Abstract. During a taxonomic study of the species of *Croton* sect. *Adenophylli* occurring in Brazil, approximately 140 collections usually identified as *Croton echiooides*, *C. rhamnifolius* or *C. rhamnifoliooides* caught our attention due to the distinct morphology of vegetative and reproductive organs. After the analysis of these collections, we concluded that they represent a new species, *C. sertanejus* Sodré & M.J.Silva sp. nov., which was also corroborated by an anatomical study of their leaves. This new species can be differentiated by pseudomonopodial branching, leaves with petioles up to 1.7 cm long, 4–6 subsessile nectary glands and indumentum of sessile trichomes on both surfaces. Detailed descriptions, including details of leaf anatomy, are provided for *C. sertanejus* sp. nov. and *C. echiooides*, its closely related species. We also formalize the synonymization of *C. kalkmannii* under *C. echiooides* and re-evaluate the typification of these names, in order to better clarify their taxonomic status.

Keywords. Crotoneae, diversity, endemism, flora, taxonomy.

Introduction

Croton L. is a monophyletic genus and includes about 1300 tropical species, of which 300 occur in Brazil (van Ee *et al.* 2011; Caruzo *et al.* 2020). It is recognized worldwide specially by having stellate or lepidote trichomes on the vegetative and reproductive parts, leaves usually entire with nectary glands at the apex of the petiole or base of the leaf blade, inflexed stamens in bud, flowers in thyrses, the pistillate flowers commonly in basal cymules and monochlamydeous, or if dichlamydeous then with reduced petals, and dichlamydeous staminate flowers in the distal cymules (Webster 1993; Berry *et al.* 2005; van Ee *et al.* 2011). This genus, although well delimited morphologically and phylogenetically, has several species with difficult taxonomy or with circumscription problems (Lima & Pirani 2003; Sodré & Silva 2020).

In Brazil, species of *Croton* occur in several habitats, although they are mostly represented in dry areas, such as the Caatinga Seasonally Dry Tropical Forest (SDTF), from where about 70 ‘marmeleiros’ or

‘velames’ (vernacular names for *Croton*) are reported (Carneiro-Torres 2009; Caruzo *et al.* 2020). During a taxonomic study of *Croton* sect. *Adenophylli* Griseb. occurring in Brazil, hundreds of collections from Caatinga identified as *C. echoioides* Baill., *C. rhamnifolius* Kunth. or *C. rhamnifolioides* Pax & K.Hoffm. caught our attention because they were very variable in terms of the pattern of the branches and the shape, number and position of leaf nectary glands. The analysis of these collections, including types of all aforementioned species, indicated the discovery of a new species. Here, we describe and illustrate this new species, which we name *Croton sertanejus* sp. nov., and also provide updated descriptions, illustrations and comments for *Croton echoioides*. In addition to macromorphological characters, which are very similar between these two related species, we added leaf anatomical characters, which have been shown to be useful in separating species in the genus (Soares 2013; Barbosa *et al.* 2018; Feio *et al.* 2018; Sodré *et al.* 2019b, 2022; Sodré & Silva 2020; Rosa *et al.* 2021).

Material and methods

Croton echoioides and *C. sertanejus* sp. nov. are described based on an analysis of 90 physical specimens and 145 herbarium scans, including types, deposited in 38 Brazilian herbaria (ALCB, ASE, BHCB, BOTU, CEN, CEPEC, CSTR, EAC, ESA, HST, HRCB, HUFU, HUEFS, HUEM, HUESB, HUNEB, HURB, HVASF, HTSA, INPA, IPA, JPB, MAC, MBM, MG, PEUFR, RB, RON, SP, SPF, TEPB, UB, UEC, UESC, UFG, UFP, UFRN and VIES), and 14 foreign herbaria (A, BR, C, CTES, G, K, L, MEL, MO, NY, P, U, US and W). Acronyms of herbaria follow Index Herbariorum (Thiers continuously updated), except for the following repositories:

CSTR = Herbarium Rita Baltazar de Lima, Federal University of Campina Grande, Paraíba, Brazil
HTSA = Herbarium Tropical Semi-arid, Embrapa Tropical Semi-arid, Petrolina, Pernambuco, Brazil
HST = Herbarium Sergio Tavares, Department of Forest Science, Federal Rural University of Pernambuco, Pernambuco, Brazil

When physical specimens were not available, their digital images were obtained from GBIF (<https://www.gbif.org/>), Reflora (<http://reflora.jbrj.gov.br/reflora/herbarioVirtual/>), Specieslink (<http://www.splink.org.br/>) or Jstor Global Plants (<https://plants.jstor.org/>). All localities are given verbatim from the specimen labels. All measurements and morphological comparison between *C. sertanejus* sp. nov. and related species are based on an examination of the mentioned specimens. The terminologies used follow the specialized literature of the genus (e.g., Webster *et al.* 1996; Kainulainen *et al.* 2017; Sodré *et al.* 2019a), as well as the works of Radford *et al.* (1974) and Harris & Harris (2001), with the exception of the term pseudomonopodial, used to refer to a growth pattern with an elongated main stem with usually shortened secondary branches that gives the plant a monopodial growth aspect. Information about the types of vegetation, soil, altitude where the species was found, and their vernacular names were taken from the labels of the specimens, while the flowering and fruiting was inferred from the presence of flowers and/or fruits in fertile materials and observation of the month in which they were collected.

The geographical distribution map was created using the software QGIS Geographic Information System (ver. 3.12; QGIS.org) with the coordinates from the labels of the exsiccatae listed here; for those without georeferencing data, we used the coordinates of the municipality where the specimen was collected. This same geographic coordinate dataset of the species was used to estimate the extent of occurrence (EOO) and area of occupancy (AOO) with the Geospatial Conservation Assessment Tool (GeoCAT; Bachman *et al.* 2011) using a cell width of 8 km. The conservation status of the species was then evaluated according to IUCN (2017). A digital line drawing was made in a drawing table and then processed in image processing applications.

