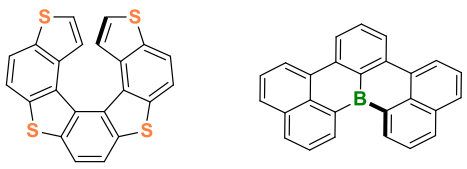
Zusammenfassung

Die Einführung eines trigonalen Boratoms in den Kern eines polyaromatischen Kohlenwasserstoffs (PAH) ist ein äußerst leistungsfähiges Werkzeug, um organische Gerüste mit optoelektronischen Eigenschaften und optimaler Verdichtung im festen Zustand zu versehen.[1] Bor-dotierte PAHs (B-PAHs) lassen sich jedoch aufgrund ihrer schlechten Löslichkeit oft schlecht verarbeiten. Die Verzerrung des Molekülgerüsts ist eine geeignete Strategie, um die Löslichkeitseigenschaften von B-PAHs zu verbessern und gleichzeitig gute Stapelungseigenschaften und eine ausreichende elektronische Konjugation zu erhalten. Eine extreme Verzerrung der Molekülstruktur kann bei schraubenförmigen PAHs erreicht werden, nämlich bei Helicenen[2] , bei denen es sich um schraubenförmige, inhärent chirale Polyzyklen handelt, die aus ortho-fusionierten aromatischen oder heteroaromatischen Ringen bestehen. Es wird erwartet, dass das Vorhandensein einer Helixstruktur in B-PAHs ihre physikalisch-chemischen Eigenschaften stark beeinflusst und zu Verbindungen führt, die sich durch besondere Merkmale auszeichnen, die für Anwendungen in funktionellen Materialien der nächsten Generation vielversprechend sind. Trotz des großen Potenzials dieser Verbindungsklasse sind in der Literatur nur wenige Beispiele für Borahelicene bekannt, die hauptsächlich aus Strukturen auf der Basis von Carbohelicenen bestehen.[3–5] Die beträchtliche strukturelle Vielfalt, die durch die Einführung verschiedener Bora-Heterocyclen (Oxaborin, Borol, Borepin) und anderer heteroaromatischer Ringe (Thiophen, Furan, Pyrrol) in dasselbe helikale Gerüst erreicht werden kann, deutet jedoch darauf hin, dass eine große Vielfalt von Verbindungen mit faszinierenden Eigenschaften über derzeit unerforschte synthetische Wege zugänglich sein könnte. Der Entwurf, die Synthese und die Untersuchung der Eigenschaften neuer Boraheterohelicene (**BHHs**) ist daher ein wichtiges Forschungsthema und Gegenstand dieses PhD-Projekts, das darauf abzielt, mehrere **BHHs** mit struktureller Vielfalt zu erhalten, sowie ihre Reaktivität, elektrochemischen und photophysikalischen Eigenschaften zu untersuchen, um ihr Potenzial als Bausteine für die Materialwissenschaft besser zu verstehen.

Die Arbeit wurde zum Teil an der Universität Mailand in den Labors von Prof. Emanuela Licandro und zum Teil an der Goethe-Universität Frankfurt am Main unter der Leitung von Prof. Dr. Matthias Wagner im Rahmen eines Co-Tutelle-Programms durchgeführt. Aufgrund der langjährigen Erfahrung der Gruppe von Prof. Licandro in der Synthese von Tetrathia[7]helicenen (**7TH**, Abbildung 1) und der Gruppe von Prof. Dr. Wagner in der Synthese von Bor-dotierten PAHs (z.B. Bor[4]helicen **4BH**; Abbildung 1) habe ich dieses Promotionsprojekt konzipiert, um eine Reihe von Thiahelicenen zu entwickeln, die eine oder mehrere B-O-Bindungen im Helixgerüst enthalten.



7TH 4BH

Abbildung 1. Tetrathia[7]helicen (**7TH**) und Bor[4]helicen (**4BH**).

Tetrathia[7]helicene, die aus abwechselnd fusionierten Thiophen- und Benzolringen bestehen, sind konfigurationsstabile Heterohelicene, die als Enantiomerenpaar vorliegen.[6] Diese Molekülklasse ist besonders interessant, da sie die Eigenschaften von Oligothiophenen mit denen von Helicenen vereint, was zu Systemen mit besonderen elektronischen und chiroptischen Eigenschaften führt, die sie zu attraktiven Bausteinen für Anwendungen in zahlreichen Wissenschaftsbereichen machen, darunter Optoelektronik,[7] Katalyse,[8] und Biologie.[9] Die Einführung eines trigonalen Boratoms in ein Thiahelicen-Gerüst führt zu einer neuen Klasse von unerforschten Bor-π-konjugierten Molekülen mit potenziell interessanten Eigenschaften.

Die vorliegende Doktorarbeit sollte daher einen bedeutenden Beitrag zur Entwicklung innovativer und vielseitiger Synthesen von BO-dotierten Tetrathia[7]helicenen sowie zur Untersuchung ihrer stereochemischen und optoelektronischen Eigenschaften leisten, um mögliche Anwendungen dieser Systeme in der Materialwissenschaft zu ermitteln.

Die ersten ausgewählten Strukturen mit einem oder zwei Oxaborinringen im Helixgerüst sind in Abbildung 2 dargestellt. Die Anwesenheit der sperrigen Mesitylgruppe am Boratom ist notwendig, um die Stabilität des Moleküls zu gewährleisten. Es ist bemerkenswert, dass Verbindung **2** das Skelettisomer von **1** ist, da die Richtung der B-O-Bindung in den beiden Molekülen entgegengesetzt ist. Im Verlauf der Forschungsarbeit wurde nach der Bewertung der photophysikalischen Eigenschaften von **1** das Helicen **2** entwickelt, um Informationen über die Struktur-Eigenschafts-Beziehung zu erhalten und zu bewerten, wie die Position der BO-Bindung im Helixgerüst die elektronischen Eigenschaften von BO-dotierten Thiahelicenen beeinflussen kann.

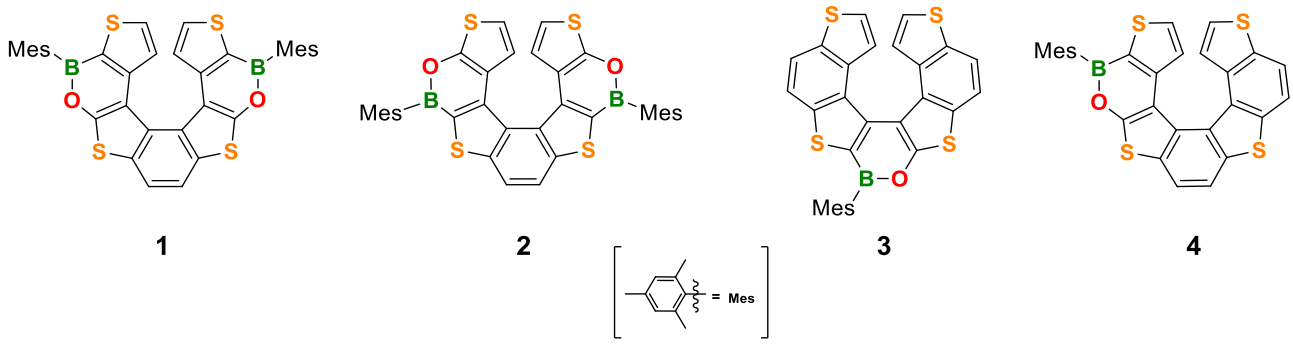


Abbildung 2. Erste ausgewählte Borathia[7]helicen-Strukturen.

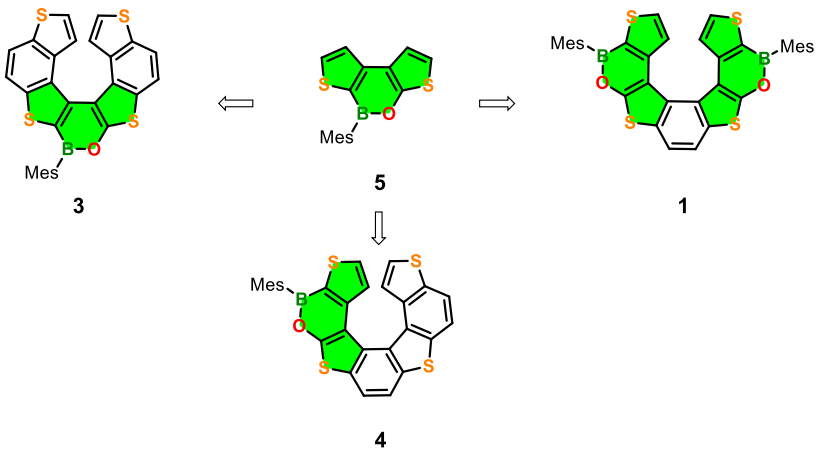
Im Einzelnen hat sich die Arbeit auf die folgenden Hauptziele konzentriert:

1) Untersuchung der Synthese und der Eigenschaften des doppelt BO-dotierten Tetrathia[7]helicen **1** und seines "BO-Isomers" **2**;
2) Vorstudie zur Synthese von einfach BO-dotierten Tetrathia[7]helicenen **3** und **4**.

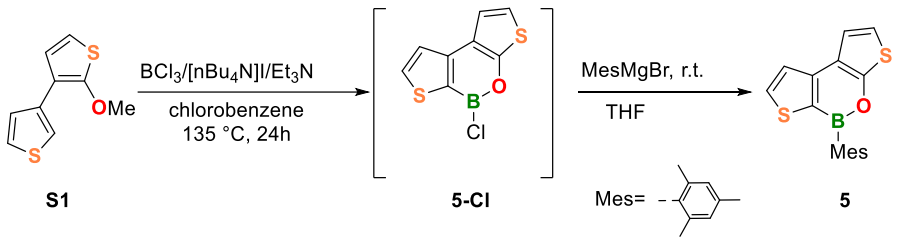
Untersuchung der Synthese und der Eigenschaften von BO-dotiertem Tetrathia[7]helicen 1

In der Literatur sind keine Beispiele für borhaltige Tetrathiahelicene bekannt. Im Rahmen dieses Forschungsprojekts haben wir mehrere geeignete Strategien für die Synthese der Zielmoleküle und ihrer Vorstufen entwickelt. In einem allgemeinen Syntheseschema wurde die Dithienooxaborin-**5**-Einheit als potenzieller gemeinsamer Baustein für die in Schema 1 dargestellten ausgewählten Strukturen **1**, **3** und **4** identifiziert.



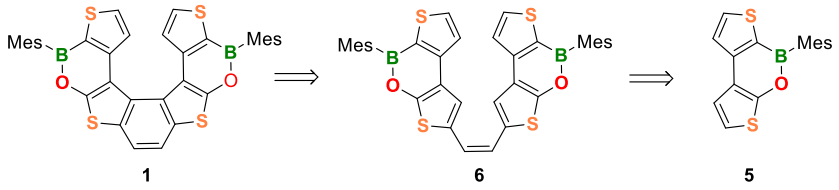
Schema 1. Allgemeines Syntheseschema für BO-dotierte Thiahelicene **1**, **3**, **4**.

Die Synthese des in der Literatur unbekannten Dithienooxaborins **5** (Schema 2) war das erste Ziel der Arbeit und wurde wie in Schema 2 gezeigt durch Behandlung des bekannten Methoxybithiophens **S1**[6] mit BCl_3 in Gegenwart von Et_3 N und [nBu_4 N]I realisiert, um das Zwischenprodukt **5-Cl** zu erhalten, das nach Behandlung mit MesMgBr das gewünschte Dithienyloxaborin **5** in 77 % Ausbeute ergab.



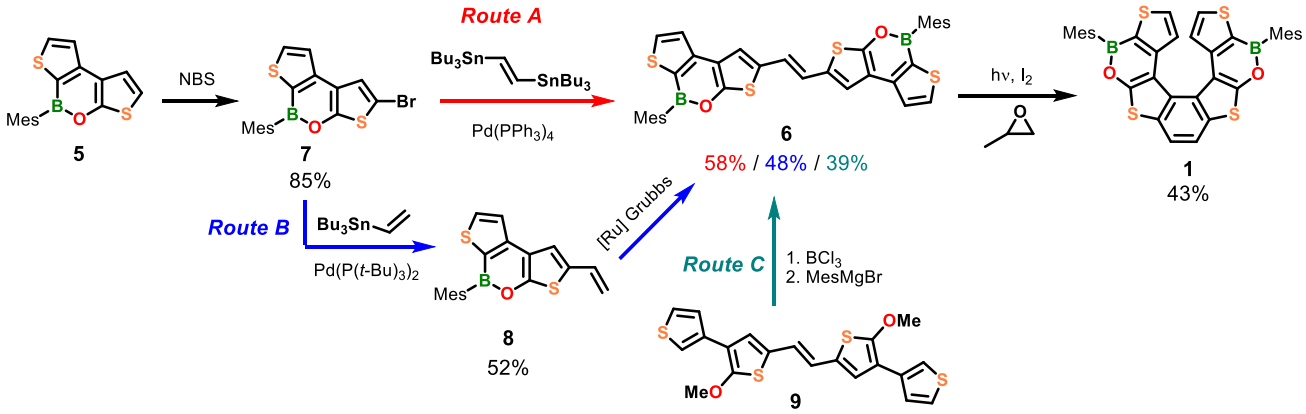
Schema 2. Synthese von **5**.

Ausgehend von Oxaborin **5** haben wir zunächst verschiedene Ansätze zur Herstellung von Helicen **1** in Betracht gezogen (Schema 3), entschieden uns aber unter Einbeziehung einiger vorläufiger Experimente für den in Schema 3 dargestellten Weg der Retrosynthese, bei dem das Ziel-Helicen **1** durch Photocyclisierung des BO-haltigen Alkenvorläufers **6** aus Dithieno-Oxaborin **5** erhalten wird**.**



Schema 3. Vorgeschlagene retrosynthetische Analyse für **1**.

Die Synthese von **1** wird in Schema 4 näher erläutert.



Schema 4. Syntheseweg zu Dioxabora-tetrathia[7]helicen **1.**

Ausgehend von Oxaborin **5** wurde die Synthese des Schlüsselintermediats Alken **6** eingehend untersucht und über drei verschiedene Routen (*Route A*, *B*, *C*) durchgeführt.

In den *Routen A* und *B* wurde das Oxaborin **5** mit N-Bromsuccinimid (NBS) bromiert, um α-Bromoxaborin **7** zu erhalten, das in der *Route A* mit 1,2-Bis(tributylstannyl)ethen durch eine Stille-Kupplung unter Verwendung von Pd(PPh)$_{34}$ als Katalysator umgesetzt wurde und Alken ***trans*-6** mit 58 % Ausbeute lieferte. Bei der *Route B* wurde **7** zunächst einer Stille-Kupplung mit Vinyltributylzinn unter Verwendung von Pd[P(*t-Bu*)]$_{32}$ als Katalysator unterzogen, was **8** in 52 % Ausbeute ergab, gefolgt von einer Dimerisierung durch eine Grubbs-Metathese, die zu **6** in 48 % Ausbeute führte. Die alternative *Route C* ermöglichte es, das Alken **6** in 39 % Ausbeute durch eine andere Strategie zu erhalten, die eine späte Bildung der beiden Oxaborinringe ausgehend von dem geeigneten bis-methoxyfunktionalisierten Alken **9** beinhaltet.[10] Trotz der geringeren Ausbeute ist es bemerkenswert, dass dieser Weg potenziell geeignet ist, um auf einfache Weise oxaborinsubstituierte Alkene mit verschiedenen heteroaromatischen Ringen zu erhalten.

Der letzte Schritt, die Photocyclisierung von Alken **6**, wurde in Benzol unter Verwendung einer 405-nm-LED-Lampe in Gegenwart von I_2 und Propylenoxid (um das in der Photocyclisierung gebildete HI einzufangen) durchgeführt und ergab erfolgreich das neue doppelt BO-dotierte Thiahelicen **1** in 43 % Ausbeute. Alle in Schema 4 gezeigten Verbindungen sind neu und wurden durch ^{1}H, ^{13}C und ^{11}B NMR, HRMS, CV und UV/Vis-Analyse vollständig charakterisiert und ihre Molekularstrukturen durch Röntgenkristallographie aufgeklärt. Die molekulare Röntgenstruktur des Targets Dioxabora-Thiahelicen **1** ist in Abbildung 3 dargestellt.

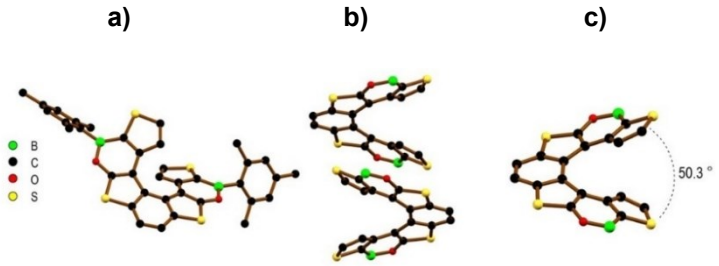


Abbildung 3. a) Röntgenmolekülstruktur des **1**-(*M*)-Enantiomers. b) Packung des (*P*)/(*M*)-Paares der Enantiomere c) Seitenansicht, Interplanarwinkel zwischen den beiden endständigen Thiophenringen; in b) und c) sind die Mesitylgruppen aus Gründen der Übersichtlichkeit weggelassen.

Wie bereits erwähnt, ist Borahelicen **1** ein chirales Molekül. Chiroptische und kinetische Studien zu **1** wurden in Zusammenarbeit mit der Gruppe von Prof. Claudio Villani (Universität Rom "La Sapienza") und Prof. Giovanna Longhi (Universität Brescia) durchgeführt. Die beiden Enantiomere (*P*)-/(*M*)-**1** wurden durch chirale HPLC aufgetrennt (Abbildung 4a, blaue Spur) und erwiesen sich bei Raumtemperatur als konfigurationsstabil mit optischen Rotationswerten von +97.7° bzw. –97.5°. An den Enantiomeren von **1** wurden optische Stabilitätsstudien durchgeführt, die es ermöglichten, die freie Energie der Racemisierung $\Delta G_{rac}^{\ddagger} = 26.9 \pm 0.1$ kcal mol^{-1} zu bestimmen, die deutlich niedriger ist als die der Thiahelicene,[11] was darauf hindeutet, dass die BO-Dotierung die mechanische Festigkeit des Helixgerüsts stark beeinflusst. Zirkulardichroismus (CD)-Spektren der beiden Enantiomere zeigten ein perfektes spiegelbildliches Verhältnis (Abbildung 4b, schwarze und rote Spur). Zur Bestimmung der absoluten Konfigurationen der beiden Enantiomere wurde das CD-Spektrum von (*M*)-**1** mit TD-DFT berechnet (Abbildung 4b, orange gestrichelte Spur). Die gute Übereinstimmung zwischen den berechneten und den experimentellen Daten ermöglichte es, die (*M*)-Konfiguration dem zweiten eluierten Enantiomer zuzuordnen ($\alpha_D = -97.5°$).

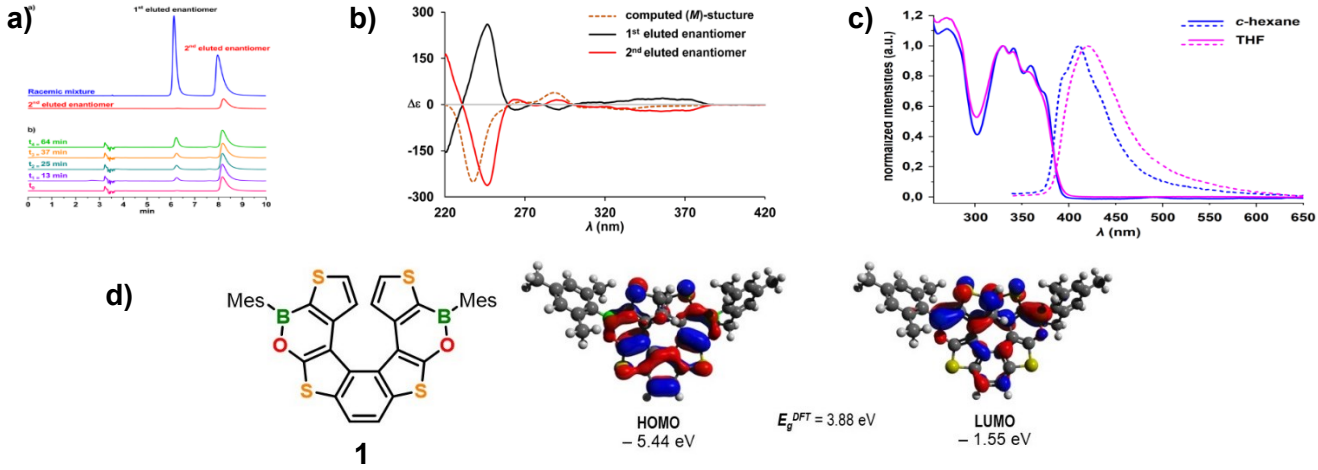

Abbildung 4. a) oben: Analytische HPLC-Auflösung von **1** in n-Hexan/CH_2Cl_2 (95:5), schwarze und rote Spur; berechnetes CD-Spektrum von (*M*)-**1** auf dem e M06/6-311g G(d,p)-Niveau, orange gestrichelte Spur. c) Absorptions-/Emissionsspektren von **1** in *c*-Hexan und THF. d) HOMO/LUMO-Verteilungen von **1** berechnet auf dem B3LYP/6-31G*-Niveau.

Um das Potenzial von BO-dotiertem Helicen **1** für materialwissenschaftliche Anwendungen zu bewerten (z. B. als Baustein für Emissions-/Elektronentransportmaterialien für OLED-Geräte), wurden seine Eigenschaften auch mittels zyklischer Voltammetrie, UV/Fluoreszenzspektroskopie sowie DFT/TD-DFT-Berechnungen untersucht. Die zyklische Voltammetrie zeigte zwei irreversible Redoxereignisse mit Spitzenpotentialen von E_{pc} = –2.83 und -3,01 V im kathodischen Scan. DFT-Berechnungen ergaben, dass die LUMO-Orbitale (E_{LUMO}^{DFT} = -1.55 eV) hauptsächlich an den terminalen, formal B(sp^2)-substituierten Thiophenringen lokalisiert sind, während die HOMO-Orbitale (E_{HOMO}^{DFT} = –5.44 eV) über das gesamte helikale Fragment verteilt sind (Abbildung 4d). Die UV-/Fluoreszenzspektroskopie ergab, dass **1** ein blauer Emitter ist und seine Emissionsbande eine teilweise aufgelöste Schwingungsfeinstruktur in *c*-Hexan zeigt (Abbildung 4c, blaue Spur) mit einer Photolumineszenz-Quanteneffizienz von Φ_{PL} = 6 % (*c*-Hexan*;* vgl. Vorläufer **7TH**: $\lambda_{em} \approx$ 405 nm, Φ_{PL} = 5%). [12] Die Ergebnisse der optoelektronischen Studien zeigen, dass **1** nicht für Anwendungen in funktionellen Materialien geeignet ist, aber dass die vielseitigen synthetischen Ansätze zu seiner Herstellung (siehe Schema 4) vielfältige strukturelle Modifikationen (Umkehrung der BO-Vektoren, BN-Dotierung) ermöglichen, die als Werkzeug zur Gewinnung neuer Derivate mit verbesserten optoelektronischen Leistungen dienen könnten. Helicen **1** ist das erste BO-dotierte Thiahelicen in der Literatur und die Ergebnisse dieser Studie wurden als Forschungsartikel in Angewandte Chemie Int. Ed. veröffentlicht.[13]

Untersuchung der Synthese und der Eigenschaften von BO-dotiertem Tetrathia[7]helicen 2

Auf der Grundlage der photophysikalischen Eigenschaften von **1** und mit dem Ziel, seine optoelektronischen Eigenschaften zu verbessern (z. B. rotverschobene Absorption-Emission/ höheres Φ_{PL}), haben wir das Helicen **2** (Abbildung 5) entwickelt, ein Skelettisomer von **1**, das durch die formale Umkehrung der beiden BO-Bindungen im Ausgangsmaterial **1** entstanden ist.

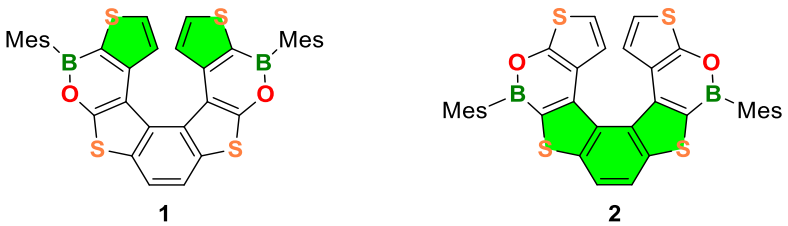

Abbildung 5. Struktur und LUMO-Verteilung (grün) von **1** und, erwartete LUMO-Verteilung des 2-Isomers mit BO-invertierten Bindungen.

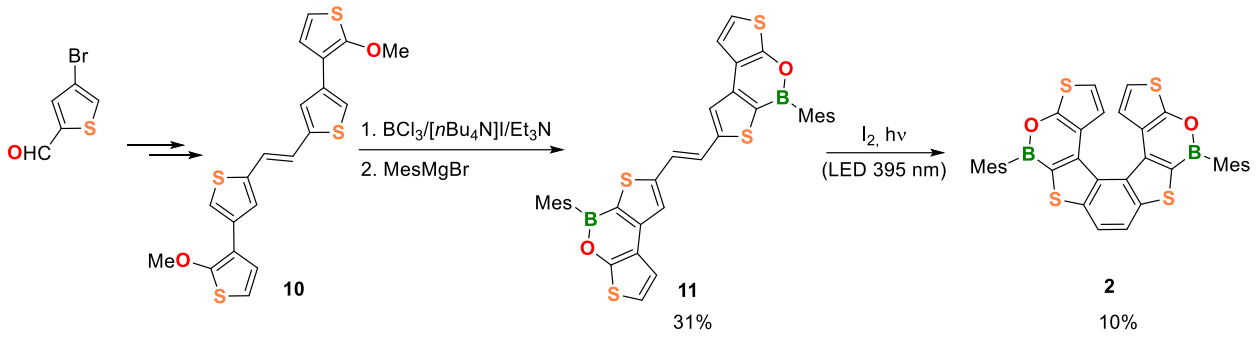
Es wird erwartet, dass **2** LUMO-Orbitale aufweist, die sich über das gesamte zentrale Thiophen-Benzol-Thiophen-Fragment (BDT) erstrecken und nicht über die endständigen Thiophenringe wie in **1** (Abbildung 5). Die Erweiterung der LUMO-Orbitale sollte zu einer verringerten Energielücke, rotverschobenen

Absorptions-/Emissionsbanden, erhöhtem Reduktionsvermögen und somit zu verbesserten optoelektronischen Leistungen führen. Diese Hypothese wurde auch durch vorläufige DFT-Berechnungen bestätigt (Abbildung 6b).

Das Bora-Helicen-Isomer **2** wurde nach der späteren Borylierungsstrategie synthetisiert (siehe *Route C* für **1** in Schema 4). Zu diesem Zweck wurde das Alken **10,** das in guter Ausbeute aus 3-Brom-2-thiophencarbaldehyd hergestellt wurde (Schema 5), zunächst boryliert, um **11** zu erhalten und dann mit einer LED-Lampe bei 395 nm photocyclisiert, wodurch das Ziel-Helicen **2** entstand.



Schema 5. Syntheseweg zum BO-dotierten Tetrathia[7]helicen-Isomer **2**.

Obwohl das Syntheseprotokoll noch optimiert werden muss, konnte mit dem Verfahren Bora-Helicen **2** als zweites Beispiel für ein doppelt mit Bor dotiertes Thiahelicen in ausreichender Menge für die analytische und photophysikalische Charakterisierung gewonnen werden (Abbildung 6).

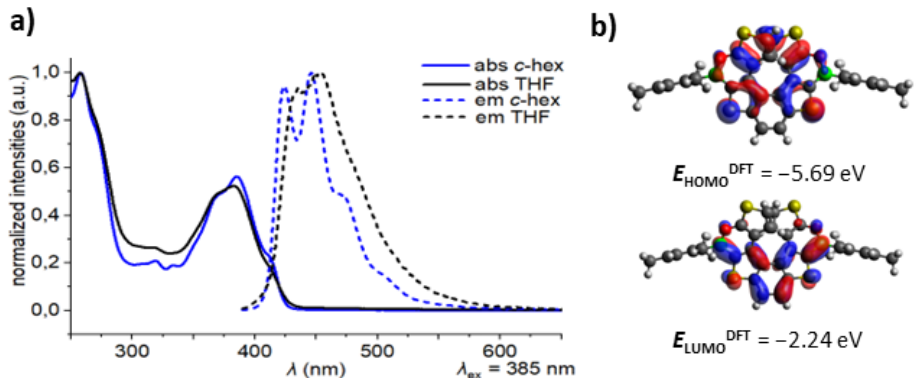


Abbildung 6. a) UV/Fluoreszenzspektren von **2** in *c*-Hexan (blaue Spur) und THF (schwarze Spur). b) HOMO/LUMO-Verteilung von **2**, berechnet auf dem B3LYP/6-31G*-Niveau.

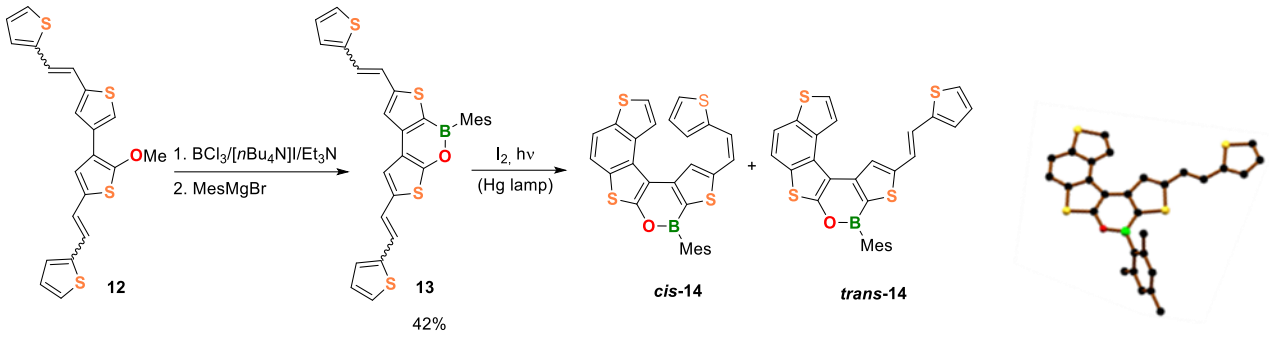
In *c*-Hexan weist **2** eine strukturierte UV/Vis-Absorptionsbande auf, wobei die am stärksten bathochrome Schulter bei 413 nm erscheint (Abbildung 6a, blaue Linie). Zum Vergleich: Die entsprechende Schulter im Spektrum von **1** befindet sich bei 374 nm. **2** ist ein blauer Emitter, und seine Emissionsbande zeigt eine teilweise aufgelöste Schwingungsfeinstruktur mit der hypsochromen Schulter bei 472 nm und einer Photolumineszenz-Quanteneffizienz von Φ_{PL} = 7% (*c*-Hexan; vgl. **1**: $\lambda_{em} \approx$ 411 nm, Φ_{PL} = 6%). Die Absorptions- und Emissionsbanden von **2** sind gegenüber denen von **1** deutlich rotverschoben. DFT-

Berechnungen ergaben, dass das LUMO von **2** über das gesamte zentrale Thiophen-Benzol-Thiophen-Fragment verteilt ist und sich somit weiter erstreckt als das von **1**.

Zusammengenommen haben diese Ergebnisse gezeigt, dass die Inversion der BO-Vektoren ein geeignetes Mittel zur Abstimmung des LUMO von BO-dotierten Thiahelicenen darstellt. Obwohl sie im speziellen Fall von **2** keine nennenswerten Auswirkungen auf die optoelektronischen Leistungen hatte (immer noch niedriges Φ_{PL} und nur geringfügige Senkung der LUMO-Energie), bilden sie die Grundlage für die strukturelle Entwicklung neuer Derivate mit abgestimmten elektronischen Eigenschaften. Die Razemisierungskinetik und die chiroptischen Eigenschaften von **2** werden in Zukunft untersucht werden. In der Zwischenzeit war die Arbeit auf die Synthese der Oxabora-Thiahelicene **3** und **4** ausgerichtet, die einen Oxaborinring in verschiedenen Positionen des Helixgerüsts enthalten (siehe Abbildung 2).

Vorläufige Studie über die Synthese von einfach BO-dotierten Tetrathia[7]helicenen 3 und 4

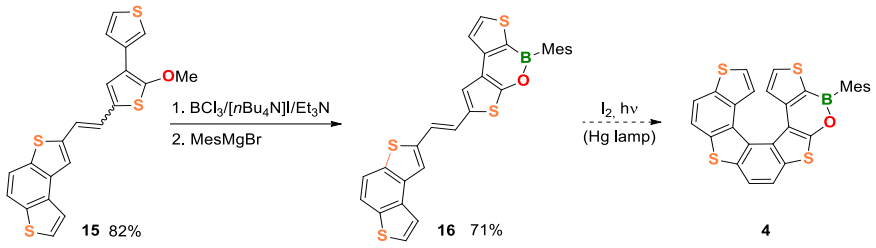
Für die Synthese von mono-BO-dotiertem Thiahelicen **3** haben wir erneut die Borylierung von Bis-Alken **12** in Betracht gezogen, um das Oxaborin-Derivat **13** vor dem Schritt der Photocyclisierung zu erhalten. Dieser letzte Schritt zur Gewinnung von **3** wird derzeit untersucht, obwohl erste photochemische Versuche es ermöglichten, ein fast äquimolares Gemisch von cis/trans-Isomeren des mono ringgeschlossenen Produkts **14** zu isolieren (Schema 6). Die beiden Strukturen wurden durch ^{1}H NMR und ^{HH}COSY-Spektren identifiziert. Darüber hinaus wurden Kristalle von ***trans*-14** gewonnen, deren Struktur durch HRMS und Röntgenanalyse bestätigt wurde (Abbildung 7).



Schema 6. Synthese und Photocyclisierung von **13**.

Abbildung 7. Röntgenstruktur von ***trans*-14**.

Derselbe Syntheseansatz wurde auch verwendet, um mono-BO-dotiertes Helicen **4** (Schema **7**) zu erhalten, ausgehend von dem benzodithiofenfunktionalisiertem Alken **15**, das in guter Ausbeute zum Alken **16** boryliert wurde und dessen optoelektronische und elektrochemische Eigenschaften untersucht wurden. Die anschließende Photocyclisierung von **16** zu Helicen **4** wird derzeit untersucht, da der photochemische Schritt bisher den Engpass beider Synthesesequenzen darstellt.



Schema 7. Synthetischer Weg zu **4**.

Schlussfolgerungen

Ziel dieser Doktorarbeit war die Untersuchung einer neuen Klasse von chiralen Thiaheterohelicenen, die mit einer oder zwei BO-Bindungen dotiert sind. Trotz der besonders anspruchsvollen Herausforderung aus synthetischer Sicht konnten die neuartigen Borahelicene **1** und **2** erfolgreich hergestellt und im Fall von **1** die vollständige optoelektronische, elektrochemische und stereochemische Untersuchung abgeschlossen und in Angewandte Chemie Int. Ausgabe publiziert werden.[13] Darüber hinaus wurde die synthetische Untersuchung von zwei weiteren Borahelicenen, nämlich **3** und **4,** fortgesetzt und wird derzeit noch weiter untersucht.

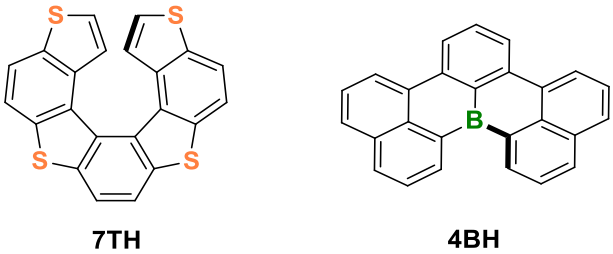
1. Abstract

The introduction of a trigonal boron atom into a polyaromatic hydrocarbon (PAH) core is an extremely powerful tool to provide organic scaffolds with optoelectronic properties as well as optimal packing in the solid state.[1] However, boron-doped PAHs (B-PAHs) often display low processability due to their poor solubility. The distortion of the molecular scaffold provides a suitable strategy to enhance the solubility properties of B-PAHs while maintaining good stacking properties and sufficient electronic conjugation. Extreme distortion of the molecular structure can be achieved in helical-shaped PAHs, namely helicenes[2] which are screw-shaped inherently chiral polycycles, formed by ortho-fused aromatic or heteroaromatic rings. The presence of a helical structure in B-PAHs is expected to strongly influence their physico-chemical properties leading to compounds characterized by peculiar features promising for applications in next generation functional materials. Despite the great potential of this class of compounds, only few examples of borahelicenes have been reported in the literature and those mainly consist of carbohelicene-based structures.[3–5] However, the considerable structural diversity achievable by introducing different bora-heterocycles (oxaborine, borole, borepin) and other heteroaromatic rings (thiophene, furan, pyrrole) into the same helical scaffold, suggests that a large variety of compounds with intriguing features could be accessible via currently unexplored synthetic routes. The design, synthesis, and properties investigation of new boraheterohelicenes (**BHHs**) is therefore a relevant research topic and is the object of this PhD project, aimed to obtain several **BHHs** with structural diversity, as well as to study their reactivity, electrochemical and photophysical features for better understanding their potential as building blocks for material science.

The thesis work was carried out in part at the University of Milan in the laboratories of Prof. Emanuela Licandro and in part at the Goethe Universität Frankfurt am Main under the supervision of Prof. Dr. Matthias Wagner, within a co-tutelle programme.

Owing to the long-standing expertise of Prof. Licandro group in the synthesis of tetrathia[7]helicenes (**7TH** Figure 1) and that of Prof. Dr. Wagner group in the synthesis of boron-doped PAHs (e.g. boron[4]helicene **4BH**; Figure 1), I conceived this PhD project designing a series of thiahelicenes containing one or more B-O bond into the helical scaffold.



7TH **4BH**

Figure 1. Tetrathia[7]helicene (**7TH**) and boron[4]helicene (**4BH**).

Tetrathia[7]helicenes, consisting of thiophene and benzene rings fused in an alternating fashion, are configurationally stable heterohelicenes which exist as pair of enantiomers.[6] This class of molecules is

particularly interesting since it merges the properties of oligothiophenes with those of helicenes, giving rise to systems with peculiar electronic and chiroptical properties which make them appealing building blocks for applications in manifold fields of science, including optoelectronics,[7] catalysis,[8] and biology.[9] The introduction of trigonal boron atom into a thiahelicene scaffold gives rise to a novel class of unexplored boron π-conjugated molecules with potentially interesting features.

The present Ph.D. thesis was therefore intended to provide a meaningful contribution in the development of innovative and versatile syntheses of BO-doped tetrathia[7]helicenes as well as the study of their stereochemical and optoelectronic properties to identify potential applications of these systems in material science.

The first selected structures containing one or two oxaborine rings in the helical scaffold are shown in figure 2. The presence of the bulky mesityl group at the boron atom is necessary to ensure stability to the molecule. It is noteworthy that compound **2** is the skeletal isomer of **1**, as the direction of the B-O bond is opposite in the two molecules. In the course of the research work, after the evaluation of the photophysical properties of **1,** helicene **2** was designed to get information on the structure-property relationship and evaluate how the position of the BO-bond into the helical scaffold can influence the electronic properties of BO-doped thiahelicenes.

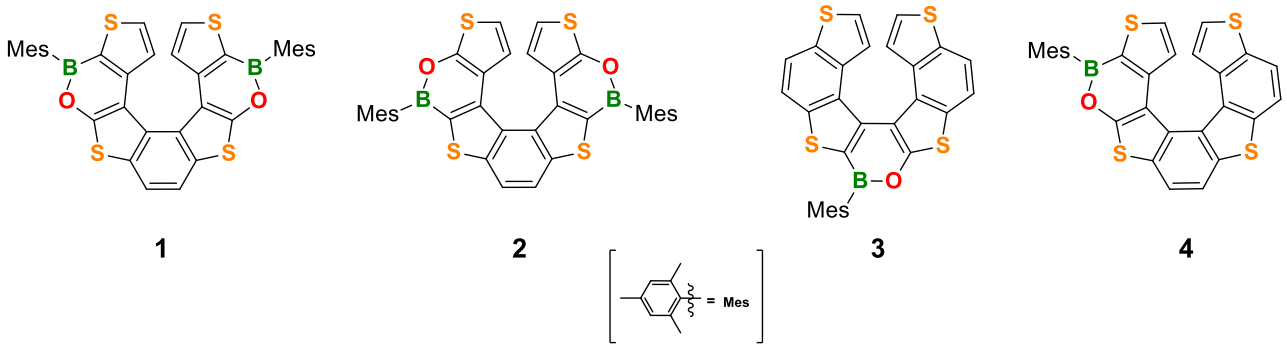


Figure 2. First selected borathia[7]helicene structures.

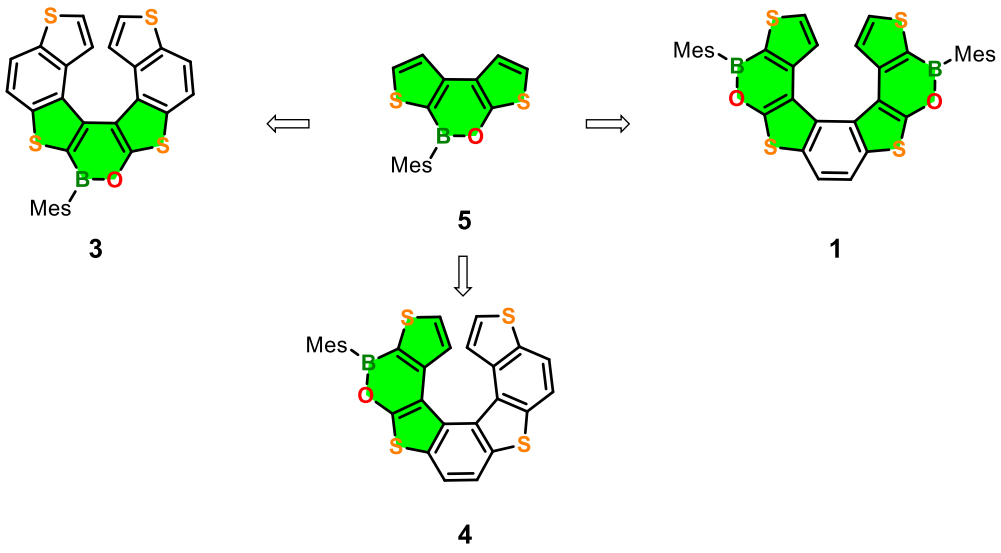
In detail the thesis work has been focused on the following main goals:

1) study of the synthesis and properties of the doubly BO-doped tetrathia[7]helicene **1**; and its "BO- isomer" **2**;

2) preliminary study of the synthesis of singly BO-doped tetrathia[7]helicenes **3** and **4**.

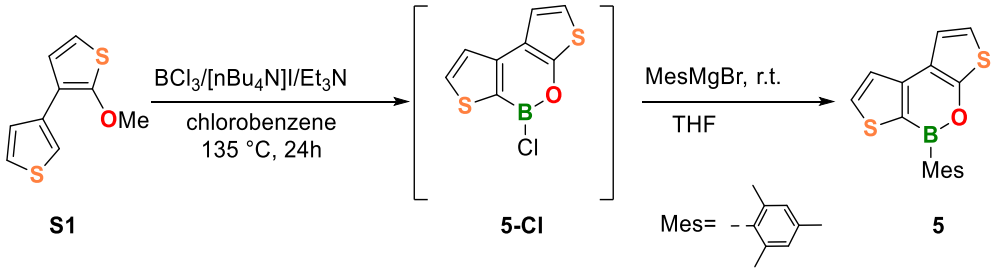
Study of the synthesis and properties of the BO-doped tetrathia[7]helicene 1

No examples of boron containing tetrathiahelicenes have been reported in the literature and within this research project we have designed several suitable strategies for the synthesis of the target molecules and their precursors. In a general synthetic scheme, dithienooxaborine **5** unit was identified as a potential common building block for the selected structures **1**, **3** and **4** reported in Scheme 1.



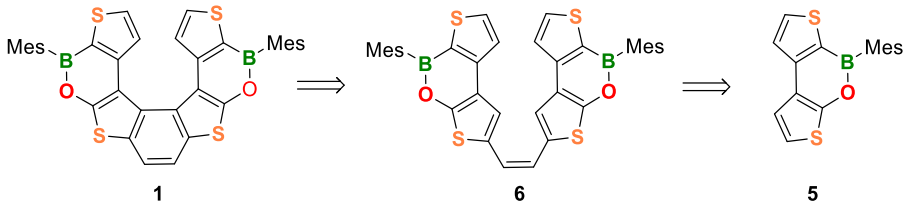
Scheme 1. General synthetic scheme for BO-doped thiahelicenes **1**, **3**, **4**.

The synthesis of dithienooxaborine **5** (Scheme 2), unknown in the literature was the first target of the work and was realized as shown in Scheme 2 by treatment of the known methoxy bithiophene **S1**[6] with BCl_3 in the presence of Et_3N and [nBu$_4$N]I to give the intermediate **5-Cl** which, upon treatment with MesMgBr afforded the target dithienyloxaborine **5** in 77% yield.



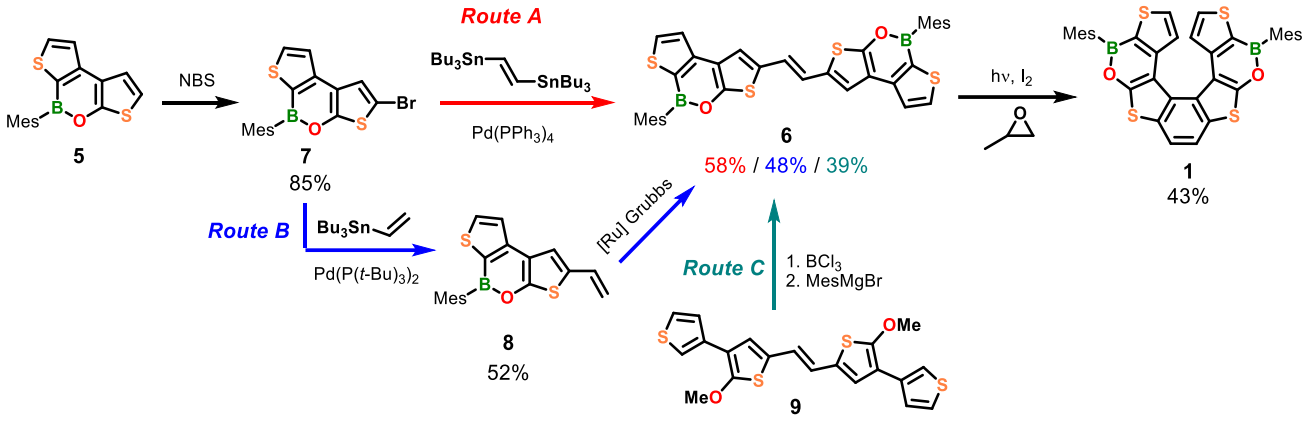
Scheme 2. Synthesis of **5**.

Starting from oxaborine **5** we considered different approaches to helicene **1** (Scheme 3) but, also in the light of some preliminary experiments, we selected the route showed as retrosynthesis in Scheme 3, in which the target helicene **1** is obtained by photocyclization of the BO-containing alkene precursor **6** prepared from dithieno oxaborine **5**.



Scheme 3. Proposed retrosynthetic analysis for **1**.

The synthesis of **1** is further detailed in Scheme 4.



Scheme 4. Synthetic route to dioxabora-tetrathia[7]helicene **1**.

Starting from oxaborine **5** the synthesis of key intermediate alkene **6,** was deeply investigated and carried out *via* three different routes (*Route A*, *B*, *C*).

In the *Route A* and *B*, the oxaborine **5** was brominated with *N*-bromosuccinimide (NBS) to give α-bromo oxaborine **7** which in the *Route A,* was reacted with 1,2-bis(tributylstannyl)ethene, through a Stille coupling, using $Pd(PPh_3)_4$ as catalyst affording alkene *trans*-**6** in 58% yield. In the *route B*, **7** was, firstly, submitted to a Stille coupling with vinyl tributyltin using $Pd[P(t\text{-}Bu)_3]_2$ as catalyst, giving **8** in 52% yield, followed by dimerization *via* Grubbs metathesis, leading to **6** in 48% yield. Alternative *Route C* allowed to get the alkene **6** in 39% through a different strategy that involves a late-stage formation of the two oxaborine rings starting from the suitable bis-methoxy functionalized alkene **9**.[10] Although the lower yield, it is noteworthy that this route is potentially suitable to get in an easy way oxaborine substituted alkenes containing different heteroaromatic rings.

As last step, the photocyclization of alkene **6**, was performed in benzene by using a 405 nm LED lamp in the presence of I_2 and propylene oxide (to trap HI formed in the photocyclization step) and successfully gave the new doubly BO-doped thiahelicene **1** in 43% yield. All the compounds shown in Scheme 4 are new and were completely characterized by ^{1}H, ^{13}C, and ^{11}B NMR, HRMS, CV and UV/Vis analysis and their molecular structures elucidated by X-ray crystallography. The molecular X-ray structure of the target dioxabora-thiahelicene **1** is shown in Figure 3.

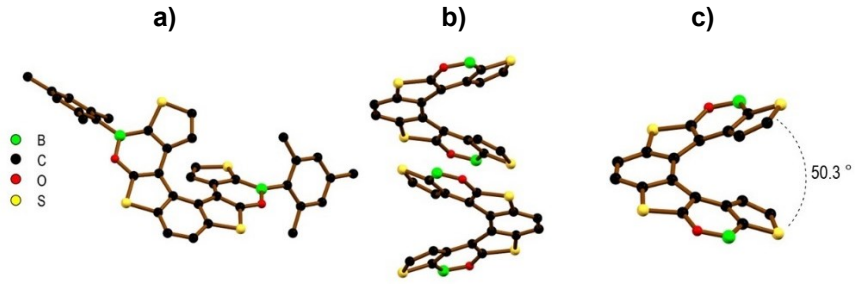


Figure 3. a) X-ray molecular structure of **1**-(*M*)-enantiomer. b) packing of the (*P*)/(*M*)-pair of enantiomers c) side view, interplanar angle between the two terminal thiophene rings; in b) and c) mesityl groups are omitted for clarity.

As previously mentioned, borahelicene **1** is a chiral molecule and chiroptical and kinetic studies on **1** were conducted in collaboration with the group of Prof. Claudio Villani (University of Rome "La Sapienza") and Prof. Giovanna Longhi (University of Brescia).

The two enantiomers (*P*)-/(*M*)-**1** were resolved by chiral-HPLC (Figure 4a, blue trace) and revealed to be configurationally stable at room temperature with optical rotation values of +97.7° and –97.5°, respectively. Optical stability studies were conducted on the **1** enantiomers allowing to determine the free energy of racemization $\Delta G_{rac}^{\ddagger}$ = 26.9 ± 0.1 kcal mol^{-1}, which is significantly lower than that of thiahelicenes,[11] thus indicating that BO-doping strongly influences the mechanical rigidity of the helical framework. Circular dichroism (CD) spectra of the two enantiomers showed a perfect mirror-image relationship (Figure 4b, black and red trace). To determine the absolute configurations of the two enantiomers, the CD spectrum of (*M*)-**1** was calculated by TD-DFT (Figure 4b, orange dashed trace) and the good correspondence between computed and experimental data allowed to assign the (*M*)-configuration to the second eluted enantiomer (α_D= –97.5°).

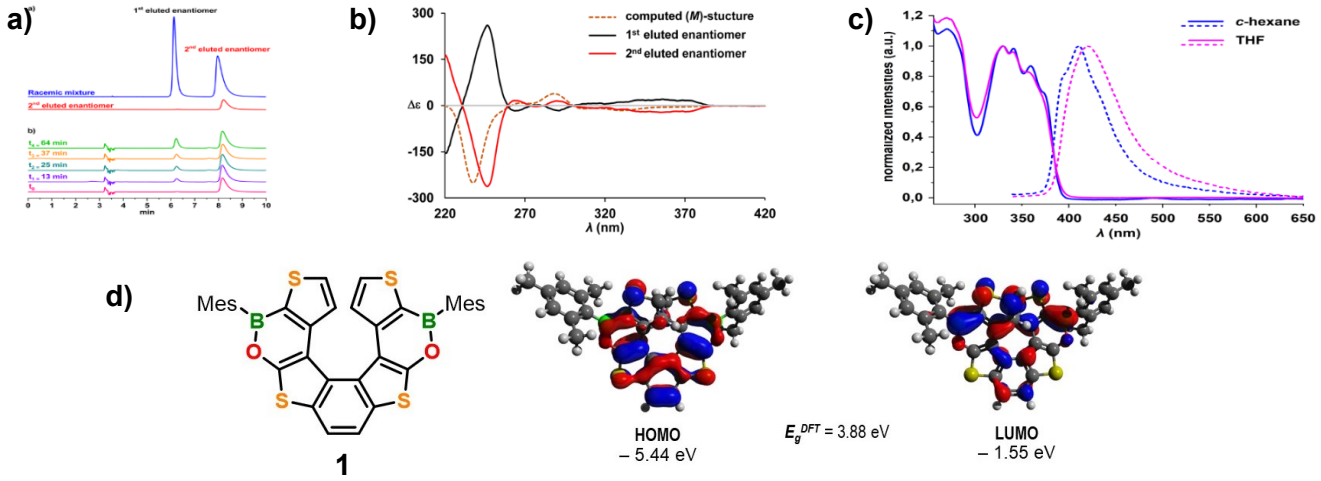

Figure 4. a) top: Analytical HPLC resolution of **1** in *n*-hexane/CH_2Cl_2 (95:5), black and red trace; computed CD spectrum of (*M*)-**1** at the e M06/6-311g G(d,p) level, orange dashed trace. c) absorption/emission spectra of **1** in *c*-hexane and THF. d) HOMO/LUMO distributions of **1** calculated at the B3LYP/6-31G* level.

To evaluate the potential of BO-doped helicene **1** for applications in material science (*e.g.,* building block for emissive/electron transport materials for OLED devices), its properties were also investigated by means of cyclic voltammetry, UV/Fluorescence spectroscopy, as well as DFT/TD-DFT calculations. Cyclic voltammetry showed two irreversible redox events with peak potentials of E_{pc} = –2.83 and –3.01 V in the cathodic scan. DFT calculations revealed as LUMO orbitals (E_{LUMO}^{DFT} = –1.55 eV) are mainly localized on the terminal, formally B(sp^2)-substituted thiophene rings, while HOMO orbitals (E_{HOMO}^{DFT} = –5.44 eV) spread over the whole helical fragment (Figure 4d). UV/Fluorescence spectroscopy proved that **1** is a blue emitter and its emission band shows a partially resolved vibrational fine structure in *c*-hexane (Figure 4c, blue trace) with a photoluminescence quantum efficiency is Φ_{PL} = 6% (*c*-hexane; *cf.* parent **7TH**: $\lambda_{em} \approx 405$ nm, Φ_{PL} = 5%).[12] Results of optoelectronic studies revealed as **1** is not suitable for applications in functional materials but the versatile synthetic approaches set-up for its preparation (see Scheme 4) open up to manifold structural modifications (inversion of BO vectors, BN doping) which could serve as tool to obtain new derivatives with enhanced optoelectronic performances. Out to date, helicene **1** represents the first BO-doped thiahelicene in the literature, and the results of this study has been published as a research article in Agewandte Chemie Int. Ed..[13]

Study of the synthesis and properties of the BO-doped tetrathia[7]helicene 2

On the basis of the photophysical properties of **1**, with the aim of improving its optoelectronic properties (*e.g.,* red-shifted absorption-emission/ higher Φ_{PL}), we designed the helicene **2** (Figure 5), skeletal isomer of **1**, which is derived by the formal inversion of the two BO bonds in the parent **1** that we presumed could be a tool to affect the electronic properties, by influencing the distribution and the extension of the LUMO orbitals within the helical framework.

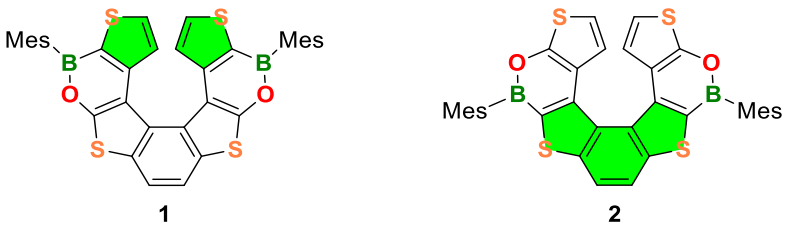

Figure 5. Structure and LUMO distribution (green) of **1** and, expected LUMO distribution of the **2** isomer with BO-inverted bonds.

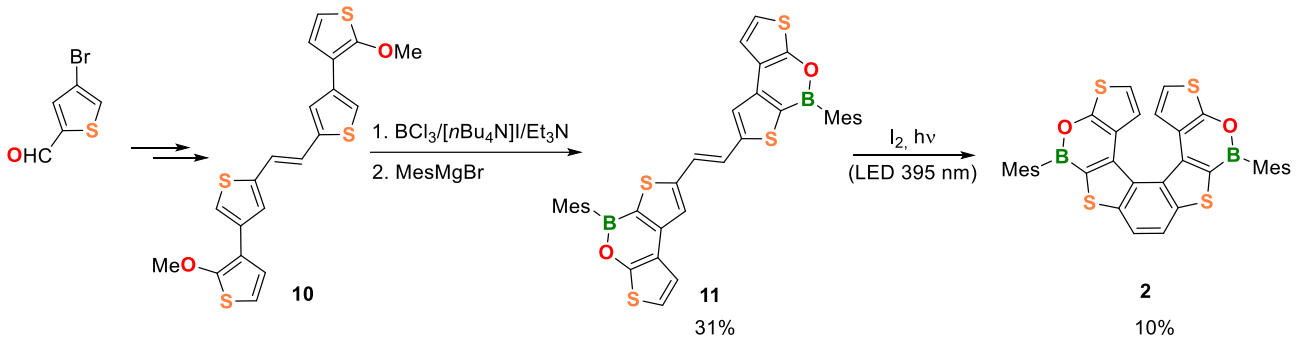
In fact, **2** is expected to display LUMO orbitals extended over the whole thiophene-benzene-thiophene (BDT) central fragment rather than terminal thiophene rings as in **1** (Figure 5). The LUMO extension should provide a narrowed energy-gap, redshifted absorption/emission bands, increased reducing abilities and thus enhanced optoelectronic performances. This hypothesis was also supported by preliminary DFT calculation (Figure 6b).

