The Official Spring 2008 Sire Summary

Foreword

The Spring 2008 Sire Summary represents the tenth official run of the Multiple-Breed International Cattle Evaluation (MB-ICE) system, and the 18th edition of the Maine-Anjou National Sire Summary.

This issue features carcass EPDs published for the Maine-Anjou breed. The carcass EPDs are listed in a special supplement to the Maine Anjou Sire Summary following the listing of Young Sires. The carcass EPDs are the result of the MB-ICE Carcass System, which has several key features making it extremely useful to Maine Anjou breeders. First, the MB-ICE Carcass system is the first multi-breed carcass evaluation. Similar to the weight trait evaluation, MB-ICE Carcass Evaluation accounts for breed composition differences. Second, this genetic evaluation uses both carcass and ultrasonic phenotypes in a multiple trait genetic model. Paired traits are analyzed in four evaluations. Traits are paired in these groups: Carcass Weight and Scan Weight, Marbling and Percent Intramuscular Fat (IMF), Fat Thickness and Ultrasound Fat Thickness, Rib-eye Area and Ultrasound Rib-eye Area. Percent retail cuts is computed as a linear index of Carcass Weight, Fat Thickness and Rib-eye Area EPDs. Third, the evaluation incorporates external Angus and Red Angus Carcass and Ultrasound EPD data for sires with progeny in the MB-ICE evaluation.

The carcass records included in the evaluation for the Maine Anjou breed are the result of the breed's participation in the NCBA Carcass Merit Project and continuing contribution of records from the AMAA sanctioned AMAA National Maine-Anjou Influenced Steer and Heifer Feeding Trial. Ultrasound body composition measures on yearling bulls and heifers are submitted by breeders to

the Centralized Ultrasound Processing (CUP) lab which then forwards interpreted scan data to AMAA. Ultrasound body composition measurements of a sire's progeny are an economical and reliable way to gather useful information for estimation of the sire's carcass trait genetic merit.

The information contained herein is compiled from records in the American Maine-Anjou Association office submitted by individual members and non-members. The American Maine-Anjou Association, its officers, directors and employees assume no responsibility for its contents or the use or interpretation of information published herein, although the American Maine-Anjou Association has made efforts to accurately report information on the animals contained herein.

Maine-Anjou National Cattle Evaluation

In the 18th edition of the Maine-Anjou National Sire Summary, the EPDs for animals recorded in the Maine-Anjou herd book have been computed using the Multiple-Breed International Cattle Evaluation (MB-ICE) system developed by scientists at Cornell University and the American Simmental Association. The AMAA entered into an agreement with the ASA which enabled the AMAA data base to be combined with the data bases of the American Simmental Association, Canadian Simmental Association, and the American Chianina Association for genetic evaluation.

The MB-ICE system has the following advantages to earlier genetic evaluation systems used by the AMAA:

- 1) The MB-ICE system represents the best scientific techniques for describing differences in the breeding values among animals with different genetic backgrounds;
- 2) The MB-ICE system provides comparisons among all animals in the database regardless of their fraction of Maine-Anjou breeding;
- 3) The MB-ICE system provides a better biological description of Maine-Anjou and Maine-Anjou influenced cattle by a) including the differences between Maine-Anjou genes and genes coming from other breeds; b) adjusting for heterosis generated by crossing Maine-Anjou and other breeds; and c) factoring out differences due to age of dam effects among cows with different breed backgrounds;
- 4) The MB-ICE system has recently been improved by

incorporating the ability to utilize genetic predictors (EPDs) from other breed genetic evaluations. Maine-Anjou, like other breeds in the evaluation, has seen an influx of Angus and Red Angus genetics used in the development of percentage or composite animals. Many of the sires used in this manner are either high accuracy AI sires or have more progeny and pedigree information in their native breed genetic evaluation. It makes sense to leverage this genetic data to increase the precision and accuracy of genetic predictions generated by the MB-ICE system. EPDs for Angus sires and Red Angus sires with progeny in the MB-ICE database and an external Yearling Weight EPD accuracy of 0.30 or higher, were incorporated into the genetic evaluation that produced the EPDs published in this sire summary.

