

Catalogue of terrestrial gastropods from Galápagos (except Bulimulidae and Succineidae) with description of a new species of *Ambrosiella* ODHNER (Achatinellidae)

(Mollusca: Gastropoda)

SERGIO E. MIQUEL¹ & HENRI W. HERRERA^{2,3}

Abstract

Excluding the families Bulimulidae and Succineidae, 27 species of land shells were identified in the Galápagos Archipelago (Ecuador), recorded in 14 islands. Many of the species are endemic, belonging to Helicinidae (two species), Achatinellidae (two), Pupillidae (four), Vallonidae (two), Strobilopsidae (one), Pristilomatidae (two), and Euconulidae (three). The most abundant records are found in the human inhabited islands: Santa Cruz, San Cristóbal, Isabela and Floreana. None of the families or genera is exclusive to the archipelago; the only endemic subgenus is *Strobilops* (*Nesostrobilops*). The most widespread species is *Gastrocopta munita*, recorded from 12 islands. Only a few species are recorded as unique to a single island (e.g., *Nesopupa (Infranesopupa) galapagensis*). A new species of *Ambrosiella* (Achatinellidae) from Floreana is described: characterized by a parietal lamella in the aperture, this species is related to the Chilean insular fauna. Human inhabited islands host several exotic species of inadvertently introduced micromolluscs and slugs, and one intentional introduction (*Lissachatina fulica*). Although the introduced species are dominant in anthropogenic altered sectors of the islands, they have also invaded natural areas. New records extend the distribution of almost all terrestrial gastropod species in the Archipelago.

Key words: Molluscs, Neritimorpha, Pulmonata, South America, Ecuador, Galápagos.

Introduction

Numerous scientific expeditions have been undertaken to the Galápagos Islands, officially named the Archipiélago de Colón (Columbus Archipelago), (Map 1), in the course of the nineteenth and twentieth centuries, during which several specimens of flora and fauna were collected. Among the most important were the Petrel Expedition (1875), the U. S. Fish Commission Steamer “Albatross” (1887–1888), the Stanford-Hopkins Expedition (1898–1899) and the expedition organized by the

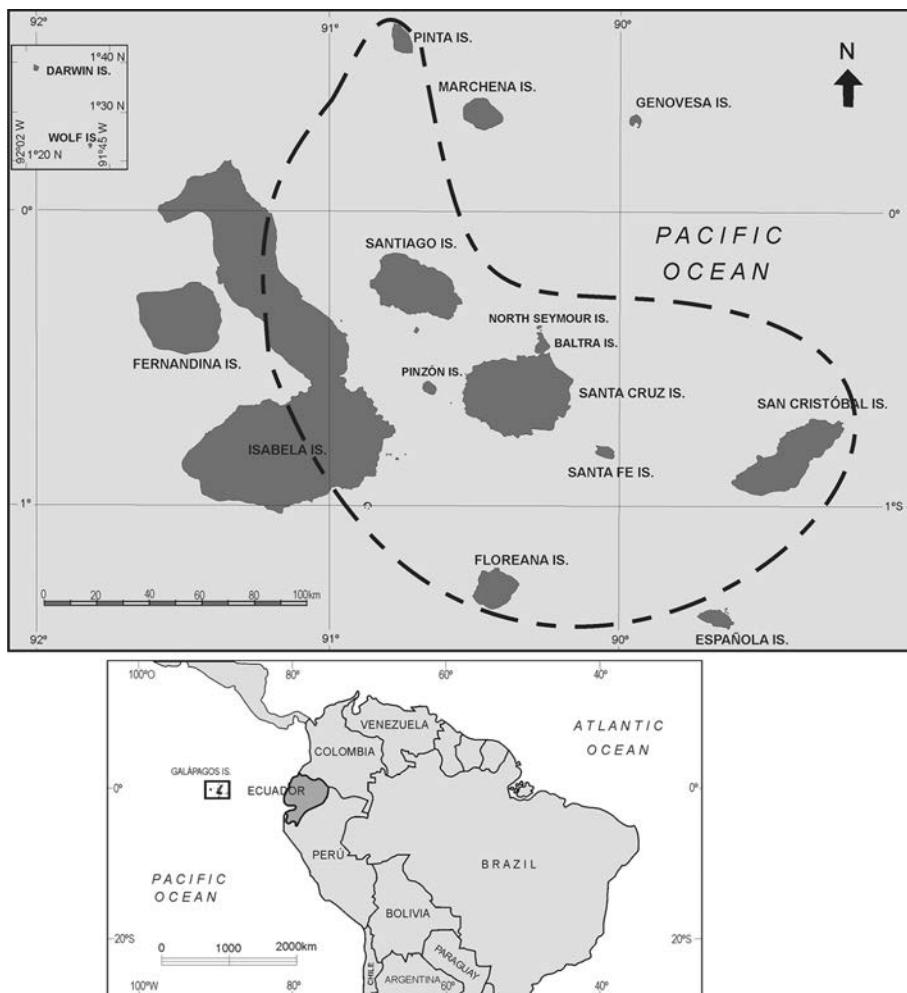

California Academy of Sciences (1905–1906). Currently, most of the specimens are deposited in institutions in the United States of America (Academy of Natural Sciences of Philadelphia, California Academy of Sciences and United States of Natural Museum).

In 1894, STEARNS summarized the malacological records published in the nineteenth century by REIBISCH (1893), DALL (1892, 1893) and others authors. DALL was the major contributor to the description of terrestrial gas-

tropods from Galápagos, contributing to species of the families Helicinidae, Tornatellidae, Strobilopsidae, Pristilomatidae, and Euconulidae (DALL 1892, 1893, 1900, 1917). REIBISCH (1893), PILSBRY (1931, 1934), VAG-

VOLGYI (1974) and WU & ITOW (1988) further contributed to the records of these micromollusc families.

This catalogue is mainly based on the study of the collection of terrestrial molluscs housed at the Charles Darwin Foundation (Puerto Ayora, Santa Cruz Island, Galápagos), whose history and objectives have been discussed by KRAMER (2009) and PARENT et al. (2012). It is intended to update the knowledge of such terrestrial molluscs through descriptions, illustrations, and distributions maps, with the exception of Bulimulidae and Succineidae, which are being subject of up-coming studies (Parent, pers.commun.), updating the old edited catalogue (DALL & OCHSNER, 1928) referred to these two families.

The genus *Ambrosiella* ODHNER 1963 is cited for the first time outside its native range in the San Ambrosio Island, Chile, with the description of a new species, *A. floreanae*, from Floreana Island.

Materials and methods

The materials are housed in the Terrestrial Invertebrate Collection of the Charles Darwin Foundation in Puerto Ayora, comprising about 350 samples. Most of this collection is based on shells, many of them preserved in ethanol. Some of them were photographed

in the Service of Scanning Electron Microscopy of the Museo Argentino de Ciencias Naturales “Bernardino Rivadavia”. Material housed in foreign repositories (some of them types) and some other material, determined at specific and/or generic level, were included in the text and analysed in the Table 2. For the distributions, the islands are cited according to the official Spanish names currently in use, while for type localities, they are named as they appear in the original nomenclature (Table 1) (SNELL et al. 1996). The records for the generic discrimination are summarized in Table 2.

Description (shell): Shell small, depressed, with rounded periphery; spire depressed; suture very distinct, not channelled; base moderately convex; peristome not thickened nor reflected; epidermis of a bright reddish chestnut, polished, but with obvious regular incremental lines; base with a thin white callus merging into the lower lip without notch or angle; operculum smooth, whitish, angulated only at the upper extreme; 2.3 × 3.3 mm (DALL 1896).

Measurements of figured specimen CDF: 3.50 × 2.70 mm (ICCDRS 0036988).

Type locality: “On leaves of plants on Chatham Is. at an elevation of 1,600 feet above the sea” (DALL 1896) (San Cristóbal, 525 m.a.s.l.).

Known distribution: Floreana, Isabela, San Cristóbal and Santa Cruz Islands; in San Cristóbal to 295 to 656 m.a.s.l., “among the mosses and rocks” (STEARNS 1894).

Records in CDF collection: Lives in areas of agriculture of Isabela and San Cristóbal and natural areas of Floreana.

Holocene distribution: Floreana and Santa Cruz Islands (CHAMBERS & STEADMAN 1986; see USNM Coll.).

Remark: WAGNER (1907–11) classified it in the Pacific genus *Sturanya* WAGNER 1905.

Type series: Lectotype: USNM 107324 (selected by CHAMBERS & STEADMAN 1986 as “Holotype”, R. HERSCHLER, pers. comm., 2011); Paralectotypes: USNM 887514/15; Paralectotypes (ex “paratypes”): MCZ Malacology 25420/10. San Cristóbal Is.

Description (shell): Shell high, more conical and slightly larger, blackish periostracum which is raised on the spire between sutures into two or three fringed

Figs 1–2 *Helicina nesiotica* DALL 1892. Fig. 1 Lectotype. USNM 107324. San Cristóbal Island. Fig. 2 ICCDRS 0036988. Floreana, Cerro Pajas. — Figs 3–4 *Helicina ochsneri* DALL 1917. Fig. 3 CAS-IZ 66448.00. Lectotype. Isabela Island. Fig. 4 ICCDRS 0036566, Santa Cruz Island.

short spiral threads; the periostracum appears to be of an adhesive nature and all the specimens in their original condition are more or less covered with a blackish coating; 4.7 × 3.5 mm (DALL 1917).

Measurements of figured specimen CDF: 2.93 × 3.67 mm, 4.25 whorls (ICCDRS 0036566).

