Abstract

Annotated checklist of marine and fresh water fishes is reported from the Hyuga Nada area, including Miyazaki Prefecture, southern coastal area of Oita Prefecture and eastern coast of Kagoshima Prefecture, southwestern Japan. Such fishes are classified into 228 families, 680 genera and 1,340 species including 24 subspecies and 1 hybrid, consisting of natural inhabitants in the area, and invasive and introduced fishes as alien species out of Japan or from the other areas. Confirmation of each species on identification is based on voucher specimens kept in Miyazaki University and other museums, photographs of fishes taken in the area, confirmed photographs in websites and references formerly reported before August 2016. Fish occurrence tendency by our gross observation is noted at each species.

Key Words: Hyuga Nada, fish fauna, Miyazaki Prefecture, eastern Kagoshima Prefecture, southern Oita Prefecture

Introduction

Faunal research in fishes of the Hyuga Nada area, mainly Miyazaki Prefecture, has not demonstrated before 1980, except for partial reports on freshwater fishes reported by Yamane¹⁻²⁾, Yamane *et al.*³⁾, Akazaki & Juso⁴⁾ and Akazaki *et al.*⁵⁾. The gross faunal research on fishes of Miyazaki Prefecture was firstly reported by Iwatsuki⁶⁾ in 1983, which showed 665 species including marine and freshwater species but is not yet reviewed unfortunately although the recent fish faunas in Ehime⁷⁾, Kochi (http://www.kochi-u.ac.jp/w3museum/Fish_Labo/FishCatalog/Orders.html) and Kagoshima⁸⁾ prefectures have been reported in website or books.

* For correspondence (e-mail: kimura-s@bio.mie-u.ac.jp)

Of the adjacent areas to Miyazaki Prefecture, the fish faunas of southern part of Oita Prefecture (southern coastal area of Saganoseki, a boarder of Seto Inland Sea) and the eastern coastal area of Osumi Peninsula, Kagoshima Prefecture, are closely similar to that of Miyazaki Prefecture, because the following characteristic fishes are found in those areas as relatively common from juveniles to adults: famously known Akame *Lates japonicus*⁹⁻¹³⁾, Namimatsukasa *Myripristes kochiensis*¹⁴⁾, Yamatoitohikisagi *Gerres microphthalmus*¹⁵⁾, Sedakadaimyosagi *G. akazakii*¹⁶⁾ and Oninouchiwa *Platyrrhina hyugaensis*¹⁷⁾. Therefore, those areas can be included in the Hyuga Nada area.

A lot of ichthyological new findings including taxonomy have been surprisingly accumulated by Nakabo's book with pictorial keys in the Japanese Archipelago¹⁸⁾ and Eschmeyer's catalog of fishes (updated), worldwide¹⁹⁻²⁰⁾. Such contributions have given us exact and speedy identification, and newly views in fish research of the Hyuga Nada area.

Several familial fishes [carangids, lutjanids, caesionids, girellids and kyphosids²¹⁻²³⁾], ecological research^{9-13, 24-25, 26)}, taxonomical studies^{14-17, 27-40)}, distributional extension and records^{15-17, 29, 37-63)}, endangered species^{12, 28, 47, 60)} and introduced fishes^{3, 6, 12, 31, 61-62, 64)} have been increasingly reported from the Hyuga Nada area since 1980 and then, is herein reviewed, plus a brief review on fishes of Miyazaki Prefecture⁶³⁾. Other local fish faunas of the pacific coasts of Japan⁶⁵⁻⁶⁷⁾, Sea of Japan⁶⁸⁻⁷⁰⁾, Taiwan⁷¹⁾, the South China Sea⁷²⁾ from the northeastern Pacific have been energetically studied by many researchers. The region shows the highest catches in the world⁷³⁻⁷⁵⁾.

