Abstract

Saint Katherine protectorate is one of the most floristically diverse spots in the Middle East. A field surveys, as well as critical revision of herbarium specimens, were carried out during 2013-2020 revealed that 430 taxa belonging to 283 genera and 62 families. The life-forms are classified into seven life forms with dominance of Therophytes (39%) followed by Chamaephyte (24.7%). Chorological study indicated that 52% of recorded taxa were mono-regional native to Saharo–Arabian (29%), Irano–Turanian (10.39%), Mediterranean (7.4%), Sudanin (4%) while tropical and sub- tropical represented by (0.2%) only. 223 taxa were mono-regional, 127 taxa were bi-regional, while 16 taxa were endemic and Steno-endemic. Investigated taxa distributed in four microhabitats; terraces, slopes, gorges, and wadi bed the last two were the most diversity. The present study investigated that presence of *Papaver somniferum* is a new record to flora of Egypt, eight new records to Sinai and thirty four new records to the study area.

Keywords: Chorology, life forms, new record, Saint Katherine Protectorate

Introduction

Floristic composition is a reflection of plant diversity of a geographic region (Rafay et al. 2013); a floristic inventory is the main source of botanical information and provides an appropriate starting point for supplementary comprehensive studies of a specific geographic area (Keith 1988). Plant life form as the growth form that represents an adaptation to specific environmental conditions (Galán de Mera et al. 1999) can reflect the climatic adaptability and then the whole vegetation in a particular ecosystem would be an expression of the prevailing climate (Batalha et al., 2002).

Sinai Peninsula is the meeting place of the old world (Grainger 2003), it occupies 6.1% of the surface of Egypt; it is rich both in the number of species and the high

percentage of endemics as it hosts 1262 taxa (Boulos 2009). According to (Zahran and Willis 2009) Sinai Peninsula stands in four phytogeographical regions: Mediterranean, Irano-Turanian, Sudano-Decanian and Saharo – Arabian. The majority of Sinai belongs to the Sahara-Arabian phytogeographical region. Its vegetation is characterized by sparseness vegetation; while the high mountains of southern Sinai support mainly Irano-Turanian vegetation. (Danin Avinoan 1986).

Saint Katherine Protectorate (SKP) (sometimes spelled as Saint Catherine protectorate) spreads over virtually the entire mountain massif of South Sinai, with an area of about 4350 km². and lies between 33° 55' to 34° 30'E and 28° 30' to 28° 35'N

with an elevation up to 2641 m above sea level (asl); it lies in a Saharan-Mediterranean climate with extremely dry, hot summers and cold winters; average rainfall is 60 mm / year, It is the coolest area in Egypt. Mean maximum temperature in August is 36° while winters are relatively cool with mean minimum temperature of -7.8° in February (Grainger 2003). SKP is one of the most floristically diverse spots in the Middle East (Boulos 2009) with a significant proportion of endemic species as it hosts 17 endemic taxa (Ghaly 2015) out of them 6 are endangered and /or critically endangered; the majority of SKP endemic taxa classified as steno-endemic (Ghaly 2015; Hosni *et al.* 2013) The diversity of both landforms and geologic structures of SKP leads to the differentiation of a six microhabitats namely; farsh (Basine), caves, terraces, slopes, wadis and gorges the last two microhabitats have dykes that trap water resulting in significant plant cover (Khedr 2007).

According to (Fayed *et al.* 2004) and (Shaltout *et al.* 2004) the total number of taxa in Saint Katherine protectorate is 472, belonging to 272 genera and 64 families, (Fayed *et al.* 2010) carried out Partial Survey in SKP; and listed 134 species belonging to 117 genera and representing 38 families. Since this date there is no partial or whole survey throughout SKP even if there are many climatic changes, human impacts and threats (Omar *et al.* 2015).

The authors aim to (1) carrying out field survey in an area where few floristic studies had been done before, (2) documented chorological affinities and life spans (3) confirmation the presence of *Papaver somniferum* L. as a new record in flora of Egypt, (4) reporting 8 new taxa to Sinai, and 34 new taxa to SKP.

