backups</b>	
Alert ID:	38
Description:	<p>Checks whether the last log backups were successful, and provides information about a failed log backup for a service or volume.</p> <p>As log backups are created automatically, this is the only way to notify users. This check should therefore be performed frequently and be accorded high priority.</p> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin-top: 10px;"> <p><b>i Note</b></p> <p>Log backups are created in separate backup destinations for each volume. For this reason, log backups need to be checked for each volume.</p> </div>
Alert Text:	The last log backup was not successful for volume <no> (<service> at <host>:<port>).

<b>Alert: Check last log backups</b>	
User Action:	Find out why a log backup was not successful and resolve the problem.
Default Interval:	15 minutes

<b>Alert: Runtime of the currently running log backups</b>	
Alert ID:	65
Description:	Determines whether the most recent log backup terminates in the specified time.
Alert Text:	A log backup with ID <id> has been running for longer than <value> seconds.
User Action:	Investigate why the log backup runs for too long, and resolve the issue.
Default Interval:	60 seconds

<b>Alert: Storage snapshot (data snapshot) is prepared</b>	
Alert ID:	66
Description:	Determines whether the period, during which the database is prepared for a data snapshot, exceeds a given threshold.
Alert Text:	The database was prepared for a data snapshot for longer than <value> seconds.
User Action:	Investigate why the data snapshot was not confirmed or abandoned, and resolve the issue.
Default Interval:	5 minutes

<b>Alert: Enable automatic log backup</b>	
Alert ID:	69
Description:	Determines whether automatic log backup is enabled.
Alert Text:	Automatic log backup is disabled.
User Action:	Enable automatic log backup.
Default Interval:	15 minutes

## 11.3 Scaling SAP HANA

There are two general approaches you can take to scale your SAP HANA system: scale up and scale out.

**Scale up** means increasing the size of one physical machine by increasing the amount of RAM available for processing.

**Scale out** means combining multiple independent computers into one system. The main reason for distributing a system across multiple hosts (that is, scaling out) is to overcome the hardware limitations of a single physical server. This allows an SAP HANA system to distribute the load between multiple servers. In a distributed system, each index server is usually assigned to its own host to achieve maximum performance. It is possible to assign different tables to different hosts (partitioning the database), as well as to split a single table between hosts (partitioning of tables).

[Starting and Stopping Distributed SAP HANA Systems Using SAPControl \[page 1654\]](#)

## 11.3.1 Aspects of Scalability

Before you decide how to scale your SAP HANA implementation, there are a number of aspects that need to be considered, such as scaling data, performance, applications, and hardware.

### Scaling the Data

One technique you can use to deal with planned data growth is to purchase more physical RAM than is initially required to set the allocation limit according to your needs, and then to increase it over time to adapt to your data. Once you have reached the physical limits of a single server, you can scale out over multiple machines to create a distributed SAP HANA system. You can do this by distributing different schemas and tables to different servers (complete data and user separation). However, this is not always possible, for example, when a single fact table is larger than the server's RAM size.

The most important strategy for scaling your data is **data partitioning**. Partitioning supports the creation of very large tables (billions of rows) by breaking them into smaller chunks that can be placed on different machines. Partitioning is transparent for most SQL queries and other data manipulations.

For more information, see the section on managing tables.

### Scaling Performance

SAP HANA's performance is derived from its efficient, parallelized approach. The more computation cores your SAP HANA server has, the better the overall system performance is.

Scaling performance requires a more detailed understanding of your workload and performance expectations. Using simulations and estimations of your typical query workloads, you can determine the expected load that a typical SAP HANA installation may comfortably manage. At the workload level, a rough prediction of scalability can be established by measuring the average CPU utilization while the workload is running. For example, an average CPU utilization of 45% may indicate that the system can be loaded 2X before showing a significant reduction in individual query response time.

For more information, see the sections on workload management and performance analysis.

### Scaling the Application

Partitioning can be used to scale the application as it supports an increasing number of concurrent sessions and complex analytical queries by spreading the calculations across multiple hosts. Particular care must be taken in distributing the data so that the majority of queries match partitioning pruning rules. This accomplishes two goals: directing different users to different hosts (load balancing) and avoiding the network overhead related to frequent data joins across hosts.

## Scaling Hardware

SAP HANA is offered in a number of ways – in the form of an on-premise appliance, delivered in a number of different configurations and "sizes" by certified hardware partners or by using the tailored data center integration model, and as part of a cloud-based service. This creates different system design options with respect to scale-up and scale-out variations. To maximize performance and throughput, SAP recommends that you scale up as far as possible (acquire the configuration with the highest processor and memory specification for the application workload), before scaling out (for deployments with even greater data volume requirements).

### **i** Note

The SAP HANA hardware partners have different building blocks for their scale-out implementations. Therefore, you should always consult with your hardware partner when planning your scale-out strategy.

## 11.3.2 Adding and Removing Hosts

After installation, it is possible to add hosts to a single-host or multiple-host SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM).

Before you add or remove hosts, it is important to understand multiple-host system concepts, as well as the SAP HANA database lifecycle manager. Also, be aware that changing the number of hosts may affect how you back up and recover SAP HANA.

For more information about installing SAP HANA, see the *SAP HANA Server Installation and Update Guide*.

## 11.3.2.1 Multiple-Host System Concepts

It is important to review multiple-host system concepts like host grouping and storage options before installing a multiple-host system.

### Host Types

When configuring a multiple-host system, the additional hosts must be defined as **worker** hosts or **standby** hosts (worker is default). Worker machines process data; standby machines do not handle any processing and instead wait to take over processes in the case of worker machine failure.

### Auto-Failover for High Availability

As an in-memory database, SAP HANA is not only concerned with maintaining the reliability of its data in the event of failures, but also with resuming operations with most of that data loaded back in memory as quickly as possible. Host auto-failover is a local fault recovery solution that can be used as a supplemental or alternative measure to system replication. One (or more) standby hosts are added to a SAP HANA system, and configured to work in standby mode.

Before installing a multiple-host system, it is important to consider whether high availability is necessary and how hosts should be grouped to ensure preferred host auto-failover. For host auto-failover to be successful, if the active (worker) host fails, the standby host takes over its role by starting its database instance using the persisted data and log files of the failed host. The name server of one of the SAP HANA instances acts as the cluster manager that pings all hosts regularly. If a failing host is detected, the cluster manager ensures that the standby host takes over the role and the failing host is no longer allowed write access to the files (called fencing) so that they do not become corrupted. The crash of a single service does not trigger failover since services are normally restarted by `hdbdaemon`. For more information, see *Setting Up Host Auto-Failover* in the *SAP HANA Administration Guide*.

### Host Grouping

Host grouping does not affect the load distribution among worker hosts - the load is distributed among all workers in an SAP HANA system. If there are multiple standby hosts in a system, host grouping should be considered, because host grouping decides the allocation of standby resources if a worker machine fails. If no host group is specified, all hosts belong to one host group called "default". The more standby hosts in one host group, the more failover security.

If the standby hosts are each in a different host group, the standby host in the same group as the failing worker host is preferred. Only if no standby host is available in the same host group, the system will try to fail over to a standby host, which is part of another host group. The advantage of this configuration is that in an SAP HANA system with mixed machine resources, similar sized machines can be grouped together. If a small worker host fails, and a small standby in the same group takes over, the processes are moved to a machine with similar resources, which allows processing to continue as usual with optimal resource allocation.

## Worker Host Grouping for Warm Data

If you use SAP Business Warehouse to apply a temperature-based data strategy you can significantly optimize the usage of memory and hardware resources by reserving one node of the scaled-out HANA landscape exclusively for warm data. Due to information lifecycle management, multi-temperature strategies are often applied, whereby data is classified by access frequency as either hot, warm, or cold. Depending on this classification and data usage, this data is stored in different memory areas.

A multi-temperature memory strategy may be required for different reasons, for example:

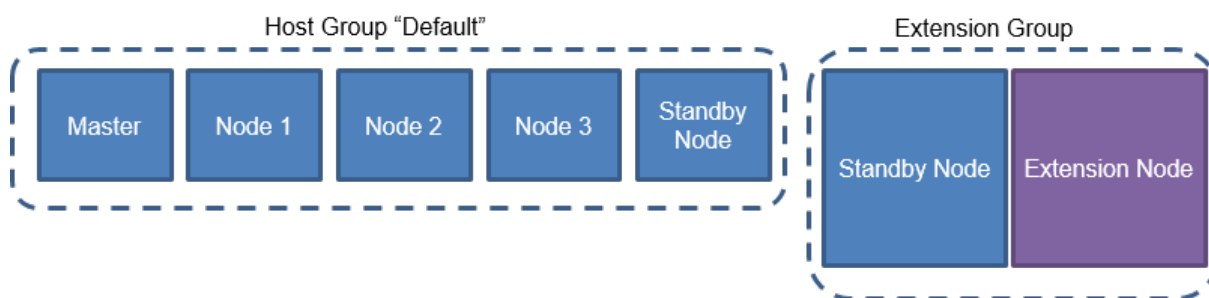

- Storage of historical data
- Clickstream logs for multiple years of Web data and detailed machine logs
- Guidelines for saving company data, such as the need to save all data for at least seven years due to legal reasons.

The standard SAP HANA sizing guidelines allow for a data footprint of 50% of the available RAM. This ensures that all data can be kept in RAM at all times and there is sufficient space for intermediate result sets. These sizing guidelines can be significantly relaxed on the extension group, since 'warm' data is accessed:

- less frequently
- with reduced performance SLAs
- with less CPU-intensive processes
- only partially at the same time.

To implement a multi-temperature memory strategy, you can assign hosts to worker groups. Hot and warm data is then distributed across hosts. To increase performance and memory usage, a slave node is assigned to

a separate *Extension Node*. Unlike the standard nodes (master and slave), the extension node is intended exclusively for data that is not accessed as frequently (warm) as other data (hot).

For more information, see *Data Temperature: Extension Node for Business Warehouse* in the *SAP HANA Administration Guide* and SAP Note 2453736.

## Storage and File System Options

In single-host SAP HANA systems, it is possible to use local file systems residing on direct-attached internal or external storage devices, such as SCSI hard drives, SSDs, SAN storage, or NAS. However, in order to build a multiple-host system with failover capabilities this is not sufficient. Either the chosen file system type or the SAN Infrastructure along with a SAP HANA functionality capable of disc fencing must ensure the following:

- The standby host has file access to data and log volumes of the failed host.
- The failed worker host no longer has access to write to files - called fencing.

There are two fundamentally different storage configurations which meet the two conditions above: **shared storage devices** or **separate storage devices with failover reassignment**. Do not confuse "shared storage" with the installation directory `/hana/shared` that must be shared across all hosts.

## Shared File Systems

A shared storage subsystem, which is accessed using file systems such as NFS or IBM's GPFS, makes it easy to ensure that the standby host has access to all active host files in the system. In a shared storage solution, the externally attached storage subsystem devices are capable of providing dynamic mount points for hosts. Since shared storage subsystems vary in their handling of fencing, it is the responsibility of the hardware partner and their storage partners to develop a corruption-safe failover solution which is specific for the file system used to access that storage subsystem. An NFSv3 storage solution must be used in combination with the storage connector supplied by the hardware partner. NFSv4 and GPFS storage solutions can optionally be used with a storage connector.

A shared storage system could be configured as in the diagram below, however mounts may differ among hardware partners and their configurations. For more information, see the *SAP HANA Storage Whitepaper* available in SAP Note 1900823 in Related Information.

## Non-shared Storage

It is also possible to assign every SAP HANA host a separate storage, which has nothing mounted except the shared area. A SAN storage must be used in combination with the SAP Fiber Channel Storage Connector, which SAP HANA offers storage technology vendors. During failover, SAP HANA uses the storage connector API to tell the storage device driver to remount the required data and logs volumes to the standby host and fence off the same volumes from the failed host.

In a non-shared environment, separate storage is used in combination with the storage connector API. For more information about the storage connector API, see the *SAP Fiber Channel Storage Connector Admin Guide* available in SAP Note 1900823 in Related Information.

### 11.3.2.2 Host Addition Concepts

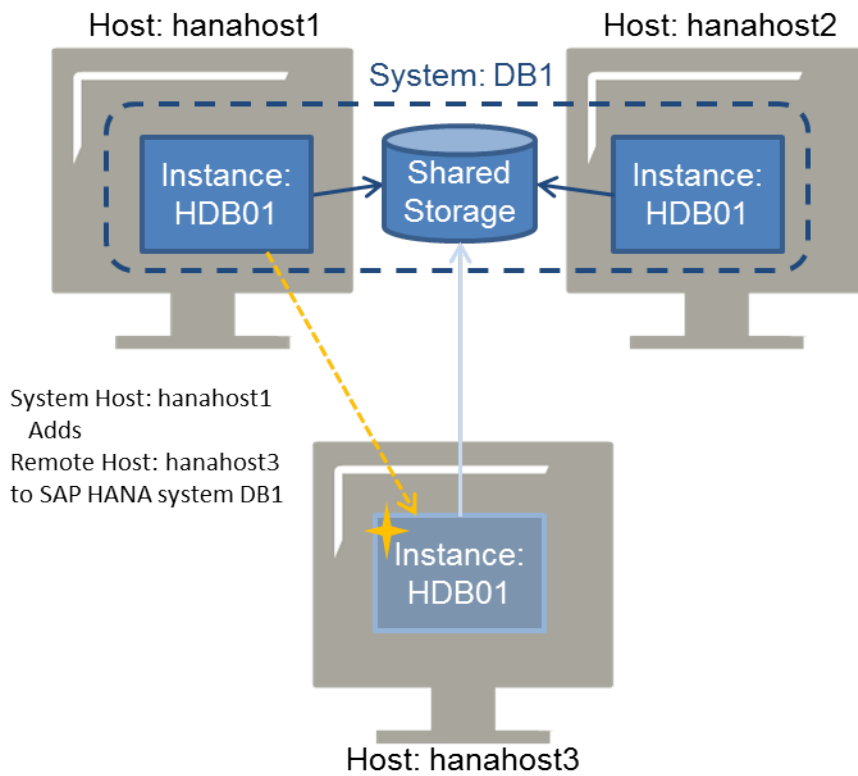

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM).

Using either the SAP HANA database lifecycle manager graphical user or command-line interface, one or multiple hosts can be added to an SAP HANA system in a variety of ways. The configuration options change depending on how the host is added.

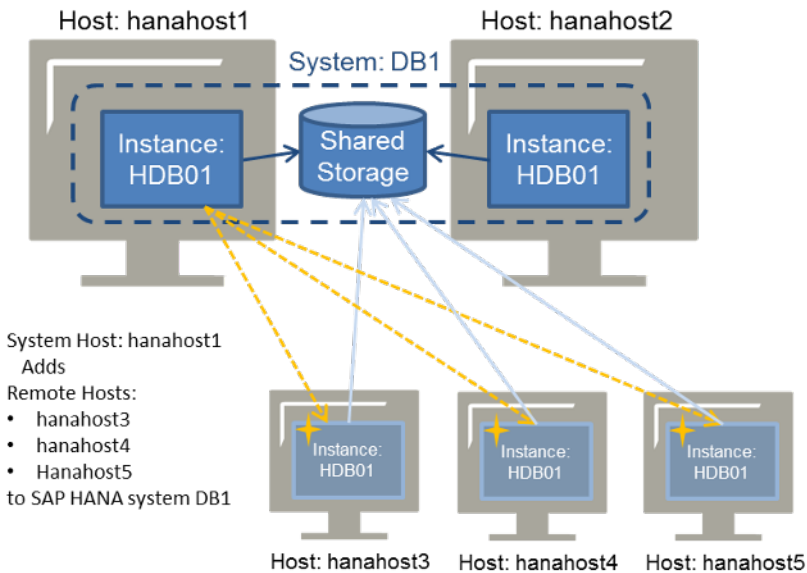

#### Adding Hosts from an Integrated Host

The first consideration is whether the host you are logged on to is integrated in the system. If you are logged on to a configured system host, then you are on an integrated host and adding a non-integrated host to the system. In the diagram below, the hosts in the dotted line (hanahost1 and hanahost2) are integrated hosts because they both belong to the SAP HANA system DB1. Consider being logged on to hanahost1, and adding non-integrated host, hanahost3, to the SAP HANA system. The SAP HANA database lifecycle manager is started on the integrated host, hanahost1, and the addhost configuration task is carried out. The host information for hanahost3 is entered, and hanahost3 is configured as either a worker host or standby host. As soon as the addhost configuration task is finished, hanahost3 has access to the shared storage of the DB1 system.

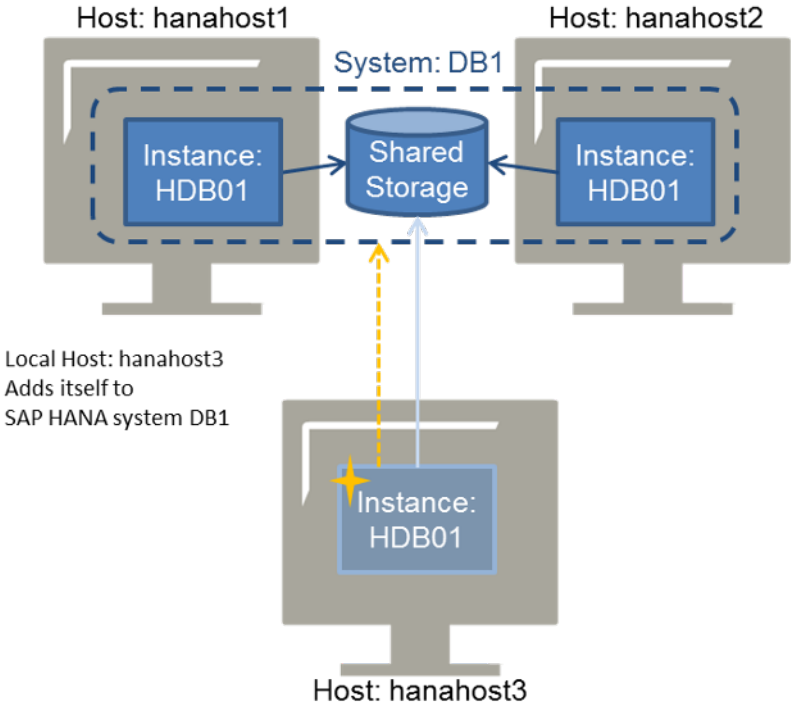

It is also possible to add multiple non-integrated hosts to the same system at one time. In the diagram below, three remote hosts (hanahost3, hanahost4, hanahost5) are added to the SAP HANA system (DB1) from a system host (hanahost1).

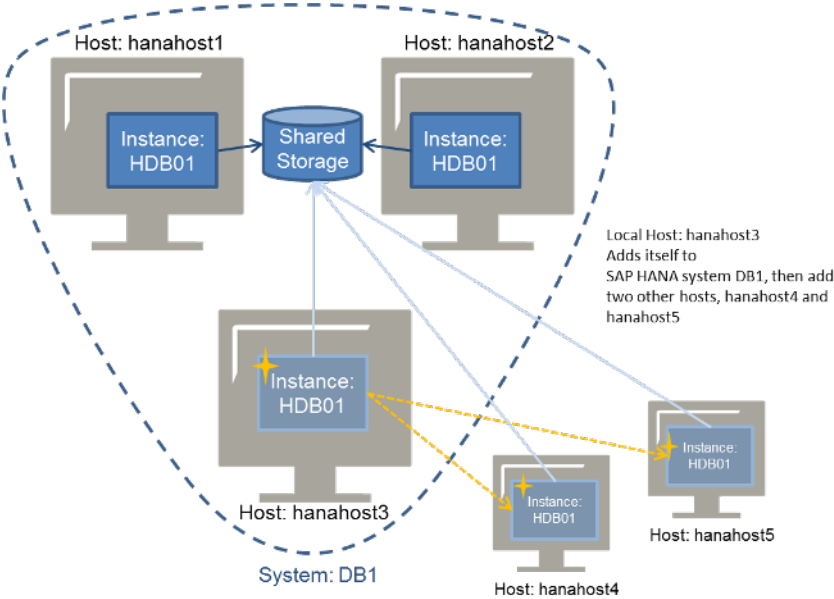

## Adding Hosts from a Non-Integrated Host

Alternatively, a non-integrated host can add itself to an SAP HANA system. This is referred to as adding a host from a non-integrated host, because you are logged on to a host which you want to add to the system.

To add multiple hosts to an SAP HANA system from a non-integrated host, first the non-integrated host must be added (and, therefore, become integrated), and then it can add more hosts. The SAP HANA database lifecycle manager interface is designed so that the non-integrated host and the additional hosts can be added in the same procedure. In the diagram below, the non-integrated host has already been newly added to the system (become integrated), and is now adding the other hosts.

## Related Information

[Add Hosts Using the Command-Line Interface \[page 1622\]](#)

### 11.3.2.3 Adding Hosts to an SAP HANA System

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program or the SAP HANA database lifecycle manager (HDBLCM) Web user interface.

If you want to configure a new multiple-host (distributed) system during installation, see the multiple-host system installation information in the *SAP HANA Server Installation and Update Guide*.

Before adding a host to an SAP HANA system, you need to consider the following:

- If you are adding hosts from a host that is already integrated in the SAP HANA system
- If the system is a single-host or multiple-host system
- How many hosts you want to add to the system at one time

For more information about how these conditions affect the addition of hosts to an SAP HANA system see the host addition concepts in Related Information.

If you are adding a host to a single-host system, the listen interface is automatically configured to global during the host addition. After the host is added to the system, the internal network address can be defined and the inter-service communication can be reconfigured to a different setting, if required. For more information about configuring inter-service communication, see Related Information.

## Related Information

[Multiple-Host System Concepts \[page 1612\]](#)

[Add Hosts Using the Graphical User Interface \[page 1620\]](#)

[Add Hosts Using the Command-Line Interface \[page 1622\]](#)

[Add Hosts Using the Web User Interface \[page 1625\]](#)

## 11.3.2.3.1 Add Hosts Using the Graphical User Interface

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the graphical user interface.

### Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw,no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcmlgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

#### i Note

To activate the local secure (LSS) store during installation, run `hdblcmlgui` with the parameter `secure_store=localsecurestore`.

3. Select [Add Hosts to SAP HANA System](#) from the activity options. Then select [Next](#).
4. Select [Add Host...](#) to define the required parameters. Then select [Next](#).

Field Name	Description
<a href="#">Host Name</a>	Specifies the host name of the machine.

Field Name	Description
<i>Role</i>	<p>Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments.</p> <ul style="list-style-type: none"> <li>○ Database Worker (worker) - A worker host (default) is used for database processing.</li> <li>○ Database Standby (standby) - A standby host is idle and available for fail-over in a high-availability environment.</li> <li>○ Database Elastic Compute Server (compute) - Database elastic compute server</li> <li>○ Dynamic Tiering Worker (extended_storage_worker) - Worker host for SAP HANA dynamic tiering</li> <li>○ Dynamic Tiering Standby (extended_storage_standby) - Standby host for SAP HANA dynamic tiering</li> <li>○ Accelerator for SAP ASE Worker (ets_worker) - Worker host for SAP HANA accelerator for SAP ASE</li> <li>○ Accelerator for SAP ASE Standby (ets_standby) - Standby host for SAP HANA accelerator for SAP ASE</li> <li>○ Streaming Analytics (streaming) - Host for SAP HANA streaming analytics</li> <li>○ XS advanced runtime worker (xs_worker) - Host for SAP HANA XS advanced runtime</li> <li>○ XS advanced runtime standby (xs_standby) - Standby host for SAP HANA XS advanced runtime</li> </ul>
<i>Worker Group</i>	<p>Specifies the worker group of the host. If undefined, the worker group is named "default". If you are using extension node for Business Warehouse, you must name the worker group "worker_dt".</p>
<i>High-Availability Group</i>	<p>Specifies the host group ID for failover scenarios. If undefined, the host group is named "default".</p>
<i>Storage Partition</i>	<p>Specifies the storage partition number, which is a logical role number assigned to non-shared storage devices in a storage connector API. Standby hosts do not have a storage partition.</p>

5. Define additional system properties.

Field Name	Description
<i>Inter-Service Communication</i>	<p>Specifies the listen interface for the internal network communication.</p> <p><code>global</code> - Binds the processes to all interfaces. This option does not require an internal network address entry.</p> <p><code>internal</code> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.</p>
<i>Internal Network Address</i>	<p>Specifies the internal subset address in CIDR notation.</p> <p>If you define a value other than <code>local</code>, the local interfaces will always be open.</p>
<i>Certificate Host Name</i>	<p>Specifies the hostname used for generation of self-signed SSL certificates for the SAP Host Agent.</p>

6. Review the summary, and select [Add Hosts](#) to finalize the configuration.

## Results

You have added one or more new hosts to an SAP HANA system. The SAP HANA system you have configured is a multiple-host system.

The new hosts have been added to the SAP HANA landscape information. The new hosts have been added to the landscape information of the system database.

### 11.3.2.3.2 Add Hosts Using the Command-Line Interface

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface.

#### Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

#### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcml --addhosts=<host>[, <host2>]
```

where the syntax for the `addhosts` call option is as follows:

```
<host name>:role=<role name>:group=<group ID>:storage_partition=<partition number>
```

Field Name	Description
<code>&lt;host name&gt;</code>	Specifies the host name of the machine.
<code>role</code>	Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments. <ul style="list-style-type: none"> <li>○ <code>worker</code> - A worker host (default) is used for database processing.</li> <li>○ <code>standby</code> - A standby host is idle and available for failover in a high-availability environment.</li> <li>○ <code>compute</code> - Database elastic compute server</li> <li>○ <code>extended_storage_worker</code> - Worker host for SAP HANA dynamic tiering</li> <li>○ <code>extended_storage_standby</code> - Standby host for SAP HANA dynamic tiering</li> <li>○ <code>ets_worker</code> - Worker host for SAP HANA accelerator for SAP ASE</li> <li>○ <code>ets_standby</code> - Standby host for SAP HANA accelerator for SAP ASE</li> <li>○ <code>streaming</code> - Host for SAP HANA streaming analytics</li> <li>○ <code>xs_worker</code> - Host for SAP HANA XS advanced runtime</li> <li>○ <code>xs_standby</code> - Standby host for SAP HANA XS advanced runtime</li> </ul>
<code>workergroup</code>	Specifies the worker group of the host. If undefined, the worker group is named "default". If you are using extension node for Business Warehouse, you must name the worker group "worker_dt".
<code>group</code>	Specifies the host group ID for failover scenarios. If undefined, the host group is named "default".
<code>storage_partition</code>	Specifies the storage partition number, which is a logical role number assigned to non-shared storage devices in a storage connector API. Standby hosts do not have a storage partition.

The required parameters depend on the type of host addition you are performing: host addition from an integrated host to a multiple-host system, host addition from an integrated host to a single-host system, or host addition from a non-integrated host. For more information about host addition types, see Related Information.

### **i** Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the `hdblcm` directory of the SAP HANA system, execute the following command:

```
./hdblcm --action=add_hosts --help
```

3. Select the index for the `add_hosts` action.
4. Define additional system properties.

Field Name	Description
<i>Inter-Service Communication</i>	Specifies the listen interface for the internal network communication.  <i>global</i> - Binds the processes to all interfaces. This option does not require an internal network address entry. <i>internal</i> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.
<i>Internal Network Address</i>	Specifies the internal subset address in CIDR notation.  If you define a value other than <i>local</i> , the local interfaces will always be open.
<i>Certificate Host Name</i>	Specifies the hostname used for generation of self-signed SSL certificates for the SAP Host Agent.

- Review the summary, and select *y* to finalize the configuration.

## Results

You have added one or more new hosts to an SAP HANA system. The SAP HANA system you have configured is a multiple-host system.

The new hosts have been added to the SAP HANA landscape information. The new hosts have been added to the landscape information of the system database.

This configuration task can also be performed in batch mode and using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

## Example

The following example adds two hosts, *Host1* and *Host2* to a single-host SAP HANA system. The role of the two hosts is *worker*, by default. No SSH keys are installed. A trusted connection between the hosts is configured and therefore, root user password is not required. The listen interface of the SAP HANA system is changed to *global*.

```
./hdblcm --action=add_hosts --addhosts=host1,host2 --root_user=lmroot --listen_interface=global
```

### 11.3.2.3.3 Add Hosts Using the Web User Interface

You can add hosts to an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) Web user interface.

#### Prerequisites

- On the host, which is to be added, SAP Host Agent is installed with SSL configured. The SAP Host Agent will create the `<sapsys>` group, if it does not exist prior to installation. Make sure that the group ID of the `<sapsys>` group is the same on all hosts.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<SID>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<SID>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) will not modify the properties of any existing user or group.
- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing  **Tools**  **Compatibility View Settings** .
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release

- Google Chrome - Latest version
- SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
- Mac OS - Safari 5.1 or higher

### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

## Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser: <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

### i Note

The URL is case sensitive. Make sure you enter upper and lower case letters correctly.

<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"> <li>1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code></li> </ol>
-------------------------	---

### i Note

FQDN = fully qualified domain name

2. Drill down on the name of the system from *My Resources* or from a group.
3. The links in *Platform Lifecycle Management* each launch additional functionality, giving you expanded capabilities for managing the resource.

2. Select the *Add Hosts* tile.
3. Optional: Modify the following parameters in the *Advanced Parameters Configuration* dialog. To access the *Advanced Parameters Configuration* dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

Option	Description
<b>import_xs_content</b>	Imports SAP HANA XS advanced runtime content.
<b>Install or Update SAP Host Agent</b>	Installs or updates SAP Host Agent.
<b>Do Not Start Added Hosts</b>	Does not start hosts after addition.
<b>Do Not Modify 'etc/sudoers' File</b>	Prevents the file <code>/etc/sudoers</code> from being modified.
<b>Timeouts</b>	Sets customized timeouts ( <code>start_instance</code> , <code>start_service</code> )

4. Provide the necessary credentials, then select *Add Host*.

5. Define the required host parameters. Then select **OK**.

Field Name	Description
<i>Host Name</i>	Specifies the host name of the machine.
<i>Role</i>	<p>Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments.</p> <ul style="list-style-type: none"> <li>○ Database Worker (worker) - A worker host (default) is used for database processing.</li> <li>○ Database Standby (standby) - A standby host is idle and available for fail-over in a high-availability environment.</li> <li>○ Database Elastic Compute Server (compute) - Database elastic compute server</li> <li>○ Dynamic Tiering Worker (extended_storage_worker) - Worker host for SAP HANA dynamic tiering</li> <li>○ Dynamic Tiering Standby (extended_storage_standby) - Standby host for SAP HANA dynamic tiering</li> <li>○ Accelerator for SAP ASE Worker (ets_worker) - Worker host for SAP HANA accelerator for SAP ASE</li> <li>○ Accelerator for SAP ASE Standby (ets_standby) - Standby host for SAP HANA accelerator for SAP ASE</li> <li>○ Streaming Analytics (streaming) - Host for SAP HANA streaming analytics</li> <li>○ XS advanced runtime worker (xs_worker) - Host for SAP HANA XS advanced runtime</li> <li>○ XS advanced runtime standby (xs_standby) - Standby host for SAP HANA XS advanced runtime</li> </ul>
<i>Worker Group</i>	Specifies the worker group of the host. If undefined, the worker group is named "default". If you are using extension node for Business Warehouse, you must name the worker group "worker_dt".
<i>High-Availability Group</i>	Specifies the host group ID for failover scenarios. If undefined, the host group is named "default".
<i>Storage Partition</i>	Specifies the storage partition number, which is a logical role number assigned to non-shared storage devices in a storage connector API. Standby hosts do not have a storage partition.

6. Define additional system properties.

Field Name	Description
<i>Inter-Service Communication</i>	<p>Specifies the listen interface for the internal network communication.</p> <p><code>global</code> - Binds the processes to all interfaces. This option does not require an internal network address entry.</p> <p><code>internal</code> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.</p>
<i>Internal Network Address</i>	<p>Specifies the internal subset address in CIDR notation.</p> <p>If you define a value other than <code>local</code>, the local interfaces will always be open.</p>

7. Review the summary, and select [Run](#) to finalize the configuration.

## Results

You have added one or more new hosts to an SAP HANA system. The SAP HANA system you have configured is a multiple-host system.

The new hosts have been added to the SAP HANA landscape information. The new hosts have been added to the landscape information of the system database.

### 11.3.2.4 Removing Hosts from an SAP HANA System

You can remove hosts from an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program or the SAP HANA database lifecycle manager (HDBLCM) Web user interface.

## Related Information

[Remove Hosts Using the Graphical User Interface \[page 1628\]](#)

[Remove Hosts Using the Command-Line Interface \[page 1630\]](#)

[Remove Hosts Using the Web User Interface \[page 1631\]](#)

[Add or Remove Services in a Tenant Database \[page 272\]](#)

#### 11.3.2.4.1 Remove Hosts Using the Graphical User Interface

You can remove hosts from an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) in the graphical user interface.

## Prerequisites

- You are logged in as root user.

- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- If you want to remove a host that runs the coordinator name server, another host that will take over the role of the coordinator name server must be up and running.
- You have removed all tenant-specific services from the host.
- You are logged on as root user or as the system administrator user `<sid>adm`.

### ⚠ Caution

Removing a host breaks the backup history of the database. To ensure that the database is fully recoverable, perform a full backup (data backup or storage snapshot) immediately after adding a service.

## Procedure

1. Remove tenant-specific services. For more information, see *Remove a Service from a Tenant Database in the SAP HANA Tenant Databases Operations Guide*.
2. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcmm
```

By default, `<sapmnt>` is `/hana/shared`.

3. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcmmgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

### i Note

To activate the local secure (LSS) store during installation, run `hdblcmmgui` with the parameter `secure_store=localsecurestore`.

4. Select *Remove Hosts from the SAP HANA System* from the activity options. Then select *Next*.
5. Select the host you would like to remove from the system. Then select *Next*.

You also have a choice to enable the following:

Field Name	Description
<i>Keep System Administrator User</i>	Keeps the system administrator user ( <code>&lt;sid&gt;adm</code> ) from the source system to be used in the target system.
<i>Keep Home Directory of System Administrator</i>	Prevents the home directory of the source system administrator user ( <code>&lt;sid&gt;adm</code> ) from being removed.

6. Enter the required credentials. Then select *Next*.
7. Review the summary, and select *Remove Hosts* to finalize the configuration.

## Results

You have removed one or more new hosts from an SAP HANA system. This configuration task can also be performed using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

### 11.3.2.4.2 Remove Hosts Using the Command-Line Interface

You can remove hosts from an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) in the command-line interface.

## Prerequisites

- You are logged in as root user.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- If you want to remove a host that runs the coordinator name server, another host that will take over the role of the coordinator name server must be up and running.
- You have removed all tenant-specific services from the host.
- You are logged on as root user or as the system administrator user `<sid>adm`.

### ⚠ Caution

Removing a host breaks the backup history of the database. To ensure that the database is fully recoverable, perform a full backup (data backup or storage snapshot) immediately after adding a service.

## Procedure

1. Remove tenant-specific services. For more information, see *Remove a Service from a Tenant Database* in the *SAP HANA Tenant Databases Operations Guide*.
2. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdb1cm
```

By default, `<sapmnt>` is `/hana/shared`.

3. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcm
```

4. Select the index for the `remove_hosts` action.
5. Select the hosts to be removed as a comma-separated list of indexes, and specify the following system properties:

Field Name	Description
<i>Keep System Administrator User</i>	Keeps the system administrator user ( <code>&lt;sid&gt;adm</code> ) from the source system to be used in the target system.
<i>Keep Home Directory of System Administrator</i>	Prevents the home directory of the source system administrator user ( <code>&lt;sid&gt;adm</code> ) from being removed.

6. Review the summary, and select `y` to finalize the configuration.

## Results

You have removed one or more new hosts from an SAP HANA system. This configuration task can also be performed in batch mode and using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

### 11.3.2.4.3 Remove Hosts Using the Web User Interface

You can remove hosts from an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) Web user interface.

## Prerequisites

- You are logged in as root user.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- If you want to remove a host that runs the coordinator name server, another host that will take over the role of the coordinator name server must be up and running.

- You have removed all tenant-specific services from the host.
- You are logged on as root user or as the system administrator user `<sid>adm`.

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing [Tools > Compatibility View Settings](#).
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release
    - Google Chrome - Latest version
  - SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
  - Mac OS - Safari 5.1 or higher

### **i** Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

### **⚠** Caution

Removing a host breaks the backup history of the database. To ensure that the database is fully recoverable, perform a full backup (data backup or storage snapshot) immediately after adding a service.

## Procedure

1. Remove tenant-specific services. For more information, see *Remove a Service from a Tenant Database* in the *SAP HANA Tenant Databases Operations Guide*.
2. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser: <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

Option	Description
	<p><b>i Note</b></p> <p>The URL is case sensitive. Make sure you enter upper and lower case letters correctly.</p>
<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"> <li>1. ## 11.3.3 Configuring Host Roles

After installation, it is possible to add and remove host roles in a single-host or multiple-host SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM).

Before you add or remove a host role, it is important to understand multiple-host system concepts, and also the SAP HANA database lifecycle manager host addition concepts. Also, be aware that changing the number of hosts may affect how you back up and recover SAP HANA.

Only component-specific host roles can be added or removed. The roles `worker` and `standby` cannot be added or removed.

An SAP HANA system can also be configured with multiple host roles on single hosts during installation using the SAP HANA database lifecycle manager. For more information about installing an SAP HANA multiple-host system, see the *SAP HANA Server Installation and Update Guide*.

### 11.3.3.1 Adding Host Roles

You can add host roles to hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program.

### Related Information

[Add Host Roles Using the Graphical User Interface \[page 1635\]](#)

[Add Host Roles Using the Command-Line Interface \[page 1636\]](#)

[Add Host Roles Using the Web User Interface \[page 1637\]](#)

## 11.3.3.1.1 Add Host Roles Using the Graphical User Interface

You can add host roles to hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the graphical user interface.

### Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcmlgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

#### i Note

To activate the local secure (LSS) store during installation, run `hdblcmlgui` with the parameter `secure_store=localsecurestore`.

3. Select [Add Host Roles](#) from the activity options. Then select [Next](#).
4. Select [Assign Roles...](#) to assign additional host roles to each host. Then select [Next](#).

Field Name	Description
<i>Role</i>	<p>Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments.</p> <ul style="list-style-type: none"> <li>○ Database Worker (worker) - A worker host (default) is used for database processing.</li> <li>○ Database Standby (standby) - A standby host is idle and available for fail-over in a high-availability environment.</li> <li>○ Database Elastic Compute Server (compute) - Database elastic compute server</li> <li>○ Dynamic Tiering Worker (extended_storage_worker) - Worker host for SAP HANA dynamic tiering</li> <li>○ Dynamic Tiering Standby (extended_storage_standby) - Standby host for SAP HANA dynamic tiering</li> <li>○ Accelerator for SAP ASE Worker (ets_worker) - Worker host for SAP HANA accelerator for SAP ASE</li> <li>○ Accelerator for SAP ASE Standby (ets_standby) - Standby host for SAP HANA accelerator for SAP ASE</li> <li>○ Streaming Analytics (streaming) - Host for SAP HANA streaming analytics</li> <li>○ XS advanced runtime worker (xs_worker) - Host for SAP HANA XS advanced runtime</li> <li>○ XS advanced runtime standby (xs_standby) - Standby host for SAP HANA XS advanced runtime</li> </ul>

5. Review the summary, and select *Run* to finalize the configuration.

### 11.3.3.1.2 Add Host Roles Using the Command-Line Interface

You can add host roles to hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface.

#### Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdbclm
```

By default, <sapmnt> is /hana/shared.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdbclm --action=add_host_roles
```

3. Select the hosts to which you would like to assign additional roles.
4. Select the additional host roles that you want to assign for each host.

Field Name	Description
role	<p>Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments.</p> <ul style="list-style-type: none"><li>◦ <code>worker</code> - A worker host (default) is used for database processing.</li><li>◦ <code>standby</code> - A standby host is idle and available for failover in a high-availability environment.</li><li>◦ <code>compute</code> - Database elastic compute server</li><li>◦ <code>extended_storage_worker</code> - Worker host for SAP HANA dynamic tiering</li><li>◦ <code>extended_storage_standby</code> - Standby host for SAP HANA dynamic tiering</li><li>◦ <code>ets_worker</code> - Worker host for SAP HANA accelerator for SAP ASE</li><li>◦ <code>ets_standby</code> - Standby host for SAP HANA accelerator for SAP ASE</li><li>◦ <code>streaming</code> - Host for SAP HANA streaming analytics</li><li>◦ <code>xs_worker</code> - Host for SAP HANA XS advanced runtime</li><li>◦ <code>xs_standby</code> - Standby host for SAP HANA XS advanced runtime</li></ul>

5. Enter the required credentials.
6. Review the summary, and select `y` to finalize the configuration.

### 11.3.3.1.3 Add Host Roles Using the Web User Interface

You can add host roles to hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the Web user interface.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).

- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing **Tools > Compatibility View Settings**.
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release
    - Google Chrome - Latest version
  - SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
  - Mac OS - Safari 5.1 or higher

### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

## Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser: <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

### i Note

The URL is case sensitive. Make sure you enter upper and lower case letters correctly.

<b>SAP HANA cockpit</b>	1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code>
-------------------------	--

Option	Description
	<p><b>i Note</b></p> <p>FQDN = fully qualified domain name</p> <ol style="list-style-type: none"> <li>Drill down on the name of the system from <a href="#">My Resources</a> or from a group.</li> <li>The links in <a href="#">Platform Lifecycle Management</a> each launch additional functionality, giving you expanded capabilities for managing the resource.</li> </ol>

- Select the [Add Host Roles](#) tile.
- Optional: Modify the following parameters in the [Advanced Parameters Configuration](#) dialog. To access the [Advanced Parameters Configuration](#) dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Do Not Start Hosts After Addition of Roles</b>	Does not start hosts after addition of roles.
<b>Do Not Modify 'etc/sudoers' File</b>	Prevents the file <code>/etc/sudoers</code> from being modified.
<b>Timeouts</b>	Sets customized timeouts ( <code>start_instance</code> , <code>start_service</code> , <code>stop_instance</code> , <code>stop_service</code> ).

- Select the hosts to which you would like to assign additional roles.
- Select the additional host roles that you want to assign for each host.

Field Name	Description
<code>role</code>	<p>Specifies the purpose of the SAP HANA host. Although multiple host roles may be assigned, check the corresponding documentation for the SAP HANA option for what configurations are supported in production environments.</p> <ul style="list-style-type: none"> <li><code>worker</code> - A worker host (default) is used for database processing.</li> <li><code>standby</code> - A standby host is idle and available for failover in a high-availability environment.</li> <li><code>compute</code> - Database elastic compute server</li> <li><code>extended_storage_worker</code> - Worker host for SAP HANA dynamic tiering</li> <li><code>extended_storage_standby</code> - Standby host for SAP HANA dynamic tiering</li> <li><code>ets_worker</code> - Worker host for SAP HANA accelerator for SAP ASE</li> <li><code>ets_standby</code> - Standby host for SAP HANA accelerator for SAP ASE</li> <li><code>streaming</code> - Host for SAP HANA streaming analytics</li> <li><code>xs_worker</code> - Host for SAP HANA XS advanced runtime</li> <li><code>xs_standby</code> - Standby host for SAP HANA XS advanced runtime</li> </ul>

- Enter the required credentials.
- Review the summary, and select [Add Roles](#) to finalize the configuration.

### 11.3.3.2 Removing Host Roles

You can remove host roles from hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program.

## Related Information

[Remove Host Roles Using the Graphical User Interface \[page 1640\]](#)

[Remove Host Roles Using the Command-Line Interface \[page 1641\]](#)

[Remove Host Roles Using the Web User Interface \[page 1642\]](#)

#### 11.3.3.2.1 Remove Host Roles Using the Graphical User Interface

You can remove host roles from hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the graphical user interface.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories `<sapmnt>` and `<sapmnt>/<SID>`.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user `<sid>adm`.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (`<sid>adm`) user may exist on the additional host. Make sure that you have the password of the existing `<sid>adm` user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, <sapmnt> is /hana/shared.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcmlgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

### i Note

To activate the local secure (LSS) store during installation, run `hdblcmlgui` with the parameter `secure_store=localsecurestore`.

3. Select [Remove Host Roles](#) from the activity options. Then select [Next](#).
4. Select [Remove Roles...](#) to remove host roles from a host. Then select [Next](#).
5. Review the summary, and select [Run](#) to finalize the configuration.

## 11.3.3.2 Remove Host Roles Using the Command-Line Interface

You can remove host roles from hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the command-line interface.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw, no_root_squash`).
- The host has access to the installation directories <sapmnt> and <sapmnt>/<SID>.
- The SAP HANA system has been installed with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on as root user or as the system administrator user <sid>adm.
- The difference between the system time set on the installation host and the additional host is not greater than 180 seconds.
- The operating system administrator (<sid>adm) user may exist on the additional host. Make sure that you have the password of the existing <sid>adm user, and that the user attributes and group assignments are correct. The SAP HANA database lifecycle manager (HDBLCM) resident program will not modify the properties of any existing user or group.

## Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdbclm
```

By default, <sapmnt> is /hana/shared.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdbclm --action=remove_host_roles
```

3. Select the hosts for which you would like to remove roles.
4. Select the host roles that you want to remove for each host.
5. Enter the required credentials.
6. Review the summary, and select **y** to finalize the configuration.

### 11.3.3.2.3 Remove Host Roles Using the Web User Interface

You can remove host roles from hosts in an SAP HANA system using the SAP HANA database lifecycle manager (HDBLCM) resident program in the Web user interface.

## Prerequisites

- The SAP HANA system has been installed with its server software on a shared file system (export options `rw,no_root_squash`).
- The host has access to the installation directories <sapmnt> and <sapmnt>/<SID>.
- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing **Tools > Compatibility View Settings**.
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release

- Google Chrome - Latest version
- SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
- Mac OS - Safari 5.1 or higher

### i Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

## Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser:  <code>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</code>

### i Note

The URL is case sensitive. Make sure you enter upper and lower case letters correctly.

<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"> <li>1. Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. <code>https://&lt;host_FQDN&gt;:&lt;port&gt;</code></li> </ol>
-------------------------	---

### i Note

FQDN = fully qualified domain name

2. Drill down on the name of the system from *My Resources* or from a group.
3. The links in *Platform Lifecycle Management* each launch additional functionality, giving you expanded capabilities for managing the resource.

2. Select the *Remove Host Roles* tile.
3. Optional: Modify the following parameters in the *Advanced Parameters Configuration* dialog. To access the *Advanced Parameters Configuration* dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Do Not Remove XS Advanced OS Users</b>	Prevents the XS advanced runtime OS Users from being removed.
<b>Do Not Start Hosts After Removal of Roles</b>	Does not start hosts after removal of roles.
<b>Do Not Modify 'etc/sudoers' File</b>	Prevents the file <code>/etc/sudoers</code> from being modified.
<b>Timeouts</b>	Sets customized timeouts ( <code>start_instance</code> , <code>start_service</code> , <code>stop_instance</code> , <code>stop_service</code> ).

4. Select the hosts for which you would like to remove roles.
5. Select the host roles that you want to remove for each host. Then select *Next*.
6. Enter the relevant credentials. Then select *Next*.
7. Review the summary, and select *Remove Roles* to finalize the configuration.

### 11.3.4 Configuring the Network for Multiple Hosts

As part of setting up a distributed system you should configure the network parameters to optimize performance. Make sure you do this before you add additional hosts because one server needs to be available so that you can connect to the SAP HANA studio.

You map host names to IP addresses by editing the section `internal_hostname_resolution` in the `global.ini` file.

General Network Layout

The figure shows a sample cluster with external addresses (10.68.22.\*) and internal (192.168.2.\*) addresses. To redirect the internal communication over the local network backbone, you could map the internal addresses to the host names of SAP HANA servers as shown in this example:

```
[communication]
listeninterface = .internal
#listeninterface = .global
#listeninterface = .local
#listeninterface = 192.168.2.0/24
[internal_hostname_resolution]
192.168.2.101 = hana01
192.168.2.102 = hana02
```

```
192.168.2.103 = hana03
```

For increased security, you can limit the binding of the processes in the `communication` section of the `global.ini` file. The option `listeninterface` can be set in one of the following ways:

- You can set it to one of the predefined keywords:
  - `.global`
  - `.internal`
  - `.local`

### **i** Note

You must include the dot at the beginning of the keyword.

- You can set it to a subnet in CIDR notation (classless inter-domain routing).

The `.global` keyword (default) lets the process bind to all interfaces. The `.local` keyword opens the communication ports for internal usage on the local interfaces (which are 127.0.0.1 in IPv4 notation). This configuration is only an option for single host installations as the server is not reachable from the outside. These two options do not require a valid `internal_hostname_resolution` section.

If you specify a keyword other than `.local`, or if you specify a list of networks in CIDR notation, the local interfaces will always be open.

With the `.internal` setup, an `internal_hostname_resolution` section is required. This configuration scans `internal_hostname_resolution` for the local address of the host. The process is bound to this address only (and to all localhost interfaces). So you should add all hosts and their respective addresses to the `global.ini` immediately after installation of the first server. The SAP HANA instance on the first server then needs to be restarted for the changes to take effect. After that, the remaining hosts may be added.

With this configuration the whole landscape uses the internal network immediately after installation. To reduce the possibility of errors, it is also possible to install the whole landscape first without SAP HANA network configuration. This lets you run tests first before you establish the network. Then the configuration options remain the same and the whole SAP HANA landscape needs to be restarted for your changes to take effect.

It is possible to monitor the network using the [Monitor Network](#) link in the SAP HANA cockpit. The [Measure Network Speed](#) link on the [Monitor Network](#) page offers the possibility to measure the network speed between the hosts in a scale-out SAP HANA database. The [Network Speed Check](#) list offers an overview of all network channels between the involved hosts starting with the slowest network connection.

## Further Information

An SAP Community blog [How to configure HANA network communication channels – Part 2: Internal network](#) gives further details of these features.

## Related Information

[Internal Host Name Resolution \[page 1213\]](#)

## 11.3.4.1 Configuring SAP HANA Inter-Service Communication

In addition to external network connections, SAP HANA uses separate, dedicated connections exclusively for internal communication. These internal communication channels can be defined using the SAP HANA database lifecycle manager.

In a multiple-host system environment, inter-service communication takes place between the hosts of a multiple-host system on one site. Certified SAP HANA hosts contain a separate network interface card that is configured as part of a private network, using separate IP addresses and ports.

To prevent unauthorized access to the database via the internal communication channels in multiple-host systems, you can isolate internal network ports from client network. To do so, you route communication between the hosts of a multiple-host environment onto a specified network and bind those internal network services exclusively to the network interface.

In addition, this feature can now be used in the presence of a secondary site (system replication scenario). However, note that additional ports used for communication between primary and secondary sites are opened on the network interface. These ports need to be protected.

### **i** Note

In single-host scenarios, the same communication channels are used for communication between the different processes on a single host. The internal IP addresses/ports are by default bound to the local interface. In multi-host scenarios, the specified network prefix must point to a network shared by all hosts. For security reasons, the network should belong to an internal network.

## Related Information

[Configure SAP HANA Inter-Service Communication Using the Graphical User Interface \[page 1647\]](#)

[Configure SAP HANA Inter-Service Communication Using the Command-Line Interface \[page 1649\]](#)

[Configure SAP HANA Inter-Service Communication Using the Web User Interface \[page 1651\]](#)

## 11.3.4.1.1 Configure SAP HANA Inter-Service Communication Using the Graphical User Interface

To prevent unauthorized access to the SAP HANA system via the internal communication channels in multiple-host systems, you can configure inter-service communication using the SAP HANA database lifecycle manager graphical user interface.

### Prerequisites

- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on with the required root user or system administrator user `<sid>adm` credentials.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the graphical user interface:

```
./hdblcmlgui
```

The SAP HANA database lifecycle manager graphical user interface appears.

#### **i** Note

To activate the local secure (LSS) store during installation, run `hdblcmlgui` with the parameter `secure_store=localsecurestore`.

3. Select [Configure Inter-Service Communication](#) from the activity options. Then select [Next](#).
4. Define the required parameters. Then select [Next](#).

Field Name	Description
<i>Inter-Service Communication</i>	<p>Specifies the listen interface for the internal network communication.</p> <p><code>global</code> - Binds the processes to all interfaces. This option does not require an internal network address entry.</p> <p><code>internal</code> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.</p> <p><code>local</code> - Opens the communication ports for internal usage on the local interfaces. This configuration is only an option for single installations as the server is not reachable from outside. This option does not require an internal network address entry.</p> <p>If you define a value other than <code>local</code>, the local interfaces will always be open.</p>
<i>Internal Network Address</i>	Specifies the internal subset address in CIDR notation.

5. Review the summary, and select *Run* to finalize the configuration.

You can find more information about SAP HANA system internal network and the network security recommendations, in the *SAP HANA Master*, *SAP HANA Security Guide*, and the Network Administration section of this *SAP HANA Administration Guide*.

## Results

You have configured the inter-service communication of an SAP HANA system. The parameter values are entered in the `global.ini` configuration file under `[communication]`.

## Related Information

[Network Administration \[page 1179\]](#)

## 11.3.4.1.2 Configure SAP HANA Inter-Service Communication Using the Command-Line Interface

To prevent unauthorized access to the SAP HANA system via the internal communication channels in multiple-host systems, you can configure inter-service communication using the SAP HANA database lifecycle manager command-line interface.

### Prerequisites

- The SAP HANA system has been installed or updated with the SAP HANA database lifecycle manager (HDBLCM).
- The SAP HANA database server is up and running.
- You are logged on with the required root user or system administrator user `<sid>adm` credentials.

### Procedure

1. Change to the SAP HANA resident HDBLCM directory:

```
cd <sapmnt>/<SID>/hdblcml
```

By default, `<sapmnt>` is `/hana/shared`.

2. Start the SAP HANA database lifecycle manager interactively in the command line:

```
./hdblcml
```

3. Select the index for the `configure_internal_network` action. Then select `Enter`.
4. Define the required parameters.

Field Name	Description
<i>Inter-Service Communication</i>	<p>Specifies the listen interface for the internal network communication.</p> <p><code>global</code> - Binds the processes to all interfaces. This option does not require an internal network address entry.</p> <p><code>internal</code> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.</p> <p><code>local</code> - Opens the communication ports for internal usage on the local interfaces. This configuration is only an option for single installations as the server is not reachable from outside. This option does not require an internal network address entry.</p> <p>If you define a value other than <code>local</code>, the local interfaces will always be open.</p>
<i>Internal Network Address</i>	<p>Specifies the internal subset address in CIDR notation.</p>

For more information about parameters for the `configure_internal_network` action, see [Related Information](#).

5. Review the summary, and select `y` to finalize the configuration.

## Results

You have configured the inter-service communication of an SAP HANA system. The parameter values are entered in the `global.ini` configuration file under `[communication]`.

This configuration task can also be performed in batch mode and using a configuration file. For more information about the available configuration methods, see *Using the SAP HANA Platform LCM Tools*.

### i Note

When using the command line, the options can be set interactively during configuration only if they are marked as interactive in the help description. All other options have to be specified in the command line. To call the help, in the SAP HANA resident HDBLCM directory of the SAP HANA system, execute the following command:

```
./hdbclm --action=configure_internal_network --help
```

You can find more information about SAP HANA system internal network and the network security recommendations, in *SAP HANA Master Guide*, *SAP HANA Security Guide*, and in the scaling SAP HANA information in the Network Administration section of this *SAP HANA Administration Guide*.

## Example

The following example configures the internal network communication with internal interface:

```
./hdbclm --action=configure_internal_network --listen_interface=internal --  
internal_address=10.66.8/21
```

## 11.3.4.1.3 Configure SAP HANA Inter-Service Communication Using the Web User Interface

To prevent unauthorized access to the SAP HANA system via the internal communication channels in multiple-host systems, you can configure inter-service communication using the SAP HANA database lifecycle manager Web user interface.

### Prerequisites

You should verify that the following prerequisites are fulfilled before trying to access the SAP HANA database lifecycle manager from a Web browser.

- The communication port 1129 is open.  
Port 1129 is required for the SSL communication with the SAP Host Agent in a standalone browser via HTTPS.
- The following Web browser requirements are fulfilled:
  - Microsoft Windows
    - Internet Explorer - Version 9 or higher  
If you are running Internet Explorer version 9, make sure that your browser is not running in compatibility mode with your SAP HANA host. You can check this in your browser by choosing **Tools > Compatibility View Settings**.
    - Microsoft Edge
    - Mozilla Firefox - Latest version and Extended Support Release
    - Google Chrome - Latest version
  - SUSE Linux - Mozilla Firefox with XULRunner 10.0.4 ESR
  - Mac OS - Safari 5.1 or higher

#### Note

For more information about supported Web browsers for the SAP HANA database lifecycle manager Web interface, see the browser support for `sap.m` library in the *SAPUI5 Developer Guide*.

- You are logged on as the system administrator user `<sid>adm`.
- The `<sid>adm` user has read and execute permissions for the directory that contains the installation medium.

### Procedure

1. Access the SAP HANA HDBLCM Web user interface.

Option	Description
<b>Web browser</b>	Enter the SAP HANA database lifecycle manager (HDBLCM) URL in an HTML5-enabled browser:

Option	Description
	<p>https://&lt;hostname&gt;:1129/lmsl/HDBLCM/&lt;SID&gt;/index.html</p> <div style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>The URL is case sensitive. Make sure you enter upper and lower case letters correctly.</p> </div>

<b>SAP HANA cockpit</b>	<ol style="list-style-type: none"> <li>Enter the URL of the SAP HANA cockpit administration and monitoring console in your browser. https://&lt;host_FQDN&gt;:&lt;port&gt;</li> </ol> <div style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>FQDN = fully qualified domain name</p> </div> <ol style="list-style-type: none"> <li>Drill down on the name of the system from <i>My Resources</i> or from a group.</li> <li>The links in <i>Platform Lifecycle Management</i> each launch additional functionality, giving you expanded capabilities for managing the resource.</li> </ol>
-------------------------	--

- Select the *Configure Inter-Service Communication* tile.
- Optional: Modify the following parameters in the *Advanced Parameters Configuration* dialog. To access the *Advanced Parameters Configuration* dialog, click on the gear icon in the footer bar of the SAP HANA HDBLCM Web user interface.

Option	Description
<b>nostart</b>	Prevents the SAP HANA system from being started.
<b>Timeouts</b>	Sets customized timeouts ( <code>start_instance</code> , <code>start_service</code> , <code>stop_instance</code> , <code>stop_service</code> ).

- Provide the password of the <sid>adm user, then select *Next*.
- Specify values for the following fields:

Field Name	Description
<i>Inter-Service Communication</i>	<p>Specifies the listen interface for the internal network communication.</p> <p><code>global</code> - Binds the processes to all interfaces. This option does not require an internal network address entry.</p> <p><code>internal</code> - Binds the processes to this address only and to all local host interfaces. This option requires an internal network address entry.</p> <p><code>local</code> - Opens the communication ports for internal usage on the local interfaces. This configuration is only an option for single installations as the server is not reachable from outside. This option does not require an internal network address entry.</p> <p>If you define a value other than <code>local</code>, the local interfaces will always be open.</p>
<i>Internal Network Address</i>	Specifies the internal subset address in CIDR notation.

- Review the summary, and select *Run* to finalize the configuration.

You can find more information about SAP HANA system internal network and the network security recommendations, in the *SAP HANA Master*, *SAP HANA Security Guide*, and the Network Administration section of this *SAP HANA Administration Guide*.

## Results

You have configured the inter-service communication of an SAP HANA system. The parameter values are entered in the `global.ini` configuration file under `[communication]`.

[Network Administration \[page 1179\]](#)

### 11.3.4.1.4 Monitoring the Network Between Multiple Hosts

For scale-out systems, it's possible to monitor network traffic between hosts using the *Monitor Network* link in the SAP HANA cockpit.

In the *Monitoring* or *All* view, on the *Database Overview* page, click *Network Monitor* on the *Monitoring* card. On the *Monitor Network* page, you can view the number of hosts and use the following tabs to monitor the network for multiple hosts:

- *Network Traffic*  
Use this tab to understand the role of each host and the size of the sent (*Request Size*) and received data (*Response Size*) between the hosts of the scale-out SAP HANA database. The sender host sends requests to the receiver host which responds. You can change the unit on the top right.
- *Network Speed Check (Internal Communication)*  
The list offers an overview of all network channels between the involved hosts starting with the slowest network connection.  
The *Measure Network Speed* link offers the possibility to measure the network speed between the hosts in a scale-out SAP HANA database. You can select the size of the package for the speed check.
- *Network Speed Check (System Replication Communication)*  
The list offers an overview of all network channels between the involved hosts in the system replication configuration.  
The *Measure Network Speed* link offers the possibility to measure the network speed between the hosts in a system replication configuration.

## 11.3.5 Scaling SAP HANA Extended Application Services, Classic Model

If you have an application based on SAP HANA XS classic, you can configure multiple SAP HANA XS instances to work in a scale out SAP HANA system.

### Context

If you are expecting a high degree of concurrency, you may want to distribute the XS classic server across the various hosts in your system. This is not enabled at the system level by default. You can manually change this setting to the system level in the Administration editor by performing the following steps.

### Procedure

1. In the Administration editor, choose the *Configuration* tab.
2. Enter the string "instances" in the Filter box.  
This search string returns a list of instances.
3. Change the instances setting to system level
  - a. Set the value of instances to "1" on the system level for `xsengine` and `sapwebdisp`.
4. Clear any entries on host level
  - a. Right-click on the green circle and choose *Delete* to clear any entries on the host level
  - b. In the *Delete Configuration Value* dialog box select the check box beside *HOST* layer and choose *Delete*.

### Related Information

[Change a System Property in SAP HANA Studio \[page 323\]](#)

[Configure HTTP Load Balancing for SAP HANA Extended Application Services, Classic Model \[page 1375\]](#)

## 11.3.6 Starting and Stopping Distributed SAP HANA Systems Using SAPControl

You can use `SAPControl` to start or stop all the hosts in a scaled-out SAP HANA system from the command line.

#### i Note

You must be logged on to the SAP system host as user `<sid>adm` or as a user with root permissions.

Action	Command
Start the system	<pre>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function StartSystem HDB</pre>
Stop the system	<pre>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function StopSystem HDB</pre>
Query current status of all hosts in the system	<pre>/usr/sap/hostctrl/exe/sapcontrol -nr &lt;instance_number&gt; -function GetSystemInstanceList</pre>

### **i** Note

HDB start or HDB stop only starts and stops the local host.

# 12 SAP HANA Deployment Infrastructure (DI) Administration

SAP HDI provides tools that enable the deployment of database artifacts to the run-time environment.

The SAP HANA Deployment Infrastructure, or HDI for short, provides a service that enables you to deploy database development artifacts to so-called containers. This service includes a family of consistent design-time artifacts for all key SAP HANA platform database features which describe the target (run-time) state of SAP HANA database artifacts, for example: tables, views, or procedures. These artifacts are modeled, staged (uploaded), built, and deployed into SAP HANA.

## ! Restriction

The HDI focuses strictly on deployment; HDI does not include any version-control tools, nor does it provide any tools for life-cycle management.

HDI provides its services using a separate database process named `diserver`. On systems where XS advanced is installed, HDI is already enabled. On systems where HDI is not already enabled, the `diserver` process must usually be enabled by the database administrator before HDI can be used. If required by the usage scenario, other database process may also need to be started as well.

In the context of SAP HANA extended application services (XS advanced), the SAP HANA service broker is used to create and drop HDI containers; each HDI container comprises a design-time container (DTC) and a run-time container (RTC). The HDI deployment tools deploy database artifacts to an HDI container. Design-time database objects are typically located in the `db/` folder of the application design-time hierarchy. The deployment process populates the database run-time with the specified catalog objects. In addition to database artifacts, HDI also enables you to import and export table content such as business configuration data and translatable texts.

## → Tip

For more information about HDI administrator roles, the tasks each HDI administrator is expected to perform, and the scope of each HDI administrator's responsibility, see *SAP HANA Deployment Infrastructure Reference* in *Related Information* below. This HDI Reference also included details of the SAP SQL API for run-time content development in HANA DI as well as the complete list of database-related design-time artifacts and the corresponding build plug-in.

## Related Information

## 12.1 SAP HANA DI Administration at a Glance

An overview of the HDI administration process including the administrator users who set up and maintain HDI and its components.

The relationships between the various roles involved in the maintenance of HDI containers and the corresponding scope of each role is shown in the following diagram:

### HDI Administration

HDI provides its services using a separate database process named `diserver`. On systems where XS advanced is installed, HDI is already enabled; on other systems where XS advanced is not installed, the `diserver` process must usually be enabled by the database administrator before HDI can be used. If required by the usage scenario, other database process may also need to be started as well.

The database administrator SYSTEM is needed for the first-time enabling of HDI in SAP HANA and for creating an HDI administrator, who then performs the tasks required to set up and maintain other HDI administrators, if required.

#### i Note

SYSTEM user privileges are required to create the first HDI administrator, who can then create other HDI administrators. After creation of the first HDI administrator, the SYSTEM user can be deactivated.

Created by the database administrator, the HDI administrator is responsible for the setup and overall maintenance of HDI. The role of the HDI administrator includes configuring general HDI parameters,

maintaining containers and container groups (for example, by creating and dropping containers and container groups), and managing container-group administrator privileges, for example, by granting and revoking HDI container-group access permissions.

The HDI container-group administrator manages a set of containers in container groups assigned by the HDI administrator. Container-group management tasks include: granting and revoking container (and container-group) **administrator** access privileges; granting and revoking container **user** access privileges (for example, for temporary support purposes); maintaining containers and container groups.

#### → Tip

The APIs of a container group “G” are in the `_SYS_DI#G` schema.

The HDI container administrator manages one or more containers assigned by the container-group administrator. The role of the container-manager focuses primarily on configuring and controlling access to the HDI containers used to store the database objects deployed by the SAP HANA Deployment Infrastructure deploy service and repairing any problems that occur with run-time objects in the assigned HDI containers. An HDI container administrator can manage one or more containers in one HDI container group or multiple containers distributed across multiple container groups.

#### → Tip

The APIs of a container “C” are in the `C#DI` schema.

## HDI Containers

The SAP HANA Deployment Infrastructure (HDI) provides a service that enables you to deploy database development artifacts to so-called containers. This service includes a family of consistent design-time artifacts for all key HANA platform database features which describe the target (run-time) state of SAP HANA database artifacts, for example: tables, views, or procedures. These artifacts are modeled, staged (uploaded), built, and deployed into SAP HANA.

#### i Note

The HDI focuses strictly on deployment; HDI does not include any version-control tools, nor does it provide any tools for life-cycle management.

The SAP HANA service broker is used to create and destroy HDI containers; each HDI container comprises a design-time container (DTC), which is an isolated environment used to store design-time files, and a run-time container (RTC), which is used to store deployed objects built according to the specification stored in the corresponding design-time artifacts.

The deployment process populates the database run-time with the specified catalog objects. In addition to database artifacts, HDI also enables you to import and export table content such as business configuration data and translatable texts.

#### ! Restriction

HDI enables you to deploy database objects only; it is not possible (or necessary) to deploy application-layer artifacts such as JavaScript programs or OData objects.

The configuration of HDI containers also involves the creation and configuration of the following design-time artifacts:

- Container deployment configuration (`.hdi.config`)  
A JSON file containing a list of the bindings between database artifact types (for example, sequence, procedure, table) and the corresponding deployment plug in (and version).
- Run-time container namespace rules (`.hdi.namespace`)  
A JSON file containing a list of design-time file suffixes and the naming rules for the corresponding runtime locations.

→ Tip

You can apply the rules defined in the `.hdi.namespace` file either exclusively to the folder it is located in or to the folder it is located in **and** its subfolders.

## HDI Container Groups

HDI container groups are logical collections of the HDI containers used to store the objects deployed by the SAP HANA Deployment Infrastructure deploy service. After creation, an HDI container group can be assigned to a dedicated container-group administrator, who must be granted the privileges required to perform the typical tasks associated with the administration of container group, for example: granting and revoking container (and container-group) access privileges; and maintaining container groups (and the containers assigned to the groups).

→ Tip

Container groups are intended to make life easier when multiple administrators require access to containers from different contexts, for example, XS advanced, ABAP, or other development groups working in native SAP HANA contexts.

The HDI administrator can create container groups for a target audience whose container-related requirements are unique or where there is an obvious benefit for a logical separation, for example, between ABAP and applications running in the XS advanced model run-time environment.

→ Tip

For more information about HDI administrator roles, the tasks each HDI administrator is expected to perform, and the scope of each HDI administrator's responsibility, see *SAP HANA Deployment Infrastructure Reference* in *Related Information* below. This HDI Reference also included details of the SAP SQL API for run-time content development in HANA DI as well as the complete list of database-related design-time artifacts and the corresponding build plug-in.

## 12.2 SAP HANA DI Administrator Roles

HDI administration involves a number of tasks that must be performed by different administrator roles.

The following table describes the scope of the various HDI administrator roles and lists the most common tasks the administrators are expected to perform.

HDI Admin Scope, Roles, and Tasks

HDI Role	Description	Common Tasks
Database administrator	The database administrator SYSTEM is needed for initially enabling HDI and for creating an HDI administrator.	<ul style="list-style-type: none"> <li>Enable HDI</li> <li>Create an HDI administrator</li> <li>Grant and revoke HDI administrator privileges</li> </ul>
<div style="background-color: #f0f0f0; padding: 10px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>SYSTEM user privileges are required to create the first HDI administrator, who can then create other HDI administrators. After creation of the first HDI administrator, the SYSTEM user can be deactivated.</p> </div>		
HDI administrator	Configures general HDI parameters, maintains containers and container groups, and manages container group administrator privileges.	<ul style="list-style-type: none"> <li>Configure HDI</li> <li>Create and drop containers and container groups</li> <li>Grant and revoke required access privileges</li> <li>Maintain containers and container groups</li> <li>Move containers between container groups</li> </ul>
HDI container-group administrator	Manages the container groups assigned by the HDI administrator. The APIs of a container group "G" are in the <code>_SYS_DI#G</code> schema.	<ul style="list-style-type: none"> <li>Grant and revoke container (and container-group) <b>administrator</b> access privileges</li> <li>Import and export containers (for support purposes)</li> <li>Grant and revoke container <b>user</b> access privileges (for support purposes)</li> <li>Maintain containers and container groups</li> </ul>

HDI Role	Description	Common Tasks
HDI container administrator	Configures and controls access to a container and manages run-time objects in the assigned containers. The APIs of a container "C" are in the C#DI schema.	<ul style="list-style-type: none"> <li>Grant and revoke container <b>administrator</b> access privileges</li> <li>Configure libraries and parameters</li> <li>Grant and revoke roles from schemas to users</li> <li>Grant and revoke user access to container schemas</li> <li>Cancel an asynchronous make operation</li> </ul>

#### → Tip

For more information about HDI administrator roles, the tasks each HDI administrator is expected to perform, and the scope of each HDI administrator's responsibility, see *SAP HANA Deployment Infrastructure Reference* in *Related Information* below. This HDI Reference also included details of the SAP SQL API for run-time content development in HANA DI as well as the complete list of database-related design-time artifacts and the corresponding build plug-in.

## Related Information

[The SAP HANA Deployment Infrastructure Reference](#)

## 12.3 SAP HANA DI Administrator Tasks

Learn how responsibility for maintenance tasks is split between SAP HANA DI (HDI) administrators.

HDI provides its services using a separate database process named `diserver`. On systems where XS advanced is installed, HDI is already enabled; on other systems where XS advanced is not installed, the `diserver` process must usually be enabled by the database administrator before HDI can be used.

#### i Note

If required by the usage scenario, other database process may also need to be started as well.

Maintaining the HDI, its containers, and container groups, involves the following high-level administration tasks:

- Enabling the HDI
  - A database administrator with SYSTEM privileges starts the HDI for the first time, creates the necessary administrator users, and assigns the new users the access privileges required to administrate the HDI.
- Maintaining the HDI
  - An HDI administrator configures HDI, creates HDI container groups, and grants and revokes the access privileges required by the HDI container-group administrators.

- Maintaining HDI containers groups  
HDI container-group administrators drop and create HDI containers, grant and revoke container (and container-group) access privileges, and import and export containers (for support purposes).
- Maintaining HDI containers  
HDI container administrators grant and revoke container-based access privileges, configure libraries and parameters, and grant and revoke access to a HDI container's schemas.

→ Tip

For more information about HDI administrator roles, the tasks each HDI administrator is expected to perform, and the scope of each HDI administrator's responsibility, see *SAP HANA Deployment Infrastructure Reference* in *Related Information* below. This HDI Reference also included details of the SAP SQL API for run-time content development in HANA DI as well as the complete list of database-related design-time artifacts and the corresponding build plug-in.

## Related Information

[The SAP HANA Deployment Infrastructure Reference](#)

## 12.4 The SQL API for SAP HANA DI

An SQL application programming interface (API) is available to help maintain the SAP HANA Deployment Infrastructure (DI).

SAP HANA Deployment Infrastructure (HDI) can be seen as a layer on top of the SAP HANA database. The HDI includes an SQL-based API that is accessible by means of standard SAP HANA SQL connection data. The following APIs are provided to help you manage and work with HDI:

SQL APIs for HDI

HDI API	Description
HDI administration API	Used mainly for managing container groups and the administrative access to them. Use of the HDI administration API requires the privileges of an HDI administrator.
	<p><b>i Note</b></p> <p>SYSTEM user privileges are required to create the first HDI administrator, who can then create other HDI administrators, if required. After creation of the first HDI administrator, the SYSTEM user can be deactivated.</p>
HDI container group administration API	Used for managing a set of containers inside a container group and the administrative access to them. To use this API, a user needs to be granted the privileges of an HDI container group administrator by an HDI administrator.

HDI API	Description
HDI container administration API	Used for configuring a container and controlling the access to it. To use this API, a user needs to be granted the privileges of an HDI container administrator by an HDI container group administrator.
HDI container content development API:	Used for enabling applications to deploy or undeploy HDI artifacts within a container and manage access to the containers. To use this API, a user must be granted the privileges of an HDI container content developer by an HDI container administrator.

### → Tip

For more information about HDI administrator roles, the tasks each HDI administrator is expected to perform, and the scope of each HDI administrator's responsibility, see *SAP HANA Deployment Infrastructure Reference* in *Related Information* below. This HDI Reference also included details of the SAP SQL API for run-time content development in HANA DI as well as the complete list of database-related design-time artifacts and the corresponding build plug-in.

## 12.5 SAP HANA DI Security

An overview of the tools used to configure and ensure security in the SAP HANA Deployment Infrastructure (HANA DI or HDI).

The following list provides an overview of the security aspects that you need to consider when setting up and using the SAP HDI infrastructure:

### i Note

For more information about an individual security area, see the *SAP HDI Administration* section of the *The SAP HANA Deployment Infrastructure Reference* in *Related information* below.

- **Technical System Landscape of SAP HDI**  
An overview of the architecture of SAP HDI and which protocols for communication between the various high-level components
- **SAP HDI Users**  
An overview of the predefined users which SAP HDI relies on and a description of each user's scope
- **SAP HDI Database Roles**  
An overview of the predefined database roles that are required to operate the SAP HANA Deployment Infrastructure (HDI) along with a description of each role

- **Data Storage Security in SAP HDI**  
An overview of the mechanisms used to secure and protect critical data managed by the SAP HDI
- **Network and Communication Security with SAP HDI**  
An overview of the security mechanisms applied to networking and communication in the context of SAP HDI
- **Security-relevant Logging and Tracing in SAP HDI**  
An overview of the auditing process, which enables you to trace the different kinds of operations performed by HDI users in the context of SAP HDI
- **Data Protection and Privacy in SAP HDI**  
An overview of SAP HDI's adherence to (and compliance with) data protection and privacy regulations
- **SAP HDI Security in the Context of XS Advanced**  
An overview of the security considerations to bear in mind when enabling SAP HDI for use in the context of SAP HANA extended application services, advanced model

### **i Note**

SAP HDI is a service layer on top of the SAP HANA platform, so information about other components in other sections of the SAP HANA Security Guide might also apply.

# 13 Application Run-Time Services

Maintain the SAP HANA XS run-time environment for XS classic and XS advanced applications.

The SAP HANA administration cockpit provides the tools you need to maintain and manage the various components of the SAP HANA XS run-time environment. Whether you are providing administration and support services for applications running in the XS classic run time or you need to set up and maintain an XS advanced run time in SAP HANA, the administration cockpit provides a selection of tools to help you perform your tasks quickly and easily.

- SAP HANA XS classic model  
Maintain and manage the various components of the SAP HANA XS classic Model (XS classic) run-time environment
- SAP HANA XS advanced model  
Maintain and manage the various components of the SAP HANA XS Advanced Model (XS advanced) run-time environment

## Related Information

[Maintaining the SAP HANA XS Classic Model Run Time \[page 1665\]](#)

[Maintaining the SAP HANA XS Advanced Model Run Time \[page 1786\]](#)

## 13.1 Maintaining the SAP HANA XS Classic Model Run Time

Maintain the SAP HANA XS classic model run-time environment.

A number of administration tools are available to enable you to maintain and manage the various components of the SAP HANA XS classic model (XS classic) run-time environment. In the SAP HANA administration cockpit, the *XS Administration* tile catalog contains the *Administration and Monitoring* tile, which contains the following tools:

### i Note

In the SAP HANA cockpit, tiles and tile catalogs are only visible to users who have been assigned the privileges granted by role `sap.hana.uis.db::SITE_DESIGNER`. In addition, some of the tools listed below are only available to users to whom the suitable role has been assigned. For example, a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator` includes the authorization required for unrestricted access to all the tools used to manage the configuration settings for SAP HANA XS application security and the related user-authentication providers; a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator` enables unrestricted access only to the *SAML Identity Providers Configuration* tools.

- [XS Artifact Administration](#)  
Monitor the system usage of the applications running in the XS Advanced Model run-time
- [SAML Service Provider](#)  
Configure an SAP HANA system to act as an SAML service provider for SSO authentication.
- [SAML Identity Provider](#)  
Configure an SAML identity provider for use by the SAML service provider to authenticate the users signing in by means of SSO.
- [SMTP Configuration](#)  
Maintain and manage details of the SMTP server that is available for use by all applications running on an SAP HANA XS classic model server.
- [Trust Manager](#)  
Configure SAML Identity providers (IDP) for SAP HANA XS classic model applications that use SAML assertions as the log-on authentication method.
- [XS Job Dashboard](#)  
Create, schedule, and manage long running operations jobs in the SAP HANA XS classic model run-time environment.

## Related Information

[SAP HANA XS Classic Administration Tools \[page 1666\]](#)

[SAP HANA XS Classic Administration Roles \[page 1668\]](#)

[SAP HANA XS Classic Configuration Parameters \[page 1671\]](#)

### 13.1.1 SAP HANA XS Classic Administration Tools

SAP HANA XS includes a Web-based tool that enables you to maintain important parts of the application-development environment, for example, security and authentication methods.

The *SAP HANA XS Administration Tool* is a Web-based tool that enables you to configure and maintain the basic administration-related elements of the application-development process and environment. The features included in the Web-based *SAP HANA XS Administration Tool* cover the following areas:

#### i Note

The availability of screens, tabs, and UI controls (for example, *Add*, *Edit*, or *Save* buttons) is based on the privileges granted in the assigned user roles. For example, a user who has a role based on the role template `sap.hana.xs.admin.roles::HTTPDestViewer` can view HTTP destinations; a user assigned a role based on the role template `sap.hana.xs.admin.roles::SQLCCAdministrator` can not only view but also **edit** SQL connection configurations.

## Administration Tools for SAP HANA XS Applications

Tool Name	Description	Scope
<i>XS Artifact Administration</i>	Maintain runtime configurations for individual applications or a complete application hierarchy. The configuration defined for an application is inherited by any application further down the application package hierarchy.	<ul style="list-style-type: none"> <li>• Application security (public/private)</li> <li>• User-authentication methods (basic, form-based, logon tickets, X509, SAML)</li> <li>• CORS setup for cross-origin resource sharing</li> <li>• Custom headers: enable support for X-Frame-Options HTTP header</li> <li>• HTTP destinations</li> <li>• SQL connection configurations (for SQL connections for users other than the user specified in the HTTP request).</li> </ul>
<i>SAML Service Provider</i>	Configure an SAP HANA system to act as an SAML service provider for SSO authentication.	<ul style="list-style-type: none"> <li>• Management of SAML <b>service</b>-providers, including URLs and meta-data management</li> </ul>
<i>SAML Identity Provider</i>	Configure an SAML identity provider for use by the SAML service provider to authenticate the users signing in by means of SSO.	<ul style="list-style-type: none"> <li>• Management of SAML <b>identity</b>-providers, including IDP metadata, certificates, and destinations</li> </ul>
<i>SMTP Configuration</i>	Define the details of the SMTP server that is available for use by all applications running on an SAP HANA XS server.	<ul style="list-style-type: none"> <li>• SMTP host settings</li> <li>• Authentication type</li> <li>• Transport security</li> </ul>
<i>Trust Manager</i>	Maintain the certificates used to establish trust relationships between servers used by SAP HANA XS applications.	<ul style="list-style-type: none"> <li>• Trust store configuration and management</li> <li>• Certificate management</li> </ul>
<i>XS Job Dashboard</i>	Monitor and maintain SAP HANA XS job schedules defined using the XS job syntax	<ul style="list-style-type: none"> <li>• Enable the job scheduler</li> <li>• Monitor job-schedule status</li> <li>• Display and maintain schedule's runtime configuration</li> <li>• Add schedules to (or delete from) an XS job</li> </ul>

## Additional Tools in SAP HANA XS Classic

The following table lists some tools that are not strictly part of the SAP HANA XS Administration tool set. The tools are included here primarily for the sake of convenience but also because the tools are installed with the delivery unit which contains the XS Administration tools.

## Translation Text Details

Tool Name	Description	Scope
<a href="#">Online Translation Tool</a>	Maintain translations, for example, for UI text elements	<ul style="list-style-type: none"><li>• Add, modify, delete translation texts</li><li>• Export translation text from SAP HANA to an XML-based xliif-format file</li><li>• Import translation text into SAP HANA.</li></ul>
<a href="#">User Self Service Tools</a>	A set of tools that enable you to maintain user self-service requests and administrate the self-service tools themselves.	<ul style="list-style-type: none"><li>• Activate the user self-service tools</li><li>• Maintain user self-service requests</li><li>• Maintain user black/white lists</li><li>• Maintain user self-service e-mail templates</li></ul>

## Related Information

## 13.1.2 SAP HANA XS Classic Administration Roles

SAP HANA uses roles to control access to the Web-based tool that enable you to maintain important parts of the application-development environment, for example, security and authentication methods.

When using the Web-based tools provided by SAP HANA XS, the availability of features, screens, tabs, and UI controls (for example, *Add*, *Edit*, or *Save*, or *Delete* buttons) is based on privileges. For the sake of convenience, the specific privileges required to use the features provided with a particular tool have been collected into a selection of predefined roles, which you can use as templates to create your own roles and assign to the user who wants to use a tool. For example, a user assigned a role based on `sap.hana.xs.admin.roles::HTTPDestViewer` can display HTTP destinations but not change them in any way; a user assigned a role based on `sap.hana.xs.admin.roles::SQLCCAdministrator` can view SQL connection configurations and modify them, too.

### → Recommendation

As repository roles delivered with SAP HANA can change when a new version of the package is deployed, either do not use them directly but instead as a template for creating your own roles, or have a regular review process in place to verify that they still contain only privileges that are in line with your organization's

security policy. Furthermore, if repository package privileges are granted by a role, we recommend that these privileges be restricted to your organization's packages rather than the complete repository. To do this, for each package privilege (`REPO.*`) that occurs in a role template and is granted on `.REPO_PACKAGE_ROOT`, check whether the privilege can and should be granted to a single package or a small number of specific packages rather than the full repository.

#### SAP HANA XS Administration Tools Roles

SAP HANA XS Role	Description
HTTPDestAdministrator	Full access to the details of HTTP destination configurations (display and edit)
HTTPDestViewer	Read-only access to HTTP destination configurations, which are used to specify connection details for outbound connections, for example, using the server-side JavaScript Connectivity API that is included with SAP HANA XS.
RuntimeConfAdministrator	Full access to the configuration settings for SAP HANA XS application security and the related user-authentication providers.
RuntimeConfViewer	Read-only access to the configuration settings for SAP HANA XS application security and the related user-authentication providers, for example, SAML or X509.
JobAdministrator	Full access to the configuration settings for SAP HANA XS job schedules (defined in <code>.xsjob</code> files); you can specify start/stop times, the user account to run the job, and the language locale.
JobViewer	Read-only access to the configuration settings for SAP HANA XS job schedules (defined in <code>.xsjob</code> files).
JobScheduleAdministrator	Full access to the <i>XS Job Dashboard</i> tool, which you can use to add and delete XS job schedules, maintain individual schedules, and enable the scheduling feature.
oAuthAdmin	Required when setting the client secret during administration of the OAuth client configuration ( <code>.xsoauthclientconfig</code> ) artifact.
SAMLAdministrator	Full access to the details of SAML configurations, including both the service provider and the identity providers. You can add new entries and make changes to existing service or identity providers and parse the resulting metadata.
SAMLViewer	Read-only access to SAML configurations, which are used to provide details of SAML service providers and identity providers.
SMTPDestAdministrator	Full access to the details of SMTP destination configurations, which are used to define details of the SMTP relay server that SAP HANA XS applications use to send e-mails. The administrator role enables you to add new entries and make changes to an existing configuration, for example, the host name and port number, logon credentials and authentication type, and any transport security settings.
SMTPDestViewer	Read-only access to SMTP destination configurations, which are used to define details of the SMTP relay server that SAP HANA XS applications can use to send e-mails.
SQLCCAdministrator	Full access to the details of SQL connection configurations (SQLCC).
SQLCCViewer	Read-only access to SQL connection configurations (SQLCC), which are used to enable the execution of SQL statements from inside your server-side JavaScript application with credentials that are different to the credentials of the requesting user.
TrustStoreAdministrator	Full access to the SAP HANA XS <i>Trust Manager</i> tool, which the administrator uses to maintain secure <b>outbound</b> communication, for example, the SSL/TLS certificates required by SAP HANA XS applications that connect to an ABAP system.

SAP HANA XS Role	Description
TrustStoreViewer	Read-only access to the trust store, which contains the server's root certificate or the certificate of the certification authority that signed the server's certificate.

## Additional SAP HANA XS Roles

The following table lists roles for tools that are not strictly part of the SAP HANA XS Administration toolset. The roles are included here for the sake of convenience and because the roles, and the tools to which they correspond, are (with the exception of the *WebDispatcherAdmin/Viewer*) installed with the delivery unit which contains the XS Administration tools.

Additional Roles for SAP HANA XS Administration Tools

SAP HANA XS Role	Description
translator	The role <i>sap.hana.xs.translationTool.roles::translator</i> enables an SAP HANA user to maintain translation text strings with the SAP HANA Online Translation Tool.
USSAdministrator	The role <i>sap.hana.xs.selfService.admin.roles::USSAdministrator</i> is assigned to the user responsible for administrating the requests sent by users using self-service tools. For example, it enables the activation of users who request a new user account in the SAP HANA database and allows the user-self-service administrator to manage self-service-specific blacklists for users, e-mail addresses, domains, and IP addresses.
USSExecutor	The role <i>sap.hana.xs.selfService.user.roles::USSExecutor</i> is assigned to the technical user that is used to respond to and execute user-self-service requests, for example, to create a new account or request a new password.
WebDispatcherAdmin	The role <i>sap.hana.xs.wdisp.admin::WebDispatcherAdmin</i> enables full access to the SAP HANA <i>Web Dispatcher Administration</i> tool, which the administrator uses to maintain secure <b>inbound</b> communication, for example, to enable SSL/TLS connections between an ABAP system and an SAP HANA XS application.
WebDispatcherMonitor	The role <i>sap.hana.xs.wdisp.admin::WebDispatcherMonitor</i> enables read-only access to the information displayed in the SAP HANA <i>Web Dispatcher Administration</i> tool.
WebDispatcherHTTPTracingViewer	Read-only access to the HTTP setting of SAP HANA XS applications running on the selected SAP HANA instance. This role extends the <i>JobViewer</i> role to enable the user to view details of the <i>xsjob</i> configuration ( <i>httptracing.xsjob</i> ) that starts and stops the HTTP tracing tasks.
WebDispatcherHTTPTracingAdministrator	Full access required to maintain HTTP tracing on the SAP Web Dispatcher for SAP HANA XS applications. This role extends the <i>JobAdministrator</i> role to enable the user to maintain the XS job file ( <i>httptracing.xsjob</i> ) used to configure and enable HTTP tracing for XS applications on the SAP Web Dispatcher.

## 13.1.3 SAP HANA XS Classic Classic Configuration Parameters

An overview of the parameters that the administrator can set to configure how the various components of the XS engine work.

The `xsengine.ini` section of the SAP HANA configuration screen is split into a number of subsections, each of which reflects one of the individual components of the SAP HANA XS engine. Each section contains one or more parameters whose values you can change, where appropriate, to suit the requirements of your system landscape. To display the configuration details of the XS engine in SAP HANA studio, double-click a system in the *Systems* view, choose the *Configuration* tab, and expand the *xsengine.ini* element.

### Note

For security reasons, all parameters in the `communication` section of **all** `.ini` configuration files are blacklisted by default; properties included in a blacklist can only be changed by a system administrator. For more information, see *Default Blacklisted System Properties* in the *SAP HANA Administration Guide*.

XS Engine Configuration Parameters (xsengine.ini)

Configuration Section	Description
<a href="#">application_container [page 1672]</a>	Application-related configuration settings, for example, the list of applications that are trusted by the XS engine or the libraries that can be loaded from an <code>xsconfunc</code> call.
<a href="#">authentication [page 1672]</a>	Options for application-related authentication settings, for example, the location of trust stores.
<a href="#">communication [page 1672]</a>	Options for application-related connection requests and configuration, for example, time-outs, port numbers, and maximum number of data end points allowed by the XS engine
<a href="#">customer_usage [page 1673]</a>	Options for customer-specific usage scenarios in SAP HANA application services, for example, to enable HTTP tracing of XS applications on the SAP Web Dispatcher.
<a href="#">debugger [page 1673]</a>	Settings for the debugging tools, for example, for XS JavaScript.
<a href="#">httpservlet [page 1674]</a>	Options for the SAP HANA XS Web server, for example, port numbers, and maximum number of sessions and threads allowed
<a href="#">odata [page 1675]</a>	Configuration settings for OData requests
<a href="#">scheduler [page 1675]</a>	Configuration options for the XS job scheduler, which is used to run an XS Javascript or SQLScript as a task in the background at regular intervals

### Note

Some configuration parameters for the SAP HANA XS engine require additional parameters to be set for other SAP HANA components, for example, the SAP Web Dispatcher.

SAP Web Dispatcher Configuration Parameters (webdispatcher.ini)

Configuration Section	Description
<a href="#">webdispatcher.ini/profile [page 1675]</a>	Configuration options for the SAP Web Dispatcher, for example: HTTP tracing of SAP HANA XS applications, logs, allowed connections

## application\_container

Use the `application_container` section of the `xsengine.ini` file to set configuration options for the application container component of the SAP HANA XS engine, which includes not only the XS application container, but also containers for C++ and JavaScript applications. In this section of the `xsengine.ini` file, you can modify the list of applications that are trusted by the XS engine or the libraries that can be loaded from an `xscfunc` call.

Parameter	Description	Example Value	Default Value
<code>application_list</code>	Comma-separated list of libraries that can be loaded from an <code>xscfunc</code> call	<code>libxsdxs, InformationAccess</code>	<code>libxsdxs, InformationAccess, libtrustmanager, libxsauthenticator, libxsbase</code>

## authentication

Use the `authentication` section of the `xsengine.ini` file to set configuration options for application-related authentication settings, for example, the system ID and hostname of the server providing SAP logon certificates for single sign-on (SSO) purposes.

Parameter	Description	Example Value	Default Value
<code>logonticket_redirect_url</code>	URL that is used to redirect the client to a system that provides SAP logon tickets for SSO authentication	<code>http://link.to.portal/loginService</code>	None

## communication

Use the `communication` section of the `xsengine.ini` file to set configuration options for application-related connection requests to SAP HANA, for example, timeouts, port numbers, and maximum number of data end points allowed by the XS engine.

Parameter	Description	Example Value	Default Value
<code>default_read_timeout</code>	Time (in milliseconds) before a connection request is closed	<code>-1, 30, 60</code>	<code>-1</code> (no time set)
<code>default_read_timeout_override</code>	Ignore setting for <code>default_read_timeout</code>	No, Yes	Yes
<code>listenport</code>	The port number on which the XS Web server listens for requests	<code>30007</code>	<code>3\$(SAPSYSTEM)07</code>

Parameter	Description	Example Value	Default Value
enforced_http_proxy	Override the outgoing proxy settings used for the HTTP/S client, for example, defined in an HTTP/SMTP destination configuration or an <code>httpClient.request()</code> method.	myhost.name.com	None
enforced_https_proxy		myhost.name.com	None
enforced_outbound_proxy	Set the proxy not just for HTTP and HTTPS but for <b>all</b> outgoing protocols, for example: SMTP, socks, ...	myhost.name.com	None
maxchannels	Maximum number of concurrent channels allowed by the XS Web server	Unsigned integer, for example, 1000	4000
maxendpoints	Maximum number of concurrent data endpoints that the XS Web server can expose	Unsigned integer, for example, 1000	4000

## customer\_usage

The `customer_usage` section of the `xsengine.ini` file is used by the *SAP Web Dispatcher HTTP Tracing* tool to set configuration for SAP HANA application services, for example, to enable HTTP tracing of XS applications on the SAP Web Dispatcher.

Parameter	Description	Example Value	Default Value
<code>/path/to/the/XSapp</code>	The fully qualified path to (and the name of) the application to be traced, for example, <code>sap.hana.ide</code> or <code>sap.hana.xs.admin</code> .	<code>icm/HTTP/logging_n</code>	N/A  The parameter <code>/path/to/XSapp</code> is set (or removed) automatically when the administrator uses the <i>XS Admin Tools</i> to enable (or disable) HTTP tracing on the SAP Web Dispatcher for an application.

**→ Tip**

The parameter value `icm/HTTP/logging_n` is the same as the key defined in the `webdispatcher.ini/profile` section of the configuration parameters, and "n" must be a unique number.

## debugger

Use the `debugger` section of the `xsengine.ini` file to set configuration options for the SAP HANA XS JavaScript debugging tools.

Parameter	Description	Example Value	Default Value
enabled	Enable debugging functionality	True/False	False

## httpserver

Use the `httpserver` section of the `xsengine.ini` file to set configuration options for the SAP HANA XS Web server, for example, port numbers, and maximum number of sessions and threads allowed.

Parameter	Description	Example Value	Default Value
developer_mode	Enable verbose output for HTTP codes/messages	True/False	False
embedded	Enable the SAP HANA XS engine to run in embedded mode (in the index server). See SAP Note <a href="#">1849775</a> .	True/False	False
login_screen_background_image	URL to the image displayed as background in the logon screen, with the following prerequisites: <ul style="list-style-type: none"> <li>• File must be reachable by http(s)</li> <li>• No requirement for authentication or authorization</li> <li>• Recommended minimum resolution of image: 1600*1200</li> <li>• A technical user has to be assigned to the XSSQLCC artifact <code>/sap/hana/xs/selfService/user/selfService.xsSQLCC</code>. The technical user must be assigned the role <a href="#">sap.hana.xs.selfService.user.roles.USSExecutor</a>. This user will be used to query the details from the server.</li> </ul>	<code>/sap/hana/xs/ui/Image.jpg</code>	None
max_message_size_mb	Maximum allowed size (in megabytes) of an HTTP request or response	Unsigned integer, for example, 10	100
max_request_runtime	Maximum runtime (in seconds) of an HTTP request targeting an XSJS application. Can be extended in case of long-running database operations.	Unsigned integer, for example, 10	300
maxsessions	Maximum number of registered sessions, not including unauthenticated sessions that are not being debugged	Unsigned integer, for example, 10000	50,000
root_page	Enables requests to the root URI <code>/</code> to be redirected to the URI set with this parameter	<code>/sap/xs/path/root.html</code>	None
sessiontimeout	Amount of time (in seconds) before an inactive session is closed	Unsigned integer, for example, 60	900

## odata

Use the `odata` section of the `xengine.ini` file to set configuration options for OData requests.

Parameter	Description	Example Value	Default Value
<code>allow_nullable_keys</code>	Specify if "key" entity elements can ( <code>null</code> ) or cannot ( <code>not null</code> ) have the value <code>NULL</code> .	<code>True/False</code>	<code>False</code>

## scheduler

Use the `scheduler` section of the `xengine.ini` file to set configuration options for the XS job scheduler, which is used to run an XS Javascript or SQLScript as a task in the background at regular intervals

Parameter	Description	Example Value	Default Value
<code>enabled</code>	Activate the XS job-scheduler service. Set to <code>true</code> on one XS host only; this enables <code>xsjob</code> scheduling for the selected instance	<code>True/False</code>	<code>False</code>
<code>sessiontimeout</code>	The amount of time (in seconds) to wait for a job to complete	<code>300 seconds</code>	<code>900 seconds</code>
<code>disable_job_after_restarts</code>	The maximum number of unsuccessful attempts to start a job before the job schedule is automatically disabled	<code>3</code>	<code>5</code>

## webdispatcher.ini/profile

Use the `profile` section of the `webdispatcher.ini` file to set configuration options for customer-specific usage scenarios in SAP HANA application services, for example, to enable HTTP tracing of XS applications on the SAP Web Dispatcher.

Parameter	Description	Example Value	Default Value
icm/HTTP/logging_n	<p>Defines the application-specific log, where “_n” is a unique number. The key's value defines the following:</p> <ul style="list-style-type: none"> <li>• PREFIX= the fully qualified path to (and the name of) the application to be traced, for example, <code>sap.hana.xs.admin</code></li> <li>• LOGFILE= the location of the log file used to store the trace information; the location includes a variable for the application's name (<code>access_log_app-</code>) and the year, month, and day (<code>%y-%m-%d</code>)</li> <li>• MAXSIZEKB= the maximum allowed size and format of the trace file</li> <li>• SWITCHTF=the time of the day when the new log file is created (DAY/NIGHT)</li> <li>• LOGFORMAT= the format of the trace file content, for example: CLF (common log format), CLFMOD (modified CLF), SAP (SAP log file format), SAPSMD, ...</li> <li>• FLUSH=enable or disable the log flush mechanism</li> </ul>	<pre>PREFIX=/sap/hana/ide/, LOGFILE=\$( _LOCAL_HOST_NAME) / trace/ access_log_sap.hana.ide -%y-%m-%d, MAXSIZEKB=10000 SWITCHTF=day, LOGFORMAT=SAP, FLUSH=1</pre>	<p>N/A</p> <p>The parameter <code>icm/HTTP/logging_n</code> is set (or removed) automatically when the administrator uses the <i>XS Admin Tools</i> to enable (or disable) HTTP tracing on the SAP Web Dispatcher for an application.</p>

→ Tip

The parameter `icm/HTTP/logging_n` is also used as the value for the key defined in the `customer_usage` section of the `xsengine.ini` file.

## 13.1.4 Maintaining Application Runtime Configurations

Application runtime configurations specify the security measures that are implemented for access to applications.

The *SAP HANA XS Administration Tool* includes the *XS APPLICATIONS* tool, which you can use to create and maintain runtime configurations for individual applications or a complete application hierarchy. The configuration defined for an application is inherited by any application further down the application package hierarchy. A runtime configuration takes precedence over any runtime configuration located in an application package above it in the package hierarchy.

### Note

SAP HANA uses roles to grant access to the features provided by the *SAP HANA XS Administration Tool*. To access the tools required to configure SAP HANA XS runtime configurations, you must have a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator` assigned.

You can maintain the following aspects of the application runtime configuration:

### → Tip

Runtime configuration settings override any settings in the application's corresponding application-access (`.xsaccess`) configuration file.

- Application security  
Enable/Disable user-authentication checks when starting an application
- User authentication methods (SAML, SPNego, X509, logon tickets, ...)  
Enable one or more authentication methods that applications use to authenticate user requests for content.
- Cross Origin Request Sharing (CORS)  
Enable support for cross-origin requests, for example, by allowing the modification of the request header. Allowing the sharing of cross-origin resources permits Web pages to make HTTP requests to another domain, where normally such requests would automatically be refused by the Web browser's security policy.
- Custom Headers  
Enable support for the X-Frame-Options HTTP header field, which allows the server to instruct the client browser whether or not to display transmitted content in frames that are part of other Web pages. You can also enable this setting in the application's corresponding `.xsaccess` configuration file.
- SQL connection configurations (SQLCC)  
Edit the details of an SQL connection configuration, which you use to enable the execution of SQL statements from inside your server-side JavaScript application with credentials that are different to the credentials of the requesting user
- HTTP destination configurations  
Edit the details of an HTTP destination configuration, which you use to defines connection details for services running on a specific host, whose details you want to define and distribute
- XS Job Schedules

Edit the details of an XS Job, for example to set the user account under which the job runs, define a start or stop time, and browse the job's log files.

