

REVISION OF GENERA OF THE DRAGONETS (PISCES: CALLIONYMIDAE)

TETSUJI NAKABO

Department of Fisheries, Faculty of Agriculture, Kyoto University

With Text-figures 1-30 and Tables 1-2

Abstract

The fishes of this family Callionymidae are classified into 19 genera. The twelve genera are redefined and the other seven genera are established as new. A key to the genera is given. The habitat and geographic distribution of each genus are shown. The external characters, especially cephalic lateral lines, lateral lines on the body, body size, body form, body color, eye diameter and secondary sexual characters, are discussed in relation to the systematics of this family.

Introduction

Since Linnaeus (1758) first established the genus *Callionymus*, the classification of this family has been revised several times. Gill (1860) was the first to divide *Callionymus* into three genera, *Callionymus*, *Synchiropus* and *Dactylopus*. The Callionymidae was then studied by Bleeker (1879), Jordan and Fowler (1903), McCulloch (1926), Ninni (1934), Fowler (1914), Schultz and Woods (1948), de Beaufort (1951), Ochiai *et al.* (1955), Schultz (1960), Smith (1963), Mees (1963), Davis (1966), Johnson (1971), Fricke (1980) and Fricke (1981c). Because the callionymids show remarkable sexual dimorphism, the identification of the specimens belonging to this family has constrained much difficulty. Thus, taxonomic studies on the Callionymidae remain insufficient; the genera have not been defined adequately, probably because most investigators did not observe the internal characters of the specimens, and most fishes studied were taken only from their local waters.

In the present study, the confused classification of the Callionymidae is examined and its genera are reviewed on the basis of specimens from almost all part of the world. The habitat and geographic distribution of each genus are also described. The congeneric species are found to occupy roughly the similar kind of habitat, which supports the generic status ecologically. The geographic distribution of each genus tells us one of the aspects in the evolutionary history. Osteologically, each of the genera retained in this study is also distinguished from others (Nakabo, unpublished).

I here propose a new classification for the Callionymidae, which includes 19 genera encompassing 7 new ones, and 139 valid species (Table 1). I could not classify the following 8 species because of insufficient information about them:

Callionymus orientalis Bloch and Schneider (1801), *Callionymus achates* De Vis (1883), *Callionymus caeruleonotatus* Gilbert (1905), *Callionymus inversicoloratus* Seale (1909), *Synchiropus zamboangana* Seale (1909), *Callionymus wilburi* Here (1935), *Callionymus mortenseni* Suwardji (1965) and *Callionymus sausai* Maul (1972). Therefore, I have excluded them from the present list.

Materials and Methods

The specimens used for making the generic revision of the Callionymidae are shown in Table 1. These specimens have been preserved in 10 % formalin, 70 % ethyl alcohol or 40 % isopropyl alcohol and are deposited at the following institutions: Australian Museum, Sydney; Academy of Natural Sciences of Philadelphia; British Museum (Natural History), London; California Academy of Sciences, San Francisco; Department of Biology, Faculty of Sciences, Kochi University; Department of Biology, University of the Ryukyus; Department of Fisheries, Faculty of Agriculture, Kyoto University; Department of Zoology, University Museum, University of Tokyo; Fisheries Research Station, Kyoto University; Far Seas Fisheries Research Laboratory; Laboratory of Marine Zoology, Faculty of Fisheries, Hokkaido University; Marine Science Museum, Tokai University; Museum of Tokyo University of Fisheries; Miyazaki University; Naturhistorisches Museum Wien; Department of Zoology, Natural Science Museum, Tokyo; Queensland Museum, Brisbane; J.L.B. Smith Institute of Ichthyology, Rhodes University, Grahamstown; Sammlung

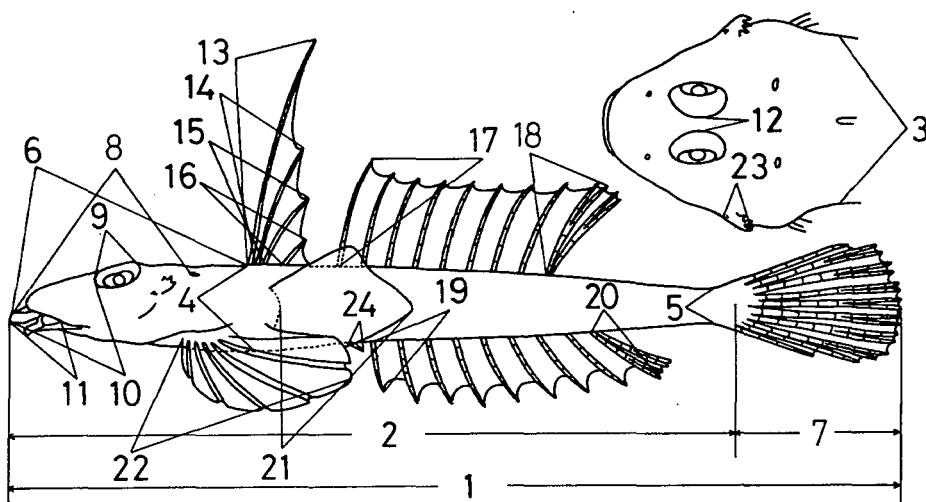

Fig. 1. Diagrammatic illustration showing the measuring methods of the portions of callionymid body. 1, total length; 2, standard length; 3, body width; 4, body depth; 5, caudal peduncle depth; 6, predorsal length; 7, caudal fin length; 8, head length; 9, eye diameter; 10, snout length; 11, upper jaw length; 12, interorbital width; 13, 1st dorsal spine length; 14, 2nd dorsal spine length; 15, 3rd dorsal spine length; 16, 4th dorsal spine length; 17, 1st dorsal ray length; 18, last dorsal ray length; 19, 1st anal ray length; 20, last anal ray length; 21, pectoral fin length; 22, pelvic fin length; 23, preopercular spine length; 24, anal papilla length

Table 1. Callionymid genera and species arranged in conformity with the new scheme, and specimens examined during the revision of the genera.

Genera and species	Number of specimens	Standard length (mm)
<i>Callionymus</i> Linnaeus, 1758		
<i>C. lyra</i> Linnaeus, 1758	11	124.6–178.5
<i>C. pusillus</i> Delaroche, 1809	6	28.8– 80.4
<i>C. maculatus</i> Rafinesque, 1810	4	78.2–101.5
<i>C. rissoides</i> LeSueur, 1814	3	39.9– 47.4
<i>C. reticulatus</i> Valenciennes, 1837	5	31.6– 60.6
<i>Bathyallionymus</i> n. g.		
<i>B. kaianus</i> (Günther, 1880)	91	67.2–146.3
* <i>B. carebares</i> (Alcock, 1890)		
<i>B. sokonumerae</i> (Kamohara, 1936)	21	53.0–140.1
<i>B. moretonensis</i> (Johnson, 1971)	11	74.7–148.0
* <i>B. kotthausi</i> (Kotthaus, 1977)		
* <i>B. africanus</i> (Kotthaus, 1977)		
<i>B. regani</i> (Nakabo, 1979)	11	114.5–157.5
<i>B. formosanus</i> (Fricke, 1981)	16	96.6–171.4
* <i>B. whiteheadi</i> (Fricke, 1981)		
* <i>B. guentheri</i> (Fricke, 1981)		
* <i>B. altipinnis</i> (Fricke, 1981)		
<i>Foetorepus</i> Whitley, 1931		
<i>F. calauropomus</i> (Richardson, 1844)	2	111.0–131.8
<i>F. altivelis</i> (Temminck and Schlegel, 1845)	55	55.2–185.7
<i>F. phaeton</i> (Günther, 1861)	3	86.0–121.0
<i>F. phasis</i> (Günther, 1880)	1	47.4
<i>F. agassizii</i> (Goode and Bean, 1888)	1	62.1
<i>F. atrilabiatus</i> (Garman, 1899)	1	27.4
* <i>F. apricus</i> (McCulloch, 1926)		
<i>F. monacanthus</i> (Smith, 1936)	1	101.2
* <i>F. bicornis</i> (Norman, 1939)		
* <i>F. grinnelli</i> (Fowler, 1941)		
<i>F. delandi</i> (Fowler, 1943)	10	92.9–156.8
<i>F. sp. 1</i> (from the Emperor Seamounts)	1	105.5
<i>F. sp. 2</i> (<i>Callionymus phasis</i> of McCann, 1972)	1	90.7
<i>F. sp. 3</i> (from the western Atlantic)	3	41.6– 58.0
<i>F. sp. 4</i> (<i>Callionymus corallinus</i> of Kamohara, 1951)	2	115.4–142.3
<i>Eocallionymus</i>		
<i>E. papilio</i> (Günther, 1864)	8	26.0– 68.7
<i>Paracallionymus</i> Barnard, 1927		
<i>P. costatus</i> (Boulenger, 1898)	2	38.0– 46.1
* <i>P. fowleri</i> Poll, 1949		
<i>Neosynchiropus</i> n. g.		
<i>N. ocellatus</i> (Pallas, 1770)	46	9.6– 78.7
* <i>N. marmoratus</i> (Peters, 1855)		
<i>N. rubrovinctus</i> (Gilbert, 1905)	1	18.0
* <i>N. sechellensis</i> (Regan, 1908)		
<i>N. tijimai</i> (Jordan and Thompson, 1914)	9	48.0– 77.3
<i>N. morrisoni</i> (Schultz, 1960)	2	30.8– 43.2

Fricke, Braunschweig; University of Michigan, Museum of Zoology; National Museum of the Smithsonian Institution; Western Australian Museum, Perth; and Yokosuka City Museum.

The methods that were used to measure body parts are shown in Fig. 1. The counting of fin rays follows the method of Hubbs and Lagler (1947). The lowermost pectoral rays were counted as having divided tips when it was impossible to recognize whether or not they were divided. Posteriormost tip of preopercular spine was not counted as upward process on the inner side. Proportional measurements of the genera are shown in Table 2.

The cephalic lateral line canals are observed by injecting black ink.

Taxonomy

Family Callionymidae

Body depressed. No scales on any part of body. Gill-opening small and oval, located on dorsal surface of posterior part of head. Preopercle with a retrorse strong spine. Upper jaw protractile downward (except *Eleutherochir*). A nostril on each side of preorbital region. Mouth small, protracted ventrally in most species. Teeth on both upper and lower jaws villiform in broad bands. Palatine and vomer toothless. Anal papilla conical, longer in males than in females. Lateral line canal well developed, single, reaching base of caudal fin or tip of a median caudal ray. Cephalic lateral line canal well developed; supraorbital canal single on interorbital space, bifurcating at preorbital region and opening before and after a nostril with a pore; anterior infraorbital canal placed above the posterior part of maxillary; posterior

infraorbital canal extending forward below eye; supratemporal canal present; preoperculo-mandibular canal below preopercular spine opening with 5 pores. Most of lateral line canal raised from skin and surrounded by sensory cells and degenerate elliptical scales (Ochiai, 1963) which can be stained with alizarin Red-S. Anal papilla conical, longer in males than in females as primary sexual character.

Dorsal fin separated into 2 parts (rarely the first absent): anterior composed of soft four spines, (rarely one or three), posterior of soft rays; dorsal rays unbranched except for the last. Pectoral fin large. Pelvic fin large and round, connected by a membrane to base of pectoral fin. Anal fin composed of soft rays; anal rays unbranched except for the last. Caudal fin with 10 rays.

Secondary sexual characters are remarkable in the adult male.

Key to the genera of the Callionymidae

- A₁ Upper edge of lower jaw with many fleshy papillae; mouth expanded laterally *Eleutherochir* (p. 109).
- A₂ Upper edge of lower jaw without fleshy papillae; mouth small and not expanded laterally.
 - B₁ A longitudinal dermal fold present on lower part of lateral side of body..... *Diplogrammus* (p. 97).
 - B₂ No longitudinal dermal fold present on lower part of lateral side of body.
 - C₁ Tip of each dorsal ray bifurcate or multifurcate except last branched one.
 - D₁ Tip of each dorsal ray multifurcate except last branched one..... *Pterosynchiropus* (p. 93).
 - D₂ Tip of each dorsal ray bifurcate except the last branched one.
 - E₁ Pelvic spine and first pelvic ray fused to an elongate rod separated from the other pelvic rays..... *Dactylopus* (p. 101).
 - E₂ Pelvic spine and five rays connected by a membrane.
 - F₁ A transverse lateral line commissure on dorsal surface of caudal peduncle.
 - G₁ Some long, transverse branches of lateral line canal present on dorsal surface of body..... *Synchiropus* (p. 98).
 - G₂ No long, transverse branch of lateral line present on dorsal surface of body *Eocallionymus* (p. 89).
 - F₂ No transverse lateral line commissure on dorsal surface of caudal peduncle.
 - H₁ Preopercular spine with 1 or 2 upward processes on inner side.
 - I₁ Tip of each branch of last anal ray simple..... *Foetorepus* (p. 87).
 - I₂ Tip of each branch of last anal ray bifurcate..... *Neosynchiropus* (p. 92).
 - H₂ Preopercular spine straight and elongate with an antrorse process at base, many short upward processes on inner side *Orbonyx* (p. 100).
 - C₂ Tip of each dorsal ray simple except last branched one.
 - J₁ Preopercular spine simple without process; lateral line with many long, conspicuously transverse upward branches..... *Paracallionymus* (p. 90).
 - J₂ Preopercular spine with some processes.

- K₁ Preopercular spine with no antrorse process at base.
- L₁ A transverse lateral line commissure present on dorsal surface of caudal peduncle *Callionymus* (p. 84).
- L₂ No transverse lateral line commissure present on dorsal surface of caudal peduncle.
- M₁ 9 dorsal and 8 anal rays *Minysynchiropus* (p. 94).
- M₂ 8 dorsal and 7 anal rays *Paradiplogrammus* (p. 95).
- K₂ Preopercular spine with an antrorse process at base or with many processes on outer side.
- N₁ Preopercular spine with several processes on outer and inner sides *Spinicapitichthys* (p. 106).
- N₂ Preopercular spine with an antrorse process at base and one or many upward processes on inner side.
- O₁ No transverse lateral line commissure on dorsal surface of caudal peduncle.
- P₁ A pair of supraorbital cirri present *Anaora* (p. 108).
- P₂ No supraorbital cirrus present.
- Q₁ Preopercular spine straight with many short upward processes on the inner side.
- R₁ 9 dorsal and 8 anal rays *Calliurichthys* (p. 102).
- R₂ 8 dorsal and 7 anal rays *Pseudocalliurichthys* (p. 104).
- Q₂ Preopercular spine strongly curved upward at the posterior end, and with several upward processes on the inner side *Paradiplogrammus* (p. 95).
- O₂ A transverse lateral line commissure present on dorsal surface of caudal peduncle.
- S₁ Tips of one or two median caudal rays simple..... *Bathycallionymus* (p. 86).
- S₁ Tips of 6 or 7 median caudal rays bifurcate.
- T₁ Some long, or separated short transverse branches of lateral line canal present on dorsal surface of body.
- U₁ Preopercular spine short and slightly curved upward at the posterior end *Callionymus* (p. 84).
- U₂ Preopercular spine elongate and straight with many short upward processes on the inner side. *Calliurichthys*. (p. 102)
- T₂ Neither long, nor separated short transverse branch of lateral line canal present on dorsal surface of body..... *Repomucenus* (p. 105).

