A new species of *Characidium* is described from the Cerrado biome, in Brasília, Distrito Federal, Central Brazil. The new species can be readily diagnosed by the presence of two or three longitudinal rows of dots along the body sides, absence of bars, by the short pectoral fin, which does not reach the vertical through the dorsal fin origin. Additional useful diagnostic characters are the scaled isthmus, absence of the adipose fin, and the terminal mouth. The new species is only known from the córrego Taquara and its tributaries, a tributary of ribeirão do Gama, upstream from lago Paranoá, in the upper rio Paraná basin. In accordance to the IUCN Red List Categories and Criteria, the new species is categorized as Critically Endangered.

**Keywords:** Endangered species, IUCN, Lago Paranoá, Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística, Rio Paraná basin.

Uma nova espécie de *Characidium* é descrita do bioma Cerrado em Brasília, Distrito Federal, Brasil Central. A nova espécie pode ser diagnosticada pela presença de duas ou três fileiras longitudinais de pontos no corpo, ausência de barras e nadadeira peitoral curta, que não alcança a vertical que passa pela origem da nadadeira dorsal. Caracteres adicionais úteis na diagnose são o istmo escamado, a ausência da nadadeira adiposa e a boca terminal. A nova espécie é conhecida apenas do córrego Taquara e seus tributários, tributário do ribeirão do Gama a montante do Lago Paranoá, na bacia do alto rio Paraná. De acordo com os Critérios e Categorias para Listas Vermelhas da IUCN, a nova espécie é categorizada como uma Criticamente Ameaçada.

**Palavras-chave:** Bacia do rio Paraná, Espécies Ameaçadas, IUCN, Lago Paranoá, Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística.

## INTRODUCTION

*Characidium* Reinhardt, 1867 is a genus of Neotropical fishes currently including 79 valid species, distributed between Panamá and northern Argentina (Agudelo-Zamora *et al.*, 2020a,b; Flausino Junior *et al.*, 2020; Fricke *et al.*, 2020; Zanata *et al.*, 2020a; Zanata, Ohara, 2020; Teixeira, Melo, 2021). The genus is considered to be monophyletic based on a single synapomorphy, the presence of a basicaudal spot, which is not present in all species (Buckup, 1993a).

The Brazilian Cerrado has high endemism of freshwater fishes because this biome contains the watersheds of some of the major South-American hydrological basins (Nogueira *et al.*, 2010; Reis *et al.*, 2016). In the past 20 years, the taxonomic knowledge regarding the diversity of *Characidium* in the Brazilian Cerrado has received increased attention, resulting in descriptions of eight species: *C. barbosai* Flausino Junior, Lima, Machado & Melo, 2020, endemic to the tributaries of the upper rio Guaporé, Serra da Borda; *C. cacah* Zanata, Ribeiro, Araújo-Porto, Pessali & Oliveira-Silva, 2020, from the rio das Velhas, rio São Francisco basin; *C. mirim* Netto-Ferreira, Birindelli & Buckup, 2013, endemic to tributaries of the upper rio das Mortes, rio Tocantins basin, Chapada dos Guimarães; *C. nupelia* da Graça, Pavanelli & Buckup, 2008, from the rio Cuiabá upstream from the Pantanal Matogrossense, rio Paraguay basin; *C. satoi* Melo & Oyakawa, 2015, from rio Curral das Éguas, rio São Francisco basin; *C. stigmosum* Melo & Buckup, 2002, from rio Paraná, rio Tocantins basin Chapada dos Veadeiros; *C. xanthopterum* Silveira, Langeani, da Graça, Pavanelli & Buckup, 2008, widespread in the upper rio Paraná and upper rio Tocantins basins; and *C. xavante* da Graça, Pavanelli & Buckup, 2008, from rio Culuene, upper rio Xingu, Amazon basin (Melo, Buckup, 2002; Da Graça *et al.*, 2008; Netto-Ferreira *et al.*, 2013; Melo, Oyakawa, 2015; Mendonça, Netto-Ferreira, 2015; Flausino Junior *et al.*, 2020; Zanata *et al.*, 2020b).

A new *Characidium* species is herein described from Brasília, Distrito Federal, based on specimens collected in the córrego Taquara and its tributaries, in the headwaters of the ribeirão do Gama, upstream from the lago Paranoá, rio São Bartolomeu drainage, in the upper rio Paraná basin. Most specimens used for the present description were

collected at the Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística (RECOR). In addition, the conservation status of the species is also discussed.

## MATERIAL AND METHODS

Morphometric and meristic data were obtained from the left side of specimens, under a binocular stereomicroscope, according to Buckup (1993b), with modifications proposed by Melo, Oyakawa (2015). Measurements were taken using a digital caliper to 0.1 mm. Meristic data are given along the description, followed by the frequencies of each count in parentheses, and an asterisk (\*) indicating the values for the holotype. Terminology for pigmentation of body follows Leitão, Buckup (2014) and Flausino Junior *et al.* (2020). Osteological features were observed in cleared-and-stained specimens (cs), prepared according to Taylor, Van Dyke (1985). Osteological nomenclature follows Weitzman (1962) and Vari, Harold (2001), with the addition of posterior cleithral process. The vertebral counts included the four anterior-most elements modified into the Weberian Apparatus counted individually and the compound element of caudal fin was counted as a single element. Supernumerary elements in dorsal and anal fins were counted only from cleared and stained individuals. Osteological illustrations were made on a Zeiss Discovery V12 stereomicroscope connected to a camera with auto-montage mechanism. The gonads examined macroscopically through a small incision made in the flank, and sex and stage of gonadal development were evaluated according to Vazzoler (1996).