### 13.1.4.1 Create an Application Runtime Configuration

For SAP HANA XS applications, the runtime configuration defines the security and authentication settings to use when granting access to an application of the content it exposes.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the [SAP HANA XS Administration Tool](#). For example, to access the tools required to perform any tasks relating to application runtime configuration, you must have a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator`.

## Context

The runtime configuration for an SAP HANA XS application specifies the settings the application uses when it is launched, for example, in response to a user request. If the same settings you define in a runtime configuration are also defined in a design-time file but with a different value, the runtime configuration takes precedence. To create a runtime configuration for an SAP HANA XS application, perform the following steps:

## Procedure

1. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who

logs on must have the privileges required to perform administration tasks with the *XS Administration Tools*.

2. Start the SAP HANA *XS Artifact Administration* tool.  
In the *Runtime Configuration Details* page you can maintain details of the runtime configurations for the various applications in your package hierarchy.
3. Define the runtime configuration for your application.

#### **i** Note

The runtime configuration you define is inherited by all sub-packages in the package hierarchy.

- a. Configure the application security:

Choose the *Edit* button in the *Security & Authentication* tab to can configure the following security options:

- *Public (no authentication required)*  
Enable/Disable authentication for application requests.

#### → Tip

If you **disable** authentication in the *Security and Authentication* panel, the *Authentication Types* options (for example, SAML or logon tickets) are hidden.

- *Force SSL*  
Enable the force SSL option if you want the application to refuse browser requests that do not use secure HTTP (SSL/HTTPS) for client connections.

#### **i** Note

The setting for this runtime option overrides the design-time setting for the *force\_ssl* keyword in the application's `.xsaccess` file.

- *Prevent Public Access for Sub-Packages*  
Ensure that public access only applies to the current package; all subpackages are hidden.

#### **i** Note

This option is not available for packages shipped with SAP HANA.

- b. Configure the methods the applications must use to authenticate users.

The *Authentication Types* list is only visible if the *Public (no authentication required)* option is disabled.

#### **i** Note

You can select multiple authentication methods which are used in a specific order of priority, for example: first SAML, then logon tickets, and if the user-logon fails for both methods, then basic logon is offered.

To ensure that, during the authentication process, the password is transmitted in encrypted form, it is strongly recommended to enable SSL/HTTPS for all application connections to the XS engine.

- c. Enable support for cross-origin request sharing (CORS), if required.

The *CORS* tab enables you to allow the sharing of cross-origin resources; this permits Web pages to make HTTP requests to another domain, where normally such requests would automatically be refused by the Web browser's security policy.

- d. Enable support for custom headers, if required.

Use the *Custom Headers* tab to configure support for custom headers in the response. This feature enables you to set X-Frame options that allow frames in a Web page to display content from another Web site.

Check the option *Enable Custom Headers* and choose the one of the entries in the list of *X-Frame Options*, for example:

- DENY
- SAMEORIGIN
- ALLOW-FROM <URL>

You can only specify one URL with the ALLOW-FROM option, for example: "value": "ALLOW-FROM http://www.site.com".

#### **i** Note

To allow an application to use custom headers, you must enable the *Custom Headers* option.

4. Save the runtime configuration.

#### **i** Note

Use the *Reset* button to reset the runtime configuration to its previous state; use the *Revert* button to undo changes to the runtime-configuration options in the current tab.

## Related Information

[Application Runtime Configuration Details \[page 1680\]](#)

[Configure HTTPS \(SSL\) for Client Application Access \[page 1715\]](#)

### 13.1.4.1.1 Application Runtime Configuration Details

In the *XS Artifact Administration* tool, the *Runtime Configuration Details* tab displays information about runtime settings configured for the currently selected application or artifact. You can use the *Runtime Configuration Details* tab to maintain the following details of the runtime configuration:

- [Security & Authentication \[page 1680\]](#)
- [CORS \[page 1681\]](#)
- [Custom Headers \[page 1682\]](#)

## Security & Authentication

The *Security & Authentication* tab in the *Runtime Configuration Details* tool enables you to view details of the security settings defined to control access to an application service running on SAP HANA, for example, the

type of access allowed (user/public) and the method used to authenticate users. The following table indicates which information can be defined.

#### Security and Authentication Details

UI Element	Description	Example
<a href="#">Authentication Type</a>	Enables/Disables requirement for user authentication to access an application service. If you <b>enable</b> authentication, you must select the methods that the application applies to authenticate users, for example, SAML or logon tickets.	Public (No Authentication Required)
<a href="#">Connection Security</a>	Allows only secure HTTPS access to an application; insecure standard HTTP requests are refused. To ensure that passwords are transmitted in encrypted form during the authentication process, it is strongly recommended to enable SSL/HTTPS for all application connections to the XS engine. If you set the <i>force_ssl</i> option, you must ensure that the SAP Web Dispatcher is configured to accept and manage HTTPS requests.	SSL Enforced
<a href="#">Public Access for Sub-Packages</a>	Enables public access to sub packages in an application package hierarchy. This setting cannot be changed for packages shipped with SAP HANA.	Allowed
<a href="#">Authentication Methods</a>	Defines one of more methods that the application service uses to authenticate users requesting access. If multiple methods are selected, an order of priority applies: from most to least secure, for example, <i>SAML</i> , <i>Form Based</i> , and then <i>Basic</i> .	SAML, X509
<a href="#">SAML Identity Provider</a>	The name of the SAML IDP used to verify SAML certificates; this setting is only required if SAML is chosen as one of the authentication methods. <i>Not Applicable</i> indicates that no SAML IDP is configured.	SAMLIDP1

## CORS

The *CORS* tab in the *Runtime Configuration Details* tool enables you to view details of the settings defined to control access to your application resource from other Web browsers. For example, you can specify where requests can originate from or what is allowed in the request and response headers. The following table indicates which information can be defined for Cross Origin Resource Sharing.

#### CORS Settings

CORS Option	Description
<a href="#">Cross Origin Resource Sharing</a>	Enable/Disable requests from other browser sessions to an application.
<a href="#">ALLOWED ORIGINS</a>	A single host name or a comma-separated list of host names that are allowed by the server, for example: <code>www.sap.com</code> or <code>*.sap.com</code> . If no host is specified, the default <code>**</code> (all) applies. Note that matching is case-sensitive.
<a href="#">ALLOWED HEADERS</a>	A single header or a comma-separated list of <b>request</b> headers that are allowed by the server. If no request header is specified, no default value is supplied.

CORS Option	Description
<a href="#">EXPOSED HEADERS</a>	A single header or a comma-separated list of <b>response</b> headers that are allowed to be exposed. If no response header is specified for exposure, no default value is supplied.
<a href="#">ALLOWED METHODS</a>	A single permitted method or a comma-separated list of methods that are allowed by the server, for example, "GET", "POST". If no method is specified, the default "GET", "POST", "HEAD", "OPTIONS" (all) applies. Note that matching is case-sensitive.
<a href="#">MAX AGE</a>	A single value specifying how long a preflight request should be cached for. If no value is specified, the default time of "3600" (seconds) applies.

## Custom Headers

The [Custom Headers](#) tab in the [Runtime Configuration Details](#) tool enables you to configure support for custom headers in the HTTP response. This feature enables you to set X-Frame options that allow frames in a Web page to display content from another Web site.

Custom Headers Details

UI Element	Description	Example
<a href="#">Custom Headers</a>	Enable/Disable the use of custom headers in HTTP response.	Disabled
<a href="#">X-Frame Options</a>	Allow/Deny requests to display content from the same or another Web site. Note that you can only specify <b>one</b> URL with the ALLOW-FROM option, for example: "value": "ALLOW-FROM http://www.site.com".	DENY, SAMEORIGIN, ALLOW-FROM

## Related Information

[Create an Application Runtime Configuration \[page 1678\]](#)

### 13.1.4.2 Edit an SQL Connection Configuration

In SAP HANA Extended Application Services (SAP HANA XS), you use the SQL connection configuration to enable the execution of SQL statements from inside your server-side JavaScript application with credentials that are different to the credentials of the requesting user.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the [SAP HANA XS Administration Tool](#). For example, to access the tools required to perform any tasks relating to SQL connection

configuration (SQLCC), you must have a role based on the role template `sap.hana.xs.admin.roles::SQLCCAdministrator`. This role includes the related role `sap.hana.xs.admin.roles::SQLCCViewer`

## Context

The SQL connection configuration enables the execution of SQL statements from inside your server-side JavaScript application with credentials that are different to the credentials of the requesting user. You can use the *XS Artifact Administration* tool to change the user name in the XS SQL connection-configuration file.

## Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *XS Artifact Administration* tool.

2. Start the SAP HANA *XS Artifact Administration* tool.

In the *XS Artifact Administration* tool you can manage the runtime configurations for the various applications in your package hierarchy.

3. Locate the SQL connection configuration object.

In the *Application Objects* list, locate and select the object containing the SQL connection configuration that you want to edit; SQL connection configuration objects have the file extension `.xssqlcc`. The details are displayed in the *SQL Connection Details* panel.

4. Maintain the SQL connection details.

The *SQL Connection Details* allows you to modify details of the database user whose credentials are used to establish the SQL connection defined in the SQLCC object. If a role is specified in the `role_for_auto_user` parameter, SAP HANA assigns the role defined in `role_for_auto_user` to the new auto-generated user.

### i Note

If you bind the XS SQL connection to a specific existing database user (not the auto user), you must provide the user's password. If do not provide a password for the specified database user, you cannot save the changes to the SQLCC object's runtime configuration.

5. Set the run-time status of the XS SQL connection configuration.

You must set the runtime status of the XS SQL connection configuration to *Active*; the run-time status can only be changed by an administrator. When the run-time status of the XSQL connection configuration is

set to *active*, SAP HANA automatically generates a new user (`XSSQLCC_AUTO_USER_...`) for the XSSQL connection configuration object and assigns the role defined in `role_for_auto_user` to the new auto-generated user.

6. Save the changes.

## Related Information

[SQL Connection Details \[page 1684\]](#)

### 13.1.4.2.1 SQL Connection Details

The SQL-connection configuration file specifies the details of a connection to the database.

The database connection established by the SQL-connection configuration file enables the execution of SQL statements with credentials that are different to the credentials of the requesting user, for example, from inside a server-side (XS) JavaScript application.

The *SQL Connection Details* tab in the *XS Artifact Administration* tool enables you to view details of the XS SQL connection configurations that you have defined, for example, the package location, and the user bound to the SQL connection. The following table indicates which information can be viewed.

SQL Connection Details

UI Element	Description	Example
<i>Package</i>	The name of the repository package containing the currently selected SQL connection configuration	testApp
<i>Description</i>	A short description of the selected SQL connection configuration	Admin SQL connection
<i>Username</i>	The name of the user to whom you want to bind the SQL connection configuration. If no user is specified, SAP HANA automatically generates the user <code>XSSQLCC_AUTO_USER_...</code> when the run-time status of the XSSQL connection configuration is set to <i>Active</i> . The new auto-user is assigned the role specified in <i>Role for Auto User</i> . If you bind the SQL connection manually to a specific SAP HANA user, you must supply the user's password to enable a connection to be established <b>and</b> ensure that the user has the necessary privileges (for example, by assigning a role).	XSSQLCC_AUTO_USER[...]
<i>Password</i>	The password for the user bound to the SQL connection configuration. A password is not required for the automatically generated <code>XSSQLCC_AUTO_USER_...</code> .	*****
<i>Assigned by</i>	The name of the user who assigned the user defined in <i>Username</i> to the currently selected SQL connection configuration	JohnDoe

UI Element	Description	Example
<i>Role for Auto User</i>	The name of (and package path to) the role to be assigned to the new auto-user that is generated when the run-time status of the XSSQL connection configuration is set to <i>active</i>	acme.com.xs.roles::JobAdministrator
<i>Status</i>	The current runtime status of the XSSQL connection configuration (active/inactive)	active

## Related Information

[Edit an SQL Connection Configuration \[page 1682\]](#)

### 13.1.4.3 Edit an HTTP Destination Runtime Configuration

An HTTP destination defines connection details for services running on a specific host, whose details you want to define and distribute. The HTTP destination can be referenced by an application.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the [SAP HANA XS Administration Tool](#). For example, to access the tools required to perform any tasks relating to HTTP destination configuration (HTTPDest), you must have a role based on the role template `sap.hana.xs.admin.roles::HTTPDestAdministrator`.

## Context

To edit an HTTP destination using the [SAP HANA XS Administration Tool](#), perform the following steps:

## Procedure

1. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who

logs on must have the privileges required to perform administration tasks with the *XS Artifact Administration* tool.

2. Start the SAP HANA *XS Artifact Administration* tool.  
Use the *XS Artifact Administration* tool to manage the runtime configurations for the various applications in your package hierarchy.
3. Locate the HTTP destination configuration object that you want to edit.  
In the *Application Objects* list, locate and select the object containing the HTTP destination configuration that you want to edit. HTTP destination configuration objects have the suffix `.xshttpdest`. The details are displayed in the *HTTP Destination Details* panel.
4. Edit the details of the HTTP destination configuration.

To edit the details of an HTTP destination configuration, choose the *Edit* button in the screen displaying the details you want to edit, for example:

- *General Information*  
Host name and port of the server to connect to, any path prefix (to add to the start of the URL used to connect to the service on the remote host, and a timeout setting for the time allowed to connect to the remote host.

#### **i** Note

The *Extends* option is only available if the HTTP destination you are modifying is being used to extend the configuration defined in another HTTP destination.

- *Proxy Details*  
Details of the proxy type (*None*, *HTTP*, or *Socks*), the name of the system hosting the proxy service, the port to connect on and the user credentials required to establish the connection.

#### **⚠** Caution

The proxy-server settings you define here are overridden by any SAP HANA system wide setting for a proxy server, for example, defined by the `enforced_outbound_proxy` parameter in the `communication` section of the `xsengine.ini` configuration file.

- *Authentication Details*
  - *SSL Enabled*  
SSL for outbound connections between SAP HANA XS and the host named in the HTTP destination configuration.  
You must choose an *SSL Authentication Type*. If you choose *Client Certificate* (default), you must specify the *Trust Store* where the certificates are stored. You can choose an existing trust store from a list of stores configured for the SAP HANA instance (in the *Trust Store* drop-down menu), or create a new trust store using the *Trust Manager*.  
*SSL Host Check* (`true | false`) enables a check which verifies that the certificate used for authentication is valid (matches the host). If the certificate does not match, SSL terminates.
  - *Authentication Type* (for example, *none*, *basic*, *SAP Assertion Ticket*, *SAML*, or *SAML Assertion Propagation*).

#### **i** Note

The *Authentication Type* you select determines what (and how much) additional information is required.

For example, for the [SAP Assertion Ticket](#) authentication type, you must provide the SAP SID and client number of the instance providing the service. The value displayed (if any) is the one already defined in the design-time representation of the HTTP destination configuration. Any changes you make to the runtime configuration (here) are synchronized with the design-time configuration artifact.

For [SAML](#), the values displayed reflect the parameters set in the corresponding design-time representation of the HTTP destination configuration, for example,

`ConfigFileName.xshttpdest`. For more information, see [HTTP Destination Details](#) in [Related Information](#).

- [OAuth Details](#)

You cannot enter this information manually; the information is read from the design-time configuration file that describes the OAuth application, for example, `oauthDriveApp.xsoauthappconfig`. To display a list of available OAuth application-configuration packages (files with the suffix `*.xsoauthappconfig`) on your SAP HANA system, choose [Browse OAuth App Configs](#) and select a package from the list. The location of the package containing the OAuth application-configuration you choose is used to populate the [OAuth App Config Package](#) field; the name of the OAuth application-configuration you choose is used to populate the [OAuth App Config Name](#) field.

5. Save the changes.

Saving the changes to the HTTP destination configuration automatically commits the HTTP destination configuration object to the SAP HANA repository and activates it.

→ Tip

Use the [Reset](#) button to reset the runtime configuration to its previous state; use the [Revert](#) button to undo changes to the runtime-configuration options in the current tab.

## Related Information

[SAP HANA XS Classic Classic Configuration Parameters \[page 1671\]](#)

### 13.1.4.3.1 HTTP Destination Details

An HTTP destination defines connection details for services running on a specific host, whose details you want to define and distribute

In the [XS Artifact Administration](#) tool, the [HTTP Destination Details](#) tab displays information about the currently selected HTTP destination. You can use the [HTTP Destination Details](#) tab to maintain the following details of the runtime configuration:

- [General Information \[page 1688\]](#)
- [Proxy Details \[page 1688\]](#)
- [Authentication Details \[page 1689\]](#)
- [OAuth Details \[page 1690\]](#)

## General Information

The *General Information* tab in the *HTTP Destination Details* tool enables you to view details of the HTTP destination that you have defined, for example, the name of the destination host, the port to connect on, and a short description. The following table indicates which information can be viewed.

### HTTP Destination Details

UI Element	Description	Example
<i>Extends</i>	The name of another HTTP destination configuration which the currently selected configuration is using as a base but also modifying.	gfn.xshttpdest
<i>Description</i>	A short description of the selected HTTP destination	Service @ Destination
<i>Host</i>	The name of the system hosting the services defined in the HTTP destination configuration	download.finance.acme.com
<i>Port</i>	The port to connect to on the remote host	80
<i>Path Prefix</i>	The prefix to add to the start of the URL used to connect to the service on the remote host	/d/quotes.csv?f=a
<i>Timeout</i>	The time allowed to connect to the remote host defined in the HTTP destination	0

## Proxy Details

The *Proxy Details* tab in the *HTTP Destination Details* tool enables you to view details of the proxy service used by the HTTP destination that you have defined, for example, the name of the proxy host, the port to connect on, and the user credentials required to establish a connection. The following table indicates which information can be viewed and configured.

### Proxy Server Details

UI Element	Description	Example
<i>Proxy Type</i>	The type of proxy service, for example: None, HTTP, or SOCKS.	HTTP
<i>Proxy Host</i>	The name of the system hosting the proxy service used by the HTTP destination	proxy.host.acme.com
<i>Proxy Port</i>	The port to connect to on the system hosting the proxy service	8080
<i>Proxy User</i>	The user credentials required to connect to the proxy service	johndoe

### Note

The proxy-server settings you define here are overridden by any SAP HANA system-wide setting for a proxy server, for example, defined by the `enforced_outbound_proxy` parameter in the `communication` section of the `xsengine.ini` configuration file.

## Authentication Details

The *Authentication Details* tab in the *HTTP Destination Details* tool enables you to view details of the authentication service used by the HTTP destination that you have defined, for example, the authentication **type** and the trust store used to maintain any SSL client certificates. The following table indicates which information can be viewed and modified.

### Authentication Details

UI Element	Description	Example
<i>Authentication Type</i>	The type of service used for authentication, for example: <i>None</i> , <i>Basic</i> , <i>SAP Assertion Ticket</i> , <i>SAML</i> , or <i>SAML Assertion Propagation</i>	<i>SAML</i>
<i>Communication Security</i>	Enable or disable SSL communication. If you enable SSL, you must select an <i>SSL Authentication Type</i> .	<i>SSL Enabled</i>
<i>SSL Authentication Type</i>	The type of authentication used for SSL, for example, <i>Client Certificate</i> (default) or <i>Anonymous</i> . If you choose <i>Client Certificate</i> , you must specify the trust store where the certificates are located.	<i>Client Certificate</i>
<i>SSL Host Check</i>	Enable or disable the SSL host check; the check verifies that the certificate used for authentication is valid (matches the host).	Enabled
<i>Trust Store</i>	The name of the trust store used to maintain security certificates required during the authentication process; select from the drop-down list	SAPLogon

The following table lists the choices available when configuring the authentication type for an HTTP destination.

### HTTP Destination: Authentication Type

UI Element	Description	Example
<i>None</i>	No user authentication is performed	-
<i>Basic</i>	The <i>Name</i> of the user whose account is used to log on to the HTTP destination using basic authentication	JohnDoe
	The <i>password</i> of the user specified in <i>Name</i>	*****
<i>SAP Assertion Ticket</i>	System ID ( <i>SAP SID</i> ) of the SAP instance providing the SAP Assertion Ticket service	GFN
	<i>Client number</i> of the SAP instance providing the SAP Assertion Ticket service	007
<i>SAML</i>	The <i>Entity ID</i> of the remote SAML party	accounts.acme.com
	<i>User Mapping</i> : a list of name-ID mappings, for example, <i>Unspecified</i> , <i>Email</i> , <i>Email</i> , <i>Unspecified</i>	Email
	<i>Assertion Consumer Service</i> defines the way in which SAML assertions and responses are sent, for example: as an authorization header or POST parameter.	Assertion as POST parameter
	Additional <i>Attributes</i> for the SAML Assertion.	Email

UI Element	Description	Example
<a href="#">SAML Assertion Propagation</a>	Allow an SAML token to be forwarded from the server where the token was received to another server.	N/A

For the authentication type [SAML](#), the values displayed reflect the parameters set in the corresponding design-time representation of the HTTP destination configuration, as illustrated in the following table:

HTTP Destination SAML Runtime:Design-Time Parameters

SAML Runtime Parameter	SAML Design-Time Parameter	Description
<a href="#">Entity ID</a>	samlProvider	The entity ID of the remote SAML party
<a href="#">Assertion Consumer Service</a>	samlACS	The way in which SAML assertions or responses are sent
<a href="#">Attributes</a>	samlAttributes	Additional attributes for the SAML Assertion.
<a href="#">User Mapping</a>	samlNameId	A list of name-ID mappings, for example, <a href="#">e-mail</a> .

## OAuth Details

The [OAuth Details](#) tab in the [HTTP Destination Details](#) tool enables you to view details of the OAuth package used by the HTTP destination that you have defined. An OAuth configuration package is a collection of configuration files that define the details of how an application uses OAuth to enable logon to a resource running on a remote HTTP destination. The following table indicates the information that can be viewed.

HTTP Destination: OAuth Information

UI Element	Description	Example
<a href="#">OAuth App Config Package</a>	The name of the repository package containing the OAuth application-configuration	sap.hana.xs.oauth.lib.providerconfig
<a href="#">OAuth App Config Name</a>	The name of the OAuth application-configuration (repository artifacts with the suffix <code>.xssoauthappconfig</code> )	abap.xsoauthappconfig

### Note

You cannot enter this information manually; the information is read from the design-time configuration file that describes the OAuth application, for example, `oauthDriveApp.xsoauthappconfig`.

## Related Information

[Edit an HTTP Destination Runtime Configuration \[page 1685\]](#)

## 13.1.5 Managing Trust Relationships

Trust relationships enable you to establish secure connections between known servers whose identity can be confirmed by a signed certificate. The certificates are stored in a trust store.

The *SAP HANA XS Administration Tool* includes the *Trust Manager*, which is an application that you can use to create and maintain the certificates used to establish trust relationships between servers. You can use the *Trust Manager* to perform the following tasks.

### i Note

SAP HANA uses roles to grant access to the features provided by the *SAP HANA XS Administration Tool*. To access the tools required to maintain trust relationships between SAP HANA and other systems, you must have a role based on the role template `sap.hana.xs.admin.roles::TrustStoreAdministrator`.

- Add/Delete a trust store  
SAP HANA makes use of multiple trust stores. The trust stores listed below are provided by default.

### i Note

The trust stores listed below are located in the **file system**. In some cases, it is possible and recommended to use trust stores that exist in the database as database objects. In-database trust stores (referred to as certificate collections) contain the required client certificates, which are also stored in the database. We recommend using in-database certificate collections where possible. For more information, see *Managing Client Certificates in the SAP HANA Database*.

- The SAP HANA trust store (`sapshr.pse`)  
Used for secure SQL and SAML or OAuth scenario, `sapshr.pse` is installed automatically and is available by default.

### → Recommendation

For user authentication based on X.509 certificates and SAML assertions, we recommend creating separate certificate collections with the purposes *X.509* and *SAML* instead of using the file system-based trust store `sapshr.pse`.

- The SAP Web Dispatcher trust store (`SAPSSLS.pse`)  
Required for SSL connections using the Secure Socket Layer, `SAPSSLS.pse` is installed automatically and is available by default.
- The SAP Logon Ticket trust store (`saplogon.pse`)  
**Optional:** `saplogon.pse` is only necessary if an SAP HANA XS application requires an SAP logon ticket from a user at logon

### → Recommendation

For user authentication based on logon tickets, we recommend creating a certificate collection with the purpose *SAP LOGON* instead of using the file system-based trust store `saplogon.pse`.

- The client authentication trust store (`SAPSSLC.pse`)  
**Optional:** `SAPSSLC.pse` is only required for client connections, for example, that use the SQL client interface (`hdbsql`).
- Manage your own certificates

- Import a private key
- Create a certificate request
- Have the requested certificate signed by a certificate authority
- Import the signed certificate into the trust store
- Manage server certificates
  - HTTP destinations (via SSL/HTTPS)
  - Certificate authorities (for example, “Verisign” or “TC TrustCenter Universal”)

The *Trust Manager* tool enables you to configure the out-bound view; that is, trust relationships with remote systems that provide services required by SAP HANA XS applications. If you want to configure the **in-bound** view (for example, incoming requests **to** SAP HANA), use the SAP HANA *Web Dispatcher Administration* tool.

- Out-bound trust  
Secure communication and trust for out-bound communication, for example, between an SAP HANA XS application and an ABAP system using SSL/TLS.
- In-bound trust  
Secure communication and trust for in-bound communication, for example, between an SAP HANA XS application and an ABAP system using SSL/TLS.

Both the *Trust Manager* and the *Web Dispatcher Administration* tools are available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/wdisp/admin`.

#### **i** Note

Access to the *Web Dispatcher Administration* tool is enabled by the role `sap.hana.xs.wdisp.admin::WebDispatcherAdmin`.

## Related Information

[Add/Edit a Trust Store \[page 1693\]](#)

[Import a Server Certificate \[page 1696\]](#)

[Create Your Own Certificate \[page 1694\]](#)

## 13.1.5.1 Add/Edit a Trust Store

The trust store enables you to maintain a list of servers that you trust; the trust is based on a certificate you import into the trust store and which can be signed by a certificate authority, for example, Verisign or TCTrustCenter.

### Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS Administration Tool. To access the tools required to add a trust store, you must have a role based on the role template `sap.hana.xs.admin.roles::TrustStoreAdministrator`.

### Context

#### → Recommendation

This procedure describes how to create a trust store in the file system. We recommend creating trust stores in the database (referred to as certificate stores) where possible. For more information, see the section *Managing Client Certificates in the SAP HANA Database*.

To enter the details of trust store, you can use the *SAP HANA XS Administration Tool*, as described in the following steps.

#### ⚠ Caution

To maintain the details of a trust store, you must be familiar with the concepts of trust stores and the certificates they contain.

### Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must also have the privileges required to perform the administration tasks associated with trust stores.

2. Start the *Trust Manager*.

The *Trust Manager* is available in the list of SAP HANA XS administration tools.

3. Create the new trust store.

In the *Create Trust Store* dialog, you must provide a name for the new trust store.

a. In the *Trust Store* pane, choose *Add* to open the *Create Trust Store* dialog.

b. Type a name for the new trust store and choose *OK*.

Choose *OK* to add the trust store to the list of trust stores known to SAP HANA XS.

4. Define the details of the new trust store.

You can use the *Own Certificate* and *Certificate List* to manage the certificates you import for the servers that are known to and trusted by SAP HANA XS.

## Related Information

[Import a Server Certificate \[page 1696\]](#)

[Create Your Own Certificate \[page 1694\]](#)

## 13.1.5.2 Create Your Own Certificate

The trust store enables you to maintain a list of servers that you trust; the trust is based on a certificate you import into the trust store and which can be signed by a certificate authority, for example, Verisign or TCTrustCenter.

## Prerequisites

### i Note

This feature is available with restricted releases. If you want to use it, refer to SAP Note 1779803. See the Related Information section for the direct link.

SAP HANA uses roles to determine the level of access to the features provided by the *SAP HANA XS Administration Tool*. To access the tools required to perform trust manager tasks, you must have a role based on the role template `sap.hana.xs.admin.roles::TrustStoreAdministrator`.

## Context

You can use the certificates stored in the trust store to secure the communication between trusted servers, for example, with SSL/HTTPS. However, you must also create a certificate that you can use to authenticate the identity of the SAP HANA server, too.

To create your own certificate and import it into your trust store, perform the following steps:

## Procedure

1. Start the *SAP HANA XS Administration Tool*.

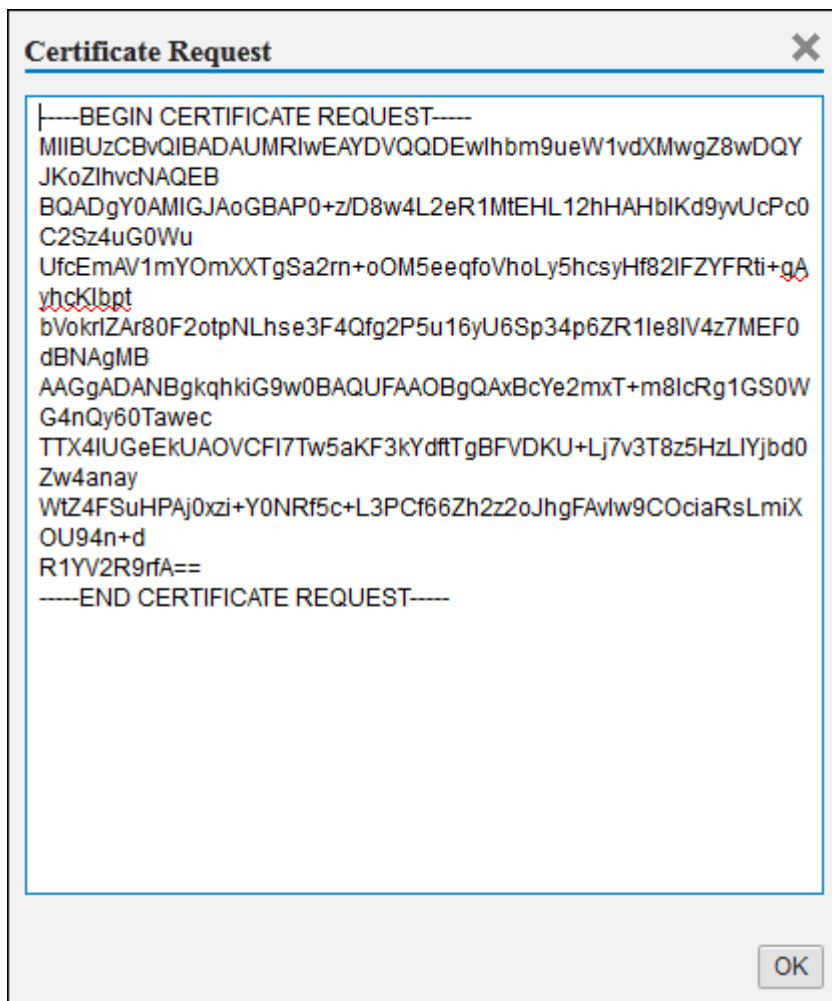

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *Trust Manager* tool.

2. Start the SAP HANA XS *Trust Manager* tool.  
In the list of tools, choose *Trust Manager* tab to display the screen where you can manage the certificates in your trust store.
3. Create a certificate request.

In the *Own Certificate* panel, choose **► Certificate Actions ► Create CA Request ►**.

4. Send the certificate request to a certificate authority for signing.

You must send the certificate request to a certificate authority (CA) to have it signed; you import the response from the CA into your trust store.

5. Import the signed certificate into the trust store.

This may be a trust store in the file system (for example, `sapsrv.pse`) or an in-memory certificate collection with the purpose *SAML* (recommended).

Option	Description
<b>Certificate collection with purpose <i>SAML</i> (recommended)</b>	Use the SAP HANA cockpit to import the certificate into the certificate store and then add it to the relevant collection. For more information, see the section on managing certificates.
<b>Trust store in the file system</b>	In the <i>Own Certificate</i> panel, choose ► <i>Certificate Actions</i> ► <i>Put CA Response</i> ►. The imported certificate is displayed in the certificate list.

## Related Information

[SAP Note 1779803](#)

[Add/Edit a Trust Store \[page 1693\]](#)

### 13.1.5.3 Import a Server Certificate

A server certificates enables you to establish a trusted relationship between SAP HANA and the server described in the server certificate. You import the certificates into the trust store.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the *SAP HANA XS Administration Tool*. To access the tools required to perform trust manager tasks, you must have a role based on the role template `sap.hana.xs.admin.roles::TrustStoreAdministrator`.

## Context

### → Recommendation

This procedure describes how to import a server certificate into a trust store in the file system. We recommend creating trust stores in the database (referred to as certificate stores) where possible. For more information about how to import certificates into the in-memory certificate store and add them to certificate collections, see the section *Managing Client Certificates in the SAP HANA Database*.

The trust store enables you to maintain a list of servers that you trust; the trust is based on a certificate you import into the trust store and which can be signed by a certificate authority, for example, Verisign or TCTrustCenter. You can use the certificates to secure the communication between the trusted servers, for example, with SSL/HTTPS.

To import a certificate into your trust store, perform the following steps.

## Procedure

1. Obtain a copy of the certificate you want to import into your trust store.  
You can export a certificate from a server and save it to a temporary location.

2. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *Trust Manager* tool.

3. Start the SAP HANA XS *Trust Manager* tool.  
In the list of tools, choose the *Trust Manager* tab to display the screen where you can manage the certificates in your trust store.

4. Locate the copy of the certificate you want to import into the trust store.

In the *Certificate List* panel, choose ► *Import Certificate* ► *Browse...* ► and navigate to the folder containing the certificate you want to import.

### i Note

Trust certificates usually have a recognizable suffix such as `.crt`, for example, `TCTrustCenterUniversalCAIII.crt`.

5. Import the certificate into the trust store.  
In the *Import Certificate* dialog, choose *Import Certificate*.

### i Note

If you are importing a certificate you created yourself, you must provide a password to complete the import operation.

The imported certificate is displayed in the certificate list.

## Related Information

[Add/Edit a Trust Store \[page 1693\]](#)

## 13.1.6 Maintaining SAML Providers

You can configure an SAP HANA system to act as a service provider for Single Sign On (SSO) authentication based on Security Assertion Markup Language (SAML) certificates.

The *SAP HANA XS Administration Tool* includes the *SAML CONFIGURATION* application, which you can use to configure SAP HANA system to act as an SAML service provider for SSO authentication. You must perform this step if you want your SAP HANA XS applications to use SAML as the logon authentication method, for example, by enabling the *SAML* option in the *AUTHENTICATION* panel in the *XS APPLICATIONS* tool

### i Note

SAP HANA uses roles to grant access to the features provided by the *SAP HANA XS Administration Tool*. To access the tools required to configure an SAP HANA system to act as an SAML service provider, you must have a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator`.

You can use the *SAML CONFIGURATION* tool to perform the following tasks:

- Configure an SAP HANA system to act as a service provider
- Add a new SAML Identity provider (IDP)
- Modify the details of an existing SAML Identity provider (IDP)

### i Note

To maintain a SAML identity provider (IDP), you must be logged on to SAP HANA with the credentials of the system user.

### i Note

If you want your SAP HANA system to validate audience restrictions in SAML assertions, you need to set the `[authentication] saml_service_provider_name` configuration parameter. If the parameter is not set, an SAP HANA system ignores a possible audience restriction tag in a SAML assertion. By default, in SAP HANA tenant databases the parameter is set to the tenant name and the instance ID, for example, 'TENANT01'. For the system database, the parameter is empty by default.

## Related Information

[Configure an SAP HANA System as an SAML Service Provider \[page 1699\]](#)

[Add a SAML Identity Provider in SAP HANA Studio \[page 842\]](#)

## 13.1.6.1 Configure an SAP HANA System as an SAML Service Provider

SAP HANA supports the use of authentication based on Security Assertion Markup Language (SAML) certificates.

### Prerequisites

SAP HANA user roles are used to determine the level of access to the features provided by the [SAP HANA XS Administration Tool](#). To access the tools required to configure an SAP HANA system to act as an SAML service provider, you must have a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator`.

### Context

You can configure an SAP HANA system to act as a service provider for authentication based on Security Assertion Markup Language (SAML) certificates. You must perform this step if you want your the SAP HANA XS applications to use SAML as the user authentication method.

#### ⚠ Caution

To maintain the details of SAML service providers, you must be familiar with the technical background of SAML SSO mechanisms and requirements.

### Procedure

1. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform SAML administration tasks.

2. Start the SAP HANA XS [SAML Service Provider](#) tool.  
In the list of tools, choose [SAML Service Provider](#) to display the screen where you can enter details of the SAML service provider you want to configure.
3. Enter details of the SAML service provider.  
In the [Service Provider Information](#) panel choose [Edit](#); you must provide the following information:

### i Note

The information you enter is used to populate the XML document saved as the SAML service-provider metadata.

- **Name**  
This can be any name but, for troubleshooting purposes, is usually the fully qualified name of the system hosting the SAML service.
- **Organization Name**  
According to the oasis SAML standard, the name of the organization responsible for the SAML service described here. The name you enter here is wrapped in the XML tag <OrganizationName> used in the SAML certificate. The organization name can (but does not have to) be human readable.
- **Organization Display Name**  
According to the oasis SAML standard, the human-readable form of the name of the organization responsible for the SAML service described here. The name you enter here is wrapped in the XML tag <OrganizationDisplayname> that is contained in the SAML certificate.
- **Organization URL**  
A URL that specifies a location where a user can find additional information about the organization responsible for the SAML service you describe in this task.

The information you enter in the various configuration tabs and screens is added to the appropriate tags in the XML document displayed in the *Metadata* tab.

#### 4. Save the SAML service-provider configuration.

Choose *Save*; the XML document describing the SAML service is parsed and, if no errors are found, saved.

## Related Information

[SAML Service Provider Details \[page 1700\]](#)

### 13.1.6.1.1 SAML Service Provider Details

An SAP HANA system can act as an SAML service provider for SSO authentication.

An SAP HANA system can act as a service provider for authentication based on Security Assertion Markup Language (SAML) certificates. The *SAML Service Provider* tool displays the following screens to help you maintain details of the SAML service provider:

- [Service Provider Information \[page 1701\]](#)
- [Service Provider Configuration \[page 1701\]](#)
- [Metadata \[page 1701\]](#)

### i Note

The information you enter is used to populate the XML document saved as the SAML service-provider metadata.

## Service Provider Information

The *Service Provider Information* tab in the *SAML Service Provider* tool enables you to provide details of the SAML service provider. The following table indicates which information is required.

UI Element	Description	Example
<a href="#">Name</a>	The fully qualified name of the system hosting the SAML service	SAMLSP01
<a href="#">Organisation Name</a>	The name of the organisation responsible for the SAML service provider. The name you enter is wrapped in the XML tag <OrganizationName> used in the SAML certificate. <i>Organization Name</i> can (but does not have to) be human readable	SAP
<a href="#">Organisation Display Name</a>	The human-readable name of the organisation responsible for the SAML service provider. The name you enter here is wrapped in the XML tag <OrganizationDisplayname> used in the SAML certificate.	SAP
<a href="#">Organisation URL</a>	A location where a user can find additional information about the organization responsible for the SAML service	sap.com

## Service Provider Configuration

The *Service Provider Configuration* tab in the *SAML Service Provider* tool enables you to maintain details of the SAML service provider used to handle SAML assertions. The following table indicates which information is required.

UI Element	Description	Example
<a href="#">Hash</a>	The hash algorithm use to encode SAML assertions	SHA256
<a href="#">Add Key Info</a>	If <Keyinfo> node should be included in the XML signature; default = yes	"yes" or "no"
<a href="#">Default Application Path</a>	Path to the application requiring logon user credentials provided by the SAML service provider, if the SSO request is initiated by an SAML identity provider	/
<a href="#">Assertion Timeout</a>	Period of time (in seconds) for which SAML assertion requests for SSO initiated by an SAML service provider remain valid; default=10 minutes	1000
<a href="#">Default Role</a>	Default SAP HANA role assigned to new SAML users	JobViewer

## Service Provider Metadata

The *Metadata* tab in the *SAML Service Provider* tool enables you to view details of the SAML service provider used to handle SAML assertions. The metadata document includes the information you enter in the *Service Provider Information* and *Service Provider Configuration* tabs.

Field Name	Description
<a href="#">Metadata</a>	An XML file containing details of the SAML service provider used to handle SAML assertions

## 13.1.6.2 Add an SAML Identity Provider

SAP HANA supports the use of SSO authentication based on Security Assertion Markup Language (SAML) certificates. An identity provider is used by the service provider to authenticate the users signing in by means of SSO.

### Prerequisites

- The SAP HANA trust store contains the server certificate that will be used to generate SAML SP metadata and validate SAML assertions (service provider certificate). We recommend that you use an in-memory certificate collection with purpose [SAML](#). For more information, see the section on managing client certificates.
- SAP HANA user roles are used to determine the level of access to the features provided by the SAP HANA XS Administration Tool. To access the tools required to add an SAML identity provider (SAML IDP), you must have a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator`.
- You need access to the XML document containing the IDP metadata that describes the SAML identity provider (SAML IDP) you want to add.

### Context

To enter the details of SAML identity providers, you can use the [SAP HANA XS Administration Tool](#), as described in the following steps:

#### Caution

To maintain the details of an SAML identity provider, you must be familiar with the technical background of SAML SSO mechanisms and requirements.

### Procedure

1. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform SAML administration tasks.

#### 2. Add an SAML SSO identity provider (IDP).

The information required to maintain details of an SAML IDP is specified in an XML document containing the IDP metadata. This document should be available as part of the SAML service you want SAP HANA XS to use. The only information you must provide manually is the name of the new IDP; the IDP name must be unique.

- a. In the *SAML Identity Provider List*, choose [\[+\]](#) to display the *Add Identity Provider Info* pane.
- b. In the *Add Identity Provider Info* pane, paste the contents of the XML document containing the IDP metadata into the *Metadata* box.

If the contents of the XML document are valid, the parsing process extracts the information required to insert into the *Subject*, *Entity ID*, and *Issuer* fields in the *General Data* screen area, and the URL fields in the *Destination* screen area, for example, *Base URL* and *SingleSignOn URL (\*)*.

- c. In the *Name* box of the *General Data* screen area, enter a name for the new SAML SSO identity provider.

### i Note

The name of the SAML IDP is mandatory and must be unique; it appears in the list of available SAML IDPs that is displayed, if you select SAML as the authentication method for SAP HANA XS applications to use, for example, in the *Authentication* screen area of the *XS Artifact Administration* tool.

#### 3. Save the details of the new SAML identity provider.

Choose [Save](#) to save the details of the SAML identity provider and add the new SAML IDP to the list of known SAML IDPs.

The new SAML IDP is displayed in the list of known IDPs shown in the *SAML Identity Provider List*.

#### 4. Check the details of the new SAML IDP.

Select the new SAML IDP in the list of known SAML IDPs to display the IDP's details in the information panel.

## Next Steps

Copy the certificate from the SAML IDP metadata document and add it to the SAP HANA trust store for SAML authentication (certificate collection with purpose [SAML](#)). For more information, see *Configure SSO with SAML Authentication for SAP HANA XS Applications*.

## Related Information

[Configure an SAP HANA System as an SAML Service Provider \[page 1699\]](#)

[Modify an Existing SAML Identity Provider \[page 1705\]](#)

[SAML Identity Provider Details \[page 1704\]](#)

[Configure SSO with SAML Authentication for SAP HANA XS Applications \[page 1725\]](#)

## 13.1.6.2.1 SAML Identity Provider Details

An SAML identity provider is used by the SAML service provider to authenticate users signing in by means of a single sign-on (SSO) mechanism.

SAP HANA supports the use of SSO authentication based on Security Assertion Markup Language (SAML) certificates. An SAML identity provider is used by the SAML service provider to authenticate users who sign in to an application by means of SSO. As part of the SAML IDP configuration, you specify the following options:

- [General data \[page 1704\]](#)
- [HTTP Destination \[page 1704\]](#)

### General Data

The *General Data* screen area in the *SAML Identity Provider* tool enables you to maintain details of the SAML identity provider. The following table indicates which information can be maintained.

General SAML IDP Details

UI Element	Description	Example
<i>Name</i>	The name of the SAML identity provider is mandatory and must be unique.	ACCOUNTS_ACME_COM
<i>Subject</i>	SAML IDP is specified in an XML document containing the IDP metadata	CN=CPS Production, OU=WebKm, O=ACME, L=Accra, C=GH
<i>Issuer</i>	SAML IDP is specified in an XML document containing the IDP metadata	CN=CPS Production, OU=WebKm, O=ACME, L=Accra, C=GH
<i>Entity ID</i>	The entity ID of the remote SAML party	accounts.acme.com
<i>Dynamic User Creation</i>	Enable or disable the dynamic creation of new SAML users.	Disabled

### Destination

The *Destination* screen area in the *SAML Identity Provider* tool enables you to maintain details of the HTTP destination for the system hosting the SAML identity provider service. You must provide a base URL for the SAML IDP as well as further, more detailed, information about the location of the resources that provide the sign-on and sign-off services. The following table indicates which information can be maintained.

#### Details of the SAML IDP's HTTP Destination

UI Element	Description	Example
<i>Base URL</i>	The resource location where the SAML identity provider is reachable.	https://accounts.acme.com:443
<i>SingleSignOn URL (RedirectBinding)</i>	URL of the IDP endpoint for SSO requests using SAML redirect binding	/saml2/idp/sso/accounts.acme.com
<i>SingleSignOn URL (PostBinding)</i>	URL of the IDP endpoint for SSO requests using SAML post binding	/saml2/idp/sso/accounts.acme.com
<i>SingleLogout URL (RedirectBinding)</i>	URL of the IDP endpoint for single logout (SLO) requests using SAML redirect binding	/saml2/idp/slo/accounts.sap.com
<i>SingleLogout URL (PostBinding)</i>	URL of the IDP endpoint for single logout (SLO) requests using SAML post binding	/saml2/idp/slo/accounts.sap.com

SAML bindings describe a protocol used to transport SAML messages: both the requests and the responses. The following bindings are relevant for the configuration of the HTTP destination for the SAML identity provider.:

- Redirect binding  
The SAML message is in the URL itself as a query parameter. Redirect bindings enforce limitations on the message and ZLIB compression is required.
- Post binding  
The SAML message is transported inside an HTTP body in the `POST` parameter. There is no limitation on the message and no compression needed.

### 13.1.6.3 Modify an Existing SAML Identity Provider

SAP HANA supports the use of SSO authentication based on Security Assertion Markup Language (SAML) certificates. An identity provider is used by the service provider to authenticate the users signing in by means of SSO.

#### Prerequisites

- SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS Administration Tool. To access the tools required to add an SAML identity provider, you must have a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator`.
- You have access to the XML document containing the IDP metadata that describes the SAML identity provider (SAML IDP) you want to modify.

## Context

To edit the details of an SAML identity provider, you can use the [SAP HANA XS Administration Tool](#), as described in the following steps:

### ⚠ Caution

To maintain the details of SAML identity providers, you must be familiar with the technical background of SAML SSO mechanisms and requirements.

## Procedure

1. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform SAML administration tasks.

2. Start the [SAML Identity Provider](#) tool.

Choose [SAML Identity Provider](#) in the list of tools displayed on the left-hand side of the [SAP HANA XS Administration Tool](#) window.

3. Select the SAML identity provider, whose details you want to modify.

The list of available SAML IDPs is displayed in the [SAML Identity Provider List](#) on the left-hand side of the [SAML Identity Provider](#) tool.

4. Modify the details of the selected SAML SSO identity provider (IDP).

The information required to maintain details of an SAML IDP is specified in an XML document containing the IDP metadata. This document should be available as part of the SAML service you want SAP HANA XS to use.

- a. Paste the contents of the XML document containing the IDP metadata into the [Metadata](#) box in the [Add Identity Provider Info](#) screen area.

If the contents of the XML document are valid, the parsing process extracts the information required to insert into the [Subject](#), [Entity ID](#), and [Issuer](#) fields in the [General Data](#) screen area, and the URL fields in the [Destination](#) screen area.

5. Save the modifications to the SAML identity provider.

Choose [Save](#) to save the changes.

## Related Information

[Add an SAML Identity Provider \[page 1702\]](#)

## 13.1.7 Maintaining SMTP Server Configurations

Define details of the SMTP server that SAP HANA XS can use to respond to requests from applications to send e-mails.

The SMTP configuration defines the details of the SMTP server that is available for use by all applications running on an SAP HANA XS server. You can configure one SMTP server per SAP HANA XS server. As part of the configuration, you also specify the following options:

- General SMTP details
- Logon authentication type
- Transport-channel security type
- Other settings

### i Note

SAP does not provide any e-mail services. You will need to set up your own e-mail servers or cooperate with an external e-mail provider of your choice. You can configure only one SMTP server for each SAP HANA XS instance.

## SMTP Host System Details

When defining the details of the SMTP server to be used by the SAP HANA XS applications, you must specify the following elements:

- *Mail Server Host*  
The name or the IP address of the system hosting the SMTP relay server that the XS applications can use to send an e-mail, for example, `<smtp.mail.host>` or `"localhost"` if the system hosting the SMTP server is the same as the one hosting the XS instance.
- *Mail Server Port*  
The port number to use for connections to the SMTP relay server, for example, `25`.

### i Note

The port number to use can change according to the security type specified for the SMTP transport channel, for example, 465 (SMTPS) or 587 (STARTTLS).

## SMTP Logon Authentication Type

You must tell SAP HANA XS which method the SMTP server uses to authenticate the logon credentials of the user that SAP HANA uses to establish the connection. The available choices for the authentication type are: *None*, *Auto*, *Logon*, *Plain*, *CRAM-MD5*, or *Digest-MD5*.

If you choose the option *None*, no logon credentials are required for the connection to the SMTP relay server. If you choose the option *Auto*, SAP HANA XS checks the authentication mechanisms supported by the SMTP relay server and selects one automatically according to the following order of preference: *Digest-MD5*, *CRAM-MD5*, *Plain*, *Login*, or *None*.

### i Note

For all authentication-type options except *None*, you must specify the name and password of the user whose credentials SAP HANA XS uses to log on to the SMTP server.

## SMTP Transport-Channel Security Type

When you set up the SMTP configuration, you must specify the security type used to encrypt the transport channel between the SAP HANA XS server and the SMTP server; you can choose any of the following values:

- *None*  
This is default value for the transport security type; the channel used to communicate with the SMTP relay server is not encrypted. Note that it is possible that both SAP HANA XS and the specified SMTP relay server are running in the same trusted network or even on the same host.
- *STARTTLS*  
You can specify STARTTLS as the transport security only if it is supported by the SMTP relay server. If it is not supported, the application trying to send an e-mail encounters an error and the requested e-mail message is not sent.
- *SSL/TLS*  
Use an SSL/TLS-wrapped channel to communicate with the SMTP relay server. If SSL/TLS is not supported by the SMTP relay server then the connection cannot be established, the application trying to send an e-mail encounters an error, and the requested e-mail message is not sent. If you choose SSL/TLS as the transport security type, you will very probably have to specify a different port, usually 465, in the SMTP host section. You will also have to specify the name of the trust store holding the certificates and keys required to establish a trusted connection with the SMTP server.

### i Note

If the SMTP relay server's certificate cannot be verified, then the connection to the specified SMTP server cannot be established, the application trying to send an e-mail encounters an error, and the requested e-mail message is not sent.

## Socket Proxy Settings

If your system uses a proxy service for Socket Secure (SOCKS) routing, you need to enable support using the SOCKS Proxy toggle button (ON) and, in addition, provide connection details for the system where the proxy service is running, for example:

### ⚠ Caution

The proxy-server settings you define here are overridden by any SAP HANA system wide setting for a proxy server, for example, defined by the `enforced_outbound_proxy` parameter in the `communication` section of the `xsengine.ini` configuration file.

- *Proxy Host*  
The name of the system hosting the SOCKS proxy service

- *Proxy Port*  
The port number to use for connections to the SOCKS proxy server running on the host specified in *Proxy Host*
- *Proxy Username*  
The name of the user whose account is used to log on to the SOCKS proxy server system specified in *Proxy Host*
- *Proxy Password*  
The password of the user whose account is used to log on to the SOCKS proxy server system specified in *Proxy Host*

## Other Settings

You can specify the maximum length of time (in milliseconds) that SAP HANA XS must wait for a response from the SMTP relay server with which it is trying to establish a connection; the default value is 60000 milliseconds (1 minute). If the specified timeout limit is reached, the connection is reset and the application requesting the connection encounters an error.

### i Note

If a connection is reset due to a timeout problem, the state of any sent e-mail messages is unknown. However, some useful information might be available in the logs of the SMTP relay server.

## Related Information

[Create an SMTP Configuration \[page 1709\]](#)

[SAP HANA XS Classic Configuration Parameters \[page 1671\]](#)

### 13.1.7.1 Create an SMTP Configuration

Define the settings an SAP HANA XS application uses for outbound connections to an SMTP server.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the *SAP HANA XS Administration Tool*. To access the *SMTP Configuration* tools that enable you to set up an SMTP server for SAP HANA XS applications, you must have roles based on the following role templates:

- `sap.hana.xs.admin.roles::RuntimeConfAdministrator`
- `sap.hana.xs.admin.roles::SMTPDestAdministrator`

## Context

The SMTP configuration defines the details of the SMTP server that is available for use by all applications running on an SAP HANA XS server. You can configure one SMTP server per SAP HANA XS server. As part of the configuration, you also specify what authentication type to use when establishing the connection as well as the security type used to encrypt the transport channel between the SAP HANA XS server and the SMTP server, for example, SSL or TLS. To create an SMTP configuration for an SAP HANA XS application, perform the following steps:

## Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *SMTP Configurations* tool.

2. Start the *SMTP Configurations* tool.

In the list of XS Administration tools, choose *SMTP Configurations* to display the screen where you can manage the configuration of the SMTP server used by SAP HANA XS applications.

### i Note

SAP does not provide any e-mail services. You will need to set up your own e-mail servers or cooperate with an external e-mail provider of your choice. You can configure only one SMTP server for each SAP HANA XS instance.

3. Specify details of the system hosting the SMTP server that the SAP HANA XS applications must use. Provide the name of the system hosting the SMTP server and the port number required to open a connection.

### i Note

If SSL or TLS is required to encrypt the transport channel, the port number will probably change, for example, to 465 (SMTPS) or 587 (STARTTLS).

4. Specify the authentication settings required for access to the SMTP host.

Choose an authentication method from the *Authentication Type* drop-down list, for example, *auto*, *logon*, or *none* and, if necessary, the user credentials required to log on to the SMTP server.

### → Tip

If you choose *auto*, setup checks the authentication mechanisms supported by the specified SMTP server and selects one in the following order of preference: *Digest-MD5*, *CRAM-MD5*, *Plain*, *Login*, and *None*.

5. Specify the security settings for the transport-channel.

The transport channel is used for the communication between the SAP HANA XS application and the SMTP server. If you choose either the *STARTTLS* or the *SSL/TLS* option, use the *Trust Store* drop-down list to specify the trust store where the certificates and keys for the SMTP sever are located.

#### **i** Note

If you choose the option *None*, the channel used to communicate with the SMTP relay server is not encrypted.

6. Define the timeout setting for connections to the specified SMTP server.

You can specify the maximum length of time (in milliseconds) that SAP HANA XS must wait for a response from the SMTP server with which it is trying to establish a connection; the default value is 60000 milliseconds (1 minute).

#### **i** Note

If the specified timeout limit is reached, the connection is reset and the application requesting the connection encounters an error.

7. Define the socket proxy settings.

If your system uses a proxy service for Socket Secure (SOCKS) routing, you need to enable support using the *SOCKS Proxy* toggle button (*ON*) and, in addition, provide connection details for the system where the proxy service is running, for example, the host name, the port number to use for connections, and the user credentials required to log on.

#### **⚠** Caution

The proxy-server settings you define here are overridden by any SAP HANA system wide setting for a proxy server, for example, defined by the `enforced_outbound_proxy` parameter in the `communication` section of the `xsengine.ini` configuration file.

8. Save the changes you have made to the SMTP configuration.

## Related Information

[Maintaining SMTP Server Configurations \[page 1707\]](#)

[SMTP Configuration Details \[page 1711\]](#)

### 13.1.7.1.1 SMTP Configuration Details

The SMTP configuration defines the details of the SMTP server that is available for use by all applications running on an SAP HANA XS server.

As part of the SMTP configuration, you specify the following options:

- [General SMTP settings \[page 1712\]](#)

- [Logon authentication type \[page 1712\]](#)
- [Transport security type \[page 1713\]](#)
- [Socket proxy settings \[page 1713\]](#)
- [Other settings \[page 1713\]](#)

## General SMTP settings

The *General SMTP Settings* screen area of the *SMTP Configurations* tool enables you to maintain the basic details of the system hosting the SMTP server that SAP HANA XS applications use to send e-mail. The following table indicates which information can be maintained.

UI Element	Description	Example
<i>Mail Server Host</i>	The name of the system hosting the SMTP server.	localhost, <hostname>.
<i>Mail Server Port</i>	The port to connect to on the SMTP server. The port number will change depending on the choices made for the transport-security settings described below (None, SSL/TLS, STARTTLS)	25, 465, 587

### i Note

SAP does not provide any e-mail services. You will need to set up your own e-mail server or make arrangements with an external e-mail provider of your choice. You can configure only one SMTP server for each SAP HANA XS instance.

## Authentication

The *Authentication* screen area of the *SMTP Configurations* tool enables you to maintain details of the user credentials required to log on to the system hosting the SMTP server and the mechanism used during the logon process to carry out user authentication. The following table indicates which information can be maintained.

UI Element	Description	Example
<i>Authentication Type</i>	The method used by the SMTP server to authenticate the credentials of the user that SAP HANA uses to establish the connection	None, Auto, Logon, Plain, CRAM-MD5, or Digest-MD5.
<i>Username</i>	For all authentication-type options except <i>None</i> , the name and password of the user whose credentials SAP HANA XS uses to log on to the SMTP server.	johndoe
<i>Password</i>	For all authentication-type options except <i>None</i> , the password of the user whose credentials SAP HANA XS uses to log on to the SMTP server.	*****

## Transport Security Settings

The *Transport Security Settings* screen area of the *SMTP Configurations* tool enables you to maintain details of the security type used to encrypt the transport channel between the SAP HANA XS server and the SMTP server. The following table indicates which information can be maintained.

UI Element	Description	Example
<i>Transport Security</i>	The method used by the SMTP server to authenticate the credentials of the user that SAP HANA uses to establish the connection	None, STARTTLS, SSL/TLS
<i>Trust Store</i>	Contains the certificates used to establish trust relationships between servers, for example, SAP HANA XS and the SMTP server	sapspv.pse

## Socket Proxy Settings

The *Socket Proxy Settings* screen area of the *SMTP Configurations* tool enables you to maintain details of the system hosting the proxy service used by the SMTP server for Secure Socket (SOCKS) routing. The following table indicates which information can be maintained.

UI Element	Description	Example
<i>SOCKS Proxy</i>	Enable/Disable Socket Secure (SOCKS) routing	N/A
<i>Proxy Host</i>	Name of the system hosting the proxy service for Socket Secure (SOCKS) routing	smtp.host.acme.com
<i>Proxy Port</i>	Port number to use for connections to the proxy server	1080
<i>Proxy Username</i>	Name of the user required to log on to the proxy server	johndoe
<i>Proxy Password</i>	Password for the user required to log on to the proxy server	****

## Other Settings

The *Other Settings* screen area of the *SMTP Configurations* tool enables you to maintain additional details of the SMTP server, for example, the connection timeout setting. The following table indicates which information can be maintained.

UI Element	Description	Example
<i>Timeout</i>	Maximum length of time (in milliseconds) that SAP HANA XS must wait for a response from the SMTP server with which it is trying to establish a connection	60,000 milliseconds (1 minute)

### 13.1.8 Maintaining HTTP Access to SAP HANA

Ensure that Web-based applications have access to SAP HANA via HTTP.

To enable access to the services provided by the XS-based applications that you develop for SAP HANA, you need to ensure that client applications can access the SAP HANA XS Web server by HTTP or HTTPS. As part of the configuration process, you also need to configure SSL (for use with secure HTTP), set up the SAP Web Dispatcher (for example, to use non-default ports or secure HTTP), and maintain the trust stores that store the certificates required for secure communication. In addition, in a multi-database environment, you also need to configure HTTP access to multi-tenant database containers.

Maintaining HTTP access to SAP HANA includes one or more of the following tasks:

- **Configure HTTPS (SSL) for client application access**  
Configure the SAP Web Dispatcher to use HTTPS (SSL) for incoming requests from UI front ends and applications, for example, SAP HANA applications. The requests are then forwarded by the SAP Web Dispatcher to SAP HANA.
- **Maintain standard HTTP port numbers for SAP HANA XS**  
Check or change the default HTTP port settings, for example, to ensure that standard ports 80 and 443 are used for client access to the SAP HANA XS Web server by HTTP or HTTPS, respectively.
- **Configure HTTP access to multi-tenant database containers**  
Configure the internal SAP Web Dispatcher so that, in an environment where multiple tenant database containers are available, the SAP Web Dispatcher knows which client requests to dispatch to which tenant database, for example, on the basis of alias DNS names.

## Related Information

[Configure HTTPS \(SSL\) for Client Application Access \[page 1715\]](#)

[Maintain Standard HTTP Port Numbers with SAP HANA XS \[page 1716\]](#)

[Configure HTTP\(S\) Access to Tenant Databases via SAP HANA XS Classic \[page 1718\]](#)

## 13.1.8.1 Configure HTTPS (SSL) for Client Application Access

To improve the security of your SAP HANA landscape, you can configure the SAP Web Dispatcher to use HTTPS (SSL) for incoming requests from UI front ends and applications, for example, SAP HANA applications. The requests are then forwarded to SAP HANA.

### Prerequisites

If you want to set up a secure SSL connection (Secure Socket Layer) between client applications and the SAP Web Dispatcher, the following components are prerequisites:

- The CommonCryptoLib library (`libsapcrypto.so`)  
CommonCryptoLib (`libsapcrypto.so`) is installed by default as part of SAP HANA server installation at `$DIR_EXECUTABLE`.
- You have a role based on the role template `sap.hana.xs.wdisp.admin::WebDispatcherAdmin`. This is required to access the SAP HANA [Web Dispatcher Administration](#) tool.

### Context

The SAP Web dispatcher lies between the Internet and your SAP system. It is the entry point for HTTP(s) requests into your system. To configure the SAP Web Dispatcher to use SSL for inbound application requests, perform the following steps.

### Procedure

1. Start the [SAP HANA Web Dispatcher Administration](#) tool.

The [SAP HANA Web Dispatcher Administration](#) tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/wdisp/admin/`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the [Web Administration Interface](#) of the [SAP HANA Web Dispatcher Administration](#) tool.

2. Create an SSL key pair and a certificate request:

The SSL key pair is created with the default `SAPSSLS.pse` trust store; if you want to create a new SSL key pair, choose [Recreate PSE](#) in the [PSE Management](#) tool. To create a certificate request, perform the following steps:

- a. Open the [PSE Management](#) tool.

In the *SAP HANA Web Dispatcher Administration* tool, choose **SSL and Trust Configuration** > **PSE Management**.

- b. Create the certificate request.

In the *PSE Management* screen area, choose *Create CA Request*.

- c. Submit the generated certificate request to your certificate authority (CA) for signing.

Copy the contents of the certificate request from the *CA Request of PSE SAPSSLS.pse* screen area and send it to your certificate signing authority.

3. Import the signed certificate.

Add a copy of the signed certificate to the *SAPSSLS.pse* trust store. The certificate-request response must be generated in the correct format, for example, PKCS#7 certificate chain, which contains both the requester's and the issuing CA's certificates. If the response contains only the requester's certificate in PEM (Privacy Enhanced Mail) format and no CA certificate, the system can still build the correct format. However, in this case, the issuing CA's root certificate must already be available in the same certificate store into which you import the requester's certificate.

#### → Tip

Make sure that the date and time settings on the server hosting the SAP Web Dispatcher are correct and synchronized with the certificate authority (CA) that issued the certificate you import, otherwise the certificate might be interpreted as invalid.

- a. Open the *PSE Management* tool.

In the *SAP HANA Web Dispatcher Administration* tool, choose **SSL and Trust Configuration** > **PSE Management**.

- b. Select the target trust store.

In the *Manage PSE* screen area, choose *SAPSSLS.pse* from the drop-down menu.

- c. Import the signed certificate request.

In the *PSE Attributes* screen area, choose *Import CA Response* and copy the signed certificate response from your CA into the *Import CA Request of PSE SAPSSLS.pse* screen area.

## 13.1.8.2 Maintain Standard HTTP Port Numbers with SAP HANA XS

The default HTTP port settings for SAP HANA XS include an SAP HANA instance number, for example, `80<SAP HANA instance>` (8000). You can change the default settings, for example, to ensure that standard ports 80 and 443 are used for client access to the SAP HANA XS Web server by HTTP or HTTPS.

### Prerequisites

To configure the SAP HANA XS server to use the standard HTTP ports 80 and 443, bear in mind the following prerequisites:

- Superuser authorization is required to bind ports with a number less than (<) 1024 (well-known ports) on a UNIX system
- Neither the ICM process nor the SAP Web Dispatcher has the superuser authorization.

## Context

By default, the SAP HANA XS Web server is configured to use the port numbers 80<SAP HANA instance number> for HTTP and 43<SAP HANA instance number> for HTTPS requests from clients. You can change this behavior, for example, to configure the SAP HANA XS server to use the standard HTTP ports 80 and 443, as follows:

## Procedure

1. Open the instance profile of your SAP Web Dispatcher.

The SAP Web Dispatcher profile can be found in the following location in the SAP HANA studio:

► [SAP HANA Administration Console](#) ► [Configuration](#) ► [webdispatcher](#) ► [\[profile\]](#) ►

2. Check and, if necessary, modify the HTTP/S port settings in the SAP Web Dispatcher profile, as follows:

```
icm/server_port_0 = PROT=HTTP, PORT=80, PROCTIMEOUT=600, EXTBIND=1
icm/server_port_1 = PROT=HTTPS, PORT=443, PROCTIMEOUT=600, EXTBIND=1
```

Save the changes to the SAP Web Dispatcher profile.

3. Bind the default SSL port to use.

Since only users with superuser authorization rights can bind ports with a number less than (<) 1024 (well-known ports) on a UNIX system, and the ICM process or the SAP Web Dispatcher should not have these rights (and ICM cannot have them for technical reasons), the port must be bound by an external program and the listen socket then transferred to the calling process. You can use the `icmbnd` command.

### i Note

The installation process creates the file `icmbnd.new`, which you must rename to `icmbnd` and configure as described below. This applies after a system update, too.

Since superuser privileges are required to bind ports with a number lower than 1024, you must change the owner and permissions of the `icmbnd` command, for example, from `<SID>adm` to user `root`.

- a. Change the owner of the `icmbnd` command:

```
$> chown root:sapsys icmbnd
```

- b. Change the permissions for the `icmbnd` command:

```
$> chmod 4750 icmbnd
```

- c. Check the new permissions for the `icmbnd` command:

```
$> ls -al
```

```
rwsr-x 1 root sapsys 1048044 Feb 13 16:19 icmbnd
```

## Related Information

[SAP Web Dispatcher: Binding Ports < 1024 on UNIX](#)

### 13.1.8.3 Configure HTTP(S) Access to Tenant Databases via SAP HANA XS Classic

To enable Web-based applications to send HTTP(S) requests to tenant databases via the SAP HANA XS classic server, the internal SAP Web Dispatcher must be configured so it knows which requests to dispatch to which database on the basis of DNS alias host names. You do this by specifying the public URL of every tenant database in the `xsengine.ini` configuration file.

## Prerequisites

- You are logged on to the system database.
- You have the system privilege INIFILE ADMIN.
- The network administrator has defined an alias hostname in your organization's Domain Name System (DNS) for every tenant database in the SAP HANA system. The alias hostname must refer to the hostname of the machine that is used for HTTP(S) access to the tenant database.
- You have a role based on the role template `sap.hana.xs.wdisp.admin::WebDispatcherAdmin`. This is required to access the SAP HANA Web Dispatcher Administration tool for configuring HTTPS.

## Context

The XS classic server allows Web-based applications to access SAP HANA via HTTP(S). The internal Web Dispatcher of the SAP HANA system manages these incoming HTTP(S) requests. To allow applications to send requests to specific databases, every tenant database needs an alias host name. Requests to the alias host name can then be forwarded to the XS server of the corresponding tenant database. Requests with the physical host name in the HTTP host header are forwarded to the XS server running on the system database.

The default HTTP ports are used in all cases, that is, 80<instance> (HTTP) and 43<instance> (HTTPS). Alias host names are mapped to internal HTTP(S) ports so that incoming requests can be routed to the correct database.

You configure HTTP(S) access to tenant databases by specifying in the `xsengine.ini` file the URLs by which each tenant database is publicly accessible. The system then automatically configures the Web Dispatcher by generating the required profile entries in the `webdispatcher.ini` configuration file. It is not necessary to specify the URL of the system database, this is done automatically.

## i Note

This automatic configuration of the Web Dispatcher is controlled by the parameter `[profile] wdisp/system_auto_configuration` in the `webdispatcher.ini` configuration file. If this parameter is set to **false**, you need to configure the `webdispatcher.ini` file manually.

For HTTPS access, you must subsequently configure the required client certificates and trust stores using the SAP Web Dispatcher Administration tool. The following approaches are supported:

- Using a single "wildcard" server certificate in a single trust store that covers all databases in the system  
Wildcard certificates are more flexible when tenant databases are frequently added and deleted. However, if you use a wildcard certificate, either the server requires its own sub-domain or you must ensure that the certificate cannot be abused from other servers.

## ⚠ Caution

Do not use a wildcard server certificate if strict isolation between tenant databases is required. If authentication relies on a wildcard certificate and a shared trust store, users of one tenant database will be able to log on to other databases in the system.

- Using individual certificates in individual trust stores for each database  
Individual certificates for each database are more suitable in a flat domain structure for individual servers. They also ensure strict isolation between tenant databases. However, they involve more administrative effort to maintain.

## Procedure

1. Specify the public URLs of all tenant databases in the `xsengine.ini` file in one of the following ways:

Option	Description
SAP HANA studio	<ol style="list-style-type: none"><li>1. Open the Administration editor and choose the <i>Configuration</i> tab.</li><li>2. Navigate to the <code>xsengine.ini</code> file and expand the <code>public_urls</code> section.</li><li>3. For each tenant database in the system, add the new properties <code>http_url</code> and <code>https_url</code> at the <b>database layer</b> and enter its public URL as the value:<ul style="list-style-type: none"><li>◦ <code>http://&lt;virtual_hostname&gt;:80&lt;instance&gt;</code></li><li>◦ <code>https://&lt;virtual_hostname&gt;:43&lt;instance&gt;</code></li></ul></li></ol>

## i Note

The scheme (`http/https`) must be included in the URL.

SQL	<p>For each tenant database, execute the statements:</p> <ul style="list-style-type: none"><li>◦ <code>ALTER SYSTEM ALTER CONFIGURATION ('xsengine.ini', 'database', '&lt;tenant_DB_name&gt;') SET ('public_urls', 'http_url') = 'http://&lt;virtual_hostname&gt;:80&lt;instance&gt;' WITH RECONFIGURE;</code></li><li>◦ <code>ALTER SYSTEM ALTER CONFIGURATION ('xsengine.ini', 'database', '&lt;tenant_DB_name&gt;') SET ('public_urls', 'https_url') = 'https://&lt;virtual_hostname&gt;:43&lt;instance&gt;' WITH RECONFIGURE;</code></li></ul>
-----	--

## i Note

The following values are set at the **default layer** and represent the URLs of the system database:

- `http://$(SAPLOCALHOST):80$(SAPSYSTEM)`
- `https://$(SAPLOCALHOST):43$(SAPSYSTEM)`

By default, the system database initially retrieves any request with the port `80<instance_no>`. However, as soon as you configure the URLs of tenant databases, it is available under `http://<localhost>:80<instance>` only, and not the fully qualified domain name (FQDN). The local host is known to SAP HANA without the FQDN.

If you want to change this default behavior and configure a different URL for the system database, you can do so by executing the following statement:

```
ALTER SYSTEM ALTER CONFIGURATION ('nameserver.ini', 'system')
SET('public_urls', 'http_url') = 'http://<virtual_hostname>:80<instance>'
WITH RECONFIGURE;
```

New entries are now created in the `webdispatcher.ini` file at the host layer for every database. You can verify this by executing the following statement (from the system database):

```
SELECT KEY, VALUE, LAYER_NAME FROM SYS.M_INIFILE_CONTENTS WHERE FILE_NAME =
'webdispatcher.ini' AND SECTION = 'profile' AND KEY LIKE 'wdisp/system%'
```

This returns the following result for example:

KEY	VALUE	LAYER_NAME
wdisp/system_0	GENERATED, SID=SYS, EXTSRV=http://localhost:30014, SRCVHOST='myhost'	DEFAULT
wdisp/system_1	GENERATED, SID=MYD, EXTSRV=http://localhost:30042, SRCVHOST='mydatabase.example.com'	HOST

## 2. Optional: Secure incoming communication by configuring HTTPS.

Option	Description
<b>Single certificate for all databases</b>	<ol style="list-style-type: none"> <li>1. Start the SAP HANA Web Dispatcher Administration tool at <code>http://&lt;localhost&gt;:80&lt;instance&gt;/sap/hana/xs/wdisp/admin/</code>.</li> <li>2. For the default <code>SAPSSLS.pse</code> trust store, create a new SSL key pair and certificate request: <ol style="list-style-type: none"> <li>1. From the main menu, choose <b>SSL and Trust Configuration</b> &gt; <b>PSE Management</b>.</li> <li>2. From the <b>Manage PSE</b> menu, choose <b>SAPSSLS.pse</b>.</li> <li>3. Choose <b>Recreate PSE</b>.</li> <li>4. Enter a distinguished name that matches the host name of all tenant databases.</li> </ol> </li> </ol> <div style="border: 1px solid #0070c0; padding: 5px; margin: 5px 0;"> <p><b>❖ Example</b></p> <ul style="list-style-type: none"> <li>○ Physical host name: <code>myhost.example.com</code></li> <li>○ Tenant host name 1: <code>mydatabase1.example.com</code></li> <li>○ Tenant host name 2: <code>mydatabase2.example.com</code></li> </ul> <p>In this case, you specify <b>CN=*.example.com</b> as the DN, thus creating a server certificate that matches all tenant databases and the system database.</p> </div> <ol style="list-style-type: none"> <li>5. Choose <b>Create</b>.</li> <li>6. Create a certificate request and submit to your certificate authority (CA) for signing (<b>Create CA Response</b>).</li> </ol>
	<ol style="list-style-type: none"> <li>3. Import the signed certificate</li> </ol>

For more information, see *Configure HTTPS (SSL) for Client Application Access*.

Option	Description
<b>Individual certificates for each database</b>	<ol style="list-style-type: none"> <li>1. Start the SAP HANA Web Dispatcher Administration tool at <code>http://&lt;localhost&gt;:80&lt;instance&gt;/sap/hana/xs/wdisp/admin/</code>.</li> <li>2. For each tenant database and the system database, create a new trust store with a unique certificate: <ol style="list-style-type: none"> <li>1. From the main menu, choose <b>SSL and Trust Configuration</b> &gt; <b>PSE Management</b>.</li> <li>2. On the PSE management screen, choose <b>Create New PSE</b>.</li> <li>3. Enter a file name for the new PSE. <div data-bbox="501 573 667 609" data-label="Section-Header"> <h4>❖ Example</h4> </div> <pre>example.pse</pre> </li> </ol> </li> <li>4. Enter the distinguished name: <div data-bbox="478 712 1362 770" data-label="Text"> <p><b>CN=&lt;host name used for the tenant database in the public_urls section of the xsengine.ini file&gt;</b></p> </div> </li> <li>5. Choose <b>Create</b>.</li> <li>6. For the new PSE, create a certificate request and submit to your CA for signing (<b>Create CA Response</b>).</li> <li>7. Import the signed certificate into the new PSE (<b>Import CA Response</b>).</li> </ol>
	<ol style="list-style-type: none"> <li>3. Configure the Web Dispatcher to use multiple certificates: <ol style="list-style-type: none"> <li>1. In the <code>webdispatcher.ini</code> file, create or change the parameter <code>[profile] icm/ssl_config_0</code>, specifying as the value: <div data-bbox="478 999 1321 1061" data-label="Text"> <p><b>ID=ssl_config_main, CRED=SAPSSLS.pse, SNI_CREDS=&lt;semicolon (';') separated list of database PSE files&gt;</b></p> </div> </li> <li>2. Add <b>,SSLCONFIG=ssl_config_main</b> to the value of the <code>icm/server_port</code> parameter for the HTTPS port (by default <code>icm/server_port_1</code>). <div data-bbox="501 1155 655 1191" data-label="Section-Header"> <h4>❖ Example</h4> </div> <pre>icm/server_port_1 = PROT=HTTPS,PORT=4443\$ (SAPSYSTEM),PROCTIMEOUT=600, SSLCONFIG=ssl_config_main</pre> </li> </ol> </li> </ol>

## Results

You can access the XS server of tenant databases via the configured URLs.

### → Tip

If you experience slow response times when accessing the XS server of a tenant database (for example, Web-based applications running on the tenant database), this indicates that the server is not able to resolve the host name correctly using the DNS and retries repeatedly. If this is the case, contact your network administrator for a detailed problem analysis.

As a workaround, you can manually override virtual host name resolution on the machine where the browser is running by modifying the `/etc/hosts` file on the local machine. In this file, append a new line, starting with the static IP address of the server, followed by the virtual host name of your tenant database, for example, "10.20.30.40 mydatabase.example.com". To edit this file you need admin or root privileges.

## Next Steps

Optional: Enable access to Web-based applications from the SAP HANA studio.

Some Web-based tools are accessible from the SAP HANA studio, for example, the SAP HANA cockpit and SAP HANA Lifecycle Management tool. If you want to be able to access these tools from a tenant database registered in the studio, you must specify the alias hostname in the properties. You can do this as follows:

1. In the *Systems* view, right-click the tenant database and choose *Properties*.
2. Open the *XS Properties* page and enter the alias hostname in the *XS Host* field.

## 13.1.9 Maintaining Single Sign-On for SAP HANA XS Applications

You can configure SAP HANA applications to use single sign-on (SSO) authentication to confirm the logon credentials of a user calling an application service. SAP HANA supports SSO certificates based on the Security Assertion Markup Language (SAML) or X.509.

If you want your the SAP HANA XS applications to use an SSO certificate based on SAML or X.509 as the logon authentication method, you must perform the following high-level steps:

1. Maintain the SAP HANA trust store.  
SAP HANA makes use of multiple trust stores; the trust stores listed below are provided by default.

### i Note

The trust stores listed below are located in the **file system**. In some cases, it is possible and recommended to use trust stores that exist in the database as database objects. In-database trust stores (referred to as certificate collections) contain the required client certificates, which are also stored in the database. We recommend using in-database certificate collections where possible. For more information, see *Managing Client Certificates in the SAP HANA Database*.

- The SAP HANA trust store (`sapsrv.pse`)  
Used for secure SQL and SAML or OAuth scenario, `sapsrv.pse` is installed automatically and is available by default.

### → Recommendation

For user authentication based on X.509 certificates and SAML assertions, we recommend creating separate certificate collections with the purposes *X.509* and *SAML* instead of using the file system-based trust store `sapsrv.pse`.

- The SAP Web Dispatcher trust store (`SAPSSLS.pse`)  
Required for secure connections using the Secure Socket Layer (SSL) protocol, `SAPSSLS.pse` is installed automatically and is available by default.
- The SAP Logon Ticket trust store (`saplogon.pse`)  
**Optional:** `saplogon.pse` is only necessary if an SAP HANA XS application requires an SAP logon ticket from a user at logon.

#### → Recommendation

For user authentication based on logon tickets, we recommend creating a certificate collection with the purpose *SAP LOGON* instead of using the file system-based trust store `saplogon.pse`.

- The client authentication trust store (`SAPSSLC.pse`)  
**Optional:** `SAPSSLC.pse` is only required for client connections, for example, that use the SQL client interface (`hdbsql`).
2. Choose the SSO authentication method and configure the trust relationships:  
Trust relationships are required between SAP HANA and any remote system providing services that an SAP HANA XS application requires.
    - SSO with X.509 certificates  
Add the root certificate of the Certification Authority (CA) for trusted X.509 certificates to both the SAP HANA trust store **and** the trust store for the SAP Web Dispatcher.
    - SSO with SAML certificates  
Obtain, authenticate, and import the SAML identity provider (IDP) metadata (an XML document) for the SAML service provider.
  3. Maintain the SSO provider for SAP HANA XS  
Maintain a runtime configuration for the SAP HANA application, which indicates that user authentication is by means of SSO certificates based on either SAML or X.509.

## Related Information

[Configure SSO with X.509 Authentication for SAP HANA XS Applications \[page 1723\]](#)

[Configure SSO with SAML Authentication for SAP HANA XS Applications \[page 1725\]](#)

### 13.1.9.1 Configure SSO with X.509 Authentication for SAP HANA XS Applications

SAP HANA applications can use single sign-on (SSO) authentication with X.509 certificates to confirm the logon credentials of a user calling an application service.

#### Prerequisites

- You have a role based on the role template  
`sap.hana.xs.admin.roles::RuntimeConfAdministrator`.

- The CommonCryptoLib library (`libsapcrypto.so`) is installed and available.
- A certificate collection with the purpose `X.509` is available. For more information, see *Managing Client Certificates in the SAP HANA Database*.
- The SAP Web Dispatcher trust store (`SAPSSLS.pse`) is available.

## Context

To enable SAP HANA applications to use single sign-on (SSO) authentication with X.509 certificates to confirm the logon credentials of a user, you need to add the root certificate of the Certification Authority that issues trusted X.509 certificates to both the SAP HANA trust store for X.509 authentication and the trust store of the SAP Web Dispatcher, `SAPSSLS.pse`.

## Procedure

1. Add the root certificate (for example, `SSO_CA.der`) to the SAP HANA trust store, that is the certificate collection with purpose `X.509`.
  - a. Open the SAP HANA cockpit.
  - b. Open the *Certificate Store* app.
  - c. Import the root certificate into the certificate store.
  - d. Open the *Certificate Collections* app.
  - e. Select the collection with purpose `X.509`.
  - f. Add the root certificate to this collection.
2. Add the root certificate (for example, `SSO_CA.der`) to the SAP Web Dispatcher trust store (`SAPSSLS.pse`).
  - a. Start the *SAP HANA Web Dispatcher Administration* tool.
  - b. Open the *PSE Management* tool.
 

In the *SAP HANA Web Dispatcher Administration* tool, choose **SSL and Trust Configuration** **PSE Management**.
  - c. Specify the trust store (PSE file) for the import operation.
 

In the *PSE Management* screen area, choose `SAPSSLS.pse` from the *Manage PSE* drop-down list.
  - d. Import the `SSO_CA.der` certificate.
 

In the *Trusted Certificates* screen area, choose *Import Certificate*.

Alternatively, you can also use the `sapgenpse` tool to import the `SSO_CA.der` certificate.

```
./sapgenpse maintain_pk -p /usr/sap/<SAPHANAInstance>/HDB<InstNo>/
<Hostname>/sec/SAPSSLS.pse -a SSO_CA.der
```

3. Maintain the authentication settings in the runtime configuration for your SAP HANA XS application.
 

You can use the Web-based SAP HANA XS Administration *Trust Manager* tool to complete this step. The tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

## i Note

The user maintaining the security settings needs the privileges granted by the SAP HANA XS role *TrustStoreAdministrator*.

4. Create a database user whose identity is defined in an X.509 certificate issued by your CA.
  - a. Create a new user in the SAP HANA database based on the details specified in an existing X.509 certificate.

The following example shows how to use the SQL statement `CREATE USER WITH IDENTITY` to create the database user "MyUserName" and the corresponding X.509 certificate:

```
CREATE USER MyUserName WITH IDENTITY 'CN=MyUserName, O=SAP-AG, C=DE' ISSUER 'CN=SSO_CA, O=SAP-AG, C=DE' FOR X509
```
  - b. Import into the Web browser the X.509 certificate that is to be used to authenticate the new database user.
5. Use a Web browser to test the logon authentication settings for the SAP HANA application.

When you enter the URL for your application in the Web browser, the Web browser prompts you to select a certificate, which enables you to log on without supplying logon credentials manually.

## 13.1.9.2 Configure SSO with SAML Authentication for SAP HANA XS Applications

SAP HANA applications can use single sign-on (SSO) authentication with SAML assertions to confirm the logon credentials of a user calling an application service. SAML assertions are certificates that comply with the Security Assertion Markup Language.

### Prerequisites

- You have an advanced understanding of how SAML works.
- The CommonCryptoLib library (`libsapcrypto.so`) is installed and available on the SAP HANA server.
- You are authorized to edit the certificate collection with purpose *SAML*. You need system privilege `CERTIFICATE ADMIN` and object privilege `ALTER` on the collection. For more information, see *Managing Client Certificates*.
- An SAML identity provider (IDP) is available and the corresponding SAML metadata (in the form of an XML document). For more information see *Add an SAML Identity Provider*.
- You have root/administrator access to the SAP HANA system that is configured to act as an SAML **service** provider.
- To maintain security and authentication settings for SAP HANA XS applications, you must have a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator`. To maintain SAML settings for SAP HANA XS applications, you need a role based on the role template `sap.hana.xs.admin.roles::SAMLAdministrator`.

## Context

To enable SAP HANA applications to use single sign-on (SSO) authentication with SAML assertions to confirm the logon credentials of a user, you must copy the SAML certificate from the SAML IDP metadata document and add the certificate to the SAP HANA trust store for SAML authentication.

## Procedure

1. Gather the metadata for the SAML identity provider (IDP).  
This SAML IDP metadata typically takes the form of an XML document, which you can obtain from your security system administrator.
2. Extract the certificate string (which is DER encoded) from the SAML IDP metadata document.  
The certificate string is located in the `ds:X509Certificate` tag. For the SAP ID service, the certificate string could look like the following (incomplete) code example:

```
MIICHTCCAYagAwIBAgIETKTcJjANBgkqhkiG9w0BAQUFADBTMQswCQYDVQQGEwJERTEPMA0G...
```

3. Paste the extracted SAML certificate string into a file called `sapid.cer`.
4. Add the BEGIN and END tags to the SAML certificate.

The following example of a SAML certificate is incomplete; it is intended for illustration purposes only.

```
-----BEGIN CERTIFICATE-----  
MIICHTCCAYagAwIBAgIETKTcJjANBgkqhkiG9w0BAQUFADBTMQswCQYDVQQGEwJERTEPMA0G...  
-----END CERTIFICATE-----
```

5. Import the contents of the SAML certificate (`sapid.cer`) into the SAP HANA trust store, that is the certificate collection with purpose [SAML](#).
  - a. Open the SAP HANA cockpit.
  - b. Open the [Certificate Store](#) app.
  - c. Import the SAML certificate (`sapid.cer`) into the certificate store.
  - d. Open the [Certificate Collections](#) app.
  - e. Select the collection with purpose [SAML](#).
  - f. Add the SAML certificate (`sapid.cer`) to this collection.
6. Configure your SAP HANA system to act as an SAML service provider.  
For more information, see [Configure an SAP HANA System as an SAML Service Provider](#).
7. Maintain the authentication settings in the runtime configuration for the SAP HANA XS application for which you want to enable SSO with SAML authentication.

You can use the Web-based [SAP HANA XS Administration Tool](#) to complete this step. The tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### Note

The user maintaining the authentication settings in an application's runtime configuration needs the privileges granted by the SAP HANA XS role [RuntimeConfAdministrator](#).

## Related Information

[Maintaining SAML Providers \[page 1698\]](#)

### 13.1.9.3 Configure SSO with SAP Logon Tickets for SAP HANA XS Applications

SAP HANA applications can use single sign-on (SSO) authentication with SAP logon tickets to confirm the logon credentials of the user calling an application service.

#### Prerequisites

- You have administrator access to the SAP HANA system hosting the applications to which you want to enable access with SAP logon tickets.
- To maintain security and authentication settings for SAP HANA XS applications, you must have a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator`.
- The CommonCryptoLib library `libsapcrypto.so` is installed and available.
- A certificate collection with the purpose *SAP LOGON* is available. For more information, see *Managing Client Certificates in the SAP HANA Database*.

#### Context

To enable SAP HANA applications to use single sign-on (SSO) authentication with SAP logon tickets to confirm the logon credentials of a user requesting an application service, you must ensure that an SAP server is available that can issue SAP logon tickets. In addition, you need to add the server certificate of the ticket-issuing system to the SAP HANA trust store for authentication using logon tickets.

#### Procedure

1. Add the server certificate of the SAP system that issues SAP logon tickets to the SAP HANA trust store, that is the certificate collection with purpose *SAP LOGON*.
  - a. Open the SAP HANA cockpit.
  - b. Open the *Certificate Store* app.
  - c. Import the server certificate of the ticket-issuing system into the certificate store.
  - d. Open the *Certificate Collections* app.
  - e. Select the collection with purpose *SAP LOGON*.
  - f. Add the server certificate of the ticket-issuing system to this collection.

2. In SAP HANA, configure the details of the server that issues SAP logon tickets.

This step is optional but ensures that an SAP logon ticket can always be obtained in those cases where no SAP logon ticket is immediately available for the user trying to log on.

xsengine.ini		◆
application_container		
authentication		◆
logonticket_redirect_url	https://vmw.sap.com:44333/sap/bc/	●

- a. Start the SAP HANA studio and open the *Administration* perspective.
- b. In the *Configuration* tab, expand (or add) the section **xsengine.ini** **authentication**.
- c. Set (or add) the parameter: `logonticket_redirect_url`.

Enter the URL that points to the system and service issuing SAP logon tickets, for example:

```
https://<hostname>:<portnumber>/<path/to/logon_ticket/service>
```

- `<hostname>`  
The hostname of the server issuing/storing the SAP logon tickets
- `<portnumber>`  
The port number accepting connections on the target server issuing/storing the SAP logon tickets
- `</path/to/logon_ticket/service>`  
Path to the service on the target system which handles the request for the SAP logon ticket. You can write your own custom ABAP service to handle these requests.

For example, the following URL would enable access to the **custom** (user-defined) SAP logon ticket service `zredirectwlogon` using port 44333 on the ABAP server `host.acme.com`:

```
https://host.acme.com:44333/sap/bc/zredirectwlogon?sap-client=<SAPClientNr>.
```

3. Maintain the runtime configuration for the application that you want to use SAP logon tickets for user authentication.

You can use the Web-based *SAP HANA XS Administration Tool* to complete this step. The tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`. Choose *XS Artifact Administration*.

### Note

The user maintaining the security settings needs the privileges granted by the SAP HANA XS role *RuntimeConfAdministrator*.

- a. Locate the root package of the application whose runtime configuration you want to modify.  
Use the *Packages* list in the *Application Objects* pane.
- b. In the *Security & Authentication* tab, enable support for *SAP Logon/Assertion Ticket*.
- c. Save the changes you have made.

## 13.1.9.4 Configure Outbound SSO with Assertion Tickets

Assertion tickets are a form of bearer token that one application server uses to identify and authenticate a user on another application server, for example, in a single-sign-on (SSO) scenario. You can set up SAP HANA to function as the provider of the assertion tickets required to log on to a remote SAP server.

### Prerequisites

To configure SAP HANA to use SAP assertion tickets to authenticate users who log on with SSO, note the following prerequisites:

- Your SAP HANA system is configured to use SSL
- You have administrator access to the SAP HANA system hosting the applications to which you want to enable access with SAP assertion tickets.
- To maintain security and authentication settings for SAP HANA XS applications, you must have a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator`. To maintain an HTTP destination, you need a role based on the role template `sap.hana.xs.admin.roles::HTTPDestAdministrator`.
- You know the system ID (SID) and client number of the SAP HANA system
- You know the system ID (SID) and client number of the remote SAP ABAP server that hosts the HTTP service (assertion-ticket provider) used by your XSJS application
- You have the permissions required to run transaction **STRUSTSSO2** in the ABAP system with which you want to establish a trust relationship.
- The CommonCryptoLib library `libsapcrypto.so` is installed and available on your SAP HANA system.
- You have read SAP Note [1982597](#)  concerning SAP logon tickets and assertion tickets which are created with UTF-8.

### Context

SAP HANA XS enables you to build XSJS applications that use single sign-on services with authentication using SAP assertion tickets to consume additional Web services, for example, provided by a remote ABAP application server. If the XSJS application service requires access to remote services, you can create an HTTP destination that defines the logon details required by the remote ABAP system and specifies SSO with SAP assertion tickets as the logon authentication method. The assertion ticket is included in the header of the HTTP request sent by the application service; the remote system reads the HTTP header and uses the assertion to log the requesting user on automatically.

### Procedure

1. Create the SAP HANA trust store for the assertion tickets, for example, `saplogonSign.pse`.

This trust store is used to issue the assertion tickets required for automatic logon to remote SAP systems using SSO.

```
sapgenpse gen_pse -p saplogonSign.pse "CN=<HOST>.<DOMAIN>, OU=<INSTANCE>, O=<ORG>, C=<COUNTRY>"
```

You are prompted to have the ticket signed by a Certificate Authority (CA):

- a. Copy the certificate request and have it signed by a known CA service.
- b. Copy the signed certificate results from the CA to the directory `/usr/sap/<SID>/HDB<Instance Number>/<machine name>/sec` on your SAP HANA system and name the file `saplogonSign.cer`.
- c. Import the signed certificate into the trust store.

```
./sapgenpse import_own_cert -c saplogonSign.cer -p saplogonSign.pse -r SAPNetCA.cer
```

2. Export the certificate that SAP HANA uses to sign assertion tickets.

You need to save the exported certificate to a local file for future use.

- a. Export the SAP HANA certificate from the SAP HANA trust store, for example, using the following command:

```
sapgenpse export_own_cert -p saplogonSign.pse
```

- b. Copy the output to a local file on your system.

3. Set up the trust relationship between SAP HANA and the remote SAP ABAP system you want to enable automatic logon with SSO and assertion tickets.

The remote SAP system hosting the HTTP service you want your XSJS application to use must trust the SAP HANA system hosting the XSJS service itself and acting as a provider of SAP assertion tickets.

- a. Log on to the target ABAP system and run transaction **STRUSTSSO2**.
- b. Select the system PSE (trust store).
- c. Choose the *import certificate* button in the certificate section.
- d. Select the SAP HANA certificate you signed in the previous step and import it.
- e. Choose the *Add to certificate list* button.
- f. Choose the *Add to ACL* button.
- g. Provide the system ID (SID) for the SAP HANA system; the client number is 000.
- h. Save the configuration.

4. Import the certificate of the system you want to trust for inbound SSO.

### **i** Note

This step is optional; it is only required if you want to use SAP logon tickets for inbound SSO requests, too.

5. On the SAP HANA system, edit the configuration variable used to specify the name of the trust store for SAP assertion tickets.

Start the SAP HANA studio's *Administration Console* perspective and edit the parameter `saplogontickettruststore`. You can find the `saplogontickettruststore` parameter in

► `[indexserver | xsengine].ini` ► *authentication* ► `saplogontickettruststore` ►.

indexserver.ini		
[ ] authentication		
saml_service_provider_name		● http://localhost6.locald...
saplogontickettrace		● true
saplogontickettruststore		● saplogonSign.pse
session_cookie_validity_tir	180	

6. Maintain an HTTP destination for the XSJS service that needs access to a remote SAP system and set the authentication type to *SAP Assertion Ticket*.

You define the details of an HTTP destination in a configuration file that requires a specific syntax. The configuration file containing the details of the HTTP destination must have the file extension `.xshttpdest`.

### ⚠ Caution

The HTTP destination configuration and the XSJS application that uses it must reside in the same application package. An application cannot reference an HTTP destination configuration that is located in another application package.

- a. Create a plain-text file called `<MyHTTPdestination>.xshttpdest` and open it in a text editor.
- b. Use the following code to help you define the HTTP destination details.

### i Note

Change the entries for the host name, port, system ID and client to suit your own requirements.

```
host = "<ABAP_server_name>";
port = <ABAP_HTTPS_PortNumber>;
description = "my SAP assertion ticket target";
useSSL = true;
pathPrefix = "";
authType = AssertionTicket;
useProxy = false;
proxyHost = "";
proxyPort = 0;
timeout = 0;
remoteSID = "<ABAP_SID>";
remoteClient = "<ABAP_ClientNumber>";
```

- c. Save and activate the file.

### i Note

By default, saving the modified file automatically commits the saved version to the repository; you do not need to commit the file before activating it.

7. View the activated HTTP destination.  
You can use the *SAP HANA XS Administration Tool* to check the contents of an HTTP destination configuration.

### i Note

To make changes to the HTTP Destination configuration, you must use a text editor, save the changes and reactivate the file.

- a. Open a Web browser.
- b. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### i Note

To access details of HTTP destinations in the *SAP HANA XS Administration Tool*, you must have a role based on the role template `sap.hana.xs.admin.roles::HTTPDestAdministrator`.

- c. Locate the package containing the HTTP destination `<MyHTTPdestination>.xshttpdest`.  
Expand the nodes in the *Application Objects* pane to locate the package where the HTTP destination resides and select the HTTP destination to display details in the right pane.
8. Check the specified system ID (SID) and the client of the remote SAP system referenced in the HTTP destination.
  - a. Enable the *SAP Assertion Ticket* radio button.
  - b. Check (or enter) the SID and client number for the remote SAP system in the *SAP SID* and *SAP Client* text boxes respectively.
9. Save the changes to the HTTP destination and use it in an XSJS application service.

#### → Tip

You can reference an HTTP destination from an XSJS service using the function `$.net.http.readDestination("<packageName>", "<HTTPDestinationName>")`

## 13.1.10 Maintaining User Self Service Tools

User self-service tools enable SAP HANA users to trigger account-related tasks, for example, the creation of a new database account.

By default, the user self-service tools are disabled. The SAP HANA administrator must activate the user self-service feature to provide users with access to embedded tools they can use to request the creation of a new user account in the SAP HANA database or request a new password.

Setting up and maintaining user-self-service tools for SAP HANA includes the following high-level tasks:

- Enable user self-service tools
- Request a new user account
- Display a list of the current user requests
- Reject a user/user request
- Enable access to the user-self-service administration tool

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`

#### i Note

To log on, use the name and password of the user who has a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

Enabling and maintaining the tools required to manage user self-service requests in SAP HANA involves the creation of a dedicated technical user and the assignment of dedicated roles.

- **Administrator**  
The user who manages the self-service requests and access lists must be assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`; the user self-service administrator is the same user as the user associated with the email address defined in the `xsengine.ini` parameter `sender_email`. The self-service administrator receives an e-mail in response to each self-service request; the e-mail contains a list of tasks to perform.
- **Technical user**  
A dedicated technical user, who is used to execute tasks associated with user self-service requests, for example, sending e-mails in response to user requests. Technical users cannot be used to log on to SAP HANA.

## Related Information

[Enable User Self-Service Tools \[page 1733\]](#)

[User Self-Service Roles \[page 1735\]](#)

### 13.1.10.1 Enable User Self-Service Tools

User self-service tools are not enabled by default; they must be activated by the SAP HANA administrator.

## Prerequisites

To enable user self-service tools in SAP HANA, you must have the following privileges:

- Access to SAP HANA as SAP HANA database administrator
- Access to specific features provided by the SAP HANA XS administration tools, which requires the privileges granted by the following roles:
  - `sap.hana.xs.admin.roles::RuntimeConfAdministrator`
  - `sap.hana.xs.admin.roles::SQLCCAdministrator`
  - `sap.hana.xs.admin.roles::SMTPDestAdministrator`
  - `sap.hana.xs.ide.roles::SecurityAdmin`
  - `sap.hana.xs.selfService.admin.roles::USSAdministrator` (to log on to the user self-service administration tool)
- Access to the following SAP HANA tools:
  - [SAP HANA XS Administration Tool](#)
  - [SAP HANA Web-based Development Workbench](#)
  - [SAP HANA USS Administration Tool](#) (user self-service administration tool)

## Context

By default, SAP HANA user self-service tools are disabled; the tools are neither visible in the user interface nor configured in SAP HANA. To provide access to embedded tools that enable users to request the creation of a new user account in the SAP HANA database or set a new password, the SAP HANA administrator must activate and set up the user self-service feature.

## Procedure

1. Configure the XSSQLCC technical user required to run the user self-service tools.

A technical user is required to execute user self-service requests; the technical user must be granted a role based on the role template `sap.hana.xs.selfService.user.roles::USSExecutor` and associated with the XSSQLCC artifact `selfService.xssqlcc`.

2. Set the required user-self-service parameters in the `xsengine.ini` file.

As part of the process of enabling user self-service tools in SAP HANA, you must set a number of configuration parameters, for example, to specify the email address to use when responding to user requests or enable support for password-reset services. The parameters must be set in the `user_self_service` section of the `xsengine.ini` file.

### i Note

If the section `user_self_service` does not already exist, the SAP HANA administrator must create it.

