Boahtteáiggi sámi boazodoalu suvdilis hálddašeapmi vásiha stuora hástalusaid čatnon Ártisa jođánis rievdamii. Sámi boazoealáhus ovddasta ealáhusa ja eallinvuogi mii lea vuodđuduvvon práksisii ja máhttui mii lea ovdánan guhkit áigge vásáhusaid bokte, go eallá garra dálkkiid siste ja hirbmat rievdadeaddji dilálašvuodain Ártalaš birrasis. Dát dutkanprošeakta lea Sámi allaskuvlla mihtuid ja strategiija vuođul, ja addá máhttovuodu boahtteáiggi boazoealáhus masterprográmmii fágaraštildeddji lahkoneamiin.

Prošeakta galgá dutkat árbevirolaš ja kultuvrralaš máhtu Sámi boazoealáhusas ja vejolašvuodaid mat leat árbevirolaš máhtus ja dieđalašmáhtus go fuomášupmi lea rievdan ja seanadan heiveheapmi, ja geahččala čilget vuostálasvuoda dán guokte máhttomáilmmis mat leat oktiičatnon ja fátmmastit iešguđet lahkoneamiid boazoealáhusa ja boazobargguid vuodđoosiide.

RIEVDAN háliida buktit ođđa máhtu ja ipmárdusa ja dáinna lágiin lasihit suvdilisvuoda boazoealáhusas ja boazobargguin, ja loahpas nannet seanadeami gaskal min máhttomáilmmiid.

Rievdan

The future sustainable governance of Sámi reindeer husbandry will face major challenges related to rapid change in the Arctic. Sámi reindeer husbandry represents a livelihood and way of life based on practices and knowledge developed through long-term experiences in living under harsh and highly variable conditions in the Arctic environment. This research project is based on and according to goals and strategies set by Sami University of Applied Sciences and will provide a knowledge base for a future Master's degree Programme in Reindeer Husbandry Studies using a multidisciplinary approach.

The project will research traditional cultural capabilities in Sámi reindeer husbandry and the opportunities embedded in traditional knowledge and scientific knowledge with a focus on adaptation to change and reconciliation, and will attempt to explain the tensions between the two interlinked spheres of knowledge involving different approaches to basic aspects of reindeer husbandry and herding.

RIEVDAN hopes to contribute to new knowledge and understanding in order to increase sustainability in reindeer husbandry and herding, and finally strengthen the reconciliation between the interlinked and conflicted spheres of knowledge.

WAYS OF KNOWING ABOUT SÁMI REINDEER HERDER'S FOOD

BOAZOSÁPMELAČČAID BIEPMUID MÁHTTOVUOGIT

This research has documented Sámi reindeer herders' traditional knowledge about food system in Guovdageaidnu, Northern Norway.

The work shows there are different ways of knowing in Sámi reindeer herders' food system, which can be shown through language and holistic understanding.

Such knowledge is still alive in Sámi homes where herders utilize the whole reindeer in a sustainable way.

- Main finding from this research is that Sámi reindeer herders have a unique and complex traditional knowledge system of their Indigenous food resources based on holistic understanding and practices developed through generations.
- The quality assessment starts already in the pastures where each reindeer is observed and by careful selection chosen for slaughter.
- These assessments continue until the meat is prepared and eaten.
- Such a selection process and the use of slaughtering method with specialized tenderization procedure in cold conditions with the skin kept on the carcass, provides tender, high-quality meat and blood and hygienic reindeer meat.
- Sámi reindeer herders' advanced and systematic knowledge and ways to assess fat degree provide information about the reindeer meat quality through concepts.
- The ways of slaughtering and butchering determine the type of food the family consumes.
- Conservation methods, based on good practice of traditional knowledge, are used to preserve the meat.
- Sámi reindeer herders food sovereignty can be strengthened through reconciliation of reindeer herders' traditional knowledge with scientific knowledge.

Multidisciplinary study

Methods used:

- interviews
- participating observations
- filming and sound recording
- photographs
- literature review and archival studies review
- Sámi linguistics with concept analysis
- co-production of knowledge
- pH- and temperature measuring

The different methods used gives a rich data material and a possibility to assess the research from different angles.

Dutkanbargu lea dokumenteren Guovdageainnu boazosápmelaččaid árbevirolaš máhtu biepmu birra.

Bargu čájeha ahte boazosápmelaččain leat iešguđetlágán máhtut biepmuid birra maid ovdanbuktet giela ja holisttalaš ipmárdusa bokte.

Máhttu lea ain anus sámi ruovttuin gos bastevaš vuigiin ávkkástallet olles bohcco.