The MB-ICE system has two basic components. A model describing factors influencing an animal's record and a system of equations built on the model which provides predictions of genetic merit using a procedure called Best Linear Unbiased Prediction (BLUP). The EPDs were calculated using a multiple trait model that included random effects for birth weight direct, weaning weight direct, weaning weight maternal, weaning permanent environment, and post-weaning gain direct. The fixed effects included management group, breed of founder, age of dam, direct heterosis, and maternal heterosis.

Management Group

In the MB-ICE system, all calves are placed in the same

(continued on following page)

management group as long as they are the same sex born in the same herd and season, and managed together and treated alike. Compared to previous Maine-Anjou evaluations, the requirement for same percentage Maine-Anjou has been dropped in the MB-ICE analysis. The differences due to breed and heterosis are handled by the breed of founder and heterosis effects.

Breed of Founder

The phrase, Breed of Founder, is used to indicate that a random sample of genes from various breeds are not needed to evaluate breed differences. The breed of founder effects are developed by tracing pedigrees and determining the most distant animals (founder) in each pedigree. A time trend is included in the breed of founder effects to account for the genetic trend present in each breed group. The MB-ICE system uses two sources of information to evaluate breed differences: 1) Estimates derived from the published crossbreeding studies; and 2) the actual breed information in the data.

Age of Dam

The MB-ICE system provides age of dam adjustments using the cow's age in days and based on her breed background and sex of her calf. The age of dam effects are estimated directly by the MB-ICE system so the age of dam factors are adjusted for the other effects in the evaluation. For birth weight direct and post-weaning gain direct, the breed differences included in the age of dam adjustments are used to account for maternal breed differences. For percentage or crossbred cows, the age of dam adjustment is a weighted average of the breeds represented in the dam.

Heterosis

Heterosis or hybrid vigor is produced when crossing parents with different breed backgrounds. Heterosis provides an increase in performance that is not part of the animal's breeding value. In the MB-ICE system, heterosis affects a calf's performance in two ways: direct heterosis of the calf and the maternal heterosis of the dam for weaning weight. The MB-ICE system adjusts the calf's performance for the direct heterosis expressed by the calf, and in the case of weaning weight, the maternal heterosis expressed by the dam.

Genetic Base

Expected Progeny Differences are computed relative to a reference point or genetic base. Though the choice of the base is an arbitrary decision, the genetic base does determine the magnitude and sign of the EPDs. The genetic base for the Maine-Anjou National Cattle evaluation was modified beginning with the Spring 2005 Sire Summary. The new base was set to make Maine Anjou EPDs easier to use by commercial producers. Since so many commercial producers are familiar with Angus EPDs, adjusting Maine Anjou EPDs so that Maine Anjou and Angus EPDs have similar averages will make them easier to use. The EPDs of Maine Anjou animals born in 2002 were adjusted so they have the averages listed in the following table.

Year 2002 born Maine Anjou EPD averages following base adjustment.

<u>Trait</u>	<u>Average</u>
Birth Weight	2.80
Weaning Weight	39.50
Yearling Weight	78.50
Maternal Milk	19.30
Maternal Weaning Weight	39.00
Carcass Weight	1.59
Percent Retail Product	0.31
Marbling	0.20
Fat Thickness	0.00
Rib-eye Area	0.17

Aside from making the EPDs easier to use by commercial producers, the new Maine Anjou base helps Maine Anjou seedstock producers to overcome an unfair marketing disadvantage in the seedstock industry. In the past, EPDs of Maine Anjou were lower than those of other beef breeds due to differences in each breed's EPD base. The lower EPD values of Maine Anjou led some commercial producers to *incorrectly* believe that Maine Anjou animals didn't perform as well for various traits as some other breeds do. Making a base adjustment will hopefully correct this misconception and even the playing field between Maine Anjou and other breeds.

It is important to realize that the modifications made to the Maine Anjou base only effects the mean or average of EPDs. The same set of constant base adjustments were added to the EPD of all Maine Anjou animals. The relative differences between two bulls will remain the same, assuming no additional data was included in the most recent evaluation.

