## TO OUR READERS.

— x —

A LETTER was delivered at our office some few days since, beginning with an inquiry, but with no other signature than our monogram,

“What an appropriate monogram of Horticulture, Journalists of Hives, to support the H, and the H holds up that sister of mine, whose scribble H always remind her of a broken gate

and concluding with this postscript:—

that is! It may be taken to mean Journalists and Journalists of Hens. The J, too, seems the J, just as eo-Editors ought to do; though you sometimes insert, declares that that J and fastened to a post.”

Now, it so happened that the J was reading aloud the letter to the H, and when he had concluded that sentence he stopped and said, “‘MAUD’S’ sister wrote that. These ladies are both Yorkshire—here’s the Leeds postmark.”

But H, no doubt better satisfied with being compared to a gate than J was with his likeness to a post, made a response neither negative nor affirmative, but evasive, for he said, “Read on.” So J read on as follows:—“Our cattle-yard has suffered dreadfully from the rinderpest; but that has nothing to do with the Journal writers, unless ‘WILTSHIRE RECTOR’ takes his title in kind. And Cousin Anne, who married Phelim O’Donoghue, of Ballygarth House, in Sligo, can’t settle to anything for fear of the Fenians; but I suppose they are no connections of the gentleman who writes about Potatoes and Wine, though he is a Fenn. And then those dreadful failures—I suppose that they won’t injure the Journal, unless J and H have shares in the Agra, the London Chatham & Dover, and the Overend things. My sister says that she dares say they have, for men who write much rarely have common sense; and if J and H have had to do with those things, she thinks the Journal may fail too. It would be a thousand pities, for I really believe it does a little good. Our curate takes it, and I know laid out his flower garden from something drawn in it; and we give our copy to Harry Martin, who married our cook and settled in Craven, and he sends it to his brother in New Zealand. Mrs. Martin wrote to her sister, our housemaid, the other day; and I must make one extract, because I know it will please J and H, to whom I beg, in conclusion, to say, no longer jocularly, I wish many happy New Years. This is the extract:—‘Martin does what the Journal tells him, and has just said, “I really do not know what I should have done without it. I should have ‘gone all wrong,’ for I do not know any one who could have given me a word of advice.” And his brother’s letter from New Zealand last month said, “The Journal *does* remind me of home so; and I now say, as I often say when reading, God bless the Editors, and prosper their work.”

“That will do for a Preface,” said H; but he and J must add that neither rinderpest, nor Fenianism, nor ruined speculations have weakened the resources of the Journal. Its staff is unscathed and strengthened; its circulation increased; and they hope that the J will continue to “support the H,” and the H to “uphold the J,” for many years to come.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 74.9°; and its night temperature 50.4°. The greatest heat was 97°, on the 5th, 1852; and the lowest cold 33°, on the 9th, 1863. The greatest fall of rain was 0.82 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ALTERNANTHERA SPATHULATA,  
ALTERNANTHERA SESSILIS AMŒNA,  
AND TELEIANATHERA FICOIDEA VERSICOLOR.

HAVING exhibited the above plants at the International Horticultural Exhibition at South Kensington, I have received so many letters inquiring as to their habit,

size, height, hardiness, where plants can be procured, &c., that I fear all have not received the information sought; and as I still receive letters respecting them, the following few remarks, I trust, will give the required information.

In the first place I received one plant of each of the above last autumn from Mr. B. S. Williams, of the Victoria Nursery, Holloway, and I was so pleased with their appearance that I determined at once to propagate a stock of them. This I did, and I have bedded out about two thousand. If I mistake not, these plants will prove one of the greatest boons to the flower garden that have been secured for some time, the Iresine excepted. My predictions respecting the Iresine give me every confidence. I was the first to recommend it for flower-garden decoration; and although I have had many hard battles to fight in its favour, I believe I have come off a conqueror, and if further proof is required with regard to its usefulness and beauty, I may state that upwards of five thousand plants of it are here bedded out this season.

ALTERNANTHERA SPATHULATA (Brazil).—This is of close compact growth, and will be found a beautiful plant for edgings or ribbon-borders. I have a plant of it 20 inches in diameter, and only 5 inches in height. It is a delightful little plant, and a free grower; it has been bedded out about three weeks, and has withstood 5° of frost without injury. Its colours vary with the situation in which it is placed, being pink and green, maroon, &c.; full exposure to the sun will, I believe, be found most suitable to its colouring.

ALTERNANTHERA SESSILIS AMŒNA (Brazil).—I have not so large a stock of this as of spathulata; it is of much stiffer growth, and appears to spread close to the ground. This is likewise suitable for edgings. The foliage is much larger than that of spathulata, and the habit is entirely different; the plant does not exceed, with me at present, 5 inches in height, and could be pegged down almost flat. It was planted out at the same time as the preceding, and sustained no injury from frost.

TELEIANATHERA FICOIDEA VERSICOLOR (India).—This is of much taller growth than either of the above. My largest plant is 2 feet in diameter and 1 foot in height. It differs from the Alternantheras in colour, and is a plant that attracts

the attention of every one. The foliage is much larger and rounder than that of the Alternantheras, and its habit strong and upright. Its colours are pink and maroon in some positions, but in this respect the plant varies much in different situations. I believe all the three plants named will bear the full sun, and grow freely either in a dry or moist situation. The Teleianthera was bedded-out with the others, and received no injury from frost.

I have two circular beds planted as follows—viz., Alternanthera spathulata in the first row, Alternanthera sessilis amœna in the second, and Teleianthera ficoidea versicolor in the centre, and if I am not mistaken these beds will here be the gems of the season, notwithstanding the tens of thousands of plants used in bedding and bordering at Osberton. They are already very attractive, and much admired.

I trust that those who have a stock of the three plants will advertise, it being just the time for planting without risk and to give them a fair trial, so that they may not, like the Iresine, be condemned in consequence of mere mismanagement and an unfavourable summer. All the above are easily propagated, and are of rapid growth. For the present I will not speculate upon which is the best, or speak more fully of them, but I shall content myself by merely introducing them to public notice, with a strong recommendation to try them.—EDWARD BENNETT, Gardener to G. S. Poljambe, Esq., Osberton Hall.

ROSES ON THEIR OWN ROOTS.

THE facts that the Dog Rose, or Briar, is very prolific in suckers on light soils, and that the Roses upon it are short-lived, have caused attention to be paid to those who advocated the growing of Roses upon their own roots, and we have such plants offered for sale by the dozen, hundred, and thousand; and so great is the demand that very often when a person decides on having a group of Roses on their own roots the variety required is "sold out."

Experience leads me to the conclusion that the days of the Briar as a stock on many soils, and particularly on those which are light, are numbered; and though the Manetti will make a vigorous plant in a very short time, yet even it on light dry soils is not to live many days. I have had Roses, both dwarfs and standards, on the Briar doing exceedingly well on cold, wet, heavy clay soil, where the Rose on its own roots could not, did not, live, and the Manetti on the same soil afforded a plant at first more vigorous than the Briar, but not after the third year, neither it nor the Briar pushing more than an occasional sucker. The Manetti does better in a greater variety of soils than either the Briar or Roses on their own roots, and for making a plant soon it is vastly superior to either; but I cannot say that it equals the Briar on heavy cold soils after the third year, whilst on light soils it may and does make a vigorous plant, and affords a great show of bloom long before Roses on their roots become what we may term established. After the second year, however, it does not surpass them either in plant or bloom, and would then seem to require removal, as, after lifting, it makes a first-class growth, and no stock seems to impart such a degree of vigour and to be attended

BOTAN  
GARD

with such fine flowers as the Manetti in the second year after planting. The Dog Rose is productive of a greater amount of bloom than the Manetti, so much so on light soils that the Roses worked on the former only make a few inches of growth and then bloom, the strength of the Briar being expended on the production of suckers, which come thicker and faster as the Rose becomes weaker and the stock older. The Manetti, on the other hand, gives larger blooms, owing to its being a better feeder.

My object in making these remarks is to learn the experience of others. My own is, 1st, That Roses on the Briar do well on strong cold soils, and are eligible for groups or otherwise; but on poor and light soils the Roses on it do not do well either as standards or as dwarfs for groups, on account of their tendency to produce suckers and their shortness of existence. 2nd, That the Manetti stock succeeds on either strong or medium-textured soils, and makes a much better plant, and the Roses worked on it produce finer trusses and blooms, than those either on the Briar or their own roots; but on light soils it is as short-lived as the Briar, though it grows vigorously for a few years, and much more so than either the Briar or the Rose on its own roots. 3rd, That the Rose on its own roots, though it takes a longer time to make a plant than the Manetti, is more desirable for groups than either the Briar or Manetti on account of its compact growth, its freedom from suckers, and the durability of the plants; but this applies only to rather light and warm soils; for on strong cold soils Roses on their own roots do not do well.

Now, Roses on their own roots take some time to become established, and they do not grow so freely for a while as when worked on the Manetti stock, and they therefore require very liberal treatment, particularly where the soil is light and hot, and this is the soil most suitable for most of the Tea-scented and China Roses. These varieties, as everybody knows, are not so hardy as the Perpetuals, and are often destroyed or killed to the ground by frost, and if they happen to be grafted or budded on the Manetti or Briar very often the Rose is killed; but if cut off to the ground when on their own roots, they push from the bottom. For groups, I find if Tea, China, and Bourbon varieties, and indeed all Roses, are to succeed on light soils, it must be by growing them on their own roots, and for the three classes named, a dry soil is particularly suitable, because it does not induce strong late growths, and there is, consequently, less danger of injury from frost. It is a well-known fact, that plants on dry soils will withstand a greater amount of cold than when grown on strong soil. For groups, where the soil is not strong, all kinds of Roses succeed best on their own roots, and where the soil is light and hot it is the only eligible mode of culture for the more tender classes, as Tea and China Roses.

The most suitable season for the propagation of the Rose by cuttings is now at hand, and this should be done when the blooming is past, and before the second growth takes place. Shoots that have bloomed have the wood sufficiently ripe for propagation, and so have those which have not done so, but have formed the terminal bud. The moderately strong shoots are best for cuttings. They should have three joints or buds, and be cut transversely below the lowest one, removing the leaf there, but leaving the others untouched. In taking a shoot for a cutting, cut it about three eyes from the point at which it has its rise on the shoot of last year, and avoid the two uppermost eyes beneath the place where bloom was, as the shoots from these joints or eyes are not generally so free in growth as those situated lower down. The cuttings having been taken off above the uppermost leaf by a slanting cut from the back towards the leaf, and three-quarters of an inch above it, they should be inserted singly in 60-sized pots. In preparing the cutting-pans, a piece of broken pot should be placed over the hole, and the pot half filled with crocks broken very small, and passed through a sieve with a quarter-inch mesh; fill up to the rim with light loam, peat, and silver sand in equal parts, and in the centre of each pot make a hole down to the crocks with a dibble exceeding the cuttings in diameter as little as possible. Drop a little silver sand into the hole, say from a quarter to half an inch, put in the cutting with its base resting on the sand, and fill up round the cutting with silver sand, then give the pot a sharp tap on the potting-bench.

For the reception of the pots a frame placed on a gentle hot-bed of 75°, and covered with from 4 to 6 inches of old tan or sawdust should be in readiness, and in this the pots are to be plunged to the rim. A gentle watering should next be given, and then the lights may be put on. The frame must be kept

close, and shaded from the sun, and the cuttings should be gently sprinkled overhead every morning. In a fortnight they will have callused, and new shoots will be forming; these may grow an inch or two, and then the cuttings should be transferred to another hotbed, gradually withdrawing the shade, and admitting air daily, so as to have them well hardened off by the end of ten days or a fortnight. They may then be potted into 4½-inch pots with the ball entire (crocks and all) in a compost of rich turfy loam, and be again plunged in the bed, and kept rather close for a few days, after which plunge the pots in coal ashes in an open situation, and in September shift the plants into six-inch pots, and plunge these to the rim in coal ashes in a cold frame. If, however, the young plants have grown but little, and the pots are not full of roots, let them remain in 4½-inch pots for the winter. I find that cuttings of Tea, China, and Bourbon Roses struck in this manner early in summer, make very nice pot plants for blooming in the following year. This is the best of all modes of striking Rose cuttings that I have tried, and answers equally well for Moss Roses, only they require more time to root, and must remain in the first hotbed fully a week longer than Perpetuals. Provence Roses also require more patience, so do the Damask Perpetuals.

Another mode of propagation by cuttings is, when the bloom is just over, to prepare and pot cuttings as above described, to place them in a cold frame, and keep close and shaded from bright sun, and sprinkled overhead every morning. They must remain in the frame until they have made shoots 2 inches long, and should then be gradually hardened off, and shifted into larger pots; those 4½ inches in diameter will be large enough. If the varieties are Perpetuals, the plants will do plunged in coal ashes in a dry, open, but sheltered situation, and will be eligible for turning out in spring for groups in the flower garden; but if they belong to the Tea or China section, it will be well to winter them in a frame, and afford protection during severe weather. By this method the Moss Roses do not strike with such certainty as the Perpetuals, but root fairly, and so will most of the Tea varieties.

I have tried placing the cuttings in a bed both with and without heat, and covering them with a frame kept close and shaded, sprinkling them every day; but, though the cuttings rooted freely, the loss in potting consequent on the injury done to the roots was a greater drawback than the labour saved by not placing them in pots in the first instance. I lost a great many after potting, but scarcely one when they were placed in pots in the cutting state. I can only state my experience, and that is, do not pot them until the following spring if you put the cuttings in a bed without pots, for the roots are so very tender that the least touch will break them, and they turn black and die off at the stem as if from some unknown cause. I am certain that the cuttings do not like to be disturbed so soon after the callosity is formed and the delicate fibrils emitted.

Another method which I have tried, and shall now describe, is to take cuttings of the well-ripened fresh wood by the middle or end of September, and plant them under a hand-glass or in a frame with lights in a warm situation. The cuttings must have a sprinkling of water occasionally, also shade from bright sun, but when the callosity is formed, as it will be in a month, give air, and continue to do so in mild humid weather during the winter. In the following April, after having been exposed to the atmosphere, they may be taken up and potted, or planted out finally in the beds.

The essentials to success are to put in those cuttings only that are taken from shoots which have flowered or formed the terminal bud or leaf, and this before the shoots have commenced a second growth; to avoid deluging them with water, and yet to keep the atmosphere moist and shaded, so as to preserve the foliage fresh until the cuttings have rooted, or at least until a callus has been formed; to be very careful in potting so as not to injure the tender roots; not to pot or disturb the cuttings until they have rooted and are well hardened off; and, lastly, not to keep the soil very wet after potting. Above all, avoid putting in any spare shoots, sappy, gross, and but partially ripened, for though these root freely, and seem to flourish, their stems turn black and they perish at a time when rapid growth is expected.—G. ABBEY.

TESTIMONIAL TO THE REV. S. REYNOLDS HOLE.—At a dinner held at Anderson's Hotel, Fleet Street, on Thursday evening, this gentleman was presented with a handsome silver urn in

acknowledgment of his exertions in connection with the National Rose Show, which owes its origin to him. The Rev. H. H. Dombrain occupied the chair.

### ZONALE GERANIUMS WANTED.

NOTWITHSTANDING the many attacks that are made on the reigning fashion, it is seldom that they have any further effect than that of encouraging what was intended to be put down; and perhaps in some cases it is as well that it is so, for it is not always that those who assume to be leaders of public taste are correct in the views they take. As an instance of the inutility of opposing public opinion, let us only look at bedding plants, which from very small beginnings have assumed an importance which no one ever dreamed of, and it is not too much to affirm that their cultivation is still increasing, and probably may do so for some time yet. This increase in their use has not been effected without bringing certain classes of plants more prominently forward than others; and although some have been driven from the field, or nearly so, others have succeeded them. Thus the list, in spite of weedings and (as our worthy coadjutor, "D." of Deal, says), hanging-days, is as numerous as ever, more so, certainly, in the bewildering catalogues of varieties, while the number of species adapted for bedding purposes is fully equal to what it was a dozen years ago. There is, however, a difference in the estimation in which certain plants were held at that time and now; some have fallen into oblivion, or nearly so, while others are more patronised every year. Of the latter class is that to which I would now more particularly call the attention of the skillful hybridiser, as something more is wanted than we now possess, and with that I think it is in his power to furnish us.

Taking, therefore, Zonale Geraniums as a class of plants which is every day more and more cultivated, the question to be asked is, What further improvement is wanted? Several varieties seem to possess all that is really needed in their respective tints as flowers, and the truss and foliage are alike good, and, besides, every year dozens of other kinds are added to the list. Some of them are doubtless some little improvement on others of a like kind before them, while many are not so good. Now, would it be called a restrictive and unconstitutional policy to shut up the present lists from further additions or innovations within the circle that is well represented, and only allow addition at such points as are of real value in carrying out the object aimed at? To make this more plain let us glance at what we now possess, and see where additions can be well made; and taking the class of Zonale bedding Geraniums which are cultivated for their flowering qualities, we have already almost every conceivable tint, from white up to dark crimson, embracing many shades of flesh colour, pink, salmon, rosy salmon, scarlet, and crimson. Many other intervening colours or tints might be enumerated, but enough have been named to show that our existing list is a tolerably extensive one. Thus, those who keep pace with the fashion in trying all or a great portion of the varieties sent out each year by different cultivators will have accumulated a mass of varieties perplexing by their names, and equally so by the resemblance which many of them bear to those grown before.

Now, good as many of the bedding Geraniums of the present day undoubtedly are, I by no means affirm that further improvement is not wanted, and this, doubtless, is now and then exhibited by some of the new varieties sent out; still I cannot but think that if unexplored channels were more sought after, additions of more importance would be made to our lists. Assuming that growers should pronounce themselves satisfied with the flesh-coloured, pink, salmon, and scarlet sections, and their intermediate tints, cannot a better representation of the deep crimson or magenta class be furnished? I do not pretend to be well versed in the varieties said to possess these colours, but the best in my own collection fall short of what I think is wanted here, Magenta, Imperial Crimson, and Pink Pearl being the nearest approach I have, and these evidently capable of great improvement in habit, colour of bloom, and other qualities. My object, therefore, now is to ask those who take so much trouble year after year in producing new kinds to try to obtain improvements in the deep crimson and magenta varieties. Those of other colours are plentiful enough, and indeed there are many to spare, but there seems no reason to doubt but that the Zonale Geranium may be coaxed to produce flowers of as bright a purple as the Dahlia; and many other fancy colours might also be obtained.

Now, the above advice to raisers of new varieties to prosecute their labours in the way directed, does not preclude novelties being sought for in other directions. Amongst the many valuable acquisitions bequeathed to the world by the late Mr. Beaton, there is one scarcely verifying its name, "Indian Yellow." Might I ask those who push their improvements to the greatest extent that such can be carried, to try if by degrees they cannot bring out in this Geranium a colour more resembling that of a yellow *Calceolaria*? This I hardly expect will be accomplished, but an approach to such a result may be effected. A yellow Geranium would be something extraordinary, and it deserves the notice of those interested in striking out new paths, and as the existing kinds, as stated above, may do pretty well now without further amendment, I trust these hints may induce some to direct their attention in the direction indicated; improvements may likewise be effected in other channels on which but little attention has been bestowed, and these being equally important may be sought for at the same time. I allude more especially to the Ivy-leaved kinds, which have not by any means reached the position I expect they will hold some day as ornaments of the parterre. A very indifferent gold-edged one, with the old crimson, white, and pink-flowered varieties, are all that I am acquainted with, and each is capable of improvement. I hope some one will try his skill at hybridising this section with the Zonale, so as to give a more upright flower-stem, and a more robust habit. Could not Mr. Wills, who has done so much with the Verbena by hybridising the hardy herbaceous one with the finer-flowered class, do something with these Geraniums also? They seem to deserve notice; and their adaptability to hot sunny situations where there is scarcely soil enough for other plants to live, as in vases, baskets, &c., give them claims on our attention hitherto not sufficiently recognised.

It would be extending this paper too far were I to enumerate what is wanted in the variegated line. This, however, seems likely to be pursued pretty well, and there promises to be no lack of gold and silver-edged varieties, with the addition of zones of various colours. Of them it is not my purpose here to speak, neither would I restrict those who aim at the obtaining the colours required to be too particular as regards the habit of the plant. Once supply the tint wanted, and other qualities will follow. The task, however, is I expect only one of time, its accomplishment will assuredly come, and as bedding Geraniums form, unquestionably, the most important feature in all gardens, it follows that any additional colour in which this plant can array itself will make it the more acceptable. I trust the hints above given may not have been in vain. I might have pursued the subject further, and might even have asked if such classes of Geraniums as the old Shrubland Pet, a small Oak-leaved variety, could not be improved; but I find I am trespassing on other ground, and therefore beat a retreat, trusting some one will endeavour to supply the wants indicated.—J. ROBSON.

### PLASTER FOR BUDDING ROSES.

PERHAPS the following remarks on budding Roses may be of use to some of your readers. I have adopted, with complete success, a plan which has been new to all those to whom I mentioned it, and by which much expenditure of time and trouble is saved, and I think a great amount of certainty obtained.

Instead of either bast or worsted I use some common adhesive plaster. With this I can bud three Roses in the same time that I can bud one with bast. The plaster adheres at once exactly where it is required; no tying is necessary, and the operation can be performed with great neatness and exactness, as well as rapidity. The plaster I used was some common white adhesive plaster, bought at the chemist's (called diachylon), and cut into narrow strips. I do not know whether my plan is absolutely new, but it has been so to all those to whom I have mentioned it, and I feel sure that your readers who try it will find it thoroughly successful.

Another plan, which was shown to me by a lady, has proved so useful to me, and is so little practised, that I think it worth while to mention it also. It is that of budding any convenient branch of a Briar, either in a hedge or elsewhere, and when the bud has taken, cutting off the branch, and planting it, with the bud on, like any ordinary Rose cutting. In this way shapely plants, especially suited for pots, may be obtained; and the plan is very useful if you happen not to have

sufficient stocks ready for your buds. I now seldom bud a stock without inserting some additional buds higher up on the branches, which I can afterwards cut off, and plant as cuttings.

I shall be glad to learn your opinion whether the plans which I have thus suggested recommend themselves to professional gardeners.—*AMATEUR, Harrow-on-the-Hill.*

## ROYAL HORTICULTURAL SOCIETY.

NATIONAL ROSE SHOW.—JUNE 28TH.

THE very hot weather of the last few days had acted in two ways on Roses. It had certainly brought a vast number of flowers into bloom which, but for it, would have been kept back, and so increased the amount of stands exhibited; but I am not sure that it tended to increase the quality of the blooms, for cloudy weather with occasional glimpses of sunshine is, I conceive, the best for Roses; and it is because this is the character of our weather generally that we possess so much advantage over the French growers. A few days of their tropical weather forces the Roses into bloom, and thus they rarely attain the size and quality that we are in the habit of seeing. Now, the flowers looked *blanc*, like some fair maiden who, although very charming indeed, shows the effect of the last night's dissipation, and whom, while you cannot help admiring with the homage that beauty always demands and obtains, yet you cannot but wish you saw fresher and more natural. The day, too, was very, very hot; and Roses which I saw put up well very soon began to show their eyes, and those not of the most brilliant character. While saying this I must at the same time add there were some really grand blooms, and I think the amateurs, especially, were in great force. There were some stands, indeed, which were the perfection of growth; there were others which ought to have been put under the table.

The Class for eighteen new Roses of 1864 and 1865 brought five competitors—Messrs. Paul & Son, Fraser, Cant, Francis, and Keynes. In Messrs. Paul & Son's collection were *Alpaide de Rotalier*, in good condition; *Centifolia rosea*, too thin; *Rushton Radclyffe*, fine, but colour a little gone; *Alfred Colomb*, magnificent flower, one of the best, but here again the colour was a little faded by the heat; *Duke of Wellington*, very bright scarlet, good shape, and excellent; *Maréchal Niel*, very good; *Madame Victor Verdier*, very fine; *Madame Fillion*, a beautiful flesh-coloured flower; *Madame Charles Verdier*, too flat; *Princess Mary of Cambridge*, good; *Belle Normande*, too watery in colour; *Engèle Verdier*, dark, inclined to show the eye. In Mr. Fraser's stand were *Marguerite Dombrain*, a fine full Rose; *Maréchal Souchet*, good; *King's Acre*, too coarse; *Prince de Porcia*, very bright and good; *Pline*, rough and thin; *Gabriel de Peyronny*, somewhat rough; *Alfred Colomb*, very fine. In Mr. Cant's stand were *Joséphine Beauharnais*, a fine light-coloured flower; *Marguerite Dombrain*, good, and somewhat similar to the preceding; *Duke of Wellington*, very good; *Charles Rouillard*, very fine; and *Maréchal Niel*. Mr. Keynes's collection contained large flowers, but wanting a little in refinement. There was a fine bloom of *Xavier Olibo*, which has, however, an awkward way of twisting itself about, and not opening freely; *Général Jacqueminot* does the same, but *Xavier Olibo* being stiffer in petal than the *Général*, this cause prevents it from opening at all sometimes, otherwise it would be a magnificent dark flower. Mr. Francis had amongst others *Xavier Olibo*, *Souvenir de William Wood*, &c.

In the Class for twelve trusses of any new kind Messrs. Paul & Son had a stand of *Marguerite de St. Amand*, a splendid Rose, of a bright flesh colour, and a decided acquisition. Mr. Keynes had *Madame Moreau*, very large and bright, but too saucer-like to suit my taste, especially for showing in this way. It will take a good place as a back row flower, but it is not the style we want. *Pierre Notting* from Paul and Son was good, but it had a tendency to show the eye, which detracted from its merits. Mr. Cant had *Marguerite de St. Amand*, very good.

Awards—For eighteen new Roses of 1864 and 1865: first, Messrs. Paul & Son; second, Mr. Fraser; third, Mr. Keynes; fourth, Mr. Cant. For twelve of 1864: first, withheld; second, Messrs. Paul and Son. For twelve trusses of any other new kind: first, Mr. Cant; second, Mr. Keynes; third, Messrs. Paul & Son.

The stands for decoration were decidedly pretty, and most of them in good taste. Mr. Soder, gardener to Osgood Hanbury, Esq., Brentwood, had an oval stand with Fern leaves; springing from it was an oval frame with a glass vase at the base, and surmounted with another glass vase, all containing nice blooms of Roses. Miss Wint, of Brighton, had a stand composed of five tapering glasses, the centre one being tall, and glass stems coming from it to each of the smaller ones. Mr. Hedge had a very pretty stand with some fine flowers, and a beautiful Moss Rose bud on the top. Another stand, one of Mr. March's pattern, was very handsomely set up with abundance of Maiden-hair Fern interspersed through it. It will thus be seen there is a little deviation from Mr. March's original pattern, although there is hardly one, I think, even now prettier than it, especially when tastefully set up.

Awards—For decorated baskets or vases of Roses: first, Mr. Marlow, gardener to J. Wigan, Esq., Mordlake; second, Mr. Hedge; third, Mr. Soder. For bouquets: first, Mr. Chard; second, Messrs. Francis; third, Mr. Hedge.

I should have added that the Show generally was held in the large

conservatory, with a canvas awning stretched over it. It was, however, far too warm, and the Roses very soon felt the effect of the heat. The stands for decoration were in the side arcade, where also were some nice plants from Mr. Bull, and Pinks from Mr. Charles Turner, of Slough. On the whole the Show was very successful, and some of the best-known friends of the Rose were amongst the Judges.—*D., Deal.*

THE general features of the Exhibition held at South Kensington, on Thursday last, with which was incorporated the National Rose Show, having been stated above, it remains for us to give the names of the prizetakers and of the varieties which they exhibited.

In Class I., single trusses of seventy-two kinds, Messrs. Paul and Son, and Mr. Cant, of Colchester, had each very fine exhibitions. From the former came fine blooms of *Xavier Olibo*, *Madame Bontin*, *Olivier Delhomme*, *Maréchal Niel*, *Gloire de Dijon*, *Devoniensis*, *Madame Vidot*, Mrs. William Paul, fine violet crimson with a fiery centre; *John Hopper*, *Comtesse de Chabrillant*, *Beauty of Waltham*, *Princess Mary of Cambridge*, *Madame Boll*, *Alba rosea*, *Baron Adolphe de Rothschild*, *Lonise Magan*, *Souvenir d'Elise*, very large and beautiful; *Rushton Radclyffe*, *Centifolia rosea*, *Louise de Savoie*, *Prince de Porcia*, fine scarlet; *Centa de Nanteuil*, *Lælia*, *Baron Gemella*, and *Louise de Savoie*.

Mr. Cant had *Marie Baumann*, very large, rosy crimson; *Madame Charles Wood*, a fine crimson; *Dac de Rohan*, *Xavier Olibo*, *Comtesse de Chabrillant*, *Madame Victor Verdier*, *Devoniensis*, *Niphotos*, *Marguerite de St. Amand*, *Victor Verdier*, fine; and with few exceptions the whole of his blooms were remarkable for size. It may also be remarked, that in these and some other stands the trusses were set up with buds.

Mr. Keynes had fine blooms of *Madame Sertot*, white; *François Lacharme*, *John Hopper*, *Pierre Notting*, *Triomphe de Rennes*, *Gloire de Dijon*, *Mlle. Bonnaire*, very prettily tinged with rose in the centre; *Moiret*, *Duchesse de Caylus*, and *Maréchal Niel*.

Awards—Equal first, Messrs. Paul & Son, and Mr. Cant; second, Mr. Keynes; third, Messrs. Francis.

In Class II., forty-eight kinds, three trusses, there was a very fine display, particularly in the stands of Mr. Turner, of Slough, and Mr. Keynes. The varieties seen to best advantage were *Olivier Delhomme*, *Virginal*, beautiful in colour; *Coupe d'Hébé*, Mrs. Rivers, *John Hopper*, *Gloire de Dijon*, *Souvenir d'Ami*, *Charles Lefebvre*, *Xavier Olibo*, *Le Rhone*, rich crimson scarlet, *François Lacharme*, *Baron Gemella*, *Marguerite de St. Amand*, *Engèle Verdier*, dark violet purple; *Beauty of Waltham*, *Joseph Fiala*, violet shaded crimson scarlet; *Duchesse de Caylus*, bright rosy crimson, and very full; *Denis Helye*, *Alba rosea*, *Madame Victor Verdier*, *Comtesse de Chabrillant*, *Dr. Andry*, *Madame Boll*, *Prince of Wales*, rosy crimson; *Maurence Bernardin*, *La Brillante*, *Madame Vidot*, *General Castillane*, *Laurent Descourt*, purplish scarlet, brighter in the centre, and many others which it would be tedious to enumerate.

Awards—First, Mr. Turner; second, Mr. Keynes; third, Messrs. Francis; fourth, Messrs. Paul & Son.

Class III., was for twenty-four kinds, three trusses. Here Mr. Cant took the lead with, among others, remarkably fine trusses of *La Brillante*, very bright in colour; *John Hopper*, *François Lacharme*, *Marie Baumann*, very large and full; *Prince Camille de Rohan*, *Mlle. Bonnaire*, and *Madame Charles Wood*. Messrs. Paul & Son, who were second, had *Princess Mary of Cambridge*, *La Ville de St. Denis*, and *Queen Victoria*, large, white, shaded with delicate rose; Mr. Turner, fine trusses of *Maurence Bernardin*, *Senateur Vaisse*, *Jules Margottin*, *Comtesse de Chabrillant*, *La Reine*, *Madame Knorr*, *Marguerite de St. Amand*, and *La Tour de Croay*, very large; and Mr. Keynes, *Madame Charles Wood*, *Dac de Rohan*, pretty buds of *Madame Fortado*, *Victor Verdier*, *Madame Clemence Joigneaux*, lilac rose; and *Le Baron de Rothschild*, deep crimson scarlet. *Alfred Colomb*, bright rosy red, came from Messrs. J. & C. Lee.

Awards—First, Mr. Cant; second, Messrs. Paul & Son; third, Mr. Turner; fourth, Mr. Keynes. Commended, Messrs. Francis.

In Class IV., single trusses of twenty-four kinds, Mr. Turner had a fine bud of *Devoniensis*, *Duchesse de Caylus*, very fine; *Madame Josephine Guyet*, *Madame Victor Verdier*, *Madame Fortado*, *Gloire de Dijon*, *Devoniensis*, *Jules Margottin*, and *La Reine*; and in other stands were fine examples of several of the above, *Senateur Vaisse*, *William Griffiths*, *Maréchal Niel*, *Madame Charles Wood*, *Charles Lefebvre*, *Victor Verdier*, *Le Rhone*, *Marguerite de St. Amand*, *Robens*, *Lælia*, *Marie Banmann*, and *Alphonse Damaizin*.

Awards—First, Mr. Turner; second, Mr. Cant; third, Messrs. Paul & Son; fourth, Mr. Keynes.

In the Amateurs' classes, all for single trusses, there were many excellent stands, and but few that could not be considered fair.

In Class V., forty-eight kinds, Mr. Hedge, Reed Hall, Colchester, took the first honours with a set in which we remarked fine blooms of *Madame Charles Wood*, a fine bud of *La Boule d'Or*, *François Lacharme*, *Pierre Notting*, *Marie Baumann*, *Madame Villermoz*, *Souvenir d'Elise Vardon*, *William Griffiths*, *La Ville de St. Denis*, *Mathurin Regnier*, and *Anna de Diesbach*. He had also a fine truss of *Cloth of Gold*, a variety which this year seems to be unusually fine, consisting of five blooms. Mr. Ingle, gardener to C. G. Round, Esq., Colchester, had *Engèle Desgaches*, cream, tinged with rose; Mrs. Rivers, *Souvenir d'Elise*, *Devoniensis*, *George Paul*, *Lord Macanlay*, very dark crimson; *Madame Victor Verdier*, *Caroline de Sausal*, and *Maurence*

Bernardin. From Mr. Moffat, gardener to the Hon. Mrs. Maynard, Easton Lodge, Dunmow, came Empereur de Maroc, Devonensis, Beauty of Waltham, Gloire de Dijon, Madame Bell, and Imperatrice Eugénie, small, white, tinged with blush. In the stands of other exhibitors in the same class we noticed Joseph Fiala, Spotted Queen, carnation-striped; Gloire de Santenay, L'Enfant Trouvé, and Juncu.

Awards—First, Mr. Hedge; equal second, Mr. Moffat and Mr. Ingle; third, J. Hollingworth, Esq.; fourth, Mr. Chard.

Class VI. was for thirty-six kinds. Here we noted Madame Bravy, Prince Léon, Madame Masson, violet, to which colour it changes from crimson; Mrs. Rivers, and Beauty of Waltham from Mr. Ingle; and from Mr. Hedge and others, Souvenir d'Elise Varden, some 5 or 6 inches across; Cloth of Gold, Louise Magnan, Oriflamme de St. Louis, bright crimson; Anna de Diesbach, Charles Lawson, and Général Jacqueminet. André Leray, a fine-coloured flower, was shown by Mr. Wright, gardener to Mrs. Ramsden.

Awards—First, Mr. Ingle; second, Mr. Hedge; equal third, Mr. Chard and Mr. Marcham; fourth, Dr. Cooper.

In Class VII., twenty-four kinds, the best exhibition was that of Mr. R. B. Postans, of Brentwood, who had fine blooms of Triomphe de Caen, violet crimson, with a scarlet centre; François Lacharme, Charles Lefebvre, John Hopper, L'Esmeralda, Prince Camille de Rohan, Empereur de Maroc, Olivier Delhomme, and Madame Bell. Mr. May, gardener to C. Worthington, Esq., Caversham Priory, also exhibited Prince Camille de Rohan, Lord Macaulay, and others, in very good condition; and Mr. Dennis, Folkington, Madame Maurin, and Bongère Tea Roses, the one white, the other fawn. There were several other good exhibitions in the same class.

Awards—First, R. B. Postans, Esq.; equal second, Mr. May and Mr. Dennis; equal third, Mr. Plester and the Rev. Canon Fisher; fourth, Rev. V. Knox Child.

In Class VIII., twelve kinds, the following were in fine condition—viz., Gloire de Dijon, John Hopper, Marie Baumann, Charles Lefebvre, Cloth of Gold, Madame Bravy, Sénateur Vaisse, Auguste Mié, and Mlle. Emain, a pretty white Perpetual.

Awards—First, Rev. V. Knox Child; second, R. B. Postans, Esq.; third, Mr. Dennis; fourth, Mr. Plester.

Class XII. was for the best twelve trusses of yellow Roses, consisting of not less than six kinds; and the only exhibitor was Mr. Hedge, to whom was awarded a first prize for Narcisse, La Boule d'Or, poor; Triomphe de Reunes, Celine Forestier, and L'Enfant Trouvé, a strong sport of Elise Sauvage; and Cloth of Gold.

In Class XIII., for the best collection of yellow Roses, Mr. Hedge was again first with Cloth of Gold, L'Enfant Trouvé, fine; Mélanie Oger, Narcisse, and Smith's Yellow. Messrs. Paul & Son were second with Gloire de Dijon, Vicomtesse De Cazes, Lamarque, Madame Falcot, Madame William, Louise de Savoie, Marquise de Foucault, and Auguste Vacher.

Tea-scented and Noisette Roses, though not sufficiently varied in colour to make an effective display, are always welcome on account of their fragrance. They chiefly consisted of La Boule d'Or, Triomphe de Rennes, Gloire de Dijon, Gloire de Bordeaux, Madame Bravy, Souvenir d'Elise, Joséphine Malton, Eugène Desgaches, Souvenir d'un Ami, some fine examples of L'Enfant Trouvé, Louise de Savoie, Homer, Alpha rosea, America, Niphotos, and Celine Forestier.

Awards—For twelve trusses (Amateurs): first, Mr. Ingle; second, Mr. May; third, Mr. Hedge. For twelve trusses (Nurserymen): first, Messrs. Paul & Son; second, Mr. Cant; third, Mr. Keynes. For twelve single blooms; first, Mr. Cant; second, Mr. Hedge; third, Mr. Keynes.

Of Moss Roses only one stand was shown, that being from Messrs. Paul & Son, who were awarded a first prize. It contained Salet, the Crested Moss, Bath White, Comtesse Murinais, and one or two others.

Pot Roses formed a very effective bank, the plants being in profuse bloom, though the flowers were not individually so attractive as earlier in the season. President from Mr. Turner, and Maréchal Niel from Mr. Wm. Paul, were especially fine; and Rashton Radelyffe, Pierre Notting, and other recent varieties, were also well represented.

Awards—For twenty-four: first, Mr. Turner; equal second, Messrs. Paul & Son and Mr. William Paul. For twenty new Roses: first, Messrs. Paul & Son, second, Mr. W. Paul.

Miscellaneous subjects consisted of new Marantas, Bertolonia margaritacea, Liliun auratum, Eranthemum argyrenum, having the foliage veined with white, and some other plants from Mr. Bull; and of fine Pinks from Mr. Turner and Mr. Bragg, of Slough, and Mr. Hooper, Bath, who also exhibited Carnations, Pansies, and Phloxes. Mr. Bird, gardener to the Hon. A. F. Ashley, Epping, exhibited thirty-six varieties of Hunt's Sweet Williams; and, as usual, from Messrs. Barr & Sagen and Carter & Co., came Fern-cases, plant-baskets, &c. The latter firm also exhibited variegated Maize, tricolor-leaved Pelargoniums, and very large pods of Laxton's Perfection Pea.

The handsome silver tea-urn, presented on the evening of the Show to the Rev. S. Reynolds Hole, stood in the conservatory in the midst of that exhibition of which he was the originator, and which, by his influence and example, he has so largely contributed to raise to a position worthy of England's national emblem—the Rose.

Mr. W. H. BAXTER, Curator of the Oxford Botanic Garden, has, we are happy to learn, been appointed to the Curatorship

of the University New Park. We understand that he hopes to be able to form an arboretum there, which will be a desirable and useful addition to the Botanic Garden, where there is not sufficient space for one calculated to be of real use.

### PRIZE FOR FIFTY CUT ROSES.

At a Rose show held here on Wednesday last, June 20th, an objection was made to the first-prize collection of fifty cut Roses, on the ground that fifty-one were shown for fifty. Two fully open Roses were shown in the same truss, and this was held by the objector to disqualify the collection. The Judges affirmed their decision, at least a majority of them; but as this is the first Rose show in Jersey, they would be glad to have your opinion in the next issue of your valuable paper.—ONE OF THE JUDGES.

[The additional Rose was a disqualification, for it is a sound rule to insist upon the printed schedule being strictly complied with. There is a reason here for such strictness, because when the competition is close the award has to be decided by points, and every bloom may add to the number.—EDS.]

### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

THE twenty-third Anniversary Meeting was held at the London Tavern on Wednesday last, the 27th ult., Sir C. Wentworth Dilke, Bart., in the chair. Among those present were Alderman Mechi, Professor Bentley, the Rev. Joshua Dix, Dr. Hogg, Messrs. T. Brandreth Gibbs, R. Wrench, G. Child, Bull, Edmonds, Gibson, J. & C. Lee, W. Paul, Turner, Veitch, Williams, Cutbush, &c. After the usual loyal toasts had been given and enthusiastically responded to, the Chairman in proposing the toast of the evening, "Success to the Gardeners' Royal Benevolent Institution," said that it was an Institution which ought to be supported by the public at large, as well as by gardeners, but by neither was it supported as it should be. He was one of those who thought that the occupation of a gardener was that in which the most mind is required, and the least is obtained from the master. He would like to see the working gardener on an equality with the intelligent artisan, but that was not the case now. Take a bricklayer or a carpenter, the education required by either is small, and so, too, was their responsibility; but the labour of a gardener is great, his responsibility often heavy, and to properly carry out his duties a considerable amount of education is required; and yet gentlemen having gardens, and good gardeners too, want a perfect man, and are prepared to pay him 20s. a-week! Thus it was that gardeners could not lay up much for their old age; and thus, too, it was that the Institution must also be dependant, to a considerable extent, on the more wealthy classes for support. There was a rule of the Institution—an extremely wise, extremely good, and extremely prudent rule—that a man who had subscribed for fifteen years might be admitted without an election; but that period was a long time to look forward to, and he hoped that increased funds would enable them to reduce the time to twelve years, to ten years, or even less. Some papers by Mr. D. Fish on gardeners' wages had lately appeared, and though in these the disadvantages under which gardeners labour were well stated, he differed from the writer *in toto*. The whole question of wages was simply one of supply and demand, and in this case the supply exceeded the demand. He doubted whether gardeners' wages would ever materially rise, because a number of day labourers are employed at 12s. per week, and these are continually forcing themselves upwards. Such men at 18s. per week are preferred to those at 30s. a-week, and so long as this continues to be the case wages must be low. More especially at the present crisis did he think that much advance was hopeless, for the expenses of many an establishment would be cut down to the lowest figure. What was the effect of the railway panic of 1847? Why, the amount of donations to the Institution fell to one-third of that subscribed in any previous year. The Chairman then referring to the International Horticultural Exhibition, said that about a year ago some of those present attended a meeting for the purpose of inaugurating it, and he was asked to take his part; others had been asked to take the undertaking under their wing, but the one had not the funds, and the other had not the pluck; but, said Sir Wentworth, "We (the Executive Committee), found the funds, and we found the pluck." Besides that, they had entertained their foreign visitors at the Guildhall, which the Corporation had lent for the purpose; but mind, the Executive found the dinner, and he believed their visitors had expressed their satisfaction at the reception which had been given them. The undertaking, however, was not a light one. His friend on the left (Mr. C. Lee), said that £9000 would pay the expenses; but he (the Chairman), said £12,000 would not do it. The Exhibition was, therefore, a speculation, and they entered into it, knowing that whatever might be the loss the gain would not be theirs; but they had resolved from the first, that if they did meet with success the Institution should profit by it. The Exhibition had proved an entire success, £3000 profit having

been netted, and of that sum the Committee had decided to give one-third to the Institution. The Royal Horticultural Society had been asked to take one-third of the profits for their assistance and the use of their garden, but the offer was refused, and nothing but £300 down in hard cash would do; otherwise that Society would have had £1000 also. The Chairman then read a letter from Sir Daniel Cooper, Bart., enclosing a cheque for £1000, and concluded by urging the claims of the charity, and expressing a hope that those present would raise the amount to £2000.

Mr. BRANDRETH T. GIBBS then proposed the health of the Chairman, and alluded to the services which he had rendered to the Institution, and his endeavours to forward the interests of horticulture.

The CHAIRMAN, in returning thanks, said that he did not know whether they would look upon him as a public nuisance for troubling them so often, but still he felt he must trouble them again, and tell those present that they who gave so largely, as some had done that night, even to the extent of £30, were real friends to this Society. But there were other real friends, and these were those who subscribed large sums from year to year (and no man contributes more than twice to a charity in which he does not take an interest)—these were the great friends to whom the Society would have to look for its principal support. If all would only put their shoulders to the wheel they could make it a powerful institution in a short time, and some there were who had determined to do so. As far as he was concerned, he could only say that whenever he could assist them, they might command his services. This year they had had their Chairman one who had a windfall to announce; but next year they would have Sir Robert Peel, and he hoped that they would give him the reception which he deserved. He then proposed the health of the Treasurer, Mr. Wrench.

Mr. WRENCH, in returning thanks, remarked that on such occasions it was customary to have only three figures to the subscription total, but he was glad to see that on this occasion it had increased to four. The Institution had since the last anniversary experienced the loss of two of its Vice-Presidents, Sir Joseph Paxton and Dr. Lindley, who had taken a warm interest in it, and if all would do the same its benefits would be very much increased.

Mr. G. GODWIN then proposed "Success to the Royal Horticultural and Botanic Societies," coupled with the names of Dr. Hogg, the Rev. Joshua Dix, and Professor Bentley.

Dr. HOGG, in returning thanks, said that he had lately been so much accustomed to return thanks for the Secretaries of the International Horticultural Exhibition, that he was afraid he should have to do what history is said never to do—repeat himself. He recollected the first meeting of the originators of that Exhibition, and he thought he might safely say that they were the half dozen "men of pluck" who put down their £10 a-piece to start the undertaking; but that sum was a long way off £13,000; still, they persevered, and though at times the Committee had had their misgivings, they had borne on by a fixed resolution safely to the end.

The Rev. JOSHUA DIX, in responding, defended the Royal Horticultural Society in regard to their having required £300 to be paid for the use of their grounds and other facilities. For, said he, had the Council entered into any arrangement for contingent profits, they would have been playing with money that did not belong to them. It should be remembered that on the opening of the Exhibition, when its financial success appeared somewhat doubtful, an appeal was made to them for an extension of time in the use of the grounds, &c., and what did the Council do? They said, "We will waive all claims for an additional sum of money; we will not accept it; we grant you the extension of privilege for nothing."

Professor BENTLEY said he very fully appreciated the very kind manner in which the toast had been received. He had been connected with the Royal Botanic Society for eighteen years, and all his life with plants, but till last year he never knew the men personally who were the great plant-growers of this country, and he had formed a high estimation of their sterling qualities.

Mr. CUTLER (the Secretary), then read a list of subscriptions put down at the dinner to the amount of £260, after which his health was proposed by the Chairman.

Mr. Alderman MECH said he considered himself an old friend of theirs, having occupied the chair in 1857. He might be accused of having been a truant since then, but the truth was he had been taken up with the Agricultural Benevolent Society, and he was sure that they would be glad to hear that it had £5000 a-year, and that there were at the present time one hundred recipients of its benefits. They had all heard Sir C. W. Dilke, and they, as well as he, knew that he was a great advocate of horticulture. At the late Show there had been £3000 profits, and £1000 had been given to the Gardeners' Benevolent Institution, but he did not see the reason why the whole £3000 should not have been given. He then proposed the "Nursery and Seed Trade," coupled with the names of Mr. Veitch and Mr. Child.

Mr. VEITCH returned thanks in a very effective speech, remarking that the Committee of the International Horticultural Exhibition had shown what England could do, and what its gardeners could do. He loved horticulture because it was an intellectual pursuit, although not such a money-making business as some in the city of London, and he loved it for its own sake. With regard to the question of wages, it was a thing to be bewailed that the carpenter and other mechanics should be in a far better position than the generality of gardeners. Labourers,

it was true, helped to keep down wages, by trying to do everything and often doing nothing well; and he considered the best remedy for this state of things, the best way to secure an increase of the gardener's wages, would be to educate him, and then employers would find it to their profit to employ the educated man. He, therefore, said, Let us lovers of horticulture do all that we can, not only to increase our numbers, but to raise the standard of education as well.

Mr. CHILD briefly returned thanks for himself and the seed trade.

"The Stewards," coupled with the name of Mr. Shaw, and "The Ladies," were then given.

Mr. JOHN GOULD VEITCH having returned thanks for the ladies, the company broke up.

The room was decorated with a profusion of flowers contributed by Messrs. Lee, Turner, Fraser, Williams, and others, and there was an excellent dessert. The dinner-table ornaments were kindly lent gratuitously by Messrs. Howell & James, of Regent Street.

## A WORD ON BEHALF OF SMALL ORCHARD HOUSES.

THESE useful structures have hardly met with a just criticism at the hands of writers on the subject. Whilst admitting their general inferiority to the larger houses, now so common, and for which it is safe to predict a still greater development, it would also be fair to state that in proper hands small orchard-houses may be rendered eminently useful. From the very fact of their small size they present considerations of value to that numerous class whose means are limited, and who also cannot devote much time to them. Space, too, in small gardens is difficult to spare. We have here, then, three very serious considerations—viz., time, space, and money, and these leave us much to say in favour of small structures. Let us, then, allow them their proper place in the public estimation. One thing is certain—that by the amateur doubtful of his resources they will always be selected. In large gardens they are obviously out of place, except as Orangeries, or for retarding a portion of the crop by placing them with a colder exposure, which, by the way, is the right manner of retarding any fruit.

If the small number of entries for the orchard-house trees in pots, which were submitted to Messrs. Rivers, Ewing, and myself at the Great Show was a true indication that public taste in this matter had endorsed that of some critics, all question of large *versus* small houses would be needless; but a round of subsequent visits to friends and others possessing them of all sizes enables me to state that orchard-houses never were so flourishing. In one case an amateur, with the aid of a rough workman or two, manages alone an immense house 250 feet long, and can show as good fruit as need be expected, and pruning so equal as to be unsurpassed. He is about to lengthen this house to 500 feet, and there is no reason why he should fail with this lordly house, but, rather, there is every chance of greater results. This case establishes what amateurs, really in earnest, trusting to their common-sense principles, and employing only the same amount of skill as is shown by so many lady florists, can do with large orchard-houses.

In the second instance I was shown by an amateur of very limited means what can be effected by careful attention with extremely small structures for growing fruit. In his small garden, where every available space was carefully economised, were two small span-roofed houses. The oldest of these, some ten years old, was only 18 feet by 9. To the ridge was only 7 feet; the sides were 4½ feet high. This stood east and west. The other house was 16 feet by 12, and had ventilating shutters 1 foot wide, all round, and others at the top, at each end. This house stood north and south. The whole number of trees was no less than eighty (chiefly pyramids in 13-inch pots), and consisted of Peaches, Nectarines, Plums, Pears, and choice Apple trees. By the different position of these houses, and by plunging a portion of the Plums in the open ground during the last week of June, a succession of fruit was secured, and more room given to the Peaches to ripen. The crop looked fine, and the foliage was without a stain, so that this amateur will probably have more Peaches than can be found on many an extensive wall, this evil year of blight, and bloodshed. Without these houses what chance would he have had of choice fruit in a small, unwall garden?

At Sawbridgeworth, also, where I stayed two days, were houses 100 feet long, and but 7 feet high to the ridge, yet they were full of fine pyramidal Apricot trees, well loaded. My first house was but 50 feet long, and is still very early. It has defects enough, no doubt, but it is always full of Peaches. The

truth then seems to be, that amateurs, by ordinary attention to well-known rules, ought to manage small as well as large orchard-houses, without much difference in trouble.

Peaches on the open wall can this year be counted without any difficulty, but in all the orchard-houses I have seen there is a good crop. This is a fact worth many words.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

### COUNTRY SCRAPS.—No. I.

It was in the little village of Boxted, Essex, that I first found a fungus which I have never since met with. It was a damp day in autumn that I was wending my way through a short lane which ran near our own quiet church—certainly possessing various characteristics of architecture, but neat and cleanly within; and I was pondering upon the still resting-place of my young mother, who with her baby boy lay in that small portion of ground known as "God's acre," awaiting the summons of the Master of the flowers there cut down and withered, to awake to renewed life under the resuscitating beams of the Sun of Righteousness. Thinking, too, I was of the glory and happiness of those two souls who walked in holy communion through those fields of light and love above; and from the contemplation of this heavenly region I came back to the realisation of the fact that I must put aside my day dreams, and close my eyes to the magic mirror that was in the soul within me and grapple again with the world, all motherless as I was; and it is a hard world for a woman to fight her way in, and sometimes the case is even harder where

"Men must work, but women must weep."

To sit still and weep is destructive to mind and body: therefore if it be but to sweep the house, rather work; it will keep the brain from wearing itself out before the body, which is the most pitiable case in nature. But, as I was saying, I gave up useless regrets, and being but a maiden in my teens, I was not very likely to let "grief prey on my damask cheeks." No, I rather held the motto that care killed a cat, and so betook myself to the amusement of seeking in the dripping bank close by for what I was always expecting and hoping to find—something unknown to the botanical world. What a grand day this would have been for me to come upon the "philosopher's stone." Had I been a man I should have attached myself to some exploring expedition; but Nature not favouring me in this line, I more humbly enjoy my own quiet depredations in our own English hedgerows. That day, however, I did find something, and something which a subsequent letter from Professor Henslow led me to believe was not so very common. How my young heart bounded for joy when he requested that "the young lady would kindly procure more specimens if any were to be found, and send them to him packed carefully in a box, as the Curator of the Ipswich Museum only possessed two of these fungi, and possibly another year they might altogether disappear from the spot where they were gathered." He described the specimens as those of the Starry Puff-ball. The part which contained the "puff," as we children called it, he, I remember, designated as "the furnace." Of course my hat was soon donned, and off I went with a small basket. I found a few more plants in the same locality, but no more in that lane, although I searched both sides of it. This fungus is entirely concealed by the vegetation around, and therefore, perhaps, is it found so rarely. Finding its haunt was amongst rotten sticks and decayed leaves, I thought I would search a bank beneath a large Hawthorn tree which stood near our house, and which answered that description, and there, to my infinite delight, I found quite a nest of my treasures. My basket was soon filled. Perhaps I sent the Professor a dozen and half of these fungi, keeping also some for ourselves. I remember the peculiar appearance of these strange plants very well: some of them had five and some four segments, like legs descending from "the furnace," and meeting five or four (as the case might be), other divisions ascending from the earthy-looking foundation from which they rose. We kept some of the specimens in a china saucer upon the chiffonière in the drawing-room, and they awoke the curiosity of all who saw them, whether botanists or not. I dare say the Curator of the Ipswich Museum no longer complains of a paucity of specimens.

I have somewhere read that there is a peculiar narcotic property in the fumes of the common Puff-ball when burnt, and that it has been used on this account to take the honey from hives without destroying the bees; but whether it is still so

used I am unable to say. I have seen farmers stooping to secure some of the powder from these fungi, using it as a styptic to prevent the bleeding from a recent cut; and I knew a country gentleman who always kept a small stock in reserve in the neighbourhood of his shaving chattels, to resort to in that unlucky moment which comes alike to the strongest and weakest-minded of our "lords," when putting that last dainty touch in the matinal beautifications which would have been "all well had it ended well," as old Shakespeare hath it, but which, on the contrary, was productive of the keenest cut of all—a cut which wounded physiognomy and vanity at the same time. Maternal Nature, however, comes to the aid of all her suffering children; and from the simple bosom of the earth we may on all sides possess ourselves of the necessary curatives if we only know where to seek them, and will not, as we so often do, "despise the day of small things." The humble cottager frequently knows more of the uses of the plants and herbs around her than we who consider ourselves the more enlightened portion of the community ever dream of. They may be called old wives' nostrums, but after all there is often a medical virtue which would warrant further research. In the wilder parts of Yorkshire the gude dame seems often in requisition with her homely medicaments, and marvellous tales are told in the peculiar northern dialect of miraculous cures thereby effected. The narratives, however, lose so much of their pith from the recapitulation in our southern tongue, that I will not pretend to detail them.

Speaking of Yorkshire, although my visit there has been too late in the season to aid me in making any fresh additions to my hortus sicus, still from friends living in the county I have gathered details of several plants which are, perhaps, rather local, but which abound in some parts of that rich botanical shire. The *Narcissus biflorus*, Pale *Narcissus*, is mentioned by Henry Baines, Sub-Curator to the Yorkshire Philosophical Society (1840), as being found "in a field in which is a stone quarry, on the left of the high road to Aske from Richmond; at Thornborough, near Thirsk; near Rotherham; near Horsey church; near Ripon; in meadows at Sowerby and Warley, near Halifax." Certain it is that in a meadow a short distance from York there are bulbs of this uncommon plant. In the spring it throws up its pale and delicate flowers. My brother's gardener was upon the point of removing the plants to his newly laid out garden; fortunately, to prevent this desecration, the Rev. botanist appeared upon the spot, and forbade the unhallowed act. My brother had his doubts whether the bulbs might not have been thrown out with manure from some garden; but upon consideration he withdrew this idea, as the fields had for a long time been used only as pasture for cattle, and there was no garden in their immediate vicinity.

Another plant which is not very common in the south of England, although it has been found in Norfolk and Suffolk, is the Giant Bellflower, *Campanula latifolia*. In Yorkshire it finds many habitats. Some very fine specimens are to be found in a ditch in Clifton "ings." These "ings" are meadows lying close to the river which runs through the old city, and forms such a picturesque scene when viewed from one of the bridges which span it. The *Campanula latifolia* is also found near Fulford church, at Roche Abbey, and in many other parts of this county. A crop which is quite unfamiliar to my southern eye, and which was just beginning to cover some fields, in which it was pointed out to me, was that of numerous healthy-looking Teazels. The appearance which they present is that of a field of young Thistles. Of course their well-doing is a matter of anxiety in the large cloth-making districts in the north.—A SURGEON'S WIFE.

### DUTY-FREE TOBACCO FOR GARDEN PURPOSES.

THE "Richmond Cavendish Company," to enable them to prepare a cheap composition for fumigation and other garden purposes, have applied to the trade and others interested in horticulture to sign petitions to the Lords of the Treasury and Commissioners of Customs, asking that Tobacco may be duty free for such purposes. Such remission of duty would, of course, promote the trade of the Company, but it would also be advantageous to the gardening community, therefore we recommend the petitions to the support of our readers. The following is a copy:—

"To the Lords of the Treasury.

"We, the seedsmen, florists, nurserymen, market gardeners,

and others, interested in horticultural pursuits, respectfully submit to your Lordships, that we may be permitted to use Tobacco in the form of pastiles, free of duty, for the purpose of fumigation, in order to destroy the insect vermin which are so injurious to plants and trees.

"Various preparations have been tried, but it is well known, that Tobacco is, of all other things, the most efficacious; and it would be extensively used if its high cost, owing to the duty levied upon it, did not make it too expensive an article for general application.

"In praying that this petition be granted, your petitioners would most respectfully point out, that similar concessions have been made in other cases, the use of rum in methylated spirit, and of Tobacco, for sheepwash, having been granted under circumstances of a similar character.

"The objection that the use of Tobacco, free of duty, for horticultural purposes might prove injurious to the revenue, could no doubt be met by imposing such restrictions on the mode of preparing the Tobacco in bond, for the pastiles, as would entirely prevent the possibility of its being employed for any other than the purpose for which your petitioners respectfully ask permission to use it. The method we would propose is to grind a proportion of two-thirds of Tobacco together with one-third of common soot and fish oil; or to add such other ingredients as the chemist to the Government might suggest for the more effectual destruction of the Tobacco.

"In the event of your Lordships kindly granting the prayer of your petitioners, you will confer a favour of great value to a large class of persons connected with horticultural pursuits in this country, and a favour which will undoubtedly prove a general benefit to the public.

"And your petitioners will ever pray."

### HYDRANGEA HORTENSIS FOR OUT-DOOR DECORATION.

PERHAPS no plant has been more generally cultivated than this variety of Hydrangea since its introduction by Sir J. Banks. It is a very imposing plant when seen in its smallest form in the Covent Garden style; but when seen out of doors in autumn, 7 feet high, in the form of a large shrub, with thousands of monstrous flowers resting on fine broad green leaves, it presents the grandest subject that can be seen in our climate in connection with the flower garden, or decorating the margin of ornamental water, where it is most at home. The propagation of this plant is so simple, and its culture in pots so well understood, that I will not intrude with remarks on anything save what relates to its out-door culture.

It is frequently asserted that the Hydrangea will only succeed in favourable localities near the sea. In the west of England and south of Ireland it may be seen with large shrubs, flowering freely without any protection; but it may also be seen thirty miles inland quite as fine by some attention to culture. The *Hydrangea hortensis* is a wonderful plant to suit situation; it may be seen in monstrous cymes on a wall facing south. On a north wall it will flower equally grand, although not so abundantly; under the branches of trees, on the edge of a pond, or planted on a rock it will flower profusely. It must not be inferred from this that good culture is not necessary; there is no common plant on which high culture will tell more strikingly.

In commencing with young plants, the practice here is to grow them on a bed of loam and peat in a rough state; the plants are planted on the surface, and mulched with rotted dung and watered as frequently as circumstances will permit. The plants are removed and protected in winter until the wood assumes a shrubby character, when they are permanently planted out, or kept in borders, and regularly transplanted to suit requirements.

In a climate where frost would destroy the annual shoots the plants may be taken up and put into any sort of shed with straw, or any other thatch, to keep out frost. In this sort of treatment it is important to maintain the vigour of the plants, and to this end it is necessary, when the plants are laid in, to pack firmly moist earth about the roots. No more trouble will be required until the latter end of May, when the plants may be put into summer quarters, when the weak shoots should be freely thinned out, and the beds well watered. The *Hydrangea* will flower but sparingly if planted deep. Surface-feeding will produce the best result in flower, and prevent the weakly shoots that are sure to come from deep

planting. Our practice here is to top-dress heavily the large plants with rich pond mud about the end of May, and this treatment has lengthened the continuation of bloom. Water is the great element of success in cultivating the *Hydrangea*. In many places where flowers are cultivated that element is scarce, but in special cases deep pits may be dug and filled up with peaty sods or other spongy materials: this has been done here with success. Some of the pits were dug out 6 feet deep, the hole filled in with rough sods, on top of which was put a layer of stiff clay, on which was put a layer of rotted dung, and *Hydrangeas* planted over the surface-level. The object of the pits is to secure uniform moisture. The plants are a large size, and flower to admiration. I have tried with various earths the changing of the flowers from pink to blue. I have found the same result in pure clay, pure peat, and in the simple bodies; experience forbids me giving any decided opinion on this matter. Some of the American varieties of *Hydrangea* thrive well here, and are very beautiful hardy-flowering shrubs. The *Hydrangea japonica* is no use out of doors.—CHARLES McDONALD, Woodstock, Co. Kilkenny.—(*Scottish Gardener*.)

[The late Mr. Donald Beaton told us that "Cuttings of the *Hydrangea* made in February may be made to flower blue or pink at will. If the mother plant produced blue flowers in the former seasons, and you force it in February, cut off your cuttings as soon as they make three joints, and when they are rooted place them in a rich, light compost, say one-half leaf mould or very rotten dung, and the rest of any good garden soil, they never fail to produce pink flowers; whereas, if taken from a pink-flowering parent, and after rooting you grow them in strong yellow loam, with about a sixth part of iron filings mixed with it instead of sand, nine out of ten of them will produce blue flowers. I have proved this over and over again, and have seen it in other hands, but I never could get an August cutting to differ in colour from that of the parent plant. The reason seems to be that the juices of the parent plant have already, by a season's growth, formed the substance, or the organised matter, as the physiologists call it, out of which flowers are produced, so that no after-treatment is able to counteract the effect; whereas cuttings separated from a plant at so early an age as when they only attain a few inches in length, and are then made to grow in iron rust and loam otherwise impregnated with iron, which is well known to favour the production of blue flowers in the *Hydrangea*, the organised matter referred to is formed from juices impregnated with iron oxide, and so produces blue flowers. The intensity of the blue is, I believe, according to the perfect oxidation of the iron. Chalk water never fails to counteract this effect of the oxide on the flowers, as we have often proved here, so that, to give the fairest chance to the experiment of getting blue *Hydrangeas*, I would recommend the cuttings to be taken as early in the spring as possible, to strike or root them in red sand, to grow them in nothing but red loam and iron filings, according to the above proportions, and never to water them but with rain water; but I am not sure whether rusty water from hot-water pipes would not add to the success of the experiment; at any rate this rusty water is not injurious to these *Hydrangeas*. In some parts of the country the natural soil will produce blue *Hydrangeas*, and in such places it is difficult to meet with pink ones; and, what is singular enough, the *Rhododendrons* will flourish in such soil, although apparently devoid of all traces of vegetable matter. There is also a kind of peat earth which invariably turns the pink to a blue *Hydrangea*, but all the peat that we have access to here (Suffolk), does just the contrary."]

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE Junc meeting of this Society was held on the 4th ult., the President, Sir John Lubbock, F.R.S., &c., being in the chair. Count Mniszeck, of Paris, and Messrs. Salvin and Turner were elected members of the Society. Amongst the donations received since the last meeting were the "Transactions" of the Society of Natural Science of Philadelphia, the Smithsonian Institute, the Stettin Society of Entomology, &c., including new Memoirs on the Coleoptera of North America, by Dr. J. Lecote; the "Genera des Coléoptères" of Duval, and the work of the Rev. Hamlet Clark on the Phytophagous Beetles, Part I.

Dr. Wallace, of Colchester, the author of the Society's prize essay on the cultivation of the new *Ailanthus* Silk-worm, just published, communicated a note on the colours of the larvae of that species, and some observations on the new Oak Silk-worm, *Saturnia Yama-mai*, from Japan. Professor Brayley forwarded some extracts from the Report of Consul Zohrab on the trade of Boriánsk for 1865, trans-

mitted to the Foreign Office, and recently presented to Parliament, containing a notice of the ill effects produced by the bite of a large black venomous species of Spider which appeared amongst the Wheat at harvest time, and had bitten more than three hundred persons, the bite being followed by a hard white spot, which, when encaistered, produced a new wound; ordinarily the Spider fed upon Loenests. Mr. McLachlan communicated a note on the cocoon of a species of Caddice Fly (*Linnephilus* sp.), which, although originally formed by the larva beneath the surface of the water, had gradually been raised to the height of 2 feet above it, causing the enclosed pupa to dry and shrivel up, thus exhibiting a fault in the instinct of the larva not often observed in the insect tribes.

Mr. Pascoe exhibited a number of minute Beetles collected by the Rev. G. Bostock, of Freemantle, in Western Australia, chiefly in Ants' nests, several of which are of very great interest, belonging to the genera *Artibeus*, *Anthicus*, *Ptinus*, and a new genus apparently allied to *Pansus*, of which he read descriptions.

Professor Westwood exhibited drawings and read descriptions of some new Goliath Beetles from tropical Africa, chiefly from the collections of Count Muisezek and J. Aspinall Turner, Esq. Mr. Stainton exhibited a specimen of a minute Moth, *Gelechia leucomelanella*, which he had succeeded in rearing from galls found upon *Gypsophila saxifraga* at Mentone in the spring. Mr. C. A. Wilson, of Adelaide, South Australia, communicated a further portion of his notes on the Buprestidae, &c., of New South Wales.

## RAIDS AFTER FERNS.—No. 5.

### HAMPSHIRE.

"WE go to town every year." Yes, in these days one cannot aspire to anything like gentility without the above warranty. One must go to town every year; one must risk one's life in the streets, be stifled in academies, buy "best bonnets" for flower shows and fashionable churches, even supposing one be sufficiently strong-minded to resist opera and ball. Yes, the sacrifice must be made, and the time to offer it on the world's altar is just the very time when nightingales are making the woods vocal with their song, when the trees are robbing themselves in fresh young leaves, and flower after flower peeps up in meadow and copse from its wintry hiding-place. When Nature, in obedience to her Maker, is busiest in decking out her pleasant places for our gratification, we run away from her in thankless indifference, and will not watch her movements or listen to her pure voice.

I usually take my London life very much as I take a tonic—an occasional tea-spoonful in a very large dose of country; and how glad I am to turn away from the dreary round of noise, and bustle, and sin that those great streets disclose none can tell. Each station that places a barrier of so many miles between us is hailed with delight. I look out of the carriage window and nod my head at my old companions of forest and field, as if years instead of days had separated us.

From London, at her busiest and noisiest, I escaped into the bright pure air of Hampshire, the noise of the roll of carriages giving place to the gentle whisperings of the wind amongst Beech and Fir, to which I listen in lazy enjoyment from a hammock slung Indian fashion between trees. Presently I hear the tramp of little feet and the sound of merry voices, together with sundry discordant bells and clappers, and a general shout of "The bees! the bees!" A knowing twist of the hammock, and I, too, armed with a watering-pot and a stick, am serenading a fine swarm, till from a splendid Rose bush they are safely hived in their straw dwelling-place, beneath the friendly shade of a fine *Ailanthus glandulosa*.

What flower shows and morning concerts are to the town, that are bees to a bee-keeping country. No other excitement is needed. Always swarming, or going to swarm, always being hived, or being lost and skirred after, they are the one thought uppermost in men's minds. Even places of worship are not exempt from the prevailing epidemic, for hatless heads and smock frocks peep mysteriously in at half-open doors, beckoning to other smock frocks that rise and disappear with that peculiar noise of clumsy stealthiness that is so dear to Hampshire-loving ears; and after church, mayhap, it is only "the parson's bees as were a-swarming"—an event in which all the community most heartily sympathise. Yet in the very teeth of the bees I had my raid. A few minutes' walk, and I was in Havant "Thicket," sacred at present to Ferns, wild flowers, and adders.

There are a hundred paths leading into the mysterious fastnesses of Havant Thicket, each diverging into the other, till the unwary traveller gets involved in a mesh of thread-like ways that lead him into quags, and bogs, and adders' homes in most uncomfortable fashion. A good hunt in the thicket, how-

ever, is worth all the peril, for it is full of treasures. Here and there I found a space covered with a very small Myrtle-like Willow, with dark shining leaf and woolly catkins, which looked like a bog Myrtle, on which innumerable caterpillars had spun their nests, trailing over the ground. In the neighbourhood this plant is called the "Flowering Willow," and is supposed to be rare; I should (perhaps ignorantly) set it down as the *Salix arbuscula*. Near to the Willow, growing in great profusion, was the *Genista anglica*, its sharp thorns painfully reminding one that it was *anglica* and not *tinctoria*, for which I searched in vain.

Parasitical upon the shrubs we found, but not frequently, *Orobanche rapum*, while growing on every side were *Listera ovata*, *Orchis maculata*, and *Habenaria bifolia*, the latter scenting my Fern-bag with its rich perfume. But not alone did *H. bifolia* scent the bag, for wandering further into the thicket one came on a large bed of Lilies of the Valley!—must I call them *Convallaria majalis*? Yes, I will, for I hold that if none but Latin names were in use for all plants the science of botany would be greatly simplified, and bad memories would not be hampered with two exertions instead of one. At any rate, lying in their greenwood bed there the pure white flowerets were ringing their bells to the wild bees' song, and looking to my mind's eye so like a hundred things they most surely were not, that I could but sit down on the branch of an old tree and hold short speech with them before I dragged them from their lurking-place into the rude gaze of the world.

Not far from the Lily-bed there was a pool bordered with *Myosotis palustris*, while trailing over the Briars was the little *Lysimachia nemorum*, the *L. nummularia* completely covering the ground, though the blossoms were not yet opened. Of the commoner wild flowers, every little nook, every sunny glade, bore bright evidence. In some places the earth was rose colour with *Pedicularis*; in another blue with *Polygala*, while every now and then our crushing feet caused the *Mentha sylvestris* and *Thymus serpyllum* to emit a strong and pleasant odour.

And at last the Ferns! In days gone by I have often said, "Oh, nothing grows in Havant Thicket but *Pteris* (only in disdain I called it *Bracken*); but now I know better, and I look forward to many a successful raid amongst the adders. First, there was *Lastrea montana*, but as I only saw two plants of it during several walks, I conclude that the soil or air of the Thicket is not congenial to it. I wonder if I might here be allowed to enter a trembling protest against this Fern being placed amongst the *Lastreas*, with which it appears to me to have little affinity, its usually naked clusters of round sori pointing rather to *Polypodium*.

Abounding in the Thicket was *Lastrea cristata* var. *spinulosa*, while of *Lastrea dilatata* I saw but very little. *L. cristata spinulosa* is always a trouble to me, and that in many ways. If it be a simple variety of *L. cristata*, having no pretensions to rank amongst species, how is it that it is found growing in profusion where its original parent has never been heard of? If I understand species aright, I shall not be satisfied till the wandering habit of *L. spinulosa* can be explained. Perhaps I may yet find *L. cristata* in Hampshire, or, perhaps, I may live to see *spinulosa* in the family of *L. dilatata*.

In this particular raid I was charmed with the different forms assumed by the *Pteris aquilina*. I found it in its variety *vera*, and in many cases it was also considerably forked, assuming the appearance of *multifida*. Of *Filix-mas* there were several plants of a supposed variety, for which Mr. Wollaston is claiming the honour of a separate place amongst species, under the name of *Lastrea propinqua*. It differs considerably from the normal form of *Filix-mas*, and has many varieties or sub-varieties of its own.

Not far from the Thicket there is a beautiful hunting-ground called the Holt, where noble Beech trees tower towards the heavens, and the earth at their feet is covered with the white blossoms of *Asperula odorata*; where *Digitalis* of the tallest, and *Prim*—(I must say)—roses, of the loveliest abound, and there I found a very curious variety of *Filix-mas*, lax in growth, pale in colouring, and irregular in form of pinnule. I have not yet had it named, for I have yet to prove that I am the first who has noticed it.

Besides the *Lastrea Filix-mas* there are several good varieties of *Athyrium Filix-fœmina* growing in the Holt, and many a beautiful wild plant, I may not stay to enumerate. Even during the time bestowed on the *Filices*, the bees have swarmed for the third time, kettledrums have sounded a retreat, and the scattered forces are dispersed for ever.

From Havant Thicket I passed on to Stoke's Bay, and as I sat upon the beach watching the "Pearl" steaming up and down the Bay, in sight of the fair Isle of Wight, I gathered close by my side the handsome yellow *Glaucium flavum*, *Sedum anglicum*, *Statice armeria*, *Hieracium pilosella*, the silvery *Potentilla anserina*, and many another little flower which gladdened the sandy waste by its bright presence, while the neighbouring corn fields were brilliant with the deep blue of *Centaurea cyanus*, and the fiery *Papaver rhæas*.

I noticed in the hedges *Polystichum angulare*, but I did not make any particular search till I arrived in the neighbourhood of the New Forest, where, in many a grassy lane and sheltered hedge, I knew that I should be rewarded by finding Ferns of many species, and, as I hoped, of many varieties. I remembered how in days gone by, the adders and I had glided in and out amongst Bracken and silvery Birch and Hornbeam, attracted by the same sunbeams playing on our path, and each darting away scared at the other's presence. I remembered the tall *Lastreas* in the Embley Wood, and how I had sat down there on a stile, puzzling with rueful face over different species which to my untutored eyes would not seem distinct. I remembered the deep blue of the undulating distance transformed into liquid light as the rich gleams of the setting sun fell upon it; the sheltered nooks, with the pretty cottage, and the gleeful children playing about the doors; the white bloom of the "merry" trees. I called to mind the tall *Osmundas* of the forest; the green banks of *Asplenium adiantum-nigrum*; the ditches of *Blechnum spicatum*, together with the fair waters of the Rhododendron-bordered lake, where for the first time I had found the bright *Narthecium ossifragum*, and over whose surface, when frozen, I had been many times ignominiously skated in a chair. I knew the home of *Lastrea montana*, and the lanes where *Polystichum aculeatum* would leave no room for *angulare*. I had heard how *Asplenium trichomanes* had gradually retreated from its old haunts to more out-of-the-way localities; so, armed with my trowel and my bag, I had little else to do than to rush off to the different spots, collect what I required, searching as I went for anything new.

I found no *Lastrea cristata* var. *spinulosa*, but I did find a handsome form of *Lastrea*, of which one of our best Fern authorities writes—"This *Lastrea* is one that has puzzled me a great deal, and I have often in the lake district gone up to it believing it to be an *Athyrium*, and then found out my mistake. Whether it is a species or a variety of *propinqua* (I think certainly not of *Filix-mas*), I cannot yet determine. It is deliciously hay-scented, which is different to the other forms."

Of *Athyrium Filix-femina* I found a beautiful variety, in form like *odontomanes*, but more delicately chiselled. I have long cherished a hope that eventually what is now called the variety *odontomanes* may be recognised as a species, and a separate place in Ferndom be assigned to it.

Should my *Athyrium* prove worthy, I shall dedicate it to Miss Florence Nightingale, for it grew where her footsteps must have often fallen as she walked to and fro on her errands of mercy.—FERN-HUNTRER.

## NOTES ON TRUFFLES AND TRUFFLE CULTURE.

BY C. E. PROOME, ESQ.

THE numerous varieties of Fungi that are exposed for sale in the markets of France and Italy must induce a feeling of surprise that so little attention has been paid to their culture by the horticulturists both of Great Britain and the Continent. The Mushroom is the only species at all commonly made use of in this country; the Blewitt may sometimes, indeed, be seen in Covent Garden, but it is a species far inferior in flavour to many others of our Fungi, and it is certainly not the produce of our gardens. Truffles, which are frequently seen, and so highly esteemed in continental markets as to command a high price, are comparatively rarely to be met with in our own, and even Covent Garden can boast but of one native kind, and that an inferior one—viz., *Tuber aestivum*. There are, however, various reasons for this neglect of Nature's benefits that operate with us, that do not apply with equal force to our continental neighbours, such as distressing cases of poisoning from the indiscriminate use of Fungi gathered by persons ignorant of the qualities of the various species, a danger in great measure guarded against abroad by the appointment of an official person capable of determining the noxious or innocent nature of the species brought for sale. What tends, however, still more,

perhaps, to increase our objection to their use, is the natural inaptitude of our countrymen to acquire the art of cookery, which is a very important element in suiting these plants to human digestion; added to which, there is the difficulty of adopting new customs, or changes of diet. Were a taste for these productions, however, once established, we should soon find numerous species brought forward as valuable additions to our means of sustenance.

Notwithstanding that Truffles have been considered articles of luxury, and have commanded a high price from the time of the Romans down to the present, and that it has ever been the aim of horticulturists to bring them into the number of regular garden crops, they seem hitherto to have defied all efforts to reclaim them, and to resemble, in their intractable disposition, the wild ass, "whose house has been made the wilderness, and the barren land his dwellings, who scorneth the multitude of the city, and the range of the mountains is his pasture." If this, then, be a correct representation of their character, it is a question whether it would not be easier to cultivate them by assisting Nature in her own way, than to restrict her within our limits by forcing these denizens of the forest to occupy a place in our kitchen gardens. It would seem, indeed, that the amount of shade they demand is such as to be incompatible with the requirements of a garden. But let us see what has been done hitherto in the various endeavours made to grow Truffles by the assistance of art. And here we cannot do better than give the information with which the Messrs. Tulasne present us in their beautiful work on *Iypogæous Fungi*. They mention four species of Truffles exclusively in use in France—viz., *T. melanosporum*, *T. brumale*, *T. aestivum*, and *T. mesentericum*, of which two, or perhaps three, occur in Great Britain. *Tuber aestivum* is apparently the only species to be met with in a recent state in our shops; *T. mesentericum* may at times occur, but it has not yet been noticed there. *T. brumale*, if our plant is identical with Tulasne's, has hitherto been found in England of too small a size to be worth sending to market. In Italy there are other kinds, one of which, *T. magnatum*, commands a higher price than any other; and in the southern parts of Italy, Sicily, Syria, and Africa, another species, *Terfezia leonis*, is of common use as an article of food.

The true Truffles have rough seeds, which, seen under the older and imperfect microscopes, resembled somewhat a Truffle in miniature, and early writers concluded that the mature plant was merely one of these seeds largely developed in all directions. The Tulasnes have proved, however, by careful observations that they germinate in the same way as do those of most other Fungi—viz., by giving origin to delicate threads, which spread in the surrounding soil, and that from such threads the young Truffles arise, probably after some kind of impregnation, which is as yet, notwithstanding the researches of recent observers, involved in obscurity. The fact of the existence of a mycelium in Truffles, resembling that of Mushrooms, must be taken into consideration in any attempt that may be made to cultivate them.

The soils in which edible Truffles are found in France are always calcareous or calcareous clays, which accords generally with my own experience. *Tuber mesentericum* occurs, however, in ferruginous sands, as is also the case with another species, *Hydnotrya Tulasnei*, which, or a closely allied kind, is largely eaten in Bohemia, under the name of *Czerwena Tartoffle*. Messrs. Tulasne describe the soil of a Truffle district near Loudun, Vienne, as composed of rolled fragments of calcareous matter, mixed with fine quartzose sands, lying on a thick bed of compact marly clay, which easily splits up into thin layers. It contains, in 1000 parts, 500 of calcareous matter, 325 of clay and iron, 150 of quartzose sand, and 25 parts, more or less, of vegetable mould. But they attribute a still great influence in the production of these plants to the presence of trees—a condition necessary perhaps to their growth, in order to keep off the heat of the direct sun-rays. Our authors testify, indeed, that this is not always indispensable; and I have seen Truffles dug up on the bare sloping sides of the Italian mountains.

Some persons have supposed that these Fungi are parasitic on the roots of trees. This the Tulasnes expressly deny, on the strength of observations and inquiries instituted to that end, and I can confirm them in this matter, and would remark that the frequent presence of certain galls attached to the small roots of Oaks, resembling young Truffles so strongly as often to deceive me for a time, may have given origin to this error.

Some trees appear to be more favourable to the production of Truffles than others. Oak and Hornbeam are especially mentioned; but, besides these, Chestnut, Birch, Box, and Hazel are alluded to. I have generally found *Tuber aestivum* under Beech trees, but also under Hazel; *Tuber macrosporum* under Oaks; and *T. brumale* under Oaks and Abbe. The men who collect Truffles for Covent Garden obtain them chiefly under Beech, and in mixed plantations of Fir and Beech. The Truffle-grounds of France are remarkable for the sterility of the surface, the cause of which has given rise to many conjectures—viz., that Truffles exercise a prejudicial influence on all plants in contact with or proximity to themselves, by appropriating their nutriment in a manner similar to the Rhizoctonia; but a more probable reason of this sterility is the frequent digging to which the Truffle-grounds are subjected by the collectors; for, as Truffles are not truly parasitic, it would attribute an inconceivable amount of influence to their mycelium to suppose them capable by its means of destroying all the surrounding vegetation. And we may remark, that some species occur in grassy places, as in the forest of Vincennes, according to Tulasne; and so with *T. macrosporum* and *T. brumale*, as I find them. It seems to be a better explanation of this sterility, so generally accompanying Truffles, that they can only succeed well where they find a comparative freedom from other vegetable growth, arising from causes independent of themselves, and that they are the result, and not the cause, of this sterility.

In common with many other Fungi, Truffles do not bear to be disturbed in their early stages; so that the collectors are careful in their researches after the summer species, as *T. aestivum* and *T. mesentericum*, not to stir the ground more deeply than is absolutely necessary, as by so doing they would destroy the winter crop of the more valuable kinds, *T. melanosporum* and *T. brumale*. Any disturbance of the soil in winter, when the latter are mature, does no harm, but rather aids in their culture, by rendering the mould more suitable for the germination of their spores and the growth of their mycelium. From Messrs. Tulasne's observations it would seem that three or four months suffice for the development of these plants; they state that they have met with *Tuber mesentericum* about as large as grains of Millet in the beginning of October, which must acquire their full size before the end of December; for about that time they find this species in its mature condition alone. And it is supposed that the warm rains of August are highly conducive to the fertility of the Truffle-ground, and that the abundance or scantiness of the crop depends very much on the nature of that period. These plants grow without any special care or tendance; but as they are not unfrequently found, both in France and Italy, on the borders of corn fields, where they are ploughed up in the cultivation of the land, it would seem that they succeed as well in ground that has been stirred and manured as in that which has been left to its natural condition.

Some notion may be obtained of the extent to which the trade in Truffles is carried in France, when we read that in the market of Apt alone 1600 kilogrammes (about 3500 lbs.), are exposed for sale every week in the height of the season, and that the lowest estimate of the quantity sold during the winter amounts to 15,000 kilogrammes (nearly 33,000 lbs. weight). According to another account, the Department of Vaucluse yields from 25,900 to 30,000 kilogrammes annually. The vast quantity that must, therefore, be procured and sold in all the French provinces where they grow, and the large revenue arising therefrom, should be a great inducement to the proprietors of suitable localities to attempt their cultivation in England.

Many trials have been made to subject these vegetables to a regular system of culture, but hitherto without success. We owe to the Count de Borch and to M. de Bernholz the chief accounts of these attempts. They inform us that a compost was prepared of pure mud and vegetable soil, mixed with dry leaves and sawdust, in which, when properly moistened, mature Truffles were placed in winter, either whole or in fragments, and that after the lapse of some time small Truffles were found in the compost. But the result was discouraging rather than otherwise. The most successful plan consisted in sowing acorns over a considerable extent of land of a calcareous nature; and when the young Oaks had attained the age of ten or twelve years, Truffles were found in the intervals between the trees. This process was carried on in the neighbourhood of Loudun, where Truffle-beds had formerly existed, but where they had long ceased to be productive—a fact indicating the

aptitude of the soil for the purpose. In this case no attempt was made to produce Truffles by placing ripe specimens in the earth; but they sprang up of themselves, from spores probably contained in the soil. The young trees were left rather wide apart, and were cut for the first time about the twelfth year from the sowing, and afterwards at intervals of from seven to nine years. Truffles were thus obtained for a period of from twenty-five to thirty years, after which the plantations ceased to be productive, owing, it was said, to the ground being too much shaded by the branches of the young trees, a remedy for which might have been found by thinning out the trees; but this would not be adopted till all the barren tracts called "galluches," had been planted. The brushwood, by being thus thinned-out, would be converted into timber trees, and the Truffle-grounds rendered permanent, like those of Poitou, which are commonly situated under the shade of lofty trees. It is the opinion of the Messrs. Tulasne that the regular cultivation of Truffles in gardens can never be so successful as this so-called indirect culture at Loudun, &c.; but they think that a satisfactory result might be obtained in suitable soils by planting fragments of mature Truffles in wooded localities, taking care that the other conditions of the spots selected should be analogous to those of the regular Truffle-grounds; and they recommend a judicious thinning of the trees, and clearing the surface from brushwood, &c., which prevents at once the beneficial effects of rain and of the direct sun-rays. It is added that this species of industry has added much to the value of certain districts of Loudun and Civray, which were previously comparatively worthless, and has enriched many of the proprietors, who now make periodical sowings of acorns, thus bringing in a certain portion of wood as Truffle-grounds each year. At Bonardeline, for instance, the annual return from Truffles in a plantation of less than half an acre, was from £4 to £5. Another case is adduced in the arrondissement of Apt, where several proprietors have made plantations; the trees are left about 5 or 6 yards apart; and so soon as their branches meet and shade the ground too much, they are thinned-out.

The districts of England especially suited to produce Truffles would thus appear to be situated on the great band of calcareous beds which run diagonally across the island from the south-eastern corner of Devonshire to the mouth of the Wash in Norfolk, occupying all the country that lies to the south-east of such a line, including the counties of Somerset, Dorset, Wilts, Gloucester, Hampshire, Berkshire, Kent, Hertfordshire, and parts of Northampton, Norfolk, and Lincoln; and it is to the proprietors of land in those districts that we must look for any successful attempts to cultivate these Fungi.

A great proportion of the Truffles exposed for sale in Covent Garden comes from Wiltshire and Hampshire, and the opinions of those who make it their business to collect them coincide completely with those of Messrs. Tulasne cited above. I have been informed by one of these men, that whenever a plantation of Beech, or Beech and Fir, is made on the chalk districts of Salisbury Plain, after the lapse of a few years Truffles are produced; and that these plantations continue productive for a period of from ten to fifteen years, after which they cease to be so. It has been observed that the species most available for culinary purposes with us is *Tuber aestivum*, a species considered in France as of far less value than *T. melanosporum* and *T. brumale*; and it might be worth while to obtain well-matured specimens of these species from France, and distribute them while quite fresh in some locality producing our indigenous kinds, to ascertain if we could not thus obtain a superior race of Truffles. *Tuber aestivum* is commonly worth about 2s. 6d. per 1 lb. in Covent Garden, whilst in Italy *Tuber magnatum* fetches from fifteen to seventeen francs, and *T. melanosporum* almost as much. Should horticulturists be tempted to try their skill in the artificial production of these Fungi, they should bear in mind the conditions most suitable to their nature as above recorded. They might succeed, for instance, in producing them in Filbert-plantations or in gardens thickly set with fruit trees; and they should plant mature specimens in well-trenched ground on a calcareous substratum, and be careful not to stir the soil to any depth till the autumn or winter of the following year, in order not to disturb the mycelium; and it would be well perhaps, in case they find a successful result, not to take too largely of the crop the first year or two, but to give them time to establish themselves thoroughly in the locality. It would seem, however, that, when once established, deep stirrings of the soil would tend rather to encourage than to check their increase, as giving the

mycelium a lighter soil in which to vegetate, and preventing the growth of roots of surrounding trees, &c., which might deprive the Truffles of the requisite nutriment.

It might be as well to try the growth of *Tuber macrosporum*, as it is an indigenous species, and might become a source of profit, notwithstanding its garlic odour. Those who possess woods or plantations of Beech in calcareous soils, which are not already productive of Truffles, might succeed perhaps in rendering them so by trenching patches of ground beneath the trees, so as to clear away the brushwood, grass, and roots for a considerable space, and planting ripe Truffles in the trenched spaces, and then allowing time for them to produce their mycelium. And when the roots of surrounding trees again encroach on the selected spots, they might be checked by deep digging around their margins.—(*Journal of the Royal Horticultural Society.*)

## DÉJEUNER AT MR. WM. PAUL'S NURSERIES AT WALTHAM CROSS.

On Tuesday last the Executive Committee of the International Horticultural Exhibition recently held at South Kensington, paid a complimentary and friendly visit of inspection to Mr. Wm. Paul's nursery grounds at Waltham Cross. The gentlemen arrived per train at 11.30—the down mail stopping specially at Waltham station for the occasion. They walked direct from the platform to the nurseries, by a private pathway adjoining the line, bordered with Roses; and were soon admiring the extensive and beautiful collection of flowers and shrubs, which are to be found in vast profusion there. The Roses first attracted attention, the entrance being lined with them, also the edge of the grounds nearest to the railway. These are not only cultivated, but bred by Mr. W. Paul. The Geraniums were next examined with much interest: of these favourite flowers Mr. W. Paul has a new race in Mr. Beaton's stock. While walking up the principal broadway of greenward, the varieties of hardy ornamental-foliaged trees with their purple, silver, and gold leaves commanded much admiration. These in gentlemen's gardens would pleasantly vary the monotony of uniform green foliage: of such Mr. W. Paul has a large collection, we were told the best in Europe. There are Oak leaves almost black, Maple leaves almost white, Spanish Chestnuts of golden hue, and almost every intervening shade of foliage. The fruit trees, especially some fine kinds of Pears, were also particularly noticed; and the visitors were busily engaged examining trees, shrubs, and flowers, until they were called in to partake of a sumptuous breakfast, set out in a conservatory in excellent style by Messrs. Ring & Brymer, of Cornhill.

Mr. Wm. Paul presided: there were also present, Sir C. Wentworth Dilke, Bart., M.P.; Professor Bentley (King's College); Sir D. Cooper, Bart., (late Speaker of the House of Assembly, Sydney); R. Fortune, Esq. (the Chinese and Japanese traveller); the Rev. Joshua Dix, M.A. (Rector of Allhallows, London); the Rev. K. N. Brandon (Incumbent of Waltham Cross); the Rev. J. Paxton Hood; Robert Hogg, LL.D.; Messrs. Thomas Moore, F.L.S., J. Smith, G. Gibson, Wm. Bull, C. Edmunds, R. B. Knight, W. F. Siddall, W. A. Sadler, H. Stormout, T. Rivers, J. Harding, G. Eyles, C. Lee, C. Turner, W. Wakefield, Osborn, Williams, and others.

After the repast, thanks were returned, and

Sir C. WENTWORTH DILKE said, they ought not to separate without drinking the health of their worthy host, Mr. Wm. Paul (hear, hear). They were all deeply indebted to him for his kindness in allowing them to come and have the opportunity of looking over his extensive establishment, and after the kindness with which they had been received he was sure they would all heartily drink to "The health and prosperity of their host and all connected with him" (cheers).

Mr. W. PAUL briefly said he appreciated the honour Sir Wentworth Dilke had done him, and he scarcely could find words to express his gratification to these gentlemen who had done him the honour of coming to Waltham Cross to see his establishment. He knew they set a great value on time, and, therefore, would not say more than to thank them for the kindness with which they had received Sir Wentworth Dilke's proposition.

Mr. W. Paul soon after rose again and said, he had the honour of proposing a toast which he was sure would be received with acclamation. The International Horticultural Exhibition has been a grand and complete success. If they looked for the causes which had contributed to that success, they would find them many and various, but these most vividly before him were the energy, judgment, and administrative skill displayed by the Chairman of the Executive Council (hear). There were already written on his escutcheon the symbolic figures of 1851 and 1862; and to these must now be added a symbol of less magnitude, but not of less beauty, the Horticultural symbol, 1866. He had never worked on a committee where such courtesy was shown by the Chairman to the suggestions of every individual member, and where there was such unanimity of purpose and such a spirit of fairness manifest. Members of the Committee had no difficulty in having their remarks listened to; and the most abstruse suggestions were carefully canvassed to see if there was anything in them. He proposed

they should drink the health of the Chairman of the Executive Committee (cheers).

Sir C. W. DILKE returned thanks, and said the terms in which the toast had been proposed, and the manner in which it had been received were together far greater than were warranted by the small services he had rendered. Had he been aware of what Mr. Paul was about to propose he would have suggested a removal into the gardens; but with reference to the recent Exhibition he had done his best, and he thought that was all any one could do. The Exhibition had been produced by the gardening interests of the country, and all the Committee had to do was to keep it moving, and in a straightforward direction. So many gentlemen had put their entire heart and soul in the Exhibition that it could not help going on—it only required a little guiding now and then. He felt pleased and proud at its success, and as a Horticultural Exhibition it had never been surpassed. He thought it possible that France might profit by what had been seen there, and might, perhaps, equal them in future years. He thanked them for the kind manner in which they had received the toast (cheers).

Mr. W. PAUL proposed "the health of the Treasurer of the Exhibition, Sir Daniel Cooper," and paid a high compliment to him for the financial skill he had displayed. Success in finance, he said, was only estimated by results. The original estimate of the Exhibition was £13,000, but they did not shrink from the risk; they went on, and now they had paid all their bills, and had £3000 still in hand (cheers).

Sir D. COOPER, in acknowledging the toast, remarked that the success of the Show had fully verified the anticipations of those who knew the interest felt in floral exhibitions. He had been accustomed to money affairs for many years: he had done the best he could for the Exhibition, and was amply rewarded for all his exertions by the kind thanks they had given him. He believed the success of the International Exhibition would be a great deal towards the promotion of horticulture in this country (cheers).

Mr. W. PAUL proposed "The health of the Secretaries of the Exhibition, Dr. Hogg, Mr. Moore, and Dr. Masters." Their tasks had not been light; but their aid had been readily, cheerfully, and most ably given.

Dr. HOGG said he had not intended to rise, but Mr. Moore kept making such signals to him, he was obliged to get up and return thanks. If he were to say the duties had been light, he should only mislead them; but to one could tell them better than Mr. Moore how onerous they were, for he had borne the brunt of them all. It was a great gratification to them to know the Exhibition had been successful; and he was sure that the services the Secretaries had rendered had been cheerfully given (cheers).

Mr. MOORE also briefly returned thanks.

Mr. PAUL proposed "The Healths of the Councils of the Royal Horticultural and Botanic Societies." A member of the Council of each Society was present, and they all knew the value of the efforts made by these Societies for the promotion of horticulture. With the toast he coupled the names of Professor Bentley and the Rev. Joshua Dix.

The Rev. JOSHUA DIX returned thanks, and said, as a member of the Council of the Royal Horticultural Society, he felt he was only doing his duty in trying to promote the success of the Exhibition all he possibly could. He hoped a better day was dawning upon the Horticultural Society, and that before long it would attain that proud position in which it ought to be; and if the representatives of the Society would only be kind, gentle, and unanimous in their requirements, he saw no reason why it should not be one of the finest horticultural societies in the world.

Professor BENTLEY returned thanks on behalf of the Royal Botanic Society.

Mr. PAUL proposed "The Provincial Press," and the health of a gentleman present connected with one of their papers—Mr. Pollard, of the *Herts Guardian*.

Mr. POLLARD returned thanks.

Sir D. COOPER said they had drunk the healths of the Chairman, of the Treasurer, Secretaries, and others; but there was one without drinking which they ought not to separate. It was those who had made the Exhibition successful—"The Visitors." It was clear that this Exhibition of flowers had reached the hearts of the people, and it was a fact that the Horticultural and Botanic Societies would not fail to remember. It showed that the people could appreciate the beautiful collections lately exhibited, and with the toast he begged to give the name of Mr. Wakefield.

Mr. WAKEFIELD, in reply, said the public were really the parties who had most gratification in the matter. The poor had paid their shillings, the rich their higher entrance fees, and all had been amply rewarded by viewing the beautiful and splendid collection gathered together (cheers).

Sir C. W. DILKE said the gentleman who spoke last was a very valuable person—he represented the £15,000. When the project first started some said they would all be ruined. But he knew something of the class of persons who would come, and was not in the least alarmed, though he did not expect it would turn out quite so successful as far as £ s. d. was concerned: and there again he had to thank Mr. Wakefield and the fifteen-thousand pounders (laughter). But they ought not to forget after all a class to whose efforts they might chiefly attribute the success—he meant the Exhibitors. He therefore proposed their healths, and coupled with the toast the name of Mr. Turner.

Mr. TURNER said he thought Mr. Lee ought to return thanks. Mr. Lee had done very much for the Exhibition, and deserved their thanks; for what he himself had done he had already been rewarded, in obtaining a considerable number of prizes. The exhibitors had worked hand and hand together, and there had been no jealousy, and that was the chief reason of their great success (cheers).

Dr. HOGG said he was sorry to trespass on their time, but there was one other toast to propose. They had drunk the healths of the Committee, Treasurer, the £15,000 men, and others, but there was still one to name, whose efforts would bear comparison with those of any other; he meant Mr. Gibson, architect of the Exhibition (cheers). He had brought an amount of talent and genius to bear on the design for the Exhibition, such as he never knew brought to bear in any similar manner before (cheers). But it was not merely the labour, and skill, and genius which Mr. Gibson had given towards the work, the time and trouble he had bestowed on it were such as he could not express, and they could not imagine. He was there at all times and in all weathers; to him they were mainly indebted for its grand success, and he felt it equally an honour as a pleasure to propose his health (cheers).

Mr. GIBSON was loudly cheered on rising. He said they had done him too much honour, and he felt he was not deserving of it. It had been a labour of love to him, and if he had really contributed towards the success of the Exhibition, the knowledge of that fact was a sufficient reward (cheers). But he had valuable assistance in his son and Mr. Eyles, and it was a happy hit the adapting their plan to the requirements of the Show.

The Rev. J. DIX proposed "The health of Mrs. Paul" (loud cheering, amidst which Professor Bentley proposed to include Mr. Paul's juvenile family).

Mr. PAUL briefly returned thanks.

Mr. FORTUNE proposed "The health of the Building Committee and Mr. Lee" (of Hammersmith).

Mr. LEE acknowledged the toast.

Sir C.W. DILKE at some length eloquently expressed his sense of the obligations owing to Dr. Hooker for the very kind and valuable aid he had rendered.

Mr. SMITH, Curator of the Royal Botanic Gardens, Kew, returned thanks for Dr. Hooker, and said his humble efforts would always be at their service in case of a similar exhibition.

W. A. SADLER, Esq., proposed "The Ladies," who had brought the beauties of nature to vie with those of art at their recent exhibition (cheers).

After a few humorous speeches the party broke up.—(*Herts Guardian*.)

## LIBERALITY IN GARDENING.

In this art "it is the liberal hand which maketh rich."

Liberality in providing implements is the saving both of time and labour. The more perfect his instruments, the more profitable are they.

Liberality to the earth, in seed, culture, and compost, is the source of its bounty. Thus it is in horticulture, as in every part of creation, a wise and paternal Providence has inseparably connected our duty and our happiness.

In raising domestic animals, the condition of man's success is kindness and benevolence to them.

In cultivating the earth, the condition of man's success is his industry upon it.—**JOSIAH QUINCY.**

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

PERSEVERE in hoeing and forking up the surface of the soil in every department, it is the groundwork of success. *Broccoli*, let there be no delay in planting out a good breadth of White and Purple Cape, also Cauliflowers and Grange's Early White Broccoli, which if true is invaluable late in autumn. Trench up and fill with these kinds of crops every space as the early crops go off, not one vacant spot or corner should now be left uncropped. *Cauliflowers*, break down the leaves over the most forward, and afford a good supply of liquid manure. *Cucumbers*, see that these and Vegetable Marrows do not want for liquid manure and water; peg down the bines as they advance, and attend to stopping. *Endive*, a full sowing may now be made for the main crop, and any beds already sown had better be thinned out, and the thinnings transplanted. For our own part we do not recommend early sowing, because we consider Lettuces much superior for every purpose for which *Endive* can be required at this season, and, therefore, never sow until all danger of its running to seed is over. The Small Green Curled is the hardiest for winter use, but for the autumn crop the Large Green Curled is a splendid sort, planted in very rich soil at 2 feet apart each way. This sort will not bear severe

frost, nor does it keep in store so well as the Small Green Curled, and, therefore, for all late purposes the latter should only be sown. The Large-leaved Batavian is also a useful variety. Where *Chicory* is in request for salads, now is the proper time to sow it. *Herbs*, take the first opportunity as soon as the various kinds are sufficiently advanced to cut a portion for drying; the best time is as soon as the blossoms are expanded, because they are then the most aromatic. It is hardly necessary to add that they must be cut when perfectly dry and dried quickly in the shade. *Lettuces*, tie up for blanching, and make successional sowings. Sow *Radishes* and other salading for successional. *Scarlet Runners*, make the last sowing, and give those advancing a little assistance in training them up the stakes. Thin, earth up, and stop advancing crops of *Dwarf Kidney Beans*, and sow the latest successional crop. *Spinach*, keep up the sowings. *Tomatoes*, nail those that are planted against walls, and stop their shoots where they are growing strong.

### FRUIT GARDEN.

The season being what is called a very growing one, increased diligence must be exercised in keeping all young wood properly nailed to the walls, to guard against the effect of high winds. Gooseberries and Currants trained against north walls should have the leaders nailed in, and all side offshoots spurred down to within a few joints of the base. Peaches, Nectarines, and, indeed, wall trees in general, will be greatly benefited by occasional strong syringings, whether infested with aphides or not, because independently of washing away all filth, which of itself is beneficial, it disturbs and routs out woodlice, earwigs, and other vermin, which are sure to congregate amongst the shreds, and at the back of the shoots, and which, if left undisturbed, will tell a tale by-and-by. Strawberries are now abundantly repaying those who have bestowed a reasonable amount of care in their cultivation, without which no good results can ever accrue. Let them be kept well gathered as they become ripe, as if left on they retard the swelling and ripening of those remaining. Continue the thinning of Grapes, and keep the growth judiciously stopped.

### FLOWER GARDEN.

Cuttings of Roses (where they can be obtained), may now be taken, and planted in a close, cold frame in a northern aspect. In about a month they will have shown a disposition to strike root, when they may be taken up carefully, potted, and plunged in a slight bottom heat. Treated thus they make nice plants in a short time, and if kept under slight protection during winter, will fill their pots with roots, and be ready for planting out next May. Now that the hedging-out stock is fairly cleared off, and growing freely in its summer quarters, there will be more space and time to attend to the propagation of favourite hardy plants; and no time should be lost in putting in a good supply of cuttings of such as it may be thought desirable to increase, for the propagation of the hedging-out stock for next season will soon require attention. Sow Brompton and Queen Stocks for spring flowering, selecting for them a piece of light rich soil, and never letting the surface become dry until the plants are well above ground, for there is no time to be lost if these are to be had strong for blooming next May, and at that season we have nothing more beautiful or half so fragrant as well-grown plants of the latter. Attend to the tying up of Hollyhocks and Dahlias. Reduce occasionally some of the blossoms in the bud state, on some of the very free-flowering Perpetual Roses. It will cause them to keep longer in bloom. Let gross shoots on fancy Roses be pinched when a few eyes long, after the manner of fruit trees.

### GREENHOUSE AND CONSERVATORY.

Contributions from the stove should still assist the ordinary stock in maintaining the gaiety of the conservatory. The removal of some of the larger specimens from the stove will afford much useful space for the young and delicate portion of the stock, which should now be sifted and otherwise encouraged. Where stove and greenhouse plants afford suitable cuttings, propagation may still be pursued, as, generally speaking, it can be practised with greater success in the early than in the latter part of the year. It should be remembered that the propagation of most plants is facilitated by the employment of bottom heat and bell-glasses. It will be necessary frequently to look over greenhouse plants plunged out of doors, to check the havoc of worms and the robbery of weeds, and attend to their security from the effects of high winds. The Camellias and Azaleas for early flowering will have set their buds, and should be removed to a sheltered shady situation out of doors; for if

kept in heat they will be apt to make a second growth, which must be avoided, as it prevents their flowering so freely as would otherwise be the case. Give every possible attention to plants for autumn and early-winter flowering—as *Lilium lancifolium*, *Chrysanthemums*, *Salvia splendens*, *Globe Amaranths*, tree *Carnations*, *Scarlet Geraniums*, *Cinerarias*, *Gesneras*, *Begonias*, *Euphorbias*, &c. Let these have plenty of pot-room, good rich compost, a moist atmosphere, and plenty of space for the perfect development of their foliage, regulating the temperature according to the nature of the plants, and they will make very rapid progress. *Selago distans* is an exceedingly useful winter-flowering plant, requiring merely a cold pit to grow it, and flowering through a long season; but we have nothing that surpasses the *Epacris*, the winter-blooming *Ericas*, and the *Cytisuses*. Among comparatively modern plants *Sericographis Ghiesbreghtiana* is really good for the decoration of the conservatory in winter, as also the blue *Conoclinium*, and the singular-looking *Thyreacanthus rutilans* is first-rate for a rather warm house, but it is not generally found to answer for winter use in the conservatory. The atmosphere of plant-houses can hardly be kept too moist at this season, but it is easy to err in the opposite direction: therefore sprinkle every available surface frequently, and syringe growing stock lightly twice a-day during bright weather. Avoid a too free use of shading, and ventilate freely in order to secure compact growth. Herbaceous *Calceolarias* which have done blooming should have their flower-stems removed forthwith, and the plants should afterwards be placed in a shady situation under the protection of a frame. Take care that they are perfectly free from insects; and to keep the thrips, which is a deadly enemy, at bay, fumigate the frame about once a-fortnight with tobacco.

## STOVE.

Many of the basket *Oreolids* will soon be protruding their roots through the moss or soil, and a little additional fibrous peat or moss should be added in due time. Stove stock in general will gain some more room by the removal of large specimens into the conservatory or greenhouse. Let young growing things be stopped in due time, and keep up a moist yet free atmosphere.

## PLANT-PITS OR FRAMES.

These will require abundance of air and the most careful watering daily. Some of the delicate stock will at times require shading through the middle of the day, especially where unplunged.—W. KEANE.

## DOINGS OF THE LAST WEEK.

VERY hot drying weather, preparatory, we expect, to another thunder-storm; but meantime, in the brightness of the sun very trying to newly planted things, and causing many plants pretty well established to hang their heads.

## KITCHEN GARDEN.

Delayed putting out *Celery*, but got the beds ready; and as the large fine plants are as yet doing no harm to each other, they will suffer little from transplanting with large balls. Prepared ground for Winter Greens and Coleworts, but will wait for duller weather before planting, more especially as there is so much besides to do, and we would rather lessen the labour of watering as much as possible. In fact, we are not so forward as we would wish a good many of our readers to be, and have been obliged to do many things by snatches, which it would have been truer economy to have finished at once.

Here is one of the great differences between a gentleman's gardener and an artisan. The former must often do merely a portion of a job to serve its turn in the meantime, when the finishing it off and letting other things wait would be the most economical as respects labour; but then in the jarring of interests, and each interest calling out to be first served, the wholly-finishing process would often interfere with the question of supply and demand. This, too, is often forgotten when comparisons are instituted between gentlemen's gardens and market gardens. In the former a great supply of any one thing at once is often tantamount to so much waste, and induces at least a feeling of satiety. In the other case so long as there is a market it signifies nothing, unless it be more advantageous that a great supply should come in at once, and the ground be thus cleared for a future crop. The cultivating of so many acres, in acres of this and acres of that, and the cultivating the same number of acres in merely poles of this and quarter rods of that, to come in in regular succession to each

other, presupposes a very different affair as respects even the labour involved. In the first case, merely as abridging labour and clearing the ground, there can be no question as to the economy and profit when a suitable market is to be found. As little question can there be of the advantage of the gentleman's-garden plan, where a constant supply, and not a glut at any one time, is required. Possessors of gardens are apt to say that they can purchase cheaper than they grow, and this is very likely, and on the simple principles alluded to above; but they should recollect that in the country they could not so purchase at all without considerable additional expense in the way of carriage, and the further from the market the greater would be the uncertainty of getting served with what they want, and the greater certainty of being served with stale produce instead of fresh. Every possessor of a garden ought, besides, clearly to understand that it is very different as respects labour alone to grow only one crop on an acre of ground, and in a space of the same extent to grow a score or a hundred. The freshness of the produce and the regular succession do and ought to constitute the most valuable returns from a gentleman's garden.

A correspondent tells us that some gentlemen far north, when they go to London, visit Covent Garden two or three times a-week, and send an account of all they see to their gardener, with his couple of men, and wonder why they cannot have such things, and as early. The articles referred to they give no means for forcing, and yet those they had seen had either been forced, or at a later period brought by steamer from the north of Africa, the south of France, the Channel Islands, or the south of Devonshire and Cornwall. It would be a good thing if such observers would do more than observe, that they would purchase at an early period, and the lesson might not be quite forgotten. We recollect a case in point. What seemed a basket of very early Cherries, was taken hold of, and was to be made much of in the way of joggling up the county folks, where the trees were scarcely out of bloom, and as there were ladies in the case, the price for once was not allowed to be a matter of moment. We were told in confidence afterwards, that instead of a little basketful there was only one layer, and that each Cherry cost nearly a shilling. The same person was "done for" with a basket of nice Strawberries, which he presented to a lady, but there was something like an appreciation of his gardener which he had never felt before, when the bill for the nice basket was handed in, and he paid 4s. 6d. per ounce for them. It ought to be clearly understood, that no single garden can ever equal Covent Garden, where are collected the produce of thousands of gardens, and from great varieties of climate at home and abroad; but a knowledge of Covent Garden prices, and especially for early productions, would often do much good, and make the country garden more valued, merely in an economical point of view.

Had enough of ground trenched and dug to sow some more Peas, Dwarf Kidney Beans, and Turnip Radishes, and used the tops of *Celery* trenches for planting out Peas from semi-circular drain tiles, after they were sufficiently high for the pheasants not to meddle with them. These, when well watered and staked, had the ridge covered over with old stubble and short grass, to keep the heat and dryness out, for the ground is now quite hot enough for Peas. The last sowings will consist of such kinds as *Dickson's Favourite*, *Maclean's Advancer*, to be followed by a few of *Sangster's*, and probably *Tom Thumb*, under protection. Cauliflower stands the hot days rather badly, though all crisp and erect enough in the morning; and to save watering placed some litter, long dung, and grass, all over the quarter, to keep the fierce sun off the ground. If we have a thunder shower by or before Sunday, the virtues of the mulching will increase the vigour of the plants. This mulching alone enables the plants to stand well, even in the bright sun. When the leaves hang wetted for two or three days, the flower or head of young plants is apt to button prematurely, and either a small or a scattered head, instead of a large close one, is the consequence. If the bright weather continue we shall be obliged to shade Lettuces even on sloping north banks. This is a substitute for watering, and takes much less time.

Took the chance to have a general hoeing of weeds, the late warm rains having caused them to grow with great rapidity. Thinned before the ground became hard most of the spring-sown Onions, and pricked out some as previously detailed. We could not find time and opportunity to transplant in spring the Onions sown in autumn, and they are not so good in consequence. We have uniformly found that such Onions as were transplanted early in spring made better, larger, and firmer

bulbs than those left in the ground without moving them, partly owing, we believe, to the necks of the bulbs getting too deep. See last week as to transplanting.

FRUIT GARDEN.

In addition to thinning fruit, watering, syringing, &c., the chief work here has been gathering green Gooseberries for jam which some prefer to that from ripe fruit, and protecting by every means in our power Cherries and Strawberries from birds. Will any one tell us of a sure, and simple, and expeditious mode for thinning by poison myriads of sparrows? We have a great dislike to have anything to do with tasteless inodorous poisons—as arsenic, &c. We tried a little nuxvomica boiled, and steeped a little Wheat in it, but according to our preparation the sparrows only enjoyed the feed. Of course, we would have placed it where no domestic animal, pheasants, &c., would be likely to get at it. We threw a handful of our stuff near some Peas, and there a score of sparrows were at it in two minutes. We should not like to use anything that would not be quick in its results. There is something horrible in the idea of keeping any living thing in torture. It is next to impossible to fix net in such a manner that they cannot get through it or under it. Pieces of white paper suspended from strings will keep them away for a little, but all these contrivances only act until the birds become used to them. We once had a very alarming guy that put himself into all sorts of fierce positions, but though he awed for a short time as a deterrent to evil doers, ere many days elapsed the sparrows in their impudence used his head as a flirting rendezvous.

After such warm days gave the orchard-houses an extra syringing of the cleanest water we could. We can scarcely obtain any water that does not leave a sediment on the foliage when very freely used. Threw a little whitening water over the glass of the Peach-house, and over pits and frames, to prevent the sun acting too powerfully. Thinned out shoots in Fig-pit, and shortened those showing the second crop. The early Figs have just the weather they like, if the fruit is protected by a thin layer of leaves from the fierceness of the sun. Proceeded with thinning Grapes in dull mornings, and here, too, left a good shade of leaves between the glass and the bunch. A dense shade would be prejudicial, but under a moderate shade the berries swell and colour better than when almost exposed to the sun's rays. The finest shining blue-black we ever saw on a Hamburg, was a bunch against a wall, and to see it you had to move aside the foliage in front of it. On the open walls, and even in some of the quarters, owing, we presume, to the sudden heat, honeydew is appearing on fruit trees and bushes, and is almost sure to be followed by insects if let alone. Nothing is more effectual than a good slushing from the engine with clear water, or water clear after having a little quicklime dissolved in it. The successions of heats and colds have been sudden. Within a space of a few hours we have had hoar frost and then a roasting heat, and these sudden changes are hurtful to vegetable as well as animal life. In a moderate degree, a considerable difference in temperature gives a robustness to vegetable life. For instance: night being the period of repose, provided the temperature changes either way gradually, and there is no close moist air to do the mischief, many plants that require a high temperature to bring them to perfection, will do much better in a temperature from sunshine during the day of from 85° to 90°, and allowed to drop to from 55° to 60° at night, than if kept up artificially to the exciting temperature of 70° in darkness.

Here we find we had forgotten to put two little matters in their proper place. First, as respects the giant and the different kinds of small *Rhubarb*. As we sent in large *Rhubarb* for preserving, and the weather, too, being hot, we thought we might as well have a stewing of *Rhubarb*, as with its general accompaniments it is more palatable than the druggist's *rhubarb* take it how you will. Well, somehow the huge *Rhubarb*, grand to look at, did not quite remind us of the flavour of the *Rhubarb* of old times, so another day we had a dish of the small *Rhubarb*, the stalks about the size of our thumb, and there seemed no comparison, the smaller being so much richer in flavour, in colour, and so much firmer in texture. Long ago we used to grow Buck's Early Scarlet, or early something. Why, a pudding or a tart of that little old sort looked almost as tempting as a dish of finely coloured Nectarines stewed as a tart. This seemed to be one of the instances in which great increase in bulk is anything but all gain, and is a sort of corroboration of the old proverb, which our six-foot men will be slow to believe, that what is very valuable is generally held in little room.

The other matter referred to a letter from a correspondent, stating that his *Mushroom-bed*, bearing well, was sadly troubled with slugs, snails, and little worms; that he had resolved to stop them, and had watered heavily with lime water, but that what Mushrooms he had in crop were becoming like so many pieces of leather, and no more seemed to be coming, and he wants to know what to do. Well, we fear he must make a new bed as soon as he can. As a chance he might sweep the bed clean of all the Mushrooms up, and if the bed be not very wet water with clear water, to get the quicklime away from the spawn. If that has not been much hurt with the lime water, the Mushrooms will yet rise and come all right; but if the watering was heavy enough to soak whilst at all acrid the spawn, the bed will do no more good. We do not think that calcareous soil, or mild lime or chalk in the soil, would have the least prejudicial effect, but quicklime is the bane of the *Mushroom*, and all the fungus tribe to which we ever applied it. We have seen fairy rings that spread outwards and outwards for years, longer than the recollections of the oldest inhabitants, arrested in their course of taking fresh leases, by a plentiful dressing of quicklime. It quickly arrests the spreading of some troublesome confervæ in pits and pots, and may be relied on as an antagonist, and not the friend of the whole fungus family.

We have made a shallow bed for Mushrooms in a shed, which is now nearly fit for spawning. Just as last year, part of a bed that bore all last summer, and had been neglected in winter, has been bearing again for two months, and is even now covered, whilst the beds in the house made of better stuff in winter are quite exhausted. We believe that in most cases where failures occur, it is from mistaken kindness, or from too great anxiety in preparing the materials. The most of this bed in the shed was made of litter and stubble, with a casing of several inches of droppings on the surface. The richer the materials at this season, say nearly all droppings, the longer must you wait before it will be fit for spawning. Now is a good time to make spawn, the bricks or cakes will dry so soon.

ORNAMENTAL DEPARTMENT.

See previous weeks as to syringing and watering. We have merely syringed the last-planted beds as yet, and do not wish to water if we can help it, as there is plenty of routine to go through without that. It is well to have a reserve-bed of Asters, &c., which lift with nice balls. Even *Chrysanthemums* may yet be planted out. Now is a good time to bud *Roses*. *Hollyhocks* must be secured from the wind. Cuttings of *Pinks* may now be inserted under a hand-light, and of many other spring-flowering plants as previously alluded to. Many bedding plants not used may now be potted and kept in reserve and for autumn blooming in-doors as wanted. *Cinerarias* planted out need plenty of water, to enable them to throw up strong suckers for potting; seedlings need potting off and pricking off, and so do lots of *Primulas*, of which one can hardly have enough in winter, as if kept in small pots they do so admirably for filling inside little vases, never suffering from the moving. Cleaned *Azaleas*, potted *Balsams*, packed basket *Orchids*, &c., and kept all plant-houses with stages and floors sprinkled with water frequently to moderate the heat and dryness.—R. F.

COVENT GARDEN MARKET.—JUNE 30.

CHERRIES are now coming in from open standards, from all the chief fruit-growing districts, and we have an excellent supply of *Strawberries* and *Gooseberries*. Hothouse fruit is also abundant, and prices are receding. The Potato trade is good for all first-class sorts. Arrivals from the Continent are heavy: comprising *Cherries*, *Apricots*, *Melons*, and two or three varieties of common *Plums*.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

CINERARIA SEEDLING (*Bertha*).—The flowers were dried up as if they had been put into an oven. Flowers should be sent in a box which cannot be destroyed by the post-office punch, and between layers of damp moss.

PEAS MILDEWEED (*Gregory*).—The Peas are mildewed. Mulch over the roots, and water plentifully every evening whilst dry hot weather lasts.

WORK ON GARDENING (*H. W.*).—"The Garden Manual" will suit you. You can have it free by post from our office if you enclose twenty postage stamps with your address.

VARIETY OF BEECH (*Lady King*).—It is the crested variety of the common Beech, and is called by botanists *Fagus sylvatica cristata*.

LADY DOWNE'S GRAPE (*Iago*).—The berries are very severely spotted, "the Spot" being the name by which gardeners distinguish the disease. It is an ulceration caused, we believe, by the roots not being able to supply sap sufficient to sustain the rapid development of the plant and its fruit. Keeping the roots warmer and moister by means of weak manure waterings, and the head of the plant cooler and drier, are the remedies suggested. The *Euphorbia* was smashed.

AMARYLLISES (*J. S.*).—The *Amaryllis belladonna* will only grow in autumn and winter, and there should be no attempt to make it grow now. *Formosissima* has a good deal of the same habit, but may be forced into growth when rested. The other kinds, we presume, belong to *Hippeastrum*, and are more under control than *A. belladonna*. All that have gone to rest leave alone, keeping the soil neither moist nor dry until they begin to grow, then water and encourage. Those growing now encourage with all the light possible and plenty of water, and refrain from watering as the leaves get a little yellow. When they start after resting they will show bloom. The greenhouse one to which you allude we presume is the *Vulturna purpurea*; that should never be quite dry.