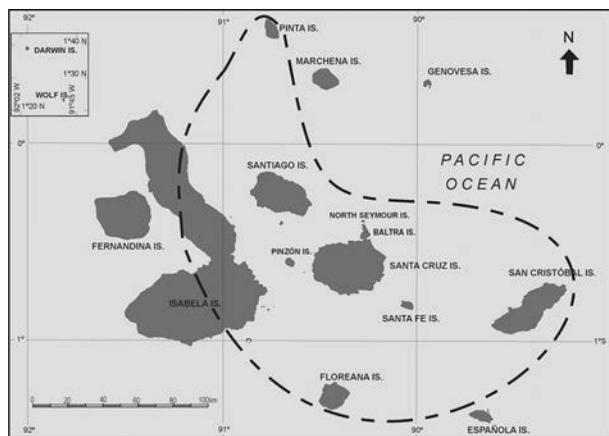

Type locality: “Albemarle Is., eight miles west of Turtle Cove, near salt lagoon; and at Cowley Mountain on moist ground, 350 to 500 feet above the sea” (DALL 1917) (Isabela Island, 115–164 m.a.s.l.).

Known distribution: Isabela and San Cristóbal Islands.

Records in CDF collection: Floreana, Isabela, Pinta, San Cristóbal, Santa Cruz and Santiago Islands. Reported in an urban area of Santa Cruz Island (Bellavista), in areas of agriculture of Isabela and San Cristóbal, and *Scalesia* zone and the interior of the crater of Cerro Pajas (Floreana).

Type series: Lectotype: CAS-IZ 66448.00; Parlectotypes: CAS-IZ 64158.00/5 (C. PIOTROWSKI, pers. comm., 2011); USNM 216021/5, USNM 216022/4. ISA, Cowley Mountain.

Description (shell): Shell small, with a blunt apex and six rounded whorls; suture very distinct; horn-colored; surface polished, delicately marked with lines of growth; base rounded, relatively rather widely umbilicated; aperture with the margin hardly thickened, rounded in front and at the suture; pillar broad, thin; body with a single elevated, thin, sharp lamina, extending spirally inward from a point a little behind the peristome and nearly equidistant from the inner and outer lips; 3.0 × 1.6 mm (DALL, 1896; PILSBRY 1915).

Measurements of figured specimen CDF: 2.33 × 1.33 mm, 4.25 whorls (ICCDRS 0036629).

Type locality of *T. chathamensis*: “Chatham Is., on ferns at 1,600–2,000 feet above sea level” (DALL, 1896) (San Cristóbal, 525–656 m.a.s.l.).

Type locality of *B. (P.) cymatoferus*: San Cristóbal Island.

Known distribution: Fernandina, Floreana, Isabela, Pinzón, San Cristóbal and Santa Cruz Islands. On the fronds of ferns (DALL & OCHSNER 1928).

Records in CDF collection: Floreana, Isabela, Pinta, San Cristóbal and Santa Cruz Islands. In areas of agriculture of Floreana, San Cristóbal and Santa Cruz; in Sierra Negra/Pampa and Cerro Pajas (*Scalesia*

zone and crater) (Floreana), and in *Miconia* zone (Santa Cruz).

Holocene distribution: Santa Cruz Island (CHAMBERS & STEADMAN 1986; see USNM, NRS w/n and BPBM Colls. (ODHNER 1951 and CHAMBERS & STEADMAN 1986).

Remark: see DALL (1896) and CHAMBERS & STEADMAN (1986) for more synonymies.

Type series: *L. chathamensis*: Syntypes: USNM 107322/6.

1988 *Tornatellides kahoolavensis* WU & ITOW 1988: 12.

Diagnosis (shell): Shell turrited, with 6 whorls convex, imperforate, last whorl larger than the spire, parietal edge of the aperture with a medial, sharp and concave lamella; columella with one or two lamellae, the lower is strong, the upper is weak and not always present; colour nearly uniform brown.

Description (shell): Shell turrited, with 6 whorls slightly convex, imperforate, thin, 1.75 higher than wide, apex acute, suture rather deep; last whorl larger than the spire (between 60–65 % respect to the length), aperture is somewhat oblique, tight, almost 2/3 respect to the last whorl, parietal edge with a medial, sharp and concave lamella, internal wall of aperture is smooth; columella straight, with one or two lamellae, the lower is strong, the upper is weak and not always present (can be inadvertent when its position is very internal); growth lines faintly marked; colour nearly uniform weakly brown.

Measurements of holotype ICCDRS 0036992-1: 2.50 × 1.30 mm, 6 whorls (ICCDRS 0036992).

Type locality: Ecuador, Galápagos province, Floreana Is., Pampa de Alviar, S1°18'47.99" W90°26'6.72". Coll. R. Martínez, 15/I/2011.

Actual distribution: Floreana Island, Galápagos province, Ecuador.

Type series: holotype ICCDRS 0036992-1; 13 paratypes ICCDRS 0036992-2; 1 paratype: ICCDRS 0036932. — Additional paratypes: Ecuador, Galápagos province, Floreana Island, Pampa de Alviar, 1°18'47.99"S 90°26'6.72"W. Measurements of some type specimens of *Ambrosiella floreanae* n. sp. (all of them show the described lamellae).

Types	height × width	whorls
Holotype ICCDRS 0036992	2.50 × 1.30	6.00
Paratype ICCDRS 0036932	1.30 × 0.90	3.50
Paratype ICCDRS 0037032	2.00 × 1.20	4.75
Paratype ICCDRS 0037032	1.05 × 0.80	3.50
Paratype ICCDRS 0037050	2.35 × 1.45	5.25
Paratype ICCDRS 0037050	1.70 × 1.15	3.50
Paratype ICCDRS 0037050	1.20 × 0.90	2.25

Remark: *Tornatellides kahoolavense* Pilsbry & Cooke, 1915 (p. 211, pl. 46, figs. 3, 4, 7), from Hawaii, was cited by Wu & Itow (1988) for Santa Cruz and Floreana Islands (*Tornatellides kahoolavense*: UCM 34089. 1 spec. broken. Coll. Syuzo Ito, 2/II/1964. Galápagos Islands, Floreana Island, 470 m altitude, from *Macrea* plant). It was not possible to confirm this record, but the image of the specimen is similar to *A. floreanae* n. sp.

Comparisons with related species: *Ambrosiella kuscheli* ODHNER 1963, type species by monotypy of *Ambrosiella* ODHNER 1963 from San Ambrosio Island (Desventuradas Islands, Chile) is characterized by 6 × 2.6 mm and 6 to 7 whorls, and a protoconch with a weakly spiral sculpture. *Tornatellides kahoolavense* differs in the aperture (number and size of lamellae), its protoconch lacks spiral grooves, and it has 6 whorls and 3.2 × 1.5 mm.

A photograph of a unique specimen of *T. kahoolavense* (UCM 34089) shows its similarities with *A. floreanae*. *Tornatellina bilamellata* ANTON 1839 from Pascua Island and Archipago Juan Fernández and *Tornatellides idae* PILSBRY & COOKE 1915 and *T. diptyx* PILSBRY & COOKE 1915, both from Hawaii, are different in number of columellar lamellae and the presence of internal ribs on the inner wall of the aperture.

1972 *Gastrocopta munita* REIBISCH, — HERTLEIN: 31.
1991 *Gastrocopta munita* REIBISCH, — CHAMBERS: 309.

Description (shell): Shell ovate-cylindric, whorls 5 to 5 1/3, convex; deeply rimate, with obtuse apex; thin, diaphanous, smooth, opaque, pale corneous or whitish; suture moderately deep; aperture subvertical, rounded, calloused; a bituberculate entering fold on the parietal wall of the aperture, another simple, somewhat receding one on the columella, as well as 4 smaller denticles within the outer lip, which, however, are often lacking, excepting the one opposite the parietal lamella; the broad peristome is reflected and the margins are connected by a rounded callous; 2.5 × 1.5 mm (REIBISCH 1893; PILSBRY 1916).

Measurements of figured specimen CDF: 2.30 × 1.27 mm, 5 whorls (ICCDRS 0036663).

Type locality: “Albemarle Is., on shrubs near the seashore” (REIBISCH 1893). By PILSBRY (1916: 97), Tagus Cove could be considered its typical locality (Isabela Is.).

Known distribution: Baltra, Daphne Mayor, Fernandina, Floreana, Genovesa, Isabela, Pinzón and Santa Fe. Dubiously, in San Cristóbal Island.

Records in CDF collection: Fernandina, Floreana, Genovesa, Isabela, Pinta, Pinzón, Santa Cruz, Santiago and Seymour Norte. In natural environments of Genovesa Island (Darwin Bay), in *Scalesia* zone and Cerro Pajas of Floreana Island, in Sierra Negra/Pampa and the arid high area, in “guayabillos” and in Pega-Pega forest of Volcán Alcedo in Isabela Island; in “guayabillos” of Santiago Island, and areas of agriculture of Isabela Island.

Remarks: It is the most common and widely distributed species of *Gastrocopta* of the Galápagos Islands (DALL & OCHSNER 1928), HERTLEIN (1932) report it “under bushes, on top of the plateau on the southeast part of South Seymour Is.”. SMITH (1971) cited *Gastrocopta* cf. *G. munita* for San Cristóbal. REIBISCH (1893: 29, Taf. II, Fig. 13) reported *Gastrocopta wolfi* (MILLER 1879) to “900–2,000 feet” in San Cristóbal Island, but PILSBRY (1918: 357) said that *G. wolfi* lives in continental Ecuador, and it is absent in Galápagos. *Pupilla reibischii* DALL in DALL & OCHSNER 1928 from Isabela Island, could be a similar species to *G. munita* (PILSBRY 1918: 358; 1931: 67), although DALL & OCHSNER (1928: 174) considered it a different species.