3. Configure the SMTP server that SAP HANA XS applications can use to send e-mails.

An SMTP server is required to send automatic e-mails in response to the requests users make with SAP HANA user-self-service tools.

### i Note

You can configure only one SMTP server per SAP HANA XS server. If an SMTP server is already available, you can skip this step.

4. Configure access to the user self-service administration tools.

You must assign a role based on the role template

`sap.hana.xs.selfService.admin.roles::USSAdministrator` to the user who requires access to the user-self-service administration tools. The user self-service administrator maintains user self-service requests and access blacklists and whitelists.

### → Tip

The user self-service administrator is the user who owns the e-mail address defined in the `sender_email` parameter in the `user_self_service` section of the `xsengine.ini` SAP HANA configuration file.

## Related Information

[Set up the Technical User for Self-Service Tools \[page 1736\]](#)

[Configure an SMTP Server for User Self-Service Tools \[page 1737\]](#)

[Configure Access to User-Self-Service Administration Tool \[page 1739\]](#)

### 13.1.10.1.1 User Self-Service Roles

Dedicated roles are provided to enable access to and the administration of user-self-service tools.

User-self-service tools enable users to request basic database-account services using tools displayed in the user interface. For example, if the self-service tools are enabled, users can request the creation of a new account or a password reset if a password has been forgotten. Additional tools are provided to help administrate the user-self-service requests.

#### → Recommendation

As repository roles delivered with SAP HANA can change when a new version of the package is deployed, either do not use them directly but instead as a template for creating your own roles, or have a regular review process in place to verify that they still contain only privileges that are in line with your organization's security policy. Furthermore, if repository package privileges are granted by a role, we recommend that these privileges be restricted to your organization's packages rather than the complete repository. To do this, for each package privilege (`REPO.*`) that occurs in a role template and is granted on `.REPO_PACKAGE_ROOT`, check whether the privilege can and should be granted to a single package or a small number of specific packages rather than the full repository.

#### User Self-Service Roles

SAP HANA Role	Description
sap.hana.xs.selfService.user.roles::USSAdministrator	<p>Role assigned to the user responsible for administrating the requests sent by users using self-service tools. For example, it provides access to the <i>USS Administration</i> tool, which enables the activation of users who request a new user account in the SAP HANA database and allows the user-self-service administrator to maintain self-service-specific blacklists for user requests, e-mail addresses, domains, and IP addresses.</p> <p>The <i>USS Administrator</i> role also provides access to the tools required to assign roles to (and activate) users in SAP HANA, for example:</p> <ul style="list-style-type: none"><li>• System privileges: USER ADMIN</li><li>• Object privileges: SELECT on the tables USERS (SYS) and USER_PARAMETERS (SYS)</li></ul>
sap.hana.xs.selfService.user.roles::USSExecutor	<p>Role assigned to the technical user that will be used to respond to and execute user-self-service requests, for example, to create a new account or request a new password.</p>

## 13.1.10.1.2 Set up the Technical User for Self-Service Tools

Configure the configuration connection (XSSQLCC) and the technical user which are required to execute user self-service requests.

### Prerequisites

To complete the steps in this task, you must have the following privileges:

- Access to SAP HANA as the administrator
- Access to specific features provided by the *SAP HANA XS Administration Tool* and the *SAP HANA Web-based Development Workbench*, which requires roles based on the following role templates:
  - `sap.hana.xs.admin.roles::RuntimeConfAdministrator`
  - `sap.hana.xs.admin.roles::SQLCCAdministrator`
  - `sap.hana.xs.ide.roles::SecurityAdmin`

### Context

A technical user is required to execute user self-service requests; the technical user must have a role based on the role template `sap.hana.xs.selfService.user.roles::USSExecutor` and associated with the design-time XSSQLCC artifact `selfService.xssqlcc`.

### Procedure

1. Create the XSSQLCC technical user required to execute the user self-service requests.
    - a. Open the *SAP HANA Web-based Development Workbench* and start the *Security* tool.  
The *Security* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/ide/security`.
- i Note**  
Access to the *Security* tool in the *SAP HANA Web-based Development Workbench* requires a role based on the role template `sap.hana.xs.ide.roles::SecurityAdmin`.
- b. Right-click the node **Security > Users** and choose *New User*
  - c. Specify the required details for the new technical user.  
You must provide a name and authentication credentials.
  - d. Assign a role based on the role template `sap.hana.xs.selfService.user.roles::USSExecutor` to the new technical user.
  - e. Save your changes to add the new technical user.
2. Assign the new technical user to the `selfService.xssqlcc` artifact.

The technical user you assign to the `selfService.xssqlcc` artifact executes all user-self-service requests, which requires a role based on the role template `sap.hana.xs.selfService.user.roles::USSExecutor`. The `selfService.xssqlcc` artifact provides the appropriate access to SAP HANA.

- a. Start the Web-based *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### **i Note**

To edit `xssqlcc` artifacts with the *SAP HANA XS Administration Tool*, you must have roles based on the following role templates: `sap.hana.xs.admin.roles::RuntimeConfAdministrator` and `sap.hana.xs.admin.roles::SQLCCAdministrator`.

- b. Locate the artifact SQL connection-configuration artifact `selfService.xssqlcc`.

In the *Application Objects* screen, navigate to the package `/sap/hana/xs/selfService/user`.

- c. Assign a technical user to the `selfService.xssqlcc` artifact.

This is the technical user who will be used to execute all user-self-service requests. The user must be assigned a role based on the role template

`sap.hana.xs.selfService.user.roles::USSExecutor`. You must provide the user name and the corresponding password.

## **Related Information**

[Enable User Self-Service Tools \[page 1733\]](#)

### **13.1.10.1.3 Configure an SMTP Server for User Self-Service Tools**

An SMTP server is required to enable SAP HANA to respond to user self-service requests.

## **Prerequisites**

To complete the steps in this task, you must have the following privileges:

- Access to SAP HANA as the administrator
- Access to specific features provided by the *SAP HANA XS Administration Tool* and the *SAP HANA Web-based Development Workbench*, which requires roles based on the following role templates:
  - `sap.hana.xs.admin.roles::RuntimeConfAdministrator`
  - `sap.hana.xs.admin.roles::SMTPDestAdministrator`

## Context

To enable SAP HANA to send automatic e-mails in response to the requests users make with SAP HANA user-self-service tools, you must configure a new SMTP server, or make SAP HANA aware of an existing SMTP server.

### i Note

You can configure only one SMTP server per SAP HANA XS server. If an SMTP server is already configured, you can use the configured server; you do not have to complete this task.

## Procedure

1. Start the Web-based *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

### i Note

To access to the *SAP HANA XS Administration Tool*, you need a role based on the role template `sap.hana.xs.admin.roles::RuntimeConfAdministrator`.

2. Start the *SMTP Configuration* tool .

### i Note

To access to the *SMTP Configuration* tool in the *SAP HANA XS Administration Tool*, you need a role based on the delivered role `sap.hana.xs.admin.roles::SMTPDestAdministrator`.

3. Specify the details of the SMTP server that the user-self-service tools use to reply to service requests. You need to specify the fully qualified domain name of the SMTP server and the port to use for connections, for example, 25 (standard).

### → Tip

For more information about setting up an SMTP server, see *Related Links* below.

## Related Information

[Enable User Self-Service Tools \[page 1733\]](#)

[Maintaining SMTP Server Configurations \[page 1707\]](#)

## 13.1.10.1.4 Configure Access to User-Self-Service Administration Tool

SAP HANA provides an administration tool that enables you to maintain user self-service requests.

### Context

Access to the user-self-service administration tools is only possible to users with a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`. The user self-service administrator maintains user self-service requests and access-control blacklists and whitelists.

#### → Tip

The user self-service administrator is the user who owns the e-mail address defined in the `sender_email` parameter in the `user_self_service` section of the `xsengine.ini` SAP HANA configuration file.

### Procedure

1. Open the *SAP HANA Web-based Development Workbench* and start the *Security* tool.  
The *Security* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/ide/security`.

#### i Note

To access to the *Security* tool in the *SAP HANA Web-based Development Workbench*, you need a role based on the role template `sap.hana.xs.ide.roles::SecurityAdmin`.

2. Configure the user-self-service administrator.  
You can create a new user or assign a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator` to an existing user.
  - a. In the *Security* tool, right-click the node **Security > Users** and choose the user for whom you want to enable access to the user-self-service administration tools.
  - b. Assign a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator` to the selected user.
  - c. Save your changes.
3. Log on to the user-self-service administration tool as the new user-self-service administrator.  
Verify that you have the permissions required to access to the *USS Administration* tool; the tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`.

### i Note

To log on to the *USS Administration* tool, use the name and password of the user to whom you assigned the role based on the role template

`sap.hana.xs.selfService.admin.roles::USSAdministrator` in the previous step.

## Related Information

[Enable User Self-Service Tools \[page 1733\]](#)

[Display all User Self-Service Requests \[page 1743\]](#)

[Maintain User Self-Service Access Lists \[page 1752\]](#)

## 13.1.10.1.5 Maintain User Self-Service Initialization Parameters

Selected INI parameters can be used to configure how the USS tools respond to user requests and which actions are allowed by default.

### Prerequisites

SAP HANA user roles are used to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

### Context

As part of the process of enabling user self-service tools in SAP HANA, you must set a number of configuration parameters, for example, to activate the self-service tools, specify the email address to use when responding to user requests, or enable support for password-reset services. The parameters you maintain here are synchronized with the corresponding parameters in the `user_self_service` section of the `xsengine.ini` file for the SAP HANA system where you want make self-service tools available.

To display and maintain the initialization parameters for the user self-service tools, perform the following steps:

## Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`

### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

2. Display the list of user-self-service requests.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

### i Note

You can also use the *USS Administration* tool to maintain access lists.

3. Choose the *INI Parameters* tool.

4. Set the initialization parameters as required.

Some parameters are enabled (true) or disabled (false); other parameters require a value to be set, for example, a user's e-mail address or the maximum number of times a user can request a new account with USS tools.

### i Note

The parameters you maintain here are synchronized with the corresponding parameters in the `user_self_service` section of the `xsengine.ini` file for the SAP HANA system where you want make self-service tools available.

## Related Information

[User Self-Service Initialization Parameters \[page 1741\]](#)

### 13.1.10.1.5.1 User Self-Service Initialization Parameters

Initialization (INI) parameters can be used to configure which USS tools are enabled and how the USS tools react to user requests.

In the *USS Administration* tool, the *INI Parameters* tool displays the mandatory parameters that must be set to enable and configure user-self-service and, in some cases, specify how they can be used. The following table indicates which parameters must be set.

## Note

The USS initialization parameters you set with USS administration tools correspond to (and are synchronized with) the SAP HANA parameters listed in the `user_self_service` section of the `xsengine.ini` configuration file.

### USS INI Parameter Details

UI Element	Description	Parameter Name	Default
<a href="#">Automatic User Creation</a>	<p>Controls if a user creation request requires approval from user administration. In both cases the administrator has to assign roles to the new user.</p> <ul style="list-style-type: none"><li><b>Disabled:</b> Requests for a new user account require administrator approval for account activation.</li><li><b>Enabled:</b> The user is automatically created <b>and activated</b> as a restricted user.</li></ul>	<code>automatic_user_creation</code>	Disabled/False
<a href="#">Forgot Password</a>	<p>Defines if the system supports password recovery with user-self-service tools. The parameter controls not only the display of the <a href="#">Forgot Password</a> button in the UI logon screen but also the enablement of the corresponding user-self-service backend services.</p>	<code>forgot_password</code>	Disabled/False
<a href="#">Request New user</a>	<p>Enables system support for user-self-service tools. The parameter controls not only the display of the <a href="#">Request New User</a> button in the UI logon screen but also the enablement of the corresponding user-self-service backend services.</p>	<code>request_new_user</code>	Disabled/False
<a href="#">Reset Locked User</a>	<p>Enables support for a password reset for a locked user. Reset password will be forbidden for locked users if the value is <a href="#">Disabled</a>.</p>	<code>reset_locked_user</code>	Disabled/False
<a href="#">Sender E-Mail Address</a>	<p>The email address used for sending out auto-generated replies to user self-service requests, for example, <code>uss.admin@acme.com</code>. Ideally, this is the e-mail address used by the self-service administrator, who is assigned a role based on the role template <code>sap.hana.xs.selfService.admin.roles:USSAdministrator</code> and maintains self-service requests and access lists.</p>	<code>sender_email</code>	None
<a href="#">Token Expiry Time</a>	<p>The time duration (in seconds) for which a generated token (and the corresponding request for a new user or password reset) is valid.</p>	<code>token_expiry_time</code>	3600
<a href="#">User Creation Request Count</a>	<p>The number of times a user can use user-self-service tools to request a new user account. The user is determined by a combination of user name and e-mail address.</p>	<code>user_creation_request_count</code>	3

## Optional USS Parameters

It is possible to customize the background image displayed in the logon Web page, for example, by specifying the URL to the image displayed as background in the logon screen. However the following prerequisites apply:

- The image file specified in the URL must be reachable by http(s)
- The URL does not require authentication or authorization
- The recommended minimum resolution of the specified background image is: 1600\*1200
- A technical user has to be assigned to the XSSQLCC artifact `/sap/hana/xs/selfService/user/selfService.xssqlcc`. The technical user must also be assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSExecutor`. This user will be used to query the details from the server.

### i Note

The parameter `login_screen_background_image` must be set in the `httpservers` section of the SAP HANA `xengine.ini` configuration file and can only be set with SAP HANA studio tools.

Optional User Self-Service Configuration Parameters

Parameter Name	Section Name	Description	Example	Default
<code>login_screen_background_image</code>	<code>httpservers</code>	URL to the image displayed as background in the logon screen	<code>/sap/hana/xs/ui/Image.jpg</code>	None

## Related Information

[Maintain User Self-Service Initialization Parameters \[page 1740\]](#)

## 13.1.10.2 Display all User Self-Service Requests

Display a list of all the user creation requests which have been sent using user self-service tools.

## Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

## Context

The user-self-service administrator is the user associated with the e-mail address defined in the `xengine.ini` parameter `sender_email`. The user-self-service administrator can use the *USS Administration* tool to view a list of all the self-service requests received from users. Each user self-service request includes the following details:

- User name
- Creation date and time
- Number of pending self-service requests made by the same user

To display all user self-service requests, perform the following steps:

## Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`.

### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

2. Display the access-control list that you want to maintain.

You can maintain access-control lists for the following conditions:

- Domain
- E-mail address
- IP ranges

3. Maintain entries for the selected access-control list.

You can use the *Add* and *Delete* buttons to manage the list entries.

### → Tip

To delete an entry from an access-control list, first check one or more items in the list and choose *Delete*.

## Related Information

[Display all User Self-Service Requests \[page 1743\]](#)

[Activate a User Account \[page 1749\]](#)

[Reject a User Self-Service Request \[page 1750\]](#)

## 13.1.10.3 Request a New User Account

Request a new user account with user-self-service tools.

### Prerequisites

- User-self-service tools are enabled in SAP HANA
- The required technical user (with the role *USSExecutor* is configured and available to respond to user-self-service requests

### Context

If the self-service tools are enabled, a user can use the tools to request a new user account in the SAP HANA database. A valid e-mail address is required to complete the account-creation process, and the administrator must activate the new account and assign user roles and privileges.

To request a new database account in SAP HANA, a user must perform the following steps:

### Procedure

1. Logon to SAP HANA using the Web-based interface.  
The SAP HANA *Logon* screen is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/formLogin/login.html`.
2. Request a new user SAP HANA account.  
Click the *Request Account* link in the bottom right-hand side of the logon screen.
3. Specify basic details for the new user.  
In the *Request Account* screen, you must supply a name and a valid e-mail address, which the user-self-service tools use to respond to the request.
  - a. Enter a name for the new database user.
  - b. Enter a valid e-mail address for the new database user.  
The e-mail address is used to sent the user messages with links to use to start the account activation process.
4. Submit the request for a new account.  
After submitting the account-creation request, the user receives the following automatically generated e-mails:
  - Address verification  
An e-mail with a link that verifies the target e-mail address
  - User-self-service request administratration  
An e-mail that contains the following links:

- Open the *SAP HANA XS Administration Tool* tool that enables an account be set up and activated for the new user
  - Display a list of all pending user-self-service requests
5. Set a password and security question for the new user account
 

The user requesting the new database account must set a password and choose a security question that is used in the event of a forgotten-password request. An answer must be supplied for the selected security question.
  6. Activate the new user account.
 

The user self-service administrator must activate the new user account to enable the new user to log on to SAP HANA. Activation involves assigning roles to the new user as well as privileges, for example: objects, application, package.

## 13.1.10.4 Maintain Your User Profile

Each user account is associated with a profile; the user who owns the profile must adjust the settings to suit personal preferences.

### Prerequisites

- User-self-service tools are enabled in SAP HANA.
- A user profile exists; a user profile is created automatically on activation of a user account in SAP HANA.
- The profile owner has the privileges granted by the role `sap.hana.xs.formLogin.profile::ProfileOwner`.

### Context

When a new user account is activated, the corresponding account profile is created with default settings. The new user must log on to SAP HANA and adjust some of the default settings, for example, the default password. It is also mandatory to choose a security question and set the corresponding answer.

### Procedure

1. Log on to SAP HANA using the Web-based interface.
 

The SAP HANA *Logon* screen is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/formLogin/login.html`.
2. Start the profile manager.
 

The *Manage Profile* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/formLogin/profile/`.

3. Maintain your security settings.

It is mandatory to choose a security question from the drop-down list and provide a corresponding answer. You can also change the e-mail address to use for communication.

**i Note**

The question and answer are used to confirm logon credentials, whenever the owner of the profile attempts to make any changes to the profile.

4. Change the initial (default) password.

**i Note**

In SAP HANA, rules apply that restrict which characters you can use in the password you set.

5. Maintain your profile preferences.

You can change set the language locale for your account and set preferences for the way that the date and time is displayed, for example:

- *Date Format: YYYY-MM-DD* ("2014-12-25")
- *Time Format:*
  - *HH24:MI* ("15:30" )
  - *HH12:MI* ("3:30pm")
- *Locale: English (en)*

**i Note**

Application developers need to ensure that the applications they create are able to take account of the preference set in a user's profile.

## Related Information

[Request a New User Account \[page 1745\]](#)

### 13.1.10.4.1 User Profile Details

Each user account has a corresponding account profile.

When a new user account is activated, the corresponding account profile is created with default settings. The new user must log on to SAP HANA and adjust some of the default settings, for example, the default password. It is also mandatory to choose a security question and set the corresponding answer. The *User Self Services Manage Profile* tool displays the following screens to help you maintain details of the SAML service provider:

- [Security Settings \[page 1748\]](#)
- [Preferences \[page 1748\]](#)
- [Change Password \[page 1748\]](#)

## Security Settings

The *Security Settings* screen area in the USS *Manage Profile* tool enables you to maintain details of the security settings for your SAP HANA user account. The following table indicates which details can be maintained.

UI Element	Description	Example
<i>Email Address</i>	The e-mail address of the user to whom the account and profile belong. USS notifications are sent to the specified address.	Kwame.Ampomah@acme.com
<i>Security Question</i>	The security question to ask when you make any changes to the user profile details.	What is your favorite sport?
<i>Security Answer</i>	Text string that you use as the answer to the security question	squash

## Preferences

The *Preferences* screen area in the USS *Manage Profile* tool enables you to maintain details of the display preferences for your SAP HANA user account. The following table indicates which details can be maintained.

UI Element	Description	Example
<i>Date Format</i>	The way in which the date is displayed in the applications you use, for example, <i>2014-12-25</i>	YYYY-MM-DD
<i>Time Format</i>	The way in which the time is displayed in the applications you use, for example, <i>15:30</i> (HH24:MI) or <i>3:30pm</i> (HH12:MI)	HH24:MI
<i>Locale</i>	The language environment and settings to apply for the applications you use	English (en) or Chinese (zh)

## Change Password

The *Change Password* screen area in the USS *Manage Profile* tool enables you to maintain details of your SAP HANA user account. The following table indicates which details can be maintained.

UI Element	Description	Example
<i>Old Password</i>	The initial password assigned when the account was activated or, if changed, the currently valid password	*****
<i>New Password</i>	The new password	*****
<i>Repeat Password</i>	Confirm the new password you entered in <i>New Password</i>	*****

## Related Information

[Maintain Your User Profile \[page 1746\]](#)

### 13.1.10.5 Activate a User Account

Enable a new user account in the SAP HANA database in response to a user self-service request.

#### Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

#### Context

When a user requests a new account, the user account is created but disabled by default. The user who sent the request cannot use the account to log on to SAP HANA until the SAP HANA user-self service administrator activates the account. The self-service administrator must manually activate the account and assign the necessary roles, too.

##### i Note

On activation of the new user account, an e-mail is automatically sent to the user containing the security token required to enable the new user to set a password for the new account.

To activate a new account in response to a user self-service request, perform the following steps:

#### Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`.

##### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

2. Display the list of user-self-service requests.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

#### i Note

You can also use the *USS Administration* tool to maintain access lists.

3. Assign roles to a new user.
  - a. In the *Username* column of the *User Self Service Requests* screen, check the box next the user you want to activate.
  - b. In the *Administration* column, choose *Assign Roles*.

The link opens the *Security* tool in the SAP HANA Web-based Development Workbench and displays the selected user. Select the appropriate roles to assign to the new user from the list of roles displayed.

#### i Note

To help decide which roles are appropriate for the user request, use the path indicated in the *Request Origin* column to see which tool the user is trying to access. For example, `/sap/hana/ide/editor` is the SAP HANA Editor tool, which requires a role based on the role template `sap.hana.ide.roles::EditorDeveloper`.

4. Activate the selected new user.

In the *User Self Service Requests* page, choose *Activate and Notify* to send an e-mail to the corresponding user indicating that the requested account is active and ready for use.

[Maintain User Self-Service Access Lists \[page 1752\]](#)

[Display all User Self-Service Requests \[page 1743\]](#)

## 13.1.10.6 Reject a User Self-Service Request

Refuse a self-service request to create a new user account in the SAP HANA database.

### Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

## Context

When a user requests a new account, the user account is created but disabled by default. The user who sent the request cannot use the account to log on to SAP HANA until the SAP HANA user-self service administrator activates the account and assigns the appropriate roles. The user-self-service administrator can also choose to reject the request for a new user account in the SAP HANA database, for example, by adding the user to the user-requests blacklist.

### i Note

On activation of the new user account, an e-mail is automatically sent to the user containing the security token required to enable the new user to set a password for the new account.

To refuse a self-service request to create a new user account in the SAP HANA database, perform the following steps:

## Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`.

### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

2. Display the list of user-self-service requests.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

### i Note

You can also use the *USS Administration* tool to maintain access lists.

3. Reject the user's request for a new database account.
  - a. In the *Username* column of the *User Self Service Requests* screen, check the box next the user, whose request for a new account you want to reject.
  - b. Choose *Add to blacklist* in the bottom right-hand corner of the screen.

The link opens the *Security* tool in the SAP HANA Web-based Development Workbench and displays the selected user. Select the appropriate roles to assign to the new user from the list of roles displayed.
4. Check the rejected user has been added to the user-requests blacklist.

## Related Information

[Maintain User Self-Service Access Lists \[page 1752\]](#)

## 13.1.10.7 Maintain User Self-Service Access Lists

Access to self-service tools can be controlled using denylists and allowlists, for example, for email addresses.

### Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

### Context

The user self-service administrator can control access to self-service features by maintaining denylists and allowlists for the following areas:

- User requests
- Network domains
- IP addresses
- E-mail addresses
- DB users

#### i Note

Users whose requests exceed the value set in the `xsengine.ini` parameter `user_creation_request_count` are no longer able to submit any requests. If necessary, the administrator can add such users to the access denylist.

To display all user self-service access lists, perform the following steps:

### Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`.

#### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

2. Display the list of user-self-service requests.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

### i Note

You can also use the *USS Administration* tool to maintain access lists.

## Related Information

[User Self-Service Access Lists \[page 1753\]](#)

### 13.1.10.7.1 User Self-Service Access Lists

Access to self-service features is controlled by blacklists and whitelists.

The user self-service administrator can control access to user-self-service tools using the *USS Administration* by maintaining access lists. The access lists included with the *USS Administration* are described in the following table.

User Self-Service Access List Details

List Name	Description
User Requests	A list of all pending requests sent with user-self-service tools, including the name of the user who sent the request and the corresponding e-mail address. Users who have more requests than the value set in the <code>xengine.ini</code> parameter <code>user_creation_request_count</code> are automatically added to the access blacklist.
Network Domains	A list of network domains, which can be used to permit or deny user self-service requests from one or more specific domains, for example, "acme.com". If a user self-service request for a new user account arrives from a user with an e-mail address associated with a whitelisted domain, the new user account is created as a <b>restricted</b> user and activated without requiring any administrator intervention. Users on the domain black list are no longer permitted to create a user self-service request.
IP Addresses	A list of IP addresses (or names), which can be used to permit or deny user self-service requests from one or more specific IP addresses, for example, "* .122 .10". The same rules for blacklists and whitelists apply as for network domains above.
E-mail addresses	A list of e-mail addresses, which can be used to permit or deny user self-service requests from a specific e-mail address, for example, "joe.doe@acme.com" or "jane.doe@acme.com". The same rules for blacklists and whitelists apply as for network domains and IP addresses above.

List Name	Description
DB Users	<p>The names of the database users who are not allowed to change their respective SAP HANA password using USS reset-password tools, for example, j_oedoe or j_anedoe. The following additional restrictions apply:</p> <ul style="list-style-type: none"> <li>• By default, it is not possible to use USS tools to reset the password for the SYSTEM user.</li> <li>• The USS administrator cannot add to the <i>DB Users</i> list any user who logs on to SAP HANA with single sign-on (SSO) credentials.</li> <li>• Users who log on to SAP HANA with SSO credentials cannot use USS tools to reset their password.</li> </ul>

## 13.1.10.8 Maintain User Self-Service E-Mail Templates

Default templates enable you to format the contents of the auto-generated e-mails sent when user self-service (USS) tools are employed to request a new account in SAP HANA or recovery a forgotten password.

### Prerequisites

SAP HANA uses roles to determine the level of access to the features provided by the SAP HANA XS administration tools. To access the tools required to maintain user self-service requests, you must have a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

### Context

The user self-service administrator can modify the contents of the automatically generated e-mails that are sent to users during the USS account-creation process. Templates exist for the responses to the following actions: user requests, account activation, and forgotten passwords.

To display and maintain the current e-mail templates for user self-service features, perform the following steps:

### Procedure

1. Start the user-self-service administration tool.

The *USS Administration* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/selfService/admin`

#### i Note

To log on, use the name and password of the user who has been assigned a role based on the role template `sap.hana.xs.selfService.admin.roles::USSAdministrator`.

2. Display the list of user-self-service requests.

When you open the *USS Administration* tool, the list of user-self-service requests is displayed by default.

#### **i** Note

You can also use the *USS Administration* tool to maintain access lists.

3. Choose the *Email Templates* tool.
4. Choose the required e-mail template.

The following templates are available for automatically generated e-mails:

- User request  
E-mail sent in response to a user self-service request for a new SAP HANA user account
- User activation  
E-mail sent when a new SAP HANA user account has been activated
- Password Recovery  
E-mail sent in response to a user self-service request to set a new SAP HANA password, for example, because the user has forgotten the current password.

## Related Information

[User Self-Service E-Mail Templates \[page 1755\]](#)

### 13.1.10.8.1 User Self-Service E-Mail Templates

USS provides templates that can be used to format the content of auto-generated e-mails.

In the *USS Administration* tool, the *Email Templates* tool displays information about the templates used to format the content of auto-generated e-mails that are used during the process of creating a new SAP HANA user account. You can use the *Email Templates* tab to maintain the following details:

- [User Request \[page 1755\]](#)
- [User Activation \[page 1756\]](#)
- [Forgot Password \[page 1756\]](#)

## User Request

The *User Request* tab in the *Email Templates* tool enables you to maintain templates that are used to generate the e-mails sent in response to a user request to create a new account in SAP HANA; the e-mails are sent to the USS administrator and the user who submitted a USS request. The following table indicates which information can be viewed and modified.

#### User Request E-Mail Template Details

UI Element	Description	Example
<i>To</i>	The email address of the USS administrator	admin.uss@acme.com
<i>Subject</i>	The text you want to appear in the e-mail's <i>Subject</i> box	New user account
<i>Body</i>	The text of the e-mail sent either to the USS admin indicating that a new request for a SAP HANA user account has been received and needs attention or to the user who submitted a request and indicating that the request for a new account has been received and is being processed	Dear USS Admin, ...

## User Activation

The *User Activation* tab in the *Email Templates* tool enables you to maintain templates for the account-activation e-mails sent to the user who uses USS tools to submit a request for a new account in SAP HANA; the e-mail informs the user that the requested account is active and can be used to log on to SAP HANA. The following table indicates which information can be viewed and modified.

#### User Activation E-Mail Template Details

UI Element	Description	Example
<i>To</i>	The email address of the user whose new accounts has been activated	admin.uss@acme.com
<i>Subject</i>	The text you want to appear in the e-mail's <i>Subject</i> box	SAP HANA account status
<i>Body</i>	The text of the e-mail sent either to the new SAP HANA user indicating that an account has been activated and can be used to log on to SAP HANA	Dear [ <i>&lt;User Name&gt;</i> ], ...

## Forgot Password

The *Forgot Password* tab in the *Email Templates* tool enables you to maintain the template used to generate e-mails that are sent to SAP HANA users who submit a USS request to reset a password. The following table indicates which information can be viewed and modified.

#### Forgot Password E-Mail Template Details

UI Element	Description	Example
<i>To</i>	The email address of the user who submitted a request to reset a password	jane.doe@acme.com
<i>Subject</i>	The text you want to appear in the e-mail's <i>Subject</i> box	Reset account password
<i>Body</i>	The text of the e-mail to the SAP HANA user indicating that a request to reset an SAP HANA password has been received and action is required from the user	Dear [ <i>&lt;User Name&gt;</i> ], ...

## Related Information

[Maintain User Self-Service E-Mail Templates \[page 1754\]](#)

### 13.1.11 Scheduling XS Jobs

Scheduled jobs define recurring tasks that run in the background. The JavaScript API `$ .jobs` allows developers to add and remove schedules from such jobs.

If you want to define a recurring task, one that runs at a scheduled interval, you can specify details of the job in a `.xsjob` file. The time schedule is configured using `cron`-like syntax. You can use the job defined in an `.xsjob` file to run an XS Javascript or SQLScript at regular intervals. To create and enable a recurring task using the `xsjob` feature, you perform the following high-level tasks:

#### i Note

The tasks required to set up a scheduled job in SAP HANA XS are performed by two distinct user roles: the application developer and the SAP HANA administrator. In addition, to maintain details of an XS job in the [SAP HANA XS Administration Tool](#), the administrator user requires the privileges granted by the role template `sap.hana.xs.admin.roles::JobAdministrator`.

Setting up Scheduled Jobs in SAP HANA XS.

Step	Task	User Role	Tool
1	Create the function or script you want to run at regular intervals	Application developer	Text editor
2	Create the job file <code>.xsjob</code> that defines details of the recurring task	Application developer	Text editor
3	Maintain the corresponding runtime configuration for the <code>xsjob</code>	SAP HANA administrator	XS Job Dashboard
4	Enable the job-scheduling feature in SAP HANA XS	SAP HANA administrator	XS Job Dashboard
5	Check the job logs to ensure the job is running according to schedule.	SAP HANA administrator	XS Job Dashboard

## Related Information

## 13.1.11.1 Maintain XS Job Details

XS job schedules are defined by developers; the XS job-scheduling feature must be set up by a system administrator.

### Prerequisites

To enable the XS Job schedule feature in SAP HANA XS, the following prerequisites apply:

- You have administrator access to an SAP HANA system.
- You have been granted a role based on the role template `sap.hana.xs.admin.roles::JobAdministrator`.
- An XS job file that has been activated in the repository.

### Context

To enable developers to define and deploy job schedules using the XS job feature, the system administrator must first set up the environment and enable some essential options.

### Procedure

1. Enable the job-scheduling feature in SAP HANA XS.

This step requires the permissions granted to the SAP HANA administrator.

#### i Note

It is not possible to enable the scheduler for more than one host in a distributed SAP HANA XS landscape.

- a. In the *XS Job Dashboard* set the *Scheduler Enabled* toggle button to **YES**.

Toggling the setting for the *Scheduler Enabled* button in the *XS Job Dashboard* also changes the current value of the SAP HANA configuration variable `xsengine.ini > scheduler > enabled`, which is set in the *Configuration* tab of the SAP HANA studio's *Administration* perspective.

2. Maintain the XS job's runtime configuration.

- a. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

- b. Open the *XS Job Dashboard*.

### i Note

To maintain details of an XS job using the Web-based *XS Administration Tool* you need the privileges granted in the SAP HANA user role `sap.hana.xs.admin.roles::JobAdministrator`.

- c. Maintain the details of the XS job.

In the *Job Details* tab, select the XS Job whose details you want to maintain. In the *Configuration* tab, you need to specify the following details:

- o *User*  
The user account in which the `xscron` job runs, for example, **SYSTEM**
- o *Password*  
For security reasons, you must provide a password for the specified user.

### i Note

If you do not provide a user password, you cannot save the changes to the XS Job object's runtime configuration.

- o *Locale*  
The language encoding required for the locale in which the `xscron` job runs, for example, **en\_US**
- o *Start/Stop time*  
An optional value to set time during which the `xscron` job runs. You must enter the values using the syntax used for the SAP HANA data type `LocalDate` and `LocalTime`, for example, **2013-11-05 00:30:00** (thirty minutes past midnight on the 5th of November 2013).
- o *Active*  
Enable or disable the job schedule

- d. Save the job.

Choose *Save Job* to save and activate the changes to the job schedule.

3. Check the logs to ensure the job is running according to schedule.

You can view the list of `xsjob` schedules in the *Job Details* tab of the *XS Job Details* window. The information displayed includes the XS cron setup that defines the schedule, the current status of the job schedule, as well as the start and finish times.

## Related Information

[The XS Job Dashboard \[page 1759\]](#)

[The XS Job File \[page 1769\]](#)

### 13.1.11.1.1 The XS Job Dashboard

The *XS Job Dashboard* is the central point of control for monitoring and maintaining job schedules that have been defined using the XS Job syntax.

The *XS Job Dashboard* displays details of the currently active job schedules that have been configured for the selected SAP HANA system using XS job files. The XS job file uses a cron-like syntax to specify the schedule at

which the service defined in an XS JavaScript or SQLScript must run. You can use the *Scheduler Enabled* button in the *XS Job Dashboard* to enable schedules for all XS jobs globally.

### **i** Note

Toggling the setting for the *Scheduler Enabled* button also changes the current value of the SAP HANA configuration variable `xsengine.ini > scheduler > enabled`, which is set in the *Configuration* tab of the SAP HANA studio's *Administration* perspective.

For each XS job displayed in the *XS Job Dashboard*, you can see the following details:

- **Name**  
The name of the XS Job; this is name of the design-time artifact in the SAP HANA repository, for example, `MyJob.xsjob`
- **Package**  
The name of the repository package that contains the XS Job
- **User**  
The name of the user whose database account is used to run the XS Job schedule
- **Status**  
The current status of the XS job schedule, for example, *ACTIVE/INACTIVE*; you can change the status in the *XS Job Details* screen
- **Start/Stop time**  
An optional value to set the period of time during which the job runs. You must enter the values using the syntax used for the SAP HANA data type `LocalDate` and `LocalTime`, for example, `2014-11-05 00:30:00` (thirty minutes past midnight on the 5th of November 2014).
- **Session Timeout(s)**  
The number of times that the scheduled job run encountered a session timeout
- **Last Run Status**  
The status of the scheduled job when it last ran, for example: *Success*, *Error*, or *Running*

## Related Information

[Maintain XS Job Details \[page 1758\]](#)

### 13.1.11.1.2 XS Job Details

Details of the runtime configuration of XS Job schedules and the XS jobs the schedules are used to manage.

In the *XS Job Dashboard*, the *XS Job Details* tab displays information about the currently active job schedules that have been configured for the selected SAP HANA system and the corresponding XS job files. You can use the *XS Job Details* tab to maintain the following details of the XS Jobs' runtime configuration:

- [General Job Details \[page 1761\]](#)
- [Runtime Configuration \[page 1762\]](#)
- [Log Cleanup \[page 1762\]](#)

## Job Details

The *Job Details* tab in the *XS Job Details* tool enables you to view details of the XS Jobs that you have defined and scheduled to run, for example, the name of the XS job and a short description. The following table indicates which information can be viewed.

### i Note

The details displayed are defined in the design-time artifact that describes the selected XS Job.

#### Job Details

UI Element	Description	Example
<i>Name</i>	Text string used to specify the name (including full repository path) of the XS Job scheduled to run.	sap.hana.testtools::schedule
<i>Description</i>	A short description of the XS job defined in <i>Name</i>	Run XSUnit
<i>Action</i>	Text string used to specify the path to the function to be called as part of the XS Job defined in <i>Name</i>	sap.hana.testtools:TestRunner.xsjs::run

Runtime schedules for XS Jobs contain the following details.

### i Note

Some of the values described (for example, *Origin* or *Changed ...*) are read only; it is not possible to modify them.

#### Schedules

UI Element	Description	Example
<i>ID</i>	The ID allocated to the job schedule	3
<i>XSCron</i>	The schedule for the specified task (defined in the "action" keyword); the schedule is defined using cron-like syntax.	2015 * * fri 12 0 0
<i>Parameter</i>	A value to be used during the action operation. You can add as many parameters as you like as long as they are mapped to a parameter in the function itself.	Depends on job
<i>Planned Time</i>	The time at which an XS job is expected to run; if it does not run as planned, it is added to the job queue.	2014-11-05 00:30:00
<i>Status</i>	Indicates if the schedule is active or inactive	Active
<i>Start Time</i>	An optional value signifying the beginning of the period of time (schedule) during which the XS job runs	2014-11-05 00:30:00
<i>Finish Time</i>	An optional value signifying the end of the period of time (schedule) during which the XS job runs	2014-11-12 00:30:00
<i>Time Taken (s)</i>	The amount of time taken (in seconds) for the job/action to complete	5

UI Element	Description	Example
<i>Description</i>	A short ( <b>optional</b> ) description of the XS job schedule.	gfn test schedule
	<p>→ Tip</p> <p>It is not possible to show the <i>Description</i> of a deleted job schedule, even if a description was defined when configuring the original job schedule. If the <i>Description</i> field in the job <i>Logs</i> view is empty, either no description was provided for the corresponding job schedule or the job schedule has been deleted. If no description was provided when configuring a job schedule, the <i>Description</i> field in the <i>Job Details</i> tab <b>always</b> remains empty.</p>	
<i>Origin</i>	The type of object used to define the schedule: <i>DESIGNTIME</i> (repository artifact) or <i>RUNTIME</i> (catalog object).	DESIGNTIME
<i>Changed By</i>	Name of the SAP HANA user who added or changed the XS job schedule	johndoe
<i>Changed At</i>	Time at which the schedule was changed	2015-01-30 14:19:59

## Configuration

The *Configuration* tab in the *XS Job Details* tool enables you to maintain details of the runtime configuration for XS Jobs that you have scheduled to run. The following table indicates which information can be maintained.

XS Job Configuration

UI Element	Description	Example
<i>User</i>	The user account in which the xs cron job runs.	SYSTEM
<i>Password</i>	Password for the specified <i>user</i>	****
<i>Locale</i>	The language encoding required for the locale in which the xs cron job runs	en_US
<i>Start Time</i>	Start time for the XS Job using the syntax required by the SAP HANA data type <code>LocalDate</code> and <code>LocalTime</code>	2013-11-05 00:30:00
<i>End Time</i>	End time for the XS Job using the syntax required by the SAP HANA data type <code>LocalDate</code> and <code>LocalTime</code>	2013-11-05 00:30:00
<i>Session Timeout</i>	Time in seconds for which the session is valid	0
<i>Active</i>	Indicates if the schedule is active or inactive	Active

## Log Cleanup

The *Log Cleanup* tab in the *XS Job Details* tool enables you to create an XS Job that cleans up the logs of all XS Job currently running in the system. You can also create one schedule for each job in the system and allow users to configure the schedule in the *Job Details* dialog.

By default, XS Job logs are not cleaned up; no logs or log entries are deleted. If a cleanup of XS Job logs is required, the parameters can be set so that only those job-log entries for an XSJob that are older than N days are deleted, where N can be configured as a job parameter. Users can also specify the frequency of the cleanup schedule. The following table indicates which information can be maintained.

### ! Restriction

To enable or disable the cleanup of XS Job logs, you need the permissions assigned to the *JobAdministrator* role.

#### XS Job Log Cleanup

UI Element	Description	Example
<i>Enabled</i>	Enable the log-cleanup schedule	Yes
<i>XCron</i>	The schedule for the specified XS Job log-cleanup task; the schedule is defined using cron-like syntax. In this example, the cleanup is scheduled to run every last Sunday of the month at 09:00 hours. (9am)	* * * -1.sun 9 0 0
<i>Day</i>	The number of days for which logs are retained (not cleaned up). For example, 1 retains all XS job logs from the day before the schedule starts and deletes all job logs that are two days old or older.	1

## Related Information

[Scheduling XS Jobs \[page 1757\]](#)

## 13.1.11.2 Clean up XS Job Logs

Clean up the log entries generated in the SAP HANA database by the XS jobs that are running in the SAP HANA system.

### Prerequisites

To enable the XS Job schedule feature in SAP HANA XS, the following prerequisites apply:

- You have administrator access to an SAP HANA system.
- You have been granted a role based on the role template `sap.hana.xs.admin.roles::JobAdministrator`.
- You have enabled the job-scheduling feature in SAP HANA XS.

- You have maintained details of the XS Job whose log entries you want to clean up.
- You have enabled the XS Job `sap.hana.xs.admin.jobs.server.common::cleanJobLog` that is used to clean up job-log entries
- You have activated the SQLCC artifact `sap.hana.xs.admin.jobs.server.common::cleanJobLog.xssqlcc` that is used by the cleanup job; this artifact creates a connection to SAP HANA with the `JobLogAdmin` privileges required to remove entries from the XS-job log (as defined in `cleanJobLog`)

## Context

XS jobs write their logs to the table `_sys_xs.job_log` in the SAP HANA database. Since this table can grow in size very quickly, as more and more jobs and schedules are created, it is recommended to clean up the old job log entries. You can set up an XS Job that runs at a defined schedule and deletes all old log file entries for a particular XS job from the SAP HANA XS job-log table.

## Procedure

1. Maintain the XS job's runtime configuration.

- a. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

- b. Open the *XS Job Dashboard*.

### i Note

To maintain details of an XS job using the Web-based *XS Administration Tool* you need the privileges granted in the SAP HANA user role `sap.hana.xs.admin.roles::JobAdministrator`.

2. Configure details of the XS job schedule.

In the *Job Details* tab, select the XS Job whose details you want to maintain. In the *Configuration* tab, you need to specify the following details:

- *User*

The user account in which the `xscron` job runs, for example, **SYSTEM**

- *Password*

For security reasons, you must provide a password for the specified user.

### i Note

If you do not provide a user password, you cannot save the changes to the XS Job object's run-time configuration.

- *Locale*

The language encoding required for the locale in which the `xscron` job runs, for example, **en\_US**

- *Start/Stop time*

An optional value to set time during which the `xscron` job runs. You must enter the values using the syntax used for the SAP HANA data type `LocalDate` and `LocalTime`, for example, **2013-11-05 00:30:00** (thirty minutes past midnight on the 5th of November 2013).

- *Active*  
Enable or disable the job schedule.

3. Ensure that the old log entries written by the XS job are cleaned up.

To enable a scheduled clean up of log entries in the SAP HANA database, you need to set up the following details:

- *Enabled*  
Set the status of the job schedule used to clean up the XS job-related log entries
- *XSCron*  
Define the schedule using XS cron syntax (year, month, day, day of the week, hour, minute, second) at which the cleanup job runs.  
**\* \* \* -1.sun 9 0 0**  
This example runs the job on the last Sunday of every month at 9am.
- *Day*  
Specify the number of days for which log entries should be **retained**. For example, to delete all log entries that are older than two days, enter the value "2".

4. Save the job.

Choose *Save Job* to save and activate the changes to the job schedule.

5. Check the status of the new job and schedule.

You can view the list of `xsjob` schedules in the *Job Details* tab of the *XS Job Details* window. The information displayed includes the XS cron setup that defines the schedule, the current status of the job schedule, as well as the start and finish times.

6. Check the logs to ensure the job is running according to schedule.

#### → Tip

If the *Description* field for a specific job log is empty in the *View Logs* list, this is typically an indication that either no description was defined for the job or the log has been deleted as part of the cleanup operation.

## 13.1.11.3 Tutorial: Schedule an XS Job

The `xsjob` file enables you to run a service (for example, an XS JavaScript or an SQLScript) at a scheduled interval.

### Prerequisites

- You have access to an SAP HANA system.
- You have a role based on the role template `sap.hana.xs.admin.roles::JobAdministrator`.
- You have a role based on the role template `sap.hana.xs.admin.roles::HTTPDestAdministrator`.

#### Note

This tutorial combines tasks that are typically performed by two different roles: the application developer and the database administrator. The developer would not normally require the privileges granted to the `sap.hana.xs.admin.roles::JobAdministrator` role, the `sap.hana.xs.admin.roles::HTTPDestAdministrator` role, or the SAP HANA administrator.

### Context

In this tutorial, you learn how to schedule a job that triggers an XS JavaScript application that reads the latest value of a share price from a public financial service available on the Internet. You also see how to check that the XS job is working and running on schedule.

To schedule an XS job to trigger an XS JavaScript to run at a specified interval, perform the following steps:

### Procedure

1. Create the application package structure that contains the artifacts you create and maintain in this tutorial. Create a root package called `yahoo`. You use the new `yahoo` package to contain the files and artifacts required to complete this tutorial.

```
/yahoo/  
  .xsapp           // application descriptor  
  yahoo.xsjob      // job schedule definition  
  yahoo.xshttpdest // HTTP destination details  
  yahoo.xsjs       // Script to run on schedule
```

2. Write the XS JavaScript code that you want to run at the interval defined in an XS job schedule. The following XS JavaScript connects to a public financial service on the Internet to check and download the latest prices for stocks and shares.

Create an XS JavaScript file called `yahoo.xsjs` and add the code shown in the following example:

```
function readStock(input) {
```

```

var stock = input.stock;

var dest = $.net.http.readDestination("yahoo", "yahoo");
var client = new $.net.http.Client();
var req = new $.web.WebRequest($.net.http.GET, "/d/quotes.csv?f=a&s=" +
stock);
client.request(req, dest);
var response = client.getResponse();
var stockValue;
if(response.body)
    stockValue = parseInt(response.body.asString(), 10);
var sql = "INSERT INTO stock_values VALUES (NOW(), ?)";
var conn = $.db.getConnection();
var pstmt = conn.prepareStatement(sql);
pstmt.setDouble(1, stockValue);
pstmt.execute();
conn.commit();
conn.close();
}

```

Save and activate the changes in the SAP HANA Repository.

### i Note

Saving a file in a shared project automatically commits the saved version of the file to the repository. To explicitly commit a file to the repository, right-click the file (or the project containing the file) and choose **Team > Commit** from the context-sensitive popup menu.

3. Create an HTTP destination file using the wizard to provide access to the external service (via an outbound connection).

Since the financial service used in this tutorial is hosted on an external server, you must create an HTTP destination file, which provides details of the server, for example, the server name and the port to use for HTTP access.

### i Note

To maintain the runtime configuration details using the Web-based *XS Administration Tool* you need the privileges granted in the SAP HANA user role `sap.hana.xs.admin.roles::HTTPDestAdministrator`.

Create a file called `yahoo.xshttpdest` and add the following content:

```

host = "download.finance.yahoo.com";
port = 80;

```

Save and activate the changes in the SAP HANA Repository.

4. Create the XS job file using the wizard to define the details of the schedule at which the job runs.

The XS job file uses a `cron`-like syntax to define the schedule at which the XS JavaScript must run. This job file triggers the script `yahoo.xsjs` on the 59th second of every minute and provides the name "SAP.DE" as the parameter for the stock value to check.

Create a file called `yahoo.xsjob` and add the following code:

```

{
  "description": "Read stock value",
  "action": "yahoo:yahoo.xsjs::readStock",
  "schedules": [
    {
      "description": "Read current stock value",
      "xcron": "* * * * * 59",
    }
  ]
}

```

```

        "parameter": {
            "stock": "SAP.DE"
        }
    ]
}

```

Save and activate the changes in the SAP HANA Repository.

5. Maintain the XS job's runtime configuration.

You maintain details of an XS Job's runtime configuration in the [XS Job Dashboard](#).

a. Start the [SAP HANA XS Administration Tool](#).

The [SAP HANA XS Administration Tool](#) is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

b. Maintain the details of the XS job.

### Note

To maintain details of an XS job using the Web-based [XS Administration Tool](#) you need the privileges granted in the SAP HANA user role `sap.hana.xs.admin.roles::JobAdministrator`.

You need to specify the following details:

- [User](#)  
The user account in which the job runs, for example, **SYSTEM**
- [Password](#)  
The password required for user, whose account is used to run the job.
- [Locale](#)  
The language encoding required for the locale in which the job runs, for example, **en\_US**
- [Start/Stop time](#)  
An optional value to set the period of time during which the job runs. Enter the values using the syntax used for the SAP HANA data type `LocalDate` and `LocalTime`, for example, **2014-11-05 00:30:00** (thirty minutes past midnight on the 5th of November 2014).
- [Active](#)  
Enable or disable the job schedule
- [Session timeout](#)  
Specify the session timeout for this XSJob in seconds. If you specify a value of 0 (zero) seconds for the XSJob's session timeout, the XSJob checks if a value is defined for the `sessiontimeout` key in the section `scheduler` of the `xsengine.ini` file. If no such key exists, the default session timeout of 900 seconds is used. If you want to define a non-default value for the scheduler's `sessiontimeout` key, you must create the key in the `scheduler` section of the `xsengine.ini` file and supply the desired timeout value, for example, 600 seconds.

### Caution

It is not recommended to specify a value of 0 (zero) for the `sessiontimeout` key; this disables the session-timeout feature for all jobs started by the scheduler.

c. Save the job.

Choose [Save Job](#) to save and activate the changes to the job schedule.

6. Enable the job-scheduling feature in SAP HANA XS.

This step requires the permissions granted to the SAP HANA administrator.

### i Note

It is not possible to enable the scheduler for more than one host in a distributed SAP HANA XS landscape.

- a. In the *XS Job Dashboard* set the *Scheduler Enabled* toggle button to **YES**.

Toggling the setting for the *Scheduler Enabled* button in the *XS Job Dashboard* changes the value set for the SAP HANA configuration variable `xsengine.ini > scheduler > enabled`, which is set in the *Configuration* tab of the SAP HANA studio's *Administration* perspective.

7. Check the job logs to ensure the XS job is active and running according to the defined schedule.

You can view the `xsjob` logs in the *XS Job Dashboard* tab of the *SAP HANA XS Administration Tool*.

### i Note

To maintain details of an XS job using the Web-based *XS Administration Tool* you need the privileges granted in the SAP HANA user role `sap.hana.xs.admin.roles::JobAdministrator`.

If the job does not run at the expected schedule, the information displayed in the `xsjob` logs includes details of the error that caused the job to fail.

## Related Information

[The XS Job File \[page 1769\]](#)

[XS Job-File Keyword Options](#)

### 13.1.11.3.1 The XS Job File

The `.xsjob` file defines the details of a task that you want to run (for example, an XS JavaScript or an SQLScript) at a scheduled interval.

The XS job file uses a `cron`-like syntax to define the schedule at which the service defined in an XS JavaScript or SQLScript must run, as you can see in the following example, which runs the specified job (the stock-price checking service `yahoo.xsjs`) on the 59th second minute of every minute.

```
{
  "description": "Read stock value",
  "action": "yahoo:yahoo.xsjs::readStock",
  "schedules": [
    {
      "description": "Read current stock value",
      "xscron": "* * * * * 59",
      "parameter": {
        "stock": "SAP.DE"
      }
    }
  ]
}
```

When defining the job schedule in the `xsjob` file, pay particular attention to the entries for the following keywords:

- `action`  
Text string used to specify the path to the function to be called as part of the job.

```
"action": "<package_path>:<XSJS_Service>.xsjs::<FunctionName>",
```

### i Note

You can also call SQLScripts using the `action` keyword.

- `description`  
Text string used to provide context when the XSjob file is displayed in the *SAP HANA XS Administration* tool.
- `xscron`  
The schedule for the specified task (defined in the “`action`” keyword); the schedule is defined using cron-like syntax.
- `parameter`  
A value to be used during the action operation. In this example, the parameter is the name of the stock `SAP.DE` provided as an input for the parameter (`stock`) defined in the `readStock` function triggered by the `xsjob` action. You can add as many parameters as you like as long as they are mapped to a parameter in the function itself.

The following examples illustrate how to define an `xscron` entry including how to use expressions in the various `xscron` entries (day, month, hour, minutes,...):

- `2013 * * fri 12 0 0`  
Every Friday of 2013 at 12:00 hours
- `* * 3:-2 * 12:14 0 0`  
Every hour between 12:00 and 14:00 hours on every day of the month between the third day of the month and the second-last day.

### → Tip

In the day field, third from the left, you can use a negative value to count days backwards from the end of the month. For example, `* * -3 * 9 0 0` means: three days from the end of every month at 09:00.

- `* * * * * */5 *`  
Every five minutes (`*/5`) and at any point (`*`) within the specified minute.

### i Note

Using the asterisk (`*`) as a wild card in the seconds field can lead to some unexpected consequences, if the scheduled job takes less than 59 seconds to complete; namely, the scheduled job restarts on completion. If the scheduled job is very short (for example, 10 seconds long), it restarts repeatedly until the specified minute ends.

To prevent short-running jobs from restarting on completion, schedule the job to start at a specific second in the minute. For example, `* * * * * */5 20` indicates that the scheduled job should run every five minutes and, in addition, at the 20th second in the specified minute.

- `* * * -1.sun 9 0 0`

Every last Sunday of a month at 09:00 hours

### 13.1.12 Maintaining Translation Text Strings

Maintain the translated text strings used in an application's user interface, error messages, and documentation.

For the purposes of localisation (L10N), you can provide the text strings displayed in an application's user interface in multiple languages, for example, English, French, or Chinese. You can also provide notifications and error messages in the same, local languages. To manage and maintain these translated text strings, SAP HANA provides an online translation tool (OTT). The translation of the text strings themselves can be performed manually or with suggestions provided by an external service, for example, SAP Translation Hub. Access to external translation services is not covered by the SAP HANA license and usually requires a user account.

Setting up and maintaining the online translation tools for SAP HANA includes the following high-level tasks:

- Enabling the translation tool
- Accessing packages in the SAP HANA repository
- Maintaining text strings in the source and target languages  
This task involves maintaining the contents of the following SAP HANA tables:
  - ACTIVE\_CONTENT\_TEXT
  - ACTIVE\_CONTEXT\_TEXT\_CONTENT
  - ACTIVE\_OBJECT\_TEXT
  - ACTIVE\_OBJECT\_TEXT\_CONTENT
- Enabling access to a remote text-translation service (**optional**)

#### ! Restriction

Access to external translation services is not granted in the SAP HANA license. To use external translation services such as the *SAP Translation Hub*, an additional license is required. In addition, the *SAP Translation Hub* is currently available only for Beta testing.

- Maintaining HTTP destinations for any remote systems that provide services used by the *Online Translation Tool* (**optional**)  
Remote translation services such as *SAP Translation Hub* can provide access to a database of translated text strings, which are used to provide suggestions in the target language. To access such a remote service, you must maintain an HTTP destination (or extend an existing destination) that provides details of the host system where the translation service is running as well as a valid user account and logon authentication. You must also ensure that a trust relationship exists between the translation server and SAP HANA, for example, by importing the translation server's client certificate into the SAP HANA trust store.

The SAP HANA *Online Translation Tool* is available on the SAP HANA XS Web server at the following URL:

`http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/translationTool/`

#### → Tip

The privileges required to use the SAP HANA *Online Translation Tool* (OTT) are granted by the role `templatesap.hana.xs.translationTool.roles::translator`.

## Related Information

## 13.1.12.1 Create and Edit Text Translations

Maintain translations for text strings displayed in an SAP HANA application's user interface.

### Prerequisites

To maintain translated text for an application in SAP HANA XS, the following prerequisites apply:

- You have access to an SAP HANA system.
- You have the privileges required to access the repository packages containing the text strings to be localized/translated.
- You have a role based on the role template `sap.hana.xs.translationTool.roles::translator`.
- If you want to make use of optional external translation services, you must maintain access to the translation server system.

#### ! Restriction

Access to external translation services is not granted in the SAP HANA license. To use external translation services such as the *SAP Translation Hub*, an additional license is required. The *SAP Translation Hub* is currently available only for BETA testing.

Details of the remote systems where the translation service is running (for example, SAP Translation Hub) are defined in HTTP destination configuration files along with details of any corresponding user account and authentication certificates.

## Context

An application's user interface and notifications can be translated from the original source language (for example, English) into one or more local (target) languages, for example, French, Spanish, or Japanese. You can either translate the texts manually or with the help of an (optional) external translation service. To provide translations of the UI text strings for your SAP HANA application, perform the following steps:

## Procedure

1. Start the *SAP HANA Online Translation Tool*.

The *SAP HANA Online Translation Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/translationTool`.

### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must also have the privileges required to perform the tasks associated with the maintenance of translation texts.

2. Select the delivery unit that contains the application with the text strings you want to translate.

Use the *Delivery Unit* drop-down list to select a delivery unit.

### → Tip

The name of the vendor associated with the selected delivery unit is displayed automatically in the *Vendor* field, for example, *acme.com*; the vendor name cannot be changed here.

3. Select the package that contains the text strings you want to translate.

Use the *Package* drop-down list to select a package. If the selected package contains text elements, they are displayed alphabetically in a list.

### → Tip

The original source language associated with the contents of the selected package is displayed automatically.

4. Enable access to a text-translation service, for example, *SAP Translation Hub*. (**optional**).

### ! Restriction

Access to external translation services is not granted in the SAP HANA license. To use external translation services, an additional license is required.

If you want to make use of the services provided by a translation server, you need to maintain an HTTP destination **extension** that provide details of the host system where the translation service is running; access to the translation service usually requires a user account and logon authentication. You must also ensure that a trust relationship exists between the translation server and SAP HANA, for example, by importing the translation server's client certificate into the SAP HANA trust store that you are using to handle authentication for this HTTP destination.

The HTTP destination configuration

`sap.hana.xs.translationTool.server:translationService.xshttpdest` defines details of the server hosting the SAP Translation Hub service. Although you cannot edit this destination configuration, note that you can use an HTTP destination **extension** to change the details, for example, to point to an alternative host name.

5. Add a translation for a text element.

For a given text element in the *Text ID* list, you can provide a suitable translation in one or more languages, for example: French (*fr*), Spanish (*es*), and Japanese (*ja*).

a. Expand the desired UI text element.

In the *Text ID* list, locate and expand the element for which you want to provide a translation.

b. Add a translation.

Choose *Add Translation*.

c. Select the desired language for the translation from the *Target Language* drop-down list.

d. In the *Target Language Text* box, type the translation for the selected text element.

→ Tip

If the *SAP Translation Hub* option is enabled, language-specific suggestions for possible translation matches are provided as you type. If you see a suggestion that is suitable, use the mouse to select the suggested text.

e. Add another translation.

Choose *Add Translation*

f. Edit an existing translation

Choose the *Edit* icon next to the translation you want to modify and make the required changes.

6. Save your additions and changes.

Choose *Save* to store the added translations or any modifications in the appropriate tables in the SAP HANA database.

## Related Information

[Online Translation Tool Details \[page 1775\]](#)

[Export and Import Translated Text \[page 1777\]](#)

[Edit an HTTP Destination Runtime Configuration \[page 1685\]](#)

[Managing Trust Relationships \[page 1691\]](#)

## 13.1.12.1.1 Online Translation Tool Details

Display details of the source text for an application's user interface elements and, if available, any available translations.

The *Online Translation Tool* tool enables you to view details of the text elements contained in the individual packages of an SAP HANA application. The following table indicates which information can be viewed.

### Note

The privileges required to use the SAP HANA *Online Translation Tool* (OTT) are granted by the role template `sap.hana.xs.ott.roles::translator`.

#### Translation Text Details

UI Element	Description	Example
<i>Delivery Unit</i>	Name of the SAP HANA delivery unit (DU) that contains the default text strings for which a translation is required along with the name of the vendor associated with the selected delivery unit	ACME_XS_BASE - acme.com
<i>Package</i>	The name of (and path to) the package containing the text strings for which a translation is required	acme.com.app.ui.login
<i>Source language</i>	Short name of the source language for the text strings contained in the selected package, for example: en (English), fr (French), ja, (Japanese)	en
<i>Target Language</i>	Long or short name of the target language for the text strings contained in the selected package, for example: Bulgarian (bg), French (fr), Japanese (ja)	Chinese (zh)
<i>Domains</i>	The SAP product-specific translation domain to which the selected DU/package belongs, for example, <i>Financial Accounting</i> or <i>Customer Relationship Management</i> . Domains are used in the translation process to determine the correct terminology for a text string that has to be translated; the same text might require a different translation depending on the domain (or application) in which it is used. Suggestions from a remote translation service such as the SAP Translation Hub are restricted to the currently selected domain.	"Basis", or "Accounting - General"

UI Element	Description	Example
<i>Enable Translation Hub</i>	<p>Enable automatic suggestions (in the <i>Target language text</i> box) for translation texts using a remote service such as SAP Translation Hub; the suggestions are provided by a remote translation database.</p> <div style="border: 1px solid orange; padding: 5px; margin: 10px 0;"> <p><b>! Restriction</b></p> <p>Access to external translation services is not granted in the SAP HANA license. To use external translation services such as the <i>SAP Translation Hub</i>, an additional license is required. The <i>SAP Translation Hub</i> is currently available only for BETA testing.</p> </div> <p>Access to the remote translation service usually requires a user account and logon authentication. You also need to maintain an HTTP destination (or extend an existing one) for the translation server system and ensure the server system is trusted by SAP HANA, for example, by importing the translation server's client certificate into the SAP HANA trust store.</p>	Yes/No
<i>Text ID</i>	The name/ID of the UI element for which a text string is required. This could be a tab title, a box name, a notification, or an error message.	LOGON_LABEL
<i>Default Text</i>	The text string associated with the text ID	HANA Logon
<i>Target Language Text</i>	Proposed/accepted translation (in the target language) of the text string displayed (in the source language) in the <i>Default Text</i> field. Activate the <i>Enable Translation Hub</i> option to enable auto-suggestions in the target language.	-
<i>Source Object</i>	The name of the design-time artifact that contains the UI text strings.	logonForm.hdbtextbundle

## 13.1.12.2 Export and Import Translated Text

Transport text translations between systems using the industry-standard, XML-based `xliff` format.

### Prerequisites

To export and import translated text for an application in SAP HANA XS, the following prerequisites apply:

- You have access to an SAP HANA system.
- You have access to the repository packages containing the text strings to be localized/translated.
- You have been granted a role based on the role template  
`sap.hana.xs.translationTool.roles::translator`.

### Context

An application's user interface and notifications can be translated from the original source language (for example, English) into one or more target local languages, for example, French, Spanish, or Japanese. To provide translations of the UI text strings for your SAP HANA application, perform the following steps:

### Procedure

1. Start the *SAP HANA Online Translation Tool*.

The *SAP HANA Online Translation Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/translationTool`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must also have the privileges required to perform the tasks associated with the maintenance of translation texts.

2. Select the delivery unit that contains the application with the text strings you want to translate.

Use the *Delivery Unit* drop-down list to select a delivery unit.

#### → Tip

The name of the vendor associated with the selected delivery unit is displayed automatically in the *Vendor* field, for example, *acme.com*. You cannot change this here.

3. Select the package that contains the text strings you want to translate.

Use the *Package* drop-down list to select a package. If the selected package contains text elements, they are displayed automatically in an alphabetically ordered list.

#### → Tip

The original source language associated with the contents of the selected package is displayed automatically.

4. Export the UI text elements from the local source system.

You can export the translation texts to an archive on a local file system using the industry-standard, XML-based `xliff` format.

5. Import the UI text elements to the remote target system.

You can import the translation texts into SAP HANA from an archive whose content are stored using the industry-standard, XML-based `xliff` format.

6. Confirm that the import operation was successful.

Check the status of the following tables in the SAP HANA database:

- ACTIVE\_CONTENT\_TEXT
- ACTIVE\_CONTEXT\_TEXT\_CONTENT
- ACTIVE\_OBJECT\_TEXT
- ACTIVE\_OBJECT\_TEXT\_CONTENT

## Related Information

[Online Translation Tool Details \[page 1775\]](#)

[Create and Edit Text Translations \[page 1772\]](#)

## 13.1.13 Maintaining HTTP Traces for SAP HANA XS Applications

HTTP tracing for individual SAP HANA XS applications can be enabled on the SAP HANA Web Dispatcher.

The *SAP HANA XS Administration Tools* include the *SAP Web Dispatcher HTTP Tracing* application, which you can use to enable and disable HTTP tracing on the SAP Web Dispatcher for SAP HANA XS applications.

### i Note

SAP HANA uses roles to grant access to the features provided by the *SAP HANA XS Administration Tool*. To access the administration tools required to manage HTTP tracing on the SAP Web Dispatcher, you must have a role based on the role template `WebDispatcherHTTPTracingAdministrator`. The role template `WebDispatcherHTTPTracingViewer` contains the privileges for read-only access to the *SAP Web Dispatcher HTTP Tracing* tool.

You can use the *SAP HANA XS Administration Tools* to perform the following tasks:

- Display a list of all traced applications  
List all applications defined in the system. Details include the application's metadata, information about HTTP tracing configuration for the particular application, the status of the XS job that starts the tracing process, and HTTP tracing log information.

- Enable HTTP tracing  
**Enable** HTTP tracing for selected SAP HANA XS applications
- Disable HTTP tracing  
**Disable** HTTP tracing for selected SAP HANA XS applications

Tracing is managed by the XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob`, which runs at a predefined schedule. If you enable or disable HTTP tracing, you must modify the XS job file accordingly.

#### → Tip

Administrator access to the XS job details requires the privileges granted by the role template `sap.hana.xs.admin.roles::JobAdministrator`. These privileges are already included in the `WebDispatcherHTTPTracingAdministrator` role template, which is required to use the [SAP Web Dispatcher HTTP Tracing](#).

HTTP tracing is enabled by setting configuration parameters in SAP HANA XS (`xsengine.ini`) and the SAP Web Dispatcher (`webdispatcher.ini`). If an SAP HANA XS application is defined in a parameter in `xsengine.ini`, then HTTP tracing is enabled for the specified application. If not, then HTTP tracing is disabled for the application.

#### i Note

If HTTP tracing is disabled for an application, the corresponding HTTP trace parameters in `xsengine.ini` and `webdispatcher.ini` are removed. If you re-enable HTTP tracing on the SAP Web Dispatcher for the same application, the required parameters are recreated automatically.

Connections to the database are performed with the SQL auto-user defined in `/sap/hana/xs/admin/webdispatcher/server/common/httpTracing.xssqlcc`.

## Related Information

[SAP HANA XS Classic Administration Roles \[page 1668\]](#)

[Enable HTTP Tracing for an SAP HANA XS Application \[page 1782\]](#)

[Maintain XS Job Details \[page 1758\]](#)

## 13.1.13.1 Display the HTTP Trace Status of SAP HANA XS Applications

Display a list of SAP HANA XS applications which shows the status of HTTP tracing.

### Prerequisites

To use the *SAP HANA XS Administration Tool* to view the current status of HTTP tracing for SAP HANA XS applications, the following prerequisites apply:

- You have administrator access to an SAP HANA system.
- You have been granted roles based on one of the following role templates:
  - `sap.hana.xs.admin.roles::WebDispatcherHTTPTracingViewer`
  - `sap.hana.xs.admin.roles::WebDispatcherHTTPTracingAdministrator`

### Context

To use the *SAP HANA XS Administration Tool* to display a list of applications and the HTTP trace status, perform the following steps:

### Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *SAP Web Dispatcher HTTP Tracing* tool.

2. Start the *SAP Web Dispatcher HTTP Tracing* tool.

In the list of XS Administration tools, choose *SAP Web Dispatcher HTTP Tracing*.

3. Display a list of the SAP HANA XS applications running on the system to which you are connected; the *HTTP Tracing Enabled* column indicates (Yes/No if HTTP tracing is enabled for the application).

#### → Tip

You can use the search box to display a list of only those applications that match a particular string, for example, "`admin`".

## Related Information

[Enable HTTP Tracing for an SAP HANA XS Application \[page 1782\]](#)

[Application HTTP Tracing Details \[page 1781\]](#)

### 13.1.13.1.1 Application HTTP Tracing Details

Display a list of the SAP HANA XS applications for which HTTP tracing is enabled on the SAP Web Dispatcher.

The *XS Applications* tab in the *SAP Web Dispatcher HTTP Tracing* tool enables you to view a list of the SAP HANA XS applications for which HTTP tracing is enabled on the SAP Web Dispatcher. The following table indicates which information can be viewed.

#### → Tip

You can use the search box to display a list of the applications that match a particular string, for example, “**admin**”.

Job Details

UI Element	Description	Example
<i>SAP Web Dispatcher HTTP Tracing Job</i>	The SAP HANA XS job used to start the tracing operation for the listed applications	httptracing.xsjob
<i>ACTIVE/INACTIVE</i>	The current status of the HTTP tracing job that manages the tracing operation for the selected applications	ACTIVE
<i>Application Name</i>	The full path to (and the name of) the SAP HANA XS application for which HTTP tracing is enabled on the SAP Web Dispatcher	sap.hana.xs.admin
<i>Delivery Unit</i>	The name of the delivery unit that contains the application specified in <i>Application Name</i>	HANA_XS_ADMIN
<i>Vendor</i>	The name of the vendor responsible for the creation and maintenance of the delivery unit that contains the traced application	sap.com
<i>HTTP Tracing Enabled</i>	The current tracing status: No (disabled); yes (enabled)	Yes

## Related Information

[Enable HTTP Tracing for an SAP HANA XS Application \[page 1782\]](#)

## 13.1.13.2 Enable HTTP Tracing for an SAP HANA XS Application

HTTP tracing on the SAP Web Dispatcher can be enabled for one or more SAP HANA XS applications

### Prerequisites

To enable HTTP tracing on the SAP Web Dispatcher for SAP HANA XS applications, the following prerequisites apply:

- You have administrator access to an SAP HANA system.
- You have been granted a role based on the role template `sap.hana.xs.admin.roles::WebDispatcherHTTPTracingAdministrator`.
- The XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob` is configured and running. (By default, the job runs at 12:00 every day.)
- The XS SQL connection configuration `/sap/hana/xs/admin/webdispatcher/server/common/httpTracing.xssqlcc` is active (available by default).

### Context

To enable HTTP tracing on the SAP Web Dispatcher for an application, you must perform the following steps:

### Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

#### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *SAP Web Dispatcher HTTP Tracing* tool.

2. Start the *SAP Web Dispatcher HTTP Tracing* tool.  
In the list of XS administration tools, choose *SAP Web Dispatcher HTTP Tracing*.
3. Display a list of the SAP HANA XS applications running on the system to which you are connected.

#### → Tip

You can use the search box to display a list of only those applications that match a particular string, for example, "`admin`".

4. Enable HTTP tracing for an application.

In the *XS Applications* tab, the *HTTP Tracing Enabled* column indicates if HTTP tracing is enabled or not (*Yes/No*) for the application.

- a. In the *XS Applications* tab, choose *Edit*.
- b. **Check** the box for the application for which you want to enable HTTP tracing.
- c. In the *XS Applications* tab, choose *Save*.

Saving the changes to the configuration enables HTTP tracing and automatically sets the following configuration parameters (keys):

- Configuration section: `webdispatcher.ini/profile`
  - key  
`icm/HTTP/logging_n`
  - value  
`PREFIX=/path/to/app/, LOGFILE=$( _LOCAL_HOST_NAME )/trace/access_log_app-%y-%m-%d, MAXSIZEKB=10000, SWITCHTF=day, LOGFORMAT=SAP, FLUSH=1`
- Configuration section: `xsengine.ini/customer_usage`
  - key=`/path/to/appname/`
  - value=`icm/HTTP/logging_n`

→ Tip

This is the value defined for the key `webdispatcher.ini/profile`.

5. Update the XS job used to start the trace operation.

The XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob` is used to stop and start HTTP tracing on the SAP Web Dispatcher for individual XS applications. The current status of the XS job is indicated in the *SAP Web Dispatcher HTTP Tracing* dialog.

- a. In the *SAP Web Dispatcher HTTP Tracing* dialog, click the link to the XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob`.

The *XS Job Details* window displays a brief description of the XS job and information about any configured schedules.

- b. Choose the *Configuration* tab to set up the XS job.
- c. Type the name of a user with the required permission to run the XS job and the corresponding password.
- d. Check the *Active* box.
- e. Choose *Save Job* to update the XS job and start the HTTP tracing.

i Note

A user name and password are required to save the changes you make to the XS job.

6. Check the new log file is created and contains entries.

The log file is located in the folder you specified in the `webdispatcher.ini/profile` key `icm/HTTP/logging_n`, for example:

```
LOGFILE=$( _LOCAL_HOST_NAME )/trace/access_log_app-%y-%m-%d
```

Where `app` is the name of the application whose HTTP traffic you are tracing.

[SAP HANA XS Classic Administration Roles \[page 1668\]](#)

### 13.1.13.3 Disable HTTP Tracing for an SAP HANA XS Application

HTTP tracing on the SAP Web Dispatcher can be disabled for one or more SAP HANA XS applications.

#### Prerequisites

To enable HTTP tracing on the SAP Web Dispatcher for SAP HANA XS applications, the following prerequisites apply:

- You have administrator access to an SAP HANA system.
- You have been granted a role based on the role template `sap.hana.xs.admin.roles::WebDispatcherHTTPTracingAdministrator`.
- The XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob` is configured and running. (By default, the job runs at 12:00 every day.)
- The XS SQL connection configuration `/sap/hana/xs/admin/webdispatcher/server/common/httpTracing.xssqlcc` is active (available by default).

#### Context

To disable HTTP tracing on the SAP Web Dispatcher for an application, you must perform the following steps:

#### Procedure

1. Start the *SAP HANA XS Administration Tool*.

The *SAP HANA XS Administration Tool* tool is available on the SAP HANA XS Web server at the following URL: `http://<WebServerHost>:80<SAPHANAinstance>/sap/hana/xs/admin/`.

##### i Note

In the default configuration, the URL redirects the request to a logon screen, which requires the credentials of an authenticated SAP HANA database user to complete the logon process. The user who logs on must have the privileges required to perform administration tasks with the *SAP Web Dispatcher HTTP Tracing* tool.

2. Start the *SAP Web Dispatcher HTTP Tracing* tool.

In the list of XS administration tools, choose *SAP Web Dispatcher HTTP Tracing*.

3. Display a list of the SAP HANA XS applications running on the system to which you are connected.

#### → Tip

You can use the search box to display a list of only those applications that match a particular string, for example, "admin".

4. Disable HTTP tracing for an application.

In the *XS Applications* tab, the *HTTP Tracing Enabled* column indicates if HTTP tracing is enabled or not (*Yes/No*) for the application.

- a. In the *XS Applications* tab, choose *Edit*.
- b. **Uncheck** the box for the application for which you want to **disable** HTTP tracing.
- c. In the *XS Applications* tab, choose *Save*.

Saving the changes to the configuration disables HTTP tracing for the selected application and **removes** the following parameters (keys):

- Configuration section: `webdispatcher.ini/profile`
  - `key=icm/HTTP/logging_n`
- Configuration section: `xsengine.ini/customer_usage`  
For example:
  - `key=/path/to/appname/`

5. Update the XS job used to stop the trace operation.

The XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob` is used to stop and start HTTP tracing on the SAP Web Dispatcher for individual XS applications. The current status of the XS job is indicated in the *SAP Web Dispatcher HTTP Tracing* dialog.

- a. In the *SAP Web Dispatcher HTTP Tracing* dialog, click the link to the XS job `sap.hana.xs.admin.webdispatcher.jobs::httptracing.xsjob`.

The *XS Job Details* window displays a brief description of the XS job and information about any configured schedules.

- b. Choose the *Configuration* tab to set up the XS job.
- c. Type the name of a user with the required permission to run the XS job and the corresponding password
- d. Uncheck the *Active* box.
- e. Choose *Save Job* to update the XS job and stop the HTTP tracing.

#### i Note

A user name and password are required to save the changes you make to the XS job.

6. Check that tracing has been switched off and **no** new logs files are being created.

The log files for the traced application are located in the folder you specified in the `webdispatcher.ini/profile` key `icm/HTTP/logging_n`, for example:

```
LOGFILE=$( _LOCAL_HOST_NAME )/trace/access_log_app-%y-%m-%d
```

Where `app` is the name of the application whose HTTP traffic you are tracing.

## 13.2 Maintaining the SAP HANA XS Advanced Model Run Time

Maintain the SAP HANA XS advanced model run-time environment.

From HANA 1.0 SPS 11, SAP HANA includes an additional run-time environment for application development: SAP HANA extended application services (XS), advanced model. SAP HANA XS, advanced model represents an evolution of the application server architecture within SAP HANA by building upon the strengths (and expanding the scope) of SAP HANA extended application services (XS), classic model. SAP recommends that customers and partners who want to develop new applications use SAP HANA XS advanced model.

### → Tip

If you want to migrate existing XS classic applications to run in the new XS advanced run-time environment, SAP recommends that you first check the features available with the installed version of XS advanced; if the XS advanced features match the requirements of the XS classic application you want to migrate, then you can start the migration process.

SAP HANA extended application services, advanced model (XS advanced) is a platform that enables the management of polyglot Web-based applications built on micro-services but also supports the more traditional "monolithic" application. That means that, while XS classic applications were restricted to a server-side JavaScript dialect called XSJS, applications in XS advanced can be written in a programming language of your choice. By default, the platform supports Java, Node.js and XSJS, and Python, but also contains a plug-in concept that enables the use of additional "custom" languages, too. Moreover, in contrast to XS classic, XS advanced applications are not executed by a central server. Instead, each application has its own server and run-time environment – an architecture that enables a very flexible composition of applications using the concept of micro-services.

In XS advanced, an application can either be comprised of several independent and replaceable components or it can reuse services that are already present on the platform, and each component can be developed, maintained, and updated individually. This allows a high level of flexibility in terms of deployment. For example, an application can be composed of a Java and a Node.js component, each of which can be developed and updated independently, and, if required, the same application can reuse an additional service written in Python.

It is the task of the XS advanced run time to try to reduce to a minimum the additional complexity this advanced concept might introduce. For example, the XS advanced run-time environment is responsible for connecting micro-services together to form a complete application. XS advanced starts, stops, and monitors applications, and provides a simple means of connecting applications to backing services such as the SAP HANA database (using a concept called "service brokers", which provide components for user authentication and the higher level application deployment services). Note that XS advanced is designed in a way that makes it possible to write business applications that can be moved from the on-premise platform to the SAP Cloud Platform and vice versa.

### → Tip

For general information, advice, and a list of frequently asked questions about XS advanced issues and solutions, see *Related Information* below.

## Downloading XS Advanced from SAP Marketplace

SAP HANA Extended Application Services, advanced model, is available not only on the SAP HANA media but also as a separate component on SAP Marketplace. Users with the required S-User ID can download the latest version of XS advanced component in the package `SAP_EXTENDED_APP_SERVICES_1` from the following location:

▶ [Service Marketplace](#) ▶ [Software Downloads \[Downloads\]](#) ▶ [SUPPORT PACKAGES & PATCHES](#) ▶ [By Alphabetical Index \(A-Z\)](#) ▶ [H](#) ▶ [SAP HANA PLATFORM EDITION](#) ▶

- ▶ [SAP HANA PLATFORM EDITION 1.0](#) ▶ [XS ADVANCED RUNTIME](#) ▶ [SAP EXTENDED APP SERVICES 1](#) ▶
- ▶ [SAP HANA PLATFORM EDITION 2.0](#) ▶ [SAP EXTENDED APP SERVICES 1](#) ▶

### → Tip

SAP HANA Extended Application Services, advanced model, is backwards compatible; you can provide access to new features by installing the latest version of the XS advanced component even on older versions of SAP HANA. To download the package `SAP_EXTENDED_APP_SERVICES_1`, see *SAP Software Download Center* in *Related Information* below.

## 13.2.1 XS Advanced Platform Components

An overview of the main components of the XS advanced model run-time environment.

The SAP HANA XS advanced model run-time environment is comprised of the components illustrated in the following diagram and described in more detail in the corresponding sections.

## The XS Advanced Controller

The XS advanced Controller (XS Controller) is a central component of the platform and is deployed once within an SAP HANA system. The XS Controller has the following purposes:

1. The XS Controller provides an application programming interface (API) for the platform user (administrators or application developers). The API enables users to perform the following tasks:
  - Maintain applications and service instances (resources provided by backing services)
  - Maintain XS advanced role collections (by means of an API provided by the XS User Account and Authentication service)
  - Maintain application run-time environments
  - Maintain application build packs (a convenient way to bring in custom programming languages for applications)

### → Tip

A command-line based administration tool (the `xs` client) and a GUI based tool (the XS Advanced Admin Cockpit) are provided to help administrators maintain the XS advanced model run-time platform. For more information, see *Related Information* below.

2. The XS Controller maintains the state of the XS advanced platform and communicates with a group of Execution Agents which are used to start, monitor, or stop applications running in the XS advanced run-time environment.

## The XS Advanced Execution Agent

The Execution Agent manages and monitors application instances. Several Execution Agents can be connected to the XS Controller, for example, if it is necessary to scale out application instances to several hosts.

Managed by the `xsexecagent` service, Execution Agents are primarily responsible for starting and stopping application instances. To be reachable for end users, launched application instances typically provide a public HTTP port. The Execution Agent checks the availability of this end point regularly. Instances of an application that are no longer reachable are restarted automatically.

In a distributed system, different instances of the same application do not necessarily run on the same host, although it is possible to pin applications to a particular host. If spaces are mapped to different OS users, the Execution Agents also ensure that application instances running in different spaces are not visible to each other at the operating system (OS) level.

## XS Advanced User Account and Authentication

The XS advanced User Account and Authentication (UAA) is the component that handles user-authentication requests for platform users as well as for business users.

The UAA service is a multi-tenant identity management service. The UAA's primary role is as an OAuth2 provider, issuing tokens for client applications to use when they act on behalf of XS advanced (or Cloud Foundry) users. The UAA can also authenticate users with their XS advanced (or Cloud Foundry) credentials and can act as an SSO service using those credentials (or others).

As well as various other management functions, the UAA provides end points for the management of user accounts and for registering OAuth2 clients.

You can configure an SAP HANA system to act as a service provider for XS advanced applications that use Single Sign On (SSO) authentication based on Security Assertion Markup Language (SAML) certificates. An SAML identity provider is used by the SAML service provider to authenticate users signing in by means of a single sign-on mechanism. If SAP HANA XS advanced applications are configured to use SAML assertions as the logon authentication method, then an SAML IdP is required. It is also possible to assign roles automatically to users who log on to an application by means of single sign-on with SAML assertions.

### → Tip

For more information about maintaining SAML Identity Providers (IdP) in XS advanced, see *Related Information* below.

## XS Advanced Platform Router

The Platform Router is the Web-dispatcher component that exposes all public end points of XS advanced platform components as well as for the running applications. The Platform Router is also responsible for load-balancing requests between several instances of an application. One or more end points (so called routes) can be exposed per application.

## XS Advanced Application Instances

By default, the XS advanced platform supports applications written in Java, Node.js, server-side JavaScript (XSJS), and Python, as well as other “custom” languages.

When an application is started by a platform user, the Execution Agent starts one or more instances of this application. Each application is run in its own environment and file-system sandbox. In this way, several application instances can be started, for example, depending on the current load an application has to take, without affecting the other application instances.

The number of application instances can be adapted (scaled) during run time. All instances of an applications are exposed under the same route, which means they share the same URI, a feature that enables transparent load-balancing. Using a round-robin algorithm, the Platform Router balances the load by distributing requests between available application instances. Sticky sessions are used to ensure proper caching of data inside single application instances.

## XS Advanced Backing Services

Backing Services provide resources to applications. Arbitrary backing services can be connected to the XS advanced platform by so-called "Service Brokers". The service broker provides a standardized interface to the XS Controller to fetch credentials for a particular backing service. The credentials are exposed to applications by means of so-called "service instances".

### → Tip

For more information about the XS advanced Service Broker, see *Related Information* below.

A platform user can create a service instance and bind this service instance to a particular application, while in the background the XS Controller will fetch the corresponding credentials. When starting the application, the XS Controller injects these credentials into the environment of the application instance, which enables the application to use the backing service.

## SAP HANA Database

The XS advanced platform uses SAP HANA as persistence as well as an infrastructure provider to manage the life cycle of XS advanced services, so it is important that you monitor the operation of SAP HANA databases on a regular basis.

Although SAP HANA actively alerts you about critical problems and situations, keeping an eye on resource usage and performance can help you identify patterns, forecast requirements, and recognize when something is wrong.

You can monitor SAP HANA using the SAP HANA Cockpit. The tools in the SAP HANA Cockpit rely on the monitoring and alerting information provided by system views and the statistics service.

## Platform Administration

During installation of the SAP HANA XS advanced run-time component, a user named `XSA_ADMIN` is created and granted the privileges required to administrate the XS advanced run-time environment. The `XSA_ADMIN` user can be used to log in to the XS advanced platform, perform administration tasks, or create further administration or restricted users, for example, using the following tools:

- Command-line tools:
  - `xs`  
Maintain XS advanced run-time components (applications, services, brokers, etc.)
  - `XSA`  
Stop, start XS advanced run-time instances.

### i Note

Some `XSA` command require `XSA_ADMIN` user privileges; most `XSA` commands require only `<sid>adm` privileges, for example, `XSA restart`.

- GUI-based tools:  
XS Advanced Admin Cockpit.

## 13.2.2 Maintaining the XS Advanced Run-time Environment with a Command-Line Interface

Use command-line tools to administrate and maintain XS advanced-model run-time components.

SAP HANA provides the following tools to enable you to maintain your XS advanced run-time environment from the command line:

- The `xs` command-line interface  
A selection of utilities to help you maintain not only the applications that are deployed to the XS advanced run-time environment, but also the run-time environment itself, for example, the organizations and spaces, and the users who need access and use it.

```
xs <command> [<ARGUMENTS>] [<OPTIONS>]
```

The `xs` CLI is automatically installed along with the XS advanced platform on an SAP HANA system. If the `xs` CLI is not added to the SAP HANA system's `<PATH>` environment variable, you can find the executable in the default location `/bin/xs`. The `xs` CLI can also be used from a remote computer which connects over a secure connection to the SAP HANA system where you want to perform the administration tasks.

### → Tip

To use the `xs` CLI, you must first log on to an SAP HANA system as the operating-system user `<SID>adm` and then log on to the `xs` CLI, for example, as a user with `XSA_ADMIN` privileges. For more information about how to log on to the `xs` CLI, see *Related Information* below.

- The `XSA` command-line interface  
A selection of utilities to help you maintain XS advanced run-time instances, for example, enable, disable, restart XS advanced, or maintain domain certificates, etc.

```
XSA {COMMAND} [--OPTIONS]
```

### ! Restriction

To use the `XSA` command, you must log on as the operating-system user `<SID>adm`.

## Related Information

[Maintaining XS Advanced Run-Time Components with the XS CLI \[page 1792\]](#)

[Maintaining XS Advanced Run-Time Instances with the XSA CLI \[page 1888\]](#)

[Maintaining the XS Advanced Run-time Environment with a Graphical User Interface \[page 1906\]](#)

### 13.2.2.1 Maintaining XS Advanced Run-Time Components with the XS CLI

Use the `xs` command-line interface (CLI) to manage the XS advanced run-time environment.

SAP HANA provides a command-line interface that enables you to maintain not only the applications that are deployed to the XS advanced run-time environment, but also specific elements of the run-time environment itself, for example, the components that enable it, and the users who access and use it. For example, you can use the XS CLI to maintain and manage the following components:

- Logon and setup
- XS advanced applications, routes, and tasks
- Organizations and spaces
- Domains and certificates
- Services
- Build packs, run-time environments, and the blob store
- XS advanced users
- Security aspects
- XS advanced application deployment, installation, and life cycle

#### → Tip

You can install and use the `xs` command-line interface tools over a secure connection from a remote machine. For more information about where to find and how to download the `xs` command-line interface tools, see *The XS Command-Line Interface* in *Related Information*.

## Related Information

[The XS Command-Line Interface \[page 1792\]](#)

[Logging on and Getting Started with the XS CLI \[page 1795\]](#)

### 13.2.2.1.1 The XS Command-Line Interface

A list of all the categories and areas covered by the `xs` command-line interface (CLI).

The `xs` command-line interface is a set of tools that enable the administration of the XS advanced run time from the command-line. The `xs` CLI is automatically installed on the SAP HANA system during installation of

XS Advanced. However, you can also install the `xs` CLI tools on a remote machine and log on to the XS advanced run-time environment from the remote machine using a secure connection.

#### → Tip

The XS advanced command-line client is available for download from SAP Service Marketplace for those people with the required S-User ID. Alternatively, you can find it on the SAP HANA installation media.

### Downloading the `xs` CLI from the Service Marketplace

Users with the required S-User ID can download the `xs` CLI from the SAP Service Marketplace:

► [Service Marketplace](#) ► [Software Downloads \[Downloads\]](#) ► [SUPPORT PACKAGES & PATCHES](#) ► [By Alphabetical Index \(A-Z\)](#) ► [H](#) ► [SAP HANA PLATFORM EDITION](#) ⌵:

- ► [SAP HANA PLATFORM EDITION 1.0](#) ► [XS ADVANCED RUNTIME](#) ► [XS RUNTIME 1](#) ⌵
- ► [SAP HANA PLATFORM EDITION 2.0](#) ► [XS RUNTIME 1](#) ⌵

### Downloading the `xs` CLI from the SAP HANA Media

The `xs` CLI is also available for download from the SAP HANA installation media. You can find the Zip archive `xs.onpremise.runtime.client*` in the following location on the SAP HANA media:

```
DATA_UNITS/XSA_CLIENT_10/xs.onpremise.runtime.client_<platform>-<version>.zip
```

#### → Tip

Extract the contents of the Zip archive to the desired location. On Unix machines, the default location is the directory `/bin`.

## Usage

```
xs <command> [<ARGUMENTS>] [<OPTIONS>]
```

To display information about a specific `xs` command:

```
xs help <command>
```

To display a list of all available `xs` commands, along with information about environment variables, and global options:

```
xs help -a
```

XS Command Overview

Command Category	Description
Logon and setup	User logon, view user-organization (and space) targets, set API URLs
Application Management	Maintain SAP HANA XS applications: list, deploy, start, stop, stage, [...]

Command Category	Description
Services Management	Maintain SAP HANA XS services: list, create, delete, bind, update, [...]
Organizations	Maintain user organizations: create, list, rename, delete, [...]
Spaces	Manage user spaces: create, list, rename, delete, [...]
Domains	Manage XS advanced domains: create, list, delete, set certificates, [...]
Certificates	Manage XS advanced certificates: set, unset, list trusted certificates
Routes	Maintain application routes: create, list, map, unmap, delete, [...]
Build Packs	Maintain application build-packs: create, list, update, rename, delete, [...]
Run-time Environments	Maintain XS run-times: create, list, display information, search, update, delete, [...]
Tasks	Maintain XS application-related tasks: list, run, cancel
User Administration	Maintain SAP HANA users: create, list, purge, delete, set/unset organizations, spaces, roles, [...]
Administration	Maintain XS application traces and backups
Tenant Databases	Manage and maintain tenant databases and their mapping to organizations and spaces
Configuration	Set and maintain environment variables and groups
Blob Store	Manage and maintain the contents of the blob store
Advanced	Retrieve and display OAuth tokens for the current session
Other Commands	Display information about the SAP HANA XS version, CLI, and system
Plug-ins	Additional commands as plug-ins; install/remove product components, deploy multi-target applications (MTA)

[Logging on and Getting Started with the XS CLI \[page 1795\]](#)

[SAP HANA Developer Guide for XS Advanced Model](#)

## 13.2.2.1.2 Logging on and Getting Started with the XS CLI

Get to know the basic commands available with the `xs` command-line interface.

In this section, you learn how to use the `xs` command-line interface (CLI) to perform the following tasks:

- Display a list of all `xs` commands
- Display details of a specific `xs` command
- Log on to (and out of) an instance of SAP HANA XS, advanced model

### → Tip

For information about predefined SAP HANA XS advanced users, for example, system and technical users, see *User Administration and Authentication in SAP HANA XS Advanced* in the *SAP HANA Security Guide*.

## Getting Help

The `xs` command-line interface provides comprehensive help for each `xs` command. To display an overview of all available `xs` commands included with the `xs` CLI, use the help command as shown in the following example:

```
$ xs help -a
```

To display usage details of a specific `xs` command, add the name of the command to the help command as shown in the following example:

```
$ xs help <command>
```

To display details of the current version of the `xs` command-line client, use the `version` command as shown in the following example:

```
$ xs version
```

## Logging on

During logon the `xs` CLI tries to connect to the so-called API URL of the XS Controller. To find out the current API URL, log on to the SAP HANA system as the operating-system user `<SID>adm` and run the following command:

```
$ xs-admin-login --api  
https://api.example.org:31030
```

You can use the URL displayed in the command output to log on to the XS advanced instance with the `xs` CLI from a remote session:

### → Tip

If you do not specify any user name in the `xs login` command, the `xs` CLI prompts you for the logon credentials you want to use.

```
$ xs login -a https://api.example.org:31030
USERNAME> XSA_ADMIN
PASSWORD> ****
Authenticating...
ORG: myorg
```

By default, the logon process targets the organization that was created during installation, for example, `myorg`. The first time you log on to XS advanced, you are asked to specify the organizational space you want to log on to from a list of available spaces, as illustrated in the following example:

```
Existing spaces:
0. PROD
1. SAP
SPACE> 0
SPACE: PROD
```

Choose the space you want to log on to by entering the corresponding number in the list, for example, `0` to select `PROD` as the target logon space. After successful logon, XS advanced displays a short summary of the logon details, as illustrated in the following example:

```
API endpoint: https://api.example.org:31030 (API version: 1)
User: XSA_ADMIN
Org: myorg
Space: PROD
```

If used remotely, the `xs` client needs a trust certificate to establish a secure connection. For more information about obtaining this trust certificate, see [Trust Certificates \[page 1797\]](#).

Alternatively, if you fully trust the network connection to the server, you can skip the SSL validation process, as shown in the following example:

### ⚠ Caution

It is strongly recommended **not** to skip SSL validation in a production environment.

### ≡ Sample Code

```
xs login -a <API URL> -u <username> --skip-ssl-validation
```

### → Tip

If you already logged on to an SAP HANA system as the operating-system user `<SID>adm`, you can use the command `xs-admin-login` (without any parameters or options) as a shortcut to log on to the XS advanced run time as user `XSA_ADMIN`. The `xs-admin-login` command automatically sets up the `xs` CLI and logs you on as `XSA_ADMIN` after prompting for the corresponding password.

## Trust Certificates

If you log on to XS advanced from a remote machine, the `xs` CLI requires a trusted certificate to establish a secure connection, unless `https` is disabled or a certificate signed by a well-known CA is used at the XS Controller. For your convenience, a public trust certificate is stored on the SAP HANA system at the following location:

```
/hana/shared/<SID>/xs/controller_data/controller/ssl-pub/default.root.crt.pem
```

The certificate file can be copied to the client, where it can then be consumed by using the `--cacert` option, as illustrated in the following example:

```
$ xs login -a https://api.example.org:8080 --cacert <PATH>
```

`<PATH>` indicates the location on the client machine of the file `default.root.crt.pem` which contains the certificate to use to establish the trusted connection.

### → Tip

Neither of these steps is necessary if a certificate signed by a well-known CA is available. For more information about certificates and trusted connections, see *Maintaining Domains* in *Related Information*.

## Logging off

To log out of the `xs` command-line interface client session, use the `logout` command as shown in the following example:

```
$ xs logout
```

## Related Information

[Maintaining Trust Certificates in XS Advanced \[page 1850\]](#)

### 13.2.2.1.3 Displaying the System Overview

Display an overview of the current configuration and status of the main XS advanced components.

If you are logged on to the XS advanced platform with the `xs` command-line interface, you can display an overview of all the most important components of the XS advanced instance, for example, the Execution

Agents and the XS Advanced Controller, as illustrated in the following example of the `xs system-info` command:

#### Output Code

Displaying XS Advanced Information

```
$ xs system-info
Getting system infrastructure information...
```

#### ! Restriction

To execute the `xs system-info` command, you need XS advanced administrator permissions.

The output generated by the `xs system-info` command includes information about the following XS advanced components:

- [Execution Agents \[page 1798\]](#)
- [XS Controller Server Version \[page 1799\]](#)
- [Registered Service URLs \[page 1801\]](#)
- [Applications \[page 1801\]](#)
- [Organizations And Spaces \[page 1802\]](#)

## XS Advanced Execution Agents

The Execution Agents section of the information displayed by the `xs system-info` includes details of the execution agents that are currently connected to the XS advanced Controller, as displayed in the following example output:

#### Output Code

`xs system-info` command output

```
Execution agents:
-----
1. host1.example.org:53648
   created at Dec 14, 2017 9:10:23 AM
   port range 50000-50499
   os.arch amd64
   os.name Linux
   java.vendor SAP AG
   java.version 1.8.0_144
   os.version 3.12.62-60.62-default
   sun.arch.data.model 64
   version v1.0.72
2. host2.example.org:53574
   created at Dec 14, 2017 9:11:24 AM
   port range 50000-50499
   os.arch amd64
   os.name Linux
   java.vendor SAP AG
   java.version 1.8.0_144
   os.version 3.12.62-60.62-default
   sun.arch.data.model 64
   version v1.0.72
```

In this example, two execution agents on "host1.example.org" and "host2.example.org" are connected to schedule application instances on. For each execution agent, additional information is displayed like:

- The host on which the Execution Agent is running
- The date and time when the Execution Agent was started
- The port range the Execution Agent uses for applications on its host
- The platform and version of the SAP Java Virtual Machine (JVM) that is running the Execution Agent
- The version of the Execution Agent

#### → Tip

If you need to scale out your application, you can add additional execution agents to an SAP HANA system by adding additional SAP HANA hosts with role "xs\_worker".

## XS Advanced Controller

The command `xs system-info` displays information about the XS Controller, as shown in the following example:

#### Output Code

`xs system-info` Command Output

```
Controller server version information:
-----
name                XS Controller
support             http://service.sap.com/message
build              v1.0.72
api version        1
software version   1.0.72.0
content version    1.0.72.0
state              READY
description        SAP XS Runtime on premise
controller endpoint https://example.org:30030
authorization endpoint https://example.org:30032/uaa-security
accept encoding    gzip, x-gzip
usage              apps: 8, routes: 8, services: 16
                   instances: 0 starting, 6 running, 3 stopped, ...
                   1 crashed, 0 timed out
database type      HANA_MULTI
database info      HDB 2.00.022.00.1511184640
runtime database   SYSTEMDB
```

The following table lists and explains the information that the `xs system-info` command displays about the XS Controller.