MUSHROOMS IN ORCHARD-HOUSE SOIL (*Orchard*).—A few Mushrooms would do no harm, but in such quantities as you mention they will injure the roots of the fruit trees. You introduced the spawn in the manure from the brewery. The best plan is to strew the ground over with quicklime and water, or you may use lime water by putting a bushel of quicklime to a hogshead of water.

STEPHANOTIS FLORIBUNDA PRUNING (*C. M. Major*).—The long twining shoots ought not to be stopped but trained at their full length, and not too closely together, so that the wood may have the full benefit of light. All pruning should be confined to cutting out the old weak shoots. The main point to be attended to is to secure a good growth and thorough exposure afterwards to light and air, with a diminished supply of water at the root, and corresponding dryness of the atmosphere.

ORANGE TREES UNFRUITFUL (*Idem*).—Your plan of stopping the Orange trees is wrong, as they flower from the uppermost eyes of the shoots. If you cease to stop them (for which there is no necessity unless the head is thin), keep the heads thin so that light and air may be admitted to every part, and grow the trees in a light airy house. We think that yours, like ours, will produce a profusion of blossom and too many fruit by one-half. Whilst growing keep the trees well watered and syringed, and in winter do not overwater, keeping them just sufficiently moist to preserve the foliage.

MIGNONETTE CULTURE (*A. S. W.*).—We shall shortly give particulars of its culture, both in pots and in the open ground.

RED SPIDER (*M. D.*).—We regret having overlooked your communication. We are making inquiries, and will publish an article on the subject shortly.

SHADING CALADIUMS AND FINE-FOLIAGED PLANTS (*Dumbartonshire*).—*Caladiums* and all plants, whether requiring shade or not, are best grown near the glass, but not nearer than from 9 inches to 1 foot. On very bright days they require partial shade from 9 A.M. to 4 P.M., as their beauty is thus much prolonged; but the more light a plant has the more bright will be the colour of the foliage of whatever shade that may be and to some plants it is absolutely necessary to bring out the colour of the leaves, as, for instance, in the case of *Crotons*, *Dracænas*, *Pandanus*, *Yuccas*, &c. Exposure to the full sun is injurious in the case of other plants, for instance, variegated-leaved *Begonias*, *Ferns*, &c. Not knowing what plants you possess we can only generalise; but if you send us particulars we shall be happy to help you further.

CLIMBER FOR GREENHOUSE (*E. H.*).—It is difficult to say which is the best climber for a greenhouse. We give you the option of deciding, and name three: *Lapageria rosea*, *Mandevilla suaveolens*, and *Habrothamnus clegans*.

PLUM TREE LEAVES BLIGHTED (*W. J.*).—The blight on the sprigs of the Plum tree is caused by a species of aphid, which you will find in the curled portion of the leaves. Your best remedy will be to shorten the shoots to four leaves, and syringe the trees in the evening with water in which soft soap has been dissolved at the rate of 2 ozs. to the gallon. This, applied on alternate evenings with pure water, will soon clear the trees. Treat the Apple and Cherry trees in the same way.

BRUGMANSIA SCAEVOLENS LEAVES FALLING (*H.*).—The old leaf sent is exhausted by red spider, and the young leaf is also attacked. Forcibly syringe the foliage on the under side with water twice a-day, morning and evening, and every other evening employ water in which soft soap has been dissolved at the rate of 1 oz. to the gallon, not stronger. Keep the plant well watered at the root. Use the soap solution twice or thrice, or until the spider disappears, then discontinue it, but still syringe morning and evening with water only.

SELECT PERENNIALS (*H. B.*).—*Agrostemma coronaria*, rosy crimson, 2 feet; *Lycnis Haageana superba*, orange, 2 to 2½ feet; *Tritoma uvaria glaucescens*, orange scarlet and yellow, 3 feet; *Spiraea filipendula plena*, white, and sweet, 2 feet; *Tritonia aurea*, orange yellow, 2½ feet; *Lythrum roseum superbum*, rose, 2 feet; *Phlox*, herbaceous in variety; *Lilium Brownii*, white, 2½ to 3 feet; *Geum coccineum grandiflorum*, 2½ feet, crimson; and *Delphinium belladonna*, sky blue, 3 feet. If your soil is cold, then in place of *Tritonia aurea* have *Oenothera Lamarckiana*. All are summer and autumn blooming.

MAKING WATER SOFT (*Idem*).—We have found no plan better for softening hard water than exposing it for a few days to the atmosphere. The water not only becomes less hard, but is aired and warmed, and is in every way better for watering plants than water from a well or spring.

AVOIDING DRIP (*Anti-drip*).—We find this best prevented by double glazing, which, though rather more expensive at first, effects a great saving of fuel, so that it is a cheaper plan in the long run than ordinary glazing.

VINE MILDEWEED (*Subscriber*).—The leaf sent was severely infested with Oidium, or Vine mildew, in its worst form. Dust the mildewed leaves with flowers of sulphur, and in a few days syringe the sulphur off. If the mildew reappear, thoroughly dust the parts affected immediately with flowers of sulphur.

SELECT GERANIUMS FOR BEDDING (*E. H.*).—Christine, pink; Helen Lindsay, rosy pink; Stella, dark scarlet; Spitfire, scarlet; Tom Thumb, scarlet; Cybister, scarlet crimson; Lord Palmerston, deep crimson; Attraction, bright scarlet; Paul L'Abbé, salmon; Madame Vancher, white; Woodwardiana, carmine; and Scarlet Globe. Of variegated Geraniums, Golden Chain and Gold Leaf of the gold-edged; Bijou, Alma, and Shottesham Pet of the silver-edged sorts, Manglesi being one of the oldest and most useful of that section; and Argus and Mrs. Pollock of the tricolor sorts. All are good bedders, but they are surpassed by others for pot culture, of which we give names of a few: Blackheath Beauty, salmon; Rebecca, cherry; Mrs. Wm. Paul, rosy pink; Lord Chancellor, salmon pink; Tintoretto, rose suffused with pink; Eclipse, scarlet; Herald of Spring, orange, tinted cerise; and to these you may add the preceding, except the first, they being attractive in pots. Variegated for pots: all those named, and Burning Bush, Sunset, Calford Beauty, Italia Unita, Mrs. Benyon, Red Rover, Honeycomb, and Fontainebleau. If too many are named, select what is required according to the colour, one or more of each.

SELECT VERBENAS (*Idem*).—Purple King, purple; Ariosto Improved, mulberry; Firefly, scarlet; Magnifique, crimson; Géant des Batailles, deep crimson; Melindres splendens, dazzling scarlet; Mrs. Holford, white; Crimson King, crimson; Beauty of England, white; Isa Eckford, puce; Celestial, blue; and Garibaldi, purplish rose, white centre.

BEST WHITE EDGING PLANT (*Idem*).—*Cerastium tomentosum* is usually preferred as a white edging plant, for it is so easy of management, may be cut into any form, and is so dwarf, compact, and neat.

OLD EXPOSED GUANO (*H. B.*).—The guano which has been in an open box for two years would still do some good; but it never was pure guano, but mixed with a large quantity of sand.

WHITE BEDDING PLANTS (*Idem*).—There are no really good white-flowered bedding plants except *Verbenas*, and of these *Beauty of England*, *Mrs. Holford*, and *White Lady* are the best. To make up for this deficiency in white-flowering plants, we have for edgings *Cerastium tomentosum* and *Eibensteinii*; for rugs of white in beds, or lines in borders, *Centaurea candidissima* and *C. ragusina*, also *Cineraria maritima* and *Gnaphalium lanatum*; *Salvia argentea* for a back line or centre to a bed; and *Stachys lanata* for a silvery carpet under trees, or where few things would grow.

NEWLY-PLANTED VINE (*Delta*).—We are inclined to think that your Royal Vineyard Vine is not doing well in consequence of the early planting, and allowing four bunches upon it when, as we presume, it is a weak Vine. Then your allowing it to produce two canes weakens it still further, and yet we think it is doing fairly, and would have done well had you cut it in closely to two eyes, and not allowed it to carry any fruit this season. As a late Grape the Royal Vineyard, like many others, is rather impatient of early forcing, and then, though not a bad setter, the berries do not stone, and only attain about half their usual size. We have had no complaints of this, nor of its being a weak grower.

PEACH LEAVES PERFORATED (*Idem*).—The Peach leaves sent are eaten by some grub, which you may find on looking under the foliage towards dusk. A good syringing on one evening with a solution of 2 ozs. of soft soap to a gallon of water, and with clear water on the next, will do much to keep the tree free of the grubs and other insect pests. Three syringings of soap solution will be sufficient, but the syringings of water cannot be too frequent so long as the days are hot.

SEEDLING GERANIUM (*C. Daeth*).—The petals were all shed, but judging from their colour and the horseshoe leaf, we do not think it differs from many others.

TUMOURS ON LEAVES (*H. P.*).—The swellings on the leaves forwarded do not appear to have been caused by the punctures of a gall fly, but are morbid growths arising from some derangement in the functions of the leaves. We do not remember any query about a bee hive.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending June 30th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

WHAT FOWLS SHALL I KEEP?

No one will be intelligent who does not ask questions. My brother presided on Thursday last at a large horn sheep sale—2465 sheep, late the property of James Davis, Esq., our old friend. I went to say "grace," and to support my brother. I met there a well-known poultry judge, George Andrews, Esq., of Dorchester. Determined to gain all the information I could, I asked him which were the best poultry to keep. He replied, "Bantams will give the most food, eggs, and flesh, for the least cost; but the best to have are a cross between the Game cock and Malay, keeping both kinds pure." I told him that in all competitions there were tricks. He said, "Poultry tricks were worse than horse-racing." I received his permission to give his opinion. I gave my friend, Archdeacon Huxtable, Mr. Beldon's second-prize Silver Dorkings, at York. I lately saw them, they are magnificent. I am much inclined to Dorkings.—W. F. KADLYFFE, *Okeford Fitzpaine*.

[We shall be obliged by others giving their opinions, or rather the results of their experience. If a supply of both eggs at the time they are dearest, and good table fowls are required, we are in favour of dark Cochin China pullets, and a Dorking cock.—Eds.]

FAILURES IN HATCHING.

JANUARY 19th, set nine eggs in hothouse: found, in twenty-four days, one egg added, others eaten. February 1st, set thirteen eggs in hothouse: hen left them in a week. February 26th, set twelve eggs in hothouse: in three weeks all bad. March 21st, set thirteen eggs in hothouse: in three weeks all bad. May 12th, set fourteen eggs in hothouse: in three weeks one egg only left. May 14th, set fourteen eggs in hothouse: in three weeks two chicks dead and four eggs eaten, others added. Lost seventy-five eggs!

The hens sat regularly, and only came off the nests once a-day for food and drink; but you will perceive that three hens ate part of the eggs. Am I to kill every hen guilty of eating eggs? My cocks are two to three years old, and the hens are about the same age. I had a Crève Cœur (pullet, said to be), from a first-rate establishment well known to you; she never laid an egg, and cost, when ready for cooking, 10s. a-pound. What do you think will be the balance of my poultry account on the 30th of June? I do not overfeed, and look after them myself! Have you a column for amateur poultry breeders who become bankrupt?—A TWO-YEARS AMATEUR, BUT NOT DAUNTED.

[You have mismanagement somewhere, and if you appear in our list of poultry bankrupts we shall be obliged, we fear, to suspend your certificate when we have made sufficient inquiry into your case. We cannot understand the prevalence of bad eggs. We do not believe they are naturally so, because some had chickens in them, and we believe they all had. You have bad sitters and egg-eaters, and they will spoil all eggs entrusted to them. An unimpregnated egg will not change under a hen, because, having no germ, it has no life. An added egg has had the principle of life more or less developed, and it has then been allowed to die; this renders decay possible, and it takes place. Hens are in a highly diseased or unnatural state when they eat the eggs on which they are sitting. We should not be surprised if the atmosphere of a hothouse was the cause of

it. Pheasants and Partridges, or hens that steal a nest in a hedge or dry ditch, never do it. Take them out of the hothouse, let them run naturally, and sit on the ground, feed well, but moderately, and we believe you will find a different balance next year, or this year with late chickens.]

CLITHEROE AGRICULTURAL SOCIETY.—We are glad to find that the Committee of this Association have set an example worthy of imitation in allotting the prize money usually given to horned cattle, which are this year excluded, to the poultry. On reference to our advertising columns it will be seen that the prizes are very liberal, and we trust that the increased patronage of poultry amateurs will justify the Association in repeating the experiment annually. Adequate protection from sun and rain will be provided.

MY APIARY.—No. 2.

HOW I WORK IT.

HAVING fixed upon the Swiss chalet as the most appropriate form of villa residence for my bees, it seemed only natural that the floors of the galleries running round it, externally, should serve as their settle-boards. This was accordingly done, and the inside ledges on which the hives rest, were made to correspond exactly with these, the lower ledge being 1 foot 7 inches from the floor, the upper one, 3 feet 7 inches, for instead of shelves, I have a fixed ledge 1½ inch thick, supporting the front of the bottom boards of my boxes, and a bar supported by an upright in the centre for the backs to rest upon, which arrangement I find more convenient. The inside of my house is 7 feet square, which allows sufficient room for six hives in front (three in a tier), and four on each side, fourteen in all, the door being at the back or north side. There are two windows in the front, or south side, above the top tier of hives; but I find this arrangement inconvenient, and I should recommend only one window for a bee-house, and that, if possible, at the back, where there are no hives, the whole of it being made to open easily, and, at the same time to admit of being easily darkened by a closely-fitting shutter. The sides of my house are 7 feet high to the plate, the roof having a pitch of 2 feet 8 inches from this to the centre, and overlapping 2 feet all round. The material used in the construction is three-inch deal, boarded inside and out with thin planks tongued and beaded. The tunnels, therefore, through which the bees have to enter from the galleries to the inside ledges, are nearly 4 inches long, and the floor-board of each hive has to be fitted closely and exactly to the mouth of this. The whole building is set upon three courses of brickwork. There is, as the engraving shows (see page 465), a wide shelf running along the outside front of the house, upon which I have sometimes placed hives or boxes, but never, as yet, with bees in them, having found fourteen stocks, as many as I could keep with safety in this locality.

I am not aware that there is anything peculiar in my system of management, as I have adopted L. L. Langstroth's plan of frame hives, and work them very much according to the directions given in his book, either making all my swarms artificially, when I wish to increase the number of my stocks, or adopting the plan which he recommends, of making three out of two by driving and removing, and which he pronounces to be the best plan of all for increasing stocks, and keeping them strong. But it may be well, perhaps, to mention one peculiar feature in my arrangements this year, as likely to interest our

apiarian friends, and that is, that I am trying the plan recommended by one of the correspondents of THE JOURNAL OF HORTICULTURE of last year, and make half my stocks enter at the top instead of the bottom of the hive, and during the summer season I find them work quite as well as before; but I fancy that the bottom boards require more frequent cleaning in the spring, and I have not as yet hit upon a plan of doing this with facility, as I am obliged to screw the front of the top of my hive on the ledge, and it is, therefore, not so easy to remove it as before. My reason for trying this plan was, that I found my two tiers of hives inconveniently close for supering, but by putting my lower tier under instead of above the inside ledge, I have secured abundance of room between the two.

In my next I may say something of Friendly Unions, of which there have been more than one instance in my apiary, and of Hunger Swarms.—SIBERT-ON-THE-WOLD.

NADIRING.

I HAVE closely followed the directions given in your Number for July 11th, 1865, respecting the management of Stewarton hives. The bees were wintered in two boxes. On May 18th they had taken possession of a super, and on May 26th had nearly filled it. I, therefore, added a third breeding-box as a nadir. This box they appear to me to have filled; but it has been, I fear, at the cost of the super, as that remains in very much the same condition as on the 26th of May. Is there any objection under these circumstances to my appropriating the stores of the nadir, or at all events such a portion of them as does not contain brood comb? I should be much obliged also by being informed whether the inactivity in the super is the result of any mistake in the management.

I may add, that having read that the addition of a nadir tended to quicken the work in a super, I added one to a small straw hive, and the result has been the same as with the Stewarton—viz., that no further progress has been made in the super.—H.

[We doubt whether you will find much honey in the nadir, but see no objection to your appropriating what may be there, if you wish to do so. It does not follow that the bees ceased working in the super because you had added a nadir. We should be more disposed to attribute the suspension of their labours to the recent break in the honey harvest, and shall not be surprised if you find the present glorious weather set them as hard at work again as ever.]

REGICIDE.

On going into my apiary on the morning of the 20th ult., I found two or three bees coming out of the cap of a royal cell. I thought it was so from the size of it. I again went into my garden, and found (about 12 o'clock) the enclosed queen on the alighting-board dead, with about twenty or thirty bees around her. I must tell you that for two or three nights before this, I heard piping going on. The hive in question is one of Carr's bar-and-frame hives, and I am working a super upon it. It has not swarmed, nor do I think it will, for they have half filled it with comb, and should have had a considerable quantity of honey had not the weather been so cold and wet here (Denton) during the previous ten days. I wish to know if you think her an old queen, and what will be the consequences.—W. W. C.

[When the queen reached us we found her crushed perfectly flat by the manipulations of the post-office officials, so that we can do no more than hazard a guess as to her history. So far as we can judge from the colour and appearance of her remains, we are inclined to believe her to be the old queen which has been slaughtered by a juvenile rival. Although this occurrence is somewhat unusual, it is by no means without precedent, and we should think it likely to be followed by the issue of a swarm.]

FORMING STOCKS IN AUTUMN FROM CONDEMNED BEES.

I wish to increase my stock of bees, and beg to know your opinion of the following method of doing so.

I would buy from a cottager the bees which he would otherwise kill, and would myself superintend their being driven

from the full hive into an empty one. When I had brought them home I would supply them with as much sugar and water as they would take. Is it possible for bees so late in the season, say August or September, to construct combs in which to store up an artificial supply for the winter?

I suppose it would be desirable to unite two stocks. A cottager should let me have these (useless to him), for 2s. 6d., and the bees might take 10 lbs. of sugar, value 5s. If successful, would not this be the best, or rather the cheapest, method of obtaining stocks? I fear there is some difficulty in uniting swarms.—ONE OF YOUR CONSTANT READERS.

[We never find it necessary to pay for condemned bees, the cottagers in our neighbourhood being only too glad to be spared the trouble of applying brimstone. Even with this advantage we estimate the cost of establishing a stock in the autumn from condemned bees as being about equal to that of a good swarm in spring. The inhabitants of at least two hives (three are better), should be driven into one domicile, and will require, say two dozen pounds of lump sugar converted into syrup by the addition of water in the proportion of two parts of the latter to three of the former by weight, and boiled a minute or two, to enable them to form and store a sufficient quantity of new comb to stand the winter.

There is rarely any difficulty in uniting swarms.]

AN ALBINO REDBREAST.—A few days ago I captured a pure white Robin. It is a young bird about seven or eight week old. It has pink eyes and beak, and feet of a delicate yellow colour. Will some one inform me whether it is likely to moult into its proper colour, and what is about the value of such a bird?—A. B. BAILEY, Shooter's Hills, Longton, Staffordshire.

OUR LETTER BOX.

MOULTING (A. J.).—As a rule, fowls moult as soon as laying and sitting are over—that is, about the end of July. The time to recommence laying varies, but adult fowls seldom lay till the end of January. Some breeds moult in less time than others; it lasts about two months. Spanish are longer about it.

GAME FOWLS (J. Maton).—The loss of one spur by an accident is no detriment to a Game cock in exhibition. There are two Duckwings, the old copper-saddled and the silver Duckwing. The hens of the former have the Robin or salmon breast, and generally a little bluish on the wing, but the latter must have none of it anywhere.

COCHIN-CHINA HEN INJURED (A Reader).—Your hen is injured in the back. It often happens at this time of year when the cocks are too numerous. As you say she is about to sit, she has, of course, ceased to lay, or the same appearance would be presented if she were egg-bound. As it is always necessary in such cases that the patients should be separated from the others, you cannot do better than let her sit.

WHITE TURKEY POULT (W.).—A White Turkey is not a *rara avis*, but it is very uncommon to breed them from coloured birds. You will have no difficulty in obtaining a proper mate, as there is a distinct breed of them. The present case may be a sport, or it may be there has at some time been some white blood in one of the birds, and she has thrown back to it.

EXCRESCENCES ON SPANISH FOWLS' FACES (A. W.).—Most of the excrescences you name are the result of pecking. Hens are very fond of pecking the cocks' faces, but cocks and hens are now alike getting shabby. It is an unnatural habit, and often arises from diseased or disordered body. A free supply of lettuce will cure most of these disorders; we have found it most advantageous.

FATTENING BRAHMA POOTRAS, TURKEYS, AND GESE (Idem).—Brahmas should be very well fed, but allowed liberty. Turkeys and Geese should be shut up; an out-house or even a large pigstye is good for either, but if Turkeys are put in it must be hurdled all round with hurdles lengthwise, and leaning inwards. They must also have perches. Good ground oats mixed with new milk, and a little grease added, are very good food for the Brahmas. Turkeys require the same or barley-meal, with a little peameal mixed, if with milk so much the better. They feed well out of a pig-trough. Geese want oats, bran, gravel, grass, and some people give tallow chandler's greaves.

POULTRY MARKET.—JULY 2.

THE excessive heat has caused very fresh poultry to make larger prices than it would have done in cooler weather, but much was spoiled.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 75.7°; and its night temperature 50.5°. The greatest heat was 93°, on the 14th, 1847; and the lowest cold 34°, on the 16th, 1863. The greatest fall of rain was 1.60 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ROSE STOCKS.

HERE has been so much written by our great rosarians on stocks for Roses, that it may almost appear presumptuous in me to reopen a subject that has been, apparently, so thoroughly ventilated. I only do so for the purpose of calling attention to the following stocks, which I do not remember to have seen mentioned before, they are what is called the Shanghai Rose and Fortune's White Banksian Rose. They are both of them most invaluable as stocks for the more delicate kinds of Roses.

Four years ago I received some cuttings of Fortune's White Banksian Rose from my friend Mr. Drewitt, of the Denbies, near Dorking, where it may be seen to great perfection in the glass arcade. It, the beautiful Gloire de Dijon, and the other beauties of the Denbies, are worth travelling some hundreds of miles to see. About the same time Sir Philip Egerton obtained a plant of the Shanghai Rose in one of the Royal Horticultural Society's ballots for new plants. Two of the plants that had been raised from Mr. Drewitt's cuttings from the White Banksian were planted out in the large Camellia-house at Oulton Park, and as the plants grew so rapidly, it struck me that they would make useful stocks for working the more delicate kinds of Tea Roses on. I accordingly inserted some buds on the plants in different places, and found that the union between the stock and bud was very soon complete, and the bud speedily commenced to push vigorously, going far to prove that Fortune's White Banksian is the finest of all stocks on which to graft or bud the more delicate kinds of Tea Roses. One of the most important points in the favour of this stock is that the bark will at all times very readily part from the wood, even if the latter is two or more years old, provided the plant at the time is in a free-growing state.

Another great advantage is that cuttings strike very readily, and as the plant soon furnishes itself with a large number of healthy roots, it takes but a short time to establish itself. Any kind of Tea Rose may, therefore, be worked on it, either by grafting or budding, very soon after it has been struck; and after it has well established itself, the Rose worked on it will afford some extraordinarily fine blooms, such as cannot be produced by any other stock, and there is no fear of the stock sending out any suckers below the surface of the soil. The cuttings which I put in are generally about 3 or 4 inches long, and if they have a heel attached so much the more rapidly will they strike; but where this cannot be managed they will be found to strike very readily from cuttings made in the ordinary way. I invariably find that if the cuttings are cut slanting, instead of straight across, they always strike

more freely, and grow more rapidly after they have struck, because there is a greater surface from which roots can be emitted when the cut is made from 1 to 1½ inch long. The cut should be commenced about the same distance above the eye as it comes out below it, leaving the bud about midway, and if the cutting is taken from the middle of the shoot two eyes will be sufficient. That at the base must be cut clean out to prevent its throwing up any shoots from below the soil, and that at the top must be carefully preserved to form the future plant. I generally use thumb pots, putting one cutting in each, and as soon as the cuttings have struck they are shifted into 48-sized pots.

When the roots have reached the sides of the pot the plants may be either grafted or budded, according to the state of the bud or graft and the stock; if it is found that the stock is not sufficiently strong for budding it may be grafted. In doing this, however, great care is necessary, for if too deep a cut is made the young free-growing stock will often break off. The top of the plant should be left intact for the purpose of drawing up the sap. A small clean cut is all that is necessary to be made, and it should be as near the base as possible, and the graft must be made to fit as nearly as possible the cut in the stock. If this is bound round with a small piece of matting just to keep the graft from slipping out of its place, finishing the operation with a covering of Thomson's styptic, the union between the graft and the stock will soon be complete.

As soon as the operation of grafting has been finished the plants operated on should be plunged in a very gentle hotbed, and after the grafts have taken they must be gradually inured to a cooler temperature; a sudden check caused by bringing the plants from a close and humid atmosphere, even after the union between the stock and graft is complete, will in most cases cause the graft to dwindle away, and if it do not die altogether it will be years before it gain sufficient strength to grow with any vigour.

Plants of the Shanghai Rose were planted out against a south wall, and the first year after they were planted they grew at a most astonishing rate; shoots 12 and even 15 feet long were produced in one season. Some of these I made into cuttings 2½ inches long, and a piece of ground having been firmly trodden and afterwards nicely levelled off, shallow trenches, 2 inches deep, were then cut at 10 inches apart, and the cuttings were placed against the upright side, some road sand being sprinkled beneath them and around their bases. The soil was then firmly trodden about them. The cuttings were prepared just in the same way as recommended for the Banksian cuttings. Scarcely a cutting missed, and as soon as they were rooted they grew very rapidly, and in a short time afterwards many of them were budded.

All kinds of Roses appear to take and grow with great vigour on the Shanghai Rose stock, and if the bud is cut clean out from the base of the cutting there is no fear of the plants sending up root suckers, which is one of the worst faults of the Manetti stock. The plant is perfectly hardy, even in a very cold and wet climate like that of Cheshire. I therefore venture to predict a brilliant future

for the Roses worked on this stock for the open ground; and the advantages will be equally great in the case of Tea Roses grown on the White Banksian Rose for pot-culture and in-door cultivation.—J. WILLS.

### RED SPIDER AND THIRPS ON VINES.

I COULD NOT discern a single insect on the Vine leaf sent by "R. H. B.;" but there were traces of red spider, and two or three marks as if thrips had also been nibbling. He will easily know the red spider, whether it has obtained the red colour or not, by its quick movements and its rather round dimensions. The thrips, whether of a blackish, brownish, or whitish colour, according to its age, is two or three times the length of the red spider, but no thicker in the body, and he must have quick eyes to note the dimensions of the insect, as when he comes near it, it is almost sure to jump beyond reach. This jumping will at once enable him to guess what insect he has, or if he has both.

"R. H. B.'s" Vines are quite forward enough, the berries being nearly swelled to their full size, to enable him to use strong measures; but if the berries are not colouring I would not hesitate under the circumstances to give the whole plant, and especially the foliage, a good lashing with Gishurst, or with softsoap water at the rate of from 1 to 2 ozs. to the gallon, shading the house the day afterwards, keeping it rather close, and then following for a week afterwards with good syringings, about 4 o'clock p.m., with clear water at 120°. Moisture is the aversion of the red spider; a dry heat its greatest enjoyment. Sulphur fumes are also a great annoyance, though I do not think they kill the intruder so much as make him uncomfortable, and cause him to be glad to shift his quarters. As for sulphur itself, he cares no more for it than he would do for any other dust, walking amongst it with the greatest seeming enjoyment when it is scattered over a leaf. When the active principles of the sulphur can be conveyed in water, or the fumes driven off at a temperature not above 160°, the red spider seems to be rendered very uncomfortable.

The washing with Gishurst, as an antagonist to the red spider, depends very much for its efficacy on the sulphur suspended. In the case of Gishurst, or softsoap water, if either be boiled ten minutes and then allowed to settle, they mix better with the water, and no marks are left on the foliage. Followed the day after with clean water, I do not think that the slightest marks would be left on the berry. As easily obtainable, no better remedy for many insects is to be found than softsoap water. I have found that it quickly settles red spiders which are alive, as well as other insects quite as difficult to master. The mischief is, that wherever they find a lodging they keep their place good for some time by successive generations. For destroying insects softsoap is far superior to bar soap; but I am not learned enough to know whether that is owing to the potash it contains, instead of the soda, which forms a part of the bar soap. The softsoap water seems to act, to a certain extent, like glue water; but at the strength stated, and referred to lately in "Doings of the Last Week," it leaves no traces behind it, and does no harm to Peach trees nor Vines. At that strength it would not be safe to syringe Cucumbers or Melons, unless they were much shaded, until they had had two or three syringings with clear water. I mention this by way of a caution.

The mode of application is also of importance. People hear of a remedy and straightway resort to it; but they are either too careless or fail to attend to some simple matters of detail, and then they blame the plan instead of themselves.

This spring some shoots of Peaches, quite killed with Gishurst, were sent to me. It had not only been applied hot, but three times stronger than any directions of the inventor would have warranted. A short time ago, a few Peach leaves, spotted and disfigured, were sent with an angry note, the purport of which was—"See what your soap water has done." As for the water I can say nothing, nor of the strength, but from the few leaves I could have collected as much as a quarter of an ounce of softsoap in its original state—how applied I know not. If the softsoap had been previously boiled, and then mixed with the warmed water, I make bold to say not a particle of the soap in its original form would have been found on the stems or leaves. Many of our best medicines are poisons when taken in quantity.

While advertizing to red spider, I may also allude to a case of killing some shoots with strong lime sulphur water, a wash

which, as recommended by me, keeps down, if it does not destroy, the intruder, and leaves no trace of its application on the foliage of Peach or Vine, nor yet on the fruit when young; but which is injurious to such fruit, and especially the fruit of Strawberries, after they begin to swell. The liquid had been used far too strong. The strength which I advised, and which never should be exceeded, and for all tender plants should be much reduced, is as follows:—Take 1 lb. of sulphur and 1 lb. of quicklime, mix together with a gallon of water, boil for ten or more minutes, allow to settle until cool, then pour off the bright liquid into a vessel that can be kept close; earthenware is best. Add one quart, or a quarter of an English pint, of this strong acrid liquor to six gallons of water, and stir and use, and even then the milky liquid will smell more than a bed of Onions when you walk through them. I know of no method superior to this for communicating the acrid properties of sulphur to water. At the above strength, though whitish in appearance, the liquid will leave no mark or residuum on the foliage; it will also clear the leaves of Strawberry plants, but it will injure the fruit if the latter has come to its second swelling. A few quarts of such a powerful liquid will go a long way, but if people, disregarding minutiae, will use a quart instead of a quart, or gill, and do mischief, that is their affair.

As involving a little more labour but making more certain in the end, there is another remedy for red spider, and that is to shorten and remove all laterals, and then sponge the leaves with softsoap water at about 2 ozs. to the gallon. The red spider chiefly congregates on the lower side of the leaves, and a handy man will soon go over a small house and thus sponge every leaf.

Much may be done with the hands and fingers; in fact, many insects might thus be destroyed in the time we are getting other means and appliances ready. For instance, early in the season green fly is apt to attack the buds of Strawberry plants just coming into bloom in houses. A good smoking with tobacco will destroy all the insects that are alive, but as we go along, examining as to watering, I much prefer that all such should be squeezed between the thumb and fingers, the heads being afterwards well washed with the syringe. By attending to such matters at once, I have often passed through many seasons and never required to give any smokings to early Strawberries.

Even when it would not be advisable to wash the leaves owing to the forwardness of the fruit, a damp atmosphere may be maintained by damping the walls, floors, stages, &c., and fumes of sulphur may be given off by daubing the walls with sulphur paint made of sulphur and water, and better still with sulphur and strong soap water. The heating pipes, or flues, may also be well smeared, but the heat of either in such a case should not exceed 160°.

For thrips, all such means as the above will also be so far effectual in making the merry jumping fellow uncomfortable; but to destroy him tobacco smoke must be resorted to, and that frequently, each time following within two or three days of the other, as, if ever allowed to establish themselves, fresh broods will be hatched for some time after the first colonies have been destroyed. For moveable plants much infested, I have found no plan better than immersing the head of the plant in soap water, glue water, or tobacco water, allowing the plant to stand in a shady place for a couple of days, and then syringing it well with water at about 120°. After smoking a house and keeping it as close as safety will permit the following day, a good syringing with clean water would be advisable, but if the Grapes are colouring it is best dispensed with.

Even with the hands a great deal may be done with this insect in a small way. If on Vines, the insects usually exhaust one leaf before they go to another, and most generally prefer old leaves to younger ones. A good deal may be done in the way of riddance by going over the vinery, and taking off quietly, but quickly, every leaf so affected, rolling it up, and placing it at once in a bag or the pocket, and then burning the proceeds. When I had less to do I used to keep Cucumbers and Melons clear of this destructive visitor by examining those grown on trellises in a small house, and whenever one showed on a leaf, daubing him at once with thumb and finger wetted either with clean, or, better still, with soap water. In such a case the eye and the thumb must be quicker than the flea-like jump of the intruder, or the art must be obtained, which can only be learned by experience, of perceiving as it were by intuition which way the little fellow will jump. A very little time thus spent in a morning would go a good way towards keeping

insects down, and save much trouble and expense in fumigating, &c.; for in small places the expense of tobacco is a serious item, and if the smoking is too long delayed it is too often expense thrown away. Where the labour power is at all near the mark, a great deal can be done in keeping down insects by means of nimble fingers, and the free use of the syringe with clear water.

If "R. H. B.," however, has the thrips on his Vines, I would advise him to pocket or bag carefully some of the worst leaves; to fumigate with shag tobacco the same evening; to keep the house shaded and as close as he can next day to be safe; to preserve a rather moist atmosphere by wetting the walls, stages, paths, &c.; and on the afternoon of the second day to give a free lashing from the syringe all over the foliage. For red spider wash or syringe as above stated, shut up close, and on the next evening when the leaves are dry put on a fire, and keep the heat specified above on the smeared pipes or flue. Bear in mind this simple fact, that all smokings with tobacco and other fumigations are most safe and effectual when presented to a dry leaf. If damp the insects are so far sheltered; and how, we know not exactly, the wetter the leaf the greater the danger to vegetable vitality from such smokings.—R. F.

### CULTURE OF HERBACEOUS CALCEOLARIAS.

In the first place, every endeavour should be made to secure a packet of first-class seed from a well-proven source, as the bad sorts require just the same space and attention as the good; besides, the pleasure in the end of having a superior to an inferior quality of flowers will infinitely outbalance the extra trouble and expense.

About the beginning of July, the seeds ought to be sown in pans well drained, on the following compost, after being thoroughly incorporated—two-fourths rich fibry loam, one-fourth leaf mould and old mushroom-bed dung, one-fourth silver or river sand, the whole put through a fine riddle. Fill the pans about half up with crocks, putting a thin layer of the fibry portions of the riddings over the crocks, the remaining half fill with the soil, when slightly press and smooth the surface, then scatter over the seeds, and finish with sifting a little soil over, and give a sprinkling of water through a fine rose.

The pans may be placed in a shaded part of a pit or frame, near the glass, where they can get a little bottom heat, or, better, on the back shelf of a vinery, near the ventilators, where they may have the advantage of both heat and air. If the Vine-reds are insufficient to shade the pans with their leaves, pieces of glass whitewashed above will be found necessary to cover them until the plants have made some progress, and can stand exposure.

Remove daily the drops that will gather on the under surface of the glass, so that they do not fall among the young plants, and never permit the plants or soil to get dry or crusted, but keep both slightly moist with water.

When the seedlings have made sufficient strength to be handled, prick them in lines into boxes, and give a good shower through a fine rose, that will lay the earth to their roots, and return them to their old quarters, shading as before, until they are on their feet again, when they may be removed to a cold frame or pit; place them near the glass, shading in strong sunshine, and giving sufficient air to harden them off by degrees to the full exposure of air and light.

Continue to keep their foliage damp, and never allow them to flag for want of water at the root, or with the sun, throughout any stage of their growth, and in a short time they will be prepared for a shift into pots 3 inches in diameter; cut out their balls carefully into squares, and place them individually into the pots, using soil the same as recommended for the pans, only more rough. The plants will not appear to suffer from the shift, but will continue growing, which growth ought not to have a check up to the time the flowers make their appearance.

If green fly pay them a visit, take advantage of them when the foliage is dry, by giving a smart smoking with tobacco paper, and administer a good lashing with the syringe after the smoke has passed away.

In a short time, if all prospers, the roots will be through the soil, when a larger shift will be requisite, which on no consideration ought to be neglected, or put off till to-morrow—procrastination, or any other cause of prevention, will be found ruinous, as nothing can be worse than allowing them to get pot-bound, in which case the consequence will surely be stunted plants, that will send up flower-stalks weak and premature; whereas

a regular succession of shiftings up to 10-inch pots, will produce really good plants. About the beginning of November, prepare a place in the greenhouse as near as possible to the glass without endangering them to frost. Place them there for the winter, after carefully washing and clearing the pots of weeds, being careful not to break the leaves in the operation, and continue to treat, as regards watering, syringing overhead, and potting, when needful, as the winter passes. As soon as the plants are established in their last shift, give a good soaking of liquid manure, at the rate of 40 gallons of rain water to 1 lb. guano once a-week, up to the time the flowers begin to expand, when it may be discontinued. Turn the plants every time you have occasion to water, that they may be well balanced with the foliage, and, as seen as the flower-stalks are of sufficient length, stake out, and finally stage to flower.—A. KERR (in *Scottish Gardener*).

### EUCCHARIS GRANDIFLORA.

The large plants exhibited at the International Horticultural Exhibition on the 22nd of May last are now throwing up a greater number of flower-spikes than when shown, and will be in full flower in the course of ten or twelve days. Their having been removed from the stove to retard for the International accounts for their not being in flower earlier. A small plant now in full flower has never been subjected to anything but stove temperature. I find one portion of the bulbs rest of their own accord, while the others are growing and flowering. They are supplied with a couple of large watering-potsful of clear liquid manure every alternate day.—W. HOWARD, *Gardener to James Howard, Esq., Bedford Hill, Balham.*

### HEAT SAVED VERSUS HEAT USED.

In your Journal of June 12th I read a long article on flued walls, and as this and its kindred subjects have long occupied my attention, I hope Mr. G. Abbey will excuse my assuming that his article was not what is called an exhaustive one, and will permit me to assist him in his effort to ascertain why flued walls are not, as a rule, successful. To see clearly, we have all first to get rid of our prejudices; in fact, try for a season to forget what we know, and I am quite sure for a gardener of the present day, who is expected to make either a south wall or a flued wall successful, this is especially needful. He must be able to forget and cease to sigh after the grand houses in the nobleman's garden where he went as an improver, before his mind will be open to believe that without all the costly appliances now considered necessary, good fruit can be grown at its usual season, and bring himself to take the pains required. Is it not written, "Man shall earn his bread by the sweat of his brow?" which means, I believe, by labour assisted by steady thoughtful care, nay, even anxious care, for who has not felt the cold moisture start on his forehead as he hurried, fearing his forgetfulness had ruined all his hopes? Then why should it be considered, as it undoubtedly is, beneath a gardener to waste his time in growing fruit if his master does not supply him with a house so replete with appliances, that the fruit produced will cost a fabulous sum per pound? This cost of production is quite lost sight of, and the simple means that enabled the last generation to produce good crops are neglected, in order that the time and attention may be devoted to what is properly out of season. I mean, that if gardeners understood the capabilities of the houses under their care they would by forcing have had these crops out of hand, and thus been able to devote their time and attention to the walls. Gardening should be looked upon as a business, and gardens worked for a profit, and then they will be carried on with economy and spirit, which bring with them a certain amount of anxiety, without which no business is healthy.

From whence come the fine Pears? The answer is ready—from France; but this does not explain my meaning. To what system do we owe their production? Those who have not travelled much, or resided for a time in France, have very little idea of the number of gentlemen with small incomes, who think they would lose their claim to be considered gentlemen if they went into trade; but, fortunately for them, selling the produce of the farm and the garden is not considered as being in trade; and what better way of lengthening out a small income than by means of a good kitchen garden? So these educated men give their minds to the subject, and not only make it pay, but find in it a healthy, pleasurable occu-

pation. Was it not Sir Joseph Paxton who said, "That gardening was the only hobby he knew which, if carried to excess, did no harm?"

In this country gentlemen consider their own time of too much value to devote it to the study of gardening, and look upon it as something beneath a gentleman; it is, therefore, left to the gardener, and he is often only intent on beating his neighbours at the autumn show, and never thinks that the summer is precious time, which should be economised by having previously done all that he could. He, poor fellow, has no hope that extra produce from the garden will improve his position, and as all things act and re-act, it ends in his being looked upon as one of the expenses of housekeeping that must be, and he finds, accordingly, that his trade is one of the worst paid.

Let me, then, encourage those who think it is worth their while to say, "What man has done, man may do," for the sun's rays are as warm as ever, and if its heat is "saved," or, here I may use a better term, economised—that is, made to last as long as possible, it will be found that in sunny districts as much heat can be obtained during the summer months as is now "used" in the best heated structures. In Speechly's day, which takes us back to a period when iron pipes were unused, the best example of a forcing-house was the Dutch—a flued wall 10 feet high, with a glass front 5 feet from the wall at the bottom, and 3 feet from the wall at the top. The two important points here are the nearly-straight glass front to catch all the light, and the small area the flue was expected to heat. Such a house, he says, will enable you to ripen the fruit in May. As the season advances, he adds, your requirements diminish, for the sun will be higher, and therefore the pitch of the roof can be lower, enabling the house to be wider. He also says there is now no longer a necessity for a glass front, and for walls; oiled paper put on at night will do, and it will also replace the glass on frames, which can then be used for a better purpose. Miller goes over the same ground and gives the same reasons. When gas was introduced it is related of a shopman, that he was so pleased as to say it was better than daylight, and would save all the trouble of having windows; and now pipe heat is so convenient, that many gardeners act as if they thought it was better than sun heat. It certainly is much more regular, and saves the constant care over the ventilators required when the sun heat is permitted to enter.

We still find a heated glass wall is the best forcing structure; it is not safe without heat, because it brings on the trees too fast, and is not able to keep the late frosts out; therefore, after a heated glass wall, a sheeted-up wall is preferred. The Rev. W. F. Radclyffe, of Okford Fitzpaine, is very successful with his wall, he sheets the trees over every night, and leaves them so covered on very cold days. By this treatment he not only saves them from the late frosts, but how much radiation does he retain? Then, will glass walls without heat fail if they have the same careful treatment to retain the heat otherwise lost by radiation? I think not, and when trees have been forwarded by means of a flued wall, they should be protected by a good sheet, not a mere net, and the thermometer should be closely watched that this heat is not employed when it is not required. The thermometer should be considered by each gardener as his best friend. Let those, then, who have such walls, read what Mr. Radclyffe wrote for your pages, give no more heat than is required, syringe with care, shut up early while the sun heat is still in the wall, and I shall be very much surprised if they do not find the thermometer indicate that a much higher temperature has been retained than is required, and I am sure they have no need to fear that the crop will end in being ruined with red spider. I will go further than this, and say I have a very strong belief that the attention of the gardening world has been so taken up and occupied with the advantages cheap glass has conferred, that south walls have not received their proper notice, and it will be found if due care is taken to retard the trees as long as possible in the spring, so that the sun may have attained some power before what I may call the growth of the crop has commenced, that they will, if the care I have previously advised be taken of them, ripen their fruit as early as similar trees on the back wall of an unheated orchard-house, and quite two weeks before those in any other unheated glass structure. I some time since invited, through your valuable Journal, our orchard-house authorities to join me in trying experiments in this useful field of inquiry, and I hope before the summer is over we may hear some good reports from some of them, meantime our thanks are due to Mr. W. F. Rad-

clyffe, he has preserved his faith in good old plans that have been called slow, and now serves to make me, for one, wish I had not run any faster.

I send you what may interest some, the maxima and minima temperatures for each week during the summer at Stornoway, where Mr. Rivers says there is a successful unheated orchard-house. It will show how little heat is required.

ENTERTAINMENT GIVEN BY MR. W. WILSON SAUNDERS.

ON Friday last Mr. W. Wilson Saunders, of Highfield, Reigate, gave his annual entertainment to the members of the Entomological Society and to several others of his scientific friends. The programme commenced with the mustering of the visitors on the arrival of the 9.10 A.M. train from Charing Cross, who, headed by Mr. Saunders, wended their way through the town and along the road which leads across Reigate Common. Proceeding in that direction they passed Flanchford, and describing a semicircle round the town they reached Sidlow Bridge, where the party refreshed themselves by luncheon. The weather being unsettled and varied by alternate thunderstorms and sunshine, much of the pleasure that generally attends these pleasant excursions was marred. On returning to Reigate at 5 o'clock the party found a large addition to their numbers of those who, prevented by the threatening aspect of the weather, did not arrive till later in the day. But a very important part of the day's performance was yet to be gone through, for in the Town Hall Mr. Saunders had prepared a most sumptuous and elegant entertainment, to which his guests were all invited. Not fewer than 150 gentlemen sat down to this entertainment under the presidency of Mr. Saunders himself, supported on the right by Sir John Lubbock, Bart., Mr. Bennett, of the British Museum, and Mr. George Bask, Zoological Secretary of the Linnæan Society; and on the left by the Mayor of Reigate, Lieut.-Col. Scott, R.E., Secretary of the Royal Horticultural Society, Professor Westwood, of Oxford, and Mr. Currey, Botanical Secretary to the Linnæan Society. After the loyal toasts, proposed by the Chairman, he gave "The President of the Entomological Society," to which Sir John Lubbock responded in a humorous and clever speech. Mr. Saunders then gave "The Treasurer and Secretary," which were duly responded to by those gentlemen. Then followed "The Royal Society," the parent of all the scientific societies of this country, to which Mr. Bask replied; "The Linnæan Society and Mr. Currey;" "The Royal Horticultural Society and Colonel Scott and Dr. Hogg," to which those gentlemen respectively responded; "The Authorities of the British Museum and Mr. Bennett;" "The Schools of Science and Professor Westwood," &c.

All who were present united most cordially in doing justice to the toast of Mr. Wilson Saunders' health, proposed in earnest terms by Sir John Lubbock; and with a warmth of feeling which every individual could not but feel found a responsive echo in his own breast.

About half-past eight o'clock the party separated, thanking the generous and kind-hearted patron of all the sciences for a day of infinite pleasure.

THE BRIDAL BOUQUET OF THE PRINCESS HELENA was by special permission presented by Messrs. Veitch & Sons, of the Royal Exotic Nursery, Chelsea. It was composed of Orange Blossom, Myrtle, choice Orchideous flowers, Gardenias, Stephanotis, &c., and elegantly trimmed with real Honiton lace to match the dress. The Myrtle was sent from Osborne by command of Her Majesty, and was taken from plants propagated from that used in the bridal bouquet of H.R.H. the Crown Princess of Prussia.

## WEATHER IN NORTH OF IRELAND.

THINKING that the weather we have had lately in this "far north" part of Her Majesty's dominions may be of some interest, I send the following observations made during the week ending June 29th.

	Therm. during 24 hours in shade.		Hygrom. at 12 o'clock noon.		Wind.
	Max.	Min.	Dry Bulb.	Wet Bulb.	
June 22nd....	67°	47°	67°	62°	S.W. Showery.
" 23rd....	78°	55°	78°	70°	S. Cloudy.
" 24th....	83°	49°	81°	70°	S.W. and to N. Clear.
" 25th....	87°	49°	87°	75°	N.E.E. Clear.
" 26th....	91°	55°	88°	74°	S.E. Clear.
" 27th....	75°	54°	72°	66°	N. Cloudy.
" 28th....	76°	48°	72°	64°	N. Clear.
" 29th....	85°	51°	85°	72°	S. Clear, but with heavy rain at night.

—ALBAN GOODMAN, *The Palace Gardens, Londonderry.*

## CULTURE OF FERNS FROM THE SPORE.

This is easily accomplished with most of the families both native and exotic. The following will be found a very effectual mode of treatment for natives:—

At the beginning of March, select a warm corner of the side stage of the greenhouse; place in a board 2 feet square, then break small a quantity of crocks, and cover the board to the depth of half an inch, chop up very fine a little sphagnum moss, and cover the crocks; next sift through a fine sieve a quantity of sandy peat, with a small proportion of fresh loam, then mix up with a quantity of silver sand equal to both, press the moss level, and lay this compost on an inch deep, and when done, slightly smooth and press lightly over the surface, then give a slight watering out of a fine rose, and when the water has subsided, sprinkle on the spores pretty thick, and finish by putting a hand-glass over all, first painting or whitewashing the glass to cast off the sun's rays; keep the glass close, excepting on days of strong sunshine, when the glass ought to be raised a little at one side up to the moment the plants make their appearance, giving a sprinkling of water when the surface shows signs of getting dry; thus continue to keep the soil damp, but stagnant water must be avoided.

The plants, in the first stages of formation, will be recognised in the minute cups that make their appearance on the beds, and which will soon start up fronds. As soon as they can be handled, remove the board off the stage, and place another in its stead, which cover as recommended for the others, only making the bed of earth double the thickness. Take the plants singly out with a pointed stick, and prick into narrow rows on the new bed; give a slight watering out of a fine rose, and return the glass as before; keep shaded for a few days until the plants have begun root-action. When air can be admitted by degrees, in a few weeks the plants will be fit for pots, when all danger is past.—A. KERR (in *Scottish Gardener*).

## ROYAL HORTICULTURAL SOCIETY.

JULY 3RD.

FLORAL COMMITTEE.—At this meeting Messrs. Buckhouse, of York, exhibited a very fine specimen of a new *Dipladenia*, *D. amabilis*, with very large bright rosy flowers, a very superb variety, which was awarded a first-class certificate; also a good variety of *Lælia purpurata*. Mr. Bartleman, Leybourne Grange, received a first-class certificate for a seedling hybrid *Zonale Pelargonium*, King of the Nosegays, with large trusses of bright orange-scarlet flowers, which promises to be a most useful bedding plant. Mr. William Paul received a first-class certificate for *Zonale* hybrid *Nosegay* Nimrod, trusses of bright orange scarlet, very free flowering. Mr. W. Paul also exhibited several other seedlings, which have been noticed before, Rebecca, St. George, and Blue Bell, and a variegated form of *Hibiscus syriacus*. From Mr. R. Burcham came a small collection of British plants found on Hamstead Heath, two varieties of *Drosera rotundifolia*, and *Maianthemum bifidum*, considered rather a rare plant. Messrs. Osborn, Fulham, sent six fine Heaths, which were awarded a special certificate; and Mr. Watson, St. Albans, received first-class certificates for two seedling tricolor *Zonale Pelargoniums*—Miss Watson, a variety quite equal to Mrs. Pollock, the colours perhaps brighter, and Mrs. Dix, a compact-growing plant with medium foliage, with a dark almost black zone, encircling a bright red inner zone. Mr. Watson likewise exhibited *Zonale tricolor* *Nosegay* King of Nosegays, and *Zonale* *Enchantress*, with dark zonate foliage. Mr. Brewer, gardener to — Terry, Esq., Fulham, received a special certificate for a very handsome plant of *Lilium auratum*, bearing twelve lovely flowers. Mr. James Keeler,

gardener to John Todd, Esq., sent two seedling *Zonale Pelargoniums*—*Delicatum*, and *Samba*, a very dark scarlet; and Mr. Anderson, gardener to T. Dawson, Esq., Meadow Bank, exhibited some fine specimens of cut Orchids, which were awarded a special certificate. Messrs. F. G. Henderson received a first-class certificate for *Caladium Napoleon III.*, a fine variety with bright green foliage, mottled with deep rosy markings and veins; and they also exhibited cut specimens of *Allamanda Schottii* Hendersoni, with fine, large, deep yellow flowers; doubts were expressed as to its being a distinct variety. From the same firm came also *Orchis maculata superba*, and three most magnificent spikes of seedling *Zonale Pelargonium* Duke of Edinburgh, with pale yellowish leaves, marked with a bronzy zone; also fine specimens of *Pelargoniums Italia Unita*, Lucy Grieve, &c. Messrs. Sturt and Mein, Kelso, had a seedling hybrid *Statice* Duchess, very much like *profusa*; and Messrs. Lee, Hammersmith, two seedling *Ericas*—viz., *E. tricolor pulchella*, a pale-coloured flower, but pretty, to which was awarded a second-class certificate, and *E. ampullacea oblata*, a white variety of no particular merit.

W. Wentworth Buller, Esq., sent some beautiful specimens of cut Orchids, which were awarded a special certificate; also, a plant of an old and well-known Orchid, *Promenaea stapeloides*. Messrs. Veitch, as usual, contributed largely to the exhibition both novel and interesting plants. First-class certificates were awarded to the following:—*Nepenthes laurata*, a very curious Pitcher-plant; *Nepenthes* sp., from Borneo; *Lomaria dura*, a valuable hardy greenhouse Fern; *Lomaria ciliata*, very beautiful and distinct; *Davallia alpina*, *Davallia parvula*; *Acalypha tricolor*, a stove plant with dark yellow and red-mottled leaves; *Nierembergia* sp., quite hardy, with pale flowers like *N. filiculis*; and a cut specimen of *Dipladenia amabilis*. A second-class certificate was awarded for *Pescatorea*, or *Hautleya*, *cerina*; and a special certificate for a very handsome specimen of *Blandfordia nobilis*. In the general collection we noticed a new *Sphaerogone*; *Lomaria Belli*, which had received a first-class certificate; *Lomaria zamiaefolia*, and *Lomaria Moritziana*, which it was requested should be sent again. A collection of plants from the Society's gardens at South Kensington, contained Orchids and a very fine specimen of the late-flowering *Rhododendron Jenkinsii*, which was awarded a special certificate. A very interesting though small collection of plants was sent from the Chiswick Gardens. Among them were a very fine Fern, *Stenochlæna tenuifolia*; cut specimens of *Liriodendron tulipiferum*, the Tulip tree; also two kinds of Horse-chestnut, *Aesculus indica* and *Aesculus californica*.

FRUIT COMMITTEE.—Mr. C. Oldham, Honorary Secretary of the Wrexham Floral and Horticultural Society, exhibited two seedling Strawberries, Sir Watkin and Denbigh Seedling; and from Mr. Turner, Slough, came a fine large-fruited variety called Dr. Hogg, to which a first-class certificate was awarded. Further mention of these will be found beneath. From the Society's garden at Chiswick came fruit of Sir Charles Napier, Reeves's Eclipse, La Constante, and Vicomtesse Hericart de Thury; also three early varieties of Cherries. The only other fruit shown consisted of British Queen Strawberries from Mr. Keeler, Wood House, Dulwich; and Grosse Mignonne Peaches from Mr. Merett, Battersea Rise.

FORTNIGHTLY MEETING.—Viscount Sandon, M.P., in the chair. The awards of the Floral Committee having been announced, Dr. Hogg made a few remarks on the subjects brought before the Fruit Committee. Denbigh Seedling Strawberry, he said, was a large coarse-looking variety with a peculiarly acid flavour, and Sir Watkin, a seedling from Sir Harry impregnated with Black Prince, had a long conical fruit, very similar to Williams's Black Roseberry, and black firm flesh with an insipid flavour. With regard to Strawberry Dr. Hogg, for which Mr. Tarver had received a first-class certificate, it was raised by Mr. Bradley, the gardener at Elton Manor, who was also the raiser of Oscar, Sir Joseph Paxton, and other varieties. The fruit was described as being wedge-shaped, somewhat corrugated longitudinally, of a pale red colour, with white flesh, and a flavour similar to that of the British Queen. Unlike that kind, however, it was stated to colour regularly all over, and to be much more hardy and a better bearer. With reference to the varieties from Chiswick, Dr. Hogg said of Vicomtesse Hericart de Thury, that it is an abundant bearer, having a high flavour perhaps unsurpassed by any other kind. La Constante, raised by M. de Jonghe, of Brussels, bore carriage better than, perhaps, any other kind, the flesh being firm and solid, and the flavour was high. Eclipse, it was remarked, is of all the varieties used for forcing that which possesses, perhaps, the richest Pine flavour, but that this is not so good when the plants are grown out of doors.

The Rev. M. J. Berkeley then offered some remarks on the subjects exhibited. The *Eriogonum* shown at the previous meeting by Mr. Thompson, of Ipswich, was first alluded to, and then the hardy trailing *Nierembergia*, exhibited by Messrs. Veitch. This was stated to have come from Tucman, and its soft, lilac flowers were said to bear considerable resemblance to those of *N. filiculis*. *Acalypha tricolor*, imported from the New Hebrides by the same firm, next came under notice, and though very unlike most *Euphorbiaceae* plants, it nevertheless belonged to the same natural order as these. *Davallia alpina* and *parvula*, as well as *Lomaria ciliata*, were then adverted to, and the latter, however unlike a Tree Fern as exhibited, was stated to be in reality such. *Stenochlæna tenuifolia*, from the Society's garden, was the next plant noticed, and it was mentioned that the pinnae have

a marginal gland, or nerve, near the base on the upper edge, and that the veins form narrow costal areoles, from which parallel forked veins run out to the margin. Concerning *Æsculus indica* and *Æsculus californica*, both handsome Chestnuts, which come into bloom after all others are over, notes were read from the "Botanical Magazine," vols. lxxxiv. and lxxxv., in which both are figured. They form, it was stated, hardy moderate-sized trees of considerable beauty; but *Æsculus indica* was said to be somewhat difficult to cultivate. Mr. Berkeley then made some remarks on a disease in some Grapes that had been submitted to his inspection. In these the stalks were more or less withered, and the berries shrivelled like raisins, but without retaining their sweetness. They exhibited spots of decay, and with respect to these there was this peculiarity, that they had occurred at three different times, and that there was always a clearly-defined line between the healthy and decomposed portions of the berry. The first spots of decay had dried up, others had formed, and these had been succeeded by a third set. This peculiar disease, as well as some others, is attributed by Mr. Berkeley to a low state of vitality. As an instance of disease proceeding from a contrary condition of the plant, the gummy exudations frequently seen on the bunches were mentioned, and Dr. Hogg had drawn his attention to the fact that superabundant matter is frequently thrown off by the stigma, where it forms a globule, and the pollen being thus prevented from acting on the stigma, the fruit fails to set—a common cause of complaint with some varieties.

Mr. Bateman said that before he made any observations on the works of Nature he would direct attention to those of art, as exemplified by specimens of the application of a process by which leaves, Ferns, Sea-weeds, &c., may be impressed on porcelain, a clever invention, which we owe to Mr. Cox, of the Royal Polytechnic Institution, Regent Street. By Mr. Cox's "Ceramic Porcelain Process" as it is called, the characteristic outlines and venation of Ferns, leaves, feathers, Sea-weeds, and other natural objects are reproduced and indelibly burnt in upon the surface of every description of china, &c., at, it is said, much less cost than by mere pictorial agency. By this process, Mr. Bateman remarked, the inventor had done on imperishable porcelain what Mr. Henry Bradbury had some years ago effected on perishable paper in that grand work produced by Messrs. Bradbury & Evans—"Nature-printed Ferns." Here, then, we might have a fund of enjoyment, for ladies might have their Fern sets or their Seaweed sets, just as they now have their Fuchsia sets and their Rose sets. A coloured plate of the beautiful *Camoensia*, discovered by Dr. Welwitsch in Africa, was next exhibited, and as it belongs to an order of plants whose seeds are easily imported, a hope was expressed that it might not be long before it was introduced into this country. Attention was then directed to a cone of *Gunnera scabra*, perhaps the largest hardy herbaceous plant in our gardens. It was perfectly hardy in the miserable climate of North Staffordshire, and on account of the size and beauty of the leaves it was well worthy of cultivation by those fond of fine-foliaged plants. That it was not so extensively grown as it deserved, might be partly attributable to its being slow of increase. Those who were curious to see it would find a plant of it in the herbaceous garden at Kew. Blooms of the Tulip tree, together with others of a fine variety of it, called *Liriodendron tulipiferum obtusilobum*, at present in great beauty in the Society's garden at Chiswick, then came under notice. A fine avenue of Tulip trees at Dresden having been mentioned, it was remarked that in its power of enduring the smoky atmosphere of towns, the tree would probably be found to be a rival to the Plane.

Orchids were the next subject to which Mr. Bateman directed attention. Among those from his own garden was *Promeneia citrina*, one pseudo-bulb of which had produced two flowers of different colours, one being bright yellow, the other pure white. He had never seen a similar case among Orchids; but he recollected Mr. Clowes once showing him a *Miltonia*, from opposite sides of a pseudo-bulb of which issued flowers of different sizes. It was, indeed, difficult to say where the pranks of this curious race of plants might end. Cut specimens were shown by W. W. Buller, Esq., and it was stated that at the next meeting that gentleman would probably have something to say in reference to the cultivation of Orchids and double-glazing. Among cut flowers of Orchids from Mr. Anderson, gardener to T. Dawson, Esq., Meadow Bank, Glasgow, was a beautiful variety of *Dendrobium* in the way of *densiflorum*, bicolor, or Griffithii. With respect to Cattleyas, Mr. Anderson asked where *C. Mossii* ended and *C. labiata* began. That question had been answered a year or two ago. *C. quadricolor*, Wagneri, and Warneri, were all well-marked varieties of the one species, which went all through the Isthmus of Panama, till in the form of *C. labiata* it ended in Brazil. *Pescatorea crina*, shown by Messrs. Veitch, next occupied attention, and it was stated that though a wooden cut it had been published some years ago by Dr. Lindley, no coloured plate of it had as yet appeared, but that one would shortly be given in the "Botanical Magazine." The plant had been named in compliment to M. Pescatore, one of the most enthusiastic lovers of Orchids which the French empire ever produced, and rivalled only by Cousin Schiller among the Germans. In connection with *Angraecum caudatum*, a cut specimen of which was shown to the meeting, Mr. Bateman remarked that about this time last year he had the honour of naming an *Angraecum* after Capt. Grant, one of the discoverers of the source of the Nile; and he now had to direct attention to another, named after the distinguished traveller M. du Chaila, in commemoration of his discoveries in West Africa, in the country of the hideous

gorilla. This species, which is figured in the "Botanical Magazine" of the present month, was said to rival the *A. caudatum* of Sierra Leone. After the last meeting, Professor Owen, said Mr. Bateman, had shown him a *Cyrtanthus* bearing umbels of glowing crimson scarlet flowers, and a plant of it now exhibited still gave indications of considerable beauty. This was said to have been sent to Professor Owen by Mr. Bain, the discoverer of the strange *Dicynodonts*, or two-fanged reptiles of South Africa, (fossils of the Trias period), and was stated to have been found in the Karroos, or ravines of a mountain range about 800 miles north of Cape Town, and at an elevation of 1000 feet above the sea. In summer it succeeds out of doors in this country, but in winter it requires the protection of a greenhouse. The plant shown was presented to the Society, and Mr. Bateman moved that a vote of thanks be given to Professor Owen.

Mr. Bateman next offered some remarks on *Sirex juvenens*, which has been comparatively unnoticed for many years, though its attacks are much more frequent than generally supposed, and a piece of a dead Larch was furnished by G. C. Antrobus, Esq., of Eaton Hall, Cheshire, as an example of the way in which this insect perforates timber. All trees of trees, said Mr. Bateman, have their peculiar insect-pests, thus Larches, Pines, and Silver Firs are each attacked by different enemies. All know how destructive *Scolytus destructor* is to Elms, and that about this time of the year the *Hylurgus pimiperda* bores up the centre of the young shoots of Pine trees, causing them to snap off with the first gale of wind. These pests confine their depredations to live trees: but *Sirex juvenens* is even more to be dreaded. Curtis several years ago stated that the *Sirices* appear to be most destructive to dead trees and timber, which is not surprising when it is stated that the eggs are deposited by hundreds, and that the maggots when full grown are about 14 inch in length. *S. juvenens* made its appearance during July, August, and September in Fir groves in Norfolk, Suffolk, Hants, and Yorkshire, and specimens of it were shown to Mr. Curtis by the Hon. Charles Harris, who detected it in Fir plantations at Heron Court, the seat of Lord Malmesbury. "With us," said Mr. Harris, "at the age of twenty the Fir trees die to a great extent. The summer of 1825 and 1826 was peculiarly destructive to them, from its intense heat and drought, and I am certain that I never saw any trace of a *Sirex* except on dead trees. The smell of the turpentine would fully account for this, and the only spot where we could detect the *Sirex* in a standing plantation of shorter trees was on some dead stumps that had evidently been overgrown." From this it appears that the mischief arises from allowing dead trees to remain standing or lying about; and timber ought to be well examined before it is employed in building. "For," said Mr. Curtis, "I understand that considerable numbers of the males have been taken flying about the tower of York Minster, no doubt seeking the females which were issuing from the timbers that supported the roof, and which would be of course greatly weakened by the continued operations of the larvae, as well as rendered more combustible by the multitude of passages and the quantity of dust which they create." Singularly enough, said Mr. Bateman, Mr. Curtis's prediction as to fire was soon verified; for in 1829, very shortly after the above was written, York Minster was the scene of a conflagration. Mr. Bateman added that he had only become acquainted with *Sirex juvenens* about this time last year, and it was marvellous, he said, that after eluding exposure for nearly a quarter of a century its evil deeds should now be proclaimed. It was also stated on the authority of Mr. A. Murray that the insect had made its appearance with Mr. Thomson, of Banchory House, Aberdeenshire. Mr. Buller said he had known this *Sirex* for years in Devonshire, where it appeared to confine its operations to wood either wholly dead or decaying. Palings and Larch posts were attacked by it, but he had not seen it on live trees. Mr. Bateman here remarked that it seemed only to make its appearance after very hot summers, but when detected every possible means should be used to extirpate it.

WEEKLY SHOW, July 7th.—At this Meeting there was a good exhibition of vegetables, and some excellent trays of Carnations and Picotees. In the class for twelve Carnations, Mr. Hooper, of Vine Nursery, Bath, took the first prize, and Mr. Shackell, of Oldfield Nursery, Bath, the second; they were beautiful blooms, as were also the twelve Picotees exhibited by the same gentlemen, by whom the prizes were taken in the same order. For the best basket of miscellaneous cut flowers, Mr. McIndoe, gardener to Coles Child, Esq., of Bromley, took the first prize, and Mr. Bartlett, of Hammersmith, the second. In the collection of vegetables, Mr. McIndoe was again first, Mr. Young, gardener to R. Barclay, Esq., of Highgate, second, and Mr. Plester, of Elsenham Hall Gardens, Essex, was third. In the miscellaneous class, Mr. Butcher, gardener to A. Bond, Esq., took a first-class certificate for a very fine specimen of Falham Cabbage, and Mr. Young was similarly rewarded for a large specimen of the Enfield Market, which is a more form of the former. Two meritorious designs of flower gardens were shown by Mr. Brown, of Southwood Lane, Highgate, and Mr. Hill, Angel Row, Highgate. The former took his plan from that of the International Exhibition, and both received extra prizes. Mr. Ward, gardener to F. N. Miller, Esq., Bishop Stortford, received a second prize for three handsome Pines; and Mr. Young, gardener to R. Barclay, Esq., extra prizes for a collection of *Caladiums*, and one of *Agaves*; also a first-class certificate for *Leptopteris superba*, and one of the second class for *Erica Parmentieriana rosea*.

## ROYAL BOTANIC SOCIETY'S SHOW.

JULY 4TH.

THE last Show of the season took place on Wednesday last, and though the weather was by no means favourable, there was a large attendance of visitors, among whom the fairer sex as usual greatly predominated. Their pleasure, however, in promeneing the lawn was greatly marred by the frequent cold showers which made the turf damp, and the day throughout was very ungenial for that period of the year which is usually the warmest. The plants did not appear to be so numerous as at the earlier exhibitions, nor did they on the whole exhibit that freshness and profusion of bloom which rendered them so attractive in May; but fruit was shown in great abundance, variety, and excellence, constituting, in fact, the most important feature of the Show.

**STOVE AND GREENHOUSE PLANTS.**—Of these Mr. Peed, gardener to Mrs. Tredwell, Lower Norwood, exhibited a fine collection of ten, prominent among which was a magnificent specimen of *Ixora salicifolia*, a worked plant about 5½ feet high, and bearing in great profusion heads of orange flowers from 7 to 8 inches in diameter. This was certainly the finest plant of its kind that we remember; and although some two or three years ago, Mr. Whitbread exhibited a remarkable specimen, we question whether it was equal to that shown by Mr. Peed. *Allamanda grandiflora* and *Dracophyllum gracile* from the same exhibitor were also fine, and *Rondeletia speciosa* was likewise noticeable in his collection. In that of Mr. Rhodes, Azalea Apollo was still in very good bloom, and he had besides by far the finest *Kalosanthe* in the Show, a round-headed plant of coccinea, about a yard across, and presenting a glowing mass of rich scarlet. *Phænocoma prolifera*, a large plant, with its rosy crimson overclustering flowers quite as large as a five-shilling piece; a very good *Ixora coccinea*, and large plants of *Hedera fuchsoides*, and *Pinelea mirabilis*, also came from Mr. Rhodes; and from Mr. Williams, a very fine specimen of *Phænocoma prolifera*, 6 feet across and in profuse bloom, together with *Bougainvillea glabra*, *Allamanda grandiflora*, and *Erythrina crista-galli*, whose showy red flowers are not usually seen at exhibitions. Mrs. Glendinning & Sons sent *Allamanda Aubletii* in very good bloom, but not so showy as *A. grandiflora*; and inferior plants of it also appeared in other collections; also, a fine specimen of *Viuca oculata*; Mr. Baxendale, Guildford, had *Rhynchospermum jasmiioides* and *Bignonia grandiflora*, assorting well with an *Allamanda* near it, though differing in being reddish orange instead of yellow. Mr. Kaile, gardener to Earl Lovelace, had a very good plant of *Rhynchospermum jasmiioides*; and Mr. A. Ingram, gardener to J. J. Blandy, Esq., Reading, the beautiful purplish violet *Pteroma elegans*, in fine bloom; *Kalosanthes coccinea superba*; *Clerodendron Thomsoni*, full of flower; and *Statice profusa*. Mr. Ward, gardener to F. G. Wilkies, Esq., Leyton, took, however, the lead in the Amateurs' class for six, with, among others, *Allamanda grandiflora*, small but in excellent bloom; *Statice macrophylla*, with a profusion of its purplish lilac flowers in dense corymbs; *Stephanotis floribunda*, and *Phænocoma prolifera* *Barnesii*. Mr. Kemp had the showy scarlet *Clerodendron Kämpferi*; and Mr. Wilkie, gardener to I. McHenry, Esq., a very good specimen of *Dracophyllum gracile*.

Awards—For ten: first, Mr. Peed; second, Mr. J. Wheeler, gardener to J. Philpott, Esq. For eight (Nurserymen): first, Mr. Rhodes; second, Mr. Williams; third, Mr. Baxendale; fourth, Mrs. Glendinning & Sons. For eight (Amateurs): first, Mr. Kaile; second, Mr. G. Wheeler, gardener to Sir F. Goldsmid, Bart. For six: first, Mr. Ward; second, Mr. A. Ingram; third, Mr. Wilkie; fourth, Mr. Kemp.

**FINE-FOLIAGED PLANTS AND FERNS** were rather numerous, and being judiciously placed in the bays between the flowering plants, these were not overpowered, nor overpowering as they sometimes are by too much colour being impressed on the eye. Mr. Williams, Holloway, had, in a set of ten, fine specimens of *Cordylina indivisa*, *Cycas circinalis*, *Dracena lineata*, *Chamærops humilis*, *Cyathæa dealbata*, and variegated Aloe-leaved *Yucca*, and in another collection *Alocasia Lowii* in splendid condition, *Dracena marginata*, with the leaves narrowly edged with red, a fine *Latania borbonica*, and *Zamia pumilus*, very thick in the trunk. Mr. Barley, Albert Nursery, Bayswater, also sent various Palms and *Alpinia natans*. Of Amateurs, Mr. Taylor, gardener to J. Yates, Esq., Highgate, had a very fine specimen of *Sabal Blackburiana*, *Zamia spiralis*, *Eucephalartos latifrons*, and other *Cycads*, and a good plant of *Litsea juncea*. From Messrs. Barnard, Gell, Glendinning, and Young, came the Date Palm, *Rhopala*, *Sphaerogone latifolia*, *Alocasia macrorhiza variegata*, *Dracenas*, *Marantas*, *Pandanads*, one or two *Caladiums*; *Panicum sulcatum*, a broad-leaved Grass; and *Anthurium cordifolium*.

Awards—For ten (Nurserymen): first, Mr. Williams; second, Messrs. Glendinning; third, Mr. Barley. For ten (Amateurs): first, Mr. Taylor; second, Mr. Gell; third, Mr. Young. For six: first, Mr. Taylor; second, Mr. Barnard.

Exotic Ferns from Messrs. Taylor, Williams, Barnard, and Young, comprised good specimens of *Cyatheas*, *Cibotiums*, *Dicksonias*, *Woodwardia radicans*, *Todea africana*, *Pteris cretica albo-lineata* and *argyrea*, *Phlebodium anacra*, *Adiantum trapeziforme* and *formosum*.

Awards—For twelve (Nurserymen): first, Mr. Williams. For twelve (Amateurs): first, Mr. Taylor; second, Mr. Barnard; third, Mr. Young.

Of British Ferns, the best twelve came from Messrs. Ivory & Son, of Dorking, and consisted of *Lastrea Filix-ina* Ingravouii, *Athyrium Filix-femina* Grantia, the crested variety of the Royal Fern, *Poly-stichum aculeatum* acrocladon, and angulare grandiceps, *Trichomanes radicans*, *Asplenium trichomanes* Moulei, very pretty; *Scelopendrium vulgare crispum latum*, *Lastrea montana* Nowelliana, *Pseudathyrium flexile*, *Blechnum spicatum crispum*, and *Adiantum capillus-Veneris*. Collections, including various forms of the above genera, also came from Mr. Kaile and Mr. Kemp, gardener to Earl Percy.

HEATHS comprised fine specimens of the brilliant *Parmentieriana rosea*, *Savilleana*, *Ventricosa* *Bothwelliana* and *coccinea*, tricolor varieties; *Aitoniana*, *eastronica*, and *Turnbulli*, white; *obovata*, *Massoni* major, *ampullacea* major, *eximia*, *nobilis*, orange; *depressa*, and *Cavendishii*, the last two, however, rather past their best.

Awards—For eight (Nurserymen): first, Messrs. Jackson & Sons; second, Mr. Rhodes; third, Messrs. F. & A. Smith. For eight (Amateurs): first, Mr. Peed; second, Mr. Ward; equal third, Mr. A. Ingram and Mr. J. Wheeler, gardener to J. Philpott, Esq.

ORCHIDS were not numerously shown, nor were they in the same fine condition as at the first Show. Mr. Bullen, gardener to A. Turner, Esq., Leicester, had *Trichopilia crispata* with certainly not less than thirty fine blooms, a fine specimen of *Aërides odoratum majus*, *Saccolabium Blumei* majus with five spikes, *Cattleya Acklandia* with three blooms, *C. superba*, very brilliant in colour; *Cypripedium Veitchii* with four fine blooms, and a good example of *C. barbatum superbum*; Mr. Wiggins had *Cattleya Wagneri*, *Cypripedium Hookeri* and *Stonei*, *Odontoglossum hastilabium*, *Aërides*, and a *Vanda*; and Mr. Williams sent, among others, a fine specimen of *Aërides odoratum majus*, also *Aërides Lobbi*, *Phalænopsis grandiflora*, and *Cypripedium barbatum superbum*. From other exhibitors came *Phalænopsis Luddemanniana*, *Cattleya Mossie*, the old *Broughtonia sanguinea*, *Calanthe masuca*, *Lælia purpurata*, *Odontoglossum hastilabium* and *cordatum*, the pretty *Miltonia spectabilis*, and *Vanda Batemanii*.

Awards—For ten: first, Mr. Bullen; second, withheld; third, Mr. Peed. For six: first, Mr. Williams; second, Mr. Parker; third, Mr. Rhodes. For six: first, Mr. Wiggins; second, G. Cooper, Esq.; Old Kent Road; third, Mr. Hill, gardener to R. Hanbury, Esq.; fourth, Mr. J. Wheeler; fifth, Mr. Willcock, gardener to Dr. Pattison, St. John's Wood.

**FUCHSIAS.**—Only three collections were shown, and of these the best came from Mr. Brockwell, Edmonton, whose plants were from 6 to 7 feet high and well-grown and flowered. Among dark varieties were good examples of Sir Colin Campbell, Lord of the Isles, and Sensation; among light sorts, Wiltshire Lass, Minnie Banks, Reine Blanche, and Schiller; and among kinds with white corollas, the best were Madame Cornelissen and Coespica.

Awards—For six: first, Mr. Brockwell; second, Mr. Weston, gardener to D. Martineau, Esq., Clapham Park; third, Mr. Filce, gardener to J. Shutter, Esq.

**PELARGONIUMS** were inferior both in the size of the plants and bloom to those exhibited at the previous Show, when Mr. Bailey's and Mr. Turner's plants attracted such general admiration. Mr. Fraser, however, on this occasion had good plants of Favourite, Pericles, Beacon, Mille, Patti, Desdemona, Caractacus, Leader, and Maiden Fair. Mr. Nye, gardener to G. Foster, Esq., had fine specimens of Fairest of the Fair, Perdita, Mille, Patti, and International; also Spotted Gem, Lord Clyde, and Pericles; and Mr. Ward had Caractacus, Lilacium, Royal Albert, Desdemona, and Pericles. In the class for six varieties Mr. Wiggins, gardener to W. Beck, Esq., had good plants of John Hoyle, Eurydice, Diana, Album formosum, Exhibition, and Isabel. Of Fancy varieties, Mr. Fraser had good examples of Zœ, Undine, Bridesmaid, Helen, Hebe, and Aemo. Of Scarlets, the best came from Mr. Windsor, Walthamstow, who contributed Sir Robert Peel and Prime Minister, scarlet; Virgo Marie, white; Princess and Eugénie Mèzard, salmon; and Highgate Rival, salmon scarlet, all well grown.

Awards—For nine: first, Mr. Fraser. For nine (Amateurs): first, Mr. Nye; second, Mr. Ward; third, Mr. Wiggins. For six Fancy: first, Mr. Fraser. For six Scarlet: first, Mr. Windsor; second, Mr. Catlin; third, Mr. Hawes; fourth, Mr. Logan. For varieties of 1863-4: first, Mr. Fraser; second, Mr. Wiggins.

**ROSES.**—Messrs. Paul & Son exhibited some very good plants in pots, among which Duc de Rohau, Comte de Nauteuil, Duchesse de Caylus, Leopold L., Comtesse de Chabrilaut, and Madame Victor Verdier, were particularly fine; and of cut blooms, fine stands were shown by Messrs. Paul & Son, Ingle, Chard, J. Hollingworth, Turner, and Marlow, containing in addition to the above-named varieties fine examples of William Griffiths, Gloire de Santenay, Senateur Vaise, Gloire de Dijon, Maurice Beruardin, Madame Bravy, Souvenir de Malmaison, and others.

Awards—For fifty: first, Mr. Turner; second, Messrs. Paul & Son; third, Mr. Fraser. For twenty-five: first, Mr. Ingle; second, Mr. Chard; third, Mr. Hollingworth. For twenty-four: first, Mr. Turner; second, Mr. Ingle; third, Mr. Marlow.

**NEW PLANTS AND SEEDLINGS** were numerously shown. Messrs. Veitch had first-class certificates for the true *Peperomia arifolia*. *Davallia parvula* very pretty, *Drosera capensis*, *Nepenthes lacinata*, *Maranta Lindeni*, *Lomaria Belli*, *recurva*, and *ciliata*; *Davallia alpina*; a species of *Adiantum* with copper-coloured young fronds; a

pretty little *Nierembergia*, and *Acalypha tricolor*. To the same firm second-class certificates were awarded for a Bornean *Nepenthes*, and a handsome *Spharogone* from Bolivia. Several of these are noticed in another column. Messrs. Veitch also exhibited *Retinospora obtusa aurea*, having foliage beautifully tinged with gold, *Begonia Pearcei*, and *Alternanthera spatulata*. From Mr. Ball came also a numerous collection, of which the following plants received first-class certificates—viz., *Maranta Lindenii*, *Pandanus latissimus*, with rather broad pale green leaves; *P. Porteanus*, much more slender than the preceding, *Rogiera grassissima*, with small pale rose-coloured flowers slightly scented; *Latania rubra*, *Adiantum velutinum*, *Peperomia argyrea*, and *Athyrium Goringianum pictum*, variegated with white after the manner of *Pteris argyrea*, but much more slightly marked. The same exhibitor had second-class certificates for *Cinchona nobilis*, with handsome leaves having a red midrib; a variegated *Plajus grandifolius*, *Philodendron bipinnatifidum*, and *Echeveria atropurpurea*, with brownish red leaves. First-class certificates were also awarded to Messrs. Waterer & Godfrey for *Cupressus Lawsoniana argentea*, a glaucous variety of that fine species; to Mr. R. Parker for *Goodyera pubescens intermedia*, and *Statice floribunda* with purplish violet flowers; and to Messrs. Backhouse, York, for *Dipladenia amabilis*, noticed in our Floral Committee report. Similar awards were made to Messrs. Ivery & Son for *Athyrium Filix-femina pulcherrimum*, to Messrs. Jackson for *Peperomia arifolia*, to Mr. Williams, Holloway, for *Lomaria rigida* and an *Adiantum*, and to Messrs. E. G. Henderson for *Caladium Napoleon III.* Second-class certificates were given to Mr. Fraser, Lea Bridge, for *Lilium auratum caudatum*, of a purer white than the common variety, and not spotted; to Messrs. Ivery for a *Polystichum*; and to Mr. Williams for *Lindsea cultrata*. Among seedling florists' flowers Mr. Watson had first-class certificates for *Geraniums* Miss Watson and Mrs. Dix, both of which have been already noticed, and a similar award was made to Mr. G. Smith, Hornsey Road, for *Nosegay Pelargonium La Grande*, a fine scarlet; also to Mr. Tirebuck, Linton, for *Emily Morland*, a scarlet zonal. Messrs. F. & A. Smith, who exhibited numerous zonal and tricolor-leaved varieties, received certificates of the first-class for *Sunbeam*, bright scarlet, large trusses; *Diadem* and *Charmer*, orange scarlet; and *Glorious*, deep scarlet; also certificates of the second class for *Vandyke*, Mrs. Charles Barry, Conqueror, Magnificent, and *Scarlet Dwarf*. Mr. W. Paul again exhibited several varieties of the zonal and *Nosegay* sections, and had certificates of the first-class for *Nimrod*, *Waltham Gem*, *Rebecca*, *St. George*, and *Sir Joseph Paxton*; and of the second class for *Scarlet Dwarf* and *Cardinal*. Mr. Turner had a first-class certificate for *International* and *Lady Constance Grosvenor*, the former a crimson scarlet zonal variety, and the latter a fine scarlet. *Verbenas* *Anricula* and *Harry Law* exhibited by Mr. Perry, of Castle Bromwich, likewise received first-class certificates, and Messrs. Downie & Co.'s fine bedding *Pansy Imperial Blue*, a second-class one. Several showy *Clematises* were shown by Mr. Townsend, Horsey; and a pretty white *Lobelia*, called *Miss Murphy*, likely to be useful for bedding, shown by Messrs. Dobson & Son, received a first-class certificate.

**MISCELLANEOUS.**—Mr. Parker, Tooting, exhibited *Yucca canaliculata* producing its creamy inflorescence, *Acanthus montanus* with rather ornamental foliage, *Spharogone cinnamomica*, and a showy *Amaryllis* called *marginata conspicua*. Mrs. Glouning & Sons had *Gesneras* and *Anacochilis*; and good stands of *Pinks*, *Carnations*, and *Picotees*, came from Mr. Turner, Slough, Mr. Hooper, Bath, and others. Annuals were also shown by Messrs. Hooper & Co., of Covent Garden.

#### FRUIT.

The display of fruit, as already stated, was large in quantity and excellent in quality. Nearly one hundred Pines were shown, and upwards of two hundred bunches of Grapes, most of these, too, being large and very well grown. The first prize for a collection was awarded to Mr. Rawbone, gardener to C. Campbell, Esq., Ashbourne, for a Queen Pine of 4½ lbs., three excellent bunches of Black Hamburg Grapes weighing in all 7½ lbs., Golden Hamburgs, Trentham Hybrid Melon, fine Royal George Peaches, Elrige Nectarines, and Keens' Seedling Strawberries. Mr. Robinson, gardener to R. Benyon, Esq., M.P., Reading, was second with a Queen Pine, Black and Golden Hamburg Grapes, Golden Perfection Melon, Grosse Mignonne Peaches, Elrige Nectarines, Figs, Strawberries, and Cherries. Mr. Turner was third with a Queen Pine, Buckland Sweetwater and Black Hamburg Grapes, a Melon, *Violette Hâtive* Peaches, Elrige Nectarines, and Dr. Hogg Strawberry; and Mr. Miller, gardener to Earl Cravan, Combe Abbey, was fourth with six fine Ripley Queen Pines, Muscat and Black Hamburg Grapes, Melons, Peaches, Nectarines, and Strawberries. Mr. Turnbull, gardener to the Duke of Marlborough, was fifth; and Mr. Sage, gardener to Earl Brownlow, Ashridge, sixth.

**PINE APPLES.**—In collections of four fruit, not less than two kinds, Mr. Hannan, gardener to R. T. Crawshaw, Esq., Cyfarthfa Castle, was first with two fine Providences, weighing respectively 8 and 9 lbs., and two good fruit of the Black Jamaica. Mr. Young, gardener to Crawshaw Bailey, Esq., Aberaman, was third with Providence weighing 7 lbs. 2 ozs., and 7 lbs. 6 ozs. each, and well-ripened Queens of 4 lbs. 2 ozs., and 4 lbs. 6 ozs.; and equal third prizes were awarded to Mr. Miles, gardener to Lord Carrington, and Mr. Young, gardener to W. H. Stone, Esq., M.P., Leigh Park, the former having Smooth-leaved Cayennes weighing a little more than 5 lbs., a Prickly Cayenne

of 4 lbs. 6 ozs., and an Enville of 4½ lbs.; whilst Mr. Young had two excellent Queens, a Providence, and a Black Jamaica.

Of Providence Pines several large and handsome fruit were shown. Mr. Hannan was first with a noble fruit of 10 lbs., and Mr. Young, Aberaman, second, with one which, though not so heavy by 1¼ lb., was more handsome. Mr. Elstone, gardener to S. Lawrence, Esq., Clapham Park, was third with one of 8½ lbs.; and extra prizes were awarded to Mr. Bailey, gardener to T. T. Drake, Esq., Shardeloes, for a fruit weighing 8½ lbs.; to Mr. Deville, gardener to Major Martin, for one of 8 lbs.; to Mr. Gell, gardener to Mrs. Beaufoy, South Lambeth; to Mr. Jones, gardener to Lady Mill; and to Mr. Speed, gardener to Sir E. Walker, Bart., Bury Hill, Mansfield.

Among Queens by far the best was a well-ripened fruit of the extraordinary weight of 7 lbs. 6 ozs., shown by Mr. Ward, gardener to F. N. Miller, Esq., Bishop Stortford, and to which, of course, the first prize was awarded. Mr. Brice, gardener to J. Iermite, Esq., of Finchley, was second with a finely ripened fruit weighing 5 lbs. 4 ozs.; and Mr. Young, Aberaman, third, with a fine fruit of 5 lbs. Mr. Perkins, Staunmore; Mr. Holliday, gardener to H. Walmsley, Esq., Acton; Mr. Kemp; Mr. Hannan; and Mr. Coles, gardener to R. H. Page, Esq., Beckenham; and Mr. Drevitt, had also very good fruit of this variety, which in several cases was shown of a heavier weight than it has usually been seen of late years, when first prizes have frequently been taken by fruits under 4 lbs. in weight. Special mention must also be made of a dozen Queens weighing 63 lbs., exhibited by Mr. Ward, all of which were handsome fruit and in beautiful condition.

In the class for any variety no first prize was awarded; the second was given to Mr. R. Smith, gardener to H. Walker, Esq., Calderstone, for a well-ripened Black Jamaica; and the third to Mr. Gardiner, gardener to E. P. Shirley, Esq., Eastington Park, Stratford-on-Avon, for a fruit of the same variety weighing 3½ lbs. Mr. Kemp, gardener to E. Benthall, Esq., had a Black Antigua, for which an extra prize was awarded.

GRAPES made a splendid display, especially the Black Hamburgs. In the class for three kinds Mr. Meredith had a wonderfully fine exhibition, consisting of Black Hamburgs, remarkable both for size of bunch and berry, their fine colour, and their beautiful bloom; Black Prince, and Trentham Black also very fine. Mr. Meredith here walked over the course, all the other competitors being a long way behind. No second prize was awarded, but equal third prizes were given to Mr. Osborn, Finchley, for well-ripened Buckland Sweetwater, good Muscats but not ripe, and Black Hamburg; to Mr. Horwood, gardener to G. H. Turnbull, Esq., Rookery Down, Kent, for Black Prince, small Muscats, and Black Hamburgs; to Mr. Tansley, gardener to A. Moss, Esq., Chadwell Heath, for Muscat of Alexandria, Black Hamburgs, and Canon Hall; and to Mr. Sage, gardener to Earl Howe, Atherstone, for good bunches of Black Hamburg, Black Prince, and Buckland Sweetwater. In the same class Mr. M. Henderson, gardener to Sir G. Beaumont, Bart., Coleorton Hall, exhibited very good Black Hamburg and White Muscadine, and Mr. Turnbull, Eleubine, large bunches of Black Prince, but not sufficiently ripe.

In the class for three bunches of Black Hamburgs, Mr. Meredith and Mr. Clement, East Barnet, were placed equal first with large and beautifully-coloured bunches, and in each case densely covered with a beautiful bloom. Those from Mr. Meredith weighed collectively 10½ lbs., and were very even in size of berry. Mr. Squires, gardener to H. Ludlow, Esq., Heywood House, Westbury, was second with good large-berried bunches but a little deficient in colour; Mr. Osborn, and Mr. Pople, West Monsey, were equal third; and Mr. Speed, Bury Hill, fourth, with small but well-coloured bunches. Good exhibitions in the same class also came from Mr. Wallis, gardener to J. Dixon, Esq., Astle Park, Mr. Rawbone, and Mr. M. Henderson.

In baskets Mr. Meredith was again first with Black Hamburg large and finely coloured, Mr. Tansley being second with very good Canon Hall; and Mr. M. Henderson, Mr. Hannan, Mr. Pople, and Mr. Osborn, had equal third prizes, all for Black Hamburg, except Mr. Osborn, who had Muscats.

In the class for Black Prince, or West's St. Peter's, the former variety was almost exclusively shown. With it Mr. Turnbull, gardener to the Duke of Marlborough, was first with large bunches, but not so finely coloured as we have seen; Mr. Sage, gardener to Earl Howe, was second with good bunches of the same kind; and others came from Mr. Allen, gardener to E. Hopwood, Esq., Manchester, and Mr. Goldsmith, gardener to Sir W. Farquhar, Bart., one of those from the former being 16 inches in length, but it, as well as the two smaller bunches on each side of it, were deficient in colour. Mr. Allport, gardener to H. Aykroyd, Esq., had compact bunches of West's St. Peter's beautifully coloured.

Muscats from Mr. Turner, of Slough, were beautifully ripened, being of a rich golden-amber colour, in respect to ripeness far before all the other bunches. The second prize went to Mr. Pizzie, gardener to F. Edwards, Esq., Pickeridge; and the third to Mr. Clement, for very good bunches, but not quite ripe.

In the class for any kind, Mr. Record, gardener to Colonel Loyd, Hawhurst, Kent, was first with Marchioness of Hastings, the three bunches weighing collectively 8 lbs. 3 ozs.; and Mr. Lynn, gardener to Lord Boston, Hedsor, second, with fine bunches of Buckland Sweetwater, but not sufficiently ripe. Good White Muscadines, from Mr. M. Henderson, were third. The only other kinds which we noticed

were Red Frontignan and Golden Hambargh. In the Miscellaneous Class a prize was also awarded to Mr. Meredith, for a bunch, or rather series of bunches on a single stalk, weighing 7½ lbs., and, notwithstanding its large size, perfection in colour and bloom.

MELONS were shown to the number of about two score. In the Green fleshed class, the best were a Hybrid Cashmere, from Mr. Weir, gardener to Mrs. Hodgson, Hampstead; and Combe Abbey Hybrid, from Mr. Miller, gardener to Lord Craven. Golden Perfection and Conqueror of Europe, respectively from Mr. Ross, gardener to Col. Byre, Welford Park; and Mr. Record, gardener to Col. Loyd, were placed equal second. In the Scarlet-fleshed class, Mr. Weir was again first with Improved Windsor Prize; and Scarlet Gem from Mr. Beech, gardener to T. Allcock, Esq., Epsom, and Mr. Goldsmith, was second.

PEACHES and NECTARINES.—Of Royal Charlotte and Violette Hâtive Peaches, remarkably fine fruit were shown by Mr. Sawkins, gardener to A. Smith, Esq., Bramfield; and Royal George and finely-coloured Galande Peaches came from Mr. Horwood. Mr. Miller, gardener to Earl Craven, had fine Violette Hâtive Peaches and Nectarines; and Brugnon and Scarlet Nectarines from Mr. Allen, gardener to Capt. Glegg, Withington Hall, were also good; so too were the Grosse Mignonne and Royal George Peaches from Mr. Beech. Royal George Peaches and Elrage Nectarines were also shown in good perfection by Mr. Masters, gardener to the Earl of Macclesfield, and by Mr. Sage, gardener to Earl Browlow. In the class for four dishes, Mr. Allen, gardener to Capt. Glegg, Withington Hall, had Bellegrave, and Noblesse Peaches, and Scarlet and Brugnon Nectarines, the whole of which were fine. Mr. Masters had good fruit of Royal George and Early Grosse Mignonne Peaches, and Elrage and Violette Hâtive Nectarines; whilst Mr. Young, gardener to W. H. Stone, Esq., Messrs. Jackson, of Kingston, and Mr. Turnbull had also good exhibitions.

Awards—For four dishes: first, Mr. Allen; second, Mr. Masters; third, Mr. Young; equal fourth, Mr. Turnbull and Messrs. Jackson. For two dishes: first, Mr. Sawkins; equal second, Mr. Miller and Mr. Horwood; equal third, Mr. Allen and Mr. Beech; fourth, Mr. Masters.

STRAWBERRIES.—Mr. Widdowson, gardener to J. H. Barnes, Esq., Rickmansworth, furnished the best four dishes—viz., Empress Eugénie, Sir Charles Napier, President, and Oscar, all large and fine. Mr. Turner, Slough, had Dr. Hogg, Léon de St. Lannier (a large cockscomb-shaped fruit), Sir C. Napier, and Sir Joseph Paxton; and Mr. McIndoe, gardener to Coles Child, Esq., Bromley, exhibited Comte de Paris, Marguerite, Empress Eugénie, and President. Mr. Lydiard, Batheaston, sent British Queen, Sir C. Napier, Sir J. Paxton, and Comte de Paris. From Mr. Horwood, Cudham, came two fine basketsful of Kitley's Goliath; and Mr. Bailey, Shardeloes, had a seedling named Princess Mary, said to be very prolific, and to possess a well-marked Pine flavour.

Awards—First, Mr. Widdowson; second, Mr. Turner; third, Mr. McIndoe; fourth, Mr. Lydiard.

MISCELLANEOUS.—Although classes were assigned to several other fruits, the exhibitions in these were so few that they will be most conveniently noticed under this head. For Plums, Mr. McIndoe, gardener to Coles Child, Esq., Bromley, was first with a kind of Gage called De Galopin, and Mr. Ingram, gardener to J. J. Blandy, Esq., second with Victoria. Of Figs, fine fruit of the Brown Turkey from Mr. Miles, gardener to Lord Carrington, were first; the same kind from Mr. Robinson, gardener to R. Benyon, Esq., second; and what was called Bonjasotte blanche, from Mr. Blake, gardener to E. Green, Esq., Ware, third. In Black Cherries, Mr. Turner was first with Black Tartarian, large and beautifully ripened; Mr. Hill, gardener to R. Hanbury, Esq., The Poles, second with fine fruit of the same variety. Of White Cherries, the best were Bigarrea from Mr. Widdowson and Mr. Turner, who were first and second, and Elton from Mr. Hill, who took an equal second prize. Mr. Turner also exhibited fine fruit of Black Eagle, Werder's and Knight's Early Black, Black Tartarian, May Duke, Bigarreau, and Elton. From Mr. Henderson, Coleorton Hall, came a box of very good Elrage and Violette Hâtive Nectarines; and from Mr. Osborn, Finchley, Grosse Mignonne Peaches. French Crab Apples were shown in excellent preservation by Mr. Ross, Welford Park; Raspberries by Mr. Marcham, Drayton House, Ealing; and Apples, Pears, Peaches, and other orchard-house trees in pots by Mr. Fraser, Lea Bridge.

THE REIGATE ROSE ASSOCIATION'S SHOW was held in the Public Hall, Reigate, on June 30th. The centre of the Hall was occupied by two parallel tables containing the stands of the members for competition, the sides by similar tables on which were placed many beautiful plants to be presently noticed with the boxes of Roses brought by nurserymen, not for competition, but kindly lent by them to assist in rendering the Show effective. They came from Messrs. Paul & Son, Cheshunt; Mr. Mitchell, of Pildown; Messrs. Ivery and Son, Dorking; and Mr. John Cattell, Westerham. The table along the end of the Hall was covered with bouquets, arranged chiefly with Fern and other foliage, and suitable for dinner-table decoration. These bouquets were exhibited by Mrs. Wilson Sanders and the ladies of Reigate, Redhill, and the immediate neighbourhood, and for taste and elegance fully merited the praise liberally bestowed upon them. A Rose was shown which may, or may not, according as future experiments shall prove, exercise some influence in Rose culture. It is a Briar Rose from the Himalaya Mountains, exhibited by Mr. W. W. Saunders, the founder of the Association. A branch of it, about

4 feet in length, was one mass of white bloom, in bunches (corymbs), of eight or ten together. It is quite new to this country, of beautiful foliage and flowers, and of itself worthy of cultivation. It is also perfectly hardy and of vigorous growth, hence the probability of its being suitable for stocks. At six o'clock in the evening the Show was opened free to the working men of the town and their families, who availed themselves of the privilege in great numbers. The lively interest shown by them during their inspection, proved that this regulation of the Committee was duly appreciated by them. The cut flowers were afterwards distributed among those present.—A. H. K.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

MECONOPSIS NEPALENSIS (Nepalese Meconopsis).—*Nat. ord.*, Papaveraceæ. *Linn.*, Polyandria Monogynia. Native of Nepal and Sikkim Himalaya, at elevations of 10-11,000 feet. Flowers yellow, "stately, and beautiful." Introduced by Messrs. Backhouse, of York.—(*Bot. Mag.*, t. 5585.)

POLYSTACHYA PUBESCENS (Hairy-stemmed Polystachya).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Southern Africa. Flowers yellow, striped with crimson.—(*Ibid.*, t. 5586.)

LOBELIA NICOTIANEFOLIA (Tobacco-leaved Lobelia).—*Nat. ord.*, Lobeliaceæ. *Linn.*, Pentandria Monogynia. Native of the mountains of peninsular India and Ceylon. Flowers white, tinted with blue.—(*Ibid.*, t. 5587.)

ANCYLOGYNE LONGIFLORA (Long-flowered Ancylogyne).—*Nat. ord.*, Acanthaceæ. *Linn.*, Diandria Monogynia. Native of Guayquil. Introduced by Messrs. Veitch & Sons. Flowers crimsoned-purple.—(*Ibid.*, t. 5588.)

ANGRÆCUM CHAILLUNUM (Du Chaillu's Angraecum).—*Nat. ord.*, Orchidaceæ. *Linn.*, Gynandria Monandria. Native of Western Africa, sent by the well-abused M. du Chaillu, from the Gaboon. Flowers white, tinged with green.—(*Ibid.*, t. 5589.)

BOHEMIAN BLACK BIGARREAU.—This is "one of the largest and finest of our Black Heart class of Cherries. It is a variety that was introduced by Mr. Rivers, of Sawbridgeworth, under the name of Bigarreau Radowesnitzer, a name the correct pronunciation of which must in no small degree prove a stumblingblock to English gardeners; and we have therefore rendered it into English by calling it Bohemian Black Bigarreau, in allusion to the country whence it is said to have its origin. Whether we regard this variety as to its size, flavour, or earliness, it is equally valuable. It ripens early in July, and is of the largest size, of a roundish heart-shape, very even and regular in its outline; skin shining, and jet black. The characteristically short stalk is very stout, and dark green. Flesh quite black, firm, but not so firm and crackling as Bigarreaux generally are, but juicy, richly flavoured, and delicious. We would recommend this to be grown in every collection."—(*Florist and Pomologist*, v., 137.)

## GARDENERS' BENEVOLENT INSTITUTION.

WHEN at the dinner of this excellent Institution the other evening one or two thoughts crossed my mind. First, a fifteen-years annual payment of one guinea to entitle a subscriber to be placed on the pension list without the expenses of an election seems rather much; I would make this ten years. Then I would open a 10s. 6d. annual subscription for gardeners under thirty years of age, and rule a twenty-years subscription to entitle them to the same benefits. I believe this would produce a good revenue, and associate the young gardeners with the Institution, and secure their active influence and support. Let me, in support of this argument, bring into view the fact that the difference between an annual subscription of 10s. 6d. and 21s. is important to many young gardeners, whose remuneration, never high, is very low in early life.

Further, when I compare this with other benevolent institutions I think that, considering the numbers and influence of the gardening interest and its supporters, it does not receive all the support that might be expected. This does not, in my opinion, arise from any want of charitable feeling, but because its claims are not forcibly and often enough put before the public. Perhaps this has been left undone on the score of expense; but I believe that a judicious expenditure under this head would pay. Why not map out the country, and have a committee in every town ten miles distant, so that each committee might have a circle of ten miles diameter to work, canvassing every gardener and lover of gardening within it? This

would, of course, entail expenses of printing, posting, advertising, &c.; but to guard against injudicious expenditure of the Society's funds a good commission might be allowed on the subscriptions actually obtained. I believe men would be found willing to undertake this small risk, and would in no case withhold from the general fund more than was required to cover expenses.—WILLIAM PAUL, *Waltham Cross, N.*

### PLANTING ORNAMENTAL TREES AND SHRUBS.

PLANTING is an operation too often very indifferently performed, and the trees so frequently "stuck in" plainly testify mismanagement by the tardiness of their after-growth. Digging a hole and putting a tree in it is one thing, planting a tree is quite another. Of the latter I will now speak.

Trees of all kinds should be planted in prepared soil. The soil should be dug out to a depth of 2 feet, and that at bottom ought to be loosened to a depth of at least 1 foot. The openings so made should be larger than the ball, or extent of the roots, and they should not be round nor square, but in the shape of a cross, or of two rectangles placed across each other. Two rectangles, each 12 feet by 6 feet, placed across each other at right angles will be sufficient for moderate-sized trees, but for larger trees three such, 16 feet long by 6 or 8 feet wide, placed across each other, will not be too much. The space, however, let it be what it may, should be such that the inner radius will contain the roots without cramping them, and not only that, but leave a foot clear of prepared earth for them to ramify through before they come in contact with the firm or poor soil.

It is usual to make the pits or holes round, but this has the effect of introducing the growing fibres of the trees into the poor soil all at once, and thus a check is given, which causes many persons to inquire why the tree so planted should do well for a year or two after planting, and then all at once come to a standstill, and even retrograde. When a tree is planted in a round or square hole it is much in the same position as if it were planted in a pot or tub. The roots spread and take up all or most of the food contained in the circular or square pit, and by this time the head shuts out the rain; then the roots, not having extended further than the head, derive little benefit from rains, and, being introduced to the firm poor soil all at once, they feel the loss of the prepared or loose soil, and show that loss in the growths made. By planting, however, in cross-shaped pits the roots will extend rapidly through the prepared soil, and some of them coming in contact with the firm and poor soil almost immediately this will be penetrated by them; and those in the arms of the cross being in good soil will keep up a free growth until the others become established in the firm soil. At the same time the roots being attracted by the loose soil in the arms of the cross will be at a greater distance from the stem, and, therefore, derive the benefit of rains; whereas were the trees planted in round pits the head would exclude most of the rain, and the roots being deprived of that moisture to a great extent, the growths would be poor in consequence, and the necessity for artificial watering would be much increased.

*Fig. 1* will convey an idea of the advantages resulting from planting in cross-shaped instead of circular or square pits. Of these not the least is the dovetailing, so to speak, of the roots in the prepared soil; another consists in the moisture retained gradually rendering penetrable to the roots a larger surface of the hard ground at the sides of the hole. Besides, the trees are more secure against winds, and the sides do not give so great a check to the roots as those of a circular pit.

In preparing to plant, the earth taken out of the pits ought to be mixed with a quantity of good, loamy, rich soil. If the soil is poor, one-fourth of the worst should be taken from it, and double its bulk of fresh soil ought to be well mixed with the remaining portion, and the whole, or enough to fill the pit level with the surface, will have to be returned to the pit. If the soil taken out is good, all that is required will be to mix with it one-fourth of fresh soil. Whatever the quantity of bad soil, or stones separated from that taken out of the pits, the remainder should be mixed with one-fourth more fresh soil than the amount taken away. Compost suitable for mixing with the soil in planting may be obtained in most places by collecting ditch-cleanings, weeds, and rubbish of all kinds, and its quality will be improved by mixing with it parings from the sides of highways and road-scrappings, a large per-centage of

which in country districts consists of tree leaves. Such heaps turned over twice, and a cartload of fresh lime added to every ten of compost at the last turning, form excellent top-dressings for grass lands, besides being useful for giving trees a start at the time of planting. There ought to be such heaps of compost at hand, large or small, in every garden. From returning

*Fig. 1.*

the loosened soil taken out of the pit, together with that added to it, the trees will stand on a knoll, and such knolls or mounds should all be of the same height, as they will be if the foregoing directions be adhered to. Before planting the tree the soil in the centre of the pit should be elevated about 9 inches above the surface, and the cone thus formed should have the top flattened to the extent of about 3 feet. If the roots render it necessary, it should be hollowed out with the bottom convex rather than concave; for, when the bottom is concave the points of the roots are apt to be turned upwards, whereas they should incline from the stem of the plant downwards. In all cases the hole must be large enough to admit the roots without cramping or turning them from their natural position.

*Fig. 2.*

*Fig. 2* shows a tree planted in a convex-bottomed opening, with the roots coming straight from the root-stem; *fig. 3*, one placed in a hole with the bottom concave, the points of all the principal roots, from which the smaller roots take their rise, pointing upwards; whilst in *fig. 4* we have a tree planted in a raised mound, the top for about 2 feet from the stem of the tree being hollowed out, or concave, for watering the tree after planting. The opening so made, when the tree has become established, or before dry weather sets in, is mulched with stones or rough pieces of turf, either of which will lie open and permit of the basin holding water, and at the same time prevent rapid evaporation. The mode of staking the tree is also shown, for it is necessary after planting to maintain the stem in an upright position, otherwise the wind may force it from the perpendicular when the roots are emitting fresh fibres, and thus destroy many of them; besides, a tree liable to be moved by the wind is sure to have its roots dis-

placed and injured, and trees blown over a few times for want of staking will soon be fit only for firewood.

Fig. 3.

The tree having been planted, watered, and the head adjusted by staking, the hill or cone should be sloped down all round and turfed over, or sown with grass seeds, the turf taken from the ground in the first instance, it is presumed, being mixed with the soil as it was returned to the pit, where it will be very beneficial in promoting growth. In planting trees and shrubs they should not be placed lower in the soil than will be sufficient to cover the uppermost roots with from 3 to 6 inches of soil; in fact, the base or setting-on of the roots should be nearly level with the surface, the roots radiating from it at that point being spread out at a slight angle into the soil.

Fig. 4.

By planting the trees on hills we seek to produce the same effect as if the trees had sprung out of the earth naturally, rising, as they invariably do, from an elevated base occasioned by the rising and swelling of the collar. Though the mounds may be rather high, they will sink down so as to be in a few years only about half their original height; ultimately every tree so planted will rise out of a gently elevated base, and this adds to the dignity of expression, without which no tree can have a natural appearance, and that it must have to look well. Imagine the shaft of a tree rising abruptly out of a flat surface, and appearing no thicker at its base than it is higher up! There is no such thing in nature, yet such trees are very common in pleasure-grounds in consequence of neglect in not keeping the roots considerably higher than the general surface at the time of planting. When a tree is planted in a pit 2 feet or more deep, and after planting the ground round it is trodden and watered, by the sinking of the soil the tree will stand in a hollow after the lapse of a few years. This hollow, especially in pleasure grounds, will be filled up from time to time by the gardener, and the collar of the tree, instead of being above the surface as it is naturally, will be buried in firm soil to the depth of from 6 inches to 1 foot. This ruins the effect of all trees, greatly retards their growth, causes or decreases the tendency to produce flowers

and fruit, brings on disease at the collar, and occasions the death of many kinds of Coniferæ. It is better to plant high, so that after the ground in which the tree is planted has become consolidated the mound may require lowering by scraping away some soil from the collar, so as to leave a portion of the main roots bare, than to plant low and have to add soil there, producing the objectionable appearance referred to.

Fig. 5.

Fig. 5 represents the result of the proper mode of planting; fig. 6, the result of planting a tree in loose soil and level

Fig. 6.

with the surrounding surface; fig. 7, the result of the latter in dressed ground, showing the collar buried in the soil, retarding its growth, and bringing on premature decay.

Fig. 7.

When a clump of trees has to be planted it may be desirable to trench the whole of the ground 2 feet deep, and in that case they may be planted on the level, for the soil will settle equally, and cannot cause the collar to settle deeper in the earth than it was when first planted. The same remarks apply to trees planted to form belts, and in plantations, though it is desirable even then to plant on slightly elevated ridges, the trees, of course, being planted on the apex of the ridge, and the underwood in the furrows.

When trees and shrubs are planted with balls of earth adhering to the roots it may not be desirable to plant them on a raised cone, but instead of digging out a hole, and planting them at such a depth as to permit of the ball being covered with from 3 to 6 inches of soil, it may be as well to consider whether doing so is not placing the collar lower than the general surface. In all poor, dry, shallow soils, and very strong, heavy, clay ground, it would be much the better to place the tree, with the ball on or but a few inches below the general surface, and to place soil around, so as to form a cone, covering the ball with from 3 to 6 inches of soil, and dishd out at the top so as to hold water. The sides of the cone so formed should be concave rather than convex, so that the fresh soil may unite kindly with the firm soil instead of cracking. Trees so planted will thrive much better than those planted on the level. They look much better, and grow more vigorously.

As to the best time for planting differences of opinion may exist, but that, I think, is chiefly to be attributed to different soils. Where the soil is light and dry the best time to plant deciduous trees is in autumn, as early as the fall of the leaf will allow; but where the soil is cold, wet, and tenacious, I have found that trees planted in March succeed better than when planted in autumn, especially if the winter is unusually wet. Spring, a little before they start into growth, is the most suitable time to plant evergreen shrubs and trees. Planting in their case may also be carried out in autumn, but not until growth has been perfected, and as early as possible, and then, if the soil is wet and cold, it is ten to one that they will not form a single fibre.

It is desirable to plant young trees in preference to those which are large, though the latter are calculated to give effect at once. Removing large trees is waste of money. There is the preparing of the tree for removal, transporting it to its destination, staking or otherwise fixing it when planted, mulching the ground around, watering afterwards, perhaps throughout the summer, and all this costs as much as would prepare the soil, and plant twenty different species, including the purchase of the trees. I grant that the effect of large trees is striking and immediate; but even if they thrive, which is always a matter of doubt, they bear no comparison with young trees planted in prepared soil. Take the large tree, it lingers on from the first, producing year after year a still more sickly and feeble vegetation, until it finally decays; but the young tree even from the first season makes strong and vigorous shoots, attaining yearly a still greater degree of perfection and beauty. Yearly the young tree makes ample and visible return for the care and trouble bestowed upon it, while a large tree often remains a constant reproach to the transplant. Every practical gardener knows that in almost all situations, if he be allowed to prepare the soil properly and select trees suitable, he can produce a tree in seven years fit for any purpose in landscape scenery, quite equal in bulk to any transplantable tree, and having the advantage of being firmly rooted in the soil, and in circumstances to increase rapidly every year.—G. ABBEY.

### ORCHARD-HOUSE TREES IN POTS.

MANY failures are owing to the wood growing too strong, and it, consequently, being imperfectly ripened, the fruit-buds are apt to fall off immaturity. The best remedy for this is to lessen water towards autumn, and to lift the pots out of the soil, breaking any roots that pass through into the ground, and then watering and syringing a little to prevent the leaves flagging. This, and the pinching-in during summer, will ensure well-ripened wood; and strength for the swelling buds to neutralise the roots lost by lifting the pots, can be communicated by picking away with a stick some of the surface soil of the pots and adding rich surface compost in the autumn. Fresh fibres will form in that during the winter, and will much help the swelling buds in the spring.

A correspondent, "INQUIREB," says the trees he has have weak shoots, and the fruit shrivels. In this case weakness, instead of strength of growth, has chiefly to be contended against. I think it very likely that the burnt appearance at the ends of the shoots is owing either to mildew or insects, or to a weak, unhealthy condition of the plants. This condition I have seen produced by giving the plants too much rank manure, either in the solid or liquid state. A man may be injured as easily by eating too much rich food as by not having enough of plain nourishing food to sustain the wear and tear of life. Without knowing more of the treatment of your plants than you tell, it is impossible to say what is the cause of their present weakly condition; but in default of that evidence I would be inclined to say that your trees are suffering from want of nourishment.

Fruit trees in pots, it must be recollected, have such little space to root in, that they are almost wholly dependant on what you do for them. If the pots are set on shelves, or merely on the surface of the ground, they are still more dependant than when partially plunged in the soil. Independently of the roots that will find their way out of the pot in the latter case, and which help the swelling fruit, the protecting of the pot helps to keep the roots in a more equal state as respects temperature and moisture. Even then, however, in bright weather, they will want watering often, say once a-day, and in duller weather every other day during the growing season. Deficient watering is one cause of the trees in pots frequently failing. I have alluded to the ripening of the wood in the autumn. If the trees are lifted to help the ripening of wood, water must be given afterwards to prevent anything like shrivelling. Even in winter the roots, though they may be rather dry, should not be dry. I have known buds and young fruit fall in spring, because the roots had been too dry and inoperative in winter. Frequent dryness in summer will not only cause the fruit to fall, but also render the trees unhealthy. One of the pleasures of the culture of fruit trees in pots is the almost constant demands they make on your attention. It is a wise provision in nature, that we become most attached to that which demands most of our care. When this somewhat nursing attachment between us and our fruit trees in pots

ceases or languishes, it is about time to think of dissolving the connection. Watering, therefore, must be an element of pleasure to the amateur who wishes to succeed with fruit trees in pots. Not only so, but in such limited space the water must be richer than common pond or rain water. This richness is easily given by mulching or top-dressing.

I have alluded to top-dressing in autumn. By the time the trees are showing bloom, as much soot or superphosphate as can be held between the thumb and three fingers may be strewed over the surface of each pot of 16 inches, or as much guano as may be taken or held between the thumb and fore-finger, and this may be repeated in a week, the watering washing it in gradually. As the season becomes warmer, however, a mulching of rotten dung an inch or two deep may be packed over the surface of the pot, and whilst some nourishment will be obtained, the mulching as long as it remains will lessen evaporation, and therefore save such frequent waterings. This mulching may need repeating again during the summer, for it soon wastes away in such circumstances. Even with this mulching, clear manure waterings, weak rather than strong, will be an advantage if given at every second or third watering. For instance, a bushel of horse-droppings may be steeped eight days in a thirty-six-gallon barrel, half a bushel of sheep or deer droppings, a peck of soot, and a little lime for clearing, 2 lbs. of superphosphate, and 1 lb. of guano; the two last to be used at once, the soot to stand twenty-four hours. About half the quantity will do for the next brewing, as some virtues will remain after the first watering. I am thus particular, because over-rich waterings are as bad as weak ones, but in an opposite way. Mulching the surface is one of the easiest ways for giving manure waterings, especially when the watering is done with a coarse rose, and when time can be spared, it is also better for the plants, as more air is taken down with the water from a rose to the roots. Unless on fresh mulching, however, it is seldom I use the rose, just on account of the time it takes to let the water down. The spout is used instead, though not so good.

Now, if, after reading this, you come to the conclusion that your trees are suffering from poverty, I would advise the scraping off as much of the surface soil, and breaking the surface with a pointed stick of what was left as would not hurt any of the active fibres, then add a little, say an inch, of nice, fresh, rough, mellow loam, and then top-dress with half-rotten dung, say horse-droppings that had been thrown into a heap to heat and destroy all the corn that might be in them. Afterwards water for a week with clear water, and then alternately with weak manure water, or scatter a pinch of strong manure on the mulching, to be washed through it, as previously stated. If, as suspected, poverty is the cause, the trees will improve under this regimen before the autumn, and lay the foundation for future success, and thus you will be doing the best whatever the ultimate destination of the trees.

I have presupposed that the roots are sufficiently drained, for stagnant moisture will cause the appearances you describe, as well as want of water and poverty. I also presuppose that the tops of the trees are kept clean by frequent syringings after the fruit has fairly set.

As you have such a nice house it would be a pity to take it down again; and as for the trees, I fear, if your description is correct, that you will scarcely make a market of them "at almost any price;" but I see no reason why you should not succeed with them in pots if you give them the requisite, and that is very constant, attention. Even the watering alone takes a great deal of time and care. If the trees were planted out, they would be more independent of your care, but they would also be less under your control.

If the trees have suffered from poverty the above treatment would be the best preparation for planting them out. The best time for doing it would be as soon as the fruit was gathered, and the best mode, if the trees were still to be grown as dwarf bushes and standards, would be merely to break the outside of the ball a little, so as to let the fibres out into the soil, and the fresher the soil the better.

If, however, you have any reason to believe that the trees have suffered from stagnant moisture, and the soil from that cause has a sodden claggy appearance, or it has become of an unhealthy character from a superabundance of rich waterings or dressings, it would be advisable to wait a little longer until the leaves began to change colour, and then in a large tub wash away all the old soil, and lay the roots out anew in fresh loam, and keep the house rather close and the trees syringed for a couple of weeks afterwards, and give a little

shade if the weather is bright, so as to insure the wood being plump. Under such circumstances new roots will soon form, and if the plants are not so very far gone you may be as much troubled next season with strong growth as you are now with weak growth.

To keep the bushes, &c., small after planting-out, it will require a good deal of judicious root-pruning. To make the most of such a house for fruit with the least amount of labour and care, I would fix a trellis on each side of the span, 15 inches from the glass. I would plant-out the best plants on each side, and train to the trellis, and keep the others in pots until the trellis was full. If there were still doubts as to your trees being quite suitable for that trellis, you could obtain from six to eight trained trees for the trellis, three or four on each side, and keep those you have in pots until the covered trellis left no room for them. Though I have lots of pots doing well, I am convinced that for profit nothing beats the trellis under the glass. Even in lean-to's, with trees against the back wall, and some sort of trellis for some three-quarters of the width in front, I am pretty certain that a trellis up the roof under the glass would be the most profitable. Planting-out and keeping as dwarfs in the house has also its advantages, and chiefly on the score of augmented interest, and being placed more under the control of a lady or gentleman amateur; but on the score of economy every way I do not think anything will surpass a trellis at a uniform distance from the glass, which uniformity alone gives a better security for all the fruit being equally well flavoured. I shall be glad to hear further on the subject.—R. F.

### NEW BOOK.

*Wayside Flora; or, Gleanings from Rock and Field towards Rome.* By NONA BELLAIRS. London: Smith, Elder, & Co.

WE welcome this little volume, the contents of which we need not praise, for they have, for the most part, been published in our pages. They are worthy of a separate form, and it is wishing a good wish when we say that we would not that any civilised being could be found who did not enjoy what is there written.

