The natural product cepafungin I was recently reported to be one of the most potent covalent inhibitors of the 20S proteasome core particle through a series of in vitro activity assays. Here, we report a short chemoenzymatic total synthesis of cepafungin I featuring the use of a regioselective enzymatic oxidation to prepare a key hydroxylated amino acid building block in a scalable fashion. The strategy developed herein enabled access to a chemoproteomic probe, which in turn revealed the exceptional selectivity and potency of cepafungin I towards the b2 and b5 subunits of the proteasome. Further structure-activity relationship studies suggest the key role of the hydroxyl group in the macrocycle and the identity of the lipid tail in modulating the potency of this natural product family. This study lays the groundwork for further medicinal chemistry exploration to fully realize the anticancer potential of cepafungin I.

Abstract: The natural product cepafungin I was recently reported to be one of the most potent covalent inhibitors of the 20S proteasome core particle through a series of in vitro activity assays. Here, we report a short chemoenzymatic total synthesis of cepafungin I featuring the use of a regioselective enzymatic oxidation to prepare a key hydroxylated amino acid building block in a scalable fashion. The strategy developed herein enabled access to a chemoproteomic probe, which in turn revealed the exceptional selectivity and potency of cepafungin I towards the $\beta 2$ and $\beta 5$ subunits of the proteasome. Further structure-activity relationship studies suggest the key role of the hydroxyl group in the macrocycle and the identity of the lipid tail in modulating the potency of this natural product family. This study lays the groundwork for further medicinal chemistry exploration to fully realize the anticancer potential of cepafungin I.

Introduction

Cepafungin I and glidobactin A are two macrolactams belonging to a larger family of natural products called the syrbactins (Fig. 1). Members of this family share a common 12-membered macrolactam core consisting of a vinyllogous amino acid and a lysine residue that may exist in various oxidation states. Further diversity can be found within the tail portion of the natural products: while the cepafungins and the glidobactins possess unsaturated fatty acid tails, all syrbactins contain a Val-Val unit that is linked via a unique ureido moiety.¹ Initial biological evaluation suggested that the glidobactins and the cepafungins exhibit moderate antifungal activity and potent antitumor activity against P388 leukemia in mice.^{2a,b} More recently, it has been determined that the latter activity arises from inhibition of the 20S proteasome core particle (CP) via covalent engagement of two distinct catalytically-active Thr 10γ residues by the unsaturated lactam motif of the macrocycle.³ Cepafungin I, in particular, exhibits remarkably strong inhibitory activity relative to all known proteasome inhibitors to date (IC_{50} of 4 nM against the $\beta 5$ subunit of yeast CP).⁴ The proteasome is a multiprotein complex that plays a critical role in protein degradation. Given the centrality of the proteasome in the regulation of cell cycle and apoptosis, its inhibition constitutes a promising modality for cancer therapy. In support of this notion, three proteasome inhibitors, bortezomib, carfilzomib and ixazomib, have been approved by the U.S. Food and Drug Administration for the treatment of multiple myeloma. However, both bortezomib and carfilzomib have been reported to exhibit several side effects such as thrombocytopenia and high occurrence of relapse and chemoresistance have also been reported.⁵ Thus, there is still an urgent need to advance new proteasome inhibitors as drug candidates that will address these issues.

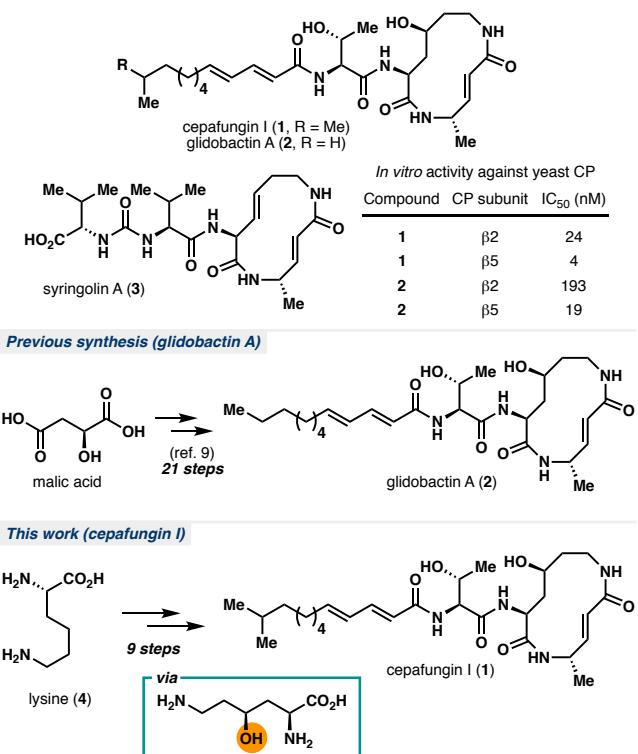

Figure 1. The syrbactins family of natural products, their respective inhibitory activities on the 20S proteasome, prior approach to glidobactin A and our synthetic strategy towards cepafungin I.

Similar to bortezomib, the syrbactins trigger apoptosis by eliciting p53 accumulation and inhibiting NF- κ B activity.¹ Pioneering studies by Bachmann and co-workers using a syrbactin derivative additionally showed that while this compound exhibited cytotoxic effects on cancer cell lines, the effect was most pronounced in multiple myeloma.⁶ Recent research has begun to elucidate certain resistance mechanisms in multiple myeloma. While current proteasome inhibitors primarily inhibit the $\beta 5$ subunit, it has been shown that co-inhibition of the $\beta 2$ subunit prevents recovery of proteasome activity by causing aggregation/inactivation of the proteasomal transcription factor Nrf1. Notably, the cytotoxicities of bortezomib and carfilzomib towards solid tumor cells (e.g., triple negative breast cancer) are significantly enhanced in this manner, whereas either drug had otherwise not shown clinical efficacy on its own. Moreover, co-inhibition of $\beta 5$ with $\beta 2$ provides a stronger antineoplastic effect than with $\beta 1$, highlighting the importance of advancing new proteasome inhibitors with equipotent activity for these subunits.^{7,8} Cepafungin I, with its low nanomolar activity towards $\beta 5$ and $\beta 2$ (IC_{50} = 4 nM and 24 nM, respectively), stands as an attractive candidate for such purpose.

A seminal work by Schmidt and coworkers in 1992 established the first total synthesis of glidobactin A.⁹ Starting from malic acid, the synthesis of the natural product was achieved in 21 steps. While a landmark achievement, this approach suffers from high step count due to inefficient functional group interconversions and extraneous protecting group manipulations. For example, the synthesis of the key 4-hydroxylysine moiety took place in 12 steps from malic acid, featuring HWE homologation, asymmetric hydrogenation and displacement of the terminal alcohol with NaN₃. Efforts by Ichikawa,^{10a,b,c} Pirrung,¹¹ Stephenson¹² and others^{13a,b,c,d} have established viable synthetic routes to the syrbactins. However, these routes would not be amenable to the introduction of the key 2° alcohol within the embedded lysine unit.