We here report an annotated checklist of the Hyuga Nada area, southwestern Japan as basic biological information of faunal research as the first step. Such includes natural inhabitants in the Hyuga Nada area, and invasive and introduced fishes as alien species out of Japan or the other areas in Japan. Confirmation of each species is based on voucher specimens (museum collection of MUFS, Fisheries Sciences, Miyazaki University and other museum collection), photographs of fishes taken in the area, confirmed photographs in websites, and references formerly reported before August 2016. Fish occurrence tendency by our gross observation is noted at each species.

Material and Methods

Species confirmation is basically based on fish collection (shown as **S** in Table 1, voucher specimen[s]) of MUFS museum collection (Miyazaki University, Fisheries Sciences) as well as photographs (shown as **P**) and website confirmations (shown as **W**). Furthermore, fish records which were formerly reported before are based on references (shown as **REF**). Identification follows Nakabo's fish book on key¹⁸⁾ and other recent review papers including website of the Catalog of Fishes with the family¹⁹⁻²⁰⁾.

Occurrence tendency of fishes from the Hyuga Nada area are grossly noted at each species as Very Common (**VC**), Common (**C**), Rare (**R**), Very Rare (**VR**), and Extinct (**E**). Furthermore, exotic species from foreign countries and Japanese domestic species introduced to the Hyuga Nada area are indicated as **INF** and **INJ**, respectively. Each judgement of their species confirmation and occurrence tendency at each species is indicated after scientific name, shown in Table 1. Detailed information (catalogued number, collection site and other ecological data) can be accessed to contact with the first and second authors or staff of the department of Miyazaki University.

The Hyuga Nada area is defined as the follows: marine and fresh water areas in Miyazaki Prefecture, plus from the adjacent coast of southern part of Oita Prefecture (southern coastal area of Saganoseki, boarder of the Seto Inland Sea) to eastern coast of Osumi Peninsula, Kagoshima Prefecture. Furthermore, the Hyuga Nada area includes an area from coastal line to ca. 100 km offshore, being grossly parallel

coastal line to the Kuroshio Current. The checklist of the Hyuga Nada area is included until August 2016. The family also follows van der Laan *et al.*²⁰⁾ Each species is alphabetically arranged under genus and species at each family in Table 1.

Table 1 Annotated checklist of marine and freshwater fishes in the Hyuga Nada area, southern Japan. Confirmation is based on voucher specimens (S), photographs (P), websites (W), and references (REF). Fish occurrence tendency is noted on the basis of gross observation: Very common (VC), common (C), rare (R), Very rare (VR) and extinct (Ext). Invasive species from foreign species and Japanese domestic species are shown as IF and ID, plus justification for rearing, extinction, and naturalized condition in parenthesis.

Results

The fishes in the area are classified into 227 families, 678 genera and 1,332 species including 24 subspecies and 1 hybrid, consisting of fishes as natural inhabitants in the Hyuga Nada area and introduced fishes as alien species out of Japan or the other area in Japan. All annotated checklist are shown in Table 1.

In addition, eight species were added from the Hyuga Nada Area after submission of this report: Osujikurohagi (P) *Acanthurus blochii* Valenciennes 1835, Kamoharaginpo (P) *Meiacanthus kamoharai* Tomiyama 1956, Kakureuoka (S) Carapidae sp., Gigi (P) *Tachysurus nudiceps* (Sauvage 1883), Kokutenfugu (S) *Arothron nigropunctatus* (Schneider 1801), Hohosujitarumi (S) *Macolor macularis* Fowlwer 1931, Yaseharisenbon (S) *Diodon eydouxii* Brissout & Barneville 1846, and Yatsumeunagika (S) Petromyzontidae sp. (Ammocoetes larva).

