Abstract *Salpichlaena* is a distinctive fern genus characterised by 2-pinnate climbing fronds with indeterminate growth. The number of species in the genus has been a matter of debate. Taxonomic studies are made difficult by within-frond variability in pinna morphology and size, and by herbarium material being incomplete. We systematically documented 62 morphological traits in 283 herbarium specimens and sequenced 52 *Salpichlaena* and 11 outgroup specimens. DNA sequences included plastid genes (*rbcL*, *rpoC1* and *rps4*), intergenic spacers (*rps4-trnS*, *trnH-psbA* and *trnG-trnR*) and a nuclear gene (*pgiC*). Phylogenetic analyses based on the plastid markers divided the samples into six major clades. We recognise the three deepest clades as distinct species (*S. hookeriana*, *S. papyrus* sp. nov. and *S. volubilis*), and each of the four shallower clades as a subspecies of *S. volubilis*. Furthermore, we suggest that a group of specimens, placed into different clades in the plastid and nuclear trees and showing mixed morphological characters, represent a fourth species of hybrid origin (*S. hybrida* sp. nov.). The most important diagnostic characters are: degree of lamina reduction in fertile pinnules; pinna/pinnule apex incisions, pinna/pinnule margin thickness and lamina texture in sterile pinna/pinnules; presence or absence of foliar buds; shape of scales; and the appearance of the abaxial surface of the lamina (uniform or with stomata on small white protuberances). Each of the four species can be identified by several diagnostic characters, and their geographical ranges are broad and partly overlapping. In contrast, the subspecies are mostly allopatric and their morphological limits are diffuse.

INTRODUCTION

Blechnaceae is a sub-cosmopolitan fern family with about 267 species. The latest classification of the family (De Gasper et al. 2017) divided it into three monophyletic subfamilies:

1. *Woodwardioideae*, with 15 species and a largely north-temperate and amphiocceanic distribution;
2. *Stenochlaenoideae*, with about 12 species in three tropical genera (including *Salpichlaena* J.Sm.); and
3. *Blechnoideae*, with about 239 species especially in the southern hemisphere but also in north-temperate regions (De Gasper et al. 2016).

Within the subfamily *Stenochlaenoideae*, *Salpichlaena* has been resolved as sister to the clade formed by *Stenochlaena* and *Telmatoblechnum* Perrie, D.J.Ohlsen & Brownsey (De Gasper et al. 2017).

Salpichlaena is a neotropical genus that occurs from Nicaragua to Bolivia, throughout Amazonia and the Atlantic coastal rain forest, and in the Lesser Antilles (Tryon & Tryon 1982). Adult plants are characterised by indeterminately growing twining rachises, which give the plants a climbing habit and make it possible for the fronds to reach up to the height of 15 m in the forest canopy. This highly unusual habit is only shared by one other fern genus, *Lygodium* Sw. (Tryon & Tryon 1982). Frond complexity in *Salpichlaena* increases during ontogeny: small juvenile plants produce simple fronds and larger juvenile plants 1-pinnate fronds, with each frond generally being longer (and having more pinnae) than the preceding one, until the plant is old enough to produce climbing indeterminately growing 2-pinnate fronds (Tuomisto & Groot 1995). According to Robbin

C. Moran (pers. comm.), adult plants in Central America may intermittently produce 1-pinnate fronds between the 2-pinnate ones, but we have not observed this phenomenon in Amazonia. Only the 2-pinnate fronds produce fertile pinnae, and these can be either monomorphic or dimorphic. If dimorphic, the fertile pinnules are narrower than the sterile, with the degree of fertile pinnule contraction depending on the species (Smith 1995).

The first species of *Salpichlaena* was described in 1824 as *Blechnum voluble* Kaulf. (Kaulffuss 1824) and transferred in 1841 to the new genus *Salpichlaena* as *S. volubilis* (Kaulf.) J.Sm. (Smith 1841). A second name, *Lomaria volubilis* Hook., appeared in 1860 (Hooker 1860) and was changed to *Spicanta hookeriana* by Kuntze in 1891 (Kuntze 1891). Later on, Alston (1932) transferred the species to *Salpichlaena* as *S. hookeriana* (Kuntze) Alston. In 1990, A.R. Smith made a new combination, *S. lomarioidea* (Baker) A.R.Sm., based on *Blechnum voluble* var. *lomarioidea* Baker (Smith 1990), but later he treated this as a synonym of *S. hookeriana* (Smith 1995). The most recent species described in the genus is *S. thalassica* Grayum & R.C.Moran (Moran 1990).

The number of taxa recognised within the genus *Salpichlaena*, as well as their delimitation and appropriate taxonomic rank, has been controversial. Different authors have given different taxonomic significance for the observed morphological variation. Some have recognised 'geotypes' (Vareschi 1969) or varieties (Baker 1870, Smith 1990) within broadly defined species. Tryon & Tryon (1982) denied the validity of *Lomaria volubilis* (*S. hookeriana*) even as a form and accepted only a single species. Murillo (2001) came to the same conclusion based on morphological investigation of Colombian material, and attributed the morphological variation to climatic and edaphic conditions. Giudice et al. (2008) accepted two species, *S. hookeriana* and *S. volubilis*, in their revision of the genus. They argued that the diagnostic characters of *S. thalassica*

¹ Ølgaaard 2395 is a mixed collection with sheet 1/3 representing *S. papyrus* and sheets 2–3/3 representing *S. volubilis* subsp. *amazonica*.² The accession numbers beginning with KJ were published in Lehtonen et al. (2015).

(elevation of occurrence and length of the petiolule of the basal fertile pinnule) were not consistent, and consequently synonymized this name under *S. volubilis*.

A pervasive problem for taxonomical studies on *Salpichlaena* is the morphological variability found in the herbarium material due to the climbing habit and indeterminate growth of the 2-pinnate fronds. Pinna size and morphology vary along the rachis and possibly also directly in response to height from the ground and/or light conditions in the forest canopy (pers. obs.). It is in practice impossible to collect an entire climbing frond, so herbarium material of *Salpichlaena* is almost always incomplete, and usually the label provides no information on the relative position of the preserved pinnae. Obviously, the non-climbing fronds would fit on a herbarium sheet, but they are never fertile. Since most collectors avoid gathering sterile material, the non-climbing fronds are poorly represented in herbaria. Consequently, specimens in herbaria are generally represented by one or two pinnae taken from an undefined part of the climbing frond, which complicates comparative taxonomic work. Such discrimination against non-climbing fronds is unnecessary, since our experience is that climbing and non-climbing fronds can usually be identified to species equally well: sterile pinnae have similar scales as well as similar lamina texture, margins and apices whether they are climbing or not.

As a complementary tool for traditional taxonomic methods, quite a few molecular methods for species delimitation have been developed (e.g., Doyle 1995, Brower 1999, Puillandre et al. 2012, Zhang et al. 2013). These take into account genetic relatedness and thereby can provide a more objective way than visual inspection to establish species boundaries.

Here we combine morphological and molecular methods:

1. to establish the delimitation among and number of species or other taxa in the genus *Salpichlaena*;
2. to propose a phylogenetic hypothesis for the evolutionary relationships of the taxa; and
3. to provide a key to the species.

MATERIALS AND METHODS

Morphological studies

We measured 62 morphological traits on 283 *Salpichlaena* specimens, and studied 1074 specimens deposited in AAU, CAY, INPA, K, P, TUR, US and USM herbaria (all herbarium acronyms according to Thiers, continuously updated). We observed the shape of fronds, pinnae and pinnules as well as their margin and apex type, lamina texture, lamina dimorphism and presence of foliar buds. We measured the fronds, pinnae, pinnules, petioles, petiolules and scales with a ruler and a caliper. We used the stereoscope and microscope to observe and measure scales, hairs, stomata and spores. In addition,

to infer the distribution and range of morphological variation within the taxa, we studied more than 1000 specimens from the digital collections of several herbaria (AAU, ALCB, AMAZ, BHCB, BM, CAY, CR, CVRD/VALE, F, FLOR, FURB, HUEFS, INPA, K, LE, MO, NY, P, RON, SP, SPF, UC, UEC, US, USM and Z). Digital images of BHCB, BM, CR, LE, MO, SPF, UC and Z herbaria were provided by the curators; ALCB, CVRD, FLOR, FURB, HUEFS, part of INPA, RON and UEC were obtained from INCT-Herbario Virtual da Flora e dos Fungos (<http://inct.splink.org.br>); F from Field Museum webpage (<http://emuweb.fieldmuseum.org/botany/detailed.php>); AAU, AMAZ, K, P, US and USM images were taken by GC; CAY by SL; and NY and SP by HT. Representative specimens for each geographical region are mentioned under Additional specimens seen. The complete list of specimens studied is provided in the Identification list of *Salpichlaena* specimens. Herbarium barcodes, named 'code(s)', are used when collector and collection number are not available.

Molecular studies

Laboratory procedures

We used herbarium material as well as silicagel dried material for DNA extractions (Table 1). Total genomic DNA was extracted from 52 *Salpichlaena* and 11 outgroup specimens (Table 1). For the extractions we used E.Z.N.A. SP Plant DNA Kit (Omega Bio-tek, Doraville, Georgia) following the protocol for dry samples or NucleoSpin Plant II kit (Macherey-Nagel, Germany). Polymerase chain reaction (PCR) amplifications were executed using PuReTaq Ready-To-Go (PCR) Beads (GE Healthcare UK Limited). PCR was used to amplify the plastid genes *rbcL*, *rpoC1* and *rps4*, and plastid intergenic spacers *rps4-trnS*, *trnH-psbA* and *trnG-trnR*, and the nuclear gene *pgiC*. The PCR tubes contained approximately 32 µl of solution composed by 25 µl of ddH₂O, 1 µl of each primer and 5 µl of the extraction template. PCR primers and protocols are detailed in Table 2. Purification and sequencing of the PCR products was done by Macrogen Inc. (Seoul, South Korea). Sample information and GenBank accession codes are listed in Table 1. The final data matrices and the resulting trees are available in TreeBASE (study number TB2:S22278).

Phylogenetic analyses

We used PhyDe version 1.0 (Müller et al. 2010) to examine the DNA sequences, to compare forward and reverse chromatograms and to edit them. The sequences were aligned with default parameters using MAFFT version 7.149 (Katoh & Standley 2013). We then used Bayesian Information Criterion to select the best model for each marker using jModelTest-2.1.10 (Darriba et al. 2012). Since variation in sequence length is generally considered to be phylogenetically relevant information (e.g., Giribet & Wheeler 1999, Simmons et al. 2001), we

performed simple gap coding (Simmons & Ochoterena 2000) to the aligned sequences using SeqState 1.4.1 (Müller 2005). The aligned DNA sequences and binary coded gap data were combined for data analyses. Following the results of model testing, the evolutionary model for *pgiC*, *trnH-psbA*, *rps4*, *rps4-trnS* and *trnG-trnR* was set to HKY+G with default flat Dirichlet prior probability distribution and for *rbcL* and *rpoC1* to K80+G with a fixed (equal) prior probability distribution. For the binary coded gap data a Standard Discrete Model was applied with options coding = variable and rates = gamma to accommodate lack of constant characters and variable rates of change. We performed Bayesian inference with MrBayes version 3.2 (Ronquist et al. 2012) to build phylogenetic trees for each marker. Four chains of 10 000 000 generations were run sampling every 1 000th generation. After verifying that the resulting trees had no supported conflict (PP > 0.75), we combined the five plastid datasets with SequenceMatrix (Meier et al. 2006). However, conflict was observed between the trees of plastid and nuclear markers and the nuclear *pgiC* was analysed separately. Final trees were inferred as above, except that for *pgiC* 5 000 000 more generations were run in order to achieve convergence. The first 25 % of trees were discarded as burn-in and a 50 % majority rule consensus tree was calculated from the remaining trees. FigTree v. 1.4 (Rambaut 2006–2012) was used for editing the tree.

Molecular species delimitation

We applied two molecular species delimitation methods to our chloroplast dataset to investigate putative species boundaries within *Salpichlaena*. First, we analysed the aligned sequences using Automatic Barcode Gap Discovery (ABGD; Puillandre et al. 2012) on the webserver (<http://wwwabi.snv.jussieu.fr/public/abgd/abgdweb.html>). This method assumes that the degree of sequence divergence is larger between than within species, and that the interspecific sequence divergence range does not overlap with the intraspecific divergence range, resulting in a barcode gap in pairwise differences between individual sequences (Puillandre et al. 2012). We detected barcode gaps separately for each molecular marker using an intraspecific prior divergence ranging from P = 0.001 to P = 0.1, the default proxy for the minimum gap width X = 1.5, and applying the Kimura 2-Parameter evolution model (Kimura 1980). Out-group sequences were excluded from the alignments before the analyses. ABGD allows recursive partitioning in which the initial partitions can be further split if an additional barcode gap is detected inside the partition (Puillandre et al. 2012). This generally results in a higher number of putative species and poorer match with established taxonomies (Puillandre et al. 2012). We therefore ignored recursive partitioning here and only consider the initial partitions.

