Abstract

Astyanax Baird & Girard, 1854 is one of the most specific fish genera among the characiforms, occurring in freshwater environments between the United States and central Argentina. *Astyanax viridis* sp. n was described from specimens from southeastern Brazil, earlier identified as *A. janeiroensis*. These specimens are differentiated from *A. janeiroensis* holotype, mainly in the maximum maxilla length (35.1-38.9% HL), pelvic-anal fin distances (19.0-21.9% SL) and number of rays divided into anal fin (18-19), justifying its description as a new species. *Astyanax viridis* sp. n. it presents a horizontally triangular humeral spot (atypical in *Astyanax*), sharing it with *A. laticeps*, *A. scabripinnis* and *A. serratus*, forming a small exclusive group, inserted in the *A. scabripinnis* species complex, defined by the elongated body, with depth less than 40% SL and reduced number of rays in the anal fin (17-20). It differs from these three species in that it has 4 large teeth in the dentary (vs. 5), by the head length (26.2-27.9% HL vs. 20.9-21.3%; 23.0-25.2% and 33.9-35.3% HL, in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively) and pelvic-anal fin distance (19.1-21.9% SL vs. 30.0-31.5%; 22.0-24.9% and 28.8-31.8% SL in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively). *Astyanax viridis* sp. n. occurs sympatrically with several other species of the genus, *A. aff. bimaculatus* (*A. bimaculatus* complex), *A. giton*, *A. hastatus*, *A. parahybae* and *A. taeniatus* (*A. fasciatus* complex) and *A. intermedius* (*A. scabripinnis* complex), being found in backwater areas in streams and rivers. The new species occurs in the main coastal basins, in the states of Espírito Santo, Minas Gerais, Rio de Janeiro and São Paulo.

Keywords: *Astyanax*; New Species; Southeastern Brazilian Basins; Taxonomy

Introduction

Astyanax Baird & Girard, 1854 is one of the most diverse fish genera among the Order Characiformes, occurring in freshwater environments from the southern United States to central Argentina [1-19]. The current definition of *Astyanax* is based on the combination of characters [6], which are, however widespread among genera in the Characidae (ie. two rows of premaxillary teeth, five teeth in the inner premaxillary series, lateral line complete, adipose fin present, and caudal fin naked) [2]. *Astyanax* species were separated in three subgenera [6]: *Astyanax* Baird & Girard, 1854 (predorsal scales series regular), *Poecilurichthys* Gill, 1858 (predorsal scales series irregular) and *Zygogaster* Eigenmann, 1913,

defined for preventral scales series keeled) and. Currently, there are 177 valid *Astyanax* species, with the increase of 40 new species described only in the last 10 years [7]. *Astyanax* does not represent a monophyletic entity [15,17] and the taxonomic status of some species is not completely clear [9]. *Astyanax janeiroensis* was included in *Deuterodon* Eigenmann, 1907 [20] in spite of characteristics that differs this species from those included in *Deuterodon*.

In the basins of southeastern Brazil, excepted coastal basins between São Paulo and Espírito Santo, 7 species were described [*A. altiparanae* Garutti & Britski, 2000, *A. cuveri*, *A. lacustris*, and *A. rivularis*, all (Lütken, 1875), *A. fasciatus* (Günther, 1860), *A. paranae* Eigenmann, 1914 and *A. schubarti*

Britski, 1964]. In lowlands coastal basins between São Paulo and Espírito Santo were found 11 species: *A. depressirostris* Miranda Ribeiro, 1908, *A. hastatus* Myers, 1928, *A. giton*, *A. intermedius*, *A. janeiroensis* and *A. parahybae*, all Eigenmann, 1908, *A. jenynsii* and *A. jequitinhonhae*, both (Steindahner, 1877), *A. ribeirae* Eigenmann, 1911, *A. taeniatus* and *A. scabripinnis*, both (Jenyns, 1842). These species are generally found in backwater areas in streams and rivers in the different basins of southeastern Brazil, in lowland areas [14], with the exception of *A. intermedius*, also found at higher altitudes, and in some locations, the only species found [3]. Several taxonomic problems (ie. Validity and correct delimitation of some species, misidentifications of types) regarding them still persist, being this article a contribution to a better understanding of the taxonomic limits of part of extensive material of *Astyanax* in southeastern Brazilian coastal basins.