- Dutkamuša váldofoadus lea ahte boazosápmelaččain lea earenoamáš ja ollislaš árbevirolaš máhtovuogádat biepmuset birra mii lea buolvvaid čađa ovdánahttojuvvon.
- Dievas ealo luhte juo álget árvoštallet bohccuid go válljejit niestebohcco.
- Bierrguid ja buiddiid árvoštallan bistá dassáži lea ráhkadan biepmu bierrgus ja borran dan.
- Árbevirolaš njuovvamin ja bakkahemiin beassá bearaš borrat buori ja dipma bierrgu mii lea maid ráinnas. Bierrgu šaddá buorre ja varra álbmái.
- Dárkilis ja systemáhtalaš máhttu ja diehtu árvoštallet bohccobierrgu kvalitehta ovdanbuktet doahpagaidda čađa go árvoštallet buoidehivvodaga.
- Njuovvan- ja rihtenvuohki mearrida makkár biepmu bearaš borra.
- Riibadanvuogit leat árbevirolaš vuogit vurket bierrguid.
- Boazosápmelaččaid biepmosuverenitehta sáhtta buoridit go ovttaštattá sin árbevirolaš máhtu ja dieđalaš máhtu.

Fágaidrasttildeaddji bargu

Metodat adnon:

- Jearahallamat
- oassálasti áicamat
- filbmen ja jiena bádden
- govat
- lohkaamusaidd- ja arkiivadieđuid analyseren
- doabaanalysa
- máhtuid ovttasbuvttadeapmi
- pH-árvvu ja temperatuvrra mihtideapmi

Go atná mánggalágán metodaid čohkket diehtovuodu, de šaddet dutkamii bohtosat mat ovdanbuktet iešguđetlágán dieđuid ja beliid áššis.

Results

Herders' planning, decision-making and practices are based knowledge on the 8 seasons, different daily or weekly cyclizes, and 9 herding periods in a reindeer year. These contain different sub-cycles that are a part of a larger system based on the year, the lunar month and day/night.

Cycles; the biological cycles of reindeer, like rutting season, calving season, dropped or cast antlers and moulting fur; sexual behavioral cycles; cycles relative to climate and snow, cycles of extreme years (goavvi) and cycles that include reindeer herding periods throughout the year.

- Aspects of herding in winter are based on experience, knowledge, and the ability to observe (read nature) and calculate how to manage the herd within the framework of a traditional knowledge base. These primarily consists of traditional continuous observation, judgment of the herd, combination of relevant factors in every situation, and mental monitoring of variability and changes in time and space in the use of grazing land and grazing conditions.
- This also consists of anticipating situations and developments in near and more distant futures and make plans and decisions to sustain the herd based on weather conditions related to special weeks and days of the year that can provide information about what to expect are crucial
- This knowledge is articulated and structured linguistically (reindeer herding language) with categories that are passed on to future generations. These includes subsystems linked to different types of science and knowledge such as hydrology, meteorology, biology, topography, animal welfare, land management, adaptation strategies to climatic conditions, etc.

This study is a multidisciplinary study, using methods for communicating with herders, and co-production of knowledge between reindeer herders and scientists

Reindeer herding strategies and practices are highly complicated and systematic enterprises containing different types of knowledge on how the biological and gender-based behavioral aspects of reindeer and their movement in time and space are connected to climate, temperature, and snow metamorphism.

Understanding the field of reindeer herding relies on various categories of thought, namely knowledge of reindeer, environment, landscape, weather, and specific knowledge of the mutual relations in these subjects, and characteristics i.e., specific differences in reindeer, snow, and weather, and on landscapes.

LEARNING BY HERDING

- Transmission of reindeer herding knowledge and skills

GUOÐOHETTIIN OAHPPAT

- Fievrredit boazodoallomáhtu ja gálggaid

The development of detailed practical reindeer herding knowledge and the accumulation of the learner's personal wisdom are crucial to ensure sustainability and resilience in reindeer herding and reindeer husbandry.

Learning by herding and the process of transferring reindeer husbandry knowledge is a lifelong process.

Hukset dárkellis praktihkalaš guodohanmáhtu ja hukset penšuvnnalaš jierpmálašvuoda lea mearrideaddji sihkekarastit ceavzilis ja nanu guodoheami ja boazoealáhusa.

Guodohettiin oahppan ja dan proseassat fievrredit boazodoallomáhtu lea olles eallima proseassa

Learning by herding represents an indigenous learning system and process of learning traditional knowledge and skills.