Material and methods

An inventory of all available specimens was compiled based on field surveys that carried out in Saint Katherine Protectorate, South Sinai, Egypt during 2013-2020 as well as critical revision of herbarium specimens hosted in SKP herbarium, collected taxa were identified according to (Feinbrun-Dothan 1986, 1978; Täckholm 1974; Zohary, 1973, 1966; Boulos, 2005, 2002, 2000, 1999). Taxa names were reconciled against Kew's Plants of the World Online (POWO 2021) which was also used as reference for families and genera classification. For the few species that were not found in POWO the authors followed (GBIF 2021).

Voucher specimens were kept at Saint Katherine Protectorate Herbarium (SKPH) without identification numbers. **Life forms** were followed (Raunkiaer, 1934), when several life forms were given for a taxon, the most representative one was chosen; variation in the life form in the field was not considered, **phytogeographical affinity**, the general approach and terminology of (Zohary 1973) for the Saharo-Arabian and Sudanian regions, each species Phytogeographical affinity was obtained from (Abd El-Ghani 1985, 1981); when these resources for a single taxon gave more than one phytogeographical element, the most appropriate was used, **vegetation type and floristic division** according to (Boulos 2005, 2002, 2000, 1999). The specimens were first checked in (Boulos 2005, 2002, 2000, 1999; Fayed *et al.* 2004; Moustafa *et al.* 1998; Shaltout *et al.* 2004; Täckholm 1974) ,for their presence in Egypt, Sinai and SKP, **rarity and endemism** based on IUCN red list 2018 <https://www.iucnredlist.org>, (Omar *et al.* 2015; Walter and Harriet 1997).

Floristic study of Saint Katherine protectorate, Sinai

Density, frequency, and different diversity indices calculation

Shannon index was calculated using the formula $H' = - \sum P_i \ln P_i$ (Pielou 1975). The relative concentration of dominance within each plot was assessed by the **Simpson diversity index** $D=1- \sum n_i (n_i-1)/N(N-1)$. **Species richness** was calculated as the average number of species/ sampling plot. **Density of species (i)** is calculated as the total number of individuals of species (i) in all sampled plots/ area of sampled plots. **Frequency** is the number of times a plant species occurs in a given number of quadrats. **One-way ANOVA** was performed to calculate the significance of differences in diversity indices, both average density and frequency between different quadrates that

varied in different microhabitats using SPSS software version 22.

Results and discussion

Floristic composition

Despite its small area, SKP region has high floristic richness as it hosts approximately 23% of Egyptian flora (Fayed et al. 2004; Shaltout et al. 2004) and 28% of Egyptian endemic taxa (Ghaly 2015), a total of 430 taxa including 27 infraspecific from the study area were identified; belonging to 283 genera and 62 families(see Appendix 1) of these *Papaver somniferum* is a new record to flora of Egypt , eight taxa are new records to Sinai and thirty four are new records to Saint Katherine Protectorate in addition to sixteen endemic taxa (table 1) .

<i>Pallenis spinosa</i> (L.) Cass.	Asteraceae	New record to SKP
<i>Papaver somniferum</i> L.	Papaveraceae	New record to Egypt, Sinai & SKP
<i>Piptatherum holciforme</i> (M. Bieb.) Roem. & Schult.	Poaceae	New record to SKP
<i>Spergularia marina</i> (L.) Griseb.	Caryophyllaceae	New record to SKP
<i>Stellaria media</i> (L.) Vill.	Caryophyllaceae	New record to SKP
<i>Tribulus pentandrus</i> Forssk.	Zygophyllaceae	New record to SKP
<i>Tricholaena teneriffae</i> (L. f.) Link.	Poaceae	New record to SKP
<i>Vicia articulata</i> Hornem	Fabaceae	New record to Sinai & SKP
<i>Withania somnifera</i> (L.) Dunal	Solanaceae	New record to SKP
<i>Ziziphora tenuior</i> L.	Lamiaceae	New record to SKP

The surveyed flora represented by Angiospermae (Dicotyledoneae 363 taxa, and Monocotyledoneae 61 taxa) while Gymnospermae and Pteridophyta represented by three species for each. More than 60% of the recorded taxa belong to

only 10 species rich families. The largest families were Asteraceae, Poaceae and Fabaceae while nine families were represented by two species, and the remaining twenty-three families were represented by one species only (Fig 1).