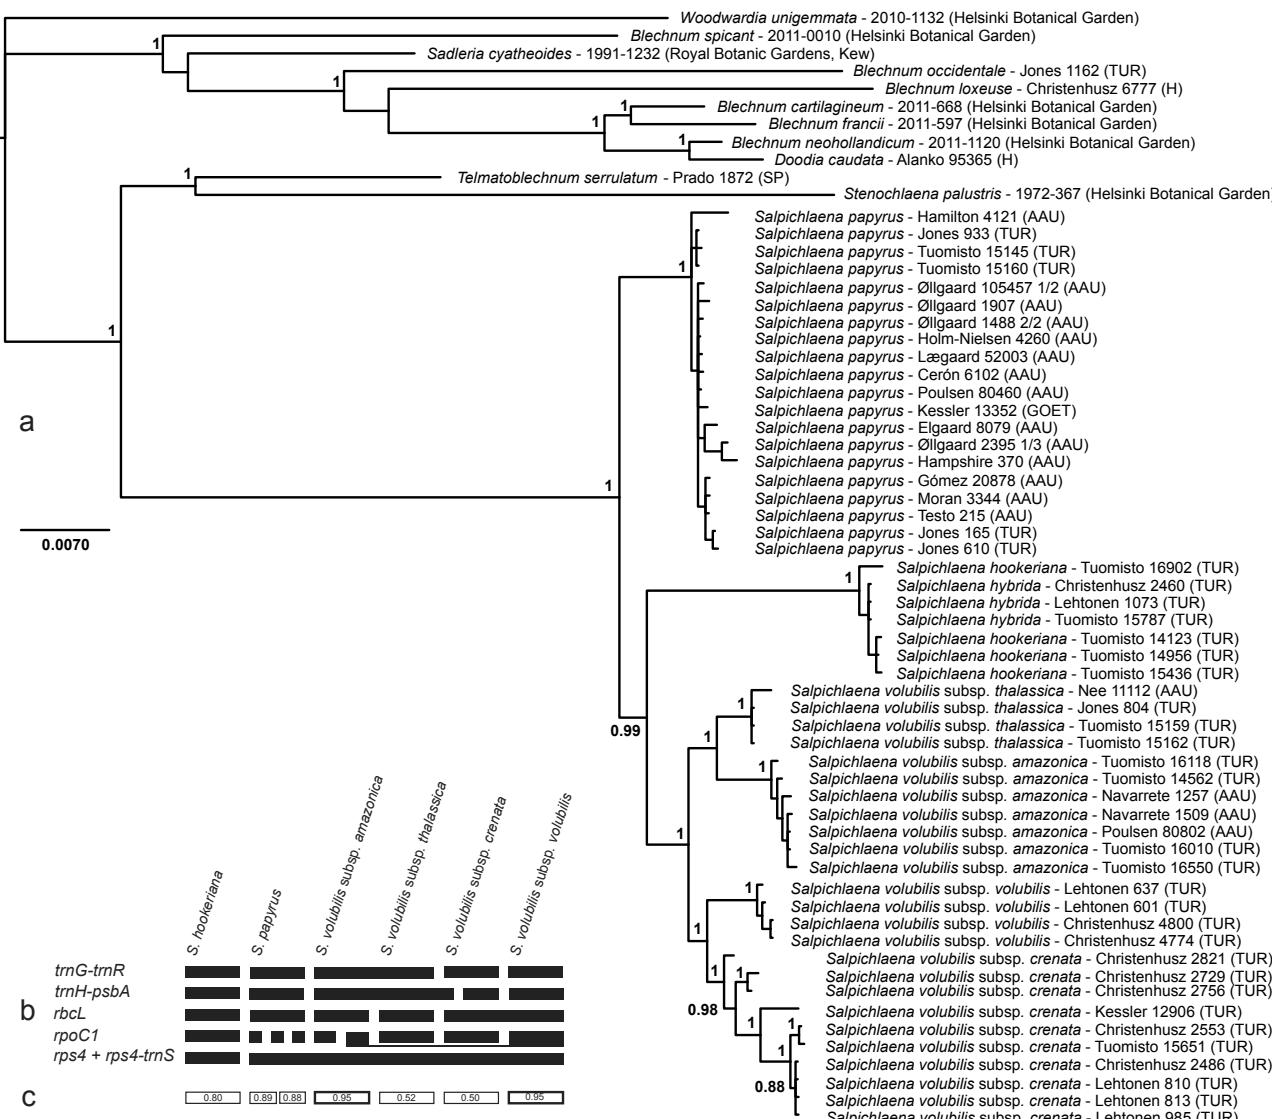

Fig. 1 Plastid phylogeny and species delimitation. a. A Bayesian majority rule consensus tree based on the combined data of five plastid markers with posterior probabilities shown at the nodes; b. ABGD species delimitation at prior maximum divergence of intraspecific diversity 1.67×10^{-3} ; c. bPTP species delimitation with posterior probabilities.

In addition, we applied a Bayesian implementation of the Poisson Tree Processes model (bPTP) to delimit species boundaries based on a phylogenetic input tree and the number of substitutions on its branches (Zhang et al. 2013). This method assumes that the number of substitutions is significantly higher between species than within species. We used the tree obtained from a combined analysis of five plastid markers as input tree and ran 200 000 MCMC generations in the bPTP webserver (<http://species.h-its.org/ptp/>) with a thinning value of 100 and 15 % burn-in.

RESULTS

Molecular phylogenetics

The alignment of the combined plastid markers consisted of 3 950 base pairs. The resulting phylogenetic tree shows a well supported *Salpichlaena* as sister to a well supported clade formed by *Telmatoblechnum* and *Stenochlaena* (Fig. 1). Within *Salpichlaena*, the tree shows six major clades with high support. We recognise the three deepest clades at species level: *S. hookeriana*, *S. papyrus* sp. nov. and *S. volubilis*. Within *S. volubilis*, we recognise the four distinct clades at subspecific level: subsp. *amazonica* subsp. nov., subsp. *crenata* subsp. nov., subsp. *thalassica* stat. nov. and subsp. *volubilis* (Fig. 1). Our nuclear phylogenetic tree is generally very poorly resolved, but it shows *S. hookeriana*, *S. volubilis* subsp. *amazonica* and *S. volubilis* subsp. *thalassica* as well-supported clades. *Salpichlaena volubilis* subsp. *crenata*, *S. papyrus* and *S. volubilis* subsp. *volubilis* remain unresolved (Fig. 2). A set of specimens that are unresolved within *S. hookeriana* in the plastid tree are

nested in a single clade with high support within *S. volubilis* subsp. *amazonica* in the nuclear tree. We propose that these specimens represent a new species that has emerged from a single hybridization event between *S. hookeriana* (the maternal parent) and *S. volubilis* subsp. *amazonica* (the paternal parent), and recognise this taxon as *S. hybrida* sp. nov.

Morphology

We found that the most useful characters to differentiate *Salpichlaena* species and subspecies are: degree of foliar dimorphism, apical incisions and texture of the lamina, margin type, shape of the scales on the abaxial axes, presence or absence of foliar buds, and the appearance of the abaxial surface of the lamina. A single character is typically not enough for reliable identification, but two or three characters in combination usually are.

Salpichlaena hookeriana and *S. papyrus* differ from *S. volubilis* and *S. hybrida* by having strongly serrate apices in sterile pinnae and pinnules (Fig. 3). Apices are entire in *S. hybrida* and *S. volubilis*, although in some subspecies of *S. volubilis* they can be crenate or even slightly serrate (Fig. 3). Because serration is generally less obvious in fertile pinnules, *S. papyrus* is most reliably distinguished from *S. volubilis* on the basis of sterile pinnules.

Salpichlaena hookeriana is unique in its foliar dimorphism, which is so strong that fertile pinnules are almost devoid of lamina (Fig. 5). Furthermore, *S. hookeriana* often has a foliar bud at the base of one or more pinnae or pinnules in the climbing fronds (Fig. 4b), a character that is extremely rare in *S. papyrus* and has never been observed in *S. hybrida* or *S. volubilis*.

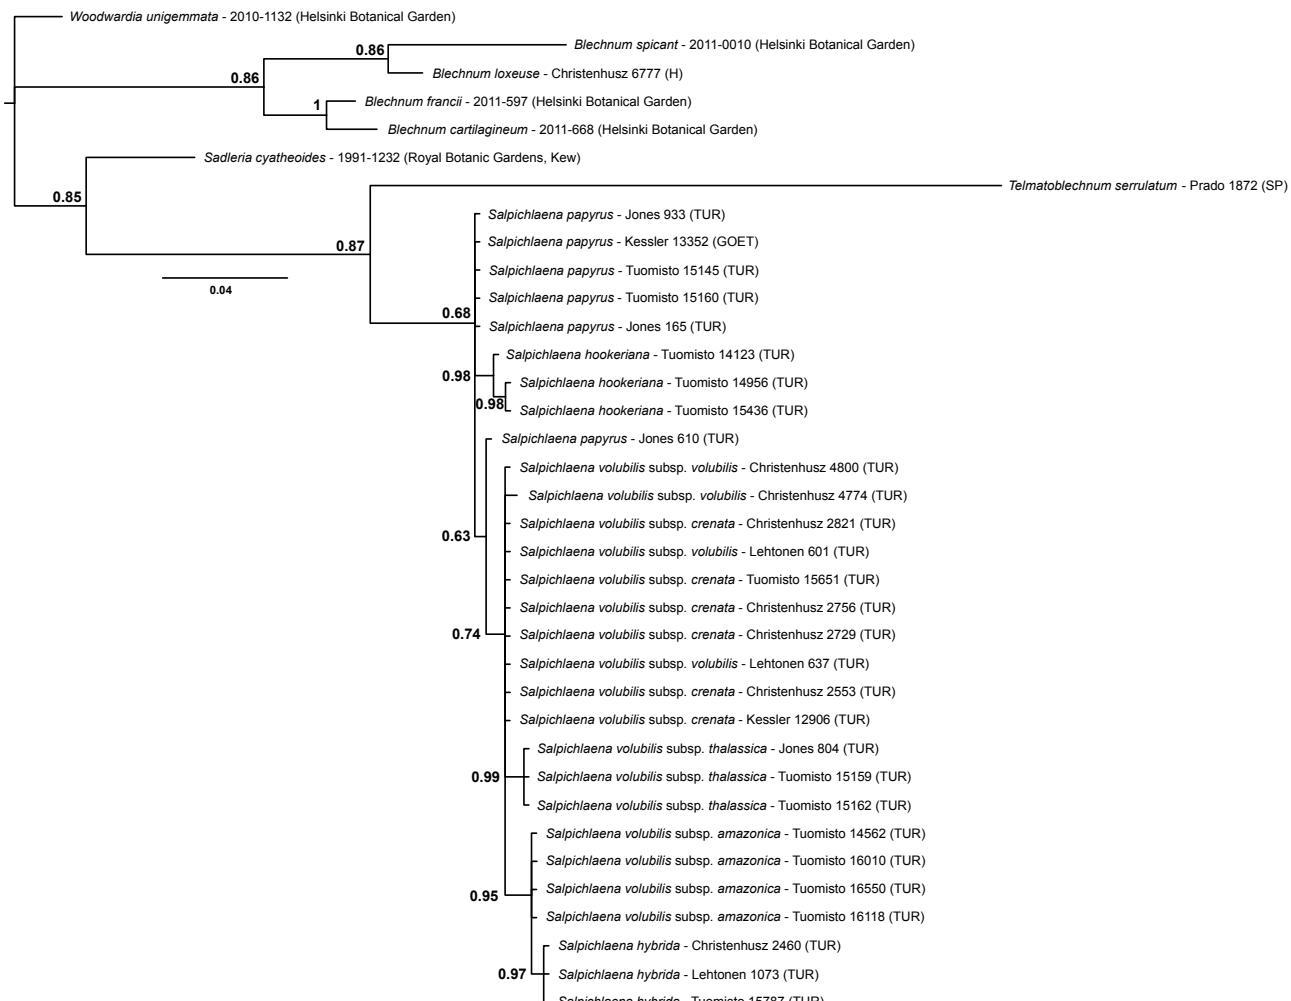

Fig. 2 A Bayesian majority rule consensus tree based on the nuclear *pgIC* gene with posterior probabilities shown at the nodes.

Fig. 4 *Salpichlaena*. a. Habit of a climbing adult *S. volubilis* subsp. *volubilis*; b. foliar bud of *S. hookeriana*; c. sori covered by indusia, *S. volubilis* subsp. *volubilis*; d. costal scales of *S. papyrus*; e. abaxial lamina of *S. volubilis* subsp. *thalassica* with stomata on white laminal protuberances; f. abaxial lamina of *S. volubilis* subsp. *amazonica* uniform without white protuberances; g. non-climbing fronds of *S. volubilis* subsp. *amazonica* (b. Cárdenas 1755; c. Christenhusz 4800 2/2; d. Jones 165; e. Jones 650; f. Navarrete 1509; b–e.TUR; f. AAU). — Scale bar: 1 cm.

Salpichlaena papyrus differs from all other species in that the scales on costulae, costae and rachises are either broad and resemble crumpled paper or are ovate with small or no appendices (Fig. 4d). In the other species, scales are more slender and have long appendices.

Although we did not find clear-cut differences between the *S. volubilis* subspecies, we found some character combinations that usually identify them.

Fronds, pinnae and pinnules of subsp. *amazonica* and subsp. *thalassica* have cartilaginous margins and entire or almost entire apices with a few small, sometimes serration-like teeth that are limited to the cartilaginous margin and do not cut into the lamina tissue (Fig. 3d, f). These subspecies have also chartaceous to coriaceous texture and generally broader sterile pinnules (2.4–8.6 cm) than the other taxa (1.2–5 cm). Under the stereoscope, subsp. *thalassica* can usually be differentiated from subsp. *amazonica* by the location of the stomata on small whitish protuberances of the lamina, whereas in *S. amazonica* the abaxial side of the lamina looks uniform (Fig. 4e–f).

The key characters to differentiate *S. volubilis* subsp. *volubilis* from the other taxa are the entire frond/pinna/pinnule apices (Fig. 3g), herbaceous lamina texture, and lack of cartilaginous margin in sterile pinnae (in fertile pinnae, both the lamina and the margin are slightly thickened). *Salpichlaena volubilis* subsp. *crenata* has crenate (Fig. 3e) to slightly serrate pinnule apices, but in contrast to subsp. *thalassica* and subsp. *amazonica*, the incisions cut through the only slightly cartilaginous margin to the lamina.