For the anatomical study, three samples of each species were fixed in FAA (formaldehyde, acetic acid, and 50% ethanol; 1:1:18, v/v) for 48 h, and later stored in 70% ethanol (Johansen 1940). Freehand sections were made from the median part of the petiole and the leaves. Sections were bleached with a 20% sodium

hypochlorite solution, washed in distilled water, stained with aqueous solutions of 1% Astra Blue and 1% Safranin (Bukatsch 1972), and mounted on slides in glycerin:distilled water (1:1 v/v) solution. The sections were examined under an optical light microscope attached to a microscope camera. Description of the leaf anatomy follows usual terminology in anatomical studies (Metcalfe & Chalk 1979, 1983; Evert 2006) and terminology consulted in previous studies of the genus (Feio *et al.* 2018; Sodré *et al.* 2019b; Sodré & Silva 2020).

Results

Taxonomy

Class Magnoliopsida Brongn.
Order Malpighiales Mart.
Family Euphorbiaceae Juss.
Genus *Croton* L.

Croton sertanejus Sodré & M.J.Silva sp. nov.

urn:lsid:ipni.org:names:77305496-1

Figs 1–2

Diagnosis

Croton sertanejus sp. nov. differs from *C. echiodoides* due to pseudomonopodial branching, with an elongated main stem with shortened secondary branches in an alternate arrangement (vs di- or trichotomous branching in *C. echiodoides*), petiole 0.4–1.7(–2) cm long (vs (1.8–)3–8.1 cm), leaf blade base with 4–6 subsessile nectary glands facing both surfaces (vs with 2 stipitate nectary glands facing the abaxial surface), equal pistillate sepals (vs subequal or strongly unequal), and styles 2–3 mm long (vs 4–5.5 mm).

Etymology

‘*Sertanejo*’, in Portuguese, refers to people native to the Caatinga region, also known as ‘*sertão*’, that extends to all the states of northeast Brazil and the northern Minas Gerais.

Description

Shrubs or trees, (1)–1.5–5(–7) m tall, erect, pseudomonopodial branching, with main stem extended bearing lateral alternate branches, frequently with galls; latex scarce, clear; sweetish odor; stems very rigid, cylindric, straight or tortuous, striated or smooth in young branches; whitish, yellowish, or slightly

ferrugineous tomentose indumentum of multiradiate or stellate-porrect trichomes with stipe 0.05–0.1 mm long, stellate-porrect trichomes with one-plane whorl of 8–12 free lateral rays and multiradiate trichomes with two or three whorls of 16–30 free lateral rays, in both trichomes lateral rays 0.15–0.7 mm long and central ray 0.15–0.25(–0.7) mm long. Leaves alternate, leaf blades (3–)4–8 times as long as petioles; stipules 0.5–0.8 × 0.15–0.3 mm, triangular, lanceolate or linear, with 4 sessile ovoid glands at base and/or one subglobose gland at apex, with stellate-porrect trichomes on both surfaces; petioles 0.4–1.7(–2) cm long; leaf blades 2.2–8.9 × 1.2–4.7 cm, oval-elliptic, elliptic, ovate or oval-lanceolate, sometimes lanceolate or narrowly elliptic, membranaceous, base obtuse or rounded, sometimes slightly cordate or truncate with 4–6 patelliform nectary glands 0.2–0.7 mm diam., subsessile with stipe 0.1–0.2 mm long, at least two facing adaxial surface and other two facing abaxial surface; apex acute, obtuse, mucronate or apiculate, sometimes slightly emarginate or acuminate; margin entire or less commonly serrulate with globose sessile glands (colleters); venation brochidodromous with 4–8 pairs of secondary veins impressed on adaxial surface and slightly prominent on abaxial surface; discolorous, adaxial surface dark green with hirtellous indumentum of simple, 2–4-radiate or stellate-porrect trichomes, stellate-porrect trichomes with 6–11 lateral rays, sessile, lateral rays 0.2–0.5 mm long, porrect ray up to 1 mm long; abaxial surface light green with shortly tomentose indumentum of stellate-porrect trichomes with 6–8 lateral rays or multiradiate trichomes with 11–16 lateral rays, both sessile, lateral rays 0.2–0.7 mm long, central ray 0.2–0.8 mm long. Thyrases 2.8–16 cm long, peduncle 0.4–2.5 cm long, terminal, bisexual with 4–10 solitary pistillate flowers sparsely, rarely densely, distributed on $\frac{1}{4}$ – $\frac{1}{2}$ of inflorescence axis, or thyrases unisexual staminate, less commonly unisexual pistillate; staminate cymules with 2–4 flowers, staminate flower bracts 0.4–1 × 0.4–0.7 mm, triangular, oval or oblong, margin entire, with 2 or 3 subglobose sessile glands at base, indumentum of stellate-porrect trichomes on external surface and hirsute indumentum of simple trichomes on margin, glabrous internally; 2 staminate flower bracteoles per cymule, 0.3–0.7 × 0.15–0.3 mm, triangular or ovate, with glands and indumentum similar to those of bracts; pistillate flower bracts 0.5–1(–2.2) × 0.3–0.8(–1) mm, triangular, margin entire, with ovoid or subglobose sessile glands, with sessile stellate-porrect trichomes externally, glabrous or glabrescent internally; 2 bracteoles per pistillate flower, 0.3–0.8 × 0.1–0.4 mm, linear or triangular, with subglobose glands at base. Staminate flowers 5–8 mm long; pedicels 1.6–4.7 mm long, glabrous, glabrescent, pubescent or tomentose; calyces 5(6)-partite, greenish with whitish indumentum, lobes 1.4–2 × 0.9–1.3 mm, ovate or largely ovate, united in $\frac{1}{6}$ – $\frac{1}{4}$ of length, apex obtuse or acute, dorsal surface with shortly tomentose indumentum of

