## PART 1 PROGRAMMERS GUIDE

<b>CHAPTER 1</b>	<b>Introduction to PBNI .....</b>	<b>3</b>
	About PBNI .....	3
	Understanding PowerBuilder extensions .....	4
	Embedding the PBVM in a C++ application .....	6
	The elements of PBNI .....	6
	The PBNI SDK .....	8
	Comparing PBNI and JNI.....	10
<b>CHAPTER 2</b>	<b>Building PowerBuilder Extensions .....</b>	<b>11</b>
	Nonvisual extension example .....	11
	Building the pbadd PowerBuilder extension.....	12
	Using the extension in PowerBuilder.....	15
	Creating a PowerBuilder extension .....	17
	Step 1: Decide on a feature to implement .....	18
	Step 2: Define the classes and functions in the extension .....	18
	Step 3: Declare native classes and global functions .....	21
	Step 4: Implement native classes and global functions.....	22
	Step 5: Export methods to create class instances .....	24
	Step 6: Build a PBX.....	26
	Adding an extension to a PowerBuilder target .....	26
	Using the extension.....	27
	Creating and using a visual extension .....	28
	Step 1: Decide on a feature to implement .....	28
	Step 2: Define the classes and functions in the extension .....	29
	Step 3: Declare visual classes and global functions .....	29
	Step 4: Implement native classes.....	29
	Step 5: Export methods to create class instances .....	29
	Step 6: Build and use a PBX .....	30
	Step 7: Use the visual extension in an application .....	30

CHAPTER 3	Creating visual class instances .....	31
	Event processing in visual extensions .....	34
	Using an event name with return type and arguments.....	34
	Using an event name with a PowerBuilder event ID .....	37
	Processing events sent to the parent of the window .....	38
	Calling PowerScript from an extension .....	39
	Example: Calling PowerBuilder functions.....	42
	Exception handling and debugging .....	43
CHAPTER 4	<b>Creating Marshaler Extensions .....</b>	<b>45</b>
	About marshaler extensions.....	45
	Developing the PowerBuilder extension .....	46
	Step 1: Describe the extension .....	47
	Step 2: Implement the creator class.....	48
	Step 3: Implement the marshaler class .....	51
	Generating proxies for Java classes .....	53
	Calling the Java class from PowerBuilder.....	54
CHAPTER 5	<b>Exchanging Data with PowerBuilder .....</b>	<b>55</b>
	About exchanging data with PowerBuilder.....	55
	Passing values between extensions and the PBVM .....	55
	PBCallInfo structure .....	56
	IPB_Arguments interface .....	56
	IPB_Value interface.....	57
	Using the IPB_Session interface.....	59
	Saving data from IPB_Value to a local variable .....	61
	Using variables throughout a session .....	63
	Handling enumerated types .....	64
PART 2	<b>Calling PowerBuilder from C++.....</b>	<b>65</b>
	About calling PowerScript from C++ applications .....	65
	Calling PowerBuilder objects from C++ .....	66
	Creating a PowerBuilder object to be called from C++ .....	66
	Getting the signature of a function .....	67
	Creating the C++ application.....	68
	Running the C++ application .....	72
	Accessing result sets .....	72
	Processing PowerBuilder messages in C++ .....	73
	Examples.....	73
	More PBNI possibilities .....	78

<b>CHAPTER 6</b>	<b>PBNI Types and Return Values .....</b>	<b>83</b>
	PowerBuilder to PBNI datatype mappings .....	83
	Types for access to PowerBuilder data.....	84
	PBNI enumerated types .....	84
	Error return values .....	86
<b>CHAPTER 7</b>	<b>PBNI Interfaces, Structures, and Methods .....</b>	<b>87</b>
	Header file contents .....	88
	Class and interface summary.....	88
	IPB_Arguments interface .....	90
	GetAt .....	90
	GetCount .....	91
	IPB_ResultSetAccessor interface .....	92
	AddRef .....	92
	GetColumnCount.....	92
	GetColumnMetaData.....	93
	GetItemData .....	94

# About This Book

## Audience

This book is for C++ programmers who will use the PowerBuilder® Native Interface (PBNI) to build PowerBuilder extensions. The book assumes that you are familiar with the C++ language and a C++ development tool.

## Related documents

This book contains information about building PowerBuilder extensions. The *PowerBuilder Extension Reference* contains information about using extensions that are provided with PowerBuilder.

## Other sources of information

Use the Sybase® Getting Started CD and the Sybase Product Documentation Web site to learn more about your product:

- The Getting Started CD contains release bulletins and installation guides in PDF format. It is included with your software. To read or print documents on the Getting Started CD, you need Adobe Acrobat Reader, which you can download at no charge from the Adobe Web site using a link provided on the CD.
- The Sybase Product Documentation Web site is accessible using a standard Web browser. In addition to product documentation, you will find links to EBFs/Maintenance, Technical Documents, Case Management, Solved Cases, newsgroups, and the Sybase Developer Network.

To access the Sybase Product Documentation Web site, go to Product Documentation at <http://www.sybase.com/support/manuals/>.

## Conventions

The formatting conventions used in this manual are:

Formatting example	To indicate
Retrieve and Update	When used in descriptive text, this font indicates: <ul style="list-style-type: none"><li>• Command, function, and method names</li><li>• Keywords such as true, false, and null</li><li>• Datatypes such as integer and char</li><li>• Database column names such as emp_id and f_name</li><li>• User-defined objects such as dw_emp or w_main</li></ul>

---

Formatting example	To indicate
<i>variable or file name</i>	<p>When used in descriptive text and syntax descriptions, oblique font indicates:</p> <ul style="list-style-type: none"> <li>Variables, such as <i>myCounter</i></li> <li>Parts of input text that must be substituted, such as <i>pblname.pbd</i></li> <li>File and path names</li> </ul>
File>Save	<p>Menu names and menu items are displayed in plain text. The greater than symbol (&gt;) shows you how to navigate menu selections. For example, File&gt;Save indicates “select Save from the File menu.”</p>
<code>dw_1.Update()</code>	<p>Monospace font indicates:</p> <ul style="list-style-type: none"> <li>Information that you enter in a dialog box or on a command line</li> <li>Sample script fragments</li> <li>Sample output fragments</li> </ul>

#### If you need help

Each Sybase installation that has purchased a support contract has one or more designated people who are authorized to contact Sybase Technical Support. If you cannot resolve a problem using the documentation or online help, please have the designated person contact Sybase Technical Support or the Sybase subsidiary in your area.

P A R T   1

# Programmers Guide

This part provides an introduction to the PowerBuilder Native Interface and a guide to creating PowerBuilder extensions and interacting with PowerBuilder.

## About this chapter

This chapter provides a brief introduction to the PowerBuilder Native Interface.

## Contents

Topic	Page
About PBNI	3
The elements of PBNI	6
The PBNI SDK	8
Comparing PBNI and JNI	10

## About PBNI

PBNI is a standard programming interface that enables developers to extend the functionality of PowerBuilder. Using PBNI, you can create extensions to PowerBuilder—nonvisual, visual, and marshaler extensions—and embed the PowerBuilder virtual machine (PBVM) into C++ applications. Through the Java Native Interface (JNI) and PBNI, Java applications can also communicate with the PBVM.

---

### Use with .NET targets

You can use the built-in Web services client extension (*pwsclient125.pbx*) in applications that you plan to deploy to .NET as a PowerBuilder .NET Windows Forms application. You *cannot* use any other PBNI extensions in a .NET target.

---

---

### Code samples

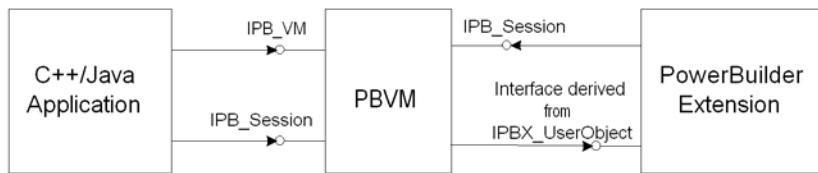

This documentation contains two complete but very simple examples that illustrate some basic principles of using the PowerBuilder Native Interface (PBNI): “Nonvisual extension example” on page 11 and “Creating a PowerBuilder object to be called from C++” on page 66. For more real-world examples, see the PBNI section of the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com/>.

---

The following diagram illustrates the two-way communication, with both PowerBuilder extensions and external applications, that PBNI provides for the PBVM. As the diagram shows, a PowerBuilder extension communicates with the PBVM through the IPB\_Session interface, and the PBVM communicates with the extension through an interface derived from IPBX\_UserObject.

C++ and Java extensions communicate with the PBVM through the IPB\_VM and IPB\_Session interfaces.

**Figure 1-1: Interaction between the PBVM and external applications and extensions**

## Understanding PowerBuilder extensions

A PowerBuilder extension is just what its name suggests: an extension to PowerBuilder functionality provided by you, by a third party, or by Sybase. All PowerBuilder extensions communicate with the PBVM through an interface called IPB\_Session. This interface and other PBNI objects and interfaces are described in “The elements of PBNI” on page 6.

PowerBuilder provides its own extensions, including a PBDOM XML parser and classes that support SOAP clients for Web services. In future releases, Sybase might develop more new features as PBNI extensions instead of embedding them in the PowerBuilder VM (PBVM), so that the size of the PBVM can be minimized. Extensions are also available from third party contributors; for the latest samples and utilities, see the PBNI section of the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com/>.

### Nonvisual extensions

The most frequently used type of PowerBuilder extension is a nonvisual extension. Nonvisual extensions provide a way to call C and C++ functions from PowerBuilder with more flexibility than the previous solution of declaring a function in a script. They also allow you to use object-oriented techniques when working with external objects.

A nonvisual extension is a DLL, written in C++, that exposes one or more native classes and/or global functions. Classes are used in a PowerBuilder application as though they were class user objects created in PowerBuilder—a native class is simply a PowerScript class that is implemented in C++. Global functions in an extension are used like global functions declared in the Function painter.

Nonvisual extensions allow you to use datatypes in C++ that map to standard PowerBuilder datatypes. PBNI provides predefined datatypes that map to PowerBuilder datatypes, so that you can use PowerBuilder datatypes when you invoke the methods of the native class, and the native class can use predefined types to call back into PowerBuilder. For more information about predefined types, see Chapter 6, “PBNI Types and Return Values.”

You can use native classes to call back into the PBVM from the C++ code and trigger PowerBuilder events and invoke functions. You can also call external functions that require callback functions. For example, if your PowerBuilder application uses an extension that is a SAX XML parser, the SAX parser can send information back to the PowerBuilder application about the items it has encountered in the XML document that it is parsing. In response, the PowerBuilder application can send back instructions on how to handle those items.

Possible uses for a nonvisual extension include:

- A wrapper for a Component Object Model (COM) component that references a user-defined COM interface that cannot be mapped to a PowerBuilder datatype
- A PowerBuilder interface for database backups and administration using the SQL Anywhere™ dbtools (which require callback functions)
- Wrappers for any open source C++ libraries that provide standard utilities

PowerBuilder extensions run faster than standard PowerBuilder user objects because they are compiled in native machine code instead of PowerBuilder pseudocode (Pcode). PBNI complies with the C++ specification, so well-programmed code is portable at the source code level.

#### Visual extensions

Visual extensions can be used as if they were PowerBuilder visual user objects—you can place them in windows or on other visual controls. Visual extensions allow you to create a subclass of the Windows procedure (`winproc`) of a visual component so that you can use the latest “look and feel” for your applications.

Marshaler extensions	Marshaler extensions act as bridges between PowerBuilder and other components, such as Enterprise JavaBeans (EJB) components, Java classes, Web services, and CORBA components. PowerBuilder provides a marshaler extension for creating clients for EJB components running in any J2EE-compliant application server. Other techniques for calling EJBs from PowerBuilder do not provide a standard way to marshal PowerBuilder requests to other components and unmarshal the result back to PowerBuilder.
----------------------	---

## **Embedding the PBVM in a C++ application**

Many PowerBuilder users have developed sophisticated custom class user objects that handle intensive database operations or other functionality. Such objects can already be used in external applications. However, limitations on the use of some datatypes and of overloaded functions, as well as other coding restrictions, diminishes the value of this technique.

To have direct access to a custom class user object running in the PBVM, and to take advantage of PBNI functions for data access and exchange, you can load the PBVM in the C++ application, create a session, and invoke the custom class user object's functions from the external application.

Communication between the PBVM and a C++ application is based primarily on two interfaces: IPB\_VM and IPB\_Session.

Interacting with Java	To call Java classes from PowerBuilder, you can build a marshaler extension that invokes Java methods through JNI, as described in Chapter 3, “Creating Marshaler Extensions.” You can also use JNI to allow Java to call into PowerBuilder through C or C++. For an example, see the PowerBuilder CodeXchange Web site at <a href="http://powerbuilder.codexchange.sybase.com">http://powerbuilder.codexchange.sybase.com</a> .
-----------------------	--

## **The elements of PBNI**

To enable the features described in the previous section, PBNI provides interfaces, structures, global functions, and helper classes. These elements are described in more detail in the reference section of this guide. See Chapter 7, “PBNI Interfaces, Structures, and Methods.” This section provides an overview.

Interfaces	The IPB_VM interface is used to load PowerBuilder applications in third-party applications and interoperate with the PowerBuilder virtual machine (PBVM).
------------	---

IPB\_Session is an abstract interface that defines methods for performing various actions such as accessing PowerScript data, creating PowerBuilder objects, and calling PowerScript functions.

The IPB\_Value and IPB\_Arguments interfaces enable you to pass values between the PowerBuilder VM and PowerBuilder extension modules.

The IPB\_Value interface represents a PowerBuilder value, which could be one of the PowerBuilder standard datatypes such as integer, long, string, and so forth. It provides information about each variable, including its type, null flag, access privileges, array or simple type, and reference type.

The IPB\_Arguments interface represents the arguments passed to a PowerScript function and is used to access the data.

The IPB\_ResultSetAccessor and IPB\_RSItemData interfaces enable you to access data in a DataWindow or DataStore.

All PowerBuilder native classes inherit from the IPBX\_NonVisualObject interface or the IPBX\_VisualObject interface, which in turn inherit from the IPBX\_UserObject interface. You must implement the `Invoke` method in the inherited class to enable PowerBuilder to invoke methods in the native class.

Marshaler extensions contain a class that inherits from the IPBX\_Marshaler interface. You must implement the `InvokeRemoteMethod` method in the inherited class to enable PowerBuilder to invoke methods on remote objects represented by a proxy.

**Structures** The PBCallInfo structure holds arguments and return type information for function calls between PBNI and PowerBuilder. To access the information in PBCallInfo, use the IPB\_Arguments interface.

The PBArrayInfo structure stores information about arrays.

The PB\_DateData, PB\_TimeData, and PB\_DateTimeData structures are used to pass DataWindow and DataStore data.

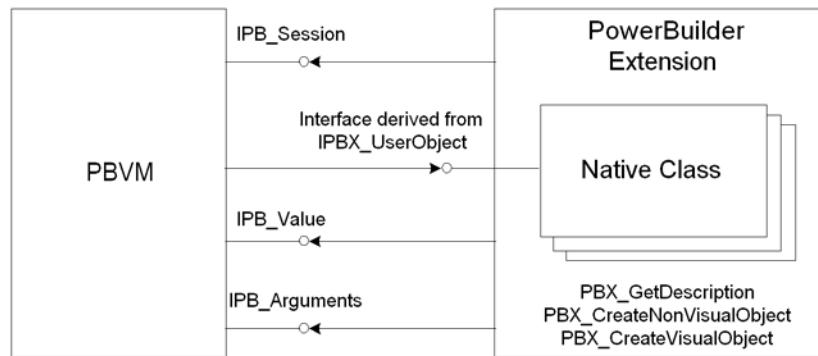

**Global functions** Every PowerBuilder extension object must export global functions that enable the PowerBuilder VM to create instances of the object and use its methods. The PBX\_GetDescription function describes the classes and functions in the extension. The PBX\_CreateNonVisualObject function enables the PBVM to create instances of the nonvisual classes in an extension, and the PBX\_CreateVisualObject function does the same for visual classes.

**Helper classes** Several helper classes, such as PBOBJECTCREATOR, PBARRAYACCESSOR, and PBEVENTTRIGGER, make it easier to program with PBNI.

Interaction between an extension and the PBVM

The following diagram summarizes how an extension interacts with the PBVM.

**Figure 1-2: Interaction between an extension and the PowerBuilder VM**

## The PBNI SDK

When you install PowerBuilder, the Software Development Kit (SDK) for PBNI is installed in the *PowerBuilder 12.50\SDK\PBNI* directory. The SDK tools, *pbsig125* and *pbx2pbd125*, are also installed in the *Shared\PowerBuilder* directory so that they are available in your path.

The SDK contains the components shown in the following table.

**Table 1-1: Contents of the PBNI SDK**

Component	Description
<i>pbx2pbd125.exe</i>	A tool that generates a PBD file from a PowerBuilder extension file. The extension file is a DLL file that must export a set of PBNI functions. The DLL is usually called a PBX and can be given the suffix <i>.pbx</i> .
<i>pbsig125.exe</i>	A tool that generates a set of strings representing the return type and arguments of each function in a PBL. Use these strings to call PowerBuilder functions from external modules.
<i>include\pbni.h</i>	A header file that defines the structures and interfaces used to build PowerBuilder extensions.
<i>include\pbarray.h</i>	A header file that contains helper classes that make it easier to create arrays and access data in them.

<b>Component</b>	<b>Description</b>
<i>include\pbfield.h</i>	A header file that contains helper classes that make it easier to access data in fields.
<i>include\pbtraits.h</i>	A header file used by <i>pbarray.h</i> and <i>pbfield.h</i> that provides specializations for the <i>pbvalue_type</i> enumerated types.
<i>include\pbext.h</i>	A header file that defines the functions that PowerBuilder extension functions must export.
<i>include\pbevtid.h</i>	A header file that maps the PowerBuilder event IDs to event names for use in visual extensions.
<i>include\pbnimd.h</i>	A header file that defines machine-dependent datatypes used in <i>pjni.h</i> .
<i>include\pbrsa.h</i>	A header file that defines interfaces and structures used to access DataWindow and DataStore data.
<i>src\pbarray.cpp</i>	A source file that must be added to your project if you want to use the following helper classes defined in <i>pbarray.h</i> :  PBArrayAccessor PBOBJECTArrayAccessor PBBoundedArrayCreator PBBoundedObjectArrayCreator PBUnboundedArrayCreator PBUnboundedObjectArrayCreator
<i>src\pbfuninv.cpp</i>	A source file that must be added to your project if you want to use the following helper classes defined in <i>pjni.h</i> :  PBGlobalFunctionInvoker PBOBJECTFunctionInvoker PBEVENTTrigger
<i>src\pbobject.cpp</i>	A source file that must be added to your project if you want to use the following helper class defined in <i>pjni.h</i> : PBOBJECTCreator.
<i>wizards\VCProjects 8.0</i>	A Microsoft Visual Studio 2005 wizard that makes it easier for you to create PBNI projects.
<i>wizards\VCProjects 7.1</i>	A Microsoft Visual Studio .NET 2003 wizard that makes it easier for you to create PBNI projects.
<i>wizards\VCProjects 7.0</i>	A Microsoft Visual Studio .NET 2002 wizard that makes it easier for you to create PBNI projects.
<i>wizards\VCWizards</i>	Files required by the Visual Studio wizards.
<i>pjni125.hlp</i> , <i>pjni125.cnt</i>	Help files for PBNI.

## Comparing PBNI and JNI

If you have used the Java Native Interface (JNI), which allows Java applications and C and C++ modules to interoperate, you might find it helpful to be aware of the similarities in the two interfaces and the differences between them.

The IPB\_VM interface in PBNI is analogous to the JavaVM type, and the IPB\_Session interface in PBNI is analogous to JNIEnv. For JNI, you use the javap command to obtain a string that encodes the signature of each method in a native class. For PBNI, the pbsig125 tool performs the same function.

The major difference between the two interfaces is in how a native function or class is declared.

In JNI, you must use the native keyword to declare that a function is native, but you cannot simply declare a class as native. You must define your classes in Java source code, use the javah tool to generate a C header file that defines a C prototype for each native method, then implement the individual C or C++ functions, using #include to include the generated header file.

PBNI provides an object-oriented approach—you declare a class as native in the C++ code by inheriting from the IPBX\_NonVisualObject or IPBX\_VisualObject struct.

# Building PowerBuilder Extensions

## About this chapter

This chapter describes how to build a PowerBuilder extension. It begins with a sample application that uses a simple nonvisual extension.

## Contents

Topic	Page
Nonvisual extension example	11
Creating a PowerBuilder extension	17
Adding an extension to a PowerBuilder target	26
Using the extension	27
Creating and using a visual extension	28
Creating visual class instances	31
Event processing in visual extensions	34
Calling PowerScript from an extension	39
Exception handling and debugging	43

## Nonvisual extension example

To illustrate the principles involved in building and using an extension, this chapter starts with a sample application that uses a PowerBuilder extension to perform a simple arithmetic operation. Ordinarily, this is not a task that needs PBNI, but it is used here to make the basic process clear. The rest of this chapter describes building extensions in more detail.

---

### PBX file suffix

PowerBuilder extensions are DLL files but typically use the file extension *.pbx* instead of *.dll*. Your extension is compiled into a PBX file by default if you use the wizard described in the Appendix, “Using the Visual Studio Wizards.”

---

For more realistic examples, see the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>.

The following sample application has two main steps:

- Building the pbadd PowerBuilder extension
- Using the extension in PowerBuilder

## Building the pbadd PowerBuilder extension

In this example, the C++ code is in three files:

- The class declaration is in a header file, *pbadd.h*
- The standard functions that every PowerBuilder extension must expose are in *main.cpp*
- The implementation of the class is in *pbadd.cpp*.

### ❖ To implement the pbadd extension:

- 1 Create the *pbadd.h* header file.

The *pbadd.h* header file declares the pbadd class. The file includes *pbext.h*, which must be included in all PowerBuilder extensions because it declares the ancestor classes for native classes and the standard functions that the extension must expose. Here is the code for *pbadd.h*:

```
#include "pbext.h"
class pbadd: public IPBX_NonVisualObject
{
public:
    pbadd();
    virtual ~pbadd();
    PBXRESULT Invoke(
        IPB_Session    *session,
        pbobject       obj,
        pbmethodID     mid,
        PBCallInfo     *ci);

    int f_add(IPB_Session*, pbint, pbint);

    // Enum used to provide entry points for each
    // method in the class - the only one in this case
    // is mAdd
    enum MethodIDs
    {
        mAdd = 0
    };
}
```

```
    private:  
        virtual void Destroy();  
    };
```

- 2 Create the *main.cpp* file, which includes *pbadd.h* and implements the standard functions, *PBX\_GetDescription* and *PBX\_CreateNonvisualObject*:
  - *PBX\_GetDescription* is used to pass the descriptions of classes in the extension to PowerBuilder.
  - The *PBX\_CreateNonVisualObject* method creates the object instance. The PowerScript CREATE statement maps to this PBNI method.

The following is the code for *main.cpp*:

```
#include "pbadd.h"  
// initialize the PBX  
BOOL APIENTRY DllMain(HANDLE hModule,  
                      DWORD ul_reason_for_all,  
                      LPVOID lpReserved  
                      )  
{  
    switch(ul_reason_for_all)  
    {  
        case DLL_PROCESS_ATTACH:  
        case DLL_THREAD_ATTACH:  
        case DLL_THREAD_DETACH:  
        case DLL_PROCESS_DETACH:  
            break;  
    }  
    return TRUE;  
}  
  
// describe the pbadd class  
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()  
{  
    static const TCHAR desc[] = {  
        "class pbadd from nonvisualobject \n" \  
        "function int f_add(int a,int b)\n" \  
        "end class \n"  
    };  
    return desc;  
}
```

```
// export the required PBX_CreateNonVisualObject
// function so that the PBVM can
// create an instance of the class
PBXEXPORT PBXRESULT PBXCALL
PBX_CreateNonVisualObject
(
    IPB_Session*      pbSession,
    pbobject          pbobj,
    LPCSTR            xtraName,
    IPBX_NonVisualObject **obj
)
{
    // if the calling function requests the pbadd
    // class, create an instance
    if (strcmp(xtraName,"pbadd")==0)
    {
        *obj=new pbadd;
    }
    return 0;
};
```

- 3 Create the *pbadd.cpp* file, which includes *pbadd.h* and contains the implementation of the *pbadd* class and its single method, *f\_add*.

```
#include "pbadd.h"

// Implement the required Invoke method
PBXRESULT pbadd:: Invoke(IPB_Session *Session,
    pbobject obj, pbmethodID mid, PBCallInfo *ci)
{
    // if the method to call is f_add
    if (mid == mAdd)
    {
        int sum = f_add(Session, ci->pArgs->GetAt(0)->
            GetInt(), ci->pArgs->GetAt(1)->GetInt());
        ci->returnValue->SetInt(sum);
    }
    return PBX_OK;
}

// constructor and destructor
pbadd:: pbadd()
{
}
pbadd:: ~pbadd()
{
}
```

```
// implement the class's f_add method
int pbadd:: f_add(IPB_Session* session, pbint arg1,
                  pbint arg2)
{
    return arg1+arg2;
}

// Implement the required Destroy method
void pbadd::Destroy()
{
    delete this;
}
```

❖ **To compile and link the PBX:**

- In your C++ development tool or on the command line, compile and link the PBX.

Make sure the *include* directory in *PowerBuilder 12.5\SDK\PBNI* is in your include path. For this example, the generated DLL is called *pbadd.pbx*.

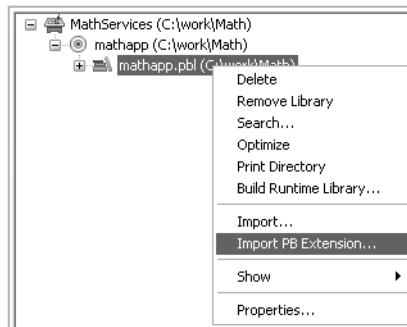

## Using the extension in PowerBuilder

To use the PowerBuilder native class in a PowerBuilder application, import the object descriptions in the PBX file into a library in your application.

❖ **To import the extension into an application:**

- 1 Copy the PBX (or DLL) file to a directory on your application's path.
- 2 In PowerBuilder, create a new workspace.
- 3 On the Target page of the New dialog box, select the Application icon to create a new target, library, and application object.

- 4 In the System Tree, expand the new target, right-click the library, and select Import PB Extension from the pop-up menu.

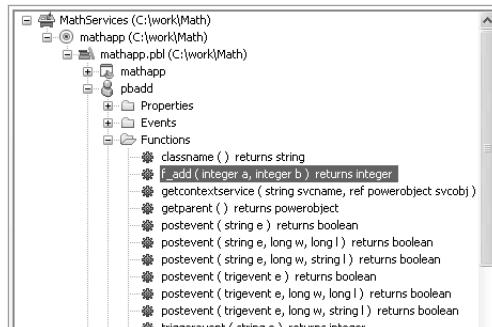

- 5 Navigate to the location of the *pbadd.pbx* file and click Open.

❖ To invoke the *f\_add* function in PowerBuilder:

- 1 Create a new window called *w\_add*, and add three single-line edit boxes and a command button to it.
- 2 Declare an instance variable called *mypbadd* for the *pbadd* native class, and then add this script to the button's Clicked event:

```
TRY
    mypbadd = CREATE pbadd
    sle_3.text = string (mypbadd.f_add( &
        integer(sle_1.text), integer(sle_2.text)))
CATCH (runtimeerror re)
    MessageBox("Error", &
        "pbadd native class could not be created: " + &
        re.getmessage() )
END TRY
```

The *pbadd* class displays in the System Tree. As shown in the following screen shot, you can expand its function list:

- 3 Add `open(w_add)` to the application's Open event.
- 4 Run the application.

The application runs just as it would if you had created a custom class user object in PowerBuilder with an `f_add` function. If PowerBuilder cannot find `pbadd.pbx`, the runtime error in the Clicked event script will be triggered and caught. Put `pbadd.pbx` in the same directory as the executable or the PowerBuilder runtime DLLs to make sure it can be found.

## Creating a PowerBuilder extension

To build a PowerBuilder extension, follow these steps:

- Step 1: Decide on a feature to implement.
- Step 2: Define the classes and functions in the extension.
- Step 3: Declare native classes and global functions.
- Step 4: Implement native classes and global functions.
- Step 5: Export methods to create class instances.
- Step 6: Build a PBX.

These steps apply whether you are building a nonvisual or a visual extension. The differences between building nonvisual and visual extensions are described in “Creating and using a visual extension” on page 28. This section focuses primarily on nonvisual extensions.

### Required methods

All PowerBuilder nonvisual extensions must export two methods: `PBX_GetDescription` and `PBX_CreateNonVisualObject`. The use of these methods is described in “Step 2: Define the classes and functions in the extension” on page 18 and “Step 5: Export methods to create class instances” on page 24.

PowerBuilder visual extensions must export `PBX_GetDescription` and `PBX_CreateVisualObject`. See “Creating and using a visual extension” on page 28.

If the extension declares global functions, it must also export the `PBX_InvokeGlobalFunction` method.

For every native class, you must implement two PBNI methods, `Invoke` and `Destroy`, in addition to the methods the class will provide. The use of these PBNI methods is described in “Step 4: Implement native classes and global functions” on page 22.

## **Step 1: Decide on a feature to implement**

The first step in building a PowerBuilder extension is to identify a problem that an extension can solve. This might be a feature that can be coded more efficiently and easily in C++ than in PowerScript, or that requires the use of callback functions or nonstandard datatypes. You might also have access to existing C++ classes that perform the tasks you want to add to a PowerBuilder application, or you might want to create a wrapper for existing standard utilities written in C++.

For possible uses of PowerBuilder extensions, see “Understanding PowerBuilder extensions” on page 4.

For examples of PowerBuilder extensions, see the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>.

## **Step 2: Define the classes and functions in the extension**

Your C++ code must expose two standard methods that enable PowerBuilder to recognize each native class and create instances of the class. One of these methods is `PBX_GetDescription`.

Use `PBX_GetDescription` to pass the descriptions of classes and global functions in the PowerBuilder extension to PowerBuilder. Every extension must export this method. Importing the PBX or DLL file into a PBL converts the description of the extension into PowerScript and adds it to the PBL as source code. The keyword `native` in the source code indicates that the PowerBuilder type was defined in an extension.

All the classes or global functions in an extension module are passed in a single description. The examples that follow illustrate how you define classes and functions in a description. For the full syntax, see `PBX_GetDescription` on page 246.

**Describing nonvisual classes**

Nonvisual classes can inherit from the NonVisualObject PowerBuilder system class or any of its descendants. While a native class can inherit from a user-defined user object, Sybase recommends that you use only system classes. Each native class can provide several functions, subroutines, and events.

The following example shows how you use the PBX\_GetDescription method in the C++ code for an extension that includes three nonvisual classes.

*ClassName1* inherits from NonVisualObject, *ClassName2* inherits from Exception, and *ClassName3* inherits from Transaction. All three classes must be in a single description passed by PBX\_GetDescription:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        // Description begins here
        "class ClassName1 from NonVisualObject\n"
        "function integer objectFunction(integer a[]) \n"
        "subroutine objectSubroutine(integer ai_ref) \n"
        "event integer eventName(integer b) \n"
        "end class\n"

        "class ClassName2 from Exception\n"
        "function integer objectFunction(readonly
            integer ai) \n"
        "subroutine objectSubroutine(integer arg) \n"
        "event integer eventName(integer arg) \n"
        "end class\n"

        "class ClassName3 from Transaction\n"
        "function integer objectFunction(integer arg) \n"
        "subroutine objectSubroutine(integer arg) \n"
        "event integer eventName(integer arg) \n"
        "end class\n"
        // Description ends here
    };
    return desc;
}
```

**Describing visual classes**

Visual native classes can inherit only from the UserObject PowerBuilder system class. The PowerBuilder VM considers any class that inherits from UserObject to be a visual class. All other native classes are considered to be nonvisual classes. For more information about how to describe visual classes, see “Creating and using a visual extension” on page 28.

**Describing global functions**

An extension can include global functions as well as classes. This example shows a description for two global functions:

```
"globalfunctions \n" \
"function int g_1(int a, int b)\n" \
"function long g_2(long a, long b)\n" \
"end globalfunctions\n"
```

The syntax and usage of global functions defined in an extension are the same as for global functions defined in the Function painter in PowerBuilder.

---

**Global functions cannot be overloaded**

Like global functions in PowerScript, global functions in a PowerBuilder extension cannot be overloaded.

---

**Using forward declarations**

PowerBuilder extensions can provide multiple classes. A class can reference any class that is defined *earlier* in the description, but if it references a class defined *later* in the description, you must provide a forward declaration. This example shows a description that includes forward declarations for two classes, nativeclass\_1 and nativeclass\_2, that reference each other. This example also demonstrates that a single description can include global functions as well as classes:

```
"forward\n" \
"class nativeclass_1 from nonvisualobject\n" \
"class nativeclass_2 from nonvisualobject\n" \
"end forward\n" \

"class nativeclass_1 from nonvisualobject \n" \
"function int add(nativeclass_2 a, int b)\n" \
"function int sub(int a, int b)\n" \
"end class \n" \

"class nativeclass_2 from nonvisualobject \n" \
"function int add(nativeclass_1 a, int b)\n" \
"function int sub(int a, int b)\n" \
"end class \n"

"globalfunctions \n" \
"function int g_1(int a, int b)\n" \
"function long g_2(long a, long b)\n" \
"end globalfunctions\n"
```

## Step 3: Declare native classes and global functions

For each native class that the nonvisual extension supports, declare an ANSI C++ class that inherits from IPBX\_NonVisualObject, which is the ancestor class for all nonvisual PowerBuilder native classes.

The declaration of the class can be placed in a header file, and it must include `Invoke` and `Destroy` methods. This is a simple prototype for a nonvisual class:

```
#include "pbext.h"

class CMyClass : public IPBX_NonVisualObject
{
enum MethodIDs
{
    mFunca = 0,
    mFuncb = 1
};
public:
    // constructor, destructor
    CMyClass()
    virtual ~CMyClass()

    // member methods
    PBXRESULT Invoke(
        IPB_Session    *session,
        pbobject      obj,
        pbmethodID    mid,
        PBCallInfo    *ci
    );
    void Destroy();

private:
    void funcA(IPB_Session* session, pbobject obj,
               PBCallInfo* ci);
    void funcB(IPB_Session* session, pbobject obj,
               PBCallInfo* ci);
};
```

If you declare global functions in your extension, the extension must export the PBX\_InvokeGlobalFunction method. The following PBX\_GetDescription call declares three global functions: bitAnd, bitOr, and bitXor:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "globalfunctions\n"
        "function int bitAnd(int a, int b)\n"
        "function int bitOr(int a, int b)\n"
        "function int bitXor(int a, int b)\n"
        "end globalfunctions\n"
    };

    return desc;
}
```

## **Step 4: Implement native classes and global functions**

The implementation of each class must include the implementation of the Invoke and Destroy methods, as well as all the methods declared for the class. Invoke and Destroy are methods of the IPBX\_UserObject interface.

When the PowerBuilder application calls a method on the native class, the PBVM calls the Invoke method, which dispatches the call based on the method ID or method name. The method name is used when the method is called dynamically.

The Invoke method must be coded to invoke each method in the class. The example that follows shows a switch-case statement that invokes either funcA or funcB, depending on the value of the method ID. When the PowerBuilder application has finished using an instance of a native class, the PBVM calls the Destroy method.

This example does not show the implementation of the methods of the class itself:

```
PBXRESULT MyClass::Invoke(IPB_Session *session,
pbobject obj, pbmethodID mid, PBCallInfo *ci)
{
    PBXRESULT result = PBX_OK;

    switch (mid)
    {
        case mFunca:
            result = funcA(session, obj, ci);
            break;

        case mFuncb:
            result = funcB(session, obj, ci);
            break;

        default:
            result = PBX_E_INVOKE_FAILURE;
            break;
    }

    return result;
}
// Implementation of funcA and funcB not shown
void Destroy()
{
    delete this;
}
```

The following PBX\_InvokeGlobalFunction contains the implementation of the three global functions included in the description shown in “Step 3: Declare native classes and global functions” on page 21:

```
PBXEXPORT PBXRESULT PBXCALL PBX_InvokeGlobalFunction
(
    IPB_Session*    pbsession,
    LPCTSTR         functionName,
    PBCallInfo*     ci
)
{

    PBXRESULT pbrResult = PBX_OK;

    int arg1 = ci->pArgs->GetAt(0)->GetInt();
    int arg2 = ci->pArgs->GetAt(1)->GetInt();

    if (strcmp(functionName, "bitand") == 0)
    {
        ci->returnValue->SetInt(arg1 & arg2);
    }else if (strcmp(functionName, "bitor") == 0)
    {
        ci->returnValue->SetInt(arg1 | arg2);
    }else if (strcmp(functionName, "bitxor") == 0)
    {
        ci->returnValue->SetInt(arg1 ^ arg2);
    }else
    {
        return PBX_FAIL;
    }

    return pbrResult;
}
```

## Step 5: Export methods to create class instances

PowerBuilder creates nonvisual and visual class instances differently:

- For visual classes, the instance is created when the window or visual control in which the class is used is opened. See “Creating visual class instances” on page 31.
- For nonvisual classes, the instance is created when the PowerBuilder CREATE statement is used. This is described next.

When the PowerBuilder application creates an instance of a nonvisual class using the PowerScript CREATE statement, the PBVM calls the PBX\_CreateNonVisualObject method in the extension. Every extension that contains nonvisual native classes must export this method.

In the same way that multiple classes are included in a single description passed by PBX\_GetDescription, PBX\_CreateNonVisualObject can be used to create multiple classes.

In this example, the extension has three classes. An IF statement compares the name of the class passed in from the PowerBuilder CREATE statement to the name of each of the classes in the extension in turn and creates an instance of the first class with a matching name. You could also use a CASE statement. The class name in the string comparison must be all lowercase:

```
PBXEXPORT PBXRESULT PBXCALL PBX_CreateNonVisualObject(
    IPB_Session * session,
    pbobject obj,
    LPCSTR className,
    IPBX_NonVisualObject **nvobj
)
{
    PBXRESULT result = PBX_OK;
    // The class name must not contain uppercase
    if ( strcmp( className, "classone" ) == 0 )
        *nvobj = new ClassOne;
    else if ( strcmp( className, "classtwo" ) == 0 )
        *nvobj = new ClassTwo( session );
    else if ( strcmp( className, "classthree" ) == 0 )
        *nvobj = new ClassThree;
    else
    {
        *nvobj = NULL;
        result = PBX_E_NO_SUCH_CLASS;
    }
    return PBX_OK;
};
```

## Step 6: Build a PBX

Using your C++ development tool or the command line, build a PBX from your C++ classes.

When you compile and link the C++ code, verify the following:

- The *include* directory for the PBNI SDK, typically *PowerBuilder 12.5\SDK\PBNI\include*, must be in your include path.
- If you use any helper classes, make sure the source file that contains them is added to your project. For a list of classes, see the table in “The PBNI SDK” on page 8.

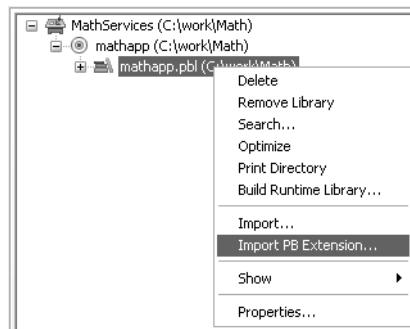

Now you are ready to use the extension in a PowerBuilder application.

## Adding an extension to a PowerBuilder target

The simplest way to add a PowerBuilder native class to a PowerBuilder target is to import the object descriptions in the PBX file into a library in the PowerBuilder System Tree. You can also use a command-line tool to create a PBD file from a PBX file and add it to the target’s library search path. See `pbx2pbd125` on page 259.

### ❖ To import the descriptions in an extension into a library:

- 1 Copy the PBX file into a directory on the application’s path.
- 2 In the System Tree, expand the target in which you want to use the extension, right-click a library, and select Import PB Extension from the pop-up menu.

- 3 Navigate to the location of the PBX file and click Open.

Each class in the PBX displays in the System Tree so that you can expand it, view its properties, events, and methods, and drag and drop to add them to your scripts.

## Using the extension

### Using nonvisual classes

In PowerScript, use the classes in a nonvisual extension just as you would a custom class user object: Declare an instance of the object, use the CREATE statement to create the instance, invoke the object's functions, and destroy the instance when you have finished with it. You can inherit from the native classes if you want to add functions or events to the class.

At runtime, instances of the native class are created as normal PowerBuilder objects.

In this example, the extension module contains two nonvisual native classes: fontcallback and fontenumerator. A PowerBuilder custom class user object, nvo\_font, inherits from the fontcallback class. These statements create instances of both classes:

```
fontenumerator fe  
nvo_font uf  
fe = create fontenumerator  
uf = create nvo_font
```

After an instance of a native class has been created, the PowerBuilder application can call methods on the object. Each native class must implement an Invoke method that the PowerBuilder VM calls when the PowerBuilder application calls one of the native class's methods. Then, the Invoke method dispatches the method call based on the method ID or method name. The method name is used when a native method is called dynamically.

Using the previous example, this statement invokes the enumprinterfonts method of the instance of the fontenumerator class:

```
fe.enumprinterfonts(uf)
```

### Destroying the PBNI object instance

When the PowerBuilder application no longer needs an instance of a nonvisual class and a DESTROY statement is issued, by either the user or the garbage collector, or when the window or visual control that contains a visual class is closed, the PowerBuilder VM destroys the instance by calling the native class's Destroy method.

## **Creating and using a visual extension**

In general, you follow the same steps to create and use a visual extension that you do to create a nonvisual extension:

- Step 1: Decide on a feature to implement.
  - Step 2: Define the classes and functions in the extension.
  - Step 3: Declare visual classes and global functions.
  - Step 4: Implement native classes.
  - Step 5: Export methods to create class instances.
  - Step 6: Build and use a PBX.
  - Step 7: Use the visual extension in an application.
- 

### **Using PowerBuilder visual objects in C++**

For information about using PowerBuilder visual objects from a C++ application, see “Processing PowerBuilder messages in C++” on page 73.

---

### **Step 1: Decide on a feature to implement**

You can choose to use visual extensions to implement controls with a specific purpose or that use a custom look and feel. For some examples of visual extensions, see the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>.

