ABSTRACT

The high-pressure elastic behavior and the *P*-induced structure evolution of a natural cancrinite from Cameroun {Na_{6.59}Ca_{0.93}[Si₆Al₆O₂₄](CO₃)_{1.04}F_{0.41}·2H₂O, *a* = 12.5976(6) Å, *c* = 5 .1168(2) Å, space group: *P*6₃} were investigated by in situ single-crystal X-ray diffraction under hydrostatic conditions up to 6.63(2) GPa with a diamond-anvil cell. The *P*-*V* data were fitted with an isothermal Birch-Murnaghan type equation of state (BM EoS) truncated to the third order. Weighted fit (by the uncertainty in *P* and *V*) gave the following elastic parameters: $V_0 = 702.0(7)$ Å³, $K_{V0} = 51(2)$ GPa, and $K'_V = 2.9(4)$. A linearized BM EoS was used to fit the *a*-*P* and *c*-*P* data, giving the following refined parameters: $a_0 = 12.593(5)$ Å, $K_{a0} = 64(4)$ GPa, $K'_a = 4.5(9)$, for the *a*-axis, and $c_0 = 5.112(3)$ Å, $K_{c0} = 36(1)$ GPa, $K'_c = 1.9(3)$ for the *c*-axis (elastic anisotropy: K_{a0} : $K_{c0} = 1.78:1$). A subtle change of the elastic behavior appears to occur at *P* > 4.62 GPa, and so the elastic behavior was also described on the basis of BM EOS valid between 0.0001–4.62 and 5.00–6.63 GPa, respectively. The high-pressure structure refinements allowed the description of the main deformation mechanisms responsible for the anisotropic compression of cancrinite on (0001) and along [0001]. A comparative analysis of the structure evolution in response of the applied pressure and temperature of isotypic materials with cancrinite-like topology is carried out.

Keywords: Cancrinite, zeolites, high pressure, compressibility, structure evolution

INTRODUCTION

Cancrinite is a feldspathoid with ideal chemical formula $(Na,Ca)_{7-8}[Al_6Si_6O_{12}](CO_3)_{1,2-1,7}\cdot 2H_2O$, which can form as a primary phase in low-SiO₂ alkaline rocks in the late hydrothermal stages or as the alteration product of nepheline- or sodalite-group minerals. It is the parent member of a group including about 20 minerals (Bonaccorsi and Merlino 2005; Cámara et al. 2005, 2010; Rastvetaeva et al. 2007; Bonaccorsi et al. 2012), among which the most common are davyne and vishnevite.

Cancrinite has an open-framework structure (framework density = $16.9 \text{ T}/1000 \text{ Å}^3$, Baerlocher et al. 2007), with CAN (i.e. cancrinite-type) topology. Its framework is built up by 12-, 6-, and 4-membered rings of tetrahedra in a way that planes of 6-membered rings perpendicular to [0001] (hereafter 6mRs1[0001]) are stacked according to an ...ABAB... closepacking sequence (Fig. 1). The resulting framework consists of columns of base-sharing cages (Fig. 1), the so-called cancrinite, or undecahedral or ε cages (Baerlocher et al. 2007), and isooriented 12mRs-channels parallel to [0001] (Figs. 1 and 2). Cages and channels are connected by distorted 6mRs windows parallel to [0001] (hereafter 6mR//[0001]) (Fig. 2). Moreover, 4mRs form double zigzag chains (Baerlocher et al. 2007) running parallel to [0001] (Fig. 1). The topological symmetry of the CAN framework type is $P6_3/mmc$, with idealized lattice constants a =12.494 and c = 5.254 Å (Baerlocher et al. 2007).

Over the last 40 years, cancrinite-like materials have been extensively studied for their structure-related properties. Many studies have been devoted to the superstructure reflections often found in cancrinites, governed by the ordering of the carbonate groups and their vacancies along [0001] (e.g., Grundy and Hassan 1982; Brown and Cesbron 1973; Foit et al. 1973; Hassan and Buseck 1992), but also for the occurrence and use of cancrinite in many technological processes: e.g., as final product of Na-aluminosilicates precipitation from liquor during the Bayer process for the refining of bauxite (Gerson and Zheng 1997; Barnes et al.