In accordance with its postulated hybrid origin, *S. hybrida* shares characters with both *S. hookeriana* and *S. volubilis* subsp. *amazonica*. The length and width of pinnae in the 1-pinnate non-climbing fronds are similar to those in subsp. *amazonica*, but *S. hybrida* has a more herbaceous lamina texture. In contrast, pinnules in the 2-pinnate climbing fronds of *S. hybrida* resemble more the pinnules of *S. hookeriana* in size, texture and shape, but the pinnule apices are entire in the former and serrate in the latter.

Species delimitation analyses

The number of species delimited by ABGD varied depending on the molecular marker and the prior maximum intraspecific divergence (P) that was used (Table 3; Fig. 1b). The most consistent results were obtained with *rbcL*, *trnH-psbA* and *trnG-trnR*, all of which recognised five taxa throughout the P values used. Out of the five taxa, however, only *S. papyrus* and *S. hookeriana* were identically delimited by these markers. Within *S. volubilis*, alternative delimitations emerged. Both *trnH-psbA* and *trnG-trnR* indicated that *S. volubilis* subsp. *thalassica* and subsp. *amazonica* are conspecific, whereas *rbcL* recognised them as distinct species. On the other hand, subsp. *crenata* and subsp. *volubilis* were grouped together as a single species by *rbcL*, but recognised as separate species by *trnG-trnR* and mixed as two non-monophyletic species by *trnH-psbA*. The remaining molecular

markers (*rps4*, *rps4-trnS*, *rpoC1*) were less conclusive, although *S. hookeriana* was consistently recognised (Fig. 1b)

The bPTP analysis recognised seven species within *Salpichlaena*, but only two of them received a Bayesian posterior value $\geq 95\%$ (*S. volubilis* subsp. *amazonica* $Bpp = 0.99$ and subsp. *volubilis* $Bpp = 0.95$). Two species were recognised within *S. papyrus* ($Bpp = 0.89$ and $Bpp = 0.88$). The remaining species recognised by bPTP were *S. hookeriana* ($Bpp = 0.80$), *S. volubilis* subsp. *thalassica* ($Bpp = 0.52$) and *S. volubilis* subsp. *crenata* ($Bpp = 0.50$) (Fig. 1c).

DISCUSSION

The phylogenetic position of *Salpichlaena* as sister to the clade formed by *Telmatoblechnum* and *Stenochlaena* in our tree is congruent with the current understanding of the evolutionary history of Blechnaceae (Lehtonen 2011, Perrie et al. 2014, De Gasper et al. 2017).

Based on our results, we suggest a new classification for *Salpichlaena*: it contains four species, one of which has four subspecies. Out of the formerly described species, we accept two, *S. hookeriana* and *S. volubilis*, at the species rank, but place *S. thalassica* at the subspecific rank within *S. volubilis*. We describe two new species, *S. papyrus* and *S. hybrida*, and two new subspecies, *S. volubilis* subsp. *amazonica* and *S. volubilis* subsp. *crenata*.

On morphological grounds, we have considered *S. hookeriana*, *S. papyrus* and *S. volubilis* as distinct species for some time already (see Tuomisto & Groot 1995 for discussion on *S. hookeriana* and *S. volubilis*; *S. papyrus* was referred to as *Salpichlaena* sp. 1 in Jones et al. 2006, 2008). Here we recognise all three at the species rank. They are morphologically distinct and the fact that they form well-supported clades in the plastid phylogeny despite overlapping distributions in Amazonia suggests that they are independent evolutionary lineages. Furthermore, the species delimitation analyses were mostly congruent at this level: both ABGD and bPTP invariably supported *S. hookeriana* as distinct species, and almost always recognised *S. papyrus*.

A group of specimens from the Guyana shield was found to have some morphological characters of *S. hookeriana* and others similar to *S. volubilis* subsp. *amazonica*. We were able to sequence some of these specimens, and they consistently grouped together with *S. hookeriana* in the plastid phylogeny but were nested as a clade within *S. volubilis* subsp. *amazonica* in the nuclear *pgiC* tree. Based on this, we suggest that they represent hybrids between the two taxa. Because the chloroplast genome is maternally inherited in ferns (Gastony & Yatskievych 1992, Vogel et al. 1998), we consider *S. hookeriana* as the maternal progenitor and *S. volubilis* subsp. *amazonica* as the paternal progenitor. Interestingly, the proposed hybrids seem to be absent from most of Amazonia where the putative parent taxa co-occur. The distribution of the three species only

overlaps in northern Brazil and in the Guianas, which may be the area where the original hybridization took place. Unfortunately, we have not been able to study the morphology or viability of the spores, as none of the physical specimens we have had access to was fertile.

The *S. volubilis* clade is a taxonomical challenge. The specimens vary morphologically and different molecular species delimitation analyses gave different suggestions on how to split it. The ABGD delimitation split this clade differently for each molecular marker, and none of these delimitations was congruent with the bPTP delimitation, which split the clade into four species (Fig. 1b–c). However, the four clades recognised in the plastid consensus tree received high support. Mostly we found these four clades allopatric and morphologically distinguishable, but specimens with intermediate characteristics were found especially in the areas where two clades meet. Such behaviour is considered typical for taxa of subspecific rank (Mayr 1942, Patten 2015).

Salpichlaena volubilis subsp. *thalassica* can usually be identified from *S. volubilis* subsp. *amazonica* by the location of stomata on white laminal protuberances in the former. However, in the northernmost part of the Andes, this characteristic is not so obvious and morphological delimitation of these taxa may not be possible. Likewise, some specimens of *S. volubilis* subsp. *amazonica* approach in their appearance *S. volubilis* subsp. *crenata*. *Salpichlaena volubilis* subsp. *crenata* from the Caribbean and northern South America and *S. volubilis* subsp. *volubilis* from the Atlantic Forest are generally distinct, but again, some specimens are morphologically indistinguishable. Within *S. volubilis* subsp. *crenata*, there are four smaller well-supported clades with specimens of somewhat distinct morphologies between the clades. Such variability could suggest the presence of further subspecies in this clade, but we did not have enough material from the relevant areas to test if the differences are consistent.

Our conclusions disagree with those of Vareschi (1968), who recognised *S. volubilis* as a single species having two ‘geotypes’. His drawings indicate the presence of big scales in the axes of ‘geotype’ *euvolubilis* (Fig. T100-2 in Vareschi 1968) and strong frond dimorphism in ‘geotype’ *maegdefrauiana* (Fig. T100-3,4 in Vareschi 1968). We conclude that the former ‘geotype’ corresponds to *S. papyrus* and the latter to *S. hookeriana*.

Similarly, Murillo (2001) accepted only one polymorphic species in the genus based solely on material from Colombia. We have checked the specimens listed in her publication and found them to represent three taxa as defined here: *S. hookeriana* (e.g., Schultes 15410, US), *S. papyrus* (e.g., Forero 5461, US) and *S. volubilis* subsp. *thalassica* (e.g., Haught 1299, US). Murillo (2001) based her conclusion on the variability of characters and on the measurements of pinnae and pinnules. Although we agree that *Salpichlaena* is morphologically highly variable, we find characters like foliar dimorphism, incisions of pinna and pinnule apices, and shape of scales consistent enough to be used to delimit morphologically cohesive groups. The fact that these correspond with groups identified by molecular markers further supports treating them as different taxa.

Moran (1990) originally described *S. thalassica* on the basis of blue-green fronds, the occurrence of the species on higher elevations and the long stalks of the basal fertile pinnules. Giudice et al. (2008) disagreed with the significance of these characters and pointed out that the length of the basal fertile pinnule stalk did not correlate with the elevation when viewed over a larger geographical extent. In addition, since they could not observe the colour differences in herbarium material, they did not find support for separating *S. thalassica* from *S. volubilis*.

We did not have an opportunity to make a systematic study of frond colour in the field, and since herbarium specimens invariably lose their original lamina colour, we are unable to confirm whether the colour is a diagnostic character. The length of the petiolule of the basal fertile pinnule seems not to be diagnostic: it differs little between subsp. *thalassica* (up to 1.7 cm) and the other taxa (up to 1.5 cm).

Given that Grayum & Moran in Moran (1990) focused on specimens from Costa Rica and Panama, it seems clear that they were comparing *S. volubilis* subsp. *thalassica* with *S. papyrus*. Hence, we agree with their original conclusion that there are two distinct species in the area. However, they happened to describe as a new species the one we consider to be distinct from the type of *S. volubilis* only at the subspecies level.

We agree with Giudice et al. (2008) that important diagnostic characters to differentiate *S. hookeriana* from *S. volubilis* are foliar dimorphism and presence of foliar buds. They also mentioned the appearance of the costal scales, which we found to be useful to distinguish *S. papyrus* (whose scales are more generally formless and resemble crumpled paper) from all the other taxa (whose scales are lanceolate to ovoid and always have long appendices). Giudice et al. (2008) also mentioned that *S. hookeriana* can be differentiated from *S. volubilis* by the presence of glandular hairs on the abaxial surface of the costa, but we have observed microscopic hairs more often in *S. volubilis* subsp. *thalassica* and subsp. *amazonica* than in *S. hookeriana*.

A major obstacle for *Salpichlaena* taxonomy is that herbarium specimens tend to be incomplete. Although it is unpractical to collect an entire climbing frond, it is important to collect both sterile and fertile material. The taxon-specific diagnostic characters are, for most *Salpichlaena* taxa, much more obvious in sterile than in fertile pinnae. Therefore, sterile specimens (including those consisting of non-climbing fronds only) can usually be identified all the way to the subspecific level, but specimens consisting of fertile pinnae only are more difficult to identify.

TAXONOMIC TREATMENT

Salpichlaena

Salpichlaena J.Sm. (1841) 168. — Type: *Salpichlaena volubilis* (Kaulf.) J.Sm. (1841) 168.

Terrestrial. Rhizome long-creeping, dorsiventral, 0.3–0.8 cm diam; scales 2–5(–9) mm long, brown to black, usually with a lighter margin. Fronds almost monomorphic to strongly dimorphic, with twining rachises, up to 15 m long. Petioles abaxially terete, adaxially sulcated with one omega-shaped vascular bundle, glabrous, with catenate hairs and yellowish to brown scales. Laminae entire in juveniles, 1- (or 2-)pinnate in non-climbing and 2-pinnate in climbing fronds. Pinnae subopposite to opposite; herbaceous to coriaceous, margin cartilaginous to not cartilaginous, catenate hairs of 2 or 3 cells on abaxial side of the lamina, mostly on the veins; axes glabrous, sparsely hairy or scaly, veins parallel, simple or once-forked. Pinnules subopposite to opposite (alternate), fertile ones generally narrower than sterile, lanceolate, elliptic to oblanceolate, petiolulate to sessile or winged; apex acuminate, attenuate, caudate, cuspidate or cuneate, with entire, crenate or serrate margin, base round to attenuate. Sori linear at both sides of the costule covered by a firm dark-brown indusium that opens towards the costa, paraphyses absent. Spores monolet, ellipsoid-reniform with vesicles on the surface, monolet, 0.7–1 µm; n = 40 (Walker 1973; count from Trinidad).

IDENTIFICATION KEY TO SPECIES

1. Fertile pinnae almost without lamina; apices of sterile pinnae/pinnules serrate; pinnae/pinnules elliptic; laminar buds common in climbing fronds at the pinna bases 1. *S. hookeriana*
1. Fertile pinnae with lamina; apices of sterile pinnae/pinnules entire, crenate or serrate; if serrate, pinne/pinnules lanceolate; laminar buds in climbing fronds absent or very rare 2
2. Apices of sterile pinnae/pinnules obviously serrate; costal scales broad and shapeless, like crumpled paper, or ovate with or without small appendices 3. *S. papyrus*
2. Apices of sterile pinnae/pinnules entire, crenate to slightly serrate; costal scales lanceolate or ovate, always with long appendices 3
3. Sterile pinnae/pinnules broadly elliptic to oblanceolate, herbaceous, margin sometimes slightly cartilaginous 2. *S. hybrida*
3. Sterile pinnae/pinnules of variable shape; if broadly elliptic, then chartaceous-coriaceous with clearly cartilaginous margin, if lanceolate, then herbaceous-chartaceous with only slightly or not at all cartilaginous margin 4. *S. volubilis*

1. *Salpichlaena hookeriana* (Kuntze) Alston — Fig. 3a, 4b, 5; Map 1

Salpichlaena hookeriana (Kuntze) Alston (1932) 312.

Lomaria volubilis Hook. (1860) 39. — *Blechnum volubile* Kaulf. var. *lomarioidea* Baker (1870) 428. Replacement name for *Lomaria volubilis* Hook. at a new rank. — *Spicanta hookeriana* Kuntze (1891) 821. Replacement name for *L. volubilis* Hook., non *Spicanta volubilis* (Kaulf.) Kuntze. — *Salpichlaena lomarioidea* (Baker) A.R.Sm. (1990) 250, nom. illeg. superfl. — Type: Spruce R 1263 (lectotype K K000633415, designated here; isolectotypes

K K000633413, K000633414, NY 02617982, 02617987, P P00347482), Brazil, Amazonas, Barra.

Etymology. Species named after William Jackson Hooker (1785–1865).