In this paper, *Astyanax viridis* sp. n. was proposed. Differs for other species with same humeral spot pattern, include *A. janeiroensis*, for different measures showed in results and discussion. From other *Astyanax* species for humeral spot (horizontally triangular vs. distinct other shapes).

Material and Methods

Specimens

57 specimens (fixed in 10% formaldehyde and preserved in 70% alcohol) from the Fish Ecology Laboratory - Federal Rural University of Rio de Janeiro (LEP-UFRRJ) collection and other Brazilian scientific collections were examined [Department of Zoology of São José do Rio Preto University - State University of São Paulo (DZSJR); Capão Natural Museum (MHNCI), Curitiba, Paraná; National Museum - Federal University of Rio de Janeiro (MNRJ)] and international (photos, morphometric and meristic data and specimens themselves) [Academy of Natural Sciences of Drexel University (ANPS), Philadelphia, Pennsylvania; Museum of Comparative Zoology (MCZ), Cambridge, Massachusetts and California Academy of San Francisco (CAS), San Francisco, California, the four in the United States; Naturhistorisches Museum of Wien (NMW) in Vienna, Austria; Natural History Museum (BMNH) in London, England; University Museum of Zoology (UMZC), Cambridge, England and Smithsonian Institution National Museum of Natural History, Department of Vertebrate Zoology, Division of Fishes (USMN), Washington D.C., United States [21].

Examination of Specimens

The measurements used in this study were made under a stereoscopic microscope, using a millimeter-accurate digital

caliper and as the counts, followed [19].

Results

- Order Characiformes Goodrich, 1909
- Family Characidae Latreille, 1825
- Genus *Astyanax* Baird & Girard, 1854

Horizontally triangular humeral spot group species (Figure 1).

Defined for distinct shape of humeral spot (horizontally triangular) (Figure 1), not founded in none others species of *Astyanax*. The actual new species and *A. laticeps*, *A. scabripinnis* and *A. serratus* were inserted in this small group. These four species were placed in subgenus *Astyanax* (regular predorsal scale series) (Figure 2), with the others southeastern Brazilian species, except *A. altiparanae* and *A. lacustris* inserted in *A. bimaculatus* species complex, belongs in subgenus *Poecilurichthys* (irregular predorsal scales series) (Figure 2).

Table 2: Non-overlapping morphometric data between *Astyanax viridis* sp. n. Salgado, 2021; N=57 and *Astyanax janeiroensis* Eigenmann, 1908 - Holotype.

Diagnosis

Astyanax viridis sp. n. Salgado, 2021 belongs *A. scabripinnis* species complex, with triangular humeral spot. Inside this group, it differs from these three species in that it has 4 large teeth in the dentary (vs. 5) (figure 5), by the head length (26.2-27.9% HL vs. 20.9-21.3%; 23.0-25.2% and 33.9-35.3% HL, in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively) and pelvic-anal fin distance (19.1-21.9% SL vs.

30.0-31.5%; 22.0-24.9% and 28.8-31.8% SL in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively).