Genus *Callionymus* Linnaeus, 1758

(Figs. 2, 21A, 23, 24A, 29B-C)

Callionymus Linnaeus, 1758, Syst. Nat. ed. X, Vol. 1, p. 249 (type-species by original designation; *Callionymus lyra*).

DESCRIPTION: D. III-IV, 6-10; A. 9; P₁. i+16-20; P₂. I, 5; C. i+7+ii.

Body elongate and depressed. Gill-opening located midway between posterior edge of eye and upper origin of pectoral fin. Tip of upper jaw protruding anterior. Preopercular spine short, with an antrorse process at base and two upward processes on inner side; each process and posterior tip barbed (in *C. risso* and *C. pusillus*, without an antrorse process at base; each process and posterior tip not barbed). Infraorbital canal not extending below eye. Postocular commissure connected with preoperculo-mandibular canal, but in some species not connected; the latter above preopercular spine with a short retrorse branch (in *C. risso* and *C. pusillus*, the latter divided into 7-8 short parts). Lateral line reaching tip of a median caudal ray; the line of opposite side interconnected by a transverse branch across dorsal surface of caudal peduncle; several long transverse branches of lateral line on dorsal surface of body (in *C. risso* and *C. pusillus*, several separated short transverse branches there).

First dorsal fin beginning behind gill-opening. Dorsal and anal rays simple except last branched rays. Upper half of pectoral fin slightly emarginated, lower half rounded. Caudal fin rounded.

Color in preserved specimens. Body marbled brown above, white below. In *C. lyra*, body marbled sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: In *C. reticulatus* and *C. maculatus*, the second

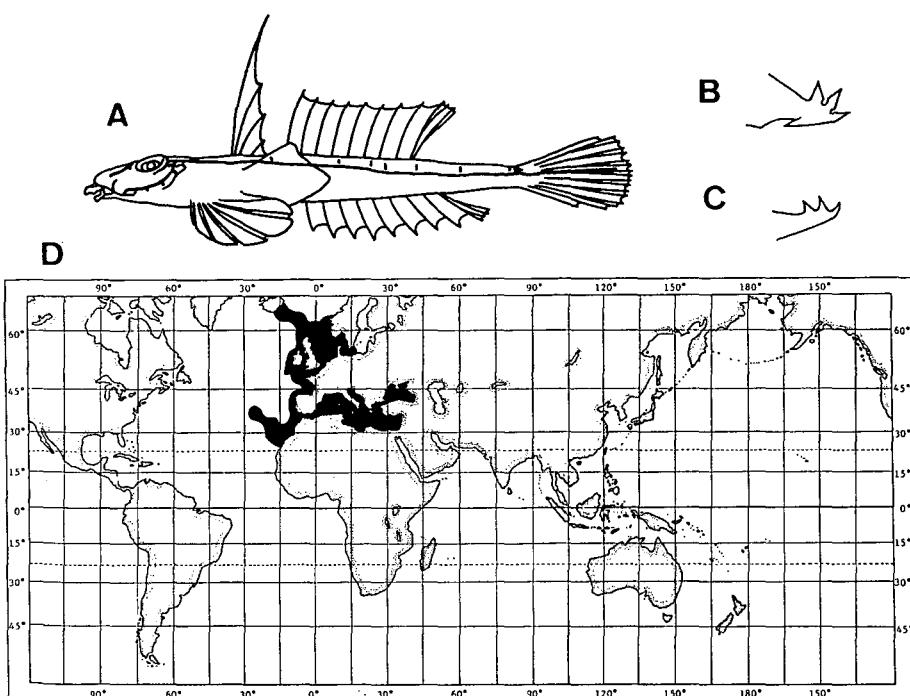

Fig. 2. *Callionymus*. A, lateral view of a *C. lyra*, male. Solid lines show the lateral line canals; B, preopercular spine of *C. lyra*; C, preopercular spine of *C. risso*; D, geographic distribution of the genus.

dorsal and anal fins of the male are remarkably large and are more colorful than those of the female.

HABITAT: Sandy-muddy bottoms in shallow to deep waters of the continental shelf, banks or seamounts.

GEOGRAPHIC DISTRIBUTION: the northeastern Atlantic; the Mediterranean.

REMARKS: Historically, the term *Callionymus* has been applied to most of the species belonging to the family Callionymidae. The results of this study show that the name, *Callionymus* should be limited to those five species distributed in the northeastern Atlantic and the Mediterranean.

Five species of this genus are divided into the following two groups in the preopercular spine and lateral line: *C. lyra*, *C. reticulatus* and *C. maculatus*; *C. risso* and *C. pusillus*. These two groups may be correspond to subgeneric status. The latter two species seem to be more specialized in the cephalic lateral line than the former three.

Callionymus (except *C. risso* and *C. pusillus*) is closely related to *Bathycallionymus*, both having the barbed process on the preopercular spine. Some species of these two genera are alike in their patterns of secondary sexual dimorphism.

Genus *Bathycallionymus* n. g.

(Figs. 3, 26A, 29G)

Bathycallionymus (type-species by original designation: *Callionymus kaianus* Günther).

DESCRIPTION: D. IV, 9; A. 9; P₁. ii+17-19; P₂. I, 5; C. i+3+ii+2+ii or i+3+i+3+ii.

Body elongate and depressed. Eye very large. Interorbital space very narrow and concave. Gill-opening located midway between posterior edge of eye and upper origin of pectoral fin. Tip of upper jaw protruding anterior. Preopercular spine with an antorse process at base and two upward processes on inner side; posterior upward process and posterior tip barbed. Infraorbital canal not extending below eye, with a long downward branch. Postocular commissure not connected to preoperculo-mandibular canal.

First dorsal fin beginning behind gill-opening. Tip of each dorsal ray, except last branched ray, simple. Upper half of pectoral fin slightly emarginated, lower half rounded. Tip of each anal ray simple. Tips of one or two median caudal rays simple.

Color in life. In *B. regani*, body sepia-brown above and below. But, in other species, body olive-brown above, white below.

Color in preserved specimens. Both sepia- and olive-brown colors somewhat darkened.

SECONDARY SEXUAL DIMORPHISM: In some species of this genus, the second dorsal and anal fins of the male are remarkably larger and are more colorful than in the female.

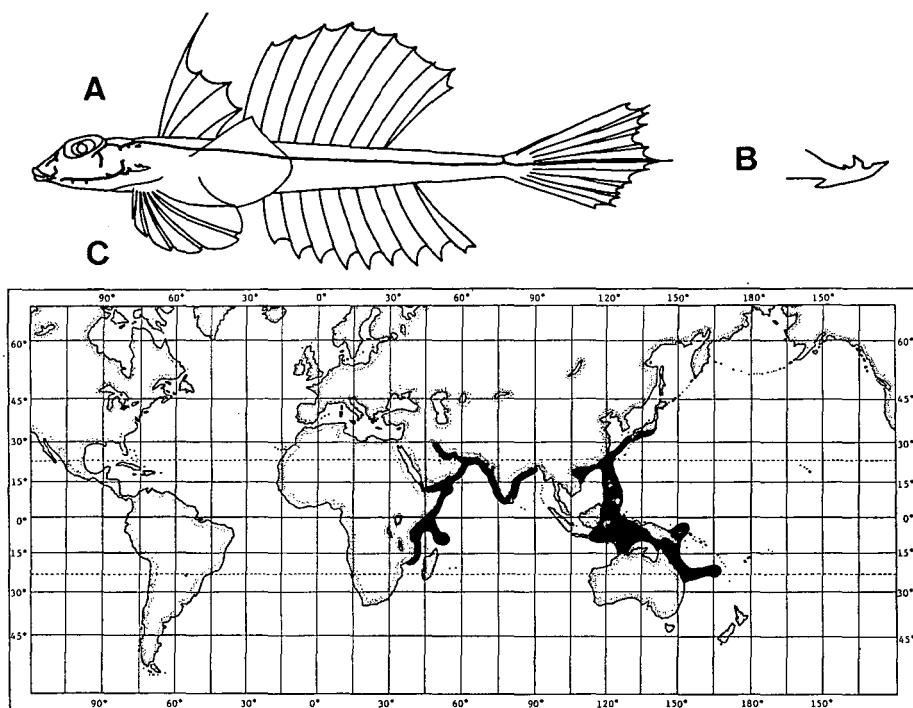

Fig. 3. *Bathycallionymus*. A, lateral view of a *B. formosanus*, male. Solid lines show the lateral line canals; B, preopercular spine of *B. kaianus*; C, geographic distribution of the genus.

HABITAT: Sandy-muddy bottoms in deep waters near the edge of the continental shelf, banks or seamounts.

GEOGRAPHIC DISTRIBUTION: northeastern coast of Africa; the Persian Gulf and western and eastern coasts of India; the western Pacific (Japan, the East China Sea, the South China Sea, New Guinea and north Australia).

REMARKS: This new genus is closely related to *Callionymus* in its general physiognomy, especially the shape of the preopercular spine. It differs from the latter in having no commissure between the postocular commissure and the preoperculo-mandibular canal, no long transverse branches of the lateral line on the dorsal surface of the body and only one or two simple median caudal rays.

This new genus corresponds to the *kaianus*-group of the genus *Callionymus* described by Fricke (1981 e).

The generic name “*Bathycallionymus*” refers to the genus living in deep waters near the edge of the continental shelf.

Genus *Foetorepus* Whitley, 1931

(Figs. 4, 21A, 29J)

Foetorepus Whitley, 1931a, Aust. Zool. 6, p. 323 (type-species by original designation: *Callionymus calauroponus* Richardson).

Yerutius Whitley, 1931b, Rec. Aust. Mus. 18, p. 115 (type-species by original designation: *Callionymus apricus* McCulloch).

DESCRIPTION: D. IV, 8; A. 7; P₁. i+18-21; P₂. I. 5; C. i+7+ii.

Body slightly depressed. Eye very large. Preopercular spine without an antrorse process at base, but with 1-2 upward processes on inner side; its posterior end pointed. Snout short; its tip located almost at anterior tip of upper jaw. Gill-opening located somewhat behind middle between the posterior edge of eye and upper origin of pectoral fin. Infraorbital canal not extending below eye. Postocular commissure connected with preoperculo-mandibular canal; the latter above preopercular spine with a short retrorse branch. Lateral line of opposite side not interconnected on dorsal surface of caudal peduncle.

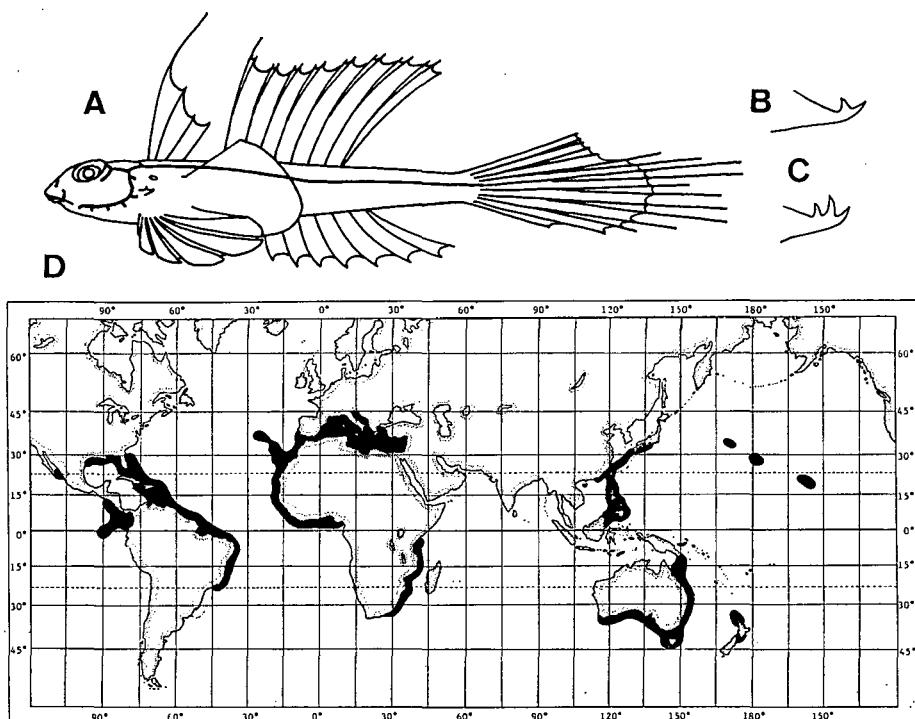

Fig. 4. *Foetorepus*. A, lateral view of a *F. altivelis*, male. Solid lines show the lateral line canals; B, preopercular spine of *F. altivelis*; C, preopercular spine of *F. phaeton*; D, geographic distribution of the genus.

First dorsal fin beginning just behind origin of pelvic fin. Tip of each dorsal ray, except posterior branch of last ray, bifurcate. Pectoral fin rounded. Tip of each anal ray simple. Caudal fin more elongate in males than in females, or lower half of caudal fin slightly filamentous in some species.

Color in life. In most species, body reddish with inconspicuous olive-brown marks above, white below.

Color in preserved specimens. Reddish color faded to creamy white. In *F.*

calauropomus, sepia-brown body above, white below.

SECONDARY SEXUAL DIMORPHISM: The second dorsal and caudal fins of the male are larger than those of the female. The lower caudal rays of the male in some species are filamentous.

HABITAT: Sandy-muddy bottoms in deep waters near the edge of the continental shelf, and on banks or seamounts.

GEOGRAPHIC DISTRIBUTION: Baja California; west coast of the Isthmus of Panama; middle part of the western Atlantic; middle part of the eastern Atlantic; the Mediterranean; coast of southeastern Africa; western Pacific (Japan, the Philippines, New Guinea and east and south Australia); New Zealand; the middle Pacific (Emperor Seamounts and the Hawaiis).

REMARKS: Whitley (1931 a) established the genus *Foetorepus* on the basis of *Callionymus calauropomus* Richardson. Later (1931 b), he also established the genus *Yerutius* on the basis of *Callionymus apricus* McCulloch. Because these two fishes have common characters they can not be separated into two genera; they should belong to the prior genus, *Foetorepus*. Since Whitley (1931 a), did not define this genus sufficiently, *Foetorepus* has been redifined in this study.

The figure for the original description of the dorsal rays of *F. calauropomus* differ somewhat from the description of this genus. In the figure, the first dorsal ray is simple and the posterior branch of the last dorsal ray, bifurcate; whereas, for the specimens examined in this study and the specimen, BM(NH) 1855. 9. 19. 183 (A. Wheeler, personal communication), the former is bifurcate and the latter simple. The specimens used for this study do agree well in color pattern with the figure used for the original description. McCulloch (1926) first pointed out these variations. The other species of *Foetorepus* examined for this study did not have these variations. Their second dorsal fin is the same as the fin of specimens of *F. calauropomus* which I examined for this study. Therefore, I have adopted the above description for the second dorsal fin of *Foetorepus*.

Genus *Eocallionymus* n. g.

(Figs. 5, 21C, 29F)

Eocallionymus (type-species by original designation: *Callionymus papilio* Günther).

DESCRIPTION: D. IV, 7; A. 6; P₁. i+18—19; P₂. I, 5; C. i+7+ii.

