16 **S1) Miller Range 13004 albitic glass**

17 Within one of our aliquots of Miller Range (MIL) 13004, we analyzed albitic glass which  
18 was commonly associated with fractures and voids and is present as a minor to trace phase. Prior  
19 work has identified albitic glasses in aubrites, including MIL 13004 (Wilbur et al., 2022), which  
20 is commonly interpreted as a product of partial melting on the aubrite parent body. We find  
21 higher SiO<sub>2</sub> (74 wt.% vs. 67.8 wt.%) and Al<sub>2</sub>O<sub>3</sub> (21 wt.% vs. 17.9 wt.%) contents and much

22 lower Na<sub>2</sub>O (3.9 wt.% vs. 10.97 wt.%) contents in albitic glass from our aliquot of MIL 13004  
23 albitic glass (Table 4) than the values reported by Wilbur et al. (2022). We suggest this  
24 discrepancy in major element compositions likely reflects heterogeneity in glass compositions  
25 between sample aliquots as our measured values resemble the L871 glass of Fogel (2005), but a  
26 systematic study on several aliquots is needed to validate this hypothesis. Overall, albitic melts in  
27 aubrites have been suggested to be the product of high degrees of partial melting ( $\leq 50\%$ ) and  
28 late-stage melts (Fogel, 2005; Keil et al., 2011). The H<sub>2</sub>O contents ( $\sim 0.6 - 3.3 \mu\text{g/g}$ ) of the MIL  
29 13004 albitic glass are below the LOD (see Section 4.2) and have highly variable F ( $\sim 95 - 190$   
30  $\mu\text{g/g}$ ) and Cl contents ( $560 - 640 \mu\text{g/g}$ ) that are consistent across the 01/22 and 02/22 analytical  
31 sessions (Table S3, analyses 483 – 491; Table S5, analysis 1034). The F contents of the albitic  
32 glass are about 1 to 2 orders of magnitude higher than all other analyzed phases and the Cl  
33 contents are several orders of magnitude higher (Table 5). The origin of these high halogen  
34 contents is unclear, but it may be the result of interaction with a halogen rich-fluid on the aubrite  
35 parent body, partial dissolution of halogen rich sulfides such as djerfisherite, or terrestrial  
36 weathering and alteration (e.g., Krähenbühl et al., 1998; Velbel, 2014). If we are to consider  
37 equilibrium with respect to H<sub>2</sub>O between the albitic glass ( $\sim 0.6 - 3.3 \mu\text{g/g H}_2\text{O}$ ) and enstatite  
38 ( $5 \pm 2 \mu\text{g/g H}_2\text{O}$ ; 1 SD) in MIL 13004, then we have a minimum apparent mineral-melt H<sub>2</sub>O  
39 partition coefficient ( $D = \frac{[\text{H}_2\text{O}]_{\text{mineral}}}{[\text{H}_2\text{O}]_{\text{melt}}}$ ) of  $\sim 0.9$ , which is orders of magnitude higher than  
40 experimentally determined mineral-melt partition coefficients for enstatite (Grant et al., 2006)  
41 and orthopyroxene (e.g., Aubaud et al., 2004; Grant et al., 2007; Hauri et al., 2006). This either  
42 reflects disequilibrium between the minerals and the melt for H<sub>2</sub>O or previously uncharacterized  
43 partitioning behavior for H<sub>2</sub>O at low total H<sub>2</sub>O contents or pressure, as has been suggested for  
44 natural and experimental samples (Peterson et al., 2023; Sarafian et al., 2019). More

45 experimental work is required to evaluate these possibilities. Nevertheless, we elect to exclude  
46 these values for the albitic glass as they may represent disequilibrium, could have low H<sub>2</sub>O  
47 contents as the result of production as a high-degree or late-stage partial melt, and the estimates  
48 for glass H<sub>2</sub>O contents based upon experimentally derived partition coefficients give a higher  
49 estimate (~1500 μg/g H<sub>2</sub>O vs. < ~3.3 μg/g H<sub>2</sub>O). Notably, if we were to use the measured value  
50 of MIL 13004 albitic glass in our estimates for the bulk H<sub>2</sub>O contents of aubrites, our bulk  
51 estimates would be lowered in glass-bearing cases (see Sections 5.1.3 and 5.2), thereby not  
52 affecting our conclusions.