PEAR BLOOMING ON THE PRESENT YEAR'S WOOD.—I have a large Jargonelle Pear with several blooms on the present year's wood, some of which have set very freely. Some of the Apple trees are also showing bloom, but unfertile.—H. S.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

THE weather is now very suitable for planting out good breadths of Brussels Sprouts, Savoys, Curled Kale, and Broccolis of sorts. Where the ground is occupied by patches of early or second early Potatoes, to be used in the course of the month, it is a good plan to part the haulm between every second row, and plant Knight's Protecting Broccoli or other spring sorts to stand the winter. The increased space between the rows gives room to earth them up to the neck, they grow stiff and hardy, and are fit to withstand the frosts of our most severe winters. *Beans*, top these and the tall varieties of Peas, as they are growing very rampant this year from the wet weather. *Celery*, ridge out for the main crop, also a trench of *Cardoons* where they are looked for. *Cauliflower*, make sowings in the middle of the month, also of *Walcheren*, *Snow's*, and *Grange's Broccoli* for planting for late lifting, to be packed in beds in the open air. As soon as frosty nights are apprehended a spot is selected for laying them in, in beds 4 or 5 feet wide, with alleys about 2 or 3 feet in width, to retain the litter for covering in frosty nights. It is by far the best way of keeping up through the winter a good supply of fine white heads, devoid of the disagreeable smell and colour they acquire when kept in sheds or sand. *Endive*, sow the main crop, and plant out a few of the earliest sowings. *Leeks*, transplant; they are better of being earthed up like *Celery* to the depth of 6 inches. *Cucumbers*, peg down the shoots of the pickling sorts, to keep them from being blown about by the wind. *Capsicums* and *Tomatoes*, keep them nailed to the walls or wooden fences; thin also or stop their shoots frequently, as they require all the sun possible, to produce good crops of fruit in our climate. *Lettuces*, continue to sow; also *Radishes* and *Salads* of all sorts according to the consumption. *Potatoes*, earth up the late sorts.

#### FRUIT GARDEN.

See that Peaches, Nectarines, and Apricots are nailed, if not already done, as the wind is sometimes very strong about this time, and makes sad havoc with the shoots. Vines on the open walls still require rubbing off the useless shoots, nailing in those that are useful, and thinning the Grapes. Currants and Gooseberries require all the watery useless shoots to be thinned out. It is a good plan for keeping Red Currants till the latest period for tarts, &c., to select some of the best bushes on a dry day, thin all the shoots from the fruit, drive a strong stake in the middle of the bush, and tie all the branches to it, then wrap one or two good garden mats round it. From bushes treated in this way a supply may be kept up till November. Trained fruit-tree espaliers should have useless shoots removed. The Elton and British Queen Strawberries are colouring badly and rotting in shaded situations, owing to the wet weather. The fruitstalks ought to be propped up with forked sticks, to expose the fruit to as much sun and light as possible.

#### FLOWER GARDEN.

Attend to the greenhouse plants now placed out of doors. See that worms do not effect an entry into the pots and close the drainage. Attend to the routine of tying, stopping, and other details. Carnations and Picotees may now be layered, and a stock of cuttings of Geraniums put in. Bulbs may be taken up and stored away until the autumn, and their places immediately occupied with flowers from the reserve stock. Perpetual Roses will be benefited by an application of manure water to insure a healthy second bloom. A better production of bloom will be obtained by picking off excessive buds. Russian Violets may be separated, and fresh plantations made. Mow and roll grass. Attend to walks, the weather at present encouraging the growth of weeds. The present is a favourable time for putting in cuttings of all the more showy herbaceous plants, selecting for the purpose the small shoots not furnished with bloom. A north border is a suitable place to strike them, and a hand-glass will facilitate their rooting quickly. Go over the beds frequently, and keep the young shoots of Verbenas, Petunias, &c., nicely regulated and pegged down until the ground be fairly covered, after which greater freedom of growth may be permitted. On light dry soils two or three applications of weak manure water, given at intervals of a few days and when the ground is moist, will greatly assist the plants to cover the beds without loss of time.

#### GREENHOUSE AND CONSERVATORY.

The beauty of the most of the softwooded plants in the conservatory may be considerably prolonged by the use of weak manure water, which should be given occasionally. Indeed, such things as Achimenes, Clerodendrons, &c., may be had in full beauty for several months if they are supplied with manure water; but care must be taken not to give it too strong, especially at first. Keep the atmosphere as moist as possible, but avoid damp at night by leaving sufficient air on to cause a gentle circulation, and spare no attention that will keep the plants clear of insects. Stock for autumn and winter flowering will now require some care to bring it sufficiently forward to be useful at the proper time. Chinese Primulas, especially the double varieties, if at all backward, may now be placed in a close frame and shaded from the sun, when they will be found to make satisfactory progress. Cinerarias for early flowering should also be potted and started at once, choosing the strongest suckers for the purpose, and placing them in a close shady frame until they have become rooted. They are sometimes attacked by thrips, but if they are kept cool and moist and smoked occasionally no danger need be apprehended from this or other pests, and they will grow vigorously. Whilst house-creepers are in an active growth, make it a rule to go over them frequently, in order that they may not grow into a confused state. The same may be said of creepers in pots, which require attention for the same reason every few days. Any shoots which have done flowering should be cut back, and a crowded growth avoided. A number of hardwooded plants which were cut back some weeks since, will now have recovered themselves and be commencing a fresh growth. This is the proper time to shift into larger pots any plants requiring it. Carefully loosen the outside roots. After potting keep the plants closer for a few days, and syringe them daily; but avoid giving any more water to the roots than is sufficient to preserve the old ball moist. To prevent watering so quickly after potting, let the roots of the plants be well moistened before being potted.

## STOVE.

As many of the principal plants will now be in the conservatory, advantage must be taken of their absence to encourage the plants for winter blooming, especially such as *Justicias*, *Eranthemums*, *Begonias*, *Aphelandras*, *Euphorbias*, &c., and a batch of *Achimenes picta* and *Gesnera zebrina* must be started for the same purpose. *Rondeletia speciosa* is an excellent winter plant when sufficient heat can be afforded, and *Torenia asiatica* and *Pentas carnea*, especially the latter, are very useful plants. *Luculia gratissima* and *Pinceana* must be placed in a sheltered corner in the open air to ripen the wood and set the bloom; never mind the leaves turning brown, they will soon recover that when placed in heat again. Maintain a moist growing temperature with plenty of air, and guard against insects. So far as *Oreheids* are concerned, those showing indications of matured growth may be removed to the cool end of the house for a few weeks, and afterwards placed in quarters where the temperature and atmospheric moisture will not interfere with the slow progress of the plant towards a state of rest. *Dendrobiums* and others of that class should be grown on till the shoots are of sufficient height. Remove the first appearance of every form of weed or insect, and keep the sponge constantly at work, for much of the health and vigour of plants depend upon this. See that no plants are neglected in consequence of standing in corners or behind large plants. Arrange and re-arrange frequently, for doing so tends materially to promote the well-being of the plants, while it heightens in a high degree the interest of the house.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

THE thunderstorms and the rains which we expected have come, and, if injurious to some things, have furnished a good opportunity for turning over and filling with Winter Greens every bit of unoccupied ground.

Planted out a good piece of Coleworts between Peas that will soon be off. These we generally plant a foot apart in the rows, and the rows are a foot apart. Planted out also a border of the Early Elm Savoy, a sweet little vegetable that comes in early, and which does well a foot apart. These are as useful in the autumn and early winter as the dwarf and larger Savoys are at Christmas. Our manure for these, Brussels Sprouts and Scotch Kale, has chiefly consisted of *mowings*, short and longer, allowed to lie in a heap until in strong heat and incipient decomposition, and then trenched down in the bottom of the trench. This manure gives assistance to the plants long before the roots reach it, and before that takes place it will have lost its rankness. When we used to pride ourselves on having large Celery fit for use in July, we took out deep trenches, say 2 feet in depth and 4 feet in width, put in 18 inches of this hot grass and litter, trod it firmly, covered it with 6 inches of soil, again trod it firmly, and then put on 6 inches of rotten dung and soil. The heat from the decomposing grass pushed the Celery along, and it was becoming sweet and mild and much reduced in bulk before the Celery roots took hold of it. Where there is labour at command there need be no standing still for bottom heat after such mowings come in. When mixed with rather dry litter such a mixture will afford heat a long time, until, in fact, the litter has become decomposed; and if there is from 12 to 15 inches of sweet or more decomposed material above it, the rankness will not hurt anything; but of course, if either the roots or leaves came in contact with that rankness directly it would be very prejudicial.

We recollect when, from want of anything better, and wishing to have all the benefit of the heating short grass in the ground, we first used it as a heavy dressing for a piece of Cauliflowers; the Cauliflowers grew wonderfully fast, but owing to the trenching being carelessly performed—the ground left level, some shoveled in hills and dales—there being great depressions over the trenches where an extra quantity of such manure had been placed, and in those places where the mowings had been left near the surface some plants suffered, looking in bright sun as if the roots had been nibbled by wireworm. We knew well enough what was the matter, and kept our own council. Such fresh material should, for all fresh plantations, be from 12 to 18 inches from the surface. When people shall be less frightened to use such rank stuff the mowings and sweepings might often be taken to a quarter in

the kitchen garden, and two wheelings instead of one might be avoided.

Those who would be afraid to use such rich manures as these grass mowings and sweepings make when in this rank state, instead of allowing them to lie and rot (and most of their best properties thus escape into the atmosphere), should have them covered over with earth or with part of the general rubbish-heap, and then the latter will be greatly enriched in its manurial properties. Even when used fresh, as manure, or for giving heat to plants in frames, danger will be averted if the materials do not come near the roots, and no steam or vapour escape into the atmosphere of the space occupied by the leaves. When used, therefore, for bottom or for top heat, no crevice should be left to allow the strong steam to pass upwards, for it will assuredly kill all that it can reach in a close atmosphere.

*Celery*.—Took the opportunity to plant out several large beds. We use the beds of any convenient size, as the width is of but little importance where the earthing-up is done well. This season our beds are 4 feet wide, with 3½-foot-wide spaces between them, these ridges being cropped alternately with Peas, staked, and with dwarf crops of Kidney Beans, &c., so that there may be no difficulty in passing along the dwarf-cropped ridge to water the two beds of Celery; and then the rows of Peas, with the stakes, give a shade to a certain extent. When we used each ridge for Peas we had them wider, and the beds also wider. These beds were taken out about 15 inches deep, and the soil laid on the ridges on each side. Then in the bed was placed about 6 inches deep of half-rotten dung from old hotbeds, and that was dug-in and incorporated with the soil, and then was added about 6 inches more of rotten leaf mould and hotbed dung, with a little soil chopped from the sides mixed with it. In such beds we have often put four rows, but this season we have only put three rows, the plants standing a foot apart each way, and the outside rows being nearly a foot from the side of the trench. Even such kinds as the Dwarf Incomparable require that space to form nice stubby plants, and strong-growing kinds need more room. Where room is scarce the beds may be from 6 to 8 feet wide, and then a bed will give a large number of plants. When the plants are tied before earthing-up, the mere width of the bed does not interfere in the least with their easy management.

So far as our experience goes, plants in wide beds are not so apt to bolt, even when planted early, as those in trenches from 9 to 12 inches wide, as the roots do not come so readily against the firm sides of the trench. When merely some 3 or 4 inches of rotten manure are given to a trench a foot wide or so, strong Celery plants would soon begin to feel like a plant in a pot, which will ever have a tendency to throw up a flower-stem as the roots become firm round the sides of the pot. Plenty of water and doing away with the bit-by-bit earthing-up of early Celery, are, however, the great preventives against running-up flower-stalks. The whole theory of this has already been explained. We must not say what the Celery will be this season, but this we can say, that where such simple details can be attended to, there need not be a single run head of early Celery.

The planting, too, though trifling, is also of some importance. A farmer friend used often to speak of a row which he once had, and the perspiration into which he was thrown in carrying the plants home. He had the plants with large balls of roots, and in his rotten muck they did grow, and never suffered from the moving.

We noticed in some of our beds a few plants flagging, which they had no business to do with the balls with which they ought to have been lifted from the pricked-out bed. The man had been planting with a hand trowel, a very nice implement for ordinary purposes, but not at all calculated for such fine plants with large masses of fibrous roots in the rotten leaf mould. It could only be done properly by making good trenches with the spade; for then the ball could be laid in at the proper depth, and the fibres would not be crushed by the ball being squeezed into a hole too small for it. This little matter is often neglected when planting with a trowel. The hole should always be large enough to permit of the fibres going out freely into the loose fresh-turned soil.

Even when plunging plants in pots in a bed, where nicety as to appearance and the welfare of the plants are considered, the hole made should always be large enough; it is in every way better to throw a little material into the bottom of the hole in order to keep the pot to the right level, instead of attempting to squeeze the pot down, for then it will not long

maintain the same level with the others, and free drainage will to a great extent be prevented. Of course in this trowel or spade planting the whole process is intended to be quite different from dibble planting. In the latter case the roots are generally few, and with but little earth about them. In their case the firming of the earth about the roots is the chief point, and, as previously explained, this can only be well done with one stroke of the dibble inserted in an oblique direction to the plant, and then brought sharply up to the perpendicular. So put in a plant will be more firm than if it had received half a dozen pottering strokes from the dibble. We are always suspicious of the plants being hung—that is, the roots suspended in an open space, when the planter uses more than three strokes of the dibble—one to make the hole, one to fasten the plant, and a back stroke with the point to partially fill the hole made by the second stroke.

FRUIT DEPARTMENT.

Very much as described in previous weeks' notices. Protecting and gathering fruit, syringing orchard-houses, thinning Grapes, lessening shade in earlier houses, and nipping out a few bad berries inclined to damp from drip, and watering as required. Peaches and Figs swelling to ripening want plenty of water and plenty of air, as dryness at the root will arrest free swelling, and a close atmosphere will cause Figs to damp at the points, and Peaches to be deficient in flavour.

ORNAMENTAL DEPARTMENT.

Here we have had much to do in mowing, clearing, &c., the rains making the grass grow too fast for the mowing machine. Potting Cinerarias, Primulas, &c.; giving Epacris a good open place in a pit to harden growth, regulating conservatory, making up any faults in flower-beds, &c., but we have time to allude to two things only this week.

First, placing greenhouse plants out of doors. We do not think there is any advantage in this if it could be avoided. A place a little shaded, but commanding either the morning or afternoon sun for few hours, is generally best; but if the plants are inured to it by degrees, even Heaths, Epacris, Cytisus, &c., will suffer little from a south exposure if the pots are protected from the sun's rays. A piece of mat or a turf on the south side of the pot would often be sufficient. Under such circumstances, and as avoiding much extra attention in summer, plunging the pot to within an inch of the rim, either in ashes, or sand, or even earth, is a good plan, as there is no chance of the fibres being scorched, and the firmness of the pot gives a security against high winds to the head of the plant; but in plunging thus in summer all valuable plants, and especially all those with hair-like fibres, the hole should be large enough to permit of two bricks, or two tiles, or stones, being set on their sides at the bottom of the hole, with an open space between them. The pot will stand on the bricks, and the open free space will alike keep the worms away and secure drainage.

A second matter to be borne in mind, both in-doors and out of doors, is that all supports for plants, sticks, &c., are necessary evils—evils, therefore to be hidden instead of exhibited. All necessary supports should therefore be kept out of sight as much as possible. Young shoots of any shrub or tree with the bark on are, therefore, better than all clean-shaved sticks; and all plants grown to a stem in the pyramidal form may be secured with one stake only, the subsidiary branches being kept secure by a loop of small string, generally more inconspicuous than matting. Even rather large Geraniums and Calceolarias may be made pretty secure by means of one stick in time, and the other shoots hasted to it with a loop. One would imagine at times that the stakes were the objects to be looked at, instead of the plant, and one step in the right direction will be taken when even the one stake necessary for most plants shall cease to be an object of attraction—be, in fact, looked upon as a drawback, which it is necessary to conceal as much as possible.—R. F.

WELLINGTONIA.—In your Number for June 26th, Mr. Robson asked for memoranda touching Wellingtonias. At Shotover House, Oxon, there is a remarkably well-grown specimen. It was planted in 1859, and had then attained a height of 6 inches. In June, 1862, the circumference of the base (at ground) was 9 inches, the height 4 feet 3 inches. In June, 1866, the dimensions of the same tree were as follows: height, 12½ feet; circumference of branches, 37½ feet; circumference of trunk at 6 inches from the ground, 29 inches.—C. F. W., Forest Hill, Oxon.

COVENT GARDEN MARKET.—JULY 7.

SUPPLIES of both home-grown and foreign fruit are well kept up, and as the London season is now drawing to a close, the more choice productions will rapidly decline in prices. Pines are in excess of the demand, and there are heavy arrivals from the West Indies. Soft fruit generally, notwithstanding the rain of last week, has been good in bulk and appearance, but deficient in quality. Good elegant Potatoes can now be obtained at prices ranging from 6s. to 9s. per bushel.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

LIVE AND LEARN.—We have a letter for you, which we will forward to where you may direct.

BOOK (*A Young Amateur, Winchester*).—"The Garden Manual" will suit you. It can be had free by post from our office if you enclose twenty postage stamps with your address, ordering the book.

CLEARING A LAWN OF DAISIES (*A. W.*).—The best plan is during moist weather to take them up with an old knife, and to persist in doing this for a year. A dressing of rich compost in March, so as to cover the lawn about a quarter of an inch deep, would make the grass grow and the Daisies also, but as the latter are thus stimulated to raise their heads too high the mowing takes them off. We have a croquet ground in which Daisies caused us much trouble, but since we manured it every year in March, and applied a dressing of guano at the rate of 2 cwt. per acre in the first moist weather in May, and a similar dressing in July, we have seen few Daisies, and the sward is excellent. A lawn adjoining is the very opposite; the ground is poor, and the Daisies and weeds there find a home from the poorness of the grasses. If you grub up the Daisies and weeds, we would advise you to give a good dressing of rich compost in March, and to sow in April, when there is a prospect of rain, *Cynosurus cristatus*, 4 lbs.; *Festuca duriuscula*, 4 lbs.; *Festuca tenifolia*, 2 lbs.; and, if shaded by trees, *Poa nemoralis*, 2 lbs., if not 1 lb.; *Trifolium minus*, 4 lbs.; and, if light dry soil, *Lotus corniculatus minor*, 1 lb., but if wet omit it. Immediately after sowing rake the lawn with an iron rake, and roll.

CARNATIONS, PICOTEES, PINKS (*C. M.*)—Carnations have coloured stripes from the centre of the petals quite through to their edges. Picotees have colour only round the extreme edge of the petals, like a border. Pinks have only a band of colour, rough on both sides, and with some white between it and the edge of the petals; there is colour also at the base of each petal, so as to form an eye. Your Rose leaves have been eaten by some caterpillar.

ROUND SCYTHE STONES.—Can any of your readers inform me where I can purchase round scythe stones, called "Real Welsh Waterloo Scythe Stones," made by a Wm. Foster?—A GARDENER AND CONSTANT READER.

LONICERA AUREO-RETICULATA BLOOMING.—We have received so many notes stating where it is blooming that it need not be regarded now as extraordinary.

PAPER READ AT THE BOTANICAL CONGRESS (*G. T. S.*).—We have no copy of the paper you refer to. Have you Pearson's "On Orchard-houses?" You can have it free by post from our office for twenty postage stamps.

LINNEAN SOCIETY (*Botanica*).—To become a Fellow of the Linnean Society you must be proposed and seconded by a Fellow, each of whom has personal knowledge of you; pay six guineas as an entrance fee, and £3 as an annual subscription.

**PRIZE FOR FIFTY ROSES.**—The fifty-one Roses mentioned at page 5 should have been disqualified. I advise the Jersey rosarians to word their prize schedule thus:—"For fifty cut Roses in fifty distinct varieties." There can then be no mistake. Fifty cut Roses may be mistaken for one variety, or any number of varieties. They might add, in reference to Roses, fruits, or vegetables, that any greater or less number than is specified will disqualify. Single blooms without buds count for a truss; I advise them not to permit the addition of foliage, a common practice in the country, but disallowed in London.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

**DESTROYING EARWIGS (W. Hullet).**—A good plan is to place a little dry moss in the bottom of a small flower-pot, and invert the latter on the top of a peg or stick amongst the plants, and so high that one edge will rest on the soil and the other be half an inch or so above it. The earwigs will congregate in the moss, the traps should therefore be examined every day or every other day, and the earwigs shaken into boiling water. The stems of Broad Beans cut into six-inch lengths, and laid horizontally among the plants, are good traps, and so are the stems of Jerusalem Artichokes, Sunflower, and Giant Cow Parsnip (*Herscleum giganteum*), when cut into lengths of 6 to 8 inches. The best of all traps are of metal, and they may be had of all nursery and seedsmen.

**TRITOMA UVARIA AND BURCHELLI (Fynette).**—They belong to the natural order Liliaceæ and sub-order Aloeæ. The former was but little grown until during the last few years, yet it was introduced from the Cape of Good Hope in 1707. Good loam, enriched with one-third leaf mould and well-reduced hotbed manure, suits it. If the soil is wet and heavy it would be improved by the addition of one-fourth sharp sand. All it requires is a mulching of leaf mould or littery manure three parts reduced placed round the crown in autumn after blooming. The dead foliage should not be cut off until spring, as if left it forms a protection to the crown. If the weather prove dry during the throwing up of the spike and flowering, copious supplies of liquid manure are beneficial. It stands with us on a lawn unprotected, and every year produces from twenty to thirty spikes of bloom in September. It is there even finer than in an open border, where it has proved equally hardy. As a proof of its hardiness we may state that it withstood without protection the severe winter of 1860 and 1861 in an open border two hundred miles north of Gloucestershire. There is no difference as to treatment between *T. uvaria* and *T. burchelli*, but they are very distinct; the latter is more dwarf and compact and very bright in colour.

**FLOWER DEVICE (R. W.).**—You will find the information you seek as to the arrangement of the colours in Vol. I., New Series, pages 181, 151, 191, 240, 299, 918, 933, 132, 172, 211, 212, 251, 271, 355, and 375. If you peruse these carefully we think you will be able to hit off a design. We cannot furnish such.

**DISTINGUISHING RIPE MELONS (Idem).**—When a Melon is ripe it will turn to a yellowish colour, and have a grateful odour. It should be cut before it is dead ripe, and before the fruit parts from the footstalk. Cut it with an inch of the footstalk attached. All the Melons will not be ripe at one time; they should not, therefore, be all cut at once.

**PEACH TREE LEAVES BLISTERED (Old Soldier, Dublin).**—The leaf sent is now showing the effects of the late spring frosts. We consider that the evil has been produced by a rupture of the sap-vessels from exposure to cold. The only measures to adopt are to syringe the trees freely in the evenings of hot days, to pick off the worst leaves, and, should the foliage become covered with a white powder, or be attacked by mildew, to dust it with flowers of sulphur. The fruit is now falling in consequence of its not having stoned.

**ROSE TREE LEAVES EATEN (C. F. W.).**—You can do much to rid your trees of the destroyers by spreading a white sheet under the heads, and shaking them a little after dark. The marauders will fall on the sheet, and may readily be destroyed. You may also make the leaves distasteful to them by syringing every other night with water in which soft soap has been dissolved at the rate of 2 ozs. to the gallon.

**THUNBERGIA FRAGRANS (E. J.).**—It is quite true, as you say, that this is not a "new" plant, for it was cultivated at Kew in 1796, and a drawing of it is in the "Botanical Magazine" published in 1817; but if a plant has been lost, and reintroduced, nurserymen may be excused for representing it as a novelty.

**PELARGONIUM (M. B.).**—The varieties of the strain of which you enclosed a truss, are far too numerous and nearly resembling each other for us to be able to tell its name.

**TURNEPS BOLTING (F., Westmoreland).**—We know of no better plan of preventing their running to seed than thinning them well, and keeping them properly supplied with water. Good rich soil, and thinning well, with copious supplies of water, are the great points in securing crisp early Turnips.

**APHELANDRA LEOPOLDI CULTURE (A Constant Reader).**—It is not a plant requiring much water, and should only be watered when the soil becomes dry, and then it should have a good watering. It requires the heat of a stove, a light situation, and an average amount of air. A moist atmosphere, but not so as to wet the foliage, is essential; the plant should not have too much pot room. A compost of two-thirds sandy peat and one-third turfy loam, with a free admixture of sand, suits it; very liberal drainage is necessary.

**ACCUDA SEEDS GERMINATING (Idem).**—You may expect the seeds of the *Accuda* to vegetate by August if they were sown as soon as ripe, but if not do not throw away the pots containing them, but keep them in a greenhouse fully twelve months longer, and the soil moist.

**SEEDLING GERANIUMS FLOWERING (Amateur of Ayr).**—If the seed be sown in the spring in a gentle heat, and the seedlings be forwarded, they will flower in autumn, but not well until the second year. The best plan is to sow the seed early in the autumn, or as soon as ripe, the seedlings to be hardened off before winter. They flower with certainty in the following year.

**BOOKS ON GARDENING (Idem).**—Thompson's "Gardener's Assistant," 31s. 6d.; Lindley's "Theory of Horticulture," 21s.; London's "Encyclopedia of Plants," £3 13s. 6d.; and McIntosh's "Book of the Garden," £3. If these are not too expensive, the following will suit you:—"The Science and Practice of Gardening," 3s.; "Out-Door Gardening," 1s. 6d.; "In-Door Gardening," 1s. 6d.; and "The Garden Manual," 1s. 6d. These works are well suited for amateurs. They may each be had free by post from our office for 2d. extra.

**COLCHICAN LAUREL (Colchican).**—It is a variety of the common Laurel, and called botanically *Cerasus laurocerasus var. colchica*. It was introduced from Belgium in 1841, is very hardy, has long pointed leaves, and might be planted whenever the common Laurel is desirable.

**ILLUSTRATED BOOK ON MOTHS (J. B., Durham).**—There is no such book at so low a price as 10s. Stainton's Manual of British Moths and Butterflies contains woodcuts of many of the species, but they are not coloured. It is an excellent book, and nearest the price you name.

**NAMES OF PLANTS (C. M.).**—*Cratægus crus-galli*. (*Alphal*).—2, *Alonsoa acutifolia*; 3, *Pilea muscosa*. (*H. B.*).—A *Crinum*, uncertain which species from the specimen received. (*E. S. C.*)—*Lastrea dilatata*. (*T. S.*)—1, *Orchis maculata*; 2, *Gymnadenia conopsea*; 2, *Saxif repens*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 7th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun. . . 1	29.511	29.465	72	45	67	62	E.	.13	Rain, showery; fine at night.
Mon. . . 2	29.488	29.327	70	45	66	62	W.	.04	Fine; masses of low white clouds; cold and windy.
Tues. . . 3	29.369	29.351	66	46	65	61½	W.	.16	White and dusky clouds; showery; rain at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

THE FOWLS YOU SHOULD KEEP.

BEING AN ANSWER TO REV. W. F. RADCLIFFE.

As a slight return for the valuable instruction on the subject of roses, which I have many times received from Mr. Radclyffe, to say nothing of the entertaining way in which his advice has been frequently given, and, in addition, that Mr. Radclyffe is a brother clergyman: I beg to give my answer to his question of last week, "What fowls shall I keep?"

But, Mr. Radclyffe, you have given us no data. Soil is not mentioned—whether you live on clay, sand, or chalk; climate is not mentioned—aspect ditto; whether yours is a sunny slope or top of a hill, or wooded or open. Nothing is given; only I know you live in the country. Upon that one datum I must perceive build my reply.

There is much to say for Bantams, but when you show your collected eggs there will be the domestic rejoinder, "Oh! but what bits of things!" and you will collapse—at least I did. Next Cochins—concerning the egg-laying, you would probably be well satisfied; but as to the eating, may our friends the Editors have Cochins for dinner to their hearts' content—that is, when I do not dine with them. I gave a Cochin to my man, and he declared that his jaws ached for hours afterwards, I think he even said days, but I presume that was an exaggeration.

Then passing by Game which are most beautiful, but, perhaps, as a man of peace, Mr. Radclyffe might object to them, and quite objecting to a cross between Malay and Game, also keeping to the one fact, the country, I pass by the town-suited varieties, Spanish and Malays. I come then to Dorkings; but is the soil a dry one? or it may be that Mr. Radclyffe would have a great number of funerals among his young ones, and no mortuary fees for compensation. Then, somehow, Dorkings

are scarcely pretty enough for pets, and I imagine Mr. Radclyffe to be fond of pets. Dorkings, with all their merits, the chief being as an article of food, have such a farm-yard look about them, that they seem out of place unless walking among oorn ricks.

I now come to the variety I earnestly recommend to Mr. Radclyffe—that is, Hamburgs. I sat down and talked over their merits and demerits the other day with a parishioner of mine, who has kept them several years. He assured me, and he was a poor man who scarcely feeds high enough, that he has had eggs regularly from before Christmas to this time. I can vouch for the truth of this, as, but for my poor neighbour's Hamburgs, I should many a time have lacked my Sunday egg, a necessity with me after my second service. Then Hamburgs are very healthy, and never broody. Should Mr. Radclyffe wish for chickens, which he perhaps will, though a secondary object, I would advise that he should follow my plan—keep a few Game hens with his Hamburgs. These laying fawn-coloured eggs, and the Hamburgs white, there could be no mistake, and Game hens are excellent sitters and mothers, and are of a suitable size to bring up Hamburgs.

There is, however, yet another reason—the Hamburgs are so very pretty, everybody admires them at once, everybody gentle or simple, whether of the Adam or Eve variety. I see by my "Clergy List" that Mr. Radclyffe is at least of my standing. Well, he may have, then, a wife and family, and I assure him from the tiniest child up to mamma, and down again from mamma to the youngest domestic just from the village school, all will expatiate on the beauty of the Hamburgs. Lady visitors, for there are always lady visitors where there are ladies, will at once approve. Or, I will suppose—

"When thought is warm, and fancy flows,  
What will not argument sometimes suppose?"—

that Mr. Radclyffe lives a bachelor, and, if so, I am sure ladies come to see his roses, his peaches, and—himself. Now in future he will like to take them from flower garden to poultry yard, but if he have Cochins they, the ladies, will serve him as they did me (alas! 'tis true), and one and all exclaim with that feminine shudder which draws back the corners of the mouth, tightens the neck, and raises the shoulders, "Oh! what horrors! what frights!" And this is not pleasant—it humbles one, it reflects painfully upon one's judgment, for in vain I tried to draw attention to the sensible-looking heads of my Cochins hens, and the various beauties of that variety, but 'twas all in vain. Now it is, "What pets! what darlings! what beauties!"—and this is consolatory to an owner, the pretty phrases sound so very prettily. Perhaps Mr. Radclyffe will plead that he is wholly indifferent to praise or blame from such a quarter, but that I doubt. However, leaving the point unsettled, I beg to recommend Hamburgs; there are the two colours, silver and gold, and the four varieties to choose from. I am glad to find that Mr. Radclyffe is about to become a poultry fancier, and although *some* persons keeping fowls may have "tricks worse than in horseracing," yet he will find *many* kind, honest, genial hearts among poultry fanciers. Of this let him take the word of one whose experience among them has been extensive—viz., of—WILTSHIRE RECTOR.

#### PROFIT FROM DUCKS.

WHEN I sent you a few lines respecting the profit to be obtained from feeding Ducks I did not enter into any detailed account of their management; for although this result was somewhat of a surprise to myself, I did not feel assured that the communication was of sufficient interest to insure its insertion in your columns. However, I willingly comply with Mr. Beyton's request.

Outside my garden wall is a small strip of ground bounded by a brook. By this land is a glazed shed 24 feet long by 9 wide, wherein the Ducks were kept, and the hen removed when they were a fortnight old.

The shed is used to barden off bedding plants after their removal from a vinery, and with this use the Ducks did not at all interfere. The floor was covered with rotten dung from an old Guenber-bed. This proved useful for manure water, and as a top-dressing for Peach trees in pots and dwarf fruit trees generally.

The Ducks were fed at 6, 9, 12, and 7 P.M. Grains were not given until the Ducks were a month old, and were mixed with a small quantity of Indian corn meal. At first they did not eat all the grains purchased, for it was necessary to purchase

half a bushel at a time; but when they were seven weeks old they consumed exactly a bushel a-week.

When about five or six weeks old they looked miserable, dirty, and with weak eyes; but this was all changed directly they were allowed to go into the water daily. I may mention that two of my neighbours who keep Ducks were so pleased with the appearance of mine, that they inquired the mode of feeding, and I was strongly urged to send them to a poultry exhibition which was held in the town at that time, to show what Ducks could be brought to in eight weeks. The garden refuse consisted of a bed of seventy lettuces which ran to seed. After the daily cooking was finished some cabbage was generally boiled for the Ducks. Our household consists of nine, and although not extravagant, there is much food which but for the Ducks would have been wasted. I am aware that these circumstances are unusually favourable; still the result is so remarkable, there must be some other cause.

For some time past I have recommended my friends to feed their poultry principally on grains, but till this year never had the opportunity of testing this plan for myself. I believe it is from the quantity of this food that the success is due. To feed a Duck of a month old on barley meal—an expensive, highly fattening food—is probably a mistake: it should be reserved for the last few days of his life. After my last letter the weather became so hot that the glazed shed was unsafe; the Ducks were therefore obliged to be allowed to go into the water all day. The effect was most marked. They no longer cared to eat lettuce, and consumed much less food, seldom coming home until supper time. The Ducks were kept in the centre of a large town, but there was never any difficulty in persuading them to return by a whistle at bedtime. Lastly, at the time I wrote Ducks were selling at 7s. 6d. to 8s. a-couple at the poulterers'.—B. A.

P.S.—I enclose my name.

#### BURY ST. EDMUNDS POULTRY SHOW.

DEPRIVED as this Meeting was, in consequence of the cattle plague, of the additional attraction of cattle, poultry formed no mean substitute, and proved, perhaps, one of the most popular features of the whole Show; nevertheless, many were the inducements held out to popular favour, more especially by those who exhibit implements at such agricultural meetings. All of us admit that just at this season of the year "Duck and green peas" form a very acceptable addition to our viands; nor can we resist the digression of naming to our readers a curious machine which we witnessed in full operation, by which the shelling of green peas is accomplished with a perfection and dexterity none of us could believe possible. The peas as gathered are poured out into a hepper, and simply by the rapid turning of a handle that requires a very small amount of muscular exertion, the shells are voided from between two rollers, somewhat crushed, but the peas themselves are received into a large tin receptacle quite uninjured and ready for boiling. So perfect is the whole arrangement, that on the most careful inspection not a single pea could be found that was at all bruised; and even after the most vigilant search among the shells, not a pea as large as a hempseed was found to have been passed over. A bushel of peas may thus be easily shelled in from twelve to fifteen minutes. Well might many of the bystanders exclaim, "Well, what next?"

But to the poultry especially. The Committee well deserve every credit for their arrangements, as all the poultry were exhibited on one single tier. Every possible provision was made for the safety of the birds themselves and the accommodation of the public, in case the weather should prove unfavourable. The Abbey grounds, where the Show took place, are not only extensive, but kept in a manner that reflects credit on the managers of this subscription place of recreation. That the poultry as a whole lacked that condition so all-important to such meetings is admitted as inseparable from the time of year alone, but still the principal classes were well filled with first-rate birds.

Game fowls stood first on the prize schedule, and although there was no lack of competitors, the struggle rested in every class of this variety between those great guns in Game fowls, Mr. Fletcher, of Manchester, and Mr. Mathews, of Stowmarket. The competition was necessarily close, Mr. Mathews taking three first prizes for Game, the same number of second prizes, and a third prize as well. Mr. Fletcher, with the limited entry of only four pens, took a first, second, and third prize, besides the five-guinea silver cup for the best pen of any variety of Game fowls exhibited. They were Duckwings. How so experienced an exhibitor could send his fourth pen, containing an admirable Red Pile cock with bright yellow legs, mated with a very capital hen, but rejoicing in brilliant willow legs, can only be accounted for from some error in packing, for to have thus selected them is quite out of the question. Though as single birds so good, they were, as a pair, of course simply passed over. Considering the great difficulty of exhibiting Game fowls just at this season, the Bury Show was wonderfully good. The fact is, that just prior to the annual moulting, any effort to force Game cocks into first-rate condition at once produces

the loss of feathers, and thus hastens the very trouble which owners are so scrupulous to avoid. In *Grey Dorkings*, Mr. Henry Lingwood's birds showed to great advantage, being large honey specimens, the chickens showing well, and promising to be a pen of which we shall doubtless hear more on future occasions. This gentleman took two silver five-guinea pens (one for the best general collection restricted to the county alone), chiefly by the excellence of his *Dorkings*, both *Grey* and *White*. Perhaps want of condition was more apparent in the *Cochin* classes and the *Brahmas* than in any others, many of the best birds just now being ragged as colts after a winter in a strawyard. The *Hamburgs* did not show to the advantage which they will when they have assumed their new feathers. Of *Polish* fowls only one pen was shown. The "Selling Class" was not well filled, nor could this well be otherwise, when the entry was 6s. a-pen, and the sale price restricted to 30s. So great an onlay, when the carriage is also deducted from the receipts, will always prevent a full competition. Our experience proves, that with a 3s. entry no class ever pays a Society better than a "Selling Class," though dealers in poultry repudiate its adoption as a spoil-trade. In the class for any variety of *Bantams*, a pen of "Rumpless Bantams" were exhibited, one of the hens being so very cleverly dubbed as to make what had been a flat comb assimilate pretty closely to its fellows, which were rosy-combed. The artifice was at once detected, and disqualification ensued.

We never saw a better display of *Aylesbury Ducklings*, but the *Rouens* were so thoroughly intolerable, that the prizes in the latter class were withheld *in toto*. The *Turkey* class was especially creditable throughout, not a single specimen being other than excellent.

The *Pigeon* classes are, perhaps, most justly treated by saying as little as possibly can be said against them. *Blues* and *Blacks*, *Reds* and *Blacks* exhibited in pairs, was a general fault, no attention being evidently given to matching them; nevertheless here and there was to be seen an excellent pen, but the *Bury St. Edmunds Pigeon-fanciers* have evidently as yet not passed their novitiate. Altogether, however, the Show was a capital one; it was very well attended, and the weather was favourable.

**GAME** (Black-breasted and other Reds).—First, S. Matthew, Stowmarket. Second and Third, J. Fletcher, Stoneclough, near Manchester. Highly Commended, S. Matthew.

**GAME** (Duckwing and other Greys).—First and Silver Cup, J. Fletcher. Second and Third, S. Matthew. Commended, S. Matthew.

**GAME** (White and Piles).—First and Second, S. Matthew.

**DORKINGS** (Coloured).—Silver Cup, First, and Second, H. Lingwood, Needham Market. Third, T. Tatham. Commended, J. Frost, Wickham Market.

**DORKINGS** (White).—First, Second, and Commended, H. Lingwood.

**DORKINGS** (Any colour).—*Chickens*.—First, H. Lingwood. Second, H. Lingwood. Highly Commended, J. Frost; H. Lingwood; F. Parlett, Chelmsford; E. Leech. Commended, Dr. Campbell, Brentwood.

**COCHIN-CHINA** (Buff).—Silver Cup, First, and Second, H. Lingwood. Third, Rev. C. Spencer, Atleborough. Highly Commended, Mrs. Burrell, Ipswich. Commended, H. Payne.

**COCHIN-CHINA** (Any other colour).—First, Rev. C. H. Lucas (White). Second, Mrs. Seamons, Hartwell, Aylesbury. *Chickens*.—First, H. Lingwood. Second, Rev. C. Spencer. Highly Commended, Rev. C. H. Lucas (White); Mrs. Burrell (Buff); Rev. M. R. Barnard (White); H. Lingwood.

**BRAHMA** (Footed).—First, J. Piekles, Bridge Road (Dark Pencilled). Second, J. Wright (Dark). Third, Mrs. Seamons. Commended, G. H. Roberts (Dark).

**SPANISH**.—First, R. Wright. Second, withheld. Third, R. B. Postans, Brentwood, Essex.

**HAMBURG** (Golden-pencilled).—First, A. K. Wood, Buraside, Kendal. Second, C. Havers. Third, Mrs. Burrell.

**HAMBURG** (Silver-pencilled).—First, A. K. Wood. Second, withheld. Third, T. J. Saltmarsh, Chelmsford.

**HAMBURG** (Golden-spangled).—First, A. K. Wood. Second, J. Wright, Woodbridge.

**HAMBURG** (Silver-spangled).—First, A. K. Wood. Second, Rev. F. Tearle. Third, Mrs. Burrell.

**POLISH** (Any variety).—Second, Mrs. Burrell (Silver-spangled). First, withheld.

**BANTAMS** (Game).—First, R. B. Postans. Second and Third, G. Manning, Springfield.

**BANTAMS** (Any other variety).—First and Second, Rev. F. Tearle (White, clean-legged). Third, withheld.

**ANY OTHER DISTINCT VARIETY NOT NAMED**.—First and Second, National Poultry Company (Limited) (La Fleche, Houdan). Highly Commended, Mrs. Burrell (Silkies). Commended, Mrs. Burrell (Black Hamburgs).

**SELLING CLASS** (Any variety).—First, Dr. Campbell. Second, National Poultry Company (Limited) (Crève Cœur).

#### SINGLE COCKS.

**GAME**.—First and Second, S. Matthew.

**DORKINGS**.—Second, H. Lingwood. Commended, Dr. Campbell; F. Parlett.

**COCHIN**.—First, G. Manning. Second and Commended, H. Lingwood.

**SPANISH**.—Prize, F. Crook.

**DUCKS** (Aylesbury).—First and Second, Mrs. M. Seamons. Highly Commended, Mrs. Burrell; E. Leech. Commended, Miss Shaw.

**TURKEYS** (Any colour).—First, W. Wright. Second, E. Leech. Highly Commended, Miss Shaw.

**PIGEONS**.—*Carriers* (Any colour).—Prize, H. A. Oskea. Highly Commended, R. Futter; H. A. Oskea. *Tumblers* (Any colour).—Prize, R. Futter. *Any other Variety*.—Prize, National Poultry Company (Limited) (Runts).

The Silver Cup value £5 for the best collection of Poultry, exhibited by a resident of the county, was awarded to Mr. H. Lingwood, of Needham Market.

Edward Hewitt, Esq., of Eden Cottage, Sparkbrook, officiated as Judge.

#### LOST SWARM RECOVERED NEXT DAY.

Is there any account on record of a swarm remaining suspended in the open air during a night? On the 21st of June I missed a swarm from one of my hives, and did not discover its whereabouts until 7.30 a.m. next day. I found it suspended from the branch of an apple tree in my neighbour's garden in a perfectly quiescent state. A considerable amount of rain had fallen during the night, which may account for the very torpid state the bees assumed. They were soon hived, and are now working well.—C. F. W., *Forest Hill, Oxon.*

[Bees have not only remained suspended from a branch during the night, but have even been known to build comb in such a position.]

#### BEE SWARMING IN A CHIMNEY.

A few days ago I had a very fine first swarm from one of my hives. The bees settled upon a bush near the hive, where several previous swarms had located themselves. Some delay occurred in hiving the swarm, owing to a difficulty in procuring a hive, and in the meantime the precaution of covering the bush with a white cloth was, unfortunately, neglected. Before the swarm could be secured, the scorching rays of the sun drove the bees from the bush, and they took refuge in a lofty chimney at some considerable distance from my house. Ladders were procured, and the bees were found clustered under a narrow ledge in a corner of the chimney-pot. A hive, duly sweetened inside with honey, was placed on the top of the pot, and covered with a cloth tied round the pot, so that no bees could escape. In the morning we found that not a bee had ascended into the hive, and the swarm remained fixed in its former situation. Hoping that it might go up during the day we left the hive on the top of the chimney, opening the mouth, and placing a narrow board for the bees to enter and go out from the hive. At night, however, matters remained *in statu quo*, and we resolved to try to force the bees out of the chimney. We accordingly fired pistols, burned brown paper, and adopted other expedients of the same nature, but with no other result than to bring down a few stragglers on to the hearth. At last we lowered a square tin from the top of the chimney-pot, and gently brushed the bees into it, then drew it up, and emptied the bees into the hive. Having cleared all the bees out of the chimney, and put a bunch of nettles in the place occupied by them, we left the hive on the roof near the chimney to collect the stragglers, intending to remove it on the following day. Next morning there were a good many bees in the hive, but when we came to remove it at night not one was to be found either in the hive or in the chimney. Digusted with the treatment they had received they had migrated, and nothing has been heard of them since. Will you kindly tell me whether you can suggest any other means than those which were adopted to remove the swarm from the chimney? I should mention that a piece of comb, more than 6 inches square, was made by the bees during the day they inhabited the chimney.—F., *Westmoreland.*

[Active measure should have been resorted to at once instead of being deferred until the next day, and we know of none that promise better results than those successfully resorted to by "Squire" in a similar emergency, and which were thus described by him in page 82 of our ninth volume:—"A rope with a light weight attached was let down very gently from the top of the flue in which the bees had settled, and when this made its appearance at the bottom of the chimney, a bundle of fresh grass, well damped and as nearly as possible the size of the flue, was attached to it, and the whole was then drawn gently to the top of the chimney, upon which an empty hive had been already properly placed; into this the bees at once ascended, and were removed to their destination without further difficulty.]"

#### SPARROWS EATING BEES—DRIVING—SWARMS RETURNING.

Your correspondent "A BLACKHEATH'AN," writes, June 26th, that he has been troubled this year with sparrows feeding their young with the bees. The same proceeding has come under my notice this year, having observed it upwards of six weeks at my own hives. The sparrows having their nest in the roof of the house, I have no chance of destroying their nests.

Around this neighbourhood there are many bees kept, but I cannot bear of any one else having to complain of the sparrows. My employer has a dozen hives, and I have watched to see if their bees get picked up, but I have never seen them thus attacked, nor were mine until this year.

My practice in driving bees is, after the bees have been driven in the autumn, to unite them to other stocks, but I kept one stock in a hive by itself, feeding it liberally through the winter last year, and it will well repay me for my trouble, it being now a strong colony, with bees hanging out at the hive, when I put on a small super and found the hive very heavy.

The syrup I fed them with was made from 12 lbs. of sugar without any honey in it.

Around here cottagers are still very fond of the match or sulphur, and my employer kindly allowed me to go and drive several hives for parties around here, to introduce the system of driving instead of destroying; but I find most of them did not live through the winter, which I attribute to their not being well and liberally fed.

Swarms have been very late around here, and many have returned to their hives again after being hived. One of mine has been hived twice and returned both times. A neighbour's did the same, but stayed the third time. Our rector had one which swarmed, went back, and stayed the second time. He had another the other day, and they have not come out again as yet.—M., Sheldon, near Birmingham.

### SUPERIORITY OF THE LIGURIAN BEE.

The readers of "our Journal" will, I think, be interested in what I am doing with my new apian friends the Ligurians. I am endeavouring to test their qualities by a simple *experimentum crucis*, by the adoption of the old straw-hive system, pure and genuine, and of course my experiments in this direction, *in omnibus ceteris paribus*, will settle certain criteria more satisfactorily than the more scientific mode of propagation by artificial swarming. I am hiving them, then, this season, by the old method: stowing away the swarms as they make their appearance, and am brought to these conclusions:—

1st, As regards the localities which they select for swarming, I see no difference in any respect whatever between the Ligurian and common black bees. All mine have alighted favourably for hiving, and that not more than a few yards from their domiciles.

2nd, As regards their comparative good nature, my conclusions are that they are far more energetic and irascible in defending their queen than are common bees, and without a bee dress and strong gloves it would be, in nine cases out of ten, absolutely dangerous to attempt to hive them, if not impossible. When in their hives I do not perceive that they are less harmless than their less aristocratic *confères*.

3rd, They are prolific to a degree, and with a rapidity which is perfectly astonishing, as the following results will show. I began the present season with six Ligurian stocks, I think pure:—

1st, Swarmed May 27th, and threw out a large swarm of cast and colt. June 8th.

2nd, Swarmed June 3rd; cast June 15th. I expect every moment a third swarm from this.

3rd, Swarmed also June 3rd; cast June 19th; colt. June 21st.

4th, Swarmed June 8th; cast June 19th; colt. June 21st.

5th, Swarmed June 9th; cast June 20th; colt. June 22nd.

6th, Swarmed June 23rd. This was my best and strongest stock, but it had a large box beneath the hive, which accounts for its being last.

Besides this, I have had two maiden swarms, and expect another to-day (June 26th). The first maiden swarm came after having been hived twenty days; the second in twenty-nine days. This surely shows that the Ligurians are as active as they are prolific.

4th, This proves also that the old system cannot be adopted with Ligurians without doubling at least the size of their hives. To make my experiments absolutely and fairly comparative, I used hives of the usual kind, in common use in my neighbourhood. I daresay some will smile and think this a bungling system of experimentation; but at all events I have got some facts worth having. About the honey harvest I cannot speak with any certainty; but when I ponder on their multiplication I cannot help thinking of "poor curates" with large families and no prospect of preferment. *Nous verrons*. I began

the season with six hives. I have already, with these, twenty-three! and have capped at least half-a-dozen more!!—WILLIAM LAW, Marston Trussell Rectory, Theddingworth, Rugby.

P.S.—Since the above was written I have had another second swarm, and unless I had taken means to prevent it, should have had on Saturday last (30th June), two more maiden swarms, and one of these from a cast, which came out on 8th of June. The account of the Ligurian department of my apiary, therefore stands thus:—I began with six hives; I have now in full work, and with every prospect of making good stocks, twenty-three hives, and had I not prevented two from swarming, should have had twenty-five! All this is the result simply of natural swarming, in which I have allowed the bees to follow their own instincts. My experiments have been carried out on the fairest principles I could adopt, and are strictly comparative. I had no other object than simply to ascertain for myself, and in my own way, whether the Ligurian bee is really so superior to the common species as it has been described to be, and I have no hesitation in saying that the result is that I am so thoroughly convinced of their superiority in every way, that I mean to keep no others.

[It may not be amiss to add that the above extraordinary results have actually been achieved by two stocks which left my apiary, one in the autumn of 1864, and the other during the spring of 1865.—A DEVONSHIRE BEE-KEEPER.]

### SECOND SWARMS—TAKING HONEY FROM SUPERS—LIGURIANS.

BEING as yet but a novice in the management of bees, I am anxious for information under the following circumstances. I began this season with three good strong stock hives:—

No. 1 is rather a small common straw hive, and it gave me on the 26th of May a very fine swarm.

No. 2 is also very strong, and in a large wooden hive, having externally nearly the same appearance as Tegetmeier's hive, as figured at page 13 of "Bee-keeping for the Many," but arranged inside in the following manner:—The bottom or main part of the hive is 13½ inches square inside by 11 inches deep, fitted with eight bars from front to back of the hive, and which, unfortunately, are fixed, and prevent my obtaining artificial swarms. Above the bars half-inch strips of wood are fixed, dividing the top into four equal squares, into which fit four six-inch square moveable boxes or supers; by placing thin sheets of zinc or glass under the supers, communication with the hive is cut off, and it can again be restored at pleasure to any one or all of the supers by drawing out the sheets of zinc or glass. From the half-inch spaces between the bars affording such free access to the supers I never have the least trouble in the bees taking to them. I may add that the two sides of the bottom or main part of the hive are furnished with a window about 5 inches square and covered with a sliding shutter; the supers also have each a small window about 3 inches square, which is very convenient for ascertaining the state of the supers, and also, in my case, adds very greatly to the pleasure I have in watching the progress and rejoicing in the prosperity of my industrious little favourites. A moveable casing of half-inch wood forms the roof and covers the supers, and in winter I keep it neatly and warmly thatched with hay and straw down to below the floor-board, my object being to encourage early breeding.

This hive, No. 2, sent off a very strong swarm on June 6th, and at the present time has the four supers well filled with honey, and also a good quantity in the bottom or main part of the hive.

No. 3 is a large-sized straw hive, and very strong (it is a swarm from No. 1 of last year, and came off on May 19th). This year No. 3 has given me, June 3rd, a strong swarm which came off by 9 o'clock a.m.

Now as I have been anxious to increase the number of my hives, I have expected second swarms from each, being so strong, in about from nine to fourteen days from first swarms, but up to this date I have had none, although for the last four or five days each of the three hives has clustered outside *en masse*, quite equal to anything I have seen preceding first swarms, the inside of the hives also appearing much disturbed, but as yet I have failed to hear the cry of a queen in any of the three. The maximum temperature here in the shade has been during the last eight days as follows:—June 21st, 70°, 67°, 78°, 83°, 87°, 91°, 75°, and to-day, June 28th, 76°. This

evening very few bees are clustered outside of either No. 1 or 3, but all are still unusually noisy.

I am afraid that I have trespassed too much upon your space, but perhaps others also may be benefited by the information I seek upon the following points:—

First, am I still likely to have second swarms, and, if before the 7th of July, can I, by the help of a good season and judicious feeding, hope to bring them safely through the winter?

Second, when I take the honey from the supers in No. 2 should I allow communication to the supers during the winter; also, what is your opinion of my No. 2 hive?

Third, as I have been lately informed that the Ligurian bee has been introduced into this district (the north of Ireland), and are reported very favourably of, might I be able to preserve an artificial swarm obtained—say at least before the middle of July, and what would be a fair value for a swarm of Ligurians? I may add that I have this season put my swarms into hives that allow of supering in future.—ALBAN GOODMAN.

[Second swarms are not likely to issue after so long an interval, but, should they do so, their probable preservation through the winter is only a question of a few pounds of sugar judiciously administered. When a swarm issues early in the morning we always suspect its being the second, and fear, therefore, that the prime swarm from No. 3 may have escaped you. Communication with supers should be closed during winter. Your hive No. 2 is not one that we should prefer. Mr. Woodbury, of Mount Radford, Exeter, sent the Ligurians to Ireland, and you had therefore better write to him direct for information concerning them.]

### BEES DESERTING THEIR HIVES—ARTIFICIAL SWARMS.

SOME extraordinary instances of bees deserting their hives have come to my knowledge this season, and I am quite unable to account for the great difference observable in the conduct of bees at different times under similar circumstances. A cottager lost his only hive last autumn; the bees gradually dwindling down to zero. The hive had swarmed, and the young queen was probably lost on her trip, or killed on her return by her own subjects. The hive was, however, filled with comb, and well stored with honey, and I told the owner that I would stock it with bees if he sent it up to my house. About three weeks ago I introduced a good second swarm into the hive, and kept them in my own garden for about a fortnight, that the young queen might stand a chance of mating with one of my drones; I then allowed the cottager to take the hive home in the evening. The following day the bees came out *en masse*, and after being hived five or six times in an empty hive, ultimately went off altogether, and were lost. The hive contained a good deal of brood, proving that the queen was all right; yet these bees, either with or without a queen, (as she might, though it is improbable, have been killed in the removal), completely abandoned their hive, though it was well furnished with both brood and honey.

Again: another bee-keeper hived a prime swarm on the 2nd of last month (June), the bees filled the hive with comb and honey, and it also contained brood, yet they completely deserted the hive on one of the last days, leaving their brood and stores behind.

The great heat is the only cause I can assign for such extraordinary proceedings. On the other hand, I have several times had queenless stocks which have guarded their stores and retained possession of their hives until the bees have nearly all died off from old age.

In forming swarms by driving it is no doubt a great advantage to employ two stocks; but I have been perfectly successful, both this season and on former occasions, with only one hive. Two-thirds, perhaps, of the bees were driven into an empty hive at seven o'clock in the morning of a fine day, the stock was replaced upon its old stand, and the swarm, after it had been a short time in the empty hive, was knocked out *en masse*, and induced to enter a unicombed hive in a different part of the same garden, and nearly all the driven bees stuck to their queen in the new domicile. I have made second swarms in the same way, and find the driven bees adhere to their new quarters nearly or quite as well as a natural swarm.—J. E. B.

[The satisfactory adherence of the artificial swarm to its new domicile was probably owing to the bees having been compelled

to run into it, a hint which was given some time ago by our valued correspondent "R. S.," touching the removal of stocks to short distances, and which, it appears, may also be very useful in the formation of artificial swarms.]

### OUR LETTER BOX.

**FEEDING POULTRY (J. L.).**—The result would seem to prove your system is not far wrong; and the falling off in the last few days may be accounted for by the change in the weather, constant damp, and absence of sun. These most affect the youngest, and they are the sufferers. We will give you our free opinion of the dietary. Some years since we tried the Mark Lane sweepings, but did not think they answered: there is too much dirt in them, and the corn, with the exception of the maize, was of the thinnest description. We approve the oatmeal, but would rather give whole corn than coarse middlings. Everything seems provided that can be necessary for poultry. Your adults and forward chickens, with a grass run and farmyard, want no pampering, but it is impossible to feed young chickens too well. To enable you to "do" them as they require, it is well to remove them with the hens from the immediate neighbourhood of the old and older birds. A dry sheltered spot for the hen, and a newly mown grass run for the chickens, are desirable. When chickens are falling, cooked meat chopped very fine is desirable food.

**CRESTS OF BLACK POLANDS (E., Westmoreland).**—The crest of your chickens will come white, except just in front, if they are pure bred. We could speak more positively if you had named their age.

**CHICKENS DYING (W. S. P.).**—The "attempt to swallow," that you mention is generally the result of a disease called the "gapes," and is caused by the presence of worms in the windpipe. The birds gape in the vain effort to get rid of the intruders. From their position they are hard to get at. There are divers cures and operations, but wherever the disease appears some chickens always die. A hen's tail feather stripped within an inch of its extremity and dipped in turpentine, put down the windpipe, not the gullet, until it reaches the worms, kills them, and the operation causes the bird to sneeze and throw them up. The operation is a nice one, as a mistake is often made, and the feather put down the gullet, which is useless. The best remedy we know is to give camphor freely in pills about the size of a pea, and to give water strongly impregnated with it, in fact, what our grandmothers used to call "camphor julep." After a time the whole body of the bird is imbued with camphor, and it kills the worms. It is thought, and we agree with it, that these parasites are gained by drinking bad water. All fowls prefer drinking from a puddle of dirty rain water to any vessel of clean spring water. The opportunity should not, therefore, be afforded to them. Old birds do not catch this disease. Chickens recover if they can outlive the worms; but as they never do so unassisted, it is well to feed liberally on bread and ale in order to keep them up. There has, however, been a disorder among chickens which has caused blindness and death in a few hours, the eyes being closed by a thick gum. We have watched it closely, and it is not skin to roup. It is, however, very fatal; but if taken early and treated with beer and camphor, two-thirds of those attacked recover.

**DUCKS WHERE WATER IS DEFICIENT (Commercial).**—Rouen Ducks are, we believe, the best to suit you. Aylesburys are preferable if you have hens under which to put the eggs, as they are non-sitters, as they lay very many eggs, and fatten easily. Rouen and Aylesbury are the desirable breeds on account of their size.

**INFLAMED VENT IN CHICKENS (J. A. C.).**—We have seen no cases of epidemic such as you mention. Redness and inflammation of the vent almost always arise from a disordered stomach, when the evacuations get stinky and sticky, and part always adheres to the vent, causing pain and inflammation. Pea and beanmeal will cause this, and when the vent gets entirely closed, death soon follows, every evacuation helps to close the vent, just as each piece of mud helps to form a swallow's nest. As it is impossible to treat a whole yard as you would a few cases, we advise such food as would be likely to meet the case—ground oats mixed slack, and given three times per day in moderate quantities, and as much lettuce as you can give. The latter is the cure for it, and if the litters have gone to seed and stalk as much the better. We know no more valuable poultry medicine than this last.

**HENS DISORDERED (J. R.).**—They are evidently very much out of order, digestion impaired and egg-organs inflamed. Give each a desert-spoonful of castor oil; feed on soft food only—mashed potatoes with a little oatmeal added, and abundance of lettuce leaves. Let them have a heap of coal ashes and limy rubbish to bask in.

**INCUBATORS (J. A. C.).**—If properly managed any one of these advertised will hatch the eggs placed in it. The difficulty begins as soon as the chickens are produced. Hatching is easier than rearing.

**STRENGTHENING A LIGURIAN STOCK (A. T., Jersey).**—Combs of common brood added to a Ligurian stock strengthen the colony, and although the bees thus produced will not turn to Ligurians they will, owing to the brief life of worker bees at this season, rapidly disappear without leaving any permanent stain on the purity of the Italians.

**PREVENTING SWARMING (D. R., Rochdale).**—Withdrawing slides and thereby giving access to glasses cannot always be relied upon to prevent swarming. The rise of temperature in the interior of a hive prior to swarming is probably owing to the crowded state of its population.

**VALUE OF SECOND SWARMS (D. Ross).**—A second swarm is not considered so good as the first, nor is it so likely to survive the winter. The price of swarms varies so much in different localities that it is difficult to offer an opinion, but we have often purchased good first swarms for the sum you mention.

**TRANSFERRING ARTIFICIAL SWARM FROM A NUCLEUS BOX TO A WOODBURY HIVE (A. B.).**—An artificial swarm formed in a nucleus box on the 31st of May, may now be shifted into a full-sized hive, but it is well first to ascertain that it possesses a fertile queen. We find the average time for the production of a queen to be fourteen days from the formation of an artificial swarm, and a similar period usually elapses before she commences egg-laying.

WEEKLY CALENDAR.

Day of Month.		Day of Week.		JULY 17—23, 1866.			Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock before Sun.	Day of Year.	
Day of Month.	Day of Week.			Day.	Night.	Mean.	Days.	m.	h.	m.	h.	m.	h.	m.	h.	Days	m.	s.

23	M	Amellus lychmitis.		74.0	51.9	63.0	19	12	4	0	8	30	4	48	0	6	10	204

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 73.0°; and its night temperature 50.9°. The greatest heat was 94°, on the 17th, 1834; and the lowest cold 32°, on the 23rd, 1863. The greatest fall of rain was 1.37 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

SAND FOR CULTURAL PURPOSES.

ALTHOUGH simple, and to be met with almost everywhere, yet few things are either less understood or so disregarded as sand—that indispensable adjunct to the

compost-ground and potting-bench.

Sand, with scarcely an exception, is a necessary ingredient in every mixture, and whatever the class of plant operated with, and whether it is dissected for the purpose of obtaining an increased number of subjects, or it is only treated to a larger share of the good things of this world to enable it to expand itself into larger dimensions, sand seems as necessary a material to help out either of these works as mother earth herself; and in giving directions as to the mixtures best adapted to the wants of each plant, sand is sure to be one of the ingredients. Let us, therefore, see what is the action of sand on the soils we deal with, and reason from that whether much of the material called sand is not improperly used. At all events, let us determine what ought to be understood by the term sand as used in horticulture, the mode of employing this substance, and other matters bearing on the subject.

In the first place it will be generally admitted that sand forms a component part in all soils; even the stiffest clays are not without a trace of it, but its presence in some other descriptions of soil is more apparent, and the term sandy soil is applied, perhaps, to a soil that contains a large percentage of that material, which soil nevertheless differs widely from another that contains quite as much sand, the difference in the sand constituting in fact the difference in the character of the two soils. Let the traveller take a stroll along the seashore on some of the coasts that are characterised as sandy, and he will see abundance of a material that has by the action of time and a little mixture of other ingredients formed itself into a sort of natural embankment, repelling the waves of the ocean, and becoming a fitting receptacle for the roots of maritime herbage. The sand has been so often steeped in salt water that, for a time at least, it seems to be so charged with salt as to be unfit for some of the purposes for which sand is used, as the making of mortar; and in horticulture those for which it can be employed are few. It is "sand," however, and when that term is used an inexperienced person might possibly suppose that any kind would do, and that existing in some places in great abundance might be used when it would be hurtful. Sands of other kinds are also to be had in more or less abundance, and some of these having a wide reputation are, perhaps, more likely to do harm than sea sand, whose saline qualities being known is received with caution by the great bulk of horticulturists.

Sand from the banks of rivers has certainly many advantages over that from the side of the ocean, if such rivers are not tidal ones, and the stream of water is free from all noxious qualities. I am rather disposed at all times to give the preference to river sand over all others, as being more free from mineral matters; and its exposure to the atmosphere, when it has been lying some time on the side of the banks, sweetens it and fits it better for vegetation than sand taken from a pit or cutting. Possibly some very exact and expert propagator of Epacrises, Boronias, and other hardwooded plants may find fault with its being too coarse for his use, because his tiny little cuttings cannot be properly fixed in it, and a finer and closer-grained material has to be obtained; but for mixing with the ordinary soils of the potting-bench river sand will generally be found preferable to any other, as well as for mixing more largely still in the open ground when it can be had in sufficient abundance.

Next in importance to sand obtained from the sides or channels of running streams is the kind not unusually called drift sand, which is to be had by the sides of roads composed of stones grinding into an open sand, which, however, all road stones do not. On the contrary, some of them furnish a kind of mud, which hardens into the consistency of cement, and is of course inadmissible for purposes where sand is wanted. By the sides of some roads, however, and in districts where sand forms an important ingredient in the composition of the soil, the heavy rains, washing the more muddy and soluble parts away into the valleys or ditches, carry with them a portion of the sand, and leave it not unusually midway in their course, intermixing with it, perhaps, more or less gravel and other refuse; but in ordinary rural districts, free from the taint of factories or mines, such admixtures seldom unfit this kind of sand for cultural purposes, and drift sand may be set down as being tolerably pure and suitable for horticultural use.

We now come to the class of sand most difficult to deal with, and that certainly in which the greatest mistakes are made—pit sand, which is also more extensively used than any other. Being good in appearance, handy, and abundant, it has acquired a reputation which it is questionable if it deserves as a promoter of vegetation; besides, it differs so widely in its character that it would not be prudent to pass other than a qualified opinion on its merits. Certain kinds of sand, however, have for many years had a reputation for cultural purposes which it is almost treason to assail. Many years ago, when it was very common, as indeed it still is, to admire things most that came from a distance, Calais sand had the reputation of being the best, although it seems to be less plentiful there than at Boulogne; eventually, however, it was found out that there was plenty of good sand in England, and Reigate sand was in most request. This sand has all the properties likely to captivate buyers, being pure white in colour, and sufficiently open to render the soils with which it is intermixed more porous, while it is fine enough to close in around a cutting that can only be inserted from a quarter to half an inch deep. Reigate sand is, therefore, in great demand, and it

is, perhaps, deserving of all the praise that has been bestowed on it when used for the class of plants for which it is suitable; but that its use can be recommended for all kinds of plants is by no means clear; on the contrary, there is every reason to believe that for some it is very improper. To make this appear more plainly, let us look at the character of the sands which form the ingredients of the soils in which the various plants cultivated in gardens flourish, and in doing so I shall presuppose that all other pit sands are only suitable to the plants for which each is fitted by its chemical constituents.

Without entering into detail as to the requirements of each class of plants, we may roughly divide these into the two classes most dissimilar in respect to the soil in which they thrive best, and preferring, the one a calcareous, the other a peaty soil. Both these classes of plants require an admixture of sand in the medium in which they grow, and in general both soils are furnished with it in greater or less amount. The sand, however, is not alike in both, that in each soil partaking to a certain extent of the other constituents of the mixture of which it forms a part; and supposing it were possible to separate the sand from the one soil and add it to the other, the result would in all probability be unsatisfactory in consequence of the antagonistic properties of the materials so mixed. Instances of this kind are sometimes met with in other branches of industry than horticulture. I remember once noticing a large heap of mortar that had lain some time, and which showed beyond the possibility of a doubt the indiscretion of mixing substances together that had no affinity. A bright yellow sand, sharp enough to entrap an unwary builder into the belief that it would make good mortar, had been mixed with lime in the usual way, and not being all wanted, a large heap lay some months, when, on its being examined, it was found that the lime was all but gone. The sand had "eaten it up," as the labourer truly enough said, and the reason was plain enough. The sand was strongly impregnated with iron, and, instead of uniting with the lime, the result was the destruction of the latter as far as the mortar was concerned. Now, it is easy to perceive that something of the kind must occur when sand of an unsuitable character forms a component part in a mixture for cultural purposes; and although neutral sands may with propriety be mixed with either calcareous or peaty soil, all sands used at the potting-bench are not neutral, like the river sand previously alluded to, and the drift sand also, though less pure perhaps. Supposing any one were tempted to use the pure white sand, which is dug in such large quantities in some neighbourhoods for the manufacture of glass, as an ingredient in a compost for growing Heaths or Rhododendrons, assuredly the result could not be satisfactory; rather let a soil containing iron be used, and the chances of a favourable result will be greater.

In advocating the use of sand charged with iron, where American plants are grown, I by no means recommend a too strong dose of it, for I have seen very fatal results follow the planting of this class of plants in a sort of bog peat, too much impregnated with that metal, but at the same time I have also seen the evil effects of a silicious sand used for the same purpose. A medium ought to be aimed at, and let the sand used for American plants be only impregnated with a little iron, but not at all so for other plants. The pleasing appearance of nice white sand is a strong inducement to use it whenever sand is wanted, and few people give themselves the trouble to find out whether it is likely to suit the purpose they put it to or not; but at the same time grey or yellow sand is equally useful, and the latter is more likely to answer in the case of a peaty soil. I would advise these who have the opportunity of using the last two, to try them for growing Heaths, and for other purposes where they are brought in contact with peaty soil, while the fine white sand so extensively employed for domestic use, may be tried with good effect among plants not requiring peat.

All sand charged with poisonous matters should be avoided; a sort of greyish sandy material is found very extensively in some mining districts, and is so poisonous that it kills all plants on which it is laid, and is often used to throw on courtyards or walks for the purpose of killing the weeds there. Such a substance, of course, should never find its way into mixtures intended for the culture of plants, and a sand, even though containing a small proportion of anything deleterious, should also be avoided.

Although sand generally serves to increase the fertility of the ground, yet where it exists in too great a proportion, it has the contrary effect. The reason of this appears to be its want

of adhesion, and the consequent too free access of air to the roots, as well as the plants having to exist on such liquid food as can be derived from external sources, and failing these they suffer, just as plants cultivated in pots must in a great measure depend on periodical waterings. Sand here becomes an important agent, as it prevents the soil clogging, and allows the superfluous water to pass off easily. This branch of the subject, however, is only mentioned here to show the utility of sand as an agent in the hands of the cultivator, and it is one to which he has hitherto not paid so much attention as it deserves.

—J. ROSSON.

## STRAWBERRIES.

Owing to M. Van Houtte having facetiously dubbed me "the sole arbiter" of the fate of seedling Strawberries, of course you will expect that annually I shall say something on the subject. I must, however, though much gratified by his estimate, decline to be more than the expressor of an honest opinion. I cannot be answerable for what is put in my mouth.

My Strawberries of all kinds were removed here late in the spring from Rushton; and, considering this disadvantage, they have done well. I here found these sorts, youthful and established, and they have cropped finely—Rivers's Eliza, Trollope's Victoria, Eugénie, and Eleanor. The following sorts I brought with me:—Sir J. Paxton, Eclipse, Royal Hautbois, Rivers's Eliza, Old Pine, Scarlet Pine, Dr. Hogg, Mr. Radclyffe, John Powell, Bicton Pine, Eugénie, Wonderful, Frogmore Late Pine, and Cockscomb—a famous lot of good-constituted and heavy cropping Strawberries, save one, the Old Pine. This has been erroneously said to be the same as the Scarlet Pine, which is more like the Rival Queen than any other. I fancy the latter is a seedling from the Scarlet Pine. The Scarlet Pine is a better setter than the Rival Queen, and is not subject, as the Rival Queen is, to deformed, abortive, and cancerous berries. The Scarlet Pine is the best flavoured Strawberry here, or that I have ever tasted. I obtained my Scarlet Pines from the late Mr. Nicholson, and the Old Pines from G. Sparkes, Esq., of Bromley. They are not the same Strawberry.

Before I proceed to speak of tried Strawberries, I must mention, that, allured by a touching picture, I bought late in the spring twenty plants of "The Lady" (Underhill), which I deprived of their flowers. They are growing strongly, and are commencing to run. It is of no use to crop late spring-planted Strawberries. Deprive them of their flowers and the plants will gain strength at once, run quickly, and do much better the following year. You cannot judge accurately of them till they have a large volume of perpendicular and horizontal roots. I gave 30s. and 3s. carriage for "The Lady"—a very cheap lot.

Before giving a list of Strawberries that can be recommended, let me notice new Strawberries that I have sufficiently tried.

1. Dr. Hogg (Bradley).—This is A1 in every respect. A noble dish of it was furnished by Mr. Turner, of the Royal Nurseries, Slough, for the Hole testimonial dinner.\* It is in constitution a Queen, more regularly coloured. It is hardy, fine-foliated, a heavy cropper, and has grown well in my chalky land at Rushton, and still better in my fine, sandy, deep loam here. I beg to universally recommend it.

2. Mr. Radclyffe.—Sent to me as Mr. Ingram's No. 10. This is a splendid production from the Royal Gardens, Frogmore. I must hasten to acknowledge the high compliment paid to me. I wrote to Mr. Ingram to ask what name he had determined upon. I received a kind answer saying, that by my permission he would call it Mr. Radclyffe. I beg publicly to thank him for the honour done to me. It is also in constitution a Queen, hardy, fine Queen-foliated, a good cropper, large, and Queen-flavoured. Mr. Ingram's opinion of it is—"It is equal to the Queen in all respects, but has a better constitution." I beg to endorse this.

3. Cockscomb (Mr. Ingram).—This is a very valuable Strawberry. It is suitable for all classes. It is hardy, a fine grower, an immense cropper, of huge size, and of excellent flavour in the Queen line. No Strawberry removed here from Rushton has borne more heavily than this, and the Royal Hautbois, which is a jewel!

These three are all late Strawberries. They are sure to

\* I attended the Hole testimonial dinner at Anderton's. The "tear-n" (by Garrard & Co.), presented by the Rose growers of England, to the Rev. S. R. Hole, originator of the National Rose Show, was elegant. I can hardly say how much pleasure I felt on the occasion. Long may this, in every respect noble specimen of the human race, live to enjoy with his wife and family this graceful and well-deserved tribute.

retain their place in a good catalogue for many years, perhaps for ever.

I now give a list of honest, hardy, sure, and heavy-cropping Strawberries, from which a person may select without fear.

*Early*.—Sir J. Paxton and Eclipse.

*Second Early*.—Rivers's Eliza; Trollope's Victoria, a great favourite at dessert; Empress Eugénie, a good friend, but coarse and not highly flavoured.

*Later*.—Scarlet Pine and John Powell, both first-rate; Wonderful, and Bieton Pine, peculiar and valuable.

*Very Late*.—Frogmore Late Pine, a most noble sort; Dr. Hogg, Mr. Radclyffe, and Cockscorb.

These are a noble lot, you cannot burn your fingers. In the celestial bodies there are different glories, so it is here.

I have now only to recommend the Royal Hautbois and the old Red and White Alpines, which I began the season with, and they are cropping heavily now. I am fond of them without sugar, but with sugar and cream and a glass of sauterne or sherry, they are the best of all. Hautbois and Alpine Strawberries should be dead-ripe before picked.

If more mid-season Strawberries are wanted, perhaps Oscar and President, which I have lately tasted in my clergyman's garden (the Rev. R. Price), and thought excellent, would be good further selections.—W. F. RADCLYFFE, *Okeford Fitzpaine*.

### THE ROSE GARDENS OF LYONS.

I THINK there are very few persons who, looking at Lyons for the first, or indeed for the twentieth time, would ever think of it as a place celebrated for Roses. Its rivers are broad and muddy; its new part a poor imitation of Paris; its older portion full of the most abominable stenches that ever offended the nose of a poor mortal; and to one fresh from the lovely scenes of Switzerland, its glare and its treeless appearance detracted vastly from what I had heard and remembered of its greatness. It was nearly thirty years since I had visited it—when not a railway was constructed in France, when the journey to Marseilles took up the best part of a week, and when the pleasures of travelling were considerably lessened by the confinement, dirt, and dust of a diligence. I remember then it took forty-eight hours of continuous travelling to get from Paris to Châlons-sur-Saône. We did it in five. But even then I recollect Lyons did not strike me very much, yet in size and importance it is the second city in France. Although so celebrated for its silk and velvet, it does not give you the idea of a great manufacturing place. The tall smoke-emitting chimnies that are so plentiful at Manchester and in our manufacturing districts generally are not to be seen here, from the fact that the weavers work in their own houses, and that hand-looms and not machinery are employed.

Where, one would ask, can the Rose gardens be? Where are the lovely spots where *Senateur Vaïsse*, Charles Lefebvre, Madame Falcot, and a host of the (Rose) world's most celebrated characters saw the light? Where are the lovely nymphs that watched these nascent beauties, where the chivalrous knights who proclaimed their peerlessness against all comers, in what shady vale was their education carried out, I could not for the life of me imagine. There is a wonderful deal of "bosh" talked about the sunny south, and persons imagine that the south of France must be the most charming place imaginable. When that "vile north-easter" blows right through one—when catarrhs are the rage, and gruel and hot water in request—then one may draw a deep sigh, and wish he were in the "sunny south." But there is a reverse to the medal. Go there now, and what a different tale you would have to tell. It is warm enough here, even though there is a gentle breeze coming in from the Downs; but there they have perhaps the "mistral" blowing hot and scorching from the south. Not a Rose is to be seen; they are all *abimé* with the fierce heat of a few days. You must try and sit with every window and door closed, for the admission of air is only letting in the atmosphere of a furnace. All this is unfavourable, one would say, to Rose-growing; but what about the soil?—this must be cool and deep. No such thing. What I saw was hot and scorching enough, full of stones, and very unsuitable for the growth of the queen of flowers; and yet we do know that from this place have come some of the very best of our Roses; and the names of Lacharme, Guillot père et fils, Ducher, Liaud, Damaizin, Goned, &c., who are inhabitants of Lyons, testify to the truth of this. In fact, those very conditions which are adverse to the growth of the Rose are favourable to the pro-

duction of new varieties. They have not to complain, as we too often have, of cold and wet summers, of seeds rotting in their heaps, and of expectations doomed to disappointment. The seed sets early and ripens rapidly, and this is more especially the case when the Roses are planted against a wall with a south aspect. Hence they are able to excel us in the raising of seedlings, especially amongst the Teas and Noisettes; although I have no hesitation in saying that we excel them in the growth of our trees, and in the size and quality of our blooms.

The chief object that I had in visiting Lyons was to find out the truthfulness of the statement made to me last autumn by Lacharme—that he had a Perpetual Rose of a "true yellow" colour. I felt quite confident, that if it were true it was such a step as we had not of late years seen, and that, as I had been appealed to about it, it would be most desirable to obtain correct information. While I was hesitating about extending my journey from Paris to Lyons, I was solicited by one of our most eminent introducers of novelties, Mr. Bull, of Chelsea, to report on it, and whatever information I am able to give on the point rosarians are indebted to him for it.

Despairing of finding my way to Lacharme's, which I knew to be some distance off, and knowing from experience that names well known to us may be little known even in their immediate localities, I secured the services of a "cocher," and after various inquiries, found far down on the banks of the river, and hard by one of the numerous forts with which Lyons is encircled, the place I was in quest of. It was an unpretending-looking house, and the garden gave no indication of the greatness that was due to it; neatness certainly was not its characteristic. Lacharme was in one of his other gardens, and I had to wait some little time before he made his appearance; when he did he struck me at once as an honest and sensible man. We sat down and had a little chat together; I found there was some kind of embarrassment about him when I told him that I had come to Lyons on purpose to see his yellow Hybrid Perpetual, and I began to fear there was some screw loose. I would here remark that the French Rose-growers do not quite understand our taste for yellow Roses, they do not themselves seem to think much about them, and also do not see why we do not admire their "ardoisè" flowers, that indescribable slaty colour appearing to have great charms for them; and hence the advent of a genuine yellow Perpetual would not seem to them so great a feat, but that there is connected with it the commercial gain of a flower that would be sure to sell well in England, England being their chief market at all times, and now more especially, when this awful and wretched war is desolating Germany, where they have been in the habit of supplying many orders every year.

We walked on through his grounds, which were singularly untidy, across to another garden, where, on a wall facing the south, he has a large quantity of Teas and Noisettes planted, and where he has matured most of the seed from whence he has raised the Roses which have made his name famous. We talked of and saw many of these Roses as we walked along, but still I did not see the yellow Perpetual. I saw Alfred Colomb, which I did not hesitate last year to pronounce, from the blooms I saw of it, to be a fine Rose, and which both here and in my own garden has merited the praise I gave it. Souvenir de Dr. Jamain is also dark and rich in colour, but I am afraid too small to suit our taste; the petals are thick and firm, but there are too few of them; while Prudence Bresson, a great flaunting flower, with petals of immense size and brilliancy of colour, is more like a semi-double Peony than a Rose. Its effect seen at a distance is very striking, but it will not do for us. Charles Lefebvre and Souvenir de la Malmaison were there in quantities, but the blooms were certainly not so fine as I have seen them in England. At last we came to where the yellow Rose was said to be, and great was my disappointment, and, I believe, honestly that of Lacharme himself. The truth is, he has been the raiser of many Hybrid Noisettes, such as Louise Darzens, Charles Maynard, Madame Gustave Bonnet, &c., and that it is in this class, which are not really Hybrid Perpetuals, that he believed he had obtained what he announced. I saw the plant not absolutely in flower, but with the buds partly open, and it has no pretensions to being a yellow Rose. It came last year with a good deal of yellow in it, and Lacharme was in hopes that this would be permanent. But alas! this year it has only shown a very faint tinge of yellow in the centre of the flower—*un peu jaunâtre*, and it will not be sent out as a yellow Rose. I am not at all sure that it may not be the *avant-courreur* of a yellow Rose; but even then, if of this class,

It would hardly be worth much, as they all partake too closely of the Noisette character to be really valuable to us. White Roses are scarce; but we want something larger, of better form, and harder constitution than those which I have already mentioned.

I believe Lacharme has had to stand a good deal of chaffing about his yellow Rose, but I for one acquit him of all desire to "do" us, and believe it is one of those disappointments to which the raiser of seedlings is subjected. How often have I seen at my neighbour and friend, Mr. Banks's, seedling Fuchsias of the most promising character, but of which, when I asked the following year, I was told they turned out valueless; and so it is with the Rose. One and all, however, gave the credit to Charles Lefebvre, as being the finest Rose out; while of yellow Roses I was asked, "What do you desire more than *Maréchal Niel*?" We had, after our tour round the gardens, a quiet chat together about Roses and Rose-lovers, and I confess I could not but regard with respect the man who has been so good a raiser of Roses, and has contributed so much to our enjoyment, as François Lacharme.—D., *Deal*.

### POISONED SEEDS.

In your impression of the 3rd inst. Mr. Fish wishes to know if any tasteless poison can be procured for the purpose of blinding the feathered depredators of his fruit, &c. As he has for years given me many valuable hints, may I offer him one in return?

The Act of 16th & 17th Viet., c. 113 (1863), enacts (*inter alia*), that any person who shall knowingly or wilfully sow, cast, set, lay, put, or place, or cause to be sown, &c., any poisoned grain, seed, or meal (by 17th & 18th Viet., c. 115, extended to meat also), shall forfeit on summary conviction £10; but this prohibition is not to extend to seed so "dressed" for agricultural purposes only. Mr. Fish may therefore steep in poison the seeds he actually sows, but he must not scatter poisoned seed, &c., about.

I shall conclude by merely stating that half the penalty goes to an informer, and that accessories informing are freed from penalty.—LEX.

### THE CULTURE OF ADIANTUM CUNEATUM IN A SITTING-ROOM.

I HAVE been asked to state what has been the treatment of the Fern which gained the *Gardeners' Chronicle* first prize at the Horticultural Society's Show last June. It has been very simple, my great aim having been to bear in mind what was most natural to the plant. It has been usually grown from June to December, in a Paxtonian basket suspended in a south-east window; the soil being a compost of peat, fine sand, and cocoa-nut fibre. While in full growth (from about April to the end of October), I have watered it very freely with a very fine rose, completely deluging the plant, but always being careful afterwards to draw off the water from beneath, so as not to rot the roots. When the fructification is over and the old fronds begin to die off, I remove them gradually until about December, when I usually strip the plant of all old fronds, this giving me room to train the young fronds as they come up; these I always train to hang over the basket—it is easier to do it when the plant is clear, and plenty more fronds come on to fill up the middle.

During the winter months, from November to April, twice a-week is usually sufficient for watering. This year when I found the plant was to be exhibited, I removed it from the south-east aspect to a north-west one in the same room, and lowered the basket on a level with the window, for I found the height drew the fronds. About the beginning of May I again put it in the south-east aspect, and on the 18th of June it had attained the perfection in which it was exhibited; but I must add that the plant is much finer now than when it was shown, and will be still finer in August, and that I believe the chief element of success is the perfect drainage secured by the structure of the Paxtonian basket, which was provided for me by Messrs. Barr & Sugden, King Street, Covent Garden.—C. D., *Deal*.

**OROBANCHE MINOR.**—On the root of a scarlet Geranium in one of the beds in my garden is growing a plant of *Orobanché*

minor. Is not this rather an unusual position for it? It usually grows on Clover.—A. R., *Bromley*.

[It is a very unusual growth-place for the *O. minor*; but it is known to victimise other plants than Clover. Loefling found it in Spain growing on the roots of Elms.]

### TRANSPLANTING THE WELLINGTONIA GIGANTEA.

I READ with much interest Mr. Robson's article in the Number of June 26th, on transplanting this Conifer. It interested me more especially, because I had recently removed a good-sized specimen, and I am sorry to say that I fear I shall lose it.

I purchased it from a nurseryman about four miles distant from my own house. This was, I think, in March last, and being an expensive tree, and about 7 or 8 feet high, I gave directions to have it very carefully taken up. This was done, and when it arrived at my garden it was immediately planted on one side of the lawn, in the place prepared for its reception. It was carefully watered daily by my gardener, and for a month appeared to suffer little or nothing from the change, but soon afterwards it showed symptoms of turning brown, and to-day it looks like rusty old iron. It is living, but I am afraid it will be a long time in recovering, even if it ultimately do so.

If Mr. Robson would give me any suggestions as to the proper mode of treating it now, he would confer a great favour upon me. Mine is a very good specimen, and I should not like to lose it without some effort to save it. Probably, if I have eventually to replace it, the same result will follow.—T. M. SHUTTLEWORTH, *Lancashire*.

[This case so closely resembles others which have occurred here, that the result may be attributed to the same cause. Most likely the tree had stood two years or more in the place it came from. This I believe to be the cause of most of the failures in transplanting the Wellingtonia, for the season, in this part of England at least, has been favourable for transplanted shrubs and trees, there having been no long periods of drought. Perhaps if the tree had been screened in some way from the sun and drying winds, and its top frequently syringed, the juices might have been retained in the stem and branches; but I do not think watering at the root called for at any time when there is moisture there. Most likely if the tree be examined a few green twigs will be found near the bottom, but with their tips mostly dead; and such, too, will be the case with the whole of the top for a great part of its length. If this be so, the tree will be disfigured for some years, but it may recover in time, not by the present leader being restored to life, but by one of the lower branches being converted into a leader. If appearance for the time is of no moment, I would recommend that one of these branches be tied up to the existing leader, not cutting the latter out, but simply tying up one of the most likely branches to it—not rigidly tight at first, but, assuming the branch to be horizontal or, perhaps, slightly pendant, I would raise it a little way at first, and a week or so afterwards raise it somewhat further, until by degrees it had attained the proper upright position. The Wellingtonia appears to furnish itself with a fresh leader with as great ease as a deciduous tree, and it would, doubtless, do this without coaxing, but if a little management can accomplish the object sooner, it is worth trying. I am by no means an advocate for much knife work, and if the appearance of the dead part of the tree be not thought too unsightly, I would let most of it remain for a time; at all events do not cut it back to the live wood, otherwise this will die away in a great measure.

With regard to replacing the tree by another, that must remain a question with yourself. If its unsightliness cannot be endured, then remove it and plant another in September, taking especial care that it shall be one that was transplanted the autumn before. Most probably such plants will not appear so fine as that which is now the subject of complaint, but there is more likelihood of their affording a successful result. I may observe, that in September, when the tree is transplanted, if the weather be dry it will be advisable to afford shade for a time, and to water over the top as well as at the root, and then I have no doubt that the result will be satisfactory. If it be any consolation to Mr. Shuttleworth to know that others have suffered from transplanting the Wellingtonia, I may repeat what was stated in the former article, that several fine trees of it planted here last January have failed in a similar manner. Some of these will be treated as described above, while half

a dozen have been replaced by trees of less size removed in June, and these, though not in pots, have not appeared to suffer in the least. However, being small they afford no parallel to large specimens, although they confirm in a certain degree the view taken in my former article, that March is, perhaps, the worst time for transplanting the *Wellingtonia*. —J. R.]

### RED SPIDER.

RED SPIDER is, perhaps, the most destructive of all the insects which the horticulturist has to combat. Being small, and confining its first attacks to the under side of the leaves, it is not easy of recognition in its early stages of development; but in a very short time foliage attacked by it assumes a sickly, yellowish appearance on the upper surface, and the parts immediately over the spots where the insect is at work become dotted with a number of minute whitish specks if the leaves are those of the Peach or Fig tree, but if they are those of the Vine the specks are of a yellowish hue. These specks or dots increase in size until the whole leaf acquires a yellow and mature appearance, and its powers of exhalation and inhalation being destroyed it falls off. The small specks or dots on the upper surface of the leaves are the best evidence of the presence of red spider, and if the under side of such leaves be examined there will be observed between the principal nerves a number of minute specks or dots. These, on being touched with the point of a pin, will be seen to move about at a rapid rate, and if observed with the aid of a lens they will be found to be in constant motion, busy on that part of the leaf which they have for greater security enveloped in a network of the finest threads conceivable. If measures be not taken to check the spread of the insect on its first appearance it will rapidly wrap the leaf in a fine network, and will not cease its work of destruction until the juices of the leaf have been so completely exhausted that it becomes totally incapable of performing any of its functions, and falls off.

It is well to remember that the leaf of a Vine or other plant may have every appearance of being attacked by red spider, and yet that the insect may not be present; for the upper surface of a partly scorched leaf has much the same aspect as one suffering from red spider, but instead of specks or dots, scorched leaves usually exhibit blotches; besides, in addition to the dots on the upper surface, there are others corresponding to them on the under surface, and when there are both, and those on the under side move when touched, it is certain that the leaves are not scorched, but infested with red spider.

Though the insect is termed the red spider, scarcely one upon a leaf will be found of that colour, most of them being of a grey, inclining to a reddish brown, and having whitish heads and legs. The colour and size of the insects vary in the case of different plants, for on some they are much brighter in colour and larger than on others.

The red spider attacks a great variety of plants, but chiefly those which have large glossy leaves and require a large supply of water; and yet it does not exclusively confine itself to the smooth-leaved plants, but is as partial to the Egg-plant as to the Violet or Strawberry. It appears to be constant in nothing but in showing the same tokens of its presence, and in this respect it varies but slightly, if at all. Not being an entomologist, I must leave a full description of the insect to those more qualified for the task; and here I may observe that a text-book on insects injurious to garden crops, published at a moderate price, would be a boon to many, who, like myself, are willing to learn and yet cannot obtain a work on the subject, except at a cost totally disproportionate to their means.

Of red spider I am only acquainted with two kinds, or species. 1st, The small and very active one that attacks Vines, Melons, and most cultivated plants grown under glass or in warm situations out-doors. 2nd, A comparatively large one, which I have only found on the Gooseberry and Ivy. I have known the latter attack Gooseberry bushes with such severity as to make them look as if they had been scorched. This is very commonly the case on light gravelly soils.

Red spider destroys the vitality of the leaves, checks growth, and when its attacks are severe altogether arrests it. It prevents the flowers expanding or attaining their perfection, as well as the swelling and maturation of the fruit, and impairs the well-doing of the plant. It likewise, by stopping growth, limits the action of the roots, converting a vigorous plant into one which is sickly.

Predisposing causes innumerable have been assigned for its

attacks, but the principal appear to be a dry atmosphere and a high temperature, with too little air at night. Some entertain the opinion that no plant would be attacked by insects if it were healthy; but I have not yet seen a plant, however healthy to all appearance, that did not become infested with some insect. The green aphid is equally partial to a strong shoot of the Rose as to a weak, drawn shoot of the *Pelargonium*, and it is the same with most insects; come they do, and whatever they attack is checked in growth, and more or less reduced in health, vigour, and fertility. In whatever state a plant may be attacked, whether weak or strong, the effects are the same; it becomes impaired in health and vigour, and when freed from insects it regains both. Surely this does not show that constitutional ill health and impaired vigour are essentials to insect attacks. I believe that they are not induced so much by any peculiar condition of the plant as by the atmosphere being favourable to the development and increase of the insects. Make a plant as unhealthy as we may, it will not be attacked by the insect peculiar to it until we also produce an atmosphere favourable to that insect.

That the red spider delights in and is encouraged by a dry atmosphere none having experience of it will doubt, and it is most abundant where the heat in houses is artificially derived from flues or hot-water pipes. I can also affirm, from many years' daily observations, that where there is a plentiful supply of atmospheric moisture, a temperature from fire or natural heat no more than the plant requires, and thorough ventilation, that the attacks of red spider are not grievous. Any one having experience in forcing Vines, Melons, &c., knows how much more liable to the attacks of red spider are the crops obtained by employing great artificial heat than those to which less artificial heat and more air are given; nor can those who wash or syringe their Peach trees have failed to find how free of red spider such trees are, whilst others not syringed are literally eaten up if dry weather prevail. A dry atmosphere, too high a temperature, especially at night, and insufficient ventilation, are the conditions under which red spider presents itself; but there are cases in which it will appear when none of the conditions favourable to its existence are present. Still, the fact of the insect existing may be taken as evidence that the air is too dry, too hot, or imperfectly ventilated.

The great agent in the destruction of red spider is water, which may not inaptly be termed its natural enemy. Water forcibly driven against foliage infested with red spider will free it of the pest, and that is the best means to adopt in the case of plants which will not be injured by its application; syringing with soft water is the best remedy as well as preventive which I have tried. Whenever a plant shows unmistakable signs of the presence of red spider, it is well to syringe it forcibly, directing the water against the under side of the leaves, and this is best done in the evening at the time of shutting up the house, or, if the house is not closed, or the plants are exposed, after the sun has declined in power. Bear in mind that syringing once or twice is not of any great avail, but it must be persisted in until the trees are cleared. The only cases in which the use of water for the destruction of red spider cannot be recommended, are when the trees or plants are in flower, for then a dry atmosphere may be desirable for the setting of the fruit, and when a tree is ripening its fruit or wood then a free use of the syringe may not be advisable. When syringing can be adopted it will be found the very best means for the prevention and destruction of insect enemies. It is conducive to health and vigour, frees the leaves of dust, and lessens the evils of an artificial or dry atmosphere. It is objected to syringing that it is not natural, and cannot be otherwise than injurious, it being sufficient if the atmosphere be kept moist by sprinkling the floors, walls, &c., and by the evaporation of water from troughs upon the hot-water pipes. Such may be the case, but I have failed to experience it, having seen the foliage of the Vine brown and ready to fall off by the time the fruit was ripe, and Peaches shedding their leaves before the wood was mature.

When the syringe cannot be used, then we must look elsewhere for the means of destroying the red spider; and here I would discriminate between plants which can, and others which cannot, bear an application destructive to the insect. I may instance the Vine and Melon as plants to which a solution of soft soap at the rate of 2 ozs. to the gallon cannot be safely applied, and yet soft-soap water of this strength is effectual, and not injurious to the foliage of most trees and plants, when applied with a syringe so as to thoroughly wet every leaf on both sides. Three applications on alternate evenings will be

sufficient to destroy a whole generation of red spider. The Vine, Melon, and Cucumber are the only plants which I have found injured by it, for it stains the fruit of the first, and disfigures the foliage of the other two.

Should it not be desirable to syringe, or if plants are attacked to which the soap solution would be injurious, a good remedy is to make the floors, walls, &c., wet by syringing them without wetting the foliage of the plants or trees—this should be done on shutting up the house—half filling pots that will hold 1½ peck with fresh unslacked lime, and then filling up with water, and scattering on this 1 oz. of sulphur vivum. Two pots will be sufficient for a house 30 feet long, 18 feet wide, and of an average height, but if high three will be necessary. The heat of the lime will cause rapid evaporation, and the fumes of the sulphur are carried along with the water, and, unless sulphur be volatilised, it is worse than useless as a destroyer of red spider. The plants should be syringed in the morning, but in the case of Grapes colouring, fruit ripening, or plants being in flower, doing so would prove disastrous. An application of this kind should be made once a-week, or twice if the attack is severe. This remedy, it should be remembered, must not be used until the leaves have attained their full size and become somewhat firm, otherwise they will be disfigured. It is more effectual when a good syringing follows, as the insects, if not stifled, are so sick as to be easily washed off.

Another method, in which it is not absolutely necessary to syringe the plants, consists in making the hot-water pipes so hot that the hand when placed on them cannot bear the heat more than a minute, and, after closing the house, to coat them with sulphur brought to the consistency of paint with water in which soft soap has been dissolved at the rate of 4 ozs. to the gallon. The paint thus formed should be applied from end to end of the pipes or flues, and be lightly syringed until the house is full of steam, and unless the fumes of the sulphur are strong enough to drive the operator out of the house they will not destroy red spider. This remedy, like the preceding, must not be employed unless the foliage is somewhat mature, as in the case of the fruit approaching maturity or becoming ripe. Two applications will in most cases prove effectual.

The last remedy which I have to note is sprinkling the floors, walls, &c., morning and evening, with 4 ozs. of Peruvian guano dissolved in a gallon of water, and especially at the time of shutting up the house. The atmosphere is thus largely impregnated with ammonia, and in such red spider cannot live.

Prevention is in all cases better than cure, and to this end a dressing applied in winter to trees that are liable to be attacked will be found effectual, coating not only the stems and branches but the walls. This dressing may be made of soft soap at the rate of 4 ozs. to every gallon of water, with enough of this to equal parts of flowers of sulphur and fresh lime to bring them to the consistency of paint for the trees, and of whitewash for the walls. The application should be repeated on the walls and heated surface when the leaves attain their full size, and again when the fruit commences to ripen. Its action depends on the fumes of the sulphur being generated by artificial or sun heat, and the soft soap causes the mixture to adhere; the lime, too, is a powerful remedy against spider, and its more formidable rival mildew. By thus dressing the stems and branches the eggs are destroyed.

Lastly, daily sprinkling the floors and every available surface, from the time that growth commences, with soot water, made by placing in a cask a peck of dry soot, and pouring over it thirty gallons of water, will produce an atmosphere in which red spider will rarely appear. Soot water, with the addition of a peck of sheep's dung to thirty gallons of water, is excellent for filling evaporation-troughs, and so, too, is guano, at the rate of 4 ozs. to the gallon of water. For syringing, the soot water should be clear, and it will not injure the most delicate foliage; but guano water for syringing, should not only be clear but strained, and not stronger than 1 oz. to the gallon. Dressing with soot borders in which are trees or plants liable to be attacked, is a very good preventive; also watering overhead with guano water in the evening; but the best of all preventives and remedies is to keep the plants moist, to give plenty of air, and to maintain as cool an atmosphere as is consistent with their healthy development.—G. ABBEY.

POTATO ONION.—I have just dug up my crop of this variety. The sets were small bulbs. These have now become large bulbs, but, singular to say, there is but one Onion in the whole crop which has divided itself, and that has separated only into

two. The crop, therefore, differs from the common Onion only in dying down earlier, and in not showing any flowers. The soil was light and rich, the situation sheltered. I should be glad to learn if any of your readers have ever found their Potato Onions refuse to increase by the root.—G. S.

### ROYAL HORTICULTURAL SOCIETY.

At the Saturday Show of the 14th instant prizes were offered for the best collection of six Carnations, and also for six Picotees. In the former Mr. Britton, of Corston, near Bath, was first; Mr. E. F. Kingston, Militia Barracks, Bath, second; and Mr. Henry Grant, Midford, near Bath, third. For Picotees, Mr. Britton was again first; Mr. Grant, second; and Mr. Kingston, third. For the miscellaneous collection of fruit, Mr. Richard Marcham, gardener to E. Oates, Esq., of Hanwell, was first, and Mr. Young, gardener to R. Barclay, Esq., Highgate, second. There was a considerable variety of miscellaneous subjects exhibited. Mr. Hooper, of Vine Nursery, Widcombe Hill, Bath, obtained extra prizes for a beautiful collection of twenty-four Carnations, twenty-four Picotees, twenty-four Cloves, twenty-four Pinks, and twenty-four yellow Picotees. Mrs. Hooke, of Morville Lodge, Fulham, obtained a second-class certificate for cut blooms of Verbenas, and Mr. R. Marcham a first-class certificate for twenty-four cut Roses. Mrs. Hooke also received a first-class certificate for a fine plant of Liliun anatum, and Mr. Young was awarded an extra prize for a collection of miscellaneous plants.

### GNAPHALIUM LANATUM.

I FOUND this last season to be one of the most useful white-foliaged plants we possess, more especially for groundwork, where a distinct colour is required; and it is furthermore most manageable in all respects. The way I employed it was as follows:—With some circular beds at this place I formed a star pattern; this I filled with Frogmore Scarlet; for the rest of the circle I used the Gnaphalium; at the same time I had a band all round. The arrangement, simple though it is, had a charming effect. Much of this effect depends upon pinching and pegging down, until a dense carpet is formed; if allowed to ramble naturally it presents an untidy appearance in such a position and for such a purpose as I planted it. It may not be quite hardy in some localities, but with slight protection I am inclined to believe it will withstand the cold of our ordinary winters. Up to this date, January 14th, it remains out-doors here, and is not much injured; but to be safe, a few store pots may be struck in autumn, and wintered under glass, which, with a shift in spring, and placed in moderate heat, will produce cuttings enough in a short time, as it strikes freely.—J. E. (in *Scottish Gardener*).

### FIFTY CUT ROSES.

I AM sorry to trouble you again with regard to the first-prize collection of fifty cut Roses at the late Jersey Show. From your answer I suspected that the point sent for your decision had been misunderstood; and my suspicion is now quite confirmed by the letter of the Rev. W. F. Radclyffe in your Number of the 10th inst., which I have only just received. This misapprehension seems to have arisen from my anxiety to be concise and yet give the exact words of the objection. The objector said, "There were fifty-one Roses." He should have said, "There were fifty-one blooms." The collection in question consisted of only fifty trusses, one of which had two fully open blooms (he did not object to buds), and he meant to say that one of these blooms should have been cut off, or, in other words, that the prize was offered for single flowers, and not for single trusses. Now, as the prize schedule did not specify single flowers, the Judges decided that the class was open to single trusses also, and therefore refused to disqualify the stand in question.

This, then, is the question for your decision: If a prize were offered for "fifty cut Roses, distinct kinds," would you disqualify a stand of fifty trusses? One is almost tempted to be severe, and ask why the splendid truss of Cloth of Gold (noticed in the same Number, page 4), did not obtain a disqualification for Mr. Hedge instead of contributing towards his victory. Of course the schedule in our case was in fault; but the Judges were called upon to award the prizes as the schedule stood, and not to amend it.

I need hardly say that I am much obliged to Mr. Radelyffe for noticing my communication, though he is rather hard upon the Jersey rosarians; and I cannot neglect the opportunity of thanking him for the very great pleasure and profit I have derived from his excellent articles on the queen of flowers. "Our Journal" is certainly never more welcome at our fireside than when "Rushton Radelyffe" is to the fore in a raid among the Roses.—ONE OF THE JUDGES.

[There was no misapprehension on our part, nor do we think there was on the part of Mr. Radelyffe. As you put the case now, we could not suppose that any one for an instant would have a doubt. "Fifty trusses" ought not to be allowed even to be exhibited for a prize offered for "fifty cut Roses." What was intended by those who worded the schedule is immaterial. "Cut Roses" mean single opened flowers, flower-buds with them are unobjectionable. The fifty-first Rose, in the case, as it occurred, disqualified the collection.—EDS.]

### DRIP AND DOUBLE-GLAZING.

In answer to "D. Y. S." and other inquirers:—

1st, There is no difficulty in explaining how a span-roofed house, 27 feet wide and 23 feet high, with the one end to the prevailing wind, is, independently of heating, warmer than a low house chiefly a lean-to, 12 feet wide and 12 feet high, as the prevailing south wind would strike along the whole front instead of partially on the sides, as in the other case. Again, the great body of the air enclosed in the larger house renders all sudden changes in the external atmosphere less perceptible. This is a matter that has never received a sufficient amount of attention. Without any heating, such buildings as the large conservatory at Kew, at Chatsworth, and even the huge Crystal Palace, are less quickly heated and less quickly cooled than smaller houses. Much has been done in maintaining a high temperature in forcing-pits; but even that was effected by keeping in the heated air by covering the glass with some non-conducting material at night, whenever the expense of fuel was an object. Without that covering there was always danger in cold nights whenever the fire went out, and that danger would have been much diminished if the quantity of air enclosed had been three or four times as great. The more air that is enclosed under a similar plane of glass surface the more regular and easily managed, as respects temperature, will be the enclosed atmosphere. We can imagine that in a continued frost a house 23 feet in height would come to be as cold as one merely 12 feet in height, but it would be a considerable time in falling so low in temperature; and just because it is longer in cooling, so the larger building will be longer in heating. A large house, therefore, holds out greater inducements to carelessness in air-giving and furnace-regulating than a small one—a matter that should not be lost sight of by those amateurs who must have their house for plants, and yet must be away for the greater part of the day. A house containing only a few feet of atmospheric air might have everything burned up in it, whilst a house containing a double quantity of enclosed air would suffer but little. In a house somewhat lofty, and a little air given at the back early, a man may go to his business in the changeable spring months with the certainty of finding all right when he returns in the afternoon.

2nd, Protecting low houses and pits, whilst securing an equable temperature, also prevents the plants suffering from drip. Drip is the result of the condensation of the moisture, existing in the atmosphere of the house in a state of vapour, coming in contact with the cold exposed glass as a condenser. The more moisture in the enclosed atmosphere, and the greater the difference between the inside and the outside temperature, the more will this condensation of moisture take place. Every lap in the glass encourages this condensed moisture to fall all over the house. In single-glazing, the plane surface of Beard's plan prevents the drip falling; the moisture trickles down the plane of glass and gets outside the house. Other contrivances have been adopted for taking the condensed moisture down the grooved sash-bars, and then returning it to the house over the heating apparatus, so as to keep the atmosphere duly moist. Perhaps the most successful mode for keeping the moisture in the atmosphere of the house and preventing alike condensation and the consequent drip, is double-glazing the roof. In all such cases the outer glazing should be moveable if the inner glass should be fixed. From 4 to 6 inches between the inner and outer planes of glass would be a suitable distance. We are not so sure of the plan answering thoroughly in some

kinds of fruit-houses, but for plant-houses it answers admirably. We hope some friends will tell where our correspondent will see the plan in operation. On a large scale he will see it successfully practised by Mr. Bewley, near Dublin, whose place has been described twice at least in these pages. The more close—that is, free from openings, the two planes of glass are, the more thoroughly will they prevent condensation and drip. The double glass acts more perfectly in this respect than a mat or a sheet thrown over a pit or frame, because a closely enclosed body of air, whilst it does little to keep out light, is one of the best non-conductors of heat. As alluded to above in the case of forcing-houses, the chief value of double-glazing is the regularity of the temperature thus easily secured. If the enclosed body of still air prevents the lower or inside plane of glass becoming cold, there can be no condensation, and no consequent drip.

3rd, Much may be done in common houses with a high temperature and a moist atmosphere, in preventing drip even in cold nights, by leaving just a little air on, especially at the highest point in the roof; the moistest air would thus escape, and a little more firing and evaporating-pans would be wanted.—R. F.

### PAMPAS GRASS—PROPAGATING GLOXINIAS BY THE LEAVES.

THE gardener did not cut the Pampas Grass down early in spring, and about 18 inches of the flag seems dead. If the dead part of the flag were cut off, would the bottom green part grow? It is a large bush, but has never yet flowered. The gardener last winter tied it straight up a pole. Would that injure it? Can Gloxinias be propagated by their leaves?—A SUBSCRIBER.

[After what the winter of 1860 and 1861 did with Pampas Grass, we would cut none of it down in winter or spring. Every decayed part might be removed in spring, but the old leaves furnish a good protection. The tying-up of the leaves would increase the protection. Give your plant plenty of water and rich top-dressings now, and we hope you will have plenty of flower-stems in the autumn.

The Gloxinia propagates freely from the leaves. The easiest way is to cut off a leaf with a good piece of the leafstalk, and plant the latter in pots just as you would cuttings. The leaf if thus kept in a shady moist place will soon form a tuber at the base of the stalk. Another plan is to take the leaf, notch it at the back where all the smaller nervures meet the midrib, fix the leaf by small pins flat on a damp surface, and small tubers will form at all the notched parts. Another simple plan is, to take a leaf, split it up at the midrib, and then cut outwards to the outside in strips—say one-quarter of an inch wide, plant these thickly in a pot, the part with the midrib being lowest, and almost every one of these slips of leaves will form a tuber at the base. It is thus easy to multiply any kind of Gloxinia, or of fine-leaved Begonia, which may be propagated in the same way. By these modes you do not obtain so large a tuber as when you use a leaf for a single tuber instead of a score or more. A moist, warm, shady place is necessary for success when the leaves are thus cut up into shreds.]

### DOUBLE-GLAZING.

THE very important subject of double-glazing is claiming a good deal of attention just now, and deservedly so. It is not our purpose to say one word about the desirability of a second covering; every gardener knows its value. To be able to maintain the proper amount of heat and moisture, with moderate firing, is the point, as well as shielding us from the evils of sudden depressions, which sometimes overtake us unawares. Double-glazing is nothing new; it has for many years been practised in all northern continental countries for window and other purposes. We are not about to advocate the application of this principle to all garden structures—only to such as are employed for early forcing. Cucumber and propagating-houses, Pine and plant-stoves, &c.—in short wherever strong heat is required. To these structures we think we can easily prove that double-glazing would be by far the best and cheapest mode. If we for a moment notice the many abortive attempts that have been made, and are still being made, by anxious men to cover the roofs of forcing-houses, whether by canvas, frigi domo, or even "horsecloth material," and knowing, as we do, that

almost all these attempts end in failure, if not in mischief, we shall soon turn our thoughts to something else. Coverings may be useful on still frosty nights, but these are not the nights when they are most needed. Only have one of those strong gales which have been rather frequent this year, and where is your covering? most likely all in shreds, with perhaps not a little glass broken to boot!

Have any of your readers ever practised another plan, which may be called "covering-in"? This is to be applied inside the glass; have your frigi domo made the proper size of the roof to be covered, and fitted with curtain rings, top and bottom, to slip along on wires fitted up on purpose—one along by the front plate, another at the top of the house; or, if a span, just below the ridge. By means of lines and pulleys, this cloth could be drawn forwards or backwards to one or both ends of a house with a clear roof very easily, and being near the glass would no doubt prevent a large amount of heat escaping, or prevent the cooling action of the glass on the temperature of the house. In vineries the iron work for supporting the Vines would be in the way; but if the practice were good, a piece could be made for each sash; there is plenty of room between the Vines and glass, as Vines are generally trained up 16 or 18 inches below the glass. But supposing this plan to answer, it would be an expensive plan as all coverings are. Let us just look at the commercial point, for we must be prepared to prove that our project "will pay," or at all events to prove that one project is better and cheaper than another. Well, take frigi domo, which is perhaps the best and cheapest fabric we can employ for covering, either outside or in; the first cost of this is at least 10d. per yard, or something more than a penny a-foot, without binding, fitting, or anything else, which will bring it up to at least a shilling a-yard. How long will it last? allowing for the sake of argument that it answers its purpose; will one season wear it out? if not, we will give two; so here is a cost of 6d. per yard per year with a very doubtful advantage.

Look now at glass—good sheet at 16s. per 100 feet—not quite 2d. per foot, or less than 1s. 6d. per yard. The work of glazing and painting would doubtless double this amount, or perhaps even a little more; but if it did, we have something permanent, and something which will answer its purpose. Coverings, as we have just seen, abortive as they are, will in ten years cost at least 5s. per yard. Take now your glazing and painting at a good price, say 5d. per foot, or 3s. 9d. per yard—and this is unfair, because the woodwork must be painted even if you have no second glass; but take it at 3s. 9d.—and at the end of ten years it will be very little worse than when new; a small percentage will cover the breakage in the ordinary course of events; and this comparison will prove the great expense of all endeavours at covering hothouses. We will now come to what we think the best way of applying the principle of double-glazing to garden structures, first premising that we do not mean to say that it would be easily or cheaply applied to an old or sash-made roof. That is a mode of construction which we do not advocate; we are quite aware that many of our best gardeners approve of it, and consider that it has great advantages, but for our own part we confess we cannot see these advantages; we see a heavier, more cumbersome, and more expensive roof, but certainly not advantages sufficient to compensate for these drawbacks. But take a rafter-roof, either lean-to or span, the ribs running from the front plate to the top, the glass placed on these rafters without any framework whatever, and we have a very simple affair. If your house is narrow, and the rafters not more than 12 or 14 feet long, rafters of 4 inches by 2 would be sufficient for double glass; but if the rafters run from 17 to 20 feet, we would say 5 inches by 2½, or 5½ inches by 3. Should the roof be rather flat, it is a good plan to have every fourth rafter at least 3 inches thick, for strength, as well as for another reason which will appear as we proceed.

The ribs or rafters need not be closer than 18 or 21 inches, made to take 20-inch squares is a very good size. We will now take our rafter of 5½ inches by 2½, and show how it is to be prepared for glazing. We would first, however, observe that in sawing out, these rafters ought to be cut in pairs—that is, in pieces of course the proper depth, but 3½ inches wide; then every piece would make two rafters, just in the same way as cutting out weather-board. Our two rafters would be 2½ inches by half an inch each; the quarter is allowed for working. On the top of each rafter, after it is fixed on the roof, nail a strip three-quarters of an inch thick and 1½ inch wide, thus leaving half an inch on each side as a rabbet for the glass. Then at 3 inches from the top edge of this rabbet nail on another strip, 1½ inch wide, half an inch at one side, and tapered off

to nothing at the other. This is the rabbet for the inner jacket of glass. Every carpenter knows that strips nailed on as here recommended must be laid on in good white lead; that properly done, there is no fear of wet getting in. The rafters are cut tapering for two reasons—first, to allow the same sized glass to be used for both coats, outer and inner; also as the portion below the glass is tapered off, the roof will look neat and light.

Grooves might be ploughed out in the sides of the rafters, and the glass slipped in edge to edge; but it is very questionable whether sheet-glass can thus be fitted sufficiently close; and, should an accident occur, how is a square to be replaced? With a rabbet, a portion of it could easily be taken out at one side—the glass put in, the piece replaced, and the thing is done.

These fixed roofs are sometimes ventilated by openings in the back wall of lean-to's, and at the ends, or along the centre of the ridge in spans; but a very simple plan is to have narrow lights along the top, 2½ feet wide, and 7 feet long. These may work on pivots, or up and down on castors the same as other lights. If they are made to run down, let the castors come on the thickest, or three-inch rafters, where they can be allowed a little more bite. However, there can be no difficulty about the ventilation. We find the narrow lights work very well on the top of the rafters.

Such are a few crude remarks on this important subject. We believe this subject has an interesting future, and it is well to see that the plan can be carried out at moderate expense. Nothing has been said about the advantages to be gained as compensation for increased expense; these will occur to every one;—improved health of whatever is grown, saving of coals, less labour, and less anxiety in the minds of those who have the responsibility. I fully expect we shall soon see plenty of double roofs.—A. DAWSON, *Road Ashton (in Scottish Gardener)*.

#### HERBACEOUS CALCEOLARIAS.

I WAS much pleased to read in the last Number of the Journal, page 21, so able and excellent a paper by Mr. Kerr, from the "Scottish Gardener," on the cultivation of herbaceous Calceolarias. The first and most essential requisite to form a fine collection, Mr. Kerr remarks, is to secure seed from a first-rate strain. Now, as I had the great pleasure of seeing this spring some of the best herbaceous Calceolarias ever exhibited, grown by Mr. Robert Neill, of Rivington, near Chorley, Lancashire, I can most confidently recommend amateurs and others at once to secure packets, now advertised, of this famous seed. I can guarantee that no one will be disappointed, and am certain that the flowers produced from this excellent strain will give the greatest satisfaction. Out of specimens of some twenty or more varieties that I examined there was not an inferior flower among them; form, colour, and texture were all first rate. That Mr. Neill is anxious to establish his reputation for his very excellent strain of this beautiful flower there can be no doubt; he has taken considerable pains to do so, which fact will, I feel certain, ensure a supply of his genuine seed.—J. D.

#### NOTES ON THE WAY TO THE HOLY SEPULCHRE.—No. 3.

So wondrously is the history of the Holy Land interwoven with that of the land of Egypt, that in writing of the one it seems impossible to avoid the mention of the other. The "going down into Egypt" is a natural prelude to the "coming out" into Palestine. "A people come out of Egypt" was at one time the distinctive appellation of the children of Israel; while of the Redeemer Himself it is written, "Out of Egypt have I called my Son." Strangely typical is this sojourning amidst the "flesh pots" of Egypt, before the journey in the wilderness, with its hardly-repressed longings after past pleasures, leads us to the Promised Land at last.

I have nothing about wild flowers to tell in this chapter, for but few plants spring up from the desert sand, and horticulture has at no time been in any great request—perhaps from the scarcity of rain, for we read that showers are very rare, excepting on the seacoast sometimes not happening twice in the year; or it may be, that where the cultivation of land is both difficult and expensive it is expected to be remunerative; and so we read of Olives and Rice and corn, of fruit and

vegetables, rather than of flowers. And yet I think that a few notes gathered from the unchangeable features of this ancient country may be of interest, ever bearing in mind how intimately it is mixed up with all the Sacred Writings, and that there still remains this great promise for the land "whom the Lord of Hosts shall bless, saying, Blessed be Egypt my people." More than three thousand years ago and Egypt had its history, its civilisation, its arts and sciences, its priesthood, and its kings. Its physical features and natural products are now much what they were in those far-off times. The royal Nile, tracing its majestic way, still sweeps through the length of the land, and spreads fertility and blessings on every side, although these gifts are sometimes sadly changed into devastation and misery, when the capricious waters rise above their ordinary elevation, carrying away both man and beast in their relentless course.

The flax and fine linen of Egypt, so often mentioned in Holy Writ, are represented now in the Cotton fields, towards the cultivation of which the alluvial deposits of the Nile, together with its cleverly constructed canals and embankments, are made subservient. When the Cotton is gathered crops of Beans, Clover, and Barley take its place, artificial irrigation making up for want of rain. "The peasantry," says Mr. Wanklyn in a letter to the Secretary of the Cotton Supply Association, "are most intelligent cultivators, and invariably pursue the most productive systems. They have nothing to learn in that way; indeed, our English farmers might learn a good deal from them in the careful cultivation of every available yard of land. The cleanness of the growing crops—not a weed to be seen, and the manner in which they protect some of their crops, by putting upright reeds along each row of seeds to shelter the young plants from the winds, are worthy of notice." This growing of Cotton has had a prejudicial effect on that other production of the soil for which Egypt was even more noted than for its flax. In days of old "there was corn in Egypt;" but in 1865 Mr. Wanklyn writes, "Much of the land shows unmistakable signs of exhaustion from being over-cropped in Cotton. Other crops have been neglected; and the people are paying dearly for food which has been imported for them, whereas they formerly exported large quantities of cereals."

The race of Pharaohs and of taskmasters does not seem to be extinct. From the remote days of the shepherd kings down to this present hour, the government of Egypt has been its curse. Burdens grievous to be borne have been laid on the children of the soil as well as on strangers, and "all manner of service in the field, wherein they made them serve, has been with rigour." So heavy still are the taxes in money and in produce, that we read that the poor farmer, or "fellah," is often compelled to steal from his own crops sufficient for the need of his half-starving family, which he carefully hides away from the tax-gatherer's eye. Mr. Wanklyn speaks of £1 being paid to the present Government for every acre of cultivated land, and of the rent of land being £5 an acre.

Next in importance to the people, in whose eyes the occupation of a shepherd was an abomination, after the corn comes the fish. When in the wilderness the children of Israel "remembered the fish which they did eat in Egypt freely;" and in the prophetic curse uttered by Isaiah against Egypt, a part of it is that "The fishers also shall mourn," and "they shall be broken in the purposes thereof, all that make sluices and ponds for fish."

In the journal which was sent to me with the plants, the habitats of which I have to describe, I find this passage, referring to a visit which the writer paid to examine some excavations recently made by a gentleman while preparing to build a new house near Alexandria. "We found it well worth a visit; water-tanks and room-walls had been exhumed in very perfect condition, but the gem of the place was the fish-tank, about 12 feet square, and having in its sides, all round, jars built into the cement for the fish to hide in." The exhumed villa was of Roman architecture, and the prophecy of Isaiah was uttered many hundred years before Egypt became a Roman province. Yet centuries since the fish pond was filled up with sand and earth, and now the ancient jars and the tank itself have been destroyed, the purposes thereof having long ago been rendered useless.

Even more unchangeable in their aspect than the great river are the deserts of Egypt; but with the desert the modern traveller has but little to do: he looks at it from the windows of a railway carriage, or, perhaps, he slowly walks by the side of the train, trying in vain to realise something of the horrors of the wilder-

ness. How often, when reading of the exodus of the children of Israel, have I tried to picture to myself that "evil place," which "is no place of seed, or of Figs, or of Vines, or of Pomegranates," and where there was "no water to drink," and "no bread," in which they were condemned to wander for so many weary years.

Accustomed to the fresh rich verdure of England, or to the more glowing beauty of the Continent, how can one who has never travelled in the East gain with any degree of truthfulness an idea of the desert with its trackless wastes of glaring sand?—of that "immense ocean of loose reddish sand, unlimited to the eye, heaped up in enormous ridges running parallel to each other from north to south, undulation after undulation, each swelling 200 or 300 feet in average height, with slant sides and rounded crests furrowed in every direction by the capricious gales of the desert," where "in the depths between, the traveller finds himself, as it were, imprisoned in a suffocating sand-pit, hemmed in by burning walls on every side; while at other times while labouring up the slope, he overlooks what seems a vast sea of fire, swelling under a heavy monsoon wind, and ruffled by a cross blast into little red hot waves," where there is no "shelter nor rest for eye or limb amid torrents of light and heat poured from above on an answering glare reflected below." We cannot realise this, and yet as we read, a faint reflection comes over us of that longing with which the escaped Israelites turned back in thought to the juicy fruits and vegetables, to the cool clay water-pots of the land of their bondage. I know that the deserts of Lower Egypt, and the "desert of the wandering," differ considerably from those of central Arabia. The limits are more circumscribed, and their features of barren desolation are not marked in such vivid characters, they are more intersected with vegetation, more fertilised by springs; but it seems to me that in realising one we are helped to realise the other.