Discussion

Fish fauna of the Hyuga Nada area in the northwestern Pacific

A total of 228 families, 680 genera and 1,340 species including 24 subspecies and one hybrid (Table 1) are confirmed in the Hyuga Nada area. In Kochi Prefecture, the northeastern adjacent prefecture of the Hyuga Nada area, 1,913 species of fishes were listed in 2006: (http://www.kochi-u.ac.jp/w3museum/Fish_Labo/FishCatalog/Orders.html), but the number of fish species is currently considered over and over 2,000 (H. Endo, pers. comm.). It reaches beyond half of all known Japanese species if it is considered 4,210 species from the Japanese Archipelagos¹⁸⁾. It seems that fish diversity in Kochi Prefecture is richer than that of the Hyuga Nada area because the Kuroshio Current directly encounters Kochi Prefecture. Larval and juvenile fishes of tropical and subtropical species in the Ryukyu Islands, Japan, would be easily transported directly into the coastal area of Kochi Prefecture although we guess that such number would include a lot of killing migratory fishes like chaetodontids.

In the southern adjacent area, Kagoshima Prefecture including Yakushima and Tanegashima Islands⁸⁾, the fish fauna includes ca. 1,500 species (H. Motomura, pers. comm.) as well as 1,517 species for Sagami Bay near Tokyo⁶⁵⁾ (1,688 in February 2017, H. Senou, pers. comm.). From Ago Bay and its adjacent waters, Mie Prefecture, Kimura and Suzuki⁶⁶⁻⁶⁷⁾ reported 375 species of fishes, but now the FRLM museum collection shows 1,243 species on the basis of only voucher specimens collected from Mie Prefecture. We consider that the fish accounts of the Hyuga Nada area might be able to increase until ca. 1,500 species by further research.

On the other hand, the fish faunas in East China Sea and Yellow Sea (K. Hoshino, pers. comm.; unpublished checklist), Wakasa Bay, Kyoto Prefecture⁶⁸⁾ and Hokkaido⁶⁹⁾ are confirmed 1,158 species, over ca. 600, and ca. 650, respectively. Combined accounts from local fisheries stations of each prefecture along the coast of Sea of Japan by references' basis reaches at 1,396⁷⁰⁾. Furthermore, southwestern Taiwan, and South China Sea show 2,133⁷¹⁾, and 3,365⁷²⁾ species of fishes, respectively. The updated checklist of fishes in the Ryukyu Islands, Japan, is not published but it could include simply more than 2,500 species [vs. 4,210¹⁸⁾, known from Japan].

Fishes from the East Asian Shelf or northwestern Pacific (FAO Area 61) have demonstrated the richest and highest catches in the world⁷³⁾. Many endemic species from the East Asian Shelf including the Japanese Archipelago can be confirmed¹⁸⁾. Such endemic species are considered usually temperate fishes. It is interesting and important for ichthyologists to know what percent of such endemic species in all accounts of the East Asia Shelf or the Hyuga Nada area is found because endemic fish list and its percentage indicate very useful species for judgements of fisheries management (beneficial and commercial species for human beings), conservation (protection) of endangered species, and characteristics of local fauna like the Hyuga Nada area.

However, endemism in fishes of northwestern Pacific (FAO Area 61) has not been enough evaluated unfortunately. A value of 10% was chosen by Briggs⁷⁴⁾ for an area to qualify as a distinct province after an examination of endemism rates in numerous areas. Notably, this minimum value would admit most of the areas that were previously recognized as provinces on the basis of less formal criteria by Briggs & Bowen⁷⁵⁾, which admitted several segments of Oriental Province (Western North Pacific Region), but endemism of East Asia could not be evaluated for Taiwan, China and Vietnam in the southern region of the East Asia together with notes of "Although there are no recent taxonomic evaluations (known to us), the older literature demonstrated considerable endemism in ascidians, pycnogonids and fishes (Briggs, 1974)". Further criteria of endemism for northwestern Pacific is needed for basic biological information of fisheries

resource management as well as the evaluation (characteristics) of the Hyuga Nada area in northwestern Pacific.