Results and Discussion

Similar to previous studies, we recognized that an efficient route to 4-hydroxylysine (or its synthetic equivalent) would hold the key to the development of a practical synthesis of cepefungin I. If such a route could be identified, iterative condensations with alanine and an acetate equivalent would rapidly generate the macrocyclic core of the natural product. We have previously established the biosynthetic origin of the 4-hydroxylysine moiety of glidobactin A.¹⁴ Within the pathway, a nonheme dioxygenase, GlbB, catalyzes the direct C-H hydroxylation of free-standing lysine at the C4 position prior to loading of the product onto the nonribosomal peptide synthetase assembly line. Substrate scope examination of GlbB revealed that while the enzyme exhibits a narrow substrate specificity, it is able to hydroxylate lysine with remarkably high catalytic efficiency. In our hands, however, large-scale biocatalytic hydroxylation with purified GlbB was hampered by poor scalability as the reaction gave poor conversion when conducted at > 100 mg scale. While this issue could be solved by conducting the reaction with clarified lysate of cells expressing GlbB, the poor soluble expression of GlbB led to sub-optimal titer (**Fig. 2**). Gratifyingly, co-expression of chaperones GroES/EL was found to increase soluble expression of GlbB, which translates to ca. 5-fold improvement in reaction conversion and yield on small scale. For large scale reactions, ca. 6–7 g of lysine could be fully converted to its C4-hydroxylated counterpart in a single pass with 1 L of clarified cell lysate (final OD₆₀₀ = 12.5), corresponding to a titer of ca. 6–7 g/L based on the original volume of the expression culture.

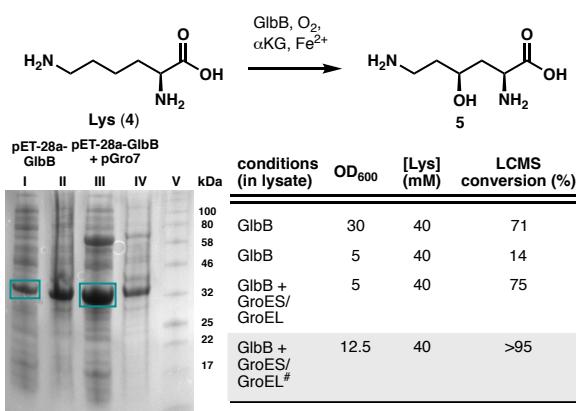

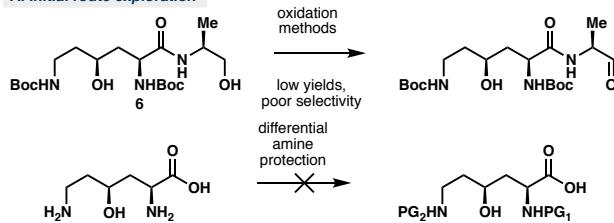

Figure 2. Optimization of preparative scale hydroxylation of **4** with GlBb. Co-expression of chaperones GroES/GroEL was found to improve the soluble

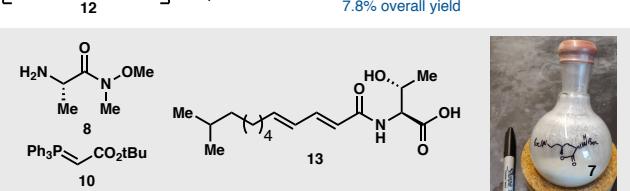

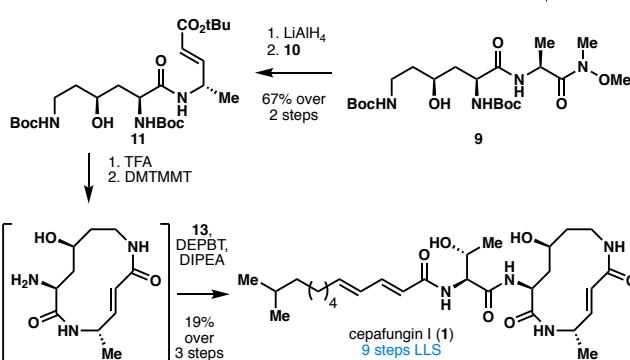

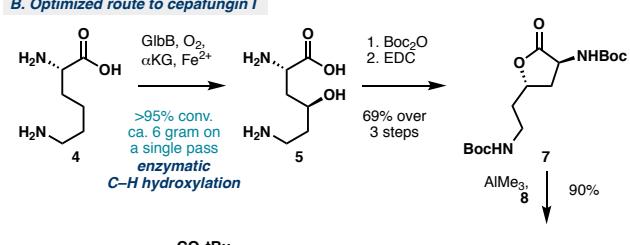

expression of GlbB, resulting in ca. 5-fold improvement in reaction conversion. Lanes (I) and (III): soluble fraction, lanes (II) and (IV): insoluble fraction, lane (V): protein ladder. #Reaction conducted at 6 gram scale.

Having solved the material throughput issue for the production of **5**, we turned our attention to its conversion to the macrocyclic core of **1**. We have previously described the conversion of **5** to intermediate **6** by way of coupling with alaninol.¹⁴ However, attempts to selectively oxidize the 1° alcohol of **6** were beset by low yields and poor selectivity (**Scheme 1A**). Similarly, attempts to effect differential protections of the α - and ε -amine proved problematic due to the presence of the C4-OH. An alternative route was thus devised to circumvent these issues (**Scheme 1B**). Lactone **7**, prepared routinely on multi-gram scale in 3 steps from lysine, was reacted with Weinreb amide **8** in the presence of AlMe₃ to afford dipeptide **9** in 90% yield. Treatment of **9** with LiAlH₄ effected a clean reduction of the Weinreb amide moiety to the corresponding aldehyde without any observable over-reduction or side reactivity with any of the carbonyl groups in the molecule. Olefination with Wittig reagent **10** furnished enoate **11**, which constitutes the protected linear form of the target macrocyclic core. As a testament to the robustness of the route, more than 1.5 g of **11** could be prepared in a single pass.

While global deprotection of **11** could be achieved cleanly under acidic conditions, the subsequent macrolactamization step required extensive optimization (See **Table S1** for optimization). This observation was in line with previous efforts in the total synthesis of glidobactin A and the syrbactins where late-stage macrolactamization typically proceeded in less than 30% yield.^{9,12,13a,c,d} Eventually, DMTMMT was identified as the optimal coupling reagent, providing ~60% NMR yield of the desired macrolactam.¹⁵ Due to the high polarity of **12**, we elected to bypass any purification step and used the compound in a crude form for subsequent coupling with the fully elaborated tail fragment **13**. Extensive screening of peptide coupling conditions (**Table S2**) eventually identified DEPBT as an optimal coupling reagent for this step, leading to the formation of the target natural product in 19% yield from **11**. Overall, our chemoenzymatic synthesis of cepafungin I proceeded in 9 steps (longest linear sequence) and 7.9% overall yield from lysine. By virtue of this chemoenzymatic strategy, our route provides exceptionally rapid access to the key hydroxylysine residue and overcomes longstanding challenges associated with synthetic access to syrbactins bearing 2° alcohol at the L-lysine fragment. This route also highlights DMTMMT as a superior macrolactamization reagent to construct the strained 12-membered ring. Finally, the modularity of this route enables the rapid construction of synthetic analogs and chemoproteomic probes for further biological evaluation (*vide infra*).