DALL & OCHSNER (1928) said that *Gastrocopta* (as *Pupilla*) lives in Marchena Island, although we did not see specimens from this island (Table 2). VAGVOLGYI (1979) indicated the existence of 8 species of *Gastrocopta* in Galápagos, but he never edited details of this opinion; none of the specimens were located.

Type series: Syntype ANSP 5613/1 (*G. (P.) reibischii* DALL). Isabela (Albemarle) Is. Tajus Cove; Syntypes CAS-IZ 1905-06 (C. PIOTROWSKI, pers. comm., 2011).

- 1986 *Gastrocopta clausa* REIBISCH, – CHAMBERS & STEADMAN: 95.
- 1991 *Gastrocopta clausa* REIBISCH, – CHAMBERS: 309.

Description (shell): Shell ovate cylindric with obtuse summit, 4 2/3 convex whorls, deeply rimate, thin, smooth, matt, pale corneous or whitish, suture rather deep, aperture nearly vertical, round, narrowed by numerous teeth, the bipartite parietal tooth runs deeply into the throat, also the columellar tooth; in the outer wall there are two small denticles, something wanting, on each side of the strongly developed middle tooth, which stands opposite the parietal tooth; the peristome expands but little and is hardly reflected, the ends joined by a rounded callous; 2.20 × 1.25 mm (REIBISCH 1893; PILSBRY 1916).

Map 4: Distribution of *Gastrocopta munita* (broken and dotted line), *Gastrocopta clausa* (broken line), *Gastrocopta duncana* (black islands) and *Nesopupa (Infranesopupa) galapagensis* (white area).

Measurements of figured specimen CDF: 1.95 × 0.90 mm, 4.25 whorls (ICCDRS 0037038).

Type locality: "Indefatigable Is., on shrubs near the seashore" (REIBISCH 1893) (Santa Cruz Island).

Known distribution: Fernandina, Floreana, Isabela, Pinta, Pinzón, San Cristóbal and Santa Cruz Islands.

Records in CDF collection: Floreana Island (natural areas).

Holocene distribution: Floreana and Santa Cruz Islands (CHAMBERS & STEADMAN 1986; see USNM Coll.).

Type series: Syntypes: CAS-IZ 1905-06 (C. PIOTROWSKI, pers. comm., 2011); Syntypes: ANSP 152703. Pinzón (Duncan) Is., S. side; ANSP 152704. Floreana (Charles) Is., Black Beach; Syntypes: ANSP 152718. Gastrocopta duncana PILSBRY 1931

Fig. 16, map 4

- 1931 *Gastrocopta duncana* PILSBRY: 65.
- 1934 *Gastrocopta duncana* PILSBRY, – PILSBRY: pl. 17, figs. 1–2.
- 1986 *Gastrocopta duncana* PILSBRY, – CHAMBERS & STEADMAN: 95.
- 1991 *Gastrocopta duncana* PILSBRY, – CHAMBERS: 309.

Description (shell): Shell oblong, 5 ½ whorls moderately convex, the last without wave or crest behind the outer lip; surface glossy, very weakly, finely marked with growth lines; colour translucent cinnamon, aperture tawny; the aperture is shortly oval; peristome reflected, strongly thickened within, the outer lip becoming nar-

rowed above; the terminations of lip are connected by a rather short, somewhat heavy parietal callus, thin at the edge; three or four teeth, angulo-parietal lamella strong, simple and straight, columellar lamella rather strong, horizontal, lower palatal fold rather strong, entering, the upper-palatal minute and tubercular, often wanting; the summits of the teeth are whitish; 2.75×1.2 mm (PILSBRY 1931).

Type locality: "Duncan Is., on the south side, from about 500 feet to near the summit" (PILSBRY 1931) (Pinzón Island, 164 m.a.s.l.).

Known distribution: Pinzón Island.

Holocene distribution: Santa Cruz Island (CHAMBERS & STEADMAN 1986; see USNM Coll.).

Type series: Lectotype + 3 paralectotypes: ANSP 152689/1+3; Paralectotypes ANSP 152690/8. Pinzón (Duncan) Is., Nr. summit; Paralectotypes: ANSP 152691/5. Nesopupinae STEENBERG 1925

Nesopupa PILSBRY 1900

Nesopupa (Infranesopupa) COOKE & PILSBRY in PILSBRY 1920

Nesopupa (Infranesopupa) galapagensis VAGVOLGYI 1974

Fig. 17, map 4

- 1974 *Nesopupa (Infranesopupa) galapagensis* VAGVOLGYI: 86.
- 1975 *Nesopupa (Infranesopupa) galapagensis* VAGVOLGYI, – VAGVOLGYI: 475.
- 1991 *Nesopupa galapagensis* VAGVOLGYI, – CHAMBERS: 309.

Description (shell): Shell nearly cylindrical, cylindrical-oval or oval, whorls convex, sutures deep, particularly so in the cylindrical specimens; the last whorl ascends upon the penultimate one prior to the aperture; slightly in the oval specimens, more distinctly in the cylindrical ones; the umbilicus is minute; the aperture is oval-triangular with a notch on the outer lip formed by the inward and forward projecting middle part of the outer lip; the lips are slightly reflected; the parietal wall is covered by a weak callus that connects the origin of the outer and inner lips; corresponding to the lip swelling there is a weak and wide annular crest on the outside of the shell; 1.9×1.1 mm (VAGVOLGYI 1974).

Type locality: "Peak 2974", central highlands, Santiago Is." (VAGVOLGYI 1974).

Known distribution: Santiago Island.

Type series: Holotype: ANSP 332451; Paratypes ANSP 332452; DM Paratypes 70650.

Valloniidae MORSE 1864

Pupisoma STOLICZKA 1873

Pupisoma (Pupisoma?) galapagorum PILSBRY 1934

Figs 19–19, map 5

- 1934 *Pupisoma galapagorum* PILSBRY: 114, pl. 16, figs. 7–9.
- 1963 *Pupisoma galapagorum* PILSBRY, – BAKER: 201.
- 1988 *Pupisoma galapagorum* PILSBRY, – WU & ITOW: 12, fig. 2.
- 1991 *Pupisoma galapagorum* PILSBRY, – CHAMBERS: 309.

Description (shell): Shell globose, conic, or turbinate, with obtuse apex; umbilicate, the umbilicus contained about five times in the diameter; cinnamon-brown; whorls are strongly convex, joined by a very deeply impressed suture; the last whorl rounded basally around the open umbilicus; aperture rotund, slightly oblique; lip thin, the columellar margin broadly reflected, half covering the umbilicus in a front view, but scarcely imprinting upon it in a basal view; sculpture of fine, close wrinkles, irregularly developed, being weak or nearly effaced in places, and absent on the embryonic $1\frac{1}{2}$ whorls; also a weak and very minute pitting, which is also quite irregularly developed, and in some places replaced by granulation; there is no spiral striation; 1.56×1.36 mm (PILSBRY 1934).

Measurements of figured specimen CDF: 1.67×1.47 mm, 4 whorls (ICCDRS 0036856).

Type locality: "Chatham Is., on a wooded hill on the right side of the road from Wreck Bay to Progreso, near the point where the road emerges into the grassy zone" (PILSBRY 1934) (San Cristóbal Island).

Known distribution: Floreana, San Cristóbal and Santa Cruz Islands.

Records in CDF collection: Anthropogenic and natural areas of Floreana, Isabela, and Santa Cruz.

Remark: HAUSDORF (2007) synonymized this species with *Pupisoma (Pupisoma?) comicolense* BAKER 1928, from México, for conchological comparison.

Type series: Lectotype: ANSP 152716a (BAKER 1963).

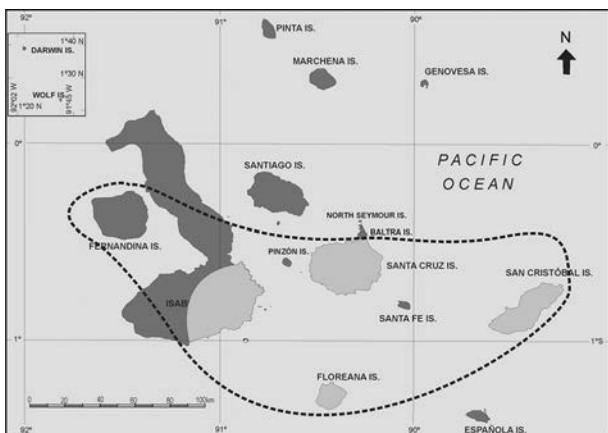

CDF material examined: FLO: ICCDRS 0036673/1. Finca "La Primavera". 300 m.a.s.l.; ICCDRS 0036931/1. Pampa de Alviar. $1^{\circ}18'47.99''$ S $90^{\circ}26'6.72''$ W.  2007 *Pupisoma (Ptychopatula) dioscoricola* ADAMS, – HAUSDORF: 1483, figs. 1, 2, 6.

Description (shell): Shell globose, conic, with obtuse apex, whorls strongly convex; perforate, cinnamon-colored, glossy; sculpture of unequal growth-wrinkles crossed by fine, impressed spiral lines about equally distinct over the whole last whorl; earlier whorls with granulate striae or somewhat irregular granulation, partly confluent into striae; the tip of the apex is slightly depressed; aperture truncate-rounded, oblique; peristome thin, the columellar margin whitish, dilated triangularly and broadly over the perforation; columella concave; 1.55 × 1.55 mm (PILSBRY 1948).

