## I. EXECUTIVE SUMMARY

This report details a large, but preliminary, collection of insects from the Kona Forest Unit of the Hakalau National Wildlife Refuge. Visits to the Refuge were carried out by vehicle from July 1999 until October 2000 when the survey was interrupted by loss of road access to the Refuge. The purpose of this survey was to inventory endemic insect taxa likely to respond to future forest restoration efforts, including the removal of feral ungulates from the Refuge. Additionally, selected alien insect species were also collected. Before the inventory was undertaken, 296 historical species records were compiled for the South Kona region. Using this list and other summaries for the Island of Hawai‘i, nine groups of endemic insects were targeted, including 4 genera of beetles; pomace flies; yellow-faced bees; 2 genera of moths; and Hawaiian damselflies. These target groups were chosen because species richness within these taxa increases the opportunity for documenting changes in native insect communities as a consequence of resource management activities. Many of these groups also contain Fish and Wildlife Species of Concern or Candidate Endangered Species. Survey work was initiated over 750 m long contour transects at 500 m intervals between 762 m and 1676 m elevation. A total of 1683 specimen lots comprising a total of 9330 individual specimens were collected and analyzed. Among alien invertebrates of concern that were detected, yellowjacket wasps were widely established in the Refuge and their populations underwent seasonal outbreaks typical of other mesic forest populations on the island. Three scientific publications so far have directly resulted from the analysis of native insect taxa from the Refuge and specimen data has also contributed to one comprehensive taxonomic monograph. One interesting finding is the occurrence of the ‘ohe leafroller, *Omiodes asaphombra*, at light traps on the refuge. This endemic moth was once thought to be extinct and has only been found breeding on ‘ohe, or *Joinvillea ascendens*. This indigenous plant is very rare on the island of Hawaii and has not been recorded from the refuge or anywhere on the west side of the island. The most significant finding of this project was the discovery of a population of the rare picture-wing pomace fly, *Drosophila heteroneura*. *Drosophila heteroneura* is a Candidate Endangered Species found only on the Island of Hawai‘i. Images of the hammer-headed males of this pomace fly have frequently been used to illustrate the uniqueness of Hawai‘i’s insect fauna and *D. heteroneura* has been one of the most intensively researched native insects in the state. However, the fly now appears to be extirpated from all of its previously known historical range. The observations of *D. heteroneura* on the Refuge are the first observations of this species in the wild in approximately ten years. As of 1999, the Refuge supported the only known extant population of this unique Hawaiian picture-wing fly. It is recommended that management of the Kona Forest Unit to foster preservation of this and other rare Hawaiian insects should include suppression of alien yellowjacket wasps.

## **II. INTRODUCTION**

### **A. Purpose of Rapid Assessment**

It is widely recognized that invertebrates play a key role in ecosystem processes in Hawai‘i and elsewhere. However, due to the huge diversity of invertebrates present in any particular area, unbounded surveys of all invertebrate taxa are, by nature, very labor intensive. Generally, when conducting these types of broad surveys, it is not feasible to identify all (or even most) of the specimens to the species level, making it difficult to separate diversity into native and alien components, or to assess the status of certain rare species. When broad collecting techniques are employed in an area, surveyors are typically faced with more specimens than they can identify or curate, resulting in a backlog of unidentified or unsorted specimens.

As an alternative to all-encompassing surveys, recent focus has been placed on rapid assessments of invertebrate fauna. A rapid assessment is an attempt to approximate the relative richness of invertebrate species in an area without directly counting the number of species present. Oliver and Beattie (1996) explored cost-effective survey methods for invertebrates, and mentioned five potential approaches to rapid assessment: (1) the use of target taxa in place of all taxa; (2) the use of restricted sampling in place of intensive sampling; (3) the use of morphospecies in place of true species; (4) the use of taxonomic ranks other than species (e.g. families or orders); and (5) extrapolation of species accumulation functions to estimate true species richness.

For the present survey, we utilized methods (1) and (5) above. Oliver and Beattie (1996) found that, although focusing on a single group of insects did not provide consistent richness estimates, using several taxa as surrogates was useful in comparing invertebrate diversity. Colwell and Coddington (1994) explored different methods of extrapolating species accumulation curves to estimate true species richness. We employed a combination of these techniques, targeting nine genera of endemic insects, to serve as “surrogate” taxa representing all native insects, and extrapolating species accumulation curves to estimate the completeness of our surveys and the relative species richness between sites on the Refuge. Because our efforts were focused on groups that contained species of concern, we were also able to assess the status of individual species that might be particularly threatened.

### **B. Target Genera**

Nine groups of endemic insects were targeted: *Proterhinus* (Coleoptera: Aglycyderidae), *Plagithmysus* (Coleoptera: Cerambycidae), *Rhyncogonus* (Coleoptera: Curculionidae), *Eopenthes* (Coleoptera: Elateridae), *Drosophila* (Diptera: Drosophilidae), *Hylaeus* (Hymenoptera: Colletidae), *Omiodes* (Lepidoptera: Crambidae), *Scotorythra* (Lepidoptera: Geometridae), and *Megalagrion* (Odonata: Coenagrionidae). These target groups were chosen because species richness within these groups and abundances of species within these groups are likely to respond to forest recovery following the removal of feral ungulates. Many of these groups also contain species of concern (Table 1).

**Table 1.** Attributes of invertebrate target genera (based on Nishida, 1997). CE = USFWS Candidate Endangered Species; SOC = USFWS Species of Concern.

Order	Family	Genus	Species in Hawai‘i	Species on Hawai‘i Island	CE from Hawai‘i Island	SOC from Hawai‘i Island
Coleoptera	Aglycyderidae	<i>Proterhinus</i>	177	23	0	0
Coleoptera	Cerambycidae	<i>Plagithmysus</i>	140	39	0	12
Coleoptera	Curculionidae	<i>Rhyncogonus</i>	47	2	0	1
Coleoptera	Elateridae	<i>Eopenthes</i>	34	3	0	2
Diptera	Drosophilidae	<i>Drosophila</i>	389	141	5	0
Hymenoptera	Colletidae	<i>Hylaeus</i>	61	28	0	17
Lepidoptera	Crambidae	<i>Omiodes</i>	23	19	0	10
Lepidoptera	Geometridae	<i>Scotorythra</i>	38	20	0	0
Odonata	Coenagrionidae	<i>Megalagrion</i>	23	7	2	2

### ***Proterhinus* (Coleoptera: Aglycyderidae)**

Host plants: *Acacia koa*, *Aleurites moluccana*, *Antidesma* spp., *Bobea* spp., *Broussaisia arguta*, *Chamaesyce* spp., *Cibotium* spp., *Coprosma* spp., *Cyrtandra* spp., *Gossypium* spp., *Hedyotis* spp., *Hibiscadelphus* spp., *Lipochaeta* spp., *Metrosideros polymorpha*, *Myoporum sandwicense*, *Perotettia sandwicensis*, *Pipturus albidus*, *Psychotria* spp., *Sophora chrysophylla*, *Wikstroemia* spp.

Weevils from the genus *Proterhinus* are tiny, slow-moving beetles, most of which inhabit dead twigs and stems of woody plants. Larvae of this genus tend to be very host-specific, utilizing one or a few species of plants. It is not entirely clear how host-specific adult *Proterhinus* beetles are; they are more mobile than larvae, and may therefore be less restricted to specific host plants (Swezey, 1938). Therefore, collection of an adult beetle on a particular plant does not imply that the beetle was utilizing that plant as a host. The genus *Proterhinus* is found only in the Hawaiian Islands, and there is a high degree of island endemism in the group; most species are found on only one island (Nishida, 1997).

Taxonomically, *Proterhinus* is a very troublesome genus. Although tiny, these beetles exhibit a large amount of both interspecific and intraspecific morphological diversity, as well as sexual dimorphism, making species-level determinations very difficult (Perkins, 1900). Even sorting specimens into distinct morphotypes is not always straightforward. Although there have been over 170 species described, it is estimated that there are as many as 250 endemic species in the islands (Howarth and Mull, 1992). In this survey, “best guess” determinations have been made for all *Proterhinus* specimens collected, based on available keys, host plant records, and comparison with identified specimens at the Bishop Museum.

Due to the high degree of specificity of *Proterhinus* larvae, it is very likely that beetle species occurring on rare host plants will be rare themselves. Because of this specificity and diversity, *Proterhinus* weevils may potentially be used as indicators of success for habitat-based

conservation initiatives, in which their presence or absence may serve as a measure of the health and ecological function of host plant populations.

#### ***Plagithmysus* (Coleoptera: Cerambycidae)**

Host plants: nearly all trees and large shrubs.

Long-horned beetles in the genus *Plagithmysus* are much larger than *Proterhinus* weevils, and are often very showy and active. Perhaps due in part to its diversity of size and color variations, this group has been fairly well studied, and there is a good deal of knowledge regarding host relationships (Gressitt and Davis, 1969).

Like the *Proterhinus* weevils, *Plagithmysus* beetles tend to be very specific in their larval host preference. Adults lay eggs in recently fallen (or in some cases, still living) branches. This results in a very narrow window of opportunity, as wood that is too old will not support the larvae. *Plagithmysus* larval development tends to be slow; some larvae take more than a year to develop into adults, depending on the size of the beetle and the nutrient content of its food source.

Because they often utilize only wood of a certain age and species, populations of *Plagithmysus* beetles must have access to sufficiently large populations of host plants. If a given beetle species breeds in recently fallen trees of a given plant species, there must be enough plants of that species to ensure a steady supply of dead or dying wood. Some species of *Plagithmysus* attack living trees, usually killing a portion of the tree in the process of feeding on it.

An unfortunate drawback of surveying for these beetles is that it relies heavily on rearing adults from host material. This requires that surveyors locate host plants in the proper state of decay, bring portions of these plants into the laboratory, and rear adults from the plant parts. Although the actual rearing of insects from wood samples is easily accomplished, the chances are slim of locating natural falls of many different host plants. One way to circumvent this problem would be to actively cut branches from plants, leave them exposed to the elements (and potential oviposition), and then bring them back to the laboratory for rearing. This would not be a feasible or advisable procedure when dealing with rare plant species.

#### ***Rhyncogonus* (Coleoptera: Curculionidae)**

Host plants: *Acacia koa*, *Bidens* spp., *Broussaisia arguta*, *Chenopodium oahuense*, *Dodonaea viscosa*, *Nestegis sandwicensis*, and many others.

On Hawai‘i Island, the genus *Rhyncogonus* is represented by only two described species, *R. giffardi* and *R. stellaris*. Little is known about either species, which have been collected from a few localities in Kona. The former is known from only two specimens collected at Pu‘u Wa‘awa‘a in 1917 and 1937; its host is unknown. The latter has been collected from several localities in the area of Waikoloa and Pōhakuloa, most recently in 2002, on *Bidens* and *Chenopodium* (Samuelson, 2003).

Generally, *Rhyncogonus* are nocturnal leaf-feeders, likely burrowing into leaf litter or soil during the day. As such, surveying for these beetles is best conducted by examining foliage at night, with headlamps (Al Samuelson, pers. comm.).

### ***Eopenthes* (Coleoptera: Elateridae)**

Host plants: visits blossoms of native plants, including *Metrosideros polymorpha*.

The genus *Eopenthes*, endemic to the Hawaiian Islands, is a large genus of click beetles. They are generally restricted to mountain regions where native vegetation is dominant (Van Zwaluwenburg, 1959). The genus includes 33 species, three of which have been recorded from Hawai‘i Island: *E. cognatus*, *E. konae*, and *E. tinctus*.

Van Zwaluwenburg (1959) summarized the natural history of these beetles. Larvae of *Eopenthes* are found in decaying wood, and probably feed on other invertebrates. Adults are diurnal, and are unusual in that they feed on nectar, swarming around flowers of native plants. *Eopenthes* are also seasonal insects, active almost exclusively during the summer months and best collected by sweep netting on native vegetation. According to Van Zwaluwenburg, most species in this genus are extremely rare.

### ***Drosophila* (Diptera: Drosophilidae)**

Host plants: *Acacia koa*, *Alectryon macrococcus*, *Aleurites moluccana*, bracket fungi, *Chamaesyce* spp., *Charpentiera* spp., *Cheirodendron* spp., *Cibotium* spp., *Clermontia* spp., *Cyanea* spp., *Delissea* spp., *Dubautia plantaginea*, *Freycinetia arborea*, *Hibiscus arnottianus*, *Ilex anomala*, *Lobelia* spp., *Marattia douglasii*, *Melicope* spp., *Myoporum sandwicense*, *Myrsine* spp., *Nestegis sandwicensis*, *Piper methysticum*, *Pipturus albidus*, *Pittosporum* spp., *Pisonia* spp., *Pleomele* spp., *Pouteria* spp., *Pritchardia* spp., *Pteralyxia macrocarpa*, *Reynoldsdia sandwicensis*, *Sadleria* spp., *Sapindus* spp., *Solanum sodomaeum*, *Sophora chrysophylla*, *Tetraplasandra* spp., *Touchardia latifolia*, *Urera* spp., *Wikstroemia* spp.

The Hawaiian representatives of the genus *Drosophila* are probably the most actively studied group of insects in Hawai‘i. Over 330 species of *Drosophila* are currently described, and there are thought to be at least 250 additional species yet to be described. Most drosophilids breed in rotting bark, leaves, flowers, or fruit and are host specific, utilizing one or a few types of host plants for oviposition.

### ***Hylaeus* (Hymenoptera: Colletidae)**

Host plants: adults visit many native blossoms, especially *Cheirodendron trigynum*, *Dodonaea viscosa*, *Metrosideros polymorpha*, *Myoporum sandwicense*, *Sophora chrysophylla*, and *Styphelia tameiameiae*.

Of the 61 species of Hawaiian yellow-faced bees (*Hylaeus* spp.), 34 species statewide and 18 species on Hawai‘i Island are species of concern (formerly Category 2 candidate endangered species) (Daly and Magnacca, 2003; Bishop Museum, 2004). In many species of *Hylaeus*, male bees have distinct yellow markings on the fronts of their heads, giving them the common name “yellow-faced bees”. These yellow markings are often used to distinguish between species of bees.

Yellow-faced bees visit blossoms of native plants for nectar, and are important pollinators in Hawaiian ecosystems. They are generally not host-specific. *Hylaeus* bees are best collected by sweep netting around flowering vegetation, although they are also commonly collected on yellow sticky traps.

### ***Omiodes* (Lepidoptera: Crambidae)**

Host plants: *Astelia menziesiana*, *Cocos nucifera*, *Dianella sandwicensis*, *Erythrina sandwicensis*, grasses, *Musa* spp., *Pritchardia* spp., sedges.

Hawaiian leaf-roller moths in the genus *Omiodes* primarily utilize monocots as host plants, but the degree of host specificity varies between species. Some species feed on many kinds of grasses, while most are tied to a single genus or species of plant. The larvae of these moths roll or fold leaves, or bind them together with silk to create a retreat. In addition to light trapping, larvae can be collected from their host plants and successfully reared in the laboratory.