Multiple myeloma (MM) has remained the main indication for clinical trials of novel proteasome inhibitor drug candidates since the FDA approval of the first-in-class drug Velcade (bortezomib) in 2003.¹⁶ Accordingly, we started our biological investigations with cytotoxicity measurements of **1** in the commonly used MM cell lines RPMI 8226 and MM1.R to evaluate its potential as a cancer drug candidate. Cells were treated with various concentrations of **1** for 24 h or 48 h and the percentage of viable cells was determined via the WST-1 assay (**Fig. 3A**). Indeed, **1** proved potently toxic and the measured cytotoxicity after 48 h treatment (EC₅₀s of 31 nM for RPMI 8226 and 23 nM for MM1.R) aligned well with the previously reported data for clinical proteasome inhibitor drugs bortezomib (30 nM for RPMI 8226; 3 nM for MM1.R¹⁷) and carfilzomib (5 nM for RPMI 8226¹⁸). Although **1** and structurally related natural products have previously been shown to inhibit proteasomal subunits PSMB2 (β2) and PSMB5 (β5) in purified yeast⁴ and mammalian¹⁹ proteasomes, direct target engagement of proteasomes by the syrbactins in mammalian cells has not yet been shown. Accordingly, we decided to perform a deep profiling of cellular targets of **1** using a classical chemoproteomics approach. For this purpose, we synthesized probe **14**, an alkyne-tagged derivative of **1** (**Fig. 3**). RPMI 8226 lysates were treated with increasing concentrations of **14** for 1 h at r.t. and the probe-labeled proteins were then conjugated to TAMRA azide using copper(I)-catalyzed alkyne-azide cycloaddition (CuAAC)²⁰, separated by SDS-PAGE and visualized by in-gel fluorescence scanning (**Fig. S1A**). The gel profile revealed only a few bands, thus suggesting low proteomic promiscuity of **14**. To examine whether **14** can be used as a clickable analog of **1**, we performed a gel-based competitive profiling experiment. RPMI 8226 cells were treated *in situ* with

various concentrations of **1** for 6 h, lysed, and then treated with 10 μM **14** for 1 h, followed by TAMRA conjugation and protein visualization, as described above (**Figs. 3B, S1B**). Excitingly, only a few bands were successfully competed at nanomolar concentrations, suggesting high potency and selectivity of **1** towards its targets. To identify the targeted protein targets, we performed an *in situ* competitive LC-MS/MS-based experiment. Briefly, RPMI 8226 cells were treated with 100 nM **1** for 6 hours, lysed, then treated with 10 μM **14** followed by CuAAC-mediated conjugation of biotin azide, enrichment with streptavidin beads, trypsin digestion, and LC-MS/MS analysis. Out of 764 proteins enriched by **14**, only 5 were >50% competed by **1** (**Figs. 3C, 3D; Table S1**). Strikingly, all 5 identified targets were 20S proteasome subunits: PSMB5, PSMB10, PSMA5, PSMB1, and PSMB2. Such high selectivity is remarkable, especially considering that the structure of **1** contains two electrophilic α, β-unsaturated amides that could potentially engage hundreds of reactive cysteines.²¹

Quantification was performed using the WST-1 assay (relative values ± SD and EC₅₀s; *n* = 3). (B) Gel-based competitive *in situ* profiling of targets of **1**. RPMI 8226 cells were treated with various concentrations of **1** for 6 h, lysed, and treated with 10 μM **14**. (C) Log₂ LFQ ratios of proteins identified from the *in situ* competitive pull-down experiment with 100 nM **1** or DMSO and with 10 μM **14** (*n* = 6, three biologicals and two technicals each). (D) Cellular targets of **1** (>50% competition) in RPMI 8226 cells. Quantification was performed using the label-free quantification (LFQ) method (*n* = 6).

We chose to further validate the engagement of PSMB2 (Proteasome 20S Subunit β2) and PSMB5 (Proteasome 20S Subunit β5) by **1**, because their chemical co-inhibition has been

shown to be particularly cytotoxic in proteasome inhibitor-resistant MM cells and has therefore emerged as a promising therapeutic strategy.²² To confirm PSMB2 and PSMB5 as targets, both proteins were cloned as FLAG-tagged versions and overexpressed in HEK293T cells. PSMB2 and PSMB5-expressing cells were lysed and the lysates labeled with 30 μ M **14** for 1 h, followed by conjugation to TAMRA azide, separation by SDS-PAGE, and visualization of probe-bound proteins by *in-gel* fluorescence scanning (**Figs. 4A, S2**). A new labeled band was clearly seen in the overexpressed lane of both gels, indicating successful labeling of both overexpressed proteins, PSMB2-F and PSMB5-F. Having confirmed both proteins as targets of cezapafungin I, we successfully assigned the fluorescence bands in the gel profile of **14** to respective proteasome subunits as previously described^{18,23,24} and quantified the *in situ* IC₅₀ values of **1** for the endogenously expressed proteasome subunits, yielding IC₅₀s of 7.5 nM for PSMB5 and 35 nM for PSMB2 (**Figs. S3A, B**). Interestingly, these values only slightly deviate from previously reported IC₅₀s for inhibition of purified yeast proteasome subunits by **1** (PSMB5: 4 nM; PSMB2: 24 nM⁴). In order to gain more insight into the structure-activity relationship between **1** and PSMB5, we synthesized several derivatives of **1** (**Fig. 4**) and compared their ability to inhibit β 5 activity in RPMI 8226 cells. Cells were treated with various concentrations of compounds for 6 hours, then lysed and treated with the fluorogenic β 5 subunit-selective fluorogenic substrate Suc-LLVY-AMC.²⁵ Release of the 7-Amino-4-methylcoumarin (AMC) fluorophore via proteolytic cleavage by β 5 was followed over time and quantified to obtain IC₅₀ values (**Fig. 4B**). From all compounds tested, **1** most potently inhibited the β 5 subunit activity. In agreement with prior work,⁴ terminal methyl branching in **1** leads to a nearly fivefold increase in β 5 inhibitory activity compared to **2** (glidobactin A). The difference in potency between **15** (desoxycezapafungin) and **1**, over tenfold loss, is in agreement with a recently reported potency difference between **2** and its corresponding desoxy-macrocyclic variant luminmycin A.¹⁹ Additionally, **16** (saturated cezapafungin) demonstrated a fourteen-fold loss in potency compared to **1**. These results suggest that the secondary alcohol on the macrocycle and the 2,4-dienamide motif on the tail region of **1** are critical for the β 5 inhibitory activity.