Borahelicene isomer **2** was synthesised following the late stage borylation strategy (see *Route C* for **1** in Scheme 4). To this aim the alkene **10,** prepared in good yield from 3-bromo-2-thiophencarbaldehyde (Scheme 5), was first borylated to give **11**, then submitted to photocyclization using a 395 nm LED lamp affording the target helicene **2.**



Scheme 5. Synthetic route to BO-doped tetrathia[7]helicene isomer **2**.

Although the synthetic protocol needs to be optimized, the procedure allowed to obtain bora-helicene **2** as a second example of doubly boron-doped thiahelicene, and in enough amount for the analytical and photophysical characterization (Figure 6).

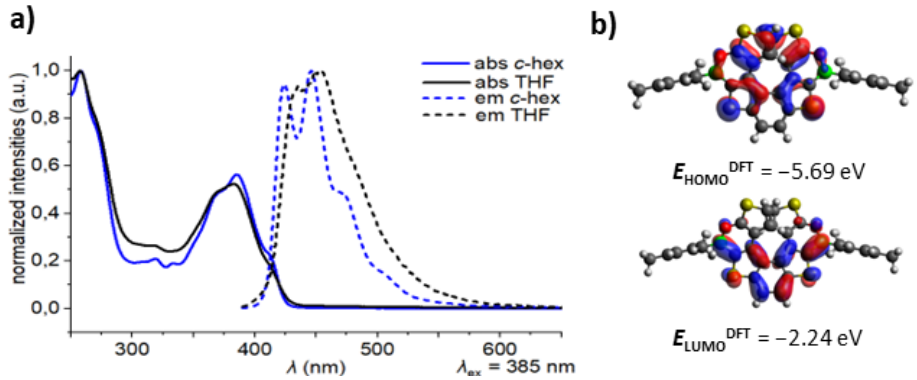


Figure 6. a) UV/Fluorescence spectra of **2** in *c*-hexane (blue trace) and THF (black trace). b) HOMO/LUMO distribution of **2** calculated at the B3LYP/6-31G* level.

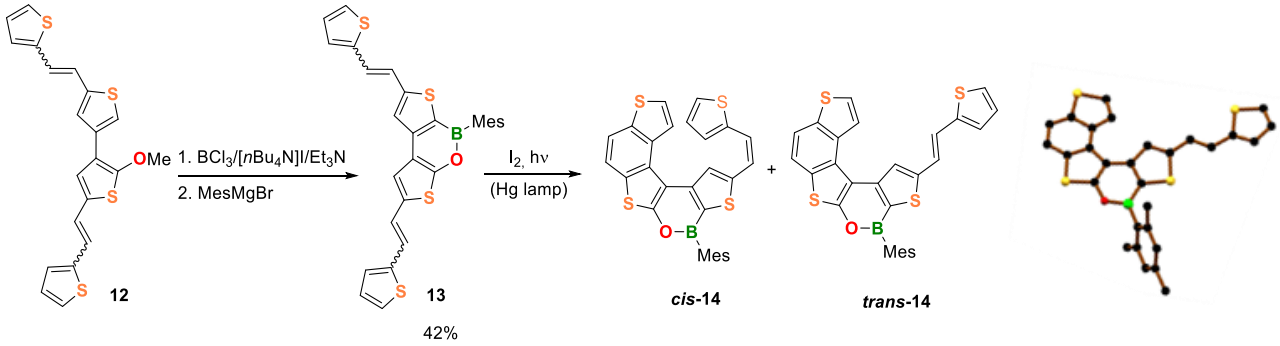
In *c*-hexane, **2** exhibits a structured UV/vis absorption band with the most bathochromic shoulder appearing at 413 nm (Figure 6a, blue line). For comparison, the corresponding shoulder in the spectrum of **1** is found at 374 nm. **2** is a blue emitter, and its emission band shows a partly resolved vibrational fine structure with the most hypsochromic shoulder at 472 nm and a photoluminescence quantum efficiency is Φ_{PL} = 7% (*c*-hexane; *cf.* **1**: $\lambda_{em} \approx$ 411 nm, Φ_{PL} = 6%). Absorption and emission bands of **2** are substantially red-shifted with respect to those of **1**. DFT calculations showed as the LUMO of **2** is distributed over the whole thiophene-benzene-thiophene central fragment and thus is more extended than that of **1**.

Taken together, these results revealed as the inversion of BO vectors represents a suitable tool to tune the LUMO of BO-doped thiahelicenes and, although in the specific case of **2** it did not have appreciable effect

on the optoelectronic performances (still low Φ_{PL} and only slight lowering of the LUMO energy), they set the basis for the structural design of new derivatives with tuned electronic properties. Racemization kinetics and chiroptical properties of **2** will be carried out in the future, meanwhile the thesis work was addressed to the synthesis of oxabora thiahelicenes **3** and **4** containing one oxaborine ring in different position of the helical scaffold (see Figure 2).

Preliminary study of the synthesis of singly BO-doped tetrathia[7]helicenes 3 and 4

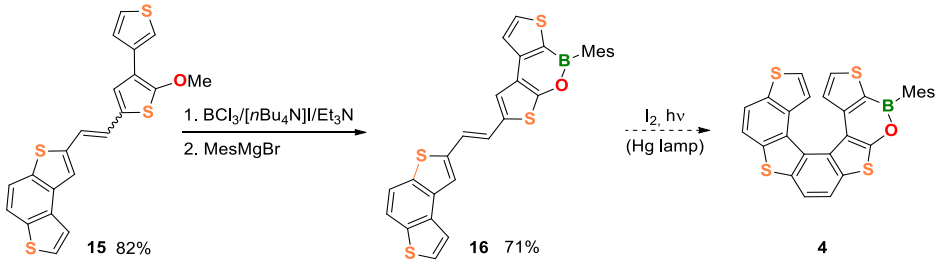
For the synthesis of mono-BO-doped thiahelicene **3**, again we considered the borylation of bis-alkene **12** to give oxaborine derivative **13,** before the photocyclization step. This latter to achieve **3** is currently under investigation although first photochemical trials allowed to isolate an almost equimolar mixture of *cis*/*trans* isomers of the mono ring-closed product **14** (Scheme 6). The two structures were identified by ^{1}H NMR, ^{HH}COSY spectra. In addition, crystals of *trans*-**14** were obtained, and its structure was confirmed by HRMS and X-ray analysis (Figure 7).



Scheme 6. Synthesis and photocyclization of **13**.

Figure 7. X-ray structure of *trans*-**14**.

The same synthetic approach was also used to obtain mono-BO-doped helicene **4** (Scheme **7**), starting from the benzodithiofene functionalized alkene **15** that was borylated in good yield to give alkene **16**, whose optoelectronic and electrochemical properties were investigated. The subsequent photocyclization of **16** to helicene **4** is currently under investigation as the photochemical step, up to now, represents the bottleneck of both synthetic sequences.



Scheme 7. Synthetic route to **4**.

Conclusions

This PhD thesis aimed at investigating a new class of chiral thiaheterohelicenes doped with one or two BO-bonds. This challenge has been particularly demanding from a synthetic point of view, but novel borahelicenes **1** and **2** have successfully been prepared and, in the case of **1**, its complete optoelectronic, electrochemical and stereochemical study was completed and published on Angewandte Chemie Int. Ed.[13] Moreover, the synthetic study of two additional borahelicenes, namely **3** and **4** has been carried on and is currently still ongoing.

2. Introduction

2.1 Conjugated materials

In recent years conjugated organic materials have attracted much attention for applications in organic electronics, because these molecular systems offer many advantages as potential replacement for conventional inorganic materials (*i.e.*, silicon and metals) in terms of cheap fabrication and environmental friendly devices.[1] In contrast to silicon-based technologies, organic materials[2] can be used for a variety of applications due to their processing advantages (e.g. low temperatures and cost) and their unique physical, optical and electronic properties. Organic components can be produced using processes such as gas phase deposition, spin coating or printing processes that do not require highly equipped clean room laboratories and enables particularly rapid coverage of large substrates. In particular, the fabrication of multi-layer components, *e.g.,* by sequential application of individual layers, is proving to be extremely effective.[3] The combination of transparent substrates with transparent electrodes also makes it possible to produce fully transparent devices that would not be possible using inorganic semiconductors. In addition, processing at low temperatures and the mechanical flexibility of organic materials make flexible or foldable displays (or solar cells) accessible, thus opening up completely new areas of technology and application.[4]

The most established sectors of organic electronics are those regarding *light-emitting* devices and lighting elements namely: organic light-emitting diode (OLED),[5] organic thin-film transistors (OTFT),[6] organic field-effect transistor (OFET)[7] and organic photo-voltaic cell (OPVC).[8] Among these, OLEDs are among the most studied electronic devices whose structure and basic operating principle are illustrated by a schematic diagram in Figure 1.

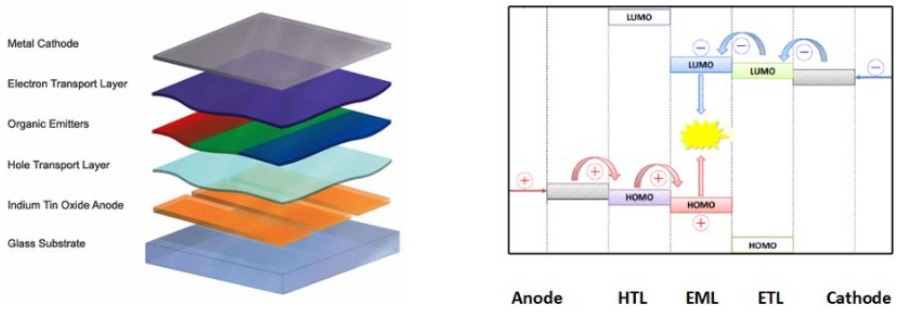

Figure 1. OLED structure and working principle.

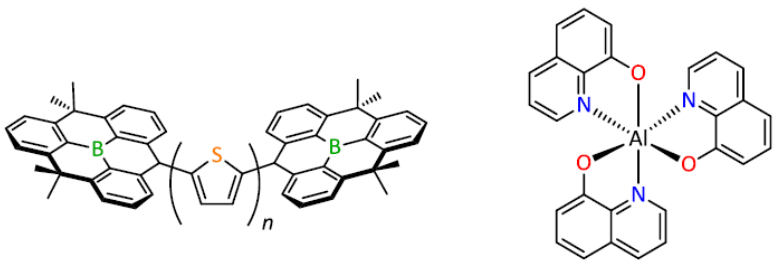
OLEDs consist of several thin layers of organic semiconductor materials that are sandwiched between two contacts (anode and cathode). In general, light production is induced by electric charges, exploiting the electroluminescence of the semiconducting material. Electrons or holes are respectively injected into the LUMO (lower unoccupied molecular orbital) or HOMO (highest occupied molecular orbital) of the emitting organic layer (EML) and move in an externally applied field to the so-called recombination region. As soon as the distance between the charge carriers becomes smaller than the Coulomb capture radius, Frenkel excitons (electron-hole pairs) are formed. By recombining the charge carriers, the electrons fall into the lower energy level and release this energy in the form of photons, thus the excited molecules relax into their electronic ground state. The wavelength or colour of the emitted light depends on the size of the band gap between the HOMO and LUMO levels of the emitter materials.[7] If the emitted light is to be within the visible light spectrum, this distance shall be between 1.6 and 3.3 eV.[9]

Modern multi-layer OLEDs have also additional layers to simplify carrier injection at the electrode interfaces and to divide the large potential barriers between the individual layers into smaller potential differences.[10] For this purpose, hole transport layers (HTL) and electron transport layers (ETL) with different properties are used. Organic p-type semiconductors such as diphenyl amine or carbazole derivatives, characterized by a high HOMO level, are typically used as HTL materials. On the other hand, for ETL materials organic n-type semiconductors such as phenanthroline, which enable particular high electron mobility, are used.

Especially in the development of efficient ETL materials there is still a great need for research, since the general electron mobility in organic materials is very low compared to inorganic materials and therefore the selection of organic n-type semiconductors is reduced to a very small number of electron-poor compounds.[9]

For a few years now, organoboranes have come to the fore as candidates for ETL materials. These compounds not only have excellent redox properties, but often exhibit strong luminescence with high quantum yields.

As one of the first examples, compound **I** (Figure 2),[11] which consists of two boron-doped acceptor units and a thiophene (n = 1) or 2,2'-bithiophene (n = 2) donor bridge, was successfully integrated into OLEDs as ETL material. Compound **I** showed a comparable performance as the tris(8-hydroxyquinoline)aluminium **II** complex (Figure 2), which has been predominantly used in OLEDs so far.[12]



I **II**

Figure 2. Boron and aluminium organo-complexes usued in OLED.

2.1.1. Photophysical principles of light or current absorption

Interactions of organic molecules with light or electric current strongly depend on the electronic structure and the energetic states of each compound. If the energy of an incident photon corresponds to the energy difference of the two energetic states of the molecule, the photon is absorbed (e.g., S_0->S_1). According to the Franck-Condon principle, higher vibronic states of excited levels are occupied. Relaxation processes following the absorption ones lead to both radiant and radiation-free transitions, which return the molecule to its ground state.[13] Main relaxation process can be divided into different groups: fluorescence (FL), internal conversion (IC), intersystem crossing (ISC) and phosphorescence (P), shown in Figure 3 as Jablonski diagram.

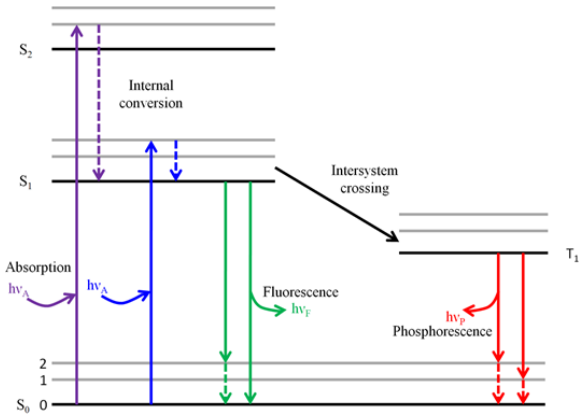


Figure 3. *Jablonski* diagram.

In fluorescence (F), a large part of the absorbed energy is spontaneously re-emitted as electromagnetic radiation. According to Kasha's rule, this is usually done from the lowest vibronic state v_0 of S_1 and is therefore independent of the excitation wavelength, however also weak $S_2 \rightarrow S_0$ transitions take place. The wavelength of the electromagnetic radiation is redshifted in relation to the wavelength of the incoming photon, since a part of the originally absorbed energy is released non radiatively by oscillation relaxation. The difference between the excitation wavelength and the emission wavelength is called Stokes shift.

The most important parameter to evaluate fluorophores is the quantum yield Φ_{PL}. It corresponds to the ratio of the absorbed photons and the photon emitted by fluorescence.

Many chromophores show intensive fluorescence in diluted solution after excitation. As the concentration increases, the fluorescence intensity is attenuated. This phenomenon, called *self-quenching,* is often observed in aromatic compounds and plays an important role especially in molecules with small Stokes shifts, since absorption and emission spectra partially overlap.[14] In extreme cases, strong intermolecular π-π interactions (π-stacking) in condensed phase lead to radiation-free deactivation processes of the aggregated molecules, e.g. via external vibrational relaxation. The phenomenon is called *aggregation-caused quenching* (ACQ).[13]

A opposite photophysical phenomenon is *aggregation-induced-emission* (AIE). In AIE, weakly luminescent chromophores become efficient emitters due to the formation of aggregates.[15]

Suitable fluorophores for semiconductor materials must have a sufficiently small band gap in addition to the delocalized π system.[16] A suitable strategy to adjust the band gap of a π conjugated system is the introduction of suitable π-electron donor and π-electron acceptor substituents into the carbon skeleton. Electron donor and electron-acceptor groups influence HOMO and LUMO energy levels and thus the optoelectronic properties of the molecules. As an alternative adjusting tool, the exchange of a carbon atom with a heteroatom is a suitable option. Basically, two cases can be distinguished:

i) the doping with an electron donor atom, such as nitrogen, sulphur, phosphorus or oxygen;
ii) the incorporation of an electron acceptor atom, such as boron.

In the literature, various examples of polycyclic (hetero)aromatic hydrocarbons doped with boron, nitrogen, phosphorus, oxygen, and sulphur atoms can be found.[17] Among these, organic boron chromophores in which a trigonal-planar boron atom is present in π conjugated aromatic systems are, nowadays, really important in the field of organic electronics. These include an abundance of organoboron compounds, which are now mainly established in the field of OLED, OPVC, and OTFT materials.[18,17a]

2.2 Polycyclic aromatic hydrocarbons (PAHs) and helicenes

2.2.1 General concepts

Polycyclic aromatic hydrocarbons (PAHs)[19] are composed of several fused aromatic rings, which are characterized by more or less pronounced delocalized π–electron systems. Within the scaffolds, all carbon atoms are sp^2-hybridized, while the non-hybridized p_z orbitals are perpendicular to the molecular plane therefore allowing overlap over the entire system.

Proper design of PAH molecular structures allows to obtain systems often showing narrowed band gaps, predictable supramolecular arrangements, and enhanced charge-carrier properties,[20] thus providing materials for organic light-emitting diodes (OLEDs), organic field-effect transistors (OFETs), organic photovoltaic cells (OPVs), and for lithium batteries.

As an example of PAHs widely used in optoelectronic devices,[21] anthracene, tetracene and pentacene structures are reported in Figure 4.

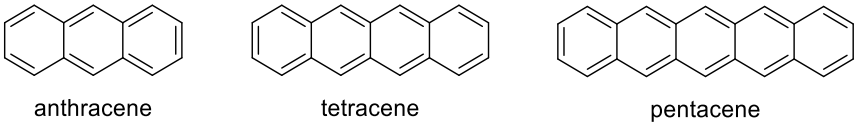

Figure 4. Anthracene, tetracene and pentacene structures.

The increasing number of *ortho*-fused benzene rings strongly contributes to the extension of the π-conjugated system of acenes, leading to redshift absorption and emission bands and narrower band gaps. However, despite their excellent photophysical and electrochemical properties,[22] flat polyaromatics often display scarce solubility in common organic solvents thus reducing processability and characterizability in the liquid phase.

To overcome these drawbacks, a suitable option is to introduce solubilizing groups such as alkyl chains or bulky aryl groups. However, the introduction of side groups often interferes with the stacking properties of the related molecules, leading to reduced charge carrier mobilities and therefore reduced optoelectronic performances.

As an alternative to the introduction of solubilizing group, the distortion of the molecular scaffold can enhance the solubility of PAHs, leading to better processability in solution without dramatically altering their stacking abilities. Furthermore, distortion of the carbon skeleton leaves orbital interactions within the π-system sufficiently large to produce similar properties as in comparable planar compounds.

Abolition of planarity can be achieved by linking of neighbouring rings in different ways leading to diverse structural features of PAHs peripheral regions, which can generally be divided into three subcategories: bay, cove and fjord regions (Figure 5).[23]

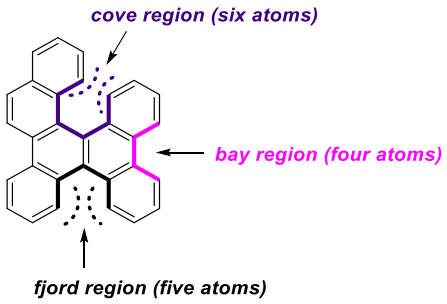

Figure 5. Schematic representation of the different peripheral regions in PAHs.

In contrast to bay regions, the occurrence of fjord or cove regions leads to a distortion of the three-dimensional structure of PAHs. Responsible for this is the steric repulsion of the hydrogen atoms that protrude into the corresponding regions. The extreme case of a particularly strong twist can be observed in the structural class of helicenes. The first helicene was synthesized in the early '900,[24] but the term "helicene" was first introduced almost 60 years later.[25]

Helicenes are characterized by non-planar screw-shaped skeletons formed by ortho-fused benzene or other aromatic rings, which adopt a helical configuration, due to geometrical constraints and overlapping of the terminal rings (Figure 6).[26]

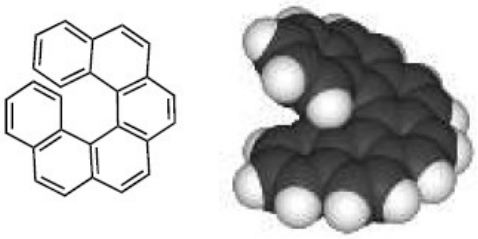

Figure 6. Carbo[6]helicene 2D and 3D structure.

Because of the steric hindrance of the terminal rings, helicenes can wind in opposite directions; they are chiral molecules even in absence of stereogenic centres, and possess a C2-symmetric axis, which is perpendicular to the helical axis (Figure 7).

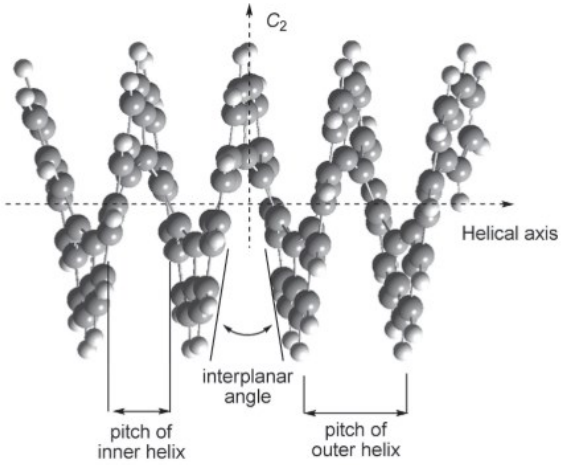

Figure 7. Helicene C2-symmetric axis.

The interconversion barrier between carbohelicene enantiomers, composed by six or more *ortho*-fused benzene rings, is sufficiently high to allow the existence of two optical antipodes, and on the basis of the helicity rule proposed by Cahn, Ingold and Prelog in 1966, a left-handed helix is designated "minus" and denoted by *M*, whereas a right-handed one is designated "plus" and denoted by *P* (Figure 8a).[27] Moreover, according to the results of ORD and CD spectroscopy, as a general trend in a homochiral series, the *P* series of helicenes has a (+) dextrorotatory specific rotation and the *M* series has a (−) levorotatory specific rotation.[28] The helical topology of helicenes provides a high optical rotation and high circular dichroism values.

As the number of fused rings increases, the helicene spirals up along the helical axis to form a cylindrical structure with a constant pitch (in both the inner and the outer helixes). For helicenes composed of six membered aromatic rings, it takes nearly six rings to cover a complete 360 °C rotation of a screw while, in structures containing five-member heterocycles, more rings are required: this is due to the smaller in-plane turn (θ) that five-membered rings contribute to the helical structure (Figure 8b).

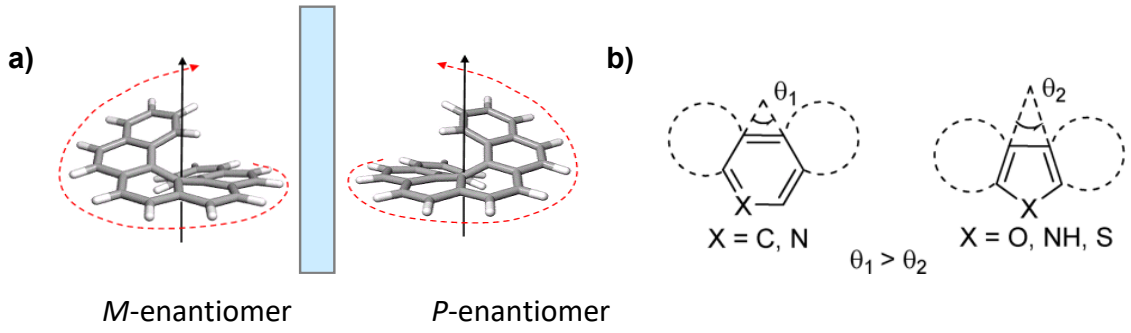

Figure 8. a) Carbo[6]helicene *P*- and *M*- enantiomers; b) in-plane turn (θ) of six- and five-membered rings.

About the nomenclature, according to IUPAC rules, helicene are named as follows: 1) number of fused aromatic rings in helical framework, indicated by the number *n* in brackets "[*n*]", followed by 2) the term "helicene". A helicene composed by six aromatic rings will be therefore named [6]helicene.

Helicenes which are exclusively composed by fused benzene rings are classified as carbohelicenes (the prefix *carbo*- is added before the name), while helicenes incorporating heteroaromatic rings into the helical scaffold are named as heterohelicenes (the prefix *hetero*- is added before the name).

Most of the reported heterohelicenes incorporate p-block elements-based heteroaromatic rings: pyrroles (N, *aza*-), thiophenes (S, *thia*-), furans (O, *oxa*-), phopholanes (P, *phospha*-), siloles (Si, *sila*-). Following the nomenclature those will be therefore named as aza[n]helicenes, thia[n]helicenes, oxa[n]helicenes, phospha[n]helicenes, and sila[n]helicenes, respectively (Figure 9).[29] The number of heteroaromatic rings is indicated using the prefix: "di" for 2, "tri" for 3, "tetra" for 4, and so on.

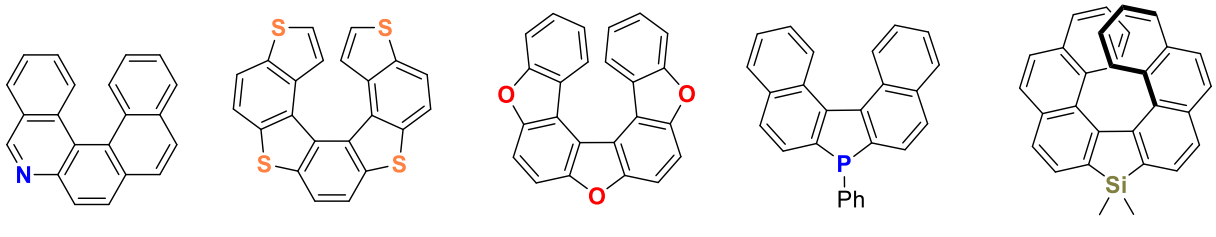

Figure 9. Examples of heterohelicenes.

2.2.2 Properties and applications of helicenes

Helicenes combine the key attributes of both PAHs and chiral molecules and show interesting electronic and optical properties.

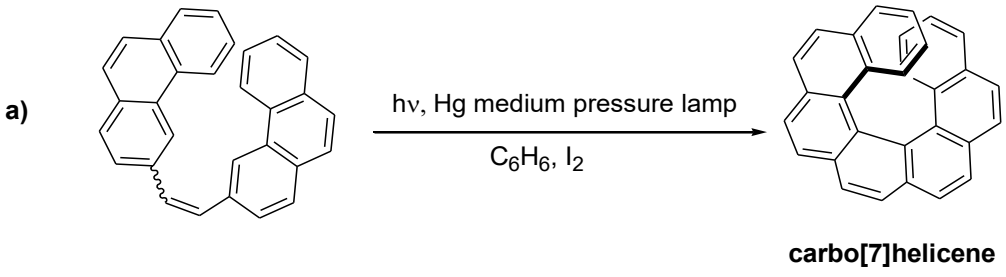
Furthermore configurationally stable helicenes show unique solid-state packing (due to chiral recognition), unusual molecular dynamics (as 'molecular springs'), and remarkable optoelectronic properties (due to their chiral electronically excited states) and thus they are particularly interesting in the field of materials science *e.g.*, to develop antiglare displays consisting of OLEDs in which the electroluminescence is directly circularly polarized (CP-OLED).[30]

The π-interactions within the polyaromatic system of helicenes give rise to structured absorption and emission bands and, despite the non-planarity, in helicenes HOMO-LUMO overlap is still sufficient to get peculiar intermolecular electronic interactions.[31] Generally, the increase of the number of ortho fused rings results in helicenes with a reduced HOMO-LUMO gap (E_g), as effect of the π-π overlap across the helix.[32] Helicenes often display fluorescence but the associated quantum yields (Φ_{PL}) are low due to non-emissive quenching processes (intersystem crossing).

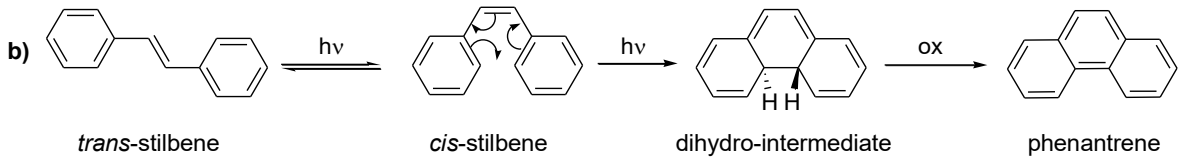
The functionalization of the helix with suitable accepting or donor groups represents a suitable tool to get compounds with tuned optoelectronic properties. However, this strategy is scarcely appealing since it could have a strong influence on the intermolecular interactions (π-stacking) and therefore be detrimental for charge carrier properties. In the last decades, the incorporation of p-block atoms into the helix has come to the fore as a tool to obtain systems with enhanced optoelectronic properties, without heavily influencing the π-stacking properties.

2.2.3 Synthesis of helicenes

From a synthetic point of view, the most relevant strategy to prepare helicenes is the Mallory photocyclization of suitable stilbene derivatives [33] The oxidative photocyclization of stilbene derivatives was first used in 1967 by Martin [34] (Scheme 1a) for the synthesis of carbo[7]helicenes starting from a *cis*/*trans*-mixture of the corresponding stilbene precursor.



Scheme 1a. First example of photochemical synthesis of [7]helicene.



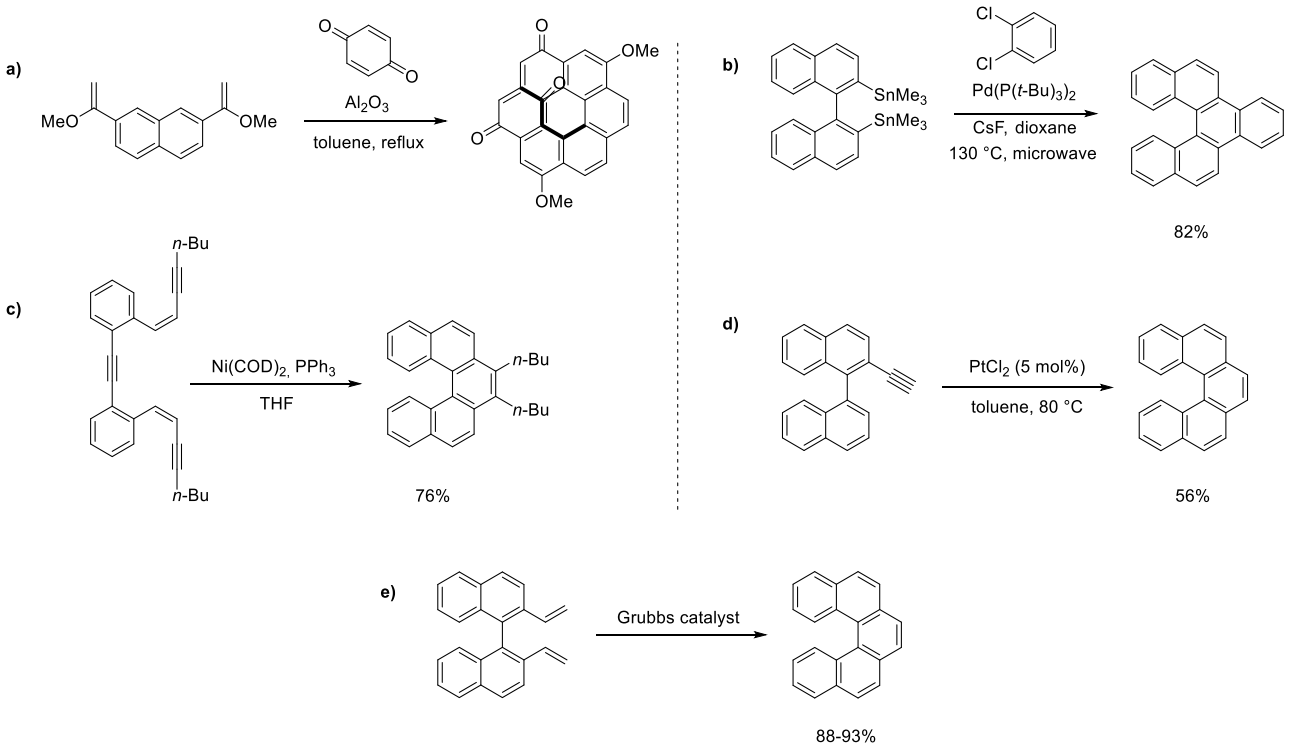
Scheme 1b. Mechanism of the Mallory photocyclization.

The Mallory photocyclization (illustrated for the simple stilbene in Scheme 1b) occurs on *cis*-isomer, but in general, it is not necessary to prepare selectively the *cis*-isomer of the starting alkene because even using *trans*-stilbene or a *trans*/*cis* mixture, the first step of the reaction is the light-promoted *trans*-to-*cis* isomerization. The subsequent cyclization gives the dihydro intermediate that is oxidized to helicene in the presence of air or iodine.

The Mallory photocyclization for obtaining helicenes was widely investigated and later optimized in terms of yield and selectivity[35] Although widely used, this synthetic way still presents some drawbacks, mainly related to the high-dilution conditions, which are required to avoid intermolecular dimerization, and the specific photochemical equipment needed (photochemical reactors/lamp).

In the last decades, alternative strategies for helicene synthesis have been reported[36] and these include the use of different reactions among which Diels-Alder[37] cycloadditions (Scheme 2a), Stille coupling[38] (Scheme 2b), metal-catalyzed [2+2+2] cycloisomerization (Scheme 2c,d),[39, 40] ring-closing metathesis[41] (Scheme 2e).

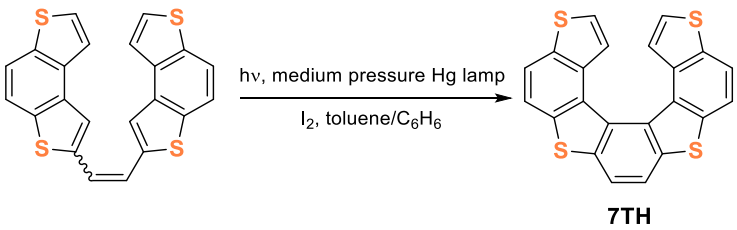
No enantioselective version of photocyclization reactions have been currently reported while several methods involving the use of Diels-Alder,[42] metal-catalysed cyclizations,[43] and metathesis[44] have been described in the literature for the synthesis of enantiopure helicenes.



Scheme 2. Alternative methods for helicene synthesis: a) two-fold Diels-Alder; b) two-fold Stille coupling; c) Ni(0)-catalysed intramolecular [2+2+2] cycloaddition; d) π-acid catalysed cycloisomerization using a Pt(II)-catalyst; e) ring-closing metathesis.

Despite the huge development of alternative methods and the known drawbacks, the Mallory photocyclization of stilbene derivatives still represents one of the most efficient and popular methods to prepare helicenes and heterohelicenes, due to its versatility and owing to the easy preparation of stilbene precursors.

Photocyclization reactions have been largely applied as key step in the synthesis of heterohelicenes, and especially of tetrathia[7]helicenes (**7THs**).[45] which are an interesting class of heterohelicene combining the properties of oligo-thiophenes with those of helicenes (Scheme 3). The presence of sulphur atoms along the outer ridge of the helix provides the opportunity to modify the electronic and optical properties thanks, *inter alia*, to S-S interactions in the solid state.[46]



Scheme 3. Synthesis of tetrathia[7]helicene (**7TH**) *via* oxidative photocyclization.

Our research group has a long-standing expertise in the synthesis of thiahelicene systems and, in the last years, contributed to the development of this field with the setup of innovative strategies to prepare different functionalized tetrathia[7]helicenes **7THs** *e.g., via* a stereospecific Suzuki-type reaction using (Z)-boronic esters or *via* a metal catalysed annulation of suitable precursors.[47] Hence, steric and electronic properties of thiahelicenes can be modulated by introducing substituents of different nature and size on the helical scaffold and this is facilitated by the presence of the thiophene rings. In fact, exploiting the thiophene reactivity, thiahelicene or its precursors can be easily and regioselectively functionalized by direct electrophilic substitution or through generation of α-anions followed by reaction with electrophiles.

Tetrathia[7]helicenes also represent an example of how the presence of a heteroatom in the helical skeleton could be a tool to obtain systems with enhanced optoelectronic properties, without heavily influencing the π-stacking properties (Figure 10).

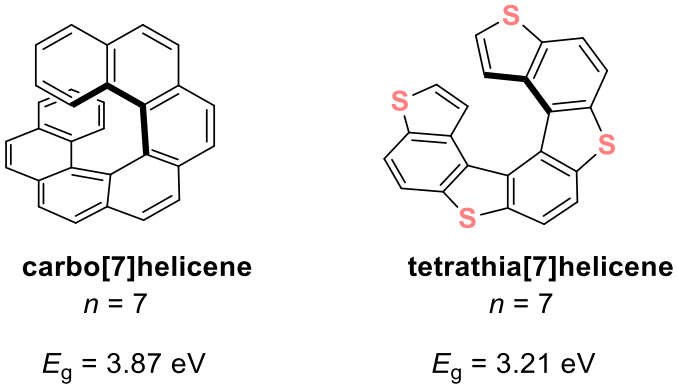


Figure 10. E_g values of selected helicene and heterohelicene systems.

In fact ranging from carbo[7]helicene to [7]helicene (7TH) a ≈0.7 eV E_g reduction can be obtained (Figure 10).[48] This last example shows as the doping of helicene scaffolds with p-block elements, is nowadays the most effective strategy to get helical systems with fine-tuned electronic properties and thus is a promising tool for the development of new building blocks for functional materials.

In this context, the introduction of trigonal boron atom into a thiahelicene scaffold could give rise to a novel class of unexplored boron π-conjugated molecules with potentially intriguing properties.

2.3 Boron containing π-systems: general concepts

Tri-coordinate boron π-systems, characterized by uncharged boron atoms, are isostructural and isoelectronic to carbenium ions with a trigonal-planar geometry. The boron vacant p_z orbital extends the π-conjugation pathway and exerts a strong π-acceptor effect (Figure 11).

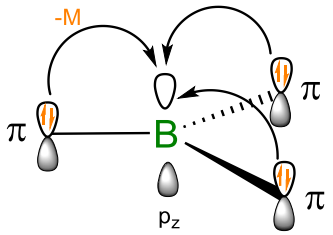

Figure 11. Electronic structure of a tri-coordinate boron π–system.

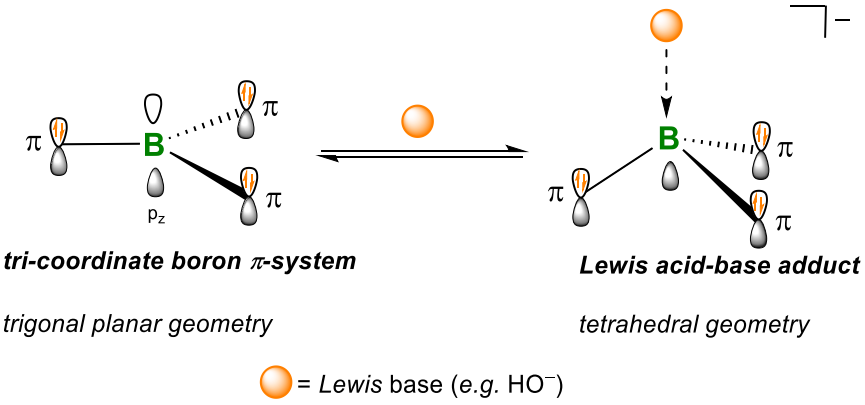
Generally, the insertion of trigonal boron centres contributes to stabilizing the LUMO of the molecule and, to less extent, the HOMO. The resulting decrease in the LUMO energy affects the energy gap and in turn optoelectronic characteristics of the compound as well as its electron accepting abilities.[49]

Furthermore, boron functionalized π–systems often display high luminescence performances making them suitable building blocks for emissive materials as well as for n-type semiconductors.

As a drawback, the empty p_z orbital of the boron atom behaves as a Lewis acid and generally makes tri-coordinate boron compounds extremely reactive towards Lewis bases, including water.

When a Lewis base is coordinated to the boron atom, the geometry of the boron in the corresponding Lewis acid-base adduct changes from trigonal-planar to tetrahedral, thus interrupting the π–conjugation (Scheme 4).



Scheme 4. Lewis acid-base adduct formation.

To discourage adduct formation, a rational structural design of the molecule is always required: three different stabilization strategies have been regarded as suitable tools to stabilize the trigonal geometry in boranes (Figure 12).

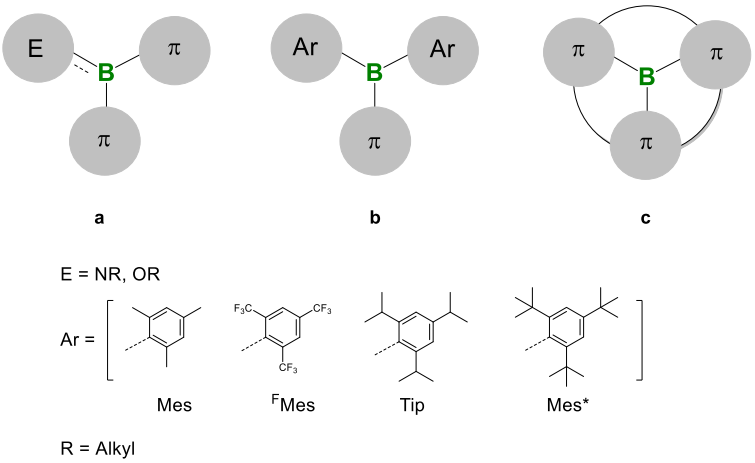


Figure 12. Boranes stabilization strategies.

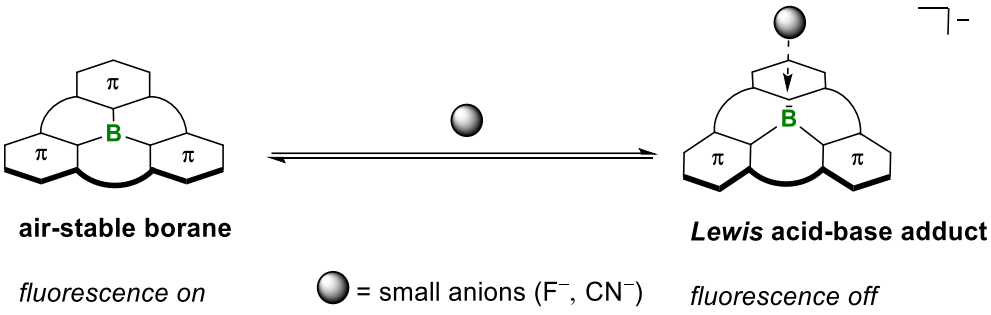
a) Introduction of a π-donor substituent "**E**", such as an amino or alkoxy group, to reduce the electron deficiency at the boron atom through partial double-bond formation.[17a]

b) Introduction of one or two bulky "Ar" groups, such as mesityl (Mes), fluoromesityl (^{F}Mes) etc., onto the boron site: the "propeller arrangement" of such *o*-substituted benzenes generally shields the p_z orbital from Lewis bases attack.[50]

c) Incorporation of the boron atom at the central position of the π-system (*e.g.* in the core of a carbon skeleton) to provide full structural constraint of the boron atom within the rigid carbon skeleton.[51] Although these compounds do not have any steric protection of the boron site in the vertical direction, the Lewis acid-base adduct formation is less feasible since the reaction of the planar carbon structure with a Lewis base would lead to a thermodynamically unfavoured adduct with tetrahedral geometry, in which the rigid carbon skeleton is highly distorted.

Despite the attack from nucleophiles is hampered, air-stable boranes can still exert Lewis acidic character and are reactive towards small anions such as fluoride and cyanide (Scheme 5) and in this case the adduct formation can be exploited in chemo-sensors.[52]



Scheme 5. Reaction of an air-stable borane with small anions.

In fact, in the adduct the interruption of the conjugation brings to quenching of the fluorescence, thus allowing the detection of the anions. This phenomenon can be reversibly switched on or off in many cases.

Due to the above-mentioned features, organoboranes are extremely attractive building blocks in various fields of applications ranging from material science to biology, and several conjugated molecules doped with one or more trigonal boron atoms have been reported over the past decades. [17,18]

In particular, the formal insertion of boron atom(s) into polycyclic aromatic hydrocarbons[19] is of great interest as it enables the formation of a powerful class of molecules, namely boron-doped PAHs.[17a]

Recently, these boron-embedded polycycles have polarised the research interest as they combine excellent luminescence and charge transport properties with predictable supramolecular arrangements, making them promising building blocks for next generation functional materials.

For the classification of B-PAH structures is helpful to define the nomenclature of bora-heterocycles[53] which are formally derived from the 1) insertion of borylene unit(s) into cyclobutadiene, fulvene and benzene, which generates the antiaromatic borole **A**, 1,4-dibora-2,5-cyclohexadiene **B**, borine **C** and the aromatic borepin **D**, or 2) replacement of a benzene C=C bond with a B=E (E = O, N) bond, which generates the aromatic 1,2-oxa/aza- borine ring **F** (Figure 13).

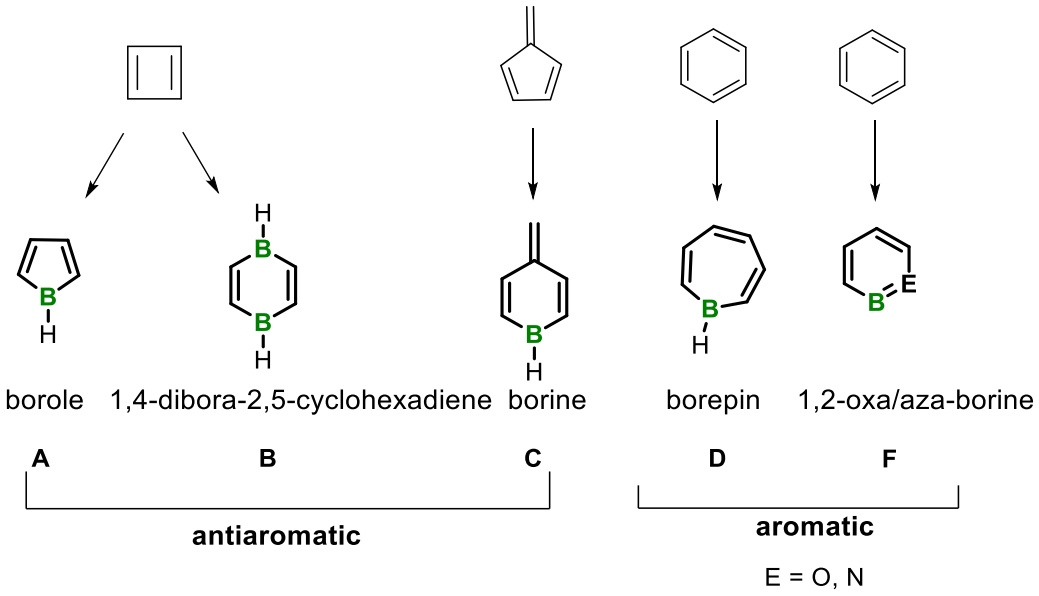


Figure 13. Nomenclature of bora-heterocycles.

More extended π-structures incorporating bora heterocycles **A**, **B**, **D**, **F** can be further defined as borafluorene, diboraanthracene, dibenzo borepine and oxa/azabora phenanthrene and have been synthesized over the past decades (Figure 14).[54]

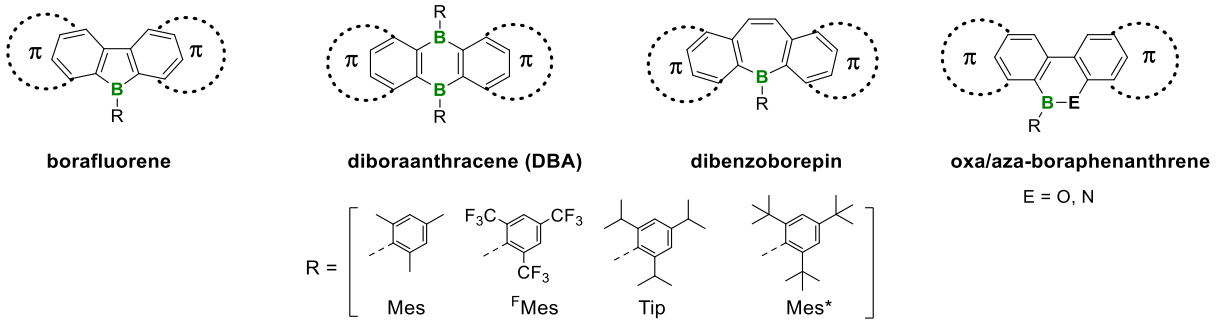

Figure 14. General borafluorene, diboraanthracene and dibenzoborepin structures.

2.3.1 Properties and applications of distorted B-PAHs and B-doped helicenes

Boron containing polycyclic aromatic compounds (B-PAHs) usually show peculiar spectroscopic and electrochemical properties such as red-shifted emission and absorption bands, high photoluminescence quantum yields (Φ_{PL}) and low reduction potentials (E_{red}) suitable for applications in optoelectronics.

In addition to planar compounds, recently, configurationally stable distorted boron-doped PAHs have also been reported and showed good solubility properties, unaltered stacking abilities and appreciable orbital interactions to produce similar performance as comparable planar systems.[55]

Most frequently, sp^2 hybridized boron atoms [B(sp^2)] are linked to an electron donor heteroatom (N, O) and resulting B–N/B–O linkages are beneficial for the stability of the boron centre, due to its partial double bond formation.

Despite their great potential, B(sp^2)-doped helicenes are rare and the large part of the reported boron-doped helicenes includes B(sp^3)-doped compounds.[56] Very recently, some helical-shaped B(sp^2)-PAHs have been reported and, in addition to interesting photophysical and redox properties, they showed unprecedented charge carrier mobilities.

As representative examples, borahelicenes **1**-**7** are shown in Figure 15.

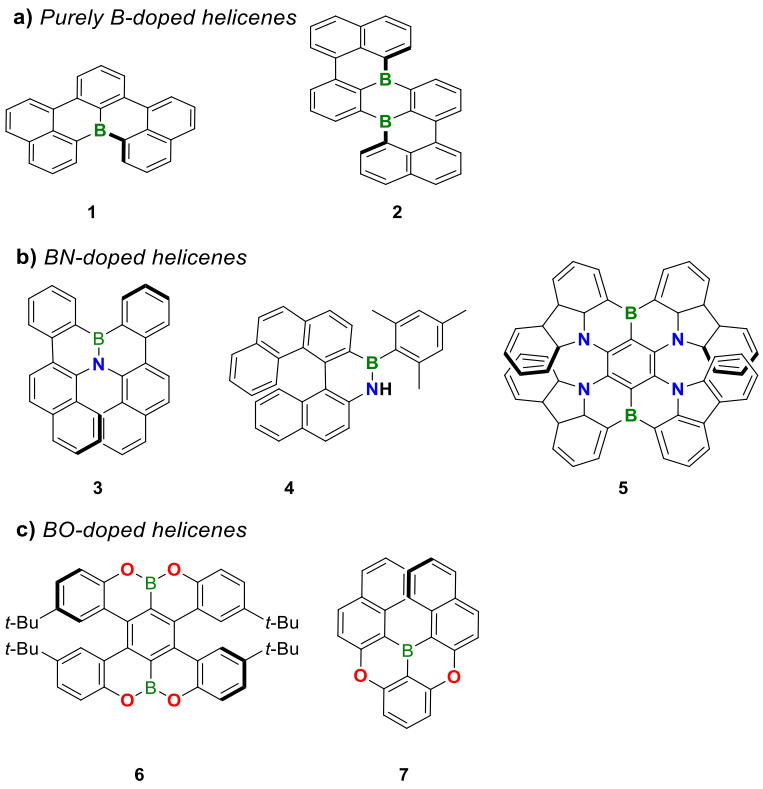

Figure 15. Structure of borahelicenes **1-7**.

Two examples of purely B-doped helicenes (**1** and **2**) have been reported (across 2015 and 2019) by Wagner.[57,58] In particular, the B-doped [4]helicene **1** that showed E_g = 2.60 eV, Φ_{PL} = 81% and suitable redox features, was successfully integrated as emissive component in an OLED device.

Regarding BN-doped helicene, the helicene **3** showed unprecedented and interesting spin carrier inversion[55] between racemate and single enantiomers, which display p- and n-type semiconducting character respectively. Recently Wang reported a double helicene **5** incorporating 1,4-azaborine rings which showed E_g = 1.81 eV and Φ_{PL} = 100%.[59]

Oxaborine-containing helicenes **6** and **7** also showed peculiar properties. Remarkably **6** showed Φ_{PL} = 65% and an excellent ambipolar semiconductor activity; moreover **6** resulted to be CPL-active with a g_{lum} = 1.7×10^{-3} for both enantiomers.[60,61]

In general, all the B-doped helical structures containing aza- and oxa-borine rings (**1-7**) displayed excellent solubility, spectroscopic, electrochemical, and stacking properties.

Moreover, in addition to their optical and redox properties, borahelicenes, due to their inherent chirality and configurational stability, are also attractive in the field of asymmetric synthesis therefore expanding the range of their potential applications.

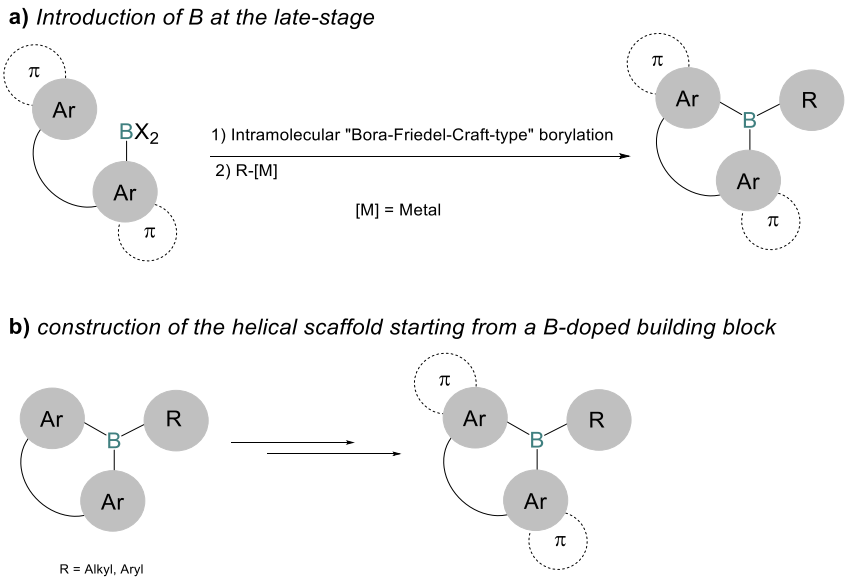
2.3.2 Synthesis of B-doped helicenes

Synthetic methods reported for the preparation of borahelicenes have as a crucial step the introduction of boron atoms into the molecular scaffold, to form a boron-containing ring. This step is performed *via* intramolecular Friedel-Craft-type electrophilic aromatic substitution [62] and, for the synthesis of heterocycles containing the BN/BO bond, a N- or O- *ortho*-directing group is needed.[63] Generally these reactions require forcing experimental conditions (heating at elevated temperatures) and, the use of a non-nucleophilic base (acting as proton scavenger) is crucial. In some cases, the addition of a Lewis acid can be used as tool to enhance the electrophilicity of the borylating species.

In general, the synthetic strategies reported for the synthesis of borahelicenes are be divided in two main categories:

a) *synthetic strategies involving the introduction of boron at the late-stage* through an intramolecular electrophilic borylation (Scheme 6a) - when boron is positioned at the outer edge of the helix, the electrophilic borylation is followed by a nucleophilic substitution to introduce bulky substituents on the boron centre (using organometallic reagents, *e.g.,* aryl Grignard);

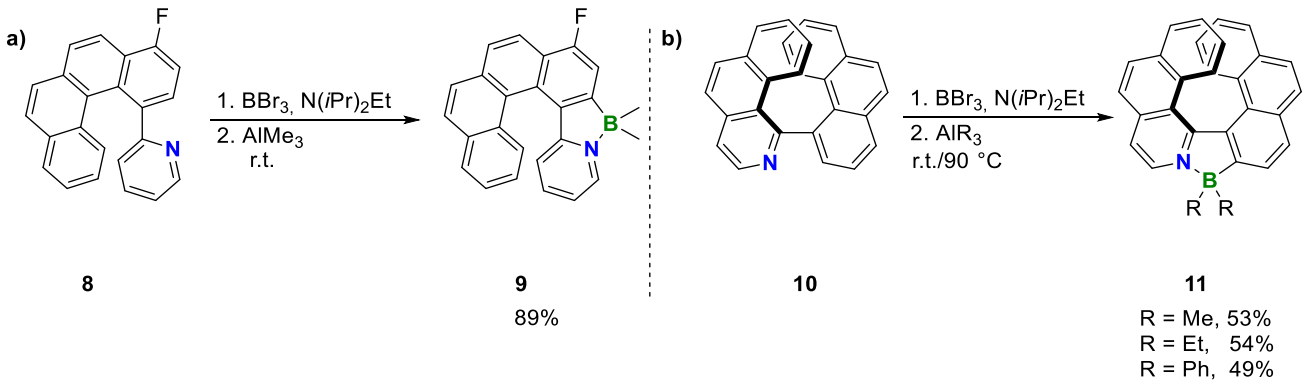
b) *construction of the helical scaffold starting from a B-doped building block* (Scheme 6b).