Not far from Cairo, and from the ancient ruins of Memphis, across the Nile, to the west, rising from a plain of sand, stand the Pyramids of Gyzeh, mentioned by Herodotus as having been built upwards of four hundred years before he visited Egypt, or about nine hundred years before Christ. He also states (on, I believe, the authority of the priests of Memphis), that 100,000 men were twenty years building what is called the Great Pyramid, which, covering a space of thirteen acres, rises, or would rise if about 20 feet of its apex had not been destroyed, to a height of about 480 feet.

All the Pyramids have square bases, and their sides face the cardinal points, rising in steps which gradually diminish in size till they taper to a point, or rather would do so, if that point were not broken off, and a flat form left in its stead.

These stupendous monuments, so silent, grand, and solitary, add to the shores of the Nile another unchangeable feature. They extend at irregular distances for more than sixty miles on the west side of the Nile, without change, as we count change, yet slowly and surely these silent witnesses to the mutability of all earthly architecture, are passing away, and at the present time I believe there is not one which is left in a state of perfect preservation. Immutability or exemption from change seems the one great "idea" of Egypt, exemplified in her laws, her customs, and her architecture. The lives of thousands were sacrificed again and again to show forth this idea—an idea, containing within it elements at once the most puerile and the most noble; puerile, indeed, when it sacrifices life and happiness to earthly fame; but noble beyond all words when allowed to develop itself into its true shape—the immortality of the soul.

Of the wild flowers of Egypt, I have only the few that I mentioned in the last paper, as found growing by the seashore. "There is little to interest the horticulturist in Egypt," writes Mr. Wanklyn. "The much-talked-of Shooobra Gardens (the gardens of Halcem Pasha), near Cairo, are vaunted solely because they are the only thing of the kind in the country; but 'they are not what we should call gardens at home' (as the intelligent English gardener remarked to me), being more plantations of trees, planted in a star-fish pattern, with cross paths, so that there is a shady walk for all hours. The flowers were but the common kinds of Roses, and flowering shrubs of ordinary character."

In the centre of the garden at Shooobra there is a fountain surrounded by an open building, with a marble floor, on which couches are placed, and the whole description reads to me green and fresh, and luxuriously cool, especially after the description

of the hot, dried-up Pyramids, and the hard-working Nile, which is always being made to act contrary to its inclinations; now banked out, now let loose, now irrigating Cotton fields and gardens according to fixed measure, and now worried by steam engines into all sorts of uncomfortable positions. After all the bustle and heat of agriculture and nature, methinks horticultural taste was best shown in the Pasha's garden, by the quiet repose of those shady walks, where the eye was not distracted by brilliancy of colouring, nor the mind by the extraordinary character of the shrubs.

Although wild flowers in Egypt may be few, there yet remain its fruits, and of these I find there are Mulberries, Apricots, Peaches, and Plums, Grapes, Figs, Prickly Pears, Pomegranates, Dates, Lemons, and Oranges, with, later in the year, Bananas. Egypt has its Olives and its Vines. Its fields produce Wheat, Barley, Beans, Vetches, Clover, Flax, Indian Corn, Cotton, Sugar Cane, Rice, Tobacco; while Water Melons, Cucumbers, and Lettuces, grow side by side with the Leeks, the Onions, and the Garlic, for which the thirsting Israelites longed in that great and terrible wilderness, where their very "souls felt dried away" within them.—*FILIX-FÆMINA*.

## A DAY IN THE DOMAIN, AUCKLAND, NEW ZEALAND.

BY MRS. C. M. ROSE.

A LOVELY morning in early summer, the sky blue and cloudless, and the pleasant sunlight just tinging each wave with gold as they ripple gently on the bosom of the broad placid bay.

Well provided with kits and baskets containing the needful provision for our party, and trying in vain to restrain the dancing footsteps of the children within the bounds of decorum, as we pass along the busier streets, we set forth upon our pleasant excursion. Presently we have gained the Grafton Road, and here the children break bounds altogether, and progress as pleases them best for the remainder of the distance. After duly admiring the delicious bit of sea view, which opens to the left across Mechanics' Bay, we enter the shrubberies of the Domain, and join a large number of pedestrians, all making the best of their way to the scene of enjoyment, and with the same object of pleasure in view. Up the winding paths, through a sea of green foliage on all sides, catching a glimpse occasionally of lovely flowering shrubs, some of which would be treasures in any English greenhouse. You hear the murmuring of the stream far below you on the right, and can hardly fail to admire the lovely specimens of Fern and other trees which overshadow it. Still onward glides the pleasant track, now through green glades chequered with summer sunshine, and again through cool dells overhung with tall trees, whose interlacing boughs make a welcome shade from the now fast increasing heat. Soon you hear the sound of voices and merry laughter, and in a few minutes you stand in the shadows of that grove of trees so well known to the inhabitants of Auckland as the gathering place for the summer sports of their juvenile population.

Surely this is the most suitable place in the world for a summer day's out-door amusement. Innocent and healthy recreation seems the rule in all directions, and taking possession of one of the many benches which seem fixed under the trees for the special use of the elders of the party, we give ourselves up to the complete enjoyment of the scene before us. A dozen or two of strong swings, which seem extensively patronised, are in active operation around us, and close to each a group of girls, each eagerly awaiting her turn at the much-loved exercise. Young faces decked with smiles everywhere meet the eye, each seeming to be thoroughly imbued with the true spirit of enjoyment.

In the open space outside sports of every description appear to be going on, and thither, after resting for awhile, our party bend their steps.

On the left, we perceive a group of young people dancing to the music of an accordion, whilst, scattered over the grass in every direction, various parties are busily pursuing games of football, French and English, and the immemorial "kiss in the ring." Good humour everywhere prevails, and the occasional tumbles and mishaps apparently only add to the general fund of amusement.

But our appetites warn us that the dinner-hour is near, and a table-cloth spread on the grass under the trees does duty for

a more ostentatious board, and is seen covered with eatables of various descriptions, which are doubly enjoyed in company with the fresh air and the happy scene around us. How the young people seem to relish the racing to and fro to the spring for the water, which is our only beverage! But, by-and-by, they are off to their sports again, and we proceed to put in practice a plan we have formed for taking a quiet stroll through the grounds, finishing with an inspection of the flower garden, not forgetting to notice the stately swans, whose aquatic home is just outside the entrance.

What an inestimable privilege the unrestricted enjoyment of these grounds must be to the inhabitants of Auckland, and it is a matter of surprise that they are not more eagerly frequented by those who love beautiful scenery and a profusion of flowers. There are few European capitals where such a place so close to the city would not be almost inconveniently crowded on most fine days in summer. Those who possess floral tastes will find them fully gratified here in the garden; memory is hued as your old English favourites meet your eye, visions of the green lanes and quaint old gardens of your childish home seem to rise before you, and a sigh is involuntarily given to that best time of innocence when Violets and Primroses were more highly prized than the richest jewels, and wild Strawberries a more eagerly sought-for prize than any which life since those days has brought us. Plants which you remember carefully tending as the delicate pets of your conservatory, are here hardy trees flourishing in the open air, their gorgeous tints and foreign-looking foliage reminding us at every step of the lovely climate and fruitful soil of this the land of our adoption. And now once more we are wending our way slowly to the summit of the hill, wishing to see how the lovely panorama there visible looks in the golden light of the coming sunset.

Before us lies Parnell, its white houses looking peaceful and happy on its green hills sloping so gently to the water's edge; beyond that a broad expanse of the purple glittering sea, and still further the outlines of blue hills blending with the sky in the far distance. The spires of the different churches, the residence of the bishop, and the many pretty villas peeping from nests of green foliage, form a picture which will not easily be forgotten, and truly rural and pleasant in its aspect, for the wooded expanse of the Domain here hides the busier streets and suburbs of the city from view. To the right are the villages of Newmarket and Epsom, and the well-known outlines of the hills beneath whose shadows they repose, whilst behind us rises Mount Eden, grand in the savage beauty of its aspect at this distance, and already growing dark with the purple shades of the coming night. We choose a quiet path for our homeward walk, not caring to have interrupted the pleasant train of thought into which we had fallen, and we linger by the way enjoying the beauty of the twilight which, though brief, is lovely enough to remind us of that immortalised by the poet as

"The purple twilight dim"

through which

"The happy princess followed him."

But the moon rises suddenly over the dark tree tops, flooding the scene with a brilliancy of light unknown in colder latitudes, and, softened by the distance, we can catch the sound of the well-known air played by the band of music returning with a numerous body of the holiday-makers to the city. We have reached the brow of the last hill, and before us gleam the lights from the familiar streets of Auckland, and we have one more day of happiness to add to the brighter side of our life account.

## THE VINEYARDS OF GERMANY.

A VISIT TO THE CELEBRATED HOCK VINEYARDS—THE GREAT WINE YEAR OF 1865—PRICES AND QUALITY OF WINES, &c.

THE Rhine Gau, so called, extends from a point opposite the city of Mayence, on the east bank of the Rhine, and extends down to Rudesheim. It is generally, however, understood to begin at Biebrich, the summer residence of the Duke of Nassau, which is only about a couple of miles below where the river Maine enters the Rhine. Near this are the great Hock vineyards, where that unrivalled wine known by the name of Hock is produced. These vineyards front on the river Maine, and are only distant about a dozen miles from the city of Frankfurt. For a distance of two or three miles on the bank of the river, there is a narrow belt of land, in some places not more than 40 rods, and in others not over 80 rods in width, covered

with the Grape from which most of the Hock is made. These lands have a gradual slope down to the river, and a fine southern exposure. The lands are of a good quality, and have been used for the purpose of raising Grapes for more than a century past.

Among the most celebrated in this section for the Hock wines are the graperies of Mr. Pabstman, known as the Victoria, and one belonging to the city of Frankfort. The extent of Mr. Pabstman's I should think not over twenty acres, lying in a body, but he has many other little tracts near by, not contiguous to each other, used also for this purpose.

Many other persons own little strips of land varying from an acre to two or three acres each, lying in a square form, or in the shape of a parallelogram, also running down to the river bank, devoted to the culture of the Grape. None of the owners of these lands live upon them, but they and the labourers have to come a distance of from two to five miles every day to work them. The residence of the owners or of the workmen is generally at some village not far distant.

Several proprietors of vintages, owning a dozen or more acres of these lands, have them cut up into as many pieces, not any two of which adjoin each other. This small division, it seems, came from the frequent partitions of estates among numerous heirs, and you can always depend upon a German family being large! Some of these tracts are tilled by the owners, while others are let out to tenants, who either pay a fixed rent in cash for the land, or deliver a certain quantity of wine.

It is said that there does not average more than one year in five favourable to the production of wine, or known as good wine years. Looking back for a period of about fifty years, the best for wines were 1811, 1822, 1834, 1846, 1857, 1858, 1861, 1862, and 1865.

These wine lands are very valuable here, and are worth not less than 2500 florins the acre. It is not uncommon for the proprietors to expend on manure from 80 to 100 florins per year, and even then they yield in some years a profit of from five to ten per cent.

On the high rocky hills, below on the Rhine, or further up the Maine, where the Vine is also extensively grown, the lands are not so good or valuable, nor are the wines there made as good. A proper slope and exposure to the sun seems necessary for the successful cultivation of the Vine, in order, to get all the sun possible. I think in all my travels I never saw any Grapes growing on level land. There is never too much sunshine in Germany, and all there is seems to be required for the Grapes. The year 1865 is, however, an exception, and the summer will compare favourably with America. During a part of July, and even of September, the mercury has been for days among the nineties, a fact which has not been before known in the recollection of the oldest inhabitant. During the whole month of September and up to the beginning of the second week in October, not a drop of rain has fallen, and hardly a cloud has been visible in the horizon. It has during all this time, from morning until night, been one continuous beautiful sunshine. The barometer has stood for weeks at an average of 28 inches, and has hardly varied.

In July and part of August our summer would compare favourably with the northern part of the United States. For days and days in July and August the thermometer stood at 28°, which was up among the nineties by Fahrenheit's scale. Generally speaking, when it was so hot in the daytime it was cool and pleasant in the evening. The effect of so much sunshine and so much hot weather has been to make the Grapes both rich and sweet. The quality will be very fine, but the quantity very much less. It is really believed that the produce of this year will not be equal to half of that of 1863 or 1864, which were unfavourable years, having been too wet and cold during those summers.

The wine merchants, however, have a way of making both ends meet, and they are honest enough to own to some very harmless adulterations, such as mixing the sour wines produced in wet years with the sweet wines of warm seasons. They allege, however, that with sufficient age, this mixture becomes very fine wine and very palatable.

The wines of 1865 will only be able to be bought and drunk by princes and "merchant princes."

The dark-skinned Grape generally ripens sooner than the white, but it is not so sweet or fragrant, and, in consequence, it is not so generally produced. The Burgundy Grape is said only to flourish well in clay soils; and from this Grape, which is grown to a small extent in the Rhine Gau and the Palatinate, is made the famous red wine known as Asmanhausen and In-

gelheimer. The people of this country do not drink the red wine so much as the white.

The Hock vineyards do not contain, all told, more than 75 to 80 acres, and in ordinary and good years the produce is not over 600 "stucks," (a stuck is about 1500 bottles), which gives us a total of 900,000 bottles; yet we are assured by reliable men engaged in the wine trade, that there are sold every year at the auctions no less than 6000 stucks, all purporting to be genuine Hock.

The kinds of Grape mostly grown in these great vineyards are the Reislung, Traminer, Gut Edelen, Roland Orleans, Clevern, Fleisch, Oestreith. From the Reislung variety are made those wines so celebrated and well-known throughout the world, such as the Johannisberger, Steinberger, Catinet, Raunthaler, Berg, Liebfraumilch, and Marcobrunner. Very good wines are also made from the Traminer. The Fleisch is a red Grape; the Clevern a reddish purple colour, but is more grown in the Palatinate than here. The Gut Edelen and Fleisch have very thin skins, and are only used as table Grapes. The Reislung never produces in quantity as much juice as any of the other varieties, but it brings a much larger price. The Oestreith seems to be the general favourite for ordinary wines, and from this Grape is made most of the sparkling Hock and Moselle.

For the Johannisberger and other celebrated wines, in consequence of the demand for them, the wine merchants are unable to fill the orders; so they obtain wines produced in other localities, which assimilate to the taste of the respective wines, and label them with these popular names. They are sometimes nearly as good, though an experienced wine merchant will detect the difference at once by the taste, as quickly as he discerns the growth of one year from another.

At most of the hotels the label does not indicate what the wines are, nor, in fact, can they afford them at the ridiculously low prices marked, such as from 15 to 30 cents a-bottle. Poor wine—that is, of a bad year, is even cheaper than vinegar. This latter article ought to be cheap and good in a wine country, but I am sorry to say it is not.—FRANKFORT (in *Cincinnati Gazette*.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

TAKE advantage of dry weather to eradicate weeds. *Asparagus*, as the production of strong heads next spring will depend mainly on the present summer culture, let the beds, after being cleaned, be mulched with short grass or half-rotten manure. Liquid manure, in which a portion of salt has been dissolved, should then be applied freely for the next month or six weeks, or the salt may be spread over the beds, so as to be washed in by the rains and waterings. *Artichokes* (Globe), and *Sea-kale* will be improved by similar treatment. *Celery*, the main crops must now be put out without delay; let the plants be well supplied with pure water, and shaded for a few days if necessary; the early crops should be liberally supplied with liquid manure, and the soil about them frequently stirred with a fork, but by no means make any attempt at moulding them up, until they have nearly attained the desired growth. *Cauliflowers*, water freely. *Carrots*, make a small sowing, if they are in request for drawing young; sow also a few more *Onions* for the same purpose. The Tripoli answers best. The autumn-sown *Onions* transplanted in the spring are very fine this season, and will now be attaining their full growth; as soon as this is perceived, lay the tops down with the back of a wooden rake for some time previous to pulling. *Cabbages*, make another sowing for autumn use. *Lettuce*, water this and *Radishes*, or other vegetables which require being grown quickly to have them crisp and tender. We need scarcely remark, that in all cases vegetables will be improved in size by giving manure water, if it can be procured for all purposes in sufficient quantities. *Peas*, continue to earth-up and stake. The last sowing may be now made; the Early Frame is recommended, but Knight's Dwarf Marrows will also succeed, if the season prove fine. *Potatoes*, the spaces between the rows to be deeply forked up and planted with Brussels Sprouts, Kale, Coleworts, and other winter and spring Greens; they will not interfere with the well-doing of the Potatoes, the lifting of which will be of great benefit to the plants. *Turnips*, keep up good successional sowings; a large breadth may now be put in. Remember that charred refuse suits them well, and that dry wood ashes sprinkled over them when they are wet, is a good preventive against the fly. *Scarlet Runners*, earth-up and stake, unless they are required

dwarf, when the tops should be frequently picked out; but it is always best to stake them, if possible, both for neatness and productiveness. *Salads*, look well to successions. *Tomatoes*, keep them well thinned out and constantly nailed.

#### FRUIT GARDEN.

The principal operations here will consist in keeping the young wood of wall fruit trees constantly nailed in. The laterals from the young wood of Peaches and Nectarines may be spurred down to the first joint, which spurs will often produce fruit, but do not trust to these laterals for filling up the walls, as they seldom become sufficiently matured to produce good fruit. As many of our improved Pears for the dessert, as well as some other fruits, cannot be produced in proper flavour without an increase of warmth and light, more especially the latter, they will, no doubt, continue to be grown by individuals who esteem horticultural productions not by their mere marketable value irrespective of flavour, but chiefly on account of the latter quality. Limitation at the root, then, we would urge, as we have done before, is the only sure foundation of a dwarfing system, which ought to be, in varied degrees, the guiding principle in all artificial training. As the weather has now set in extremely hot, and is likely to continue so, we strongly advise that all the superfluous breastwood be removed from Pears, or at least pinched off. When the drought begins to affect the root, and intense sunshine prevails overhead for several successive days, a new habit becomes speedily induced in most fruit trees—elaboration begins to reach or overtake absorption. If the trees are very gross, we would advise the taking away as many shoots entirely as will permit the solar rays to visit the bud being organised for a future blossom; the rest may be left as safety valves to decoy away any undue amount of sap in a temporary way, taking care, however, to pinch off their terminal points. The process here recommended is applicable to nearly all our fruit-bearing trees, and is scarcely more difficult than pulling away tall weeds from a bed of Cucumbers, in order to admit the sun's rays to the blossoms, for in such a point of view may the buds of fruit trees in course of organisation be regarded.

#### FLOWER GARDEN.

If the dry and hot weather continue much watering will be necessary here. Even the ordinary herbaceous plants should have a thorough soaking once or twice a-week. Indeed, it is more necessary with these than with mass flowers, which have now, of course, become well established. The amateur's interest is kept up by the progressive development of the Carnation and Picotee, which now reward all his care and attention by the development of their beauties. The Tulip, Ranunculus, Auricula, and Polyanthus have passed away for the season, and these especial favourites will for a time fill the void. When the shoots are sufficiently long layering may be commenced; this is performed by cutting through the second or third joint, and bringing the knife out on the lower side, so as to make "a tongue." The small portion of stem beyond the joint is cut back to it, and when pegged down in the soil, which should be fine, the layer will there emit roots. The amateur after a few trials will be enabled to perform this operation with facility.

#### GREENHOUSE AND CONSERVATORY.

Watering in a frequent and methodical way is now a matter of great importance in these structures; indeed, without a proper application of this useful element all other appliances will be of little value. It will be necessary to keep pans of water beneath some pot-bound and needy plants. *Nerium splendens*, when well grown, thrives admirably thus treated. Let all stock for flowering through the dreary winter months receive every attention; grown quickly with frequent stoppings, it will be necessary to have the plants somewhat pot-bound by the end of August and cooled down for a few weeks.

#### COLD PITS.

The stock here will now be growing freely, and should be frequently examined individually to see that all is going right, for plants when growing rapidly very speedily suffer through any neglect in watering or from the attacks of insects. Examine young specimens that were potted early in the season, and shift at once such as require more pot room, so as to have the pots moderately well filled with roots before winter, in which state they are more easily carried through the winter than when either over or under-potted. *Leschenaultias* should be carefully examined for green fly, and smoked at once if at all infested, and the flowers should be regularly picked off

young plants of these as they appear. *Chorezemas*, *Bossiasas*, &c., must also be frequently examined for red spider, and should be laid on their sides on a clean mat and thoroughly washed with the syringe, repeating this as often as may be necessary to thoroughly eradicate the pest. Young specimens of valuable hardwooded plants should be carefully trained, keeping the shoots nicely tied out or pegged down in order to secure close, compact foundations, upon which future success very largely depends.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

The heavy rains had beaten the ground like iron among crops newly sown and planted, and much time has been taken up in forking and hoeing the ground, to let the air in, and to prevent cracking. A few weeks ago we adverted to the importance of a rather firm surface, in order that the ground might become well heated by the sun's rays; but now there is no lack of heat in the soil, and a loose surface is best in every way for the generality of plants, admitting mere air to the roots, and keeping out the excessive heat. The drenching rains brought with them whole armies of *slugs* and snails, that did not show their presence in the dry weather, and dusting with soot, lime, and wood ashes became the order of the day; and not second in importance was a stirring of the surface, first because the slug does not like to be disturbed, and, secondly, because no lady in silk slippers loves more than he a smooth surface. We found the leaves in a piece of fresh-planted Cauliflower well perforated afresh every morning, and yet at our ordinary time of rising (from five to six o'clock) we could not find a trace of a single slug, though the slimy marks of where they had been were conspicuous enough. The ground had been beaten so hard and smooth by the rains, that they had managed to hide themselves beneath the clods of the nearest rough ground before the sun had gained much power. The running the hoe and the points of a fork through such baked ground, and a dusting of soot and lime, make their journeyings anything but pleasant. Buttered or greased young Cabbage leaves, or better still, where they can be obtained, a handful of brewers' grains are great attractions; but considerable experience leads us to the opinion, that if the ground be well stirred and kept rough at the surface all such troublesome fellows will in dug ground bid you good-bye. The most troublesome of all when they take possession are those with longish bodies, black on the top, and yellowish beneath. Soot, lime, ashes, or anything but salt, seems thrown away on their tough skins; but fortunately they have great love for a smooth surface, and after heavy dews or warm rains if found anywhere they will be most plentiful on smooth gravel walks, and the best plan is to pick them up, and put them in a pot in powdered salt. That soon settles them.

Sowed main crops of late Lettuce, Cauliflower, a little Cabbage, and a good piece of Endive, and planted out from previous sowings, choosing chiefly shady positions at present. The north side of a bank is also a good place for sowing *Turnips* at present. They feel the effects of the heats of autumn less, and eat milder than when fully exposed to the sun. There are many fine *Turnips*, and some yellow ones, as the Maltese, that can scarcely be surpassed for flavour; but of all *Turnips* for main table supply commend us to the American Stone or American Red-top. This *Turnip* is of a purplish colour at top, the lower part is white; but it is all white inside, and so firm, juicy, and sweet, that every cook we know prefers it when it can be obtained to anything else. We have eaten a bit raw with our knife, and thought it much sweeter than many a Melon we have tasted when judging, that looked well and sent out a rich odour, but of which the taste was such that something in the liquid way was sadly wanted to take it away. Wherever many Melons have to be tasted there ought to be a bottle of wine near at hand. For the main features of the kitchen garden, see notices of previous weeks.

One thing we ought to mention, as a mere act of justice to ourselves and others. We have stated the difficulties we have had to surmount with game, and the attendant evils in the shape of out-of-the-way armies of birds of all kinds; these we would find little or no fault with in moderation, as independently of their beauty, their harmony, &c., we do believe that they do us good when they are kept within their proper limits, but they become little better than a plague when they would clear off all the produce, and look for more. We are not the less obliged to the correspondent who uses red lead mixed with

his seed, to keep the birds at bay, though we ourselves have also used it successfully, and, perhaps, too much so, as we have reason to believe that it killed many birds, as well as kept them away. We have no evidence as respects pheasants, but we would be afraid to use it for Peas, if we thought it would injure these birds. If it merely kept them away we would be glad, and would use it largely if similarly circumstanced next year, as though we have long planted out early Peas with advantage, we find that when forced to plant out successional crops they do not thrive like those sown without considerable trouble and labour. In our own case we found it was of no use sowing Peas before May. After that the pheasants did not seem to care about digging them out. Before that nothing, we believe, but small wire netting would have kept them away, and all common netting would be next to useless, if there was a chance of the pheasants being hung in the netting. Would some correspondent tell us if the red lead would be sufficient to keep pheasants from eating the Peas when sown? If they do eat them we expect that they will suffer for it, and that is not what we want.

FRUIT GARDEN.

Much the same as in previous weeks. Look back and notice what was said as to covering the ground for Strawberries to keep them clean. With such wet weather and the heavy crops the rains helped to produce, nothing could have been worse than the grass we largely used, instead of straw or litter. In fine, dry weather it would have been all well. Took off lots of runners, and put into small pots at once to avoid layering. Other departments much the same as previously stated. Figs have been plentiful and fine from the heat.

ORNAMENTAL DEPARTMENT.

Mowed, rolled, and hoed flower-beds, as weeds were coming up plentifully. Potted and repotted, and commenced fresh arranging verandahs and conservatories. The beds in the flower garden will give little trouble, we think, this season.—R. F.

TRADE CATALOGUE RECEIVED.

Henry Cannell, Fuchsia Nursery, Station Road, Woolwich.—Autumn Catalogue of *Fuchsias, Verbenas, Petunias, &c.*

COVENT GARDEN MARKET.—JULY 14.

SUPPLIES abundant, demand falling off, and we have again to report large arrivals of West Indian Peas and other foreign produce. English Peas are also very plentiful, and in little request at present.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All

communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

FUCHSIAS (*R. H.*).—There are far too many varieties nearly alike, and especially of the strains like the specimens sent, for us to be able to name them.

CLIMBER FOR CONSERVATORY (*J. J. J.*).—We think *Bomarea multiflora*, a handsome climber, with deep yellow flowers spotted with crimson, would answer your purpose. *Taesoia mollissima* will not do out of doors, nor on the back of the conservatory if at all shaded by plants in front.

REPORTING CAMELLIA (*Idem*).—It will not only be advisable, but absolutely necessary to repot a Camellia, the pot of which is very heavy, and almost black with moss, for this shows the drainage to be bad, and the soil sour. After turning the plant out of the pot, pick away the old soil without disturbing or breaking the very tender fibres, remove the old drainage, afford a clean pot, and drain well. Use for potting a compost of two-thirds turfy loam, chopped with a spade, and one-third sandy peat, adding one-sixth of silver sand. Do not shift into too large a pot, but one which will hold the roots without cramping.

STRAWBERRIES (*Mallow*).—The following, extracted from "Hogg's Fruit Manual," are the descriptions you ask for.—"Sir Harry.—Fruit very large, roundish, irregular, frequently cockscomb-shaped. Seeds large, and deeply embedded. Skin dark crimson, becoming almost black when fully ripe. Flesh dark red, not very firm, but tender, very juicy, and richly flavoured." "Old Pine (Black Pine; Carolina; Scarlet Pine).—Fruit medium-sized, ovate, even and regular, and with a glossy neck. Seeds prominent. Skin deep red. Flesh pale red, very firm and solid, with a fine sprightly and very rich Pine flavour. After all there are very few that equal, far less surpass, the Old Pine in flavour, but it is not a good bearer." "British Queen (Myatt's British Queen).—Fruit large, sometimes very large, roundish, flattened, and cockscomb-shaped, the smaller fruit ovate or conical. Skin pale red, colouring unevenly, being frequently white or greenish-white at the apex. Flesh white, firm, juicy, and with a remarkably rich and exquisite flavour. The great fault of this variety is that the plant is so very tender; it will not succeed in all soils and situations, and it is generally an indifferent bearer." "Frogmore Late Pine.—Fruit very large, conical, and cockscomb-shaped, with a glossy neck like the Old Pine. Seeds not deeply embedded. Skin glossy, bright red, becoming dark red, and almost black when ripe. Flesh tender and very juicy, red throughout, richly flavoured, and a good deal of the Pine aroma when well ripened. This is a late variety than an abundant bearer, coming in with the Elton, but much less acid than that variety." "Oscar.—Fruit large, ovate, and angular, sometimes flattened and wedge-shaped. Seeds rather large and deeply embedded, which give the surface a coarse appearance. Skin dark shining red, becoming almost black when fully ripe. Flesh red throughout, very firm and solid, juicy, and richly flavoured. An excellent variety for a general crop, coming in a few days after Black Prince; a most abundant bearer, and, from its firmness, bears carriage well." "Rifeman (Ingram's).—Fruit very large, ovate or cockscomb-shaped, and corrugated. Skin bright salmon-coloured. Seeds prominent. Flesh solid, white, firm, juicy, richly flavoured. The plant is of vigorous habit of growth, and is an abundant bearer." "Wonderful (Jeyes' Wonderful; Myatt's Prolific).—Fruit large, conical, frequently cockscomb-shaped, and fingered. Skin pale red, and whitish at the apex. Seeds numerous and prominent. Flesh white, tender, melting, juicy, and sweet, briskly flavoured, and with a fine aroma. A very excellent fruit, which forces well." "La Constante.—Fruit large, conical, and regularly formed. Seeds not deeply embedded. Skin of a brilliant lively crimson. Flesh white, with a rosy tinge, firm, juicy, richly flavoured, and with a fine piquancy. A first-rate Strawberry, and an abundant bearer. When forced it bears abundantly, and preserves its flavour well." The Geranium seedlings from Malta will probably not be of any value.

VINE LEAVES (*Fitis*).—We could not find a single red spider on the leaves, but there were marks that led us to the conclusion that either red spider or thrips had been present, but in very small numbers. The traces of mildew were even less apparent. If you are convinced that it exists, which we are not, plenty of air, and sulphur on the walls, stages, &c., will be your best help. There are traces of warts on the leaves, and scalded spots, and the best remedy for both is more air, and that given early enough to prevent the moisture in the house being turned into hot vapour. Last week you would see what was said about thrips and red spider, and both may be easily discerned. At present we think you chiefly want more air and that given, especially at the back, before the sun strikes the house. You must, however, judge for yourself, for leaves sent in a letter seldom have the insects, which might have molested them at home.

MILDREW ON PEACH LEAVES (*G. F.*).—The white down along the midrib on the under side of your leaves is a parasitical fungus. Dust under the leaves with flowers of sulphur, allow the sulphur to remain on the leaves for two or three days, and then syringe. If needed repeat the application of the sulphur. Do you mulch the surface of the earth in the pots, water freely, and admit air abundantly day and night? This treatment is all-essential for successful culture of fruit trees in orchard-houses during this hot dry weather.

GRAPES SPOTTED (*A Constant Subscriber*).—"The spot," as gardeners call the ulcer which has attacked your Muscat of Alexandria Grapes, is caused by want of root-action. Remove the soil from over the roots, replace it, not more than 6 inches deep, by a compost of one-third decayed stable dung, and two thirds light soil. Water the roots freely with tepid water every second day; and admit air night and day during this hot weather.

**CALADIUMS** (*Misc. It.*).—For exhibition, in addition to *Caladium argyrites*, *Chantini*, *bicolor magnifica*, and *Wightii*, *Caladiums Brogniarti*, *Belleynei*, *Baraquinii*, *mirabile*, and *Leopoldi*, are desirable.

**STRAWBERRIES** (*M. C.*).—The post-office officials had smashed the paper box into one mass, and we could hardly discern your initials. Fruits must be enclosed in a wooden or tin box, and kept separate from each other by freshly gathered leaves.

**NAMES OF FRUIT** (*J. It.*).—The contents of both boxes were British Queen Strawberry. Its characters are given in the previous page. It is a variety which any nurseryman ought to be able to supply true. You will find in another column remarks by the Rev. W. F. Radclyffe on the subject of Strawberries.

**NAMES OF PLANTS** (*M. B., Staffordshire*).—*Funaria officinalis*, common Fumitory.

### METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 14th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun. . . 8	30.131	30.084	68	55	64	60	S.W.	.03	Densely overcast; slight rain at night.
Mon. . . 9	30.193	30.080	79	54	64	60	S.W.	.00	Overcast; fine; very fine; warm at night.
Tues. . 10	30.266	30.250	85	50	65	60	W.	.00	Very fine, dry air; very hot sun; exceedingly fine.
Wed. . 11	30.286	30.229	82	48	66	61	N.E.	.00	Very fine; dry uniform haze; hot; very fine.
Thurs. 12	30.183	30.072	80	53	68	62	S.	.00	Slight haze; hot and dry; very fine; hot at night.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### MOULTING.

We have often looked with interest at the moulting of fowls—the process of putting off the spring and summer clothing, and remaking that which will be useful in the winter. Our handsomest favourites are now what our man calls “getting seedy.” The Spanish plumage has lost its gloss; the combs no longer feel like velvet to the touch, and there is an inclination in the white face to narrow its size. The accurate pencilling of our Brahmas is lost in a dingy, mossy, rusty colour. Our Dorkings have lost not only the appearance, but the reality of their weight. Our Ducks and drakes are all alike, and the gaudy Golden Pheasant of last month shows only here and there remains of his old beauty, looking like “the George,” hanging on the post of the attic bed, among the torn and shabby furniture in the painting of “The Last Days of Buckingham.” They have all done their duty. They have laid, and reared their broods, and now when the pullets are beginning to supply eggs, the old birds ask for their natural rest. We are too often prone to forget that this rest is necessary for them—indeed, essential. They are preparing for next season. During the remainder of the summer they will be recruiting the strength that will enable them to form new clothing. The shabby, worn-out plumage of the summer, the naked backs, and broken feathers, would be but poor helps during the cold days and long nights of winter.

We are led to this subject by the numerous letters on moulting which we receive at this season. Fowls have hardly yet begun, but where they have left off laying, the approach may be easily seen. Some seem to have much greater difficulty than others. Spanish are a long time naked. All the non-sitters feather more slowly than the others. It may be because they lay a greater number of eggs, and that the production of them causes more exhaustion of the system than the twenty-one days of the sitters. Certain it is, however, that moulting is an effort, and taxes the bird so much, that at such a time any old weakness or partially cured disease is sure to show itself again. Thus, years ago, when roup was so common and fatal, wherever it had been in a yard, it always reappeared at moulting-time.

The feathers are at first but small blue stubs in the skin; the end is very soft, pulpy, and bleeding; it shows itself through the hole in the skin, which is ready to let it pass, and is then a perfectly round blue tube. This grows both in length and rotundity. If one of them be pulled out and examined shortly before it opens or bursts, the feather will be found beautifully rolled up, but the quill is not formed. After the feather has shown itself, the end still retains its pulpy and bleeding appearance; through it the feather derives the sustenance from the body of the bird, which is necessary for its development. As soon as it is fully formed, the end hardens and becomes the quill. There is no growth or reparative process after this. If the feather be broken or cut off, the quill will remain till the moulting season comes round again. The body, however, cannot go on producing fresh feathers. If a

particular feather be pulled out of a black-plumaged bird as fast as it is formed, it gives evidence of weakness by coming white.

No men have ever studied fowls so closely as those who breed and trained Game cocks. They never dub a bird—*i.e.*, remove his comb, deaf-ear, and gills, while he has any soft feathers about him. He is not in a state of strength to bear the operation. Birds that have their full liberty, and are well fed, always moult well, but when they are kept in confinement, care and precaution are sometimes, not always, necessary. The effect of food may be proved by a fact. Quails and bullfinches are exceedingly fond of hempseed. This is of a very heating nature, and if they are allowed to eat too much of it their plumage becomes nearly black. If they are fed entirely on it their bodies are so heated that they moult with great difficulty, and their flight feathers do not form at all. The system of the bird becomes so heated that everything is dried up, and no nourishment is possible. The feathers, like plants, die for lack of moisture. If improper food have this effect, then judicious feeding ought to assist. We have already said that if the birds are at liberty they will find all they require; but if they are shut up they must have plenty of cooling food. We know none so good as lettuce, and if it has gone to seed and is stalky so much the better. Sods of growing grass, and plenty of fresh mould with them, are also excellent. One thing requires to be watched—they will sometimes in a dissatisfied habit of body begin to peck and eat each other's feathers. If a fowl do this it should be at once removed, as it will not only spoil the plumage of the others, but it will teach them the same habit. When a bare spot appears on a fowl it should be rubbed with grease which is quite free from salt.

Sometimes a fowl will be seen while moulting to be continually picking or scratching at one spot of its body. On examination it will be found that one or more feathers have failed in passing through the opening in the skin that is provided for the purpose. They keep on growing, but they grow under the skin, looking like a worm beneath it. This causes much pain. It is common in the top-knots of Polands. The remedy is a very easy one. Take a stout needle and pass it under the quill-end of the covered feather, then draw the feather from under the skin.

#### WHITE COCHIN-CHINAS.

“A love of Cochins no cold medium knows.”

Do insert these few lines in answer to “WILTSHIRE RECTOR,” who cannot know how beautiful White Cochins are. They are the most profitable poultry I ever kept; laying abundantly winter and summer. They are, too, the best of mothers, and will lay again in a fortnight after bringing off a brood.

I lay upwards of two hundred of their chickens this season. I am quite sorry to hear “WILTSHIRE RECTOR” speak of them in the terms he does. He cannot mean pure-bred White Cochins, for they are most beautiful. I suppose his were very old, and a mongrel breed, to be such horrid frights as he describes them in your Journal of the 10th.

For table there is none to equal a fine young Cochin roasted; so “WILTSHIRE RECTOR” must allude to an old tough hen, to

which he invites the Editors to dinner. I should be most happy, if you will pay a visit to Bedford, to show you my Cochins, and also to have some for dinner—but no "WILTSHIRE RECTOR."—E. CLARKE, *Ivy House, Bedford.*

[We beg "WILTSHIRE RECTOR" to remember that this is warm weather—extremely hot, in fact—we further beg him to remember that no lady will endure detraction of her pets; and, lastly, we beg him to remember the proverb of this lady's county, "Men's minds, crooked as Crawley Brook," so his judgment may be atwist. Thus remembering, he will reply mildly—and ask permission to accompany us to the dinner at Ivy House—and when asked to return thanks after the repast, he will *not* use the formula—

"For Cochins leggy, dry, and tough,  
I'm thankful—but I've had enough."]

### FOWLS YOU SHOULD KEEP.

MARCH 3rd.—Sat thirteen eggs, hatched twelve, reared nine; cat killed three.

JUNE 6th.—Sat fifteen eggs, hatched thirteen; twelve living. Both these sittings were from the same Dorking hen, the old rooster's particular favourite.

I never yet to my knowledge had a hen eat her eggs. I am very careful in supplying my fowls with plenty of green meat, builder's rubbish, and clean pump water daily. I do not now give meat or bones to pick. I make my hens' nests in a secluded corner of an outhouse as follows:—I make a slight hollow in the ground, take some rather stiff earth, and beat it into the hollow with the fist until firm and smooth. I then place clean straw, regulating the quantity according to the time of year, very little being used with the June sitting. I lift my sitting hen off at the same time every morning, provide her with a dust bath, clean water, and food (whole barley or fig dust), and before she is allowed to return to her nest I place her on the wet grass, so that her feet and under feathers may be slightly damped: this plan I prefer to sprinkling the eggs.

The best layers which I have ever had come from some eggs purchased at a farmhouse, where they told me Cochins, Spanish, and Dorkings had been allowed to run together.

I submit that as distinct breeds Dorkings and Brahmas are very profitable, but a cross between these two would give a still better return. My egg return for the last six months gives the following:—January, 65; February, 68; March, 77; April, 62; May, 73; June, 58. Stock, 4 Dorkings and 2 Brahmas. Dorking cock.—J. M. S.

### WOODHORN AND NEWBIGGIN POULTRY SHOW.

THE first Exhibition of the Woodhorn and Newbiggin Poultry and Pigeon Show was held in a large marquee erected on a choice site at Newbiggin-by-the-Sea, on Saturday, the 7th inst. Although it is only about six or seven weeks since the idea of holding a poultry show at the above place was first mooted, yet all parties interested in its success bestirred themselves most energetically, and we are glad to say their efforts were well rewarded. The gentry and inhabitants of the district supported it in a most substantial manner. The Committee have no doubt that they will be enabled to double the money value of the prizes at the next show, as well as to offer silver cups for certain classes. Many of the birds shown had taken prizes at the Bath and West of England Show recently held at Salisbury, and at others of the principal shows in the kingdom. A magnificent pair of Buff Cochins-Chinas and a pen of Game Bantams from Mr. Edward Fearon, of Whitehaven, arrived, we are sorry to say, too late for competition. The total number of entries was 117, one only of which was for Pigeons. The following is a list of the prizetakers:—

- GAME (Duckwing).—First, H. Rogers, Bedlington Colliery. Second, P. Wilkinson, Bedlington.
- GAME (Black-breasted and other Reds).—First, G. Joice, Bedlington. Second, H. Rogers.
- GAME (Any other variety).—First, J. Achincloss, Barrington Colliery. Second, J. Muter, Newbiggin-by-the-Sea. *Hens*.—First, H. Rogers. Second, R. Wailles, Netherton Colliery.
- HAMBURGERS (Golden-pencilled).—First, A. K. Wood, Burneside, Kendal. Second, J. Smith, Netherton.
- HAMBURGERS (Silver-pencilled).—First, A. K. Wood. Second, J. Sim, Cramlington.
- HAMBURGERS (Golden-spangled).—First, J. Achincloss. Second, J. Sim.
- HAMBURGERS (Silver-spangled).—First, A. K. Wood. Second, J. Martin, Cowpen Colliery.
- DORKINGS (Coloured).—First, Miss Wilson, Woodhorn. Second, J. Graham, Durham. *Chickens*.—First and Second, J. Graham.
- DORKING HEN (Any variety).—First, Miss Wilson. Second, J. Graham.

- DORKINGS (White).—First, F. E. Schofield, Morpeth. Second, G. Joice.
- SPANISH (Black).—First, J. Taylor, Newbiggin-by-the-Sea. Second, J. Stalker, Sleekburn Colliery. *Chickens*.—First, M. Gibson, Woodhorn.
- BRAHMA POOTRAS.—First, Mrs. Chrisp, Hawkhill. Second, J. O'Leary, High Trewit, Rothbury.
- BARN-DOOR FOWL.—First, R. Brnn, Newbiggin-by-the-Sea. Second, Mrs. Shanks, Newbiggin-by-the-Sea.
- ANY OTHER VARIETY NOT MENTIONED EXCEPT BANTAMS.—Prize, T. Finlay, Newbiggin-by-the-Sea.
- GAME BANTAMS (Black-breasted and other Red).—First, T. C. Harrison, Hull. Second, W. Davison, Belside Colliery. Highly Commended, Miss S. F. Wilson, Woodhorn; G. Dowie, Netherton.
- GAME (Any other variety).—First, Miss Wilson. Second, J. Sim.
- BANTAMS (Any other variety).—First, T. C. Harrison. Second, Miss S. F. Wilson.
- GUINEA FOWL.—First, T. C. Harrison. Second, G. Johnson, Barrington Colliery.
- PEACOCKS.—First, Mrs. Parker, Newcastle. Second, O. Richardson, Newbiggin-by-the-Sea.
- TURKEYS.—First, Miss Wilson. Second, Miss S. F. Wilson.
- GEESE.—First, J. Angus, jun., Morpeth. Second, Miss Wilson.
- DUCKS (Aylesbury).—First, J. Manghan, Newbiggin-by-the-Sea. Second, J. Taylor.
- DUCKS (Rouen).—First, Mrs. Wilson, Woodhorn. Second, J. O'Leary.
- DUCKS (Any other variety).—First, R. S. Bambridge, Woodhorn Grange. Second, T. C. Harrison.
- JACODINS.—Prize, J. Willis, Woodhorn.

Mr. W. Trotter, of South Acomb, Bywells, Stocksfield, officiated as Judge.

### A MASCULINE HEN.

THE following is my brother's account of a mule bird which is stuffed, and stands in his hall at Hyde, Bere Regis, Blandford, Dorset.—W. F. RADCLIFFE.

"All I can remember about the mule bird is, that she is half Bantam, and was kept for twelve years to breed Pheasants up. About the ninth year we observed a couple of tail feathers curled like a cock's long tail feathers, and some appearance of the cock's hackle about the neck, and on the rump. Next year her plumage became more decidedly like a cock's. She put on two more curled feathers in the tail, and the hackle on the neck and rump were more decided. She did not lay after the first appearance of the male plumage. She crowed something like a cock; and the labourers, to whom she was well known, say they saw her exhibit other masculine propensities. Spurs appeared about the commencement of the change. On opening her body the whole of the ovaries were found to be completely ossified. The man who stuffed her showed her to a member of the British Museum, who heard my statement, which he said was quite correct. Up to that time no one believed the stuffer, but thought that it was a cock bird. However, this person said, 'Look at her comb, and there can be no doubt.' I would give her to any public institution. If living she would be thirty years old. The bird died in moulting at twelve years old."—C. J. RADCLIFFE.

P.S.—I beg in my brother's name to put the destination of the bird for a public institution—South Kensington Museum for choice—into the hands of the Editors of THE JOURNAL OF HORTICULTURE.—W. F. RADCLIFFE.

### SUCCESSFUL FOWL CULTURE.

SEEING the long catalogue of "Failures in Hatching" in your Number for July 3rd, I thought an experience of somewhat different character might serve to encourage my more unfortunate brother amateurs still to persevere.

My adult stock consisted at the beginning of the season of three Brahma, two Cochins, and two Game hens about nine months old, two Game and two cross-bred hens two years old, one Brahma cock one year old, one ditto nine months old.

From February 10th to June 23rd I set 153 eggs under eleven hens, hatched ninety chickens, and lost sixty-three eggs as follows:—Six stolen, five chicks dead in shell, fifty-two bad. Of these last, forty-four were purchased eggs obtained from noted breeders who regularly advertise in the Journal; eighty-nine eggs were from my own fowls, of which only fourteen were bad; the loss has been in the purchased eggs. How is it that they so often turn out bad? Is it owing to the birds moving frequently from show to show? If so, is there no remedy for this disappointment and loss?

My chickens are all well. I always attend to them myself the first thing in the morning, and give them generally barley-meal made stiff, in which I always put a little of Day's Game paste, taking care to wash out the pans and give them fresh

water. The result is, that they are all thriving, and I have not had one case of gapes this season.

I am convinced that poultry properly attended to is not only a pleasure to keep, but a source of no small profit, though, by-the-by, I do not think I shall purchase so many eggs next year. I have a small orchard, about half an acre, which I divided in two parts, keeping one exclusively for chickens.—AN EIGHTEEN-MONTHS AMATEUR, *S. Devon*.

#### NOTES ON BIRDS OF PREY IN ESSEX.—No. 1.

*A Royal Eagle* was shot about twenty years ago in Takeley Forest, and I remember one being shot at Waltham Abbey, in the marshes.

*The Osprey or Fishing Eagle*.—A very fine one once lived for two or three years about Latton and Nettleswell. I have sometimes been very near to it. I do not know what became of it at last. One has since been shot at Pishiobury.

*Kites* formerly existed at Great Parndon; they used to breed in Parndon woods, but they are all destroyed.

*The Moor Buzzard*.—There used to be a tract of boggy ground, with several woods, extending from Latton Mill to Burnt Mill, and I have there seen this rare bird twice or thrice, but have not known it to continue there.

*Common Buzzards* were so frequent that I have seen them alight on the barn at the place where I lived, and they were almost continually to be seen sailing over the meadows. They used to breed in Latton and Nettleswell woods. Not one now remains.

*Gosh Hawks* used to breed in Hyde Hall wood.

*The Sparrow Hawk*.—This active and interesting bird is now very seldom seen; but at one time it was frequent. If the farmers execrate the sparrows they should preserve this Hawk, as its food consists almost exclusively of sparrows.

*The Lanner*.—I once saw this large Hawk in Hyde Hall wood, and I have seen it both in Harlow and Latton Park woods, but it has always been very rare.

*The Peregrine Falcon*.—This has been shot in Stanstead Marsh and in Gilston Park, and I have seen it in Epping Forest.

*The Kestrel, or Hovering Hawk*.—This beautiful and interesting little bird used to enliven the country by its pretty hovering and its plaintive note; but it is now nearly exterminated by the game-keepers, although it does not meddle with any kind of game. No bird is of greater service to the farmer, for if mice are not exclusively its food they are very nearly so. It enters barns and other outbuildings, where not too public, in the same manner as owls; and wherever this bird's nest used to be found (generally in the old nest of a crow or magpie), it was invariably lined with the skins of mice. In spite, however, of all its services and its beauty, it has gone—been destroyed by the keepers.

*The Hobby*.—This small Hawk was more rare than either of the preceding, and appeared to prey mostly on the larger insects, as it was generally seen hawking round trees or darting very rapidly along. It also kept itself more secluded in woods.

*The Merlin*, the smallest of the native Hawks, is very rare, and is said to be migratory, arriving in this country in October; but a nest with two young ones was once taken in Ongar Park Wood, and I had the care of one of the young birds for some months. One, a few years since, chased a sparrow into a greenhouse, at Sheering, and was caught, and of course was killed by the ignorant fellow who caught it.

The above are all the species of the Falcon tribe with which I am acquainted.—D. S. FRENCH.

[The foregoing are a portion of a few pages of MS. (we wish they were many more), written by an old man long resident on the western borders of Essex, who, though slightly educated, was a good botanist and ornithologist. They are the mere records of his own observations, yet are very interesting, and are all that remain of their author's writings. He has recently died.]

**TAVISTOCK POULTRY SHOW**.—The Committee have done wisely to alter their first proposal—namely, that exhibitors were to find their own pens. The Committee will find the pens, charging 6d. for each; but there are no entry-fees. The Committee will be obliged by the loan of ornamental poultry or birds not intended for competition.

#### BEEES DYING OF DYSENTERY.

ALL the bees in one of my hives are dying, and I should be very much obliged if you could tell me what to do with them. It is a May swarm which was taken in a straw hive, and which I afterwards chloroformed and put into an Ayrshire wooden hive. The weather was very wet at the time, and the hive got wet and mouldy inside. I brought them into the house, took out the slides, put a piece of gauze on the top so as to ventilate them, and gave them some barley sugar. After a couple of days the bees seemed all right, and I put the hive out again. This was between three and four weeks ago. They are now dying by hundreds, and the rest seem to be listlessly hanging together doing nothing. Yesterday I removed them to a clean floor-board, taking away all the dead, and to-day the floor-board is again covered with dead, also the ground in front of the hive. Where each one dies there is a large drop of stuff the colour of yellow ochre, some of which I enclose in a leaf.

Can you suggest any reason for their dying, or anything to do with them? Can there be anything poisonous in the ordinary barley sugar sold in shops? I was surprised also to see a lot of earwigs in the hive. How is it the bees allow them?—G. THURLOW, *Backland, near Dover*.

[Your bees appear to be suffering from dysentery arising from the first instance from the injurious effects of chloroform, and aggravated by their being subsequently fed whilst confined to their hive. There is nothing poisonous in ordinary barley sugar. If the present glorious weather fails to ameliorate the disease, we should very much fear that it is incurable. Have you made trial of the remedy to which you referred, and of which you spoke so favourably in page 282 of our eighth volume?]

#### LIGURIANS IN STAFFORDSHIRE—BEEES AS REGICIDES.

ALL the young Ligurian queens I reared last season (nine in number) lived safely through the winter, and in every instance, although several must have been rendered fertile by black drones, all their progeny are beautifully-marked Italians. I saw the original queen this morning, and she still seems to be in full vigour, and has filled her hive with a vast deal of brood.

Dr. Bevan observes that storified hives seldom swarm. My experience is, that with Italian bees, they almost invariably swarm, in spite of every precaution.

I have this season adopted the plan recommended by "A RENFREWSHIRE BEE-KEEPER"—i.e., a super with guide combs has first been placed over the stock, and in a few days (after the bees have fairly entered, and commenced to work), a nadir has been placed under the stock hive. A second shallow super was in due course placed over the first super, and in a few days a second nadir under the stock, and finally a third addition was made to the super; but in spite of all this accommodation, before the first super was completed a vast swarm issued forth on Sunday last (June 24th), and out of four hives similarly treated only one has abstained from swarming.

A curious case of swarming occurred the day before yesterday (June 26). A fortnight ago I made a swarm by removing the queen and a large portion of the bees from a frame hive, and putting them into an ordinary cottager's hive furnished with empty comb. A frame containing two or three nearly mature royal cells was inserted into the stock, and one of these duly produced a queen, and I considered the hive secure from swarming, having removed all the native royal cells a day or two after the Italian cells had been introduced.

On the 26th of June, however, the hive swarmed at about 10 A.M., the bees remained quiet after being hived until about 4 o'clock, when they seemed to have lost their queen. (I had in the meantime examined the stock carefully, and failed to find either queen or tenanted royal cell, and did not think they had a queen). I turned up the hive in which the swarm had been hived, and soon espied a deadly knot of regicides. I took them out and pulled off the assailants one by one, until I had released the queen; but as she was a very small one, and was a good deal misshapen about the abdomen (the result, I believe, of the murderous attack she had experienced), I at once crushed her, and allowed the bees to return home; this they did almost at once, showing that no second queen had accompanied the swarm. I believe the queen was impregnated; she was nine or ten days old.

Yesterday (June 27th) I found that a swarm had issued from

a nucleus, and wishing to obtain the young queen, only just matured, for another hive, and at the same time compel the swarm to return home, I turned up the hive in which the swarm was, but after looking about for some time, as the queen did not turn up, I began to examine the mass in detail, and observing a rather dense cluster near the centre, rolled it out, and found, as I expected, that the young queen was incarcerated, exactly as in the previous instance. I removed her assailants one by one, and was glad to find the queen uninjured, and I succeeded in introducing her to another nucleus, which had either destroyed or lost its own queen some time before. The bees soon returned home, proving that they had not a more favoured monarch left with them. I have lost several young queens this season, but only one in 1865.

How is it possible to account for this apparent perversion of instinct? The weather is fine, and honey most abundant, and yet my bees have in several instances destroyed young queens which they themselves have reared and tended.—J. E. B.

### APIARIANS BEWARE !

The foes of your favourites are increasing. Sparrows as well as tom-tits are arrayed against you, and last, though not least, the cuckoo. The parish schoolmaster of Lochmaben has had a whole hive of bees destroyed in little more than one day by a cuckoo, which was encouraged to visit his garden; and two or three other hives in the vicinity have been ruined by the same enemy, so I am assured. That eminent naturalist Sir William Jardine believes the cuckoo will eat bees, and has sent an account of the above-mentioned facts to the "Science Gossip Journal." Now, without calling in question the veracity of any person, I beg to state as my opinion, that neither the sparrow nor the cuckoo is an enemy of the bee. I imagine the Lochmaben hives perished by famine, and that the dying bees were simply appropriated as legitimate food by the cuckoo. Sparrows abound in my apiary, and though they may occasionally destroy a bee, their chief employment consists in catching flies that torment the hives.

If "A BLACKHEATH'AN" will take the trouble of opening the stomachs of the progeny of apicidal sparrows, I am convinced he will desist from the war of extermination which he has begun to wage on a class of birds that do much good and little injury in the garden.—R. S.

### UNITING BEES—MANY QUESTIONS.

Will you inform me as to the course I ought to have pursued with my bees? On Saturday, the 7th inst., those in a Neighbour's hive swarmed for a second time, not having taken to the supers put on. I tried to unite the swarm with a first swarm from a common straw hive, and which was in a ten-bar hive (they swarmed exactly two weeks before the others); but the bees in the bar hive have killed all the others.

The mode in which we endeavoured to unite the swarms was as follows:—On Saturday night, about a quarter to ten o'clock (as recommended in the "Bee Manual"), an hour and a half after sunset, we took the new swarm, and, having spread a cloth on the ground, knocked the bees out on the cloth, and then began looking for the queen, but as we could not find her, we took the bar hive, and leaving its floor-board behind, put it on the top of the bees on the cloth. We then left them to rise into the hive, and join the other bees; and this we expected they would do. The bar hive has three bars full of comb, and partly sealed. Then in the morning, about a quarter to four o'clock, we returned the bar hive to the floor-board and to the stand, but when we came to look at the cloth there seemed to be as many bees under where the hive had stood as the night before; so we put them on the floor-board, and fastened the hive down; but all the day (Sunday) the inmates were carrying out bees either dead or alive, and the ground was covered with the dead and dying. I forgot to state that we found the queen in the morning, after we had removed most of the bees to the floor-board.

Did I pursue the right course in looking for the queen? and would the union have been all right if I had found her on the Saturday evening? If not, what reason do you assign for the bees killing the new swarm? We have the queen under a glass, will it be of any use to keep her? Should covers to hives be of a light or a dark colour? Why did not the bees in the Neighbour's hive take to the supers? Do you think, as I imagine, that we put on the supers rather too early? The bees,

however, went up into them, and filled them, but did no work; but when the bees swarmed the first time they left them quite empty, and I found a little bit of comb at the bottom of each glass, of which there were three. Are Ligurian queens desirable? Could I take the honey from two common straw hives, and put the bees in a bar hive, adding to them a swarm which came off to-day and another which I expect soon? and when would be the right time to do so? I do not like killing the bees to take the honey. Would it be well to add any more bees to the swarm in the bar hive: a second swarm, or one lot of the old bees—that is, a swarm of last year? One of the straw hives has swarmed twice, and the other once, and this is the one that I expect will again. I have three or four times had to straighten the comb on the bars, how is this to be obviated, for the bees do not seem to care about building straight? Of course when I see to it I am attacked accordingly. I weighed the bar hive before I tried to unite the swarm, and it had gained nothing, so that I conclude the inmates must have killed all the new comers. Is it necessary in catching a swarm of bees to smear the inside of the hive with syrup of some sort? Have the Neighbour's cottage hives enough ventilation, for the top only ventilates the supers? Do bees dislike large glass windows in the sides of their hives, with a door to keep the light out? How far do bees generally go to fetch honey? Does taking out the bars to look at them injure the young bees? and how long does it take to hatch out brood? Will this year's swarms have any young bees before autumn? Is there more than one sort of common bee? I do not mean drones but workers, for some hives seem to have larger bees than others.—G. J.

P.S.—Do any drones go off with second and third swarms?

[We can scarcely tell why the attempted union turned out so complete a failure. Another time and under apparently precisely similar circumstances you may be equally successful. The use of a little smoke, and sprinkling both lots of bees with syrup scented by the addition of a little peppermint water would render future success more probable. The queen of a second swarm not being fertilised would be of little use to an expert, to you she is of no value whatever. A light colour is the best for hive covers. If the supers had been furnished with some pieces of clean comb the bees would have been more likely to have taken to them. We have no doubt as to the superiority of Ligurian queens. The best time for driving the bees and taking the honey from your two common hives would be three weeks after the issue of the first swarm in each case, as all the brood from the old queen (with the exception, perhaps, of a few drones) would then be hatched out, whilst the young queen would scarcely have commenced egg-laying. If the inhabitants of the two hives do not form a sufficient population, you may add a swarm, or perhaps we should rather say, add them to a swarm, as the best way would probably be to drive them at once from their own hives up into that containing the swarm. We always superintend the formation of combs ourselves by examining them occasionally whilst in progress, and correcting irregularities as they arise. We should not at this time attempt to add more bees to the hive which has evinced so decided a disinclination to fraternise with the reinforcement you have already offered to it. Smearing the inside of hives with honey or syrup of any kind is, we believe, quite unnecessary. Extra ventilation when necessary may be given to storied hives by wedging up the supers about the eighth of an inch, as well as by raising the front of the hive itself a little from its floor-board. Large windows are great evils in bee-hives from their tendency to promote the condensation of internal moisture. We believe from a mile to a mile and a half to be about the limit of the profitable flight of the bee. Workers mature in about twenty-one days, and a hive containing a swarm of this season will be left in the autumn almost entirely in the possession of young bees bred since it was tenanted. There is but one kind of hive bee indigenous in this country; any variation in the size of workers is, therefore, accidental. Drones generally accompany both second and third swarms.]

### SUPERSTITIONS ABOUT BEES.

SOME time ago a man brought a second swarm of bees to my employer's apiary. When about to leave them he tapped the hive and said, "Bees! bees! I have brought you to work for a new master; be industrious." I asked him if he thought the bees could understand him, and he said he always did it;

also, that it is the custom when any one of their owner's family dies to tell them, or else they would die too.

I laughed at his notions, thinking it was an exceptional case, when next day another man told me much the same tale. I asked him for a proof of his theory, for although he had told his bees his father was dead, they all died.

He said that if the bees settled on dead wood it was a sign of some one in the house dying; and that it brought bad luck to sell the bees unless for gold; but his father sometimes exchanged his bees for a small pig.

To Mrs. A—, an aged matron, I said, "You have more sense, I hope, than to think there is anything in telling the bees if one of your family die?" "Why, I should expect them all to die," she replied, "if I did not do so."

Another man had two casts, and I recommended for them liberal feeding. "Oh, he said, a small bit of lump sugar as large as his finger nail would last them two or three days," so he backed his own opinion, and gave them the "small bit." His bees went to sleep in the winter, and he looked for their waking again, but to no purpose—they were dead.—M.

P.S.—A super in my employer's apiary, 6 inches in circumference, has brood comb in it this season. I have never seen such a case before. The hive is a flat-topped straw hive.

### FEROCITY OF INDIAN BEES.

The following instance of the ferocity of the large Indian honey bee, *Apis dorsata*, is related in a recent number of "Kind Words:"—

"Having failed to observe some nests of bees in the clump of shady trees under which our camp was pitched, they were disturbed by the smoke of a fire our servants had made to cook by, and at once turned out by swarms, attacking men and animals, especially our horses that were picketed in a row close to our tent. These poor beasts began to kick and plunge fearfully, so, thinking to give them a chance of escape, I ran towards them and cut their head and heel-ropes with my large hunting knife, getting well stung while so doing. But the horses, being now free, instead of at once running away as we had hoped they would do, began to fight with each other in the most fearful manner, being all, no doubt, perfectly maddened by the stings of the bees (myriads of which were flying about), they reared, bit, and kicked each other most desperately, till at last, becoming entangled in the loose ropes by which they had been tethered, all five horses were rolling on the ground together, making a terrible noise and dust. The bees now attacked me so badly that I was obliged to leave the horses and run for it, which I did, followed by a swarm of bees, until a stump tripped me up, when they punished me fearfully, although I had a soldier's great-coat on at the time. One of our goats passed me crying piteously, with a swarm of bees about it. This poor goat died then and there from the stings, after going a few yards further. We had next to catch the horses. These poor animals were much swollen all over their bodies, for these wild bees are very large, and stung far worse than the common English bee. When one nest is disturbed the other swarms in the neighbourhood seem to also turn out to their assistance.

"On a very large tree, not far from this spot, we counted eighteen bees' nests, each about 2 feet long by about 15 inches broad. Up this tree were the marks of bears' claws distinctly visible, for bears are in the habit, at night, of climbing up after the honey, of which they are very fond. The *beets*\* declared they had seen one, by moonlight, seated along a branch clawing down these nests with both paws, and greedily swallowing bees, wax, honey, and all, seeming quite proof against their stings. It was very usual to find marks of where bears had climbed trees on which were bees' nests, so this account seems likely enough to be true.

"The bees had disabled me, robbed me of my sight for a time, and laid me on my back with fever."

### OUR LETTER BOX.

[N.B.—We are very sorry some of the following answers have been delayed, having been accidentally misplaced.]

COCHIN-CHINA HEN'S HEAD SWOLLEN (*A. L. Z.*).—We have seen no such swelling of the head to twice its natural size as you describe. She has, perhaps, been stung by something. We should bathe it freely with cold water, and should bleed at the root of the comb.

\* Native hunters.

CHICKENS DROOPING (*M. A. H.*).—Remove your chickens to fresh ground, provide them with heaps of dust or road grit, and mix a little black sulphur with it. Feed them for a short time on stimulating food, till they get over their troublous time. Growing the crown and tail feathers are the "children's diseases" of chickens.

WHITE CRÈVE CŒURS (*X. Y. Z.*).—We have not seen any white Crève Cœur fowls, nor do we know of any. We therefore consider those you name a freak of nature. We are not surprised at it. There seems to be a tendency in all black animals to throw white produce at times—Spanish fowls for instance. As we sit writing we can see two hens with as much white as black in their plumage. The young of the Silver-Grey Rabbits are born black, yet in almost every litter there is a white one. All breeders of black poultry know how common these freaks are. Black Cochins "went out" because no one could obtain a really black cock. A close examination of any cock of a black breed will almost always result in the discovery of red, yellow, or white feathers. In the case of the Crève Cœur this circumstance is not so remarkable, as, although white feathers are not desirable, they are not disqualifications.

SWOLLEN CROPS (*Old Subscriber but Young Poultry Woman*).—It is difficult to give the cause of the "hanging crop." It is common to all breeds of fowls. We have Spanish, Dorking, Crève Cœur, and Brahma with it. It is not by any means desirable, but neither does it detract from their utility. It shows only at this time of year, when the plumage has become old and scanty. The treatment is to feed sparingly, and to confine the birds where they can be kept from all water, except a little, which is absolutely necessary, three times per day, when they should be allowed to drink a little, but the water should not be left within their reach.

CHICKENS WITH DROOPING WINGS AND BLIND (*W. T.*).—Your chickens have been suffering from that which we must call the epidemic of the season. Our chickens have had the same, but it has not been fatal. We have washed the heads, eyes, and nostrils with vinegar and water, and we have given camphor internally, and have put it in their water. We have not lost one in twenty, and many cases which we thought hopeless, and put away in what we term our hopeless ward, have entirely recovered. The chickens that are visited with this complaint, seem to grow only in the head, which becomes, or appears to be, too large for the body; the beak appears long and sharp, and the eyes large, but after a time they go on and almost recover the lost ground.

IMPARTING A TAINT (*M. R. B.*).—A Cochín-China cock cannot taint a Cochín-China hen from his having been with hens of another kind.

GAPES (*A. J. P., Sibertwood*).—Your chickens seem to have the gapes. Treat them as directed for that disease in our last week's Number.

RATTLING IN THE THROAT OF CHICKENS (*Cochin*).—If it arises from excess of mucus, as it probably does, a diet of soft food only, with bread soaked in ale once daily, and abundance of lettuce leaves, will remove the annoyance.

TURKEY COCK PARALYSED (*W. H. R.*).—The bird must be well and thoroughly purged. He must be kept clean, and when the evacuations become natural—that is, white and green, you may then resort to stimulants—bread steeped in strong ale, and camphor both in the food and water.

VALUE OF PEACOCKS (*A. M. J.*).—Peacocks have varied much in value of late. At present, as they will be moulting, they are worth little—perhaps about 15s. each. They will be worth more in the winter. Hens are not saleable at present. Chickens are too young to sell at a fortnight old. When a little older they are saleable poultry. Write to Baily, 113, Mount Street, Grosvenor Square. If your Pea Fowls are not of the common sort they are at any time saleable. Baily will buy them.

USE OF THE WHITE AND YOLK IN FORMING THE CHICKEN (*J. H. Y.*).—Both are essential for the formation of the chick, and the process of the formation is thus epitomised in "The Poultry Book," first edition. "The yolk is lighter than the albumen, and hence it always floats to that part of the egg which is uppermost; and the lightest part of the yolk is that occupied with the vitelline. From this circumstance the germ is always near the warmth of the old birds. To keep the germ from coming in contact with the shell, and to prevent its being bruised, there is, on each side, a tough, spiral, and highly elastic filament, which is attached, at one extremity, to the membrane covering the yolk; it then passes through the white, and is fastened at the other to the membrane of the albumen. These are called chalazae. These cords allow a layer of albumen to lie between the germ and the shell. During incubation, the albumen disappears before the yolk. The reason of this is very interesting. About four days after incubation has commenced an admixture takes place between the two. In the hen to the thirteenth day, in aquatic birds a few days longer, a part of the albumen lies at the bottom of the shell, in a gelatinous thick state. This is opposite to the chick, and more or less attached to the yolk. About the fourth day of incubation the yolk changes colour, becomes paler, and alters in shape. If the contents of the shell be examined carefully, by being turned out, a white circular line will be found at the lower part of the yolk. The space within this circle becomes pale, thin, and undulated, and it is finally ruptured. Through this opening the white enters, and mixes with the yolk. The dense albumen spoken of before closes up the opening as a valve, by which ingress alone is allowed. This may be best seen about the fourteenth day. Afterwards the opening gets smaller and smaller, as the albumen decreases, and is finally closed. Around this opening is arranged a wreath of blood-vessels."

SENDING BLACKBIRDS AND THRUSHES TO NEW ZEALAND (*John Stuart*).—Take the young birds from the nest when they are tolerably feathered, but not so old but that they will open their mouths to be fed. Make a paste of ground oats with water, add a little sharp to prevent its being sticky, also a little cheese mashed up. This food can be made fresh every day, and will do to rear them on, and to feed them with during the voyage. A dozen pairs would require a cage 6 feet long by 2 feet high, and 18 inches wide; but if the birds were kept very clean and allowed to wash their feathers, they would do with less room. The perches should not cross each other, nor overhang. A little fine gravel for them to peck at occasionally would be useful, as well as a few grocer's currants for the Blackbirds. Cochín and Brahma eggs if taken a long voyage should be packed quite fresh in air-tight jars. Wool, I should think, would be the best packing, as it would resist the changes of temperature, as the eggs should not be allowed to get too hot nor too cold. The box should be hung up in a cabin, not put into the hold. We do not know what has been the result of any trials of hatching after so long a voyage. Perhaps some correspondent may be able to inform us.—B. P. BRENT.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 74.6°; and its night temperature 50.7°. The greatest heat was 92°, on the 25th, 1841; and the lowest cold 35°, on the 30th, 1863. The greatest fall of rain was 1.39 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

BEDDING PELARGONIUMS.

VALUABLE hints on the requirements of the present day have again been thrown out by Mr. Robson, and although there is at the present time an endless variety of bedding

Pelargoniums, he has very justly said that they do not come up to the desired standard. Many of those raised by our late friend Mr. Donald Beaton, although novel in colour, do not possess that neat habit so necessary in the bedding Pelargonium. His great triumph in that class, I consider, is Stella, although there are several others of great merit; for instance, Cybister, Spread Eagle, and Black Dwarf. The last, I think, will prove to be one of the very best of his last batch of seedlings. The varieties which are the most novel in colour are also, unfortunately, too strong in habit and much too rampant to be retained as bedding plants. We possess, however, in the varieties named beneath some magnificent shades of colour, and having obtained these, as Mr. Robson very justly remarks, the habit can easily be secured.

In Alexandra we have a beautiful reddish claret; in Glowworm, a rich shade of crimson; whilst Black Dwarf presents a fine mass of dark velvety crimson. The trusses of this variety are very large and compact, producing a very dazzling effect when placed in juxtaposition with other suitable colours. Amy Hogg is also of a very pretty shade of colour, and is a most useful variety for pot-culture and conservatory decoration, presenting to the eye immense trusses of rose-coloured flowers of fine form and substance. Amy Hogg is certainly a gem of the first water under glass, where it may be said to reign supreme; but in the open ground it will not bear the variations of temperature. There the magnificent trusses of bloom become smaller and less in number as the plant gains vigour, and the foliage increases both in size and quantity, until at last the fair Amy, if she were permitted to stray from her regal palace, would disdain to own her more unfortunate sister who has to bear the inclemency of the weather in the open ground. In the variety called Indian Yellow we have another rich and valuable shade, although the yellow is at present invisible. It is, nevertheless, an invaluable acquisition for conservatory decoration; but when planted out in the open ground, like the preceding it grows too freely, and the proportion of foliage is too great for the quantity of bloom; its habit is also bad, but when the roots are confined in pots it forms a fine object when trained against a pillar or wall in a conservatory. Orange Nosegay is another variety valuable on account of its colour, but, like the foregoing, too rampant in its habit. I have obtained from this some varieties of fine habit by crossing it with

P. hybridum and a variety which I raised about three or four years ago, and which I had the pleasure of naming Robert Fish. These plants are very dwarf in habit, and produce very large trusses of bloom on straight upright footstalks well above the foliage, which is deep green, smooth, and glossy. In colour the flowers, too, are several shades brighter than Orange Nosegay, and the trusses are larger and more compact than those of that kind. Certain of these seedlings will, I think, satisfy some of Mr. Robson's wants, and stand the ordeal of criticism.

I think that I have also anticipated Mr. Robson's wishes by producing various shades of magenta by crossing some of my best seedling Nosegays with the Zonale section. One seedling which I have this season is remarkably good; it is in colour a beautiful cerise-shaded magenta, with a truss the very counterpart of Amy Hogg, from which it was raised. The individual flowers are also of fine shape and substance, and the habit of the plant is all that could be desired; it has also neat, light green foliage, and by its flowering in a very young state, I have little doubt but that it will be a very profuse bloomer. This, with hundreds of other seedlings, is now showing bloom in great profusion, although the seeds were only sown in the second week in January of the present year. They have all had their tops taken off and struck, and it is the plants thus propagated that are principally flowering first. Many of the most promising have been beheaded the second time, and are now nice plants showing bloom-buds freely. I have also this season what I shall call a liliputian race of bedding Pelargoniums; these are all very close and compact in habit, and bear large trusses of finely-shaped flowers. They belong to another section obtained by crossing the double varieties with the Zonale kinds, and promise to be great acquisitions. The foliage is of great substance, and the flowers exhibit a great advance in size and form.

I now come to the Tricolor and Bronze-foliaged section. Here the double varieties sent out last year have done me good service; for plants so remarkable for the beauty of their foliage I have never seen. I have also little doubt that many of them will produce double flowers as well. These have not yet flowered. By crossing the Tricolor section with the pollen of the double varieties more substance has been thrown into the foliage, and the markings are, consequently, more definite. Besides, the foliage being so much thicker the plants will be enabled to withstand the frequent variations of temperature to which we are so often subjected; there is also a greater proportion of green in the centre of the leaf, which sets it off to much greater advantage, and enables it to stand the hot rays of the sun without injury.

The varieties produced by the double kinds, fertilised with the pollen taken from the Bronze section, are also remarkable for the beauty of their foliage, which is very large in the case of some of the plants. These, for distant effect, will be very fine; I can conceive nothing more beautiful than large plants of these dotted about here and there in suitable positions amongst subtropical plants. The magnificent tints of colour exhibited by their foliage would produce a charming effect along with other plants

possessing only the natural tints. The varieties from which the pollen was taken were all planted out in the trial-ground at Chiswick last summer, and received the highest awards of the Floral Committee of the Royal Horticultural Society. Their names are Circlet, Gaiety, President Lincoln, and Beauty of Oulton. The last-named is certainly the finest bedding Pelargonium which I have ever raised before the present season, and I predict for it a long and brilliant future. It is in the present season in this cold, wet, and smoky climate even more beautiful than it was at Oulton Park or at Chiswick last year. Its habit is everything that can be desired; it is remarkably free in growth, is very easily kept through the winter months, and can be propagated very rapidly. As an instance of this I may state that I only sent six small plants of it to Chiswick last year, and that there, under the able superintendance of Mr. Barron, upwards of two hundred fine plants have been obtained from them.\* It can be propagated all through the winter months if the cuttings are placed in a nice airy temperature. The ease with which varieties of this section can be propagated and kept through the winter months gives them a great advantage over the Tricolor section, of which Mrs. Pollock is the type. A large bed of Mrs. Pollock in the flower garden here bears no comparison in point of beauty with Beauty of Oulton, although both varieties are so distinct in character that they may be planted side by side with good effect. I should not venture to say so much in praise of one of my own production, but that I feel sure that what I have stated will be borne out by others when they shall have seen the effect which Beauty of Oulton will produce in this and future seasons.

There is also another section which will prove an important addition for the decoration of the flower garden. One of the best of these varieties—namely, General Longstreet, is of fine habit, and has bright golden leaves and large compact trusses of deep scarlet flowers. This is a great improvement on the well-known Golden Fleece and Cloth of Gold. By crossing Stella with pollen taken from General Longstreet I have obtained a beautiful golden Stella, with a habit more compact than Stella, and the truss rather closer to the foliage, which I consider is an advantage. The only fault I find with Stella is that the fine trusses of bloom are too high above the foliage, too much of the flower-stalk being seen between the flowers and the leaves. The next variety operated on was Christine; pollen taken from General Longstreet was used in this instance, by which means I have obtained a golden Christine. The plant is of exactly the same habit as the old Christine, but has beautiful yellow foliage, and rosy pink flowers, the latter forming a nice contrast with the yellow leaves.

Pollen from General Longstreet was also used for fertilising some blooms of the very dwarf and compact bedding Geranium known as Little David, and the result in the first season was a plant the very counterpart of that variety in habit and profusion of bloom. In the following year this was crossed with pollen taken from Christine, and a beautiful dwarf plant was obtained, having nice golden foliage and pink flowers the exact colour of Christine, and borne in great profusion well above the foliage. The plant does not grow more than from 4 to 6 inches high. Two great novelties in this section have just unfolded their beautiful petals to my admiring gaze—they are a golden Cybister and a golden Spread Eagle; in the former the flowers are of wonderful substance, and the truss promises to be very large and compact, whilst the foliage is also very beautiful, having a dark zone on a yellow ground.

I must here thank Mr. Robson for the valuable suggestions which he has made, and I shall use every endeavour to supply the wants which he points out. He is quite right; there is certainly a very wide field yet left for the hybridiser, although we appear to have brought the Pelargonium to the highest state of perfection. I had already contemplated the possibility of an advance in the Ivy-leaf section, and I cannot perceive why gold, silver, and tricolor-leaved varieties should not be produced in this as well as the Zonale class. With that object in view I shall at once procure the materials for a start, and hope to report a favourable progress next season.

Whilst writing on bedding plants I would direct Mr. Robson's attention to *Viola cornuta*. Each season with me its beauty and usefulness increase, and it is at present magnificent. No

amount of rain or sunshine appears to impair its beauty. If Mr. Robson does not already possess it he must lose no time in procuring it.—J. WILLS.

## DWARF FRUIT TREES AND ORCHARD-HOUSES IN AMERICA.

DWARF or quince-rooted Pear trees have been propagated and sold to an immense extent in the United States, but until we received the instructions of Mr. Rivers's "Miniature Fruit Garden" the results obtained from such trees were generally very unsatisfactory. Large pyramids, grown on Quince roots, in rich soil, without summer pruning, were either barren for many years, or, if fruitful, soon became sickly. It was literally growing standard trees, in point of size, on Quince roots. We now understand that a dwarf tree should be kept in size a dwarf tree by summer pruning, and should be maintained in vigour by high culture.

The effect of the Quince root upon a Pear tree is evidently something like the process of "ringing" upon a branch. It checks the return flow of sap to the roots by the difference in the texture of the Quince and Pear wood; and hence, while it makes the tops of the trees grow luxuriantly, and produces larger and finer fruit, it in reality checks root-growth, and enfeebles the tree. I feel assured that the roots of a dwarf Pear tree on Quince roots do not grow so freely as the roots of a Quince tree on its own stock. Hence it is evident that dwarf bush culture for dwarf Pear trees is far preferable to large pyramids on Quince roots. Millions upon millions of Quince-rooted Pear trees have been planted in the United States within the last fifteen or twenty years; but very few, so far as I know, have produced any profitable results, except such as have subsequently rooted from the Pear stock. Large numbers of dwarf trees are still in existence, however, which are supposed to be still on Quince roots—trees of very large size, prolific and healthy, and upwards of thirty years old; but these are mostly in small private gardens, in rich soil, and well protected from cold winds and other adverse influences.

The chief points in dwarf Pear culture seem to be to ascertain what Pears will thrive best and produce fruit of the highest quality on Quince roots in a given soil and locality, and then to plant closely, and keep the trees down to the "miniature" bush form and size, cultivate well, thin the fruit, and seek to obtain fine specimens only. This I understand to be the Rivers method of dwarf Pear culture, a system which is very rapidly making its way in America. English editions of the "Miniature Fruit Garden" have been imported here for many years, and may be found in the hands of all our most intelligent cultivators; and quite recently an American edition has been published.

I have an orchard containing upwards of 20,000 dwarf Pear trees, which were formerly pruned on the old pyramidal system, but which I have now brought under the system of bush culture, by summer pinching and pruning, with the most gratifying results. My trees are planted in rows 5 feet apart, and from 2½ to 5 feet apart in the rows. We cultivate the spaces in one direction with the plough and horse-hoe, or horse-cultivator, and keep the other spaces clean with the hand-hoe. No grass is permitted to grow in the entire orchard. The plantation was commenced about eight years ago, and the larger portion of the trees is just now coming into bearing.

We have but little difficulty in ripening wood or fruit in the climate of Philadelphia, which is quite as warm in summer as the south of France. Indeed, we have intensely hot, bright, dry summers, and suffer more from excess of sunlight than from want of it. Our atmosphere is also too dry to grow certain Pears in perfection. Many Pears are attacked with black spots (fungus), and crack so as to become worthless. Transplanting and root-pruning are here hazardous operations, while mulching is exceedingly useful. We are much troubled with the quince-borer (*Saperda bivittata*), with the bark louse or scale (*Coccus*), and with the curculio or plum weevil, which last insect punctures and disfigures the Pears very much, but does not cause them to drop. The borer and the curculio, I believe, you do not have in England. The summer pear blight or fire blight (not the American blight), which prevails to a fearful extent in the more northern parts of the United States, is not so prevalent here, though cases do now and then occur. The root blight in dwarf trees, I think arises from want of proper or healthy root-growth. A great many Pear trees never make a healthy union with the Quince.

\* I have heard from a reliable source that the finest lot of bedding Geraniums for health and beauty ever seen, have been grown at Chiswick this spring.

Orchard-houses have been erected very extensively upon the Rivers plan in the middle and northern States of America; but the results have not been very satisfactory in a majority of instances—not because this method of cultivating fruit will not succeed here, but because it is not so much required by the exigencies of our climate, and because fruit is so abundant and cheap, and the orchard-house is too expensive for us. Only a heated or forced orchard-house is of any value so far as the sale of fruit is concerned. In a cold or unheated house, the trees are apt to be over-stimulated by the hot bright sunshine in February and March, and chilled and frosted in April. Besides, we cannot ripen Peaches and Nectarines in our orchard-houses until very late, unless we remove the pots into the open air as soon as the fruit begins to colour. We lose time and flavour by keeping the pots in the house till the fruit is fully ripened.

The orchard-house is highly useful as an appendage to a gentleman's garden to grow Plums, Nectarines, and Apricots, which can only be had with certainty and in perfection under the protection of glass, on account of the ravages of the curculio (or plum beetle), which out of doors ruins all these fruits. Even Peaches do not escape injury from this cause, and Cherries are here totally destroyed by this insect. Very free ventilation is not quite so much required in orchard-houses here as in England, as our atmosphere is usually so very dry; on the contrary, wet paths and evaporating-troughs to maintain a high degree of moisture are more needed.

The cordon plan of pruning on single stems, and on the branches of bush trees, is beginning to be practised in the United States, and is gaining favour very rapidly. It is a curious fact that the plan of making cordons by summer pinching was invented in the United States by Captain Austin, of Boston, and put into actual practice on a large scale sixteen or eighteen years ago. The trees were grown with five or six cordon branches rising from the main stem, the central shoot or leader being cut out at a distance of 3 or 4 feet from the ground. Captain Austin called his method the wine-glass pattern. He now has trees fully and precisely grown upon the cordon plan sixteen or eighteen years old; indeed, I think they have been fruiting for nearly that length of time. He certainly commenced the system long before anything had been published on the subject in France, and an account of it appeared in "Hovey's Magazine" at Boston as an original discovery several years ago.

The curate's vinery, or ground vinery, is now much talked about, and I have introduced half a dozen of them into my garden on trial this season. We are apprehensive that they will not answer without much modification in management, on account of our intensely hot sunshine in summer.

Thus it will be perceived that we are under many obligations to the author of the "Miniature Fruit Garden" and the "Orchard-House" for useful hints on fruit-culture, which are now being applied on a large scale, and soon will be universally, I think, in America. Large orchards and fruit-houses are now managed on the Rivers plans; the Rivers books are being republished in America; and hundreds of cultivators, I am sure, like myself, watch with eagerness for the genial and instructive articles from the Rivers pen in THE JOURNAL OF HORTICULTURE, which is taken by many of the leading cultivators in America, and by all the principal horticultural societies in the United States.—J. S. HOUGHTON, Philadelphia, U.S., America.

#### LORD CLYDE STRAWBERRY.

In M. Van Houtte's catalogue, No. 108, page 97, the above Strawberry, as raised by Mr. Dean, of Shipley, was recommended upon the authority of Mr. Radelyffe as being "the most valuable Strawberry ever known," uniting three eminent qualities—"exquisite flavour, large-sized fruit, and exceedingly prolific." I am sorry to find that this kind is nothing else than the old Chinese Strawberry, in France commonly called Ananas, or Ananas de la Halle, a sort long ago rejected as not worthy of cultivation, producing a prodigious number of leaves, and runners in any quantity, but scarcely any fruit. I procured plants from parties who had them from M. Van Houtte, as well as from Mr. Dean, and they both turned out alike. I think the horticultural world has never witnessed a greater mystification.—FERDINAND GLOEDE, Les Sablons, Seine et Marne.

[What Mr. Radelyffe said of the Strawberry is contained in this paragraph of our Journal, published July 5th, 1865:—

"As regards Lord Clyde, I had only two plants of it, and being under a hot south wall, the blooms happened to come out early, and were destroyed by a very severe frost. I was amused at M. Van Houtte's very flattering notice of me in his catalogue. He says of me, 'He is the most experienced and best judge of Strawberries in England.' 'He is the most caustic and picturesque writer, sparing no one; neither in prose nor in verse.' 'Till this great judge says, "To be or not to be," raisers are in a state of the greatest anxiety.' I can only say that 'from the sublime to the ridiculous there is but a step.' What I said of Lord Clyde and John Powell was this:—'They were the best novelties here, and were rich and good.' We happen to know that Mr. Radelyffe did not find Lord Clyde answer, but that he still cultivates John Powell."]

#### VARIEGATED GERANIUMS.

Ma. J. WILLS, of Hantroyde, sent a paper on the raising of variegated Geraniums to the Botanical Congress. In that paper he maintains chance impregnation as being the cause of sports in seedling Geraniums, but this theory is so opposed to my own experience that I wish to call attention to the subject. Any fact in connection with the hybridisation of plants is so interesting, that I hope those who observe such will report them.

If I understand Mr. Wills's paper, he intends to say, that if two variegated Geraniums—say Mrs. Pollock and Sunset, to name two well-known varieties—he crossed and all other pollen excluded, the result will be seedlings variegated and halfway between the two parents, but that if other pollen have access to the flowers the result will be some green, and some partly green and partly variegated; also, that if extraordinary precautions be not taken the latter result is inevitable, the air being charged with pollen; and lastly, that however performed and whatever precautions may have been taken, the result is not satisfactory if much electricity happens to be in the atmosphere at the time. What a convenient thing electricity is! Too much or too little will account for anything. Do your crops fail? are they unexpectedly good? are they diseased? do your seedlings sport? do your single flowers produce double flowers? or your double flowers turn single?—the cause is too much or too little electricity in the atmosphere.

Well, I shall not attempt to disprove the theory that the strange chemical change, if it be chemical, which has turned our dark bronze Zonale Geraniums into pink, crimson, and scarlet, is dependant, or not dependant, on a deficiency of electricity, but proceed to examine the pollen question.

According to Mr. Wills the air of a house in which Geraniums are growing is so impregnated with pollen that he uses the expression—"I am sure the house was very much charged with pollen." How was he sure? Could he see it, or smell it? How did he appreciate its presence? If the air of a house in which Geraniums are growing be so loaded with diffused pollen, almost every bloom in the house ought to produce seed. Is this the case? The old Rose Christine, Bendatler, and many others will seed anywhere, but as they seed freely when grown alone it is manifest they are self-impregnated.

I have in one of my houses two shelves at the south end, each holding about twenty plants of the best variegated Geraniums. One lot has been carefully fertilised every morning, and every plant is full of seed; the others have been left untouched, and though the kinds are the same as those seeding freely, there is not one pod of seed formed on the twenty plants. Diffused pollen has not been very active in my case. Having had one house 100 feet long and 24 feet wide full of seedling Geraniums this year, besides some hundreds more which it would not hold, I have had some experience, you will say, in this matter, but I have failed to reduce to a certainty the breeding of fancy varieties, though very well satisfied with the result.

It appears to me that after crossing to the best of your judgment your chances are in proportion to the number proved, whether new fruit or flowers be your object. Of course, the raiser of a dozen seedlings may obtain a better variety than he who grows thousands; but victory generally follows the strong battalions.

When Mrs. Pollock was first sent out I crossed it with Woodwardiana, the produce were all green Zonales; one of them with bright orange scarlet flowers I called after a neighbour, William Underwood, and sold at 18s. per dozen. Though this was raised three years ago, and one of about a dozen seed-

lings it is superior to every kind now flowering here, and I have such a number of varieties that they are quite bewildering. In breeding for tricoloured foliage, I find that some seedlings come up quite white and die, some are variegated from the first, and some which are quite green for six months become variegated afterwards, whilst a large proportion are permanently green.—J. R. PEARSON, *Chilwell*.

### WELLINGTONIA GIGANTEA PLANTING.

THE Wellingtonia is a tree that will mark an era in the history of our planting and woodlands. Mr. Robson, with his usual practical attention and discernment, has drawn attention (see page 467), to the planting of this tree, and other matters which deserve the attention of the planter. Mr. Robson has left little for me to say, further than to confirm what he has so well stated regarding the risk of transplanting large Wellingtonias.

Seeing that a few years will bring the smallest healthy plant of this mammoth tree to a size to gratify the eye, and give new effect to the landscape, it is little to be regretted that large plants do not remove successfully. About four years ago I assisted a gentleman in laying out a piece of pleasure ground, in which Wellingtonias were to be a feature. Contrary to my advice large plants were purchased; at least one-third of the plants died, and last autumn the best of the survivors had not made more than 2 feet of new growth.

In June, 1863, four seedling Wellingtonias were planted at Woodstock Park (Ireland); their height at the time of planting ranged from 10 to 16 inches, and they had an abundance of roots, having been transferred from the seed-pot to turf sods on an open border, and twice transplanted. On the 6th of July, 1866, the respective heights of the four trees were as follows:—No. 1, 10 feet 2 inches; No. 2, 9 feet 3 inches; No. 3, 10 feet 11 inches; No. 4, 8 feet 3 inches. The average spread of the branches was 7 feet, and the circumference of the stem of the best tree at 6 inches from the ground, was 1 foot 7 inches.

The trees referred to are growing on a stiff clay slate, which was dug out of a cut from 6 to 10 feet below the surface level, and carted to where the trees grow, in order to widen the ground to correspond with an avenue line. This I state with the object of showing that the Wellingtonia will thrive on the worst of tree soil if allowed depth.

The Wellingtonia, like its rival in style of growth, the *Cryptomeria japonica*, will only be a scrub on dry ground. The tissues of the Wellingtonia, as may readily be inferred from its nature, are immensely large, and it rapidly forms gigantic roots. Some of the best roots of the best tree here, which was killed by fungus two years ago, were upwards of 6 inches in diameter. Such tissues and roots are important considerations in transplanting young trees, much more those of large size.

I have frequently observed that, when the Wellingtonia was in the height of its growth, a few cold days would cause the young shoots to shrink, and in a short time afterwards they appeared as if blighted.—CHAS. McDONALD.

### SYNONYMES OF FRUITS.

YOUR correspondent "FRUIT GROWER" should buy that excellent work "Hogg's Fruit Manual." The author could not well recommend it. Its usefulness, however, should be made known. The descriptions of various fruits are truthful, so far as I know anything about them. One great use of the book is the statement of the various synonymes under which the same fruit tree has been sold.

Grosse Mignonne Peach: the synonymes of this are Avant, Early Purple Avant, Early Vineyard, Forster's Early, French Mignonne, Grimwood's Royal George, Johnson's Early Purple Avant, Neil's Early Purple, Padley's Early Purple, Ronald's Galande, Royal Kensington, Royal Sovereign, Smooth-leaved Royal George, Superb Royal, Grosse Mignonne Veloutée, Grosse Mignonne Ordinaire, Hâtive de Ferrières, Mignonne Veloutée.

Royal George Peach: this has seven synonymes. Bellegarde, which is the same as the French Galande (the Violette Hâtive being the same as the English Galande), has five synonymes. I beg to make a remark here. We began with "Grosse," and this excellent and most laborious book will show you the "gross" frauds to which you will be subject without such a guide.

Nectarines: the Early Newington has five synonymes, Elruge has five synonymes, Violette Hâtive has nine synonymes. The last two are two of the best Nectarines. There are many other Peaches and Nectarines which have synonymes. It is not necessary to go through an elaborate work of 414 pages, written on kinds of fruit by such an acknowledged authority, but I can conscientiously recommend it, and advise all who wish good fruit-information, and who do not wish to be imposed upon, at once to procure it.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

### ROSE CULTURE.

ALTHOUGH strictly an amateur, and having my time much occupied, I venture to express my surprise that Mr. Abbey should speak of "the Dog Rose or Briar" in a way that will lead a novice to think all Briars are alike, and that one experiment with one sort, or with any one variety of Rose worked upon it in a given soil, is conclusive.

Of course there are good and bad—that is, weak and strong, or clean and scrubby Briars, but there are more than this: there are varieties of Briars, some much more thorny than others, and I think some discrimination can be used in selecting suitable stocks for Roses of peculiar habit or character. An amateur can choose his stocks for grafting or budding one by one, and if the nurseryman cannot do this he could sort them into distinct parcels and plant them in distinct "pieces," and then use them with discrimination. The colour of the bark will show a red stock from a white stock; and, again, the thorns more or less thickly crowding the stem will enable the grafter to judge which to take for very thorny Roses, such as Madame Damage.

I grow all varieties, except Tea-scented China, with success on the Dog Rose in light soil not very favourable to Roses—at least I have good plants ranging in age from ten to fourteen years. Suckers will destroy them speedily if not removed; and for this reason, and for another potent reason in light soil, keeping them at home, with the ground necessarily much enriched—the plants must be lifted, and wisely root-pruned as well as head-pruned annually or biennially with a bold hand; and if any amateur on light soil lose heart at enjoying only partial success by adopting this treatment, I confidently say, Persevere. This custom of lifting will generally retard the date of blooming, as pruning the heads cannot be done until the head shows healthy signs of life. To this there may be one exception, and that is Noisettes; they may be "fixtures" if root-pruned and refreshed with turfy loam and well-rotted dung every year. If the plan above recommended is faithfully followed on open soil in open situations, there can be no possible question of success, but in proportion to the neglect of it so will be the proportion of failure.

As to the Manetti stock it is my firm belief that its value is for the nurseryman, and not for the amateur; not only amateurs themselves, but their gardeners—seventy-five per cent of them—will allow the Manetti thief to rob the Rose, the suckers so artfully intertwine themselves with the foliage and shoots of the graft.

On their own roots many valuable sorts both Hybrid Perpetuals, Bourbons, and Teas, will thrive, and will not thrive in any other way; and these are what are called "weak," "dwarf," and "robust." For Hybrid Perpetuals I will instance Cardinal Patrizzi; for Bourbon (an old and good Rose), Julie de Fontenelle; and for Tea, Louise de Savoie—but, with me, while these will do well, General Washington (H.P.) is inferior on its own roots, and my belief is that many sorts of strong-growing Hybrid Perpetuals and Bourbons, when established on their own roots, rapidly degenerate in quality and character—that is to say, in size and perfection of form. It is the former treatment on the Briar which affords the best opportunity of preserving the merits of every esteemed Rose. Without the curb, combined with good living, the best of us are sure to run to waste.—CHARLES ELLIS.

### FIFTY CUT ROSES.

I DARE say the framers of the Jersey schedule meant trusses with buds and numbers of expanded Roses; still, they did not so word it. Perhaps the following would put an end to misapprehension in future—"Fifty trusses, with buds or any number of expanded Roses. A single bloom to count for a

trass." I am not aware of being hard on the Jersey rosarians; but if what I said has given that impression, I beg to apologise.—W. F. RADCLIFFE.

## ROYAL HORTICULTURAL SOCIETY.

JULY 17TH.

**FLORAL COMMITTEE.**—Mr. Bull exhibited a very fine collection of plants, including Ferns, Palms, &c. A first-class certificate was awarded to him for *Lantana rubra*, a fine Palm, and one of the second class for *Echeveria atropurpurea*. This plant will be found useful to contrast with other species of *Echeveria* used for margins to flowerbeds. Among the collection was a variegated *Athyrium*—*Goringianum pictum*, but the plant was too young to show its true character or beauty as a variegated Fern. This Fern was exhibited in great beauty by Mr. Standish, Royal Nurseries, Ascot, at the International Horticultural Exhibition. The plants exhibited this day were evidently seedlings. From Mr. Bull came also small plants of *Pandanus Porteanus*, which it was requested should be sent again, *Cinchona nobilis*, *Philodendron bipinnatifidum*, *Cycas pinnosa*, a very singular plant, and *Amorphophallus grandis*; but some doubts were raised as to the identity of this species with *A. nivosus*, a doubt which is to be settled at the next meeting. A special certificate was awarded to Mr. Bull for this interesting collection.

Messrs. Veitch exhibited some fine specimens of many beautiful plants, and among them *Rhododendrons* Princess Royal and Princess Alice, the white *Lapageria*, and a new *Anthurium* called *regale*; but the plants being too young for any decision to be arrived at as to their merits, it was requested that they should be sent again. Messrs. Veitch also exhibited *Cattleya quadricolor*, a pale variety of *C. Mossiae*; *Nepenthes ampullacea vittata major*, a very curious form of this interesting family; *Oncidium barbatum*; *Pandanus Limnai*, *Disa grandiflora*, and several other interesting plants. First-class certificates were awarded to the same firm for a handsome-foiled plant, *Aphelandra* species; *Polystichum* sp., a very handsome greenhouse plant, and nearly hardy; *Lomaria Lechleri* from Chili; *Nierembergia rivularis*, a beautiful white-flowering plant, much larger than the usual form of *Nierembergia*, half-hardy, and which, treated as a bedding-out plant, will be found very useful. Second-class certificates were awarded for *Maranta* sp., and *Pteridophyllum zeylanicum*, an elegant ornamental-foiled plant.

Mr. Wm. Paul sent four seedling *Zonale* *Nosegay* *Pelargoniums*—viz., *Dr. Hogg*, *Scarlet Dwarf*, *Waltham Scarlet*, and *Lilacium*, but not apparently in a condition for being satisfactorily adjudicated upon. There are so many good *Nosegays*, and so much alike, that it requires something quite new in colour to surpass them, or in many cases to equal them. The large bold truss of *Stella* and *La Grande*, or the King of the *Nosegays*, must be the models of perfection in this class of flowers. Plants producing thin and lax trusses, however bright in colour, are not desirable or useful for bedding-purposes, for which alone *Nosegays* can be used. Mr. F. Gill, Blandford, sent seven seedling *Verbenas*, not one of them sufficiently distinct from those in cultivation; and Mr. Booth, a cut specimen of *Philadelphus Stewarti*, a late-flowering *Syringa*. Mr. Sherratt, gardener to James Bateman, Esq., had a first-class certificate for a cut spike of *Grammatophyllum Ellisii*, of which mention will be found farther on. Mr. John Mann, Brentwood, sent a collection of thirty-two seedling *Zonale*, *Nosegay*, and other *Pelargoniums*. Two were selected by the Committee as promising varieties to be seen again. They were *Guardsman*, a bright orange scarlet *Nosegay*, and *Dwarf Queen of Whites*, a very pure white. Mr. Trotman also exhibited a seedling *Nosegay* *Pelargonium* called *Fire King*; and Mr. George Macintosh, Hammersmith, seedling *Nosegay* *Pelargonium* *Lady Palmerston*; likewise dwarf compact plants of *Pyrethrum purpureum*, the result of severe cultivation.

Messrs. Osborn, Fulham, were awarded a special certificate for six small but beautiful specimens of *Heaths*; and Messrs. Lee, Hammersmith, contributed *Amaranthus elegantissimus*, very similar to *Amaranthus bicolor*. Mr. Green, gardener to W. Wilson Saunders, Esq., received a special certificate for an interesting group of plants, and some cut specimens of *Orchids* were sent from E. Wright, Esq., of Birmingham. C. J. Perry, Esq., of the same place, exhibited five seedling *Verbenas*, of which Henry Law received a second-class certificate: it is of a deep cherry colour with a dark centre. A special certificate was also awarded Mr. Perry for his beautiful collection of cut *Verbenas*. Messrs. E. G. Henderson, Wellington Road, received a first-class certificate for a novel *Pelargonium* called *Grande odoratum*. This award was made from the probability that the plant will prove the parent of a new section of *Pelargoniums*, having high-coloured and well-formed flowers, with scented foliage; the leaves in form resemble those of the Oak-leaved and Fair Helen section, and have their peculiar and agreeable scent. The plants produced large trusses of tolerably well-shaped flowers, capable of much improvement. This property has long been desired, and was particularly alluded to by W. Wilson Saunders in his interesting lecture given last year on the *Pelargonium* and *Cape Geraniums*. Messrs. Henderson also exhibited *Lady Cullum*, one of the tricoloured section of *Zonales*, perhaps the best yet sent out by that firm, and which received a first-class certificate in 1864; a specimen of the double

*Pelargonium Gloire de Nancy*, alluded to in a recent report; and *Desfontainia spinosa*, a beautiful greenhouse shrub. A collection of variegated *Zonale* *Pelargoniums* was sent from the Chiswick gardens, and a nice little collection of *Palms* from South Kensington, as well as a collection of *Orchids*, among which were *Grobya Amberstii*, rather rare, and a *Stanhopea*. Messrs. Veitch exhibited cut specimens of that beautiful and showy hardy climber *Mutisia decurrens*, and its bright starry orange flowers were much admired. This plant is very ornamental for covering a wall, making shoots rapidly, and displaying an abundance of its superb flowers.

**FRUIT COMMITTEE.**—Mr. Tillery, gardener to the Duke of Portland, Welbeck, sent a small collection of fruit consisting of large and finely-ripened *Bellegarde* Peaches, *Elruge* Nectarines, *Bigarreau Napoleon* Cherries, and Sir Charles Napier and *Eupress Eugénie* Strawberries. From Messrs. Backhouse, York, came a seedling Strawberry with small, acid, dark-crimson berries; and from the Society's garden at Chiswick eighteen sorts of Lancashire Gooseberries. Mr. Gill, Dorset Nursery, Blandford, exhibited a variegated Cabbage, which no one, we should imagine, would prefer to a green-leaved one either for appearance on the ground or at table; and Messrs. Stuart & Mein, of Kelso, pods of *Raphanus caudatus*, or Long-podded Radish.

**FORTNIGHTLY MEETING.**—W. W. Saunders, Esq., F.R.S., in the chair. The Chairman said that before proceeding with the regular business of the meeting, the pleasing duty devolved upon him of presenting Mr. Bull, of Chelsea, with a gold medal of the value of £25, called the Prince Consort's medal, which was instituted as a reward to the person gaining the greatest number of marks at the Saturday Shows. Although several competitors had obtained a large number of marks, Mr. Bull was the winner by a very considerable majority; the Society was also indebted to him for his numerous contributions of new plants at the Tuesday Meetings.

Mr. Bull said "My duty to-day is one of the most agreeable and pleasing character. It is to return thanks for the presentation of this extremely handsome medal, a medal that I shall prize more than any award I have ever received, and for the reason that it has been presented to me somewhat publicly by the Council of the Royal Horticultural Society, a Society that has done more to benefit horticulture, done more to increase a taste and love for it, and extend a knowledge of it, than any other agency extant. It is now many years ago that the Society instituted flower shows at Chiswick, and it is not too much to say that those shows first gave thousands the knowledge, not only of different classes of plants, but of the perfection and beauty to which they could be brought. That naturally increased and extended the taste and love for flowers and plants, but the Society did not stop there—it sent its collectors abroad to ransack forest and jungle, mountain and vale, to search for novelties and find floral treasures wherewith to gratify the taste it had created. In addition to that, the Society distributed a Journal among the Fellows, which gave practical information on most subjects relating to horticulture. These things are of the past, but what of the present? Why! the Society is still leading and creating a taste for horticulture. Chiswick shows were good, so they have been copied, until we have large flower shows too frequently, for they are nearly all thrust into two months of the year, until their number, frequency, and similarity have become almost satiating. The Horticultural Society seeing this, has re-organised its Tuesday Shows and Scientific Meetings. These meetings, as most of you know, are not new; the Society formerly held them under the guidance of that eminent botanist, Dr. Lindley, whose portrait hangs above me; in the interest of horticulture the Council have thought it best to revive them, and now they are attaining an importance, and are watched with an interest, that must be beneficial both to horticulture and the Society. These Tuesday Shows extend throughout the year, and by and through them, fruit and flowers for every season will be brought before the Fellows and the public, and hence the culture of fruit and flowers will be encouraged and horticulture benefited accordingly. Looking at all these things, I cannot as a horticulturist be otherwise than pleased at receiving this handsome medal from the Society. But there is another reason why I shall be proud of this medal, and that is, that the Society has associated with it the name of one of whom all England is proud, one who was always associated with art and science, who was himself not only fond of horticulture, but was also President of this Society, as indeed he was connected with everything that tended to the progress or benefit of mankind; and horticulture has a powerful tendency to that benefit, for it affords an innocent, instructive, and enjoyable occupation to those who have leisure time, a health-giving relaxation to those whose energies are taxed to the utmost in this age of severe competition; and it exercises an elevating, humanising influence for good on the artisan and mechanic. Associated, then, with the name of that great and good man, the Prince Consort, this medal to me will be a charming *souvenir* of his memory."

The Rev. Joshua Dix having read the awards of the Floral Committee, remarked that the bedding plants at Chiswick are now in great beauty, especially the Scarlet *Pelargoniums*, in addition to which there is a fine collection of ornamental-foiled plants.

Dr. Hogg said that the Fruit Committee had made no awards, in fact the only subject of any novelty was a Strawberry from Messrs. Backhouse, a hybrid between the *Elton* and *Fragaria lucida*, and that was of more interest in horticulture than to connoisseurs, because it might serve as the basis of future hybridisation. There was a small

collection of fruit from Mr. Tillery, comprising fine Peaches and Nectarines, and Bigarreau Napoleon Cherry, a variety which, from its very large size, its handsome appearance, and its excellent flavour, is one of the most desirable and useful of Cherries. He would supplement the observations made by Mr. Dix respecting the garden at Chiswick by stating, that in addition to the hedging and fine-folaged plants there is there an extensive collection of Strawberries and Gooseberries, fruit of which might be tasted by Fellows on application to Mr. Barron, and among other subjects which might be named the Vines in the large conservatory and pits are just now of great interest.

The Rev. M. J. Berkeley said, that before proceeding to review the subjects exhibited on the present occasion, he had to state that the *Nierembergia* sent by Messrs. Veitch to the last meeting had on examination proved to be entirely new, and accordingly it had been named *N. Veitchii*. On the same occasion he had regretted that *N. rivularis* was not before the meeting, for although it had been figured in Miers' Illustrations of South American Plants, it was new to gardens. He might, however, mention, that it possesses this peculiarity, that at every node there are one or two glandular spots which throw out roots, so that the plant may in this way be increased indefinitely. *Acalypha tricolor*, shown at the last meeting, and supposed by Messrs. Veitch to be a native of the New Hebrides, appeared to be a variety of the Indian *Caturus hispida* of Linnæus. The next plant referred to was *Cassia floribunda*, and Mr. Berkeley regretted its not being before the meeting, for it did not appear to be sufficiently known in this country; but at Paris, where it goes by a variety of names, it is a favourite bedding plant. It is a native of Mexico, whence it was introduced into this country in 1818, and requires to be kept in a stove in winter. Mr. Berkeley then remarked that there were two plants exhibited under what were evidently wrong names; one was called a *Dioscorea*, though it was utterly impossible that it could belong to that genus, and the other a *Pteridophyllum*, though it was certainly not a *Fumariaceae* plant. The pretty orange fruit of *Momordica charantia* then came under notice, as well as the use made of *M. balsamina* in curing wounds. For this purpose the fruit is cut open before it is ripe, put into oil, and exposed to the sun until the oil becomes red, when the latter may be applied to the wound which it is desired to heal. Of *Athyrium Goringianum pictum*, from Mr. Bull, it was remarked that though small in its present state the fronds would attain a much greater length, and that the variegation would then be more marked. An *Achmea*, from Belize, exhibited by Mr. Wilson Saunders, was then compared with *Achmea Mertensii*, figured some years ago in the "Botanical Magazine," and to which it was stated to bear considerable resemblance, but to differ in the flowers, being yellow instead of red, and not so closely set in the spike. Mr. Berkeley, in concluding his remarks, observed that the *Pelargoniums* at Chiswick were grown in small beds side by side so as to afford great facilities for comparison, and though the relative merits of the varieties had been marked by the Floral Committee, people could judge for themselves.

The Chairman here observed with respect to *Pelargoniums*, that he wished to call attention to those with sweet-scented leaves. He had cultivated *Pelargoniums* for many years, and had always been grieved to see that every effort had been directed towards obtaining fine flowers, but in securing this object the scent of the leaves had been in a great measure lost. He yet hoped, however, to see fine flowers combined with sweet-scented foliage and good habit.

Mr. Bateman apologised for the absence of Mr. W. Wentworth Buller who was to have made some remarks on Orchid culture and double-glazing, but unfortunately he had been called to the country. Before saying anything about the Orchids, he (Mr. Bateman) wished to direct attention to a plant of climbing habit with most brilliant-coloured flowers, *Mutisia decurrens*, introduced some years ago by Messrs. Veitch, from the Andes, through their collector, Mr. Pearce, and figured in the "Botanical Magazine" in 1861. It was there stated to have stood the severe winter of 1860-61 unharmed in the open air at Exeter, but he was happy to be able to inform the meeting that when he left his garden in Cheshire, than which a worse climate could hardly be found, it was in flower on a wall where it had never received any protection whatever. The brilliant orange flowers glittered like gasjets, and he considered it the most beautiful hardy plant introduced for several years. Passing on now to the Orchids, Mr. Anderson, of Meadow Bank, Glasgow, had sent one or two Orchids, and amongst them *Cattleya citrina*, remarkable for two things, the length of its vernacular name, the other its habit of growing in a downward instead of an upward direction. Another flower sent by Mr. Anderson was *Anguloa eburnea*, a plant with singularly formed white flowers, which, he might mention, had attracted the attention of the Princess Alexandra last year more than any other Orchid. The next plant which he would notice was *Grobya Amherstiae*, which was figured in the "Botanical Magazine" in 1835, and had now, after an interval of thirty years, produced its sombre-coloured flowers. He now came to a plant with a very long name, *Grammatophyllum Ellisii*. Its generic appellation was given in consequence of the leaves appearing to bear certain characters or letters, and old Rumphius even went so far as to name certain of these. Some of them were said to resemble Hebrew characters, others Samaritan, and others again to be more nearly approaching the Roman letters. The specific name was that of its discoverer, the Rev. William Ellis, whose work on Madagascar and his missionary labours in that island

were well known. The plant was figured in the "Botanical Magazine" in 1859, but there was every reason to believe that it had subsequently been lost till a year or two ago, when fresh specimens came into the hands of Messrs. Veitch. One of these Mr. Bateman said he had secured; it grew vigorously, and about three weeks ago showed flower, but he was sorry he could not bring the plant to London with him, and he had, therefore, to content himself with cutting off the spike and placing it on a young specimen which Messrs. Veitch had kindly lent him for the purpose. After remarking that though Madagascar is so near to Africa its flora, at least as far as Orchids are concerned, is very distinct from that of the mainland, Mr. Bateman drew attention to that splendid terrestrial Orchid, *Disa grandiflora*, which Mr. Leach, of Clapham, was the first to flower, and has continued to be most successful in cultivating. Having thus touched at the Cape, Mr. Bateman said he next came to central Africa, a part of the world which had always been fruitful in monsters, and, holding up an *Angraecum*, he observed that though M. Du Chaillu had no found that, he was fortunate enough to import another, which had been figured and described in the "Botanical Magazine" of this month under the name of *Angraecum Chailluanum*. Mr. Bateman then introduced M. Du Chaillu to the meeting, and invited him to offer some remarks on African Orchids.

M. Du Chaillu said that he felt some diffidence in speaking of Orchids, not having made hotany his study, although he had been a collector of objects of natural history of every description, and among them large numbers of plants. Unfortunately, however, on his return from his last expedition he had lost on the voyage most of those which he had collected. Orchids, he said, are chiefly found in equatorial Africa near the coast, and become more scarce in the interior. There they chiefly exist on hardwooded trees growing on the banks of streams, and in the dry season, which lasts for three months, they are shrivelled up; but when the rains, which last for nine months, set in, they grow luxuriantly and flower profusely, scenting the air with a delightful fragrance. The species are few in number, but when they do occur they grow in large masses and have a striking effect. Many of the Ferns in the same region are also very beautiful.

The Rev. Mr. Ellis having been called upon to make some observations on the flora of Madagascar, said that whilst in that island it was his custom to send out natives to collect plants in those parts of the interior which he could not visit himself. He then described the zones into which the vegetation of Madagascar is distributed, and the locality in which he found the *Grammatophyllum* named after him. It was growing in the fork of a large tree by the bank of a river, and had an amazing quantity of short, white, fleshy roots; and he had always found that it succeeded best when afforded plenty of water and air. With regard to other Orchids, he did not think that collectors would find any superior to *Angraecum sesquipedale*, which occurred in the lowest and hottest districts, selecting for its habitation trees on the borders of the forest, and growing on the driest parts of the branches and trunks, and where it would not be much shaded by foliage, thus indicating that it requires plenty of air and light. Mr. Ellis then adverted to a charming *Anætochil*, with lilac flowers and green and silvery-marked foliage, and stated that many very beautiful Ferns also exist in Madagascar, some of which would no doubt prove valuable acquisitions.

On the motion of the Chairman a vote of thanks was unanimously accorded to M. Du Chaillu and Mr. Ellis.

The meeting was so numerously attended that it was only with difficulty that the Council-room served to contain the audience. Several new members were elected, and one Society, the Keovil District Floral and Horticultural Society, was admitted into union.

WEEKLY SHOW, July 21st.—In the class for six Hollyhocks in spikes, Mr. W. Chater, of Saffron Walden, showed some excellent specimens, which received the first prize, and the same gentleman took first prize in the class for twenty-four cut blooms. In the class for the best collection of vegetables there was a keen competition, which resulted in Mr. Hill, Angel Row, Highgate, being first. Mr. B. Porter, gardener to Hon. A. F. Ashley, Copt Hall, Essex, second; and Mr. Young, gardener to R. Barclay, Esq., Highgate, third. For the best six Lilliums, Mr. Cutbush received a second prize, there being no competition. In the miscellaneous class Messrs. Cutbush received a second-class certificate for a cut bloom of Phlox, and extra prizes for six miscellaneous plants and six Heaths.

## BLOOMSBURY FLOWER SHOW,

The annual Exhibition of window plants belonging to the working classes of the parish of St. George, Bloomsbury, was held on Tuesday last, the 17th inst., in the gardens behind the Foundling Hospital, and was very well attended.

The competitors were as usual divided into several classes, children, servants, and adults severally competing among themselves. There was no marked improvement over former years; nor should we expect to find it, as the exhibitors have not much chance of adding to their stock of either gardening knowledge or appliances. With two exceptions the classes were well filled, and the competition was as a rule very close. We were glad to see that in spite of the very small number of plants exhibited in the class for ragged schools no diminution was

made in the prize list. Those who are in any doubt as to the plants which will best stand London air may learn much at these exhibitions. To judge from what came under our notice on Tuesday last, we should say that no plant flourishes more than the French Marigold, of which we saw several boxes filled with most healthy plants. It is worthy of mention, that in the class for servants Susan Hydo has carried off the first prize for *Fuchsias* in four consecutive years with the same plant. Leaving out of consideration the class for plants which had not been kept in the possession of the exhibitors, there scarcely seemed to be as many plants on the tables as in previous years; but there was certainly a less number of those unhappy specimens which only serve to set off their more flourishing neighbours.

The prizes were distributed by Lord Shaftesbury in the evening. We think this ceremony would be less tedious if his Lordship presented the first prizes only. As at present arranged, the patience of those who are anxious to hear the speeches is most sorely tried. The weather was most favourable, and all who were present seemed thoroughly to enjoy the gardens and music.

## BEDDING PLANTS AT THE ROYAL NURSERIES, SLOUGH.

EVERY one who has been in the habit of attending the London shows knows the magnificent *Azaleas* which Mr. Turner exhibits—masses of bloom which are wonderful even to us, and which strike foreigners with amazement; but the *Azalea* season is over, the plants have been divested of their gay attire, and they are now going to rest preparatory to a fresh campaign; the visitor, therefore, must not, and, if a practical man, will not, expect to feast his eyes on their beauties. *Auriculas*, too, another flower with which Mr. Turner holds a leading position, are likewise over; *Dahlias* not commenced, and those gorgeous specimens of show *Pelargoniums* and charming *Fancies* are also at rest, or just beginning to start. What, then, is there to be seen at the Royal Nurseries? is a question which will naturally be asked; but it admits of a very simple answer—The bedding plants; and it is with respect to these and not the general features of the nursery (although there is much in it to interest), that we propose giving a few notes.

At the present time certainly no plant is more popular or more extensively planted for flower garden decoration than the *Pelargonium*, and within the last few years the improvements which have been effected in the size and colours of its flowers have been so great as to throw most of the old varieties far into the shade. Not a year passes in which dozens at least of new kinds are not brought before the public, all with the character of being more or less an advance on existing sorts; and indeed many of them are so to a slight extent, though not equal to others which appear contemporaneously, whilst others again are really striking improvements. Owing to this continual succession of novelties the difficulty of selection is very great; and it is rendered all the more so, because, to judge of the value of a plant for bedding-purposes, it is not sufficient to see a single plant in a pot, but its effect in a mass must be looked to. The opportunities of doing this are rare, hence varieties totally unsuitable in habit, or only fit for pot-culture, are often planted, and disappointment is the result. Mr. Turner, however, both for his own information and that of his customers, has this year planted a very extensive collection of the newest and best bedding *Pelargoniums*, and that, too, in the case of the great majority of the varieties in such numbers that their value for flower garden decoration can be judged with a considerable degree of certainty. The collection, then, in a utilitarian point of view, is well worthy of inspection, and it is equally so on account of its ornamental effect.

Among *Nosegay Pelargoniums*, Dowager Duchess of Sutherland, raised by Mr. Fleming, of Cliveden, and which has on more than one occasion been noticed in these pages in terms of high commendation, was remarkable for its magnificent trusses of magenta rose-coloured flowers, having a scarlet shade on the upper petals. The habit is vigorous, the leaves faintly zoned, the trusses much larger than those of either *Stella* or *Cybister*, and when bedded-out the plant is very showy and effective. Even in pots, though *Nosegays* are not generally considered eligible for that mode of culture, owing to the large size of its trusses and their profusion, this variety has a fine effect. Last year it received a first-class certificate from the Floral Committee of the Royal Horticultural Society, and at a meeting held in June last a superb specimen of it, exhibited by Mr. Turner, excited much admiration. Altogether it is of first-class merit. Of other varieties of the same class, *Cybister* was producing immense trusses; and of its prototype *Stella*,

which is numerous planted, it would be superfluous to speak, its value for bedding being now so generally recognised. *Black Dwarf* is very good, so is *International*, which is more of a crimson shade, and *Surpasse Stella*, a fine orange salmon, has trusses quite as large as *Stella*. *Amy Hogg* is producing trusses of remarkable size, and the colour is most beautiful, and *Orange Nosegay* is also remarkably fine. Other kinds, particularly good were *Black Dwarf*; *Walham Seedling*, intermediate between the latter and *Cybister*; *Countess of Sefton*, a plain-leaved kind with beautiful soft rose-coloured flowers, very bright and effective, especially when viewed at a distance; and *Multiflora*, bright scarlet, very dwarf and free-blooming.

Of *Zonale* varieties not being *Nosegays* the most remarkable were *Mrs. William Paul*, rosy pink, white eye, very dwarf and free-flowering; *Rose Rendatier*, producing fine large globular trusses; *Madame Barre*, deep pink, with plain foliage, and the habit of *Tom Thumb*, apparently a desirable free-flowering kind for small beds. *Souvenir de Brasseville* is a very attractive soft salmon rose, either for pots or beds; and *Wilton Seedling* is a large, soft, rose-coloured flower, and the plant is free-flowering and more dwarf than *Beauty of Suresnes*; the leaves are of a light green and faintly zoned. Among salmon varieties the most noticeable were *Emile Licau*, deep salmon; *La Prophète*, very dwarf and upright, deep salmon, bordered with white; *Madame Rongière*, pale salmon, shading off to white, very free; *Mathilde Moret*, distinct salmon centre edged with white; *St. Fiacre*, salmon, of a very free rather dwarf habit; *Madame Rudersdorff*, very compact in habit, salmon, edged with white, and more deeply than in *Madame Rougère*.