Body slightly depressed. Eye moderately large. Preopercular spine without an antrorse process, but with an upward process on inner side, and its posterior tip curved dorsally. Snout short; its tip almost at tip of upper jaw. Gill-opening located midway between posterior edge of eye and upper origin of the pectoral fin. Infraorbital canal not extending below eye. Postocular commissure connected to the preoperculo-mandibular canal; the latter above preopercular spine with a short retrorse branch. Lateral line reaching tip of median caudal ray; the line of opposite side interconnected by a transverse branch across dorsal surface of caudal

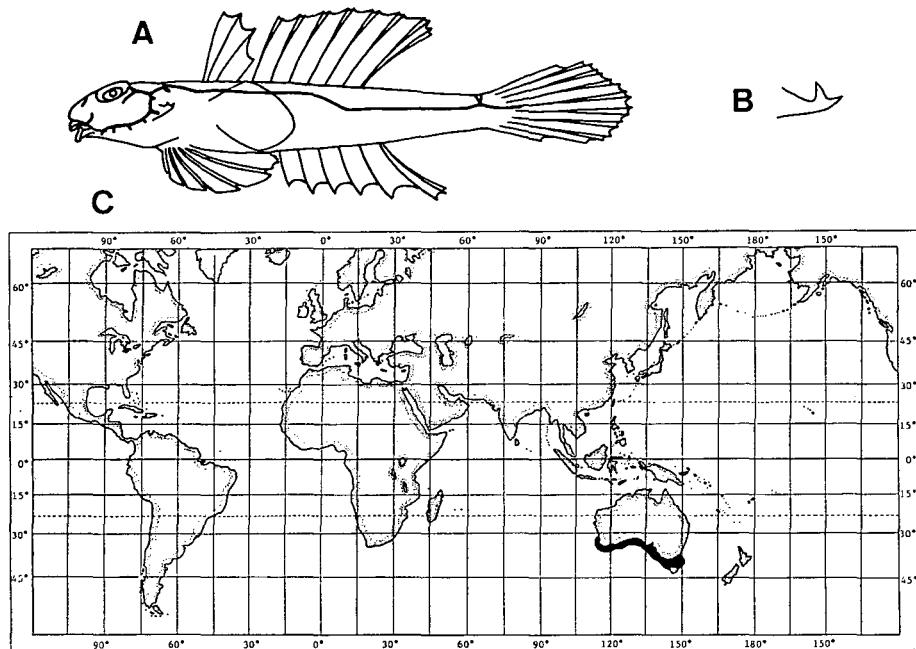

Fig. 5. *Eocallionymus*. A, lateral view of a *E. papilio*, male. Solid lines show the lateral line canals; B, preopercular spine of *E. papilio*; C, geographic distribution of the genus.

peduncle.

First dorsal fin small, and beginning almost at upper origin of pectoral fin. Tip of each dorsal ray bifurcate. Pectoral fin rounded. Tip of each anal ray simple.

Color in preserved specimens. Body marbled dark sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: Fins of the male are slightly larger than those of the female. The color pattern of each unpaired fin is slightly more colorful in the male than in the female.

HABITAT: Sandy bottoms with pebbles in shallow waters (D.F. Hoese, personal communication).

GEOGRAPHIC DISTRIBUTION: south coast of Australia.

REMARKS: This new genus is much like *Foetorepus* and *Neosynchiropus* in its general physiognomy, especially the preopercular spine. One difference is the lateral line commissure on the dorsal surface of the caudal peduncle.

The generic name “*Eocallionymus*” means one of the earliest dragonet, because this genus has the most primitive osteological characters (Nakabo, unpublished).

Genus *Paracallionymus* Barnard, 1927

(Figs. 6, 26B, 29E)

Paracallionymus Barnard, 1927, Ann. South African Mus. 21, p. 448 (type-species by original designation: *Callionymus costatus* Boulenger).

DESCRIPTION: D. IV, 9–10; A. 9; P₁. i+18–19; P₂. I, 5; C. i+7+ii.

Body elongate and depressed. Eye very large. Gill-opening located midway between posterior edge of eye and upper origin of pectoral fin. Upper jaw protruding anterior. Preopercular spine simple, only sharply pointed. Infraorbital canal bifurcate and not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray, with many transverse branches upward and downward; upward branches long, with 4–5 short retrorse branches; the line of opposite side interconnected by a transverse branch across dorsal surface of caudal peduncle.

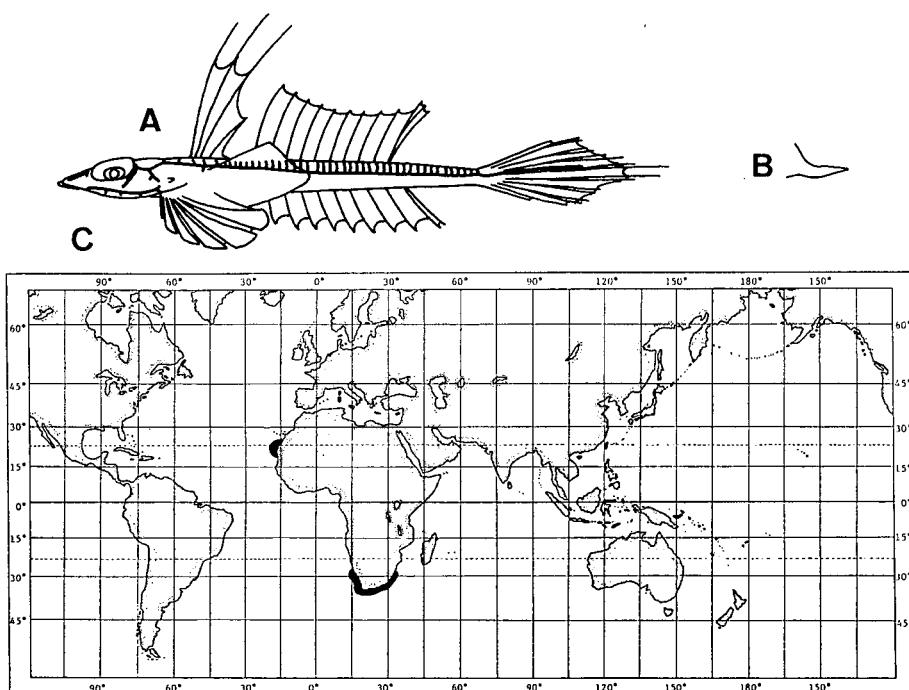

Fig. 6. *Paracallionymus*. A, lateral view of a *P. costatus*, male. Solid lines show the lateral line canals; B, preopercular spine of *P. costatus*; C, geographic distribution of the genus.

First dorsal fin beginning before upper origin of pectoral fin. Tips of each dorsal and anal ray, except last branched ray, simple. Pectoral fin lanceolate.

Color in preserved specimens. Body colorless.

SECONDARY SEXUAL DIMORPHISM: The first dorsal and caudal fins of the male are elongate (but, only the male observed).

HABITAT: Sandy-muddy bottoms in deep waters (South Africa) and in shallow waters (Baie de Pulpito).

GEOGRAPHIC DISTRIBUTION: South Africa; Rio de Oro, western Africa.

Genus *Neosynchiropus* n. g.

(Figs. 7, 24B, 29J)

Neosynchiropus (type-species by original designation: *Callionymus ocellatus* Pallas).

DESCRIPTION: D. IV, 8; A. 7; P₁. i+17-21, ii+17-19, iii+18; P₂. I, 5; C. i+7+ii.

Body cylindrical. Eye moderately large. Gill-opening just behind middle between posterior edge of eye and upper origin of the pectoral fin. Tip of snout slightly anterior to tip of upper jaw. Preopercular spine with no antrorse process at base, and 1-2 upward processes on inner side; its posterior end pointed (in *N. ijimae*, with an antrorse process at base, and in *N. sechellensis*, with 1 or 2 small antrorse ones). Infraorbital canal not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray; the line of opposite side not connected by a transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning behind the gill-opening. Tip of each dorsal ray bifurcate. Pectoral fin rounded. Tip of each anal ray bifurcate in some species. Caudal fin rounded.

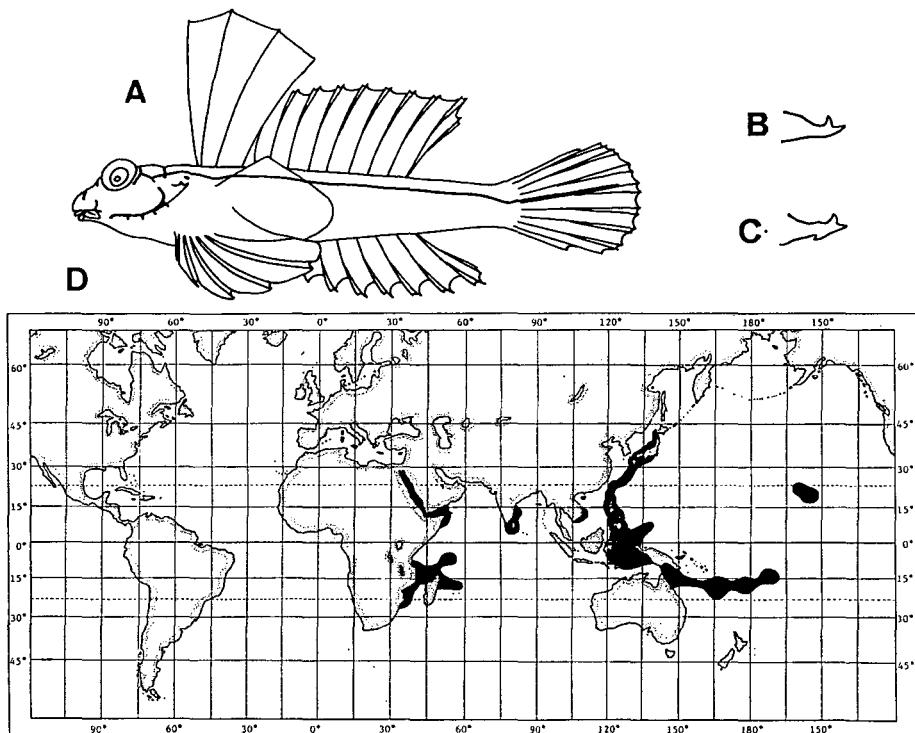

Fig. 7. *Neosynchiropus*. A, lateral view of a *N. ocellatus*, male. Solid lines show the lateral line canals; B, preopercular spine of *N. ocellatus*; C, preopercular spine of *N. ijimai*; D, geographic distribution of the genus.

Color in preserved specimens. Body marbled dark sepia-brown, white below.

SECONDARY SEXUAL DIMORPHISM: The male has a remarkably larger and more colorful first dorsal fin than the female.

HABITAT: Sandy bottoms in coral reefs, tidal pools and weedy beds around islands.

GEOGRAPHIC DISTRIBUTION: southeastern coast of Africa; east coast of India; the western Pacific; the Hawaiian Isls.

REMARKS: This new genus is much like *Synchiropus* and *Eocallionymus* in its general physiognomy, especially body form and color pattern. It differs in having no lateral line commissure on the dorsal surface of the caudal peduncle.

Genus *Pterosynchiropus* n. g.

(Figs. 8, 24C, 29J)

Pterosynchiropus (type-species by original designation: *Callionymus splendidus* Herre).

DESCRIPTION: D. IV, 8; A. 7; P₁. i+29—30; P₂. I, 5; C. i+8+i.

Body cylindrical, posterior half slightly compressed. Eye large. Gill-opening just behind middle between posterior edge of eye and upper origin of pectoral fin. Tip of snout almost at tip of upper jaw. Preopercular spine with no antrorse process

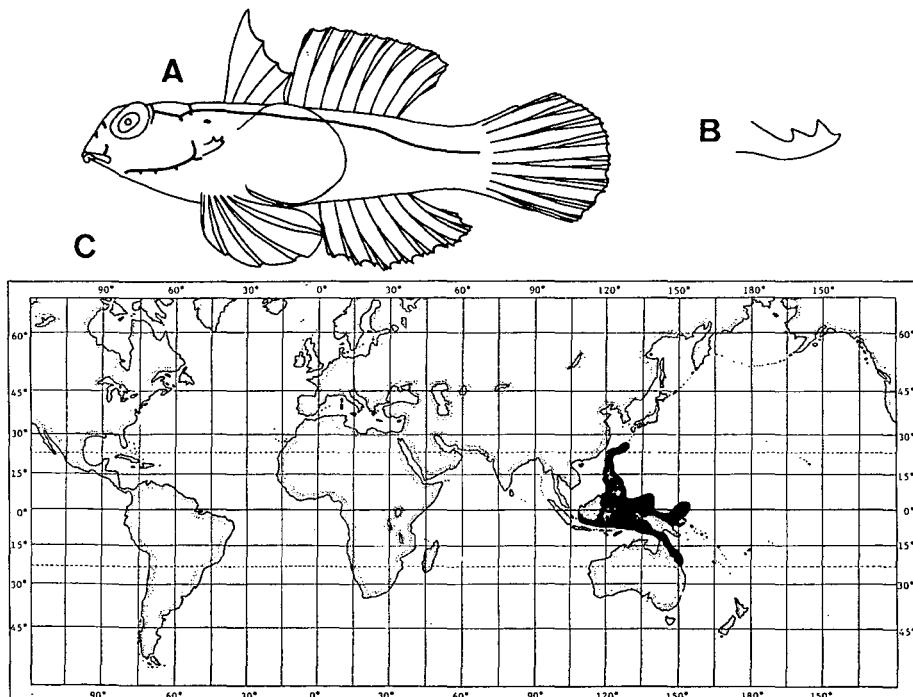

Fig. 8. *Pterosynchiropus*. A, lateral view of *P. splendidus*. Solid lines show the lateral line canals; B, preopercular spine of *P. splendidus*; C, geographic distribution of the genus.

at base, 2-3 upward processes, posterior end curved upward. Caudal peduncle very compressed and deep. Infraorbital canal not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching base of caudal fin; the line of opposite side not connected by a transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning behind gill-opening. Tip of each dorsal and anal ray multifurcate. Pectoral fin large and rounded, many more rays than in other genera. Membrane between pelvic fin and base of pectoral fin very narrow. Caudal fin rounded; median eight caudal fin rays multifurcate.

Color in preserved specimens. Body colorful.

SECONDARY SEXUAL DIMORPHISM: First dorsal spine is elongate and filamentous.

HABITAT: Coral reefs around islands.

GEOGRAPHIC DISTRIBUTION: the Ryukyu Isls.; the Philippines; Great Barrier Reef.

REMARKS: This new genus is very like *Neosynchiropus* in its general physiognomy, but differs in having multifurcate tips on its dorsal, anal and caudal rays, a compressed caudal peduncle and a broad pectoral fin with many rays.

Species belonging to this genus seem to swim among corals above the bottom as in the photograph in Wheeler (1975). The diagnostic characters of *Pterosynchiropus* must be related to their peculiar manner of swimming which is unique among callionymid fishes. Therefore, this genus has been named "*Pterosynchiropus*".

Genus *Minysynchiropus* n. g.

(Figs. 9, 21D, 29J)

Minysynchiropus (type-species by original designation: *Synchiropus laddi* Schultz).