The characteristics of this learning and transfer process:

- Reindeer husbandry parents organize and facilitate learning strategies for how the children are to achieve reindeer husbandry competence best
- Reindeer herding competence is complex and deals with many different subject areas, which together constitute the body of knowledge necessary to function as a skilled reindeer herder
- Life-long learning with learning levels
- Multiple and systematic learning methods with concretization
- Includes most of the elements indicative of traditional knowledge systems like being informal, intuitive, oral, practical, experimental, inclusive, and holistic
- Multidisciplinary content
- Reindeer herding language is significant in learning outcomes
- Different learning arenas related to various tasks throughout the year
- The responsibility of transmission of knowledge is added to the family, the household, siida members, and other reindeer herders
- Feedback and assessment from tutors /teachers are parts of the learning process

Reindeer herders have developed extensive knowledge of reindeer herding and reindeer husbandry and the environment sound surroundings. A quote from the early 1700s explains that the knowledge transmission among Sami people does not depend on formal school education but traditional knowledge, which provides learning in many disciplines in line with science, e.g., glaciology, topography, place name, weather, animal welfare, land management, the

Western school knowledge transmission	Reindeer herding knowledge transmission
Formalized education	The prerequisite for reindeer herders, but not formalized learning
Educational/school-based learning	Learning through work and collaboration
Surface level-processing combined as factual knowledge and including deep level-processing	Deep level-processing, as with in-depth learning, understand and be able to use the knowledge in new situations
Based on written transmission	Based on oral transmission
Special languages related to themes	Learning is rooted in specialized language related to tasks
Themed	Holistic

behaviour of reindeer, botany, navigation, astrology, mathematics, economics, strategy thinking a panning, cosmology, and values.

New generations are introduced to reindeer herding since childhood, and in this way, they already have early knowledge of the various elements and tasks. The transmission of knowledge thus includes these knowledge bases passed from one generation to the next.

The reindeer herding teachers use multiple methods, thought processes, philosophies, concepts, and experiences in their teaching of reindeer herding children for they need to achieve and apply knowledge about reindeer herding and the natural world.

During the past years, we have been registering changes in our pasturelands connected to climatic conditions. Survival and fertility of reindeer are severely reduced unless we feed the reindeer and maintain stable body weight and nutritional conditions throughout the winter.

The proposed solution is feeding the reindeer during the winter:

1. Secured survival ability
2. Increased fertility from 35% to 90+ %
3. Reindeer become tamer, less patrolling km with snowmobile, reindeer cover less territory during mid-winter as nutrition is abundant.
4. Increased funding from the government to cultivate feed and build access roads to suitable areas for feed production.
5. In Greenland, feed distribution in cultivated areas will fertilize the land as reindeer feces and urine become evenly distributed. This reduces the necessity of buying expensive fertilizers and supports local sustainability.
6. Improved feed harvesting fields by introducing suitable herbs and grasses preferred by reindeer, such as legumes and others. There is already scientific information available from earlier research. We just need to bring the information to the top of the table again.

Cultivation of suitable feed production areas within the reindeer herding districts, as to reduce the cost of transport as well as engaging other relatives and persons from the reindeer herding communities in the synergy of job creation that comes with the reindeer husbandry. Opportunity submerges to reestablish the use of land that was earlier used for dairy cow feed production, with the transition to producing suitable winter feed for reindeer. This implicates research and training of youth in the use of machinery in feed production. This may appear cross-cultural, from pure pastoralism to semi-pastoralism. Yet it is practiced already in reindeer herding in Scandinavia.

Láidehus:

- RESEARCH METHODOLOGY AND ETHICS

- DUTKAMA METODOLOGIIJA JA ETIHKKA

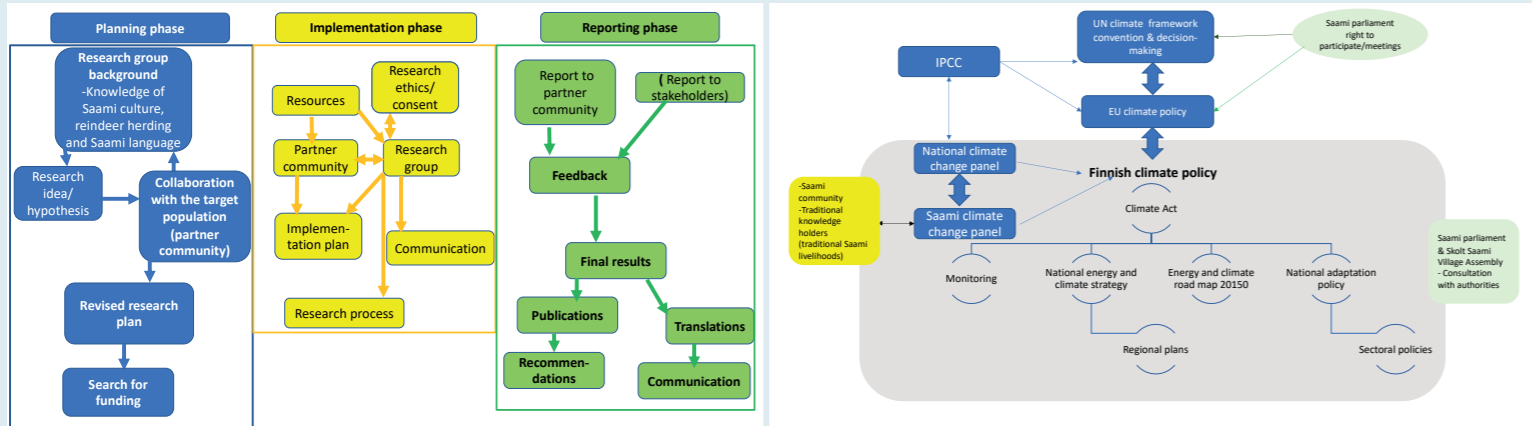

Figure 7: Concept of co-production of knowledge adapted to the workshop results

The research presents the results of the “Feasibility study on co-production of knowledge between researchers and indigenous communities for climate change adaptation” – a project of the International Centre for Reindeer Husbandry (ICR), funded by Nordforsk. The research hypothesis was that with the ethical and systematic co-production of knowledge, the academia and Sámi communities can find ways for culturally sustainable adaptation.

The workshop revealed that reindeer herders want the research to be effective and concrete, finding solutions to the challenges faced by the Sámi together with the Sámi community. Participants considered previous collaborations with academia largely negative. The workshops saw an opportunity for cooperation if herders are treated as equals and the researchers have expertise on Sámi culture, reindeer herding, and knowledge of the Sámi language.

Co-production of knowledge is one of the innovations needed to address climate change. Based on the workshop results, we see the process of knowledge co-production as contextual, ethical, and adaptive. Co-production of knowledge at a local level can be an effective method of climate change mitigation and improvements of legislation and administration. The major challenge is transforming information into State’s actions and decisions. The interaction of researchers and the Sámi community alone is not enough.

The workshops have shown that Sámi are interested in ethical cooperation with academia. The traditional system of project planning, where researchers plan a project, apply for funding, and only in the implementation phase collaborate with the target population is no longer sufficient when studying Sámi reindeer herding culture. The workshops have created a basis for ethical and equitable co-production of knowledge together with the scientific community and highlighted themes that are important for the Sámi community to be studied deeper.

Loss of reindeer grazing land in Finnmark, Norway, and effects on biodiversity: GLOBIO3 AS DECISION SUPPORT TOOL AT ARCTIC LOCAL LEVEL

Guohtuneatnamiid massin Finnmárkkus, Norggas, ja váikkuhusat biologalaš mánggabealatvuodaide: GLOBIO3 VEAHKKENEAVVUN MEARRÁDUSAIDE ÁRKTALAŠ BÁIKKÁLAŠ DÁSIIDE

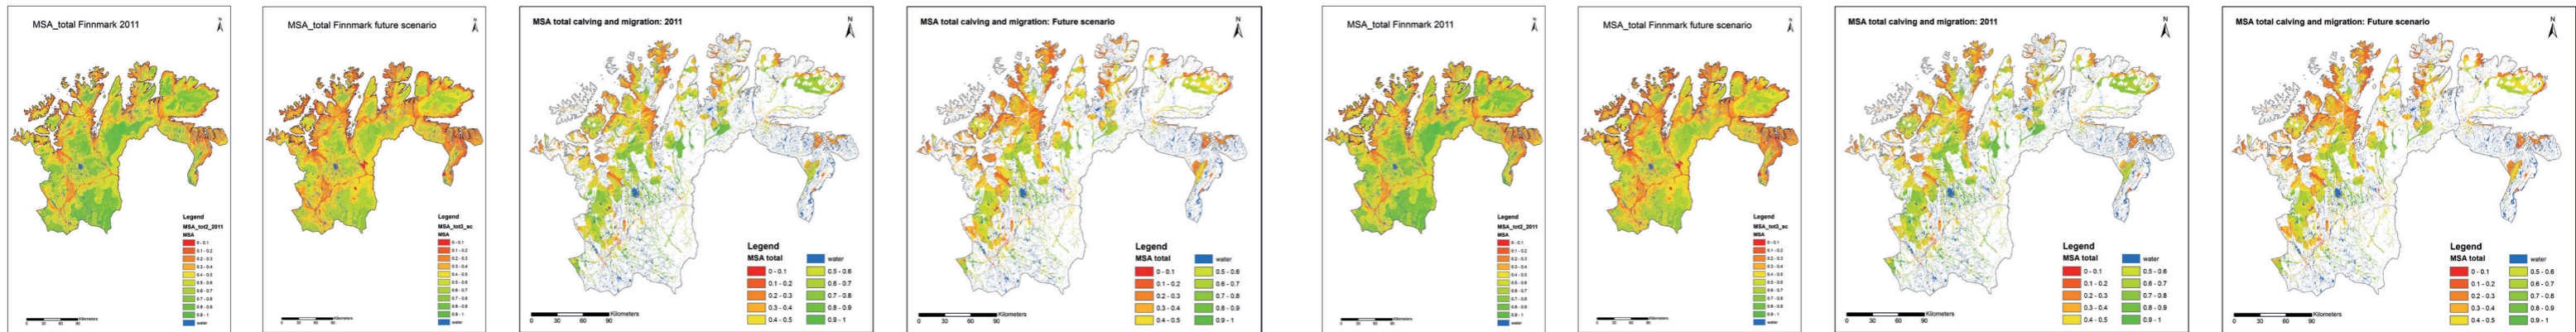

Figure 9.5. MSA in 2011 versus projected MSA in 2030 for Finnmark, with overall reduction from 0.54 to 0.43.