0003-004X/12/0506-872\$05.00/DOI: http://dx.doi.org/10.2138/am.2012.4039

The cancrinite structure was first described by Pauling (1930) and then refined by Jarchow (1965) in the space group $P6_3$, the symmetry reduction being due to the full Si/Al-ordering in the tetrahedral framework. The extraframework population consists of ··· Na-H2O-Na-H2O··· chains lying in the cancrinite cages and by CO₃²⁻ groups lying in two mutually exclusive and partially occupied positions in the center of the 12mRs-channels, occupied also by mixed Na/Ca sites near the channel wall (Figs. 3 and 4). In cancrinite the ... Na-H₂O-Na... chains show one shorter and one longer Na-H2O bond distances. In contrast, in the isotypic davyne or microsommite (Bonaccorsi and Merlino 2005), ... Ca-Cl... chains show constant bond lengths. In the 12mRs-channel, different anions (e.g., SO₄⁻, NO₃⁻, Cl⁻, OH⁻) or H₂O molecules can replace CO₃²⁻ in natural or synthetic cancrinites (e.g., Grundy and Hassan 1982; Hassan and Grundy 1984, 1991; Bresciani-Pahor et al. 1982; Buhl et al. 2000; Fechtelkord et al. 2001; Ballirano and Maras 2005).

^{*} E-mail: diego.gatta@unimi.it

1999) or as a precipitation product in nuclear waste tanks at the Hanford site (Washington, U.S.A.), and as product of the reaction between simulated leaked waste fluids and quartz- or kaolinitebearing sediments at the same site (Buck and McNamara 2004; Bickmore et al. 2001; Zhao et al. 2004). Moreover, Zhao et al. (2004) reported a sorption capacity for Cs⁺ ions in waste fluids,

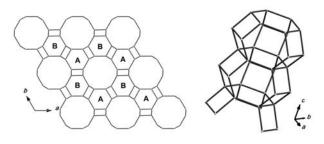

FIGURE 1. (left) The building scheme of the CAN framework: planes of 6-membered rings of tetrahedra perpendicular to [0001] are stacked according to an ABAB close-packing sequence. (**right**) A column, parallel to [0001], of base-sharing ε cages. Three double zigzag chains run along the column.

whereas Poborchii (1994) and Poborchii et al. (2002) studied the optical properties of Se_2^2 and Se_2^- in the cancrinite channels.

Only a few studies have been devoted to the behavior of cancrinite under non-ambient conditions. Hassan et al. (2006) performed an in situ high-temperature X-ray powder diffraction study up to 1275 K, and reported: (1) a phase transition with loss of the superstructure reflections at ~797 K, (2) a continuous dehydration process toward a full dehydration at 918 K coupled with (3) a minimal loss of CO₂. The results of an in situ hightemperature single-crystal X-ray diffraction study up to 673 K were reported by Isupova et al. (2010), whereas the description of the elastic behavior and structure evolution at low-temperature (LT) conditions (down to 100 K) was recently provided by Gatta et al. (2012) by in situ LT single-crystal X-ray diffraction. Gatta and Lee (2008) described the elastic behavior and the pressureinduced structure evolution of Na₆Cs₂Ga₆Ge₆O₂₄·Ge(OH)₆, a synthetic compound isotypic with cancrinite, by means of in situ high-pressure (HP) synchrotron powder diffraction up to 5.01 GPa. However, to the best of our knowledge, no study has to date been devoted to the HP behavior of a natural cancrinite. In this light, the aim of this study is to describe the elastic

(c and d) The 6mR \perp [0001] at room *P* (c) and at 6.63 GPa (d). The *P*-induced anti-cooperative rotation of adjacent tetrahedra (ditrigonalization) is shown.

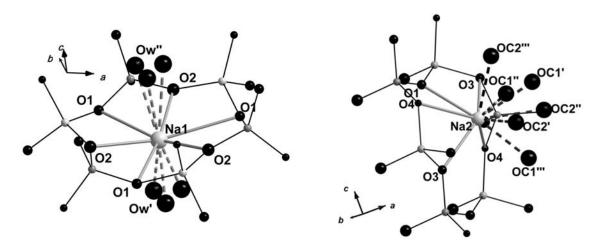

FIGURE 3. (left) The coordination shell of the Na1 site. Dashed lines represent mutually exclusive Na-Ow bond lengths. (right) The coordination shell of the Na2 site (i.e., five framework oxygen on a side and up to three carbonate oxygen on the opposite side, maximum C.N. = 8).