## 53 **S2) Potential, non-NAM, carriers of H in aubrites**

54 We analyzed H<sub>2</sub>O in enstatite, forsterite, diopside, and plagioclase in aubrites. NAMs  
55 constitute >~99 vol. % of aubrites on average; however, it is possible that other minor or trace  
56 phases (e.g., glass, sulfides, or metal) could concentrate water and represent major contributions  
57 to aubrite water budgets despite their low abundances. We consider this possibility in the  
58 following section.

### 59 *S2.1 Other silicate minerals*

60 On average, aubrites are ~75 – 98 vol. % enstatite (Keil, 2010) and lack primary hydrous  
61 phases. Rare instances of secondary fluor-amphibole (Bevan et al., 1977; Graham et al., 1977)  
62 and roedderite (Fogel, 2002; Hsu, 1998), which may reflect igneous crystallization or a low  
63 temperature event, have been identified in aubrites. Notably, fluor-amphibole has only been  
64 identified in vugs in Mayo Belwa, an impact melt breccia, and is nearly end-member  
65 fluororichterite (Bevan et al., 1977; Graham et al., 1977; Rubin, 2010). Considering that vugs in  
66 Mayo Belwa are modestly abundant (< 5 vol. %), not all vugs contain fluor-amphibole, vugs

67 commonly contain several phases (Rubin, 2010), the fluor-amphibole is nearly end-member  
68 fluorrichterite, indicating the W position in the structure is composed almost entirely of F  
69 instead of OH, and fluor-amphibole has only been identified as a secondary phase in Mayo  
70 Belwa, it likely constitutes a negligible contribution to the bulk H<sub>2</sub>O content of average aubritic  
71 materials. Due to the rarity and potentially secondary origin of amphibole in Mayo Belwa, we  
72 suggest it is likely not reflective of the H<sub>2</sub>O content of average aubritic material. Despite being  
73 an end-member in the H<sub>2</sub>O-bearing Milarite-type mineral group (Gagné and Hawthorne, 2016;  
74 Seifert and Schreyer, 1969), we do not consider roedderite (end-member empirical formula:  
75 Na<sub>1.5</sub>K<sub>0.5</sub>Mg<sub>3.75</sub>Fe<sup>2+</sup><sub>1.25</sub>Si<sub>12</sub>O<sub>30</sub>) as a major carrier of H<sub>2</sub>O as: 1) there is no clear indication of H<sub>2</sub>O  
76 in the roedderite structure (Forbes et al., 1972); and 2) the H<sub>2</sub>O contents of Milarite-type  
77 minerals are poorly constrained and many species are anhydrous (Gagné and Hawthorne, 2016).  
78 Therefore, any primary H<sub>2</sub>O (or other H-bearing species) in aubrites is likely to be hosted in  
79 NAMs, silicate glass, sulfides, and FeNi metal. For phases not analyzed in this study, we provide  
80 a first order estimate of their H<sub>2</sub>O contents based upon our measured H<sub>2</sub>O concentrations and  
81 experimentally determined partition coefficients.

## 82 *S2.2 Silicate glass*

83 We can provide a first order estimate of the H<sub>2</sub>O content of unmeasured phases by  
84 assuming all unmeasured phases are in equilibrium with enstatite and that partition coefficients  
85 determined under terrestrial conditions are applicable to aubrite parent bodies (see Section S3).  
86 We select enstatite as our reference mineral instead of forsterite or feldspar as our phase average  
87 for enstatite is based upon 86 analyses across all seven aubrites investigated compared to 4  
88 analyses for feldspar, and 3 analyses for forsterite. Using our measured enstatite H<sub>2</sub>O contents  
89 and published partition coefficients (Dobson et al., 1995), we estimate that silicate glass in

90 equilibrium with enstatite would contain ~1500  $\mu\text{g/g H}_2\text{O}$ . If we instead use Shallowater  
91 plagioclase (24  $\mu\text{g/g H}_2\text{O}$ ) as our reference phase, then we estimate that silicate glass would  
92 contain ~628  $\mu\text{g/g H}_2\text{O}$  (Lin et al., 2019). We note, that with the exception of a feldspathic clast  
93 in LAR 04316, silicate glass is absent or a trace phase in aubrites (Keil, 2010), thereby limiting  
94 the contribution of silicate glass to the  $\text{H}_2\text{O}$  budget of aubrites.