Next, we sought to investigate if **1** mediates the expected biological downstream response similar to other proteasome inhibitors. One of the key cellular responses of proteasome inhibition is the accumulation of polyubiquitinated proteins, gradually leading to dysfunction and apoptosis.²⁶ Indeed, Western blot of lysates from **1**-treated RPMI 8226 cells using a mono-/poly-ubiquitin-conjugate specific antibody showed a concentration-dependent increase in ubiquitinated proteins (**Fig. 4C**). Next, we probed the same lysates by Western blot for Poly(ADP-Ribose) Polymerase (PARP-1) and observed PARP-1 cleavage in **1**-treated samples, indicating that **1** induced apoptotic cell death (**Fig. 4C**).²⁷ Finally, we performed a global proteomics experiment to identify proteins that accumulate or are upregulated in RPMI 8226 cells upon **1** treatment in comparison to the treatment with the clinical proteasome inhibitor drug bortezomib (BTZ). Cells were treated for 14 h with either **1** or BTZ at concentrations matching their corresponding EC₅₀ values at the 24 h timepoint (**Figs. 3A, S4**). Cells were lysed, proteins digested, and peptides analyzed by LC-MS/MS. Out of 3700 quantified proteins, 88 proteins were significantly upregulated (FDR 0.05; S₀ 0.01) in **1**-treated samples and 25 in BTZ-treated samples compared to

DMSO control samples (**Figs. 4D, S5; Table S4**). Indeed, 19 of 25 proteins upregulated in BTZ-treated samples, were also upregulated in proteomic samples from **1**-treated cells, thus confirming highly similar mode of action for these two compounds. Notably, 11 out of these 19 common targets have previously been reported to be upregulated upon proteasome inhibition in general (HERPUD1,²⁸ KIAA0101, RRM2,²⁹ CDC6,³⁰ CCNB1,³¹ NUSAP1,³² ORC1,³³ CYBA,³⁴ CKAP2,³⁵ KRT18,³⁶ TPX2³⁷) and 5 more targets (BAG3,³⁸ SRXN1, HMOX1, SQSMT1,³⁹ HSPA1A/B⁴⁰) specifically upon bortezomib treatment. Altogether, our data show that **1** is a potent and highly selective covalent inhibitor of the 20S proteasome that mediates downstream effects similar to the clinical drug BTZ in multiple myeloma cells.

Conclusion

By harnessing the ability of GlbB to hydroxylate L-lysine in a selective and efficient fashion, we have developed a concise chemoenzymatic synthesis of cepafungin I. Despite challenges in the late-stage macrocyclization and amide coupling steps, cepafungin I could be obtained in *ca.* 8% yield over 9 steps (longest linear sequence). The modularity of this route allowed the development of a chemoproteomic probe to interrogate the cellular targets of cepafungin I. Our chemoproteomics studies revealed that cepafungin I is able to covalently engage 20S proteasome subunits PSMB2 and PSMB5 with exceptional selectivity and that cepafungin I elicit many similar downstream biological responses to the clinically-approved proteasome inhibitor drug bortezomib. Contemporaneous to our efforts, Böttcher and co-workers reported the development of an activity-based probe by derivatization of syringolin A that was obtained from its native producer and showed the ability of the syrbactins to coinhibit PSMB2 and PSMB5 with high potency.¹⁹ Complementary to Böttcher's findings, our work provides the first proteome-wide identification of syrbactin protein targets in cancer cells and validation of their downstream biological effects via in-depth quantitative proteomics analyses. Moreover, the synthetic strategy developed herein enabled access to both natural and unnatural cepafungin analogs for initial structure-activity relationship studies. Especially notable in this regard is the observation that the macrocyclic secondary alcohol, as well as the degree of unsaturation and the terminal branching of the lipid tail, are critical for high inhibitory potency. Further medicinal chemistry exploration featuring the use of other hydroxylated amino acids⁴¹ and alternative lipid tails is ongoing in our laboratory.

General materials and methods

Unless otherwise noted, all chemicals and reagents for chemical reactions were purchased at the highest commercial quality and used without further purification. Reactions were monitored by thin layer chromatography (TLC) and liquid chromatography/mass spectrometry (LC/MS). TLC was performed with 0.25 mm E. Merck silica plates (60F-254) using short-wave UV light as the visualizing agent, and ninhydrin or KMnO₄ and heat as developing agents. Sonication was performed using a Qsonica Q500 sonicator. LC/MS was performed with an Agilent 1260 Infinity System equipped with Poroshell 120 EC-C18 column (3.0 x 50 mm, 2.7 μm). HRMS(ESI-TOF) was performed with an Agilent 1260 Infinity System equipped with Poroshell 120 EC-C18 column (4.6 x 5.0 mm, 2.7 μm) and an Agilent G6230B TOF LC/MS. Preparative HPLC was performed on an Agilent 1260 Infinity II system equipped with a Dr. Maisch Reprosil 100 C18 column (10 x 250 mm, 5 μm), or on an Agilent 1260 Infinity system equipped with a Varian Dynamax C18 column (21.4 x 250 mm, 10 μm). NMR spectra were recorded on a Bruker AVANCE AV400 (400 MHz and 100 MHz) or Bruker AVANCE AV600 (600 MHz and 151 MHz) and calibrated using residual non-deuterated solvent. Specific rotations were measured on Autopol IV polarimeter (Rudolph Research Analytical). DMEM/High glucose media (with L-Glutamine and sodium pyruvate), RPMI 1640 media (with L-Glutamine), phosphate buffered saline (PBS), MEM Non-Essential Amino Acids, Penicillin Streptomycin (Pen/Strep), opti-MEM and Trypsin-EDTA were obtained from Life Technologies. Protein concentration was determined using the Bradford assay (Bio-Rad). Expression plasmids for PSMB2-Myc-DDK and PSMB5-Myc-DDK were obtained from Origene. Plasmids were prepared using the QIAprep Spin Miniprep Kit (Qiagen). Primary antibodies were purchased from Cell Signaling Technology Inc. unless otherwise noted and secondary antibodies were acquired from Jackson ImmunoResearch Laboratories Inc.

Bacterial strain construction

pET-28a(+)::GlbB expression vector was obtained from Genscript as described previously.^{S1} *E. coli* BL21(DE3) harboring pET-28a(+)::GlbB and pGro7 was constructed by transforming electrocompetent *E. coli* BL21(DE3) with the appropriate plasmids.

Chemoenzymatic synthesis of cepafungin I

Enzymatic hydroxylation of L-lysine:

200 mL of TB media containing 25 µg/mL chloramphenicol and 50 µg/mL kanamycin was inoculated with 1 mL of an overnight culture of *E. coli* BL21(DE3) cells harboring pET-28a(+)::GlbB and pGro7. The culture was shaken at 250 rpm at 36 °C for approximately 2.5 hours or until an optical density of 0.6 was reached. The culture was then cooled on ice (20 minutes) and induced by adding IPTG and arabinose to a final concentration of 0.025 mM and 1 mg/mL, respectively. The culture was allowed to continue for another 20 hours at 23 °C and shaking at 250 rpm. Cells were harvested by centrifugation at 4200 rpm at 4 °C for 15 minutes, then resuspended in pH = 8 kPi buffer (150 mL) to an optical density of 25. The cells were lysed by sonication for 3 minutes (1 second on, 4 seconds off) at 0 °C and 50% amplitude. Cell debris was pelleted by centrifugation and the supernatant was diluted to 250 mL with pH = 8 kPi buffer into a 1L Erlenmeyer flask containing L-lysine (1.46 g, 10 mmol, 1 eq, 40 mM final concentration), α-ketoglutaric acid (2.83 g, 12.5 mmol, 1.25 eq, 50 mM final concentration), ascorbic acid (440 mg, 2.5 mmol, 0.25 eq, 10 mM final concentration) and FeSO₄•7H₂O (139 mg, 0.5 mmol, 0.05 eq, 2 mM final concentration). The mixture was shaken at 200 rpm at 23 °C overnight or until completion as judged by LC-MS.