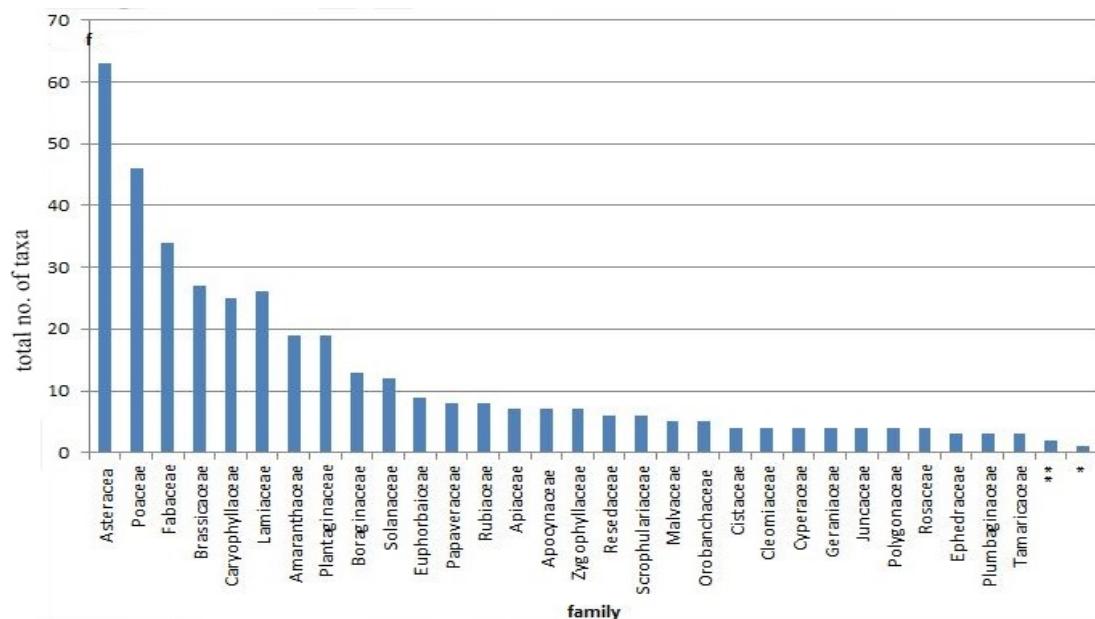

Fig (1) Representative number of taxa of the recorded families; * = 23 families represented by one taxon, and ** = 9 families represented by two taxa.

Floristic study of Saint Katherine protectorate, Sinai

Investigated taxa classified into herbaceous plants (301 taxa); shrubs (92 taxa); sub Shrubs (16 taxa), trees (12 taxa), Climber (5 taxa), reeds and Herb/ Subshrub represented by 2 taxa for each (Fig 2), the

dominance of herbaceous taxa over the other growth habits can be recognized to their short life cycle that enables them to resist the instability of the harsh environmental condition (Gomaa 2012) .