Introduction:

Competing land use and climate change are threats to the pasture land of Sámi reindeer herding. Reindeer pastures are exposed to the development of infrastructure, hydropower, mineral exploration, recreational cabin areas, and wind power. Land use conflicts are exacerbated under climate policy with wind power plants in reindeer herding areas. Analysis of biodiversity loss by the GLOBIO3 model is suggested as a tool for decision support, in consultation with Sámi reindeer owners, taking into account the traditional knowledge of reindeer herding.

Results:

Impacts of climate change and physical developments on Sámi reindeer herding land in Finnmark, Norway, are explored with the GLOBIO3 model, used to assess biodiversity loss. By comparing the situation in 2011 and future scenarios, trends for biodiversity loss and implications of change in biodiversity were discussed with Sámi reindeer owners. Biodiversity loss is measured by a reduction in MSA. The biodiversity loss until 2011 and projected future loss in 2030, due to land use change, infrastructure, fragmentation, and climate change, are shown in maps for Finnmark (Figure 1). According to this analysis the remaining biodiversity in Finnmark in 2011 was 54 per cent of the intact situation, i. e. MSA was 0.54. Results of the study show that with a scenario of + 7 degrees Celsius in annual mean temperature in the Arctic regions, climate change will be the largest contributor to additional biodiversity loss. For reindeer calving grounds, the analysis indicates that in 2011, compared to a situation of intact biodiversity, about 50 percent of the biodiversity of has been lost, and it is expected to be reduced with another 10 percent in the scenario for 2030. Especially the quality of the calving grounds is essential for reindeer herding. A case study of consequences of the Nussir mining project applies a method of impact zones and provides an in-depth study of the landscape, reporting a great concern among reindeer owners that cumulative impacts on pastures may cause reindeer herding in their district to collapse.

Method:

GLOBIO3 is a spatial model, based on map layers in a geographical information system (GIS). For actual and projected future developments of infrastructure until 2030, data were gathered from national sources, regional plans for Finnmark (county governor's office), and municipal zoning plans, with information from all municipalities in Finnmark, in publicly available reports and websites. The GLOBIO3 results were discussed in consultations with Sámi reindeer owners.