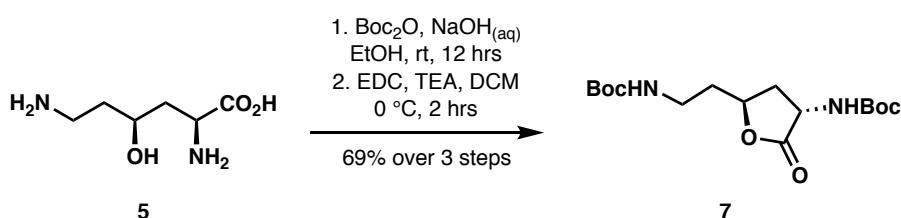

The reaction mixture was then acidified to pH = 2 with concentrated HCl and centrifugated at 4200 rpm at 4 °C for 15 minutes. The supernatant containing crude 4-hydroxylysine **5** was carried forward to the next step without further purification. For characterization purposes, the crude product was purified by ion exchange chromatography with Dowex 50WX8 resin.

Boc protection and lactonization of crude 4-hydroxyllysine 5:

The above supernatant was concentrated to ~33 mL then basified to pH 11 with 2 M NaOH. Boc₂O (8.73 g, 40 mmol, 4 eq) in 17 mL ethanol was added and the mixture was allowed to stir at room temperature. The mixture was re-basified to pH 11 after 3.5 hours and allowed to continue stirring overnight or until completion as indicated by LC-MS. Ethanol was removed *in vacuo* and the mixture was diluted with 50 mL ethyl acetate. The pH of the mixture was adjusted to 2 with 6 M HCl and the aqueous layer was separated and further extracted with ethyl acetate (3 x 50 mL). The combined organic layers were washed with brine, dried over Na₂SO₄ and concentrated *in vacuo* to provide 4.29 g crude di-Boc-4-hydroxylysine that was used without further purification.

The crude Boc-protected hydroxylysine (4.29 g) was dissolved in 50 mL anhydrous DCM, cooled to 0 °C, then treated with EDC•HCl (1.92 g, 10 mmol, 1 eq) followed by triethylamine (1.39 mL, 10 mmol, 1 eq). The reaction was stirred under argon at 0 °C for 2 hours or until completion as indicated by TLC. The reaction was concentrated to dryness. The resulting residue was dissolved in 100 mL ethyl acetate and washed with water (3 x 20 mL) and brine, then dried over Na₂SO₄. Purification by silica flash chromatography (step gradient 35-40-50% ethyl acetate in hexanes) provided pure lactone **7** (2.39 g, 69%).

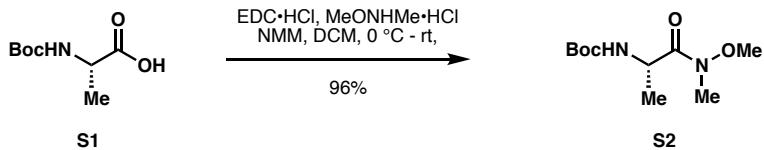

Note: the above 3-step sequence can be scaled up to 6.90 grams of L-lysine (47.2 mmol) to provide 9.53 grams of lactone **7** (59% yield).

Synthesis of dipeptide 9:

Amine hydrochloride **8** (5.71 g, 33.9 mmol, 5 eq) was set stirring (undissolved) in 85 mL anhydrous THF. The mixture was cooled to -20 °C, then a 2 M solution of trimethylaluminum in anhydrous toluene was added dropwise (16.8 mL, 4.95 eq). *Synthesis of branched alcohol **S7**:*

Following a procedure adapted from Melaugh et al.,^{S2} lithium chloride (6.66 g, 157 mmol, 2.05 eq) was flame-dried in a 250 mL round-bottom flask under high vacuum. Solid copper(II) chloride (10.3 g, 76.6 mmol, 1 eq) was added under argon. The combined reagents were then dissolved in 105 mL anhydrous THF to provide a dark red solution of Li_2CuCl_4 .

A flame-dried 3-neck 1L flask fitted with a reflux condenser was charged with magnesium turnings (12.9 g, 531 mmol, 1.18 eq with respect to 2-bromopropane) and 200 mL anhydrous THF. With rapid stirring, 2-bromopropane (42.3 mL, 451 mmol, 6.5 eq with respect to **15**) was added dropwise until refluxing began, at which point the flask was lowered into a water bath. Upon complete addition, the water bath was removed and the reaction was allowed to stir under argon for 30 minutes to produce a dark gray suspension of **S5**. The mixture was cooled to -78°C , and bromoalcohol **S6** (12.6 g, 69.6 mmol, 1 eq) was added in 10 mL dry THF, followed by the above solution of Li_2CuCl_4 (~ 0.7 M in THF, 105 mL, 1.1 eq with respect to **S6**). Upon complete addition, the reaction was removed from its cooling bath and allowed to warm to room temperature. Reaction progress was monitored by TLC until completion at 1 hour. The reaction was then carefully quenched at 0°C with 50 mL saturated NH_4Cl solution, filtered through a sintered glass funnel, and the filtrate was concentrated *in vacuo* to remove most of the THF. The mixture was diluted with 100 mL ethyl acetate and 100 mL water. The layers were separated, and the aqueous phase was extracted with ethyl acetate (3 x 200 mL). The combined organic layers were washed with 50 mL each of saturated aqueous NaHCO_3 and brine, then dried over Na_2SO_4 . Purification by silica flash chromatography (90:10 hexanes:ethyl acetate) provided pure **16** as a colorless liquid (8.38 g, 84%).

Synthesis of branched alcohol S28:

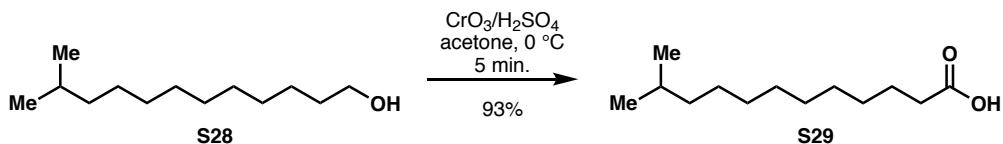

Following a procedure adapted from Melaugh et al.,² lithium chloride (1.61 g, 42.4 mmol, 2.05 eq) was flame-dried in a 250 mL round-bottom flask under high vacuum. Solid copper(II) chloride (2.50 g, 18.6 mmol, 1 eq) was added under argon. The combined reagents were then dissolved in 25 mL anhydrous THF to provide a dark red solution of Li_2CuCl_4 .