With the Maine-Anjou base, breeders should not worry about the meaning of zero. Rather, breeders need to know the average EPDs for the group of animals they are interested in, e.g. Active Sires, Active Cows, Non-Parent Bulls, etc. Rather than comparing the EPDs to zero, breeders should rely on the average EPDs and percentile tables to make informed decisions.

Even though the magnitude of the Maine Anjou EPDs are now similar to those of the Angus breed, Maine Anjou and Angus EPD are NOT directly comparable. The Maine Anjou EPDs are produced in a separate genetic evaluation with different data adjustments and computational strategies as compared to the Angus breed's genetic evaluation. The 2007 US MARC Across Breed EPD Adjustment table released at the 2007 Beef Improvement Federation meetings can be used with Spring 2008 Maine Anjou EPDs to compare Maine Anjou animals' EPDs with animals of other breeds. The 2007 table will provide appropriate across breed adjustments. The EPDs in this sire summary are only comparable to other Maine Anjou animals whose EPDs were produced in the Spring 2008 MB-ICE genetic evaluation.

Criteria for Listing

Listing Order

Sires are published in one of three major lists: Main, Young and Inactive. Within each major list, sires are sorted by their registered name. Bulls of different percentage categories (Fullblood, Purebred, 7/8 and 3/4) are dispersed throughout all three lists.

Main List of Active Sires

In order to appear in the main listing, a bull must be at least 75 percent Maine-Anjou, have an accuracy value for weaning weight EPD of at least .45, and have progeny submitted since Jan. 1, 2004.

(continued on following page)

Criteria for Listing (continued from page 2)

This ensures that sires in the main listing represent those currently being used by Maine-Anjou breeders.

Young Sire Supplement

The Young Sire Supplement consists of bulls born after Jan. 1, 2002, that have at least .27 accuracy EPD level for weaning weight but did not meet minimum requirements to make the main listing. The purpose of the Young Sire Supplement is to provide data on the most heavily used young bulls.

Carcass Sires

Bulls in the Carcass Sire Listing are those with a carcass weight EPD accuracy of at least 0.30 and appear in either the Main, Young or Inactive Sire listing.

Inactive Sires

A list of inactive sires is provided as a pedigree reference. This list consists of bulls that have weaning weight EPD accuracy of .60 or greater, but have had little or no activity in the last three years and thus did not make the main sire listing. Many of these bulls were quite popular at one time and appear in the pedigrees of a number of bulls and females currently in production.

Different Percentages of Maine-Anjou Breeding

Different heterosis (hybrid vigor) levels are associated with different percentages of Maine-Anjou breeding. Through MB-ICE, heterosis has been accounted for in this genetic analysis. One must be aware though, that mating animals of partially common breed types will result in less heterosis than mating of animals of totally different breeds.

EPD Possible Change by Accuracy Level (Plus or Minus)

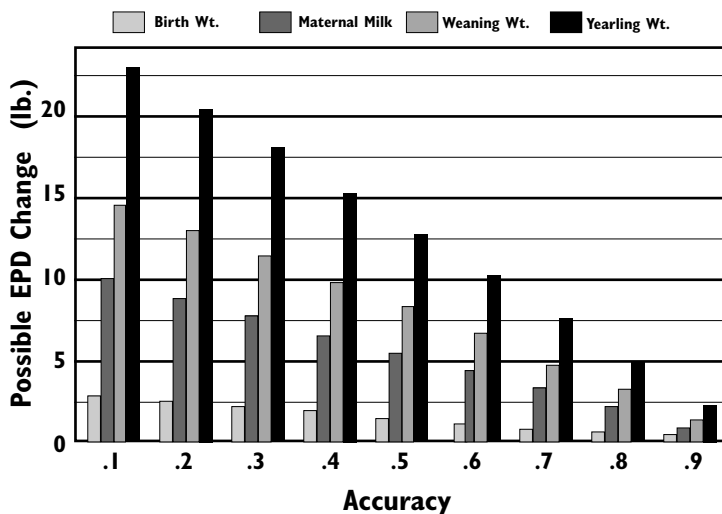

ACC	Birth Weight	Weaning Weight	Maternal Milk	Yearling Weight
0.0	3.0	16.3	11.9	25.7
0.1	2.7	14.7	10.7	23.1
0.2	2.4	13.0	9.5	20.3
0.3	2.1	11.4	8.3	18.0
0.4	1.8	9.8	7.1	15.4
0.5	1.5	8.2	6.0	12.9
0.6	1.2	6.5	4.8	10.3
0.7	.9	4.9	3.6	7.7
0.8	.6	3.3	2.4	5.1
0.9	.3	1.6	1.2	2.6
1.0	0.0	0.0	0.0	0.0