Description

Lower and moderately robust body. Greatest body depth between dorsal and pelvic fins origin. Dorsal profile rounded from snout tip to supra-occipital process. Convex from this point to dorsal fin and straight between dorsal and adipose

fins. Convex ventral profile between snout tip and pelvic fin, slightly concave isthmus base of this region until pelvic fin origin, convex between pelvic and anal fins and straight along anal fin base. Caudal elongated peduncle with slightly concave dorsal and ventral profiles. Head with length slightly greater than depth. Interorbital region convex. Eye rounded. Mouth terminal, very slightly inclined, transversal, broad. Lips firm, rather thin. Mandible slightly protrudes. Tongue depressed, rounded, and with anterior margin free, rather broad. Inner buccal folds broad. Nostrils together, anterior simple pore with hind cutaneous rim exposing larger posterior aperture in crescent, and anterior falls about last third in snout length. Maxillary, vertically inclined, free, reaching vertically through pupil, slightly curved, width four times in depth. First infraorbital covering small area of maxillary, and spear-shaped; second infraorbital triangular; third infraorbital kidney shape; fourth to seventh infraorbitals triangular. Pre-opercule with subretilinal lower border; concave anterior and convex posterior. Opercle free border without tiny protuberance on superior third and with anterior and posterior borders parallel along the upper half in relation to depth.

Premaxillary with 2 series of teeth, external with 4* (52) and 5 (5) pentacuspid teeth. Five (57) teeth in internal series. First tooth (symphysial), symmetrical and pentacuspid; Second and third with 5 to 7 cusps and sixth and seventh teeth with 4 to 5 cusps, forming a smooth concave arch in ventral view, gradually decreasing in size and number of cusps. Maxillary with 1 (5) to 2* pentacuspid teeth (52). Dentary with four larger teeth, being first to third tetra or pentacuspid, fifth tricuspid tooth (57), followed by 3 to 5 smaller and unicuspis to bicuspid teeth. All teeth have broad cusps, central one being more developed, giving tooth a wide shape.

Dorsal fin with ii + 9 (57) rays. First unbranched first ray approximately half length of second. Dorsal fin distal margin convex. Dorsal fin origin at half standard length. Adipose fin located vertically over to anal fin median rays. Pectoral fin with i + 11 (16) and 12* (41) rays, its origin anterior to operculum posterior margin, when compressed to body can reach pelvic fin origin, in individuals up to 87.8 mm CP. Pelvic fin with i + 7 (57) rays, its origin anterior to vertical dorsal fin origin, when fastened to body does not reach anal fin origin. Anal fin with 3 (22) or iv* (45) + 18 (7) and 19* (50) radii, slightly concave edge. Anal fin origin just below dorsal fin origin. Forked caudal fin with similar lobes in length and i + 17 + i (57) principal rays. Twelve (4) and 13* (6) dorsal procurrent rays and 10* (6) and 11 (2) procurent rays.

Scales cycloid. Scales disposed in even longitudinal series parallel with lateral line scales mostly uniform in

size except those variably smaller along predorsal, breast, preventral, postventral, caudal base and along anal fin base. Ventral fin with free scaly pointed axillary flaps about 2/5 length of fin. Lateral line complete and decurved slightly below median axis, and extending up a little low alongside of caudal peduncle with 37 (36), 38 (11) or 39* (10) perforated scales. Scales series above lateral line 5 (2), 6* (62) or 7 (3). Scales series below lateral line 4 (2), 5* (61) or 6 (2). Scales predorsal series 9 (2), 10 (11), 11 (43) or 12* (6) scales. Sixteen* (47) or 18 (10) longitudinal scales series around caudal peduncle. Anal-fin margin scales series 15* (44), 16 (1) or 17 (12).

Five * (6) and six (2) supraneurals. Pre-caudal vertebrae 13 (2) or 14* (6) and caudal vertebrae 18* (2) or 19* (6) and total 31 (2) or 32* (6). Neural spines 31 (2) or 32* (6) and hemal spine 18* (2) or 19 (6). First dorsal fin pterygiophore inserted behind neural spine of 10th (1) or 11th* (7) vertebra and last dorsal fin pterygiophore inserted at front of 17th* (7) or 18th (1) neural spine. First anal fin pterygiophore inserted behind 18th* (7) or 19th (1) vertebra hemal spine and last anal fin pterygiophore inserted at front of 28th* (7) or 29 (1) vertebral hemal thorn. Gill rakers: 8 (41) and 9* (16) + i + 11 (15) and 12* (42) on first gill arch.