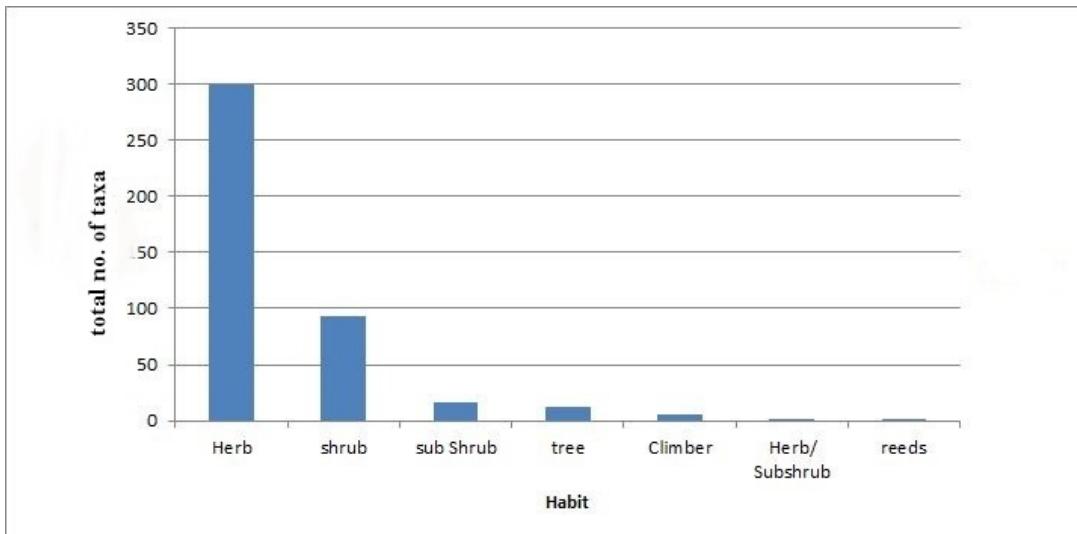

Fig (2) Number of taxa in relation to their habit

Life spans and Life forms

Investigated taxa classified into six groups dominant by Perennial (234 taxa), annual (173 taxa), annual / short perennial (13 taxa), annual/ biennial and biennial

represented by four taxa for each and biennial/ perennial represented only by one taxon (Fig 3).

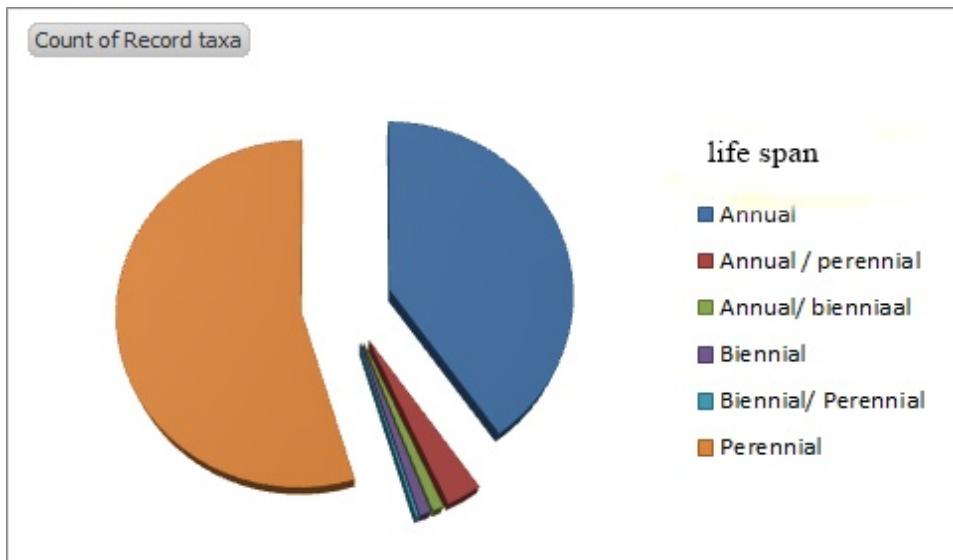

Fig (3) life span of the recorded taxa

Life forms spectrum is characteristic of an arid ecosystem with the dominance of therophytes (171) followed by chamaephyte (106 taxa), hemicryptophyte (102 taxa), phanerophyte (34 taxa), geophyte (11 taxa), parasite (4 taxa) and helophyte represented only by two species (Fig 4), with agreement with previous studies e.g (Elgamal 2020; Moustafa and Zaghloul 1996) Life-form

spectrum in our result is typical of an arid desert region with the dominance of therophytes and this support the concept of (Cain 1950; Deschenes 1969) that arid conditions and overgrazing are so prevalent on grasslands tend to increase therophytes percentage through the introduction and spread of weedy grasses and forbs of this life form.