Characteristic species from the Hyuga Nada area and their freshwater species

Akame *Lates japonicus*⁹⁻¹³⁾, Nanimatsukasa *Myripristes kochiensis*¹⁴⁾, Yamatoitohikisagi *Gerres microphthalmus*¹⁵⁾, Sedakadaimyosagi *G. akazakii*¹⁶⁾ and Oninouchiwa *Platyrhina hyugaensis*¹⁷⁾ are always found in the Hyuga Nada area as relatively common from juveniles to adults as briefly noted in **Introduction**. Further, such species rarely or sporadically occur along the Pacific coasts of Kinki, Tokai, and Kanto, but do not occur in western Kyushu, the Ryukyu Islands, South Korea, Taiwan, and China⁹⁻¹⁷⁾. Therefore, these fishes are considered as characteristic or symbolic coastal species in the Hyuga Nada area. In addition, Toyo-urumakasago *Scorpaenopsis orientalis*²⁷⁾ is considered as nearly characteristic species in the Hyuga Nada area although its range extends to Kagoshima Prefecture, Tanegashima and Mishima Islands (as limited distribution; H. Motomura pers. comm.). In the freshwater fishes, it is known only to a single endemic species in Miyazaki Prefecture, Oyodo-shimadojyo *Cobitis sakahoko*²⁸⁾, which it was recently described.

Fish faunal differences between the northern and southern Hyuga Nada areas

A lot of ichthyological papers in the Hyuga Nada area have been reported in faunal reports, ecological research, taxonomical studies, distributional extension and introduced fishes as cited in Introduction. Subsequently, the first author reported many first records of species reported from the southern Hyuga Nada area. Four tropical carangid species occurred from the southern Hyuga Nada area as the first records from Japan: Kuroboshi-hiraaji *Alepes djedaba*⁴¹⁾, Teru-meaji *Selar boops*⁴²⁾, Kogane-marukoban *Trachinotus mookalee*⁴³⁾ and Ookuichiikekatsuo *Scomberoides commersonianus*⁴⁴⁾, these facts suggest strong effect by global warming because higher change of seawater temperature increased in +1.21°C in the Hyuga Nada area (as a changed area of the highest temperature within Pacific coast of the Japanese waters) for past 100 years (http://www.data.jma.go.jp/kaiyou/data/shindan/a_1/japan_warm/japan_warm.html). Furthermore, the above four species have never been reported from the Ryukyu Islands, Japan, as well as the northern Hyuga Nada but were known from Taiwan or China. Accordingly, these facts strongly suggest their origin or population from Taiwan and China^{46, 71)}.

Sake *Oncorhynchus keta* as a poorly known species^{47, 63)} of the Hyuga Nada area in Japan, Menada *Liza haematocheilus*, Umitanago *Ditrema temminckii temminckii*, Kujime *Hexagrammos agrammus*, Idatenkajika *Ocyneutes maschalalis*, Aya-anahaze *Pseudoblennius marmoratus*, Anahaze *Pseudoblennius percoides*, Kirinanahaze *Pseudoblennius* sp. 3¹⁸⁾, Urokokajika *Stlengis misakia*, Asahianahaze *Pseudoblennius cottooides*, Kusauo *Liparis tanakae*, Bikunin *Liparis tessellatus*, Shirouo *Leucopssarion petersii*, Ishigarei *Kareius bicolorata*, and Amimehagi *Rudarius ercodes* were found even only in the northern Hyuga Nada area as the southernmost record of Pacific coast of southwestern Japan. These fishes are justified as northern originated fishes in north or northwestern Pacific. Such species basically occurs southward to Kadokawa Bay and Hyuga City, Miyazaki Prefecture. We had never seen such species in the southern Hyuga Nada area from Kawaminami-cho, Miyazaki Prefecture, through the Nichinan Coast, to Shibusi Bay, Kagoshima Prefecture before around 2000. In addition, we saw Ishigarei only once (15 January 2014; MUFS 45633) but we have never seen another famous Japanese and endemic flatfish, Makogarei *Pleuronectes yokohamae*, being characteristics in the Hyuga Nada area, too.