Ecoregions classified according to Dinerstein *et al.* (2017) (available at <https://ecoregions2017.appspot.com>). Abbreviations for Brazilian States: AL = Alagoas; BA = Bahia; CE = Ceará; ES = Espírito Santo; DF = Federal District; GO = Goiás; MA = Maranhão; MG = Minas Gerais; PB = Paraíba; PE = Pernambuco; PI = Piauí; RJ = Rio de Janeiro; RN = Rio Grande do Norte; SE = Sergipe; SP = São Paulo; TO = Tocantins.

stellate-porrect sessile trichomes, villous at the apex, glabrous ventrally; petals 5(6), 2–2.9 × 0.6–1.2 mm, obovate or oblanceolate, apex rounded or obtuse, villous basally along margins at $\frac{1}{3}$ – $\frac{1}{2}$ of length; stamens 15–25(–27), 2.5–3.5 mm long, filaments 2–3 mm long, glabrous or villous only basally, anthers 0.5–0.7 × 0.4–0.7 mm, suborbicular or largely ellipsoid; nectary disks 5-segmented, segments transversely oblong, whitish, receptacle villous. Pistillate flowers 3.5–5.3 mm long, pedicels 0.8–1.5 mm long; sepals 5, 1–1.7 × 0.6–0.8 mm, equal, ovate or triangular, apex acute, margin entire, without glands, externally with pubescent or tomentose indumentum of stellate-porrect or multiradiate sessile trichomes, internally sparsely pubescent or glabrescent; petals globose 0.1–0.2 mm diam. or laminar 0.5–1.3 × 0.05–0.4 mm, linear or triangular, glabrous or with stellate trichomes externally; ovaries 1.2–1.4 × 1.3–1.8 mm, subglobose, with whitish tomentose indumentum of stellate-porrect shortly stipitate trichomes; styles 3, 2–3 mm long, united in $\frac{1}{6}$ – $\frac{1}{3}$ of length, then branching into 6 terminal tips, externally with glabrescent or pubescent indumentum of stellate trichomes basally; nectary disks 5-segmented or 5-lobed, segments or lobes transversely oblong, whitish. Capsules 5.7–6 mm diam., globose, greenish, pedicel 1.2–2.5(–4) mm long, columella with three flattened or slightly ascending tips; seeds 4.8–4.9 × 3–3.1 mm, ellipsoid, brownish, with smooth surface, slightly foveolate, caruncle hat-shaped, 1.8–2.2 mm large, whitish.

Distribution, habitat and phenology

Croton sertanejus sp. nov. is endemic to the Caatinga, a Brazilian Seasonally Dry Tropical Forest, with records for the states of Bahia, Ceará, Minas Gerais, Paraíba, Pernambuco, Piauí and Sergipe (Fig. 3). It grows amid the shrubby or arboreal physiognomies of scrub/forest vegetation, close or not to water courses, sometimes associated with rocky outcrops and on sandy or clay soils, between 160 and 930 m of elevation. This species was found with flowers from December to April and fruits from January to May.

Vernacular names

The new species is popularly known as ‘Caatinga-branca’ (Pernambuco), ‘Cassatinga’ (Bahia), ‘Cassutinga’ (Bahia), ‘Marmeiro’ (Bahia), ‘Marmeiro-de-folha-miúda’ (Paraíba), ‘Marmeiro-preto’ (Piauí), ‘Quebra-faca’ (Bahia, Ceará, Pernambuco, Piauí) or ‘Quebra-facão’ (Bahia, Pernambuco, Piauí).

Preliminary conservation status

This species has an Extent of Occurrence estimated to be 494 273 km² and Area of Occupancy of 5696 km² and is known from more than 100 different locations in seven states, many of them recently collected. Therefore, its conservation status was provisionally assessed as Least Concern. Despite this, the frequent use of its wood for firewood or fences and its leaves and bark in popular medicine or as food for goats may affect the conservation of their natural populations in the near future.

Description

Subshrubs or shrubs, 0.6–2(–3) m tall, erect, usually few-branched with tender, cylindric, straight, smooth (not striate) branches ramifying in di- or trichotomies, sometimes with galls throughout plant; latex abundant, orange or reddish; odoriferous (but not sweetish); whitish or ferruginous indumentum of stellate-rotate, stellate-lepidote or stellate-porrect trichomes, all with (5–)8–18 lateral rays in single-plane whorl, each ray 0.2–0.6 mm long, free or united up to 10–30% of their length, central ray 0.1–0.3(–0.5) mm long, stipe 0.1–0.2 mm long. Leaves alternate, or sometimes subopposite or subwhorled near the inflorescences, leaf blades as long as petioles or up to 3 times as long as petioles; stipules 1–3.5 × 0.45–0.6 mm, triangular or lanceolate, without conspicuous glands or with 2 very short globose glands, with hirtellous or glabrescent indumentum of simples trichomes ventrally and dense to sparse indumentum of stellate-porrect trichomes dorsally; petioles (1.8–)3–8.1 cm long; leaf blades 4.3–13.6 × 2.7–8.2 cm,

Fig. 4. *Croton echiooides* Baill. **A.** Flowering branch. **B.** Detail of the indumentum of the stems and stipule. **C₁–C₂**. Trichomes of the stems. **C₁**. Stellate-rotate trichome. **C₂**. Sodré.