## Step 2: Define the classes and functions in the extension

The description for a visual class follows the same rules as for a nonvisual class, but it must inherit from the UserObject system class:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class myvisualext from userobject\n"
        "subroutine func_1(int arg1, int arg2)\n"
        "subroutine func_2(string arga)\n"
        "end class\n"
    };

    return desc;
}
```

There are no events in the preceding example, but a typical visual extension makes use of events such as mouse clicks. There are two ways to declare and handle events. See “Event processing in visual extensions” on page 34.

## Step 3: Declare visual classes and global functions

You declare native visual classes in the same way as nonvisual classes, except that you declare an ANSI C++ class that inherits from IPBX\_VisualObject, which is the ancestor class for all nonvisual PowerBuilder native classes, instead of from IPBX\_NonVisualObject. You can also declare global functions in a visual extension. See “Step 3: Declare native classes and global functions” on page 21 in the section on nonvisual extensions.

## Step 4: Implement native classes

You implement Invoke and Destroy methods and any class or global functions the same way for visual extensions as for nonvisual extensions. See “Step 4: Implement native classes and global functions” on page 22.

## Step 5: Export methods to create class instances

The major difference between visual and nonvisual extensions is in how instances of the class are created. See “Creating visual class instances” on page 31.

## **Step 6: Build and use a PBX**

As for nonvisual extensions, you must build a PBX, import it into the application, and put the PBX in the execution path. See “Step 6: Build a PBX” on page 26 and “Adding an extension to a PowerBuilder target” on page 26 in the section on nonvisual extensions.

## **Step 7: Use the visual extension in an application**

You do not need to declare an instance of a visual class or use the CREATE statement to create an instance. The PBVM creates an instance when the window or visual control in which the visual class resides is opened, as described in “Creating visual class instances” on page 31. You can invoke the object’s functions the same way that you invoke a nonvisual object’s functions.

❖ **To use a visual extension:**

- 1 Select File>Inherit from the PowerBuilder menu and select the PBD in the Libraries list in the Inherit from Object dialog box.
- 2 Select the visual class and click OK.
- 3 In the User Object painter, size the visual object and make any other changes you need.
- 4 Save the object.

You can now drag the new user object from the System Tree directly onto a window or onto another visual control, such as a tab control, and use it like any other visual user object.

---

### **Code samples**

The code fragments in the rest of this section are based on complete sample applications that you can find on the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>.

---

## Creating visual class instances

When the window or other visual control in which a visual native class resides is created in a PowerBuilder application, the PBVM calls the `PBX_CreateVisualObject` method in the extension automatically—the PowerBuilder application developer does not need to write a `CREATE` statement in a script. The PBVM also calls the `IPBX_VisualObject`'s `CreateControl` method. Every extension that contains visual native classes must export `PBX_CreateVisualObject` and implement `CreateControl`.

The following is sample code for `PBX_CreateVisualObject`:

```
PBXEXPORT PBXRESULT PBXCALL PBX_CreateVisualObject
(
    IPB_Session*          pbsession,
    pbobject               pbobj,
    LPCTSTR                className,
    IPBX_VisualObject**  *obj
)
{
    PBXRESULT result = PBX_OK;

    string cn(className);
    if (cn.compare("visualext") == 0)
    {
        *obj = new CVisualExt(pbsession, pbobj);
    }
    else
    {
        *obj = NULL;
        result = PBX_FAIL;
    }

    return PBX_OK;
};
```

Registering the  
window class

Before CreateControl can be called, the window class must be registered. This code uses the Windows RegisterClass method to register the window class with the class name s\_className:

```
void CVisualExt::RegisterClass()
{
    WNDCLASS wndclass;

    wndclass.style = CS_GLOBALCLASS | CS_DBLCLKS;
    wndclass.lpfnWndProc = WindowProc;
    wndclass.cbClsExtra = 0;
    wndclass.cbWndExtra = 0;
    wndclass.hInstance = g_dll_hModule;
    wndclass.hIcon = NULL;
    wndclass.hCursor = LoadCursor (NULL, IDC_ARROW);
    wndclass.hbrBackground = (HBRUSH) (COLOR_WINDOW + 1);
    wndclass.lpszMenuName = NULL;
    wndclass.lpszClassName = s_className;

    ::RegisterClass (&wndclass);
}
```

You must also implement the Windows UnregisterClass method to unregister the class when the window is closed:

```
void CVisualExt::UnregisterClass()
{
    ::UnregisterClass(s_className, g_dll_hModule);
}
```

The RegisterClass and UnregisterClass methods are called in the initialization code for the PBX. This is the Visual C++ DllMain method:

```
BOOL APIENTRY DllMain( HANDLE hModule,
                       DWORD reasonForCall,
                       LPVOID lpReserved
)
{
    g_dll_hModule = (HMODULE) hModule;

    switch (reasonForCall)
    {
        case DLL_PROCESS_ATTACH:
            CVisualExt::RegisterClass();
            break;

        case DLL_THREAD_ATTACH:
        case DLL_THREAD_DETACH:
    }
```

```

        break;

    case DLL_PROCESS_DETACH:
        CVVisualExt::UnregisterClass();
        break;
    }
    return TRUE;
}

```

### Implementing CreateControl

Every visual native class must implement the IPBX\_VisualObject CreateControl method. After getting the class name with the IPBX\_VisualObject GetClassName method, CreateControl passes the class name to the Windows CreateWindowEx method to create the window, then returns the window handle to the PBVM:

```

TCHAR CVVisualExt::s_className[] = "PBVisualExt";

LPCTSTR CVVisualExt::GetWindowClassName()
{
    return s_className;
}

HWND CVVisualExt::CreateControl
(
    DWORD dwExStyle,           // extended window style
    LPCTSTR lpWindowName,     // window name
    DWORD dwStyle,             // window style
    int x,                     // horizontal position of window
    int y,                     // vertical position of window
    int nWidth,                // window width
    int nHeight,               // window height
    HWND hWndParent,           // handle to parent or
                               // owner window
    HINSTANCE hInstance       // handle to application
                               // instance
)
{
    d_hwnd = CreateWindowEx(dwExStyle, s_className,
                           lpWindowName, dwStyle, x, y, nWidth, nHeight,
                           hWndParent, NULL, hInstance, NULL);

    ::SetWindowLong(d_hwnd, GWL_USERDATA, (LONG)this);
    return d_hwnd;
}

```

## Event processing in visual extensions

A visual extension can have a window procedure that can process any Windows message or user-defined message. The PBVM passes all such messages to the visual extension, which can intercept messages and either process or ignore them.

WindowProc is an application-defined callback function that processes messages sent to a window. In the example in this section, a WM\_PAINT message is sent to the extension when an action in the PowerBuilder application causes the window to be redrawn. When the extension receives the message, it repaints an area in the window using the current values for text and color set by the user of the application.

The following example also captures mouse clicks and double clicks, and triggers the Onclick and Ondoubleclick event scripts in the PowerBuilder application. You can use two different syntaxes for describing events:

```
event returnType eventName(args_desc) newline
event eventName pbevent_token newline
```

## Using an event name with return type and arguments

The following description uses the first syntax. The class has two events, onclick and ondoubleclick:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class visualext from userobject\n"
        "event int onclick()\n"
        "event int ondoubleclick()\n"
        "subroutine setcolor(int r, int g, int b)\n"
        "subroutine settext(string txt)\n"
        "end class\n"
    };
    return desc;
}
```

**Capturing messages  
and mouse clicks**

The code in the extension captures the Windows messages that cause the window to be drawn, as well as mouse clicks and double clicks:

```
LRESULT CALLBACK CVisualExt::WindowProc(
    HWND hwnd,
    UINT uMsg,
    WPARAM wParam,
    LPARAM lParam
)
{
    CVisualExt* ext = (CVisualExt*)::GetWindowLong(hwnd,
        GWL_USERDATA);
    switch(uMsg) {

        case WM_CREATE:
            return 0;

        case WM_SIZE:
            return 0;

        case WM_COMMAND:
            return 0;

        case WM_PAINT: {
            PAINTSTRUCT ps;
            HDC hdc = BeginPaint(hwnd, &ps);
            RECT rc;
            GetClientRect(hwnd, &rc);
            LOGBRUSH lb;
            lb.lbStyle = BS_SOLID;

            // Get color using the visual class's GetColor method
            lb.lbColor = ext->GetColor();
            HBRUSH hbrush = CreateBrushIndirect(&lb);
            HBRUSH hbrOld = (HBRUSH)SelectObject(hdc,
                hbrush);
            Rectangle(hdc, rc.left, rc.top, rc.right-rc.left,
                rc.bottom-rc.top);
            SelectObject(hdc, hbrOld);
            DeleteObject(hbrush);

            // Get text using the visual class's GetText method
            DrawText(hdc, ext->GetText(),
                ext->GetTextLength(), &rc,
                DT_CENTER|DT_VCENTER|DT_SINGLELINE);
            EndPaint(hwnd, &ps);
        }
    }
}
```

```
        }

        return 0;

// Trigger event scripts in the PowerBuilder application
case WM_LBUTTONDOWN:
    ext->TriggerEvent ("onclick");
    break;

case WM_LBUTTONDBLCLK:
    ext->TriggerEvent ("ondoubleclick");
    break;
}

return DefWindowProc(hwnd, uMsg, wParam, lParam);
}
```

Triggering click events

The following is the TriggerEvent method that triggers the Onclick and Ondoubleclick events:

```
void CVisualExt::TriggerEvent (LPCTSTR eventName)
{
    pbclass cls = d_session->GetClass(d_pbobj);
    pbmethodID mid = d_session->GetMethodID(cls,
        eventName, PBRT_EVENT, "I");

    PBCallInfo ci;
    d_session->InitCallInfo(cls, mid, &ci);
    d_session->TriggerEvent(d_pbobj, mid, &ci);
    d_session->FreeCallInfo(&ci);
}
```

## Using an event name with a PowerBuilder event ID

A simpler way to trigger events in a visual extension uses direct mapping of Windows messages to PowerBuilder events. The following class description contains the same two events, but in this case they use the alternative syntax that maps the event name to a PowerBuilder token name:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class visualext from userobject\n"
        "event onclick pbm_lbuttonup\n"
        "event ondoubleclick pbm_lbuttondblclk\n"
        "subroutine setcolor(int r, int g, int b)\n"
        "subroutine settext(string txt)\n"
        "end class\n"
    };
    return desc;
}
```

Generating event syntax automatically

Importing the extension generates the Onclick and Ondoubleclick events with the appropriate arguments automatically, and at runtime, the PBVM fires the events. You do not need to capture the Windows messages WM\_LBUTTONUP and WM\_LBUTTONDOWNDBLCLK in the extension.

In the following description, *onclick* is the event name and *pbm\_lbuttonup* is the event token name. Notice that the event name is not followed by empty parentheses as it is when you use the return type and arguments technique for describing the event:

```
"event onclick pbm_lbuttonup\n"
```

About the token name

The token name is a string that maps to an internal PowerBuilder event ID defined in the header file *pbevid.h*. The first ID in this file is PB\_NULL. For all other IDs in the file, there is a fixed relationship between the name that you use in the description and the event ID in *pbevid.h*. The name is the same as the ID with the letter *m* appended to the *pb* prefix. You must use lowercase in the description.

For example, the event ID *PB\_ACTIVATE* in *pbevid.h* maps to the token name *pbm\_activate*. In the description provided with *PBX\_GetDescription*, you must use the name *pbm\_activate*. If the event name you provide does not exist, importing the extension generates an error message. See the *pbevid.h* file for a complete list of mapped IDs.

## Processing events sent to the parent of the window

Some Windows messages, such as WM\_COMMAND and WM\_NOTIFY, are sent to the parent of an object and not to the object itself. Such messages cannot be caught in the visual extension's window procedure. The PBVM calls the GetEventID method to process these messages, as follows:

- If the message is mapped to a PowerBuilder event, GetEventID returns the event's identifier, for example PB\_BNCLICKED, and the event is fired automatically.
- If the message is not mapped to an event, GetEventID returns the value PB\_NULL and the message is discarded.

In the following example, the GetEventID function returns the identifier PB\_BNCLICKED if a WM\_COMMAND message with the notification code BN\_CLICKED was sent. It returns the identifier PB\_ENCHANGE if a WM\_NOTIFY message was sent. Otherwise, it returns PB\_NULL.

```
TCHAR CVisualExt::s_className[] = "PBVisualExt";

LPCTSTR CVisualExt::GetWindowClassName()
{
    return s_className;
}

HWND CVisualExt::CreateControl
(
    DWORD dwExStyle,           // extended window style
    LPCTSTR lpWindowName,     // window name
    DWORD dwStyle,             // window style
    int x,                     // horizontal position of window
    int y,                     // vertical position of window
    int nWidth,                // window width
    int nHeight,               // window height
    HWND hWndParent,           // handle of parent or owner window
    HINSTANCE hInstance // handle of application instance
)
{
    d_hwnd = CreateWindowEx(dwExStyle, s_className,
                           lpWindowName, dwStyle, x, y, nWidth, nHeight,
                           hWndParent, NULL, hInstance, NULL);

    ::SetWindowLong(d_hwnd, GWL_USERDATA, (LONG)this);

    return d_hwnd;
}
```

```
int CVvisualExt::GetEventID(
    HWND      hWnd,          /* Handle of parent window */
    UINT      iMsg,          /* Message sent to parent window*/
    WPARAM    wParam,        /* Word parameter of message*/
    LPARAM    lParam         /* Long parameter of message*/
)
{
    if (iMsg == WM_COMMAND)
    {
        if ((HWND)lParam == d_hwnd)
        {
            switch(HIWORD(wParam))
            {
                case BN_CLICKED:
                    return PB_BNCLICKED;
                    break;
            }
        }
    }

    if (iMsg == WM_NOTIFY)
    {
        return PB_ENCHANGE;
    }
    return PB_NULL;
}
```

## Calling PowerScript from an extension

You can call PowerBuilder system functions through IPB\_Session. The InitCallInfo method simplifies the process of setting up the call information. You need to provide the arguments to the InitCallInfo method, including an identifier for the PowerBuilder function you want to call.

The identifier can be returned from the GetMethodID or FindMatchingFunction method.

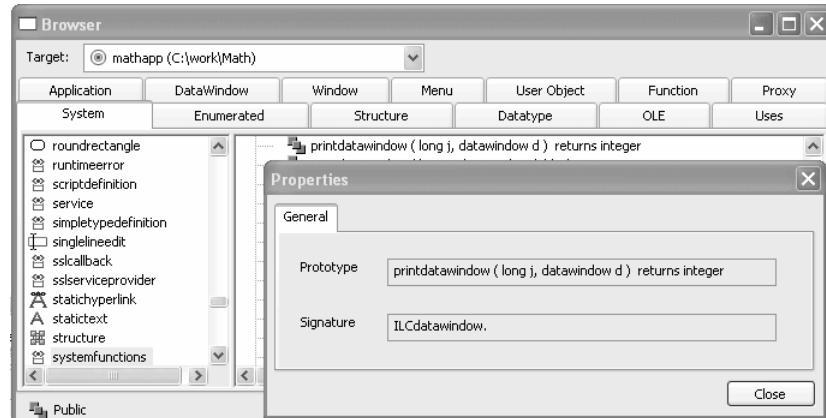

### Using GetMethodID

To get the function's ID using the GetMethodID method, you need the function's signature:

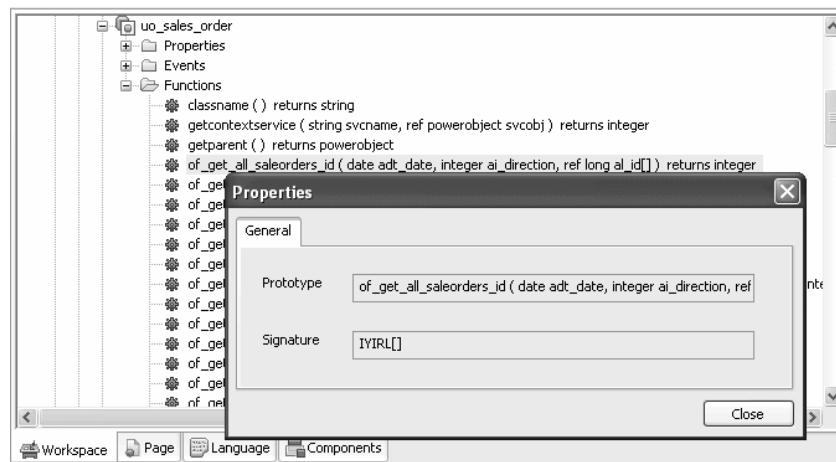

```
PbmethodID GetMethodID(pbclass c/s, LPCTSTR
methodName, PBRoutineType rt, LPCTSTR signature);
```

The *signature* argument in this method call is a string representing the method's return type and arguments. You can obtain this string in the Browser.

For example, to obtain the signature of a system function, select systemfunctions from the left pane of the System page, right-click the function in the right pane, and select Properties from its pop-up menu:

For methods in your application, you can expand the object that contains it in the System Tree, select the function or event, and select Properties from its pop-up menu:

Consider this function:

```
of_get_trans ( ref transaction atr_trans ) returns  
(none)
```

The signature for this function is `QRCtransaction`. Q indicates that the function does not return a value, R that the argument is passed by reference, and Ctransaction that the argument is a PowerBuilder system object of type transaction.

You can use the `pbsig125` command-line tool to obtain a function's signature. However, the `pbsig125` tool does not report the signature of functions that are inherited from an ancestor object unless they are extended in the descendant, and it does not report event signatures.

For more information about using `pbsig125`, and an explanation of all the formats used in the signature, see `pbsig125` on page 255.

#### Using FindMatchingFunction

Instead of the string that `GetMethodID` uses, the `FindMatchingFunction` function provides another way to get the method ID. Some short signatures can be difficult to parse, and signatures that include PowerBuilder system objects or Java classes can be much longer.

`FindMatchingFunction` uses a “readable signature” instead of the string used by `GetMethodID`:

```
FindMatchingFunction(pbclass cls, LPCTSTR methodName,  
PBRoutineType rt, LPCTSTR readableSignature)
```

The `readableSignature` argument is a comma-separated list of the arguments of the function. Unlike the string used by `GetMethodID`, it does not include the return type. For example, for a function called `uf_test` that takes two arguments, an int by value and a double by reference, the call to `FindMatchingFunction` looks like this:

```
mid = Session -> FindMatchingFunction(cls, "uf_test",  
PBRT_FUNCTION, "int, double");
```

#### Invoking PowerBuilder functions

The following methods are those you use most frequently to invoke PowerBuilder functions. For descriptions of each method, see `IPB_Session` interface on page 96.

```
PbmethodID GetMethodID(pbclass cls, LPCTSTR methodName,  
PBRoutineType rt, LPCTSTR signature, pbboolean publiconly)  
PBXRESULT InitCallInfo(pbclass cls, pbmethodID mid, PBCallInfo *ci)  
void FreeCallInfo(PBCallInfo *ci)  
PBXRESULT Add<Type>Argument(PBCallInfo *ci, PBType v);  
PBXRESULT InvokeClassFunction(pbclass cls, pbmethodID mid,  
PBCallInfo *ci)
```

```
PBXRESULT InvokeObjectFunction(pbobject obj, pbmethodID mid,
    PBCallInfo *ci)
PBXRESULT TriggerEvent(pbobject obj, pbmethodID mid,
    PBCallInfo *ci)
```

## Example: Calling PowerBuilder functions

In this code fragment, the class and method ID returned by calls to the IPB\_Session GetClass and GetMethodID methods are used to initialize a PBCallInfo structure, called ci, using the IPB\_Session InitCallInfo method.

After a new *pbstring* variable is created, the value of that string is set to the value of the first argument in the PBCallInfo structure.

```
BOOL CALLBACK CFontEnumerator::EnumFontProc
(
    LPLOGFONT lplf,
    LPNEWTEXTMETRIC lpntm,
    DWORD FontType,
    LPVOID userData
)
{
    UserData* ud = (UserData*)userData;
    pbclass clz = ud->session->GetClass(ud->object);
    pbmethodID mid = ud->session->GetMethodID
        (clz, "onnewfont", PBRT_EVENT, "IS");

    PBCallInfo ci;
    ud->session->InitCallInfo(clz, mid, &ci);

    // create a new string variable and set its value
    // to the value in the first argument in the
    // PBCallInfo structure
    pbstring str = ud->session->NewString
        (lplf->lfFaceName);
    ci.pArgs->GetAt(0)->SetString(str);

    ud->session->TriggerEvent(ud->object, mid, &ci);
    pbint ret = ci.returnValue->GetInt();

    ud->session->FreeCallInfo(&ci);
    return ret == 1 ? TRUE : FALSE;
}
```

## Exception handling and debugging

To handle errors, you use the error codes returned from PBNI methods. Some functions of the IPB\_Session interface return detailed error codes that make debugging easier.

Native methods, such as the IPBX\_UserObject Invoke method, return either PBX\_OK or PBX\_FAIL if the extension encounters a serious problem from which it cannot recover.

Whenever the PowerBuilder VM gets PBX\_FAIL from a native method, it throws a PBXRuntimeError in the PowerBuilder application.

PBXRuntimeError inherits from the PowerBuilder RuntimeError system object and can be caught and handled in a script in the same way as any exception in PowerBuilder.

To catch these errors, wrap your PowerScript call in a try-catch block as follows:

```
TRY
    n_cpp_pbniobj      obj
    obj = CREATE n_cpp_pbniobj
    obj.of_test( arg1 )
CATCH ( PBXRuntimeError re )
    MessageBox( "Caught error", re.getMessage() )
END TRY
```

The IPB\_Session interface provides a set of methods to handle exceptions that occur in native code. Use HasExceptionThrown to determine whether an exception occurred. If it did, use GetException to get the current exception object so that it can be handled. If necessary, you can throw exceptions to PowerBuilder with ThrowException. When an exception has been handled, use ClearException to clear it.

### Debugging

You cannot edit a native class in the PowerBuilder development environment, and you cannot enter native methods in the PowerBuilder debugger because the methods are C++ methods. You must use a C/C++ debugger to debug an extension module.

# Creating Marshaler Extensions

About this chapter

This chapter describes how to create marshaler extensions.

Contents

Topic	Page
About marshaler extensions	45
Developing the PowerBuilder extension	46
Generating proxies for Java classes	53
Calling the Java class from PowerBuilder	54

## About marshaler extensions

Marshaler extensions can act as bridges between PowerBuilder and other components, such as EJB components, Java classes, and Web services, as long as those components can be called from C++.

To create a marshaler extension, build a PBX that contains at least one class that implements the IPBX\_Marshaler interface, as well as one or more native classes. The extension must contain code that associates the marshaler with a proxy for the component you want to call.

If you build a marshaler extension, you should also provide a tool that generates proxies so the components can be called from PowerBuilder. For example, PowerBuilder provides a marshaler extension for calling EJB components from PowerBuilder, and it provides a tool for generating proxies for EJB components.

This chapter provides an overview based on the Java Marshaler sample application, which can be downloaded from the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>, and shows some extracts from the sample.

This chapter describes the major tasks involved in:

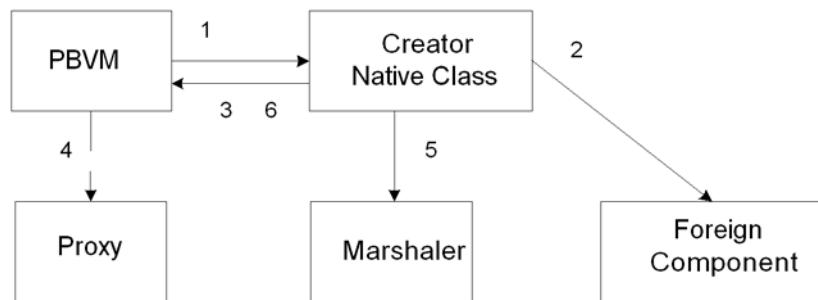

- Developing the PowerBuilder extension
- Generating proxies for Java classes
- Calling the Java class from PowerBuilder

This chapter does not show detailed code samples, and the fragments shown simplify the coding involved. For a more complete understanding of the process of building a marshaler extension, download the sample available on the Web site.

## Developing the PowerBuilder extension

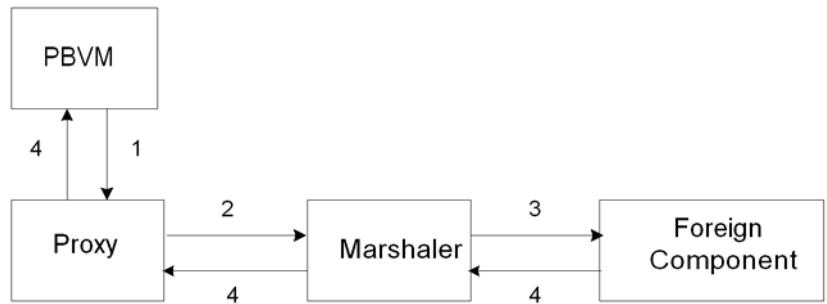

A PowerBuilder marshaler extension usually provides a native class that acts as a creator. This class defines a function that creates an instance of the foreign component that is specified in the parameters passed into the function (1). If it succeeds in creating an instance of the foreign component (2), it creates a proxy for it using the PBVM (3, 4), creates a marshaler object (5), and associates the marshaler with the proxy (6).

*Figure 3-1: Creating a foreign component, proxy, and marshaler*

When a function of the proxy object is called in PowerScript, the PBVM calls the `InvokeRemoteMethod` function on the marshaler object through the proxy (1, 2). The marshaler object translates PowerBuilder function calls into requests that the foreign component understands, sends the requests (3), waits for a response, and send the results back to PowerBuilder (4).

**Figure 3-2: Invoking a remote method**

To develop the extension, you need to:

- Step 1: Describe the extension
- Step 2: Implement the creator class
- Step 3: Implement the marshaler class

## Step 1: Describe the extension

The class that implements the creator, called `CJavaVM` in the following example, must export the `PBX_GetDescription` function. It inherits from `NonVisualObject` and has two functions, `CreateJavaObject` and `CreateJavaVM`:

```

PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class javavm from nonvisualobject\n"
        "function long createjavavm(string classpath,"
        "string properties[])\n"
        "function long createjavaobject(ref powerobject"
        "proxyobject, readonly string javaclassname,"
        "readonly string proxyname)\n"
        "end class\n"
    };
    return desc;
}
  
```

## Step 2: Implement the creator class

Like any nonvisual native class, the CJavaVM class must implement the Invoke and Destroy functions in addition to the class functions CreateJavaObject and CreateJavaVM.

The CreateJavaVm function of CjavaVM gets the classpath and properties from the PBCallInfo structure. Then it loads the Java VM by calling the loadJavaVM function of a wrapper class called JavaVMWrapper. The JavaVMWrapper class encapsulates the JavaVM interface provided by JNI.

The CreateJavaObject function creates an instance of a Java class based on the given class name, creates a PowerBuilder proxy object for the Java object, creates a JavaMarshaler object, and associates the marshaler object with the proxy object.

The following is the CreateJavaObject function:

```
PBXRESULT CJavaVM::CreateJavaObject
{
    IPB_Session *session,
    pobject      obj,
    PBCallInfo   *ci
}
{
    enum
    {
        kSuccessful = 0,
        kInvalidJavaClassName = -1,
        kFailedToCreateJavaClass = -2,
        kInvalidProxyName = -3,
        kFailToCreateProxy = -4
    };

    // Get java class name.
    string jclassName;

    {
        pbstring jcn = ci->pArgs->GetAt(1)->GetPBString();
        if (jcn == NULL)
        {
            ci->returnValue->SetLong(kInvalidJavaClassName);
            return PBX_OK;
        }
    }
}
```

```
        else
        {
            jclassName = session->GetString(jcn);
        }
    }

    // Create java object
JavaVMWrapper* jvm = JavaVMWrapper::instance();
JNIEnv* env = jvm->getEnv();

jclass jcls = env->FindClass(jclassName.c_str());
jobject jobj = NULL;

if (jcls != NULL)
{
    JLocalRef lrClz(env, jcls);

    jmethodID mid = env->GetMethodID(jcls, "<init>",
                                         "()V");
    if (mid != NULL)
    {
        jobj = env->NewObject(jcls, mid);
    }
}

// Get PowerBuilder proxy name
string proxyName;

{
    pbstring pn = ci->pArgs->GetAt(2)->GetPBString();

    if (pn == NULL)
    {
        ci->returnValue->SetLong(kInvalidProxyName);
        return PBX_OK;
    }
    else
    {
        proxyName = session->GetString(pn);
    }
}
```

```
// Find proxy class
pbgroup group = session->FindGroup(proxyName.c_str(), 
    pbgroup_proxy);
if (group == NULL)
{
    ci->returnValue->SetLong(kInvalidProxyName);
    return PBX_OK;
}

pbclass cls = session->FindClass(group,
proxyName.c_str());
if (cls == NULL)
{
    ci->returnValue->SetLong(kInvalidProxyName);
    return PBX_OK;
}

// Create PowerBuilder proxy object.
pbproxyObject proxy = session->NewProxyObject(cls);
if (proxy == NULL)
{
    ci->returnValue->SetLong(kFailToCreateProxy);
    return PBX_OK;
}

// Create JavaMarshaler
JavaMarshaler* marshaler = new JavaMarshaler(env,
proxy, job);

// Associate the JavaMarshaler with the proxy
session->SetMarshaler(proxy, marshaler);

ci->pArgs->GetAt(0)->SetObject(proxy);

ci->returnValue->SetLong(kSuccessful);

return PBX_OK;
}
```

## Step 3: Implement the marshaler class

The marshaler class must implement the `InvokeRemoteMethod` function. It also needs to provide a `Destroy` function and get the handle of the module. This is the declaration:

```
#include <jni.h>
#include <pbext.h>

class JavaMarshaler : public IPBX_Marshaler
{
    jobject      d_jobject;
    pbproxyObject  d_pobject;

public:
    JavaMarshaler(JNIEnv* env, pbproxyObject pobj,
jobject ejbobj);
    ~JavaMarshaler();

    virtual PBXRESULT InvokeRemoteMethod
    (
        IPB_Session* session,
        pbproxyObject obj,
        LPCSTR     method_name,
        PBCallInfo* ci
    );

    virtual pbulong GetModuleHandle();

    virtual void Destroy();
};
```

The `InvokeRemoteMethod` function calls Java functions through JNI. This is the implementation in *JavaMarshaler.cpp*:

```
#include "JavaMarshaler.h"
#include "JMethod.h"
#include "JavaVMWrapper.h"

extern pbulong g_dll_hModule;

pbulong JavaMarshaler::GetModuleHandle()
{
    return g_dll_hModule;
}
```

```
//*****
// JavaMarshaler
//*****
JavaMarshaler::JavaMarshaler
(
    JNIEnv*      env,
    pbproxyObject  pbobj,
    jobject      ejbobj
)
: d_jobject (env->NewGlobalRef(ejbobj)),
  d_pbobject (pbobj)
{
}

JavaMarshaler::~JavaMarshaler()
{
    JNIEnv* env = JavaVMWrapper::instance()->getEnv();

    if (d_jobject != NULL && env != NULL)
        env->DeleteGlobalRef(d_jobject);
}

PBXRESULT JavaMarshaler::InvokeRemoteMethod
(
    IPB_Session*   session,
    pbproxyObject  obj,
    LPCSTR         szMethodDesc,
    PBCallInfo*    ci
)
{
    static char* eFailedToInvokeJavaMethod =
        "Failed to invoke the Java method.";

    JNIEnv* env = JavaVMWrapper::instance()->getEnv();
    JMethod method(this, szMethodDesc);

    try
    {
        if (d_jobject != NULL)
        {
            method.invoke(session, env, d_jobject, ci);
            if (env->ExceptionCheck() == JNI_TRUE)
            {
                string error(eFailedToInvokeJavaMethod);
                error += "\n";
                // Throw exception here
            }
        }
    }
}
```

```
        return PBX_E_INVALID_ARGUMENT;
    }
}
catch(...)

{
}

return PBX_OK;
}

void JavaMarshaler::Destroy()
{
    delete this;
}
```

## Generating proxies for Java classes

You need to develop PowerBuilder proxies for the Java classes you want to invoke from PowerBuilder. You can develop proxies using Java reflection, from Java source code directly, or using the `javap` tool. For example, suppose you want to invoke this Java class:

```
public class Converter
{
    public double dollarToYen(double dollar);
    public double yenToEuro(double yen);
}
```

The PowerBuilder proxy for this Java class could be stored in a file called `converter.srx` that looks like this:

```
$PBExportHeader$converter.srx
$PBExportComments$Proxy generated for Java class

global type Converter from nonvisualobject
end type
global Converter Converter

forward prototypes
    public:
function double dollarToYen(double ad_1) alias
    for "dollarToYen,(D)D"
```

```
function double yenToEuro(double ad_1) alias
    for "yenToEuro, (D) D"
end prototypes
```

Notice that both PowerBuilder proxy methods have an alias containing the Java method name and method signature. This is necessary because Java is case sensitive, but PowerBuilder is not. The extension uses the alias information is used by the extension to find the corresponding Java methods.

To add the proxy to a PowerScript target, select the library where the proxy will be stored in the System Tree, select Import from the pop-up menu, and browse to select *converter.srx*.

## Calling the Java class from PowerBuilder

In the open event of a window, create a Java VM:

```
// instance variable: javavm i_jvm
string properties []
i_jvm = create javavm
string classpath
i_jvm.createjavavm(classpath, properties)
```

In the clicked event of a button on the window, create an instance of the Converter class using the CreateJavaObject method of the JavaVM instance, and call the conv method on the Converter class:

```
converter conv
double yen
i_jvm.createjavaobject(conv, "Converter", "converter")
yen = conv.dollarToYen(100.0)
messagebox("Yen", string(yen))
```

When the CreateJavaObject method is called in PowerScript, the PBVM calls the corresponding C++ method in the extension. The C++ method creates a Java Converter object through JNI. If it is successful, the method creates an instance of the PowerBuilder Converter proxy and a JavaMarshaler object, and associates the JavaMarshaler object with the PowerBuilder proxy.

When `conv.dollarToYen(100.0)` is called in PowerScript, the PowerBuilder VM calls the `InvokeRemoteMethod` method on the JavaMarshaler object, which delegates the call to the Java Converter object though JNI and returns the result to PowerBuilder.

# Exchanging Data with PowerBuilder

## About this chapter

This chapter describes how PBNI extensions exchange data with PowerBuilder.

## Contents

Topic	Page
About exchanging data with PowerBuilder	55
Passing values between extensions and the PBVM	55
Using the IPB_Session interface	59
Saving data from IPB_Value to a local variable	61
Using variables throughout a session	63
Handling enumerated types	64

## About exchanging data with PowerBuilder

You can use the IPB\_Session interface or the IPB\_Value and IPB\_Arguments interfaces to exchange data between PowerBuilder and PBNI. The IPB\_Session interface contains many virtual functions that enable the C++ code in an extension to interact with the PBVM. The IPB\_Value and IPB\_Arguments interfaces contain methods that you can use to pass values between PowerBuilder and extensions.

## Passing values between extensions and the PBVM

PBNI uses two interfaces, IPB\_Value and IPB\_Arguments, to pass PowerBuilder values between the PBVM and extension PBXs. The PBNICallInfo structure holds the data.

## PBCallInfo structure

The PBCallInfo structure is used to hold data and return type information for calls between extensions and the PBVM. It has three public members:

```
IPB.Arguments* pArgs;  
IPB.Value*    returnValue;  
pbclass       returnClass;
```

The following code initializes a PBCallInfo structure using the IPB\_Session InitCallInfo method. After allocating a PBCallInfo structure called *ci*, the IPB\_Session GetClass and GetMethodID methods are used to get the class and method ID of the current method. Then, these parameters are used to initialize the *ci* structure:

```
pbclass cls;  
pbmethodID mid;  
PBCallInfo* ci = new PBCallInfo;  
  
cls = Session -> GetClass(myobj);  
mid = Session -> GetMethodID(cls, "myfunc",  
    PBRT_FUNCTION, "II");  
  
Session -> InitCallInfo(cls, mid, ci);
```

When you have finished using a PBCallInfo structure, you must call FreeCallInfo to release the allocated memory:

```
Session -> FreeCallInfo(ci);  
delete ci;
```

The IPB\_Arguments and IPB\_Value interfaces have methods that enable you to pass values between the PBVM and PowerBuilder extension modules using PBCallInfo to hold the data.

## IPB\_Arguments interface

The IPB\_Arguments interface has two methods:

- GetCount obtains the number of arguments in a method call.
- GetAt obtains the value at a specific index of the pArgs member of the PBCallInfo structure. For each argument, GetAt returns a pointer to the IPB\_Value interface.

The following code fragment uses GetCount and GetAt in a FOR loop to process different argument types. The `ci->pArgs -> GetCount()` statement gets the number of arguments, and `ci -> pArgs -> GetAt(i)` gets the value at the index *i*. This value is a pointer to the IPB\_Value interface on which IPB\_Value methods, such as IsArray and GetArray, can be called (see "IPB\_Value interface" next) :

```
int i;
for (i=0; i < ci->pArgs -> GetCount(); i++)
{
    pbuint ArgsType;
    if( ci -> pArgs -> GetAt(i) -> IsArray())
        pArguments[i].array_val =
            ci -> pArgs -> GetAt(i) -> GetArray();
        continue;
}

if( ci -> pArgs -> GetAt(i) -> IsObject())
{
    if (ci -> pArgs -> GetAt(i) -> IsNull())
        pArguments[i].obj_val=0;
    else
        pArguments[i].obj_val =
            ci -> pArgs -> GetAt(i) -> GetObject();
    continue;
}
...
...
```

## IPB\_Value interface

IPB\_Value has three sets of methods: helper methods, set methods, and get methods.

### Helper methods

The IPB\_Value interface helper methods provide access to information about variables and arguments, including the value's class and type, whether it is an array or simple type, whether it is set by reference, and whether the null flag is set. There is also a method that sets the value to null:

```
virtual pbclass      GetClass() const = 0;
virtual pbint        GetType() const = 0;
virtual pbboolean    IsArray() const = 0;
virtual pbboolean    IsObject() const = 0;
virtual pbboolean    IsByRef() const = 0;
virtual pbboolean    IsNull() const = 0;
virtual PBXRESULT   SetToNull() = 0;
```

The example shown in the previous section, “IPB\_Arguments interface” on page 56, shows how you can use three of these methods: IsArray, IsObject, and IsNull.

This example shows how you can use the SetToNull method to set the returnValue member of the PBCallInfo structure to null:

```
if ( ci->pArgs->GetAt(0)->IsNull() ||  
    ci->pArgs->GetAt(1)->IsNull() )  
{  
    // if either of the passed arguments is null,  
    // return the null value  
    ci->returnValue->SetToNull();
```

#### Set methods

The IPB\_Value set methods set values in the PBCallInfo structure. There is a set method for each PowerBuilder datatype: SetInt, SetUint, SetLong, SetUlong, and so on. These methods automatically set the value represented by IPB\_Value to not null. The syntax is:

```
virtual PBXRESULT Set<type>(<pbtype> arg);
```

For example, the SetLong method takes an argument of type pblong.

In this example, the method has two integer arguments, set to *int\_val1* and *int\_val2*:

```
ci-> pArgs -> GetAt(0) -> SetInt(int_val1);  
ci-> pArgs -> GetAt(1) -> SetInt(int_val2);
```

The IPB\_Value set methods set the datatype of the value represented by IPB\_Value to a specific type. If the original type of the value is any, you can set it to any other type. Then, because the value now has a specific type, setting it to another type later returns the error PBX\_E\_MISMATCHED\_DATA\_TYPE. If the argument is readonly, the error PBX\_E\_READONLY\_ARGS is returned.

#### Get methods

The IPB\_Value get methods obtain values from the PBCallInfo structure. There is a get method for each PowerBuilder datatype: GetInt, GetUint, GetLong, GetUlong, and so on. The syntax is:

```
virtual <pbtype> Get<type>();
```

For example, the GetString method returns a value of type pbstring.

The following example uses the IPB\_Value GetAt method to assign the value at the first index of the pArgs member of the PBCallInfo structure to a variable of type IPB\_Value\* called *pArg*. If *pArg* is not null, the GetLong method sets the variable *longval* to the value in *pArg*:

```
PBCallInfo *ci  
...
```

```
pblong longval = NULL;  
IPB_Value* pArg = ci->pArgs->GetAt(0);  
  
if (!pArg->IsNull())  
    longval = pArg->GetLong();
```

If the value is null, or if you use a get method that is expected to return one datatype when the value is a different datatype (such as using GetLong when the datatype is parray), the result returned is undetermined.

The get methods can also be used with the *returnValue* member of PBCallInfo:

```
ret_val = ci.returnValue->GetInt();  
return ret_val;
```

## Using the IPB\_Session interface

The IPB\_Session interface is an abstract interface that enables the PBVM to interact with PowerBuilder extensions and with external applications. It defines hundreds of methods for accessing PowerScript variables, calling PowerScript methods, handling exceptions, and setting a marshaler to convert PowerBuilder data formats to the user's communication protocol.

The IPB\_Session interface includes several categories of methods:

- Class accessor methods are used to find PowerBuilder classes, call PowerBuilder methods and events, and get and set instance variables of PowerBuilder objects.
- Exception-handling methods communicate with the PowerBuilder exception handling mechanism.
- Array accessor methods create and access PowerBuilder bounded and unbounded arrays.
- Result set accessor methods work with result sets in DataStores and DataWindow controls.
- Typed data access methods create and access data of the PowerBuilder types string, double, decimal, blob, date, time, datetime, and so forth.
- Proxy access methods provide an interface for the implementation of new protocols.
- The Release method releases the IPB\_Session object itself.

For a complete list of methods, see IPB\_Session interface on page 96.

You use IPB\_Session methods in conjunction with IPB\_Value and IPB\_Arguments methods.

The following code fragment shows the body of a method that tests whether a date passed to a PBNI function is handled correctly by a PowerBuilder function. It uses the IPB\_Value SetToNull, SetDate, and IsNull methods to set and test the date values in the PBCallInfo structure, as well as the IPB\_Session SplitDate, SetDate, and NewDate methods.