Scheme 6. Main synthetic strategies reported for the synthesis of borahelicenes.

Boron-doped aromatics are often very reactive towards nucleophiles, including water and sometimes not benchtop-stable. Furthermore, organoboranes are incompatible with some of the commonly used organic

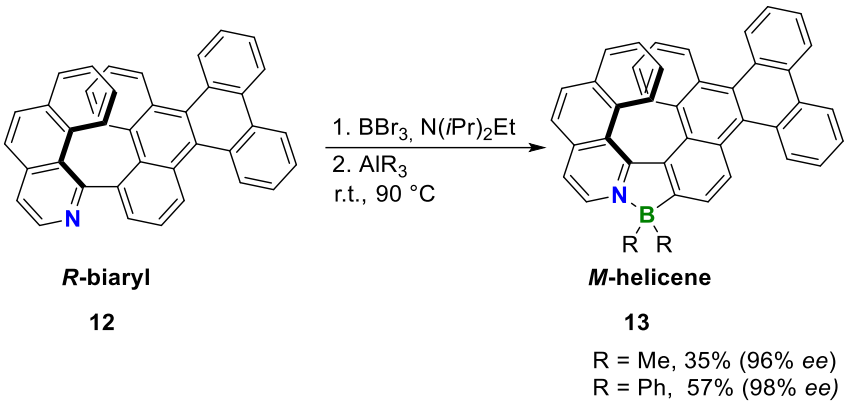
transformations. Due to these drawbacks, for both B(sp^2) and B(sp^3)-doped helicenes, most of the reported syntheses exploit the first strategy, while the second one is rare (Scheme 7a, 7b).



Scheme 7. Selected examples of B(sp^3)-doped helicenes synthesized by introduction of the boron at the late stage.

Regarding B(sp^3)-doped helicenes, in 2017 Crassous *et al*. reported a series of B(sp^3)-N doped helicenes obtained by N-directed borylation performed by treatment of aryl substituted 2-pyridines **8** with BBr_3 in presence of N(*i*Pr)$_2$Et, followed by the addition of $AlMe_3$ to introduce methyl groups onto the boron atom(s). As an example, the synthesis of **9** is reported in Scheme 7a.[56] This protocol allows to get access to a wide series of helicenes in mild conditions. Later in 2021 Nowak-Krol, using the same synthetic approach, reported new examples of B(sp^3)-N helicenes, showing as by increasing the temperature at the nucleophilic substitution stage, is it possible to introduce also aryl groups on the boron atom (Scheme 7b, reaction of **10** to **11**).[64]

More recently, the same group reported the first example of enantiospecific synthesis of BN-doped helicenes starting from axially chiral biaryls (Scheme 8).[65]



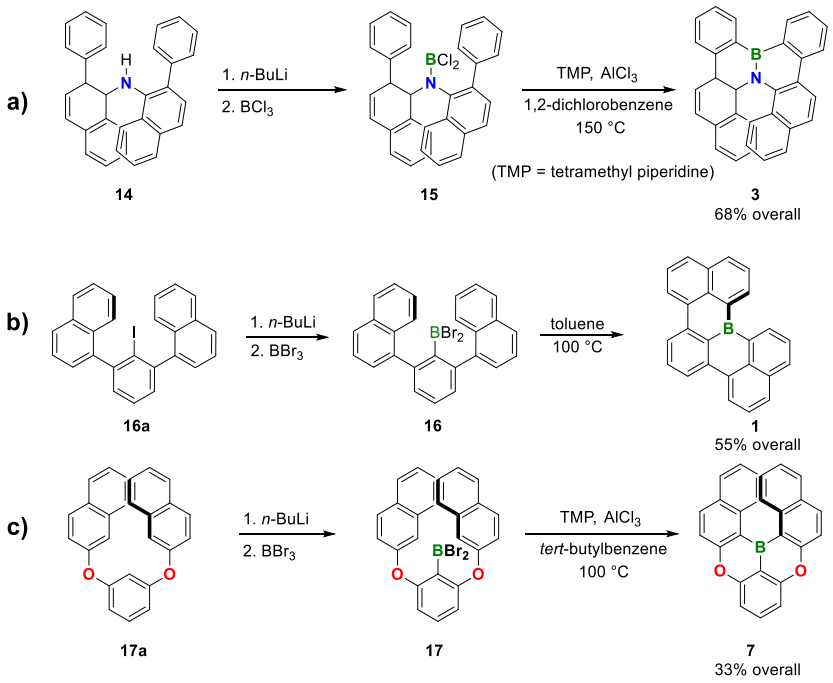
Scheme 8. First reported example of enantioselective synthesis of B(sp^3)N-helicenes. For simplicity only the synthesis of the *M*-helicene is reported.

The synthesis, performed starting from both enantiomers of biaryl **12** (pure enantiomers were obtained *via* chiral-HPLC separation exploits the axial-to-helical chirality transfer and allowed to get *P* and *M* helicenes **13** in high *ee%* (only the reaction of the *R*-enantiomer has been shown in Scheme 8).

Regarding trigonal B(sp^2)-helicenes, the late-stage borylation reactions can be divided in two sub-classes:

- *heteroatom-directed borylations*, for the synthesis of BO/BN bonds containing helicenes, involving an Ar-E-BX_2 (X = Cl, Br) intermediate (Scheme 9a);

- *direct carbon electrophilic borylations*, involving an Ar-BX_2 (X = Cl, Br) intermediate, for the synthesis of purely B(sp^2)-doped helicenes – (Scheme 9b) or helicenes in which the boron atom is not directly linked to a heteroatom (*e.g.,* 1,4-oxaborine-containing helicenes, *Scheme* 9c).
Representative examples for both cases were reported by Hatakeyama (Scheme 9).[55,66,61]

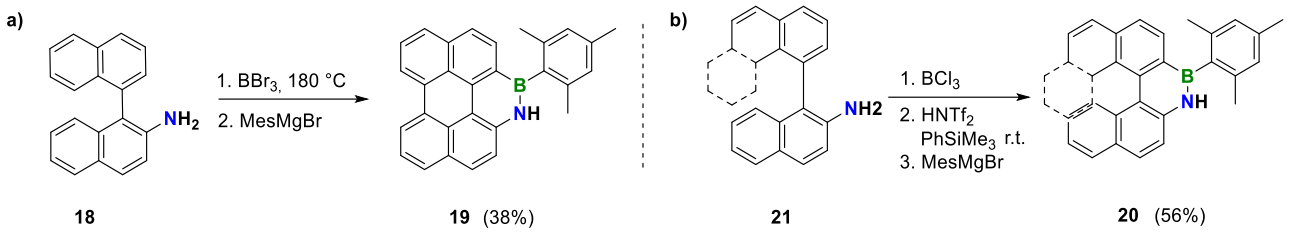


Scheme 9. Selected examples of B(sp^2)-doped helicenes synthesized by introduction of the boron at the late stage.

In detail, for the synthesis of BN-doped helicenes, the treatment of the suitable diaryl amine **14** with *n*-BuLi followed by the addition of BCl_3 gives access to the Ar_2N-BCl_2 intermediate **15** which**,** heated in the presence of tetrametylpyridine (TMP) and $AlCl_3$ gives the helicene **3** *via* two-fold intramolecular electrophilic borylation (Scheme 9a).[55] In the case of the purely B-doped **1** and 1,4-oxaborine containing **7,** the procedure is similar but the two-fold intramolecular borylation proceeds *via* an Ar-BX_2 intermediate (**16**/**17**) (Scheme 9b,c).[66,61]

One of the main disadvantages of introducing B(sp^2) atoms at the late-stage, is that this strategy dictates the helicene topology by imposing π-extended architectures and thus limiting the number of regular helical structures achievable (*e.g.* **3** in Scheme 9a or **5** in Figure 15).[55,59]

Especially for the synthesis of B(sp^2)-doped helicenes, a second drawback of the late-stage procedure is the formation of the B(sp^2)-C(sp^2) bond that, very often in the case of long (extended)helices, must occur against the steric strain of the helix making the ring-closure unfavourable. Therefore, in those cases, the borylation requires forcing conditions, which could lead to unwanted side-reactions like Lewis-acid-mediated Scholl reactions[67] (**18** to **19** Scheme 10a).

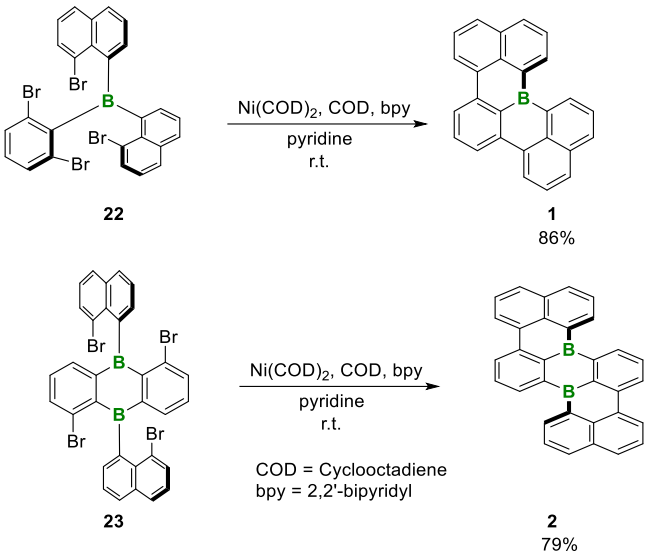


Scheme 10.

To overcome these issues, recently, Ingleson, Nowak-Krol and co-workers reported an enhanced procedure which allows the synthesis of BN-doped [6]helicenes in mild conditions (Scheme 10b).[68] In this case the use of $HNTf_2$ and $PhSiMe_3$ resulted to be crucial and allowed to achieve helicenes **20** in good yield using mild conditions starting from the corresponding binaphtyl amine **21**. Despite these encouraging results, steric strain remains as one of the main issues in the use of the late-stage strategy, especially in the case of long-sized helicenes.

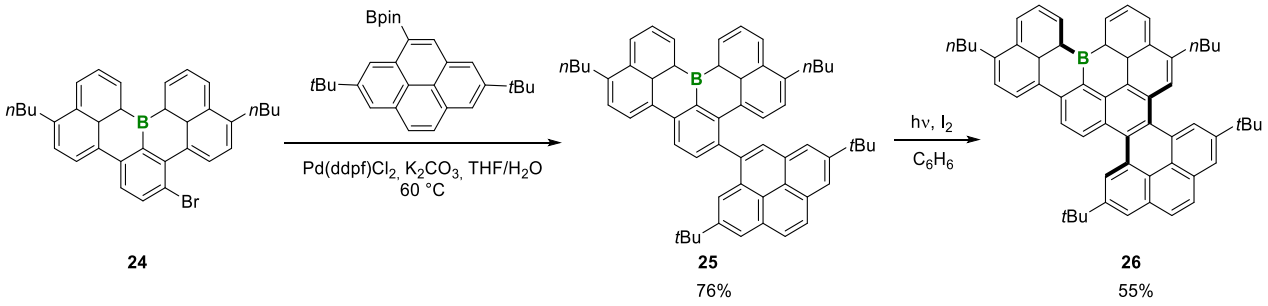
Regarding the second strategy, that is the construction of the π-conjugated system starting from a B-doped building blocks, only few examples have been reported in the literature.

As one of the rare examples, recently Wagner reported the synthesis of mono- and doubly-B(sp^2)-doped helicenes **1**[57] and **2**[58] through two-fold intramolecular Yamamoto coupling starting from suitably functionalized triarylborane/diboraanthracene building blocks **22**/**23**. (Scheme 11).



Scheme 11.

As a second example, recently Dou and Wang reported the synthesis of B-doped nanoribbons incorporating one or two B-[4]helicene moieties using a photocyclization reaction in the last step (Scheme 12), and this is one of the rare case of photocyclization involving boron containing aromatics.[69]



Scheme 12. Example of photocyclization involving boron containing aromatics

In detail the synthesis starts from the brominated B-doped building block **24** which is then functionalized *via* Suzuki coupling to give **25** and finally photocyclized *via* irradiation in benzene in presence of I_2 to give the double-helicene **26** (Scheme 12). This is one of the few examples of the use of a photocyclization involving boron containing aromatics, since photochemical conditions are often incompatible with most boron componds and constitute a good premise to the design of synthetic strategy to B-doped helical molecules involving photo-induced ring closures.

Considering the state of the art of the research on borahelicenes and the promising features of this class of compounds, the design and the setup of new synthetic routes to get new borahelicenes, as well as the investigation of their physico-chemical properties, is therefore a relevant research topic and is the object of the present Ph.D. thesis.

3. Aim of the project

This Ph.D. project was aimed to study and develop innovative and versatile syntheses of new boraheterohelicenes as well as the study of their stereochemical and optoelectronic properties to identify potential applications of these systems in material science.

The thesis work was carried out in part at the University of Milan in the laboratories of Prof. Emanuela Licandro and in part at the Goethe Universität Frankfurt am Main under the supervision of Prof. Dr. Matthias Wagner, within a co-tutelle programme. Owing to the long-standing expertise of Prof. Licandro group in the synthesis of tetrathia[7]helicenes (**7TH**) and that of Prof. Dr. Wagner group in the synthesis of boron-doped PAHs, I conceived this PhD project designing a series of tetrathia[7]helicenes incorporating one or two oxaborine rings into the helical scaffold and bearing mesityl group(s) on the boron atom(s) (Figure).

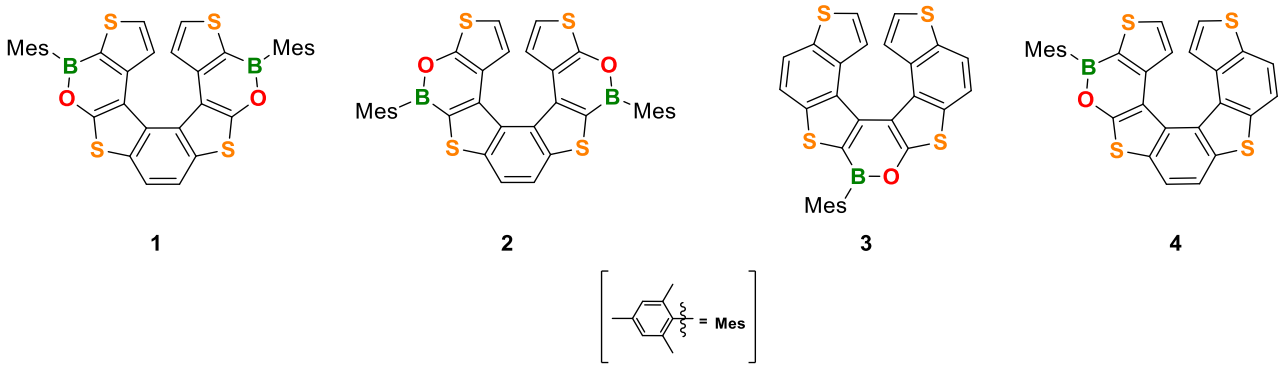


Figure: Designed BO-doped tetrathia[7]helicenes.

In detail, **1** and **2** structures incorporate two 1,2-oxaborine rings into the lateral region of the helical scaffold, while **3** and **4** contain one 1,2-oxaborine ring into the central or lateral part of the helix respectively.

The main goals of the present thesis can be divided as follows:

i. *the study of methodologies for the synthesis of the designed BO-doped tetrathia[7]helicenes;*

ii. *the study of the electrochemical, photophysical properties of all of the new BO-doped helicenes and intermediates by a combined experimental and theoretical effort (analysis/investigation) ;*

iii. *the study of the stereochemical and chiroptical properties of the BO-doped tetrathia[7]helicene target structures.*

For the sake of simplicity, results obtained concerning the topics covered in this PhD thesis have been organized in three chapters.

- *Chapter 1*: *Study of the synthesis and properties of the doubly BO-doped tetrathia[7]helicene **1***.

  This chapter deals with the study of synthetic methodologies to achieve **1** as well as the study of the electrochemical, photophysical and theoretical properties of **1** and all its BO-doped intermediates. Results of the stereochemical studies conducted on **1** are also discussed.

- *Chapter 2*: *Study of the synthesis and properties of the doubly BO-doped tetrathia[7]helicene* **2**.

  This chapter deals with the study of synthetic methodologies to achieve **2** as well as the study of the electrochemical, photophysical and theoretical properties of **2** and all its BO-doped intermediates.

  *Chapter 3: Preliminary study of the synthesis of the singly BO-doped tetrathia[7]helicene **3** and **4**.* This chapter deals with the study of synthetic methodologies to obtain BO-doped and precursors of **3** and **4,** as well as the study of electrochemical, photophysical and theoretical properties of the most relevant intermediates.

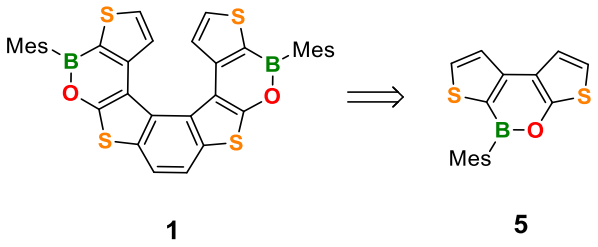
4. Results and Discussion

4.1 Study of the synthesis and properties of the BO-doped tetrathia[7]helicene 1

4.1.1 Synthesis, NMR and crystallographic characterization of 1

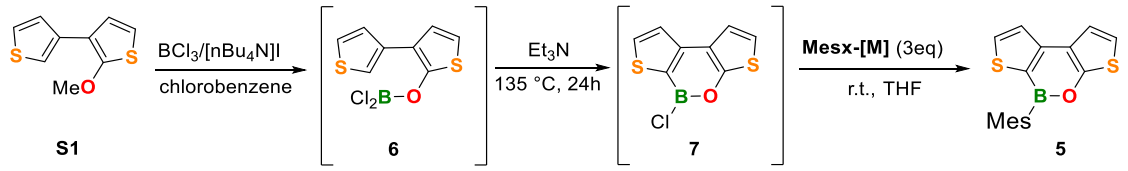
In the first part of my PhD I faced the synthesis of the doubly BO-doped tetrathia[7]helicene **1**, which incorporates four thiophene rings and two oxaborine rings into the helical scaffold and bears mesityl groups on the boron atoms. Looking at a possible retrosynthetic analysis of **1** (Scheme 1), the mesityl dithienooxaborine **5**, was identified as potential building block.



1 **5**

Scheme 1. Dithienooxaborine **5** as potential building block for **1**.

Although some dithieno oxaborines are known in the literature,[1] the mesityl oxaborine **5** has not been reported and therefore its synthesis was setup starting from the known methoxy bithiophene **S1** (prepared according to the literature;[1] see Section 2.1 of the Experimental Part) *via* intramolecular demethylative borylation followed by the addition of an organometallic reagent to introduce the mesityl group (Scheme 2).



Mes_x-[M]	
MesMgBr	62 - 77%
MesCu	26%
MesLi	4%
Mes_2Zn	0%

Scheme 2. Synthesis of the mesityl diethienooxaborine **5**.

In detail **S1** was treated with BCl_3 and [*n*Bu_4N]I at room temperature, giving the demethylated Ar-O-BCl_2 species **6** (the use of [*n*Bu_4N]I is needed to promote the demethylation). The heating of **6** at 135 °C in the presence of Et_3N (acting as proton scavenger) furnished the intermediate **7** through intramolecular borylation.[2] Finally the treatment of **7** with the suitable organometallic reagent, allowed to introduce the mesityl ring *via* nucleophilic substitution at the boron atom.

It is worth to mention that the study of this one-pot procedure required a careful setup of the experimental protocol, including: the choice of proper glassware (Schlenk apparatus, J-Young flask), the preparation of the organometallic reagents (*e.g.,* mesityl Grignard) and the purification of solvents and additives (chlorobenzene, Et_3N were distilled over CaH_2).

Several organometallic reagents were tested, among them MesMgBr (3 eq is the optimal stoichiometry) gave the best results affording **5** in yields up to 77% on a 500 mg-scale. The structure of **5**, that proved to be a benchtop-stable compound, was elucidated by accurate NMR analyses, and confirmed by X-ray (Figure 1 and Figure S87). Diagnostic proton and carbon shifts mentioned in the following discussion are recaped in Figure 4.

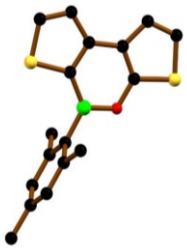


Figure 1. X-ray crystal structure of **5**. Crystal system: monoclinic, space group: P 21/n. B: green, C: black, O: red, S: yellow spheres; picture generated with the crystallographic software *Mercury*.

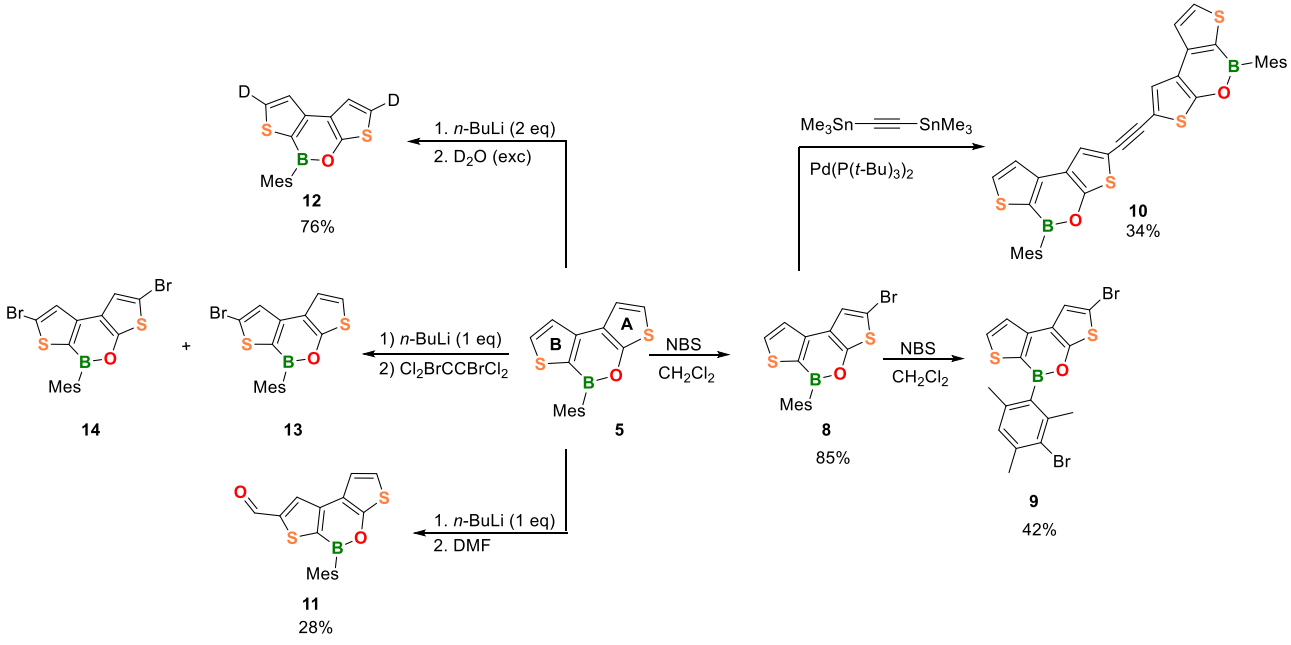
In the ^{1}H NMR spectrum, of high diagnostic value are the signals of protons in the α positions of the two thiophene rings of **5**: due to π-conjugation with the electron-withdrawing B or the electron-donating O atom, the CH nuclei of the electron-poor borylated thiophene are significantly deshielded ($\delta(^1H)$ = 7.98, $\delta(^{13}C)$ = 138.2) compared to those of the electron-rich oxygenated thiophene ($\delta(^1H)$ = 6.96, $\delta(^{13}C)$ = 114.8).

Once optimized the synthesis of **5**, its stability and reactivity have been investigated as a premise to the design of a suitable synthetic way to helicene **1**. Reactions carried out on **5** are depicted in Scheme 3.



Scheme 3. Investigation of the mesityl diethienooxaborine **5** reactivity.

Given the presence of the B-O bond, we hypothesized different reactivity of the two thiophene rings A and B: "oxygenated thiophene A" was supposed to be the most electron rich, and thus more reactive towards electrophiles, while "borylated thiophene B" was expected to be less electron rich and having the more acidic α-proton. To test the possibility of a selective functionalization of the two thiophene rings we performed a series of experiments (Scheme 3 and Section 13 of the Experimental Part).

Bromination with *N*-bromosuccinimide (NBS) revealed that **5** is reactive towards electrophiles and can be selectively brominated on the α position of the oxygenated thiophene ring using a slight excess (1.2 eq) of NBS that gave the brominated **8** in 85% yield (Scheme 3, right).

Bromo-dithienooxaborine **8** was completely characterized and the NMR analysis confirmed that the Br atom was selectively introduced next to the S atom into the oxygenated thiophene ring A, as evidenced of the disappearance of the proton resonance at 6.96 ppm and by a further upfield shift of the corresponding ^{13}C resonance (from 114.8 to 103.1 ppm) as a result of the magnetic anisotropy effect of the attached Br substituent (see Figure 4). The structure of **8** was further confirmed by X-ray analysis (Figure 2 and Figure S88).

Figure 2. X-ray crystal structure of **8**. Crystal system: monoclinic, space group: C 2/c. B: green, C: black, O: red, S: yellow, Br: brown spheres; picture generated with the crystallographic software *Mercury*.

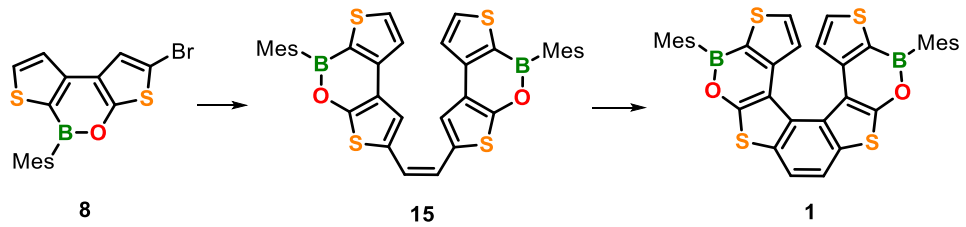
To evaluate the possibility to achieve double bromination, **8** was in turn treated with 1.5 eq of NBS but the reaction led to the bromination on the mesityl ring, and **9** was the only isolated compound. Furthermore, the reaction of **8** with 1,2-bis(trimethyl)stannylacetylene in the presence of $Pd(P(t\text{-}Bu)_3)_2$ as catalyst gave **10** in 34% yield, showing as α-brominated oxaborine **8** is a potentially useful building block for the construction of more extended systems (Scheme 3, right).

Next, we tested the reactivity of **5** towards strong bases (*e.g., n*-BuLi; Scheme 3, left). The treatment of **5** with 1 eq of *n*-BuLi followed by the addition of an excess of DMF gave **11** in 28% yield, showing that it is possible to selectively functionalize the "borylated thiophene" α-position under these conditions. Although the possibility to get the di-anion on the two thiophene α-positions was confirmed by deuteration test (**12** obtained in 76% yield), attempts of two-fold formylation, using 2 eq of *n*-BuLi resulted in decomposition products.

We then tried to achieve selective bromination of the "borylated thiophene B" and thus **5** was treated with *n*-BuLi and then reacted with $Cl_2BrCCBrCl_2$ giving the expected brominated product **13** in modest yield besides the doubly brominated **14** and starting oxaborine **5**.

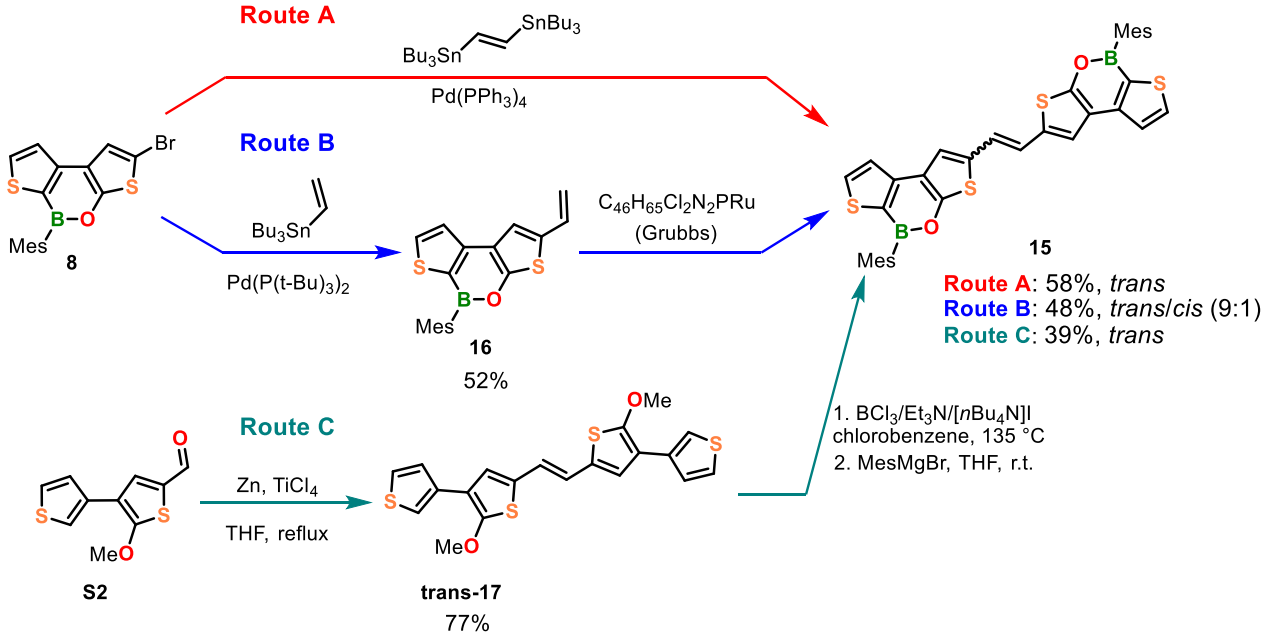
These preliminary tests showed how the dithienooxaborine **5** can be a useful building block with peculiar reactivity at the two thiophene α positions and could allow the preparation of a wide range of derivatives.

As the bromoderivative **8** can be obtained in mild conditions and in good yield, we selected a synthetic route to helicene **1** starting from **8** (Scheme 4) used as precursor of alkene **15**, (for simplicity, in the scheme, only the *cis*-isomer **15** is indicated) from which **1** can be obtained *via* Mallory photocyclization.



Scheme 4. Synthetic route designed for **1**.

The synthesis of alkene **15** was deeply investigated and carried out using three synthetic routes (*Route A*, *Route B*, *Route C*) as shown in Scheme 6.



Scheme 6. Synthetic routes to the stilbene derivative **15**.

In both *Route A* and *Route B* brominated oxaborine **8** was used as starting material.

Following *Route A*, **8** was subjected to a Stille coupling with the commercially available *trans*-1,2-bis(tributylstannyl)ethylene in the presence of $Pd(PPh_3)_4$ as catalyst and gave the target stilbene derivative **15**

in 58% yield as *trans*-isomer. The *trans*-**15** NMR spectra (Figure 4), showed for protons of the terminal thiophene rings signals at δ = 7.99 and δ = 7.60 and the corresponding carbon nuclei at C(α) = 138.4 ppm and C(β) = 123.0 ppm. Moreover, the ethylene bridge protons give rise to new resonances at $\delta(^1H)$ = 7.02 and $\delta(^{13}C)$ = 121.6. The *trans*-configuration was confirmed by X-ray crystallography (Figure 3 and Figure S89).

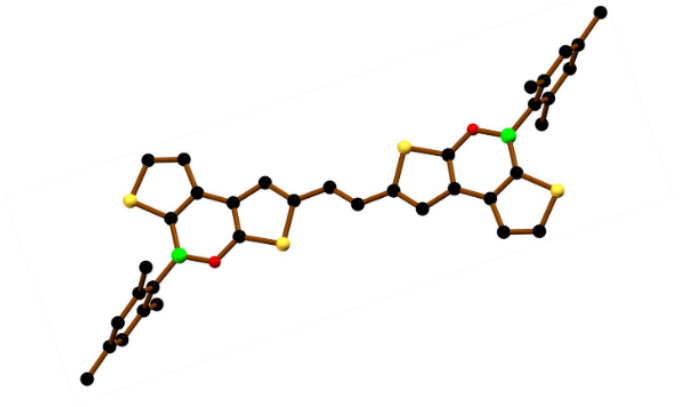


Figure 3. X-ray crystal structure of *trans*-**15**. Crystal system: monoclinic, space group: P 21/c. B: green, C: black, O: red, S: yellow spheres picture generated with the crystallographic software *Mercury*.

In the *Route B* (Scheme 6), **5** was first submitted to a Stille coupling with the commercial tributylvinyltin and Pd(P(*t*-Bu)$_3$)$_2$ and gave the vinyl derivative **16** (y = 52%) which was then dimerized *via* metathesis reaction, to give the alkene **15** in 48% yield as *trans*/*cis* (9:1) mixture (NMR resonance of the olefinic proton of the *trans*-isomer at $\delta(^1H)$ = 7.02 while that of the *cis*-isomer at $\delta(^1H)$ = 6.67; Figure 4).

Although this second route has a modest yield, it is worth to note that the metathesis reaction of **16** represents the first example of such a reaction carried out on a BO-doped aromatic.

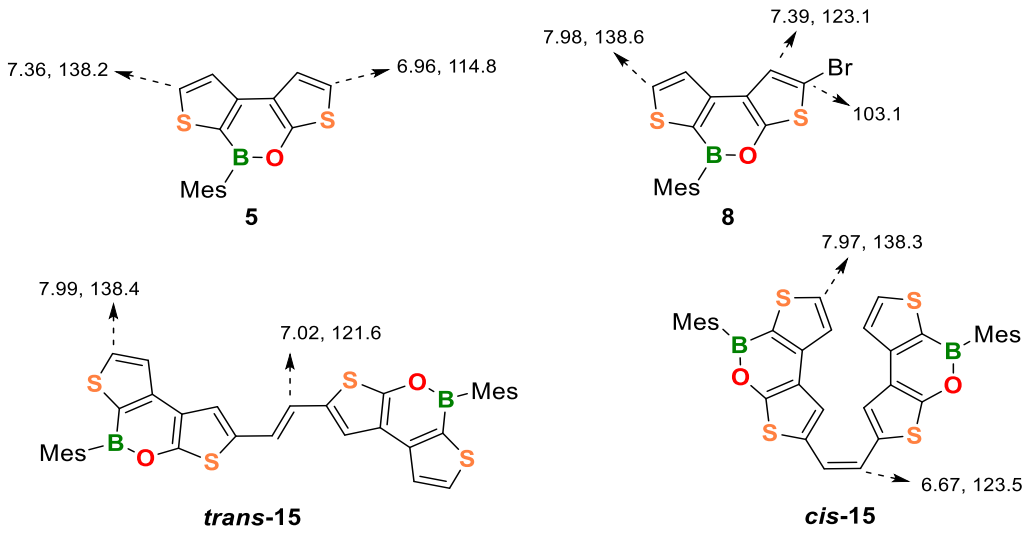

Figure 4. Diagnostic proton and carbon shifts of **5**, **8**, *trans*-**15** and *cis*-**15**.

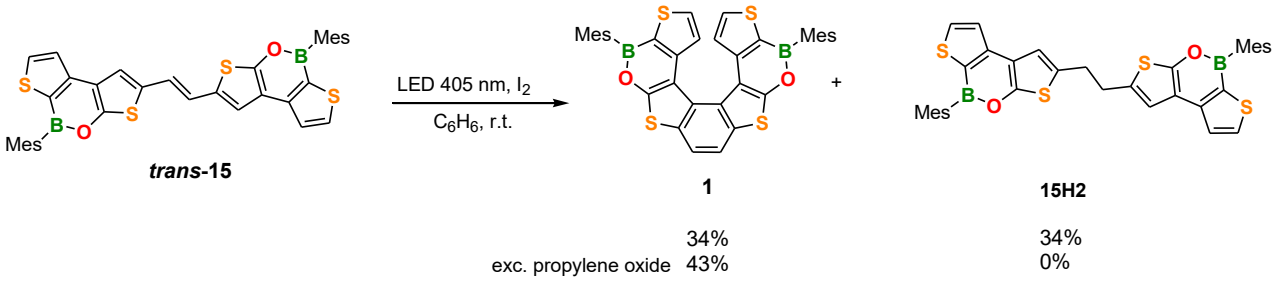
In Route *C* (Scheme 6), a different approach to **15** was considered, in which the oxaborine rings are constructed, as late stage, on a suitable alkene derivative, in this case *trans*-**17**, that was prepared in 77% yield by a McMurry coupling of methoxy bithienyl aldehyde **S2**.[3] The subsequent borylation of *trans*-**17**, gave **15** in 39% yield as *trans*-isomer.

Although this last synthesis showed a modest yield, it represents a more versatile method as by varying nature of the starting methoxy aldehyde, it could be possible to have access to stilbene derivatives incorporating different heteroaromatic rings.

The final step to obtain **1** is a Mallory photocyclization that required an accurate setup. As previously explained (see Introduction) the first step of this reaction is the photoinduced *trans*/*cis* isomerisation. As in our case *trans*-**15** was always obtained as major isomer, before starting investigating the photocyclization step, the photochemical interconversion of *trans*-**15** to *cis*-**15** was tested by NMR experiments in C_6D_6 with different light sources. (Figure S1 and S2). A 405 nm LED performed the task most efficiently (*trans*/*cis* (1:4) after 30 min; C_6D_6, r.t.) and was therefore used for the subsequent synthesis of the helicene **1** (Scheme 7).



Scheme 7. Synthesis of tetrathia[7]helicene **1**.

The photocyclization was therefore carried out using a 405 nm LED lamp in benzene as solvent and using I_2 as oxidant (Figure S3). The target helicene **1** was obtained in 34% besides an almost equimolar amount of the hydrogenated alkene side-product **15H2** (structure confirmed by NMR and X-ray analysis; Figure S93), generated by the reduction of the double bond by HI produced during the photochemical process.[4]

To suppress the formation of **15H2**, the photocyclization was performed in the same conditions but using an excess of propylene oxide (as HI scavenger) and **1** was isolated in 43% yield as sole product; **1** represents the first example of BO-doped tetrathia[7]helicenes and its structure **1** was confirmed by accurate NMR experiments and X-ray analysis (Figure 5, Figure 6; full details are provided in the Experimental Part).

In the NMR spectrum of **1**, (Figure 5) the former ethylene bridge CH groups, now in the benzene ring resonate at $\delta(^1H)$ = 7.81 and $\delta(^{13}C)$ = 119.0. Moreover, the signal for the H atoms in the β-positions of the thiophene adjacent to the former double bond has disappeared, and the resonance of the appended (now quaternary) C atoms is detectable at 117.3 ppm (see Figure 4). The protons on the α and β position in the terminal thiophene rings resonate at $\delta(^1H)$ = 7.37 and δ (^1H) = 7.19 while in the precursor *trans*-**15** those are significantly deshielded and resonate at $\delta(^1H)$ = 7.99 and $\delta(^1H)$ = 7.60 (*cf.* in **7TH** $\delta(^1H)$ = 6.83 and 6.67).

This shielding effect could be attributed to the helical 3D-strucutre, in which each terminal thiophene ring falls in the shielding region of the corresponding ring in the opposite helicene wing.

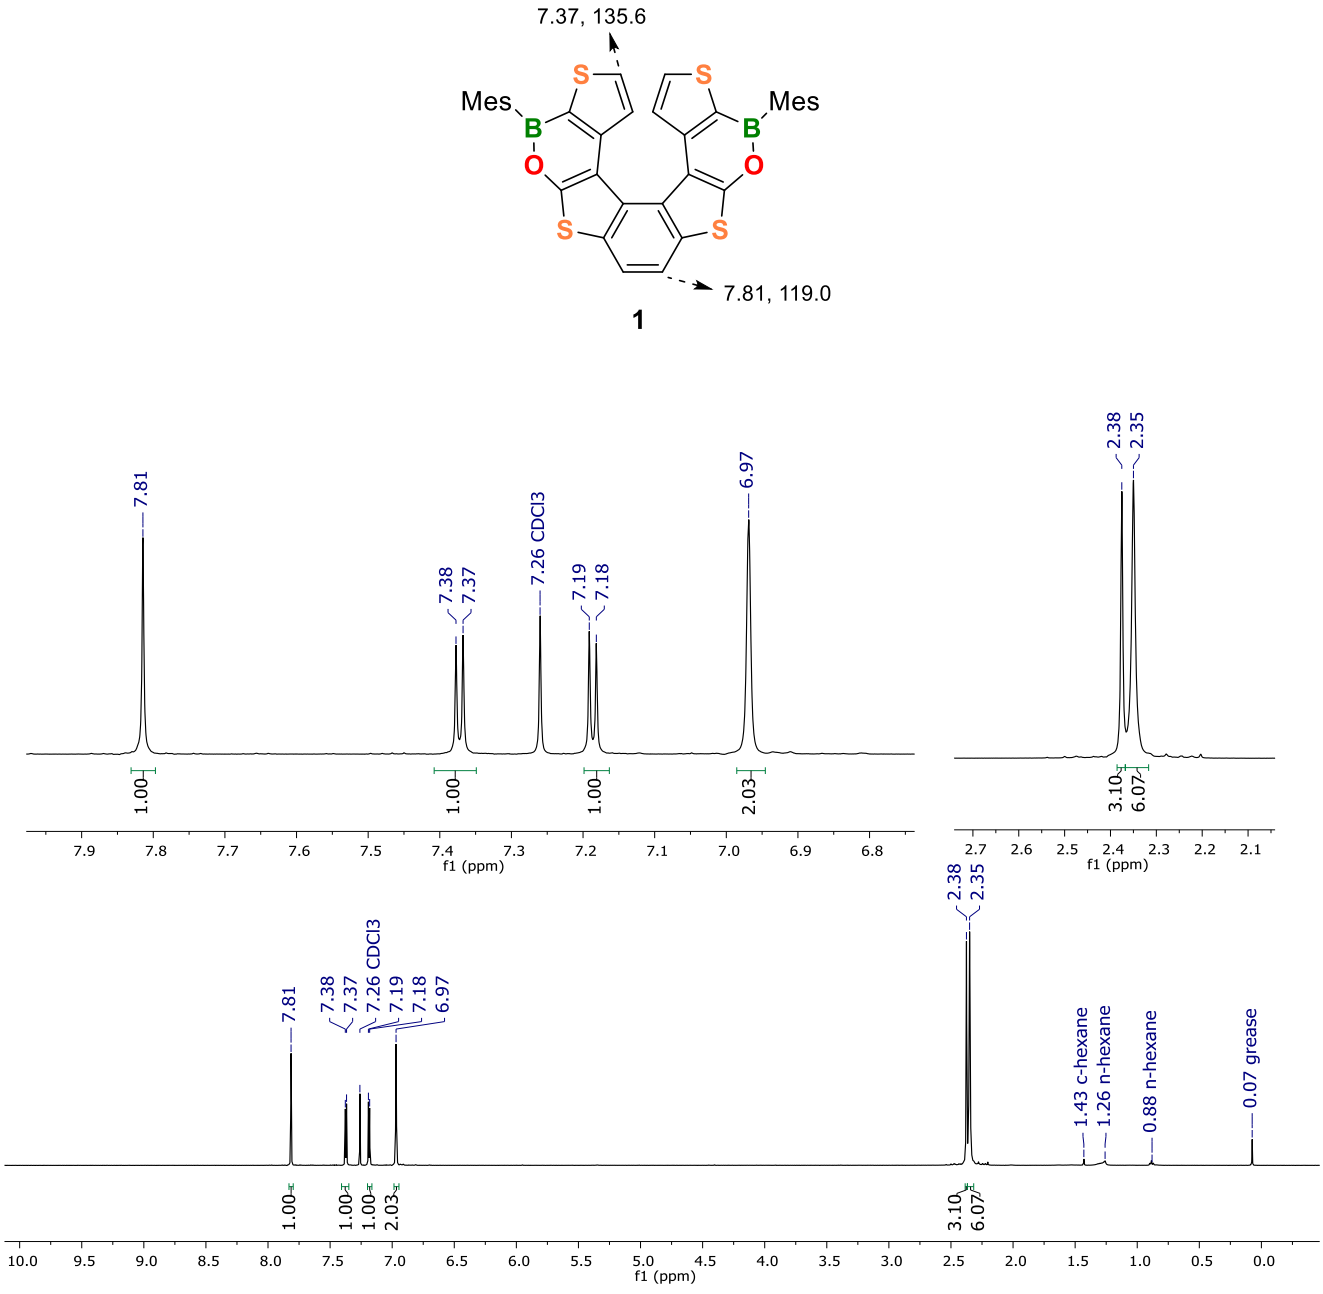


Figure 5. Top: diagnostic proton and carbon shifts of **1**; bottom: ^{1}H NMR spectrum of **1**.

Helicene **1** crystallizes as racemic mixture of the (*P*)- and (*M*)-enantiomers in the low-symmetric triclinic crystal system (Figure 6a,c). A dihedral angle of 50.26(9)° between the two terminal thiophene rings is

associated with intramolecular centroid···centroid distances of 4.153(6) Å (Figure 6b). The central benzene ring is significantly twisted, as indicated by a torsion angle of 9.7° between the (H)C–C(H) vector and the opposite C–C bond. Unlike most mesityl-protected B-doped polycyclic aromatic hydrocarbons (PAHs),[6] the mesityl substituents in **1** are not orthogonally positioned to the attached B-containing heterocycles.

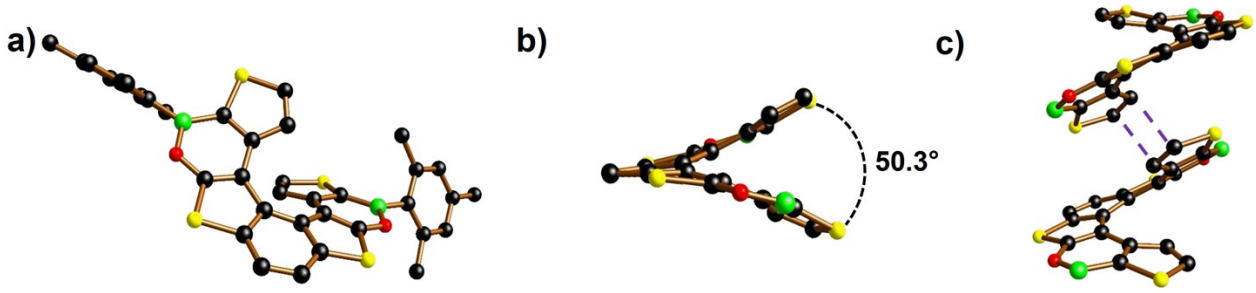

Figure 6. a) Front view of (*M*)-**1** with H atoms omitted for clarity.[5] b) Dihedral angle between the terminal thiophene rings of (*M*)-**1**; H atoms and Mes rings are omitted for clarity. c) π-Stacking interaction between a (*P*)/(*M*)-pair of **1** with H atoms and mesityl rings omitted for clarity. Grey lines indicate the shortest intermolecular C···C contacts; crystal system: triclinic, space gorup: P -1. B: green, C: black, O: red, S: yellow spheres; X-ray picture generated with the crystallographic software *Diamond*.

The reason apparently lies in the neighboring O/S atoms and the annulated five-membered thiophene ring, which impose a lower steric strain compared to CH fragments and annulated six-membered aryl units. The B–O bond lengths of 1.402(4) and 1.401(5) Å are slightly larger than that in the reference compound 9-mesityl-10,9-oxaboraphenanthrene (av. B–O = 1.378 Å; av. Mes//O–B–C = 104.1(3) and 84.8(3)° for two crystallographically independent molecules in the asymmetric unit.[7] In the crystal, the two enantiomers show heterochiral assembly; alternating molecules of (*P*)- and (*M*)-**1** form infinite rods by means of π-stacking interactions between thiophene rings with shortest intermolecular C···C contacts of 3.427(5) and 3.457(4) Å (grey lines in Figure 6c; in this respect, the packing of (*P*)-/(*M*)-**1** and **7TH** are the same[7a]). Remarkably, the shortest intermolecular S···S distances are smaller than the intramolecular ones (3.9911(14) and 5.8156(2) Å, respectively).

4.1.2 Stereochemical studies of 1

Once setup the synthesis of **1**, the work continued with the investigation of its chiroptical, kinetic and theoretical studies. Chiroptical and kinetic studies on **1** were conducted in collaboration with the group of Prof. Giovanna Longhi (University of Brescia) and Prof. Claudio Villani (University of Rome "La Sapienza").

Preliminary racemization tests showed that the enantiomers of **1** are stereochemically stable at room temperature. Thus, the analytical HPLC resolution was scaled up to the semipreparative level using the same

eluent (*n*-hexane/CH_2Cl_2 (95:5); Chiralpak IA). Racemization studies were conducted on the second eluted enantiomer, which was isolated in slightly higher enantiomeric excess (*e.e.*=97.4 %, R_t≈8 min; Figure 7a, red trace). The collected fractions containing only the second eluted enantiomer were combined and evaporated at room temperature. The solid residue was dissolved in decalin and subjected to thermal racemization at 80 °C. The changes in the enantiomeric excess of the sample were monitored by chiral-HPLC (Figure 7b). The racemization progress was monitored by the decrease in the enantiomeric excess of the sample. The interconversion of the two enantiomers proceeded smoothly: after only 13 min, the *e.e.* dropped from 97.4 % to 80.6 % and the elution peak of the first enantiomer (R_t ≈ 6 min) began to emerge (Figure 7b, purple trace). The *e.e.* data were collected over 64 min and used to determine the enantiomerization constant k_{enant}=8.15×10^{-5} s^{-1} (see Section 10 of the Experimental Part) and the associated free energy of activation $\Delta G_{enant}^{\neq}$=27.4±0.1 kcal mol^{-1} (at 353 K).[8] The $\Delta G_{enant}^{\neq}$ value of the $(BO)_2$-doped tetrathia[7]helicene **1** is considerably lower than the corresponding values determined for the enantiomerization of the parent **7TH** ($\Delta G_{enant}^{\neq}$=39.4 kcal mol^{-1})[9] and even carbo[6]helicene ($\Delta G_{enant}^{\neq}$=36.4 kcal mol^{-1}).[10] Thus, the formal replacement of two C=C bonds by B=O bonds within the helical framework apparently increases the flexibility of the molecular scaffold, consistent with the lower double-bond character of the latter.

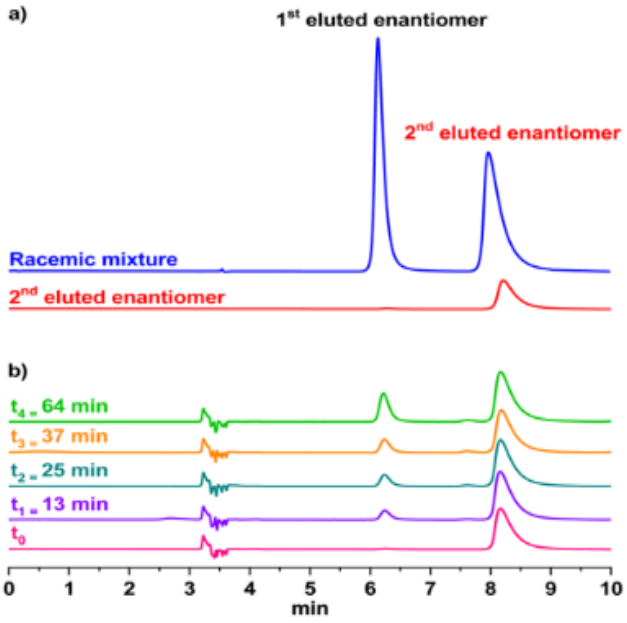

Figure 7. a) top: Analytical HPLC resolution of **1** (Chiralpak IA, *n*-hexane/CH_2Cl_2 (95:5)); bottom: thermal racemization studies of **1** second eluted enantiomer (R_t ≈ 8 min) in decalin at 80 °C; solvent peak: R_t ≈ 3 min.

Circular dichroism (CD) spectra of the two enantiomers showed a perfect mirror-image relationship between the first and second eluted enantiomer of **1** (Figure 8, black and red trace); the optical rotation values are +97.7° and −97.5°, respectively.

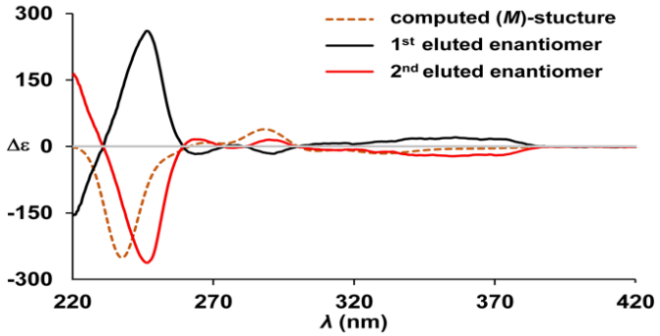

Figure 8. Circular dichroism (CD) spectra of the first (black trace) and the second (red trace) eluted enantiomer of **1**, recorded in *n*-hexane/CH_2Cl_2 (95 : 5) at 20 °C. Computed CD spectrum for the optimized (*M*)-structure (orange dashed trace; multiplied by a factor of 1.5).

To determine the absolute configurations of the two eluted enantiomers, the (*M*)-structure of **1** was optimized at the M06/6-311g G(d,p) level of theory. Only one energy minimum was obtained, and no other stable conformer was found, even about a possible different orientation of the mesityl groups. The optimized gas-phase structure (C_2 symmetry) compares well with the crystallographically determined molecular geometry; the experimentally observed marked deviation of the dihedral angle Mes//O−B−C from 90° is qualitatively reproduced (calcd. 65.5°; av. exptl. 58.8°). The CD spectrum of (*M*)-**1** was calculated by TD-DFT at the same level of theory (Figure 8, orange dashed trace). The agreement between the computed and one of the experimental CD spectra allows us to assign the (*M*)-configuration with certainty to the second eluted enantiomer (R_t≈8 min): good correspondence is observed for the broad negative feature centred at 350 nm, which can be attributed to the first three transitions with weak negative rotational strength (Figures 8 and S107). The two weak positive peaks experimentally observed at 293 and 265 nm are also well reproduced, as is the intense negative feature at 247 nm (calcd. 240 nm). The relatively small rotational strength computed for the first transition (HOMO→LUMO) is due to the fact that the electric and magnetic transition dipole moments are nearly perpendicular to each other. The CD spectrum of (*M*)-**1** is different from those of typical helicenes[11] and thiahelicenes,[12] in that it shows only weak features in the 370–260 nm range (Figure S107), but with a more intense absorption feature for the first electronic transition (Figures S107, S108, and Tables S18, S19). This is another example for the well-known fact that the lowest-energy transitions of helicenes are substituent-sensitive,[13] while the overall shape of the spectrum is determined by the helicene backbone.

The energy barrier for enantiomerization of **1** was computed by optimizing the ground state of (*M*)-**1** and the transition state to (*P*)-**1** at the PBE1-PBE/TZVP level with empirical dispersion corrections.[14] The obtained enantiomerization barrier of 35 kcal mol^{-1} is about 8 kcal mol^{-1} higher than the experimentally found value of $\Delta G_{enant}^{\neq}$=27.4±0.1 kcal mol^{-1} (at 353 K);[15] the same barrier was obtained for the model compound **1*** carrying H atoms in place of the Mes groups. We also compared the enantiomerization barrier of the model compound **1*** with those of carbo[6]helicene and tetrathia[7]helicene **7TH** by performing a relaxed interconversion scan considering also diffuse functions at the PBE1-PBE/6-311++G(d,p) level with empirical dispersion corrections (Figures S109 and S110). Despite the seven-ring backbone of **1***, its barrier

is the lowest of the three compounds (**1***: 35 kcal mol^{-1}, carbo[6]helicene: 38 kcal mol^{-1}, and **7TH**: 40 kcal mol^{-1}). A comparison of the minimum and transition-state structures of **1*** and **7TH** indicates that the smaller double-bond character of the B=O pairs indeed allows for greater flexibility of the six-membered heterocycle compared to a carbonaceous benzene ring (Figure 9 and Figure S58).

The above-mentioned atom-ring plane distances are listed in the right top corner.

4.1.3 Electrochemical and spectroscopic characterization and DFT calculation of 1 and its BO-doped intermediates

Cyclic voltammograms were recorded in THF with [*n*Bu$_4$N][PF$_6$] as supporting electrolyte and are referenced against the ferrocene/ferricinium couple (FcH/FcH$^+$). In the cathodic scan, borahelicene **1** shows two irreversible redox events with peak potentials of E_{pc} = −2.83 and −3.01 V (Table 1 and Figure S61, S62). For comparison, the starting oxaborine **5** is somewhat harder to reduce with an E_{pc} value of −2.96 V (Figure S59). When two redox-active **5**-type sites are connected via a 1,2-ethenediyl bridge (as in the case of *trans*-**15**), the first reduction event at $E_{1/2}$ = −2.54 V becomes quasi-reversible while the second remains largely irreversible (E_{pc} = −2.90 V). We attribute the easier reduction of *trans*-**15** relative to **5** to the more extended π-conjugation pathway in the former (*trans*-**15** adopts a fully planar structure in the solid state; Figure 3 and Figure S89). This interpretation is supported by the fact that the redox potential of saturated **15H2** is again

cathodically shifted to E_{pc} = −2.90 V (Figure S68). In summary, the degree of electronic communication between the two **5**-type sites in the helically twisted compound **1** appears to be lower than in its planar precursor *trans*-**15**.

[a] Resolved vibrational fine structure. [b] Quantum yields were determined by using a calibrated integrating sphere. [c] Optical band gap E_g^{opt} = 1240/ λ_{onset}. [d] E_{LUMO} = −4.8 eV − $E_{1/2}^{Red1}$ (FcH/FcH$^+$ = –4.8 eV vs vacuum level). [e] Shoulder. [f] Computed value (TD-DFT). [g] Quantum yields measured in THF. [h] $E_{1/2}$ value of the quasi-reversible process.