Hawaiian *Omiodes* moths have a very interesting history, partly due to the fact that two species of this genus have been economic pests: *O. accepta* is the sugarcane leaf-roller, and *O. blackburni* is the coconut leaf-roller. Because of their economic importance, these species were targeted for biological control using parasitoid wasps and flies. Many of these parasitoids have since been implicated in the decline of numerous species of Hawaiian Lepidoptera. Zimmerman (1958b) reported that in some species of *Omiodes*, parasitism by foreign wasps and flies exceeded 90% in the field. The Hawai‘i Biological Survey currently lists fourteen species that are thought to be extinct (Bishop Museum, 2002). Half of the 18 species recorded from Hawai‘i Island are categorized as species of concern. Seven of the species from this island are island endemics.

### ***Scotorythra* (Lepidoptera: Geometridae)**

Host plants: *Acacia koa*, *Antidesma* spp., *Diospyros* spp., *Dodonaea viscosa*, *Dubautia* spp., ferns, *Hedyotis* spp., *Metrosideros polymorpha*, *Pipturus albidus*, *Pisonia* spp., *Psydrax odorata*, *Rubus hawaiiensis*, *Santalum* spp., *Sapindus* spp., *Tetraplasandra* spp., *Vaccinium* spp..

Of the Hawaiian moths, members of the genus *Scotorythra* are some of the most commonly encountered in forested regions. Larvae of *Scotorythra* are “loopers” or “measuring worms,” and are an important food source for native birds. Although the larvae of most species are nocturnal foliage feeders, and hide in moss or under bark during the daytime, many birds seek them out as prey and feed them to chicks (Zimmerman, 1958a).

As in the *Omiodes* moths, the degree of specificity and island endemism of *Scotorythra* species varies greatly; a few species are found on many plant species and on many islands, while some are only found on a single plant species on a single island. Of the twenty species present on Hawai‘i Island, eight are island endemics.

There is a great deal of variation between individuals of most species of *Scotorythra*, making identification somewhat difficult. Amanda Heddle, PhD student at University of California at Berkeley, is currently revising this genus, and, as a product of her research, will provide recommendations to managers regarding the status of and threats to *Scotorythra* species.

### ***Megalagrion* (Odonata: Coenagrionidae)**

Host plants and habitat: aquatic habitats, *Astelia menziesiana*, *Freycinetia arborea*.

Hawaiian damselflies in the genus *Megalagrion* are among the most beautiful native insects, exhibiting striking color patterns from bright red, to blue, to bright yellow. Dr. Dan Polhemus

and the Hawai‘i Biological Survey have recently conducted surveys, in an effort to determine the status and distributions of *Megalagrion* species throughout the islands (Polhemus, 1994).

The immatures of most damselflies are aquatic, living in streams, ponds, or seeps. The Hawaiian species vary greatly in their habitat requirements and have occupied most of the aquatic niches available in the islands; some prefer clean, rapidly flowing streams, while others prefer small pools, and still others prefer montane bogs (Polhemus and Asquith, 1996). Their specialized habitat requirements make *Megalagrion* species somewhat simpler to survey than other species, since if certain habitat is obviously not available, one can confidently assume that certain species are absent.

A few species in the genus *Megalagrion* are terrestrial. On Hawai‘i Island, *M. koelense* lives in the leaf axils of pa‘iniu (*Astelia menziesiana*), and occurs in native wet forest when this plant is sufficiently abundant and environmental conditions are adequate.

### **III. HISTORICAL COLLECTION RECORDS**

For all target genera, historical collection records were compiled from many sources, most notably the online Candidate and Species of Concern Specimen Database (Bishop Museum, 2004). In addition to querying this database and searching through individual specimen records, specimen data was gathered from several monographs and ecological studies. Appendix 2 lists all species that were documented from Kona Forest Unit or elsewhere on the leeward side of Hawai‘i Island, along with a summary of specimen data and sources of this data. The numbers of species of each genus recorded from Kona are as follows: *Eopenthes* (3), *Plagithmysus* (26), *Proterhinus* (15), *Rhyncogonus* (2), *Drosophila* (47), *Hylaeus* (17), *Omiodes* (4), *Scotorythra* (10), *Megalagrion* (7).

### **IV. SURVEY METHODS**

#### **A. Transect design**

During their first visit to the Refuge in November 1999, surveyors established four transects at elevations of roughly 762, 1067, 1372, and 1676 m (2500, 3500, 4500, and 5500 ft) (Figure 1). Surveyors located these elevations along the south boundary road using an altimeter/barometer, and blazed transects at ten degrees azimuth true. Transects were marked with the following scheme using vinyl flagging. The beginnings of transects were marked by a single white flag with red polka dots. Transects were then marked using solid red flags, and 10m increments (measured using hip chain) were labeled using solid white vinyl flagging. Transects were extended during subsequent visits to the Refuge. See Table 2 for details and irregularities.

#### **B. Monthly monitoring stations**

Forty-nine stations were established along the south boundary road. Stations were placed approximately 160 m (0.1 mile as measured by a digital vehicle odometer) apart from each other on the north side of the road, and marked with solid blue flagging. Station one was located at the eastern end of the road, at an elevation of approximately 1830 m, and station forty-nine was located at the western end, at an elevation of approximately 579 m.

**Table 2.** Attributes of contour transects at the Kona Forest Unit of Hakalau National Wildlife Refuge. Transects were marked with red flags, with white flags at 10 m intervals and a white flag with red spots at the start.

Transect No.	Elevation (ft)	Elevation (m)	Length (m)	Azimuth (true)
1	2500	762	700	0-110m: 98°
				110-500m: 15°
				500-700m: 10°
2	3500	1067	2550	10°
3	4500	1372	2000	10°
4	5500	1676	2270	10°

### C. Yellowjacket monitoring

Populations of western yellowjacket wasps (*Vespula pensylvanica*) were monitored using Seabright Laboratories (Emeryville, CA) plastic yellowjacket traps. Traps were hung from branches at the 49 stations along the south boundary road and were baited with heptyl butyrate, a chemical attractant. Microcentrifuge tubes (1.5 ml) were filled with heptyl butyrate, a wick made of rolled paper was inserted in the tubes, and tubes were placed inside the traps. On a monthly basis, wasps were collected, and traps were rebaited with heptyl butyrate. Numbers of worker and queen yellowjackets were recorded, as well as non-target invertebrates.

### D. Yellow sticky traps

Yellow sticky traps manufactured by Seabright Laboratories (Emeryville, CA) were used for the purpose of monitoring populations of two-spotted leafhopper, *Sophonia rufofascia*. In addition, *Hylaeus* bees and elaterid beetles were regularly captured on sticky cards. Sticky traps were 10 cm wide, 16 cm tall, bright yellow, and coated on both sides with an adhesive. Traps were hung from branches near yellowjacket traps along the south boundary road, and were collected and replaced monthly at the same time as yellowjacket traps. After collection, traps were brought into the laboratory and numbers of two-spotted leafhoppers, *Hylaeus* bees, and elaterid beetles were counted and recorded. *Hylaeus* bees and elaterid beetles were removed from the cards using a citrus-based solvent, and preserved in 95% ethanol. Sticky traps were set up for the first time in November 1999 at the 49 monitoring stations along the south boundary road. In November, these traps were only exposed for a period of six days, but beginning in January 2000, they were checked on a monthly basis (every 4 weeks).

In February 2000, in addition to those along the south boundary road, sticky traps were set up along transects at elevations of 1067 m, 1372 m, and between 1463 m and 1524 m (the temporary *Drosophila* bait loop). These traps were left in place for seven days, and processed in the same way as other sticky traps.

### E. Ant monitoring

Ant surveys were conducted in November 1999, February 2000, May 2000, and June 2000. Ant abundance and diversity was assessed using protein and carbohydrate baits along the south boundary road. Canned cat food was used as a protein bait, and guava jam was used as a carbohydrate bait. Two plastic specimen cup lids were placed in a shady area at each of the 49 monitoring stations. One tablespoon of protein bait was spooned onto one of the lids, and one tablespoon of carbohydrate bait on the other. In November, May and June, baits were left in place overnight and checked the following morning. In February, baits were applied in the

morning and checked in the afternoon. Surveyors counted numbers of ants on each bait and collected voucher specimens from each bait containing ants. In addition, surveyors recorded presence of non-target invertebrates. Ants and non-target invertebrates were preserved in ethanol and brought back to USGS Kilauea Field Station (KFS) for identification.

#### **F. Daytime branch beating**

Surveyors walked along each transect, searching for woody plant species within five meters on either side of the transect. When a plant species was observed to be particularly abundant (e.g. *Metrosideros polymorpha*), individuals with many dead twigs or blossoms were shaken or beaten to dislodge *Eopenthes*, *Proterhinus*, and *Rhyncogonus* beetles. Surveyors specifically targeted plant species which were more likely to provide habitat for the beetles, but selected no more than six individuals of a particular species per transect.

When a potential host plant was located, a white sheet was laid under an overhanging branch (or in the case of smaller shrubs, wrapped around the base of the whole plant). The branch (or entire plant) was then given seven firm shakes, with enough force to dislodge small dead twigs and dead leaves. Surveyors spent 5 minutes looking over the sheet for beetles or other target insects. Then, shaking twigs and other debris from the sheet as gently as possible, surveyors repositioned the sheet on the ground, and searched again for target insects. All target specimens were collected and recorded, along with host plant information and location, and placed in a vial with a unique, pre-printed label. Non-targets were not collected or recorded unless they were of particular interest. When finished looking over the sheet, surveyors forcefully shook off debris, and continued on to the next plant.

Daytime branch beating was completed on each transect as well as on potential host plants along the south boundary road and in the vicinity of the campsite. Lepidoptera larvae were kept alive and brought back to KFS, where surveyors attempted to rear them to adulthood under laboratory conditions.

Plant species targeted during daytime branch beating:

**762 m:**

*Metrosideros polymorpha*, *Antidesma platyphyllum*, *Psychotria hawaiensis*, *Ilex anomala*, *Cibotium menziesii*, *Clermontia clermontioides*

**1067 m:**

*Metrosideros polymorpha*, *Cheirodendron trigynum*, *Broussaisia arguta*, *Cibotium glaucum*, *Myrsine* spp., *Hedyotis* sp., *Perotettia sandwicensis*, *Coprosma* sp., *Clermontia clermontioides*

**1372 m:**

*Cheirodendron trigynum*, *Myrsine* sp., *Ilex anomala*, *Broussaisia arguta*, *Cibotium glaucum*, *Metrosideros polymorpha*, *Perotettia sandwicensis*, *Vaccinium calycinum*, *Rubus hawaiensis*, *Coprosma* sp., *Pipturus albidus*, *Clermontia clermontioides*, *Melicope* sp.

**1676 m:**

*Metrosideros polymorpha*, *Styphelia tameiameiae*, *Acacia koa*, *Myoporum sandwicense*, *Clermontia clermontioides*, *Myrsine* spp., *Pittosporum hosmeri*, *Rubus hawaiensis*, *Vaccinium calycinum*, *Coprosma* sp.

**South boundary road:**

*Pipturus albidus*, *Acacia koa*, *Ilex anomala*, *Metrosideros polymorpha*, *Broussaisia arguta*

**Field camp:**

*Pipturus albidus, Ilex anomala, Myoporum sandwicense*

#### **G. Nighttime branch beating**

Branch beating was also employed at night to target larvae of *Scotorythra* spp., and adult *Rhyncogonus* beetles, both of which are primarily nocturnal. Night surveys were conducted in a similar manner to daytime surveys, but due to safety precautions, surveyors did not venture more than 200m from the south boundary road. As a result, surveyors were not able to sample as many different plant species as they were during the daytime. Nocturnal branch beating was also conducted in the vicinity of the campsite. Lepidoptera larvae were kept alive and brought back to KFS, where surveyors attempted to rear them to adulthood under laboratory conditions.

Plant species targeted during nocturnal branch beating:

**762 m:**

*Metrosideros polymorpha, Antidesma platyphyllum*

**1067 m:**

*Metrosideros polymorpha, Vaccinium calycinum, Myrsine spp.*

**1372 m:**

*Myrsine spp., Cheirodendron trigynum, Perrottetia sandwicensis, Melicope sp., Pipturus albidus, Rubus hawaiiensis, Hedyotis sp., Coprosma sp., Clermontia clermontioides, Broussaisia arguta*

**1676 m:**

*Metrosideros polymorpha*

**Field camp:**

*Acacia koa, Ilex anomala, Pipturus albidus*

#### **H. Pitfall traps**

In mid-November, ten pitfall traps were set within the first 300m of each of the four transects. Each trap consisted of a 16 oz. cup filled with 12 oz. of either soapy water or beer. Traps were sunken into the ground so that their rims were flush with the surrounding soil surface, and were sheltered from rain or litterfall by a plastic shield. Five of the traps at each transect were unbaited (soapy water), and five were baited (beer). Traps were left in place for one week, after which they were collected and sorted into taxonomic groups. All invertebrate specimens collected from pitfall traps were preserved in ethanol and archived using Biota software (Colwell, 1996).

#### **I. Pan traps**

In mid-November, ten pan traps were set at 10 m intervals along the first 150 m of each transect. Traps consisted of shallow green pans, 25cm in diameter and 3.5 cm deep, filled with 12 oz. of soapy water. Traps were set directly on the ground to the side of the transects and left in place for 24 hours.

During mid-February, pan traps were set between 500 m and 600 m on the transects at 1067 m and 1372 m, as well as on the temporary bait loop between 1463 m and 1524 m. Again, ten traps were set on each transect, at 10 m intervals, and traps were left in place for 24 hours.

Specimens collected from pan traps were preserved in ethanol and brought back to the laboratory, where they were sorted into taxonomic groups. As with those from pitfall samples, all specimens

from pan traps were identified to taxonomic levels of varying specificity, preserved, and archived using Biota (Colwell, 1996).

### **J. Light trapping**

Lepidopteran targets were collected using two light trapping strategies: sheet traps and bucket traps. Both trap types utilized circular, 22W, fluorescent, UV bulbs attached to ballasts manufactured by BioQuip Products (Gardena, CA). Two 6V batteries were connected in series to provide power to the 12V systems. Trapping was conducted in relatively open areas to maximize visibility of the lights to flying insects.

Each sheet trap consisted of a white sheet hung horizontally on a rope between two branches or trees. Lights were hung from the middle of the rope, illuminating the sheet. Specimens were collected (killed using ethyl acetate) and brought to KFS to be pinned and identified. White sheet traps were more labor intensive as they required surveyors to be present at the trap, but proved to be a more selective and productive method than bucket trapping. Light trapping using sheets was conducted a total of eight times: four times at the field camp and one time on each of the four transects.