Non-climbing and sterile climbing fronds with herbaceous (chartaceous) lamina texture, pinnae and pinnule margins not cartilaginous; scales on abaxial axes lanceolate with long, sometimes bifurcated appendices (stick-like scales formed by a long apical row of cells and usually two shorter lateral basal cells); stomata rarely on white laminal protuberances. *Non-climbing* entire fronds up to 27 by 2.4 cm. Non-climbing 1-pinnate fronds 34–77 cm. Pinnae up to 6 pairs; apical one elliptic (lanceolate), 8.7–20.5 by 1.9–4.3 cm; lateral ones elliptic, oblanceolate (lanceolate), 9–19.7 by 1.8–4.4 cm; apex acuminate (attenuate), with serrate margin; base acute. *Climbing* fronds with pinnae strongly dimorphic, fertile pinnae almost without any laminar tissue. Pinnules opposite to subopposite. *Fertile pinnules* in 1–7 pairs; apical one linear, 12.4–36.3 by 0.1–0.4 cm; lateral ones linear, 8.4–31 by 0.1–0.4 cm. *Sterile pinnules* in 2–6 pairs; apical one elliptic (lanceolate), 12.7–35 by 2.4–5.8 cm, apex acuminate (attenuate) with serrate margin, serration sometimes extending more than 1/4 of the length of the pinnule, base acute, equilateral to slightly oblique; lateral ones elliptic (oblanceolate, lanceolate), 9–24.3 cm, apex acuminate, attenuate, base obtuse, cuneate, acute, equilateral to oblique; petiolulate, sessile, rarely winged; sometimes foliar buds on the base of pinnule.

Distribution — *Salpichlaena hookeriana* occurs mostly in Amazonia, reaching Mato Grosso do Sul in the south.

Habitat & Ecology — Primary lowland rain forest. Grows in poorly drained areas including palm swamps, near creeks and less often near paths. On brownish sandy and clay soil. Altitude 50–700 m.

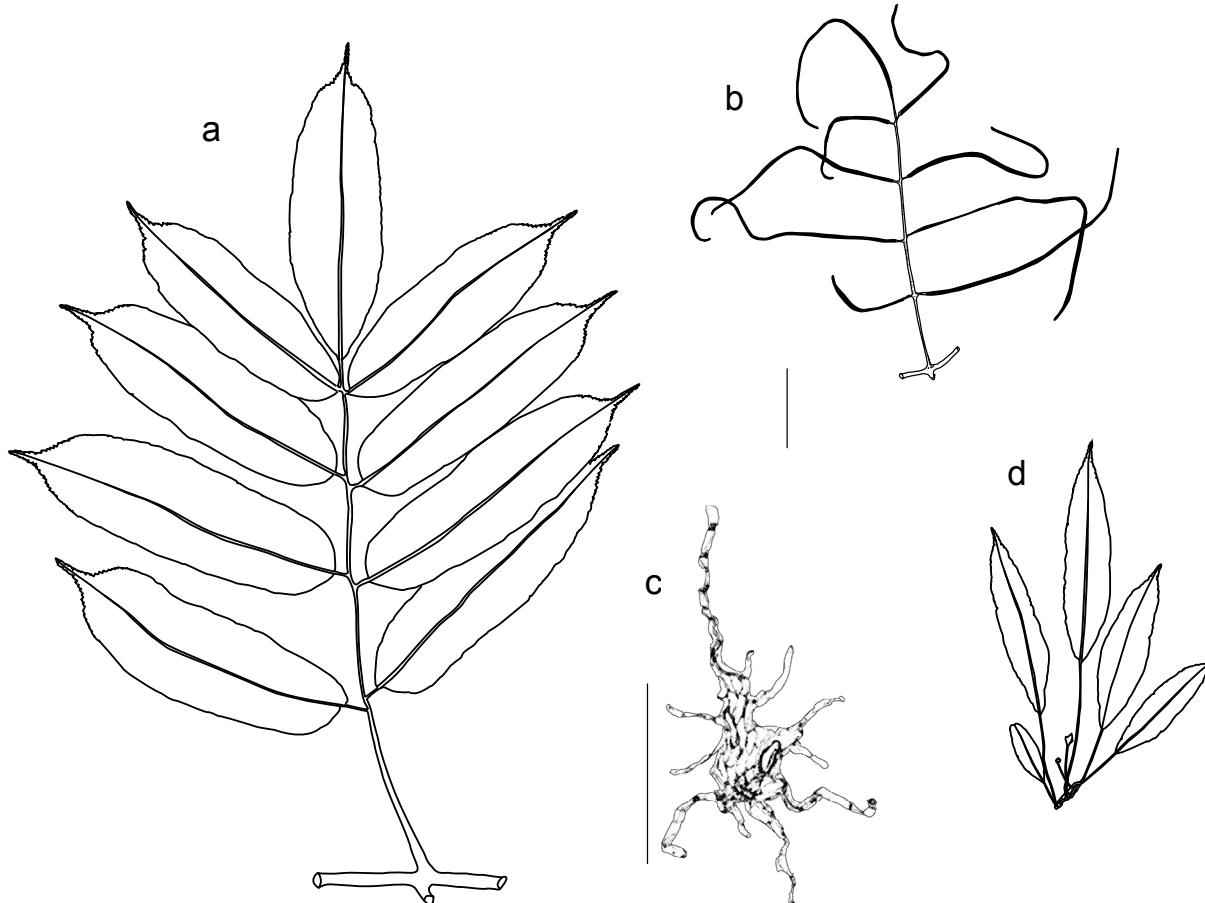

Fig. 5 *Salpichlaena hookeriana*. a. Sterile pinna; b. fertile pinna; c. costal scale; d. juvenile (a. Tuomisto 16902; b. Tuomisto 15436; c. Cárdenas 1754; d. Tuomisto 14771; all TUR). — Scale bar: a–b, d = 5 cm; c = 0.5 mm.

Additional specimens seen. BOLIVIA, Beni, 5 km NW of Guayaramerín, 24 Jan. 1978, Anderson WR 11824 (US). – BRAZIL, Amazonas, Mun. Presidente Figueiredo, na margem da Rodovia AM-240, 2 Feb. 2008, Prado J et al. 1863 (NY, SP, TUR); Carauari, 3–5 km north-west from the village of Lago do Pupunha, Río Juruá, S $5^{\circ}34'W67^{\circ}48'$, 100–140 m, 12 June 2012, Tuomisto H et al. 16902 (SP, TUR); Rio Preto da Eva, S $2^{\circ}37'W59^{\circ}37'$, 80–120 m, 23 Jan. 2008, Tuomisto et al. 15436 (INPA, SP, TUR). – COLOMBIA, Vaupés, Río Piraparaná (tributary of Río Apaporis), Caño Teemefía, S $0^{\circ}15'W70^{\circ}30'$, 10 Sept. 1952, Schultes RE & Cabrera I 17449 (US); Vichada, Gaviotas, Caño Urimica, 130–160 m, 8 Dec. 1972, Murillo TM 1582 (AAU, P). – GUYANA, Potaro-Siparuni, Pakaraima Mts, Ireng River, 4 km upstream from Kurutuik Falls along Topaima stream, N $5^{\circ}05'00''W60^{\circ}02'00''$, 685 m, 27 Oct. 1994, Mutchnick P et al. 240 (CAY, US); Upper Takutu-Upper Essequibo, Acarai Mts, 8 km S of Sipu River, N $01^{\circ}21'58''57'$, 610 m, 3 Sept. 1998, Clarke D et al. 7429 (CAY, US). – PERU, Loreto, Loreto, Río Pucacuro, S $3^{\circ}17'W74^{\circ}59'$, 100–200 m, 14 Jan. 2005, Tuomisto H et al. 14123 (AMAZ, TUR, UC, USM); Loreto, Río Tigre, S $3^{\circ}33'W74^{\circ}39'$, 100–200 m, 6 Feb. 2005, Tuomisto H et al. 14956 (AMAZ, TUR); Mariscal Ramón Castilla, Río Yaguasyacu, 2–5 km SW from the village of Puerto Izango, S $3^{\circ}18'W72^{\circ}1'$, 100–150 m, 23 May 1997, Tuomisto H et al. 11252 (AAU, AMAZ, TUR, UC, USM); Mariscal Ramón Castilla, Río Yaguasyacu, 2 km S from the village of Puerto Izango, S $3^{\circ}19'W72^{\circ}00'$, 100–150 m, 20 Aug. 1998, Tuomisto H et al. 12677 (AMAZ, TUR, USM); Maynas, Estación Biológica Quebrada Blanco, S $4^{\circ}21'W73^{\circ}9'$, 110 m, 17 Sept. 2010, Cárdenas GG et al. 1755 (AMAZ, TUR); Requena, Río Ucayali, 2 km N from the biological station Jenaro Herrera, S $4^{\circ}52'W73^{\circ}39'$, 100–200 m, 18 Sept. 1998, Tuomisto H et al. 12785 (AMAZ, TUR, USM). – VENEZUELA, Amazonas, Cerro Sipapo (Paráque), 2 Feb. 1949, Maguire B & Politi L 28766 (K, US).

Notes — *Salpichlaena hookeriana* is unique within the genus in the nearly complete absence of laminar tissue in fertile pinnales. Serrate apices of the sterile pinnae and the presence of foliar buds differentiate it from *S. hybrida* and *S. volubilis*. Foliar buds are common on climbing fronds and occur at the base of the pinnae and sometimes at the base of pinnules. They are more frequent in sterile than in fertile pinnae. Foliar buds have also been seen in *S. papyrus*, but only rarely. The non-climbing fronds of the *S. hookeriana* can be separated from the co-occurring *S. volubilis* subsp. *amazonica* by smaller size and higher number of pinnae.

The clearly serrate pinna/pinnule apices is a character that *S. hookeriana* shares with *S. papyrus* but not with the other species. The sterile fronds of these two species can be differentiated by the scales: in *S. hookeriana*, scales are lanceolate

and have long appendices, whereas in *S. papyrus* they are formless and resemble crumpled paper and usually lack appendices. In addition, *S. hookeriana* has elliptic pinnules with herbaceous texture whereas *S. papyrus* has more lanceolate chartaceous pinnules.

2. *Salpichlaena hybrida* Lehtonen, G.G.Cárdenas & Tuomisto, sp. nov. — Fig. 3b, 6; Map1

Intermediate between *S. hookeriana* and *S. volubilis* subsp. *amazonica*. Differs from the former by lack of foliar buds, presence of laminar tissue in fertile pinnae and larger pinnae in the non-climbing fronds; and from the latter by the herbaceous texture of the lamina and thin rather than cartilaginous pinna/pinnule margin. — Type: Christenhusz, M.J.M., Bollendorff, S.M., Maas, P.J.M. & Maas-van de Kamer, H. 2460 (holo TUR (mounted on three sheets: 576477, 576478, 576479); iso CAY, NY, U), French Guiana, Commune Montsinéry-Tonnégrande, Bagne des Annamites, km 15 along Route Départementale 5, near Rivière de Tonnégrande, N $4^{\circ}48'W52^{\circ}29'$, 21 Feb. 2003.

Etymology. The specific epithet refers to the postulated hybrid origin of the species.

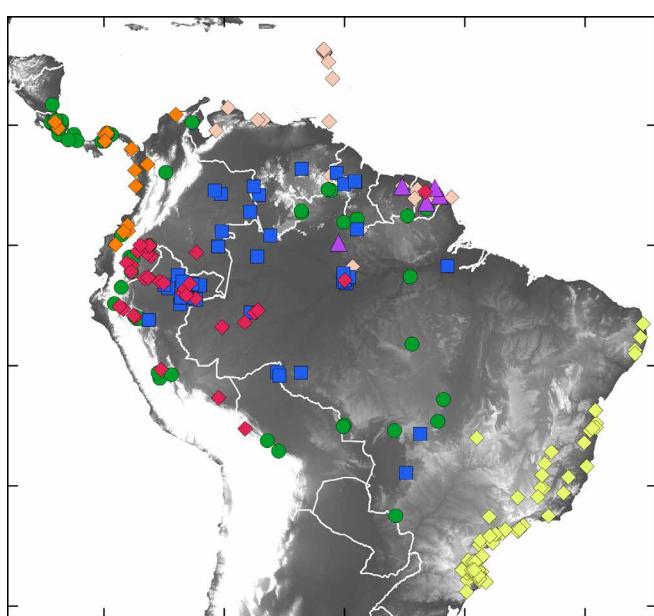

Climbing and non-climbing fronds with herbaceous lamina texture, pinnae and pinnule margins not cartilaginous (to slightly cartilaginous); scales on abaxial axes lanceolate with long appendices sometimes divided and bifurcate, some stick-like scales formed by a long apical row of cells and usually two shorter basal lateral cells; stomata rarely on white laminal protuberances. Non-climbing 1-pinnate fronds 62–151 cm. Pinnae up to 4 pairs; apical one elliptic (ob lanceolate), 22.6–46 by 6.4–8 cm; lateral ones ob lanceolate, 22.7–35 by 6–7.2 cm; apex acuminate (caudate), with entire (slightly serrate) margin; base obtuse, acute. Climbing fronds with dimorphic pinnae. Pinnules opposite to subopposite. Fertile pinnales in up to 6 pairs; apical one elliptic, lanceolate, slightly ob lanceolate, 20 by 4.1 cm, apex caudate, entire, base acute, oblique up to 0.1 cm; lateral ones elliptic (ob lanceolate), 19.5 by 4.1 cm, apex caudate, entire, base obtuse, slightly oblique. Sterile pinnales in 2–4 pairs; apical one elliptic, slightly ob lanceolate, 13–20 by 3.8–6.6 cm, apex acuminate (caudate), entire to slightly serrate, base acute, slightly oblique; lateral ones ob lanceolate, 9.5–15.8 by 2.9 cm, apex acuminate, caudate, entire, base obtuse, equilateral to oblique; petiolulate, rarely sessile or winged.

Distribution — *Salpichlaena hybrida* occurs in northern Brazil (Roraima), French Guiana and Suriname.