General abbreviations are as follows: SL, Standard Length; HL, Head Length; cs, cleared and stained. Acronyms for fish collections are as follows: MNRJ, Museu Nacional, Rio de Janeiro; MZUSP, Museu de Zoologia da Universidade de São Paulo; ZUEC, Museu de Zoologia da Universidade de Campinas; IBGE, Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística fish collection. Abbreviations of main areas of conservation are as follows: EEJBB – Estação Ecológica Jardim Botânico de Brasília; FAL–UNB, Estação Experimental Fazenda Águas Limpas da Universidade de Brasília; EEC–UNB, Estação Ecológica da Universidade de Brasília; RECOR – Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística. Only specimens in good conditions were selected as types. Maps presented in figure 4 were produced using Quantum GIS (QGIS.org, 2020), with the QuickMapServices plugin. Maps presented in Figure 5 were produced using Google Earth Pro (Google, 2020), with the aid of the timeline function. The extent of occurrence was calculated with the aid of Google Earth Pro (Google, 2020), drawing the smallest polygon in which no internal angle exceeds 180 degrees and which contains all the sites of occurrence (IUCN Standards and Petitions Subcommittee, 2019). A regression analysis was performed using the computer program Microsoft Excel (MICROSOFT, 2020), comparing the standard length with the ratio between standard length and body depth at dorsal-fin origin.

## RESULTS

### *Characidium onca*, new species

urn:lsid:zoobank.org:act:A4755AF5-77AF-46FA-B034-49DD4A46D2B4

Ribeiro; MZUSP 125808, 1, 35.4 mm SL, collected with holotype; ZUEC 17241, 4, 27.0–34.7 mm SL, collected with MZUSP 125803; ZUEC 17242, 2, 38.7–40.1 mm SL, collected with MZUSP 125797; ZUEC 17243, 3, 23.5–26.8 mm SL, collected with MZUSP 125800; ZUEC 17244, 1, 31.2 mm SL, collected with MZUSP 125801.

**Non-types.** All from Brazil, Brasília, Distrito Federal, upper rio Paraná basin, rio Taquara drainage. IBGE 1022, 2, 31.9–36.6 mm SL, córrego Roncador; IBGE 1023, 1, 20.4 mm SL, collected with IBGE 1022; IBGE 1070, 1, 24.2 mm SL, córrego Taquara; IBGE 1089, 1, 25.4 mm SL, córrego Onça; IBGE 12, 1, 39.8 mm SL, córrego Roncador; IBGE 152, 1, 23.5 mm SL, córrego Taquara; IBGE 170, 1, 31.1 mm SL, córrego Taquara; IBGE 899, 1, 28.3 mm SL, córrego Taquara; IBGE 934, 1, 35.9 mm SL, córrego da Onça; IBGE 935, 1, 17.8 mm SL, collected with IBGE 934; IBGE 936, 1, 21.9 mm SL, collected with IBGE 934; IBGE 988, 1, 22.5 mm SL, córrego Tapera; IBGE 1729, 1, 35.4 mm SL, córrego Taquara.

**Diagnosis.** *Characidium onca* can be distinguished from its congeners except *C. chancoense* Agudelo-Zamora, Ortega-Lara & Taphorn, 2020, *C. japuhybense* Travassos, 1949, *C. lauroi* Travassos, 1949, *C. oiticicai* Travassos, 1967, *C. pellucidum* Eigenmann, 1909, *C. phoxocephalum* Eigenmann, 1912, *C. pteroides* Eigenmann, 1909, *C. schubarti* Travassos, 1955, *C. stigmosum*, and *C. travassosi* Melo, Buckup & Oyakawa, 2016 by small dots on the side of body present (*vs.* spots absent), and from these exceptions by the dots arranged in two or three well-marked, longitudinal lines (*vs.* dots irregularly distributed); and by the pectoral fin short, not reaching the vertical that passes through the origin of the dorsal fin (*vs.* tip of pectoral fin reaching or extending posterior to the vertical that passes through the origin of dorsal fin). It further differs from *C. chancoense*, *C. japuhybense*, *C. lauroi*, *C. helmeri*, *C. pellucidum*, *C. phoxocephalum*, *C. pteroides*, and *C. schubarti* by the adipose fin absent (*vs.* adipose fin present); from *C. stigmosum*, *C. japuhybense*, *C. longum*, and *C. pteroides* by the bars absent (*vs.* bars present); from *C.*

*japuhybense*, *C. lauroi*, *C. helmeri*, *C. oiticicai*, *C. schubarti*, and *C. travassosi* by the isthmus scaled (*vs.* isthmus scaleless); and from *C. pellucidum* and *C. pteroides* by the blotches on dorsum absent (*vs.* sickle-shaped, reddish-brown blotches present, formed by the fragmentation of vertical bars on sides of body present), and longitudinal stripe present (*vs.* absent).

**Description.** Morphometric data summarized in Tab. 1. Largest examined specimen 40.1 mm SL. Body elongate. Dorsal profile moderately convex between snout tip and dorsal-fin base, gently convex between dorsal and caudal-fin. Ventral profile gently convex between dentary tip and anal-fin origin, slightly convex at anal-fin base; almost straight between anal and caudal-fin bases. Belly strongly accentuated arched in females with well-developed ovary. Greatest depth of body at dorsal-fin origin.

Snout in lateral view triangular and short, its tip at level of center of eye. Mouth

**TABLE 1 |** Morphometric data for *Characidium onca*. Range values are for holotype and paratypes. N = total number of specimens examined; SD = Standard Deviation.

Characters	Holotype	N	Range	Mean	SD

**FIGURE 2 |** Paratypes of *Characidium onca*. **A–B.** MZUSP 125798, 23.8–27.0 mm SL respectively, córrego Taquara; **C.** MZUSP 125795, 28.6 mm SL, córrego Roncador; **D.** ZUEC 17242, 38.7 mm SL, córrego Roncador; **E–F.** MZUSP 125797, 39.0–44.1 mm SL, respectively, córrego Roncador. Scale bar = 5 mm.

small, terminal. Snout-maxillary tip about equal to diameter of orbit; tip of maxilla reaching level of anterior margin of orbit. Orbit nearly rounded, margin of orbit free. Cheek narrow, its depth less than one third of eye diameter. Nares distinctly separated, distance between nares shorter than distance between posterior naris and eye. Dermal flap along posterior border of anterior naris, and to anterior margin of posterior naris.