ovate, elliptic, largely ovate, largely or narrowly elliptic, oblong or lanceolate, membranaceous, base slightly cordate or cordate, less commonly rounded, truncate or obtuse, with 2(3) stipitate-patelliform, cylindric or obconic nectary glands 0.3–0.7 mm diam., stipe 0.5–1.4 mm long, with stellate trichomes, facing abaxial surface; apex acute, obtuse, acuminate, mucronate or apiculate; margin entire with globose sessile glands; venation brochidodromous with 6–10 pairs of secondary veins slightly prominent on both surfaces; discolorous, adaxial surface dark green, glabrous or with sparse indumentum of simple, 2–4-radiate trichomes and sessile stellate-porrect (6–10 lateral rays) trichomes, lateral rays 0.2–0.6 mm long, porrect ray 0.2–0.8 mm long, abaxial surface light green or whitish with shortly tomentose, pubescent or glabrescent indumentum of stellate-porrect or stellate-rotate trichomes, sometimes multiradiate, all with 8–16 lateral rays usually in single-plane whorl, or two-plane whorls in multiradiate trichomes, lateral rays 0.4–1.2 mm long, central ray 0.05–0.8 mm long, stipe 0.1–0.3 mm long. Thyrses 10.4–34.6 cm long, peduncles 1.5–4.5 cm long, terminal, bisexual with 2–18 solitary pistillate flowers sparsely distributed on $\frac{1}{8}$ – $\frac{1}{2}$ of inflorescence axis and staminate cymules with 3–6 flowers, less commonly with bisexual cymules in median portion of rachis, or thyrses unisexual staminate; staminate flower bracts 0.7–1.2 × 0.4–0.7 mm, triangular or ovate, margin entire, sometimes with 2 ovoid sessile glands (colleters) at base, with pubescent, hirtellous or glabrescent indumentum of simple trichomes ventrally and hirtellous indumentum of stellate-porrect trichomes dorsally, mainly on margin, 2 or more staminate flower bracteoles per cymule 0.5–0.6 × 0.2–0.3 mm, lanceolate or triangular, with glands and indumentum similar to those of bracts; pistillate flower bracts 0.9–1.1 × 0.7–1 mm, triangular or largely ovate, margin entire, apex acute or acuminate, with two ovoid or subglobose sessile glands (colleters) at base and one at apex, with glabrescent or hirsute-tomentose indumentum of stipitate stellate-porrect or 4-radiate trichomes on both surfaces, 2 pistillate flower bracteoles 0.2–0.6 × 0.15–0.3 mm, triangular, with glands and indumentum similar to those of bracts. Staminate flowers 3.5–6.5(–8) mm long; pedicels 0.8–3(–5.7) mm long, glabrous, glabrescent, or sometimes pubescent; calyces 5-partite, yellow-orange or slightly reddish with hyaline indumentum, lobes 1.6–2.1 × 0.9–1.3 mm, ovate, united in $\frac{1}{6}$ – $\frac{1}{5}$ of length, apex obtuse, dorsal surface with densely to sparsely pubescent or hirtellous indumentum of stellate-porrect sessile trichomes, villous at apex, glabrous internally; petals 5, 1.9–3 × 0.75–0.9 mm, obovate or oboval-ob lanceolate, apex obtuse, truncate or rounded, villous basally along margins at $\frac{1}{4}$ of length and shortly villous at apex; stamens 16–19, 2.3–3.8 mm long, filaments 1.6–3 mm long, glabrous, anthers 0.6–0.8 × 0.4–0.5 mm, ellipsoid or oblongoid; nectary disks 5-segmented, segments transversely oblong or suborbicular, orange, receptacle villous. Pistillate flowers 3–5 mm long, sessile or pedicels 0.1–1(–1.2) mm long, tomentose; sepals 5(6), 1.3–3 × 0.6–1.3 mm, subequal or strongly unequal, ovate, narrowly triangular, oval-oblong or oval-lanceolate, apex acute, margin entire, without glands, dorsally with sparsely to densely pubescent or tomentose indumentum of stellate-porrect trichomes, margin with hirsute indumentum of simple trichomes and ventrally with glabrescent, pubescent or hirtellous indumentum of simple and fasciculate trichomes; petals globose ca 0.2 mm diam. or laminar 0.6–1.3 × 0.25–0.35(–0.4) mm, lanceolate, glabrous or pubescent; ovary 0.8–1.1 × 0.9–1.6 mm, with subglobose, hirtellous or tomentose indumentum of stellate-porrect shortly stipitate trichomes; styles 3, (2.8)–4–5.5 mm long, united along lower $\frac{1}{10}$ of their length, then branching into 6 terminal tips, externally with hirsute, hirtellous or pubescent indumentum of stellate-porrect or simple trichomes along less than $\frac{1}{2}$ of their length; nectary disks 5-segmented, segments transversely oblong, yellowish. Capsules 4.8–5.5 × 5.5–6 mm, compressed-globose, greenish, pedicels 0.5–1.5 mm long, columella with three flattened or slightly ascending tips; seeds 4.2–4.8 × 3.1–3.5 mm, largely ellipsoid, grayish, smooth surface, slightly foveolate, caruncle hat-shaped 1–2 mm large.

Distribution, habitat and phenology

Croton echoioides has been cited by Carneiro-Torres (2009), Silva *et al.* (2010) and Caruzo *et al.* (2020) as a species endemic to Brazil distributed in areas of Caatinga and Caatinga-Cerrado transition in the states of Alagoas, Bahia, Ceará, Minas Gerais, Paraíba, Pernambuco, Piauí and Rio Grande do Norte. We confirm occurrence of the species in the states mentioned above, except for Alagoas and Rio Grande do Norte, and provide the first record for the states of Espírito Santo and Rio de Janeiro. This species was

found in seasonal dry forest, humid forest, caatinga, in transition areas between caatinga and cerrado, ‘carrasco’ or ‘tabuleiro litorâneo’ growing preferentially on sandy soils, sometimes with outcrops of quartzite, and stony or sandy-clay soils between 30 and 1200 meters a.s.l. It was usually found with flowers from November to April, and with fruits from December to June.

Vernacular names

‘Velame’ (Ceará), ‘Velame-da-serra’ (Pernambuco), ‘Velame-branco’ (Piauí).

Preliminary conservation status

Croton echoioides has an Extent of Occurrence estimated to be 910 000 km² comprising at least 80 subpopulations and has an estimated Area of Occupancy of 4544 km² (based on an 8 km² cell size) and is therefore provisionally assessed as Least Concern. However, it is worth noting that only three of these known subpopulations occur within protected areas (Experimental Station of the IPA, Serra Talhada, Pernambuco; RPPN Serra das Almas, Cratéus, Ceará; and Morro do Chapéu State Park, Bahia), all the others are in non-protected areas, which may have implications for the conservation of the species in the future.