### 95 *S2.3 Metals and sulfides*

96 Previous studies have experimentally constrained the partitioning of H between metal and  
97 silicate and suggest that H is incompatible in Fe metal at low pressures (Clesi et al., 2018;  
98 Gaillard et al., 2022; Li et al., 2015; Malavergne et al., 2019; Okuchi, 1997; Tagawa et al.,  
99 2021). We are unaware of any studies that experimentally constrain sulfide – silicate H  
100 partitioning. Therefore, we assume that metal and sulfides have similar  $\text{H}_2\text{O}$  partition  
101 coefficients. By combining our measured enstatite, forsterite, diopside, and feldspar  $\text{H}_2\text{O}$   
102 contents, calculated glass  $\text{H}_2\text{O}$  contents (Table 6), and the modal mineralogy of our samples  
103 (Table 2), we estimate that the silicate portions of our analyzed main group aubrites all contain <  
104 ~5  $\mu\text{g/g H}_2\text{O}$  (Supplementary File “Aubs\_calcs.xlsx”). We take a metal – silicate H partition  
105 coefficient of 0.22 (Gaillard et al., 2022) and our calculated silicate  $\text{H}_2\text{O}$  contents (~5  $\mu\text{g/g H}_2\text{O}$ ),  
106 which yield metal and sulfide  $\text{H}_2\text{O}$  (quantified from total H) concentrations of ~1  $\mu\text{g/g}$ . Metal  
107 and sulfides in aubrites are minor to trace phases (Keil, 2010), and the low estimated  $\text{H}_2\text{O}$   
108 content (~1  $\mu\text{g/g H}_2\text{O}$ ) suggests metal and sulfide in aubrites are unlikely to be an abundant  
109 source of  $\text{H}_2\text{O}$  in aubrites. Overall, we suggest trace silicate material (Section S2.1), silicate glass  
110 (Section S2.2), and metals and sulfides are either too low in abundance or too  $\text{H}_2\text{O}$  poor to serve  
111 as major reservoirs of  $\text{H}_2\text{O}$  in aubrites.

112 **S3) Do our  $\text{H}_2\text{O}$  analyses reflect equilibrium or disequilibrium in aubrite NAMs?**

113           Despite experimentally determined partition coefficients permitting equilibrium between  
114 the phases measured in this study (Section 5.1.3), it is possible that the measured H<sub>2</sub>O  
115 concentrations in NAMs have been disturbed by disequilibrium processes such as H-loss due to  
116 thermal metamorphism or shock heating or H-enrichment due to hydrothermal alteration. To a  
117 first order, if disequilibrium processes affected our grains, we would expect to observe gradients  
118 in H<sub>2</sub>O concentrations across grains, however, for samples where transects could be measured  
119 (i.e., MIL 13004, Norton County, Shallowater), no H<sub>2</sub>O gradients are observed (Fig. S12 – S16).  
120 Aubrite enstatite H<sub>2</sub>O contents exhibit a weak correlation with degree of shock (Fig. 2B), which  
121 may suggest that aubrite H<sub>2</sub>O contents could have been modified by secondary processes.  
122 Notably, any thermal process (e.g., shock heating, thermal metamorphism) would be expected to  
123 reduce the H<sub>2</sub>O content of aubrite silicates, resulting in normal zonation, which is not observed.  
124 Therefore, we suggest that H-loss processes such as thermal metamorphism or shock heating are  
125 unlikely to have caused major modifications to the measured H<sub>2</sub>O contents of our NAMs. It is  
126 also possible that aubrite silicates may have undergone H-enrichment during hydrothermal  
127 events. However, hydrous phases are rare in aubrites and are of an unclear origin (see Section  
128 5.3.1; Keil, 2010), arguing against any widespread hydrothermal events on aubrite parent bodies.  
129 Overall, we suggest that the effect of secondary processes on the measured H<sub>2</sub>O concentrations is  
130 likely minimal. Furthermore, regardless of whether or not our analyses reflect equilibrium, our  
131 analyses represent the most accurate determination of aubrite silicate H<sub>2</sub>O contents, allowing for  
132 more precise evaluations of bulk Aubrite H<sub>2</sub>O contents and the potential for H-delivery to the  
133 Earth by aubrite-like material.