#### XS Controller Information

Information	Description
name	The name of the XS advanced component
support	The URL to use to contact a support team

Information	Description
<code>build</code>	The built version of the XS Controller
<code>api version</code>	The version of the REST interface provided by the XS Controller
<code>software version</code>	The installed version of the XS advanced system components.
	<p><b>i Note</b></p> <p>In a standard installation, <code>software version</code> and <code>content version</code> must match.</p>
<code>content version</code>	The installed version of the XS advanced core applications package (for example, <code>deploy-service</code> and <code>product-installer</code> ).
	<p><b>i Note</b></p> <p>In a standard installation, <code>software version</code> and <code>content version</code> must match.</p>
<code>state</code>	<p>The current state of the XS advanced run-time, which can be one of the following:</p> <ul style="list-style-type: none"> <li>• <code>STARTUP</code> XS advanced is currently starting</li> <li>• <code>READY</code> XS advanced is installed correctly</li> <li>• <code>INSTALLATION_PENDING</code> The initial XS advanced installation is not yet complete</li> <li>• <code>UPDATE_PENDING</code> The XS advanced update is not yet complete</li> </ul>
<code>description</code>	A short summary of the type of installed component, for example, <code>SAP XS Runtime on premise</code>
<code>controller endpoint</code>	The REST end point for requests to the XS Controller API (also known as the "API URL")
<code>authorization endpoint</code>	The REST end point for authorization requests
<code>usage</code>	Information about the number of applications and application instances and their current status, for example: <code>starting</code> , <code>running</code> , <code>stopped</code> , etc.
<code>database type</code>	<p>The type of the underlying SAP HANA database installed; this can be either of the following:</p> <ul style="list-style-type: none"> <li>• <code>HANA_MULTI</code> SAP HANA multiple database-container system</li> <li>• <code>HANA_SINGLE</code> SAP HANA single database-container system</li> </ul>
<code>database info</code>	The version of the underlying SAP HANA database

Information	Description
runtime database	The database containing the persistence of the XS Advanced system components

## XS Advanced Service URLs

The `xs system-info` command displays information about the services URLs registered by deployed XS advanced applications. XS advanced applications can maintain a service URL during installation to publish their application end point:

### Output Code

`xs system-info` Command Output

Registered service URLs:

```
-----
deploy-service      https://example.org:51004
product-installer   https://example.org:51005
[...]
```

## XS Advanced Applications Overview

The `xs system-info` command uses the "Applications" section to display statistics about the applications deployed in the XS advanced system and the current known status, as illustrated in the following example output:

### Output Code

`xs system-info` Command Output

Applications:

```
-----
Deployed applications: 8
Running applications:  6
Stopped applications:  2
```

## Organizations And Spaces in XS Advanced

The `Organizations` and `Spaces` section of the information displayed by the `xs system-info` command displays statistics about the distribution of applications across the configured organizations and spaces, as illustrated in the following example:

```
⌘ Output Code
xs system-info Command Output

Organizations and spaces:
Organization      Space           Number of apps  User:
-----
myorg
|-                PROD            0               abcxs
|-                SAP             8               sapabcxs
```

In the example displayed, the organization "myorg" contains two spaces named "PROD" and "SAP". In addition to the number of applications deployed in each space, the information displayed also indicates the name of the operating-system user (for example, `<SID>xs`) used to start the XS advanced application.

[Maintaining the XS Advanced Run-time Environment with a Command-Line Interface \[page 1791\]](#)

## 13.2.2.1.4 Maintaining Organizations and Spaces in XS Advanced

Use the `xs` command-line interface to configure and maintain organizations and spaces in XS advanced.

The examples in this section show how to use the `xs` command-line interface (CLI) to perform the following tasks:

- [Navigating Through Organizations and Spaces \[page 1803\]](#)
- [Maintaining Spaces \[page 1805\]](#)
- [Maintaining Organizations \[page 1805\]](#)
- [Isolating Applications at the Operating-System Level \[page 1806\]](#)
- [Custom Operating-System Users \[page 1807\]](#)

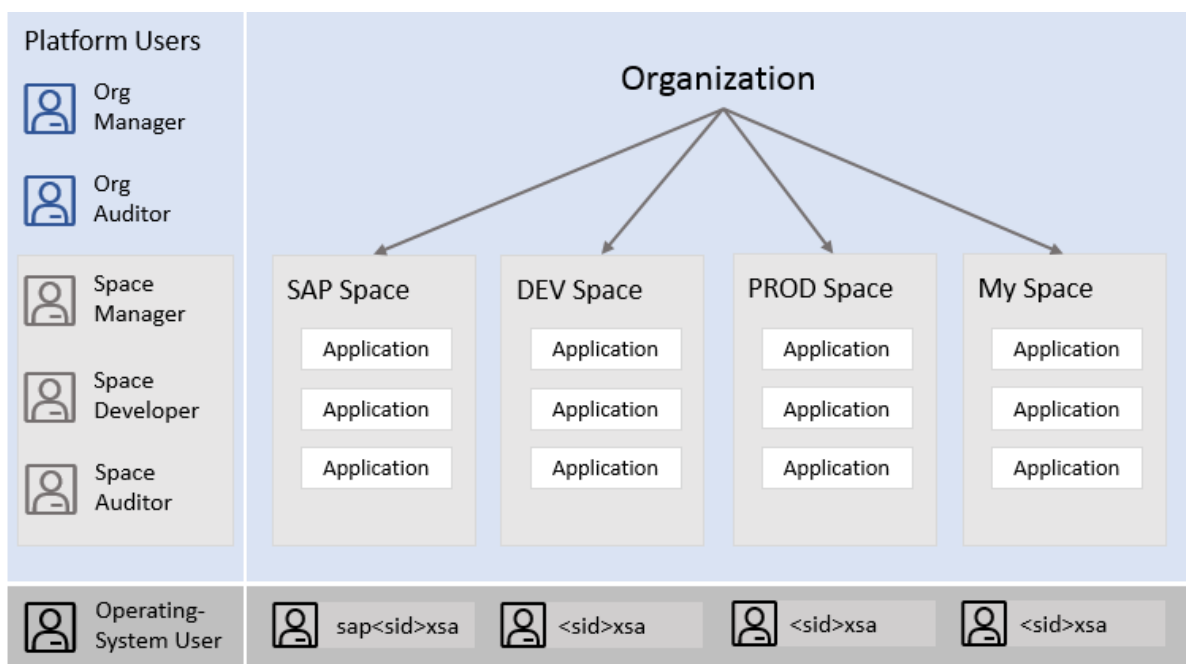

### Overview

XS advanced applications can be grouped together by means of a hierarchy of so-called organizations and spaces. An organization forms a logical group of spaces. Information about application domains and server

certificates is also tied to organizations. In XS advanced, a “space” is not only a way to form a logical group of applications, it is also a trust zone. Applications cannot use any resources that were created in another space (for example, service instances), and application processes are also isolated at the space level by using operating-system users to start the application processes, as described in [Custom Operating-System Users \[page 1807\]](#) below.

→ Tip

See *Maintaining Platform Users in Related Information* for more information about user roles in organizations and spaces. For more information about the underlying security concepts for organizations and spaces, see the *SAP HANA Security Guide in Related Information* below.

## Navigating Through Organizations and Spaces in XS Advanced

During the installation of XS advanced, one organization and two spaces are created by default:

- An organization with a custom name
- A space named `SAP` which contains the default XS advanced applications provided by SAP
- A space for custom development or deployment; by default, this space is named `PROD`.

To display a list of all organizations configured in an XS advanced run-time instance, run the following command, which in this example, shows the organizations `acme` and `corp`:

```
$ xs orgs
Getting orgs...
name
-----
acme
```

```
corp
```

To view the spaces configured in the currently targeted organization, use the command `xs spaces`, as shown in the following example:

```
$ xs spaces
Getting spaces in org acme as XSA_ADMIN ...
name    user
-----
DEV     xsaxsa
PROD    xsaxsa
SAP     sapxsaxsa
```

### → Tip

The space `name` is shown along with the name of the operating-system `user` whose account is used to start applications in the specified space, for example, the user `xsaxsa` starts applications in spaces `DEV` and `PROD`, and the user `sapxsaxsa` starts applications in space `SAP`.

You can set the target for the `xs` CLI to a specific organization and space by using the `xs target` command, as shown in the following example:

```
$ xs target -o <org-name> -s <space-name>
```

When you have set the target organization and space, you can use the `xs apps` command to display a list of the applications currently running there:

```
$ xs apps
Getting apps in org "acme" / space "SAP" as XSA_ADMIN...
Found apps:
name                state    instances memory    disk        urls
-----
auditlog-db         STOPPED  0/1      16.0 MB  <unlimited> <none>
auditlog-server     STARTED  1/1      256 MB   <unlimited> https://acme.org:
auditlog-broker     STARTED  1/1      64.0 MB  <unlimited> https://acme.org:
deploy-service      STARTED  1/1      280 MB   <unlimited> https://acme.org:
component-registry-db STOPPED  0/1      16.0 MB  <unlimited> <none>
product-installer   STARTED  1/1      256 MB   <unlimited> https://acme.org:
auditlog-odata      STARTED  1/1      128 MB   <unlimited> https://acme.org:
auditlog-ui         STARTED  1/1      64.0 MB  <unlimited> https://acme.org:
xsa-admin-backend   STARTED  1/1      128 MB   <unlimited> https://acme.org:
xsa-admin           STARTED  1/1      128 MB   <unlimited> https://acme.org:
```

To display details of the currently targeted organization and space, use the command `xs target` without any parameters or options, as illustrated in the following example:

```
$ xs target
API endpoint: https://xsa.acme.com:30030 (API version: 1)
User:        XSA_ADMIN
Org:         acme
Space:       SAP
```

To change to a specific target organization and space, use the `xs target` command with the options `-o <ORG>` `-s <SPACE>`, as illustrated in the following example:

```
$ xs target -o acme -s DEV
```

## Maintaining Spaces in XS Advanced

In some advanced use cases, the default space setup is not sufficient to meet the needs of your environment. For example, if you want to separate applications currently in development from applications that have been tested (so that they run in different spaces), you can create additional spaces, for example, named `DEV` and `TEST`. Similarly, you can separate different development teams by ensuring that they work in different spaces. To create a new space, use the command `xs create-space`, as shown in the following example:

```
$ xs create-space DEV

Creating space DEV in org acme as XSA_ADMIN...
OK
```

The command shown in the example above will create an empty space named `DEV` within the currently targeted organization `acme`.

### → Tip

The `xs create-space` command does not automatically switch target to the new space `DEV`; you must manually set the new space as the new target, for example, with the command `xs target -s <SPACE>`.

To delete an existing space, use the command `xs delete-space`, as shown in the following example:

```
$ xs delete-space DEV

Really delete the space "DEV" in org "acme"? (y/n) > y
Deleted space "DEV".
```

You can change the name of an existing space, too, as illustrated in the following example, which shows how to change the name of the space `DEV` to `TEST`:

```
$ xs rename-space DEV TEST

Renaming space "DEV" in org "acme"...
OK
```

## Maintaining Organizations in XS Advanced

Organizations are particularly useful if you want to expose one group of applications by means of a different domain name to the one used by another group of applications. Hence, organizations can be used to reflect the organizational structure of your company or corporation. In order to create a new, empty organization, use the command `xs create-org`:

```
$ xs create-org myorg
OK
```

### → Tip

The `xs create-org` command does not automatically switch target to the new organization `myorg`; you must manually set the new organization as the new target, for example, with the command `xs target -o <ORGANIZATION>`.

To delete an existing organization, use the command `xs delete-org`, as shown in the following example:

```
$ xs delete-org myorg

Deleting org "myorg"...
Really delete the org "myorg"? (y/n) > y
Deleted org "myorg".
```

### ⚠ Caution

The `xs delete-org` command also deletes **all spaces** contained in the deleted organization along with all related resources such as applications, service instances, and routes. Note that all applications running in any of the deleted organization's spaces must be stopped before you delete the organization.

You can change the name of an existing organization, too, as illustrated in the following example, which shows how to change the name of the organization "acme" to "test":

```
$ xs rename-org acme test
OK
```

## Isolating XS Advanced Applications at the Operating-System Level

Instances of running application can be isolated at the space level. This means that processes of application instances started in the same space are run as the same operating system user. You can also specify that application processes from different spaces are executed as different operating system users. In this way, application processes from an isolated space are not allowed to access the process environment and the file system of other applications or the SAP HANA system itself.

During installation, two restricted operating system users are automatically created by `hdblcm` and assigned to default XS advanced spaces. These users are automatically maintained by `hdblcm` if an additional `xs_worker` host is added to the SAP HANA system or during any rename operation. The following table shows the mapping of the default operating system users to XS advanced spaces;

Default Username-Space Mapping in XS Advanced

User Name	Space Name
<code>sap&lt;SID&gt;xsa</code>	SAP
<code>&lt;SID&gt;xsa</code>	Custom space (for example, <code>PROD</code> ); this is the default user name for newly created spaces

In this example, application processes in the space `SAP` run as user `sap<SID>xsa` while application processes in the space `PROD` will run as user `<SID>xsa`. User names are combined with the System ID (SID) of the SAP HANA system. This is to prevent any clashes between user names when several SAP HANA systems are installed on the same host. To change the operating system user mapping for a particular space, use the command `xs update-space`, as shown in the following example:

```
$ xs update-space <space-name> -u <OS-user-name>
```

### i Note

You cannot change the mapping between operating-system user and a space if applications are still running inside the targeted space. You must stop all applications that are running in a space before changing the operating-system user mapping.

To revert to the default settings for the mapping between space and operating-system user, use the `--unset-user` option as shown in the following example:

```
$ xs update-space <space-name> --unset-user
```

## Custom Operating-System Users

The command `xs update-space` does not create the underlying operating system user. If a custom operating system user is required in addition to the default operating system users, the new custom operating-system user must be created first and on all SAP HANA hosts performing the role of `xs_worker` or `xs_standby`.

### i Note

The operating-system user associated with a space only requires a restricted set of privileges.

The operating-system user associated with a space only requires a restricted set of privileges:

- The operating system user does **not** need any elevated or superuser privileges
- The operating system user must **not** be in the group `sapsys`
- No secondary groups are required
- No `home/` directory is required
- No user logon is required

In addition, if you use a SAP HANA version older than HANA 2.0 SPS 02 Rev. 1, it is necessary to adapt the `sudo` configuration file `/etc/sudoers`. For more details about how to set up a new operating system user and adapt the `sudoers` configuration files, see also SAP Note [2243156](#).

## Related Information

[Maintaining Platform Users in XS Advanced \[page 1810\]](#)

[The XS Command-Line Interface \[page 1792\]](#)

[SAP HANA Security Guide](#)

## 13.2.2.1.5 Maintaining Organization Quotas

Set limits for application instances for XS advanced organizations and maintain organizational quota plans.

Organization quotas are named sets of restrictions applied to an organization by an organization manager. For example a quota might limit an organization to create up to 10 application instances. Because organization quotas are a collection of such individual limits they are also referred to as quota plan, quota definition or simply quotas. The limits supported by organization quotas are shown in the table below.

XS Advanced Organization Limits

Limit	Description
App instance limit	The total number of instances of started applications allowed in the specified organization. Instances of stopped applications do not count toward this instance limit.  <b>i Note</b> “-1” represents an unlimited amount. (Default: “-1”)
Max instances per application	The total number of running instances allowed per application in the specified organization.  <b>i Note</b> “-1” represents an unlimited amount. (Default: “100”)
Service instances limit	The total number of service instances allowed in the specified organization.  <b>i Note</b> “-1” represents an unlimited amount. (Default: “-1”)

When a new organization is created, an organization quota named "default" is automatically assigned to it; this is referred to as the "default quota". Although the default quota cannot be deleted, the values can be modified by an administrative user. Only an XS advanced controller administrator can use the quota commands to create, update, or delete an organization quota. An organization manager can use the quota commands to assign a quota to an organization.

### Creating a Quota Plan for an Organization

The following example shows how to use the `xs create-quota` command to set a quota plan for the current target organization:

```
xs create-quota quota1 -a 10 -ma 5 -s 4
```

The command illustrated in the example above creates a quota named "quota1" that limits the total amount of started application instances (-a) to "10"; the maximum amount of running instances per application (-ma) to "5"; and the total amount of service instances (-s) to "4". Where no option is specified, the default value for the respective limit is assigned.

## Reading an Organization Quota Plan

The following example shows how to use the `xs quotas` command to display a list of all existing organization quota plans:

### **xs quotas**

Getting Quota Definitions...

name	app instances	max instances per app	service instances
default	unlimited	100	unlimited
quotat1	10	5	4

To display details of a specific quota, use the `xs quota <QUOTA_NAME>` command, as illustrated in the following example:

### **xs quota quotat1**

Property	Value
Name	quotat1
Service instances limit	unlimited
App instance limit	unlimited
Max instances per app	100

## Assigning a Quota Plan to an Organization

The following example shows how to use the `xs set-quota` command to assign a quota plan to a specific organization:

```
xs set-quota org1 quotat1
```

The command illustrated in the example above assigns the quota named "quotat1" to the organization named "org1". Assigning of a quota to an organization will fail if the limits set in the assigned quota are already being broken by the organization. For example if the organization has 100 application instances, then a quota with a total application instance limit of "10" cannot be assigned.

### **i Note**

A quota can be assigned to multiple organizations. Any changes made to the quota will affect all the organizations it is assigned to.

To view the quota definition assigned to an organization use the command "xs org". The example below demonstrates an elaborate use:

### **xs org org1**

Getting info for org "org1" as user "XSA\_ADMIN"...

```
name:      org1
domains:   example.org
quota:     quotat1
spaces:    spacel
```

```
created: May 30, 2018 8:55:36 AM
updated: May 30, 2018 8:55:36 AM
```

## Deleting a Quota Plan

The following example shows how to use the `xs delete-quota` command to unassign and remove a quota plan:

```
xs delete-quota quota1
```

The command illustrated in the example above deletes the quota named "quota1".

### ! Restriction

An organization quota can only be deleted if it is not assigned to any organization. The quota named "default" cannot be deleted.

## Related Information

[Maintaining Organizations and Spaces in XS Advanced \[page 1802\]](#)

## 13.2.2.1.6 Maintaining Platform Users in XS Advanced

Use the `xs` command-line interface to maintain XS advanced users.

Users who have access to the XS advanced platform (so-called platform users) can be sorted into the following categories:

- Platform administrators  
For example, `XSA_ADMIN`, who are allowed to perform any platform operation in any organization and space.
- Restricted users  
For example, developers and organization or space manager, who have restricted permissions in specific organizations or spaces. A role model exists for restricted platform users, which is defined in the *SAP HANA Security Guide*. For more details about this user model, see *Related Information*.

## Maintaining SAP HANA Users

You can use SAP HANA database users as XS advanced users. By default, SAP HANA database users are assigned the role `XS_PUBLIC`. The `xs` command-line interface provides commands that enable you to maintain

XS Advanced SAP HANA users. To create a new database user with XS advanced capabilities, use the command `xs create-user`, as illustrated in the following example:

### → Tip

The option `--platform` automatically assigns the role collection `XS_CONTROLLER_USER` described in *Predefined Role Collections* below.

```
xs create-user <USERNAME> --platform
```

XS advanced users can change their own password by logging in to the XS advanced platform with the `xs` CLI and running the command `xs passwd`, as illustrated in the following example:

```
xs passwd
```

XS advanced administrators can change or reset the password of other users by specifying the name of the user whose password they want to change, as illustrated in the following example:

```
xs passwd <OTHER_USER>
```

XS administrators can also use the `xs` CLI to delete a user of the XS advanced platform, as illustrated in the following example:

```
xs delete-user <OTHER_USER>
```

To complete the configuration of SAP HANA users as XS advanced users, you can use the `xs` CLI to assign one or more predefined role collections to the XS advanced users as described in the following sections.

## Viewing Role Collections

New XS advanced platform users are created by assigning predefined platform role collections to existing SAP HANA users, for example, with the `xs` CLI, as described in this section. The following table shows the XS advanced role collections that exist for platform users:

### i Note

You can also use IdP users as XS advanced platform users. However, it is not possible to assign role collections to IdP users, you must map a SAML group, instead.

XS Advanced Role Collections

Role Collection	Description
<code>XS_CONTROLLER_ADMIN</code>	The platform administrator
<code>XS_CONTROLLER_ADMIN_READ_ONLY</code>	The platform administrator with read only permissions
<code>XS_CONTROLLER_GLOBAL_AUDITOR</code>	Similar to the platform administrator but only with some restrictions like system configuration and credentials access

Role Collection	Description
XS_CONTROLLER_USER	Enables a restricted user who has refined permissions in organizations and spaces
XS_CONTROLLER_CREDENTIALS_VIEWER	Similar to the controller user with additional application credentials access
XS_CONTROLLER_AUDITOR	Enables a restricted read-only user who has refined permissions on organizations and spaces
XS_USER_ADMIN	Enables a user who can create and maintain other users
XS_AUTHORIZATION_ADMIN	Enables a user who can view, create and maintain role collections
XS_MONITOR_ADMIN	Enables a user who can set or change the trace level.

## Viewing Available Role Collections

You can use the command `xs role-collections` to view all available XS advanced role collections. The command output shows details of role collections for the XS advanced platform as well as the role collections created for XS advanced applications, as illustrated in the following example:

### Sample Code

```
$ xs role-collections

Getting role collections as user "XSA_ADMIN"...

role collection          description
-----
AUDITLOG_VIEWER
XS_AUTHORIZATION_ADMIN  Authorizations for XS role builder
XS_AUTHORIZATION_DISPLAY Authorizations for XS role viewer
XS_USER_ADMIN           Admin authorizations for XS user management
XS_USER_DISPLAY         Display authorizations for XS user
XS_USER_PUBLIC          Default authorizations for XS user
XS_MONITOR_ADMIN        Authorizations for XS monitoring management
XS_MONITOR_DISPLAY      Authorizations for XS monitoring display
XS_SUBSCRIPTION_ADMIN   Authorizations for XS subscriptions
XS_SUBSCRIPTION_DISPLAY Authorizations for XS subscriptions display
XS_TENANT_ADMIN         Authorizations for XS tenants management
XS_TENANT_DISPLAY       Authorizations for XS tenants display
XS_CONTROLLER_ADMIN     Authorizations for XS controller admin
XS_CONTROLLER_ADMIN_READ_ONLY
admin                  Authorizations for XS controller read-only
XS_CONTROLLER_GLOBAL_AUDITOR
auditor                Authorizations for XS controller global
XS_CONTROLLER_USER      Authorizations for XS controller user
XS_CONTROLLER_AUDITOR   Authorizations for XS controller auditor
XS_CONTROLLER_CREDENTIALS_VIEWER
credentials viewer     Authorizations for XS controller
```

## Viewing Assigned Role Collections

To view the role collections assigned to a specific user, use the command `xs assigned-role-collections`, as illustrated in the following example for user `XSA_ADMIN`:

### Output Code

Role Collections Assigned to a User

```
$ xs assigned-role-collections XSA_ADMIN

role collection      description
-----
XS_CONTROLLER_ADMIN  Authorizations for XS controller admin
XS_AUTHORIZATION_ADMIN  Authorizations for XS role builder
XS_USER_ADMIN        Admin authorizations for XS user management
AUDITLOG_VIEWER
```

In the example output above, the default admin user `XSA_ADMIN` has a role collection `XS_CONTROLLER_ADMIN` that enables the administrator to perform **any** task in **any** XS advanced organization and space. In addition, `XSA_ADMIN` has the role collections `XS_AUTHORIZATION_ADMIN` and `XS_USER_ADMIN`, which enable the administrator user to create other users and maintain and assign role collections. `XSA_ADMIN` has an additional application role collection that provides the permissions required to view audit logs.

## Assigning Role Collections

The following sections describe how to create new administrators and restricted users for the XS advanced platform by assigning the corresponding role collection and setting permissions that apply for particular organizations and spaces.

### Creating XS Advanced Administrator Users

To create a new XS advanced administrator user, it is necessary to have an existing "non-restricted" SAP HANA user in the database where XS advanced keeps its persistence. The following example shows how to use the `hdbsql` utility to create an SAP HANA user. Log on to the SAP HANA system with `hdbsql` as a user with the `User.Admin` role and execute the following SQL command:

```
=> CREATE USER XSA_ADMIN2 PASSWORD "Welcome1"
0 rows affected (overall time 25.359 msec; server time 23.375 msec)
```

If you are logged to the XS advanced platform as an XS advanced administrator (for example, `XSA_ADMIN`), you can grant the new XS advanced administrator user (`XSA_ADMIN2`) the necessary controller roles `XS_CONTROLLER_ADMIN`, `XS_USER_ADMIN`, and `XS_AUTHORIZATION_ADMIN`, for example, using the command `xs assign-role-collection`:

### Sample Code

```
$ xs assign-role-collection XS_CONTROLLER_ADMIN XSA_ADMIN2

Assigning role collection "XS_CONTROLLER_ADMIN" to user "XSA_ADMIN2"...
OK

$ xs assign-role-collection XS_USER_ADMIN XSA_ADMIN2
```

```
Assigning role collection "XS_USER_ADMIN" to user "XSA_ADMIN2"...  
OK
```

```
$ xs assign-role-collection XS_AUTHORIZATION_ADMIN XSA_ADMIN2  
  
Assigning role collection "XS_AUTHORIZATION_ADMIN" to user "XSA_ADMIN2"...  
OK
```

The XSA\_ADMIN2 can be now used to perform administrator tasks on the XS Advanced platform.

## ! Restriction

To log on to the new XS advanced administrator account (XSA\_ADMIN2) an initial password change is required. Once logged in, you are prompted by the xs CLI or the UAA login page to change your initial password. Alternatively, you can use the command `hdbsql` to set the new password.

## Creating XS Advanced Restricted Users

To create a new XS advanced restricted user, it is necessary to have an existing SAP HANA user in the database where XS advanced keeps its persistence. The following example shows how to use the `hdbsql` utility to create an SAP HANA user. Log on to the SAP HANA system with `hdbsql` as a user with the `User.Admin` role and execute the following SQL command:

```
=> CREATE RESTRICTED USER NEW_XSA_USER PASSWORD "Welcome1"  
0 rows affected (overall time 26.582 msec; server time 24.367 msec)
```

Note, that for XS advanced restricted users, restricted HANA users (without `PUBLIC` role assignment) are sufficient.

As an alternative, you can also execute `xs create-user` as XS advanced administrator:

```
=> xs create-user NEW_XSA_USER --platform  
PASSWORD>  
Checking if user "NEW_XSA_USER" already exists (as "XSA_ADMIN")...  
Creating user "NEW_XSA_USER" as "XSA_ADMIN"...  
Password for user NEW_XSA_USER>  
Confirm the password>  
OK
```

Note, that by specifying the option `--platform` the role collection `XS_CONTROLLER_USER` is automatically assigned. For more information about `xs create-user`, see *XS CLI: User Administration* in the *Related Links*.

If you are logged on to the XS advanced platform as an XS advanced administrator (for example, XSA\_ADMIN), you can grant the new XS advanced user (NEW\_XSA\_USER) the necessary controller roles `XS_CONTROLLER_USER` manually, for example, using the command `xs assign-role-collection`:

```
$ xs assign-role-collection XS_CONTROLLER_USER NEW_XSA_USER  
  
Assigning role collection "XS_CONTROLLER_USER" to user "NEW_XSA_USER"...  
OK
```

The assignment of the role collection `XS_CONTROLLER_USER` enables the new user to log on to the XS advanced platform. Since the created user is restricted, the user still does not have any XS Controller privileges. For this reason, it is necessary to assign XS Controller roles to the restricted XS advanced user at both the organization and space level, as described in the following sections.

## Assigning Controller Roles

XS administrators can set roles and permissions at the organization level or at the space level.

### Setting Roles and Permissions at the Organization Level

The `xs` command-line client includes the command `xs set-org-role`, which you can use to grant organization-specific roles to users. For example, to grant the user `XSA_USER` the `OrgManager` role in the organization "acme", run the following command:

```
$ xs set-org-role XSA_USER acme OrgManager
OrgManager Adding role 'OrgManager' to user NEW_XSA_USER in org "acme" ...
OK
```

To set user permissions at the organization level, you must log on to XS advanced with either administrator privileges or as a restricted user with the role `OrgManager` in the organization where you want to grant user roles and privileges. The following table lists the roles you can grant to an organization user:

XS Advanced Organization Roles

Organization Role	Privileges
<code>OrgManager</code>	Create and modify spaces in an organization Assign roles and privileges to other organization users
<code>OrgAuditor</code>	Browse through spaces inside an organization

For users maintained in an external IdP, the `--origin` option enables you to specify the name of the IdP where the external user is maintained while setting the organization role, for example, with the `xs set-org-role` command. The following example shows how to specify that the user `XSA_USER` comes from the IdP origin "accounts":

```
$ xs set-org-role XSA_USER acme OrgManager --origin accounts
```

To view the users available for an organization, use the command `xs org-users`. The command displays user name, the assigned role, origin and the deactivation state, as illustrated in the example below:

```
$xs org-users acme
Listing users in org "acme" by role ...
role          user          origin  deactivated
-----
OrgManager    TESTUSER1     yes
```

To remove a role already assigned to an organization user, use the `xs unset-org-role` command, as illustrated in the following example:

```
$ xs unset-org-role XSA_USER acme OrgManager
```

## Setting Roles and Permissions at the Space Level

The `xs` command-line client includes the command `xs set-space-role`, which you can use to grant space-specific roles to users. For example, to grant the user `NEW_XSA_USER` the `SpaceManager` role for a space called "DEV" in an organization named "acme", run the following command:

```
$ xs set-space-role NEW_XSA_USER acme DEV SpaceManager
Adding role 'SpaceManager' to user NEW_XSA_USER in space "DEV" in org "acme" ...
OK
```

To set user permissions at the space level, you must log on to XS advanced with either administrator privileges or as a restricted user with the role `SpaceManager` in the space where you want to grant user roles and privileges. The following table lists the roles you can grant to a space user:

XS Advanced Organization Roles

Space Role	Privileges
<code>SpaceManager</code>	Modify a space Assign roles and privileges to other space users
<code>SpaceDeveloper</code>	Modify a space
<code>SpaceAuditor</code>	Browse through any space where you have the <code>SpaceAuditor</code> role

For users maintained in an external IdP, the `--origin` option enables you to specify the name of the IdP where the external user is maintained while setting the space role, for example, with the `xs set-space-role` command. The following example shows how to specify that the user `XSA_USER` comes from the IdP origin "accounts":

```
$ xs set-space-role XSA_USER acme SpaceManager --origin accounts
```

To view the users in a space, use the `xs space-users` command. The command displays user name, the assigned role, origin and the deactivation state of the space user, as illustrated in the example below:

```
$ xs space-users acme SAP
Listing users in space "SAP" of org "acme" by role ...
role          user          origin    deactivated
-----
SpaceManager  TESTUSER2
```

To remove a role already assigned to a space user, use the `unset-space-role` command, as illustrated in the following example:

```
$ xs unset-space-role XSA_USER acme DEV SpaceManager
```

To view all the users on the platform that have been assigned a role, use the `xs users` command. The command shows the name, origin and the deactivation state of the users, as illustrated in the example below:

```
$ xs users
Getting users...
user          origin    deactivated
-----
TESTUSER1                yes
TESTUSER2
```

## Note

Users marked as 'orphaned' are SAP HANA database users that have been deleted from the database but are still known to the XS Controller. To clean these users up and remove their connection to the XS Controller, run the command `xs purge-users`.

## 13.2.2.1.7 Displaying Application Information in XS Advanced

Use the `xs` command-line interface to deploy and maintain XS advanced applications.

After navigating to a particular organization and space, you can explore the resources contained in a space. A space contains different types of resources, for example: applications, service instances, and routes. The information in the following sections focuses on application resources and aims to help you perform the following application-related tasks in an XS advanced space:

- [Displaying Deployed XS Advanced Applications in a Space \[page 1817\]](#)
- [Displaying Details of an Individual XS Advanced Application \[page 1819\]](#)
- [Displaying XS Advanced Application Logs \[page 1821\]](#)
- [Displaying XS Advanced Application Events \[page 1823\]](#)
- [Displaying XS Advanced Application Files \[page 1824\]](#)

## Displaying Deployed XS Advanced Applications in a Space

When you set a space as a particular “target”, you can use the `xs` CLI to display information about the XS advanced applications running in the target space, as shown in the following example:

### Output Code

```
$ xs apps
Getting apps in org "acme" / space "SAP" as XSA_ADMIN...
Found apps:
name                state      requested instances memory  disk  alerts  urls
-----
```

auditlog-db	STOPPED	0/1	16.0 MB	<unlimited>	<none>
auditlog-server	STARTED	1/1	256 MB	<unlimited>	https:
auditlog-broker	STARTED	1/1	64.0 MB	<unlimited>	https:
deploy-service	STARTED	1/1	280 MB	<unlimited>	https:
component-registry-db	STOPPED	0/1	16.0 MB	<unlimited>	<none>
product-installer	STARTED	1/1	256 MB	<unlimited>	https:
auditlog-odata	STARTED	1/1	128 MB	<unlimited>	https:
auditlog-ui	STARTED	1/1	64.0 MB	<unlimited>	https:
xsa-admin-backend	STARTED	1/1	128 MB	<unlimited>	https:
xsa-admin	STARTED	1/1	128 MB	<unlimited>	https:
demo-app	STARTED	2/3	256 MB	<unlimited>	1/1/1 https:
demo-app2	STARTED	0/1	256 MB	<unlimited>	DOWN! https:

The information displayed in the example above includes the following details:

#### XS Advanced Application Details

Property	Description
name	The names of the XS advanced applications deployed in the current organization/space
requested state	<p>The <b>targeted</b> state of the application, for example, <code>STARTED</code> or <code>STOPPED</code>. This state results from a request by an administrator to start or stop an application.</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>→ Tip</p> <p>The <code>requested state</code> does not indicate the <b>actual</b> state of any application instances. The actual status of an application is displayed in the <code>instances</code> property.</p> </div>
instances	<p>The actual status of an application, described by two numbers separated by a slash, for example, <code>0/1</code>:</p> <ul style="list-style-type: none"> <li>• The number of application instances that are currently running</li> <li>• The targeted number of running instances</li> </ul> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p>→ Tip</p> <p>An application is fully started if the number of running instances matches the targeted number of running instances, for example, <code>1/1</code>.</p> </div>
memory	The amount of memory assigned to the application
disk	The disk quota allocated for use by the application
alerts	Information about problems with the application. If there were crashes of application instances, three values are displayed, for example, "1/1/1", which represent the number of crashes within different periods of time (short term: 5 minutes, mid-term: 1 hour, long-term: 1 day). If XS advanced cannot start an application, 'DOWN!' is displayed.
urls	The Universal Resource Location (URL), defined in a "route" where the application is accessible

When reading the information displayed by the `xs apps` command, bear in mind the following details:

- For most applications, the expected number of application instances are running.
- Some applications are `STOPPED` either automatically or at the request of an XS advanced administrator.

Any application that performs a single task stops automatically as soon as it completes the assigned task. For example, the applications `*-db` in the example above (`auditlog-db` and `component-registry-db`) perform a one-off task such as initial database deployment. After the deployment tasks finishes, the database application is stopped to save system resources.

- The application `demo-app2` is down and no further application instances will be started by XS advanced.
- Only 2 of the possible 3 instances of the application "demo-app" are started. There was a crash of an instance within the last 5 minutes. This could indicate a problem that needs further investigation.

## Displaying Details of an XS Advanced Application Instance

To display detailed information about a specific instance of an XS advanced application, use the `xs app <appName>` command, as shown in the following example:

### Output Code

```
$ xs app demo-app

Showing status and information about "demo-app"
name:                demo-app
requested state:     STARTED
instances:           1
memory:              128 MB
disk:                <unlimited>
buildpack:           sap_nodejs_buildpack
urls:                https://acme.org:63055
created:             Oct 17, 2017 2:46:40 PM
updated:             Nov 28, 2017 11:14:04 AM
weighted instance uptime: 99.6 %
ALERTS:              There were crashes!
  short term (last 5 m)  1
  mid term  (last 1 h)   1
  long term  (last 1 d)  1
  total                    2

index  created                state  host      port  os user
-----
0      Oct 19, 2017 1:34:08 PM  CRASHED acme.org  50012 xsaxsa

Instances of droplet 2 created at Nov 28, 2017 11:14:10 AM
index  created                state  host      port  os user
-----
0      Nov 28, 2017 10:13:44 AM  STOPPED acme01  50030 xsaxsa
1      Nov 28, 2017 11:14:48 AM  RUNNING acme01  50030 xsaxsa
2      Nov 28, 2017 11:14:48 AM  RUNNING acme01  50031 xsaxsa
3      Nov 28, 2017 11:14:48 AM  CRASHED acme01  50033 xsaxsa
4      Nov 28, 2017 11:15:53 AM  STARTING acme01  50032 xsaxsa
```

If alerts for an application are present, the `xs app` command shows detailed information about those alerts. For example, it shows the number of application crashes within short-, mid-, and long-term periods as well as the total number of crashes registered for an application.

For each application instance, the `xs app` command displays the following information:

- `index`  
The index of the application instance used to reference it with further commands
- `created`

The time at which the application instance is created

- `state`

The current state of the application instance:

- `STARTING`

The application instance has started, for example, at the request of an administrator, but is not yet accessible.

- `RUNNING`

The application instance started successfully and is accessible.

- `STOPPED`

The application instance stopped, for example, at the request of an administrator, and is not accessible.

- `CRASHED`

The application instance terminated unexpectedly.

#### → Tip

You can use the command `xs delete-app-instances` to clean up instances of an application in the state `CRASHED`.

- `host`

The host on which the application instance is started

- `internal port`

The internal port of the application instance

#### → Tip

The internal port is not the port on which the application is reachable by a business user; it is the number of the **internal** system port to which the XS advanced Platform Router forwards requests. The external end point for an application instance is exposed by the Platform Router.

- `os user`

The operating system user in whose account the processes of the specified application instances are started.

The output returned by the `xs app` command also includes information about the selected application's "technical" version and "droplet" version. Each time you stage an application as part of the deployment push to the XS advanced run-time platform, a so-called droplet is created which can be referenced by an index. Although it is often the case that only application instances of the most recent droplet are running, it is also important to understand that information about a certain number of previous droplets and application instances is kept for supportability reasons. In the example output above, two droplets of the same application are running, and in the command output, the droplets are indicated by "droplet 1" and "droplet 2", where `droplet 2` is the most recent version of the application.

- `droplet 2`

The most recent version of the application, as indicated by the creation time stamp, and the higher the droplet index the more recent the version. You can also see that two application instances are currently running and one application instance is still starting, which explains why the expected number of application instances has not yet been reached. One application instance crashed recently which caused the alert. One application instance of droplet 2 is `STOPPED`, which means that this instance of the application was started but the application processes are no longer running.

### Note

The contents of the `STOPPED` application instance's file system sandbox are retained so that support teams can analyze log and applications files at a later point in time, if necessary.

- `droplet q`  
The previous version of the application. The application instance with index 0 of droplet 1 is in state `CRASHED`, which means that the application was started before but terminated unexpectedly. Similarly to stopped applications, the file-system sandbox of crashed application instances is kept for the most recent instances so that support teams can analyze log and application files to find out the cause of the error.

### → Tip

Only the five most recently stopped or crashed instances are kept; any older application instances are deleted automatically.

## Displaying XS Advanced Application Logs

To query the logs written by an XS advanced application (for example, output written to `stdout` and `stderr` as well as any access logs), run the `xs logs` command, as illustrated in the following example:

```
$ xs logs myAPP
```

When called without parameters, the `xs logs` command switches to "tailing" mode, where only newly written application logs are displayed in the system output, and the command prompt is returned when the user presses the keyboard combination: `CTRL` + `C`. To display the most recent entries of an application's logs, use the option `--recent` as shown in the following example:

```
$ xs logs myAPP --recent
```

To display all logs written by an application, use the option `--all` as shown in the following example:

```
$ xs logs myAPP -all
```

By default, the `xs logs` command displays the logs of **all** application instances. If you are only interested in the logs of a particular instance of an application, you can reference the application instance by including the command options `--droplet` and `--instance`. For example, if you want to display the logs of the crashed instance of the `demo-app` application in the example above, run the following command:

### ≡ Output Code

```
$ xs logs demo-app --all --droplet 1 --instance 0

11/27/17 4:04:57.122 PM [API] OUT Created app 'demo-app' [Org 'myorg', ...
11/27/17 4:04:57.360 PM [API] OUT Updated files for app 'demo-app' [Org...
11/27/17 4:04:57.390 PM [API] OUT Created droplet with id 1 of app 'demo-...
11/27/17 4:04:57.398 PM [API] OUT Staging Droplet with id 1 of app demo-a...
11/27/17 4:04:59.875 PM [STG/1] OUT Node.js
11/27/17 4:05:00.555 PM [STG/1] OUT Node.js buildpack version 3.3.2 [...]
11/27/17 4:05:02.066 PM [STG/1] OUT Copying SSL CA certificates...
...
```

## → Tip

Each log entry includes a time stamp, followed by the log source in brackets, followed by the log type and the actual log message. For more information about log sources and log types as well as how to filter for a specific type or source, see the following sections.

## XS Advanced Application Log Sources

The following tables lists the sources used by XS advanced applications when writing log files:

XS Advanced Application Logfile sources

Log Source	Description
[API]	A log entry created by the XS advanced platform regarding this application
[STG/<Droplet index>]	A log entry created by the staging process regarding this application. The entry displays the droplet index as a suffix. For example, "STG/1" means that this staging process produced the droplet with index 1
[APP/<Droplet index>-<Instance index>]	The output of an application instance, either on <code>stdout</code> (prefixed with 'OUT') or on <code>stderr</code> (prefixed with 'ERR'). In the log type tag, the droplet and application instance is encoded in this case. In the example output above, "APP/1-0" means that the application instance with index 0 of droplet 1 dumped a log line to <code>stdout</code> .
[RTR]	The access log for this application created by the Platform Router (RTR)

It is possible to filter for certain log sources by specifying a log source (or multiple sources in a comma-separated list) in the option "`--source`" with the `xs logs` command, as shown in the following example:

### Output Code

```
$ xs logs demo-app --all --source RTR
11/28/17 6:28:58.000 PM [RTR] OUT ##.##.209.139 - to acme.corp:63018 "GET...
11/28/17 6:28:58.000 PM [RTR] OUT ##.##.209.139 - to acme.corp:63018 "GET..."
```

## XS Advanced Application Log Types

A log source may contain log lines of different **types**. The following table lists the available log types:

XS Advanced Application Log File Types

Log Type	Description
OUT	A log entry was written to Standard Out ( <code>stdout</code> )
ERR	A log entry was written to Standard Error ( <code>stderr</code> )
ACC	The log line was written to the application instance's access log file

Log Type	Description
LOG	The log line was written in list log format to <code>stdout</code> and the logger starts with <code>"/ Application"</code>
SYS	The log line was written in list-log format to <code>stdout</code>

It is possible to filter the output to display only content from particular log **types**, for example, by specifying a log type (or multiple types in a comma-separated list) in the option `--source` with the `xs logs` command, as shown in the following example:

```
$ xs logs demo-app --all --type ERR
11/27/17 6:29:58.123 PM [APP/1-0] ERR Segmentation fault
```

You can combine options and log files as shown in the following example:

```
xs logs demo-app --recent --source APP --type ERR
11/27/17 6:29:58.123 PM [APP/1-0] ERR Segmentation fault
```

## Displaying XS Advanced Application Events

The XS Controller saves important events that occur during the life time of an application. Viewing the events provide an overview of the changes made to an application from the point of view of the XS advanced platform:

```
⌘ Output Code

$ xs events deploy-service

Showing events for app "deploy-service" and user XSA_ADMIN

time          level  component  message
-----
Dec 1, 2017
11:26:00 AM   INFO   APPLICATION Created app 'deploy-service' [Org ...
11:26:00 AM   INFO   SERVICE   Created service binding between app...
[...]
11:26:04 AM   INFO   APPLICATION Updated files for app 'deploy-service'...
11:26:04 AM   INFO   DROPLET   Created droplet with id 1 of app 'deploy-...
11:26:04 AM   INFO   DROPLET   Staging Droplet with id 1 of app deploy-...
11:26:21 AM   INFO   DROPLET   Staged app 'deploy-service' [Org...
[...]
```

The application-specific information displayed in the output is grouped by day (for example, Dec 1. 2017) and typically covers the high-level areas listed and described in the following table:

XS Advanced Application Event Output

Event Information	Description
time	The exact time when the event occurred

Event Information	Description
level	The severity level assigned to the event, for example, INFO, ERROR, etc.
component	The name of the component that caused the event, for example: APPLICATION, SERVICE, DROPLET, etc.
message	The message text describing the event

## Displaying XS Advanced Application Files

If an application is uploaded to the XS advanced run-time platform and staged, the application files are stored in a so called droplet. If an application instances are subsequently started, the files contained in the droplet are extracted into the file system for the instance to be executed. That means, application files exist on different layers, and the `xs files` command enables you to view the files by choosing the layer you are particularly interested in.

### Application Instance Files

To view the files of the currently running application instance, use the `xs files` command with the application name and no further parameters.

#### Output Code

```
$ xs files deploy-service

Getting files of app "deploy-service" ...

dxwr - META-INF/
dxwr - WEB-INF/
  wr 154 B index.html
dxwr - logs/
```

For each file or directory, `xs files` displays information about the following components:

- The file type and system permissions (d=directory; x=executable; w=writeable; r=readable)
- The size of the file
- The name of the file or directory

To view detailed information about an specific directory tree, add the name of the directory to the command, as shown in the following example.

#### Output Code

```
$ xs files deploy-service META-INF/

Getting files of app "deploy-service" ...

dxwr - META-INF/
dxwr - WEB-INF/
  wr 154 B index.html
dxwr - logs/
```

To view detailed information about an individual file, specify the full path for the file, as shown in the following example.

#### Output Code

```
$ xs files deploy-service index.html

Getting files of app "deploy-service" ...

== "index.html" =====
<!DOCTYPE html>
<html>
<head>
<meta charset="ISO-8859-1">
<title>XS2 ALM Service</title>
</head>
<body>Welcome to XS2 ALM Service!
</body>
</html>
```

### Application Droplet Files

To view detailed information about the contents of application droplets, use `xs files` command with the `--droplet-index` option, as shown in the following example:

```
$ xs <myAPP> --droplet-files [--droplet-index <index>]
```

The command shows the contents of the root directory of an application's droplet. By default, the latest droplet is displayed. However, you can choose to display details of a specific droplet by specifying its index, for example, with the option `--droplet-index`. For more information about how to display an application's droplet index, use the `xs app <myApp>` command as described in *Displaying Application Details* above.

To download all files associated with an application instance (or droplet) to a target directory on your local disk, use the option `--download <target directory>`, as illustrated in the following example:

```
$ xs <myAPP> --download <target directory>
```

### Related Information

[The XS Command-Line Interface \[page 1792\]](#)

## 13.2.2.1.8 Maintaining Applications in XS Advanced

Deploy applications to the XS advanced run-time environment

The most common task performed when maintaining applications in XS advanced is the deployment of XS advanced applications to the run-time environment. Although XS advanced provides tools to maintain entire business applications consisting of multiple micro-services, the XS command-line interface includes

commands that enable administrators to maintain micro-services individually. In addition, the XS CLI also provides commands that help support the maintenance of XS advanced applications during their life cycle:

- [Deploying Multi-Target Applications \(MTA\) \[page 1826\]](#)
- [Deploying individual applications \(microservices\) \[page 1827\]](#)
- [Starting and restarting applications \[page 1829\]](#)
- [Restaging applications \[page 1829\]](#)
- [Configuring Application Health Checks \[page 1830\]](#)

## Maintaining SAP Products

The commands `xs install` and `xs uninstall` provided by the Product Installer can be used to maintain SAP products. For more information about using these commands to perform application life-cycle management tasks in XS advanced, see *Related Information*.

## Maintaining Multi-Target Applications in XS Advanced

Multi-Target Applications (MTA) are applications composed of one or more microservices. An MTA is delivered in an archive with the file extension `.mtar` (multi-target application archive). The MTAR contains a meta-data description (MTAD, multi-target-application description) as well as the application code itself in a single deployment package. The deployment is performed by the so called Deploy Service, which deploys the individual micro-services specified by an MTAR, creates the corresponding service instances and takes care of connecting the deployed micro-services. To deploy an application in MTAR format, use the command `xs deploy`, as illustrated in the following example:

```
$ xs deploy mybusinessapp.mtar
```

To display a list of all currently deployed MTAs, use the command `xs mtas`, as illustrated in the following example:

### ≡, Output Code

#### Listing the Deployed MTAs

```
$ xs mtas
```

```
Getting multi-target apps in org "mymorg" / space "SAP" as XSA_ADMIN...  
Found multi-target apps:
```

mta id	version
com.sap.xsa.admin	1.5.5
com.sap.xs.auditlog.ui	1.0.0
com.sap.xs.jobscheduler	1.6.2
com.sap.core.account	1.1.2
alm-product-installer	1.13.7

To display an overview of the resources and microservices associated with a specific MTA, use the `xs mta` command, as illustrated in the following example:

## Output Code

### Listing the Deployed MTAs

```
$ xs mta com.sap.xs.jobscheduler

Getting information for multi-target app "com.sap.xs.jobscheduler"
in org "orgname" / space "SAP" as XSA_ADMIN...
Showing information about "com.sap.xs.jobscheduler" version: 1.6.2

Apps:
name                    state    inst  mem    disk          urls
-----
jobscheduler-backend   STARTED  1/1   256MB <unlimited>  https://host1:51022
jobscheduler-broker    STARTED  1/1   256MB <unlimited>  https://host1:51021
jobscheduler-dashboard STARTED  1/1   256MB <unlimited>  https://host1:51023
jobscheduler-db        STOPPED  0/1   256MB <unlimited>  <none>
jobscheduler-rest      STARTED  1/1   256MB <unlimited>  https://host1:51017
jobscheduler-service   STARTED  1/1   512MB <unlimited>  https://host1:51020

Services:
name                    service  plan

jobscheduler-db-container hana     hdi-shared
jobscheduler-uaa       xsuaa    default
jobscheduler-securestore hana     securestore
```

To undeploy all micro-services belonging to a deployed MTA, use the command `xs undeploy`, as illustrated in the following example:

```
$ xs undeploy com.sap.xs.jobscheduler
```

## Maintaining Individual Microservices in XS Advanced

To deploy a single XS advanced application, log on the XS advanced run-time instance and use the command `xs push` to deploy the application to the organization and space where you want the application to run, as illustrated in the following example:

```
xs push MY-APP
```

During the deployment the XS advanced runtime performs following tasks:

1. Upload and store the new application files
2. Create or update application meta data
3. Create and bind routes
4. Bind required service instances
5. Choose the appropriate application run time environment
6. Create a droplet of the application
7. Select available execution agents to run the droplet
8. Start the application instances

## ☰ Output Code

### Deploying a Single Application in XS Advanced

```
$ xs push

MY-APP Creating app "MY-APP" in org "orgname" / space "SAP" as XSA_ADMIN...

```

## i Note

XS advanced applications that use services (for example, database or file-system) are not completely functional the services are provisioned and bound to the application. For more information about maintaining services in XS advanced, see *Related Information*.

Before you push the application to XS advanced, bear in mind the following additional options that might be useful or required when performing a custom deployment:

- Custom host name, port or domain:  
You can specify a custom route during deployment. The route is a combination of the domain and subdomain and must be globally unique. This is true whether you specify a portion of the route or allow XS advanced to use defaults.
- Custom start command:  
You can specify a custom command to start instances of the application; this custom command replace the automatically detected start command.

- Custom memory limit:  
You can specify the maximum amount of memory that each instance of the application can use.

### i Note

For more information about setting memory limits, see *Scaling Applications in XS Advanced in Related Information* below.

## Starting and Restarting XS Advanced Applications

After pushing the application “`xs push MY-APP`” the XS advanced run-time environment starts the application with the **default** start command of the appropriate build pack. If you want to use a custom start command, use the “-c” option with the `xs push` command, as shown in the following example.

```
$ xs push MY-APP -c "node MY-APP.js"
```

The custom command that you provide with the -c option becomes the default start command and is used for subsequent updates (`xs push MY-APP`) of the application. To reset to the start command used by the default build pack start command, use the special start parameter value “`null`”, as illustrated in the following example:

```
$ xs push MY-APP -c "null"
```

The commands `xs start` and `xs stop` are used to start or stop an application. This always affects all application instances, but it does not change the number of instances configured for scaling the application. When an application is started, the most recent droplet and the current settings for the application environment variables are used. To restart your application, run the following command:

```
$ xs restart MY-APP
```

Restarting an application stops and restarts it with the most recent droplet and environment variable settings. This is required for “refreshing” the application after any operation that modifies the application's environment, for example, binding a new service or directly setting environment variable values.

### i Note

If an environment variable is also consumed by the build pack, then restarting an application might not be enough to effect the desired change. In this case, the application must first be restaged for the change to take effect.

## Restaging XS Advanced Applications

Restaging an application compiles a new droplet of the staged application. Staging an application can be useful in the following cases:

- You changed the application environment
- The application must consume an updated application run time

- The application must use an updated set of trust certificates

### i Note

A restaged application continues to run during staging; the application only restarts, if you call the `xs restart` command.

To restage your application, use the `xs restage` command, as shown in the following example:

```
$ xs restage MY-APP
```

### i Note

Restaging an application compiles a new droplet from the application without updating the application source. To update the application source, push (deploy) the application again.

## Configuring XS Advanced Application Health Checks

XS advanced determines the state of application instances by means of so-called application health checks. An application health check is a monitoring process that periodically checks the status of an application instance. If one check fails, the application instance is marked as `CRASHED` and automatically restarted. For more information about the possible status of an XS advanced application instance, for example, `STOPPED`, `STARTING`, or `RUNNING`, etc., see *Displaying Application Information in XS Advanced in Related Information* below.

### → Tip

If tracing is enabled, the health-check status reports are written to the log file of the XS advanced execution agent.

XS advanced supports the following types of application health check:

- **Process:**  
The health check examines that the application instance process is running.
- **Port:**  
The health check opens a TCP connection on the application instance port and checks that the port is connectable. This is the default health check type.
- **HTTP:**  
The health check makes a HTTP GET request to a specified application end point and checks that the response code is 200.

It is possible to set the type of application health check either during application deployment (for example, with the `"xs push"` command or in the application's `manifest.yml` file) or if the application is already running with the `"xs set-health-check"` command.

## Health Check Configuration Options

You can use the `xs push` command to set the health check for a specific application, using the options listed in the following table:

Application Health-Check Configuration Options

Health-Check Option	Description
<code>-u &lt;HEALTH_CHECK_TYPE&gt;</code>	The application health check type. Valid values are <code>port</code> , <code>process</code> or <code>http</code> . The default is <code>port</code> .
<code>--health-check-timeout &lt;TIMEOUT&gt;</code>	The XS advanced runtime will wait at most the specified time for a successful health check after the initial startup of an instance. If no health check was successful after the timeout was reached, the instance will be marked as crashed and the instance will be terminated. The default is to wait indefinitely.
<code>--health-check-http-endpoint &lt;HEALTH_CHECK_ENDPOINT&gt;</code>	The end point for the HTTP request provided by an application. This option is only relevant for the health-check type <code>http</code> . The default value is <code>"/"</code> .
<code>--invocation-timeout &lt;HTTP_INVOCATION_TIMEOUT&gt;</code>	The timeout for each HTTP <code>GET</code> request. This option is only relevant for the health-check type <code>http</code> . The default value is 1 second.

In the following example, the command pushes an application and configures the health check type `'http'` with a health check timeout of 180 seconds using the HTTP endpoint `"/healthcheck"` and a GET request timeout of 5 seconds:

```
$ xs push demo-app -u http --health-check-timeout 180 --health-check-http-endpoint /healthcheck --invocation-timeout 5
```

The following example shows how to specify the same configuration in the application manifest:

```
---
...
health-check-type: http
health-check-http-endpoint: /healthcheck
invocation-timeout: 5
```

If the application has already been pushed, you can use the `xs set-health-check` command to configure health checks, as illustrated in the following example:

```
xs set-health-check <application> http --endpoint /healthcheck --invocation-timeout 5
```

### Note

You must restart the application to enable the configured health checks.

## Viewing the Health Check Configuration for an Application

You can use the `xs get-health-check` display the current health-check configuration, as illustrated in the following example:

```
$ xs get-health-check demo-app
```

```
name : demo-app
health check type : http
endpoint : /
invocation timeout (in seconds) : 1
```

OK

### 13.2.2.1.9 Scaling Applications in XS Advanced

Configure applications to handle increased traffic on demand.

Scaling an application can enable it to handle increased traffic on demand, for example, to meet the needs associated with increased user load. The command `xs scale` can be used to increase or decrease the number of running application instances (also known as horizontal scaling) or to change the resource limit of existing application instances (vertical scaling).

#### Horizontal Scaling

You can horizontally scale your application by specifying the number of application instances that should be allowed, as illustrated in the following example, which sets the maximum number of instances to five (5):

```
$ xs scale MY-APP -i 5
```

This configures the XS advanced run-time environment to increase or decrease the number of instances of the specified application to match the number of instances specified.

#### **i** Note

The consumption of file-system and memory resources increases with the number of application instances. In addition, the application itself determines whether it supports horizontal scaling, that is, whether it can manage several application instances running in parallel.

A round-robin policy is used to distribute newly created application instances among available hosts bearing the role `xs_worker`. You can use host pinning to refine the set of `xs_worker` hosts where instances of specific applications will be scheduled to run. For more information about host pinning, see *Related Information*. To

decrease the number of application instances, the same round-robin policy is used to remove application instances from affected `xs_worker` hosts. The load generated by requests sent to a scaled application is automatically balanced across all application instances by the XS advanced Platform Router. Although, by default, a weighted round-robin policy is used to balance the load associated with requests among application instances, it is nonetheless possible to choose from the other load-balancing algorithms provided by the SAP WebDispatcher.

## Vertical Scaling

To change the memory limits for existing applications, use the command "xs scale" with the option "-m", for example:

```
$ xs scale MY-APP -m 1G
```

In this example, the memory limit of the application `MY-APP` is changed to 1 GB. To define the unit of size, you can either use "M" (for megabytes) or "G" for gigabytes. For the new settings to be effective, restage and restart the corresponding application, for example, with the commands `xs restage` and `xs restart`, respectively. For more information about restaging and restarting application in XS advanced, see *Related Information*.

### ! Restriction

By default, memory limits currently are only valid for Java applications. However, you can use the `OPTIMIZE_MEMORY` option to configure a memory limit for Node.js applications, too.

To limit the memory for Node.js applications globally, use the following command:

```
xs update-staging-environment-variable-group --add OPTIMIZE_MEMORY true
```

Alternatively, you can use the following command to configure the memory setting for individual Node.js applications:

```
xs set-env <app> OPTIMIZE_MEMORY true
```

In both cases, the memory limit for an applications becomes active, when the application is restaged.

[Maintaining Applications in XS Advanced \[page 1825\]](#)

## 13.2.2.110 Maintaining Services in XS Advanced

Use the `xs` command-line interface to maintain so-called “Backing Services” for applications running in the XS advanced run-time platform.

Backing Services are the medium by which applications running in the XS advanced run-time platform can access resources, for example: a database, an offering for audit logging, or user authentication.

Backing Services are connected with applications by creating so called service instances within XS advanced. During the creation of a service instance, XS advanced creates the backing-service resource by means of a so-called “service broker”. By adding custom service brokers, arbitrary backing services can be connected to XS advanced. At some point, the service instance is bound to an application. In this way, all the information required for access to the backing service is injected into the process environment of an application instance.

- [Listing Backing Services in the Market Place \[page 1834\]](#)
- [Maintaining Service Instances \[page 1835\]](#)
- [Creating User Provided Services \[page 1837\]](#)
- [Binding Service Instances to Applications \[page 1838\]](#)
- [Maintaining Service Keys \[page 1838\]](#)
- [Maintaining Service Brokers \[page 1839\]](#)
- [Maintaining Syslog Drain Services \[page 1840\]](#)

### Listing Backing Services in the Market Place

Typically the service broker provides credentials to the application to access the service. In XS advanced, the list of available backing services provided by service brokers is displayed in the service “market place”, as shown in the following example:

```
☰ Output Code

$ xs marketplace

Getting services from marketplace...

service      plans      description
-----
fs-storage   free       xs file service provides.
xsuaa        default, devuser, space  Manage app authorizati...
hana         hdi-shared, sbss, schema, securestore  SAP HANA database
managed-hana hdi-shared, schema, securestore  Creates service instan...
auditlog     free       Audit log broker on XSA..
```

The output from the `xs marketplace` command displays the following information:

- `service`  
The name of the backing service
- `plan`  
The available service plans a particular backing service provides. A service plan determines the type or category of service that an individual backing service provides. For example the `hana` service can be used to get a single container (`schema`) or provide access to the SAP HANA Secure Store (`securestore`).

- `description`  
A short summary of the backing service

## Maintaining Service Instances

To make use of a service, an instance of the service must be created and an XS advanced application must be bound to the specified service instance. When a service instance is created, resources are allocated within the respective backing service. To create a service instance, use the command `xs create-service` and choose a service name and a service plan from the marketplace, as illustrated in the following example:

```
$ xs create-service hana hdi-shared myservice
Creating service "myservice"...
  create in progress
  create succeeded
OK
```

You can configure service instances by passing a set of parameters with the option `-c` in JSON format. You can also add tags to the service instance with the option `-t`; the information is passed to the bound applications. Service instances are created within a particular space and cannot be used from other spaces.

The `xs update-service` command enables you to update a service instance, for example, by modifying its service plan as well as any parameters or tags:

```
$ xs update-service myservice -t mytag
Updating service instance "myservice"...
OK
```

### ⚠ Caution

The corresponding service broker determines what happens during a service update. For example, changing the plan of an existing service could result in a new allocation of service resources within the backing service, and this could lead to the deletion of all previous data represented by this service instance.

The `xs rename-service` command enables you to rename a service instance, as illustrated in the following example:

```
$ xs rename-service myservice newservice
OK
```

### i Note

Renaming a service instance has no effect on the backing resource represented by the service instance.

The `xs delete-service` command enables you to remove a service instance along with all associated data, as illustrated in the following example:

```
$ xs delete-service myservice
Really delete service instance "myservice"? (y/n) > y
Deleting service instance "myservice"...
OK
```

Since a service instance is maintained and persisted not only at the service broker but also at the XS Controller, the service-related information should be consistent in both places. If the service information is lost at the

service broker, for example, because it has been manually deleted, you can use the purge option (`xs delete-service --purge`) to forcibly remove the service information from the XS Controller as well.

To display a list of all currently available service instances in a space, use the command `xs services` as illustrated in the following example:

```

Output Code
Viewing Available Service Instances

$ xs services

Getting services from marketplace...

name                service    plan          last operation    bound
apps
-----
auditlog-db-container    hana      hdi-shared    create succeeded
auditlog-db, auditlog-...
auditlog-sbss           hana      sbss          create succeeded
auditlog-server, auditlog
deploy-service-auditlog  auditlog  free          create succeeded  deploy-
service
deploy-service-fss       fs-storage free          create succeeded  deploy-
service
deploy-service-ss        hana      securestore   create succeeded  deploy-
service
deploy-service-database  hana      schema        create succeeded  deploy-
service
deploy-service-uaa       xsuaa     default       create succeeded  deploy-
service
product-installer-dbase  hana      schema        create succeeded
product-installer
component-registry-dbase hana      hdi-shared    create succeeded
component-registry-db, ...

```

The output from the `xs services` command displays the following information:

- `name`  
The name of the service instance
- `service`  
The name of the backing service
- `plan`  
The available service plans a particular backing service provides. A service plan determines the type or category of service that an individual backing service provides. For example the `hana` service can be used to get a single container (`schema`) or provide access to the SAP HANA Secure Store (`securestore`).
- `last operation`  
Shows the last performed operation (create, update, delete) and its state (in progress, succeeded, failed).
- `bound apps`  
Shows all applications bound to the service.

## Creating User Provided Services

Since user-provided services do not require a service broker they are not chosen from the service catalog. Instead, the credentials for a user-provided services are provided when creating the service instance, as illustrated in the following example:

### ≡ Output Code

User Credentials in JSON for a User-Provided Service

```
$ xs create-user-provided-service my-up-service -p
'{"host":"example.org","username":"admin","password":"pa55woRD"}'
```

Created environment (excerpt):

```
{
  "name" : "my-up-service",
  "credentials" : {
    "password" : "pa55woRD",
    "host" : "example.org",
    "username" : "admin"
  }
}
```

### → Tip

The combination of operating system, shell, or terminal type determines the “quote” or “escape” characters required when providing the parameter string in JSON format. For more information about the correct quoting, see `xs help create-user-provided-service`.

The `xs` CLI also has an interactive mode, which you can use to specify the fields of the service credentials as parameters, for example, with the `-p` option and a comma-separated list.

### ≡ Output Code

Interactive User Credentials for a User-Provided Service

```
$ xs create-user-provided-service my-up-service -p host,username,password
host> example.org
username> admin
password> pa55woRD
```

Created environment (excerpt):

```
{
  "name" : "my-up-service",
  "credentials" : {
    "password" : "pa55woRD",
    "host" : "example.org",
    "username" : "admin"
  }
}
```

## Binding Service Instances to Applications

To connect an application with a particular backing service resource, you must bind the corresponding service instance to the application using the `xs bind-service` command, as illustrated in the following example:

```
$ xs bind-service myapp myservice
OK
TIP: Use 'xs restart' to ensure your env variable changes take effect
```

It is also possible to pass binding parameters in JSON format by using the option `-c`. The effect of binding parameters depends very much on the corresponding backing service. After restarting the bound application, credentials required for access to the backing service can be found in the environment variable `<VCAP_SERVICES>` in the application environment. To remove a service-binding, call the command `xs unbind-service`, as illustrated in the following example:

```
$ xs unbind-service myapp myservice
OK
```

## Maintaining Service Keys

Service keys provide a way to query the credentials required for a service without having to bind the service instance to an application. To create a service key use the `xs create-service-key` command, as shown in the following example:

```
$ xs create-service-key myservice myservicekey

Creating service key "myservicekey" for service instance "myservice" ...
OK
```

Service keys are created within a particular space and cannot be used from other spaces. After creating a service key, you can view the service credentials by calling the command `xs service-key`, as illustrated in the following example:

### Output Code

```
$ xs service-key my-service my-service-key

Getting service key "my-service-key" for service instance "my-service" ...
{
  "host" : "host1.acme.org",
  "user" : "1EBB56E88DYS76",
  "password" : "Dd2f8RVCP8gr1[...]v"
}
OK
```

To display a list of all existing service keys, use the command `xs service-keys`:

### Output Code

```
$ xs service-keys

Getting service keys in org "orgname" / space "SAP" as XSA_ADMIN...
```

```

service instance  name
-----
myservice        myservicekey

```

To remove a service key, use the command `xs delete-service-key`:

#### Output Code

```

$ xs delete-service-key myservice myservicekey

Really delete service key "myservicekey" for service instance "myservice"?
(y/n) > y
Deleting service key "myservicekey" for service instance "myservice" ...
OK

```

## Maintaining Service Brokers

The service broker interface provides a way to connect arbitrary backing service with the XS advanced platform. XS advanced implements the open service broker API (version 12.2). To view the service brokers currently connected to the XS advanced platform, use the `xs service-brokers` command, as shown in the following example:

#### Output Code

```

$ xs service-brokers

Getting service brokers...
Found service brokers:

name          url
-----
fs-storage    https://acme.org:30033/v2/fs-service
uaa-security  https://acme.org:30033/uaa-security
hdi-broker    https://acme.org:30033/hdi-broker
instance-manager https://acme.org:30033/instance-manager
auditlog      https://acme.org:30033

```

You can add your own service broker with the command `xs create-service-broker`, as illustrated in the following example:

#### Output Code

```

$ xs create-service-broker mybroker user passwd https://acme.org:8080/activemq

OK

```

After a service broker has been created, the backing services provided by this service broker immediately show up in the service catalog, also known as the marketplace.

To rename an existing service broker, use the following command:

#### ≡, Output Code

```
$ xs rename-service-broker mybroker newbroker
OK
```

If a service broker is moved to a different URL or the credentials for a service broker change, you can update an existing service broker to reflect the new URL and new credentials by calling the command `xs update-service-broker`, as illustrated in the following example:

#### ≡, Output Code

```
$ xs update-service-broker mybroker user passwd https://acme.org:1080/activemq
OK
```

To remove an existing service broker from the XS advanced platform, use the following command:

#### ≡, Output Code

```
$ xs delete-service-broker mybroker

Really delete service broker "mybroker"? (y/n) > y
Deleting service broker "mybroker"...
OK
```

## Maintaining Syslog Drain Services

In order to stream application logs to an external log management service, for example an Elastic (ELK) stack, you can make use of so called “syslog-drain services”. These services define a URL to the `syslog`-compatible end point of the log-management service: the so-called syslog drain. The same application logs that can be streamed to a `syslog` drain can be accessed with the command `xs logs`, as described in *Displaying Application Information in Related Information*. XS advanced supports syslog drains which are able to parse log messages according to the standards described in RFC 5424.

To start streaming logs from your application to the syslog drain, you need to create a user-provided service and bind it to your application. The following example shows how to use the `xs` command-line interface to create the corresponding user-provided service; you need to specify a service name and, by means of the parameter `-l`, the URL of the syslog drain:

```
$ xs create-user-provided-service my-drain -l syslog://syslog-drain.example.org:
1234
OK
```

The log messages can be delivered via TCP, TCP over TLS, or HTTPs, as shown in the following table, which provides an overview of the format of the syslog-drain URL that XS advanced expects for the supported protocols:

URL Formats for Syslog Drain in XS Advanced

Protocol	Syslog-drain URL Format
TCP	<code>syslog://syslog-drain.example.org:1234</code>
TCP over TLS	<code>syslog-tls://syslog-drain.example.org:1234</code>
HTTPs	<code>https://syslog-drain.example.org:1234</code>

Next, you need to bind the created service to your XS advanced application, as illustrated in the following example:

```
$ xs bind-service my-app my-drain
OK
TIP: Use 'xs restart' to ensure your env variable changes take effect
```

After a short delay all new logs generated by the bound application will be streamed to the syslog drain. A restart of the application is not required, as the syslog-drain service binding does not affect the environment variables of the application.

If you are streaming logs to a syslog drain that uses TLS, make sure that the required trust certificates are available to the XS Controller. For more information about how to configure trust certificates please see *Maintaining Trust Certificates* in *Related Information* below.

Bear in mind that additional configuration might be required within the log-management service of your choice. For more information, see *The Syslog Protocol* in *Related Information*.

### 13.2.2.1.11 Maintaining Application Routes in XS Advanced

Use the `xs` command-line interface to maintain routes for XS advanced applications.

Routes provide applications and their instances with a public HTTP endpoint. A route represents a URL that can be mapped to one or more applications. HTTP traffic that is sent to a route is forwarded by the Platform Router to one of the instances of the mapped applications. The selection of the application instance is decided by a round-robin algorithm. The Platform Router acts as the central routing and load-balancing component within XS advanced.

Usually a route is mapped to a single application. When scaling the application to multiple instances, traffic sent to the route is load-balanced between all instances. Mapping a route to multiple applications might for example make sense in cases where a blue-green deployment is performed.

## Routing Modes

During installation of SAP HANA XS advanced model you can select between two routing modes: **ports** and **host names**. If the administrator configures the routing mode “ports”, the XS advanced platform creates routes based on distinct **ports**, as illustrated in the following URLs representing different port-based routes:

- `https://acme.org:50000`
- `https://acme.org:50001`

If the administrator configures the routing mode “host names”, the XS advanced platform creates routes based on distinct sub-domains, as illustrated in the following URLs representing different host-name-based routes:

- `https://app1.acme.org`
- `https://app2.acme.org`

### → Tip

For more information about technical prerequisites and security implications of the two routing modes see SAP Note [2245631](#), *Domains and Routing Configuration for SAP HANA Extended Application Services, Advanced Model*.

In the “hostnames” routing mode, the XS advanced platform can also create routes based on ports, which is especially useful if you also want to use TCP routes, which always require a dedicated port.

To simplify the creation of port-based routes, you can configure a default port range for the platform, for example, by setting XS advanced platform parameters. In this way, a free port from the declared port range can be used if no port is explicitly defined when creating a route. The port range should be treated as **reserved**, and SAP HANA XS advanced expects that no other processes on the SAP HANA hosts use ports within the declared port range. If you are running multiple SAP HANA XS advanced systems on the same host, it is important to separate the default port range for each XS advanced system from each other.

### → Tip

For more information about setting a default port range for XS advanced, see SAP Note [2507070](#), *Multiple XS Advanced Systems on the Same Host*.

## Viewing Routes

To see which routes have been mapped to XS advanced applications in the current space, use the `xs routes` command, as illustrated in the following example:

```
⌘ Output Code
Route List in "hostnames" Routing Mode

$ xs routes

Getting routes in org "XSA" / space "SAP" as XSA_ADMIN...

host                domain    port    path  type  apps
-----
-
auditlog-server     acme.org          /    HTTP  auditlog-server
auditlog-broker     acme.org          /    HTTP  auditlog-broker
deploy-service      acme.org          /    HTTP  deploy-service
xsa-sap-product-installer acme.org          /    HTTP  product-installer
xsa-sap-auditlog-odata acme.org          /    HTTP  auditlog-odata
xsa-sap-auditlog-ui acme.org          /    HTTP  auditlog-ui
                    acme.org  50510  /    TCP   hello-world-tcp
                    acme.org  50500  /    TCPS  hello-world-tcps
```

The information displayed in the example above includes the following details:

### XS Advanced Application Details

Property	Description
host	The host of the specified route. The host can only be set where hostname-based routing is used.
domain	The domain name used by the specified route.  <b>→ Tip</b> For more information about domains, see <i>Maintaining Domains</i> in <i>Related Information</i> .
port	The port that is dedicated to the specified route. The port can only be set if the route is a port-based route.  <b>→ Tip</b> Host-name-based routes use the default router port.
path	The URL path of the specified route. Using different URL paths you can create multiple routes with the same host or port.
type	The protocol used for the specified route, which can be one of the following: HTTP, TCP, or TCPS.
apps	The applications bound to the specified route

## Creating and Mapping Routes

You can use the `xs map-route` and `xs unmap-route` commands to map routes to applications and remove the mappings between applications and routes. Similarly, the commands `xs create-route` and `xs delete-route` can be used to create new routes and delete them.

When creating a route, you can define a custom URL path instead of using the default URL path, ("/"). When forwarding the request to the application instance, the request is sent via the same URL path as the one that is defined in the route. As a result, applications must serve requests on the defined URL path. Using different URL paths enables you to create multiple routes that use the same sub-domain or port, as illustrated in the following examples:

- `https://app.acme.org/frontend`
- `https://app.acme.org/backend`

The default type of a route is HTTP. This means that the traffic on this route must adhere to the HTTPs (HTTP over SSL) protocol, which is used within XS advanced by default. It is also possible to change this configuration globally, in order to use plain HTTP routes. If a route is created with type HTTP, the XS advanced Platform Router can enable certain HTTP features for this route, for example: Sticky Sessions, HTTP access logs, or certain timeouts. The XS advanced platform is also able to provide additional information to the application instances through HTTP headers (for example, `X-Forwarded-Proto` and `X-Forwarded-Port`). Routes, which are based on hosts, can only be used with the HTTP type, as the Platform Router routes these requests to the correct application instances based on the `HTTP Host` header.

It is also possible to create routes of type "TCP" or "TCPs". It is important to remember that the XS advanced Platform Router does not expect a specific protocol on TCP routes; it simply forwards the TCP traffic to the application instances using the mapped route. TCP routes must, however, use their own distinct port and are not allowed to use hosts. All HTTP features are disabled for TCP routes, so it only makes sense to use these routes if the application requires a protocol other than HTTP. In addition, since the XS advanced Platform Router does not terminate SSL, for TCP routes you can also terminate SSL traffic at the application instance.

You can also use the route type "TCPs", which expects at least SSL-encrypted TCP traffic and allows the XS advanced Platform Router to terminate the SSL connection. The application instance receives plain TCP traffic. The advantage of using "TCPs" is that the XS advanced application does not require any SSL configuration, and you can continue to rely on the domain certificates you have configured within SAP HANA XS advanced.

## 13.2.2.112 Maintaining the XS Advanced Application Environment

Use environment variables to configure an XS advanced application's behavior.

When an application instance is started in XS advanced, several configuration parameters are injected into the application's process environment; the parameters specify information about the following elements:

- Application properties
- Information about backing services
- Custom environment values

### → Tip

You can use environment variables to transport custom configuration parameters to application instances.

## Viewing the Application Environment

The command `xs env` displays an overview of an application's environment. The command output is split into two sections: `System-Provided` and `User-Provided`, as illustrated in the following example:

```
$ xs env demo-app

Getting env variables for app "demo-app"...
OK

System-Provided:
{
  "VCAP_APPLICATION" : {
    "start" : "2018-01-02 16:51:41 +0100",
    "application_id" : "927c0822-3734-4c91-9796-432ddd1a9ed4",
    "instance_id" : "927c0822-3734-4c91-9796-432ddd1a9ed4",
    "space_id" : "eccc5bd5-934b-4472-b32c-009d6497e93b",
    "application_name" : "demo-app",
    "organization_name" : "myorg",
    "space_name" : "PROD",
    "started_at_timestamp" : "1514908301002",
    "started_at" : "2018-01-02 16:51:41 +0100",
    "state_timestamp" : "1513239094881",
    "full_application_uris" : [ "https://demo-app.example.org" ],
    "application_uris" : [ "demo-app.example.org" ],
    "uris" : [ "demo-app.example.org" ],
    "version" : "3d397398-0f1a-4d07-b9e6-88f33d8387b0",
    "application_version" : "3d397398-0f1a-4d07-b9e6-88f33d8387b0"
  },
  "VCAP_SERVICES" : {
    "hana" : [ {
      "name" : "demo-app-database",
      "label" : "hana",
      "tags" : [ "hana", "database", "relational" ],
      "plan" : "schema",
      "credentials" : {
        "schema" : "USR_EHLDI8B567MXSPX1BLGSJJW7J",
        "password" : "1h0FH1R9o7WvC5AHmI_522DU8kLPIYKM",
        "driver" : "com.sap.db.jdbc.Driver",
        "port" : "31313",
        "host" : "962.acme.com",
```

```

      "db_hosts" : [ {
        "port" : 31313,
        "host" : "962.acme.com"
      } ],
      "user" : "USR_EHLDI8B567MXSPX1BLGSJJW7J",
      "url" : "jdbc:sap://962.acme.com:31313/?
currentschema=USR_EHLDI8B567MXSPX1BLGSJJW7J"
    }
  }
}
User-Provided:
  custom-value: 1234

```

## System-Provided Environment Variables

System-provided environment variables are calculated by XS advanced and cannot be changed the user. The following environment variables contain application and service-binding properties:

- `VCAP_APPLICATION`  
Contains application properties in JSON format, for example, the time stamp of the last application start time, unique application identifiers, organization and space coordinates, and application URLs.
- `VCAP_SERVICES`  
Contains information about the bound backing services in JSON format. For each backing service, the information includes the credentials required for access to the specified backing service.

For more details about *Maintaining Services*, see *Related Information* below.

## User-Provided Environment Variables

Custom user-provided environment variables can be set by the user or are set by the deployer of the application.

## Modifying the Application Environment

To add a new environment variable or alter the value of an existing environment variable, use the command `xs set-env`, as shown in the following example:

### i Note

How an application consumes the value you set with the `xs set-env` command depends very much on the application itself.

### ≡ Output Code

Setting Environment Variables in XS Advanced

```
$ xs set-env demo-app "http_proxy" "proxy:8080"
```

```
Setting env variable "http_proxy" to "proxy:8080" for app "demo-app"...
```

```
OK
```

```
TIP: Use 'xs restage' followed by 'xs restart' to ensure your env variable
changes take effect
```

To remove a new environment variable from the existing application environment, use the command `xs unset-env`, as shown in the following example:

### Output Code

Setting Environment Variables in XS Advanced

```
$ xs unset-env demo-app http_proxy

Removing variable "http_proxy" from environment of app "demo-app"...
OK
TIP: Use 'xs restage' followed by 'xs restart' to ensure your env variable
changes take effect
```

Any change to the application environment is visible in the output of the `xs env` command immediately. However, the effect of the change will only be applied to the application after the application has been restarted.

### → Tip

If the buildpack that compiles the application consumes the altered environment variables, you must restage the application, too.

## Global Environment Variables

It is possible to set global environment values for all applications; this avoids having to set the environment for each application individually. A common use case for such a scenario would be when applying proxy settings.

### Running Environment Variable Groups

To set a group of environment variables for all newly started applications, use the command `xs set-running-environment-variable-group`. You can pass a group of variables by specifying a JSON structure as a command-line option, as illustrated in the following example:

### i Note

This command overwrites any existing running environment variable group you have configured.

### Output Code

Setting Running Environment Variables in XS Advanced

```
$ xs set-running-environment-variable-group '{"no_proxy":"localhost"}'

Setting the contents of the running environment variable group as XSA_ADMIN...

Variable Name      Assigned Value
-----
no_proxy           localhost
```

To edit single variables for the currently running environment, it is more convenient to use the command `"xs update-running-environment-variable-group"` (or `"xs urevg"` for short). This command enables you

not only to add single new environment variables and change the value of existing variables, but also to remove variables from the running environment. In the following example, the `xs urevlg` command sets the value of the variable `my_db_host` to `dbhost.acme.org` by adding the variable to the running environment (if it is not yet part of the running environment-variable group) or by updating the existing variable to the new value:

```
$ xs update-running-environment-variable-group --add my_db_host dbhost.acme.org

Updating the contents of the running environment variable group as XSA_ADMIN...
Variable "my_db_host" updated.
Updated environment variables:

Variable Name      Assigned Value
-----
no_proxy           localhost
my_db_host         dbhost.acme.org
```

To remove any variable from the running environment-variable group, use the option `--remove` as illustrated in the following example:

```
$ xs update-running-environment-variable-group --remove my_db_host

Updating the contents of the running environment variable group as XSA_ADMIN...
Variable "my_db_host" removed.
Updated environment variables:

Variable Name      Assigned Value
-----
no_proxy           localhost
```

To view the currently configured running environment-variable group, use the command `xs running-environment-variable-group`, as shown in the following example:

### **i** Note

Environment variables in the running environment-variable group have no effect on the staging processes.

### Output Code

Displaying the Running Environment Variables Group in XS Advanced

```
$ xs running-environment-variable-group

Retrieving the contents of the running environment variable group as
XSA_ADMIN...

Variable Name      Assigned Value
-----
no_proxy           localhost
```

## Staging Environment Variable Groups

To set a group of environment variables that is only exposed to build packs during the application staging process, use the command `xs set-staging-environment-variable-group`, as illustrated in the following example:

### **i** Note

This command overwrites any existing **staging** environment variable group you have configured.

## Output Code

### Setting Staging Environment Variables in XS Advanced

```
$ xs set-staging-environment-variable-group '{"no_proxy":"localhost"}'
Setting the contents of the staging environment variable group as XSA_ADMIN...

Variable Name      Assigned Value
-----
no_proxy           localhost
```

To edit single variables for the currently staging environment, you can use the command `xs update-staging-environment-variable-group` (or `xs usevg` for short). The `xs usevg` command enables you not only to add single new environment variables and change the value of existing variables, but also to remove variables from the staging environment. In the following example, the `xs usevg` command sets the value of the variable `my_db_host` to `dbhost.acme.org` by adding the variable to the staging environment (if it is not yet part of the staging environment-variable group) or by updating the existing variable to the new value:

```
$ xs update-staging-environment-variable-group --add my_db_host dbhost.acme.org
Updating the contents of the staging environment variable group as XSA_ADMIN...
Variable "my_db_host" updated.
Updated environment variables:

Variable Name      Assigned Value
-----
no_proxy           localhost
my_db_host         dbhost.acme.org
```

To remove any variable from the staging environment-variable group, use the option `--remove` as illustrated in the following example:

```
$ xs update-staging-environment-variable-group --remove my_db_host
Updating the contents of the staging environment variable group as XSA_ADMIN...
Variable "my_db_host" removed.
Updated environment variables:

Variable Name      Assigned Value
-----
no_proxy           localhost
```

To view the currently configured staging environment variable group, use the command `xs staging-environment-variable-group`, as shown in the following example:

## Output Code

### Displaying the Staging Environment Variables Group in XS Advanced

```
$ xs staging-environment-variable-group
Retrieving the contents of the staging environment variable group as
XSA_ADMIN...

Variable Name      Assigned Value
-----
no_proxy           localhost
```

## Related Information

[Maintaining Services in XS Advanced \[page 1834\]](#)

### 13.2.2.1.13 Maintaining Trust Certificates in XS Advanced

Use the `xs` command-line interface to maintaining trust certificates for the XS advanced run-time platform.

The XS advanced run-time environment and the applications running in XS advanced use SSL connections wherever possible. Applications connect to each other using HTTPs and can also be configured to use SSL when connecting to the SAP HANA database. Although the XS advanced platform components (for example, the XS Controller) use the SAP HANA system PKI to securely communicate with each other and with the SAP HANA database, nonetheless it might be necessary to configure additional SSL trust certificates, especially when connecting securely to end points that are located outside the XS advanced run-time environment. Since application run times (for example, Java or Node.js) usually already include their own certificate trust stores, configuring additional SSL trust certificates might only be necessary when using certificates, which are not signed by a well known certificate authority (CA). This usually is the case for certificates signed by a corporate CA or self-signed certificates.

The XS advanced run-time platform includes tools that enable administrators to maintain and manage the certificates used to set up trusted relationships; you can use the tools to upload custom trust certificates to the platform. The trust certificates are used by the platform components (for example, the XS Controller) and can be propagated to the applications by the build packs. For example, the propagation of the certificates is performed by default when using either the SAP Node.js or the SAP Java build pack. However, you can use **custom** trust certificates, for example, when if you have configured a custom "certificate authority" within your corporation.

By adding the root certificate of your certificate authority, you enable any application to establish fully trusted SSL sessions with corporate servers, even those configured outside the SAP HANA system. In addition to custom trust certificates, the XS advanced run-time platform can be used to manage **domain** certificates. For more information, see *Maintaining Domains* in *Related Information* below.

#### → Tip

Domain certificates are treated the same way as custom trust certificates; both types of certificates are available to **all**.

## Viewing Trust Certificates

To display a list of custom trust certificates, use the `xs trusted-certificates`, as illustrated in the following example:

#### ≡ Output Code

```
$ xs trusted-certificates
```

```
Retrieving the list of trusted certificates as XSA_ADMIN...
```

```

Alias: CORPORATE_CA
-----
Subject:          CN=CORPORATE Root CA,O=SAP SE,L=Walldorf,C=DE
Issuer:          CN=CORPORATE Root CA,O=SAP SE,L=Walldorf,C=DE
Valid from:      Sun Jan 01 12:00:00 UTC 2017
Valid until:     Thu Jan 01 11:59:59 UTC 2032
Signature algorithm: SHA256withRSA

Alias: HANA_SSL
-----
Used within HANA Broker service bindings
Subject:          CN=hanahost,O=SAP SE,L=Walldorf,C=DE
Issuer:          CN=hanahost,O=SAP SE,L=Walldorf,C=DE
Valid from:      Sun Jan 01 12:00:00 UTC 2017
Valid until:     Mon Jan 01 11:59:59 UTC 2018
Signature algorithm: SHA256withRSA
Alias: SSO_CA
-----
Used for validation of certificate-based client authentication
Subject:          CN=CORPORATE SSO CA,O=SAP SE,L=Walldorf,C=DE
Issuer:          CN=CORPORATE SSO CA,O=SAP SE,L=Walldorf,C=DE
Valid from:      Sun Jan 01 12:00:00 UTC 2017
Valid until:     Thu Jan 01 11:59:59 UTC 2032
Signature algorithm: SHA256withRSA

```

The `xs trusted-certificates` command displays a list of all trust certificates including the alias for a certificated (if defined) and some additional information that is extracted from the certificate itself, for example, the subject, the issuer and the period for which the certificate is valid.

## Adding Trust Certificates

To upload a custom trust certificate, use the command `xs trust-certificate`, as illustrated in the following example:

### Output Code

```
$ xs trust-certificate <ALIAS> -c <PATH>
```

In the example command output above, `<ALIAS>` is an arbitrary name and has no special meaning. `<PATH>`, however, must point to a valid certificate file, which must be a X.509 certificate in the PEM format.

### ⚠ Caution

All trust certificates are passed to all applications and can be used to validate SSL sessions to any server.

The core components of the XS advanced platform, for example, the XS Controller and the XS UAA, rely on these trust certificates to establish trusted SSL connections.

## SAP HANA SSL Trust Certificates

If you want to use SSL to encrypt connections between the SAP HANA database and SAP HANA XS advanced, you must upload to the XS advanced trusted-certificate store the root certificate of the server certificate, which

is used by your SAP HANA database. When adding this trusted certificate, pass the additional option "--hana-broker". This is required to enable the propagation of the certificate to applications, which use the SAP HANA Broker to obtain details of their SAP HANA database connection. For example, Node.js applications rely on this information to determine which certificate should be used to validate the database SSL connection.

Only one trust certificate can be used with the SAP HANA Broker. If you are using multiple tenant databases, all server certificates of these tenant databases must be signed by the same root certificate. If you are adding trust certificates to remote SAP HANA systems that are not managed by the SAP HANA Broker (for example, SAP HANA systems managed within SAP HANA Cockpit 2.0), simply upload these certificates as standard trust certificates.

#### → Tip

For information how to setup SSL encryption between SAP HANA XS advanced model and the SAP HANA database it is running on, see SAP Note [2300943](#) (Enabling SSL encryption for database connections for SAP HANA extended application services, advanced model).

## Client Authentication Trust Certificates

The XS advanced platform router supports the validation of client certificates to allow certificate-based authentication. The platform router also has the option to request client certificates if at least one trust certificate for client authentication has been configured in XS advanced. The validated client certificate is passed on to platform services and applications in the HTTP header "X-Forwarded-Client-Cert".

The certificates used by the platform router to validate a client certificate during the SSL handshake must be uploaded to XS advanced using the `xs trust-certificate` command together with the `--client-auth` option. Certificates that are uploaded using the `--client-auth` option are not propagated to applications.

#### i Note

It is strongly recommended to use root CA certificates as client-authentication trust certificates; it is not recommended to upload user-specific client-authentication trust certificates.

## Related Information

[Maintaining Domains in XS Advanced \[page 1853\]](#)

[Maintaining XS Advanced Run-Time Components with the XS CLI \[page 1792\]](#)

[The XS Command-Line Interface \[page 1792\]](#)

## 13.2.2.1.14 Maintaining Domains in XS Advanced

Use the `xs` command-line interface to maintain domains and domain certificates for the XS advanced run-time platform.

During installation you need to specify a default domain. This domain is used when creating URLs for the platform components and when creating the routes of the applications created by the initial installation. The default domain is a shared domain, which means it can be used from within any organization. When creating additional domains one can limit the usage of a domain to a specific organization. The domain are called private domains and can then only be used by routes created in that organization. The example URLs show what two routes using different domains might look like: Domains are the building blocks for application routes. Routes reference domains and specify a subdomain or a port on a domain, which can then be bound to applications. You can have multiple domains in your XS advanced system. DNS entries for these domains need to point to the Platform Router.

- `https://app.acme.org`
- `https://app.myotherdomain.com`

To display a list of all domains, run the following command:

```
Sample Code

xs domains

Getting domains...

name                type                org
-----
acme.org             shared (default)
myotherdomain.com   shared
privatedomain.com   private             XSA
```

The information displayed in the example above includes the following details:

XS Advanced Application Details

Property	Description
shared (default)	Domains are the building blocks for application routes. Routes reference domains and specify aThe default domain that is available to (shared between) all organizations
shared	A domain that is available to all organizations
private	Domains that are only available to a single organization

If XS advanced is configured to use the host-name-based routing mode, the XS advanced platform automatically creates subdomains for a domain when a new route is created. To ensure that this is possible, DNS entries for the domains need to include a wild-card DNS entry, which needs to point to the XS advanced Platform Router. For more information about the prerequisites for configuring and using domains in XS advanced, see SAP Note [2245631](#), *Domains and routing configuration for SAP HANA extended application services, advanced model*.

## Managing Domain Certificates

You can configure SSL certificates for every domain: the SSL certificate for a domain is used for every application route that uses this domain. By default, the XS advanced platform automatically generates a self-signed SSL certificate for every domain; the XS advanced administrator can replace this self-signed SSL certificate with a certificate signed by a well-known certificate authority. If the “host names” routing mode is enabled, it is necessary to deploy a wild-card certificate to each domain, since routes for a domain are created as subdomains. If you are using the “ports” routing mode, wild-card certificates are not needed.

### Note

Wild-card certificates include the domain name (for example, "example.org") and an additional wildcard entry such as "\*.example.org" in the certificate, as illustrated in the following example.

To display a list of domain certificates for each configured domain, use the `xs domain-certificates`, as illustrated in the following example:

### Output Code

```
$ xs domain-certificates

Retrieving the list of domain certificates as XSA_ADMIN...

Domain: acme.org
-----
Last updated at:           Sun Jan 01 12:00:00 UTC 2017
Created by:                Platform (self-signed)
Subject:                   CN=acme.org,OU=XS,O=ACME SE,C=GH
Subject alternative names: [[2, .acme.org], [1, *.acme.org]]
Issuer:                    CN=acme.org,OU=XS,O=ACME SE,C=GH
Valid from:                Sun Jan 01 12:00:00 UTC 2017
Valid until:                Sun Jan 01 12:00:00 UTC 2018
Signature algorithm:       SHA256withRSA
```

In addition to domain certificates, the XS advanced run-time platform can be used to manage custom trust certificates. For more information, see *Maintaining Trust Certificates* in *Related Information* below.

### Tip

Domain certificates are treated the same way as custom trust certificates; both types of certificates are available to **all** XS advanced applications.

For more information about how to set certificates for the XS advanced run-time platform, see SAP Note [2243019](#).

## Setting Domain Certificates in PEM Format

To configure your own certificate for a domain you can use the "xs set-certificate" command. The command requires a private key in PKCS8 PEM format and the full certificate chain in X.509 PEM format. The following example walks you through the process of creating a CA-signed certificate and setting it as the domain certificate. It uses the command-line tool `openssl`.

### → Tip

For more information about creating CA-signed certificates, see SAP Note [2243019](#) (Providing SSL certificates for domains defined in SAP HANA extended application services, advanced model).

As part of the process of creating a domain certificate, you must first create a certificate-signing request, which you would normally define in the `openssl` configuration files, but can also do on the command line, in a bash script, as illustrated in the following very simple example, in which the contents of the `subjectAltName` and `subject` fields must be adapted to fit to the corresponding domain name:

```
openssl req -new -sha256 -newkey rsa:4096 -nodes \  
-keyout domain.key \  
-subj "/CN=acme.org/C=GH/ST=ACC/O=ACME/OU=XS" \  
-reqexts SAN \  
-config <(cat /etc/ssl/openssl.cnf \  
<(printf "\n[SAN]\nsubjectAltName=DNS:acme.org,DNS:*.acme.org")) \  
-out domain.csr
```

### ⚠ Caution

Make sure that the file generated by the process are only readable by the user running the script.

After you have successfully created a certificate signing request in the file `domain.csr` and a new private key in the file `domain.key`, you need to provide the certificate signing request to the certificate authority of your choice. You must follow the CA-specific process to have the certificate signed and then download the signed certificate as `domain.crt`. Note that you also need all the intermediate certificates and the root certificate which were used by the certificate authority to sign your domain certificate. In the following example, we assume the certificate authority used an intermediate CA certificate `intermediate.crt` for signing purposes, and the intermediate certificate was signed by the root CA certificate (`root.crt`).

Since the private key must be in PKCS8 format, use the `openssl` command to perform the conversion, as illustrated in the following example:

```
openssl pkcs8 -topk8 -nocrypt -in domain.key -out domain.pk8
```

You can now configure the certificate in XS advanced by running the `xs set-certificate` command, as illustrated in the following example:

```
xs set-certificate example.org -c root.crt intermediate.crt domain.crt -k  
domain.pk8
```

### → Tip

The platform performs a connectivity check using the new certificate and returns an error message if it detects that there is something wrong with the certificate. You can remove the files `domain.pk8`, `domain.key`, and `domain.csr` after completing this step.

To ensure the settings take full effect, restart the XS advanced system by running the `XSA` command as `<sid>adm`, as illustrated in the following example:

```
XSA restart
```

## Setting Domain Certificates in PSE Format

It is also possible to use the `set-certificates` command to configure CA-signed domain certificates in the PSE-format, as shown in the following example. The first step is to create a new PSE container together with a certificate signing request. To create the PSE container, use the `sapgenpse` command, as illustrated in the following example:

### i Note

The subject and subject alternative names parameters need to be adapted to suit your use case. You should also remember to protect the PSE container with a suitable PIN and ensure that the generated files are only readable by trusted users who really need access to the sensitive data stored in the file.

```
sapgenpse gen_pse -p domain.pse -r domain.csr -k "GN-dNSName:example.org" -k "GN-dNSName:*.example.org" "CN=example.org, C=DE, ST=BW, O=SAP, OU=XS"
```

If the command completes successfully, the certificate signing request will be available in the file "domain.csr", and a new PSE container with the name "domain.pse" is created. Next, you need to provide the certificate signing request to the certificate authority of your choice. You must follow the CA-specific process to have the certificate signed. Request the certificate from the CA as a PKCS7 container; this container includes the signed certificate, all intermediate certificates, and the root certificate.

The next step is to import the signed certificate and its certificate chain into the PSE container. Put the PKCS7 response you receive from your CA in a file called "domain.p7" and import it into the PSE container using the following command:

```
sapgenpse import_own_cert -p domain.pse -c domain.p7
```

You can now configure the certificate using the following command:

```
xs set-certificate example.org --pse domain.pse
```

### → Tip

The platform performs a connectivity check using the new certificate and returns an error message if it detects that there is something wrong with the certificate. You can remove the files "domain.pse", "domain.p7", and "domain.csr" after completing this step.

To ensure the settings take full effect, restart the XS advanced system by running the `XSA` command as `<sid>adm`, as illustrated in the following example:

```
XSA restart
```

## Related Information

[Maintaining XS Advanced Run-Time Components with the XS CLI \[page 1792\]](#)

[The XS Command-Line Interface \[page 1792\]](#)

## 13.2.2.1.15 Maintaining Tenant Databases in XS Advanced

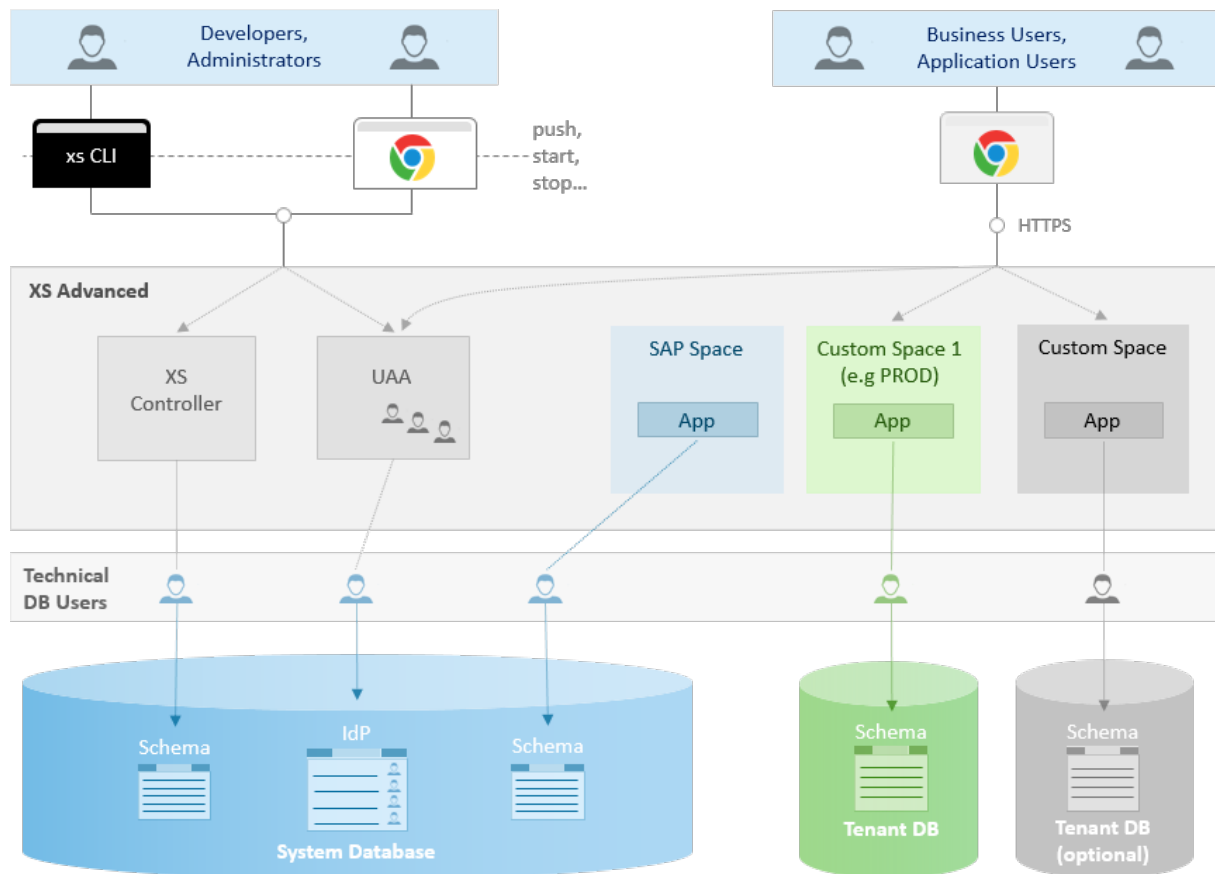

Use the `xs` command-line interface to maintain tenant database for the XS advanced run-time platform.

This section describes how XS advanced integrates into a multiple-database containers (MDC) setup in SAP HANA.

Although XS advanced is a system-wide service, it uses a dedicated database for the persistence of XS advanced system data, for example, meta-data about applications, spaces, and organizations. An XS advanced space, however, can be mapped to an arbitrary tenant databases in an SAP HANA system. In this way, custom applications within an XS advanced space can use the mapped tenant database to persist application data. Although there is already a data isolation concept based on SAP HDI containers within a single database, using different tenant databases for different XS advanced spaces enables even stronger isolation of application data.