DESCRIPTION: D. IV, 9; A. 8; P₁. ii+16, iii+14-15, iv+13-14; P₂. I, 5; C. i+7+ii.

Body cylindrical. Eye large. Gill-opening just behind middle between posterior edge of eye and upper origin of pectoral fin. Tip of snout almost at tip of upper jaw. Preopercular spine with no antrorse process at base, many upward ones on inner side; posterior tip strongly curved upward. Infraorbital canal not extending below eye. Postocular commissure connected to preoperculo-mandibular canal, the latter above preopercular spine with a short retrorse branch. Lateral line reaching tip of a median caudal ray; line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning just behind gill-opening. Tip of each dorsal ray, except last branched one, simple. Pectoral fin rounded. Tip of each anal ray simple. Caudal fin rounded.

Color in preserved specimens. Body almost creamy white with some inconspicuous, faintly dark marks.

SECONDARY SEXUAL DIMORPHISM: First dorsal fin of the male is markedly larger

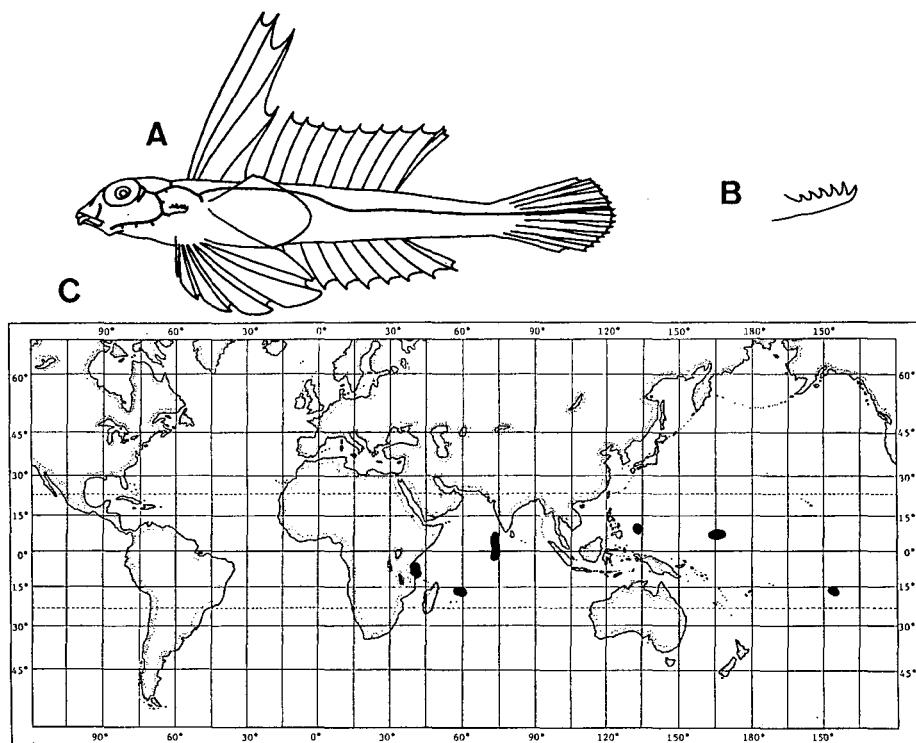

Fig. 9. *Minysynchiropus*. A, lateral view of a *M. laddi*, male. Solid lines show the lateral line canals; B, preopercular spine of *M. laddi*; C, geographic distribution of the genus.

than that of the female.

HABITAT: Sandy bottoms in tidal pools and coral reefs around islands.

GEOGRAPHIC DISTRIBUTION: the Indian Ocean; the western and southern Pacific.

REMARKS: This new genus includes only the species, *M. laddi* (Schultz). *Synchiropus postulus* Smith and *Synchiropus (Synchiropus) minutulus* Fricke are the synonyms of *M. laddi*. The characters to separate these three species, which are pointed out by Fricke (1981 c), seems to be infraspecific variations.

It is very small when mature. Male specimens about 20 mm in standard length had conspicuous secondary sexual characters. Therefore, this new genus has been named "*Minysynchiropus*".

This new genus is very like *Paradiplogrammus* and *Diplogrammus* in the shape of its preopercular spine.

Genus *Paradiplogrammus* n. g.

(Figs. 10, 24D, 29J)

Paradiplogrammus (type-species by original designation: *Callionymus enneactis* Bleeker).

DESCRIPTION: D. IV, 8–9; A. 7–8; P₁. i+15–20, ii+14–15; P₂. I, 5; C. i+7+ii.

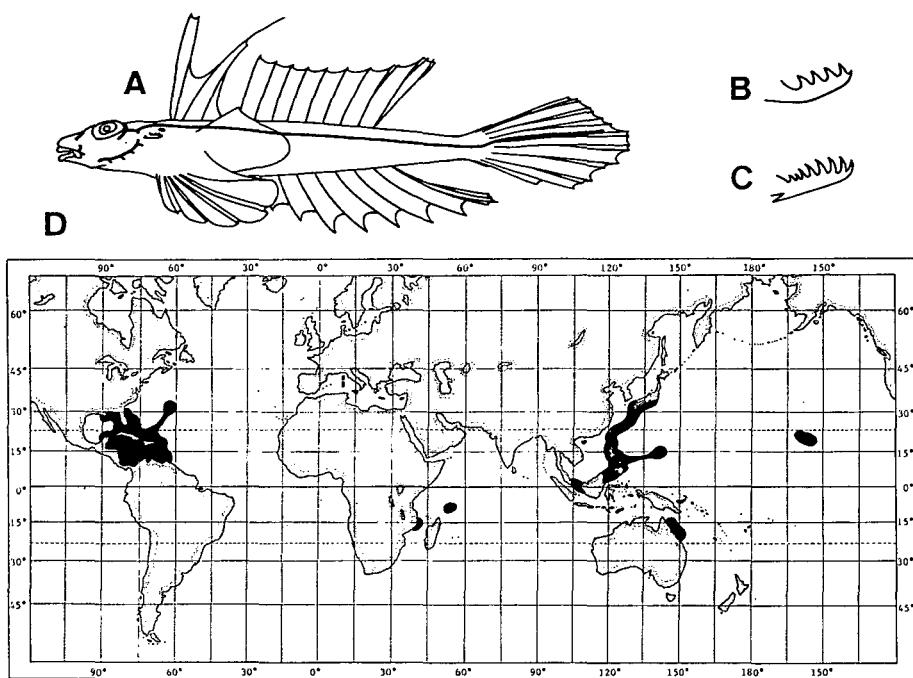

Fig. 10. *Paradiplogrammus*. A, lateral view of a *P. calliste*, male. Solid lines show the lateral line canals; B, preopercular spine of *P. sp.*; C, preopercular spine of *P. corallinus*; D, geographic distribution of the genus.

Body moderately depressed. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Tip of snout almost at tip of upper jaw. Preopercular spine with antrorse process at base (in some species none), many upward ones on inner side; posterior end strongly curved upward. Infraorbital canal not extending below eye; postocular commissure not connected with preoperculo-mandibular canal. Lateral line reaching near tip of a median caudal ray; the line of opposite side not connected by a transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning just behind gill-opening; tips of most dorsal rays simple.

Pectoral fin double truncate. Tip of each anal ray, except last branched one, simple. Caudal fin rounded.

Color in preserved specimens. Body marbled dark brown above, white below.

SECONDARY SEXUAL DIMORPHISM: First dorsal fin of the male is markedly larger and more colorful than that of the female.

HABITAT: Sandy bottoms in weedy beds, pebbles, rocks and corals in shallow waters around islands.

GEOGRAPHIC DISTRIBUTION: middle part of the western Atlantic; the western Indian Ocean; the western Pacific; the Hawaiian Isls.

REMARKS: This new genus is closely related to *Diplogrammus* in its general physiognomy, especially that of the preopercular spine, but differs in having no dermal fold on the lateral ventral side of the body.

Genus *Diplogrammus* Gill, 1865

(Figs. 11, 24E, 26C, 27, 29J)

Diplogrammus Gill, 1865, Lyc. Nat. Hist. New York, p. 143 (type-species by original designation: *Callionymus goramensis* Bleeker).

Calymmicthys Jordan and Thompson, 1914, Mem. Carnegie Mus., 6 (4), p. 296 (type-species by original designation: *Calymmicthys xenicus* Jordan and Thompson).

Dicallionymus Fowler, 1941, Proc. U.S. Nat. Mus., 90 (3106), p. 29 (type-species by original designation: *Callionymus goramensis* Bleeker).

Dermosteira Schiltz, 1943, U.S. Nat. Mus. Bull. 180, p. 267 (type-species by original designation: *Dermosteira dorothaea* Schultz).

Climacogrammus Smith, 1963, Rhodes Univ. Ichthyol. Bull., 28, p. 550 (type-species by original designation: *Diplogrammus (Climacogrammus) inflatus* Smith).

Diplogrammoidea Smith, 1963, Rhodes Univ. Ichthyol. Bull., 28, p. 551 (type-species by original designation: *Diplogrammus (Diplogrammoides) gruveli* Smith).

Chalinops Smith, 1963, Rhodes Univ. Ichthyol. Bull., 28, p. 552 (type-species by original designation: *Callionymus floridæ* Fowler).

DESCRIPTION: D. IV, 6-8; A. 4-7; P₁. i+16-18, ii+15-17; P₂. I, 5; C. i+7+ii.

Body depressed. Eye moderately large. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin; opercular flap as enlarged posterior part of subopercle below gill-opening in some species. Tip of snout almost at

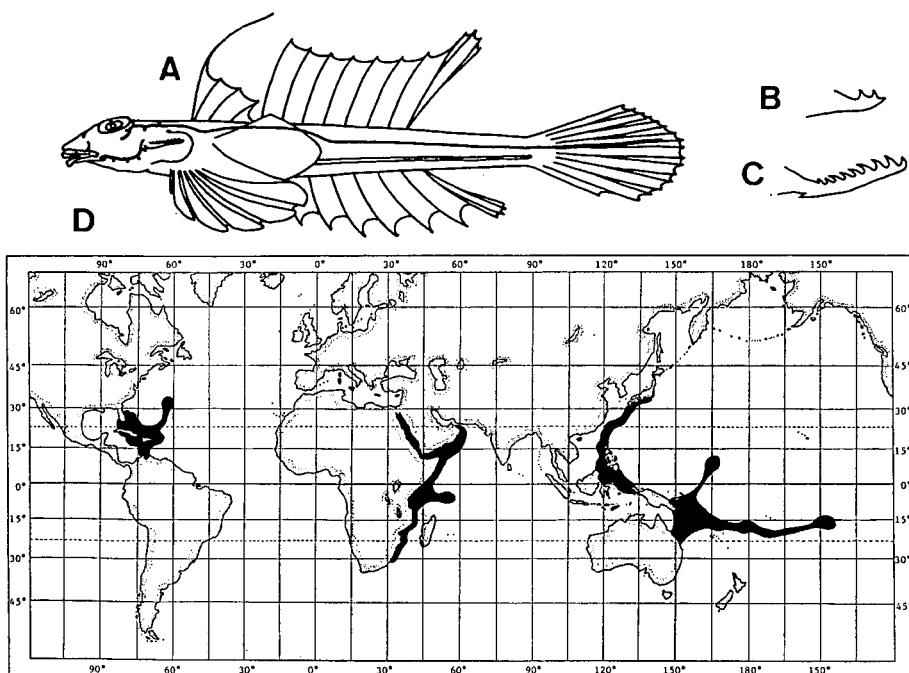

Fig. 11. *Diplogrammus*. A, lateral view of a *D. xenicus*, male. Solid lines show the lateral line canals; B, preopercular spine of *D. pauciradiatus*; C, preopercular spine of *D. xenicus*; D, geographic distribution of the genus.

tip of upper jaw. Preopercular spine with antrorse process at base, many upward ones on inner side; posterior end strongly curved upward in some species. In others, preopercular spine with no antrorse process at base and two upward ones on inner side; posterior end slightly curved upward. Infraorbital canal not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle. Longitudinal dermal fold on lateral ventral side of body.

First dorsal fin begins before upper origin of pectoral fin. Tip of each dorsal and anal ray simple or bifurcate. Pectoral fin rounded or lanceolate.

Color in preserved specimens. Body marbled dark brown above, white below.

SECONDARY SEXUAL DIMORPHISM: In some species, the first dorsal fin of the male is markedly larger than that of the female.

HABITAT: Sandy bottoms near weedy beds, pebbles and corals in shallow waters around islands.

GEOGRAPHIC DISTRIBUTION: middle part of the western Atlantic; the western Indian Ocean (the Red Sea, southeastern Africa); the western and southern Pacific.

REMARKS: Many genera and subgenera have been established for the species of this genus because of the number of diagnostic characters. But the species have a common longitudinal dermal fold on the lateral ventral side of the body. No other callionymid species have this character; therefore, all these divisions should be included in the genus *Diplogrammus*.

Genus *Synchiropus* Gill, 1860

(Figs. 12, 25A, 29A)

Synchiropus Gill, 1860, Proc. Acad. Nat. Sci. Philad., 1859, p. 129 (type-species by original designation: *Callionymus lateralis* Richardson).

DESCRIPTION: D. IV, 8; A. 7; P₁. i+18; P₂, I, 5; C. i+7+ii.

Body cylindrical. Eye moderately large. Gill-opening on upper lateral side of body and after middle between posterior edge of eye and upper origin of pectoral fin. Snout short; its tip almost at tip of upper jaw. Preopercular spine elongate and straight with no antrorse process at base, two upward processes on inner side. Supraorbital canal not extending to tip of snout. Infraorbital canal simple, and not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray; line of opposite side interconnected by transverse branch across dorsal surface of caudal peduncle; several long transverse branches on each side of dorsal surface of body; cross-shaped, separated branch before transverse commissure on caudal peduncle.

First dorsal fin beginning behind gill-opening. Tip of each dorsal ray bifurcate. Tip of each anal ray, except last branched one, simple. Upper half of pectoral fin slightly emarginated, lower half rounded. Caudal fin rounded.

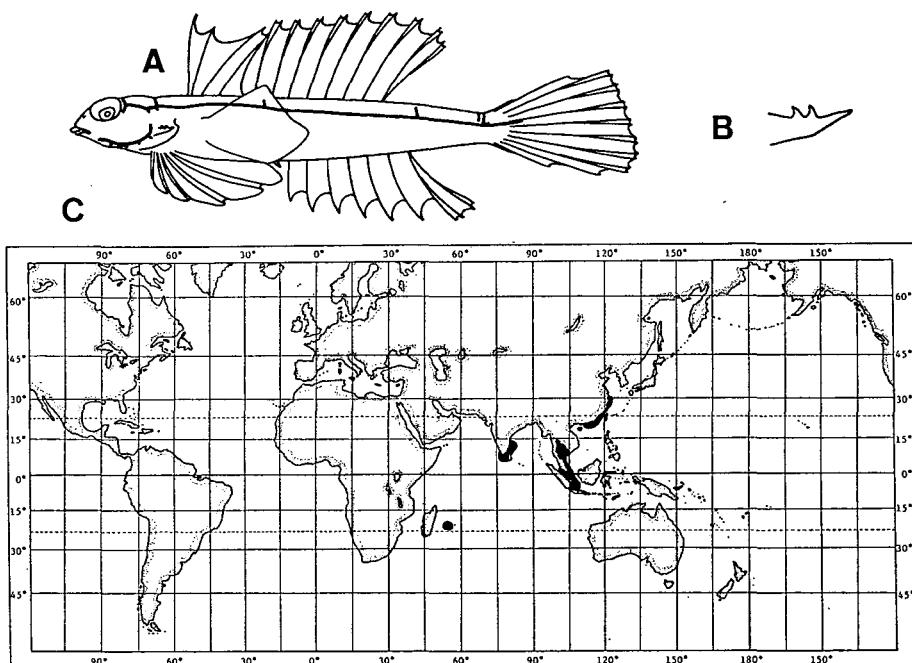

Fig. 12. *Synchiropus*. A, lateral view of a *S. ornatus*, male. Solid lines show the lateral line canals; B, preopercular spine of *S. ornatus*; C, geographic distribution of the genus.