A flame-dried 3-neck 500 mL flask fitted with a reflux condenser was charged with magnesium turnings (3.14 g, 129 mmol, 1.18 eq with respect to 2-bromopropane) and 50 mL anhydrous THF. With rapid stirring, 2-bromopropane (10.3 mL, 110 mmol, 6.5 eq with respect to S27) was added dropwise until refluxing began, at which point the flask was lowered into a water bath. Upon complete addition, the water bath was removed and the reaction was allowed to stir under argon for 30 minutes to produce a dark gray suspension of S5. The mixture was cooled to -78 °C, and bromoalcohol S27 (4.00 g, 16.9 mmol, 1 eq) was added in 4.2 mL dry THF, followed by the above solution of Li_2CuCl_4 (1.5 M in THF, 25.4 mL, 1.1 eq with respect to S27). Upon complete addition, the reaction was removed from its cooling bath and allowed to warm to room temperature. Reaction progress was monitored by TLC until completion at 1 hour. The reaction was then carefully quenched at 0 °C with 50 mL saturated NH_4Cl solution, filtered through a sintered glass funnel, and the filtrate concentrated *in vacuo* to remove most of the THF. The mixture was diluted with 100 mL ethyl acetate and 100 mL 1M HCl. The layers were separated, and the aqueous phase was extracted with ethyl acetate (3 x 50 mL). The combined organic layers were washed with 50 mL each of water, saturated aqueous NaHCO_3 and brine, then dried over Na_2SO_4 . Purification by silica flash chromatography (90:10 hexanes:ethyl acetate) provided pure S28 as a colorless liquid (3.22 g, 95%).

Chemoproteomics Experimental Procedures

Cell culture and lysate preparation

RPMI 8226 and MM1.R cells were maintained in RPMI-1640 media. HEK293T cells were maintained in DMEM. All media were supplemented with 10% fetal calf serum (FCS), non-essential amino acids and penicillin/streptomycin. Cells were grown at 37 °C under 5% CO₂ atmosphere. Cells were allowed to grow to confluence, harvested by pipeting, then washed 2 times in PBS by brief centrifugation at 300 x g at 4 °C and resuspended in PBS. Cells were lysed by needle sonication to obtain cell lysates and protein concentration was determined using the Bradford assay.

Cell toxicity assays

RPMI 8226 (20,000 cells/well) or MM1.R (20,000 cells/well) cells were seeded in a 96-well plate in cell culture media supplemented with indicated concentrations of either **1** or bortezomib (BTZ) (1,000x stock in DMSO) and cultured for either 24 or 48 hours. Toxicity was determined using the WST-1 assay (Roche) according to the protocol of the manufacturer. EC₅₀ values were calculated with GraphPad Prism (V7.02).

Preparation of proteomes for SDS-PAGE activity-based probe profiling experiments

Proteins in full cell lysate (2 mg/mL, 25 μL) were treated with indicated concentrations of **14** (1 μL of 25x stock in DMSO) or DMSO for one hour at r.t. Click chemistry was then initiated by the addition of TAMRA alkyne (Click Chemistry Tools, 25x stock in DMSO), tris(2-carboxyethyl)phosphine hydrochloride (TCEP, Alfa Aesar, 1 mM, fresh 50x stock in water), tris[(1-benzyl-1*H*-1,2,3-triazol-4-yl)methyl]amine (TBTA, Sigma-Aldrich, 100 μM, 16x stock in DMSO:*t*BuOH 1:4), and copper(II) sulfate (1 mM, 50x stock in water) to the lysate and incubated in the dark for one hour at r.t. SDS-PAGE reducing loading buffer (4x) was added and proteins were separated using an 11% SDS-PAGE gel. Gels were visualized using a Sapphire Biomolecular Imager (Azure Biosystems), then stained using Coomassie Brilliant Blue (CBB). Images were quantified with ImageJ.

Gel-based in situ competitive experiments

RPMI 8226 cells were seeded in a 6-well plate (1,000,000 cells/well) in cell culture media supplemented with indicated concentrations of **1** (1'000x stock in DMSO) or DMSO and cultured for 6 hours. Cells were then collected and lysed as described above. Lysates (2 mg/mL, 25 µL) were treated with **14** (10 µM; 1 µL of 25x stock in DMSO) for one hour at r.t. Click chemistry, reducing SDS-PAGE and visualization were performed as described above.

In situ competitive 14 pulldown experiment for mass spectrometry

RPMI 8226 cells were seeded in 14 cm Petri dishes and cultured as previously described until they reached confluence. Cell culture media was then removed and the cells were incubated in fresh media with either **1** (100 nM; 25 µL of 1000x stock in DMSO) or DMSO for 6 hours. Cells were washed two times with PBS and harvested by centrifugation, resuspended in PBS and lysed as described above. The protein concentration of the lysate was determined using the Bradford assay. Lysates (2.32 mg/mL, 645 µL) were treated with **14** (10 µM; 6.51 µL of 100x stock in DMSO) for one hour at r.t. and subjected to click chemistry using biotin azide (30 µM, 50x stock in DMSO), tris(2-carboxyethyl)phosphine hydrochloride (TCEP) (1 mM, 50x fresh stock in water), tris[(1-benzyl-1H-1,2,3-triazol-4-yl)methyl]amine (TBTA) (100 µM, 16x stock in DMSO:tBuOH 1:4), and copper(II) sulfate (1 mM, 50x stock in water) for one hour at r.t. Protein was precipitated by adding methanol/chloroform/water (4:1:3 v/v) to the reaction mixture and the turbid mixture was centrifuged for five minutes at 14,000 x g at 4 °C yielding a protein layer between the aqueous and organic layers. The protein layer was isolated, dried and solubilized in 2 % SDS in PBS via sonication. The proteome was centrifuged at 4,700 x g for five minutes and the supernatant was transferred to a new tube. PBS was added to give a final SDS concentration of 0.2 %. Streptavidin agarose beads (150 µL, ProteoChem) were added and the mixture was rotated overnight at r.t. Beads were washed with 1 % SDS in PBS (1x 10 mL), PBS (3x 10 mL), and water (3x 10 mL). Beads were resuspended in 6 M urea in PBS (500 µL), reduced with 10 mM neutralized TCEP (200 mM fresh stock in water) for 30 minutes at r.t. and alkylated with 25 mM iodoacetamide (400 mM fresh stock in water) for 30 minutes at r.t. in the dark. Beads were pelleted by centrifugation (1'400 x g, 2 minutes) and resuspended in 150 µL of 2 M urea in 50 mM NH₄HCO₃, 1 mM CaCl₂ (100x stock in water) and trypsin (Thermo Scientific, 1.5 µL of 0.5 µg/µL). The digestion was performed for 12 hours at 37 °C. Samples were acidified to a final concentration of 5 % acetic

acid, desalted over a self-packed C18 spin column and dried. Samples were analyzed by LC-MS/MS (described below) and the MS data was processed with MaxQuant (described below).