```
// booleanisNull[], pbobject myobj,
// and pbdate* d_date arguments passed in
pbclass cls;
pbmethodID mid;
PBCallInfo* ci = new PBCallInfo;
pbdate ret_date;
pbint yy,mm,dd;

cls = Session->GetClass(myobj);
mid = Session->GetMethodID(cls, "uf_getdate_byref",
    PBRT_FUNCTION, "YR");
Session->InitCallInfo(cls, mid, ci);

if (isNull[0])
    ci -> pArgs -> GetAt(0) -> SetToNull();
else
    ci-> pArgs -> GetAt(0) -> SetDate(*d_date);

Session->InvokeObjectFunction(myobj, mid, ci);

Session->SplitDate(ci->pArgs->GetAt(0)->GetDate(),
    &yy,&mm,&dd);
Session->SetDate(*d_date, yy, mm, dd);

if (ci-> returnValue -> IsNull())
{
    ret_date = Session-> NewDate();
    Session-> SetDate(ret_val, 1900, 1, 1);
}
else
{
    ret_date = Session-> NewDate();
    Session -> SplitDate(ci-> returnValue -> GetDate(),
        &yy,&mm,&dd);
    Session -> SetDate(ret_val,yy,mm,dd);
}
```

```
Session -> FreeCallInfo(ci);
delete ci;
return ret_date;
```

## Saving data from IPB\_Value to a local variable

To avoid memory leaks, you must call `FreeCallInfo` to free the values stored in the `PBCallInfo` structure after using the structure. However, after making a function call, you might want to save the return value or a by reference argument value into a local variable you can use later.

There are techniques for saving values so they are still available after the call to `FreeCallInfo`. How you save your result into a local variable depends on whether you want to save a simple value, a pointer value, or an object value.

### Saving simple values

Saving simple values is straightforward. When you call one of the `IPB_Value` `Get<type>` methods for a simple value, such as `GetInt` or `GetReal`, the actual data is returned. As a result, you can simply save the values of any of the following datatypes:

```
pbvalue_byte
pbvalue_int
pbvalue_uint
pbvalue_long
pbvalue_ulong
pbvalue_real
pbvalue_double
pbvalue_longlong
pbvalue_boolean
pbvalue_char
```

### Saving pointer values

A pointer value does not contain data. It contains a pointer to a memory location where the data is stored. When you call one of the `IPB_Value` `Get<type>` methods for a pointer value, such as `GetBlob` or `GetTime`, it returns a pointer to memory that is also pointed to by `IPB_Value`.

When you call `FreeCallInfo`, the memory to which `IPB_Value` points is released and the data is deleted. Because this is the same data pointed to by the pointer returned by the `Get<type>` method, that pointer can no longer be used to represent the data.

This applies to the following pointer value datatypes, as well as to the pbarray datatype:

```
pbvalue_dec  
pbvalue_string  
pbvalue_blob  
pbvalue_date  
pbvalue_time  
pbvalue_datetime
```

If you want to save the data in a pointer value, you can use the AcquireValue, AcquireArrayItemValue, and ReleaseValue methods to acquire and release the data. These methods clone a new IPB\_Value that is not freed until you call ReleaseValue and reset the existing IPB\_Value pointer.

---

#### **Can be used for other datatypes**

You can use AcquireValue and AcquireArrayItemValue to acquire values of any datatype.

---

Like the Get<type> methods, AcquireValue and AcquireArrayItemValue return a pointer to the memory where the data is stored, but they also reset the IPB\_Value pointer so that IPB\_Value no longer points to the actual data. When you call FreeCallInfo, the data pointed to by the value acquired using AcquireValue and AcquireArrayItemValue is unaffected.

The original value is reset to zero or null, so it can no longer be used. Attempts to get or acquire the original value return zero or null until another IPB\_Value is set to the value.

If the IPB\_Value acquired using AcquireValue is an array, the entire array is acquired. To acquire only an element of the array, use AcquireArrayItemValue. When you have finished using the data, you must free the memory using the ReleaseValue method.

The processing that the AcquireArrayItemValue and ReleaseValue methods perform results in poor performance when handling large arrays. It is more efficient to get the type of the array and handle each type with appropriate type-specific functions.

---

#### **Caution**

You *must* call the ReleaseValue method to free the data. If you do not do so, a memory leak will occur. You *must not* call ReleaseValue to release a pointer that was not acquired using AcquireValue and AcquireArrayItemValue. Doing so might cause the PBVM to crash.

---

**Saving object values**

Strictly speaking, object values are also pointer values, but the PBVM handles them differently. You use the IPB\_Session AddLocalRef and AddGlobalRef methods to add a reference to the object. If there is a reference to an object, it is not deleted when FreeCallInfo is called.

When you no longer need the object, call RemoveLocalRef or RemoveGlobalRef to decrease the reference count for the object. If the reference count is decreased to zero, the object is deleted automatically.

There is an important difference between AddLocalRef and AddGlobalRef. A reference added by AddLocalRef can be deleted automatically when the local frame is popped up. The local frame can be popped by calling PopLocalFrame or when the current function returns. However, a reference added by AddGlobalRef is deleted only when RemoveGlobalRef is called or the session ends.

You must use these methods in pairs; that is, use RemoveLocalRef to remove references created with AddLocalRef, and use RemoveGlobalRef to remove references created with AddGlobalRef.

## Using variables throughout a session

The SetProp function enables you to use a variable value throughout an IPB session without using a global variable, which is susceptible to namespace conflicts with other sessions. SetProp is one of a set of three functions:

- Use SetProp to register a new variable with the session or to change the value of an existing variable.
- Use GetProp to access the variable.
- Use RemoveProp to remove the variable from the list of variables associated with the session when it is no longer needed.

This set of functions is particularly useful for working with multiple threads of execution in EAServer.

Suppose you want to throw an exception from within a PBNI extension and the exception itself is also defined by the PBNI extension. You call the IPB\_Session NewObject function to create an instance of the exception, causing the PBX\_CreateNonVisualObject function to be called.

One way to set the value of the fields of the exception before the function returns in a thread-safe manner is to create a new object or structure to hold the exception information before calling NewObject. You can call SetProp to store the structure or the object in the current IPB\_Session. When PBX\_CreateNonVisualObject is called, you can call GetProp to get the structure or object to obtain the exception information, then call RemoveProp to remove the data you stored in the current session.

You can also use these functions when initializing and uninitialized a session. If the extension exports the PBX\_NOTIFY function, the PBVM calls PBX\_Notify immediately after an extension PBX is loaded and just before the PBX is unloaded. You can use this function to initialize and uninitialized a session. For example, you could create a session manager object, and store it in the IPB session using the SetProp function. Later, you could use GetProp to obtain the session object.

## Handling enumerated types

The GetEnumItemValue and GetEnumItemName functions allow you to convert the name of an enumerated value to an integer value, and to convert an integer value to the name of an enumerated value.

This example gets the numeric value for the boolean! enumerated value, then uses it to return the string value:

```
pblong lType = session->GetEnumItemValue( "object" ,  
    boolean" ) ; // returns 138  
LPCTSTR szEnum = session->GetEnumItemName( "object" ,  
    lType ) ; // returns "boolean"
```

Notice that the second argument in the GetEnumItemValue call, the enumerated value, must *not* have an appended exclamation mark (!).

To return an enumerated value from an extension to PowerScript, use the SetLong function to set the value of the enumerated variable into IPB\_Value (you cannot use SetInt or SetShort).

To obtain an enumerated variable's value, you can use GetInt or GetShort as well as GetLong, as long as the value is in the appropriate range. For example, if you attempt to use GetInt to obtain a value that is more than 32767, the returned value is truncated.

# Calling PowerBuilder from C++

## About this chapter

A third-party application or server written in C++ can load the PowerBuilder VM, use PowerBuilder nonvisual objects, and use PowerBuilder visual controls. This chapter uses some simple examples to illustrate the process.

## About calling PowerScript from C++ applications

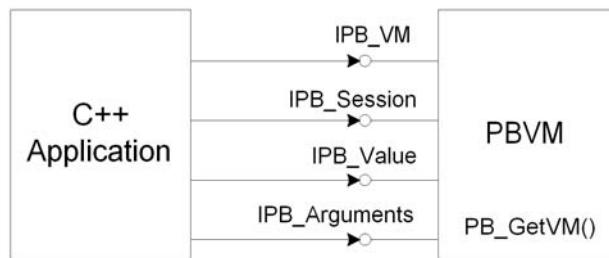

If you have a PowerBuilder custom class user object that performs intensive programming that would be useful to an application that you need to write in C++, you can access the object directly from the C++ application using PBNI. You do not need to make the user object into a COM component or automation server.

To call functions on a PowerBuilder object, you can embed the PBVM in the C++ application. The C++ application must load the PBVM by loading *pbvm125.dll* with the Windows LoadLibrary function, get a pointer to the IPB\_Vm interface by calling the PB\_GetVm function exported by *pbvm125.dll*, and create a session by calling the IPB\_Vm CreateSession function.

The application can then create an instance of the PowerBuilder class and invoke its functions through the IPB\_Session interface.

The following figure illustrates the relationship between the C++ application and the interfaces provided by the PBVM.

**Figure 5-1: Embedding the PBVM in a C++ application**

## Calling PowerBuilder objects from C++

This section presents a simple example that illustrates how to call a function on a PowerBuilder custom class user object from a C++ application:

- Creating a PowerBuilder object to be called from C++
- Getting the signature of a function
- Creating the C++ application
- Running the C++ application

### Creating a PowerBuilder object to be called from C++

To keep the code for this example simple, create an application with one custom class user object that has one function. The function returns the product of two integers:

- 1 In PowerBuilder, create a new workspace.
- 2 Select the Application icon from the Target page of the New dialog box and name the application loadpbvm.
- 3 Select the Custom Class icon from the PB Object page of the New dialog box.

- 4 In the Function prototype window, create a function with this signature:

```
f_mult ( integer arg1, integer arg2 ) returns
integer
```

- 5 Save the user object as nvo\_mult and close the User Object painter.

## Getting the signature of a function

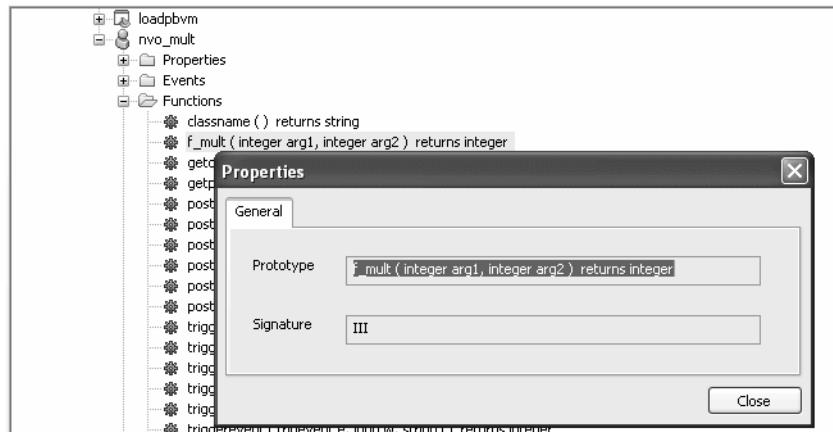

To write the C++ code that invokes the f\_mult function, you need to obtain its method ID. The method ID is used to initialize the PBCallInfo structure and to invoke the function. There are two IPB\_Session functions that return a method ID: GetMethodID, which takes a signature, and FindMatchingFunction, which takes a comma-separated list of arguments. You use the same functions when you call PowerScript from the code in your extension; see “Calling PowerScript from an extension” on page 39.

If you want to use GetMethodID, you need a signature. This function is simple enough that you do not need a tool to obtain a signature—the signature is the string `III`, which indicates that the function returns an integer and takes two integers as arguments.

For more complicated functions, you can get the signature from the System Tree or with the pbsig125 tool.

### Getting a signature from the System Tree

To get the signature of f\_mult in the System Tree, expand nvo\_mult, right-click on the f\_mult function, and select Properties from the pop-up menu. The signature displays in the Properties dialog box in the Signature text box:

Getting a signature  
using pbsig125

To get the signature of f\_mult with pbsig125, type the following at a command prompt:

```
pbsig125 d:\pb1s\loadpbvm.pbl
```

In the output of pbsig125, the comment on the last line contains the signature to be passed as the method ID argument to GetMethodID:

```
PB Object Name: loadpbvm

PB Object Name: nvo_mult
    public function integer f_mult (integer arg1,
        integer arg2)
    /* III */
```

For more information about the pbsig125 tool and the format of method signatures, see pbsig125 on page 255.

## Creating the C++ application

To create the C++ application, follow these steps:

- 1 Load the PowerBuilder VM
- 2 Call PB\_GetVM to get a pointer to the IPB\_VM interface
- 3 Create an IPB\_Session object within IPB\_VM
- 4 Create an instance of the PowerBuilder object
- 5 Initialize the PBCallInfo structure
- 6 Call the PowerBuilder function
- 7 Write cleanup code

## Load the PowerBuilder VM

In your C++ development tool, create a new console application project. The *include* directory for the PBNI SDK, typically *PowerBuilder 12.5\SDK\PBNI\include*, must be in your include path. If you use any helper classes, the source file that contains them must be added to your project. For a list of files and helper classes, see the table in “The PBNI SDK” on page 8.

The code for the C++ application creates an IPB\_VM object using the PB\_GetVM function and loads the PowerBuilder VM:

```
#include "pbext.h"
#include "stdio.h"

typedef PBXEXPORT PBXRESULT (*P_PB_GetVM) (IPB_VM** vm);

int main(int argc, char *argv[])
{
    IPB_Session* session;
    IPB_VM* pbvm = NULL;

    //Load the PowerBuilder VM module
    HINSTANCE hinst = LoadLibrary("pbvm125.dll");
    if ( hinst== NULL) return 0;
    fprintf(stderr, "Loaded PBVM successfully\n");
}
```

## Call PB\_GetVM to get a pointer to the IPB\_VM interface

The next step is to call the PB\_GetVM function to get a pointer to the IPB\_VM interface:

```
P_PB_GetVM getvm = (P_PB_GetVM)GetProcAddress
    (hinst,"PB_GetVM");
if (getvm == NULL) return 0;

getvm(&pbvm);
if (pbvm == NULL) return 0;
```

## Create an IPB\_Session object within IPB\_VM

Next create an IPB\_Session object within IPB\_VM, using the PowerBuilder application's name and library list as arguments:

```
// loadpbvm.pbl must contain an application object
// named loadpbvm and it must be on the search path
// for the executable file
LPCTSTR LibList[] = {"loadpbvm.pbl"};
if ( pbvm->CreateSession("loadpbvm", LibList, 1,
    &session) != PBX_OK )
{
    fprintf(stderr, "Error in CreateSession\n");
    return 1;
}
fprintf(stderr, "Created session successfully\n");
```

## Create an instance of the PowerBuilder object

After the session has been created, the C++ application can create PowerBuilder objects and call PowerBuilder functions in that session.

You use the FindGroup function to locate the group that contains the user object you want to use. FindGroup takes the name of the object as its first argument, and an enumerated type as its second argument. You are looking for a user object, so the second argument is pbgroup\_userobject.

You pass the group returned from FindGroup to the FindClass function to get a class that you can pass to the NewObject function:

```
// Create the PowerBuilder object contained
// in loadpbvm.pbl.
// First find the group that contains the
// user object nvo_mult
pbgroup group = session->FindGroup("nvo_mult",
    pbgroup_userobject);
if (group == NULL) return 0;

// Now find the class nvo_mult in the group
pbclass cls = session->FindClass(group, "nvo_mult");
if (cls == NULL) return 0;

// Create an instance of the PowerBuilder object
pbobject pobj = session->NewObject(cls);
```

## Initialize the PBCallInfo structure

Next, get the method ID for the function you want to call and initialize a PBCallInfo structure. You pass the signature obtained in “Getting the signature of a function” on page 67 to the GetMethodID function:

```
// PBCallInfo contains arguments and return value
PBCallInfo ci;

// To call the class member function f_mult,
// pass its signature as the last argument
// to GetMethodID
pbmethodID mid = session->GetMethodID(cls, "f_mult",
    PBRT_FUNCTION, "III");

// Initialize call info structure based on method ID
session->InitCallInfo(cls, mid, &ci);
```

You could use `FindMatchingFunction` instead of `GetMethodID` to get the method ID. The call would look like this, because `f_mult` takes two integer arguments:

```
pbmethodID mid = session->FindMatchingFunction(cls,  
    "f_mult", PBRT_FUNCTION, "int, int");
```

## Call the PowerBuilder function

Before you call the function, you must supply the integers to be multiplied. For the sake of simplicity, the following code sets them directly in the `PBMethodInfo` structure.

```
// Set IN arguments. The prototype of the function is  
// integer f_mult(integer arg1, integer arg2)  
ci.pArgs->GetAt(0)->SetInt(123);  
ci.pArgs->GetAt(1)->SetInt(45);
```

Finally call the function, wrapping it in a try-catch statement to handle any runtime errors:

```
// Call the function  
try  
{  
    session->InvokeObjectFunction(pobj, mid, &ci);  
  
    // Was PB exception thrown?  
    if (session->HasExceptionThrown())  
    {  
        // Handle PB exception  
        session->ClearException();  
    }  
}  
catch (...)  
{  
    // Handle C++ exception  
}  
  
// Get the return value and print it to the console  
pbint ret = ci.returnValue->GetInt();  
fprintf(stderr, "The product of 123 and 45 is %i\n",  
    ret);
```

## Write cleanup code

When you have finished with the PBCallInfo structure, call FreeCallInfo to release the memory allocated to it, then delete the structure, release the session, and free the library:

```
// Release Call Info  
session->FreeCallInfo(&ci);  
delete &ci;  
  
// Release session  
session->Release();  
return 0;  
FreeLibrary(hinst);  
}
```

## Running the C++ application

When you run the compiled executable file at the command prompt, if the PowerBuilder VM is loaded and the session is created successfully, the following output displays in the command window:

```
Loaded PBVM successfully  
Created session successfully  
The product of 123 and 45 is 5535
```

# Accessing result sets

You can use the IPB\_ResultSetAccessor interface to access result sets in PowerBuilder. Use the IPB\_Session GetResultSetAccessor method to create an instance of the interface using a result set returned from PowerBuilder as the method's argument. You can then use the IPB\_ResultSetAccessor's getColumnCount, GetRowCount, GetItemData, and GetColumnMetaData methods to obtain information from the result set.

GetItemData uses the IPB\_RSItemData interface to handle the data in each cell in the result set. If the data has a date, time, or datetime datatype, it is stored in a PB\_DateData, PB\_TimeData, or PB\_DateTimeData structure.

To create a result set that can be passed to PowerBuilder, use the IPB\_Session CreateResultSet method. See CreateResultSet on page 108 for an example.

## Processing PowerBuilder messages in C++

You can open a PowerBuilder window from a C++ application or from an extension, but to make sure that events triggered in the window or control are processed, you need to make sure that the C++ application processes PowerBuilder messages. The IPB\_Session ProcessPBMessge function lets you do this.

Each time the ProcessPBMessge function is called, it attempts to retrieve a message from the PowerBuilder message queue and process it. The function is similar to the PowerBuilder Yield function, which yields control to other graphic objects and pulls messages from PowerBuilder objects and other graphic objects from the queue. However, ProcessPBMessge processes only one message at a time, and it processes only PowerBuilder messages.

Messages are added to the PowerBuilder message queue when you call the PostEvent function.

*ProcessPBMessge  
must be called  
repeatedly*

You need to make sure that the ProcessPBMessge function is called repeatedly. For most C++ applications, you can provide a message loop in the main function and insert the IPB\_Session ProcessPBMessge function in the message loop. This is shown in the example that follows.

If you use Microsoft Foundation Classes (MFC), you cannot modify the built-in message loop. To ensure that the ProcessPBMessge function is called repeatedly, you can overload the CWnd::WindowProc function and insert ProcessPBMessge into the overloaded function:

```
LRESULT CCallPBVCtrl::WindowProc(UINT message,
    WPARAM wParam, LPARAM lParam)
{
    d_session->ProcessPBMessge();
    return CDialog::WindowProc(message, wParam, lParam);
}
```

## Examples

The following code fragments are from a C++ program that opens a window. The window has a menu item that invokes the Open event of a PowerBuilder application.

Calling  
*ProcessPBMessag*e

The call to ProcessPBMessag is in a loop in the WinMain function:

```
int __stdcall WinMain(HINSTANCE hInstance,
                      HINSTANCE hPrevInstance,
                      LPSTR lpCmdLine,
                      int nCmdShow)
{
    MSG msg;

    WNDCLASSEX wcex;

    // initialization code omitted
    ...
    RegisterClassEx(&wcex);

    HWND hWnd = CreateWindow(szWndClsName,
                            "OpenPBWindow", WS_OVERLAPPEDWINDOW,
                            CW_USEDEFAULT, 0, CW_USEDEFAULT, 0, NULL, NULL,
                            hInstance, NULL);

    if (!hWnd)
    {
        return FALSE;
    }

    ShowWindow(hWnd, nCmdShow);
    UpdateWindow(hWnd);

    try
    {
        while (GetMessage(&msg, NULL, 0, 0))
        {
            TranslateMessage(&msg);
            DispatchMessage(&msg);

            // Call to ProcessPBMessag
            if (session)
                session->ProcessPBMessag();
        }
    }
    catch(...)
    {
        MessageBox(NULL, "Exception occurs",
                  "Exception", MB_OK);
    }
    return msg.wParam;
}
```

### Loading the PBVM and triggering an event

In the WndProc function, when the WM\_CREATE message is passed, the PBVM is loaded and the library list, containing *openwin.pbl*, is passed to CreateSession. When the user selects the menu item that opens the PowerBuilder window, the FindGroup, FindClass, and GetMethodID functions obtain the information needed to create a new application object, initialize the PBCallInfo structure, and trigger the application object's Open event:

```
LRESULT CALLBACK WndProc(HWND hWnd, UINT message,
    WPARAM wParam, LPARAM lParam)
{
    int wmId, wmEvent;
    PAINTSTRUCT ps;
    HDC hdc;

    switch (message)
    {
        case WM_CREATE:
        {
            // Load the PBVM
            hPBVMInst = ::LoadLibrary("pbvm125.dll");
            P_PB_GetVM getvm = (P_PB_GetVM)
                GetProcAddress(hPBVMInst, "PB_GetVM");
            IPB_VM* vm = NULL;
            getvm(&vm);

            // Define the library list and create the session
            static const char *liblist[] = {"openwin.pbl"};
            vm->CreateSession("openwin", liblist, 1,
                &session);
            break;
        }

        case WM_COMMAND:
            wmId     = LOWORD(wParam);
            wmEvent  = HIWORD(wParam);
            // Parse the menu selections:
            switch (wmId)
            {
                case ID_PB_VISUAL:
                {
                    // Initialize PBCallInfo and trigger the
                    // application open event
                    try
                    {
                        pbgroup group = session->FindGroup
                            ("openwin", pbgroup_application);

```

```
pbclass cls = session->FindClass(group,
                                    "openwin");
pbmethodID mid = session->GetMethodID
    (cls, "open", PBRT_EVENT, "QS");
pobject obj = session->NewObject(cls);

PBCallInfo ci;
session->InitCallInfo(cls, mid, &ci);
session->TriggerEvent(obj, mid, &ci);
session->FreeCallInfo(&ci);
}

catch(...)
{
    MessageBox(NULL, "Exception occurs",
               "Exception", MB_OK);
}
break;
}
default:
    return DefWindowProc(hWnd, message, wParam,
                         lParam);
}
break;
case WM_PAINT:
    hdc = BeginPaint(hWnd, &ps);
    RECT rt;
    GetClientRect(hWnd, &rt);
    EndPaint(hWnd, &ps);
    break;
case WM_DESTROY:
    session->Release();
    session = NULL;
    FreeLibrary(hPBVMInst);
    PostQuitMessage(0);
    break;
default:
    return DefWindowProc(hWnd, message, wParam,
                         lParam);
}
return 0;
}
```

**Testing ProcessPBMessage**

You can test the ProcessPBMessage function with a simple PowerBuilder application like this one:

- 1 Create a PowerBuilder application called openwin in *openwin.pbl*.
- 2 Create a main window, *w\_main*, with three buttons.
- 3 Insert a window-level function, *of\_setcolor*, that takes three integers as arguments and has this script:

```
this.backcolor = rgb(red,green,blue)
```

- 4 Insert a window-level user event, *ue\_test*, with this script:

```
MessageBox("ue_test", "This is a user event")
```

- 5 Provide the following scripts for the clicked events of the buttons:

```
//cb_1:  
MessageBox("Button 1", "Clicked")  
parent.of_setcolor(255, 255, 0)
```

```
//cb_2:  
MessageBox("Button 2", "Clicked")  
parent.PostEvent("ue_event") // not fired  
parent.of_setcolor(255, 0, 0)
```

```
//cb_3:  
MessageBox("Button 3", "Clicked")  
cb_1.PostEvent(Clicked!) // not fired
```

- 6 Script the application's Open event:

```
open (w_main)
```

When the ProcessPBMessage function is included in the C++ application, the application runs from C++ as it does in PowerBuilder. The posted events in *cb\_2* and *cb\_3* are processed.

Now try commenting out these lines in the C++ application, recompiling, and running the application again:

```
if (session)  
    session->ProcessPBMessage();
```

The message boxes still display (response windows have their own message loop) and the *of\_setcolor* function is called, but the posted events do not fire.

## More PBNI possibilities

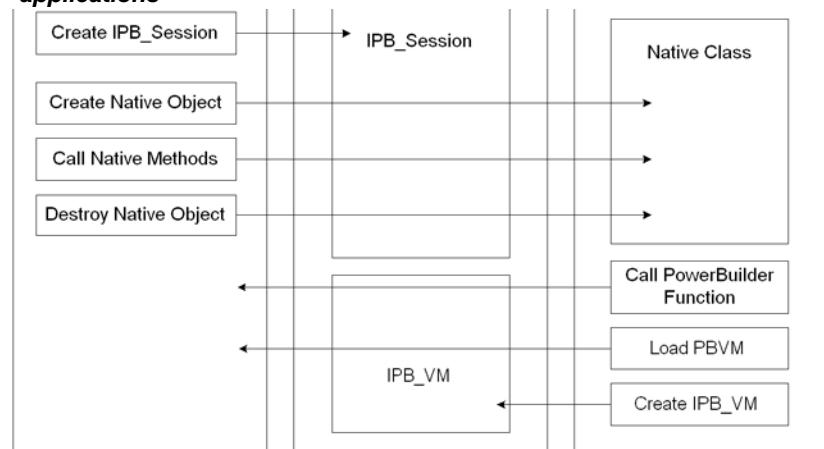

The ability to create visual, nonvisual, and marshaler extensions, and to call PowerBuilder objects from external C++ applications, opens up numerous opportunities to combine these capabilities to develop more complex applications.

Writing an extension that loads the PBVM

Most of the examples in this book and on the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com> show you how to create an extension in C++ and use it in PowerBuilder, or how to write a C++ application that loads the PowerBuilder VM.

You could also write an extension that loads the PowerBuilder VM and uses a custom class user object, using the techniques described in this chapter. The following figure depicts the interaction between the PBVM and an external application that uses an extension.

**Figure 5-2: Interaction between PBNI, the PBVM, and external applications**

Calling PowerBuilder from Java

You can combine the ability to call PowerBuilder classes from C++, as described in this chapter, with the ability to create marshaler extensions, as described in Chapter 3, “Creating Marshaler Extensions,” to call PowerBuilder from Java.

One way to do this is to create a Java proxy class that declares static native methods that can be called to load the PBVM, create PowerBuilder sessions, create PowerBuilder objects, and invoke PowerScript functions. These native methods can call into the PBVM through PBNI. Additional Java classes that represent the PBVM, PowerBuilder sessions, and PowerBuilder objects can be based on the proxy class.

The Java classes call the Java native methods through JNI, whereas the Java native methods call PowerBuilder through PBNI.

There is a sample that illustrates these techniques on the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>.

# Reference

This part contains reference information for PBNI  
datatypes, interfaces, and tools.

# PBNI Types and Return Values

## About this chapter

This chapter contains information about the datatypes, enumerated types, and error return values used by the PowerBuilder Native Interface.

## Contents

Topic	Page
PowerBuilder to PBNI datatype mappings	83
Types for access to PowerBuilder data	84
PBNI enumerated types	84
Error return values	86

## PowerBuilder to PBNI datatype mappings

The following table maps PowerBuilder datatypes to predefined datatypes used in PBNI C++ modules.

*Table 6-1: Predefined datatype mappings*

PowerBuilder datatype	Predefined datatype
Int	pbint
Uint	pbuint
Byte	pbyte
Long	pblong
Longlong	pblonglong
Ulong	pbulong
Boolean	pbboolean
Real	pbreal
Double	pdblue
Decimal	pbdec
Date	pbdate
Time	pbtme
DateTime	pbdatetime
Char	pbchar
Blob	pbblob

PowerBuilder datatype	Predefined datatype
String	pbstring
Powerobject	pobject

## Types for access to PowerBuilder data

The types in the following table enable access to PowerBuilder data.

**Table 6-2: Types for access to PowerBuilder data**

Datatype	Description
pbgroup	Used to access PowerBuilder group information. A group is a container of PowerBuilder classes.
pbclass	Used to access PowerBuilder class definition information.
pbmethoID	Used to access the method ID of a PowerBuilder global or member function.
pbfieldID	Used to access an instance variable.
parray	Used to access array information and data items.

## PBNI enumerated types

Enumerated types for PowerBuilder groups

The pbgroup\_type enumerated types are used in IPB\_Session FindGroup calls to identify the type of group required.

**Table 6-3: Enumerated types for PowerBuilder groups**

Value	PowerBuilder object
pbgroup_application	Application
pbgroup_datawindow	DataWindow definition
pbgroup_function	Global function
pbgroup_menu	Menu
pbgroup_proxy	Proxy definition for a remote object
pbgroup_structure	PowerBuilder structure type
pbgroup_userobject	PowerBuilder user object
pbgroup_window	Window
pbgroup_unknown	Unknown group

Enumerated types for PowerBuilder values

The pbvalue\_type enumerated types are used in methods such as the IPB\_Value GetType method and the IPB\_Session NewUnboundedSimpleArray method to identify the type of PowerBuilder data.

**Table 6-4: Enumerated types for PowerBuilder values**

Value	PowerBuilder datatype
pbvalue_notype	Undetermined datatype.
pbvalue_int	Int
pbvalue_uint	Uint
pbvalue_byte	Byte
pbvalue_long	Long
pbvalue_longlong	Longlong
pbvalue_ulong	Ulong
pbvalue_real	Real
pbvalue_double	Double
pbvalue_dec	Decimal
pbvalue_string	String
pbvalue_boolean	Boolean
pbvalue_any	Any (changed to another datatype when set explicitly)
pbvalue_blob	Blob
pbvalue_date	Date
pbvalue_time	Time
pbvalue_datetime	DateTime
pbvalue_char	Char

Enumerated types for PowerBuilder routines

The pbrt\_type enumerated types are used in IPB\_Session GetMethodID calls to identify the type of routine required.

**Table 6-5: Enumerated types for PowerBuilder routines**

Value	Routine type
PBRT_FUNCTION	Function
PBRT_EVENT	Event

## Error return values

The following table shows the PBXRESULT return values and error codes returned from PBNI methods.

**Table 6-6: PBXResult return values**

Value of PBXResult	Error code
PBX_OK	0
PBX_SUCCESS	0
PBX_FAIL	-1
PBX_E_NO_REGISTER_FUNCTION	-1
PBX_E_REGISTRATION_FAILED	-2
PBX_E_BUILD_GROUP_FAILED	-3
PBX_E_INVALID_ARGUMENT	-4
PBX_E_INVOKE_METHOD_INACCESSABLE	-5
PBX_E_INVOKE_WRONG_NUM_ARGS	-6
PBX_E_INVOKE_REFARG_ERROR	-7
PBX_E_INVOKE_METHOD_AMBIGUOUS	-8
PBX_E_INVOKE_FAILURE	-9
PBX_E_MISMATCHED_DATA_TYPE	-10
PBX_E_OUTOF_MEMORY	-11
PBX_E_GET_PBVM_FAILED	-12
PBX_E_NO SUCH_CLASS	-13
PBX_E_CAN_NOT_LOCATE_APPLICATION	-14
PBX_E_INVALID_METHOD_ID	-15
PBX_E_READONLY_ARGS	-16
PBX_E_ARRAY_INDEX_OUTOF_BOUNDS	-100

# PBNI Interfaces, Structures, and Methods

## About this chapter

This chapter contains reference information about the classes, structures, and methods of the PowerBuilder Native Interface.

## Header file contents

	PBNI classes and interfaces are defined in a set of header files.
pbni.h	The classes, structures, and methods defined in the header file <i>pbni.h</i> allow PowerBuilder extension modules to interact with PowerBuilder. This file also includes the <i>pbarray.h</i> , <i>pbfield.h</i> , and <i>pbnimd.h</i> header files.
pbarray.h, pbfield.h, pbtraits.h, and pbnimd.h	<i>pbarray.h</i> contains helper classes that make it easier to create arrays and access data in them. <i>pbfield.h</i> contains a helper class that makes it easier to access fields. Both header files rely on <i>pbtraits.h</i> , which provides specializations for the Value enumerated types. <i>pbnimd.h</i> contains machine-specific datatype definitions. These files should not be included directly in your code.
pbext.h	The classes, structures, and methods defined in the header file <i>pbext.h</i> must be implemented in PowerBuilder extension modules to allow PowerBuilder applications to use the extension modules. <i>pbext.h</i> includes <i>pbni.h</i> and <i>pbevid.h</i> .
pbevid.h	<i>pbevid.h</i> contains mappings from PowerBuilder event strings to internal event identifiers. These mappings allow the PBVM to automatically fire events that you include in the description of an extension. For more information, see “Event processing in visual extensions” on page 34.
prsa.h	<i>prsa.h</i> contains structures and interfaces used to access data in DataStores and DataWindow controls.

## Class and interface summary

This table lists the classes and interfaces that make up PBNI. After the table, the classes and interfaces are listed in alphabetical order. The methods for each class are listed in alphabetical order after the class description.

Several additional helper classes that are defined in *pbni.h* are not listed in the table. These helper classes include:

- PBArrayInfoHolder and PBCallInfoHolder – used to hold a PBArrayInfo or PBCallInfo variable and release it when it is out of scope
- PBEVENTTrigger, PBOBJECTFunctionInvoker, and PBGlobalFunctionInvoker – used to trigger events and call object and global functions

**Table 7-1: PBNI class and interface summary**

<b>Object</b>	<b>Description</b>	<b>Defined in</b>
IPB_Arguments interface	Used to access the arguments of the PBCallInfo structure.	<i>pbni.h</i>
IPB_ResultSetAccessor interface	Used to access data in a DataWindow or DataStore.	<i>pbrsa.h</i>
IPB_RSItemData interface	Used to set data values in a result set from a DataWindow or DataStore.	<i>pbrsa.h</i>
IPB_Session interface	Used to interoperate with PowerBuilder. An abstract interface, it defines methods for accessing PowerScript data, calling PowerScript functions, catching and throwing PowerScript exceptions, and setting a marshaler to convert PowerBuilder data formats to the user's communication protocol.	<i>pbni.h</i>
IPB_Value interface	Used to hold PowerBuilder data, IPB_Value contains information about each variable, including its type, null flag, access privileges, array or simple type, and reference type.	<i>pbni.h</i>
IPB_VM interface	Used to load PowerBuilder applications in third-party applications and interoperate with the PowerBuilder virtual machine (PBVM).	<i>pbni.h</i>
PBArrayInfo structure	Used to hold information about arrays.	<i>pbni.h</i>
PBCallInfo structure	Used to hold arguments and return type information in function calls between PBNI and PowerBuilder.	<i>pbni.h</i>
PB_DateData structure	Used to pass data of type Date in the SetData function in the IPB_RSItemData interface.	<i>pbrsa.h</i>
PB_DateTimeData structure	Used to pass data of type DateTime in the SetData function in the IPB_RSItemData interface.	<i>pbrsa.h</i>
PB_TimeData structure	Used to pass data of type Time in the SetData function in the IPB_RSItemData interface.	<i>pbrsa.h</i>
PBX_DrawItemStruct structure	Used to hold the properties of an external visual control that you want to draw using the PBX_DrawVisualObject function.	<i>pbext.h</i>
PBArrayAccessor template class	Used to access items in an array.	<i>pbarry.h</i>
PBObjectArrayAccessor class	Used to access items in an object array.	<i>pbarry.h</i>
PBBoundedArrayCreator template class	Used to create bounded arrays.	<i>pbarry.h</i>
PBBoundedObjectArrayCreator class	Used to create bounded object arrays.	<i>pbarry.h</i>
PBBoundedObjectArrayCreator class	Used to create unbounded arrays.	<i>pbarry.h</i>
PBUnboundedObjectArrayCreator class	Used to create unbounded object arrays.	<i>pbarry.h</i>

Object	Description	Defined in
IPBX_Marshaler interface	Used to invoke remote methods and convert PowerBuilder data formats to the user's communication protocol. A marshaler extension is a PowerBuilder extension that acts as the bridge between PowerBuilder and other components, such as EJBs, Java classes, CORBA objects, Web services, and so on.	<i>pbext.h</i>
IPBX_NonVisualObject interface	Inherits from IPBX_UserObject and is the direct ancestor class of nonvisual PowerBuilder native classes.	<i>pbext.h</i>
IPBX_UserObject interface	The ancestor class of PowerBuilder native classes. It has two functions, <i>Destroy</i> and <i>Invoke</i> .	<i>pbext.h</i>
IPBX_VisualObject interface	Inherits from IPBX_UserObject and is the direct ancestor class of visual PowerBuilder native classes.	<i>pbext.h</i>
Exported methods	Some exported methods <i>must</i> be implemented in PowerBuilder extension modules.	<i>pbext.h</i>
Method exported by PowerBuilder VM	The PB_GetVM method is exported by the PowerBuilder VM and is used to pass the IPB_VM interface to the user.	<i>pbni.h</i>

## IPB\_Arguments interface

Description	The IPB_Arguments and IPB_Value interfaces are used to pass values between the PowerBuilder VM and PowerBuilder extension modules. Each argument is represented by a pointer to the IPB_Value interface.
Methods	The IPB_Arguments interface has two methods, <i>GetAt</i> and <i>GetCount</i> .

### GetAt

Description	Returns a pointer to the IPB_Value interface representing an argument whose order in the list of arguments is indicated by a specified index.
Syntax	<code>GetAt ( pbint <i>index</i> )</code>

Argument	Description
<i>index</i>	A valid index into the PBCallInfo structure

Return value	IPB_Value*.
Examples	In the following code fragment, <i>GetAt</i> obtains the first value in the PBCallInfo structure. The value has been passed in from the calling function.