Color in preserved specimens. Body marbled dark sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: It could not be studied.

HABITAT: Muddy bottom on the continental shelf.

GEOGRAPHIC DISTRIBUTION: Tropical waters in the Indo-West Pacific.

REMARKS: Gill (1860) established *Synchiropus* on the basis of five species. Subsequently, Regan (1908), Jordan and Thompson (1914), Norman (1939), Fowler (1941), Schultz and Woods (1948), de Beaufort (1951), Matsubara (1955), Schultz (1960), Ochiai (1963) and Smith (1963) included species with no antorse process at the base of the preopercular spine in the genus *Synchiropus*. Recently, summing up the characters experienced by the earlier workers, Fricke (1981c) regarded *Synchiropus* as the genus characterized by the following: 1, gill openings sublateral or lateral in position; 2, base of preopercular spine usually without an antorse process; 3, rays of second dorsal fin usually all branched, the last divided at its base; 4, membrane behind the last spine of the first dorsal fin small or absent; 5, Snout very short, usually shorter than eye; 6–10, characters in the neurocranium.

My study, however, shows that, *Synchiropus* should include only species like *S. lateralis*, first described in *Synchiropus* by Gill (1860). Many of the species included into *Synchiropus* by the authors above, especially Fricke, are divided into seven genera (*Foetorepus*, *Eocallionymus*, *Minysynchiropus*, *Neosynchiropus*, *Pterosynchiropus*, *Synchiropus* and *Orbonyx*) in the present study. The characters summed up by Fricke are too

variable to be treated as the generic characters and the seven genera have their own osteological characters (Nakabo, unpublished).

Genus *Orbonyx* Whitley, 1947

(Figs. 13, 25B, 29J)

Orbonyx Whitley, 1947, Aust. Zool., 11, p. 150 (type-species by original designation: *Callionymus* (*Calliurichthys*) *rameus* McCulloch).

DESCRIPTION: D. IV, 8; A. 7: P₁. i+17—18; P₂. I, 5; C. i+7+ii.

Body slightly depressed. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Snout short; its tip almost at tip of upper jaw. Preopercular spine straight and elongate with an antorse process at base, many short upward ones on inner side. Supraorbital canal not extending to tip of snout. Infraorbital canal simple, not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray; line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning at gill-opening. Tip of each dorsal ray bifurcate. Upper half of pectoral fin emarginated, lower half rounded. Tip of each anal ray,

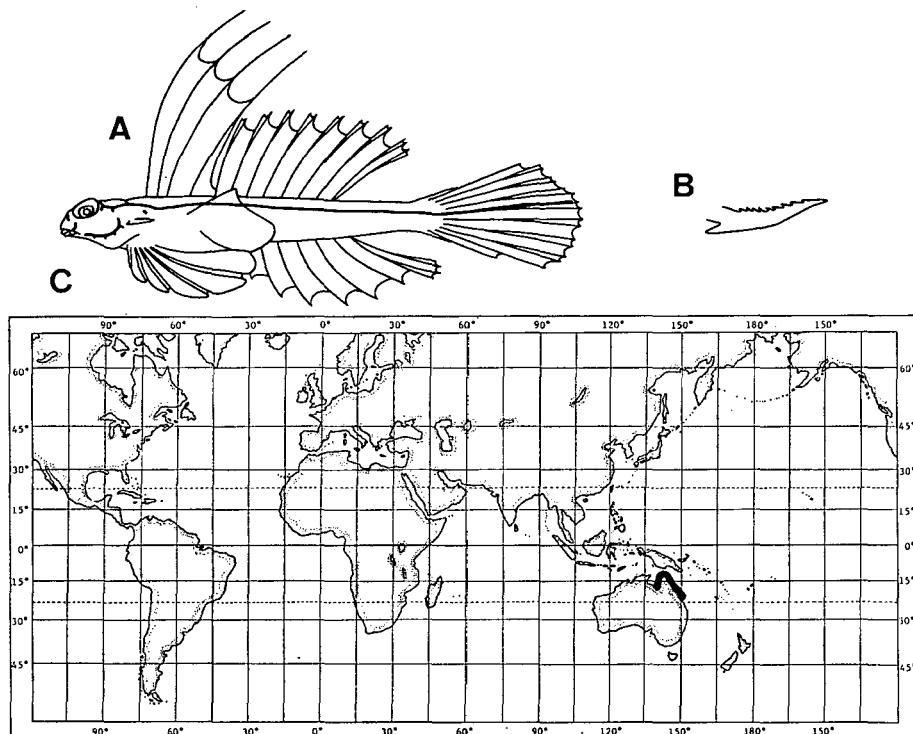

Fig. 13. *Orbonyx*. A, lateral view of a *O. rameus*, female. Solid lines show the lateral line canals; B, preopercular spine of *O. rameus*; C, geographic distribution of the genus.

except last branched one, simple. Caudal fin rounded.

Color in preserved specimens. Body marbled dark sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: First dorsal fins of males and females are markedly large; slightly larger in the male than in the female in *O. rameus*.

HABITAT: Sandy rubble bottoms.

GEOGRAPHIC DISTRIBUTION: coast of Queensland, Australia.

REMARKS: *Orbonyxus* is closely related to *Dactylopus* in its general physiognomy, but differs from it in the pelvic fin and preopercular spine.

Genus *Dactylopus* Gill, 1860

(Figs. 14, 25C, 29J)

Dactylopus Gill, 1860, Proc. Acad. Nat. Sci. Philad., 1859, p. 130 (type-species by original designation: *Callionymus dactylopus* Valenciennes).

Vulsus Günther, 1861, Cat. Brit. Mus., III, p. 151 (type-species by original designation: *Callionymus dactylopus* Valenciennes).

DESCRIPTION: D. IV, 8; A. 7; P₁. ii+17; P₂. I, 1-4; C. i+7+ii.

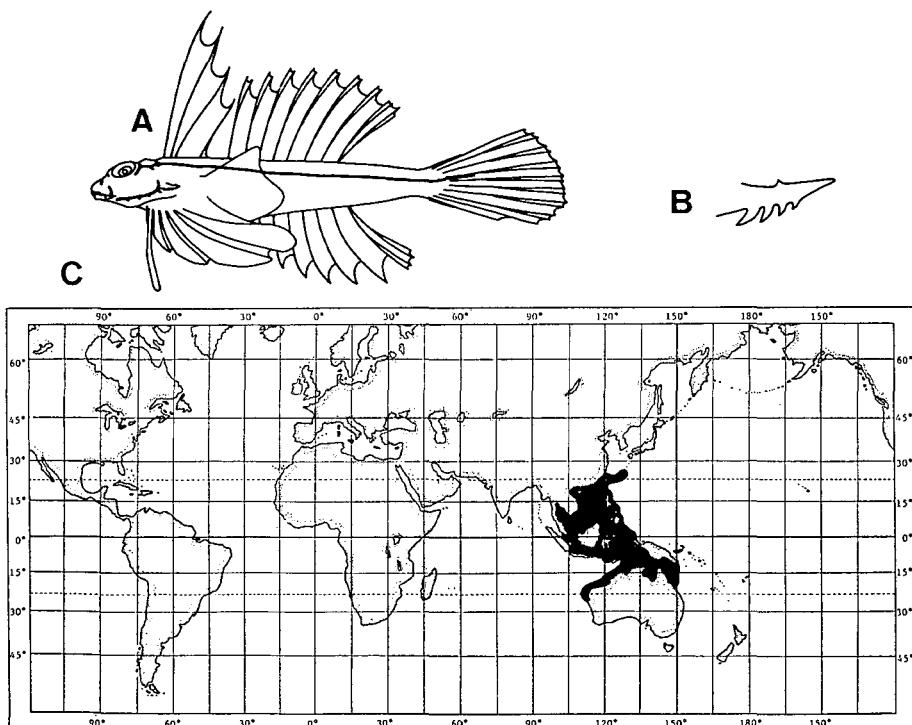

Fig. 14. *Dactylopus*. A, lateral view of a *D. dactylopus*, female. Solid lines show the lateral line canals; B, preopercular spine of *D. dactylopus*; C, geographic distribution of the genus.

Body slightly depressed. Gill-opening behind middle between posterior edge of eye and upper origin of pectoral fin. Snout short; its tip almost at tip of upper jaw. Occipital region rugose. Preopercular spine straight with several antrorse processes on outer side, several small upward ones on inner side. Supraorbital canal not extending to tip of snout. Infraorbital canal simple, not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray; line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning well before gill-opening. Tip of each dorsal ray bifurcate. Upper half of pectoral fin slightly emarginated, lower half rounded. Pelvic spine and first pelvic ray fused form elongate rod separated from other pelvic rays. Tip of each anal ray, except last branched one, simple.

Color in preserved specimens. Body marbled dark sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: Each tip of dorsal spine are elongate and filamentous in the male, but not in the female.

HABITAT: Sandy rubble bottoms in shallow waters around islands.

GEOGRAPHIC DISTRIBUTION: the western Pacific and north coast of Australia.

Genus *Calliurichthys* Jordan and Fowler, 1903

(Figs. 15, 22A, 26E, 29D. J. K.)

Calliurichthys Jordan and Fowler, 1903, Proc. U.S. Nat. Mus., 25 (1305), p. 941 (type-species by original designation: *Callionymus japonicus* Houttuyn).

DESCRIPTION: D. IV, 9; A. 8; P₁. ii+16—19; P₂. I, 5; C. i+7+ii.

Body elongate and strongly depressed. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Tip of snout a little behind tip of upper jaw (in males of some species, almost at tip of upper jaw). Occipital region rugose. Preopercular spine straight and elongate with an antrorse process at base, many short upward processes on inner side. Supraorbital canal not extending near tip of snout. Infraorbital canal branched, not extending below eye (in *C. japonicus*, extends below eye). Postocular commissure connected to preoperculo-mandibular canal in some species, but in others the latter canal cut above preopercular spine. Short antrorse branch of canal near distal end of preoperculo-mandibular canal. Lateral line reaching tip of median caudal ray; line of opposite side interconnected by transverse branch across dorsal surface of caudal peduncle (in *C. neptunius* interconnected both on dorsal and ventral surfaces). In most species, several separated short transverse branches on each side of dorsal surface of body and T-shaped separated branch before transverse commissure on caudal peduncle.

First dorsal fin beginning behind gill-opening. Tip of each dorsal and anal ray, except last branched one, simple. Upper half of pectoral fin slightly emarginated, lower half rounded.

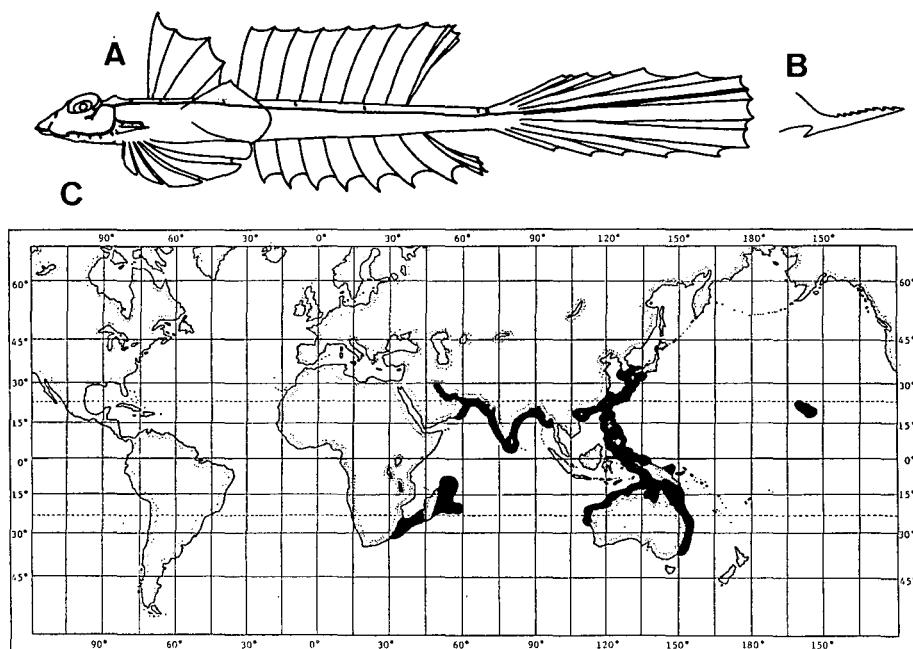

Fig. 15. *Calliurichthys*. A, lateral view of a *C. japonicus*, female. Solid lines show the lateral line canals; B, preopercular spine of *C. japonicus*; C, geographic distribution of the genus.

Color in preserved specimens. Body marbled dark sepia-brown above, white below.

SECONDARY SEXUAL DIMORPHISM: In most species, the male has a much longer caudal fin than the female, almost equal to its body length.

HABITAT: Sandy-muddy bottoms on the continental shelf, its edges and on banks.

GEOGRAPHIC DISTRIBUTION: coastal waters of the Indian Ocean (including the Red Sea and Persian Gulf); the western Pacific (including the East China and South China Seas); west, north and east coasts of Australia; the Hawaiian Isls.

REMARKS: Jordan and Fowler (1903) established *Calliurichthys* on the basis of three species from Japan, *Callionymus japonicus* Houttuyn, *Callionymus variegatus* Temminck and Schlegel, and *Calliurichthys doryssus* Jordan and Fowler because these three have a straight preopercular spine with several short upward processes on the inner side. McCulloch (1926) and Fricke (1980) regarded *Calliurichthys* as a subgenus of *Callionymus*. de Beaufort (1951) and Ochiai *et al.* (1955) considered this genus a synonym for *Callionymus*. Barnard (1927) regarded *Calliurichthys* a valid genus.

My study shows that *Calliurichthys*, as established by Jordan and Fowler, should be separated into three genera, *Calliurichthys*, *Pseudocalliurichthys* and *Repomucenus*. Their respective diagnostic characters represent distinct generic phenomena. *Calliurichthys* should be separated from *Callionymus* and limited only to species having the characters described above.

Genus *Pseudocalliurichthys* n. g.

(Figs. 16, 25D, 26D, 29J)

Pseudocalliurichthys (type-species by original designation: *Callionymus variegatus* Temminck and Schlegel).

DESCRIPTION: D. IV, 8; A. 7; P₁. i+17-18, ii+14-17; P₂. I, 5; C. i+7+ii.