Habitat & Ecology — Terra firme rain forest, on white sand and poorly drained soil, close to creeks and paths. Altitude 0–130 m.

Additional specimens seen (paratypes). BRAZIL, Roraima, Rorainópolis, about 5 km W along a side road starting at km 120–130 (RR) of the Manaus - Boa Vista road, N $0^{\circ}13'W60^{\circ}29'$, 80–130 m, 18 Feb. 2008, Tuomisto H et al. 15787 (TUR). – FRENCH GUIANA, Cayenne, road N2 from Régina to Saint-Georges de l'Oyapock, km 127, N $4^{\circ}9'W52^{\circ}6'$, 70 m, 29 Oct. 2013, Lehtonen S & Geniez C 1073 (CAY, TUR); environs du lieu-dit 'Roche-bateau', sur la Crique Nouvelle-France, 11 Mar. 1976, Raynal A & Tirel C 18572 (P). – SURINAME, Brokopondo, Brownsberg Nature Park, Mazaroni vallen, waterfalls on very steep slope of at least 60°, N $4^{\circ}56'W55^{\circ}12'$, 400–500 m, 6 Mar. 2003, Christenhusz MJM & Bollendorff SM 2581 (TUR).

Notes — The climbing sterile pinnae are elliptic and similar in appearance to those of *S. hookeriana*, but the pinnule apices are entire instead of serrate. Non-climbing fronds are similar to those of *S. volubilis* subsp. *amazonica* in having large pinnae, but in *S. hybrida* they have herbaceous texture and lack the cartilaginous margin. *Salpichlaena hybrida* can be differentiated from *S. papyrus* by the entire pinnule apices and by the scales similar to those in *S. hookeriana* in contrast to the scales of *S. papyrus* resembling crumpled paper. *Salpichlaena hybrida* differs from *S. volubilis* subsp. *volubilis* by shorter and broader pinnales, and from *S. volubilis* subsp. *crenata* by shorter pinnales and by thinner lamina texture.

Map 1 Distribution of *Salpichlaena hookeriana* (Kuntze) Alston (■), *S. hybrida* Lehtonen, G.G.Cárdenas & Tuomisto (▲), *S. papyrus* G.G.Cárdenas, Tuomisto & Lehtonen (●), *S. volubilis* (Kaulf.) J.Sm. subsp. *volubilis* (◆), *S. volubilis* subsp. *amazonica* G.G.Cárdenas & Tuomisto (◆), *S. volubilis* subsp. *crenata* G.G.Cárdenas & Tuomisto (◆), *S. volubilis* subsp. *thalassica* (Grayum & R.C. Moran) G.G.Cárdenas & Tuomisto (◆).

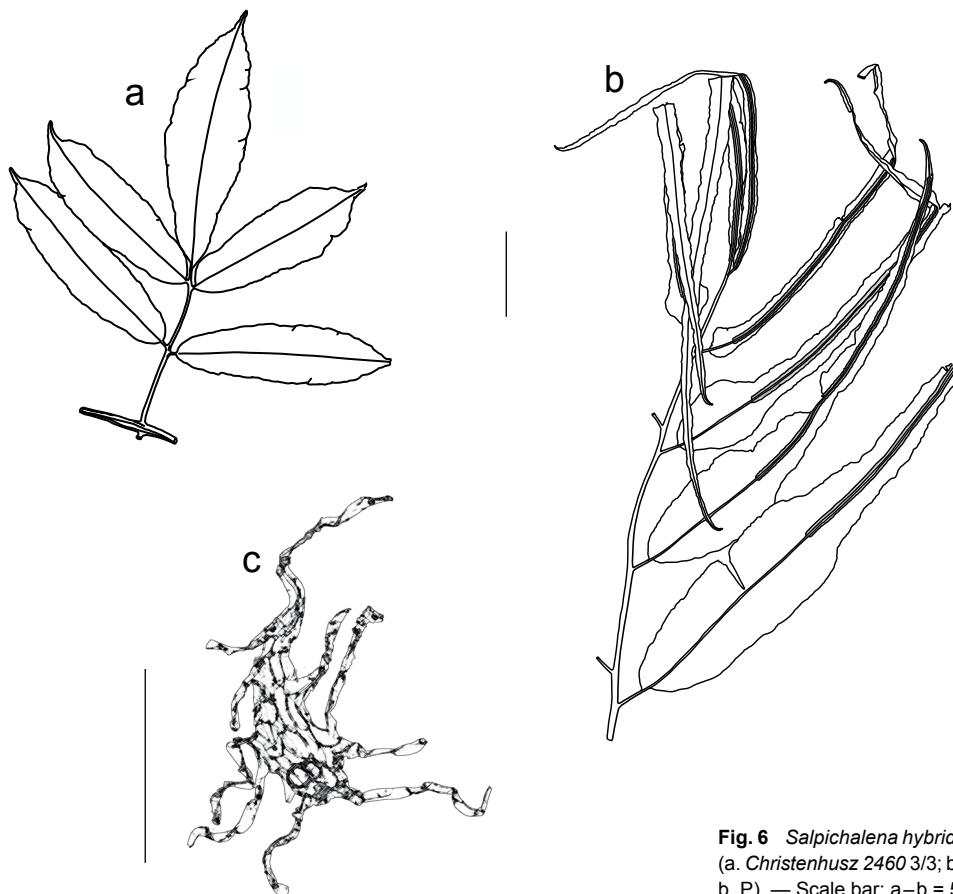

Fig. 6 *Salpichlaena hybrida*. a. Sterile pinna; b. fertile pinna; c. costal scale (a. Christenhusz 2460 3/3; b. Raynal 18572; c. Christenhusz 2460; a, c. TUR; b. P). — Scale bar: a–b = 5 cm; c = 0.5 mm.

We did not have physical access to fertile specimens of *S. hybrida* and the description of the fertile state is based on a few morphologically identified specimens seen as digital images. Hence, we do not have molecular support for the identification of the fertile specimens. Among the specimens seen, *Raynal A & Tirel C 18572* (P01326148) can be considered most typical as it clearly shows mixed characters of the presumed parental taxa.

3. *Salpichlaena papyrus* G.G.Cárdenas, Tuomisto & Lehtonen, sp. nov. — Fig. 3c, 7; Map 1

Salpichlaena papyrus can be recognised by its scales on the abaxial axes having an appearance of crumpled paper, or being broadly ovate with no appendices or only small ones. — Type: Jones M & Olivas P 165 (holo CR (CR0241094), iso LSCR, TUR (mounted on two sheets: 591746, 591747), USJ), Costa Rica, Heredia, Sarapiquí, La Selva Biological Station, nearest grid post P1000:50, N10°26' W84°1', 50–150 m, 7 Aug. 2001.

Etymology. The specific epithet refers to the scales, which have the distinctive appearance of crumpled paper.

Climbing and non-climbing fronds with herbaceous, chartaceous (to coriaceous) lamina texture, pinnae and pinnule margins not cartilaginous (to slightly cartilaginous); scales on abaxial axes formless resembling crumpled paper or ovate with no appendices or only short ones (1–3 cells); stomata often on white protuberances of the lamina. *Non-climbing* entire fronds up to 32 by 3 cm. Non-climbing 1-pinnate fronds 20–80 cm. Pinnae up to 9 pairs, apical one lanceolate (elliptic), 11.2–22.2 by 2–2.7 cm; lateral ones lanceolate, parallel-sided (elliptic), 6.3–19.2 by 1.5–2.8 cm; basal ones rarely pinnate; apex acuminate (attenuate), with serrate margin; base obtuse. *Climbing* fronds with pinnae almost monomorphic, although fertile pinnae usually narrower than sterile. Pinnules subopposite to opposite (alternate). *Fertile* pinnules in 2–11 pairs; apical one lanceolate, lanceolate-elliptic, elliptic-lanceolate (falcate), 12–27.7 by

0.8–2.1 cm, apex attenuate, serrate margin (to entire), base obtuse, cuneate, equilateral to oblique; lateral ones lanceolate, elliptic, elliptic-lanceolate, parallel-sided (falcate), 12.6–22.7 by 0.6–1.8 cm, apex attenuate, long-attenuate, acuminate, caudate or serrate, base obtuse, equilateral to slightly oblique. *Sterile* pinnules in 3–10 pairs; apical one lanceolate, parallel-sided (elliptic), 10.7–24.5 by 0.9–3.7 cm, apex attenuate, acuminate, serrate margin, base round, acute, equilateral to oblique; lateral ones lanceolate, parallel-sided (elliptic), 9.6–20.4 by 1.8–3.3 cm, apex acuminate, attenuate (caudate), serrate margin, base obtuse (acute), equilateral to oblique; petiolulate, sessile, rarely winged. Foliar buds rarely present at the base of pinnules.

Distribution — *Salpichlaena papyrus* occurs in Central America in Costa Rica, Nicaragua and Panama, and in South America in Bolivia, Brazil, Colombia, Ecuador, French Guiana, Guyana, Paraguay, Peru and Venezuela.

Habitat & Ecology — In primary rain forests on variable topographies on relatively well-illuminated sites near paths, tree fall gaps, streams, cliffs and ravines, also along forest borders and in disturbed forests. Reported from clayey to loamy soils. Altitude 50–1830 m.

Additional specimens seen (paratypes). BOLIVIA, Beni, Ballivián, al sud de la Misión Fatima, 950 m, 24 May 1988, Beck G, et al. 16372 (F). — BRAZIL, Mato Grosso, Chapada dos Guimaraes, Veu das Noivas, 16 Feb. 1988, Salino A 402 (AAU, BHCB, UEC). — COLOMBIA, Meta, Llanos, 457 m, Mar. 1948, Sandeman C 5868 (K); Nariño, 2 km E of Barbacoas, just s of Río Telembí, N1°40' W78°8', 100 m, 13 Oct. 1943, Fosberg FR 21245 (US). — COSTA RICA, Cartago, forest near the entrance to Parque Nacional Tapantí, 1270 m, 3 Aug. 1983, Moran R 3344 (AAU, MO); Heredia, Sarapiquí, La Selva biological station, nearest grid post 3400:750, N10°26' W84°1', 50–150 m, 21 May 2007, Jones M & Putkonen M 610 (TUR); San José, Parque Nacional Braulio Carrillo, Estación La Montura, Sendero A de 0–250 m, 22 Jan. 1984, Gómez LD et al. 20878 (AAU). — ECUADOR, Morona-Santiago, Mutintz, SE of Makuma, c. 1 km along trail to Tunantza, S2°11' W77°44', 675 m, 31 Oct. 1996, Øllgaard B & Navarrete H 1907 (AAU); Zamora-Chinchipe, Rd. Notes — *Salpichlaena papyrus* shares the serrate pinnule apices with *S. hookeriana*, but can be differentiated from it in any ontogenetical state by the scales that are formless and resembling crumpled paper, and in the fertile state by the presence of laminar tissue in the fertile pinnules. Furthermore, the usually higher number of pinnules, more lanceolate pinnule shape and more chartaceous texture of lamina are distinguishing characters.

The scales in *S. papyrus* are unlike those in any other species with an appearance of crumpled paper without clear shape (more often on the costa), or ovate with no appendices or only small ones (1 or 2 cells) (more often on the rachis and petiolule). Specimens with ovate scales and longer appendices have been observed in Peru, Bolivia and South-East Brazil. Scales on the rachises and petiolules are often big enough to be easily observed by the naked eye.

The serrate pinnule apices of *S. papyrus* are usually distinctive enough to allow differentiating it from *S. volubilis* and *S. hybrida*. However, the serration is less clear in fertile pinnules, which also have thicker lamina texture and more tendency towards a cartilaginous margin than the sterile pinnules do. Therefore, material consisting only of fertile pinnae can be difficult to identify to species, especially if the fronds are already so old that the scales have been eroded.

Foliar buds exist but are very rare in *S. papyrus*: out of the more than 300 specimens we studied, only two had foliar buds (*Øllgaard 105457 AAU* and *Holm-Nielsen et al. 25341, AAU*, both from Ecuador). This contrasts with *S. hookeriana*, where foliar buds are very common. The non-climbing fronds in *S. papyrus* are sometimes 2-pinnate, a character that we have not observed in any other taxa.

Salpichlaena papyrus and *S. volubilis* subsp. *thalassica* are the only *Salpichlaena* taxa occurring in Central America and along the western side of the Andes, where they are broadly sympatric. The non-climbing fronds of *S. papyrus* usually are smaller and have higher number of pinnae than *S. volubilis* subsp. *thalassica*.

4. *Salpichlaena volubilis* (Kaulf.) J.Sm. — Fig. 3d–g, 8–11; Map 1

Salpichlaena volubilis (Kaulf.) J.Sm. (1841) 168.

Blechnum volabile Kaulf. (1824) 159. — *Spicanta volubilis* (Kaulf.) Kuntze (1891) 821. — Type: Korte A & Kniess A 2825 (neotype FLOR FLOR0059465, designated here; isoneotype FURB FURB06861), Brazil, Santa Catarina, Ascurra, Guaricanas, S27°00'00" W49°24'36", 281 m, 15 Mar. 2010.

Blechnum scandens Bory (1828) 272. — *Salpichlaena scandens* (Bory) C.Presl (1851) 122. — Type: Brazil, Sta. Catherine, Durville s.n. 1827 (lectotype P00347471 designated here).

Etymology. The specific epithet refers to the twining petioles and rachises.