Leaf anatomy notes

In general, the anatomy of the leaf blades and petiole of *Croton echoioides* and *C. sertanejus* sp. nov. is relatively similar. Both species have hipostomatic leaves, with stomata on the same level as the other cells of the epidermis, which is unistratified and composed of cells of varying sizes, rectangular or rounded, and has a thin cuticle. The mesophyll in both species is dorsoventral, with a layer of palisade parenchyma and another layer of spongy parenchyma, both with druses (Fig. 6 F, H, L). The leaf margins have rounded outlines and the mesophyll and epidermis are not differentiated from the rest (Fig. 6I, M). The vascular bundles are collateral, surrounded by a conspicuous parenchyma sheath in the smaller vascular bundles and with annular (Fig. 6 E) or angular collenchyma cells adjacent to the phloem on the abaxial surface (Fig. 6J). The primary veins of both species have a convex ventral side with 5 to 6 layers of angular collenchyma cells (Fig. 6P, T). The dorsal side is rounded with 4 layers of angular collenchyma cells in subepidermal position (Fig. 6U) followed by a variable number of layers of ground parenchyma (Fig. 6N, R). The primary vein has a collateral vascular cylinder (Fig. 6O, S) with druses in the phloem. The petiole of the two species has a circular dorsal side and truncated or slightly concave ventral side in cross section. The cortex is composed of angular collenchyma and ground parenchyma. The vascular cylinder is collateral with united bundles, and there are also two accessory vascular cylinders on the ventral side (Fig. 7A, F). The pericycle is always associated with gelatinous fibers (Fig. 7C–E, I–J), which also surround the accessory vascular bundles (Fig. 7B, G). Druses are associated with phloematic parenchyma (Fig. 7D–E, I–J), as in primary veins.

Despite the similar anatomical characteristics mentioned above, which are to be expected from morphologically and geographically related species, important anatomical characteristics differentiate *C. sertanejus* sp. nov. from *C. echoioides*. Leaf trichomes are stipitate in *C. echoioides*, with stipe 50–300 µm long (Figs 6A, 7A), and the leaf blade is often glabrous on the adaxial face (Fig. 6A), whereas in *C. sertanejus* the trichomes occur on both faces and are sessile (Fig. 6B–C), or with a stipe up to 30 µm (Fig. 7F) or just with a set of cells at the base forming a cushion (Fig. 6D). The leaf blade of *C. sertanejus* also has subglobose unicellular idioblasts on the abaxial surface (Fig. 6K), which were not observed in *C. echoioides*. In the primary veins, *C. echoioides* presents the U-shaped vascular cylinder (or open arch) and the palisade parenchyma is continuous between the two faces of the leaf blade (Fig. 6N), as can also be seen in the smaller vascular bundles of the leaf blades (Fig. 6E). In *C. sertanejus*, however, the vascular cylinder of primary veins is circular (or closed arch), and the palisade parenchyma is discontinuous between the two faces of the leaf blade (Fig. 6R). In the petiole, the accessory vascular cylinders are