Body elongate and depressed. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Snout very long. Upper jaw well protruding anterior. Occipital region rugose. Preopercular spine straight with antorse process at base, many short upward processes on inner side. Supraorbital canal not extending to tip of snout. Infraorbital canal not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line nearly reaching tip of median caudal ray; line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle.

First dorsal fin beginning behind gill-opening. Tip of each dorsal and anal ray, except last branched one, simple. Upper half of pectoral fin slightly emarginated, lower half rounded.

Color in preserved specimens. Body marbled dark brown (like the surface of a sandy bottom) above, white below.

SECONDARY SEXUAL DIMORPHISM: In *P. variegatus*, the male has two filamentous

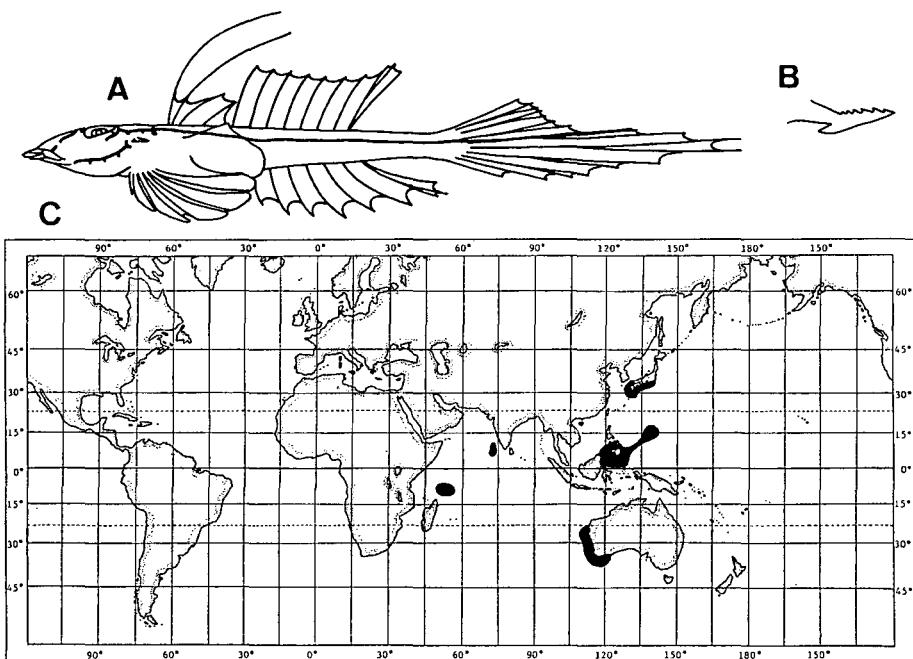

Fig. 16. *Pseudocalliurichthys*. A, lateral view of a *P. variegatus*, male. Solid lines show the lateral line canals; B, preopercular spine of *P. variegatus*; C, geographic distribution of the genus.

dorsal spines and markedly elongate caudal fin.

HABITAT: Sandy bottoms in coral reefs and weedy beds around islands.

GEOGRAPHIC DISTRIBUTION: the Indian Ocean; the western Pacific; coast of western Australia.

REMARKS: *Pseudocalliuichthys* is closely related to *Calliuichthys* in its straight and serrated preopercular spine and a rugose occipital region. It differs in the number of dorsal and anal rays, and in having no short separated transverse branch of the lateral line. This genus also is closely related to *Repomucenus* because of the preopercular spine found during early stages of its growth and its body color.

Genus *Repomucenus* Whitley, 1931

(Figs. 17, 22B, 29H-I)

Repomucenus Whitley, 1931a, Aust. Zool., 6 (4), p. 323 (type-species by original designation: *Callionymus calcaratus* Macleay).

Callimucenus Whitley, 1934, Suppl. Checklist Fishes New South Wales, ed. 3, No. 398, p. 418 (type-species by original designation: *Callionymus macdonaldi*).

Velesionymus Whitley, 1934, ibid, p. 418 (type-species by original designation: *Callionymus limiceps*).

DESCRIPTION: D. III-IV, 9 (mostly IV, 9); A. 8-9 (mostly 9); P₁. i+16-21; P₂. I, 5; C. i+7+ii.

Body elongate and strongly depressed. Eye moderately large. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Snout long. Upper jaw protruding anterior. Preopercular spine with an antorse process at base, several upward processes on inner side; posterior end slightly curved upward (in some species, almost straight with several short upward processes). Supraorbital canal extending nearly to tip of snout. Infraorbital canal extending below eye with several downward or upward branches. Postocular commissure connected to preoperculo-mandibular canal; the latter above preopercular spine with an antorse and a retrorse short branches, below them with a long retrorse branch.

First dorsal fin beginning behind gill-opening. Second dorsal fin emarginated. Tip of each dorsal and anal ray, except last branched ones, simple. Upper half of pectoral fin emarginated, lower half rounded.

Color in preserved specimens. Body marbled brown (like the surface of a sandy bottom), white below.

SECONDARY SEXUAL DIMORPHISM: In some species, the first dorsal fin of the male is much larger and more colorful than that of the female; the dorsal rays of the male are elongate and filamentous.

HABITAT: Sandy-muddy bottoms on the continental shelf.

GEOGRAPHIC DISTRIBUTION: coastal waters of the Indian Ocean (including the Red Sea and Persian Gulf); the western Pacific (including the East China and South China Seas); all coasts of Australia; the eastern Mediterranean near the Suez Canal.

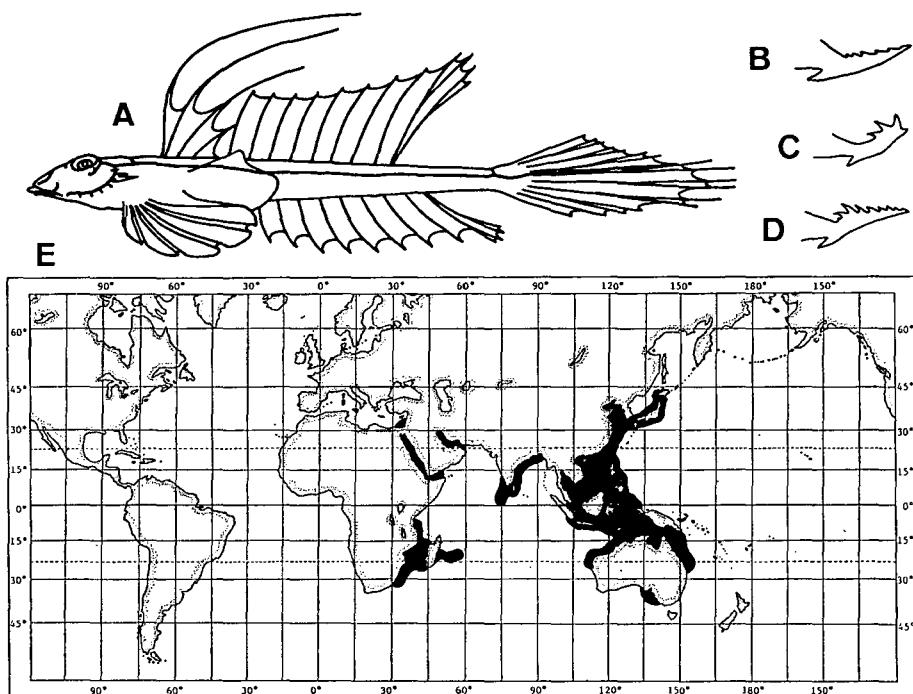

Fig. 17. *Repomucenus*. A, lateral view of a *R. huguenini*, male. Solid lines show the lateral line canals; B, C and D, preopercular spine of *R. huguenini*, *R. richardsonii* and *R. belcheri*; E, geographic distribution of the genus.

REMARKS: Whitley (1931a) established *Repomucenus* on the basis of *Callionymus calcaratus*, but his description of this genus is not definitive. In 1934, he established *Callimucenus* and *Velesionymus* on the bases of *Callionymus macdonaldi* and *C. limiceps*. These three species have common diagnostic characters and should be included in the genus *Repomucenus*.

Almost all the members of the genus *Repomucenus* have been included in *Callionymus*; but *Repomucenus* differs from *Callionymus* in the preopercular spine, the pattern of the cephalic lateral line and the long transverse branch of the lateral line. Therefore, the two genera should be separated.

Repomucenus originally was not distributed in the Mediterranean. *R. filamentosus* found in the eastern Mediterranean, is from the Red Sea (Tortonese, 1964; Ben-Tuvia, 1978).

This genus has the most species of this family.

Genus *Spinicapitichthys* Fricke, 1980

(Figs. 18, 28, 29J-K)

Spinicapitichthys Fricke, 1980, East. Ann. Mus. Civico St. Nat. Genova, 83, p. 60 (type-species by original designation: *Callionymus spiniceps* Regan).

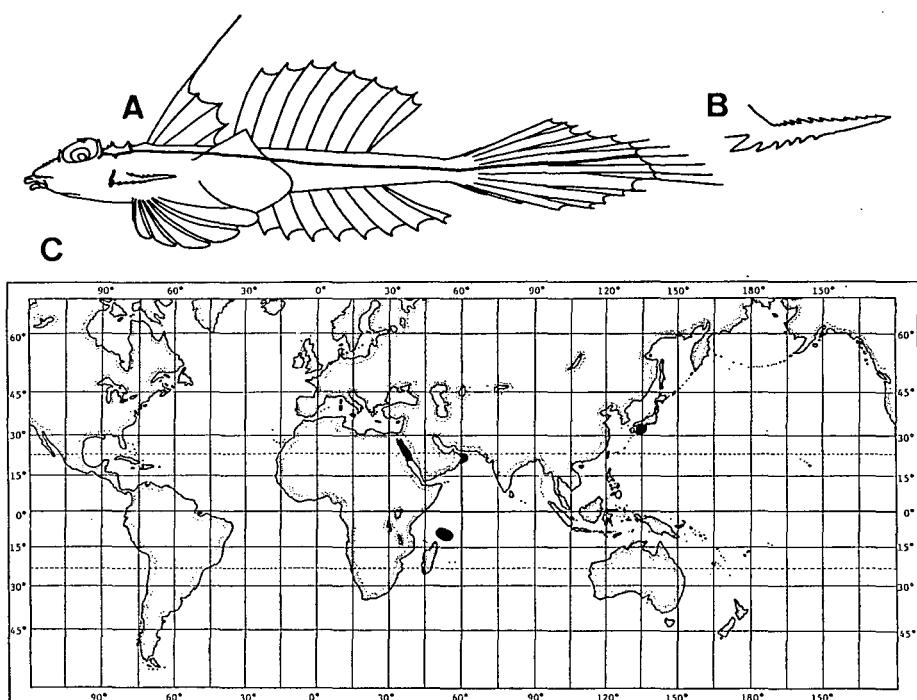

Fig. 18. *Spinicapitichthys*. A, lateral view of a *S. spiniceps*, female. Solid lines show the lateral line canals; B, preopercular spine of *S. spiniceps*; C, geographic distribution of the genus.

DESCRIPTION: D. IV, 8; A. 8; P₁. i+18–20; P₂. I, 5; C. i+7+ii.

Body elongate and depressed. Eye large. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Upper jaw protruding anterior. Occipital region with spines. Preopercular spine straight, many processes on outer and inner sides. Supraorbital canal extending slightly after nasal pore. Infraorbital canal simple, not extending below eye. Preoperculo-mandibular canal very short, only near preopercular spine. Lateral line reaching tip of median caudal ray; line of opposite side not interconnected on dorsal surface of caudal peduncle in most species (in *S. oxycephalus* interconnected both on dorsal and ventral surfaces).

First dorsal fin beginning at gill-opening. Tip of each ray of dorsal and anal fins simple. Upper half of pectoral fin slightly emarginated, lower half rounded.

Color in preserved specimens. Body marbled brown above, white below.

SECONDARY SEXUAL DIMORPHISM: The caudal fin of the male is longer than that of the female.

HABITAT: Sandy-muddy bottoms in deep waters near the edge of the continental shelf and on banks.

GEOGRAPHIC DISTRIBUTION: Gulf of Suez; the Seychelles, Saya de Malha Bank; Muscat; Japan.

REMARKS: Fricke (1980) established *Spinicapitichthys* a subgenus of *Callionymus*.

But *Spinicapitichthys* should be regarded as a genus separate from *Callionymus*. Many of its conspicuous diagnostic characters are generic ones.

Genus *Anaora* Gray, 1835

(Figs. 19, 25E, 29J)

Anaora Gray, 1835, Illustrations of Indian Zoology (type-species by original designation: *Anaora tentaculata* Gray).

Amora Gray, 1835, Illustrations of Indian Zoology (may be a typographical error).

DESCRIPTION: D. IV, 8; A. 7; P₁. 21–25 (tips of most rays simple); P₂. I, 5; C. ii+6+ii.

Body cylindrical. Eye moderately large. Short thread-like cirrus on the dorsoposterior edge of eye. Gill-opening midway between posterior edge of eye and upper origin of pectoral fin. Upper jaw protractile, oblique ventrally. Teeth on both upper and lower jaws degenerative. Preopercular spine with an antrorse process at base, upward process on inner side; posterior end pointed. Occipital region with a pair of bony tubercles. Infraorbital canal not extending below eye. Postocular commissure not connected to preoperculo-mandibular canal. Lateral line reaching base of caudal fin; line of opposite side not interconnected by transverse branch on dorsal surface of caudal peduncle.

First dorsal fin short, beginning slightly before upper origin of pectoral fin. Second dorsal fin emarginated. Tip of each dorsal and anal ray, except last branched ray, simple. Caudal fin with 6 bifurcate rays.

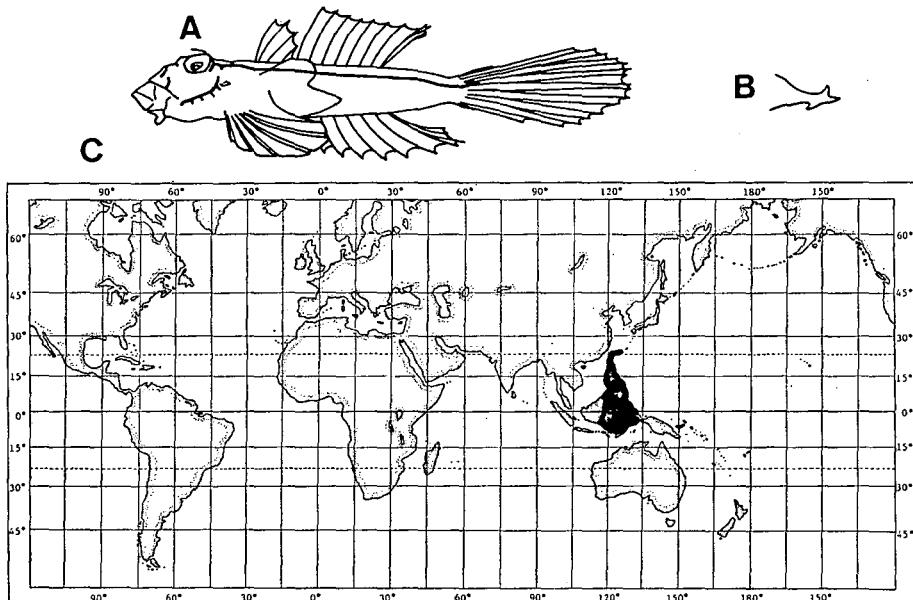

Fig. 19. *Anaora*. A lateral view of a *A. tentaculata*, male. Solid lines show the lateral line canals; B, preopercular spine of *A. tentaculata*; C, geographic distribution of the genus.