COMPARATIVE ANALYSES OF LOCAL HISTORICAL AND FUTURE CLIMATE CONDITIONS IMPORTANT FOR REINDEER HERDING

in Finnmark, Norway and the Yamal Nenets Autonomous Okrug, Russia

BUOHTASTAHTTI GUORAHALLAMAT OVDEŠ JA BOAHTTEVAŠ BÁIKKÁLAŠ DÁLKKÁDAGAIN MAT LEAT DEHÁLAČČAT BOAZODOLLUI

Finnmárkkus, Norggas ja Yamal Nenets Autonoma Okrugas, Ruoššas

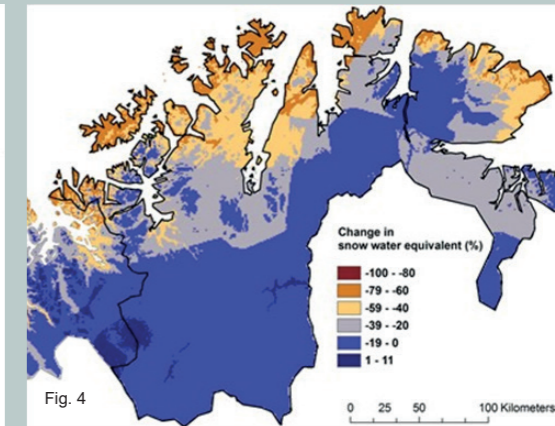

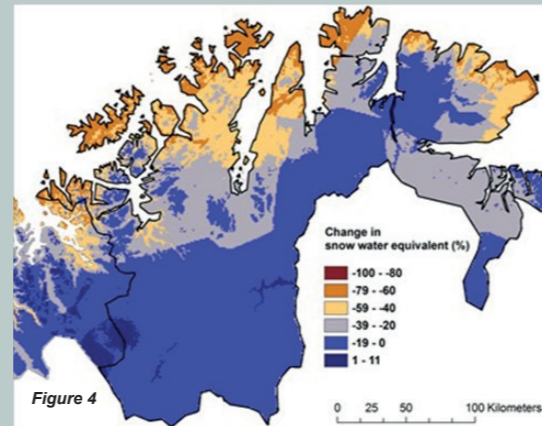

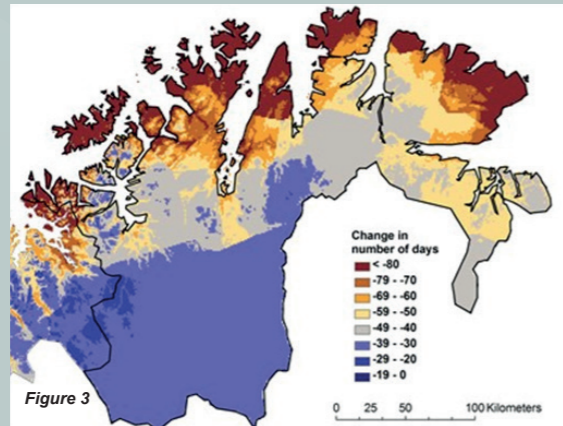

Figure 1 = Extracted from Figure 8.1 in the manuscript (produced by Julia Lutz)

Introduction:

At high latitudes, temperatures and precipitation are projected to increase under global warming. It will affect snow cover, snow amounts, and snow structure, which again will affect reindeer husbandry. In this study, we summarise the current climate change and further projections for the future climate in Finnmark and Yamal Nenets Autonomous Okrug (Figure 1). We also point out knowledge gaps.

Results:

In Finnmark, average winter (Dec-Jan-Feb) temperatures in the period 1961-1990 were about -5 °C at the coast, slightly lower in the fjords, and typically 10 °C lower inland. In the Yamal Nenets Autonomous Okrug (YNAO) average winter temperatures were even lower, ranging from -20 to -25 °C. Temperatures are presently increasing in the area, and towards the end of this century, winter temperatures in the YNAO may, under a medium-high emission scenario, while inland Finnmark may experience conditions that were earlier found along the fjords (Figure 2).

The snow season in 1961-1990 typically lasted from 6 to 8 months in Finnmark. Higher temperatures have already led to a reduced snow season, and model calculations indicate a 3-month reduction along the coast, where it is the shortest today, while the inland snow season may be one month shorter towards the end of the century (Figure 3). Along the coast, a 60% reduction in the winter maximum snow amount is projected towards the end of the century. In the interior of Finnmark, considerably smaller changes are projected in maximum snow amounts, as average precipitation is projected to increase, implicating increased snowfall during winter (Figure 4). Maximum snow amounts in the inland have increased during the last 50 years and may continue to increase slightly at some inland sites, though they will decrease in most places. The maximum snow depth will everywhere occur earlier in the season.

Higher winter temperatures will lead to changes in the snow structure. Compared to herders' reports, the SNOWPACK model successfully reproduces high-density snow layers during the past decades. High-density layers result from rain-on-snow events, or simply warm spells in the snow season, followed by below-zero temperatures. An example is shown from the winter of 1967-1968 (Figure 5 and Figure 6).

ADAPTATION TO CHANGE IN REINDEER HUSBANDRY IN THE REPUBLIC OF SAKHA (Yakutia), Russia

HEIVEHEAPMI BOAZODOALU RIEVDAMII SAKHA (YAKUTIA) Republihkas, Ruoššas

Figure 5. Young reindeer herders in the taiga zone of Southern Yakutia must not be left behind and have equal support as those in the Arctic zone of Yakutia. The past hundred years of transforming reindeer husbandry and collectivization has affected traditional knowledge transfer from one generation to another. The original family-based system was gone after the Indigenous lifestyle became sedentary.

Author of the photo: Yuri Kokovin, Nerjunginskiy District. Young Evenki couple with their child (2018)

Fig. 5 Nuorra boazodoallit Taiga avadagas

Fig. 9

Figure 1. The Republic of Sakha (Yakutia) is located in the north-eastern part of the Eurasian continent and is the largest region of the Russian Federation. While 30% of the Republic's territory belong to the protected areas of Russia, global warming and globalization affect the four regions investigated differently:

Introduction

With 170,000 reindeer and 1,295 herders, Yakutia is a vital region for the reindeer herding economy of five Indigenous peoples – Evenki, Even, Dolgan, Yukaghir and Chukchi. The paper looks at characteristics of reindeer herding and reindeer herding peoples and analyzes historical transformations of reindeer husbandry in Yakutia. The study shows the climate change impact on the reindeer herding development in four reindeer herding regions of Yakutia and also analyzes herders' adaptation to change and challenges caused by predators

Results:

Unfavorable weather phenomena for reindeer herding are extreme low temperatures, high snow cover (height from 1m and more), sharp warming (thaw) in winter, wet snow (during the hotel period), rain (in winter), blizzards, blizzards and abnormal heat in summer. This leads to different consequences, such as the death of reindeer, low business output, the death of young animals, exhaustion from lack of food due to pasture endowment. The corralization of reindeer and other work sometimes takes place one month late, which also has a negative impact on reindeer herding. The condition for the success of traditional reindeer husbandry is the informal economic environment. The number of reindeer has reduced in all regions, but the number of reindeer herders decreased more in the south (taiga) than in the north (tundra). The large population of wolves (3,500) and 14,000-17,000 bears in Yakutia became a challenge to reindeer herding communities. Its is important in engaging Indigenous reindeer herding communities and their traditional knowledge in developing mechanisms for adaptation to climate change and predation issues. The industrial Soviet transformation of reindeer husbandry in Yakutia affected the Indigenous communities. The past hundred years of transforming reindeer husbandry and collectivisation have affected traditional knowledge transfer from one generation to another. The original family-based system was gone after the Indigenous lifestyle became sedentary. There is a need for technical and financial assistance in the development of traditional livelihoods. This educational goal should reside on the best available adaptation knowledge. It is necessary to offer new means of delivering education to practitioners of traditional livelihoods, especially those in remote areas.

Method:

Thus, data from stations in four reindeer herding districts of Yakutia were used to analyze changes and data from Hydrometeorological Center of Russia. Primary data was collected through interviews and discussions with reindeer herders from Yakutia. Statistical reports on reindeer number in Yakutia from 1969-2018 were used to analyze characteristics and statistics of reindeer and reindeer herds in Yakutia.

Figure 9. Soviet reindeer husbandry innovations focused on enhancing meat production, which determined the herd structure with a predominance of the female population. This caused a setback in the traditional relationship between humans and reindeer. The reindeer were no longer a family member but a source of meat production.

Fig. 2

Figure 3. Adaptation to climate change in reindeer husbandry must include protection of grazing land and avoiding blocking of migration routes and calving ground. (Photo: S.D. Mathiesen)

Indigenous reindeer herders in the Circumpolar North are facing climate and socio-economic changes that threaten herders' economic and cultural well-being and transform their operational environment.

We suggest the following strategies in the reindeer herding societies:

Co-production of knowledge, an adaptation strategy in which the academia and Indigenous reindeer herding peoples can apply an ethical and systematic co-production framework.

Adaptation through feeding in winter, when access to forage is restricted. Supplementary feed can improve survival in winter and increase the herd tameness.

Adaptation through changing the herd structure and reducing vulnerability, for example, through castration. Castrated male reindeer do not rut, are calmer, and heavier, and are better at finding feed. The reintroduction of castrates in Norway could be a survival strategy for individual animals and the herd.

Adaptation through the protection of critical grazing land and migration routes. Adaptation involves maintaining nomadic pastoralism and requires increasing competence locally through research and training: it is important to develop courses on the degradation of grazing land. This also involves a paradigm shift in the perception of reindeer herders' Traditional Knowledge, innovative landscape management, and self-determination.

Adaptation through an improved economy. Adaptation is about securing reindeer herders' control over their value chain. It is possible through the creation of local products rather than competing with imported industrial beef and pork. Adaptation to an improved economy should include a strengthening of the family-based reindeer husbandry.

Adaptation strategies' development depends on using foundational scientific perspectives and insights from herders' Traditional Knowledge. Reindeer herding practices are based on generations of accumulated experience, conserved, developed, and adapted to the climatic and administrative systems of the Arctic. Reindeer herders' resilience is about finding ways to strengthen their societies – from within.

Figure 2. Nenets reindeer herding brigade on the Yamal peninsula in early June 2009. Drying bread on the sleds after a long spring migration showcases the importance of a family-based economy. (Photo: S.D. Mathiesen)

in the Republic of Sakha (Yakutia)

TRENDS AND EFFECTS OF CLIMATE CHANGE ON REINDEER HUSBANDRY

DÁLKKÁDAGAI RIEVDAMAT JA VÁIKKUHUSAT BOAZODOALLO-EALÁHUSSII SAKHA (Yakutia) Republihkas