Bucket traps were manufactured by Bioquip Products and consisted of white, five-gallon buckets equipped with vanes and funnels designed to divert insects into the buckets. As a killing agent, sponges saturated with ethyl acetate were placed in the bottom of the buckets. This type of trap did not require surveyors to be present beyond setup, so traps could be set up, turned on, and allowed to run overnight. However, bucket traps collected invertebrates indiscriminately, resulting in greater captures of non-target insects. They also seemed to be less successful than sheet traps in attracting *Omiodes* and *Scotorythra* moths. Bucket traps were used a total of eight times – two nights at each of the four transects.

### **K. Baiting for *Drosophila* spp.**

Picture-wing pomace flies (*Drosophila* spp.) were surveyed using sponges baited with fermented mushrooms and bananas. Mushroom bait was prepared by mixing chopped store-bought white mushrooms with water and yeast, and allowing this mixture to ferment for at least one week. This very fragrant liquid bait was then applied to sponges using spray bottles. Banana bait was prepared by mixing mashed bananas with yeast, and allowing the mixture to ferment and rise overnight. Red sponges (previously disinfected by boiling) were soaked in water and tacked to trees, at about eye-level, along transects. Mushroom bait was sprayed (ten sprays per sponge) onto all faces of each sponge and about a tablespoon of banana bait was spread on the lower half of the front face of each sponge. Sponges were left undisturbed for at least thirty minutes before they were revisited.

To check the sponges, surveyors approached them slowly, being careful not to breathe on the sponges or otherwise disturb perched flies. Picture wing *Drosophila* were sight-identified and counted. Unknown flies were collected alive in vials. Some voucher specimens of non-native and native, non-picture wing *Drosophila* were collected and preserved in alcohol.

Surveys for *Drosophila* spp. were conducted on the Refuge in November 1999 and February 2000. In November 1999, surveyors baited transects at elevations of 762 m, 1067 m, 1372 m, and 1676 m. In February 2000, surveyors baited transects at elevations of 1067 m and 1372 m, and a bait loop was set up at between elevations of between 1463 m and 1524 m, near the south boundary road.

#### **L. Laboratory rearing of *Drosophila* spp.**

Throughout the survey, surveyors collected samples from the host plants of targeted species of *Drosophila*. Samples were sealed in plastic bags, and kept cool until they could be brought back to the laboratory. At KFS, samples were weighed, then placed in 128 oz. plastic jars. The bottoms of jars were lined with clean, moist sand. Jars were examined carefully about three times weekly, and any emerging invertebrates were recorded, removed and preserved in alcohol.

Rotting branches of *Clermontia clermontioides* and *Cheirodendron trigynum*, documented hosts for *D. heteroneura* and/or *D. silvestris*, were targeted for collection. A total of 14 stems of *C. clermontioides* and two stems of *C. trigynum*, in addition to two samples of fungus, were collected from various locations on the Refuge.

#### **M. Laboratory rearing of *Plagithmysus* spp.**

Samples of dead branches and/or twigs were collected from *Acacia koa* (N=4), *Clermontia clermontioides* (N=2), *Metrosideros polymorpha* (N=1) and *Pittosporum hosmeri* (N=2). Larger samples were sealed in wooden boxes which had holes drilled in one side. Clear plastic vials were secured over these holes. As beetles emerged, they were attracted to light emanating through the holes and crawled into the vials. Small samples were placed in plastic containers lined with moist sand. Samples were checked about three times weekly, and any emerging invertebrates were recorded and preserved.

#### **N. Surveys of *Astelia menziesiana* and other host plants of *Omiodes* spp. and *Megalagrion* spp.**

Surveyors examined transects at elevations of 762 m, 1067 m, 1372 m and 1676 m for suitable host plants of *Omiodes* spp. and *Megalagrion* spp., and brought live specimens of these insects back to KFS to rear them to adulthood. Surveyors walked down transects, searching five meters on either side of the transect for *Astelia menziesiana*, *Dianella sandwicensis*, and *Carex* spp. When surveyors located one of these plants, they gently pulled back the leaves of the rosette and searched the leaf axils for naiads of *Megalagrion* spp. or larvae of *Omiodes* spp. Surveyors also searched other grasses and sedges for larvae *Omiodes* spp., but since these plants were often present in great numbers, only a select number were examined. When surveyors located an insect of interest, they collected it in a small vial with a small amount of material (about one leaf) from the host plant. Specimens were kept cool and brought back to KFS. Specimens were examined three times weekly, and were provided with fresh, locally collected plant material as needed. When insects metamorphosed into adults, they were pinned and identified.

#### **O. General collecting**

In addition to focused survey methods, surveyors searched for targeted insects whenever they came across potential host plants or habitat in the Refuge. Specimens were recorded, preserved and brought back to KFS for identification and curation.

#### **P. Data Analysis**

All specimens from target groups were identified to species. Other invertebrates of interest were identified to varying taxonomic levels, depending on availability of taxonomic literature and

human resources. All specimens were cataloged using Biota (Colwell, 1996) and assigned a unique specimen code.

EstimateS software (Version 6, Colwell, 1997) was used to calculate estimates of species richness, and to generate randomized species accumulation curves for surveys. To estimate the completeness of our surveys, we used the non-linear model function of Systat 9 (SPSS Inc., 1998) along with the richness estimators and accumulation curves created by EstimateS.

## V. RESULTS

### A. Native Target Species

#### *Proterhinus* spp. (Coleoptera: Aglycyderidae)

A total of 71 specimens of *Proterhinus* weevils were collected from the Refuge. These specimens have been identified to five species: *P. affinis*, *P. ferrugineus*, *P. hawaiiensis*, *P. similis*, and *P. subangularis*. Due to a lack of taxonomic clarity within this group and the lack of active expertise, our determinations should be treated as “best guess” determinations based on existing keys and systematic literature. Distributions of the five species are shown by Figures 2 and 3. See Appendix 4 for specimen-level information.

Six specimens of *P. ferrugineus* were collected from five plant species: *Broussasia arguta*, *Cibotium menziesii*, *Coprosma* sp., *Ilex anomala*, and *Metrosideros polymorpha*. *Proterhinus ferrugineus* was collected from contour transects at 762 m, 1067 m, and 1372 m. Swezey (1938) reports the host plants of this species to be tree ferns from the genera *Cibotium* and *Sadleria*. It is likely that our collections from other plants do not indicate new host records, as these specimens were not necessarily breeding or living in these plants. One specimen of *P. ferrugineus* was excavated from a dead stem of *Cibotium menziesii* at 762 m elevation, while the other five specimens were collected by shaking foliage onto sheets. Tree ferns (*Cibotium* spp.) were present near all localities where *P. ferrugineus* was collected.

Six specimens of *P. subangularis* were collected from *Antidesma platyphylla* and *Psychotria hawaiiensis* on the 762 m contour transect. Swezey (1938) considered this species to be specific to plants in the genus *Psychotria*. Trees of *Psychotria hawaiiensis* were present in close proximity to all collection sites for *P. subangularis*, so it is possible that specimens collected on *Antidesma platyphylla* had migrated from *Psychotria hawaiiensis*.

*Proterhinus similis* is regarded as the most abundant and widespread of the five species. Forty specimens identified as this were collected from all four contour transects, as well as at the field camp and along the southern boundary. It was collected from eight plant species: *Cibotium glaucum*, *Broussasia arguta*, *Coprosma* sp., *Ilex anomala*, *Metrosideros polymorpha*, *Myoporum sandwicense*, *Pipturus albidus*, and *Psychotria hawaiiensis*. Neither Perkins (1900) or Swezey (1938) list a host plant for *P. similis* so it is possible that this species may be more general in its host preference than other *Proterhinus* species. The majority of our specimens were collected from *Metrosideros polymorpha*.

Five specimens of *P. hawaiiensis* were collected from *Coprosma* sp. from contour transects at 1067 m and 1676 m, and eleven specimens of *P. affinis* were collected from *Myrsine* sp. from contour transects at 1076 m and 1372 m.

### ***Plagithmysus* spp. (Coleoptera: Cerambycidae)**

Four species of *Plagithmysus* longhorn beetles were collected on the Refuge: *P. bilineatus*, *P. debilis*, *P. nodifer*, and *P. new species A*.

Three specimens of *P. bilineatus* were collected in August 2000 from the 1676 m transect near a group of recently felled *Acacia koa* and *Metrosideros polymorpha*. *Metrosideros polymorpha* is the recorded host for this species of beetle (Gressitt and Davis, 1969), so it is likely that the specimens had gathered to oviposit in the felled trees. Although there is much variation in size within all *Plagithmysus* beetles species, *P. bilineatus* is generally characterized as a large beetle with striking coloration.

*Plagithmysus debilis* was reared from *Acacia koa* (recorded host) branches collected from the contour transect at 1676 m and near the field camp. *Plagithmysus debilis* is a generally small, brown, drab beetle (Gressitt and Davis, 1969).

*Plagithmysus nodifer* was reared from *Acacia koa* branches collected from the contour transect at 1676 m and near the field camp. *Plagithmysus nodifer* is a generally large, darkly colored beetle with striking yellow markings on its body.

Four specimens of *Plagithmysus* new species A were reared from two samples of dead or dying branches of *Pittosporum hosmeri*, which were collected from the contour transect at 1676 m. To our knowledge, no species of *Plagithmysus* from Hawai‘i Island have been reported to use *Pittosporum* as a host. These specimens have been examined by Dr. Al Samuelson of the Bishop Museum, and represent a new species and a new host record for the island. They will be described and named by Dr. Samuelson.

### ***Rhyncogonus* spp. (Coleoptera: Curculionidae)**

Despite both nocturnal and diurnal branch beating on a wide variety of plants, no specimens of *Rhyncogonus* were collected on the Refuge.

### ***Eopenthes* spp. (Coleoptera: Elateridae)**

One specimen of *Eopenthes* was collected from blossoms of *Ilex anomala* along the southern boundary of the Refuge at an elevation of 900 m. Individuals were observed at several locations, swarming *Ilex* blossoms, but only one specimen was within reach of surveyors. Upon examination of our specimen, and comparison with types from the Bishop Museum, Dr. Samuelson determined it to be closest to *E. cognatus*, but was not completely confident in this determination. We are therefore calling it *Eopenthes* species near *cognatus*. *Eopenthes cognatus* was previously given the status of a “Category 2” species (Beattie, 1994). However, USFWS no longer recognizes Category 2 species, referred to now as “Species of Concern”.

### ***Drosophila* spp. (Diptera: Drosophilidae)**

Six species of endemic picture-wing pomace flies were observed on the Refuge: *D. basisetae*, *D. conspicua*, *D. heteroneura*, *D. silvestris*, *D. sproati*, and *D. tanythrix* (the last is not a true picture-wing but is closely related and similarly large-sized). A grand total of 314 picture-wing flies were observed on contour transects at 762, 1067, and 1372 m, and on the bait loop between 1463 m and 1524 m. No picture-wing flies were observed on bait sponges at 1676 m, but *D.*

*heteroneura* was collected from host material on this transect. Distributions of *Drosophila* species are shown on Figures 4-6.

Of the eight *D. basisetae* individuals observed during the February 2000 survey, two were observed on the transect at 1067 m, and six were observed on the transect at 1372 m.

Four *D. conspicua* were observed during the November 1999 and February 2000 surveys. Two of these individuals were observed on the 1067 m transect and two on the 1372 m transect.

Thirteen *D. silvestris* individuals were observed during the November 1999 and February 2000 surveys, representing 4% of the picture-wings observed. The species was observed at the 1372 m transect and at the temporary bait loop.

A total of 80 individuals of *D. sproati* were observed during the November 1999 and February 2000 surveys, on the 1067 m and 1372 m transects and the temporary bait loop. *D. sproati* comprised 25% of the picture-wings observed during the span of the survey.

A total of 93 individuals of *D. tanythrix* were observed during the November 1999 and February 2000 surveys, on the 762 m, 1067 m, and 1372 m transects. This represents 30% of the picture-wing flies observed during the survey.

A total of 116 specimens of *Drosophila heteroneura* were observed on the Refuge during the November 1999 and February 2000 surveys. *D. heteroneura* was observed on transects at 1067 m and 1372 m, and on the temporary bait loop between 1463 m and 1524 m. *D. heteroneura* proved to be the most abundant picture-wing fly, comprising 37% of the total number of picture wings collected on the Refuge. An additional four specimens of *D. heteroneura* were reared from *Clermontia clermontiodes* branches collected from the transect at 1372 m and 1676 m.

These records for *Drosophila heteroneura* represent the first observations of this species in the wild in approximately 10 years, despite intensive searches of historical habitats. The population of *D. heteroneura* at the Kona Forest Unit is the only known extant population of this species (Foote, 1999).

#### ***Hylaeus* spp. (Hymenoptera: Colletidae)**

Ten species of *Hylaeus* bees were collected on the Refuge: *H. coniceps*, *H. connectens*, *H. crabronoides*, *H. difficilis*, *H. dumetorum*, *H. filicum*, *H. pubescens*, *H. specularis*, *H. sphecodoides*, and *H. volcanicus*. Of these species, all except *H. filicum* and *H. pubescens* were collected from sticky traps along the southern boundary of the Refuge. Three species, *H. crabronoides*, *H. filicum*, and *H. specularis* are extremely rare and local, with one other recent collection site or none (*H. specularis*; unlike the other two this species is also found on other islands, but is rare everywhere). For distributions of *Hylaeus* species, see Figures 7-9. Karl Magnacca, PhD student at Cornell University, identified all specimens and the specimen data from the Refuge has been included in a recent monograph on yellow-faced bees from Hawai‘i (Daly & Magnacca, 2003).

#### ***Omiodes* spp. (Lepidoptera: Crambidae)**

Four species of *Omiodes* leafroller moths were collected on the Refuge: *O. accepta*, *O. asaphombra*, *O. localis* and *O. scotaea*. Distributions of *Omiodes* moths are shown by Figure 10.

Altogether, 49 specimens of *Omiodes* moths were collected at all four contour transects and at the field camp. *Omiodes iridias* and *O. scotaea* (possible synonyms) were collected along the transect at 1372m. During surveys for *Astelia menzeisiana* and other host plants along all four contour transects, *Omiodes* larvae were collected and successfully reared only from the 1372 m transect. *Astelia menzeisiana* was found to be present only on the transects at 1372 m and at 1676 m.

A total of 27 specimens of *O. accepta*, the sugarcane leafroller, were collected by light-trapping on the Refuge. These specimens were collected at 762 m, 1372 m, 1676 m, and at the field camp. This species of *Omiodes* is a generalist on grasses and sedges, and is one of the most common and widespread of the group (Zimmerman, 1958b). It is present on all of the main islands, and was once an economically important pest of sugarcane.

Four specimens of *O. asaphombra*, the ‘ohe leafroller, were collected from light traps located on the transect at 1372 m, and at field camp. This species was listed in 1994 as a “Category 2” species, and indicated as “possibly extinct” (Beattie, 1994). The Category 2 designation is no longer recognized by the Fish and Wildlife Service. The Hawai‘i Biological Survey presently includes this species on its list of extinct species. Zimmerman (1958b) reported this moth to be restricted to *Joinvillea ascendens*, an indigenous plant that is very rare on Hawai‘i Island. We assume that *O. asaphombra* is utilizing a different plant, since *Joinvillea* is not recorded from KFU and there are no records of the plant from the leeward side of the island (Haines, et al. 2003; appendix 3).