```
PBCallInfo ci;
LPCSTR myPBNIObj = NULL;
IPB_Value* pArg0 = ci->pArgs->GetAt(0);
if (!pArg0->IsNull())
{
    pbstring t = pArg0->GetString();
    if (t != NULL)
        myPBNIObj = session->GetString(t);
}
```

[GetCount](#)

## GetCount

Description

Obtains the number of arguments in an instance of PBCallInfo.

Syntax

`GetCount ()`

Return value

`pbint`.

Examples

This example uses `GetCount` in a FOR loop used to process different argument types:

```
int i;
for (i=0; i < ci->pArgs->GetCount(); i++)
{
    pbuint ArgsType;

    if (ci->pArgs->GetAt(i)->IsArray())

        pArguments[i].array_val =
            ci->pArgs->GetAt(i)->GetArray();
        continue;
    }

    if (ci->pArgs->GetAt(i)->IsObject())
    {
        if (ci->pArgs->GetAt(i)->IsNull())
            pArguments[i].obj_val=0;
        else
            pArguments[i].obj_val =
                ci->pArgs->GetAt(i)->GetObject();
        continue;
    }
    ...
}
```

## **IPB\_ResultAccessor interface**

**Description** The IPB\_ResultAccessor interface is used to access result sets in DataWindow and DataStore objects.

**Methods** The IPB\_ResultAccessor interface has six methods:

AddRef  
GetColumnCount  
GetColumnMetaData  
GetItemData  
GetRowCount  
Release

### **AddRef**

<b>Description</b>	When you call the CreateResultSet function of interface IPB_Session, you need to pass an argument of type IPB_ResultAccessor. The AddRef function is called on that argument and the Release function is called when the pbobject is destroyed.
<b>Syntax</b>	AddRef ()
<b>Return value</b>	None.
<b>See also</b>	CreateResultSet GetColumnCount

### **GetColumnCount**

<b>Description</b>	Obtains the number of columns.
<b>Syntax</b>	GetColumnCount ()
<b>Return value</b>	Unsigned long.
<b>Examples</b>	This statement stores the number of columns in *numCols:  <code>*numCols = d_rsAccessor-&gt;GetColumnCount();</code>
<b>See also</b>	CreateResultSet GetRowCount

## GetColumnMetaData

Description	Obtains a column's metadata. The column number of the first column is 1. Memory must be allocated for <i>columnName</i> before this function call. The pointer values can be null.										
Syntax	GetColumnMetaData (unsigned long <i>columnNum</i> , LPTSTR <i>columnName</i> , pbvalue_type* <i>type</i> , unsigned long* <i>width</i> )										
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>columnNum</i></td><td>The number of the column for which you want to obtain metadata</td></tr> <tr> <td><i>columnName</i></td><td>The name of the specified column</td></tr> <tr> <td><i>type</i></td><td>A pointer to the type of the specified column</td></tr> <tr> <td><i>width</i></td><td>A pointer to the width of the specified column</td></tr> </tbody> </table>	Argument	Description	<i>columnNum</i>	The number of the column for which you want to obtain metadata	<i>columnName</i>	The name of the specified column	<i>type</i>	A pointer to the type of the specified column	<i>width</i>	A pointer to the width of the specified column
Argument	Description										
<i>columnNum</i>	The number of the column for which you want to obtain metadata										
<i>columnName</i>	The name of the specified column										
<i>type</i>	A pointer to the type of the specified column										
<i>width</i>	A pointer to the width of the specified column										
Return value	None.										
Examples	This example gets the number of columns in a result set and allocates an array to hold the types of each column:										
	<pre>CRsltSet::CRsltSet(IPB_ResultSetAccessor* rsAccessor)     :m_lRefCount (0), d_rsAccessor(rsAccessor) {     rsAccessor-&gt;AddRef ();     // for each column     ULONG nNumColumns = d_rsAccessor-&gt;GetColumnCount ();     d_arrColTypes = new USHORT[nNumColumns + 1];     for (ULONG nColumn=1; nColumn &lt;= nNumColumns;         ++nColumn)     {         // get the column type into the array         pbvalue_type type;         d_rsAccessor-&gt;GetColumnMetaData (nColumn,             NULL, &amp;type, NULL);         d_arrColTypes[nColumn] = (USHORT)type;     } }</pre>										
See also	<a href="#">CreateResultSet</a> <a href="#">GetColumnCount</a> <a href="#">GetItemData</a> <a href="#">GetRowCount</a>										

## GetItemData

Description	Accesses the data in a cell. The first row is 1 and the first column is 1.								
Syntax	GetItemData(unsigned long <i>row</i> , unsigned long <i>col</i> , IPB_RSItemData* <i>data</i> )								
	<table border="1"><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>row</i></td><td>The row number of the cell</td></tr><tr><td><i>col</i></td><td>The column number of the cell</td></tr><tr><td><i>data</i></td><td>A pointer to an IPB_RSItemData structure</td></tr></tbody></table>	Argument	Description	<i>row</i>	The row number of the cell	<i>col</i>	The column number of the cell	<i>data</i>	A pointer to an IPB_RSItemData structure
Argument	Description								
<i>row</i>	The row number of the cell								
<i>col</i>	The column number of the cell								
<i>data</i>	A pointer to an IPB_RSItemData structure								
Return value	Boolean.								
Examples	This example stores the data in the first row and column in the IPB_RSItemData structure <i>sd</i> :								
	<pre>d_rsAccessor-&gt;GetItemData(1, 1, &amp;sd);</pre>								
Usage	If the value of <i>data</i> is null, this function issues the callback <i>data</i> -> <i>SetNull</i> . If the value is not null, it issues the callback <i>data</i> -> <i>SetData</i> . For more information, examine the IPB_RSItemData interface.								
See also	<a href="#">CreateResultSet</a> <a href="#">GetColumnCount</a> <a href="#">GetColumnMetaData</a> <a href="#">GetRowCount</a> <a href="#">IPB_RSItemData interface</a> <a href="#">SetData</a> <a href="#">SetNull</a>								

## GetRowCount

Description	Obtains the number of rows.
Syntax	GetRowCount ( )
Return value	Unsigned long.
Examples	This statement stores the number of rows in * <i>numRows</i> :
	<pre>*numRows = d_rsAccessor-&gt;GetRowCount();</pre>
See also	<a href="#">CreateResultSet</a> <a href="#">GetColumnCount</a> <a href="#">GetColumnMetaData</a> <a href="#">GetItemData</a>

## Release

Description	When you call the CreateResultSet function of interface IPB_Session, you need to pass an argument of type IPB_ResultSetAccessor. The AddRef function is called on that argument and the Release function is called when the pobject is destroyed.
Syntax	Release ( )
Return value	None.
See also	AddRef CreateResultSet

## IPB\_RSItemData interface

Description	The IPB_RSItemData interface is used as an argument to the GetItemData function of IPB_ResultSetAccessor.
Methods	The IPB_RSItemData interface has two methods: SetData and SetNull.

## SetData

Description	Sets the data in an IPB_RSItemData structure when the GetItemData function of IPB_ResultSetAccessor is called and the data value is not null.
Syntax	SetData(unsigned long <i>len</i> , void* <i>data</i> )

Argument	Description
<i>len</i>	The length of the data
<i>data</i>	A void pointer to the address of the data

Return value	None.
Usage	If the cell datatype is: <ul style="list-style-type: none"><li>• string and decimal, the address points to a string</li><li>• date, the address points to a PB_DateData structure</li><li>• time, the address points to a PB_TimeData structure</li><li>• datetime, the address points to a PB_DateTimeData structure</li><li>• another datatype, the address points to data of the corresponding type</li></ul>

See also	GetItemData SetNull PB_DateData structure PB_DateTimeData structure PB_TimeData structure
----------	---

## SetNull

Description	Sets the data in an IPB_RSItemData structure to null when the GetItemData function of IPB_ResultSetAccessor is called and the data value is not null.
Syntax	SetNull()
Return value	None.
See also	GetItemData SetData

# IPB\_Session interface

Description	The IPB_Session interface is used to interoperate with PowerBuilder. An abstract interface, it defines methods for accessing PowerScript data, calling PowerScript functions, catching and throwing PowerScript exceptions, and setting a marshaler to convert PowerBuilder data formats to the user's communication protocol.
Methods	This table lists functions by category. Full descriptions in alphabetic order follow the table.

**Table 7-2: IPB\_Session methods by category**

Purpose	Method	Description
Managing sessions	Release	Releases this IPB session. The IPB_Session object becomes invalid after the call.
Managing object references	AddGlobalRef	Adds a global reference to the specified PowerBuilder object.
	AddLocalRef	Adds a local reference to the specified PowerBuilder object.
	NewObject	Creates a new object of the specified type.
	PopLocalFrame	Pops the current local reference frame from the current native method stack frame.

Purpose	Method	Description
Managing shared properties	PushLocalFrame	Pushes a local reference frame onto the current native method stack frame.
	RemoveGlobalRef	Removes a global reference to the specified PowerBuilder object.
	RemoveLocalRef	Removes a local reference to the specified PowerBuilder object.
Managing shared properties	GetProp	Retrieves a pointer to the data value of a variable that has been registered as a shared property for the current IPB session.
	RemoveProp	Removes the specified variable from the list of properties of the current IPB session.
	SetProp	Adds a new variable to the list of properties of the current session or changes the value of an existing variable.
Handling the PowerBuilder message queue	ProcessPBMessage	Checks the PowerBuilder message queue and, if there is a message in the queue, attempts to process it.
Handling exceptions	ClearException	Clears the current PowerBuilder exception object.
	GetException	Obtains the current thrown exception object.
	HasExceptionThrown	Checks for the existence of an exception that has been thrown but not cleared.
	ThrowException	Throws a PowerBuilder exception or inherited exception, replacing the existing exception if one exists.
Passing arguments	Add<type>Argument	Adds an argument in a variable argument PowerBuilder call.
	FreeCallInfo	Frees memory allocated by InitCallInfo.
	InitCallInfo	Initializes the PBCallInfo structure.
Finding PowerBuilder classes and objects	FindGroup	Searches for a group with a given name and group type in the current library list.
	FindClass	Searches for a class with a given name within a given group.
	FindClassByClassID	Searches for a class with a given name and a given ID.
	GetClass	Returns the class handle of a PowerBuilder object.
	GetClassName	Returns the name of a class in lowercase.
	GetCurrGroup	Returns the name of the current group.
	GetSuperClass	Returns the base class of a class, if any.

Purpose	Method	Description
	GetSystemClass	Returns the system class handle of a PowerBuilder object.
	GetSystemGroup	Returns the class that contains all the system global functions.
	IsAutoInstantiate	Returns true if the specified class is an autoinstantiated class; otherwise returns false.
Working with functions and events	FindMatchingFunction	Finds a function that has the specified argument list.
	GetMethodID	Returns the ID of the requested function.
	GetMethodIDByEventID	Returns the ID of the function that has a given predefined PowerBuilder event ID.
	InvokeClassFunction	Invokes system or user global functions.
	InvokeObjectFunction	Invokes a class member function.
	TriggerEvent	Triggers a PowerBuilder event.
Working with enumerated variables	GetEnumItemName	Obtains the name of an enumerated variable.
	GetEnumItemValue	Obtains the value of an enumerated variable.
Working with global variables	GetGlobalVarID	Returns the name of a global variable.
	GetGlobalVarType	Returns the datatype of a global variable.
	Get<type>GlobalVar	Returns the value of a global variable of a specific datatype.
	GetPBAnyGlobalVar	Obtains the value of a global variable of type Any.
	IsGlobalVarArray	Returns true if the global variable contains an array, otherwise returns false.
	IsGlobalVarNull	Returns true if the global variable contains a null value, otherwise returns false.
	IsGlobalVarObject	Returns true if the global variable contains a pbobject, otherwise returns false.
	Set<type>GlobalVar	Sets the value of a global variable of a specific datatype.
	SetGlobalVarToNull	Sets the value of a shared variable to null.
Working with shared variables	GetSharedVarID	Returns the name of a shared variable.
	GetSharedVarType	Returns the datatype of a shared variable.
	Get<type>SharedVar	Returns the value of a shared variable of a specific datatype.

Purpose	Method	Description
Working with shared variables	GetPBAnySharedVar	Obtains the value of a shared variable of type Any.
	IsSharedVarArray	Returns true if the shared variable contains an array, otherwise returns false.
	IsSharedVarNull	Returns true if the shared variable contains a null value, otherwise returns false.
	IsSharedVarObject	Returns true if the shared variable contains a pbobject, otherwise returns false.
	Set<type>SharedVar	Sets the value of a shared variable of a specific datatype.
	SetSharedVarToNull	Sets the value of a shared variable to null.
Working with arrays	Get<type>ArrayItem	Returns the value of an array item of a specific datatype.
	GetArrayInfo	Obtains information about an array.
	GetArrayItemType	Obtains the datatype of an item in an array.
	GetArrayLength	Returns the length of an array.
	GetPBAnyArrayItem	Obtains the value of an array item of type Any.
	IsArrayItemNull	Returns true if the array item contains an array, otherwise returns false.
	NewBoundedSimpleArray	Creates a bounded simple data array.
	NewUnboundedSimpleArray	Creates an unbounded simple data array.
	NewBoundedObjectArray	Creates a bounded PowerBuilder object or structure array.
	NewUnboundedObjectArray	Creates an unbounded PowerBuilder object or structure data array.
	ReleaseArrayInfo	Releases memory returned by GetArrayInfo.
	Set<type>ArrayItem	Sets the value of an array item of a specific datatype.
	SetArrayItemToNull	Sets the value of an array item to null.
Working with strings	GetStringLength	Returns the length of a string in bytes without the terminator.
	GetString	Returns a pointer to the string passed in as an argument.
	NewString	Creates a new string.
	ReleaseString	Releases the memory used by a string.
	SetString	Frees an existing string and assigns a new string value to it.

Purpose	Method	Description
Working with binary large objects	GetBlob	Returns a pointer to the data buffer for a blob.
	GetBlobLength	Returns the length in bytes of blob data in a buffer.
	NewBlob	Creates a new blob and duplicates a buffer for the new blob data.
	SetBlob	Destroys the existing data in a blob and copies data into it from a buffer.
Working with decimal values	GetDecimalString	Converts decimal data in a pbdec object to a string.
	NewDecimal	Allocates resources for a new decimal data object.
	ReleaseDecimalString	Frees the memory acquired using GetDecimalString.
	SetDecimal	Converts a string to a decimal.
Working with date and time values	GetDateString	Converts data in a pbdate object to a string.
	GetDateTimeString	Converts data in a pbdatetime object to a string.
	GetTimeString	Converts data in a pbtime object to a string.
	NewDate	Creates a new pbdate data object.
	NewDateTime	Creates a new pbdatetime data object.
	NewTime	Creates a new pbtime data object.
	ReleaseDateString	Frees the memory acquired using GetDateString.
	ReleaseDateTimeString	Frees the memory acquired using GetDateTimeString.
	ReleaseTimeString	Frees the memory acquired using GetTimeString.
	SetDate	Resets the value of the specified pbdate object.
	SetDateTime	Resets the value of the specified pbdatetime object.
	SetTime	Resets the value of the specified pbtime object.
	SplitDate	Splits the specified pbdate object into a year, month, and day.
	SplitDateTime	Splits the specified pbdatetime object into a year, month, and day.
	SplitTime	Splits the specified pbtime object into a year, month, and day.

Purpose	Method	Description
Working with data values	AcquireArrayItemValue	Clones the data in the PBCallInfo structure in an array item and resets the IPB_Value pointer.
	AcquireValue	Clones the data in the PBCallInfo structure and resets the IPB_Value pointer.
	ReleaseValue	Frees the value acquired by the AcquireValue or AcquireArrayItemValue method.
	SetValue	Sets the value of one IPB_Value object to the value of another IPB_Value object
Working with fields	GetFieldID	Obtains the internal ID of a class instance variable.
	GetFieldName	Obtains the name of the specified field.
	GetFieldType	Obtains the datatype of a class instance variable.
	GetNumOfFields	Obtains the number of fields in the specified class.
	GetPBAAnyField	Obtains the value of a variable of type Any.
	Get<type>Field	Obtains a pointer to the instance variable data for a specified variable.
	IsFieldArray	Returns true if the field contains an array, otherwise returns false.
	IsFieldNull	Returns true if the field contains a null value array, otherwise returns false.
	IsFieldObject	Returns true if the field contains a pbobject, otherwise returns false.
	Set<type>Field	A set of datatype-specific functions. Sets the value of an instance field of an object.
	Set<type>Field	A set of datatype-specific functions. Sets the value of an instance field of an object.
	UpdateField	Refreshes a visual property of a PowerBuilder object.
Working with native classes	GetNativeInterface	Obtains a pointer to the interface of a native class.
	IsNativeObject	Determines whether a pbobject is an instance of a native class.
Accessing result sets from DataWindows and DataStores	CreateResultSet	Creates a result set object using a pointer to an IPB_ResultSetAccessor object.
	GetResultSetAccessor	Obtains an interface through which you can read data from a result set.
	ReleaseResultSetAccessor	Releases the pointer obtained using GetResultSetAccessor.

Purpose	Method	Description
Working with marshaler extensions	GetMarshaler	Obtains the marshaler object associated with a proxy object.
	NewProxyObject	Creates a proxy for a remote object.
	SetMarshaler	Sets a marshaler that will be used to invoke remote methods and convert PowerBuilder data formats to the user's communication protocol.

## AcquireArrayItemValue

Description      Clones the data in the PBCallInfo structure in an array item and resets the IPB\_Value pointer.

Syntax      AcquireArrayItemValue( pbarray *array*, pblong *dim*[ ] )

Argument	Description
<i>array</i>	A valid pbarray structure.
<i>dim</i>	A pblong array to hold the indexes of all dimensions of the array. The size of the array must equal the dimensions of <i>array</i> .

Return value      IPB\_Value\*.

Examples      This FOR loop acquires the value of an item in an array and sets the value in another array:

```
for( i=1; i <= bound; i++)
{
    dim[0] = i;
    ipv = Session -> AcquireArrayItemValue(refArg, dim);
    Session -> SetArrayItemValue(*i_array, dim, ipv);
    Session -> ReleaseValue(ipv);
}
```

Usage      The AcquireArrayItemValue method enables you to retain the data in the PBCallInfo structure for a single array item.

The AcquireArrayItemValue method is independent of the type of the data but is most useful for acquiring the value of pointer values, such as pbvalue\_string, pbvalue\_blob, and so on. When you call FreeInfo, the data is not freed and the pointer returned by AcquireArrayItemValue is still valid.

When you no longer need the data, you *must* call the ReleaseValue method to free the data. Failing to do so causes a memory leak.

The PBVM clones a new IPB\_Value and resets the existing one. If you attempt to get or acquire the original value, the value returned is zero or null until another IPB\_Value is set to the value.

---

### Working with large arrays

The processing that the AcquireArrayItemValue and ReleaseValue methods perform results in poor performance when handling large arrays. It is more efficient to get the type of the array and handle each type with appropriate type-specific functions.

---

See also

ReleaseValue

## AcquireValue

Description

Clones the data in the PBCallInfo structure and resets the IPB\_Value pointer.

Syntax

AcquireValue ( IPBValue\* *value* )

Argument	Description
<i>value</i>	The value to be returned

Return value

IPB\_Value\*.

Examples

The AcquireValue method is used to obtain a message argument value. Later, when the value is no longer needed, it is released using ReleaseValue to avoid memory leaks:

```
// Acquire a value
MessageArg = session->AcquireValue
    ( ci->pArgs->GetAt(0) );
pbstring pbMessage = MessageArg->GetString() ;
Message = (LPSTR)session->GetString(pbMessage) ;
...
// Cleanup phase
if (MessageArg)
{
    Session->ReleaseValue ( MessageArg ) ;
}
```

Usage

The AcquireValue method enables you to retain the data in the PBCallInfo structure. The AcquireValue method is independent of the type of the data but is most useful for acquiring the value of pointer values such as pbvalue\_string, pbvalue\_blob, and so on. When you call FreeInfo, the data is not freed and the pointer returned by AcquireValue is still valid.

If the value acquired is an array, the entire array is acquired. To acquire a single element in an array, use the AcquireItemValue method.

When you no longer need the data, you *must* call the ReleaseValue method to free the data. Failing to do so causes a memory leak.

The PBVM clones a new IPB\_Value and resets the existing one. If you attempt to get or acquire the original value, the value returned is zero or null until another IPB\_Value is set to the value.

## Add<type>Argument

Description	Adds an argument of a specific type in a variable argument PowerBuilder call.
Syntax	<code>AddArrayArgument ( PBCallInfo *ci, pbblob value, pbboolean IsNull )</code> <code>AddBlobArgument ( PBCallInfo *ci, pbblob value, pbboolean IsNull )</code> <code>AddBoolArgument ( PBCallInfo *ci, pbboolean value, pbboolean IsNull )</code> <code>AddByteArgument ( PBCallInfo *ci, pbbyte value, pbboolean IsNull )</code> <code>AddCharArgument ( PBCallInfo *ci, pbchar value, pbboolean IsNull )</code> <code>AddDateArgument ( PBCallInfo *ci, pbdate value, pbboolean IsNull )</code> <code>AddDateTimeArgument ( PBCallInfo *ci, pbdatetime value, pbboolean IsNull )</code> <code>AddDecArgument ( PBCallInfo *ci, pbdec value, pbboolean IsNull )</code> <code>AddDoubleArgument ( PBCallInfo *ci, pbdouble value, pbboolean IsNull )</code> <code>AddIntArgument ( PBCallInfo *ci, pbint value, pbboolean IsNull )</code> <code>AddLongArgument ( PBCallInfo *ci, pblong value, pbboolean IsNull )</code> <code>AddLongLongArgument ( PBCallInfo *ci, pbllong value, pbboolean IsNull )</code> <code>AddObjectArgument ( PBCallInfo *ci, pbobject value, pbboolean IsNull )</code> <code>AddPBStringArgument ( PBCallInfo *ci, pbstring value, pbboolean IsNull )</code> <code>AddRealArgument ( PBCallInfo *ci, pbreal value, pbboolean IsNull )</code> <code>AddStringArgument ( PBCallInfo *ci, LPCTSTR value, pbboolean IsNull )</code> <code>AddTimeArgument ( PBCallInfo *ci, pbtime value, pbboolean IsNull )</code> <code>AddUintArgument ( PBCallInfo *ci, pbuint value, pbboolean IsNull )</code> <code>AddUlongArgument ( PBCallInfo *ci, pbulong value, pbboolean IsNull )</code>

Argument	Description
<i>ci</i>	The PBCallInfo to which the argument is to be added.
<i>value</i>	The value to be added to the arguments array.
<i>IsNull</i>	Indicates whether the argument is null. The default is false.

Return value PBXRESULT. PBX\_OK on success.

Examples This code tests that adding an integer argument to a PBCallInfo structure *ci* works correctly:

```
long Cmy_pbni:: f_Retrieve(IPB_Session* session, pbint
retrieve_args, pobject dwobj)
{
    pbclass cls;
    pbmethodID mid;
    PBCallInfo* ci = new PBCallInfo;
    pblong ret_val;
    PBXRESULT ret;

    cls = session-> GetClass(dwobj);
    mid = session-> GetMethodID
        (cls, "retrieve", PBRT_FUNCTION, "LAV");
    if (mid == kUndefinedMethodID)
        return -1;

    session-> InitCallInfo(cls, mid, ci);

    ci-> pArgs-> GetAt(0)-> SetInt(retrieve_args);
    session-> AddIntArgument(ci, retrieve_args, false);

    ret = session-> InvokeObjectFunction(dwobj, mid, ci);
    if (ret!= PBX_OK)
        ret_val= ret;
    else
        ret_val= ci-> returnValue-> GetLong();

    session-> FreeCallInfo(ci);
    delete ci;

    return ret_val;
}
```

Usage	This call is used in variable argument PowerBuilder calls, such as <code>datawindow.retrieve(arg)</code> . After the call, the value returned by <code>ci-&gt;pArgs-&gt;GetCount()</code> increases by one.
See also	<a href="#">GetCount</a> <a href="#">InvokeClassFunction</a> <a href="#">InvokeObjectFunction</a>

## AddGlobalRef

Description Adds a global reference to the specified PowerBuilder object.

Syntax `AddGlobalRef (pbobject obj)`

Argument	Description
<code>obj</code>	A valid PowerBuilder object handle

Return value `pbclass` or `null` on error.

Examples This example checks whether a return value is `null`, and if it is not, adds a global reference to it to the session:

```
if (ci->returnValue-> IsNull())
    ret_val = 0;
else
{
    ret_val = ci->returnValue-> GetObject();
    Session -> AddGlobalRef(ret_val);
}
```

See also [RemoveGlobalRef](#)

## AddLocalRef

Description Adds a local reference to the specified PowerBuilder object.

Syntax `AddLocalRef (pbobject obj)`

<b>Argument</b>	<b>Description</b>
<i>obj</i>	A valid PowerBuilder object handle

Return value pbclass or null on error.

Examples This example defines functions that add and remove local references:

```
void MyPBNIClass::reference()
{
    d_session->AddLocalRef(d_pbobject) ;
}

void MyPBNIClass::unreference()
{
    if(d_pbobject != NULL)
        d_session->RemoveLocalRef(d_pbobject) ;
}
```

See also [PopLocalFrame](#)  
[PushLocalFrame](#)  
[RemoveLocalRef](#)

## ClearException

Description Clears the current PowerBuilder exception object.

Syntax `ClearException ()`

Return value None.

Usage `HasExceptionThrown` returns false after a call to `ClearException`. If no exception has been thrown, this call has no effect.

See also [GetException](#)  
[HasExceptionThrown](#)  
[ThrowException](#)

## CreateResultSet

Description      Creates a result set object using a pointer to an IPB\_ResultSetAccessor object.

Syntax      CreateResultSet (IPB\_ResultSetAccessor\* *rs*)

Argument	Description
<i>rs</i>	A pointer to an IPB_ResultSetAccessor object

Return value      pbobject.

Examples      This example loads the PBVM and calls the f\_ret and f\_in functions in the custom class user object n\_rs in the PBL *pbrs.pbl*. The PowerScript for the functions is shown after the C++ code:

```
#include "stdafx.h"
#include "windows.h"
#include "pbni.h"
#include "vector"
using std::vector;

void main(int argc, char* argv[])
{
    HINSTANCE hinst = LoadLibrary("pbvm125.dll");

    typedef PBXRESULT (*P_PB_GetVM)(IPB_VM** vm);

    P_PB_GetVM getvm = (P_PB_GetVM)GetProcAddress(hinst,
        "PB_GetVM");
    IPB_VM* pbvm;

    getvm(&pbvm);

    IPB_Session* session = NULL;
    vector<LPCSTR> ll(1);

    ll[0] = "pbrs.pbl";

    pbvm->CreateSession("pbrs", &ll[0], 1, &session);

    pbgroup group = session->FindGroup("n_rs",
        pbgroup_userobject);
    if (group == NULL) return;

    pbclass cls = session->FindClass(group, "n_rs");
    if (cls == NULL) return;

    pbobject obj = session->NewObject(cls);
```

```
    if (obj == NULL) return;

    pbmethodID mid = session->GetMethodID(cls, "f_ret",
        PBRT_FUNCTION, "Cresultset.");
    PBCallInfo ci;
    session->InitCallInfo(cls, mid, &ci);
    session->InvokeObjectFunction(obj, mid, &ci);

    // Use the result set returned from f_ret to
    // create an IPB_ResultSetAccessor rsa
    pobject rs = ci.returnValue->GetObject();
    IPB_ResultSetAccessor* rsa =
        session->GetResultSetAccessor(rs);

    // Create a result set object from rsa
    pobject rsobj = session->CreateResultSet(rsa);

    // Call the f_in method
    mid = session->GetMethodID(cls, "f_in",
        PBRT_FUNCTION, "IRCresultset.");
    PBCallInfo ci1;
    session->InitCallInfo(cls, mid, &ci1);
    // Set the result set object rsobj as the
    // argument for f_in
    ci1.pArgs->GetAt(0)->SetObject(rsobj);
    session->InvokeObjectFunction(obj, mid, &ci1);

    session->FreeCallInfo(&ci);
    session->FreeCallInfo(&ci1);
}
```

f\_ret retrieves data from a database into a DataStore and generates a result set:

```
ResultSet rs
DataStore ds

Long sts
Integer li_ret

// Profile EAS Demo DB V125
SQLCA.DBMS = "ODBC"
SQLCA.AutoCommit = False
SQLCA.DBParm = &
    "ConnectionString='DSN=EAS Demo DB
V125;UID=dba;PWD=sql'"
```

```
connect using sqlca;

ds = Create DataStore
ds.DataObject = ""
ds.DataObject = "d_rs"
ds.SetTransObject(sqlca)
w_main.dw_1.SetTransObject(sqlca)

long ll_ret, rows, rows2
ll_ret = ds.Retrieve()
ll_ret = w_main.dw_1.Retrieve()
//ds.sharedata(w_main.dw_1)
rows = ds.RowCount()
rows2 = w_main.dw_1.RowCount()
messagebox("info from f_ret", " row count is " +
    + string(rows) + " or " + string(rows2))
sts = ds.GenerateResultSet(rs)

Return rs
```

f\_in takes a result set, *rs*, as an argument and uses it to create a DataStore:

```
DataStore ds
Int cnt, li_ret

ds = Create DataStore
ds.CreateFrom(rs)
cnt = ds.RowCount()
messagebox("info from f_in", "row count is " +
    + string(cnt))
Return cnt
```

#### Usage

To use the IPB\_ResultSetAccessor interface, load the PBVM, obtain a result set from a PowerBuilder application, and call GetResultSetAccessor on this result set to get an IPB\_ResultSetAccessor interface object. You can then call the methods of this object to get information about the result set. You can also call CreateResultSet using this object as an argument to create a result set that you can return to PowerBuilder.

When you call CreateResultSet, the AddRef function of the IPB\_ResultSetAccessor interface is called on the *rs* argument implicitly to add a reference to the interface pointer.

GetResultSetAccessor  
IPB\_ResultSetAccessor interface  
ReleaseResultSetAccessor

## FindClass

Description	Searches for a class with a given name within a given group.						
Syntax	<code>FindClass(pbgroup <i>group</i>, LPCTSTR <i>name</i>)</code>						
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>group</i></td><td>The handle of the group in which the class resides</td></tr> <tr> <td><i>name</i></td><td>The class name in lowercase</td></tr> </tbody> </table>	Argument	Description	<i>group</i>	The handle of the group in which the class resides	<i>name</i>	The class name in lowercase
Argument	Description						
<i>group</i>	The handle of the group in which the class resides						
<i>name</i>	The class name in lowercase						
Return value	<code>pbclass</code> or <code>null</code> on failure.						
Examples	This example finds the group associated with the <code>f_getrow</code> function and uses the group to find the class:						
	<pre>group = session-&gt;FindGroup ("f_getrow",     pbgroup_function); if ( group==NULL )     return; cls = session-&gt;<b>FindClass</b>(group, "f_getrow"); if ( cls==NULL )     return;</pre>						
Usage	This method searches for a PowerBuilder class with the given name in the given group. For example, in a window definition <code>w_1</code> , <code>w_1</code> is a group, and controls contained in it are all classes of group <code>w_1</code> .						
See also	<a href="#">FindGroup</a> <a href="#">NewObject</a>						

## FindClassByClassID

Description	Searches for a class with a given name and a given ID.						
Syntax	<code>FindClass(pbgroup <i>group</i>, pbint <i>classID</i>)</code>						
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>group</i></td><td>The handle of the group in which the class resides</td></tr> <tr> <td><i>classID</i></td><td>The class name in lowercase</td></tr> </tbody> </table>	Argument	Description	<i>group</i>	The handle of the group in which the class resides	<i>classID</i>	The class name in lowercase
Argument	Description						
<i>group</i>	The handle of the group in which the class resides						
<i>classID</i>	The class name in lowercase						
Return value	<code>pbclass</code> or <code>null</code> on failure.						
Usage	This method searches for a PowerBuilder class with the given name and the given ID.						
See also	<a href="#">FindGroup</a> <a href="#">NewObject</a>						

## FindGroup

Description Searches for a group with a given name and group type in the current library list.

Syntax `FindGroup(LPCTSTR name, pbgroup_type type)`

Argument	Description
<i>name</i>	The group name in lowercase
<i>type</i>	An enumerated type defined in pbgroup_type

Return value `pbgroup` or `null` on failure.

Examples This example finds the group associated with `user_exception` and uses the group to find the class:

```
group = session->FindGroup("user_exception",
                           pbgroup_userobject);
if ( group==NULL )
    return;
cls = session->FindClass(group, "user_exception")
```

See also [FindClass](#)  
[NewObject](#)

## FindMatchingFunction

Description Finds a function that has the specified argument list.

Syntax `FindMatchingFunction(pbclass cls, LPCTSTR methodName, PBRoutineType rt, LPCTSTR readableSignature)`

Argument	Description
<i>cls</i>	<code>pbclass</code> containing the method.
<i>methodName</i>	The string name of the method in lowercase.
<i>rt</i>	Type of the method: <code>PBRT_FUNCTION</code> for function or <code>PBRT_EVENT</code> for event.
<i>readableSignature</i>	A comma-separated string listing the types of the method's arguments. The return type of the method is not included in the string. See the Usage section for examples.

Return value `pbmethodID`.

**Examples**

This example returns the method ID of a function named `uf_test` that takes an integer and a double as arguments:

```
pbclass cls;
pbmethodID mid;
PBCallInfo* ci = new PBCallInfo;
unsigned long ret_val;

cls = Session -> GetClass(myobj);
mid = Session -> FindMatchingFunction(cls, "uf_test",
    PBRT_FUNCTION, "int, double");

Session -> InitCallInfo(cls, mid, ci);
```

**Usage**

`FindMatchingFunction` provides an alternative to the `GetMethodID` function. It requires a list of the function's arguments (the *readableSignature*) instead of the signature obtained using the `pbsig125` tool.

This table shows the *readableSignature* for each of several functions.

**Table 7-3: FindMatchingFunction readable signature examples**

Function prototype	Signature
<code>void test1()</code>	" "
<code>int test2()</code>	" "
<code>string test3(int a, double b)</code>	"int, double"
<code>datastore test4(powerobject a[], double b[2 to 10, 1 to 7])</code>	"powerobject[], double[2 to 10, 1 to 7]"
<code>int test5(readonly int a[10,20], ref long c[])</code>	"readonly int[10,20], ref long[]"

`FindMatchingFunction` does not check the access type of the function, so you can use it to obtain the method ID of a private function. `GetMethodID` cannot obtain the method ID of a private function.

**See also**

[GetMethodID](#)

## FreeCallInfo

Description	Frees memory allocated by InitCallInfo.				
Syntax	<code>FreeCallInfo(PBCallInfo *ci)</code>				
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><code>ci</code></td><td>A pointer to the preallocated PBCallInfo structure</td></tr></tbody></table>	Argument	Description	<code>ci</code>	A pointer to the preallocated PBCallInfo structure
Argument	Description				
<code>ci</code>	A pointer to the preallocated PBCallInfo structure				
Return value	None.				
Examples	FreeCallInfo should be called when the PBCallInfo structure is no longer needed:  <pre>Session-&gt;InvokeObjectFunction(myobj, mid, ci);  ret_val = ci.returnValue-&gt;GetInt(); Session-&gt; <b>FreeCallInfo</b>(ci); delete ci; return ret_val;</pre>				
Usage	This method frees memory allocated by InitCallInfo but does not free the structure <code>ci</code> itself.				
See also	<a href="#">InitCallInfo</a>				

## Get<type>ArrayItem

Description	Obtains the value of an array item of a specified type.
Syntax	<code>GetBlobArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetBoolArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetByteArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetCharArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetDateArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetDateTimeArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetDecArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetDoubleArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetIntArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetLongArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetLongLongArrayItem (pbarray array, pblonglong dim[ ], pbboolean&amp; IsNull)</code> <code>GetObjectArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code> <code>GetRealArrayItem ( pbarray array, pblong dim[ ], pbboolean&amp; IsNull )</code>

```
GetStringArrayItem ( pbarray array, pblong dim[ ], pbboolean& IsNull )
GetTimeArrayItem ( pbarray array, pblong dim[ ], pbboolean& IsNull )
GetUintArrayItem ( pbarray array, pblong dim[ ], pbboolean& IsNull )
GetUlongArrayItem ( pbarray array, pblong dim[ ], pbboolean& IsNull )
```

Argument	Description
<i>array</i>	A valid pbarray structure
<i>dim</i>	The dimension of the array item to be obtained
<i>IsNull</i>	Indicates whether the array item is null

Return value      The value of the array item.

Examples      This example gets the value of an array item of type pbobject:

```
pbobject      pPDBObject = NULL;
pbboolean     bIsNull = 0;
pblong        dim[1];

dim[0] = pbl + 1;
pPDBObject = session->GetObjectArrayItem(array, dim,
                                             bIsNull);
```

## Get<type>Field

Description A set of methods that gets the value of an instance field of an object.

Syntax GetArrayField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetBlobField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetBoolField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetByteField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetCharField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetDateField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetDateTimeField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetDecField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetDoubleField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetIntField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetLongField( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetLongLongField( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetObjectField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetRealField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetStringField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetTimeField ( pbobject *obj*, pbfieldID *fid*, pbint *value* )

GetUintField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

GetUlongField ( pbobject *obj*, pbfieldID *fid*, pbboolean& *isNull* )

Argument	Description
<i>obj</i>	The handle of the object whose field is to be accessed
<i>fid</i>	The field ID of the specified object
<i>isNull</i>	Indicates whether the field is null

Return value

A predefined PBNI datatype that corresponds to the PowerBuilder datatype in the method name.

Examples

This example gets the value of a field of type pbstring:

```
pbboolean   isNull;
pbstring pstr =
    session->GetStringField(proxy, fid, isNull);
if (pstr != NULL)
{
    myclass = session->GetString(pstr);
    // process myclass
```

}

## Get<type>GlobalVar

**Description** A set of methods that gets the value of a global variable of a specific datatype.

**Syntax**

GetArrayGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetBlobGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetBoolGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetByteGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetCharGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetDateGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetDateTimeGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetDecGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetDoubleGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetIntGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetLongGlobalVar( pbfieldID *fid*, pbboolean& *isNull* )  
GetLongLongGlobalVar( pbfieldID *fid*, pbboolean& *isNull* )  
GetObjectGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetRealGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetStringGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetTimeGlobalVar ( pbfieldID *fid*, pbint *value* )  
GetUintGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )  
GetUlongGlobalVar ( pbfieldID *fid*, pbboolean& *isNull* )

Argument	Description
<i>fid</i>	The field ID of the global variable
<i>isNull</i>	Indicates whether the variable is null

Return value	A predefined PBNI datatype that corresponds to the PowerBuilder datatype in the method name.
Examples	This code gets the value of a global variable of datatype long using its field ID: <pre>fid = session -&gt; GetGlobalVarID("l_gvar"); l_val = session -&gt; <b>GetLongGlobalVar</b>(fid, isNull); session -&gt; SetLongGlobalVar(fid, l_val + 1);</pre>
See also	<a href="#">GetGlobalVarID</a> <a href="#">GetGlobalVarType</a> <a href="#">IsGlobalVarArray</a> <a href="#">IsGlobalVarNull</a> <a href="#">IsGlobalVarObject</a> <a href="#">SetGlobalVarToNull</a> <a href="#">Set&lt;type&gt;GlobalVar</a>

## Get<type>SharedVar

Description	A set of methods that gets the value of a shared variable of a specific datatype.
Syntax	<a href="#">GetArraySharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetBlobSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetBoolSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetByteSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetCharSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetDateSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetDateTimeSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetDecSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetDoubleSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetIntSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetLongSharedVar( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetLongLongSharedVar( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetObjectSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetRealSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetStringSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetTimeSharedVar ( pbgroup group, pbfieldID fid, pbint value )</a> <a href="#">GetUintSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a> <a href="#">GetUlongSharedVar ( pbgroup group, pbfieldID fid, pbboolean&amp; isNull )</a>

Argument	Description
<i>group</i>	The group whose shared variable is to be accessed
<i>fid</i>	The field ID of the shared variable
<i>isNull</i>	Indicates whether the variable is null

**Return value** A predefined PBNI datatype that corresponds to the PowerBuilder datatype in the method name.

**Examples** This code gets the value of a shared variable of type integer:

```
curGroup = session -> GetCurrGroup();
fid = session -> GetSharedVarID(curGroup, "i_svar");
if (fid == 0xffff)
{
    MessageBox(NULL, "Illegal fid!", "default", MB_OK);
    return;
}
i_val = session-> GetIntSharedVar(curGroup, fid,
    isNull);
session-> SetIntSharedVar(curGroup, fid, i_val+1);
```

**See also** [GetSharedVarID](#)  
[GetSharedVarType](#)  
[IsSharedVarArray](#)  
[IsSharedVarNull](#)  
[IsSharedVarObject](#)  
[Set<type>SharedVar](#)  
[SetSharedVarToNull](#)

## GetArrayInfo

Description      Obtains information about an array.

Syntax      `GetArrayInfo(pbarray array)`

Argument	Description
<code>array</code>	A valid array handle

Return value      `PBArrayInfo*`.

Examples      This IF-ELSE statement populates a PBArrayInfo structure if the array in the first value of a PBCallInfo structure is not null:

```
if ( !(ci->pArgs->GetAt(0)->IsNull()) )  
{  
    array = ci->pArgs->GetAt(0)->GetArray();  
    pArrayInfo = session->GetArrayInfo (array);  
    pArrayItemCount = session->GetArrayLength(array);  
}  
else  
{  
    // NULL array  
    pArrayItemCount = 0;  
}
```

Usage      If the array is an unbounded array, the bounds information in PBArrayInfo is undetermined. The returned PBArrayInfo must be freed later by `ReleaseArrayInfo`.

[Set<type>ArrayItem](#)

## GetArrayItemType

Description                Obtains the datatype of an item in an array.

Syntax                `GetArrayItemType( pbarray array, pblong dim[ ] )`

Argument	Description
<i>array</i>	A valid pbarray structure.
<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .

Return value            pbuint.

See also                [Get<type>ArrayItem](#)

[GetArrayInfo](#)

[SetArrayItemToNull](#)

[SetArrayItemValue](#)

[Set<type>ArrayItem](#)

## GetArrayLength

Description                    Obtains the length of an array.

Syntax                    `GetArrayLength(parray array)`

Argument	Description
<code>array</code>	A valid array handle

Return value                    `pblong`.

Examples                    This IF-ELSE statement populates a PBArrayInfo structure. If the array in the first value of a PBCallInfo structure is not null, it sets the value of the *pArrayItemCount* variable to the length of the array:

```
if ( !(ci->pArgs->GetAt(0)->IsNull()) )  
{  
    array = ci->pArgs->GetAt(0)->GetArray();  
    pArrayInfo = session->GetArrayInfo (array);  
    pArrayItemCount = session->GetArrayLength(array);  
}  
else  
{  
    // NULL array  
    pArrayItemCount = 0;  
}
```

[SetArrayItemToNull](#)  
[SetArrayItemValue](#)  
[Set<type>ArrayItem](#)

## GetBlob

Description Returns a pointer to the data buffer for a blob.

Syntax `GetBlob(ppblob bin)`

Argument	Description
<i>bin</i>	A pointer to the source buffer

Return value `void*`.

Examples In this CASE clause, the value returned from GetBlob is cast to the LPCTSTR variable *pStr*. If it is not null, the return value in the PBCallInfo structure is set to the value of the blob:

```
case pbvalue_blob:  
    pStr = (LPCTSTR)Session-> GetBlob(retVal.blob_val);  
    if (strncmp(pStr, "null", 4)==0 )  
        ci -> returnValue ->SetToNull();  
    else  
    {  
        ci -> returnValue->SetBlob(retVal.blob_val);  
        Session -> ReleaseValue(retVal);  
    }  
    break;
```

See also [GetBlobLength](#)  
[NewBlob](#)  
[SetBlob](#)

## GetBlobLength

Description      Returns the length in bytes of blob data in a buffer.

Syntax      GetBlobLength (pbblob *bin*)

Argument	Description
<i>bin</i>	A pointer to the source buffer

Return value      pblong.

Examples      In this example, the IPB\_Value GetBlob function is used to get a blob value from the PBCallInfo structure. The length of the blob is used as an argument to the NewBlob function:

```
PBCallInfo* ci = new PBCallInfo;
pbblob ret_val;
pblong bloblen;

ret_val = ci.returnValue-> GetBlob();
bloblen = Session-> GetBlobLength(ret_val);
ret_val = Session-> NewBlob
    (Session->GetBlob(ret_val), bloblen);
```

See also      [GetBlob](#)  
[NewBlob](#)  
[SetBlob](#)

## GetClass

**Description** Returns the class handle of a PowerBuilder object. This function is most frequently used to obtain a class handle for use with the GetMethodID function.

**Syntax** `GetClass (pbobject obj)`

<b>Argument</b>	<b>Description</b>
<i>obj</i>	A valid PowerBuilder object handle

**Return value** pbclass or null on error.

**Examples** In this example, GetClass is used to obtain the class of a variable of type UserData so that the class can be used as an argument to the GetMethodID function:

```
BOOL CALLBACK CFontEnumerator::EnumFontProc
(
    LPLOGFONT lplf,
    LPNEWTEXTMETRIC lpntm,
    DWORD FontType,
    LPVOID userData
)
{
    UserData* ud = (UserData*)userData;
    pbclass clz = ud->session->GetClass(ud->object);
    pbmethodID mid = ud->session->GetMethodID
        (clz, "onnewfont", PBRT_EVENT, "IS");