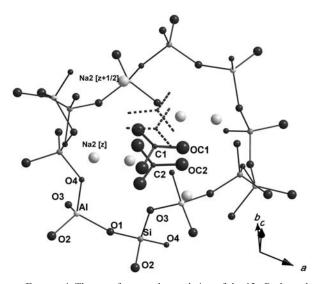

FIGURE 4. The extraframework population of the 12mR channel, with the Na2 site close to the wall and the carbonate anions lying at the center. Different stacking sequences of the CO3- groups and their vacancies are possible.

behavior and the P-induced structure evolution of a natural cancrinite, with no evidence of superstructure reflections at ambient conditions, by in situ single-crystal X-ray diffraction under hydrostatic conditions. The formulation of the isothermal equation of state, along with the description of the main deformation mechanisms of the tetrahedral framework and the behavior of the extraframework population will be provided. Furthermore, a comparative analysis of the structure evolution in response of the applied pressure of the natural cancrinite here investigated and of Na₆Cs₂Ga₆Ge₆O₂₄·Ge(OH)₆ (Gatta and Lee 2008) will be carried out.

MATERIALS AND METHODS

The single-crystal X-ray diffraction experiments were performed on a platy crystal of natural cancrinite free of defects under the polarized microscope, collected from the same gem-quality sample from Cameroun used by Della Ventura et al. (2009), for a single-crystal neutron diffraction experiment and polarized infrared spectroscopy, and by Gatta et al. (2012), for a LT single-crystal X-ray diffraction study. Cancrinite crystals from this sample do not show any evidence of superstructure reflections. The chemical composition, obtained by electron microprobe analysis in wavelength-dispersive mode, is Na_{6.59}Ca_{0.93}[Si₆Al₆O₂₄] $(CO_3)_{1.04}F_{0.41} \cdot 2H_2O \ (Z=1)$ (Della Ventura et al. 2009).

An intensity data collection with the crystal in air was first performed using an Xcalibur-Oxford Diffraction diffractometer equipped with a CCD detector,

operating at 50 kV and 40 mA with a monochromatized MoKa radiation source and a detector-sample distance fixed at 80 mm. A combination of ω and ϕ scans was chosen to maximize data coverage and redundancy. The step scan was 1°/ frame along with an exposure time of 60 s/frame (Table 1). A total number of 19933 reflections, out of which 1980 unique for symmetry, were collected up to $2\theta_{max} = 70^{\circ}$, showing a metrically hexagonal lattice with systematic extinctions consistent with the space group P63 (Table 1). The refined unit-cell parameters were: a = 12.5976(6), c = 5.1168(2) Å, and V = 703.2(1) Å³ (Table 1). Intensities were then integrated, corrected for Lorentz-polarization (L_p) and for absorption effects (analytical absorption corrections by Gaussian integration based upon the physical description of the crystal) using the CrysAlis software package (Oxford Diffraction 2010). Further details pertaining to the data collection strategy are in Table 1. A hydrogen-free structure refinement of cancrinite was then performed with the SHELX-97 program (Sheldrick 1997), starting from the atomic coordinates of Della Ventura et al. (2009) in the space group P63. Neutral atomic scattering factors for Si, Al, Na, Ca, C, and O from the International Tables of Crystallography (Wilson and Prince 1999) were used. A mixed scattering curve of Na and Ca was used to model the Na2 site, and the site occupancy factors of C1 and C2 were constrained to be equal to that of Oc1 and Oc2, respectively. The H₂O oxygen site (Ow), lying off the threefold axis in three symmetry-related and mutually exclusive positions, was modeled with a site occupancy factor (s.o.f.) of 1/3. The C-Oc bond lengths were restrained to 1.300 ± 0.005 Å, on the basis of the neutron refinement reported by Della Ventura et al. (2009). In the last cycles of the refinement, the displacement parameters of all the atomic sites were refined anisotropically; only C, Oc, and Ow sites were refined isotropically, due to a significant correlation among the refined parameters likely ascribable to the positional disorder of the carbonate groups and H2O molecules (Grundy and Hassan 1982; Della Ventura et al. 2009). The refinement converged to an agreement factor R_1 of 5.6% for 1092 reflections with $F_0 > 4\sigma(F_0)$. At the end of the refinement, no significant correlation was observed in the variance-covariance matrix and the residual peaks in the difference-Fourier function of the electron density were between +0.77/-0.55 e⁻/Å³. Further details pertaining to the structure refinement are in Table 1.