Percentile Categories

A percentile-based category is assigned to each EPD of bulls in the Main and Young Sire Supplement. A bull's category describes his rank compared to all other bulls listed in the Sire Summary. Ranking is broken down into ten 10 percentile categories. A 10 star (10*) indicates a bull is in the top 10 percent of all bulls listed in the Sire Summary for that particular trait. Eight stars (8*) indicates a bull is in the third 10 percent (those between 20 percent and 30 percent) of all bulls listed in the Sire Summary for that particular trait. Three stars (3*) indicates a bull is in between the 70th and 80th percentile. Using the percentile-based categories can make identifying bulls that excel in multiple traits simpler.

Note: Expected Progeny Differences (EPDs) may be used to estimate how future progeny of the subject animal will compare to progeny of other animals within the breed. The key words are estimate, future, compare and within breed. EPDs are not designed to predict the performance of one or two progeny of a sire, but rather should be used to compare bulls based on estimated progeny performance. EPDs predict differences, not absolutes.

EPD Possible Change by Accuracy Level

What Are EPDs?

Expected Progeny Differences (EPDs) may be used to estimate how future progeny of the subject animal will compare to progeny of other animals within the breed. The key words are estimate, future, compare and within breed. EPDs are not designed to predict the performance of one or two progeny of a sire, but rather should be used to compare bulls based on estimated progeny performance. EPDs predict differences, not absolutes. They describe the genetic value of an animal much like a feed tag describes the contents of a feed sack.

EPDs are computed as part of the AMAA National Cattle Evaluation (NCE) program. The NCE program represents the application of the most recent genetic and computing technology for calculating EPDs for beef cattle. The Maine-Anjou NCE program incorporates all available performance into the prediction

of an individual's EPD for a specific trait. An EPD may be based on any combination of individual performance, pedigree and progeny performance information. In addition, EPDs are more accurate than anything previously available because they account for the following factors:

- Genetic value of cows to which a bull is bred.
- Environmental differences affecting contemporary groups.
- Genetic values of other parents in the contemporary group.
- Genetic trend.

EPDs are reported in pounds for birth weight, weaning weight, maternal milk, maternal milk & growth and yearling weight.

1. Sire Information

Sires are listed in alphabetical order according to their registered name. Also included in this column are the bull's date of birth, registration number, breed percentage, color (if available), horned/polled/scurred status, sire (S), breeder (B) and current owners (O).

2. Birth Weight

Progeny can be expected to weigh 1.3 lb. more at birth than progeny sired by a bull with an EPD of 1.1 lb. (2.4 minus 1.1 = 1.3 lb.) Birth weight is an indicator of calving ease. Larger birth weight EPDs usually indicate more calving difficulty.

3. Weaning Weight

Weaning EPD reflects pre-weaning growth. Calves sired by the above bull should have a 15 lb. advantage in 205-day adjusted weaning weight compared to calves sired by a bull with an EPD of 28 lb. (43 minus 28 = 15 lb.)

4. Maternal Milk

The milking ability of a sire's daughters expressed in pounds of calf weaned. It predicts the difference in average weaning weight of sires' daughters' progeny due to milking ability. Daughters of the sire in the above example should produce progeny with 205-day weights averaging 4 lb. more (as a result of greater milk production) than daughters of a bull with a maternal milk EPD of 15 lb. (19 minus 15 = 4 lb.). This difference in weaning weight is due to total milk production over the entire lactation.