## XS Advanced in the System Database

The following figure shows the setup when XS advanced is installed in the system database, that is, uses the system database for system data:

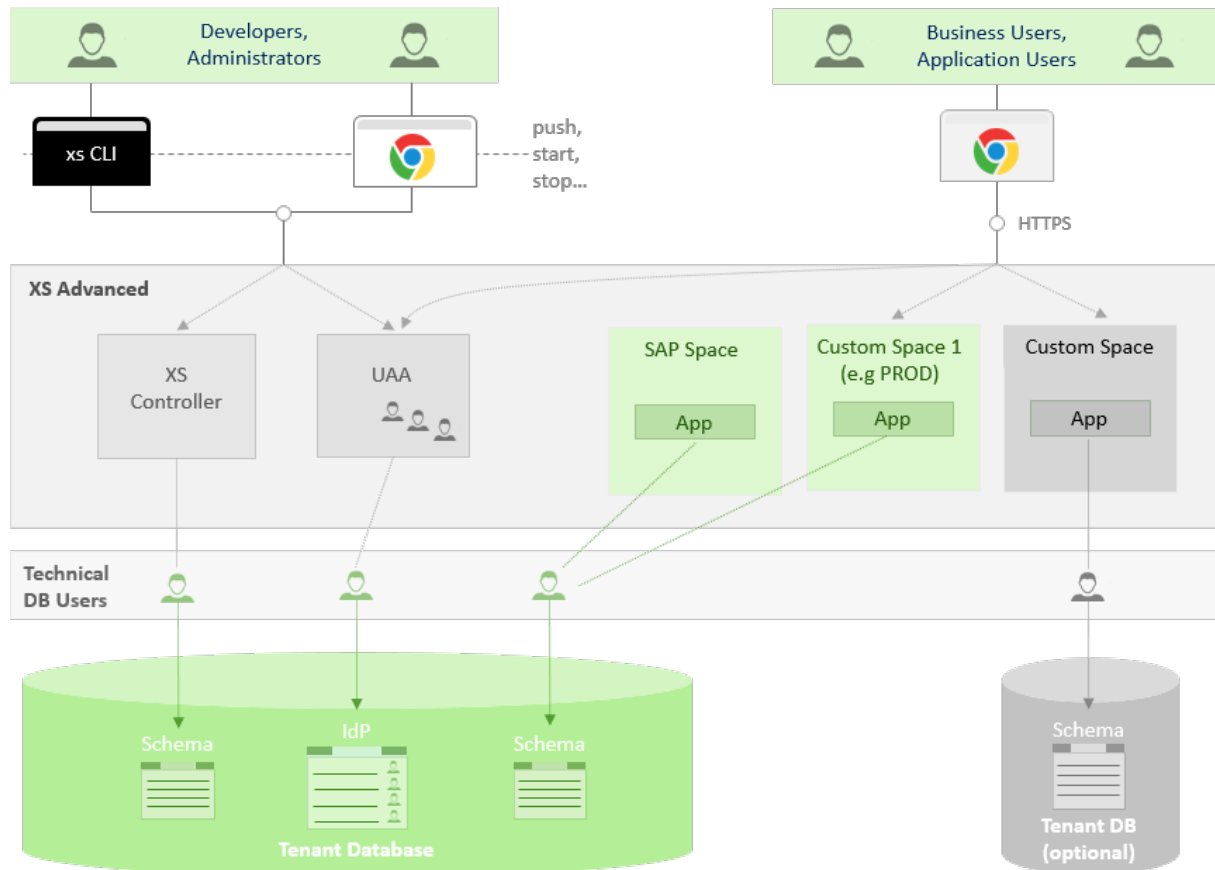

XS advanced in the System Database (Fresh Installation)

- XS Advanced platform services and the User Account and Authentication (UAA) service use the System database as persistence
- UAA uses the System database as an Identity Provider (IdP). This means that database users created in the System database can be used as XS advanced platform users or business users.
- The SAP space is mapped to the System database by default. This means that XS advanced core applications use the System database as persistence.
- A custom space (for example 'PROD') is mapped to the default tenant database. This means that applications bound to SAP HANA service instances in the custom space use the default tenant database as persistence.
- Newly created spaces are mapped by default to the default tenant database.
- It is possible to map additional tenant databases if required.

Although there is already a data-isolation concept based on HDI Containers within a single database, using different tenant databases for different spaces enables even stronger isolation of application-specific data.

## XS Advanced in a Tenant Database

The following figure shows the setup when XS advanced is installed in a tenant database, that is, uses the tenant database for system data:

XS advanced in a Tenant Database (Fresh Installation)

- XS Advanced platform services and the User Account and Authentication (UAA) service use a tenant database as persistence
- UAA uses the a tenant database as an Identity Provider (IdP). This means that database users created in the tenant database can be used as XS advanced platform users or business users.
- The SAP space is mapped to the same tenant database where XS advanced in installed. This means that XS advanced system applications use this tenant database as persistence.
- A custom space (for example 'PROD') is mapped to the same tenant database where XS advanced in installed. This means that applications bound to SAP HANA service instances in the custom space use this tenant database as persistence.
- Newly created spaces are mapped by default to the same tenant database.
- It is possible to map additional tenant databases if required.

## Viewing Tenant Databases in XS Advanced

As an XS advanced administrator, you can use the `xs tenant-databases` command to display a list of the current mappings between spaces and tenant databases, as illustrated in the following example:

```
⌘ Output Code
Viewing Mapped Tenant Database

$ xs tenant-databases

Getting tenant databases as XSA_ADMIN...

name      XSA  status  host           sql-port  mappings
-----
MYTENANT1 no    active  h1.acme.org    30041
MYTENANT2 no    active  h2.acme.org    30044
XSA       yes   active  h3.acme.org    30015    <default>, orgname:PROD
SYSTEMDB  yes   active  h3.acme.org    30013    orgname:SAP
```

The information displayed in the example above includes the following details:

### XS Advanced Application Details

Property	Description
name	The name of the database tenant
XSA	The listed tenant database is enabled ("yes") or not yet enabled ("no") for use with XS advanced
status	An <i>active</i> tenant database is up, running, and available; a tenant database that is "inactive" is either stopped, in the process of being created, or otherwise unavailable.
host	The name of the master host on where the tenant database is running
sql-port	The port to use for SQL connections to this tenant database's master host
mappings	A comma-separated list of the XS advanced spaces ( <code>org:space</code> ) that are mapped to the tenant database

In the example describes the following mapping configuration:

- The tenant databases `MYTENANT1` and `MYTENANT2` are active, but not yet enabled for use with XS advanced.
- The tenant database `XSA` is enabled for use in XS advanced and the tenant is mapped by default when a new XS advanced space is created. In addition, the tenant database `XSA` is mapped explicitly to the space `PROD` in the organization `orgname`.
- The `systemDB` is used by applications in space `SAP` within the organization `orgname`.

## Enabling Tenant Databases for XS Advanced

To register a new tenant database, for example, `MYTENANT1`, for use in XS advanced use the following command:

```
$ xs enable-tenant-database MYTENANT1
```

If you use the `xs` CLI to create a new tenant database, the new database is immediately **enabled** for use with XS advanced, as shown in the following example:

### Output Code

```
$ xs tenant-databases
```

```
Getting tenant databases as XSA_ADMIN...
```

name	XSA	status	host	sql-port	mappings
MYTENANT1	yes	active	h1.acme.org	30041	
MYTENANT2	no	active	h2.acme.org	30044	
XSA	yes	active	h3.acme.org	30015	<default>, orgname:PROD
SYSTEMDB	yes	active	h4.acme.org	30013	orgname:SAP

### → Tip

The `XSA` column indicates if a tenant database is either enabled (`yes`) or disabled (`no`) for use in XS advanced. A **disabled** database also does not have either a host or an SQL port assigned.

Alternatively, you can use the `xs` command `xs create-tenant-database`, which creates a tenant DB and registers it for use with XS advanced automatically:

```
$ xs create-tenant-database MYTENANT3
```

## Mapping Tenant Databases in XS Advanced

After a tenant database is enabled for use with XS advanced, you can map organizations and spaces to the newly enabled tenant database with the `xs map-tenant-database` command, as shown in the following example:

```
$ xs map-tenant-database -o orgname -s myspace MYTENANT1
$ xs map-tenant-database -o myorg2 MYTENANT2
```

### → Tip

If you map a tenant database to an organization, the mapping is inherited by **all** spaces in the mapped organization, as long as no tenant is set explicitly.

To display an overview of the mappings between tenant databases and organizations and spaces, use the `xs tenant-database-mappings` command, as shown in the following example:

#### Output Code

```
$ xs tenant-database-mappings

Getting tenant database mappings as XSA_ADMIN...

organizations and spaces      tenant databases
-----
myorg2                        MYTENANT2
myorg2:dev                    MYTENANT2 (inherited from orgname)
orgname                       XSA (inherited from global)
orgname:PROD                  XSA
orgname:SAP                   SYSTEMDB
orgname:myspace              MYTENANT1
```

If the same space or organization is mapped to multiple tenant databases, you can use the `--default` option to specify one of the tenant databases as the default database, as shown in the following command:

```
$ xs map-tenant-database -o orgname -s myspace MYTENANT2 --default
```

The selected **default** tenant database is flagged in the output of the `xs tenant-database-mappings` command as shown in the following example:

#### Output Code

```
$ xs tenant-database-mappings

Getting tenant database mappings as XSA_ADMIN...

organizations and spaces      tenant databases
-----
[...]
orgname:myspace              MYTENANT1, MYTENANT2 (default)
[...]
```

If no default tenant database is declared or you want to use a particular mapped tenant database for a certain SAP HANA service instance, you must specify the GUID of the target database whenever you create an SAP HANA service in the target space, as illustrated in the following example:

```
$ xs create-service hana hdi-shared myservice -c '{"database_id":
"0e140209-5e3a-42b3-8c7a-21260eba4287"}'
```

To display a list of know tenant databases and the corresponding database GUIDs use the `--guids` option, as shown in the following example:

#### Output Code

```
$ xs tenant-databases --guids

Getting tenant databases as XSA_ADMIN...

name      XSA  status  host           sql-port  id              mappings
-----
MYTENANT1 yes   active  h1.acme.com    30041     0e140209-...   orgname:myspace
```

## Unmapping and Deleting Tenant Databases in XS Advanced

To unmap a tenant database from a space or organization, use the command `xs unmap-tenant-database`, as shown in the following example:

```
$ xs unmap-tenant-database -o orgname -s myspace MYTENANT1
```

To disable a tenant DB for use with XS advanced, use the command `xs disable-tenant-database`, as shown in the following example:

```
$ xs disable-tenant-database MYTENANT1
```

To delete a tenant database, use the command `xs delete-tenant-database`. You need to specify the credentials for the system users of both the System database (`SYSTEMDB`) and the specified tenant database (`MYTENANT2`), as shown in the following example:

```
$ xs delete-tenant-database MYTENANT2 -n <TENANTDB_SYSTEM_USER> -t <PASSWD> -u <SYSTEMDB_SYSTEM_USER> -p <PASSWD>
```

### ⚠ Caution

Deleting a tenant database destroys all data within the specified tenant database. In addition, if you use the SQL command-line interface (CLI) to delete a tenant database that is mapped to an organization or space in XS advanced, the database mapping in XS advanced is not removed, and XS advanced is not made aware of the deletion of the tenant DB, which can lead to problems for XS advanced.

## Renaming Tenant Databases in XS Advanced

You can rename not only the tenant database where XS advanced is installed but also a tenant database that is registered for use with XS advanced, as follows:

1. Stop the XS advanced platform.

```
$ XSA disable
```

2. Rename the tenant database.

For more information about how to rename a tenant database, see *Related Information* below.

3. Restart the XS advanced platform:

After renaming a tenant database, the command you use to restart XS advanced depends on whether the renamed database is registered for use with XS advanced and whether XS advanced is installed in the database that is renamed.

1. A tenant database in which XS advanced is installed.

If you have renamed the tenant database where XS advanced is installed, use the following command to restart XS advanced:

```
$ XSA select-xsa-runtime-db <new tenant database name> --skip-fss
```

This activates XS advanced for the renamed tenant database and then starts XS advanced, too.

2. A tenant database that is registered with XS advanced.

If you have renamed a tenant database that is registered for use with XS advanced, use the following command to restart XS advanced:

```
$ XSA enable
```

This ensures that, during startup, XS advanced notices the new name for the registered tenant database and adapts all existing service instances that use the renamed database.

### 13.2.2.16 Maintaining Host Pinning

Use the `xs` command-line interface to maintain services for applications running in the XS advanced run-time platform.

Host pinning enables you to “pin” an XS advanced application to a particular set of hosts that have been assigned the role `xs_worker`. In this way, you can control where applications run and ensure they can only be run on a particular host or in a specific space. Pinning applications to a particular host provides the following benefits:

- **Isolation**  
Ensure that applications run inside the same SAP HANA system but completely isolated from one another on specific (different) hosts.
- **Sizing**  
Exploit application-specific hardware and sizing benefits which are only available on particular hosts

XS advanced distinguishes between the following host pinning modes:

- `strict`  
The pinned application will only start if one of the pinned hosts is available. (Default)
- `relaxed`  
The pinned application will start even if none of the pinned hosts is available.

## Viewing Currently Pinned Hosts

You can display a list of the applications that are currently pinned in the target space. The following example shows that no applications are pinned to any host or space, and no **default** pinning configuration has been set up yet:

### Output Code

```
$ xs pinned-hosts

Getting apps in org "orgname" / space "SAP" as XSA_ADMIN...

Found apps:

app                pinned to    mode
-----
auditlog-db        <not set>
auditlog-server    <not set>
auditlog-broker    <not set>
deploy-service     <not set>
component-registry-db <not set>
product-installer  <not set>
auditlog-odata     <not set>
auditlog-ui        <not set>

Default host pinning for target space "SAP": <no pinning>
```

## Viewing Hosts Available for Pinning

To pin applications to certain hosts, you first need to find out which hosts are available for pinning duties, for example, by using the command `xs system-info`, which displays a list of all hosts running an execution agent (assigned the `xs_worker` role) along with some additional details, as illustrated in the following example:

### Output Code

```
$ xs system-info

Getting system infrastructure information...

Execution agents:
-----
1. host1.acme.org:47588
   created at      Dec 15, 2017 7:50:48 AM
   port range      50000-50499
   os.arch          amd64
   os.name          Linux
   java.vendor      SAP AG
   java.version     1.8.0_144
   os.version       3.12.74-60.64.40-default
   sun.arch.data.model 64
   version          v1.0.70

2. host2.acme.org:63506
   created at      Dec 15, 2017 8:25:08 AM
   port range      50000-50499
   os.arch          amd64
   os.name          Linux
```

```
java.vendor      SAP AG
java.version     1.8.0_144
os.version       3.12.74-60.64.40-default
sun.arch.data.model 64
version         v1.0.70
[...]
```

The system output shown in the example above shows two running Execution Agents (index: 1 and 2), which can be used to pin applications to the hosts where the agents are registered.

## Pinning Applications to Hosts

It is possible to pin either specific applications or entire spaces to a particular host or hosts. To pin an application to specific hosts, use the command `xs pin-hosts <application> <host>`. There are two ways to specify the respective host when using the `xs pin-hosts` command:

- Specify the Execution Agent index  
The index is the number associated with the hosts listed by the `xs system-info` command - "1" or "2" in the example above.
- Specify the host name  
The host name is listed along side the "index" in the output displayed by the `xs system-info` command.

The following two commands are equivalent and pin the application `auditlog-ui` to the host `host2.acme.org`:

```
$ xs pin-hosts auditlog-ui --eas 2
```

```
$ xs pin-hosts auditlog-ui --hosts host2.acme.org
```

Assuming you are logged on to the same XS advanced system where you ran the `xs system-info` command in the example, above, the following command pins the `deploy-service` application to the same host where Execution Agent 2 is running, but in `relaxed` pinning mode:

```
$ xs pin-hosts deploy-service --eas 2 --relaxed
```

### → Tip

To change an existing host-pinning setting, use the `--unset-pinning` option.

To pin a space to a host, you can use the `xs update-space` command, which works in a similar way to the `xs pin-hosts` command. For example, to pin the space "SAP" to the host `host2.acme.org`, run the following command:

```
$ xs update-space SAP --hosts host2.acme.org
```

To display details of all currently pinned hosts, use the `xs pinned-hosts` command, as illustrated in the following example:

### ↵ Output Code

```
$ xs pinned-hosts
```

```
Getting apps in org "orgname" / space "SAP" as XSA_ADMIN...
Found apps:
```

app	pinned to	mode
auditlog-db	<not set>	
auditlog-server	<not set>	
auditlog-broker	<not set>	
deploy-service	host2.acme.org	relaxed
component-registry-db	<not set>	
product-installer	<not set>	
auditlog-odata	<not set>	
auditlog-ui	host2.acme.org	strict

```
Default host pinning for target space "SAP":
[host2.acme.org] (strict)
```

### Note

To apply and enable the new (or modified) host-pinning configuration, you must restart the pinned applications. Explicit host-pinning settings for an application takes precedence over the host-pinning settings for the space in which the application is deployed and running.

## Troubleshooting Host-Pinning Problems

Stopping the Execution Agent on a host (for example, `host2.example.org`) by removing the `xs_worker` role from a host illustrates the difference between “strict” and “relaxed” pinning. A short time after the Execution Agent stops, the state of the pinned applications look like in the following example:

### Output Code

```
$ xs apps

Getting apps in org "acme" / space "SAP" as XSA_ADMIN...
Found apps:

name                requested  instances  memory  urls
                    state
-----
[...]
deploy-service      STARTED   1/1        280 MB  https://deploy-service.ex[...]
[...]
auditlog-ui         STARTED   0/1        64.0 MB https://auditlog-ui.examp[...]
```

The output from the `xs apps` command shows in the `instances` column that the `auditlog-ui` application could not start; this is because the pinning mode was set to “strict”. The `deploy-service` command, however, was able to start because the pinning mode was “relaxed”. The logs for the `auditlog-ui` application contains the information illustrated in the following example:

### Output Code

```
$ xs logs auditlog-ui --last 2
```

```
Connected, dumping recent logs for app "auditlog-ui"
12/15/17 [...PM] [API] ERR Number of running instances for app 'auditlog-ui'
12/15/17 [...PM] [API] ERR Failed to start an instance of app 'auditlog-ui'
```

## Related Information

[The XS Command-Line Interface \[page 1792\]](#)

[The XSA Command Reference \[page 1888\]](#)

### 13.2.2.17 Maintaining Build Packs in XS Advanced

Build packs transform application code into an application droplet that can be deployed to the appropriate run-time environment.

A build pack is the component that XS advanced uses to transform application code into an application droplet, which can be run as an application instance on the XS advanced platform. This transformation process is called "staging". When pushing an application to the run-time environment, the appropriate build pack is automatically detected for the pushed application, and the application is staged using the selected build pack. For example, if you push a WAR file, the Java build pack detects that it is the appropriate build pack to create a usable Tomcat application from that WAR file. Usually a build pack adds the corresponding run time environment (for example, Node.js or Tomcat) along with any specified dependencies (for example, Node modules) to the application being pushed, and it may even add additional libraries (for examples, JDBC drivers) and configure the application to connect to bound services.

## Viewing Installed Build Packs

By default XS advanced comes with a set of default build packs that are supported by SAP. The command `xs buildpacks` shows a list of all the build packs installed on the XS advanced platform. The following example shows a list of all default build packs:

```
$ xs buildpacks
Getting buildpacks...
buildpacks          version  position  enabled  locked
-----
sap_java_buildpack  1.6.23   1         true
sap_nodejs_buildpack  3.4.3   2         true    true
sap_python_buildpack  0.2.2   4         true
```

The names of the build packs are generally self-explanatory; in the example above, the build packs names indicate support for Java, Node.js, and Python applications.

The value for the position attribute displayed in the output of the `xs buildpacks` command is important if the build pack needs to be detected automatically. This is because the detection procedures for the various build packs are executed in the order of their positions; in this example: position 1, 2, or 4. The first build pack to

report that it has detected an application it thinks it is able to stage is used. Build packs that are `enabled` can be used for staging an application; disabled build packs are not able to detect any uploaded files or indicate that they are responsible for staging a particular type of application. The default setting for `enabled` is `"true"`. Locking a build pack ensures that the locked build pack stays at the current version; it cannot be updated with a new version. The default setting for `locked` is `"false"`.

## Creating a Build Pack

You can use the `xs create-buildpack` command to create your own custom build pack. Creating your own build pack is useful if you want to run applications in XS advanced, which are written in a programming language that is not supported by the default build packs. For example, if you want to run a Go application in XS advanced, you will need to write your own custom build pack for Go. For more information about creating custom build packs, see the section *"Custom Build Packs in XS Advanced"* in the *SAP HANA Developer Guide for XS Advanced* (in *Related Information* below). After you have implemented your custom build pack, you can upload it to the XS advanced platform by running the following command, which would place it at position 5 in the build pack detection process:

```
xs create-buildpack my_custom_buildpack /path/to/my_custom_buildpack 5
```

## Updating a Build Pack

You can update a build pack by using the `"xs update-buildpack"` command, for example:

```
xs update-buildpack my_custom_buildpack -p /path/to/version2/my_custom_buildpack
```

The default build packs provided by SAP are automatically updated with new features and security patches, when you update the XS advanced platform.

Updating a build pack does not directly affect any applications that were staged with the old version of the build pack. If a security patch or a new feature of the build pack is applied to an application, the application needs to be restaged. Restaging happens when the application is deployed or pushed. A restage, however, can also be triggered individually. After restaging an application, it is necessary to restart the application, too, in order to ensure the execution of the new droplet produced by the new version of the build pack, as illustrated in the following example:

```
xs restage <app_name>
xs restart <app_name>
```

It is also possible to enforce a restage of all applications. However the procedure requires a restart of XS advanced. To trigger a restart of all application, log on to XS Advanced as the `<sid>adm` user and run the following (XSA) commands:

```
XSA restage-at-startup
XSA restart
```

## Using Git Build Packs

Creating and updating a build pack as described in this section, requires administrator privileges within the XS advanced platform. However, when pushing an application, it is also possible to specify a git repository that contains the source code of a build pack, as illustrated in the following example

```
xs push my-application -f my-manifest.yml -b https://my-git-server.example.com/  
my_custom_buildpack.git
```

In this scenario, the build pack is downloaded from the specified git repository and used when staging the pushed application. Note that it is only possible to specify a Git repository URI that is also valid for the `git clone` command. The URI can use either the `git` or the `https` protocol and needs to be reachable from the XS Controller host, and the source code of the build pack must be available in the default branch of the repository. Note that if you are calling a Git server via HTTPs, it might be necessary to configure the correct trust certificates first. For more information about how to configure trust certificates within XS advanced, see *Maintaining Trust Certificates in Related Information* below.

[SAP HANA Developer Guide for XS Advanced Model](#)

### 13.2.2.18 Maintaining Service URLs

The SAP HANA XS advanced platform supports the creation and maintenance of a list of service URLs, which consist of a service name and the corresponding URL. Some service URL mappings are created during installation of XS advanced, but additional URLs can be registered by an administrator at any point in time. Usually, the service URL points to an application running on the XS advanced platform, but the URL could also point to an external service.

This list of registered service URLs can be read by client tools, for example, the `xs` command-line tool without requiring any logon credentials. If the XS Controller API URL is set, the known service URLs are displayed in the output of the `xs version` command, as illustrated in the following example:

#### Output Code

Registered Service URLs

```
$ xs version  
...  
-----  
Registered service URLs:  
deploy-service           = https://deploy-service.xsa.example.com:35033  
product-installer        = https://orgname-sap-product-installer.xsa.examp...  
job-scheduler-dashboard = https://jobscheduler-dashboard.xsa.example.com:350  
product-installer-ui     = https://orgname-sap-product-installer-ui.xsa.ex...  
xsa-cockpit              = https://xsa-cockpit.xsa.example.com:35033
```

Links to the services are also created on the status page that is delivered to a Web browser that is pointed to the XS advanced API URL. In addition, the platform provides a redirection mechanism for the registered services. Pointing a Web browser to `<API-URL>/go/xsa-cockpit` redirects the browser to the URL registered for the service `xsa-cockpit`. This is particularly useful if you want to provide stable and predictable links to front-end applications even in **port**-routing mode without having to create routes with static ports.

## Registering Service URLs

Service URLs for applications deployed on the XS advanced platform can be registered automatically using the corresponding feature in the application's `mtad.yaml` deployment descriptor. XS advanced administrators can, however, also register a service URL manually, using the `xs register-service-url` command, as illustrated in the following example:

### Output Code

Register a Service URL

```
$ xs register-service-url myservice https://myservice.xsa.example.com
```

To display a list of all currently registered service URLs, run the following command:

### Output Code

List all Registered Service URLs

```
$ xs service-urls
...
-----
Registered service URLs:
  deploy-service           = https://deploy-service.xsa.example.com:35033
  product-installer        = https://orgname-sap-product-installer.xsa.exempl...
  job-scheduler-dashboard = https://jobscheduler-dashboard.xsa.example.com:3503
  product-installer-ui     = https://orgname-sap-product-installer-ui.xsa.exa...
  xsa-cockpit              = https://xsa-cockpit.xsa.example.com:35033
```

## Unregistering Service URLs

Service URLs can be manually removed from this list of registered service URLs by using the `xs unregister-service-url` command, as illustrated in the following example:

### Output Code

Unregister a Service URL

```
$ xs unregister-service-url myservice
...
Removed registration of service name "myservice" with URL "https://
myservice.xsa.example.com".
OK
```

## Related Information

[Maintaining XS Advanced Run-Time Components with the XS CLI \[page 1792\]](#)

### 13.2.2.1.19 Building Roles for XS Advanced Applications

Use authorization artifacts to control access to XS advanced applications.

In XS advanced, application developers create and deploy application-based authorization artifacts for business users. Administrators use this information to build roles, define sets of roles called role collections, and assign these collections to business users or user groups. In this way, they control the users' permissions and, as a result, access to the applications.

## Role Templates

Applications define role templates acting as a blueprint for real-life role instances. Based on these role templates, administrators create role instances by filling in concrete values for attributes defined by role templates. For example a role template for editing actions on HR data could have an attribute to configure the region or country to restrict the editing permission to. To display the role templates provided by applications in the current target space or made available globally, use the command `xs role-templates`, as illustrated in the following example:

### Output Code

Role Templates for XS Advanced Applications

```
$ xs role-templates
```

```
Getting role templates in space "SAP" as user "XSA_ADMIN"...
```

app	role template	attributes	description
alm	ControllerAdmin		Template for Ctrl Admin
xs_role_admin	XS_ROLE_ADMIN		Auths for XS role build
fileprocessor	Admin		Role for Admin UI
	API		Role for API access
	Auditor		Role for read-only acce
auditlog-ui	AuditLogViewer		View all auditlogs
java-hello-world	Viewer	Country	View all books
	Editor	Country, CostCenter	Edit, delete the books

In the example above, the role templates “Viewer” and “Editor” of the application `java-hello-world` are examples for role templates with attributes (`Country` and `CostCenter`). It is not possible to assign role templates directly to users; a specific instance of the role template must be created first, in the form of a role, which is described in more detail in the next section.

## Roles in XS Advanced Applications

If you are basing a role on a role template that does not specify any attributes, creating the role is a straightforward process, for example, using the `xs create-role` command, as illustrated in the following example:

```
$ xs create-role fileprocessor Admin FP-Admin "Role for fileprocessor Admin UI
access"
Creating role "FP-Admin" for app "fileprocessor" using role template "Admin" as
user "XSA_ADMIN"...
OK
```

The example command above creates a new role called `FP-Admin` from the `Admin` template of the `fileprocessor` application. No attributes are specified in this example, but it is always a good idea to provide a description for the new role; this information is used when the role instance is created and appear in the list of roles that can be displayed with the `xs roles` command, as illustrated in the following example:

### Output Code

#### Displaying XS Advanced Application Roles

```
$ xs roles

Getting application roles in space "SAP" as user "XSA_ADMIN"...
Found roles:
```

name	app	template	descript
XS_CONTROLLER_ADMIN	<cloud_controller>	XS_CONTROLLER_ADMIN	Default
XS_CONTROLLER_AUDITOR	<cloud_controller>	XS_CONTROLLER_AUDITOR	Default
XS_CONTROLLER_USER	<cloud_controller>	XS_CONTROLLER_USER	Default
XS_AUTHORIZATION_ADMIN	<xs_authorization>	XS_AUTHORIZATION_ADMIN	Default
XS_AUTHORIZATION_DISPLAY	<xs_authorization>	XS_AUTHORIZATION_DISPLAY	Default
XS_MONITOR_ADMIN	<xs_monitor>	XS_MONITOR_ADMIN	Default
XS_MONITOR_DISPLAY	<xs_monitor>	XS_MONITOR_DISPLAY	Default
XS_SUBSCRIPTION_ADMIN	<xs_subscription>	XS_SUBSCRIPTION_ADMIN	Default
XS_SUBSCRIPTION_DISPLAY	<xs_subscription>	XS_SUBSCRIPTION_DISPLAY	Default
XS_TENANT_ADMIN	<xs_tenant>	XS_TENANT_ADMIN	Default
XS_TENANT_DISPLAY	<xs_tenant>	XS_TENANT_DISPLAY	Default
XS_USER_ADMIN	<xs_user>	XS_USER_ADMIN	Default
XS_USER_DISPLAY	<xs_user>	XS_USER_DISPLAY	Default
XS_USER_PUBLIC	<xs_user>	XS_USER_PUBLIC	Default
ControllerAdmin	alm	ControllerAdmin	Default
XS_ROLE_ADMIN	xs_role_admin	XS_ROLE_ADMIN	Default
AuditLogViewer	auditlog-ui	AuditLogViewer	Default
API	fileprocessor	API	Default
Admin	fileprocessor	Admin	Default
Auditor	fileprocessor	Auditor	Default
FP-Admin	fileprocessor	Admin	Admin UI

The `xs roles` command shows all application roles scoped for the current target space and any global roles. In addition to roles created from application-defined role templates, there are also some roles defined by the platform itself. Platform-defined roles typically have names starting with "xs\_" and the origin of the role is shown in angle brackets `<...>` to distinguish them from normal application roles.

When creating a role from a role template with attributes, the `xs create-role` command prompts the user to specify the values to use for all the attributes. Alternatively, the attribute values can be provided on the command line with the option `-a ATTRIBUTES` where `ATTRIBUTES` can either be a JSON format structure with

all attribute values, or the path to a text file that contains the JSON structure. A convenient way to create such a file is by letting the xs client create it for a given role template, as illustrated in the following example:

#### Output Code

Creating a Sample `attributes.json` File for a Role Template

```
$ xs create-role java-hello-world Editor --create-sample attributes.json
Creating attribute values sample file for role template "Editor" for app
"java-hello-world"...
OK
```

The resulting file `attributes.json` can then be edited in any text editor to fill in the desired values. To create a new role with these attributes and the edited values, use the option `-a attributes.json` as illustrated in the following example:

#### Output Code

Creating an Application Role Using Attribute Values Stored in a JSON File

```
$ xs create-role java-hello-world Editor Editor-Germany -a attributes.json
"Editor role for Germany"
Creating role "Editor-Germany" for app "java-hello-world" using role template
"Editor" as user "XSA_ADMIN"...
OK
```

The details of the newly created (or any other) role can be displayed using the `xs role` command. The details include a description of the role, the provided scopes, and any attribute values, as illustrated in the following example:

#### Output Code

Displaying Details of an Application Role

```
$ xs role Editor-Germany

Getting role "Editor-Germany" in space "SAP" as user "XSA_ADMIN"...

name:           Editor-Germany
description:    Editor role for Germany
app:            java-hello-world
template:       Editor (Edit and Delete the books)

scope           description
-----
java-hello-world!i1.Create  create
java-hello-world!i1.Delete  delete

attribute  value    source  description
-----
Country    Germany  static  Country
CostCenter de-01    static  CostCenter
```

## Role Collections in XS Advanced

In XS advanced, roles are not directly assigned to users; they are managed in reusable role collections that can, for example, list all the roles required to perform a specific task. New role collections can be created using the `xs create-role-collection` command, as illustrated in the following example:

### Output Code

Creating a Role Collection

```
$ xs create-role-collection Example-Collection "An example role collection"
Creating role collection "Example-Collection" as user "XSA_ADMIN"...
OK
```

To display existing role collections, use the command `xs role-collections`, as illustrated in the following example:

### Output Code

Displaying a List of Role Collections

```
$ xs role-collections

Getting role collections as user "XSA_ADMIN"...

role collection          description
-----
AUDITLOG_VIEWER
XS_AUTHORIZATION_ADMIN   Authorizations for XS role builder
XS_AUTHORIZATION_DISPLAY Authorizations for XS role viewer
XS_USER_ADMIN            Admin authorizations for XS user management
XS_USER_DISPLAY          Display authorizations for XS user management
XS_USER_PUBLIC           Default authorizations for XS user
XS_MONITOR_ADMIN         Authorizations for XS monitoring management
XS_MONITOR_DISPLAY       Authorizations for XS monitoring display
XS_SUBSCRIPTION_ADMIN    Authorizations for XS subscriptions management
XS_SUBSCRIPTION_DISPLAY  Authorizations for XS subscriptions display
XS_TENANT_ADMIN          Authorizations for XS tenants management
XS_TENANT_DISPLAY        Authorizations for XS tenants display
XS_CONTROLLER_ADMIN      Authorizations for XS controller admin
XS_CONTROLLER_USER       Authorizations for XS controller user
XS_CONTROLLER_AUDITOR    Authorizations for XS controller auditor
Example-Collection       An example role collection
```

You can add individual roles to (or remove them from) a role collection using the command `xs update-role-collection`, as illustrated in the following example:

### Output Code

Adding a Role to a Role Collection

```
$ xs update-role-collection Example-Collection --add-role FP-Admin
Getting role "FP-Admin" in space "SAP" as user "XSA_ADMIN"...
Updating role collection "Example-Collection" as user "XSA_ADMIN"...
OK
```

To show the contents of a role collection, use the command `xs role-collection`, as shown in the following example:

#### Output Code

Displaying Details of a Role Collection

```
$ xs role-collection Example-Collection

Getting role collection "Example-Collection" as user "XSA_ADMIN"...
Roles of role collection "Example-Collection" (An example role collection):

name                app                space                template  description
-----
FP-Admin            fileprocessor      orgname:SAP         Admin     Role Admin UI access
Editor-Germany     java-hello-world  orgname:SAP         Editor    Edit role for Germany
```

## Assigning Role Collections

The final step in role management is assigning the role collection to users. The XS command-line client provides the `assign-role-collection` command for this purpose, as shown in the following example:

#### Output Code

Assigning a Role Collection to an XS Advanced User

```
$ xs assign-role-collection Example-Collection MYUSER

Assigning role collection "Example-Collection" to user "MYUSER"...
OK
```

Use the `xs unassign-role-collection` command to remove any role collections assigned to users. To display the role collections currently assigned to a user, use the `xs assigned-role-collections` command, as illustrated in the following example:

#### Output Code

Displaying Details of Assigned Role Collections

```
$ xs assigned-role-collections MYUSER

Getting role collections assigned to user "MYUSER"...

role collection      description
-----
XS_USER_PUBLIC       Default authorizations for XS user
Example-Collection   An example role collection
```

## Related Information

[Maintaining Platform Users in XS Advanced \[page 1810\]](#)

## 13.2.2.1.20 Maintaining XS Advanced Application Run Times

Keep XS advanced application run-time versions up to date.

Applications run times are used by buildpacks to compile an application during the staging process. XS advanced keeps a store for application run times such as virtual machines for Java, Node.js, application containers, and so on. The application run-time store is automatically updated with most recent version of the application run time when XS advanced is updated to a new version. However, the XS advanced administrator can also maintain application run times manually.

### Viewing Installed Application Run Times

To display a list of the installed run-time environments in XS advanced, use the `xs runtimes` command, as illustrated in the following example:

```
Output Code
Listing Installed Run-Time Environments

$ xs runtimes

Getting runtimes...

type          version id resolved active description                                bound
-----
hanajdbc1     120.20 7 true  true  SAP HANA JDBC Driver 1.120.20              0
hanajdbc2     3.19   6 true  true  SAP HANA JDBC Driver 2.3.19                4
node6.12      2.1    3 true  true  Node.js 6.12.2.1 for Linux x86...         0
node8.9       3.5    2 true  true  Node.js 8.9.3.5 for Linux x86-...        10
sapjvm8       1.35   4 true  true  SAP JVM 8 Patchlevel 35 for Liux          0
sapjvm8_jre   1.35   5 true  true  SAP JVM JRE 8 Patchlevel 35 fo...         4
tomcat8       5.23   0 true  true  Apache Tomcat Web Container 8....         4
tomee1.7_jaxrs 5       1 true  true  Apache TomEE jaxrs 1.7.5                  0
```

For each application run time environment, the following information is displayed:

#### Application Run-Time Environment Details

Information	Description
type	The name of the application run-time environment
version	The version of the application run-time environment
id	The index of the application run time by which it is referenced in other <code>xs</code> CLI commands (for example, <code>xs runtime</code> )
resolved	The indicated application run time is correctly detected by the XS advanced run time environment [true   false]
active	The application run time is enabled for use by build packs [true   false]

Information	Description
description	A short summary of the application run-time details
bound apps	The number of applications currently using the application run time

## Finding Bound Applications

To display a list of all applications that use a particular application run time environment, use the `xs runtime` command and specify a particular run time with the run-time index, as illustrated in the following example:

### → Tip

The run-time index is displayed in the `id` column of the output of the `xs runtimes` command.

### ≡ Output Code

Listing Applications Bound to a Specific Run Time

```
$ xs runtime -i 7

Showing information about "node10.23"
type:      node10.23
version:   1.0
id:        7
description: Node.js 10.23.1 for Linux x86-64
resolved:  true
active:    true
bound apps:
org  space  apps          requested state  currently used  used
after restart
-----
org  SAP    auditlog-db   STOPPED          no               yes
      --    auditlog-broker STARTED          yes              yes
```

In addition to the organization, space and application name, you also display the information if the app is currently started. The last two columns provide information about how the application is bound to the specified run time:

- `currently used`:  
Indicates if there are currently running instances of the application that are using the specified run time.
- `used after restart`:  
Indicates if the specified run time will be used when the application is restarted.

You can use the information displayed by the `xs runtime` command to check which applications need to be restaged if a new application run time has been installed and, in addition, to ensure that all relevant applications are using the specified application run-time environment.

## Pinning Run Time Environments to Applications

Normally, the buildpack chooses the latest version of an application run time during application staging. However, in support cases, you can pin a specific version of a run time to an application, forcing the buildpack to use the specified run-time version during application staging. For example using the command `xs pin-runtime` and the options `<ALIAS>`, `<APP>`, and `-i <PINNED_RUNTIME>`, you can ensure that the application run time with index `<PINNED_RUNTIME>` is always used when an application build pack requests a run time with the name `<ALIAS>`.

The `<ALIAS>` can either be an exact run-time type (for example, "node8.9" to pin a fixed run-time version if the application build pack requires the Node.js version 8.9) or a prefix of a run-time type (for example, "node8" to pin a fixed run-time version if the application build pack requires any version of Node.js version 8.\*).

### ⚠ Caution

Support for run-time pinning is provided for Java and Node.js types only.

In the following example, a Node.js application is pinned to a Node.js "6" run time **type** despite the fact that the buildpack would normally choose a Node.js run time of type "8":

### → Tip

The run-time type is displayed in the `type` column of the output of the `xs runtimes` command.

### ≡ Output Code

Pinning Applications to a Run-Time Type

```
$ xs pin-runtime node8 myapp -i 3
Updating app "myapp" in org "myorg" / space "PROD" as XSA_ADMIN...
```

To ensure that the specified changes take effect, the target application must be re-staged and re-started. You can use the `xs pinned-runtimes` to display a list of the mappings between run times and applications, and filter the output for a specific application name, as illustrated in the following example:

### ≡ Output Code

Displaying Pinned Run Times

```
$ xs runtimes myapp
Showing pinned runtimes for app "myapp".
alias  type      version id resolved active description                                bound
-----
node8  node6.12  2.1    3 true   true   Node.js 6.12.2.1 Linux x86...                0
```

To undo the changes, and revert to the previous run-time settings, use the `xs unpin-runtime` command, as illustrated in the following example:

#### ☰ Output Code

Removing Application-to-Run-Time Pinnings

```
$ xs unpin-runtime node8 myapp  
Updating app "myapp" in org "myorg" / space "PROD" as XSA_ADMIN...
```

## Creating and Uploading a New Run Time

You can upload a new run time to XS advanced with the command `xs create-runtime`; you need to specify the directory or .zip file containing the application run time that you want to upload, as illustrated in the following example:

```
$ xs create-runtime -p Python-2.7.6
```

#### ! Restriction

Only application run times supported by XS advanced can be uploaded, for example: SAP JVM, SAP Node.js, Python, Tomcat, TomEE, and HANA JDBC driver.

## Updating Run Times

When updating XS advanced, the default application run times are automatically maintained and updated as well, for example, to provide security patches.

#### i Note

Manually uploaded application run times are not included in the automatic update.

To ensure that all applications use the updated application run times, all applications must be restaged and restarted. You can use the commands `xs restage` and `xs restart` to restage and restart individual applications manually, or use the `XSA` command to restage **all** applications during XS advanced startup, as illustrated in the following example:

#### i Note

Log on to the SAP HANA system as `<sid>adm`.

```
$ XSA restage-at-startup  
$ XSA restart
```

#### ⚠ Caution

These XSA commands restart not only XS advanced but also all applications.

## Removing Outdated Run Times

Although an update of XS advanced may install new versions of run times, the update process does not automatically remove old run-time versions. To remove an outdated run time, first make sure that the runtime is no longer used by any applications, for example, by using the `xs runtime` command to display details about the runtime you want to remove, as shown in the following sample:

```
$ xs runtime -i 7

Showing information about "node10.23"
  type:      node10.23
  version:   1.0
  id:        7
  description: Node.js 10.23.1 for Linux x86-64
  resolved:  true
  active:    true
  bound apps:
  org  space  apps                requested state  currently used  used after
  restart
-----
  org  SAP    auditlog-db          STOPPED         no              yes
      --    auditlog-broker     STARTED         yes             yes
```

To make sure that a run time is no longer in use and can safely be removed, perform the following steps:

1. Restage any bound application that shows a "yes" in the "used after restart" column.
2. If, after restaging, there is still a "yes" in the "used after restart" column, then the application is not compatible with a newer version of the run time. In this case, the application itself has to be updated.
3. When all bound applications display "no" in the "used after restart" column, restart all applications that display "yes" in the "currently used" column.
4. At this point, there should be no application with "yes" in either the `currently used` or `used after restart` columns, which confirms that the outdated run time is no longer being actively used by any application. However, applications could still be bound to this run time, for example, due to stopped application instances that are kept for the purposes of post-mortem analysis. For this reason, it is recommended to use the `xs update-runtime` command to disable the outdated run time and prevent any future use by any application, as shown in the following example:

```
xs update-runtime -i <ID> --disable
```

5. To completely remove the run time, delete any existing stopped application instances that are still referencing the outdated run time. You can do this by executing the following command for each bound application:

```
xs delete-app-instances <APP> --stopped --crashed
```

6. Now, you can safely remove the runtime, as follows:

```
xs delete-runtime -i <ID>
```

## Related Information

[Maintaining Applications in XS Advanced \[page 1825\]](#)

## 13.2.2.1.21 Maintaining Tasks in XS Advanced

Schedule and manage one-off tasks with XS advanced applications.

XS advanced applications are Web applications that on startup open a port and then remain available to respond to user requests until the applications are stopped. This type of application life-cycle is not appropriate for all types of work. For example, it is not appropriate for initialization or setup tasks that need to be performed only once and do not require any user interaction; these types of problems are best handled by using so called one-off tasks. One-off tasks are special application instances that are started by specifying a particular custom command on application startup. No route is created for a one-off task, which means that the custom command can perform any type of activity that does not require user interaction. After the custom command exits, the one-off tasks finishes and reports the command's exit code to the user.

### Running a One-Off Task

Before using an application to perform a one-off task, the corresponding application must first be deployed, as described in *Maintaining Applications in Related Information*. After the application has been successfully deployed, the command `xs run-task` can be used to create a new task instance to run it. The following arguments have to be used to specify the required information in the `run-task` command:

1. The name of the application (and therefore the droplet files for the task execution)
2. A name for the new task
3. The command to execute

The following example shows what a typical task start command looks like:

#### Output Code

```
$ xs run-task my-app my-task "echo Hello World" --wait-for-completion
Running task "my-task" on app "my-app"...
Task finished successfully.
```

The new task "my-task" is started based on the current droplet and environment variable settings of the application "my-app". Any additional environment variable values that are required can be provided by using the option `-e` with the command `run-task`. The option `--wait-for-completion` forces the client to wait for the task execution to finish. With this option, the success (or failure) of the task execution is reported at the end; without this option, the task execution is started asynchronously and the `run-task` command returns immediately.

#### → Tip

You can display the current state of a task by using the `xs tasks` command.

## Checking the Current State of Tasks

The command `xs tasks` is used to display a list of existing tasks for a given application and check their current state, as shown in the following example:

### Output Code

```
$ xs tasks my-app
Listing tasks for app "my-app"...
-----
index  name      created                command                state
-----
7      bad-task  Apr 25, 2018 10:07:43 AM non-existing command  FAILED
      Failure reason: Process terminated with exit code 1
8      my-task   Apr 25, 2018 10:08:22 AM echo Hello World      SUCCEEDED
```

Although failed tasks have an additional short failure reason message, more useful information can be found in the task-execution output.

## Displaying Task Output

The task execution is very similar to the execution of regular apps. Therefore, the output of the task can be found in the logs of the corresponding application. As documented in [Displaying Application Logs](#), the command `xs logs` is used to display the application logs. For the example above, the log output could look like this:

### Output Code

```
$ xs logs my-app --recent
Connected, dumping recent logs for app "my-app"...
-----
4/25/18 10:07:43.385 AM [API] OUT Starting new task instance '39660f9d-6eed...
4/25/18 10:07:45.124 AM [APP/1-7/bad-task] OUT
4/25/18 10:07:45.124 AM [APP/1-7/bad-task] OUT /hana/shared/ABC/xs/app_work...
4/25/18 10:07:45.127 AM [APP/1-7/bad-task] ERR 'non-existing...
4/25/18 10:07:45.127 AM [APP/1-7/bad-task] ERR operable program or batch fi...
4/25/18 10:07:49.043 AM [API] ERR Crashed instance [state CRASHED, index 7]...
4/25/18 10:08:22.774 AM [API] OUT Starting new task instance '09d52632-d616...
4/25/18 10:08:24.014 AM [APP/1-8/my-task] OUT
4/25/18 10:08:24.014 AM [APP/1-8/my-task] OUT /hana/shared/ABC/app_working/...
4/25/18 10:08:24.018 AM [APP/1-8/my-task] OUT Hello World
```

The log output reveals details of the failed task, which in the example above concerns the use of an unrecognized command (`non-existing`). The log lines relevant for a given task can be found by looking for the task name and task index within the log line **source** string, which is enclosed in square brackets in the log output, for example, `[APP/1-7/bad-task]`. The name and index associated with a task are displayed in the output of the `xs tasks` command.

The successful "Hello World" task shown in the log output has the index "8" and the name "my-task" and it was executed using the first droplet of the `my-app` application. As a result, the output of this task is marked with the source string `[APP/1-8/my-task]`.

[The XS Command-Line Interface \[page 1792\]](#)

### 13.2.2.1.22 Scanning and Reporting XS Advanced Application Artifacts

Generate and display reports with details of dependencies between application artifacts and resources in XS advanced.

Web applications typically include a large number of software components such as Java archives (`.jar`) or Node.js modules (`.js`). In most cases, these artifacts are third-party (probably open-source) components that need special attention. And these components are not only in the application bundle pushed to the server; a significant amount of additional artifacts can be added by the platform itself during application deployment, for example: UI-framework artifacts, middleware, or low-level modules such as database drivers or cryptographic libraries. Regardless of origin, all artifacts in a staged application potentially contribute to productive code. For this reason, it is crucial to be able to get a complete overview of all artifacts that an application references either directly or indirectly, in order to identify the following:

- Vulnerable (open-source) components
- Components with well-known functional flaws
- Outdated or redundant component versions
- Components with license restrictions

The xs CLI commands `find-app-artifacts`, `find-droplet-artifacts`, `find-runtime-artifacts`, and `find-buildpack-artifacts` are suitable for analyzing artifact dependencies of a single XS advanced controller resource such as an application, a droplet (a staged application), a deployed run time, or a build pack. When scanning a broader range of resources on the server, for example, a whole space or even an organization, it makes sense to start with the command `xs find-artifacts`, which provides the same basic features for analyzing and filtering artifacts, but operates on a larger set of resources. In their initial version, all artifact-reporting tools for XS advanced applications are limited to the detection of Java archives and Node.js modules.

#### → Tip

You can use operating-specific tools to pipe the report output generated by the `find-*-artifacts` commands to other commands such as `grep` or to a specific file. If the search completes successfully but nothing is found that matches the search query, the commands have process exit code "0". If the search query finds a match, "-1" is returned, and "1" if the commands finish unsuccessfully.

## Displaying the Usage of Application Modules

After deploying an application `my-web-app` to the XS advanced platform, you can find out which version of a particular Node.js module (for example, `express`) was uploaded to the server during application deployment.

To scan the uploaded application's artifacts, run the command `xs find-app-artifacts` as a user with the privileges required to read application artifacts:

### Note

The current `xs` target must be the space where the application is running.

### Output Code

```
$ xs find-app-artifacts my-web-app -n express*

Finding artifacts of app "my-web-app" with name wild card "express*"...

+ APP "my-web-app" in space "SAP" of org "test" created at Jan 18, 2018
  12:33:03 PM (STARTED)
    NPM express 4.15.3
      path: /node_modules/express
    NPM express-session 1.15.3
      path: /node_modules/express-session

Found Artifacts   Affected Apps
-----
2                  1
```

The report returned by the `xs find-app-artifacts` command shows that the deployed application `my-web-app` uses the modules `express` version 4.15.3 and `express-session` version 1.15.3, and that both modules are located in the `node-modules` folder.

### Tip

The command `xs find-app-artifacts <APPNAME>` displays *\*all\** components uploaded with the application.

You can use the following options with **all** find-artifact commands:

- `--artifact-info`  
Displays meta information about the artifacts, if available, for example, vendor, license, etc.
- `--artifact-tree`  
Displays the logical dependency tree of the components, if available. This helps understand which artifacts are referenced transitively by a direct dependency.

## Showing Which Artifacts the Platform Adds During Application Staging

If you push a Spring-based Java application (for example, containing `.jar` files) to the XS advanced run-time platform, it is important to understand that, in addition to the Java archives required to implement the application logic, the Java build pack also adds a number of Java archives from the build pack content itself, as well as from several run times. You can use the command `xs find-droplet-artifacts` to display a report with details of all the artifacts in the target application's current droplet. The report displayed by the `xs find-`

droplet-artifacts command also shows higher-level resources such as the application itself and the build pack and run times used, as illustrated in the following example:

### Output Code

```
$ xs find-droplet-artifacts my-spring-app

Finding artifacts of app "my-spring-app"...

+ DROPLET of application "my-spring-app" with index 3 in space "PROD" of
org "test" created at Jan 19, 2018 1:47:39 PM (1 RUNNING, 1 STOPPED)
+ APP "my-spring-app" in space "PROD" of org "test" created at Sep 17, 2018
3:11:07 PM (STARTED)
  JAR spring-security-core 4.2.3.RELEASE
    path: /app/WEB-INF/lib/spring-security-core-4.2.3.RELEASE.jar
  JAR spring-security-oauth2 2.3.3.RELEASE
    path: /app/WEB-INF/lib/spring-security-oauth2-2.3.3.RELEASE.jar
  JAR spring-security-web 4.2.3.RELEASE
    path: /app/WEB-INF/lib/spring-security-web-4.2.3.RELEASE.jar
  JAR spring-web 4.3.15.RELEASE
    path: /app/WEB-INF/lib/spring-web-4.3.15.RELEASE.jar
  [...]
+ BUILDPACK "sap_java_buildpack" 1.7.8
  JAR httpclient 4.5.3
    path: /app/META-INF/.sap_java_buildpack/tomcat/impl/httpclient-4.5.3...
  JAR httpcore 4.4.6
    path: /app/META-INF/.sap_java_buildpack/tomcat/impl/httpcore-4.4.6.jar
  JAR java-container-security 0.30.1
    path: /app/META-INF/.sap_java_buildpack/tomcat/impl/java-container-sec
  [...]
+ RUNTIME "hanajdbc2" 2.3.53
  JAR ngdbc 2.3.53
    path: /app/META-INF/.sap_java_buildpack/hana_jdbc/ngdbc-2.3.53.jar
+ RUNTIME "sapjvm8_jre" 8.1.43
  JAR rt 1.8.0_181
    path: /app/META-INF/.sap_java_buildpack/sapjvm/lib/rt.jar
  [...]
+ RUNTIME "tomcat8" 8.5.32
  JAR tomcat-api 8.5.32
    path: /app/META-INF/.sap_java_buildpack/tomcat/lib/tomcat-api.jar
  JAR tomcat-coyote 8.5.32
    path: /app/META-INF/.sap_java_buildpack/tomcat/lib/tomcat-coyote.jar
  JAR tomcat-websocket 8.5.32
    path: /app/META-INF/.sap_java_buildpack/tomcat/lib/tomcat-websocket.jar
  [...]

Found Artifacts    Affected Droplets
-----
226                1
```

The example above shows that the Spring-based application droplet contains the following artifacts:

- Application "my-spring-app"
- Build pack "sap-java-buildpack" (version 1.7.8)
- Run time "hanajdbc2" (version 2.3.53)
- Run time "sapjvm8\_jre" (version 8.1.43)
- Run time "tomcat8" (version 8.5.32)

In total, the report found 226 artifacts matching the search criteria my-spring-app.

## Listing the Artifact Versions Used in Productive Code

You can use the `xs` command-line tools to check if specific versions of an application component are still in use. This type of report is useful if a particular version of an application component is known to have a vulnerability or a proven functional flaw. For example, the `xs find-artifacts` command enables you to scan a large set of application resources on the server within a customizable search range: applications, droplets, run times, or build packs.

Since, generally speaking, the scope of the scan is determined by the privileges granted to the XS advanced platform user who runs the scan, it is recommended that application-artifact scans are run by a platform administrator user, in order to ensure that all resources available on the server are analyzed. You can limit the scope of a scan, for example, to search within a specific organization or space, by using the options `"-o <ORG>"` and `"-s <SPACE>"`.

The following example shows how to run a search with the scope set to the Java archive `security-commons` with major version "0" and minor version "26", which is outdated and needs to be replaced:

### Output Code

```
$ xs find-artifacts -n security-commons* -v 0.26.*
Finding all artifacts of droplets with name wild card "security-commons*"
and version wild card "0.26.*"...
+ DROPLET of application "my-java-app" with index 1 in space "PROD"
  of org "test" created at Jan 20, 2018 9:02:42 AM (1 RUNNING, 1 STOPPED)
  + BUILDPACK "sap_java_buildpack" <outdated version, latest version:1.7.8>...
    JAR security-commons 0.26.13 (OUTDATED)
    path: /app/META-INF/.sap_java_buildpack/tomcat/impl/security-commons-0.26
Found Artifacts      Outdated Artifacts      Affected Droplets
-----
2                    2                    1
There are outdated artifact versions in search scope.
Restage and restart affected apps to replace them with current versions
available on the platform.
```

The command output in the example above shows that a droplet of a running instance of the application "my-java-app" is using an outdated version (0.26.13); the dependency was apparently introduced by "sap\_java\_buildpack". The first "OUTDATED" tag in the example above indicates that the build pack "sap\_java\_buildpack" on the platform has been updated to version 1.7.8 after the application "my-java-app" was staged; restaging the application should update this dependency.

### Note

After staging the `my-java-app` application with the current build pack, it is necessary to restart the application to activate the updates.

## 13.2.2.2 Maintaining XS Advanced Run-Time Instances with the XSA CLI

Manage XS advanced services without stopping the SAP HANA database.

Similar to the `HDB` command that lists all SAP HANA services, the `xsa` command enables you to manage XS advanced instances without having to stop and restart the SAP HANA database. With the `xsa` command, you can manage XS advanced components, for example, the controller (`xscontroller`), the execution agent (`xsexecutionagent`), and the `xsaaserver` that provides services for User Accounts and Authentication (UAA).

With the `xsa` command, you can perform the following actions on an instance of the XS advanced run time:

- Enable
- Disable
- Restart
- Set a domain certificate
- Reset the default domain certificate for an XS advanced run-time instance
- Restage all applications that are running when the XS advanced run-time instance is restarted
- Backup and restore the Secure Store file system
- Delete user data from log files

### Related Information

### 13.2.2.2.1 The XSA Command Reference

Commands to help maintain XS advanced run-time instances, for example, enable, disable, or restart.

```
XSA {COMMAND} [--OPTIONS]
```

The following table lists the `xsa` commands that are most commonly used:

#### ! Restriction

To use the `xsa` command, you must log on as the operating-system user `<SID>adm`.

XSA Commands Overview

Command	Description
<code>help</code>	Display an overview of all command help parameters and options
<code>enable</code>	Enable a disabled XS advanced run-time instance

Command	Description
<code>disable</code>	Disable a running instance of the XS advanced run time
<code>restart</code>	Disable and re-enable an XS advanced run-time instance
<code>set-certificate</code>	Set the certificate for the default domain after the XS Controller is shut down
<code>reset-certificate</code>	Reset the certificate for the default domain and restart the XS advanced run-time instance
<code>trust-certificate</code>	Add a trusted certificate
<code>restage-at-startup</code>	Restage all applications that are running when the XS advanced instance (controller) is restarted
<code>backup-ssfs</code>	Store the current XS advanced Secure Store File System (SSFS) configuration in an encrypted database table
<code>recover-ssfs</code>	Restore the XS advanced Secure Store File System (SSFS) configuration from an encrypted database table
<code>diagnose</code>	Run tests that help diagnose problems with the XS advanced system
<code>backup-fss</code>	Create a backup copy of the file-system services in the database
<code>recover-fss</code>	Restore the file-system service instances from the database
<code>collect-traces</code>	Creates a zip containing the trace files of the XS advanced services
<code>delete-personal-data</code>	Erase user data from the log files
<code>du</code>	Provides the disk usage for application instances and file-system service
<code>grant-privileges-to-support-user</code>	Grants an SAP HANA user access to XS advanced database schemas
<code>list-tenants</code>	Lists all (tenant) databases registered for XS advanced
	<div style="background-color: #f0f0f0; padding: 10px; border-left: 2px solid #0070c0;"> <p><b>→ Tip</b> You can also verify the credentials of the technical XS advanced users within tenants used by XS advanced.</p> </div>
<code>select-xsa-runtime-db</code>	If a database already contains an XS advanced installation, this command activates XS advanced for the specified tenant database
<code>unlock-technical-users</code>	Ensures the connectivity of all technical XSA database users
<code>renew-passwords-of-technical-users</code>	Set a new password for all technical users required by XS advanced system services.

Command	Description
<code>update-tenants</code>	Allow the SAP HANA broker to maintain databases regarding rights and roles needed for operation.

## enable

Enable a disabled XS advanced run-time instance.

### Usage

```
XSA enable [--localhost] [--verbose] [--async]
```

### Options

Command Options Overview

Option	Description
<code>--localhost</code>	Restrict the operation to the local host
<code>--verbose</code>	Display all available information during the selected operation
<code>--async</code>	Return to the command prompt without waiting for the command to complete

## disable

Disable a running instance of the XS advanced run time.

### Usage

```
XSA disable [--localhost] [--verbose] [--async]
```

### Options

Command Options Overview

Option	Description
<code>--localhost</code>	Restrict the operation to the local host
<code>--verbose</code>	Display all available information during the selected operation
<code>--async</code>	Return to the command prompt without waiting for the command to complete

## restart

Disable and re-enable an XS advanced run-time instance.

### Usage

```
XSA restart [--localhost] [--verbose] [--async]
```

### Options

Command Options Overview

Option	Description
<code>--localhost</code>	Restrict the operation to the local host
<code>--verbose</code>	Display all available information during the selected operation
<code>--async</code>	Return to the command prompt without waiting for the command to complete

## set-certificate

Set the certificate for the default domain of an XS advanced run-time instance.

### Note

The `set-certificate` command enables you to set a valid domain certificate without the need to start the XS advanced controller first.

By default, all applications and the XS advanced controller are reached by means of the default domain that is configured during the installation operation. To enable HTTPS communication, it is necessary to configure an SSL certificate for the default domain or, alternatively, use the self-signed certificate provided by XS advanced. If the certificate provided for the default domain expires, neither the applications nor the XS advanced controller can be reached. In addition, the XS Controller will not be reachable after a restart because the initial availability checks will fail. The `set-certificate` command enables you to resolve the problem by setting the certificate for the default domain.

### Usage

```
XSA set-certificate [--cert <CERTIFICATE_FILE>] [--key <KEY_FILE>] [--verbose] [--async]
```

## Options

Command Options Overview

Option	Description
<code>--cert</code> <code>&lt;CERTIFICATE_FILE&gt;</code>	Specify the file containing the public certificate to use
<code>--key &lt;KEY_FILE&gt;</code>	Specify the file containing the private key to use
<code>--verbose</code>	Display all available information during the selected operation
<code>--async</code>	Return to the command prompt without waiting for the command to complete

## reset-certificate

Reset the certificate for the default domain and restart the XS advanced run-time instance.

### → Tip

The `reset-certificate` command can only be used to generate a new **self-signed certificate**, which is helpful in cases when you just want to get the XS advanced controller running again after a certificate is outdated.

By default, all applications and the XS advanced controller are reached by means of the default domain that is configured during the installation operation. To enable HTTPS communication, it is necessary to configure an SSL certificate for the default domain or, alternatively, use the self-signed certificate provided by XS advanced. If the certificate provided for the default domain expires, neither the applications nor the XS advanced controller can be reached. In addition, the XS Controller will not be reachable after a restart because the initial availability checks will fail. The `reset-certificate` command enables you to reset the certificate for the default domain to resolve the problem.

## Usage

```
XSA reset-certificate [--verbose] [--async]
```

## Options

Command Options Overview

Option	Description
<code>--verbose</code>	Display all available information during the selected operation
<code>--async</code>	Return to the command prompt without waiting for the command to complete

## trust-certificate

Adds a trusted certificate, even if the XS advanced controller is not running.

### Usage

```
XSA trust-certificate [--alias <ALIAS>] [--cert <CERTIFICATE_FILE>] [--hana-broker] [--client-auth] [--verbose]
```

### Options

Command Options Overview

Option	Description
-a, --alias <ALIAS>	The alias of the trusted certificate
-c, --cert <CERTIFICATE_FILE>	The path to the X.509 certificate file in PEM format.
--client-auth	Use the certificate for validation of certificate-based client authentication
--hana-broker	Add the certificate to the service bindings issued by the SAP HANA service broker.
--verbose	Display all available information during the selected operation

## restage-at-startup

On restart of the XS advanced instance (controller), restage all applications that were running in the XS advanced instance before the restart. Restaging applications ensures that they have access to any security fixes for deployment build packs and run-time environments that are available.

### Usage

```
XSA restage-at-startup [--verbose]
```

#### → Tip

The XS advanced instance is not restarted automatically; you must restart the XS advanced instance yourself manually.

### Options

Command Options Overview

Option	Description
--verbose	Display all available information during the selected operation

## backup-ssfs

Store the current XS advanced Secure Store File System (SSFS) configuration in an encrypted database table.

### Usage

```
XSA backup-ssfs [--verbose]
```

#### i Note

The `backup-ssfs` command replaces the command `save-ssfs-to-dbss`.

### Options

Command Options Overview

Option	Description
<code>--verbose</code>	Display all available information during the selected operation

## recover-ssfs

Restore the XS advanced Secure Store File System (SSFS) configuration from an encrypted database table.

### Usage

```
XSA recover-ssfs [-u <system_db_user>] [-p <system_db_password>] [-n <db_host_port>] [--verbose]
```

#### i Note

The `recover-ssfs` command replaces the command `restore-dbss-to-ssfs`.

### Options

Command Options Overview

Option	Description
<code>-u</code> <code>&lt;system_db_user&gt;</code>	The name of the system database user
<code>-p</code> <code>&lt;system_db_password&gt;</code>	The password of the system database user.

#### i Note

If you do not provide the password with the command, you are prompted to provide it interactively.

Option	Description
<code>-n, --database-name &lt;database_name&gt;</code>	The database name to use to establish a connection to the tenant database where XS advanced keeps its persistence, for example, in a multi-tenant database container (MDC) system that was migrated from a single database container system.
	<div style="border: 1px solid #ccc; background-color: #f9f9f9; padding: 10px;"> <p><b>i Note</b></p> <p>This information is not required if XS advanced keeps its persistence in the System database (default).</p> </div>
<code>--verbose</code>	Display all available information during the selected operation

## diagnose

Run tests that help diagnose problems with the XS advanced system. The command writes its findings to `stdout` as well as to a dedicated trace file. The path to the location of the trace file is added to the end of the output written to `stdout`.

### Usage

```
XSA diagnose [--verbose]
```

## backup-fss

Creates a backup of the file-system services (FSS) in the database. The command backs up all existing FSS instances, unless the `--services` option is specified. If a FSS instance is deleted then the corresponding backup is also removed from the database.

### Usage

```
XSA backup-fss [--services <service>] [--list-services] [--verbose]
```

## Options

Command Options Overview

Option	Description
<code>-s, --services &lt;services&gt;</code>	Specify a single GUID or a list of GUIDs of file-system service instances to back up.
	Execute <code>xs services</code> with option <code>--guids</code> to get the GUID for a particular service instance.

Option	Description
-l, --list-services	Displays a list of the existing backups
--verbose	Display all available information during the selected operation

## recover-fss

Restores the file-system service (FSS) instances from the database. The command recovers all FSS instances with existing backups unless the `--services` option is specified.

### Usage

```
XSA recover-fss [--services <service>] [--list-services] [--verbose]
```

Command Options Overview

Option	Description
-s, --services <services>	Specify a single GUID or a list of GUIDs of file-system-service (FSS) instances to recover Execute <code>xs services</code> with option <code>--guids</code> to get the GUID for a particular service instance.
-l, --list-services	Display a list of the existing backups
-f, --force	Force execution of the recover command without requiring any user confirmation
--verbose	Display all available information during the selected operation

## delete-personal-data

Remove user data from the log files generated in an XS advanced run-time instance. The `delete-personal-data` command triggers log-rotation for all log files and removes all user-related data (for example, user names, IP addresses) from the log files up to a specified point in time. You can use the `delete-personal-data` command to clean up the following types of XS advanced log files:

- XS advanced Controller log files (`controller_#.log`)
- XS advanced Execution Agent log files (`ea_#.log`)
- HTTP application-access files (`webdispatcher`)
- Application trace files (`myApp.trace`)
- User Account and Authentication (UAA) service artifacts

## Usage

```
XSA delete-personal-data [--until <DATE>] [--force] [--exclude <EXCLUDES>] [--user <NAME>] [--verbose]
```

## Options

Command Options Overview

Option	Description
<code>-u, --until &lt;DATE&gt;</code>	The date that specifies the last day of the period of time for which you want to delete log-file entries that contain user-related information.
	<b>→ Tip</b> <DATE> must be specified in the format YYYY-MM-DD, for example, 2017-06-30.
<code>-f, --force</code>	Force execution of the data-deletion command without requiring any user confirmation
<code>-e, --exclude &lt;EXCLUDES&gt;</code>	Exclude the specified log types from the deletion operation. Multiple log types are specified in a comma-separated list consisting of the following values: [ PLATFORM, AUDIT, APP, ACCESS, USERS ]
<code>--user &lt;NAME&gt;</code>	The name of the XS advanced <b>administrator</b> user in whose account the data-deletion command will run
<code>--verbose</code>	Display all available information during the selected operation

## collect-traces

Creates a Zip file containing the trace files written by the XS advanced services; the created zip file overwrites any existing Zip file previously created by the `collect-traces` command.

## Usage

```
XSA collect-traces --output <xsa_traces.zip>
```

## Options

Command Options Overview

Option	Description
<code>-o, --output &lt;xsa_traces.zip&gt;</code>	The path to the Zip file containing the collected trace files

## grant-privileges-to-support-user

Grants an SAP HANA user access to XS advanced database schemas. If the target user does not already exist, a new user is created with the specified name.

### → Tip

Using this command does not require the privileges of the `SYSTEM`.

A lesser-privileged user can be created and used to call the `grant-privileges-to-support-user` command; this user must have the following privileges:

- `SYSTEM` privilege `USER ADMIN`
- `EXECUTE` privileges on the following procedures:
  - `SYS_XS_SUPPORT.XS_SUPPORT_GRANT_SELECT`
  - `SYS_XS_SUPPORT.XS_SUPPORT_GRANT_ALL`
  - `SYS_XS_SUPPORT.XS_SUPPORT_REVOKE_ALL`

## Usage

```
XSA grant-privileges-to-support-user --support-user <SUPPORT_USER_NAME>
[--system-user <SYSTEM_USER_NAME>] [--system-password <SYSTEM_USER_PASSWORD>]
[--support-password <SUPPORT_USER_PASSWORD>] [--grant-all]
```

## Options

Command Options Overview

Option	Description
<code>--system-user</code> <code>&lt;SYSTEM_USER_NAME&gt;</code>	The name of the <code>SYSTEM</code> user of the XS advanced run-time database
<code>--system-password</code> <code>&lt;SYSTEM_USER_PASSWORD&gt;</code> <code>ORD&gt;</code>	The password of the <code>SYSTEM</code> user of the XS advanced run time database.  <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>SYSTEM</code> user. If no password is specified, the system interactively requests one.
<code>-u, --support-user</code> <code>&lt;</code> <code>SUPPORT_USER_NAME&gt;</code>	The name of the support user to whom support privileges should be granted.  <b>i Note</b> If the target user does not already exist, a new user is created with the specified name.

Option	Description
<code>-p, --support-password &lt;SUPPORT_USER_PASSWORD&gt;</code>	The password of the support user to whom access privileges are to be granted.  <b>i Note</b> If no password is specified, the system interactively requests one, and creates a new user with the specified name, if the target user does not already exist.
<code>-a, --grant-all</code>	Grant <b>all</b> access privileges, not only <code>SELECT</code> privileges

## du

Provides the disk usage for application instances and file-system service.

### Usage

```
XSA du [--app] [--fss] [--orderby <ORDERBY>] [--orderdir <ORDERDIR>]
```

### Options

Command Options Overview

Option	Description
<code>-a, --app</code>	Display the disk usage for application instances running on target XS advanced hosts
<code>-f, --fss</code>	Display the disk usage for the file-system service  <b>i Note</b> Requires SAP HANA to be started.
<code>--orderby &lt;ORDERBY&gt;</code>	Sort by specific columns for application disk usage  <b>→ Tip</b> The option accepts comma-separated values.
<code>--orderdir &lt;ORDERDIR&gt;</code>	Specify the sort order direction for application disk usage, for example, <code>asc(ending)</code> or <code>desc(ending)</code>

## list-tenants

Display details of all (tenant) databases registered for use with XS advanced model. It is also possible to check the validity of the user credentials that XS advanced uses to connect to each registered database.

## Usage

```
list-tenants [--user <XSA admin user>] [--password <XSA admin password>] [--check-credentials]
```

## Options

Command Options Overview

Option	Description
<code>-u, --user &lt;XSA admin user&gt;</code>	The name of an XS advanced administration user (for example, XSA_ADMIN)
<code>-p, --password &lt;XSA admin password&gt;</code>	The password for the XS advanced administration user specified with the <code>--user</code> option
<code>--check-credentials</code>	Verify the credentials of the XS advanced technical users that XS advanced uses to connect to each registered database

## select-xsa-runtime-db

If a database already contains an XS advanced installation, this command activates XS advanced for the specified tenant database. As of XS advanced 1.0.116 this command makes a backup of the file-system service instances, stores it in the currently active XS advanced database and restores the file-system services stored in the target database. It establishes database trust between UAA and the tenant databases, that are registered in the target XS advanced system.

## Usage

```
select-xsa-runtime-db --tenant-db-name <tenant_db_name>
[--tenant-db-system-user <tenant_db_system_user>] [--tenant-db-system-user-
password <tenant_db_system_user_password>]
[--system-db-user <system_db_user>] [--system-db-password <system_db_password>]
[--user <XSA admin user>] [--password <XSA admin password>] [--skip-fss]
```

## Options

Command Options Overview

Option	Description
<code>-n, --tenant-db-name &lt;tenant_db_name&gt;</code>	The name of the tenant database
<code>-t, --tenant-db-system-user &lt;tenant_db_system_user&gt;</code>	The name of the tenant database's SYSTEM user

Option	Description
<code>-p, --tenant-db-system-user-password &lt;tenant_db_system_user_password&gt;</code>	<p>The password of the tenant database's <code>SYSTEM</code> user</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>⚠ Caution</b></p> <p>For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>SYSTEM</code> user. If no password is specified, the system interactively requests one.</p> </div>
<code>-c, --system-db-password &lt;system_db_password&gt;</code>	<p>The password of the <code>SYSTEM</code> database user</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>⚠ Caution</b></p> <p>For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>SYSTEM</code> user. If no password is specified, the system interactively requests one.</p> </div>
<code>-s, --system-db-user &lt;system_db_user&gt;</code>	The name of the <code>SYSTEM</code> database user
<code>-u, --user &lt;XSA admin user&gt;</code>	The name of the XS advanced administrator ( <code>XSA_ADMIN</code> ) user
<code>-x, --password &lt;XSA admin password&gt;</code>	<p>The password of the XS advanced administrator (<code>XSA_ADMIN</code>) user</p> <div style="border: 1px solid #ccc; padding: 5px; background-color: #f9f9f9;"> <p><b>⚠ Caution</b></p> <p>For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>XSA_ADMIN</code> user. If no password is specified, the system interactively requests one.</p> </div>
<code>-s , skip-fss</code>	Skip backup and restore of the file system service instances. (Available with XSA > 1.0.115)

## unlock-technical-users

Ensures the connectivity of all technical XSA database users.

### Usage

```
unlock-technical-users [--user <XSA admin user>] [--password <XSA admin password>]
[--system-db-system-user <system_db_user>] [--system-db-system-user-password <param>]
[--xsa-db-system-user <system_db_user>] [--xsa-db-system-user-password <param>]
```

## Options

### Command Options Overview

Option	Description
<code>-u, --user &lt;XSA admin user&gt;</code>	The name of the XS advanced administrator (XSA_ADMIN) user
<code>-p, --password &lt;XSA admin password&gt;</code>	The password of the XS advanced administrator (XSA_ADMIN) user <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the XSA_ADMIN user. If no password is specified, the system interactively requests one.
<code>-s, --system-db-system-user &lt;system_db_user&gt;</code>	The name of the SYSTEM user of the system database
<code>-c, --system-db-system-user-password &lt;param&gt;</code>	The password for the SYSTEM user of the system database <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the SYSTEM user. If no password is specified, the system interactively requests one.
<code>-t, --xsa-db-system-user &lt;xsa_db_system_user&gt;</code>	The name of the SYSTEM user of the database where XS advanced is installed
<code>-v, --xsa-db-system-user-password &lt;param&gt;</code>	The password of the SYSTEM user of the database where XS advanced is installed <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the SYSTEM user. If no password is specified, the system interactively requests one.

## renew-passwords-of-technical-users

Sets a new password for all technical users required by XS advanced system services.

### Usage

```
renew-passwords-of-technical-users [--user <XSA admin user>] [--password <XSA admin password>]  
[--system-db-system-user <system_db_user>] [--system-db-system-user-password
```

```
<param>]
[--xsa-db-system-user <system_db_user>] [--xsa-db-system-user-password <param>]
```

## Options

Command Options Overview

Option	Description
<code>-u, --user &lt;XSA admin user&gt;</code>	The name of the XS advanced administrator ( <code>XSA_ADMIN</code> ) user
<code>-p, --password &lt;XSA admin password&gt;</code>	The password of the XS advanced administrator ( <code>XSA_ADMIN</code> ) user <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>XSA_ADMIN</code> user. If no password is specified, the system interactively requests one.
<code>-s, --system-db-system-user &lt;system_db_user&gt;</code>	The name of the <code>SYSTEM</code> user of the system database
<code>-c, --system-db-system-user-password &lt;param&gt;</code>	The password for the <code>SYSTEM</code> user of the system database <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>SYSTEM</code> user. If no password is specified, the system interactively requests one.
<code>-t, --xsa-db-system-user &lt;xsa_db_system_user&gt;</code>	The name of the <code>SYSTEM</code> user of the database where XS advanced is installed
<code>-v, --xsa-db-system-user-password &lt;param&gt;</code>	The password of the <code>SYSTEM</code> user of the database where XS advanced is installed <b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the <code>SYSTEM</code> user. If no password is specified, the system interactively requests one.

## update-tenants

Allows XS advanced to grant new permissions, coming with a new SAP HANA version, to database artifacts used by XS advanced applications.

## Usage

```
update-tenants [--user <XSA admin user>] [--password <XSA admin password>]
[--databases <list_of_databases>] [-rebind-hana-broker-services ]
```

## Options

Command Options Overview

Option	Description
<code>-u, --user &lt;XSA admin user&gt;</code>	The name of the XS advanced administrator (XSA_ADMIN) user
<code>-p, --password &lt;XSA admin password&gt;</code>	The password of the XS advanced administrator (XSA_ADMIN) user
	<b>⚠ Caution</b> For security reasons, it is not recommended to use the <code>--password</code> option to specify a password for the XSA_ADMIN user. If no password is specified, the system interactively requests one.
<code>-d, --databases &lt;list_of databases_to_update&gt;</code>	Names of databases to update. By default, all databases registered for XS advanced are updated
<code>-r, --rebind-hana-broker-services</code>	Rebind all SAP HANA broker service bindings, mapped to processed databases, to update required HDI container permissions.

## Related Information

[Maintaining XS Advanced Run-Time Instances with the XSA CLI \[page 1888\]](#)

### 13.2.2.2.2 Data Protection and Privacy Tools in XS Advanced

Ensure the protection of private user data in XS advanced.

To comply with data privacy regulations, it must be possible to delete personal and private data stored in an XS advanced system. The XS advanced run-time environment stores the following types of user-related data:

- IP addresses and user names in the audit log and trace files
- IP addresses in the router access logs
- User names in the application log files
- Shadow users in the UAA

XS advanced administrators can use the command `XSA delete-personal-data` to remove personal and private data. For example, the following command ensures the deletion of all personal data until the second of January 2018:

```
XSA delete-personal-data -u 2018-01-02
```

The `--exclude` enables you to prevent certain types of user information from being included in the delete operation, for example, if it is necessary to keep the information in order to meet other regulations, such as maintaining the integrity of the audit log, where the information is required. The `delete-personal-data` command enables you to delete sensitive information from the following types of sources:

- PLATFORM  
The platform logs including the event log in the database and the trace files
- AUDIT  
The audit log files of XS advanced
- APP  
The application log files
- ACCESS  
The Webdispatcher access logs
- USERS  
The shadow users in the User Account and Authentication (UAA) server

The following command deletes personal data from all sources in XS advanced **except** the XS advanced audit logs up until February 2, 2019:

```
XSA delete-personal-data -u 2019-01-02 --exclude AUDIT
```

### Caution

It is not possible to use this command to delete entries stored in the SAP HANA audit log. For more information about deleting entries stored in the SAP HANA audit log, see *Delete Audit Entries* in *Related Information*.

Data cannot be recovered after deletion. The only exception to this rule is the shadow users in the User Account and Authentication server (UAA), which are created again the next time the users log in. Log files are not included in the SAP HANA backup.

## 13.2.3 Maintaining the XS Advanced Run-time Environment with a Graphical User Interface

Use a graphical user interface to administrate and maintain XS advanced-model run-time components.

SAP HANA XS advanced model includes a Web-browser-based administration tool called XS Advanced Cockpit with a graphical user interface that enables you to maintain important elements of the XS advanced application-development environment, for example, security and authentication methods.

The XS Advanced Cockpit includes a selection of tools and features which enable you to configure and maintain the basic administration-related elements of the application-development process for the XS advanced run-time environment.

### Related Information

### 13.2.3.1 Maintaining the XS Advanced Runtime Environment with SAP HANA XS Advanced Cockpit

SAP HANA XS Advanced Cockpit is a graphical user interface that enables you to configure and maintain the basic administration-related elements of the application development process for the XS advanced runtime environment. The home page appears after you log on to XS Advanced Cockpit. The navigation pane on the left contains various runtime options. You can find more runtime options under *More...* in the left navigation pane. Based on your role in an organization, you can see one or more options for performing tasks specific to your role. The pane on the right displays organizations. You can be a member of one or more organizations. To work with applications and services, you need to navigate to spaces within an organization. For more information about working with organizations and spaces, see *Maintaining Organizations and Spaces in XS Advanced* in the *Related Information* section. The table below provides a brief overview and scope of the different runtime options:

Runtime Options	Description	Scope
Organization and Space Management	Create, list, or delete organizations and spaces in the XS advanced model runtime.	<ul style="list-style-type: none"> <li>Managing organizations</li> <li>Managing spaces</li> <li>Managing users in organizations and spaces</li> <li>Managing XS advanced business-user roles for organizations and spaces</li> <li>Managing applications and services within a space</li> </ul>
SAML Identity Provider	Configure an SAML identity provider for use by XS advanced applications that need to authenticate the XS advanced business users signing in by means of SSO.	<ul style="list-style-type: none"> <li>Managing SAML identity providers, including IDP metadata, certificates, and destinations</li> </ul>
Tenant Databases	Manage, maintain, and configure SAP HANA tenant databases for use with SAP HANA XS advanced model applications.	<ul style="list-style-type: none"> <li>Managing tenant databases in XS advanced</li> <li>Creating tenant databases in XS advanced</li> <li>Preparing tenant databases</li> </ul>
Host Management	Manage the SAP HANA hosts that are pinned to SAP HANA XS advanced applications or spaces.	<ul style="list-style-type: none"> <li>Displaying a list of SAP HANA hosts that are pinned to XS advanced applications or spaces</li> </ul>
User Management	Maintain and manage database users for SAP HANA XS advanced	<ul style="list-style-type: none"> <li>Creating XS advanced platform users</li> </ul>
Application Monitoring	Monitor the system resources used by applications running in the XS advanced model runtime environment.	<ul style="list-style-type: none"> <li>Monitoring application use of system resources</li> </ul>
Trusted Certificates	Manage and maintain the certificates used to establish secure and trusted connections between SAP HANA systems and SAP HANA XS advanced applications.	<ul style="list-style-type: none"> <li>Adding certificates</li> <li>Displaying a list of certificates and details</li> </ul>
Application Management	Perform various actions on an application, such as scaling an application, stopping or restarting an application, establishing secured access, verifying application logs or events for troubleshooting.	<ul style="list-style-type: none"> <li>Scaling application instances up or down</li> <li>Managing application security</li> <li>Troubleshooting an application</li> </ul>

## Related Information

### 13.2.3.1.1 Managing Users in XS Advanced

The *User Management* option in the XS Advanced Cockpit enables you to create a new user or add a user from SAP HANA so that users have the required authentication and authorization to work with the various runtime options included with the XS Advanced platform. You can perform the following tasks:

- Create a new user
- Modify user details
- Search for a user
- Delete a user

#### 13.2.3.1.1.1 Create Users in XS Advanced

### Context

This option enables you to create users or to promote existing SAP HANA users to access organizations and spaces in the SAP HANA XS Advanced runtime (including XS Advanced Cockpit).

### Procedure

1. In the home navigation pane, choose *User Management*.
2. On the *User Management* screen, choose any of the following options:
  - *New User*: Choose this option to create a user.
  - *Migrate SAP HANA User*: Choose this option to promote an existing SAP HANA user to an XS Advanced runtime user. You can either provide the SAP HANA user ID or select the user from the user list.

## Related Information

[User Details \[page 1910\]](#)

## 13.2.3.1.1.2 Manage Users

### Context

You can perform multiple actions to maintain user details, such as update user details, reset password, assign role collection, search, or delete users from the XS Advanced Cockpit.

### Procedure

1. In the home navigation pane, choose [User Management](#).
2. On the [User Management](#) screen, perform any of the following tasks:

Task	Choose	Description
Update user details	 (Edit User)	You can modify user details such as first name, last name, or e-mail address for the selected user. This option is available underneath the <a href="#">Actions</a> column.
Reset password of a user	 (Change Password)	You can change the password required to access the XS Advanced runtime including the XS Advanced Cockpit. This option is available underneath the <a href="#">Actions</a> column.
Assign role collections to a user	 (Assign Role Collections)	As well as the default role collection that is available for all users, you can add additional role collections and assign them to specific users. This option is available underneath the <a href="#">Actions</a> column.
Delete a user	 (Delete User)	This option deletes a user. This option is available underneath the <a href="#">Actions</a> column.

Task	Choose	Description
Search for a specific user	Search	If your member management screen contains a long list of users, you can use the search option to list a specific user. You can search for users using any of the following user details: member ID, user name, or role collection.

## Related Information

[Assign Roles to Role Collection \[page 1934\]](#)

[Control Access to Applications \[page 1922\]](#)

[User Details \[page 1910\]](#)

### 13.2.3.1.1.2.1 User Details

You can view the details of an XS Advanced platform user with the XS Advanced Cockpit. These are the details that are provided in the *New User* dialog.

User Interface Element	Description
User ID	Unique ID of the XS Advanced user. This is a mandatory field.
First Name	First name of the user.
Last Name	Last name of the user.
E-Mail	E-mail address of the user to whom the account belongs. The e-mail address must be unique to the user. This is a mandatory field.
Password	Password for the XS Advanced user. This is a mandatory field.

## 13.2.3.1.2 Maintaining Organizations and Spaces in XS Advanced

Organization is a logical entity to group spaces. By default, an organization does contain a space. You can create one or more spaces to enable developers to collaborate by sharing resource, services, and applications. Access to the shared resources, services, and applications is controlled by roles, for example, Organization Manager or Organization Auditor. The role defines the scope of permissions available for a user in an organization. For example, an Organization Manager can add new users to organizations, create, modify, or delete organizational spaces, and add domains to the organization.

A space enables users to develop and maintain applications. Each space provides shared access to users of the space for application development, deployment, and maintenance. Access to the resources is controlled by roles, for example, Space Manager, Space Developer, or Space Auditor. The role defines the scope of permissions available for a user in a space. For example, a Space Developer can deploy and start an application.

You can perform the following tasks within an organization and space:

- Create an organization
- Manage an organization
- Maintain users in an organization
- Create a space
- Manage a space
- Maintain users in a space

### Related Information

[Maintaining Organizations and Spaces in XS Advanced \[page 1802\]](#)

## 13.2.3.1.2.1 Create an Organization

### Context

You create an organization to establish a collaborative environment for sharing resources, services, and applications.

## Procedure

1. In the home navigation pane, choose [Organizations](#).
2. On the [Organizations](#) screen, choose [New Organization](#).
3. Provide the following details:

User Interface Element	Description
Name	Provide a name for the organization. This field is mandatory.
Assign Roles to User	This option provides the self-service option of assigning one or both of the roles (Organization Manager or Organization Auditor). You need to have these roles to perform organizational tasks.

## 13.2.3.1.2.2 Manage an Organization

### Context

You can update the details or delete organizations.

### Procedure

1. In the home navigation pane, choose [Organizations](#).
2. On the [Organizations](#) screen, perform any of the following tasks:

Tasks	Choose	Description
Update organizational details	 (Edit)	You can update details such as the name of an organization.
Delete an organization	 (Delete)	You can remove an organization.

Tasks	Choose	Description
Search for an organization	Search	If you want to view only a specific organization from the list of organizations, enter the organization name in the search field.

### 13.2.3.1.2.3 Maintain Users in an Organization

#### Context

To perform tasks within an organization, you need to add users to specific roles within the organization. Roles give controlled access to users within an organization.

#### Procedure

1. In the home navigation pane, choose *Organizations*.
2. In the right pane, choose an organization tile.
3. In the members navigation pane, choose *Members*.
4. On the *Members* page, choose *Add Members*.
5. Enter one or more user IDs.
6. Assign one or both of the roles.

#### Related Information

[Maintaining Platform Users in XS Advanced \[page 1810\]](#)

### 13.2.3.1.2.3.1 Organizational Roles

You can grant or restrict access to organizations by assigning roles. The following table lists the roles that you can assign to XS Advanced users in an organization:

Role	Description
Organization Manager	An Organization Manager can perform the following tasks: <ul style="list-style-type: none"> <li>• Create and manage organization users</li> <li>• Create, modify, or delete organizational spaces</li> <li>• Add domains to the organization</li> </ul>
Organization Auditor	An Organization Auditor can perform the following tasks: <ul style="list-style-type: none"> <li>• View all users in the organization</li> <li>• View the roles assigned to a user (or users) in the organization</li> <li>• View spaces within an organization</li> </ul>

## 13.2.3.1.2.4 Create a Space

### Prerequisites

You are already a member of an organization and have the Organization Manager role.

### Context

You create a space to enable users to develop and maintain applications.

### Procedure

1. In the home navigation pane, choose [Organizations](#).
2. On the [Organizations](#) screen, select an organization.
3. On the [Spaces](#) screen, choose [New Space](#).
4. Provide the following details:

User Interface Element	Description
Space Name	Provide a name for the space. This field is mandatory.

User Interface Element	Description
Assign space roles	This is a self-service option for assigning one or all of the roles (Manager, Developer, or Auditor). You need to have these roles to perform space-related tasks.

## 13.2.3.1.2.5 Manage a Space

### Prerequisites

You have already selected an organization.

### Context

A space contains various deployed applications and resources such as services and members. You can perform various tasks in a space, such as stop, start, delete, or search for an application. You can also do the following:

- Bind a service to an application deployed to the space
- Assign (pin) one or more hosts (SAP HANA systems) to a space

### Procedure

1. In the space navigation pane, choose [Spaces](#).
2. On the [Spaces](#) screen, perform any of the following tasks:

Task	Choose	Description
Start a stopped application	 (Start)	You can use this option to start an application from its stopped state.
Stop an application that is running	 (Stop)	You can use this option to stop an application that is currently running.

Task	Choose	Description
Delete an application	 (Delete)	You can use this option to remove an application from a space.
Search for an application	Search	If a space contains a long list of deployed applications, you can use the search option to list a specific application. Search for an application using the application name.
Manage an application	application name	You can use this option to perform multiple tasks within an application, such as define security, check application logs or events, and so on.
Assign one or more hosts to a space	Pinned Hosts	<p>You can use this option to select one or more hosts from the displayed list. The applications in the space will be deployed to the selected hosts. You can define one of the following modes:</p> <ul style="list-style-type: none"> <li>○ Strict: In this mode, an application cannot start if the pinned host is not available.</li> <li>○ Relaxed: In this mode, an application can start on another host if the pinned host is not available.</li> </ul>
<div style="background-color: #f0f0f0; padding: 5px; border: 1px solid #ccc;"> <p><b>i Note</b></p> <p>You can switch from one mode to the other.</p> </div>		
Add users to a space	Members	You can use this option to grant permissions to users to perform specific tasks within the space. For more information, see <a href="#">Maintain Users in a Space [page 1917]</a> .
Use a service within the space	Service Marketplace / Service Instances / User-Provided Services	You can use this option to use the services available within the space with any applications deployed to the space.

## Related Information

[Managing XS Advanced Applications \[page 1919\]](#)

## 13.2.3.1.2.6 Maintain Users in a Space

### Prerequisites

- You are already a member of the organization that contains the space.
- You have the Space Manager role in the space.

### Context

To enable users to perform tasks within a space, you need to add the users to the space within the organization. Roles give controlled access to users within a space.

### Procedure

1. In the space navigation pane, choose *Spaces*.
2. On the *Spaces* screen, select a space.
3. In the navigation pane, choose *Members*.
4. On the members page, choose *Add Members*.
5. Enter one or more user IDs.
6. Assign one or all of the roles.

### Related Information

[Maintaining Platform Users in XS Advanced \[page 1810\]](#)

#### 13.2.3.1.2.6.1 Space Roles

You can grant or restrict access to spaces by assigning roles. The following table lists the roles that you can assign to XS Advanced users in a space:

Role	Description
Space Manager	<p>A Space Manager can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• Manage users in the selected space</li> <li>• View details of applications running in the space (for example: status, instances, service bindings, and resource usage)</li> </ul>
Space Developer	<p>A Space Developer can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• Deploy, start, stop an application</li> <li>• Bind an application to (or unbind an application from) a service</li> <li>• View details of applications running in the space (for example: status, instances, service bindings, and resource usage)</li> </ul>
Space Auditor	<p>A Space Auditor can perform the following tasks:</p> <ul style="list-style-type: none"> <li>• View details of applications running in the space (for example: status, instances, service bindings, and resource usage)</li> </ul>

### 13.2.3.1.3 Monitoring the SAP HANA XS Advanced Model Runtime Environment

Monitoring provides details of system resources used by application instances running in the XS Advanced model runtime environment. You also have the option to sort and group resources. You can also monitor a specific application instance.

For example, you can see memory allocation and how long the application has been running.

#### 13.2.3.1.3.1 View Utilized System Resources

##### Context

You can view the system resources utilized by an application.

## Procedure

1. In the space navigation pane, choose [Spaces](#).
2. In the space navigation pane, choose [Monitoring](#).  
Applications and their respective consumption details are listed.
3. To sort or group applications based on resource consumption details, choose  (View Settings).
4. In the [View](#) dialog, choose [Sort By](#) or [Group By](#) to arrange applications.

### 13.2.3.1.3.1.1 Resource Details

The Monitoring screen provides resource details of the XS applications running in the XS Advanced runtime. The following table contains description of the resource details:

User Interface Element	Description
Name	Name of the application
Memory (KB)	Amount of memory used by an application
CPU (ms)	Amount of processing time (in milliseconds) used by the application
User Mode (ms)	Amount of user-mode time (in milliseconds) consumed by an application. In user mode, an application cannot directly access hardware or modify memory; it can only do so by means of a proxy such as an API.
Kernel Mode (ms)	Amount of kernel-mode time (in milliseconds) consumed by an application. In kernel mode, an application has unrestricted access to CPU instructions and memory addresses.
Access Count	The number of times an application has been accessed.
MTA	Name of the multi-target application (MTA) to which the listed application belongs.
Host	The name of the host where the listed instance of an XS Advanced application is running.

### 13.2.3.1.4 Managing XS Advanced Applications

The application overview page provides various options available for the application.

You can stop an application that is currently running. You can also restart the application. For example, if you need to make changes to the active application, you can stop and restart the application to apply the changes.

You can also create a new application instance. For example, if the performance of your application is impaired because of excessive load on the application, you can manually start a new instance of the application to take up any new load.

## 13.2.3.1.4.1 Manage an Application

### Context

You can use the application overview page to perform various tasks.

### Procedure

1. In the spaces navigation pane, select an application.
2. On the [Overview](#) page, you can perform the following tasks:

Task	Choose	Description
Start an application that is currently stopped	Start	If an application is in a stopped state, use this option to start it again.
Stop an active application	Stop	If you want to stop an application, use this option.
Delete an application	Delete	This option deletes the application.
Create a new instance of an application	+Instance, - Instance	The + Instance option creates a new instance of an application. To delete an instance, choose - Instance.
View system resources consumed by an instance of the application	 Instance Monitoring	This option displays system resources consumed by an application instance. You can select an instance to view the resource consumption by each process within the instance.

Task	Choose	Description
View SAP HANA systems pinned to the application	 Pinned Hosts	<p>This option displays SAP HANA systems that are pinned to host your application. The <i>Pinned Hosts</i> screen displays the following options:</p> <ul style="list-style-type: none"> <li>○ Pin to Host: Choose this option to pin the application to the listed hosts. <b>Strict</b> is the default pin mode. In this mode, the application cannot start if the pinned host is not available. You can also choose the <b>Relaxed</b> pin mode. In this mode, the application can start on any other host if the pinned host is not available.</li> <li>○ Change Pin Mode: Choose this option to switch between the available pin modes.</li> </ul>
View logs specific to your application	 Logs	<p>This option displays logs generated by the application. You can choose the following options on the <i>Logs</i> screen:</p> <ul style="list-style-type: none"> <li>○ Change Log Level: Use this option to display log details of a specific type, such as fatal, error, warning, and so on.</li> <li>○ Source: View logs of the specified source.</li> <li>○ Type: View logs of specified types.</li> <li>○ Recent /All: View recent or all logs.</li> <li>○ Download: Download recent or all logs.</li> </ul>
View actions performed on your application	 Events	<p>This option displays actions performed on the application.</p>
Bind an application to a service available in the service marketplace	Service Bindings	<p>This option enables you to use a service available from the service marketplace with your application.</p>

## Related Information

[Managing Services in XS Advanced \[page 1940\]](#)

[Displaying Application Information in XS Advanced \[page 1817\]](#)

## 13.2.3.1.4.2 Control Access to Applications

### Context

You can create user roles in the SAP HANA XS Advanced Cockpit to control access to XS Advanced applications. These roles are derived from role templates defined in the security description (xs-security.json) of applications that have been registered as OAuth 2.0 clients in the User Account and Authentication (UAA) service during application deployment. The application security description file also contains details of the authorization scopes that are used for application access, and defines any attributes that need to be applied. You can then add roles to role collections before the roles are assigned to SAP HANA database users or users logging on with SAML 2.0 assertions.

### Procedure

1. On the organization overview screen, choose a space.  
A list of applications deployed in the space appears.
2. In the application pane, select an application from the *Name* column.  
The application overview page appears.
3. In the navigation pane, choose *Security*.
4. Perform the following actions to control secured access to the application:

Task	Choose	Description
Create a new role	Roles from the navigation pane	<p>This option enables you to create roles. A role is an instance of a role template. You can create a role based on a role template and assign the role to a role collection. Role collections are then assigned to SAP HANA users or SAML 2.0 groups. Provide the following details to create a role:</p> <ul style="list-style-type: none"> <li>○ Name: Name of the role</li> <li>○ Description: Additional details about the role</li> <li>○ Template: Templates are predefined for an application. Choosing a template identifies the scope and attribute applicable for the role.</li> <li>○ Attribute: Provides attribute details applied to the role. Depending on the value of the attributes defined, access to resources is either granted or restricted. For example, in a sales scenario, the attribute region emea could be used to restrict access to the sales orders for the geographical region EMEA.</li> </ul>
Update a role description	Roles from the navigation pane. In the <i>Roles</i> pane, choose  (Edit) underneath the <i>Actions</i> column.	This option enables you to update the role description.
Delete a role	Roles from the navigation pane. In the <i>Roles</i> pane, choose  (Delete) underneath the <i>Actions</i> column.	This option enables you to delete a role.
Assign roles to role collections	Roles from the navigation pane. In the <i>Roles</i> pane, choose  (Add to role collection) underneath the <i>Actions</i> column.	This option enables you to assign roles to role collections.
Check scopes applicable for the role	Scopes from the navigation pane	This option enables you to view permissions available for a role.

Task	Choose	Description
Check attributes	Attributes from the navigation pane	Attributes define information that comes with the respective user, for example, 'cost center' or 'country'. This information can only be resolved at runtime.
Check role templates available for the application	Role templates from the navigation pane	The role template defines the type of access permitted for an application, for example, the authorization scope and any attributes that need to be applied.

### 13.2.3.1.5 Managing Hosts in XS Advanced

This page displays the host systems on which XS Advanced applications are running. It provides specific details about the number of applications running on a host system and the spaces pinned to it. It also displays whether an application can only run on a specific host.

#### Related Information

[Maintaining Host Pinning \[page 1864\]](#)

#### 13.2.3.1.5.1 View Host Systems

#### Context

#### Procedure

1. In the home navigation pane, choose *Host Management*.
2. Select a specific host to view the applications that can only run on this host and the spaces that are pinned to it.

## 13.2.3.1.5.1.1 Host System Details

The host management page displays the following information:

User Interface Element	Description
Host ID	Displays the host system.
Exclusive Pin	The value <b>Yes</b> indicates that the system is available exclusively for specific applications and spaces. The value <b>No</b> indicates that the system is available as a shared entity for all applications and spaces.
Pinned Applications	Displays the number of applications that are set to run on the host system.
Pinned Spaces	Displays the number of spaces mapped to the host system.

Pinned Applications section: This section displays an application and the corresponding space where it is deployed.

Pinned Spaces section: This section displays a space and the corresponding organization to which it belongs.

## 13.2.3.1.6 Maintaining Database Instances in XS Advanced

Applications deployed within a space in XS Advanced must be able to persist data. The XS Advanced Cockpit includes an option to maintain a database to persist application data. You can perform the following tasks to persist data:

- Create a database in XS Advanced
- Search for a database by name (or part of a name) in XS Advanced
- Display the status of all databases currently available in XS Advanced
- Enable a database for use with XS Advanced
- Disable a database in XS Advanced
- Delete a database in XS Advanced
- Map a database to an organization or space

### Related Information

[Maintaining Tenant Databases in XS Advanced \[page 1857\]](#)

## 13.2.3.1.6.1 Create a Database

### Context

Create a database to store data from applications available in XS Advanced.