An ETH-type diamond-anvil cell (DAC, Miletich et al. 2000), was used for the high-pressure experiments. A T301 steel foil, 0.250 mm thick, was used as a gasket, which was pre-indented to a thickness of about 0.110 mm before drilling a micro-hole (~0.300 mm in diameter) by spark-erosion. The same crystal of cancrinite previously investigated at ambient conditions was placed into the gasket hole along with some ruby chips and a single crystal of quartz used as Pstandards (Mao et al. 1986; Angel et al. 1997). A 4:1 mixture of methanol:ethanol was used as hydrostatic pressure-transmitting medium (Angel et al. 2007). Lattice parameters were measured between 0.0001 and 6.63(2) GPa (Table 2), using 42 Bragg reflections with a KUMA KM4 point-detector diffractometer, operating at 50 kV and 40 mA with a graphite monochromatized MoKa radiation source.

Ten intensity data collections between 0.0001 GPa (with crystal in the DAC without any pressure medium) and 6.63(3) GPa (Table 1) were performed with an Xcalibur-Oxford Diffraction diffractometer equipped with a CCD (graphitemonochromatized MoK α radiation). A combination of ω and ω scans was used with steps of 0.5°/frame and an exposure time of 60 s/frame (Table 1). No violations of the reflection conditions expected for the space group P63 were observed within the P range investigated. Integrated intensity data were corrected for $L_{\rm p}$ and absorption effects due to the crystal and the DAC using the ABSORB computer program (Angel 2004). The HP structure refinements based on the intensity data collected with the crystal in the DAC were performed with the SHELX-97 program (Sheldrick 1997). The number of the refined parameters was reduced to 45: all the occupancy factors were constrained to the values refined with the crystal in air and the atomic displacement parameters (dp's) were all refined isotropically. In addition, the dp's for the C1-C2 and Oc1-Oc2 pairs were constrained to be equal, respectively. As for the structure model at room conditions, the C-Oc bond lengths were restrained to 1.300 ± 0.005 Å³. The refinements converged for all the HP data sets with R_1 always lower than 8.9%, with no significant correlation between the refined parameters and residual peaks in the difference-Fourier maps lower than $\pm 0.96 \ e^{-/\text{Å}^3}$.

Atomic fractional coordinates, site occupancy factors, and atomic displacement parameters pertaining to the structure refinements at room P and HP are given in Table 3; bond distances and angles are listed in Table 4. Refined anisotropic displacement parameters are available in the CIF¹ (deposited).

RESULTS

Elastic behavior

The evolution of the unit-cell parameters of cancrinite up to 6.63(2) GPa is shown in Figure 5. The unit-cell parameters measured in decompression showed that the pressure-induced structural evolution of up to ~6.6 GPa is completely reversible.

The *P-V* between 0.0001 and 6.63 GPa data were first fitted with an isothermal Birch-Murnaghan type equation of state truncated to the third-order (BM-III EoS, Birch 1947), using the EoS-Fit v5.2 program (Angel 2000). Weighted fit (by the uncertainty in *P* and *V*) gives the following elastic parameters: $V_0 = 702.0(7)$ Å³, $K_{V0} = 51(2)$ GPa, and $K_{V} = 2.9(4)$. The evolution of the Eulerian strain vs. the normalized pressure within the entire *P* range investigated { f_e - F_e plot, $f_e = [(V_0/V)^{2/3} - 1]/2$ and $F_e = P/[3f_e(1 + 2f_e)^{5/2}]$, Angel 2000} is shown in Figure 5, suggesting that the isothermal volume compression in cancrinite can be described with a third-order BM EoS, giving a bulk modulus at room *P* of $F_e(0) = 50(1)$ and its *P*-derivative of 3.2(3). A "linearized" BM-III equation of state was used to fit

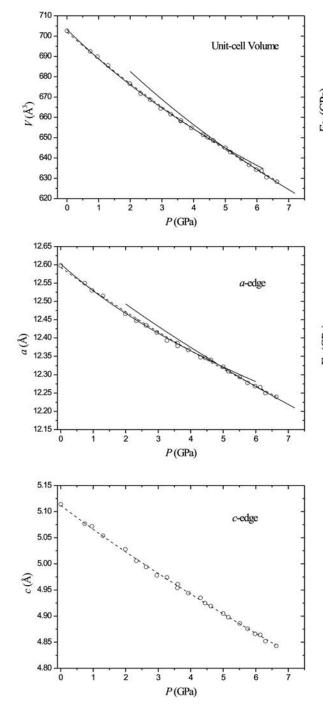

¹ Deposit item AM-12-039, CIFs. Deposit items are available two ways: For a paper copy contact the Business Office of the Mineralogical Society of America (see inside front cover of recent issue) for price information. For an electronic copy visit the MSA web site at http://www.minsocam.org, go to the *American Mineralogist* Contents, find the table of contents for the specific volume/issue wanted, and then click on the deposit link there.

