Table SI. Taxonomic treatment and criteria used to allocate the puzzling snake species posted by Facebook users.

Taxa	Taxonomic issue	Criteria	Taxonomic entity employed
<i>Atractus</i> spp.	Crypticity	The genus <i>Atractus</i> comprises about 150 currently recognized species of cryptozoic snakes of which nearly 43 species inhabiting in Colombia (Passos et al. 2009, Angarita-Sierra 2019, Pomar-Gómez et al. 2021). Its high level of local endemism, notorious population polymorphism and geographic variability, as well as its strong resembling both sympatric and allopatric species makes the <i>Atractus</i> species hard to allocated into accurate taxon. Moreover, most of the diagnostic characters are placed into the hemipenial morphology and pholidosis (Passos & Lynch 2010). Hence, most of the Colombian <i>Atractus</i> species are hard to be identified taxonomically based on a picture or video, despite the picture or video have good quality. Consequently, based on a picture or video posted in that Facebook groups, we only allocated into a snake taxon when we were able to make an accurate taxonomical identification helped by the references aforesaid.	<i>Atractus</i> (unknown species) <i>Atractus cf elaps</i> <i>Atractus cf sanguineus</i> <i>Atractus clarki</i> <i>Atractus crassicaudatus</i> <i>Atractus lasallei</i> <i>Atractus obesus</i> <i>Atractus titanicus</i> <i>Atractus univittatus</i>
<i>Boa constrictor</i> , <i>B. imperator</i>	Crypticity	According Card et al. (2016) together with the wide diversity of ecosystems they inhabit, collectively suggest that the genus may represent multiple species. Morphological variation within <i>Boa</i> also includes instances of dwarfism observed in multiple offshore island populations. Despite this substantial diversity, the systematics of the genus <i>Boa</i> has received little attention until very recently. In this study we examined the genetic structure and phylogenetic relationships of <i>Boa</i> populations using mitochondrial sequences and genome-wide SNP data obtained from RADseq. We analyzed these data at multiple geographic scales using a combination of phylogenetic inference (including coalescent-based species delimitation, Colombian <i>Boa</i> populations have high mitochondrial lineage diversity. Hence, these authors recommend a comprehensive sampling of Colombia population to achieve a full understanding of the lineage diversity in <i>Boa</i> . Besides, currently there are not available diagnostic characters that allows to distinguish between Central and South American lineages proposed by Card et al. (2016) together with the wide diversity of ecosystems they inhabit, collectively suggest that the genus may represent multiple species. Morphological variation within <i>Boa</i> also includes instances of dwarfism observed in multiple offshore island populations. Despite this substantial diversity, the systematics of the genus <i>Boa</i> has received little attention until very recently. In this study we examined the genetic structure and phylogenetic relationships of <i>Boa</i> populations using mitochondrial sequences and genome-wide SNP data obtained from RADseq. We analyzed these data at multiple geographic scales using a combination of phylogenetic inference (including coalescent-based species delimitation, both present in Colombia. Therefore, in this study we considered <i>Boa constrictor</i> as species complex.	<i>Boa constrictor</i>
<i>Chironius</i> spp.	Ontogenetic shift	Currently, Colombia harbours ten species of snakes representing the genus <i>Chironius</i> (Uetz et al. 2020). Due its body size, color pattern and distribution most of them could be easily identified taxonomically based on a picture or video with middle or good quality, helped by the references aforesaid. However, the juveniles of all <i>Chironius</i> species have a highly variable color pattern with a close interspecific resembling (Dixon et al. 1993). Consequently, there are hard to identify the taxonomic identity of the <i>Chironius</i> spp., juveniles based on a picture or video, despite of its quality. Therefore, the taxonomic identification of all <i>Chironius</i> spp., juveniles posted was limited at genus level.	<i>Chironius carinatus</i> <i>Chironius flavopictus</i> <i>Chironius fuscus</i> <i>Chironius grandisquamis</i> <i>Chironius monticola</i> <i>Chironius scurculus</i> <i>Chironius spixii</i>