UV/vis absorption was recorded in cyclohexane and THF; in *c*-hexane, **1** exhibits a structured band with the most bathochromic shoulder appearing at 374 nm (Figure 7a, blue trace; Table 1). For comparison, the corresponding shoulder in the spectrum of tetrathia[7]helicene **7TH** is found at 392 nm.[16] **1** is a blue emitter and its emission band shows a partly resolved vibrational fine structure with the most hypsochromic shoulder at 411 nm; the photoluminescence quantum efficiency is Φ_{PL} = 6% (*c*-hexane; cf. tetrathia[7]helicene: $\lambda_{em} \approx$ 405 nm, Φ_{PL} = 5%).[17] The reference systems **5**, **15H2**, and *trans*-**15** absorb/emit at 335/366 nm, 342/374 nm, and 403/419 nm, respectively (Table 1, Figure 10a-c).

According to time-dependent density functional theory (TD-DFT) calculations, the first transitions of **1**, *trans*-**15**, and **5** are HOMO→LUMO transitions (Table 1, see also Tables S18–S20, Figure S108, and section 10.3 of the Experimental Part). Despite the smaller dihedral angles Mes//O–B–C (59.0(5)°, 58.6(6)°), the contributions of the mesityl substituents to the HOMO/LUMO frontier orbitals of **1** is negligible (Figure 10d). Moreover, it is worth to note that HOMO-LUMO calculations showed as while HOMO is spread over the entire helical scaffold, LUMO localizes on the two terminal thiophene rings, close to the boron atoms (Figure 10d). Taken together, these results confirm that **1** has a much more delocalized π-electron system than **5** and **15H2**, but the effective conjugation length is smaller than for *trans*-**15**. We therefore conclude that BO-doping does not have a major influence on the electronic spectra of $\mathbf{7}^{\mathbf{TH}}$.

Conclusions

The $(BO)_2$-doped tetrathia[7]helicene **1** was obtained via an efficient four-step synthesis, including a Mallory photocyclization step, which has rarely been used for the synthesis of B-containing polycyclic aromatic hydrocarbons. Despite its configurational stability at room temperature, the racemization and enantiomerization barriers of **1** are significantly lower than that of its non-doped congener, the tetrathia[7]helicene **(7TH)**. This is presumably due to the weaker π-donor bond within the BO pair, which renders the oxaborine heterocycles more conformationally flexible than benzene rings. To date, boron-heteroatom doping has been performed mainly on planar polycyclic aromatic hydrocarbons, where conformational flexibility is not an issue, and is therefore considered primarily as a tool for manipulating the electronic structures of π-electron systems. Our results now indicate that the incorporation of BO pairs can also be a means of influencing the mechanical rigidity of polyaromatic entities. Even though **1** has a rather low photoluminescence quantum efficiency of Φ_{PL} = 6%, its synthesis protocol should allow manifold optimizations in the future, such as BN doping, inversion of the BO/BN vectors, or facile late-stage derivatization at the terminal thiophene rings.

4.2 Study of the synthesis and properties of the BO-doped tetrathia[7]helicene 2

On the basis of the photophysical properties of borahelicene **1** and with the aim of obtaining structures with better optoelectronic properties than **1**, I designed helicene **2**, isomer of **1** which is derived by the formal inversion of the two BO bonds in the parent **1** (Figure 11). I assumed that this structural modification could be a tool to affect the electronic properties, by influencing the distribution and the extension of the LUMO orbitals within the helical framework.

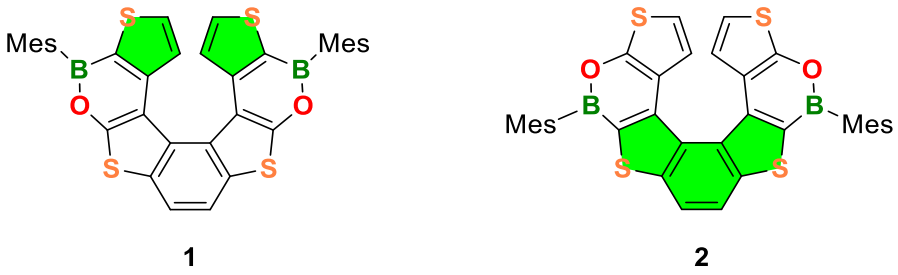

Figure 11. Structure and LUMO distribution (green) of **1** and, expected LUMO distribution of the **2** isomer with BO-inverted bonds.

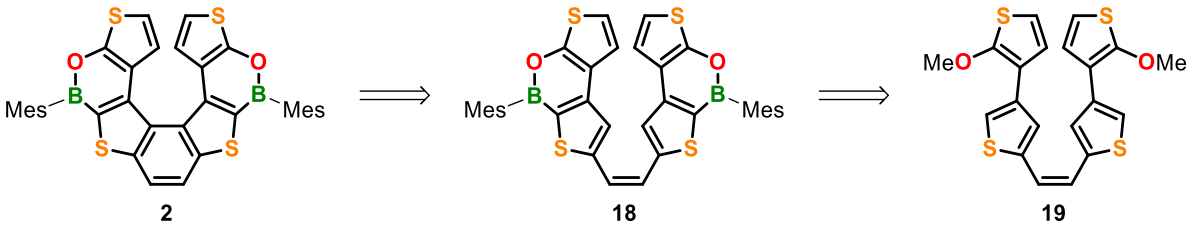
In fact, **2** is expected to display LUMO orbitals extended over the whole *thiophene-benzene-thiophene* (BDT) central fragment rather than over the terminal thiophene rings (Figure 11). Extension of the LUMO contributes to provide narrowed energy-gap, redshifted absorption/emission bands, increased reducing abilities and thus enhancing optoelectronic performances. This hypothesis was also supported by preliminary DFT calculation.

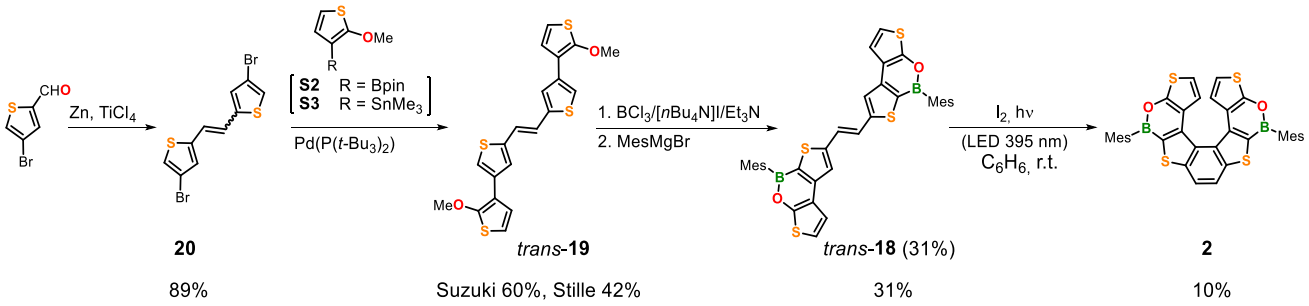
4.2.1 Synthesis and NMR characterization of 2

The designed synthesis of **2** (as in *Route C* for **1)** involves, in the last step, the photocyclization of the alkene **18** (isomer of **15**), which in turn can be synthesized by late-stage borylation of the bis-methoxy functionalized alkene **19** (Scheme 8).



Scheme 8. Designed retrosynthetic analysis for **2**.

The whole synthetic scheme to obtain **2**, starting from 4-bromo-2-thiophenecarbaldehyde, is depicted in scheme 9.



Scheme 9. Synthetic route to **2**.

In detail, 4-bromo-2-thiophenecarbaldehyde was converted into dibromo alkene *trans*-**20** *via* McMurry coupling in 89% yield; the *trans* configuration was confirmed by X-ray crystallography (Figure 12a and Figure S94). Suzuki or Stille coupling with the corresponding coupling partners (boronic ester **S2** or stannane **S3**) gave dimethoxy alkene **19** in 60% and 42% yield respectively. Although the Suzuki coupling gave a better yield, the preferred route for **19** relies on the Stille coupling, due to the difficult synthesis of the boronic ester **S2**. The *trans* configuration of **19** was again confirmed by X-ray crystallography (Figure 12b and Figure S95). The following borylation of **19** was performed by using the standard borylation procedure with BCl_3/[nBu$_4$N]I/Et$_3$N in chlorobenzene at 135 °C and subsequent addition of an excess of MesMgBr. *Trans*-**18** was obtained in 31% yield after purification; also in this case the *trans*-configuration was confirmed by X-ray crystallography (Figure 12c and Figure S96).

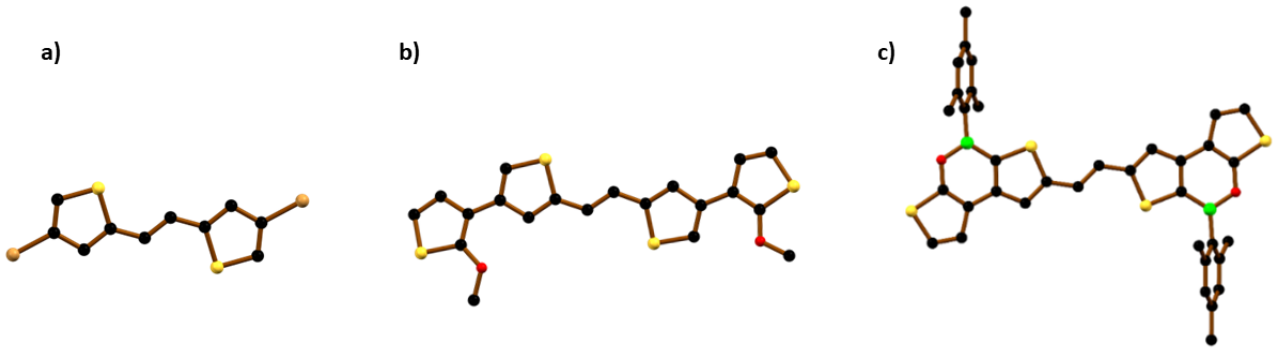


Figure 12. X-ray crystal structure of: a) *trans*-**20**, crystal system: orthorombic, space group: Pbca b) *trans*-**19**, crystal system: orthorhombic, space group: F d d 2 and c) *trans*-**18**, crystal system: monoclinic, space group: P21/c. B: green, C: black, O: red, S: yellow, Br: brown spheres; picture generated with the crystallographic software *Mercury*.

NMR spectrum of *trans*-**18** showed that the inversion of BO-bonds (with respect to *trans*-**15**) causes a substantial upfield shift of both proton and carbon resonances (see Figure 13). As an example, in *trans*-**18** protons on the α and β position in the terminal thiophene rings, substituted with the electron donor O atom, resonate at $\delta(^1H)$ = 7.32 and $\delta(^1H)$ = 6.96 respectively while in the corresponding isomer *trans*-**15** are significantly deshielded and resonate at $\delta(^1H)$ = 7.99 and $\delta(^1H)$ = 7.60 due to the electron withdrawing effect of the B atom. The same effect can be observed in ^{13}C shifts: *trans*-**18** C(α) and C(β) resonate at 120.3 ppm and 114.9 ppm, while are significantly deshielded in *trans*-**15**, C(α) = 138.4 ppm and C(β) = 123.0 ppm (see Figure 13).

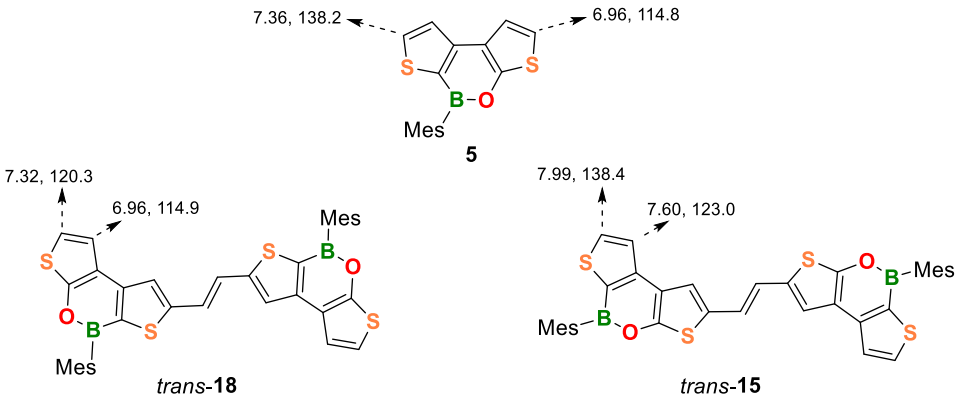

Figure 13. Diagnostic proton and carbon shifts of **5**, *trans*-**15**, *trans*-**18**.

The photocyclization of *trans*-**18** was performed using a 395 nm LED lamp in the presence of I_2 as oxidant and furnished the desired helicene **2** in 10% yield; **2** was fully characterized from analytical, computational, and optoelectronic point of view. Comparison of the NMR spectra of **2** and its isomer **1**, reflect the switch of the electronic properties caused by the BO-bonds inversion (Figure 13a).

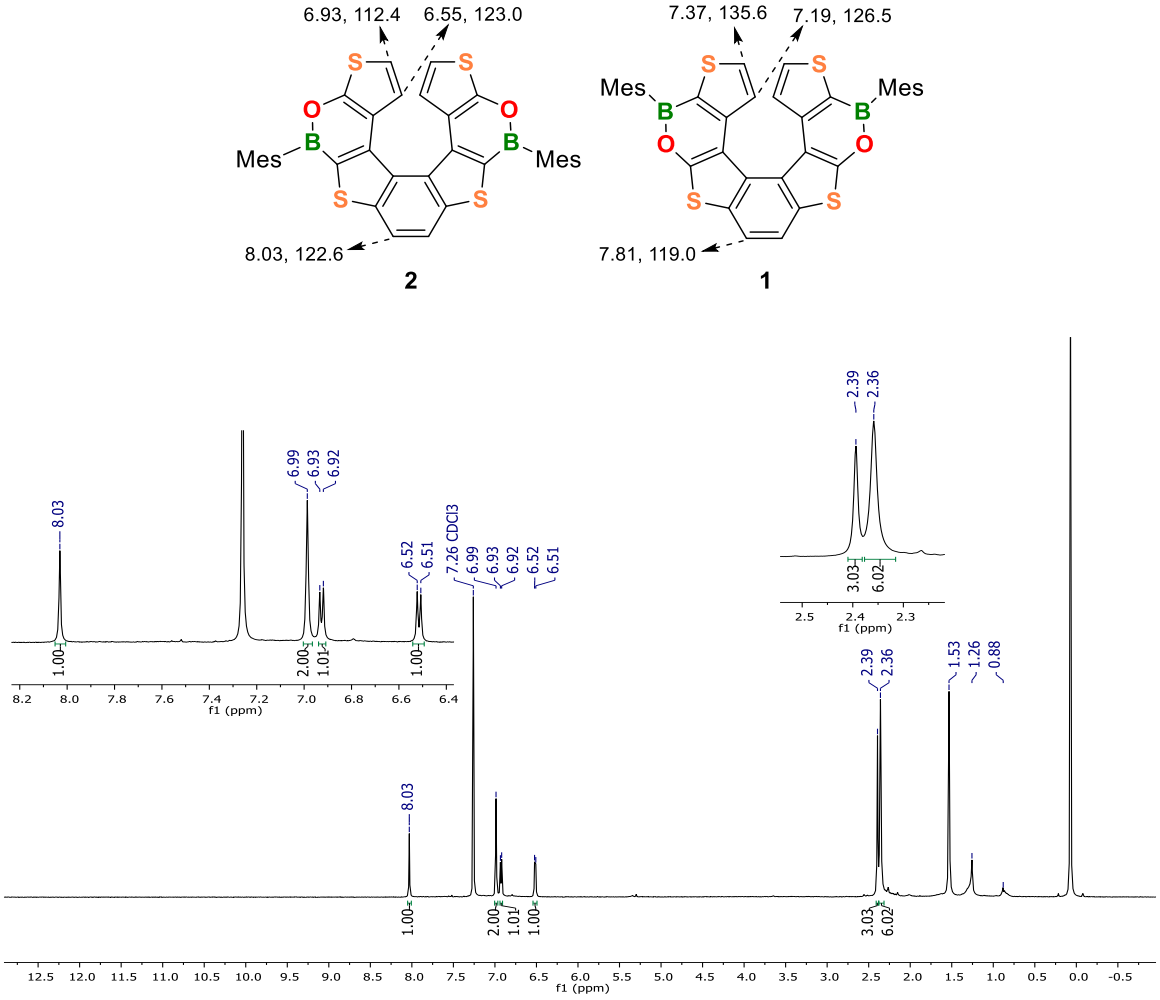

Figure 13a. Top: diagnostic proton and carbon shifts of **1** and **2**; bottom: ^{1}H NMR spectrum of **2**.

In detail, in helicene **2** protons on the α and β position in the terminal "oxygenated thiophene rings", resonate at $\delta(^1H)$ = 6.93 and δ (^1H) = 6.52 respectively, while in helicene **1** the same protons resonate at $\delta(^1H)$ = 7.37 and $\delta(^1H)$ = 7.19 (*cf.* in **7TH** $\delta(^1H)$ = 6.83 and 6.67). Interestingly α and β protons of the terminal thiophene rings of **2** are upfielded in the olefinic region and revealed to be even more shielded of the corresponding protons in the dithienyloxaborine **5** ($\delta(^1H)$ = 6.96 and $\delta(^1H)$ = 7.36 respectively). The same trend can be observed in ^{13}C shifts: **2** C(α) and C(β) resonate at 112.4 and 123.0 ppm respectively, while are significantly deshielded in **1,** C(α) = 135.6 ppm and C(β) = 126.5 ppm (Figure 13).

This behaviour, as for **1**, could be attributed to the effect of the helical 3D-structure, in which each terminal thiophene ring falls in the shielded region of the corresponding ring in the opposite helicene wing.

Similarly to what observed for thiophene rings, due to proximity of the trigonal boron atoms, protons of the central benzene ring in **2** are significantly downshielded and resonate at $\delta(^1H)$ = 8.03, while those of **1** resonate at $\delta(^1H)$ = 7.81 ppm. The same trend can be observed in the ^{13}C NMR ($\delta(^{13}C)$ = 122.6 and $\delta(^{13}C)$ = 119.0 respectively; see Figure 13).

The study was then completed investigating the optoelectronic properties of borahelicene **2** and its borylated alkene precursor **18** and comparing them with those of isomers **1** and **15** previously synthesized.

4.2.3 Electrochemical, spectroscopic, and theoretical characterization of 2 and *trans*-18

Comparison of BO-doped tetrathia[7]helicenes 2 and 1

HOMO/LUMO distributions of **2** were calculated at the B3LYP/6-31G* level of theory (figure 14). Calculations revealed that the inversion of BO-bonds in helicene **2** produces peculiar and different electronic properties than those of the parent **1**. By looking at the HOMO orbitals, these stay pretty unchanged in both terms of energy and distribution over the helical scaffold. Interestingly, contrary to **1**, in **2** the central benzene ring outer C=C bond does not give any contribution to HOMO.

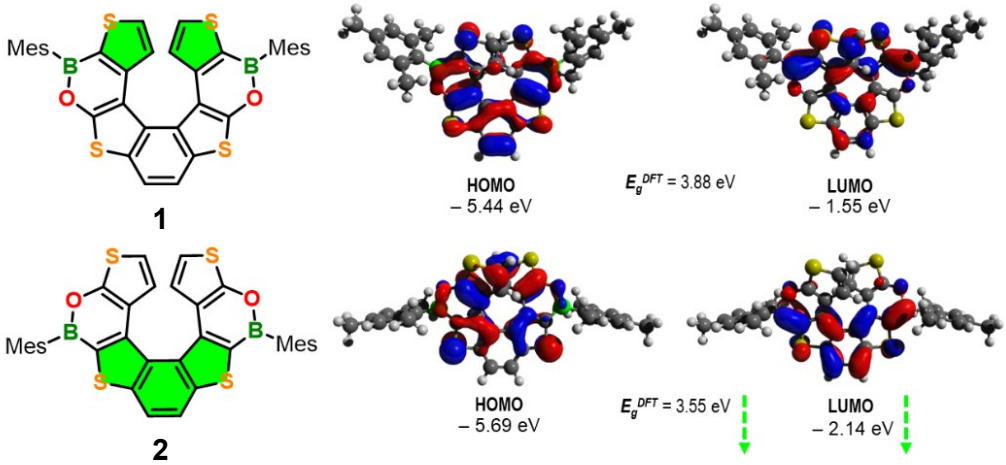

Figure 14. HOMO/LUMO distributions of **2** and **1** calculated at the B3LYP/6-31G* level.

Regarding LUMO orbitals, comparing **2** and **1**, calculations show how the LUMO of **2** is significantly lower than that of **1** (–2.14 eV *vs.* –1.55 eV) and, as expected, it is localized over the thiophene-benzene-thiophene central fragment of the molecule.

Cyclic voltammetry measurements of **2** (recorded in THF with [nBu$_4$N][PF$_6$] as supporting electrolyte and referenced against (FcH/FcH$^+$ couple) showed one irreversible reduction process E_{pc} = −2.68 V in the cathodic scan and an irreversible oxidation peak in the anodic scan E_{pa} = 0.82 V (Table 2 and Figure S72, S73).

Helicene **2** is easier to be reduced than its isomer **1** (E_{pc} = –2.83 V), thus indicating that the BO-bond inversion affects the LUMO orbitals. In fact, experimental LUMO of **2** E_{LUMO} = –2.12 eV, is slightly lower than that of **1** E_{LUMO} = –1.97 eV.

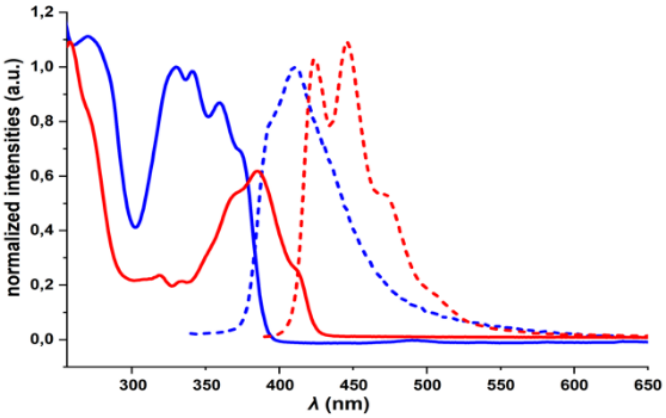

Figure 15. Absorption (solid lines) and emission (dashed lines) spectra of **2** (red) and **1** (blue) in *c*-hexane.

In *c*-hexane, **2** exhibits a structured UV/vis absorption band with the most bathochromic shoulder appearing at 413 nm (Figure 15, blue line; Table 2). For comparison, the corresponding shoulder in the spectrum of **2** is found at 374 nm. **2** is a blue emitter and its emission band shows a partly resolved vibrational fine structure with the most hypsochromic band at 472 nm (Figure 15, red dashed line; Table 2); the photoluminescence quantum efficiency is Φ_{PL} = 7% (*c*-hexane; *cf.* **1**: $\lambda_{em} \approx$ 411 nm, Φ_{PL} = 6%). Optical measurements revealed as the BO-bonds inversion produces a substantial redshift in both absorption and emission bands accompanied by a reduction of the energy gap ($E_g^{opt}{}_{\mathbf{2}}$ = 2.90 eV *vs.* $E_g^{opt}{}_{\mathbf{1}}$ =3.16 eV), while photoluminescence efficiency remained unaffected.

Comparison between alkenes trans-18 and trans-15

Cyclic voltammograms of *trans*-**18**, similar to what observed for *trans*-**15**, showed a quasi-reversible reduction process $E^{I}_{pc} = -1.97$ V, accompanied by a largely irreversible reduction peak $E^{II}_{pc} = -2.26$ V in the cathodic scan (Figure S70; Table 2). The effect of the BO-inversion is evidenced, when comparing the potential values of the two stilbenes *trans*-**18**/*trans*-**15**, $E^{I}_{pc\mathbf{18}} = -1.97$, $E^{II}_{pc\mathbf{18}} = -2.26$ V / $E^{I}_{pc\mathbf{15}} = -2.54$, $E^{II}_{pc\mathbf{15}} = -2.90$ V: *trans*-**18** shows significantly lower reduction potentials, compatible with its structure, supposed to be more electron-poor than that of the parent *trans*-**15**. For *trans*-**18** no oxidation peaks were observed in the anodic scan, as in the case of *trans*-**15**.

Experimental LUMO values measured for *trans*-**18** ($E_{LUMO} = -2.83$ eV) is lower than that of its isomer *trans*-**15** ($E_{LUMO} = -2.26$ eV) and DFT calculations revealed as, for both isomers, HOMO and LUMO are mainly localized in the central thiophene-ethylene-thiophene fragment (Figure 16a).

Regarding the optical properties, in the absorption spectrum (Figure 16b) *trans*-**18** shows main bands at 370, 393 nm, slightly blueshifted with respect to *trans*-**15** (383, 403 nm) and a shoulder at 414 nm with an associated energy gap of $E_g^{opt} = -2.85$ eV close to that of *trans*-**15** ($E_g^{opt} = -2.93$ eV).

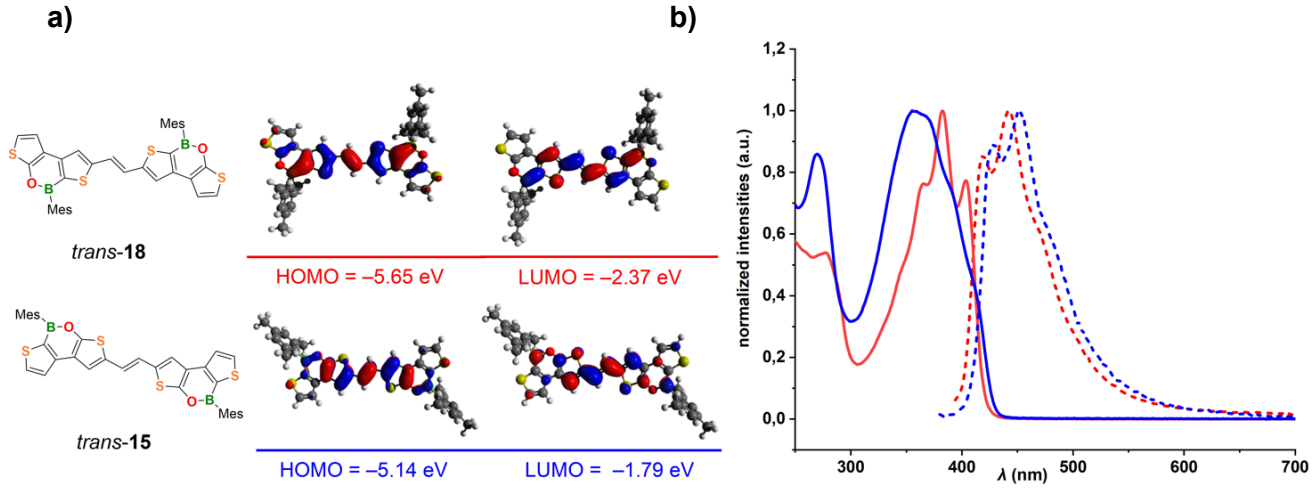

Figure 16. a) HOMO/LUMO distributions of *trans*-**18** and *trans*-**15** calculated at the B3LYP/6-31G* level. b) Absorption (solid lines) and emission (dashed lines) spectra of *trans*-**18** (blue) and *trans*-**15** (red) in *c*-hexane.

Conversely, in the *trans*-**18** emission spectra two structurally fine resolved bands can be found at 429 and 452 nm, and these are slightly redshifted with respect to these of *trans*-**15** (419, 443 nm). *Trans*-**18** showed $\Phi_{PL} = 6\%$ in *c*-hexane, considerably lower than that of *trans*-**15** (the same trend was observed in THF, see Table 2).

Table 2: Photophysical and electrochemical data of the boron-doped compounds. Optical measurements were performed in *c*-hexane, and electrochemical measurements were performed in THF (room temperature, supporting electrolyte: [nBu$_4$N][PF$_6$] (0.1 M), scan rate 100 or 200 mV s^{-1}).

Conclusions

Taken together, these results revealed as the inversion of BO vectors in the thiahelicene scaffold did not have appreciable effect on the optoelectronic performances in the specific case of **1** and **2** (Φ_{PL1} = 6%/ Φ_{PL2} = 7%) but anyway it represents a valuable strategy to modulate the properties of this class of compounds. In fact, the position of boron in the helical scaffold resulted to be a suitable tool to influence the extension of LUMO and get red-shifted absorption and emission bands, thus setting the basis for the structural design of new derivatives.

Future studies will also include the investigation of racemization kinetics and chiroptical properties of **2**.

[15] Enantiomerization is the reversible conversion of a single enantiomer into the other one. The corresponding rate constant is k_{enant}. Racemization is the irreversible conversion of a sample of single enantiomers or of a non-racemic mixture of enantiomers into the racemate. The corresponding rate constant is k_{rac}. Comparison of calculated and experimental energy barriers was done using the enantiomerization barrier obtained from k_{enant}, which is calculated from the experimentally determined k_{rac} according to: $k_{enant} = 0.5k_{rac}$=8.15×10−5 s−1. The

free energy for the enantiomerization process ($\Delta G_{enant}^{\neq}$) was obtained by using the Eyring equation and setting a transmission coefficient equal to 1.

4.3 BO-doped tetrathia[7]helicenes 3 and 4

Once completed the synthesis of the doubly BO-doped helicenes **1** and **2**, in the last part of my Ph.D. I focused on the study of the synthesis of singly BO-doped helicenes **3** and **4** (Figure 17).

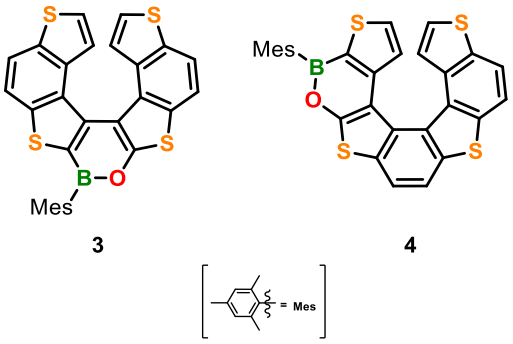

Figure 17. Structure of singly BO-doped tetrathia[7]helicenes **3** and **4**.

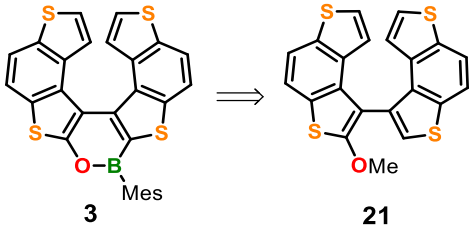
In detail **3** incorporates one oxaborine ring into the central region of the helical scaffold, while in **4** the oxaborine ring is positioned in the side of the helix.

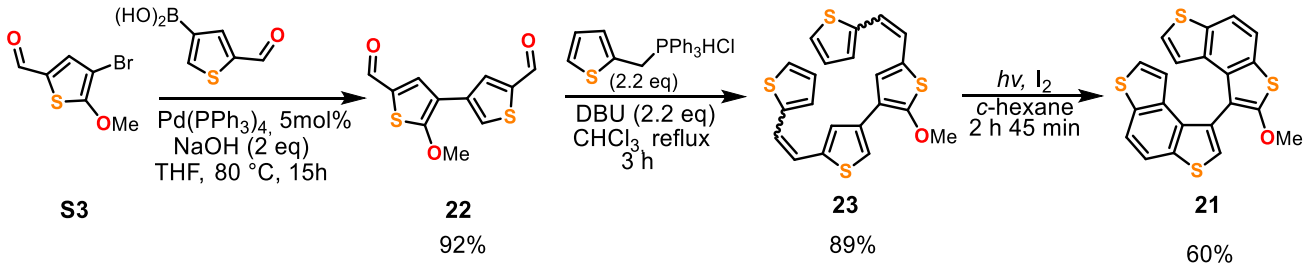
4.3.1 Preliminary study of the synthesis of tetrathia[7]helicene 3

For the synthesis of **3**, the methoxy functionalized bis-benzodithiophene (bis-BDT) **21** was selected as possible direct precursor (Scheme 10), on which to run the oxaborine ring closure.



Scheme 10. Possible retrosynthetic analysis of **3**.

The synthesis of **21** (Scheme 11) was carried out starting from 3-bromo-4-methoxythiophene-2-carbaldehyde **S3**, which was in turn prepared following a known procedure[1] (Section 2.1 in the Experimental Part).



Scheme 11. Synthesis of the bis-BDT **21**.

Aldehyde **S3** was then subjected to a Suzuki coupling with the commercially available thiophene-2-carbaldehyde-4-boronic acid using $Pd(PPh_3)_4$ as catalyst and gave the dialdehyde **22** in 92% yield. The structure of **22** was also confirmed by X-ray analysis (Figure 18 and Figure S97).

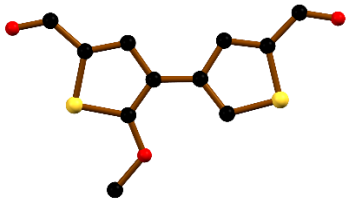


Figure 18. X-ray crystal structure of **22**. Crystal system: monoclinic, space group: P 21/n. C: black, O: red, S: yellow spheres. Picture generated with the crystallographic software *Mercury*.

Subsequent double-Wittig reaction of **22** with thiophene triphenylphosphonium bromide gave the corresponding bis-alkene derivative **23** in 89% yield as a mixture of four isomers (*cis*,*cis*; *cis*,*trans*; *trans,trans*; *trans*,*cis*). **23** was treated with Et_2O and filtered. The residue thus obtained was dissolved in *n*-pentane/CH_2Cl_2 and let evaporate slowly. *Trans*,*trans*-**X3** isomer crystallized out of the mixture (Figure 19 and S98) and its structure confirmed by X-ray analysis. (Figure 19)

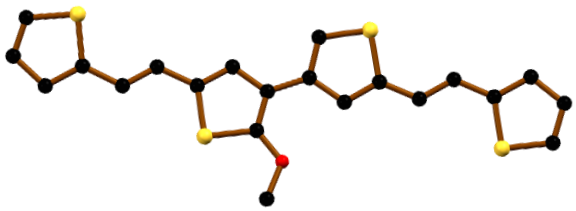

Figure 19. X-ray crystal structure of *trans,trans*-**23**. Crystal system: orthorombic, space group: F d d 2. C: black, O: red, S: yellow spheres. Picture generated with the crystallographic software *Mercury*.

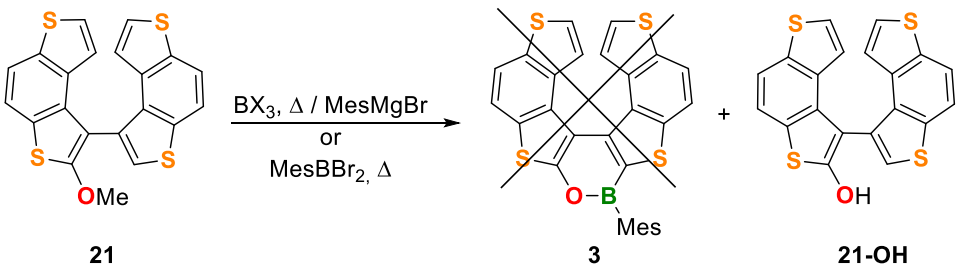
Finally, photocyclization of **23** isomers using a medium pressure mercury lamp and I_2 as oxidant, afforded the desired methoxy bis-BDT **21** in 60% yield after chromatographic purification. Next, the borylation step was investigated (Scheme 12).



Scheme 12. Demethylative borylation of **21**.

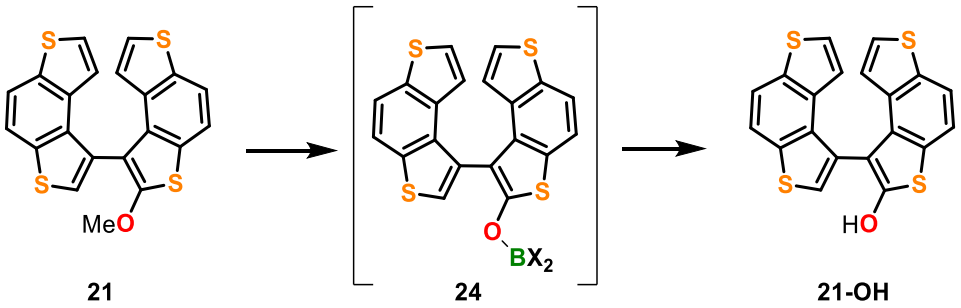
Borylation was attempted by using various boron sources (BCl_3, BBr_3, $MesBBr_2$) at different temperatures (Table 3) but all the trials failed to provide the desired helicene **3**, and only the hydroxy derivative **21-OH** was isolated beside unidentified degradation products.

Table 3. Borylation attempts. Entry 1, 2: preparative experiments; entry 3: NMR experiment performed using a flame-sealed NMR tube in a thermostated oven.

Entry	Borane	Base	additive	solvent	temperature
1	BCl_3 (1.0 M in THF)	Et_3N (1.0 eq.)	*n*[Bu_4N]I (1.2 eq.)	chlorobenzene	135 °C
2	BBr_3 (0.5 M in *n*-hexane)	Et_3N (1.0 eq.)	//	chlorobenzene	135 °C
3	$MesBBr_2$	Et_3N (1.0 eq.)	//	C_6D_6	135 to 180 °C

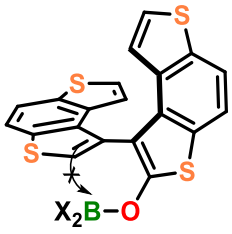
21-OH was characterized by NMR analysis: in both ^1H and ^{13}C NMR spectra the OMe signal ($\delta(^1H)$ = 3.91) disappeared, a new proton signal was present at $\delta(^1H)$= 6.31 which was assigned to the -OH group as also confirmed through a deuteration experiment (see Figure S46A); full assignment of **21**/**21-OH** protons and carbon resonances is given in the Experimental Part.

The isolation of **21-OH** suggests as the first demethylation step of **21** works and gives the intermediate **24**, which then fails to undergo intramolecular electrophilic borylation and is then hydrolyzed during the purification step to give **21-OH** (Scheme 13).



Scheme 13. Formation of the **21-OH** by-product.

A possible rationale for this result can be found in the intrinsic nature of the intermediate **24** (Figure 20) since: 1) the α position of the BDT, which should undergo the borylation, is scarcely activated to SEAr and 2) the rotation around the C-C bond connecting the BDT fragments placed in a twisted conformation, is probably hindered.



24
X = Cl, Br

Figure 20. Intermediate **24**.

Attempts to get single crystals of **24** or **21-OH** suitable for X-ray analysis unfortunately failed, but it was possible to obtain crystals of the starting bis-BDT **21** (Figure 10). X-ray diffraction of **21** revealed the presence of four conformers which are characterized by the different reciprocal orientation of the -OMe group and the unfunctionalized BDT fragment (Figure 21 and Figure S99).

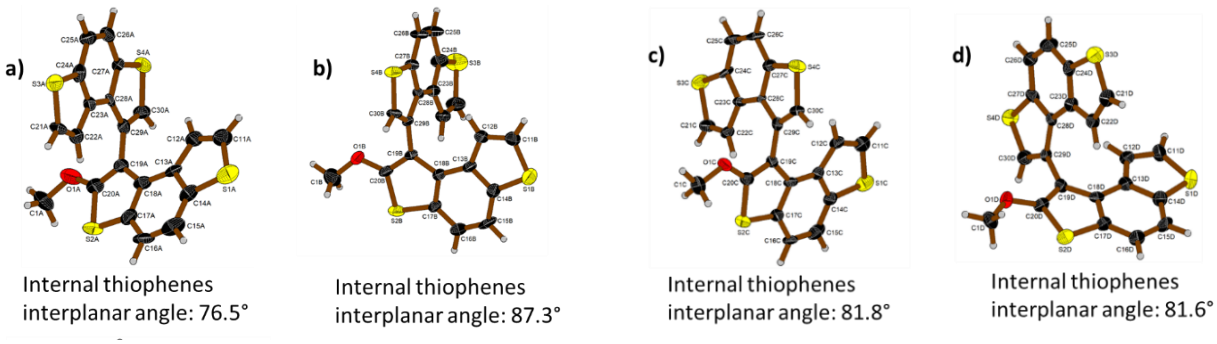


Figure 21. X-ray crystal structure of the four **21** conformers. Crystal system: triclinic, space group: P $^{-}$1. C: black, O: red, S: yellow spheres. ORTEPs generated with the IUCr Web service (http://publcif.iucr.org/services/tools/).

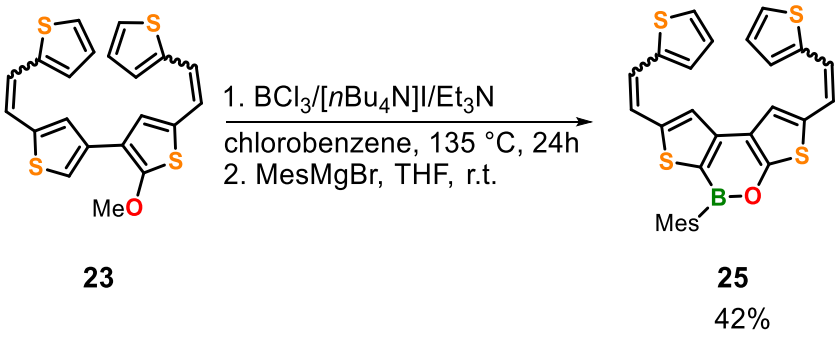
However, in the four conformations the two internal thiophene rings are twisted by an angle ranging from 76.5 to 87.3 ° (Figure 21) as result of the hindered rotation around the C-C bond connecting the two BDT fragments. These structural data support the previous hypothesis that the B(sp^2)-C(sp^2) bond must build against steric factors making ring-closure unfavourable.

In light of these considerations, we thought to modify the synthetic strategy and we runned the borylation before the formation the BDT rings on the less sterically constrained bisalkene precursor **23** (Scheme 14). The borylation, using "our standard conditions" gave the bis-olefinated oxaborine **25,** in moderate yield (42%) after column chromatography, as a mixture of *cis/trans* isomers.



23 **25**
42%

Scheme 14. Synthesis of the bis-olefinated oxaborine **25**.

The subsequent treatment with *n*-pentane allowed to isolate the pure *trans*,*trans*-isomer of **25**, whose structure was confirmed by NMR and X-ray analysis (Figure 22 and Figure S100).

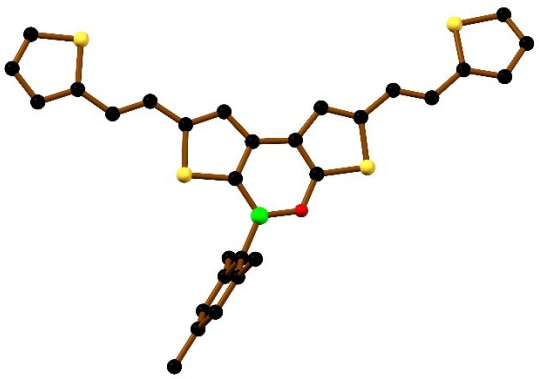


Figure 22. X-ray crystal structure of **25**. Crystal system: orthorombic, space group: P 21 21 21. B: green, C: black, O: red, S: yellow spheres. Picture generated with the crystallographic software *Mercury*.

All proton and carbon resonances of **25** were assigned. It is worth to note that proton resonances of **25** well reflect the different electronic features of the two formally B- and O-substituted fragments of the molecule. As an example, protons on the α and β position of the terminal thiophene on the "B-substituted side" of the molecule resonate at $\delta(^1H)$ = 7.27 and $\delta(^1H)$ = 7.21, while the corresponding protons "on the O-substituted side" are significantly shielded upfield and resonate in the 7.01-7.03 ppm region; the same trend is observed for olefinic protons (see Figure 23). The ^{11}B shift for **25** is $\delta(^{11}B)$ = 41.70 (Figure 23).

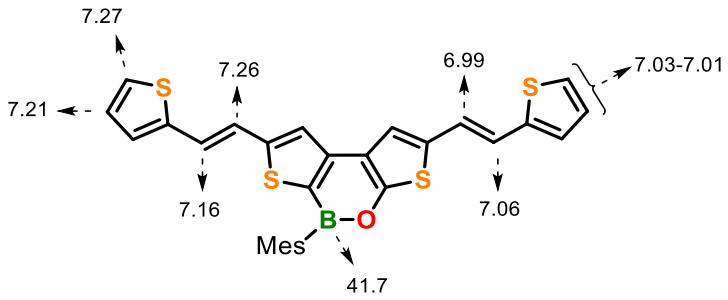

Figure 23. Diagnostic proton and boron shifts of *trans,trans*-**25**.

Cyclovoltammetry of *trans,trans*-**25** was run in THF solution (Figure S74, S75) and showed an irreversible reduction peak in the cathodic scan, E_{pc} = –2.21 V. *trans,trans*-**25** is thus easier to reduce than the oxaborine substructure **5** (E_{pc} = –2.96 V), according to its more extended conjugation pathway. Interestingly, in the anodic scan, **25** showed a first quasi-reversible oxidation event E_{pa} = 0.61 V, accompanied by a largely irreversible process E_{pa} = 0.99 V which could be attributed to oxidation processes involving the α-positions of the two terminal thiophene rings.

Absorption and emission spectra of *trans,trans*-**25** were performed in *c*-hexane THF and $CHCl_3$ (Figure 24). Absorption spectrum of *trans,trans*-**25** showed three main bands at 283, 365 and 382 nm; the calculated energy gap is Eg^{opt} = 2.69 eV, which is the lowest of all the whole BO-doped series of compounds presented in this thesis. Compound **25** is a blue emitter and its fluorescence spectrum (*c*-hexane) and showed (Figure 24) resolved vibrational fine structure with maxima at 445, 472 and 500 nm, accompanied by a shoulder at 535 nm. The associated quantum yield of **25** in *c*-hexane is Φ_{PL} = 12% while the quantum yields in polar

solvents are significantly lower (Φ_{PL}^{THF} = 3%, $\Phi_{PL}^{CHCl_3}$ = 5%). Interestingly, *trans,trans*-**25** is characterized by a considerable solvatochromic effect and emits in the green in polar solvents (THF, λ_{em} = 535 nm; $CHCl_3$, λ_{em} = 553 nm), thus revealing a polar excited state.

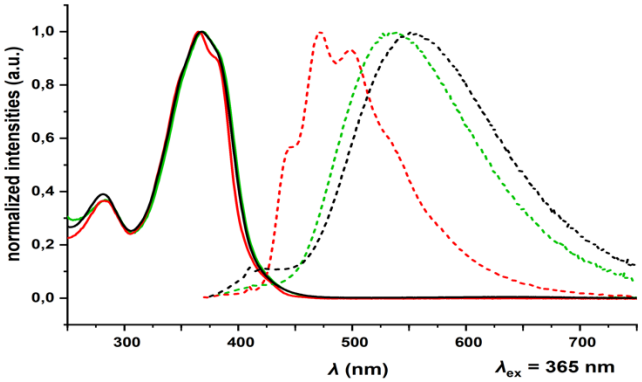

Figure 24. Absorption (solid line) and emission (dashed line) spectra of **25** in *c*-hexane (red), THF (black) and $CHCl_3$ (green).

DFT calculations revealed as the HOMO and LUMO are located on the O- and B- fragment respectively (Figure 25), similarly to what observed for the BO-doped compounds previously showed (see Chapter 1, 2).

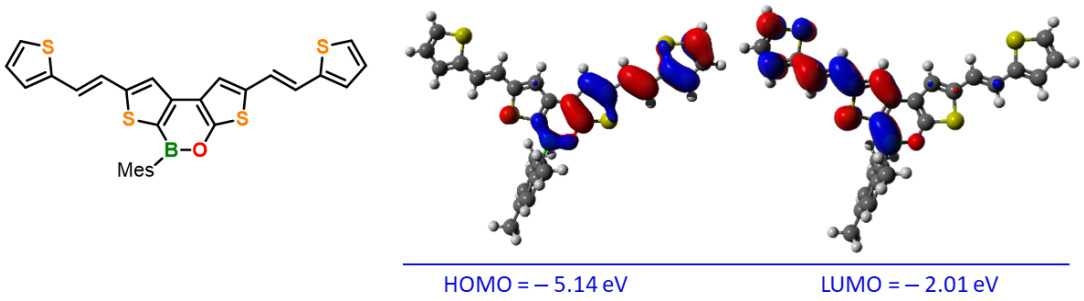

Figure 25. HOMO (left) and LUMO (right) distributions of **25** calculated at the B3LYP/6-31G* level.

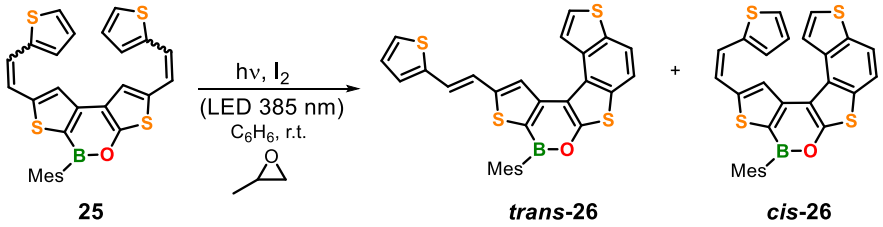
The photocyclization of **25** was then investigated, the reaction was performed in benzene solution irradiating for 3.5 h with a 385 nm LED lamp at room temperature in the presence of 2 equiv of I_2 and an excess of propylene oxide (Scheme 15). Only the mono-ring closure product **26** was obtained, after chromatographic purification, as an inseparable mixture of *trans*- and *cis*- isomers in ≈60:40 ratio. The increasing of the irradiation time to 12 h allowed to obtain a mixture enriched in the *cis*-isomer (≈40:60, see Figure S50, S51).



Scheme 15. Photocyclization of **25**.

^{1}H NMR analysis (aided by ^{HH}COSY experiments) performed on the isomeric mixtures of **26** allowed to assign most of the proton resonances of both structures (see Experimental Part). Moreover, the structure was confirmed by HRMS and, single crystals of *trans*-**26** suitable for X-ray analysis, were obtained by slow evaporation of a saturated solution of *trans*/*cis*-**26** (≈60:40) (Figure 26 and Figure S100).

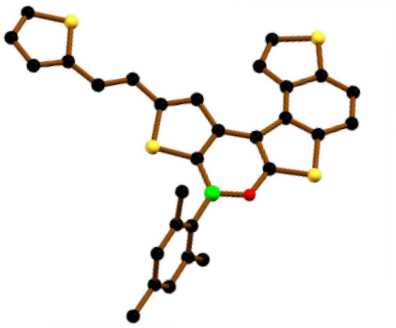


Figure 26. X-ray crystal structure of *trans*-**26** by-product. B: green, C: black, O: red, S: yellow spheres. Picture generated with the crystallographic software *Mercury*.

These preliminary results about the photocyclization of **25** are rather promising for the obtainment of helicene **3** and deserve a further investigation, that is currently ongoing. Although the target borahelicene **3** has still not been isolated, DFT calculations were run to get insights about its HOMO-LUMO distribution (Figure 27). Similarly to the case of its bisalkene precursor *trans,trans*-**25**, HOMO is mainly located in the oxygenated helicene wing, while LUMO is mainly spread on the opposite borylated wing. Taken together, these results confirm that, as in the case of borahelicenes **1** and **2**, the HOMO and LUMO distributions strongly depends on the position of the B-O bond(s) into the helical scaffold.

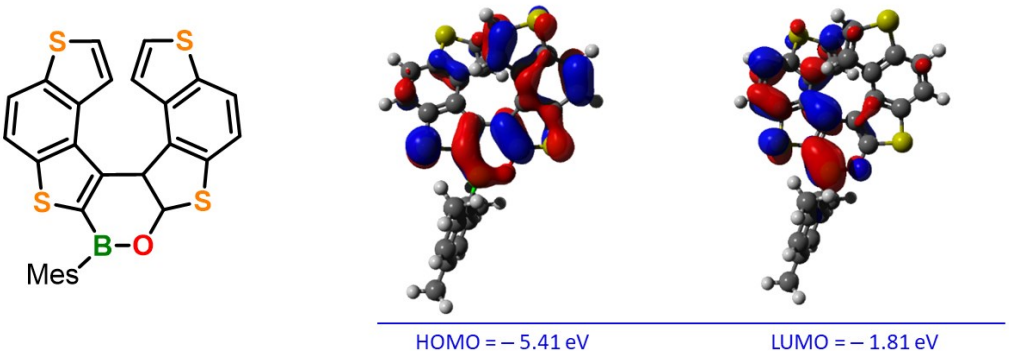

Figure 27. HOMO (left) and LUMO (right) distributions of **3** calculated at the B3LYP/6-31G* level.

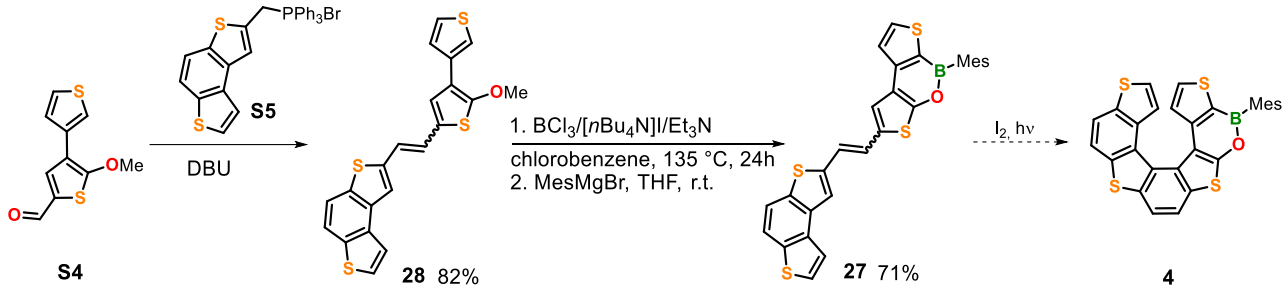
4.3.2 Preliminary study of the synthesis of tetrathia[7]helicene 4

Finally, I started investigating the synthesis of borahelicene **4** which contains one 1,2-oxaborine ring in the side position of the helical scaffold. The synthesis of **4** again exploits the photocyclization of the "oxaborine containing" alkene **27**, which in turn can be synthesized by late-stage borylation of the methoxy functionalized alkene **28** (Scheme 16).



Scheme 16. Designed synthetic route to **4**.

The starting material of this sequence is the methoxy bithiophene aldehyde **S4** which was prepared according to literature procedures and completely characterized, since just few data were reported in the original article[2] (see Section 2.1). The following Wittig olefination with the BDT phosphonium salt **S5**, using DBU as base, gave **28** in 82% average yield, in a ≈3:2 *trans*/*cis* ratio.

The isomers of alkene **28** were separated by column chromatography. *Trans*-**28** NMR characterization was quite difficult, due to its scarce solubility (slightly soluble only in DMSO, THF, chlorobenzene). However, it was possible to assign most of the proton and carbon resonances and assign the *trans*/*cis*-configuration of the two isomers of 28 on the basis of their olefinic protons coupling constants, $^{3}J(\mathrm{H,H})_{trans}$ = 15.9 Hz and $^{3}J(\mathrm{H,H})_{cis}$ = 12.4 Hz.

Alkene **28** was therefore subjected to borylation reaction following our standard procedure and gave the key precursor **27** that was obtained in good yield (71%), predominantly as *trans* isomer. In the NMR spectrum of *trans*-**27** olefinic protons at $\delta(^{1}\mathrm{H})$ = 7.15 and $\delta(^{1}\mathrm{H})$ = 7.20, showed a reciprocal coupling constant of ^{3}J = 15.7 Hz, again the borylated thiophene α proton was significantly deshielded and resonates at $\delta(^{1}\mathrm{H})$ = 8.00, similarly to that of *trans*-**15** $\delta(^{1}\mathrm{H})$ = 7.99, which incorporates the same substructure (see Figure 28). The ^{11}B NMR shift measured for **27** is $\delta(^{11}\mathrm{B})$ = 42.12.

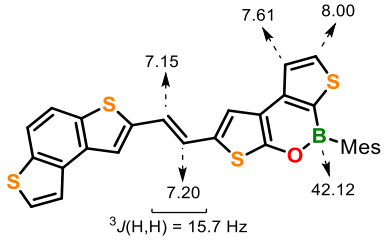


Figure 28. Diagnostic proton and boron shifts of *trans*-**27**.

Cyclic voltammetry measurements of *trans*-**27** were performed in THF. In the cathodic scan, *trans*-**27** showed an irreversible reduction process, with peak potential at E_{pc} = – 2.37 V. Similarly to what observed for the bisalkene **25**, two irreversible oxidation processes resulted from the anodic scan (E^{I}_{pa} = 0.63 V, E^{II}_{pa} = 0.76 V) and again these can be attributed to oxidation processes involving the terminal thiophene ring α positions. Alkene *trans*-**27** is harder to be reduced than the singly BO-doped bisalkene *trans*,*trans*-**25** (– 2.37 V *vs*. – 2.21 V; – 2.43 eV *vs*. – 2.59 eV) and the experimental HOMO and LUMO values are –5.43 eV and – 2.43 eV respectively.

DFT calculations revealed that both HOMO and LUMO are spread over the central thiophene-ethylene-thiophene fragment of the molecule 27 (Figure 29a), (as in the case of the alkenes *trans*-**15** and *trans*-**18** (See Chapter 1 and 2)). Absorption and emission spectra were measured in *c*-hexane and THF but the solvatochromic effect was negligible. Absorption spectrum of *trans*-**27** in *c*-hexane showed main absorption bands at 388 and 410 nm and an associated E_g^{opt} = 2.89 eV (Figure 29b).