Various shades of scarlet were best represented in *Roi d'Italie*, *Herald of Spring*, *Prince Imperial*, a dwarf free-flowering brilliant orange scarlet, with dark-zoned leaves; *Monsieur Mangenet*, clear orange scarlet, dark-zoned foliage; *Lucius*, immense globular trusses of rosy scarlet, darkly zoned foliage; *La Peyrouse*, very large trusses, and apparently a continuous bloomer, plain foliage; *Mr. G. Natchet*, a first-rate dwarf orange scarlet, with large globular heads and zoned foliage; *Monsieur Thiers*, dwarf, with darkly-zoned leaves, and the individual flowers large; *Sobieski*, of similar habit, but deeper in colour; *La Niagra*, orange scarlet, large trusses borne high above the foliage, suitable for the centres of clumps; *Prime Minister*, very dwarf, producing large trusses of bright scarlet flowers with a white eye, very attractive; *Magnet*, very small and compact, with small plain foliage, and small trusses of orange scarlet flowers, but freely produced; *Clipper*, a first-rate sort, with large trusses of bright scarlet flowers, individually large, and of fine form; *Victoria de Puebla*, very large, globular, stiff trusses of salmon scarlet flowers, freely produced; and *Dr. Lindley*, with very large scarlet flowers of fine form and substance, but not produced in large trusses. Especial mention must also be made of *Nosegay Lady Constance Grosvenor*, a most brilliant scarlet, brighter than *Cybister*, having dark-zoned leaves, and closely covering the ground as if pegged down. *Beauty of Oulton*, noticed in another page, was very fine, both in flowers and foliage, and will doubtless become a general favourite; and *Duchess (Paul)* was also noticeable for its large globular heads and free-flowering.

Of white kinds the best were *Bull's Purity*, pure white, vigorous, and a free bloomer; *Madame Werle*, with a delicate pink centre shading off to white; *Snowball*, very dwarf; and *Marie Virgo*, a very free bloomer, with the trusses thrown well above the foliage, which is deeply zoned.

*Verbenas* are also grown in considerable numbers, and among these we noticed *King of Lilacs*, with fine trusses of pale lilac flowers; *Champion*, the colour of *Géant des Batailles*, but with a white eye; and *La Grande Boule de Neige*, a very fine white, forming an excellent companion as regards height to *Purple King*. A dwarf *Tropæolum* called *Slough Pet*, a light orange scarlet, with small foliage, and flowering very profusely, made an excellent line near the margin of a large bed, and would be very effective in parks and other large places.

Although the bedding plants are the principal object to which we wished to direct attention, a few remarks on the other features of the nursery may be made. Mr. Turner's home ground at Slough altogether amounts to twenty acres, and his nurseries at Salt Hill and Uxbridge to as much more. In various parts of the ground, and especially near the entrance, are several fine specimens of *Araucaria imbricata*, *Wellingtonia gigantea*, and *Picea Nordmanniana*; and of the latter, as well as of *Picea nobilis*, we observed fine quarters of seedling plants in the best of health, and of a size fit for planting. *Picea Nordmanniana* and *nobilis* are somewhat of a speciality with

Mr. Turner. He grows them to the extent of several thousands, and, in common with the other Conifers, much labour is spent upon them in transplanting every year. Of Roses Mr. Turner has about four acres, occupied by plants remarkable for the health of their foliage and the size of the wood. Besides the standards and dwarfs, there is an extensive stock of pot Roses plunged in the quarters. The Rose-quarters, notwithstanding the hot dry weather, are in excellent bloom, and the following Hybrid Perpetuals were especially fine—viz., Charles Lefebvre, Leopold L., Marguerite de St. Amand, Madame Victor Didier, Maurice Bernardin, Duchesse de Caylus, La Duchesse de Morny, Dr. Andry, Duc de Rohan, Pierre Notting, and Mdle. Bonnaire. Among Teas we noticed the beautiful Alba rosea, which is very free-flowering out of doors, Madame Villermoz, Narcisse, and Homer, an edged Rose, very useful for cutting for bouquets. Jean d'Arc seemed a nice free-flowering garden variety. Near the Rose ground was a space enclosed by hedges, in which were about 1700 pots of Carnations and Picotees.

In the houses, as already mentioned, the Pelargoniums were either cut down or ripening off, and several large houses were filled with such plants; others contained the large show specimens of Azaleas completing their growth; and in other houses were some four hundred Achimenes, several pots of Liliun auratum, and a number of Gloxinias. In a range of pits there was a number of bouquet Dahlias, and as these are becoming great favourites we asked Mr. Turner which he considered the best and most useful, when he named the following:—Burning Coal, deep yellow, with intense scarlet tip; Dr. Schwebes, rich scarlet; Glow-worm, bright red, fine; King of Purples, dark purplish maroon; Little Arthur, crimson, good bedder; Little-Love, pale, shaded rose; Little Mistress, violet purple; Multiflora, light blush, tipped with violet purple; North Light, bright scarlet, fine; Prince of Lilliputians, maroon; Progress, pale peach; Shadow, rosy crimson.

Turning from the houses again into the principal walk, by the side of which is a very effective ribbon border, planted with Lobelia Paxtoniana in the front row, then Aurea floribunda Calceolaria, Stella Geranium, and Double White Pyrethrum alternately with Perilla nankinensis, we passed on to the ground where there is an extensive stock of Apples, Pears, Peaches, and Nectarines, with strong, solid, short-jointed wood. Here were several rows of Premier Pea, remarkable for its extreme productiveness. It is a late, green, wrinkled Marrow growing 4 feet high, as already stated an extraordinary bearer, producing on an average seven peas in a pod, sweet, and of excellent flavour. Although said to be nearly allied to Maclean's Prolific, certainly the two as grown at Slough from seed sown the same day were very different both in height and productiveness.

#### ENTOMOLOGICAL SOCIETY'S MEETING.

The July meeting of this Society was held on the 2nd inst., the President, Sir John Lubbock, Bart., F.R.S., being in the chair, The Hon. T. D. Grey, M.P., and C. Ward, Esq., of Halifax, were elected members. A number of valuable entomological works recently published by the Society were upon the table.

Mr. Stainton exhibited a bead of *Typha latifolia*, showing the manner in which the caterpillars of the small Moth, *Laverna phragmitella*, feed within it; also specimens of a *Gelechia*, closely allied to *G. leucamelanella*, which he had succeeded in rearing from galls found upon *Gypsophila saxifraga*, Mentoue, in the spring. The occurrence of galls formed by Lepidopterous insects, the larvæ of which reside within them in the same manner as the Cynipidæ, is very rare. Mr. F. Bond exhibited the rare *Sesia philanthiformis*, *Dianthæcia casia*, and several species of Phycita, one of which appeared to be undescribed, all from the Isle of Man, collected by Messrs. Hopley and Greening; also some bred specimens of *Papilio Machaon*, remarkable for their gigantic size.

Mr. Edwin Shepherd also exhibited a specimen of *Dianthæcia casia*, supposed to have been taken in Yorkshire by Mr. Bentley. Mr. Edward Saunders exhibited a collection of Mexican Butterflies, recently formed by Mr. Bouchard, amongst which was a remarkable specimen of an *Euterge*, in which the colours of the different sexes were shown by the opposite wings, the right side being white and the left yellow, with the ordinary dark markings.

Mr. Pascoe called attention to a paper by Mr. Albert Muller, in the "Zoologist," and read an extract from Von Tschudi's "Thierleben der Alpenwelt," relative to the action of insects settling or falling upon the snow at considerable altitudes in Alpine situations, and upon the manner in which they then sink into it, in consequence of the radiation of heat from their bodies, as stated by Mr. Pascoe in a former communication to the Society. Professor Brayley considered this to be the true cause of the phenomenon, and that it did not result from the presence of an increased amount of oxygen in the melting snow, as

had been asserted by some writers. Professor Westwood instanced similar results produced by the falling of hive bees on snow in this country.

The President read a series of extracts from M. Balbiani's recently published memoir on the microscopical anatomy and physiology of Aphides, in which, from the structure of the cells of the ovarian tubes and other curious particulars, the author was disposed to consider that the common Plant Lice are truly hermaphrodites, by which the production from a single Aphid of eggs and young for many generations, might be accounted for. It was, however, suggested that the production of decided male and female Aphides with fully developed wings at fixed periods of the year, seemed to militate against such a theory.

Mr. Stainton gave an account of an epidemic which had broken out on the Rye in the neighbourhood of St. Etienne, caused, as was believed, by the attacks of the caterpillars of a small Moth, *Oecsenheimeria taurella*, which gnaws through the stems below the ear, and not by its feeding on the flowers of this cereal, as had been erroneously stated. Some notes were read on the caterpillars of the two Butterflies, *Charaxes Jasius* and *Melitæa provincialis*, found in the south of France by the Rev. L. Timins. The former is becoming very rare, in consequence of the *Arbutus unedo*, on which the larvæ feed, being gradually rooted up for fuel by the peasants, especially near Hyères. Mr. Stevens exhibited specimens of two species of the remarkable Cornuted Beetles, *Durocephalus*, from North India and China, and the Secretary communicated a note from the *North China Herald* on the large trade in Chinese insect-wax, in which it was stated that as much as 5000 cwt. was annually exported from one port in the north of that country.

#### COUNTRY SCRAPS.—No. 2.

AGAIN, amongst the Yorkshire flora is found the *Tulipa sylvestris*. Smith says of it, that its favourite habitats are old chalk-pits, but that it is not common, and he mentions as localities, "chalk-pit at Carrow Abbey; near Norwich; near Bury; at Whipsnade, Herefordshire; at Melbury, near Shaftesbury; and on Muswell Hill, Middlesex; also in a field near Hamilton, Scotland; and near Brechin." He describes the flower as "somewhat drooping, sweet-scented, bright yellow, externally greenish. Linnaeus and Haller thought this plant had escaped from gardens in Sweden and Switzerland. It is, however, perfectly wild at present, and extremely abundant in many old chalk-pits, though the bulbs run so far into the ground that they rarely flower. Nothing can be more distinct as a species." Thus far writes Smith of the plant in question, he does not mention its Yorkshire home, which I find is "between Hexthorpe and Sprotborough broats." (Yorkshire again! What can the word mean? Is it a dene or a marsh?) "Broats," yes that is the word, and I think we must invoke some Yorkshiremen to enlighten us as to its meaning.

The foregoing difficulty reminds me of one equally unresolvable, which occurred to me in a walk through York some years ago. Passing an ironmonger's shop displayed in large letters upon a printed card, was—"A Fog to Let." A "fog" to let! Whatever is a "fog"? The usual acceptation of the term I understand, but taking it in that sense, I think there would be few demands for such a thing. Well, I pondered and pondered, and no nearer did I arrive at any satisfactory conclusion, so I determined to let the weighty matter stand over until I returned to my brother's. What a hearty laugh greeted me as I asked for a solution to my query. "Was it a dogcart or a mangle?" "A dogcart! or a mangle! Why, don't you know what a fog is?" "No, I have not the remotest idea, but something evidently connected with ironmongery." Another laugh was all the response for some minutes, and then came the long-anticipated revelation. A "fog" was the second crop, or "after-grass," as it was sometimes termed, which sprang up after the first had been cut and made into hay.

I must confess a great ignorance of Yorkshire words, I am only acquainted with the native hospitality, and tables groaning under the weight of mysterious pies, and cakes of all sorts, the names of which I also in my confirmed simplicity eschew. I know that the mention of the various Ferns which beautify the hills and dales there causes me very often to covet their possession, and I am ashamed to say it was just after coming from a missionary meeting the other evening, and whilst sitting at supper near a Yorkshire clergyman, that he innocently, enough aroused the covetous nature which dwelt within me, by giving me the details of an excursion which he and his family had lately made into one of the wilder spots in his own grand county. It was, I believe, at a distance of some miles beyond Bolton, that they came upon a complete mass of *Poly-podium phegopteris* and *P. dryopteris* intermingled, all grow-

ing amongst the wildest rocks, which yet were apparently covered with verdure; there, too, grew in rich bosses the *Ruta muraria*, and another Fern of rather a larger growth, and which he described as consisting of a frond divided into three portions. "Not being great at Ferns," he said, he could not venture upon names, but he thought this one was called the Ivy Fern. My great pet, the *Cryptopteris fragilis*, also reigned there in its pristine beauty, and by its side *Asplenium viride* and *trichomanes*. All the above rioted together in one small spot, and probably had remained for years in undisturbed luxuriance and solitude until the fatal day when the clergyman and his boys ransacked the place.

I find that both the Beech and Oak Ferns are rather common in this county, and that in a wood near Whitby they grow in large patches upon some fallen trees. Oh! these hilly countries, with their brave northern breezes, are the true homes of chieftains, and of border lore, and of Ferns and Heather. Many a tradition of the rough times lang syne may be heard when weary with our excursions we sit down awhile, and enter into a chat with the gude wife, who, with her knitting in her hand, welcomes us to her cottage door; and not only must we seek these traditions amongst the lowly, for they are engraved on the heart of the high-born border lady also, whose cradle song was a recital of the valiant deeds done by her ancestors, and whose childish hours by the dim firelight were hougled by details of ancient struggles for life and glory, and it is her woman's pride that she

"Lives in a mountain land,  
Where a flight without wings is at her command."

With the poet she sings—

"Above, the king eagle's realm we share;  
Below, the haunts of the shy brown hare:  
Thousand fields with their lakes a-shine,  
Far hamlet and town, and the ocean line,—  
Beechen valley, and Bilberry dell,  
And glen where the ooches and fairies dwell,  
With heaps and bosses,  
Of Plume Fern and Mosses,  
Scarlet Rowan, and slight Bluebell,  
The Plumo Fern grows by the waterfall,  
Where the Ash sprays tremble, one and all,  
And cool air murmurs, and wild birds call."

But I love our southern lands, I think, the best—the feminine habits, quiet pride, and gentle bearing of the women; and in strolling our long summer evenings, through the woodland paths, when nought but the nightingale's love song is heard, then there is more that speaks to the heart of purity, and love, and heaven, than the dark Pines and aurora borealis of the north.—A SURGEON'S WIFE.

### SOME OF MANY THINGS ON A SMALL SCALE.

My garden altogether is about two acres, and I have in one block a small Mushroom-house with the bed 12 feet long, and the furnace at one end, which is fed outside, and well covered inside the house with brickwork and sand—two pipes heat this house; then I have a small place 12 feet by 9, which I dignify by the name of the vinery. There I have Muscat Hamburg Grapes just colouring, and I train Brown Turkey Figs against the back wall, and the trees bear abundantly, though many of the fruit are rather deficient in flavour. This house is heated by two four-inch pipes round the front, one end, and the back, with troughs on the pipes; and there is a small cistern, fed by the flow, and emptying into the return, so that the water constantly circulates and gives a handy supply of warm water when required. This cistern is placed in the division wall which separates "the vinery" from the adjoining house, and thus supplies both; this adjoining house I call the Fig-house; it is of the same size as the vinery, and is planted with the White Marsilles at the back, and the floor is divided by a narrow path into two borders, where other Fig trees are planted, and seem doing well. There is a border outside in which are the roots of two Vines which I am training across the house, one stem from each, which will not, I think, unduly shade the Figs. In front of this, 9 feet distant, I have a Cucumber-house 17 feet by 7, with a four-inch pipe in front, three ditto under bed, and one ditto at back, which flows into a large cistern emptying into the return, and creating abundance of steam. All the pipes are, besides, trenched, and I can fill the troughs under the bed at pleasure. Near this house stands the orchard-house, 42 feet by 14, with a four-inch pipe, trenched, running round the front 30 feet of it; I only use this pipe in hard frost during the blooming period. The trees are in 15-inch pots.

I have been thus particular in my description that you may see I am fond of a garden, and not likely lightly to wish to give up any part of it. The whole of these buildings are on my own plan; the furnace in the Mushroom-house heats them all, or any portion of them at pleasure. It has been my custom to work my garden by employing lads out of the village. I teach them all I can, and at about eighteen years of age procure them better situations. I have had two at a time, and the under one is able to become the head when the older one leaves me. I begin with 4s. per week, and raise their wages to 12s. or 13s.; I take the boys at about fourteen years of age. I also employ a clever labourer for the heavy work when required. I am the parson of the parish.

Now as to the orchard-house trees. They are greatly improved since I wrote last, and I see no disease on the new leaves. I have thirty-two Peaches and Nectarines, and I think perhaps twenty dozen fruit will stand. One end of the house is filled with Plums and Cherries, and the other one is a blank. This is my third season. The trees are most carefully and regularly tended. In the autumn we take out the soil 4 inches wide and 6 inches deep, and replace with new soil enriched with manure. We top-dress in summer with horse-droppings and malt dust. We syringe well every evening (I tried it in the morning also but the leaves got scorched), we water according to the weather, we pinch in the shoots, we move the pots during the summer to break the fibres rooting through the holes, we carefully watch for insects, dressing when required with soft soap and quassa, we give air early and abundantly all round the house; but each year the first growth of leaves become as it were burnt at the tip, the burn gradually extending upwards till half the leaf is gone, and comes off in your hand like tinder. This is the case with almost all my Peach trees—Plums quite as bad as Peaches; some of the Vines and Figs which are in borders, some in inside and some in outside borders, are affected too. What can be the cause? I thought, perhaps too much water. I thought that perhaps we had not rammed the new soil enough, as the water certainly passes very quickly through the pots. I can detect no insect at all. The water is chiefly rain water, as I have close to my house a large brick tank, but when rain water fails I supply the tank with hard water by a flexible tube from the kitchen pump. This, however, seldom is required in the early summer, and that is the time when the mischief appears. I have sent the leaves to various persons, and can get no cure prescribed. I dislike to see the foliage damaged, and to be unable to apply a remedy. I am, however, glad to say that the weak wood seems strengthening. I cannot help doubting—first, whether it is well to be so often breaking off the fibres which root through the pots into the border; second, whether the incessant pinching of the shoots as advised by Mr. Rivers is well—it seems to snub the trees and fairly tire out their good humour. I am inclined to let the shoots grow longer, and not shorten more than two or three times at most in the summer, for I suppose growth of shoots promotes action at the roots. My Cucumbers are good, I have cut nearly two hundred; not being able to sow the seed till April 21, as my alterations were not finished till that day. My Melons are good, I have thirty-five in one four-light frame, each about 18 inches round, and these were very late-sown also.—INQUIRER.

[The arrangements, so far as the description goes, seem to be handy and economical. In the vinery the want of flavour in some of the Figs against the back wall is owing to the shade, and if the Vines are allowed to monopolise the whole of the roof the Figs would first be flavourless and then cease to produce altogether. To keep these Figs in good order the Vine stems should not be less than 3½ to 4 feet apart, and spaces should be kept open for the light to reach the Figs. We knew a vinery where the Figs did well against the back wall, but the Vines obtained the mastery, and by degrees the Figs became barren, except a little piece close to the ridge, where they managed to get light. The same remark applies to the Fig-house. One Vine trained lengthwise about the middle of the house will do no harm, but, if several stems are taken, the Fig trees will suffer. Because the tree flourishes as respects growth in comparative shade, many people think that it will fruit also in rather dense shade, but they will ere long have such an idea dissipated. In fact, Figs require quite as much direct light on the foliage as any other fruit-bearing plant, but, provided the foliage has thus plenty of sunshine, the fruit will be best when shaded by their own leaves.

2nd, Your arrangement of the water-cistern with the hot-water pipes passing through it is very good. Partly through our recommendation such cisterns or tanks are found in scores of

places, and yet we have still nothing of the kind, and feel a difficulty often in obtaining the necessary amount of warm water. Advising and practising are, therefore, frequently different things. We know of no plan so good for obtaining moderately heated water. A boiler, large copper, or kettle, is also useful for securing very hot water when desirable. We would often boil manure water made from different kinds of droppings if we could, and thus avoid taking the eggs and larvæ of insects into our soil.

All the other arrangements, and the modes of management seem very satisfactory.

3rd, After carefully reading your treatment of the orchard trees in pots, we have no doubt that weakness is the chief evil with which they are affected, and that weakness might be the result of using too large pots at first for the size of the plants, and too little or too much nourishment, or an unsuitable soil in the first case. To make sure of the soil, as soon as the fruit is gathered, we would advise turning some of the plants out and examining the roots, giving fresh loam, if necessary. There is also just a possibility that the droppings you use for mulching may be rather fresh. If used fresh, and from high-fed horses, the water that passes through them at first will be rather strong; but we can lay no great stress on this, in such a case of experienced gardening, and where other subjects are thriving so well. We think you have alluded to some things in the treatment that will at least tend to promote weakness, and render the plants less able to withstand the sun's rays in spring and early summer, such as—

1st, The cutting off the fibres so often that come through the holes in the pots. We would advise never doing this except in the autumn, to help the ripening of the wood. We would never touch them during the summer. Hence the advantage of pots standing on soil, or at least partly in the soil. These fibres encourage growth, and the swelling of the fruit.

2nd, There may be something in the soil being so loose. It cannot be made too firm, with the help of a round stick to beat it firm.

3rd, You can hardly in autumn, if the trees are growing well, take away 6 inches of the surface soil without taking away and injuring the surface fibres, and this should be avoided. If you can pick out the soil carefully from among a few fibres, and put fresh soil among them, and water so that they suffer no check, all well; but when much depth can be removed with safety, we would almost be inclined to fresh pot at once. If the fibres are near the surface and healthy, be content with from 1 to 2 inches of fresh compost.

4th, In such a condition of your trees you are quite right as to the early and continuous stepping. Let the shoots be 6 or 8 inches long before nipping them, and do it seldom until the trees have gained strength.

5th, After cutting the roots through the holes in the pots in the autumn, top-dressing, watering, &c., do you leave the pots exposed to what weather may come in winter, mild or frosty, with only the glass protection over them? If so, here may be some cause of your disappointment. Pots plunged with a little litter on the surface, will be safe from the severest frost. Plants in pots however hardy, with the pots exposed to severe frost, will have the roots injured, if the soil is not drier than it ought to be, to be safe. If the pots were exposed all the winter, this might render the roots less able to meet the wants of the expanding leaves early in the season. If protected, of course the idea goes for nothing.

Lastly, Be the real cause what it may, as the scorching seems to take place only in spring and early summer, and you give air early and plentifully, if you have no openings at the ridge we would have some made, as the syringing in the morning ought not to blister the leaves if there is plenty of air and the glass is free from burning spots. That it is tolerably so we infer from the fact that the points of the leaves wither up and the blisters are not made in the body of the leaf, leaving the inference that in hot sun the plants have more demands on them than they can meet. We would, then, for a season or two lessen these demands in the early summer months by slightly shading the house. This may be done by many means. One of the simplest and the best, so far as economy is concerned, is spattering the glass with whitened water, say a piece of whitening as large as a good-sized marble powdered and dissolved in a pail of water, and thrown neatly on with the syringe. This done in the early sunny days might enable the plants ere long to meet all the demands upon them without flinching. These large squares of glass in orchard-houses try plants at all weakly much more than the old houses.—R. F.]

## MIGNONETTE CULTURE.

IT MAY be excused recurrence to the cultivation of this plant when I say I write in order to meet the wishes of many correspondents. I am the more diffident, as at page 430, Vol. V., New Series, I gave my then experience; and in Vol. IV., page 272, our able and experienced coadjutor, Mr. Fish, goes fully into the subject. It is not that I have anything to add to the one article or differ from the other, but solely from the number of inquiries, that am I induced to take up the subject.

For some time I have striven to obtain a hardy Mignonette having the fragrance of *Reseda odorata*, but my attempts have hitherto proved unsuccessful, for neither our own species (*R. lutea*) from the chalk, nor its near neighbour from the Mediterranean (Palestine)—viz., *R. mediterranea*, a large flowering annual, will hybridise with the Egyptian species (*R. odorata*). Question, Is there any known hybrid between an annual or biennial and a perennial?

The out-door culture of Mignonette is that of a hardy annual. Like many it does the best from self-sown seed, and in some instances is the reverse of certain from sown seed. Ground that at any time has been occupied with Mignonette will for many years annually produce a number of plants; but in one or two instances seed has almost entirely failed on ground newly broken up, and though there were few plants in the first year, in the second their number was by no means small.

Mignonette thrives best in a rich, loamy, well-drained soil, and does fairly in most soils and situations. It succeeds best when sown not very early, and when the soil is in good working order. The ground should be well worked, enriched by a dressing of leaf mould or well-rotted manure, pulverised, and raked fine. The seed should be scattered thickly and evenly, for it is much easier to thin than to transplant this plant. The end of March is sufficiently early to sow on light and dry soils, but the seed will vegetate more freely if it be not sown so soon, the plants coming up when self-sown chiefly during May. On strong soils it does best when sown from the beginning of April to the middle of May, and that is the time during which the seed is most sure to vegetate. The seeds being sown, they should be thinly covered with light fine soil to the depth of about a quarter of an inch. Should the weather prove dry, a gentle watering occasionally will do much to secure speedy germination, and the healthy growth of the young plants. When sufficiently large to handle, the plants should be thinned to 3 inches apart, which is a good distance for plants in lines; but for clumps it is not well to leave more than five of the strongest, and for beds they should not be left nearer than 6 inches apart every way. The size of plant and flower are dependant on the goodness of the ground and room afforded the plants. An open situation is the only suitable one, and beyond a good watering during dry weather, nothing more is needed for the growth of Mignonette out of doors.

Its culture in boxes is the same as that in the open ground, only the box should have holes at the bottom, and a drainage of crocks or the siftings of the compost to one-fourth the depth, the remaining space to be filled with a compost of good turfy loam two-thirds, and one-third leaf soil. A gentle rapping of the box on the petting-bench or floor will settle the soil sufficiently to allow of the seeds being sown and covered with soil, leaving space below the edges for watering. The box being placed in a warm situation, the seed may be sown in March, and if the soil be kept moist the plants will come up well. In their early stages the plants are impatient of much watering, and it is only after they attain a good size, have been thinned, and fill the box with their roots, that a good supply of water is necessary, and then weak liquid manure may be given at every alternate watering. To have fine plants it is necessary to thin them well. To have fine, healthy plants, successional sowings may be made up to the end of May or the beginning of June.

IN POTS.—For plants to bloom early, or in autumn and through the winter, small and clean pots should be selected, and these known as 60's are the right size. These being drained, and filled to within half an inch of the rim with a compost of turfy loam, leaf mould, and sandy peat in equal parts, with a free admixture of silver sand, and the surface being made smooth, scatter half-a-dozen good plump seeds thereon, and cover with a quarter of an inch of fine soil. The back of a Cucumber or hotbed-frame is the best position for the pots, and there the plants will soon appear, the soil being kept moist. When the plants come up the pots should be brought as near the glass as practicable, and give air plentifully to keep

the plants stiff; when they are half an inch or so in height make choice of the two strongest and cut the others away just below the surface, and by the time these have grown an inch in height the weaker one should be cut away.

When the pots are full of roots, but before these become matted, shift the plants into 4½-inch pots, and plunge the latter in a mild heat and near the glass, and on side shoots appearing pinch out their points at the second leaf, placing a small stake by the leader or centre shoot, which is not to be stopped until it shows for bloom, then its point must be taken out; and all the side shoots as they appear should be closely pinched-in to one joint, being careful in removing the centre from them not to remove the leaf along with it. The stake should be put in at a distance from the stem, say 1½ inch, for as the plant grows a stouter stake will be required, and it is desirable to have it in the same hole, so that the roots may not be injured in thrusting it in. The stem is to be neatly and loosely tied to the stake, and when this becomes too short it should be replaced by a longer one. If the centre show for flower take out its point, and the strongest and best placed shoot proceeding from the stopping should be trained in its place. This may require to be done repeatedly before a stem 20 inches or 2 feet high can be obtained, and until the height of stem required be attained no flowers should be allowed to remain on any part of the plant, but all should be pinched out so soon as they show. The leader not being pinched, or only to prevent flowering, and the side shoots closely pinched, the centre shoot will grow up, and when it is as high as you wish, pinch it, as well as the side shoots, whenever they show for flower, and this is to be continued until the plant becomes well furnished.

The pots being pretty well filled with roots, the plants may be potted into 8-inch pots, or, if strong, 12-inch pots will not be too large, as this is the last shift; but if the plants are extra strong, and extra-sized specimens be desired, a 15-inch pot may be employed. At this potting the soil should be chopped and broken with a spade, but not sifted, as it is desirable to have it free and open. It may consist of two-thirds turfy yellow or hazel loam, and one-third leaf mould, and still further to guard against moisture becoming stagnant, add one part each of lumps of peat of the size of a hazel up to that of a walnut, and charcoal of the same size, the whole well mixed. The pots should be cleaned and efficiently drained, that being of primary importance. The plants should be well watered prior to potting, so that the soil may be moist at the time of potting, and yet it should not be very wet. In potting, as the soil is rough, it should be pressed tight, the centre of the pot kept rather high—that is, the collar kept at least on a level with the rim of the pot, and the surface covered with half an inch or so of fine soil. The soil being in nice condition as to moisture, and a nice mild hothed at command in which the pots can be three-parts plunged, the roots will soon extend themselves to the fresh soil, and take firm hold of that. The plants will do best in a cold pit and elevated on an inverted pot, as then the water drains away freely, and they can be brought the nearer to the glass. They cannot have too much air, and a gentle syringing morning and evening is beneficial, they being kept well supplied with water; but anything like deluging them is injurious. As a rule, they should not be watered so long as the soil remains moist.

I am averse to any training of the head by means of sticks, wires, &c., and would much rather see a smaller specimen than one displaying more ingenuity in the arrangement of stakes and wires than is shown in that of the head without them, it requiring no little care and judgment (as the shoots are so very brittle, and liable to part from the stem whence they take their rise), in the disposal of the shoots, so as to produce a good and evenly-balanced head, and it is a result that only skill and practice can secure; but if the requisite care and judgment cannot be exercised, then a stout stake should be put in in the place of the old stake, and it should be as high as the plant is required to be. A stake half an inch in diameter is not too thick. I then burn a small hole through the stake on a level with the rim of the pot, and another immediately above it in the opposite direction, and through these holes push wires that reach 6 inches beyond the rim of the pot, and a wire fastened to the points of these will form a circle, and two or three more inwards from that will furnish means for fastening the shoots. Six inches higher up the stake I repeat the same proceeding, only the circle is 6 inches less in diameter, and in this way proceed until the top of the plant is reached within 6 inches, lessening the diameter of the circles 6 inches

for every 6 inches of height. This is the way to form pyramids; and if we wish for a stem the process is the same, only we put the first wires where the head begins. The shoots will require training and tying, and, perhaps, stopping, in addition to nipping off the flower-buds to make them branch; but I usually find the stopping consequent on the removing of the flower-buds sufficient.

The removal of the flower-buds should be strenuously persisted in until the head is formed, and afterwards no truss should be allowed to pod, but on the blooms seeding they should be removed, and this is the secret of keeping the plants healthy and profuse-blooming. The pots being full of roots, weak liquid manure will be of advantage once or twice a-week, and it may be given whilst the plants are in bloom, but not in dull damp weather. Until the pots are full of roots water should be given rather sparingly, and at all times with care, for a deluging of water is a certain forerunner of a stagnant soil, the sequel being a sickly plant. The plants should, however, have the soil kept moist.

A light and airy situation and plenty of room, ensuring light equally on all sides, is desirable, and a temperature of from 45° to 50° suits the plants in winter, allowing a rise from sun, advantage being taken of that to admit more air, and of this they can hardly have too much to prevent damping.

Of the kinds I prefer the large-flowering, it being of stronger habit and bolder in truss, but what is gained in strength and largeness of truss is lost in the greater profusion of its less vigorous compeer's blooms and its dense habit, and in this respect I think the two kinds are in their claims nearly if not quite equal, but that is a matter of taste. The two kinds are the same in their requirements, but the common variety is the easier managed.

As to keeping the plants from year to year, I do not care about doing so, as they are only to be kept with care, that consisting in top-dressing in spring, and for a time stopping and thinning the shoots, not permitting any to flower during the summer, and keeping the flowers well thinned even during the flowering season, if the blooms are expected to be at all large, not suffering any to seed. It is better to raise plants annually, or sow the seed in spring, and grow plants on for blooming in winter and spring. They are stronger and better in every way than older plants.—G. ABBEY.

#### GOSSIP ABOUT CANTERBURY, NEW ZEALAND.

A FINE specimen of the Pomegranate fruit has been seen in Christ Church, from Governor's Bay, which shows the great advantage which the inhabitants of the Peninsula have over those on the plains in climate. *Glycine sinensis* is doing very well here; but Fortune's white variety has, to the best of my knowledge, not arrived in New Zealand yet. The leaves of *Ailanthus*, or Lady Dorothy Nevill's Silkworm tree, in a very vigorous state of health, are killed by a late severe frost. I do not know whence our Acclimatisation Society intends to obtain the silkworms for us. *Brugmansia Knightii* flowers and grows well out of doors here. Walnut trees have begun to bear fruit well at about nine years old. From acorns sown about ten years ago the young trees are bearing heavy crops. Sycamores of the same age are full of keys. Green Peas have been in season with me from November 13th to April 15th, a pretty good spell for Green Peas to be in season. The natives of Poverty Bay are said to have manufactured from Peaches, Plums, and other fruits, a species of rum or arrack, which has a highly intoxicating effect. We have now growing in one of our nurseries a variegated *Dracena*, or, in New Zealand phrase, a variegated Cabbage tree, found on Mount Sinclair. A new Grass has been discovered, as yet unknown to our New Zealand botanists. It is described as a beautiful species, somewhat resembling the ordinary *Arundo conspicua*, or "Toi toi," but larger. It is said to be somewhat rare. Japan Lilies flower very beautifully during our autumn months. Evergreens of all kinds make a second growth after our hot summer weather is over. Junipers and Arbor Vites now seed very freely with us, and the *Cupressus* as well. Double *Potunias* flower sometimes 4 inches across, and are of all shades and colours. Double *Zinnias* and double *Clarkias* have now become very plentiful in our gardens.

It is contemplated to form a new horticultural garden here. Application has been made by a deputation to our Government for a piece of ground for that purpose, and the Secretary of Public Works told them the terms on which the Society could

hold a part of the Government domain, and that no title could be given the Society to the ground, but that it would be leased to them at a peppercorn rental for three years, subject to renewal at the pleasure of Government. Some of the members objected to these terms, thinking that the next Government might be less willing to encourage the Society than the present. I am afraid this scheme cannot be carried out for the present, public attention being drawn so much towards the gold fields; in fact, nothing else is talked about here with the exception of politics.

*Lilium lancifolium punctatum* flowers and does well in this country. Onions grow to a very large size here. One this season weighed 1 lb. 9 ozs., and its dimensions were 15½ inches by 13. Roses bloom very freely a second time in the autumn, particularly the Bourbon section. They make a second growth after our hot summer months. This autumn, also, we have a good show of *Chrysanthemums*, particularly with Fortune's Pompon varieties, some of them form quite a bush, and produce thousands of flowers. The different kinds of Thorns have begun to fruit with us as well as the Mountain Ash, *Pinus Pinaster*, now from 15 to 20 feet high, very full of cones and some of them shedding their seeds on the ground, may be seen here and there about Christ Church. This was the first *Pinus* planted in Canterbury. Grafted Rose *Acacia* on Cobbett's *Acacia* (*Robinia pseud-Acacia*), as standards, are doing well and flower beautifully the first season. We have now growing here for the first time this season seedlings of *Catalpa*, thousands of *Yews*, *Judas Tree*, *Celtis orientalis*, different varieties of the Plane Tree, from imported plants, all flourishing and doing well.

The other day, April 10th, I read an advertisement in one of our newspapers under this head—"Notice to Landscape Gardeners. Tenders are invited for laying out a garden according to plan and specification to be seen at a certain seed shop in the town. Sealed tenders to be addressed to the owner before such a date." This is a novel way in doing business in gardening matters.

On April 7th, heavy clouds during the day indicated rain, and in the afternoon flashes of lightning were observed. In the evening several showers of hail fell, accompanied with rain. Towards morning the temperature lowered considerably, and a sharp frost was experienced, which left evidence of its severity upon Dahlias and tender annuals in exposed gardens—a timely warning for us to protect without delay. On April 17th, we were visited by a very violent gale from the south-west. It had been gradually rising for some time, and increased in intensity about 6.30 p.m. By five it had reached a terrific height. The stem of a fine specimen of *Pinaster Fir*, about 20 feet high, and very full of young cones, was split in two, and one-half of the tree now lies prostrate on the ground, and much other damage has been done to forest trees in particular. It denuded the trees of all their leaves, with their usual autumnal tints. I always notice when we read of bad weather in England, we come in for our share here sooner or later afterwards. The wind blew the squares of glass out of my frames, and sent them flying all over the place to a very great distance.

*Wellingtonia gigantea*, *Cedrus deodara*, and *Cypripedium macrocarpa* are becoming great favourites here, for they grow very fast and soon form handsome plants. We now have seedlings of Cedar of Lebanon doing well for the first time this season. We are only 21 feet above the level of the sea on the plains.

Our provincial geologist with his staff returned to Christ Church on the night of April 19th, from the head waters of the Rakai, after an absence of six weeks. He has brought a very extensive herbarium of the alpine flora, containing many interesting undescribed species; also, a box of beautiful alpine plants in a living state for the purpose of acclimatisation, along with many alpine birds hitherto unknown. He mentions the scenery to be as magnificent and stupendous as any in the world.

Letters have been received here from Dr. Mueller, of Melbourne, stating that our *Pittosporas* are such lovely, hardy, and quick-growing plants, that thousands of them are wanted for the cemeteries, town churches, and schools of Victoria. He states that seeds of them will be accepted with the utmost gratitude, also that they have not a single plant of our *Aralia Shalflira* (?) Our *Dicksonia squarrosa* he states is very common in Victoria, but they have no *Cyathea dealbata*.

Our botanical news from the west coast gold fields is of a very cheering nature. One part of the country on the road from Christ Church would well repay the botanist for the trouble of a visit, the specimens of vegetable life being many

of them quite new, and also remarkable for beauty of foliage and blossom. Amongst them were seen *Ranunculus nivalis* (sometimes called *R. Lyalli*), distinguished for its circular concave leaves, at least 9 inches in diameter, supported in the centre by a strong stalk resembling in form that of the English meadow Buttercup, and for its large handsome blossoms of snowy whiteness. *Veronicas* are in great profusion. There is also a *Gentian* with pure white flowers, and many other shrubs and herbaceous plants of a very ornamental and interesting appearance. Amongst other plants are *Fagus Cunninghamii*, *purpurea*, and *antarctica*; *Capodetes serrata* (?); *Astelia nervosa*; *Celmisia coriacea*, *spectabilis*, *petiolata*, and *longifolia*; *Dracophyllum Traversii*; *Olearia Greyii*; three species of *Orchids*; *Clematis hexasepala*, and the yellow-flowering *Senecio Lyalli*. The most beautiful of all and in great profusion, clothing the sides of the hills with bright scarlet blossoms, are *Metrosideros lucida* and other varieties of the "Rata," or native Myrtle. Ferns are in great variety, and beauty on the west side of the range, especially *Leptopteris superba*, one of the rarest and handsomest of the New Zealand Ferns. The maximum temperature in the shade at Hokitika, on March 23th, was 67.0°; the min. 39.0°; range, 28.0°. *Tamarix gallica* we have doing very well with us now. Our winter is coming in very dry with cold, clear, frosty nights, and at the present time a few of those "golden showers," which London describes as so favourable to agriculture and horticulture would be acceptable.

What I have been writing will show the attention which Canterbury is paying to gardening, that we have a good many gardeners at any rate, and I firmly believe that New Zealand is more calculated to make a happy home for gardeners than any other colony.—WILLIAM SWALE, May 14th, 1866.

[We wish that others of our readers in others of our colonies would send similar useful and interesting "gossip."—Ens.]

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

PLY the fork incessantly amongst the growing crops of Cauliflowers, Broccoli, and Winter Greens, and continue to manure and trench-up every piece of ground as it becomes vacant, in order to plant it with late crops of a similar character. *Broccoli*, by dint of good management and a knowledge of the kinds, it is possible in these days to supply a family with Broccoli or Cauliflowers all the year round. The most difficult period, perhaps, is the month of January. Many new kinds have come into notice of late, and many old kinds have been revived with new names. The following, if they can be obtained true, we would particularly recommend:—The Cauliflower, the Cape Broccoli, Grange's Impregnated (now sold under new names), the Branching or Sprouting, Knight's Protecting, Melville's Superior Late White, Somers's Particularly Late White, Snow's Winter White, and Walcheren. Somers's Particularly Late White is so very late, that it continues the spring Broccoli until early Cauliflowers come in. *Brussels Sprouts* are the hardest and most prolific of Greens, and deserve attention even in an agricultural point of view. Too many can scarcely be put out at this season, and they may be planted very closely together. *Cabbage*, reserve and prepare a patch of ground for the sowings to stand the winter. The soil should be of a light sandy nature, and not too rich, as it encourages a luxuriant growth, which is apt to make them tender. *Celery*, prepare trenches for the late crops, water the growing crops, and stir the soil about them. *Endive*, plant out finally the strongest from the early sowings, and sow more for late crops. *Lettuce*, sow more, and keep up a good succession of Radishes and salads. *Onions*, pull up the crops of winter Onions, lay them in rows turned to the sun, and frequently turn them until the stalks are withered, when they will be fit for storing. As they are liable to decay if bruised, they should be carefully handled, and not thrown about like so many stones. Let them be very dry when stored, and be spread out thinly, not laid in heaps. *Shallots* and *Garlic* should also be taken up and dried for storing. *Peas*, the late-sown should have attention paid to watering and staking. *Spinach*, a good breadth sown now in rich ground will afford many successive pickings in the autumn, and tend materially to save the winter beds from being picked before they become strong.

### FRUIT GARDEN.

Attend to previous directions in regard to thinning and

stopping the young shoots of all trained fruit trees, and now make the final thinning of Peaches and Nectarines, of course leaving the heaviest crop on the most vigorous trees and strongest branches. As a general rule no two fruit should be left together. Plums of the large kinds, as well as the finer sorts of Pears, should also be thinned if the crop is too heavy. Young Peach and Apricot trees, when making over-vigorous leaders, should have the points of the branches shortened to encourage them to make other shoots less vigorous and of a fruitful character. This will obviate the necessity of shortening them back at the winter pruning. Layer the runners of Strawberries intended for pot culture, as well as those required for making new plantations. All spare runners may be cut away, and keep the plants free from weeds. Thin and stop shoots of Figs as soon as they have made a growth of about 6 inches, and remove all useless shoots from Vines. Keep the fruit close to the wall and shaded by the foliage from the sun.

#### FLOWER GARDEN.

The various Roses should now receive constant attention, as to good staking, disbudding stopping, top-dressing or liquid-manuring, and budding. As to the latter operation, the principle of ripening the wood should be kept in view. The excitable kinds should be budded directly, and on stocks with a strong root-action, and those buds which push in a month or so after the process should by no means be suffered to bloom, but have their tops pinched off when they have produced four or five good leaves. They will then solidify their growth before winter. Proceed with the propagation of favourite sorts which it may be desirable to increase either by budding or cuttings. The Hybrid Perpetuals, Teas, Chinas, and Bourbons are generally preferred on their own roots, and firm short-jointed shoots of these root freely at this season; but to insure success they should be afforded a slight bottom heat, be carefully shaded, and not kept too warm until they emit roots. They will, however, root under a hand-glass on a shady border. Remove suckers. Cut back the shoots of the autumn-flowering varieties to the most promising eye as soon as all the bloom buds are expanded and begin to fade. Take up Ranunculuses as soon as the leaves turn yellow, and allow the roots to dry in the shade. Cover the blooms of Carnations and Picotees as they expand, placing cardboard collars beneath them. As soon as the Pink pipping root, prick them out in good soil. Look to Dahlias; when they have attained a good size they should have the side shoots properly thinned out, leaving three or four of the best and strongest shoots. Examine the fastenings carefully; if they have become too tight and are cutting the stem, remove and re-tie them with a stronger material, allowing plenty of room to admit of the stem increasing in size. See that the pots on the top of the stakes are gone over every morning, and all the earwigs that are found, destroyed. These insects, in common with others, are very numerous this season, therefore the greater the necessity for lessening their number.

#### GREENHOUSE AND CONSERVATORY.

Now that many of the Camellias, Azaleas, and other plants have been removed to their summer quarters out of doors, painting or other repairs required by any of the plant-houses will be more conveniently done than at any other season. When houses are painted sufficiently often to keep the paint always good, which is the cheapest method in the end, there will be no difficulty in getting the wood dry; but when the wood is allowed to become nearly bare before repainting is thought of, the house should be kept dry inside, covering the outside with some waterproof material in the case of showers, and allowing a week or ten days of bright warm weather to thoroughly dry the wood before the work is commenced. This is trying weather for hardwooded pot plants, and those who do not pay strict attention to them now will probably not find it worth their while a few weeks hence. Above all things see that they are not suffering from the want of water, especially on that side of the pot on which the sun's rays strike, and keep a sharp look-out for insects. The red spider will soon play havoc among Chlorozemas if not closely watched, as also the mildew on such plants as *C. Henchmanni* and *angustifolia*. To guard against both pests on these and many other plants, it is a good plan to lay them on their sides, and, after giving them a thorough good watering with a syringe and clean water, to dust the under side of the leaves with sulphur. This, after remaining on a week or ten days, may be washed off again, and will generally clean the mildewed plants for the season. A good watering will also be beneficial to most pot plants at the present time. We do not mean a mere sprinkling, but a thorough good wash-

ing to each plant separately. On hot dry days give the plants in the evening a sprinkling, and also the ground on which they stand. *Pimelea spectabilis*, and other kinds which have done blooming, must have the branches liberally shortened-in, and be set in a cool, shady place to break, as must also the different kinds of *Polygalas*. *Aotus graeillima* must be cut down close to the pot; and *Leschenaultias*, which are becoming shabby, must have all the flowers and flower-buds removed, and be placed in a cool place to start again. Take care that they are clear of insects, and sprinkle them once or twice a-day in warm weather. Lose no time in bringing the potting of specimens to a close, and be careful with the plants afterwards until they begin to show signs of growth.

#### STOVE.

If there are sickly or bad-rooted specimens here they must be frequently examined for red spider, otherwise they will become a nursery for this pest, from which it will soon spread to adjoining plants. See that young growing stock is not allowed to suffer for want of pot room, and attend carefully to watering, giving manure water to all plants in free growth that enjoy it. Gardenias, &c., which have been removed to the conservatory while in bloom, should be replaced in heat as soon as their beauty is over, in order to allow of their growth being ripened before the dull, cloudy days set in. Encourage the progress of the young stock for winter blooming, maintaining a moist and comparatively high temperature.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

PLANTED out Coleworts and Ulm Savoy in a dull day. These will do very well 12 or 14 inches apart. This little Savoy is useful in the autumn, and takes but little room. Sowed Turnips and Radishes in shade, on the north side of banks, and planted out Lettuces, Endive, &c., and Cauliflower that had been previously pricked out, lifting with balls, and planting in a trench. We were disappointed on examining a piece of Cauliflowers to-day, which on passing along we had frequently admired on account of their dwarf appearance, the huge leaves resting on the ground. As some of the leaves had a greyish appearance, we gave the plants a watering from the house-sewage tank, and then we found that our healthy, fine-looking, dwarf specimens might as well have been on the rubbish-heap, as the centres had all been nipped out, either by pheasants, partridges, wood pigeons, or some similar fraternity. This had been done long before the flower had formed, and if the whole piece had been so treated, we should have been at a loss for a succession.

The chief work in the kitchen garden has been hoeing and loosening the ground among all growing crops; for the late rains, and the subsequent bright sun had left a hard surface, which would soon have evaporated the moisture, and cracked our stiff soil into fissures. It is amazing where such armies of weeds could come from, for where a fortnight or three weeks ago a small one could not be seen, the ground became covered with a mass of rampant intruders, and if let alone would soon have been beyond the reach of the hoe, and weeding by hand must not be thought of in these days, if it can possibly be prevented.

Gave good waterings to ridge and Gherkin Cucumbers, Vegetable Marrows, &c., and some sewage water to crops of Greens, Savoys, &c., and threw a little salt among Sea-kale, and Asparagus rows. Cucumbers in beds that were becoming exhausted, were cleared off, and the places well cleared and supplied with fresh soil and fresh plants. We have seen nothing of the Cucumber disease this season, but it is provoking that even now we cannot tell either what brought it, or what took it away. When it does make its appearance there seems nothing so effectual for keeping it in check as frequent changes of crop and fresh rather poor soil; but after having been a little troubled with it for years, we are as much in ignorance about it as ever. It seldom made its appearance with us until late in summer, the early Cucumbers being free from it, and just as people with a little box began to have Cucumbers in plenty, with us they began to be scarce. Last season we only had some traces of it late, and we hope this year we shall have none at all; but it is yet too early to speak with certainty. When once it takes possession of a plant great care may prevent its progress, but we never could make such a plant thoroughly healthy again. The best plan is to take what it will give, until you have fresh plants to take its place.

If rain do not come in a day or two, we shall be obliged to water, much against our will, as the moisture which comes from the clouds is more refreshing than anything we can give in that line, at least, on a large scale; for a small space might be watered in an evening, when it would be out of place to attempt so treating a large garden, unless arrangements were made accordingly. In general, garden labourers require the evening to look after their own gardens.

#### FRUIT DEPARTMENT.

A main feature of the week has been securing fruit, as Strawberries and Raspberries for preserving. The glut of the former is now over, and the fruit will be smaller in consequence. We could keep none except what were netted. Raspberries we kept pretty closely picked as they ripened, and used many modes for keeping intruders away. Cuthill's Black Prince Strawberry makes a beautiful preserve; it is so much firmer than the old small scarlets that were so much admired. What has been procured latest will be the best. What was gathered soon after the heavy rains would need more boiling.

Every year there come in our way many wondrously economical plans for preserving small fruits. We scarcely ever found out the economy of using less sugar than a pound in weight to a pound of fruit, or a similar amount of sugar to a pint of juice. If much less is used you must diminish the quantity by boiling longer than the regular twenty minutes, or you run the risk of mouldiness, or wasting away, after you have put your preserves into dishes. Some time ago a lady, who baked her sugar and baked her fruit before squeezing and boiling all right enough, attacked us very triumphantly on our scepticism, and boasted how she used hardly more than half of the pound of sugar, and that her preserves always kept well. On requesting to see a dish some six weeks after making, even then the triumph of economy was considerably lessened, as the vessels that were filled were not more than half filled when thus examined.

Cherries, that in ordinary weather and securely netted would have lasted some time, will have to be used ere long, as the excessive heat is causing them to be inclined to shrivel, and in some cases ants are attacking them. Some blackbirds get their feet entangled in flying against the netting kept well out from the wall, but they will often cause the net to rebound to the wall, pick the best Cherries through the meshes, and get off with flying colours. To be safe from them the net should be scarcely of one-half-inch mesh. Even then, if the net be close to the trees, or can be made to go close, they will sit on the net and take what they like through it. Generally they can calculate with mathematical precision the force with which it is necessary for them to strike a distended net, so as to go with their bodies close to the trees; but several times we have found, and especially when the net is tightened with rain, that they have so miscalculated as to be sent back stunned, if not killed, from the blow of the net. Net 1 inch or more in the mesh, is of no use for keeping out many of the smaller birds.

We were obliged to "Lex" for what he states at page 42. The law against poisoning seed constitutes one of our difficulties, and, like many laws, might have a coach and four driven through it in defiance of informers; but it is always a serious affair to break a law, and it is more serious still to have anything to do with poisons if it can be avoided. Notwithstanding all this, poisons, or at least barytes, or plaster of Paris, will no doubt be used to lessen the number of rats and mice; but even for gardening-purposes we should much rather use something to keep such vermin and birds from seeds than anything that would kill them if they partook of it. Why, according to the law, we presume, if we used arsenic, or phosphorus, or nux vomica, &c., on bread or meat, and put it in the holes and runs of rats, we are liable to a ten-pound penalty, Would it be the same if we used barytes, or plaster of Paris, nicely mixed up with ground suet, oatmeal, &c.? because to a rat, a mouse, a bird, even a tomtit, we suspect the plaster of Paris would be almost as fatal as arsenic, though they would require to take it in larger quantities, and we do not think the latter is yet classed in the category of poisons.

But, without joking, we think it is very much the same as O'Connell driving a coach and six through an Act of Parliament, this law forbidding the poisoning of anything that can be exposed, and allowing to agriculturists—and gardeners too, we presume—the poisoning of seeds that are just placed under the surface of the ground—that is, sown or pretended to be sown. We recollect in making some remarks on that very useful book, useful for what it contains and the more so for its cheapness—"The Science and Practice of Gardening," rather

insisting on darkness aiding germination, such darkness as a covering of earth gives; but then, as many things if otherwise favourably situated would germinate without being buried at all under an earth cover to promote comparative darkness, what would become of the law if we sowed our seed, well poisoned, on the surface, more especially if we could summon into court the authority of one of our conductors, that darkness, and therefore covering, was not essential to germination?

It will be seen that we are alluding to this matter in a kindly spirit, as one reason why we feared to use red lead with our sown Peas was the dread that the birds who eat them, and especially the pheasants, might be injured; and we hope that some correspondent of more experience will yet help us in this matter, as what is wanted is something to repel rather than to destroy; for if the red lead encrusted on Peas would kill the pheasants, we would be as unwilling to use it as we would be to use a net of a mesh sufficient to let their head through and hang them in the process of trying to get it back again. We are sure many beside ourselves will be thankful to "Lex" for his sound information, as we country folk may very easily and somewhat innocently become entangled in the meshes of the law, from which we should all try to keep clear, as, even in a good cause and a heavy loss, the first loss is often better than a later success when law has been appealed to.

Of course, we are perfectly well aware that if a gentleman chooses to turn his pleasure grounds and his kitchen garden into a game preserve, and consequently into a preserve for much more than game, he has a perfect right to do so; and if all the produce of the garden is thus consumed, the gardener has no right to grumble so long as the employer is satisfied; but he has a right to complain when such a state of things exists that no nest of birds of any sort must be touched, no sound of the gun must ever be heard within his bounds, and yet orders should be given for produce as if none of the natural eaters-up of that produce were present to render so far nugatory his labours. Where the shoe pinches with many of us blue aprons is simply here—that whilst all these devourers are to be allowed to take what they like without let or hindrance, the gardener is expected to supply a large establishment as if he had nothing but the routine of the seasons to oppose him. We have received so many thanks for mere fair statements, that it is no credit to us to state a self-evident truth—that from the same piece of ground you cannot obtain the same results for an employer's table with the free admission of game and their attendant vermin as without it, for wherever game is thus encouraged in the garden premises you will also encourage all sorts of birds, mice, rats, &c.

Gave a good watering to some late Cherries, as the Florence, now swelling, and securely netted from the birds. To give an idea of their rapacity we may mention that on some young trees of May Duke not netted the fruit was all taken almost before it began to take its second swelling—in fact, when quite hard and colourless. Nothing relieves us from the constant next-to-unavailing contest but a good continuous rain, which, in the shape of slugs, worms, &c., brings other food near to them. We must here mention that we have never been less troubled with these marauders, showing, as mentioned last week, that in moderation birds are friends rather than enemies; but wherever pleasure gardens abut on the fruit and kitchen gardens, birds will be sure to be too numerous if left to themselves. We felt it rather annoying this spring to walk round some of the villages and find the Pear and Plum trees one mass of healthy bloom, after seeing the ground at home covered with the remains of bloom-buds, and hardly a blossom left, though if not interfered with they, too, would have been a mass of bloom.

In our case Plums and Pears, and even Apricots and Peaches, suffered chiefly from birds. By the time that Apple and Cherry trees began to swell their buds the birds must have been able to attack something else, for they interfered less with them. The clearing off the fruit-buds has made our dwarf standard Pear pyramids, &c., grow with greater vigour, and during the week an operation has been begun which we would have wished to have done sooner—namely, shortening back most of the shoots within a few inches of their base, leaving a few merely shortened at the point to continue the growth, and prevent the smaller buds being tempted to lengthen into wood-buds. For several years we have had little trouble with these dwarf trees, as the heavy crops prevented a too vigorous growth, but the birds in pretty well demolishing the fruit-buds gave too great a stimulus to mere growth, which must thus be counteracted to prepare for the fruit-buds, which we hope may have

**KALOSANTHES COCCINEA CULTURE IN A WINDOW** (*Amateur Gardener*).—The best time to propagate is the present. Select shoots without flowers, cut them below a joint, remove the leaves for a couple of inches, or half the length of the cuttings, and insert these down to the leaves in small pots filled with a compost of peat, loam, and sand in equal parts. They will root freely in a window, only do not over-water. The only danger to be guarded against in wintering them is having the soil wet. They should be kept as dry as possible without allowing the shoots to shrivel, and must be secure from frost. They do well in a compost of turfy loam, peat, and leaf mould in equal parts, with the addition of one part of small crocks and a like quantity of sand to keep the soil porous. Your plant will not require potting this year if the soil is sweet, but if this has sunk down in the pot you may repot now. Cut the plant back after blooming, and when it has made shoots 2 or 3 inches long repot.

**DESTROYING EARWIGS** (*G. C.*).—If you procure a number of earwig-traps, which may be had of any nurseryman, and elevate them on sticks, you will soon considerably thin the earwigs; and if you place sticks wherever you can, and hang on them any old cloth, the earwigs will congregate there, and may be destroyed in great numbers. You may still further thin their ranks by adopting the means described at page 34.

**ORANGE TREES FLOWERING** (*Amateur*).—Your trees now showing flower will be strengthened considerably by removing the blossoms, but retaining the shoots, as the season is now advanced. We should advise the syringing to be done in the evening. It is not uncommon for the Peach to bloom on the wood of the current year, but we do not remember seeing it so early in the season. Our correspondent has "a Peach bush in a small orchard-house with fruit on it more than half grown, and it has produced two blossoms on a shoot of the present year."

**FUCHSIAS INFESTED WITH THRIPS AND RED SPIDER** (*Old Cummock*).—The leaves sent are infested with thrips and red spider, caused by the plants having too little moisture and too high a temperature. Your

best plan of destroying them will be to syringe the plants with a solution of 2 ozs. of soft soap to the gallon of water. Take them out of the house, lay the pots on their sides, syringe that side of the plant, and, turning them, thoroughly wet every part. Repeating this washing several times will clear the plants. The leaves which have been severely attacked will, however, fall off.

**ENOOTHERA** (*W. H. B.*).—Your plant was probably *Enothera grandiflora*, which was at one time rare, but now plentiful enough in *E. Lamarekiana*, which is the same, and supposed to be new, though introduced so long ago as 1778. It can be obtained of most nurserymen. If a dwarf-growing plant is required it might be *E. macrocarpa* (*missouriensis*). It can be had of all nurserymen.

**NAMES OF FRUITS** (*J. F.*).—No. 1, Büttner's Black Heart; 2, Cerone; 3, Black Tartarian. (*G. B.*).—Purple-fruited Egg-Plant, *Solanum melongena fructu oblongo violaceo*.

**NAMES OF PLANTS** (*Mrs. Grant*).—We do not recognise the leaves, send it again when in flower. (*T. S.*).—1, *Anagallis arvensis*; 2, *Polygala vulgaris*; 3, *Erica tetralix*; 4, *Hypericum humifusum*; 5, *Veronica beccabunga*; 6, *Nasturtium palustre*. (*J. B.*).—1, *Symphoricarpos racemosus*; 2, *Hoteia japonica*; 3, *Santolina chamaecyparissus*; 4, *Stipa pennata*; 5, *Saxifraga ajugifolia*. (*Grassmere*).—A *Kalmia*, but without the leaves we cannot say what species. (*E. J.*).—1 and 2, the fronds are too young; 3, *Sedum reflexum*. (*W. W.*).—1, *Chelidonium majus*; 2, *Geranium striatum*; 3, *Lycyesteria formosa*; 4, *Anomatheca cruenta*. (*Brook*).—1, *Pteris longifolia*; 2, *Adiantum formosum*; 4, *A. tenerum*; 5, *Pteris cretica albo-lineata*; 6, 7, 8, *Selaginellas*, but the specimens insufficient. (*R. T. Wheeler*).—*Tetragonolobus purpureus*. (*H. L., Leeds*).—The sinterorean Fungi forwarded were specimens of *Melanogaster ambiguus*, usually found under Fir trees, but you can send us other specimens, or give full particulars? (*E. S. C.*).—Your Fern was named in our Number published July 10th. It was *Lastrea dilatata*.

### METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 21st.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun. . . 15	30.126	30.080	82	52	68	63½	E.	.00	Very hazy; hot and dry; very fine.
Mon. . . 16	30.065	30.034	78	52	68½	63	E.	.00	Slight haze; fine; very fine.
Tues. . 17	30.022	29.983	74	41	68	63	E.	.60	Overcast; fine; overcast; rather cold at night.

### POULTRY, BEE, and HOUSEHOLD CHRONICLE.

#### RAILWAY CHARGES—WOODBRIDGE POULTRY SHOW.

It is many weeks since the last notice on this subject appeared in "our Journal," at least the last notice from my pen. I can, however, assure all those who are interested in the matter, that it has been by no means a "dead letter." Little did I dream, as T. Hood says, "that I should ever live to see what is before me;" but I can safely say, and it may be taken in any sense "our" readers please, that I have often wished of late there were no such things as "railway charges!" What halcyon days! No poultry shows then without entries! No calculations necessary then to discover whether, after obtaining the honours of a prize, the pocket of the exhibitor will really be emptier than before the show! By-the-by, that has been my condition at Woodbridge, the Show held six weeks ago and the prize not paid yet. Although I have written to the Secretaries, no notice has been taken; *en passant*, let me say that this plan is the best to ruin the prospects of any show.

Since the last notice on the subject of railway charges, I have dispatched the "independent memorial." The signatures were nearly 120. The memorial has been acknowledged by most of the railways, and some of the replies do not look unfavourable. I have carried out the suggestion which Mr. Warren, the Secretary of the Hampshire Ornithological Society, threw out, "that the officials of poultry shows might aid in the matter." I had, therefore, a suitable form of memorial lithographed, and dispatched this form to nearly all the poultry shows I could make out. The result has been the formation of a memorial, which, as it appears to me, is one far more important than either that of the Poultry Club or the independent exhibitors, and more likely to influence the railway companies; but of this memorial more anon. One of the earliest replies was from grand-maternal Birmingham; it was accompanied by a note from the Secretary, stating that it was the wish of the Council that

their's should go as a separate memorial. I most willingly agreed to this, and Mr. Lythall kindly took charge of this memorial, and forwarded it to the various companies. Meanwhile other replies came in, and several of them were so well signed that I had the signatures lithographed and forwarded as separate memorials. They are as follows:—Chelmsford and Essex.—This memorial was kindly taken in hand by Mr. George Manning, of Chapel House, Springfield. Hampshire Ornithological, by Mr. P. Warren, the Secretary. Haslingden, by Mr. Shaw, the Secretary. Halifax and Calder Vale, by Mr. Irvine, the Secretary.

The general official memorial will be sent off in a few days, I hope. This Mr. E. Pigeon, of Lympstone, near Exeter, has kindly undertaken. It contains 253 signatures, and represents forty-nine different shows—viz., \*Birmingham, Manchester, the Yorkshire Society, Bath and West of England, Eastern Counties, \*Chelmsford and Essex, Sheffield, Roehdale, Hull, Worcester, \*Hampshire Ornithological, Whitehaven, Plymouth, Aberdeen, Wakefield, South of England, Hastings and St. Leonards, Dewsbury, Kelse, Kendal, Leicester and Waltham, Cirencester, Brentwood, Lord Tredegar's, Frome, Scarborough and East Riding, Ipswich, Hants and Berks, Ripon and Clare, Suffolk, Nantwich, Epworth, Bude Haven, Chippenham, Congridge, Calne, Market Drayton, Kingswood, Ulverstone, Loughborough, Pudsey, \*Haslingden, Atherton, Long Sutton and South Lincolnshire, Essex Agricultural, Cleveland Agricultural, \*Halifax and Calder Vale, and Newbiggin.

I do not think it can be disputed that an evil which is so widely felt that the officials of shows throughout the length and breadth of the land unite in testifying to its magnitude, is likely to remain utterly unaltered. The representatives of one show, and one only, have been found to praise railway arrangements; that show is the Walsall. I cannot but feel that the Walsall Committee have looked at the matter with different eyes than those of distant exhibitors.

There remains further to bring the subject before the meet-

\* Those marked thus \* had only the signature of the Secretary, as the other names appeared in the separate memorials.

**BANTAMS** (Black, &c.).—First, H. M. Bazley. Second, R. Higham.  
**GUINEA FOWLS**.—First, S. L. Lucas. Second, T. Philipps.  
**DUCKS** (Aylesbury).—First, J. Bines. Second, W. Bines. *Ducklings*.  
 —First, J. Bines. Second, J. Davey.  
**DUCK** (Common).—First, J. Cotton. Second, J. Piper. Third, S. T. Pickard. Fourth, Mrs. E. S. Trickey. *Ducklings*.—First and Second, F. Gloyne. Third, S. Brown.  
**DUCKS** (Rouen).—Prize, Rev. G. C. Guille.  
**GESE**.—First, J. Woodley. Second, Rev. G. C. Guille.  
**TURKEYS**.—First, Rev. G. C. Guille. Second, Miss Gorle.  
**PIGEONS** (Common).—First and Second, J. Cotton. Third, W. Brock. *Carriers*.—Prize, Rev. J. R. Whyte. *Pouters*.—Prize, J. M. Braund. *Fantails*.—Prize, J. M. Braund. *Trumpeters*.—Prize, J. M. Braund. *Tambours*.—Prize, Mrs. Bazley. *Nuns*.—Prize, Rev. J. R. Whyte.  
**RABBITS** (Longest Ear).—Prize, Master Veale. *Common*.—First, Master J. Edgcombe. Second, Master R. Francis.  
**EXTRA PRIZES** (Any pure breed).—Prize, T. Wood. *Single Cock*.—First, A. West. Second, H. Darch. Third, J. F. Delmar.  
**EXTRA PRIZES** given by William Maskell, Esq.—*Cock and two Hens*.—First, J. Davey. Second, J. Stanbury. *Ducks*.—Prize, J. Davey.

## EPHING EXHIBITION OF POULTRY AND PIGEONS.—JULY 17TH.

This Show though limited as to the number of the entries, was one of a very superior kind as regarded the greater proportion of the birds exhibited. The weather proved as satisfactory as any well-wisher of the Society could desire, and the ground on which the Show was held was well chosen. The pens were the well-known ones of Mr. Cooke, of Colchester, and every specimen was placed in a single row, so that the arrangement for the exhibition of the birds was all that could be desired. The members of the acting Committee were entire novices at the management of a poultry exhibition, and for this simple reason they deserve the greater credit for bringing everything to so satisfactory a conclusion. The weather, too, was fortunately most propitious, and as a poultry show was a novelty at Epping, the attendance was far beyond what was generally anticipated. Every pen was placed under cover, and protection was also provided for all visitors had the weather necessitated it, but happily, as just stated, the day was extremely fine.

The Grey *Dorking* class was one of the best filled in the whole Show, and Mr. Lingwood's triumph was not without severe competition. A pen of most excellent birds in this class were thrown out altogether by one hen proving to be ruptured. It should be always borne in mind that ruptured hens are as inadmissible for competition for prizes as they are utterly useless for stock purposes. The class for White *Dorkings* was at a very low ebb as to entries, but the prize birds were excellent. In the *Spanish* class only one pen was exhibited, and to it a second prize was awarded. The birds had, no doubt, some time back been of great merit, but ago had laid a heavy hand upon them; the cock was long past his best, and the coarse corrugations of the face rendered him almost sightless. In *Game* fowls, as might readily be anticipated, Mr. Mathewa, of Stowmarket, proved the lion of the day. Most of the birds in this gentleman's collection were very good indeed, but it is simply impossible just at the present period of the year to exhibit them in the height of condition on which, in *Game* fowls particularly, so much depends. In *Cochins*, the Buffs exhibited by Mr. Lingwood, of Needham Market, and the White ones belonging to Mr. Zurhorst, of Donybrook, Dublin, were most praiseworthy. Mr. Pickles again stood first with his excellent pen of Dark *Brahmas*. In *Hamburghs*, the Show was confined to but few, but the excellent pens of these beautiful varieties, sent by Mr. Wood, of Keadal, proved most attractive, as *Hamburgh* fowls seem but little known in Essex. The *Game Bantam* classes were a failure as to excellence, although a good show was anticipated. Among the *Bantams* were shown a trio of as superior *Booted Bantams* as we have seen for a long series of years. In the *Variety* class *La Flèche* and *Malays* were the prize-winners, both being pens of first-rate birds.

A single pen of *Geese* and of *Turkeys* were all that were entered, both being very good indeed. The *Geese* belonged to Mrs. Seamons, of Aylesbury, which insured something decidedly superior; but it was in *Aylesbury Ducks* that this lady far out-distanced all competitors, surprising the many visitors who for the first time witnessed the products of her yard, by the good quality and size of these. The *Rouens* were so had that every prize was withheld, the truth being rather, that not a single *Rouen Duck* was exhibited, and those *Ducks* that were sent might better have remained at their homesteads.

Although four different classes were allotted to single cocks of as many varieties, only one Buff *Cochin* was entered; he was an excellent bird, but, of course, had nothing to compete against, although journeying from the yard of Mr. Zurhorst, of Donybrook, Dublin, to look out for a rival. As a "sweepstakes" bird under such rule, if rigidly enforced, can only win by any possibility his own entry-money back again, the Judges suggested an extra prize from the general funds, which will, no doubt, be allowed by the Committee, and the bird itself well deserved it.

No entry was made in any of the classes devoted to *Pheasants*; and the small collection of *Pigeons*, with the exception of two or three pens, was not equal to what might have been hoped for in an exhibition held within seventeen miles of London. The *Siberian Ice Pigeons* were well shown, and very good specimens. As extra stock, Mrs.

Rothwell, of Epping, exhibited two capital pens of Japanese *Bantams*, a light-coloured pen and a dark one, of both of which the Judges spoke in highly commendatory terms.

Some very good *Canaries* were shown, but few in numbers. As a kind of tail-piece to the Show, Mr. Edward Milman, of Theydon Grove, sent a recently-caught Barn Owl. He seemed an object of great interest to the more juvenile visitors, but his violet efforts to escape proved beyond question that his comforts were but little increased by their uproarious plaudits.

The Show was concluded satisfactorily to all parties, and no doubt will become an annual institution.

**DORKINGS** (Coloured).—First, H. Lingwood, Barking, Needham Market, Suffolk. Second, F. Parlett, St. John's Road, Chelmsford. *Chickens*.—Extra Prize, W. H. Walker, Shenfield, Brentwood.

**DORKING** (White or Silver-Grey).—First, Miss Arkwright, Mark Hall, Harlow. Second, W. H. Walker.

**SPANISH** (Black).—First withheld. Second, R. B. Postans, Brentwood. **GAME** (Black-breasted and other Reds).—First and Second, S. Mathew, Chilton House, Stowmarket. Highly Commended, J. Jeken, Eltham, Kent. **GAME** (Any other colour).—First and Second, S. Mathew (Duckwing Game, Piles.)

**COCHIN-CHINA** (Buff).—First, H. Lingwood. Second, J. Thompson, Writtle.

**COCHIN-CHINA** (Any other colour).—First, F. W. Zurhorst, Donybrook, Dublin (White). Second, Rev. M. R. Barnard, Margretting Vicarage, Ingatstone (White).

**BRAHMAS** (Dark or Light).—First, J. H. Pickles. Second, E. Sheerman, Chelmsford (Brahma Pouter). Highly Commended, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks.

**HAMBURGH** (Silver-pencilled).—First, A. K. Wood, Burnside, Keadal, Westmoreland. Second, T. J. Saltmarsh, Mildmay Road, Chelmsford.

**HAMBURGH** (Gold-pencilled).—First, C. Havers, The Beacons, Ingatstone. Second, A. K. Wood.

**HAMBURGH** (Gold-spangled).—Prize, A. K. Wood.

**HAMBURGH** (Silver-spangled).—Prize, A. K. Wood.

**GAME BANTAMS** (Black-breasted and other Reds).—First, R. B. Postans. Second, Rev. G. Rayner, Kelvedon Hatch Rectory, near Brentwood.

**GAME BANTAMS** (Any other colour).—Prize, G. Manning, Springfield (Duckwing).

**BANTAMS** (Black or White).—Prize, J. R. Jessop, Beverley Road, Hull.

**BANTAMS** (Any other variety).—Prize, G. Griggs, Oathands, near Romford (Cuckoo).

**ANY OTHER DISTINCT VARIETY**.—First, F. W. Zurhorst (La Flèche). Second, J. Hinton, Hinton, near Bath (Malay).

**TURKEYS** (Any colour).—Prize, W. Wright, Fulburn, Cambridgeshire.

**GESE** (Any colour).—Prize, Mrs. M. Seamons, Hartwell, Aylesbury, Bucks.

**DUCKS** (White).—First and Second, Mrs. M. Seamons. Highly Commended, W. Tippler, Roxwell; E. W. Green, Bury St. Edmunds.

**COCHIN-CHINA COCK** (Any colour).—Prize and Extra Prize, F. W. Zurhorst (Buff).

**PIGEONS**.—*Carriers* (Any colour).—First and Second, E. Dames, Chigwell (Black and Light). *Any other variety*.—First and Second, F. Broemel, Lewisham (Siberian Ice and Russian Porcelain Pigeons).

**CANARIES**.—*Cock*.—First, G. Hall, Romford. Second, R. Counter, Romford. *Hen*.—First, R. Counter. Second, G. Hall. *Males*.—Prize, R. Counter.

**RABBITS** (Lop-eared).—*Buck*.—First, G. Hall. Second, E. Lawrence, South Weald, Brentwood. Commended, E. Lawrence. *Doc*.—First, E. B. Barnard, Fair Green, Sawbridgeworth. Second, E. Lawrence. Highly Commended, Rev. H. Foster, Theydon Gernon Rectory.

Mr. Tegetmeier, of Muswell Hill, London, and Mr. Hewitt, of Sparkbrook, Birmingham, officiated as the Arbitrators.

## HAMBURGHS WANDERING.

SEEING that "WILTSHIRE RECTOR" recommends *Hamburghs* to an inquiring friend, I should like to know whether he finds in them the one fault which I do—namely, a strong propensity to lay away from home, in which case, as they do not sit, undiscovered eggs accumulate to an undesirable extent. I once found fifty-six, all laid by one hen. I have, however, a good deal of wild shrubbery adjoining the poultry-house.—**A WILTSHIRE FARMER.**

[I would observe that the tendency to lay away from home which some fowls manifest, among them some *Hamburghs*, which "A WILTSHIRE FARMER" rightly terms their "one fault," may be much checked by making the birds very tame. This may be easily done by feeding the fowls near to the house, going among them with dinner-plate scrapings, and other niceties. If you enter some yards the fowls fly from you like wild birds; in others, where they are tame, they walk fearlessly around you as domesticated birds ought. Again, if fowls are allowed to roost anywhere, it is no wonder if they lay anywhere. I think the tendency to lay away from home exists in all those varieties of fowls which love to wander; in fact, they are more like wild birds. I have in former years been much troubled with *Game* hens laying in hedges, but they were invariably those which I had not bred, and were always to the last shy of company.

I think that "A WILTSHIRE FARMER" has hit upon the chief cause of his trouble, when he says, "I have, however, a good deal of wild shrubbery adjoining the poultry-house." His satis-

faction must be, that if he loses some eggs it is only some out of very many laid, and the egg-collecting boy must be told to keep his eyes about him. A breeder of Hamburgs of many years duration tells me that only a few of her's had this fault, one hen out of several, which it was best to kill. I will add that I always recommend Dorkings as the best birds for the farmer, though Hamburgs are charming pets for amateurs who live in the country.—WILTSHIRE RECTOR.]

### EXTRACTING THE GAPES WORM.

I HAVE seen the remedy recommended for gapes by "G. W., Cardiff," in THE JOURNAL OF HORTICULTURE for June 12th. How is it possible to introduce the gut into the windpipe? It seems to be the throat of the chicken it, or a feather, goes into, and how can the difference be known and made? I have been told by a medical man that it is very difficult to introduce anything into the windpipe.—F. P.

[The medical man is right, it is difficult to introduce anything into the windpipe, but by no means impossible or injurious. We are always cautious how we attempt it with anything as hard as gut, but we work freely with a feather, as danger is impossible. If it have the effect of a erumb going the wrong way so much the better, the coughing will get rid of some of the worms. When the bird breathes, the feather can be introduced. You may not succeed the first or second time, but you will at last. We dip a feather in turpentine.]

### THE EGYPTIAN BEE.—PART I.

#### ITS MANAGEMENT IN EGYPT, AND ITS INTRODUCTION INTO GERMANY.

"In conclusion the author enters upon the question of the acclimatisation of new forms of bees. For Europe he thinks the most valuable form would be the Egyptian, partly on account of their beauty, and partly because of their unwillingness to use their stings, which appears to be common to all African bees, and is also one of the recommendations of the Italian bee."—*Annals and Magazine of Natural History* for May, 1863.

SOME time before the appearance of Mr. Dallas's epitomised translation of Dr. Gerstaecker's paper on "The Geographical Distribution and Varieties of the Honey Bee," from which the above extract is taken, I had become aware of the value attributed by the learned German to the Egyptian race of honey bees (*Apis fasciata*), and had taken steps for obtaining it by sending an order to a distinguished mercantile firm in that country, to whom I had obtained an introduction, for three colonies of bees, accompanying my order with full instructions for packing and transporting them to England. This order was, however, never executed, for reasons which I could not at the time comprehend, but which the following narrative explains clearly enough, and the whole affair remained in abeyance until last year, when I learned that the Berlin Acclimatisation Society had taken the matter in hand, with what success Herr Vogel, the distinguished German apiarian who has acted for the Society, shall relate for himself.—A DEVONSHIRE BEE-KEEPER.

"We believe that Egypt was included in the range of the creation of the bee, since, on account of the obscurity and insufficient knowledge we possess of the ancient history of this country, we can neither prove that our favourite insect spread by degrees voluntarily into it, nor that it was man who introduced the bee into the valley of the Nile.

"The historical fact that the ancient Egyptians were a cultivated people gives us reason enough to suppose that the bee was domesticated in Egypt in the earliest times. Although we do not find it reckoned among the animals that were considered sacred, yet different antiquarians are of opinion that the mythical sacredness of the bee was likewise intimated in the name of Apis, by which name the sacred bull of the Egyptians was called, as the name of the sacred bull is identical with the later Latin denomination of the bee. It would be overhasty to infer from the biblical account that because the old patriarch Jacob amongst other presents also sent honey to "the man" in Egypt, that the bee did not exist in Egypt at that time, and that therefore Jacob wished to make a valuable present of honey to Joseph. According to the opinion of biblical commentators the honey (*D'basch*), mentioned in Gen. liii, 11, was not the honey of bees, but a kind of succedaneum, a thickened grape juice, which was afterwards also taken from Pales-

tine into Egypt, which was poorer in honey. It is still at the present day called Dibs.

"The ancient Egyptians used the Nile to obtain rich harvests, and the ancient Egyptian bee-keepers understood also how to use the river for profiting from the plants through their bees by carrying on an extensive wander-bee-keeping on the great river. As Upper Egypt is hotter than Lower Egypt, and the country there is sooner freed from the inundation, the honey-yielding plants also develop themselves earlier. In Lower and Middle Egypt the bee-hives having been previously numbered, were piled in a pyramidal form on boats specially constructed for this purpose, and were taken up the Nile with the wandering bee-house.

"When the chief gathering in Upper Egypt was over, they were shipped a few miles lower down the stream, and a halt was again made so long as the bees found plenty of food. In the beginning of February the stocks arrived in Lower Egypt, where they were again delivered to their owners. The bee-keepers of Upper Egypt who had accompanied them, after their hives had profited by the pasture near the sea, went home again with their heavy stocks up the stream, in April.

"The civilisation of Egypt fading by degrees, and becoming worn-out and effete, ultimately expired under the rule of the fanatical Mahometans. With the vanishing culture, bee-keeping in Egypt, old and extensive as it was, sunk too; at least, modern travellers no longer see anything of wander-bee-keeping on the Nile. A change has taken place in Egypt also in modern times. At present it is only those Arabs (Fellahs) who are settled and carry on agriculture and a few Copts who keep bees, whilst the Bedonins living on the borders of the desert keep none at all. From the small number of inhabitants in the country (about three millions), we may judge of the very small number of bee-keepers there. Bees are most extensively cultivated in Upper Egypt. They are kept there in moveable earthenware vessels, and it is said that these vessels are immediately walled in. In Middle and Lower Egypt there are but few apiaries. An architect named Kinder travelled in the neighbourhood of Cairo for some time without discovering one apiary. Besides earthenware vessels, the bee-dwellings here also consist of clay cylinders. Straw hives do not seem to be in use, and when the word *körbe* (straw hives), is used in accounts of travels in Egypt, when speaking of bee-keeping in that country, it probably means bee-hives only.

"I only know the Egyptian cylinders by sight. They are made of the Nile mud, from which material also the poor people in that country construct their miserable cottages. Such a cylinder is about 15 inches diameter inside, by 3 feet long, and has, therefore, about the same internal dimensions as a large Dzierzon hive. It is 1½ to 2 inches in thickness. The hive is closed at both ends by means of circular discs made of the same material; and the entrance, which is but small, is made in one of these discs. Cross sticks are not employed. The cylinders lie in a horizontal position, and are placed, like draining tiles, under the shade of a tree. The stock which was introduced into Germany stood in Egypt until its removal under the large tree in the English churchyard at Cairo. The hive of the imported stock was a cylinder, only about one-third of the size of the usual hives, made so small purposely for transportation. February is the swarming season in Upper, and March in Lower, Egypt. The imported stock is a small second swarm, which issued in the latter end of March. An artificial increase of stocks is not known. Bee-caps are unknown. The Egyptian bee-keepers always approach their bees with their faces unprotected, hive the swarms, and deprive the bees of honey according as they have gathered. The Egyptian clover, *Trifolium alexandrinum*, is the favourite plant of the bee.

(To be continued.)

### SIZE OF HIVES—BLACK BEES.

I HAVE a prime swarm hived June 10th, which has to-day, (July 12th), as late as six o'clock, clustered on and underneath the alighting-board of a frame hive (mentioned below as oblong). It has been very warm here. How can I stop this in future? As I can make my own hives I followed the directions given in the "Bee-keeper's Manual" for frame hives, and was afterwards told they were too large for this part (North Cheshire); so I then made my next hive to consist of eight frames of the same size as the previous one instead of ten, thus making it a parallelogram. Will this matter?

Why are all bees not Ligurians called black bees? Mine

are brown. Are they a different species and superior to the others? What would you estimate the weight of honey a Woodbury hive should hold?—A. M.

[The mere shape of your hives is of no importance; but whoever told you that the ten-frame Woodbury hive was too large for your locality was mistaken, as is proved by the bees of the swarm clustering outside your eight-frame hive. Additional room had better be given to them by putting on a good-sized super. The so-called black bees are really a dark brown, and yours do not differ from others in that respect. The common bee is quite as dark as any nigger we have ever seen.

We scarcely understand your last question. A Woodbury hive, like all others, should contain sufficient honey to enable its inhabitants to stand the winter, say 15 or 20 lbs. If completely filled, it may contain nearly 50 lbs.]

### UNITING WEAK STOCKS.

LAST autumn I purchased twenty-four hives of bees, in common straw hives. Twelve of them I selected to take and twelve to keep, the latter were second and third swarms, and very light. I fumigated the twelve strong ones, and united the bees to the weak lot, six out of the twelve of which had not 1 lb. of honey each. These I fed all winter with syrup made of 3 lbs. of white sugar with 1 lb. of water, and gave it at the top of the hives in glass bottles, with black net tied over the mouths of the bottles.

I was obliged to winter the hives at the back of a south wall, where the sun never shone on them at all through the winter, and so damp was the place that the bottom boards were nearly always mouldy, but I cleaned them and dried them before a fire as often as I conveniently could. I likewise cleaned the covers, and dried them.

Early in spring, when the bees began to stir, I looked into all the hives, and to my dismay found the inside of the hives very wet, and the straw rotten; the combs also were mouldy, except where the bees had clustered. On the 30th of March I cut all the mouldy comb away, and made a quantity of barley-sugar, and fed the bees with it. I afterwards found that two stocks out of the twelve were queenless, so I united them to the weakest stocks.

I then took a small allotment garden, in which I erected a bee house, and placed my stocks in it. Since then they have done remarkably well as far as working and thriving goes, but they hung out, and would not swarm; so, on the 21st of last month, I drove them into empty straw hives. I then knocked them out of the straw hives on to the ground, and put a Woodbury bar and frame hive easily over them. In this way I drove seven hives, some of which went back, but I drove them again the next day; then I drove two of them again in about a fortnight afterwards, and another swarmed of its own accord.

My stock of colonies is now twenty—ten old stocks and ten swarms, all doing well except one old stock, which is queenless. Into this I should like to put a pure Ligurian queen. Can you inform me where I could obtain one, and what her cost would be?—ISRAEL TODD.

[Write to T. W. Woodbury, Esq., Mount Radford, Exeter. Perhaps he can assist you in obtaining a pure Ligurian queen.]

### CONSEQUENCES OF REMOVING A SUPER—GREEN HONEY.

I TOOK a large straw super from a stock hive full of honey on the 14th inst., and replaced it at once by a glass super covered from the light. There was a good deal of brood comb in the super, and I thought I saw a queen, but she was so dragged with honey that I could hardly be sure. The comb was very soft from the heat. Since Saturday a massacre has been going on, and there are hundreds, probably thousands, of dead and dying lying in front of the hive. Have I done anything wrong? Shall I leave the glass super on? The hive was of very strong one, and had never swarmed. The honey is of a pale green, and in some parts turbid.—W. D. A., *Hampstead*.

[We do not see anything wrong in your proceeding, unless it should turn out, as appears probable, that by spilling some of the contents of the super you have attracted robbers, and thus induced an attack by the bees of other hives, which has resulted

in the death of thousands as you describe. On the other hand, it is just possible that one of those singular interneecine wars has broken out within the hive itself which sometimes, although rarely, follow disturbances among bees, and for which it is difficult satisfactorily to account. It can do no harm to leave the super on for the present, but it should be removed when the honey season is over. Green honey is a phenomenon with which we are entirely unacquainted, but which must result from some peculiarity in the pasturage.]

### NOTES AND QUERIES.

I KEPT five stocks through the winter, and they all commenced working well in the spring. Two of them were swarms two years ago, and each of them threw off two swarms last season; another was a top swarm last year, another a second swarm, and the last was two hives driven together. All at once, however, the driven hive and the two old hives seemed to fall off and to dwindle away. Can you tell the cause of it? There was not a drone among the bees in one hive which I destroyed. Do you think it was on account of their not having any drones that the bees did not breed?

The top swarm threw off a top swarm on June 20th, and a second on June 23rd. Between the first and second swarms the bees dragged four queens out, and, after the second, other five queens. How do you account for so many queens, and the second swarm so soon after the first? We had a hive three years ago that cast three swarms within eight days, and dragged eight queens out between them.—A CONSTANT READER.

[We are unable satisfactorily to account for the fact that without apparent disease stocks sometimes seem to dwindle in spring, until at last, as in your case, so few workers remain that breeding languishes if it does not entirely cease. It is certain that the absence of drones has nothing whatever to do with it, whilst we have often proved that in these cases the breeding powers of the queens themselves are not always defective, since, when the population of their hives has once been sufficiently recruited, they have frequently shown themselves equal to the task, not only of maintaining, but of rapidly increasing it. Swarms follow at short intervals when several young queens mature nearly at the same time, but we can give no reason for the fact that some stocks form many more royal cells than others.]

### OUR LETTER BOX.

PRESERVING EGGS FOR WINTER USE (*Harriet*).—Some preserve eggs by coating them with butter, or with anything that will render them airtight. Our own way is to keep them in lime, and we can put them on the breakfast table in December as breakfast, and almost as new-laid, eggs. Take a large common breadpan; fill the bottom with lime slaked to such consistence that eggs being stuck in it will retain their position. When the bottom is filled with them as closely as can be, but without touching each other, pour lime in a liquid state over them till they are covered, and a smooth surface is presented. As soon as this is the case, and you have eggs enough to form another layer, follow the same process until the pan is full. You must, of course, suit the size of your pan to the number of eggs you are likely to have. When they are likely to come slowly it is better to have a deep vessel, as they should be put in fresh, and it takes some time in autumn to obtain a large number. The appearance of a drop of blood in the yolk of the egg and the dropped egg are all unimportant. They merely remind us that the end of the laying season is at hand.

BRAHMA POOTRAS VULTURE-HOCKED (*J. N.*).—So far from being necessary that Brahmas should be vulture-hocked to be successful at a poultry show, it is a very great disadvantage; and if they are shown against birds that are not so disfigured it becomes a disqualification. Neither Cochins nor Brahmas should have vulture hocks.—B.

BRETAGNE COWS (*James H.*).—You had better call on Mr. Baker, Half-Moon Passage, Gracechurch Street. He sells this variety. If the price do not suit you, we recommend you to inquire in Ireland for one of the Kerry cows. They are not more than from 3 feet 2 inches to 3 feet 6 inches high.

### POULTRY MARKET.—JULY 21.

WE are gradually drifting into autumn trade, but everything has been out of joint through the unusual heat. A few fresh goods have made very large prices, while many consignments have been thrown away. Should the weather keep moderately cool, low prices only will be realised

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 75.1°; and its night temperature 51.0°. The greatest heat was 92°, on the 2nd, 1856; and the lowest cold 31°, on the 2nd, 1864. The greatest fall of rain was 1.23 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

THE HYDRANGEA AS A HARDY SHRUB.

LAD am I to see that Mr. McDonald has called attention (page 8), to the cultivation for out-door decoration of this highly ornamental plant, for it has hitherto been

more neglected than it ought to have been. Some persons, perhaps, may have thought it too tender, and in consequence disregarded it, while others, having only an indifferent situation, have unjustly condemned it because a hard winter killed it to the ground.

Probably the most successful cultivators of the Hydrangea are those cottagers who have turned out an overgrown pot plant in some snug corner, where it thrives and flowers year after year with a vigour which only plants in suitable positions acquire. More rarely it is met with in some shrubbery, or near a residence built a century or more ago; but if it is employed as an ornamental object it is too often merely brought forward when in flower, and taken away when its beauties are on the decline; yet few plants look so well as a well-grown specimen of Hydrangea, whether it bloom pink or green, and no plant with which I am acquainted is more easily managed, or, rather, does better when left alone. Some villages, I may remark, derive much of their beauty from the number of specimens of this plant by which the front gardens are ornamented, and these cases might easily be multiplied.

Like Mr. McDonald I certainly recommend Hydrangea hortensis most, but would nevertheless now and then have a plant of H. japonica as well. A year or two ago a gentleman brought me a bloom of the latter gathered in a villa garden a few miles from Tunbridge Wells, and which was of the most lovely blue, more so than I ever remember to have seen in the Hydrangea hortensis, the buds in the interior of the corymb being equally good in colour with the expanded marginal flowers, and in size and other features it was all that was wanted. The district is, I believe, famous for Hydrangeas, and I can testify to the robust appearance of the plants, but have not seen them in flower. The soil is a sort of yellow sandy loam, on which the wild Heath may now and then be met with, and where Rhododendrons thrive well. It cannot be called a peat, nevertheless, but one of those intermediate soils which suit a large number of plants, and I am told that both pink and blue Hydrangea flowers are produced upon it. There is no stagnant water, and the subsoil is open, porous, and accessible to the roots of trees to a good depth, but turf and shallow-rooted plants suffer much from drought.

It is obvious by the appearance of the plants that shade is of much service to the Hydrangea, as the best foliage is always met with in shaded places; but the plant will

accommodate itself to a sunny situation, and is often met with in such, as well as in all kinds of soils and positions, damp and dry, sunny and shady. It is, besides, much more hardy than is often supposed. One of the largest plants I ever remember seeing was in a garden situated only a few miles south of the Tweed, upwards of twenty miles from the coast, and as bleak as could well be imagined. There was, however, a little shelter on the north side of the garden, but the Hydrangea was in no way benefited by the walls or other shelter. The situation was dry, and the substratum a sort of freestone shatter, resting on deep beds of that material. The flowers were pink. If this plant has continued to flourish it must be a magnificent specimen now, for at the time I saw it, several years previous to 1830, it must have been from 10 to 12 feet in diameter. The Hydrangea does not seem disposed to attain a considerable height, but rather to spread along the ground, and it is seldom that I have met with one more than 5 or 6 feet high unless supported by artificial means. In this respect it differs much from the Fuchsia; where the hardy kinds of the latter endure our winters they present a much more upright shrub than the Hydrangea, and like it they are deserving of more attention than they usually receive. The positions suitable for these hardy Fuchsias, however, differ much from that best adapted for the Hydrangea. A dry stony soil in the full sun, and where the substratum will allow the roots to descend a great depth, suits them best. Some that we have here scarcely lost their tips last winter, and they flowered early and well; but they usually lose some unripened wood, and consequently do not bloom so early. Extraordinarily hard winters will, however, tell on these plants, but it is now several years since the main stems were cut down. Returning, however, to the Hydrangea, I may state that hitherto we have not been so successful with it. The position allotted to it seems to have been too dry; the flowers are produced plentifully enough, but it is distressing to see them droop in a very dry period, when watering by hand is out of the question.

The variegated variety of Hydrangea seems to be a sport of H. japonica. I find, however, that when planted out of doors it loses much of the whiteness which renders it useful as a plant for forcing, and, consequently, it is of less importance outside than could be wished. Of the other Hydrangeas I have not had sufficient experience to give an opinion, but one called H. arborescens seems not to be worth growing. While we have Hydrangea hortensis exhibiting itself in different colours, very often in a way that seems approaching capriciousness (for sometimes one half of a plant will flower blue and the other pink), we have an important field for inquiry, and it is evident that the causes which produce this are far from being fully understood, and nothing but a more extensive culture of the plant under various circumstances will furnish decisive proof of the causes of its flowers changing their colour. At the same time let it be fully understood that experiments with this plant will in general be more satisfactory if carried out in the open ground instead of in pots, because in the latter the potting mixture may have its properties

changed or modified by the water that is artificially supplied. I have known Cape Heaths and similar plants languish and fall into ill health, and now and then some of them die, from being supplied with spring water from a chalk well; and I expect that it must have been something of this kind that prevented the *Hydrangea* flowering blue when grown in peat soil by our late worthy writer, Mr. Beaton, or, if not this, that some other neutralising agency had been at work. This, however, like many other matters connected with the culture of this remarkable plant, deserves to be further inquired into, and the result given to the world.—J. Robson.

#### NOTES FROM NEW JERSEY, U.S.

It was extremely cold weather when last I wrote to you—colder, it is believed, than ever before felt in our part of New Jersey. The thermometer registered 20° below zero. One would suppose that when the cold became so severe as this, two or three degrees more or less would hardly make much difference; but as a cold of 18° below zero kills the fruit-buds of the Peach, the difference was to us between Peaches or no Peaches. In our garden, where last season we had bushels, not one is now (July 7th) to be seen.

We thought that so cold a winter would bring as compensation an early spring; but it was not so. There was a good deal of frost in May, and towards the end of that month one cold night killed not only many tender garden plants, but, sweeping through the low grounds in the woods, blackened the new growth of even hardy forest trees and shrubs. The young shoots of the Chestnut tree and *Kalmia latifolia* especially suffered, although the wood of the latter when ripened is so hardy as to endure 35° below zero, a temperature not very unusual in the winters of some New England States. It seems strange that the young wood of such hardy subjects should be as tender as hothouse plants.

After the 1st of June, with us there is but little danger of frost, and all bedding plants may be safely put out. The sun by this time is powerful, warming the ground well by day; and the nights being still a little cool in the early part of the month, plants are by night in a sort of natural hotbed, which starts the roots at once into vigorous growth. After the middle of the month the heat increases so rapidly that about the 1st of July we generally reach the maximum of our summer heat. The following observations, made in a neighbouring town, will show what this maximum is:—

	7 A.M.	12 A.M.	3 P.M.	6 P.M.
Tuesday, June 19th .....	64°	72°	72°	70°
Wednesday, June 20th .....	60°	78°	82°	80°
Thursday, June 21st .....	66°	88°	88°	85°
Friday, June 22nd .....	69°	88°	91°	86°
Saturday, June 23rd .....	75°	84°	87°	78°
Monday, June 25th .....	76°	97°	98°	94°
Tuesday, June 26th .....	79°	94°	..	..
Wednesday, June 27th .....	80°	95°	96°	90°
Thursday, June 28th .....	70°	71°	73°	72°
Friday, June 29th .....	63°	71°	71°	71°
Saturday, June 30th .....	63°	74°	80°	69°
Monday, July 2d .....	68°	84°	86°	81°
Tuesday, July 3rd .....	70°	92°	..	..

Fancy 98° in the shade for a working-day temperature. This, I confess, is an extraordinary degree of heat, even for us; but 90° is a point often reached during the summer. After three or four days of such hot weather we generally have a thunder shower, which freshens the flagging vegetation and cools the air to 70° or 80°. Every season, either in summer or early autumn, we have many consecutive days of very dry weather, during which most plants seem to suffer almost beyond endurance. These hot and dry days are, however, followed by heavy dews, furnishing wonderful refreshment; and such weather it is that gives the flavour to the Peach and the Melon, and drives the Indian Corn rapidly to maturity.

One of your correspondents speaks of my mentioning sandy ground as best for Melons, and also rightly says that our Peach trees are not on the Plum stock. With us the Plum stock for Peach-growing is only tolerated on very heavy clay soil, and not one tree in a thousand has other than the Peach stock. As for Melons, those in our immediate neighbourhood are so delicious in flavour, that as some toasts are drunk standing and in silence, I sometimes think our Melons should be eaten kneeling for thankfulness. The soil is new, and so light as to be almost drifting sand, containing only vegetable matter enough to give it the colour of light brown sugar. About two

parts of this soil and one part of half-rotted stable manure make the mixture we use.

It may be interesting to you to know how some of the bedding plants used in England endure our scorching sun. Today (July 7th), the heat has been again very great—from 93° to 96°—so oppressive, indeed, that most of the labourers, unable to endure it, went home before noon.

Iresine, fully exposed, has not quite so good a colour as when planted in partial shade. My plants of this were well forwarded in the hothouse, and are now 15 inches high, bushy, and in vigorous health. Should I be fortunate enough to have a flower on the Iresine I will send it to you. *Coleus Verschaffelti* is magnificent both in sun and shade; the lower leaves, when fully exposed, being beautifully toned with bronze. *Coleus atropurpureus* also does well. *Centaurea candidissima* thrives remarkably; so also do *Lantanas*, most of the *Zonale Geraniums*, *Gazamias*, *Verbenas* (if mulched), and *Heliotrope*. This last is said to need slight shade, but I do not find it so. *Phlox Drummondii* and *Portulaca* are most brilliant, especially the *Portulaca*, which seems to do best in the hottest and driest sand. The sun closes the flowers about noon; but until then a bed of mixed colours is one of the gayest sights imaginable. I have *Viola cornuta*, and *Lobelia speciosa*, *marmorata*, and *Snowflake* as edgings. The *Lobelia* stand well—better than the *Viola*. *Petunias* thrive, growing so vigorously in good soil that many of the blotched and variegated kinds have a tendency to run to self colours. *Roses* suffer much with the heat; and *Fuchsias*, of course, must have shade to keep life in them. Among variegated *Geraniums* I have Mrs. Pollock, Burning Bush, *Picturatum*, *Glowworm*, and others. Though planted in a sheltered bed, so far they have not advanced much.

The flower from which I derive the most satisfaction is the *Gladiolus*, to which our soil seems to be in every way suitable. Last season from one spike of *Madame de Vetry* I had twenty-seven blooms. This season I had over from Paris all M. Souchet's novelties, except *Maréchal Vaillant*, also many others not in my collection. Some having started into growth during the voyage, I potted and forwarded them in the greenhouse. Among the high-priced novelties *Shakspeare* and *Milton* have already bloomed, and they fully sustain M. Souchet's good name. *Shakspeare* especially is most admirable—a far finer flower than *Reine Victoria*, in the same style. It seems, indeed, entitled to be called, as in the catalogue, perfection. *Milton* comes with me rather more rosy than is described, being a rosy blush nicely flaked with rose, a fine flower.

Thinking of *Gladiolus*, however, I cannot forbear telling you how fine they are for dinner-table decoration when arranged with slim and tall-growing Ferns. We had the other day a piece of this sort with *Princess of Wales* in the centre, surrounded by one or two *El Dorado*, *Madame de Basseville*, *Penelope*, *Brenchleyensis*, *Walter Scott*, and *Canary*. A few *Fuchsias* drooping here and there under the Ferns gave a charming effect.—GEORGE SUEZ, *South Amboy, New Jersey*.

#### THE GARDENERS' ROYAL BENEVOLENT INSTITUTION.

MUCH pleased was I, and so, I have no doubt, were many more besides myself, with the valuable suggestions offered by Mr. W. Paul, in his article on the above in *THE JOURNAL OF HORTICULTURE* for July 10th, as it seemed to be the first step towards uniting gardeners in forming one brotherhood or society, such as all other trades or professions have, to assist the aged, to benefit the afflicted, and to regulate the wages. Why should not the gardeners have theirs? Surely they are as able and willing to form a society as those pursuing any other calling, and I think I may add without boasting, being one of their number, that they are as intelligent and steady as any class of men who work for their living. I am aware that several articles have been written in your *Journal* on the subject of wages, &c., which have been ably answered by Mr. Fish from time to time in a very kind and considerate manner; but as nothing definite has come of them, and as the above Institution purports to be for the benefit of gardeners, could not its influence be extended for their benefit? Perhaps I may be asking too much, but it is a fact that there are scores, and I think I might say hundreds, of gardeners totally ignorant of the existence and the benefits to be derived from such a Society, except what they may read in the occasional articles that appear in *THE JOURNAL OF HORTICULTURE*. Now, as a first step in the matter,

I would suggest to the Editors the advisability of presenting us with an article on the origin, the working, and the benefits to be derived from the Gardeners' Royal Benevolent Institution, and I am certain that by so doing they would oblige a great number of their readers.—P. DIXON.

ROSES SENT OUT IN 1865.

It is not possible to form a correct estimate of the merits of a Rose till it has undergone a period of trial which shall embrace a sufficient time to determine the most important points connected with it. These are: the flower—its colour, shape, and size—and the constitution of the plant—its habit, foliage, and blooming qualities; hence, if we see only the flower, we have but one half, and that the least half, of the information which we seek, and it is not till we have the living plant under our notice for a complete season that we can judge fairly of its merits or otherwise. In taking down the names of new Roses as seen for the first time at the great exhibitions these circumstances should be borne in mind, particularly by those who intend to purchase, in order to prevent after-disappointment. I have known many instances of this: such Roses as Madame Furtado, Impératrice Eugénie, Le Rhone, Louis XIV., H. Laurentius, and François Lacharme, are well-attested examples, all of them being, when perfectly grown, among the most beautiful of Roses, and sure to attract attention; but it is only in favoured situations that they will grow, owing to defect in constitution.

The Roses received from France, with others raised by English growers, and sent out in the spring of 1865, were in number only a little short of one hundred varieties, and have now been among us sufficiently long to enable us to state something definitely about them. In the schedules of the Rose shows, they are for the present year considered new, but I have not characterised them as such from there having been more than half as many sent out since—that is, in the spring of the present year. Of the latter I can add nothing to what has been already stated by our respected correspondents, Mr. Radclyffe and "D. Deal." My evidence, too, on the former must be considered rather as corroborative than otherwise of the sound judgment arrived at, and correct information furnished, by those gentlemen in their interesting articles. It is derived from plants growing in my own garden on the Manetti stock, and in a very light soil, from others in the garden of a valued friend, Mr. W. T. Sargant, Brooke Lodge, Redhill, both on the Dog Rose and Manetti, in strong clayey loam, and as seen in large quantities in the nursery of Mr. William Paul, at Waltham Cross, which I recently had the pleasure of inspecting.

So far as yet proved, the Roses of 1865 show a somewhat greater proportion of the whole number to be good than for several years previously. It would be rash to say that they are equally good, which is not the case, but they are of sufficient excellence to secure a place in the rosery for some time to come, and some of them show marked improvement over older varieties.

I subjoin a list, not, indeed, assumed to be complete, but all of them contained in it can safely be recommended, and to use Mr. Radclyffe's expression, "people will not burn their fingers with them."

Abbé Berléze  
Achille Gonod  
Belle Normande  
Charles Margottin  
Charles Wood  
Dr. Andry  
Duchesse de Caylus  
Duke of Wellington  
Elizabeth Vigneron  
Glory of Waltham  
Général d'Hautpoul  
Jean Rosenkranz  
Madame Verschaffelt

Madame Charles Verdier  
Madame Elise Vilmorin  
Madame Moreau  
Mlle. Amélie Halphen  
Merchal Niel  
Marguerite de St. Amand  
Rushton Radclyffe  
Semiramis  
Triomphe des Français  
Xavier Olibo  
Beauty of Westerham  
King's Acre

To particularise a few of the above.

*Belle Normande* is a very vigorous grower, with flowers like Duchesse d'Orléans. I do not, however, think it is better than our old favourite.

*Charles Wood* will supplant Louis XIV., being vigorous in habit, with larger flowers, and equally good in colour.

*Duchesse de Caylus* is probably the best in the list; a most lovely carmine Rose, of perfect form.

*Duke of Wellington* will be welcomed as quite distinct from any other of the scarlet crimson tribe, which are now so numerous, and must be weeded out.

*Dr. Andry* and *Général d'Hautpoul* are two of M. Eugène Verdier's seedlings, both very fine in form and colour.

*Elizabeth Vigneron* is a fine Rose, both for the show-box, and for garden decoration. It was magnificent last autumn.

*Glory of Waltham* fully merits its name. It is without doubt the grandest climbing Rose known.

*Mlle. Amélie Halphen* is another carmine Rose of great beauty.

*Marchal Niel* is the "sensation" Rose of the year. Last winter was not sufficiently severe to test its hardiness, but the frequency of its appearance in the show-boxes seems to indicate a free-blooming quality.

*Madame Charles Verdier* is a very large and full Rose; it may be pronounced good, with the qualifying remark that its form is not pleasing.

*Marguerite de St. Amand* is one of the best. As a light Rose it may be put down as "a decided acquisition."

*Rushton Radclyffe* is a fine full Rose, and when quite open globular and imbricated—that is, the petals overlap like the tiles on a house. The respected name with which it is associated also gives it a claim to consideration.

*Xavier Olibo* requires further trial before I can speak confidently of it. There is room to hope that it will prove a valuable addition to our dark Roses.

*Beauty of Westerham* and *King's Acre*, as English seedlings, should be favourably noticed as instances of the efforts of our own growers. The powerful fragrance of the first is a very strong point in its favour.

To speak of the nursery at Waltham Cross and not to notice the bedding Pelargoniums would be an almost unpardonable negligence. The gorgeous beds now in full bloom, in contrast with the well-arranged clumps of hardy shrubs and other plants, for which this nursery is also famous, are very remarkable. It is not difficult to imagine how anxious the lovers of the bedding-out system, and they are legion, must be to possess this beautiful strain of colour as seen in Rebecca, St. George, Salmon Nosegay, &c., which must, indeed, be seen to be appreciated.—ADOLPHUS H. KENT.

PEACH-TREE PRUNING.

"THE Modern Peach-Pruner," by the Rev. Thomas Bréchant, has been already printed in separate articles in THE JOURNAL OF HORTICULTURE. I have now perused it in its collected form, which has enabled me more easily to compare its several parts; and I advise all Peach-pruners to obtain the volume, consisting of 178 pages. Its contents are as follows: The first part is introductory, containing the History of the Peach, the Theory of Vegetation, Phenomena Connected with Growth, Soils and Manures, Aspects and Shelters, Transplanting, and Useful Maxims. The second part is on Long Pruning, containing five sections. The third part is on Close Pruning, containing five sections; and in my opinion the grand secret lies in these five sections. A mixture of spurring and pinching to 6 or 8 inches is the system that I have always pursued, and I have found it answer. My ten trees, planted here so late as April this year, are so pruned, and they will bear well next season. I showed them yesterday to my old friends Mr. and Mrs. Farquharson, who approved of the plan.

The fourth part, containing four sections, relates to Orchard-house Pruning and Training, and to Variations from Seed, by Mr. Rivers. The Appendix is also by Mr. Rivers, and contains three sections:—On Diseases and Insects, a list of choice Peaches and Nectarines for the open wall, and another list for orchard-houses.

The work is a very valuable one, and should be in the hands of all those persons who profess to prune Peach trees. Long pruning may suit the more genial climate of France, but short pruning, or rather short pinching and spurring, is best adapted to England. I conclude by thanking Mr. Bréchant and also Mr. Rivers.—W. F. RADCLYFFE, Okeford Fitzpaine.

POTATO ONION.—Your correspondent, "G. S.," in the Number for the 17th inst., wishes to know if any of your readers has, like himself, found their Potato Onions refuse to increase in number. Small bulbs when planted always grow large, and rarely ever split; but good-sized bulbs always divide into from two to seven bulbs, or even more. I often wonder that Potato Onions are not more grown, as by deep culture, with plenty of manure and watering well with weak manure water during the

growing season, a heavier crop may be obtained from them than from any other Onion which I have tried. We always selected our Onions for showing from them, and were generally successful. Their only fault is their not keeping late in the spring. We always grow James's Longkeeping, or some similar kind, for late use.—W. C.

### HINTS ON HYBRIDISING FRUITS.

HAVING been occupied for many years in hybridising plants, and being very fond of it, I at length turned my attention to fruits: I commenced with Grapes.

My object was to make the Muscat easier to cultivate, and increase the size of the Frontignan; also to make the large coarse kinds of a better flavour, and to improve the early ones.

I began, in the first instance, with the Muscat of Alexandria, one of the most difficult Grapes to cultivate, and the Trovèren Muscat, a remarkably free grower, but a long time in coming to maturity. It is a most delicious Grape, though not so highly musked as the former. I expected to obtain Grapes less difficult to cultivate, and was partly right; but I was rather astonished at the final results. It should be premised that the Trovèren is a round Grape; the Muscat of Alexandria an oval one. The latter I made the female parent; and out of thirty seedlings no two were alike. The first three that fruited were black, one being a large early Grape, in shape an oval, with a fruitstalk like a piece of wire; it was of a very fine flavour, with the slightest possible taste of Muscat, and hung well. This was a great success and well worth all my trouble. The other two were late ones, with large round berries, but nothing else remarkable about them. In the following year I fruited ten or twelve more from the same lot. One of these was of a beautiful white or golden colour, and ripened quite as soon as the Hamburg; its fine vinous flavour was exquisite, mingled as it was with a Muscat taste about half as strong as that of its parents. This also had very stiff fruitstalks, and kept a very long time. Another, and this astonished me more than anything else, was a perfect miniature of the Muscat of Alexandria, perfectly oval, and with the strongest Muscat flavour that I ever tasted, but it was no larger than a Red Currant! I have not as yet discovered anything very remarkable among the others. The next experiment I tried was with General Marmorata (no doubt a white seedling variety of the Hamburg) crossed by Burchard's Amber Cluster [Early White Malvasia]. My object was to obtain a very early Grape; and in this I succeeded beyond my expectations, as I got a very fine white transparent Grape like the Amber Cluster, but as large as the Hamburg, and fully five weeks earlier than that kind. This of course is a great gain, and what has been much wanted, as the Sweet-water Grapes are very bad setters, and the Muscadine is too small for table use. The next crosses were between Blanc de Saumur and Chasselas Musqué, and Chasselas Musqué and the Citronelle. From these two crosses I have obtained the most delicious kinds that ever came under my notice, more so even than the old Frontignan and Chasselas Musqué. Two of them are sweet-scented, smelling, when the sun shines on them, like Orange-blossom. Nothing I have ever seen can compare with them in flavour and productiveness; their size, too, is very large, some of them being as large again as the Frontignan.

Two other most remarkable crosses are Chasselas Musqué fertilised by the Long Noir Durant, a large oval black Grape, on a very large bunch, but of an inferior flavour. This cross produced Grapes of various colours, black, pink, and grizzly, but all quite round. The next time I made Long Noir Durant the female parent; and, curiously enough, the result was almost identical with the former, there not being an oval berry obtained. A very slight Muscat taste is observable in a few; but in the greater number it is not observable at all.

These are the results from about 500 seedlings that I have raised and 400 sorts that I have fruited; I have some more yet to fruit, such as the Canon Hall crossed by the Japanese one.

As the result of my experience, I am convinced that no one can tell, in raising a lot of seedling Grapes, what they will be likely to get, they vary so much.

I next directed my attention to Peaches.

My object was to obtain Peaches with Nectarine-flavour, and I am glad to say I have succeeded. The Nectarines I made the female plants were the Violette Hâtive, Pitmaston Orange, and the Stanwick, crossed with the Noblesse and Barrington

Peaches. Although the Violette Hâtive Nectarine had a small flower, still, when crossed with the large-flowering Peaches, eight out of twelve were large-flowered; and out of fifteen kinds fruited this summer only one was a Nectarine, the others were all Peaches, most of them with the Nectarine flavour. Two of them were especially delicious, having a beautiful Nectarine flavour, melting like a Peach, but full-coloured like the former fruit. The stones that produced the seedlings were sown in the beginning of February 1863; the greater part of them flowered in February 1864; but the fruit fell off. I now have one planted out in my Peach-house that will have next June ten or twelve dozen Peaches on it. It is 10 feet high, about the same width, and covered with fine-blooming wood.—JOHN STANDISH, Royal Nursery, Ascot, Berks (in *Journal of the Royal Horticultural Society*).

### THE ROSE GARDENS OF LYONS.

UNDER the guidance of Mademoiselle Joséphine Lacharme—not exactly the fair nymph whom one would imagine ought to wait upon the queen of flowers, but a jolly good tempered and communicative maiden, who gave me on our way the history of her brothers and sisters, who all seemed well to do—I found any way to Damaizin's, through fortifications and past fosses and glacis, which give one the idea in France that either her children are very rebellious and want very much keeping down, or else that she has very naughty neighbours who are continually on the watch to plunder her; and then into dusty roads ankle deep in white dust, which after a good storm will be converted into deliciously tenacious mud, to find, alas! that Damaizin was not at home, and that Madame Damaizin could not give me any information on the subject of the new Roses. I saw enough, however, to enable me to say that his garden is very neatly kept, and in this respect very different from Lacharme's.

On again through the dust and heat of a broiling day I toiled to Ducher's, for there were no *fiacres* to be had here, and I had sent home mine. Here, however, I was more fortunate; Ducher was at home, and on my mentioning my name I was cheerfully recognised, and shown over his grounds. These are not large, and I forgot to ask him whether he had grounds elsewhere, but there were some good Roses to be seen. He at once said, "Ah! I will show you a beautiful Rose, I suppose called after your daughter;" and there truly was a grand bloom of Mademoiselle Marguerite, which he pronounced to be one of the very best Roses of this year. He has several seedlings to be let out this year, and one of them, of which I shall have the name (having only the number now), I consider to be the best Rose I saw abroad. He has striven to avoid the blood of Général Jacqueminot, and has succeeded in obtaining some good Roses. One is a seedling of La Reine, another a seedling from William Jesse like Baronne Prevost in shape, and the one already alluded to a seedling of William Jesse and Madame Domage, very good shape, free-flowering, and bright in colour, a distinct and good Rose. He showed me a plant with the very darkest foliage I ever saw, I think, in a Hybrid Perpetual, but the flower was white! and opened but indifferently.

I had yet another journey to make to Guillot fils, so well known to all Rose-growers by name, and Ducher accompanied me there. Generally speaking this is not a good plan to adopt, for there is a reluctance in a French Rose-grower to show you his novelties before another; but as M. Guillot had been prepared for my visit, I did not mind this, and I found that when we arrived there Ducher left me to go round the garden alone with the proprietor. M. Guillot has given us many good Roses, and as he had written to me strongly in favour of a new Tea Rose of his, I was anxious to see it. It will be, I believe, a valuable acquisition. It is a very beautiful flower, of a bright yellow colour, the centre sometimes peach, the habit of the plant vigorous, and the flowers freely produced. It is so called, I believe, Bouton d'Or. He has another yellow not so good, and a fine-looking seedling of Général Jacqueminot of imbricated form; this may prove to be a good Rose. There was also a Rose of which I hope great things, but it is not to be let out till 1867, a Hybrid Tea—Tea and Hybrid China I believe, or Perpetual—the colour a bright rose, and the flowers large. I hope to make a further acquaintance with this flower. Joséphine Beatharnais, one of Guillot's flowers of this year, is beautiful. President Mâs I do not consider much; and Flâne is quite a second-rate flower, and coarse. While waiting here, and refreshing myself with a glass of Bordeaux,

which I found very good after a heating morning's walk, Genod, who is favourably known to us as the raiser of Madame Moreau, came in and promised, as I was now anxious to get back to Lyons, where I had left my better half, to bring to the hotel blooms of his new Roses. This he did in the evening, and amongst them he had a fine flower in the way of Virginal, only somewhat larger; another was in the way of Madame Fillion, a light pink, and very promising.

It will thus be seen that I do not consider that anything very remarkable is coming to us from Lyons this autumn. When the lists are out, and I can compare the numbers with the names given to them by the raisers, I shall hope to say something more positive; but I can only repeat now that I do not think I have seen any new Rose abroad equal to Ward's seedling, Mrs. Ward. Since then he has sent me a box of blooms of another variety, Mrs. John Berners, which also promises well. It is an imbricated flower, of good size and bright colour, and very vigorous.

Tired as I was with my morning work, it did not prevent me from taking a broiling walk up to the church of Nôtre Dame des Fourvières, whence, in favourable weather, Mont Blanc, although a hundred miles distant, can be seen; but the day was too fine, the heat causing a haze which obscured the view. After dinner we started off for Paris by night train, and it was not surprising, I think, that I felt considerably tired the next day. I enjoyed, however, amazingly my walk amongst the Rose gardens of Lyons, and was glad to bring home any scrap of information that may be useful to the Rose-growers of England.—D., Deal.

### HORTICULTURE IN HUNGARY.

SOME observations from an eye-witness of the condition of horticulture in one of the most beautiful countries of the south-east of Europe, can scarcely be unacceptable, when it is considered how very little, comparatively, is known of a country which contains no less than 6155 geographical square miles. My residence for three years was at Szüd, in the neighbourhood of Schemnitz; but I have had frequent opportunities of visiting other parts of the country, to which my observations equally apply.

As the vegetables more commonly in use, including Tomatoes, are supplied almost entirely by field cultivation, the kitchen garden is by no means the prominent object which it is in England. The vineyards supply the finer kinds of fruit—as Peaches, Nectarines, Apricots, Medlars, and Figs; while different kinds of Gourds are planted along the boundaries, forming a loose kind of enclosure. Some of these are cultivated merely as food for cattle; others are used as Vegetable Marrows, amongst which is a very superior one known under the name of Spargel-Kürbiss (or Asparagus Pumpkin), while others are a favourite food when baked. *Cucurbita melanosperma* is amongst the kinds which are cultivated; but it does not appear that they have, at least north of the Danube, any variety of *Cucurbita moschata*, which almost supersedes the Vegetable Marrow where the heat is sufficient.

The commoner kinds of fruit, as Cherries, Mulberries, Walnuts, Strawberries, and Raspberries, grow on the mountains, on the roadside, or by every ditch or waste piece of ground; so that even in bad years the proprietor has a constant supply without any pains, and in good years he merely gathers the best, and lets every one, after he is served, take what he pleases. In fact, travellers, or, indeed, every passer-by, help themselves for the most part without any let or hindrance. The orchard is almost exclusively devoted to the cultivation of Plums (which are grown in enormous quantities), for drying, a process which is performed on hurdles in a low-heated oven. The varieties, however, in cultivation are very inferior to those which yield the better kinds of French Plums of commerce. A few Pears and Apples are grown, but of very inferior quality. Wall fruit is unknown. It cannot be expected, therefore, that much attention should be devoted to the kitchen garden, though a few hotbeds, as in England, are made for the rearing of Brinjals, and other plants which require to be brought forward artificially. The better kinds of Melons and Cucumbers are grown on the open ground in the garden, while the large coarser kinds and Water Melons (which are of excellent quality), are consigned to the field. Cabbages, Carrots, the different kinds of Kidney Beans, some of which are of very superior quality, and a few other vegetables, have garden culture. A very small kind of Pulse, known under the name of Rice Beans, used frequently

for soup, and belonging apparently to the genus *Dolichos*, with one or two other sub-tropical varieties, is an object of cultivation. Fruit trees, with the exception of a few Apricots and Plums, are for the most part excluded; as regards those beyond the pale, scarcely anything is done in the way of pruning beyond chopping off the dead or useless branches, which takes place in April.