<i>Clelia cleia</i> , <i>Clelia equatoriana</i> , <i>Pseudoboa neuwiedii</i>	Ontogenetic shift	Adult color pattern of <i>Clelia cleia</i> , <i>Clelia equatoriana</i> , and <i>Pseudoboa neuwiedii</i> are easily distinguished between them (Carvajal-Cogollo 2019). However, newborns and juveniles color pattern of these snake species are barely distinguished (Lozano & Angarita-Sierra 2018, Torres-Carvajal et al. 2020). The dorsal and caudal scales counts allow distinguished between these species, but these characters are difficult to state from picture or video posted. Therefore, we were able to make an accurate taxonomical identification of these species based only adult specimens. Newborns and juveniles were allocated as <i>Clelia</i> / <i>Pseudoboa</i> category and its was not included in the species analyses.	<i>Clelia</i> / <i>Pseudoboa</i> <i>Clelia cleia</i> <i>Clelia equatoriana</i> <i>Pseudoboa neuwiedii</i>
<i>Erythrolamprus epinephalus</i>	Crypticity	<i>Erythrolamprus epinephalus</i> is one of the most widespread and variable species of genus <i>Erythrolamprus</i> of Central and South America, having 14 subspecies based on pholidosis, color patterns and maxillary teeth (Dixon 1983). Several authors have been considering <i>Erythrolamprus epinephalus</i> as species complex composed by a multiple distinct evolutionary linages (Torres-Carvajal & Hinojosa 2020). Since Dixon early efforts, there are no available a comprehensive taxonomic assessment of the Colombian populations. In Colombia, this taxon inhabiting in the trans-Andean region from the sea level up to 3000 m of elevation, being represented by five subspecies: <i>L. e. opisthotaenia</i> ; <i>L. e. lamonae</i> , <i>L. e. epinephelus</i> , <i>L. e. bimaculatus</i> , and <i>L. e. pseudocobella</i> . All these subspecies exhibit intergrades between them making difficult to state from a picture or video posted an accurate taxonomic identification. Therefore, we resolved to allocate into <i>Erythrolamprus epinephalus</i> all the specimens that clearly matching with geographic and color pattern of <i>L. e. bimaculatus</i> described by Dixon (1983). The remaining specimens were allocated as <i>Erythrolamprus cf epinephalus</i> despitess of its similarities with <i>L. e. opisthotaenia</i> ; <i>L. e. lamonae</i> or <i>L. e. pseudocobella</i> . Finally, according with a recent study which is nearly to be publish (J. D. Lynch pers. comm. 2020) <i>L. e. bimaculatus</i> could be stated as full species, thus, we resolved to allocate all the specimens that clearly match with the geographic distribution and color pattern of <i>L. e. bimaculatus</i> into <i>Erythrolamprus bimaculatus</i> .	<i>Erythrolamprus epinephalus</i> <i>Erythrolamprus cf epinephalus</i> <i>Erythrolamprus bimaculatus</i>
<i>Leptodeira annulata</i> <i>L. septentrionalis</i>	Crypticity	According with Duellman (1958) in Colombia inhabiting two species of the genus <i>Leptodeira</i> : <i>Leptodeira annulata</i> having three subspecies <i>L. a. annulata</i> , <i>L. a. ashmeadi</i> , <i>L. a. ashmeadi+rhombiera</i> ; and <i>L. s. septentrionalis</i> with a single subspecies <i>L. s. ornata</i> . The diagnostic characters that allow to distinguish between these species are coined in its hemipenial morphology, while differences between subspecies are based on color pattern and some scales count (e.g., dorsal scale reductions). Besides, these species exhibit allopatric distributions inhabiting the populations of <i>Leptodeira annulata</i> in the cis-Andean ecosystems while <i>L. s. septentrionalis</i> in the trans-Andean ecosystems of Colombia. Daza et al. (2009) tested the hypotheses stated by Duellman (1958) employing molecular evidence, founding a polyphyly of the species <i>L. annulata</i> and <i>L. s. septentrionalis</i> , in which genetic distance did not work as criterion for species delimitation. However, an ongoing comprehensive study of the hemipenial morphology of the genus <i>Leptodeira</i> , which have a special interest in Colombian species by covering all the subspecies reported (Angarita-Sierra unpublished data), shows that hemipenial morphology of trans-Andean Colombian population mismatch the hemipenial architecture of <i>L. s. septentrionalis</i> described by Duellman (1958), but in the opposite, this populations have an accurate match with hemipenial architecture of <i>L. annulata</i> depicted by the same author. Therefore, we named all the <i>Leptodeira</i> Colombian populations reported by Facebook users as <i>Leptodeira annulata</i> .	<i>Leptodeira annulata</i>