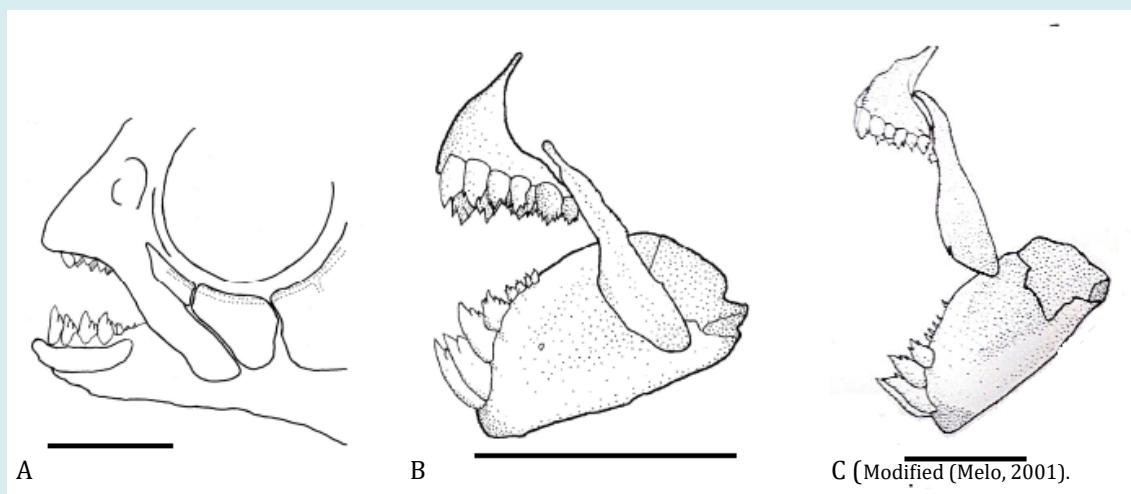

Figure 5: Larger dentary teeth of (A) (5 larger teeth) BMNH 1917.7.14.15, *Astyanax scabripinnis*, 68.5 mm SL, Holotype, drainage of Guanabara Bay, Rio de Janeiro, Rio de Janeiro, Brazil. (B) (4 larger teeth) MNRJ 17456, *Astyanax* aff. *bimaculatus*, 45.7 mm SL, Tanque stream (tributary of the right bank of the Paraíba do Sul river), locality of Passa Três, Carmo, Rio de Janeiro, Brazil. (C) (4 larger teeth) MNRJ 11009, *Astyanax viridis* sp. n. Salgado, 2021, 82.5 mm SL, Fundo river, Maricá, Rio de Janeiro, Brazil. (Bars scale = 5.0 mm).

Color in Alcohol

Dorsal region of head and body dark brown. Lateral and ventral regions of head, flanks and ventral region of body cream. Upper and lower lips, infraorbital, maxillary and opercular areas cream. Horizontally triangular humeral spot, with 1 and 1/2 scales in depth (2 series above lateral line) and 5 scales in length (2 series above lateral line). Inconspicuous silver-blackened longitudinal stripe starting two scales posteriorly to humeral spot extending to caudal peduncle where it undergoes a slight narrowing and soon after widening again forming a small triangular peduncle spot extending to end of median caudal rays. Stripe with 1 to 2 scales in depth and 18 to 19 scales in length, and peduncle spot with 1 scale in depth (1 series above lateral line) and 9 scales in length. Hyaline and reddish fins (Figure 6).

Figure 6: *Astyanax viridis* sp. n. Salgado, 2021: freshly captured specimen from the Ubatiba River, Guaratiba, Maricá, Rio de Janeiro, Brazil.

Color in Life

Superior lip and dorsal region of dark green head. Inferior lip, silver infraorbital and opercular bones. White ventral region. Dorsal and lateral regions of body greenish. Silver longitudinal stripe and conspicuous blackish and peduncular patches. Hyaline, greenish fins with reddish anal fin and caudal areas (Figure 7).