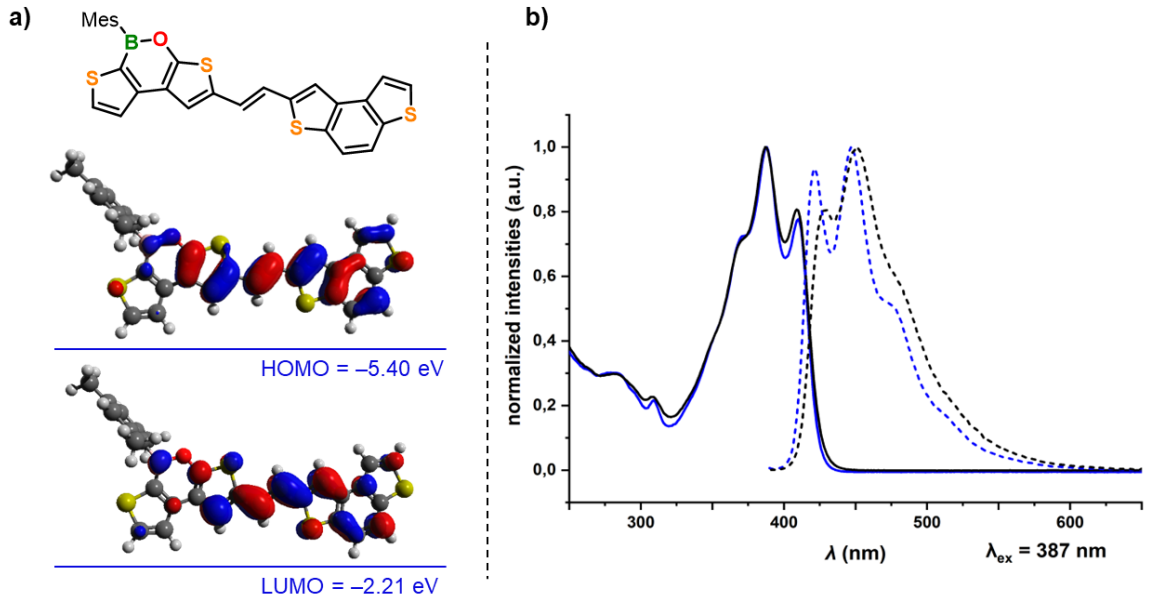

Figure 29. a) HOMO (top) and LUMO (bottom) distributions of *trans*-**27** calculated at the B3LYP/6-31G* level. b) Absorption (solid lines) and emission (dashed lines) spectra of *trans*-**27** in in *c*-hexane (blue) and THF (black).

In the emission spectra *trans*-**27** shows two bands with resolved vibrational fine structure at 421 and 488 nm accompanied by a shoulder at 517. *Trans*-**27** is a blue emitter; the associated quantum yield in *c*-hexane is Φ_{PL} = 23%, while is slightly lower in THF, Φ_{PL} = 17%. Thus, *trans*-**27** is the most efficient emitter in the whole series of BO-doped compounds presented in this thesis. The photocyclization of **27** to **4** will be investigated soon and once completed the synthesis, its analytical, spectroscopic, electrochemical, theoretical, stereochemical characterization will be performed.

5. Conclusions

This PhD thesis was aimed at investigating a new class of chiral thiaheterohelicenes doped with one or two boron atoms. Few borahelicenes examples have been reported in the literature and the synthetic strategies and routes to access this class of compounds are still underdeveloped. This target has been particularly challenging and demanding from a synthetic point of view, and it required a meticulous setup of the experimental procedures, especially for the borylation steps.

Novel chiral borahelicenes **1** and **2** were successfully obtained following unprecedented synthetic routes which combine the chemistry of helicenes and that of boron-doped PAHs, and the investigation of the synthesis of two additional borahelicenes, namely **3** and **4** has already been started and is presently still ongoing.

In particular the doubly (BO)-doped tetrathia[7]helicene **1** was obtained via an efficient four-step synthesis, including a Mallory photocyclization step, which has rarely been used for the synthesis of B-containing polycyclic aromatic hydrocarbons. The chiroptical properties of **1** were investigated, its (*P*)-/(*M*)-enantiomers were resolved by chiral HPLC and their absolute configuration was established combining computed and experimental CD spectra. The results of this complete study were published as research article on *Angewandte Chemie Int. Ed.* (L. Menduti, C. Baldoli, S. Manetto, M. Bolte, H.-W. Lerner, G. Longhi, C. Villani, E. Licandro, M. Wagner *Angew. Chem. Int. Ed.* **2023**, *62*, *5*, e202215468).

In general, the extensive experimental work was supported by a deep NMR and crystallographic characterization of all synthesized compounds which allowed their correct identification and characterization. The electrooptical features of new molecules were investigated by cyclic voltammetry, UV/Vis and fluorescence spectroscopy while DFT calculations were run to analyse the energetic landscape of these systems.

The synthetic routes developed in this thesis should allow for manifold optimizations in the future (such as BN-doping, introduction of different heteroaromatic rings) and thus open up for the synthesis of new and more complex borahelicene structures.

Taken together, the results presented in this thesis represent a meaningful contribution to the development of the field of borahelicenes and, in the specific case of BO-doped thiahelicenes, thus setting solid basis for the development in the design and the synthesis of new helicene derivatives with enhanced properties.

Table of contents

1. General experimental remarks

If not stated otherwise, all reactions and manipulations were carried out under dry nitrogen atmosphere using Schlenk techniques. THF was distilled from Na/benzophenone and degassed by purging with dry argon or nitrogen for at least 30 min (coupling reactions). Chlorobenzene, dimethylformamide (DMF) and Et_3N were distilled from CaH_2 and stored over molecular sieves (3 Å). C_6D_6 and $CDCl_3$ were stored over molecular sieves (3 Å). MesMgBr and *n*-BuLi were titrated according to literature prior to use.[S1] Reaction mixtures in flasks were heated by using an oil bath.

If not stated otherwise, commercially available compounds were used as received.

In photochemical experiments, a medium-pressure Hg lamp (Helios Italquartz; 150 W) or 385, 395 and 405 nm LED lamps (*Sahlmann Photochemical Solutions*) were used.

Column chromatography was performed using silica gel 60 (*Macherey–Nagel*, *Simga Aldrich*; 70–230 mesh). Melting points were measured with Melting points were recorded with a Büchi Melting Point B-540 apparatus. NMR spectra were recorded at 298 K using the following spectrometers: Bruker Avance-300, Avance-400, Avance Neo-400, Avance-500, or DRX-600. Chemical shift values are referenced to (residual) solvent signals ($^1H/^{13}C\{^1H\}$; C_6D_6: δ = 7.16/128.06; $CDCl_3$: δ = 7.26/77.16) or external BF_3•Et_2O (^{11}B: δ = 0.00). Abbreviations: s = singlet, d = doublet, dd = doublet of doublets, br. = broad, n.o. = not observed, eq. = equivalent, Mp = melting point. Resonances of carbon atoms attached to boron atoms were typically broadened and sometimes not observed due to the quadrupolar relaxation of boron. Resonance assignments were aided by ^{13}C APT, ^{H,H}COSY, ^{H,C}HSQC, and ^{H,C}HMBC spectra.

High-resolution mass spectra were measured using: electron ionization (EI) spectrometer (FISONS-Vg Autospec-M246), *Thermo Fisher Scientific* MALDI LTQ Orbitrap XL spectrometer (2,5-dihydroxybenzoic acid or α-cyano-4-hydroxycinnamic acid as the matrix), MALDI-TOF/TOF Autoflex III-Bruker Daltonics.

UV–vis absorption spectra were obtained on a *Shimadzu* UV–vis–NIR 3600 spectrophotometer or a *Varian* Cary 50 Scan or a *Varian* Cary 60 Scan UV/Vis spectrophotometer in a 1 cm path length quartz cell.

Photoluminescence quantum yields (Φ_{PL}) were measured with a *Jasco* FP-8300 spectrofluorometer equipped with a calibrated *Jasco* ILF-835 100 mm-diameter integrating sphere and analyzed using the *Jasco* FWQE-880 software or a C11347 *Quantaurus* - Absolute Photoluminescence Quantum Yield Spectrometer (Hamamatsu Photonics U.K), equipped with a 150 W Xenon lamp, an integrating sphere and a multi-channel detector.

Steady state emission and excitation spectra and photoluminescence lifetimes were obtained with a FLS 980 spectrofluorimeter (Edinburg Instrument Ltd.). Continuous excitation for the steady state measurements was provided by a 450 W Xenon arc lamp. Emission spectra were corrected for the detector sensitivity. Photoluminescence lifetime measurements, determined by TCSPC (time-correlated single-photon counting) method, were performed using an Edinburgh Picosecond Pulsed Diode Laser EPL-445 (Edinburg Instrument Ltd.), in nitrogen degassed solutions (10^{-5}-10^{-7} mol L^{-1}).

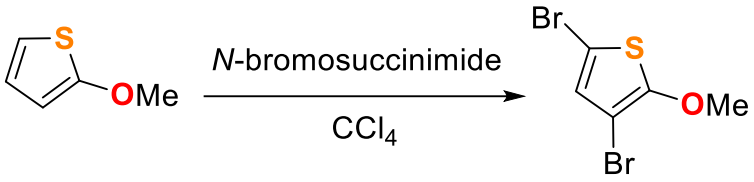
Cyclic voltammetry (CV) measurements of **5**, **15**, **16**, **1**, and **15H2** were performed in a glovebox at room temperature in a one-chamber, three-electrode cell using an *EG&G* Princeton Applied Research 263A potentiostat. A platinum-disk electrode (2.00 mm diameter) was used as the working electrode with a platinum-wire counter electrode and a silver-wire reference electrode, which was coated with AgCl by immersion into HCl/HNO_3 (3:1). Prior to measurements, THF was dried with Na/benzophenone, and degassed by three freeze-pump-thaw cycles. [nBu$_4$N][PF_6] (used as received; *Sigma Aldrich*) was employed as the supporting electrolyte (0.1 mol L^{-1}). All potential values were referenced against the FcH/FcH^+ redox couple (FcH = ferrocene; $E_{1/2}$ = 0 V). Scan rates were varied between 100 and 400 mV s^{-1}.

Cyclic voltammetry (CV) measurements of **18**, **2**, **25**, and **27** were performed using an AutoLab PGStat potentiostat and a classical three electrode glass minicell (working volume about 3 mL), including as working electrode a glassy carbon GC disk (Metrohm, S=0.033 cm2) polished by diamond powder (1 μm Aldrich) on a wet cloth (Struers DP-NAP), as counter electrode a platinum disk, and as reference electrode a saturated aqueous calomel one (SCE) inserted in a compartment with the working medium ending in a porous frit, to avoid contamination of the working solution by water and KCl traces. Experiments were run at scan rates ranging 0.1–2 V/s on 0.00075 M solutions in THF+0.1 M tetrabutylammonium hexafluorophosphate $TBAPF_6$ as the supporting electrolyte, previously deaerated by nitrogen bubbling. Positive and negative half cycles have been separately recorded to avoid reciprocal contamination by electron transfer products. The reported potentials have been normalized vs. the formal potential of the intersolvental ferricinium/ferrocene (FcH+|FcH) reference redox couple, recorded in the same conditions. HPLC-resolution and semipreparative separation of the enantiomers were carried using a *Dionex* Ultimate 300 RS HPLC system equipped with a column (250×4.6 mm I.D. 5, 10 μm) containing the Chiralpak IA chiral stationary phase; eluant was delivered at flow rate of 1.0 mL/min. Optical rotation and CD spectra were recorded on a *Jasco J 715* CD spectrometer.

2. Starting materials preparation

2.1 Thiophene starting materials

2.1.1 Synthesis of S7[S2]

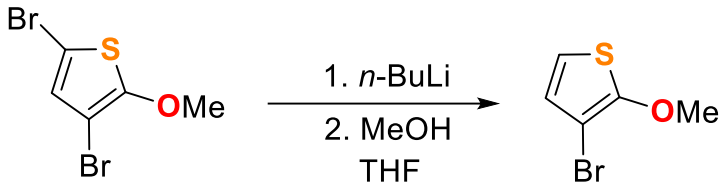


S7

A 250 ml two-necked flask equipped with a thermometer was charged with 2-methoxythiophene (5.00 g, 43.80 mmol) and CCl_4 (88 mL). The resulting yellowish solution was cooled to 5 °C and *N*-bromosuccinimide (15.65 g, 87.93 mmol, 2.00 equiv) was added in six portions during 1 h. The reaction mixture (yellow) was therefore allowed to warm up to room temperature and stirred for 24 hours (the reaction progress was checked by ^{1}H NMR). The reaction mixture was cooled with ice and then filtered to remove insoluble residues. The solution thus obtained was washed with water (150 mL). The organic phases were dried over Na_2SO_4, filtered and the solvent removed under reduced pressure. The crude product thus obtained was distilled under vacuo (bp. 94-95 °C, 2.5 mmHg) yielding 10.90 g of **S7** as a yellow oil (40.1 mmol, 92%).

^{1}H NMR (250 MHz, $CDCl_3$): δ = 6.75 (s, 1H), 3.93 (s, 3H).

2.1.2 Synthesis of S8[S2]



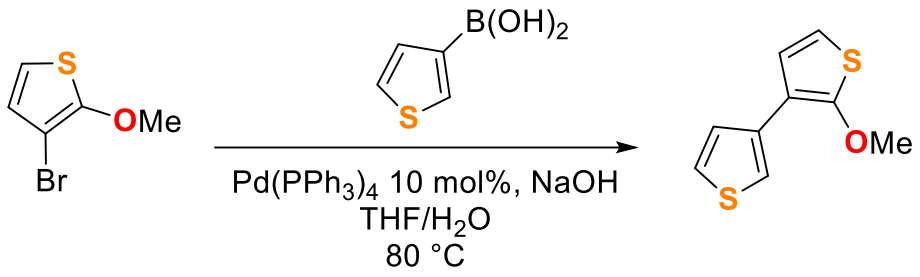
S7 **S8**

A 100 ml flame dried two-necked flask (equipped with a dropping funnel) was charged with **S7** (3.71 g, 14.32 mmol, 1 equiv) and THF (34 mL). The resulting dark red solution was cooled to –78 °C and *n*-BuLi (1.35 M in hexanes; 10.6 mL, 14.32 mmol, 1.05 eq) was diluted with dry THF (9 mL) and added dropwise (20 min). The resulting brown mixture was therefore stirred at the same temperature for 10 min, quenched with MeOH (5 mL, added slowly) and allowed to warm up to room temperature.

The solvent was removed and the residue was taken up with CH_2Cl_2 (50 ml). Water (70 mL) was added, the organic phase was separated and the aqueous phase was extracted with CH_2Cl_2 (4×30 mL). The combined organic layers were dried over Na_2SO_4 and filtered. The solvent was removed and the crude product was distilled under vacuo (56-58 °C, 1.5 mmHg) yielding 2.15 g of **S8** as a yellowish oil (11.15 mmol, 82%). The ^{1}H NMR chemical shifts correspond to the reference values.

^{1}H NMR (600 MHz, $CDCl_3$): δ = 6.75 (d, ^3J(H,H) = 6.0 Hz, 1H), 6.65 (d, ^3J(H,H) = 6.0 Hz, 1H), 3.97 (s, 3H).

2.1.3 Synthesis of S1[S3]



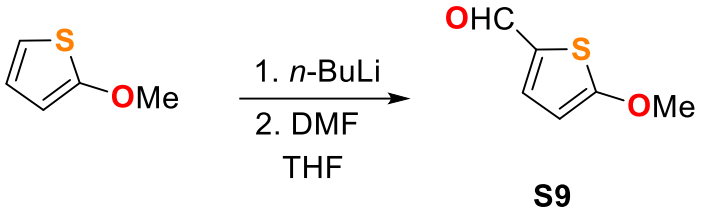
S8 **S1**

A flame-dried 100 mL J-Young flask was charged with **S8** (524 mg, 2.71 mmol), 3-thienylboronic acid (417 mg, 3.26 mmol, 1.20 equiv), $Pd(PPh_3)_4$ (157 mg, 0.135 mmol, 0.05 equiv) and THF (12 mL). NaOH 3M (1.8 mL, 5.43 mmol, 2.0 equiv) was added and the resulting dark reaction mixture warmed up to 80 °C and stirred for 2.5 d.

After cooling to room temperature, the THF was removed and the reaction mixture was taken up with CH_2Cl_2 (20 mL), water (10 mL) was added, and the two phases separated. The aqueous phase was extracted with CH_2Cl_2 (3 × 15 mL). The collected organic phases were dried over Na_2SO_4, filtered and the solvent was evaporated. The crude product was purified via column chromatography (*c*-hexane/CH_2Cl_2 (10:1)) affording **S1** as a yellowish oil (478 mg, 2.43 mmol, 90%).

^{1}H NMR (250 MHz, $CDCl_3$): δ = 7.53 (dd, *J*(H,H) = 3.0 Hz, *J*(H,H) = 1.3 Hz, 1H), 7.44 (dd, *J*(H,H) = 5.0 Hz, *J*(H,H) = 1.3 Hz, 1H), 7.32 (dd, *J*(H,H) = 5.0 Hz, *J*(H,H) = 3.0 Hz, 1H), 7.07 (d, *J*(H,H) = 5.9 Hz, 1H), 6.62 (d, *J*(H,H) = 5.9 Hz, 1H,), 4.00 (s, 3H).

2.1.4 Synthesis of S9[S4]



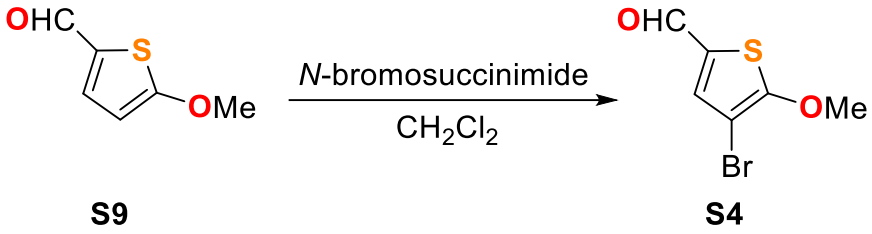
S9

A flame-dried two-necked flask equipped with a dropping funnel was charged with 2-methoxythiophene (2.5 g, 21.19 mmol) and THF (30 mL). The resulting yellowish mixture was cooled to –78 °C. *n*-BuLi (1.40 M in hexanes; 16.12 mL, 22.68 mol, 1.04 eq.) was added dropwise during 10 min and the resulting yellow clear solution was stirred at –78 °C for 1 hour.

DMF (4.72 g, 64.6 mmol, 2.95 eq.) was added dropwise yielding a deep yellow solution which was stirred at –78 °C for 45 min. NH_4Cl sat. aqueous solution (5 mL) was added, and the reaction mixture was allowed to warm up to room temperature. THF was removed and the residue was taken up with AcOEt (30 mL). Water (50 mL) was added, and the two layers were separated. The aqueous phase was extracted with AcOEt (3×20 mL) and the combined organic phases were dried over Na_2SO_4 and filtered. **S9** was obtained as a red-orange oil (3.10 g, 21.8 mmol, y = quantitative) and it was proved to be the desired product by ^{1}H NMR analysis.

^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.66 (s, 1H), 7.50 (d, *J*(H,H) = 4.3 Hz, 1H), 6.34 (d, *J*(H,H) = 4.3 Hz, 1H), 3.98 (s, 3H).

2.1.5 Synthesis of S4[S5]



S9 **S4**

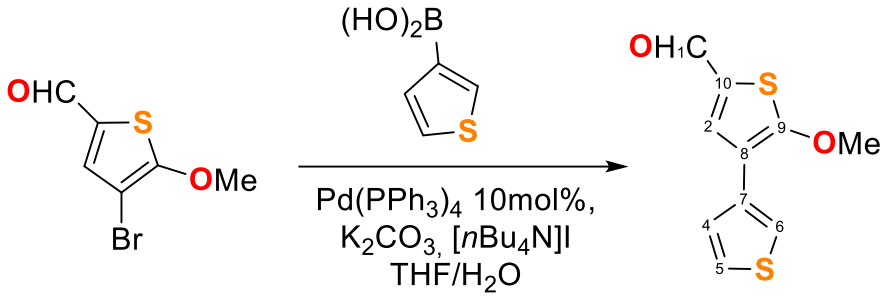
S9 (2.02 g, 14.18 mmol) was dissolved in CH_2Cl_2 (30 mL) and the resulting mixture was treated with *N*-bromo succinimide (2.63 g, 14.75 mmol, 1.04 eq.), added in portions during 30 min. The reaction progress was checked by TLC. After 5 h, TLC showed complete conversion of the starting material.

The reaction mixture was thus poured into water (50 mL) and, after separation of the two layers, the organic phase was washed with water (3×30 mL), while the aqueous phase was extracted with CH_2Cl_2 (30 mL). The combined organic phases were dried over Na_2SO_4, filtered and the solvent was removed. The crude product thus obtained was washed with Et_2O yielding **S4** as a pale-yellow solid (2.27 g, 10.30 mmol, 73%). Et_2O mother liquors were evaporated and the residue thus obtained was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (1:3)), yielding additional 630 mg of **S4** (2.85 mmol, 20%). Total yield: 93%.

The ^{1}H NMR chemical shifts correspond to the reference values.

^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.66 (s, 1H), 7.55 (s, 1H), 4.09 (s, 3H).
Mp: 113-114 °C.

2.1.6 Synthesis of S5[S6]



S4 **S5**

A flame-dried J-Young flask was charged with **S4** (502 mg, 2.26 mmol), 3-thienylboronic acid (296 mg, 2.26 mmol, 1 eq.), [*n*Bu$_4$N]Br (83 mg, 0.23 mmol, 0.1 eq.), K_2CO_3 (629 mg, 4.53 mmol, 2 eq.) and a THF/H_2O (5:1) solvent mixture (12 mL). $Pd(PPh_3)_4$ (213 mg, 0.18 mmol, 0.08 eq.) was added and the resulting yellow mixture was heated to 80 °C and stirred for 12 h. The reaction progress was checked by TLC (*n*-hexane/CH_2Cl_2 (1:3)). TLC after 12 h showed complete conversion of the starting material.

The reaction mixture was thus allowed to cool to room temperature and the solvent was evaporated. The residue was taken up with CH_2Cl_2 (30 mL) and water (20 mL) was added. After separation of the two layers, the aqueous phase was extracted with CH_2Cl_2 (3×15 mL). The collected organic phases were dried over Na_2SO_4 and filtered. The solvent was removed, and the crude product was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (1:3)). **S5** was thereby obtained as an orange solid (404 mg, 1.80 mmol, 80%).

S5 *^{1}H and ^{13}C resonances assignment:*

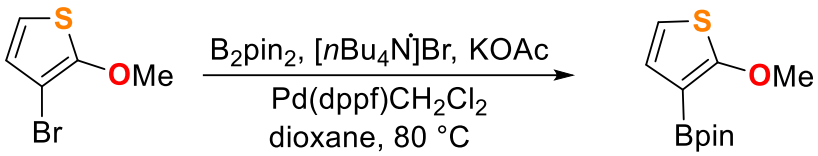
^{1}H NMR (300 MHz, $CDCl_3$): δ = 9.72 (s, 1H; H-1), 7.82 (s, 1H; H-2), 7.59 (dd, ^3J (H,H) = 2.9, ^4J (H,H) = 1.3 Hz, 1H; H-6), 7.40 (dd, ^3J (H,H) =5.0 Hz, ^5J (H,H)=1.3 Hz, 1H; H-4), 7.38 (dd, ^3J(H,H) =5 Hz, dd, ^4J (H,H) =2.9 Hz, 1H; H-5), 4.14 (s, 3H; OMe).

^{13}C{^{1}H}NMR (75 MHz, $CDCl_3$): δ = 182.2 (C-1), 170.1 (C-10), 137.1 (C-2), δ=133.4 (C-9), 128.2 (C-8), 126.55 (C-4), 125.7 (C-5), δ=121.5 (C-6), 118.7 (C-7), 61.9 (OMe).

IR: $\nu_{C=O}$: 1631 cm^{-1}.

Mp: 87.7 – 88.2 °C.

2.1.1 Synthesis of S2[S8]

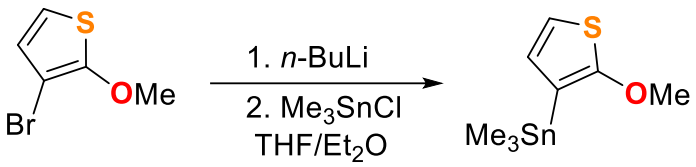


S8 **S2**

A flame-dried J-Young flask was charged with **S8** (1.50 g, 7.77 mmol, 1.00 eq.), bis-pinacolato diboron (2.24 g, 9.32 mmol, 1.20 eq.), KOAc (1.53 g, 15.5 mmol, 2.00 eq.), TBAB (56 mg, 170 µmol, 0.025 eq.), Pd(dppf)·CH_2Cl_2 (140 mg, 155 µmol, 0.02 eq.) and evacuated for 1 h. Dioxane (8 mL) was added and the resulting mixture was heated to 80 °C for 18 h. The solvent was evaporated, and the residue was purified via column chromatography (*c*-hex/CH_2Cl_2 (1:1)). **S2** was obtained as a yellow solid, in mixture with 7% B_2pin_2 (255 mg, 1.06 mmol, 14%).

^{1}H NMR (250 MHz, $CDCl_3$): δ = 7.01 (d, ^3J(H,H) = 5.7 Hz, 1H), 6.53 (d, ^3J(H,H) = 5.7 Hz, 1H), 3.98 (s, 3H), 1.32 (s, 12H).

2.1.2 Synthesis of S3[S7]



S8 **S3**

A flame-dried two-necked flask equipped with a dropping funnel was charged with **S8** (3.22 g, 16.68 mmol) and Et_2O (16 mL). The orange solution thus obtained was cooled to –78 °C and *n*-BuLi (1.40 M in hexanes; 13 mL, 18.20 mmol , 1.05 eq.) was added dropwise during 15 min. The dropping funnel was washed with THF (16 mL).

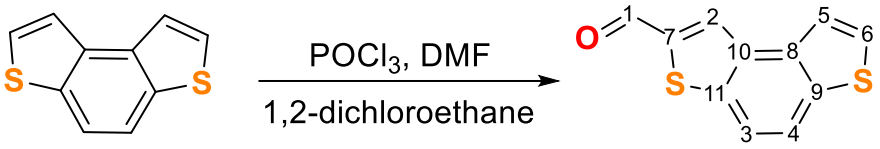
The orange suspension thus obtained was stirred at –78 °C for additional 45 min and then treated with a THF solution (16 mL) of Me_3SnCl (3.08 g, 19.05 mmol, 1.1 eq.), added during 3-5 min. The resulting orange solution was stirred at –78 °C for 2 h. The reaction mixture was therefore allowed to warm up to room temperature and water (30 mL) was added. The two layers were separated, and the aqueous phase was extracted with Et_2O. The combined organic phases were dried over Na_2SO_4, filtered and the solvent evaporated. The crude product was purified *via* distillation under vacuum (55-58 °C, 0.7 mmHg). **S3** was thereby obtained as yellowish oil (4.06 g, 14.65 mmol, 88%).

^{1}H NMR (300 MHz, $CDCl_3$): δ = 6.73 (d, *J*(H,H) = 5.5 Hz, 1H), 6.71 (d, *J*(H,H) = 5.5 Hz, H), 3.89 (s, 3H), 0.28 (s, 9H).

2.2 Benzodithiophene (BDT) starting materials

Benzodithiophene (BDT) was prepared according to literature procedures.[S9]

2.2.1 Synthesis of S10[S10]



BDT **S10**

Preparation of the Vilsmeier salt:

A 100 mL two-necked flask was charged with DMF (12 ml, 159 mmol, 30 eq.) and 1,2-dichloroethane (5 mL). The reaction mixture was cooled to 0 °C and $POCl_3$ (15 mL, 159 mmol, 30 eq.) was added. The resulting yellow solution was therefore allowed to warm up to room temperature and then heated to 50 °C and stirred for 1 h.

*Preparation of **10**:*

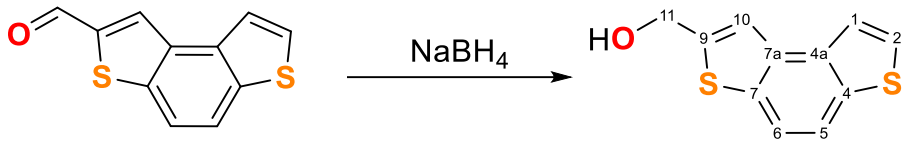
A 100 mL two-necked flask equipped with a reflux condenser was charged with **BDT** (1.0 g, 5.30 mmol, 1 eq.) and 1,2-dichloroethane (22 mL). The Vilsmeier salt (30 eq.) was added dropwise at room temperature (using a Pasteur pipette) during 30 min. The resulting orange reaction mixture was heated to 85 °C and stirred for 24 h. The reaction progress was checked by TLC.

Note: reaction mixture samples were washed with water prior to deposition onto the TLC plate.

After cooling to room temperature, the solvent was evaporated. The residue was taken up with AcOEt (100 mL), poured into ice-cold water (150 mL) and the resulting biphasic mixture was stirred for 15 min. After separation of the two layers, the aqueous phase was extracted with CH_2Cl_2 and the collected organic phases were dried over Na_2SO_4 and filtered. The solvent was removed, and the crude product was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (6:4)). **S10** was obtained as a yellow solid (838 mg, 3.84 mmol, 72%).

^{1}H NMR (400 MHz, $CDCl_3$): δ = 10.16 (s, 1H; H-1), 8.38 (s,1H; H-2), 7.98 (d, ^3J(H,H) = 8.7 Hz, 1H; H-3), 7.82 (d, ^3J(H,H) =8.7 Hz, 1H; H-4), 7.77 (d, ^3J(H,H) = 5.4 Hz, 1H; H-5), 7.68 (d, ^3J(H,H) = 5.4 Hz, 1H; H-6).
^{13}C{^{1}H}NMR (75 MHz, $CDCl_3$): δ = 184.38 (C-1), 143.26 (C-7), 140.73 (C-10), 137.31 (C-8), 136.15 (C-11), 133.98 (C-9), 131.79 (C-2), 128.51 (C-6), 123.07 (C-3), 121.28 (C-5), 119.17 (C-4).
M.p.: 101.8-102.6 °C.

2.2.2 Synthesis of S11[S11]



S10 **S11**

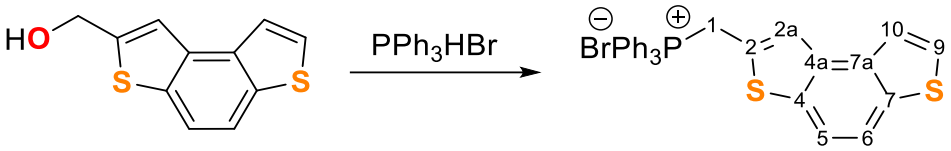
A 50 mL two-necked flask was charged with **S10** (838 mg, 3.84 mmol), THF (8 mL) and EtOH (10 mL). The resulting solution was cooled to 0 °C and $NaBH_4$ (146 mg, 3.84 mmol, 1eq.) was added. The reaction mixture was therefore allowed to warm up to room temperature and stirred for 5 h. The reaction progress was checked by TLC (CH_2Cl_2).

The solvent was evaporated, and the residue was taken up with CH_2Cl_2 and washed with water. The organic phases were dried over Na_2SO_4, filtered and the solvent was removed under reduced pressure. **S11** was thereby obtained as a white solid (806 mg, 3.66 mmol, 95%).

^{1}H NMR (400 MHz, $CDCl_3$): δ = 7.83 (d, 2H, H-5), 7.73 (d, 2H, H-6), 7.66 (d, ^2J(H-H)=5.4 Hz, 1H, H-1), 7.61 (s,1H, H-10), δ=7.56 (d, ^2J (H,H) =5.4 Hz, 1H; H-2), δ=5.04 (d, ^2J(H,H) =6 Hz, 1H, H-11), δ=1.93 (t, ^2J(H,H) =6 Hz, 1H, OH)

^{13}C{^{1}H}NMR (75 MHz, $CDCl_3$): δ = 145.22 (C-9), 136.73 (C-4a/ C-7a), 136.68 (C-4a/ C-7a), 134.73 (C-4/ C-7), 134.64 (C-4/ C-7), 126.74 (C-2), 121.90 (C-1), 119.88 (C-10), 119.01 (C-5/ C-6), 118.86 (C-5/ C-6), 61.1 (C-11).

2.2.3 Synthesis of S6



S11 **S6**

A 50 mL two-necked flask equipped with a reflux condenser was charged with **S11** (2.06 g, 9.35 mmol), $CHCl_3$ (52 mL) and PPh_3HBr (5.45 g, 15.9 mmol, 1.7 eq.). The resulting yellow mixture was heated to reflux for 5 h. The reaction progress was checked by TLC (CH_2Cl_2).

The solvent was removed, and the residue was washed with Et_2O (to remove triphenylphosphine by-product; $^{31}P\{^1H\}$ (122 MHz, DMSO): δ = –5.0) and $CHCl_3$ (to remove the chloroform phosphonium salt side-product; $^{31}P\{^1H\}$ (122 MHz, DMSO): δ = 29.3).

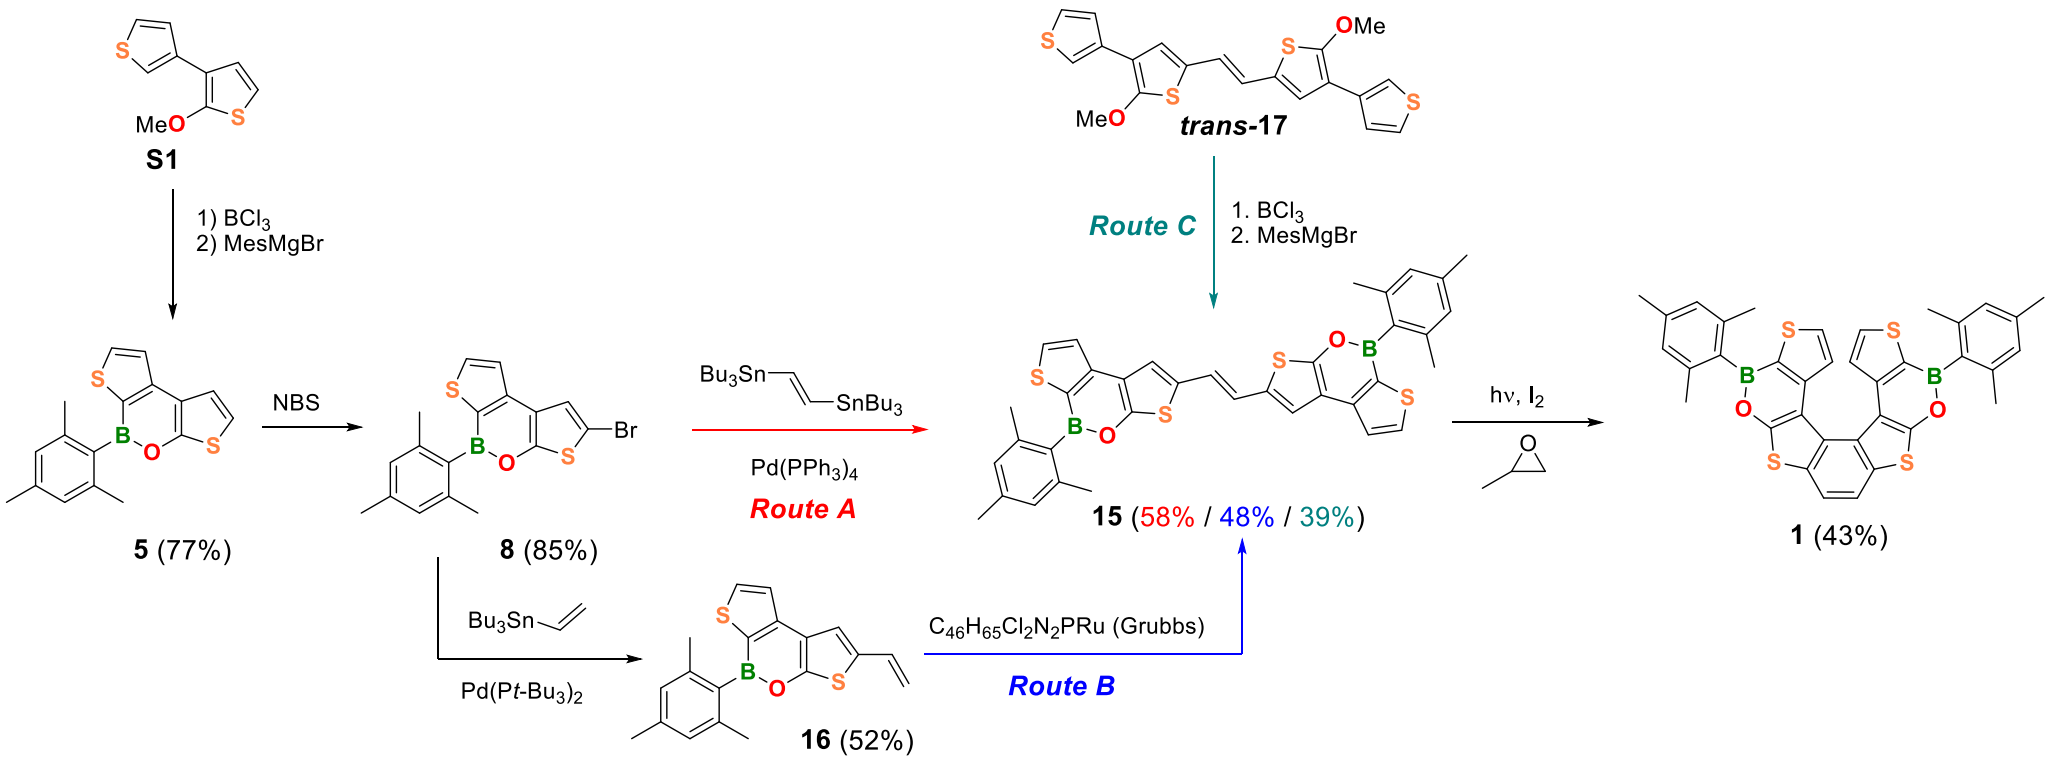
S6 was thereby obtained as a white solid (5.0 g, 9.17 mmol, y = 98%).

^{1}H NMR (300 MHz, DMSO): δ = 7.14-6.69 (m, 7 H), 6.99-6.82 (m, 11H), 6.83 (d, *J*(H,H) = 5.3 Hz, 1H), 6.69 (d, *J*(H,H) = 3.2 Hz, 1H), 4.89 (d, ^{2}*J*(H,P) = 15.1 Hz, 2H; H-1).

^{13}C{^{1}H}NMR (75 MHz, $CDCl_3$): δ = 136.4 (d, *J*(C,P) = 9.9 Hz), 135.36 (*p*-CH phenyl group), 133.96 (d, *J*(C,P) = 10.0 Hz; *o*/*m*-CH phenyl group), 133.32 (d, *J*(C,P) = 2.5 Hz), 130.28 (d, *J*(C,P) = 12.5 Hz; *o*/*m*-CH phenyl group), 128.43, 125.58 (d, *J*(C,P) = 8.6 Hz), 121.88, 119.74, 118.53, 118.23, 117.10, 25.09 (d, *J*(C,P) = 50.7 Hz; C-1).

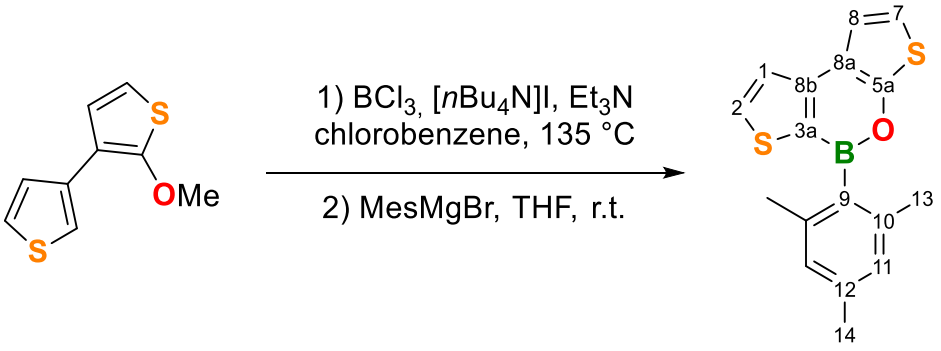
^{31}P{^{1}H}NMR (121.5 MHz, $CDCl_3$): δ = 21.6.

3. Synthesis of tetrathia[7]helicene 1



Scheme S1: Synthetic route to tetrathia[7]helicene **1**. Full details about the synthesis of **S1** are provided in section *2.1 Thiophene starting materials*.

3.1 Synthesis of 5



S1 **5**

A flame-dried 100 mL J-Young tube was charged with **S1** (510 mg, 2.60 mmol), [*n*Bu$_4$N]I (1.15 g, 3.12 mmol, 1.20 eq.), and chlorobenzene (18 mL). The yellowish mixture was treated with BCl_3 (1.0 M in hexanes; 3.90 mL, 3.90 mmol, 1.50 eq.) and stirred at room temperature for 2 min. Et_3N (362 µL, 2.60 mmol, 1.00 eq.) was added and the orange mixture thus obtained was heated to 135 °C and stirred for 24 h. After cooling to room temperature, the solvent was evaporated to dryness and THF (18 mL) was added. MesMgBr (1.0 M in THF; 7.79 mL, 7.79 mmol, 3.00 eq.) was added dropwise at room temperature to give a clear, orange-colored solution, which was stirred for 1 h. The solvent was removed under reduced pressure and the residue was purified by column chromatography (15 cm silica gel, d = 3.5 cm, *c*-hexane, R_f = 0.20). **5** was obtained as an off-white solid (620 mg, 2.00 mmol, 77%). Single crystals suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of **5** in *n*-hexane/CH_2Cl_2 (1:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.98 (d, ^3J(H,H) = 4.8 Hz, 1H; H-2), 7.64 (d, ^3J(H,H) = 4.8 Hz, 1H; H-1), 7.36 (d, ^3J(H,H) = 5.9 Hz, 1H; H-8), 6.96 (d, ^3J(H,H) = 5.9 Hz, 1H; H-7), 6.92 (s, 2H; H-11), 2.35 (s, 3H; H-14), 2.25 (s, 6H; H-13).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 158.4 (C-5a), 147.5 (C-8b), 140.6 (C-10), 138.9 (C-12), 138.2 (C-2), 133.7* (C-9), 131.8* (C-3a), 127.6 (C-11), 123.0 (C-1), 120.38 (C-8), 120.35 (C-8a), 114.8 (C-7), 22.8 (C-13), 21.5 (C-14). *) unequivocally detected only in the ^{H,C}HMBC spectrum.

^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.7 ($h_{1/2} \approx$ 180 Hz).

HRMS (MALDI): Calculated *m/z* for $[C_{17}H_{15}BOS_2]^+$: 310.0652; found: 310.0655.

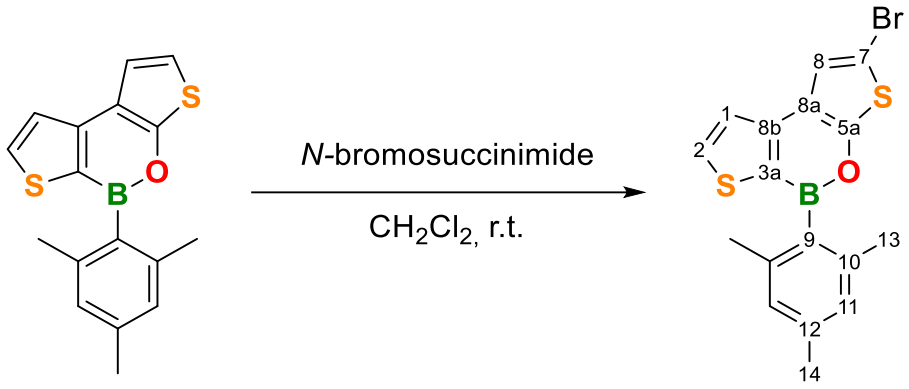
UV/Vis (*c*-hexane): λ_{max} (ε / mol^{-1}dm^{3}cm^{-1}) = 313 (sh), 320 (24300), 335 (sh).

Fluorescence (*c*-hexane, λ_{ex} = 320 nm): λ_{max} = 366, 380 nm (resolved vibrational fine structure); Φ_{PL} = 6%.

Cyclic voltammetry (THF, 0.1 M [*n*Bu$_4$N][PF$_6$], 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: E_{pc} = −2.96 V, E_{pa} = −2.81 V.

Mp: 102.5-104.5 °C.

3.2 Synthesis of 8



5 **8**

A 50 mL flask was charged with **5** (500 mg, 1.61 mmol) and CH_2Cl_2 (18 mL). Neat *N*-bromosuccinimide (344 mg, 1.93 mmol, 1.20 eq.) was added in one portion at room temperature and the resulting clear, orange-colored solution was stirred overnight (the completion of the reaction was confirmed by TLC). The solvent was removed under reduced pressure, and the solid residue was purified by column chromatography (15 cm silica gel, d = 3.5 cm, *c*-hexane, R_f = 0.30). **8** was obtained as a white solid (530 mg, 1.36 mmol, 85%). Single crystals suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of **8** in *n*-hexane/CH_2Cl_2 (2:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.98 (d, ^3J(H,H) = 4.8 Hz, 1H; H-2), 7.56 (d, ^3J(H,H) = 4.8 Hz, 1H; H-1), 7.39 (s, 1H; H-8), 6.92 (s, 2H; H-11), 2.35 (s, 3H; H-14), 2.23 (s, 6H; H-13).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 157.5 (C-5a), 146.3 (C-8b), 140.6 (C-10), 139.1 (C-12), 138.6 (C-2), 133.3* (C-9), 132.2* (C-3a), 127.6 (C-11), 123.1 (C-8), 122.9 (C-1), 120.8 (C-8a), 103.1 (C-7), 22.7 (C-13), 21.5 (C-14). *) unequivocally detected only in the ^{H,C}HMBC spectrum.

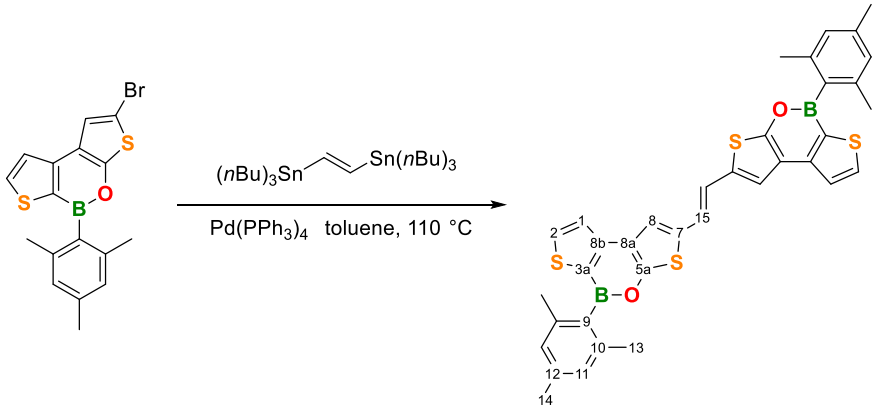
^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.5 ($h_{1/2}$ ≈ 210 Hz).

HRMS (MALDI): Calculated *m/z* for $[C_{17}H_{14}BBrOS_2]^+$: 387.9757; found: 387.9755.

Mp: 134-136 °C.

3.3 Synthesis of 15 (*via* Stille-type coupling)

Note: *trans*-1,2-bis(*n*Bu$_3$Sn)ethylene was purchased from *Alfa Aesar* and used as received; the same chemical purchased from different suppliers may be contaminated with *trans*-1,2-bis(*n*Bu$_3$Sn)acetylene.



8 ***trans*-15**

A flame-dried 250 mL J-Young round-bottom flask was charged with **16** (304 mg, 0.78 mmol) and evacuated for 30 min. Toluene (40 mL), *trans*-1,2-bis(*n*Bu$_3$Sn)ethylene (216 µL, 0.39 mmol, 0.50 eq.), and Pd(PPh$_3$)$_4$ (108 mg, 0.094 mmol, 0.12 eq.) were added, the Young-tap was closed, and the red mixture was heated with stirring to 110 °C for 24 h. After cooling to room temperature, the solvent was removed under reduced pressure, and the residue was purified by column chromatography (13 cm silica gel, d = 3.0 cm, *c*-hexane/CH_2Cl_2 (5:1), R_f = 0.28). The fractions containing *trans*-**15** (with only traces of *cis*-**15**) were combined and evaporated to dryness. The dark yellow residue was treated with *n*-hexane (to remove soluble *n*Bu$_3$SnBr and *cis*-**15**), and the resulting suspension was filtered. *trans*-**15** was thereby isolated as a yellow solid (146 mg, 0.23 mmol, 58%). Single crystals suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of *trans*-**15** in $CDCl_3$.

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.99 (d, ^3J(H,H) = 4.7 Hz, 2H; H-2), 7.60 (d, ^3J(H,H) = 4.8 Hz, 2H; H-1), 7.29 (s, 2H; H-8), 7.02 (s, 2H; H-15), 6.93 (s, 4H; H-11), 2.36 (s, 6H; H-14), 2.27 (s, 12H; H-13).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 157.3 (C-5a), 147.0 (C-8b), 140.7 (C-10), 139.1 (C-12), 138.4 (C-2), 133.5 (br.; C-9), 132.1 (br.; C-3a), 131.9 (C-7), 127.6 (C-11), 123.0 (C-1), 121.6 (C-15), 121.1 (C-8a), 119.4 (C-8), 22.8 (C-13), 21.5 (C-14).

^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.4 ($h_{1/2} \approx$ 490 Hz).

HRMS (MALDI): Calculated *m/z* for $[C_{36}H_{30}B_2O_2S_4]^+$: 644.1309; found: 644.1322.

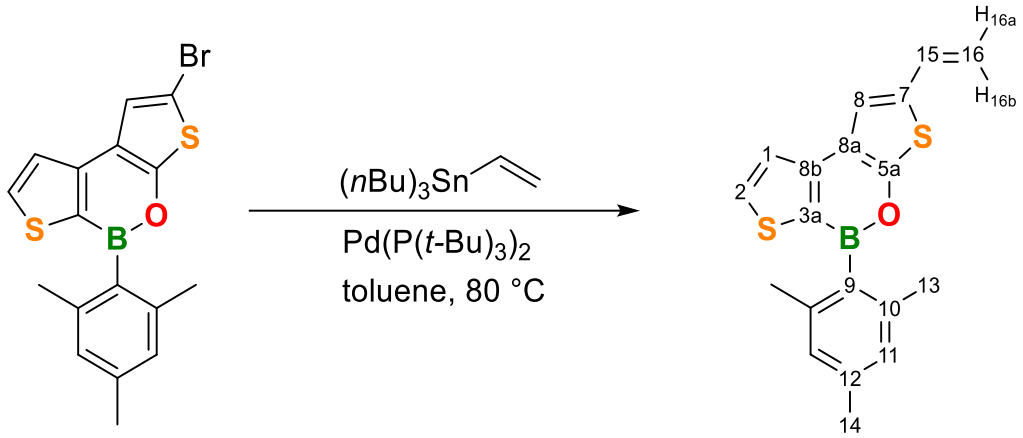
UV/Vis (*c*-hexane): λ_{max} (ε / mol^{-1}dm^{3}cm^{-1}) = 278 (26300), 344 (sh), 364 (44100), 383 (58700), 403 (45100).

Fluorescence (*c*-hexane, λ_{ex} = 385 nm): λ_{max} = 419, 443 nm (resolved vibrational fine structure); Φ_{PL} = 11%.

Cyclic voltammetry (THF, [*n*Bu$_4$N][PF$_6$] 0.1 M, 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: $E^{I}_{1/2}$ = – 2.54 V, E^{II}_{pc} = –2.90 V, E^{II}_{pa} = – 2.79 V.

Mp: >300 °C (decomposition).

3.4 Synthesis of 16



8 **16**

A flame-dried 250 mL J-Young round-bottom flask was charged with **8** (449 mg, 1.15 mmol) and evacuated for 30 min. Toluene (60 mL), nBu$_3$(vinyl)Sn (369 µL, 1.27 mmol, 1.1 eq.), and Pd(P(t-Bu)$_3$)$_2$ (29.5 mg, 0.058 mmol, 0.05 eq.) were added, the Young-tap was closed, and the red mixture was heated with stirring to 80 °C for 24 h. After cooling to room temperature, the solvent was removed under reduced pressure and the solid residue was purified by column chromatography (13 cm silica gel, d = 3.0 cm, c-hexane/CH_2Cl_2 (5:1), R_f = 0.42). The fractions containing **16** were combined and evaporated to dryness. The yellow residue was treated with n-pentane and the resulting suspension was filtered to remove nBu$_3$SnBr. **8** was isolated as a pale-yellow solid (200 mg, 0.59 mmol, 52%). Single crystals suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of **16** in n-hexane/CH_2Cl_2 (2:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.97 (d, ^3J(H,H) = 4.8 Hz, 1H; H-2), 7.58 (d, ^3J(H,H) = 4.8 Hz, 1H; H-1), 7.21 (s, 1H; H-8), 6.92 (s, 2H; H-11), 6.83 (dd, ^3J(H,H) = 17.2, 10.8 Hz, 1H; H-15), 5.53 (d, ^3J(H,H) = 17.2 Hz, 1H; H-16b), 5.17 (d, ^3J(H,H) = 10.8 Hz, 1H; H-16a), 2.34 (s, 3H; H-14), 2.24 (s, 6H; H-13).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 157.3 (C-5a), 147.2 (C-8b), 140.6 (C-10), 139.0 (C-12), 138.3 (C-2), 132.7 (C-7), 132.6* (C-9), 132.0* (C-3a) 130.6 (C-15), 127.6 (C-11), 122.9 (C-1), 120.7 (C-8a), 119.1 (C-8), 113.0 (C-16), 22.7 (C-13), 21.5 (C-14). *) unequivocally detected only in the ^{H,C}HMBC spectrum.

^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.4 ($h_{1/2} \approx$ 250 Hz).

HRMS (MALDI): Calculated m/z for $[C_{19}H_{17}BOS_2]^+$: 336.08084; found: 336.08085.

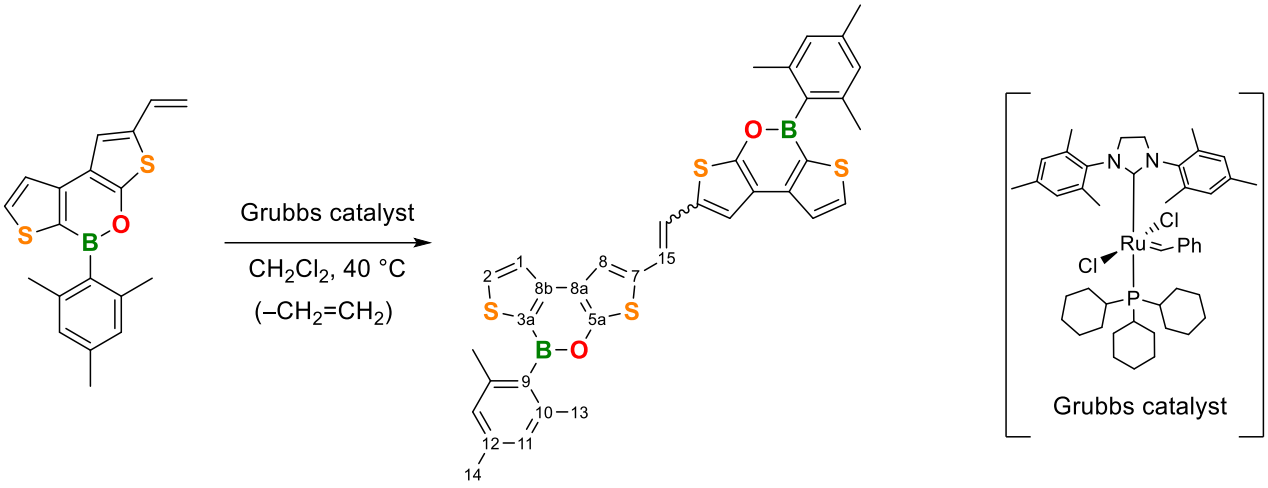
UV/Vis (c-hexane): λ_{max} (ε / mol^{-1}dm^{3}cm^{-1}) = 265 (27700), 275 (sh), 328 (26400).

Fluorescence (c-hexane, λ_{ex} = 328 nm): λ_{max} = 388, 402 nm (resolved vibrational fine structure); Φ_{PL} = 15%.

Cyclic voltammetry (THF, [nBu$_4$N][PF$_6$] 0.1 M, 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: E_{pc} = −2.93 V.

Mp: 108.7-110.8 °C.

3.5 Synthesis of 15 (*via* Grubbs metathesis)



16 **15**

A flame-dried 40 mL Schlenk flask was charged with **16** (85 mg, 0.25 mmol), Grubbs catalyst (8.6 mg, 0.01 mmol, 0.04 eq.), and CH_2Cl_2 (1 mL). The dark-red solution thus obtained was stirred at 40 °C for 2 d (the reaction progress was monitored by TLC). **Note:** The reaction mixture was briefly exposed to vacuum after 1 d to remove the ethylene byproduct. After cooling to room temperature, the solvent was removed under reduced pressure and the dark red residue was purified by column chromatography (12 cm silica gel, d = 2.0 cm, *c*-hexane/CH_2Cl_2 (5:1), R_f = 0.28). **15** was obtained as a yellow solid (39 mg, 0.06 mmol, 48%); *trans/cis* ratio ≈ 9:1 (determined by ^{1}H NMR spectroscopy).

trans-15

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.99 (d, ^3J(H,H) = 4.7 Hz, 2H; H-2), 7.60 (d, ^3J(H,H) = 4.8 Hz, 2H; H-1), 7.29 (s, 2H; H-8), 7.02 (s, 2H; H-15), 6.93 (s, 4H; H-11), 2.36 (s, 6H: H-14), 2.27 (s, 12H; H-13).

(C-8b).