Taxa	Taxonomic issue	Criteria	Taxonomic entity employed
<i>Mastigodryas</i> spp.	Ontogenetic shift	The genus <i>Mastigodryas</i> in Colombia comprise five species distributed in both cis and trans-Andean regions. Like the ontogenetic shift seen in juveniles of all <i>Chironius</i> species, juveniles of <i>Mastigodryas</i> species exhibit highly variable color pattern with a close interspecific resembling (Siqueira et al. 2013, Montingelli et al. 2019). Therefore, the taxonomic identification of all <i>Mastigodryas</i> spp., juveniles posted was limited at genus level	<i>Mastigodryas</i> <i>boddaerti</i> <i>Mastigodryas</i> <i>danieli</i> <i>Mastigodryas</i> <i>pleii</i>
<i>Micrurus lemniscatus</i>	Crypticity	<i>Micrurus lemniscatus</i> has been a controversial taxon. Under this name, species such as <i>M. lemniscatus</i> , <i>M. carvalhoi</i> , <i>M. diutius</i> , <i>M. frontifasciatus</i> , and <i>M. helleri</i> have been treated either as distinct species or subspecies of <i>Micrurus lemniscatus</i> . Besides, other species full stated such as <i>M. filiformis</i> , <i>M. isozonus</i> , <i>M. potyguara</i> , and <i>M. serranus</i> have also been proposed to belong to the <i>M. lemniscatus</i> complex. According with the molecular phylogeny analysis performed by Hurtado-Gómez et al. (2021) <i>M. lemniscatus</i> , <i>M. carvalhoi</i> , <i>M. diutius</i> , <i>M. frontifasciatus</i> , and <i>M. helleri</i> have been treated either as distinct species or subspecies of <i>M. lemniscatus</i> . Additional species (<i>M. filiformis</i> , <i>M. isozonus</i> , <i>M. potyguara</i> , <i>M. serranus</i> , <i>Micrurus lemniscatus</i> (<i>sensu stricto</i>) are not inhabiting in the Colombian ecosystems. In opposition, Colombian populations traditionally assigned to <i>M. helleri</i> represent two non-sister lineages, one occurring along the Andean foothills and the other in lowland Amazonia. According Hurtado-Gómez et al. (2021) <i>M. lemniscatus</i> , <i>M. carvalhoi</i> , <i>M. diutius</i> , <i>M. frontifasciatus</i> , and <i>M. helleri</i> have been treated either as distinct species or subspecies of <i>M. lemniscatus</i> . Additional species (<i>M. filiformis</i> , <i>M. isozonus</i> , <i>M. potyguara</i> , <i>M. serranus</i> <i>M. helleri</i> was restricted to the populations of the Andean foothills. Therefore, the three posts named as " <i>Micrurus lemniscatus</i> " from Amazonian foothills localities (Caquetá department) were renamed as <i>M. helleri</i> adopting the taxonomic proposal by Hurtado-Gómez et al. (2021) <i>M. lemniscatus</i> , <i>M. carvalhoi</i> , <i>M. diutius</i> , <i>M. frontifasciatus</i> , and <i>M. helleri</i> have been treated either as distinct species or subspecies of <i>M. lemniscatus</i> . Additional species (<i>M. filiformis</i> , <i>M. isozonus</i> , <i>M. potyguara</i> , <i>M. serranus</i>). Nevertheless, the taxonomic identification made by Facebook administrators were not penalized.	<i>Micrurus helleri</i>
<i>Oxybelis aeneus</i>	Crypticity	Historically, <i>Oxybelis aeneus</i> has been considered a single species widely distributed from southern Arizona through the Neotropics into southeastern Brazil. Nevertheless, recently several species have been erected from North America and Central American, Western and Central Amazon populations highlighting the crypticity of the brown vine snake (Jadin et al. 2021). According with the molecular phylogeny analysis performed Jadin et al. (2019) <i>Oxybelis aeneus</i> , is considered a single species despite the fact its distribution covers an estimated 10% of the Earth's land surface, inhabiting a variety of ecosystems throughout North, Central, and South America and is distributed across numerous biogeographic barriers. Here we assemble a multilocus molecular dataset (i.e. cyt b, ND4, cmos, PRLR within <i>Oxybelis aeneus</i> complex were found four clearly differentiate lineages across North America and Central American. These authors suggest that northern South American populations of <i>O. aeneus</i> could represent more than one hidden lineage, as well as undescribed species. However, these populations lack comprehensive studies, particularly, samples of Colombian populations have not included into molecular analyses, or they were poorly represented in morphological studies. Therefore, due the lack of new evidence that helps to understand <i>Oxybelis aeneus</i> complex inhabiting Colombia, we retained all the Colombian populations under the name <i>Oxybelis aeneus</i> .	<i>Oxybelis aeneus</i>