5. Maternal Weaning Wt.

Maternal Weaning Weight reflects what the sire is expected to transmit to his daughters for a combination of growth genetics through weaning and genetics for milking ability. It is an estimate of daughters' progeny weaning weight. The bull in the above example should sire daughters with progeny weaning weights averaging 6 lb. heavier than progeny of a bull's daughters with a Maternal Weaning Weight EPD of 34 lb. (40 minus 34 = 6 lb.). It is equal to one-half the sire's weaning weight EPD, plus all of his milk EPD. No accuracy is associated with this since it is simply a mathematical combination of two other EPDs. This EPD is sometimes referred to as "total maternal" or "combined maternal."

6. Yearling Weight

Yearling EPD for this sire indicates his progeny should be 12 lb. above the average of progeny of a bull with an EPD of 77 lb. Yearling EPD reflects differences in the 365-day adjusted yearling weight for progeny. It is the best estimate of total growth.

7. Herds

Number of herds in which progeny were raised with recorded measurements for each trait. Number of herds gives a general indication of progeny distribution.

8. Progeny

The number of progeny sired by the bull with recorded measurements for each specific trait. Number of progeny should not be used in lieu of

accuracy, but simply to further clarify accuracy values.

9. Ranking

A bull's ranking describes his rank compared to all other bulls listed in the Sire Summary. Ranking is broken down into ten 10 percentile categories. A 10-star (10*) indicates a bull is in the top 10 percent of all bulls listed in the Sire Summary for that particular trait. Eight stars (8*) indicates a bull is in the third 10 percent (those between 20 percent and 30 percent) of all bulls listed in the Sire Summary for that particular trait. Three stars (3*) indicates a bull is between the 70th and 80th percentile. The chart on page 7 shows the minimum EPD values for each of the 10 percentile categories.

10. Daughters

The number of daughters sired by the bull which have produced progeny with weaning weight records. Number of daughters should not be used in lieu of accuracy, but simply to further clarify Maternal Milk and Maternal Milk & Growth accuracy values.

Carcass EPD Supplement

11. Carcass Weight

Carcass Weight EPD reflects differences in the 450-day adjusted hot carcass weight (pounds) of progeny. Carcass Weight EPD for this sire indicates his progeny should be 5.0 lb. above the average of progeny of a bull with an EPD of 0.0 lb.

12. Percent Retail Cuts

Percent Retail Cuts EPD reflects the expected genetic differences in the percentage of boneless closely trimmed retail cuts (PBCTRC) of progeny. PBCTRC is a measure of cutability and is closely related to USDA Yield Grade. Positive values represent expectations of progeny with more desirable cutability (a higher percentage of retail cuts).

13. Marbling

Marbling EPD reflects differences in expected progeny marbling scores (intramuscular fat). Marbling EPD is measured in marbling score units. For example the progeny of a sire that has a Marbling EPD of 0.50 would be expected to average one-half marbling score better than progeny of a sire with Marbling EPD 0.00.

14. Fat Thickness

Fat Thickness EPD reflects expected differences in a sire's progeny for the carcass measurement of inches of 12th rib fat thickness. A negative Fat Thickness EPD reflects the expectation of progeny having less fat thickness (leaner carcass). Fat thickness is one of the components used to determine USDA Yield Grade and estimates of cutability.

15. Rib-eye Area

Rib-eye Area EPD reflects expected differences in a sire's progeny for the carcass measurement of square inches of rib-eye area taken between the 12th and 13th ribs. Rib-eye area is one of the components used to determine USDA Yield Grade and estimates of cutability. Positive Rib-eye Area EPDs are reflect larger average progeny rib-eye area.

Percentile Breakdown of EPDs for Maine-Anjou

A percentile chart for the Maine-Anjou breed's active sires (those producing a calf with a performance record since 2006) appears below. This can be used to get a better idea of how a bull ranks in the current group of active sires in the Maine-Anjou breed. The chart is divided into 5 percent increments for each trait. The top

5 percent are further divided into 1 percent increments.

Very few bulls rank at the top in every trait, but through careful evaluation you should be able to find bulls to match your specifications. To see how the table may be used, let's look at our example bull used previously.