Measurements of figured specimen CDF: 1.80 × 1.87 mm, 3.50 whorls (ICCDRS 0036685).

Type locality: Jamaica.

Distribution: United States of America (Florida and Texas) to south Brazil and north Argentina. Some of this distribution could be anthropogenic (HAUSDORF 2007).

Known distribution: Fernandina, San Cristóbal and Santa Cruz Islands.

Records in CDF collection: Isabela Island (“guayabillos” zone in Volcán Alcedo) and Santa Cruz Islands (disturbed natural area).

Remark: This species is cited for “Galapagos” (PILSBRY (1948: 1008).

Type series: Syntypes MCZ Malacology 135518/3. Jamaica; Syntypes: MHNG INVE 38728/4. Jamaica (as “paratypes”, Y. FINET, pers. comm., 2011).

Description (shell): Shell depressed, of about 4.5 moderately convex and regularly increasing

whorls; translucent olive buff; glossy in appearance but weakly sculptured with growth wrinkles an extremely faint, minute spiral striae, the base smoother; umbilicus about 0.2 of shell diameter; aperture deeply lunate, wider than high; columella scarcely reflected; peristome thin; protoconch of 1.5 whorls, smooth but for microscopic growth lines and spiral striae at periphery; up to 3 mm high by 6 mm in diameter (BAKER 1999).

Measurements of figured specimen CDF: 4.60 × 2.00 mm, 4.75 whorls (ICCDRS 0036610/2).

Type locality: North America (BAKER 1999).

Natural distribution: Nearctic region and Central America (BAKER 1999).

Map 6: Distribution of *Strobilos (Nesostrobilos) helleri* (dotted line) and *Retinella?* spp. (broken line).

Anthropogenic distribution: Europe, Israel, Kenya, South Africa, Madagascar, Hong Kong, Japan, Hawaii, America, Australia and New Zealand (PILSBRY 1946; BAKER 1999).

Records in CDF collection: San Cristóbal Island, in agricultural areas. First record for Galápagos.

Fig. 25, map 6

- 1893 *Hyalinia chathamensis* DALL: 54.
- 1896 *Vitreia chathamensis* DALL, — DALL: 448, pl. 15, figs. 3, 10.
- 1900 *Vitreia chathamensis* DALL, — DALL: 93.
- 1928 *Vitreia chathamensis* DALL, — DALL & OCHSNER: 155.
- 1971 *Retinella?* *chathamensis* DALL, — SMITH: 7.
- 1986 *Retinella?* *chathamensis* DALL, — CHAMBERS & STEADMAN: 102.
- 1991 *Retinella?* *chathamensis* DALL, — CHAMBERS: 309.

Description (shell): Shell small, thin, straw colored, depressed, with four rounded polished whorls; suture distinct; sculpture of numerous radiating, slightly flexuous, indented lines; umbilicus deep, exhibiting all the whorls, but rather narrow; 3.0 × 1.3 mm (DALL 1893).

Measurements of figured specimen CDF: 1.67 × 3.33 mm, 4.25 whorls (ICCDRS 0036593).

Type locality: "Chatham Is., 1,600 feet" (DALL 1893) (San Cristóbal Island, 525 m.a.s.l.).

Known distribution: Isabela, Pinta, San Cristóbal, Santa Cruz and Santiago Islands.

Records in CDF collection: Pinta and in the *Miconia* zone of Santa Cruz.

Holocene distribution: Santa Cruz Island (CHAMBERS & STEADMAN 1986; see USNM Coll.).

Remark: Its actual generic assignation must be revised.

Type series: Holotype: USNM 107316. San Cristóbal (Chatham) Is., SW end, on leaves of plants.

CDF material examined: PIN: ICCDRS 0036590/27. 1500 ft.; ICCDRS 0036591/11. 1800 ft.; ICCDRS 0036594/1. 1300 ft.; SCZ: ICCDRS 0036592/1 + 0036593/5.

Retinella? *actinophora* (DALL 1900)

Figs 26–27, map 6

1900 *Vitreia actinophora* DALL: 93, pl. VIII, figs. 11, 16, 17.

1928 *Vitreia actinophora* DALL, — DALL & OCHSNER: 155.

1991 *Retinella?* *actinophora* DALL, — CHAMBERS: 309.

Description (shell): Shell small, with four brilliant polished, subtranslucent, olivaceous whorls; spire depressed but slightly rounded, with a distinct suture; embryonic whorl and a half smooth, succeeding whorls near the suture with well-defined close-set incised lines in harmony with the lines of growth but short, rarely extending to the periphery; last whorl evenly rounded, base smooth, convex, with a narrow deep umbilicus; aperture oblique, hardly expanded, the peristome sharp, thin, the pillar and outer lips not approximated; 2.0 × 4.0 mm. 4 whorls (DALL 1900).

Type locality: "Top of mountain near Tagus Cove, Albemarle Is." (DALL 1900) (Isabela Island).

Known distribution: Isabela, San Cristóbal and Santiago Islands.

Remark: VAGVOLGYI (1975) identified to this species as *Glyphyalinia* MARTENS 1892.

Type series: Syntype USNM 108513/1 (R. HERSHLER, pers. comm., 2011). Syntype CAS-IZ 168006.00/1. Isabela (Albermale) Is., top of mountain. (C. PIOTROWSKI, pers. comm., 2011).

Euconulidae BARKER 1928

Habroconus FISCHER & CROSSE 1872

Habroconus (*Pseudoguppya*) BAKER 1925

Habroconus (*Pseudoguppya*) aff. *pacificus* (PFEIFFER 1846)

Fig. 28, map 7

1846 *Helix Pacifica* PFEIFFER: Symbolae 3: 66.

1848 *Helix pacifica* PFEIFFER, — PFEIFFER: 52.

- 1938 *Guppya pacifica* PFEIFFER, – HANNA & HERTLEIN: 131.
 1941 *Habroconus (Pseudoguppya) pacificus* PFEIFFER, – BAKER: 226, pl. 60, fig. 13; pl. 44, fig. 7.
 1963 *Habroconus (Pseudoguppya) pacificus* PFEIFFER, – HERTLEIN: 242.

Description (shell): Shell usually with fairly high spire, thread carinate on 6th whorl but becoming weakly angular on 7th; light to brownish corneous, sometimes with brown varices, dullish above but somewhat polished below, thin and subtransparent; later whorls more moderately flattened above with growth-threads considerably stronger than and rendering spiral striae obscure, above; base with weak spiral striae; aperture barely angular at 80° to shell-axis; peristome about 15° to shell-axis, weakly arcuate near columella, which is shorter and more nearly vertical; 5.67 × 4.0 mm (PFEIFFER 1848; BAKER 1941).

Measurements of figured specimen CDF: 2.20 × 2.73 mm, 4.25 whorls (ICCDRS 0036624).

Type locality: Cocos Island, Costa Rica.

Known distribution: ? Isabela Island (ANSP, det. as *Guppya gundlachi* PFEIFFER 1840 by PILSBRY).

Records in CDF collection: Isabela, Pinta, San Cristóbal, Santa Cruz and Santiago Islands. In natural areas of Isabela Island (Sierra Negra/Pampa, guayabillos zone of Volcán Alcedo), and in Santa Cruz Island (Los Gemelos), and in anthropogenic areas of Isabela, San Cristóbal and Santiago.

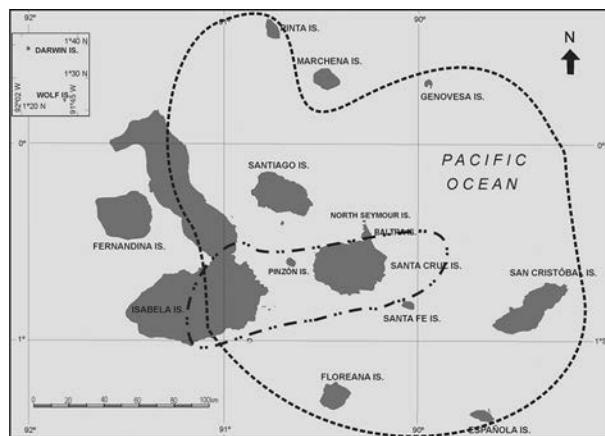

Remark: Its actual generic assignation must be revised.

 1991 *Habroconus? galapaganus* DALL, – CHAMBERS: 309.

Description (shell): Shell small, with 5 whorls rounded, a very well marked suture, the height is greater in proportion to the number of whorls; very brilliant surface; 3.25 × 2.5 mm (DALL 1893).

Measurements of figured specimen CDF: 2.00 × 2.73 mm, 5.50 whorls (ICCDRS 0036830).

Type locality: "Chatham Is., 1,600 feet" (DALL 1893); Southwest of Chatham (DALL 1896) (San Cristóbal Island, 525 m.a.s.l.).

Known distribution: Floreana, Pinta, Pinzón, San Cristóbal, Santa Cruz and Santiago Islands. In Santiago, DALL & OCHSNER 1928 found this species "in the forest zone at 1,000 to 1,800 feet, and under stones at 750 feet" (328 to 590, and 246 m.a.s.l.).

Records in CDF collection: In agricultural areas and Volcán Alcedo on Isabela Island, and *Scalesia* and *Miconia* zones and anthropogenic areas of Santa Cruz Island.

Holocene distribution: Santa Cruz Island (CHAMBERS & STEADMAN 1986; see USNM Coll.).

Remark: its actual generic assignation must be revised.