LC-MS/MS analysis

Peptides were resuspended in water with 0.1 % formic acid (FA) and analyzed using EASY-nLC 1200 nano-UHPLC coupled to a Q Exactive HF-X Quadrupole-Orbitrap mass spectrometer (Thermo Scientific). The chromatography column consisted of a 50 cm long, 75 µm i.d. microcapillary capped by a 5 µm tip and packed with ReproSil-Pur 120 C18-AQ 2.4 µm beads (Dr. Maisch GmbH). LC solvents were 0.1 % FA in H₂O (Buffer A) and 0.1 % FA in 90 % MeCN: 10 % H₂O (Buffer B). Peptides were eluted into the MS at a flow rate of 300 nL/min. over a 240 min. linear gradient (5-35 % Buffer B) at 65 °C. Data was acquired in data-dependent mode (top-20, NCE 28, R = 7,500) after full MS scan (R = 60,000, m/z 400-1,300). Dynamic exclusion was set to 10 s, peptide match to prefer and isotope exclusion was enabled.

MaxQuant analysis

The MS data was analyzed with MaxQuant^{S6} (V1.6.1.0) and searched against the human proteome (Uniprot) and a common list of contaminants (included in MaxQuant). The first peptide search tolerance was set at 20 ppm, 10 ppm was used for the main peptide search and fragment mass tolerance was set to 0.02 Da. The false discovery rate for peptides, proteins and sites identification was set to 1%. The minimum peptide length was set to 6 amino acids and peptide re-quantification and label-free quantification (MaxLFQ) were enabled. The ‘match between runs’ function was activated for the global changes in protein expression experiment. The minimal number of peptides per protein was set to two. Methionine oxidation was searched as a variable modification and carbamidomethylation of cysteines was searched as a fixed modification.

Transfection and Western blot

HEK293T cells were seeded (6,000,000 cells in 20 mL DMEM 10% FCS without Pen/Strep) in a 10 cm Petri dish and left overnight to attach. Cells were transfected using a mixture of 96 µg PEI MAX 40000 (Polysciences Inc.) and 24 µg DNA in 2 mL opti-MEM. After 24 hours, cells were harvested by scraping, washed two times with PBS and lysates were prepared and treated with 30 µM **14** as described above. Click chemistry, reducing SDS-PAGE and visualization were performed as described above. Proteins were transferred to a PVDF membrane using a Trans-Blot Turbo transfer system (Bio-Rad). Membrane was blocked with 5% milk in Tris-Buffered Saline

with 0.1 % Tween 20 (TBST) for one hour. Rabbit polyclonal antibody against DYKDDDDK (FLAG) (CST, #2368S, 1/1,000 in 5% milk in TBST) and α -tubulin (CST, #2144S, 1/1,000 in 5% milk in TBST) were added and incubated overnight at 4 °C. Membrane was washed three times for five minutes with TBST and incubated with Alexa Fluor 647-AffiniPure Donkey Anti-Rabbit IgG (H+L) (Jackson ImmunoResearch Inc., 711-605-152, 1/500 in 5 % milk in TBST) for one hour at r.t. Membrane was washed four times for five minutes with TBST and visualized with a Sapphire Biomolecular Imager (Azure Biosystems).

RPMI 8226 cells were seeded in a 6-well plate (1,000,000 cells/well) in cell culture media supplemented with indicated concentrations of **1**, **2**, **15** or **16** (1,000x stock in DMSO) or DMSO and cultured for 6 hours. Cells were then collected and lysed as described above. Lysates (1 mg/mL, 25 μ L) were dispensed into 100 μ L assay buffer (PBS (pH 7.4), MgCl₂ (1.5 mM), EDTA (1 mM), EGTA (1 mM), sucrose (250 mM) and freshly added DTT (5 mM), ATP (2 mM) and proteasome substrate Suc-LLVY-AMC (Enzo Life Sciences, 100 μ M, 1 μ L of 100x stock in DMSO)) in the wells of a black / clear bottom 96-well plate. The plate was incubated at 37 °C for two hours and fluorescence was read at A_{360ex}/A_{460em} using a Synergy H1 hybrid multi-mode microplate reader (Biotek). The protocol was modified from reference S7. IC₅₀ values were calculated with GraphPad Prism (V7.02).

Western Blot for mono- / polyubiquitinated conjugates and PARP-1

RPMI 8226 cells were seeded in a 6-well plate (1,000,000 cells/well) in cell culture media supplemented with indicated concentrations of **1** (1,000x stock in DMSO) or DMSO and cultured for 6 hours. Cells were then quickly washed twice in PBS and lysed using RIPA buffer (20 mM Tris, 150 mM NaCl, 2 mM EDTA, 0.1 % SDS, 1 % NP-40, 0.25 % deoxycholate, 1 mM PMSF) plus protease inhibitor cocktail (100x, RPI Corp., Cat.No. P50700-1) for five minutes on ice. Cells were quickly sonicated using a needle sonicator, the lysate was spun down in a tabletop centrifuge at 17000 x g for 10 minutes at 4 °C and the cleared lysate was transferred into a new microtube. Protein concentration was measured using the BCA protein assay (Thermo Fisher, Cat No. 23225). SDS-PAGE was performed as previously described and wet transfer to a PVDF membrane was done at 350 mA for one hour. Membrane was blocked with 5 % milk in TBST for one hour. Primary antibodies against respective proteins: PARP-1 (CST, #9532, 1:1,000 in 5 % BSA in TBST), mono- / polyubiquitinated conjugate antibody (Enzo Life Sciences, Prod. No. BML-

PW8805, 1:500 in 5 % milk in TBST), and α -tubulin antibody (CST, #2144S, 1:1,000 in 5 % milk in TBST)), were added and incubated overnight at 4 °C. Membrane was washed three times for five minutes with TBST and incubated for one hour at r.t. with Alexa Fluor 647-AffiniPure Donkey Anti-Rabbit IgG (Jackson ImmunoResearch Inc., 711-605-152) or Alexa Fluor 488-AffiniPure Donkey Anti-Mouse IgG (Jackson ImmunoResearch Inc., 715-545-150). Membrane was washed four times for five minutes with TBST and visualized with a Sapphire Biomolecular Imager (Azure Biosystems).

Global proteomic profiling of cells treated with 1 or bortezomib using Mass Spectrometry.

RPMI 8226 cells were seeded in a 6-well plate (1,000,000 cells/well) in cell culture media supplemented with **1** (100 nM, 1,000x stock in DMSO), bortezomib (BTZ, 2.5 nM, 1,000x stock in DMSO) or DMSO and cultured for 6 hours. Cells were then collected and lysed in PBS as described earlier and protein concentration was measured using the Bradford assay. Proteins (30 μ g) were then denatured in 6 M urea in 50 mM NH₄HCO₃, reduced with 10 mM tris(2-carboxyethyl)phosphine hydrochloride (TCEP) for 30 minutes and alkylated with 25 mM iodoacetamide for 30 minutes in the dark. Samples were diluted to 2 M urea with 50 mM NH₄HCO₃, and digested with trypsin (Thermo Scientific, 1.5 μ L of 0.5 μ g/ μ L) in the presence of 1 mM CaCl₂ (100 \times stock in water). The digestion was performed for 12 hours at 37 °C. Samples were acidified to a final concentration of 5% acetic acid, desalted over a self-packed C18 spin column, and dried. Samples were analyzed by LC-MS/MS (see above), and the MS data were processed with MaxQuant (see above).