### Procedure

1. In the home navigation pane, choose *Tenant Databases*.
2. On the *Tenant Databases* screen, choose *New Tenant Database*.

The new database is created with the status *Creating*. Eventually, the status automatically changes to *Running* or *Not Running*.

### Related Information

[Database Details \[page 1926\]](#)

#### 13.2.3.1.6.1.1 Database Details

You provide the following details while creating a new logical database:

User Interface Element	Description
Name	Name of the database

User Interface Element	Description
Internal Port	<p>This is an optional field. You can provide details of a specific port on the system to run the tenant database. The port must adhere to one of the following rules:</p> <ul style="list-style-type: none"> <li>Accepts a value range and meets the condition <math>(\text{port number} - (30000 + 40)) \% 3 == 0</math>. For example, the range can vary from 30040 to 30100.</li> </ul> <div style="border: 1px solid #ccc; background-color: #f0f0f0; padding: 10px; margin: 10px 0;"> <p><b>i Note</b></p> <p>The port value (3&lt;instance number&gt;00) varies with the instance number. If the instance number is 08, the port value will be 30800. Confirm the instance number on your system and provide the respective port details.</p> </div> <ul style="list-style-type: none"> <li>Accepts the port number of the default index server.</li> </ul>
Host	This is an optional field. If you want to host the tenant database on a specific system, provide the host details.
Tenant Database Password	Provide the password of the SYSTEM user to access the tenant database.
System Database User	Provide the SYSTEM user name as available on the SAP HANA system database.
System Database Password	Provide the password of the SYSTEM user of the SAP HANA system database.

## 13.2.3.1.6.2 Manage a Database

### Context

To use a database once you have created it, you need to enable and map the database to an organization or space.

### Procedure

- In the home navigation pane, choose *Tenant Database*.

2. On the *Tenant Database* screen, you can perform any of the following tasks:

Task	Choose	Description
Make a logical database available for use	Enable	To use the database once you have created it, you need to enable it. The enabled database is available for use in XS Advanced. This is a toggle option. After enabling, the toggle option appears as <i>Disable</i> .
Use an organization or space with a database	 (Map)	To persist application data, you must map an organization or a space to the database. You can map an organization to a single database whereas a space can be mapped to multiple databases or vice versa.
Prevent a database from being used	 (Disable)	To ensure that a database is no longer available for use with XS Advanced, you must disable the database. The selected database is then no longer available for use.
Delete a database	 (Delete)	You can remove a database by deleting it.
Search for a specific database from a list of available databases	Search	You can use <i>Search</i> to find an existing database by name (or any part of the name). If you enter only part of a name, the search option filters the list of logical databases and displays only those whose names include the string you typed. For example, if you type DB in the search field, the list of databases displayed is restricted to any names that contain "DB"; for example, "MyTenantDB", "DB1", or "MyLogicalDB5".

### 13.2.3.1.7 Managing Trust Certificates in XS Advanced

For secure connections between SAP HANA systems and XS Advanced applications, each system needs to maintain a trusted certificate. This page displays a list of certificates currently used to establish trusted

connections. It also displays whether the current certificate being used is still active, expired, or is due to expire. You can perform the following tasks:

- Create a certificate
- Set a certificate for the default domain
- Manage certificates

## Related Information

[Maintaining Trust Certificates in XS Advanced \[page 1850\]](#)

### 13.2.3.1.7.1 Upload a Certificate

#### Context

This option allows you to upload an existing certificate.

#### Procedure

1. In the home navigation pane, choose **Security** > **Trust Certificates**.
2. Choose **New Trust Certificate**.
3. In the **New Trust Certificate** dialog, provide the following details:

User Interface Element	Description
Alias	Name for the new trusted certificate. This name appears in the <i>Alias</i> column of the <i>Trusted Certificates</i> list.
Choose Certificate	Browse to the file containing the certificate.
Use with SAP HANA Service Broker	This option means that the certificate can be used when establishing the database connection.

## 13.2.3.1.7.2 Set Default Certificate

### Context

You also have the option to set a certificate for the default domain.

### Procedure

1. In the home navigation pane, choose ► *Security* ► *Trust Certificates* ►.
2. Choose *Set Platform Default Certificate*.
3. In the *Set Platform Default Certificate* dialog, provide the following details:

User Interface Element	Description
Choose Certificate	Browse to the file containing the certificate.
Choose Key	Private key in PKCS8 PEM format.

## 13.2.3.1.7.3 Manage Certificates

### Context

You can view created certificates or delete any unwanted certificates.

### Procedure

1. In the home navigation pane, choose ► *Security* ► *Trust Certificates* ►.
2. On the *Trust Certificates* screen, perform any of the following tasks:

Task	Choose	Description
View a certificate	 (View)	You can use this option to view the details of a certificate. This option is available underneath the <i>Actions</i> column.
Delete a certificate	 (Delete)	You can use this option to delete any unwanted certificates. This option is available under the <i>Actions</i> column.
Search for a specific certificate	Search	If the <i>Trust Certificates</i> screen lists a large number of certificates, you can use the search option to list a specific certificate. You can search for a certificate using any of the following certificate details:  alias, usage, issuer, or valid details.

### 13.2.3.1.8 Maintaining Security in XS Advanced

During application development, developers create authorization information for business users. This information is made available to the administrators who complete the authorization setup. They are responsible for assigning authorizations to business users.

Developers store authorization information as design-time role templates in the security descriptor file *xs-security.json*. Using the xsuaa service broker, they deploy the security information to a dedicated XS Advanced application. The XS Advanced administrators view the authorization information in role templates, which they use as part of the runtime configuration. The administrators use the role templates to build roles, which are aggregated in role collections. The role collections are then assigned to business users.

The tasks required to set up authorization artifacts in SAP HANA XS Advanced are performed using two distinct user roles: the application developer and the SAP HANA XS Advanced administrator. After the authorization artifacts have been deployed as role templates, the administrator of the SAP HANA XS Advanced application uses the role templates provided by the developers to build role collections and assign them to business users using the SAP HANA XS Advanced Cockpit.

#### i Note

To test authorization artifacts after deployment, developers can use the role templates to build role collections and assign authorizations to business users in the SAP HANA XS Advanced Cockpit.

The table below lists the sequence of tasks along with the user roles needed to set up authorization artifacts:

## Note

Application developers must have the *Space Developer* role in the required space. XS Advanced administrators must have the *XS\_AUTHORIZATION\_ADMIN* role.

Step	Task	User Role	Option to be Used
1	Specify the security descriptor file containing the functional authorization scopes for your application.	Application Developer	Text Editor
2	Create role templates for the XS Advanced application using the security descriptor file.	Application Developer	Text Editor
3	Create a service instance from the xsuaa service in XS Advanced using the service broker.	Application Developer	XS Advanced CLI tool / XS Advanced Cockpit
4	Bind the service instance to the XS Advanced application by including it in the manifest file.	Application Developer	Text Editor
5	Deploy the XS Advanced application.	Application Developer	XS Advanced CLI tool
6	If required, create a new role using role templates available within the application in the XS Advanced Cockpit.	XS Advanced administrator	Access applications within the space.
7	Create a role collection and assign roles to it.	XS Advanced administrator	Access applications within the space.
8	Assign the role collection to an SAML 2.0 identity provider or to SAP HANA database users.	XS Advanced administrator	Access applications within the space. Access SAML Identity Provider.
9	Assign the users to roles using the role collections	XS Advanced administrator	User interface of SAP HANA XS Advanced Cockpit

## Related Information

[Control Access to Applications \[page 1922\]](#)

[Managing SAML Identity Providers in XS Advanced \[page 1935\]](#)

[Manage Users \[page 1909\]](#)

[Map Role Collections to SAML IDP \[page 1939\]](#)

### 13.2.3.1.8.1 Access to XS Advanced Cockpit

#### Context

The XS Advanced Cockpit displays all the options required to maintain the XS Advanced model runtime configurations. The options listed in the following table are available only to users who have been assigned the suitable role collection. The table shows the role collection required to use an option.

Options	Role Collection	Comments
Monitor	XS_CONTROLLER_ADMIN	Based on the role collection assigned, the user is permitted to perform some, most, or all operations in the application. The different role collections are: <ul style="list-style-type: none"><li>• Admin : No access restrictions</li><li>• User: Modify access within the assigned organization or space</li><li>• Auditor: Read-only access within the assigned organization or space</li></ul>
Organization and Space Management	XS_CONTROLLER_USER or	
SAP HANA Service Broker Configuration	XS_CONTROLLER_AUDITOR	
Application Roles	XS_AUTHORIZATION_ADMIN or	Based on the role collection assigned, the user is permitted to perform some (or all) operations in the XS Advanced Cockpit. The different role collections are: <ul style="list-style-type: none"><li>• Admin: Full admin edit access to the tool</li><li>• Display: Read-only access to the tool</li></ul>
Trust Configuration	XS_AUTHORIZATION_DISPLAY	
Member Management	XS_USER_ADMIN	Based on the role collection assigned, the user is permitted to perform all operations in the application.

Options	Role Collection	Comments
SAP HANA Database Setup	XS_CONTROLLER_ADMIN	The user is permitted to perform all operations in the application.
Trusted Certificates		

As an administrator, you can see the default role collections available for your current role.

## Procedure

1. In the home navigation pane, choose **Security > Role Collections**.
2. On the *Role Collections* screen, perform any of the following tasks:

Tasks	Choose	Description
Create a new role collection	New Role Collection	You can use this option to create a role collection.
Edit a role collection	 (Edit)	You can use this option to update descriptions of the role collections that you have created. You cannot edit a default role collection.
Delete a role collection	 (Delete)	You can use this option to delete a role collection that you have created. You cannot delete the default role collection.

### 13.2.3.1.8.2 Assign Roles to Role Collection

#### Context

As an administrator, you can control access to applications by providing role-based access to business users. To provide role-based access, you select the role templates and roles available for an XS Advanced application. You then assign the roles to role collections. The role collections are then assigned to business users to authorize them to access the application.

## Procedure

1. In the home navigation pane, choose **Security** > **Role Collections**.
2. On the **Role Collections** screen, choose the name of the role collection that you created.
3. On the **Overview** screen, choose **Add Role**.
4. In the **Add Role** dialog, select an application from the **Application Identifier**.
5. Choose the respective **Role Template** and **Role**.

## Related Information

[Manage Users \[page 1909\]](#)

[Map Role Collections to SAML IDP \[page 1939\]](#)

### 13.2.3.1.9 Managing SAML Identity Providers in XS Advanced

You can configure an SAP HANA system to act as a service provider for XS Advanced applications that use single sign-on (SSO) authentication based on Security Assertion Markup Language (SAML) certificates.

The XS Advanced Cockpit includes Trust Configuration, which you can use to configure SAML identity providers at runtime. You must perform this step if you want your SAP HANA XS Advanced applications to use SAML assertions as the logon authentication method.

You can perform the following tasks:

- Create an SAML identity provider (IDP)
- Manage trust configurations
- Map role collections to an SAML IDP

#### **i** Note

If you want to use strong cryptographic keys with at least 256 bit in the SAML 2.0 assertion token, you must install Java Cryptography Extension (JCE) in your SAP JVM and activate the use of 'unlimited' cryptographic keys. Refer to SAP Note 1240081.

## Related Information

[SAP Note 1240081](#)

## 13.2.3.1.9.1 Create an SAML Identity Provider

### Prerequisites

You have configured the SAML identity provider with the assertion attribute **Groups** to be sent at runtime. Ensure that you have entered **G** in uppercase.

### Context

You need to create an SAML Identity Provider (IDP) for an SAML service provider to authenticate users signing in to the application by means of single sign-on (SSO). SAP HANA supports the use of SSO authentication based on Security Assertion Markup Language (SAML) certificates.

### Procedure

1. In the home navigation pane, choose **Security** > **Trust Configuration**.
2. On the **Trust Configuration** screen, choose **New Trust Configuration**.
3. Provide the required values.

### Related Information

[Trust Configuration Details \[page 1936\]](#)

## 13.2.3.1.9.1.1 Trust Configuration Details

You can choose the **Edit** option to view details of an SAML IDP. To provide the required details for trust configuration, choose **New Trust Configuration**.

User Interface Element	Description
Upload	Choose this button to upload the XML format of the SAML certificate.

User Interface Element	Description
Origin Key	Unique name for the SAML identity provider. This value is mandatory.
Name	Name of the remote SAML identity provider.
Description	More details describing the SAML identity provider.
Status	State of the SAML identity provider.
Show SAML login link on login page	If the value is set as <b>Yes</b> , the SAML link appears on the logon page.
Link Text	The text representing the SAML logon URL on the logon page.
Metadata	The text containing the SAML certificate.
Show Details	If the contents of the XML document are valid, the parsing process extracts the information that needs to be inserted into the Origin Key, Subject, Entity ID, and Issuer fields, and the URL fields such as Single Sign-On URLs and Single Log-out URLs.
Parse	Choose this option to validate the SAML certificate if it is copied in XML format.
SingleSignOn URL (RedirectBinding)	URL of the IDP endpoint for SSO requests using SAML redirect binding.
SingleSignOn URL (PostBinding)	URL of the IDP endpoint for SSO requests using SAML post binding.
SingleLogout URL (RedirectBinding)	URL of the IDP endpoint for single logout (SLO) requests using SAML redirect binding.
SingleLogout URL (PostBinding)	URL of the IDP endpoint for single logout (SLO) requests using SAML post binding.

## 13.2.3.1.9.2 Manage Trust Configuration

### Prerequisites

You have configured the SAML identity provider with the assertion attribute **Groups** to be sent at runtime. Ensure that you have entered **G** in uppercase. For information about how to configure the identity provider of

your choice, see the topic [Federation Attribute Settings of Any Identity Provider](#) in the SAP Cloud Platform guide.

## Context

You can modify the status or metadata details of SAML certificates. You can also delete unwanted certificates.

## Procedure

1. In the home navigation pane, choose [Security](#) > [Trust Configuration](#).
2. On the [Trust Configuration](#) screen, perform any of the following tasks:

Task	Choose	Description
Update the status of an SAML certificate	 (Edit)	You can use this option to change the status of a certificate. This option is available underneath the <a href="#">Actions</a> column.
Update the SAML metadata	Name of the <a href="#">SAML IDP</a> > <a href="#">Edit</a>	You can use this option to modify the SAML metadata.
Delete an unwanted SAML certificate	 (Delete)	You can use this option to delete an SAML certificate. This option is available underneath the <a href="#">Actions</a> column.

### 13.2.3.1.9.3 Generate Metadata to Configure Identity Provider

## Context

You need to generate a metadata (XML) file that contains information about the service provider (SAP HANA system) to configure the SAML identity provider. You do not have to be logged on to the SAP HANA XS Advanced Cockpit to generate the metadata.

## Procedure

1. Access the XS Advanced Cockpit logon screen.
2. In the address bar, replace /login with /saml/metadata.  
<authorizationEndpoint>/saml/metadata

Authorization end-point can be found by executing the command `xs -v` on the command line and looking for the key **authorizationEndpoint**. The metadata is downloaded. You can use the downloaded metadata to configure the SAML identity provider. The final step for providing SAML users with access to applications in the XS Advanced Cockpit is to map SAML assertion attributes with XSA attributes.

## Related Information

[Map Role Collections to SAML IDP \[page 1939\]](#)

[The XS Command-Line Interface \[page 1792\]](#)

## 13.2.3.1.9.4 Map Role Collections to SAML IDP

### Prerequisites

You have configured the SAML identity provider with the assertion attribute **Groups** to be sent at runtime. Ensure that you have entered **G** in uppercase.

### Context

Users maintained in an SAML identity provider need authorization scopes to access XS Advanced applications. These scopes are contained in roles grouped in role collections. To provide authorization scope to SAML users logging on to an application using single sign-on (SSO), or using SAML-based SSO, you need to map SAML assertion attributes to XSA attributes.

## Procedure

1. In the home navigation pane, choose **Security** > **Trust Configuration**.
2. On the **Trust Configuration** page, choose the name of the SAML IDP.  
The **Overview** page of the SAML IDP appears.

3. In the trust configuration navigation pane, choose [Role Collection Mappings](#).
4. Choose [New Role Collection Mapping](#).
5. In the [Create Role Collection Mapping](#) dialog, provide the following details:

User Interface Element	Description
Role Collection	The dropdown list contains names of assertion-based role collections associated with the selected application.
Attribute	Displays the attribute defined in the selected application's security configuration (xs-security.json) file. Currently, the only attribute allowed is <a href="#">Groups</a> .
Operator	The operator to be used along with the attribute in the specified rule. Currently, the only operator allowed is <a href="#">equals</a> .
Value	The value of the attribute to be used for the rule that triggers the assignment of the selected role collection.

### 13.2.3.1.10 Managing Services in XS Advanced

Every space contains a service marketplace.

The marketplace displays SAP-approved services available for the space. Based on your role, you can access and use the services with your application. To use a service with your application, create an instance of the service. Once the instance is created, you can bind the instance to your application. You can also bind the application later using the [Service Instance](#) page, which lists instances of services.

User-provided services enable you to use services with your application that are not listed in the service marketplace, or custom services.

#### Related Information

[Maintaining Services in XS Advanced \[page 1834\]](#)

## 13.2.3.1.10.1 Create Service Instances

### Context

To use a service from a service marketplace with an XS Advanced application, you need to create an instance of the service. Once the instance is created, you bind it to the application.

### Procedure

1. Navigate to the Organization > Space in which the application is deployed.
2. Choose the application.  
The application overview page appears.
3. In the navigation pane, choose *Service Bindings*.
4. In the service bindings pane, choose *Bind Service*.
5. Choose one of the following options:
  - *Service from the Catalog*: Use this option to bind to a service instance from the service marketplace.
  - *User-Provided Services*: Use this option to bind to a user-provided service instance.
6. Choose *Next*.
7. Select a service.
8. Choose *Next*.
9. Choose one of the following options:
  - *Create new instance*: This option creates a new instance of the service. Accordingly, choose a service plan.
  - *Re-use existing instance*: This option enables you to bind the application to an existing instance of the service.
10. Choose *Next*.
11. (Optional) Provide parameters that need to be passed to the application during binding, or provide a file with JSON format.
12. Choose *Next*.
13. Enter a name for the service instance.
14. Choose *Finish*.

The service instance is created and then bound to the application.

## 13.2.3.1.10.2 Manage User-Provided Services

### Context

To use services that are not listed in the service marketplace with your application, you need user-provided services. User-provided service instances deliver service credentials to an application. A service instance for user-provided services behaves like the service instance created from the service marketplace.

### Procedure

1. In the space navigation pane, choose **Services** > **User-Provided Services**.
2. In the **User-Provided Services** pane, choose **New Instance**.
3. Provide an instance name.
4. Enter the service credentials required to deliver to the application.
5. Choose **Save**.

The service instance is created. Similarly to services from the service marketplace, you need to bind the user-provided service instance to an application.

### Related Information

[Create Service Instances \[page 1941\]](#)

## 13.2.3.1.11 Viewing Audit Logs in XS Advanced

You can use audit logs to check the various system logs (data access logs, security event logs, configuration change logs, or data modification logs) for the Java runtime environment using different criteria. You can use any of the logs for troubleshooting and identifying the cause of an issue.

Before you can use the XS Advanced Audit Log UI, you must make the following configuration settings:

- Configure your application for the audit log service.
- Set the necessary authorizations for your user.

To access the Audit Log tool, you can use either the XSA\_ADMIN user (who already has the required scopes) or a different user, to whom you must assign a role collection that includes the AuditLogViewer role. You can choose the application and configure a role collection with the following information:

- Application name: auditlog-ui

- Application role: AuditLogViewer
- Template name: AuditLogViewer

Choose *User Management* to assign the custom role collection to the user.

## Related Information

[Configure an Application to Use the Audit Log Service](#)

### 13.2.3.1.11.1 Start Audit Log Viewer from SAP HANA XS Advanced Cockpit

Use the Audit Log Viewer to display XS advanced audit logs.

## Prerequisites

- You have configured your application for the audit log service. For more information, see *Configure an Application to Use the Audit Log Service*.
- You have set the necessary authorizations for your user. For more information, see *Viewing Audit Logs in XS Advanced*.

## Procedure

1. In the SAP HANA XS Advanced Cockpit home navigation pane, choose *More...*  
The *View Audit Logs* tile appears.
2. Choose the *View Audit Logs* tile to display the *Audit Logs* interface.

## Results

You are redirected to the *Audit Logs* Viewer.

## Related Information

[Configure an Application to Use the Audit Log Service](#)

## 13.2.3.2 Scheduling Jobs in XS Advanced

The Job Scheduler service enables you to create and schedule long-running operations or jobs.

In the SAP HANA XS advanced model, Job Scheduler is an application service. The Job Scheduler service enables you to create and schedule long-running operations or jobs. This service is deployed during the installation of the SAP HANA XS advanced model.

For high availability of Job Scheduler service, you can scale the service. All components of the Job Scheduler application such as Job Scheduler service, Job Scheduler REST, and Job Scheduler Broker support scaling. Scaling is required in scenarios where you have too many schedules, resulting in job execution delays. You need to scale only the job scheduler service component for the delay scenario. Scaling of the job scheduler service involves increasing the instance of the service. For more information about scaling applications, refer the *Scaling Applications in XS Advanced* topic.

The following table lists the sequence of tasks required to use an instance of the Job Scheduler service:

### i Note

To configure and setup Job Scheduler, you require specific roles and permissions.

Step	Task	Role
1	Configure the Service Broker for Job Scheduler	Space Developer
2	Create a Job Scheduler Service Instance	Space Developer
3	Bind an Application to the Job Scheduler Service	Space Developer
4	Maintain jobs and job schedules	Administrator. To access and use the Job Scheduler Dashboard without having an administrator role, refer <i>The Job Scheduler Dashboard</i> topic.

## Job Scheduler Execution Mode

Job Scheduler supports the following **modes** for applications to execute a job:

- Synchronous Mode  
Suitable for jobs that run for a short span of time, for example, an OData service endpoint. If an application uses this mode, it must adhere to the following guidelines:
  - When the scheduler invokes the endpoint, the application must return the response with appropriate HTTP status codes, indicating success or failure.
  - To indicate success, the application must use a suitable standard status code between 200 and 399, except 202-ACCEPTED.
  - To indicate an execution failure, the application must use one of the server error codes as outlined in the HTTP protocol specification.
- Asynchronous Mode  
Suitable for jobs that run for a long span of time, for example, endpoints which trigger batch processing. If an application uses this mode, it must comply with the following guidelines and workflow:

- When the scheduler invokes the endpoint, it passes the request headers **x-sap-job-id**, **x-sap-job-schedule-id**, **x-sap-job-run-id**, and **x-sap-scheduler-host** values for the Job ID, Job Schedule ID, Job Run ID, and the Job Scheduler Host URI, respectively. The application must extract the header values and store them using a suitable mechanism, such as in-memory storage that uses caches or libraries, or persistent storage that uses a database.
- The application must return an acknowledgement response with the HTTP status code **202-ACCEPTED**. This response is an indication to the scheduler that the application has accepted and is processing the request. If the application returns a server error code, the scheduler interprets it as a failure of the job run.
- After the application completes the job processing, it must invoke the **Job Run Log Update** API to indicate success or failure and (optionally) create log text for the job run. For information about this API, see *Job Scheduler REST API for XS Advanced* topic . The path parameters for the **Job Run Log Update** API call must be the values of the headers as described above.
- If the application doesn't invoke the **Job Run Log Update** API, the scheduler isn't notified of the status of the job run and, after a configurable time interval, reverts the job to the status UNKNOWN.

## Behavior of Job Scheduler

Job Scheduler contains certain default behaviors that you can override. To override the default behavior, define parameters with specific values in the mtaext file during deployment. For more information about the mtaext file, refer to the topic *The MTA Deployment Extension Descriptor*, in the *SAP HANA Developer Guide for SAP HANA XS Advanced Model*. The default behaviors are as follows:

- Triggering missed executions (**ENABLE\_MISFIRE**): Job Scheduler uses this parameter to trigger all missed schedules as soon as it recovers from downtime.
- Checking new schedules (**SCHEDULER\_CHECKIN\_INTERVAL**): This parameter defines the duration after which Job Scheduler checks for new schedules. The value for this parameter is set in seconds. The default value being 120 seconds (2 mins). You can configure this duration based on system/application requirements. It is recommended not to set the polling duration for less than 60 seconds (1 minute).
- Make Job Scheduler configurable (**ENABLE\_JOBSCHEDULER**): This parameter enables Job Scheduler to poll for new schedules or run any queries. Disabling this option will prevent Job Scheduler from creating or editing any new jobs or schedules.

With the release of **XS Advanced Job Scheduler version SP06 Patch 14 for XS SERVICES 1 or 1.6.15**, deployment of XS Advanced Job Scheduler can be configured to override the default behaviors.

For overriding the default behavior in case of previous deployments, you can upgrade the Job Scheduler component to **SP06 Patch 14 for XS SERVICES 1** or version **1.6.15** or higher.

### Note

Use the mtaext file for any Job Scheduler deployment, install, or update scenarios. In the absence of this file, existing values will be overwritten by default values.

Default values are overridden by changing specific properties in the mtaext file. A sample mtaext file with default behavior appears as below:

### Sample Code

```
_schema-version: "2.0.0"
```

```

ID: com.sap.xs.jobscheduler
extends: com.sap.xs.jobscheduler
modules:
  - name: jobscheduler-service
    properties:
      ENABLE_MISFIRE: "true"
      ENABLE_JOBSCHEDULER: "true"
      SCHEDULER_CHECKIN_INTERVAL: 120
  - name: jobscheduler-broker
    properties:
      ENABLE_JOBSCHEDULER: "true"

```

Deploy jobscheduler with the mtaext file using the command

```
xs deploy <Job_scheduler.mtar> -e <absolute-path-of-mtaext-file>
```

### ❁ Example

```
xs deploy MTA_archive.mtar -e myMTADeployExtension.mtaext
```

## Job Scheduler Execution Type

Job Scheduler provides the following **types** of schedules for a job:

- **Recurring Schedule**  
Runs periodically at a specified time, dates, or interval. Recurring schedules can be created in the following ways:
  - The `repeatInterval` parameter:  
Defines the interval in human-readable text (for example, "2 minutes"), which can be used to set up a recurring schedule. The repeat interval defines the gap between each run of the schedule.
  - The `cron` parameter:  
Defines a `cron` expression (for example, "`cron`": "`* * * * *`" ) used to represent a set of times, when the job is executed. The cron format referred here is the `xscron` format and not the publicly used Linux `cron`. For more details about the `xscron` format, see *The XS Job File in Related Information* below.
  - The `repeatAt` parameter:  
Defines the exact time, every day, when the job is executed.
- **One-Time Schedule**  
Runs only once at the specified time. One-time schedules can be created in the following ways:
  - Human-readable text string:  
A human-readable text string that defines the specific time for schedule execution (for example: "10 hours from now", "3.30pm", or "Friday at 2am" )
  - Using a `Date` object, with a pre-defined format, for example,  
"`startTime`": { "`date`": "2015-10-20 4:30 +0000", "`format`": "YYYY-MM-DD HH:mm Z" }  
The string is checked against both IETF-compliant RFC 2822 timestamps and ISO-8601

## Job Scheduler Access

Job Scheduler can be accessed and used in the following ways during application development:

- APIs:  
The Job Scheduler service offers RESTfull and client specific APIs for Java and Node.js. The administrator **scope** is required to use the Job Scheduler API to maintain run time configurations for jobs and job schedules.
- User Interface:  
The *Job Scheduler Dashboard* is the tool used to manage the jobs and job schedules. Administrator authorization is required to maintain jobs and job schedules in the *Job Scheduler Dashboard*. For more information about permissions required to access the dashboard, see *The Job Scheduler Dashboard* topic.

### i Note

You can program actions in any programming language or platform. The runtime also supports jobs created in the SAP HANA XS classic version.

### 13.2.3.2.1 Maintain Jobs and Job Schedules in XS Advanced

Maintain run time configurations for jobs and job schedules in SAP HANA XS advanced.

## Prerequisites

- The service broker and the service instance for the Job Scheduler service are available.
- The application using the Job Schedule is deployed in the space and bound to the Job Scheduler service instance.
- You have the authorization scope for POST, PUT, and DELETE requests (for example, *jobscheduler.Admin*).
- To access the *Job Scheduler Dashboard*, you must have the authorization scopes defined in the roles grouped together in one of the following role collections:
  - XS\_CONTROLLER\_ADMIN  
Full access: no access restrictions
  - XS\_CONTROLLER\_USER

- Modify and read-only access
- XS\_CONTROLLER\_AUDITOR
  - Read-only access

### → Tip

Role collections can be assigned to an SAP HANA user in SAP HANA studio by means of user parameters, for example, XS\_RC\_XS\_CONTROLLER\_ADMIN or XS\_RC\_XS\_CONTROLLER\_USER, or XS\_RC\_XS\_CONTROLLER\_AUDITOR.

## Context

To maintain jobs and job schedules, you use the Job Scheduler REST APIs (for example, *Job Creation*, *Job Configuration*, or *Job Deletion*) as illustrated in the following examples.

### i Note

The code examples are not always complete; they are intended for illustration purposes only.

## Procedure

1. Create a new job.

Use the *Job Creation* API (POST /scheduler/Jobs), as illustrated in the example request:

```
POST /scheduler/jobs HTTP/1.1
Host: localhost:4242
Authorization: Basic YWJjOmRlZg==
Content-Type: application/json
Cache-Control: no-cache
{"name":"validateSalesOrder", "description": "cron job that validates sales
order requests", "action":"http://salesOrderApp.hana.acme.com:40023/
salesOrders/validate","active": true, "httpMethod":"PUT", "schedules":
[{"cron":"* * * * * */10", "description": "this schedule runs every 10
seconds", "data":{"salesOrderId":"1234"}, "active": true, "startTime":
{"date": "2015-10-20 04:30 +0000", "format": "YYYY-MM-DD HH:mm Z"}}]}
```

The response to the job-creation request should look like the following example:

```
{"name": "validateSalesOrder", "action":"http://salesOrderApp.hana.acme.com:
40023/salesOrders/
validate","active":true,"httpMethod":"PUT","description":"cron job that
validates sales order
requests","startTime":null,"endTime":null,"signatureVersion":0,"schedules":
[{"active":true,"startTime":"2015-10-20
04:30:00","endTime":null,"description":"every 10 seconds, every 2
minutes","data":{"salesOrderId":"1234"},"cron":"* * * * * */
10","type":"recurring","scheduleId":"cb5c9def-
e2a0-4294-8a51-61e4db373f99"}], "_id":3}
Headers:
Connection → keep-alive
Content-Length → 468
```

```
Content-Type → application/json; charset=utf-8
Date → Mon, 09 Nov 2016 09:08:53 GMT
ETag → W/"1d4-P7BnAm3yordzbrYyJtpalg"
Location → /scheduler/jobs/3
X-Powered-By → Express
```

## 2. Modify (configure) a new job.

Use the *Job Configuration* API (PUT /scheduler/Jobs), as illustrated in the example request:

```
PUT /scheduler/jobs/3 HTTP/1.1
Host: localhost:4242
Authorization: Basic YWJjOmRlZg==
Content-Type: application/json
Cache-Control: no-cache
{"active": true, "user": "abc", "password": "def", "httpMethod": "GET"}
```

The response to the job-configuration request should look like the following example:

```
{"success": true}
Headers:
Connection → keep-alive
Content-Length → 16
Content-Type → application/json; charset=utf-8
Date → Mon, 09 Nov 2016 09:30:36 GMT
ETag → W/"10-c2PoX+nt7m8FOksxlYjAhg"
X-Powered-By → Express
```

## 3. Delete an existing job.

Use the *Job Deletion* API (DELETE /scheduler/Jobs), as illustrated in the example request:

```
DELETE /scheduler/jobs/4 HTTP/1.1
Host: localhost:4242
Authorization: Basic YWJjOmRlZg==
Content-Type: application/json
Cache-Control: no-cache
```

The response to the job-deletion request should look like the following example:

```
{"success": true}
Headers:
Connection → keep-alive
Content-Length → 16
Content-Type → application/json; charset=utf-8
Date → Mon, 09 Nov 2016 09:30:36 GMT
ETag → W/"10-c2PoX+nt7m8FOksxlYjAhg"
X-Powered-By → Express
```

## 4. Create a new job schedule.

Use the *Job Schedule Creation* API (POST /scheduler/jobs/3/schedules), as illustrated in the example request:

```
POST /scheduler/jobs/3/schedules HTTP/1.1
Host: localhost:4242
Authorization: Basic YWJjOmRlZg==
Content-Type: application/json
Cache-Control: no-cache
{"repeatEvery": "2 hours", "data": {"order_id": "abcd"}, "active": true,
 "description": "New Schedule", "startTime": {"date": "2016-04-21", "format":
 "YYYY-MM-DD"}}
```

The response to the job-schedule creation request should look like the following example:

```
"repeatInterval": "2
hours", "repeatAt": null, "time": null, "cron": null, "data": "{ \"order_id\": \"abcd
\\\" }\", \"description\": \"New
Schedule\", \"type\": \"recurring\", \"active\": true, \"startTime\": \"2016-04-21
18:30:00\", \"endTime\": null, \"jobId\": 3, \"scheduleId\": \"0e29c67c-563e-4931-
af08-43acb10813e8\"}
Headers:
Connection → keep-alive
Content-Length → 274
Content-Type → application/json; charset=utf-8
Date → Mon, 09 Nov 2016 09:42:13 GMT
ETag → W/\"112-rdQSXHBVY0u6JNI/Wf0I7w\"
Location → /scheduler/jobs/3/schedules/0e29c67c-563e-4931-af08-43acb10813e8
X-Powered-By → Express
```

#### 5. Delete an existing job schedule.

Use the *Job Schedule Deletion* API (DELETE /scheduler/jobs/3/schedules), as illustrated in the example request:

```
DELETE /scheduler/jobs/4 HTTP/1.1
Host: localhost:4242
Authorization: Basic YWJjOmRlZg==
Content-Type: application/json
Cache-Control: no-cache
```

The response to the job-schedule deletion request should look like the following example:

```
{ \"success\": true }
Headers:
Connection → keep-alive
Content-Length → 16
Content-Type → application/json; charset=utf-8
Date → Mon, 09 Nov 2016 09:51:39 GMT
ETag → W/\"10-c2PoX+nt7m8FOksxlyjAhg\"
X-Powered-By → Express
```

[Job Scheduler REST API for XS Advanced \[page 1950\]](#)

[The Job Scheduler Dashboard \[page 1967\]](#)

[Scheduling Jobs in XS Advanced \[page 1944\]](#)

### 13.2.3.2.1.1 Job Scheduler REST API for XS Advanced

The Job Scheduler APIs enable applications to use the functionality provided in Job Scheduler.

The Job Scheduler-as-a-Service is a microservice component, which enables you to create, schedule, and run application tasks. The component exposes REST endpoints for interaction, with JSON as the format for data communication. The Job Scheduler API for SAP HANA XS advanced includes the commands listed in the following table. For more information about the configuration parameters required for the request, see the API documentation provided with the *Job Scheduler Dashboard* tool.

## i Note

Access to the APIs is controlled by authorization scopes, for example, `admin` for `POST` and `PUT` requests, or `view` for `GET` requests. Scopes are built into roles, which can be assigned to users in role collections. The Job Scheduler REST APIs are protected with basic authentication.

An application, which has been bound to the Job Scheduler service and wants to interact with the Job Scheduler service, must extract the authentication credentials from the `<VCAP_SERVICES>` environment variable and use these credentials to call the REST APIs. To invoke the API, the user-authentication credentials must be encoded and passed in the "Authorization" header. If the credentials are not passed or they are passed wrongly, the APIs return a response with the status code "401- Unauthorized".

In this section, you can find information about the following topics:

- [Command Overview](#)
- [Human-Readable Dates](#)
- [Time Formats](#)

## Command Overview

XS Advanced Job Scheduler REST API

API	Description	Required Scope
<a href="#">Job Creation</a>	Used to create a job. Job creation can accept a collection of job schedules to be created.	<code>admin</code>
<a href="#">Job Configuration</a>	Configure a job with updated run time information. The API can also be used to create a job if a Job with the Job Name in the URI segment, is not found.	<code>admin</code>
<a href="#">Job Deletion</a>	Delete a job and purge all its run time information such as job schedules and logs.	<code>admin</code>
<a href="#">Job Schedule Creation</a>	Create a job schedule for a specified job. All job configuration values (Action URL, HTTP Method, User, Password & Job Activation Status) are valid for the newly created schedule. A job schedule will only run if both the job and the schedule are active.	<code>admin</code>
<a href="#">Job Schedule Modification</a>	Configure the run time information of a job schedule for a specified job. All job configuration values (for example: Action URL, HTTP Method, User, Password, and Job Activation Status) remain valid for the modified schedule.	<code>admin</code>
<a href="#">Job Schedule Deletion</a>	Delete and purge run time information of the job schedule of the specified job. All related information like job schedule configurations and logs are purged. The processing of the schedule is also immediately stopped.	<code>admin</code>

API	Description	Required Scope
<a href="#">Bulk Job Schedule Activation</a> <a href="#">Bulk Job Schedule Deactivation</a>	This is a utility API used to activate or deactivate all existing schedules of a job. This API triggers the immediate processing (or a halt in processing) of all job schedules for the specified job.	admin
<a href="#">Job Details</a>	Retrieve the saved details and configurations of a specified job. If the <code>displaySchedules</code> parameter is not provided, the schedules for the job are not returned and only the job details are returned.	view
<a href="#">Job Schedule Details</a>	Retrieve the saved details and configurations of a specified job schedule & optionally the generated logs for the schedule.	view
<a href="#">Bulk Job Schedule Deletion</a>	Delete and purge run time information of all the currently configured job schedules of the specified job. All related information like job schedule configurations and logs are purged. The processing of the schedules is also immediately stopped.	admin
<a href="#">Job Run Log Update</a>	Used by applications, to inform the Job Scheduler about the status of an asynchronous, long-running job run.	admin

## Job Creation

To create a job schedule, at least one of the fields `repeatAt`, `repeatEvery`, `cron` and `time` must be used. The response from the job creation API is a JSON body with the job details, including the ID of the job.

- **Route**

POST /scheduler/jobs

- **Response**

A JSON body containing the job details, including the ID of the job with status code "201-CREATED", if the call was successful. A location header with the relative path to the job-details is included in the response.

### Sample Code

```
{
  "name": "validateSalesOrder",
  "description": "cron job that validates sales order requests",
  "action": "http://salesOrderApp.hana.ondemand.com:40023/salesOrders/validate",
  "active": true,
  "httpMethod": "PUT",
  "schedules": [
    {
      "cron": "* * * * */10 0",
      "description": "this schedule runs every 10 minutes",
      "data": {
        "salesOrderId": "1234"
      },
      "active": true,
      "startTime": {
        "date": "2015-10-20 04:30 +0000",
        "format": "YYYY-MM-DD HH:mm Z"
      }
    }
  ]
}
```

```

    }
  }
]
}

Response:
{
  "name": "validateSalesOrder",
  "action": "http://<application-url>/action",
  "active": true,
  "httpMethod": "PUT",
  "description": "cron job that validates sales order requests",
  "startTime": null,
  "endTime": null,
  "signatureVersion": 0,
  "schedules": [
    {
      "active": true,
      "startTime": "2015-10-20 04:30:00",
      "endTime": null,
      "description": "every 10 seconds, every 2 minutes",
      "data": "{\"salesOrderId\":\"1234\"}",
      "cron": "* * * * * */10",
      "type": "recurring",
      "scheduleId": "schedule ID details"
    }
  ],
  "_id": 3
}

```

The job schedule creation request is defined with the parameters listed in the following table:

### i Note

Parameters marked with an asterisk (\*) are mandatory.

#### Job Creation: Request Body Fields

Request Field	Type	Description
name *	String	The unique name of the job to be created
		<h3>i Note</h3> <p>If a job with the same name for the technical user credentials already exists, the job creation request fails.</p>
description	String	Describes the user-defined job
action *	String	The fully qualified URL endpoint to be called when the job runs, for example: http://host.acme.com/app/call
active	Boolean	Defines if the job should be activated on creation. Allowed values are: <ul style="list-style-type: none"> <li>false (default) The job is in inactive mode on creation</li> <li>true The job is activated on creation</li> </ul>

Request Field	Type	Description
httpMethod	String	The HTTP method to be used to call the end-point URL for the job action . Allowed values are: GET, POST (default), PUT, and DELETE
startTime	Object	The start time for the job. If the start time is specified for the job, the scheduler checks if a start time is provided for the schedule as well. If a start time is provided for the schedule, it is used for determining the start of the schedule run. If no job-schedule start time is defined, the start time for the job is used. The date and time-formats must be specified as strings.
endTime	Object	The end time for the job. If the end time is specified for a job, the scheduler checks if an end time is provided for the schedule as well. If an end time is provided for the schedule, it is used for determining the end of the schedule run. If not, the end time for the job is used. The date and time-formats must be specified as strings.
schedules *	Array	The array of job schedule objects, to be created on job creation.

The `schedules` parameter can be used to provide details of the job schedule (as properties of each job schedule object); the following table lists the permitted properties:

#### Schedule Parameter Fields

Schedule Field	Type	Description
data	object	Optional data to be passed to the job action endpoint when invoked. Typically, the custom data is sent based on the HTTP method configured for invoking the end point URL, for example: <code>{ "dataParam": "somevalue" }</code>
time	string or object	For one-time schedules, the parameter denoting the time at which the task executes. A human-readable text can be used to specify the time, for example, "3.30pm" or "tomorrow at 2am". If an object is used, the date and time-formats must be specified as strings.
repeatInterval	string	For recurring schedules, the parameter denoting the intervals when the schedule should run. The parameter supports the use of human readable formats.
repeatAt	string	For recurring schedules, the parameter denoting the exact time when the job schedule must run. A human-readable text can be used to denote a specified time, for example, "3.30pm" or "tomorrow at 2am", if the schedule runs repeatedly.
cron	string	For recurring schedules, the parameter denoting the cron pattern. It must be a valid cron tab format, for example: <code>"* * * * * */10"</code>
startTime	object	The time when the job scheduling should start. The date and time-formats must be specified as strings.

Schedule Field	Type	Description
endTime	object	The time when the job scheduling should end. The date and time-formats must be specified as strings
description	string	The user-provided description of the job schedule

## Job Configuration

Configure a job with updated run time information. The API can also be used to create a job if a Job with the Job Name in the URI segment, is not found. If the API is being used to create a job, the parameters must conform to the same constraints as provided in the Job Creation API

- **Route**

```
PUT /scheduler/jobs/:jobId
```

```
PUT /scheduler/jobs/:jobName
```

“:jobId” is the ID of the job previously created using the Job Creation API. If the job name is used in the URI, it is first checked if the job with the name, exists. If no such named job exists, the API tries to create the job. If it does exist, the API configures the job with the details provided in the request body.

### i Note

If the API is used to create a job, care must be taken to ensure that the job name in the request URI matches the name of the job in the request body. If the names do not match, an error is returned.

- **Response**

If the API finds an existing job, the response has a status code of “200-OK”, if the call was successful. The response has a status code of “201-CREATED”, if the API is used to create a new job; for new jobs, a location header containing the relative path to the job-details is returned in the response.

### Sample Code

```
PUT /schedule/jobs/5 HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
content-length: 500
{"active": true, "user":"abc", "password":"def", "httpMethod": "GET"}
```

```
Response:
status: 200 OK
content-type: application/json; charset=utf-8
{"success": true}
```

### Sample Code

```
PUT /schedule/jobs/jobwhichdoesnotexist HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
content-length: 500
{"name":"jobwhichdoesnotexist", "jobDescription": "greet the world
periodically", "action":"http://httpbin.org/basic-auth/abc/
```

```
def", "active": true, "httpMethod": "GET", "schedules": [{"repeatEvery": "2
minutes", "scheduleDescription": "every 2 minutes, run this schedule", "data":
{"time": "abc"}, "active": true}, {"cron": "* * * * *", "scheduleDescription":
"every 4 minutes, run this schedule", "data": {"time": "abc"}, "active":
false}]}
```

```
Response:
status: 201 CREATED
content-type: application/json; charset=utf-8
{"_id": 120, "name": "jobwhichdoesnotexist", "description": "", "action": "http://
httpbin.org/basic-auth/abc/
def", "active": true, "user": null, "httpMethod": "GET", "schedules":
[{"scheduleId": "b373469c-c6d4-4d5f-a002-c56f18455dc5", "description": "Default
Schedule", "data":
{"time": "abc"}, "type": "recurring", "active": true, "startTime": null, "endTime": nul
l, "repeatInterval": "2 minutes"}, {"scheduleId": "2f98471c-26de-4293-ae53-
e4a16e1513f5", "description": "Default Schedule", "data":
{"time": "abc"}, "type": "recurring", "active": false, "startTime": null, "endTime": nu
ll, "cron": "* * * * *"}]}
```

The job schedule configuration request is defined with the parameters listed in the following table:

#### Job Creation: Request Body Fields

Request Field	Type	Description
active	Boolean	Defines if the job should be activated on configuration. Allowed values are: <ul style="list-style-type: none"> <li>false (default) The job is in inactive mode when configured</li> <li>true The job is active when configured</li> </ul>
user	String	The name of the user account to run the configured job
password	String	The password for the user account to run the configured job
httpMethod	String	The HTTP method to be used to call the end-point URL for the job action . Allowed values are: GET, POST (default), PUT, and DELETE
startTime	Object	The start time for the job. If the start time is specified for the job, the scheduler checks if a start time is provided for the schedule as well. If a start time is provided for the schedule, it is used for determining the start of the schedule run. If no job-schedule start time is defined, the start time for the job is used. The date and time-formats must be specified as strings.
endTime	Object	The end time for the job. If the end time is specified for a job, the scheduler checks if an end time is provided for the schedule as well. If an end time is provided for the schedule, it is used for determining the end of the schedule run. If not, the end time for the job is used. The date and time-formats must be specified as strings.

## Job Deletion

Delete a job and purge all its run time information such as job schedules and logs.

- **Route**  
DELETE /scheduler/jobs/:jobId
- **Response**  
If the call is successful, the response has a status code "200-OK" and includes a JSON response {"success": true}.

### Sample Code

```
DELETE /schedule/jobs/:jobId HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
```

```
Response: Status: 200 OK
Content-Type: application/json;charset=utf-8
{"success":true}
```

## Job Schedule Creation

Create a job schedule for a specified job. All job configuration values (Action URL, HTTP Method, User, Password & Job Activation Status) are valid for the newly created schedule. A job schedule will only run if both the job and the schedule are active.

- **Route**  
POST /scheduler/jobs/:jobId/schedules
- **Response**  
If the call is successful, the response has a status code of "201-CREATED". A location header with the relative path to the schedule-details, is returned in the response.

### Sample Code

```
PUT /scheduler/jobs/3/schedules
{
  "repeatInterval":"2 hours",
  "active":true,
  "description":"New Schedule",
  "startTime": {
    "date": "2017-08-21",
    "format": "YYYY-MM-DD"
  }
}
```

```
Response:
{
  "repeatInterval": "2 hours",
  "repeatAt": null,
  "time": null,
  "cron": null,
  "data": "{\\"order_id\\":\\"abcd\\"}",
  "description": "New Schedule",
```

```

    "type": "recurring",
    "active": true,
    "startTime": "2015-04-20 18:30:00",
    "endTime": null,
    "jobId": 3,
    "scheduleId": "<schedule ID details>"
  }

```

#### Job Schedule Creation Parameters

Request Field	Type	Description
time	string or object	For one-time schedules, the parameter denoting the time at which the task executes. A human-readable text can be used to specify the time, for example, "3.30pm" or "tomorrow at 2am". If an object is used, the date and time-formats must be specified as strings.
repeatInterval	string	For recurring schedules, the parameter denoting the interval when the schedule should run. The parameter supports the use of human readable formats.
repeatAt	string	For recurring schedules, the parameter denoting the exact time when the job schedule must run. A human-readable text can be used to denote a specified time, for example, "3.30pm" or "tomorrow at 2am", if the schedule runs repeatedly.
cron	string	For recurring schedules, the parameter denoting the cron pattern. It must be a valid crontab format, for example: "* * * * * */10"
data	object	The parameter denoting optional data to be passed to the job action endpoint when invoked. Typically, the custom data is sent based on the HTTP method configured for invoking the end point URL, for example: {"dataParam": "somevalue" }
startTime	object	The time when the job scheduling should start. The date and time-formats must be specified as strings.
endTime	object	The time when the job scheduling should end. The date and time-formats must be specified as strings
active	Boolean	Defines if the job should be activated on configuration. Allowed values are: <ul style="list-style-type: none"> <li>• false (default) The job is in inactive mode when configured</li> <li>• true The job is active when configured</li> </ul>
description	string	The user-provided description of the job schedule

## Job Schedule Modification

Configure the run time information of a job schedule for a specified job. All job configuration values (for example: Action URL, HTTP Method, User, Password, and Job Activation Status) remain valid for the modified schedule.

- **Route**  
PUT /scheduler/jobs/:jobId/schedules/:scheduleId
- **Response**  
If the call is successful, the response has a status code of 200– OK.

Calling this API stops further scheduling of the previously configured job schedule and, if activated, the processing for the newly configured schedule is started. This API cannot be used to change the scheduling mode for the job schedule. For example, if the schedule was created as a recurring “cron”-type schedule, it cannot be changed to a “repeatEvery”-type schedule. However, existing schedule values can be changed.

### Sample Code

```
PUT /schedule/jobs/:jobId/schedules/:scheduleId HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
content-length: 500
{"description": "Edited Schedule", "startTime": {"date": "2013-02-08
09:30:26.123"}, "endTime": {"date": "2015-06-08 09:30:26.123"}, "active":
true, "cron": "* * * * *"} }
```

```
Response:
Status: 200 OK
Content-Type: application/json; charset=utf-8
{"scheduleId":"80e23846-734e-4b4b-a130-159a492ec482","name":"greet the
world3","data":{"time":"abc"},"type":"recurring","priority":
0,"action":"http://httpbin.org/basic-auth/abc/
def","nextRunAt":"2015-04-23T03:58:21.358Z","startTime":"2013-02-08T04:00:26.1
23Z","endTime":"2015-06-08T04:00:26.123Z","active":true,"description":"Edited
Schedule","jobId":"136","cron":"* * * * *"} }
```

### Job Schedule Modification Parameters

Request Field	Type	Description
time	string or object	For one-time schedules, the parameter denoting the time at which the task executes. A human-readable text can be used to specify the time, for example, “3.30pm” or “tomorrow at 2am”. If an object is used, the date and time-formats must be specified as strings.
repeatInterval	string	For recurring schedules, the parameter denoting the interval when the schedule should run. The parameter supports the use of human readable formats.
repeatAt	string	For recurring schedules, the parameter denoting the exact time when the job schedule must run. A human-readable text can be used to denote a specified time, for example, “3.30pm” or “tomorrow at 2am”, if the schedule runs repeatedly.

Request Field	Type	Description
<code>cron</code>	string	For recurring schedules, the parameter denoting the <code>cron</code> pattern. It must be a valid <code>crontab</code> format, for example: <code>"* * * * * */10"</code>
<code>data</code>	object	The parameter denoting optional data to be passed to the job action endpoint when invoked. Typically, the custom data is sent based on the HTTP method configured for invoking the end point URL,for example: <code>{"dataParam": "somevalue"}</code>
<code>startTime</code>	object	The time when the job scheduling should start. The date and time-formats must be specified as strings.
<code>endTime</code>	object	The time when the job scheduling should end. The date and time-formats must be specified as strings
<code>active</code>	Boolean	Defines if the job should be activated on configuration. Allowed values are: <ul style="list-style-type: none"> <li><code>false</code> (default) The job is in inactive mode when configured</li> <li><code>true</code> The job is active when configured</li> </ul>
<code>description</code>	string	The user-provided description of the job schedule

## Job Schedule Deletion

Delete and purge run time information of the job schedule of the specified job. All related information like job schedule configurations and logs are purged. The processing of the schedule is also immediately stopped.

### ⚠ Caution

This API removes all the run time configuration information of the job schedule, irrespective of whether the schedule is active or not.

- **Route**

```
DELETE /scheduler/jobs/:jobId/schedules/:scheduleId
```

- **Response**

If the call is successful, the response has a status code, "200-OK" and includes a JSON response `{"success": true}`.

### 📄 Sample Code

```
DELETE /scheduler/jobs/:jobId/schedules/:scheduleId HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
```

```
Response: {"success": true}
Status Code: 200 OK
```

## Bulk Job Schedule Activation/Deactivation

This is a utility API used to activate or deactivate all existing schedules of a job.

- **Route**

```
POST /scheduler/jobs/:jobId/schedules/activationStatus
```

- **Response**

If the call is successful, the response has a status code, "200-OK" and includes a JSON response

```
{"success": true}.
```

### Sample Code

```
POST /scheduler/jobs/:jobId/schedules/activationStatus HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
{"activationStatus": true}
```

```
Response: {"success": true}
Status Code: 200 OK
```

### Bulk Job Schedule Activation Parameters

Request Field	Type	Description
activationStatus	Boolean	The desired activation status of the job schedules for the job. Allowed values for the activation status are: <ul style="list-style-type: none"><li>• false (default) All job schedules for the specified job should be <b>de</b>activated</li><li>• true All job schedules for the specified job should be activated</li></ul>

## Job Details

Retrieve the saved details and configurations of a specified job.

- **Route**

```
GET /scheduler/jobs/:jobId?displaySchedules=true
GET /scheduler/jobs?jobId=:jobId&displaySchedules=true Route
GET /scheduler/jobs?name=:jobName&displaySchedules=true
```

- **Response**

If the call is successful, the response has a status code, "200-OK" and includes a JSON response with the

schedule details, for example: {"schedules": [{"data": {"time": "abc"}, "type": "recurring", "repeatInterval": "2 minutes", "active": false, "startTime": null, "endTime": null, "repeatAt": null, [...]}.}

### Sample Code

```
GET /scheduler/jobs/:jobId?displaySchedules=true HTTP/1.1
content-type:application/json;charset=utf-8
```

```
host:https://scheduler.service.acme.com
```

```
Response:
Status: 200 OK
Content-type: application/json;charset=utf-8
{"schedules":[{"data":{"time":"abc"},"type":"recurring","repeatInterval":"2
minutes","active":false,"startTime":null,"endTime":null,"repeatAt":null,"sched
uleId":"0d3b4cc1-0f7b-4ee6-ab12-63d474b900f2","description":"Default
Schedule"}, {"data":{"time":"abc"},"type":"recurring","cron":"* * * *
*","active":false,"startTime":null,"endTime":null,"repeatAt":null,"scheduleId"
:"1b1bb70f-cada-46c9-9974-a7a1b87ba24f","description":"Default
Schedule"}],"name":"greet the world2","description":"","action":"http://
httpbin.org/basic-auth/abc/
def","user":null,"httpMethod":"GET","active":false,"_id":111}
```

#### Job Details Parameters

Request Field	Type	Description
displaySchedules	Boolean	Display details of the job schedules for the job. Allowed values for the job details are: <ul style="list-style-type: none"><li>• false Do <b>not</b> display details of job schedules for the specified job</li><li>• true Display details of job schedules for the specified job</li></ul>
jobId	String	The job ID needed to query for the job details. This can be passed as a URI segment parameter or as a query parameter.
name	String	The job name needed to query the job details. This can be passed as a query parameter

## Job Schedule Details

Retrieve the saved details and configurations of a specified job schedule & optionally the generated logs for the schedule. Either `:jobId` or `:name` is required to invoke this API. If `displayLogs` is not provided, the logs for the schedule are not returned and only the schedule details are returned.

- **Route**

```
GET /scheduler/jobs/:jobId/schedules/:scheduleId?displayLogs=true
```

- **Response**

If the call is successful, the response has a status code, "200-OK" and includes a JSON response with the schedule details, for example: `{"data":`

```
 {"time":"abc"},"type":"recurring","repeatInterval":"2
minutes","plannedTime":"2015-04-19T15:12:44.000Z","active":true,"startTime":null
,"endTime":null,"nextRunAt": "2017-08-11 10:00:00","repeatAt":null, [...]}.
```

#### Sample Code

```
GET /scheduler/jobs/112/schedules/550d1b96-8002-4d0d-850e-368aaa591671?
displayLogs=true
HTTP/1.1 content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com
```

```

Response:
Status: 200 OK
Content-Type: application/json; charset=utf-8
{"data":{"time":"abc"},"type":"recurring","repeatInterval":"2
minutes","plannedTime":"2015-04-19T15:12:44.000Z","active":true,"startTime":nu
ll,"endTime":null,"nextRunAt": "2017-08-11 10:00:00","repeatAt":null,"logs":
[{"text":null,"httpStatus":null,"executionTime":null,"status":"SCHEDULED","sch
eduleTime":"2015-04-19T15:10:53.000Z","completionTime":null}], "scheduleId":"55
0d1b96-8002-4d0d-850e-368aaa591671","description":"Default Schedule"}

```

#### Job Schedule Details Parameters

Request Parameter	Type	Description
displayLogs	Boolean	Controls whether the API should return ( <code>true</code> ) all the generated logs for the job schedule or not ( <code>false</code> )

## Bulk Job Schedule Deletion

Delete and purge run time information of all the currently configured job schedules of the specified job. All related information like job schedule configurations and logs are purged. The processing of the schedules is also immediately stopped.

### ⚠ Caution

This API removes all the run time configuration information of the job schedule, irrespective of whether the schedule is active or not.

- **Route**  
DELETE /scheduler/jobs/:jobId/schedules
- **Response**  
If the call is successful, the response has a status code, "200-OK" and includes a JSON response {"success": true}.

### ☰ Sample Code

```

DELETE /scheduler/jobs/:jobId/schedules HTTP/1.1
content-type:application/json;charset=utf-8
host:https://scheduler.service.acme.com

```

```

Response: {"success": true}
Status Code: 200 OK

```

## Job Run Log Update

Inform the Job Scheduler about the status of an asynchronous, long-running job run. This API must be invoked by the application after the asynchronous execution of the job has completed, with the status of the job run and optionally some text about the job execution.

### ⚠ Caution

This API must be invoked by the application after the **asynchronous** execution of the job has completed, with the status of the job run and optionally some text about the job execution.

- **Route**

PUT /scheduler/jobs/:jobId/schedules/:scheduleId/runs/:runId

### i Note

Parameters marked with an asterisk (\*) are mandatory.

#### Job Run Log Update Parameters

Request Parameter	Type	Description
success *	Boolean	Indicates that the job run was successful ( <code>true</code> ) or failed ( <code>false</code> )
message	String	Additional log/text about the job run

## Human Readable Dates

The job scheduler for XS advanced supports human readable dates and ranges for the parameters `time`, `repeatAt` and `repeatEvery`, which are used for configuring job schedules. The job scheduler uses an embedded English language date parser for this facility. Valid human readable strings for the parameters are shown below:

### i Note

The date parser expects a valid readable string; invalid strings will either throw parser errors or cause the job scheduling to happen inconsistently.

#### Date and Time Parameters

Parameter	Comments	Examples
<code>time</code>	Designates a particular timestamp for running a job schedule. If an invalid string is provided, the scheduler falls back to the current timestamp and runs the schedule immediately. The following example strings are valid for the <code>time</code> parameter:	"10 hours from now" "20 minutes from now" "in 2 hours" "tomorrow at 4pm" "next week monday at 5am" "9pm tonight" "3.30pm"

Parameter	Comments	Examples
repeatAt	Represents a convenient way to create daily timestamp-based schedules. The string should designate a particular timestamp for repeatedly running a job schedule. This follows the same pattern as the recommendations for the "time" parameter, barring a few discrepancies. While the text for the "time" parameter must denote something concrete and in the future, the 'repeatAt' must designate a timestamp, which is valid and constant daily. If an invalid string is used, the scheduler falls back to the current timestamp and runs the schedule immediately.	"4.40pm" "18.40" "6.20am" "17.20:30 "
<div style="background-color: #f0f0f0; padding: 10px; border-left: 2px solid #0070c0;"> <p><b>i Note</b></p> <p>Second-based precision can sometimes be inaccurately timed; timezones must be specified using the offset (in hours), for example, "+07:00"</p> </div>		
repeatInterval	The string should designate a interval to repeat the job execution. Word strings for denoting the numeric value are not supported yet. For example, for "twenty minutes", use "20 minutes" to denote the interval. Supported time-units for this parameter are "years", "months", "weeks", "days", "hours", "minutes", "seconds".	"10 hours " "2 days " "3 seconds"

## Date and Time Formats in Job Schedule Parameters

The date-time parameters for job schedules (for example, `startTime`, `endTime`, and `time`) can be passed as objects, with the mandatory `date` field denoting the date as a string and an optional `format` field denoting a date-time format for correctly parsing the user-provided date value. If the parameters are passed as strings, they must be valid date representations, in either the ISO-8601 or IETF-compliant RFC 2822 formats. For object representations, the following rules apply:

- Date field as input**  
 If only the date field is provided as input, the string is checked against both IETF-compliant RFC 2822 time stamps and ISO-8601. If the date string is of an unknown format, the parser displays an error. For ISO-8601 compliant dates, calendar dates (for example, "2013-02-08"), week dates ("2013-W06-5"), ordinal dates ("2013-039") and time-based dates ("2013-02-08 09+07:00") are all supported.
- Date string format**  
 If the format of the date string is customized, an optional format string can be passed. The allowed parsing tokens are as described in the following table:

Date and Time Parameters

Input Token	Example	Description
YYYY	2014	4 digit year

Input Token	Example	Description
YY	14	2 digit year
Q	1-4	Quarter of year. Sets month to first month in quarter
M MM	1-12	Month number
MMM MMMM	January- Dec	Month name in locale
D DD 1- 31		Day of month
Do	1st- 31st	Day of month with ordinal
DDD DDDD	1-365	Day of year
X	1410715640.579	Unix Timestamp
x	1410715640579	Unix Timestamp (ms)
gggg	2015	Locale 4 digit week year
gg	15	Locale 2 digit week year
w ww	1- 53	Locale week of year
e	1-7	Locale day of week
GGGG	2015	ISO 4-digit week year
GG	15	ISO 2-digit week year
W WW	1- 53	ISO week of year
E	1-7	ISO day of week
H HH	0 -23	24 Hour Time
h hh	1-12	12 hour time used with 'a A'
a A	am pm	Post or ante meridiem
m mm	0 -59	Minutes
s ss	0 -59	Seconds
S	0 -9	Tenths of a second
SS	0 -99	Hundredths of a second
SSS	0 -999	Thousandths of a second
Z ZZ	+12:00	Offset from UTC as +-HH:mm, +-HHmm, or Z

## Date-Time Format Examples

- `startTime`  
"startTime": {"date": "2015-10-20 4:30 +0000", "format": "YYYY-MM-DD HH:mm Z"}  
4.30 UTC on 20th Oct 2015
- `endTime`  
"endTime": {"date": "2015-W06-5"}  
Friday, February 06, 2015
- `time`  
"time": {"date": "2010-10-20 4:30", "format": "YYYY-MM-DD HH:mm"}  
4.30 Local Time (the timezone for the scheduler service is considered here)

## Related Information

[Scheduling Jobs in XS Advanced](#)

### 13.2.3.2.1.2 The Job Scheduler Dashboard

The Job Scheduler dashboard enables you to manage job schedules for a service instance.

The dashboard lists the available jobs. Select a job to create a schedule or to view existing schedules.

## How to access the Job Scheduler dashboard

### 1. Get the Dashboard URL

To access the Job Scheduler dashboard, you can connect remotely using secure shell (SSH) to the SAP XS Advanced server and perform the following steps:

1. List the applications running on the server using the command `xs apps`.
2. In the *URL* column, identify the relevant URL for the application ("jobscheduler-dashboard" for Job Scheduler).
3. Copy the URL to any Web browser to launch the application.

#### i Note

If a valid certificate is not available, the Web browser indicates an issue with the certificate. To resolve the issue, add the required certificate.

4. Enter the logon credentials to access the application.

### 2. Permission to Access the Dashboard

The administrator role with the **XS\_CONTROLLER\_ADMIN** role template contains the **controller.admin** permission. This role template gives you full access to perform all the administration-related tasks. If you do not have the administrator role, you need the roles and role collection templates listed in the table below to view or modify settings.

Task	Roles Required	Role Collection Template Required
Open the dashboard and only view the job listing page	Org Manager Space Developer	jobscheduler_viewer_template
<p><b>i Note</b> You cannot create jobs.</p>		
Configure settings	Org Manager Space Developer	jobscheduler_config_template
Create or edit jobs or schedules	Org Manager Space Developer	jobscheduler_admin_template

### i Note

If you already have the permission to create or edit jobs or schedules, you still need **jobscheduler\_config\_template** to configure settings.

The SAP HANA administrator creates a role collection and adds the Job Scheduler roles to the role collection. For more information, see *Maintaining the SAP HANA XS Advanced Model Run Time* in the *SAP HANA Administration Guide*.

## Dashboard Screens

The following table contains the various screens available on the dashboard and their descriptions:

Screen	Description
<a href="#">Configuration</a>	<p>Enables you to maintain the global configuration required for a specific Job Scheduler service instance.</p> <ul style="list-style-type: none"> <li>• <b>Max. Invocation Attempts:</b> The number of attempts made by the Job Scheduler to reach the job action endpoint before it deactivates the job. If the Job Scheduler fails repeatedly to reach the endpoint, it sets the job to inactive. The default value of this parameter is 3.</li> <li>• <b>Asynchronous Execution timeout (ms):</b> The duration (in milliseconds) that the Job Scheduler waits for a response for the asynchronous job from the application endpoint. If the application does not provide a response in the specified duration, the run status is set to COMPLETED/UNKNOWN.</li> </ul>

Screen	Description
<a href="#">Jobs</a>	Lists all the jobs created for a specific service instance. You can delete a job or navigate to the job details by choosing the job name.
<a href="#">Overview</a>	Displays the details of the selected job. You can edit a job.
<a href="#">Schedules</a>	Enables you to create and configure schedules for a job. To access schedules, select a job listed on the dashboard. The <a href="#">Schedules</a> screen is displayed. Select a schedule to see the history and logs corresponding to the schedule. To display the run logs of a schedule, choose <a href="#">Logs</a> .
<a href="#">Action History</a>	Maintains the history of a job or schedule for a specific job.

## 13.2.4 XS Advanced User Management

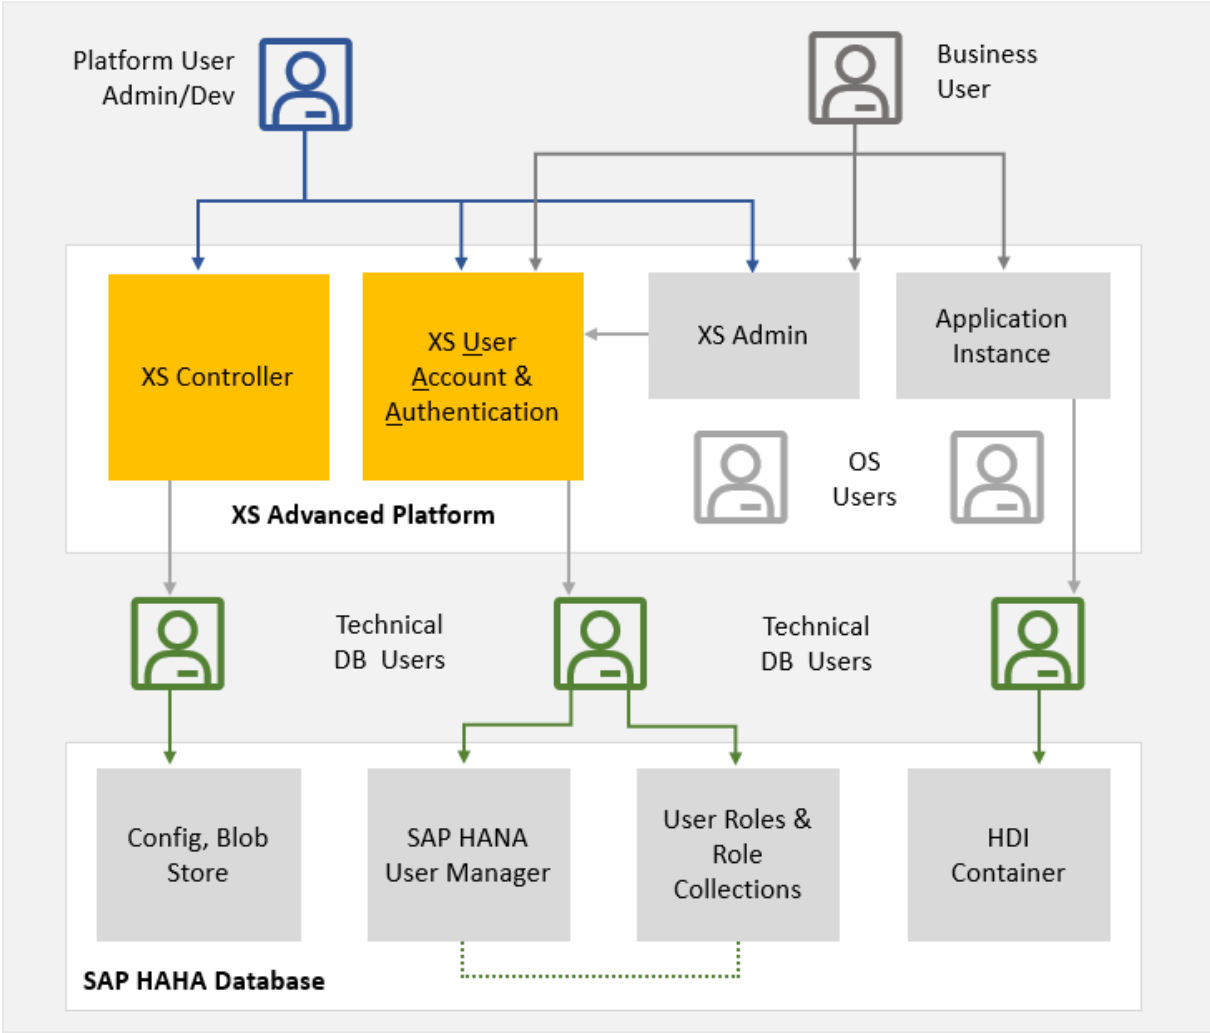

Manage XS advanced users with the tools integrated into the XS advanced platform.

SAP HANA XS, advanced model, requires the configuration and availability of a number of different users, for example: application developers, application users, and XS advanced administrators, as well as technical users, which includes technical database users: database users with restricted permissions. You can manage the users and their roles and scopes with a selection of tools, for example, the `xs` command-line interface, the [XS Admin Tools](#), or an Identity Provider (IdP).

### XS Advanced User Overview

In traditional application servers, user information is kept in a local user store. However, although the SAP HANA XS advanced platform uses the underlying SAP HANA user store as an Identity Provider (IdP) by default, it is possible to integrate an external IdP such as SAP ID Service or SAP Cloud Identity. It is also possible to configure a custom IdP provided the IdP implements the SAML 2.0 standard.

The **User Account and Authentication (UAA)** service represents the central platform service for the management and authentication of users, as illustrated in the following diagram:

User Account and Authentication Service (UAA)

User information, such as first name, last name, user ID and user privileges, is provided in the form of signed OAuth2 access tokens the central UAA issues when a client logs in successfully. For more information about the authentication procedure, see the section on XS advanced user authentication.

### XS Advanced User Categories

XS advanced users access the back-end instances typically through end-user interfaces such as a Web browser or command-line tools. Unlike technical users, application users and some types of system user can be also identified by personal data such as name, e-mail address, and so on. As the same identity provider is the basis for all of XS advanced users, an application user may also be granted developer privileges and the other way around.

XS advanced users who have their source in the SAP HANA user store (default) are typically restricted users with no access to SAP HANA database schemas. In contrast, applications and server components use

**technical SAP HANA users** with certain access privileges. The platform passes these credentials to applications, enabling them to execute SQL statements, if the XS advanced user has sufficient privileges. Decoupling XS advanced users from technical users is the precondition for leveraging external IdPs, even though XS advanced users are also SAP HANA users by default. As technical SAP HANA users are generated by the platform in the background, you typically won't use them to interact with the system.

The XS Advanced User Account and Authentication (UAA) service provides the authentication end point for individual users who need to interact either with SAP HANA XS, advanced model, or with applications deployed and running on the XS advanced model platform. Although such users are often referred to simply as **XS advanced users**, they can have the following roles and areas of responsibility:

- [Platform users \[page 1971\]](#)
- [Application or business users \[page 1971\]](#)
- [Operating-system users \[page 1971\]](#)
- [Technical database users \[page 1972\]](#)

## XS Advanced Platform User

Platform users are administrators or developers who are assigned to one or more specific organizations or spaces in the XS advanced platform. An XS advanced administrator user (for example, `XSA_ADMIN`) is allowed to perform any platform operation in any organization or space. However, it is also possible to maintain additional platform user **roles** and use them to restrict the type of access granted to certain users for particular organizations or spaces. XS advanced “administration users” are system users who manage the configuration of the XS advanced application server components, and in particular the XS Controller.

XS advanced platform users are SAP HANA users who have been assigned to a specific XS advanced role collection. Non-administrator platform users can also be managed by means of an external Identity Provider (IdP).

### → Tip

You can use the `xs` command-line interface to maintain XS advanced platform users. For more information, see *Maintaining Platform Users in XS Advanced with the XS CLI* in *Related Information* below.

## XS Advanced Application (Business) User

Often referred to as “business users”, application users interact with application instances deployed to and running on the XS advanced run-time platform. Application users are also referred to as business users, for example, employees, customers, and so on.

Application users can be identified by personal data such as name or e-mail address, and this data along with other credentials are stored in a user store, for example, an Identity Provider (IdP); any request to log on to an XS advanced application is managed by the XS advanced User Account and Authentication service (UAA). Authorization scopes (defined in user roles) are granted to application users to restrict or enable access to particular data.

## XS Advanced Operating-System Users

In the context of XS advanced, the following predefined operating system users are available by default:

- `<sid>adm`  
Operating-system and administrative SAP HANA system user who owns all platform services as well as the system's file storage.
- `sap<sid>xsa`

Operating-system user required for staging and running applications in the pre-configured `SAP` space.

- `<sid>xsa`

Operating-system user required for staging and running applications in the pre-configured `PROD` space.

The `<SID>adm` operating system user exists to provide an operating system context. From the operating system perspective, the operating system administrator is the user that owns all SAP HANA files and all related operating system processes. Certain administration operations require the operating system user's credentials, for example, starting or stopping the system.

### **i Note**

XS advanced application files are also owned by the `*xsa` operating-system users `sap<sid>xsa` and `<sid>xsa`.

## **XS Advanced Technical Database User**

A technical database user does not correspond to a real person and should be used for administrative tasks such as creating objects and granting privileges for a particular application. For example, an application server may log on to the SAP HANA database using a dedicated technical database user. In the context of XS advanced, technical SAP HANA users are generated by the platform in the background.

For XS advanced, the technical user `SYS_XS_RUNTIME` owns the XS Advanced Controller's SAP HANA schema, which contains the Blob Store, Config Store, and Secure Store. Similarly, the technical user `SYS_XS_UAA` owns the SAP HANA schema provided for the User Account and Authentication (UAA) for user management

Additional technical database users are created on demand and as required for application-specific purposes. For example, the `SBSS_*` users are created as a result of an application-service binding. XS advanced also makes use of a number of `USR_*` users, too; `USR_*` users are created by the SAP HANA Service Broker for the service plans `schema`, `securestore`, and `sbss`. Similar to the predefined users created when binding an application to an HDI container, `USR_*` users are used by applications to access their schema. For more information, see *Predefined Users* in *Related Information* below.

### **i Note**

With HANA 2.0 SPS 03, the SAP HANA Service Broker no longer uses the `SBSS_*` prefix for HDI container users. Instead, these HDI container users have the name of the corresponding HDI container as the prefix. For example, for users created during service binding, the following format is used:  
`<HDI_Container_Name>_<GUID>_DT` (design-time access) or `<HDI_Container_Name>_<GUID>_RT` (run-time access). Binding users are assigned the role `PUBLIC` by default.

## 13.2.4.1 Predefined Users in XS Advanced

The installation of the XS advanced application server creates a small set of predefined users that enable the operation of the underlying system.

The system's super user (<sid>adm) needs to be available in order to manage the life cycle of the system. Similarly, an administrative XS advanced system user (XSA\_ADMIN by default) is necessary to perform the initial setup of the application server, for example, granting other users the privilege to create spaces in a dedicated organization and so on. Technical database users are created during installation for all server components that need to persist data in SAP HANA schemas.

This topic contains information about the following types of predefined users in XS advanced:

- [Predefined XS Advanced System Users](#)
- [Predefined SAP HANA Technical Users](#)
- [Predefined XS Advanced Operating-System Users](#)

### Predefined XS Advanced System Users

The table below lists the predefined XS advanced system users that are necessary for operating the XS advanced application server. First, an administrative user named XSA\_ADMIN is required for the XS advanced Controller; this administrative user configures the application server at a global level. Non-administrative users of the XS advanced Controller are not allowed to perform administration tasks, for example, uploading custom certificates, adding custom buildpacks, or registering platform service URLs. Bear in mind that, although the credentials for the technical users for the SAP HANA Service Broker and UAA Broker are generated automatically during installation, the XSA\_ADMIN user is created interactively with a user-defined password. As a first-level administrator user with irrevocable privileges, the XSA\_ADMIN has unlimited access to the XS advanced Controller and therefore needs to be handled carefully.

#### → Recommendation

- Keep the number of people with XSA\_ADMIN credentials as small as possible. Where possible, delegate specific tasks such as space management to users with less privileges instead.
- Avoid creating other powerful users with privileges similar to XSA\_ADMIN.
- Change the XSA\_ADMIN password at regular intervals and avoid sharing the same password.

User ID	User Type	Description
XSA_ADMIN	XS advanced user	Administrative user for the XS advanced application server with unlimited access to XS advanced Controller API

User ID	User Type	Description
SYS_XS_SUPPORT	Database user	Owns the stored procedures used to grant access privileges on schemas of XS-advanced-related technical database users. Permission to call the stored procedures is also granted to the SYSTEM user. See also SAP note 2656132 in <i>Related Information</i> below.

**i Note**

The SYS\_XS\_SUPPORT user is deactivated by default.

Although the technical users in this table are created in the SAP HANA database, and database authentication checks are used to confirm the technical users' credentials, the technical users are not used to connect to the SAP HANA database.

## Predefined Technical SAP HANA Users

Most of the server agents require a data store in the SAP HANA database and therefore need secure access to schemas. For this reason, a dedicated technical SAP HANA user is generated for each such schema, and the credentials of the technical SAP HANA user are passed to the server agent. As the management of technical users is performed at the infrastructure level, end users do not interact with these users.

### Caution

It is not recommended to change the properties of a predefined technical SAP HANA user, for example, by changing a user's password or deactivating a user. Modifying a technical user manually will cause XS advanced services to stop working properly. However, for security reasons, it is recommended to rotate the passwords of these technical users from time to time, for example, with the XSA command-line interface and the command `XSA renew-passwords-of-technical-users`, as described in the *SAP HANA Administration Guide*.

Starting with SPS04, the technical users listed in the following table are grouped into a single user group named `SYS_XS_UG_RUNTIME_<db-id>`, where `<db-id>` is the unique identifier for a database. The only exception to this user-group rule is `SYS_XSA`, which is created in the user group `SYS_XS_UG_RUNTIME`. These technical users are used to connect to the SAP HANA database with a specific set of conditions.

User ID	Service	Description
HDI_ADMIN_USER	SAP HANA service broker	Owns SAP HANA schema of SAP HANA Service Broker

User ID	Service	Description
HDI_BROKER_CONTROLLER	SAP HANA service broker	Has authorization to access the service broker API of SAP HANA service broker
SYS_XS_HANA_BROKER	SAP HANA service broker	Owns the SAP HANA Service Broker's SAP HANA schema
SYS_XS_HANA_BROKER_INTERNAL	SAP HANA service broker	Has authorization to execute stored procedures for creating users, and so on.
SYS_XS_INSTANCE_MANAGER_ADMIN_USER	Instance Manager	Owns SAP HANA schema of the Instance Manager
SYS_XS_INSTANCE_MANAGER_BROKER_USER	Instance Manager	Has authorization to access service broker API of Instance Manager
SYS_XS_OID_USER	OIDC	Owns the SAP HANA schema for the OpenID Connect provider
SYS_XS_OID_USER_SEC	OIDC	Owns the SAP HANA secure store for the OpenID Connect provider
SYS_XS_RUNTIME	Controller	Owns the Controller's SAP HANA schema containing BlobStore, ConfigStore and SecureStore
SYS_XS_SBSS	SAP HANA service broker	Owns SAP HANA schema containing procedures to generate user passwords in a secure manner; used by the SAP HANA service broker
SYS_XS_SYSTEMDB_INFO	Controller	Has authorization to access database system catalog and configuration
SYS_XS_UAA	UAA	Owns the UAA's SAP HANA schema for user management
SYS_XS_UAA_SEC	UAA	Owns the UAA's SAP HANA secure store for user credentials
SYS_XS_UAA_USER_ADMIN	UAA	Owns the UAA stored procedures that perform user-management operations and assign role collections
SYS_XSA	Installer	Owns SAP HANA schema containing a unique tenant ID

User ID	Service	Description
<code>_SYS_DI</code>	HDI	Owns all HDI SQL-based APIs, for example all API procedures in the <code>_SYS_DI</code> schema and API procedures in containers
<code>_SYS_DI_*_CATALOG</code>	HDI	Technical users used by the HDI to access database system catalog tables and views
<code>_SYS_DI_SU</code>	HDI	Technical superuser of the HDI created at installation time
<code>_SYS_DI_TO</code>	HDI	Owns transaction and connections of all internal HDI transactions

### Technical Users for HDI Schema-Based Containers

The deployment of database objects with SAP HANA Deployment Infrastructure (HDI) is based on a container model where each container corresponds roughly to a database schema. Each schema, and the database objects deployed into the schema, are owned by a dedicated technical database user.

For every container deployed, a new technical database user and schema with the same name as the container are created. Additional schemas and technical users required for metadata and deployment APIs are also created.

For example, for a container named `s`, HDI creates the following users:

- `s`:  
The user who is the owner of the container schema `s`
- User `s#DI`:  
The user who is the owner of the schema `s#DI` containing metadata and deployment APIs
- User `s#OO`:  
The user who is the owner of database objects in schema `s`
- Users `_DI#s#METADATA_COM_SAP_HANA_DI_<metadata>`:  
The users who are the owners of schemas containing build plug-in metadata

These technical users are used internally by HDI only. They are created as restricted database users who do not have any privileges by default (not even the role `PUBLIC`). They cannot be used to log on to the database.

For more information, see *Maintaining HDI Containers* in the *SAP HANA Developer Guide (For SAP HANA XS Advanced Model)*.

### Technical Users for Default Application Services

XS advanced applications can make use of a number of services managed by a service broker. To make use of a service, an instance of the service must be created and the application must be bound to the specified service instance. Several services are available by default; they are installed with the XS advanced run-time platform.

The installation of the following default application services results in the creation of a number of internal technical users:

- `Product-Installer`  
Used for the installation and installation management of applications
- `Deploy-Service`

Used in the technical deployment of applications packaged in multi-target application (MTA) archives

The operation of binding these services to an application generates a technical user and random password according to the following naming convention `USR_<generated_ID>`. These technical users are required to make database schemas available for applications. For every combination of application and schema, such a technical user is created.

In addition, the `Job-Scheduler` service, used to create and schedule long-running operations in the XS advanced environment, uses an HDI container with the `SBSS_` prefix and a randomly generated name. The above-mentioned HDI schemas and users will be created for this container.

For more information, see *The SAP HANA XS Advanced Services: Deployment Infrastructure* in the *SAP HANA Developer Guide (For SAP HANA XS Advanced Model)*.

## User Groups for XS Advanced Technical Users

Starting with SAP HANA 2.0 SPS04, technical SAP HANA users are managed in user groups. This is also true for the technical users owned by the XS advanced run-time and the users created when the SAP HANA Service Broker creates a service instance or a service binding. The following table provides an overview of the user groups that contain users who are relevant for XS advanced:

User Group Name	Description	Example Group Members
<code>SYS_XS_UG_RUNTIME_&lt;db-id&gt;</code>	Includes all technical users created by the core XS advanced run-time services	<code>SYS_XS_RUNTIME</code> <code>SYS_XS_UAA</code>
<code>_SYS_DI #SYS_XS_HANA_BROKER</code>	Includes all technical users created when the SAP HANA service broker creates a service instance with the service plan "hdi-shared"	If "S" is the container name, then: <code>S</code> <code>S#DI</code> <code>S#OO</code>
<code>SYS_XS_UG_BROKER_HDI_SHARED</code> <code>#SYS_XS_HANA_BROKER</code>	Includes all service binding users created when the SAP HANA service broker creates a service instance with the service plan "hdi-shared"	<code>*_RT</code> <code>*_DT</code>
<code>SYS_XS_UG_BROKER_SCHEMA</code> <code>#SYS_XS_HANA_BROKER</code>	Includes all technical users created when the SAP HANA service broker creates a service instance with the service plan "schema"	<code>USR_*</code>
<code>SYS_XS_UG_BROKER_SECSTORE</code> <code>#SYS_XS_HANA_BROKER</code>	Includes all technical users created when the SAP HANA service broker creates a service instance with the service plan "securestore"	<code>USR_*</code>
<code>SYS_XS_UG_BROKER_SBSS</code> <code>#SYS_XS_HANA_BROKER</code>	Includes all technical users created when the SAP HANA service broker creates a service instance with the service plan "sbss"	<code>USR_*</code>

## Predefined XS Advanced Operating System Users

Ultimately all platform services are made up of operating-system (OS) artifacts such as OS processes, network sockets, and file storage. Since operating systems come with their own user management features, these artifacts are out of necessity owned by OS users. Consequently, the XS advanced application server cannot be run without at least one OS user, although dedicated XS advanced users are able to perform the majority of the operational tasks.

The installation procedure creates the “super” OS user `<sid>adm` for the entire SAP HANA system. As the owner of all operating-system processes, the `<sid>adm` user is very powerful from a security perspective. For this reason, we strongly recommend that you limit the number of people with `<sid>adm` credentials as far as possible.

The following XS advanced platform services launch new processes at run time:

- Execution Agents start application instances.
- The application “Stager” spawns processes running build packs during application staging.

In both cases, custom code comes to execution. If these processes ran as the system's `<sid>adm` user, the whole system could be compromised. To prevent this, the platform generally spawns external processes with OS users that are attached to the application's space. To support this approach, the initial setup includes OS user `<sid>xsa` user for the PROD space and OS user `sap<sid>xsa` for the SAP space.

### Note

For more information about user and application isolation in organizations and spaces, see *Maintaining Organizations and Spaces in XS Advanced* in *Related Information* below.

The following table summarizes the operating-system users that are available immediately after installation:

User ID	Type	Description
<code>&lt;sid&gt;adm</code>	OS user	Administrative SAP HANA system user who owns all platform services as well as the system's file storage
<code>&lt;sid&gt;xsa</code>	OS user	OS user for staging and running applications in the pre-configured PROD space
<code>sap&lt;sid&gt;xsa</code>	OS user	OS user for staging and running applications in the pre-configured SAP space

## 13.2.4.2 Predefined XS Advanced Database Roles

Several predefined database roles are necessary for the operation of the XS advanced model application server.

### i Note

The following roles are SQL-based roles that are available in the catalog of the SAP HANA database.

Role	Description
<code>_SYS_DI_OO_DEFAULTS</code>	<p>This role contains the set of default privileges that are granted to all HDI container object owner users (&lt;container&gt;#OO users). SAP HANA DI uses this role internally to grant default privileges instead of using the PUBLIC role. It contains only privileges to SYS views where additional security checks apply.</p> <p>The role contains SELECT privileges on the views: <code>SYS.DUMMY</code>, <code>SYS.PROCEDURES</code>, <code>SYS.PROCEDURE_PARAMETERS</code>, <code>SYS.TABLES</code>, <code>SYS.TABLE_COLUMNS</code>.</p> <p>This role is not intended to be granted to database users.</p> <div data-bbox="821 1238 1391 1355"><h3>i Note</h3><p>Do <b>not</b> extend this role in a production system.</p></div>

Role	Description
SYS_XB_SBSS_VIEWER	<p>This role contains selected privileges for monitoring the status of the Service Broker Security Support (SBSS) component.</p> <p>The SBSS component provides service brokers with functions for creating, validating, and deleting the credentials they need for service bindings. Credential handling is achieved by creating restricted database users with secure random passwords.</p> <p>Specifically, this role contains read access to the SBSS component version table, in addition to read access to the SBSS bindings table that lists the credential names that have already been created with the SBSS API as well as some meta data for the bound credentials.</p> <p>This role is intended only for support users so they can query information such as SBSS version, number of credentials, names of services brokers that called the SBSS API.</p>

**! Restriction**

This role does not grant access to any SBSS credentials.

## 13.2.5 XS Advanced System Configuration Parameters

The XS advanced platform can be configured with a selection of system parameters.

Most system parameters are set to a default value during the installation of the XS advanced platform component. If necessary, however, a small selection of XS advanced system parameters can be changed after the installation, too, for example, to meet the requirements of your system landscape and usage patterns. If you need to change the default SSL port or set up a fail-over router, you can change system properties with SAP Cockpit, SAP HANA Studio, or by editing the configuration file itself, for example, `xscontroller.ini`.

**i Note**

The XS advanced run-time platform reads its configuration from the SAP HANA initialization (`.ini`) files. To apply any changes made to the XS advanced system parameters, restart the XS advanced run time.

This section contains information about the following XS advanced configuration parameters:

- [Global XS Advanced Configuration Parameters \[page 1981\]](#)
- [XS Advanced Controller Configuration \[page 1981\]](#)
- [XS Advanced Execution Agent Configuration \[page 1986\]](#)

## Global XS Advanced Configuration Parameters

The following table lists the system-wide parameters that can be changed in the `global.ini` file and suggests possible scenarios where a change might be necessary.

XS Advanced Global System Parameters `global.ini`

Property Name	Ini-File Section	Default Value	Description	Reason for Change
<code>basepath_xsa_app-workspace</code>	<code>persistence</code>	<code>hana/shared/&lt;SID&gt;/xs/app_working</code>	The path to the working directory of XS advanced. The directory is used for the execution of staging processes and applications. All files in this directory exist only temporarily. If the working directory is changed, it is not necessary to copy the directory contents to the new working directory.	If the startup times for staging processes and applications are slow, change the path to a location on the local file system with a good I/O throughput rather than the shared file system.
<code>xsa_sizing</code>	<code>system_information</code>	<code>M</code>	The sizing profile of the XS advanced platform. For more information, see SAP Note <a href="#">2509043</a> .	You have a development system or you expect a lot of business users on the production system.

## Configuration Parameters for the XS Advanced Controller

If you need to change the behavior of the XS advanced Controller, the following table lists the parameters that you can modify in the `xscontroller.ini` file and suggests possible scenarios where a change might be necessary.

XS Controller System Parameters (xscontroller.ini)

Property Name	Ini-File Section	Default Value	Description	Reason for Change
syslog	audit	false	Write the audit log to the file system (default) or into the system log.	You want the audit log messages written into the system log.
default_domain	communication	Set during installation	The domain used for the URLs of platform components, for example, the XS Controller or XS UAA. The domain is also used by default for all application URLs (routes).	<p>Set up a fail-over router.</p> <p>Change the application URLs.</p> <p>Set up an additional reverse proxy in front of XS advanced.</p>
router_port	communication	3<instance nr>33	The port the XS advanced platform router is listening on if the <code>hostnames</code> routing mode is enabled. The port number is used for every URL or route.	<p>You want to use the default SSL port 443 to reach your applications.</p> <div data-bbox="1166 1010 1394 1207" data-label="Text"> <p><b>i Note</b> This requires some additional configuration steps.</p> </div> <div data-bbox="927 1117 1153 1733" data-label="Text"> <p><b>i Note</b> If you configure the router port to a port &lt; 1024, you must set the appropriate file permissions for the <code>icmbnd</code> binary at <code>/hana/shared/&lt;SID&gt;/xs/router/webdispatcher</code>, for example, <code>chown root:sapsys</code> and <code>chmod 4750</code>.</p> </div>
router_portrange_start	communication	51000	The range of ports used by the XS advanced platform to generate port-based routes if no specific port is defined.	<p>You want to create more than 500 routes.</p> <p>You want to run several XS advanced systems on one host.</p>

Property Name	Ini-File Section	Default Value	Description	Reason for Change
router_portrange_end	communication	51500		<p>→ Tip</p> <p>The port-range modification should be completed before the installation of the second system. For more details, see SAP Notes <a href="#">2507070</a> and <a href="#">2243156</a>.</p> <p>A change to the port range after installation of XS advanced is not recommended because it will not have any effect on the current routes.</p>
router_https	communication	true	Determines whether the Platform Router provides HTTPs or HTTP endpoints for URLs and routes	You fully trust the network from which applications are accessed and want to disable HTTPs due to the additional performance overhead of SSL.
internal_https	communication	true	Determines whether the XS advanced platform components communicate using HTTPs and client certificate authentication based on the SAP HANA System PKI. If the property is turned off, no authentication between the XS Controller and the Execution Agents is performed.	You fully trust the network from which applications are accessed and want to disable HTTPs due to the additional performance overhead of SSL.

Property Name	Ini-File Section	Default Value	Description	Reason for Change
jdbc_ssl	communication	false	<p>Determines whether the XS advanced platform components and applications should use SSL encrypted communication with the SAP HANA database.</p> <div data-bbox="927 663 1153 1167" style="background-color: #f0f0f0; padding: 5px;"> <p><b>i Note</b></p> <p>Additional configuration steps are required to ensure that all applications are capable of establishing an SSL connection successfully. For more information see <i>Maintaining Trust Certificates in Related Information</i> and SAP Note <a href="#">2300943</a>.</p> </div>	<p>You want to:</p> <ul style="list-style-type: none"> <li>• Ensure connections with the HANA database are encrypted</li> <li>• Enable SSL enforcement for connections to the SAP HANA database.</li> </ul>

Property Name	Ini-File Section	Default Value	Description	Reason for Change
jdbc_ssl_validate_certificate	communication	false	<p>Determines whether the XS advanced applications should validate the SAP HANA SSL certificate; this requires additional configuration, which is described in <i>Maintaining Trust Certificates</i>.</p> <div style="border-left: 2px solid orange; padding-left: 10px; margin-top: 10px;"> <p><b>! Restriction</b></p> <p>This property only effects Java-based applications running in the XS advanced run-time environment.</p> </div> <p>SSL validation cannot be switched off for other (non-Java) application run time environments. The XS advanced platform components always validate the SSL certificate, as they are using the System PKI to establish trusted SSL communication with the SAP HANA database.</p>	You want to ensure that the encrypted connection of applications with the SAP HANA database are not vulnerable to man-in-the-middle attacks.
jdbc_ssl_certificate_hostname	communication	-	<p>Specifies the host name to use when validating the SSL certificate during the SSL handshake.</p> <div style="border-left: 2px solid orange; padding-left: 10px; margin-top: 10px;"> <p><b>! Restriction</b></p> <p>This property only effects Java-based applications running in the XS advanced run-time environment.</p> </div>	The host name in the certificate does not match the host name the XS advanced run time environment uses to connect to the SAP HANA database.

Property Name	Ini-File Section	Default Value	Description	Reason for Change
mdc_dispatcher	general	true	Determines whether MDC Dispatcher or the sudo command is used to start application instances as different operating-system (OS) users.	You want to ensure the sudo-based user switch is used, regardless of the SAP HANA version.
<div style="background-color: #e0e0e0; padding: 5px; border: 1px solid #ccc;"> <p>→ Tip</p> <p>For more information see SAP Note <a href="#">2243156</a>.</p> </div>				
default_space_user	general	<sid>xsa	Determines the operating-system user defined as the default user for a newly created space. The specified default space user is used to start application instances in the target space.	You do not want to use the <sid>xsa user created by the command hdb1cm as the default space user.

## Configuration Parameters for the XS Advanced Execution Agent

If you need to change the behavior of the XS advanced Execution Agent, the following table lists the parameters that you can modify in the `xsexecagent.ini` file and suggests possible scenarios where a change might be necessary.

XS Execution Agent System Parameters (xsexecagent.ini)

Property Name	Ini-File Section	Default Value	Description	Reason for Change
listen_portrange_start	communication	50000	The ports from this range are used to assign the internal port to an application instance. These ports are not supposed to be reached externally. Externally the application instances are reached via the Webdispatcher.	You want to run more than 1000 apps  You want to run several XS advanced systems on one host.
<div style="background-color: #e0e0e0; padding: 5px; border: 1px solid #ccc;"> <p>→ Tip</p> <p>Since ports are dynamically assigned to applica-</p> </div>				

Property Name	Ini-File Section	Default Value	Description	Reason for Change
listen_portrange_end	communication	50999		<p>tion instances during startup, you can change this property after installation. For more information see SAP Note <a href="#">2507070</a>.</p>
exclusive	communication	false	<p>If you pin applications to specific Execution Agents, this property controls whether the Execution Agent can start only its pinned applications or other applications, too.</p>	<p>You want to prevent applications from running on the same host.</p> <p><b>→ Tip</b> For more information, see <i>Maintaining Host Pinning</i> in <i>Related Information</i>.</p>

## 13.2.6 Backup and Recovery in XS Advanced

Back up and restore XS advanced persistent data.

Since XS advanced stores most of its persistent data within the SAP HANA database, you can use the SAP HANA tools and mechanisms to back up and restore XS advanced. There is, however, some persistent data, namely the file-system service, which is not automatically included in the SAP HANA backup. XS advanced provides tools to store this information within the database manually and restore it back to the file system.

### ! Restriction

Earlier versions of SAP HANA do not automatically back up the file-system secure store that is used by XS advanced. For detailed instructions about how to back up XS advanced using earlier SAP HANA versions, see SAP Note [2300937](#).

## Performing a Backup of XS Advanced

The procedure for backing up XS advanced model differs according to the options you chose when you set up XS advanced during installation, for example, whether you installed XS advanced in the system database or a tenant database, as described in the following sections.

### → Tip

For more information about installing XS advanced in the System database or in a custom database, see *XS Advanced Database Setup Options* in *Related Information* below

### Backup with XS Advanced Installed in the System Database

In this scenario, the XS advanced platform services (for example XS Controller) store all persistent data, such as application and service metadata, run times, build packs, and application droplets within the System database of the SAP HANA Platform. Applications running on XS advanced might store their persistent data within the System database or within a tenant database, depending on the respective configuration of the org and space the application is deployed to. For more information, see *Maintaining Tenant Databases* in *Related Information*.

If you want to back up an XS advanced system which is installed in the System database you must always back up the System database and all of the tenant databases. For more information about how to back up the System database and tenant databases, see *SAP HANA Backup* in *Related Information* below.

### i Note

To avoid backup inconsistencies between the System database and different tenant databases, it is recommend to use the SAP HANA Point-in-Time recovery option when recovering the backup. Point-in-Time recovery ensures that the System database and all of the tenant databases are recovered to the same consistent state. During the backup take note of a suitable point in time that is before the first database backup.

1. Back up the file-system service.

To include the File-System Service (FSS) in an XS advanced back up operation, run the `backup-fss` command as `<sid>adm`, as shown in the following example:

```
$ XSA backup-fss
```

Applications can store data in other backing services provided by service brokers, for example, the file-system service. The file-system service is used by SAP Web IDE to store some of its persistent data. XS advanced provides the tools needed to store the contents of the file-system service within the System database and restore the contents at a later point in time. You need to back up the XS advanced file-system service before you perform the back up of the System database.

### i Note

Work spaces that are created in SAP Web IDE during the period between the backup of the file-system service and the backup of the System database are not contained in the backup.

2. Back up the databases.

First back up the System database and then all the tenant databases. For more details of how to back up the databases, see *SAP HANA Backup* in *Related Information*.

## → Remember

Note the current point in time before performing the first backup; the time is used when recovering all databases to the same point in time using Point-in-Time recovery.

## Backup with XS Advanced Installed in a Tenant Database

In this scenario, the XS advanced platform services (for example XS Controller) store all persistent data, such as application and service metadata, run times, build packs, and application droplets within a tenant database of the SAP HANA Platform. Applications running on XS advanced might store their persistent data within the same or a different tenant database, depending on the respective configuration of the organization and space the application is deployed to. For more information, see *Maintaining Tenant Databases* in *Related Information*.

If you want to back up a XS advanced system which is installed in a tenant database you must always back up all of the tenant databases that are registered with XS advanced. For more information about how to back up the tenant databases, see *SAP HANA Backup* in *Related Information* below.

To avoid backup inconsistencies between the System database and different tenant databases, it is recommended to use the SAP HANA Point-in-Time recovery option when recovering the backup. Point-in-time recovery ensures that the System database and all of the tenant databases are recovered to the same consistent state. During the backup take note of a suitable point in time that is before the first database backup.