Percentile rankings compared to all active Maine-Anjou Sires for XYZ Superbull

Trait	EPDs	% Rank	Carcass Trait	EPDs	% Rank
Birth Wt.	2.4	Upper 35%	Carcass Wt.	5.0	20%
Weaning Wt.	43	40%	Percent Retail Cuts	0.36	20%
Mat. Milk	19	60%	Marbling	0.26	10%
Mat. Weaning Wt.	40	50%	Fat Thickness	-0.01	20%
Yearling Wt.	89	25%	Rib-eye Area	0.22	20%

Since EPDs may be used to compare young bulls that are not parents, the average EPDs and ranges and a percentile breakdown for animals born in 2006-2007 are also provided. These tables are useful for comparing the EPDs of calves born in these years. Moreover, since the recent change is relatively small, it can be used as a benchmark for all young calves.

The breakdown chart and EPD ranges for the active cows with a calf reported since Jan. 1, 2006, allow one to compare his or her herd with all active cows in the Maine-Anjou breed.

The Percentile Breakdown charts and Genetic Trend graphs for the MaineTainer cattle appear on pages 8 and 9.

Genetic Trend

The graphs at right and below illustrate the genetic trends in the Maine-Anjou breed. All animals in the analysis were used to generate this information. This includes Fullblood and Purebred animals as well as lower percentage Maine-Anjou cattle. In general, the EPD changes from one year to the next are quite small. This does not mean the performance of the cattle has not changed over the years. The actual weights taken on animals are phenotypic measurements. Phenotypic changes can be made through changing not only an animal's genetics, but also by changing an animal's environment.

Maine Anjou Growth & Maternal Traits Genetic Trend – 1988 to 2007

Questions & Answers

If a bull has a yearling weight EPD of +80 lb., does this mean he will add 80 lb. to yearling weights?

It is important to remember that EPDs do not predict performance; they merely allow us to compare the average expected performance of progeny of different bulls. This bull, when compared to another bull within the same breed with a 65 lb. yearling EPD, would be expected to produce an additional 15 lb. of yearling weight if both were randomly mated to a large number of cows in the same environment.

Does a +15 lb. milk EPD mean an extra 15 lb. of milk?

No. Maternal milk EPDs are expressed in pounds of calf weaning weight, not in pounds of milk. In an attempt to explain how this works, let's consider a contemporary group of calves where there is a prediction of how each calf should rank within that group based on weaning weight EPDs of the sires and dams represented. Assume that a bull has daughters that consistently wean calves that are 15 lb. above the predicted rank when compared to daughters of other bulls in the same contemporary group. This greater weaning weight is credited to milk production, even though other environmental factors may also play a role.

Do I need to know what the breed average is for birth weight before I select a bull?

Absolute breed averages for birth weight or any other traits do not exist because of non-genetic environmental factors such as climate, nutrition, management systems, etc. For example, we know that birth weights may be as much as 15 to 20 lb. lower in Florida than in Montana, strictly due to variation in temperature, humidity and grass quality. Thus, breed averages will vary from one herd to the next and the only way you will know what breed average is in your herd is with experience gained by using proven bulls with high accuracy. Remember, EPDs are meant to predict differences in progeny performance rather than determine absolute performance.

Can Maine-Anjou EPDs be compared to other breeds' EPDs?

No. EPDs from AMAA cannot be directly compared to any other breed's EPDs. This includes Hereford, Charolais, Angus, Simmental and all other breeds.

How much confidence can I have in an EPD with a low accuracy value less than .30?

If you were able to sample several bulls with low accuracy, on the average the EPDs would do a fairly good job of sorting the bulls into high, medium and low performance levels. However, when you are selecting only one bull, "on the average" is not good enough, so you really need to know the possible change associated with the given accuracy. For example, let's assume the minimum yearling weight you are willing to accept is 70 lb., and you were considering a bull with a yearling weight EPD of +85 lb. with an accuracy of .40. Next we look at the Possible Change Value table on page 3 and find a value of ± 15.4 for yearling weight with an accuracy of .40. This bull may work for you because +85 minus 15.4 is 69.6 lb., which is slightly lower than the acceptable level of 70 lb. It is true that the bull could stay the same or even go up in yearling weight EPD. You must decide how much risk you are willing to accept. For a given accuracy, approximately 67 percent of the bulls will not change more than plus or minus the possible change value when re-evaluated with additional progeny information. The table for converting accuracy to possible change is printed on page 3 of this Sire Summary. Please note that possible change values differ for each trait.