Premaxillary teeth arranged in single row, with 5(2), 6\*(14), 7(7), or 8(1) unicuspид teeth, increasing in size from lateral to medial (Fig. 3A). Maxillary teeth absent (Fig. 3A). Dentary teeth arranged in two rows; outer row with 7(1), 6(3), 9\*(16), 10(3), or 11(1) teeth, increasing in size from lateral to medial, medial teeth tricuspid with lateral cusps reduced, lateral teeth unicuspид, medial teeth larger and tricuspid; inner row with 9(1 cs), or 14(2 cs) teeth, minute and conical (Fig. 3B). Ectopterygoid teeth arranged in single row, with 6(1 cs), or 7(2 cs) teeth, minute and conical. Mesopterygoid teeth absent. Branchiostegal rays 5(3 cs); four attached to anterior ceratohyal (3 cs), one

attached to posterior ceratohyal (3 cs). Total gill rakers on first arch 12(2); gill rakers attached to epibranchial 4(1), or 5(2); gill rakers attached to ceratobranchial 6(1), or 7(2); gill rakers attached to basibranchial 2(3).

Scales cycloid; parallel radii present on posterior field of scale, circuli on exposed field absent. Lateral line complete, with 33(4), 34\*(10), 35(8), 36(1) perforated scales. Scales above lateral line 4.5\*(24). Scales below lateral line 4\*(24). Circumpeduncular scales 14\*(24). Pre-dorsal scales series regularly arranged; scales on pre-dorsal series 11(4), 12(14), or 13\*(8). Scales between anus and anal fin 2(9) or 3(15). Isthmus scaled.