<i>Porthidium lansbergii</i>	Crypticity	<i>Porthidium lansbergii</i> is a pitviper species distributed from the Isthmian–Pacific dry forests in Panamá through the Chocó–Darién region, Urabá moist forests and Magdalena valley dry forest, as well as the northwest up to xeric-dry forests in northern Venezuela (Campbell & Lamar 2004, Natera-Mumaw et al. 2015). Historically, Colombian populations have been stated as junior synonyms of several taxa, being confusing with similar species of <i>Porthidium</i> in Central America (Campbell & Lamar 2004). Despite that previous taxonomic studies have resulted in various taxonomic rearrangements with description of new species [<i>P. arcosae</i> (Schäfti and Kramer 1993), <i>P. dunnii</i> (Hartweg and Oliver 1936), <i>P. hespere</i> (Campbell 1976), <i>P. porrasi</i> , <i>P. ophryomegas</i> , <i>P. volcanicum</i> , <i>P. yucatanicum</i>]. Nevertheless, Colombian populations remains far from to be completely understood. Currently, an ongoing study that explore the Colombian <i>P. lansbergii</i> complex (S.D Cubides-Cubillos pers. comm. 2021), point out that some populations hidden undescribed entities which can be distinguished based on molecular and morphological evidence. Therefore, due the lack published evidence that helps to understand <i>P. lansbergii</i> complex inhabiting Colombia, we retained all the Colombian populations under the name <i>P. lansbergii</i> when the specimens reported have a suitable matched with the diagnostic characters described by Campbell & Lamar (2004), otherwise, we named all the specimens reported as <i>Porthidium cf lansbergii</i> .	<i>Porthidium cf lansbergii</i> <i>Porthidium lansbergii</i>
<i>Stenorrhina degenhardtii</i>	Crypticity	The scorpion-eating snake <i>Stenorrhina degenhardtii</i> is widely distributed from southern Mexico through Central America and northern South America, encompassing lowlands of Colombia, Venezuela, and western Ecuador and Peru (Uetz et al. 2020). Its formal type locality is La Esperanza, Popayán, Colombia (Laurent 1949, Stuart 1963, ZFMK 36828). However, other populations have types assigned across its distribution range, but some of these have not been erected formally as subspecies (<i>Stenorrhina d. degenhardtii</i> , <i>S. d. kennicottiana</i> , <i>Stenorrhina d. mexicana</i> , <i>S. d. ocellata</i> , <i>S. d. ventralis</i>) (Uetz et al. 2020). Colombian populations of <i>Stenorrhina degenhardtii</i> exhibits broad morphological variability across ecoregions, suggesting that under the name <i>S. degenhardtii</i> could be hidden undescribed species. Besides, most of the <i>S. degenhardtii</i> posted by Facebook users hardly match with the diagnostic color pattern described by Laurent (1949), Savage (2002), Köhler (2003), Natera-Mumaw et al. (2015). Therefore, due the lack of published evidence that helps to understand <i>S. degenhardtii</i> complex inhabiting Colombia, we retained all the Colombian populations under the name <i>Stenorrhina cf degenhardtii</i> .	<i>Stenorrhina cf degenhardtii</i>

Taxa	Taxonomic issue	Criteria	Taxonomic entity employed
<i>Tantilla melanocephala</i>	Crypticity	<p><i>Tantilla melanocephala</i> is the most widespread species of the genus <i>Tantilla</i> in South America, ranging from Colombia to northern Argentina and Uruguay, including the islands of Trinidad and Tobago. However, recent studies have shown that some populations allocated historically under the name <i>T. melanocephala</i> (Wilson & Townsend 2007) represent divergent lineages, as well as undescribed species (Ray & Ruback 2015, Wilson et al. 2016, Jowers et al. 2020, Townsend et al. 2020) cryptozoic and semi-fossorial species. Morphological data of <i>Tantilla melanocephala</i> in the Eastern Caribbean region, and more precisely on the islands of Trinidad and Tobago and nearby Venezuela, have