Type series: Syntypes: USNM 107315/3. San Cristóbal (Chatham) Is., SW end.

- 2014 *Lissachatina fulica* BOWDICH, – CAUSTON et al.: 61.

Description (shell): Shell with 7 to 9 convex whorls, from very slender to moderately obese, a sharply conical spire, and broadly impressed sutures; aperture relatively short, the outer lip is usually sharp and thin, rarely somewhat thickened or even slightly expanded in very old specimens, it is very convex, evenly curved into a regular semi-ellipse, and inserted on the body-whorl at a sharp, open angle, the upper part of the body-whorl being scarcely or not flattened behind the lip; columella more or less concave, sometimes rather weakly so, in which case may be slightly or even much twisted; a umbilical slit completely closed and the columella truncate, both columella and parietal callus are white or bluish-white; 171 × 81 mm (BEQUAERT 1950).

Measurements of figured specimen: 77.0 × 41.0 mm (Agrocalidad s/n).

Type locality: Mauritius Island, Africa.

Natural distribution: Subsaharan oriental Africa.

Anthropogenic distribution: worldwide.

Remarks: This species has a high adaptability to different habitat conditions in natural or anthropogenic areas (WWW.SENASA.GOV.AR 2011). It is a polyphagous species, which causes important damages in tropical and subtropical crops. In Brazil, it preys on more than 100 species of plants, like for example cotton, banana, all kind of vegetables etc. (RODRIGUEZ 2006). This species can be a host of the nematodes *Angyostrongylus (A.) cantonensis* (CHEN) and *A. costaricensis* (MORERA & CÉSPEDES), causing meningoencephalitis and human abdominal angiostrongylosis (WWW.SENASA.GOV.AR 2011).

Known distribution: Santa Cruz Island.

CDF material examined: SCZ: ICCDRS 0073063/54. Barrio El Edén, Puerto Ayora. ICCDRS 0040430/184. Barrio El Edén, Puerto Ayora; ICCDRS 0040429/2. Barrio Matazano, Puerto Ayora (0°44'16.35" S 90°18'45.40 W).

Ferussaciidae BOURGUIGNAT 1883

Cecilioides FÉRUSSAC 1814

Cecilioides (Cecilioides) acicula (O. F. MÜLLER 1774)

Fig. 34, map 10

1900 *Cecilioides acicula* O. F. MÜLLER, – ADAMS: 297.
1909 *Cecilioides (Cecilioides) acicula* O. F. MÜLLER, – PILSBRY: 9, pl. 1, figs. 1, 2, 5–8.
1946 *Cecilioides acicula* O. F. MÜLLER, – PILSBRY: 185, fig. 89 (a).
1995 *Cecilioides acicula* O. F. MÜLLER, – MIQUEL et al.: 26.
1997 *Cecilioides acicula* O. F. MÜLLER, – MIQUEL & PARENT: 110, fig. 2.
1999 *Cecilioides (Cecilioides) acicula* O. F. MÜLLER, – BARKER: 59, figs. 36, 76, 117, 146, 172, 198, 226, C9, M13, M14, M56, M57, map 9.

Description (shell): Shell very narrowly lanceolate with regularly tapered spire, with 5 or 6 scarcely convex whorls, polished and smooth except for very weak spiral striae, thin, transparent, tinged yellow or golden brown in live specimens owing to colour of underlying digestive gland, imperforate; aperture pyriform, narrowed and acute above, rounded at base, with outer lip thin and flexuous, and parietal wall not calloused; columella slightly calloused, with a columellar fold in juveniles, and abruptly truncate at its union with basal margin of aperture lip in adults; protoconch blunt, rounded, smooth or with faint growth lines; 4.5 × 1.2 mm (BARKER 1999).

Type locality: Central and Western Europe.

Natural distribution: Palearctic region (BARKER 1999).

Anthropogenic distribution: Northern Europe, United States of America, Bermuda, Barbados, Hawaii, Azores, Canary Island, South Africa, Australia and New Zealand (BARKER 1999), Argentina and Uruguay (MIQUEL et al. 1995).

Known distribution: Santa Cruz Island (El Chato). See CAS-IZ Col.

Ceciliooides (Karolus) Folin in FOLIN & PERIER 1870

***Ceciliooides (Karolus) consobrina* (ORBIGNY 1841)**

Fig. 33, map 7

- 1841 *Achatina consobrina* ORBIGNY: 170; Atlas: 1842, Tab. 11 bis; figs. 10–12 (as “*michauidiana*”).

 1948 *Ceciliooides (Caecilianopsis) consobrina* ORBIGNY, — HYLTON SCOTT: 254.
 2003 *Ceciliooides consobrina consobrina* ORBIGNY, — RAMÍREZ et al.: 276.

Description (shell): Shell subcylindric, 5 whorls very slightly convex, the last oblong, half of the total length; pellucid, glossy, white, finely striate; spire of nearly equal diameter to the end, very obtuse; sutures slightly marked; columella twisted and truncate; aperture ovate-oblong, 1/3 of the total length; peristome acute; protoconch smooth; 2.0 × 0.67 mm (PILSBRY 1909; MIQUEL & AGUIRRE 2011).

Measurements of figured specimen CDF: 1.70 × 0.70 mm, 3 whorls (ICCDRS 0036824).

Type locality: Near Matanzas, Cuba.

Distribution: Caribe and South America to Argentina.

Known distribution: not represented.

Records in CDF collection: In agricultural areas and Volcán Alcedo of Isabela and Santa Cruz Island (El Chato). First record for Galápagos.

Remark: The subgeneric affiliation is provided by ZILCH (1959).

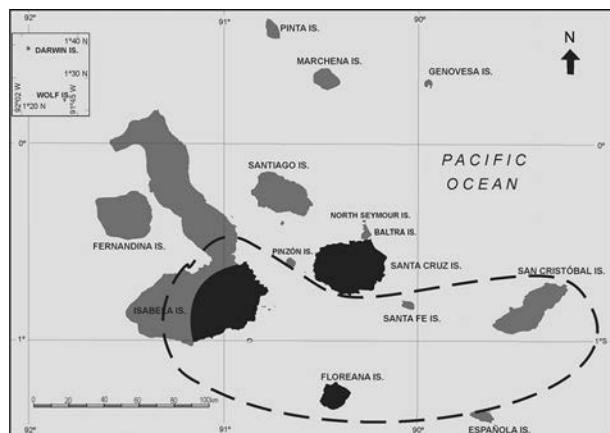

CDF material examined: ISA: ICCDRS 0036549/2. AA. S00°86'46.6" W91°01'51.1"; ICCDRS 0036823/1. VA. Zona Pega-Pega; ICCDRS 0036824/1. VA. Guayabillos; ICCDRS 0036827/1. ZA; ICCDRS 0036550/2. AA.  2006 *Geostilbia gundlachi* PFEIFFER, — SIMONE: 184, fig. 667.

Description (shell): Shell with obtuse, rounded apex, 5 whorls, very obliquely coiled, quite convex and parted by an impressed suture; the last whorl is evenly convex; the aperture is ovate, effuse at the base; the outer lip arches forward strongly in the middle; the columella is a little concave, and near the base is obsoletely truncate; in most fully adult shells the columella has a rather heavy callus which passes up over part of the parietal wall; the colour is pale corneous-brown, or sometimes almost clear corneous, there is no spiral stria-
tion; 4 to 5 mm (PILSBRY 1946).

Measurements of figured specimen: 3.70 × 1.20 mm (PILSBRY 1909).

Type locality: ? West Indies.

Natural distribution: West Indies: Cuba, Jamaica, Haití.

Anthropogenic distribution: Widely spread by man (United States of America, Panama, Brazil, Saint Helena, New Caledonia) (COWIE 1997).

Known distribution: ? Galápagos. Although it is mentioned in the website of CDF (PARENT et al. 2012), its record it is not yet confirmed.

Remark: *Ceciliooides* sp. is cited for Floreana Island by SMITH (1966).

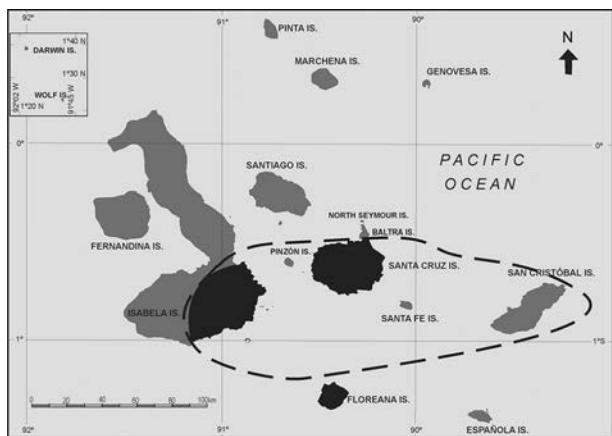

Records in CDF collection: not represented.

Subulinidae FISCHER & CROSSE 1877

***Subulina* BECK 1837**

***Subulina octona* (BRUGUIÈRE 1792)**

Fig. 37, map 9

 1966 *Subulina octona* BRUGUIÈRE, — SMITH: 243.
 1988 *Subulina octona* BRUGUIÈRE, — AUFFENBERG & STANGE: 1.

Description (shell): Shell with 9 to 11 whorls quite convex, imperforate, thin, translucent, turrited, regularly tapering to the obtuse summit, irregularly wrinkle-striate, parted by a deep and in places irregularly crenulated suture, the first 2 1/2 or 3 whorls regularly crenulated by a series of short, fine subsutural folds; yellowish-corneous, very glossy; aperture small, ovate, somewhat oblique; outer lip thin; columella concave above, obliquely and deeply truncate at its base (PILSBRY 1946).