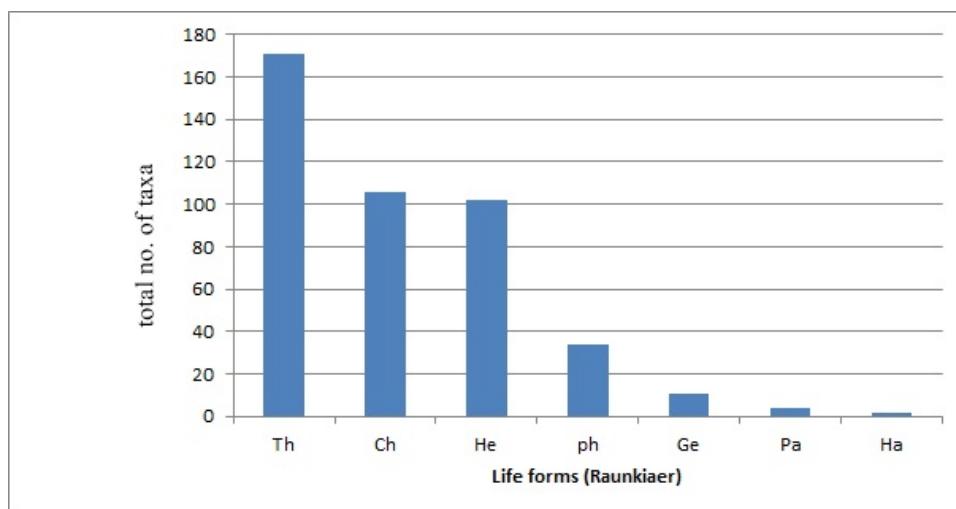

Fig (4) Life forms of the recorded taxa, He = Hemicryptophyte, Ch = chamaephyte, Th = Therophytes, Ph = Phaneroohyte, Ge = Geophyte, Pa = Parasite and Ha = Helophyte.

Phytogeographical affinities

Surveyed taxa related to 6 phytogeographical regions thus the Mediterranean region, Saharo – Arabian, Irano-Turanian, Sudano – Deccanian, Tropical and sub-tropic region. The analysis of surveyed flora chorology revealed that 52% taxa were monoregional native to Saharo – Arabian (29%), Irano- Turanian

(10.39%), Mediterranean (7.39%), Sudanin (4%) while tropical and sub- tropical represented by (0.2%) only. 127 taxa were bi-regional, 63 taxa were recognized in more than two phytogeographical regions and/ or pluri- regional while 16 were endemic and Steno-endemic (Fig 5).