    PBCallInfo ci;
    ud->session->InitCallInfo(clz, mid, &ci);

    pbstring str = ud->session->NewString
        (lplf->lffFaceName);
    ci.pArgs->GetAt(0)->SetPBString(str);
    ud->session->TriggerEvent(ud->object, mid, &ci);
    pbint ret = ci.returnValue->GetInt();
    ud->session->FreeCallInfo(&ci);

    return ret == 1 ? TRUE : FALSE;
}
```

**See also** [GetClassName](#)  
[GetMethodID](#)

## GetClassName

Description	Returns the name of a class in lowercase.				
Syntax	GetClassName(pbclass <i>cls</i> )				
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>cls</i></td><td>A valid class handle</td></tr></tbody></table>	Argument	Description	<i>cls</i>	A valid class handle
Argument	Description				
<i>cls</i>	A valid class handle				
Return value	LPCTSTR.				
Examples	This example gets the name of a class and sets the size of the variable <i>stLength</i> to the length of the returned string plus 1:				
	<pre>LPCTSTR myClassName = session-&gt;GetClassName( myClass ); size_t stLength = strlen( (LPSTR)myClassName ) + 1;</pre>				
Usage	When you have finished using the name, call the ReleaseString method to free the memory acquired.				
See also	<a href="#">GetClass</a> <a href="#">ReleaseString</a>				

## GetCurrGroup

Description	Obtains the name of the current group.
Syntax	GetCurrGroup()
Return value	pbgroup or null on failure.
Examples	This example gets the name of the current group and uses it to obtain the identifier of a shared variable, get the shared variable's value, and reset the shared variable's value:
	<pre>curGroup = session -&gt; GetCurrGroup(); fid = session -&gt; GetSharedVarID(curGroup, "i_svar"); if (fid == 0xffff) {     MessageBox(NULL, "Illegal fid!", "default", MB_OK);     return; } i_val = session-&gt;GetIntSharedVar(curGroup, fid,    isNull); session-&gt;SetIntSharedVar(curGroup, fid, i_val+1);</pre>
See also	<a href="#">Get&lt;type&gt;SharedVar</a> <a href="#">GetSharedVarID</a> <a href="#">Set&lt;type&gt;SharedVar</a>

## GetDateString

Description Converts data in a pbdate object to a string.

Syntax `GetString(pbdate date)`

Argument	Description
<i>date</i>	The pbdate data object to be converted to a string.

Return value LPCTSTR.

See also `NewDate`  
`ReleaseDateString`  
`SetDate`

## GetDateTimeString

Description Converts data in a pbdatetime object to a string.

Syntax `GetDateTimeString(pbdatetime datetime)`

Argument	Description
<i>datetime</i>	The pbdatetime data object to be converted to a string.

Return value LPCTSTR.

See also `NewDateTime`  
`ReleaseDateTimeString`  
`SetDateTime`

## GetDecimalString

Description Converts decimal data in a pbdec object to a string.

Syntax `GetDecimalString(pbdec dec)`

Argument	Description
<code>dec</code>	The pbdec data object to be converted to a string.

Return value LPCTSTR.

Examples This code checks whether a value in the PBCallInfo structure is null. If it is not, it sets the value in the *pArguments* array to the value in PBCallInfo:

```
case pbvalue_dec:  
    if (ci->pArgs->GetAt(i)->IsNull())  
    {  
        pArguments[i].dec_val = Session->NewDecimal();  
        Session->SetDecimal(pArguments[i].dec_val, "1.0");  
    }  
    else  
        pArguments[i].dec_val =  
            ci->pArgs->GetAt(i)->GetDecimalString();  
    break;
```

See also

NewDecimal  
ReleaseDecimalString  
SetDecimal

## GetEnumItemName

Description Obtains the name of an enumerated variable.

Syntax `GetEnumItemName(LPCTSTR enumName, long enumItemValue)`

Return value LPCTSTR.

Usage When you have finished using the name, call the ReleaseString method to free the memory acquired.

See also GetEnumItemValue  
ReleaseString

## GetEnumItemValue

Description	Obtains the value of an enumerated variable.
Syntax	<code>GetEnumItemValue(LPCTSTR enumName, LPCTSTR enumItemName)</code>
Return value	Long.
Examples	This example gets the numeric value for the boolean! enumerated value, then uses it to return the string value:

```
pblong lType = session->GetEnumItemValue("object",
    boolean" ); // returns 138
LPCTSTR szEnum = session->GetEnumItemName( "object",
    lType ); // returns "boolean"
```

Usage	GetEnumItemValue and GetEnumItemName support enumerated types. They allow you to convert the name of an enumerated value, a string with an appended exclamation mark (!), to an integer value, and vice versa.
-------	--

---

### The ! character must be omitted

When you use these functions, the *enumItemName* should not use the appended exclamation mark (!) character.

---

To return an enumerated value from an extension to PowerScript, you must use the SetLong function to set the value of the enumerated variable into IPB\_Value. Using SetInt or SetShort fails. However, you can use GetInt or GetShort as well as GetLong to obtain the enumerated variable's value, assuming the value is in the appropriate range. For example, if you attempt to use GetInt to obtain a value that is more than 32767, the returned value is truncated.

See also	<a href="#">GetEnumItemName</a>
----------	---------------------------------

## GetException

Description	Obtains the current thrown exception object.
Syntax	GetException ()
Return value	pbobject.
Examples	This code gets the current exception object, clears the exception, and gets the class of the exception object:

```
pbclass cls;
pbobject ex;
...
ex = session-> GetException();
session-> ClearException();
cls = session-> GetClass(ex);
```

See also	ClearException HasExceptionThrown
----------	--------------------------------------

## GetFieldID

Description	Obtains the internal ID of a class instance variable.						
Syntax	GetFieldID(pbclass <i>cls</i> , LPCTSTR <i>fieldName</i> )						
Argument	<table border="1"><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>cls</i></td><td>The class in which the field resides</td></tr><tr><td><i>fieldName</i></td><td>The instance member name, in lowercase</td></tr></tbody></table>	Argument	Description	<i>cls</i>	The class in which the field resides	<i>fieldName</i>	The instance member name, in lowercase
Argument	Description						
<i>cls</i>	The class in which the field resides						
<i>fieldName</i>	The instance member name, in lowercase						
Return value	pbfieldID or 0xffff if a field ID cannot be found.						

Examples	This function obtains the identifier of a class's visible field, if it exists, and uses it to set the value of the field:
----------	---

```
void CallBack::f_setvisible(IPB_Session* session,
                            pbobject dwobj)
{
    pbclass cls;
    IPB_Value* pv;
    pbfieldID fid;
    pbstring strttmp;
    bool isTrue;
    pbboolean isNull;

    cls = session-> GetClass(dwobj);
    fid = session-> GetFieldID(cls, "visible");
```

```
        if (fid == kUndefinedFieldID)
            return;
        isTrue = session->GetBoolField(dwobj, fid, isNull);
        if (isTrue)
            session -> SetBoolField(dwobj, fid, false);
        else
            session -> SetBoolField(dwobj, fid, true);
        return ;
    }
```

**Usage**

GetFieldID is one of a set of functions that allows native code to access the fields of Java objects and get and set their values. You use GetFieldID to retrieve the value of a field, specifying the class name and the field name. The field ID returned can be used as an argument to the related functions.

[SetFieldToNull](#)

## GetFieldName

**Description**

Obtains the name of the specified field.

**Syntax**

GetFieldName(pbclass *cls*, pbfieldID *fid*)

Argument	Description
<i>cls</i>	The class that defines the field
<i>fid</i>	The internal ID of the class instance variable

**Return value**

LPCTSTR. The field name of the specified field. If an incorrect field ID is specified, this function returns null.

**Usage**

When you have finished using the name, call the [ReleaseString](#) method to free the memory acquired.

**See also**

[GetFieldID](#)  
[ReleaseString](#)

## GetFieldType

Description                   Obtains the datatype of a field declared by a class.

Syntax                   **GetFieldType(pbclass *cls*, pbfieldID *fid*)**

Argument	Description
<i>cls</i>	The class that defines the field
<i>fid</i>	The internal ID of the class instance variable

Return value               pbint. A simple datatype defined in the list of pbvalue\_type enumerated types, such as pbvalue\_int. See “PBNI enumerated types” on page 84.

Examples                   This statement gets the type of the specified field ID:

```
pbint pbfieldType = session->GetFieldType(cls, fid);
```

See also                   GetFieldID

Get<type>Field  
GetNumOfFields  
IsFieldArray  
IsFieldNull  
IsFieldObject  
Set<type>Field  
SetFieldToNull

## GetGlobalVarID

Description                   Returns the internal ID of a global variable.

Syntax                   **GetGlobalVarID(LPCTSTR *name*)**

Argument	Description
<i>name</i>	The name of the global variable in lowercase

Return value               pbfieldID or null on failure.

Examples                   This example gets the internal identifier of a long variable and uses it to get and set a global variable:

```
fid = session -> GetGlobalVarID("l_gvar");
l_val = session -> GetLongGlobalVar(fid, isNull);
session -> SetLongGlobalVar(fid, l_val + 1);
```

See also                   GetGlobalVarType  
Get<type>GlobalVar  
IsGlobalVarArray

IsGlobalVarNull  
IsGlobalVarObject  
SetGlobalVarToNull  
Set<type>GlobalVar

## GetGlobalVarType

Description                    Obtains the datatype of a global variable.

Syntax                    `GetGlobalVarType(pbfieldID fid)`

<b>Argument</b>	<b>Description</b>
<i>fid</i>	The internal ID of the class instance variable

Return value                `pbuint`. A simple datatype defined in the list of pbvalue\_type enumerated types.

Examples                    This code tests getting and setting a global integer variable using the field ID *fid*:

```
fid = session -> GetGlobalVarID("i_gvar");
if (session -> GetGlobalVarType(fid) == pbvalue_int)
{
    i_val=session -> GetIntGlobalVar(fid,isNull);
    session -> SetIntGlobalVar(fid,i_val+1);
}
```

See also                    [GetGlobalVarID](#)  
[Get<type>GlobalVar](#)  
[IsGlobalVarArray](#)  
[IsGlobalVarNull](#)  
[IsGlobalVarObject](#)  
[SetGlobalVarToNull](#)  
[Set<type>GlobalVar](#)

## GetMarshaler

Description      Obtains the marshaler object associated with a proxy object.

Syntax      **GetMarshaler(pbproxyObject obj)**

Argument	Description
<i>obj</i>	An object of type pbproxyObject for which you want to find the marshaler.

Return value      IPBX\_Marshaler\*.

Examples      This code creates a Java marshaler object and associates it with a proxy. Later, GetMarshaler is used to get the marshaler object:

```
// Create JavaMarshaler
JavaMarshaler* marshaler = new JavaMarshaler(env,
    proxy, jobj);

// Associate the JavaMarshaler with the
// PowerBuilder proxy
session-> SetMarshaler(proxy, marshaler);

ci-> pArgs-> GetAt(0)-> SetObject(proxy);

ci-> returnValue-> SetLong(kSuccessful);

return PBX_OK;
...
// Get the marshaler
IPBX_Marshaler* pIPBX_Marshaler = NULL;

pIPBX_Marshaler =(IPBX_Marshaler*)session
    -> GetMarshaler(proxy);
```

See also      [SetMarshaler](#)

## GetMethodID

Description	Returns the ID of the requested method.
Syntax	GetMethodID(pbclass <i>cls</i> , LPCTSTR <i>methodName</i> , PBRoutineType <i>rt</i> , LPCTSTR <i>signature</i> , pbboolean <i>publicOnly</i> )

Argument	Description
<i>cls</i>	pbclass containing the function.
<i>methodName</i>	The string name of the method in lowercase.
<i>rt</i>	Type of the method: PBRT_FUNCTION for function or PBRT_EVENT for event.
<i>signature</i>	Internal signature of the PowerBuilder function, used to identify polymorphic methods in one class. Obtained with the pbsig125 tool. If the signature is a null string (" "), the first method found with the name <i>methodName</i> is returned.
<i>publicOnly</i>	A boolean that determines whether only public methods are searched (true) or all methods are searched (false). The default is true.

Return value	pbMethodID of the method or kUndefinedMethodID on error.
Examples	This function uses GetMethodID to obtain the identifier ( <i>mid</i> ) of the onnewfont function so that the identifier can be used to initialize the PBCallInfo structure and call the function:

```

BOOL CALLBACK CFontEnumerator::EnumFontProc
(
    LPLOGFONT lplf,
    LPNEWTEXTMETRIC lpntm,
    DWORD FontType,
    LPVOID userData
)
{
    UserData* ud = (UserData*)userData;
    pbclass clz = ud->session->GetClass(ud->object);
    pbmethodID mid = ud->session->GetMethodID(clz,
        "onnewfont", PBRT_EVENT, "IS");

    PBCallInfo ci;
    ud->session->InitCallInfo(clz, mid, &ci);
    pbstring str = ud->session->
        NewString(lplf->lfFaceName);
    ci.pArgs->GetAt(0)->SetPBString(str);
    ud->session->TriggerEvent(ud->object, mid, &ci);
    pbint ret = ci.returnValue->GetInt();
}

```

```
        ud->session->FreeCallInfo(&ci) ;

        return ret == 1 ? TRUE : FALSE;
    }
```

**Usage**

The GetMethodID function is used to obtain the ID of a method so you can use it to invoke functions and trigger events.

**See also**

[FindMatchingFunction](#)

[InvokeObjectFunction](#)

[TriggerEvent](#)

“Calling PowerScript from an extension” on page 39

## GetMethodIDByEventID

**Description**

Returns the ID of the method that has a given predefined PowerBuilder event ID.

**Syntax**

GetMethodIDByEventID(pbclass *c/s*, LPCTSTR *eventID*)

Argument	Description
<i>cls</i>	pbclass containing the method
<i>eventID</i>	A PowerBuilder predefined event string, such as pbm_bnclicked

**Return value**

pbMethodID of the method or kUndefinedMethodID on error.

**Examples**

This statement obtains the ID of the event identified by the name *pbm\_lbuttonup*:

```
pbmethodID mid = d_session->GetMethodIDByEventID(clz,
    "pbm_lbuttonup");
```

**See also**

[GetMethodID](#)

## GetNativeInterface

Description                Obtains a pointer to the interface of a native class.

Syntax                **GetNativeInterface(pbobject *obj*)**

<b>Argument</b>	<b>Description</b>
<i>obj</i>	A valid object handle

Return value            IPBX\_UserObject.

Examples                This example invokes the function `f_retrieve` in the native class `Cmy_pbni` to retrieve a DataWindow object:

```
long f_retrieve(IPB_Session* session, pbint iarg,
                pbobject dwObj, pbobject extObj)
{
    Imy_pbni* pImy_pbni = NULL;
    pblong lRet;
    if (session -> IsNativeObject(extObj) )
    {
        pImy_pbni = (Imy_pbni*) session ->
                      GetNativeInterface(extObj);

        lRet = pImy_pbni-> f_Retrieve(session,
                                         iarg, dwObj);
    }
    return lRet;
}
```

Usage                Use this method in conjunction with `IsNativeObject` to obtain a direct reference to the `IPBX_UserObject` associated with a native class in the same PowerBuilder extension. The class and its methods can then be accessed directly.

See also              `IsNativeObject`

## GetNumOfFields

Description	Returns the number of fields in the specified class.				
Syntax	GetNumOfFields(pbclass <i>cls</i> )				
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>cls</i></td><td>A valid class handle for the class whose field is to be accessed</td></tr></tbody></table>	Argument	Description	<i>cls</i>	A valid class handle for the class whose field is to be accessed
Argument	Description				
<i>cls</i>	A valid class handle for the class whose field is to be accessed				
Return value	pbulong.				
Examples	This code gets the numbers of fields in the class <i>clz</i> :				
	<pre>pbclass clz = d_session-&gt;GetClass(d_pobj) ; pbulong nf = d_session-&gt;<b>GetNumOfFields</b>(clz) ;</pre>				
See also	<a href="#">GetFieldID</a> <a href="#">Get&lt;type&gt;Field</a> <a href="#">IsFieldArray</a> <a href="#">IsFieldNull</a> <a href="#">IsFieldObject</a> <a href="#">SetFieldToNull</a> <a href="#">Set&lt;type&gt;Field</a>				

## GetPBAnyArrayList

Description	Obtains the value of a global variable of type Any.								
Syntax	<b>GetPBAnyArrayList( pbarray array, pblong dim[], pbboolean&amp; isNull )</b>								
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>array</i></td><td>A valid pbarray structure.</td></tr><tr><td><i>dim</i></td><td>A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i>.</td></tr><tr><td><i>isNull</i></td><td>Indicates whether the variable is null</td></tr></tbody></table>	Argument	Description	<i>array</i>	A valid pbarray structure.	<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .	<i>isNull</i>	Indicates whether the variable is null
Argument	Description								
<i>array</i>	A valid pbarray structure.								
<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .								
<i>isNull</i>	Indicates whether the variable is null								
Return value	IPB_Value*.								
Usage	See <a href="#">GetPBAnyField</a> .								
See also	<a href="#">GetPBAnyField</a> <a href="#">GetPBAnyGlobalVar</a> <a href="#">GetPBAnySharedVar</a>								

## GetPBAnyField

Description

Obtains the value of a variable of type Any.

Syntax

`GetPBAnyField( pbobject obj, pbfieldID fid, pbboolean& isNull )`

Argument	Description
<i>obj</i>	A valid object handle for the object whose value is to be obtained
<i>fid</i>	The field ID of the variable
<i>isNull</i>	Indicates whether the variable is null

Return value

`IPB_Value*`.

Examples

This example tests all the functions used to get the value of variables of type Any, using PushLocalFrame and PopLocalFrame to simulate the scope of a function call:

```

session->PushLocalFrame();
pbgroup vgroup = session->FindGroup("n_test",
    pbgroup_userobject);
pbclass vcls = session->FindClass(vgroup, "n_test");
pbobject vobj = session->NewObject(vcls);
pbboolean isNull;

pbfieldID vfid = session->GetFieldID(vcls, "i_a");
IPB_Value* value = session->GetPBAnyField(vobj,
    vfid, isNull);
pbstring str = value->GetString(); // save actual value

vfid = session->GetSharedVarID(vgroup, "s_a");
value = session->GetPBAnySharedVar(vgroup,
    vfid, isNull);
//Get the actual value here.

vfid = session->GetGlobalVarID("g_a");
value = session->GetPBAnyGlobalVar(vfid, isNull);
//Get the actual value here.

vfid = session->GetFieldID(vcls, "i_array");
pbarray arr = session->GetArrayField(vobj,
    vfid, isNull); //Get the any array first.

long dim = 1;
value = session->GetPBAnyArrayItem(arr, &dim, isNull);
//Get the actual value here.
session->PopLocalFrame();

```

**Usage**

The value you retrieve must be of datatype Any to use this function; that is, the variable associated with the function must be declared as a variable of type Any in the development environment. If it is not, the function returns a null pointer and the value of *isNull* is set to true.

This function returns a pointer to an IPB\_Value instance. When it is called, memory is allocated for the returned IPB\_Value instance, and the pointer is recorded in the current local frame. The pointer is deleted automatically when the current local frame is popped, which occurs when the current local function returns (you can also call PopLocalFrame to force the frame to be popped).

If you want to use the value returned, you must save the value pointed to by the IPB\_Value instance (not the IPB\_Value instance itself) before the frame is popped. If you save the pointer itself, the value is only valid until the original value is destroyed.

You can use the AcquireValue function to save the value, or one of the IPB\_Value Get<type> functions. For example, the following code saves the string value in the IPB\_Value instance *ivalue* into the string *str*. The value in *str* can be used after the local frame is popped and *ivalue* is deleted:

```
IPB_Value* ivalue = session->GetPBAnyField(vobj, vfid,  
    isNull);  
pbstring str = ivalue->GetString();
```

If you do not know the actual datatype of the Any variable, use the IPB\_Value GetType function to get its datatype first, then use the appropriate get function to get its value.

---

**IPB\_Value holds a reference to the original value**

The value in the IPB\_Value instance is a reference to the original value. If you change the actual value of the returned IPB\_Value, the original value is also changed. If you use the AcquireValue function to save the value, it clones a new IPB\_Value and resets the existing IPB\_Value pointer.

---

[GetPBAnyGlobalVar](#)  
[GetPBAnySharedVar](#)

## GetPBAnyGlobalVar

Description                Obtains the value of a global variable of type Any.  
 Syntax                 GetPBAnyGlobalVar( pbfieldID *fid*, pbboolean& *isNull* )

<b>Argument</b>	<b>Description</b>
<i>fid</i>	The field ID of the variable
<i>isNull</i>	Indicates whether the variable is null

Return value            IPB\_Value\*.  
 Usage                  See GetPBAnyField.  
 See also               GetPBAnyArrayItem  
                         GetPBAnyField  
                         GetPBAnySharedVar

## GetPBAnySharedVar

Description                Obtains the value of a shared variable of type Any.  
 Syntax                 GetPBAnySharedVar( pbgroup *group*, pbfieldID *fid*, pbboolean& *isNull* )

<b>Argument</b>	<b>Description</b>
<i>group</i>	The group to which the variable belongs
<i>fid</i>	The field ID of the variable
<i>isNull</i>	Indicates whether the variable is null

Return value            IPB\_Value\*.  
 Usage                  See GetPBAnyField.  
 See also               GetPBAnyArrayItem  
                         GetPBAnyField  
                         GetPBAnyGlobalVar

## GetProp

Description      Retrieves a pointer to the data value of a variable that has been registered as a shared property for the current IPB session.

Syntax      GetProp(LPCTSTR *name*)

Argument	Description
<i>name</i>	The name of the variable whose value is to be retrieved.

Return value      Void\*. If the variable does not exist, returns null.

Examples      See SetProp.

Usage      The variable's name must first be registered with the session using the SetProp function.

See also      RemoveProp  
SetProp

## GetResultSetAccessor

Description      Obtains an interface through which you can read data from a result set.

Syntax      GetResultSetAccessor (pbobject *rs*)

Argument	Description
<i>rs</i>	A pbobject holding a result set obtained using CreateResultSet

Return value      IPB\_ResultSetAccessor

Examples      This example gets a result set, *rs*, from the return value of a PowerScript function and uses it to create an IPB\_ResultSetAccessor object, *rsa*:

```
pbobject rs = ci.returnValue->GetObject () ;
IPB_ResultSetAccessor* rsa =
    session->GetResultSetAccessor(rs);
```

See also      CreateResultSet  
ReleaseResultSetAccessor

## GetSharedVarID

Description	Returns the internal ID of a shared variable.						
Syntax	<code>GetSharedVarID(pbgroup group, LPCTSTR fieldname)</code>						
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>group</i></td><td>The group to which the shared variable belongs</td></tr><tr><td><i>fieldname</i></td><td>The name of the field that contains the shared variable, in lowercase</td></tr></tbody></table>	Argument	Description	<i>group</i>	The group to which the shared variable belongs	<i>fieldname</i>	The name of the field that contains the shared variable, in lowercase
Argument	Description						
<i>group</i>	The group to which the shared variable belongs						
<i>fieldname</i>	The name of the field that contains the shared variable, in lowercase						
Return value	<code>pbfieldID</code> . Returns 0xffff if the ID cannot be found.						
Examples	This code uses <code>GetSharedVarID</code> to obtain the field ID of a shared variable, then uses that ID to obtain the value of the variable:						
	<pre>curGroup = session -&gt; GetCurrGroup(); fid = session -&gt; <b>GetSharedVarID</b>(curGroup, "i_svar"); if (fid == 0xffff) {     MessageBox(NULL, "Illegal fid!", "default", MB_OK);     return; } i_val = session -&gt; GetIntSharedVar(curGroup, fid,    isNull);</pre>						
See also	<a href="#">Get&lt;type&gt;SharedVar</a> <a href="#">GetSharedVarType</a> <a href="#">IsSharedVarArray</a> <a href="#">IsSharedVarNull</a> <a href="#">IsSharedVarObject</a> <a href="#">Set&lt;type&gt;SharedVar</a> <a href="#">SetSharedVarToNull</a>						

## GetSharedVarType

Description                    Obtains the datatype of the specified shared variable.

Syntax                    **GetSharedVarType ( pbgroup *group*, pbfieldID *fid* )**

Argument	Description
<i>group</i>	The group to which the shared variable belongs
<i>fid</i>	The internal field ID of the shared variable

Return value                pbuint. A simple datatype defined in the list of pbvalue\_type enumerated types.

Examples                    This example gets the field ID of a shared variable, then uses that ID to get the type of the shared variable:

```
pbuint pbvaltype;
curGroup = session -> GetCurrGroup();
fid = session -> GetSharedVarID(curGroup, "i_svar");
pbvaltype = session -> GetSharedVarType(curGroup, fid);
```

See also                    [Get<type>SharedVar](#)  
[GetSharedVarID](#)  
[IsSharedVarArray](#)  
[IsSharedVarNull](#)  
[IsSharedVarObject](#)  
[Set<type>SharedVar](#)  
[SetSharedVarToNull](#)

## GetString

Description	Returns a pointer to the string passed in as an argument.				
Syntax	GetString (pbstring* <i>string</i> )				
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>string</i></td><td>A pointer to a pbstring</td></tr> </tbody> </table>	Argument	Description	<i>string</i>	A pointer to a pbstring
Argument	Description				
<i>string</i>	A pointer to a pbstring				
Return value	LPCTSTR.				
Examples	<p>This example uses the IPB_Value GetString function to obtain a string value from the PBCallInfo structure. If the string is not null, the IPB_Session GetString function sets the value of the <i>proxyname</i> string to a pointer to the returned value:</p> <pre> string proxyName; {     pbstring pn = ci-&gt;pArgs-&gt;GetAt(2)-&gt;GetString();      if (pn == NULL)     {         ci-&gt;returnValue-&gt;SetLong(kInvalidProxyName);         return PBX_OK;     }     else     {         proxyName = session-&gt;GetString(pn);     } } </pre>				
Usage	When you have finished using the string, call the ReleaseString method to free the memory acquired.				
See also	<a href="#">GetStringLength</a> <a href="#">NewString</a> <a href="#">ReleaseString</a> <a href="#">SetString</a>				

## GetStringLength

Description      Returns the length of a string in bytes without the terminator.

Syntax      **GetStringLength** (*pbstring string*)

Argument	Description
<i>string</i>	The pbstring whose length is to be determined

Return value      *pblong*.

Examples      These statements set the value of a *pblong* variable to the length of a string:

```
pblong long_val;
pbstring str_val;
long_val = session-> GetStringLength( str_val );
```

See also      [GetString](#)  
[NewString](#)  
[SetString](#)

## GetSuperClass

Description      Returns the ancestor class of the specified class, if any.

Syntax      **GetSuperClass**(*pbclass c/s*)

Argument	Description
<i>cls</i>	A valid class handle for the descendent class

Return value      *pbclass* or 0 if the class has no ancestor.

Examples      These statements get the class of an object in the PBCallInfo structure, the ancestor class of that class, and then the name of the ancestor class:

```
pbclass cls, cls_parent;
LPCSTR clsname;

cls = Session-> GetClass(ci-> pArgs-> GetAt(0)->
    GetObject());
cls_parent = Session-> GetSuperClass(cls);
clsname = Session-> GetClassName(cls_parent);
```

See also      [GetClass](#)  
[GetClassName](#)

## GetSystemClass

Description Returns the first system class that the input class inherits from.

Syntax `GetSystemClass (pbclass cls)`

Argument	Description
<i>cls</i>	A descendent class whose ancestor system class is to be determined

Return value `pbclass` or null on error.

See also [GetMethodID](#)  
[GetSystemGroup](#)

## GetSystemGroup

Description Returns a PowerBuilder internal system group.

Syntax `GetSystemGroup()`

Return value `pbclass` or null on error.

Usage `GetSystemGroup` returns the PowerBuilder internal system group, which contains all the system types such as `PowerObject`, `NonVisualObject`, `Structure`, `Window`, `CommandButton`, and so on. You can use this system group to obtain a system class. You might need to call PowerScript functions in the PowerBuilder extension. To achieve this, you first need to get the `pbclass` that the PowerScript function class resides in. This code gets the PowerBuilder system function class:

```
pbgroup sysGroup = session->GetSystemGroup();
pbclass sysFuncClass = session->FindClass(sysGroup,
    "SystemFunctions");
```

After you get the system class, you can obtain the method ID of a PowerScript function by calling `FindMatchingFunction`, and then you can invoke the PowerScript function.

See also [FindMatchingFunction](#)  
[GetSystemClass](#)

## GetTimeString

Description Converts data in a pbtime object to a string.

Syntax `GetString(pftime time)`

Argument	Description
<code>time</code>	The pbtime data object to be converted to a string.

Return value `LPCTSTR`.

See also [NewString](#)  
[ReleaseTimeString](#)  
[SetString](#)

## HasExceptionThrown

Description Checks for the existence of an exception that has been thrown but not cleared.

Syntax `HasExceptionThrown()`

Return value `pbboolean`. Returns true if a PowerBuilder exception has been thrown but not cleared.

Examples This example tests whether an exception has been thrown so it can be handled and cleared:

```
try
{
    session->InvokeObjectFunction(pbobj, mid, &ci);
    // Was PB exception thrown?
    if (session-> HasExceptionThrown())
    {
        // Handle PB exception
        session-> ClearException();
    }
}
```

See also [ClearException](#)  
[GetException](#)  
[ThrowException](#)

## HasPBVisualObject

Description	Determines whether any PowerBuilder windows, visible or hidden, are still in existence.
Syntax	HasPBVisualObject()
Return value	pbboolean. Returns true if any PowerBuilder windows are still alive. If any windows that are <i>not</i> response windows are still alive, the PowerBuilder application returns immediately unless you manually add a message loop.
Examples	This example is similar to the example for RestartRequested, but it includes a call to HasPBVisualObject that opens a message loop if the return value is true:

```
PBXRESULT    PB_MyWinAppRunner::RunApplication()
{
    PBXRESULT res;
    pbboolean restart = FALSE;

    do
    {
        res = StartApplication();
        if (res == PBX_OK)
        // Process message dispatch
        {
            if ( GetSession()->HasPBVisualObject() )
            {
                MSG msg;
                while ( GetMessage(&msg, 0, 0, 0) )
                {
                    TranslateMessage(&msg);
                    DispatchMessage(&msg);

                    if ( !GetSession()->HasPBVisualObject() )
                        break;
                }
            }
        }
        else
            break;

        restart = GetSession()->RestartRequested();
        if (restart)
            RecreateSession();
    } while (restart);

    return CleanApplication();
}
```

Usage	RestartRequested and HasVisualPBObject are used in the implementation of the IPB_VM RunApplication function. You no longer need to use an external message loop to check for Windows messages when you call the RunApplication function as you did in versions of PBNI prior to PowerBuilder 10.5.
See also	<a href="#">RestartRequested</a> <a href="#">RunApplication</a>

## InitCallInfo

Description      Initializes the PBCallInfo structure.

Syntax      `InitCallInfo(pbclass cls, pbmethodID mid, PBCallInfo *ci)`

Argument	Description
<i>cls</i>	The pbclass containing the method
<i>mid</i>	The pbMethodID returned by GetMethodID
<i>ci</i>	A pointer to a preallocated PBCallInfo structure

Return value      PBXRESULT. Returns PBX\_OK on success, and PBX\_E\_INVALID\_ARGUMENT on failure.

Examples      This example shows the implementation of a TriggerEvent function in a visual class. It takes an event name as an argument, obtains the class and method ID needed to initialize the PBCallInfo structure, triggers the event, and frees the PBCallInfo structure:

```
void CVisualExt::TriggerEvent (LPCTSTR eventName)
{
    pbclass clz = d_session->GetClass(d_pbobj);
    pbmethodID mid = d_session->GetMethodID(clz,
                                                eventName, PBRT_EVENT, "I");

    PBCallInfo ci;
    d_session->InitCallInfo(clz, mid, &ci);
    d_session->TriggerEvent(d_pbobj, mid, &ci);
    d_session->FreeCallInfo(&ci);
}
```

Usage      On return, this method allocates enough space for the arguments, and then initializes the arguments and return value. You must set appropriate values in the PBCallInfo structure. Note that the structure itself must have been allocated before the call.

See also      [FreeCallInfo](#)

## InvokeClassFunction

Description	Invokes system or user global functions.								
Syntax	<code>InvokeClassFunction(pbclass <i>cls</i>, pbmethodID <i>mid</i>, PBCallInfo *<i>ci</i>)</code>								
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>cls</i></td><td>The class that contains the global function. If this is a system function, <i>cls</i> is obtained with <code>GetSystemFunctionsClass</code>; otherwise, it is obtained with <code>FindGroup</code> and <code>FindClass</code>, with the function name as the group/class name.</td></tr> <tr> <td><i>mid</i></td><td>The <code>pbMethodID</code> returned by <code>GetMethodID</code>.</td></tr> <tr> <td><i>ci</i></td><td>A pointer to a preallocated <code>PBCallInfo</code> structure.</td></tr> </tbody> </table>	Argument	Description	<i>cls</i>	The class that contains the global function. If this is a system function, <i>cls</i> is obtained with <code>GetSystemFunctionsClass</code> ; otherwise, it is obtained with <code>FindGroup</code> and <code>FindClass</code> , with the function name as the group/class name.	<i>mid</i>	The <code>pbMethodID</code> returned by <code>GetMethodID</code> .	<i>ci</i>	A pointer to a preallocated <code>PBCallInfo</code> structure.
Argument	Description								
<i>cls</i>	The class that contains the global function. If this is a system function, <i>cls</i> is obtained with <code>GetSystemFunctionsClass</code> ; otherwise, it is obtained with <code>FindGroup</code> and <code>FindClass</code> , with the function name as the group/class name.								
<i>mid</i>	The <code>pbMethodID</code> returned by <code>GetMethodID</code> .								
<i>ci</i>	A pointer to a preallocated <code>PBCallInfo</code> structure.								
Return value	<p>PBXRESULT. Returns <code>PBX_OK</code> for success, or one of the following for failure:</p> <p><code>PBX_E_INVALID_ARGUMENT</code>  <code>PBX_E_INVOKE_METHOD_INACCESSABLE</code>  <code>PBX_E_INVOKE_WRONG_NUM_ARGS</code>  <code>PBX_E_INVOKE_REFARG_ERROR</code>  <code>PBX_E_INVOKE_METHOD_AMBIGUOUS</code>  <code>PBX_E_INVOKE_FAILURE</code>  <code>PBX_E_INVOKE_FAILURE</code></p>								
Examples	This example gets the PowerBuilder system class and uses it to invoke the <code>double</code> function:								
	<pre>cls = session-&gt;GetSystemClass(); mid = session-&gt;GetMethodID(     (cls, "double", PBRT_FUNCTION, "DA"); session-&gt;InitCallInfo(cls, mid, ci); ci-&gt;pArgs -&gt; GetAt(0) -&gt; SetPBString(mystr); session -&gt; <b>InvokeClassFunction</b>(cls, mid, ci);</pre>								
Usage	On return, this method allocates enough spaces for the arguments, and then initializes arguments and return value. You must set appropriate values in the <code>PBCallInfo</code> structure. Note that the structure itself must have been allocated before the call.								
See also	<code>InvokeObjectFunction</code>								

## InvokeObjectFunction

Description                    Invokes a class member method.

Syntax                    `InvokeObjectFunction(pbobject obj, pbmethodID mid, PBCallInfo *ci)`

Argument	Description
<i>obj</i>	The pbobject containing the method
<i>mid</i>	The pbMethodID returned by GetMethodID
<i>ci</i>	A pointer to a preallocated PBCallInfo structure

Return value                    PBXRESULT. Returns PBX\_OK for success, or one of the following for failure:

PBX\_E\_INVALID\_ARGUMENT  
PBX\_E\_INVOKE\_METHOD\_INACCESSABLE  
PBX\_E\_INVOKE\_WRONG\_NUM\_ARGS  
PBX\_E\_INVOKE\_REFARG\_ERROR  
PBX\_E\_INVOKE\_METHOD\_AMBIGUOUS  
PBX\_E\_INVOKE\_FAILURE  
PBX\_E\_INVOKE\_FAILURE

Examples                    This code invokes the DataWindow Update function and returns its integer return value:

```
pbclass cls;
pbmethodID mid;
PBCallInfo* ci = new PBCallInfo;
pbint ret_val;

cls = session->GetClass(dwobj);
mid = session->GetMethodID
      (cls, "Update", PBRT_FUNCTION, "I");
session->InitCallInfo(cls, mid, ci);

session->InvokeObjectFunction(dwobj, mid, ci);

ret_val = ci.returnValue->GetInt();
session->FreeCallInfo(ci);
delete ci;
return ret_val;
```

See also                    [InvokeClassFunction](#)

## IsArrayItemNull

**Description** Returns true if the array item contains a null value; otherwise it returns false.

**Syntax** IsArrayItemNull( pbarray *array*, pblong *dim*[ ] )

Argument	Description
<i>array</i>	A valid pbarray structure that you want to check for a null-valued array item.
<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .

**Return value** pbboolean.

**See also** GetArrayType  
Set<type>ArrayItem  
SetArrayItemToNull

## IsAutoInstantiate

**Description** Returns true if the specified class is an autoinstantiated class; otherwise it returns false.

**Syntax** IsAutoInstantiate(pbclass)

Argument	Description
<i>cls</i>	A valid class handle or structure

**Return value** pbboolean.

## IsFieldArray

**Description** Returns true if the field of the specified object is an array; otherwise it returns false.

**Syntax** IsFieldArray(pbclass *cls*, pbfield *fid*)

Argument	Description
<i>cls</i>	A valid class handle for the class whose field is to be accessed
<i>fid</i>	The field ID of the specified object

**Return value** pbboolean.

**Examples**

This code tests whether the field identified by *fid* is an array, and if so, gets the array value:

```
fid = session->GetFieldID(cls, "arr_val");
if (session->IsFieldArray(cls, fid))
{
    arr_val=session->GetArrayField(myobj, fid, isNull);
    ...
}
```

## IsFieldNull

**Description**

Returns true if the field of the specified object is a null value; otherwise it returns false.

**Syntax**

`IsFieldNull(pbobject obj, pbfield fid)`

Argument	Description
<i>obj</i>	A valid object handle for the object whose field is to be accessed
<i>fid</i>	The field ID of the specified object

**Return value**

pbboolean.

**Examples**

These statements test whether the field identified by *fid* is null:

```
fid = session -> GetFieldID(cls, "i_val");
if (session -> IsFieldNull(myobj, fid))
```

## IsFieldObject

**Description** Returns true if the field of the specified object is an object; otherwise it returns false.

**Syntax** `IsFieldObject(pbclass cls, pbfield fid)`

Argument	Description
<i>cls</i>	A valid class handle for the class whose field is to be accessed
<i>fid</i>	The field ID of the specified object

**Return value** `pbboolean`.

**Examples** These statements test whether the field identified by *fid* is an object:

```
fid = session -> GetFieldID(cls, "obj_val");
if (session -> IsFieldObject(myobj, fid))
```

## IsGlobalVarArray

**Description** Returns true if the global variable contains an array; otherwise it returns false.

**Syntax** `IsGlobalVarArray(pbfield fid)`

Argument	Description
<i>fid</i>	The field ID of the global variable

**Return value** `pbboolean`.

**Examples** These statements test whether the field identified by *fid* is a global variable array:

```
fid = session -> GetGlobalVarID("arr_gvar");
if (session -> IsGlobalVarArray(fid))
{
    arr_val=session -> GetArrayGlobalVar(fid, isNull);
    ...
}
```

## See also

## IsGlobalVarNull

Description      Returns true if the global variable contains a null value; otherwise it returns false.

Syntax      IsGlobalVarNull( pbfield *fid*)

Argument	Description
<i>fid</i>	The field ID of the global variable

Return value      pbboolean.

Examples      These statements test whether the field identified by *fid* is a global variable array:

```
fid = session -> GetGlobalVarID("arr_gvar");
if (session -> IsGlobalVarArray(fid))
{
    arr_val=session -> GetArrayGlobalVar(fid, isNull);
    ...
}
```

## IsGlobalVarObject

**Description** Returns true if the global variable contains an object; otherwise it returns false.

**Syntax** IsGlobalVarObject( pbfield *fid*)

<b>Argument</b>	<b>Description</b>
<i>fid</i>	The field ID of the global variable

**Return value** pbboolean.

**Examples** These statements test whether the field identified by *fid* is a global variable object. If it is, its value is set to another global variable object:

```
fid = session -> GetGlobalVarID("obj2_gvar");
if (session -> IsGlobalVarObject(fid))
{
    obj_val = session -> GetObjectGlobalVar(fid,
       isNull);
    cls = session -> GetClass(obj_val);
    fid = session -> GetFieldID(cls, "text");
    s_val = session -> GetStringField(obj_val, fid,
       isNull);
    mystr = session -> GetString(s_val);
    // Set the value of obj2_gvar to obj1_gvar
    fid = session -> GetGlobalVarID("obj1_gvar");
    session -> SetObjectGlobalVar(fid, obj_val);
}
```

## IsNativeObject

Description      Determines whether a pbobject is an instance of a native class.

Syntax      IsNativeObject(pbobject *obj*)

Argument	Description
<i>obj</i>	A valid object handle

Return value      pbboolean.

Examples      The f\_getrow function uses IsNativeObject to test whether *extObj* is a native class. If so, it gets the native interface and invokes the f\_getrowcount function in the other class:

```
long f_getrow(IPB_Session* session, pbobject dwObj,
              pbobject extObj)
{
    long lRet;
    IMy_pbni* pIMy_pbni = NULL;
    IPBX_NonVisualObject* pp=NULL;

    if (session -> IsNativeObject(extObj) )
    {
        pp = (IPBX_NonVisualObject*) session ->
            GetNativeInterface(extObj);
        pIMy_pbni = static_cast<IMy_pbni*>(pp);
        lRet = pIMy_pbni-> f_GetRowCount(session, dwObj);
    }
    return lRet;
}
```

Usage      Use this method in conjunction with GetNativeInterface to obtain a direct reference to the IPBX\_UserObject associated with another native class, so that the class and its methods can be accessed directly.

See also      [GetNativeInterface](#)

## IsSharedVarArray

Description	Returns true if the shared variable contains an array; otherwise it returns false.
Syntax	<code>IsSharedVarArray(pbgroup group, pbfield fid)</code>
Argument	Description
<i>group</i>	The group whose shared variable is to be accessed
<i>fid</i>	The field ID of the shared variable
Return value	<code>pbboolean</code> .
See also	<code>Get&lt;type&gt;SharedVar</code> <code>GetSharedVarID</code> <code>GetSharedVarType</code> <code>IsSharedVarNull</code> <code>IsSharedVarObject</code> <code>Set&lt;type&gt;SharedVar</code> <code>SetSharedVarToNull</code>

## IsSharedVarNull

Description	Returns true if the shared variable contains a null value; otherwise it returns false.
Syntax	<code>IsSharedVarNull(pbgroup group, pbfield fid)</code>
Argument	Description
<i>group</i>	The group whose shared variable is to be accessed
<i>fid</i>	The field ID of the shared variable
Return value	<code>pbboolean</code> .
See also	<code>Get&lt;type&gt;SharedVar</code> <code>GetSharedVarID</code> <code>GetSharedVarType</code> <code>IsSharedVarArray</code> <code>IsSharedVarObject</code> <code>Set&lt;type&gt;SharedVar</code> <code>SetSharedVarToNull</code>

## IsSharedVarObject

Description                Returns true if the shared variable contains an object; otherwise it returns false.

Syntax                `IsSharedVarObject(pbgroup group, pbfield fid)`

Argument	Description
<code>group</code>	The group whose shared variable is to be accessed
<code>fid</code>	The field ID of the shared variable

Return value            `pbboolean`.

See also                [Get<type>SharedVar](#)  
[GetSharedVarID](#)  
[GetSharedVarType](#)  
[IsSharedVarArray](#)  
[IsSharedVarNull](#)  
[Set<type>SharedVar](#)  
[SetSharedVarToNull](#)

## NewBlob

Description                Creates a new blob and duplicates a buffer for the new blob data.

Syntax                `NewBlob (const void* bin, pblong len)`

Argument	Description
<code>bin</code>	A void pointer that points to the source buffer
<code>len</code>	The length in bytes of the data in the buffer

Return value            `pbblob`.

Examples                If the blob value in the PBCallInfo structure is null, this code creates a new blob value with four bytes in the *pArguments* array; otherwise, it sets the blob value in the *pArguments* array to the value in the PBCallInfo structure:

```
if (ci->pArgs->GetAt(i)->IsNull())
    pArguments[i].blob_val =
        Session->NewBlob("null", 4);
else
    pArguments[i].blob_val =
        ci->pArgs->GetAt(i)->GetBlob();
```

Usage                The buffer containing the new blob data is freed when `PopLocalFrame` is called.

See also                [PopLocalFrame](#)  
[SetBlob](#)

## NewBoundedObjectArray

Description

Creates a bounded PowerBuilder object or structure array.

Syntax

`NewBoundedObjectArray(pbclass cls, pbuint dimension,  
PBArrayInfo::ArrayBound* bounds)`

Argument	Description
<i>cls</i>	A valid class handle of the type of PowerBuilder object or structure array to be created
<i>dimension</i>	A number greater than one that indicates the dimension of the array to be created
<i>bounds</i>	An array containing the upper and lower boundaries of the array to be created

Return value

`pbaray` or `null` on failure.

Examples

```
int size;
pbaray pbin_a;
PBArrayInfo* ai;
PBXRESULT ret;
pbclass cls;
pbgroup group;

size = sizeof(PBArrayInfo) +
       sizeof(PBArrayInfo::ArrayBound);
ai = (PBArrayInfo*)malloc(size);
ai-> bounds[0].upperBound=2;
ai-> bounds[0].lowerBound=1;
ai-> bounds[1].upperBound=2;
ai-> bounds[1].lowerBound=1;
ai-> numDimensions=2;

// Create new array pbin_a
group = session->FindGroup("w_main", pbgroup_window);
if (group==NULL)
    return;
cls = session->FindClass(group, "commandbutton");
if( cls==NULL)
    return;
pbin_a = session->NewBoundedObjectArray(cls,
                                             ai-> numDimensions, ai-> bounds);
```

## NewBoundedSimpleArray

Description      Creates a bounded simple data array.

Syntax      `NewBoundedSimpleArray(pbuint type, pbuint dimension,  
PBArrayInfo::ArrayBound* bounds)`

Argument	Description
<i>type</i>	An enumerated variable of type pbvalue_* indicating the type of simple unbounded array to be created
<i>dimension</i>	A number greater than one that indicates the dimension of the array to be created
<i>bounds</i>	An array containing the upper and lower boundaries of the array to be created

Return value      pbarray or null on failure.

## NewDate

Description	Creates a new pbdate data object.
Syntax	<code>NewDate()</code>
Return value	<code>pbdate</code> .
Examples	This example tests whether a date value exists, and, if it does not, it creates a new pbdate object and sets its value to the first day in January, 1900:
	<pre>if (ci-&gt;pArgs-&gt;GetAt(0)-&gt;IsNull()) {     pArguments[i].date_val = Session-&gt;<b>NewDate</b>(); }  Session-&gt;SetDate(pArguments[i].date_val,                   1900,1,1); // Date: 1900-01-01 isNull[i]=true; } else {     pArguments[i].date_val =         ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetDate();     isNull[i]=false; }</pre>
Usage	The initial value is 1900-1-1.
See also	<a href="#">SetDate</a> <a href="#">SplitDate</a>

## NewDateTime

Description	Creates a new pbdatetime data object.
Syntax	<code>NewDateTime()</code>
Return value	<code>pbdatetime</code> .
Examples	This example tests whether a date/time value exists, and, if it does not, it creates a new pbdate object and sets its value to the beginning of January, 1900:
	<pre>if (ci-&gt;pArgs-&gt;GetAt(i)-&gt;IsNull()) {     pArguments[i].datetime_val=Session-&gt;<b>NewDateTime</b>();     Session-&gt;SetDateTime(pArguments[i].datetime_val,         1900, 1, 1, 1, 1, 1); // Datetime:                            // 1900-01-01 01:01:01 } else {     pArguments[i].datetime_val =         ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetDateTime(); }</pre>
Usage	The initial value is 1900-1-1 0:0:0.0.
See also	<a href="#">SetDateTime</a> <a href="#">SplitDateTime</a>

## NewDecimal

Description	Allocates resources for a new decimal data object.
Syntax	<code>NewDecimal()</code>
Return value	<code>pbdec</code> or null on failure.
Examples	<pre>if (ci-&gt;pArgs-&gt;GetAt(i)-&gt;IsNull()) {     pArguments[i].dec_val=Session-&gt;<b>NewDecimal</b>();     Session-&gt;SetDecimal(pArguments[i].dec_val,"1.0"); } else {     pArguments[i].dec_val =         ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetDecimal(); }</pre>
See also	<a href="#">GetDecimalString</a> <a href="#">ReleaseDecimalString</a> <a href="#">SetDecimal</a>

## NewObject

Description Creates a new object of the specified type.

Syntax `NewObject(pbclass c/s)`

Argument	Description
<code>cls</code>	The type of object or structure instance to be created

Return value `pbobject` of the given class or structure.

Examples

```
pbclass cls;
pbobject ex;
pbgroup group;

group = session->FindGroup
    ("user_exception", pbgroup_userobject);
if (group==NULL)
    return;
cls = session->FindClass(group, "user_exception");
if (group==NULL)
    return;
ex = session->NewObject(cls);
```

Usage The returned object's life cycle is restricted to the current frame unless `AddGlobalRef` is called on the object.

See also [FindClass](#)  
[FindGroup](#)

## NewProxyObject

Description      Creates a proxy for a remote object. The proxy is used to extend the network protocol in PowerBuilder.

Syntax      NewProxyObject(pbclass *cls*)

Argument	Description
<i>cls</i>	The type of object or structure instance to be created

Return value      pbproxyobject.

Examples      This example creates a new proxy object, creates a marshaler, and associates the marshaler with the proxy object:

```
pbproxyObject proxy = session->NewProxyObject(cls) ;
if (proxy == NULL)
{
    ci->returnValue->SetLong(kFailToCreateProxy) ;
    return PBX_OK;
}

// Create MyMarshaler
MyMarshaler* marshaler = new MyMarshaler(env,
    proxy, obj);

// Associate MyMarshaler with the proxy
session->SetMarshaler(proxy, marshaler);

ci->pArgs->GetAt(0)->SetObject(proxy);

ci->returnValue->SetLong(kSuccessful);

return PBX_OK;
```

See also      GetMarshaler  
SetMarshaler

## NewString

Description	Creates a new string.
Syntax	<code>NewString(LPCTSTR)</code>
Return value	<code>pbstring</code> .
Examples	<pre>pbclass cls;  cls = session-&gt;GetSystemFunctionsClass(); if( cls == NULL ) {     ret_val = session-&gt;<b>NewString</b>("null");     return ret_val; }</pre>
Usage	The returned string is destroyed when <code>PopLocalFrame</code> is called.
See also	<code>SetString</code>

## NewTime

Description	Creates a new <code>pftime</code> data object.
Syntax	<code>NewTime()</code>
Return value	<code>pftime</code> .
Examples	These statements split a time into hours, minutes, and seconds, and then use the resulting values to set the value of a new time object:
	<pre>Session-&gt;SplitTime(ci.returnValue-&gt;GetTime(), &amp;hh,                      &amp;mm, &amp;ss); ret_val = Session-&gt; <b>NewTime</b>(); Session-&gt; SetTime(ret_val, hh, mm, ss);</pre>
Usage	The initial value is 0:0:0.0.
See also	<code>SetTime</code> <code>SplitTime</code>

## NewUnboundedObjectArray

Description              Creates an unbounded PowerBuilder object or structure data array.

Syntax              NewUnboundedObjectArray(pbclass *cls*)

Argument	Description
<i>cls</i>	A valid class handle of the type of PowerBuilder object or structure array to be created

Return value              pbarray or null on failure.

Usage              An unbounded array can have only one dimension, so no dimension information is needed.

See also              Get<type>ArrayItem  
GetArrayInfo  
GetArrayItemType  
GetArrayLength  
IsArrayItemNull  
NewBoundedObjectArray  
NewBoundedSimpleArray  
NewUnboundedSimpleArray  
ReleaseArrayInfo  
Set<type>ArrayItem  
SetArrayItemToNull  
SetArrayItemValue

## NewUnboundedSimpleArray

Description	Creates an unbounded simple data array.
Syntax	<code>NewUnboundedSimpleArray(pbuint type)</code>

Argument	Description
<code>type</code>	An enumerated variable of type <code>pbvalue_*</code> indicating the type of simple unbounded array to be created

Return value	<code>pbaray</code> or <code>null</code> on failure.
--------------	--

Examples	This example creates an unbounded simple data array of the type returned by the <code>getDataType</code> method, which returns a string of the form <code>dt_type</code> . Most of the case statements have been removed for the sake of brevity:
----------	---

```

if (d_returnType.isArray())
{
    returnValue.l = env->CallObjectMethodA(obj,
        mid, values.get());
    pbaray v;

    switch(d_returnType.getDataType())
    {
        case dt_boolean:
            v = session->NewUnboundedSimpleArray
                (pbvalue_boolean);
            break;

        case dt_short:
            v = session->NewUnboundedSimpleArray
                (pbvalue_int);
            break;
        // CASE statements omitted
        ...
        default:
            v = session->NewUnboundedSimpleArray
                (pbvalue_any);
            break;
    }

    ci->returnValue->SetArray(v);
}

```

Usage	An unbounded array can have only one dimension, so no dimension information is needed.
-------	--

See also	<a href="#">Get&lt;type&gt;ArrayItem</a> <a href="#">GetArrayInfo</a> <a href="#">GetArrayItemType</a> <a href="#">GetArrayLength</a> <a href="#">IsArrayItemNull</a> <a href="#">NewBoundedObjectArray</a> <a href="#">NewBoundedSimpleArray</a> <a href="#">NewUnboundedObjectArray</a> <a href="#">ReleaseArrayInfo</a> <a href="#">Set&lt;type&gt;ArrayItem</a> <a href="#">SetArrayItemToNull</a> <a href="#">SetArrayItemValue</a>
----------	---

## **PopLocalFrame**

Description	Pops the current local reference frame from the current native method stack frame, removing all local references to the objects added in that local frame. All the pbobject, pbstring, and pbdecimal variables created by calling NewDecimal, NewObject, or NewString in the current frame are destroyed automatically.
Syntax	<code>PopLocalFrame()</code>
Return value	None.
See also	<a href="#">AddLocalRef</a> <a href="#">PushLocalFrame</a> <a href="#">RemoveLocalRef</a>

## **ProcessPBMessage**

Description	Checks the PowerBuilder message queue and, if there is a message in the queue, attempts to process it.
Syntax	<code>ProcessPBMessage()</code>
Return value	<code>pbboolean</code> . Returns true if a PowerBuilder message was processed, and false otherwise.

**Examples**

This message loop in a WinMain function processes a PowerBuilder message if a message has been received and an IPB session is running:

```
try
{
    while (GetMessage (&msg, NULL, 0, 0))
    {
        TranslateMessage (&msg);
        DispatchMessage (&msg);

        // Call to ProcessPBMessag
        if (session)
            session->ProcessPBMessage ();
    }
}
```

This overloaded WindowProc function in an MFC application processes a PowerBuilder message:

```
LRESULT CCallPBVCtrl::WindowProc(UINT message,
    WPARAM wParam, LPARAM lParam)
{
    d_session->ProcessPBMessag();
    return CDialog::WindowProc(message, wParam, lParam);
}
```

**Usage**

Each time this function is called, it attempts to retrieve a message from the PowerBuilder message queue and process it. It is similar to the PowerBuilder Yield function; however, ProcessPBMessag processes only one message at a time, and it processes only PowerBuilder messages. The Yield function also processes Windows messages.

Use this function when PowerBuilder windows or visual controls are called from C++ applications or from extensions to ensure that events posted to the PowerBuilder message queue are processed.

If the function is not inserted in the C++ application in a way that results in it being called repeatedly, posted events are not processed in the PowerBuilder application.

For most applications, ProcessPBMessag can be inserted in a message loop in the WinMain function. If you use Microsoft Foundation Classes (MFC), you cannot modify the built-in message loop. To ensure that the ProcessPBMessag function is called repeatedly, you can overload the CWnd::WindowProc function and insert ProcessPBMessag into the overloaded function.

## PushLocalFrame

Description	Pushes a local reference frame onto the current native method stack frame. A local frame is analogous to a scope in C++.
Syntax	PushLocalFrame()
Return value	None.
See also	PopLocalFrame RemoveLocalRef

## Release

Description	Releases the current IPB_Session. The IPB_Session object becomes invalid after the call.
Syntax	Release()
Return value	None.
Examples	This example shows a call to Release. The example checks whether there is a valid session object before attempting to release it:

```
if (pIPB_ObjectFactory)
{
    pIPB_ObjectFactory->Release();
    pIPB_ObjectFactory = NULL;
}
```

## ReleaseArrayInfo

Description	Releases memory returned by GetArrayInfo.
Syntax	ReleaseArrayInfo(PBArrayInfo* <i>pbararrayinfo</i> )
Argument	<b>pbararrayinfo</b>
	A valid PBArrayInfo handle
Return value	PBXRESULT. PBX_OK for success.
Examples	This example shows how ReleaseArrayInfo should be called when memory allocated by GetArrayInfo is no longer needed:

```
PBArrayInfo* ai;
...
session->ReleaseArrayInfo(ai);
```

Usage	If the array is an unbounded array, the bounds information in PBArrayInfo is undetermined.
See also	<a href="#">Get&lt;type&gt;ArrayItem</a> <a href="#">GetArrayInfo</a> <a href="#">GetArrayItemType</a> <a href="#">GetArrayLength</a> <a href="#">IsArrayItemNull</a> <a href="#">NewBoundedObjectArray</a> <a href="#">NewBoundedSimpleArray</a> <a href="#">NewUnboundedObjectArray</a> <a href="#">NewUnboundedSimpleArray</a> <a href="#">Set&lt;type&gt;ArrayItem</a> <a href="#">SetArrayItemToNull</a> <a href="#">SetArrayItemValue</a>

## ReleaseDateString

Description      Frees the memory acquired using [GetDateString](#).

Syntax      `ReleaseDateString(LPCTSTR string)`

Argument	Description
<code>string</code>	The string to be released from memory

Return value      None.

See also      [GetDateString](#)

## ReleaseDateTimeString

Description      Frees the memory acquired using [GetDateTimeString](#).

Syntax      `ReleaseDateTimeString(LPCTSTR string)`

Argument	Description
<code>string</code>	The string to be released from memory

Return value      None.

See also      [GetDateTimeString](#)

## ReleaseDecimalString

Description                   Frees the memory acquired using GetDecimalString.

Syntax                   ReleaseDecimalString(LPCTSTR *string*)

Argument	Description
<i>string</i>	The string to be released from memory

Return value               None.

See also                   GetDecimalString

## ReleaseResultSetAccessor

Description                   Releases the pointer obtained using GetResultSetAccessor.

Syntax                   ReleaseResultSetAccessor (IPB\_ResultSetAccessor\* *rs*)

Argument	Description
<i>rs</i>	A pointer to the IPB_ResultSetAccessor object to be released

Return value               None.

Examples                   This statement releases the IPB\_ResultSetAccessor object *rsa*:

```
Session->ReleaseResultSetAccessor(rsa) ;
```

Usage                      When you call ReleaseResultSetAccessor, the Release function of the IPB\_ResultSetAccessor interface is called on the *rs* argument to release the interface pointer.

See also                   CreateResultSet  
                          GetResultSetAccessor

## ReleaseString

**Description**      Frees the memory acquired using `GetString`, `GetClassName`, `GetFieldName`, or `GetEnumItemName`.

**Syntax**      `ReleaseString(LPCTSTR string)`

<b>Argument</b>	<b>Description</b>
<code>string</code>	The string to be released from memory

**Return value**      None.

**Examples**      The following example gets a pointer to each of two strings passed in as arguments, concatenates them in a new string, then releases the memory used by the original strings:

```
pbstring psppcls:: f_add_string(IPB_Session* session,
pbstring arg1, pbstring arg2)
{
    LPCTSTR pStr1,pStr2;
    TCHAR tmp[100];
    pbstring ret;

    pStr1=session-> GetString(arg1);
    pStr2=session-> GetString(arg2);
    _tcscpy(tmp,pStr1);
    _tcscat(tmp,pStr2);
    ret = session -> NewString(tmp);
    session-> ReleaseString(pStr1);
    session-> ReleaseString(pStr2);

    return ret ;
}
```

**Usage**      Do not use this function to release a string obtained using `GetDateString`, `GetTimeString`, `GetDateTimeString`, or `GetDecimalString`. Each of these Get methods has a corresponding Release method.

**See also**      [GetClassName](#)  
[GetEnumItemName](#)  
[GetFieldName](#)  
[GetString](#)

## ReleaseTimeString

Description                   Frees the memory acquired using GetTimeString.

Syntax                   ReleaseTimeString(LPCTSTR *string*)

Argument	Description
<i>string</i>	The string to be released from memory

Return value               None.

See also                   GetTimeString

## ReleaseValue

Description                   Frees the IPB\_Value acquired using AcquireValue or AcquireArrayItemValue.

Syntax                   ReleaseValue(IPB\_Value\* *value*)

Argument	Description
<i>value</i>	The string to be released from memory

Return value               None.

Examples                   The AcquireValue method is used to obtain a message argument value. Later, when the value is no longer needed, it is released using ReleaseValue to avoid memory leaks:

```
// Acquire a value
MessageArg = session->AcquireValue
( ci->pArgs->GetAt(0) );
pbstring pbMessage = MessageArg->GetString() ;
Message = (LPSTR)session->GetString(pbMessage) ;
...
// Cleanup phase
if (MessageArg)
{
    Session->ReleaseValue ( MessageArg ) ;
}
```

Usage When you no longer need the data acquired using the AcquireValue or AcquireArrayItemValue method, you *must* call the ReleaseValue method to free the data. Failing to do so causes a memory leak.

---

**Warning!** Do not use ReleaseValue to release a value that was not acquired using AcquireValue or AcquireArrayItemValue. If you do, the PowerBuilder VM might crash.

---

See also            [AcquireArrayItemValue](#)  
                      [AcquireValue](#)

## RemoveGlobalRef

Description            Removes a global reference to the specified PowerBuilder object.

Syntax            `RemoveGlobalRef (pbobject obj)`

Argument	Description
<code>obj</code>	A valid PowerBuilder object handle

Return value        None.

Examples

```
void MyPBNIClass::reference()
{
    d_session->AddGlobalRef(d_pbobject);
}

void MyPBNIClass::unreference()
{
    if(d_pbobject != NULL)
        d_session -> RemoveGlobalRef(d_pbobject);
}
```

See also            [AddGlobalRef](#)

## RemoveLocalRef

Description                    Removes a local reference to the specified PowerBuilder object.

Syntax                    RemoveLocalRef (pbobject *obj*)

<b>Argument</b>	<b>Description</b>
<i>obj</i>	A valid PowerBuilder object handle

Return value                None.

See also                    AddLocalRef

PopLocalFrame

PushLocalFrame

## RemoveProp

Description                    Removes the specified variable from the list of properties of the current IPB session. You must free the memory to which the property points.

Syntax                    RemoveProp(LPCTSTR *name*)

<b>Argument</b>	<b>Description</b>
<i>name</i>	The name of the variable to be removed

Return value                None.

Examples                    These statements remove *prop\_name* from the list of variables associated with the session and delete the pointer created to point to the variables value:

```
session -> RemoveProp (prop_name) ;
delete SetValue;
```

Usage                      SetProp enables you to use a variable value throughout an IPB session. Use RemoveProp to remove the variable from the list of variables associated with the session when it is no longer needed. You must also free the memory associated with the variable.

See also                    GetProp  
SetProp

## RestartRequested

Description	Determines whether the PowerBuilder system function Restart has been called.
Syntax	HasPBVisualObject()
Return value	pbboolean. Returns true when the PowerBuilder system function Restart is called. When RestartRequested returns true, you should destroy the existing IPB_Session object and create a new one to restart the application.
Examples	<p>In the following example, StartApplication, RecreateSession, and CleanApplication are functions of the PB_MyConsoleAppRunner class. StartApplication is similar to the IP_VM RunApplication function, but it uses an existing session. RecreateSession releases the current session and creates a new one. CleanApplication triggers the application's Close event and releases resources. In the example, RestartRequested is called in a DO loop to test whether the PowerBuilder Restart function has been called. If it has, the RecreateSession function is called:</p> <pre>PBXRESULT PB_MyConsoleAppRunner::RunApplication() {     PBXRESULT res;     pbboolean restart = FALSE;      do     {         res = StartApplication();         if (res != PBX_OK)             break;          restart = GetSession() -&gt;RestartRequested();         if (restart)             RecreateSession();      } while (restart);      return CleanApplication(); }</pre>
Usage	RestartRequested and HasVisualPBOObject are used in the implementation of the IPB_VM RunApplication function. You no longer need to use an external message loop to check for Windows messages when you call the RunApplication function as you did in versions of PBNI prior to PowerBuilder 10.5.
See also	HasPBVisualObject RunApplication

## Set<type>ArrayItem

Description	Assigns a value to an array item of a specific type.
Syntax	<code>SetBlobArrayItem ( pbarray array, pblong dim[ ], pbblob value )</code> <code>SetBoolArrayItem ( pbarray array, pblong dim[ ], pbboolean value )</code> <code>SetByteArrayItem ( pbarray array, pblong dim[ ], pbbyte value )</code> <code>SetCharArrayItem ( pbarray array, pblong dim[ ], pbchar value )</code> <code>SetDateArrayItem ( pbarray array, pblong dim[ ], pbdate value )</code> <code>SetDateTimeArrayItem ( pbarray array, pblong dim[ ], pbdatetime value )</code> <code>SetDecArrayItem ( pbarray array, pblong dim[ ], pbdec value )</code> <code>SetDoubleArrayItem ( pbarray array, pblong dim[ ], pbdouble value )</code> <code>SetIntArrayItem ( pbarray array, pblong dim[ ], pbint value )</code> <code>SetLongArrayItem ( pbarray array, pblong dim[ ], pblong value )</code> <code>SetLongLongArrayItem ( pbarray array, pblonglong dim[ ], pblong value )</code> <code>SetObjectArrayItem ( pbarray array, pblong dim[ ], pbobject obj )</code> <code>SetPBStringArrayItem ( pbarray array, pblong dim[ ], pbstring value )</code> <code>SetRealArrayItem ( pbarray array, pblong dim[ ], pbreal value )</code> <code>SetStringArrayItem ( pbarray array, pblong dim[ ], LPCTSTR value )</code> <code>SetTimeArrayItem ( pbarray array, pblong dim[ ], pbtime value )</code> <code>SetUintArrayItem ( pbarray array, pblong dim[ ], pbuint value )</code> <code>SetUlongArrayItem ( pbarray array, pblong dim[ ], pbulong value )</code>

Argument	Description
<code>array</code>	A valid pbarray handle.
<code>dim</code>	A pblong array to hold indexes of each dimension. The number of dimensions must equal the number of dimensions of the array.
<code>value</code>	The new value of the array item.

Return value	PBXRESULT. PBX_OK for success.  If the index exceeds the bounds of a bounded array, it returns PBX_E_ARRAY_INDEX_OUTOF_BOUNDS.  If the data passed in does not match the datatype of the array, it returns PBX_E_MISMATCHED_DATA_TYPE.
Examples	This example creates a new unbounded simple array. In the FOR loop, application-specific code (not shown here) gets array values, which are then added to the array using SetPBStringArrayItem:

```
pblong           dim[1];
char *           cstr;
pbuint          numDimensions = 1;
PBArrayInfo::ArrayBound bound;

bound.lowerBound = 1;
bound.upperBound = size;
d_pbarray = d_session->NewBoundedSimpleArray
    (pbvalue_string, numDimensions, &bound);

for (int i = 1; i <= size; i++ )
{
    dim[0] = i;
    // add application-specific code here to
    // get array value
    pbstring pValue = d_session->NewString(cstr);
    d_session->SetPBStringArrayItem(d_pbarray, dim,
        pValue);

    delete [] cstr;
}
pbv.SetArray(d_pbarray);
```

**Usage**

This method assigns the IPB\_Value pointed to by the *value* argument to the array item in the same way that the IPB\_Value *Set<type>* method sets a value.

## Set<type>Field

Description A set of methods that set a new value in an instance field of an object.

Syntax SetArrayField ( pbobject *obj*, pbfieldID *fid*, pbarray *value* )

SetBlobField ( pbobject *obj*, pbfieldID *fid*, pbblob *value* )

SetBoolField ( pbobject *obj*, pbfieldID *fid*, pbboolean *value* )

SetByteField ( pbobject *obj*, pbfieldID *fid*, pbbyte *value* )

SetCharField ( pbobject *obj*, pbfieldID *fid*, pbchar *value* )

SetDateField ( pbobject *obj*, pbfieldID *fid*, pbdate *value* )

SetDateTimeField ( pbobject *obj*, pbfieldID *fid*, pbdatetime *value* )

SetDecField ( pbobject *obj*, pbfieldID *fid*, pbdec *value* )

SetDoubleField ( pbobject *obj*, pbfieldID *fid*, pbdouble *value* )

SetIntField ( pbobject *obj*, pbfieldID *fid*, pbint *value* )

SetLongField ( pbobject *obj*, pbfieldID *fid*, pblong *value* )

SetLongLongField ( pbobject *obj*, pbfieldID *fid*, pblonglong *value* )

SetObjectField ( pbobject *obj*, pbfieldID *fid*, pbobject *value* )

SetPBStringField ( pbobject *obj*, pbfieldID *fid*, pbstring *value* )

SetRealField ( pbobject *obj*, pbfieldID *fid*, pbreal *value* )

SetStringField ( pbobject *obj*, pbfieldID *fid*, LPCTSTR *value* )

SetTimeField ( pbobject *obj*, pbfieldID *fid*, pbtime *value* )

SetUintField ( pbobject *obj*, pbfieldID *fid*, pbuint *value* )

SetUlongField ( pbobject *obj*, pbfieldID *fid*, pbulong *value* )

Argument	Description
<i>obj</i>	The handle of the object whose field is to be accessed
<i>fid</i>	The field ID of the specified object
<i>value</i>	The value to be set

Return value PBX\_RESULT.

Examples These statements set a new string value in a string field:

```
pbstring str = session->NewString(d_message.c_str());
if (str != NULL)
    session->SetPBStringField(d_pbobj, d_fidMsg, str);
```

Usage	When you change any visual property of a PowerBuilder object by calling Set<type>field functions, the property is changed but the property is not refreshed in the graphical user interface. UpdateField refreshes the visual properties of PowerBuilder objects. You must call UpdateField explicitly when changing any visual property with the Set<type>field functions.
See also	<a href="#">GetFieldID</a> <a href="#">GetFieldType</a> <a href="#">Get&lt;type&gt;Field</a> <a href="#">GetNumOfFields</a> <a href="#">IsFieldArray</a> <a href="#">IsFieldNull</a> <a href="#">IsFieldObject</a> <a href="#">SetFieldToNull</a> <a href="#">UpdateField</a>

## Set<type>GlobalVar

Description A set of methods that set the value of a global variable of a specific datatype.

Syntax

SetArrayGlobalVar ( pbfieldID *fid*, pbarray *value* )  
SetBlobGlobalVar ( pbfieldID *fid*, pbblob *value* )  
SetBoolGlobalVar ( pbfieldID *fid*, pbboolean *value* )  
SetByteGlobalVar ( pbfieldID *fid*, pbbyte *value* )  
SetCharGlobalVar ( pbfieldID *fid*, pbchar *value* )  
SetDateGlobalVar ( pbfieldID *fid*, pbdate *value* )  
SetDateTimeGlobalVar ( pbfieldID *fid*, pbdatetime *value* )  
SetDecGlobalVar ( pbfieldID *fid*, pbdec *value* )  
SetDoubleGlobalVar ( pbfieldID *fid*, pbdouble *value* )  
SetIntGlobalVar ( pbfieldID *fid*, pbint *value* )  
SetLongGlobalVar( pbfieldID *fid*, pblong *value* )  
SetLongLongGlobalVar( pbfieldID *fid*, pblonglong *value* )  
SetObjectGlobalVar ( pbfieldID *fid*, pbobject *value* )  
SetPBStringGlobalVar ( pbfieldID *fid*, pbstring *value* )  
SetRealGlobalVar ( pbfieldID *fid*, pbreal *value* )  
SetStringGlobalVar ( pbfieldID *fid*, LPCTSTR *value* )  
SetTimeGlobalVar ( pbfieldID *fid*, ptptime *value* )  
SetUintGlobalVar ( pbfieldID *fid*, pbuint *value* )  
SetUlongGlobalVar ( pbfieldID *fid*, pbulong *value* )

Argument	Description
<i>fid</i>	The field ID of the global variable
<i>value</i>	The value to be set

Return value

PBX\_RESULT.

Examples

This shows how to add 1 to the value of a global variable:

```
fid = session -> GetGlobalVarID("l_gvar");
l_val = session -> GetLongGlobalVar(fid, isNull);
session -> SetLongGlobalVar(fid, l_val + 1);
```

See also

GetGlobalVarID  
GetGlobalVarType  
Get<type>GlobalVar  
IsGlobalVarObject  
SetGlobalVarToNull

## Set<type>SharedVar

Description A set of methods that set the value of a shared variable of a specific datatype.

Syntax

```
SetArraySharedVar ( pbgroup group, pbfieldID fid, pbarray value )
SetBlobSharedVar ( pbgroup group, pbfieldID fid, pbblob value )
SetBoolSharedVar ( pbgroup group, pbfieldID fid, pbboolean value )
SetByteSharedVar ( pbgroup group, pbfieldID fid, pbbyte value )
SetCharSharedVar ( pbgroup group, pbfieldID fid, pbchar value )
SetDateSharedVar ( pbgroup group, pbfieldID fid, pbdate value )
SetDateTimeSharedVar ( pbgroup group, pbfieldID fid, pbdatetime value )
SetDecSharedVar ( pbgroup group, pbfieldID fid, pbdec value )
SetDoubleSharedVar ( pbgroup group, pbfieldID fid, pbdouble value )
SetIntSharedVar ( pbgroup group, pbfieldID fid, pint value )
SetLongSharedVar( pbgroup group, pbfieldID fid, pblong value )
SetLongLongSharedVar( pbgroup group, pbfieldID fid, pblonglong value )
SetObjectSharedVar ( pbgroup group, pbfieldID fid, pbobject value )
SetPBStringSharedVar ( pbgroup group, pbfieldID fid, pbstring value )
SetRealSharedVar ( pbgroup group, pbfieldID fid, pbreal value )
SetStringSharedVar ( pbgroup group, pbfieldID fid, LPCTSTR value )
SetTimeSharedVar ( pbgroup group, pbfieldID fid, ptptime value )
SetUintSharedVar ( pbgroup group, pbfieldID fid, pbuint value )
SetUlongSharedVar ( pbgroup group, pbfieldID fid, pbulong value )
```

Argument	Description
<i>group</i>	The group whose shared variable is to be accessed
<i>fid</i>	The field ID of the shared variable
<i>value</i>	The value to be set

Return value PBX\_RESULT.

- GetSharedVarType
- IsSharedVarArray
- IsSharedVarNull
- IsSharedVarObject
- SetSharedVarToNull

## SetArrayItemToNull

Description Sets the value of an array item to a null value.

Syntax `SetArrayItemToNull( pbarray array, pblong dim[ ] )`

Argument	Description
<i>array</i>	A valid pbarray structure in which you want to set an array item to null.
<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .

Return value `pbboolean`.

See also [IsArrayItemNull](#)

## SetArrayItemValue

Description Sets the value of an array item to the value of an IPB\_Value.

Syntax `SetArrayItemValue( pbarray array, pblong dim[ ], IPB_Value* src )`

Argument	Description
<i>array</i>	A valid pbarray structure in which you want to set an array item to null.
<i>dim</i>	A pblong array to hold the indexes of each dimension of the array. The size of the array must equal the dimensions of <i>array</i> .
<i>src</i>	The value to which the array item is to be changed.

Return value None.

Examples This code sets the value of each item in an array:

```
for( i=1; i <= bound; i++)
{
    dim[0] = i;
    ipv = Session -> AcquireArrayItemValue(refArg, dim);
    Session -> SetArrayItemValue(*i_array, dim, ipv);
    Session -> ReleaseValue(ipv);
}
```

Usage The `SetArrayItemValue` method does not verify that the datatype of the replacement value matches the datatype of the original value.

---

See also	<a href="#">AcquireArrayItemValue</a> <a href="#">ReleaseValue</a> <a href="#">SetArrayItemToNull</a> <a href="#">SetValue</a>
----------	---

## SetBlob

Description      Destroys the existing data in a blob and copies data into it from a buffer.

Syntax      `SetBlob (pbblob blb, const void* bin, pblong len)`

Argument	Description
<i>blb</i>	A valid pbblob object whose value is to be reset
<i>bin</i>	A pointer to the source buffer
<i>len</i>	The length in bytes of the data in the buffer

Return value      PBXRESULT. Returns PBX\_OK for success or PBX\_E\_INVALID\_ARGUMENT if the new blob value is invalid; otherwise, returns PBX\_E\_OUTOF\_MEMORY.

Usage      A deep copy is performed. The existing value is destroyed first, and then the contents of the *bin* argument are copied into a new value.

See also      [NewBlob](#)

## SetDate

Description      Resets the value of the specified pbdate object.

Syntax      `SetDate (pbdate date, pbint year, pbint month, pbint day)`

Argument	Description
<i>date</i>	The pbdate object to be reset
<i>year</i>	A year in the range 1000 to 3000
<i>month</i>	A month in the range 1 to 12
<i>day</i>	A day in the range 1 to 31

Return value      PBX\_RESULT. PBX\_OK for success or PBX\_E\_INVALID\_ARGUMENT if the new date is invalid.

Examples      This example sets the date to March 12, 1938:

```
session->SetDate(date_val, 1938, 3, 12);
```

Usage	If the parameters are invalid, the date is reset to 1900-1-1.
See also	NewDate SplitDate

## SetDateTime

Description	Resets the value of the specified pbdatetime object.
Syntax	<code>SetDate (pbdatetime <i>dt</i>, pbint <i>year</i>, pbint <i>month</i>, pbint <i>day</i>, pbint <i>hour</i>, pbint <i>minute</i>, pbdouble <i>second</i>)</code>

Argument	Description
<i>dt</i>	The pbdatetime object to be reset
<i>year</i>	A year in the range 1000 to 3000
<i>month</i>	A month in the range 1 to 12
<i>day</i>	A day in the range 1 to 31
<i>hour</i>	An hour in the range 0 to 23
<i>minute</i>	A minute in the range 0 to 59
<i>second</i>	A second in the range 0 to 59.999999

Return value	PBX_RESULT. PBX_OK for success or PBX_E_INVALID_ARGUMENT if the new datetime is invalid.
--------------	--

Examples

This example sets the datetime value to August 19, 1982 at 10:30:45.10:

```
session->SetDate(date_val, 1982, 8, 19, 10, 30, 45.1);
```

Usage	If the parameters are invalid, the datetime value is reset to 1900-1-1 0:0:0.0.
-------	---

See also	NewDateTime SplitDateTime
----------	------------------------------

## SetDecimal

**Description** Sets the value of a decimal variable to decimal data in a string.

**Syntax** SetDecimal(pbdec *dec*, LPCTSTR *dec\_str*)

Argument	Description
<i>dec</i>	The decimal data object to be set
<i>dec_str</i>	The string containing the data to be converted to a decimal

**Return value** PBXRESULT. PBX\_OK for success.

**Examples** This example uses the IPB\_Session SetDecimal method to set the value of a variable of type pbdec, then uses the IPB\_Value SetDecimal method to set the return value in the PBCallInfo structure:

```
pbdec pbdecRet = NULL;
LPTSTR lpDecValueToReturn = NULL;

...
pbdecRet = session -> NewDecimal();
session -> SetDecimal( pbdecRet,
    (LPCTSTR)lpDecValueToReturn );
ci -> returnValue -> SetDecimal( pbdecRet );
```

**Usage** If the string contains invalid data, the decimal value is set to 0.0.

**See also** GetDecimalString

NewDecimal

ReleaseDecimalString

## SetFieldToNull

Description Sets the value of the specified field to null.

Syntax `SetFieldToNull(pbobject obj, pbfield fid)`

Argument	Description
<i>obj</i>	A valid object handle
<i>fid</i>	The field ID of the specified object

Return value None.

See also [GetFieldID](#)  
[GetFieldType](#)  
[Get<type>Field](#)  
[GetNumOfFields](#)  
[IsFieldArray](#)  
[IsFieldNull](#)  
[IsFieldObject](#)  
[Set<type>Field](#)

## SetGlobalVarToNull

Description Sets the value of the specified global variable to null.

Syntax `SetGlobalVarToNull(pbobject obj, pbfield fid)`

Argument	Description
<i>fid</i>	The field ID of the global variable

Return value None.

See also [GetGlobalVarID](#)  
[GetGlobalVarType](#)  
[Get<type>GlobalVar](#)  
[IsGlobalVarArray](#)  
[IsGlobalVarNull](#)  
[IsGlobalVarObject](#)  
[Set<type>GlobalVar](#)

## SetMarshaler

Description	Sets a marshaler that will be used to invoke remote methods and convert PowerBuilder data formats to the user's communication protocol.						
Syntax	<code>SetMarshaler(pbproxyObject <i>obj</i>, IPBX_Marshaler* <i>marshaller</i>)</code>						
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>obj</i></td><td>An object of type pbproxyObject to be used as a proxy for a remote object that was created using <code>NewProxyObject</code></td></tr> <tr> <td><i>marshaller</i></td><td>A class inherited from IPBX_Marshaler</td></tr> </tbody> </table>	Argument	Description	<i>obj</i>	An object of type pbproxyObject to be used as a proxy for a remote object that was created using <code>NewProxyObject</code>	<i>marshaller</i>	A class inherited from IPBX_Marshaler
Argument	Description						
<i>obj</i>	An object of type pbproxyObject to be used as a proxy for a remote object that was created using <code>NewProxyObject</code>						
<i>marshaller</i>	A class inherited from IPBX_Marshaler						
Return value	None.						
Examples	<p>This example creates a JavaMarshaler class and associates it with a proxy object:</p> <pre>// Create JavaMarshaler JavaMarshaler* marshaller = new JavaMarshaler(env,     proxy, job);  // Associate the JavaMarshaler with the PB proxy session-&gt;<b>SetMarshaler</b>(proxy, marshaller);  ci-&gt;pArgs-&gt;GetAt(0)-&gt;SetObject(proxy);  ci-&gt;returnValue-&gt;SetLong(kSuccessful); return PBX_OK;</pre>						
Usage	<p>The <code>SetMarshaler</code> function associates an object of type IPBX_Marshaler with a PBProxy object. It is possible to associate multiple marshaler objects with a single proxy object. It is also possible to associate one marshaler object with multiple proxy objects. Neither of these is good coding practice and should be avoided.</p> <p>Before calling <code>SetMarshaler</code>, you can call the <code>IPB_Session GetMarshaler</code> function to obtain an existing marshaler object associated with a given proxy object, and then destroy the existing marshaler object before associating a new marshaler with the proxy.</p> <p>When a proxy object is destroyed, it calls the associated marshaler object's <code>Destroy</code> method. If multiple proxy objects are associated with a single marshaler object, you need to implement some form of reference counting. Otherwise, the marshaler object is destroyed when the first associated proxy object is destroyed, and subsequent calls to the marshaler object's <code>Destroy</code> method, when other associated proxy objects are destroyed, will throw exceptions.</p>						

To avoid these issues, there should be a one-to-one relationship between marshaler and proxy objects.

GetMethodID

## SetProp

Description

Adds a new variable to the list of properties of the current session or changes the value of an existing variable.

Syntax

SetProp(LPCTSTR *name*, void\* *data*)

Argument	Description
<i>name</i>	The name of the property to be set
<i>data</i>	A pointer to the data buffer where the variable's value resides

Return value

None.

Examples

In this example, the native class has two functions. This is their description passed in the PBX\_GetDescription function:

```
"subroutine f_setprop(int a)\n"
"function int f_getprop()\n"
```

The functions are associated with these enumerated values:

```
enum MethodIDs
{
    mid_SetProp = 0,
    mid_GetProp = 1
};
```

When the *f\_setprop* function is called from PowerBuilder, the following code sets the value of the pointer *SetVal* to the integer value passed in by *f\_setprop*, then registers that value in the session with the property name *prop\_name*:

```
int* SetVal = new int;

if (mid == mid_SetProp)
{
    *SetValue = ci -> pArgs -> GetAt(0) -> GetInt();
    session -> SetProp(prop_name, SetVal);
}
```

When the `f_getprop` function is called, the following code uses `GetProp` to set the `GetValue` pointer to point to the value associated with `prop_name`, and then sets the return value to `*GetValue`:

```
if (mid == mid_GetProp)
{
    int* GetVal;
    GetValue = (int *)session -> GetProp(prop_name);
    ci -> returnValue -> SetInt(*GetVal);
}
```

#### Usage

`SetProp` enables you to use a variable value throughout an IPB session without using a global variable, which is susceptible to namespace conflicts with other sessions. `SetProp` is one of a set of three functions:

- Use `SetProp` to register a new variable with the session or to change the value of an existing variable.
- Use `GetProp` to access the variable.
- Use `RemoveProp` to remove the variable from the list of variables associated with the session when it is no longer needed.

This set of functions is particularly useful for working with multiple threads of execution in EA Server.

Suppose you want to throw an exception from within a PBNI extension and the exception itself is also defined by the PBNI extension. You call the `IPB_Session NewObject` function to create an instance of the exception, causing the `PBX_CreateNonVisualObject` function to be called.

One way to set the value of the fields of the exception before the function returns in a thread-safe manner is to create a new object or structure to hold the exception information before calling `NewObject`. You can call `SetProp` to store the structure or the object in the current `IPB_Session`. When `PBX_CreateNonVisualObject` is called, you can call `GetProp` to get the structure or object to obtain the exception information, then call `RemoveProp` to remove the data you stored in the current session.

[GetProp](#)  
[RemoveProp](#)

## SetSharedVarToNull

Description	Sets the value of the specified shared variable to null.						
Syntax	<code>SetSharedVarToNull(pbgroup <i>group</i>, pbfield <i>fid</i>)</code>						
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>group</i></td><td>The group to which the shared variable belongs</td></tr><tr><td><i>fid</i></td><td>The field ID of the shared variable</td></tr></tbody></table>	Argument	Description	<i>group</i>	The group to which the shared variable belongs	<i>fid</i>	The field ID of the shared variable
Argument	Description						
<i>group</i>	The group to which the shared variable belongs						
<i>fid</i>	The field ID of the shared variable						
Return value	None.						
Examples	This example tests the IsSharedVarNull and SetSharedVarToNull functions: <pre>curGroup = session -&gt; GetCurrGroup(); cls = session -&gt; GetClass(myobj);  fid = session -&gt; GetSharedVarID(curGroup, "i_svar"); if (session -&gt; IsSharedVarNull(curGroup, fid))     session -&gt; SetIntSharedVar(curGroup, fid, 1); else     session -&gt; SetSharedVarToNull(curGroup, fid);</pre>						
See also	<a href="#">Get&lt;type&gt;SharedVar</a> <a href="#">GetSharedVarID</a> <a href="#">GetSharedVarType</a> <a href="#">IsSharedVarArray</a> <a href="#">IsSharedVarNull</a> <a href="#">IsSharedVarObject</a> <a href="#">Set&lt;type&gt;SharedVar</a>						

## SetString

Description	Frees an existing string and assigns a new string value to it by performing a deep copy.						
Syntax	<code>SetString (pbstring <i>string</i>, LPCTSTR <i>src</i>)</code>						
	<table><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>string</i></td><td>A valid pbstring variable whose value is to be replaced</td></tr><tr><td><i>src</i></td><td>The string to be assigned to <i>string</i></td></tr></tbody></table>	Argument	Description	<i>string</i>	A valid pbstring variable whose value is to be replaced	<i>src</i>	The string to be assigned to <i>string</i>
Argument	Description						
<i>string</i>	A valid pbstring variable whose value is to be replaced						
<i>src</i>	The string to be assigned to <i>string</i>						
Return value	PBXRESULT. Returns PBX_OK for success or PBX_E_INVALID_ARGUMENT if the new string value is invalid; otherwise, returns PBX_E_OUTOF_MEMORY.						

**Examples**

This example uses the IPB\_Session SetString method to set the `ret_val` string to the return value in the PBCallInfo structure. It also uses the IPB\_Value SetPBString method to set values in PBCallInfo:

```
pbclass cls;
pbmethodID mid;
PBCallInfo* ci = new PBCallInfo;
pbstring ret_val;
LPCTSTR pStr;

cls= Session -> GetClass(myobj) ;
if (isAny)
    mid=Session-> GetMethodID(cls, "uf_any_byvalue",
        PBRT_FUNCTION, "AAAAAA");
else
    mid=Session-> GetMethodID(cls, "uf_string_byvalue",
        PBRT_FUNCTION, "SSSSSS");
Session-> InitCallInfo(cls, mid, ci);

ci-> pArgs -> GetAt(0) -> SetPBString(s_low);
ci-> pArgs -> GetAt(1) -> SetPBString(s_mid);
ci-> pArgs -> GetAt(2) -> SetPBString(s_high);
pStr = Session -> GetString(s_null);
if (pStr != 0)
{
    if (strcmp(pStr, "null") == 0 )
        ci-> pArgs -> GetAt(3) -> SetToNull();
    else
        ci-> pArgs -> GetAt(3) -> SetPBString(s_null);
}
Session -> InvokeObjectFunction(myobj, mid, ci);
ret_val = Session -> NewString("");
Session -> SetPBString(ret_val, Session->GetString
    (ci->returnValue->GetString()));
Session -> FreeCallInfo(ci);
delete ci;
return ret_val;
```

**Usage**

A deep copy is performed. The existing value is destroyed first, and then the contents of the `src` argument are copied into a new value.

**See also**

NewString

## SetTime

Description	Resets the value of the specified pbtime object.										
Syntax	<code>SetTime (pbtime time, pbint hour, pbint minute, pbdouble second)</code>										
	<table border="1"><thead><tr><th>Argument</th><th>Description</th></tr></thead><tbody><tr><td><i>time</i></td><td>The pbtime object to be reset</td></tr><tr><td><i>hour</i></td><td>An hour in the range 0 to 23</td></tr><tr><td><i>minute</i></td><td>A minute in the range 0 to 59</td></tr><tr><td><i>second</i></td><td>A second in the range 0 to 59.999999</td></tr></tbody></table>	Argument	Description	<i>time</i>	The pbtime object to be reset	<i>hour</i>	An hour in the range 0 to 23	<i>minute</i>	A minute in the range 0 to 59	<i>second</i>	A second in the range 0 to 59.999999
Argument	Description										
<i>time</i>	The pbtime object to be reset										
<i>hour</i>	An hour in the range 0 to 23										
<i>minute</i>	A minute in the range 0 to 59										
<i>second</i>	A second in the range 0 to 59.999999										
Return value	PBX_RESULT. PBX_OK for success or PBX_E_INVALID_ARGUMENT if the new time is invalid.										
Examples	This code puts a new time with the value 01:01:01 into the <i>time_val</i> property of the <i>pArguments</i> array if the value in the PBCallInfo structure is null. Otherwise it sets <i>time_val</i> to the time in the PBCallInfo structure:  <pre>if (ci-&gt;pArgs-&gt;GetAt(i)-&gt;IsNull()) {     pArguments[i].time_val = Session-&gt;NewTime();     Session-&gt;<b>SetTime</b>(pArguments[i].time_val, 1, 1, 1);     // Time: 01:01:01 } else {     pArguments[i].time_val =         ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetTime(); }</pre>										
Usage	If the parameters are invalid, the time is reset to 0:0:0.0.										
See also	<a href="#">NewTime</a> <a href="#">SplitTime</a>										

## SetValue

Description	Sets the value of one IPB_Value object to the value of another IPB_Value object.						
Syntax	<code>SetValue( IPB_Value* dest, IPB_Value* src)</code>						
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>dest</i></td><td>The value to be replaced</td></tr> <tr> <td><i>src</i></td><td>The value to which <i>dest</i> is to be changed</td></tr> </tbody> </table>	Argument	Description	<i>dest</i>	The value to be replaced	<i>src</i>	The value to which <i>dest</i> is to be changed
Argument	Description						
<i>dest</i>	The value to be replaced						
<i>src</i>	The value to which <i>dest</i> is to be changed						
Return value	None.						
Examples	These statements set the return value in the PBCallInfo structure <i>ci</i> to the value <i>IPBValue_ret</i> , then release the <i>IPBValue_ret</i> structure:						
	<code>Session -&gt; SetValue(ci -&gt; returnValue, IPBValue_ret); Session -&gt; ReleaseValue(IPBValue_ret);</code>						
Usage	Unlike the IPB_Value Set< <i>type</i> > methods, the SetValue method does not verify that the datatype of the replacement value matches the datatype of the original value. The original value is freed and a new value is cloned from the <i>src</i> value. Use this method if you want to swap two different IPB_Value objects that have different types.						
See also	<a href="#">AcquireValue</a> , <a href="#">ReleaseValue</a>						

## SplitDate

Description	Splits the specified pbdate object into a year, month, and day.										
Syntax	<code>SplitDate (pbdate date, pbint *year, pbint *month, pbint *day)</code>										
	<table border="1"> <thead> <tr> <th>Argument</th><th>Description</th></tr> </thead> <tbody> <tr> <td><i>date</i></td><td>The pbdate object to be split</td></tr> <tr> <td><i>year</i></td><td>A year in the range 1000 to 3000</td></tr> <tr> <td><i>month</i></td><td>A month in the range 1 to 12</td></tr> <tr> <td><i>day</i></td><td>A day in the range 1 to 31</td></tr> </tbody> </table>	Argument	Description	<i>date</i>	The pbdate object to be split	<i>year</i>	A year in the range 1000 to 3000	<i>month</i>	A month in the range 1 to 12	<i>day</i>	A day in the range 1 to 31
Argument	Description										
<i>date</i>	The pbdate object to be split										
<i>year</i>	A year in the range 1000 to 3000										
<i>month</i>	A month in the range 1 to 12										
<i>day</i>	A day in the range 1 to 31										
Return value	PBX_RESULT.PBX_OK for success.										
Examples	This statement splits the date in the first value in the PBCallInfo structure:										
	<code>Session -&gt; SplitDate(ci-&gt;pArgs -&gt; GetAt(0) -&gt; GetDate(), &amp;yy, &amp;mm, &amp;dd);</code>										
See also	<a href="#">NewDate</a> , <a href="#">SetDate</a> , <a href="#">SplitDateTime</a>										

## SplitDateTime

Description Splits the specified pbdatetime object into a year, month, day, hour, minute, and second.

Syntax `SplitDateTime(pbdatetime dt, pbint *year, pbint *month, pbint *day, pbint *hour, pbint *minute, pbdouble *second)`

Argument	Description
<i>dt</i>	The pbdatetime object to be split
<i>year</i>	A year in the range 1000 to 3000
<i>month</i>	A month in the range 1 to 12
<i>day</i>	A day in the range 1 to 31
<i>hour</i>	An hour in the range 0 to 23
<i>minute</i>	A minute in the range 0 to 59
<i>second</i>	A second in the range 0 to 59.999999

Return value PBX\_RESULT. PBX\_OK for success.

See also [NewDateTime](#), [SetDateTime](#), [SplitDate](#), [SplitTime](#)

## SplitTime

Description Splits the specified ptptime object into an hour, minute, and second.

Syntax `SplitTime(ptptime time, pbint *hour, pbint *minute, pbdouble *second)`

Argument	Description
<i>time</i>	The ptptime object to be split
<i>hour</i>	An hour in the range 0 to 23
<i>minute</i>	A minute in the range 0 to 59
<i>second</i>	A second in the range 0 to 59.999999

Return value PBX\_RESULT. PBX\_OK for success.

Examples These statements split a time into hours, minutes, and seconds, and then use the resulting values to set the value of a new time object:

```
Session->SplitTime(ci.returnValue->GetTime(), &hh,  
                      &mm, &ss);  
ret_val = Session-> NewTime();  
Session-> SetTime(ret_val, hh, mm, ss);
```

See also [NewTime](#)  
[SetTime](#)

## ThrowException

**Description** Throws a PowerBuilder exception or inherited exception, and replaces the existing exception if there is one.

**Syntax** ThrowException (pbobject ex)

<b>Argument</b>	<b>Description</b>
<i>ex</i>	The exception to be thrown. The exception must first be created with NewObject.

**Return value** None.

**Examples** This code creates a new exception object in the class user\_exception\_pspp, invokes its SetMessage function, and throws the exception:

```

pbclass cls;
pbmethodID mid;
pbobject ex;
pbgroup group;
PBCallInfo* ci = new PBCallInfo;

// Throw exception
group = session->FindGroup("user_exception_pspp",
    pbgroup_userobject);
if (group==NULL)
    return;
cls = session->FindClass(group, "user_exception_pspp");
if (group==NULL)
    return;
ex = session -> NewObject(cls);
mid = session->GetMethodID(cls,
    "setmessage", PBRT_FUNCTION, "QS");
session->InitCallInfo(cls,mid,ci);

ci->pArgs[0].SetPBString(session, "Test exception");

session -> InvokeObjectFunction(ex,mid,ci);
session -> ThrowException(ex);
if (!ThrowToPB)
    session -> ClearException();
session -> FreeCallInfo(ci);
delete ci;
return;

```

**See also** ClearException  
GetException  
HasExceptionThrown

## TriggerEvent

Description Triggers a PowerBuilder event.

Syntax `TriggerEvent(pbobject obj, pbmethodID mid, PBCallInfo *ci)`

Argument	Description
<i>obj</i>	The pbobject containing the method
<i>mid</i>	The pbMethodID returned by GetMethodID
<i>ci</i>	A pointer to a preallocated PBCallInfo structure

Return value PBXRESULT. Returns PBX\_OK for success, or one of the following for failure:

PBX\_E\_INVALID\_ARGUMENT  
PBX\_E\_INVOKE\_METHOD\_INACCESSABLE  
PBX\_E\_INVOKE\_WRONG\_NUM\_ARGS  
PBX\_E\_INVOKE\_REFARG\_ERROR  
PBX\_E\_INVOKE\_METHOD\_AMBIGUOUS  
PBX\_E\_INVOKE\_FAILURE

Examples This code triggers the clicked event on a DataWindow object:

```
cls = session->GetClass(dwobj) ;
mid = session->GetMethodID
    (cls, "clicked", PBRT_EVENT, "LIIILCdwobj ect.");
session->InitCallInfo(cls, mid, ci);
session->TriggerEvent(dwobj, mid, ci);
...
```

See also

[GetClass](#)  
[GetMethodID](#)

## UpdateField

Description

Refreshes a visual property of a PowerBuilder object.

Syntax

`UpdateField(pbobject obj, pbfieldID fid)`

Argument	Description
<i>obj</i>	The pbobject whose user interface property needs to be changed
<i>fid</i>	The field ID of the object

Return value

PBXRESULT. Returns success or failure.

Examples

This function changes the title of a DataWindow control:

```
void CallBack::f_newtitle(IPB_Session* session,
pbstring str_val, pbobject dwobj)
{
    pbclass cls;
    pbfieldID fid;
    cls=session->GetClass(dwobj);
    fid=session->GetFieldID(cls, "title");
    if (fid==kUndefinedFieldID)
        return;
    session -> SetPBStringField(dwobj,fid,str_val);
    session -> UpdateField(dwobj,fid);
    return ;
}
```

Usage

When you change any visual property of a PowerBuilder object by calling `Set<type>field` functions, the property is changed but the property is not refreshed in the graphical user interface. `UpdateField` refreshes the visual properties of PowerBuilder objects. You must call this function explicitly when changing any visual property with the `Set<type>field` functions.

See also

`Set<type>Field`

## IPB\_Value interface

**Description** The IPB\_Arguments and IPB\_Value interfaces pass values between the PowerBuilder VM and PowerBuilder extension modules. Through the IPB\_Value interface, you can access information about each variable, including its type, null flag, access privileges, array or simple type, and reference type.

**Methods**

**Table 7-4: IPB\_Value methods**

Method	Description
Get<type>	Set of datatype-specific methods that return a pointer to the data in IPB_Value
GetClass	Returns the class handle of a PowerBuilder object
GetType	Returns the datatype of a single data item or array
IsArray	Returns true if the IPB_Value instance contains an array, otherwise returns false
IsByRef	Returns true if the IPB_Value instance is passed by reference
IsEnum	Returns true if the IPB_Value instance contains a null value, otherwise returns false
IsObject	Returns true if the IPB_Value instance contains an object or object array, otherwise returns false
SetToNull	Used to set the data contained in the IPB_Value instance to null so that data can be reset
Set<type>	Set of datatype-specific methods that set the value of the IPB_Value instance

## Get<type>

Description	A set of datatype-specific methods that return a pointer to the data in IPB_Value.
Syntax	<code>GetArray()</code> <code>GetBlob()</code> <code>GetBool()</code> <code>GetByte()</code> <code>GetChar()</code> <code>GetDate()</code> <code>GetDateTime()</code> <code>GetDecimal()</code> <code>GetDouble()</code> <code>GetInt()</code> <code>GetLong()</code> <code>GetLongLong()</code> <code>GetObject()</code> <code>GetReal()</code> <code>GetString()</code> <code>GetTime()</code> <code>GetUint()</code> <code>GetUlong()</code>
Return value	A predefined PBNI datatype that corresponds to the PowerBuilder datatype in the method name.
Examples	This statement gets the date in the first value in the PBCallInfo structure and splits it into year, month, and day:
	<pre>Session -&gt; SplitDate(ci-&gt;pArgs -&gt; GetAt(0) -&gt;     GetDate(), &amp;yy, &amp;mm, &amp;dd);</pre>
Usage	If IPB_Value contains a null value, or if you are trying to get a specific datatype from an IPB_Value instance of another datatype, the data retrieved is undetermined. If the datatype is string, blob, decimal, time, date, datetime, array, or object, the return value points to the same address pointed to by IPB_Value. As a result, changing either the variable that holds the return value or the value of the IPB_Value instance affects the other.
See also	<code>Set&lt;type&gt;</code>

## GetClass

Description	Returns the class handle of a PowerBuilder object.
Syntax	GetClass( )
Return value	pbclass or null on error.
Examples	<pre>pbclass cls = ci-&gt;pArgs-&gt;GetAt(i)-&gt;<b>GetClass()</b>;</pre>
See also	Get<type> GetType Set<type>

## GetType

Description	Returns the datatype of a single data item or array.
Syntax	GetType()
Return value	pbuint
Examples	<pre>ArgsType = ci-&gt;pArgs-&gt;GetAt(i)-&gt;<b>GetType()</b>; switch (ArgsType) {     case pbvalue_int:         if (ci-&gt;pArgs-&gt;GetAt(i)-&gt;IsNull())             pArguments[i].int_val=1;         else             pArguments[i].int_val =                 ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetInt();         break;     ...</pre>
Usage	If the IPB_Value instance contains an object or structure, GetType returns the class ID of the data. Otherwise, it returns a simple datatype defined in the list of pbvalue_type enumerated types.
See also	Get<type> GetClass Set<type>

## IsArray

Description	Returns true if the IPB_Value instance contains an array; otherwise, returns false.
Syntax	IsArray( )
Return value	pbboolean
Examples	This example tests whether an IPB_Value instance is an array before obtaining the array:
	<pre>if(ci-&gt;pArgs-&gt;GetAt(i)-&gt;<b>IsArray()</b>) {     pArguments[i].array_val =         ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetArray();     continue; }</pre>
See also	<a href="#">IsByRef</a> <a href="#">IsEnum</a> <a href="#">IsObject</a>

## IsByRef

Description	Returns true if the IPB_Value instance contains a by reference argument; otherwise it returns false.
Syntax	IsByRef()
Return value	pbboolean
Examples	This example shows how you would use IsByRef to test whether an argument is obtained by reference:
	<pre>if(ci-&gt;pArgs-&gt;GetAt(i)-&gt;<b>IsByRef()</b>) ... </pre>
See also	<a href="#">IsArray</a> <a href="#">IsEnum</a> <a href="#">IsObject</a>

## IsEnum

Description	Returns true if the IPB_Value instance contains an enumerated value; otherwise it returns false.
Syntax	IsEnum( )
Return value	pbboolean
See also	<a href="#">GetEnumItemName</a> <a href="#">GetEnumItemValue</a>

## IsNull

Description	Returns true if the IPB_Value instance contains a null value; otherwise, it returns false.
Syntax	IsNull( )
Return value	pbboolean
Examples	This example tests whether an IPB_Value instance contains a null value before attempting to obtain its value:

```
if (ci->pArgs->GetAt(i)->IsObject())
{
    if (ci->pArgs->GetAt(i)->IsNull())
        pArguments[i].obj_val=0;
    else
        pArguments[i].obj_val =
            ci->pArgs->GetAt(i)->GetObject();
    continue;
}
...

```

See also	<a href="#">IsArray</a> <a href="#">IsByRef</a> <a href="#">IsObject</a> <a href="#">SetToNull</a>
----------	---

## IsObject

Description	Returns true if the IPB_Value instance contains an object or object array; otherwise it returns false.
Syntax	IsObject( )
Return value	pbboolean
Examples	This example tests whether an IPB_Value instance contains an object before attempting to obtain the object:
	<pre>if( ci-&gt;pArgs-&gt;GetAt(i)-&gt;<b>IsObject()</b> ) {     if( ci-&gt;pArgs-&gt;GetAt(i)-&gt;IsNull() )         pArguments[i].obj_val = 0;     else         pArguments[i].obj_val =             ci-&gt;pArgs-&gt;GetAt(i)-&gt;GetObject();     continue; } ... </pre>
See also	<a href="#">IsArray</a> <a href="#">IsByRef</a> <a href="#">IsEnum</a>

## Set<type>

Description	Set of datatype-specific methods that set the value of the IPB_Value instance.
Syntax	<code>SetArray ( pbarray array)</code> <code>SetBlob( pbblob blob )</code> <code>SetBool ( pbboolean boolean )</code> <code>SetByte ( pbbyte byte )</code> <code>SetChar ( pbchar char )</code> <code>SetDate ( pbdate date )</code> <code>SetDateTime( pbdatetime datetime )</code> <code>SetDecimal ( pbdecimal dec)</code> <code>SetDouble ( pbdouble double)</code> <code>SetInt ( pbint int )</code> <code>SetLong( pblong long )</code> <code>SetLongLong( pblonglong longlong )</code> <code>SetObject ( pbobject object )</code> <code>SetPBString ( pbstring string)</code> <code>SetReal( pbreal real )</code> <code>SetString ( LPCTSTR string)</code> <code>SetTime( pbtime time )</code> <code>SetUint( pbuint uint )</code> <code>SetUlong ( pb ulong ulong )</code>
Return value	PBXRESULT.

**Examples**

This example uses the IPB\_Value SetPBString method to set values in PBCallInfo. It also uses the IPB\_Session SetString method to set the ret\_val string to the return value in the PBCallInfo structure:

```
pbclass cls;
pbmethodID mid;
PBCallInfo* ci = new PBCallInfo;
pbstring ret_val;
LPCTSTR pStr;

cls= Session -> GetClass(myobj) ;
if (isAny)
    mid=Session-> GetMethodID(cls, "uf_any_byvalue",
        PBRT_FUNCTION, "AAAAAA");
else
    mid=Session-> GetMethodID(cls, "uf_string_byvalue",
        PBRT_FUNCTION, "SSSSSS");
Session-> InitCallInfo(cls, mid, ci);

// Call IPB_Value SetPBString method
ci-> pArgs -> GetAt(0) -> SetPBString(s_low);
ci-> pArgs -> GetAt(1) -> SetPBString(s_mid);
ci-> pArgs -> GetAt(2) -> SetPBString(s_high);
pStr = Session -> GetString(s_null);

if (pStr != 0)
{
    if (strcmp(pStr, "null") == 0 )
        ci-> pArgs -> GetAt(3) -> SetToString();
    else
        ci-> pArgs -> GetAt(3) -> SetPBString(s_null);
}

Session -> InvokeObjectFunction(myobj, mid, ci);
ret_val = Session -> NewString("");

// Call IPB_Session SetString method
Session -> SetString(ret_val, Session->GetString
    (ci->returnValue->GetString()));
Session -> FreeCallInfo(ci);
delete ci;
return ret_val;
```

**Usage** These methods automatically set the value of IPB\_Value to not null and return an error if the datatype to be set does not match the existing datatype. The error code is PBX\_E\_MISMATCHED\_DATA\_TYPE. If the value is a read-only argument, it returns the error PBX\_E\_READONLY\_ARGS. If the datatype is string or blob, a deep copy is performed. The existing value is destroyed first, and then the contents of the argument are copied into a new value.

**See also** Get<type>

## SetToNull

**Description** Sets the data contained in the IPB\_Value instance to null so the data can be reset.

**Syntax** SetToNull( )

**Return value** PBXRESULT. If the value is a read-only argument, the error PBX\_E\_READONLY\_ARGS is returned.

**Examples** This example shows the use of SetToNull when a null blob value is returned:

```
case pbvalue_blob:  
    pStr=(LPCTSTR)Session->GetBlob(retval.blob_val);  
    if (strcmp(pStr, "null", 4)==0 )  
        ci->returnValue->SetToNull();  
    else  
        ci->returnValue->SetBlob(retval.blob_val);  
    break;  
    ...
```

**See also** IsEnum

## IPB\_VM interface

Description	The IPB_VM interface loads PowerBuilder applications in third-party applications and interoperates with the PowerBuilder virtual machine (PBVM).
Methods	IPB_VM has two methods:  CreateSession RunApplication

### CreateSession

Description Creates an IPB\_Session object that can be used to call PowerBuilder functions.

Syntax `CreateSession(LPCTSTR applicationName, LPCTSTR* libraryList, pbuint numLibs, IPB_Session** session)`

Argument	Description
<i>applicationName</i>	The name of the current application object in lowercase
<i>libraryList</i>	The library list of the PowerBuilder application that contains the objects and functions to be called
<i>numLibs</i>	The number of libraries in the library list
<i>session</i>	A pointer to IPB_Session*, which will return the current IPB_Session pointer after the call

Return value PBXRESULT. PBX\_OK for success.

**Examples**

This example creates an IPB\_Session with the simple library list *mydemo.pbl*:

```
IPB_Session* session;
IPB_VM* vm = NULL;
fstream out;
ifstream in;
PBXRESULT ret;

HINSTANCE hinst=LoadLibrary("pbvm125.dll");
if ( hinst== NULL) return 0;

out<< "Loaded PowerBuilder VM successfully!"<<endl;

P_PB_GetVM getvm = (P_PB_GetVM)GetProcAddress
(hinst, "PB_GetVM");
if (getvm == NULL) return 0;

getvm(&vm);
if (vm == NULL) return 0;

static const char *liblist[] =
{
    "mydemo.pbl"
};

ret= vm->CreateSession("mydemo", liblist, 1, &session);
if (ret != PBX_OK)
{
    out << "Create session failed." << endl;
    return 0;
}
out << "Create session succeeded!" << endl;
```

**See also**

[RunApplication](#)

## RunApplication

Description	Runs the specified application.
Syntax	RunApplication(LPCTSTR <i>applicationName</i> , LPCTSTR* <i>libraryList</i> , pbuint <i>numLibs</i> , LPCSTR <i>commandLine</i> , IPB_Session** <i>session</i> )

Argument	Description
<i>applicationName</i>	The name of the application object to be run, in lowercase
<i>libraryList</i>	The library list of the application
<i>numLibs</i>	The number of libraries in the library list
<i>commandLine</i>	Parameters to be passed to the application object
<i>session</i>	A pointer to IPB_Session*, which will return the current IPB_Session pointer after the call

Return value	PBXRESULT.PBX_OK for success.
Examples	This code fragment loads the PowerBuilder VM and runs an application called <i>runapp</i> that uses one library, <i>runapp.pbd</i> . It passes in a command line with two arguments:

```

LRESULT CALLBACK WndProc(HWND hWnd, UINT message,
WPARAM wParam, LPARAM lParam)
{
    LPCTSTR szHello = "Hello world";

    // Provide command line parameters (employee ids)
    // to be passed to the PowerBuilder application
    LPCTSTR szcommandline = "102 110";

    int wmid, wmevent, ret;
    PAINTSTRUCT ps;
    HDC hdc;

    switch (message)
    {
        case WM_CREATE:
        {
            hPBVMInst = ::LoadLibrary("pbvm125.dll");
            P_PB_GetVM getvm = (P_PB_GetVM)
                GetProcAddress(hPBVMInst, "PB_GetVM");
            IPB_VM* vm = NULL;
    }
}

```

```
    getvm(&vm);

    static const char *liblist [] =
        {"runapp.pbd"};

    vm->RunApplication("runapp", liblist, 1,
        szcommandline, &session);

    break;
}
```

## IPBX\_Marshaler interface

**Description** The IPBX\_Marshaler interface is used to invoke remote methods and convert PowerBuilder data formats to the user's communication protocol. A marshaler extension is a PowerBuilder extension that acts as the bridge between PowerBuilder and other components, such as EJBs, Java classes, CORBA objects, Web services, and so on.

**Methods**

**Table 7-5: IPBX\_Marshaler methods**

Method	Description
Destroy	Destroys an instance of an object inherited from the IPBX_Marshaler structure
GetModuleHandle	Returns the handle of the PBX that contains the native class
InvokeRemoteMethod	Used in PowerBuilder marshaler native classes to call remote methods

## Destroy

**Description** Use the Destroy method to destroy instances of objects inherited from the IPBX\_Marshaler structure.

**Syntax** `Destroy()`

**Return value** None.

**Examples** This code destroys the current instance of the SampleMarshaler structure:

```
void SampleMarshaler::Destroy()
{
    delete this;
}
```

**Usage** You must implement this method in the marshaler native class after creating an instance of a marshaler structure and invoking remote methods.

**See also** [GetModuleHandle](#)  
[InvokeRemoteMethod](#)

## GetModuleHandle

Description	Returns the handle of the PBX that contains the native class. This method is required to allow the PowerBuilder VM to determine which PBXs can be unloaded.
Syntax	GetModuleHandle( )
Return value	pbulong
Examples	This code in the implementation of a marshaler class returns the handle of the PBX:

```
extern pbulong thisModuleHandle;
pbulong SampleMarshaler::GetModuleHandle()
{
    return thisModuleHandle;
}
```

The handle is set in the main module:

```
pbulong thisModuleHandle = 0;

BOOL APIENTRY DllMain( HANDLE hModule,
                      DWORD  ul_reason_for_call,
                      LPVOID lpReserved
)
{
    thisModuleHandle = (pbulong)hModule;

    switch (ul_reason_for_call)
    {
        case DLL_PROCESS_ATTACH:
        case DLL_THREAD_ATTACH:
        case DLL_THREAD_DETACH:
        case DLL_PROCESS_DETACH:
            break;
    }
    return TRUE;
}
```

Usage	You must implement this method in the marshaler native class.
See also	<a href="#">Destroy</a> <a href="#">InvokeRemoteMethod</a>

## InvokeRemoteMethod

Description	Used in PowerBuilder marshaler native classes to call remote methods.
Syntax	InvokeRemoteMethod(IPB_Session *session, pbproxyobject obj, LPCTSTR methodDesc, PBCallInfo *ci)

Argument	Description
<i>session</i>	This IPB session
<i>obj</i>	The proxy object for the remote object
<i>methodDesc</i>	An arbitrary string stored as an alias name for the remote method in the proxy, for example: function int foo(int a) alias "This is a method in remote BizTalk"
<i>ci</i>	The parameters and return value setting for the call

Return value PBXRESULT.PBX\_OK if the call succeeded.

Examples This example shows a header file for a sample marshaler class:

```
#include "sampleinclude.h"
#include <pbext.h>

class SampleMarshaler : public IPBX_Marshaler
{
private:
    string    d_mystring;
    long      d_mylong;

private:
    void myMethod(string arg1);

public:
    SampleMarshaler(
        string myString,
        long   mylong
    );
    ~SampleMarshaler();

    virtual PBXRESULT InvokeRemoteMethod
    (
        IPB_Session*   session,
        pbproxyObject  obj,
        LPCTSTR         methodDesc,
        PBCallInfo*    ci
    );
}
```

```
    virtual pbulong    GetModuleHandle();
    virtual void Destroy();

};
```

The associated C++ implementation file contains code like this:

```
PBXRESULT SampleMarshaler::InvokeRemoteMethod
(
    IPB_Session*    session,
    pbproxyObject   obj,
    LPCTSTR         methodDesc,
    PBCallInfo*     ci
)
{
    // method invocation
}
```

Usage

You must implement this method in the marshaler native class.

See also

Destroy  
GetModuleHandle

## IPBX\_NonVisualObject interface

Description

The IPBX\_NonVisualObject interface inherits from IPBX\_UserObject and is the direct ancestor class of nonvisual PowerBuilder native classes.

Methods

IPBX\_NonVisualObject inherits two methods from the IPBX\_UserObject interface: Destroy and Invoke.

## IPBX\_UserObject interface

Description	The IPBX_UserObject interface is the ancestor class of the PowerBuilder native classes.
Methods	IPBX_UserObject has two methods:Destroy and Invoke

## Destroy

Description Destroys the current instance of a PowerBuilder native class that inherits from IPBX\_UserObject.

Syntax `Destroy()`

Return value None.

Examples This example shows how you would call Destroy for the class MyPBNIClass:

```
void MyPBNIClass::Destroy()
{
    delete this;
}
```

Usage You must implement this method in the native class after creating an instance of the class and invoking remote methods.

See also [Invoke](#)

## Invoke

- Description Calls methods in PowerBuilder native classes.
- Syntax `Invoke(IPB_Session * session, pbobject obj, pbmethodID mid, PBCallInfo *ci)`

Argument	Description
<code>session</code>	This IPB session
<code>obj</code>	The PowerBuilder extension object to be invoked
<code>mid</code>	The pbMethodID returned by GetMethodID
<code>ci</code>	The parameters and return value setting for the call

- Return value PBXRESULT.PBX\_OK for success.
- Examples In this example, the method invoked depends on the value (0, 1, or 2) of the method ID returned from the GetMethodID method:

```
PBXRESULT PBNIExt::Invoke
{
    IPB_Session    *session,
    pbobject      obj,
    pbmethodID    mid,
    PBCallInfo    *ci
)
{
    PBXRESULT result = PBX_OK;

    switch (mid)
    {
        case mFuncA:
            result = FuncA(session, obj, ci);
            break;
        case mFuncB:
            result = FuncB(session, obj, ci);
            break;
        case mFuncC:
            result = FuncC(session, obj, ci);
            break;
        default:
            result = PBX_E_INVOKE_FAILURE;
            break;
    }

    return PBX_OK;
}
```

- See also [GetMethodID](#)

## IPBX\_VisualObject interface

Description	The IPBX_VisualObject interface inherits from IPBX_UserObject and is the direct ancestor class of visual PowerBuilder native classes.
Methods	<p>IPBX_VisualObject has three direct methods:</p> <ul style="list-style-type: none"> <li>CreateControl</li> <li>GetEventID</li> <li>GetWindowClassName.</li> </ul> <p>IPBX_NonVisualObject inherits two methods from the IPBX_UserObject interface:</p> <ul style="list-style-type: none"> <li>Destroy</li> <li>Invoke</li> </ul>

### CreateControl

Description	Creates a window control and returns its handle to the PowerBuilder VM.																				
Syntax	<pre>CreateControl(DWORD dwExStyle, LPCTSTR lpWindowName, DWORD dwStyle, int x, int y, int nWidth, int nHeight, HWND hWndParent, HINSTANCE hInstance)</pre>																				
	<table border="1" style="width: 100%; border-collapse: collapse;"> <thead> <tr> <th style="text-align: left; padding: 2px;">Argument</th><th style="text-align: left; padding: 2px;">Description</th></tr> </thead> <tbody> <tr> <td style="padding: 2px;"><i>dwExStyle</i></td><td style="padding: 2px;">The extended window style</td></tr> <tr> <td style="padding: 2px;"><i>lpWindowName</i></td><td style="padding: 2px;">The window name</td></tr> <tr> <td style="padding: 2px;"><i>dwStyle</i></td><td style="padding: 2px;">The window style</td></tr> <tr> <td style="padding: 2px;"><i>x</i></td><td style="padding: 2px;">The horizontal position of the window</td></tr> <tr> <td style="padding: 2px;"><i>y</i></td><td style="padding: 2px;">The vertical position of the window</td></tr> <tr> <td style="padding: 2px;"><i>nWidth</i></td><td style="padding: 2px;">The window's width</td></tr> <tr> <td style="padding: 2px;"><i>nHeight</i></td><td style="padding: 2px;">The window's height</td></tr> <tr> <td style="padding: 2px;"><i>hWndParent</i></td><td style="padding: 2px;">The handle of the parent or owner window</td></tr> <tr> <td style="padding: 2px;"><i>hInstance</i></td><td style="padding: 2px;">The handle of the application instance</td></tr> </tbody> </table>	Argument	Description	<i>dwExStyle</i>	The extended window style	<i>lpWindowName</i>	The window name	<i>dwStyle</i>	The window style	<i>x</i>	The horizontal position of the window	<i>y</i>	The vertical position of the window	<i>nWidth</i>	The window's width	<i>nHeight</i>	The window's height	<i>hWndParent</i>	The handle of the parent or owner window	<i>hInstance</i>	The handle of the application instance
Argument	Description																				
<i>dwExStyle</i>	The extended window style																				
<i>lpWindowName</i>	The window name																				
<i>dwStyle</i>	The window style																				
<i>x</i>	The horizontal position of the window																				
<i>y</i>	The vertical position of the window																				
<i>nWidth</i>	The window's width																				
<i>nHeight</i>	The window's height																				
<i>hWndParent</i>	The handle of the parent or owner window																				
<i>hInstance</i>	The handle of the application instance																				

Return value	HWND.
Examples	This is part of a visual extension example available on the Sybase Web site:
<pre>LPCTSTR CVisualExt::GetWindowClassName() {     return s_className; }  HWND CVisualExt::CreateControl</pre>	

```
(  
    DWORD dwExStyle,           // extended window style  
    LPCTSTR lpWindowName,    // window name  
    DWORD dwStyle,            // window style  
    int x,                   // horizontal position of window  
    int y,                   // vertical position of window  
    int nWidth,               // window width  
    int nHeight,              // window height  
    HWND hWndParent,          // handle to parent or owner window  
    HINSTANCE hInstance      // handle to application  
    instance  
)  
{  
    d_hwnd = CreateWindowEx(dwExStyle, s_className,  
                           lpWindowName, dwStyle, x, y, nWidth, nHeight,  
                           hWndParent, NULL, hInstance, NULL);  
  
    ::SetWindowLong(d_hwnd, GWL_USERDATA, (LONG) this);  
  
    return d_hwnd;  
}
```

**Usage**

The window must be registered before you call CreateControl.

**See also**

[GetEventID](#)

[GetWindowClassName](#)

## GetEventID

**Description** Returns the identifier of an event when the window's parent is notified that the event occurred.

**Syntax** GetEventID(HWND *hWnd*, uint *iMsg*, WPARAM *wParam*, LPARAM *lParam*)

Argument	Description
<i>hWnd</i>	The handle of the parent window.
<i>iMsg</i>	The message sent to the parent.
<i>wParam</i>	<p>The word parameter of the message. For WM_COMMAND, the high-order word specifies:</p> <ul style="list-style-type: none"> <li>• The notification code if the message is from a control</li> <li>• 1 if the message is from an accelerator</li> <li>• 0 if the message is from a menu.</li> </ul> <p>The low-order word specifies the identifier of the control, accelerator, or menu. For WM_NOTIFY, this parameter contains the identifier of the control sending the message.</p>
<i>lParam</i>	<p>The long parameter of the message. For WM_COMMAND, this parameter contains the handle of the control sending the message if the message is from a control. Otherwise, this parameter is null. For WM_NOTIFY, this parameter contains a pointer to a structure.</p>

**Return value** Integer.

**Examples** In this example, the GetEventID function returns the identifier PB\_BNCLICKED if a WM\_COMMAND message with the notification code BN\_CLICKED was sent. It returns the identifier PB\_ENCHANGE if a WM\_NOTIFY message was sent; otherwise it returns PB\_NULL.