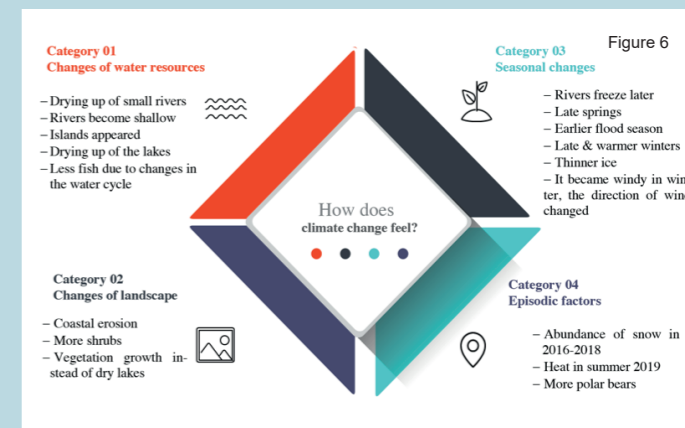

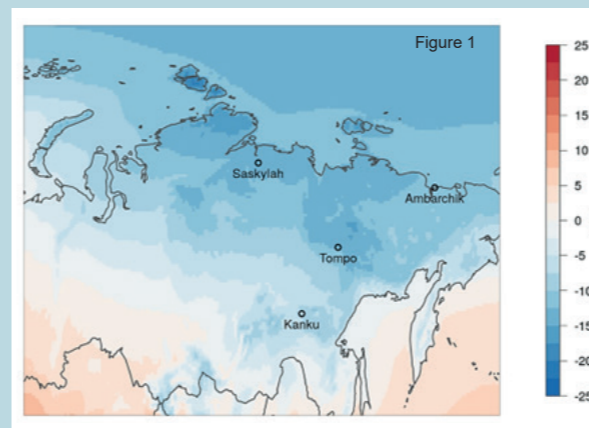

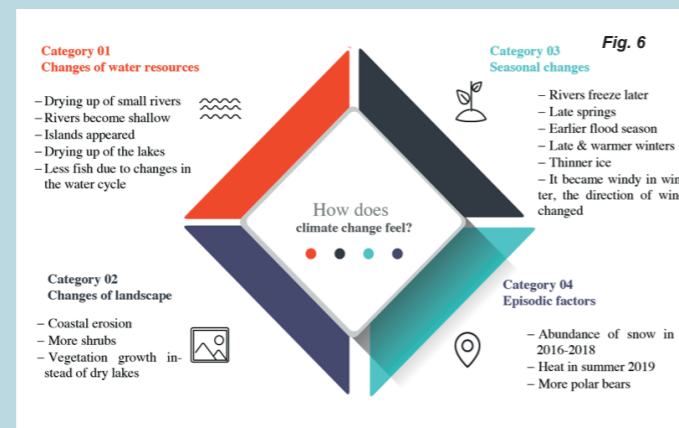

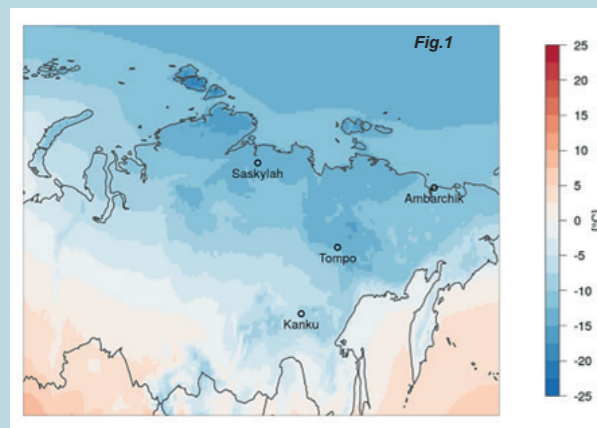

Fig. 1. Map of the four analyzed weather stations in Yakutia. The colours show the mean air temperature averaged over 1980-2019, taken from the ERA5-Land reanalysis data set.

Introduction:

This chapter provides an analysis of:

- 1) meteorological data from four weather stations in the Republic of Sakha (Yakutia) to show the changes in climatic parameters in reindeer husbandry areas;
- 2) temperature projections for the end of the 21st century;
- 3) permafrost condition and number of forest fires occurrences
- 4) indigenous peoples' perception of the impact of climate change on reindeer husbandry;
- 5) financing of resilience development in the Republic.

Results

Snow cover, precipitation and air temperature data from four weather stations: located in four reindeer husbandry areas in the tundra and taiga zones. The general trend of changes in the mean annual and seasonal air temperature and precipitation is positive for all stations. An increase in temperature and alteration in the precipitation regime cause changes in snowpack, its time frame and formation, radiation balance, circulation processes, earlier melting and flooding. The intense thawing of permafrost is accompanied by visible environmental changes such as deforestation, waterlogging and other types of land degradation which leads to additional risks associated with it. A very sharp increase in the number of forest fires in recent years is observed, mostly caused by thunderstorms and human activity. Indigenous peoples in Nizhnekolymsk ulus showed that climate change is most often mentioned issues related to water resources and changes in the natural cycle as factors of change. Financing of resilience development in the Republic, threats and challenges to the development of reindeer husbandry and proposals for overcoming them are discussed.

Method

Daily data from the stations were used to analyze changes. Student's t-test was applied to test trends of the variables for statistical significance at the 5 % level. Empirical Statistical Downscaling techniques were applied for stations to downscale the simulated temperature of 81 global climate model runs.