Floristic study of Saint Katherine protectorate, Sinai

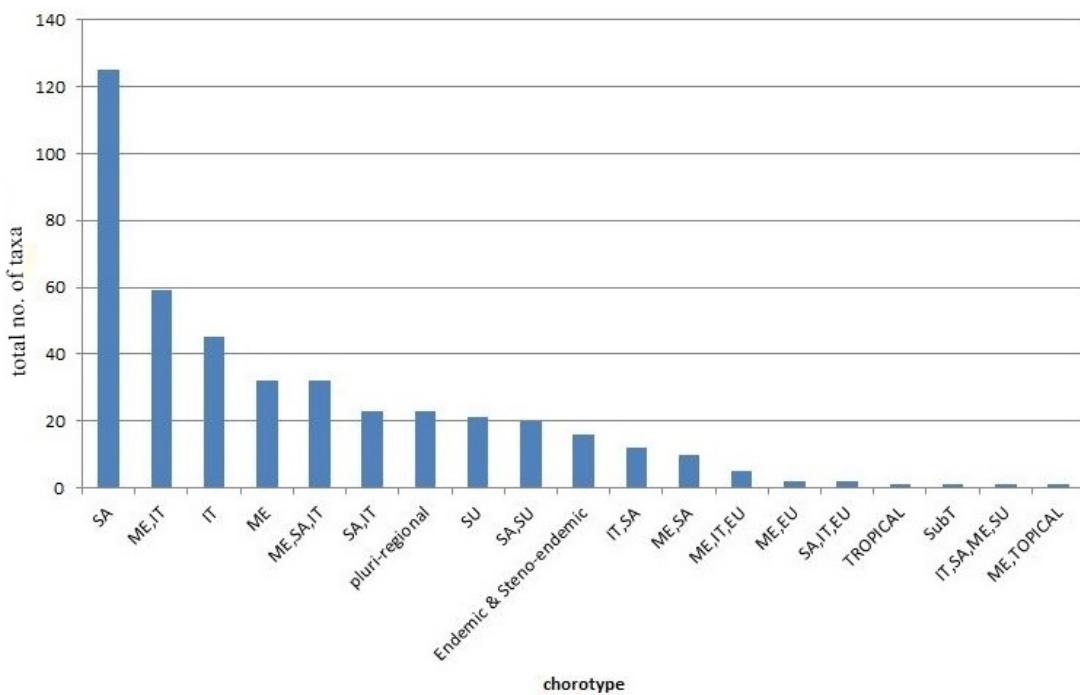

Fig (5) Chorological analysis of the recorded taxa ME = Mediterranean, IT = Irano- turanian, SA = Saharo – Arabian, SU = Sudanin, and Sub T = sub trobic

Concerning the relation between geoelements and life forms (Table 2), chamaephytes followed by therophyte; hemicryptophytes and phanerophytes make an important contribution to the Saharo–Arabian and Irano-Turanian phytogeographical regions, while halophytes and parasites were completely absent. Phanerophyte layer is composed mainly of

both Saharo- Arabian and Sudano- Deccanian geoelement. The Mediterranean geoelement was humbly represented in the tree and shrub layer. That may be recognized to the fact that the Saharo- Arabian and Sudano geoelements are good indicators for harsh ecosystems (Abd El- Ghani and Abdel-Khalik 2006).

Table (2) Distribution of the geoelements among life forms He = Hemicryptophyte, Ch = chamaephyte, Th = Therophytes, Ph = Phaneroohyte, Ge = Geophyte, Pa =Parasite and He = Helophyte. ME = Mediterranean, IT = Irano - Turanian, SA = Saharo – Arabian, SU = Sudanin, and Sub T = sub trobic. Other taxa are distributed in more than two regions

Life form	SA	IT	ME	SU	Sub T	T	Endemic	Bi- regional	Others	total
Th	36	14	14	5	1	1	0	58	42	171
Ch	49	15	6	5	0	0	4	22	5	106
He	27	12	10	3	0	0	11	30	9	102
Ph	9	3	1	8	0	0	1	11	1	34
Ge	3	0	1	0	0	0	0	3	4	11
Pa	0	1	0	0	0	0	0	1	2	4
Ha	0	0	0	0	0	0	0	0	2	2

Microhabitat diversity and abundance

Based on Khedr (2007), six microhabitats can be recognized throughout SKP these are wadi bed, terraces, slopes, gorges, farsh and caves. Investigated taxa are distributed mainly in four out of these six microhabitats viz. wadi, terraces, gorges and slopes with limited availability to farsh and caves microhabitats. The distribution of plant species was higher in gorges; wadi bed as

well as north aspect compared to the other microhabitats and aspect. In general, Shannon index, richness, frequency and density were significantly higher in gorges and wadi bed compared to the other microhabitats. Similarly, the concentration of dominance, as indicated by the Simpson index, with non-significant effect ($P > 0.05$). (Table 3).