Eleven specimens of *O. localis* were collected from light traps at 762 m, 1067 m, 1372 m, 1676 m, and at the field camp. Like *O. accepta*, *O. localis* is a common and widespread species, present on all the main Hawaiian Islands. It is a generalist on grasses and sedges, feeding on both native and alien species.

Three specimens of *O. scotaea* and four *O. iridias* were collected and reared from *Astelia menzeisiana* plants on the 1372 m transect. Zimmerman (1958b) records *Astelia* as the only host plant for these species, which are very similar and may be a single species. *Omiodes scotaea* has previously been recorded from Kaua‘i, O‘ahu, Moloka‘i, and Hawai‘i, while *O. iridias* is only recorded from Hawai‘i.

#### ***Scotorythra* spp. (Lepidoptera: Geometridae)**

Eight species of *Scotorythra* moths were collected from light traps on the Refuge: *S. apicalis*, *S. arboricolans*, *S. artemidora*, *S. euryphaea*, *S. paludicola*, *S. rara*, *S. new species 5*, and *S. new species 13*. A grand total of 168 specimens were collected from light traps at all four contour transects and at the field camp. University of California at Berkeley PhD candidate Amanda Heddle confirmed identifications of *Scotorythra* moths. Figures 11-13 show distributions of these species.

*Scotorythra apicalis* is a common species, endemic to Hawai‘i Island, but because it is rarely attracted to light traps, it is often recorded as rare (A. Heddle, pers. comm.). One adult specimen of *S. apicalis* was collected from a light trap at an elevation of 1372 m. Larvae suspected of belonging to this species were also collected near the field camp from leaves of *Ilex anomala*.

*Scotorythra arboricolans* was the most widely collected species on the Refuge, collected 33 times from light traps at the field camp and at all four transects. Zimmerman (1958a) reported the host of this species to be *Santalum* spp., but Heddle (pers. comm.) suspects that it is breeding on other

plant species as well, since it is often quite abundant in areas where *Santalum* is not present. *S. arboricolans* is fairly commonly collected and is known from most of the main Hawaiian Islands.

*Scotorythra artemidora* was also quite abundant on the Refuge; 32 specimens were collected from light traps at the field camp and at elevations of 1372 m and 1676 m. This is a common species (A. Heddle, pers. comm.), which is endemic to Hawai‘i Island. The host plant for *S. artemidora* is unknown, but there are unconfirmed records of this species from ‘ōhi‘a.

Forty specimens of *S. euryphaea* were collected from light traps at the field camp and at elevations of 1372 m and 1676 m. This species was also reared from two larvae collected on *Metrosideros polymorpha* and *Ilex anomala* at an elevation of 1676 m. As well as being one of the largest species of *Scotorythra*, *S. euryphaea* is also one of the most common and widely distributed species in the islands. It is present on Kaua‘i, O‘ahu, Moloka‘i, Maui, and Hawai‘i. *Scotorythra euryphaea* is polyphagous, feeding on a diversity of plant species.

Six specimens of *S. paludicola*, the koa moth, were collected from light traps at the field camp and at an elevation of 1676 m. Larvae suspected of belonging to this species were also collected near the field camp from *Acacia koa*, its recorded host plant. Historically, this species has experienced population outbreaks, causing defoliation of koa trees on the islands of Maui and Hawai‘i (Swezey, 1931; Davis, 1955; Mitchell and Davis, 1985).

Fifty-three specimens of *S. rara* were collected from light traps at the field camp and at elevations of 1067 m, 1372 m, and 1676 m. *Scotorythra rara* is an extremely polyphagous species, and has been reared from koa (*Acacia koa*), ‘ōhi‘a (*Metrosideros polymorpha*), ‘ōhelō (*Vaccinium*), māmaki (*Pipturus*), and ferns (Swezey, 1954), as well as non-native plants (A. Heddle, pers. comm.).

Six specimens of *Scotorythra* new species #5 were collected from light traps the field camp and from 1372 m elevation. This species will be described and named by A. Heddle. Very little is known about the relative rarity and life history of this species.

Four specimens of *Scotorythra* new species #13 were collected from light traps at the field camp. This species will also be described and named by A. Heddle. While the host plant has been identified as ‘ākala, *Rubus hawaiensis*, little else is known about this rare species.

#### ***Megalagrion* spp. (Odonata: Coenagrionidae)**

Two male specimens of *Megalagrion calliphya* were collected in May 2000 from a pool just west of the 579 m transect. Individuals were observed mating and ovipositing along the edge of the pool. Although this species prefers to breed in pools of slow moving streams, on this island it has adapted to breed in standing water. *M. calliphya* is one of the most common of the native damselflies (Polhemus and Asquith, 1996).

Surveys for *Astelia menzeisiana* (a host plant for *Megalagrion koelense*, a terrestrial species of damselfly) showed the plants to be present only along transects at 1372 m and 1676 m. Surveyors searched every *A. menzeisiana* plant located along each transect for the presence of *Megalagrion* naiads, but none were observed.

## B. Other native invertebrates of particular interest

### *Anchastus swezeyi* (Coleoptera: Elateridae)

*Anchastus swezeyi* proved to be the most common click beetle on sticky traps along the south boundary road (62 specimens), outnumbering non-native click beetles at lower elevations. Although endemic, this beetle is not considered rare, and it is not surprising that this species is relatively abundant, while *Eopenthes* spp. are apparently quite rare on the reserve.

### *Adelocera oblonga* (Coleoptera: Elateridae)

One specimen of *A. oblonga* was collected from a sticky trap at the southwestern corner of the Refuge at an elevation of 579 m. This specimen represents both a new island record and a rediscovery (Johnson et al., 2002). This species was previously known from only the type specimen collected in the 1970's in Ewa, O'ahu, where it was presumed to be adventive. It was also recently discovered in collections from Kaloko-Honokōhau National Park from 1992. The species was originally described as *Brachylacon beardsleyi* and its origin was uncertain; it has since been found to be synonymous with *A. oblonga* from the Philippines (Johnson et al., in prep.).

### *Ectemnius* spp. (Hymenoptera: Crabronidae)

Several individuals of endemic crabronid wasps (*Ectemnius atripennis*) were observed and collected at the 762 m transect by D. Foote. Wasps were seen capturing calliphorid flies and carrying them back to their nests in the soil. This behavior is consistent with what has been reported for this species (Takumi, 1999). Several species in the genus *Ectemnius* are recognized as "species of concern", but *E. atripennis* has no conservation status. A second species of *Ectemnius* was collected from the field camp, but has not been identified.

### *Eupithecia* spp. (Lepidoptera: Geometridae)

Three species of *Eupithecia* were collected from the Refuge. This genus is remarkable in that it includes several species whose larvae are ambush predators. Two species of predaceous caterpillar were collected by shaking foliage onto a sheet: *E. craterias* and *E. staurophragma*. In addition to the carnivorous caterpillars, a pollen-feeding species, *E. monticolens*, was collected at light traps.

### *Hyles wilsoni* (Lepidoptera: Sphingidae)

This large, endemic, colorful hawk moth was collected at light traps at the field camp and at all four transects. *Hyles wilsoni* feeds on plants in the family Rubiaceae, such as pilo (*Coprosma* spp.) and kōpiko (*Psychotria* spp.). This species is endemic to Hawai'i Island, and is fairly common in native mesic and wet forest.

### *Theridion grallator* (Araneae: Theridiidae)

Happy-face spiders (*Theridion grallator*) were collected from the lower reaches of the reserve along the south boundary road by shaking foliage onto a sheet. These charismatic and well-

known Hawaiian invertebrates are found on most of the main Hawaiian Islands, and are not considered particularly rare, but they are useful for teaching and engaging the public with native ecosystems.

### C. Alien species

#### Western yellowjacket, *Vespula pensylvanica* (Hymenoptera: Vespidae)

As shown by Figure 14, relative abundances of yellowjackets (*Vespula pensylvanica*) along the southern boundary of the Refuge varied over time. Wasp abundances for each survey period are expressed as number of wasps in each trap per 28 days exposure time. Wasp numbers were consistently low or absent between stations 12 and 33, corresponding to elevations between about 1067 m and 1615 m.

At the upper reaches of the Refuge (about 1646-1844 m), wasp abundance peaked between August 1999 and February 2000. Throughout the rest of the survey period, wasp numbers were low or absent at these high elevation sites. At lower elevations, wasps were present throughout the survey period, and peaked during the autumn months of both 1999 and 2000.

Future monitoring will be needed to determine whether seasonal patterns are predictable, and whether wasp numbers are increasing or decreasing; in particular, whether wasp numbers will again peak at higher elevations, and remain low in the mid-reaches of the Refuge. Correlating *Vespula* population data with seasonal rainfall and temperature data, or with surveys of native and alien vegetation, may yield greater understanding of yellowjacket population biology.

#### Two-spotted leafhopper, *Sophonia rufofascia* (Homoptera: Cicadellidae)

Two-spotted leafhoppers (*Sophonia rufofascia*) were most abundant at lower reaches of the Refuge (Figure 15), present between elevations of 579 m and 1372 m. Note that leafhopper abundances are expressed simply as number of leafhoppers present on each card, regardless of exposure period. Leafhopper abundance is not expressed as a function of exposure time, because it is likely that sticky traps become saturated with insects (and hence less effective) a short while after application. Therefore, “per day” abundances for traps exposed for shorter periods (e.g. one week) are likely not comparable to those for traps exposed for longer periods (e.g. two months). The number of leafhoppers captured on a trap in a given area is probably not linearly proportional to the length of time for which the trap has been exposed. In the future, to better determine seasonal fluctuations in abundance at the Refuge, sticky-traps should be monitored on a rigid schedule (preferably every 28 days).

These data are valid for spatial changes in abundance on the Refuge. Throughout the survey period, abundances of leafhoppers have remained roughly bimodal, peaking at elevations of about 700m and 950m, and dipping at an elevation of about 800m. As with yellowjackets, it would be interesting to correlate relative abundances of leafhopper with changes in rainfall and/or temperature, and with differences in vegetation along the southern boundary of the Refuge.

#### Ants

Four species of ants (Hymenoptera: Formicidae) were collected from the Refuge: *Cardiocondyla wroughtoni*, *Paratrechina bourbonica*, *Solenopsis papuana*, and *Tetramorium bicarinatum*. Abundances are shown by Figure 16. Ants were observed only between elevations of 579 m and

930 m, and only these elevations are shown in Fig. 16. At these elevations, *P. bourbonica* and *S. papuana* appear to be the more dominant of the four species, with *C. wroughtoni* and *T. bicarinatum* being represented by only a few specimens. However, it is difficult to infer anything about abundance based solely on data from baits, since different species often have different bait preferences. At several of the stations, both *P. bourbonica* and *S. papuana* were observed, indicating that neither species completely represses nor out-competes the other.

#### D. Diversity comparisons between sites

In terms of numbers of target species collected, the transect at 1372 m yielded the greatest number of species, with 23 target species collected. In contrast, the transect at 762 m yielded the fewest number of target species, with only 8 species collected. Table 3 lists the number of target species collected at each transect.

Comparisons across transects using all groups may be misleading, as more time was spent collecting some taxa along transects at 1067 m and 1372 m than was spent at either of the other two transects. To get a better estimate of diversity between transects, comparisons were limited to those taxa which were collected in a standardized fashion, allowing for correction of the data based on search effort. Taxa which were collected using correctable methods were *Proterhinus*, *Omiodes*, *Scotorythra*, *Drosophila*, and *Hylaeus*. EstimateS (Colwell, 1997), a program designed for estimating biodiversity, was used to calculate the estimated number of species on each transect by plotting a species accumulation curve (number of species observed versus samples taken) for these taxa, and calculating the asymptote, the estimated limit as number of samples approaches infinity. Using this analysis, an estimate of completeness could also be calculated for each transect. EstimateS offers several different methods of estimating richness, and we utilized the Abundance-based Coverage, the Incidence-based Coverage, Chao 1, and Chao 2. Presented in Table 4 are the Michaelis Menten (MM) richness estimator and Incidence-based Coverage Estimator (ICE).

Although the estimated richness for each transect varied quite a bit depending on the estimator used, all estimates calculated by EstimateS (including all indices not presented here) predicted the same ranking of transects in terms of estimated species richness: 1372 m > 1067 m > 1676 m > 762 m. Surveys for the five selected taxa at each elevation were estimated to be fairly incomplete, ranging from 43.8%-89.7%, with an average estimated completeness of 69% among the various estimates for all transects. The low level of completeness of our surveys for these taxa suggests that it is likely that an extended search effort will discover additional species in these genera. Future surveys for these groups are therefore warranted.

It is important to recognize the limitations to the use of accumulation curves for estimating species richness and survey completeness. Most importantly, the predictions are constrained by the actual sampling methods used. The predicted asymptote is the maximum number of species expected if we were to collect an infinite number of samples similar to those which we already collected. In other words, if we observe 6 species of *Drosophila* on 200 sponges baited with banana bait, and the predicted asymptote is 7 species, we estimate that if we had placed an infinite number of sponges using the same protocol, it is likely that we would have collected one additional species of *Drosophila*. This estimate makes no predictions about the number of species we would expect if we were to bait 200 sponges with a bait other than banana, or conduct surveys at a different time of day. Some *Drosophila* species might never be attracted to bait sponges, or active at night. These species would be “invisible” to any predictions based on daytime baiting, and would have to be sampled by a different method. Therefore, the number of species predicted by accumulation curves is probably an underestimate of the actual number of

species on the Refuge, since not all species within a group are equally likely to be collected by the same methods.

Table 5 summarizes all specimens of target endemic insect taxa collected. Table 6 lists additional specimens of endemic insects encountered that were not targeted in this survey. Lastly, Table 7 lists all alien insect species collected. Specimen-level data are provided in Appendix 4.

**Table 3.** Number of species in target genera collected on transects at KFU. Data are simple overall totals, unadjusted for search effort or standardized sampling. For *Hylaeus*, sticky traps along southern boundary were grouped by elevation, designating the ten traps closest to a transect as belonging to that transect.

## **VI. DISCUSSION**

### **A. Trends in diversity**

The Kona Forest Unit on all four contour transects is sufficiently intact to support populations of endemic insects. At all elevations, endemic insects were observed and/or collected along transects. However, diversity among native target genera was highest in the middle elevations of the reserve, on the transects at 1067 m and 1372 m. This is not particularly surprising, considering that the forest at these elevations appears to be the most intact forest on the Refuge.