The flower garden is of far more importance, and is in general large, and laid out in beds of various shapes, in the midst of a lawn, which is, however, not kept close-shaved as in England, but is mowed three times only in the year, as the proprietor depends on the grass plots for the maintenance of his cows in summer, the meadows being devoted to the production of hay for the winter food of the sheep. It is mowed by the cowherds, who carry it away on a curiously-shaped cart drawn by two donkeys: the cart is made without a piece of iron or a single nail. The paths are made of silt, which is brought from the larger rivers, and the beds separated from the grass by a very prettily worked edging of wickerwork, the bark of the Osiers having first been carefully removed. The flowers are of much the same sorts as those cultivated in England, though, from the severity of the winter, some perennials which succeed with us do not admit of out-door cultivation. Numerous white chairs and tables are scattered everywhere, which, with the wickerwork of the borders, give the ground a gay appearance.

What, however, strikes an English eye the most is the entire absence, in most Hungarian gardens, of anything like evergreens; for there are no Yews, no Cedars, no Firs, no Holly trees, nor anything that is green in winter; in consequence of which there is a comparative want of contrast in summer, and an appearance of utter desolation in winter. In summer the foliage is afforded chiefly by Acacias, Gleditschias, Poplars, and occasionally Oaks.

The garden is cultivated by peasant girls under the superintendence of the gardener, who are paid 2d. a-day. They always go about without shoes or stockings, as the only time when the Hungarian peasants wear shoes, which are considered a luxury, is when they are at church, or when the snow is on the ground. As was formerly the case almost universally in Scotland, the boots or shoes are carried in the hand, and put on only when they arrive at the church-door.

The tools generally used in a Hungarian garden are very large heart-shaped hoes and wooden rakes. A spade is very seldom seen. The wheelbarrow holds no more than a bushel, and is made entirely without iron, the wheel consisting of a disk of board, and the spindle of a piece of juniper or other tough wood.

The most prominent feature on entering a Hungarian gentleman's garden is the hothouses, which, though not as magnificent as they are frequently in our own gardens, are on an extensive scale, adapted to the exigencies of the climate. They are of three different kinds: 1, the Szaporító Ház (the slip or propagating-house); 2, the Hajto Ház (the forcing-house); 3, the Hideg Ház (or cool-house, answering to our greenhouse or orangery).

The Szaporító Ház is a neat structure with four stone walls and a sloping roof of glass, the front wall being 4 feet high, and the back wall 7 feet. It is heated by means of a flue, which goes round the house from the furnace to the chimney. The flue is enclosed in a wall of bricks about 3½ feet high, in which there are four doors for the insertion of pans of water, which are placed on the top of the flue. Deal boards, which have numerous holes pierced in them, are nailed to the two walls over the flue, and on these the mould is placed, the holes in the boards being first filled up with moss, so as to prevent the soil falling through, and at the same time to admit the steam which arises from the pans. Cuttings inserted in the mould, which are either uncovered or protected by bell-glasses, grow, when treated in this manner, with astonishing rapidity, and are soon ready for potting-off.

The Hajto Ház is built in the same manner as the propagating-house, but has simply a flue. Into this the cuttings are removed as soon as they are potted, and arranged on stages. The furnace is heated with wood, of which only a small quantity is necessary. It is in this house that Rose-grafting is conducted, the stocks being got forward in it by the beginning of February. The top is then sawn off horizontally, a slit made in the cut surface, and the graft inserted, and secured by a cement made of resin, wax, and Venice turpentine. When treated in this way, scarcely a single graft fails, and the trees bloom well in the summer. This method is found to answer far better than budding, which is not suited to the climate.

The Hideg Ház, or orangery, is a very large room, heated by a fine in the soil, and glazed in front after the old English fashion. The chimney is composed of a number of large quadrate pieces made of clay, each succeeding piece fitting into that beneath, and decreasing from the base upwards. The whole, which is in the inside of the house, is painted green, and has not a bad effect. The plants are beautifully arranged, and the whole forms a sort of winter garden. The Orange and Lemon trees are dispersed in pleasing groups together with the shrubs, and the flowers in variously-shaped beds; but instead of having the wickerwork edging which is seen out of doors, they are surrounded by beautiful minerals from the mines, which often contain a good deal of gold and silver.

The expense, of course, varies according to the wealth of the Magyar; but, as a general rule, it may be reckoned that it amounts to about £60 a-year; and many of the nobles do not think it derogatory to their dignity, though extremely proud of their pure descent, to diminish the expense by the sale of the plants.—MILES BERKELEY, Esq. (in the *Journal of the Royal Horticultural Society*).

### RED SPIDER AND THRIPS.

I HAVE just read Mr. Abbey's intelligent and interesting paper on red spider, and concur with him in most of his observations, as every practical gardener must. Still, everyday experience inclines me to differ from him as to the predisposing causes of parasitical diseases and insects, and of red spider in particular, believing, contrary to Mr. Abbey's opinion, that the disease is in almost every case due to certain conditions of health, and that its existence in some cases is so strictly dependant upon those conditions, that unless they are present actual contact will not produce it. Mr. Abbey considers the principal causes of red spider to be a dry atmosphere and a high temperature, with too little air at night, and that ill health does not predispose to the insect unless these conditions are present—conditions, I will just observe here, sufficient in themselves to produce ill health and thereby induce disease. But I will state facts, and let your readers judge.

The worst case of red spider and thrips I ever saw was in an aquatic-house. The centre of the house was occupied by a tank devoted to the growths of aquatics. The water in the tank was heated by pipes passing through and in contact with it, so that the atmosphere of the house was continually charged with vapour, and to such an extent at night that the leaves of the plants dropped with the weight of the condensed moisture, yet on no occasion did I ever see *Caladiums*, *Crotons*, and other plants suffer so severely from red spider and thrips. Owing to the aquatic occupants of the tank the house could not be shaded sufficiently, perhaps, but otherwise the plants referred to received every attention. The ventilation was sufficient, and the temperature was not too high for the inmates. So much for a moist atmosphere as an antidote for red spider.

Again, our Melon and Cucumber-house here is separated from a Pine-stove by a partition, and the two communicate with each other by an open doorway. Dwarf Kidney Beans were grown on the back kerb of the Pine-stove all the winter, and were at no time free from red spider and thrips. The Melon-house was also occupied by Kidney Beans before the Melons and Cucumbers were planted, so that there was no doubt about the presence of the enemy, and trusting to our own notions of warfare in the matter, the house was only slushed down with cold water, more for the sake of cleaning the glass than anything else. The bed was made up, and the Melons and Cucumbers were planted about the middle of January; and although there was constant traffic between them and the Kidney Beans by the men on duty, they remained perfectly clean, and the Melons ripened-off an excellent crop, whilst preserving their leaves perfectly green, by the end of May. The Cucumbers and Melons were grown in large pots, drained so that they could not be over-watered, and plunged in the hotbed, and the only means taken to check red spider was supplying them with abundance of water at the root, and occasional strong doses of liquid manure. The weather was cold and the firing hard, yet the Melons were rarely ever syringed overhead all the time. The vigour of the plants, as indicated by their dark glossy green leaves, was kept up entirely through the roots.

The third case is even more remarkable. In a range of new vineries here, part of the old Vines are retained. They are not unfruitful nor unhealthy, and are in general remarkably free from red spider; but having decided upon lifting their roots and renewing the border, we lifted about one-third of them last autumn. The operation, of course, checked them for this season, and they broke weakly at starting, and were attacked by red spider almost as soon as the berries were set, and it has only been kept in check by the free use of sulphur on the leaves; while those that were not lifted, the same sort in the same house, have remained almost entirely free from the insect to the present time, and except mulching the border, nothing whatever has been done to them to check it. It is our third vinery, and the Vines are now ripening-off their crop.

I will just record another instance, connected with green fly. We force annually a long pit of early Potatoes. Owing to the proximity and position of the border, rather too much bottom heat is communicated at one end of the pit during hard firing; the Potatoes are, consequently, injuriously affected by the extra stimulus, and in cold dull weather become drawn and weak. This was the case last spring, and the stems of the Potatoes for two or three lights from the boiler end, were attacked again and again by green fly, in spite of smoking and other preventive measures. The pit was planted halfway along with the same variety, but the insect progressed only so far as the Potatoes were weak and affected by the extra heat, being most numerous next the furnace, gradually disappearing as the distance from it increased, and eventually disappearing to some extent from the affected plants also as the weather improved and less fire heat became necessary, clearly proving that impaired vigour was the cause of the attack, so far as circumstances could enable any one to judge.

I could state many more such instances, but these are sufficient to prove that the occurrence of the insects, if not altogether dependant upon, is at least greatly influenced by, certain conditions of health.

I agree with Mr. Abbey, that water may be said to be the natural enemy of red spider, but I attribute the presence of the insect more to the want of moisture in the soil than in the atmosphere, and not so much to the mere absence of water as to the absence of that medium through which plants can alone absorb their food. We know that among human beings and animals poverty predisposes to disease, and it is not carrying analogy too far to suppose that plants are similarly affected. I never yet saw a perfect cure effected by any of the usual external processes and applications, and I look upon all such as merely temporary expedients, and believe that the maintenance of vigorous health is the only sure way of guarding against such parasites.—J. SIMPSON, *Wortley*.

### POISONED GRAIN. &c.

MR. FISH, referring to my letter at page 42, expresses a doubt whether in laying poisoned stuff for rats, &c., he may not be rendering himself liable to the £10 penalty under the Act.

I did not wish to trespass on your space, and therefore only gave a general sketch of the Act; but, in order to satisfy Mr. Fish, allow me to state that in the Grain Act the fine is only imposed for sowing, casting, &c., "in or upon any ground or other exposed situation;" and in the Meat Act poisoned flesh may be placed in any dwelling-house, building, or enclosed garden, or drains connected therewith (provided the same have gratings over), or in ricks, to destroy vermin, and also on land; but in the last case notice must be posted up to that effect, and written notice given at the nearest police station thereof.

The objects of these Acts are evident—viz., to preserve game and small birds. You must not scatter poisoned seed in an enclosed garden, because birds could fly over and eat it; but poisoned meat few birds would touch.

As to the question of whether you are sowing "protected" seed, or merely covering poisoned seed to try and evade the Act, that would depend on circumstances—*e. g.*, if I sow valuable flower seeds in a bed, and then intermix them with poisoned Peas or corn, the inference would be, as the fact is, that I am trying to tempt the birds with my Peas and save my flower seeds; but if I sow poisoned (red-leaded, &c.), Peas in my usual vegetable department, my real motive is difficult to guess.—LEX.

STRAWBERRY STORY.—We have received from Dr. H. Thomas of Chester, a unique sport of the Strawberry. The berry,

\* NOTE BY THE REV. M. J. BERKELEY.—I have in my possession a catalogue of the plants in the garden of a Magyar of some property, with the prices attached, as in a nurseryman's list.

very irregular in form, is ripe, and from the side grows a flower-stalk an inch long, calyx, and stamens, but no petals or pistils. On dissection, it was evident that the flower-stalk was emitted from the skin of the berry.

## ROYAL HORTICULTURAL SOCIETY.

JULY 24TH.

**FLORAL COMMITTEE.**—The Floral Committee visited the Society's gardens at Chiswick to inspect and report upon the trial plants of the present season. The Committee met in large numbers, and proceeded to examine the Zonale Pelargoniums which had received awards on former occasions. Those persons acquainted with the extensive collection of these plants cultivated in the gardens will know what numerous varieties are there to be seen. Upon the principle of reducing the numbers, avoiding similarity of varieties, and selecting only the very best and most distinct in each class, the Committee set to the work, and decided to remove from the collection several kinds which had previously received awards, but which are now surpassed by better kinds. Some fifty-eight or sixty sorts were struck off the list, not for bad qualities, but on account of their inferiority to the new varieties of the past and present year. First-class certificates were awarded to the following varieties which had received second-class certificates—viz., Harry Hoover, Red Riding Hood, and Rev. J. Dix. The last-named, which is a seedling from the Society's garden, was much admired for the profusion and brilliancy of its deep scarlet flowers and its compact habit.

First-class certificates were awarded for the following new varieties of 1866:—Orange Nosegay, Waltham Seedling, Marie Mezard, Brilliant Superbe, Variegated Stella Nosegay (Smith, Hornsey Road), Madame Barre, Miss Parfait, Madeline; second-class for Violet Hill Nosegay.

First-class certificates were awarded to the following Fuchsias:—Roderick Dhu, Enoch Arden, Father Ignatius, Lady Heytesbury, and Conspicua, all very beautiful kinds. First-class certificates were also awarded to striped Verbenas:—Mr. Wood, Madame Hermann Steuger, Oireghia, and Ada; and a second-class certificate for Attraction.

Very many of this year's novelties were not in a condition for examination, the Committee will consequently soon meet again to report upon them. The collection of Zonale Pelargoniums in pots, exhibited in the old Rose-house, was much commended and admired. Much credit is due to the gardener who has the care of them, for they were well grown, and afforded good examples of those varieties which will not endure exposure to the sun and wind. The improved aspect of the gardens was generally approved of, especially the walk from the entrance leading to the vinery. The circular beds of fine-foliaged plants, continued on each side of the gravel walk from the Zonale Pelargoniums, were highly commended, and will doubtless prove very attractive and useful to such of the Fellows as have not much knowledge of plants. They can here at one view see and select what plants are most suitable for decorative purposes out of doors, when intermingled with the gay and vivid colours of the usual bedding-out plants. The Hollyhocks were very fine, and will soon be in perfection. The whole appearance of the floral department of the garden was most satisfactory.

A large party of the Fruit and Floral Committees, after the business of the day, dined together under the old iron tent, with its innumerable iron ribs, and thus finished a very pleasant and satisfactory day. The services of Mr. Barron, the present Superintendent of the gardens, were duly acknowledged, and the Committee dispersed.

## PLANTS INJURED BY FUMES OF GAS TAR.

I BUILT a small span-roofed house, for a succession-house, 40 feet long and 10 wide, with a walk through the centre, and a tank on each side, using on the outside of the tanks and on the sides of the house a coating of gas tar. I commenced filling the house with Roses, Spiraeas, Grapo Vines, &c.—plants to get stock from. The plants being dormant, of course I could not see at first if the gas was hurting them or not, for as soon as the heat began to rise the gas began to make its appearance very plainly. On the plants commencing to grow, it killed the young shoots as fast as they grew, and in fact, killed a great many large plants, both root and branch. The Rose and Grapo Vine leaves would turn black, become contracted, and then fall off.

It being apparent that I must either shut up the house or control the gas, I went to work and bearded up the tanks, at the same time washing the ends of the house with thick water-lime, and I have at last, after a great deal of trouble and anxiety, succeeded in being able to grow plants tolerably well.

Some few years since, the President of the Rochester Gas Company being informed by a friend that gas tar was a good thing to keep off the bugs from the Squash and Cucumber

plants, resolved to try some. A few days afterwards, on being questioned as to the result, he said that it was the best thing that he had ever seen, for it had killed the bugs, but at the same time it had killed the plants likewise.—J. CHARLTON (*American Gardener's Monthly*.)

## THE CINERARIA.

THIS is one of the most useful plants we have for conservatory decoration, both in winter and spring; in fact, it seems to be almost indispensable for that purpose, for there are very few places to be met with where it is not grown—from the humblest amateurs who possess but a small greenhouse, to the castle or palace gardens; and where cut flowers are required in abundance, it is invaluable.

It is very probable that what I have to advance upon the subject is but an old tale to some of your more experienced readers; but there are numerous instances to be met with which evince that the proper treatment is not universally understood, and this, I think, will be sufficient apology for my intruding with an old subject.

Although the Cineraria can be had in flower from December up till May, yet the latter period seems to be its natural season for flowering; at no time is it to be seen in such perfection as then. The usual method of propagating is from seed, or by cuttings, or suckers that come up from the roots of the old plants. Most people use the former method when the aim is simply for conservatory decoration or for cut flowers; it is the most expeditious way, and perhaps answers the purpose equally as well; but care must be taken that the seed is saved from good varieties, as the tendency in nine cases out of ten is to degenerate. The expense of a packet of seed from some party who is well known to keep a good strain is trifling compared with the advantage gained thereby; and where it is not practicable to obtain seed from good named varieties, this is the safest resource for having good flowers. In order to have them in flower about April or May, the seed should be sown the first or second week in August in pans, using a compost of equal parts loam, leaf mould, and sand. The following method I have used with never-failing success:—I use seed-pans, but ordinary pots will do equally as well; but if pots are used, they should be filled with crocks to within 3 or 4 inches of the top, then a layer of sphagnum, then fill up to the rim with the compost, spreading the surface evenly but loosely; sow the seed on this; then with a round flat board, or the bottom of a flower-pot, press the soil gently down, and water with a fine rose—no covering is necessary; then place them under a north wall and put a hand-glass over them, and in about a week or ten days the seeds will germinate. As soon as the plants are large enough to handle, prick them off into boxes or shallow pans, about 1½ inch between each plant: the soil used should be rather light, leaf mould and sand forming a predominant proportion. They should then be placed in a cold frame, and kept close and shaded for about a week; after that plenty of air should be given, but the shading should be retained during hot sunshine in the middle of the day. When they have well filled the boxes, put them into 60-sized pots; compost for this and succeeding shifts, two parts nice February loam, one part leaf mould, one part well-decomposed cowdung, and one part clean river sand. One of the principal points that must be attended to, to have good plants, is never to allow them to get too pot-bound until such time as they are in their flowering pots—eight or nine-inch pots are generally large enough for this. If they are allowed to get too pot-bound in small pots, it causes them to throw up their flowering shoots before the plant has had sufficient nourishment to attain to a good strong crown; the consequence is a weak head of bloom. I always like to see a good strong crown, with plenty of large leaves at the bottom, before they begin to throw up their flowering shoots; if this is obtained, a good head of bloom is, with proper attention, sure to follow. They should be allowed to remain in the cold frames or pits as long as there is no danger from the approach of frost, be kept close to the glass, but not to touch it, and a free circulation of air allowed to pass through them night and day. They should likewise have plenty of space to stand in, but so as not to touch one another—better grow half the quantity than have them too crowded. The same rules should be attended to when the plants are housed in the winter time. Plenty of air should be given on all favourable occasions, but avoiding cold cutting winds. The atmosphere of the house should be kept as dry and sweet as possible; and when it is necessary to use fire heat to exclude damps, it should be applied

in the morning, and allowed to go out at night, and give plenty of air all day. As a rule, the less fire that is used the better—it should never be applied but for the purpose already mentioned, and to exclude frost. They will make considerable progress during the winter time; and towards the beginning of February, if not already done, they should have their final shift. All the young suckers they throw up should be removed, as they only tend to crowd the leaves too much, and they rarely flower at the same time that the main plant does. Tying out the side shoots should likewise be attended to to make nice uniform specimens. As soon as they begin to flower they may be removed to the conservatory, and kept cool and shaded to prolong their flowering.

The same routine applies to the cuttings as to the seedling plants, except that they should be struck towards the end of August, either in pans, or else singly in small pots, and as soon as they are well rooted pot on as recommended above.

One of the most important parts of the process I have omitted to refer to, which, if neglected, farewell to all hopes of obtaining good specimens (but the same applies to all other plants as well)—viz., watering. I do not know of any special rule to lay down for watering Cinerarias that does not hold good with mostly all other plants; to do this judiciously is only learned by practice. It must be given with caution during the winter time. A pretty safe rule at all times is to let the ball get pretty dry, but not so dry as to make the leaves flag, then water well so as to soak it through. Weak liquid manure may be given once or twice a-week after the plants get well rooted in their flowering pots.

Red spider and green fly are sometimes very troublesome. When the former pest gets itself established it is a pretty sure sign of bad cultivation. It is only with poor stunted plants that ever it gets much ahead. I have never seen it attack any plants that have been grown on, as described above, except where grown with other plants that had been affected. The best way to get rid of it is by dusting them over with sulphur. As soon as the latter pest makes the least appearance, the house ought to be fumigated immediately with tobacco paper.

Although I have confined the above remarks to plants to flower about April or May, it will be seen that the same general routine will do for earlier sowings. To have them in about Christmas the seed should be sown early in June. The best place to grow these in is a frame behind a north wall, where they only get the sun in the morning and evening. They like a cool moist place to grow in, and are very impatient of too much sun heat at this time of the year. The cooler they can be kept, the better will they grow. When the plants are done flowering, all the seedlings—except such as may have turned out to be first-rate varieties—should be thrown away, but those that are worth keeping should be put into a frame, and kept rather dry till such time as they have ripened their wood. Then cut them down and well water the balls, and plant them out on a shady border to throw up suckers for fresh cuttings.—R. M'INTOSH (in *Scottish Gardener*).

#### VARIEGATED PELARGONIUMS.

MR. J. R. PEARSON, of Chilwell, has been kind enough to offer some criticisms on the subject of my paper on the sporting of Pelargoniums, &c.; and as he has only seen an abstract of the paper presented to the Botanical Congress, I venture to ask if you will kindly publish, *in extenso*, the paper, of which I enclose a copy.

After Mr. Pearson has carefully read it through, he will see that he has not confined himself to the subject he commenced writing on. If he will kindly favour us with his views more fully on the subject, I shall be very glad to reply to the queries he has laid such stress on with regard to seeing and smelling the pollen, and also with regard to the effects of electricity on plants. Mr. Pearson appears to treat these matters very indifferently. Does he do so from a scientific point of view? or is it because he has not entered into the subject with sufficient minuteness to enable him to judge the effect produced by electricity on plants whilst they are undergoing the process of fertilisation?—J. WILLS.

#### [ON THE SPORTING OF PELARGONIUMS AND OTHER PLANTS.

BY J. WILLS, HUNTROYDE GARDENS, BURNLEY.

THIS is a subject pregnant with a vast amount of interest to many who have watched this curious phenomenon in plants year after year. Noone, I believe, has as yet been able to fathom this wonderful freak

of Nature, and any facts bearing on this extraordinary phenomenon would no doubt have a tendency in some slight degree to clear away some small portion of the mysteries that surround it. It is one of the wonderful provisions of Nature, to man almost unaccountable—a provision, nevertheless, by which many curious forms of plants are produced which could not be obtained in any other way.

I have for many years watched the growth and development of plants from seed with great interest, and the producing of new forms has been to me a never-failing source of pleasure. I will, therefore, describe some of these curious phenomena, as witnessed by me; at the same time I do not wish it to be understood that the opinions I may have formed thereon are correct, my principal object being to open up the subject, so that it may be brought under the notice of others more competent to deal with it.

The tendency to sport in the Pelargonium is highly developed in the following kinds—namely, Flower of the Day, Brilliant, and, lastly, Mrs. Pollock. The former was distributed to the public some fourteen or fifteen years ago by the Messrs. J. & C. Lee, and from the very first year of its appearance up to the present time, I have noticed green sports frequently breaking out from it. This goes to prove that the variety called Flower of the Day was originally a sport, and was not produced direct from seed, and has a tendency to prove what I have before stated, to the effect that the more delicate kinds of variegated plants cannot be perpetuated by seeds, but must be increased by propagating the sports as they occur. This constant habit of sporting in the plant above mentioned shows, in my opinion, that the original parent was a green variety, probably *Cerise Unique*. The same propensity to sport is often seen in Brilliant; and, lastly, Mrs. Pollock will often produce sports of a dark green colour, with a deep bronze zone, showing that it was originally only a common plain Horseshoe kind; but here, if I am wrong in the opinion I have formed, Mr. Gries, with whom this most valuable plant originated, will no doubt correct me.

Having mentioned three kinds of Pelargonium that are very much given to sporting, I will now state what I think may be considered one of the causes which bring this curious phenomenon about.

Three years ago some Pelargonium plants were placed in a little house used for hybridising-purposes. This house was properly constructed, and placed in a position where it was not fully exposed to the direct rays of the sun, and where it had the advantage, when necessary, of the heat from a fire at the back of a wall, which formed the back of the house. My object in placing the house in this aspect was to obviate the necessity for giving air as much as possible whilst the plants were undergoing the process of fertilisation, and every care was taken to prevent any distribution of pollen in the house; but after all my care, I found, during the following spring, after the seeds were sown and had in due course produced plants, that some adverse agency had been at work, and that I must have overlooked or neglected some important point, for the greater portion of the plants had come quite contrary to what I had anticipated; for instead of being, as I expected they would have been from the parents used, beautifully variegated, the majority of them produced plants with green or dark zoned foliage, with here and there a sport breaking out from the side of the stem. On looking about for the cause, I came to the conclusion that the small perforated zinc ventilators, which were put in different parts of the house for admitting air and excluding all kinds of insects, had not been covered over so as to prevent a current of air from passing in whilst the work of fertilisation was going on, and that pollen from some other plants that were standing near must have been dispersed by the air, and that particles of it must have come in contact with the flowers just at the time I had been fertilising them. This struck me as being the probable cause of the seedling plants sporting so constantly as they did. The following year, for the purpose of testing the truth of this idea, I subjected the same plants to precisely the same treatment, and was sure the house was very much charged with pollen at the time I fertilised the plants, for a strong breeze was blowing at the time, and there was a good deal of ripe pollen on other plants standing in the vicinity of those I had been operating on; and as soon as the seeds had germinated and the plants were sufficiently developed, it was evident that the same phenomena had occurred again. The same thing has occurred again this year, in precisely the same way, and under the same conditions; whilst of plants of the same kinds that had been fertilised, and of which every care had been taken to prevent any pollen coming in contact with them after they had been fertilised, none produced plants in accordance with the parents used, and no sports in any instance have occurred.

One of the plants operated on was a sport I obtained from Mrs. Pollock, and referred to in a previous letter, labelled No. 1. The plant, No. 3, referred to in the same letter, is the produce of a plant that had been subjected to the influence of the mixed pollen.

The above facts have led me to the conclusion that a plant, if mixed pollen be used in fertilising it, will produce sports, more or less, as the case may be, and according to the state of the air at the time fertilisation is taking place. If the air is very much charged with electricity, there will be a greater percentage of plants with a tendency to sport; but if there be little or no electricity at the time, seedlings like the female parent will predominate.

With regard to the production of variegated plants, my opinion is that the more delicate kinds are not perpetuated from seed, but by

propagating the sports. The small seedling plants of almost every kind of variegated plant are so extremely delicate in texture, that they perish in a few days after the seeds have germinated. I have noticed this in thousands of instances with small seedling variegated *Pelargoniums*; none of these, or any other small seedling variegated plants, have any of the primary colours into which a ray of light from the sun may be decomposed: hence their quick decay.

It frequently happens that one side of the seedling plant will come variegated, whilst the opposite part will be quite green, and in most instances the variegation breaks out in that part of the stem of the plant just at or a little above the position of the seed leaves. If the variegated portion of the plant is not too delicate, I have found by pinching the green part gradually away, the variegated portion will predominate as the plant grows, and in a short time will assume the mastery over the green portion. This operation, however, must be performed very gradually, by pinching or cutting away portions of the green leaves by degrees; the plant may then be perpetuated, and the work of propagation may be commenced as soon as the plant has sufficient strength to bear decapitating.

To further illustrate the difficulty of perpetuating variegated plants from seed, I may mention that three years ago I found a plant of the common Groundsel (*Senecio vulgaris*), beautifully variegated. I at once took means to prevent the birds from taking the seeds, and the plant from suffering any injury. I also frequently watched, so that I might secure all the seed, thinking I should be able to perpetuate it, and by fertilising the double garden varieties with it in the following year, should be able to produce a new and very handsome variegated bedding plant; but I was doomed to disappointment. In the spring following, the seeds were sown, and tended with every care, and I believe nearly every seed grew, but not one lived more than three days after their appearance above the surface of the soil. Another variegated form appeared the same year—namely, a plant of the common Celery (*Apium graveolens*), became also beautifully variegated; the seed was carefully preserved till the following year, when it was sown, and produced plants, the leaves of which were as white as milk. These lived till they had made the second pair of leaves, when they also died. Another case was that of a variegated *Verbena*. The plants from this also died. I could name many other instances which have come under my notice, but, I think, the above will be deemed sufficient for my present purpose.

I will now describe my experience with another class of plants that I have watched very minutely for many years past, to show its extraordinary sportive character, not in the foliage, but in the flower.

The *Verbena* has been long and deservedly looked upon as one of the most useful plants in cultivation for flower-garden decoration. The plant being an especial favourite with me. I have for many years been trying a series of experiments in cross-breeding and hybridising it, and four years ago I succeeded in producing a hybrid—the variety now known by the name of Velvet Cushion. This was, I believe, the first hybrid *Verbena* ever produced. It was obtained by crossing the old *Verbena venosa* with the garden varieties. For two years I could not get any seed from the plant; but other garden varieties that had been fertilised with the pollen from Velvet Cushion seeded very freely, and produced from 10 to 15 per cent. of plants of a similar suffruticose habit, with flowers of the same shape and substance, and of various shades of colour. Last year, for the first time, I gathered seeds from plants of Velvet Cushion growing in the open ground. There were other plants of the ordinary kinds of *Verbena*, such as Purple King, &c., growing near them. These seeds have produced but very few of the Cushion varieties. Some are exactly like Purple King both in habit and colour, the only difference at present perceptible is the elongation of the truss; some have produced scarlet flowers, others plum, pink, and, in fact, nearly every shade of colour to be found in the *Verbena*. This I attribute to the *Macroglossa stellatarum*, which was very plentiful last summer. It seemed particularly fond of hovering over and sipping the sweets from Velvet Cushion. I have frequently seen as many as from ten to fifteen at one time on a small bed.

Plants of Velvet Cushion, carefully fertilised, have this spring produced some extraordinary forms, some with flowers of immense size, others with small neat habits and liliputian flowers. These are from Velvet Cushion fertilised with the pollen of Maonetti Princess Victoria, a most valuable plant for bedding-purposes, which I obtained, two years ago, by crossing Velvet Cushion with the pollen of Maonetti L'Impératrice Elizabeth. The beautiful Scarlet Cushion was produced at the same time by crossing Velvet Cushion with the pollen of Foxhunter. Velvet Cushion has produced more than fifteen distinct forms of the *Verbena* this season, of an intermediate section between the Cushion varieties and the Maonettis. Specimens of most of them I hope shortly to place before the Floral Committee of the Royal Horticultural Society. Then, again, the plants of the common kinds have produced the most out-of-the-way shades of colour, different from those which they have ever done before with me.

The produce of some crimson flowers have been shades of blue, violet, mauve, pink, rose, lilac, purple, &c. One plant in particular has produced almost every known shade of colour. This was a beautiful striped variety I raised last year, and as it was a flower of great promise, I fertilised it with pollen from a variety of the best flowers I had. Three of the florets on each truss were fertilised with the same kind of pollen, and care was taken that a clean brush was used for

every sort of pollen. My idea was, that it would produce striped flowers in great abundance; but in this I have been deceived, for not a single striped flower has it produced, whilst flowers of the other varieties, fertilised with the pollen of the striped one, have produced many very fine stripes.

There is no plant I ever heard of so sportive and changeable in the character of its flowers, nor any plant I ever knew so capable of undergoing transformations as the *Verbena*. One of the most extraordinary instances is the following:—A flower of the Princess Victoria (Maonetti) was fertilised with the pollen taken from Scarlet Cushion, with the view of producing a scarlet Maonetti, instead of which it has produced a plant with foliage very similar to Purple King, and a flower as large as Foxhunter, and nearly of the same colour.

Having given a true statement of these curious phenomena, I must now bring my paper to a close, hoping that the subject may be resumed by some one who has had longer experience, and who may have more minutely followed up a similar series of cross-breeding than I could do, having so many other varied duties to perform in connection with the garden. This also must be my apology for any defects in this paper, and for the hurried manner in which it has been written.]

## HORTICULTURAL ENTERPRISE IN THE UNITED STATES AND CANADA.

No one can even glance through the columns of the rural journals published in the United States without being struck with the evidence they furnish as to the activity of mind and business energy which are being put forth in the department of horticulture. Floral novelties, new fruit seedlings or hybrids, ornamental shrubs, for which distant parts of the earth have been ransacked, rare seeds, and choice bulbs never before heard of, are constantly pressing into notice; and while, of course, many of them are mere pretenders to excellence, and trumpeted forth for money-making purposes, it cannot be gainsayed that we have obtained some very valuable horticultural acquisitions from our neighbours across the lines. In Strawberries and Grapes alone American horticulturists have greatly distinguished themselves. Of the former, it is only necessary to name Wilson's Albany Seedling, a treasure of untold value to the gardeners, professional and amateur, of this continent. A little acid, it has, nevertheless, qualities which place it immeasurably in advance of all competitors thus far. Yet this magnificent berry will doubtless, ere long, be surpassed by some of the seedlings which enthusiastic horticulturists are testing in their grounds. Of Grapes, we have several most valuable varieties. The originator of the Concord, Mr. Bull, of Concord, Mass., has lived to see his Vine planted by millions from Maine to Minnesota. Dr. Grant, of New York, and Mr. Rogers, of Salem, Mass., have also achieved important triumphs in Grape seedlings and hybrids. The Grape for America has, however, yet to be produced—if, indeed, our fellow-countryman, Mr. Arnold, of Paris, has not already accomplished what so many have long been aiming at—the combination of the luscious flavour of a glass-grown Grape with the hardness of an out-door Vine. Hen. M. P. Wilder, of Boston, Mass.—very high authority—in a letter that we have seen, expresses the opinion that Mr. Arnold's will prove the Grape of this continent, and that posterity will "cherish the name and bless the memory" of its originator. To all which we heartily respond, "So may it be!" When it is considered that thousands of seedlings must be grown and tested ere a single variety worth anything is obtained, and also that the process of hybridising is a very slow and difficult one, some idea will be formed of the amount of thought and labour necessary to the production of any real acquisition to our horticultural treasures. While our American neighbours are busily engaged in the search for novelties and improvements in the regions of floral and shrub beauty, they are especially diligent in the realm of fruit. They have produced Apples, Pears, Peaches, Plums, and Cherries that leave nothing further to be desired. In the department of small fruits they have been very assiduous, and have succeeded in obtaining a Gooseberry that defies the mildew, that bane of imported Gooseberries; some valuable Blackberries, the Rochelle and Kittatinny, the former a great success in the Midland States, and the latter hardy enough for the most northerly situations. It is questionable if any country be better supplied with fruit in variety and succession than is the United States at the present time.

These brilliant successes would not have been achieved but for the existence, in pretty considerable development, of horticultural tastes among the people. There has been a healthy demand for everything really valuable, whether it be for ornament or use. Eminently a practical people, the Americans

are, nevertheless, an æsthetic people. They are often extravagant in their outlays for matters of taste, ornament, and display. They cultivate the beautiful in dress, furniture, and the surroundings of their homes. Were there not a demand for the expensive novelties we see continually advertised in their agricultural and horticultural journals, they would not be offered. A seed of the *Victoria regia* for one dollar—a fine Lily bulb newly from Japan for eight dollars,—a Yeddo Grape Vine, also from Japan, for ten dollars, a new *Gladiolus* bulb or *Dahlia* tuber at three or five dollars, a new species of Spruce seed three dollars per ounce, are specimens of advertisements by no means rarely to be found in the journals referred to. The large scale on which some things are raised and sold cannot fail to attract attention. Grape cuttings are sold by the million, Cranberry vines by the barrel, and a nursery of two, or three hundred acres in extent is not uncommon. As for the sale of such common nursery articles as Apple, Pear, Plum, and Cherry trees, they are past enumeration.

Is the rage for these things excessive and reprehensible? We are not prepared to say that it is. Of all extravagance that can possibly be committed, surely there is none so excusable as that which is expended on the beautiful and useful things of nature. Condemn, if you please, costly dressing, flashy jewellery, splendid equipage, expensive cookery, and lavish architecture, but respect the eagerness to collect and plant about one's house the lovely and valuable creations of God,—the flowers and fruits that declare His glory and show forth His handiwork.

We, in Canada, need no checking in this direction, but rather urging. We have thousands of rural homes that have not a beautiful thing in all their surroundings, except the landscape and the sky. Many a farm has no fruit on it except a few Strawberries on the edge of the woods, a straggling patch or two of Raspberries in the fence corners, or maybe a few Huckleberry bushes in some neglected spot. Our nurserymen are very poorly encouraged. Any travelling irresponsible peddler of fruit trees is patronised before well-known persons who have a stake in the country and a character to maintain; and we have plenty of farmers who have yet to buy and plant their first fruit tree. Matters are improving somewhat, but we are very far behindhand in all matters of taste and refinement. There are, we are glad to know, many attractive country homes in various parts of Canada, and some neighbourhoods are fast acquiring a reputation for the culture of fruits, flowers, and rural beauty in general. But these are exceptions. We hope they will, ere long, become the rule. For natural advantages, we have a land that cannot be surpassed. Let us enrich and adorn it with fruits and flowers, with shrubs and trees. Much may be done at but little cost. The taste once exercised will improve, and busying itself to multiply the delights of home, will enjoy them with an ever-increasing relish.—(*Canada Farmer.*)

### GRAFTING ROSES.

ALTHOUGH a little behindhand, perhaps, at least as regards season, it may be interesting to some of your readers to know my system of grafting Roses. The process is so very simple, that it may be described in two or three words. I merely bind with a piece of indian-rubber band, and fasten the end with a bit of thread, that done the operation is complete. This is not only simple, but it is a cleanly and most expeditious method of grafting. I do not hesitate to say that an expert hand could work off two or three for one he could do in the usual way. There can be no mistake as to its being a successful mode of grafting, which the following facts, I think, will show.

About the beginning of March I selected a few of the best shoots I could find of two or three new varieties which I had received from the nursery about a month or so before. They had been knocked about a good deal, and even the best of the shoots looked anything but promising. Having, however, a few Manetti stocks by me, I thought I would give them a trial. I therefore grafted them in the way above mentioned, and potted them in four-inch pots, after which I placed them in a frame having a little bottom heat. They soon began to show signs of life, and towards the end of April they were fit for planting out. One or two of them are now nearly as large as the originals, and will soon be in flower. I grafted them in different ways—viz., whip with tongue, plain splice, and cleft, and with each was equally successful.

This is not all. On the 4th of May I had a small cutting

given me of a variety I had not grown. The plant from which it was taken had been shifted late and had not as yet made any growth. I put the cutting into my pocket with the full intention of placing some damp moss round it as soon as I left the garden, as I was at the time a long way from home; but, notwithstanding my good intention, I forgot all about it until I reached home in the following evening at a late hour. When I drew it from my pocket it had very much the appearance of having been baked in an oven, it was so completely shrivelled up. Thinking there might be a probability of its reviving, I put it into a tumbler with a little water and allowed it to remain until the Monday morning, when it again appeared quite plump and fresh. I had certainly little or no hope of being able to make anything of it, but as an experiment it was worth trying, I thought. I therefore looked out a suitable stock, and grafted it at about 6 inches from the ground in the way before described, and it is now also growing nicely. The stock which I used on this occasion is the same as that mentioned by me about two or three years ago, and I take this opportunity of stating, that in some respects it is superior to the Manetti; it is eligible for working above ground, which the Manetti is not; it also produces a more vigorous growth. Like the Manetti it gives no trouble whatever with suckers, will grow almost anywhere, and live through our severest winters.

I have been a little particular in relating the above circumstance, in order to show that a nice-headed standard is obtainable in one season instead of two, which, in the ordinary way, is at present required, and that with very little trouble, for the operation can be performed almost as quickly as that of budding.

My system may be objected to on the ground of expense, but I think from the price at which rings are at present sold, indian-rubber grafting bands could be produced at a very trifling cost; and of this I feel certain, that if once introduced we would one and all, professional and amateur, for the smaller kinds of plants at all events, wash our hands and say good-bye to pitch and plaster.

I am here reminded of another sort of plaster—viz., that recommended for budding by "AMATEUR," at page 3. I have not yet given it a trial, not having any of it by me, but I have tried many other things, and find that nothing answers the purpose so well as narrow tape.

The use of red lead mentioned at page 451 of the last volume is not new; it appeared in the columns of this Journal, if I mistake not, about three or four years ago. I have used it regularly since, and I take this opportunity of testifying to its efficacy as a preservative for sown seeds.—*Loch Ness.*

### ADJUSTABLE HOE.

Among the advantages possessed over the common hoe are mentioned the following:—1st, Time is saved in selecting a hoe with the blade to hang rightly; this blade being adjustable, can be set at any angle, with the handle to suit the height of the person using it; 2nd, This can be easily and quickly done by a little wrench, found neatly and conveniently screwed into the end of the handle; also, the handle can be shortened or lengthened 2½ inches when desirable, the joint being secured by teeth which are out of sight when the hoe is in working position, estimated to be as strong as any part of the hoe. 3rd, The inner side of the blade may be ground as the outer side, and when it is worn out a new one can be placed in the same handle at a small expense; also, different sized and shaped blades may be obtained. 4th, By setting the blade at a proper angle the hoe becomes converted into a light shovel or spade, and becomes useful for cutting turf-borders; also,

by setting it at a right angle it becomes useful for lifting the dirt from the bottom of post holes. 5th, It is conveniently packed for transportation.

### ORCHARD-HOUSE CULTURE.

SOME few weeks since a neighbour pointed out to me an article on orchard-house culture, and, if I remember correctly, advising those who thought of erecting small orchard-houses not to do so. In common with some neighbours I have many small orchard-houses, which have now been in work some ten or twelve years. I call them small because they are low, being 7 feet high in the centre, 4 feet at the sides, and from 10 to 12 and 14 feet wide. These houses are full of Peach, Nectarine, and Apricot trees, all in full health and vigour; I may add, as usual, for they have never yet failed in doing well. The only precaution necessary to ensure a crop of fruit is to place a pan of charcoal in each house when the trees are in full bloom, or while the fruit is young, if our spring frosts are severe, as such low structures are not spring-frost-proof like houses with lofty roofs.

I am particularly struck this season by one of these low houses full of Apricot trees, three years old, all pyramids, in 11-inch pots, in which they have been two seasons. They have been pinched-in closely during the summer, and all are perfect in shape.

Every tree—there are upwards of 150—is studded with fine fruit, from eight to twelve on each, to which number they have been thinned. In the whole of my long experience I have never seen anything in fruit culture more beautiful than this assemblage of pyramidal Apricot trees. Their management has been rather peculiar, but most simple. I have, in a paper, which will be published in the "Proceedings" of the International Botanical Congress, given a full account of the Apricot culture here, which will, I trust, one day be in your columns; I shall, therefore, forbear troubling you with it.

With regard to the management of orchard-house trees, about which I read so many peculiar opinions, it is so simple, so invariably successful here, that I cannot help feeling my eyes open widely with surprise when I read about failures. It is an oft-told tale, but repetition will, I hope, be pardoned by your readers. I can only state that any amateur who will call into exercise gardening sense will succeed. We will make the orchard-house year to commence about the end of October, it may be extended to the middle of November.

1. The trees of all kinds, except Apricots, should be top-dressed by taking out the soil and the mass of inert fibrous roots to 4 and 5 inches in depth; the former for 13 and 15-inch pots, the latter for 18-inch pots. In removing the mass of earth and fibrous roots, the rootlets, from the size of a bent of grass upwards, should be left. The top-dressing, which should be tender tenacious loam and rotten manure, should be rammed down with a stout blunt stick, and the compost be raised slightly above the rim of the pot, so as to form a concave surface, the tree in the centre. A week after the top-dressing, the custom here is to give about two gallons of water to each tree. Some refuse hay is placed on the surface and around the pot to protect the roots from frost, and all is safe for the winter. In maggy, wet weather the house may be open night and day, closing it against storms of wind; in frosty weather it may be closed.

2. Early in March, when the buds begin to swell, the trees should have water, say two or three quarts, or a gallon, according to the size of the pot and dryness of the earth in the pots; this should be given once a-week, or so, according to the state of the weather.

3. About the end of May, when the fruit is swelling, place on the soil of the pot a rich surface-dressing. This may be the (here) never-failing malt dust and horse-droppings—the latter gathered from the roads—saturated with liquid manure, but not allowed to ferment. This dressing should be above the rim of the pot, being made into the shape of a circular bolster, something like a life-preserver. The concavity retains water, which at once makes its way to the stem of the tree in the centre, and then radiates to all the roots. Horse-droppings alone, or thoroughly decomposed manure, chopped and saturated with liquid manure, make a good surface-dressing. No lumps of raw farmyard dung will do.

4. In June, and again in July, the surface-dressing must be renewed, as it will have subsided.

5. The shoots of Peach and Nectarine trees should be

pinched-in to two and three full-sized leaves almost daily till the end of July. If the house is large, and large trees are wished for, they may be pinched in to five and six full-sized leaves.

6. The trees will be kept in full health by syringing them every morning during June, July, and August, between 7 and 8, and immediately opening all the ventilators, and again syringing them between 5 and 6 in the evening, closing the ventilators. The latter evening operation should be discontinued in cool, rainy weather. In sultry weather in August the ventilators should be open night and day. The flavour of the fruit is improved by this practice.

7. Aphides of all kinds are killed with the most simple of all decoctions—4 ozs. of quassia chips boiled ten minutes in a gallon of water, to which, while cooling, 4 ozs. of soft soap are added, and mixed. None of those offensive paints, such as clay, sulphur, &c., are used; they hide the buds and disfigure the trees. In winter, when the brown Peach aphid makes its appearance on the young shoots of Peach trees, the insects are killed by the above, and in spring the green aphid is destroyed by the same.

By these few simple rules, which have been adhered to here for many years, orchard-house trees have been kept in vigorous health and fruitfulness. Why should not every lover of fruit-tree culture do likewise? I must add that my pots stand on a surface made solid by constant use; the trees make but very few fibres below, and do not require lifting to break off the roots; the surface-dressing seems to be the great attraction. None of my numerous houses has any roof ventilation; it leads to expense, and is not required.

If any of your readers wish to verify my statements they have only to make their way to the Harlow Station, Great Eastern Railway, whence it is a pleasant walk to the Sawbridge-worth Nurseries.—T. R.

### A ROSARIAN'S PROTEST.

I HAVE a grievance. I used to know the faces of all my friends at a moment's glance, but times are sadly changed. I suppose I am growing old and my sight is failing; and that is the reason why I cannot tell, when I am at a public assembly, whether I am in the presence of Monsieur le Comte de Nanteuil or the Hero of Vitry, or who is presenting me Tea—Madame Bravy or Miss Rosea Alba. As to recollecting the names of all the generals, foreigners, and great men, with their decorations and their scarlet, crimson, and red coats, or telling them one from another when apart—that I find perfectly impossible, though I have been moving in the very first circles for the last twenty years, and flattered myself I knew every one worth knowing.

Another matter is that I do not approve of the ladies' manners or their style of dress. They stand staring you out of countenance with their great eyes. Mlle. Bonnaire complained that she was completely elbowed out of the assembly at Kensington the other day by a lot of coarse individuals who had no refinement about them. As for me, I have nearly determined to retire from public society, and to have my own private coteries instead, assembling there only the most aristocratic, elegant, and distinguished of the upper ten thousand.

Perhaps another day I may tell you who my company are. In the meantime I must request you to treat this communication as strictly—SUN ROSA.

### THE APPLICATION OF MANURE.

THE amount of manure at disposal is generally a question of no little significance to the gardener, and I think we may safely affirm that the manner in which it is applied ought to be a consideration, second only to that of its possession. Although we live in the days of high farming and gardening, we have frequent evidence that not a little ignorance exists on this point, not in the field alone, but in the garden also. People reason falsely upon this, as upon many other things, thinking that because a little is beneficial, a great deal must be even more so. Manure is often applied in a way in which not only a great waste of the material itself is entailed, but in which it exercises a positively injurious action upon the very objects it was intended to benefit. It is a custom with some gardeners—not so frequent now as in times past perhaps—when planting some sorts of trees and shrubs, to bury a large quantity of raw

manure directly beneath, and in contact with the roots of the plants, thinking thereby to induce a luxuriant and vigorous growth; but nothing could be more opposed to reason, and we question very much if the advocates of such a system of manuring could give a rational explanation of their practice, or make it appear otherwise than contrary to the principles of good gardening. I refer more particularly to the system as applied to hardwooded plants. To certain classes of vegetables, such as Celery and others of a gross-feeding habit, manure, even in an unadulterated state, may be beneficial; but to such things as Gooseberries, Raspberries, or Roses, that delight in a cool substantial soil, such a practice cannot be advisable. Nevertheless, the custom prevails, and has even been recommended by some, but recent experience, on our own account, would certainly teach us to dispense with such advice.

On entering my present situation here, about fifteen months ago, one thing that particularly struck my observation in the kitchen garden was the peculiarly stunted appearance of a quarter of young Gooseberries. On examining them I found that little or no growth had been made during the season. What growth there was had evidently been made late in summer or autumn, but was at the time I examined them (November) quite dead. As far as I could ascertain, they had been planted about three years, and I could clearly perceive that from the time they had been first pruned and planted, no progress whatever had been made. I further learned that the ground had been previously prepared for Asparagus, which had failed, and that a large barrowful of old Mushroom dung had been buried beneath each Gooseberry plant at planting. For reasons which it is unnecessary to explain, it was deemed expedient to let them stand over till the following autumn, but not anticipating great results, and unwilling to lose the ground, a row of Sea-kale was sown between the rows of Gooseberries in spring, which grew amazingly, the plants averaging from 5½ to 6 feet across from point to point of the leaves. The Gooseberries, however, made no growth at all, with the exception of a few unhealthy leaves, until late in August and September, when a number of them made a few weak shoots that could not have ripened properly, and would most likely have perished in winter as formerly, had the plants been allowed to remain. I took up several, and on examining them found the roots white with fungi, covering the stem up to the surface of the ground. The roots in nearly every case were quite dead at the extremities and for some way up; when touched they fell away in the hand—soft and brittle. From the living portion of them, near the stem, a number of young roots were just pushing, which accounted for their late growth, and which would certainly have perished like the others, thereby depriving the plants of the power to start into growth the following season until late, as they were now doing. The soil about the roots was thoroughly run with spawn, which had the true Mushroom smell, and the old Mushroom dung could be turned out in solid lumps, complete masses of spawn. Later in autumn we took the whole of the plants up; and, although anxious to be economical, we could select only about three dozen fit to plant again, out of about ten dozen; the remainder had to be made up from the nursery.

We have had similar experience with Roses. It was decided to make some alteration in a part of the roserie here, as much as anything else for the sake of the Roses, which were in a very unsatisfactory state. They had been taken up and replanted some three or four years ago, and on taking them up this autumn the greater part of them were in a plight quite similar to the Gooseberries, though not so bad. It was evident that a large proportion of rough half-decayed leaf mould had been put to their roots when planted, for in lifting them it turned out in large fungoid flakes. The roots were all more or less affected, some very much; so, had time permitted, I would have washed the whole of them; but wishing to take the advantage of the mild weather in November, I had to content myself with trenching the border over deeply, and mixing some well-rotted manure with the soil, adding a quantity of fresh loam to the roots of the plants as I went on. Except in the case of some Chinas, in no instance could I discover that they had benefited by the leaf mould in the form it had been applied. Most of the plants seemed struggling for existence; whilst some of the strong-growing varieties had pushed through into the stiff loamy subsoil beneath, in some cases to a great distance. I ought to state that the natural soil here is well adapted for Roses—as indicated by their luxuriant growth and abundant bloom in other parts of the garden—being a strong loam

upon a cool dry bottom. It is certain that the character and mode of applying the manure had a good deal to do with the evil. If well-rotted cowdung had been used instead it is not likely there would have been any evil effects, from fungi at least; but I think it will be admitted that, to apply manure of any description in the manner described is not advisable. It appears to me to be like feeding a human being upon butcher's meat alone. The parallel is only a fair one, and I believe the majority of people would object to such a diet. The laws that regulate the health and well-being of plants are just as nicely balanced as in the case of human beings, and cannot be violated with impunity; and to bear this in mind and act upon it is the chief secret of success.—J. SIMPSON (in *Scottish Gardener*).

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

The weather lately has been favourable for the destruction of weeds; see that they are not allowed to seed amongst Potatoes or Asparagus, where, from the luxuriance that surrounds them, they are apt to escape detection till they have shed their seeds. Attention in proper time to such a matter does not entail a tenth part of the labour that neglect will ultimately occasion. As there is every appearance of a change to rain, finish planting out Broccoli and Winter Greens as speedily as ground can be obtained, for unless the autumn should prove very favourable, those planted after this time will not attain much size. *Endive*, let it be planted in very rich soil. *Onions*, provide ground for the winter crop. *Lettuce*, maintain a succession, and attend to other small Salads. *Parsley*, see to securing a good supply for winter use, as it is always largely in demand. A good bed should be planted in some convenient place for protecting it during severe weather in winter. The soil should be of a light texture, deep, and thoroughly drained as a preventive against damp in winter. *Spinach*, select a piece of light open ground, and prepare it for Winter Spinach by giving a heavy dressing of manure and trenching or digging it deeply. This crop should be sown at once, and in drills in beds, allowing wide alleys so as to be able to gather the crop without treading on the ground.

### FRUIT GARDEN.

The tendency to excessive luxuriance exhibited by espalier trees renders the operations of disbudding, stopping, and shortening shoots more particularly essential. The whole principle of pinching is merely this—in the first place, to pinch all young shoots not necessary for the framework of the tree; secondly, to stop those shoots which threaten to overgrow their neighbours, by which means a due equilibrium of the branches will be maintained; and, finally, having commenced a system of repression, continue it in regard to lateral shoots, which are developed by this system of stopping. While, according to the plan usually pursued, every encouragement is afforded to the powerful development of roots by the application of soil, a necessary limitation of wood destroys the balance of force between the two. Root-pruning is thus obviously suggested, and may, in the proper season, be practised with advantage. If attention has been paid to pinching the shoots according to previous directions, there will at this time probably be found on the branches which have undergone the operation a little tuft of three or four or even more lateral shoots. It is a good time now to look to the young spray; in some cases the chief shoot may be shortened back to the last lateral, allowing it to become the leader, and if that should take a development stronger than is advisable, it must again be pinched. More cases of this kind are offered by the Peach than any other fruit tree. The principle holds good with all of them. The practice above alluded to, if regularly pursued for several seasons, will yearly become less troublesome; for the tree will become accustomed to such treatment, and gradually acquire the desired habit. Keep the Vines carefully tacked in, and the laterals constantly stopped. Let the free-growing shoots of Plums be regularly laid in, as they are apt to become awkward in training if left too long. Strawberry-runners should be procured from new plantations without delay. Those who cannot spare ground for a new plantation may prick them out in prepared beds about 6 inches apart, and remove them with balls in October or in the early part of February.

### FLOWER GARDEN.

Plants of a weakly habit of growth may be assisted in dry weather by an occasional watering with manure water, but for those that grow too strongly there is no help except thinning

out and pegging down the shoots. In shortening back shoots that incline to extend beyond the edgings of the beds, avoid the least appearance of formality by thinning out the under shoots and keeping all parts of the bed of equal depth and thickness, or allowing the plants to die away, as it were, at the edges according to the arrangement. Climbers on walls must be attended to as they advance in growth, keeping the young shoots neatly laid in, &c. The climbing Roses will also require to be gone over occasionally for the purpose of cutting off decayed blooms; and any weakly old wood should be cut out at the same time, to allow of laying in the strong young shoots, which will bloom much finer next season than the old wood would do. As the seed-pods of Pansies ripen they should be gathered and dried in a shady place. Pinks planted out in store-beds will only require attention as far as regards keeping them clean. If, unfortunately, wireworms should make an attack upon them, it will be advisable to place pieces of Potato between the rows, immediately below the surface of the soil, and in the vicinity of those where the last were destroyed. Thin out Dahlias, particularly the branches of those varieties which usually flower weakly, and remove all buds which exhibit malformations; tie the lateral branches to the side sticks, going over the stock frequently. A small amount of attention now will often save a great amount of damage.

#### GREENHOUSE AND CONSERVATORY.

Specimens that have matured their season's growth should now be more sparingly supplied with water at the root in order to promote the ripening of the wood. Orange trees and other plants known to be liable to attacks of red spider must be frequently examined for this pest, and well washed with the engine immediately it is perceived, taking care not to bruise or injure the leaves, and placing the affected plants so that every leaf may be reached. Go over the twiners frequently, and keep the shoots nicely regulated, cutting them out where necessary to prevent their being too thick, and shortening any that hang down so low as to interfere with other things.

#### STOVE.

As plants should now or soon be ripening their young wood, they want as much light and moderate sunshine as possible. In the case of Orchids this is especially necessary, in order that the young leaves and pseudo-bulbs may be thoroughly matured. Plants in this condition, or nearly so, should be removed forthwith to a cool house, and care taken not to induce them at present to push again, as a fresh start would interfere with their flowering next year. *Dendrobium nobile* and others of that class sufficiently advanced in growth should also be moved to a house where they could have a moderate and steady temperature, abundance of air, and little water till their stems are ripe and their flower-buds formed. Those Orchids which are still in a growing state should be placed in the most favourable positions, and encouraged by a nice growing temperature while the weather continues favourable for ripening and hardening any growths which they may yet make. Afterwards let them be put gradually to rest.

#### COLD PITS.

The stock here will probably require re-arrangement at this time, as some of the specimens, having completed their season's growth, will be better in a shady situation out of doors, and their removal will admit of giving more space to those left. Young growing stock, and late-flowering plants that have yet to make their season's growth, should receive the most careful attention, as, if well treated, they will make rapid and vigorous growth at this season, and nothing in the way of good soil, careful potting, or proper accommodation will compensate for the want of this. Indeed, there is no possibility of securing free growth from hardwooded plants in bright hot weather, except by moderate shading, and maintaining a moist atmosphere by sprinkling the plants overhead morning and evening; and air must be given liberally to keep the wood strong, avoiding as much as possible exposure to drying winds. Any of the specimens which require more pot room should be shifted as soon as possible, taking care to have the ball moist, and keeping them rather close and the atmosphere moister than usual for a fortnight after potting. Let the young shoots be tied before they begin to fall about and crowd and injure each other. Cut down *Pelargoniums* as soon as the wood is properly hardened, and keep them very sparingly supplied with water at the root until they start into growth, but sprinkle them overhead frequently, which will cause them to break more strongly. Continue to pot *Cinerarias* as strong suckers can be obtained, placing them in a close part of the cold frame

until they become established in their pots; but avoid placing them in heat, where they speedily become a prey to insects and mildew, and never do any good.—W. KEANE.

## DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

MUCH the same as last week—loosening the soil, fresh planting vegetables, staking late Peas, and watering Peas, Cauliflowers, Coleworts, Celery, &c. The continued drought and heat seem to be telling a little on the Onions, causing some of the plants to look mildewed. Nettle young plants and seed-beds of Lettuces, Cauliflower, Radishes, &c., to keep the birds from them. Sowed seeds of Spinach. That which was sown before the beating rains does not seem to come away kindly; and Spinach, independently of its use in the kitchen, is excellent for packing with other vegetables, to keep them firm, when they are sent to a distance.

#### FRUIT GARDEN.

Proceeded with *thinning and shortening the shoots of fruit trees*, whether against walls, or on low standards and pyramids. As a general rule, the sooner the shoots are shortened at the points the better, as the sap and vigour are thrown more backward to swell the buds nearer the base of the shoot. It is a good plan to do this with Apples, Pears, Plums, &c., when the shoots are about 6 inches long, merely nipping out the points, and leaving a few to remain unstopped to carry on the flow of sap. In most places the work must be rather roughly done, especially if the stopping has been too long neglected. Then breaking off the shoots over the knife, leaving them from 3 to 6 inches long according to circumstances, is a very quick and expeditious plan, and until the next month it is as well even then to leave a few shoots unstopped. By nipping out early the points of the best-placed shoots, and taking others away within a few buds of their base, more light and air play on the shoots stopped; and in Apples, Pears, and Plums, some fine fruit-buds are thus often obtained on the base of the shoot of the present summer's growth, which would have been nothing but wood-buds if the shoots had been left unstopped.

It is best every way to do most of the necessary pruning in summer instead of winter. The summer pruning regulates the powers of the plants, and directs these powers into the most useful channels, so as to give fruit instead of a superabundance of wood-buds. Every shortening and limitation of the number of shoots now, and at an earlier period, tells upon the root-action, and the diminished vigour at the roots is followed again by a better-ripened condition of the wood. Only make sure that the roots shall not penetrate too deeply into unhealthy, unsuitable soil, in which the trees will be encouraged to greater expansion in growth than fruitfulness, and root-pruning may be pretty well dispensed with, if duly stopping and regulating the shoots in summer be attended to. All this summer pinching and stopping tells upon the buds of autumn and the crops of the following year. Winter pruning is only a makeshift, rendered necessary by neglect, either arising from carelessness, or, too often, from the force of circumstances. It exercises little influence on the tree for the succeeding year. Supposing that it has made too much and too vigorous growth, and we prune in never so closely in winter, the natural result will be, from the energies stored up in the roots, another equally luxuriant crop of strong shoots in summer; and these again would so reciprocally act on the roots, that to keep up this luxuriance they would be induced to strike down so deeply in search of moisture and food, that the restoration of a fertile condition would have to be accomplished by cutting the roots, or elevating them nearer to the air and sunlight. A diminution in growth and luxuriance, the result of summer pinching and pruning, will help to keep the roots near the surface, especially when this is aided by surface-mulching, and surface-watering, and the removing of the mulching in bright weather, that the sun may act on the soil.

Hard cutting and *pruning in winter* are chiefly useful when it is deemed necessary to give a fresh start to the tree; and then if the roots are not too much beyond control, or in clayey, damp soil, much may be done by selecting the young shoots that push, and then nipping, shortening, and regulating them to induce them to form fruit-buds. Nice compact fruitful trees are thus often made out of those which seem to have grown beyond all control, and are either barren, or produce poor, ill-flavoured fruit. In nice young trees the thumb and finger, or

a small knife, must be used in summer instead of the saw or the chisel in winter.

**Strawberry Plants.**—The season of Strawberry-gathering will with us be much shorter than usual, owing to the great heat succeeding the drenching rains. Planted-out the most of those we had forced. We had filled some frames with plants which did us excellent service after we had removed most of the plants from the houses. From these we obtained some good runners. The plants, having been turned out in good stuff, became very strong when bearing, and afterwards, and though it is contrary to our usual practice, we thought we would try an experiment with them. We cut off all the leaves except a few small ones in the centre, gave the plants a good watering to encourage them to grow afresh, and when they have formed a few more squat healthy leaves we intend taking them up and potting them in large pots, being pretty fully convinced that such plants will ripen their buds earlier than those taken from runners of the present season. We have done so in a few cases with plants that had been forced in pots, and found that they usually produced very plentifully and early, but did not generally yield individually such fine fruit as was obtained from younger plants. The dry, warm weather has made the runners of some kinds come later than usual. Our favourite mode of preparing them is to layer the runners in small pots, with a stone or pebble over them to keep them in their places, and when rooted to take them up and shift into larger pots; but this season, to save time, we have taken up many runners as soon as formed, with a piece of the string attached, and at once potted them in small pots and set them where we could keep them close, and a little shaded either with glass or calico, &c., and they are rooting nicely. We did this chiefly to avoid the trouble of watering these where they were growing naturally.

**Orchard-houses.**—These required frequent syringing to keep them right in the hot weather. Moisture, and plenty of it where the moisture will not be stagnant, is now an important agent in assisting the swelling of the fruit and the perfecting of the wood of such trees as Cherries, from which the fruit has been gathered. Having nothing else handy we sprinkled all the ground thinly with soot, and watered well with house sewage; but we gave it to no plants in pots, as some time back, when owing to dearth of water we were obliged to use sewage water or none, some of the plants in pots suffered from it. Notwithstanding the drawbacks in the shape of economy as respects watering, we are not surprised that many people with little room so much admire the pot system. What can be more beautiful than a compact Cherry in bloom? and again, when loaded like so many ropes of Onions with its ruby fruit? and then all the care in watering, &c., seems to be forgotten. We would here make one suggestion to an "OLD GRUMBLER," and that is, as his trees become older he must not stop and pinch the shoots quite so much. When every little bit of a shoot bristles with fruit-buds, and the clusters seem larger every day, then it would be kindness to let the shoots grow for a few inches, and even that growth will keep the fruit-buds more secure, for if you keep stopping-in closely you may induce these fine clusters of buds in self-defence to elongate into wood-buds and young shoots.

Judging from our own experience we would advise all having orchard-houses to go over them regularly now, not merely for arranging the shoots, cutting-in laterals, &c., but for well thinning the fruit. The evil with most of us is that as the fruit comes so thickly, though we remove bushels of young fruit, we are apt to leave hundreds too many. The thinning is generally a serious thing in these orchard-houses, even without any help but the glass and sun heat.

We will clear the Peach-house this week, a tree of the Walburton Admirable having prolonged the gathering fully a fortnight or three weeks after the others were gathered—a matter of importance in small families. As a rule, Peach-houses ought either to be small, or, if large, should be planted with a succession of kinds, as a much greater quantity of Peaches at an earlier period than can be used is next to a loss, unless they are made a marketable commodity.

Gave a good soaking to Fig trees bearing abundantly. The fruit to be packed should be gathered at mid-day as soon as they begin to crack. Those to be used at home may hang until they are much riper, and then they are good for those who love anything sweet and luscious. We had long been in the habit, as respects pruning and training, of letting them have a good deal of their own way, and we were farther confirmed in this by a visit to Mr. Tillyard, at Bentley Priory,

some time ago. The Fig trees were doing first-rate, but bore no marks of much pruning or training.

#### ORNAMENTAL DEPARTMENT.

What with the rains and the heat, *lawns* have been no insecure, but have required much extra work in cutting, rolling, &c., and fresh-laid portions and turfed-down beds have been especially troublesome, as they grew much faster than the older turf near them, telling every one, if not kept down, of the changes, whilst the beauty of a lawn greatly consists in looking all of a piece. At times, when we could not overtake the cutting so as to keep all green and short, we have secured a uniform green, by switching off with the daisy knife all plants of Bents, Plantain, and other things that appeared above the green level, and a man that can sail or swing the knife above the green herbage, will go over a large space in a little time. The sun soon puts all such cuttings out of sight, and a few hours' work even on a large lawn soon makes a great difference in the appearance. True, it is a makeshift, but provided an effect is produced, people now-a-days do not examine too closely into how the effect is produced. We admire colouring in flowers, from whatever source they come. We can revel in the bright orange of the Buttercup in the meadow, and we can become quite romantic on seeing boys and girls gathering their pinafores full of the starchy Daisy, as we did in the times long ago. We have stood wondering if anything would make a more charming little yellow flower-bed than the Lotus *coriculatus*, so abundant in some pastures and lawns; but then to enjoy the sense of the beautiful, in unison with our advanced ideas of taste, there must be a place for everything, and everything in its place. Just as we would consider the furniture quite suitable for a working man's cottage not exactly in character amid the surroundings of an elegant drawing-room; so the flowers that deck and beautify the meadow would do nothing but detract from the rich green of the lawn. Where the lawn is too large to be kept uniformly green, then prudence and good taste alike recommend that there should be less ambition as to extent, and more striving to keep what is attempted to be kept, in good condition. Everything that rises naturally above the green surface of a lawn so far destroys its beauty. A green level should be its only characteristic.

*Hollyhocks* will now want securing, and they will be benefited by frequent syringings with clear soot water, which in hot weather will keep off attacks of thrips and other insects. A good watering with manure water at the roots will also assist in producing noble spikes, if that be the object. Removing some of the side shoots will also contribute towards the attainment of this result, and these may be struck in a shady place, with or without the assistance of hand-glasses. This is the best plan for securing huge single spikes, but not in our opinion showing off the majestic plant to advantage. It never looks better than when towering in grandeur, with numbers of subsidiary flower-shoots coming from the main stem, and attending the main central spike; but that would not do for a flower show.

*Dahlias* growing freely will need staking. We like best growing to a single stem, securing to a single stake, and fastening up the subsidiary shoots, doing it so loosely that little of the stake or tying is to be seen. These, too, if the weather do not change, will need watering at the root and overhead. A good syringing in an evening with clear soot water is one of the best means of keeping away the attacks of thrips, which, if once they obtain a lodging, will spoil the blooms much for that season.

*Carnations* and *Picotees* grown in pots or beds will now want securing, well watering, syringing, and cleaning; and if perfection is desired the flower-buds should be tied to prevent the calyx bursting at the bottom. For out-of-door work no stakes are comparable to a wire twisted in corkscrew fashion. Instead of tying, all that is necessary is to place the stems in the twists, and they will be held securely. Fine masses of the commoner kinds are grand in flower gardens, where they can be free from the devastations of rabbits and hares, and grass mice, which, especially in winter, will make sad work with the best collections.

*Pinks* will now be in a good condition for striking. The taking off and making the cuttings used to be a nice job for the shed. The days of progress are now on us, and we take off the cutting, technically piping, and make it with one sharp pull, taking hold of the shoot to steady it with the left hand, catching the cutting at the second joint with the right hand, and giving a brisk pull, when it comes out of the socket of the

joint, with a cleaner base in general than any the sharpest knife could give it. These are at once inserted in sandy soil under a hand-light, shaded at first from the sun. Sometimes a little film may be left at the base of the cutting thus made, which may be removed with a sharp knife, but that will seldom be necessary. This mode has also the advantage of not spoiling much the appearance of the old plants, nor yet of injuring them much for dense flowering in the following season. The young plants struck now will produce the best flowers next season, but not in quantity like older ones.

**Cinerarias.**—Pricked off and potted off seedlings, and turned out a lot of plants done flowering after cutting them down, in order to obtain strong rooted suckers from them by-and-by. These will far surpass for blooming and health old plants grown on by any mode.

**Calceolarias.**—Now is a good time for sowing herbaceous and semi-herbaceous kinds for next season's blooming. The best mode is as follows:—Select a cool, shady place, either under hand-lights or a frame. Take six-inch pots, drain well, and fill to within 1½ inch of the rim with rough loamy soil baving sand in it, then have half an inch of finer sandy matter containing a little leaf mould or peat; water well, and let the pots stand for twenty-four hours, then level the surface, and scatter the fine seeds evenly over it. Cover with just a sprinkling of silver sand, and press again. Set the pots in their place, but thinly, and cover each with a square of glass, and keep the cinders or ashes, &c., on which the pots are set, damp. This will be better than watering the pots, as the first watering will generally give moisture enough to bring the seedlings up, and then it is better to sail or dip the pots when dryish than to water overhead. As the seedlings appear the squares of glass should be raised on one side, and ultimately removed, and ere long the little things will want pricking off.

**Flower-beds.**—Much against our will we were forced to water most of these, and especially the Calceolarias, as they were heavy with bloom. We tried to make the hoe and surface-stirring do instead of the watering-pot, and they did wonders; but a few Calceolarias showed signs of distress, and we thought it prudent to water. Scarlet Geraniums stood well. On Tuesday morning we had a heavy drizzling dew, which may end, despite the stationary condition of the barometer, in a heavy rain, which would now be acceptable to many things, though it might retard late haymaking. The day after watering we went over most of the beds with the hoe, where access could be obtained, to leave the surface rough again, alike to keep in moisture and to allow it to penetrate into the ground without running off, if it did come to us from the heavens. This is especially necessary in raised beds and borders. This watering may be a small matter where nothing more is required than fixing a hose to a supply-pipe, but it is a great labour where water is scarce, and where all that is used must be carted, wheeled, or carried. Much time and labour are often lost in gardens from the size of gates and doors preventing the access of carts, water-barrows, &c., and even where water could be brought, from the false economy of not conveying it in pipes where most wanted. Where water must be carried, the labour is vastly increased.

Placed Pelargoniums done flowering full in the sun, and will give little water that the wood may be well hardened before cutting them down. Fresh arranged verandahs and conservatory. Potted Primulas, Geraniums, Balsams, &c., and attended to plants much as described in previous weeks' notices.—R. F.

COVENT GARDEN MARKET.—JULY 28.

ALL descriptions of small fruit, such as Currants, Gooseberries, &c., are very plentiful now, and the fine weather has been most favourable for bringing them to market. Foreign produce is also abundant, and eagerly sought for to furnish our northern and midland markets. Good sound Potatoes are in sufficient quantity for all buyers.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

MELON SEEDS SPROUTING (*Allan Water*).—The seeds in a Melon long ripe, taken from it, and not dried, would readily germinate during this hot weather. Peas will germinate whilst in the pod.

FIFTY CUT ROSES (*J. Ercant, jun.; One of the Committee, &c.*).—This question needs no further discussion. "Fifty cut Roses," accepted as the wording is always accepted among gardeners, means fifty Roses in bloom, and the collection having fifty-one in bloom ought not to have had the prize. It would not have been "hard" to disqualify it, any more than it is hard to disqualify anything exhibited that does not strictly conform to the terms of the exhibition schedule. The schedule in the present instance defines "a truss" (not quite accurately), adding, "any addition, even of a leaf, will disqualify." The same strictness should be followed throughout the schedule.

LEARNING GARDENING (*A Constant Reader*).—Pay a premium to the head gardener, and, when you have been with him the stipulated time, obtain employment in a nursery for a year or two.

MILLET (*A. W.*).—It is ground and made into puddings. Apply to a wholesale seedsman.

PELARGONIUM AND GERANIUM (*J. P. Lambie*).—You ask, "What is the difference?" and we could only reply fully by giving lengthy botanical distinctions. The genus Geranium has been divided into three genera, Geranium, Pelargonium, and Erodium; but Geranium is such an old-established name, that every one is liable to apply it indiscriminately to Geraniums and Pelargoniums. They all belong to the natural order Geraniaceæ. Pelargonium is characterised by having usually seven stamens, and unequal-sized petals; Geranium, having ten stamens, and equal-sized petals; and Erodium, having five fertile anthers usually.

VARIOUS (*Ruby*).—We do not see anything better in your Tropæolum than several others in cultivation. *Gardenia florida* might grow and flower in a cool vinery, but would grow much better if kept in moderate heat during the winter and spring months, after which it would flower freely in a cool vinery. We have not used sea water, nor should we advise it to be used. A liberal dressing of salt on the surface of the Asparagus-bed in the spring is the usual mode of applying salt. No. 1 of the wild flowers is *Hyoscyamus niger*, Henbane. No. 2 we do not recognise, and should feel greatly obliged if you would send us some fresh specimens with more foliage, we would then give you the name. No. 3, seedling fronds of *Gesnunda regalis*, or Royal Fern.

JASMINE (*A. H. of B.*).—Your specimen is of the Spanish or Catalonian Jasmine (*Jasminum grandiflorum*). Although a native of the East Indies, it has long been naturalised in Spain, where it grows in the open gardens unprotected and is in bloom nearly throughout the year. It abounds in Valencia, Murcia, and Catalonia. In Portugal it is called the Italian Jasmine. The perfume sold as essence or oil of Jasmine is prepared from its flowers. Against a wall in your garden at Beckenham it is not surprising that it thrives. (*R. J. G.*)—No. 1 is the common Jasmine (*Jasminum officinale*). No. 2 the Catalonian Jasmine noticed above.

CAN AN APPLE GRAFT BE LONGER-LIVED THAN ITS PARENT TREE?—(*A. H. of B.*).—We think it can. Grafting upon a young and vigorous stock may impart to the scion a supply of sap more abundant than could be supplied by the parent stem. We do not say that grafting can perpetuate the existence of a variety of the Apple, but it may continue to invigorate a scion so long as the organs of that scion are able to elaborate a larger supply of sap.

TRITONIA ACREA LEAVES EATEN (*J. C. Beale*).—The leaves sent are eaten by some insect, which is the cause of the spots and white stripes. What insect it is, as we have no specimen, we are unable to say.

**PRIZE FOR MODEL GARDEN (Exhibitor).**—You say that the prizes offered were "No. 56, Design or Model," "No. 57, Model Garden," and a miniature garden was exhibited with beds, sand for gravel, zinc painted green for box, &c. There can be no doubt that it ought to have been exhibited in Class 57. That was especially for a model garden. Class 56 was for a design or model of any other kind.

**DRYING FERNS, &c. (E. T. W.).**—No tools are required. Spread between sheets of thick blotting paper the specimens in their natural position, placing every pinna or leaf flat and separate, and put on the top of the blotting paper a flat board and a weight of seven pounds or thereabouts. It is best to have a quire of blotting paper.

**GUANO WATER—ROSE BUDS NOT OPENING (Adnes).**—The guano should be allowed to dissolve at least twelve hours before it is applied, and being well stirred up, should be strained to free it of lumps. If you were to give your Roses a plentiful supply of water, we think that they would open the buds freely. The evil is probably caused by the dryness of the soil and atmosphere.

**NUPHAR LUTEA SOWING—MYRIOPHYLLUM SPICATUM AND ACORUS CALAMUS PLANTING (Peterborough).**—Now, or immediately after they are ripe, is a good time to sow seeds of Nuphar lutea, casting them into a pond with a foot or so of water over a muddy bottom. You may tie a small stone to the lower end of the Myriophyllum spicatum, and throw it into a depth of 9 inches or a foot of water. Acorus calamus may have a large stone tied to the root, and be cast into a foot or 18 inches deep of water over a muddy bottom. Now is a good time.

**RAPHANUS CAUDATUS (S. W.).**—It is a native of Java, and seed of this, the Long-tailed Radish, should be sown in a gentle heat, and when the seedlings are up and of a tolerable size, plant them out in the open air in good rich soil. It requires abundance of water during dry weather, and the ground about it should be frequently stirred. You will find full particulars at page 181, Vol. X., New Series. (De Foix).—Sow your single seed in an eight-inch flower-pot filled with light rich soil, burying the seed just the depth you would a common Radish seed. It needs no protection at this season.

**VINE LEAVES EATEN—LEAVES SPECKED (E. W.).**—From your description of the leaves we should attribute their skeleton-like appearance to the ravages of some caterpillar, which you may discover upon close examination of the foliage; or it may be caused by some beetle, or even earwig, and that you may ascertain by placing a white sheet beneath the Vines after dark, and shaking the Vines will cause the insects to fall upon the sheet. The specks, which we presume are in the shape of excrescences on the wood, leafstalks, and bunches, are natural, and peculiar to the Vine, and we do not consider that they eat into either the wood or the footstalks of the leaves and berries, but form a part of it. They are not injurious.

**ROOT OF VINE CUT (Idem).**—The large root you cut from 6 to 8 feet from the collar will not destroy the Vine if, as you say, it was not more than 3 inches in circumference, and did not bleed from the end left. The Vine would only be weakened by the root being cut, and by bleeding from the part detached. We cannot help thinking that a Vine forty years old must have had more roots than this; but if there were not, and the root which was cut had all the fibres lower than the cut, then it is not improbable that the part attached had not more sap stored up within it than sufficient to cause the buds to break weakly, and the shoots to fall off. It is for you to tell whether the Vine is dead or not; if alive it is probable that the few dormant eyes which are hard may break.

**VINES MILDEWED (Idem).**—The berries are mildewed, and the remedy is to dust the parts affected with flowers of sulphur. The small red specks on the footstalks of the berries are too large for red spider, and are in reality a part of the stalk itself—natural. We do not recommend the fumigation of vineries, except for the purpose of exterminating insects, and then smoking is only available for trips.

**FLIES IN VINERY (Idem).**—Make some beer very sweet with treacle, and with it quarter fill a soda-water bottle. Tie a piece of string round the neck of the bottle, and suspend it in the vinery from the roof. The flies will enter the bottle and drown themselves.

**BOTTOM HEAT FOR PINES (An Amateur).**—We have no doubt that you will have sufficient bottom heat from the hot-water pipes, provided the roots are not raised too far from the pavement above the pipes. In very severe weather you might scarcely have enough of top heat without a little protection. For ordinary occasions it would be ample.

**GROUND BETWEEN STRAWBERRY PLANTS (Inquirer).**—The ground between the plants, made hard by treading, may be pointed over with a fork to the depth of a couple of inches, but not more; for Strawberries like a firm soil, and hoeing or digging the surface deeply is to be avoided, as it injures the roots. We cannot give the names of the best Pelargoniums to be selected from a collection of fifty unless you state the names.

**POTATO DISEASE (R. Whitehorn).**—The cause of the Potato murrain has not been successfully explained even by the wisest of vegetable physiologists. To electricity, manures, inclement seasons, and other circumstances have been assigned the origin of the disease, but the Potato had been exposed to them all for centuries, yet the disease only appeared recently. We do not discern any novelty in your suggestions.

**BURNING SULPHUR IN A VINERY (Inquirer).**—Of course such a proceeding would, as you describe, destroy the leaves, the Grapes, and the young shoots. Often in this Journal have we warned amateurs against such a destructive proceeding. By burning sulphur it is converted into sulphurous acid, which is alike destructive of animal and vegetable life. Dusting the leaves with flowers of sulphur, and painting the hot-water pipes with a mixture of sulphur, water, and clay are the best modes of employing sulphur against red spider.

**CHALK IN SOIL FOR FIG TREES (A Grower of Figs).**—A little chalk in the soil of your Fig-house will do no harm, and, though we would rather apply rough lime rubbish, rough chalk will do very well. However, we have had and seen fine Figs in nothing but good loam, with top-dressings. In your proposed border 2 feet deep, on concrete, we would manage as follows:—Have from 6 to 9 inches of open rubble above the concrete, and then you can use water freely, and the 16 inches of soil will be ample for the Figs. The Castle Kennedy Fig is a very good one.

**BLACK ALCANTE GRAPE (A Constant Reader).**—The large oval berries were fertilised; the small berries were not fertilised, and this causes the difference in the size. Your Grape is Black Morocco, rather a shy setter, and should be assisted at the time of blooming.

**ROSES FOR EXHIBITION (J. S.).**—High-coloured Roses are:—Charles Lefebvre, Senateur Vaisse, Duc de Rohan, Maurice Bernardin, Prince Camille de Rohan, very dark; Empereur de Maroc, not large, but fine form, and very dark; or Pierre Notting, dark crimson. Light-coloured Roses are: Comtesse Cecile de Chabrilant, pink; Acadie, white; Gloire de Dijon, yellow; Triomphe de Rennes, yellow; Baronne Gonella (Bourbon), dove pink; Souvenir de la Malmaison, bluish; Duchesse d'Orleans, lavender bluish; Sœur des Angers or Caroline de Sansal, bluish.

**MELONS NOT SETTING (T. F. B.).**—The Melons do not set in consequence of the soil being too dry. If you water them well without making the surface wet, and give them more air, we think the flowers and embryo fruit will not turn yellow. Keep the plants healthfully moist at the root, and admit abundance of air, and they will set fruit freely if care be taken to fertilise the blossoms. To name a plant from its leaf is hazardous. The leaf sent is that of some Coleus, probably Coleus Verschaffeltii.

**ZONALE (North Riding).**—When thus spelt it is pronounced Zo-nale. Many persons prefer spelling it Zonal, and then it is pronounced Zo-nal.

**CINERARIAS FOR BEDDING-OUT (Idem).**—We have used Cinerarias as bedding plants, but they do not make a good bed, except, perhaps, for late blooming. The time to sow the seed for this purpose is the middle of February; then grow the plants in a gentle heat, and harden them off for planting-out in the beginning of June.

**LOBELIA SNOWFLAKE (Idem).**—This Lobelia is with us as good and as useful as Lobelia speciosa, only it is white instead of blue. Lobelias are more free in growth from seed, but they do not flower so soon nor so freely as plants from cuttings.

**ROSE STOCKS (Devonensis).**—You can only procure the Rose stocks, Shanghai and Fortune's White Banksian, spoken of by Mr. Wills, by buying plants of each and raising stocks from cuttings of them.

**NAMES OF PLANTS (T. W.).**—Common Henbane, Hyoscyamus niger. (W. West).—It is the Lesser Dodder (Cuscuta epithymum), a parasite, which attaches itself to the Vetch and other plants. (H. Hartwell).—Pernettya mucronata. (W. D. A.).—Hydrangea quercifolia. (F. M. C.).—1, Onoclea sensibilis, N. America; 2, Nephrodium molle, Tropics. (Aquatia).—The water-weed you send is a species of Enteroomorpha. The only way to get rid of it is to persevere in clearing it out as often as possible. We remember a similar case where a large piece of water was infested with the same weed, which was eventually destroyed in the manner mentioned.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending July 28th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

OLD AND YOUNG BIRDS AND DIFFERENT BREEDS RUNNING TOGETHER.

WHEN we were younger we spent much of our time—that is, all we had to spare—in a quiet Hampshire village. The church

was one of the old country churches; the less we say about the music the better, except that the flute and bassoon players were marvels to the children who attended church for the first time. About once in every quarter the choir sang an anthem, when it was strengthened by the assistance of a fiddle and two or three voices from a neighbouring village. It was a great day for Harley church when the anthem was sung. The pitch-pipe was brought into requisition, the instruments were tuned

together in the gallery, heads were stooped down out of sight while important consultations were held, and at last it was sung; and when the singers sat down they looked at each other and smiled, while a little buzz went through the congregation, and almost broke out into open applause. In the same way our clergyman had certain texts and sermons for certain seasons. We heard just before Lent about the sower. We had appropriate texts for harvest, for summer, for the new year, and they were well pressed home; but people got used to them, and as old John Tice passed farmer Eagle coming out of church, he would say, "The old sermon, maister, again; a body would suppose parson thought we forgot the time of year. I've heard that sermon a matter of forty times. Where shall us begin to-morrow, in horse-plat or eight acres?"

Just in the same way we have certain subjects for certain periods—they come, like the seasons, in course. We doubt whether those who heard the sermons remembered all of them, and so we judge from the queries we receive that part at least of our previous homilies are forgotten. We will take them as they come.

**INQUIRY.**—"The cock chickens are so forward that they will not run peaceably with the old birds: which should be confined?" The young ones; you may catch up twenty that have been running together, and put them in one pen; let them be well fed, and they will grow faster than when at liberty. A pen for such should be 20 feet long by 10 broad.

"F. A. S." wishes to break up all his pens now (he has three different breeds), and to let his birds run together: how is he to manage it? If there is room for them, put all your birds to roost in one large house, catch them at night, and put them on the perches. It often prevents fighting. There is neither risk nor injury in their running together till after the moulting season. You will have no eggs now that you require the birds to sit. If you wish to sit very early ones be careful to put your different breeds back in their pens in October; but if you are not intending to breed before January, it will do perfectly well if you put the birds back in November. This will give time for your pens not only to sweeten but to freshen; and your long-pent-up birds will find when at liberty the help necessary for forming their new plumage, and they will gain the strength to make them profitable occupants of their separate dwellings when the time arrives for their being again confined. These rests to the birds are like the alternations of night and day to mankind—they afford the opportunity for the reparative process to go on. Now, the surface of the pens and roosting-houses should be taken off and given to the gardener, and all water well lime-whited, and the run dug up and left rough, doors and windows left open. In fact, all should be done that can sweeten and renovate. It is the season of rest for fowls and their owners. May both enjoy it and turn it to the best account.

#### MEDICAL REPORT ON A POULTRY-YARD.

My stock for the past nine months (I only began last October), has been one cock and six hens.

Case 1st. About two months ago one hen was taken ill, and after four or five days died. Soon afterwards another died, and now some chickens six weeks old are dying one after the other. The symptoms are—soft crop, which at first sight seems very full of food, but on handling is found to be full of fluid only; loss of appetite, and after death a running of fluid from the mouth.

In the case of the first hen, I put her in a coop on some grass, gave her water only three times a-day, fed her on bread soaked in beer, or rather put it before her, for she would eat nothing, and as she was no better after five days, I one evening gave her a dessert-spoonful of castor oil. This seemed to finish her, for the next morning about ten o'clock she died, and the oil with the other fluid ran from the mouth after death.

My poultry are in an enclosed yard 26 feet by 16 feet, consist of common farmyard fowls, all but the cock and one hen, and are twelve months old. They are fed as follows—Noon, barley as much as they like to eat, then taken away; morning and night, pollard (1s. 4d. per bushel), mixed sometimes with mashed potatoes, as much as they can eat, then removed. Some lettuce is continually by them, clean spring water is given every day, and there is a sand-heap to bask in.

Case 2nd. As Brahma Pootras are so much recommended in these pages for confined yards, I in April bought a cock and hen nine months old, expecting by this time to have had a good

stock of Brahma chickens. As soon as thirteen eggs were laid I put them under a hen. I had seven chickens, three dead in the shell, and three eggs bad. The next sitting was eight Brahma and five common eggs. The common eggs all hatched, but only two of the Brahmas; the others were bad. The next sitting was thirteen Brahma eggs, and not a single chicken; was hatched. The eggs when cooked for the other fowls had some of them the yolk quite distinct from the white, and in some it was rather mixed up together, but all smelt very badly. The next sitting was six Brahma and five common eggs. The latter all produced birds. The Brahmas were all unproductive. Some were clouded, and some had the yolk and white quite distinct. To-day nine eggs should have hatched, seven common eggs, and two Brahmas. All the former have produced birds; the two Brahmas were unproductive. You will perceive that out of forty-two Brahma eggs, only nine hatched, and those nine were from eggs laid during the first three weeks I had the hen, while all the common eggs produced birds. The extraordinary thing is, that all the hens (six) are with one cock, there being only one in the yard, and I have noticed that he attends to the Brahma quite as much as to any of the common hens. I notice nothing wrong in the hen, only she has dropped a soft egg about now and then.—J. R. BEXTON.

[Loose crop is a very common complaint, but we have never heard of its being almost general in a yard. When cases like this occur, we endeavour to find the cause in the food or treatment. You say at "noon as much barley as they like, and then taken away." We suppose from this that the barley is given in a trough or some other vessel; this is incompatible with health, and would go far to account for sickness of any kind. Fowls learn to look for the daily advent of the corn-box. As soon as it is put down they rush eagerly at it, and eat all they can, a mouthful at a time. This is unnatural: a fowl should pick a grain, and not a mouthful at a time. The fowl, knowing that the food will soon be taken away, and stimulated by the presence of the others, gobbles down as much as possible, overfills the crop, and then has what in the human being would be called "a pain at the chest." By instinct the bird has recourse to water to wash it down, but it can only pass to the gizzard as that empties itself of the food previously in it. In the meantime it swells, and causes distension of the crop. We believe that from the daily recurrence of this, there is a loss of digestive powers; that the gizzard has become large, weak, and flaccid, unable to dispose of the food daily put in it. Appetite ceases, and thirst increases, the fowl drinks to the last, and dies. You must have a larger space for the chickens, that you mention is not large enough for the number you have. Give your fowls a feed of slaked meal very early in the morning, thrown about in small pieces, so long as they will run after it. Give them whole corn at midday, but scatter it broadcast over the ground. Feed again with meal in the evening. While they are suffering from pendent crops let them have water frequently, but not always by them. As soon as the cause is removed they will return to health, and may be treated accordingly. Continue the dust-heap and the lettuces. It would seem that the longer the Brahma hen remains with you, the worse her eggs are. Were the forty-two eggs laid continuously, or was there the intervention of a broody time?]

#### FOWLS YOU SHOULD KEEP.

In reference to "Fowls You Should Keep," in your Journal of the 17th, may I give my experience? The monthly return of eggs obtained by "J. M. S." from six hens appears very small. Three hens of the La Flèche breed have produced for me as follows:—May, 47; June, 54; and July to the 23rd, 28. One of the three hens has just brought off a hatch of chickens, and another has been sitting for the past ten days. I regret I cannot carry my statistics as regards these three hens further back, but the hens were only imported in April, and commenced laying at once. I have also had good fortune with Houdan and Crève Cœurs; but of the three breeds I confess to a leaning towards the stately and handsome La Flèche.

I should have mentioned that my three hens and a cock are in a run, about 8 feet square, in the suburbs of London, and that all the French fowls appear wonderfully tolerant of confinement. Were I not afraid of occupying too much space, I would give you the results of my hatching-experience, but will content myself with remarking that chicks hatched in my incubator run about with and appear quite as strong and well-to-do as those hatched at the same time under hens.—S. W., F.Z.S.

### EXTRACTING THE GAPES WORM.

I NOTICED in your Number of July 24th remarks upon extracting the gapes worm. This is a frequent disease in America, and carries off numbers of young chickens.

The plan I adopted was to take the top, say 4 inches down, of a quill feather, and strip off all the feathers except for three-quarters of an inch at the end where cut. The remaining part I cut with scissors about one-half the length, running the finger down to spread it and give it a barb-like appearance. Of the sharp part of the stem where cut I dip just the tip in sealing-wax to prevent its injuring the windpipe. I then anoint the feather with spirits of turpentine or coal oil, thrust it down the windpipe, twist it round, and then withdraw it. This barbed part brings the red gapes worms up with it. I never experienced any difficulty in doing this, and in most instances effected the cure.—JAMES SPRATT.

### ON PRESERVING EGGS.

At a late meeting of the Farmers' Institute in New York, a note was received from Mr. W. M. Brown, of Indiana, inquiring whether there is any way to pack eggs so as to keep them good from spring until the winter months? Upon this question the following discussion took place. The name of the first speaker is not given:—

There are various modes of keeping eggs, none of which are quite successful. Sometimes eggs packed in water saturated with lime keep perfectly well, and sometimes they do not. Some persons say they can keep them in water saturated with salt, others keep them packed in fine dry salt, others in charcoal dust. If packed in sand and kept in a very cool cellar, they will remain through the year. They should always be packed small end up. The best way to preserve eggs is to store them in one of Professor Nyce's preservatories.

Professor Smith, Columbia College, said that the common way of preserving eggs in the north of Europe, and which appeared to be more effectual than any other mode he had ever seen, was this:—The eggs are placed in a barrel, keg, earthen jar, or any other suitable vessel, and then melted tallow, only just warm enough to flow, is poured in, filling the interstices, and thus hermetically sealing the eggs from the air, which appears to be all that is necessary for their perfect preservation. When wanted for use they are easily obtained by warming the open end of the vessel to soften the tallow.

Mr. Solon Robinson said he thought lard or oil would answer the purpose; it would be more convenient. He had heard molasses recommended, and did not see why it would not answer perfectly.

Mr. Carpenter said he had found no difficulty in preserving eggs in fine dry salt. He packs them endwise, and about once a-month reverses the ends of the casks, or rather box with straight sides, so that a board and cloth or paper fits down and holds the contents in their place when reversed.

Professor Tillman gave it as his opinion that anything which would exclude air would preserve eggs. Recent experiments in France have developed the fact that varnishing the shell destroys the value of the egg for incubation.

Mr. E. Williams said he had seen eggs perfectly preserved by packing in meal.—(Canada Farmer.)

### NOTES ON BIRDS OF PREY IN ESSEX.—No. 2.

*Great Horned Owl.*—A very fine specimen of this noble bird was once shot in Mark Bushes, Latton, by Mr. Paine, keeper to Colonel Burgoyne, of Mark's Hall. The Colonel had it stuffed and placed in the front hall.

*Long-eared Owl.*—This is a very beautiful and rare bird. During the severe winter of 1860-61, three of them were shot in this neighbourhood—one at Sawbridgeworth, one at Harlow, and one at North Weald. This last I saw. It is an extremely rare visitor in this district, and the birds shot were probably driven southward by the intense cold.

*Short-eared Owl.*—This is still more rare than the preceding. Some years ago one was shot at Sheering Hall, but so far as I am aware, this was the only instance of its appearance. I may here remark, that Sheering Hall is situated in a vale by the river Pincey, which, until of late years, was densely wooded. It was, therefore, sometimes the resort of rare birds.

*Tengmabns Owl.*—Very rare. I saw one that was shot some

years ago in Birchanger Wood, near Bishop Stortford, and as it was only wounded, an attempt was being made to keep it alive.

*Wood Owl.*—This is a strong and fierce bird, of a dusky colour, with different shades of brown. It was so common that when a boy I always had one or two of them tame. They used to breed within a hundred yards of the house, and were great destroyers of rats. It was pleasing when walking on a fine night to hear the solemn notes of these birds responding to each other at a distance; but they are all destroyed, I believe, not one of them now remains.

*Brown Owl.*—Smaller than the preceding, of a lighter colour, and not so often seen, as it did not frequent out-buildings, but kept more to woods and other retired situations. Like the last it is now gone.

*Barn Owl.*—This beautiful and useful bird is now like the others nearly extinct. Its food consisted of mice, which it destroyed both in barns and fields; it used to begin its hunt about an hour before sunset, and continued it till daylight, thus rendering great service. Like the Kestrel Hawk, it touched no sort of Game, but it is so often destroyed by ignorant people that I fear we shall soon have to deplore its loss altogether.

*The Little Scops Owl* is said to have been seen here, but I believe it to be a mistake.—D. S. FRENCH.

### THE EGYPTIAN BEE.—PART II.

ITS INTRODUCTION INTO AND ACCLIMATISATION IN GERMANY.

(Continued from page 75.)

"OF animals hostile to bees which exist in Egypt," continues Herr Vogel, "only hornets and wasps are known to me. At a certain time in summer a boy must always be stationed near the bee-hives, in order to drive away the hornets, or else these animals would rob all the honey from the stocks. He who knows how rich Egypt is in troublesome insects may form an idea what a pest the hornets especially are for the bees and their keepers during the hot season in Egypt. If robbing a stock by wasps has once commenced, it is difficult to afford help. It is, therefore, the chief task of the watchman to ward off the first attacks of these enemies.

"As but a few Fellahs and Copts keep bees, it requires a good deal of time to find out an apiary. A European who does not know the Arabian language can discover an apiary mostly only by chance. Moreover, the Fellahs are so intolerant as often to throw great difficulties in the way of discoveries of this kind in Egypt, which difficulties cannot often be overcome, and travellers are frequently attacked by robbers. In Manzur a Copt keeps bees, who is said to be the Egyptian master of bee-keeping. Herr Hammerschmidt, a photographer, went to this man in 1863, to buy a stock for the Berlin Acclimatisation Society; the gloomy, distrustful, and very superstitious Egyptian did not, however, give a decided answer. Not even a dead bee, which was to be sent to Berlin as a sample, could Mr. Hammerschmidt obtain from him. For 15 to 20 thils. (£2 5s. to £3) only was he willing to part with a dead bee. Herr Hammerschmidt fortunately succeeded, in 1864, in finding out a small apiary in Old Cairo. The proprietor, a Fellah, who had been brought up in a European family, gave a bee as a sample, and parted with a small swarm for a considerable sum of money, he also made the hive for transportation, and had the box for packing it in made by his son, who was a joiner. This Fellah was only induced to sell the swarm by Mr. Hammerschmidt, who is a perfect master of the Arabian language, remarking to him that his name would not only be mentioned in Europe, but become immortal. This alone had the desired effect. The Fellah would not give the swarm in a wooden hive, being of opinion the bees were not accustomed to wooden hives, and would die in it. He, however, is not quite an unpractical bee-keeper. In order to compel the bees to make combs parallel to the diameter of the cylinder, he puts old combs on a small forked stick, which is exactly as long as the cylinder is high inside, and fixes them in the hive which is to be stocked. The bees fasten the inserted combs to the surface at the top of the cylinder and to the twig, and after they have been loosened at the top the Fellah can take them out with the stick, and also insert them again. The Fellahs have also partially moveable combs. The new combs which the bees make in the cylinder they make parallel to the inserted ones, and the excision of honeycombs is thereby much facilitated.

"The Egyptian bee, which is distinguished from all other known varieties by its small size and light pubescence, is

spread over the whole of Egypt. As the valley of the Nile is rather isolated in apiarian respects, this species cannot intermingle with other varieties, and therefore maintains its purity intact. This has been proved by single bees collected from different parts of the country. Arabia, in nature African, has likewise the Egyptian form of honey bee, which is proved by the specimen in the Berlin entomological collection, which was brought by Ehrenberg from Arabia Felix. The Syrian bee differs only from the Egyptian in being somewhat larger, and having a hairy yellow corselet; it is in other respects so much like the Egyptian variety that it may be considered as belonging to it. Even at the present day the Syrian form of the Egyptian bee exists in Palestine in hollow trees and clefts of rock, and it was from this bee that honey was obtained by Samson. Besides the Northern and Italian hybridous bees, and the so-called Grecian or Hymettus bee, bees are frequently found in Asia Minor, which by their light-coloured corselet-plate and small size again approach the Egyptian bee. The Egyptian form of the species with dark hairy crown of the head, goes through the Himalayas as far as China, and was called by Fabricius *Apis cerana*.\*

"As the subtropical zone is the home of the Egyptian bee, it was feared that this variety, which exists only in hot countries, would soon perish in the climate of Germany. A friend of mine informed me in 1864, that he had heard of the Egyptian bee having been introduced into England years ago, and that it had died there on account of the climate.† I can readily believe that the acclimatisation of the Egyptian bee has been attempted in England, and that it soon became extinct there; but, judging from the nature of the northern and Italian bee, I do not believe that it perished on account of the climate. Any effect of the Egyptian climate upon a being reared in Germany could only be imagined if the so-called cellular or preformation theory were true. According to the imitative or epigenese theory, which rests upon the development of all being from the bud or germ, it is quite natural to suppose that the germs of propagation, like the germs of the other organs of the animal body, should be formed and develop themselves in time, so that the influence of the Egyptian climate upon beings developed in Germany cannot be supposed. From the beginning I inferred that if the Egyptian bee could not at once bear our climate, it was doubtful whether it would ever become accustomed to it. If *Apis fasciata*, in order to be kept with profit, must be compelled to alter its nature, the acclimatisation of the insect would become impossible; for the native nature of the bee is, according to our experience, unalterable, whilst its inborn impulses are unchangeable, the Creator not enabling it to develop new instincts. The belief that bees in the West Indies leave off storing honey because they find food there uninterruptedly during the whole year is founded in mistake. Such a change in the nature of the insect cannot be imagined, as it is in direct opposition to the immutable laws which govern the nature of the bee. Horses may be broken in, dogs may be trained, nay, even lions, &c., may be tamed, but the nature of the bee neither man nor climate can alter. The latter can only regulate its instinct in every country of the earth in accordance with the variation of the seasons."

(To be continued.)

### PAINLESS EXTINCTION OF DRONES.

It is a common opinion that the massacre of the drones in a hive is a cruel and, I may almost say, unnatural proceeding. As the time has arrived when the destruction commences some of your readers may be interested in observing whether the drones suffer a painful death. I am inclined to think not, but that the body is sucked by the bees, so that the drone dies from exhaustion, whilst part of the store he has consumed is returned to the hive. I am strengthened in this opinion by the fact, that the attack is always made on a particular spot behind the

\* The name "Egyptian bee" is, strictly speaking, incorrect, because this bee is also met with in Arabia; but the species being thus styled in works on natural history, having been domesticated and cultivated in Egypt from the earliest times, and finally introduced into Germany from that country, we do not seek to change it. The us-German name, *Apis fasciata* (*fascio*, avi, atum, are, to wind or bind hands around), was given to it by the French naturalist Latreille (1838), because he considered it a species of that genus. The Latin name no doubt signifies that this bee appears to be adorned with reddish-yellow and white bands.

† This appears to be a mistake, as I believe no such attempt as that referred to was ever made.—A DEVONSHIRE BEE-KEEPER.

wings, and that drones recently killed are lighter than live bees.—HENRY HUGHES, *Loughborough*.

[We are unable to endorse your theory of the "painless extinction" of drones. Numbers, doubtless, perish of exhaustion, or are worried to death, few, if any, being actually stung; but this exhaustion seems to be the result of starvation, the unfortunate males being rigidly denied access to the stores of the hive some time before active hostilities are commenced. The attack which you notice as being made behind the wing is the mode in which a worker always endeavours to seize a hostile bee, and has, probably, this advantage, that it often enables her either to disable her adversary by dislocating the wing, or to inflict a fatal wound by curving her body and piercing with her sting the vulnerable parts underneath the abdomen.]

### HIVING A SWARM SETTLED IN A CHIMNEY.

Will you inform me what is the best method of hiving a swarm of bees which settled in a chimney leading from a flue? They cannot be reached by anything from beneath. They have been there about two months.—W. P.

[We must again confess ourselves puzzled, and shall be obliged to any of our correspondents who may be able to advise "W. P." in his difficulty. Why have the bees been permitted to remain in the chimney for so long a time as two months?]

### IS THE LIGURIAN BEE REALLY MORE PROLIFIC THAN THE COMMON BEE?

MR. LAW'S account of his Ligurian bees proves them to have been in his case certainly "prolific to a degree," but as the article is headed "Superiority of the Ligurian Bee," I must put in a claim to equal merit on this point for my old black friends, and I think I am justified in doing so by the following facts which occurred in my apiary this season.

I had, from a stock two years old, a remarkably fine swarm on the 27th of May, which, by the way, appears to have been a great swarming day in England, as well as here. This was followed in six days afterwards (the 2nd of June) by a very respectable second swarm; and this again in six days, the 8th of June, by without exception the largest and finest swarm I ever hived. The bees came away from the hive exactly at three o'clock in the afternoon, and I never remember to have seen the air in such a state of commotion, or to have heard such joyous music discoursed by my little favourites. For ten minutes at least I was quite uncertain where their final destination would be, when suddenly her majesty came down from her honeymoon flight, as I suppose, and rested on a currant bush by my side, and to my gratification she was instantaneously surrounded by her faithful subjects. The productive powers of the parent hive were, however, yet far from being exhausted, for on the 15th of June, for the fourth time, a gallant army sallied forth, all, like their predecessors, to be taken prisoners without striking a blow. These last I joined to No. 2.

Thus in less than three weeks I obtained from one hive three magnificent stocks. All of these have since not only filled the bodies of their hives, but are working merrily in glass supers, and two of them have, to my great disappointment, within the last few days thrown virgin swarms (very fine ones), but too late, I fear, to set up housekeeping arrangements for themselves this season, so I have obtained furnished lodgings for them with some kind neighbours. I do not, however, know that I am justified in using the term "kind," for I regret to say that in almost every case of uniting which I have attempted—and I have carried out my operations to the letter, as directed by all the best authorities—I have, like "G. J.," in your Number 277, been horrified by the number of dead and dying on the white cloth; in fact, the dreaded "needle gun" could not carry on the work of destruction with greater rapidity, or more fatal effect than the stings of these little rascals, when their territory is invaded at night. I have not tried peppermint; has it the effect of soothing their ire?

Although I think the facts I have stated above show that with proper management the black bee is sufficiently productive to satisfy the most exacting bee-master, still I am very anxious to introduce the Ligurian bee into this neighbourhood, and as many of my friends are equally so, any hints as to the best mode of procedure would be most acceptable. The prices

charged for Ligurians by most London and other English bee-keepers are most exorbitant, and they do not guarantee their safe arrival in Ireland.

One of my stocks (one of the best as I hoped), has behaved in a most extraordinary manner this year. I put on a bar super box in May, and they went up in crowds at once, and worked splendidly until about the 10th of June; about that time they appeared to me to be *in statu quo*, and remained so till the end of the month. On taking off the box to examine the cause, I found the passages between them clogged with drones, and the bees have never since resumed work or swarmed, although they appear at the entrance to be working most vigorously. What is the cause?—*SQUIB, Co. Kildare.*

I READ with great interest the account of the results obtained at Marston Trussel Rectory, communicated in your Journal of the 10th inst. I wish to supplement it with a statement of the results realised in an apiary in this neighbourhood, where the treatment was far from being scientific, and where the common bee (*Apis mellifica*), alone is kept. The proprietrix, for it is a female, the sister of a farmer, who interests herself in the bee department, had only four hives this spring. They were in ordinary straw skeps, and in fair condition. No. 1 cast three swarms, of which the top swarm cast other two; No. 2 cast three, of which, however, one was lost, and the top swarm cast a virgin; No. 3 cast three swarms; No. 4 cast two, making in all, along with the old stocks, eighteen. The swarms were all large. One of the virgins I obtained to people an observatory hive; and the other, which I visited to-day, was very large, so much so that a more commodious skep had to be procured for it than the one in which it was first housed. If in the case of Marston Trussel six hives swelled out to twenty-three, which might have been increased to twenty-five, in the case I am describing four became eighteen, giving the advantage in favour of the black bee. I may add that other swarms are still expected.—*PRESBYTER.*

[It seems to us that no satisfactory conclusion can be arrived at by the comparison of results obtained in different places, where the season, pasturage, and mode of management may be alike dissimilar. An impartial observer keeping both varieties in the same locality, at the same time, and under precisely similar circumstances, would in our opinion be the best, if not the only, evidence that could be offered as being at all decisive on the point.]

UNITING BEES.

A TOLERABLY large swarm came from one of my supered bar and frame hives, and I wished to unite it to a weak stock in another bar and frame hive. The following is the plan I adopted:—Having secured the swarm in a common straw hive, I placed it at 7 p.m. over the bar and frame hive, and opened the side slits in the adapter to allow the smell of the stock to rise up to the swarm. I also somewhat freely sprinkled both stock and swarm, as well as I could, with honey and water. I went to them about an hour afterwards, and all appeared quiet. Next morning the swarm was in its hive. I then placed a glass super over the stock, and resting the swarm on its top edge, gave the hive containing the swarm a smart blow or two. All the bees were now inside the super, and I gave them a second sprinkling of honey and water. Now began a fight which continued until every bee (of the intended swarm, I presume), was killed and cast out of the stock on the ground in front. Not a single bee is to be seen in the super. Query, Do the bees that sting other bees to death themselves also die, as they do when they sting human beings? If not, why not?

An immense number of bees have been hanging on and about a stock upon which there is a large bell super. Thinking it might be fit to remove I took it off the other day, but found very little honey and a good deal of brood-comb. I replaced it, and still the bees are hanging by thousands about the hive, doing nothing else. The same is the case with one of my Stewarton hives, although the top box was put on more than a week ago, and is filled with bees as idle apparently as those are that are hanging in a great bunch beneath and around the alighting-board. I suppose I must put up with their idleness.

Books say that bees will not attack people at work at a distance from the apiary. My experience and that of my children and gardener is just the opposite of this. They attack us

when we are some distance from the apiary, and pursue us relentlessly.—*T. R. DRAKE, Fittleworth Vicarage.*

[The union might have been more successful had you removed the adapter, and knocked out the swarm on the top of the exposed frames. This is, in point of fact, the mode we ourselves adopt, previously deepening the hive at the top by the addition of a square wooden frame of suitable diameter and about 1½ inch deep, upon which we place the crown-board as quickly as possible after knocking out the cluster of bees. We use, also, a little smoke and peppermint-scented syrup, but, with all these precautions, are not exempt from occasional failures. Bees that sting other bees do not always perish, because the membranes and soft integuments of the bee are so delicate and fragile as to permit of the sting being withdrawn without injury. When, however, as sometimes happens, that weapon penetrates the head or any part of the horny armour of the bee it remains immovably fixed, and the result is fatal to both combatants. The honey harvest may possibly be on the wane in your locality, as it is in ours, and this would account for the apparent inactivity of your bees. If, however, honey is still plentiful, adequate ventilation and sufficient room being afforded, they will speedily resume their wonted industry. Bees do not usually annoy persons at a distance from their hives. There can be no doubt, however, that their dispositions vary considerably, and yours seem to be unusually irascible.]

OUR LETTER BOX.

WEAK-KNEED BRAHMA POOTRA (*J. E. C. S. D.*).—It is uncommon for a Brahma cock of the age you mention to become weak at the knees; that complaint belongs to youth and old age, and unless there is something very wrong with him he ought speedily to recover. We think your stimulants should be preceded by opening medicine, and advise you to give castor oil, a table-spoonful; you may give two doses at two days' interval, and a third three days afterwards. Then feed on bread and ale, cooked meat chopped fine, and chopped egg, with ground oats slaked with milk. He should be put in a place by himself. The cross you speak of is not so good as that between a Brahma and Dorking.

PIGEONS (*P. B.*).—Runts to be good should weigh 4½ lbs. per pair. Barbs are best with pearl eyes, but often have gravel eyes. White Barbs mostly have dark eyes. Fantails may have from twenty to forty feathers in the tail, but I think one with twenty feathers and good carriage is preferable to one of bad carriage, though it may have double that number of feathers.—*B. P. BRENT.*

TREATMENT OF YOUNG CANARIES (*Sick Bird*).—Your young Canaries "becoming puffy and dropping from the perch," seem to die from inflammation of the intestines. It may arise from bad food, or from sudden changes of temperature. Let them have the same soft food to eat as that with which they were fed by the old ones, be careful to avoid pungent rape or exciting hemp. Young birds are too often hung in the hot sun, and then suddenly removed to the cool shade, which acts injuriously on their susceptible organisation. Fresh air, wholesome food, exercise and the use of the bath, are the best promoters of robust health. See that the Canary seed is good and not damaged.—*B. P. BRENT.*

EPPING POULTRY SHOW (*W. Tippler*).—When we stated the truth that the Committee were advised in the management of a poultry show, that is an admissible excuse for their shortcomings in respect to catalogues, labels, &c. &c. The Committee will be more adroit next year. Our reporter totally differs with you as to the Rouen Ducks.

SPANISH FOWLS AT THE EPPIING SHOW.—Your reporter of the Epping Poultry Show says that age had laid a heavy hand on my Spanish fowls, that the cock was long past his best, and that the heavy corrugations of the face rendered him almost sightless. Permit me, as the owner of these birds, to say that they were all hatched last year, and that the cock can see perfectly on both sides.—*R. B. POSTANS.*

CHICKENS CRAMPED (*W. R.*).—The cold and rain suddenly coming after the high temperature of the air we have had is the probable cause. Crush the wheat and barley, and give them a mash of oatmeal and ale once daily. Lettuce leaves will also be beneficial.

RABBITS (*Rabbit*).—If you enclose seven postage stamps with your direction, and order "The Rabbit Book," you will have it sent to you free by post from our office. It contains full particulars on all the subjects you mention, with portraits of the different breeds, &c.

MARKET FOR HONEY (*S. Thorne*).—Write to Messrs. Fortnum & Mason, Piccadilly, and to Messrs. Neighbour & Sons, Regent Street, stating what you have to sell.

ROSE WATER (*A. R.*).—Three quarts of water to 4 lbs. of leaves. Let the leaves soak in the water for twenty-four hours before distilling.

POULTRY MARKET.—JULY 30.

The trade is fast disappearing, all London is getting out of town, and the demand lessens every day.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 74.9°; and its night temperature 50.6°. The greatest heat was 93°, on the 10th, 1842; and the lowest cold 33°, on the 11th, 1864. The greatest fall of rain was 1.14 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

BEDDING PLANTS.

**N**QUIRIES respecting the propagation and after-management of bedding plants have been made by "AN AMATEUR GARDENER," and "A YOUNG AMATEUR," and

the reply to them will doubtless be useful to others having an equally limited amount of accommodation for the protection of their stock in winter and spring. The one has a two-light frame, and the other has, in addition, a brick pit of four lights, and they wish to know what plants they can raise and winter for bedding-out. In neither case is there a greenhouse, and nothing is said as to the means for making up a hotbed and for protection from frost, but in offering the following remarks I shall presume that leaves and litter, as well as mats, can be obtained.

**PELARGONIUMS.**—Indispensable as the bedding kinds may be for the decoration of the flower garden in summer, it is to be regretted that they cannot with certainty be wintered in a frame or pit, for though rendered safe from frost by covering the lights and banking up the sides, damp and darkness, combined with a badly-ventilated atmosphere, are so fatal that a pit or frame is practically valueless for their preservation. Although, however, the frame or pit may be useless for preserving the plants, it is not so clear that neither will be available for the plants at some stage of their growth. That bedding Pelargoniums can be produced in quantity where there is nothing but a common frame and ordinary pit I hope to be able to show, and as a substitute for a greenhouse the windows of the dwelling must be called into requisition.

The way to proceed is to have boxes made of sound three-quarter-inch red deal, or of the best Baltic timber. A nine-inch board the width of the window will do for the bottom, and for the sides and ends one of these boards should be cut up the middle. The sides and ends are to be nailed on the bottom (not to its sides), with two-inch clip nails, and a plane run over the edges will take away the sharp cutting angles of the boxes. Two coats of green paint will then render their appearance passable. When the paint is dry, place at the bottom of the boxes an inch deep of the riddlings of a compost consisting of two-thirds sandy loam and one-third river sand, to serve as drainage, affording the water a free passage to the joints of the boxes, which, being put together in the rough, will allow of the water escaping. The boxes having been filled with compost to within half an inch of the top, are to have half an inch of sand placed over the surface of the soil, and are then ready for the cuttings. There may be some difficulty in procuring the loam, I may therefore state the practice of a man who was very clever at surmounting a difficulty:

he being recommended to put in his cuttings in nothing but virgin loam and pure sand, and having neither, took a barrowful of the soil of his garden, a rather strong but not a clayey loam, and placed it under cover, a barrowful of pieces of soft bricks pounded and made fine, and a half-barrowful of sand which had been washed down a hill by rain. The whole was mixed and sifted with a sieve having quarter-inch meshes, the rough portions were placed at the bottom of the boxes, and these were filled up with the sifted soil. The result was that scarcely a cutting failed to root and winter safely, though the means were limited to a spare room, and the kitchen during very severe weather.

The boxes having been prepared, the cuttings are to be made from the first to the fourth week in August. Shoots having three good joints and not very far apart are to be cut transversely below the lowest joint with a sharp knife, and the leaf there removed, and probably that at the joint next above it as well, but that will depend on the length of the cutting and closeness of the joints. The cuttings may be from 4 to 6 inches in length, and a joint and the growing point should be left after trimming, retaining a good joint below that for insertion in the soil to the depth of a couple of inches, or up to the lowest leaf. Insert the cuttings 1 inch from the sides of the box and 1½ inch apart every way, and up to the joint of the cutting whence the leaf was not removed. Give a good watering, and set the box in an open situation in the full sun, and if there is a place hotter and more exposed to the sun than another give that the preference. Do not give more water than is sufficient to keep the soil moist, and none if the weather be at all wet or showery. As to shade do not think of it, for the sun will assist in making the cuttings hard for the winter.

When the large leaves have become dried up and withered, pick them off, and towards the end of September remove the boxes to a sheltered wall or fence where the plants can receive the full benefit of the sun, and be protected by mats or other coverings from any frosts that may occur previous to November. So long as the cuttings do not flag they should not be watered, but if they do so, and the wood seems disposed to shrivel, give enough water to show itself through the openings of the joints of the boxes.

Early in November the boxes are to be placed in their winter quarters; any unoccupied light airy room having a southern aspect will answer, and so will the inside sill of a window, except in the case of severe weather, when they must be placed in a room from which frost is excluded—a kitchen, for instance, keeping them there as long as the severe frosts last, but giving the plants the benefit of a fine day by placing them near the light, and admitting a little air. Until April they merely require the lightest and most airy situation possible consistent with their safety from frost and the exclusion of currents of cold air. As to water, it is sufficient that the leaves do not flag, and if they turn yellow and otherwise show symptoms of decay, pick them off at once. If, however, the leaves flag and show other signs of a deficiency of moisture at the root, then it will be well to give during mild weather enough

water to keep the stems from shrivelling and the leaves from flagging.

In March, if the weather is mild, the plants will begin to grow, and should be watered more freely; and during sunny days and mild showery weather, it will be very beneficial to place the boxes outside under a wall for a few hours in the day, returning them to a place of safety at night. This mode of treatment is to be continued until the middle of April, when a bed should be made of dung and leaves to a height of from 2 to 2½ feet, and covered with 4 inches of turfy loam two-thirds, and leaf mould one-third, the frame having previously been placed on the bed. In a few days the leaves and dung will have heated sufficiently to warm the soil through. If the heat be more than the hand can bear, the plants must not be put in until it has declined to a gentle heat of 70° or 75°. Then the plants are to be taken out of the boxes, and planted in the bed, cutting all roots to within 1 inch, or 1½ inch from the place whence they take their rise. The plants may be put in 3 inches apart every way. A frame of two lights, 6 feet wide, 7 feet long, will hold upwards of six hundred plants. After planting they are to have a good watering, but not a soaking, and the lights should be put on, and kept close, and if shaded for a few hours during the hottest part of the day, the cuttings will quickly form roots, and commence growing. Their points, if not previously taken off, are to be removed at once, which will cause them to become stiff and branching. A sprinkling of water early in the afternoon will be of advantage, but heavy waterings are to be avoided. None should be given at the root until the soil evidently requires moisture; then afford enough to moisten the mass.

When the plants have made shoots an inch or two in length, gradually admit air; in fact, admit it plentifully, and by the middle of May if all has gone well, strong vigorous plants will be the result. The frame may now be removed and placed on a bed of leaves and litter, as in the former case, the bed being covered with soil as before. When the bed is no more than warm turn out in it any plants of the variegated kinds which there may be in boxes, treating them in precisely the same manner as the first, and with the mild bottom heat they will speedily emit roots plentifully, and grow rapidly. By the beginning of June they will be sufficiently advanced for hardening off, by admitting more air gradually until the lights can be entirely withdrawn. On the removal of the frame, sticks should be bent over the plants so that on frosty nights mats can be thrown over them, and in severe nights it will be necessary to cover the frame with mats to protect the plants from frost.

The frame, then, will be of no service whatever to the Geraniums until spring, and even then it may be used for the raising of half-hardy annuals, the plants being retained in the boxes up to the time of planting out, the points of the shoots being taken out in March. The supply of water should be increased as growth may render necessary; as a rule, no water should be supplied until the soil requires it. After March, however, keep the soil moist, but not saturated. After the middle of May the plants may be kept outside day and night in a warm situation, protection being at hand to cover them on frosty nights. The plants in this case may be planted out from the boxes towards the end of May, taking them up with all the root practicable, and a good watering being given they will soon become established. In this case the frame will be dispensed with so far as the Pelargoniums are concerned, and that is all the better, as it may then be used for other purposes. The plants, however, will not fill the beds so soon, whilst those transplanted from the boxes into good soil on a mild hotbed may be removed with balls of earth at their roots, and will make a good show by the beginning of July.