Climbing and non-climbing fronds with herbaceous to coriaceous lamina texture, pinnae and pinnule margins with or without cartilaginous margin; scales on abaxial axes either stick-like (formed by a long apical row of cells and usually two lateral smaller rows of cells) or lanceolate with small or large body of cells and always with long appendices; stomata located on small white laminal protuberances or not. Non-climbing entire fronds up to 53 by 6.8 cm. Non-climbing 1-pinnate fronds 45–135 cm. Pinnae up to 6 pairs; apical one lanceolate, elliptic, 16.3–45.5 by 2–9.5 cm; lateral ones lanceolate, elliptic, parallel-sided, oblanceolate, 18–32.2 by 1.7–7.7 cm; apex acuminate, attenuate, cuspidate, entire, entire with few small teeth on the cartilaginous margin, crenate; base obtuse, acute. Climbing fronds with pinnae slightly dimorphic, fertile pinnae generally narrower than sterile. Pinnules opposite to alternate; in 1–7 pairs, lanceolate, elliptic, oblanceolate, parallel-sided; petiolulate, sessile (winged); apex acuminate, attenuate, caudate (apiculate, cuneate, cuspidate, falcate), entire, almost entire with few small teeth (sometimes serration-like) on the cartilaginous margin, slightly crenate, slightly serrate, base obtuse, cuneate, acute, attenuate, equilateral to oblique.

Distribution — *Salpichlaena volubilis* is widely distributed, occurring from Central America to the Lesser Antilles and southern Brazil. Each of the four subspecies has a different distribution. *Salpichlaena volubilis* subsp. *amazonica* occurs in Western Amazonia, along the eastern slopes of the Andes and in French Guiana; *S. volubilis* subsp. *crenata* occurs in the Lesser Antilles and in the northern part of South America; *S. volubilis* subsp. *thalassica* occurs in Central America and

along the western side of the Andes in northeastern South America and *S. volubilis* subsp. *volubilis* occurs in the Atlantic rain forest of southeastern Brazil.

Notes — Apices of frond, pinna and pinnule of *S. volubilis* are entire, crenate to only slightly serrate, which differentiates it from *S. hookeriana* and *S. papyrus*, whose apices are obviously serrate. Most subspecies of *S. volubilis* differ from *S. hybrida* by their more chartaceous-coriaceous lamina texture and the presence of a cartilaginous margin. Only *S. volubilis* subsp. *volubilis* has equally herbaceous texture and non-cartilaginous margin, but it differs from *S. hybrida* by having lanceolate rather than elliptic pinnules. Distinguishing characters to identify *S. volubilis* subspecies are in Table 4.

We have been unable to locate any of the original material of *Blechnum volabile* collected by Von Chamisso. The type specimen was not found in LE where Von Chamisso's collection is kept. Therefore, we designate here a neotype for *Blechnum volabile*. We have chosen a specimen collected close to Santa Catarina Island, because according to Von Chamisso's diary (Von Chamisso 1821) this is the most probable place from where he could have collected the original material. Our results suggest that only one *Salpichlaena* taxon occurs in the Brazilian Atlantic Forest, and the name *S. volubilis* should be applied to this taxon.

Two different sources have received credit for the first publication of the name *Salpichlaena volubilis*, 'The Journal of Botany vol. 4', and 'Genera Filicum', both by Hooker. 'The Journal of Botany' has priority. It was published in 1841, whereas 'Genera Filicum' was probably published in 1842 (Stafleu & Cowan 1979).

a. subsp. *volubilis* — Fig. 3g, 4a, 8; Map 1

Climbing and non-climbing fronds with herbaceous to chartaceous lamina texture, pinnae and pinnule margins not cartilaginous, or sometimes slightly cartilaginous in fertile specimens; scales on abaxial axes lanceolate and ovate with long appendices, sometimes stick-like; stomata not on white laminal protuberances. Non-climbing entire fronds up to 33 by 2.3 cm. Non-climbing 1-pinnate fronds 45–101 cm. Pinnae up to 6 pairs; apical one lanceolate, elliptic, 16.3–25.5 by 2–3.5 cm; lateral ones lanceolate (elliptic), 11.3–27.5 by 1.7–3.5 cm; apex acuminate, with entire margin; base obtuse. Climbing fronds with pinnules subopposite to opposite. Fertile pinnules in 3–7 pairs; apical one lanceolate, oblanceolate, elliptic, 12.9–18.2 by 0.75–1.8 cm, apex acuminate, attenuate (round or fan-shaped tip caused by the apical division of the main vein), entire, base

Table 4 Distinguishing characters to identify *Salpichlaena volubilis* subspecies.

Characteristic	<i>Salpichlaena volubilis</i> subspecies			
	<i>amazonica</i>	<i>crenata</i>	<i>thalassica</i>	<i>volubilis</i>
Lamina texture	chartaceous, coriaceous (herbaceous)	chartaceous, herbaceous (coriaceous)	chartaceous, herbaceous, coriaceous	herbaceous (chartaceous)
Margin texture	cartilaginous	slightly cartilaginous (cartilaginous)	cartilaginous	not cartilaginous, but sometimes yellowish
Apex margin	entire or with few small teeth cutting only into the cartilaginous margin	crenate or slightly serrate	entire or with few small teeth cutting only into the cartilaginous margin	entire
Abaxial scales	stick-like and lanceolate with long appendices	lanceolate and stick-like	stick-like and lanceolate with long appendices	lanceolate to ovate with long appendices
Lateral pinnule shape	elliptic, lanceolate, oblanceolate	lanceolate, elliptic (parallel sided)	elliptic, lanceolate (parallel sided)	lanceolate
Number of lateral pinnae (non-climbing)	up to 3	up to 3	up to 4	up to 6
Number of lateral pinnules (climbing)	1–6	1–5	1–6	2–5
Abaxial lamina surface	uniform	uniform	stomata on whitish protuberances	uniform

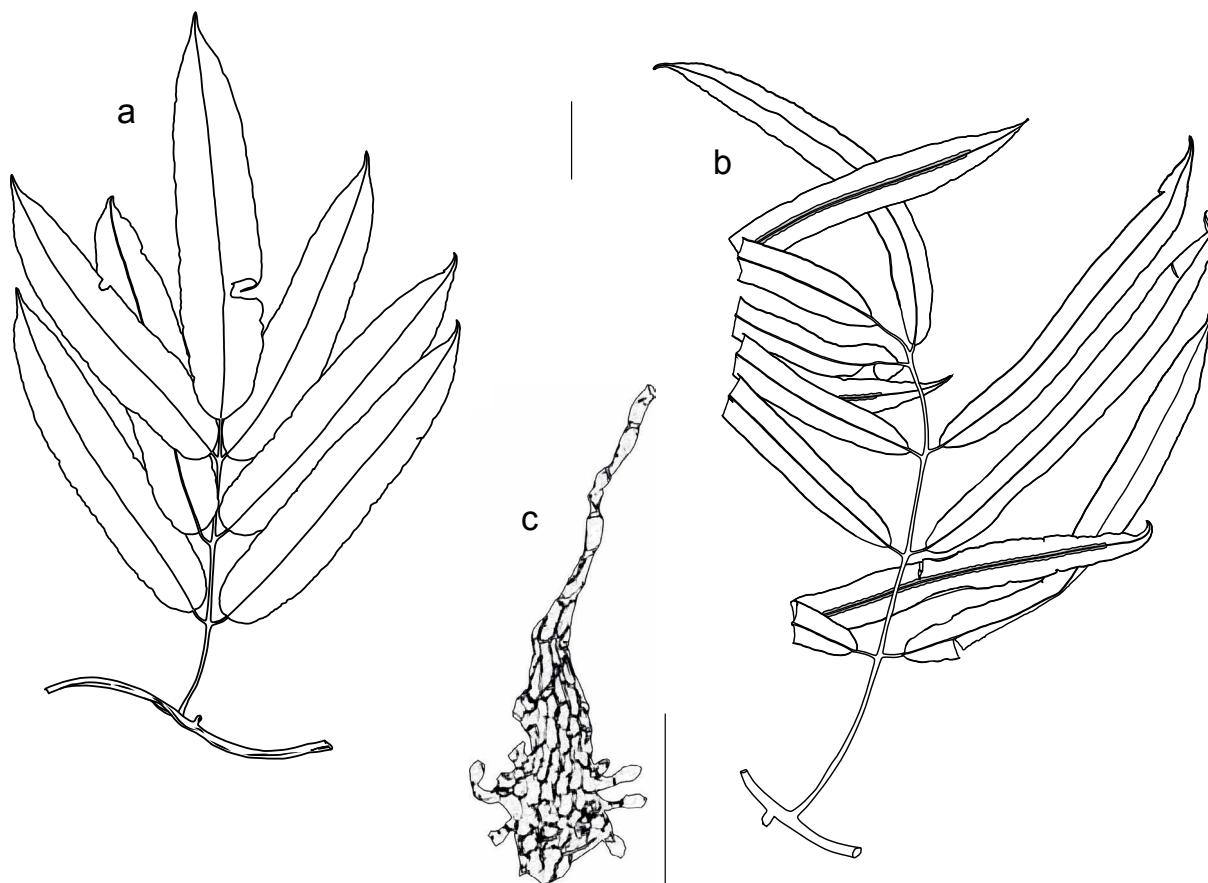

Fig. 8 *Salpichlaena volubilis* subsp. *volubilis*. a. Sterile pinna; b. fertile pinna; c. costal scale (a. Christenhusz 4955 2/2; b. Christenhusz 4831 1/2; c. Lehtonen 601; all TUR). — Scale bar: a–b = 5 cm, c = 0.5 mm.

obtuse, equilateral; lateral ones elliptic, parallel-sided, slightly oblanceolate, 12–13.6 by 0.69–1.5 cm, apex acuminate-attenuate (round or fan-shaped tip caused by the apical division of the main vein), base obtuse, attenuate, equilateral. Sterile pinnules in 2–5 pairs; apical one lanceolate, elliptic, 17.5 by 2.2 cm, apex acuminate, entire (round or fan-shaped tip caused by the apical division of the main vein), base obtuse, equilateral; lateral ones lanceolate, 13.6 by 1.9 cm, apex, acuminate, entire (round or fan-shaped tip caused by the apical division of the main vein), base obtuse, equilateral; petiolulate, sometimes winged.

Distribution — *Salpichlaena volubilis* subsp. *volubilis* occurs in the Atlantic rain forest in southeastern Brazil.

Habitat & Ecology — Terra firme, primary and disturbed Atlantic rain forest. Near open places like waterfalls and ravines. On hills, mid-slope and flat terrain. On clay soil. Altitude 0–1175 m.

Note — *Salpichlaena volubilis* subsp. *volubilis* differs from the other subspecies by its narrow pinnules with herbaceous (to chartaceous) lamina texture and non-cartilaginous to only slightly cartilaginous margin. Some specimens of subsp. *crenata* with nearly entire pinnule apices and lanceolate pinnules approach subsp. *volubilis* and cannot be reliably identified. We place the specimens from the Atlantic rain forest to subsp. *volubilis* and the specimens from eastern Amazonia, the Caribbean and Guyanas to subsp. *crenata*, but the distinction in morphology is diffuse and the amount of genetic variation within subsp. *crenata* is high.

b. subsp. *amazonica* G.G.Cárdenas & Tuomisto, subsp. nov. — Fig. 3d, 4f, 9; Map 1

Salpichlaena volubilis subsp. *amazonica* can be recognised by its chartaceous to coriaceous lamina texture, clearly cartilaginous pinnule margins, long and wide pinnules and uniform abaxial lamina. — Type: Tuomisto H, Moulatlet G, Ruckolainen K & Castro D 16904 (holotype SP; isotype INPA, TUR (mounted on four sheets: 606298–606301)), Brazil, Amazonas, Carauari, c. 7 km south from the village of Vila Ramalho, Rio Juruá, S5°35' W67°29', 100 m, 14 June 2012.

Etymology. The name refers to the geographical distribution of the sub-species in Amazonia.

Climbing and non-climbing fronds with chartaceous to coriaceous lamina texture, pinnae and pinnule margins clearly cartilaginous; scales on abaxial axes stick-like, formed by a long apical row of cells and usually two lateral smaller rows of cells, and sometimes also lanceolate scales with long appendices; stomata not (or very rarely) on white laminal protuberances. **Non-climbing** entire fronds up to 53 by 6.8 cm. Non-climbing 1-pinnate fronds

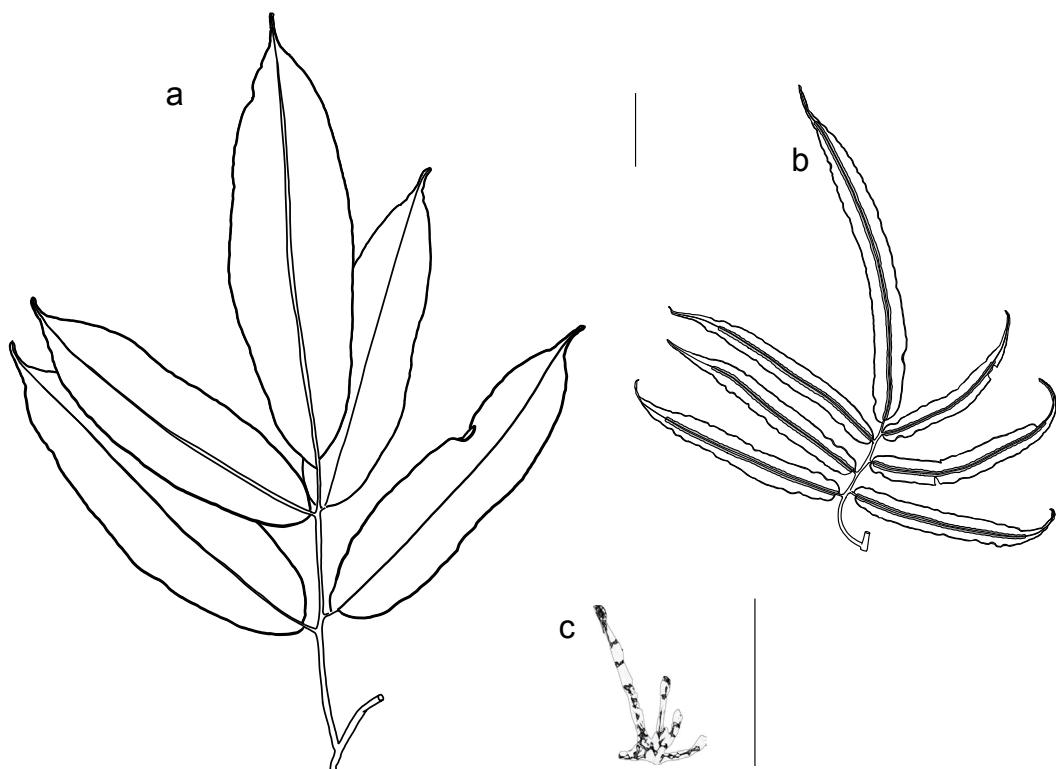

Fig. 9 *Salpichlaena volubilis* subsp. *amazonica*. a. Sterile pinna; b. fertile pinna; c. costal scale (a. Tuomisto 16904; b. Tuomisto 14562; c. Tuomisto 16010; all TUR). — Scale bar: a–b = 5 cm; c = 0.5 mm.