The rough correlation between high diversity of native targets and low abundance of invasive insects is an interesting pattern that deserves further investigation. Ants were observed only in the lower reaches of the reserve, and were found no higher than 930 m. Yellowjackets (*Vespula pensylvanica*) were conspicuously absent or low in numbers between 1067 m and 1662 m. Two-spotted leafhopper (*Sophonia rufofascia*) were for the most part found only below 1190 m. There are at least three possible explanations for the apparent inverse relationship between invasive insects and diversity of native target species. 1) Invasive insects (especially ants and yellowjackets) could be negatively affecting native invertebrates through predation and competition. It is known that ants and yellowjackets will prey heavily on native insects, especially vulnerable life stages such as larvae and pupae. 2) Invasive insect species might be more successful at colonizing disturbed habitats present at low and high elevations on the Refuge than they are at colonizing intact native forest. It is certainly true that native insect diversity generally decreases as disturbance increases. It is also possible that the yellowjackets prefer the relatively open forest produced by foraging ungulates, or that strawberry guava or uluhe fern is a preferred host of the two-spotted leafhopper. 3) Another possibility is that this pattern is an artifact of incidental colonization, and that the pattern will not remain consistent over time. These hypotheses cannot be evaluated without further monitoring and observations of predator-prey interactions.

### **B. Management implications**

Feral ungulates probably are a long-term threat to the health of invertebrate communities at the Kona Forest Unit of Hakalau NWR. Diversity of target insect groups was much lower in the areas most heavily occupied by cattle and pigs, although even the most disturbed habitat on the Refuge still supports native invertebrates. Forest quality in these areas is certainly marginal and if grazing by ungulates continues, what remains of native insect diversity in these areas will most likely be lost. As such, it is of great importance to minimize ungulate densities low in the relatively intact middle elevation forests.

Often tied to disturbance by ungulates is invasion by weeds. The invasion of lower elevations by weeds such as guava (*Psidium guajava*), strawberry guava (*P. cattleianum*), and Christmas berry (*Schinus terebinthifolius*), is no doubt partly to blame for the lower diversity of native invertebrates at these elevations. To prevent further loss of insect diversity, aggressive weeds such as these must be monitored and controlled. It is especially important that weeds be prevented from further displacing native vegetation at middle elevations, between 1000m and 1500m, since these areas seem to support the highest diversity of native insects.

Yellowjacket wasps are a very serious threat to native insect communities on the Refuge. Wasp populations should be suppressed to prevent outbreaks like those observed during our survey. Yellowjackets should be monitored for several years on a monthly basis, to establish whether the winter peak observed at high elevations was an anomaly or a recurring phenomenon. This pattern is puzzling and unexpected, since yellowjacket populations usually peak in late summer and die back during winter

months. Additional monitoring would be necessary to identify hotspots of yellowjacket activity beyond the southern boundary. Yellowjacket wasps not only have a large negative impact on native insects by direct predation and competition with native predators and pollinators, but they can have direct or indirect effects on native birds, either by lowering prey densities or by preying on nestlings.

Ants should also be monitored regularly (at least yearly). Monitoring stations should be established along the south boundary road and along other east-west transects, to monitor elevational changes in distribution over time. All of the ant species observed on the Refuge are confined to low elevations, so it is not expected that they will move into higher elevations. However, it is important to monitor ants regularly, to document incipient species, such as the little red fire ant (*Wasmannia auropunctata*) and initiate control efforts immediately, should ant species arrive that can tolerate higher elevations, including the Argentine ant (*Linepithema humile*). Ant control is difficult in dense forest, and would entail aerial application of a bait product, but it might be warranted if there is potential for ants to move into higher elevations.

Two-spotted leafhopper should also be monitored regularly. Traps should be set monthly for one or two years. After seasonal patterns have been sufficiently documented, monitoring can be reduced to once or twice yearly. There is no current management strategy for two-spotted leafhopper, but it has been implicated in the dieback of uluhe fern and possibly ‘ōhi‘a forest.

The discovery of endemic picture-wing pomace fly *Drosophila heteroneura* represents the first observation of this species in close to ten years and it is the only known population currently surviving in the wild (Foote, 1999). *Drosophila heteroneura* is currently the subject of a listing action under the Endangered Species Act by the U.S. Fish and Wildlife Service. This very unique species has been featured in numerous nature documentaries about Hawai‘i and is truly a “poster child” for Hawaiian evolutionary biology. If possible, it should be a high priority to better determine the distribution and status of this species at the Refuge. Habitat restoration efforts should include host plants of this species (e.g. *Clermontia*), and suppression of yellowjacket wasps needs to be taken as soon as road access to the Refuge is reestablished.

## VII. ACKNOWLEDGEMENTS

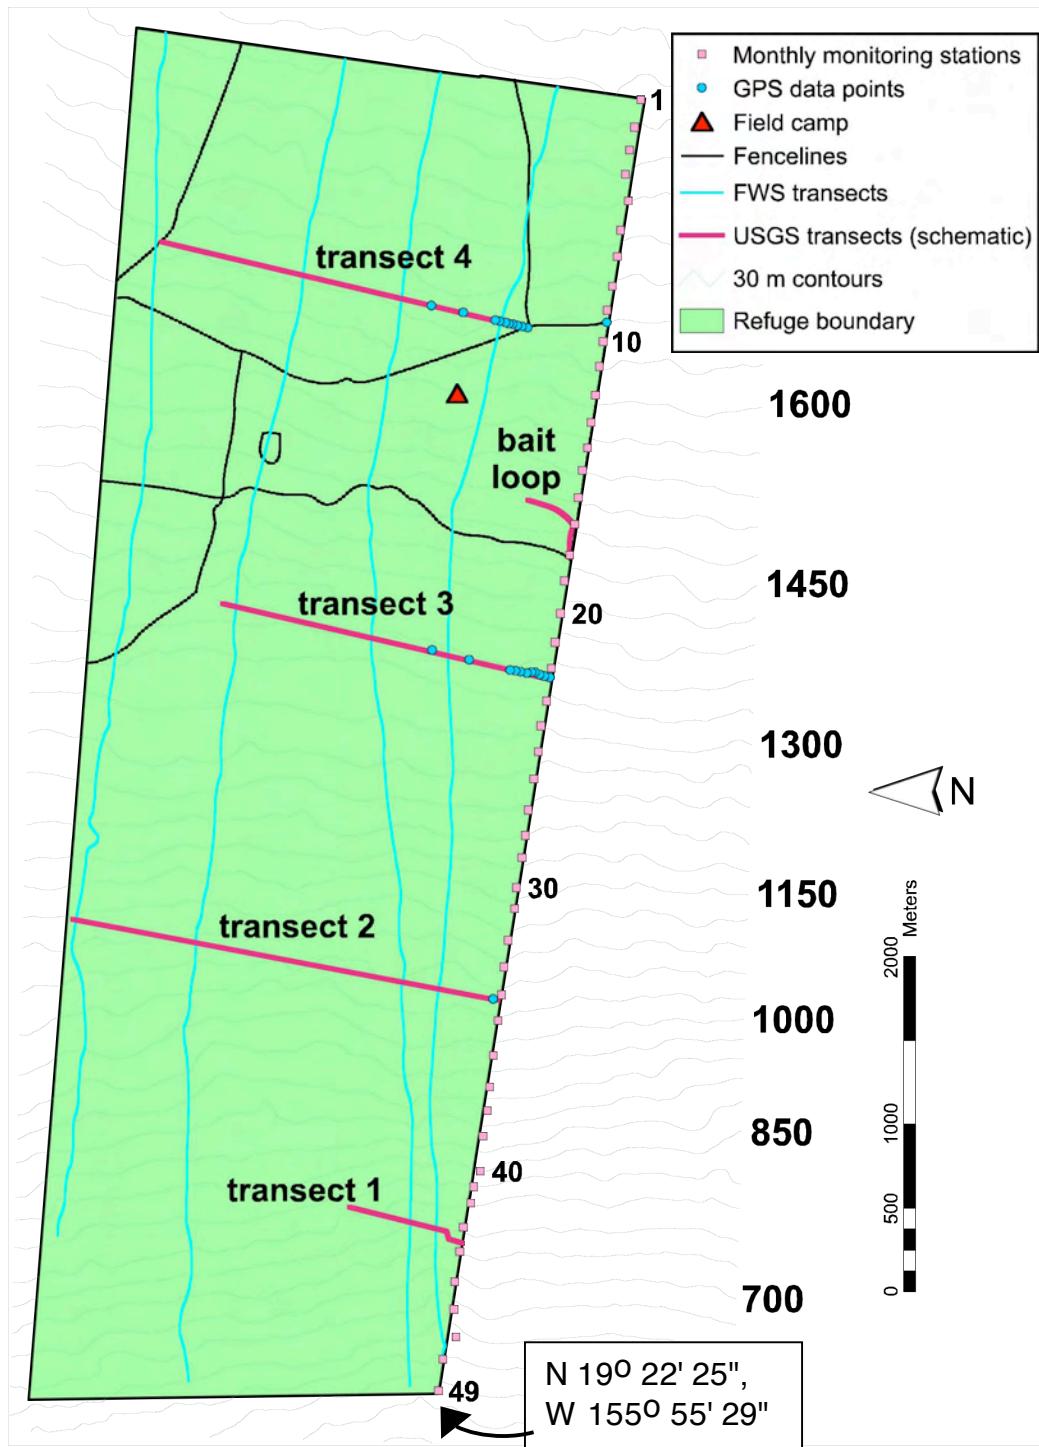

We thank Dave Ledit, Donna Ball and the rest of the staff at the Kona Forest Unit of the Hakalau National Wildlife Refuge for logistical support that helped make this survey possible. Dan Bennet, Ken Clarkson, Kirsten Heckmann, Kiko McMurry, Cam Muir, Krista Orr, Annie Paradis, Emanuela Salati, and Karin Schlappa provided field and laboratory assistance. For assistance with specimen identification we appreciate the help from Mandy Heddle, Paul Johnson, Lori Lach, Karl Magnacca, and Al Samuelson. Jim Jacobi provided a digital base map of the Refuge that allowed us to record our transect locations. Jeff Burgett, Dave Helweg, Cynthia King, Karl Magnacca, and Pamela Scheffler made helpful comments on earlier drafts of this report. This research was made possible in part thanks to support from the U.S. Fish and Wildlife Service Ecological Services Field Office in Honolulu and the U.S. Geological Survey Pacific Island Ecosystems Research Center. The authors would like to acknowledge additional support from the Pacific Cooperative Studies Unit, University of Hawai‘i at Mānoa. Any use of trade, product, or firm names in this publication is for descriptive purposes only and does not imply endorsement by the U.S. Government.

Distributions of yellow-faced bees at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 1 of 3):** *Hylaeus coniceps*, *H. connectens*, *H. crabronoides*, and *H. pubescens*. *Hylaeus* bees were monitored primarily using yellow sticky cards along the southern boundary of the Refuge. In addition, some specimens were collected by sweep netting around flowering vegetation. Determinations were made by Karl Magnacca of Cornell University.

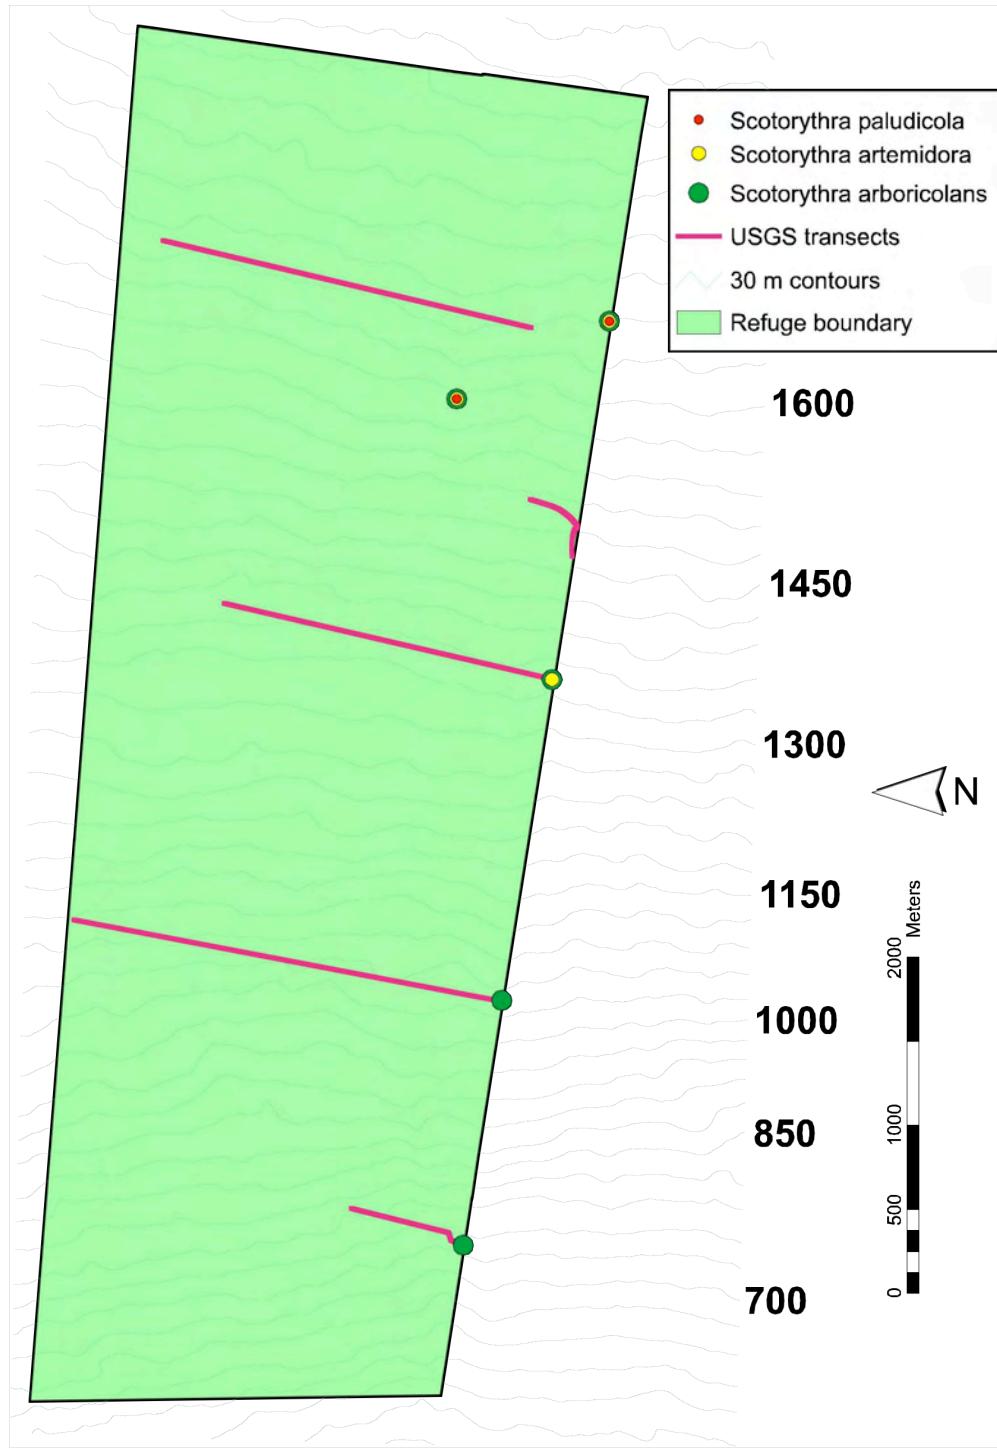

**Figure 8. Distributions of yellow-faced bees at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 2 of 3):** *Hylaeus difficilis*, *H. specularis*, and *H. volcanicus*. Hylaeus bees were monitored primarily using yellow sticky cards along the southern boundary of the Refuge. In addition, some specimens were collected by sweep netting around flowering vegetation. Determinations were made by Karl Magnacca of Cornell University.