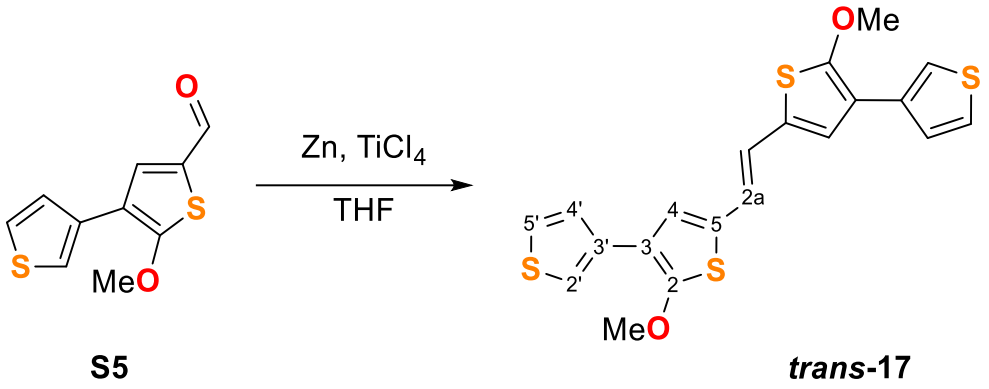
*) unequivocally detected only in the ^{H,C}HMBC spectrum.

^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.4 ($h_{1/2}$ ≈ 520 Hz).

3.6 Synthesis of 17



S5 ***trans*-17**

A flame-dried three-necked 100 mL flask (equipped with a thermometer and a reflux condenser) was charged with zinc powder (365 mg, 5.58 mmol, 2.5 eq.) and THF (17 mL). The mixture was cooled to –20 °C, and $TiCl_4$ (294 µL, 2.68 mmol, 1.2 eq.) was added. **S5** (500 mg, 2.23 mmol) was added dropwise as a THF solution (8 mL). After warming to room temperature, the reaction mixture was stirred for 1 h at 40 °C (the reaction progress was monitored by TLC). After cooling to room temperature, the reaction mixture was quenched by addition of ice-cold water (10 mL) and HCl (1.0 M; 15 mL). THF was removed using a rotary evaporator and CH_2Cl_2 (20 mL) was added. The (biphasic) mixture was thereafter filtered on a Celite® bed (washing with CH_2Cl_2). Water (20 mL) was added to the filtrate, and the two layers were separated. The aqueous phase was extracted with CH_2Cl_2 (4 × 15 mL). The combined organic phases were dried over Na_2SO_4, filtered, and the solvent was removed from the filtrate under reduced pressure. The dark brown crude product was purified by column chromatography (25 cm silica gel, d = 4.0 cm, *n*-hexane/CH_2Cl_2 (1:1), R_f = 0.48). The fractions containing *trans*-**17** (with only traces of *cis*-**17**) were combined and evaporated to dryness. The dark yellow residue was treated with *n*-pentane and the resulting suspension was filtered. *trans*-**17** was thereby isolated as a yellow solid (359 mg, 0.86 mmol, 77%). Single crystals suitable for X-ray crystallography were grown by slow evaporation of a solution of *trans*-**17** in *n*-pentane/CH_2Cl_2 (2:1).

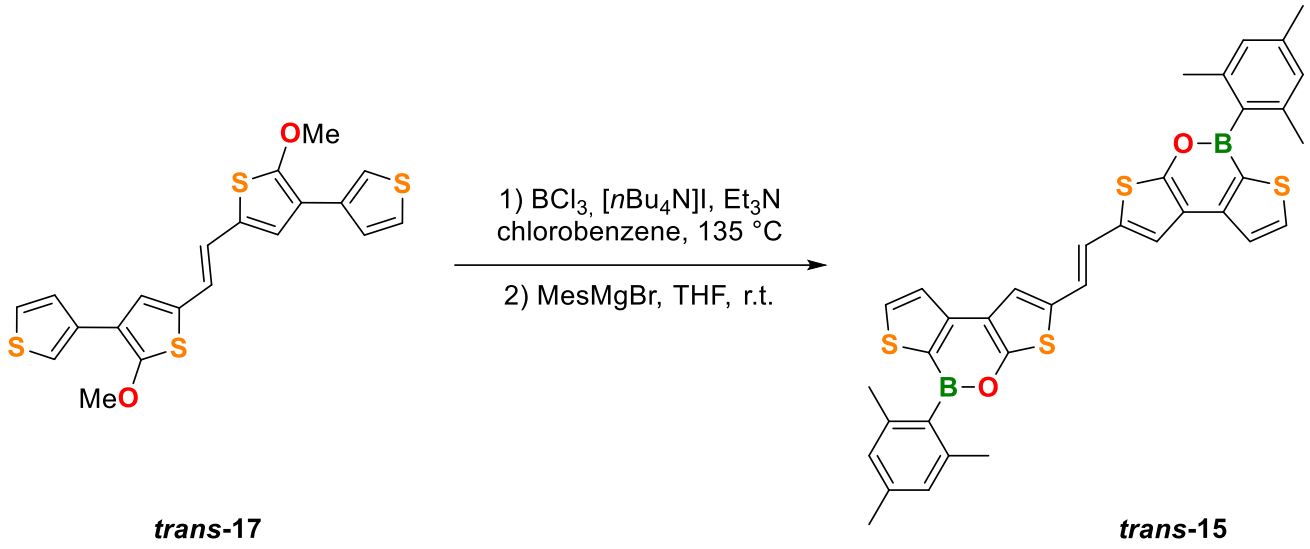
^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.51* (dd, ^4J(H,H) = 3.0 Hz, ^4J(H,H) = 1.3 Hz, 2H; H-2'), 7.41 (dd, ^3J(H,H) = 5.0 Hz, ^4J(H,H) = 1.3 Hz, 2H; H-4'), 7.33* (dd, ^3J(H,H) = 5.0 Hz, ^4J(H,H) = 3.0 Hz, 2H; H-5'), 6.96 (s, 2H; H-4), 6.72 (s, 2H; H-2a), 4.02 (s, 6H; CH_3). *) Proton shifts and J(H,H) coupling constants were assigned according to a related compound from the literature.[S12]

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 158.9 (C-2), 134.7 (C-3'), 128.4 (C-5), 126.9 (C-4'), 125.2 (C-5'), 124.5 (C-4), 120.4 (C-2'), 119.6 (C-2a), 117.2 (C-3), 61.8 (CH_3).

HRMS (MALDI): Calculated *m/z* for $[C_{20}H_{16}O_2S_4]^+$: 416.0028; found: 416.0026.

Mp: 182.5-185.0 °C.

3.7 Synthesis of 15 (*via* late stage borylation)



***trans*-17** ***trans*-15**

A flame-dried 100 mL J-Young flask was charged with *trans*-**17** (200 mg, 0.48 mmol) and [nBu$_4$N]I (426 mg, 1.15 mmol, 2.40 eq.) and then evacuated for 30 min. Chlorobenzene (3.5 mL) was added and the mixture was cooled to –10 °C. BCl_3 (1.0 M in hexanes; 1.06 mL, 1.06 mmol, 2.20 eq.) and Et_3N (134 µL, 0.96 mmol, 2.00 eq.) were added, the Young-tap was closed, and the reaction mixture was allowed to warm to room temperature. The red mixture thus obtained was stirred for 24 h at 135 °C. After cooling to room temperature, the mixture was evaporated to dryness and THF (3.5 mL) was added. MesMgBr (1.0 M in THF; 2.88 mL, 2.88 mmol, 6.00 eq.) was added dropwise at room temperature to give a clear, orange-colored solution, which was stirred for 1 h. The solvent was removed under reduced pressure and the residue was purified by column chromatography (17 cm silica gel, d = 2.0 cm, c-hexane/CH_2Cl_2 (5:1), R_f = 0.28). The fractions containing *trans*-**15** (with only traces of *cis*-**15**) were combined and evaporated to dryness. The residue was treated with n-hexane (to remove soluble *cis*-**15** and an unknown minor impurity), and the resulting suspension was filtered. *trans*-**15** was thereby obtained as a yellow solid (121 mg, 0.19 mmol, 39%).

3.8 Isomerization tests of trans-15: An NMR tube was charged with *trans*-**15** (7 mg, 0.01 mmol) and C_6D_6 (1 mL) and placed close (approx. 5 cm) to the irradiation source (Hg lamp or LED lamps). The isomerization progress was monitored by ^{1}H NMR spectroscopy after 30 min of irradiation, taking the decrease of the proton signal of *trans*-**15** (6.73 ppm) and the increase of the corresponding peak of the *cis*-isomer (6.38 ppm) as diagnostic tools.

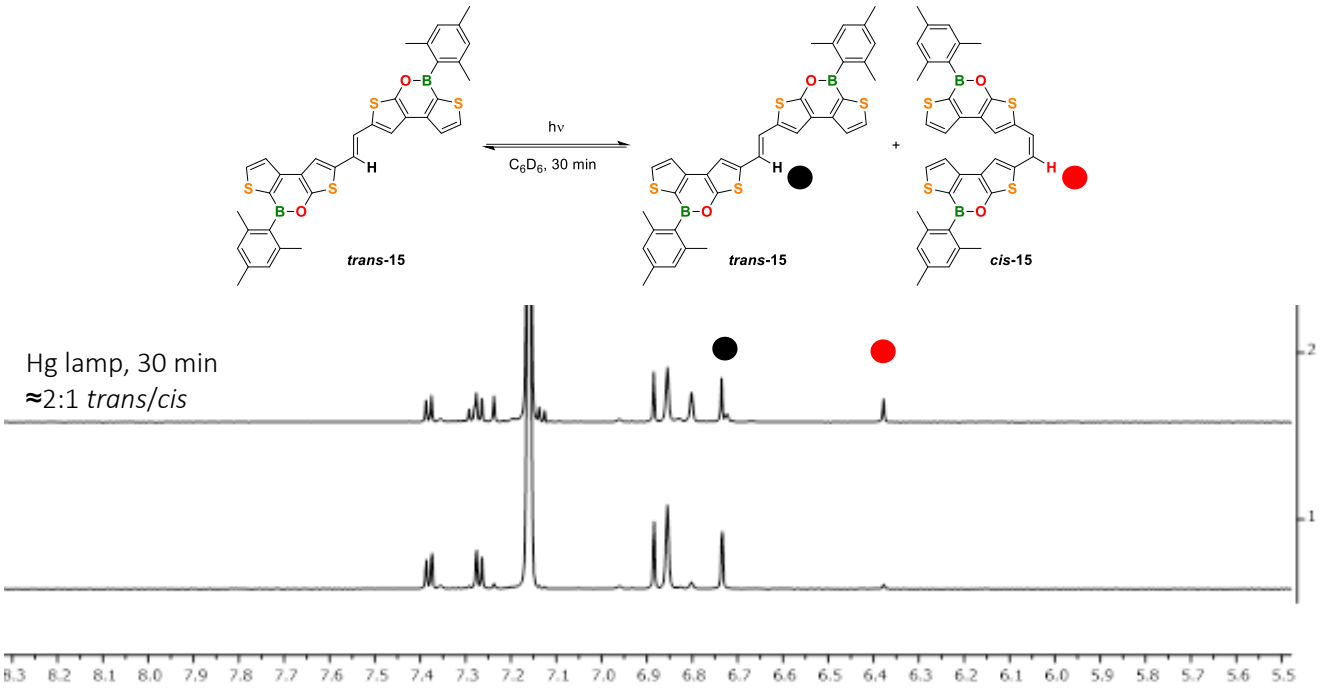


Figure S1: Irradiation of *trans*-**15** using a medium-pressure Hg lamp - ^{1}H NMR (400 MHz, C_6D_6) starting spectrum (bottom) and spectrum after 30 min of irradiation (top).

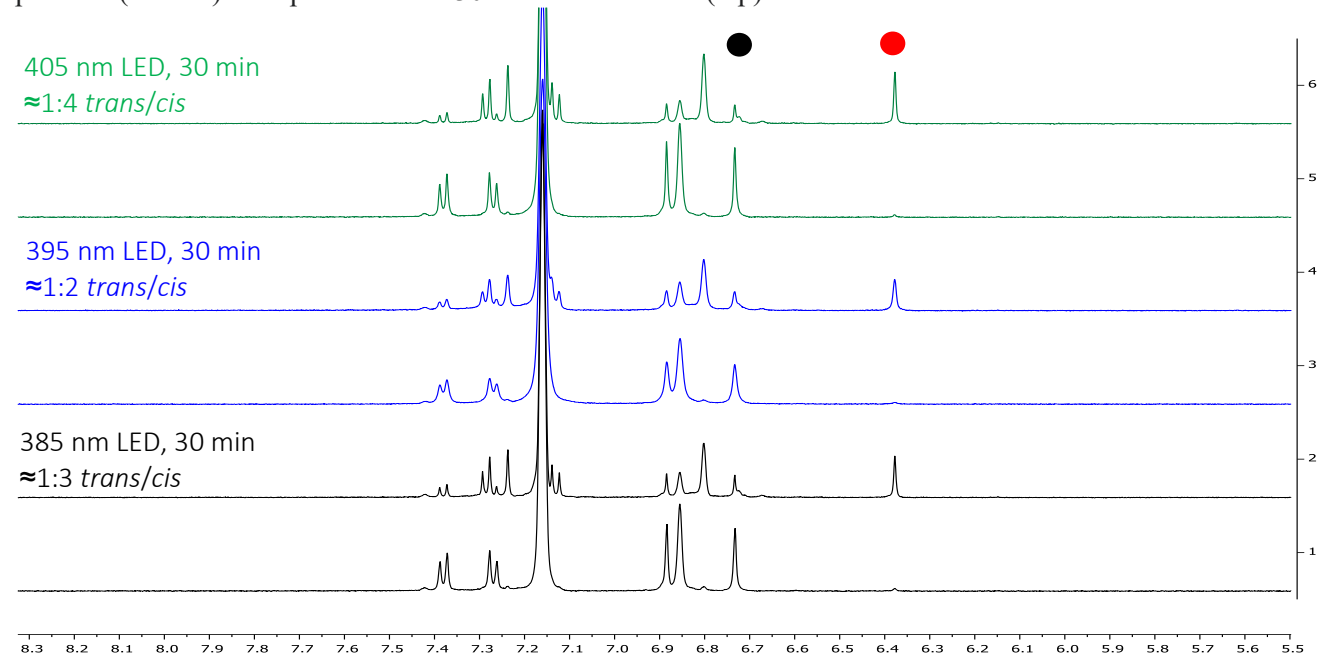

Figure S2: Irradiation of *trans*-**15** using a 385 (black spectra), 395 (blue spectra) and 405 nm (green spectra) LED - The ^{1}H NMR (300 MHz, C_6D_6) starting spectrum (bottom) and the spectrum after 30 min (top) is reported for each experiment. The outcome of the screening test of the three different LED lamps led us to use the 405-nm LED for subsequent photocyclization experiments that require *cis*-**15** as the immediate precursor.

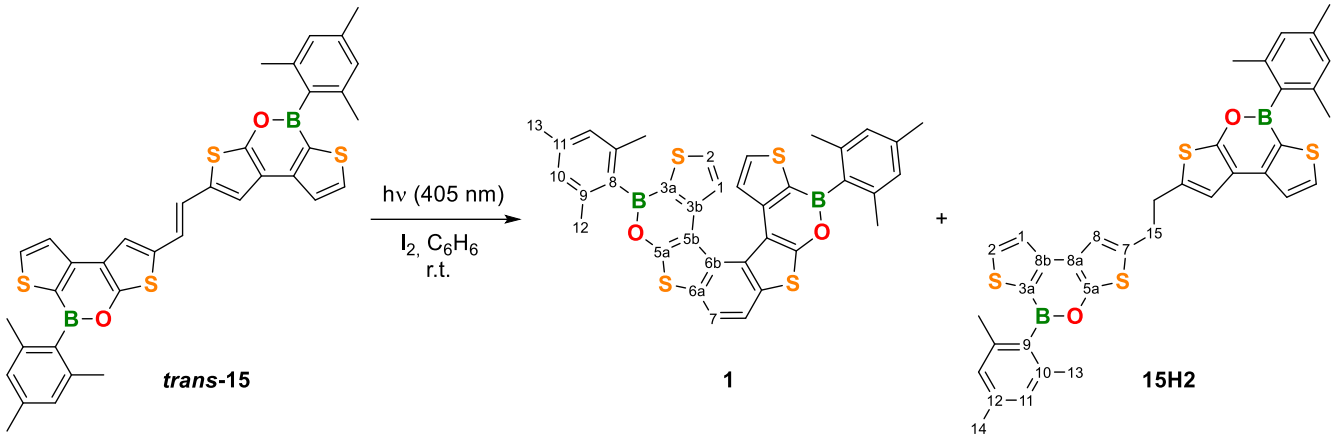
3.9 Synthesis of 1 via photocyclization without HI scavenger



A flame-dried 250 mL J-Young tube was charged with *trans*-**15** (70 mg, 0.11 mmol) and evacuated for 30 min. C_6H_6 (150 mL) was added and the resulting yellow solution was treated with I_2 (28 mg, 0.11 mmol, 1 eq.). The red solution thus obtained was irradiated for 1.5 h with an LED lamp (405 nm - placed close to the reaction vessel, approx. 5 cm, Figure **S3**; the Duran® glass used is transparent to 405 nm light).[S13] The reaction progress was monitored by TLC. The solvent was evaporated, and the residue was purified by column chromatography (13 cm silica gel, d = 2.0 cm, *c*-hexane/CH_2Cl_2 (3:1)) to furnish **1** as a white solid (24 mg, 0.037 mmol, 34%, R_f = 0.50) and **15H2** as a yellowish solid (24 mg, 0.037 mmol, 34%, R_f = 0.25).

Single crystals of **1** suitable for X-ray crystallography were grown by slow evaporation of a solution of **1** in *n*-hexane/CH_2Cl_2 (2:1) in a glovebox.

Single crystals of **15H2** suitable for X-ray crystallography were grown by slow evaporation of a solution of **15H2** in *n*-hexane/CH_2Cl_2 (3:1).

Note: H_2 transfer during photocyclization reactions using I_2, but no HI scavenger (such as propylene oxide), has been reported for stilbene derivatives.[S14]

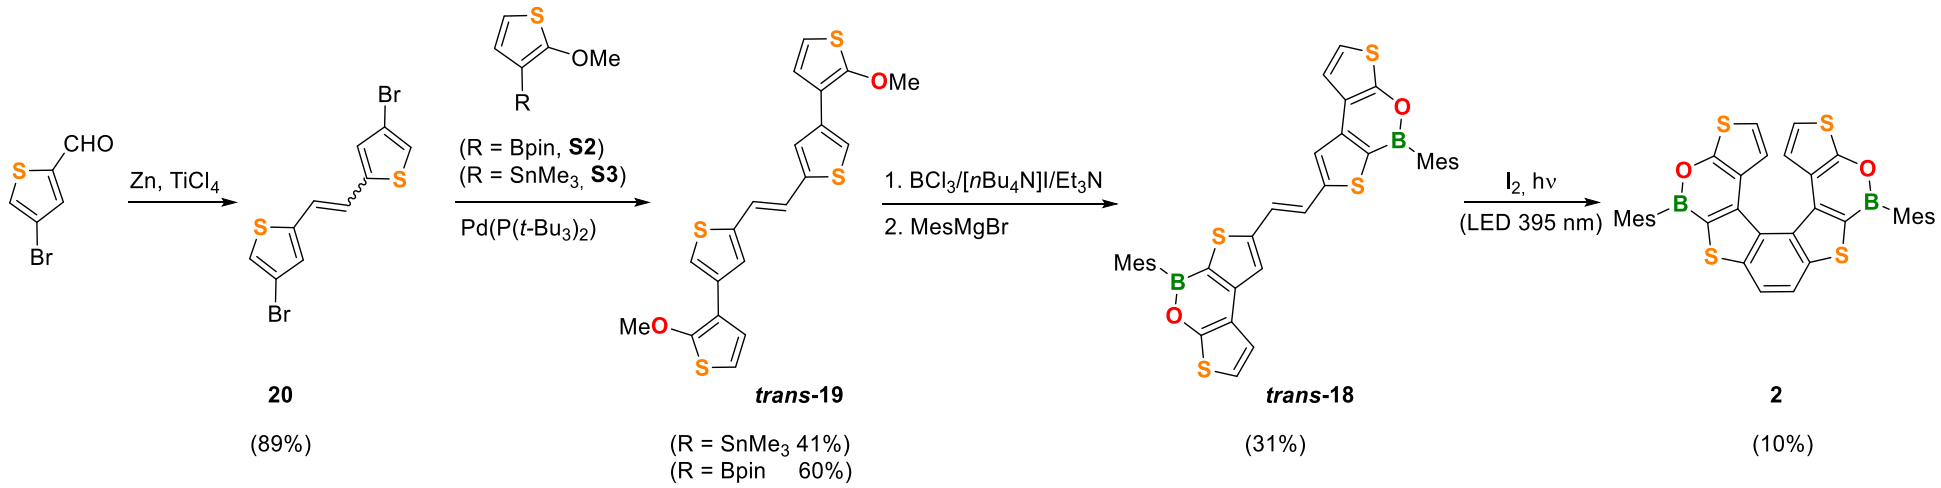
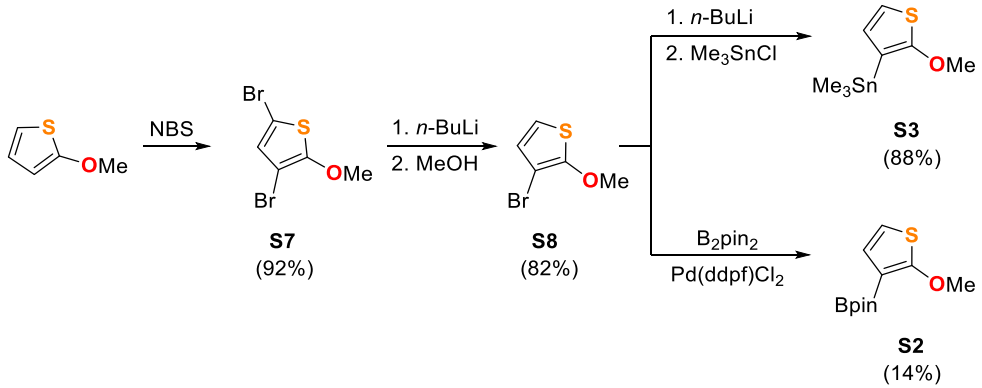
4. Synthesis of tetrathia[7]helicene 2



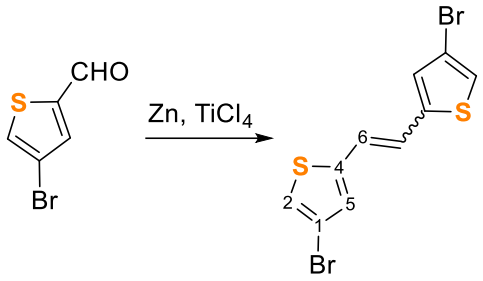
Scheme S2: Synthetic route to tetrathia[7]helicene **2**.

Synthesis of S3[S7] and S2[S8] starting materials



Scheme S3: Preparation of tetrathia[7]helicene **2** intermediates. Full details about the synthesis of **S7**, **S8**, **S2** and **S3** are provided in section *2.1 Thiophene starting materials*.

4.1 Synthesis of 20



20
(89%)

A three-necked flame-dried 250 mL flask equipped with a thermometer and a reflux condenser was charged with THF (50 mL) and zinc powder (3.45 g, 52.67 mmol, 2.57 eq.). The resulting suspension was cooled to 0 °C and $TiCl_4$ (2.70 mL, 25.13 mmol, 1.2 eq.) was added dropwise during 10 min.

Note: the temperature increased due to the progressive addition of $TiCl_4$ (to ≈10-15 °C). The dark-green mixture thus obtained was heated to reflux for 1 h. In the meantime, a dropping funnel (equipped with a stirring bar) was flame-dried under vacuum and then charged with 4-bromo-2-thiophencarbaldehyde (3.91 g, 20.49 mmol) and THF (20 mL). The aldehyde solution was added dropwise during 10 min and the reaction mixture thus obtained was refluxed for 2 h. The reaction progress was checked by TLC.

After cooling to room temperature the THF was removed under reduced pressure, the residue was taken up with CH_2Cl_2 and filtered over a celite plug (washing with CH_2Cl_2). The CH_2Cl_2 black solution was treated with water (200 mL) and after separation of the two layers, the aqueous phase was extracted with CH_2Cl_2.

Note: for each extraction step, after separation of the two phases, the organic layer was filtered over a celite plug prior to combine with the collected organic phases.

The collected organic phases were dried over Na_2SO_4, filtered and the solvent was removed under reduced pressure. The crude product was washed with Et_2O yielding 2.93 g (8.37 mmol, 82%) of an orange solid which was proved to be *trans*-**20** *via* ^{1}H NMR analysis.

Et_2O mother liquors were evaporated to dryness yielding a dark brown wet solid which was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (2:1)) yielding 263 mg (0.75 mmol, 7%) of a yellow solid which was proved to be a *cis/trans* mixture (3:1) of **20** as inferred from ^{1}H NMR analysis. Total yield = 89%.

Trans-**20** single crystals suitable for X-ray crystallography were obtained by slow evaporation of a *trans*-**20** CH_2Cl_2 saturated hot solution.

Characterization data of *trans*-**20**:

^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.10 (d, ^4J(H,H) = 1.3 Hz, 2H; H-2), 6.97 (d, ^4J(H,H) = 1.3 Hz, 2H; H-5), 6.94 (s, 2H; H-6).

^{13}C{^{1}H} NMR (75 MHz, $CDCl_3$): δ = 142.6 (C-4), 128.6 (C-5), 122.0 (C-2), 121.4 (C-6), 110.6 (C-1).

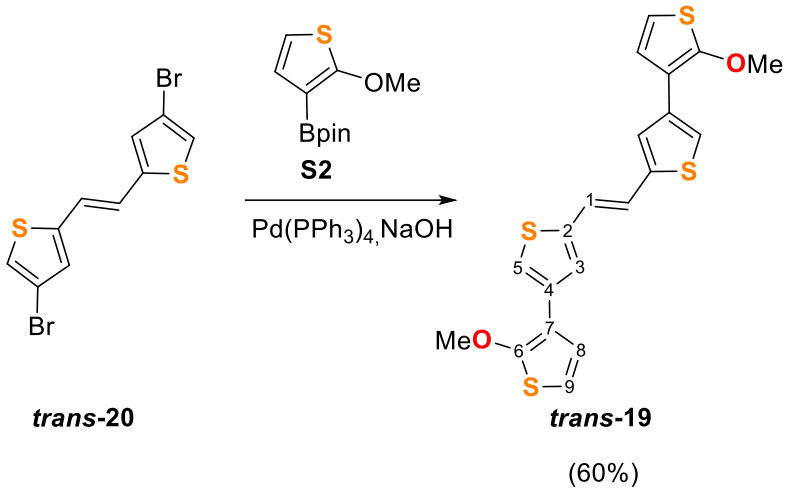
HRMS (EI+): Calculated *m/z* for $[C_{10}H_6Br_2S_2]^+$: 347.8278; found: 347.8288.

Characterization data of a **20** cis/trans (3:1) mixture:

^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.17 (d, ^{3}J(H,H) = 1.4 Hz, 2H), 7.10 (d, ^{3}J(H,H) = 1.3 Hz; *trans*-**20-**H-2), 7.00 (d, ^{3}J(H,H) = 1.3 Hz, 2H), 6.97 (d, ^{3}J(H,H) = 1.3 Hz; *trans*-**20-**H-5), 6.94 (s; *trans*-**20-**H-6), 6.55 (s, 2H).

^{13}C{^{1}H} NMR (75 MHz, $CDCl_3$): δ = 142.6 (*trans*-**20-**C-4), 139.7 (C-4), 130.9 (C-5), 128.6 (*trans*-**20-**C-5), 124.0 (C-2), 123.2 (C-6), 122.0 (*trans*-**20-**C-2), 121.4 (*trans*-**20-**C-6), 110.6 (*trans*-**20-**C-1), 109.9 (C-1).

4.2 Synthesis of 19 *via* Suzuki coupling



***trans*-20** ***trans*-19**

(60%)

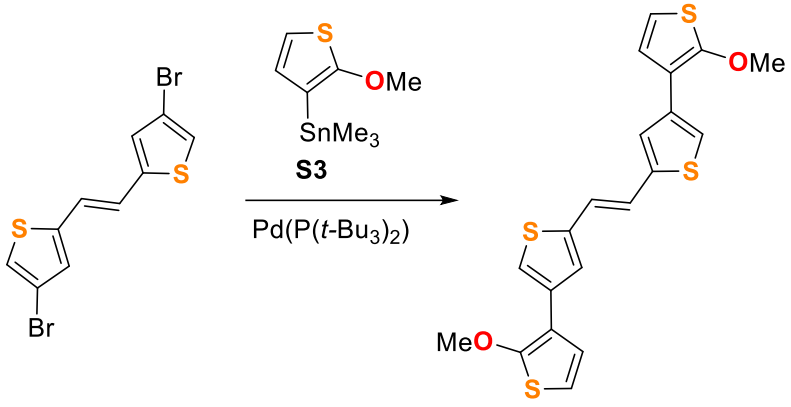
A flame-dried J-young flask was charged with *trans*-**20** (153 mg, 0.44 mmol) and **S2** (252 mg, 1.05 mmol, 2.40 eq.) and then evacuated for 30 min. THF (9 mL), $NaOH_{(aq)}$ (3M; 0.58 mL, 1.75 mmol, 4.0 eq.) and $Pd(PPh_3)_4$ (51 mg, 0.044 mmol, 0.10 eq.) were added. The dark brown mixture thus obtained was heated to 80 °C for 15 h. After cooling to room temperature, the solvent was removed under reduced pressure and the crude product was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (1:1), R_f = 0.60). The fraction containing *trans*-**19** were evaporated to dryness and the yellow residue thus obtained was washed with *n*-pentane (to remove unknown minor impurities). *Trans*-**19** was obtained as a pale-yellow solid (110 mg, 0.26 mmol, 60%). Single crystals of *trans*-**19** were obtained by slow evaporation of a saturated solution of *trans*-**19** in CH_2Cl_2/*n*-hexane (2:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.39 (d, ^4J(H, H) = 1.4 Hz, 2H, H-3), 7.36 (d, ^4J(H, H) = 1.4 Hz, 2H, H-5), 7.08 (s, 2H, H-1), 7.04 (d, ^3J(H, H) = 5.9 Hz, 2H, H-9), 6.62 (d, ^3J(H, H) = 5.9 Hz, 2H, H-8), 4.01 (s, 6H, OMe).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 160.7 (C-6), 141.9 (C-2), 135.6 (C-4), 125.8 (C-3), 125.7 (C-9), 121.7 (C-1), 119.2 (C-5), 116.3 (C-7), 111.1 (C-8), 61.9 (OMe).

HRMS (MALDI): *Calc*. *m/z* for $[C_{20}H_{16}O_2S_4]^+$: 416.0028, found 416.0026.

4.3 Synthesis of 19 *via* Stille coupling



***trans*-20** ***trans*-19**

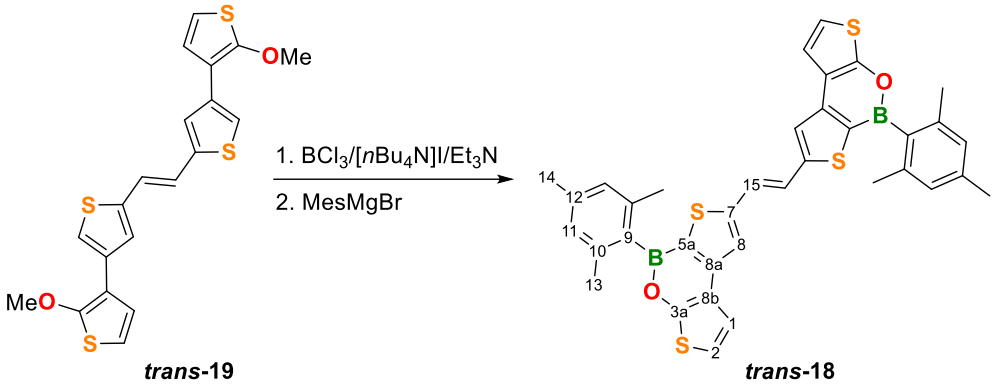
(42%)

A flame-dried 250 mL J-Young tube was charged with *trans*-**20** (430 mg, 1.23 mmol) and evacuated for 30 min. Toluene (60 mL) was added and the orange solution thus obtained was treated with **S3** (714 mg, 2.58 mmol, 2.10 eq.) and Pd(P(*t*-Bu_3)$_2$) (61 mg, 0.12 mmol, 0.10 eq.) and the resulting deep orange solution was heated to 80 °C and stirred for 17 h.

Note: after roughly 10 min heating the reaction mixture turns to dark brown.

After cooling to room temperature, toluene was removed under reduced pressure and the grey residue thus obtained was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (2:1)). The fractions containing *trans*-**19** were combined and evaporated to dryness. The yellow residue thus obtained was washed with *n*-pentane (to remove the stannane homocoupling byproduct and unknown minor impurities). *Trans*-**19** was thereby obtained as a pale-yellow solid (215 mg, 0.52 mmol, 42%).

4.4 Synthesis of 18

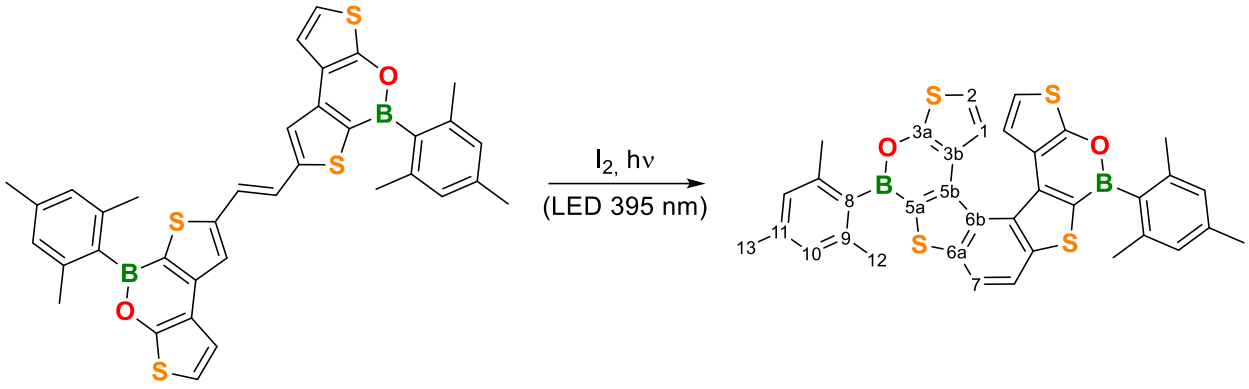


A flame-dried 100 mL J-Young tube was charged with *trans*-**19** (150 mg, 0.36 mmol), [nBu$_4$N]I (319 mg, 0.86 mmol, 2.40 eq.) and then evacuated for 30 min. Chlorobenzene (15 mL) was added and the mixture was cooled to –10 °C. BCl_3 (1.0 M in hexanes; 0.79 mL, 0.79 mmol, 2.20 eq.) and Et_3N (1.0 M in chlorobenzene; 0.72 mL, 0.72 mmol, 2.00 eq.) were added, the Young-tap was closed, and the reaction mixture was allowed to warm to room temperature. The mixture thus obtained was stirred for 24 h at 135 °C. After cooling to room temperature, the yellow-brown mixture was evaporated to dryness and THF (15 mL) was added. MesMgBr (0.95 M in THF; 2.27 mL, 2.16 mmol, 6.00 eq.) was added dropwise at room temperature to give a red mixture, which was stirred for 1 h. The solvent was removed under reduced pressure and the residue was purified by column chromatography (d = 2.0 cm, n-hexane/CH_2Cl_2 (2:1)). The fractions containing *trans*-**18** were combined and evaporated to dryness. The yellow residue thus obtained was treated with n-pentane (to remove unknown minor impurities). *Trans*-**18** was thereby obtained as a yellow solid (72 mg, 0.11 mmol, 31%).
Single crystals of *trans*-**18** suitable for X-ray analysis were obtained by slow evaporation of a saturated solution of *trans*-**18** in n-hexane/CH_2Cl_2 (2:1).

^{1}H NMR (400 MHz, $CDCl_3$): δ = 7.56 (s, 2H; H-8), 7.37 (s, 2H; H-15), 7.32 (d, ^3J(H,H) = 6.0 Hz, 2H; H-2), 6.96 (d, ^3J(H,H) = 6.0 Hz, 2H; H-1), 6.93 (s, 4H; H-11), 2.36 (s, 6H; H-14), 2.27 (s, 12H; H-13).
^{13}C{^{1}H} NMR (101 MHz, $CDCl_3$): δ = 158.9 (C-3a), 153.2 (C-8a), 147.9 (C-7), 140.6 (C-10), 139.0 (C-12), 133.6 (C-9), 131.6 (C-5a), 127.6 (C-5a), 124.8 (C-11), 122.5 (C-15), 120.3 (C-8), 120.3 (C-2), 120.0 (C-8b), 114.9 (C-1), 22.8 (C-13), 21.5 (C-14).
^{11}B NMR (128 MHz, $CDCl_3$): not detected.
Note: the presence of boron is evidenced by the typical broadened resonances of B(sp^2)-bound quaternary carbons (C-9, C-5a) and by the ^3J(C,H) coupling between C-9 (133.6 ppm) and H-11 (6.93 ppm) observed in the ^{H,C}HMBC spectrum.
HRMS (MALDI): Calculated m/z for $[C_{36}H_{30}B_2O_2S_4]^+$: 644.1315; found: 644.1326.
UV/Vis (*c*-hexane): λ_{max} (ε / mol^{-1}dm^{3}cm^{-1}) = 270 (26500), 355 (30700), 370 (30000), 393 (21500), 414 (sh).
Fluorescence (*c*-hexane, λ_{ex} = 375 nm): λ_{max} = 429, 452 nm (resolved vibrational fine structure), 489 nm (sh); Φ_{PL} = 6%.

Cyclic voltammetry (THF, 0.1 M [*n*Bu$_4$N][PF$_6$], 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: $E^{I}_{1/2}$ = −1.97 V, E^{II}_{pc} = −2.26 V, E^{II}_{pa} = −2.14 V.

4.5 Synthesis of 2



trans-**18** **2** (10%)

Seven different glass tester tubes were charged with *trans*-**18** (10 mg, 0.015mmol) and C_6H_6 (23 mL) and the resulting yellow solution was treated with I_2 (0.023 M in C_6H_6; 200 µL, 0.0045 mmol, 0.30 eq.). The orange-red solutions thus obtained were irradiated for 1.5 h with an LED lamp equipped with a glass water cooling jacket (395 nm; approx 1 cm; Figure S4; both cooling jacket glass and tester tubes glass are transparent to 395 nm light[S13]). The reaction progress was monitored by TLC. Reaction mixture of the seven tester tubes were combined, the solvent was evaporated, and the brown crude product thus obtained was purified by preparative TLC (*n*-hexane/CH_2Cl_2 (3:1)). The yellow residue thus obtained was washed with CH_2Cl_2 giving **2** as an off-white solid (7 mg, 0.01 mmol, 10%).

^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.03 (s, 2H; H-7), 6.99 (s, 4H; H-10), 6.93 (d, ^3J(H,H) = 6.0 Hz, 2H; H-2), 6.52 (d, ^3J(H,H) = 6.1 Hz, 2H; H-1), 2.39 (s, 3H; H-13), 2.36 (s, 6H; H-12).

^{13}C{^{1}H} NMR (100.6 MHz, $CDCl_3$): δ = 158.8* (C-3a), 145.5 (C-6a), 140.8 (C-11), 139.3 (C-9), 133.3* (C-8), 131.0 (C-6b), 127.8 (C-10), 123.0 (C-2), 122.6 (C-7) 121.3 (C-3b), 112.4 (C-1), 22.9 (C-12), 21.5 (C-13). *) unequivocally detected only in the ^{H,C}HMBC spectrum. C-5a, C-6a n.o.

^{11}B NMR (128.4 MHz, $CDCl_3$): not detected.

Note: the presence of boron is evidenced by the ^3J(C,H) coupling between C-8 (133.3 ppm) and H-10 (6.99 ppm) observed in the ^{H,C}HMBC spectrum.

HRMS (EI+): Calculated *m/z* for $[C_{36}H_{28}B_2O_2S_4]^+$: 642.1158; found: 642.1128.

UV/Vis (*c*-hexane): λ_{max} (ε / $mol^{-1}dm^3cm^{-1}$) = 258 (20800), 320 (sh), 322 (sh) 368 (9800), 385 (11600), 413 (4700).

Fluorescence (*c*-hexane, λ_{ex} = 385 nm): λ_{max} = 424, 446, 472 nm (resolved vibrational fine structure); 506 nm (sh); Φ_{PL} = 7%.

Cyclic voltammetry (THF, 0.1 M [*n*Bu$_4$N][PF$_6$], 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: E_{pc} = −2.68 V, E_{pa} = 0.82 V.

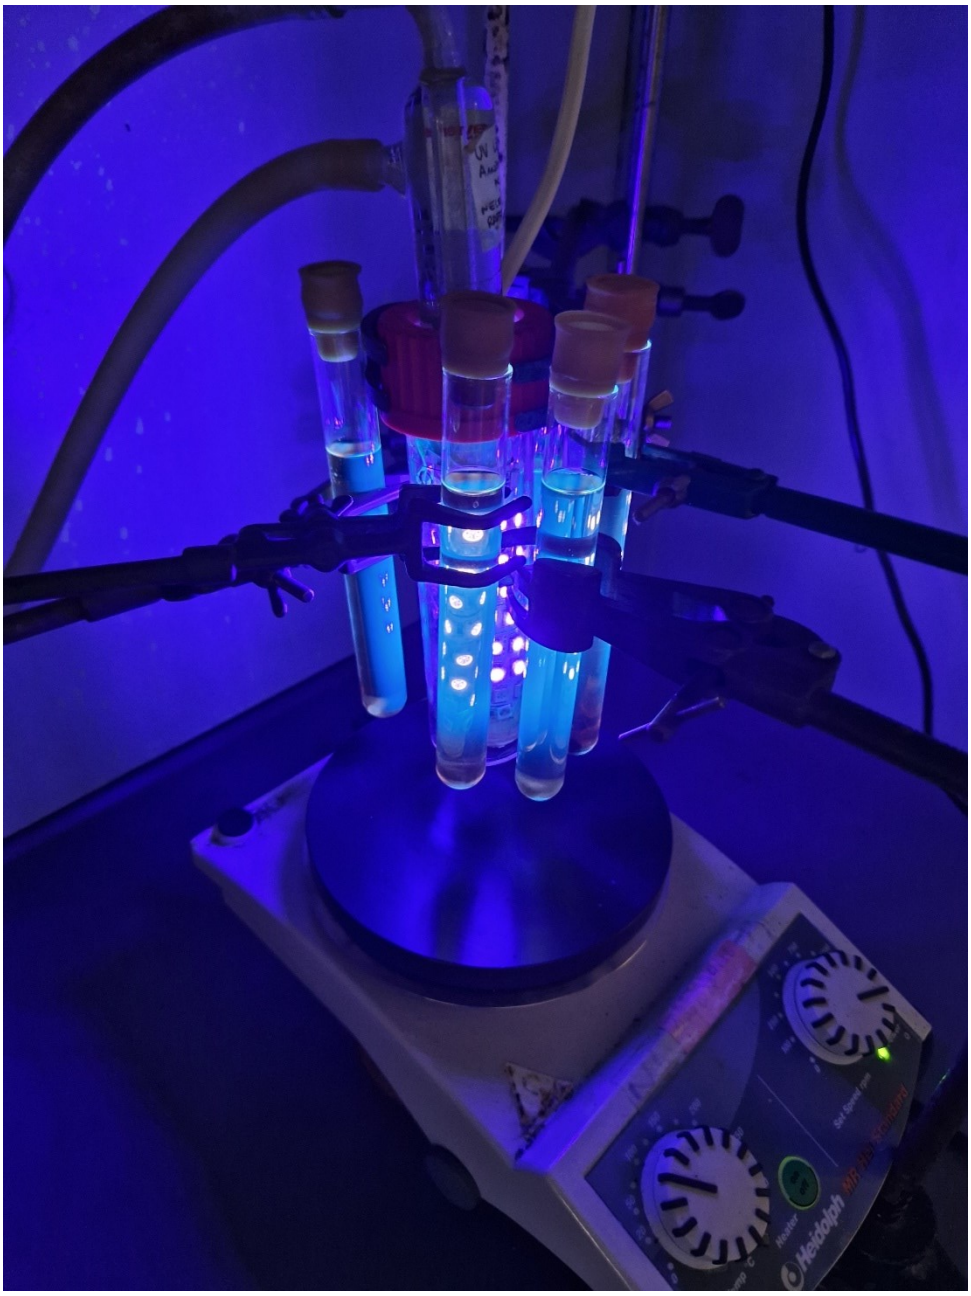


Figure S4: 2 photochemical experiments set-up.

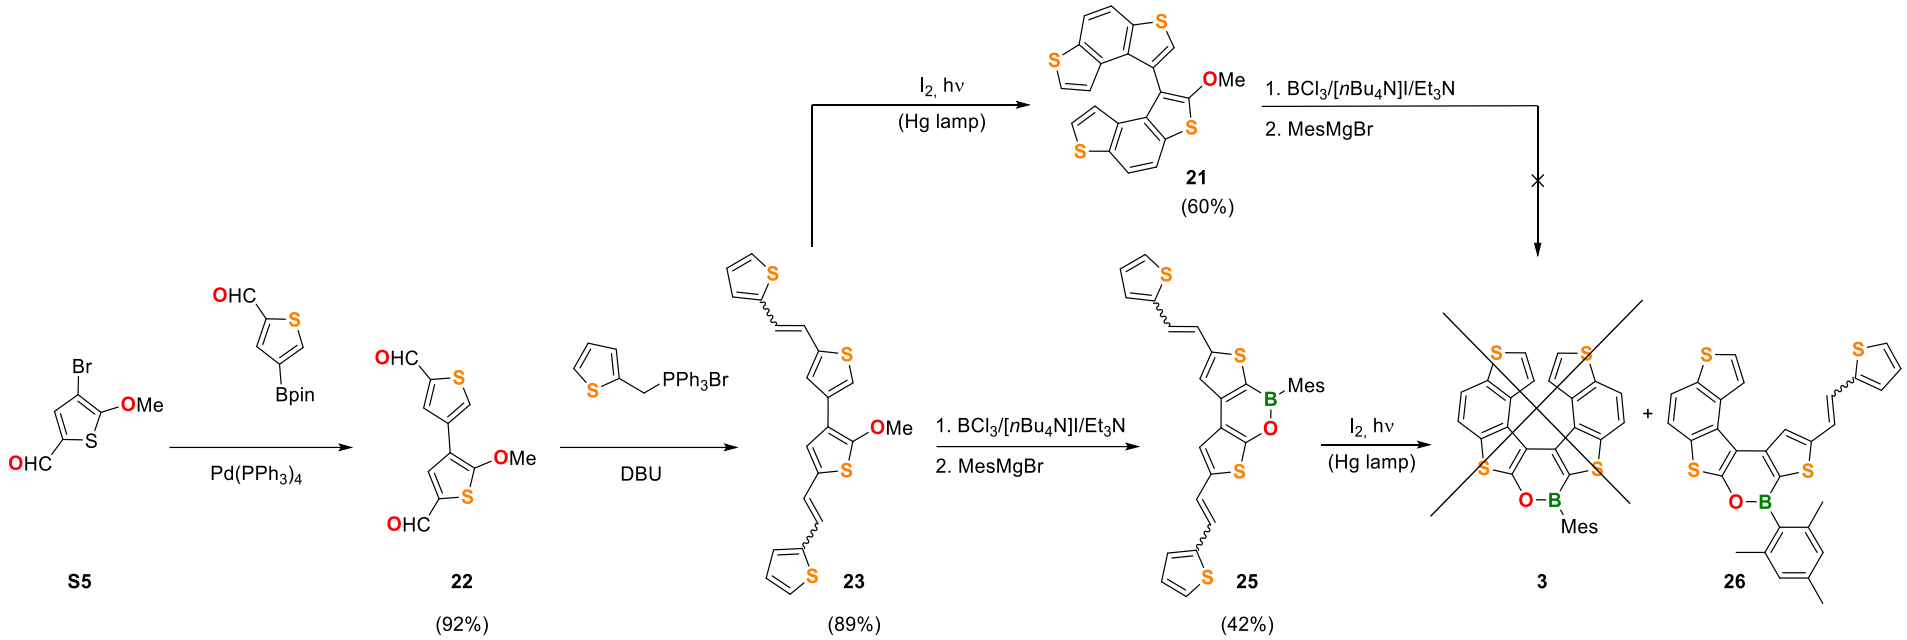
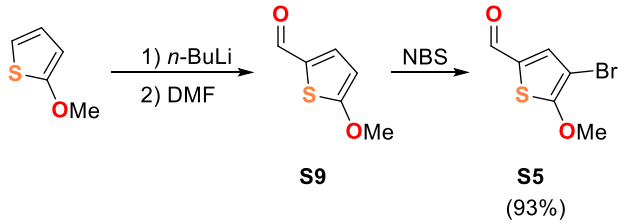
5. Synthesis of tetrathia[7]helicene 3



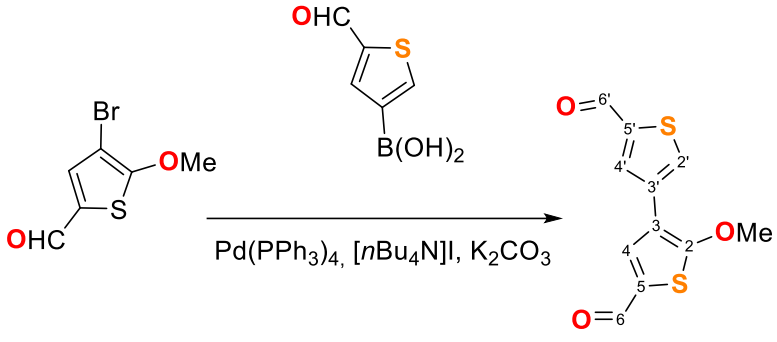
Scheme S4: Synthetic route to tetrathia[7]helicene **3**.

Synthesis of S5[S6]



Scheme S5: Preparation of tetrathia[7]helicene **3** intermediates. Full details about the synthesis of **S9** and **S5** are provided in section *2.1 Thiophene starting materials*.

5.1 Synthesis of 22



S4 **22**

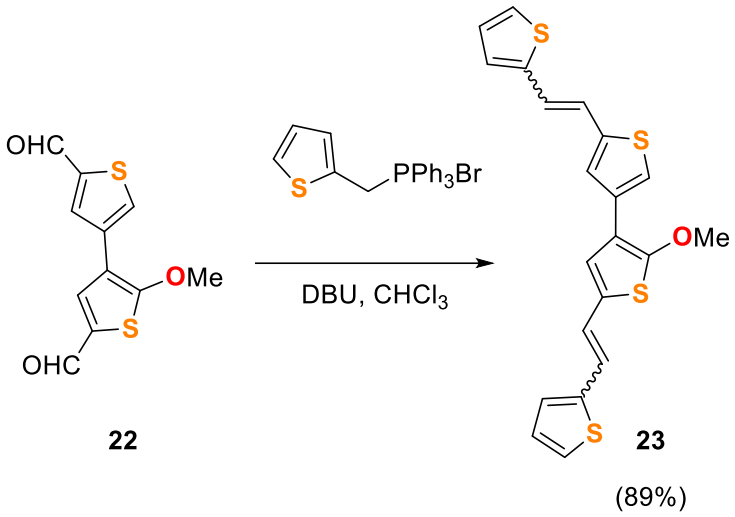
(92%)

A flame-dried 100 mL J-Young tube was charged with 2-thiophenecarbaldehyde-3-boronic acid (332 mg, 1.50 mmol), **S4** (357 mg, 1.50 mmol, 1.0 eq.), [nBu$_4$N]I (48 mg, 0.15 mmol, 0.1 eq) and then evacuated for 20 min. THF/H_2O (5:1; 11 mL) was added and the resulting suspension was treated with $Pd(PPh_3)_4$ (87 mg, 0.075 mmol, 0.05 eq) and K_2CO_3 (415 mg, 3.0 mmol, 2 eq). The Young-tap was closed, and the black mixture thus obtained was heated with stirring to 80 °C for 14 h. After cooling to room temperature, the solvent was removed under reduced pressure, and the residue was purified by column chromatography (CH_2Cl_2, then CH_2Cl_2/AcOEt (20:1), R_f = 0.30). **22** was obrained as a yellow solid (350 mg, 1.39 mmol, 92%). Single crystals of **S4** suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of **22** in n-pentane/CH_2Cl_2 (1:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 9.97 (d, ^4J(H,H) = 1.3 Hz, 1H; H-6'), 9.74 (s, 1H; H-6), 8.07 (d, ^3J(H,H) = 1.3 Hz, 1H; H-2'), 7.97 (t, ^3J(H,H) = 1.3 Hz, 1H; H-4'), 7.83 (s, 1H; H-4), 4.18 (s, 3H; CH_3).
Note: H-4' couples with H-6' and H-2' (as evidenced by the ^{HH}COSY spectrum) with almost identical coupling constant (1.2, 1.4, 1.3 Hz respectively, which have been all rounded to 1.3 Hz) giving rise to a triplet (originated by a collapsed doublet of doublets).

^{13}C{^{1}H} NMR (126 MHz, $CDCl_3$): δ = 183.00 (C-6'), 182.11 (C-6), 170.62 (C-2), 143.90 (C-3'), 136.14 (C-4), 134.87 (C-2'), 130.44 (C-4'), 128.69 (C-5), 117.05 (C-3), 62.13 (CH_3), n.o. (C-5).
HRMS (MALDI): Calculated m/z for $[C_{11}H_9O_3S_2]^+$: 252.9988; found: 252.9988.

5.2 Synthesis of 23



22 **23**

(89%)

A three-necked flask (equipped with a reflux condenser and a thermometer) was charged with triphenyl(2-thienylmethyl)phosphonium bromide (1.20 g, 2.73 mmol, 2.2 eq) and $CHCl_3$ (30 mL). DBU (416 mg, 2.73 mmol, 2.2 eq) was added and the rsulting orange solution was heated to 40 °C. **22** (313 mg, 1.24 mmol) was added in portions (during 5 min) as $CHCl_3$ suspension (12 mL). The reaction mixture was heated to 60 °C and stirred for 4 h. TLC after 4 h showed complete conversion of the starting aldehyde **22** and the presence of the desired compound **23** (R_f = 0.95) besides the mono-olefinated compound (R_f = 0.50). Additional 0.2 eq of DBU were added and the reaction mixture was stirred at 60 °C for additional 3 h. After cooling to room temperature the reaction mixture was poured into water (20 mL) and HCl 0.5 M (10 mL) was added. After separation of the two layers, the aqueous phase was extracted with CH_2Cl_2 (3 × 25 mL). The combined organic phases were dried over Na_2SO_4, filtered and the solvent removed. The brown residue thus obtained was purified by column chromatography (30 cm silica gel, d = 2.5 cm, CH_2Cl_2, R_f = 0.95). **22** was obtained as a yellow-brown solid (456 mg, 1.10 mmol, 89%). ^{1}H NMR (Figure S40) revealed the presence of the four isomers (*trans,trans; trans,cis; cis,trans; cis,cis*): those are easily detectable since the -OMe group shows four well-distinguished resonances in the ^{1}H NMR spectrum. Single crystals of *trans*,*trans*-**23** suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of **22** in *n*-pentane/CH_2Cl_2 (1:1).

To reduce the complexity of the isomers mixture and facilitate NMR characterization, **22** was treated with Et_2O and *n*-pentane and decanted and the solid thus obtained was used for NMR characterization (^{1}H and ^{13}C spectra in Figure S40 and S41). Assignment of **22** proton and carbon resonances was attempted but, due to the high complexity of both 1D and 2D spectra, it was only possible to identify few resonances (aromatic CH, double bonds and OMe protons). For simplicity, ^{1}H NMR integrals have not been listed and are shown in Figure S40 and S41. Quaternary carbons (Cq), CH (CH) and CH_3 (OMe) resonances were identified *via* ^{13}C APT.

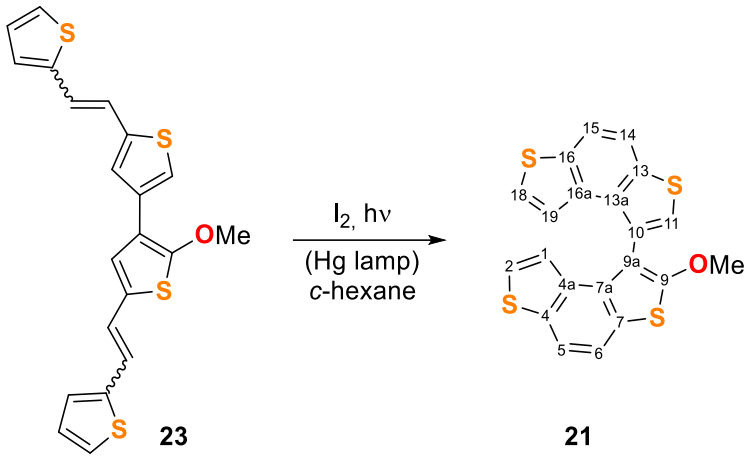
Note: following photocyclization and borylation experiments were carried out using **22** as obtained after column chromatography purification (mixture of the four isomers, ^{1}H in Figure S40).