Measurements of figured specimen CDF: 9.90 × 3.30 mm, 7 whorls (ICCDRS 0036584).

Type locality: ? Tropical America (PILSBRY 1906).

Natural distribution: Tropical America.

Anthropogenic distribution: Caribe, Africa, Asia.

Known distribution: San Cristóbal and Santa Cruz Island.

Records in CDF collection: In agricultural areas of Isabela and San Cristóbal and in Santa Cruz (urban area and *Scalesia* zone).

CDF material examined: ISA: ICCDRS 0036745/1. AA. S00°51' 00.53" W91°02'31.69"; ICCDRS 0036762/2. AA. S00°83'03.20" W91°00.83.39"; ICCDRS 0036756/2. AA. S00°86'07.58" W91°00'95.35"; ICCDRS 0036749/1. Lamellaxis STREBEL & PFEFFER in STREBEL 1882

Lamellaxis micra (ORBIGNY 1835)

Fig. 38, map 8

- 1835 *Helix micra* ORBIGNY: 9.
 1837 *Helix micra* ORBIGNY, — ORBIGNY: 262, pl. 41, figs. 18–20.
 1906 *Opeas micra* ORBIGNY, — PILSBRY: 193.
 1945 *Lamellaxis (Leptopeas?) micra* ORBIGNY, — BAKER: 90.
 1946 *Lamellaxis (Allopeas) micra* ORBIGNY, — PILSBRY: 178, fig. 85a, b, c.
 1988 *Opeas micra* ORBIGNY, — WU & ITOW: 12, fig. 2.
 1988 *Lamellaxis micra* ORBIGNY, — AUFFENBERG & STANGE: 2.

Description (shell): Shell with 6 1/4 whorls, perforate, and tapers regularly to the very obtuse apex; the first 2 or 2 1/2 whorls are smooth; then widely spaced thread-like striae appear in high relief on the weakly striate surface, and are usually strongest near the suture above; well-sculptured shells; very often the striae are much weaker, almost obsolete except immediately below the sutures; and there are intermediate forms also; aperture relatively small and ovate, outer lip thin, columella straight and reflected; 5.6 × 2.2 mm (PILSBRY 1946; AUFFENBERG & STANGE 1988).

Measurements of figured specimen CDF: 5.60 × 2.20 mm, 6.25 whorls (ICCDRS 0036641).

Type locality: Bolivian Andes, Santa Cruz de la Sierra, Bolivia.

Distribution: Mexico and Caribbean to Bolivia.

Known distribution: Floreana and San Cristóbal Islands.

Records in CDF collection: Floreana Island (agricultural zone and natural areas, and in *Scalesia*

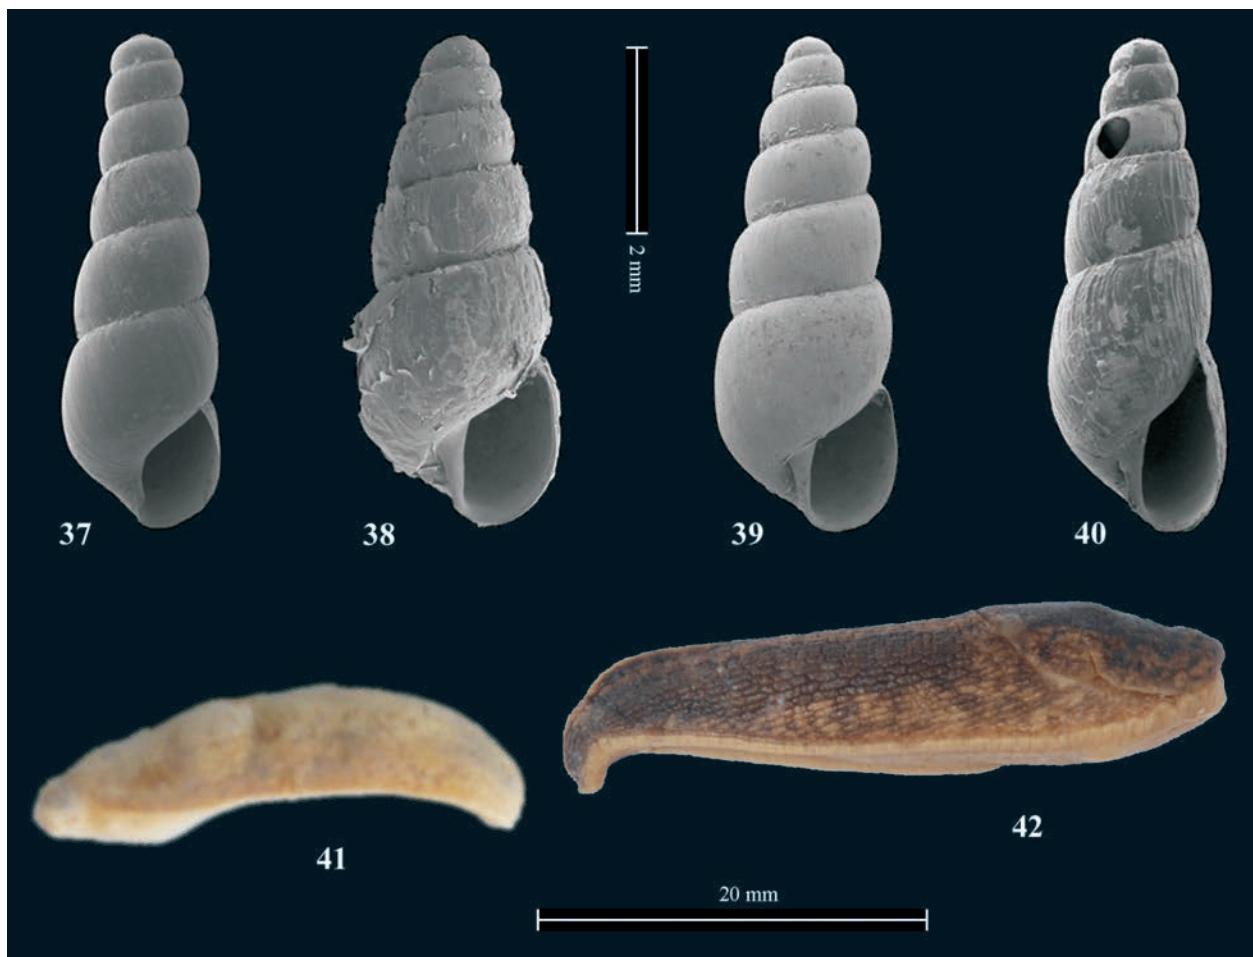

Fig. 37 *Subulina octona* (BRUGUIÈRE 1792). ICCDRS 0036584. Santa Cruz Island. — Fig. 38 *Lamellaxis micra* (ORBIGNY 1835). ICCDRS 0036641. Lamellaxis gracilis (HUTTON 1834)

Fig. 39, map 9

- 1834 *Bulimus gracilis* HUTTON: 93, 84.
- 1906 *Opeas gracile* HUTTON, — Pilsbry: 125, pl. 18, figs. 3–6.
- 1945 *Lamellaxis (Allopeas) gracilis* HUTTON, — BAKER: 88.
- 1946 *Lamellaxis (Allopeas) gracilis* HUTTON, — PILSBRY: 177, fig. 85 (f–g).

- 1959 *Lamellaxis (Allopeas) gracilis* HUTTON, — ZILCH: 349, Abb. 1285.
- 1988 *Lamellaxis gracilis* HUTTON, — AUFFENBERG & STANGE: 1.

Description (shell): Shell elongate with 9 to 12 whorls moderately convex; minutely perforate, thin, slender, regularly tapering to the small, slightly obtuse apex; translucent, pale-coloured or rather colourless; sculpture of distinct arcuate striation; aperture oval, rather long; columella straight, reflected; 10.0 × 3.0 mm (PILSBRY 1906, 1946; AUFFENBERG & STANGE 1988).

Measurements of figured specimen CDF: 6.50 × 2.20 mm, 7 whorls (ICCDRS 0036600).

Type locality: ? Mirzapur, India. Its original distribution could be in tropical America (PILSBRY 1946).

Natural distribution: ?Tropical areas of America.

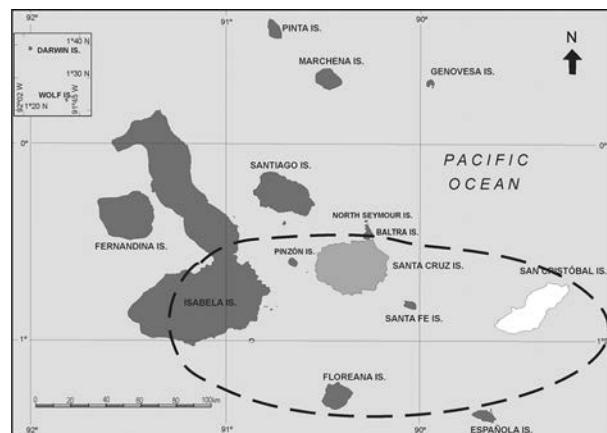

Anthropogenic distribution: Practically worldwide, in tropical and temperate areas.

Known distribution: In natural areas of San Cristóbal Island.

Records in CDF collection: In agricultural and in natural areas of Floreana (*Scalesia* zone and Cerro Pajas) and the urban area of Santa Cruz.

Remark: SMITH (1966) quoted *Lamellaxis* sp. for Santa Cruz, Española and Floreana Island. HERTLEIN (1963) considered it an exotic species in Galápagos and Cocos Island.