Subsequently, several species of Anahaze, Shirouo, and Amimehagi were often confirmed from the southern Hyuga Nada area after around 2000. The latter two species might reproduce at the area because

tens of transparent body of Shirouo (ca. 4–5 cm in total length, anadromous for spawning in lower basin of river) and Amimehagi (ca. 1–6 cm in total length) were collected from the Kumaya River estuary, the Nichinan Coast and Meitsu Harbor, Nango, respectively in 2006–2008 by the first author. This change might have suggested to be affected by the following global warming and global change of weather.

The change of their occurrence might have been strongly connected with robust Arctic sea-ice influence on the frequent Eurasian cold winters in past decades⁷⁶⁾, which resulted in the decline of seawater temperature and severe storm for southwestern Japan in winter season after 2000. This fact is strongly considered as global warming⁷⁶⁾. Abrupt change in three or four degree Celsius of higher sea temperature (ca. 19–21 °C if comparing with past temperature, 15–16 °C) and gradual decrease of mean daily seawater temperature in winter (by “big chill”) for past 10 years (2005–2015; <http://www.mz-suishi.jp/import01/06.html>) might have disturbed their usual distributional pattern of northern origin species as above noted in the Hyuga Nada area, as well as collection of deep sea fishes (for example Sakegashira *Trachipterus ishikawai* and Ryugunotsukai *Regalecus glesne*) in shallow coastal area. The latter species (MUFS 46251, ca. 330 cm in total length; http://www.the-miyanichi.co.jp/kennai/_4965.html) was collected from Meitsu, Nango, Miyazaki by set net in 31 March 2014.

Acknowledgments

We are most grateful to the former undergraduate and graduate students of K. Tsuzaki, N. Suenaga, Y. Hiraki, R. Miki, N. Hayashida, M. Ono, A. Imoto, A., S. Ishihara, A. Yamane, M. Kawakami, H. Izuimi, K. Miyamoto, K. Kudo, S. Yoshinaga, T. Fukuhara, M. Kondo, T. Fukuhara, M. Taniguchi, K. Mototani, S. Mikuni, D. Kanbayashi, K. Ooyama, K. Hiji, H. Motomura, A.I. Burhannudion, N. Nagano, K. Iwamoto, H. Ono, T. Fuchigami, K. Yokoyama, A. Nakamura, and my other undergraduate students who graduated under the first authors' supervisor (R. Sakamoto, M.S. Ramandey, and Y. Tanaka). Furthermore, we are also appreciative of H. Endo, H. Motomura, K. Hoshino, T. Yoshino, Y. Kai, F. Tashiro, H. Senou, T. Kawai, H. Imamura, M. Yabe, H.-C Ho, K.-T. Shao, J. Zhang, and J.-K. Kim for information of fish accounts at each area from the East Asia as well as Y. Hibino, M. Fukuda, K. Takahashi, A. Shinchi, I. Shiiba, T. Hayashi, K. Katsuhide, and I. Fukuda for identification and photographic confirmation of many fishes, and H. Kadokawa and H. Nakahiro for many fish donation and distributional information for faunal research in the Hyuga Nada area.

Finally, we are greatly appreciative of the constructive criticism provided by anonymous reviewers. This study was supported in part by a grant awarded to the first author, by the National Research Foundation of South Africa (Grant UID # 70611), plus partial support of grants by the Ministry of Education, Science, Sports and Culture, Tokyo, Japan (Nos. 10640684 and 11640696).

要 旨

宮崎県および隣接する大分県佐賀関南部と鹿児島県大隅半島東側を含めた、日向灘水域の魚類目録を作成した。この地域の海産魚および淡水魚として、228科680属、亜種と雑種を含む1,340種が確認された。これらはこの地域に自然分布している種と国内外から移入した外来種を含んでいる。外来種には記録の明らかな養殖魚も含まれる。今回の記録は、宮崎大学魚類学術標本に基づくもの、学術文献等に報告され確認されたもの、写真のみにより確認したもの、およびウェブサイトに掲載された写真によって確認したものを含み、それらの確認方法も記した。また各魚種についての概略的な出現傾向も記した。さらに日向灘水域における魚類の特徴や最近の出現傾向の変化についても若干の考察も加えた。