shown differences in scales and color patterns associated with these localities, which may suggest the presence of cryptic species in the region. Assessing the monophyly of <i>Tantilla melanocephala</i> is key as its paraphyly could compromise important decisions for conservation and management. In this study, we conduct phylogenetic analyses of all available <i>Tantilla</i> from GenBank (n = 11. As consequence, <i>T. melanocephala</i> is considering as species complex. Currently, an ongoing study nearly to be published (J. D. Lynch pers. comm. 2020) point out that Colombian populations represent at least two undescribed species and two subspecies that can be erected as full species due its morphology. Therefore, due the lack published evidence that helps us to distinguish among Colombian populations <i>T. melanocephala</i>, we retained all the specimens reported by Facebook users under the name <i>Tantilla cf melanocephala</i>.</p>	<i>Tantilla cf melanocephala</i>
<i>Thamnodynastes</i> spp	Crypticity	<p>The species of the genus <i>Thamnodynastes</i> are one of the hardest species to be identify based on pictures or videos given its resembling, both between sympatric and allopatric species. Most of the diagnostic characters are placed into the hemipenial morphology and pholidosis. Besides, the shallow original descriptions and lack of robust diagnostic characters are the main difficulty to determinate species identity (Trevine et al. 2021). Added to the above, <i>Thamnodynastes</i> species inhabiting Colombia represent species complexes poorly studied in the country (e.g., <i>Thamnodynastes pallidus</i> species group) that hidden undescribed species (Trevine et al. 2021). Hence, an accurate taxonomic identification of the Colombian <i>Thamnodynastes</i> populations is strongly constrained. We retained all the Colombian populations under the name <i>Thamnodynastes gambotensis</i> when the specimens reported have a suitable matched with the diagnostic characters, as well as the geographic localities described by Perez-Santos and Moreno (1989), otherwise, we named all the specimens reported as <i>Thamnodynastes sp</i></p>	<i>Thamnodynastes gambotensis</i> <i>Thamnodynastes sp</i>
<i>Xenodon rabdocephalus</i>	Crypticity	<p><i>Xenodon rabdocephalus</i> has an enormous geographic distribution, ranging from southern Mexico through Central America and northern South America, encompassing lowlands of Colombia, Venezuela, Guyana, Suriname, French Guiana, and western Ecuador and Peru (Uetz et al. 2020). Its broad distribution includes an unknown number of cryptic species, as well as junior synonymies which over the time have been dropped and resurrected several times. Myers and McDowell (2014) brought light proposing several nomenclatural actions involving species of <i>Xenodon</i>, particularly for Colombian populations. According to these authors, most of the diagnostic characters are coined into hemipenial morphology because generally the scutellation is essentially identical, and the color pattern between the species of <i>Xenodon</i> present in Colombia is highly variable. A junior synonym almost certainly outside the range of <i>Xenodon rabdocephalus</i>, (<i>sensu stricto</i>) is <i>X. angustirostris</i>. According with Myers and McDowell (2014), all trans-Andean Colombian populations historically named as <i>Xenodon rabdocephalus</i> have replaced by the resurrected of the junior synonym <i>X. angustirostris</i>. However, these authors recommend be caution in applying the name <i>angustirostris</i> until comparative hemipenial and other data can be accrued from populations throughout western Colombia and especially Middle America. On other hand, the resurrected junior <i>Xenodon suspectus</i> could be presented into the Colombian into the cis-Andean ecoregion (J. D. Lynch pers. comm. 2020). However, there are not formally evidence published. Therefore, we retained all the Colombian populations under the name <i>X. angustirostris</i> when the specimens reported have a suitable matched with the diagnostic characters described by Myers and McDowell (2014), otherwise, we named all the specimens reported as <i>Xenodon cf angustirostris</i>.</p>	<i>Xenodon cf. angustirostris</i> <i>Xenodon angustirostris</i>

Table SIII. Alimentary items recorded in the Facebook posts.