TABLE 4. Relevant bond distances (Å), ring "diameters" (Å), angles (°), areas (Å²), volumes (Å³) and the (0001)-plane corrugation (Δz, Å) at different pressures

the *a*-*P* and *c*-*P* data (Angel 2000), giving the following refined parameters: $a_0 = 12.593(5)$ Å, $K_{a0} = 64(4)$ GPa, $K'_a = 4.5(9)$, $c_0 = 5.112(3)$ Å, $K_{c0} = 36(1)$ GPa, and $K'_c = 1.9(3)$. The elastic anisotropy at room pressure is then: $K_{a0}:K_{c0} = 1.78:1$.

When one EoS is used over the entire P range investigated, a modest misfit is observed for the a-axis and the unit-cell volume, respectively, suggesting a potential change of the compressional behaviors between 4.62–5.00 GPa. On this basis, two different BM EoS fits were used to model the elastic behavior along the *a*-axis and for the unit-cell volume between 0.0001–4.62 and 5.00–6.63 GPa, respectively. The refined parameters are: $a_0 = 12.603(7)$ Å, $K_{a0} = 52(6)$ GPa, $K'_a = 11(4)$, $V_0 = 703.3(7)$ Å³, $K_{V0} = 45(2)$ GPa, and $K'_V = 6(1)$ between 0.0001 and 4.62 GPa; $a_0 = 12.63(2)$ Å, $K_{a0} = 58(4)$ GPa, $K'_a = 4$ (fixed), $V_0 = 715(4)$ Å³, $K_{V0} = 40(2)$ GPa, and $K'_V = 4$ (fixed) between 5.00 and 6.63 GPa. A further f_e - F_e plot is shown in Figure 5 with the refined V_0 obtained by the BM-III EoS fit (0.0001–4.62 GPa) and by the BM-II EoS fit (5.00–6.63 GPa), respectively.

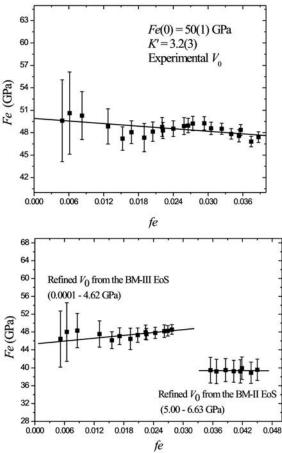

FIGURE 5. Variation of the unit-cell parameters of cancrinite with pressure and Eulerian finite strain vs. normalized stress plot (f_c - F_e plot). For the unit-cell parameters vs. *P* plots, the dotted lines represent the axial and volume BM-EoS fits between 0.0001 and 6.63 GPa, whereas the solid lines represents the BM-EoS fit between 0.0001–4.62 and 5.00–6.63 GPa, respectively (see text for further details). The e.s.d. values are of the same size of the symbols.

Structure refinements

The structure refinement of cancrinite at room *P* confirms the framework and extraframework configuration previously described (e.g., Della Ventura et al. 2009), with the ε cages stuffed by \cdots Na–H₂O–Na–H₂O \cdots chains and the 12mRs-channels with cation sites close to the channel walls (Na2), partially occupied by Na [85.4(6)%] and Ca [14.6(6)%], and CO₃^{2–} groups in the center of the channel in two mutually exclusive positions (i.e., C1 and Oc1 s.o.f. = 42.1(7)%; C2 and Oc2 s.o.f = 45.9(6)%; Table 3) (Figs. 3 and 4). The chemical formula deduced on the basis of the structure refinement is: $Na_{7.04}Ca_{0.88}[Al_6Si_6O_{24}]$ (CO₃)_{1.76}·2H₂O, and if we consider the amount of F obtained on the basis of the EMPA-WDS (i.e., 0.41 atoms per formula unit, Della Ventura et al. 2009), we obtain (after a recalculation of the C/F s.o.f.): $Na_{7.04}Ca_{0.88}[Al_6Si_6O_{24}](CO_3)_{1.15}F_{0.41}$ ·2H₂O. This chemical formula shows a slightly higher amount of Na and a lower amount of Ca with respect to the formula reported by Della Ventura et al. (2009). In fact, the sum of the electrons