**Figure 9. Distributions of yellow-faced bees at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 3 of 3):** *Hylaeus dumetorum*, *H. filicum*, and *H. sphecodoides*. Hylaeus bees were monitored primarily using yellow sticky cards along the southern boundary of the Refuge. In addition, some specimens were collected by sweep netting around flowering vegetation. Determinations were made by Karl Magnacca of Cornell University.

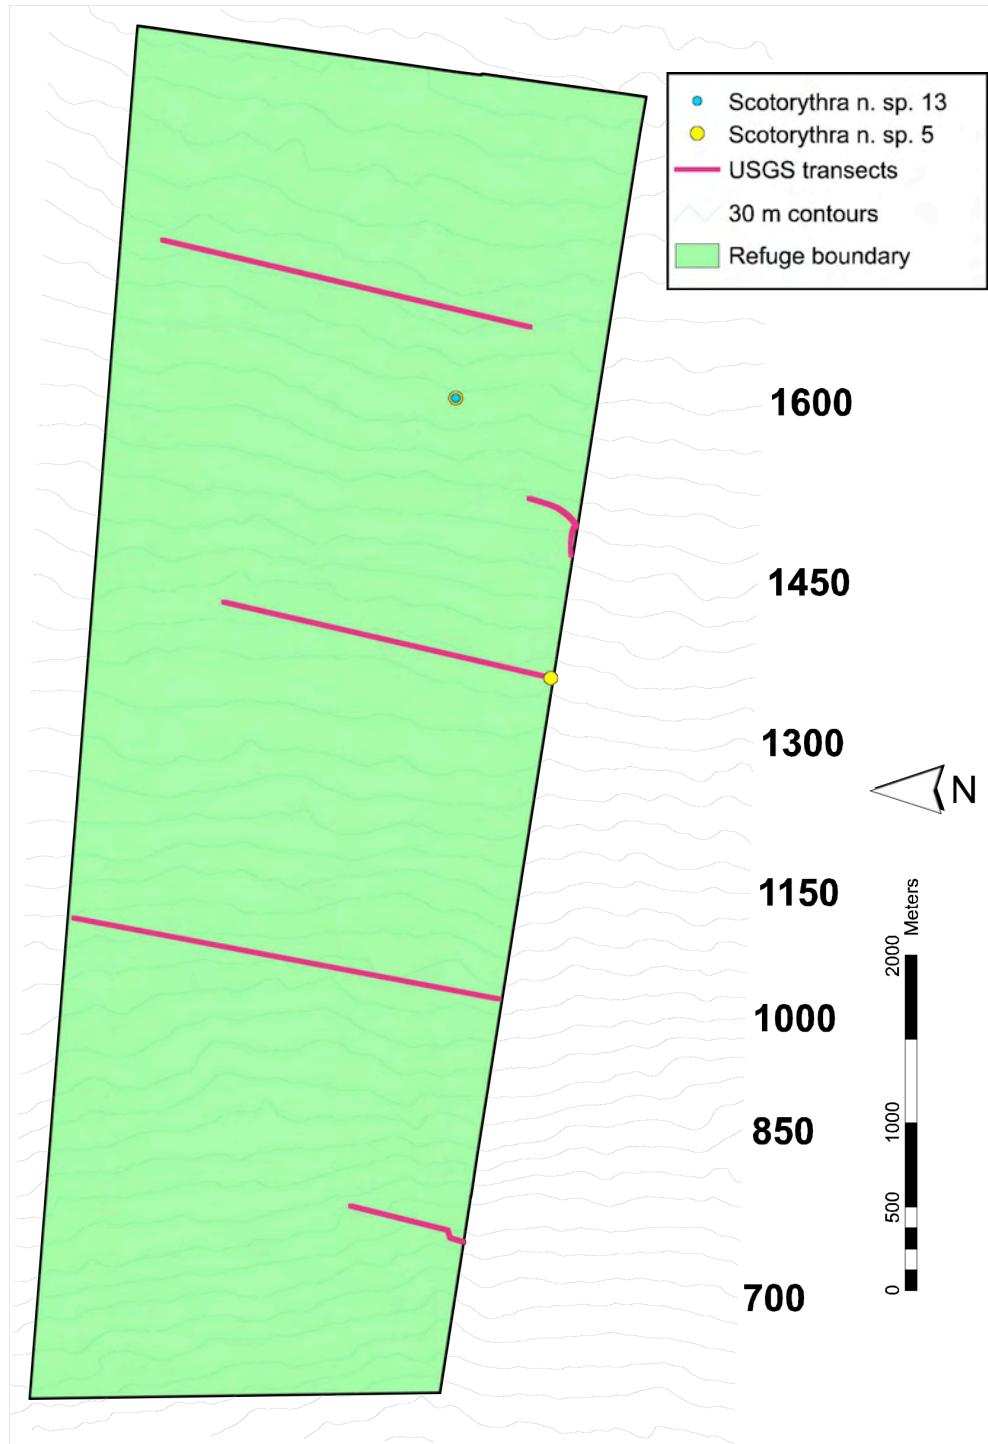

**Figure 10. Distributions of *Omiodes* leafroller moths at the Kona Forest Unit of Hakalau National Wildlife Refuge:** *Omiodes accepta*, *O. asaphombra*, *O. iridias*, *O. localis*, and *O. scotaea*. Moths were collected from light traps (sheet- and bucket-type) and transect heads and at the field camp. Surveys for larvae were also conducted along transects at elevations of 762 m, 1067 m, 1372 m, and 1676 m. Determinations were made by Will Haines.

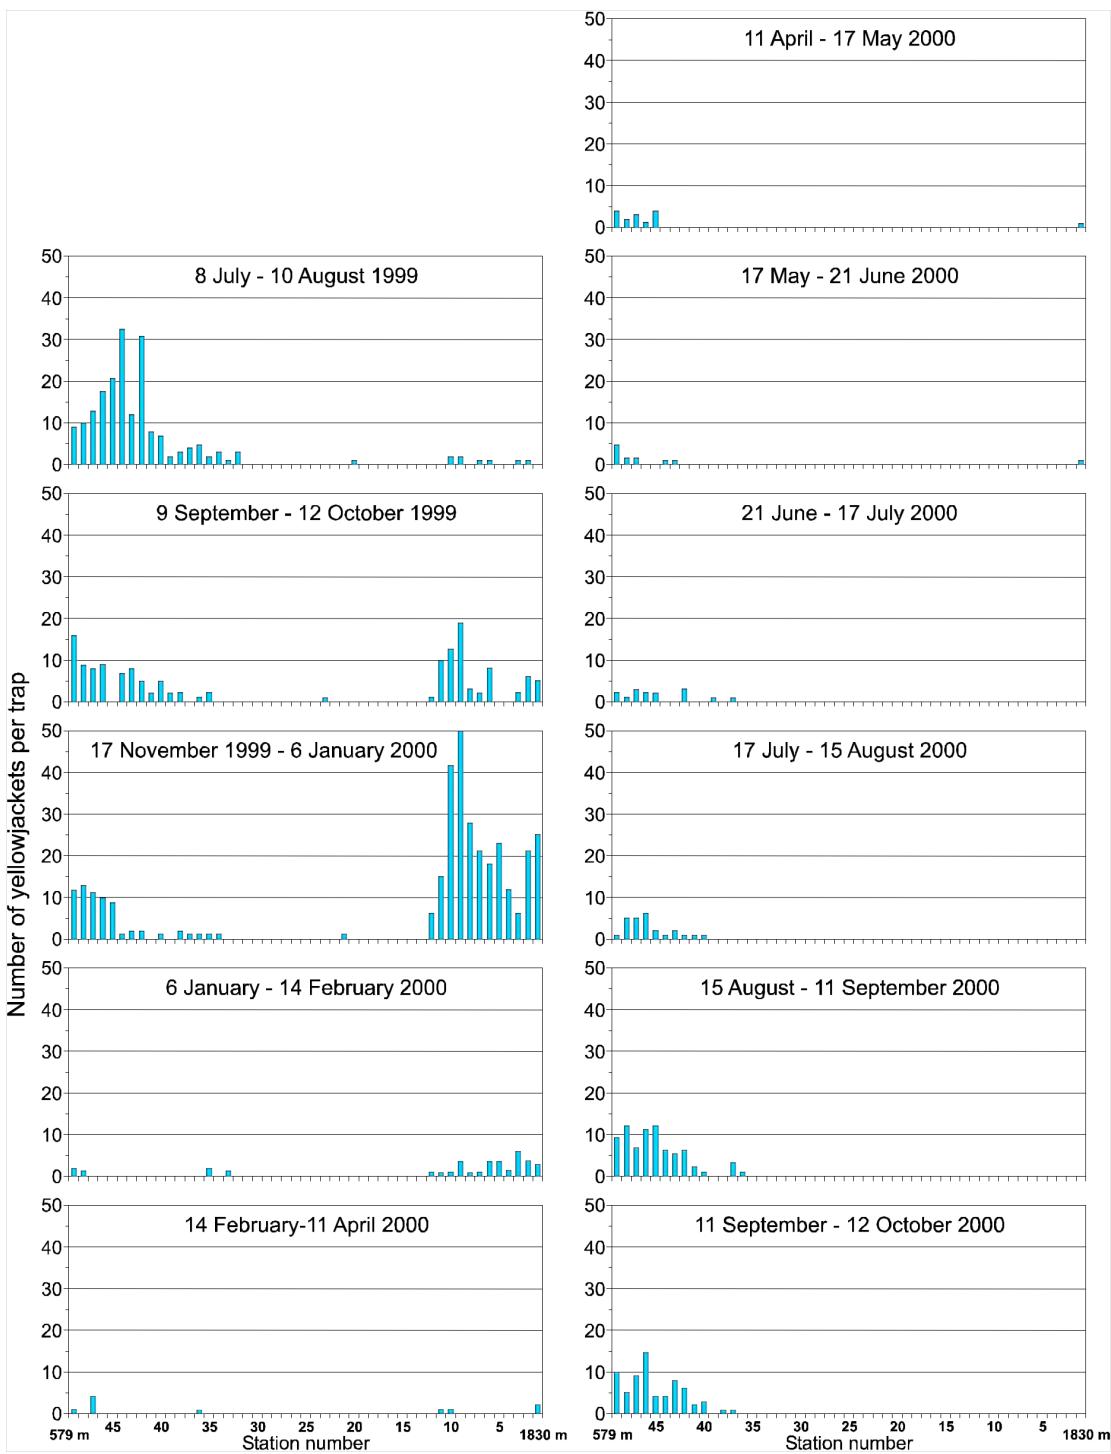

**Figure 11. Distributions of *Scotorythra* moths at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 1 of 3):** *Scotorythra arboricolans*, *S. artemidora*, and *S. paludicola*. Moths were collected from light traps (sheet- and bucket-type) at transect heads and at the field camp. Determinations were confirmed by Mandy Heddle of University of California at Berkeley.

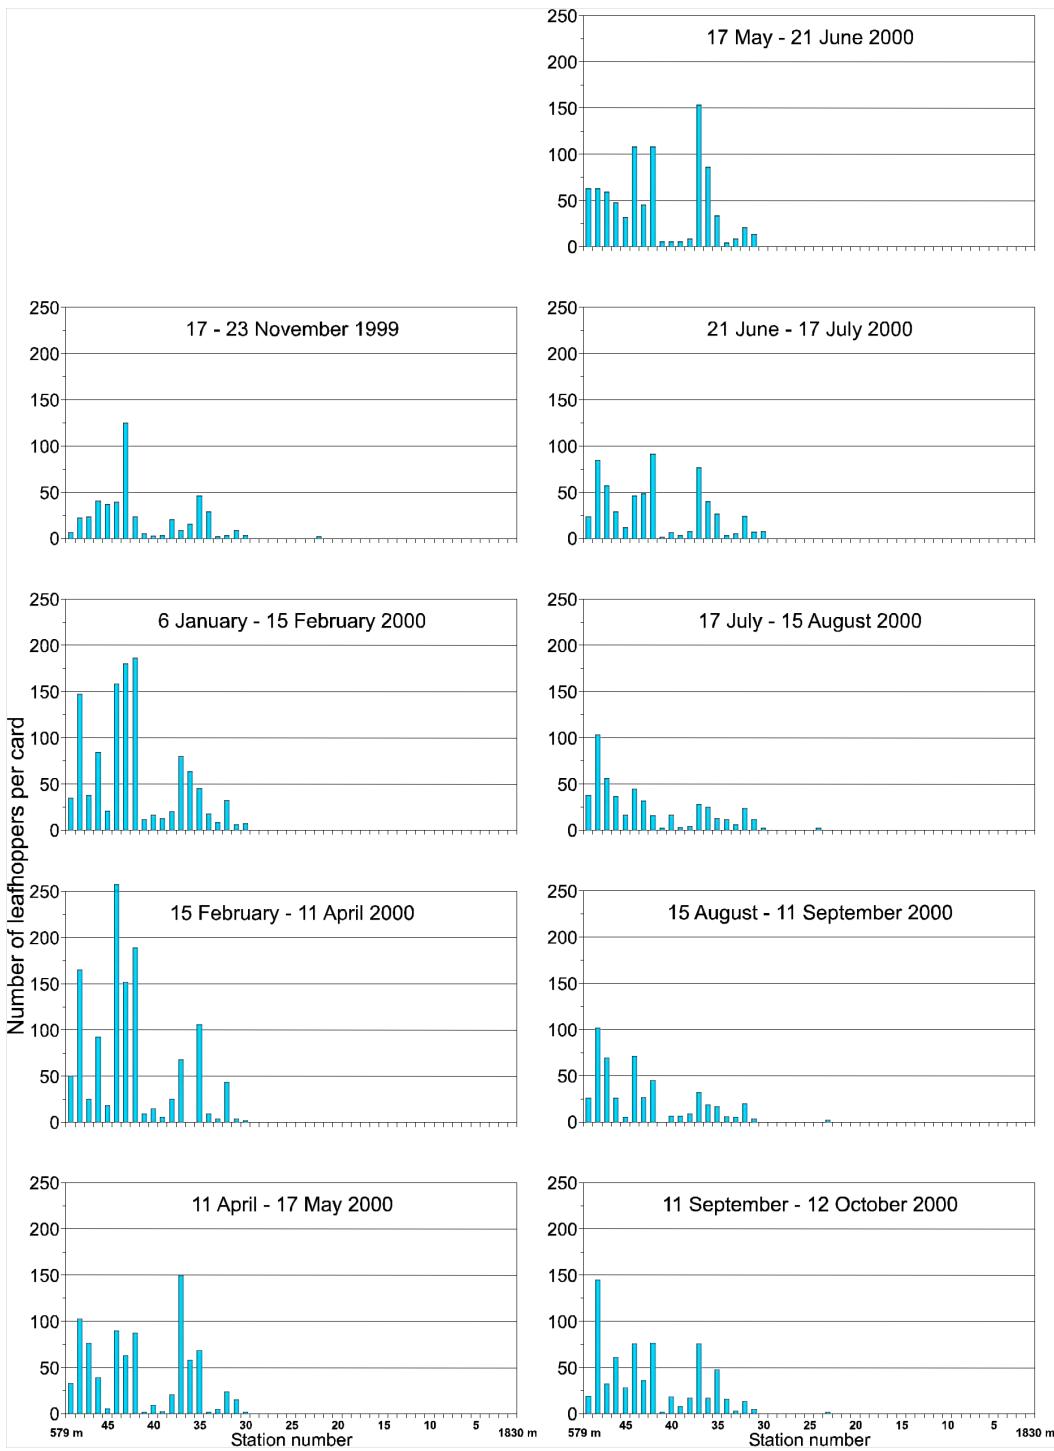

**Figure 12. Distributions of *Scotorythra* moths at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 2 of 3):** *Scotorythra apicalis*, *S. euryphaea*, and *S. rara*. Moths were collected from light traps (sheet- and bucket-type) at transect heads and at the field camp. Determinations were confirmed by Mandy Heddle of University of California at Berkeley.