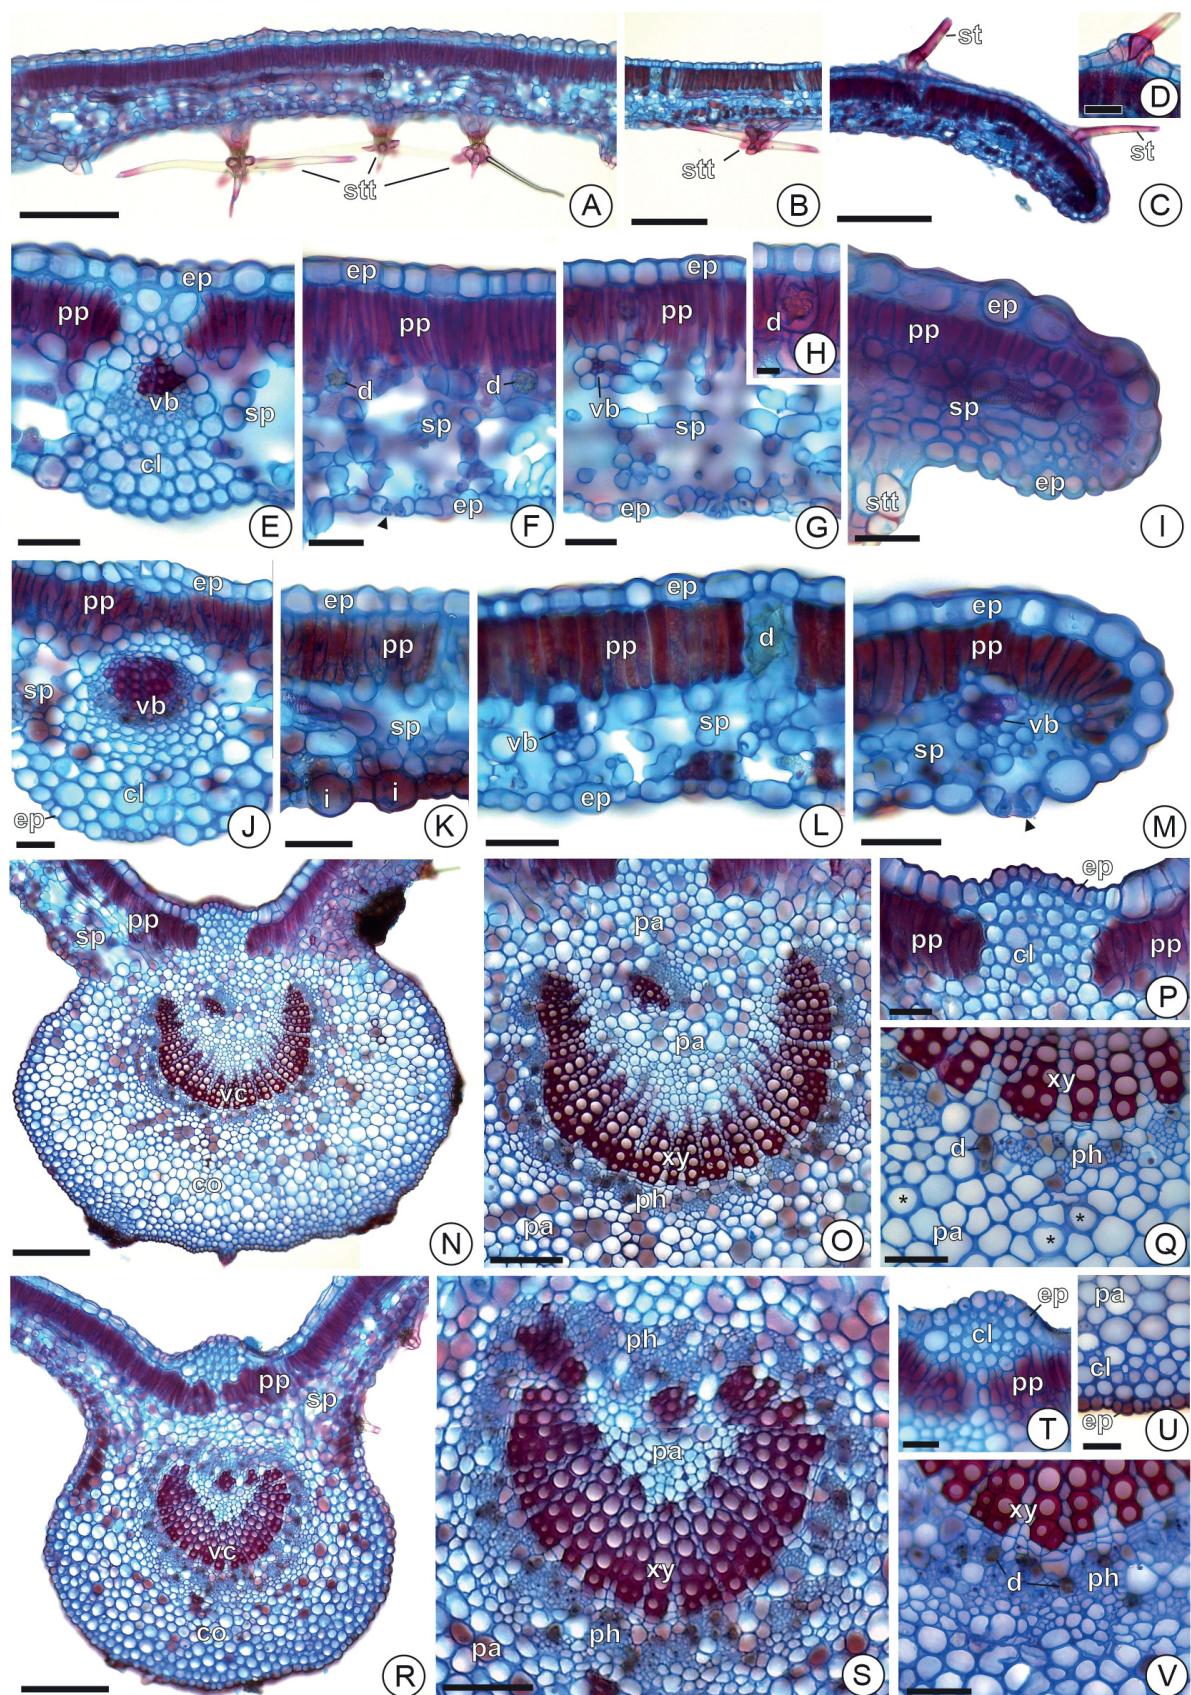

semi-lunar (open arch) and the pith has approximately 10 to 12 layers of cells in *C. echiooides*, while in *C. sertanejus* the accessory vascular cylinders are circular (closed arch) and the pith has only 4 to 6 layers. In addition, the cortex of the primary vein and petiole of *C. echiooides* have evident and numerous laticifers close to the phloem; while in *C. sertanejus* the laticifers were not observed or are not evident.

Discussion

Although *Croton sertanejus* sp. nov. is described here as a new species, it has previously been collected 129 times in seven Brazilian states. The oldest specimen was collected in 1839 in the state of Ceará by the British botanist and explorer George Gardner. This specimen is deposited on two sheets in Herbarium K and was annotated by Leon Croizat as *Croton cf. grewiaefolius*, a species from Mexico, or Croizat may have confused it with *C. grewioides* Baill. due to the similarity of the epithets. The latter species has a morphology and distribution similar to *C. sertanejus*. However, *C. sertanejus* can easily be differentiated from *C. grewioides* by its entire leaf margin without nectary glands, pistillate flowers with a short pedicel (0.8–1.5 mm long), and staminate flowers with 15–25(–27) stamens. *Croton grewioides* has serrate, crenate or serrulate leaf margins with nectary glands in the sinuses, pistillate flowers with pedicel 2–3 mm long and staminate flowers with 11(–15) stamens.