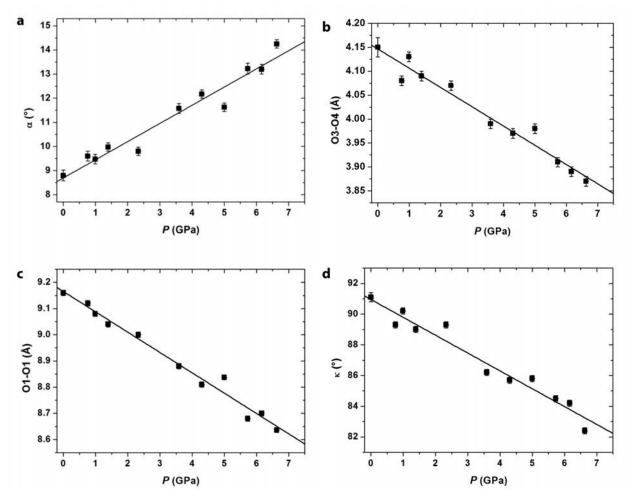

FIGURE 6. Evolution with *P* of (a) the ditrigonal rotation angle α of the 6mR \perp [0001] unit, (b) the O3-O4 diameter of the 4mR unit, (c) the O1-O1 diameter of the 12mR unit, and (d) the κ angle (O2-O2-O2) of the ε cage. The weighted linear fits through the data points are shown.

ascribable to the extraframework cations (Na and Ca) from the structure refinement is 95.4 e^- , slightly higher than 91.1 e^- from the experimental chemical analysis ($\Delta e^- \sim 4.5\%$).

The HP structure refinements showed that the general configuration of framework and extraframework population was maintained within the *P* range investigated; the main deformation mechanisms of the tetrahedral framework and of the channel and cage content are described below.

High-pressure framework behavior

At high pressure, the structure refinements show that the $6mRs \pm [0001]$ experience a ditrigonalization process, with the opening of the $\omega 1$ angle (O1-O2-O1) and the closure of $\omega 2$ angle (O2-O1-O2) (Fig. 2; Table 4). A linear increasing of the ditrigonal rotation angle α (Fig. 6; Table 4) ($\alpha = 1/6 \cdot \Sigma_i |120^\circ - \theta_i|/2$, where θ_i is the angle between the basal edges of neighboring tetrahedra articulated in the six membered ring; Brigatti and Guggenheim 2002) is observed. This unit is also compressed in response to the applied pressure as shown by the shortening of the O1-O2 distance and the reduction of the ditrigonal area subtended by the oxygen atoms (Fig. 2; Table 4). Moreover, we observed a decrease of the (A,B)-plane corrugation [defined]

as $\Delta z = [z(O)_{max} - z(O)_{min}] \cdot c$, where $z(O)_{max}$ is the maximum z coordinate of the oxygen atoms belonging to the plane, $z(O)_{min}$ the minimum one and c is the unit-cell edge length; Brigatti and Guggenheim 2002)] (Table 4).

The 4mR joint-unit shows a compression along the O3-O4 diameter (Figs. 2 and 6; Table 4), whereas an expansion is shown along O2-O2, giving as overall effect a reduction of the area subtended by the four oxygen corners (Fig. 2; Table 4). In the 12mR-channel, an almost constant value of the six symmetrically related O3-O4 distances is observed with pressure, along with a shortening of the six symmetrical O1-O1 distances (i.e., ~5.7%; Figs. 2 and 6; Table 4). The 6mR-windows connecting channels and cages (6mR//[0001]) show a strong ditrigonalization with a shortening of the O1-O1 diameter (i.e., the c edge of unit-cell), and a less pronounced contraction of the O3-O3 and O4-O4 diameters (Fig. 2; Table 4). The cancrinite cage shows a pronounced flattening along [0001], governed by the closure of the κ angle (O2-O2-O2) (Figs. 2 and 6; Table 4), whereas the maximum width on the (0001) plane, defined by the three symmetry-related diameters O2-O2 (dashed lines in Fig. 2), is constant within the P range investigated (Table 4).

The evolution of the channel volume [modeled as

 $V_{ch} = \pi \cdot [(D/2)^2] \cdot c$; with D = (O1-O1 + O3-O4)/2, where O1-O1 and O3-O4 are the independent diameters of the 12mR; Fig. 2, Table 4] and of the ε -cage volume [modeled as $V_{cg} = (V_{cell} - V_{ch})/2$] with *P* was studied. Both the V_{ch} -*P* and V_{cg} -*P* data (Table 4) were fitted with a truncated BM-III equation of state, fixing V_0 to the experimental value at P_0 . The refined elastic parameters are: K_{0ch} = 52(3) GPa, $K'_{ch} = 1.4(1.0)$ for the 12mR channel, and $K_{0cg} =$ 53(4) GPa, $K'_{cg} = 4(2)$ for the ε -cage.