65–135 cm. Pinnae up to 3 pairs; apical one elliptic, lanceolate, 21.7–45.5 by 5.4–9.5 cm; lateral ones elliptic, oblanceolate, 18.5–30.8 by 5–7.7 cm; apex acuminate, cuspidate, with entire margin or with few small teeth on the cartilaginous margin; base obtuse, acute. Climbing fronds with pinnules subopposite to alternate. Fertile pinnules in 1–7 pairs; apical one lanceolate, elliptic (parallel-sided), 21–38.3 by 1.2–3.9 cm, apex attenuate, long-attenuate, acuminate, entire or with few small teeth (sometimes serration-like) on the cartilaginous border, base acute, strongly oblique; lateral ones elliptic-oblanceolate, lanceolate, parallel-sided, 14–25 by 1.6–2.2 cm, apex acuminate, attenuate, entire or with few small teeth (sometimes serration-like) on the cartilaginous border, base obtuse, equilateral. Sterile pinnules in 1–6 pairs; apical one elliptic, lanceolate or oblanceolate, 19.3–36.7 by 3.7–8.8 cm, apex acuminate, cuspidate, apiculate, entire or with few small teeth (sometimes serration-like) on the cartilaginous border, base obtuse, acute, equilateral to strongly oblique; lateral ones elliptic, lanceolate, oblanceolate, 15.2–35.2 by 3.7–8.6 cm, apex cuspidate, acuminate (attenuate, apiculate), entire or with few small teeth (sometimes serration-like) on the cartilaginous border, base obtuse, acute, equilateral to oblique; petiolulate, sessile (winged).

Distribution — *Salpichlaena volubilis* subsp. *amazonica* occurs mostly in Western Amazonia (eastern slopes of the Andes) with a few occurrences in Central Amazonia and the Guyana Shield, in Bolivia, Brazil, Colombia, Ecuador, French Guiana and Peru.

Habitat & Ecology — Tropical rain forest, usually in terra firme, rarely in periodically inundated areas or swamps. On hills, mid-slope and flat terrain. On loamy soil. Altitude 50–1500 (–2378) m.

Additional specimens seen (paratypes). BOLIVIA, La Paz, puente de Tora (near Tipuaní), 800 m, Cárdenas M 1287 (US); near Inglis-Inglis, 1524 m, 16 Aug. 1902, Williams RS 1295 (US). — BRAZIL, Amazonas, Carauari, c. 4 km south from the village of Bom Jesus, Río Juruá, S $5^{\circ}24'$ W $67^{\circ}12'$, 100 m, 30 Mar. 2012, Tuomisto H et al. 16010 (SP, TUR); Itamarati, c. 5 km north-west from the town of Itamarati, Río Juruá, S $6^{\circ}24'$ W $68^{\circ}17'$, 120–150 m, 8 Apr.

Notes — In general appearance, *S. volubilis* subsp. *amazonica* is similar to subsp. *thalassica* and non-climbing fronds can be confused with *S. hybrida*. However, usually subsp. *amazonica* can be distinguished from subsp. *thalassica* by the uniform appearance of the abaxial lamina in contrast to the typical white protuberances of the lamina associated with stomata in subsp. *thalassica*. The chartaceous-coriaceous lamina texture and cartilaginous pinnule margins distinguish subsp. *amazonica* from *S. hybrida* and also from subsp. *volubilis*, both of which have herbaceous texture and non-cartilaginous (or only slightly cartilaginous) margins. It is more difficult to separate subsp. *amazonica* from subsp. *crenata* because their characters sometimes overlap. In subsp. *amazonica*, the pinnule apices are entire

or have small teeth that do not cut into the lamina, in contrast to subsp. *crenata* whose pinnule apices are usually crenate (sometimes slightly serrated or entire). Subsp. *amazonica* has wider pinnules, more chartaceous-herbaceous texture, and an obvious cartilaginous margin that is absent or not so obvious in subsp. *crenata*.

In the northern Andes, *S. volubilis* subsp. *amazonica* and subsp. *thalassica* are difficult to separate on morphological grounds. The distribution of our sequenced specimens suggests that *S. volubilis* subsp. *amazonica* is restricted to the eastern side of the Andes, whereas subsp. *thalassica* occurs only on the western side.

c. subsp. *crenata* G.G.Cárdenas & Tuomisto, *subsp. nov.* — Fig. 3e, 10; Map 1

Distinguished from all other *Salpichlaena* taxa by the crenate to slightly dentate-serrate apices of the sterile pinnules. — Type: *Christenhusz MJM & Katzer F* 3988 (holotype TUR (mounted on two sheets 581127, 581128); isotypes NY 02007148, 02730089, P P01419530), Guadeloupe, Basse Terre, comm. Saint-Rose, Sofaïa, route forestier de Sofaïa, Trace de Baille-Argent-Sofaïa, down to the crossing with Rivière Moustique, N16°17' W61°44', 460 m, 8 Mar. 2005.

Etymology. The infraspecific epithet refers to the crenate pinnule apices.

Climbing and non-climbing fronds with chartaceous, herbaceous (coriaceous) lamina texture, pinnae and pinnule margins slightly cartilaginous to cartilaginous; scales on abaxial axes lanceolate with long appendices, some scales stick-like with a long apical row of cells and usually two smaller lateral cells; stomata rarely on white laminal protuberances. *Non-climbing* entire fronds up to 35 by 3.8 cm. Non-climbing 1-pinnate fronds 65–91 cm. Pinnae up to 3 pairs; apical one lanceolate (elliptic), 22.5–40.7 by 3.9–5.5 cm; lateral ones lanceolate, elliptic, 18.5–29.5 by 3.9–4.4 cm; apex attenuate, with entire, crenate margin; base acute, obtuse. *Climbing* fronds with pinnae subopposite (opposite, alternate). *Fertile pinnules* in 1–5 pairs; apical one elliptic, parallel-sided, lanceolate, 17.7–33.2 by 1.8–3.3 cm, apex caudate, acuminate, slightly serrate, entire margin, base acute, slightly oblique; lateral ones lanceolate, parallel-sided, slightly oblanceolate, 10–26 by 1.2–2.9 cm, apex slightly caudate, acuminate, attenuate with slightly crenate or slightly serrate margin, sometimes with a round or fan-shaped tip caused by the apical division of the main vein, base obtuse, cuneate, equilateral to slightly oblique. *Sterile pinnules* in 1–5 pairs; apical one lanceolate, elliptic, (parallel-sided), 16–28.8 by 2.2–6.5 cm, apex acuminate, caudate, attenuate, slightly crenate, slightly serrate, sometimes with a round or fan-shaped tip caused by the apical division of the main vein, base acute, ob-

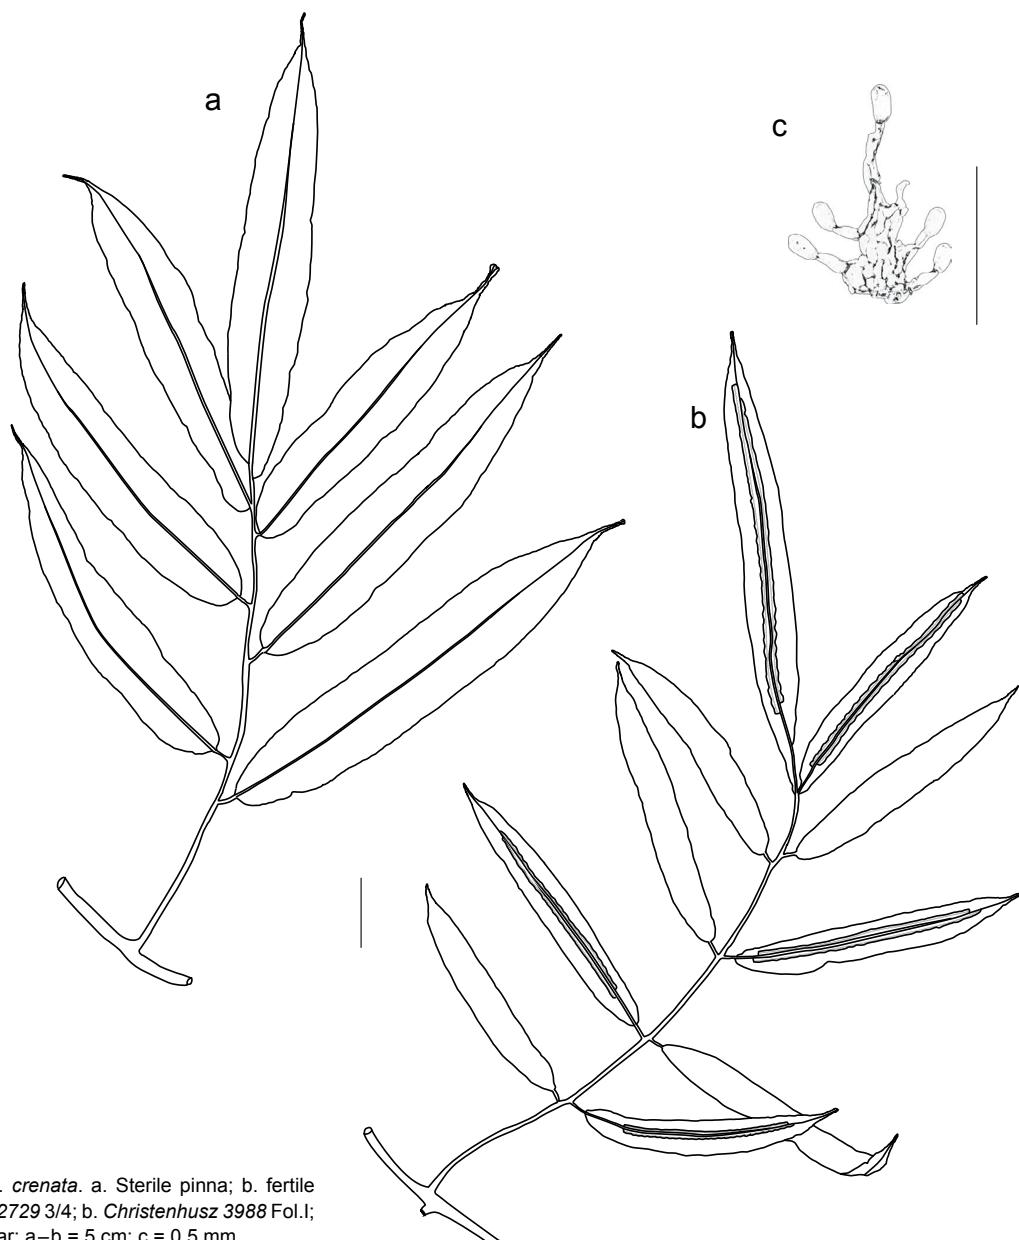

Fig. 10 *Salpichlaena volubilis* subsp. *crenata*. a. Sterile pinna; b. fertile pinna; c. costal scale (a. Christenhusz 2729 3/4; b. Christenhusz 3988 Fol.I; c. Kessler 12906; all TUR). — Scale bar: a–b = 5 cm; c = 0.5 mm.

tuse, cuneate (lobate), oblique; lateral ones lanceolate, elliptic (parallel-sided, falcate), 9–26.3 by 1.8–4.7 cm; apex attenuate, slightly crenate, slightly serrate, base acute, obtuse, equilateral to oblique; petiolulate (sessile or winged).

Distribution — *Salpichlaena volubilis* subsp. *crenata* occurs in the Lesser Antilles and in the northern part of South America, in Brazil, Dominica, Guadeloupe, French Guiana, Guyana, Martinique, Santa Lucia, Suriname, Trinidad and Tobago, Venezuela.

Habitat & Ecology — Terra firme primary rain forest, subtropical and transitional cloud forests. Along paths and along steep creekbanks. In hills and flat terrain. On clay and sandy soil. Altitude 70–1123 m.

Additional specimens seen (paratypes). Cruz, 2.5 km desde el Arco, SE del centro turístico Villa Bahareque, N10°26' W67°13.5', 1850–1950 m, 15 Aug. 1999, Mostacero J & Castillo R 259 (US).