1. Back up the file-system service.

To include the File-System Service (FSS) in an XS advanced back up operation, run the `backup-fss` command as `<sid>adm`, as shown in the following example:

```
$ XSA backup-fss
```

Applications can store data in other backing services provided by service brokers, for example, the file-system service. The file-system service is used by SAP Web IDE to store some of its persistent data. XS advanced provides the tools needed to store the contents of the file-system service within the tenant database XS advanced is installed in and restore the contents at a later point in time. You need to back up the XS advanced file-system service before you perform the back up of the tenant database, which XS advanced is installed in.

## i Note

Work spaces that have been created in SAP Web IDE during the period between the backup of the file-system service and the tenant database backup are not contained in the backup.

2. Back up the tenant databases.

To back up the tenant databases registered with XS advanced, first display a list of all the registered tenant databases, for example, by logging into SAP HANA system as `<sid>adm` and running the following command:

```
$ XSA list-tenants
```

Backup all tenant databases displayed in the command output, and make a note of the tenant database that contains the XS advanced platform persistence; this is the database that needs to be selected after recovery. For more information about how to back up SAP HANA databases, see *SAP HANA Backup* in *Related Information* below.

```
DB name: MYTENANT
```

```
[...]  
XS advanced platform persistence: YES  
[...]
```

#### → Remember

Before performing the first backup, note the current point in time; this time is used when recovering all databases to the same state using Point-in-Time recovery.

## Restoring XS Advanced from a Backup Image

The procedure for restoring XS advanced model differs according to the options you chose when you set up XS advanced during installation, for example, whether you installed XS advanced in the system database or a tenant database. For more information about installing XS advanced in the System database or in a custom database, see *XS Advanced Database Setup Options* in *Related Information* below.

#### → Tip

When restoring a backup of XS advanced, you need to restore the backup to a target system with the same version of XS advanced as (or a higher version than) the version of XS advanced on the source system at the time of the backup. If you restore the backup to a system where a higher version of XS advanced is installed, you need to update XS advanced on the target system again (to the same higher version), after the backup finishes, in order to ensure that the version of the restored XS advanced content corresponds with the XS advanced software version installed on the target system.

## Restoring XS Advanced Installed in the System Database

If you want to restore XS advanced that was installed in the system database, you need to perform the following high-level steps:

1. Disable XS advanced services.

To avoid problems during the recovery operation, it is necessary to shut down XS advanced on the system, where the XS advanced backup should be restored. To shut down XS advanced, run the following command as `<sid>adm` user:

```
$ XSA disable
```

2. Restore XS-advanced-related data.

To restore the XS advanced system from a backup, you need to restore the System database as well as **all** of the tenant databases. The order in which you perform these steps is mandatory; restore the System database first and then all of the tenant databases. It is recommended to use SAP HANA's Point-in-Time recovery option to recover all databases to a consistent state. The point in time you specify needs to be before the first database was backed up.

#### → Tip

For more information about how to recover the System database and tenant databases, for example, to a specific point in time, see in *Related Information*. below.

3. Restore the file-system service.

After you have successfully recovered the System database and all tenant databases you can restore the file-system service of XS advanced, too, using the following command as `<sid>adm`:

```
$ XSA recover-fss -f
```

4. Enable XS advanced services again.

To enable XS advanced, run the following command as `<sid>adm` user:

```
$ XSA enable
```

## Restoring XS Advanced Installed in a Tenant Database

If you want to restore XS advanced that was installed in a tenant database, you need to perform the following high-level steps:

1. Disable XS advanced services.

To avoid problems during the recovery operation, it is necessary to shut down XS advanced on the system, where the XS advanced backup should be restored. To shut down XS advanced, run the following command as the `<sid>adm` user:

```
$ XSA disable
```

2. Restore XS-advanced-related data.

To restore the XS advanced system from a backup, you need to restore **all** tenant databases that contain XS advanced data. It is recommended to use SAP HANA's Point-in-Time recovery option to recover all databases to a consistent state. The point in time you specify needs to be before the first database was backed up.

### → Tip

For more information about how to recover a tenant database, see *SAP HANA Recovery in Related Information*.

3. Point the XS advanced platform services to the tenant database containing the XS advanced platform data you just restored, for example, by running the following command as `<sid>adm` user

```
$ XSA select-xsa-runtime-db <tenant database name>
```

As of XS advanced 1.0.116, this command automatically restores the file-system service instances contained in the backup.

For details of how to identify the database containing the XS advanced platform data, see the command `XSA list-tenants` in *Backup with XS Advanced Installed in a Tenant Database* above.

4. Restore the file-system service.

### i Note

Only valid, if you use an XS advanced version smaller than 1.0.116.

```
$ XSA recover-fss -f
```

5. Enable XS advanced services again.

To restart all XS advanced services, run the following command as the `<sid>adm` user:

```
$ XSA enable
```

## 13.2.7 Logging and Auditing in XS Advanced

Set up and use logs and traces in XS advanced.

The XS Advanced platform writes different types of traces several different files in the following host-specific SAP HANA trace directories:

```
/usr/sap/<SID>/HDB<SN>/<host>/trace
```

The XS advanced platform keeps access logs concerning requests sent to XS advanced applications via the platform router centrally in the following directory:

```
/hana/shared/<SID>/xs/controller_data/controller/router/webdispatcher/logs
```

### XS Advanced Platform Tracing

Each XS Advanced platform component, for example, the XS Controller, the XS Execution Agent, or the XS User Account and Authentication service (UAA) writes detailed tracing to log files located in the SAP HANA trace directory of the host the service is running on. The following files contain the most recent log entries:

- xscontroller\_0.log
- xsexeagent\_0.log
- xsuaaserver\_0.log

#### i Note

Log files are closed and renamed (rotated) if they exceed a certain size.

Log-file rotation means that you can find older traces in files with a higher index incorporated into the file name, for example, xscontroller\_1.log or xscontroller\_2.log. The platform retains the five (5) most recent trace files for each XS advanced service. In addition, startup information is written to the following files in the SAP HANA trace directory:

- xscontroller.out
- xsexeagent.out
- xsuaaserver.out

The additional XS advanced services "HANA Broker" and "Instance Manager" write logs to the following files:

- xshanabroker\_0.log
- xsinstancemanager\_0.log

## Audit Logs

Each of the platform components writes detailed audit logs, which contain information about login attempts and any changes made to resources managed by the platform. The audit logs are stored in the following files in the SAP HANA trace directory on the respective SAP HANA host:

- hdbxscontroller\_audit\_0.log
- hdbxsexecutionagent\_audit\_0.log
- uaa-audit.log

If you enable the SAP HANA audit log, XS advanced stores audit logs from the XS Controller and the Execution Agent service in the SAP HANA audit log. Audit logs created by the UAA Service are not stored in the SAP HANA audit log. For more information about enabling the SAP HANA audit log and configuring the correct audit policy, see *Application Auditing* in *Related Information*.

### i Note

Audit logs are never deleted automatically. For more information about deleting audit logs manually, see *Data Protection and Privacy* in *Related Information*.

## Access Logs

For each route, the platform router maintains access log files with the naming pattern `access_log-<route guid>-<port>.log`, as illustrated in the following example

```
access_log-229dba84-8ed6-45d2-91b6-7b142cc58177-51004.log
```

To display details of a specific route's globally unique identifier (guid) as well as information about any bound applications, you can use the command `xs routes --guids`, as illustrated in the following example:

### Output Code

```
$ xs routes --guids

Getting routes in org "orgname" / space "SAP" as XSA_ADMIN...

host domain      port path type apps      guid
-----
-
  example.org  51006 /   HTTP  auditlog-server
a1dac8fa-620a-4093-8...
  example.org  51007 /   HTTP  auditlog-broker
66eefa83-99fe-4d42-9...
  example.org  51008 /   HTTP  deploy-service  743db7a4-cdd6-43f0-
a...
  example.org  51009 /   HTTP  product-installer
a944c3e9-2367-4c0b-8...
```

[...]

### → Tip

Access logs to applications can also be displayed with the command `xs logs`. For more information, see *Related Information*.

To display access logs for the XS Controller and XS UAA, use the following files:

- `access_log-controller-route-30030.log`
- `access_log-external-uaa-route-30032.log`

The following example shows what an individual entry looks like in an application access log:

### ≡ Output Code

#### Access Log Entries

```
[13/Feb/2018:13:23:50 +0100] 7.7.007.007 - - to example.org:30030 "GET /v2/info HTTP/1.1" 200 sent 471 in 182 by 000-controller-instance
```

An access log line has the following format:

- The timestamp at which the request was finished
- The remote IP address
- The client identification if available or "-" if not available
- The user name in case of basic authentication or "-" if not available
- The target host and port
- The http request
- The response code
- The number of bytes transferred
- The request processing time in milliseconds
- The target system identifier

In the example above, a request was sent from the IP address 7.7.007.007 to target "example.org", requesting the resource "GET /v2/info HTTP/1.1". The response had HTTP status code 200 and 421 bytes were sent in 182 milliseconds by the XS Controller.

### i Note

It is possible to enable the XS advanced platform router to record in the access logs all query parameters used in an application request. For security reasons, the default setting is "false" (disabled). For more information, see *Configuring the XS Advanced Platform Router* in *Related Information* below.

## 13.2.8 Platform Sizing in XS Advanced

Set up usage profiles and resource consumption at the application and platform levels.

According to the business scenario and load profile, XS advanced platform services have a resource consumption that needs accurate alignment with the available hardware resources. For example, operation of the XS advanced platform requires certain amount of disk space, main memory and number of network connections. In addition, the resource consumption it highly depends on the applications deployed on the platform.

### i Note

A tradeoff is required between the platform's resource consumption and the maximum load the server can handle.

By default, XS advanced is optimized for low-memory consumption, which initially limits the maximum number of concurrent requests sent by platform and application users. If you want to configure XS advanced to handle higher loads, you may need to resize the platform services accordingly without hitting resource limits. Usage profiles help administrators to cope with this task as described in the following sections.

## Usage Types and Profiles

To simplify sizing configuration, XS advanced comes with a predefined set of usage and sizing profiles enabling administrators to configure the server with a best-fit usage type and a pre-configured size profile, for example, "large" (L) or "extra large" (XL). Starting with version SPS03, XS advanced server provides the following usage types:

- `PlatformUsage` (Platform Usage)
- `AppUsage` (Application Usage)

### Platform Usage

XS advanced systems configured with the usage type `PlatformUsage` are primarily intended to serve users that interact with the platform interface (`xscontroller`), for example, when pushing applications, viewing the application status, or administrating global platform settings. For this reason, the chosen size profile scales the platform services that are responsible for processing such requests. However, the platform router has a default (medium) layout that is independent of the size profile and which assumes that only a few requests to application end points are expected. The typical use case for this usage setting is a development system, and the impact of the profile size on the platform service capabilities is illustrated in following table.

Platform Usage Profile Settings

Profile Size (Short)	Profile Size (Long)	Max. Concurrent Platform Requests
S	Small	4
M	Medium	16
L	Large	64

Profile Size (Short)	Profile Size (Long)	Max. Concurrent Platform Requests
XL	Extra Large	256

### Application Usage (AppUsage)

Systems that are mainly intended to process application requests from business users should be configured with usage type `AppUsage`. In this scenario, the server infrastructure for handling platform user requests has a default layout while the platform router is scaled according to the chosen size profile. A production system would typically use this setting. The impact of the profile size is illustrated in following table.

Application Usage Profile Settings

Profile Size (Short)	Profile Size (Long)	Max. Concurrent Application Requests
S	Small	100
M	Medium	2,000
L	Large	8,000
XL	Extra Large	32,000

## Server Configuration

By default, all usage types have profile size M (medium). You may adapt the profile size of a dedicated usage type in `global.ini` by means of the property `xsa_sizing` in section `system_information`. Using the format `<usage>:<size>` you can set the size of a specific usage type to one of the pre-defined sizes (L, XL, etc.). The following example shows a server configuration optimized to serve a maximum of 64 platform requests in parallel:

```
[system_information]
xsa_sizing = PlatformUsage:L
```

The following example shows a server configuration optimized to handle a maximum of 8,000 concurrent application requests:

```
[system_information]
xsa_sizing = AppUsage:L
```

It is possible to specify size profiles for all different usage types individually, which could be helpful in mixed scenarios. In the example below the server is configured to handle a very large number of platform users and a large number of business requests at the same time, which is the kind of scenario you would expect in a development and test system running extensive application tests:

```
[system_information]
xsa_sizing = PlatformUsage:XL, AppUsage:L
```

Providing the usage type is optional, and if it is not specified, the profile size applies to all usage types by default. So `'xsa_sizing = L'` induces the same server configuration as `'xsa_sizing =`

`PlatformUsage:L, AppUsage:L'`. This ensures the compatibility of sizing configurations for pre-SPS03 released versions of SAP HANA.

### i Note

Changes to the `xsa_sizing` property require a restart of the XS advanced server (for example, with `xsa restart`) in order to make SAP HANA aware of the modified configuration.

## Resource Consumption

Depending on the chosen platform sizing configuration, the platform services have a certain resource consumption that needs to be taken into consideration when XS advanced is activated within an SAP HANA system. For example, the XS advanced platform has a significant impact on the following resources:

- Disk space and file IO
- Main memory
- Network connections and network IO

The profile size mainly influences the amount of occupied main memory, the maximum number of network connections, and the maximum file and network IO rates. Disk space, however, is not correlated to the profile size; it is associated with the number and size of the deployed applications.

### → Tip

For more information about recommendations for resource-consumption settings, see *Related Information*.

## Application Sizing

The usage types and profile sizes specified in the corresponding section of the configuration-parameters (`.ini`) file enable only the scaling of the core platform services, which do not affect applications that are deployed to the XS advanced platform (including system applications such as the deploy service or audit log service). To meet load requirements, applications generally need to be scaled horizontally or vertically. For more information, see *Related Information*.

[Scaling Applications in XS Advanced \[page 1832\]](#)

[XS Advanced System Configuration Parameters \[page 1980\]](#)

## 13.2.9 Configuring the XS Advanced Platform Router

Use a template or INI parameters to configure the XS advanced platform router.

XS advanced model uses a dedicated instance of the SAP Web Dispatcher as the central platform router. The configuration of this Web Dispatcher instance is managed by the XS Controller and is highly dynamic; the configuration regularly changes, for example, when applications are started, stopped, or scaled, or when routes are mapped to (and unmapped from) applications. Due to this dynamic behavior, it is not possible for the administrator to change the configuration of the Web Dispatcher directly. Instead, changes to the configuration are defined in a configuration template which is used by the XS advanced platform to build the final Web Dispatcher configuration that is used by the XS advanced platform router.

The information in this section describes some examples that demonstrate the process including details of the following steps:

- [Configuring the Platform Router with the Configuration Template \[page 1998\]](#)
- [Configuring the Platform Router with INI Parameters \[page 1999\]](#)

### Configuring the Platform Router with the Configuration Template

XS advanced provides a template file `sapwebdisp.template` which you can use to override or add SAP Web Dispatcher configuration properties. For a complete reference of all configuration parameters, see the SAP Web Dispatcher documentation in *Related Information* below.

#### i Note

Properties defined in the template file take precedence over properties determined by the XS advanced platform.

Saving any changes made to the configuration template file prompts XS advanced to automatically update the Web Dispatcher, which means that it is not necessary to restart the Web Dispatcher manually. The template file can be edited by the `<sid>adm` user and is located in the "xs/" directory of the SAP HANA installation, as illustrated in the following path:

```
/hana/shared/<SID>/xs/controller_data/controller/router/webdispatcher/conf/  
sapwebdisp.template
```

Any changes made to the XS advanced router-configuration template `sapwebdisp.template` will be reflected in the actual Web Dispatcher configuration file named `sapwebdisp.pfl`

#### i Note

Some configuration properties of the SAP Web Dispatcher cannot be changed dynamically.

For changes to configuration properties of the SAP Web Dispatcher that cannot be updated dynamically, refer to the SAP Web Dispatcher documentation, for example, in *Related Information* below. In these cases, a restart of the SAP Web Dispatcher is required, for example, by sending signal 3 (SIGQUIT) to "kill" the Web Dispatcher process directly. Alternatively, you can restart the XS Controller service or the entire XS advanced platform, for example, using the `xsa restart` command. Bear in mind that restarting the XS Controller or the XS advanced platform will cause a longer downtime than restarting only the Web Dispatcher.

## ⚠ Caution

It is not recommended to use the template file to override any parameters that include an index in their key.

Although it is possible to override parameters that include an index in their key (for example, `wdisp/system_xx`), it is not recommended. This is because the XS advanced run time cannot guarantee that these indexes remain stable and always reference the same logical system. XS advanced incrementally increases the index for the parameters it sets, starting at zero. If you want to add additional parameters that use an index in their key, make sure you use a very high value as the index.

## Configuring a Load Balancing Algorithm

The SAP Web Dispatcher provides several options for requesting load balancing. For more details about what those options are and how to set up and use them, see *Load balancing via SAP Web Dispatcher* in *Related Information* below.

## Serving XS Classic with the XS Advanced Web Dispatcher

One use case for adding additional configuration to the XS advanced Web Dispatcher is related to XS classic, for example, to enable you to serve XS classic and XS advanced applications on the same TCP port. This is useful when running XS advanced in hostname-based routing mode, as you only need to open a single port for HTTPs communication in that case. The SSL settings will be taken from the XS advanced Web Dispatcher, which means you only need to configure the HTTP endpoint of XS classic, so that internal communication between the XS advanced Web Dispatcher and the XS classic Web Dispatcher can be established. To enable such a configuration, add the following line to your `sapwebdisp.template` file:

### 📄 Sample Code

Connect the XS Advanced and XS Classic Web Dispatchers in `sapwebdisp.template`

```
wdisp/system_999=NAME=ZZZ, SID=ZZZ, SRCURL=/, SRCVHOST=xsc.<default-domain>:<router-port>, SSL_ENCRYPT=0, EXTSRV=<xsc-classic-http-url>
```

Values for the placeholders `<default-domain>` and `<router-port>` can be obtained from your XS advanced, system-parameter configuration, which is described in *XS Advanced System Configuration Parameters* in *Related Information*. The value of `<xsc-classic-http-url>` `http://127.0.0.1:80<instance-nr>`". After you have adapted the template file, the XS classic start page should be available at " should reflect the HTTP end point of the XS classic Web Dispatcher. If both XS advanced and XS classic are running on the same host (for example, within a single-host SAP HANA installation), the end point for the Web Dispatcher could be `https://xsc.<default-domain>:<router-port>`".

## Configuring the Platform Router with INI Parameters

Some settings of the XS advanced Web Dispatcher can be configured by means of parameters within the file `xscontroller.ini` as described in *XS Advanced System Configuration Parameters* in *Related Information*. For example, the property `router_https` determines whether the Web Dispatcher exposes HTTP or HTTPs end points.

## Configuring TLS Versions and Cipher Suites

The TLS settings of the Web Dispatcher server ports used by the XS advanced platform can be configured by means of an INI parameter. The following INI settings are available in the `xscontroller.ini` file. If you are

running a multi-host system, with multiple `xs_worker` roles configured, the settings also need to be added to the `xsexecagent.ini` file. This is because an additional Web Dispatcher is started by Execution Agents, which are not running on the XS advanced master host.

INI Parameter for Router Cipher-Suite Setting

Property Name	Section	Default	Description
<code>Router.WebDispatcher.CipherSuites</code>	<code>router</code>	<code>135:PFS:HIGH:TLS_FALLBACK_SCSV::EC_P256:EC_HIGH</code>	The TLS cipher suite settings, provided on server ports exposed by the Web Dispatcher (enables TLS 1.0, TLS 1.1 and TLS 1.2)

For interoperability reasons, the default cipher-suite setting enables TLS 1.0, TLS 1.1 and TLS 1.2. If, however, clients are known to be compatible with TLS 1.2, it is recommended to disable all TLS versions below TLS 1.2, for example, by changing the `Router.WebDispatcher.CipherSuites` parameter in the XS advanced controller's configuration file (`xscontroller.ini`) as illustrated in the following example:

#### Sample Code

Excerpt from the XS advanced controller configuration file (`xscontroller.ini`)

```
[router]
Router.WebDispatcher.CipherSuites = 544:PFS:HIGH::EC_P256:EC_HIGH
```

For more details about the format required for the cipher-suite parameters illustrated in the example above as well as the required sequence and meaning of the values used, see SAP Note 510007 *Setting up SSL on Application Server ABAP in Related Information* below. For example:

- `544`  
512 ("TLSv1.2") + 32 ("Strict protocol version configuration option")
- `PFS`  
Indicates that Perfect Forward Secrecy (PFS) cipher suites are to be used
- `HIGH`  
Indicates the security class of the cipher suite(s) to be used
- `EC_*`  
The configuration settings for "Elliptic Curve" (EC) cryptography, for example, the key length (`EC_P256`) and the security class (`EC_HIGH`)

#### Note

All internal HTTPs ports used by XS advanced are restricted to TLS 1.2 by default.

## Logging Query Parameters

It is possible to enable the XS advanced platform router to record in the access logs all query parameters used in an application request, for example, using the `Router.WebDispatcher.LogQueryParameters` parameter in the XS advanced controller's INI file (`xscontroller.ini`). For security reasons, the default setting is "false" (disabled), and no query parameters are written to the access logs.

### ⚠ Caution

Since the logged information could include details of a sensitive nature, it is not recommended to enable this feature other than perhaps temporarily in exceptional circumstances, for example, when troubleshooting security issues.

INI Parameter for Logging Query Parameters

Property Name	Section	Default	Description
Router.WebDispatcher.Log-QueryParameters	router	false	Write the query parameters used in a request to the platform-router's access logs

## Related Information

## 13.2.10 Maintaining Single Sign-On for XS Advanced Applications

You can configure XS advanced applications to use single sign-on (SSO) authentication to confirm the logon credentials of a user calling an application service.

Single sign-on is a convenient way to authenticate a user against the XSUAA service using one or multiple available certificates. The XS advanced runtime enables you to use X.509 authentication as well as SPNEGO and Kerberos.

### i Note

To prevent a login-logout loop with SSO, it is recommended to configure a custom logout page for the XS advanced application. For more information, see the reference documentation for the application router configuration syntax.

## Related Information

[Configure SSO with X.509 Authentication for XS Advanced Applications \[page 2002\]](#)

[XS Advanced Application Router Configuration Syntax](#)

## 13.2.10.1 Configure SSO with X.509 Authentication for XS Advanced Applications

Enable SSO with X.509 certificates for user logon to applications in the XS advanced run-time environment.

### Prerequisites

- You have the role `USER_ADMIN` on your SAP HANA database.
- You have the role `XS_CONTROLLER_ADMIN` on your XS advanced runtime.
- You have an SAP HANA administration tool.
- You have the root certificate of the X.509 user certificates.
- The parameters `uaa.oidc.enableoidc` and `uaa.oidc.enablex509` in the `xsuaaserver.ini` file are set to `true`.

### Procedure

1. Add the trust certificate for client authentication.

Add the root certificate of the X.509 user certificates in PEM format to your XS advanced runtime platform.

Use the `xs trust-certificate` command with the `--client-auth` option, as illustrated in the following example:

```
xs trust-certificate <ALIAS> --client-auth -c <PATH>
```

You see a confirmation in your command prompt.

```
Adding trusted certificate <ALIAS> as <user>...  
OK
```

2. Create a database user whose identity is defined in an X.509 certificate issued by your certificate authority (CA).
  - a. Create a new user in the SAP HANA database based on the details specified in an existing X.509 certificate.

The following example shows how to use the SQL statement `CREATE USER WITH IDENTITY` to create the database user "MyUserName" and the corresponding X.509 certificate mapping:

```
CREATE USER MyUserName WITH IDENTITY 'CN=MyUserName, O=SAP-AG, C=DE'  
ISSUER 'CN=SSO_CA, O=SAP-AG, C=DE' FOR X509
```

- b. Configure the user in SAP HANA.

To edit the user for whom you want to enable SSO, use the SAP HANA administration tool of your choice: select [X509](#) and [Configure X.509 user certificates](#).

3. Use a Web browser to test the logon authentication settings for the XS advanced application.

When you enter the URL for your application in the Web browser, the Web browser prompts you to select a certificate, which enables you to log on without supplying logon credentials manually.

## Related Information

[Maintaining Trust Certificates in XS Advanced \[page 1850\]](#)

### 13.2.10.2 Configure SSO with SPNEGO and Kerberos for XS Advanced Applications

Enable SSO with SPNEGO and Kerberos for user logon to applications in the XS advanced run-time environment.

## Prerequisites

- You have configured Kerberos and SPNEGO support in your SAP HANA database.
- You have an SAP HANA administration tool.

## Context

In addition to configuring Kerberos in SAP HANA, see SAP Notes [1813724](#) and [1837331](#).

### i Note

For SPNEGO, the Kerberos keytab must contain an entry for Service Principal Name (SPN): `HTTP/<fully-qualified-host-name>`

## Procedure

1. Open your SAP HANA administration tool and set the parameter `uaa.oidc.enablespnego` in the `xsuaaserver.ini` file to `true`.
2. Configure your SAP HANA user.

Edit the user in your SAP HANA administration tool: select *Kerberos* and enter an *External ID*.

3. Test your configuration.

With the Python script from SAP Note [1813724](#) you may verify, that your logon to SAP HANA with your Kerberos credentials works.

## Related Information

[Configure Kerberos for SAP HANA Database Hosts \[page 840\]](#)

### 13.2.11 Multi-Host Setup with XS Advanced

Scale out inter-host communication and failover router with XS advanced in a multi-host setup.

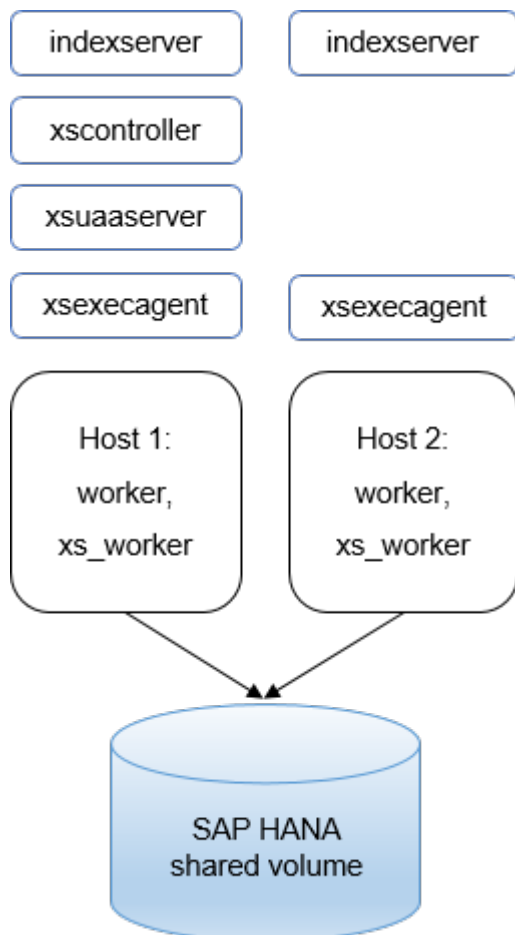

If you want to learn about how XS advanced integrates into an SAP HANA multi-host setup, see the *SAP HANA Installation Guide* in *Related Information*.

#### Scaling Out XS Advanced to Multiple Hosts

If you want to distribute XS advanced applications to more than one host, for example, in a scale-out scenario, you can assign the `xs_worker` role to additional SAP HANA hosts. Newly started application instances are distributed in a round-robin fashion among the existing hosts with the `xs_worker` role. You can also control which application is scheduled to run on which host by pinning an application to a specific host, as described in *Maintaining Host Pinning* in *Related Information* below.

## Combining "worker" and "xs\_worker" Roles on a Single Host

In order to scale-out XS advanced applications in an existing multi-host setup, you can add the `xs_worker` role to hosts that already have the `worker` role, for example, using the functionality provided by the `hdb1cm` command, as shown in the following figure:

Combining `xs_worker` and `worker` Roles on the Same Host

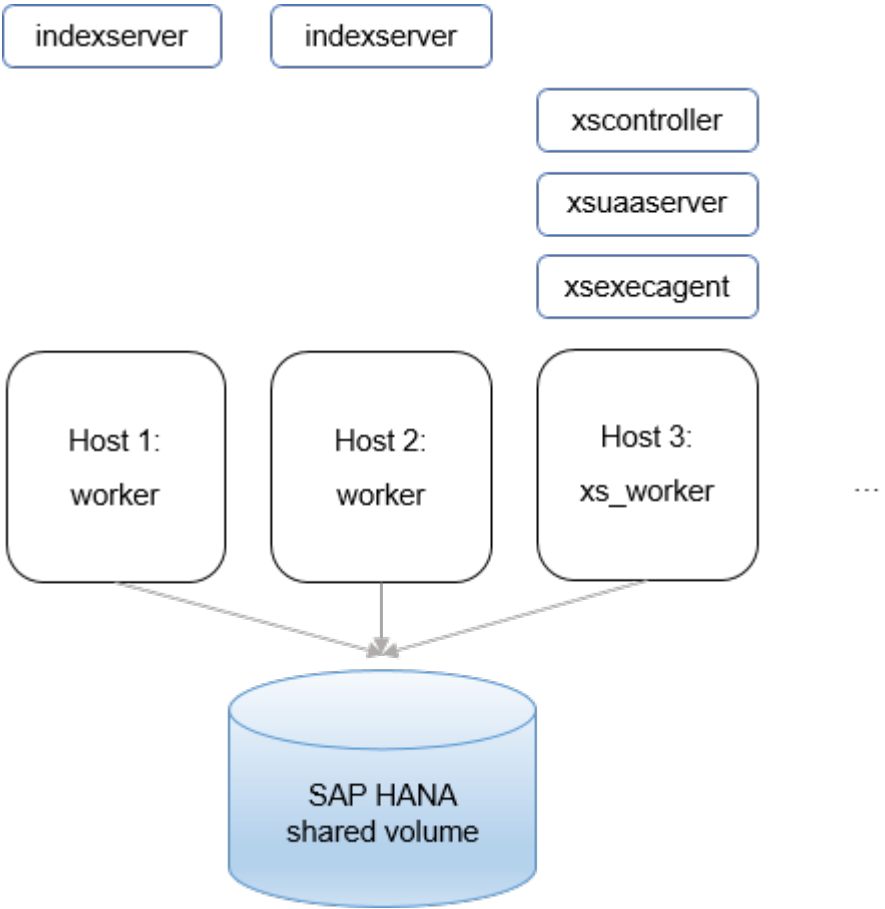

The first host assigned the `xs_worker` role runs the processes `xscontroller`, `xsuaaserver` and `xsexecagent`. Additional hosts with the `xs_worker` role only run `xsexecagent` services, which enables them to start application processes on the additional hosts as well.

For more information about assigning additional roles to hosts, see *Adding Host Roles*, in *Related Information* below.

## Separating "worker" and "xs\_worker" Roles Between Different Hosts

It is also possible to separate XS advanced application processes from SAP HANA database processes. If you add additional SAP HANA hosts and assign them only the `xs_worker` role, host resources (for example,

memory or CPU) are strictly separated between XS advanced application and database processes, as illustrated in the following diagram:

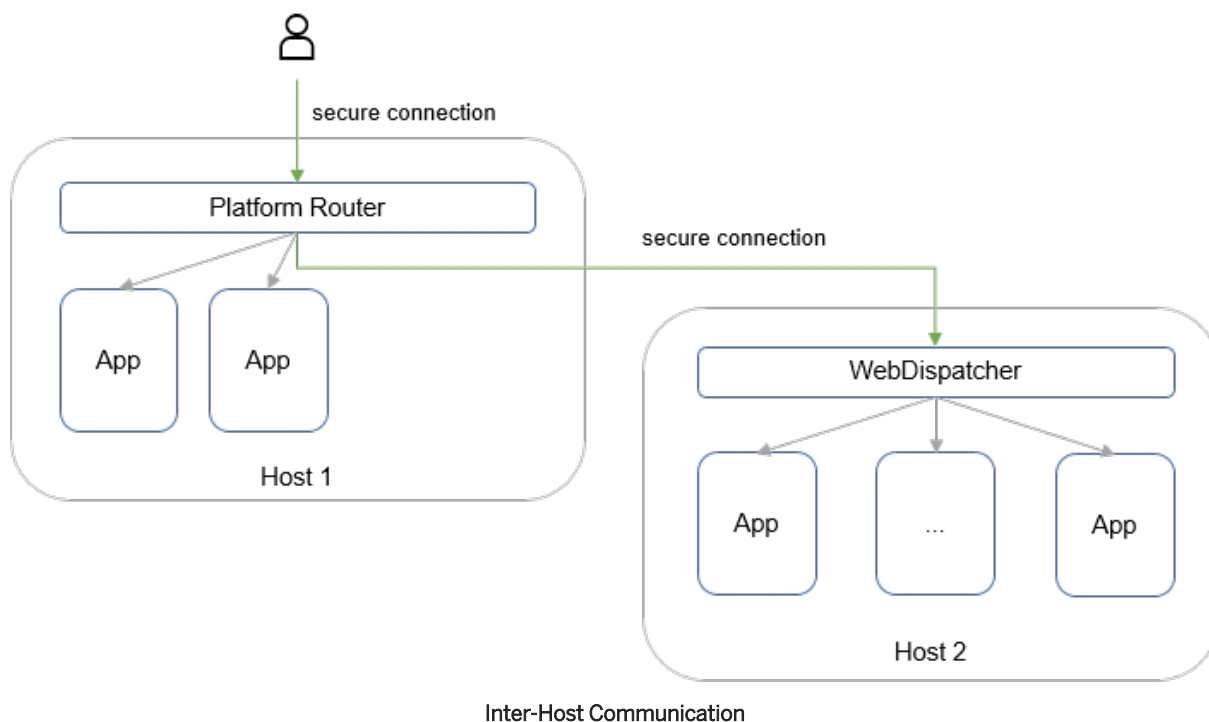

Separating worker and xs\_worker Hosts

You can combine both setup variants in the same SAP HANA system, for example, using hosts with both the `worker` and `xs_worker` role alongside hosts with only the `xs_worker` role. This scenario might be useful if you want to isolate particular applications. For more information, see *Maintaining Host Pinning* in *Related Information*.

### Inter-Host Communication

The XS advanced Platform Router is the central entry point for all requests to the XS advanced applications, even when XS advanced is scaled out across multiple hosts. To forward requests from the Platform Router to other hosts in a scale-out scenario, an extra SAP WebDispatcher process is automatically started and maintained by XS advanced on the scale-out host. For this reason, no additional custom configuration is

necessary. The Web Dispatcher receives forwarded requests on a secure TLS connection, terminates SSL, and forwards the requests to the appropriate applications instances:

## XS Advanced and Host Auto-Failover

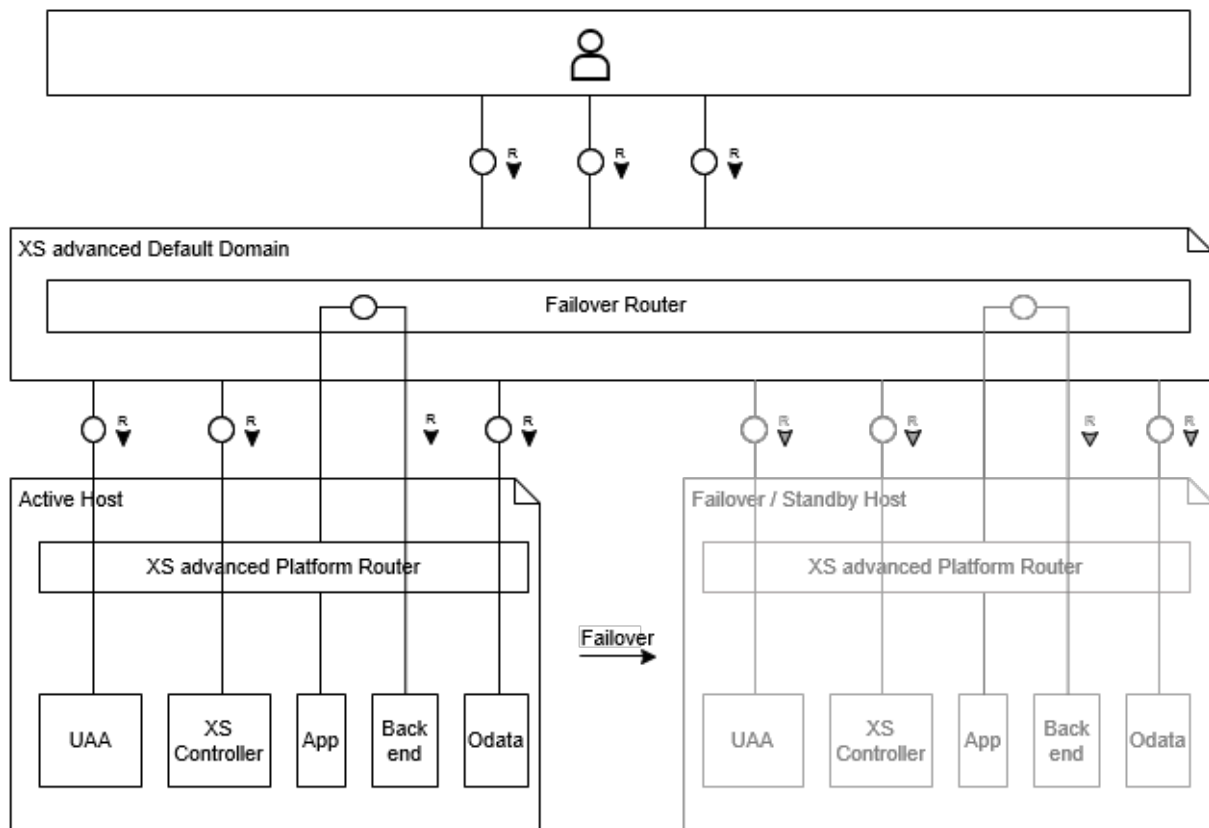

In an SAP HANA multi-host system where standby or `xs_standby` host roles are assigned or where the `xs_worker` host role is assigned to the master host candidate, host auto-failover might occur with XS advanced. If a host fails, and either a standby host or a master candidate host takes over, you must make sure that requests to the XS advanced platform and any corresponding applications are routed to the correct host even after the failover.

### → Tip

For more information regarding host auto-failover, see *Host Auto-Failover Setup with XS Advanced Run Time* in *Related Information* below.

The following options are available for routing requests:

- If no standby or `xs_standby` roles are assigned in the system, you can assign the `xs_worker` role to a host that is not a master candidate to prevent host auto-failover with XS advanced in general. For more information, see *Host Auto-Failover Parameters* in *Related Information* below.
- You can use virtual IP addresses or alias host names and make sure that after the takeover the failover hosts have the same route as the failing hosts.
- You can set up a failover router that ensures that requests to the XS advanced platform and applications are routed to the correct host even after the XS advanced platform router is moved to a different SAP HANA host, as illustrated in the following diagram:

Host Auto-Failover Setup for XS advanced

### → Tip

For more information, see *Setting Up the XS Advanced Run Time Behind a Reverse Proxy in Related Information*.

## Certificate Setup with a Failover Router

If you terminate SSL at the reverse proxy, the failover router must trust both the active and the failover (or standby) hosts. To configure this trust relationship, choose one of the following approaches:

- Create a certificate that includes the names of all the hosts in the SAP HANA system, in the *Subject Alt Names* section.

Then, install it on the XS advanced Platform Router with `xs set-certificate`

### → Tip

For more information, see *Maintaining Domains in XS Advanced in Related Information* below.

- If you are sure that there are no security risks, you can consider turning off host-name validation in the failover router.

For more information about setting up certificates, see *Establishing the Trust Relationship with a Reverse Proxy in Related Information* below, and in particular, the sections *Certificate Setup without SSL Termination at Reverse Proxy* and *Certificate Setup with SSL Termination at Reverse Proxy*.

## Shutdown in a Multi-Host Setup

It is recommended to use the `sapcontrol` command to shut down a multi-host SAP HANA system, as described in *Starting and Stopping Distributed SAP HANA Systems Using SAPControl* in *Related Information* below. If you want to stop each host individually, for example, with the command `HDB stop`, make sure that you shut down the active master host (the host currently running the master `nameserver` service) last, in order to prevent a master failover during shutdown. This is particularly important when XS advanced services are running on the active master host. During a shutdown in a multi-host scenario, XS advanced application instances switch hosts along with the `nameserver` service, which is an unnecessary operation during shutdown.

# 14 Data Access

SAP HANA supports the integration of data from many data sources to enrich your applications and deliver in-depth analysis. These include federated queries, data replication, and processes to improve data quality.

This section provides an overview of the tools and technologies that are available with SAP HANA or supported by SAP HANA for data access and data virtualization. For more information about the administration of these technologies, as well as other operations topics, refer to the documentation indicated.

## Native Capabilities for Data Access, Integration, and Quality in SAP HANA

Capability	Description	More Information
Data Federation with SAP HANA Smart Data Access (SDA)	SAP HANA SDA enables you to create virtual tables in SAP HANA that point to virtual tables on remote sources, such as SAP ASE, SAP IQ, Hadoop, and Teradata.	See <a href="#">SAP HANA Smart Data Access [page 2011]</a> and <a href="#">SAP HANA Hadoop Integration [page 2138]</a>
Data Replication and Transformation	SAP HANA smart data integration provides the architecture that supports all types of data delivery in SAP HANA: real-time, batch, and federation (SDA). It includes both data replication and data transformation services.	See the documentation for SAP HANA smart data integration and SAP HANA smart data quality option on SAP Help Portal at <a href="https://help.sap.com/viewer/p/HANA_SMART_DATA_INTEGRATION">https://help.sap.com/viewer/p/HANA_SMART_DATA_INTEGRATION</a> .

## Data Replication Technologies in the Extended SAP HANA Landscape

Capability	Description	More Information
Trigger-Based Replication	The trigger-based replication method uses the SAP Landscape Transformation (LT) Replication Server component to pass data from the source system to the SAP HANA database target system.	See the documentation for SAP HANA real-time replication on SAP Help Portal at <a href="https://help.sap.com/viewer/p/SAP_LANDSCAPE_TRANSFORMATION_REPLICATION_SERVER">https://help.sap.com/viewer/p/SAP_LANDSCAPE_TRANSFORMATION_REPLICATION_SERVER</a> .
SAP HANA Direct Extractor Connection	SAP HANA Direct Extractor Connection (DXC) provides SAP HANA with out-of-the-box foundational data models based on SAP Business Suite entities, and is a data acquisition method as well.	See <a href="#">SAP HANA Direct Extractor Connection Implementation Guide</a>

Capability	Description	More Information
Extraction Transformation Load-Based Replication	Extraction Transformation Load (ETL)-based data replication uses SAP Data Services (also called Data Services) to load relevant business data from SAP ERP to the SAP HANA database. This lets you read the business data on the application layer level.	See the documentation for SAP Data Services on SAP Help Portal at <a href="http://help.sap.com/viewer/p/SAP_DATA_SERVICES">http://help.sap.com/viewer/p/SAP_DATA_SERVICES</a>
Log-Based Replication	SAP Replication Server (SRS) moves and synchronizes transactional data including DML and DDL across the enterprise, providing low impact, guaranteed data delivery, real-time business intelligence, and zero operational downtime.	See the documentation for SAP Replication Server on SAP Help Portal at <a href="http://help.sap.com/viewer/p/SAP_REPLICATION_SERVER">http://help.sap.com/viewer/p/SAP_REPLICATION_SERVER</a>

## Related Information

[Important Disclaimer for Features in SAP HANA](#)

## 14.1 SAP HANA Smart Data Access

SAP HANA smart data access (SDA) allows you to access remote data as if the data were stored in local tables in SAP HANA, without copying the data into SAP HANA.

This capability provides operational and cost benefits and supports the development and deployment of next-generation analytical applications requiring the ability to access, synthesize, and integrate data from multiple systems in real time.

In SAP HANA, you use linked database or create virtual tables, which point to remote tables in different data sources, and then write SQL queries in SAP HANA that use these virtual tables. The SAP HANA query processor optimizes these queries by executing the relevant part of the query in the target database, returning the results of the query to SAP HANA, and then completing the operation. Physical data movement is not supported by SAP HANA smart data access.

Because smart data access is part of the SAP HANA core system, no additional licensing is required to use it. Additional support packages and patches are available for download from the SAP Software Download Center, and are installed using the SAP HANA database lifecycle manager (HDBLCM).

For a list of supported remote source databases and versions, see SAP Note 2600176 - *SAP HANA Smart Data Access Supported Remote Sources*.

## Related Information

## 14.1.1 Linked Database Overview

Linked database allows DML queries on remote sources without the need to first create virtual tables for each table referenced in a query before executing the query.

This feature makes ad-hoc access to remote data much more convenient.

Linked database uses a three-part namespace to directly identify the remote database, schema, and table name. The three-part name syntax is defined as:

```
<remote_source>.<remote_schema>.<remote_table>
```

Queries between tenant databases, known as cross-database access, also use this three-part namespace. It is possible for the name of a remote source and a tenant database to be the same. If this situation occurs, then the database name resolves to the tenant database as a cross-database query, not the remote source.

The linked database feature supports all smart data access remote sources and the LINKED DATABASE system privilege is required to use the feature.

When a query is executed, the system locates the referenced remote table and then checks to see if it has been used in previous queries. If it hasn't, then the system automatically creates an internal virtual table, which is used to process the query. Subsequent queries to the same remote table are automatically redirected to the internal virtual table. Users cannot directly access these internal virtual tables. However, they can be administered for refreshing metadata and housekeeping.

### Linked Database Optimized Mode

With optimized mode, when a query is executed, the metadata for referenced remote objects is cached locally. Internal virtual tables are no longer created. This metadata is automatically refreshed. No housekeeping tasks are required. If the remote object referenced is a view, then the metadata of the tables, which are part of the view definition, are also cached locally. You don't need to create or refresh statistics for remote objects. They are fetched automatically when needed. The global optimizer may generate a better query plan, resulting in better query performance.

While linked database is supported for all smart data access remote sources, optimized mode is only available for SAP HANA to SAP HANA workflows.

Optimized mode is disabled by default. To enable it, when you create a remote source, set the `linkeddatabase_mode` property to *optimized*. For example:

```
CREATE REMOTE SOURCE MY_HANA1 ADAPTER "hanaodbc"  
  CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=myserver:  
30115;linkeddatabase_mode=optimized'  
  WITH CREDENTIAL TYPE 'PASSWORD' USING 'user=user1;password=Test1234';
```

Linked database optimized mode has some function restrictions. For more information, see SAP Note 2605574 - *Linked Database Optimized Mode Functional Restrictions*.

## Related Information

[SAP Note 2605574](#) 

### 14.1.2 Setting Up ODBC Drivers

The communication between SAP HANA and a remote data source is based on the ODBC protocol. To use the protocol, install the appropriate drivers for the databases you want to connect to using SAP HANA smart data access.

#### Supported Remote Source Databases

For a list of supported remote source databases and versions, see SAP Note [2600176](#)  - *SAP HANA Smart Data Access Supported Remote Sources*.

#### .ODBC.INI File

SAP HANA smart data access requires that a `.odbc.ini` file exist in the administrator's home directory, even if empty. If using DSN references to create the remote source, create one entry in the `.odbc.ini` file for each remote source.

#### ODBC Driver Installation Location

Install ODBC driver library files in a location that is searched by the SAP HANA server. Libraries installed in the SAP HANA `exe` directory are found automatically. Libraries installed elsewhere require an entry in the `LD_LIBRARY_PATH` environment variable to point to this location. If SAP HANA is unable to locate the libraries, you may experience messages during SAP HANA smart data access queries stating the driver could not be loaded. To prevent possible interference with software maintenance of the SAP HANA product, we recommended that you install the ODBC files to a location other than the SAP HANA `exe` directory and add the path to the `LD_LIBRARY_PATH` environment variable.

In a scale-out landscape, install the driver on all hosts.

The `LD_LIBRARY_PATH` environment variable is configured by creating or modifying the `.customer.sh` file in the home directory of the SAP HANA administrator user to include the following entry:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/<path_to_driver_directory>
```

Since the `LD_LIBRARY_PATH` environment variable includes the directory path, the `'Driver='` entry in the DSN section of the `.odbc.ini`, or in the `CREATE REMOTE SOURCE` command only needs to contain the

library name. Restart the SAP HANA system to apply the change to the `.customer.sh` file. To validate that the changes in `.customer.sh` have taken effect, logged in as the `<sid>adm`, execute:

```
echo $LD_LIBRARY_PATH
```

### ❖ Example

If the IQ ODBC libraries are installed in `/usr/sap/sap/iaq/IQ-16_0/lib64`, the administrator's `$HOME/.customer.sh` file should include:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/sap/sap/iaq/IQ-16_0/lib64
```

This statement adds the directory `/opt/sap/IQ-16_0/lib64` to the end of the search path SAP HANA uses to find libraries.

## HADOOP (ODBC) Driver

See the *SAP HANA Hadoop Integration* guide.

## ODBC Driver Software Ownership

We recommend that you do not make the `<sid>adm` user the software the owner of the ODBC driver library files. Create a new user to become the software owner.

## Remote Sources

The process to install, configure, and create remote sources depends on the ODBC driver. Refer to the specific driver for details.

## Related Information

[SAP HANA Hadoop Integration](#)

### 14.1.2.1 SAP HANA ODBC Driver

SAP HANA Smart Data Access uses the SAP HANA ODBC driver installed with the SAP HANA server.

The SAP HANA ODBC driver only supports access to a remote SAP HANA database version SPS 10 or later. No additional configuration of the driver is required.

## 14.1.2.2 SAP IQ ODBC Driver

The SAP IQ ODBC driver is included in the SAP HANA smart data access maintenance software component, which is available for download from the SAP Software Download Center.

### Prerequisites

For encrypted connections, patch level 1 (or later) of the SAP HANA SMART DATA ACCESS 2.0 package is required.

### Context

You can use the SAP HANA database lifecycle manager (HDBLCM) to install or update the SAP HANA smart data access package, as described below.

### Procedure

1. Download and extract the maintenance SAR file to a temporary location on the SAP HANA host.
2. Log on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`), and change to the `hdblcm` directory within the `<SID>` folder.
3. Start the installer. Be sure to include the path to the location of the extracted smart data access package:

```
./hdblcm --component_dirs=/path to package
```

4. When installation is complete, use the `find` command to verify that the ODBC driver is installed. By default, the ODBC driver (`libdbodbc17_r.so` library file) is installed to `/hana/shared/<SID>/federation`. Note the full path as it is needed in future steps.

```
find /hana/shared -name libdbodbc17_r.so
```

5. Switch to the `<sid>adm` `$HOME` directory.
6. Create or modify the `.customer.sh` file to add the following line:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

7. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## Related Information

[SAP Software Download Center](#) 

### 14.1.2.3 SAP Adaptive Server Enterprise ODBC Driver

The SAP Adaptive Server Enterprise (ASE) ODBC driver is included in the SAP HANA smart data access maintenance software component, which is available for download from the SAP Software Download Center.

## Prerequisites

For encrypted connections, patch level 1 (or later) of the SAP HANA SMART DATA ACCESS 2.0 package is required.

## Context

You can use the SAP HANA database lifecycle manager (HDBLCM) to install or update the SAP HANA smart data access package, as described below.

## Procedure

1. Download and extract the maintenance SAR file to a temporary location on the SAP HANA host.
2. Log on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`), and change to the `hdb1cm` directory within the `<SID>` folder.
3. Start the installer. Be sure to include the path to the location of the extracted smart data access package:

```
./hdb1cm --component_dirs=/path to package
```

4. When installation is complete, use the `find` command to verify that the ODBC driver is installed. By default, the ODBC driver (`libsybdrvodb-sql1en8.so`) is installed to `/hana/shared/DT1/federation`. Note the full path as it is needed in future steps.

```
find /hana/shared -name libsybdrvodb-sql1en8.so
```

5. Switch to the `<sid>adm` `$HOME` directory.
6. Create or modify the `.customer.sh` file to add the following line:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

- Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## Related Information

[SAP Software Download Center](#) 

### 14.1.2.4 SAP Event Stream Processor ODBC Driver

SAP Event Stream Processor (ESP) on Linux ODBC driver is included in the ESP software package, and is available for download from the SAP Software Download Center.

## Prerequisites

Java is installed on the SAP HANA host.

## Context

The ESP ODBC driver can be installed using the *Custom* option in the full ESP installer, or from the `.../archives/esp_odbc` folder where you extracted the ESP package. If Java is not installed, and you use the full installer, the installation appears to run successfully, but the ODBC driver is not installed. If you install from the `esp_odbc` folder, an error message appears and the installation fails if Java is not installed.

## Procedure

- Download and extract the ESP package to a temporary location on the SAP HANA host.
- Download and install the unixODBC driver manager, which is included in the SAP Event Stream Processor installation package or available from your Linux provider.
- Logged on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`), change to the `location` where you extracted the ESP package.
- Change to the `../archives/esp_odbc` folder and type:

```
./setup.bin
```

- When installation is complete, use the `find` command to verify that the ODBC driver is installed. By default, the ODBC driver (`streamingpsqlodbc_lib.so`) is installed to `/opt/sybase/lib`. Note the full path as it is needed in future steps.

```
find /opt/sybase/lib -name libstreamingpsqlodbc_lib.so
```

6. Switch to the `<sid>adm $HOME` directory.
7. Create or modify the `.customer.sh` file to add the following lines:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>/lib
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>/STREAMING-1_0/odbc
```

where `<odbc_path>` is the path to the ODBC driver.

8. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## Related Information

[SAP Software Download Center](#) 

### 14.1.2.5 SAP HANA Streaming Analytics ODBC Driver

SAP HANA streaming analytics ODBC driver is installed as part of the streaming analytics installation or the streaming analytics client, and is available for download from the SAP Software Download Center.

## Context

You can create a remote source to a streaming analytics system running on another host or on the current host. If the remote source points to the current host, the streaming analytics ODBC driver is already installed as part of the streaming analytics instance. If the remote source points to a different host, install the streaming analytics client. The version of the client must be the same as the current host, not the remote host. For example, the current host is running SAP HANA 2.0 SPS 00, while the remote host is running SAP HANA 1.0 SPS 12. You would install the 2.0 client, not the SPS 12 client.

## Procedure

1. If required, install the SAP HANA streaming analytics client, which includes the ODBC driver.
2. Download and install the unixODBC driver manager, which is included in the streaming analytics installation package or available from your Linux provider.
3. Log on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`).
4. Switch to the `<sid>adm $HOME` directory.
5. Create or modify the `.customer.sh` file to add the following lines.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$STREAMING_HOME/odbc
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:$STREAMING_HOME/lib
```

### Note

If streaming analytics is already installed, these entries may already exist.

- Restart the SAP HANA instance to apply the changes to the `.customer.sh` file.

## Related Information

[SAP Software Download Center](#)

### 14.1.2.6 SAP MaxDB ODBC Driver

The SAP MaxDB ODBC driver is included in the SAP MaxDB LinuxDB server installation package, which is available for download from the SAP Software Download Center.

## Procedure

- Download and extract the client installation files to a temporary location on the SAP HANA host.
- On the SAP HANA host, logged on as the SAP HANA software owner (`<sid>adm`), switch to the location of the extracted files.
- Type:

```
./SDBINST
```

- When prompted for the software components to install, select *ODBC only*.
- When installation is complete, use the `find` command to verify that the ODBC driver is installed. By default the ODBC driver (`libsdbodbcw.so` library file) is installed to `/sapdb/clients/MAXDB`.

```
find /sapdb/ -name libsdbodbcw.so
```

- Change to the `<sid>adm` \$HOME directory.
- Add the following line to the `.customer.sh` file.

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

- Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## Related Information

[SAP Software Download Center](#)

## 14.1.2.7 Teradata ODBC Driver

Teradata drivers are packaged and distributed as a Linux RPM file. You can obtain these RPMs from Teradata.

### Procedure

1. Download and extract the files to a temporary location on the SAP HANA host.
2. On the SAP HANA host, logged on as the SAP HANA software owner (<sid>adm), install the extracted files.
  - For version 13, installation of TeraGSS\_redhatlinux-i386\_\_linux\_i386.13.10.00.06-1.tar.gz normally fails. While not required for the ODBC installation, the installation attempt prevents `sudo rpm -i tdodbc-13.10.00.04-1.noarch.rpm` from failing with missing dependencies, which is required as part of the driver installation.
  - For version 14, run `sudo rpm -i tdicu-14.10.00.04-1.noarch` to prevent a dependency error.
3. Change the default Kerberos 5 setup.

The Teradata driver loads GSS API libraries from the OS folders, which conflict with the version of libraries loaded by SAP HANA during installation. Since SAP HANA does not support single sign-on for Teradata remote sources, you can safely disable the Kerberos 5 mechanism.

- a. Edit the `/<installaton_path>/teragss/site/TdgssUserConfigFile.xml` file and add:

```
<Mechanism Name="KRB5">
  <MechanismProperties MechanismEnabled="no" />
</Mechanism>
```

- b. Remove the `/<installaton_path>/teragss/site/linux-x8664/<version>/TdgssUserConfigFile.xml` file, if it exists.
- c. As `sudo rmp`, execute:

```
/opt/teradata/teragss/linux-x8664/client/bin/run_tdgssconfig
```

## 14.1.2.8 SQL Server ODBC Driver

Remote sources for SQL Server databases require the Microsoft ODBC driver for SQL Server.

### Procedure

1. Download and extract the Microsoft ODBC driver package to a temporary location on the SAP HANA host.
2. Download and install the unixODBC driver manger as specified by SQL Server.
3. On the SAP HANA host, logged on as the SAP HANA software owner (<sid>adm), install the Microsoft ODBC driver.  
The driver installation creates the following directory: `/opt/microsoft/msodbcsql/lib64`.

4. Change to the `<sid>adm $HOME` directory.
5. Add the following line to the `.customer.sh` file:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

Depending on your setup, you might also need to add `/usr/local/lib64` to the SAP HANA administrator user's `PATH` variable.

6. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## 14.1.2.9 IBM DB2 Driver

IBM DB2 drivers are available on the IBM website.

### Procedure

1. Download and extract the IBM DB2 ODBC package to a temporary location on the SAP HANA host.
2. Download and install the unixODBC driver manager as specified by IBM DB2.
3. Log on to the SAP HANA system as the root user.
4. Create the following directory: `/opt/ibm/db2` and extract the ODBC package there.
5. Change to directory: `/opt/ibm/db2/odbc_cli/clidriver/cfg`.
6. Add a new entry to the `db2cli.ini` file, replacing the applicable information for your system.

#### Sample Code

```
[TEST_DB2]
Database=<database_name>
Protocol=TCPIP
Port=50010
Hostname=<machine_name>
```

7. Use the `find` command to verify the ODBC driver is installed. By default, the ODBC driver (`libdb2o.so.1` library file) is installed to `/opt/ibm/db2/odbc_cli/clidriver/lib`. Note the full path as it is needed in future steps.

```
find /opt/ibm -name libdb2o.so.1
```

8. Log on as the `<sid>adm` user and switch to the `<sid>adm $HOME` directory.
9. Create or modify the `.customer.sh` file to add the following line:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

10. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## 14.1.2.10 Oracle Database ODBC Driver

Remote sources for Oracle databases require the ODBC driver for Oracle.

### Context

If you are configuring SAP HANA Smart Data Access (SDA) to Oracle SuperCluster, the unixODBC driver also needs to be configured as described in SAP Note 2501150 - *HANA SDA connection to Oracle fails with ORA-12504*.

### Procedure

1. Download and extract the Oracle ODBC driver package to a temporary location on the SAP HANA host.
2. Download and install the unixODBC driver manager as specified by Oracle.
3. Install the Oracle ODBC driver package.
4. Change to `<install_path>/client64/lib` and verify it contains the ODBC driver `libsqora.so.<version>`.
5. Switch to the SAP HANA software owner (`<sid>adm`), then change to the `<sid>adm $HOME` directory.
6. Create a new `tnsnames.ora` file in the home folder. For details on the `tnsnames.ora` file, refer to the Oracle documentation.
7. Create or modify the `.customer.sh` file to add the following lines:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<install_path>/client64/lib
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:/usr/local/lib
export TNS_ADMIN=~/
```

8. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

### Related Information

[SAP Note 2501150](#) 

## 14.1.2.11 IBM Netezza Driver

IBM Netezza drivers are available on the IBM website.

### Procedure

1. Download and extract the IBM Netezza ODBC package to a temporary location on the SAP HANA host.
2. Download and install the unixODBC driver manager as specified by IBM Netezza.
3. Log on to the SAP HANA system as the root user.
4. Create a directory: `/usr/local/nz` and extract the ODBC package.
5. Change to the `linux64` folder within the path of the extracted package and type:

```
./unpack
```

6. Use the `find` command to verify the ODBC driver is installed. By default, the ODBC driver (`libnzodbc.so` library file) is installed to `usr/local/nz/lib64`. Note the full path as it is needed in future steps.

```
find /usr/local/nz -name libnzodbc.so
```

7. Log on as the `<sid>adm` user and switch to the `$HOME` directory.
8. Create or modify the `.customer.sh` file to add the following line:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<odbc_path>
```

where `<odbc_path>` is the path to the ODBC driver.

9. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## 14.1.2.12 Google BigQuery ODBC Driver

Remote sources for Google BigQuery databases require the ODBC driver for Google BigQuery.

### Procedure

1. Download the Linux 64-bit Simba ODBC driver for Google BigQuery from the Google Cloud Platform site.
2. Download and install the unixODBC driver manager as specified by Google BigQuery.
3. On the SAP HANA host, logged on as the SAP HANA software owner (`<sid>adm`), extract the file using the `--directory=/<install_path>` option.
4. Change to the folder you extracted the file to and edit the `simba.googlebigqueryodbc.ini` file. Change the following parameters:
  - o Set `DriverManagerEncoding` to use UTF-16. You will be unable to connect to the Google BigQuery database if this parameter is not set.

- Set ErrorMessagePath to point to `<install_path>/simba/googlebigqueryodbc/ErrorMessage`
  - Add `ODBCInstLib=libiodbcinst.so`
5. Create or modify the `customer.sh` file to add the following lines:

```
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<install_path>/simba/  
googlebigqueryodbc/lib/64  
export LD_LIBRARY_PATH=$LD_LIBRARY_PATH:<path_to_unixODBC_library>
```

6. Restart the SAP HANA system to apply the change to the `.customer.sh` file.

## 14.1.3 Managing Privileges

Various privileges are required to manage remote sources, virtual tables, and linked database.

### Remote Source

- Creating a remote source requires the CREATE REMOTE SOURCE system privilege.
- Managing a remote source created by another user requires additional object level privileges on the remote source. No privileges are required to manage your own remote sources.
- Managing other user's credentials on the remote source requires the CREDENTIAL ADMIN system privilege. No privileges are required to manage your own credentials.

### Virtual Tables

- Creating virtual tables requires the CREATE VIRTUAL TABLE object level privilege on the remote source.
- Managing virtual tables owned by other users requires additional object level privileges (for example, INSERT, UPDATE, DELETE). No privileges are required to manage your own virtual tables.

### Linked Database

Using and managing linked database requires the LINKED DATABASE object-level privilege on the remote source, regardless of who created the remote source. This requirement allows ad-hoc linked database access using a three part name (`<remote_source>.<schema_name>.<remote_table_name>`).

This privilege, validated on the SAP HANA side, controls access to the linked database feature. Granular access control checks are performed on the remote database system to avoid duplication of access control mechanisms. While a technical user can be used for linked database, it is recommended that secondary credentials be used for any linked database operations. Use CREDENTIAL management commands to manage the remote database user performing DML operations.

## Related Information

[GRANT Statement \(Access Control\)](#)

### 14.1.4 Managing Credentials

The following credential types (or credential modes) are supported for accessing a remote source: technical user, secondary credentials, and single sign-on with JSON Web Tokens.

Credential Type	Description
Technical user	A valid user and password in the remote database. This valid user is used by anyone using the remote source.
Secondary credentials (preferred option)	A unique access credential on the remote source assigned to a specific user.
Single sign-on with JSON Web Tokens	A JSON Web Token (JWT) is used to authenticate the user on the remote SAP HANA system. Users do not need to provide a password (SSO mode).

Both the technical user and secondary credentials types can be set up with either a password or Kerberos single sign-on.

## Related Information

[Managing Single Sign-On \(SSO\) with Kerberos \[page 2030\]](#)

[Managing Single Sign-On \(SSO\) with JSON Web Tokens \[page 2034\]](#)

[Managing Secondary Credentials \[page 2025\]](#)

#### 14.1.4.1 Managing Secondary Credentials

Secondary credentials let you assign different credentials to different users when using a remote source.

Accessing a remote database requires valid credentials on the database. All actions performed on the remote database are executed using these credentials and the privileges associated with them.

When creating a remote source, you can define a remote user name and password, called the technical user. With this configuration, all users using the remote source use the same technical user credentials to access to the remote database. If a user with secondary credentials accesses a remote source with a technical user defined, then the technical user credentials are used and the secondary credentials are ignored.

If you want to associate different remote credentials with individual users, then configure the remote source to use secondary credentials. With this configuration, users without secondary credentials can't access the remote source.

Dropping a remote source automatically drops all credentials, including secondary credentials associated with the remote source.

No privileges are required to manage your own credentials, but the CREDENTIAL ADMIN privilege is required to manage other credentials. Management of technical user credentials can be done by the owner of the remote source, or any user with the CREATE REMOTE SOURCE or CREDENTIAL ADMIN privilege.

## 14.1.4.1.1 Create Secondary Credentials for a User

Create secondary credentials for use with a remote source.

### Prerequisites

- Requires the CREDENTIAL ADMIN privilege to manage other credentials. No privileges are required to manage your own credentials.

### Context

Though not mandatory, creating the secondary credentials before creating the remote source speeds the process. Secondary credentials can only be created using SQL.

### Procedure

In an SQL console window on the local host, create secondary credentials for each user to access the remote source. The specified remote user must exist on the remote source.

```
CREATE CREDENTIAL FOR USER <HANA_user> COMPONENT 'SAPHANAFEDERATION' PURPOSE
'<remote_source_name>' TYPE 'PASSWORD' USING
'user=<remote_user_name>;password=<remote_user_password>';
```

### Example

This example creates secondary credentials for user1 to access remote source HANA2. User1 is assigned the credentials of user2 on the remote source HANA2.

```
CREATE CREDENTIAL FOR USER user1 COMPONENT 'SAPHANAFEDERATION' PURPOSE 'HANA2'
TYPE 'PASSWORD' USING 'user=user2;password=password1234>';
```

## Related Information

[CREATE CREDENTIAL Statement \(Access Control\)](#)

### 14.1.4.1.2 Delete Secondary Credentials for a User

Delete the secondary credentials assigned for use with a remote source.

#### Prerequisites

- Requires the CREDENTIAL ADMIN privilege to manage other credentials. No privileges are required to manage your own credentials.

#### Context

Secondary credentials can only be deleted using SQL.

#### Procedure

In an SQL console window on the local host, delete the secondary credentials for a specific user and remote source:

```
DROP CREDENTIAL FOR USER <HANA_user> COMPONENT 'SAPHANAFEDERATION' PURPOSE
'<remote__source_name>' TYPE 'PASSWORD';
```

#### Example

This example deletes the secondary credentials assigned to user1 for the remote source HANA2:

```
DROP CREDENTIAL FOR USER user1 COMPONENT 'SAPHANAFEDERATION' PURPOSE 'HANA2'
TYPE 'PASSWORD';
```

## Related Information

[DROP CREDENTIAL Statement \(Access Control\)](#)

### 14.1.4.1.3 Create a Remote Source Using Secondary Credentials

Create a remote source that uses secondary credentials to control access at the user level.

#### Prerequisites

- Requires the CREATE REMOTE SOURCE system privilege to manage remote sources.

### Create a Remote Source Using SQL Syntax

#### Context

Secondary credentials do not have to exist before you create the remote source without credentials, but you won't be able to connect to the remote source until they are created.

#### Procedure

In an SQL console window on the local host, create a remote source without credentials. The CONFIGURATION syntax to create a remote source depends upon the connection mode and ODBC driver.

```
CREATE REMOTE SOURCE <remote_source_name> ADAPTER <ODDBC_driver>  
CONFIGURATION <driver_specific_syntax>;
```

### Create a Remote Source Using the SAP HANA Database Explorer

#### Context

When creating the remote source, if secondary credentials for at least one user do not already exist, you can't save the remote source with the credential mode set to secondary credentials. Save the remote source with the credential mode set to *None*, create credentials for at least one user, and then modify the remote source to use secondary credentials.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select the applicable adapter.
5. Enter the properties for the specified adapter. In the *Credentials Mode* dropdown list, select *Secondary Credentials*. For adapter-specific properties, see *Creating Remote Sources*.
6. Choose *Create*.  
The system saves the change and then tests the new connection properties. If the connection fails, then a message appears, all filters are reset, and the remote object list is cleared.

## Related Information

[Creating Remote Sources \[page 2038\]](#)

### 14.1.4.1.4 Convert an Existing Remote Source to Use Secondary Credentials

Change the credentials mode of an existing remote source to use secondary credentials.

## Prerequisites

- Requires the CREATE REMOTE SOURCE system privilege to manage remote sources.

## Convert a Remote Source Using SQL Syntax

### Procedure

Execute:

```
ALTER REMOTE SOURCE <remote__source_name> DROP CREDENTIAL TYPE 'PASSWORD';
```

# Convert a Remote Source Using the SAP HANA Database Explorer

## Context

When converting the remote source, if secondary credentials for at least one user do not already exist, then you cannot save the remote source with the credential mode set to secondary credentials. Save the remote source with the credential mode set to *None*, create credentials for at least one user, and then modify the remote source to use secondary credentials.

## Procedure

1. Expand the *Catalog*.
2. Select *Remote Sources*.  
A list of remote sources appears in the catalog browser item list.
3. Select your remote source.  
The remote source editor opens.
4. Choose *Edit*.
5. In the *Credentials Mode* dropdown list, select *Secondary Credentials*.
6. Choose *Save*.  
The system saves the change and then tests the new connection properties. If the connection fails, then a message appears, all filters are reset, and the remote object list is cleared.

## 14.1.4.2 Managing Single Sign-On (SSO) with Kerberos

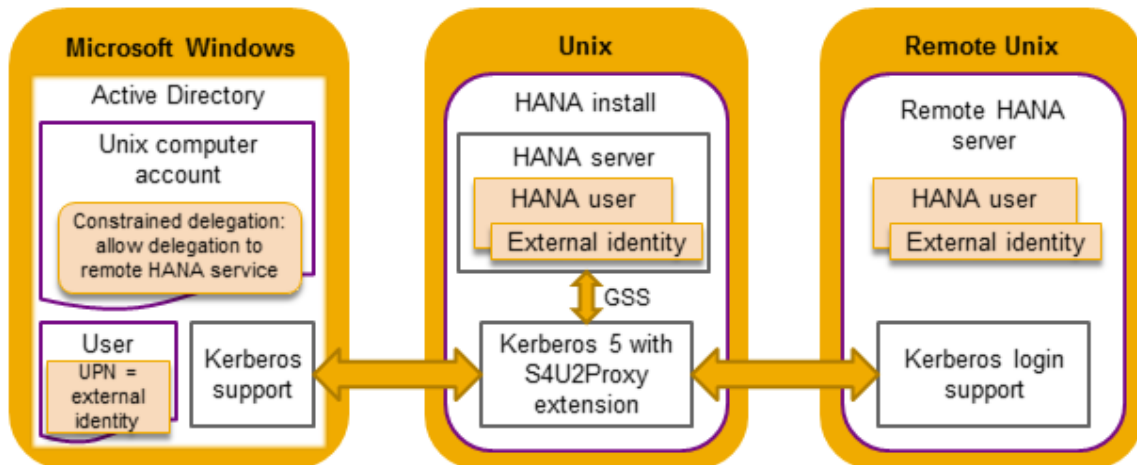

SAP HANA smart data access supports single sign-on with Kerberos for connections to SAP HANA on-premise remote sources. It is not supported for remote sources to SAP HANA service instances. Using Kerberos constrained delegation and protocol transition allows SAP HANA users to be authenticated automatically on Microsoft Windows Active Directory, without having to provide a password (SSO mode).

## Prerequisites

Microsoft Windows Server, version 2003 or later.

## Architecture Overview

The Kerberos platform architecture used in SSO authentication for connections to SAP HANA remote sources is shown below. Protocol transition is assured by Kerberos 5's S4U2Proxy extension:

1. The local SAP HANA server is authenticated only once as a computer using the `krb5_host.keytab`.
2. Users sign on to the local SAP HANA server using an authentication protocol.
3. The local SAP HANA server requests a constrained delegation ticket in its name for the SAP HANA user external identity.
4. The connection to the remote SAP HANA server is authenticated with the constrained delegation ticket.
5. In the authentication validation process, the constrained delegation ticket is validated against the remote SAP HANA service SPN.

Kerberos 5 is installed automatically together with SAP HANA. It contains the S4U (Service for User) extension needed for user impersonation and constrained delegation. Constrained delegation means that delegation can be done only to a predefined set of services. For the purposes of protocol transition, the computer on which the server is installed needs to be entrusted by the Microsoft Windows Active Directory for delegation.

Note that the Kerberos platform is used in SAP HANA for authentication only and not for session management.

## Configuration

The Kerberos configuration is defined in the following configuration files:

Configuration File	Description
<code>&lt;sidadm home&gt;/etc/krb5_hdb.conf</code>	Configuration of the Kerberos realm to be used with the SAP HANA server installed under <code>&lt;SID&gt;adm</code> .

Configuration File	Description
<sidadm home>/etc/krb5_hdb.keytab	List of service keys required to authenticate the services on the Kerberos server.
<sidadm home>/etc/krb5_host.keytab	One entry only to authenticate the host on the Kerberos server for the purpose of delegation.

If the files are present in the <sidadm home>/etc folder, the configuration is automatically taken from there, otherwise the default OS configuration in /etc/krb5.conf and /etc/krb5.keytab is used instead.

For a custom setup of Kerberos, you can overwrite the following variables in /usr/sap/<SID>/home/.customer.sh: KRB5\_CONFIG, KRB5\_KTNAME, KRB5\_CLIENT\_KTNAME. For example:

#### Sample Code

```
export KRB5_CONFIG=<conf file>
export KRB5_KTNAME=<hdb keytab file>
export KRB5_CLIENT_KTNAME=<host keytab file>
```

## 14.1.4.2.1 Configure Kerberos On Local SAP HANA

On the local SAP HANA server, configure Kerberos to support constrained delegation.

### Procedure

1. Configure the Kerberos realm to be used with the SAP HANA server and enable delegation by setting the `forwardable` parameter for Kerberos service tickets to `true` in the `krb5_hdb.conf` file.
2. On the Microsoft Windows Active Directory server, create a Windows Domain account for the SAP HANA server computer and map a host service principal name (SPN) to it.
3. Add the `hdb` service of a remote SAP HANA server to a Microsoft Windows Active Directory account in order to be able to log in to the remote SAP HANA server using Kerberos. Enable constrained delegation and protocol transition for your remote SAP HANA server in the Active Directory Users and Computers application.
4. Add a keytab entry for the `hdb` service. The keytab stores the keys needed by the SAP HANA server to take part in the authentication protocol.

### Results

For more information about how to set up SSO for SAP HANA smart data access using Kerberos and Microsoft Windows Active Directory, see the **SAP HANA Smart Data Access Single Sign-On Guide** attached to SAP Note [2303807](#).

## 14.1.4.2.2 Create a Remote Source Using Kerberos Authentication

Connect users to an SAP HANA remote source using single sign-on (SSO) with Kerberos.

### Prerequisites

- Requires the CREATE REMOTE SOURCE system privilege to manage remote sources.

### Context

Kerberos authentication is primarily used as an alternative to the technical user credential type. You can declare it as either a global credential type for the remote source or as the individual type for a given user. If a user has user level credentials defined and the remote source has global credentials defined, the global credentials are used; the user level credentials are ignored on the remote source.

### Procedure

1. Do one of:

To:	Execute:
Create global credentials	<pre>CREATE CREDENTIAL FOR COMPONENT 'SAPHANAFEDERATION' PURPOSE &lt;remote_source_name&gt; TYPE 'KERBEROS';</pre>
Create user level credentials	<pre>CREATE CREDENTIAL FOR USER &lt;user_name&gt; COMPONENT 'SAPHANAFEDERATION' PURPOSE &lt;remote_source_name&gt; TYPE 'KERBEROS';</pre>

2. Create a remote source using the credential type KERBEROS.

### Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)

### 14.1.4.3 Managing Single Sign-On (SSO) with JSON Web Tokens

SAP HANA smart data access supports single sign-on with JSON Web Tokens (JWT) for connections to SAP HANA on-premise and SAP HANA service remote sources. JWT allows SAP HANA users to be authenticated automatically on the remote SAP HANA server, without having to provide a password (SSO mode).

To use JWT in an SAP HANA smart data access scenario, the local SAP HANA system is registered as a JWT identity provider in the remote SAP HANA system. The local SAP HANA system then generates the JWTs that are required to authenticate the users accessing the remote SAP HANA system.

The JWT single sign-on process involves the following high-level steps:

1. Users sign on to the local SAP HANA system.
2. Before creating a connection to the remote SAP HANA server, SAP HANA smart data access (SDA) requests a JWT token for the user in the local SAP HANA system.
3. A JWT is issued in the local SAP HANA system and passed to SDA.
4. SDA creates a connection to the remote SAP HANA server using the JWT.
5. The connection is authenticated by the remote SAP HANA server using the JWT.

#### Related Information

[Set Up the JWT SSO Environment \[page 2034\]](#)

[Create a Remote Source with JWT Authentication \[page 2036\]](#)

[Convert an Existing Remote Source to Use JWT \[page 2037\]](#)

[Single Sign-On Using JSON Web Tokens](#)

#### 14.1.4.3.1 Set Up the JWT SSO Environment

On the local and remote SAP HANA servers, configure a JSON Web Token (JWT) single sign-on (SSO) environment for smart data access.

#### Context

The local SAP HANA system requires a private key and certificate stored in a dedicated trust store (PSE) to be able to sign the JWTs. The remote SAP HANA server also requires a PSE for JWT authentication.

The local SAP HANA system is registered as a JWT provider in the remote SAP HANA system. The name of the claim in the JWT token to be used for mapping the SAP HANA user to an external user name is defined when creating the JWT provider in the remote SAP HANA system.

The database users in the remote SAP HANA system are created with an external identity. During the authentication process, the name of the database user in the local SAP HANA system is matched with the external identity of the remote user.

Note that the standard SAP HANA JWT SSO feature is used in the remote SAP HANA server. For more information, see *Single Sign-On Using JSON Web Tokens*.

## Procedure

1. On the local SAP HANA server, set up JWT SSO as follows:
  - a. Create a PSE for signing the JWT:

```
CREATE PSE <pse_name>;
ALTER PSE <pse_name> SET OWN CERTIFICATE '
-----BEGIN RSA PRIVATE KEY-----
...
-----END RSA PRIVATE KEY-----
-----BEGIN CERTIFICATE-----
... (same as the certificate in the remote database)
-----END CERTIFICATE-----';
SET PSE <pse_name> PURPOSE JWT;
```

Note that you can create the private key and certificate using OpenSSL:

### Sample Code

```
openssl genrsa -out jwtkey.pem 2048
openssl req -new -x509 -key jwtkey.pem -out jwtpub.crt -days 3650 -subj
"/CN=JWT SignTest PublicKey"
```

2. On the remote SAP HANA server, set up JWT SSO as follows:
  - a. Create a certificate from the public certificate of the local SAP HANA database:

```
CREATE CERTIFICATE FROM '
-----BEGIN CERTIFICATE-----
... (same as the certificate in the local database)
-----END CERTIFICATE-----
' COMMENT <comment>;
```

- COMMENT: A string literal. For example, COMMENT 'JWT\_SSO\_PUB'.

The created certificate is now contained in the CERTIFICATES system view and can be added to a PSE store.

- b. Create a JWT identity provider for the local SAP HANA database:

```
CREATE JWT PROVIDER <jwt_provider_name> WITH ISSUER 'hana://<host name>/
<instance name>/<database name>' CLAIM 'user' AS EXTERNAL IDENTITY;
```

- ISSUER: The local SAP HANA database. You can find the host name and instance name in the M\_HOST\_INFORMATION monitoring view. The instance name is shown in sid.  
Example: 'hana://saphdb01/HD1/HD1'
- CLAIM: The claim name is 'user'. Note that the claim name is not freely selectable, it must be 'user'. It is used as a key in the JWT body. Its value in the JWT is the name of the database user in the local SAP HANA system.

- c. Create a PSE for JWT authentication and add the certificate created above to it. Then set the purpose of the newly created PSE to JWT:

```
CREATE PSE <pse_name>;

SELECT CERTIFICATE_ID FROM SYS.CERTIFICATES WHERE COMMENT=<comment>;
ALTER PSE <pse_name> ADD CERTIFICATE <certificate_id>;

SET PSE <pse_name> PURPOSE JWT FOR PROVIDER <jwt_provider_name>;
```

- d. Create a user and enable the JWT authentication mechanism for it:

```
CREATE USER <user_name> PASSWORD <password>;
ALTER USER <user_name> ADD IDENTITY <mapped_user_name> FOR JWT PROVIDER
<jwt_provider_name>;
ALTER USER <user_name> ENABLE JWT;
```

- (EXTERNAL) IDENTITY: A JWT provider-user mapping. The mapped JWT user name should be the name of the user in the local SAP HANA database who creates the virtual tables.

[Single Sign-On Using JSON Web Tokens](#)

## 14.1.4.3.2 Create a Remote Source with JWT Authentication

Connect users to an SAP HANA remote source using single sign-on (SSO) with JSON Web Tokens (JWT).

### Prerequisites

Requires the CREATE REMOTE SOURCE system privilege to manage remote sources.

### Procedure

As the administrator, create a remote source to the remote SAP HANA server, with the credential type JWT:

```
CREATE REMOTE SOURCE <remote_source_name> ADAPTER "hanaodbc"
CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<remote_server_name>:
3<remote_instance_number>15;'
```

```
WITH CREDENTIAL TYPE 'JWT';
```

## Next Steps

Create users and assign them the CREATE VIRTUAL TABLE object-level privilege on the remote source:

```
CREATE USER <user_name> PASSWORD <password>;  
GRANT CREATE VIRTUAL TABLE ON REMOTE SOURCE <remote_source_name> TO <user_name>;
```

When a user tries to create a virtual table using this remote source, the connection to the remote source is created using a JWT token for authentication.

## Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)

### 14.1.4.3.3 Convert an Existing Remote Source to Use JWT

Change the credential mode of an existing remote source to use JSON Web Tokens (JWT).

## Prerequisites

Requires the CREATE REMOTE SOURCE system privilege to manage remote sources.

## Procedure

1. Drop the defined credential type if the remote source has one:

```
ALTER REMOTE SOURCE <remote_source_name> DROP CREDENTIAL TYPE 'PASSWORD';
```

2. Assign the JWT credential type to the remote source:

```
ALTER REMOTE SOURCE <remote_source_name> WITH CREDENTIAL TYPE 'JWT';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

## 14.1.5 Managing Remote Sources

Create, modify, and delete remote sources.

### 14.1.5.1 Creating Remote Sources

Create a new remote source using the SAP HANA database explorer, or SQL syntax. The parameters required vary by adapter.

A remote source can be used to create virtual tables or to use the linked database feature.

For a list of supported databases and versions, see SAP Note [2600176](#) - *SAP HANA Smart Data Access Supported Remote Sources*.

#### i Note

If the SAP HANA database is configured with a high isolation level, you cannot create a remote source using a DSN entry. See SAP Note [2867216](#) - *Login Failure to Remote Source From MDC Configured With High Isolation Level*.

#### 14.1.5.1.1 Create an SAP HANA Remote Source

Create a remote source to another SAP HANA database.

#### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.
- To use an SSL connection, you have downloaded and imported the SSL certificate signed by DigiCert. See [Import Certificates for SSL Connections to Remote Sources \[page 2043\]](#).

#### Context

You can use an SAP HANA remote source with virtual tables or the linked database feature.

An SAP HANA remote source supports failover.

The remote source cannot point to the local SAP HANA instance. This scenario, which is called a loopback, can return unexpected query results and is not a supported scenario.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary or Kerberos credentials, see *Managing Credentials*.

# Create DSN Entry

## Context

### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

## Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a `.odbc.ini` file if it doesn't already exist.

The `.odbc.ini` must exist, even if empty, regardless of whether a DSN entry is being used.

3. Define one entry in the `.odbc.ini` file for each remote source. For each entry, specify the driver for the remote source adapter.

```
Driver=libodbcHDB.so
```

4. Specify the remote server.

```
ServerNode=<remote_server_name>:3<remote_instance_number>15
```

5. To use an SSL connection, enter:

```
encrypt=TRUE
```

6. To enable failover, add the failover server name to the `ServerNode` property, separated by a comma.

```
ServerNode=<remote_server_name>:  
3<remote_instance_number>15,<failover_server_name>:  
3<failover_instance_number>15
```

7. To set session specific connection information, add the `sessionVariable` property.

```
sessionVariable:<session_variable_name>=?
```

For more information, see *Session-Specific Information for Connections*.

8. To enable optimized mode, add the `linkeddatabase_mode` property.

```
linkeddatabase_mode=optimized
```

9. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Example

```
[HANA1]
Driver=libodbcHDB.so
ServerNode=my_server:30115,my_failover:30215
sessionVariable:APPLICATIONUSER=?
linkeddatabase_mode=optimized
```

## Create a Remote Source Using SQL Syntax

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_HANA ADAPTER "hanaodbc"
  CONFIGURATION 'DSN=HANA1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

To enable failover, define session variables or enable optimized mode for linked database, add the parameters to the `serverNode` property in the DSN entry in the `.odbc.ini` file.

- If not using a DSN entry, execute a CREATE REMOTE SOURCE command specifying all driver properties.

#### Sample Code

```
CREATE REMOTE SOURCE <HANA1> ADAPTER "hanaodbc"
  CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<remote_server_name>:
  3<remote_instance_number>15;'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- To use an SSL connection, enter:

```
encrypt=TRUE
```

### Sample Code

```
CREATE REMOTE SOURCE <HANA1> ADAPTER "hanaodbc"  
CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<remote_server_name>:  
3<remote_instance_number>15;encrypt=TRUE;'  
WITH CREDENTIAL TYPE 'PASSWORD' USING  
'user=<user_name>;password=<password>';
```

- To enable failover during creation, specify the failover server information in the ServerNode property.

### Sample Code

```
ServerNode=<remote_server_name>:3<remote_instance_number>15,  
<failover_server_name>:3<failover_instance_number>15;
```

- To enable optimized mode for linked database or to set session-specific connection information during creation, include the sessionVariable or linkeddatabase\_mode parameter in the ServerNode property.

### Sample Code

```
ServerNode=<remote_server_name>:3<remote_instance_number>15;  
sessionVariable:<session_variable_name>=?;linkeddatabase_mode=optimized;
```

For more information, see *Session-Specific Information for Connections*.

- For an existing remote source, to enable failover, set session specific connection information, or enable optimized mode, use ALTER REMOTE SOURCE to add the properties.

## Create a Remote Source Using the SAP HANA Database Explorer

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *HANA (ODBC)*.
5. Select the connection mode.
6. Depending on the connection selected, enter the required information:

### Adapter Properties

Property	Description
Server	Specifies the server of the remote source. Use the machine name or IP address.  To enable failover, include the failover remote source server, separated by a comma.
Port	Specifies the port number of the remote source. Use 3<instance_number>15, where <instance_number> is the instance number of the remote source.  To enable failover, include the failover remote source port number, separated by a comma.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.
Extra Adapter Properties	Specifies additional properties for the remote source. Separate properties by a semicolon. <ul style="list-style-type: none"><li>○ (To enable the optional SSL connection) encrypt=TRUE</li><li>○ (To enable the optional feature on the remote source) sessionVariable:&lt;session_variable_name&gt;=? For more information, see <i>Session-Specific Information for Connections</i>.</li><li>○ (To enable the optional feature on the remote source) linkeddatabase_mode=optimized</li></ul>

### Data Source Name

Property	Description
	To enable failover, session connection information, or optimized mode, add the properties to the DSN section of the <code>.odbc.ini</code> file before you create the remote source.
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

7. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
  - SSO (KERBEROS) - All connections to the remote source are authenticated through Kerberos single sign-on (SSO).
8. Choose [Create](#).

## Create a Remote Source to SAP HANA Cloud

### Procedure

For information about how to connect to SAP HANA Cloud, see the dedicated topic [Create an SAP HANA Cloud, SAP HANA Database Remote Source](#).

## Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)

[Session-Specific Information for Connections \[page 2116\]](#)

### 14.1.5.1.1.1 Import Certificates for SSL Connections to Remote Sources

An SSL certificate can optionally be used for connections to an SAP HANA on-premise remote source.

## Prerequisites

You have downloaded the required certificates:

Remote Source	Certificates
SAP HANA	Download the DigiCert SSL certificate: <pre>curl -O https://dl.cacerts.digicert.com/DigiCertGlobalRootCA.crt.pem</pre>

## Procedure

1. Create a PSE:

```
CREATE PSE <pse_name>;
```

2. Create a certificate:

```
CREATE CERTIFICATE FROM '
-----BEGIN CERTIFICATE-----
...
-----END CERTIFICATE-----
' COMMENT <comment>;
```

- COMMENT: A string literal that can be used as a search keyword.

The created certificate is now contained in the CERTIFICATES system view and can be added to a PSE store.

3. Add the certificate created above to the PSE:

```
SELECT CERTIFICATE_ID FROM CERTIFICATES WHERE COMMENT = '<comment>';  
ALTER PSE <pse_name> ADD CERTIFICATE <certificate_id>;
```

4. Set the purpose of the newly created PSE to REMOTE SOURCE:

```
SET PSE <pse_name> PURPOSE REMOTE SOURCE;
```

This makes the usage of the certificates in the PSE store available to all remote sources.

### **i** Note

You can restrict the usage of the certificates to a certain remote source as follows (the remote source must already exist):

```
SET PSE <pse_name> PURPOSE REMOTE SOURCE FOR REMOTE SOURCE  
<remote_source_name>;
```

## 14.1.5.1.2 Create an SAP IQ Remote Source

Create a remote source to an SAP IQ database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An SAP IQ remote source can be used with virtual tables or the linked database feature.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Context

#### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a .odbc.ini file if it doesn't already exist.

The .odbc.ini must exist, even if empty, regardless of whether a DSN entry is being used.

3. Define one entry in the .odbc.ini file for each remote source. For example:

```
[IQ1]
Driver= libdbodbc17_r.so
ServerName=<iq_server_name>
CommLinks=tcpip(host= <iq_machine_name>;port=<IQ_port>)
```

4. Restart the SAP HANA system to apply the changes to the .INI file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the .odbc.ini file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the .odbc.ini file.

### Sample Code

```
CREATE REMOTE SOURCE MY_IQ1 ADAPTER "iqodbc"  
  CONFIGURATION 'DSN=IQ1;'  
  WITH CREDENTIAL TYPE 'PASSWORD' USING  
  'user=<user_name>;password=<password>';
```

- If not using a DSN entry, execute a CREATE REMOTE SOURCE command specifying all driver properties.

### Sample Code

```
CREATE REMOTE SOURCE MY_IQ2 ADAPTER "iqodbc"  
  CONFIGURATION 'Driver=libdbodbc17_r.so;ServerName=<iq_server_name>;  
  CommLinks=tcpip(host=<iq_machine_name>;port=<IQ_port>);'  
  WITH CREDENTIAL TYPE 'PASSWORD' USING  
  'user=<user_name>;password=<password>';
```

## Create a Remote Source Using the SAP HANA Database Explorer

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *IQ (ODBC)*.
5. Select the connection mode.
6. Depending on the connection mode, enter the required information:

#### Adapter Properties

Property	Description
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

### Adapter Properties

Property	Description
Extra Adapter Properties	<p>Specifies the additional properties to complete the remote connection, in the format:</p> <pre>ServerName=&lt;iq_machine_name&gt;; CommLinks=tcpip(host=&lt;IQ_host&gt;;port=&lt;IQ_port&gt;</pre> <p>For example, the additional properties to connect to the demo database would be:</p> <pre>ServerName=&lt;iq_machine_name&gt;_iqdemo; CommLinks=tcpip(host=&lt;iq_machine_name&gt;;port=2638)</pre>

### Data Source Name

Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

7. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
8. Choose [Create](#).

## 14.1.5.1.3 Create an SAP Adaptive Server Enterprise Remote Source

Create a remote source to an SAP Adaptive Server Enterprise (ASE) database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An SAP Adaptive Server Enterprise (AES) remote source can be used with virtual tables or the linked database feature. An ASE remote source also supports failover.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Context

#### Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a `.odbc.ini` file if it doesn't already exist.

The `.odbc.ini` must exist, even if empty, regardless of whether a DSN entry is being used.

3. Define one entry in the `.odbc.ini` file for each remote source. For example:

```
[ASE1]
Server=<ase_machine_name>
Port=<ase_port>
Driver= libsybdrvodb-sql1en8.so
```

```
Database=<ase_database_name>
```

4. To enable failover in the DSN entry, add the `HASession` and `AlternateServers` property. For example:

```
[ASE1]
Server=<ase_machine_name>
Port=<ase_port>
Driver= libsybdrvodb-sqlllen8.so
Database=<ase_database_name>
HASession=1
AlternateServers=<failover_machine_name>:<failover_port_number>
```

5. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE My_ASE1 ADAPTER "aseodbc"
  CONFIGURATION 'DSN=ASE1;'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- If not using a DSN entry, execute a `CREATE REMOTE SOURCE` command specifying all driver properties.

#### Sample Code

```
CREATE REMOTE SOURCE My_ASE2 ADAPTER "aseodbc"
  CONFIGURATION
  'server=<ase_machine_name>;port=<ase_port>;Driver=libsybdrvodb-
  sqlllen8.so;Database=<ase_database_name>;'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- To enable failover, add the `HASession=1` and `AlternateServers` properties to the command.

### Sample Code

```
CREATE REMOTE SOURCE My_ASE2 ADAPTER "aseodbc"
  CONFIGURATION
  'server=<ase_machine_name>;port=<ase_port>;Driver=libsybdrvodbc-
  sqllen8.so;Database=<ase_database_name>;

  HASession=1;AlternateServers=<failover_machine_name>:<failover_port_number>;'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- Use ALTER REMOTE SOURCE to enable failover on an existing ASE remote source.

### Sample Code

```
CREATE REMOTE SOURCE My_ASE1 ADAPTER "aseodbc"
  CONFIGURATION 'DSN=ASE1;'
  HASession=1;AlternateServers=<failover_machine_name>:<failover_port_number>;'
```

## Create a Remote Source Using the SAP HANA Database Explorer

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *ASE (ODBC)*.
5. Select the connection mode.
6. Depending on the connection mode, enter the required information:

#### Adapter Properties

Property	Description
Server	Specifies the server of the ASE server.
Port	Specifies the port number of the ASE server.
Database Name	Specifies the name of the ASE server.

### Adapter Properties

Property	Description
DML Mode	Specifies if the remote source is readwrite (default) or readonly.
Extra Adapter Properties	(For failover only) Enables automatic failover for the remote source. Enter: <code>HASession=1;AlternateServers=&lt;failover_server&gt;:&lt;failover_port_number&gt;</code>

### Data Source Name

Property	Description
To enable failover, add the properties to the DSN section of the <code>.odbc.ini</code> file before you create the remote source.	
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

7. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
8. Choose *Create*.

## 14.1.5.1.4 Create an SAP Event Stream Processor Remote Source

Create a remote source to an Event Stream Processor (ESP) window.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An SAP Event Stream Processor (ESP) remote source can be used with virtual tables or the linked database feature.

SAP HANA smart data access does not currently support the BOOLEAN and BINARY data types that exist in ESP. Therefore, any virtual tables created over ESP windows containing these column types either fail or produce incorrect data.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Context

#### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a `.odbc.ini` file if it doesn't already exist.

The `.odbc.ini` must exist, even if empty, regardless of whether a DSN entry is used.

3. Define one entry in the `.odbc.ini` file for each remote source. For example:

```
[ESP1]
Driver=libstreamingpsqlodbc_a_lib.so
Database=<esp_workspace_name>/<esp_project_name>
ServerName=<esp_machine_name>
Port=<esp_port_number>
SSLMode=disable
```

4. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_ESP1 ADAPTER "odbc"
  CONFIGURATION FILE 'property_esp.ini' CONFIGURATION 'DSN=ESP1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- If not using a DSN entry, execute a `CREATE REMOTE SOURCE` command specifying all driver properties.

#### Sample Code

```
CREATE REMOTE SOURCE MY_ESP2 ADAPTER "odbc"
  CONFIGURATION FILE 'property_esp.ini'
  CONFIGURATION
  'ServerName=<esp_machine_name>;port=<esp_port_number>;Driver=libstreamin
  glibpsqlodbc_a_lib.so;
  Database=<esp_workspace_name>/<esp_project_name>;SSLmode=disable'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>;
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *ODBC (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Configuration File	Specify <code>property_esp.ini</code>
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## 14.1.5.1.5 Create an SAP HANA Streaming Analytics Remote Source

Create a remote source to a streaming analytics window.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An SAP HANA streaming analytics remote source can be used with virtual tables or the linked database feature.

SAP HANA smart data access does not currently support the BOOLEAN and BINARY data types that exist in streaming analytics. Therefore, any virtual tables created over streaming analytics windows containing these column types would either fail or produce incorrect data.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Context

#### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.

2. Create a `.odbc.ini` file if it doesn't already exist.

The `.odbc.ini` must exist, even if empty, regardless of whether a DSN entry is used.

3. Define one entry in the `.odbc.ini` file for each remote source. For example:

```
[STREAMING1]
Driver=libstreamingpsqlodbc_lib.so
Database=<streaming_workspace_name>/<streaming_project_name>
ServerName=<streaming_machine_name>
Port=3<streaming_instance_number>16
SSLMode=enable
```

4. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- If you're planning to create the remote source using a DSN entry, it already exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_STREAMING1 ADAPTER "odbc"
  CONFIGURATION FILE 'property_esp.ini' CONFIGURATION
  'DSN=STREAMING1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

- If not using a DSN entry, execute a `CREATE REMOTE SOURCE` command specifying all driver properties.

#### Sample Code

```
CREATE REMOTE SOURCE MY_STREAMING2 ADAPTER "odbc"
  CONFIGURATION FILE 'property_esp.ini'
  CONFIGURATION
  'ServerName=<streaming_machine_name>;port=3<streaming_instance_number>16
  ;
  Driver=libstreaminglibpsqlodbc_lib.so'
  Database='<streaming_workspace_name>/
  <streaming_project_name>;SSLmode=enable'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>;
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *ODBC (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Configuration File	Specify <code>property_esp.ini</code>
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## 14.1.5.1.6 Create an SAP MaxDB Remote Source

Create a remote source to an SAP MaxDB database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An SAP MaxDB remote source can be used with virtual tables or the linked database feature. Enter all passwords in uppercase only, even if it contains lower or mixed case characters. The connection fails when lower or mixed case values are supplied.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Context

#### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a .odbc.ini file if it doesn't already exist.

The .odbc.ini must exist, even if empty, regardless of whether a DSN entry is being used.

3. Define one entry in the `.odbc.ini` file for each remote source. For example:

```
[MaxDB1]
Driver=/opt/MaxDB/lib/libsdboodbcw.so
ServerNode=<maxdb_machine_name>
ServerDB=MAXDB
```

4. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Create a Remote Source Using SQL Syntax

### Context

#### i Note

These steps are only required if you plan to use a DSN entry to create your remote source.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Do one of:
  - If using a DSN entry, execute a `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_MAXDB1 ADAPTER "maxdb"
  CONFIGURATION 'DSN=MaxDB1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
    'user=<user_name>;password=<password>';
```

- If not using a DSN entry, execute a `CREATE REMOTE SOURCE` command specifying all driver properties.

#### Sample Code

```
CREATE REMOTE SOURCE MY_MaxDB2 ADAPTER "maxdb"
  CONFIGURATION
    'Driver=libsdboodbcw.so;ServerNode=<maxdb_machine_name>;ServerDB=MAXDB'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
    'user=<user_name>;password=<password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *MaxDB (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.