CDF material examined: FLO: ICCDRS 0036596/1; ICCDRS 0036597/1. Cerro Pajas. Base. 350 m; ICCDRS 0036598/1. AA. S $0^{\circ}19'39.19''$ /W 090°26'64.75"; ICCDRS 0036599/2. Opeas (Opeas) ALBERS 1850

Opeas (Opeas) pumilum (PFEIFFER 1840)

Fig. 40, map 8

- 1822 *Helix goodali* MILLER: 381 (no *Helix goodali* FÉRUSSAC 1821).
 1840 *Bulimus pumilus* PFEIFFER: 252.
 1906 *Opeas goodali* MILLER, — PILSBRY: 200, pl. 28, figs. 72–74.
 1910 *Opeas pumilum* PFEIFFER, — PILSBRY: 31.
 1946 *Opeas pumilum* PFEIFFER, — PILSBRY: 181, fig. 88. 4.
 1951 *Opeas goodali* MILLER, — ODHNER: 254.

Description (shell): Shell very minutely perforate, straightly conic, with a very obtuse apex; surface not very glossy, densely, sharply sculptured with irregular and rather strong striae very deeply curved, or arcuate; outer lip thin, and so much retracted above as to appear incised at the suture; aperture well rounded below, columellar lip reflex, 6.0 × 2.0 mm (PILSBRY 1946).

Measurements of figured specimen CDF: 4.30 × 0.80 mm (ICCDRS 0037005).

Type locality: Bristol, Great Britain.

Natural distribution: Tropical America.

Anthropogenic distribution: Europe.

Known distribution: Isabela and Santa Cruz Islands.

Records in CDF collection: urban area of Santa Cruz Island and natural areas of Floreana Island.

CDF material examined: FLO: ICCDRS 0037005/1. Arco de la Reina, (N). 1°20'10.23" S90°25'11.64" W; SCZ: ICCDRS 0036854/1. Bellavista. Predio de la Universidad Central.

Agriolimacidae WAGNER 1935

Deroceras RAFINESQUE 1820

Deroceras (Deroceras) laeve (O. F. MÜLLER 1774)

Fig. 42, map 8

- 1774 *Limax laevis* O. F. MÜLLER: 2.
 1930 *Deroceras laeve* O. F. MÜLLER, — BAKER: 41, pl. 11, figs. 1,6,7.

Map 10: Distribution of *Zonitoides (Zonitoides) arboreus* (white area), *Cecilioides (Cecilioides) acicula* and *Lissachatina fulica* (gray area), and *Sarasinula plebeia* (broken line).

- 1948 *Deroceras (Deroceras) laeve* O. F. MÜLLER, — PILSBRY: 539, figs. 289–291.
 1999 *Deroceras (Deroceras) laeve* O. F. MÜLLER, — BAKER: 32, figs. 25, 28, 68, 109, 138, 165, 191, 219, C1, M32–34, Map 1.

Description of the soft parts and limacella: Slug usually smaller, slim, posteriorly obtusely narrowing; keel short, ill defined; mantel shield about 0.5 of body length; body wall thin, transparent, usually brown, grey, or black, less frequently brownish cream, unicoloured in appearance but under magnification seen to be speckled or flecked; border of pneumostome rather inconspicuous; sole pale grey to brown, more transparent medially than laterally; genital orifice immediately posterior to right ocular peduncle; shell thin, white, oblong-oval to ovoid with right margin straight to convex, dorsal surface weakly convex, with distinct growth lines; ventral surface concave; vestigial protoconch near posterior margin, non-protruding, situated asymmetrically at left side; an organic sheet surrounding shell; upon to 25 mm in length (BAKER 1999).

Measurements of figured specimen CDF: 14.50 mm (ICCDRS 0036707).

Type locality: Frederiksø, Denmark.

Natural distribution: Palearctic region. BAKER & POTTINGER (1983) consider that Cordillera de los Andes is a part of its natural dispersion.

Anthropogenic distribution: Worldwide.

Known distribution: Cited as *Deroceras* sp. for Santa Cruz Island (SMITH 1966); and in *Scalesia* zone of anthropogenic areas.

Records in CDF collection: Floreana Island (agricultural area), Isabela Island (natural zone and agricultural areas) and Santa Cruz Island (urban area).

Discussion

Most of the studied specimens were obtained serendipitously as part of broader studies looking for other invertebrates and/or vegetation. Little or no information exists about the collection efforts, the selection of habitat to prospect, or specific collection techniques according to habitat carried out in the archipelago, though a few data are mentioned in DALL & OCHSNER (1928).

Leaving Bulimulidae and Succineidae apart, which make up the most numerous and conspicuous part of terrestrial molluscs of this area (PARENT et al. 2012), the presence of 27 species of terrestrial gastropods is now recognized; two of them belonging to the Neritimorpha, 24 taxa to Pulmonata Stylommatophora and one species to Pulmonata Systellommatophora. Endemic, native and exotic taxa are recorded, although the exact biogeographic affiliation of some species is not certainly known.

Half of them are endemic species belonging to the Helicinidae families (two species of genus *Helicina*)

Achatinellidae (one species each of genus *Tornatellides* and *Ambrosiella*), Vertiginidae (three species of *Gastrocopta* and one of *Nesopupa*) Strobilopsidae (one species of genus *Strobilops*) Pristilomatidae (two taxa; *Retinella*?) and Euconulidae (probably two species of *Habronicus* and one of *Guppya*). None of these genera is exclusive of the archipelago; only the subgenus *Strobilops* (*Nesostrobilops*), represented by a single species (*S. (N.) helleri*), is endemic to Fernandina, Isabela, San Cristóbal, Santa Cruz and Santiago Islands (Table 2).

Moreover, the only genus represented in most of the archipelago is *Gastrocopta* (Table 2). *G. munita* is living on at least 12 islands, being the species with the largest spatial range among the continental molluscs found in Galápagos and appearing on very distant islands and in different habitats. This species was found on the coast of Isabela, in forests of *Psidium* sp. (“guayabillos”) and *Pisonia* sp. (“pega-pega”) trees, as well as in the high arid zone (200 m.a.s.l.) and inside the crater of the Al-

cedo volcano. On Floreana, *G. munita* is registered in the Sierra Negra/Pampa, *Scalesia* area, in the Cerro Pajas crater and in the “guayabillos” area of Santiago. Other species of important geographic expansion are *T. chathamensis*, *G. clausa* and *H. galapaganus*, whereas *G. duncana* (Pinzón) and *N. (I.) galapagensis* (Santiago) are forms with a very restricted dispersion (Table 2).

In the human inhabited islands, a group of species of several exotic families of unnoticed introduction was recorded: (*Z. (Z.) arboreus*, Gastrodontidae), (*D. (D.) laeve*, Agriolimacidae), (*C. (C.) acicula* and *C. (G.) aperta*, Ferussaciidae), (*S. octona*, *L. gracilis* and *O. (O.) pumilum*, Subulinidae) and (*S. plebeia*, Veronicellidae) along with one species whose introduction was clearly intentional (*L. fulica*, Achatinidae). In these cases, their distributions are related to intensive human activities, since they were recorded in agricultural areas of Floreana, Isabela, and San Cristóbal and in urban areas of Santa Cruz and San Cristóbal. The fact that Santa Cruz has the largest number of alien species could be explained because of the significant presence of humans but also could be due to a more thorough survey effort. *L. fulica* is the most dangerous of the exotic terrestrial molluscs given its high reproductive capacity and its avidity.

Families including Chondrinidae, Ferussaciidae, and Subulinidae have species whose native or exotic origins are uncertain, as *C. (K.) consobrina* and *L. micra* that occur in large areas of the American continent. In the case of *P. (P.) dioscoricola*, there is evidence that its original range has been expanded due to human activities (HAUSDORF 2007). In Galápagos, all of these species are located in areas disturbed by human activity (Santa Cruz and Floreana), thus anthropogenic dispersion could be shared by other species as well.

With regard to, *H. ochsneri*, *T. chathamensis*, *G. munita*, *P. (P.) dioscoricola*, *H. (P.) aff. pacificus*, *H. galapaganus*, *C. (K.) consobrina* and *L. micra*, these can be found in natural areas such as the Alcedo volcano (Isabela), Cerro Pajas, Sierra Negra/Pampa (Floreana) and Los Gemelos (Santa Cruz), but also in disturbed, agricultural, or urban areas. Commonly, agricultural and livestock activities are located in the upper parts of the islands, due to the greater rainfall abundance at higher altitudes. Several native species were described from specimens collected in these areas, profoundly altered nowadays.

Introduced species can also be found in natural areas of Floreana and San Cristóbal (*L. gracilis*) and in areas of *Scalesia* in anthropogenic habitat of Santa Cruz (*S. octona* and *D. (D.) laeve*). They appear not only in disturbed areas, but also in natural areas of Isabela (S. Negra/Pampa).

Native and endemic forests of *Scalesia* and other vegetation, such as “guayabillos” in Isabela and Santiago, have species of both native and exotic gastropods, such as *H. ochsneri*, *T. chathamensis*, *G. munita*, *P. (P.)*

dioscoricola, *H. (P.) aff. pacificus*, *C. (K.) consobrina*, *S. octona*, *L. micra* and *L. gracilis*. Meanwhile, *H. ochsneri*, *T. chathamensis*, *G. munita*, *L. micra* and *L. gracilis* live in forests and areas with *Scalesia* on Floreana. On Santa Cruz, *D. (D.) laeve*, *H. galapaganus* and *S. octona* have been recorded in forests and areas of *Scalesia*, while *T. chathamensis*, *S. (N.) helleri*, *R. chathamensis*, *H. galapaganus* and *G. bauri* appear in areas of *Miconia*.