^{1}H NMR (500 MHz, $CDCl_3$): δ 7.46 (s, 13H), 7.42 (d, J = 1.3 Hz, 11H), 7.35 (d, J = 1.3 Hz, 12H), 7.34 (s, 13H), 7.33 – 7.32 (m, 13H), 7.29 (dd, J = 5.1, 1.1 Hz, 5H), 7.27 (s, 3H), 7.19 (t, J = 4.4 Hz, 18H), 7.17 – 7.13 (m, 60H), 7.11 (s, 4H), 7.06 (s, 23H), 7.06 – 6.97 (m, 123H), 6.96 (s, 9H), 6.92 (dd, J = 15.8, 6.7 Hz, 23H), 6.84 (dd, J (H,H) = 15.8; two overlapped isomers double bond resonances), 6.64 (d, J(H,H) = 12.0 Hz; double bond), 6.60 (d, J(H,H) = 12.0 Hz; double bond), 6.49 (d, J(H,H) = 12.0 Hz; double bond), 6.48 (d; double bond), 4.01 (s; OMe), 3.96 (s; OMe), 3.93 (s; OMe).

^{13}C NMR (126 MHz, $CDCl_3$): δ = 160.93 (Cq), 159.33 (Cq), 159.21 (Cq), 142.62 (Cq), 142.61 (Cq), 142.40 (Cq), 141.83 (Cq), 141.76 (Cq), 139.09 (Cq), 138.64 (Cq), 135.06 (Cq), 134.99 (Cq), 134.27 (Cq), 128.45 (Cq), 128.16 (Cq), 127.94 (Cq), 127.92 (Cq), 127.83 (CH), 127.68 (CH), 127.65 (CH), 127.48 (CH), 126.97 (CH), 126.83 (CH), 126.26 (CH), 126.05 (CH), 125.66 (CH), 125.59 (CH), 125.35 (CH), 125.32 (CH), 125.01 (CH), 124.92 (CH), 124.34 (CH), 124.31 (CH), 123.83 (CH), 123.80 (CH), 123.03 (CH), 122.70 (CH), 122.09 (CH), 122.05 (CH), 121.58 (CH), 121.55 (CH), 121.52 (CH), 121.45 (CH), 121.19 (CH), 120.16 (CH), 119.30 (CH), 118.89 (CH), 118.82 (CH), 116.86 (Cq), 116.72 (Cq), 115.74 (Cq), 61.71 (OMe), 61.69 (OMe), 61.55 (OMe).

HRMS (MALDI): Calculated *m/z* for $[C_{21}H_{16}OS_4]^+$: 412.0078; found: 412.0077.

5.3 Synthesis of 21



23 **21**

(60%)

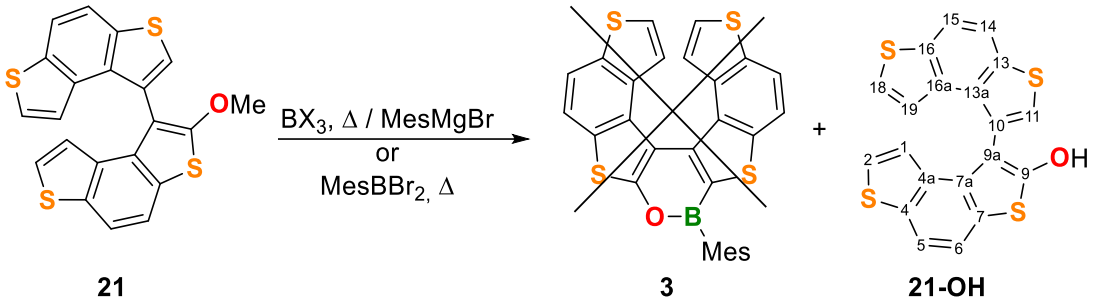
A solution of **23** (0.48 mmol) and iodine (18 mg, 0.14 mmol, 0.3 eq) in *c*-hexane (750 mL) was stirred at room temperature and irradiated with a 125 W medium-pressure Hg lamp for 2 h and 45 min. The reaction progress was checked by TLC. After the complete conversion of the starting material, the reaction mixture was filtered to remove insolubles. The purple clear solution thus obtained was washed with a saturated aqueous solution of $Na_2S_2O_3$ yielding a yellow solution. The collected organic phases were dried over Na_2SO_4, filtered and the solvent was removed under reduced pressure. The brown oily residue thus obtained was purified by column chromatography (15 cm silica gel, d = 2.0 cm, n-hexane/CH_2Cl_2 (3:1), R_f = 0.32). **21** was obtained as an off white solid (119 mg, 0.29 mmol, 60%).

^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.92 (d, ^3J(H,H) = 8.6 Hz, 1H; H-15), 7.88 (d, ^3J(H,H) = 8.7 Hz, 1H; H-14), 7.78 (d, ^3J(H,H) = 8.6 Hz, 1H; H-6), 7.72 (d, ^3J(H,H) = 8.6 Hz, 1H; H-5), 7.56 (s, 1H; H-11), 7.17 (d, ^3J(H,H) = 5.5 Hz, 1H; H-19), 7.04 (d, ^3J(H,H) = 5.5 Hz, 1H; H-1), 6.82 (d, ^3J(H,H) = 5.5 Hz, 1H; H-18), 6.41 (d, J = 5.5 Hz, 1H; H-2), 3.91 (s, 3H).

^{13}C NMR (75 MHz, $CDCl_3$): δ = 162.36 (C-9), 138.20 (C-4), 137.66 (C-16), 137.12 (C-10), 134.85 (C-16a), 134.10 (C-9a), 133.83 (C-4a), 133.33 (C-7), 130.07 (C-13), 126.57 (C-11), 126.33 (C-7a), 126.25 (C-19), 125.58 (C-1), 121.69 (C-18), 121.48 (C-2), 119.49 (C-14), 119.23 (C-15), 118.72 (C-5), 117.75 (C-6), 112.21 (C-13a), 62.00 (CH_3).

HRMS (EI+): Calculated *m/z* for $[C_{21}H_{12}OS_4]^+$: 407.9737; found: 407.9771.

5.4 21 borylation attempts



21 borylation attempts. Entry 1, 2 preparative experiments; entry 2, 3 NMR experiments performed using a flame-sealed NMR tube in a thermostated oven.

Entry	Borane	Base	additive	solvent	temperature
1	BCl_3 (1.0 M in THF)	Et_3N (1.0 eq.)	*n*[Bu_4N]I (1.2 eq.)	chlorobenzene	135 °C
2	BBr_3 (0.5 M in *n*-hexane)	Et_3N (1.0 eq.)		chlorobenzene	135 °C
3	$MesBBr_2$	Et_3N (1.0 eq.)	//	C_6D_6	135 to 180 °C

Note: **21-OH** was purified *via* column chromatography or preparative TLC (*n*-hexane/CH_2Cl_2 (7:3).

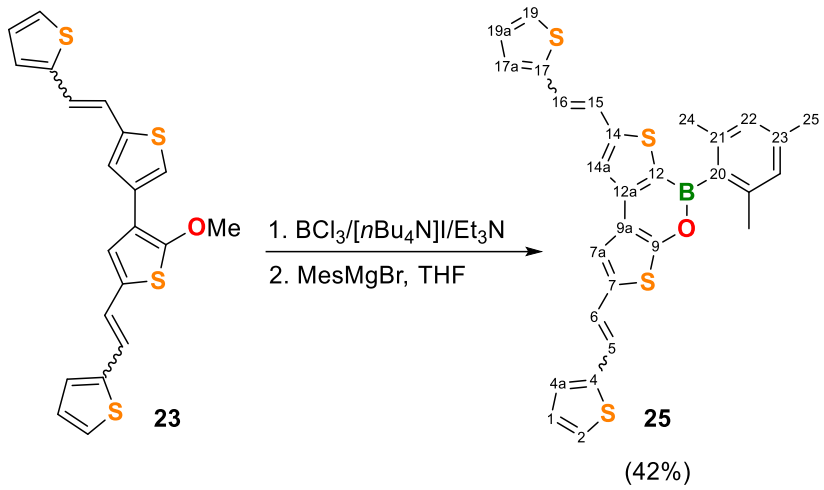
*Characterization data of **21-OH**:*

^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.16 (d, ^3J(H,H) = 5.5 Hz, 1H; H-19), 7.97 – 7.91 (m, 2H; H-6, H-15), 7.83 (d, ^3J(H,H) = 8.6 Hz, 1H; H-14), 7.67 (d, ^3J(H,H)= 5.6 Hz, 1H; H-18), 7.46 (d, ^3J(H,H) = 8.4 Hz, 1H; H-5), 7.34 (d, ^3J(H,H) = 5.5 Hz, 1H; H-1), 6.85 (s, 1H; H-11), 6.62 (d, ^3J(H,H) = 5.5 Hz, 1H; H-2), 6.31 (s, 1H; OH). Note: the assignment of the -OH resonance (6.31 ppm) was confirmed by deuteration test, see Figure S45A.

^{13}C{^{1}H} NMR (101 MHz, $CDCl_3$) δ = 139.01 (C-4), 138.47 (C-16), 138.21 (C-13), 136.43 (C-4a), 134.15 (C-16a), 132.76 (C-13/13a), 131.87 (C-13/13a), 131.03 (C-9a), 129.99 (C-7/C-7a) , 129.94 (C-7/C-7a), 129.34 (C-1), 126.69 (C-18), 125.35 (C-11), 123.67 (C-5), 122.04 (C-19), 121.77 (C-2), 119.75 (C-15), 119.42 (C-14), 118.96 (C-5). C-9 n.o.

HRMS (MALDI): Calculated *m/z* for $[C_{20}H_{10}OS_4]^+$: 392.9536; found: 392.9536.

5.5 Synthesis of 25



A flame-dried 100 mL J-Young tube was charged with **23** (150 mg, 0.36 mmol), [nBu$_4$N]I (161 mg, 0.44 mmol, 1.20 eq.), and evacuated for 30 min. Chlorobenzene (10 mL) was added and the resulting solution was cooled to –10 °C. BCl_3 (1.0 M in hexanes; 400 µL, 0.40 mmol, 1.1 eq.) and Et_3N (0.5 M in chlorobenzene; 730 µL, 0.36 mmol, 1.00 eq.) were added, the Young-tap was closed and the yellow-green reaction mixture was allowed to warm up to room temperature. The reaction mixture thus obtained was heated to 135 °C and stirred for 24 h. After cooling to room temperature a brown mixture was obtained. The solvent was evaporated to dryness and THF (10 mL) was added. MesMgBr (1.0 M in THF; 1.08 mL, 1.08 mmol, 3.00 eq.) was added dropwise at room temperature to give a red mixture, which was stirred for 1 h. The solvent was removed under reduced pressure and the residue was purified by column chromatography (17 cm silica gel, d = 2.0 cm, n-hexane/CH_2Cl_2 (5:1), R_f = 0.30). The fractions containing **25** were evaporated giving a yellow solid (80 mg, 0.15 mmol, 42%) containing the *trans,trans*-isomer as major component. **25** was washed with n-pentane and *trans,trans*-**25** (70 mg, 0.13 mmol, 37%) was thereby obtained as a bright-yellow solid. Single crystals of *trans,trans*-**25** suitable for X-ray crystallography were obtained by slow evaporation of a *trans,trans*-**25** saturated solution in n-heptane/CH_2Cl_2 (1:1).

^{1}H NMR (500 MHz, $CDCl_3$): δ = 7.46 (s, 1H; H-14a), 7.28/7.25 (d, ^3J(H,H) = 15.8 Hz, 1H; H-15), 7.27/7.26 (d, ^3J(H,H) = 5.2 Hz, 1H; H-19), 7.22 (s, 1H; H-7a), 7.21/7.20 (d, ^3J(H,H) = 5.2 Hz, 1H; H-19a), 7.18/7.15 (d, ^3J(H,H) = 15.8 Hz, 1H; H-16), 7.11(d, ^3J(H,H) = 3.4 Hz, 1H; H-17a), 7.08+7.05 (d, ^3J(H,H) = 15.8 Hz, 1H; H-6), 7.07 (d, ^3J(H,H) = 3.5 Hz, 1H; H-4a), 7.03-7.01 (dd, ^3J(H,H) = 4.8 Hz, ^4J(H,H) = 3.5 Hz, 2H; H-2, H-1), 7.01/6.98 (d, ^3J(H,H) = 15.8 Hz, 1H; H-5), 6.92 (s, 2H; H-22), 2.35 (s, 3H; H-25), 2.28 (s, 6H; H-24).
Note: Note: most of the proton resonances are overlapped and, ^{1}H assignment was aided by the analyisis of coupling constants and correlations found in ^{HH}COSY and HMBC spectra. When a single proton is indicated by two resonances separated by "/", each resonance is referred to a single peak of the corresponding doublet; for simplicity, in the section *Results and Discussion* the average has been given (es. for H-5 (δ(^{1}H) = 7.08/7.05) the given value is δ(^{1}H) = 7.06).

$^{13}C\{^1H\}$ NMR (126 MHz, $CDCl_3$): δ = 157.6 (C-9), 154.5 (C-14), 147.4 (C-12a), 142.3 (C-4), 141.8 (C-17), 140.6 (C-21), 139.0 (C-23), 133.5 (br.; C-20), 132.0 (C-7), 130.7 (br.; C-12), 128.0 (C-1/C-2), 128.0 (C-1/C-2), 127.8 (C-17a), 127.6 (C-22) , 126.3 (C-4a), 125.9 (C-19), 125.6 (C-15), 124.6 (C-19a), 122.0 (C-5), 121.2 (C-14a), 121.1 (C-6), 120.9 (C-16), 120.7 (C-9a), 119.1 (C-7a), 22.8 (C-25), 21.5 (C-24).

^{11}B NMR (96 MHz, $CDCl_3$): δ = 41.70 ($h_{1/2} \approx$ 375 Hz).

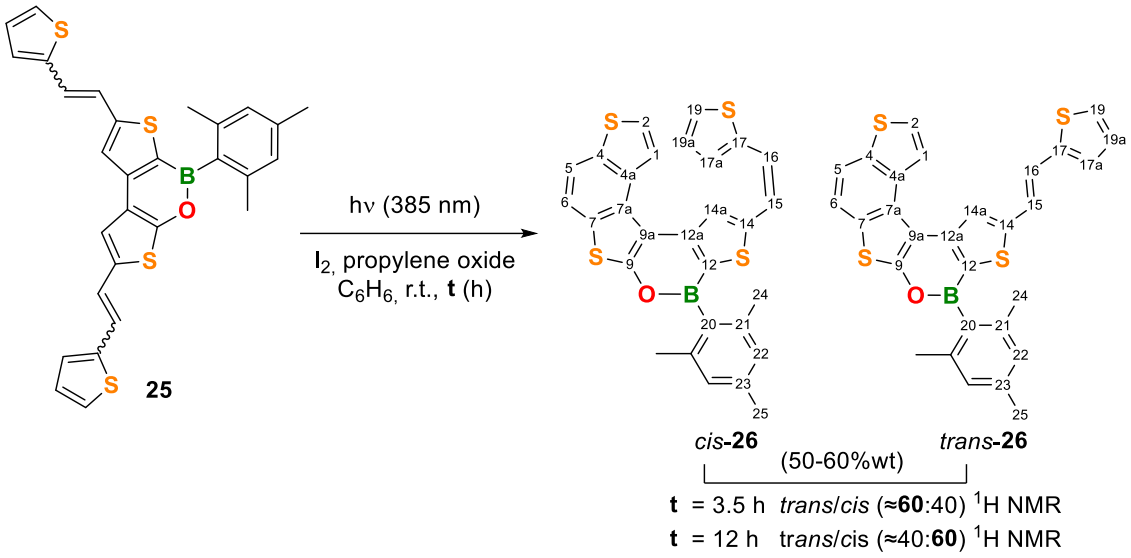
HRMS (MALDI): Calculated *m/z* for $[C_{29}H_{23}BOS_4]^+$: 526.0719; found: 526.0717.

UV/Vis (*c*-hexane): λ_{max} (ε / $mol^{-1}dm^3cm^{-1}$) = 283 (15400), 365 (41000), 382 (36500).

Fluorescence (*c*-hexane, λ_{ex} = 365 nm): λ_{max} = 445, 472, 500 nm (resolved vibrational fine structure), 535 (sh); Φ_{PL} = 12%.

Cyclic voltammetry (THF, 0.1 M [nBu$_4$N][PF$_6$], 200 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: E_{pc} = −2.21 V, E^{I}_{pa} = 0.61V, E^{II}_{pa} = 0.99 V.

5.6 Attempts of 25 photocyclization



*General procedure for **25** photocyclization:*

A flame-dried 250 mL J-Young tube was charged with **25** (70 mg, 0.13 mmol) and evacuated for 30 min. C_6H_6 (150 mL) was added and the resulting green solution was treated with I_2 (70 mg, 0.27 mmol, 2.1 eq.) and propylene oxide (1.86 mL, 26.5 mmol, 200 eq.). The red solution thus obtained was irradiated with an LED lamp (385 nm - placed close to the reaction vessel, approx. 5 cm, Figure **S3**; the Duran® glass used is transparent to 385 nm light).[S6] The reaction progress was monitored by TLC (*c*-hexane/CH_2Cl_2 (5:1)).

Note: Even though *Rf* of **25** and **26** is almost identical, it is possibile to differentiate the two products on TLC: **25** shows a yellow spot under 254, 366 nm light (the spot turns to green after exposure to air); **26** shows blue spot at 254 nm and light-blue spot at 366 nm.

The solvent was evaporated, and the residue was purified by column chromatography (15 cm silica gel, *d* = 2.0 cm, *n*-hexane/CH_2Cl_2 (5:1)). A green-yellow solid (50-60%wt) was obtained and it was proved to be a mixture of *trans*-**26**/*cis*-**26** by ^{1}H, ^{HH}COSY NMR analysis.

Experiment 1, irradiation time **t** = 3.5 h: *trans*-**26**/*cis*-**26** (≈60:40) mixture obtained after purification;
Experiment 2, irradiation time **t** = 12 h: *trans*-**26**/*cis*-**26** (≈40:60) mixture obtained after purification.

Single crystals of *trans*-**26** suitable for X-ray crystallography were grown by slow evaporation of a saturated solution of the *trans*-**26**/*cis*-**26** (≈60:40) mixture in *n*-pentane/CH_2Cl_2 (2:1) in a glovebox.

Characterization data of *cis*-**26** (see Figure S50):

^{1}H NMR (400MHz, CD_2Cl_2): δ = 8.24 (s, 1H; H-14a, 8.08 (d, ^3J(H,H) = 5.6 Hz, 1H; H-1), 7.98-7.93 (m, 1H; H-5, overlapped with *trans*-**26**), 7.80-7.75 (m, 2H; H-5/H-6, overlapped with *trans*-**26**), 7.57 (d, ^3J(H,H) = 5.6 Hz, 1H; H-2), 7.33 (d, J(H,H) = 3.7 Hz, 1H; H-17a/H-19/H-19a, overlapped with *trans*-**26**), 7.22 (d, ^3J = 3.7 Hz, 1H; H-17a/H-19/H-19a), 7.01 (t (originated by two collapsed doublets), ^3J = 3.7 Hz, 1H; H-17a/H-19/H-

19a), 6.93 (s, 2H; H-22), 6.89 (d, ^3J = 11.9 Hz, 1H; H-15), 6.77 (d, ^3J = 11.9 Hz, 1H; H-16), 2.34 (s, 3H; H-25), 2.28 (s, 6H; H-24). Assignment was aided by ^{HH}COSY spectrum.

Note: of high diagnostic value are the resonances of protons H-15 (6.89 ppm) and H-16 (6.77 ppm) showing a typical *cis*-coupling constant $^3J(H,H)_{cis}$ = 11.9 Hz.

Characterization data of *trans*-**26** (see Figure S51):

^{1}H NMR (400MHz, CD_2Cl_2): δ = 8.28 (d, ^3J(H,H) = 5.6 Hz, 1H; H-1/H-2), 8.16 (s, 1H; H-14a), 7.98-7.96 (m, 1H; H-15/16, overlapped with H-5/H-6 and *cis*-26 resonances), 7.97 (dd, ^3J(H,H) = 8.5 Hz, 1H; H-5/H-6, partly overlapped with *cis*-26 resonances), 7.80-7.75 (m, 1H; H-15/16, overlapped with H-5/H-6 and *cis*-26 resonances) 7.79(7.80/7.78) (d, ^3J(H,H) = 8.5 Hz, 1H; H-5/H-6, overlapped with *cis*-26 resonances), 7.76 (d, ^3J(H,H) = 5.6 Hz, 1H; H-1/H-2, overlapped with H-5/H-6 and *cis*-26 resonances), 7.34 (d, 1H; ^3J(H,H) = 4.1 Hz, 1H; H-17a/H-19/H-19a overlapped with *cis*-26), 7.16 (d, ^3J(H,H) = 3.5 Hz, 1H; H-17a/H-19/H-19a), 7.05 (dd, J = ^3J(H,H) = 5.1, ^3J(H,H) = 3.5 Hz, 1H; H-17a/H-19/H-19a), 6.95 (s, 2H), 2.36 (s, 3H), 2.30 (s, 6H).

^{11}B NMR (128 MHz, CD_2Cl_2): δ = 40.9 ($h_{1/2} \approx$ 220 Hz).

HRMS (MALDI): Calculated *m/z* for $[C_{29}H_{21}BOS_4]^+$: 524.0563; found: 524.0567.

^{13}C{^{1}H}NMR (1001 MHz, $CDCl_3$): δ = 142.6, 134.9, 127.9, 127.0 (C-10), 126.8, 126.6 (C-2), 126.0 (C-1), *124.2 (C-12), 122.3, 121.1, 120.6 (C-4), 119.3, 118.7, 118.6 (C-11), 62.10 (OMe). *) unequivocally detected only in the HMBC spectrum.

Note: the scarce solubility of *trans*-**28** made its ^{13}C NMR characterization difficult; although a long measurement time was employed, seven carbon resonances are missing.

*Characterization data of the fraction enriched in **cis**-**28**.*

^{1}H NMR (400 MHz, DMSO) δ = 8.06 (s, 1H; H-14), 7.96 – 7.93 (m, 2H; H-16/17+H-19/20, overlapped with the same protons of *trans*-**28**), 7.91 – 7.86 (m, 2H; H-16/17+H-19/20, overlapped with the same protons of *trans*-**28**), 7.71 (dd; *trans*-**28**, 7.68 (dd, *J*(H,H) = 3.0 Hz, *J*(H,H) = 1.3 Hz, 1H; H-4), 7.59 (dd, *J*(H,H) = 5.0 Hz, *J*(H,H) = 3.0 Hz), 7.56 (dd, *J*(H,H) = 5.0 Hz, *J*(H,H) = 3.0 Hz, 1H; H-1), 7.48 ((s, 1H; H-10)+ 7.47(d, *J*(H,H) = 1.3 Hz, 1H; H-2)), 7.17 (d, *J*(H,H) = 15.9 Hz; *trans*-**28**-H-11), 7.10 (d, *J*(H,H) = 15.9 Hz; *trans*-**28**-H-12), 6.76 (d, *J*(H,H) = 12.3 Hz, 1H; H-11), 6.71 (d, *J*(H,H) = 12.5 Hz, 1H; H-12), 4.06 (s; *trans*-**28**), 3.88 (s, 3H; OMe).

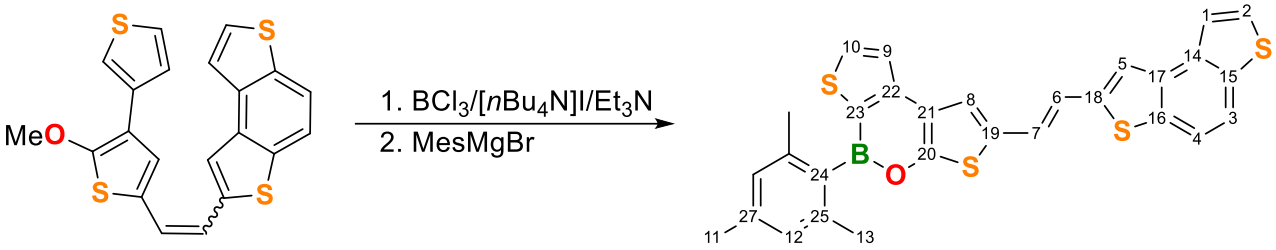
Note: for simplicity integrals of the residual *trans*-**28** have been omitted and are shown in Figure S54.

^{13}C{^{1}H}NMR (101 MHz, DMSO): δ = 160.4 (C-7), 142.5 (Cq), 139.3 (C-13), 136.2 (Cq), 136.1 (Cq), 134.2 (Cq), 134.0 (Cq), 129.1 (C-2), 127.9 (C-16/17+19/20), 127.0 (*trans*-**28**), 126.7 (C-10), 126.0 (*trans*-**28**), 125.9 (C-1), 125.0 (C-12), 124.2 (*trans*-**28**), 123.8 (C-14), 123.4 (C-9), 122.4 (C-16/17+19/20), 122.2 (*trans*-**28**), 121.1 (*trans*-**28**), 120.6 (*trans*-**28**), 120.5 (C-4), 119.9 (C-11), 119.4 (C-16/17+19/20), 119.3 (*trans*-**28**), 118.6 (*trans*-**28**), 118.6 (C-16/17+19/20), 115.6 (Cq), 62.1 (OMe; *trans*-**28**), 61.8 (OMe).

HRMS (MALDI): Calculated *m/z* for $[C_{21}H_{14}OS_4]^+$: 409.9927; found: 409.9925.

Mp: 235.5-238.4 °C.

6.2 Synthesis of 27



28 ***trans*-27**

A flame-dried 100 mL J-Young flask was charged with **28** (306 mg, 0.57 mmol), [*n*BuN]I (326 mg, 0.69 mmol, 1.2 eq.) and chlorobenzene (46 mL). The rtesulting mixture was cooled to –10 °C and BCl_3 (1.0 M in hexanes; 0.8 mL, 0.8 mmol, 1.4 eq.) was added, yielding a brownish mixture. Et_3N (0.5 M in chlorobenzene; 1.1 mL, 0.57 mmol, 1 eq.) was added and the resulting orange solution was heated to 135 °C and stirred for 24 h. After cooling to room temperature, the mixture was evaporated to dryness and THF (60 mL) was added. MesMgBr (0.9 M in THF; 2.0 mL, 1.8 mmol, 3.16 eq.) was added dropwise at room temperature and the reaction mixture was stirred for 1 h. The solvent was removed under reduced pressure and the residue was purified by column chromatography (*n*-hexane/AcOEt (95:5)). *trans*-**27** was thereby obtained as yellow solid (139 mg, 0.26 mmol, 46%).

A second fraction containing *trans*-**27** (72 mg, 0.14 mmol, 26%; determined by ^{1}H NMR) in mixture with unreacted **28** was also recovered. Total yield: 71%.

^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.00 (d, ^3J(H,H) = 4.8 Hz, 1H; H-10), 7.80 (d, ^3J(H,H) = 8.6 Hz, 1H; H-3/H-4), 7.72 (d, ^3J(H,H) = 8.6 Hz, 1H; H-3/H-4), 7.67 (d, ^3J(H,H) = 5.4 Hz, 1H; H-1/H-2), 7.62 (s, 1H; H-5 – overlapped with H-9), 7.61 (d, ^3J(H,H)= 4.8 Hz, 1H; H-9 – overlapped with H-5), 7.57 (d, ^3J(H,H) = 5.4 Hz, 1H; H-1/H-2), 7.35 (s, 1H; H-8), δ= 7.20 (d, ^3J(H,H) = 15.7 Hz, 1H; H-6), 7.15 (d, ^3J(H,H)= 15.7 Hz, 1H; H-7), 6.93 (s, 2H; H-12), 6.85 (s; *cis*-**27**), 2.36 (s, 3H; H-11), 2.30 (s; *cis*-**27**), 2.27 (s, 6H; H-13), 2.14 (s; *cis*-**27**).

^{13}C{^{1}H} NMR (100.6 MHz, $CDCl_3$): δ = 157.78 (C-20), 146.88 (C-22), 142.70 (C-18), 140.66 (C-25), 139.08 (C-27), 138.47 (C-8), 137.09 (C-15), 135.69 (C-16), 135.41 (C-17), 134.47 (C-14), 133.63* (C-24), 132.29* (C-23), 131.75 (C-19), 127.66 (C-12), 126.94 (C-2), 124.28 (C-6/C-7), 122.98 (C-9), 121.99 (C-1), 121.50 (C-6/C-7), 121.39 (C-5), 121.25 (C-21), 120.07 (C-8), 119.42 (C-4), 118.60 (C-3), 22.80 (C-13), 21.49 (C-11).

*) unequivocally detected only in the ^{H,C}HMBC spectrum.

^{11}B NMR (128.4 MHz, $CDCl_3$) δ = 42.12 ($h_{1/2}$≈ 320 Hz).

HRMS (MALDI): Calculated *m/z* for $[C_{29}H_{21}BOS_4]^+$: 523.0605; found: 523.0603.

UV/Vis (*c*-hexane): λ_{max} (ε / mol^{-1}dm^{3}cm^{-1}) = 282 (sh), 309 (12500), 370 (sh), 388 (60600), 410 (47000).

Fluorescence (*c*-hexane, λ_{ex} = 375 nm): λ_{max} = 421, 488 nm (resolved vibrational fine structure), 477, 517 nm (sh); Φ_{PL} = 23%.

Cyclic voltammetry (THF, 0.1 M [*n*Bu$_4$N][PF$_6$], 100 mV s^{-1}, vs. FcH/FcH$^+$): Cathodic scan: $E^{I}_{1/2}$ = −2.37 V, E^{I}_{pa} = 0.63 V, E^{II}_{pa} = 0.76 V.

Mp: 127.3 – 129.7 °C.

[a] Each onset wavelength (λ_{onset}) was determined by constructing a tangent on the point of inflection of the bathochromic slope of the most red-shifted absorption maximum. [b] Resolved vibrational fine structure. [c] Quantum yields were determined by using a calibrated integrating sphere. [d] $E_{HOMO} = E_{LUMO} - E_g^{opt}$, $E_{LUMO} = -4.8$ eV$-E_{1/2}^{Red1}$ (FcH/FcH$^+$ = – 4.8 eV vs vacuum level). [e] Optical band gap $E_g^{opt} = 1240/\lambda_{onset}$. [f] Quantum yields measured in THF. [g] Quantum yields measured in $CHCl_3$. [h] Compound shows no oxidation. [i] E_{HOMO}/E_{LUMO} calculated with the *maxima criterion*: $E_{HOMO} = -1e\times((E^I_{pa}/V([FcH]^+|FcH)+4.8$ V$([FcH]^+|FcH$ vs. zero)); $E_{LUMO} = -1e\times((E^I_{pc}/V([FcH]^+|FcH)+4.8$ V$([FcH]^+|FcH$ vs. zero)). [k] Compound shows no reversible reduction. sh = shoulder.

9. X-ray crystal structure analyses

Data for all structures were collected on a STOE IPDS II two-circle diffractometer with a Genix Microfocus tube with mirror optics using MoK_α radiation (λ = 0.71073 Å). The data were scaled using the frame scaling procedure in the *X-AREA* program system (Stoe & Cie, 2002).[S15] The structures were solved by direct methods using the program *SHELXS* (Sheldrick, 2008) and refined against F^2 with full-matrix least-squares techniques using the program *SHELXL* (Sheldrick, 2008).[S16]

Compounds **5**, **8**, and **16** (CCDC 2211405, CCDC 2211406, CCDC 2211407), require no special comments.

trans-**15** (CCDC 2211409) is located on a center of inversion. There is one $CDCl_3$ molecule in the asymmetric unit forming a C-H…π hydrogen bond to the center (cog) of the mesityl ring (H1L…cog = 2.42Å, C1L-H1L…cog = 160.9°; see Figure S89).

The molecule of ***trans*-17** (CCDC 2211408) is located on a center of inversion. The terminal thienyl rings are disordered over two positions with a site occupation factor of 0.515(4) for the major occupied orientation. The disordered S and C atoms sharing the same site were refined with the same coordinates and the same displacement parameters.

1 (CCDC 2211410) crystallizes as a racemic mixture of the *P* and *M* enantiomers.

In **15H2** (CCDC 2211411), one methyl group is disordered over two positions with a site occupation factor of 0.52(6) for the major occupied site.

CCDC files **5**, **8**, **16**, **17**, **15**, **1** and **15H2** (CCDC 2211405, CCDC 2211406, CCDC 2211407, CCDC 2211408, CCDC 2211409, CCDC 2211410, CCDC 2211411) contain the supplementary crystallographic data for this paper and can be obtained free of charge from he Cambridge Crystallographic Data Centre via www.ccdc.cam.ac.uk/data_request/cif.

Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures with R indices>20 have been not explicited.

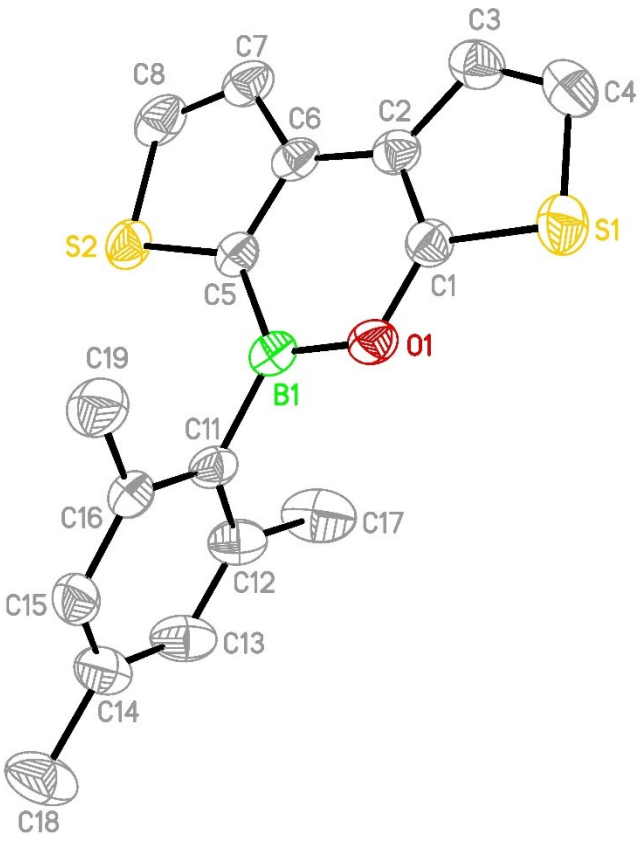

Figure S87 (CCDC 2211405): Molecular structure of **5** in the solid state. Displacement ellipsoids are drawn at the 50% probability level. Table S15: Selected crystallographic data for *trans*,*trans*-**25**.

Identification code	wa3194	
Empirical formula	C29 H23 B O S4	
Formula weight	526.52	
Temperature	173(2) K	
Wavelength	0.71073 Å	
Crystal system	Orthorhombic	
Space group	P 21 21 21	
Unit cell dimensions	a = 6.3515(5) Å	a= 90°.
	b = 18.4915(11) Å	b= 90°.
	c = 22.5750(11) Å	g = 90°.
Volume	2651.4(3) $Å^3$	
Z	4	
Density (calculated)	1.319 Mg/m^3	
Absorption coefficient	0.379 mm^{-1}	
F(000)	1096	
Crystal colour, shape	green needle	
Crystal size	0.180 x 0.040 x 0.010 mm^3	
Theta range for data collection	3.332 to 25.750°.	
Index ranges	-7<=h<=7, -22<=k<=22, -27<=l<=25	
Reflections collected	14919	
Independent reflections	4991 [R(int) = 0.0903]	
Completeness to theta = 25.000°	99.7 %	
Absorption correction	Semi-empirical from equivalents	
Max. and min. transmission	1.000 and 0.293	
Refinement method	Full-matrix least-squares on F^2	
Data / restraints / parameters	4991 / 0 / 319	
Goodness-of-fit on F^2	1.148	
Final R indices [I>2sigma(I)]	R1 = 0.0833, wR2 = 0.1707	
R indices (all data)	R1 = 0.1262, wR2 = 0.1981	
Absolute structure parameter	-0.19(17)	
Extinction coefficient	n/a	
Largest diff. peak and hole	0.390 and -0.418 e.$Å^{-3}$	

Table S16: Selected crystallographic data for *trans*-**26**.

Identification code	wa3185	
Empirical formula	C29 H21 B O S4	
Formula weight	524.51	
Temperature	173(2) K	
Wavelength	0.71073 Å	
Crystal system	Monoclinic	
Space group	P 21/c	
Unit cell dimensions	a = 6.3855(3) Å	a= 90°.
	b = 15.2250(10) Å	b= 94.505(4)°.
	c = 26.8585(14) Å	g = 90°.

R indices (all data)	R1 = 0.1899, wR2 = 0.3354	
Extinction coefficient	n/a	
Largest diff. peak and hole	0.729 and -0.507 $e.Å^{-3}$	

10.Chiroptical, kinetic and theoretical studies of 1

10.1 HPLC resolution of the 1 enantiomers and racemization kinetics

The enantiomers of **1** were resolved by HPLC on a column (250×4.6 mm I.D. 5 µm) containing the Chiralpak IA chiral stationary phase, using *n*-hexane/CH_2Cl_2 (95:5) as eluent delivered at a flow rate of 1.0 mL/min (Figure S102a).

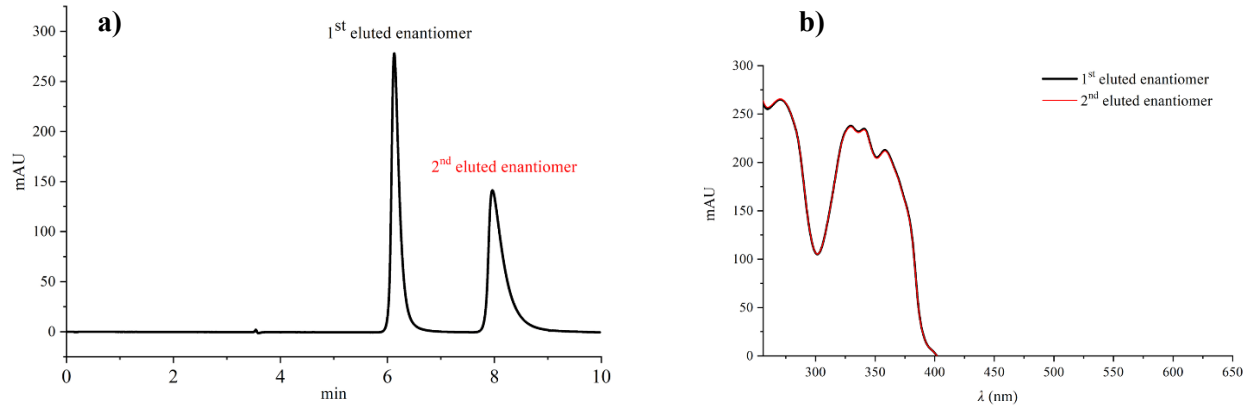

Figure S102: a) HPLC resolution of **1** – stationary phase: Chiralpak IA, mobile phase: *n*-hexane/CH_2Cl_2 (95:5), flow rate = 1.0 mL/min, 25 °C; b) UV spectra of the first and second eluted enantiomer, *n*-hexane/CH_2Cl_2 (95:5).

Table S17: HPLC resolution parameters for the separation of **1** enantiomers.

Eluted peak	R_t (min) [a]	k (t_0 = 3.55)[b]	Relative Area %	A_s [c]	α [d]	R [e]
1	6.13	0.73	51	1.67	1.70	4.9
2	7.96	1.24	49	2.47		

[a] R_t = retention time. [b] k = retention factor, t_0 = void time; k was calculated according to the equation $k = (R_t - t_0)/t_0$. [c] A_s = asymmetry factor, back-to-front ratio of a bisected peak measured at 10% of height. [d] α = selectivity, calculated from the ratio of k values, $\alpha = k_2/k_1$. [e] R = resolution, calculated according to the EP formula equation.

Enantiomers of **1** were separated at the semipreparative level on a 250×10.0mm I.D. 5 µm column using *n*-hexane/CH_2Cl_2 (95:5) as eluent and a loading of about 5 mg of **1** racemic mixture (dissolved in *n*-hexane/CH_2Cl_2 (75:25)) per run. After separation, the fraction containing the second eluted enantiomer resulted to be pure with an *e.e.* of 97.44% (Figure S103).

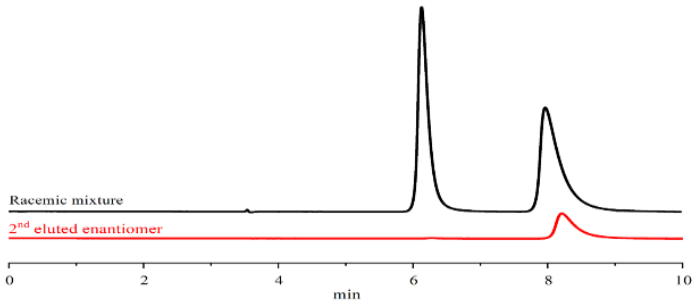

Figure S103: Second eluted enantiomer after semipreparative HPLC separation; solvent peak ($R_t \approx 3$ min).

The second eluted enantiomer was heated at 80 °C in decalin and the enantiomeric excess of the sample was checked by HPLC on the chiral stationary phase.

Data collected at different times was plotted as ln(*e.e.*) *vs* time giving a straight line from the slope of which the racemization constant ($k_{rac} = 16.30\times10^{-5}$ s^{-1}) was extracted (Figure S104). The enantiomerization constant was obtained by $k_{enant}=0.5\ k_{rac}$.

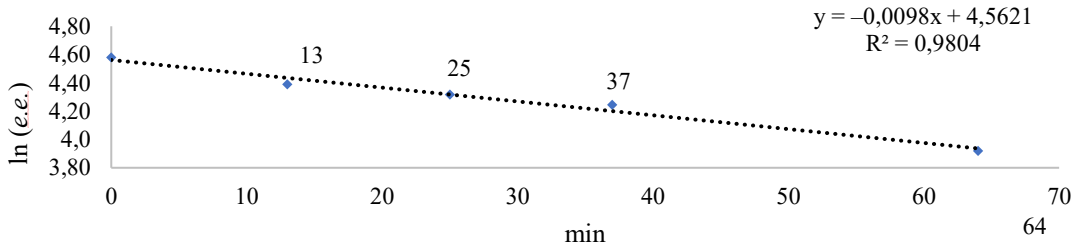

Figure S104: ln(*e.e.*) vs *time* plot used to estimate the racemization constant. The mathematical expression of the linear regression is given in the top right corner.

A free energy of activation equal to 26.9 ± 0.1 kcal/mol (353 K) and 27.4± 0.1 kcal mol^{-1} (353 K) for enantiomerization was calculated by using the Eyring equation (reported below in linear form) and setting a transmission coefficient equal to 1.

$$ln\frac{k}{T} = \frac{-\Delta H^{\ddagger}}{R}\frac{1}{T} + ln\frac{k_B}{h} + \frac{\Delta S^{\ddagger}}{R}$$

$k = k_{rac}$; $\Delta H^{\ddagger}$ = enthalpy of activation; T = absolute temperature in Kelvin (K); k_B = Boltzmann's constant; h = Planck's constant; $\Delta S^{\ddagger}$ = entropy of activation; R = universal gas constant.

The free activation of enantiomerization is calculated trought the following equation:

$$\Delta G^{\ddagger} = 4.576 * 10^{-3} * T\,[10.319 + log(T/k)]$$

Where

$$k = \kappa\left(\frac{k_B T}{h}\right) e^{-\Delta G^{\ddagger}/RT}$$

Assuming the transmission coefficient κ =1.

10.2 Optical rotation and CD spectra

Pure enantiomers showed optical rotation values of +97,75° for the first eluted and –97.5° for the second eluted one (c = 0.04 and 0.06 g/mL respectively in *n*-hexane/CH_2Cl_2 (95:5)). CD spectra were recorded in *n*-hexane/CH_2Cl_2 (95:5) as solvent (Figure S105).

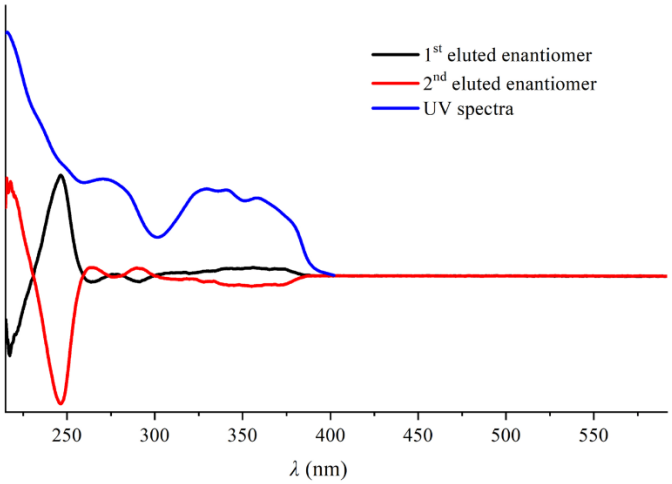

Figure S105: CD spectra of **1** first (black trace) and second (red trace) eluted enantiomers; UV spectra (blue trace).

10.3 Assignment of absolute configuration and electronic transitions characterization

To simulate the CD spectrum, TD-DFT calculations have been performed on the optimized *M* structure of **1** at M06/6-311g G(d,p) level of theory through the Gaussian 16 package.[S17] Only one minimum-energy structure has been obtained. A Gaussian bandshape has been applied to each calculated transition in correspondence of calculated wavelength with area proportional to calculated rotational strength, a bandwidth of 0.18 eV has been adopted. No wavelength shift has been applied and the calculated intensity of each transition has been multiplied by 1.5. Exactly with the same protocol CD spectrum of a model compound in which mesityl groups were replaced by hydrogen atoms (**1***, Figure S106) has been calculated.

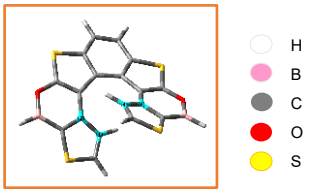

Figure S106: Model compound bearing no mesityl groups **1***.

Calculated CD spectra for compound **1** and **1*** give similar results as reported in Figure S107, where bars proportional to calculated dipole and rotational strengths placed in correspondence of the calculated wavelengths are also given.

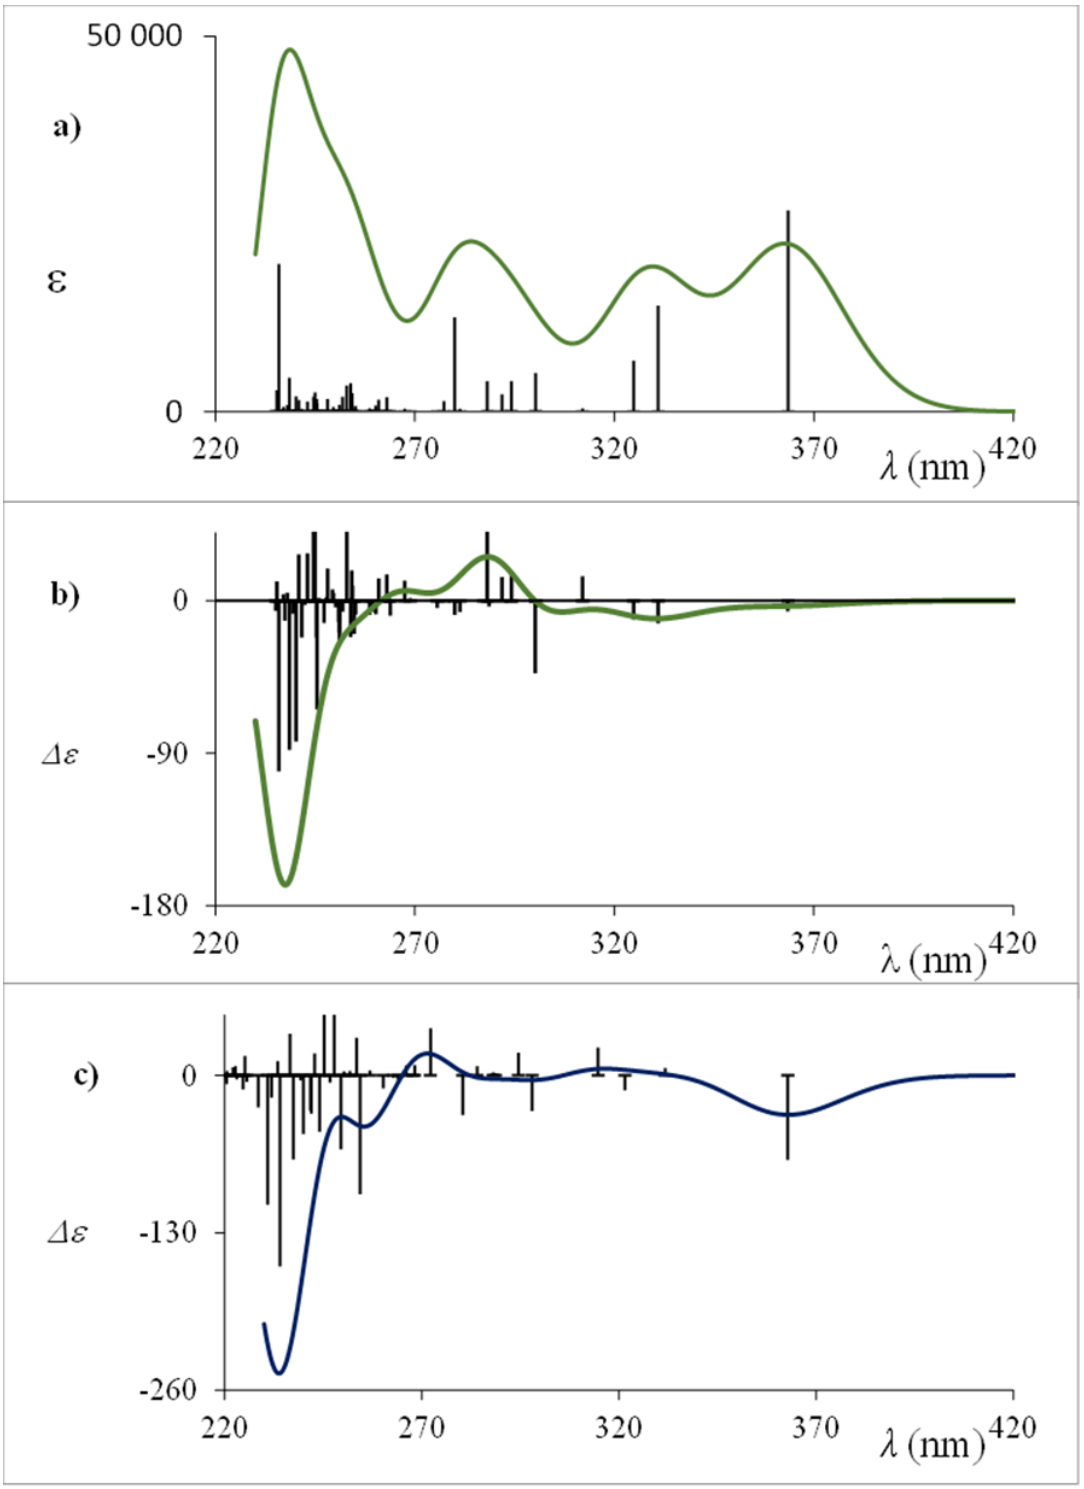

Figure S107: a) Calculated absorption spectrum of **1**; b, c) CD spectra of the *M* enantiomer of compound **1** (green trace) and **1***, bearing no mesityl groups (blue trace).

Representation of orbitals involved in the principal transitions of the two compound **1**, and **1***.

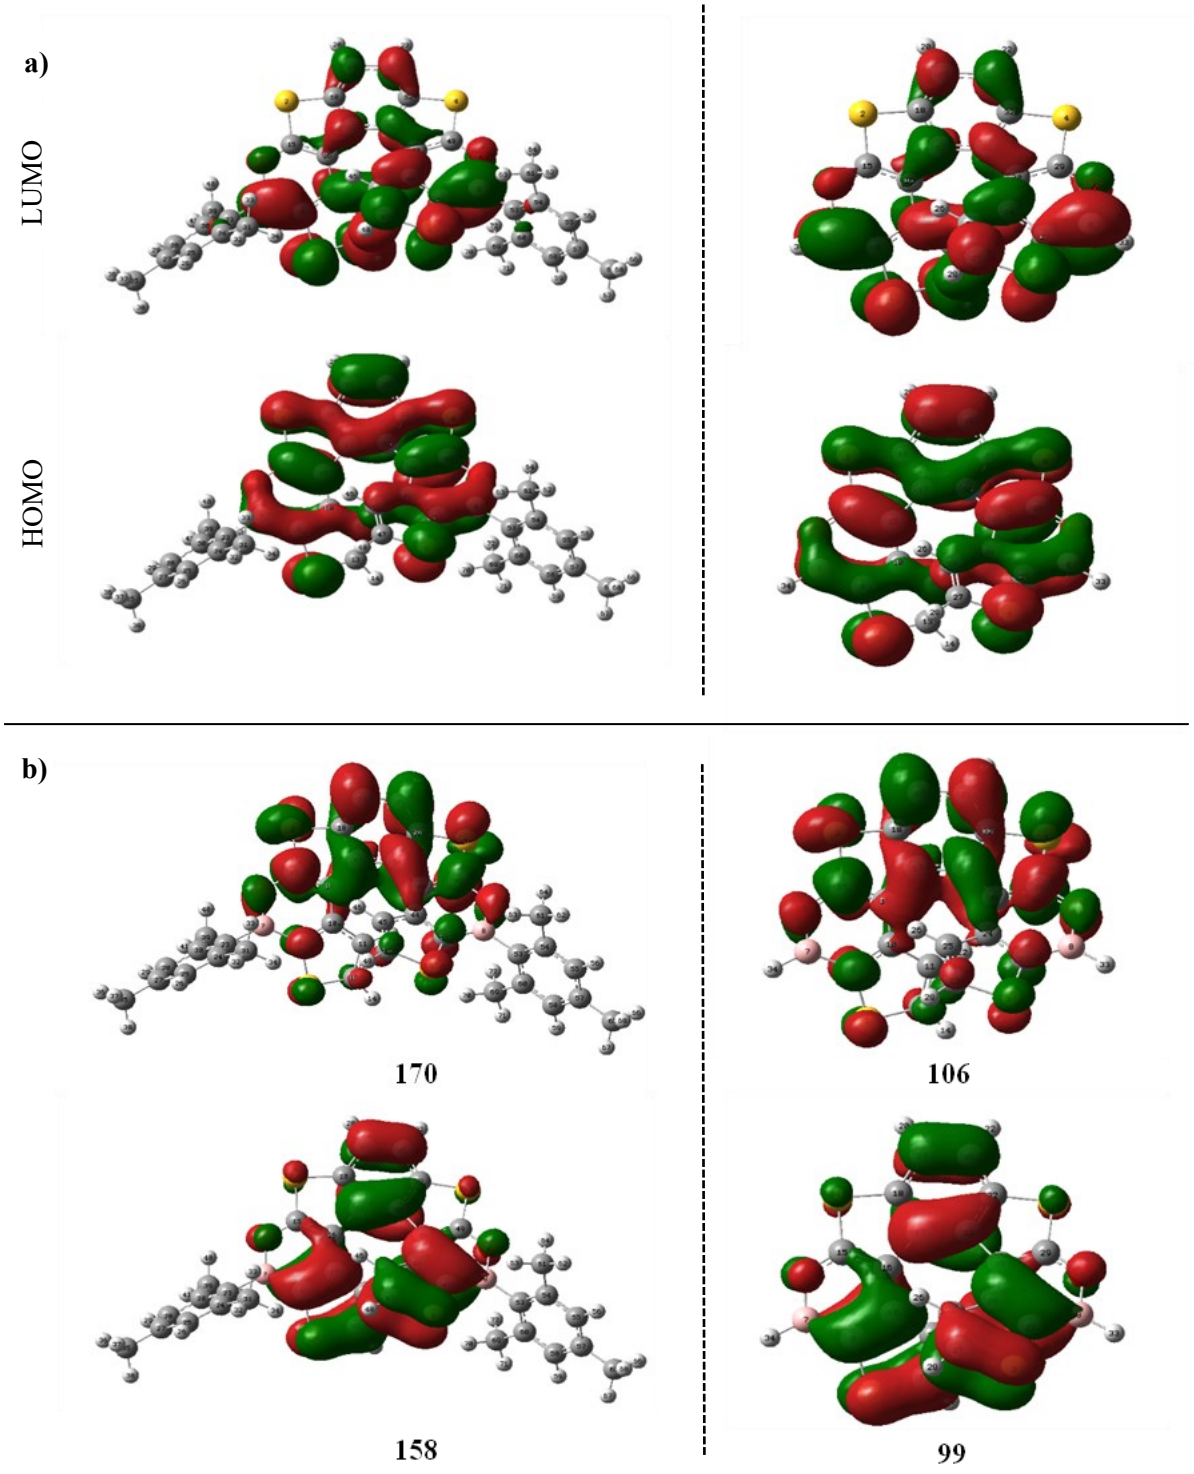

Figure S108: a) Comparison of the HOMO-LUMO orbitals involved in the first optical transition of compound **1** and the model compound **1***; b) (as an example) two of the orbitals involved in one of the transition originating the intense negative peaks about 240 nm are reported for the two compounds **1**, **1*** (from Table S18 and S19 one can appreciate that many contributions are present).

Table S18: Characteristics of the principal transition calculated for **1** (from left: for each transition, calculated energies, wavelengths, dipole strengths, rotational strengths, angle formed by electric and magnetic dipole transition moments, molecular states involved in transition).

10.4 Enantiomerization barrier calculation

Evaluation of barrier energy has been conducted via DFT calculation optimizing ground and transition state following reference[S18] at PBE1-PBE-TZVP level with empirical dispersion correction.[S19] As further test we compared the model compound **1*** with carbo[6]helicene and tetrathia[7]helicene performing a scan along a dihedral angle coordinate defined as indicated considering also diffuse functions at PBE1-PBE 6-311++G(d,p) level, with empirical dispersion corrections (Figure S109).