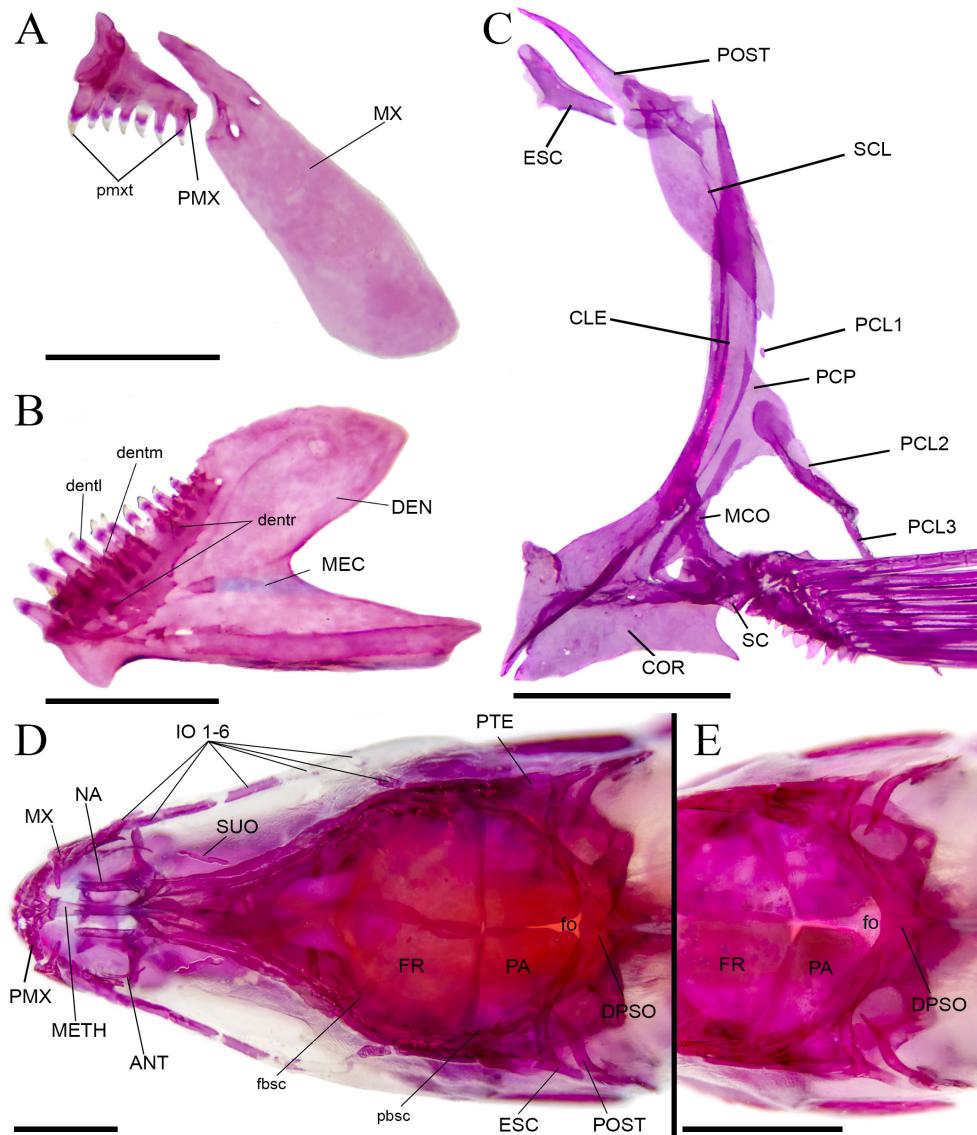

Pectoral fin short, not reaching vertical that pass through dorsal-fin origin; origin of dorsal fin at level slight anterior to pelvic-fin origin; pectoral-fin rays iii,4,iii(1), iii,5,ii\*(7), iii,6,i(7), iii,6,ii(8), or iii,6,iii(1). Pelvic fin short, not reaching anus; pelvic-fin rays ii,4,i(1), i,6,i\*(21), ii,6,ii(1), or i,7,i(1). Dorsal-fin rays iii,8(3), ii,9\*(18), iii,9(1), or i,10(2); supranumerary element on first pterygiophore of dorsal fin 1(3 cs); last dorsal-fin ray not adnate (3 cs). Anal fin not reaching ventralmost caudal-fin ray; anal-fin rays ii,6\*(24); supranumerary element on first pterygiophore of anal fin 1(3 cs); last anal-fin ray not adnate (3 cs). Principal caudal-fin rays i,8,9,i\*(24); lower procurent rays 7(2 cs), or 9(1 cs); upper procurent rays 7(1 cs) or 8(2 cs). Adipose fin absent (24).

Precaudal vertebrae 20(1 cs), or 21(2 cs); total vertebrae 35(1 cs), or 36(2 cs). Supraneurals 5(1 cs), or 7(2 cs). Postcleithrum 1 rudimentary (1) or absent (2); postcleithrum 2 and 3 present and well developed (3) (Fig. 3C). Epurals 3(3 cs); hypurals 4(1 cs) or 6(2 cs). Parietal branch of supraorbital laterosensory canal present (3 cs), elongate, reaching the parietal bone. Epiphysial branch of the supraorbital laterosensory canal present. Fontanel limited antero-laterally by parietals and posteriorly by supraoccipital (2 cs) (Fig. 3D), or extending anteriorly and contacting frontals (1 cs) (Fig. 3E). Posterior chamber of swim bladder larger than anterior chamber, 21.9–35.3% in SL (3 cs).

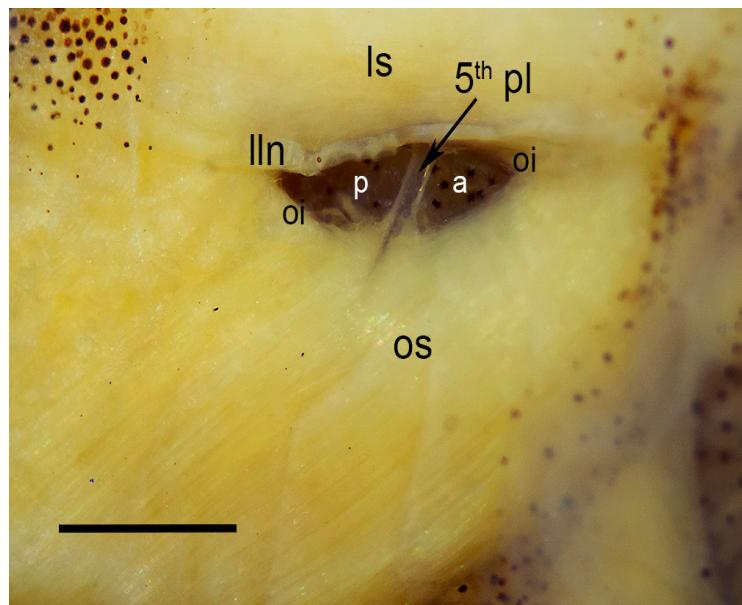

Pseudotympanum immediately posterior to supracleithrum, underneath anterior part of longitudinal stripe, antero-dorsally elongate, limited dorsally by *lateralis superficialis*, anteriorly and posteriorly, by *obliquus inferioris*, and ventrally by *obliquus superioris*; lined dorsally by lateral-line nerve. Humeral hiatus divided into anterior and posterior chambers by pleural rib of fifth. Fatty tissue filling humeral hiatus absent (Fig. 4).

**Coloration in alcohol.** Ground color of head and trunk light yellow, darker on dorsum, lighter on belly (Figs. 1–2). Cheek, distal portion of upper jaw, ventral part of head and opercle pale with widely spaced melanophores. Dorsal portion of snout and head light brown. Oblique preorbital stripe extending from snout tip to anterior portion of eye present and conspicuous. Postorbital stripe present, conspicuous. Bars on body absent. Three thin stripes present on dorsal part of body; dorsal stripe extending from head to dorsal-fin base; middle bar extending from head to caudal peduncle; and ventral bar extending from head to base do dorsa-caudal fin ray. Midlateral stripe, stout, extending from supracleithrum to caudal peduncle, not reaching base of middle caudal-fin rays. Humeral blotch absent. Basicaudal spot inconspicuous, vertically elongated. Dots arranged in two or three longitudinal rows; dorsal row of dots extending from level of cleithrum to caudal peduncle, slightly dorsal to, or overlapped by, midlateral stripe; middle and ventral rows of dots extending from posterior angle of opercle to caudal peduncle, ventrally to lateral line. Pectoral, pelvic, dorsal, anal and caudal fins mostly hyaline, or caudal and pectoral fins dusky; melanophores present only on lepidotrichia.

**Coloration in life.** Overall color pattern same as preserved. Ground color yellow to brownish with dorsum darker and belly whitish, with gold tint on opercle, eye and parts of head. A longitudinal, gold stripe present, extending along body immediately dorsal to longitudinal stripe.