High-pressure extraframework behavior

The Na1 site, which lies in the ε cage, coordinates the neighboring 6mR oxygen and two H₂O molecules (ditrigonal bipyramid coordination shell) (Fig. 3). The distortion of this polyhedron is strictly governed by the framework deformation. With increasing pressure, we observe a contraction of the Na1-O2 and an expansion of the Na1-O1 bond lengths (Table 4). The two Na1-Ow distances of the coordination polyhedron are symmetrically independent and both show a shortening with pressure (Table 4).

The sum of the refined site occupancies of the mutually exclusive carbonate groups is lower than 1 (Table 3), indicating site vacancy. The absence of any superstructure reflections suggests that these vacancies are randomly distributed along the 12mR channels. Three combinations of subsequent CO₃ groups are possible: C1-C2 [3.85(7) Å at room *P*], C1-C1, and C2-C2 [both spaced by c/2, 2.542(2) Å at room *P*] (Fig. 4; Table 4).

The Na2 site is coordinated by five framework oxygen atoms on a side and up to three carbonate oxygen atoms on the opposite side (Fig. 3). With increasing pressure, we observe a decrease of the shorter Na2-O3', Na2-O4', and Na2-O1 bond lengths and an expansion of the longer Na2-O3'' and Na2-O4'', whereas no significant change occurs for the Na2-Oc distances (Table 4).

DISCUSSION

Elastic behavior

The refined isothermal bulk modulus at room P (i.e., K_{V0} = 45-52 GPa) is similar to that of other microporous materials that share with cancrinite the presence of "6-membered rings" of tetrahedra as "secondary building units" (sensu Baerlocher et al. 2007) (Gatta 2008), among those: sodalite [i.e., $K_{V0} = 51(1)$ GPa; Hazen and Sharp 1988], levyne [i.e., $K_{V0} = 56(4)$ GPa for P < 1 GPa, 46(1) GPa for P > 1 GPa; Gatta et al. 2005], and chabazite [i.e., $K_{V0} = 35(5)$ GPa for $P \le 1$ GPa, 62(1) GPa for $P \ge 1.4$ GPa; Leardini et al. 2010]. The stiffer open-framework silicates show bulk moduli of 60–70 GPa [e.g., philippsite K_{ν_0} = 67(2) GPa, Gatta and Lee 2007; gismondine $K_{V0} = 63.8(2)$, Ori et al. 2008], whereas for the softest the range is 18–40 GPa [e.g., Na-ZSM-5 K_{V0} = 18.2(6) GPa, Arletti et al. 2011; H-ZSM-5 K_{V0} = 23.7(4) GPa, Quartieri et al. 2011; zeolite-A K_{V0} = 22.1(3), Arletti et al. 2003; heulandite $K_{\nu_0} = 27.5(2)$, Gatta et al. 2003; mordenite $K_{V0} = 41(2)$ GPa, Gatta and Lee 2006].

A subtle change in the elastic behavior of cancrinite appears to occur at P > 4.6 GPa (Fig. 5). However, the accuracy and precision of our data, along with the limited P range investigated, do not allow to have a unique picture of the elastic behavior. In addition, a potential change of the compressional mechanisms at P > 4.6 GPa is not supported by the deformation mechanisms deduced on the basis of the HP structure refinements, neither by any change of the symmetry nor by any evidence of satellite reflections (Fig. 6, Table 4).

The elastic behavior of the natural cancrinite here investigated differs significantly from that of the isotypic Na₆Cs₂Ga₆Ge₆O₂₄·Ge(OH)₆. The compressional behavior of the synthetic analog was fitted with a Murnaghan-type equation of state (Murnaghan 1937) by Gatta and Lee (2008), giving: $K_{V0} =$ 36(2) GPa and $K'_V = 9(1)$ GPa. Possible reasons for the higher compressibility at room *P*, along with the higher stiffness rate of the synthetic compound, can be found in the compression of the (Ga,Ge) tetrahedra, which is already significant in response to moderate pressure (i.e., P < 5 GPa) if compared to the almost rigid behavior of the (Si,AI) tetrahedra of the natural sample (Table 4), and in the different nature of the extraframework population.