Supplemental figures

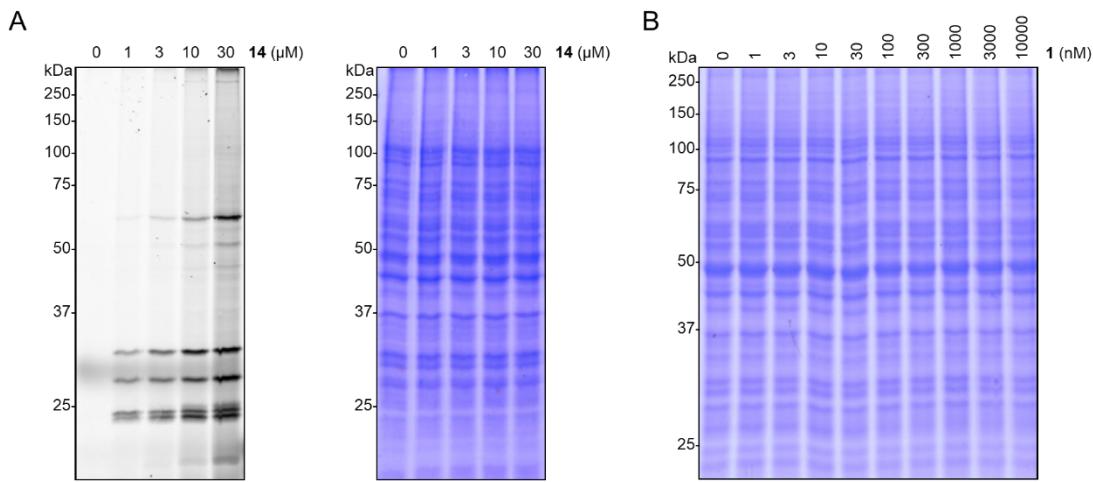

Figure S1. Probe **14** and compound **1** label proteins in a concentration-dependent manner. (A) Concentration-dependent labeling of RPMI 8226 lysates with the alkyne probe **14**. TAMRA fluorescence profile of **14** is shown on the left and the corresponding Coomassie stained gel is shown on the right. (B) Coomassie stained gel corresponding to the gel presented in Figure 3B.

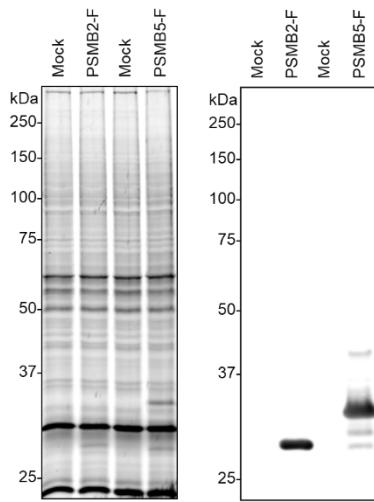

Figure S2. Labeling of mock and overexpressed PSMB2-F and PSMB5-F in HEK293T lysate with 30 μ M **14**. Full length **14** labeling fluorescence profile is shown on the left and the corresponding Western blotting profile of the same gel probed for FLAG is shown on the right. Full profiles were cropped and shown in Figure 4A.

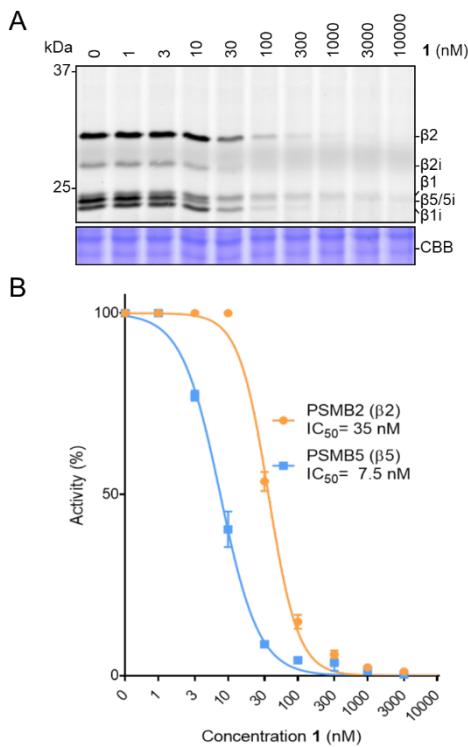

Figure S3. Measurement of *in situ* **1** IC₅₀ values for PSMB2 and PSMB5 using a competitive gel fluorescence assay. (A) Gel-based competitive *in situ* profiling of **1** targets. RPMI 8226 cells were treated with various concentrations of **1** for 6 h, lysed and treated with 10 μM **14**, followed by ‘click conjugation’ to TAMRA. Proteasome subunit band assignment was performed as previously described.^{S8} CBB staining profile is included to verify equal loading. (B) **1** IC₅₀ curves were obtained via quantification of the gel-based activity assay shown in (A).

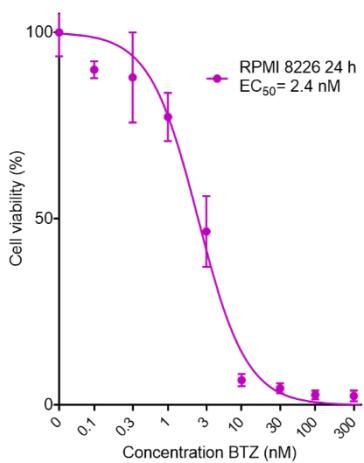

Figure S4. Cytotoxicity curve of RPMI 8226 cells treated with indicated concentrations of BTZ for 24 hours. Quantification was performed using the WST-1 assay (relative values \pm SD and EC₅₀s; $n = 3$).

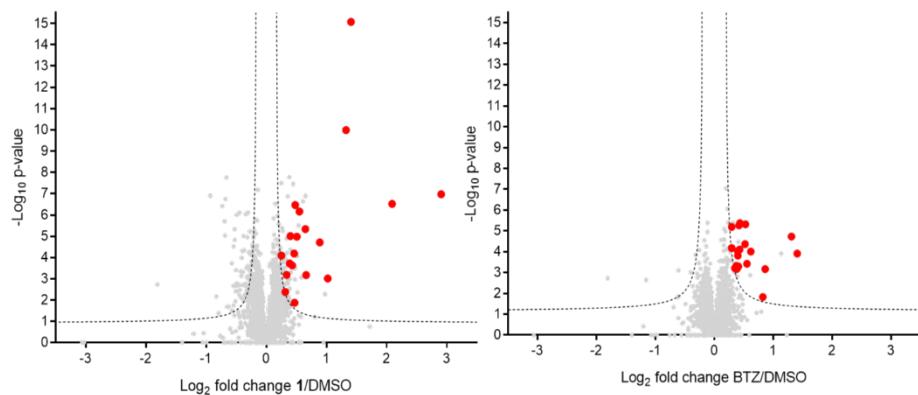

Figure S5. Volcano plots representing the global proteome profile of RPMI 8226 cells treated with 100 nM **1** vs DMSO or 2.5 nM BTZ versus DMSO. Data are represented as log₂ fold change; dotted lines represent a false discovery rate of 5% and an S₀ of 0.01, indicating an adjusted p-value of 0.05. Colored dots represent proteins (19 in total) with significantly increased expression levels in response to treatment with both **1** and BTZ.