Figure 7: *Astyanax viridis* sp. n. Salgado, 2021: live and released specimen from Mariquita river, Guapiaçu, Cachoeiras de Macacu, Rio de Janeiro, Brazil.

Sexual Dimorphism

Similar colored pattern in both sexes. Males in reproductive phase have fin hooks: anal, from last unbranched ray to 11th branched ray; pelvic, from 1st branched ray to 6th branched ray. Hooks are present distally, before and after

first branch, in anterior and posterior branch, usually only posteriorly. One hook per segment.

Etimology

The specific epithet *viridis* is a reference to the color of dorsal and lateral body regions of this new species.

Geographic Distribution

Found in tributaries of the Guanabara and Sepetiba Bays, the Paraíba do Sul River and Fluminense Coastal Basins, in the São João and Ribeira do Iguape River Basins. Espírito Santo, Minas Gerais, Rio de Janeiro and São Paulo states (Figure 8).

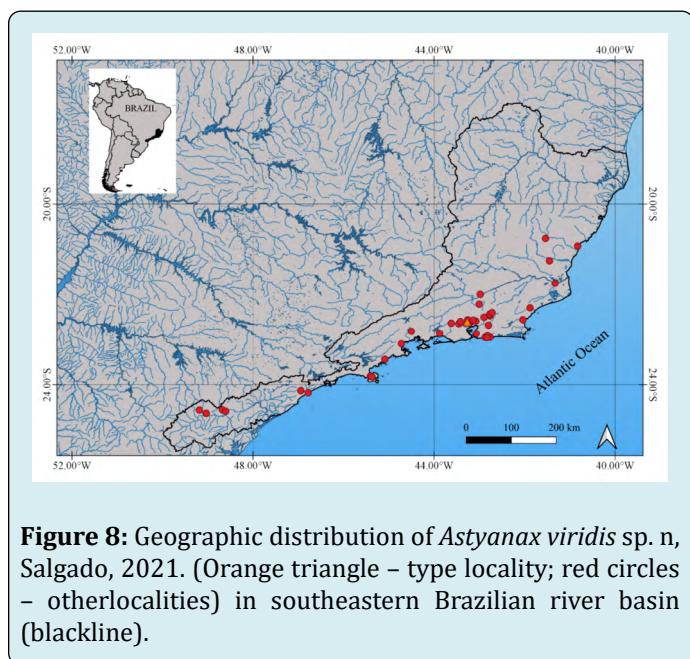

Figure 8: Geographic distribution of *Astyanax viridis* sp. n., Salgado, 2021. (Orange triangle – type locality; red circles – otherlocalities) in southeastern Brazilian river basin (blackline).

Discussion

The predorsal pattern proved to be effective in differentiating between different southeastern Brazilian coastal species, separated in subgenus *Astyanax* and *Poecilurichthys*, including *A. viridis*, corroborating [6]. The body depth (37-39%) and the number of anal fin rays (18-19) [2] were useful in the insertion of *A. viridis* in the *A. scabripinnis* complex. However, its atypical shape of humeral spot (horizontally triangular) included *A. viridis* in a small group inside this complex, formed by *A. scabripinnis* (Southeastern Brazilian coastal basins), *A. laticeps* and *A. serratus* (both from Southern Brazilian basins), even presenting a smaller number of large dentary teeth (4), which approximates it to *A. bimaculatus* complex species, with omnivorous eating habits [8]. Also according this last paper, species with graduate decreasing dentition as *Deuterodon* species have herbivorous eating habits. It was demonstrating that *Astyanax* species with four larger teeth in dentary demonstrated the omnivorous habits in these species [12]. The presence of this type of dentition in *A. viridis* could be a probable sign of convergence [4], in relation to the independent appearance of piscivorous dentition in some clades inside Characiformes. This new species has been described from abundant specimens previously identified as *A. janeiroensis* sensu Eigenmann, 1908, many listed in [14], inside *A. bimaculatus* complex, despite this different humeral spot (triangular vs. horizontally oval in this second complex), and predorsal pattern (regular vs. irregular scaled). Melo's conclusion based in this number of larger dentary teeth (4). However, those specimens of *A. viridis* differs from *A. janeiroensis* holotype (unique specimen used to described this species) [5] (Figure 1b), by several other morphological characters [ie. length of the upper jaw (35.1-38.9% HL vs. 41.4% HL), pelvic-anal fin distance (19.0-21.9% SL vs. 24.0% SL) and number of longitudinal stripe scales (18-