Specimens of *Croton sertanejus* sp. nov. were also identified as *C. echiooides* by Carneiro-Torres (2009), to which it is similar by its usually shrubby habit, ovate or elliptic leaf blades with entire margin and nectary glands at the base, inflorescences with sparse flowers and short bracts, and pistillate flowers with usually globose reduced petals and bifid styles. Both species are also endemic to eastern Brazil, occurring mainly in the Seasonally Dry Tropical Forest – Caatinga (Fig. 3). However, *Croton sertanejus* has pseudomonopodial branching with an extended main stem bearing alternate lateral branches, Figs 1A, 2C (vs di- or trichotomous branching in *C. echiooides*, Fig. 4A); petioles 0.4–1.7(–2) cm long, Fig. 1F₁–F₂ (vs (1.8–)3–8.1 cm long, Fig. 4E₁–E₃); obtuse or rounded leaf base with 4–6 nectary glands with stipe 0.1–0.2 mm long, facing the both surfaces, Fig. 1F₁–F₂, H (vs cordate or slightly cordate leaf blade base with 2(3) nectary glands with stipe 0.5–1.4 mm long, facing the abaxial surface, Fig. 4E₁–E₃, F₁–F₃); indumentum of sessile trichomes on both surfaces of leaf blades, Fig. 1J₁–J₃ (vs stipitate trichomes on abaxial surface of leaf blades, Fig. 4H₁, and glabrous or glabrescent on adaxial surface); equal pistillate flower sepals 1–1.7 × 0.6–0.8 mm, Fig. 1S₁–S₂ (vs subequal or unequal sepals, 1.3–3 ×

Fig. 6. Cross sections of the leaf blade of *C. echiooides* Baill. (A, E–I, N–Q) and *C. sertanejus* Sodré & M.J.Silva sp. nov. (B–D, J–M, R–V). **A.** Median portion of the leaf blade of *C. echiooides*, note the stipitate trichomes of abaxial surface in lateral view. **B.** Median portion of the leaf blade of *C. sertanejus*, note the sessile trichomes of abaxial surface in lateral view. **C.** Leaf margin of *C. sertanejus*, note simple trichomes of adaxial surface. **D.** Base of the trichome of adaxial surface of *C. sertanejus*. **E.** Vascular bundle of *C. echiooides*. **F–H.** Median portion of the leaf blade of *C. echiooides*. **I.** Leaf margin of *C. echiooides*. **J.** Vascular bundle of *C. sertanejus*. **K–L.** Median portion of the leaf blade of *C. sertanejus*. **M.** Leaf margin of *C. sertanejus*. **N.** Primary vein of *C. echiooides*. **O.** Detail of vascular cylinder of *C. echiooides* primary vein. **P.** Collenchyma in adaxial surface of *C. echiooides* primary vein. **Q.** Detail of the vascular bundle, note xylem, phloem, laticifer and druse. **R.** Primary vein of *C. sertanejus*. **S.** Detail of vascular cylinder of *C. sertanejus* primary vein. **T.** Collenchyma in adaxial surface of *C. echiooides* primary vein. **U.** Detail of the epidermis and cortex of *C. echiooides* primary vein. **V.** Detail of the vascular bundle, note xylem, phloem and druse. Arrowheads indicate stomata; asterisks indicate laticifers. Abbreviations: cl = collenchyma; co = cortex; d = druses; ep = epidermis; i = idioblasts; pa = ground parenchyma; ph = phloem; pp = palisade parenchyma; sp = spongy parenchyma; st = simple trichome; stt = stellate trichome; vb = vascular bundle; vc = vascular cylinder; xy = xylem. A, E–I, N–Q = R.C. Sodré et al. 3284 (BOTU); B–D, J–M, R–V = R.C. Sodré et al. 3350, holotype (BOTU). Scale bars: A–C, N, R = 200 µm; D–G, I–M, P–Q, T–V = 50 µm; H = 20 µm; O, S = 100 µm.

Asterisks indicate laticifers. Abbreviations: av = accessory vascular bundles; cl = collenchyma; co = cortex; d = druses; ep = epidermis; f = gelatinous fibers; p = pericycle; pa = ground parenchyma; ph = phloem; pi = pith; stt = stellate trichome; vc = vascular cylinder; xy = xylem. A–E = R.C. Sodré et al. 3284 (BOTU); F–J = R.C. Sodré et al. 3350, holotype (BOTU). Scale bars: A, F = 300 µm; B–D, G–H, J = 50 µm; C = 200 µm; E, I = 20 µm.

0.6–1.3 mm, Fig. 4Q, S) and styles 2–3 mm long, Figs 1T, 2E (vs styles 4–5.5 mm long, Figs 4P, U, 5D–E). Additionally, *C. sertanejus* is up to 7 meters tall with the arborescent habit frequently mentioned for the species (Fig. 2A–B); has stems, leaves and flowers with a pleasant sweet odor; branches with indumentum of multiradiate or stellate-porrect trichomes (Fig. 1D₁–D₃); scarce clear latex; inconspicuous stipules (0.5–0.8 × 0.15–0.3 mm); thyrses 2.8–16 cm long (Figs 1K, 2B–D, F); globose capsules 5.7–6 × 5.8–6 mm with pedicel 1.2–2.5(–4) mm long (Figs 1V, 2G) and ellipsoid seeds 4.8–4.9 × 3–3.1 mm (Figs 1X₁–X₂, 2K–L). *Croton echiooides* is always shrubby, up to 2.6 m tall (Fig. 5A–B); with or without odor, never sweetish; has branches with stellate-rotate, stellate-lepidote or stellate-porrect trichomes (Fig. 4C₁–C₂); orange, yellow or reddish abundant latex; conspicuous stipules, 1–3.5 × 0.45–0.6 mm (Fig. 4B, D₁–D₂); thyrses 10.4–34.6 cm long (Figs 4A, I, 5A, C–D); compressed-globose capsules 4.8–5.5 × 5.5–6 mm with pedicel 0.5–1.5 mm long (Figs 4W, 5J) and seeds largely elliptical 4.2–4.8 × 3.1–3.5 mm (Figs 4Y₁–Y₂, 5M–N).