Color in preserved specimens. Body marbled brown above, white below. In some specimens of *A. tentaculata*, body pinkish above, white below.

SECONDARY SEXUAL CHARACTERS: The caudal fin of the male is larger than that of the female.

HABITAT: Sandy bottoms in shallow waters around islands.

GEOGRAPHIC DISTRIBUTION: Ryukyu Isls.; the Philippines; Borneo, Celebes and western New Guinea.

Genus *Eleutherochir* Bleeker, 1879

(Figs. 20, 22C, 29H)

Eleutherochir Bleeker, 1879, Versl. Akad. Amsterdam, 14, p. 102 (type-species by original designation: *Callionymus opercularioides* Bleeker).

Draculo Snyder, 1911, Proc. U.S. Nat. Mus., 40 (1836), p. 545 (type-species by original designation: *Draculo mirabilis* Snyder).

Draculus Jordan, Tanaka and Snyder, 1913, J. Coll. Sci., Imp., Univ. Tokyo, 33 (1), p. 377 (may be a typographical error).

Brachycallionymus Herre and Myers, in Herre, 1936, Proc. Biol. Soc. Washington, 49, p. 12 (type-species by original designation: *Brachycallionymus mirus* Herre).

Pogonymus Gosline, 1959, Pacif. Sci. 13 (1), p. 72 (type-species by original designation: *Pogonymus pogognathus* Gosline).

Charibarbitus Smith, 1963, Rhodes Univ. Ichthyol. Bull., 28, p. 562 (type-species by original designation: *Charibarbitus celetus* Smith).

Clathropus Smith, 1965, Ann. Mag. Nat. Hist. Ser. 13, vol. 8, p. 321 (type-species by original designation: *Clathropus maugei* Smith).

DESCRIPTION: D. absent or I-IV, 9-13; A. 9-13; P₁. i+16-23; P₂. I, 5; C. i+7+ii, ii+6+ii.

Ethmoidal region strongly depressed. Mouth large laterally. Upper margin of lower lip with row of many papillae. Row of very small teeth on upper and lower jaws. Lower jaw somewhat protractile anteriorly. In some species, transverse isthmial fold connects branchiostegal membranes from each side and unfolds when lower jaw protrudes anteriorly. Preopercular spine with no antrorse process at base, 2-5 upward processes on inner side; posterior end strongly curved upward. Cephalic lateral line well developed; infraorbital canal extending to middle of cheek with some short branches. Postocular commissure connected to preoperculo-mandibular canal, the latter above preopercular spine with short and long retrorse branch. Lateral line reaching tip of median caudal ray; line of opposite side interconnected by transverse branch across dorsal surface of caudal peduncle.

First dorsal fin degenerative. Tips of posterior 1-5 dorsal rays bifurcate. Pectoral fin lanceolate. Almost no membrane between pelvic fin and pectoral fin base. Caudal fin rounded.

Color in preserved specimens. Body dark brown above, white below.

SECONDARY SEXUAL DIMORPHISM: Rare.

HABITAT: Sandy bottoms in very shallow waters (beach). One species, *Eleutherochir opercularis*, enters brackish waters.

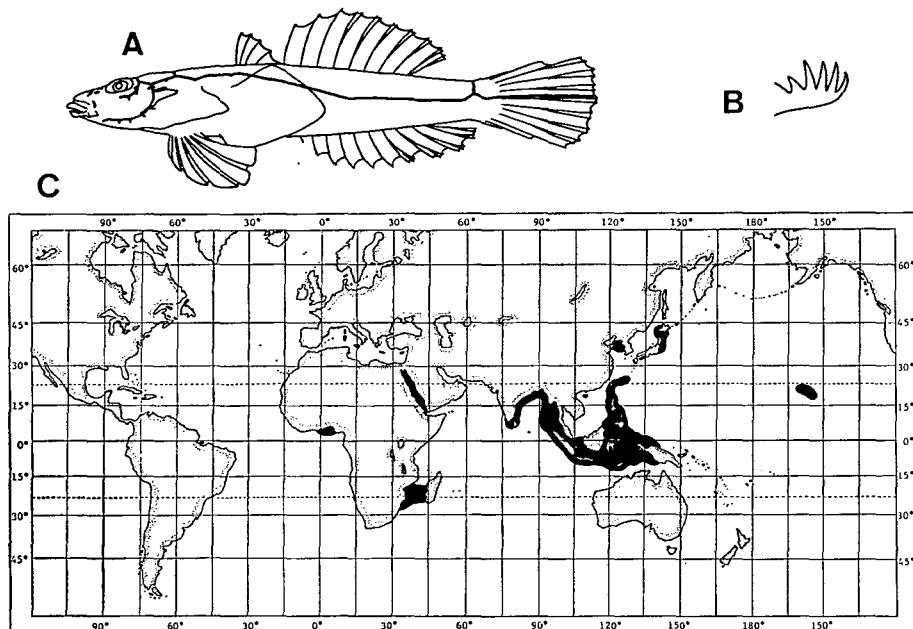

Fig. 20. *Eleutherochir*. A, lateral view of an *E. opercularis*, male. Solid lines show the lateral line canals; B, preopercular spine of *E. mirabilis*; C, geographic distribution of the genus.

GEOGRAPHIC DISTRIBUTION: coast of Nigeria; Red Sea; southeast coast of Africa; east coast of India; Indonesia; Borneo; Celebes; New Guinea; the Philippines; Japan; Po Hai; the Hawaiian Isls.

REMARKS: Bleeker established *Eleutherochir* on the basis of a protruding lower jaw, an opercular flap, and lack of a membrane between the pelvic fin and the pectoral fin base. Others have established different genera for the species in this genus because of the various diagnostic characters. But, the various genera have the diagnostic characters described above, in common, and should be included in the genus *Eleutherochir*.

Discussions of External Characters

1) Cephalic lateral line

The cephalic lateral line patterns, especially in the infraorbital and preoperculo-mandibular canals, can be separated into seven types. A simple infraorbital canal and preoperculo-mandibular canal with five short branches, Type A, is seen in *Callionymus*, *Foetorepus*, *Eocallionymus* and *Mintysynchiropus* (Fig. 22). A branched infraorbital canal and a preoperculo-mandibular canal above the preopercular spine with one or two short branches and a long branch, Type B, is seen in *Calliurichthys*, *Reponucenus* and *Eleutherochir* (Fig. 22). A branched infraorbital canal and preoperculo-mandibular canal separated into many parts, the part above the preopercular spine with

a branch, Type C, is seen in *Callionymus* (Fig. 23). A simple infraorbital canal and preoperculo-mandibular canal divided into two parts above the preopercular spine, Type D, is seen in *Callionymus*, *Neosynchiropus*, *Pterosynchiropus*, *Paradiplogrammus*, *Diplogrammus*, *Synchiropus*, *Orbonyx*, *Dactylopus*, *Pseudocalliurichthys* and *Anaora* (Figs. 24, 25). A branched infraorbital canal and preoperculo-mandibular canal divided into two parts above the preopercular spine, Type E, is seen in *Bathycallionymus*,

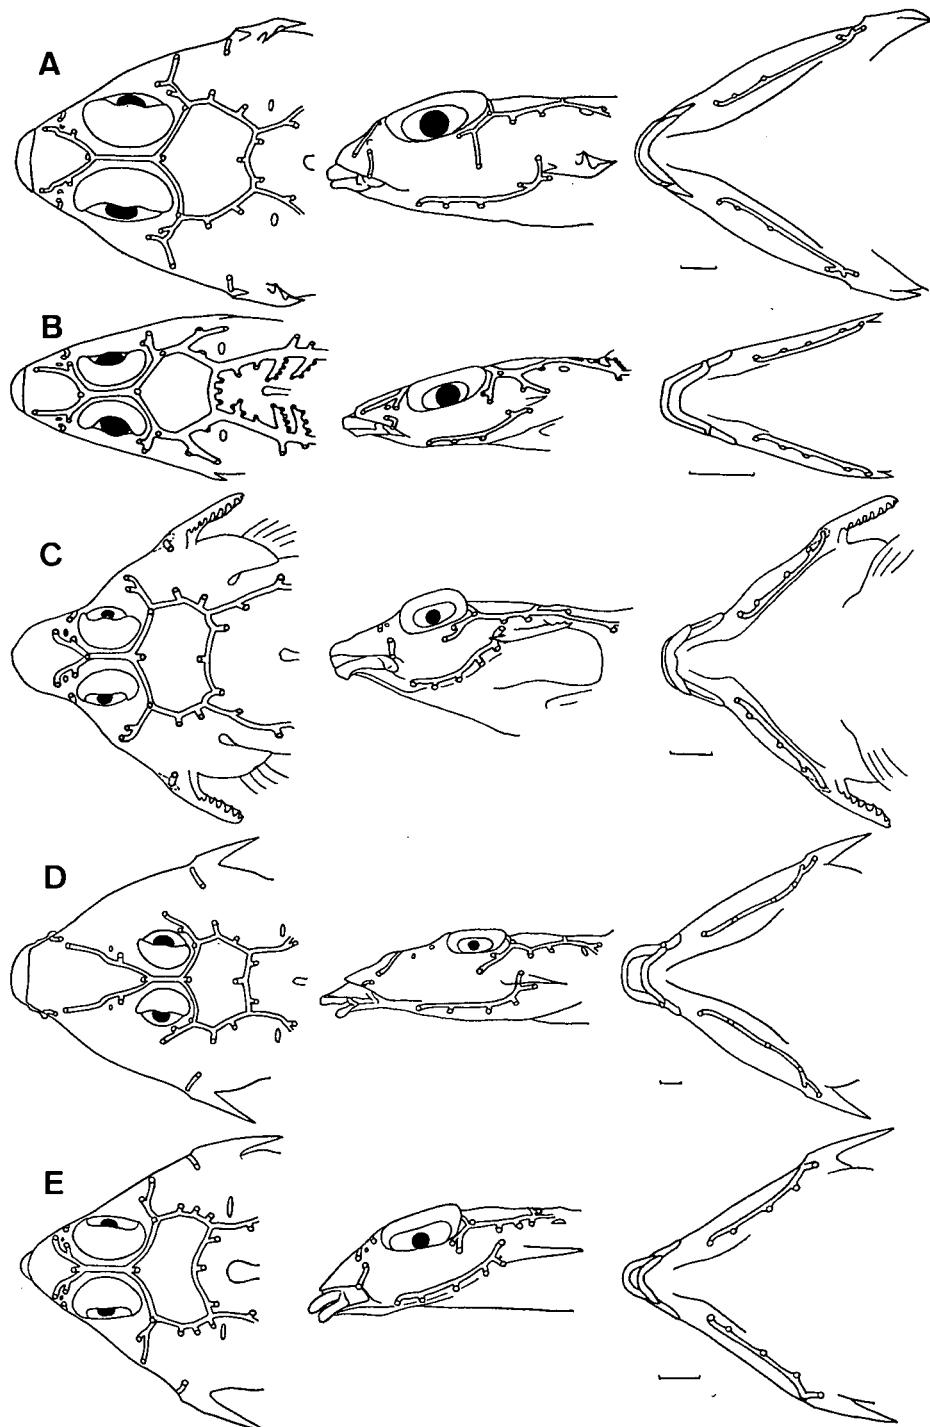

Fig. 26. The cephalic lateral line in five callionymid species. A, *Bathycallionymus moretonensis*; B, *Paracallionymus costatus*; C, *Diplogrammus xenicus*; D, *Pseudocalliurichthys goodladi*; E, *Calliurichthys grossi*. Left, dorsal view; middle, lateral view; right, ventral view. Scales indicate 5 mm.

Paracallionymus, *Diplogrammus*, *Pseudocalliurichthys* and *Calliurichthys* (Fig. 26). A simple infraorbital canal and a very short preoperculo-mandibular canal located near the preopercular spine, Type F, is seen in *Diplogrammus* (Fig. 27). A supraorbital canal that extends to just after the nasal pore, a simple infraorbital canal and a very short preoperculo-mandibular canal located near the preopercular spine, Type G, is seen in *Spinicapitichthys* (Fig. 28).

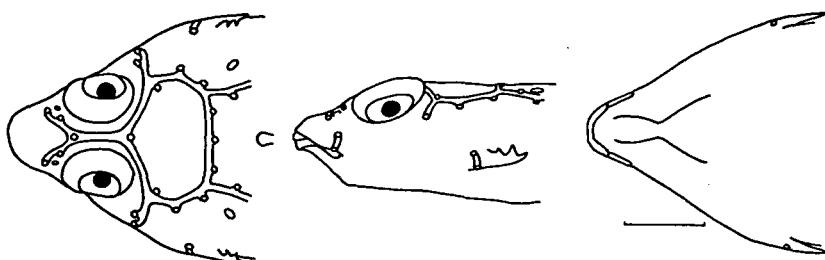

Fig. 27. The cephalic lateral line in *Diplogrammus pauciradiatus*. Left, dorsal view; middle, lateral view; right, ventral view. Scale indicates 5 mm.

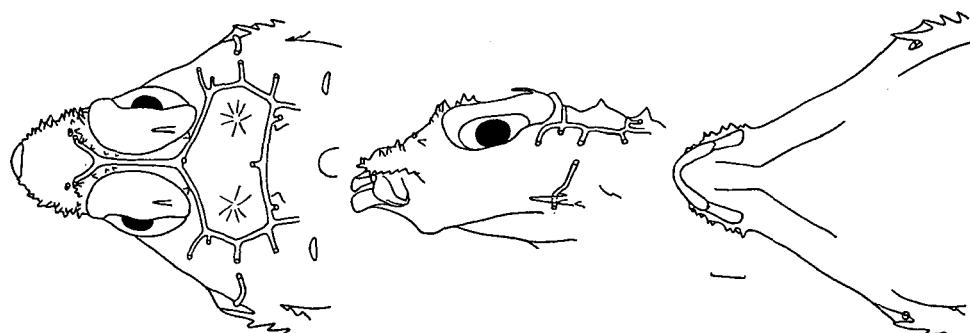

Fig. 28. The cephalic lateral line in *Spinicapitichthys spiniceps*. Left, dorsal view; middle, lateral view; right, ventral view. Scale indicates 5 mm.

A simple infraorbital canal is more primitive than other types because there are no infraorbital bones to carry it in this family; thus, a divided and extended infraorbital canal must be secondary. The preoperculo-mandibular canal of Type A must be more primitive than the other types because it is like that found in most standard percoid fish with compressed bodies.

The preoperculo-mandibular canal above the preopercular spine disappears in many genera. Because we do not know what shape this missing part had, the character of the cephalic lateral line cannot be used to determine the interrelationships among the genera. It can only be said that Type A is primitive.

Although some genera (*Callionymus*, *Calliurichthys* and *Diplogrammus*) have intra-specific variations in the cephalic lateral line, other genera (*Repomucenus* and *Eleutherodactylus*) are stable. In the latter genera, the cephalic lateral line is one of the generic characters.