**FIGURE 3 |** Osteological characteristics in *Characidium onca*, paratypes: A. Right upper jaw in medial view (MZUSP 125803); B. Right dentary in medial view (MZUSP 125803); C. Left pectoral gridle in lateral view (MZUSP 125801); D. Skull in dorsal view (MZUSP 125803); E. Posterior portion of skull in dorsal view (MZUSP 125801). Abbreviations: ANT, antorbital; CLE, cleithrum; COR, coracoid; DEN, dentary; dentl, lateral row of dentary teeth; dentm, middle row of dentary teeth; dentr, replacement lateral row of dentary teeth; DPSO, dorsal process of the supraoccipital; ESC, extrascapular; FR, frontal; fbsc, frontal branch of the supraorbital canal; fo, fontanel; IO 1-6, infraorbitals 1 to 6; MCO, mesocoracoid; MEC, Meckel's cartilage; METH, mesethmoid; MX, maxilla; NA, nasal; PAR, parietal; pbsc, parietal branch of the supraorbital canal; PCP, posterior cleithral process; PCL 1-3, postcleithrum 1 to 3; PMX, premaxilla; pmxt, premaxillary teeth; pmxtr, replacement premaxillary teeth; POST, posttemporal; PTE, pterotic; SC, scapula; SCL, supracleithrum; SUO, supraorbital. Scale bar = 1 mm.

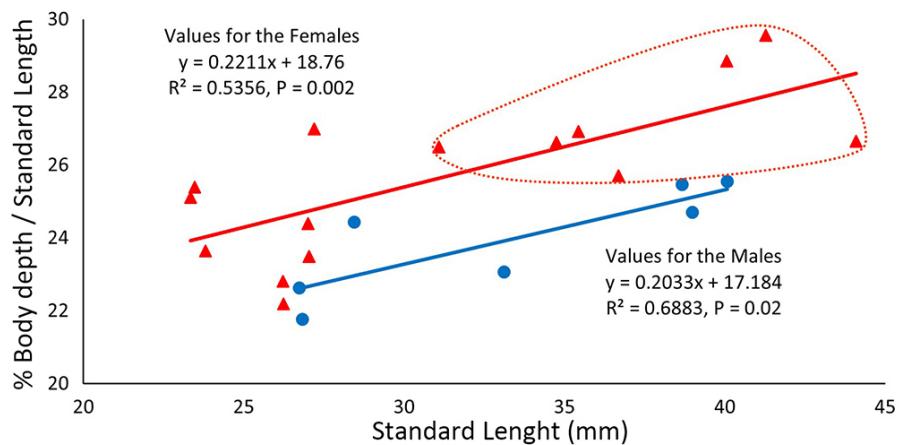

**FIGURE 4 |** Pseudotympanum in *Characidium onca* (MZUSP 125801, paratype). Abbreviations: 5<sup>th</sup> pl, pleural rib of fifth vertebra; a, anterior window of pseudotympanum; lln, lateral line nerve; ls, *lateralis superficialis*; oi, *obliquus inferioris*; os, *obliquus superioris*; p, posterior window of pseudotympanum. Scale bar = 1 mm.

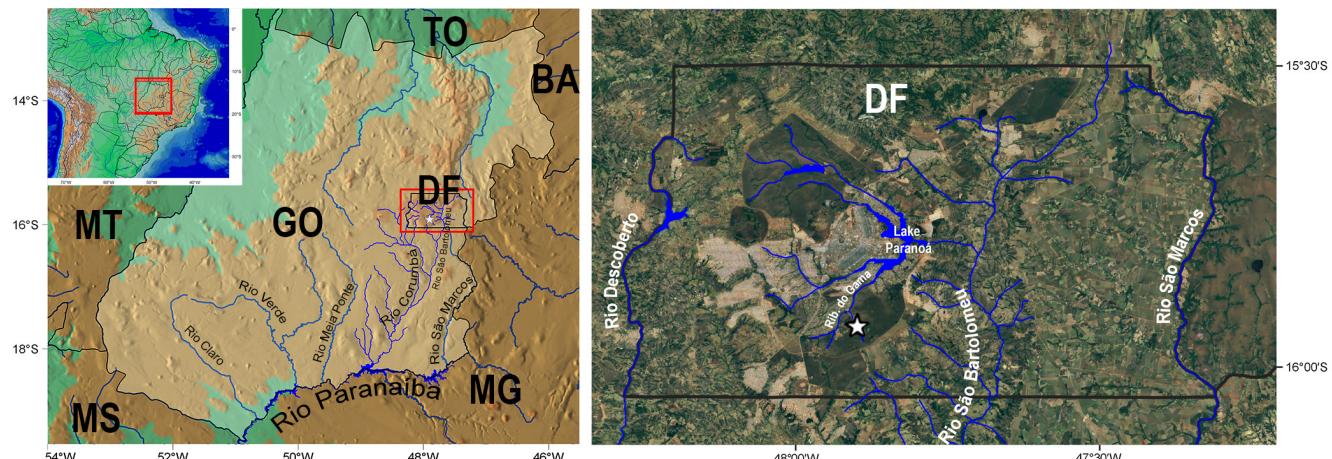

**Sexual dimorphism.** A total of 22 specimens had the sex and gonadal development stage evaluated, including eight immature females (23.3–27.2 mm SL), seven mature females (31.1–44.1 mm SL), and seven males (26.7–40.1 mm SL). The body depth at origin of dorsal fin has a statistically significant, positive growth in both females and males, varying from 22.2 to 27.0% in SL (mean 24.3%) in immature females; from 26.5 to 29.6% in SL (mean 27.3%) in mature females; and from 21.8 to 25.5 % in SL (mean 23.4%) in mature males (Fig. 5). The mature females with fully developed eggs have a largely expanded belly, resulting on a considerable deeper body and high standard deviation for the body depth at origin of dorsal (Tab. 1). Further secondary sexual dimorphic characters, such as differences in the color pattern or the lepidotrichia bony process, are absent.

**Geographical distribution.** *Characidium onca* is only known from córrego Taquara and its tributaries, itself being a tributary of the ribeirão do Gama which nowadays drains into the lago Paranoá, a tributary of the right margin of the rio São Bartolomeu, tributary of the left margin of rio the Corumbá, rio Paranaíba drainage, in the upper rio Paraná basin, Distrito Federal, Brazil (Fig. 6).