```
TCHAR CVisualExt::s_className[] = "PBVisualExt";

LPCTSTR CVisualExt::GetWindowClassName()
{
    return s_className;
}

HWND CVisualExt::CreateControl
(
```

```
    DWORD dwExStyle,           // extended window style
    LPCTSTR lpWindowName,     // window name
    DWORD dwStyle,            // window style
    int x,                   // horizontal position of window
    int y,                   // vertical position of window
    int nWidth,              // window width
    int nHeight,              // window height
    HWND hWndParent,          // handle of parent or owner window
    HINSTANCE hInstance // handle of application instance
)
{
    d_hwnd = CreateWindowEx(dwExStyle, s_className,
                           lpWindowName, dwStyle, x, y, nWidth, nHeight,
                           hWndParent, NULL, hInstance, NULL);

    ::SetWindowLong(d_hwnd, GWL_USERDATA, (LONG)this);

    return d_hwnd;
}

int CVVisualExt::GetEventID(
    HWND hWnd,             /* Handle of parent window */
    UINT iMsg,              /* Message sent to parent window*/
    WPARAM wParam,          /* Word parameter of message*/
    LPARAM lParam           /* Long parameter of message*/
)
{
    if (iMsg == WM_COMMAND)
    {
        if ((HWND)lParam == d_hwnd)
        {
            switch(HIWORD(wParam) )
            {
                case BN_CLICKED:
                    return PB_BNCLICKED;
                    break;
            }
        }
    }

    if (iMsg == WM_NOTIFY)
    {
        return PB_ENCHANGE;
    }
    return PB_NULL;
}
```

Usage	This function is used to process Windows messages, such as WM_COMMAND and WM_NOTIFY, that are sent to the parent of an object and not to the object itself. Such messages cannot be caught in the visual extension's window procedure. The PBVM calls GetEventID to process these messages.
	If the message is mapped to a PowerBuilder event, GetEventID returns the event's identifier, for example PB_BNCLICKED, and the event is fired automatically. PowerBuilder event token identifiers are mapped to unsigned integer values in the <i>pbevid.h</i> header file. The identifiers in <i>pbevid.h</i> are associated with PowerBuilder event token names. For example, the identifier PB_BNCLICKED is associated with the token name pbm_bnclicked.
	If the message is not mapped to an event, GetEventID returns the value PB_NULL and the message is discarded.
See also	<a href="#">CreateControl</a> <a href="#">GetWindowClassName</a>

## GetWindowClassName

Description	Returns the name of the window.
Syntax	<code>GetWindowClassName()</code>
Return value	<code>LPCTSTR</code> .
Examples	The string returned by <code>GetWindowClassName</code> is passed as an argument to the <code>CreateControl</code> method:
	<pre>LPCTSTR CVisualExt::GetWindowClassName() {     return s_className; }</pre>
Usage	The window must be registered before you call <code>GetWindowClassName</code> .
See also	<a href="#">CreateControl</a> <a href="#">GetEventID</a>

## PBArrayInfo structure

Description PBArrayInfo is a C++ structure used to hold information about arrays.

Properties

**Table 7-6: PBArrayInfo members**

Member	Type	Description
ArrayBound	Local struct declaration	Structure of type pblong containing the boundaries ( <i>upperBound</i> , <i>lowerBound</i> ) of a dimension.
BoundedArray	Enum data	Used in <i>arrayType</i> to identify that the array is a bounded array.
UnboundedArray	Enum data	Used in <i>arrayType</i> to identify that the array is an unbounded array.
arrayType	Enum type	Used in IPB_Session::GetArrayInfo to identify the datatype of the array. Do not set this variable manually.
valueType	pbuint	The datatype of array items. Set it to pbvalue_type if it is a simple type, or pbobject if the item is a class or structure.
numDimensions	pbuint	Number of dimensions of the array. An unbounded array can have only one dimension. The lower bound is one.
bounds	ArrayBound[]	Array bounds declaration array, used in a bounded array.

## PBCallInfo structure

Description

PBCallInfo is a C++ structure used to hold arguments and return type information in function calls between PBNI and PowerBuilder.

**Table 7-7: PBCallInfo members**

Member	Type	Description
pArgs	IPB_Arguments*	Interface used to access arguments
returnValue	IPB_Value	Holds return data after the call
returnClass	pbclass	Holds return class after the call

## PB\_DateData structure

Description The PB\_DateData structure is used to pass data of type Date in the SetData function in the IPB\_RSItemData interface.

**Table 7-8: PB\_DateData members**

Field	Description
<i>year</i>	A short identifying the year
<i>month</i>	A short identifying the month
<i>day</i>	A short identifying the day
<i>filler</i>	A short used for structure alignment only

See also SetData

## PB\_DateTimeData structure

Description The PB\_DateTimeData structure is used to pass data of type DateTime in the SetData function in the IPB\_RSItemData interface.

**Table 7-9: PB\_DateTimeData members**

Field	Description
<i>date</i>	A PB_DateData structure identifying the date
<i>time</i>	A PB_TimeData structure identifying the time

See also SetData

## PB\_TimeData structure

Description The PB\_TimeData structure is used to pass data of type Time in the SetData function in the IPB\_RSItemData interface.

**Table 7-10: PB\_TimeData members**

Field	Description
<i>hour</i>	A short identifying the hour
<i>minute</i>	A short identifying the minute
<i>second</i>	A short identifying the second
<i>filler</i>	A short used for structure alignment only

See also SetData

## PBX\_DrawItemStruct structure

### Description

The PBX\_DrawItemStruct structure contains the properties of an external visual control that you want to draw using the PBX\_DrawVisualObject function.

**Table 7-11: PBX\_DrawItemStruct members**

Field	Description
<i>x</i>	X coordinate of the visual control relative to its parent control (for example, the window that contains it).
<i>y</i>	Y coordinate of the visual control relative to its parent control.
<i>width</i>	Width of the visual control.
<i>height</i>	Height of the visual control.
<i>objectName</i>	The name of the visual object, for example: uo_1.
<i>tag</i>	Field to be used to pass any value at the user's discretion.
<i>enabled</i>	Whether the visual control is enabled. Possible values are true and false.
<i>visible</i>	Whether the visual control is visible. Possible values are true and false. In the development environment, PowerBuilder does not call the PBX_DrawVisualObject function if this field is set to false and the Design>Show Invisibles menu item is not selected.
<i>borderstyle</i>	Border style of the visual control. A value of the <i>pbborder_style</i> enumerated variable. Possible values are: <ul style="list-style-type: none"><li>• 0 – none</li><li>• 1 – shadowbox</li><li>• 2 – box</li><li>• 5 – lowered</li><li>• 6 – raised</li></ul>
<i>backColor</i>	Background color of the visual control. You can obtain the RGB value of the background color using the Windows API functions GetRValue, GetGValue, and GetBValue.

## PBArrayAccessor template class

### Description

There are two versions of the PBArrayAccessor template class. The first version is used to access the items in an array of a standard type. The second version is used to access items in a string array. The standard types are defined as ValueTypes in *pbtraits.h* and are pbint, pbuint, pbbyte, pblong, pblonglong, pbulong, pbboolean, pbreal, pbdouble, pbdec, pbdate, pbttime, pbdatetime, pbchar, pbblob, and pbstring.

PBArrayAccessor has four methods:

GetAt  
IsNull  
SetAt  
SetToNull

### GetAt

#### Description

Obtains the array item at the specified dimension.

#### Syntax

GetAt(pblong *dim*[])

#### Return value

ValueType (defined in *pbtraits.h*).

Argument	Description
<i>dim</i>	The dimension of the array item to be obtained

#### Examples

See SetAt.

#### See also

SetAt

### IsNull

#### Description

Returns true if the array item contains a null value, otherwise returns false.

#### Syntax

IsNull(pblong *dim*[ ])

Argument	Description
<i>dim</i>	The dimension of the array item to be tested

#### Return value

pbboolean.

#### See also

GetAt, SetAt, SetToNull

## SetAt

Description Sets the array item at the specified dimension.

Syntax For arrays of a specified ValueType:

SetAt(pblong *dim*[ ], ValueType *v*)

For string arrays:

SetAt(pblong *dim*[ ], LPCTSTR *string*)

SetAt(pblong *dim*[ ], pbstring *string*)

Argument	Description
<i>dim</i>	The dimension of the array item to be set
<i>v</i>	A ValueType defined in <i>pbtraits.h</i>
<i>string</i>	A string of type pbstring or LPCTSTR

Return value None.

Examples This example shows the use of GetAt and SetAt in arrays of a type specified by a ValueType:

```
template < typename T, pbvalue_type I>
void ArrayCreator<T, I>::f_unbounded_simple_array(
    IPB_Session* session,
    ifstream in,
    fstream out,
    LPCSTR data_type)
{
    pbarray out_array;
    int i;
    pblong dim[4], itemcount1, itemcount2;

    T *iarg, oarg;

    in >> itemcount1;
    iarg = new T[itemcount1];
    // Create unbounded integer array
    {
        PBUnboundedArrayCreator<I> ac(session);
        out_array = ac.GetArray();
        PBArrayAccessor<I> aa(session, out_array);
        for(i=0; i<itemcount1; i++)
            in >> iarg[i];
        for (i=0; i<itemcount1; i++)
        {
            dim[0]=i+1;
            aa.SetAt(dim, iarg[i]);
        }
    }
}
```

```
        }
        itemcount2 = session->GetArrayItemCount (out_array);
        out << "The array item count is "<< itemcount2 <<
            endl;
        for (i=0; i<itemcount2; i++)
        {
            dim[0]=i+1;
            oarg=aa.GetAt(dim);
            if (oarg != iarg[i])
                out << "*** ERROR" << endl;
            else
                out << oarg << " ";
        }
    }
    delete []iarg;
    out << endl;
    return;
}
```

See also      [GetAt](#)

## SetToNull

Description      Sets the value of the specified array item to null.

Syntax      `SetToNull(pblong dim[ ])`

Argument	Description
<code>dim</code>	The dimension of the array item to be set

Return value      None.

See also      [GetAt](#)  
[IsNull](#)  
[SetAt](#)

## PBBoundedArrayCreator template class

### Description

There are two versions of the PBBoundedArrayCreator template class. The first version is used to create a bounded array of a standard type. The standard types are defined as ValueTypes in *pbtraits.h* and are pbint, pbuint, pbbyte, pblong, pblonglong, pbulong, pbboolean, pbreal, pbdouble, pbdec, pbdate, pftime, pbdatetime, pbchar, pbblob, and pbstring. The second version is used to create a bounded array of strings.

### Methods

PBBoundedArrayCreator has two methods:

GetArray  
SetAt

## GetArray

### Description

Obtains an array that has been created.

### Syntax

GetArray()

### Return value

pbarray.

### Examples

This example sets up an array, reads in values, and then obtains the values in the array:

```
LPCTSTR *ostr_a;
char **sp;
int i;
pbarray out_array;
arrayBounds* bounds;
pbuint dim1, dim2, current_dim;
pblong itemcount1, itemcount2;
PBXRESULT ret;
PBArryInfo* ai;
pbstring *iarg, *oarg;
typedef PBBoundedArrayCreator<pbvalue_string>
    BoundedStringArrayCreator;

in >> dim1;
// allocate memory for pointer bounds
bounds = (arrayBounds*)malloc(dim1*sizeof
    (PBArryInfo::ArrayBound));
bounds = new arrayBounds[dim1];
// read in lowerbound and upperbound for each dimension
// and calculate the array item count
itemcount1 = 1;
for (i=0;i<dim1;i++)
```

```

{
    in >> bounds[i].lowerBound >> bounds[i].upperBound;
    itemcount1 = itemcount1*
        (bounds[i].upperBound - bounds[i].lowerBound +1);
}
sp = new char*[itemcount1];
ostr_a = new LPCTSTR[itemcount1];
iarg = new pbstring[itemcount1];
// Read in array items
for (i=0; i<itemcount1; i++)
{
    sp[i] = new char[20];
    in >> sp[i];
    iarg[i]= session->NewString(sp[i]);
}
// create bounded simple array and set iarg[i] to it
{
    BoundedStringArrayCreator ac(session, dim1, bounds);
    current_dim = 1;
    BoundedArrayItem<pbstring, pbvalue_string,
        BoundedStringArrayCreator>::f_set_arrayitem
        (session, ac, dim1, bounds, iarg, current_dim);
    BoundedArrayItem<pbstring, pbvalue_string,
        BoundedStringArrayCreator>::array_itemcount = 0;
    out_array = ac.GetArray();
}
}

```

See also

SetAt

## SetAt

Description

Sets a value or string to the array item at the specified dimension.

Syntax

For arrays of a specified ValueType:

SetAt(pblong *dim*[], ValueType *v*)

For string arrays:

SetAt(pblong *dim*[], LPCTSTR *string*)SetAt(pblong *dim*[], pbstring *string*)

Argument	Description
<i>dim</i>	The dimension of the array item to be set
<i>v</i>	A ValueType defined in <i>pbtraits.h</i>
<i>string</i>	A string of type pbstring or LPCTSTR

Return value

None.

Examples

This example shows the use of **SetAt** in arrays of a type specified by **ValueType**:

```
// arguments:  
// ac:  class object of PBBoundedArrayCreator or  
// PBBoundedObjectArrayCreator to set items into  
// dimensions: array dimension, can be 1,2,3,...,n  
// bounds: upper and lower bound for each dimension  
// iarg: T type array to store the data value set  
// into array creator ac  
// current_dim: remember which dimension is looped into  
  
template < typename T, pbvalue_type I, class C>  
void BoundedArrayItem<T,I,C>::f_set_arrayitem  
    (IPB_Session* session, C& ac, pblong dimensions,  
     arrayBounds* bounds, T* iarg, int current_dim)  
{  
    int i;  
    if (current_dim > dimensions)  
        return;  
    for(i= bounds[current_dim-1].lowerBound;  
        i<= bounds[current_dim-1].upperBound; i++)  
    {  
        if (current_dim == dimensions)  
        {  
            dim[current_dim-1]= i;  
            ac.SetAt(dim,iarg[array_itemcount]);  
            array_itemcount++;  
        }  
        else  
        {  
            dim[current_dim-1]= i;  
            BoundedArrayItem<T,I,C>::f_set_arrayitem  
                (session, ac, dimensions, bounds, iarg,  
                 current_dim+1);  
        }  
    }  
}
```

## PBBoundedObjectArrayCreator class

Description	The PBBoundedObjectArrayCreator class is used to create an object array.
Methods	PBBoundedObjectArrayCreator has two methods: GetArray SetAt

### GetArray

Description	Obtains an array that has been created.
Syntax	GetArray()
Return value	parray.
Examples	This example sets the values in an array and then uses GetArray to obtain the array:

```
PBBoundedObjectArrayCreator<pbvalue_string>
    ac(session);
    for (i=0;i<itemcount1;i++)
    {
        ac.SetAt(i+1,iarg[i]);
    }
    out_array = ac.GetArray();
```

See also	SetAt
----------	-------

### SetAt

Description	Sets the array item at the specified dimension.
Syntax	For arrays of a specified ValueType: SetAt(pblong dim[], ValueType v)  For string arrays: SetAt(pblong dim[], LPCTSTR string) SetAt(pblong dim[], pbstring string)

Argument	Description
dim	The dimension of the array item to be set
v	A ValueType defined in <i>pbtraits.h</i>
string	A string of type pbstring or LPCTSTR

Return value	None.
Examples	This method is included in the example for GetArray.
See also	<a href="#">GetArray</a>

## PBObjectArrayAccessor class

Description	The PBObjectArrayAccessor class is used to access the items in an object array.
Methods	PBObjectArrayAccessor has two methods:
	<a href="#">GetAt</a> <a href="#">SetAt</a>

### GetAt

Description                      Obtains the array item at the specified dimension.

Syntax                        `GetAt(pblong dim[])`

Return value                  pbobject.

Argument	Description
<code>dim</code>	The dimension of the array item to be set

Examples                      This example shows the use of GetAt in an object array:

```
PBObjectArrayAccessor aa(session, *array_val);
for (i=0;i<itemcount2;i++)
{
    dim[0] = i+1;
    oarg = aa.GetAt(dim);
    cls = session->GetClass(oarg);
    if( cls == NULL )
        return;
    fid = session->GetFieldID(cls, "text");
    if ( fid == 0xffff)
        return;
    fid_pv = session->GetFieldAddress(oarg,fid);
    mystr = fid_pv->GetString();
    ostr_a[i] = session->GetString(mystr);
}
```

See also	<a href="#">SetAt</a>
----------	-----------------------

## SetAt

Description Sets the array item at the specified dimension.

Syntax `SetAt(pblong dim[], pbobject obj)`

Argument	Description
<i>dim</i>	The dimension of the array item to be set
<i>obj</i>	A valid object handle

Return value None.

Examples This example shows the use of SetAt in an object array:

```
PBObjectArrayAccessor aa(session,*array_val);
for (i=0;i<itemcount1;i++)
{
    cls = session->FindClass(group,sp[i]);
    if( cls == NULL )
        return;
    iarg = session->NewObject(cls);
    session->ReferenceObject(iarg);
    dim[0] = i+1;
    aa.SetAt(dim, iarg);
    fid = session->GetFieldID(cls, "text");
    if ( fid == 0xffff )
        return;
    fid_pv = session->GetFieldAddress(iarg, fid);
    mystr = fid_pv->GetString();
    istr_a[i] = session->GetString(mystr);
}
```

See also [GetAt](#)

## PBUnboundedArrayCreator template class

### Description

There are two versions of the PBUnboundedArrayCreator template class. The first version is used to create an unbounded array of a standard type. The standard types are defined as ValueTypes in *pbtraits.h* and are pbint, pbbyte, pbuint, pblong, pblonglong, pb ulong, pb boolean, pb real, pb double, pb dec, pb date, pb time, pb datetime, pb char, pb blob, and pb string. The second version is used to create an unbounded array of strings.

### Methods

PBUnboundedObjectArrayCreator has two methods:

GetArray  
SetAt

## GetArray

### Description

Obtains an array that has been created.

### Syntax

GetArray()

### Return value

pbaray.

### Examples

This example sets the values in an array and then uses GetArray to obtain the array:

```
PBUnboundedArrayCreator<pbvalue_string> ac(session);
for (i=0; i<itemcount1; i++)
{
    ac.SetAt(i+1,iarg[i]);
}
out_array = ac.GetArray();
```

### See also

SetAt

## SetAt

Description Sets the array item at the specified position.

Syntax For arrays of a specified ValueType:

SetAt(pblong pos, ValueType v)

For string arrays:

SetAt(pblong pos, LPCTSTR string)

SetAt(pblong pos, pbstring string)

Argument	Description
<i>pos</i>	A pblong identifying a position in the array
<i>v</i>	A ValueType defined in <i>pbtraits.h</i>
<i>string</i>	A string of type pbstring or LPCTSTR

Return value None.

Examples This example shows the use of SetAt in arrays of a type specified by a ValueType:

```
PBUnboundedArrayCreator<I> ac(session);
in >> iarg[i];
for (i=0; i<itemcount1; i++)
{
    ac.SetAt(i+1, iarg[i]);
}
out_array = ac.GetArray();
```

See also [GetArray](#)

## PBUnboundedObjectArrayCreator class

Description	The PBUnboundedObjectArrayCreator class is used to create an object array.
Methods	PBUnboundedObjectArrayCreator has two methods:
	GetArray SetAt

### GetArray

Description	Obtains an array that has been created.
Syntax	GetArray( )
Return value	parray.
See also	SetAt

### SetAt

Description	Sets the array item at the specified dimension.
Syntax	For arrays of a specified ValueType:  SetAt( pblong pos, ValueType v )  For string arrays:  SetAt( pblong pos, LPCTSTR string ) SetAt( pblong pos, pbstring string )

Argument	Description
pos	A pblong identifying a position in the array
v	A ValueType defined in <i>pbtraits.h</i>
string	A string of type pbstring or LPCTSTR

Return value	None.
See also	GetArray

## Exported methods

**Description** The following table lists methods that must be implemented in the PowerBuilder extension module when the conditions shown in the table apply. The methods are described after the table. The PBX\_GetVersion method is used by PowerBuilder to determine whether the compiler macro UNICODE or \_UNICODE has been set. It is for internal use only.

**Methods** *Table 7-12: Methods that must be exported by all extensions*

Method	Required
PBX_CreateNonVisualObject	When the extension contains nonvisual native classes
PBX_CreateVisualObject	When the extension contains visual native classes
PBX_DrawVisualObject	When you want to be able to draw a visual representation of the visual object in the PowerBuilder development environment
PBX_GetDescription	In all extensions
PBX_InvokeGlobalFunction	When the extension contains global functions
PBX_Notify	When you need to initialize and uninitialized a session

### PBX\_CreateNonVisualObject

**Description** Creates a new instance of a nonvisual PowerBuilder extension object.

**Syntax** PBX\_CreateNonVisualObject(IPB\_Session\* *pbsession*, pbobject *pobj*, LPCTSTR *xtraname*, IPBX\_NonVisualObject \*\**obj*).

Argument	Description
<i>pbsession</i>	This IPB session
<i>pobj</i>	The name of a pbobject corresponding to the PowerBuilder extension object to be created
<i>xtraname</i>	The name of the PowerBuilder native class in lowercase
<i>obj</i>	The PowerBuilder extension object to be created

**Return value** PBXRESULT. PBX\_OK for success.

**Examples**

In this example, the extension contains several classes. The object created depends on the string value of the class name passed in.

```
PBXEXPORT PBXRESULT PBXCALL PBX_CreateNonVisualObject
(
    IPB_Session*          pbsession,
    pbobject               pbobj,
    LPCTSTR                xtraName,
    IPBX_NonVisualObject **obj
)
{
    PBXRESULT result = PBX_OK;

    string cn(className);
    if (cn.compare("class_a") == 0)
    {
        *obj = new class_a(pbobj);
    }
    else if (cn.compare("class_b") == 0)
    {
        *obj = new class_b(pbobj);
    }
    else if (cn.compare("class_c") == 0)
    {
        *obj = new class_b(pbobj);
    }
    else
    {
        *obj = NULL;
        result = PBX_E_NO_SUCH_CLASS;
    }

    return PBX_OK;
};
```

**Usage**

You must implement this method in every PowerBuilder extension module that contains nonvisual classes. When you use the CREATE statement in PowerScript to create a new PowerBuilder extension object, the PBVM calls this method.

**See also**

[PBX\\_GetDescription](#)

## PBX\_CreateVisualObject

Description

Creates a new instance of a visual PowerBuilder extension object.

Syntax

PBX\_CreateVisualObject(IPB\_Session\* *pbsession*, pbobject *pobj*,  
LPCTSTR *xtraname*, IPBX\_NonVisualObject \*\**obj*).

Argument	Description
<i>pbsession</i>	This IPB session
<i>pobj</i>	The name of a pbobject corresponding to the PowerBuilder extension object to be created
<i>xtraname</i>	The name of the PowerBuilder native class in lowercase
<i>obj</i>	The PowerBuilder extension object to be created

Return value

PBXRESULT. PBX\_OK for success.

Examples

In this example the extension contains several classes. The object created depends on the string value of the class name passed in.

```
PBXEXPORT PBXRESULT PBXCALL PBX_CreateVisualObject
(
    IPB_Session*          pbsession,
    pbobject               pobj,
    LPCTSTR                className,
    IPBX_VisualObject     **obj
)
{
    PBXRESULT result = PBX_OK;

    string cn(className);
    if (cn.compare("visualext") == 0)
    {
        *obj = new CVisualExt(pbsession, pobj);
    }
    else
    {
        *obj = NULL;
        result = PBX_FAIL;
    }
    return PBX_OK;
};
```

Usage

You must implement this method in every PowerBuilder extension module that contains visual classes. When you use a visual extension in a PowerBuilder application, the PBVM calls this method.

PBX\_GetDescription

## PBX\_DrawVisualObject

Description      Draws a visual object in the PowerBuilder development environment.

Syntax      PBX\_DrawVisualObject(HDC *hDC*, LPCTSTR *className*, const PBX\_DrawItemStruct& *property*).

Argument	Description
<i>hDC</i>	A handle to the device context of the object
<i>classname</i>	The name of the visual extension object to be drawn
<i>property</i>	A PBX_DrawItemStruct structure specifying the display properties of the object

Return value      PBXRESULT. The return value of this function is currently ignored.

Examples      This is an extension of a sample that is available on the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com>. It draws a representation of a light-emitting diode (LED) and uses Microsoft Foundation Classes (MFC):

```
PBXEXPORT PBXRESULT PBXCALL PBX_DrawVisualObject
(
    HDC hDC,
    LPCTSTR xtraName,
    const PBX_DrawItemStruct& property
)
{
    // If this PBX is dynamically linked against the MFC
    // DLLs, any functions exported from this PBX that
    // call into MFC must have the AFX_MANAGE_STATE macro
    // added at the very beginning of the function.
    AFX_MANAGE_STATE( AfxGetStaticModuleState() );

    // Variables to hold the Led control and a pointer
    // to Device Context
    CLed *myLed;
    CDC* pDC;

    // The name must not contain uppercase letters
    if ( strcmp( xtraName, "u_cpp_led" ) == 0 )
    {
        CRect rc( property.x, property.y, property.x +
            property.width, property.y + property.height );

        //Create a new LED
        myLed = new CLed();
    }
}
```

```
// Get the handle from the hDC
pDC = CDC::FromHandle(hDC);
CWnd* pWnd = pDC->GetWindow();

// Create the window
myLed->Create(NULL, WS_CHILD | WS_VISIBLE |
    SS_BITMAP, rc, pWnd);

// Function that handles the background
// rendering of the control
myLed->OnEraseBkgndIDE(pDC);

// Draw the LED in default mode (red, on, round)
myLed->DrawLed(pDC, 0, 0, 0);
myLed->SetLed(0, 0, 0);

//done
delete myLed;
}

return PBX_OK;
}
```

**Usage**

In a visual extension, export this function if you want the visual control to be drawn in the development environment. If you do not export the function, you need to run the application to see the appearance of the visual control.

**See also**

PBX\_CreateVisualObject  
PBX\_DrawItemStruct structure

## PBX\_GetDescription

Description	Passes a description of all the classes and methods in the PowerBuilder extension module to PowerBuilder.
Syntax	PBX_GetDescription ()
Return value	LPCTSTR containing the description of the module.
Examples	The following extension module contains three classes:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class class_a from nonvisualobject\n"
        "function long meth1(string classpath)\n"
        "function string meth2()\n"
        "end class\n"

        "class class_b from nonvisualobject\n"
        "subroutine sbrt1()\n"
        "subroutine sbrt2()\n"
        "function long func1()\n"
        "end class\n"

        "class class_c from nonvisualobject\n"
        "end class\n"
    };

    return desc;
}
```

The following module contains a visual class that has two subroutines (functions that do not return values), two events that require that Windows messages be captured in the extension (onclick and ondoubleclick), and one event that maps a Windows message directly to a PowerBuilder event (testmouse). The module also contains two global functions, funcA and funcB.

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "class visualext from userobject\n"
        "event int onclick()\n"
        "event int ondoubleclick()\n"
        "subroutine setcolor(int r, int g, int b)\n"
        "subroutine settext(string txt)\n"
        "event testmouse pbm_mousemove "
    };
}
```

```
    "globalfunctions\n"
    "function int funcA(int a, int b)\n"
    "function int funcB(int a, int b)\n"
    "end globalfunctions\n"
};

return desc;
}
```

**Usage**

You must implement this method in every PowerBuilder extension module. The method is exported from the PowerBuilder extension module and is used by PowerBuilder to display the prototype of each class, function, and event in the module.

The syntax of the description follows:

---

**Multiple instances**

A syntax element with an asterisk indicates that multiple instances of that element can appear in a description. For example, *[Desc]\** indicates that one description can contain multiple classes, global functions, and forward declarations.

---

```
Desc ::=  
       class_desc | globalfunc_desc | forward_desc | [Desc]*  
class_desc ::=  
       class className from parentClass newline  
           [methods_desc]* end class newline  
globalfunc_desc ::=  
       globalfunctions newLine [func_desc]* end globalfunctions  
forward_desc ::=  
       forward newLine [forwardtype_desc]* end forward  
forwardtype_desc ::=  
       class className from parentClass newline  
className ::=  
       a PowerBuilder token (cannot duplicate an existing group name)  
parentClass ::=  
       any class inherited from NonVisualObject or UserObject  
newline ::=  
       a newline character  
methods_desc ::=  
       method_desc [methods_desc]*  
method_desc ::=  
       func_desc | sub_desc | event_desc
```

```
func_desc ::=  
    function returnType funcName(args_desc) newline  
returnType ::=  
    pbType  
pbType ::=  
    any PowerBuilder type | previous declared PBNI class  
funcName ::=  
    a PowerBuilder token  
args_desc ::=  
    None | arg_desc, [args_desc]*  
arg_desc ::=  
    [ ref | readonly ] pbType argName [array_desc]  
argName ::=  
    a PowerBuilder token  
array_desc ::=  
    array declaration of PowerBuilder  
sub_desc ::=  
    subroutine subName(args_desc) newline  
event_desc ::=  
    event returnType eventName(args_desc) newline  
    | event eventName pbevent_token newline  
pbevent_token ::=  
    string
```

This syntax for event\_desc allows you to map a Windows message directly to a PowerBuilder event:

```
event eventName pbevent_token newline
```

For more information, see “Event processing in visual extensions” on page 34.

PBX\_CreateNonVisualObject  
PBX\_CreateVisualObject  
PBX\_InvokeGlobalFunction

## PBX\_InvokeGlobalFunction

**Description** Contains the implementation of one or more global functions used in the PowerBuilder extension module.

**Syntax** `PBX_InvokeGlobalFunction(IPB_Session* pbsession, LPCTSTR functionname, PBCallInfo* ci);`

Argument	Description
<code>pbsession</code>	This IPB session
<code>functionname</code>	The name of the global function
<code>ci</code>	A pointer to a preallocated PBCallInfo structure containing the parameters and return value setting for the function

**Return value** PBXRESULT. PBX\_OK for success.

**Examples** This PBX\_GetDescription call declares three global functions: bitAnd, bitOr, and bitXor:

```
PBXEXPORT LPCTSTR PBXCALL PBX_GetDescription()
{
    static const TCHAR desc[] = {
        "globalfunctions\n"
        "function int bitAnd(int a, int b)\n"
        "function int bitOr(int a, int b)\n"
        "function int bitXor(int a, int b)\n"
        "end globalfunctions\n"
    };

    return desc;
}
```

The PBX\_InvokeGlobalFunction call contains the implementation of the functions:

```
PBXEXPORT PBXRESULT PBXCALL PBX_InvokeGlobalFunction
(
    IPB_Session*    pbsession,
    LPCTSTR         functionName,
    PBCallInfo*     ci
)
{
    PBXRESULT pbrResult = PBX_OK;

    int arg1 = ci->pArgs->GetAt(0)->GetInt();
    int arg2 = ci->pArgs->GetAt(1)->GetInt();
```

```
if (strcmp(functionName, "bitand") == 0)
{
    ci->returnValue->SetInt(arg1 & arg2);
}else if (strcmp(functionName, "bitor") == 0)
{
    ci->returnValue->SetInt(arg1 | arg2);
}else if (strcmp(functionName, "bitxor") == 0)
{
    ci->returnValue->SetInt(arg1 ^ arg2);
}else
{
    return PBX_FAIL;
}

return pbrResult;
}
```

**Usage**

Use this function in a PowerBuilder native class that uses global functions. The function is exported from the PowerBuilder extension module and is used to identify global functions included in the module. Like global functions in PowerScript, global functions in PowerBuilder extensions cannot be overloaded.

**See also**

[PBX\\_GetDescription](#)

## PBX\_Notify

Description	Used to initialize and uninitialized a session.
Syntax	PBXEXPORT PBXRESULT PBXCALL PBX_Notify(IPB_Session* <i>pbsession</i> , pbint <i>reasonForCall</i> )
Return value	PBXRESULT
Examples	This sample shows code that exports PBX_Notify and displays a message box after the PBX is loaded and before it is unloaded:
	<pre>PBXEXPORT PBXRESULT PBXCALL PBX_Notify (     IPB_Session*    pbsession,     pbint           reasonForCall ) {     switch(reasonForCall)     {         case kAfterDllLoaded:             MessageBox(NULL, "After PBX loading", "", MB_OK);             break;         case kBeforeDllUnloaded:             MessageBox(NULL, "Before PBX unloading", "", MB_OK);             break;     }     return PBX_OK; }</pre>
Usage	If PBX_NOTIFY is exported, the PBVM calls PBX_Notify immediately after an extension PBX is loaded and just before the PBX is unloaded. You can use this function to initialize and uninitialized a session. For example, you could create a session manager object, and store it in the IPB session using the SetProp function. Later, you could use GetProp to obtain the session object.

## **Method exported by PowerBuilder VM**

Description	This method is exported by the PowerBuilder VM: <b>PB_GetVM</b>
-------------	--

### **PB\_GetVM**

Description	Passes the IPB_VM interface to the user.
Syntax	<b>PB_GetVM (IPB_VM** vm)</b>
Examples	This example loads the PowerBuilder VM and calls the f_getrowcount function on the nvo_dw custom class user object:

```
#include <pbext.h>
#include <iostream.h>
typedef PBXEXPORT PBXRESULT (*P_PB_GetVM) (IPB_VM** vm);

class LibraryLoader
{
public:
    LibraryLoader(LPCSTR libname)
    {
        d_hinst = LoadLibrary(libname);
    }

    ~LibraryLoader()
    {
        FreeLibrary(d_hinst);
    }

    operator HINSTANCE()
    {
        return d_hinst;
    }

private:
    HINSTANCE d_hinst;
};

int main()
{
    int int_rowcount;
    PBXRESULT ret;
    LibraryLoader loader("pbvm125.dll");
    if(loader.f_getrowcount("nvo_dw", &int_rowcount) == 0)
        cout << "Row count = " << int_rowcount << endl;
}
```

```
if ((HINSTANCE)loader == NULL) return 0;

P_PB_GetVM getvm = (P_PB_GetVM)
    GetProcAddress((HINSTANCE)loader, "PB_GetVM");
if (getvm == NULL) return 0;

IPB_VM* vm = NULL;
getvm(&vm);
if (vm == NULL) return 0;

static const char *liblist[] =
{
    "load_pbvm.pbl"
};

IPB_Session* session = NULL;
ret = vm->CreateSession
    ("load_pbvm", liblist, 1, &session);
if (ret!= PBX_OK)
{
    cout << " Create session failure!" << endl;
    return 0;
}
return 1;
}
```

**Usage**

To load the PowerBuilder VM and run a PowerBuilder application in a third-party server or application, you first create an IPB\_VM object using the PB\_GetVM method. Then, create an IPB\_Session object within IPB\_VM, using the application's name and library list as arguments.

**See also**

CreateSession

## About this chapter

This chapter describes two tools provided with the PBNI SDK:

- The pbsig125 tool gets the internal signature of a PowerBuilder function from a PBL name.
- The pbx2pbd125 tool generates a PBD from a PBX.

When you install PowerBuilder, these tools are installed in the *SDK* subdirectory of your PowerBuilder 12.5 directory and in *Shared\PowerBuilder*.

## Contents

	<b>Topic</b>	<b>Page</b>
	pbsig125	255
	pbx2pbd125	259

## pbsig125

### Description

The PowerBuilder function signature is the internal signature of a PowerBuilder function that is used to identify polymorphism functions in a class. The pbsig125 tool obtains these function signatures from a PBL.

---

### Inherited functions

You can also obtain a signature by selecting the function in the System Tree or Browser and selecting Properties from its pop-up menu. The pbsig125 tool does not report the signature of functions that are inherited from an ancestor object unless they are extended in the descendant. For such functions, you must use the Properties dialog box to obtain the signature. The Properties dialog box in the Browser also allows you to obtain the signature of PowerBuilder system functions.

---

### Syntax

`pbsig125 pbl_name`

**Examples**

This command extracts function signatures from one of the PBLs in the Code Examples sample application:

```
pbsig125 pbexamw1.pbl
```

Here is some of the output from the previous command:

```
PB Object Name: w_date_sort
    public subroutine of_sort (string as_Column,
        string as_Order)
    /* QSS */

PB Object Name: w_date_window
    public function boolean of_is_leap_year
        (integer ai_year)
    /* BI */

    public subroutine of_days ()
    /* Q */

PB Object Name: w_dde_server
    public subroutine check_hotlink (checkbox status,
        string data, string item)
    /* QCcheckbox.SS */

PB Object Name: w_dir_tree
    public function integer wfCollapse_rows (datawindow
        adw_datawindow, long al_startrow)
    /* ICdatawindow.L */
    public function long of_recurse_dir_list (string
        as_path, long al_parent)
    /* LSL */
    public function string of_build_dw_tree
        (long al_handle)
    /* SL */
```

The following example illustrates the use of a letter code to represent a PowerBuilder system class or a custom class. Consider this function:

```
function integer of_get_all_sales_orders (Ref
    s_sales_order astr_order[], date adt_date, integer
    ai_direction)
```

For this function, the pbsig125 tool returns the following string. The first argument is an unbounded array of type `s_sales_order` and is passed by reference:

```
/* IRCS_sales_order. [] YI */
```

**Usage**

The pbsig125 tool generates a string that represents the declaration and signature of all the functions and events in the PBL, including argument types, return types, and passing style. Each function and event is followed by a commented string. You pass the commented string, for example, QSS in the first comment in the previous example, as the last argument to the GetMethodID method.

For example, the following output indicates that the function returns an integer and has a single integer argument passed by reference:

```
/* IRI */
```

*PowerBuilder arrays* PowerBuilder arrays are indicated with a pair of square brackets [ ] as a suffix. For bounded arrays, the brackets enclose the bounds.

```
/* IRCdatastore.RS [] SS */
```

*PowerBuilder system or custom class* Additional letter codes represent a PowerBuilder system class or a custom class. The letter C followed by the name of a PowerBuilder object or enumerated class and a period (*Cname.*) represents an argument or return value of that type.

The following table shows how the output from pbsig125 maps to datatypes and other entities.

**Table 8-1: Return value and argument representation in pbsig125 output**

Output	Datatype
[ ]	array
A	any
B	boolean
C	class
D	double
E	byte
F	real
G	basictype
H	character
I	integer
J	cursor
K	longlong
L	long
M	decimal
N	unsigned integer (uint)
O	blob

Output	Datatype
P	dbproc
Q	No type (subroutine)
S	string
T	time
U	unsigned long (ulong)
W	datetime
Y	date
Z	objhandle

The passing style is indicated by a prefix on the type.

**Table 8-2: Passing style and varargs representation in pbsig125 output**

Prefix	Meaning
None	Pass by value
R	Pass by reference
X	Pass as read only
V	Variable arguments (varargs)

## pbx2pbd125

Description	The pbx2pbd125 tool generates a PowerBuilder dynamic library (PBD) file from a PowerBuilder extension PBX. The generated PBD can be added to the library list of any PowerBuilder application target that will use the objects and methods in the PowerBuilder extension.
Syntax	<code>pbx2pbd125 [+]</code> <i>des.pbd</i> <i>src1.pbx</i> [ <i>src2.pbx</i> <i>src3.pbx</i> ... <i>srcn.pbx</i> ]
Examples	This example generates a new PBD <i>test.pbd</i> from <i>test.pbx</i> . The input and output files are in the current directory:  <code>pbx2pbd125 test.pbd test.pbx</code>  This example appends generated information from <i>C:\myproject\src.pbx</i> to <i>C:\mypbds\des.pbd</i> . (If <i>des.pbd</i> does not exist, it is created.)  <code>pbx2pbd125 + C:\mypbds\des.pbd C:\myproject\src.pbx</code>  This example generates a new PBD <i>D:\pbds\test.pbd</i> from all the PBX files in the <i>C:\myproject</i> directory:  <code>pbx2pbd125 D:\pbds\test.pbd C:\myproject\*.pbx</code>  This example generates PBD information from all the PBX files in the <i>C:\temp</i> and <i>D:\temp</i> directories and appends the information to the existing generated PBD file <i>D:\pbds\test.pbd</i> :  <code>pbx2pbd125 + D:\pbds\test.pbd c:\temp\*.pbx d:\temp\*.pbx</code>
Usage	<p>You can import an extension into a PowerBuilder library using the Import PB Extension pop-up menu item for the library in the PowerBuilder System Tree. Prior to PowerBuilder 11.5, you had to use the <i>pbx2pbdnnn</i> tool to create a PBD file from a PBX file, then add the PBD to the library list of your PowerScript target. The tool is still available in this release.</p> <p>You can include multiple PBXes in a single PBD file. If you want to add additional PBXes to an existing PBD, use the plus (+) sign before the name of the PBD.</p> <p>The pbx2pbd125 tool is installed in the system PATH in the <i>Shared\PowerBuilder</i> directory so you can invoke it in the directory where the PBXes reside.</p> <p>If you specify an absolute path for the PBX file when you generate the PBD, the PowerBuilder application searches for the PBX <i>only in the specified path</i>.</p> <p>If you do not specify the path for the PBX file, the PowerBuilder application searches the system path for the PBX.</p>

# Appendix

This appendix describes wizards provided for Microsoft Visual Studio.

# Using the Visual Studio Wizards

## About this appendix

If you use Visual Studio .NET 2002 or 2003 or Visual Studio 2005, you can use a wizard to create a PBNI extension project. The wizard creates a project with *.cpp* and *.h* files that contain required code as well as template code to help you get started.

Check for wizard updates in the PBNI section of the PowerBuilder CodeXchange Web site at <http://powerbuilder.codexchange.sybase.com/>.

## Contents

Topic	Page
Where the wizards are installed	263
Generating a PBNI project	265
Setting project options	266
Building and using the PBX	266

## Where the wizards are installed

When you install PowerBuilder, the setup program installs four directories into the *PowerBuilder 12.5\SDK\PBNI\wizards* directory:

- *VCProjects 7.0*
- *VCProjects 7.1*
- *VCProjects 8.0*
- *VCWizards*

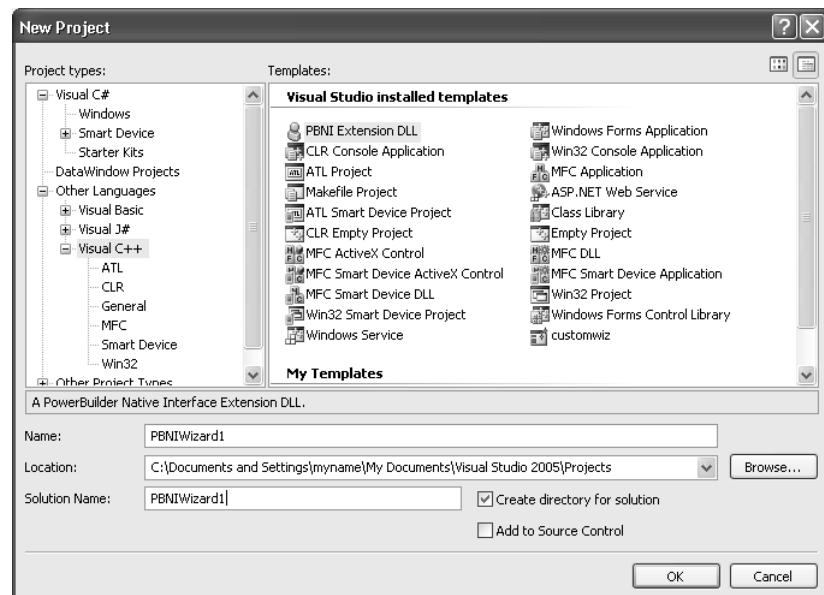

If Microsoft Visual Studio is already installed on your computer, the setup program also installs the appropriate files into your Visual Studio installation.

**Table A-1: Where wizard files are installed**

Visual Studio version	Files copied	Destination
Visual Studio 2005	<i>VCProjects 8.0</i> <i>VCWizards</i>	..\Microsoft Visual Studio 8\VC\VCProjects ..\Microsoft Visual Studio 8\VC\VCWizards
Visual Studio .NET 2003	<i>VCProjects 7.1</i> <i>VCWizards</i>	..\Microsoft Visual Studio .NET 2003\Vc7\VCProjects ..\Microsoft Visual Studio .NET 2003\Vc7\VCWizards
Visual Studio .NET 2002	<i>VCProjects 7.0</i> <i>VCWizards</i>	..\Microsoft Visual Studio .NET\Vc7\VCProjects ..\Microsoft Visual Studio .NET Vc7\VCWizards

If Visual Studio is not already installed when you install PowerBuilder, see the *install.txt* file in the *PBNI\wizards\VCWizards\PBNIWizard* directory for how to install the wizard later.

To check whether the wizard is installed in Visual Studio, select File>New>Project from the menu bar , select Visual C++ Projects, and scroll the Templates pane to see the PBNI wizard.

## Generating a PBNI project

The PBNI Application Wizard lets you choose whether to create a visual or nonvisual extension, whether to include support for Unicode and global functions, and whether to generate a header file.

❖ **To create a new PBNI project:**

- 1 Start Visual Studio, select File>New>Project, select Visual C++ Projects, and scroll the Templates pane to see the PBNI wizard.
- 2 Select PBNI Extension DLL, enter a name and location for the project, and click OK.
- 3 Click Application Settings if you want to create a visual extension or change any other settings.

The default is to create a nonvisual extension with Unicode support.

- 4 Click Finish.

See the *ReadMe.txt* file created by the wizard for a description of the generated source and header files.

## Setting project options

If the project does not build correctly, you might need to turn off precompiled headers in the project's Property Pages dialog box and set the path for the PBNI *include* files.

❖ **To set project options for PBNI library and include files:**

- 1 In Visual Studio, select Tools>Options.
- 2 Select Projects and Solutions>VC++ Directories.
- 3 Select Include Files from the Show Directories For drop-down list and click the New icon. Then click the browse button, browse to the location of the *PowerBuilder 12.5\SDK\PBNI\include* directory, and click OK.
- 4 Click OK to close the Options dialog box.

By default, the project is compiled for Unicode character sets. You can change this setting in the wizard. If you want to change it to compile for ASCII (SBCS) character sets after you have created the project, you can remove the \_UNICODE preprocessor option.

❖ **To compile for ASCII character sets:**

- 1 Select Project>*ProjectName* Properties.
- 2 Expand C/C++ and select Preprocessor.
- 3 Edit the Preprocessor Definitions to remove \_UNICODE and UNICODE.

## Building and using the PBX

When you have finished coding the project, build the project from the Build menu to create a DLL with the extension *.pbx*. By default, the extension is created in the *Debug* directory.

Then, you can import the PBX into a PBL in your PowerBuilder target and use it as described in “Using the extension” on page 27.