Eventually, specimens of *C. sertanejus* sp. nov. have also been identified as *C. conduplicatus* Kunth (*F.A. Silva* 18), *C. rhamnifolius* Kunth (*Guerra* 5528; *Fotius* 3310; *Labouriau* 941), *C. rhamnifolioides* Pax & K.Hoffm. (*Fotius* 3304, 3333; *Bautista* 716; *Pereira* 99; *Saar PCD* 509; *Passos PCD* 5109; *P.F. Souza* 107; *G. Pinto* 42272) or *C. heliotropiifolius* Kunth. (*Neves* 393), all conspecific (Govaerts *et al.* 2000; Sodré & Silva unpublished), having as valid name *C. heliotropiifolius*. However, *Croton sertanejus* differs by a pseudomonopodial branching, with an extended main stem bearing alternate lateral branches (vs di- or trichotomous branching in *C. heliotropiifolius*), leaves with nectary glands at the base of the blade (vs absent), globose fruits (vs oblong) and fruit columella with three not inflated, flattened or slightly ascending lobes at the apex (vs three inflated and ascending lobes).

Among the sections of *Croton*, the new species here described should be positioned in *Croton* sect. *Adenophylli* Griseb. for being monoecious, shrubby or arborescent, presenting leaf blades with nectary glands at the base (Fig. 1H) and entire margin without nectary glands (only with glands similar to colleters, Fig. 1I), inflorescences with unisexual cymules (Figs 1K, 2E), free, eglandular, valvate sepals of pistillate flowers, and bifid styles (Fig. 1R, S₁–S₂, T). *Croton sertanejus* sp. nov., however, presents fruit columella with a slightly trifurcate apex, with irregular, flat or slightly ascending tips, usually amorphous and not inflated (Figs 1W₁–W₃, 2H–J), unlike most species of *Croton* sect. *Adenophylli* that have a columella with three ascending and inflated lobes at the apex. This distinct columella found in *C. sertanejus* was also seen in *C. echiooides* (Figs 4X₁–X₃, 5K–L), a species that already had its systematic position confirmed in *Croton* sect. *Adenophylli* in recent phylogenies (Sodré *et al.* 2022). *Croton chimbacensis* P.E.Berry & Riina, a species described and presented as sister to *Croton* sect. *Adenophylli* in a phylogeny by Riina & Berry (2010), also presents a similar columella. Van Ee *et al.* (2011) placed *C. chimbacensis* in *C. sect. Adenophylli*, however, without sampling it in the phylogeny, and even today the systematic positioning of the species remains unresolved (van Ee & Berry 2021).

Baillon (1864) described *Croton echiooides* based on specimen *Banchet* 3718 from Jacobina in the old province of Bahia, and according to the protologue deposited in the “herb. Museum” (Herbarium P) and “herb. Delessert” (Herbarium G). The following year, Müller Argoviensis (1865) described the same specimen collected by Blanchet as *C. jacobinensis*, without mentioning the herbarium. Müller Argoviensis’s name is, therefore, a homotypical synonym of *C. echiooides* and an illegitimate posterior homonym, since Baillon (1864) had already used the binomial *C. jacobinensis* for another species from Bahia. In another work, Müller Argoviensis (1866) described *C. kalkmannii* based on the collections *Kalkmann* 145 and *Kalkmann* 146, both deposited in the “herb. Sond.” (currently in the Herbarium MEL). *Croton kalkmannii* is here synonymized with *C. echiooides* because they have indistinct branching patterns (in bifurcation or trifurcation), trichomes in the branches (stellate-rotate, stellate-lepidote or stellate-porrect), length of petioles ((1.8)–3–8.1 cm long), leaf blade bases (cordate or slightly cordate with a pair of stipitate nectary glands on abaxial surface), and length of pedicels of the pistillate flowers (0.1–1 mm long). We chose *Kalkmann* 145 [MEL2337250] as lectotype of *C. kalkmannii* because it is the most complete collection, with fully developed leaves, inflorescences with pistillate flowers, staminate flowers and buds and fruits. The notation “Herb. Sond.” in the protologue, in reference to the Sonder Herbarium,

which is housed in the Herbarium MEL, also justifies our choice. Carneiro-Torres (2009) in her doctoral thesis about the diversity of *Croton* in the Caatinga proposed the lectotypification and synonymization of *C. kalkmannii* under *C. echiooides*, however, such adjustments were never formally published. Recently, Caruzo *et al.* (2016) propose an acceptable lectotypification for *C. echiooides*, choosing the collection of Herbarium P [P00623146], among the 14 sheets deposited in 11 different herbaria.

Anatomical characters have been used in the differentiation of species in *Croton* by Soares (2013), Barbosa *et al.* (2018), Feio *et al.* (2018), Sodré *et al.* (2019b), Sodré & Silva (2020) and Rosa *et al.* (2021). These authors pointed out that useful anatomical characters are the type of trichomes, as well as the length and number of rays, and the length of the stipe, the presence of idioblasts, the stomata position on the leaf blade, the type of mesophyll, the presence of the continuous palisade parenchyma in the midrib and the margins of the blade, the outline of the petiole in cross section, the conformation of the vascular bundles of the midribs and petioles and the presence and number of accessory vascular bundles in the petiole. Although the leaves of *C. echiooides* and *C. sertanejus* sp. nov. are anatomically similar, as mentioned in the results, some of the characters already used in previous works to separate species of *Croton* have also proved useful in differentiating these two species. They are the presence of the stipe in the trichomes, the form and type of the vascular cylinder of the primary veins, the continuous or discontinuous palisade parenchyma in the primary vein, the number of layers in the pith of the petiole, the type of accessory vascular cylinders of the petiole and the presence of evident laticifers in the primary vein and petiole.

Acknowledgments

We thank M.Sc. Daniella Oliveira Diniz, curator of the UFG herbarium, for requesting a loan of collections from the herbaria. The first author would like to thank the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) for the scholarship received. Thanks are also due to the Laboratory of Vegetal Taxonomy and Morphology (LVTM) of the Federal University of Goiás (UFG) for its support in the morpho-taxonomic analysis and to the Transport Sector of the Federal University of Goiás for its support in all field trips to Bahia. The authors thank the team of the herbaria listed for allowing to examine the collections, either through visits, providing photos of the exsiccatae or sending some of them as loan. We thank Renato Galhardo Neto for preparing the illustrations. The second author would like to thank the Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq) for Scholarship in Research Productivity granted (Process no. 307371/2013-1).