**Etymology.** The specific name *onca* refers to the Portuguese name onça, used for the jaguar *Panthera onca* (Linnaeus) (Mammalia: Felidae), in an allusion to the black spots in a bright gold-yellow body. It is derived from the Latin *lyncea*, meaning lynx (Italian “lonza”, old French “l’once”), and should be pronounced as ‘õ.sə. A noun in apposition.

**FIGURE 5 |** The proportion of body depth at dorsal-fin origin (% SL) versus the standard length (mm) in females (red triangles) and males (blue dots) in *Characidium onca*. Symbols indicating the mature females are highlighted in the dashed area.

**FIGURE 6 |** Maps of the tributaries of rio Paranaíba in Goiás State, Brazil in general view (left), with the rio São Bartolomeu basin detailed in the Distrito Federal (right). The type locality of *Characidium onca* is indicated by a star in the córrego Taquara. Abbreviations: BA, Bahia; DF, Distrito Federal; GO, Goiás; MG, Minas Gerais; MS, Mato Grosso do Sul; MT, Mato Grosso; and TO, Tocantins.

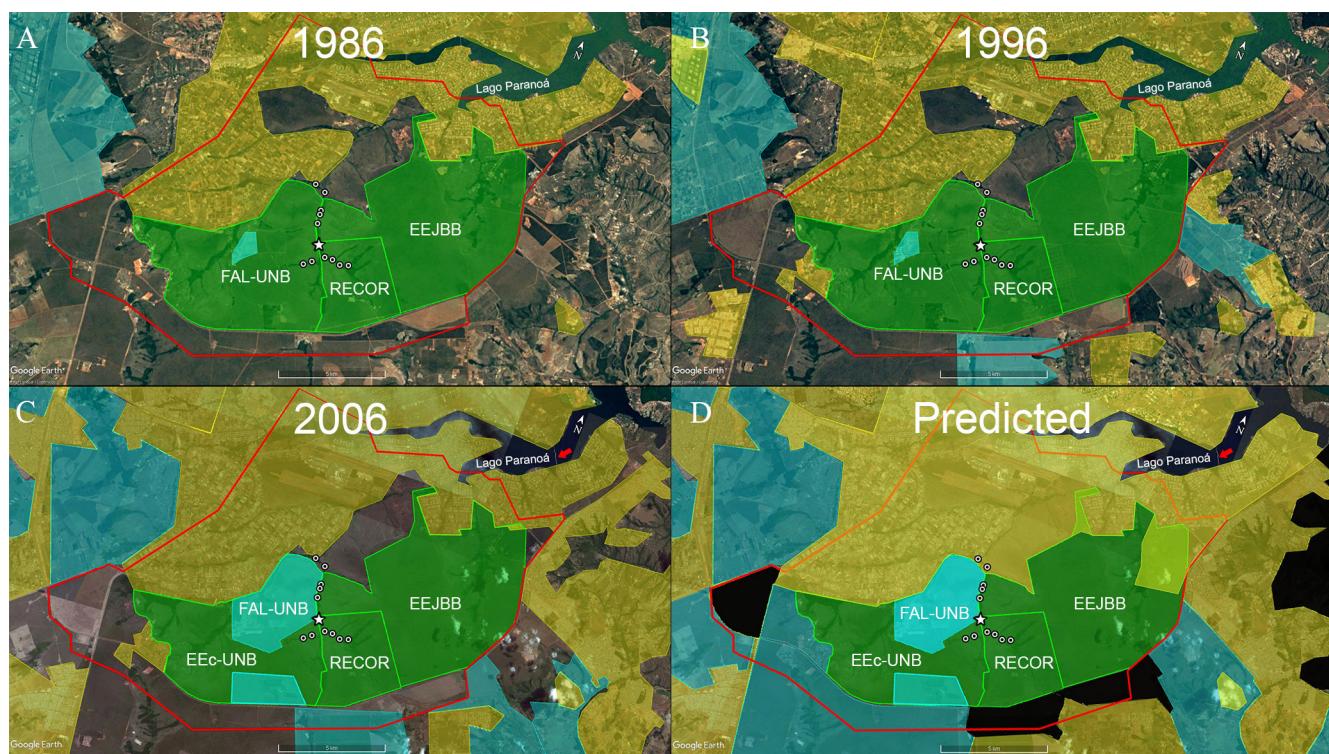

**Conservation status.** *Characidium onca* is known only from córrego Taquara and its tributaries, which have about 6.5 km of extension. Since the 1980's, the second author (MCLBR) has been sampling the drainages in the Distrito Federal and surroundings building a collection of over 1,000 lots of *Characidium* hosted mainly at the IBGE-RECOR, MZUSP and ZUEC fish collections, but *C. onca* was never found in any other drainages. Additional ichthyofaunistic inventories conducted in the Distrito Federal also did not report the presence of *C. onca* elsewhere, supporting the evidence that it truly has a narrow distribution (Ribeiro *et al.*, 2001, 2008; Aquino *et al.*, 2009; Ribeiro, 2012). The extent of occurrence of *C. onca* is calculated in 15 km<sup>2</sup> and considered a single location. Additionally, the species is naturally rare and have extremely low abundance in nature (MRSM and MCLBR, pers. obs.).

Since the construction of Brasília in 1960's, the impacts on the ribeirão do Gama drainage are gradually increasing (Figs. 7A–D). The lago Paranoá is an artificial lake formed by damming the rio Paranoá in 1959, to provide water supply, electric power and to increase the air humidity in Brasília. The Lago Paranoá extends to the lower part of the ribeirão do Gama, slightly downstream (>8 km) from the collection sites of *C. onca*, resulting on habitat loss by changing the original characteristics of a lotic into a lentic system, and by the destruction of the original riparian vegetation. The formation of the lake was followed by the introduction of several exotic species, such as the Congo tilapia *Coptodon rendalli* (Boulenger, 1897), the largemouth bass (known in Brazil as black bass) *Micropterus salmoides* (Lacepède, 1802), the bluegill *Lepomis macrochirus* Rafinesque, 1819 and the carp *Cyprinus carpio* Linnaeus, 1758 (Ribeiro *et al.*, 2001).