How are embryo transfer (ET) calves handled with respect to EPD values?

The performance records of ET calves are not considered in the calculation of EPDs for the animal or its sire and dam. The reason is because there is no way to account for the influence of the recipient female on the calf's performance. EPDs for ET animals are estimated using information from relatives until the animal has progeny with performance records.

Will mating a specific sire to my best cows affect his EPDs?

No. When calculating EPDs, the mates of a particular animal are accounted for in the analysis. In other words, breeding a sire to either high growth cows or low growth cows should not affect his EPDs. For example, let's say you have 50 cows. You breed your higher yearling weight EPD cows to Sire A and breed your lower yearling weight EPD cows to Sire B. Sire A's calves should weigh more at a year of age than Sire B's simply because of the dams. This type of mating is accounted for in the present statistical analysis.

How important is it to identify my contemporary groups correctly?

Extremely important. More inaccuracies in the genetic analysis occur from incorrectly identifying contemporary groups than any other single cause. Weaning Management Codes (feed code and group) must be used to distinguish calves which have had different opportunities to perform. Calves that have been treated differently should have different management codes.

Do I need to send in to AMAA the performance records of all my calves?

Absolutely YES. Sending in only your best calves really hurts your best sires and dams. You must record ALL calves for the analysis to be correct. If one calf has been sick and therefore weighs much less, simply give him a different management code. Also at birth, weighing the dead calves is just as important as the live calves.

Is information from central bull test stations included in the National Cattle Evaluation?

Yes. The yearling information from a test station can be used to directly compare bulls that were contemporaries prior to going to the station.

Should calves out of my first-calf heifers be in separate contemporary groups than calves out of my older cows?

A contemporary group is a group of animals who have been treated alike. If you treat your first-calf heifers differently than your mature cows, those calves should be in different contemporary groups. If you treat your first-calf heifers identically to your mature cows, both sets of calves would be considered contemporaries. Use different management codes to identify separate contemporary groups. How you manage and feed your cows is totally your decision, but calves (or dams) treated differently should be grouped separately. If you treat your first-calf heifers better than your mature cows and still group them all together, the calves out of the first-calf heifers get the added adjusted weaning weight correction as well as the superior treatment.

How can I use the stars printed for each EPD for all bulls in the Sire Summary?

The stars printed for each bull's EPDs simply indicate if his EPD places him in the top 10%, the second 10%, the third 10%, the fourth 10%, and so on, of bulls printed in the Sire Summary. The star system is a quick and easy way to tell where a bull ranks in the population. This is also a way to tell if a bull is a "balanced EPD" bull. In other words, if a sire has 6 to 10 stars for each trait, he is definitely a multiple-trait, balanced EPD bull.

How does the average Maine-Anjou animal compare to the average Hereford or Charolais or Simmental animal?

A Maine-Anjou EPD from this analysis cannot be compared accurately to EPDs from other breeds. There are many University research projects comparing breeds of beef cattle for a host of different traits. Maine-Anjou cattle have compared quite favorably to other breeds in many traits.

Glossary

Accuracy (ACC)

A measure of certainty regarding the genetic merit of an animal. Accuracy values are calculated for each EPD according to Beef Improvement Federation (BIF) Guidelines and reported as a decimal number between zero and one. Larger values indicate greater accuracy.

Birth Weight

Calf weight at birth adjusted to a mature dam equivalent. Expected progeny performance is reported in pounds. The EPD value predicts the difference in average birth weight of a bull's calves compared to calves of all other bulls evaluated. When comparing birth weight EPDs of two sires, the larger EPD indicates a heavier average birth weight for calves sired by this bull.

Carcass Weight

Carcass Weight EPD reflects differences in the 450-day adjusted hot carcass weight of progeny. Carcass Weight EPDs are estimated from progeny carcass weights and/or the genetically correlated ultrasound Scan Weight of the individual and/or progeny. Larger Carcass Weight EPDs are associated with heavier expected progeny average hot carcass weights. Carcass Weight EPD is expressed in pounds.

Expected Progeny Difference (EPD)

The expected difference in performance of a bull's progeny when compared to the average progeny performance of all evaluated bulls. The EPD is a prediction of 1/2 of an animal's breeding value or its genetic value as a parent.