High-pressure framework behavior

The main deformation mechanism in the cancrinite framework in response to the applied pressure is the anti-cooperative rotation of adjacent tetrahedra belonging to the 6mRs1[0001]. This mechanism requires that for a given tetrahedron belonging to the A plane, which shows a clockwise rotation, the four adjacent vertex-sharing tetrahedra (three on the same A plane and one on the next B plane) will show an counterclockwise rotation (Fig. 2). The 6mRs1[0001] ditrigonalization is the main effect of the anticooperative rotation mechanism, leading to the 12mR-channels contraction along the O1-O1 distances (Figs. 2 and 6). The (O1-O1/O3-O4) ratio decreases with P from 1.038(3) at 0.0001 GPa to 0.989(2) at 6.63 GPa (Table 4). The shortest free diameter of the channels (i.e., O3-O4) is nearly constant up to ~5.3-5.4 GPa and then decreases at higher pressure. On the whole, (1) the channel O1-O1 shortening coupled with (2) the 4mR joint-units compression along the O3-O4 direction and (3) the $6mRs \perp [0001]$ compression (described by the O1-O2 shortening, Table 4) are the mechanisms responsible for the P-driven contraction on the (0001) plane (Figs. 2 and 6), whereas the compression along the c axis is accommodated by (1) the ε -cage flattening, (2) the decrease of the (A,B)-planes corrugation, and (3) the ditrigonal distortion of the 6mRs//[0001] windows connecting channels and cages (Figs. 2 and 6; Table 4).

The elastic parameters obtained from the compressional behavior of the 12mR-channel and of the ε cage (Table 4) show that these units have similar bulk moduli at room *P*, but the cage becomes stiffer with increasing pressure, likely due to the presence of the \cdots Na–H₂O \cdots chains as cage-population that can hinder the compression of the cage.

The isotypic Na₆Cs₂Ga₆Ge₆O₂₄·Ge(OH)₆ variant (Gatta and Lee 2008), despite the significant differences in the nature of framework and extraframework population, shows the same *P*-induced main deformation mechanisms found in natural cancrinite. On this basis, we believe that the main deformation mechanisms here described might be intrinsically governed by the CAN framework topology. As a matter of fact, a comparison with the structural evolution of a natural cancrinite at hightemperature conditions, on the basis of the data reported by Hassan et al. (2006), shows the same deformation mechanisms, but opposite in sign, here observed at high pressure.

High-pressure extraframework behavior

At high pressure, the Na1 to framework-oxygen bond lengths variation appears to be the effect of the $6mRs\perp[0001]$ ditrigonalization, whereas the compression along [0001] governs the bond lengths shortening along the \cdots Na–H₂O–Na–H₂O \cdots chains (Fig. 3; Table 4).

Different coordination shells, with maximum coordination number (C.N.) of 8, are possible for the Na/Ca mixed Na2 site, due to the different CO₃ ordering but with a fixed coordination with 5 framework oxygen (Fig. 3). At high pressure, the expansion of the longer Na2-O3" and Na2-O4" bond lengths leads an increasingly weaker interaction with these atoms, suggesting an actual C.N. = 6 at these conditions.

The contraction of the short C1-C1 and C2-C2 distances (equal to c/2) at high pressure suggests an increasing instability for these stacking configurations in favor of the longer C1-C2 one (~3.85 Å at room *P*), if we consider the C-C distance in aragonite (~2.87 Å) as the shortest reported in carbonates (Bonaccorsi and Merlino 2005). However, previous structure refinements of natural cancrinites from X-ray and neutron diffraction data (e.g., Ballirano and Maras 2005; Della Ventura et al. 2009; Gatta et al. 2012) showed anisotropic displacement parameters of the CO₃ group significantly elongated along [0001], likely due to a positional disorder aimed to optimize the C-C distances at a local scale toward an energetically less costly configuration.

The role of the extraframework population on the highpressure structure evolution of natural cancrinite appears to be only secondary, suggesting that the *P*-induced structure response is mainly governed by the framework deformation mechanisms, which, in turn, are likely controlled by the CAN topology.

ACKNOWLEDGMENTS

Giancarlo Della Ventura and Fabio Bellatreccia (Università Roma Tre) are thanked for the crystals of cancrinite from Cameroun. Giorgio Pafundi and Bruno Pafundi are thanked for the setup of the HP-lab in Milan. The reviewers Simona Quartieri and Ronald Miletich, the Technical Editor (Ron Peterson) and the Associate Editor (Alexandra Friedrich) are thanked. This work was funded by the Italian Ministry of University and Research, MIUR-Project: 2008SPZ743.