The construction of Brasília also resulted in dynamic land use and vegetation coverage changes, with the replacement of natural areas of open fields (campo nativo) and Cerrado vegetation for agriculture and urban uses (Figs. 7A–D). Over the last two decades, the population in the Distrito Federal increased in more than 70%, from 1,737,813 in 1995 to 2,977,216, in 2016 (UNESCO, 2002). The rapid urbanization has replaced large areas of the natural Cerrado ecosystem with urban areas and agriculture land for cultivating soybean, corn, and bean. The intense use of surface and underground hydrological resources for such purposes caused water depletion and local climate changes of longer dry seasons and a predicted increase of temperature by up to 5° C (Campos, 2004; Cadamuro, Campos, 2005; Lorz *et al.*, 2012; IBGE, 2017). The most severe consequences of those impacts are loss of ecological integrity of both terrestrial and aquatic ecosystems, such as the reduction of water level in lakes, rivers and floodplains, the deterioration of water quality, changes in the fire regimes, loss of gallery forests, and the increase of river channel sedimentation that reduces habitats conditions for the species of *Characidium* (Alley *et al.*, 1999; Ribeiro *et al.*, 2018).

The distribution of *C. onca* is within the Área de Proteção Ambiental (APA) das Bacias do Gama e Cabeça de Veadو, created by the Decreto Distrital N° 9.471, of April 21<sup>st</sup>, 1986 and protected by both district (Reserva da Biosfera do Cerrado, Lei Distrital N° 742, of July 28<sup>th</sup>, 1994) and federal laws (ARIE dos córregos Capetinha e Taquara, Decreto Federal N° 91.303, of June 3<sup>rd</sup>, 1985; APA do Planalto Central, Decreto s/nº da Presidência da República, of January 10<sup>th</sup>, 2002). The APA das Bacias do Gama e Cabeça de Veadо is composed by a relatively large mosaic with more than 10,000 hectares of protected areas, including the Reserva Ecológica do IBGE (RECOR), Estação Experimental Fazenda Águas Limpas (FAL–UNB) of the University of Brasília and Estação Ecológica do Jardim Botânico (EEJBB) de Brasília, among others. The ARIE dos córregos Capetinha e Taquara was initially classified as a “Zona de Conservação Ambiental” and had a relatively low protection stability (UNESCO, 2003) (Fig. 7).

Because of its proximity to downtown Brasília, a considerable extension of the APA das Bacias do Gama e Cabeça de Veadо is already occupied by urban areas, especially in the ribeirão do Gama left margin. The mosaic composed of the FAL–UNB, RECOR and EEJBB is also under strong agricultural and real state speculations and the plans to expand the city limits includes the construction of the Juscelino Kubitschek bridge in 2002 and several changes in delimitation and management categories of the protected areas occasioned by the revision of the Distrito Federal Master Plan (Plano Diretor de Ordenamento Territorial – PDOT, Lei Complementar N° 17/1997, of January 23<sup>rd</sup>,

**FIGURE 7 |** Satellite images of the Área de Preservação Ambiental das Bacias do Gama e Cabeça de Veados (highlighted in red), showing the land use and cover changes along the past 34 years, and predicted: in **A.** year of 1986, with urban areas concentrated north of the FAL-UNB, RECOR and EEJBB; **B.** year of 1996, illustrating the beginning of expansion of urban and rural areas just east of the FAL-UNB, RECOR and EEJBB; **C.** year of 2006, after the construction of the Juscelino Kubitschek bridge in 2002, illustrating a rapid expansion of urban areas in the eastern area; and **D.**, predicted situation according to the Distrito Federal Territorial Planning Master Plan (2009, 2019). Green polygons indicate protected areas; yellow, urban areas; blue, rural areas; black, public land; and, red arrow, the Juscelino Kubitschek bridge. Abbreviations: FAL-UNB, Estação Experimental Fazenda Águas Limpas of the University of Brasília; RECOR, Reserva Ecológica do Instituto Brasileiro de Geografia e Estatística; and EEJBB, Estação Ecológica do Jardim Botânico de Brasília. Source of maps: Google Earth.

1997, revised by the Lei Complementar Nº 803/2009, of April 25<sup>th</sup>, 2009, and instituted by the Lei Distrital Nº 6.269, of January 29<sup>th</sup>, 2019). The FAL-UNB, was replaced with the Estação Experimental da UNB and, within that area, the Estação Ecológica da UNB (EEc-UNB) was circumscribed as a “Macrozona de Proteção Integral”, the RECOR and the EEJBB were classified as a “Macrozona de Proteção Integral”, but the latter had a part of its territory changed to “Urban Zone”. The expansion of human occupation in the vicinity of the mosaic resulted on the habitat fragmentation and the loss of ecological integrity of both terrestrial and aquatic ecosystems, compromising the creation of buffer zones and ecological corridors (UNESCO, 2003; Ribeiro *et al.*, 2018).

In summary, *C. onca* has a very narrow distribution in a single location that has observed impacts of human occupation and introduction of exotic species in the basin and nearby areas, and predicted impacts of reduction of the river flow and loss of water quality caused by the longer periods of the dry season and higher temperatures due to local climate changes allied to the intense use of surface and underground hydrological resources. Following the IUCN Red List Categories and Criteria (IUCN Standards and

Petitions Subcommittee, 2019), *C. onca* should be categorized as Critically Endangered (CR) because of its restricted geographic distribution (B1: Extent of occurrence <100 km<sup>2</sup>) and the following two conditions: number of location equals one (a); and continuing decline observed, estimated, inferred or projected of area extent and/or quality of habitat (biii).