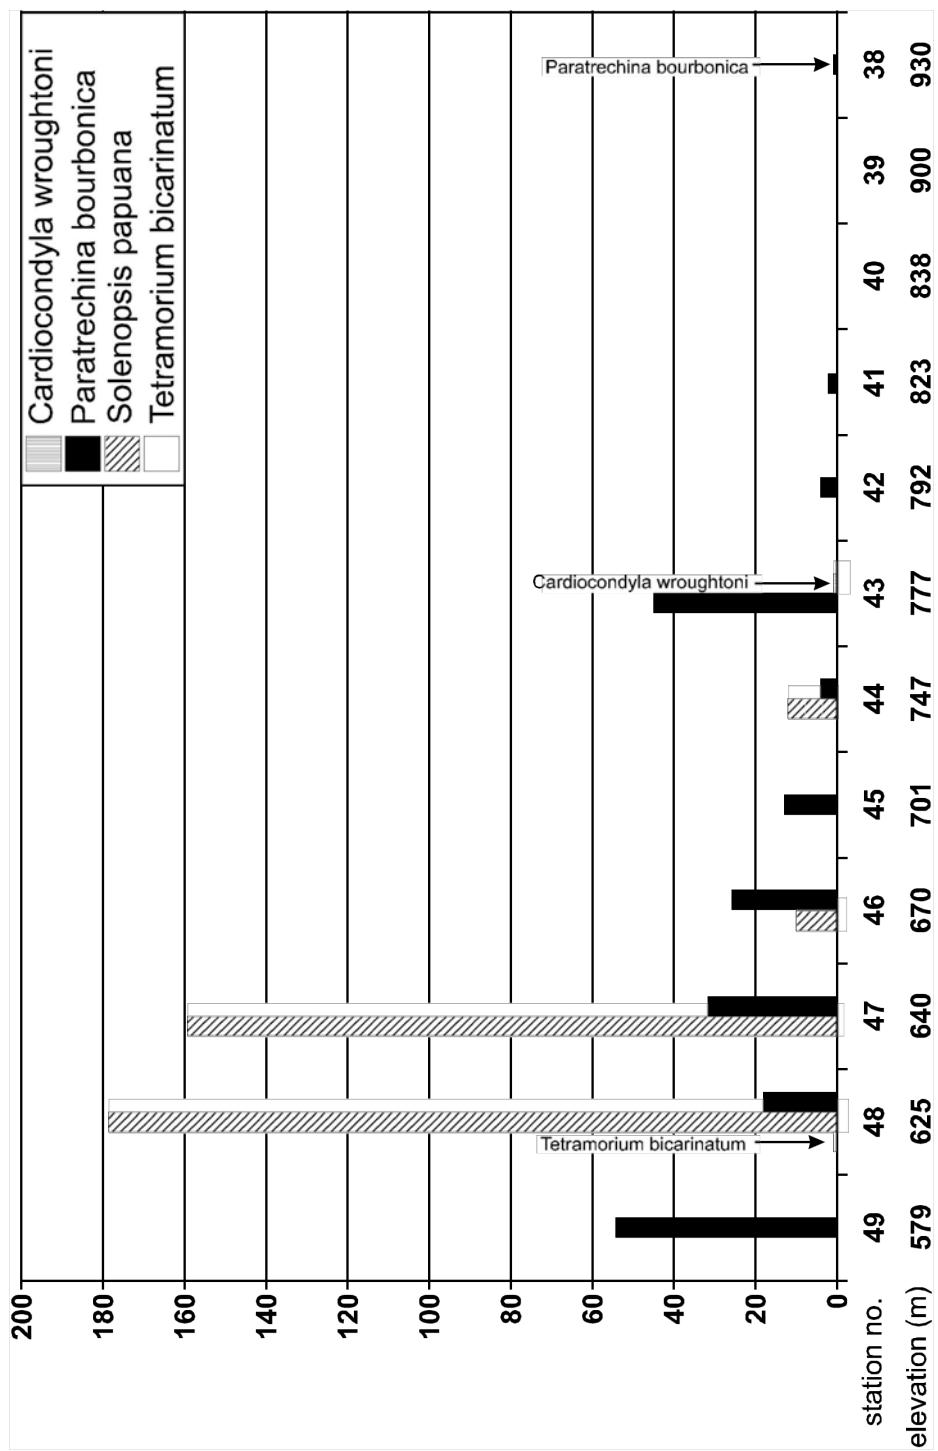

**Figure 13. Distributions of *Scotorythra* moths at the Kona Forest Unit of Hakalau National Wildlife Refuge (Part 3 of 3):** *Scotorythra* new species 5 and 13. Moths were collected from light traps (sheet- and bucket-type) at transect heads and at the field camp. Determinations were confirmed by Mandy Heddle of University of California at Berkeley.

**Figure 14. Seasonal abundances of yellowjacket wasps (*Vespula pensylvanica*) along the south boundary road of the Kona Forest Unit of Hakalau National Wildlife Refuge between 8 July 1999 and 12 October 2000.** Station numbers refer to trap stations placed along the road at intervals of 0.1 mile. Station 1 is at an elevation of 1676 m, station 49 is at an elevation of 762 m. Yellowjacket were monitored using heptyl butyrate traps. Determinations made by David Foote.

**Figure 15. Seasonal abundances of two-spotted leafhopper (*Sophonia rufofascia*) along the southern boundary of the Kona Forest Unit of Hakalau National Wildlife Refuge between 17 November 1999 and 12 October 2000.** Station numbers refer to trap stations placed along the road at intervals of 0.1 miles. Station one is at an elevation of 1844 m, while station 49 is at an elevation of 579 m. Leafhoppers were monitored using yellow sticky traps. Determinations made by David Foote.

**Figure 16. Abundances of ants (Hymenoptera: Formicidae) along the southern boundary of the Kona Forest Unit of Hakalau National Wildlife Refuge.** Ants were monitored a total of four times (November 1999, February 2000, May 2000, and June 2000) using protein and carbohydrate baits. Although ant were surveyed along the entire southern boundary (579–1844 m), ants were discovered only at elevations between 579 m and 930 m. Ant abundance is expressed as the total number of ant specimens observed at each station over all four monitoring events. Determinations were made by Will Haines and Lori Lach.

**Rediscovery of *Drosophila heteroneura* on the Island of Hawai'i**

DAVID FOOTE (Pacific Island Ecosystems Research Center, U.S. Geological Survey, P.O. Box 52, Hawaii National Park, Hawai'i 96718, USA; email: dave\_foote@usgs.gov)

*Drosophila heteroneura* Perkins is a rare picture-wing pomace fly endemic to the Island of Hawai'i and part of a group of picture-wing *Drosophila* that are currently being listed by the Fish and Wildlife Service as Threatened or Endangered under the Endangered Species Act. *Drosophila heteroneura* is one of the most intensively studied native arthropods in Hawai'i and research on the species has helped to unravel the patterns and mechanisms of speciation that has led to the formation of more than 800 species of Hawaiian *Drosophila* (e.g., Carson & Kaneshiro, 1976; Carson & Yoon, 1982, Carson, 1992). Three decades ago, when researchers first focused attention on picture-winged *Drosophila*, *D. heteroneura* was widespread, with 73 historical collection records from 16 localities over 4 of the 5 major volcanoes on the island (U.S. Fish & Wildlife Service, 1995). The extirpation of smaller populations was first reported from the Ola'a Forest of H&waii Volcanoes National Park (HVNP) in 1980 (Carson, 1986; Foote & Carson, 1994). Subsequently, *D. heteroneura* disappeared from sites in the southern and western parts of the island at locations where the species had traditionally yielded larger collections. Records maintained as part of the Hawai'i *Drosophila* Project indicate that the last collection of *D. heteroneura* occurred in 1993 at HualAlai. Since this time, concerted efforts to relocate *D. heteroneura* at historical sites have failed.

***Drosophila heteroneura* Perkins Rediscovery; Range extension**

On 16-17 November 1999 specimens of *Drosophila heteroneura* were collected in a recently established National Wildlife Refuge, north of Waiea Rd in South Kona. This represents a new population or subpopulation not previously discovered. The specimens were taken as part of a rapid biological assessment of invertebrates occurring in the Kona Forest Unit (KFU) of the Hakalau National Wildlife Refuge conducted by the Pacific

Island Ecosystem Research Center, U.S. Geological Survey. Survey work was focused along four 500-700 m transects following elevational contours at 762, 1067, 1372, and 1676 m, respectively, extending north from the southern boundary of the Refuge. Sponges containing a combination of yeast-fermented banana and mushroom bait were placed every 50 m along each transect and surveyed twice over a period of 24 hr. A total of 29 picture-wing *Drosophila* were observed and collected, including 2 female and 4 male *D. heteroneura*. All of the picture-winged species were found on the 1372 m elevation transect with the exception of *I Drosophila sproati* at 1067 m. *Drosophila silvestris* was equally abundant at this location and, together with *D. heteroneura*, comprised 42% of the picture-wings collected.

*Drosophila heteroneura* is completely sympatric with *D. silvestris* throughout its historical range between about 1000 and 1600 m altitude in montane rain forests (Carson & Yoon, 1982). The KFU observations occur approximately 12 km S of the nearest historical population of Pauahi and fall within the southern most area of the predicted range for *D. silvestris* (Carson, 1982). The habitat at the KFU 1372 m transect is *Metrosideros/Cibotium* tree fern forest with a dense understory that includes large *Clermontia clemontioides* (both subspecies, *C. c. clemontioides* and *C. c. rockiana*, occur in the Refuge). *Clermontia clemontioides* is a recorded host plant of *D. heteroneura* and appears to be relatively common throughout the Refuge between approximately 1200 and 1700 m elevation, including *Acacia/Metrosideros* forests with former pasture lands kept open by feral cattle. The range of *D. heteroneura* at KFU will be determined as part of the ongoing invertebrate inventory through December 2000.

**Material Examined:** **HAWAII:** Hakalau National Wildlife Refuge, Kona Forest Unit, along 1372 m transect, 100-600 m from S. Boundary Rd, 16-17 Nov 1999, D. Foote, et al. [all vouchers currently in culture at the laboratory of Dr. Donald Price, University of Hawaii at Hilo].

Notes

**A new generic combination and Hawaiian Island record for *Adelocera*.  
.peardsleyi (Ôhira & Reeker) (Coleoptera: Elateridae)**

PAUL J. JOHNSONI (Insect Research Collection, Box 2007A, South Dakota State University Brookings, South Dakota 57007, USA; email: paul\_johnson@sdstate.edu), WILLIAM HAINES (Pacific Island Research Center, U.S. Biological Survey, P.O. Box 144, Makawao, Hawai'i 96718, USA; email: wph3@cornell.edu) and D4VID FOOTE (Pacific Island Research Center, U.S. Geological Survey, P.O. Box 52, Hawaii National Park, Hawai'i 96718, USA; email: dave\_foote@usgs.gov)

*Brachylacon beardsleyi* Ôhira and Becker (1978) was first described and recorded from Ewa, O'ahu. No specimens of this species have since been reported from O'ahu or elsewhere, until now. Here, we provide a generic transfer of this species to *Adelocera* Latreille and report this species from the island of Hawaii.

Ôhira and Becker (1978) provided the original generic attribution of *Brachylacon beardsleyi* without discussion beyond remarking that it was "somewhat allied to *Brachylacon (Brachylacon) perrauidieri* Fleutiaux" from Cambodia. Yon Hayek (1973, 1979) reviewed the generic concepts of the genera of Elateridae assigned to the subfamily Agrypninae and reduced many generic names to synonymy, including the synonymy of *Brachylacon* Motschulsky with *Adelocera*. *Adelocera* was (redescribed and *B. perrauidieri* was assigned to this genus by von Hayek (1973). The holotype of *B. beardsleyi* is in the Bishop Museum, Honolulu, and was previously studied and photographed by Johnson. The holotype and the specimen reported above possess the salient characteristics given by von Hayek (1973, 1979) for *Adelocera* and will easily trace to this genus in her keys. Notable traits for assignment to *Adelocera* and possessed by *B. beardsleyi* include the antennal grooves being half the length of the pronotosternal grooves, antennal segment 3 longer than segment 2, metasternal tarsal grooves are transverse, tibial spurs absent, tarsal claws with ventral setae near base, and the mesepimeron forming part of the mesocoxal cavity. Since the holotype and the specimen reported below possess these characters, we propose the new combination of *Adelocera beardsleyi*.

Records of the Hawaii Biological Survey for 20PO-Part 2:

**Coleoptera:Elateriae**

***Adelocera beardsleyi* (Ôhira & Becker)      New island record;  
Rediscovery; Name change**

Between 11 April and 17 May 2000, a single specimen of *Adelocera beardsleyi* collected from a recently established National Wildlife Refuge in the district of Kona. The specimen, which has been deposited in the invertebrate collection of H Volcanoes National Park (HVNP), was collected by staff of the Pacific Island Ecosystems Research Center, U.S. Geological Survey, as part of a rapid assessment of insect species of concern at the Kona Forest Unit of the Hakalau National Wildlife Refuge. A female specimen (length 6.3 mm) was recovered from a yellow sticky trap (manufactured by Seabright Laboratories to control and monitor flying insect pests) at an elevation of 579m. Sticky traps were hung from the branches of trees and shrubs at forty-nine stations along the southern boundary of the Refuge, ranging in elevation from 579 to 1830m. Traps were replaced monthly or bi-monthly between November 17, 1999 and October 12, 2000. *A. beardsleyi* was collected from the southwest corner of the Refuge at the lowest elevation present on the Refuge. Other elaterids recovered from sticky traps during the survey included 62 specimens of endemic *Anchastus swazeyi* Van Zwedenburg at elevations from 579 to 792m, and 39 specimens of the adventive *Conoderus* (Sharp) from elevations from 579 to 1737m.