Species	Alimentary items recorded
<i>Boa constrictor</i>	Pigua (<i>Milvago chimachima</i>) Chicken (<i>Gallus gallus</i>) Cat (<i>Felis catus</i>)
<i>Chironius spixii</i>	Frog (<i>Leptodactylus</i> sp)
<i>Clelia clelia</i>	Mapaná (<i>Bothrops asper</i>)
<i>Dipsas gracilis</i>	Snail
<i>Drymarchon melanurus</i>	Toad (<i>Rhinella horribilis</i>) Musurana (<i>Clelia Clelia</i>)
<i>Erythrolamprus bizona</i>	Hunter snake (<i>Mastigodryas danieli</i>) Coral (<i>Micrurus dumerilii</i>) Bat (<i>Myotis</i> sp)
<i>Erythrolamprus mimus</i>	Coffee snake (<i>Ninia atrata</i>)
<i>Erythrolamprus pseudocorallus</i>	Ground snake (<i>Atractus</i> sp)
<i>Leptodeira annulata</i>	Toad (<i>Rhinella humboldti</i>) Frog (<i>Scinax</i> sp)
<i>Leptophis ahaetulla</i>	Toad (<i>Rhinella humboldti</i>)
<i>Lygophis lineatus</i>	Toad (<i>Rhinella humboldti</i>)
<i>Mastigodryas danieli</i>	Gekko (<i>Hemidactylus</i> sp.)
<i>Micrurus mipartitus</i>	Ground snake (<i>Atractus</i> sp.)
<i>Oxyrhopus petolarius</i>	Lobo (<i>Ameiva</i> sp.)
<i>Phrynonax polylepis</i>	Bird (Passeriformes)
<i>Pseudoboa neuwiedii</i>	Lobito (<i>Cnemidophorus</i> sp)
<i>Spilotes pullatus</i>	Bat (<i>Carollia</i> sp)

Table SIV. Snakebite accident reported by Facebook users.

Species	Patient	Department	Municipality	Fatality	Did patient receive medical assistance?
<i>Bothrops asper</i>	Person	Santander	San Vicente de Chucurí	No	Yes
	Person	Antioquia	Yarumal	No	Yes
	Person	Antioquia	Anorí	Yes	Yes
	Dog	Bolívar	Turbaco	Yes	No
<i>Bothrops sp.</i>	Person	Cundinamarca	Gachalá	No	No
<i>Epicrates maurus</i>	Person	Antioquia	Urabá, zona bananera	No	No
<i>Helicops angulatus</i>	Person	Putumayo	Orito	No	No
<i>Lachesis achrocorda</i>	Horse	Valle del Cauca	Dagua	No	Yes
<i>Micrurus dumerilii</i>	Person	Santander	Florida Blanca	No	Yes
<i>Micrurus hemprichii</i>	Person	Casanare	Yopal	No	Yes
<i>Ninia atrata</i>	Person	Antioquia	San Carlos	No	No
<i>Porthidium lansbergii</i>	Person	Antioquia	Anorí	No	Yes
<i>Thamnodynastes gambotensis</i>	Person	Sucre	Corozal	No	No

Table SV. Distribution extensions derived from Facebook posts of Colombian snake species reported in the Global Biodiversity Information Facility (GBIF). Records that fall outside the 50-km buffer around available GBIF records.