## 14.1.5.1.7 Create a Teradata Remote Source

Create a remote source to a Teradata database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

A Teradata remote source can be used with virtual tables or the linked database feature.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a .odbc.ini file if it doesn't already exist.
3. Add the following entries to the .odbc.ini file. For example:

```
[ODBC]
InstallDir=<installation_path>/client/ODBC_64
[ODBC Data Sources]
default=tdata.so
TD=tdata.so
```

4. Also in the .odbc.ini file, define one entry for each remote source. For example:

```
[TDATA1]
Driver=<installation_path>/client/ODBC_64/lib/tdata.so
DBCName=<server.com>
CharacterSet=UTF8
```

5. Restart the SAP HANA system to apply the changes to the .INI file.

# Create a Remote Source Using SQL Syntax

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. In a SQL console, connect to the tenant database.
2. Execute a `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

### Sample Code

```
CREATE REMOTE SOURCE MY_TDATA1 ADAPTER "tdodbc"  
  CONFIGURATION 'DSN=TDATA1'  
  with CREDENTIAL TYPE 'PASSWORD' USING  
  'user=<user_name>;password=<password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *TERADATA (ODBC)*.
5. Select a connection mode.
6. Enter the required connection information:

#### Data Source Name

Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

7. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
8. Choose *Create*.

### 14.1.5.1.8 Create an SQL Server Remote Source

Create a remote source to an SQL Server database.

#### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

#### Context

An SQL Server remote source can be used with virtual tables or the linked database feature.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a .odbc.ini file if it doesn't already exist.
3. Define one entry in the .odbc.ini file for each remote source. For example:

```
[MSSQL1]
Driver= /opt/microsoft/msodbcsql/lib64/libmsodbcsql-11.0.so.2260.0
Server=<sql_server_name>,<sql_port>
Database=<sql_database_name>
```

4. Restart the SAP HANA system to apply the changes to the .INI file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- A DSN entry exists in the .odbc.ini file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the .odbc.ini file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_MSSQL1 ADAPTER "mssql"
  CONFIGURATION 'DSN=MSSQL1'
  with CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *MSSQL (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## 14.1.5.1.9 Create an IBM DB2 Remote Source

Create a remote source to a DB2 database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

An IBM DB2 remote source can be used with virtual tables or the linked database feature.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.
2. Create a .odbc.ini file if it doesn't already exist.
3. Define a DSN entry in .odbc.ini file for each remote source. For example:

```
[DB2_1]
Driver=/opt/ibm/db2/odbc_cli/clidriver/lib/libdb2o.so.1
Description=TEST_DB2
```

4. Restart the SAP HANA system to apply the changes to the .INI file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- A DSN entry exists in the .odbc.ini file.

## Procedure

1. In a SQL console, connect to the tenant database.
2. Execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the `.odbc.ini` file.

### Sample Code

```
CREATE REMOTE SOURCE MY_DB2_11 ADAPTER "db2"  
  CONFIGURATION 'DSN=DB2_1'  
  WITH CREDENTIAL TYPE 'PASSWORD' USING  
  'user=<user_name>;password=<password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *DB2 (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name

Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)

[Security Aspects of SAP HANA Smart Data Access](#)

### 14.1.5.1.10 Create an Oracle Remote Source

Create a remote source to an Oracle database.

#### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

#### Context

An Oracle remote source can be used with virtual tables or the linked database feature.

Oracle remote sources support failover. Refer to your Oracle product documentation for information on configuring failover.

Oracle remote sources do not support empty strings. Values inserted into a virtual table that are generated from an Oracle remote source are transformed into NULL values if they are empty strings. This behavior also impacts some of the smart data access optimization techniques (for example, join relocation).

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm), change to the <sid>adm \$HOME directory.

2. In the `<sid>adm $HOME` folder, create a `tnsnames.ora` file if it doesn't already exist. Define one entry for each remote source. For example:

```
ORCL=
(DESCRIPTION =
  (ADDRESS = (PROTOCOL = TCP) (HOST = <oracle_hostname>) (PORT = 1521) )
  (CONNECT_DATA = (SERVER = DEDICATED) (SERVICE_NAME =
    <oracle_machine_name>) ) )
```

3. Also in the `<sid>adm $HOME` folder, create a `.odbc.ini` file if it doesn't already exist and define one entry for each remote source. For example:

```
[ORA12C_1]
Driver=<install_oracle_driver_folder>/instantclient_12_1/libsqora.so.12.1
ServerName=ORCL
```

4. To enable failover, add the `HASession` and `AlternateServers` properties to the command. For example:

```
[ORA12C_1]
Driver=<install_oracle_driver_folder>/instantclient_12_1/libsqora.so.12.1
ServerName=ORCL
HASession=1;AlternateServers=<failover_machine_name>:<failover_port_number>'
```

5. Restart the SAP HANA system to apply the changes to the files.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Execute the `CREATE REMOTE SOURCE` command, referencing the DSN entry in the `.odbc.ini` file.

#### Sample Code

```
CREATE REMOTE SOURCE MY_ORA12C_1 ADAPTER "oracle"
  CONFIGURATION 'DSN=ORA12C_1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *ORACLE (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
	To enable failover, add the properties to the DSN section of the <code>.odbc.ini</code> file before you create the remote source.
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)  
[Managing Credentials \[page 2025\]](#)

## 14.1.5.1.11 Create an IBM Netezza Remote Source

Create a remote source to an IBM Netezza database.

### Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

### Context

An IBM Netezza remote source can be used with virtual tables or the linked database feature.

The following syntax examples assume the remote source is configured to use technical user credentials. To use secondary credentials, see *Managing Credentials*.

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`), change to the `<sid>adm` \$HOME directory.
2. Add the following entry to the `odbcinst.ini` file:

```
[ODBC Drivers]
NetezzaSQL = Installed
[NetezzaSQL]
Driver           = /usr/local/nz/lib64/libnzodbc.so
Setup           = /usr/local/nz/lib64/libnzodbc.so
APILevel        = 1
ConnectFunctions = YYN
Description     = Netezza ODBC driver
DriverODBCVer   = 03.51
DebugLogging    = false
LogPath         = /tmp
UnicodeTranslationOption = utf16
CharacterTranslationOption = all
PreFetch        = 25600
Socket          = 16384
```

### i Note

Set the PreFetch property to a large value since IBM Netezza does not support multicursor on same connection.

3. Create a `.odbc.ini` file if it doesn't already exist.
4. Define a DSN entry in the `.odbc.ini` file for each remote source. For example:

```
[NTZ1]
Driver = /usr/local/nz/lib64/libnzodbc.so
Servername = <ibm_machine_name>
Port = 5480
database = <ibm_database_name>
Username = <username>
Password = <password>
UnicodeTranslationOption = utf16
CharacterTranslationOption = all
```

### i Note

The UnicodeTranslationOption entry is required for HANA to connect successfully to an IBM Netezza remote source.

5. Restart the SAP HANA system to apply the changes to the `.INI` file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the `.odbc.ini` file. For example:

#### Sample Code

```
CREATE REMOTE SOURCE MY_NTZ1_ADAPTER "netezza"
  CONFIGURATION 'DSN=NTZ1'
  WITH CREDENTIAL TYPE 'PASSWORD' USING 'user=<username>;password=
  <password>';
```

# Create a Remote Source Using the SAP HANA Database Explorer

## Prerequisites

- A DSN entry exists in the `.odbc.ini` file.

## Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.
3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *NETEZZA (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly.

6. Specify the credentials mode for the remote source.
  - Technical user – Specify a valid user and password to connect to the remote source. All connections to the remote source share the same credential for the remote source.
  - Secondary credentials – Create one credential per user per remote source. At least one secondary credential should exist before you create the remote source. If no secondary credentials exist, the credential mode is set to None, but once a secondary credential is created, the credential mode automatically switches to secondary credentials.
7. Choose *Create*.

## Related Information

[Security Aspects of SAP HANA Smart Data Access](#)

## 14.1.5.112 Create a Google BigQuery Remote Source

Create a remote source to a Google BigQuery database.

### Prerequisites

- You have the CREATE REMOTE SOURCE system privilege.
- The remote source is reachable by the network from the computer you are using.

### Context

A Google BigQuery remote source can be used with virtual tables or the linked database feature.

A Google BigQuery remote source does not support authentication using a technical user or secondary credentials. Authentication is done using either a certificate key file or OAuth, which are defined in the DSN entry in the `.odbc.ini` file.

### Procedure

Enable safe mode for Google BigQuery.

- a. If the instance does not yet have a scriptserver, connect to SYSTEMDB and in a console window, execute:

```
ALTER DATABASE <tenant_db_name> ADD 'scriptserver'.
```

- b. Connect to the tenant database. Change the value of `odbc_adapters_in_scriptserver` parameter in `indexserver.ini`.

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'SYSTEM')  
    SET ('smart_data_access', 'odbc_adapters_in_scriptserver') = 'bigquery'  
WITH RECONFIGURE;
```

## Create a DSN Entry

### Procedure

1. Log on to the SAP HANA host as the SAP HANA software owner (`<sid>adm`), change to the `<sid>adm` \$HOME directory.

2. Create a `.odbc.ini` file if it doesn't already exist and define one entry for each remote source. Use this template as a guideline.

```
[GoogleBQ]
# Description: DSN Description.
# This key is not necessary and is only to give a description of the data
source.
Description=Simba ODBC Driver for Google BigQuery (64-bit) DSN

# Driver: The location where the ODBC driver is installed to.
Driver=/opt/simba/googlebigqueryodbc/lib/64/libgooglebigqueryodbc_sb64.so

# These values can be set here, or on the connection string.
# Catalog: The catalog to connect to. This is a required setting.
Catalog=

# SQLDialect: The SQL Dialect to use. There are two SQL dialects:
# 0 = BigQuery Legacy SQL
# 1 = BigQuery Standard SQL (SQL 11)
SQLDialect=1

# OAuth Mechanism: The OAuth mechanism to use. There are two choices:
# 0 = Service Authentication
# 1 = User Authentication
#
# This is a required setting.
OAuthMechanism=0

# RefreshToken: The Refresh Token used. This can be generated from the
Windows connection dialog.
# It can also be generated by executing the following steps:
# 1. Get an Authentication by logging into Google from the following URL:
# https://accounts.google.com/o/oauth2/auth?scope=https://www.googleapis.com/
auth/bigquery&response_type=
# code&redirect_uri=urn:ietf:wg:oauth:
2.0:oob&client_id=977385342095.apps.googleusercontent.com&hl=en
# &from_login=1&as=76356ac9e8ce640b&pli=1&authuser=0
# 2. Run the get_refresh_token.sh shell script and pass in the Authentication
Token received in step 1.
# 3. Copy the Refresh Token (the text on the right-side of the colon, without
the trailing or leading spaces)
# from the output of the script. This is a required setting.
#RefreshToken=

# Email: For Service Authentication, this is a required setting. It is your
GENERATED service account email
# (not a typical Gmail account).
# It is unique and associated with at least one public/private key pair.
Email=

# KeyFile Path: For Service Authentication, this is a required setting. This
is the path to the stored keyfile (.p12).
KeyFilePath=

# Used to specify the full path of the PEM formatted file containing trusted
SSL CA certificates.
# If an empty string is passed in for the configuration, the driver expects
the trusted SSL CA
# certificates can be found in the file named cacerts.pem located in the same
directory as the
# driver's shared library.
#TrustedCerts=

# AllowLargeResults: When set to 1, the driver allows for result sets in
responses to be larger than 128 MB.
AllowLargeResults=0
```

```
# LargeResultsDataSetId: DatasetId to store temporary tables created. This
is a required setting if
# AllowLargeResults is set to 1.
LargeResultsDataSetId=_bqodbc_temp_tables

# LargeResultsTempTableExpirationTime: Time in milliseconds before the
temporary tables created expire.
# This is a required setting if AllowLargeResults is set to 1.
LargeResultsTempTableExpirationTime=3600000
```

3. Restart the SAP HANA system to apply the changes to the .INI file.

## Create a Remote Source Using SQL Syntax

### Prerequisites

- A DSN entry exists in the .odbc.ini file.

### Procedure

1. In a SQL console, connect to the tenant database.
2. Execute a CREATE REMOTE SOURCE command, referencing the DSN entry in the .odbc.ini file. For example:

#### Sample Code

```
CREATE REMOTE SOURCE BigQ ADAPTER "bigquery"
CONFIGURATION 'DSN=GoogleBQ'
```

## Create a Remote Source Using the SAP HANA Database Explorer

### Prerequisites

- A DSN entry exists in the .odbc.ini file.

### Procedure

1. Expand the *Catalog*.
2. In the context menu of the *Remote Sources* object, choose *Add Remote Source*.

3. Enter a remote source name.
4. In the *Adapter Name* dropdown list, select *BIGQUERY (GENERIC ODBC)*.
5. Enter the required connection information:

Data Source Name	
Property	Description
Data Source Name	Specifies the DSN as defined in the <code>.odbc.ini</code> file.
DML Mode	Specifies if the remote source is readwrite (default) or readonly. Only readonly is supported for a Google BigQuery remote source.

6. Choose *Create*.

## Related Information

[CREATE REMOTE SOURCE Statement \(Access Control\)](#)  
[Security Aspects of SAP HANA Smart Data Access](#)

### 14.1.5.2 Verify a Remote Source

You can use the `CHECK_REMOTE_SOURCE` procedure to verify that a remote source is correctly configured.

#### Context

When a remote source is created using the `CREATE REMOTE SOURCE` statement or modified using the `ALTER REMOTE SOURCE` statement, no errors are thrown if the configuration is not valid. The remote source is not validated until an attempt is made to establish a remote connection to it.

#### Procedure

To verify that a remote source is correctly configured, execute the following command:

```
CALL CHECK_REMOTE_SOURCE ('<remote_source_name>');
```

If the check is not successful, an error message gives the reasons for the failure, such as an invalid host name.

## 14.1.5.3 Connect to a Remote Source As a Restricted User

Configure the restricted user in an SAP HANA remote source.

### Prerequisites

Use of the restricted user is supported for SAP HANA remote sources only. The SAP HANA remote source must be running one of the following versions:

- SAP HANA 1.0 SPS 12 revision 122.20 or later
- SAP HANA 2.0 SPS 02 revision 24.05 or later
- SAP HANA 2.0 SPS 03 revision 033 or later

This functionality is not supported for remote sources running SAP HANA 2.0 SPS 00 or 01 (any revision). These limitations do not apply to the SAP HANA local source.

### Context

Restricted users are intended for provisioning users who access SAP HANA through client applications and who are not intended to have full SQL access via an SQL console. A restricted user can be granted in a remote source for SDA access (JDBC/ODBC) only and provides more access control compared to standard database users.

### Procedure

1. On the SAP HANA remote source, create the restricted user:

```
CREATE RESTRICTED USER <user_name> PASSWORD <password> NO  
FORCE_FIRST_PASSWORD_CHANGE;
```

2. Grant ODBC and JDBC access to the restricted user:

```
GRANT RESTRICTED_USER_ODBC_ACCESS, RESTRICTED_USER_JDBC_ACCESS to <user_name>;  
ALTER USER <user_name> ENABLE CLIENT CONNECT;
```

3. Grant the SDA role RESTRICTED\_USER\_SDA\_ENABLE to the restricted user on the remote source:

```
GRANT RESTRICTED_USER_SDA_ENABLE TO <user_name>;
```

4. On the local SAP HANA, create the remote source. Specify the restricted user credentials for the technical user:

## Related Information

[User Types](#)

[Create a Restricted Database User \[page 920\]](#)

[CREATE USER Statement \(Access Control\)](#)

## 14.1.5.4 Modify a Remote Source

Modify an existing remote source.

### Prerequisites

One of the following:

- You created the remote source.
- You have the CREATE REMOTE SOURCE system privilege.

## Modify a Remote Source Using SQL Syntax

### Procedure

In an SQL console, connected to the tenant database, execute:

```
ALTER REMOTE SOURCE <remote_source_name> <adapter_clause>
[ <credential_clause> ];
```

### Example

This example creates remote source, REMOTE1, and then changes the port for the remote source from 30115 to 30315.

#### Sample Code

```
CREATE REMOTE SOURCE REMOTE1 ADAPTER "hanaodbc"
  CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=my_machine:30115'
  WITH CREDENTIAL TYPE 'PASSWORD' USING
  'user=<user_name>;password=<password>';

ALTER REMOTE SOURCE REMOTE1 ADAPTER "hanaodbc"
  CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<machine_name>:30315';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

# Modify a Remote Source Using the SAP HANA Database Explorer

## Procedure

1. Expand the *Catalog*.
2. Select *Remote Sources*.  
A list of remote sources appears in the catalog browser item list.
3. Select your remote source to open the remote source editor.
4. Choose *Edit*.
5. Make the changes and choose *Save*.  
The system saves the change and then tests the new connection properties. If the connection fails, then a message appears, and all filters are reset and the remote object list is cleared.

## 14.1.5.5 Drop a Remote Source

Remove an existing remote source.

## Prerequisites

One of the following:

- You created the remote source.
- You have the CREATE REMOTE SOURCE system privilege.

## Drop a Remote Source Using SQL Syntax

### Procedure

In an SQL console, while you are connected to the tenant database, execute:

```
DROP REMOTE SOURCE <remote_source_name> CASCADE;
```

# Drop a Remote Source Using the SAP HANA Database Explorer

## Procedure

1. Expand the *Catalog*.
2. Select *Remote Sources*.  
A list of remote sources appears in the catalog browser item list.
3. In the context menu of the remote source you want to drop, choose *Delete*.
4. Select *Drop the remote source and any other objects that depend on it* and choose *Delete*.

## 14.1.5.6 List Remote Sources

Provides a list of remote sources you have privilege to.

## Procedure

In an SQL console, while you are connected to the tenant database, execute:

```
SELECT * FROM "SYS"."REMOTE_SOURCES";
```

## 14.1.5.7 Customizing the Behavior of a Remote Source

The supported behaviors of a remote source may not be the same as those of the local SAP HANA instance. Smart data access provides a set of customizable properties, capabilities, functions, and data types to help address these differences.

Customizations are on a per remote source basis. If you have multiple remote sources using the same adapter, each remote source can have its own customizations.

## 14.1.5.7.1 Configure Remote Source Properties

Customize the behavior of properties for your remote source.

### Prerequisites

You need the CREATE REMOTE SOURCE system privilege.

### Context

Properties on a remote source define how to do something on the remote database. For example, what syntax is used to obtain a list of tables or how to create temporary tables. Properties are set using string values.

Each `<property_name>` specified must be in the form `PROP_<property_name>`. All properties are disabled by default.

Use the ALTER REMOTE SOURCE statement to set and unset capabilities. For the full syntax for setting and unsetting remote source properties, see *ALTER REMOTE SOURCE Statement* in the *SAP HANA SQL and System Views Reference*.

### Procedure

1. Connected to the tenant database, open an SQL console window.
2. To set a new property value, execute:

```
ALTER REMOTE SOURCE <remote_source_name> SET PROPERTY '<property_name>' =
'<value>'
  [, '<property_name>' = '<value>' [,...];
```

3. To revert a property value to its default, execute:

```
ALTER REMOTE SOURCE <remote_source_name> UNSET PROPERTY { '<property_name>'
[, '<property_name>' [,...]| ALL };
```

### Example

This example sets the value of the property `PROP_MAX_NCHAR_STRING_LENGTH` to 5000 for remote source `RS1`.

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'PROP_MAX_NCHAR_STRING_LENGTH' = '5000';
```

This example resets the property `PROP_MAX_NCHAR_STRING_LENGTH` to its default value for remote source `RS1`.

```
ALTER REMOTE SOURCE RS1 UNSET PROPERTY 'PROP_MAX_NCHAR_STRING_LENGTH';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

[Join Relocation for Multiple Remote Sources \[page 2090\]](#)

[List Current Properties for a Remote Source \[page 2088\]](#)

## 14.1.5.7.2 Configure Remote Source Capabilities

Customize the behavior of capabilities for your remote source.

### Prerequisites

You need the `CREATE REMOTE SOURCE` system privilege.

### Context

Capabilities on a remote source define what types of functionality are supported by a remote database. For example, which join types are supported or what built-in functions are supported. Capabilities are set as true or false values.

Each `<capability_property_name>` specified must be in the form `CAP_<property_name>`. All capabilities are disabled by default.

Use the `ALTER REMOTE SOURCE` statement to set and unset capabilities. For the full syntax for setting and unsetting remote source properties, see *ALTER REMOTE SOURCE Statement* in the *SAP HANA SQL and System Views Reference*.

### Procedure

1. Connected to the tenant database, open an SQL console window.
2. To set a new capability value, execute:

```
ALTER REMOTE SOURCE <remote_source_name> SET PROPERTY  
'<capability_property_name>' = '<value>'
```

```
[, '<capability_property_name>' = '<value>' [,...];
```

3. To revert a capability value to its default, execute:

```
ALTER REMOTE SOURCE <remote_source_name> UNSET PROPERTY  
{ '<capability_property_name>' [, '<capability_property_name>' [,... ] | ALL };
```

## Example

This example sets the capability CAP\_LIMIT to false for remote source RS1.

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'CAP_LIMIT' = 'FALSE';
```

This example resets the capability CAP\_LIMIT to its default value for remote source RS1.

```
ALTER REMOTE SOURCE RS1 UNSET PROPERTY 'CAP_LIMIT';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

[List Current Properties for a Remote Source \[page 2088\]](#)

## 14.1.5.7.3 Configure Remote Source Function Pushdown

Customize the behavior of SAP HANA functions pushed down to the remote source.

### Prerequisites

You need the CREATE REMOTE SOURCE system privilege.

### Context

When you execute a query, if a built-in function does not exist on both SAP HANA and a remote database, then unexpected behavior may result when the function is pushed to the remote source. For these occurrences, you can create mappings of which remote function to use when the SAP HANA function is referenced.

Each <function\_property\_name> must be specified in the form FUNC\_<function\_name>, followed by an argument type list bounded by brackets (FUNC\_ABS[INT]) or an argument count in braces (FUNC\_ABS{1}).

Specifying false for the property value marks the function as not supported by the remote database and is never pushed down to the remote source.

Each parameter passed to the SAP HANA SQL function is mapped to a placeholder. The first parameter is mapped to \$1, the second to \$2, ... to a maximum of 99 parameters. \$\* is supported as a wildcard, which causes a comma-separated list of parameters to be inserted into the translation string.

Parameter variations are supported as follows:

Syntax	Description	Comments
FUNC_ABS = ABS()	Map a function (no arguments)	
FUNC_TO_DATE = TO_DATE(\$*)	Map a function which has variable number of arguments	When TO_DATE is used, all arguments are inserted as a comma-separated list at the \$*.
FUNC_SUBSTR{#2} = SUBSTRING(\$1, \$2)	Map a function where the number of arguments is enforced	When SUBSTR is used with two arguments, the SUBSTRING expression is used.
FUNC_LOCATE{#2} = LOCATE(\$2, \$1)	Map a function where the argument order is changed	When LOCATE is used with two arguments, the first argument is substituted for \$1 and the second argument for \$2.
FUNC_LOCATE{#2} = POSITION(\$1, \$2)	Map to different function name	When LOCATE is used with two arguments, it is remapped to use POSITION on the remote system.
FUNC_LOCATE{#2} = LOCATE(\$2 IN \$1)	Map a function where the argument order is changed, and additional syntax is used	When LOCATE is used with two arguments, the first argument is substituted for \$1 and the second for \$2. The remote system requires that the syntax use IN as a keyword.
FUNC_ABS[INT] = ABS(\$1)	Map a function where the type of arguments is specified	This function can have only one parameter and it must be of type INT. The parameter is substituted for \$1.
FUNC_CAST = CAST(\$1 AS NUMBER)	Cast arguments	Using Oracle for an example, the remote system casts the parameter to an Oracle NUMBER data type prior to calling SIGN.
FUNC_CAST{#3} = CAST (\$1 AS \$2(\$3)), FUNC_CAST{#4} = CAST (\$1 AS \$2(\$3,\$4))	Specify a different mapping depending on the number of arguments to the function	When CAST is present with three arguments, the first of these two is used. If it has four arguments, the second is used.
FUNC_ABS = false	Stop a function from being pushed down	Remapping ABS causes the query to fail.
FUNC_LOCATE{#2} = LOCATE(\$1, \$2), FUNC_LOCATE{#3} = false	Stop a function from being pushed down only for certain number of parameters	When locate is used with two arguments, the remap succeeds. When LOCATE is used with three arguments, the remap fails.

Use the ALTER REMOTE SOURCE statement to set and unset capabilities. For the full syntax for setting and unsetting remote source properties, see *ALTER REMOTE SOURCE Statement* in the *SAP HANA SQL and System Views Reference*.

## Procedure

1. Connected to the tenant database, open an SQL console window.
2. To set a new function push down value, execute:

```
ALTER REMOTE SOURCE <remote_source_name> SET PROPERTY
'<function_property_name>' = '<value>'
[, '<function_property_name>' = '<value>' [,...];
```

3. To revert a function push down value to its default, execute:

```
ALTER REMOTE SOURCE <remote_source_name> UNSET PROPERTY
{ '<function_property_name>' [, '<function_property_name>' [,...] | ALL };
```

## Example

This example sets the SAP HANA function ADD\_DAYS to use the function DATEADD(DAY) on remote source RS1.

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'FUNC_add_days' = 'DATEADD(DAY)';
```

This example resets the function FUN\_add\_days to its default value on remote source RS1.

```
ALTER REMOTE SOURCE RS1 UNSET PROPERTY 'FUNC_add_days';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)  
[List Current Properties for a Remote Source \[page 2088\]](#)

### 14.1.5.7.4 Configure Remote Source Data Type Mappings

Customize the mapping of SAP HANA data types for your remote source.

## Prerequisites

You need the CREATE REMOTE SOURCE system privilege.

## Context

If a data type does not exist on both SAP HANA and a remote database, then unexpected behavior may result when used on the remote source. For these occurrences, you can create mappings of which remote data type to use when the SAP HANA data type is referenced. For example, you map the SAP HANA data type FLOAT to DOUBLE on the remote source.

Each `<data_type_property_name>` specified must be in the form `MAPPING_SQL_<property_name>`.

Smart data access (SDA) supports a subset of the data types supported by SAP HANA core. Core data types outside the subset are automatically converted to one of the subset values when accessing a remote database.

TINYINT	DATETIME	VARBINARY
SMALLINT	FLOAT	LONGBINARY
INT	REAL	NCHAR
BIGINT	CHAR	NVARCHAR
DECIMAL	VARCHAR	LONGNCHAR
DATE	LONGCHAR	ST_GEOMETRY
TIME	BINARY	BOOLEAN

There are two kinds of data type mappings that can be customized: ODBC to SDA type mappings, and SDA to remote data base type mappings.

ODBC to SDA type mappings convert between ODBC SQL type and an SDA type. It is used when creating a virtual table to determine which HANA data type to use for each column. The standard ODBC SQL types have default mappings that should suffice but can be customized if needed. When customizing an ODBC SQL type, the property name begins with `MAPPING_<odbc_type_name>` and the value must be specified as `TYPE_<sda_data_type>`. Both `<odbc_type_name>` and `<sda_data_type>` are specified as string values.

SDA to remote data base type mappings define the syntax SDA uses when creating a remote table on the remote database, such as when creating a temporary remote table for join relocation. These values are predefined for SAP HANA supported remote database types, but can be customized as needed. For user defined adapters, a set of default data type mappings is obtained from the driver, however not all types may be customized. When customizing an SDA to remote data base type, the property name begins with `TYPE_<sda_data_type>`. Both `<sda_data_type>` and the property value are expressed as a string.

Use the `ALTER REMOTE SOURCE` statement to set and unset data type mappings. For the full syntax for setting and unsetting remote source properties, see *ALTER REMOTE SOURCE Statement* in the *SAP HANA SQL and System Views Reference*.

## Procedure

1. Connected to the tenant database, open an SQL console window.
2. To set a new data type mapping value, execute:

```
ALTER REMOTE SOURCE <remote_source_name> SET PROPERTY  
'<data_type_property_name>' = '<value>'
```

```
[, '<data_type_property_name>' = '<value>' [,...];
```

3. To revert a data type mapping value to its default, execute:

```
ALTER REMOTE SOURCE <remote_source_name> UNSET PROPERTY  
{ '<data_type_property_name>' [, '<data_type_property_name>' [,...] | ALL };
```

## Example

This example maps the SDA data type VARCHAR to NVARCHAR on remote source RS1.

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'MAPPING_SQL_VARCHAR' = 'TYPE_NVARCHAR';
```

This example resets the SAP HANA data type property MAPPING\_SQL\_VARCHAR' to its default value on remote source RS1.

```
ALTER REMOTE SOURCE RS1 UNSET PROPERTY 'MAPPING_SQL_VARCHAR';
```

This example maps the SDA data type BOOLEAN to bit on remote source RS1.

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'TYPE_BOOLEAN' = 'bit';
```

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

[List Current Properties for a Remote Source \[page 2088\]](#)

## 14.1.5.7.5 List Current Properties for a Remote Source

List the customizable properties, capabilities, functions, and data types for a specific remote source.

### Prerequisites

You need the EXECUTE privilege on the GET\_REMOTE\_SOURCE\_PROPERTIES procedure.

### Context

For a list of all customizable properties, capabilities, functions, and data types, call the procedure. In the results list, properties begin with PROP\_, capabilities with CAP\_, functions with FUNC\_, and data types with MAPPING.

## Procedure

In an SQL console, connected to the tenant database, execute the procedure:

### ❖ Example

```
CALL GET_REMOTE_SOURCE_PROPERTIES (<remote_source_name>, ?)
```

## 14.1.5.7.6 Migrate Adapter Property Files

Manually migrate customizations in the property\_<adapter\_type>.ini file.

### Prerequisites

- You need the CREATE REMOTE SOURCE system privilege.

### Context

With SAP HANA 2.0 SP S04 and later, settings for properties, capabilities, functions and data types are stored in the database. The property\_<adapter\_name>.ini file is no longer used.

If you updated your SAP HANA 2.0 system from a pre-SPS04 version and you want to continue to use customized property values, you must re-enter the customizations using the ALTER REMOTE SOURCE...SET PROPERTY statement.

If you are unsure which values were customized, compare the pre-update values in the properties\_<adapter\_name>.ini file with the post-update default values for the remote source.

To review the pre--update property\_<adapter\_name>.ini files:

1. Log on to the SAP HANA host as the SAP HANA software owner (<sid>adm).
2. Change to /usr/sap/<sid>/SYS/exe/hdb/config folder.
3. Open the property\_<adapter\_name>.ini file.

## 14.1.5.7.7 Join Relocation for Multiple Remote Sources

The remote source property `PROP_JOIN_RELOCATION_BETWEEN_SOURCES` is used when tables from different remote sources need to be joined. It allows a join to be relocated so that it occurs directly in one of the remote sources instead of in the local SAP HANA system.

When two remote tables from two remote sources (one table per remote source) are joined, both tables are pulled to the local SAP HANA system, where the join is then performed. If one of these remote tables is small and the expected join result is also small, it can be beneficial to send the smaller table to the other remote source and perform the join in the remote source with the bigger table. This approach can be effective when both of the following conditions apply:

- The smaller remote table is far smaller than the other bigger table.
- The join result is far smaller than the bigger remote table.

Because two remote sources cannot communicate directly with each other, the smaller table is first pulled to the local SAP HANA system and then sent to the other remote source.

### Prerequisites

Join relocation is only available for remote sources based on SAP HANA smart data access built-in ODBC adapters. In addition, the remote sources must support the `CAP_CRT_TEMP_TABLES` capability, which allows temporary tables to be created. The following remote sources support temporary table creation:

- SAP HANA
- SAP IQ
- SAP Adaptive Server Enterprise
- Teradata
- Oracle
- Microsoft SQL Server
- IBM DB2

For more information about the supported versions of these remote sources, see SAP Note [2600176](#) - SAP HANA Smart Data Access Supported Remote Sources.

### Join Relocation Behavior

Join relocation is enabled by default. Since it is a form of query optimization, it is chosen in a cost-based manner. This means that the SQL optimizer decides whether join relocation should be applied based on the estimated cost. Therefore, even if join relocation is enabled, it does not always result in a query plan with join relocation. By disabling join relocation, you can override the cost-based decision made by the SQL optimizer.

Note the following:

- The SQL optimizer chooses the direction of the remote push for the join relocation based on the estimated sizes of the remote tables. It does not change the direction of the remote push once it has been determined.
- The join relocation property is checked only for the remote source of the remote push target direction.

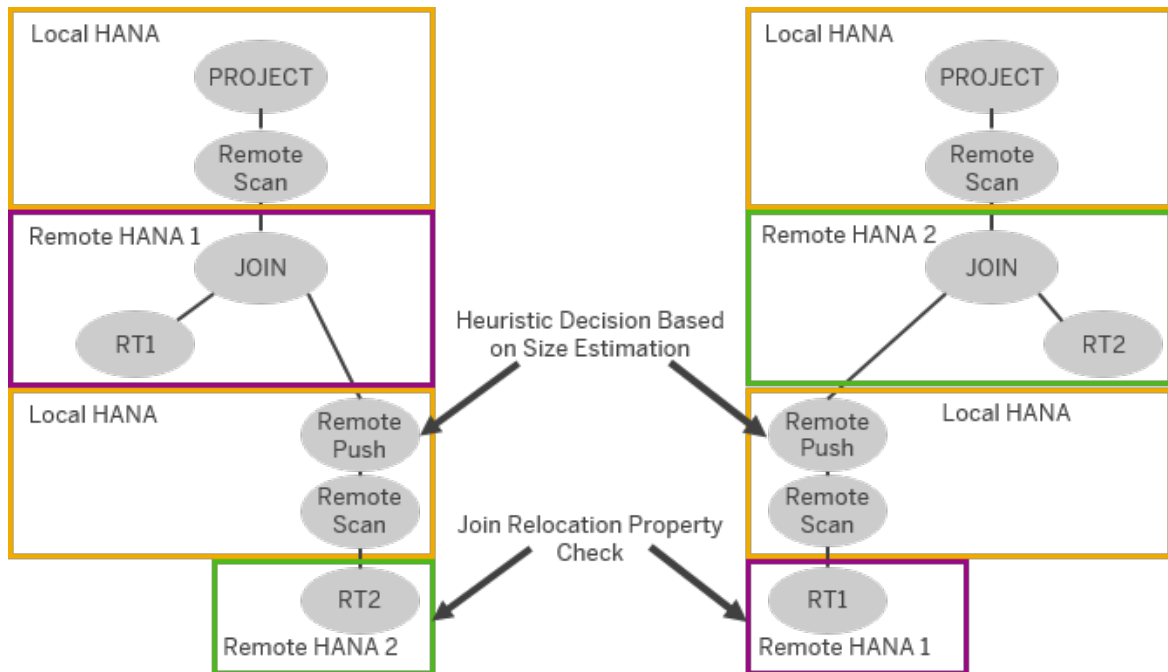

## Example

The remote tables RT1 and RT2 in the remote sources remote HANA 1 and remote HANA 2 are to be joined. The remote table RT2 is much larger than the remote table RT1.

1. Join relocation is enabled (default)

Based on the cost estimation, the SQL optimizer decides to apply join relocation.

The remote push direction shown below on the right is chosen so that the join occurs in remote HANA 2:

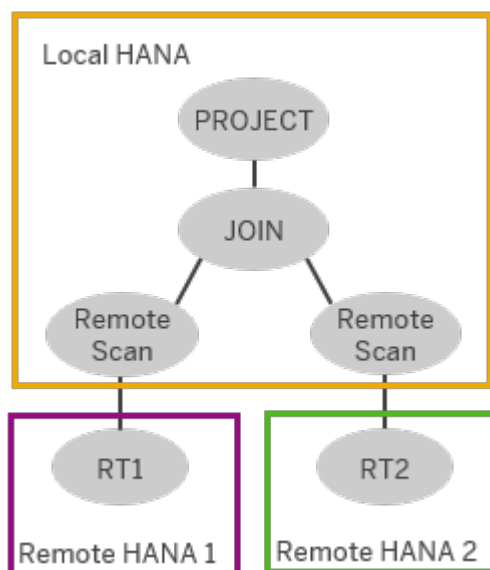

2. Disable join relocation

To override the SQL optimizer's decision, you now disable join relocation for remote HANA 1 (RS1):

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'PROP_JOIN_RELOCATION_BETWEEN_SOURCES' = 'false';
```

When you run the query again, the join now occurs in the local SAP HANA system:

### 3. Enable join relocation

To be able to benefit from the optimized query plan again, you enable join relocation for remote HANA 1 (RS1):

```
ALTER REMOTE SOURCE RS1 SET PROPERTY 'PROP_JOIN_RELOCATION_BETWEEN_SOURCES' = 'true';
```

## 14.1.6 Managing Virtual Tables

Use the SAP HANA database explorer or SQL syntax to manage virtual tables.

### i Note

- Managing virtual tables is not applicable when using linked database.
- Some management tasks are not available in all management tools.

## 14.1.6.1 Managing Virtual Tables Using SQL Syntax

Create, view, refresh, and delete virtual tables using SQL syntax.

### 14.1.6.1.1 Create a Virtual Table

Create a virtual table using SQL syntax.

#### Prerequisites

- One of the following applies:
  - You created the remote source.
  - You have the CREATE VIRTUAL TABLE object privilege on the remote source.
- To use the WITH REMOTE clause you also need the REMOTE TABLE ADMIN object privilege.

#### Context

When creating a virtual table, the remote table does not need to already exist. Including the `<table_contents_source>` and WITH REMOTE clauses in the CREATE VIRTUAL TABLE statement first creates the remote table on the remote source and then creates the associated virtual table. For the full syntax for this feature, see the CREATE VIRTUAL TABLE statement in the SAP HANA SQL Reference Guide.

When using the WITH REMOTE clause, if the credential type of the remote source is PASSWORD, then only the owner of the remote sources who set the technical user credentials has the authorization to use the WITH REMOTE clause. For all other credential types, authorization is a function of the privileges of the user on the remote source. This functionality is supported for the following remote sources:

- SAP HANA
- SAP IQ
- SAP Adaptive Service Enterprise (ASE)
- ORACLE
- Microsoft SQL Server
- IBM DB2
- Teradata
- IBM Netezza
- Google BigQuery

## Procedure

1. Open an SQL console.
2. Execute the command specifying the schema and name of the virtual table and the name of the remote source:

```
CREATE VIRTUAL TABLE [<schema_name>.<virtual_table_name>
[ ( <table_contents_source> ) ]
AT
"<remote_source>". "<database_name>". "<remote_schema_name>". "<remote_table_name
>" [ WITH REMOTE ];
```

## Example

The following statement creates virtual table HANA1\_T1 from the remote source HANA1. The remote database name is DT1 and the schema of T1 is MYSCHEMA2:

```
CREATE VIRTUAL TABLE MYSCHEM1.HANA1_T1 AT "HANA1"."DT1"."MYSCHEMA2"."T1";
```

This example first creates the remote table T2 containing integer columns a2 and b2, and then creates the virtual table VIRTUAL\_T2 from table T2.

```
CREATE VIRTUAL TABLE MYSCHEM1.VIRTUAL_T2 (a INT, b INT) AT
"HANA1"."DT1"."MYSCHEMA2"."T2" WITH REMOTE;
```

## Related Information

[CREATE VIRTUAL TABLE Statement \(Data Definition\)](#)

### 14.1.6.1.2 List Virtual Tables by Schema

Display the virtual tables of a remote source by schema using SQL syntax.

## Context

You cannot change the definition or contents while viewing.

## Procedure

1. Open an SQL console.
2. Execute the SELECT statement specifying the schema name of the virtual tables to list.

```
SELECT * FROM "SYS"."VIRTUAL_TABLES" WHERE SCHEMA_NAME='<schema_name>';
```

Tables, which you have permissions on, appear for the specified schema. The list includes both local and virtual tables.

## Example

The following statement lists the tables for schema `user1`:

```
SELECT * FROM SYS.VIRTUAL_TABLES WHERE SCHEMA_NAME='user1';
```

## Related Information

[SELECT Statement \(Data Manipulation\)](#)

### 14.1.6.1.3 Refresh a Virtual Table

Update a virtual table to reflect metadata changes in the corresponding remote source table using SQL syntax.

## Prerequisites

Requires the CREATE VIRTUAL TABLE object privilege.

## Context

When changes to the metadata in a remote table are made, the changes are not automatically reflected in the corresponding virtual table. Manually update the virtual table to reflect the changes.

## Procedure

To refresh the virtual table, execute:

```
ALTER VIRTUAL TABLE [<schema_name>."<virtual_table_name>" REFRESH DEFINITION;
```

## Example

The following statement refreshes the content of virtual table HANA1\_T1 in schema user1:

```
ALTER VIRTUAL TABLE user1."HANA1_T1" REFRESH DEFINITION;
```

## Related Information

[ALTER VIRTUAL TABLE Statement \(Data Definition\)](#)

### 14.1.6.1.4 Delete a Virtual Table

Remove an existing virtual table from the target system using SQL syntax.

## Prerequisites

- One of the following applies:
  - You created the virtual table.
  - You have the DROP privilege on the virtual table.
- To use the WITH REMOTE clause you also need the REMOTE TABLE ADMIN object privilege.

## Context

If access to a virtual table has been granted to multiple users, then deleting the table removes it for all users, not just the user deleting it.

When dropping a virtual table, if you include the WITH REMOTE clause, both the corresponding table on the remote source is also dropped. For the full syntax for this feature, see the DROP TABLE statement in the SAP HANA SQL Reference Guide.

## Procedure

1. Open an SQL console.
2. Execute:

```
DROP TABLE [<schema_name>]."<virtual_table_name>" CASCADE [ WITH REMOTE ];
```

## Example

The following statement deletes virtual table `HANA1_T1` in the schema `user1`.

```
DROP TABLE user1."HANA1_T1" CASCADE;
```

The following statement deletes virtual table `HANA1_T2` in the schema `user1` from the local source and the corresponding table on the remote source.

```
DROP TABLE user1."HANA1_T2" CASCADE WITH REMOTE;
```

## Related Information

[DROP TABLE Statement \(Data Definition\)](#)

## 14.1.6.2 Managing Virtual Tables Using the SAP HANA Database Explorer

Create virtual tables, view table content and definition, and delete virtual tables using the SAP HANA database explorer.

### 14.1.6.2.1 Create a Virtual Table

Create a virtual table from the remote object of a remote source.

#### Prerequisites

One of the following:

- You created the remote source.

- You have the CREATE VIRTUAL TABLE object privilege on the object created by another user.

## Procedure

1. In the SAP HANA database explorer, expand the *Catalog*.
2. Select *Remote Sources*.  
A list of remote sources appears in the catalog browser item list.
3. Select a remote source.  
The remote source editor opens.
4. Filter for the applicable schema and type of table and then choose *Search*.  
A list of tables on the remote source for the specified schema appears.
5. Select one or more objects and choose *Create Virtual Object(s)*.  
The *Create Virtual Object* dialog opens. If multiple objects are selected, you are prompted to provide a prefix that is then applied to each virtual table created. If only one object is selected, the virtual table is the same as the remote table name. SAP recommends you add a prefix to any virtual table name. This ensures local and virtual table names are unique and makes it easier to identify virtual tables.
6. Choose *Create*.  
A list of tables for the specified schema appears in the catalog browser. The list includes both local and virtual tables. Virtual tables are those with the green, remote sources icon ()

### 14.1.6.2.2 List Virtual Tables By Schema

Display the virtual tables of a remote source by schema using the SAP HANA database explorer.

## Context

You cannot change the definition or contents while viewing a virtual table.

## Procedure

1. In the SAP HANA database explorer, expand the *Catalog*.
2. Select *Tables*.

## Results

Tables, which you have permissions to for the specified schema, appear in the catalog browser. The list includes both local and virtual tables. Virtual tables are those with the green, remote sources icon ()

change the schema, choose the  (*Choose schema*) icon beside the schema name and select a new schema. If multiple schemas are selected, the schema name appears with each table listed.

### 14.1.6.2.3 Delete a Virtual Table

Delete an existing virtual table from your schema using the SAP HANA database explorer.

#### Prerequisites

One of the following:

- You created the virtual table.
- You have the DROP privilege on the object created by another user.
- To use the WITH REMOTE clause you also need the REMOTE TABLE ADMIN object privilege.

#### Context

If access to a virtual table has been granted to multiple users, deleting the table removes it for all users, not just the user deleting it.

#### Procedure

1. In the SAP HANA database explorer, expand the *Catalog*.
2. Select *Tables*.
3. In the context menu of the virtual table, choose *Delete*.
4. Specify how to handle any dependencies on the virtual table being dropped.

#### Results

The virtual table is deleted from the schema.

### 14.1.6.3 List All Virtual Tables

Provides a list of all virtual tables you have privilege to.

#### Procedure

Execute:

```
SELECT * FROM "SYS"."VIRTUAL_TABLES"
```

### 14.1.6.4 Check Virtual Table Definitions

The virtual table check is a procedure available in the SAP HANA database that checks for mismatches between the definition of a virtual table in the local system and the definition of the remote table it points to.

#### Prerequisites

- To run the check specifying both the schema and table, you must have either of the following:
  - The CREATE VIRTUAL TABLE object privilege on the remote source to which the virtual table belongs
  - The CATALOG READ system privilege

#### Context

It's natural that a virtual table's definition is slightly different from the target remote table's definition since columns might be converted or normalized to fit into more widely compatible column types.

The virtual table and its target remote table are regarded as consistent if the definition of the virtual table stored in the local system is identical to the table definition retrieved from the remote system at the time of the procedure call. Note that the mismatches found are not necessarily harmful.

#### Procedure

In an SQL console, execute the following:

```
CALL CHECK_VIRTUAL_TABLES('<action-name>', '<schema-name>' | NULL, '<virtual-table-name>' | NULL )
```

Parameters:

- `action-name`: The only action name that is currently valid is **CHECK**.
- `schema-name`: The schema to check. Enter **NULL** to check all schemas.
- `virtual-table-name`: The table to check. Enter **NULL** to check all tables in the schema given by `schema-name`.

## Results

The check results give, for example, the mismatches found in column definitions, primary key definitions, and table or column privileges.

The output columns are as follows:

- `SCHEMA_NAME`: The relevant schema name for the result row.
- `TABLE_NAME`: The relevant table name for the result row.
- `COLUMN_NAME`: The relevant column name for the result row, if any.
- `RESULT_CODE`: One of the following:

Result Code	Description
<code>COLUMN_ADDED</code>	Column added to remote table
<code>COLUMN_REMOVED</code>	Column removed from remote table
<code>COLUMN_TYPE_CHANGED</code>	Column type code changed
<code>COLUMN_SIZE_CHANGED</code>	Column size changed while type remained the same
<code>COLUMN_SCALE_CHANGED</code>	Column precision changed while type remained the same
<code>COLUMN_NULLABILITY_CHANGED</code>	Nullability (NULL or NOT NULL) changed
<code>PK_ADDED</code>	Primary key added to remote table
<code>PK_REMOVED</code>	Primary key removed from remote table
<code>PK_COLUMN_ADDED</code>	Column added to primary key
<code>PK_COLUMN_REMOVED</code>	Column removed from primary key
<code>TABLE_DEFINITION_CHANGED</code>	Definition value string of table changed
<code>RETRIEVAL_FAILED</code>	Retrieval of remote metadata failed

- `RESULT_MESSAGE`: Details about the inconsistency, for example, `column C1 changed nullability from NULL to NOT NULL`.
- `SEVERITY`: A mismatch can cause errors when SQL statements are executed on a virtual table with a mismatch. The `SEVERITY` indicates the probable outcome based on the `RESULT_CODE`. For example, a column added (`COLUMN_ADDED`) to a remote table does not cause any errors (an added column in the result can be ignored) whereas a column that has been removed (`COLUMN_REMOVED`) does cause an error (according to the local definition, a required column is missing).

The severity levels are as follows:

Severity	Description
INFO	Mismatch does not lead to SQL errors

Severity	Description
WARNING	Mismatch may lead to SQL errors
ERROR	Mismatch is likely to lead to SQL errors

## Example

The following statement checks all tables in all accessible schemas:

```
CALL CHECK_VIRTUAL_TABLES('CHECK', NULL, NULL)
```

An example result is shown below:

```
call SYS.CHECK_VIRTUAL_TABLES('CHECK', null, null)
```

	SCHAME_NAME	TABLE_NAME	COLUMN_NAME	RESULT_CODE	RESULT_MESSAGE	SEVERITY
1	SYSTEM	VTAB2	C1	COLUMN_NULLABILITY_CHANGED	column C1 in remote table changed nullability from NULL to NOT NULL	INFO
2	SYSTEM	VTAB2		PK_ADDED	primary key (C1) added to remote table	INFO
3	SYSTEM	VTAB1	C2	COLUMN_REMOVED	column C2 removed from remote table	WARNING
4	SYSTEM	VTAB1	C3	COLUMN_ADDED	column C3 added to remote table	INFO
5	SYSTEM	VTAB1	C5	COLUMN_TYPE_CHANGED	column C5 in remote table changed type from INTEGER to DOUBLE	WARNING
6	SYSTEM	VTAB1	C6	COLUMN_TYPE_CHANGED	column C6 in remote table changed type from DECIMAL(size: 3, scal...	WARNING
7	SYSTEM	VTAB1	C7	COLUMN_SIZE_CHANGED	column C7 in remote table changed size from 20 to 50	WARNING
8	SYSTEM	VTAB1	C8	COLUMN_SCALE_CHANGED	column C8 in remote table changed scale from 2 to 3	WARNING
9	SYSTEM	VTAB1	C8	COLUMN_SIZE_CHANGED	column C8 in remote table changed size from 3 to 4	WARNING
10	SYSTEM	VTAB1	C2	PK_COLUMN_REMOVED	column C2 removed from primary key (C1,C3) of remote table	INFO
11	SYSTEM	VTAB1	C3	PK_COLUMN_ADDED	column C3 added to primary key (C1,C3) of remote table	INFO
12	SYSTEM	VTAB3	C1	COLUMN_NULLABILITY_CHANGED	column C1 in remote table changed nullability from NOT NULL to NULL	INFO
13	SYSTEM	VTAB3	C2	COLUMN_NULLABILITY_CHANGED	column C2 in remote table changed nullability from NOT NULL to NULL	INFO
14	SYSTEM	VTAB3		PK_REMOVED	primary key (C1,C2) removed from remote table	INFO

## Next Steps

If you have found inconsistencies in the table definitions, you can resolve them by refreshing the corresponding virtual table.

## Related Information

[Refresh a Virtual Table \[page 2095\]](#)

## 14.1.6.5 EXPORT/IMPORT Virtual Tables Between SAP HANA Systems

Export virtual tables from one system and import them into another.

### Prerequisites

- A remote source must exist on the target system using the same name as the source system.
- You have the system privileges IMPORT, EXPORT, and INSERT.

### Context

You can export some or all of the existing virtual tables in the source system to a new system, specifying a new schema or database name during the process.

Both the source and target systems must be running SAP HANA 2.0 SPS 01 or later, but do not have to be running the same version.

Ensure you save the export file to a location available to the target system.

## EXPORT/IMPORT When the Schema Name Is the Same on the Target and Source Systems

### Procedure

1. On the source system, export part or all of the schema to a temporary directory.

```
EXPORT <schema_name>.[ <table_name> | "*" ] AS CSV INTO '<temporary_dir>';
```

2. Create the remote source on the target system using the same name as the source system.
3. On the target system, import the schema.

```
IMPORT "<schema_name>". "[<table_name> | * ]" AS CSV FROM '<temporary_dir>';
```

### Example

Export all tables in `MYSHEMA` to remote source `RS`, using a temporary directory `/export_hold`.

```
EXPORT MYSCHEMA."*" AS CSV INTO '/export_hold';
```

```
CREATE REMOTE SOURCE RS ADAPTER "hanaodbc" CONFIGURATION
'Driver=libodbcHDB.so;ServerNode=mymachine:30115'
  WITH CREDENTIAL TYPE 'PASSWORD' USING 'user=<user_name>;password=<password>';
IMPORT "MYSHEMA"."*" AS CSV FROM '/export_hold';
```

Export only table VT in MYSHEMA to remote source RS, using a temporary directory /export\_hold.

```
EXPORT MYSHEMA.VT AS CSV INTO '/export_hold';
CREATE REMOTE SOURCE RS ADAPTER "hanaodbc" CONFIGURATION
'Driver=libodbcHDB.so;ServerNode=mymachine:30115'
  WITH CREDENTIAL TYPE 'PASSWORD' USING 'user=<user_name>;password=<password>';
IMPORT "MYSHEMA"."VT" AS CSV FROM '/export_hold';
```

## Rename the Remote Object During Transport

### Procedure

1. On the source system, export part or all of the schema to a temporary directory.

```
EXPORT <schema_name>.[ <table_name> | "*" ] AS CSV INTO '<temporary_dir>';
```

2. Create the remote source on the target system using the same name as the source system.
3. On the target system, import the schema, specifying the <original\_database\_name> and <original\_schema\_name> and the <new\_database\_name> and <new\_schema\_name>.

```
IMPORT "<schema_name>".[<table_name> | * ] AS CSV FROM '<temporary_dir>'
  WITH RENAME REMOTE OBJECT
<remote_source>.<original_database_name>.<original_source_schema>.TBL
  TO <remote_source>.<new_database_name>.<new_source_schema>.TBL;
```

### Example

Export table VT in MYSHEMA to remote source RS, with a database name ADMIN and a schema name RS\_SCHEMA.

```
EXPORT MYSHEMA."VT" AS CSV INTO '/export_hold';
CREATE REMOTE SOURCE RS ADAPTER "hanaodbc" CONFIGURATION
'Driver=libodbcHDB.so;ServerNode=mymachine:30115'
  WITH CREDENTIAL TYPE 'PASSWORD' USING 'user=<user_name>;password=<password>';
IMPORT "MYSHEMA"."VT" AS CSV FROM '/tmp' WITH RENAME REMOTE OBJECT
RS.ADMIN.RS_SCHEMA.TBL TO RS.NEW_ADMIN.NEW_RS_SCHEMA.TBL;
```

## 14.1.7 Managing Linked Database

Management of linked database can only be performed using SQL syntax.

Managing linked database is not applicable when optimized mode is enabled.

## 14.1.7.1 Drop Linked Tables

Drop all internally generated objects associated with linked database by using the remote source.

### Prerequisites

- For linked database, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source.

### Context

The CASCADE option drops all the linked tables and dependent objects associated with linked tables. The RESTRICT option drops linked tables only if there are no dependencies on any of the linked tables. If this option is used and there are dependent objects on a linked table, then an error is raised, and all linked tables are retained. If no drop option is specified, then all internally generated linked tables with no dependencies are dropped. Linked tables with dependencies are retained.

### Procedure

To clear generated objects, execute the following in the local SAP HANA database:

```
ALTER REMOTE SOURCE <remote_source_name> DROP LINKED OBJECTS [CASCADE | RESTRICT];
```

### Example

To clear linked objects associated with the remote source MYREMOTESYS that have no current references to a linked object, execute the following in the local SAP HANA database:

#### Sample Code

```
ALTER REMOTE SOURCE MYREMOTESYS DROP LINKED OBJECTS;
```

To clear linked objects associated with the remote source MYREMOTESYS and drop any dependent objects that reference the linked object, execute the following in the local SAP HANA database:

#### Sample Code

```
ALTER REMOTE SOURCE MYREMOTESYS DROP LINKED OBJECTS CASCADE;
```

## 14.1.7.2 Refresh Linked Database

Refresh metadata for a single linked table or all linked objects using the remote source.

### Prerequisites

- If linked database optimized mode is disabled, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source.
- If database optimized mode is enabled, no additional privilege is required.

### Context

The REFRESH LINKED OBJECTS clause refreshes metadata for all linked objects. Definitions of any tables changed on the remote source are updated. Refreshing metadata could potentially take some time to execute. It is recommended that you schedule the execution within an appropriate maintenance window. The REFRESH LINKED TABLE clause refreshes metadata for a single specified table. Use this clause to perform an immediate refresh of a changed table when it would be difficult to execute the refresh on the entire linked database.

When refreshing a linked table, `<table_name>` is the name of the table on the remote source.

### Procedure

To refresh metadata on all linked objects, execute the following in the local SAP HANA database:

```
ALTER REMOTE SOURCE <remote_source> { REFRESH LINKED OBJECTS
  | REFRESH LINKED TABLE <remote_source>.<schema_name>.<table_name> };
```

### Example

To refresh metadata of all linked objects associated with remote source MYREMOTESYS, execute the following in the local SAP HANA database:

#### Sample Code

```
ALTER REMOTE SOURCE MYREMOTESYS REFRESH LINKED OBJECTS;
```

To refresh metadata for remote table MYREMOTESYS.MYTABLE on remote source MYREMOTESYS, execute the following in the local SAP HANA database:

## Sample Code

```
ALTER REMOTE SOURCE MYREMOTESYS REFRESH LINKED TABLE
MYREMOTESYS.MYSCHEMA.MYTABLE;
```

### 14.1.7.3 Synonyms

Use synonyms to create an alternative name for a virtual table or a remote table when using linked database with SAP HANA view modeling.

When creating the synonym for linked database, specify the three part name. For virtual tables, specify `<identifier>` or `<schema_name>.<identifier>`.

```
CREATE SYNONYM <synonym_name> FOR
[ [ <database_name>.]<schema_name>.]<identifier>;
```

where:

Variable	Description
<code>&lt;database_name&gt;</code>	Specifies the name of the remote source for linked database. This value is not applicable to virtual tables.
<code>&lt;schema_name&gt;</code>	For linked database, specifies the schema name of the table on the remote source. For virtual tables, specifies the local schema and virtual table name.
<code>&lt;identifier&gt;</code>	For linked database, specifies the name of the table on the remote source. For virtual tables, specifies the name of the local virtual table.

### Example

Create synonym TABLE1\_SYNONYM for table ADMIN.TABLE1 on remote source SOURCE1.

```
CREATE SYNONYM TABLE1_SYNONYM FOR SOURCE1.ADMIN.TABLE1;
```

## 14.1.8 Monitoring Remote Connections and Statements

Monitor active connections and running statements on remote connections by using SAP HANA cockpit or SQL console.

Though the same basic information is presented, the layout may differ by tool.

## 14.1.8.1 Monitor Remote Statements and Connections

View detailed information about the remote statements executed and remote connections active in the database.

### Prerequisites

You've navigated to the [Database Overview](#) page of the database you want to manage. See *Getting to the Database Overview Page* in the *SAP HANA Administration with SAP HANA Cockpit* guide.

### Context

Use the monitoring tools to monitor:

<b>Remote connections active in the database</b>	Provides details about the connections that were opened in the current session, including when the connection was opened, how many remote statements were executed, and the name of the remote source.
<b>Remote statements executed in the database</b>	Allows you to see the full SQL text of the SQL statements executed on remote sources. It also shows you when the query was started, how long the query took, and the number of records that were returned.

### Procedure

1. On the [Database Overview](#), scroll to [SAP HANA Smart Data Access Administration](#).
2. Choose the information type to monitor.
  - Running Statements
  - Active Connections

### Results

Information available for remote connections

Detail	Description
Connection	Specifies the connection ID
Adapter	Specifies the name of the adapter for the remote source

<b>Detail</b>	<b>Description</b>
Status	Specifies the status of the connection. Valid entries are CONNECTED or DISCONNECTED
Source Name	Specifies the remote source name
Source User	Specifies the user name on the remote source
Start Time	Specifies the statement start time
Statements	Specifies the number of executed statements
Details	Specifies information about the adapter properties

Information available for remote statements

<b>Detail</b>	<b>Description</b>
SQL Statement	Specifies the statement string
Start Time	Specifies the statement start time
End Time	Specifies the statement end time
SAP HANA cockpit: Statement Runtime (Seconds)	Specifies the query execution time
Status	<p>Query execution status:</p> <ul style="list-style-type: none"> <li>• Analyzing: Query is being analyzed by the query optimizer</li> <li>• Optimizing: Query is being optimized by the query optimizer</li> <li>• Executing: Query is running</li> <li>• Closed: Query has completed</li> <li>• Failed: Query execution failed</li> </ul>
Rows	Specifies the number of rows returned in the query result
Fetch Size	Specifies the byte size of fetched records
Remote Source Name	Specifies the remote source name
User	Specifies the name of the local user accessing the remote source
Transaction	Specifies the transaction ID

## 14.1.8.2 Monitor Details Using SQL Console

View detailed information about the remote statements executed and active connections active in the database.

### Context

Use the monitoring tools to monitor:

**Remote connections active in the database** Provides details about the connections that were opened in the current session, including when the connection was opened, how many remote statements were executed, and the name of the remote source.

**Remote statements executed in the database** Allows you to see the full SQL text of the SQL statements executed on remote sources. It also shows you when the query was started, how long the query took, and the number of records that were returned.

### Procedure

1. Open an SQL console.
2. For information on remote statements, execute a SELECT statement using the M\_REMOTE\_STATEMENTS system view.

```
SELECT * FROM SYS.M_REMOTE_STATEMENTS;
```

3. For information on connections, execute a SELECT statement using the M\_REMOTE\_CONNECTIONS system view.

```
SELECT * FROM SYS.M_REMOTE_CONNECTIONS;
```

### Results

M\_REMOTE\_STATEMENTS View

Details	Description
CONNECTION_ID	Specifies the connection ID
TRANSACTION_ID	Specifies the transaction ID
STATEMENT_ID	Specifies the HANA statement ID

Details	Description
REMOTE_CONNECTION_ID	Specifies the ID of the remote connection
REMOTE_SOURCE_NAME	Specifies the remote source name
START_TIME	Specifies the statement start time
END_TIME	Specifies the statement end time
FETCHED_RECORD_COUNT	Specifies the number of fetched records
FETCHED_SIZE	Specifies the byte size of fetched records
REMOTE_STATEMENT_STATUS	Specifies the statement status: EXECUTING, CLOSED
REMOTE_STATEMENT_STRING	Specifies the statement string
USER_NAME	Specifies the name of the local user accessing the remote source
REMOTE_STATEMENT_DETAILS	Specifies the statement details

#### M\_REMOTE\_CONNECTIONS View

Details	Description
CONNECTION_ID	Specifies the connection ID
REMOTE_SOURCE_NAME	Specifies the remote source name
ADAPTER NAME	Specifies the name of the adapter for the remote source
REMOTE_SOURCE_USER_NAME	Specifies the user name on the remote source
START_TIME	Specifies the statement start time
CONNECTION STATUS	Specifies the status of the connection. Valid entries are CONNECTED or DISCONNECTED
DETAILS	Specifies information about the adapter properties
STATEMENT_COUNT	Specifies the number of executed statements

[M\\_REMOTE\\_CONNECTIONS System View](#)

## 14.1.9 Support for SAP HANA Spatial

Smart data access supports spatial capabilities if the remote source is SAP HANA.

SAP HANA Spatial includes a multilayered spatial engine and supports spatial columns, spatial access methods, and spatial reference systems. SAP HANA Spatial is an SAP HANA optional component.

In the remote source, the ST\_POINT data type maps to the ST\_GEOMETRY data type in the SAP HANA virtual table.

Support for SAP HANA Spatial has some functional restrictions. For a list of these restrictions, see [2609914 - Smart Data Access - Functional Restrictions for Supporting Spatial Data Types](#).

For information on SAP HANA Spatial, see *SAP HANA Spatial Reference*.

### Related Information

[Configure Transfer Formats for Spatial Data Types \[page 2112\]](#)

[SAP HANA Spatial Reference](#)

### 14.1.9.1 Configure Transfer Formats for Spatial Data Types

Spatial data is encoded using one of the following ODBC standard formats: WKB (well-known binary) or WKT (well-known text). The default transfer format is WKB. If binary transfer is disabled, extended transfer formats should be used for data federation between the SAP HANA systems.

#### Context

Binary transfer can be disabled explicitly. It can also be disabled internally because certain data types are not supported or because the binary versions of the two SAP HANA systems are not the same.

If binary transfer has been disabled, extended transfer formats are needed. The extended transfer formats EWKB (extended well-known binary) and EWKT (extended well-known text) include the spatial reference system identifier (SRID). You can set an extended transfer format using the `spatial_xfer_format` parameter in the `indexserver.ini` file.

#### Procedure

Execute the following statement to set the `spatial_xfer_format` parameter in the `indexserver.ini` file to either 'EWKB' or 'EWKT':

### Sample Code

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini', 'SYSTEM') SET ('smart_data_access', 'spatial_xfer_format') = 'EWKB' WITH RECONFIGURE;
```

Option	Description
<b>EWKB</b> (extended well-known binary)	If you do not have empty POINT data, use 'EWKB' since it provides better performance.
<b>EWKT</b> (extended well-known text)	If you have empty POINT data, use 'EWKT'. If you do not set 'EWKT', empty POINT data will be mapped to MULTIPOINT objects that contain a single empty POINT.

## Related Information

[ALTER SYSTEM ALTER CONFIGURATION Statement \(System Management\)](#)  
[Smart Data Access System Parameters \[page 2117\]](#)

## 14.1.10 Data Type Support

Data type support varies by remote source.

The SAP HANA Smart Data Access 2.0 master note lists by remote source how data types are mapped to SAP HANA. Data types not listed are not supported.

## Related Information

[SAP Note 2352696](#)

## 14.1.11 Supported Data Types for Remote Join Pushdown and Remote Join Relocation

The data types accessed in a query are one of the factors that determine whether remote join pushdown and remote join relocation can be performed.

Even if hints such as REMOTE\_JOIN\_RELOCATION and REMOTE\_JOIN are appended to the SQL statement, the join is not pushed down to the remote source if the applicable criteria are not met. Instead, the join is executed locally.

For join pushdown to be able to work, each field accessed in the remote table (in a SELECT clause, WHERE clause, JOIN clause, and so on) must be defined with one of the data types listed below:

Supported Data Types

INT	DECIMAL_DIGIT_ARRAY	NVARCHAR
SMALLINT	DECIMAL	STRING
TINYINT	SMALLDECIMAL	NSTRING
BIGINT	REAL	SECONDDATE
FIXED8	DOUBLE	LONGDATE
FIXED12	CHAR	SECONDTIME
FIXED16	VARCHAR	DAYDATE

## Related Information

[Join Relocation for Multiple Remote Sources \[page 2090\]](#)

## 14.1.12 Functions Pushed Down to Remote Sources

When executing queries on virtual tables that use SAP HANA functions, whenever possible smart data access pushes execution of the function to the remote source to improve query performance.

The ability to push an SAP HANA function down to a remote source depends on the capabilities of the remote source. In some instances, where the SAP HANA function does not map one-to-one to a remote source function, but an equivalent remote function is available, the equivalent remote function is used. If a remote source doesn't support an SAP HANA function, the SAP HANA function is executed on the local host.

The SAP HANA Smart Data Access 2.0 master note lists by remote source the SAP HANA functions that can be pushed down, and where applicable, the equivalent remote source function. Where the SAP HANA function does not map one-to-one, the list indicates what equivalent function is pushed down.

## Related Information

[SAP Note 2352696](#) 

## 14.1.13 Automatic Failover Support

If a connection to a remote source becomes unavailable, then the remote source automatically reconnects to the failover node.

Automatic failover functionality depends on the ODBC connection configuration and whether the remote source itself supports failover.

Currently, the following ODBC connections support failover:

- SAP HANA
- SAP Adaptive Server Enterprise (ASE)
- Oracle

To enable support for failover, configure the remote source using the remote databases ODBC properties. If a connection to the remote database becomes unavailable due to failover, then SAP HANA automatically reconnects to the failover node.

For details on enabling failover, see the specific database under *Creating Remote Sources* .

### Related Information

[Creating Remote Sources \[page 2038\]](#)

## 14.1.14 Safe Mode for ODBC Connections

Provides the capability to load ODBC drivers and execute ODBC calls from within the scriptserver process. This reduces potential issues with the indexserver caused by third-party ODBC drivers.

Currently, smart data access loads the ODBC drivers required for communication with remote database as shared objects directly in the indexserver process. This can be problematic as most of these objects are third-party libraries and may not provide the stability and quality expected from SAP HANA. Any bug in the third-party ODBC driver library may cause the indexserver to crash, impacting customer productivity.

To address this, smart data access allows the scriptserver to be used as a remote driver manager service. With this configuration the ODBC driver manager and ODBC drivers are loaded and executed in the scriptserver.

This functionality is configured in the `smart_data_access > odbc_adapters_in_scriptserver` property in the `indexserver.ini` file and can be enabled and disabled (default) for individual remote sources.

Enter a comma separated list of the adapter types to use the scriptserver. Valid entries include:

Supported Database	Adapter Name
SAP HANA	hanaodbc
SAP IQ	iqodbc
SAP Adaptive Server Enterprise (ASE)	aseodbc

Supported Database	Adapter Name
SAP HANA Accelerator for ASE	ets
SAP MaxDB	maxdb
Teradata	tdodbc
SQL Server	mssql
IBM DB2	db2
IBM Netezza	netezza
Oracle	oracle
Google BigQuery	bigquery
Vora	voraodbc
Hive	hiveodbc
SAP IQ, ASE, HANA	hana_family
All supported databases excluding those included in hana_family	3rd_party
All supported databases	all

The scriptserver, disabled by default, must be enabled to use safe mode. See SAP Note [1650957](#) – SAP HANA Database: Starting the Script Server.

## 14.1.15 Session-Specific Information for Connections

Set session-specific client information on SAP HANA remote source connections.

When creating remote sources, you add syntax to specify the session information as follows:

```
sessionVariable:<session_variable_name>=?
```

When the connection is made via smart data access to the remote source, the ? is replaced with the value of the variable in the local current session context and is added to the connection string. This behavior allows values of local session variables to be used to set session variables on the remote SAP HANA system.

Variable replacement is done for every connection that is made to the remote source. Each connection to the local SAP HANA system has its own session. When a session executes a query using a virtual table, it establishes a connection to the remote SAP HANA system. The value of the variable used to generate the connection string depends on the value of the variable in the local SAP HANA session.

For example, you have set session information on the remote SAP HANA system using the variables MY\_VAR1 and MY\_VAR2. In the local session, the value of the variable MY\_VAR1 is abc and the value of the variable MY\_VAR2 is 100. When the connection to the remote SAP HANA system is established, the following values are added to the connection string: `sessionVariable:MY_VAR1=abc; sessionVariable:MY_VAR2=100`.

### Note

The session variable is a static variable. It is set only once when the first connection to the remote source is established by a query that is executed on a virtual table based on this remote source. This means that if

the value of the variable in the local SAP HANA session is changed, the session variable set on the remote source connection is not updated to reflect these changes.

This feature is supported for SAP HANA remote sources only. For configuration information, see [Create an SAP HANA Remote Source \[page 2038\]](#).

## Related Information

### 14.1.16 Smart Data Access System Parameters

Configuration parameters for smart data access are available in the `smart_data_access` and `linked_database` sections of the `indexserver.ini` file.

Default values should not be changed without direction from SAP support.

smart\_data\_access Section

Parameter Name	Description	Type	Length	Values	Default Value	Hidden
enable_binary_transfer	Specifies whether binary transfer should be used for remote execution.	BOOLEAN		TRUE FALSE	TRUE	YES
enable_remote_source_capability	Specifies the complexity of queries to be sent to the remote sources.	BOOLEAN		TRUE = any query in the remote source dialect can be sent for remote execution FALSE = only projections are sent for remote execution	TRUE	NO

Parameter Name	Description	Type	Length	Values	Default Value	Hidden
semi_join_execution_strategies	Specifies the preferred order of semi-join execution strategies.	VARCHAR	16	IT = attempt of in-clause strategy followed by attempt of temporary table strategy  TI = attempt of temporary table strategy followed by attempt of in-clause strategy  T = temporary table strategy  I = in-clause strategy  N = turns off the semi-join	IT	NO
semi_join_max_in_elements	Specifies the maximum number of values in the IN clause for semi-join usage.	INTEGER		Positive integer value	1024	NO
semi_join_max_temp_table_cardinality	Specifies the maximum number of values to be inserted in a semi-join temp table.	INTEGER		Positive integer value	16384	NO
semi_join_min_temp_table_cardinality	Specifies the minimum number of values to be inserted in a semi-join temp table.	INTEGER		Positive integer value		YES
semi_join_reduction_factor	Specifies the estimated percentage reduction required for an attribute to be considered for semi-join reduction.	TINYINT		Positive integer value		YES
semi_join_virtual_table_threshold	Specifies the minimum number of estimated rows for fact subplan, to be considered for semi-join reduction.	TINYINT		Positive integer value		YES

Parameter Name	Description	Type	Length	Values	Default Value	Hidden
spatial_xfer_format	Specifies the transfer format to be used for spatial data types. An extended transfer format should be used if binary transfer is disabled between the SAP HANA systems.	VARCHAR	16	WKB = well-known binary WKT = well-known text EWKB = extended well-known binary EWKT = extended well-known text	WKB	YES
virtual_table_format	Forces the optimizer to choose column or row-based operators.	VARCHAR	16	ROW = row based COLUMN = column based AUTO = let the optimizer choose	AUTO	NO

linked\_database Section

Parameter Name	Description	Type	Length	Values	Default Value	Hidden
linked_database_cleanup_interval	Specifies the interval in seconds to perform linked object house-keeping tasks.	integer		Positive integer value in seconds 0 = task is disabled	0	NO

## Related Information

[Configure Transfer Formats for Spatial Data Types \[page 2112\]](#)

## 14.1.17 SDA Performance Tools

There are several tools available that can impact performance for smart data access.

## 14.1.17.1 Managing Statistics

Statistics assist the query optimizer in making better decisions and work for both virtual tables and linked database.

### 14.1.17.1.1 Create Statistics on a Virtual Table or Linked Database

Create data statistic virtual objects that the query optimizer uses to make better decisions for query plans.

#### Prerequisites

One of the following:

- You created the virtual table you are creating statistics on.
- You have the ALTER privilege on the object you are creating statistics on.
- For linked database with linked database optimized mode disabled, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source. No additional privilege is required if optimized mode is enabled.

#### Context

To verify that the statement executed correctly, see *Monitor Remote Connections and Statements*.

#### Procedure

To create statistics on a virtual table or linked database, execute:

```
CREATE STATISTICS <data_statistics_name> ON <data_sources>
<data_statistics_type>
[ <data_statistics_properties> ]
[ <initial_refresh> ];
```

##### <data\_statistics\_name>

Specifies a unique name for the data statistics object.

```
<data_statistics_name> ::= [ <schema_name>.]<identifier>
```

<data\_statistics\_name> is only allowed when the result of the creation is a single data statistics object. The number of data statistics objects created by CREATE

STATISTICS is determined by the combination of `<data_statistics_type>` and the number of columns specified in `<data_sources>`.

```
<schema_name> ::= <identifier>
```

`<schema_name>` must be the same as specified for data source.

#### `<data_sources>`

Specifies the data source you want to create data statistics objects for.

```
<data_sources> ::=  
<table_name> [ ( <column_name>[, <column_name>[,... ] ] )  
[ <match_type> ]
```

For RECORD COUNT data statistics objects, you cannot specify columns as part of `<data_sources>`.

**`<table_name>`** Specifies the table name you want to create statistics on.

```
<table_name> ::=  
[ <database_name>.]<schema_name>.<identifier>
```

For linked database, `<database_name>` is the name of the remote source. For all other cases, `<database_name>` is the name of the database where the table is located.

**`<column_name>`** Specifies the column for which the data statistics are defined.

```
<column_name> ::= <identifier>
```

If no `<column_name>` is specified, then all statistics for the table that match the specified properties are altered, including table-wide statistics (RECORD COUNT).

#### `<data_statistics_type>`

Specifies the type of data statistics object to create.

```
<data_statistics_type> := TYPE <type_name>  
<type_name> ::=  
HISTOGRAM  
| SIMPLE  
| TOPK  
| SKETCH  
| SAMPLE  
| RECORD COUNT
```

A data source can have only one data statistics object of a certain type. For example, column A of table T can have one data statistics object of type HISTOGRAM and one of type SIMPLE. If the TYPE clause is not specified, then the default is HISTOGRAM. Some data statistic types may not be appropriate for a given data source.

**HISTOGRAM** Creates a data statistics object that helps the query optimizer estimate the data distribution in a single-column data source. If you specify multiple columns in `<data_sources>`, then multiple data

statistics objects (HISTOGRAM) are created--one per column specified.

- SIMPLE** Creates a data statistics object that helps the query optimizer calculate basic statistics, such as min, max, null count, count, and distinct count for a single-column data source. If you specify multiple columns in `<data_sources>`, then multiple data statistics objects are created--one per column specified. When beneficial, the SQL optimizer maintains system SIMPLE data statistics objects automatically on column and row store tables only.
- TOPK** Creates a data statistics object that helps the query optimizer identify the highest-frequency values in a table data source. If you specify multiple columns in `<data_sources>`, then multiple data statistics objects are created--one per column specified. When beneficial, the SQL optimizer maintains system TOPK data statistics objects automatically (column store only).
- SKETCH** Creates a data statistics object that helps the query optimizer estimate the number of distinct values in the data source. A data statistics object is created for the specified `<table_name>(<column-name>, ...)`, which approximates the number of distinct tuples in the projection of the table on the set of specified columns.
- SAMPLE** Creates a sample of data from `<data_source>` that the SQL optimizer can use during optimization. When beneficial, the SQL optimizer generates system SAMPLE data statistics objects automatically on column and row store tables. However, this behavior can incur a cost to performance. You can avoid this cost by creating SAMPLE data statistics objects explicitly (in advance). Creating them explicitly is especially useful in situations where sampling live table data is expensive (for example, very large tables).
- RECORD COUNT** Creates a data statistics object that helps the query optimizer calculate the number of records (rows) in a table data source. The RECORD COUNT type is a table-wide statistic. You do not specify columns in `<data_sources>` when creating a RECORD COUNT data statistics object. When beneficial, the SQL optimizer maintains system RECORD COUNT data statistics objects automatically on column and row store tables.

#### `<data_statistics_properties>`

Specifies the properties of the data statistics object.

```
<data_statistics_properties> ::=
  <data_statistics_property>[, <data_statistics_property>[, ...] ]

<data_statistics_property> ::=
  REFRESH TYPE <refresh_type>
  | ENABLE <on_off>
  | BUCKETS <unsigned_integer>
  | QERROR <numeric_literal>
```

```

| QTHETA <unsigned_integer>
| { MEMORY <memory_bytes> | MEMORY PERCENT
<memory_percentage> }
| ACCURACY <numeric_literal>
| PREFIX BITS <unsigned_integer>
| PERSISTENT <on_off>
| VALID FOR <valid_for_list>
| CONSTRAINT '<constraint_param>'

```

Restrictions to which properties apply to which statistic types are noted in the property descriptions.

### REFRESH TYPE

<refresh\_type>

Specifies the strategy for the data statistics object.

```
<refresh_type> ::= { MANUAL | DEFAULT }
```

MANUAL specifies that the database statistics object is not refreshed until a rebuild is explicitly requested by a REFRESH STATISTICS statement.

DEFAULT specifies that the database server decides the best refresh strategy based on the data source. Since only MANUAL is supported for virtual tables, DEFAULT uses MANUAL.

REFRESH TYPE only affects data statistics objects that are enabled.

### ENABLE <on\_off>

Controls whether the optimizer uses the data statistics object.

```
<on_off> ::= ON | OFF
```

ENABLE ON enables the optimizer to see the data statistics object. The data statistics object must be populated with data for the optimizer to use it. ENABLE ON specified with NO INITIAL REFRESH returns an error.

ENABLE ON is the default behavior.

ENABLE OFF disables the use of the data statistics object by the optimizer and prevents the ability to refresh the data statistics object. Data statistics objects that are not enabled can still be dropped. To make a data statistics object with ENABLE OFF accessible to the optimizer, execute an ALTER STATISTICS...ENABLE ON statement.

### BUCKETS

<unsigned\_integer>

The BUCKETS property is only for use with TYPE HISTOGRAM or TOPK. For HISTOGRAM, BUCKETS specifies the maximum number of data buckets in the HISTOGRAM. For TOPK, BUCKETS specifies the K value.

The default is automatically determined by the data statistics building algorithm in use.

**ACCURACY**  
<numeric\_literal> Controls the time and space requirements to use for the SKETCH algorithms. This parameter can only be specified when TYPE is SKETCH and must be a number between 0 and 1, with larger values causing decreased time and space requirements but poorer SKETCH resolution. The default is 0.1.

**PREFIX BITS**  
<unsigned\_integer> Controls the number of bits the SKETCH algorithms use when constructing the SKETCH statistics. Specify this parameter when TYPE is SKETCH. Its value is an integer between 0 and 63. The default is 8.

**CONSTRAINT**  
<constraint\_param> Specifies constraints to use for the specified <data\_statistics\_type>.

For SKETCH, <constraint\_param> specifies the algorithm to use to build the SKETCH. The default is LOGLOGCOUNTING; the remaining algorithms are for internal use.

```
<constraint_param> ::=
KMINVAL
| PCSA
| LINEARCOUNTING
| LOGCOUNTING
| LOGLOGCOUNTING
| SUPERLOGLOGCOUNTING
```

<initial\_refresh>

Specifies whether to populate the data statistics object with data after creation.

```
<initial_refresh> ::= [ NO ] INITIAL REFRESH
```

**INITIAL REFRESH** Creates the definition of the data statistics object and populates it with data. The default behavior is INITIAL REFRESH.

**NO INITIAL REFRESH** Creates the definition of the data statistics object, but does not populate it with data.

Use NO INITIAL REFRESH when you want to change the underlying data before refreshing the data statistics object.

You cannot specify NO INITIAL REFRESH if ENABLE OFF is not specified.

## Examples

Create SIMPLE statistics on virtual table HANA1\_T1.

```
CREATE STATISTICS "TEST1" ON HANA1_T1 (A1) TYPE SIMPLE;
```

Using linked database, create TOPK statistics on table T1 using remote source HANA1 and schema MYSCHEMA with 10 buckets.

```
CREATE STATISTICS ON HANA1.MYSCHEMA.T1 (A1) TYPE TOPK BUCKETS 10;
```

## Related Information

[Monitor Remote Statements and Connections \[page 2108\]](#)

[Alter Statistics on a Virtual Table or Linked Database \[page 2125\]](#)

[Linked Database Overview \[page 2012\]](#)

## 14.1.17.1.2 Alter Statistics on a Virtual Table or Linked Database

Alter the properties of a data statistic object for virtual tables or linked database.

### Prerequisites

One of the following:

- You own the virtual table you are altering statistics on.
- You have the ALTER privilege on the object you are altering statistics on.
- For linked database, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source.

### Procedure

To alter statistics on a virtual table or linked database, execute:

```
ALTER STATISTICS { <data_statistics_name> [,...] | ON <data_sources>
[ [ HAVING ] <match_properties> ] }
[ SET <set_data_statistics_properties> ]
[ <initial_refresh> ]
```

#### <data\_statistics\_name>

Specifies the name of the data statistics object.

```
<data_statistics_name> ::= [<schema_name>.]<identifier>
<schema_name> ::= <identifier>
```

### <data\_sources>

Specifies the data source(s) of the data statistics objects.

```
<data_sources> ::=  
<table_name> [ ( <column_name>[, <column_name>[,...]] )  
[ <match_type> ]
```

For RECORD COUNT data statistics objects, you cannot specify columns as part of <data\_sources>.

**<table\_name>** Specifies the table on which the data statistics are defined.

```
<table_name> ::=  
[ [ <database_name>.]<schema_name>.]<identifier>
```

For linked database, <database\_name> is the name of the remote source. For all other cases, <database\_name> is the name of the database where the table is located.

**<column\_name>** Specifies the column for which the data statistics are defined.

```
<column_name> ::= <identifier>
```

If no <column\_name> is specified, then all statistics for the table that match the specified properties are altered, including table-wide statistics (RECORD COUNT).

### <match\_properties>

Specifies properties to use for matching when selecting data statistics.

```
<match_properties> ::= <match_property>[...]  
<match_property> ::=  
TYPE <data_statistics_type> | REFRESH TYPE  
<refresh_type_filter>
```

If TYPE is not specified, then all data statistics objects of any type on the specified data sources are altered (ALL). For descriptions of the supported data statistics types see [Create Statistics on a Virtual Table or Linked Database \[page 2120\]](#).

**<data\_statistics\_type>** Specifies the type of data statistics objects to match when selecting the data statistics.

```
<data_statistics_type> := TYPE  
<type_name>  
<type_name> ::=  
HISTOGRAM  
| SIMPLE  
| TOPK  
| SKETCH  
| SAMPLE  
| RECORD COUNT  
| ALL
```

**<refresh\_type\_filter>** Specifies the refresh strategy to match in the data statistics objects when selecting the data statistics to alter. ALL is the default.

```
<refresh_type_filter> ::= MANUAL | ALL
```

### **<set\_data\_statistics\_properties>**

Specifies the properties of the data statistics objects to modify.

```
<data_statistics_properties> ::=  
  <data_statistics_property> [<data_statistics_property>]...  
  
<data_statistics_property> ::=  
  | REFRESH TYPE <refresh_type>  
  | ENABLE <on_off>  
  | BUCKETS <unsigned_integer>  
  | ACCURACY <numeric_literal>  
  | PREFIXBITS <unsigned_integer>  
  | PERSISTENT <on_off>  
  | CONSTRAINT <constraint_param>
```

#### **REFRESH TYPE**

##### **<refresh\_type>**

Specifies the strategy for the data statistics object.

```
<refresh_type> ::= { MANUAL | DEFAULT }
```

MANUAL specifies that the database statistics object is not refreshed until a rebuild is explicitly requested by a REFRESH STATISTICS statement.

DEFAULT specifies that the database server decides the best refresh strategy based on the data source. Since only MANUAL is supported for virtual tables, DEFAULT uses MANUAL.

REFRESH TYPE only affects data statistics objects that are enabled.

#### **ENABLE <on\_off>**

Controls whether the optimizer uses the data statistics object.

```
<on_off> ::= { ON | OFF }
```

ENABLE ON enables the optimizer to see the data statistics object. The data statistics object must be populated with data for the optimizer to use it.

ENABLE OFF disables the use of the data statistics object by the optimizer and prevents the ability to refresh the data statistics object. Data statistics objects that are not enabled can still be dropped. To make a data statistics object with ENABLE OFF accessible to the optimizer, execute an ALTER STATISTICS...ENABLE ON statement.

<b>BUCKETS</b> <unsigned_integer>	The BUCKETS property is only for use with TYPE HISTOGRAM or TOPK. For HISTOGRAM, BUCKETS specifies the maximum number of data buckets in the HISTOGRAM. For TOPK, BUCKETS specifies the K value.  The default is automatically determined by the data statistics building algorithm in use.
<b>ACCURACY</b> <numeric_literal>	Controls the time and space requirements to use for the SKETCH algorithms. This parameter can only be specified when TYPE is SKETCH and must be a number between 0 and 1, with larger values causing decreased time and space requirements but poorer SKETCH resolution. The default is 0.1.
<b>PREFIX BITS</b> <unsigned_integer>	Controls the number of bits the SKETCH algorithms use when constructing the SKETCH statistics. Specify this parameter when TYPE is SKETCH. Its value is an integer between 0 and 63. The default is 8.
<b>CONSTRAINT</b> <constraint_param>	Specifies constraints to use for the specified <data_statistics_type>.  For SKETCH, <constraint_param> specifies the algorithm to use to build the SKETCH. The default is LOGLOGCOUNTING; the remaining algorithms are for internal use.

```

<constraint_param> ::=
KMINVAL
| PCSA
| LINEARCOUNTING
| LOGCOUNTING
| LOGLOGCOUNTING
| SUPERLOGLOGCOUNTING

```

<initial\_refresh>

Specifies whether to repopulate the data statistics object with data after altering it.

```

<initial_refresh> ::= [ NO ] INITIAL REFRESH

```

If the object was built, then disabled, and is now being re-enabled, then initial refresh is not required.

- INITIAL REFRESH**      Alters the definition of the data statistics object and repopulates it with data. The default behavior is INITIAL REFRESH.
- NO INITIAL REFRESH**      Alters the definition of the data statistics object, but does not repopulate it with data.  
  
Use NO INITIAL REFRESH when you want to change the underlying data before refreshing the data statistics object.

You cannot specify NO INITIAL REFRESH if ENABLE OFF is not specified.

## Examples

Set the number of buckets to 150 for the virtual table Remote1\_A1.

```
ALTER STATISTICS ON MYSYSTEM.REMOTE2_A1 TYPE TOPK SET BUCKETS 10 NO INITIAL  
REFRESH;
```

The following example sets the number of buckets to 10 on the remote source remote2 using linked database.

```
ALTER STATISTICS ON "remote2"."SYSTEM"."A1" TYPE TOPK SET BUCKETS 10;
```

## 14.1.17.1.3 Refresh Statistics on a Virtual Table or Linked Database

Refreshes data statistic virtual objects that the query optimizer uses to make better decisions for query plans.

### Prerequisites

One of the following:

- You own the virtual table you are refreshing statistics on.
- You have the ALTER privilege on the object you are refreshing statistics on.
- For linked database, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source.

### Context

Specify EXACT to refresh a data statistics virtual object that precisely matches <data\_sources> (including column order). Specify CASCADE to refresh data statistics objects that reference at least one column in

<data\_sources>. If <match\_type> is not specified, then any data statistics objects that reference all or some of the columns specified in <data\_sources> are refreshed.

## Procedure

To refresh statistics, execute:

```
REFRESH STATISTICS { <data_statistics_name>[,<data_statistics_name>[,... ]  
| ON <data_sources> [ [HAVING] <match_properties> ] };
```

For descriptions of each supported property, see the [Alter Statistics on a Virtual Table or Linked Database \[page 2125\]](#) topic

## Example

Refresh all statistics on virtual table HANA1\_T1.

```
REFRESH STATISTICS ON MYSCHEMA.HANA1_T1;
```

Using linked database, refresh only SIMPLE statistics on table T1 using remote source HANA1 and schema MYSCHEMA1.

```
REFRESH STATISTICS ON HANA1.MYSCHEMA1.T1 TYPE SIMPLE;
```

## 14.1.17.1.4 Drop Statistics on a Virtual Table or Linked Database

Drop data statistic virtual objects that the query optimizer uses to make better decisions for query plans.

## Prerequisites

One of the following:

- You own the virtual table you are dropping statistics from.
- You have the ALTER privilege on the object you are dropping statistics from.
- For linked database, you require the LINKED DATABASE object level privilege on the remote source, regardless of who created the remote source.

## Procedure

To drop statistics on a virtual table, execute:

```
DROP STATISTICS ON [<schema_name>.] <virtual_table_name>
[ [HAVING] <match_properties> ];
```

For descriptions of each supported property, see the [Alter Statistics on a Virtual Table or Linked Database \[page 2125\]](#) topic

## Example

The following statement drops all statistics on virtual table HANA1\_T1.

```
DROP STATISTICS ON MYSCHEMA1.HANA1_T1;
```

Using linked database, the following statement drops SIMPLE statistics on table T1 using remote source HANA1 and schema MYSCHEMA2.

```
DROP STATISTICS ON HANA1.MYSCHEMA2.T1 TYPE SIMPLE
```

[Monitor Details Using SQL Console \[page 2110\]](#)

## 14.1.17.1.5 Retrieve Statistics from a Remote Source

On supported remote sources, statistics for virtual tables and linked database are retrieved by querying a remote table.

The name of the virtual table that is queried for statistics retrieval is:

Remote Source	Virtual Table Name
SAP HANA	SYSTEM.SDA_STATISTICS
SAP IQ	SYS_STATISTICS
Teradata	SYS_STATISTICS

`SYS_STATISTICS` is located on the default schema of the connection used to create the virtual tables.

When SIMPLE statistics are computed for a virtual table, the remote statistics table is queried first. If this table is not available (or has a different format), then the standard behavior used to obtain statistics from remote sources is triggered; that is, statistics queries are sent for each column in order for the statistics to be remotely computed.

The schema of the remote statistics table is as follows:

Index	Name	Type	Precision	Description
1	SCHEMA_NAME	VARCHAR	128	Schema name
2	TABLE_NAME	VARCHAR	128	Table name
3	COLUMN_NAME	VARCHAR	128	Column name
4	MIN	VARCHAR	128	String representation of the min value
5	MAX	VARCHAR		String representation of the max value
6	COUNT_STAR	INTEGER		Count (*)
7	DCOUNT	INTEGER		Distinct count
8	COUNT	INTEGER		Count (used to count NULL values)

Virtual table statistics are stored in the `DATA_STATISTICS` system table.

## 14.1.17.2 Manage Read-Write and Read-Only Access to a Remote Source

The DML mode property specifies whether read-write or read-only access to the remote source is allowed.

### Prerequisites

- Requires the ALTER object privilege on the remote source.

## Context

You can set the DML mode property using the SQL console or the SAP HANA database explorer. INSERT, UPDATE, and DELETE operations cannot be executed on virtual tables when the DML mode property is set to `readonly` on a remote source. The read-only option improves performance for SELECT queries.

When a remote source is created with the SQL console, the default setting of the DML mode is `readwrite`. Therefore, if the DML mode is not explicitly specified as either `readwrite` or `readonly`, the remote source is created in read-write mode by default. When using the SAP HANA database explorer, the default selection for the DML mode is also `readwrite`.

## Enable Read-Write or Read-Only Access Using SQL Syntax

### Procedure

1. To display the current value of the DML mode property, retrieve the remote connection details from the `M_REMOTE_CONNECTIONS` monitoring view, which provides information about the remote connections active in the database:
  - a. To ensure that the status shown in the `M_REMOTE_CONNECTIONS` view is up to date, execute:

```
CALL CHECK_REMOTE_SOURCE('<remote_source_name>');
```

- b. To retrieve the details about the remote connection, execute:

```
SELECT * FROM SYS.M_REMOTE_CONNECTIONS WHERE  
CONNECTION_ID=CURRENT_CONNECTION;
```

The `DETAILS` column shows whether a remote connection was created as `readonly` or `readwrite`. There might be multiple entries if the DML mode is `readonly`.

2. To modify the DML mode option, execute the following:
  - o To enable read-write access:

#### Sample Code

```
ALTER REMOTE SOURCE <remote_source_name> ADAPTER "hanaodbc"  
CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<remote_server_name>:  
3<remote_instance_number>15;  
dml_mode=readwrite';
```

- o To enable read-only access:

#### Sample Code

```
ALTER REMOTE SOURCE <remote_source_name> ADAPTER "hanaodbc"  
CONFIGURATION 'Driver=libodbcHDB.so;ServerNode=<remote_server_name>:  
3<remote_instance_number>15;  
dml_mode=readonly';
```

# Enable Read-Write or Read-Only Access Using the SAP HANA Database Explorer

## Procedure

1. Expand the *Catalog*.
2. Select *Remote Sources*.  
A list of remote sources appears in the catalog browser item list.
3. Select your remote source to open the remote source editor.
4. Choose *Edit*.
5. Modify the *DML Mode* field and choose *Save*.

The system saves the change and then tests the new connection properties. If the connection fails, then a message appears, all filters are reset, and the remote object list is cleared.

## Related Information

[ALTER REMOTE SOURCE Statement \(Access Control\)](#)

[M\\_REMOTE\\_CONNECTIONS System View](#)

## 14.1.17.3 Pool of Remote Connections

Use a pool of remote connections to scale out multithreaded execution. A pool of remote connections can only be used for read-only remote sources (DML\_MODE=readonly).

Provided no external updates (by third parties) occur on the remote source, full consistency is assured.

However, if external updates occur in parallel on a declared read-only remote source, then consistency can be ensured only within one SAP HANA thread.

## Configuration Parameter for Pool of Remote Connections

Use the parameter `default_connections_pool_max_size` in the `smart_data_access` section of the `indexserver.ini` file to configure a pool of remote connections:

```
indexserver.ini/smart_data_access/default_connections_pool_max_size
```

- Default value: 3
- Highest value allowed: 50

- Value to disable the connection pool: 1

The maximum number of connections allowed in one pool is controlled by the value specified in `default_connections_pool_max_size`. Each SAP HANA connection has its own connection pool for each remote source it uses. The number of connections depends on the degree of multithreading of the executed statements, but cannot exceed the number specified in `default_connections_pool_max_size`. Also, each SAP HANA node has its own connection pool, so `default_connections_pool_max_size` applies per node and is not a global maximum. The query optimizer may decide to increase the degree of parallelism by using multiple SAP HANA nodes for the query execution.

### 14.1.17.3.1 Configure the Pool of Remote Connections Parameter

Configure the number of remote connections to enable for multi-threaded execution.

#### Prerequisites

Requires the INIFILE ADMIN system privilege.

## Configure the Parameter Using SQL

#### Procedure

In an SQL console, execute:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini','SYSTEM')
  SET ('smart_data_access', 'default_connections_pool_max_size')='<value>';
```

#### Example

The following statement sets the number of connections to 10:

```
ALTER SYSTEM ALTER CONFIGURATION ('indexserver.ini','SYSTEM')
  SET ('smart_data_access', 'default_connections_pool_max_size')='10';
```

## 14.1.17.4 Results Caching for Virtual Tables and Linked Database

Only view results caching is supported for virtual tables and linked database.

You configure result caching using the `<cache_type>` parameter in the CREATE VIEW statement, or the `<alter_cache_settings_clause>` parameter in the ALTER VIEW statement. Only static result caching is supported for virtual tables and linked database. Dynamic result caching is not supported.

Caching of user-defined functions that reference virtual tables is not supported.

When you query a virtual table, if there is insufficient memory to cache the results, then an internal error message appears, the query halts, and no results are cached. To prevent this scenario, modify the view definition if possible, to filter data before caching results, partition caching between multiple views, or disable result caching. You may need to clear the SQL plan cache after modifying the view definition. Using HINT IGNORE\_PLAN\_CACHE when executing a query allows the system to validate if there is sufficient memory to cache the results before execution and helps you decide if caching should be used. However, since remote data size is only an estimate, this configuration may not prevent the error of insufficient memory.

When creating a view on virtual tables with caching configured, you must apply filters to the view definition not outside the view definition (part of the SQL query referencing the view) whenever possible. Using common filters within the view definition increases the usability and performances of the cache.

When results caching is enabled, only filters applied to the view definition are pushed down to the remote source. Filters outside of the view definition are not pushed. They are applied once the unfiltered results are cached. This behavior potentially impacts how much data is retrieved from the remote source. When results caching is disabled, and the filter is outside the view, the filter may be pushed down to the remote source, returning less data, but the results are not cached. The next time the view is used, the new query is sent to the remote source and new data is returned.

Cached views can have a retention period, which when exceeded triggers a refresh of the view on next use. The frequency of refresh can impact performance. Regularly monitor cache use. The retention period of a view should reflect the nature of the data returned. Apply a longer retention period to views returning data that is more static in nature. It is not recommended that you cache views that are rarely used, regardless of the nature of the data. The constant refresh of the data could impact performance without any potential benefits from caching.

Data in a cached view is available to all users with the SELECT privilege on the view. Remote privileges on virtual tables are validated only when a remote statement is executed, which populates the results cache. The view results cache is available to all users. Any query can populate a view results cache, but the data cached is based on the remote credentials of the current user. As a result, users querying a cached view may see less data than expected if their remote privileges are greater than those of the user who populated the cache. Conversely, users with lesser remote privileges may see data in the shared cache that they normally could not access.

Use cached views only with remote sources using technical user credentials. For all other types of remote authentications, only SAP HANA side authorizations are enforced. When executing a query, to prevent populating the results cache with data specific to credentials, include the HINT RESULT\_CACHE\_NO\_REFRESH clause.

Take careful consideration when enabling caching on views with virtual tables that point to data with static or dynamic analytical privileges or data that cannot be seen as a relational data set (that binds to relational operator rules). Remote constraints on data may not be enforced regardless of whether view results cache is enabled or not.

Result caching is disabled by default. When using HINT RESULT\_CACHE in a query on views, if result cache is configured on the views, then result caching is enabled for the query only.

Result caching is also controlled through the `<result_cache>` set of system configuration parameters within `indexserver.ini`.

For full syntax to create, alter, and drop view cache, or to enable result caching, see *SAP HANA SQL and System Views Reference*.

## Example

This statement creates a view called `view_tableA` on `tableA` with a static result cache retention period of 10 minutes:

### Sample Code

```
CREATE VIEW view_tableA AS SELECT * FROM tableA WITH STATIC CACHE RETENTION 10;
```

This statement changes the retention period from 10 minutes to 5:

### Sample Code

```
ALTER VIEW view_tableA ALTER STATIC CACHE RETENTION 5;
```

## 14.1.18 Troubleshooting Smart Data Access

Find solutions to common smart data access problems.

If you don't find your issue in the troubleshooting topics, for a list of known issues see [2352696 - SAP HANA Smart Data Access 2.0 Master Release Note](#).

### 14.1.18.1 Invalid Connection String Message When Querying a Google BigQuery Database

When executing a query using Google BigQuery as a remote source, you receive a message regarding an invalid connection string.

Ensure that the `DriverManagerEncoding` property in the `simba.googlebigqueryodbc.ini` file on the SAP HANA host is configured to use `UTF-16`. See [Google BigQuery ODBC Driver \[page 2023\]](#).

## 14.2 SAP HANA Hadoop Integration

Regardless of structure, you can combine the in-memory processing power of SAP HANA with Hadoop's ability to store and process huge amounts of data.

SAP HANA is designed for high-speed data and analytic scenarios, while Hadoop is designed for very large, unstructured data scenarios. Hadoop can scale to thousands of nodes and is designed for use in large distributed clusters and to handle big data. Combining SAP HANA with Hadoop leverages Hadoop's lower storage cost and type flexibility with the high-speed in-memory processing power and highly structured data conformity of SAP HANA.

SAP HANA Hadoop integration is designed for users who may want to start using SAP HANA with their Hadoop ecosystem.

For information about SAP HANA Hadoop Integration and SAP HANA Spark controller installation, see [SAP HANA Hadoop Integration](#).

# Important Disclaimer for Features in SAP HANA

For information about the capabilities available for your license and installation scenario, refer to the [Feature Scope Description for SAP HANA](#).