Note — Most specimens of *S. volubilis* subsp. *crenata* differ from all the other subspecies by the crenate to slightly dentate-serrate apices on sterile pinnules. When only slightly serrate (or practically entire), subsp. *crenata* may be confused with subsp. *amazonica* or subsp. *thalassica*, but the serrations in the latter two are, when present, merely small teeth in the cartilaginous border and they do not cut into the lamina, as they do in subsp. *crenata*. Fertile pinnules of subsp. *crenata* may have entire apices, and then they can be confused with fertile pinnae of the other subspecies of *S. volubilis*.

d. subsp. *thalassica* (Grayum & R.C. Moran) G.G. Cárdenas & Tuomisto, comb & stat. nov. — Fig. 3f, 4e, 11; Map 1

Salpichlaena thalassica Grayum & R.C. Moran (in Moran 1990) 591, 593. — Type: Grayum & Chazdon 6833 (holotype MO; isotype CR), Costa Rica, Heredia, forest between Río Peje and Río Sardinalito, Atlantic slope of Volcán Barva, N10°17' W84°4.5', 800–1000 m, 7 Apr. 1986.

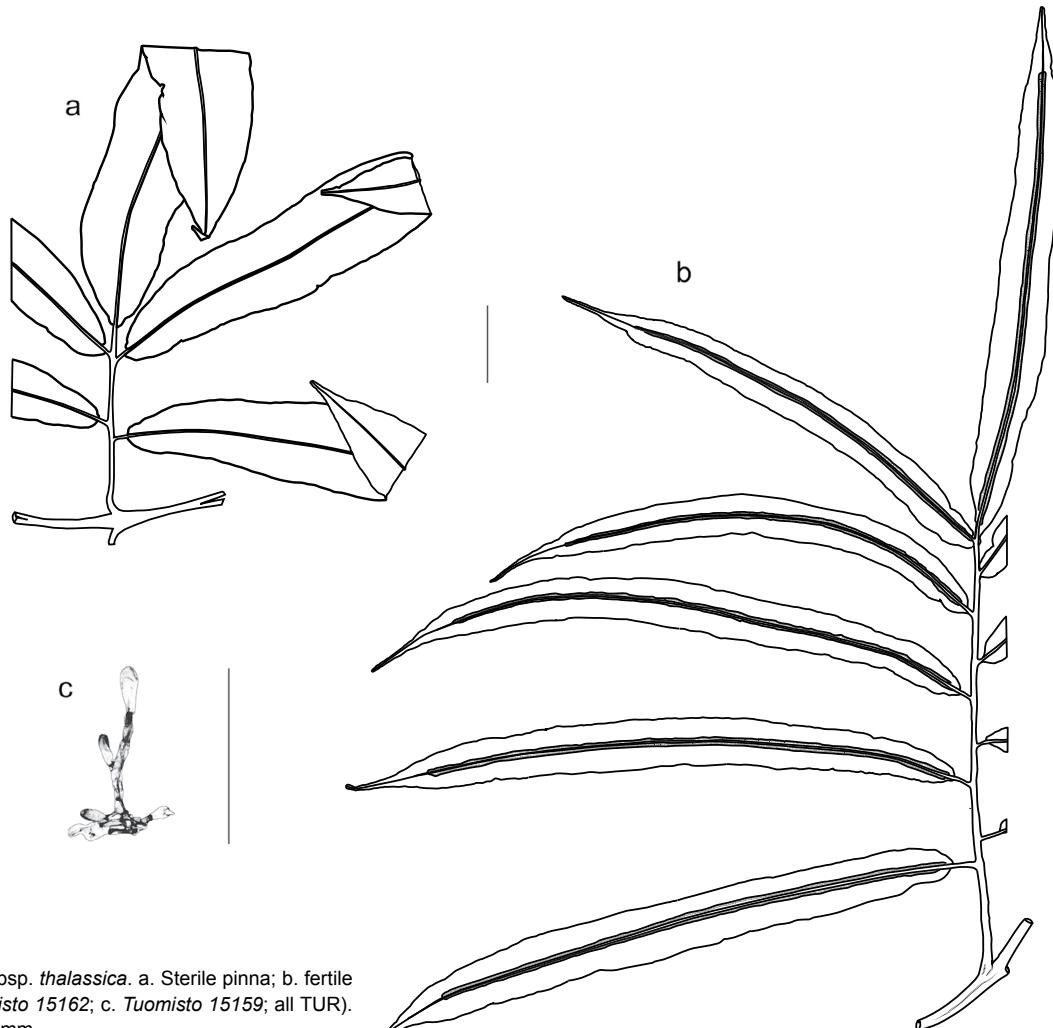

Fig. 11 *Salpichlaena volubilis* subsp. *thalassica*. a. Sterile pinna; b. fertile pinna; c. costal scale (a–b. Tuomisto 15162; c. Tuomisto 15159; all TUR). — Scale bar: a–b = 5 cm, c = 0.5 mm.

Etymology. The name refers to the bluish green colour of the fronds observed in the field.

Climbing and non-climbing fronds with chartaceous, herbaceous, coriaceous lamina texture, pinnae and pinnule margins cartilaginous; scales on abaxial axes stick-like formed by a long apical row of cells and usually two lateral smaller rows of cells and sometimes lanceolate scales with long appendices; stomata on white laminal protuberances. *Non-climbing* entire fronds up to 45 by 5 cm. Non-climbing 1-pinnate fronds 66–128 cm. Pinnae up to 4 pairs; apical one elliptic, lanceolate, 25–42 by 5.3–6.3 cm; lateral ones elliptic, parallel-sided, 18–32.2 by 3.7–5.5 cm; apex acuminate, attenuate, with entire margin; base obtuse. *Climbing* fronds with pinnules subopposite to opposite (alternate). *Fertile pinnules* in 1–5 pairs; apical one elliptic, lanceolate, parallel-sided, 18.2–30.2 by 1.1–3.1 cm, apex acuminate, attenuate (falcate), entire (slightly serrate), base cuneate, obtuse, acute, equilateral to strongly oblique; lateral ones elliptic (lanceolate, parallel-sided, falcate), 13.2–27.9 by 0.9–2.65 cm, apex acuminate, attenuate, or sometimes with a round, divided or fan-shaped tip caused by the apical division of the main vein, entire or with few small teeth (sometimes serration-like) on the cartilaginous border, base acute, obtuse, slightly oblique. *Sterile pinnules* in 1–6 pairs; apical one elliptic, lanceolate, (parallel-sided), 23–34.4 by 2.2–7.7 cm, apex acuminate, attenuate (cuspidate), entire, slightly serrate, base acute (lobate) equilateral to strongly oblique; lateral ones elliptic (lanceolate, parallel-sided), 17.3–27.7 by 2.4–6.9 cm; apex acuminate, attenuate (cuspidate, cuneate), entire or with few small teeth (sometimes serration-like) on the cartilaginous border; base obtuse, acute, entire to oblique; petiolulate, sessile (winged).

Distribution — *Salpichlaena volubilis* subsp. *thalassica* occurs in Central America and on the western side of the Andes in northeastern South America; Colombia, Costa Rica, Ecuador, Nicaragua, Panama.

Habitat & Ecology — Near stream valleys. On hills, mid-slope and flat terrain. Altitude 25–2400 m.

Additional specimens seen. COLOMBIA, Chocó, area of Baudó, on left bank of Rio Baudo, about 1.5 km upstream of stuary, 11 Feb.–28 Mar. 1967, Fuchs HP & Zanella L 21894 (AAU, K, USM); Magdalena, Sierra Nevada de Santa Marta, Cerro Ratón, serranía de San Javier, N10°53' W74°01', 1900 m, 5 Aug. 1972, Forero E & Kirkbride Jr H 672 (MO, US); Nariño, Ricáurte, 1300 m, 18 May 1941, Von Sneedern K A. 603 (AAU, MO); Valle, Cordillera Occidental, vertiente occidental: hoya del río Anchicayá, quebrada del Danubio, 300–350 m, 20 Dec. 1942, Cuatrecasas J 13726 (US). — COSTA RICA, Heredia, Braulio Carrillo National Park, N10°20' W84°10', 1215 m, 13 Nov. 1986, Hennipman E et al. 6893 (Z); San José, Tapanti, a lo largo del sendero Quebrada Segunta, 9 Apr. 1986, Berrocal J & Sánchez J 122 (CR); Mts 5 miles S of Cartago, 1800 m, 12 May 1906, Maxon WR 512 (US). — ECUADOR, Carchi, Maldonado, 1500 m, 8 Oct. 1981, Werling L & Leth-Nissen S 428A, 428B (AAU); Esmeraldas, Playa Grande, ± 2 km SE San Francisco de Cayapas, along Rio Cayapas, 16 Aug. 1967, Sparre B 18058 (P); Pichincha, Reserva Forestal ENDESA, Río Silanche, 'Corporación Forestal Juan Manuel Durini', km 113 de la carretera Quito-Pto. Notes — *Salpichlaena volubilis* subsp. *thalassica* shares with subsp. *amazonica* the chartaceous-coriaceous texture, cartilaginous margin, and the entire pinnule apices, which sometimes can have a few small teeth. However, the appearance of the

abaxial lamina sets subsp. *thalassica* apart from subsp. *amazonica*. In subsp. *thalassica*, the stomata are usually located on the top of small whitish laminal protuberances, which can be so conspicuous that they are visible to the naked eye as small white spots on the abaxial side of the lamina. In contrast, the epidermal surface of subsp. *amazonica* generally lacks the white protuberances altogether, but sometimes they may irregularly occur close to the lamina borders. Subsp. *thalassica* differs from subsp. *volubilis* and subsp. *crenata* by the presence of cartilaginous pinna margin and thicker lamina texture.

The paratype *Hampshire & Whitefoord* 370 (BM) does not belong to *S. volubilis* subsp. *thalassica* but instead represents *S. papyrus*.

NAMES EXCLUDED FROM *Salpichlaena*

The following names do not belong to *Salpichlaena* (Perrie et al. 2014, De Gasper et al. 2016, Hassler 2018).

Salpichlaena adnata (Reinw. ex de Vriese) Trevis. (1868–1869) 576 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena brasiliensis (Desv.) Trevis. (1868–1869) 574 ≡ *Neoblechnum brasiliense* (Desv.) Gasper & V.A.O.Dittrich (in De Gasper et al. 2016) 214.

Salpichlaena cartilaginea (Sw.) Trevis. (1868–1869) 575 = *Oceanipteris cartilaginea* (Sw.) Gasper & Salino (in De Gasper et al. 2016) 214.

Salpichlaena cumingiana (C.Presl) Fée (1850–1852) 79 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena denticulata (Sw.) Trevis. (1868–1869) 575 = *Telmatoblechnum indicum* (Burm.) Perrie, D.J.Ohlsen & Brownsey (in Perrie et al. 2014) 755.

Salpichlaena elongata (C.Presl) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena finlaysoniana (Wall. ex Hook. & Grev.) Fée (1850–1852) 79 ≡ *Blechnopsis finlaysoniana* (Wall. ex Hook. & Grev.) C.Presl (1851) 116.

Salpichlaena imbricata (Blume) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena latifolia (C.Presl) Trevis. (1868–1869) 575 = *Blechnopsis finlaysoniana* (Wall. ex Hook. & Grev.) C.Presl (1851) 116.

Salpichlaena longifolia (Cav.) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena malaccensis (C.Presl) Trevis. (1868–1869) 576 = *Telmatoblechnum indicum* (Burm.) Perrie, D.J.Ohlsen & Brownsey (in Perrie et al. 2014) 755.

Salpichlaena nitida (C.Presl) Trevis. (1868–1869) 574 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena orientalis (L.) Fée (1850–1852) 79 ≡ *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

Salpichlaena patersonii (R.Br.) Fée (1850–1852) 79 ≡ *Astroblechnum patersonii* (R.Br.) Gasper & V.A.O.Dittrich subsp. *patersonii* (in De Gasper et al. 2016) 203.

Salpichlaena pectinata (C.Presl) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.

- Salpichlaena pyrophylla* (Blume) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.
- Salpichlaena serrulata* (Rich.) Trevis. (1868–1869) 576 ≡ *Telmatoblechnum serrulatum* (Rich.) Perrie, D.J.Ohlsen & Brownsey (in Perrie et al. 2014) 755.
- Salpichlaena stenophylla* (C.Presl) Trevis. (1868–1869) 575 = *Blechnopsis orientalis* (L.) C.Presl (1851) 117.
- Salpichlaena striata* (C.Presl) Trevis. (1868–1869) 576 = *Telmatoblechnum indicum* (Burm.) Perrie, D.J.Ohlsen & Brownsey (in Perrie et al. 2014) 755.

Acknowledgements We thank the curators of the following herbaria for the access to the physical collections: AAU, AMAZ, CAY, INPA, K, NY, P, SP, TUR, US, USM and Z. We are especially grateful to the following persons for sending pictures of specimens on request: Alexandre Salino (BHCB), Alison Paul and Mark Carine (BM), Armando Andrade and Armando Ruiz (CR), Alexey Grebenjuk and Leonid Averianov (LE), Jim Solomon (MO), Renato de Mello-Silva and Viviane Yuri Jono (SPF), Jefferson Prado (SP), Carl Rothfels and Alan R. Smith (UC) and Eric Schuettpelz (US). We also thank Finn Borchsenius (AAU) for facilitating DNA material and for loans, Vanessa Invernón for providing references, Gabriela Giudice for clarification on typology, and Kanchi Gandhi for clarification on literature. Robbin C. Moran, an anonymous reviewer and the editor Peter Hovenkamp provided valuable comments on the manuscript. The drawings in this paper were made by Nelly Llerena. Funding from the following sources is gratefully acknowledged: Koneen Säätiö and Turun Yliopistosäätiö (personal grants to GC), Academy of Finland (research grants to HT), Oskar Öflunds Stiftelse, Synthesis Project and Doctoral Programme in Biology, Geography and Geology (BGG) (travel grants to GC). Collections in Brazil were done with the following permits: Processo CNPq n° 001693/2011-5 and Expedição científica CNPq Proc. EXC n° 030/07-CR.