Fat Thickness

Fat Thickness EPD reflects expected differences in a sire's progeny for the carcass measurement of 12th rib fat thickness at a standard 450 days of age. The EPD is scaled in inches of fat thickness. A negative Fat Thickness EPD reflects the expectation of progeny having less fat thickness (leaner carcass) on average. Fat thickness is one of the components used to determine USDA Yield Grade and estimates of cutability.

Genetic Correlation

Correlations between two traits that arise because the same genes affect both traits. When two traits are positively correlated (e.g. weaning and yearling weights) selection for an increase in one trait will result in an increase in the other trait. When two traits are negatively correlated (e.g. birth weight and calving ease) selection for an increase in one trait will result in a decrease in the other trait.

Heritability

The proportion of variation observed in a trait that is due to heredity and is transmitted to offspring (i.e. additive gene action). Heritability varies from zero to one. The higher the heritability of a trait, the more rapid should be the response to selection.

Marbling

Marbling EPD reflects differences in expected progeny marbling scores (intramuscular fat) at an age constant basis of 450 days. Marbling EPD is measured in marbling score units. For example the progeny of a sire that has a Marbling EPD of 0.50 would be expected to average one-half marbling score better than progeny of a sire with Marbling EPD 0.00. The USDA Quality Grade of Select contains animals that display marbling in the Slight score (Slight 00 – Slight 99). The Choice grade spans three marbling scores: Small 00 – Small 99 (Choice-), Modest 00 – Modest 99 (Choice) and Moderate 00 – Moderate 99 (Choice+).

Milk

The maternal ability of a bull's daughters. Expected progeny performance is expressed in pounds of calf weaning weight. The EPD value predicts the difference in average 205-day weight of a bull's daughters' calves compared to calves from daughters of all other bulls evaluated. When comparing milk EPDs of two sires, the larger milk EPD indicates heavier average weaning weights due to daughters' greater maternal ability.

Maternal Weaning Weight

The weaning weight of a bull's daughters' calves. Expected progeny performance is reported in pounds. The EPD value predicts the difference in average 205-day weight of a bull's daughters' calves compared to calves from daughters of all other bulls evaluated. The evaluation reflects both the maternal ability of a bull's daughters and the growth potential of their calves. When comparing maternal weaning weight EPDs of two sires, the larger maternal weaning weight EPD indicates heavier weaning weights due to daughters' ability to produce heavier calves.

Percent Retail Cuts

Percent Retail Cuts EPD reflects the expected genetic differences in the percentage of boneless closely trimmed retail cuts (PBCTRC) of progeny. PBCTRC is a measure of cutability and is closely related to USDA Yield Grade. Percent Retail Cuts EPD is computed as a linear index of Carcass Weight, Fat Thickness and Rib-eye Area EPDs. Positive values represent expectations of progeny with more desirable cutability (a higher percentage or retail cuts) on average.

Rib-eye Area

Rib-eye Area EPD reflects expected differences in a sire's progeny for the carcass measurement of rib-eye area taken between the 12th and 13th ribs at an age constant basis of 450 days of age. Rib-eye Area and Rib-eye Area EPD are measured in square inches. Rib eye area is one of the components used to determine USDA Yield Grade and estimates of cutability. Positive values represent expectations of progeny with larger average rib-eye area.

Weaning Weight

Calf weight taken between 160 and 250 days of age and adjusted to 205 days of age and a mature dam equivalent. Expected progeny performance is reported in pounds. The EPD value predicts the difference in average 205-day weight of a bull's calves compared to calves of all other bulls evaluated. When comparing weaning weight EPDs of two sires, the larger EPD indicates a heavier average weaning weight for calves sired by this bull.

Yearling Weight

Weight taken between 330 and 440 days of age and adjusted to 365 days of age and a mature dam equivalent. Expected progeny performance is reported in pounds. The EPD value predicts the difference in average 365-day weight of a bull's progeny compared to progeny of all other evaluated bulls. When comparing yearling weight EPDs of two sires the larger EPD indicates a heavier average yearling weight for all calves sired by this bull.