The collection site of *A. beardsleyi* is abandoned ranchland with vegetation dominated by alien invasive plant species (nomenclature for flowering plants follows Wagner *et al.* 1990; and for ferns follows Wagner, 1981). Dominant plants include guava (*Psidium guajava* L.), Christmas berry (*Schinus terebinthifolius* Raddi), and the indigenous uluhe fern (*Dicranopteris linearis* [Burm.] Underw.). Historically, prior to disturbance by humans and ungulates, the collection site was most likely dominated by 'ohi'a (*Metrosideros polymorpha* Gaud.).

**Material examined.** HAWAII. Hakalau National Wildlife Refuge, Kona Forest Unit, along southern boundary at 579 m elev. yellow sticky trap. 11 Apr-17 May 2000. W. Haines. HVNPOO3049 (HVNP).

Rediscovery of five species of *Omiodes* Guenée (Lepidoptera: Crambidae) on Hawai‘i Island

WILLIAM P. HAINES (University of Hawai‘i at Mānoa, Department of Plant and Environmental Protection Sciences, Gilmore 310, Honolulu, Hawai‘i 96822, USA; email: whaines@hawaii.edu), JON GIFFIN<sup>1</sup> (651266 Laelae Road, Kamuela, Hawai‘i 96720, USA) and DAVID FOOTE (Pacific Island Research Center, U.S. Geological Survey, P.O. Box 52, Hawaii National Park, Hawai‘i 96718, USA; email: david\_foote@usgs.gov)

1. Research Associate, Hawaii Biological Survey, Bishop Museum, 1525 Bernice Street, Honolulu, Hawai‘i 968172704, USA.

Beginning in 1980, through a contract from the U.S. Fish & Wildlife Service, an assessment of the conservation status of more than 800 species of native Hawaiian insects was undertaken by Wayne Gagné, Carl Christensen, and others (Gagné, 1982; Gagné & Christensen, 1985). Twentytwo species of endemic leafrollers in the genus *Hedylepta* (= *Omiodes*: Crambidae) were among the first groups of Lepidoptera analyzed, and Gagné (1982: Table 2) reported nine species that were “presumed recently extinct”. These results were based upon an analysis of the most recent museum specimen collection dates and an assessment of threats. The results were subsequently reported internationally (Gagné & Howarth, 1985), citing the reasons for extinctions as the combined pressures of habitat destruction, increased rarity of host plants, and the introduction of alien parasitoids for biological control. These data were subsequently reported to the U.S. Fish & Wildlife Service and became the basis for listing candidate endangered species (U.S. Fish & Wildlife Service, 1984).

Since then, 14 of the 23 known Hawaiian species of *Omiodes* leafroller moths have been variously cited as extinct or possibly extinct (Table 1) (Gagné & Howarth, 1985; Beattie, 1994; Evenhuis, 2002; IUCN, 2003). This amounts to more than half of the native species in this genus. The species currently listed as extinct by HBS are: *O. anastrepta* Meyrick, *O. anastreptioides* Swezey, *O. asaphombra* Meyrick, *O. continuatalis* Wallengren, *O. epicentra* Meyrick, *O. euryprora* Meyrick, *O. fullawayi* Swezey, *O. giffardi* Swezey, *O. iridias* Meyrick, *O. laysanensis* Meyrick, *O. meyricki* Swezey, *O. monogona* Meyrick, *O. musicola* Swezey, and *O. telegrapha* Meyrick.

An examination of the insect collections of Hawaii Volcanoes National Park and the collection of J. Giffin revealed recently collected specimens for five of these 14 species. Some of these species are represented by only a few specimens from a few localities, and may truly be threatened with extinction. Other species, however, have been quite widely collected on Hawai‘i Island. The “rediscovery” of these widespread species suggests either that they were never truly in danger of extinction (at least on this island), or that their numbers have increased in recent decades. It is possible that the previous lack of recent collection records for these species may have been due to a lack of active interest in them since the 1950s.

Much of the concern for *Omiodes* moths and the speculation surrounding their conservation status stems from the group's unusual history. Because of their occurrence on sugarcane and coconut palms, two species, *O. accepta* and *O. blackburni*, were specifically targeted for biological control using imported parasitoids between 1895 and 1958 (Funasaki et al., 1988). As early as 1954, entomologists in Hawai'i recognized a decline in populations of native *Omiodes* moths, and suggested that this decline was due in part to pressure from introduced parasitoids and predators (Swezey, 1954; Zimmerman, 1958).

However, at least some species seem to be present in good numbers, and it is clear that the conservation status of *Omiodes* moths should be reexamined. The many peculiarities of this genus, with regards to biological control (Funasaki et al., 1988), conservation biology (Gagné & Howarth, 1985), and evolutionary history (Zimmerman, 1960), make it an ideal subject for future surveys and studies.

Since the rediscoveries reported here are primarily based on incidental collections on a single island, rather than active searches for *Omiodes* moths, it is highly possible that other 'extinct' species are extant. These rediscoveries illustrate the drawbacks of relying solely on museum specimens (although they are often the best data source available), and the need for focused surveys when proposing extinction status. An attempt should be made to relocate *Omiodes* species on all islands, especially since several of the currently listed species are likely to be rare or threatened, if not yet extinct. If populations of threatened moths are located, distributions may be mapped, and actions may be taken to protect these moths by protecting their host plants and habitats.

Institutions with vouchered material are abbreviated as follows: Hawaii Volcanoes National Park (HVNP); Jon Giffin, personal collection (JGPC).

Table 1: Species of Hawaiian Omiodes currently listed as extinct. Species Agencies listing as extinct\* Rediscovered?

#### *Omiodes anastrepta* Meyrick Rediscovery

This species has historically been reported from the islands of O‘ahu, Moloka‘i, and Hawai‘i (Nishida, 2002). Its recorded host plant is *Carex wahuensis* Mey (Zimmerman, 1958). Here we report thirteen specimens, collected from wet and mesic forest on the windward and leeward sides of the island of Hawai‘i. This species was first cited as possibly extinct in 1994 by the U.S. Fish & Wildlife Service (Beattie, 1994). Subsequently, it was listed as extinct by HBS (Evenhuis, 2002).

Material examined: HAWAII: Ka‘u Distr, Hawaii Volcanoes National Park, Kipuka Kī, at white light, 10 Mar 1994, D. Foote et al., 1 specimen, 19944275a (HVNP); Ka‘u Distr, Hawaii Volcanoes National Park, Kipuka Kī, at UV light, 8 Jun 1994, D. Foote et al., 1 specimen, 19945156 (HVNP); Ka‘u Distr, Hawai‘i Volcanoes National Park, Kipuka Kī, at UV light, 1 Dec 1994, D. Foote et al. 1 specimen, 19945820 (HVNP); Ka‘u Distr, Hawaii Volcanoes National Park, Kipuka Kī, at white light, 4 Jan 1994, D. Foote et al., 1 specimen, 19945904 (HVNP); Ka‘u Distr, Hawai‘i Volcanoes National Park, Keamoku lava flow, at white light, 10 Mar 1994, D. Foote et al., 4 specimens, 19944276, 19944277, 19944278, 19944279 (HVNP); Ka‘u Distr, Hawaii Volcanoes National Park, Keamoku lava flow, at UV light, 13 Apr 1994, D. Foote et al., 1 specimen, 19944627 (HVNP); Ka‘u Distr, Hawaii Volcanoes National Park, Keamoku lava flow, at white light, 2 Mar 1994, D. Foote et al., 1

specimen, 19946031 (HVNP); Ka‘u Distr, Hawaii Volcanoes National Park, Thurston Lava Tube, at white light, 10 May 1994, D. Foote et al., 1 specimen, 19944887 (HVNP); South Hilo Distr, Hakalau National Wildlife Refuge, Maulua, 1300 m, 11 Feb 1999, D. LaPointe, 1 specimen, (HVNP); N. Kona, Hualālai, Keauhou 2, Pu‘u Lehua, 14 Dec 2000, J. Giffin, 1 specimen, (JGPC).

#### *Omiodes anastreptoides* Swezey Rediscovery

This species has historically been reported only from the island of Hawai‘i (Nishida, 2002). Larvae have been reared from a sedge, possibly *Carex wahuensis* Mey (Zimmerman, 1958). Here we report nine specimens of this species, all collected from wet forest on the windward side of the island of Hawai‘i. This species was first officially cited as a Category 2 species of concern in 1994 by the U.S. Fish & Wildlife Service (Beattie, 1994). Subsequently, it was listed as extinct by HBS (Evenhuis, 2002).

Material examined: HAWAI‘I: S. Hilo Distr, Hilo Watershed, Pu‘u O‘o boundary, at light, 2 Jul 1999, J. Giffin, 1 specimen, (JGPC); S. Kohala Distr, Kohala Forest Reserve, at light, 4 Apr 1994, 30 Aug 1994, 29 Oct 1994, J. Giffin, 4 specimens, (JGPC); S. Hilo Distr, Hakalau National Wildlife Refuge, Maulua, 1300 m, 11 Feb 1999, P.L. Little, 1 specimen, (HVNP); S. Hilo Distr, Upper Waiākea Forest Reserve, at light, 8 Jul 1999, 30 May 2000, J. Giffin, 3 specimens, (JGPC).

#### *Omiodes asaphombra* Meyrick Rediscovery

This species has historically been collected on the islands of Kaua‘i, O‘ahu, Moloka‘i, and Hawai‘i (Nishida, 2002). Here we report six specimens from the leeward and windward sides of the island of Hawai‘i. This species has only been reared from *Joinvillea adscendens* Gaudichaud, and has been reported to be specific to this plant (Swezey, 1954). Despite the fact that this plant is not known to occur on the leeward side of Hawai‘i Island, five of these six specimens were collected from the district of S. Kona. Therefore, we consider it likely that *O. asaphombra* is able to utilize another host plant. *Omiodes asaphombra* was first presumed extinct by Gagné & Howarth (1982) due to the scarcity of *Joinvillea adscendens*. It was subsequently listed as possibly extinct by FWS (Beattie, 1994), and as extinct by the IUCN (2003) and HBS (Evenhuis, 2002).

Material examined: HAWAI‘I: S. Hilo Distr, Hilo Watershed, Pu‘u O‘o boundary, at light, 2 Jul 1999, J. Giffin, 1 specimen, (JGPC); S. Kona Distr, Kona Forest Unit of Hakalau NWR, Field camp, 20 Jul 2000, W. Haines, 1 specimen, HVNP003587, (HVNP); S. Kona Distr, Kona Forest Unit of Hakalau NWR, 1372 m, 1 Aug 2000, K. Magnacca, 3 specimens, HVNP003712, HVNP003713, HVNP003714 (HVNP); S. Kona Distr, S. Kona Forest Reserve, 1500 m, at light, 10 Apr 2001, J. Giffin, 1 specimen, (JGPC).

*Omiodes continuatalis* Wallengren Rediscovery This species has been reported from all the main islands except Kaho‘olawe and Ni‘ihau (Nishida, 2002), and early entomologists reported this to be one of the most commonly seen moths in Hawai‘i in the late 1800s (Zimmerman, 1958). Recorded host plants for this species include both native and nonnative grasses, including pili, (*Heteropogon contortus* (L.)). We here report 13 specimens from mesic forest on both the windward and leeward sides of Hawai‘i Island. *Omiodes continuatalis* was first presumed extinct by Gagné & Howarth (1982) due to the loss of habitat and introduction of biocontrol agents and was subsequently listed as extinct by the International Union for Conservation of Nature (IUCN, 2003) and HBS (Evenhuis, 2002).

Material examined: HAWAI‘I: S. Kona Distr, Honomalino Forest Reserve, at light, 24 Nov 2000, J. Giffin, 2 specimens (JGPC); Ka‘u Distr, Hawaii Volcanoes National Park, Keamoku lava flow, at white light, 3 Oct 1994, D. Foote et al., 1 specimen, 19945660 (HVNP); Ka‘u Distr,

Hawaii Volcanoes National Park, Kipuka Ki, at white light, 10 Mar 1994, D. Foote et al., 3 specimens 19944272, 19944273, 19944274a (HVNP); N. Kona Distr, Pu'u Wa'awa'a, at light, 5 Apr 1994, J. Giffin, 1 specimen, (JGPC); N. Kona Distr, Pu'u Wa'awa'a, at light, 30 Jul 1994, J. Giffin, 1 specimen, (JGPC); N. Kona Distr, Pu'u Wa'awa'a, at light, 1 Nov 1994, J. Giffin, 1 specimen, (JGPC); N. Kona Distr, Pu'u Wa'awa'a, at light, 28 May 1995, J. Giffin, 1 specimen, (JGPC); S. Kona Distr, Pu'u honua o Honaunau, 1992, D. Foote et al., 3 specimens, PUHO 1992424, PUHO 1992425, PUHO 1992 449 (HVNP).

4

*Omiodes monogona* Meyrick Rediscovery This species has been historically reported from all the main islands except Kaho'olawe and Ni'iha (Nishida, 2002). Zimmerman (1958) reported its principal native host to be wiliwili, Erythrina sandwicensis Degener, but he also listed several other native and nonnative legumes as alternate hosts for the caterpillars. Here we report seven specimens, from mesic to wet forest on both windward and leeward sides of southern Hawai'i Island. *O. monogona* was first cited as possibly extinct in 1994 by the U.S. Fish & Wildlife Service (Beattie, 1994) and was subsequently listed as such by HBS (Evenhuis, 2002). Material examined: HAWAII: S. Kona Distr, Honomalino Forest Reserve, 1050 m, at light, 23 Mar 1995, J. Giffin, 1 specimen, (JGPC); Ka'u Distr, Hawaii Volcanoes National Park, Kipuka Ki, at white light, 10 Mar 1994, D. Foote et al., 2 specimens 19944274b, 19944725b (HVNP); Puna Distr, Hawaii Volcanoes National Park, Ola'a Forest Agric. Unit, at white light, 3 May 1994, D. Foote et al., 2 specimens, 19944810, 19944811, (HVNP); Ka'u Distr, Hawaii Volcanoes National Park, Kilauea Field Station, at white light, 8 May 1994, D. Foote et al., 2 specimens 19945021, 19945024 (HVNP).

**Appendix 4.** List of archived specimens collected at the Kona Forest Unit of Hakalau National Wildlife Refuge. Specimens are grouped by taxon. This list was exported from Biota, The Biodiversity Database Manager (Colwell, 1996), which was used to catalog specimens for the Hawaii Volcanoes National Park Invertebrate Collection. Taxonomic ranks in parentheses indicate that specimens were not identified to lower taxonomic levels. Total specimens (lot specimens treated as single specimens): 1683. Total individuals: 9330.