I have omitted to mention, that a box 3 feet 6 inches long, and 7½ inches wide, will hold five rows of cuttings, and twenty-eight in each row, or 140 cuttings in all. The boxes can be made of any length and width desired. The dimensions previously stated are the sizes used by myself; not that I winter my plants in windows, for I am favoured with glass, but I took the pattern from some boxes that were made and used in the manner already described, being in length the exact width of the windows. I manage to squeeze 150 cuttings into each box, and this year, owing to want of room, they were planted out direct from the boxes, and have done well.

I do not think it necessary to say anything as to putting in the cuttings in pots, for these take up much room, and the plants are no better, if so good, as those inserted in boxes.

The varieties which I would recommend are Stella, Tom

Thumb, Little David, and Crystal Palace Scarlet, of the scarlets; pink, Christine; white, Madame Vaucher; and Bijou, as a silver-edged Geranium. There is scarcely a dwelling in which a boxful of each of these, and in many cases twice that quantity, could not be wintered. I may add that any injury to the window-board may be prevented by placing the box on a piece of zinc.

The earlier the cuttings are put in after this appears the better. The wintering of old plants will be treated of in another article.—G. ABBEY.

## VISITS TO GARDENS PUBLIC AND PRIVATE.

MR. FRASER'S, LEA BRIDGE NURSERY.

THERE is unquestionably a vast deal of difference between the north and south of London. Go five miles away from the General Post-office on the south side, and you feel you are still in London; suburbs are there which contain a good deal of the "urbe," but very little of the "rus;" bricks and mortar predominate over trees and shrubs, and you involuntarily ask, "Where does London end?" But go the same distance on the north side, and you are among hedgerows and meadows, and quaint old country houses, unknown on the south side, and, despite railways, you feel that the people there enjoy a vast deal more quiet than they do elsewhere. So I felt, at least, as on a warm day in July I committed myself to the tender mercies of the Great Eastern, and finding myself safe at the Lea Bridge Station, walked along the road that leads to Epping Forest. There was plenty of life; there were pleasure parties making their way to that favourite resort; there were vans full of Sunday-school children from the crowded city, making their way to scenes of which they had been dreaming for the last six months, and which will afford them matter of talk for the next six; but with all this there was a quietness one in vain looks for at the same distance along any of the lines that go south out of London. It seemed the very place for a nursery; and I felt sure that the fame which Mr. Fraser's nursery has so long enjoyed would prove not to be undeserved. The soil was good, and the situation all that could be wished.

In their general features all large nurseries must be somewhat alike. Each proprietor has some speciality, for which he has made his name famous; but in their general features—their fruit and forest trees, their bedding and greenhouse plants, there is great similarity. Mr. Fraser has of late years been distinguished for his new Roses, Pelargoniums, Azaleas, and greenhouse plants; but of the last he has no longer the large stock of magnificent plants that he used to have. Finding it impossible to grow everything, and seeing that the sale of new plants, was more profitable than keeping up a large number of unwieldy specimens, he this spring disposed of them by auction, and has since turned his attention more to the production of larger numbers of smaller plants. July is not the month for greenhouses, and therefore my observations were confined to plants out of doors, notably to the Roses. These were still in fine bloom, and most of the varieties of the present and former years were to be seen amongst them. I noticed as very good *Joséphine Beauharnais*, of which I have already spoken; *Mademoiselle Marguerite Dombrain*, this had all been cut away, as the foreman considered it one of the very best of the year, and had therefore determined to propagate as much as possible of it; *Prince de Poireia*, a very bright-looking and excellent flower; *Alba Mutabilis*, pretty and distinct; *Alfred Colomb*, excellent; and *Jean Cherpin*, very good and rich flowers. Of those of the previous year there were fine examples of *Marie Boissée*, a Rose I had not seen before, light-coloured and good; *Semiramis*, another light-coloured Rose, very much like *Rosa Mundi*; *Duke of Wellington*, a beautifully rich-coloured flower, but somewhat uncertain, I fear; *Docteur Andry*, a beautifully-shaped and good Rose; *Marguerite de St. Amand*, a lovely Rose, and when well grown a most valuable addition to any collection; *Madame Elise Vilmorin*, somewhat rough, but a very showy Rose in a garden, though hardly fit for an exhibition stand; *Madame Charles Verdier*, a beautiful light-coloured Rose. I have not found it very vigorous with me, but it seemed to be so here. Of the older Roses there was a very large collection, and Mr. Fraser had that very day been performing the disagreeable but necessary process of consigning to the dunghheap a large number, which are now only cumberers of the ground, however much they may have been esteemed formerly. All the plants appeared in excellent condition, and free from that horrid black spot which has so

greatly injured my own plants, and which I have never seen so virulent as it has been this year.

I have rarely seen better beds of *Gladiolus* than Mr. Fraser has this year. They were in apparently the most healthy condition: and as the surface of the ground was neatly covered with cocoa-nut fibre it kept them cool, and at the same time gave a great appearance of neatness to the beds. It does seem very strange that so little encouragement is given to this fine autumnal flower about London. I was looking through the list of prizes offered by the Royal Horticultural Society at their Saturday shows, where they seem to be desirous of bringing together everything they can; and although *Asters*, *Dahlia*s, &c., were included, the *Gladiolus* is left out. It is a great matter of complaint that provincial towns should be so far beyond the metropolis in their appreciation of this noble flower, the varieties of which are each year increasing in beauty and in those properties which a florist delights in.

In common with most of our leading nurserymen Mr. Fraser has a large selection of *Zonale* and *Nosegay* *Pelargoniums*. In one large bed he has a large number of the newer sorts arranged for comparison. Amongst the most conspicuous were *Leonidas*, *Julius Cesar*, *Marie Rendatler*, *Diadem*, *Madame Werle*, *Emile Lican*, *Chieftain*, *Commissioner*, *The Clipper*, and *Excellent*. I hope to have an opportunity later in the season of entering on the merits of this class of flowers, now so popular, when I have had the opportunity of noting them in other places as well, and making comparisons with those in my own garden and Mr. Banks's. Their name is legion, and we must weed. Let me say here, however, that by far the best bedding *Geranium* of the scarlet class is one sent out some three years ago by Mr. Bull, of Chelsea, called *Editor*. I have used it this year as a back-row flower in a border, and in brilliancy and profusion of bloom it far exceeds *Attraction*, *Crystal Palace Scarlet*, &c. Its habit is sufficiently dwarf, and it has been greatly admired by all who have seen it. The leaf is plain, or with the very faintest trace of zone possible, and thus, as Mr. Robson will tell us, it is better for effect than if it were zoned.

There were some very beautiful things amongst the foreign introductions, especially amongst *Pentstemons* and *Delphiniums*. Amongst the former I was particularly pleased with *Maitre Guérin*, *Paul Racouehot*, *Lanrence*, *George Bruant*, *Richard Lenoir*, *Charles Klein*; and amongst the latter with *Triomphe de Pontoise* and *Henri Jacotot*. The main fault to be found with the *Pentstemon* as a garden flower is that the bees seem to revel in it from the abundance of pollen, and in coming out again dust all the centre of the flower, so as to make it look dirty.

*Lapageria rosea* is here in great beauty, and was, when I saw it, producing its seeds very freely. Mr. Fraser has for some years been able regularly to save a large quantity of seed. Each pod produces about fifty seeds, and when sown they come up as regularly all over the pan as if they had been cuttings inserted; and as the pods were hanging all over the roof, there must be thousands of seeds there now. I saw also large quantities of nice plants of *Clianthus Dampieri*. *Azalea*s and *Vines* looked remarkably well. The ground was very well kept—no easy matter in such a summer as this has been.

It would be tedious to enumerate all that I saw at this well-known nursery. Suffice it to say that it is well worth a visit by all who care to see a well-ordered nursery, and one where at all times novelties of some sort will be sure to be seen, and where they will always, I venture to say, receive the most courteous attention from Mr. Fraser.—D., Deal.

P.S.—Since the above was written I have received the *Crystal Palace* schedule for the autumn show, and am glad to find that the authorities, as usual, have been the first to anticipate the wishes of the floral public by greatly increasing their prizes for *Gladiolus*.—D.

*TULIPA SYLVESTRIS*.—"A SURGEON'S WIFE," quoting (page 64) Smith's account of *Tulipa sylvestris*, and adding from some private source of information its Yorkshire home "between Hexthorpe and Sprotborough boats," asks some Yorkshireman to enlighten her as to the meaning of the word. This I can easily do, as I live on the spot. The fact is, she has misread or misheard the word. There is no such word in the Yorkshire tongue, that I know of, as "boats," but in the meadows between Hexthorpe and Sprotborough boat there are many wild *Tulips*. The spot called Sprotborough boat, or boats, is where the old ferry was across the river Don, but now

no longer a ferry, but a handsome bridge, the munificent gift of Sir Joseph Copley to the neighbourhood.—A YORKSHIRE INCUMBENT, between Hexthorpe and Sprotborough boat.

### LORD CLYDE STRAWBERRY.

In the Number of July 24th, Mr. Gloede states that Lord Clyde Strawberry is "nothing else than the old Chinese, in France commonly called Ananas." Now, as I believe I know as much about Strawberries as Mr. Gloede, and that my opinion stands as high as his, I unhesitatingly say that he is wrong, and that Lord Clyde is a much superior Strawberry, and was one of a batch of seedlings raised from a cross between Sir Harry and Carolina Superba. I grew it for three years before sending it out, and I still grow it. Unfortunately runners from some barren plants were mixed with those from fruiting plants, and so, many barren plants are in existence; for at that time I was not a firm believer in the opinion that all such plants should be rooted out, but I am now fully persuaded that they should be, and every barren plant throughout my collection has been destroyed this summer.

I sent a strong plant or two to Rushiton, and asked the Rev. W. F. Radelyffe to grow it, and give me his opinion of Lord Clyde, and I was favoured with two letters; and although I have not his permission to publish them, I am sure he will only be too glad that I should have the opportunity of putting myself right before the public, and I therefore enclose the letters for your perusal, also one from Dr. Hogg. You will see that Mr. Radelyffe speaks very highly of Lord Clyde, and his opinion and the advice of friends led me to send it out.

M. Van Houtte, in my opinion, was wrong in stating that Mr. Radelyffe had described it as "the most valuable Strawberry ever known," as he never did so. That M. Van Houtte should regard Mr. Radelyffe's opinion with respect is simply to do that which all are in the habit of doing who know Mr. Radelyffe personally or by reputation; and who does not?

Every Strawberry-grower knows that some sorts will not do everywhere. Look at *La Constante*, for instance. I have repeatedly seen this struggling for an existence and making but very few runners. The other day I met with it at Gargrave in most luxuriant growth, and loaded with fruit. In the same garden Lord Clyde was promising well—a good-sized handsome fruit. There also was *Marguerite* in fine trim; whilst in another garden a few days previously I saw three rows of it, and two-thirds of the plants barren.—WILLIAM DEAN, Shipley, Yorkshire.

### SOWING POLYANTHUS SEEDS.

For the benefit of a correspondent in the *Journal* of the 24th ult., I may state that if *Primrose* or *Polyanthus* seed be sown immediately in a warm stove, and the seedlings cultivated till large enough to plant out, most of the plants will flower next April. It is curious that the *Polyanthus*, an indigenous British plant, will flourish in a close warm house for months, nay, I believe all the year round—I mean, of course, as to leaf growth. Mr. Beaton found that it was the same with *Cyclamens*, which are now cultivated thus on a large scale. Of course skill must be exercised in order to obtain a successful result.

Sow in pans, soaking the soil first with water; place them in a shaded part of the house, cover them with a pane of glass, and prick-off the seedlings as soon as possible into other pans; when the young plants have made four or five good leaves, harden-off at the back of a north wall for a week or ten days, and plant out in time to secure growth in the open air before winter.

I have sown *Primrose* seed in July, and flowered a few of the stronger plants in October of the same year. Of course this, like other go-ahead systems, requires attention to many little points of good gardening, which would take too much space to detail here.—R. T. C.

### ORCHARD-HOUSE FRUIT.

ORCHARD-HOUSE fruit is now grown so extensively, that means might easily be taken to decide a vexed question—namely, whether Peaches grown in orchard-houses are superior or inferior to those grown on walls. The Royal Horticultural Society might offer a small prize for the best three Noblesse

Peaches, to be judged by flavour only, size and colour being disregarded. The prize to be open only to fruit grown in one or other of the two following ways:—1st, In pots in a glass structure, without ever having been exposed to the direct rays of the sun in the open air. 2ndly, Grown on a wall without a glass screen at any period of their growth.—G. S.

### ON RAISING PEACHES, NECTARINES, AND OTHER FRUITS FROM SEED.

[The following paper was one of those presented by Mr. Rivers to the Botanical Congress, and will doubtless be read with much interest by horticulturists generally, and especially by those who are making experiments in the amelioration of races by seed.]

It is now some forty odd years since I entertained a peculiar theory that my old varieties of fruit had formed themselves into species, and would reproduce themselves from seed. I was well aware of the then existing practice of T. A. Knight in cross-breeding, and also the theory of Van Mons. I suppose I wished to be original, and to make myself famous, and so I commenced operations by taking the Golden Pippin, and, ignoring the works of the bees and the winds, in conveying foreign pollen to the blossoms of fruit trees, unless carefully protected by fine gauze or some other light material, I gathered some fine fruit from a Golden Pippin tree of great age, and sowed their pips. In the course of a few years the young trees raised from them bore fruit. Alas! for my theory: they gave me Apples, but not Golden Pippins—no, not one. Some, it is true, were Apples of a yellowish tinge, but very unlike in size, shape, and flavour, to what I hoped. Some pips of the Ribston Pippin, sown the same year as the above, in due time produced trees, and the trees fruit; but in this instance the children were still further removed from the likeness of the parent, for they were Apples of all shapes and sizes, and not one bearing any resemblance to our favourite Apple, the Ribston Pippin. In carrying out my idea, I soon after this sowed pips taken from the Autumn Bergamot Pear, the fruit gathered from a very old tree, its age estimated at 300 years; now, as this sort is supposed to have been in cultivation in England ever since the time of the Roman occupation, I looked forward with some hope as to what kind of Pears my seedlings would produce. I was to a certain extent gratified, for my seedling Autumn Bergamot Pears were all Bergamots—*i.e.*, they had the peculiar flattened shape in which we recognise that variety. One, in particular, was most remarkable: it was a monstrous Bergamot, with the true shape and russet coat of its parent; its flavour, however, was not up to the mark, and although gratified to find an adherence to race according with my theory, I did not gain that which I hoped for—a hardy, free-bearing, improved variety. I may, however, except one raised from the same source a few years afterwards. This at first was dry and poor in flavour, but has annually improved in quality, so that from its hardiness and fertility it may be considered worthy of cultivation. Although disappointed with my experiments with Apples, I was a little comforted by the adherence to race in my Bergamot Pears, and I continued my experiments by sowing Green Gage Plums, the opportunity happening in this wise:—Before our country was gridironed with railways, there used to be occasionally what is called a glut in the markets of perishable fruits, such as Plums, which could not be sent to long distances on account of their ripeness, and the supply being too large for the London consumption, many hundreds of bushels were often destroyed. Taking advantage of one of these gluts I once bought in Covent Garden a great number of bushels of Green Gage Plums, at 1s. 6d. per bushel; the stones of these were sown, and produced many thousands of trees. I watched these young trees for some years with much interest; the greater part of them had the habit of their parent, and were to all appearance Green Gage Plum trees; some of them were, however, remarkable for their small leaves and spines, being more like Sloes (*Prunus spinosa*) than Plums. It seemed to me as if the Green Gage had returned to its normal state, that of a small green wild Plum. In process of time a great number of these seedlings bore fruit; all that did so gave green fruit, but not one among them a superior sort worthy of a name. This adherence to race gave me much satisfaction; still I must acknowledge that since I sowed the large quantity of stones just mentioned, I have found a few only have produced a tree bearing purple Plums, thus showing that the ad-

herence to race was not to be depended upon. Still clinging to my original idea, that an improved variety of a favourite kind of fruit, with all its good qualities but with a thorough adaptation to our climate, might be raised, I took in hand another very old kind of Plum, which has been cultivated in the Touraine for many ages, and probably rivals the Green Gage as to the period of its production from seed. This is still well known as the *Précoce de Tours*. The trees of this variety, from the fruit of which I hoped to have raised an improved race, were very large, having been planted by my grandfather, and stood so isolated that I hoped to raise seedlings from them, unstained by any other variety. They caught my attention from the curious fact that they bore a fair crop only about once in five years, their blossoms being delicate and generally suffering much from our spring frosts. It is now many, many years since I selected some fruit from these trees, and sowed their stones. In the course of time the trees raised from them bore fruit, and, to my great delight, they were like their parent in colour and shape, varying only in size. One among them realised the idea I had so long entertained, that of reproducing the parent fruit with a constitution adapted to our climate. This was named the *Early Prolific Plum*, and is neither more nor less than the *Précoce de Tours*, vigorous in habit and abundantly prolific. I felt, and still feel, amply rewarded for my almost obstinate adherence to a somewhat speculative theory, and for many years of careful culture. I must not leave this remarkable variety of Plum without mentioning that I have lived to raise from my first seedlings three generations, none of them departing from the original parent in shape and colour, but varying much in quality. One among them, the exact form and size of its great-grand-parent, bids fair to be of much value; for, whereas the *Early Prolific*, and other seedlings from the same source, ripened in 1865 about July 28th, this, although the tree stood on the north side of a hedge, in a shady place, ripened its fruit on July 14th; so that by continuing to breed from one race, generation after generation, I have raised the earliest Plum known.

So attractive to me has this race of Plums been, owing to its singular and rigid adherence to race, that it seems now, in my old age, to have been the greater portion of a life's pleasant study, still incomplete; for young trees of the fourth and fifth generation of the original trees of *Précoce de Tours* exist here, and are likely, ere long, to bear fruit. At the earliest period of my essays in raising seedlings from old varieties of fruit, I sowed stones of the *Noblesse Peach*, and planted the young trees they produced against a wall; in the course of eight or ten years they all bore fruit; all were so like their parent as not to be distinguished from it.

Soon after the introduction of orchard-houses my attention was attracted by the facility with which young trees of Peaches and Nectarines could be made to bear fruit in pots. I at once determined to raise large numbers of trees from stones, and to carefully record the origin of each tree. My old instinct again came to the surface, and I fixed upon some of our most ancient varieties, intending to breed from generation to generation. Nearly, if not quite the first variety I took in hand was the *White Nectarine*, for I considered it as belonging to one of the oldest of all races of Nectarines, a *White Nectarine* being mentioned in the "*Paradisus Terrestris*" of Parkinson, upwards of two hundred years since; traditionally, it came from Asia, and probably from Northern Syria, the habitat of another kind of Nectarine equally distinct in character, the *Stanwick*. My first family of seedlings from the *White Nectarine* seemed, when the young trees blossomed, marvellously alike, and I began to look forward to another generation before I should find much change. I was now, however, agreeably disappointed, for among my little family of quasi-*White Nectarine* trees, I observed a large white Peach, which, although a Peach in appearance, had the racy brisk flavour of its parent. This remarkable production aroused my attention, and from the first fruit it produced, the stones were taken and sown; several of the trees raised from them bore fruit when four years old; the greater number of them proved to be *White Nectarines*, thus returning to the nature of their grand-parent the *White Nectarine*. Much, however, to my gratification, two of them produced Peaches; one about the size of the *Noblesse Peach*, and of the same colour, but ripening so early, that in 1864, when its first fruit was presented to me on July 14th, quite ripe, I could scarcely believe it to be true, as the *Red Nutmeg Peach* was at that time quite hard; in 1865, its fruit ripened July 18th, and I then felt satisfied it was the earliest large Peach known. The other Peach which made its appearance among

the third generation from the Nectarine, as above mentioned, proved to be a large pale-coloured variety, ripening in the middle of September.

Both these kinds of Peaches retain the flavour of the race, being remarkably piquant and agreeable when well ripened. From the experience thus gained, I feel convinced that to the White Nectarine we owe those pale-skinned Peaches, the Noblesse, the Malta, and the White Magdalene, all remarkable for their brisk flavour, and equally so for retaining in the trees the peculiar character of the White Nectarine, producing large pale flowers irregular in their shape.

My next essay, to "breed in and in," so as to establish a race of Peaches, was with that large handsome but, in England, worthless clingstone Peach, the Pavie de Pomponne. The first generation gave me one Peach, producing large flowers like its parent, but with a melting rich flesh perfectly its converse. This was named Princess of Wales. Another seedling of this generation proved to be a small-flowered sort, its fruit of medium size, skin pale yellow, and flesh so sweet (without the usual Bitter Almond flavour of most Peaches), as to be too luscious. Here was at once a wide departure from the type in all respects, except the size of the flowers in Princess of Wales. Not at all "put out" by the vagaries of the first generation, and still hoping to raise a Peach as large as the Pavie de Pomponne, with tender flesh, and, like that, a good keeper, so that in a well-managed fruit-room good Peaches might be preserved till November, I selected some fine fruit of the Princess of Wales, sowed the stones, and waited patiently. One of the first of this third generation produced, in September, 1865, such late Peaches as never before gladdened my eyes. One fruit measured 12 inches in circumference, its flesh melting, but firm and rich. This I felt to be a great triumph, and as he was then happily with us, I named it Lord Palmerston.

That well-known Nectarine, the Pitmaston Orange, next attracted my attention. Mr. Williams, of Pitmaston, always stated that this was raised from the Elruge Nectarine, a variety so diametrically opposite in flowers and fruit, that I felt a strong wish to try and reproduce its parent, by going through two or three generations of seedlings. The first generation consisted of some twelve or eighteen seedlings from the Pitmaston Nectarine, the parent tree growing in a pot in my orchard-house. I ought, perhaps, to have said that all my seedlings have been raised from fruit taken from my orchard-house trees, upwards of one hundred varieties growing in a house 100 feet long and 24 feet wide. All the trees of this generation, except one, gave orange Nectarines, like their parent; the trees also produced those large brilliant flowers peculiar to this sort. All, except one, I have said, and this to me was a remarkable exception, it was a large crimson Peach, the tree producing small deep red flowers instead of those large brilliant ones borne by its brethren. I felt doubts, and concluded that a Peach stone must have been by accident planted with the Nectarine stones. To try and solve my doubts, I at once determined to take particular notice of this Peach, to sow its stones, and to watch carefully what they would bring. Out of about twenty trees raised from them, the greater part bore Peaches like their parent, the trees also producing small flowers; but, to my great satisfaction, two of them bore orange Nectarines like their grand-parent, and the trees have the same large flowers; but the most remarkable fact in this experiment was, that two trees bore white-fleshed Nectarines, a little red at the stone, like the Elruge Nectarine, their great grand-parent, and the trees, like that variety, gave small flowers. Now, here was a strange and most interesting event in pomology. A white-fleshed Nectarine, the Elruge, with Mr. Williams, had produced a seedling with orange-coloured flesh (the Pitmaston), that had in its turn produced here a large white-fleshed Peach, and stones from that Peach have produced trees with the characters of four generations—viz., the Elruge Nectarine, the Pitmaston Orange Nectarine, the Peach (a child of the latter), and again the Pitmaston Orange Nectarine.

The Psalmist might well exclaim, "How wonderful are Thy works!" The horticulturist who thinks and works—they are too often far apart, that thinking and working—must feel those few words always uppermost, always rising. I must not leave that fertile source of interest, the Pitmaston Orange Nectarine, without adverting to one more curious fact. I have said that the greater portion of my first generation of seedlings from it were like the parent; there was one, however, which ripened ten days later, and had transparent flesh, so that it was named the Pine Apple Nectarine. I was interested in this sort, feeling that it was inclined to leave the characters of the type. I, there-

fore, raised a number of seedlings from it; they are young, being only four years old. Yet, one among them bore some fruit last year (1865), of a most remarkable character—a Peach of the largest size, with its skin green and beautifully marbled with red; its flesh of a pale lemon colour, melting, and much like a Nectarine in flavour. This peculiar Peach ripened September 30th, 1865, and was at once dedicated to Lady Palmerston.

There is a very old kind of Nectarine, known to pomologists as Fairchild's Early, a small yellow-fleshed sort, not larger than an Orleans Plum. Now, although this sort has been in cultivation for 150 years, yet no gardener seems ever to have thought of improving it by raising seedlings from it. As it is the earliest of all Nectarines, and as a good, very early Nectarine is still lacking, I turned to it with much interest, and hoped to improve it in size and earliness, so as to create a new variety worthy of cultivation. My first generation consisted of some ten or twelve young trees; they all bore fruit in due course; and were all like the parent in leaves, flowers, and fruit. The latter varied slightly in size, but on the whole they were neither more nor less than reproductions of the parent. I confess to some little disappointment, but, encouraged by the facility of inducing young trees to come into bearing in a comparatively short period, by cultivating them in pots in my orchard-house, I selected some fruit from the seedling trees, sowed their stones, and again looked forward to the result. In 1865 I was, as far as regards curiosity, greatly rewarded, for no two trees of this second generation produced fruit exactly alike. Some gave orange-coloured Peaches, one or two remarkably rich in flavour; some orange Nectarines, as large as the Pitmaston, but quite different in flavour; and, most strange of all, some gave Peaches of medium size, with rosy cheeks and flesh white and melting, like that of the Noblesse Peach. I failed in my object in obtaining a very early kind of Nectarine, but at once some stones were selected, and trees of the third generation of Fairchild's Early Nectarine are now in full growth. One very remarkable fact attended this experiment: the trees, when in blossom in 1865, were all like their grand-parent, so that I was quite unprepared for the curious transformations I have above described. The following singular changes have taken place here. The Roman Nectarine, a variety which has been under cultivation in England for 200 years, has produced from seed a nice bright red melting Peach. George the Fourth Peach, an American sort, in the first generation gave a late green Nectarine. It is well known that American Peaches in their own country, seldom or never produce Nectarines; it is, doubtless, owing to the trees being confined in a house, and standing very near together, that such remarkable changes have taken place here.

Among other curious gains that have occurred—too many to mention in detail—I may mention that a stone of Hunt's Tawny Nectarine has produced an early Peach, full-sized, and of the most delicious flavour, but without any yellow tinge in its flesh. This has the true Nectarine flavour, which I may add is very common to Peaches raised from Nectarines. The Royal George and Shanghai Peaches have produced melting Peaches, with deep yellow flesh. The Early York, from which a great number of seedling trees were raised, reproduced itself with but little variation, with one exception, which is a tree with round glands, consequently not liable to mildew. Its fruit is of the most exquisite flavour, and as early as its parent. The Hardwicke Nectarine, which has large flowers, has produced from its seed a Peach of the most decided Nectarine flavour; moreover, the tree gives small flowers.

I must, however, desist from giving a further record of other strange transformations; they have been too numerous for a paper on the subject, occurring, as they have done, among upwards of 250 seedling Peaches and Nectarines. I feel, however, constrained to mention one more curious fact. I have had some fine bearing trees of seedling Stanwick Nectarines, differing but slightly from their parent, for this sort adheres rigidly to its race for two or three generations; they were growing in a house in which were some trees of the Elruge Nectarine. Some stones of the latter were sown, and, as nearly as possible, the sort was reproduced, but they were Elruge Nectarines with the Stanwick flavour. This is not a solitary instance of a new kind of fruit imparting some of its qualities to fruits raised from seed, without artificial impregnation. The bees, always very busy in orchard-houses, fertilise numerous flowers; hence the great variety in Peaches and Nectarines raised from the stones of trees growing in them. I must not omit to mention one more curious fact. The Balgovan Nec-

tarine, a sort highly esteemed, has produced from seed a Peach, rather small, but of the most delicious Nectarine-like flavour. Apricots raised from the stones of trees grown in orchard-houses have not given, and cannot be expected to give, the immense variety that Peaches and Nectarines produce; still, out of some scores of seedlings no two can be found exactly alike. The only beneficial variation that can be hoped for is in the time of ripening, so as to have varieties earlier and later than we have at present; for no Apricot can be of much higher excellence than the variety known as the Peach Apricot.

Some progress has, however, been made; a seedling tree from the Red Masculine, one of the oldest and earliest varieties known, has given fruit larger and equally early, and a seedling tree from that curious, delicate-growing small Apricot, the Musch Musch, has given fruit much larger than its parent, and so full of delicious fragrant juice as to be, if possible, more grateful than the Peach Apricot. The Saint Ambroise, a variety rather early, has produced a seedling, the fruit on which ripened fully a month later than any other kind; and, to conclude, the Large Red or Gros Rouge has given a seedling tree, the fruit of which ripened a full month before that produced by the parent tree. There is, therefore, some hope that in time a new race of Apricots may be produced, differing in quality and season from those at present under cultivation.

It will, I think, be seen by those who venture to read this paper, that my original and rather eccentric idea—that old varieties of fruits would reproduce themselves in an improved form if successive generations were raised from seed—has, to a great extent, been realised. My prevailing feeling is that of surprise that European, and more particularly English cultivators, have suffered many ages to pass without carrying out that which I have attempted; the idea seems to me so simple, and of such great interest. If all that I have done had been attempted a century ago, what progress would have been made in fruit culture! I ought, perhaps, to state, that in this paper, fearful of fatiguing the reader, I have given but a mere abstract of my experiments. A time may come, if life is spared, when I shall give more fully all that I have learned. I have a vague suspicion that our tender kinds of fruit, that blossom very early in spring, may be improved in hardiness by close attention to the form of the petals. Early in May of this year (1866) we had here 5° of frost; the weather was dry, and no injury seemed to have been done to the blossoms of some Cherry trees which I had under close observation, the germs were green, and the petals uninjured. I observed, however, that the extreme points of the pistils were killed from the petals being thrown back, fully expanded, so as to leave them exposed. The germs swelled, and I quite expected the fruit would come to perfection. Instead of this, however, all that were marked dropped off shortly afterwards. I confess to being disappointed in this, for I had calculated that complete fertilisation had taken place, and that no injury from a slight frost could then injure the fruit.

While making observations on these blossoms my attention was drawn to others, the petals of which were incurved, so as to protect the pistils; this slight protection preserved them from injury, and the fruit set healthily, and remained on the trees, swelling gradually, and bidding fair to ripen properly. On observing this I could not help theorising, and asking myself the question, Would it not be possible, by careful attention for a series of years, to originate varieties of fruits from seed, giving blossoms with large incurved petals, so as fully to protect the parts of fructification? The idea may be in the clouds, but when one reflects on the licence which Nature gives us in allowing us to assist her by our art, we ought not to think it impossible.

I have devoted many, many years to the raising of seedling fruits—have, as a matter of course, met with many disappointments, but also much gratification; there is, as I have found, much pleasure in watching, from year to year, the character of a seedling; it is true that, after much promise, there is often a failure, but with me it has always acted as an incitement to try again. At this moment I have hundreds of seedlings of all kinds of fruits; some from fertilised flowers, showing interesting features of cross-breeding; and many others raised from old and esteemed varieties, with my old hope partly fulfilled—that new varieties, with all the excellent qualities of the old, may and will be originated and, as it were acclimatised, like the Early Prolific Plum and its descendants, which are neither more nor less than hardy varieties of the *Précoce de Tours*. It is, I fear, too true, that neither a Peach, Nectarine, nor Apricot will ever be originated with blossoms fully capable

of resisting our spring frosts, for even the common Sloe of our hedges succumbs to them; but it is quite probable that Peach trees, bearing fruit equal in quality to our old favourite, the Grosse Mignonne Peach, will be produced of a more hardy nature than the old sort; in fact, I have more than one proof of this here; to obtain this result, only the most robust-growing seedlings from old varieties should be retained. Again, much improvement will yet take place in raising early and late varieties. I have reason to believe, from what I see daily, that large and rich-flavoured Cherries may be on our tables from early in June till the end of August; Plums from July till far in November; and Peaches, Nectarines, and Apricots in orchard-houses, from early in July till late in autumn. I may be accused of enthusiasm, but I look to the future for new races of fruits, with qualities far superior to the old, and the trees of so hardy a nature as to resist some of the unfavourable tendencies of our climate. I have formed this opinion on the solid basis of close observation during a lifetime devoted to the culture of fruit trees in all stages of their growth.

GOOSEBERRY SHOW.

HELD AT THE ANGEL INN, NORTHWICH, CHESHIRE, JULY 28TH.

The following are the varieties of Gooseberries exhibited, their weights, and the names of the exhibitors:—

			dwt.	grs
Faithful Jameson	Red Seedling		17	18
George Plant	Yellow Seedling		13	17
Joseph Jones	Green Seedling		16	7
Thomas Pilkington	White Seedling		19	9
Thomas Laneley	Twin's Stockwell		36	0
Joseph Jones	Premier Prize	London	26	4
T. Laneley	Red	Stewards' Prize	Beauty	25 23
J. Wynne	Yellow	ditto	Cramp	21 10
T. Pilkington	Green	ditto	Green London	22 10
S. Shone	White	ditto	Antagonist	19 2
F. Jameson	Red	ditto	Clayton	19 16
Thomas Foster	Yellow	ditto	Oldham	19 6
T. Dobell, jun.	Green	ditto	Queen Victoria	16 12
G. Plant	White	ditto	King of Trumps	18 1
T. Laneley	Red		London	23 4
J. Jones	Red		Slaughterman	21 10
T. Laneley	Red		Eskeudr Bey	19 16
S. Shone	Red		Lord Liverpool	19 16
S. Shone	Red		Dan's Mistake	19 15
T. Pilkington	Red		Speedwell	19 14
J. Wynne	Red		Clayton	19 12
F. Jameson	Red		Beauty	19 6
T. Laneley	Yellow		Cramp	22 6
T. Pilkington	Yellow		Wasp	20 8
J. Wynne	Yellow		Leveller	20 12
F. Jameson	Yellow		Drill	20 3
F. Jameson	Yellow		Tinker	20 1
J. Jones	Yellow		Candidate	19 8
T. Pilkington	Yellow		Criterion	19 4
T. Laneley	Yellow		Unknown	18 12
J. Wynne	Green		Stockwell	23 2
T. Laneley	Green		Shiner	20 9
F. Jameson	Green		Matchless	20 9
T. Laneley	Green		Thumper	19 10
J. Jones	Green		Plunder	18 20
T. Pilkington	Green		Telegraph	18 12
T. Laneley	Green		Thunder	18 2
T. Pilkington	Green		Greenock	18 1
J. Wynne	White		Elizabeth	22 5
J. Wynne	White		Antagonist	22 2
T. Laneley	White		Hero of the Nile	19 18
T. Pilkington	White		Mitre	19 12
T. Pilkington	White		Seedling	19 9
J. Wynne	White		Snowdrop	19 5
T. Laneley	White		Freedom	19 2
J. Wynne	White		Careless	19 0

STRAWBERRY SPORT.—It may be an interesting addition to the fact communicated by Dr. H. Thomas, of Chester (page 82), to state that in June last I gathered from the open ground a ripe Eleanor Strawberry of perfect form, from the side of which a minute but perfect plant had grown, apparently emitted from the skin of the berry. I deposited this curiosity on the dining table, intending to examine it more closely, and then to plant the whole, and watch the ultimate development of my little founding. But alas! our servant, on serving breakfast, inad-

vertently threw it on the floor, where it was crushed, and my hopes vanished.—FERDINAND GLOMBE, *Les Sablons, Seine et Marne*.

### ORCHARD-HOUSE TREES.

SOME years ago the leaves in my orchard-house rotted at their tips, just as those of "INQUIRER" (page 65). Like him, I showed them to the best living authorities, but could obtain no information. This compelled me to observe and experiment for myself, and the conclusion I came to was that after the morning syringing a drop remained on the tips of those leaves which hung down; that this drop killed and rotted the tip; and that when the tip died, the remainder of the leaf was sure to die back. Having arrived at this conclusion, I left off morning syringing, and substituted for it a good damping of the floor and borders of the house, repeating the same at midday during very hot weather. Since then the foliage has been all that can be desired, and there is even less red spider than before. If any one should object that all orchard-house authorities are unanimous as to the necessity of early morning syringing (provided air be given at the same time), and that no one has ever suffered from it except "INQUIRER" and myself, I frankly own that I cannot answer the objection, but simply record my own experience.—G. S.

### WOBURN COTTAGE GARDEN SOCIETY'S SHOW, AND COTTAGE GARDEN SOCIETIES IN GENERAL.

IN these times the gardening and the general press show no want of attention to exhibitions, whether international, metropolitan, or provincial, that have for their main objects the advancement of horticulture, and the gratifying, instructing, and elevating the minds of the visitors. Notwithstanding the efforts which have been made through the pages of this Journal, and the shows for working men held in the most densely inhabited parts of the metropolis, there has not, however, as yet been, even among our philanthropists, a due recognition of the love of gardening, the love of flowers for their own sake, the love of the beautiful in all its forms, as among the quietest, most unobtrusive, and yet most successful means of refining the manners, improving the morals, and enlightening the intellects of the labouring classes.

I wish every success to the village lecture and the powerful arguments of the orator against idleness, filth, and immorality; but I have even stronger faith in the power of the silent undermining of prejudices by the every-moment sermon preached by a beautiful well-tended plant in a window—in the influence exerted upon heart and mind, when the idea gains firm hold that a flower-border near the door is better in every way than a nauseous dunghap or an ugly cesspool, both invaluable when kept in their proper place—at the greatest possible distance from the living-rooms, but when near at hand becoming the most fertile sources of uncleanness and disease. Only let such simple facts and elements of improvement be duly appreciated, and then our real exhibitions of cottage-garden produce when attempted will not be on such a small scale as they generally are—held in some retired place, and with the humblest attendant circumstances, prompting thus to little curiosity, and, from the small number of the visitors, exerting but little influence; and then, too, as in the case of some of our provincial societies, when the encouragement of cottage gardening forms a prominent part of the prospectus, we should not find the good productions of the cottager huddled into a corner, or placed in some little room by themselves, where very probably they are unnoticed by the great portion of the visitors. It should never be forgotten that a man's self-respect, without which there can be no true manliness of character, is greatly promoted by the consciousness that he is respected, and his doings noticed and approved of by others, and especially if those others are in a higher social position.

I had the pleasure of spending the greater part of the 25th of July at the Woburn cottage-garden *fête*, the tents being pitched in a large meadow close to Woburn, and the above forming either the second or third return of the annual treat. After making due allowance for the importance of having the Duke of Bedford as Patron; Lord Charles James Fox Russell as President; seven clergymen and three esquires as Vice-Presidents; Rev. J. F. Cumberlegg as Chairman of the following Committee—Messrs. Kinns, McKay, Wilson, Lewin, Ward,

Sprague, Sanders, Gilby, Manning, Woodcraft, Clarke, and Chapman—two the well-known managers of Woburn and Tinchfield Gardens, and the rest chiefly heads of departments at Woburn, and merchants and tradesmen in the town and neighbourhood, all constituting a rare combination of patronage with working energy;—but after making allowance for all this, it seemed to me that the great success of the *fête* chiefly depended on the following circumstances and arrangements:—

First, That though there was a separate class for amateurs and gentlemen's gardeners, and though many fine things were thus shown for competition, and chiefly not for competition, greatly enhancing by their beauty and variety the interest of the Show as a whole, you were never allowed to lose sight of the fact that the encouragement of superior cottage gardening was the main object contemplated in the meantime, whatever the Society may aspire to in the future. Right or wrong, the fact remains, that many who will not themselves exhibit, and who will not allow their gardeners to exhibit, nor give the smallest encouragement in this direction, will yet heartily co-operate in stirring up competition and emulation among the holders of cottage gardens.

A second element of success may be found in the large area from which the Committee of Management attracted the materials for competition. As already hinted at, I have no great faith in the continuance of good results when such a Show is confined to a single parish or a limited district, for in this case something like heart-burning and narrow-minded envy are apt to steal in and take the place of a noble generous rivalry. That man is no stander-still, but is progressing in that which is good and true, who can thoroughly rejoice that others can do better than he. A wide area does much to shut out a cankering envious spirit. I can form little idea of the space thus influenced by the Society, but along with Woburn nearly thirty parishes were represented on the exhibition tables on the 25th ult. Judging from the number of clergymen who are Vice-Presidents, &c., I should imagine that almost every clergyman in these parishes would be a supporter of the Society. A goodly number of these gentlemen at the *fête* did give a tone and character to the assemblage. I am not aware of any reason why there should not be more parishes represented, if the seventh rule of the Society is complied with—namely, "Every parish in the Society shall subscribe not less than £1 before any of the cottagers in that parish shall be allowed to compete." To encourage such subscriptions, it is stated in the eighth rule, that a free ticket will be given for every 2s. 6d. subscribed.

As an evidence on the one hand of how well the Exhibition was managed, and on the other of the anxiety to have the different parishes represented on the winning cards, only one complaint was heard of, and that from those whom all would have been anxious to please—viz., That in the hurry to finish arrangements it had been forgotten to write on the winning cards the parishes of the successful competitors. This was all down in the Secretary's book, and would, no doubt, appear in the certified list, but then it did not appear to the mingled throng of nobility, clergy, gentry, and peasantry who crowded the tents.

A third cause of success is to be found in the large-hearted liberal resolves of the Managing Committee, that this little garden Society, besides affording an unusual pleasure to working men, should offer attractions to the higher classes to join them. For this purpose a cricket match was arranged between gentlemen of the north and south of the county, to be played on the cricket ground in the park. Different games and races, with prizes, were appointed for the evening, and two bands were engaged—viz., a Militia band in the grounds of the Abbey in the forenoon, and the band of the Coldstream Guards, under the conductorship of Mr. F. Godfrey, in the Exhibition grounds in the afternoon.

Lastly, Perhaps one of the chief elements of success was the kind permission of the Duke of Bedford, that the cards which gave admission to visitors to the Exhibition ground should on that day be an *open sesame* to the splendid Park, the rides, and diversified scenery of the picturesque Evergreens, and the charming pleasure grounds, the beautiful flower-beds, the lovely conservatories, and the classic sculpture-gallery close to the Abbey.

Through the kindness of Mr. McKay I had a peep of all this, so interesting, in the morning, and greatly delighted I was; but this delight of the morning seemed to wane and to lesser amid the very same scenes in the afternoon, until it began to rest upon the memory, like an indistinct vision of

the lovely beauty which must have existed in Eden when there were no Adam and no Eve to appreciate that beauty.

Well might poets sing of "the flowers, the beautiful flowers," flowers, the stars of earth, even as the stars above us are flowers of the sky; but flowers are never so lovely as when associated with the sweet flower-stars of humanity, whose mission it has been to shine rays of comfort and of joy into many a heart and many a home. My memories of Woburn are, and must be, varied; but not the least pleasant will be associated with the buoyant life and animation of that beautiful afternoon, when the groups of flowers seemed all the more beautiful when blended and contrasted with groups of admiring ladies and gentlemen; when shrubs and evergreens seemed of a richer hue, as they sent back the rich colours of the varied dresses of the ladies; when the closely-shaven turf seemed instinct with life, as it rebounded to the elastic step of joyous youth; when the calm, unruffled lake became a polished mirror reflecting the happy groups scattered along its banks. Ah! there is a happiness in having the power and the will to help to make others happy.

With such visions imprinted on my eyes, and the grand music of the Guards ringing in my ears, I left the grounds of the Exhibition, as trains, like "time and tide," will wait for no one. I have since learned that besides those who were content with the fine park, &c., 2600 went through the gates of the grounds and conservatories, and upwards of 4000 attended the Show, and no damage or anything done that could form a cause of grievance or complaint. In walking round I heard several gentlemen comparing such good behaviour with the sad contrasts that were exhibited in London on the previous days. Among crowds there will always be a few of the fast; but as a rule the working classes are proud to be trusted, and their honour appealed to, will not abuse such confidence. In the plant-houses and grounds a few men were stationed, as a matter of prudence, but there was no seen or felt superintendence. To the visitors on that day the enjoyment of these beautiful gardens was entirely unrestricted, and the privilege was received as a boon, and acknowledged as such by happy faces and quiet orderly demeanour.

Of the particulars of this Show I will not speak, for I scarcely took a single note, and could not get near enough to read the names and the addresses of the successful competitors, and it would be invidious to mention only a few. I must be content with stating that there were between 800 and 900 entries, and some of these, as in the case of collections and baskets, contained a number of separate articles; that the hardy fruit and vegetables were on the whole good, and, as I understand, an advance on those of last year; but, on the whole, the Woburn exhibitors will have to make some progress in vegetables before they rival those that used to be shown at Northampton, Towcester, and Daventry. In one box were some very fine Grapes, and there were good Grapes and Melons in other classes. Our cottage friends must excuse me for saying that their nosegays and flowers would be all the better if more taste and care were exercised in the arrangement. In other classes there were some nice arrangements of cut flowers, in which most of the best of Beaton's Geraniums were shown, also the same varieties grown in pots, and of them all I should be inclined to select Donald Beaton as the best in its class. There were also some pretty designs worked out with flowers, and there was a large design in fruit, 8 or more feet in length, by about 4 feet in breadth, representing the arms and motto of the Bedford family, very nicely done with black, red, and white Currants. Considering the time that such a work must have taken in fixing the berries, it is a matter of regret that the fruit picture should be of such a short existence. Among the plants brought by amateurs and gentlemen's gardeners, the most conspicuous were Fuchsias, Caladiums, and Ferns. Of the last two there were good collections. In one place the tables were not over-full, as some nurserymen who had promised their aid were unable to send Roses and other subjects, owing to the hot dry weather. Mr. Woods, of the Nurseries, Hockliffe, had a very nice general collection of plants in a young state, and they seemed to attract much attention. Among these were several plants of a seedling Petunia, which, if it keep true, will be valuable for pot culture and flower garden decoration. On seeing it at a distance, I took it for a nice striped Phlox. The flowers are striped with about equal bands of crimson and white. The individual flower when expanded is larger than a shilling, and less than a florin, and the leaves are quite as small as the old Petunia phoenicea. Its compact growth, and the small size of the pretty flowers and foliage, if they

continue so, will be great recommendations for out-door culture.

Instead of dwelling on such generalities, it may be more important to notice a few matters worthy to be considered, adopted, or improved upon by other cottage garden societies.

1. Even at the gates of the pleasure grounds there were tables where necessary refreshments could be obtained, and in the Exhibition grounds were spacious tents, well filled in the afternoon by those who loved the "cheering cup;" but no intoxicating liquors were permitted. I understood that all the Committee of Management had to do with the purveyor was that the supplies should be good, and charged for at a uniform, merely remunerating, price.

2. The classes of competitors were clearly defined, and any differences in this respect were settled by the decision of the Committee. Thus, Class A was reserved entirely for common labourers, whose articles were marked with yellow papers; Class B was confined to mechanics, jobbing gardeners, and men employed in noblemen's and gentlemen's gardens, who were furnished with blue papers; and Class C was confined entirely to amateurs and gentlemen's gardeners, and these were furnished with white papers. These papers, a specimen of which, taken from a cheque-book, is annexed, the counterfoil remaining in the hands of the Secretary, contain the No. of the exhibitor, the class in which he exhibits, the No. which represents the article exhibited, and the signature of the exhibitor, to the effect that the article was grown by himself, according to Rule 2, which also states that an exhibitor can only take one prize in a class. One of these papers so signed is placed on every article exhibited. I will refer to this again presently.

EXHIBITOR'S NUMBER. (1)	EXHIBITOR'S (1) NUMBER.	1866.—CLASS A.
Woburn, 1866.		WOBURN COTTAGE GARDEN SOCIETY.
No.		EXHIBITOR'S CERTIFICATE.
Kind,		No. 10.
Name,		I hereby certify that the exhibited by me are my own property, and were grown by me in my own Garden, according to Rule 2.
Residence,		Signed, JOE SMITH.

3. The prizes offered were numerous—an excellent plan for securing a great number of competitors. I have found great difficulty at times in judging, when out of some twenty articles, and with little difference between them in point of merit, only two prizes were offered; and if the Judges could scarcely satisfy themselves, we may be sure that many exhibitors would be disheartened, especially when no extra prizes were given. "Extras" were given pretty freely at Woburn, but the number of prizes rendered them less necessary, except in particular cases. Thus we find that in Class A, for Scarlet Runners, dishes of fifty, eight prizes were offered, ranging from 5s. to 1s., for Broad Beans there were eight, for Cabbages the same, for Long Red Carrots six prizes, and for Short Red Carrots six, a good distinction; for Potato Onions there were five prizes, autumn-sown three, and spring-sown eight prizes, ranging from 6s. to 2s., and the same principle was maintained throughout with Peas, Potatoes, and everything else. For a basket of vegetables of not less than six sorts, ten prizes were offered, ranging from 15s. to 2s. In the other Classes, B and C, the same principle was maintained, but fewer prizes were offered.

4. Prizes are promptly paid at six o'clock in the evening of exhibition, according to the sixth rule. This is a matter of great importance, especially to working men who come from a distance. It saves them time and labour, and is well worthy the attention of many societies who aim at similar objects.

5. Amid so many hundred entries this prompt payment, could not be effected but for systematic arrangements, and the admirable mode by which all the results can be easily seen in the books kept by Mr. Gilby, of Woburn. Thus, the attested paper above referred to must be obtained from Mr. Gilby at least two days before the exhibition, and all articles must be on the ground by nine o'clock on the morning of exhibition. These papers, fixed to the articles, enable the Committee to arrange all according to class, the colour showing at once where they should go, and thus in common circumstances the subjects would be fit for judging. To meet prejudices, however, each paper is put in an envelope, gummed up, and merely marked outside with the letter of the class, &c., and there is no

occasion to open any except those to which prizes are awarded. Meanwhile, I presume, Mr. Gilby has his book made up from the counterfoil, and finishes it as the list of prizes is given in, when all appears at a glance. I wish I had the room to show all the columns, but the following will give a clear idea of the plan:—

Class & Exhibitor's number.	Name.	Parish.	Beans.	Peas.	Cabbage.	Carrots.	Celery.	Lettuces.	Articles shown.	Amount of prizes taken.	Total.	By whom received.
1	J. Smith	Woburn.	3	1	3	4	5	6	11	2s. 6d., 4s., 8s., 8s.	17s. 6d.	Self.
2	A. Clarke	Aspley.	2	2	2	3	4	5	4	4s., 2s. 6d.	6s. 6d.	Wife.

In this way the double page of great width is divided into columns, the first showing the class and the exhibitor's number; the second, the name of the exhibitor; the third, the parish in which he lives; then follow fifty-three columns, numbered accordingly, and each number appropriated to a distinct class of vegetables, fruit, and flowers—1, for Beans; 2, for Peas, &c., as shown as a sample in the first six columns. By running the eye along the line opposite each exhibitor's name, it is at once seen what entries he has made, and under what number he shows. Thus, if I had Mr. Gilby's book, I should see that Job Smith enters for three kinds of Beans, two of Carrots, two of Potatoes, one basket of vegetables, one of Apples, four of Raspberries, two of Heartsease, and one of Geraniums, making sixteen entries in all; but as sometimes the exhibitor changes his mind, the next column tells how many articles he actually exhibits—viz., fourteen. Then the next column shows the amount of the prizes awarded, the next the total amount, and the last the person to whom the money has been paid. From the six columns of the fifty-three, it will be seen that Alfred Clarke has two entries for Cabbage, and from the full list it would be apparent he had two entries for Currants, which come under column 24. My apology for saying so much on this matter is, that I have no recollection of meeting with a plan more simple and effective.

Lastly. A prominent feature of the Society has been the awarding of prizes for the best-kept and best-cropped allotments. Two things here are well worthy of imitation. The first is, so far as I understood, that the competition as to allotments is at present confined to two distinct districts; and as these districts are differently situated as respects soil, situation, convenience in obtaining manure, &c., they do not compete with each other, but each district of allotments has its own competition, and thus two series of prizes are awarded instead of one. The second is, that the prizes are not awarded by one visit of the adjudicators, there must be at least three visits to the allotments, and at somewhat long intervals. One gentleman, greatly interested in this matter, told me that the Judges would have made great mistakes if they had given the prizes as the result of one or two visits. The great improvement effected was chiefly owing to the conviction gaining ground that the post of honour could only be obtained by continuous exertion, and not by a mere spurt now and then. I have often noticed that in spring, when all is fresh and gay, the most lethargic will be influenced by the season, will freshen their gardens, trim their plants, and make the walk to the cottage door and all about it neat and trim; but the same garden in the autumn and the beginning of winter will look often the handiwork of the sluggard, with decaying Pea-haulm and rotten Cabbage leaves polluting the air, and the paths next to impassable with weeds. Continuous neatness and economising of materials are therefore desirable.

Well might poets sing of the—

"Cottage homes of England,  
How beautiful they stand."

And well might the painter delight in transferring to his canvases their pointed gables, their thatched, and Moss, or Honesleek-covered roofs, partly concealed by Eglantine and Honeysuckle, so that you might well imagine them to be the abodes of innocence, and happiness, and peace; but how often would a nearer view tell you that there was little of neatness and industry without, and still less of comfort within, partly owing to the want of means, and more generally owing to the want of the desire to make the most of these means. All success, then, to every effort, be it directed even by a cottage garden society, that aims at promoting industry and neatness outside the cottage,

as that will be surely followed by an increase of cleanliness, of thrift, of comfort, and happiness inside. The state of the garden, the flower-plot, or even a single plant in a pot in a window, forms no bad index to the mere passer-by of the general character of the occupiers. A hint to the wise is sufficient. We are none the worse for knowing that we are constantly, though insensibly, furnishing the materials for others to take notes of our conduct and our character.—R. FISH.

### THE REV. CHARLES MARSDEN'S GARDEN AT GARGRAVE.

GARGRAVE is very near Skipton, and about an hour's run by rail from Bradford on the Midland line to Carlisle or Lancaster. Those who delight in magnificent hills and valleys, and glorious mountain scenery, should take a run from Leeds by way of Skipton and Ingleton until tired of it, and a call at Gargrave will amply repay the lover of a good garden, and a look in at the most beautiful stained-glass windows of Gargrave church will be a treat.

Mr. Marsden is an occasional contributor to the Journal, but under a pseudonym, and his opinions may be relied on at all times, and I wish he would write a great deal more, because he is the sort of man to guide amateurs; he is backed up by a gardener who, to use one of our Yorkshire expressions, has his head screwed on right, and I always pick up scraps of information when I visit Mr. Marsden's garden. I went there a few days since to see the Strawberries, and I am confident finer plants and fruit could not be found anywhere. The soil is not what may be honestly called good, for it is too light for Strawberries, and yet they are grown well here. Mr. Marsden treats the Strawberry as an annual and biennial, rarely allowing the plants to stand more than one or two years, and he has this season very fine crops from British Queen and La Constante, planted last August; not small plants with three or four fruit to each, but full-sized plants with an abundance of fine fruit. Before advertising to the sorts, I just wish to say a word or two about the treatment they receive. His gardener told me that in preparing the ground for planting they keep the manure near the surface, and after planting they never disturb the roots, but apply manure to the surface.

What a treat it is to see La Constante growing here! in fact, I never saw it in such luxuriant health, and some rows planted in August last were wonderfully fine. Another batch of two-year-old plants were also in fine trim, and full of fruit; and a small bed which had been allowed to stand for five years had a heavy crop. Where La Constante can be grown, and it must have very liberal growth, it is a first-class Strawberry in every respect, and, as the gardener observed, so short-stemmed that the fruit is covered by the foliage, and the birds do not get at them so much as other kinds. Another great advantage of La Constante is that it keeps up a succession, for it can be gathered from as early as Prince of Wales, and as late as any other kind.

British Queen is grown to perfection here, and I saw fruit such as one expects to find about Isleworth, or at Solomon's in Covent Garden, and a good old sort it is. It will be a long time before it be driven out of the field.

Crimson Queen is much grown and valued here, for it is a very free cropper, bearing fine, handsome fruit, and firm for travelling, just the Strawberry for market; but it should be quite ripe for flavour.

Frogmore Late Pine is not so much prized here, as it is rather tender; Cox's Hybrid is a capital cropper and a good Strawberry; Ingram's Prince of Wales is a heavy cropper and early. Other sorts are grown, but to these I shall refer another time.

I shall look in again soon to take stock of the good collection of Potatoes growing here. So far as I saw, Mona's Pride was turning out well; Birmingham Prizetaker was a large handsome Kidney; Lord Raglan, a good second early Kidney, with a rough skin, but first-rate in quality, the gardener told me; Gloucester Kidney, a second early, and Milky White, both good; and Rivers's Royal Ashleaf is one of the best earliest second earlies, certainly earlier than Myatt's. Amongst vegetables I saw Beck's Green Gem Bean, the only Broad Bean now grown by many, and a delicious little variety it is, Sandringham Celery looking well, and Ivory's Nonsuch, a fine Cabbage Lettuce.

A good collection of Pears is to be found here, and I noticed a good crop on small trees against a wall of Burre Hardy, a

fine and handsome kind, and *Béurre Superfin*. Governor Wood Bigarreau Cherry is a very fine sort, and as free as the May Duke.

The flower gardening, although on a small scale here, is very pretty and effective. Two of the plants used were particularly good—viz., *Calceolaria Bijou*, a capital dark kind, and *Scrophularia nodosa variegata*, a bed of which is enough to convince any one that it is a most valuable hardy bedding plant. Against the Vicarage the beautiful *Clematises Jackmanni*, *lanuginosa*, *rubro-violacea*, and *Helène*, were blooming freely, and what grand climbers they are!—WILLIAM DEAN, *Shipley*.

### GRASSES FOR LAWNS.

The rich and continuous verdure of our lawns is the admiration of foreigners who visit this country, and is chiefly attributable to our climate. The beauty of a lawn consists in the evenness of its surface and its deep green colour at all seasons; and it is the object of this communication to show how these results may be secured both in gardens and pleasure grounds, where the grass is regularly mown, and in parks grazed by deer, sheep, or cattle. Though Grasses are a numerous family, very few indeed are of any utility to the horticulturist, and of such I shall notice only the best and those desirable for particular purposes.

**FESTUCA DURIUSCULA** (Hard Fescue Grass).—This valuable perennial Grass is thus described in a former volume:—"Roots fibrous, and sometimes throwing out short lateral shoots. Stem about 2 feet high, erect, leafy, round, streaked, smooth. Lower leaves long, very slender, stiff, pointed, bristle-shaped from their sides being pressed together, and streaked; upper leaves broader and flat; edges and keels of all roughish, and all milky green. Leaf-sheaths close, smooth. Stipules very short, cloven. Flower-head an oblong unilateral panicle, much spreading when in flower, its branches being at an acute angle, pointing upwards from the stem, rough. Spikelets more or less red, at first cylindrical, but becoming flattened as the glumes expand. Calyx sharp-pointed. Florets from four to seven in number, keeled, flattened, generally smooth, the uppermost often imperfect; the outer valve tipped with a straight rough awn

shorter than the valve; inner valve roughish at the marginal ribs, slightly cloven at the point. Stigmas cylindrical. Anthers purple, cleft at the ends."

This Fescue Grass will thrive almost anywhere, except on bleak hills, and is not particular as to soil, though it succeeds best on sandy rich loam. It grows remarkably well in the shade, retaining its verdure throughout the most severe winter, and few Grasses, if any, endure drought so well. For sheltered hills and valleys, except where very wet, it is well adapted, and it is valuable for lawns which are shaded, especially those on a dry subsoil which are so liable to become brown in summer; for after its flowering season (June), it grows quickly notwithstanding the heat and drought which then usually prevail.—G. ABBEY.

(To be continued.)

### ROYAL HORTICULTURAL SOCIETY.

WEEKLY SHOW, *August 4th*.—In Class 1. Messrs. Cutbush & Son, of Highgate, took the first prize for six handsome plants of *Hydrangea*, and in the class for six miscellaneous plants they were equally successful. In the class for the best collection of fruit there were two meritorious exhibitions. That of Messrs. Lane & Son, of Berkhamstead, which received the first prize, consisted of well-grown bunches of the following Grapes:—*Trebbiano*, *Black Prince*, *Foster's Seedling*, *Alicante*, *Chavonsh*, *White Frontignan*, *Frankenthal*, *Buckland Sweetwater*, and some excellent dishes of *Cherries*. Mr. R. Marcham, gardener to E. Oates, Esq., Byderp House, Hanwell, was second. In the Miscellaneous Class Messrs. Cutbush received an extra prize for six handsome *Fuchsias*. From the garden of the Society at Chiswick there were collections of *Hollyhocks*, *Stocks*, and *Salpiglossis*, the latter consisting of many beautiful varieties. There was also a large number of *Zonale Polargoniums* in pots, exhibiting the finest varieties of these beautiful flowers in state of great perfection. There were also fruit of the *Cucumber Huntingdonia*, a handsome variety.

### "THE LADY" STRAWBERRY.

We have received from Mr. Richard Underhill, of Birmingham, fruit of the seedling Strawberry he has recently introduced under the name of "The Lady." It is what may be called a good-sized Strawberry, not so large as the very large specimens sometimes seen, but as large as we find in an ordinary crop of fruit. The skin is pale, with a salmon or rosy tint, much like the colour of a *Hautbois*, none of the fruit being entirely red. The flesh is solid, of a rich cream colour, with a very rich flavour and powerful aroma.

### NOTES ON THE WAY TO THE HOLY SEPULCHRE.—No. 4.

#### THE PROMISED LAND.

"AND the Lord said unto Abram, after that Lot was separated from him, Lift up now thine eyes, and look from the place where thou art [Bethel], northward, and southward, and eastward, and westward: for all the land which thou seest, to thee will I give it, and to thy seed for ever."

This was Abraham's title to the Promised Land, the land flowing with milk and honey; and in these words was contained the second or earthly part of that blessing which the Creator of the whole world bestowed on him who, amidst the idolatry of the surrounding nations, acknowledged and worshipped the one true God.

Within the strict limits of the Promised Land is the ancient port of Joppa, or Jaffa, as it is now called, to which, we read in *Chronicles*, that Hiram King of Tyre sent "Cedar trees, Fir trees, and Algum trees out of Lebanon in floats by sea" for the building of the first temple at Jerusalem; and towards the building of the second temple, we find in *Ezra* that "they gave meat, and drink, and oil unto them of Zidon, and to them of Tyre, to bring Cedar trees from Lebanon to the sea of Joppa." It was from this port that *Jonah* took ship when he fled from the presence of the Lord; and it is by this re-guarded entrance that I am about to enter the Holy Land, and linger in spirit for a time amidst its sacred scenes, examining by the way its natural features and productions.

Directly the traveller lands he at once feels that he is in the East. Swarthy half-naked Arabs surround him. There is an immediate call for *backshish*; and if his visit be in the spring he will probably see on all sides crowds of pilgrims on their way either to or fro the holy sepulchre.

The town of Joppa itself is built on a hill; the narrow streets composing it are steep, and in some cases ascended by steps, with arches supporting other houses thrown across. There are still houses "by the seaside;" and one of these is shown as that once inhabited by Simon the tanner, who received and lodged St. Peter, and from whose friendly doors the Apostle went forth—journeying by the valley of Sharon—to Cæsarea, to be the means of bringing the house of Cornelius, the Gentile centurion, into the Church of Christ. Joppa is also further endeared to us as being the house where Tabitha dwelt—that "Dorcas" whose good works and almsdeeds have been a pattern for all Christian women.

The plain of Sharon—so often mentioned in the Bible as a place on which Nature has lavished the "excellency" of her choicest gifts, and as "a fold of flocks"—begins in the vicinity of Cæsarea, and extends, for about thirty miles in length and ten in breadth, as far south as Joppa and Lydda. The tract immediately along the shore is low, and in some parts marshy; the interior part, along the base of the hills, is everywhere fertile and cultivated. The wood scattered in the plain is deciduous Oak, which in the north rises into trees, but in the south these are only shrubs. Besides the Oak there is the Arbutus, with here and there plantations of Olives and Carob trees. White Clover springs spontaneously from the soil. Flocks of goats are dotted about, browsing in the valleys or on the hillsides, giving a civilised homely look to the scene. The wild flowers that have been noticed are Asphodels and Lilies, scarlet Anemones, Lavender, a pink Phlox, blue Iris, a small red Tulip, and white Asters. The *Cistus roseus* (L.), grows so abundantly that it has been supposed to represent the "Rose of Sharon" spoken of in the Song of Solomon; but amongst the Syrian plants sent to me there is a lovely species of a small white Rose, which seems to me a fitter emblem.

Kitto, in his "Physical History of Palestine," mentions, on the testimony of others, that the Fig tree and Sycamore flourish at Jaffa; that in the gardens there are the Peach tree and the Terebinth, as well as the Orange; and that a small quantity of *Cannabis vulgaris* is cultivated, which the Moslems reduce to powder, and make with it a narcotic confection, which has the same effect upon them as opium. The leaf of this plant is also smoked—a curious way of evading that "drinking of the shameful," by which title they class (according to Palgrave), smoking tobacco as the second deadly sin.

The other Jaffa plants mentioned in Kitto are *Hyoscyamus aureus*, *Parietaria officinalis*, *Lycium spinosum*, "of which the Latin monks believe the thorny crown of Christ to have been made," a species of Spurge in the hedges, *Papaver rhaeas*, and *Malva vulgaris*. Kitto also states that the Heath is cut at Jaffa and burnt, and the ashes used in the manufacture of soap. The Water Melons of Jaffa have been greatly celebrated, and the Oranges are said to be the best on the Mediterranean.

Can we picture to ourselves this city on a hill, at whose feet on one side the blue waves of the Great Sea rage and swell, or lie down in passive beauty? From the "house tops" the eye can glance away from the water over the fertile valley which spreads before you. For two or three miles there is, as it were, a belt of Date Palms (which in this locality rarely ripen their fruit to perfection), and Orange groves scenting the air with the rich perfume of their blossoms. People of fair complexion—the women wearing high pattens on their naked feet—are wandering here and there; and, added to the sweet breath of flowers, there is the music of many birds.

The route from Jaffa to Ramleh, a village situated not far from Lydda on the way to Jerusalem, is for the most part a lovely one. Pleasant sandy lanes, with hedges of Briar, from which depend wreaths of Bindweed, lead through groves of Oranges, Lemons, Pomegranates, Almonds, and Vines, with many a wild flower intermingled, amongst which the most noticeable is a beautiful species of *Salvia*. The road then emerges into open undulating plains, which extend for about fifteen miles to the foot of the "hill country." These plains are well and cleanly cultivated with grain, amongst which, near Ramleh, may be found the *Amaryllis orientalis*, "with its round terminal head thick set with florets." In the same neighbourhood, I read, the *Anemone alpina* grows abundantly, and the *Cyclamen hederaefolium* "attains a size and brightness of colour beyond its wont in Europe." While gathering the flowers there may be heard the full joyous song of the skylark as she wings her quivering flight towards heaven; and the cry of the plover will denote that one of the many pools of water abounding in the plain is at hand. There are also fields of Cucumbers and Vegetable Marrows. A few disreput-

able-looking villages are scattered in the distance, but the route avoiding these continues by the plain till it reaches Ramleh (Arimathea), where travellers are received and hospitably entertained at the Franciscan convent; and there, from its terrace in the still evening's light, they may look out on a fair eastern view. Beneath them lie gardens surrounded with hedges of Prickly Pear; tall Palm trees rise in the distance, while the heavens above are alight with stars. From amongst these perhaps they will single out one more brilliant than the rest, that their dreams may be of those "wise men," who, like themselves, had left their homes that they might worship Him, whose birth a star proclaimed, at the manger of Bethlehem.

After a two-hours ride from Ramleh the route enters a defile of the mountains, which you are told is that "highway" by which the kine bore the ark when turned loose with it by the Philistines of Ekron.

At the foot of the bleak-looking hills the traveller halts and rests for a time under the friendly shadow of some wild Fig trees, and by the wayside he may gather a lovely species of *Geranium* and the *Peganum harmala*; there, too, he may find *Erythraea centaureum*, the pretty pink blossoms of which, although a little smaller than our English Centaury, will carry him back to the hedgerows of England. Besides these there is the *Nepeta curviflora*, which grows in the neighbourhood of Jerusalem.

After the rest there comes a dreary ride of several hours over bleak hills, clothed with stunted shrubs and trees, having the look of rough coppice wood on a stony Westmoreland hill, with here and there pasturage for a few sheep and goats, the latter guarded by children in scant eastern costume, consisting of a sack tied at the waist, with two holes for the legs, and a shirt of white, blue, or snuff colour, with a loose strip of coloured calico which they throw over the head or round the body at pleasure, the girls drawing it over the face at the approach of strangers. These children offer jars of milk to the passing pilgrims, a courtesy for which they expect, and demand a little loudly, too, a small return in coppers.

As you gain the last hill top you come suddenly on the view of Jerusalem. It is a difficult task to approach the "City of God" with a mind at unity with itself, so conflicting are the sentiments that overpower you. The eighteen hundred years which have passed away since the "veil of the temple was rent in the midst," is as a watch in the night; you seem to be standing midway between the old and the new dispensations—between the living and the dead. Among the pilgrims you meet there will be Jew as well as Christian, both drawn by love to the "Holy City," both watching and waiting for a fuller manifestation of the same Messiah; but one has the firm step and glistening eye of faith, and the other the weary watchfulness of hope deferred, never to be realised on earth till the end. And mingled with all these thoughts there is the "to-day"—the knowledge of what is; the ruin of many a goodly building partially built over; villas and gardens springing up as they spring up around a modern city; vegetation struggling to assert its repairing power; young plantations of Olives, Almonds, Peach, and Apricot trees. The traveller longs to note it all, but he feels bewildered and oppressed, and all the while the beast beneath him carries him onward, even to the "gates of Jerusalem," and he is awakened from his overpowering thoughts of the ancient glory and present degradation of the city of David to find himself isolated amidst a crowd of Jew and Moslem, to both of whom he is but "a Christian dog." Before the gate there is a band of lepers, shunned and avoided alike by all; yet not quite by all, for gliding here and there in gentle ministrations to the loathsome mass of misery he sees a calm, fair woman, wearing on her bosom the badge of the Crucified—the shadow of a glory greater than that surrounding Solomon's Temple seems to be cast before her steps—there is a voice in the air proclaiming to the leprous in mind and body, "I will, be thou clean;" but he passes on, and then it is—Jerusalem.—*FILIX-POEMINA.*

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

VACANT ground, or that which can be cleared of early crops, may be still planted with winter Greens, first giving it a good dressing of manure and a good deep digging. Stir the surface of the soil among growing crops. *Broccoli*, move the earth amongst them and winter stuff, and, if earth must be laid

against the stems, let it be done right and left with a fork, keeping the work before you to avoid treading on the surface. If there is any spare ground left, plant out the latest sown Miller's Dwarf Russian. It is advisable that Broccoli intended to stand through the winter should never be planted too thickly, as it is apt to make them much more tender than when there is a good circulation of air to render them robust and hardy. *Cabbage*, there should be no delay in making the main sowings for spring supply. Bailey's Improved is an excellent variety, to which may be added the Nonpareil, Vanack, East Ham, and London Market. The first sowings may be pricked out into nursery-beds. It is always better to do so in preference to leaving them in the seed-bed, as it makes them stocky and well-rooted, and consequently better able to bear the winter. *Celery*, see that the surface soil is well stirred about it, and afford copious applications of liquid manure with a small portion of salt dissolved in it. *Lettuce*, prepare a piece of ground to be sown immediately with the Bath variety, also for winter *Onions* and Winter *Spinach*. *Peas*, the rows that have had crops planted between them must now be entirely removed and the ground well forked up. Liberal waterings twice or thrice a-week in dry weather will be required by Peas, Cauliflowers, Spinach, Artichokes, Lettuce, &c., rendering them not only better in quality, but making them last longer in perfection.

#### FRUIT GARDEN.

Follow up the system of stopping and shortening, as recommended last week. The shoots of Pears may be headed back to three or four eyes. In regulating shoots, remember that it is important that each should enjoy a due exposure to the influence of the sun. Stop and thin Raspberry suckers, and make new plantations of Strawberries.

#### FLOWER GARDEN.

Let nothing be allowed to grow out of place, but attend to the wants of growing plants by giving them their proper supports and training at this season. The next matter requiring consideration will be the propagation of stock for another year. In commencing with Pelargoniums employed for bedding purposes, raised beds of sandy soil will serve to strike the Scarlets and their allies, while the Fancies and other kinds with a delicate habit, will be better in pots, or, where large quantities are required, in a frame under glass. Under any circumstances they will require protection from heavy rains. There is a class, of which *Sidonia* is one, which strikes with difficulty by cuttings of the shoots, and is best propagated by root-cuttings. Prepare cuttings of the thickest roots about  $\frac{1}{2}$  inch in length; these should be inserted in shallow pans and plunged in a frame. The oldest plants should be selected for the purpose. Herbaceous plants and hardy bulbs, now in full beauty, should be kept in order by tying up loose growths and keeping the ground free from weeds. Novelties should have their colours and time of flowering marked down as a guide for future arrangements. Finish the propagation of any choice plants not yet in, and continue the layering of Cloves, Carnations, mule Pinks, &c., of which there is rarely an overstock. The cuttings of Laurels and other loose-growing shrubs should be proceeded with as time permits. Autumn-flowering Roses will be much strengthened and flower better during the next two months, if partially pruned and well soaked with manure water.

#### GREENHOUSE AND CONSERVATORY.

Camellias in general will now have formed their flower-buds; when such is the case it is advisable to water them freely with liquid manure. We prefer this period, too, for shifting them, doing so the moment that we can be sure that the blossom-bud is fixed. A very frequent stopping or pinching of the growing shoots of stocks for next year's purposes will now be necessary. Great advantage is derived from giving plants some kind of rest after blooming, to restore their exhausted energies, and to enable them to make a vigorous start when the new growth commences. At this season greenhouse plants done blooming should have a comparatively cool temperature, and no structure presents so many advantages for the purpose as a house with a north aspect. We may state further, that for growing delicate-leaved plants through the summer, houses having a north or north-east aspect are preferable, while for the purposes of retarding plants or preserving them in bloom they are indispensable. Such plants, therefore, as *Epacris*, *Leschenaultias*, *Pimeleas*, *Aphelexis*, and others of similar habit, which have been kept for late bloom and are now over, should be placed in a house of the above description, or in deep frames with the sashes turned towards the north, having first picked

off the old remaining blooms; here, by gentle syringing once or twice daily, the plants may remain till a new growth commences, when any pruning they may require may be performed, and they may afterwards be placed in more favourable positions for ripening their wood. The pot Roses should have all exhausted blossoms cut constantly away, and those for winter blooming should be examined as to whether they require shifting. In such cases some of the old balls should be loosened, and the head slightly reduced. The Teas are admirably adapted for pot culture; and for these we prefer mixing a little heath soil with the compost, which should be exceedingly rich, and consist of nearly one-half of the chopped turf of a rich loam. A good sprinkling of pounded charcoal and sparkling sand should be used. Of Heaths, plants of depressa and other shy-blooming kinds which have made their growth should be placed in the full sun to set the bloom, taking the precaution, however, to protect the roots by double-potting the plants. Young stock in pits or frames must be exposed to the dews every evening, and in dull weather they may be exposed throughout the day also. Repot, stake, and stop *Chrysanthemums* and other winter-blooming plants, and look to the *Pelargoniums* cut down last week, and also the *Calceolarias*; cut down the late-blooming ones if the wood is ripe. Pinks and Violets will require watering in dry weather, and a dusting of sulphur will do the latter no harm. Attention must now be paid to late-growing plants in the borders of the conservatory, for while in active growth they require a good deal of water, and insects are more troublesome than in the case of plants at rest. Give *Luculias* especially plenty of water at the root, and an occasional supply of clear weak manure water to old plants which may not be growing freely, until they have made sufficient wood to ensure a good display of flower. Manure water must not be given to young specimens in vigorous health, as in that case it would only induce too gross a growth—a condition in which they seldom flower profusely. In order to secure fine heads of bloom from this plant it should be allowed a few weeks of comparative rest after the middle of the month, keeping the roots rather dry, and exposing the plants as freely to air as can be done without injury to the foliage or the health of their neighbours. *Brugmansia sanguinea* is also a useful plant for winter and early-spring flowering, when managed so as to have it pruned, rested, and started into growth about this time. Young and vigorous plants, however, frequently require to be watered rather sparingly at this period to prevent their making a second growth. *Cinerarias* for early flowering should now be growing freely, and should be shifted when necessary, for if they are to form large specimens for flowering in winter they must not be permitted to sustain any check. Remove suckers whenever they can be obtained, and pot them for spring-flowering.

#### STOVE.

Watch closely for insects in this house, and follow former directions as to moisture and air. Those *Ixoras* which have done blooming must be cut boldly in, and started gently to make a new growth. Attend closely to the winter-blooming plants, taking care to have such growths matured as require ripening to produce bloom.—W. KEANE.

### DOINGS OF THE LAST WEEK.

#### KITCHEN GARDEN.

On the 28th ult. we had a beautiful rain, repeated again on the 1st of August. These rains have wonderfully changed the appearance of the country, and yet come so gently as to do no injury to the advancing crops in the fields, and but little even in the flower garden, except washing off bushels of *Calceolaria* blooms, giving that, however, to the plants which would encourage them to produce multitudes of fresh blossoms. We were fortunate enough to get most of the hard-baked ground stirred amongst the advancing crops, and to water some, such as Peas and Cauliflowers, a few days before the rains, and then, when the dull days and the rains came, the plants seemed to grow before our eyes.

There has been no little discussion, and many a witty remark has been levelled at us, in consequence of our advancing lately the somewhat astounding principle that it is good to water in a dull day, and when plants are very dry it is better still to water before rain was expected. We have not a doubt as to the wisdom of the proceeding; but in any case, something will be gained if the matter is thought and reasoned out. We want the plants out of doors to have the benefit of the

water we are compelled to give to the soil. We have no notion of watering the soil well, if it can be avoided, in a bright sun, with the certainty that the sun will soon exhale that moisture to soften the atmosphere for the general benefit. If so obliged to water, we try to keep the water as much as possible to its destined purpose, just on the same principle that we use dampers for our furnaces, having no such large-hearted benevolence as would induce us to send all the possible heat up the chimney to make the air a shade warmer for some surrounding villages. The Celery watered before the rain is also thanking us by its appearance now. The little Dwarf Incomparable seems much greener in colour than the others, though all seem healthy, luxuriant, and firm in texture. We will merely earth-up what we want early.

**Cabbages.**—Sowed on the 29th ult. what we intend for the main early crop, and will sow again about the 8th or 10th. We were unfortunate in our first lot this season, and had more run heads than in all the years of our practice put together. Fortunately those in the next lot were pretty early, though even they had a few runaways, whilst for years we have had the Matchless and others level all over, and not a bolted plant. What is worst is, that plants of the latter description are of little or no use afterwards. If you cut them over 6 inches from the ground you will obtain nothing but a fresh crop of bolters. If you cut over close to the ground there is just a chance that you may have several young Cabbages from the base, and only a chance, for most of the young sprouts will come showing the flower-stalk at their points. In fact, when the flower-producing tendency is formed in a Cabbage plant, hardly any management will alter it so as to produce young Cabbages instead of shoots with flowers. The great advantage of an early unbolted crop of Cabbages is, that when the first Cabbage is cut the same stump will produce several nice crops of young Cabbages afterwards before the end of autumn, and a rare picking of young sprouts throughout the winter. Planted out lots of Coleworts to succeed these now beginning to heart, giving them about 1 foot square. Such young Coleworts, just when they begin to heart a little, and well boiled, are a dish for a prince. Took the opportunity of further thinning the later Onions, Carrots, and Turnips, and planted out more Endive and Lettuces. Bright airy weather, we hope, will keep off all traces of the Potato disease. Regulated and thinned Cucumber plants in frames and ridges, and sowed for late crops.

FRUIT GARDEN.

Continued much of the work of shortening and pruning referred to last week, and commenced *potting Strawberries for forcing* next season. If we have nice plants in small pots or otherwise, we generally transfer them now singly to six-inch pots, what are called 32's. As there are some inquiries about the treatment adopted, we will state the heads of it:—First, A hard bottom full in the sun for the pots to stand on, with just a sprinkling of sand to permit of the pots standing level, and keeping a little moisture about the base of the pots. Secondly, The pots are thoroughly scrubbed inside and outside before using them. (Washing pots and cleaning sheds made the bulk of the work on the wettest day of Wednesday.) Thirdly, The pots are pretty well drained, a little moss laid over the corks, and a little soot sprinkled on the moss; the soot and the hard bottom, independently of the nourishment from the former, being chiefly intended for keeping worms at a distance, which result is also assisted by well watering the ground at times with lime water. However we may value the worms in some cases, we have no desire to let them into our Strawberry pots, as there they are sure to do injury by stopping drainage and doing away with the firmness of the soil against the roots. Fourthly, The soil we use is a rather stiff fresh loam with about a sixth part of fine leaf mould and spent Mushroom-bed dung. Such soil, and pressed, is placed deep enough over the drainage for the young plant to stand with the base of its bud about one-quarter of an inch below the rim of the pot, as it will be sure to sink a very little afterwards; and then, the roots being properly looked after, the soil is packed in and firmly beaten with a stick, so that at the top the soil will be smooth and half an inch below the rim. Fifth, These pot plants are watered with clear water until the roots begin to reach the sides of the pot, are shaded in bright sun if the leaves offer to flag, for we never like to see a single leaf distressed, have all the sun possible as soon as they can bear it, frequent manure waterings as they become strong, and less water and all the light possible towards the end of autumn. Of course, all runners should be removed as they appear. Cuthill's Black Prince for early gathering we generally grow in 4½ or 5-inch

pots, commonly called 48's and 40's, and we grow a good many plants of Keens' Seedling for early work in the same size, as the smallness of the pots and the rapidity with which they are filled with roots enable us all the sooner to have the buds matured and rested before starting them into growth. After March and April we take up and force young plants, which we will now prick out in rich borders, 6 or 7 inches apart; but for all early forcing the plants must have their pots filled with roots, and their buds be well ripened in the previous autumn.

**Netting from Birds.**—The other day we had another proof that nets if not perfectly secure are no defence for what is beneath them, but rather a temptation to the curiosity of the birds to find out what you have thus protected, and if there is a possible flaw they will find it out and enter. A piece of a border of Gooseberries had a rough frame thrown over it, and then a net or a series of nets over that, well secured at the sides, and everywhere as we thought. Next morning, between five and six, on going to the place we might have fancied ourselves at a large roosting-place for domestic fowls, as more than a score of blackbirds flew and screeched and screamed to get out. Here is where the blackbird loses his wisdom. Had the birds only kept quiet they might have had it all their own way. With several men round the net and one among the bushes inside, more than half the marauders escaped. It became difficult to find them at last, as they crouched so still and quiet by the stems of the bushes. It was considered very singular that not a single thrush or other bird was in company with the blackbirds. The beautiful cock birds with their greater daring managed to escape. The nets were again carefully gone over, every little hole patched, and the sides thoroughly secured, and for two days no more have found their way inside; but in the morning and evening, and several times during the day, numbers run up and down outside the netting, fly against it, act as if they considered themselves very ill-used, and generally go off with such a scream of defiance as seems to say, We will serve you out for keeping us out! A good many solitary thrushes and blackbirds have hung themselves in nets; but this is only the third instance that has come under our own observation, that when blackbirds thrive in company they will have no other interlopers to share the booty with them. Have any of our readers observed a similar phenomenon?

ORNAMENTAL DEPARTMENT.

Out of doors we have chiefly been employed in mowing, sweeping, and rolling grass, and regulating beds that were not fastened when planted. Cerastium edgings will also need fresh trimming, as the heat and wet have caused them to grow beyond bounds. In sheds and houses much time has been taken up in potting and cleaning, dipping Stanhopeas to give moisture enough to swell their expanding buds, potting Ferns, top-dressing, and surface-stirring the soil of plants in pots. Roses should now be budded without delay, cuttings inserted, and many out-door plants attended to. Proceeded with collecting seed, making cuttings, drying bulbs, staking Hollyhocks, thinning shoots of Dahlias, and general watering; but all these matters, have been definitely alluded to of late.—R. F.

COVENT GARDEN MARKET.—AUGUST 4.

In addition to former quotations, we may mention that the earlier varieties of Apples and Pears are both coming into the market in considerable quantities, and find a ready sale; we have, also, at the auction sales large consignments of the same fruits from France and Spain in tolerably good condition. Strawberries are now nearly over, the only sorts coming in being Myatt's Eleanor and Elton. Hothouse fruit is quite sufficient for the demand; Peaches and Nectarines are in rather better request; and of Apricots there is a short supply.

TO CORRESPONDENTS.

\* \* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once

N.B.—Many questions must remain unanswered until next week.

CHAMEROPS FORTUNI (*A.*).—No doubt the Marants would be benefited by the mature water if it be not applied too strong, but we should be in doubt as to its being beneficial to the Chamierops.

DOUBLE CANTERBURY BELLS (*Campanula*).—It is not unusual to meet with the double variety of Canterbury Bells. If you save the seed you will perpetuate the double form.

ANACHARIS ALINASTRUM (*F.*).—The only two modes of ridding a pond or lake of this weed is to pasture it with swans, which keep it under, or to dredge it with long-handled rakes. We know an instance where the latter mode was resorted to, and the weed, being thrown into heaps till it decayed, afterwards furnished an excellent manure for vegetable crops.

BRITISH BULBS (*Caroline*).—The only work on this subject illustrated with plates, is by Mrs. Loudon, and is, we presume, the expensive one you allude to. It is not possible to get such works as these illustrated at a small cost.

GREENHOUSE (*H. S.*).—A north-east aspect is certainly not an inviting one for a greenhouse; but if that is the best you can obtain, and you are desirous to erect one, you will succeed in raising flowers and fruits very fairly. We have seen both grown in a house facing directly north.

MELONS CRACKING (*M. C. J.*).—The only way in which we can account for your Melons going in the way they have done, is by their roots having penetrated beyond the frames and received a superabundance of moisture during the wet weather we have had. You say you have not watered the plants inside the frames; and as the result is attributable to an excess of moisture, there is no other solution of the cause than that we have given.

NEW PEA (*M. R. D.*).—Your Pea, even when old, is sweet and tender. The story about being found originally in a mummy is an old one, which has been related of other varieties, and may be true or not. One sort was advertised as a Mummy Pea some years ago, and proved to be the Matchless Marrow. Judging from the pods you have sent yours is not that variety. The best way to have it tested would be to send some of the seed to the Royal Horticultural Society's garden at Chiswick, addressed to Mr. Barron, who will have it sown along with the other varieties next season.

SUMMER PRUNING (*T. T., Islworth*).—In reference to what was said last week in "Doings of the Last Week," we would reply, that many systems are right, in proportion as they are carried out thoroughly. Your gardener may be perfectly right in clearing away all summer growth; stumping in the shoots as they appear, if the trellis is filled, the trees fruitful and vigorous enough, and not too vigorous to cause the fruit-buds to start prematurely. Such stumping-in tells on root-action, as alluded to last week. In general circumstances we consider it better to let the shoots grow a little, cut a part back, and then merely stop the points of the others. We observe that shoots of Apples and Pears stopped in June are making fine bold buds at the base of the shoot. We would have stopped all sooner if we could have found time, and if time permitted we would do the same with Currants, Gooseberries, &c. When we could do this effectually we have found the base of the shoots of the present year, for 6 inches or so in length, even of Currants, produce freely.

WINTER-PRUNING MORELLO CHERRIES (*Idem*).—This may be done any time from November to April, in fact, they may be pruned when in bloom, as then you can always cut to a wood-bud. In summer, the sooner the shoots are thinned, and the bulk of those intended to be left laid in to the wall, the better. If the shoots are at all strong they should be stopped, which makes them more fruitful. They do well, too, when spurred back; but generally they are allowed to bear on the young wood of last year, as in the case of the Peach. When systematically treated throughout, both Cherries and Peaches may be stopped in summer to cause them to bear on short shoots or clusters of spurs.

PERISTERIA ELATA (*Idem*).—We have no doubt that many cultivators would be glad to exchange *Azalea*, &c., for your *Peristeria*; but the best way to secure the exchange would be to advertise in our columns.

WOODlice IN A MUSHROOM-HOUSE (*E. Vinery*).—Having tried Potato traps and pouring hot water, as well as carbolic acid round the edges of the bed, and found none of these remedies effectual, you may find relief by cutting a number of new Potatoes in two, hollowing them out in the middle, and laying them on the bed. The woodlice will remain hidden under the Potatoes, and may be destroyed daily. Tods are this year unusually numerous, and a score or two put into the house would assist you more than anything we know, except Bantam fowls. We had a pit so full of woodlice that nothing could live in it, but we made it the home of a cock and two Bantam hens, and in a few days it was clear. Having put a quantity of boiled Potatoes on the floor, and covered them with a little short hay, the woodlice came to feast on the Potatoes, and the fowls in turn fed on them.

FIG TREES UNFRUITFUL (*Idem*).—The most probable cause of the trees being unfruitful is the roof of theinery being so occupied by the Vines that the Fig trees on the back wall have not sufficient light to ripen their wood. Fig trees will grow in partial shade, and fruit well, but they will not do so if the roof be entirely covered by Vines. Your taking off a ring of bark will moderate the vigour of the trees and tend to promote fruitfulness, but, unless you give them more light, we fear your chances of fruit are but small.

GRAPES SHANKING (*Idem*).—This is mainly to be attributed to the roots being in a cold, deep, undrained outside border, and the materials composing it not being in proper condition—firm, yet free. A deficiency of air and a high temperature also tend to cause shanking, and so will cold rains and heavy waterings when the fruit is ripening.

PELAGONIUMS FROM SEED (*Ipomoea*).—In our Volume IX, pages 497 and 498, you will find the treatment of seedling Pelargoniums fully described.

WATERING GERANIUMS (*Thirsty*).—In watering beds of Geraniums and other plants at this season it is best to apply the water without a rose, so as to wet the soil thoroughly, avoiding watering overhead, which destroys the flowers. If you reside in a town and near a public thoroughfare, an occasional watering overhead is beneficial, as it frees the leaves of dust and gives a fresh appearance to the plants. The spring water will answer, if pumped into an open cistern, and exposed to the atmosphere for at least forty-eight hours; it will thus be rendered much warmer and softer.

WATERING IN DRY WEATHER (*Idem*).—During a dry period frequent watering, as it tends to maintain growth, and sustain a plant in bloom, does not check flowering, though it may tend to increase the amount of foliage, but it is not possible to have a continuance of bloom without an increase of foliage. If the waterings are excessive, then, as in the case of a wet season, the foliage will be excessive.

SALVIA ARGENTEA (*J. M.*).—There is a plant under this name which is identical with *S. patula*, which is much taller and much less silvery than the true *Salvia argentea*. The latter has very silvery leaves, and is useful as a bedding or ribbon plant. Both may be propagated from cuttings, also from seed, which you may obtain through any of the leading metropolitan or provincial nurserymen.

BLOOMING ROSES AT CHRISTMAS (*W. A. B. B.*).—You can only manage this by growing some of the best autumn-blooming kinds in pots, and about this time cutting them in to four good buds of the current year. Keep them well supplied with water, and frequently syringed overhead; continue them out of doors until November, and then place them in a light and airy house with a temperature of from 45° to 50° by day without sun, and at night the thermometer may fall to 40° without injury. All they want is protection from frost. If the weather proved mild the blooms would expand out of doors, but for safety the plants are best taken under glass.

GRAPES CRACKING (*Notice*).—From your description we think with you that the Grape is the Royal Muscadine. The berries crack from the air of the house being too moist. Probably a little air at night would make all right. The berries will also crack when the soil of the border is kept unnecessarily moist; but usually a moist and badly-ventilated atmosphere is the cause of the evil.

TOP-DRESSING A VINE-BORDER (*Idem*).—Your border being very full of roots, and these being very near the surface, so much so that in autumn the soil cannot be forked over, we advise you to give a top-dressing of rich compost. We have found nothing equal to the following: two-thirds turfy loam from rotted turves a year old, cut 3 inches thick, and laid up in alternate layers with sheep-droppings, or fresh stable manure, and one-third cowdung a year old; the whole well mixed, chopped, and made somewhat fine with a spade, but not sifted; then add one-sixth of boiled half-inch bones. This compost, well mixed, and laid on the border to the depth of 3 inches, will not destroy the fibres near the surface as frosher materials are apt to do, but they will come up into it, and the vigour of the Vines will be maintained.

PROPAGATING ALOESIA CITRIBODORA OR LEMON-SCENTED VERBENA (*W. H. B.*).—The best time to propagate this plant is when the wood of the current year is from 2 to 6 inches in length. Short stubby shoots with their bases a little hardened are the best. Now is a good time to put in the cuttings, which may be side shoots about 3 or 4 inches long slipped off the plant. The lower end having been made smooth below a joint with a sharp knife, and the leaves removed for half the length of the cutting, the latter should be inserted pretty closely round the sides of a six-inch pot, drained to two-thirds its depth with broken pots, or crocks, and filled to within an inch of the rim with a compost of sandy peat, loam, and sand in equal parts, the remaining space being filled up with silver sand. Insert the cuttings pretty closely around the sides, and up to the lowest leaves, or half their length; then give a good watering, and cover with a bell-glass. Perhaps the best mode of doing this is to place the cutting-pot in one of larger size, and fill the interval between the pots with crocks, placing sand on the top; the rims should be level. Only water when necessary, and as it must always be. Place the pot in the sunniest window, and shade for an hour or two during the hottest part of the day. In six weeks the cuttings will have struck, and the bell-glass may then be entirely removed, but for three weeks previously it should be tilted a little by day, and put close down at night, wiping the glass in the morning if moisture is found to be deposited on it. The cuttings will strike, but more tardily, and with less certainty, without the glass; they strike best in a gentle hotbed.

VARIOUS (*Buz*).—1, The Scarlet Geraniums in pots, placed on the lawn and intended for the same purpose next year, we would merely house before frost, keep them rather dry all winter, give any little pruning they wanted in spring, and top-dress in the same pots after seeing the drainage was all clear. We have a few fine plants which have been about seventeen years in the same pots. 2, The best time to take cuttings of Mrs. Pollock is when you can obtain them—all the summer and autumn, and then in the spring months. The best time to take the plants out of the ground is as early as you can do so, say by the middle of October. 3, Geranium and Calceolaria cuttings: You can take the first as soon as you like. We prefer the latter in October; but you can make them now if you keep them in the coolest place you can find, under a frame or a hand-liebt. No bottom heat. 4, The Fancy Geraniums done blooming will be best set in an open place out of doors, and in dry weather wet the ground on which they stand instead of watering the plants much. When the wood is well hardened prune back, but not so much as the other kinds, and when making growth shift into similar-sized, or smaller-sized pots. 5, You may sow Dutch Clover and the finer lawn seeds now, in fact, any time when damp. 6, You may prune Laurels and Laurustinus any time before winter.

CANNA NIGRICA WITHERING (*A Constant Subscriber*).—Your plant would have done better if you had cut it down last autumn or winter, and had all the growth of this season. As it is unsightly, you had better take it up, pot it, place it in the reserve garden, keep it from frost in winter, and in winter or early in the spring cut it down to the ground.

PRUNING BLAIRII No. 2 ROSE—ARRANGING PLANTS IN A STOVE (*An Irish Subscriber*).—As to Blairii No. 2, cut out all the smaller shoots, lay in a suitable number of this season's shoots, stop them in autumn, and you will have plenty of flowering short side shoots next season. The plants in the body of your house would look well from your proposed balcony; it will shade the plants below it, but that would do for plants liking shade, as Ferns. Would you not obtain room more easily by some kind of a stage? The above considered, however, we have no fault with the balcony.

FRUIT-TREE PRUNING (*S. M. L.*).—We quite approve of your observation with reference to the pruning of pyramid fruit trees, that "it appears to be an unnecessary expenditure of sap and loss of time to wait until the end of August and then cut back to eight leaves." Our principle is to prevent the development of all unnecessary wood, and economise as much as possible the vigour of the tree for the production of fruit-bearing spurs and the increase of the fruit. We therefore advise that pinching be regularly practised during the whole of the summer, and performed so closely that it shall not cause those buds which are desired to form fruiting spurs to be forced into leaf-bearing shoots. The three-foot-long shoots should never be permitted.

SELECTIONS OF GERANIUMS (*Amateur*).—A list such as you suggest shall appear shortly. *Diens repens* is a stove overgreen.

GRAPES SCALDING (*Woodford*).—This is caused by excessive heat of the sun and the want of sufficient ventilation. Give all the air you can.

NAME OF PLANT (*S. C.*).—*Acanthus spinosus*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 4th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

FOWLS TO BE KEPT.

BEFORE deciding on the breed of poultry to be kept, it is necessary to take into consideration that which is required from the fowls, and also the conveniences possessed by the intended owner, and the nature of the soil on which they are to be kept. Unless these matters be well weighed, it is useless to ask which are the best layers, or which breed is most profitable.

Where poultry-keeping is a hobby or a fancy, the breed that is preferred will be kept, as emolument is not sought; but where a return is looked for, and a balance-sheet thought of, it is well to prepare for the profit by using such means as may seem likely to secure it. The first that suggests itself is, Where is the market, or what is the mode of sale, and which is in the greater request—eggs or poultry? Some people break off here; they cannot bear the idea of selling poultry—it seems *infra dig*. We think them wrong, but there is an escape for these. The poultry man or maid will do all the trading, merely carrying out the instructions of the master or mistress. We know an instance of a lady worth many thousands who has a large milk trade at her house on her own terms. She charges more for her milk, and buyers have to fetch it, yet she sells all, and others who carry round cannot sell. She never appears in it, the dairymaid does everything. We know another who supplies a whole neighbourhood with eggs and poultry, the dairymaid manages all. This must, then, be considered—whether it is intended to sell in this way, or whether there are conveniences for sending a basket of chickens to market. Different markets have different habits. In some poultry is a trade, in others it is an exception; but it is certain that wherever good poultry is taken it will create a demand, if none exist, provided the place where the market is held be a populous one. There is, however, a demand everywhere for eggs, and at very remunerative prices during the winter months. Then there is always the last resource of the London market. With much experience of markets, we prefer local ones; there are many drawbacks in connection with the metropolitan—carriage, commission, baskets, sending to the station; all these take from the return.

Having satisfied yourself of the requirements of the place in

the way of contribution to the food stock, next study the place itself. If there is a demand for table poultry, and you have a tolerable range—above all, if you have a farmyard, even a small one, keep Dorkings, none will pay you better. If your space is limited, and you have no farmyard, keep either Brahmas or Cochins. If the demand is for eggs rather than fowls, keep Spanish, Crève Cœur, or La Flèche. Choose a light soil if you can.

We have always preferred pure to cross-bred fowls. We think them more profitable, much handsomer, and we always know what we are about to breed; but if crosses are resorted to, even by those who manage them most skilfully, there is always doubt. We should not advise the plan of any one who would for market purposes cross a Dorking with a Brahma Pootra. The rich deep breast of the former would be diminished, and a large-boned, yellow leg substituted. The best cross is, perhaps, between the Dorking and the Game. There is nothing in it that offends; but while strength of constitution is gained, the placidity of temper that is so valuable in a bird intended to be fattened is entirely lost, and the cross between the Game and Dorking must be killed at least a month younger than the pure Dorking. We said, however, that by keeping pure birds we knew what we were breeding. A cross is generally adopted in order to develop in one breed some quality that excels in another, and then the cross is bred out. Thus, Game cock and Dorking hens, to give more strength of constitution to the latter. Second year, son to mother; third, son to daughter; fourth, son to grand-daughter, and then all appear pure Dorkings. Nothing may appear for years to indicate any mixture, and then a dozen years afterwards a friend to whom you have given some of your celebrated "Dorkings," writes you that he has bred pure Game cocks from them. This is the history of all crosses.

PUDSEY POULTRY SHOW.

(From a Correspondent.)

THE third annual Show of Poultry and Pigeons took place on Saturday, the 28th ult., in the extensive grounds belonging to the Prince of Wales Cricket Club. Unfortunately the weather was anything but favourable, as it rained all day, but the poultry were pretty well protected, and the Pigeons were shown in a spacious tent.

The pens of poultry were exceedingly good in quality, but in some classes the entries were very few. It cannot be said that a single unhealthy bird was sent, and not one bad pen, excepting the birds

shown by Mr. Broemel, under the name of "Compeine Hamburgs," and accompanied with two pairs of Pigeons with which that gentleman won the first and second prizes in the "Any other class," the former being in the worst condition and feather, while the latter were exquisitely beautiful, and fairly entitled to the position they took. Spanish headed the list, and the cup was awarded to a nice pen. *Cochins* and *Brahmas* were very good. A remarkably fine pen of Golden *Polands* stood well for the cup. A very fine pen of Black *Bantams* took the medal for Bantams.

Ronen *Ducks* were exceedingly good, and some very pretty Brown Calls and Teal were also shown.

The prize for the best pen of *Pigeons* in the Show was given to Mr. Beldon, for a fine pair of Red *Pouters*, and so good were all the classes, that it could not have been considered a mistake had the extra prize been awarded to any one of the first-prize pens.

The following prizes were awarded:—

SPANISH (Black).—Cup, H. Greenwood, Woodhall Hills. Second, H. Beldon, Bingley.

COCHIN-CHINA (Any variety).—First, H. Firth, Dudley Hill. Second, H. Beldon.

BRAHMA POOTRA.—First, J. H. Fickles, Todmorden. Second, R. Tate, Leeds.

GAME (Black-breasted or other Red).—First, H. Beanland, Dudley Hill. Second, J. Hodgson, Bowling.

GAME (Any other variety).—First, H. Beldon. Second, J. Fell & Sons, Adwalton.

GAME COCK (Any colour).—First, J. Mason, Worcester. Second, J. Hodgson.

HAMBURGS (Golden-spangled).—First, H. Beldon. Second, R. Tate.

HAMBURGS (Silver-spangled).—First and Second, H. Beldon.

HAMBURGS (Golden-pencilled).—First and Second, H. Beldon.

HAMBURGS (Silver-pencilled).—First and Second, H. Beldon.

HAMBURG (Any other variety).—First, H. Beldon. Second, J. Coulson, Stanningley.

POLAND (Any variety).—First and Second, H. Beldon.

GAME BANTAMS.—First and Second, R. Tate.

BANTAMS (Black and White).—Medal and Second, Master C. H. Hutton, Pudsey.

BANTAMS (Any other variety).—First, S. & R. Ashton, Rotherham. Second, T. C. Harrison, Hull.

DUCKS (Rouen).—First and Second, J. Wade, Adwalton.

DUCKS (Aylesbury or White).—First, E. Leech, Rochdale. Second, M. Ferrand, Dalton.

DUCKS (Any other variety).—First, T. C. Harrison. Second, Master C. H. Hutton.

ANY OTHER VARIETY OF POULTRY OR ORNAMENTAL FOWL.—First, J. S. Hedley, Rochdale. Second, Master C. H. Hutton.

PIGEONS.—*Pouters*.—Timepiece, H. Beldon. Second, E. Brown, Sheffield.

*Carriers*.—First and Second, H. Yardley, Birmingham. *Dragons*.—First, H. Yardley. Second, C. Cowburn. *Anticorns*.—First, H. Yardley. Second, R. Allison, Knotrop. *Barbs*.—First, G. Hewitt, Bradford. Second, H. Yardley.

*Ouels*.—First, C. D. E. Roys, Rochdale. Second, J. H. Fickles, Turbills. —First, G. Hewitt. Second, H. Yardley. *Archangels*.—First, H. Yardley. Second, C. Cole, Bowling. *Tumblers* (Short-faced).—First, C. D. E. Roys. Second, E. Brown. *Tumblers* (Long-faced).—First, C. D. E. Roys. Second, C. Cole. *Fantails*.—First and Second, H. Yardley. *Trumpeters*.—First, C. D. E. Roys. Second, J. Hawley, Bingley. Any other variety of Pigeons Turtle or other Doves.—First and Second, F. Broemel, Kent.

The Judges were Wm. Cannan, Esq., Bradford; and James Dixon, Esq., Bradford.

## DRIFFIELD AGRICULTURAL SOCIETY'S POULTRY SHOW.

THE annual Exhibition of poultry in connection with the above Society was held on Friday, July 27th. There were upwards of 260 entries, and many very good specimens were shown; but we were sorry to find that in many cases good ones remained unnoticed, which we think would not have been the case had Mr. Hewitt been able to keep his appointment, but unfortunately circumstances prevented him from attending.

There were several curious additions to the Show sent by two ladies in the neighborhood. One was a Stork; and the other a cage containing a pair of Sparrow Hawks, a couple of chickens, and several small birds, all apparently living together in perfect harmony.

We must mention a case of attempted deception which came to light, and very properly excited the indignation of the Judge. It appears that in this case an exhibitor had a good Dorking cock, but no hens fit to mate with him; so he borrowed a pair of hens, and with these made up a pen which obtained the first prize. After the judging was over the borrowed hens were removed, and the man's own inferior hens substituted in their place. Then a ticket was attached to the pen, offering them for sale at a low figure (30s.), with the white ribbon still fastened on the pen. Thus, any person who wished to purchase Dorkings would be tempted to buy these, thinking he was buying the birds which had been honoured with the first prize. The Judge, on this being reported to him, at once disqualified the pen and rejudged the class, giving the first prize to the pen which stood second, and the second to a commended pen; and we are informed the party was given into custody for improperly removing birds from the Show contrary to the rules.

Unfortunately the day was very unfavourable, the rain falling all the time; and many of the poor birds, being without any shelter, were soaked to the skin. In consequence of the weather, the attendance

of visitors was very limited, and only about £106 was taken at the gate, being something less than one-third of the usual amount. The following is a list of the awards:—

DORKINGS.—First, disqualified. Second, M. Hunter, York. *Chickens*.—Prize, F. Key, Beverley.

SPANISH.—First, H. Beldon, Bingley. Second, G. Holmes, Driffield. *Chickens*.—Prize, H. Beldon.

GAME (Black-breasted and other Reds).—First, W. Charter, Driffield. Second, J. Smith, Driffield. *Chickens*.—Prize, R. Hardy, Lockington.

GAME (Duckwing or other Greys).—First, W. Boyes, Beverley. Second, W. Laycup, Driffield. *Chickens*.—Prize, O. A. Young, Driffield.

GAME (Any other variety).—First, W. Charter. Second, S. Bielby, Beverley. *Chickens*.—Prize, W. Charter.

COCHIN-CHINA.—First, T. H. Barker, Hovingham. Second, H. Merkin, Driffield. *Chickens*.—Prize, T. H. Barker.

POLANDS.—First, H. Beldoo. Second, Mrs. Proctor, Hull.

HAMBURGS (Golden-spangled).—First, G. Sutton, York. Second, R. Tate, Leeds.

HAMBURGS (Silver-spangled).—First, H. Beldon. Second, T. Holmes, Driffield. *Chickens*.—Prize, H. Beldon.

HAMBURGS (Golden-pencilled).—First, G. Holmes. Second, H. Beldon. *Chickens*.—Prize, H. Beldon.

HAMBURGS (Silver-pencilled).—First, H. Beldon. Second, G. Holmes. *Chickens*.—Prize, H. Beldon.

ANY OTHER PURE AND DISTINCT BREED NOT PREVIOUSLY CLASSED.—First and Second, R. Loft, Woodmansey (Sultans). *Chickens*.—Prize, R. Loft (Sultans).

FARMYARD CROSS.—First, W. Charter. Second, G. Robinson, Frodingham.

BANTAMS (Black and White).—First, Miss Mosey, Driffield (Black). Second, J. R. Jessop, Hull (White).

BANTAMS (Any other variety).—First, R. Wilson, Norton, Malton. Second, G. Brown, Driffield.

GEES.—First, Mrs. O. A. Young, Driffield. Second, Mrs. Nicholson, Little Driffield. *Goslings*.—Prize, Mrs. Mosey, Skerne.

TURKEYS.—First, W. Charter. Second, Mrs. Dawson, Poundsworth, Driffield. *Fowls*.—Prize, Mrs. O. A. Young.

GUINEA FOWL.—Prize, Mrs. O. A. Young.

DUCKS (Aylesbury).—First, G. R. Young, Driffield. Second, M. Harrison, Warter. *Ducklings*.—Prize, E. H. Clements, Wetwang.

DUCKS (Rouen).—First, Mrs. Jordan, Eastburn. Second, R. Morris, Driffield. *Ducklings*.—Prize, Mrs. J. S. Jordan.

DUCKS (Any other variety).—First and Second, J. R. Jessop (Teal and Carolina). *Ducklings*.—Prize, Mrs. Jordan.

PROGGS.—*Coppers*.—Prize, W. Ness, West-Lutton. *Carriers*.—Prize, J. R. Jessop. *Trumpeters*.—Prize, F. Key, Beverley. *Jacobins*.—Prize, H. Topham, Bainton. *Fantails*.—Prize, R. Wilson. *Barbs*.—Prize, E. Lensoa, Driffield. *Nans*.—Prize, J. Marshall, Driffield. Any other variety.—Prize, W. Leason, Driffield.

RABBITS.—First, W. H. Young (Lop-eared). Second, J. R. Jessop (Himalayan).

### SINGLE COCK CLASS.

DORKINGS.—Prize, J. Hatfield, Cottingham.

SPANISH.—Prize, R. Tate, Leeds.

GAME (Black-breasted and other Reds).—Prize, H. M. Julian, Hull.

GAME (Duckwing or other Greys).—Prize, T. Laycup, Driffield.

GAME (Any other variety).—Prize, W. Charter.

COCHIN-CHINA.—Prize, J. Hatfield.

POLANDS.—Prize, H. Beldon.

HAMBURGS (Golden-spangled).—Prize, J. Hatfield.

HAMBURGS (Silver-spangled).—Prize, H. Beldon.

HAMBURGS (Golden-pencilled).—Prize, G. Holmes.

HAMBURGS (Silver-pencilled).—Prize, W. Wallis, Driffield.

ANY OTHER PURE AND DISTINCT BREED NOT PREVIOUSLY CLASSED.—Prize, R. Loft (Sultans).

FARMYARD CROSS.—Prize, W. Charter.

BANTAMS (Black and White).—Prize, J. R. Jessop (Black).

BANTAMS (Any other variety).—Prize, G. Blakey, Driffield.

The Judge was B. Baxter, Esq., Elslack Hall, Skipton, assisted by E. Riley, Esq., South Dalton.

## TAVISTOCK POULTRY SHOW.

THIS was held on the 1st inst., and proved highly successful. Previously the display of poultry had been confined within the narrowest limits, but a wonderful expansion has taken place; and though the prizes offered were comparatively small in amount, the competition was keen, and the number of entries very large. The Exhibition was pretty strong in *Game* fowls. There was also a very good show of *Cochins*, and some excellent specimens of *Hamburgs*, though the number of the latter was small.

*Pigeons* were not in very great force, but what were there were good.

DORKINGS (Any variety).—First, — Phillips, Calstock. Second and Third, — Reed, Calstock. *Chickens*.—First and Second, — Phillips.

GAME (Any variety).—First, Second, and Third, — Collacott, Tavistock.

COCHINS (Any variety).—First, — Phillips. Second, — Bryant, junr. Third, Rev. J. Wollocombe, Stowford. *Chickens*.—First and Second, Rev. J. Wollocombe.

HAMBURGS (Any variety).—First, M. Bawden, Tavistock. Second, — Hodge, Tavistock. Third, S. J. C. Blanchard, Tavistock. *Chickens*.—First, — Botterill, Grimstone. Second, — Williams, Tavistock.

BRAHMAS (Any variety).—First, G. Spencer, Tavistock. Second, — Kingsland, Plympton. *Chickens*.—Prize, — Kingsland, junr. Tavistock.

SPANISH (Any variety).—First and Second, — Reed, Calstock.

MINORCAS (Any variety).—Prize, — Polzace, Hayle. *Chickens*.—First — Sowden, Mary Tavy. Second, — Lang, Tavistock.

BANTAMS (Any variety).—First, C. V. Bridgman, junr., Tavistock. Second, Miss Perry, Liddon Farm, Brentor.

ANY OTHER PURE BREEDS.—First, — Bolt, Gummislake (Polands). Second, — Phillips (Polands). Third, Mrs. Maddock, Whitechurch (Guinea Fowls).

**DUCKS** (Any variety).—First, C. Willesford, Tavistock. Second, — Nowberry, Prince Town.

**PIGEONS**.—First, — Merrifield, junr. Tavistock. Second, — Williams, Tavistock. Third, J. Brawn, Tavistock.

**RABBITS**.—First, — Merrifield, jun. Second, — Baker, Tavistock. Third, Rev. J. Wollocombe.

**CAGE BIRDS.**

**CANARIES** (Yellow Belgian).—First and Second, S. J. C. Blanchard, Tavistock. Third, — Rook, Plymouth.

**CANARIES** (Other Yellow).—First, J. Brawn. Second, T. Botterill, Grimstode.

**CANARIES** (Mottled or Fancy).—Prize, — Davy, Tavistock.

**MULES**.—First, W. Williams. Second, J. Truscott.

**GOLDFINCH**.—First, — Stanbury, Tavistock. Second, S. J. C. Blanchard.

**THRUSH**.—First, J. Acton, Tavistock. Second, — Fellow, South Sydenham.

**BLACKBIRDS**.—Prize, — Hicks, Tavistock.

**BEST COLLECTION OF CAGE BIRDS**.—First, T. Botterill. Second, J. Brawn.

**JUDGES**.—Messrs. E. Cornelius, J. Stannes, and J. Doel, Union Street, Plymouth.

**NOTES ON BIRDS OF PREY IN ESSEX.—No. 3.**

The Shrikes or Butcher Birds form a connecting link between the Birds of Prey and the Pies. But three species are found in this country, and one of them is migratory. Their food consists chiefly of the larger insects, mice, and sometimes small birds. They take their name from the fact, that though their beaks are very strong, yet their talons not being strong enough to hold their prey, as with the Hawks, they hang it on a thorn and thus tear it to pieces.

The *Blue Shrike*, or *Greater Butcher Bird*, is very rare, I never saw but two.

The *Woodchat* is about the size of the Song Thrush, in colour brown, with a very bright orange spot on the top of the head. It is so very rare that I never saw but one, and that was at Gilston, on a Christmas eve; it was perched on a thorn by the side of the river, and allowed me to approach very near to it.

The *Red Shrike*, or *Lesser Butcher Bird*.—This is somewhat smaller, is migratory, arriving here about the middle of May. The male is smaller than the female, and is a beautiful bird for its size. At times it is very noisy. One, which a little boy said he had found by itself, was once brought to me, and it was easily brought up. I had a large wicker cage made for it and it lived with me for nearly four years. All the anecdotes which I could relate of this pleasing intelligent bird would fill a small volume. It was so tame that it used frequently to be allowed to go about the house, and when it pleased would return to its cage of its own accord. It was very fond of mice, and when one was given to it it would hang the mouse on the hook provided for the purpose in the cage, and thus tear it to pieces. Like Owls, it would cast up the indigestible parts of its food; it was as true as a dog could be in giving notice of the approach of a stranger to the door, and knew my step when I came home, expressing its joy by its voice and gesticulations. It was ill for a week before it died, and when I saw it lying dead, my wife telling me at the same instant "he is dead"—

"Down my cheek a tear unbidden stole."

Birds of this species used to be frequent, but have become very rare. It is now the middle of June, and I have not seen one of them. This completes the list of all the rapacious birds which I have known in this district.—D. S. FRENCH.

**TAKING HONEY FROM FRAME HIVES.**

PLEASE state in your next the proper time and manner of taking honey from frame hives, with and without supers.—AMATEUR.

[Supers should be removed when filled, or in any case as soon as the honey season is over, which of course varies in different localities. They are taken from frame hives in the usual way. If the stock hive can spare them the two side combs may be removed in October, and the bees will probably winter just as well without them, as they are very apt to become mouldy if left in the hive. Great care and judgment should, however, always be exercised in depriving a stock hive of any portion of it. stores.]

**LARVÆ ON HIVE-BOARD**.—Yesterday morning I found the entrance of one of my hives, containing my first swarm this year, strewn with larvæ, which had apparently been dragged

out of the hive by the bees. Of what is this proceeding indicative?—F., *Westmoreland*.

[Such a wholesale expulsion of larvæ indicates a sudden and considerable fall of temperature within the hive.]

**DRIVING AND UNITING BEES—ATTACHING COMBS TO BARS.**

I HAVE two hives of last year, as well as a swarm, from which I wish to take the honey and put the bees into an empty bar hive. What would be the right time at which to perform the requisite operations, and at what hour of the day? Will you also inform me how I am to manage, as I am quite inexperienced? Of course I shall have to feed the bees throughout the winter. I also thought of taking a bar of honey from another hive, inserting it in the empty hive, and putting in an empty one instead. Should this be done before the union is effected or afterwards?

What is the best way of stupefying bees? and is it injurious to do so? likewise is it needful? I shall by feeding make up the weight of both hives to about 20 lbs., exclusive of the weight of the hive. That will be heavy enough, I suppose? The bees in one of my hives have begun to kill the drones, but none of the others.

If I attach pieces of comb to the bars will the bees eat them the food I give?—G. J.

[The operation may be performed as soon as the honey season is over. The bees should be expelled by driving during the forenoon of a fine day, as described in page 59 of the fifth edition of "Bee-keeping for the Many," and we should drive the inhabitants of two stocks into the same straw skep, leaving the third to be added afterwards, or to be formed into a second colony in conjunction with another condemned stock from some neighbouring apiary.

The bees having been expelled, the combs should be cut out, and sufficient brood-comb will probably be found to admit

of a piece being attached to every bar, which may be done by means of slips of wood and binding-wire, as represented in the annexed sketch. The hive being thus furnished, the bees may

be inducted into it by being knocked out of the straw skep on a cloth spread on a table or on the ground, and the hive placed on them, supported on two sticks about an inch in diameter, laid on the cloth some 8 or 9 inches apart. As soon as the bees have ascended, the hive should be put in its place, and the combs will be so rapidly fixed by them as to permit of the removal of all artificial supports at the end of forty-eight hours. This having been effected, copious feeding by means of an inverted pickle-bottle filled regularly every evening (or morning and evening, if you wish for more rapid progress), should commence and be continued until the combs are extended and the hive reaches the desired weight, which should not be less than 20 lbs. nett in October, and proportionally more if feeding be concluded earlier in the autumn. We believe that stupefaction injures bees. It is certainly wholly unnecessary. Any combs which you attach to the bars will either be stored with food or filled with eggs by the queen, whose breeding powers will be much stimulated by the process of feeding.]

**BEE-KEEPING IN WARWICKSHIRE.**

I AM glad to be able to say that my Ligurian stock, recently obtained from Mr. Woodbury, has prospered. I succeeded in getting an artificial swarm into a second frame hive, and as I only took one brood-comb from the Ligurians they hardly felt the loss. I used a very strong stock of black bees by removing, as recommended by him. The swarm soon became strong, and went to work vigorously, and I hope have raised themselves an Italian queen. I feared that the original Ligurians would have thrown a natural swarm this month (July), they were so strong, and I could not obtain another bar-and-frame hive, so I was at a loss how to prevent them; but I gave them a large bell-glass which they are now filling, and they also hang in a large cluster at the entrance.

The hive of black bees which I used to help in making the artificial swarm was a last year's swarm, and early this last spring I cut a hole in the top of the hive (a common straw one), and fixed on a board, and they have yielded me three glasses of splendid honeycomb, weighing from 6½ to 9 lbs. each. I have also had two large glasses well filled, each from a this year's swarm.

One of my stocks threw a small second swarm on the 9th of July, and as they had been filling a glass I was anxious to make them go back to their quarters again, but could not succeed in catching the queen, though I had them on the ground on a tablecloth, and turned them over while kneeling over them for fifteen or twenty minutes, and also put them backwards and forwards into a hive several times. At last they all clustered again, and I hived them in a large bell-glass, and last week I sent them to a flower show three miles away. As they had half filled their glass, and were not numerous enough to hide their white new-made combs, they looked very well, and, together with four glasses of well-filled honeycomb, formed a very pretty group, which was much admired and gained the first prize.

I intend selling all my black bees (six stocks), this autumn, and starting next spring with only the two stocks of Ligurians, and letting them swarm naturally, using straw hives, as the bar-and-frame hives are expensive and difficult to procure. I hope that any one who tries bee-keeping may feel as well satisfied and as much interested as myself.—S. B.

### THE EGYPTIAN BEE.—PART III.

ITS ACCLIMATISATION IN THE NORTH OF GERMANY.

(Continued from page 94.)

HERR VOGEL next discusses whether the Egyptian bee is more sensitive in rough weather during summer than the northern and Italian varieties. In reference to this question he says—"Although the average annual temperature of a country or place is all that is generally stated with regard to its climate, it is not sufficient merely to quote the medium annual temperature of Egypt and North Germany, in order to judge of the probability of the successful acclimatisation of the Egyptian bee, but a statement of the average temperature of shorter spaces of times becomes necessary. We will, therefore, compare the temperature of Egypt and North Germany for the first five months in the year, according to Réaumur's thermometer.

	January.	Feb.	March.	April.	May.
Cairo (30° N. lat.) . . . . .	16.60	10.72	14.48	20.40	20.56
Berlin (50° 20' N. lat., and 31° east long.) . . . . .	10.92	13.94	15.04	14.43	11.75

"Between the temperature of the winter months at Cairo, and the summer months of Berlin we find a difference of but a few degrees. In Cairo the thermometer in winter sometimes falls as low as 3° below zero of Réaumur, but only for a short time. The chief harvest time of the Egyptian bee in its own country is during the coldest months of the year, from January to March. In May the harvest is finished in the lowlands, and many districts in Egypt then look like a dead desert. The Sheharaki districts only, which in consequence of artificial watering give three harvests annually, furnish occasionally some pasture for the bees. In districts in Germany which are poor in honey, the chief gathering takes place in May, June, and July, and these months have the same temperature as the Egyptian winter. The Egyptian bee is, therefore, quite at home in our summer—as happy as 'the little fish at the bottom of the sea.'"