**Comparative material examined.** Same as listed in Melo *et al.* (2016); Melo, Espíndola (2016); Teixeira, Melo (2021).

## DISCUSSION

Only a few species of *Characidium* have dots on sides of body: *C. chancoense*, *C. japihybense*, *C. lauroi*, *C. longum*, *C. oiticicai*, *C. pellucidum*, *C. phoxocephalum*, *C. pteroides*, *C. schubarti*, *C. stigmatum*, and *C. travassosi* (Eigenmann, 1909, 1912; Travassos, 1949a,b, 1955, 1967; Melo, Buckup, 2002; Melo *et al.*, 2016; Agudelo-Zamora *et al.*, 2020a). Buckup (1993a) produced the most inclusive phylogenetic hypothesis for the species of *Characidium*, obtaining three major clades, namely Clades C1, C4 and C4, and a polytomy at the base among those clades and the species that did not fit in any of them, such as *C. zebra* Eigenmann, 1909 and *C. hasemani* Steindachner, 1915. In accordance to such hypothesis, the species of *Characidium* having spots do not consist in a monophyletic group, as discussed below, and therefore, despite being very distinctive from its congeners, *C. onca* cannot be promptly included in any of the clades proposed by Buckup (1993a).

The Clade C1, including Clades C2 and C3, is composed of species having unscaled isthmus, the postcleithrum 1 reduced or absent, and the fontanel reduced, limited antero-laterally by the parietals, such as *C. amaila* Lujan, Agudelo-Zamora, Taphorn, Booth & López-Fernández, 2013, *C. fasciatum* Reinhardt, 1867, and *C. gomesi* Travassos, 1956 (Buckup, 1993a; Lujan *et al.*, 2013). According to Buckup (1993a), the size of the fontanel is variable among the members of Clade C1, but interspecific variation was never reported so far. *Characidium japihybense*, *C. lauroi*, *C. oiticicai*, *C. schubarti*, and *C. travassosi* also are considered as members Clade C1 and compose the *C. lauroi* group, having as main diagnostic feature the presence of small dots on body (Travassos, 1949a,b, 1955, 1967; Melo *et al.*, 2016). Within the *C. lauroi* group, the postcleithrum 1 is well developed in *C. japihybense* and *C. travassosi* and reduced in the remaining species. In *C. onca*, the postcleithrum 1 is either reduced or absent (Fig. 3C); the fontanel can either be reduced and limited antero-laterally by the parietals or elongated, reaching the frontals anteriorly (Figs. 3D–E); but the isthmus is completely scaled.

The Clade C4 is composed of the species with a single row of dentary teeth, the absence of the parietal branch of the laterosensory canal of head, and 12 or more vertical bars on body, such as *C. cacah*, *C. bahiense* Almeida, 1971, *C. interruptum* Pellegrin, 1909, and *C. stigmatum* (Buckup, 1993a; Netto-Ferreira *et al.*, 2013; Mendonça, Netto-Ferreira, 2015; Melo, Espíndola, 2016; Zanata *et al.*, 2020a). In addition, the pigmentation pattern of *C. stigmatum* is very distinctive and unique among its congeners, as the spots are enlarged and vertically elongate (Melo, Buckup, 2002). *Characidium onca* does not share any synapomorphies with the species of Clade C4 and, therefore, we refute a hypothesis

of closer relationships between *C. onca* and *C. stigmosum*. Likewise, *C. onca* lacks the synapomorphies defining the Clade C5, which includes the species with narrow and fragmented bars, the reddish-brown blotches on dorsum, and a slender body, such as *C. longum*, *C. pellucidum* and *C. pteroides* (Buckup, 1993a; Taphorn *et al.*, 2006).

*Characidium chancoense* and *C. phoxocephalum* are trans-Andean species with scaled isthmus and dots on the sides not assigned to any clade of *Characidium* (Agudelo-Zamora *et al.*, 2020a). *Characidium chancoense* has considerable fewer dots, restricted to an irregular line below the longitudinal stripe, apparently associated to the transversal bars, being remarkably similar to *C. japohyense*. *Characidium phoxocephalum* is the species that most closely resembles *C. onca* because of the numerous dots on body and the short pectoral and pelvic fins, and but can be externally distinguished by having an adipose fin. Nevertheless, osteological features suggest such external similarity would be the result of evolutionary convergence, with *C. phoxocephalum* having a well-developed postcleithrum 1 and an elongated and a finger-like posterior cleithral process (Agudelo-Zamora *et al.*, 2020a) while, in *C. onca*, the postcleithrum 1 is reduced or absent, and the posterior cleithral process being short and triangular (Fig. 4).

## ACKNOWLEDGMENTS

We would like to thank Caius Ferreira (RECOR-IBGE) for his-long time dedication to the RECOR fish collection and fieldwork assistance; for curatorial assistance, we thank Alessio Datovo, Michel D. Gianetti, Mario C. C. de Pinna and Osvaldo T. Oyakawa (MZUSP), Cristiano L. R. Moreira, Marcelo R. Britto and Paulo A. Buckup (MNRJ). We are indebted to Carla Polaz (Instituto Chico Mendes de Conservação da Biodiversidade – ICMBio) for the valuable discussion about the conservation status of the newly described species, and three anonymous reviewers for general comments along the manuscript. MRSM is supported by research grants from Conselho Nacional de Desenvolvimento Científico e Tecnológico (CNPq Universal process 433050/2016-0) and Fundação de Amparo à Pesquisa (FAPESP process 2017/12909-4), and FCTL by FAPESP (processes 2011/51532-7 and 2013/20936-0). Collecting permits were issued by the Instituto Brasileiro de Meio Ambiente e dos Recursos Naturais Renováveis (IBAMA).