280

281 **Fig. S9)** Reflected light mosaic of 1 inch indium mount containing aubrite samples analyzed as  
282 part of this study. Unlabelled samples were not analyzed as part of this study. Scale bars are 2.5  
283 mm.

284

285

286 **Fig. S10)** Reflected light image of 10 mm indium mount holding additional chips of LAR 04316  
287 and ALH 84007. Subsamples are denoted with “\_A” and “\_B”. The scale bar is 2.5 mm.

288

289

290

291 **Fig. S11)** Reflected light image of 1 inch indium mount holding Norton County and Shallowater.

292 The three small holes held the secondary standards Suprasil 3002, Herasil, and ALV-519-4-1

293 glass. The large hole held a sample that was not used in this study.

294

295

296

297 **Fig. S12)** NanoSIMS transects analyzed for H<sub>2</sub>O from grain MIL 13004L-4. A) H<sub>2</sub>O  
298 concentrations plotted against the relative position of SIMS pits as shown in B). Plotted  
299 uncertainties are the propagated uncertainty (Table S3). B) Reflected light image of MIL  
300 13004L-4 showing SIMS pits from A) highlighted in orange and labelled. Note, SIMS pits are  
301 15×15 µm. The image has a blue tint due to the light used on the microscope and polarizers.  
302 Unmarked SIMS pits are associated with other grains or were removed by the data filtering  
303 protocol (Section 3.3).

304

305

306 **Fig. S13)** NanoSIMS transects analyzed for H<sub>2</sub>O from grain MIL 13004U-1. A) H<sub>2</sub>O  
 307 concentrations plotted against the relative position of SIMS pits as shown in B). Overlapping  
 308 points were measured at the same approximate distance from the edge of the grain and represent  
 309 “duplicate” analyses. Plotted uncertainties are the propagated uncertainty (Table S3). B)  
 310 Reflected light image of MIL 13004U-1 showing SIMS pits from A) highlighted in orange and  
 311 labelled. Note, SIMS pits are 15×15 µm. The image has a blue tint due to the light used on the  
 312 microscope and polarizers.

313

314

315

316 **Fig. S14)** NanoSIMS transects analyzed for H<sub>2</sub>O from grain MIL 13004U-2. A) H<sub>2</sub>O  
 317 concentrations plotted against the relative position of SIMS pits as shown in B). Plotted  
 318 uncertainties are the propagated uncertainty (Table S3). B) Reflected light image of MIL  
 319 13004U-2 showing SIMS pits from A) highlighted in orange and labelled. Note, SIMS pits are  
 320 15×15 µm. The image has a blue tint due to the light used on the microscope and polarizers.  
 321 Unmarked SIMS pits are associated with other grains or were removed by the data filtering  
 322 protocol (Section 3.3).

323

324

325

326 **Fig. S15)** NanoSIMS transects analyzed for H<sub>2</sub>O from grain Shallowater-pyx1. A) H<sub>2</sub>O  
 327 concentrations plotted against the relative position of SIMS pits as shown in B). Overlapping  
 328 points were measured at the same approximate distance from the edge of the grain and represent  
 329 “duplicate” analyses. Plotted uncertainties are the propagated uncertainty (Table S7). B)  
 330 Reflected light image of Shallowater-pyx1 showing SIMS pits from A) highlighted in red and  
 331 labelled. Note, SIMS pits are 15×15 µm. The image has a blue tint due to the light used on the  
 332 microscope and polarizers. Unmarked SIMS pits are associated with other grains or were  
 333 removed by the data filtering protocol (Section 3.3).

334

335

336 **Fig. S16)** NanoSIMS transects analyzed for H<sub>2</sub>O from grain Shallowater-pyx4. A) H<sub>2</sub>O  
337 concentrations plotted against the relative position of SIMS pits as shown in B). Overlapping  
338 points were measured at the same approximate distance from the edge of the grain and represent  
339 “duplicate” analyses. Plotted uncertainties are the propagated uncertainty (Table S7). B)  
340 Reflected light image of Shallowater-pyx4 showing SIMS pits from A) highlighted in red and  
341 labelled. Note, SIMS pits are 15×15 µm. The image has a blue tint due to the light used on the  
342 microscope and polarizers.