Table (3). Results of one-way ANOVA of species density, frequency, and different diversity indices at different microhabitat

	Goreoge	Slope	Terraces	Wadi	F value
Shannon index	2.06	1.5	1.7	1.8	3.8
Simpson diversity index	0.873	0.85	0.87	0.89	648
Richness	10.8	6.2	7.7	10.2	7.5
Frequency	18.22	11.97	10.99	15.02	4.0
density	15.4	9.4	14.08	34.3	7.2

Goreoge ,wadi bed and north aspect sites were the most rich microhabitat and aspect while hilltops and south-facing slopes, which will be exposed to more intense insolation, will be the harshest habitats for plant growth, it seems that soil moisture and evaporation rate are among environmental factors determinants influencing species composition and richness in the arid habitat; as Goreoge and wadis have the greater merit of being a drainage system collecting water from great catchment area (El Hadidi 2000; Khedr, 2007) as well as the lowest evaporation rate (Kidron and Zohar 2010), Altitude and aspect on mountains influence the amount of water available to plants (Lomolino 2001); soils at higher altitudes dry out quickly after rain events; this can lead to very dry soils through the rest of the year. (Kidron and Zohar 2010) studied the evaporation rates in different parts of the slope in a drainage basin in the Negev Desert Highlands; they ranked Sites in the following order: north-facing aspect < wadi beds ≤ west-facing aspect ≤ east-facing aspect ≤ south-facing

Aspect < hilltops. As water is the most limiting factor for plant growth and survival in arid regions, the wadi beds and goreoges provides the most favorable conditions for plant growth.

Species that should receive more priority for conservation

According to the species endemism, are these species listed on the Red List of the International Union of Conservation (IUCN), density and frequency of these species, threats to plant species, the present study concluded that twenty five taxa classified as rare (R), with two taxa recently added to Egyptian flora as one population (Table 4); out of them sixteen species are endemic and / or steno-endemic to SKP; according to IUCN red-list six species are endangered or critically endangered. The rarity and endemism of these species indicate that they may be threatened by biotic and abiotic factors and should receive a high priority for conservation.

Floristic study of Saint Katherine protectorate, Sinai

New record to the flora of Egypt

Papaver L. one of 50 genera related to family *papaveraceae*, characteristic by absence of style and presence of stigmatic tissue arranged radially on a sessile stigmatic disc which crowns the ovary (Kadereit, 1993). *Papaver* has long been at attention for many botanists because of it is content from alkaloids like Papaverin, Codein, Morphin (Sariyar 2002) . *Papaver*

comprises 80 annual, biennial and perennial species in central and south-western Asia, central and southern Europe and northern Africa (Kadereit 1993; Kadereit et al. 1997) In Egypt *Papaver* represented by seven species namely *P. argemone* L., *P. decaisnei* Hochst. & Steud. ex Boiss., *P. dubium* L., *P. humile* Fedde, *P. hybridum* L., *P.*

macrostomum Boiss. & Huet ex Boiss. and *P.rhoeas* L. (Boulos 2009)

Papaver somniferum L., Sp. Pl.: 508 (1753)
TYPE: Lectotypified by Britton and A. Brown, Ill. Fl. N. U.S., ed. 2. 2: 136. 1913.
Syn. *Papaver setigerum* auct. non DC.;
P. somniferum L. var. *hortense* (Huss.) Corb.

Global distribution widely distributed in Europe and Asia.

Annual, 20-120 cm height. Stems erect, simple or branched, glabrous rarely bristled. Internode length 3-3.5 cm, leaves simple, alternate, oblong or ovate, toothed and lobed, rarely pinnately lobed, 4- 15 X1-

5 cm, leaf margin dentate or serrate. Flower solitary, terminal, Sepals glabrous, caduceus, petals 4 entire, obovate-orbicular, toothed, purple, red, violet or white, up to 5.5 -3.5 cm., Stamens long yellowish filaments fruit (capsule) dry and splits open when ripe, glabrous, ovate to oblong, sessile, and crowning the top of the ovary, stigmatic disk shorter than the capsule breadth, with deeply cut marginal lobes, seeds grey to black. Flowering and fruiting between February to June (Fig 6). ***Papaver somniferum*** can distinguished from other Egyptian papaver by its oblong or ovate stem-clasping leaves