Regarding the outlook for continental gastropod invasions in the Pacific Ocean islands noted by COWIE (2001), Galápagos seems to remain free from many of the potential forms that inhabit the region like species of *Lamellidea* PILSBRY 1910, *Bradybaena* BECK 1837, *Liardetia* GUDE 1913, and others of high presence in many Pacific islands. Now, in this paper we include *Zonitoides*, *Opeas*, *Achatina* and *Sarasinula* in the “Eastern Pacific outliers” (Epac) area that includes, Revillagigedo, Clipperton, Cocos, Malpelo and the Galápagos Islands, according to COWIE (2001).

Another South American region well known in connection with the invasion of gastropod exotic species is Argentina, whose inventory has been recently updated (VIRGILLITO et al. 2010, 2011; VIRGILLITO 2012; GUTIÉRREZ GREGORIC et al. in press). Both, Galápagos and Argentina, share the presence of non-indigenous molluscs of medium to small size, mostly pulmonates (at least, *C. (C.) acicula*, *L. (A.) gracilis* and *Opeas (O.) pumilum*), however, Argentina (and much of South America) differs in having presence of European Helicoidea (*Theba* RISSE 1826, *Otala* SCHUMACHER 1817, *Cryptophthalus* CHARPENTIER 1837 and *Bradybaena* BECK 1837) and slugs (*Limax* LINNAEUS 1758, *Limacus* LEHMANN 1864, *Lehmania* HEYNEMANN 1863, *Milax* GRAY 1855, and *Arion* FÉRUSSAC 1819).

The presence of *O. (O.) pumilum* has recently been detected in the tropical northern region of Argentina (Tucumán), and Oxychilidae *Oxychilus draparnaudi* (BECK 1837), has been found in a warm climate area (Ecological Reserve, Vicente López, Buenos Aires) (VIRGILLITO 2012). The latter species is still absent from the Galápagos malacological records.

Many of the introduced species in Galápagos are intermediate hosts of parasitic Strongylidae nematodes as *Z. (Z.) arboreus*, *D. (D.) laeve*, *S. octona*, *L. fulica* and *S. plebeia* (GREWAL et al. 2003); posing a risk of potentially dangerous infestations to vertebrates (humans included) or to other gastropods, either acting as definitive or intermediate hosts respectively.

The Galápagos native malacofauna is traditionally defined as akin to the faunas of Hawaii, Polynesia and the Americas. *Helicina*, *Gastrocopta*, *Guppya* and *Hubroconus* are genera represented by numerous species in South and Central America. The recent Strobilosidae are distributed in areas of North and Central America (SOLEM 1981); for its part, *Nesopupa* is widely spread in Polynesia and the Cocos Islands (VAGVOLGYI 1974).

Table 2: Presence of genera discriminated for each island. L: living; F: fossil. ■: specimens housed at ANSP, □: specimens housed at CAS (in both cases, with the generic or doubtful arrangement).

This author argues that the presence of the subgenus *Nesopupa* (*Infranesopupa*) in Hawaii and the Galápagos is due to petrel transportation (VAGVOLGYI 1975). Different growth stages (eggs, juveniles, or adults) could be transported in this way. This dispersal mode may be common for gastropods, as the final size of the species is not a limiting factor. In Argentina, populations of terrestrial micromollusk species have been found living in

avian nests, a circumstance facilitating the opportunity of its transportation (TURIENZO et al. 2012).

The Achatinellidae are abundant in Hawaii, Rapa Nui (Easter Island), and Juan Fernández (Solem, 1981) and are present in Revillagigedo Islands (México) (ZILCH 1959), Desventuradas Islands (Chile) (ODHNER 1963), and Galápagos, with at least one genus (*Ambrosiella* or *Tornatellides*). The description of *Ambrosiella floreanae*

n. sp. in one of the southernmost islands of Galápagos allows us to consider the existence of a close relationship between the malacofauna of Galápagos and San Ambrosio Island (Desventuradas Islands, Province of Valparaíso, Chile), located about 917 km from the South American coast, (26.32°S/80.00°W). Both insular areas share *Ambrosiella*, a genus described as monotypic to the islands of the Pacific Ocean (ODHNER 1963). Most likely, the species *Tornatellides mexicana* DALL 1926, described for the Socorro Island (Méjico), belongs to this genus (DALL 1926).

The outlook displayed by native and endemic gastropods from the Galápagos shows that the species distribution is quite widespread and similar among them. Exceptionally, a few have “absolute” endemism, i.e. they are restricted to a single island, namely *A. floreanae* n. sp. and *N. (I.) galapagensis*: in both cases, they also display “absolute” generic or subgeneric endemism. In the case of *C. (K.) consobrina*, its character of native or exotic species is not clear, as earlier stated.

Particularly interesting are the cases of *Ambrosiella* and *Nesopupa*, two genera biogeographically linked with two geographically distinct islands (San Ambrosio Island, Chile, approximately 25°S, and Hawaii, USA, 20°N, respectively) which are both very distant from Galápagos. In both cases, speciation processes resulted in the existence of a single species within each genus.

To *Ambrosiella* and *Nesopupa*, as to some of the other groups, soil, plant species, and topography diversity among the islands does not seem to account for greater species diversity. This is in contrast to the diversity of the genus *Bulimulus* (*Naesiota*) ALBERS 1850 in the Galapagos Archipelago, where the number of described species exceeds seventy (LOSOS & SCHLUTER 2000; PARENT & CRESPI 2006), even though there is no evidence that *B. (Naesiota)* has been presented on the islands for longer than *Ambrosiella* or *Nesopupa*.

Holocene specimens of *H. nesiota* and *G. clausa* were recorded on Floreana and Santa Cruz, while holocene records of *T. chathamensis*, *G. duncana*, *R. ? chathamensis*, *H. ? galapaganus* and *G. bauri* are restricted to Santa Cruz (CHAMBERS & STEADMAN 1986). *G. duncana* lives on Pinzón only, but has holocene records on Santa Cruz.

More thorough palaeontological studies are needed to shed light on some problematic species, especially to determine whether they were already present on the islands prior to human colonization.

Conclusions

Except Bulimulidae and Succineidae, 27 species of land shells were identified (two of Neritimorpha, 24, Pulmonata Stylommatophora and one, Pulmonata Systellommatophora). Endemic, native and exotic taxa are recorded, but the origin (native or exotic) of some species could not be determined. Half of the species are endemic, belonging

to Helicinidae, Achatinellidae, Pupillidae, Strobilopsidae, Pristilomatidae and Euconulidae. Currently, terrestrial mollusks have been recorded in 14 islands of the Galápagos Archipelago (Ecuador). The most abundant records are found in the human inhabited islands: Santa Cruz, San Cristóbal, Isabela and Floreana. Some generic arrangements are tentative or doubtful and must be confirmed through the study of the soft parts. None of the families or genera is exclusive to the archipelago; the only endemic subgenus is *Strobilos* (*Nesostrobilos*). The most widespread species is *Gastrocopta munita*, recorded in 12 of the 14 analysed islands. Only a few species are recorded as unique to a single island (e.g., *Nesopupa (Infranesopupa) galapagensis*). A new species of Tornatellidae from Floreana, *Ambrosiella floreanae*, is described: characterized by a parietal lamella in the aperture, it is related to the Chilean insular fauna. Human inhabited islands host several exotic species of inadvertently introduced micromolluscs (e.g., *Zonitoides (Z.) arboreus*) and slugs (e.g., *Sarasinula plebeia*), and one intentional introduction (*Lissachatina fulica*). Although the introduced species are dominant in anthropogenic altered sectors of the islands, they have also invaded natural areas. New records extend the distribution of almost all terrestrial gastropod species in the archipelago.

Acknowledgements

We thank the Galápagos National Park Service (GNPS) for providing export authorizations. Thanks go to the collectors listed in this study that contributed specimens and allowed us to use unpublished material. Thanks to Christine Parent (Biological Sciences, University of Idaho, USA), for allowing one of the authors (SEM) be part of her research project in 2010 and, thus, to begin his studies in Galápagos. Frank Bungartz, CDF, for his support in such work. We are grateful to P. Callomon (ANSP), Y. Finet (Muséum d'Histoire Naturelle, Genève), R. Hershler (MNHN), F. Naggs (NHM), C. Piotrowski (CAS) and S. Wu (UCM), for the photographs, bibliography, and information on materials from Galapagos preserved in their institutions, and to S. R. Gomes, for confirmation of the identity of *S. plebeia*. A.H. Breure (Netherlands Centre for Biodiversity Naturalis, Leiden, The Netherlands), for sending literature, X. Pilataxi, helped to separate specimens in 2010, M. Virgillito, assisted in collecting samples from Santa Cruz in 2011, A. Gonzalez (MACN) prepared maps, and A. Tablado (MACN) provided continued support. D. Freud (Wisconsin University), N. Boelling (Charles Darwin Research Station) and J. F. Araya (Universidad de Chile) helped with the translation of the manuscript from Spanish. This contribution was partially financially supported by PICT 2006-00468 (Agencia Nacional de Promoción Científica y Tecnológica, Argentina) and PIP 2010-0080 (Consejo Nacional de Investigaciones Científicas y Técnicas, Argentina). SEM is member of Scientific Research Career of CONICET. This publication is contribution number 2.100 of the Charles Darwin Foundation for the Galapagos Islands. We like to thank the Galápagos National park Service who has kindly granted us to carry out this investigation.