2) Lateral line on the body

The lateral line patterns on the body can be roughly separated into five types. In Type A there are many separated or attached transverse branches on the dorsal surface of the body, and a commissure of the opposite lines on the dorsal surface of the caudal peduncle. Type A is seen in *Synchiropus*, *Callionymus* and *Calliurichthys* (Fig. 29A-D). In Type B there are many transverse branches on the dorsal surface of the body, and a commissure of the opposite lines on the dorsal surface of the caudal peduncle. Type B is seen only in *Paracallionymus* (Fig. 29E). In Type C there is only the commissure of the opposite lines on the dorsal surface of the caudal peduncle. Type C is seen in *Eocallionymus*, *Bathycallionymus*, *Repomucenus* and *Eleutherochir* (Fig. 29F-I). In Type D there are no transverse branches on the dorsal surface of the body, and no commissure of the opposite lines on the dorsal surface of the caudal peduncle. Type D is seen in *Foetorepus*, *Minysynchiropus*, *Diplogrammus*, *Paradiplogrammus*, *Neosynchiropus*, *Pterosynchiropus*, *Orbonyx*, *Dactylopus*, *Pseudocalliurichthys*, *Spinicapitichthys* and *Anaora* (Fig. 29J). In Type E the opposite line is interconnected by the transverse branches on both dorsal and ventral surfaces of the caudal

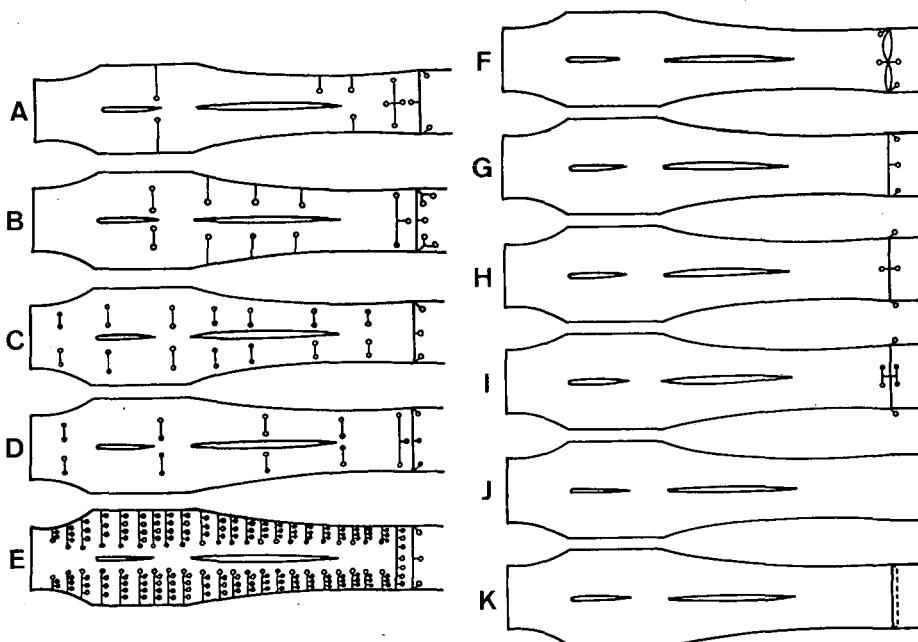

Fig. 29. Diagrammatic illustration showing the lateral line on callionymid body. A, *Synchiropus*; B, *Callionymus* (except *C. risso* and *C. pusillus*); C, *Callionymus risso* and *C. pusillus*; D, *Calliurichthys* (except *C. grossi* and *C.* sp.); E, *Paracallionymus*; F, *Eocallionymus*; G, *Bathycallionymus*; H, *Repomucenus* (except *R. huguenini*, *R. filamentosus*, *R. longi*, *R. brunneus*, *R. punctilateralis* and *R. virgis*) and *Eleutherochir*; I, *Repomucenus huguenini*, *R. filamentosus*, *R. longi*, *R. brunneus*, *R. punctilateralis* and *R. virgis*; J, *Anaora*, *Foetorepus*, *Minysynchiropus*, *Diplogrammus*, *Paradiplogrammus*, *Neosynchiropus*, *Pterosynchiropus*, *Orbonyx*, *Dactylopus*, *Pseudocalliurichthys*, *Spinicapitichthys* (except *S. oxycephalus*), *Calliurichthys grossi* and *Calliurichthys* sp.; K, *Spinicapitichthys oxycephalus* and *Calliurichthys neptunius*.

peduncle. Type E is seen in *Calliurichthys* and *Spinicapitichthys* (Fig. 29K)

It is difficult to determine which types of lateral line on the body are advanced. Three differentiations can be deduced: 1. Type D is the most primitive. Type C, A, B being successive derivations. Type E is derived from Type C; 2. Types B and C are derived from Type A, and Types D and E from Type C; 3. Types A, D and E are derived from Type C, and Type B from Type A. Types B and E could not be the origin, because each is seen in a few genus. But in some genera, lateral line on the body is one of the diagnostic characters.

3) Body size

Callionymid fishes can be divided into three groups based on their mature size: *Foetorepus*, *Callionymus*, *Bathycallionymus*, *Paracallionymus*, *Calliurichthys* and *Repomucenus* may be 150 mm or more in standard length; *Orbonyx*, *Dactylopus*, *Pseudocalliu-*
richthys and *Spinicapitichthys* may reach 100 mm; *Eocallionymus*, *Eleutherochir*, *Anaora*, *Diplogrammus*, *Paradiplogrammus*, *Minysynchiropus*, *Neosynchiropus*, *Pterosynchiropus* and *Synchiropus* may be 20–70 mm long.

A comparison of body size with habitat, shows that the six genera which reach a length of 150 mm or more live on sandy or muddy bottoms, mainly along a continental shelf. Five of the genera (exception *Paracallionymus*) have large populations world-wide. The three genera that reach a length of 100 mm live on sandy bottoms along a continental shelf or near islands. The sizes of their populations are small. The eight genera (exception *Eleutherochir*) which have lengths between 20 and 70 mm live on the sandy bottoms of coral reefs, in weedy beds, along rocky shores around islands. Their populations are small. *Eleutherochir* live on sandy bottoms in very shallow waters, in small populations.

4) Body form

The depth-width relationships of the bodies of the 19 genera are shown in Fig. 30. *Bathycallionymus*, *Calliurichthys*, *Repomucenus*, *Pseudocalliu-*
richthys and *Paracallionymus* are strongly depressed and elongate in body form. Since *Repomucenus* has the

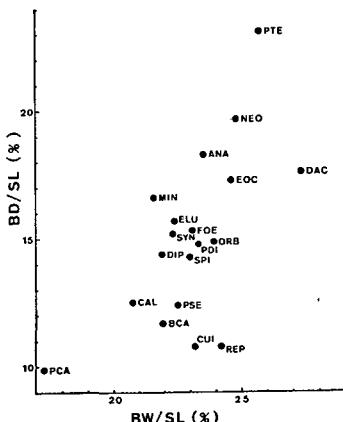

Fig. 30. The relationships between body depth and width in callionymid genera. BD, body depth; BW, body width; SL, standard length; ANA, *Anaora*; BCA, *Bathycallionymus*; CAL, *Callionymus*; CUI, *Calliurichthys*; DAC, *Dactylopus*; DIP, *Diplogrammus*; ELU, *Eleutherochir*; EOC, *Eocallionymus*; FOE, *Foetorepus*; MIN, *Minysynchiropus*; NEO, *Neosynchiropus*; ORB, *Orbonyx*; PCA, *Paracallionymus*; PDI, *Paradiplogrammus*; PSE, *Pseudocalliu-*
richthys; PTE, *Pterosynchiropus*; REP, *Repomucenus*; SPI, *Spinicapitichthys*; SYN, *Synchiropus*. Values are expressed as means between male's and female's averages.

flattest body of all, it seems to be the most adaptive to inhabit the sand-muddy bottoms on the continental shelf. *Foetorepus*, *Eocallionymus*, *Paradiplogrammus*, *Diplogrammus*, *Minysynchiropus*, *Synchiropus*, *Orbonymus*, *Dactylopus*, *Spinicapitichthys* and *Eleutherochir* are depressed and moderately elongate. *Neosynchiropus*, *Pterosynchiropus* and *Anaora* are moderately depressed, but not elongate. Since *Pterosynchiropus* has the most conical body of all, it seems to be the most adaptive to inhabit the coral reefs around islands. Strongly depressed and moderately depressed bodies seem to be derived from depressed one, because most genera have depressed body.

5) Body color

Eocallionymus, *Foetorepus calauropomus*, *Callionymus*, *Bathycallionymus regani*, *Anaora*, *Neosynchiropus*, *Synchiropus*, *Orbonymus*, *Dactylopus* and *Calliurichthys* are marbled light or dark sepia-brown. *Diplogrammus*, *Paradiplogrammus* and *Spinicapitichthys* are marbled dark brown. *Eleutherochir* is dark brown. *Minysynchiropus* is creamy white. *Bathycallionymus* (exception *B. regani*) is olive-brown. Fresh specimens of *Foetorepus* (exception *F. calauropomus*) are reddish. Fresh specimens of *Pterosynchiropus* are colorful. *Paracallionymus* is uniformly bleached. *Repomucenus* and *Pseudocalliurichthys* are marbled brown, like the surface of a sandy bottom.

As judged from the above, the sepia-brown body color is the most primitive because it is found in the most genera. Of all the genera, the body colors of *Repomucenus* and *Pseudocalliurichthys* are probably the most adaptive to sandy bottoms.

6) Eye diameter

Foetorepus, *Bathycallionymus*, *Paracallionymus* and some species of *Callionymus* have larger eyes than the others. All live mainly along deep shelf edges, on banks or on seamounts. Therefore, in the callionymid fishes, a large eye is correlated with a deep water habitat.

7) Secondary sexual dimorphism

In most callionymid species, secondary sexual dimorphism is conspicuous. The secondary sexual characters are found mainly in the unpaired fins of males. In *Diplogrammus*, *Paradiplogrammus*, *Minysynchiropus*, *Neosynchiropus*, *Paracallionymus*, *Pterosynchiropus*, *Orbonymus*, *Dactylopus*, *Pseudocalliurichthys*, and *Repomucenus*, the first dorsal fin is a conspicuously large secondary sexual character of the males. In *Callionymus* and *Bathycallionymus*, the second dorsal and anal fins are markedly expanded.

In *Calliurichthys* and *Spinicapitichthys*, the caudal fin is very elongated. Although secondary sexual dimorphism exists in *Foetorepus*, *Eocallionymus*, and *Anaora*, no markedly conspicuous unpaired fin is present. In *Eleutherochir*, secondary sexual dimorphism is rare. Secondary sexual dimorphism could not be studied in *Synchiropus* because of lack of specimens.

Male's conspicuous first dorsal fin in *Repomucenus valenciennei* (= *Callionymus flagris* in their paper) and *R. richardsonii* (= *C. richardsoni*) has a role in distinguishing species and in attracting the female (Takita and Okamoto, 1979). This also is

true of the unpaired fins in other species and genera. Thus, secondary sexual dimorphism in the unpaired fins is necessary for the maintenance of populations of species in the animal community. If the types of secondary sexual dimorphism listed above did not vary so widely, they could be used as features of the phylogeny of callionymids.

Summary

1. A new classification for Callionymidae which includes 19 genera and 139 valid species is proposed. *Callionymus*, *Foetorepus*, *Paracallionymus*, *Diplogrammus*, *Synchiropus*, *Orbonyx*, *Dactylopus*, *Calliurichthys*, *Repomucenus*, *Spinicapitichthys*, *Anaora* and *Eleutherochir* are redefined; *Bathycallionymus*, *Eocallionymus*, *Neosynchiropus*, *Pterosynchiropus*, *Minysynchiropus*, *Paradiplogrammus* and *Pseudocalliurichthys* are established as new.

2. There are 7 pattern types for the cephalic lateral line, and 5 types for the lateral line on the body. Neither line can be used to determine phylogenetic relationships among the genera; but in some genera, the pattern of the lateral line are a diagnostic character.

3. Dragonets vary in mature size from very small (20 mm in standard length) to large (200 mm).

4. The body form of the callionymid genera vary from almost conical to strongly depressed. *Pterosynchiropus* has the deepest body and *Repomucenus* has the most depressed body.

5. The callionymid show a variety of color patterns on their bodies. Marbled sepia-brown color which most genera have is the most primitive, and marbled brown color like the surface of a sandy bottom which *Repomucenus* and *Pseudocalliurichthys* have is the most adaptive to benthic life.

6. In most callionymid species, the mature male has conspicuous secondary sexual characters. In some genera the secondary sexual character shows on the first dorsal fin, but it may be manifested in the second and anal fins, or in some cases in the caudal fin.

Acknowledgements

I express my deep gratitude to Dr. Tamotsu Iwai who, as my major professor at Kyoto University, has been a constant source of help throughout this study and who made a critical reading of the entire manuscript. Special thanks are extended to Dr. Akira Ochiai, professor of Kochi University, who gave me much helpful advice and encouragement; and Dr. Eiji Harada, professor of Seto Marine Biological Laboratory, Kyoto University, who gave me the chance to publish this study.

This study would not have been possible without the generous cooperation of many people. The following persons and institutions lent or gave specimens, or accommodated me during visits: Drs. John R. Paxton, Douglass F. Hoese and Ms. Helen Larson of the Australian Museum; Drs. James E. Böhlke and William F. Smith-Vaniz of the Academy of Natural Sciences of Philadelphia; Mr. Ronald Fricke

of Braunschweig; Mr. Alwyne Wheeler of British Museum (Natural History); Mr. Akihisa Iwata of Ehime University; Drs. Tetsuya Sato, Hiroshi Hatanaka, Yasuo Nishikawa and Mr. Yuji Uozumi of Far Seas Fisheries Research Laboratory; Dr. William N. Eschmeyer of California Academy of Sciences; Mr. Hiroshi Senou of Kinki University; Dr. Izumi Nakamura and Mr. Kosaku Yamaoka of Kyoto University; Drs. Takao Igarashi, Kunio Amaoka, Messrs. Mamoru Yabe and Eiichi Yamamoto of Hokkaido University; Dr. Robert R. Miller and Mr. Stuart G. Poss of the University of Michigan; Dr. Toru Takita of Nagasaki University; Dr. Ryoichi Arai of National Science Museum, Tokyo; Dr. Harald Ahnelt of Naturhistorisches Museum Wien; Drs. Roland J. McKay and J. Johnson of Queensland Museum; Dr. Marinus Boeseman of Rijksmuseum van Natuurlijke Historie, Leiden; Mr. Tetsuo Yoshino of University of the Ryukyus; Mrs. Margaret M. Smith and Dr. Phillip C. Heemstra of J.L.B. Smith Institute of Ichthyology, Rhodes University; Mr. Eiichi Fujii of Suruga Bay Marine Biology Research Group; Dr. Fujio Yasuda, Messrs. Akira Zama and Akihiko Yatsu of Tokyo University of Fisheries; Dr. Victor G. Springer of United States National Museum of Smithsonian Institution; Dr. Gerald R. Allen of Western Australian Museum; Dr. Masayoshi Hayashi of Yokosuka City Museum.