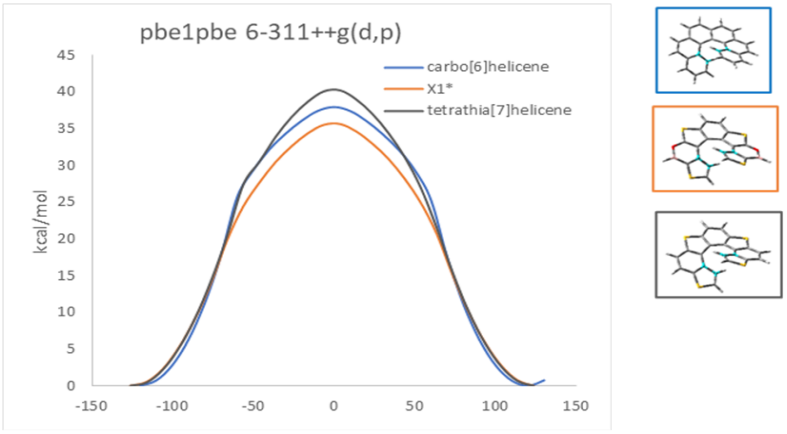

Figure S109: Comparison between the energy scan of carbo[6]helicene (blue trace), model compound **1*** (orange trace)**,** and tetrathia[7]helicene (grey trace); atoms defining the dihedral angle scan coordinate are evidenced (light blue) on the corresponding structures.

A similar analysis conducted on compound **1** and carbo[6]helicene at the semiempirical AM1 level gives the following result which, despite the low level of calculation adopted, seems to better fit experimental results (Figure S57).

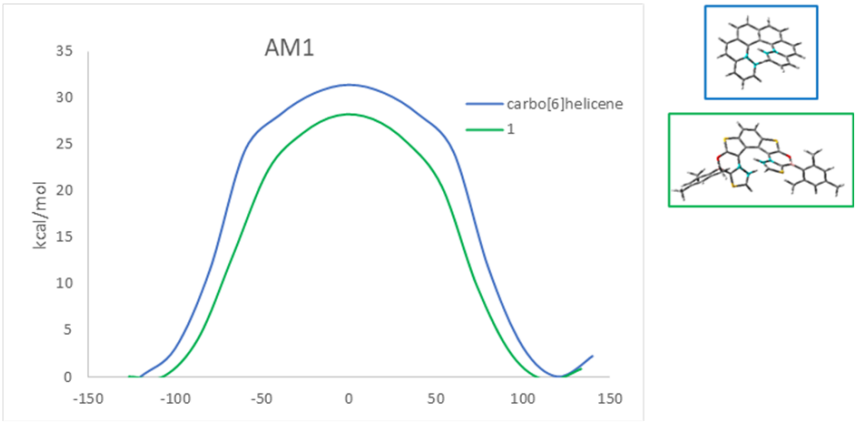

Figure S110: Comparison between the energy scan of carbo[6]helicene (blue trace) and compound **1** (green trace).

A comparison of minimum and transition state calculated structures for the model compound **1*** and tetrathia[7]helicene, with particular attention to the six-membered ring bearing oxygen and boron atoms was performed.

Once defined the average six-membered ring plane, distances of the six atoms with respect to the plane are reported: we may infer that, on average, six carbon atom force the ring to be flatter, particularly considering the transition state. Level of calculation: PBE1-PBE/6-311++G(d,p) (Figure S58).

0.080	0.081
0.040	0.082
0.065	0.032

Figure S111: Distances atom-ring plane (Å) for tetrathia[7]helicene (a) and the six-membered ring containing oxygen and boron atoms of model compound **1*** (b) in the calculated transition state structure (top) and the minimum state structure (bottom). The above-mentioned atom-ring plane distances are listed in the right top corner. The plane defined by the six ring atoms and atom-plane distances have been calculated with the software *Mercury* (https://www.ccdc.cam.ac.uk/solutions/csd-core/components/mercury).

11. Computational details and HOMO/LUMO analyses

Geometry optimizations and frequency calculations were carried out using the Gaussian 09 software package,[S20] the B3LYP functional, and the 6-31G* basis set. The stationary points were characterized as minima (no imaginary frequencies in the vibrational analysis). The graphics were produced with Avogadro 1.1.1 and POV-Ray 3.7.0.

Table S20: Computed data of the BO-doped compounds in comparison with selected experimental values (see Table S1).

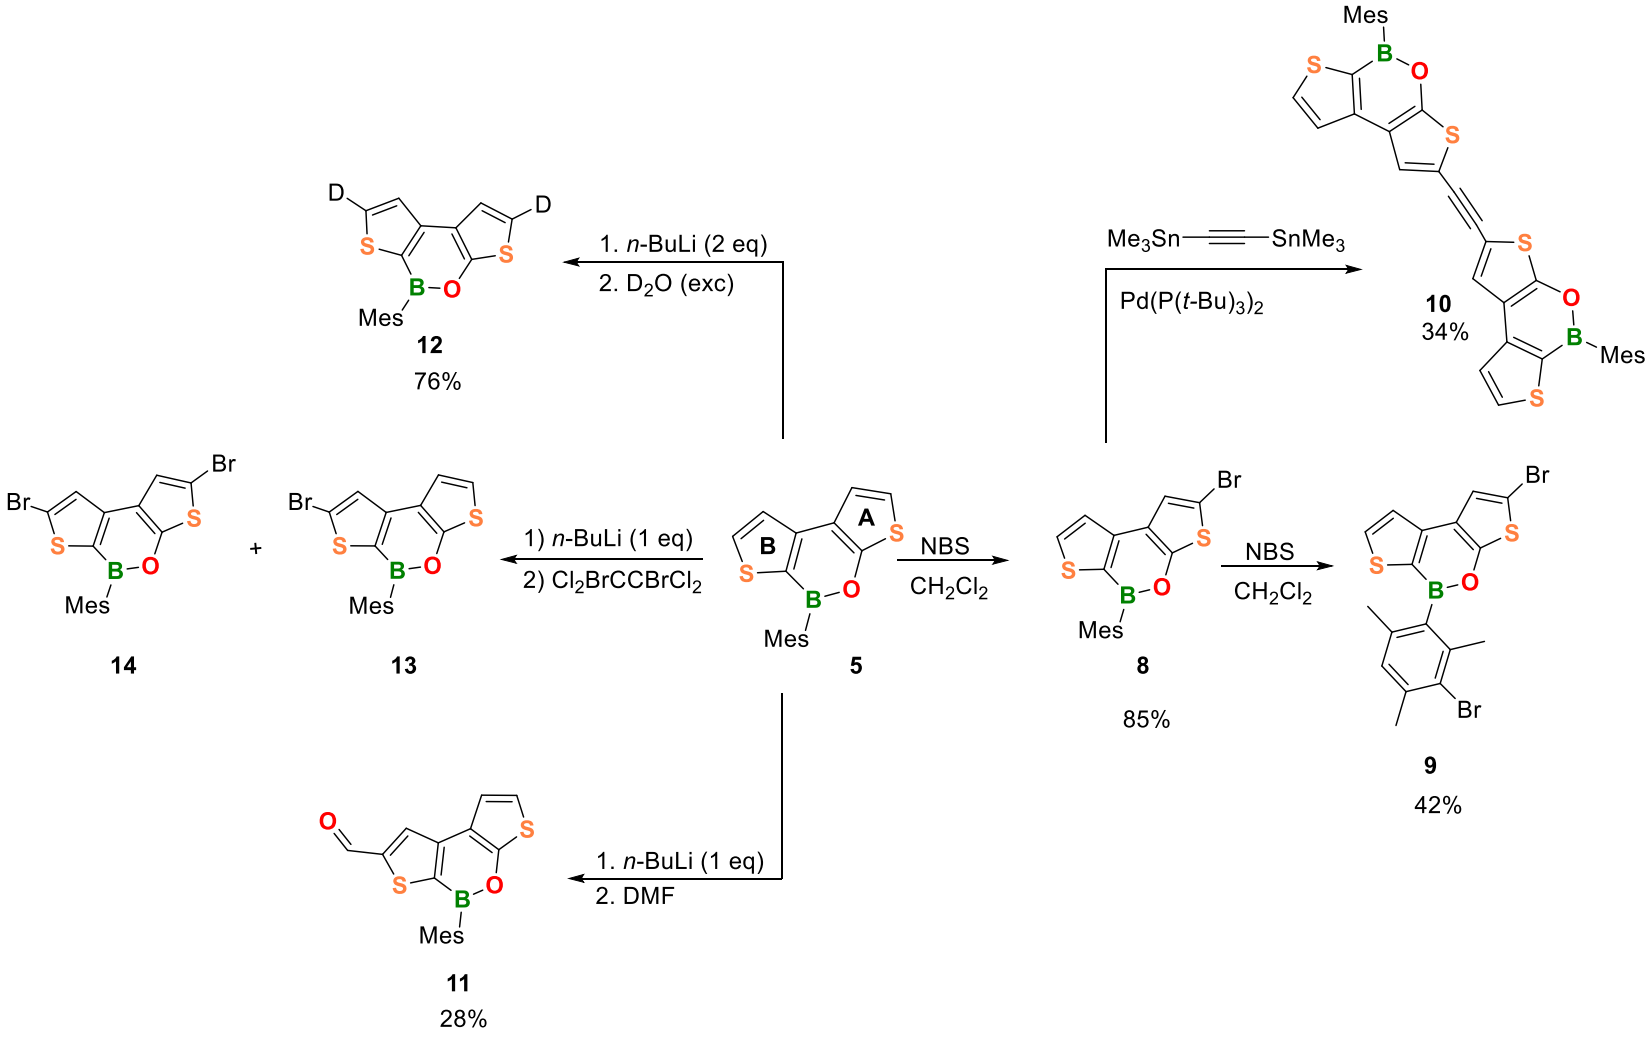
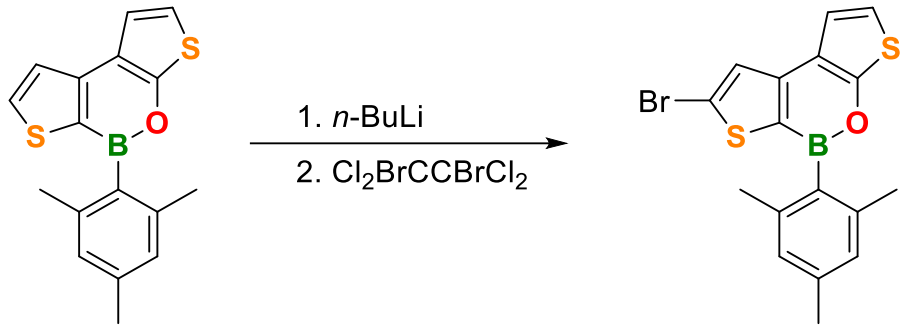
13. Reactivity test of 5: synthesis of 13, 14, 8, 11, 12, 10.



Scheme **R1.** Investigation of the mesityl diethienooxaborine **5** reactivity.

13.1 Synthesis of 13



5 **13**

A flame-dried 50 mL Schlenk flask was charged with **5** (105 mg, 0.34 mmol) and THF (4 mL). The yellowish solution thus obtained was cooled to –78 °C and, *n*-BuLi (2.23 M in hexanes; 0.16 mL, 0.46 mmol, 1.05 eq.) was added dropwise during 2 min. The resulting yellow reaction mixture was stirred for 15 min at the same temperature and then $Cl_2BrCCBrCl_2$ (138 mg, 0.43 mmol, 1.25 eq.) was added as THF solution (4 mL). The orange mixture thus obtained was slowly allowed to warm to room temperature and stirrred overnight. THF was removed and the residue was purified *via* column chromatography (18 cm silica gel, *d* = 2.5 cm; *c*-hexane/CH_2Cl_2 (11:1)). The fractions containing **13** were combined and the solvent was evaporated, giving a white solid (78 mg) which was proved to be the title compound **13** in mixture with traces of the doubly brominated compound **14**, **8** and starting **5** (see Figure R2). A second fraction, containing the starting **5** was also recovered (40 mg, 0.13 mmol, 38%).

Single crystals of **13** suitable for X-ray analysis were obtained by slow evaporation of a **13** saturated solution in *n*-hexane/CH_2Cl_2 .

Note: further experiments carried out using Br_2 as electrophile under otherwise identical conditions, allowed to isolate pure doubly brominated compound **14** (Figure R4, R5).

*Characterization data of **13***:

^{1}H NMR (400 MHz, $CDCl_3$): δ = 7.59 (s, 1H), 7.27 (d, 1H; overlapped with $CDCl_3$), 6.96 (d, ^3J(H,H) = 6.0 Hz, 1H), 6.90 (s, 2H), 2.34 (s, 3H), 2.23 (s, 6H).

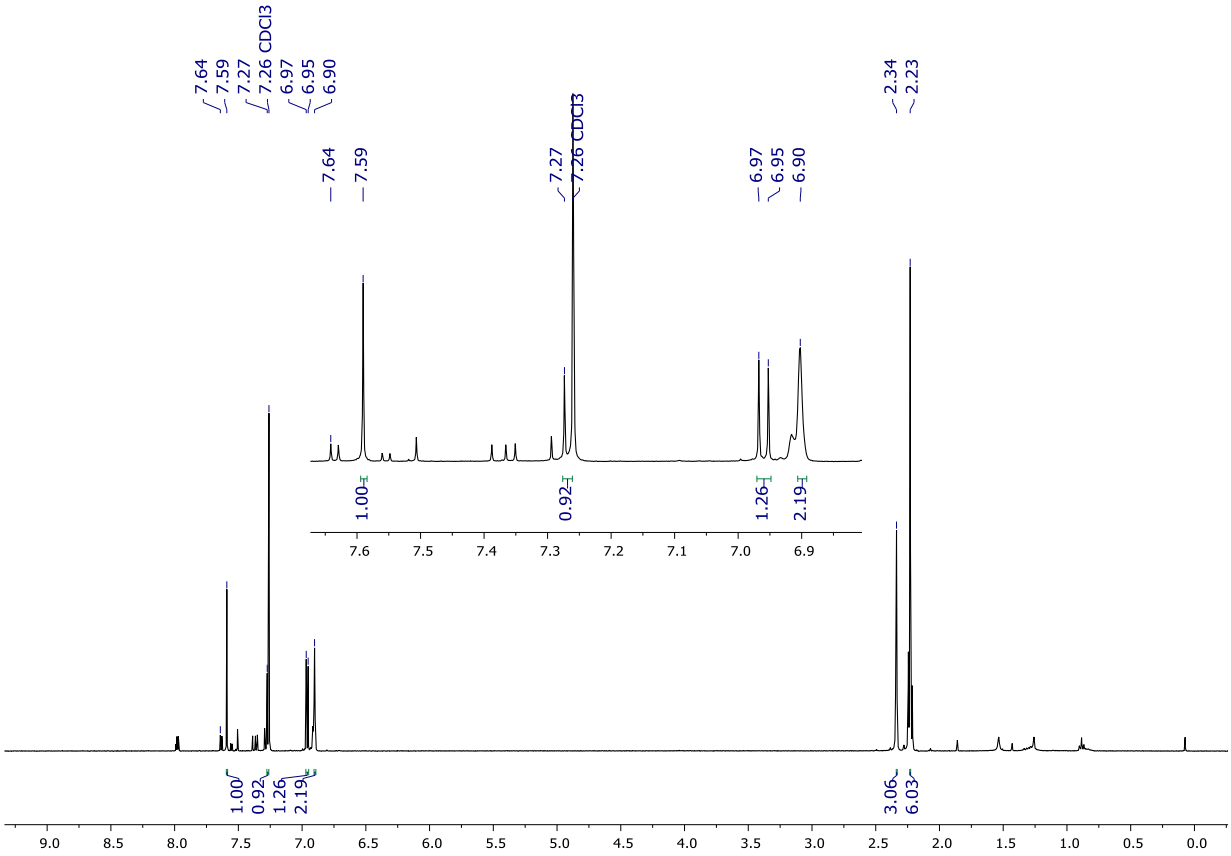


Figure R1: ^{1}H NMR spectrum of **13** ($CDCl_3$, 400 MHz).

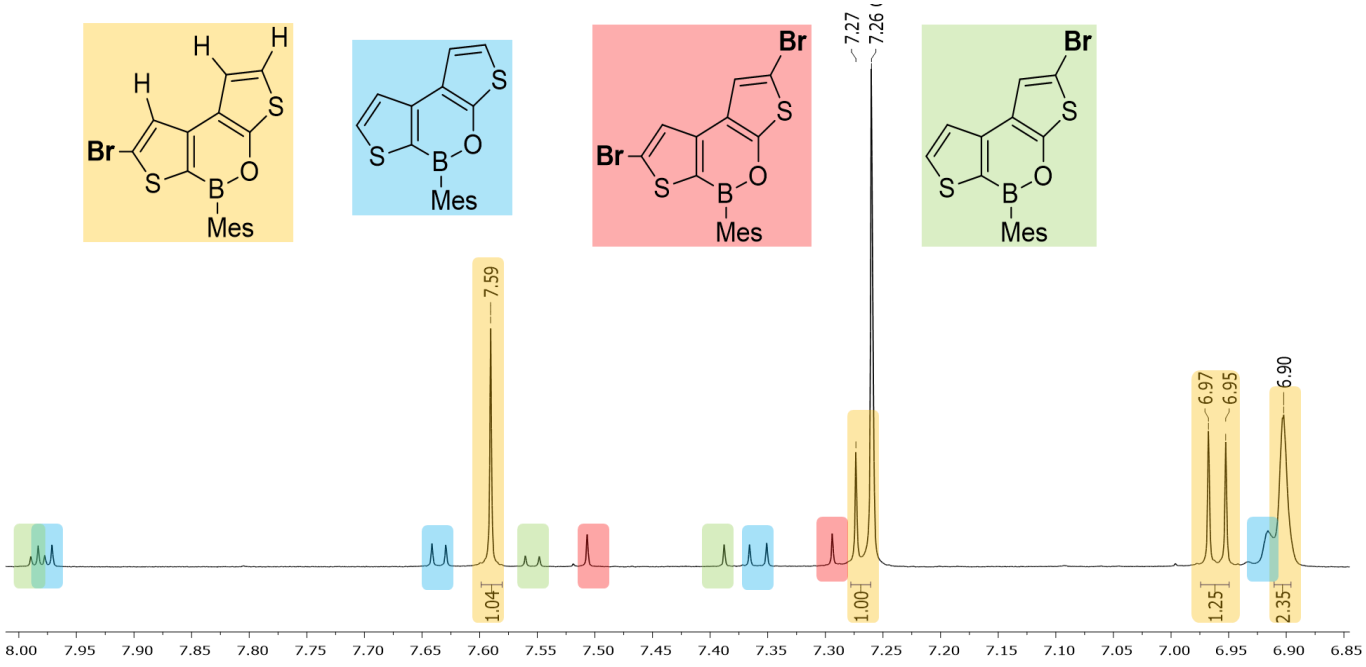

Figure R2: ^{1}H NMR spectrum of **13,** zoom of the aromatic region ($CDCl_3$, 400 MHz).

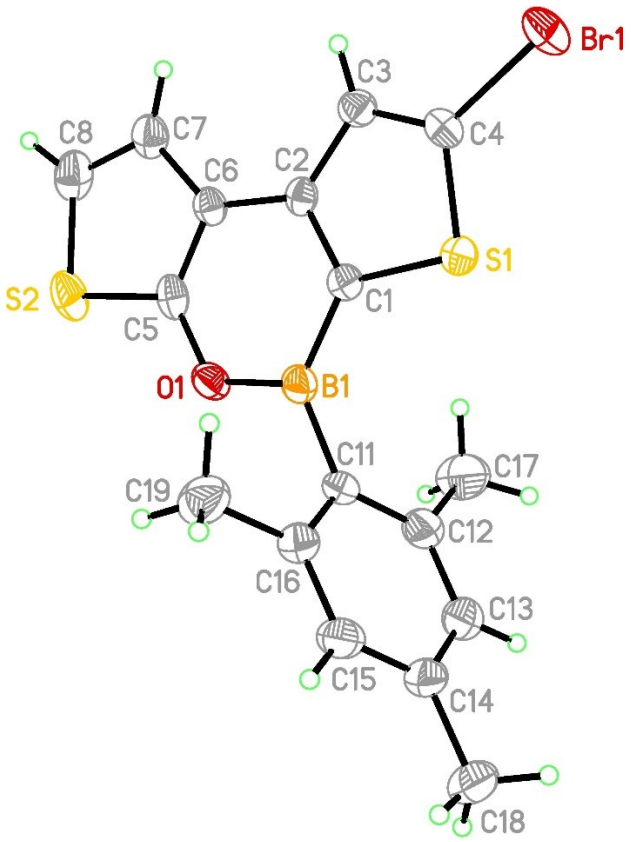

Figure R3: Molecular structure of **13** in the solid state. Displacement ellipsoids are drawn at the 50% probability level.

Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures of the present section have been not explicited.

*Characterization data of **14***:

HRMS (MALDI): Calculated *m/z* for $[C_{17}H_{13}BBr_2O]^+$: 467.8842; found: 467.8837.

^{1}H NMR (500.2 MHz, Chloroform-*d*) δ 7.51 (s, 1H), 7.29 (s, 1H), 6.90 (s, 2H), 2.33 (s, 3H), 2.21 (s, 6H).

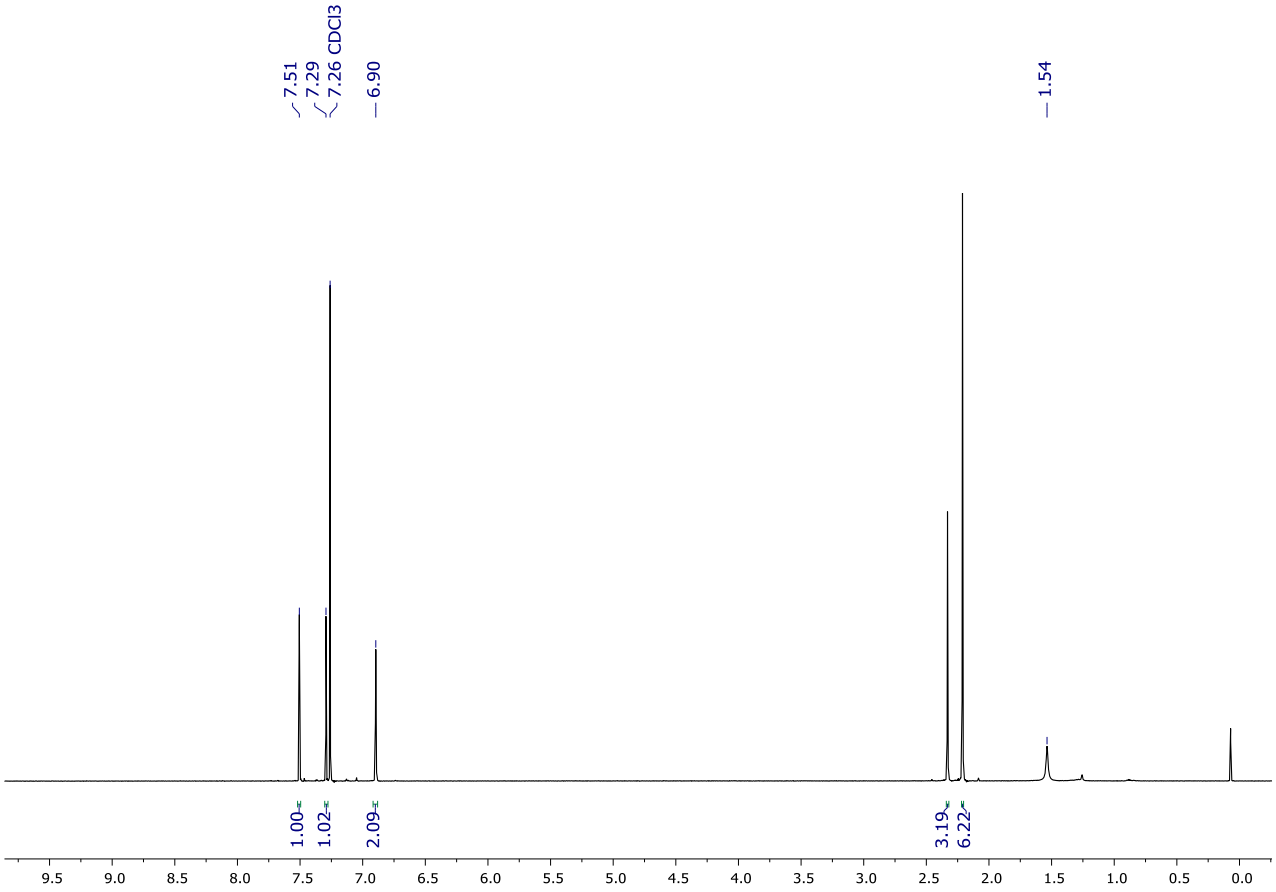

Figure R4: ^{1}H NMR spectrum of **14** ($CDCl_3$, 500 MHz).

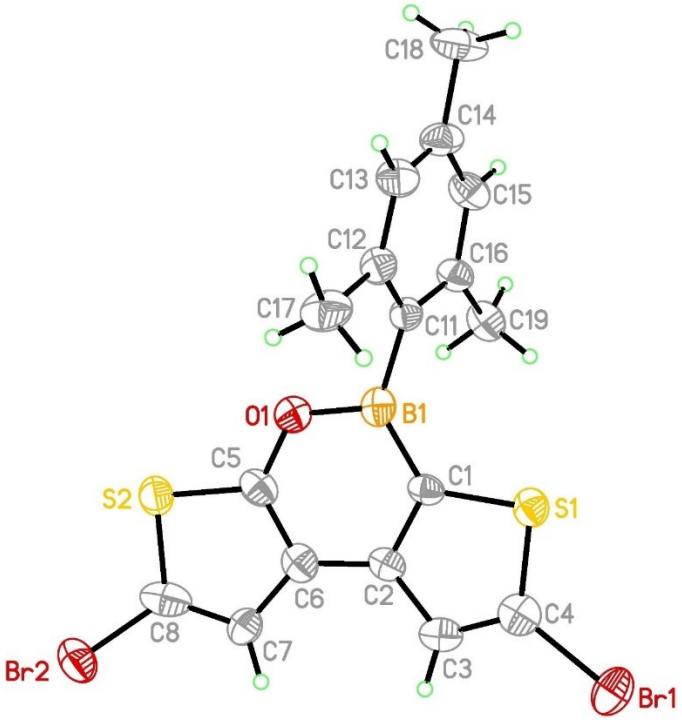

Figure R5: Molecular structure of **14** in the solid state. Displacement ellipsoids are drawn at the 50% probability level.

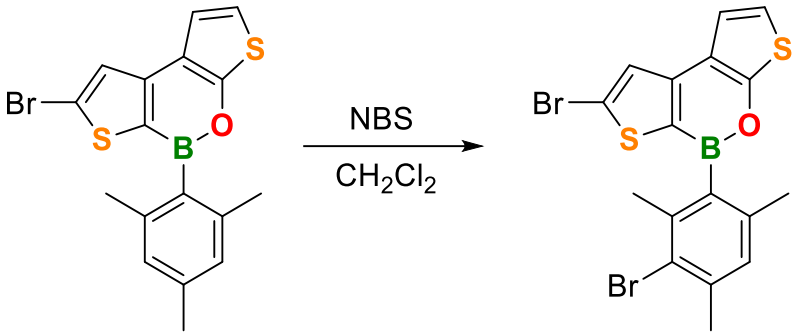
Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures of the present section have been not explicited.

13.2 Synthesis of 9



8 **9**

42%

A 50mL flask was charged with **8** (40 mg, 0.10 mmol) and CH_2Cl_2 (2.5 mL). The resulting solution was treated with NBS (22 mg, 0.12 mmol, 1.5 eq.) and stirred at room temperature for 23 h. The reaction progress was checked by TLC. After 23 h, TLC showed complete conversion of the starting material and thus the reaction was stopped.

The solvent was removed under reduced pressure and the residue was purified *via* column chromatography (8 cm silica gel, d = 2 cm; c-hexane/CH_2Cl_2 (9:1)). **9** was thereby obtained as an off-white solid (20 mg, 0.043 mmol, 42%). ^{1}H NMR showed the presence of traces of residual **8** starting material.

Single crystals of **9** suitable for X-ray analysis were obtained by slow evaporation of a saturated solution of **9** in *n*-hexane/CH_2Cl_2.

Characterization data of ***9***:

^{1}H NMR (400 MHz, $CDCl_3$): δ = 8.00 (d, ^3J(H,H)= 4.8 Hz, 1H), 7.56 (d, ^3J(H,H) = 4.8 Hz, 1H), 7.39 (s, 1H), 6.99 (s, 2H), 2.45 (s, 3H), 2.32 (s, 3H), 2.15 (s, 3H).

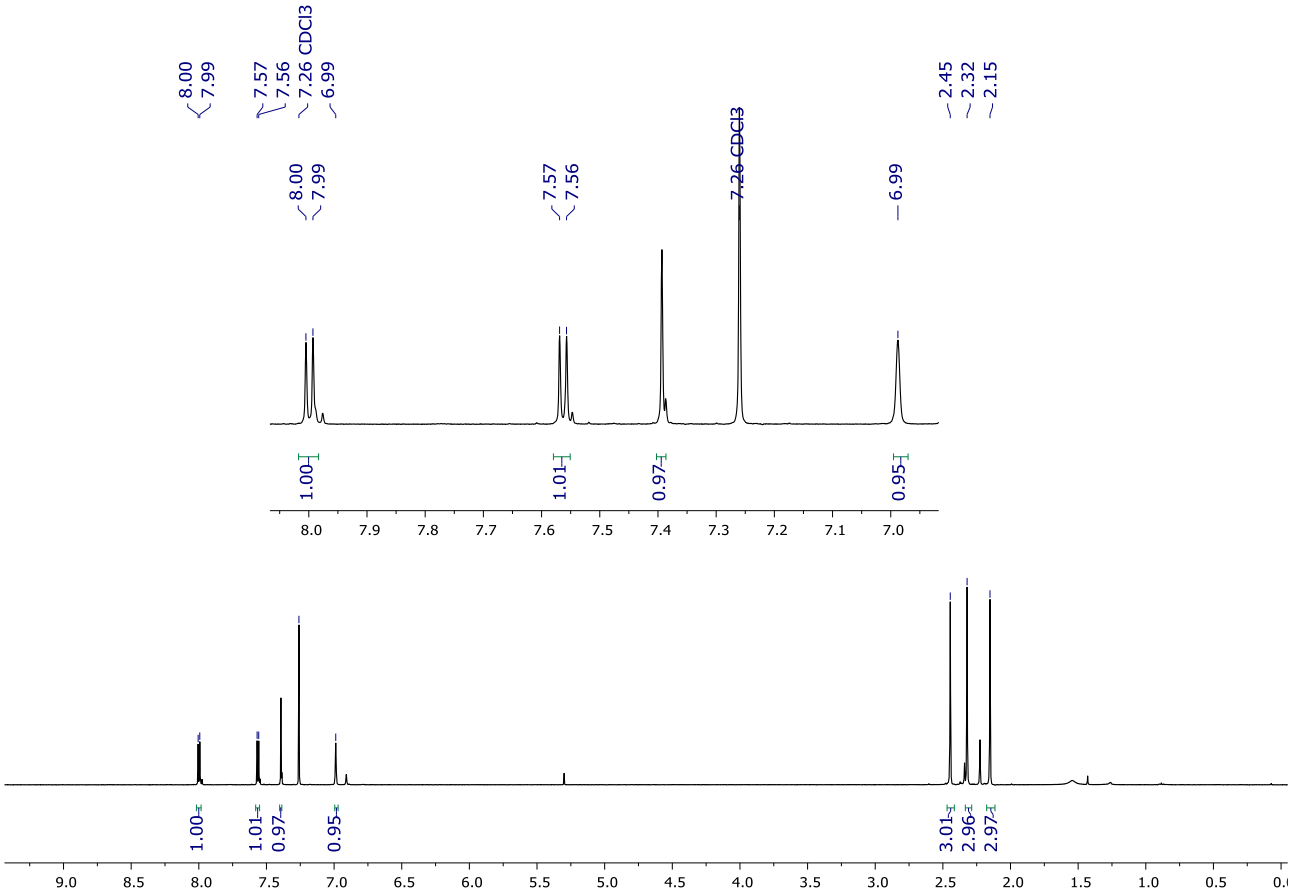


Figure R6: ^{1}H NMR spectrum of **9** ($CDCl_3$, 400 MHz).

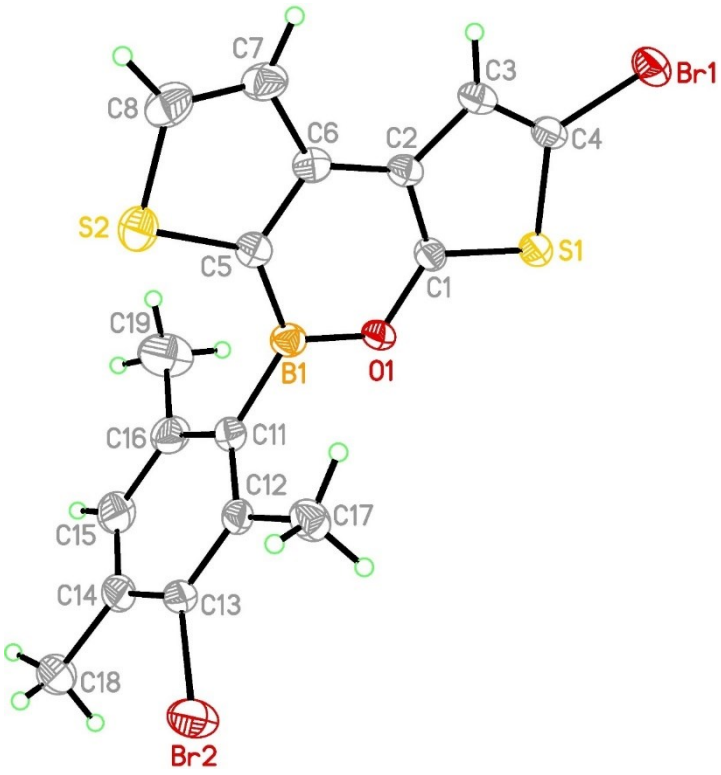

Figure R7: Molecular structure of **9** in the solid state. Displacement ellipsoids are drawn at the 50% probability level.
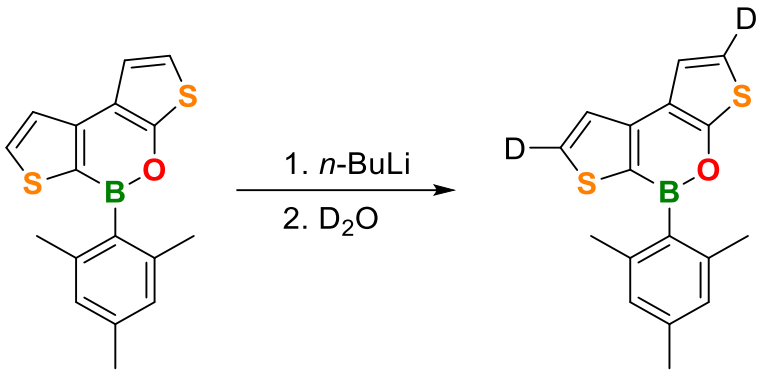
Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures of the present section have been not explicited.

13.3 Synthesis of 12



5 **12**

76%

A Schlenk flask was charged with **5** (30 mg, 0.10 mmol, 1 eq.) and THF (3 mL) and then cooled to –78 °C. The resulting solution was treated with *n*-BuLi (1.35 M in hexanes; 100 µL, 0.13 mmol, 1.3 eq.).
The reaction mixture thus obtained was stirred at –78 °C for 15 min and D_2O (300 µL, 17.72 mmol, 175 eq.) was added in one portion and the resulting orange mixture was allowed to warm up to room temperature.
THF was removed under reduced pressure, the crude material was taken up with CH_2Cl_2 (15 mL) and washed with water (5 mL). The organic phases were dried over Na_2SO_4 and the solvent was removed under reduced pressure. **12** was thereby obtained as a brown solid (24 mg, 0.076 mmol, 76%).

*Characterization data of **12***:

^{1}H NMR (300 MHz, $CDCl_3$): δ = 7.63 (s, 1H), 7.36 (s, 1H), 6.92 (s, 2H), 2.35 (s, 3H), 2.24 (s, 6H).

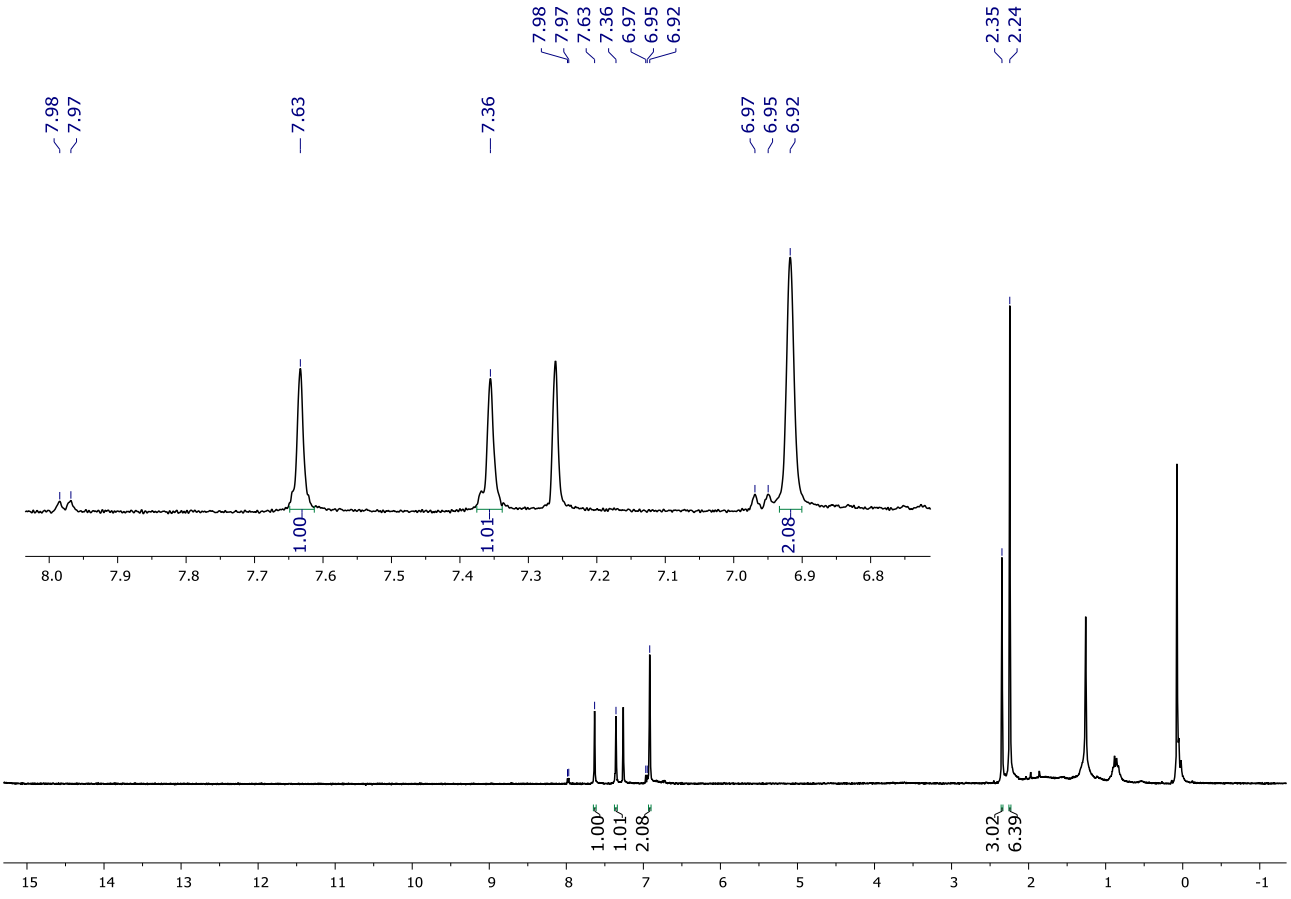


Figure R8: ^{1}H NMR spectrum of **12** ($CDCl_3$, 300 MHz).

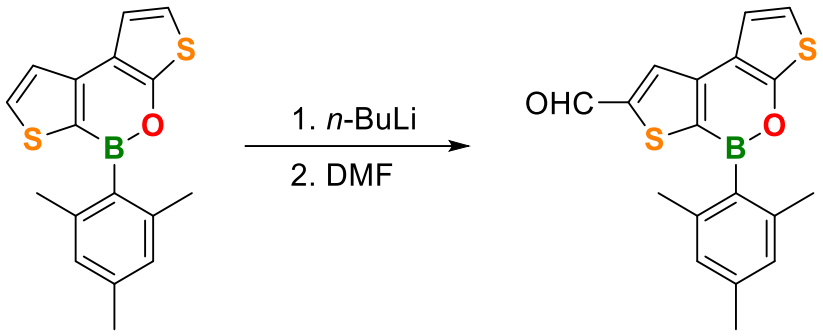
13.4 Synthesis of 11



5 **11**

28%

A flame-dried 50 mL Schlenk flask was charged with **5** (100 mg, 0.32 mmol) and THF (5 mL). The colorless solution thus obtained was cooled to –78 °C and, *n*-BuLi (1.40 M in hexanes; 240 µL, 0.34 mmol, 1.05 eq.) was added dropwise during 2 min. The resulting yellow reaction mixture was stirred for 15 min at the same temperature.

DMF (130 µL, 1.61 mmol, 5 eq.) was added and the resulting mixture was stirred at –78 °C for 30 min.

The reaction mixture was therefore allowed to warm up to room temperature and quenched with a NH_4Cl saturated solution (0.5 mL), giving a red mixture. The THF was removed and the residue was taken up with CH_2Cl_2. NH_4Cl sat. aqueous solution (20 mL) was addedd and, after separation of the two layers, the aqueous phase was extracted with CH_2Cl_2 (3×15 mL). The combined organic phases were dried over Na_2SO_4 and filtered. The solvent was removed and the residue was purified *via* column chromatography (*n*-hexane/CH_2Cl_2 (5:4)). **11** was thereby obtained as an orange solid (30 mg, 0.09 mmol, 28%).

Starting **5** (8 mg, 0.025 mmol, 8%),besides a small amount of unknown products was also recovered.

Single crystals of **11** suitable for X-ray analysis were obtained by slow evaporation of a saturated solution of **11** in *n*-hexane/CH_2Cl_2.

*Characterization data of **11**:*

^{1}H NMR (400 MHz, $CDCl_3$): δ = 10.17 (s, 1H), 8.24 (s, 1H), 7.38 (d, ^3J (H,H)= 6.0 Hz, 1H), 7.03 (d, ^3J(H,H) = 6.0 Hz, 1H), 6.92 (s, 2H), 2.35 (s, 3H), 2.23 (s, 6H).

HRMS (EI+): Calculated *m/z* for $[C_{18}H_{15}BO_2S_2]^+$: 388.0606; found: 388.0573.

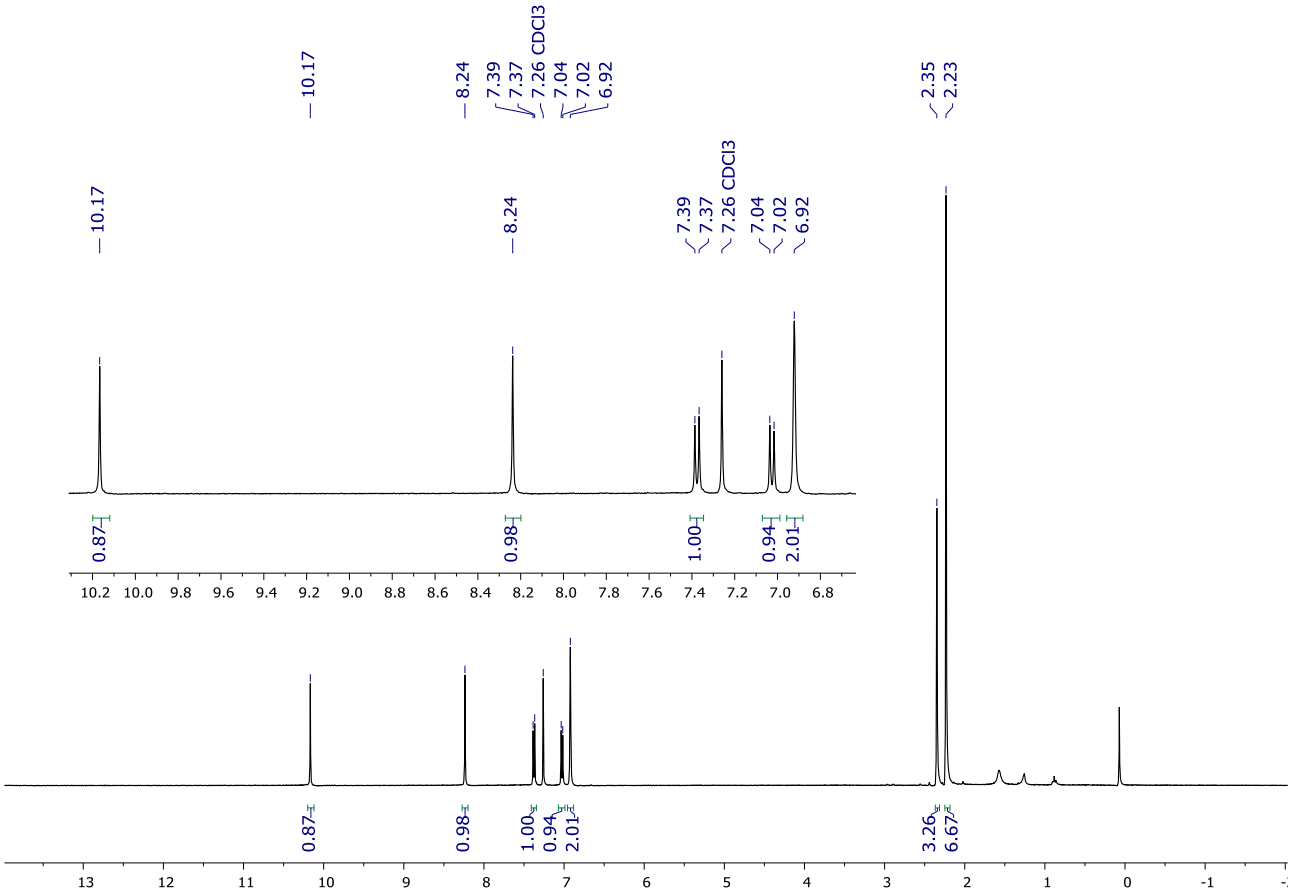


Figure R9: ^{1}H NMR spectrum of **11** ($CDCl_3$, 300 MHz).

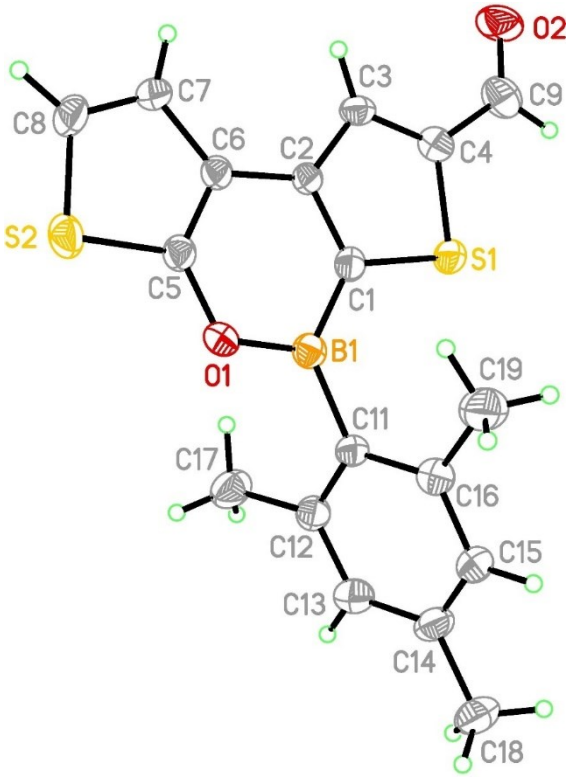

Figure R10: Molecular structure of **11** in the solid state. Displacement ellipsoids are drawn at the 50% probability level.
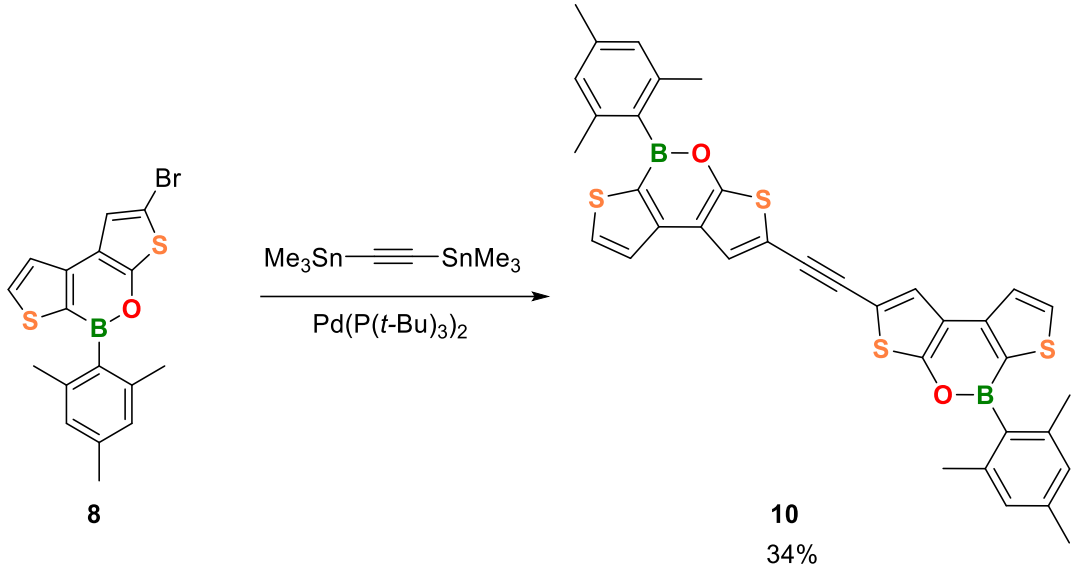
Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures of the present section have been not explicited.

13.5 Synthesis of 10



8 **10**
34%

A flame-dried 250 mL J-Young round-bottom flask was charged with **5** (540 mg, 1.39 mmol) and evacuated for 30 min. Toluene (72 mL), *trans*-1,2-bis(Me_3Sn)acetylene (244 mg, 0.69 mmol, 0.50 eq.), and $Pd(P(t\text{-}Bu)_3)_2$ (71 mg, 0.139 mmol, 0.1 eq.) were added, the Young-tap was closed, and the red mixture was heated with stirring to 80 °C for 15 h. After cooling to room temperature, the solvent was removed under reduced pressure, and the residue was purified by column chromatography (13 cm silica gel, $d = 3.0$ cm, *c*-hexane/CH_2Cl_2 (5:1)). The fractions containing **10** were combined and evaporated to dryness. The dark red residue was treated with *n*-hexane and the resulting suspension was filtered. **10** was thereby isolated as a yellow solid (151 mg, 0.24 mmol, 34%). Single crystals suitable of **10** suitable for X-ray crystallography were grown by slow evaporation of saturated solution of **10** in $CDCl_3$.

*Characterization data of **10***:

HRMS (MALDI): Calculated *m/z* for $[C_{36}H_{28}B_2O_2S_4]^+$: 642.1161; found: 642.1153.

^{1}H NMR (500 MHz, $CDCl_3$): δ = 8.01 (d, ^3J(H,H) = 4.8 Hz, 1H), 7.62 (d, ^3J(H,H)= 4.8 Hz, 1H), 7.59 (s, 1H), 6.93 (s, 2H), 2.35 (s, 3H), 2.26 (s, 6H).

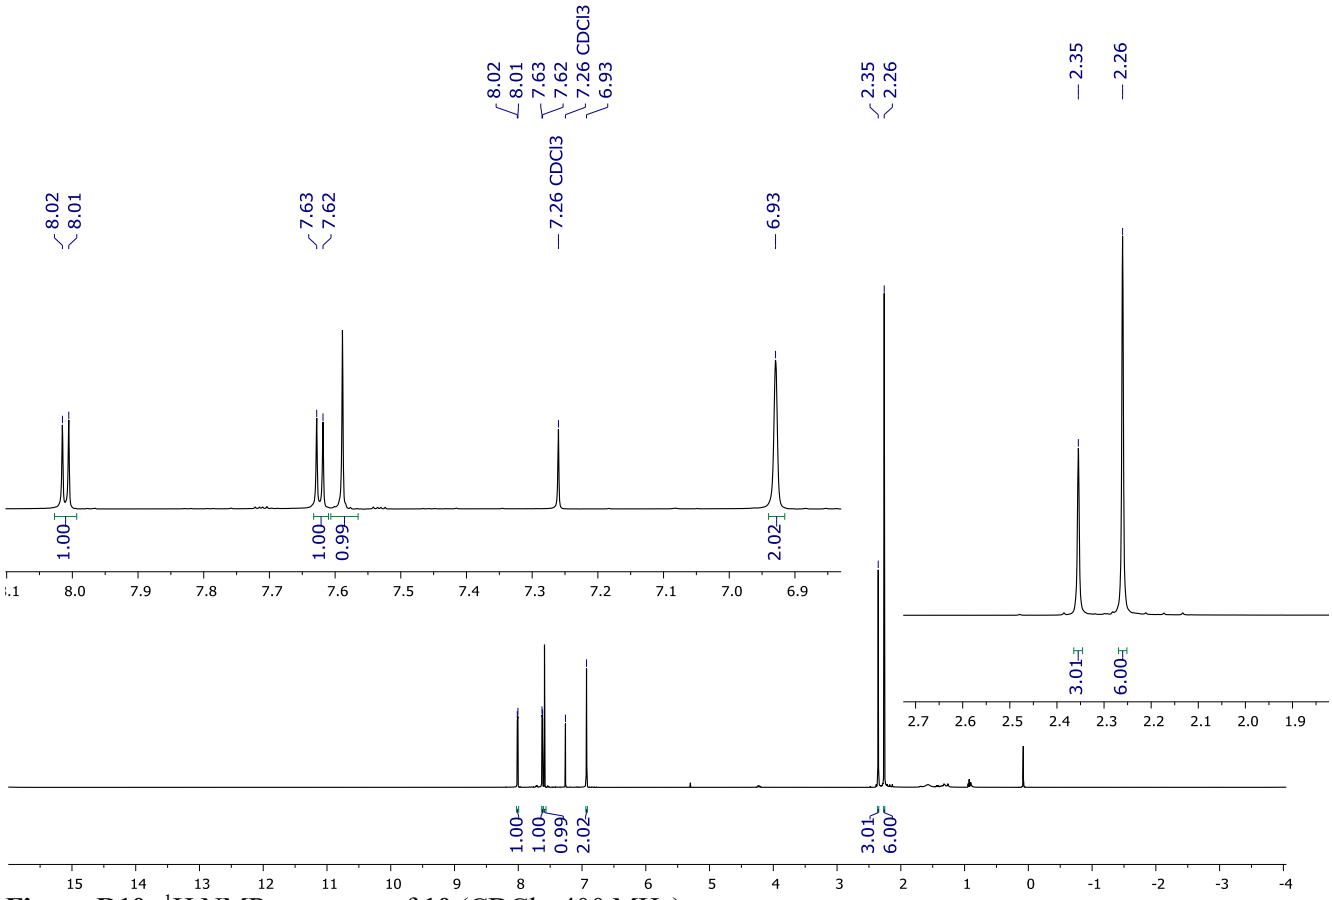


Figure R10: ^{1}H NMR spectrum of **10** ($CDCl_3$, 400 MHz).

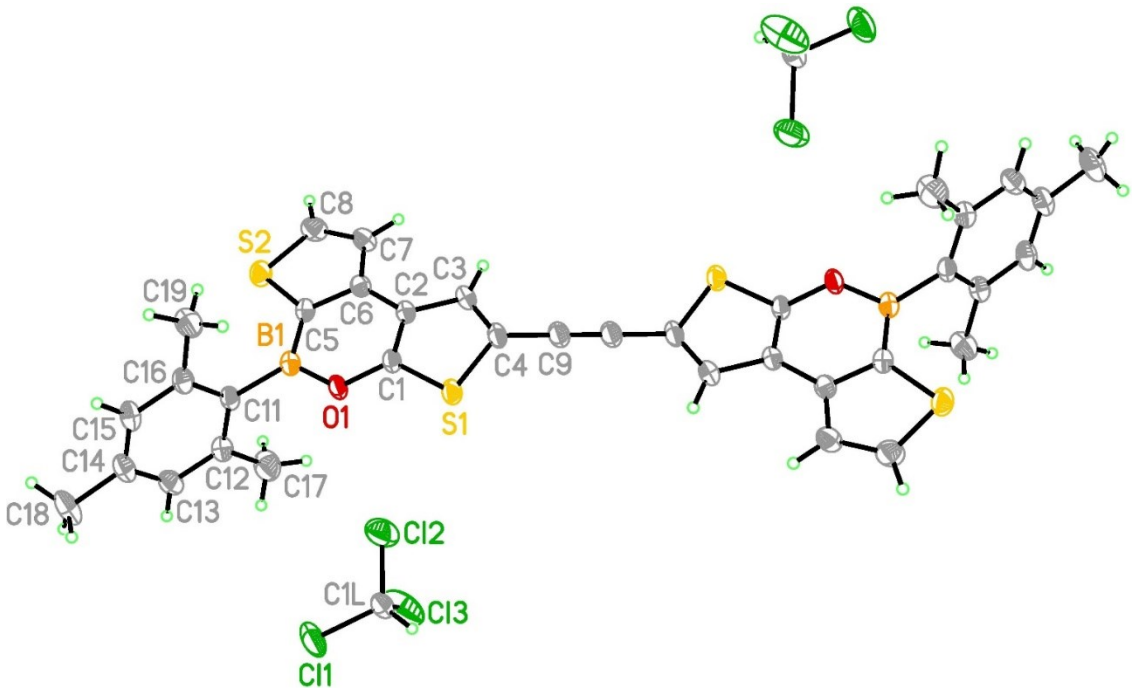

Figure R11: Molecular structure of **10** in the solid state. Displacement ellipsoids are drawn at the 50% probability level.
Note: bond lengths (A), bond angles (°), and torsion angles (°) for crystal structures of the present section have been not explicited.