19 vs. 25)], justifying its description as new species. This current research was the first to detect differences between specimens previously identified as *A. janeiroensis* in relation to the holotype of *A. janeiroensis*. The presence of many non-overlapping characters between *A. viridis* and other triangular humeral spot group species, as head length (26.2-27.9% HL vs. 20.9-21.3% HL; 23.0-25.2% HL and 33.9-35.3% HL, in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively) and pelvic-anal distance (19.1-21.9% SL vs. 30.0-31.5% SL; 22.0-24.9% SL and 28.8-31.8% SL in *A. laticeps*, *A. scabripinnis* and *A. serratus*, respectively), reinforces the validity of this species. In relation of its geographic distribution, in southeastern Brazil, *A. viridis* shared its habitat (backwater areas in streams and rivers with *A. aff. bimaculatus* (*A. bimaculatus* complex), *A. taeniatus* and *A. intermedius* (*A. scabripinnis* complex), *A. parahybae* (*A. fasciatus* complex), *A. giton* and *A. hastatus*, probably more closer to *Deuterodon* [6], and, all species with wide distribution in Southern coastal rivers basins. The presence of *A. viridis* (and these species) in almost these drainages backwater areas in streams and rivers indicates that the mountains of Serra do Mar and Bocaina do not constitute totally insurmountable geographical barriers, suggesting connections between these coastal basins, at a given moment in the past. Regarding the contributing basins of Guanabara Bay, approximately 15 thousand years ago they formed a single river (Paleo Guanabara river) [1,10] contributing to the wide dispersion of these species. Old connections between Paraíba do Sul and other coastal basins in Rio de Janeiro, due to periods of marine advance and retreat, explain the sharing of these same species between these systems [22].

Although had included *A. janeiroensis* in *Deuterodon* [20], this modification will not be followed in this article, because the differences in the dentition patterns and shape of the humeral spot between this species, and those of the subgroup to which it belongs, including the new presented here, are considered valid in the separation between those species and genera. Furthermore, the synapomorphies presented in the new definition of *Deuterodon* [20], are shared by species in *Astyanax*, including those rearranged in other genera, according to the article itself.

Conclusion

Astyanax viridis were proposed as new species inside *Astyanax* for examined material from coastal basins from southeastern Brazil. This species belongs for subgroup with triangular spots species.

Material Examined

Acknowledgement

We thank Professor PhD Donald Tarphon for reviewing the manuscript, and Msc Geysa Camilo, PhD Bruno Gorini de Araujo Passos Pacheco and Graduate Student Igor Veronese de Luna for review the article and participated in discussions with the first author on *Astyanax scabripinnis* morphological and geographical boundaries, as well as added material to be examined. For Gustavo Guedes for having collected *A. scabripinnis* individuals, retrieved data on collecting arts and ecology from the sampled localities and revised the text and having drew up the distribution map and F Gerson Araújo for conducted the final revision of the text, translated it into English and coordinated the team. For Professors PhD Filipe Augusto Gonçalves de Melo, PhD Rosana Mazzoni and PhD Ricardo Iglesias-Rios and PhD Carlos Oliveira and Graduate Student Lívia Lourenço Nery and for authorization to use of some photographs and illustrations. For CNPq and Capes development agencies for funding this research.

Compliance with Ethical Standards

Author state that the research was conducted according to ethical standards.