"At from 10° to 12° of Réaumur (55° to 60° Fahrenheit), the Egyptian bees are in full flight, at which temperature our native bees generally only begin to take wing. When the bees of an Egyptian stock begin to fly, it is not only a few single bees that fly out for some time, but the whole stock is immediately in full flight. The Egyptians always rush forth from the entrance like ants from a hole made in their nest. During mild days in November the Egyptians carried in pollen and honey, and came home in full flight, whilst only a few single bees of the other species were to be seen. I never saw Egyptians chilled. A German or Italian bee is very soon overtaken by an Egyptian bee in a race; the quickness of the children of the Nile, is, however, most apparent in the queens. A fertile German or Italian queen walks but slowly and heavily on a comb, whilst an Egyptian one runs as quickly from one

side of the comb to the other as the comb can be turned round. Great activity, quickness, and agility are the general characteristics of the natives of warm countries, and by this observation in natural history, the above-mentioned peculiarity of the Egyptian bee may be explained.

"During the hot season in Egypt the thermometer stands at 26° to 30° R. (92° to 100° F.), in Upper Egypt, even in the shade, 30° to 34° R. (100° to 110° F.). Cairo has an average temperature of 22.96° R. in June, 23.92° in July, 23.92° in August, and 20.96° in September. One might suppose, therefore, that the Egyptian bee would continue to fly out and to work in Germany even in the greatest heat, because it must have been accustomed to as great a heat in its native country. Such, however, is not the case. The Egyptian, like the northern and Italian bees, cease working when the temperature of the interior of the hive has reached about 30° R. (100° F.), and like them they remain inactive, some on the combs and inner walls of the hive, and some outside the entrance. If the bees were by their activity still more to increase the temperature of the interior of the hive, the waxen combs must soften and fall down. The inactivity of the bee, therefore, during very great heat in the interior of the hive is evidently an effect of instinct. In Egypt, also, the bee is inactive in the hot season, for the country is then bare of flowers.

"THE EGYPTIAN BEE IN THE WINTER OF GERMANY.—In Egypt the bee is able almost every day to hum joyfully through the air; but Germany has a winter in which the temperature not unfrequently falls to 20° or more below zero of Réaumur, and the cold keeps the bee imprisoned in its hive. Already before the actual introduction of the Egyptian bee, the question has been mooted whether the hive bee of Egypt could survive our severe winters. From the beginning I believed the Egyptian bee capable of wintering here, and I supported my opinion by the following passage from 'The Acclimatisation Journal,' for 1864, page 40:—"The genus Apis has a very peculiar nature—i.e., all the species, including the different varieties, of Apis have a similar and unchangeable nature and manner of living." Let us consider, then, that the genus Apis lives in permanently organised societies, and in this forms an exception among the class of insects. Humble bees' and wasps' societies are dissolved in autumn; the fertile females only hibernate during winter and survive till spring. Our ants also certainly live in lasting communities, but at about 1° R., they likewise hibernate, and the genus *Termes*, which belongs to warm climates, is not to be compared with the bee. The bee does not hibernate, it only passes into a state of rest in winter, which state is evidently conditional upon the want of that degree of warmth which is necessary for its activity. Any organic cause for the winter's rest of our bee does not exist, as it prospers equally well between the tropics without any rest in winter. The specific or personal temperature of an individual bee is very low indeed, yet the whole society in the hive produces a higher temperature, which may be felt. According to experience, the production and supply of animal warmth is intimately connected with the process of breathing and nutriment. The bee possesses a trachean system like no other insect known to Leuckart (*vide* Von Berlepsch, 'The Bee and Bee-keeping,' page 188). The more severely the bee is attacked by cold in winter, the more food it consumes, and the more it accelerates its breathing, until by actual roasting it produces that degree of warmth necessary for its existence. The extremity of the abdomens of those bees which hang on the outside of the cluster often come very near to the hoar frost in the hive, whilst in the heart of the cluster there are from 9° to 12° of warmth.\* It is universally acknowledged, that the lethargy into which our bee falls in winter, is contrary to its nature. Likewise it cannot be disputed that the winter of Germany is contrary to the nature of the Egyptian bee; it will, however, survive our winter just as well and just as badly as our northern bee, if it be kept in hives which afford shelter against too great cold. The genus Apis belongs to the cosmopolites among animals, and is able to prosper in countries the seasons of which have an extreme climate.

"Dr. Buory also states from experience, in 'The Acclimatisation Journal,' (1863, pp. 295, &c.), that a transplantation of animals from warmer to colder countries is more frequently successful than unsuccessful.

"The Egyptian stocks are quiet in winter. During only the most severe cold (3rd and 4th of January), they caused a low humming to be heard, just like the German and Italian stocks.

\* "Wie's Fischlein auf dem Grund."—Göthe.

\* 53° to 59° Fahrenheit.

It may also well be supposed that the trachean system of the Egyptian bee will be strengthened by a greater activity during our winter. On the 16th of this month (January, 1865), the bees of an Egyptian stock were flying quite strongly at 4° in the shade, and 9° R. in the sun, between 10 and 11 o'clock in the morning. No bee got chilled, and no sign of dysentery could be perceived. I could not suppress my curiosity, and opened an Egyptian stock. When I merely looked over the floor of the hive I was greatly delighted, for but a few dead bees lay there. The stock was perfectly healthy, and the queen, with her abdomen full of eggs, paraded the combs as if in summer. In two hundred to three hundred cells, eggs and larvæ were found. To-day (January 28th), at noon some bees were seen at the entrances of all the stocks, and in the Egyptian stocks also there is as yet no trace of dysentery. These observations speak strongly for a fortunate wintering of the Egyptian bee."

I may here add, that Herr Vogel's favourable anticipations were completely verified. His Egyptian protégées passed the ordeal of the German winter of 1864-5 unscathed, and were introduced into my apiary rather late the following summer, with what result will in due course be related by—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

### REMOVING SUPERS—DRIVING—WOODBURY HIVES.

I HAVE eight stocks of bees in an old straw hive, and one, or rather two, swarms which I put together in a Stewarton hive, where they are working away most beautifully and peaceably. The super is now nearly filled with honey, but the cells are not yet sealed-up. How soon may I take that away? and am I to put on another on taking that off? The hive is now three boxes in height. I notice a good number of, I think, young bees out the last few days on the landing-board, and I fear putting a fourth box under the brood one lest it may prevent stinging going on in the super; and though the bees are out, I think it is not through want of room, but excess of heat.

I would wish much to avoid destroying the bees for their honey, and as I purpose next year working the Woodbury hive, would you say, drive the bees to be deprived into the old straw hive, feeding them during the winter, putting all the swarms from the stocks into Woodbury hives next year; or should I drive into Woodbury hives? If I should do the latter, I can have them made at once.

I never drove a hive in my life, but hope to learn; so if I drive a quantity equal to a good swarm (and if there is brood in the hive, the nurses will, I understand, stop to mind that), will not the little colony be so weak as to be at the mercy of their stronger neighbours, honey, not swarms, being my object now? I am particularly anxious to know the system of driving theoretically before I practise it.

I do not know the meaning or use of the adapting-board in the Woodbury hive, and I would wish to understand its use before having any hives of that description made; and though they may be difficult for a beginner to manage at first, do you not consider it the best hive for all practical purposes?—JOHN J. SMYTH, *Rathcoursey*.

[We doubt whether the bees will, so late in the season, seal over the cells which still remain open in the super; but you must form your own opinion on this, and also as to whether the honey harvest is over in your locality. If it be so, and we should deem it probable, the super had better be removed at once, and temporary room may be given to the bees, should they require it, by nadiriug. In driving a stock of bees do not attempt half measures, but drive all or none. In your case we should drive the inhabitants of two adjoining common stocks one after the other as rapidly as possible into an empty straw hive, then cut out the combs and fit such of them as contain brood into the Woodbury frames, temporarily securing them with zinc clips, binding-wire, slips of wood, &c., as ingenuity may suggest. It will go hard if out of two hives you cannot furnish at least six, and perhaps eight or ten, frames with worker combs (drone combs should, of course, be rejected), containing more or less brood as well as some honey, and yet contrive to retain the lion's share of the latter for yourself. Having thus, either wholly or partially, furnished their new habitation, the bees may be inducted into it by being knocked out on the top of the bars (the crown-board being removed for that purpose), or on a cloth spread on the ground and the hive placed over them, resting on a couple of sticks about an

inch in diameter, and laid down on the cloth 8 or 9 inches asunder. As soon as the bees have ascended they should be put in the place previously occupied by the old hives. At the expiration of forty-eight hours all artificial support may be removed from the combs, and the stock should then be fed up to a sufficient weight to stand the winter. The adapting-board of the Woodbury hive must be substituted for the crown-board whenever a super is put on. We believe it to be the best hive for any bee-keeper who aspires to become also a bee-master.]

### BARS OF WOODBURY HIVES—PUTTING IN GUIDE-COMBS.

Why should the bars in Woodbury hives be made to separate from the frames? Would they not be better if fixed to them? I think they would. What are they left loose for? and should guide-comb be attached to every bar before putting in a swarm? Would rubbing the bars with beeswax be sufficient, as guide-combs cannot always be had? I am making a number of Woodbury hives for my apiary.—S. H.

[Mr. Woodbury, in the description of his frame hive, which appeared in page 73 of our third volume, states that he has found the power of separating his bars from their frames very advantageous, in enabling him to use frames in stock hives and bars in supers without forfeiting the advantages arising from the unlimited interchangeability of every comb in every super in the apiary; and we may add, that we know other scientific apiarians who, having commenced with the ordinary frame, have, in order to obtain these advantages, afterwards adopted what Mr. Woodbury has styled his "compound bar-frame." Use as many guide-combs extending to as nearly the entire length of the bars as you can procure. These may, however, be eked out by being alternated either with the ribbed Woodbury bar or with flat bars, to which are attached strips of artificial comb. Rubbing the bars with beeswax is of little or no use.]

### SPARROWS EATING LIVE BEES—LONGEVITY OF BEES.

NOTWITHSTANDING the doubts of one of your late correspondents, I have had again, for the third time, to make a raid upon the sparrows' nests round my dwelling, to prevent their young being fed with living bees from my apiary. So determined, however, were they at this work, that in a day or two afterwards I detected one cock bird over and over again flying up at the hives like a flycatcher, and carrying off bees returning to their homes heavily laden, and with them he was feeding in a neighbouring bush two young birds, sufficiently fledged to have escaped from the nest. He at last brought them down close to the hives, so as to save himself the trouble of a fight to and fro, and set to work in a most determined manner. This was too much for my philosophy, so calling my gardener we had only to wait about five minutes, when back he came again, and he was then and there shot, *in flagrante delicto*, and I only hope that his two children will learn a salutary lesson from their parent's fate. Another couple detected in the same act shared a similar fate, since which I have not been troubled. I cannot help thinking that a bee-eating sparrow is like a man-eating tiger in India, which, having once tasted a forbidden food easily obtainable, can only have the fatal propensity destroyed by death.

With regard to the life of the working bee, particularly during the working season—say from April till August, I think it is very short, rarely exceeding two months. In proof of this a singular circumstance happened to one of my hives containing Ligurian bees, obtained in May from Mr. Woodbury, which I will here relate. On the 1st of June I had a prime swarm from an ordinary stock of black bees, which had hardly settled in an adjoining hedge, when my only Ligurian hive unexpectedly threw a swarm, which at once joined the other. As I was absent at the time in the City, my gardener was afraid to live them together, irrespective of the chance of being stung, as they were evidently in a state of great excitement. On my return home, I after some difficulty got them into a large hive, having first captured the Ligurian queen, whose person during the operation I could not mistake from the large size and golden colour of her body. I then determined to return the united swarm to the original Ligurian stock, which I did during the evening (a process which I have always performed

satisfactorily without any fighting, many times during successive years, simply by giving three puffs of tobacco smoke to each swarm to be united, and so making them all smell foully for the time). I, of course, put on a large straw top, otherwise they could not then all have found room, and looked forward to at least 50 lbs. of honey from this immensely strong hive. As it was, however, they now managed by dint of squeezing to keep nearly all in the centre box, and though I had guide combs in the super, they did not extend them, evidently bent on not remaining. I looked out the next afternoon and evening to see which queen was turned out dead, as I have almost always found one on the ground in this plight within twenty-four hours, but could see nothing of her. On the 9th of June at eleven o'clock, the whole united mass swarmed again, and such a swarm I never had in all my experience. They tried to settle on two or three shrubs and trees, but all the houghs gave way, and the whole mass kept falling to the ground; at last they went into a hedge, which sustained them, and they were lived in a large straw cover ready at hand.

On examination I found that the Ligurian and common bees were so intermingled, both in the swarm, and the stock from whence they came, that it was impossible to state which was Ligurian and which not. Now, also came the question, Which has the Ligurian queen? I thought this a good opportunity to test the respective ages of each sort of bee, should it so happen that the old Ligurian queen remained in the stock, and the common queen with the swarm, or *vice versa*. I therefore put the combined swarm into a Stewarton hive, and on the next stand to the Ligurian, so as to afford the greatest facility in watching. At first I noticed that the swarm was pretty equally divided between Ligurian and common bees, perhaps, if anything, the former being in the majority. As regards the stock, I should say the Ligurians were as five to three, a decided majority. Both worked well, and considering the comparatively empty state of the stock hive immediately after swarming, it was wonderful how rapidly the latter increased again in numbers. Within three weeks I began to notice in the stock that the common bees were dwindling away, although in the swarm they were still about equal. Within the month the stock became five to one in favour of the Ligurian, and the swarm then began to show three or four to one in favour of the common bee, and I could easily see in the swarm numbers of the young black bees daily coming out on the alighting-board. In a similar way I could see in the stock the young Ligurians. This at once showed to me that the old Ligurian queen had remained in the stock hive, whilst the old common queen had led out the swarm. Within five or six weeks the relative proportions rapidly became twenty to one in favour of the Ligurians in the stock and ten to one in favour of the black bees in the swarm, and so on, until last Saturday (July 28), I could not detect a single black bee in the Ligurian stock, and only six Ligurian bees in the swarm, after half an hour's close watching at the entrances in the middle of a fine working day, when the bees were out in great numbers. I may add that the six Ligurians which I saw were almost worn out, their wings being ragged, and their bodies showing that peculiar dark look indicative of old age.

Both stock and swarm are very strong in bees, the latter having filled a super of about 20 lbs. of honey, which I shall shortly take off. What has become of the Ligurian in the one case and the common bees in the other? It is quite clear that they have all died off, and their places been supplied by young bees; for there is no diminution of numbers, but rather the reverse in both cases. It also follows, of course, that if the Ligurians in the one case, and the black bees in the other, have gradually and visibly died away, their contemporaries in each case, *pari passu*, must have perished too; the result is, therefore, that at all events during the working season, the whole hive is renewed within two months!

Another fact is also proved—that the duration of life of the Ligurian and common bee is about the same. Now, it does not follow that the age of the bee is always limited to two months; on the contrary, during the late autumnal and winter months, when little or no hatching of eggs can take place, I expect that the bee may live four or five months, as there is then little or no wear and tear, and their flights are limited to the neighbourhood of the hive; but it is quite evident that during the working months the mortality is immense, and only repaid by the great fecundity of the queen bee.

From the little experience which I have had of the Ligurian bee, I should say that the queens of this sort are decidedly more prolific than those of the common bee, as the increase of

population in the stocks of the black bee which have swarmed is not nearly so large as that of my Ligurian stock. The latter also seem to carry into the hive twice the quantity of farina on their legs as compared with the other sort—a sure sign of extensive breeding.

Allow me to add that, as a whole, I consider this season to have been a bad one for honey. Our main resource here is the Limes, which, although well flowered, soon withered, owing to the excessive heat of the direct rays of the sun. The white clover is now their last resource, but it is not so abundant as last year.—A BLACKHEATH'AN.

## OUR LETTER BOX.

**FEEDING FOWLS—PRESERVING EGGS IN LIME (J. R. B.).**—Nothing can be so injurious to fowls as feeding from a trough. Their own excrements, if they are healthy, will not be picked up to an injurious extent; anything else is hecfeical. We believe that food thrown down, mixed with earth, is better than clean corn. Fowls have no teeth. Our feeding will be cheaper than the trough, which is extravagant. The lime should in the first place be mixed stiff enough to cause an egg to stand upright in it. When poured over them it should, when dried, form a perfect crust. Lime water would be useless.

**AYLESBURY DUCKS (Aylesbury).**—Ducks begin to lay at eight months old. Except in case of accidents, to which they are liable, drakes begin to be useful at the same age, and are good for three or four years. We have known a drake perfectly useful at six years old. We cannot define "pulse."

**GAME CHICKENS UNABLE TO STAND (J. H.).**—The first symptoms you describe are those of great weakness, and may arise from insufficient or improper feeding, or from overgrowth. It is more frequently met with in cocks than pullets. Cochins and Spanish are subject to few if any ailments. If all your birds are kept precisely under the same circumstances as to food, liberty, nature and construction of roosting place or house, then there is only one conclusion to arrive at—it is hereditary in the strain of the cock, although he himself suffers not from it. He must be changed. As these symptoms may, however, be caused by cramp, which does not interfere with the appetite, and which may arise from a wooden, stone, or brick flooring, if such exist, remove either the flooring or the birds, and you will, we believe, find the cure. The best treatment for those affected is to feed them solely and plentifully on stale bread soaked in strong old ale.

**CRYSTAL PALACE POULTRY SHOW (M. B.).**—The shows at the Crystal Palace have been discontinued for some years. We have not heard of any intention to resume them.

**POULTRY RESULTS—CROSSING FOWLS (Two-years Subscriber).**—Your result is a very good one. Five hens in ninety-one days laid 249 eggs. Our opinion is, that it is in every way better and more profitable to keep pure than cross-bred birds. Such a cross as you mention, Cochins and Spanish, must be a mistake. The Cochins could not improve the breed of the Spanish. One is a broody hen, the other never sits; one lays a large white egg, the other a small brown one; one has a blue, the other a yellow leg. The object of a cross is to develop some particular point or quality in a bird, by obtaining a cross from one that possesses it or them in a large degree. Thus, if a particular strain of Game is losing its courage, ferocity, hardness of feather and hone, a cross is at once sought with the Malay, because it possesses all these qualities. Grey Dorkings would seem to do well with you, better than any of your crosses. If you mean to cross, never put sitters and non-sitters together. Game and Dorking make a much better cross than Game and Cochins.

**PIGEON APOPLECTIC (Jero).**—Your Fantail cock seems to be suffering from apoplexy. Do not let him have any hempseed. Give him a pill containing one grain of calomel; repeat the dose for two or three successive nights, and then purge him with castor oil.—E. P. B.

**POWTERS WITH FOUL BREATH (Amateur).**—If you examine the months of your Powters you will probably find cheesy-looking lumps, which contain matter causing the disagreeable odour you refer to. Remove the matter by scraping it away with a small wooden spatula, and rub the place thoroughly with caustic. Give your birds freedom, and put fowlers of sulphur in their water.

**BULLFINCH ASTHMATIC (Tolchard).**—Your Bullfinch appears to be asthmatic. Do not give it any hemp or rapeseed. Let it have bread and milk, and lettuce, chickweed, and groundsel; also put some Spanish liquorice in its water. Do not cut the tongue.—E. P. B.

**SISKIN (Miss Hughes).**—We suspect you have fed your Siskin on food that was too stimulating, such as hempseed and rapeseed. Confine the birds more to canary and millet, giving them occasionally a little mawseed and plenty of green food. Keep a piece of sulphur in their water.

**BREEDING MEALWORMS (E. S. C.).**—Mealworms are the young of the common black beetle (not cockroaches, which are often called black beetles). If some of them are put in a tub with some meal they will lay eggs, and these will hatch into the much-coveted mealworms for feeding cage birds. Almost any miller or baker can provide some for stock, but they do not like acknowledging them.—E. P. B.

**MULE CANARIES BREEDING.**—Some time since I wrote to you respecting Canary Mules breeding. I have now five young birds from a cock Canary and a Greenfinch hen Mule, very strong. The hen is again sitting on five eggs.—W. B. H.

**SILKWORMS (J. S. Torquay).**—Your management of the Silkworm hitherto has been perfectly correct. Whenever the grubs show a disposition to spin, put them into a small bag of paper made by twisting it in the form of a grocer's sugar-paper, and fix these against a wall or upright board with pins. In due course the moth will come out, and, after laying its eggs, die. The eggs are to be preserved all the winter, and then in the following summer they will be hatched, when you have but to repeat the process which you have gone through this season.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 73.0; and its night temperature 51.1. The greatest heat was 92°, on the 18th, 1842; and the lowest cold 38°, on the 18th, 1851. The greatest fall of rain was 1.12 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ON THE VARIEGATION AND CROSSING OF PELARGONIUMS.

It is pleasant to see a curious and difficult subject taken up with the earnest and fresh-minded enthusiasm of Mr. Wills. Years of close observation and close reason-

ing, however, combined with scientific accuracy, have yet to be gone through before he or any one else can throw much light upon this mysterious subject.

Until of late, when the taste for variegated plants has provoked experiment, variegation was supposed to be non-transmissible by seed, and this must still be considered the rule, and the contrary the exception. It is probable that most of our variegated Geraniums are sports, but it is certain that some have been raised from seed; to what extent I know not, but I have raised several myself, which were symmetrically marked from the seed leaf to the perfect plant. It is much to be desired for the interests of science that the originators of these variegated Geraniums should come forward and state their origin. Trade secrecy in these matters is in these times happily ignored by our high-caste nurserymen, now a highly educated and intellectual class of men, and I hope this appeal may not remain long unresponded to. Amongst other curious assertions is the following—viz., that a green-leaved sport from a variegated plant will again sport, but into a fresh form of variegation—golden, for instance, instead of silver. This wants confirmation.

With regard to Mr. Wills's seedlings, I do not think foreign pollen had necessarily anything to do with the matter, as the same phenomenon occurs when the accuracy of the experiment has been actual. Moreover, whether the variegated plant be the male or female parent, much the same per-centage of green and of variegated plants will appear. The strength of constitution is always in inverse proportion to the variegation, being greatest in mottled and irregularly marked plants, less in the rarer case of symmetrical or true variegation, and nil in the case of pure albinos, which I have never known to perfect a rough leaf. On examining a large number of seeds of Flower of the Day many years ago, I observed four types of seed—viz., robust green, striped green, colourless, and a modified or brownish green. The green seeds produced green plants; the striped, often seedlings of which one cotyledon was green and the other white; the colourless seeds came white; while the fourth description produced plants variously marked with white, and occasionally true variegations at once. The mottled plants threw true variegations from the part of the stem just above the place where the cotyledons existed, as observed by Mr. Wills. The green ones

remained green, but would probably have sported sooner or later.

The striped form of colour is a very curious subject, and well worthy of observation. The stripe may be traced running up through the stem from its origin, through the flower-stem, thence to the pedicel and bract, and finally into the seed itself, sometimes affecting two or three pedicels in a group, sometimes striping a single pedicel. Symmetrically-marked shoots never appear on a striped branch, in which case they are either green or white entirely, as far as I have observed. In the lower and more ripened part of the stem the two colours seemed to be more fused, and disposed to an equal development. There is also a visible difference in colour between wood which is likely to throw variegation, and such as will develop itself in purely green experiments.

In some early experiments of my own I found that the pollen of Golden Chain tinged the seedlings of green-foliaged plants plentifully with different shades and markings of yellow. The per-centage of such seedlings was rather large, and one came perfectly variegated from its birth. When this is the case the cotyledons are striped with the yellow or white colour down the midrib of each. The plant alluded to was a slow grower. I gave it to a friend in the nursery business, and never heard what became of it.

With regard to the pollen question, there is a great difference in plants as to their capability of becoming fertilised by the pollen of other plants in their neighbourhood; some seem absolutely to refuse it, while others can hardly be kept true when this, as in culinary plants, is desirable. The Geranium, certainly, when placed in proximity with other Geraniums, is liable to be fertilised by their pollen, and this, when one would think they could scarcely escape the influence of their own. Of the agency of insects in this matter there can be no possible doubt. On the other hand, I am now working at a genus of plants profusely supplied with pollen, which I grow in large numbers under glass, and in the course of five years have never observed an accidental hybrid. Whether fertilisation is effected to any great amount by floating pollen under glass I do not know, but I may suggest the following nearly crucial experiment:—Wet a pane of clean glass with glycerine, wave it in the supposed pollenised air, or let it remain there for some little time. The presence of pollen grains may then be easily detected under the microscope.

The electrical question is altogether too deep for me, although not a new observer. Such matters call for a peculiar line of investigation by very experienced hands, upon rigidly accurate principles, carried out with previously-acquired and real knowledge of the subject. The contrary leads to burying electrical wires in Wheat fields, and printing great results which occurred in consequence of the feat, without recording the quantity of manure put in at the same time, or noting any one phenomenon of any kind occurring between the seed time and harvest of the experimental crop.

As an old hybridiser, I will venture to suggest to Mr. Wills and other labourers in this field, to work upon but

few subjects each season, and to seize upon every circumstance tending to secure isolation. For instance, the plants to be experimented upon should be brought into flower as early in the season as possible, and only one or two worked upon at a time. There are several great advantages in this. When there is not too much to think about, the operator, as well as the plant, is in a beneficial state of isolation. When the real growing and flowering season of the year comes on at a later period, and multitudes of plants are bursting ungovernably into flower all around us—when no hand however quick, or eye however vigilant, can stamp out the general outburst of foreign pollen influences—when the mind is distracted and confused with the desire to take advantage of the profusion of subjects, without the leisure to attend to them all properly—no very accurate results can be expected. A temporary occupation of the mind elsewhere, or a short absence from home, may vitiate the labour of weeks, and, in fact, often does so.

Small plants of Geranium in their first shift from the cutting-pan seed very kindly in a little heat in the spring, and more especially on the first blossoms of the first truss produced. Moreover, in this case the flowers are often antherless, which is a great and real advantage, provided we have the desired pollen at hand.

The hybridist should never be without a hand-magnifying glass, with which he can often at once set his mind at rest with regard to accidental or insect-borne impurities of pollen. After all, there are strange and inexplicable occurrences met with occasionally in the matter, and so the internal evidence borne by a truly intermediate seedling is all that, at any rate, the practical man can with any certainty look to.

In the matter of variegated produce from variegated plants my own experience is but small. A Candytuft in my garden produced several generations of variegated plants; they were, however, distorted unhealthy things. I have met with others, but cannot at this moment call them to mind. Mr. Wills's instances were very interesting to me. They confirm the general disposition to lose constitution in proportion to the accession of albinism.

The splendid great scarlet Geranium, known by several superb and imperial names, now rarely seen except against the back wall of some old conservatory, is very shy to seed, but I should greatly like to see it made use of as a breeder. I seeded it in the open air late in autumn two years ago. Six plants came up, one rather better than the parent, and one more stocky: these I have kept; the rest were not so good as the old plant. Its pollen seems good, and is plentiful.

In conclusion, I beg Mr. Wills not to consider these remarks as conceived in a spirit of criticism, but as provoking and looking for a system of friendly scientific discussion and mutual enlightenment, which I could wish to see far more cultivated in the pages of yours and other high-class journals.—C.

#### AMONG THE SCOTTISH BRAES, LOCHS, AND MOUNTAINS.—No. 1.

I SHRINK from talking in a railway carriage, for I'm deaf, and my hearing-horn brings in such a mingling of words and tramroad rattle as almost to cause a brain-convulsion. So I sit in a corner well supplied with periodicals; and when weariness of eyes compels I close them, shut myself up, and shut out my companions. Whilst journeying hither I was quite successful in so excluding until Carlisle was reached, and then an elderly man with ruddy cheeks and bright brisk eyes came among us. He would talk, and would joke; and I hated him, until the following testified that he was "as weighty as witty." He nudged me, made me listen—and I omit my interlocutions from the summary—"You've THE COTTAGE GARDENER there. I've just written to them about a bit of land I have, for I should like to know whether it's just as much as it was in Edward the First's time. I have a copy of the oldest deed about it, which says, '*Continet 8 acras in campis Doncastric.*' We make it out twelve acres. THE COTTAGE GARDENER people say that what an acre was in those days no one has told, but that in the British Museum MSS. it is stated in the fourteenth century, 'A plough can commonly plough one acre per day, and sometimes more.' Well, they used oxen then, and now a pair of those beasts can plough one of our acres; so I suppose my foregoers cribbed somewhat out of the waste. Then the COTTAGE GARDENER'S people go on to talk about land measure and forty rods making a furlong; but at our school I found a different measure, for there one rod made

an *aker!* That 'furlong,' what a curious corruption that is! By the '*Statutum de admensuratione terrarum*' it was fixed to be forty *pertica* or perches of 16½ feet each, and it was called *quarantena* or *Forty-long*; so there's the parentage of our *Fur-long*."

Carlisle, however, must not be passed from without other notices; and first, as most appropriate to these pages and to the credit of the old city, let me record that the fruit and vegetable market, though held, as it should not be, in the open air, is well supplied. I never saw such a series of quart basins full of Raspberries; such large Black Currants, a fruit I would gladly see elevated into bunches more numerous berried; nor six and thirty carts in a row filled with Potatoes, and their contents retailing from scales, with which each was furnished, suspended from an iron bracket fixed to the cart's side.

Then there are the ruins of the Castle—the first English prison of Mary Queen of the Scots. Whether she was more sinning than sinned against is as doubtful as it is now whether she was beautiful or the very reverse, after seeing her many portraits in the National Collection at South Kensington. Even if she was so superlatively bad as some maintain, still she was unconvicted when at Carlisle, and yet she had no other place for exercise there than the wall-encirched space still designated "The Lady's Walk." There were no castle gardens in those days; and she might well say for a more sorrowful reason than that, "Would I were among the Heather!"

However, here lies (I am now in the cathedral aisle), he who, even after having two wives, has left as his testimony, "It is a happy world after all." Yes, beneath this slab rests William Paley, whose "Natural Theology," "Evidences of Christianity," and "Horæ Paulinæ," still stand forth unconquered wrestlers for the truth when the show unsubstantial shadows of German theology have long since ceased to deceive. He has touched slightly in his published writings, and more, I have heard, in manuscripts still unprinted, upon the plants of the ancient world; but the researches were but shallow in his days, and every year now brings light to us from previously unthought-of sources. Who ever suspected, a few months since, that the bricks of Egypt's pyramids would reveal to us some of the plants of the days of the Pharaohs? Yet true it is that they have made that revelation. Professor Unger has just shown, in a communication to the Vienna Imperial Academy of Sciences, that those bricks contain evidence of the plants existing at the time of their making. He has examined a brick from the Pyramid of Dashour, which was constructed between 3400 and 3300 B.C., consequently at the lowest calculation it is more than 5000 years old. In that brick he found the forms of plants so perfectly preserved that he had no difficulty in identifying them. Besides two sorts of grain, Wheat and Barley, he found the Tef (*Eragrostis abyssinica*); the Field Pea (*Pisum arvense*); common Flax (*Linum usitatissimum*); wild Radish (*Raphanus raphanistrum*); Corn Chrysanthemum (*Chrysanthemum segetum*); Wartwort (*Euphorbia helioscopia*); Nettle-leaved Goosefoot (*Chenopodium murale*); Bearded Hare's-ear (*Bupleurum aristatum*); and the common Vetch (*Vicia sativa*). The presence of chopped straw confirms the account of the brick-making mentioned in the Book of Exodus and Herodotus.

So there are "sermons in bricks" as well as "in stones," and, as certainly, "good in everything;" and not the least of that "good" is to be met with at Carlisle's "County Hotel." No traveller can leave that hostelry without regret, and none the less if he is to be "over the Border," as I shall be when I next write.—G.

#### VIOLA CORNUTA.

WOULD Mr. Wills say what is to be done with young plants of *Viola cornuta* raised in pots, and now 2 or 3 inches high? They are healthy, but I see no signs of flowering. They were up early in spring, and kept in the greenhouse till the hot weather, when I placed the pots in the open air. Will they bloom this season, and what am I to do with the plants in autumn?—M. K., Bristol.

[You have kept the plants too long in the greenhouse; if you had planted them out three months ago they would have been in beautiful bloom now; lose no time in planting them out. As the plants have stood so long in pots the roots must be carefully disentangled. Turn the plants out 6 or 8 inches apart in good soil, and you will soon have plenty of bloom on them, if you have the best variety. There are three dis-

tinct varieties of *Viola cornuta*; two of them are worthless, being mere weeds in comparison with that which I had the pleasure of bringing into public notice. I find that I have not said a word too much in its praise; last week I saw it in great perfection at the Deubies, near Dorking. I sent my friend Mr. Drewett a few small plants of it last autumn. In the spring he placed them in heat, where they grew very freely, and, to judge from the quantity Mr. Drewett has planted out, it is as easily propagated as a *Lobelia*. Mr. Drewett considers it one of the very best bedding plants at present in cultivation; he tells me it is a great favourite with his employer, and that all who have seen it pronounce it to be a decided acquisition. Here, although we have had constant rains, with very high winds, for the last ten days, the plant looks as bright and beautiful as ever. It had the same appearance during the dry weather which prevailed during the first fortnight of July. "M. K." should take cuttings about the first week in October, and prick them out on a piece of good ground. Having first made the surface of the soil smooth and even, he should spread a thin layer of sand over it; and then the cuttings, which should be from 2½ to 3 inches long, may be pricked in at about 2 inches apart. In doing this care should be taken to make the soil firm about the base of the cutting. After all the cuttings have been put in, give the bed a good watering. This will settle the sand around the cuttings, and hold them firm in the soil. Afterwards they may be left to take their chance, and in spring they will be nice plants ready for planting out in their permanent quarters, where they will soon gladden the eye with innumerable beautiful mauve-coloured flowers. If the position chosen for the cutting-bed is a little sheltered from cold cutting winds, the plants will grow much earlier.—  
J. WILLS.]

#### ZONALE AND NOSEGAY PELARGONIUMS.

At the season in which bedding-out plants may be considered at their prime, a few remarks on one of the most decorative and useful—the scarlet or Zonale Pelargonium, may not be out of place, more especially as the question is so frequently asked, Which are the best and most distinct sorts, which most fit for pot culture, and which for bedding-out purposes?

Two very interesting articles on this plant appeared in the *Journal* of July 24th, by Mr. J. Wills and Mr. J. Pearson; one article headed, "Bedding-out Pelargoniums," the other, "Variegated Geraniums." Now, it is evident that both these writers are discussing the same plant but using different names, in the use of which one or the other must be wrong. Beyond all doubt it must be allowed that there is a wide botanical distinction, and this distinction should settle the name. Pelargonium is the proper and only name for the plant in question, the Geranium being entirely distinct in many ways, which I need not dwell upon to explain. If the section of which I am now writing were spoken of as Zonale or Nosegay Pelargoniums, as the case may be, no difficulty could arise in understanding what was meant. Many of the readers of the *Journal* will remember the time (not many years since), when it was the careless habit of gardeners and others to call, or rather misname, the *Tropæolum* as *Nasturtium*, there being quite as great a botanical difference between these plants as between the Pelargonium and Geranium. However, time and good taste have corrected this error, and we find the proper name, *Tropæolum*, the more commonly used.

In making the following remarks on the Zonale section of Pelargoniums I shall subdivide them, and speak of them as Zonales with plain or zoned foliage, variegated Zonales, and Nosegays: by doing this I think no misunderstanding can arise. In selecting the following varieties, I would by no means wish it to be understood that I condemn all others; there may be many equally good, though I am certain not better.

Among the scarlets with plain or zoned foliage for bedding-out purposes, I can strongly recommend Faust, Punch, Clipper, Achilles, Brilliance, Monsieur G. Natchet, Trentham Scarlet; St. George and Red Dragon, two of the darkest shades of scarlet; Red Riding Hood, and Adonis, the last two conspicuous for the white centre of the flower, with very dark-zoned foliage.

In the shades of lighter scarlets, approaching salmon and rosy tints, I recommend Volcano, Excellent, Roi d'Italie, Provost, Lucius, Persian, and Herald of Spring.

In the rose-coloured section, I recommend Hector and Rebecca.

Of the white-flowering varieties, I would name Purity,

Madame Vaucher, Marie Mézard, and Marie Virgo. There is but little difference among these varieties. Purity and Marie Virgo throw their trusses rather higher above the foliage than the others.

In the shaded white and salmon section, I would select Amelina Griseau, Eugénie Mézard, Auricula, Christabel, and Monsieur Barré as distinct. The varieties in this section are endless and a great similarity prevails. None of them are suited for bedding purposes, but grown as pot plants, especially in the spring, they are most exquisite.

In the bright pink section, which is represented so well by the old favourite Christine, I would notice Beauté de Suresnes, Rose Rendatler, Pink Perfection, Mrs. Win. Paul, and Madame Barré.

Among the variegated section of the Tricolors, Mrs. Pollock, Sunset, Lucy Grieve, Lady Culham, and Sophia Cusack are, perhaps, the best; but there are many others coming forward which will take a high position.

In the white and cream-edged section, I would choose Italia Unita, Flower of Spring, Queen of Queens, Argus, Alma, Day-break, Brillant Superbe, Mountain of Snow, Silver Chain, and Venus; and in the golden-foliaged section, Beauty (Wills), Beauty of Oulton, Luna, Golden Fleece, Golden Chain, and General Longstreet. It should be remembered that soil much influences the colour of the foliage of this section, and what suits one variety does not another.

And now a word for the Nosegay Pelargoniums which prove so useful for bedding purposes, both for the effect of massing colour and profuseness of flower. The varieties of Nosegays are endless, but they may be reduced to a few if their chief qualifications be attended to—that is, the compactness and size of the truss of flowers. All varieties producing lax or spreading trusses should be discarded, and such flowers be selected as Stella, Cybister, Lord Palmerston, La Grande, Amy Hogg, Dowager Duchess of Sutherland, Waltham Seedling, Ornement des Massifs, and Black Dwarf. These represent many shades of colour.

The above list comprises sorts which flower freely and are suited for out-of-doors service; excepting the section alluded to, the white and salmon varieties, all of them make first-rate pot plants, and are useful for general purposes. A much longer list could be furnished, but I feel that it would only cause greater difficulty to persons making their own selection.

There are many excellent varieties suitable for pot culture which have been omitted.

The Zonale varieties of the present year have not been noticed, but before the season shall have passed, when they have undergone their ordeal, I purpose adverting to them.

Should any amateur within easy distance of the Royal Horticultural Society's Gardens at Chiswick feel disposed to prove the merits of the above selection, a visit to the trial-beds and the greenhouse containing specimens of Zonales as pot plants, would amply repay the trouble and increase the taste for Zonale Pelargonium cultivation under glass. The easy culture, the brilliancy of the flowers, and the variety of the foliage must gain the approval of all lovers of flowers.—J. D.

#### COMTE DE ZYANS STRAWBERRY.

PERMIT me to draw the attention of Strawberry growers to the above variety. As it is without doubt one of the most productive sorts ever raised, and as the best planting season is at hand, cultivators will do well to give it a trial, particularly those who grow for sale. About a year ago I planted a piece of ground with equal quantities of Sir Harry, Wonderful, Empress, Eliza (Rivers), and Comte de Zyans, all of which are great bearers, but I shall not be saying too much in praise of Comte de Zyans when I state that it produced twice as heavy a crop as any of the others (all of which, however, did remarkably well, particularly Empress and Wonderful), its noble fruit lying in heaps on each side of the rows. Such a sight I never saw. The fruit is large, of a light, lively red colour, and very fair-flavoured; the plant continues in bearing a long time, and, if kept well supplied with water, the last fruit will be nearly as large as the first—a most desirable property.

The reason I am induced to write this in its favour is from the fact that the variety appears to be so little known, for I have not seen it advertised in any trade catalogue except in that of Mrs. Nicholson, of Eaglescliffe, from whom my plants were obtained. I trust that some of your readers who are not acquainted with it will give it a fair trial, and let us know the

result in the pages of your paper. For market gardeners it is a first-rate sort, and if they will only give it a trial I am confident that they will never have reason to regret so doing.

Does Mr. Radclyffe know anything of it? If not, I shall be most happy to send him some plants, if they would be accepted.—W. LAURENSEN.

LAXTON'S EARLY PROLIFIC PEA.

HAVING procured a sealed packet of Peas under the name of Laxton's, I find three very distinct varieties, and they are numbered in the samples sent, 1 to 3 respectively, and I shall feel greatly obliged if you will inform me through the medium of your valuable Journal, which of the enclosed pods I am to consider Laxton's.

I am sorry to say it is not the first time that I have been victimised, or, to say the least, disappointed in purchasing "the best Pea in cultivation," and I would respectfully advise Pea growers to be shy of such a very specious term. Some three years ago I procured Sutton's Ringleader, Carter's First Crop, Dickson's First and Best, and Carpenter's Express, which I sowed side by side with Sangster's No. 1, and the result was, that I found Sutton's and Carter's alike, with the exception that Carter's had some "strangers" amongst them very like Sangster's, whilst Dickson's First and Best, and Carpenter's Express, were too much like Sangster's to be pronounced varieties.

I often see you refer to Hogg's "Fruit Manual" for information respecting fruit. Now, about three years ago there was a Peach sent out under the name of Stirling Castle, which is not noticed there. Is it worthless, or why is it not mentioned?—AN AMATEUR.

[The curved pods are Laxton's, which appear to have been mixed with Early Frame. Stirling Castle Peach is a good, but not a remarkably fine variety.]

FROM the very flattering account sent out I have been induced to try a quart of Laxton's Pea, and I must confess that I have been disappointed in it, both as to flavour as well as yield. My Peas had an excellent situation, and they had, moreover, plenty of room—viz., 6 feet asunder.—JOHN MARSLAND.

STRAWBERRY LORD CLYDE.

IN the last Number of the JOURNAL OF HORTICULTURE, page 99, I see a reply of Mr. W. Dean to my inquiry as to Lord Clyde Strawberry.

I am of the opinion, which I am sure is shared by many, that a father is not always a very impartial judge of his own children, therefore I should have preferred the opinion of other parties than Mr. Dean as to the merits of this Strawberry. In the meantime I firmly adhere to my belief, that it is nothing else than the old Chinese, and I propose to send plants to the Royal Horticultural Society, with a request to have them tried at Chiswick, as I should like to clear up the question thoroughly.

As to Mr. Dean's pretending to know as much about Strawberries as I do, I beg leave to doubt it very much, unless Mr. Dean should have spent half his lifetime amongst Strawberries, and grown all the sorts existing, as I did.—FERDINAND GLOEDE, *Les Sablons, Seine et Marne.*

THE NATIONAL GOOSEBERRY SHOW.

THIS was held at the Sir John Falstaff Inn, Market Place, Manchester, on Saturday, the 4th inst. The Gooseberries exhibited, although lighter than in the last two seasons, were in good condition, and tolerably well coloured. There was a severe competition among the growers from the principal Gooseberry districts for Dr. Hogg's prize, which terminated in favour of Mr. John Torkington, of the George Inn, Wilmslow, Cheshire, who carried off the prize for a fine specimen of Plough Boy, the most beautiful Gooseberry in cultivation; but he was pressed closely by Mr. Thomas Pilkington, of Scaresbrick, Lancashire, with a fine berry of Talfourd.

Of the seedlings there were but few worthy of notice, owing to the severe weather which occurred throughout May having

ruined the rinds, and so much damaged the fruit that but few sound berries are to be met with this season.

PREMIUM PRIZE, £2, OFFERED BY DR. ROBERT HOGG, FOR THE LARGEST BERRY OF ANY COLOUR. dwts. grs

J. Torkington	Red	Plough Boy	24	17
STEWARDS' FIRST PRIZES, 18s. EACH.

## VARIATIONS OF TEMPERATURE IN NEW YORK.

So far this has been a season of more than usually remarkable variations in temperature, the thermometer on the 8th of January in New York, and its vicinity, marking as low as 20° below zero.

As far as can be ascertained, in the absence of any official record, this is the lowest temperature that has occurred for fifty years. As experience has proved that the Peach buds can only stand 10° below zero, all anticipations of a heavy crop this season are at an end. Many cases of individual suffering occurred, amongst others one poor woman was frozen to death in bed.

This extremely low temperature was a severe test of the different systems of heating for greenhouses, &c., and many a gardener had a rough time of it, attending to his fires; for British readers must remember that gardeners here cannot obtain the efficient staff of assistants that they can at home, but in a case of emergency must put the shoulder to the wheel themselves, and not merely be contented with seeing that the thermometers in the early forcing-houses or plant-sloves are at the regulation figure.

After a rather late spring, summer set in in earnest, and for the first three weeks in July the thermometer stood above 90° every day, rising on the 17th and 18th to 104° in the shade, this being the highest figure ever recorded as occurring here. Workmen left their daily toil, business men forsook their daily avocations, hundreds were struck down by the sun, and many were prostrated who were not in the sun at all. Vegetation did not suffer much, except grass lawns, and a mark has been left on them that will not be erased this season.—DAVID FOULIS, *New York*.

## HORTICULTURE ON THE CONTINENT.

ONE of our greatest critics, Bayle, was accustomed to declare that the art of successful abridgement was very difficult of attainment. In the face, however, of this formidable axiom, I shall endeavour, in the interest of horticultural progress, and for the sake of such readers as may not habitually read continental reviews, to give a *resumé* of horticultural news according to their latest stage of development abroad. For obvious reasons these notices will not extend beyond certain branches of the subject, but in these there exists an abundance of material.

Very naturally, up to this period, the International Horticultural Exhibition has chiefly occupied the attention of foreign critics and correspondents, who, while they have rendered fair justice to the brilliant success of the show, take the liberty of criticising some of the arrangements. As one of these criticisms which I recently perused evidently contains the ideas of a practical man, and is written in a kindly spirit, it is valuable. After admiring the great tent our critic finds himself bewildered at the first aspect of the whole scene. A profusion of brilliant colours, hardly less showy foliage, cultivation in perfection throughout, and this in the case of plants only known to Parisians in solitary specimens!—But soon a sensation of uniformity in the arrangement is felt. Each object, studiously placed so as to secure its own immediate effect, is not so grouped and massed as to form an artistical whole; no *ensemble*, no effective stand-points, no striking perspectives—everything sacrificed to detail, and decentralised thereby. Small plants are brought near the line of vision of the spectator. Those which are seen to best advantage from below are elevated on coarse unadorned benches. "On the line" are those objects which best endure scrutiny. All this is a mere elementary trace, and resembles a nurseryman's display rather than that of a great exhibition which is to be a model for country shows. Such a plan may be eminently favourable for the individual specimen, but it has no artistical feature, nor beautiful grouping of masses. These, as was said previously, are the remarks of a very intelligent correspondent, and should be received as improving and by no means unfriendly criticism.

From general remarks our foreign observer passes to detail, in which he is too prolific for me to follow him in a mere summary like this. He begins with the Rose. The Rose is a traditional French glory. Nearly every variety in cultivation is of French origin; fortunately we have, says he, this consolation, for our neighbours have indeed given us a lesson. Ima-

gine huge pyramids, literal constellations of enormous and splendid blooms! Though grown under glass, they are far different from the discoloured specimens we often see in Paris. He distinguishes the names of Mr. C. Turner and Mr. W. Paul as the best growers. In *Pelargoniums*, he says, we envy not our neighbours' success; many charming and popular novelties adorn our houses; it is the perfect culture shown by Mr. Turner which leaves nothing to be desired. This is described at length as a model for French amateurs. "What shall we say of the marvellous Azaleas and plants of unheated houses? The marvels of Amsterdam and Brussels pale before them. This is one of the classical powers of English gardening. We cannot hope to rival them. Our culture is inferior to theirs, so that even plants bought in England degenerate with us." This he ascribes as due in part to the qualities of the water and the soil. *Ce loam bienfaisant* is the secret. Then follows a list of choice plants, and the names of many of our leading nurserymen are given. Mr. Baines's *Alocasia metallica* is especially noted; also the Palms of Madame Legrelle d'Hanis, of Antwerp, Messrs. Lee's magnificent *Cibotium princeps* and superb *Alocasias*, and Messrs. Veitch's *Anthuriums* are remarked as the *ne plus ultra* of splendid culture. They are minutely described, and strongly recommended. *Caladiums* shown by Messrs. Henderson, Veitch, Wattenbach, and Bleu are highly praised. The last is a distinguished French amateur, our critic says. Few Palms, the best shown by the Duke of Northumberland. I must, however, leave these sections to glance at a very popular one just now, and which our friend rather depreciates, the newest variegated and bronze golden bedding *Pelargoniums*. "It is a mania just now," he says, "amateurs fight for novelties." Pretty, no doubt, but rather "exaggerated," and a "little frivolous." "Except Missis Pollock, Sophia Cusak, and Lucy Grieve, the rest are not worth much. The fashion will pass—as it came." This, however, hardly corresponds with the opinions of other foreign nurserymen who were seen making similar wild guesses at the somewhat *outré* names they saw, and well they might. As a rule, Frenchmen take too little pains as to English nomenclature, and the Exhibition favourites will, no doubt, appear in strange guise on the continent. This is hardly fair to the grower, but unavoidable at present.

Tropical fruit trees are described—the palm for flavour being awarded to the Mangosteen; then the evergreen shrubs—so beautiful, shown by Messrs. Veitch, Standish, and Jackson. Then Mr. Salter's magnificent *Funkias*, *Arabis*, &c., are described, the contents of the Orchid tent minutely gone into, and the names of successful English and Belgian competitors given; among the former Messrs. Veitch and Bull, and among the latter Messrs. Verschaffelt and Linden are conspicuous. Ample justice is done to this important part of the subject, and the number and beauty of the novelties which were exhibited are considered to form the most striking part of the whole show, in the eyes of foreigners at least. This is what we like to know.

Our friend admires Messrs. Ivery's Ferns, and especially Mr. Turner's Tulips. In England, yellow is not a proscribed colour. Then, Mr. Henderson's plants and his able disposition of them are praised, afterwards Mr. Standish's *Rhododendrons*, Mr. Noble's plants, Mr. Brand's enormous *Eucharis grandiflora*, Messrs. Carter's New Striped Japanese Maize, so superior, it is added, to that grown in France; *Amaranthus hybridus*, shown by Mr. Knight, of Pontchartrain, near Paris; Mr. Turner's splendid lot of *Lilium auratum*; Mr. Veitch's wonderful *Maranta tubispatha*; M. Pfersdorff's *Cacti*; Mr. Foljambe's *Alternanthera*; Col. Miles's *Adiantum*; and Messrs. Backhouse's Ferns, of irreproachable culture, are noted. It would be tedious to say more than this.

After this we come to the sections of fruit, &c. "Here," says our critic, "we are surprised not to meet the master of orchard-house cultivation, Mr. Rivers; we have thus lost some superb productions;" but this could hardly be, as orchard-house trees in pots (unless forced) were then far from looking at their best. England, long so superior in forced fruits has now, it is said, rivals such as Gontier and Lambertye, who will make her look to her laurels. The forced fruits are considered superb, but less in number than was to be expected. Messrs. Lane's Vines in pots are much praised, as also Mr. Turner's specimens of Peaches, Figs, &c. "Not a Chasselas de Fontainebleau!" says our friend, in wonder. Then, however, comes the rather surprising assertion, "Our superiority in the training and pruning of trees is known and appreciated in England. The names of Messrs. Jamin & Durand, of Bourg-

la-Reine, near Paris, prove this, as taking the two first prizes." It might have also been added that, in this section they were the only exhibitors, as "your own correspondent" ought to know, having been one of the Judges.

As to vegetables, there was the same indifference as in France, and this although the Executive Committee had endeavoured to secure competition by a handsome list of prizes. "We are not alone in deploring this resistance of a class to whom these shows cannot but be beneficial." What says Covent Garden? Rhubarb, however, is cited as shown in the greatest perfection; a Cucumber, modestly called the "Invincible;" and the new Radish, very curious, but we wait to taste it before deciding.

"Du reste," nothing remarkable in the implements and machines. Garden plans very inferior indeed. "Why did not some French competitors come over and give a lesson on the drawing and composition of gardens, and show that, if in England the tradition of the fine old parks seems compromised, it is to be found in France more in honour than ever?"

Thus our critic ends as he began, by praising our great show in every detail, but considers it wanting in that exquisite and artistic grace which Parisians can alone contribute. Of course, we have all much to learn, but we have hardly anything to acquire in some important things, which is more than all can say.

The weather, as with us, has been very unfavourable on the continent. The warm and dry days of the end of June have been succeeded by cold and wet in July. Vegetation has been extremely perturbed. The Oidium, which it was hoped would not re-appear, has become prevalent. Sulphur is still in favour as a remedy. Numerous provincial horticultural exhibitions are announced. At Troyes there will be one from the 3rd to the 10th of September. A musical mass, a banquet (to which ladies will be admitted), a Venetian *jôte* in the public gardens, are a part of the programme. At Limoges another show will take place on the 13th of this month. The Pomological Society of France will hold its eleventh session at Melun, on the 14th of September. Other exhibitions are at Orleans on the 12th of August; on the 15th at Bourg; from the 29th of September to the 3rd of October, at Paris.—T. C. BRÉHAUT, *Richmond House, Guernsey.*

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 7TH.

FLORAL COMMITTEE.—This meeting was one of the best of the season, although, perhaps, the attendance of the Fellows was not so numerous. The exhibition of plants and flowers was excellent. Mr. C. Turner sent four seedling Nosegay Pelargoniums—viz., Lady Constance Grosvenor, a bright scarlet, which was awarded a first-class certificate; Duchess of Sutherland, a very showy variety, which had been awarded a first-class; International, and Countess of Sefton, good in colour, but deficient in truss. Mr. Tirebuck had fifteen seedling Zonale Pelargoniums; out of them, a Nosegay called Felix, with large pale pink trusses, was awarded a second-class certificate. Messrs. F. & A. Smith, of Dulwich, exhibited thirteen Zonale Nosegay Pelargoniums, many of them of high character, but too much resembling well-known varieties. Sunbeam, a bright orange scarlet, and King of the Nosegays, were considered the best among them. From Messrs. Smith came also a small collection of Balsams, but not equal to those which we have seen exhibited by this firm; likewise *Lomaria fluviatilis*, an old and well-known Fern.

Mr. Parker, Tooting, exhibited some interesting plants. First-class certificates were awarded for *Pleopeltis incurvata*, a handsome Fern from Java; *Nothochlæna cretacea*, a pretty Silver Fern; and *Goolyera pubescens intermedia*. A special certificate was awarded Mr. Parker for his collection. Messrs. Veitch received first-class certificates for a curious and rare Orchid—*Aeimetia* species, *Gymnostachyum* species, *Trichomanes coneinum*, and second-class certificates for *Solophyllum reticulatum* and *Ionopsis paniculata*. A special certificate was awarded for the collection, in which were the white *Lapageria*, *Rothmannia* species, *Notylia bicolor*, a very small and minute-flowering Orchid: *Vanda Roxburghii* var., a *Mel. stoma*, and a cut collection of *Gladioli*, one box containing *G. breuchleyensis*, and the other named varieties.

Mr. James Hedges, gardener to E. Wright, Esq., received a special certificate for cut specimens of *Renanthera Lowii* and *Vanda Batemanii*. Mr. Melville, Dalmeny Park, sent four seedling *Tropæolums*, like many other seedlings which are raised every year; and Mr. John Willis, Huntroyde, nine seedling Zonale Pelargoniums, not sufficiently distinct, also a collection of his hybrid seedling *Verbenas*, which must be seen planted out before their merits are decided upon. From Mr. Bracher came eight seedling *Verbenas* of no merit, and from Mr. Sherratt, gardener to James Bateman, Esq., *Cœlogyne corrugata*, to

which was awarded a second-class certificate, and Mr. Sherratt also received a special certificate for a fine collection of cut Orchids.

Mr. Bull obtained first-class certificates for *Brownea princeps* (*erecta*?) and *Brownea grandiceps*, both plants with very handsome foliage, and second-class certificates for *Broussonetia papyrifera*, a beautifully variegated shrub, and *Tradescantia vittata*. Messrs. Jackson, Kingston, were awarded a first-class certificate for *Erica Maroccanica*, a very fine variety. Mr. Gulliford, Bedford Square, exhibited a Cactus, covered with the cochineal insect; and Mr. G. Smith, Hornsey Road, two seedling Zonale Pelargoniums—Chancellor, a bright scarlet, a good flower, but too like many others; and Alexandra, white-variegated Zonale, not better than Mountain of Light or Silver Chain. Messrs. Climbush, Highgate, had a first-class certificate for *Lilium auratum splendens*, one of the best varieties yet seen in this country; the broad dull red in place of the usual orange bands made the flower, which is of excellent form, very conspicuous.

Mr. Chater, Saffron Walden, exhibited eight seedling Hollyhocks, two of which received first-class certificates—speciosa, a pale buff suffused with crimson; and Frederick Chater, a pale yellow; and a second-class certificate was awarded for Edward Speed, the flower of a difficult colour to describe, a pale purplish grey. Messrs. Henderson, Wellington Road, received a first-class certificate for Pelargonium Christine Nosegay; and a special certificate for their collection of plants. Among them were tricolor Pelargonium Lady Harriet Bliss, *Hydelym thyriforme variegatum*; *Caladium pictum*, Alphonse Karr, *pœile*; and *Curcuma flava*. Messrs. Carter sent fine plants of variegated Maize, *Lobelia Attraction*, blue and white, very like *Paxtonii*; also, *Lobelia Beauty of Ravensbourne*, dwarf compact plant, with pale lilac flowers; a second-class certificate was awarded it. Mr. Henderson, Thornton Heath Nursery, sent a long shoot of the Climbing Devonians Rose, with a fine terminal cluster of flowers. A first-class certificate was awarded this beautiful Rose. Mr. Barron, Elvaston, exhibited *Abies Douglasii brevifolia*, which was awarded a first-class certificate; also, *Abies Douglasii variegata*. W. W. Buller, Esq., received a special certificate for a collection of cut Orchids. Mr. Eckford, Coleshill, Bucks, sent twelve seedling *Verbenas*, very good flowers, but not differing from many others. From the Society's gardens, Kensington, came *Xanthosoma violacea*, in flower; and from Chiswick, a collection of plants, comprising, among others, that good old plant *Trachelium aureolum*, some named *Petunias*, and several very promising seedlings.

FRUIT COMMITTEE.—Mr. Carmichael, gardener to His Royal Highness the Prince of Wales, Sandringham, received a special certificate for a remarkably handsome Enville Pine Apple weighing 7½ lbs., doubtless the forerunner of many other fine productions from the same garden. From Mr. Keynes, Salisbury, came two Grapes, the one a pretty white seedling, and the other the Strawberry Grape, having a strongly marked Strawberry flavour; from Mr. Mathison, Addington, a seedling Black Grape; and from Mr. Cox, Madresfield Court, Great Malvern, an oval-berried Black Grape, the result of a cross between the Alicante and Muscat of Alexandria. This was stated to possess a fine flavour, but neither to it nor the other seedlings was any award made. Mr. Ingram, Huntingdon Nurseries, exhibited Easter Beurre Pears, much shrivelled; Mr. Meludoe, a seedling Gooseberry called Goldfinder; and Mr. Cooling, Bath, two dishes of Apples, and a useful-looking white Potato. Edgott Second Early Kidney Potato, a very clean-skinned variety, was shown by Mr. Neale, gardener to R. A. Cartwright, Esq., Edgott House. This and the other Potatoes were referred to Dr. Hogg for trial when cooked. Mr. Melville, gardener to the Earl of Rosebery, Dalmeny Park, exhibited the Long-podded Radish with large pods 30 inches or more in length. These, like the pods of the common Radish, are said to be very good when pickled.

FORTNIGHTLY MEETING.—J. Bateman, Esq., F.R.S., in the chair. The awards of the Committee having been announced, the Rev. M. J. Berkeley proceeded to remark on the subjects exhibited. The *Æchmea* shown at the last meeting by Mr. Wilson Saunders, and which differed in some respects from *Æ. Mertensii*, had been compared with specimens in the herbarium at Kew, but the only species at all approaching it was *Æ. pyramidalis*, of which it was probably only a variety. In a collection of fruits from the garden of the Viceroys of Egypt, shown in the end of 1864, was the plant (*Cannabis sativa*), from which is made the hashish used in the East as a narcotic, like opium. From this Mr. Berkeley said he took twelve seeds; but all the plants raised from these were eaten off by slugs, with the exception of one which proved to be variegated. From it he had this year succeeded in raising six plants, and as it is perfectly hardy and more dwarf and bushy than the common Hemp, he thought it would prove a handsome plant for shrubbery-borders. *Pleopeltis incurvata* and *Nothochlæna cretacea* next came under notice, and of the latter it was remarked that the fronds were finely powdered with silvery dust. *Rhopals* were also noticed as being handsome plants for drawing-room decoration. Attention was next directed to a *Rothmannia*, exhibited by Messrs. Veitch; to *Jussiaea ligustrifolia*, a marsh plant nearly related to the Evening Primrose; and to *Brownea princeps* and *grandiceps*. Of the last, Mr. Bateman remarked that it is an extremely handsome plant of the same natural order as the *Jonesia asoca* and *Amherstia nobilis*, having large heads of flowers and long gracefully drooping leaves. The finest specimen of it which he ever

saw was in the garden of Sir Hugh Williams, at Bodelyyddan. The cochineal insect was the next subject referred to, an *Opuntia* bearing that insect having been exhibited by Mr. Gulliford, and some details were given as to the mode of collecting the insects and preparing the valuable dye which they yield. The variegated *Broussonetia papyrifera* was then referred to as a handsome variegated plant, equally hardy with the plain-leaved sort, and the use made by the Japanese of the inner bark of the latter in producing a bibulous paper, was mentioned, as well as the fact of a tough cloth being manufactured from it by the natives of the South Sea Islands. The other plants noticed were *Trachelium caeruleum*, *Acaena nova-zealandia*, nearly allied to Burnet, and an *Odontoglossum* from Maraquita, remarkable as a botanical curiosity. Attention was also directed to a Hollyhock spike, in which several shoots had become united, as sometimes happens with *Asparagus*, and it was remarked that the upper blooms were fair, though they would not pass muster with a florist, whilst of the lower flowers every one had developed florets.

Mr. Bateman said that though there were numerous novelties among the Orchids exhibited, they all laboured under the difficulty which other new Orchids experienced—that of not being in a condition to exhibit their beauties to the best advantage. The first to which he would allude was *Vanda Bensonii*, named after Lieut.-Col. Benson, Deputy Adjutant-General of Rangoon, an enthusiastic collector of plants. As exhibited, it had miserable foliage and only a few flowers; but native specimens showed that it had not only fine foliage, but produced fourteen or fifteen flowers in a spike. There was also a remarkable *Bolbophyllum*, from Borneo, exhibited by Messrs. Veitch, having beautifully netted leaves, and an *Acineta*, from Central America, with large clusters of yellow flowers, and very distinct from any species at present known; also, from his own garden, *Cologyne corrugata*, so called from the wrinkled appearance of its pseudo-bulbs. Among the most remarkable of the old kinds was *Lælia crispata*, in beautiful bloom. This, which was first ranged under the genus *Cattleya*, had kept him waiting twenty-five years, but he had at length been rewarded by its flowering. Some varieties were obstinate in doing so, and others were the reverse, and he could now congratulate the members of the Society on having a free-flowering variety for distribution. From Mr. Bull there came an example of *Peristeria elata*, or the Dove plant, known also in Panama as *El Spirito Santo*, in consequence of the singular resemblance of the column of the flower to a dove. The plant first flowered in England with Mr. Harrison, of Liverpool, in the year in which the Liverpool and Manchester Railway was opened, and very few persons who had a love for plants did not avail themselves of that opportunity of going to Liverpool to see this beautiful plant and the rest of Mr. Harrison's wonderful collection of Orchids. He hardly knew any plant giving a more perfect representation of an animal form than the *Peristeria*, for the resemblance between it and the beautiful silvery wings of a dove might almost be said to be perfect. Of *Oncidium lanceanum* there was also an example, and coming from Surinam it required a high temperature. He remembered having sent to Demerara, now nearly thirty years ago, a collector, who, having come across this plant on a tree bending over the Essequibo river, and knowing that Henchman, another collector, employed by Messrs. Low, was but a day and a half behind him, stripped the tree of all the plants that he possibly could take and buried the rest, so that the other collector might not secure the same prize as himself. He would leave it to others to say whether or no such a course was right, and though it would admit of some discussion, he would not pretend to defend it; but this he knew, that the proceeding of Colley was very advantageous to him (Mr. Bateman), for he was enabled to make exchanges on the most advantageous terms, his plants being worth ten guineas instead of two. Poor Colley (for that was the collector's name), died two or three years ago, and he might mention that his widow, a very respectable person, still lives at 22, Hereford Street, Lisson Grove, Paddington, though in by no means good circumstances, and, as she is an excellent *cuisinière*, some of those present might be disposed to employ her. Among other Orchids for distribution was a handsome spike of *Phalanopsis grandiflora*, the queen of bridal Orchids, furnished by W. Wentworth Buller, Esq., of Strete Raleigh, who informed him that the plant from which it was cut had not been out of bloom for two years, and in that time had produced no less than thirty-two spikes, as many as five having been in flower at one time. In connection with *Notylia bicolor*, an insignificant-looking Orchid, Mr. Bateman remarked, that Mr. Wilson Saunders was about to publish a work called "The Refuge," in which all small Orchids which could not make their way in the world by their gay flowers, would have justice done to them. With reference to *Allamanda Schottii* Hendersoni, of which Mr. Bull had sent out blooms for distribution, Mr. Bateman cautioned those who might obtain them to be careful, for he knew that if the petals of *Allamanda cathartica* were put into the mouth they caused pain for a considerable time afterwards. Attention was then directed to a cut specimen of *Renanthera Lowii*, between 7 and 8 feet in length, and bearing thirty-two blooms, shown by E. Wright, Esq., of Birmingham. It was remarked that this magnificent Orchid is a native of Borneo, where it was discovered by Mr. Low, jun., and on its first introduction named *Vanda Lowii*. This *Renanthera* was remarkable for the great length of its spikes, and he might mention that, fine as the specimen before the meeting was, he had seen one a year or two ago at Mr. Rucker's, at Waudsworth, which very much surpassed it, for it had no

less than twelve racemes equally long with that exhibited, which by reason of their great length were festooned across the path, producing a most striking effect. A peculiarity which he might mention was, that the two or three flowers nearest the base of the shoot were in this species different from the rest, being thick, fleshy, and of a tawny colour. *Gramadilla* were the next subject to which Mr. Bateman alluded, and of these he had brought some (fruit of *Passiflora edulis*), from his own garden, that the visitors might taste—a privilege which he seldom enjoyed himself, so fond of them were his family. The proper way to eat the fruit was like an egg, with or without sugar, according to taste. With reference to *Passiflora macrocarpa splendens*, Mr. Bateman said he had received a letter from Mr. Hullett, who had offered it for sale at a very long price, giving the testimony of the correspondent from whom he had received the seeds as to the enormous size of the fruit, but Mr. Bateman recommended intending buyers to wait till they had seen fruit of 14 or 15 lbs. weight, which, no doubt, would be honoured by the Fruit Committee with a "double first class." After noticing a collection of Gooseberries from the Chiswick Gardens, and a hardy *Rubus*, not in condition, but said to be excellent for game preserves, and to have fruit partaking of the qualities of the Raspberry and the Blackberry, Mr. Bateman passed on to a Grape having a flavour somewhat resembling that of the Strawberry, but partaking of the foxy taste of most of the native American Grapes. He might add that America had been known to the Greenlanders long before the discovery of Columbus, and from the abundance of its wild Vines, it had received from them the name of Vineland or Wine-land.

Six new Fellows were elected, and the Longborough Horticultural Society, Sherborne Floricultural and Horticultural Society, and Tamworth General Horticultural Society were admitted into union.

WEEKLY SHOW, August 11th.—For the best collection of miscellaneous plants exhibited by nurserymen, Messrs. Cutbush, of Highgate, received the first prize. In the class for the best collection of vegetables, the first prize was awarded to a very meritorious exhibition, consisting of vegetables and herbs, from Mr. Hill, Angel Row, Highgate; the second to Mr. Plester, gardener to Mrs. Rush, Elsenham Hall; and the third to Mr. Whiting, of the Deepdene. In the Miscellaneous Class Messrs. Cutbush received an extra prize for a collection of twelve plants; and Mr. Tonkin, gardener to S. T. Keke-wich, Esq., Peamore, near Exeter, for an excellent specimen of Smooth-leaved Cayenne Pine.

#### GARDENING NOTES.

THE importance of gathering all ripe fruit before the morning sun has reached it cannot be too widely known. The Melon, especially, is scarcely fit to eat if gathered warm, and the flavour of Figs and wall fruit generally is affected to a marked degree by the condition of the fruit at the time of its removal from the tree. I believe vegetables also come under the rule.

In passing lately through Paris, I had again the opportunity of noticing the diligent care with which the flower-beds and grass plats are tended in the public gardens, and in the Bois. The bedding plants are surrounded with a thick mulching of rotten manure, which is well watered twice or thrice a-day. The grass parterres are also well watered for hours together during sunshine, by hose perforated with innumerable small holes, which spread a gentle dew in all directions. These hose are set on "travellers," so that they can be easily moved from place to place. They water a tract of 100 yards in length by about 10 in breadth at once, and without any trouble beyond the first placing in position.

Large trees are transplanted in Paris, and having been surrounded by haybands, have a funnel placed at the top of the stem to receive water, so as to keep the haybands constantly wet to prevent the tree from languishing.

In the gardens of the Tuileries, and in those round the Louvre, a pretty effect is given to the flower-beds by an earth border between the grass-bed and the flowers. This is formed of finely-sifted earth, and being slightly damped it keeps its place, and, moreover, prevents washings round the grass borders.

In planting, weeding, &c., over soft ground, it strikes me that it would be well for the workman to wear a kind of snow shoe, to save the ground from being trampled hard. Such shoes would be easily attached to the foot, and any handy man could readily make them. They would save much time and trouble in lieu of shifting boards, &c., and, being pointed in front, might be easily slipped beneath the leaves of growing plants without doing injury.

A pretty effect may be produced on lawns, &c., if, at the time of laying the turf, planks be first put down a few inches below the surface, arranged in various patterns (stars, letters, crests,

&c.), and the turf then laid above them. When the snow has fallen in winter, and begins to melt, it will be found to remain for a long time over these places, and exhibit the various devices which have been executed there, without any ill-effect being produced at other times. To those who are not in the secret it will be a source of delighted wonder. Cinders or other non-conducting substances may be used instead of planks.—D.

### MR. WILLIAM PAUL'S NURSERIES, WALTHAM CROSS.

THESE nurseries are at all seasons well worthy of a visit, and particularly just now; for apart from the high order and keeping which they everywhere manifest, they present several features of special interest. Foremost among these are the bedding Pelargoniums; then there are Roses by thousands; extensive collections of hardy ornamental shrubs, both evergreen and deciduous, now in full beauty; and for those who contemplate stocking their fruit gardens, Apples, Pears, Peaches, Nectarines, Plums, and Cherries of every useful size and form.

To the traveller by rail the most convenient mode of access is from the platform of Waltham station (Great Eastern Railway), whence a walk leads directly into the nurseries, and is continued for a quarter of a mile parallel to the railway. One side of this walk is planted with trees selected for the beauty of their foliage, and the other chiefly with Hollyhocks, now presenting noble spikes of bloom. Pursuing this walk for a short distance, and then turning to the left, we enter a broad grass walk a third of a mile in length, leading to the offices and glass houses. This walk is kept closely cut with a mowing machine, and having beds of choice evergreen shrubs on each side, it forms a most agreeable promenade in summer, whilst for traffic in winter and when the grass is damp there are parallel gravel walks. By this arrangement, which is worthy of imitation elsewhere, comfort in walking is secured in all weathers. For a considerable distance on each side of this broad grass walk the beds are extremely gay with the finest of the bedding Pelargoniums, but before referring further to these we will take a glance through the houses.

The first two houses contained Tea Roses, which, though no longer exhibiting that profusion of bloom which they did earlier in the season, were still very interesting and pretty. *Maréchal Niel*, which has this year established its reputation as one of the finest of all the Tea Roses, figuring in most of the winning stands, and exciting universal admiration, was still in great beauty. *Souvenir d'un Ami*, *Gloire de Dijon*, *Madame Falcot*, beautiful in the bud state, and *Nina* were also in very good bloom; as well as *Noisettes Celine Forestier*, *Desprez a fleur jaune*, a very hardy and vigorous kind, and *Cloth of Gold*. The next house contained a good stock of Vines for fruiting in pots, consisting of *Black Hamburg*, *Muscad of Alexandria*, *Royal Muscadine*, and *Foster's White Seedling*, all with strong wood. Four other houses were occupied with a large stock of Vines, chiefly for planting out, consisting of *Muscats*, *Black Hamburg*, *Buckland Sweet-water*, *Foster's White Seedling*, *Royal Vineyard*, *Chasselas de Falloux*, *Barbarossa*, *Lady Downe's*, *Trentham Black*, *West's St. Peter's*, *Tokay*, and several other varieties in excellent condition. In No. 4 house there was a number of standard Pelargoniums, among which were *Mrs. Pollock*, *Sunset*, *Waltham Pet*, *Madame Vancher*, and *Dr. Lindley*, a large-flowered light scarlet with a white eye. There was also a plant of *Pillar of Beauty*, a strong-growing variety well adapted for the pillars and back walls of conservatories, and a profuse and continuous bloomer. Here, too, there were several of the new *Nosegay* varieties, as *Blue Bell*, deep rosy lilac with a slight bluish tinge, and a large white blotch in the upper petals; and *Mrs. William Paul*, now pretty well known as a fine rosy pink variety. No. 5 contained a number of the new Roses in eight-inch pots, and large specimen Teas for show purposes; and the next house Pelargoniums again. Among these were *Bride*, a pretty variety for pot culture, with white flowers, having a red circle at the base of the petals; a fine specimen plant of *Wood Nymph*, about 2½ feet through, and bearing about four score trusses; and *Waltham Gem*, a promising golden-leaved variety of compact habit. The *Camellia*-house had been cleared of its regular inmates, which had been placed out of doors under tiffany, and was occupied with *Primulas* for seed, of which great care is taken in preserving a fine strain, and a lot of the long-podded *Radish*.

In other houses and pits were Roses of the Tea, *Noisette*,

*Bourbon*, and *Hybrid Perpetual* classes to the number of several thousands, and among other varieties was an extra strong stock of *Maréchal Niel*, *Madame Bravy*, *Alba rosea*, now in great demand; *Madame Goubault*, *Madame Falcot*, and *Mr. Paul's* new *Hybrid Perpetuals* *Black Prince*, *Dr. Lindley*, and *Lady Suffolk*. Various span-roofed pits were filled with new Japanese shrubs, such as the *Raphiolepis ovata*, which this spring has shown to be beautiful not only in its leaf but in its flower, and, withal, delightfully fragrant; *Skimmia japonica*; variegated *Euonymus*, and two beautifully variegated *Privets*—viz., *Ligustrum ovalifolium aureo-maculatum* and *L. sinense variegatum*, the latter exhibiting a great breadth of yellow markings, and, doubtless, hardy enough for good situations. The new *Aucubas*, too, were, of course, represented in great number as well as variety, and there were some seedlings not yet brought before the public; one was particularly worthy of notice, the foliage being broadly edged with white, and if this character remain permanent, as there seems to be no reason to doubt, it will prove a striking novelty. Another seedling was also noticeable as having leaves scarcely distinguishable from those of a *Laurel*. *Medio-picta*, *latimaculata*, and other kinds shown this year and last at the various metropolitan exhibitions, were being propagated in numbers, as from their bold variegation the demand for them will doubtless be great. Before quitting the part of the nursery where the houses are situated, we just glanced into some north pits, where, among other subjects, is a collection of *Ivies*. Of these, *marmorata nana* was noticeable as a beautiful, small-leaved, marbled variety; *rhombica*, as having elegant foliage with a regular silver margin; and *japonica* as a small-leaved, bright-looking, white-variegated sort. *Algeriensis variegata*, and *maculata*, are also handsome varieties.

We now come to the bedding Pelargoniums, which, being massed on each side of the grass walk, and most of the varieties being represented in considerable numbers, have a brilliant effect. The majority of them are of the *Nosegay* race, and either of *Mr. Beaton's* raising or seedlings which have sprung from his stock, of which it will be remembered *Mr. W. Paul* purchased the whole. First comes a bed of *Rebecca*, which must rank as one of the finest bedding varieties which we possess. Its flowers are broad-petalled, of a peculiarly soft rosy carmine, with some scarlet in the upper petals. The habit is very dwarf and compact, the leaves distinctly zoned, and the trusses stiff, bearing the flowers well above the foliage, but not too high. In addition to these good properties it has that of being very free-flowering; and, as a further proof of its merits, it may be remarked that it has been awarded a first-class certificate by the Floral Committee of the Royal Horticultural Society. *St. George* is another fine variety with plain leaves and scarlet flowers, with a chestnut shade, in large trusses; and *Waltham Seedling*, a very free-flowering dark crimson, with slight horseshoe leaves. *Phoenix*, intense scarlet, has a larger truss than the well-known *Punch*, and appears to be a very continuous bloomer; whilst *Salmon Nosegay*, also plain-leaved, is likewise remarkably free, and may be regarded as a valuable addition to the salmon-coloured varieties. In *Sir Joseph Paxton* we have a totally distinct shade of colour, more nearly approaching an orange than we have hitherto met with, and a great improvement on *Orange Nosegay*, the truss and flowers being twice the size; and in *Naiad* there is another new colour—a beautiful rosy purple with a play of scarlet in the upper petals. The flowers, indeed, are rather small, but it is a charming variety. *Cardinal*, though perhaps better for pot culture than bedding, is remarkable for its fine shape and habit, and deep scarlet colour; and *Prince of Orange*, which, like the preceding, has plain foliage, is a very free-flowering orange scarlet. *Nimrod* is another fine orange scarlet, with finely formed petals and very large trusses. The leaves are marked with a dark horseshoe, and the habit is excellent, the trusses being thrown just above the foliage. *Monte Rosa* is a pretty rosy pink, with a tinge of magenta in the lower petals, and of scarlet in the upper ones; *Lord Chancellor*, salmon pink, with very dark zoned foliage, and forming a compact bed in profuse bloom, and *Alexandra*, a sport of *Magenta Queen*, were also very noticeable. The last is of a beautiful magenta crimson, very free-flowering and effective.

Besides the above, all of which have been already before the public, there were several seedlings which will not come out until next spring. One of these, called *Dr. Hogg*, is broader in the petals than *Amy Hogg*, of a deeper rose, and has more scarlet in the top petals, whilst the trusses are equally numerous and fine. *Beauty of Waltham*, carmine and scarlet, is a

very free bloomer; and Crimson Queen, though not large in the truss, is of a much deeper colour than Stella and Cybister. Scarlet Dwarf, as its name implies, is of dwarf compact habit, and has soft rosy carmine flowers with a tinge of magenta in the lower petals, and of scarlet in the upper ones. Enchantress, magenta crimson tinged with scarlet in the upper petals, is a bright-looking variety; and Village Maid, an effective deep pink flower, conspicuously blotched with white at the base of the two upper petals. The plant is dwarf and of excellent habit, and has darkly zonate foliage. There were several unnamed seedlings of great promise, especially one or two very dark scarlets, another with pink flowers, and one with very broad petals approaching a true orange colour; but of these and many more we shall doubtless hear in due time.

The Waltham Cross Nurseries are so far-famed for their Roses, that it is scarcely necessary to remark that these constitute another leading feature, although at the time of our visit hot weather, succeeded by heavy rain, had, to some extent, marred their beauty and considerably diminished the number of blooms on the plants. Still there were acres of Roses, of varieties so numerous as to be perfectly bewildering. Through Mr. William Paul's kindness, however, we are enabled to give the following selection of varieties that will not disappoint the grower:—

*Hybrid Perpetuals*.—Alpaïde de Rotalier, Alphonse Damaizin, Auguste Rivière, Baron Adolphe de Rothschild, Beauty of Waltham, Centifolia Rosea, Charles Lefebvre, Charles Margottin, Comtesse de Chabrilant, Dr. Andry, Duc de Rohan, Duchesse de Caylus, Elizabeth Vigneron, François Lacharme, General d'Hautpoul, Glory of Waltham, Jean Rosenkrantz, John Hopper, John Keynes, Lælia, Lord Herbert, Lord Macaulay, Madame Alfred de Rougemont, Madame Emile Boyau, Madame Rousset, Madame Victor Verdier, Marguerite de St. Amand, Maurice Bernardin, Olivier Delhemme, Pierre Notting, Prince Eugène Beauharnais, Princess of Wales, Semiramis, Senateur Vaisse, Triomphe de la Terre des Roses, Triomphe des Français, Victor Verdier, William Bull.

*Bourbon*.—Souvenir de Malmaison.

*Noisette*.—Aimée Vibert, Céline Forestier, Lamarque, Sol-faterre.

*Tea*.—Alba Rosea, Belle de Villedeaux, Gloire de Dijon, Homer, Madame Falcot, Madame Villermoz, Maréchal Niel, Narcisse, Rubens, Souvenir d'un Ami.

Of new Roses, Mr. Paul recommends the following:—Alfred Colomb, Aurore Boréale, Black Prince, Charles Rouillard, Comte Alphonse de Serenye, Dr. Lindley, Fanny Pettold, Fisher Holmes, Gloire de Ducher, Hippolyte Flandrin, Jean Cherpin, Jean Lambert, John Grier, Joséphine Beauharnais, Jules César, Lady Suffield, Madame Fillion, Mdlle. Marguerite Dombraïn, Marcella, Prince de Portia, and William Rollisson.

Of Hollyhocks there is also a fine collection, comprising every shade from white to black running through yellow fawn, puce, and crimson. Several of the kinds, however, had not come fully into bloom. The finest of those which had done so were Shrubland Gem, yellow; Red Gauntlet, fiery red, a very close spike; In Memoriam, claret; Argentea, silvery white; Black Prince; Beauty of Walden, rosy pink; Beauty of Waltham, blush, very fine; George Keith, red, very fine; Electra, sulphur yellow; Mrs. Chater, rose; and Lady in White, white, very fine.

We now come to the shrubs, of which the collection is very extensive and interesting. Of Hollies there were no less than one hundred sorts, among which that called Walthamensis, with deep golden variegation, is free-growing and very effective. Indeed hardy ornamental trees with golden, silver, and purple leaves, constitute a prominent feature; these colours freely introduced amidst the preponderating masses of green are very effective, and lead one to ask how it is that our landscape gardeners do not use them more frequently in modern planting. To see them as they may be seen here would at once set at rest any doubt that might be entertained as to their effect. If they could but be shown at our exhibitions as the greenhouse and stove plants of this character have so long been, they would, no doubt, become popular, and soon enter largely into the composition of English tree-scenery. Foremost among the gold-leaved kinds were the variegated Spanish Chestnut (*Castanea vesca variegata*), the leaves as large as the ordinary Spanish Chestnut, and broadly margined with bright gold. There were no less than three variegated varieties of Dogwood (*Cornus*), all beautiful; a new variegated Beech (*Fagus*), of more rapid and elegant growth than the old variety, the gold margin of the leaf broader and

brighter; an Ash (*Fraxinus aucubæfolia*), the large and graceful leaves well blotched with gold; several varieties of Privet, the evergreen sorts broadly edged with gold, and very handsome; variegated Turkey Oak (*Quercus cerris variegata*), the variegated Weigelas and Weeping Mountain Elm. To single out these as a few of the most striking may suffice to create an interest in these hitherto neglected plants, for which we augur in no distant future a full recognition and use. Among the silver-leaved trees the *Acer negundo variegatum* is the most conspicuous; the *Shepherdia*, *Hippophaë*, *Populus argentea*, and *Tilia argentea* are also distinct, and of great merit. Among purple-leaved trees the Purple Beech (of which there is a very large-leaved and dark-coloured variety here), the purple Nut, and purple Berberis were the most striking; but there was a great variety of trees of this colour, as well as of the gold and silver hues. Passing from colour to form, the Catalpa, the Paulownia, and the Magnolias appear to be still pre-eminent for the size of the entire leaf; and for divided leaves, the *Aralia spinosa*, *Alnus imperialis asplenifolia*, *Juglans laciniata*, *Kölreuteria paniculata*, *Rhus typhina*, and *Acer platanoides laciniatum* take foremost rank. There were also varieties of Oak, *Acacia*, and Elm as pyramidal in form as the Lombardy Poplar. Of trees which produce so fine an effect in the landscape in autumn by the changes of the colour in the leaves it is too soon to speak; they were, however, in abundance—scarlet Oaks, Liquidambers, Ginkgo trees, and others, as yet in their summer dress of bright green, but which we know will on the arrival of autumn stand forth arrayed in scarlet and gold. Beautiful trees! we would have you abound in our woods and plantations, and believe you will do so at no distant date.

The stock of fruit trees is another feature deserving special attention; and to give an idea of how extensive it is, we may mention that it comprises five thousand standard Apple trees, and between two and three thousand Pear trees, not to speak of large quarters of fine healthy pyramids three and four years old, and of trees for espaliers, walls, and bush culture. There are, besides, Peaches, Plums, and Cherries for orchard-house planting, and ready trained of various sizes for walls, and, it is worthy of remark, exhibiting a healthy vigour without over-luxuriance.

#### A NOTE ON TINGRITH GARDENS, NEAR WOBURN.

In a late volume I described at some length this beautiful residence of the Misses Trevor, whose fine taste, love of the beautiful, and kindness of heart are seen in everything connected with their establishment, and in the arrangements of the pretty cottages and well-kept gardens in the village of Tingrith. I never meet there my old friend Mr. Manning without one or other of us reverting to a forenoon many years ago, when, after tramping from London to Woburn, seeing all about the gardens, and staying over-night in the neighbourhood, I walked across to Southall (Mr. S. Whitebread's), the next day, and took Tingrith and Flitwich on my way, just when the late Mr. Brooks was in the height of his enthusiasm about his interesting arboretum; for he it known to all and sundry that young men in these far-off times had limbs, and could use them, and made no great matter of twenty or forty miles or more at a stretch. Well, the simple fact that fixed that forenoon so firmly on my memory was the somewhat bold invitation from our late, then burly, friend, the gardener at Tingrith, Mr. Phillips, to go round all the place, and if I found a weed above 1 inch in height he would give me half-a-crown for it; and I soon saw little chance of making half-crowns from such an investigation. On visiting Tingrith on my way to Woburn Show Mr. Manning playfully told me I must not look for the half-crowns; but if I had I fear I should not have obtained enough to have paid my travelling expenses.

The Grapes, Peaches, and plants in the houses were, if possible, better than usual, the out-door crops good, and flower-borders, walks, &c., without a vestige of a weed, or a mark to tell that there had been storms of wind, hail, and rain. The fine lawn, however, stretching from the windows of the living-rooms (which open into the beautiful conservatory), and backed by its masses of Rhododendrons, when I first saw it on the memorable forenoon was being rolled early to scatter the dew, so that it would sooner be fit for ladies walking over it with thin-soled shoes; and that lawn, merely as an object to look at, seemed to me the other day to be the most interesting feature about the place. So well cut, so well rolled, so springy and elastic, like a thick Turkey carpet, so green from

the recent showers, so free from Plantains and other weeds was it, that I could not help wishing that many who are ambitious to have large lawns round their residences, but who either cannot or will not keep them in first-rate order, could see this little gem of a grass carpet, to be convinced that half an acre so nicely kept will be more satisfactory than half a dozen or a score of acres which can only be kept in the roughest possible way. Something would be done for gardening, and a great deal for the comfort of gardeners, were proprietors sufficiently aware of the trouble, labour, and expense of keeping a large lawn as it ought to be—labour, which often interferes with other matters being sufficiently attended to.

Connected with this small flower-garden lawn there were three changes, and I think improvements, so far as I recollect since my last visit. First, a piece of rockwork and fernery, that bristled out from the evergreen shrubbery, had been removed and transferred to a miniature glen, where, amid the spray of a fountain, and just enough and not too much shade from embowering trees, the rapid growth of some fine specimen Ferns, and the general health and luxuriance, showed that the plants have there found a suitable home.

Second, with the exception of two round beds near the mansion, about 10 feet in diameter, and nicely filled, thus—centre of scarlet Verbena, broad band of Ceanothus, and broad band outside of blue Lobelia—the flower-beds are all small, chiefly confined to groups nearer the sides than the middle of the lawn, the beds crammed with plants, and showing a dense mass of bloom; and though, perhaps, scarcely exceeding 2 or 2½ feet across, I would not have wished them larger or higher above the lawn; so much of ease, room, light and shade, and contrast and blending of colour, were thus secured, and yet from the front of the house, and still more from the windows I presume, each bed could be seen distinctly. The lawn furnished a fine example of what may be accomplished with comparatively few flowers when these are grouped so as to secure alike individuality of interest and breadth, instead of contractedness of view. Calceolarias have been almost entirely excluded, and their place supplied with yellow-leaved Geraniums; the former having proved rather uncertain for several years, and no satisfactory reason can be given further than they have become tired of the place; but I can recollect when they used to thrive admirably.

Third, the most striking feature, however, was the long wavy ribbon-border which occupied the site of the old rockwork, &c., in front of the shrubbery, and which with that shrubbery formed a grand side background to the lawn. The beds referred to, however pretty, were lost in the dazzling splendour of this nice border. It was thus planted:—Two rows of strong plants of Stella Geranium next the evergreen shrubbery, one row of strong plants of the white-leaved Centaurea, two rows thickly planted of Mrs. Pollock Geranium, and two rows of Lobelia speciosa next the grass verge that separated the border from the winding walk. Perhaps a string of Ceanothus next the grass might have improved the appearance, but as it was it was very dazzling, and owed, no doubt, a good portion of its effect to the rich green background of the shrubs, the size and vigour of the individual plants, and the unbroken lines, as there did not appear to be a single vacancy in the rows.—R. FISH.

#### PELARGONIUM ST. FIACRE.

As a bedding plant, of the whole of the Zonale Pelargoniums, this is, in my opinion, the most useful. It is not, however, till this season that I have grown it as a bedder. Its compact habit, and the profusion of its beautiful salmon-coloured flowers, are great recommendations, and it is of so hardy a character as to be uninjured by winds or rain—a quality much wanted in many other varieties. I wish I could see after a heavy rain my beds of Madame Vaucher, François Desbois, Christine, and many others, in the same perfect condition as St. Fiacre. I think that this variety must ere long find its way into every modern flower garden. Too much cannot be said in its favour.—CHARLES EDWARDS, Bristol.

TULIPA SYLVESTRIS.—I beg to thank "A YORKSHIRE INCUMBENT" for informing us (page 93), that Tulipa sylvestris is still to be found in the meadows between Hexthorpe and Sprotborough. Two years since, I was informed that in making one of the new lines of railway a quantity of ballast was laid on the

spot where Tulipa sylvestris grew, and by so doing it was completely destroyed. Had I known that it was still to be found there I should have visited the spot during the last flowering season. "A SURGEON'S WIFE" appears to have been misled by the information contained in Baines's "Flora of Yorkshire;" it reads thus—"In a field between Hexthorpe and Sprotthorpe broats, on the banks of the river Don; covering a considerable space, but flowering only sparingly." In Miall and Carrington's "Flora of the West Riding," another Yorkshire station for this interesting flower is given on the authority of the Rev. G. Pinder; but this is open to doubt, as it is not now to be found there, and it is not easily eradicated, as the bulbs run so very far into the ground.—RUSTIC ROBIN.

#### GRASSES FOR LAWNS.

(Continued from page 106).

FESTUCA OVINA (Sheep's Fescue Grass).—This Grass, represented beneath, forms a dense carpet of dark glaucous green, and is much in request, and highly prized for lawns and bowling-greens. It constitutes the principal vegetation on some hills,

especially those which are dry and steep. Though dwarf it roots deeply, and is, therefore, remarkable for remaining green during the hot summer months and the most severe winters.

FESTUCA OVINA TENUIFOLIA (Fine-leaved Fescue Grass), is of a more slender growth than the preceding, which it much resembles, and is possessed of all its excellent properties. It is to be preferred to it for lawns, where it forms a finer turf, especially on dry gravelly soils. It is admirably adapted for lawns, bowling-greens, and parks, as it is always green, summer and winter.—G. ABBEY.

(To be continued.)

#### VARIEGATED MAIZE.

I OBSERVED in your Journal a few weeks ago a complaint that the new ornamental-foiled plant, the variegated Maize, produced from seed plants devoid of any variegation. My own experience does not accord with this. Out of a packet of seed

which I purchased from Messrs. Carter & Co., of Holborn, I had eight plants, and all of them have been beautifully variegated. They grew rapidly, and soon made handsome plants. Few plants could exceed them in beauty and gracefulness when they were 2 feet high; but since that time I have been much disappointed with them. The lower leaves turn yellow and brown, grow ragged, and give to the plant a shabby appearance. I have one plant with a fine head of flower upon it. Nothing can exceed the beauty of its upper part. Its leaves are long, and of good breadth; they are beautifully variegated, and hang gracefully, but the four lower leaves are dead and yellow, the tips of four more are dead and ragged, and the effect of the plant is spoilt.

My object in writing is to elicit information, whether other growers of this promising addition to our easily-grown variegated plants have found the same defect in it.—A YORKSHIRE CLERGYMAN.

## PORTRAITS OF PLANTS, FLOWERS, AND FRUITS.

**KLEINIA FULGENS** (Brilliant-flowered Kleinia).—*Nat. ord.*, Composite. *Lim.*, Syngenesia aequalis. Native of Port Natal. A succulent plant. Flowers scarlet.—(*Bot. Mag.*, t. 5590.)

**FREMONTIA CALIFORNICA** (Californian Fremontia).—*Nat. ord.*, Malvaceae. *Lim.*, Pentandria Monogynia. A hardy Californian shrub, introduced by Messrs. Veitch, "undoubtedly the choicest early-flowering shrub introduced of late years." Blooms in June; flowers yellow.—(*Ibid.*, t. 5591.)

**FERNANDESIA ROBUSTA** (Stout Fernandesie).—*Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monogynia. Native of Guatemala. Flowers yellow, lip spotted and barred with crimson.—(*Ibid.*, t. 5592.)

**SEMPERVIVUM PAIVE** (Baron Paiva's Houseleek).—*Nat. ord.*, Crassulaceae. *Lim.*, Dodecandria Dodecagynia. Native of Gomera, one of the Canary Islands. Flowers green.—(*Ibid.*, t. 5593.)

**SANCUEZIA NOBILIS** (Brilliant-flowered Sanchezia).—*Nat. ord.*, Acanthaceae. *Lim.*, Diandria Monogynia. Introduced from Ecuador by Messrs. Veitch. A most beautiful plant; bracts bright crimson, and corollas yellow.—(*Ibid.*, t. 5594.)

**SACCOLABIUM AMPULLACEUM** (Bottle-lipped Saccolabium).—*Nat. ord.*, Orchidaceae. *Lim.*, Gynandria Monogynia. Native of Sylhet, Sikkim, and other parts of India. Flowers rosy lilac.—(*Ibid.*, t. 5595.)

**PELARGONIUMS**.—*Lord Lyon*, very large, upper petals bright rosy crimson with a dark blotch; lower petals rosy pink, slightly veined; throat pure white. *Favourite*, upper petals crimson maroon, with a narrow fiery crimson edge; lower petals deep rosy crimson with a dark spot towards the base; white throat. Both were raised by Mr. Hoyle, and in the hands of Mr. Turner, of Slough.—(*Floral Mag.*, pl. 301.)

**ROSE**.—*Miss Margaret Dombain*, a seedling from La Reine, with large, globular, bright rosy pink flowers, very full.—(*Ibid.*, pl. 302.)

**AZALEAS**.—*Charmers*, flowers large, and of good form and substance, deep amaranth, spotted in the upper petals with a darker shade. *Vivid*, fine form, brilliant magenta.

**TACSONIA VAN-VOLKEMII**.—"This charming creeper is a native of New Grenada, where it is cultivated in gardens under the name of Courouba. It found its way into Europe a few years since through M. Van Volkem, a Belgian traveller, after whom it has been named by M. Funck; but it has remained comparatively little known in this country till the beginning of the present year." Mr. R. T. Pince, of Exeter, who first invited attention to it, thus describes his method of treatment:—

"*Tacsonia Van-Volkemii* is undoubtedly one of the finest conservatory climbers ever introduced, second only to the justly and universally admired *Lapageria rosea*. The healthiness, vigour, and rapidity of its growth combine to make it highly desirable for producing immediate effect in conservatory decoration. The flowers, which are of a rich rosy crimson colour (fully 5 inches in diameter), are freely produced from the axil of each leaf, and are gracefully suspended on long slender footstalks a foot in length, so peculiarly slender and thread-like that the flowers hang, as it were, clear and detached from the foliage, and have the appearance of brilliantly-coloured parachutes suspended in the air. Our plant was put into our show-house (the temperature of which is only that of an average conservatory, air being freely admitted, and the thermometer frequently falling as low as 35° to 40° in winter), in the middle of April, 1865, and by the end of January it had

covered the ornamental rafter which spans the house, had been clothed with flowers all through the summer, and was still adorned with them. The foliage is also remarkably good, and free from that coarseness which detracts much from other *Tacsonias*.

"Our plant is growing in a mixture of rough peat, loam, and coarse sand, with abundance of drainage, and plenty of pieces of broken brickbats, corks, sandstone, and old lime rubble, mixed in with the soil. Occasional syringing and copious supplies of water to the roots during summer and autumn promote luxuriant growth. It may be requisite now and then to cut back vigorous shoots which have flowered, in order to bring up fresh flowering-stems. From the pendent position of the flowers, it is obvious that this beautiful climber can be seen to better advantage trained to a rafter or the roof of the conservatory, than if put against a wall. I have alluded to its comparative hardiness, in support of which, and in addition to the general lowness of the temperature of our show-house, I may say, in conclusion, that we had a plant of it growing luxuriantly on an eastern wall out of doors, during the summer and autumn of 1865."—(*Florist and Pomologist*, v., 161.)

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

PAY due attention to thinning out and surface-stirring among all advancing crops; gather and store seeds of such choice vegetables as it may be considered advisable to preserve; but anything very extensive in this way ought never to be attempted in gardens exclusively devoted to the purpose of cultivating vegetables for families having any pretence to taste, as in most cases disappointment and inferior qualities will be the result. Any one at all conversant with the nature of kitchen-garden produce is well aware how much the qualities of vegetables become deteriorated when grown, seeded, and reproduced upon the same ground year after year; prudence and economy would, therefore, suggest that seed-saving should be left to those who make it both a business and a study. *Broccoli*, transplant Grauge's, Snow's, and Walcheren, and the last spring *Broccoli* for lifting, to be packed in beds for the winter. *Brussels Sprouts*, these, together with *Savoys* and *Curled Kale*, may still be planted, and every spare bit of ground filled. *Cabbage*, sow seed. There are so many fine varieties that it is difficult to make a selection; *Shilling's Queen*, *Sproborough*, and *Atkins's Matchless* are good sorts for standing severe winters, and not running to seed. All, however, are not suitable to every soil. This, however, is the general season for sowing, and it is quite certain that if any plant is to be transplanted prior to, and is to stand the winter, it ought to be grown rapidly, and acquire strength early. *Cauliflower*, from the 10th to the 20th of this month is the best time to sow this and *Walcheren Broccoli* for the spring crop. *Dwarf Kidney Beans*, a few more may be tried for the last supply. *Lettuce*, sow; also *Endive*, *Chicory*, *Winter Spinach*, *Welsh* and *Deptford Onions* for drawing young throughout the winter. *Peas*, top *Marrows* as soon as they reach the height of their stakes. Dig down exhausted plantations of *Strawberries*, and let the ground be filled with winter stuff if there is not already sufficient of this planted; make a further sowing of *Turnips* if these are likely to be scarce before the winter is over. Attend to cutting and drying herbs as they become ready, and do not allow *Shallots* to remain in the ground after the tops die down, as in the event of a continuance of wet weather they will make fresh roots, which prevent their keeping.

### FRUIT GARDEN.

No superfluous shoots ought to be kept on *Peaches*, *Nectarines*, and *Apricots* after this month, so that the wood for the ensuing year may be well ripened. *Pears*, *Plums*, and *Cherries* on the walls and espaliers are amenable to the same laws. Protect fruit from birds and wasps. The *Alpine Strawberry* ought to be encouraged this month by trimming off runners and placing slates under the fruit. About the end of the month is a good time to plant a bed of *Hautbois Strawberry*, if planted earlier the plants sometimes blossom in the autumn. A good breadth of the *Grove End Strawberry* ought likewise to be planted for preserving-purposes, first making the ground rich with dung.

### FLOWER GARDEN.

Attend to the gathering and saving of choice perennial and biennial flower-seeds; these should be watched daily, and collected as they ripen. We do not advise this operation to be carried on to a great extent, as the returns would not be ade-

quate to the expense and trouble of collecting and cleaning. We merely allude to those showy species and varieties, some of which every flower gardener possesses and cultivates, and which, not being easily procurable from the seedsman, it is desirable we should endeavour to preserve. Take the opportunity of fine days for collecting; tie up in bundles, and label correctly. Seeds of plants which have burst their seed-vessels should be gathered in pans; place them in the seed-room till a wet day occurs, when the seeds can be rubbed out. Propagation of stock for next season must now be commenced and carried on with expedition, so as to secure strong, well-established plants before winter, and without the necessity of keeping them so close and warm as to induce weakly and watery growth. Hollyhocks are general favourites, but they do not afford cuttings freely, and are in general not over-plentiful in most places; these should, therefore, be examined often in search of any cuttings which they may afford, as those rooted about this time will make strong plants for next season. Attend to the tying-up of these and Dahlias. Sow Ten-week and Intermediate Stocks for spring flowering; transplant Brompton and Queen Stocks, and if the situations in which they are to flower are not at liberty, prick them out in nursery-beds, allowing them plenty of room to prevent weakly growth. Keep gravel walks perfectly clean and smooth by weeding, sweeping, and rolling as may be necessary. Keep climbers on walls within due limits. Continue to remove dead flowers from Roses, and give plenty of manure water to the autumn-blooming varieties. Plant-out rooted cuttings of Pansies in nursery-beds in a shady situation, keeping them well watered, if the weather proves dry, until they become established. Finish budding Roses at once, if not already done, and also let border Carnations, Picotees, and Cloves be layered without further loss of time.

#### GREENHOUSE AND CONSERVATORY.

It will be much to the advantage of the inmates of plant-houses, to reduce the shading after this time, to enable the plants to ripen their summer's growth, allowing more air to keep down the temperature, and so check any tendency to a second growth, which may show itself, and which can only take place at the expense of next season's bloom. Brugmansias, Clerodendrons, and other large soft-leaved plants should be frequently washed to keep down red spider, and be well supplied with liquid manure to keep them in a vigorous state of growth, which adds so much to their beauty. Remove Achimenes, Gloxinias, Tuberoses, and plants of the same habit from the conservatory when on the wane, and replenish from the reserve-houses to keep up the display. Epacris, winter-flowering Heaths, and other plants requiring to have the wood ripened early may now be placed in a sunny exposure. As the wood is already formed, nothing remains but to get it well ripened; and although water must be given equal to the demands of the plant, a dry and warm atmosphere are essential to the perfect ripening of the wood, and consequent formation of flower-buds. Should the weather prove unfit for out-of-door work, it would be advisable to take the opportunity thus afforded to effect any arrangements necessary internally. It would be a favourable moment for carefully regulating conservatory climbers, and thoroughly cleansing the house, at the same time a fresh arrangement of the plants might be carried out, and some necessary potting performed. It is injudicious to defer this last operation, when at all necessary, until late in the autumn. Plants out of doors must be frequently examined, and carefully secured against all chances of injury from ungenial weather. Continue a system of stopping and training with young plants intended for specimens. Give a shift to Chinese Primulas, Cinerarias, and Chrysanthemums. Salvias and other autumn-flowering plants should be placed in their blooming-pots. Passifloras, and, in fact, most conservatory climbers, will be growing fast, and will require frequent training. Thin out weak and overstrong shoots, and reserve only sufficient to produce the desired effect; the blooms will be considerably finer, and the plants themselves more capable of producing well-matured wood when these little attentions are performed regularly.

#### STOVE.

Such of the inmates here as are intended for the decoration of the conservatory in autumn and early winter, should be carefully looked over, shifting all that are likely to want more pot room without unnecessary loss of time, so as to have the pots well filled with roots before the flowering season. Also, keep the shoots tied out rather thinly, and expose the plants to as much sunshine as they will bear without scorching their foliage,

in order to promote sturdy growth. Give clear liquid manure to young growing specimens, and repot any of those that are intended to have another shift this season, so as to have the pots well filled with roots before winter. Maintain a moist growing atmosphere, and ply the syringe vigorously upon any plant at all infested with red spider. Various stove climbers, as Combretums, Quisqualis, Allamandas, &c., will bloom for a considerable period, if the shoots on which the flowers are borne are slightly cut in when the blooms decay.—W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

HEAVY rains have been succeeded by rather rough stormy winds, and as these have been followed by a fair amount of sunshine, the ground was speedily dried for general operations; and when it was too wet a good opportunity was afforded for bringing up arrears of shed work, washing pots, preparing sticks, grinding scythes, &c., though the latter should seldom be necessary with a good scythe and a man who wields the sharpening stone properly.

*Potatoes.*—Seized the opportunity of the dryness to take up most of the early Potatoes in the garden before they were subjected to more wet, as continued wet and a close moist atmosphere are almost sure to bring on the disease, and also because the ground was wanted for succession crops of winter Greens, &c. The Potatoes on sloping banks and in free open situations produced wonderfully heavy crops, and at present show no signs of disease; but those on flat ground, and more confined by bushes or rows of staked Peas, &c., every 10 feet or so, and which had received no earthing-up, did show signs of the old malady. Although some of our correspondents are impressed with the inutility of earthing-up the Potato under any circumstances, our own experience and observation would lead us to the conclusion that in somewhat stiff land it is better to plant rather shallow and earth-up the stems in a flatish ridge, to save the tubers from greening by exposure, and also in wet summers and autumns in order to insure the extra water running away from the tubers instead of resting about them. The grand remedies against disease are, however, fresh soil and free exposure, which cannot be easily obtained in closely cropped small kitchen gardens. The most puzzling fact of all is when, by due preparation of the soil in kitchen gardens, you obtain something like marvellous crops, as we had last season, and, just as in this, not a trace of the disease in sloping banks and open spaces; and yet, after housing the tubers quite dry and in thin layers in a cool dry place, ere two months have passed a third of the tubers are affected by the disease where one could not be found so affected at lifting-time. There is hardly a seeming evil but is attended earlier or later with a countervailing advantage; and the importance of fresh soil and an airy position for Potatoes may lead to the existence in new places of much smaller kitchen gardens, where only the earliest Potatoes shall be grown, and the main crops of these, Turnips, and Carrots, shall be obtained from open fields passing through the regular rotation of crops. Carrots and Turnips will thus be produced sweeter for the table than they can be obtained in old kitchen gardens, however attentive you may be to give them fresh soil by trenching and rotation of cropping.

*Turnips, &c.*—Thinned some sowings entirely of *Radishes*, and in other late sowings thinned the Turnips. Sowed a good piece only 15 inches apart in the rows, instead of 2 feet, as in the general crops, as the heads will not be expected to be so large, and just scattered a sprinkling of Radishes between them. A correspondent the other day was doubtful what kinds of Radishes to grow, there seemed to be such a variety in the seed lists, and asked what we thought of the long white and blackish winter sorts; to which we merely reply that we think just enough of them not to grow them, though we would not undervalue them, as tastes differ, and a single Radish is quite enough for us for a twelvemonth. Of long sorts we use the Long Scarlet and the Early Frame, and of Turnip-rooted kinds the White and the Red; but our Red this season is more of a dark crimson, and on biting it we do not think it is so tender as the Red Turnip-rooted. The White Turnip Radish when young—that is, little more in diameter than the size of a sixpence, is generally very sweet and nice, and it looks well on the table.

Of all Turnips, the sweetest to our fancy is the American Stone, or the American Red Top, from the purplish appearance of the top of the tuber, but which is of a clear white

inside, to meet the prejudices of the *artistes* of the kitchen. One great advantage of this Turnip is, that if your rows are thick, and you wish a succession from the thinnings, you may transplant them as securely as you would a lot of Lettuces, or a bed of Swede Turnips. At present we have several pieces of this Turnip where our bedding plants grow temporarily in the spring, and if there is any difference between them and those left from sowing in the usual manner, it is in the more equal appearance of the plants, the better form of the tubers, and, if possible, their milder and sweeter taste. The fact of their standing transplanting so well may often be turned to profitable account, and so out it must come, as a secret too valuable to be kept. Many crops as well as Turnips like fresh soil, but in their case it must be rich, the manure sweet, and the plants grown quickly and pulled young, to have the produce first-rate at table.

Cleared off Peas that were becoming exhausted. In general we like to sow single rows a good distance apart, with other crops between, but for two or three of the earliest crops it is often well to have a few rows about 4 feet apart, so that the space may be cleared at once, and planted with Broccoli and winter Greens. Have been busy filling such ground, and that from which such Potatoes have been raised, with Greens, and the later crops of Cauliflower, giving the latter less room than the plants would require when planted earlier in the season. Where the ground was poor, enriched it by trenching down rotter short grass and compost from the rubbish-heap. Planted out also more Coleworts, allowing no ground to remain empty, but just managing that the crops may be removed at one time, or nearly so, to suit succession crops in the spring.

The first-sown Cabbages are just through the ground, will scatter some wood ashes over them. Will sow a few more by the end of the week, and a little Cauliflower for the earliest next spring, and will sow again towards the end of the month, and in September, for successions. Made a sowing of Onions, to be repeated about the middle of the month, and again in the first week of September, the two first, chiefly for drawing when young, and the last for transplanting to bulb in spring. Sowed Spinach for autumn use, and will sow in the middle of the month, and again in the beginning of September, for winter and spring gatherings.

Celery.—Since a heavy hail shower this has been considerably spotted on the foliage, and the larger, finer plants seemed to have a yellowish tinge, of which the younger plants are free; and as they seemed damp enough, scattered a little soot over the foliage and soil, and will leave the rains to clear it away, or if they do not come soon enough, will sprinkle them overhead with water from a rose. We like to see this crop presenting a very dark, instead of a light green appearance. Those seem the least dark that were large plants when turned out, and the younger ones are making up to them in strength very fast. The first were thinned out of a bed, a part being left standing to come in early, and, therefore, the roots of those removed were a little curtailed, and, as we think we noticed at the time, they were planted with a trowel instead of a spade, to give full spreading room for the roots. The next in size were lifted with large balls from a border, and holes or trenches were made sufficiently large with the spade, so that the roots might spread out at once without any curtailment. We mention this latter matter, because the advantages of pricking out Celery in rich stuff on a hard bottom, are chiefly that the plants may be easily watered in the young state, and that the roots may be lifted in balls, and transplanted to the trench, so as to be affected by the moving as little as possible. We must find a place for some later Celery, for as yet we have scarcely three successions. The end of this and the next month are the great months for Celery-growing. Unless partially shaded it grows but little in bright weather in July. By using a little soot water in watering, we have scarcely ever been troubled with the grub in the leaves, and if it do come, in answer to several correspondents, we would say there is no cure but to squeeze them and kill them, and make the leaves distasteful to the insects that deposit the eggs beneath the cuticle of the leaf.

FRUIT GARDEN.

Went on regulating trees and potting Strawberries very much as stated last week. We regret now that we did not turn out more of our forced Strawberries early; but we could not find time. Those turned early out of pots into a border have supplied us with nice and pretty regular gatherings after the latest Strawberries were over; but to have them thus early, the forced plants must be turned out not later than May, if earlier all the better. As soon as we can find time we shall plant out

many runners in a rich piece of ground, and the earliest kinds will do for forcing next season, and others will come in for making fresh plantations of well-established plants, so that the ground destined for bearing Strawberries next season may still be cropped this winter. These are some of the moves which many must adopt where much has to be obtained from little room.

Orchard-houses.—The first would have been in if we had liked; but finding the fruit would be more valued later, we have given more air, even at the risk of causing a temporary check. Top-dressed all trees in pots the other day with a mixture of old Mushroom dung, hotbed dung, and a little soot mixed with it. These top-dressings tend to diminish the frequency of watering, and the waterings take down the nourishment of this mulching with them. As Mr. Rivers states, it is most amazing how soon this mulching disappears. Whether it is eaten up by the plants, or the water, or the air, it would be difficult to say; but the great point, whenever it disappears and the surface soil of the pot looks you in the face, is to renew the mulching. Other matters very much as in previous weeks' notices.

ORNAMENTAL DEPARTMENT.

In addition to what was alluded to last week, have been chiefly engaged in potting, and preparing for taking cuttings for the flower garden, regulating the same, and fixing after the winds and rains, and were we to go much into detail, it would be very much of a repetition of the excellent directions of Mr. Keane at page 108. If we can find time we want to divide and remove Violets, &c., and the sprinkling the Neapolitan Violets with a little sulphur from a dredge-box or a good-sized pepper-caster, will help to keep them free of red spider. Syringing them with the sulphur and lime liquid is also good for the purpose. Whatever means are used, they should be perfectly healthy before winter. The wind has given us a deal of work in the flower garden. As for the beautiful Verbenas, we suppose we must give them up here, as every night they are cropped like a carpet by rabbits and other four-footed intruders. The few flowers of to-day are gone before the morrow comes. Verbenas will never succeed until Rabbits are caught, or sent out and kept out.—R. F.

COVENT GARDEN MARKET.—AUGUST 11.

THERE is little alteration to be noticed here this week. Some fair samples of Pears from the continent have come to hand, and include Jargonelles and Beurré d'Amans, varying in price from 1s. to 3s. per doz. All other articles are quite sufficient for the demand.

TRADE CATALOGUES RECEIVED.

W. Cutbush & Son, Highgate.—*Bulb Catalogue for 1866.*  
Hamilton & Wright, Surrey Seed Warehouse, Thornton Heath, London, S.—*Select List of Bulbs.*

## TO CORRESPONDENTS.

••• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.*

**TWELVE GREENHOUSE FERNS FOR EXHIBITION (A Constant Reader).**—*Gymnogramma Velenbaliana*, *G. peruviana argyrophylla*, *Davallia aculeata*, *Goniophlebium appendiculatum*, *Neottopteryx australasica*, *Adiantum macrophyllum*, *A. emneatum*, *Asplenium racibirizon*, *Dryaria muscifolia*, *Blechnum corevadense*, *Nothochliza trichomanoides*, *Lonchitis Ghiesbreghtii*.

**TWELVE GREENHOUSE FERNS FOR EXHIBITION (Idem).**—*Gleichenia spluncea*, *G. labellata*, *Acroporus hispidus*, *Leptopteris enperha*, *Mohria thurifraga*, *Cheilanthes lendigera* or *elegans*, *Asplenium candidum*, *Balanium culcita*, *Didymochliza truncatula*, *Asplenium dimorphum (diversifolia)*, *Peris scaberrima*, and *Nephridium molle corymbiferum*.

**HARDY FERNS FOR EXHIBITION (Idem).**—*Asplenium marinum* trapeziforme, *Blechnum spicatum ramosum*, *Athyrium Filix-foemina plumosum*, *A. Filix-foemina depauperatum*, *Lastrea Filix-mas cristata*, *Osmunda regalis cristata*, *Woodsia ilvensis*, *Polystichum angulare plumosum*, *P. angulare profferum* *Wollastoni*, *Scelopendrium vulgare ramosum majus*, *S. vulgare supra-lineatum*, and *Asplenium refractum*.

**TREE FERNS FOR EXHIBITION (Idem).**—*Cyathea dealbata*, *Dicksonia antarctica*, *Cyathea Smithii*, *Dicksonia squarrosa*, *Alsophila excelsa*, and *Cibotium princeps*, which last is the only one requiring a stove temperature.

**VINES MILDEWED (F. H. and R. W.).**—The leaf sent was attacked with Oidium or Yucca mildew. The leaves and stems should be dusted with flowers of sulphur, admitting air plentifully.

**SOWING DRUMHEAD CABBAGE (Idem).**—To come in next July the seed should be sown in the second week in August.

**FUCHSIA BLOOMS DROPPING (Homo).**—We suspect you give too much water and too little air.

**DOUBLE CINERARIA (P. J. Turtor).**—Your Cineraria is only semidouble. Save the seed and sow it, and you may raise one that is perfectly double. The hardy Ferns that will suit you are *Diplazium thelypteroides*, *Lastrea cristata*, *Lastrea marginalis*, *Osmunda regalis*, *Oncoclea sensibilis*, *Stratiotopsis germanica*.

**FUCHSIA CORYMBIFLORA AND FULGENS CULTURE (C. H. D.).**—Both require the same description of soil—viz., two-thirds turfy loam and one-third leaf mould, with a free admixture of sand. Do not overpot, and avoid cutting in hard, as that and too much pot room only tend to produce foliage. The leaves and flowers drop from an insufficient supply of water and air. Whilst growing the plants should have plenty of water, air, and light, and then they flower as freely as other Fuchsias. Generally their culture is not different from that of ordinary plants. After flowering, well ripen off.

**PLANTS FOR A LONDON HOUSE-TOP GREENHOUSE (———).**—We fear that the atmosphere will be too dry for Ferns, but some of the commoner ones might be tried, and such plants as *Fuchsias*, *Myrtles*, and *Balsams* in summer, and *Chrysanthemums* in autumn. Some of the bedding *Pelargoniums* would also do, but we would not recommend the greener kinds. In winter and spring bulbs of all sorts might be had, with Cinerarias if you have the means of heating, or rather of keeping out frost, but we would not advise *Camellias* or *Azaleas*. *Salvias*, however, would do. Few Ferns succeed well in sitting-rooms till the summer be well advanced, when their foliage being hardened, they suffer less from the dry atmosphere. Common *Adiantums*, *Athyriums*, and *Polypodiums*, look as well as any, so will *Scelopendriums*, and there being several varieties of the last possessing much beauty they may with advantage be tried.

**SCORCHING OF FRUIT-TREE LEAVES.**—"W. W.," Mount House, Boston Spa, Yorkshire, would like to correspond with "Inquirer" who wants to learn the cause of his fruit-tree leaves being scorched in his greenhouse, and the means of preventing the evil.

**GRAFTING ROSES.**—Will "Loch Ness" kindly explain whether he grafted the *Manetti* stocks and immediately took them up from the open ground, and then potted them? Will he also state where the india-rubber bands are to be procured, their width and length, and how they are fastened at the end with a bit of thread? "Loch Ness" also alludes to another kind of stock than the *Manetti*, mentioned by him two or three years since.—M. D.

**VIOLA CORNUTA (W. M. W.).**—There are three varieties of *Viola cornuta*. Apply to the Messrs. E. G. Henderson, of St. John's Wood, London, for Willis's variety. Six plants will be enough to enable you to propagate a stock for next spring. As soon as the plants arrive, divide and plant them out in some rich soil. Any time in October take up a few of the strongest plants, pot them in 48-sized pots, place them in a cold frame, and, as they grow, pinch out the tops of the shoots. Instead of throwing these away, if they are an inch or so long, and you have a small cucumber-frame at liberty, prick them out in it, and they will strike sometime during the winter, but if you make use of the tops in this way cut them out with a sharp knife instead of pinching them out. Any time in March place the plants you have potted in a gentle hotbed or in any structure where there is a genial atmosphere. The plants will grow very freely, and may be propagated with care from the young free-growing shoots. By massing *Viola cornuta* as recommended above, you will have three chances of raising a stock. If you fail with your plants in heat, those left in the open ground will be safe. If you be successful in all three instances (and there is no reason why you should not), you may by next May multiply your six plants by hundreds.

**STRAWBERRY RUNNERS (E. N.).**—The runners which you have layered in pots should be detached from the parent as soon as the roots show themselves at the bottom of the pots. Plant at once in the bed prepared for them. Strawberries require a rich and deeply stirred soil, and prefer one that is strong. They do fairly but not so well on sandy as clayey soil.

**DESTROYING BROWN SCALE (Prestonian).**—The insect on the *Dentzia* sent is brown scale. Immerse the plants for a minute in a tub containing a solution of soft soap at the rate of 4 ozs. to the gallon of water heated to 120°, let them stand until dry, and then syringe with water at a temperature of 140°. Lay the pots on their sides, and turn them so as to thoroughly wet every part. Repeat the operation at intervals of three weeks until the plants are clear.

**GRAPES NOT COLOURING (Idem).**—We fear you have too heavy a crop, and do not give air enough. If the temperature you name is that of the night it is too high by 5°; and the syringing of the walls, floors, &c., in the afternoons should now be discontinued. Leave a little air on at night. (*Cliftonensis*).—We have little doubt that the Vines have been allowed to bear too heavy a crop, and that too much liquid manure has been given.

**RHODANTHE, &c. (William Hay).**—If you show the flowers in the day you will show them open, but if in the night you must show them closed.

**STANDARD ROSES WITH LARGE HEADS (Agnes).**—The size of the heads is an advantage; and we do not know what you can do to them beyond cutting back the long straggling shoots to six leaves now; and at the end of March or beginning of April the very weak and dead shoots may be removed, thinning the others if too numerous and close together, and shortening the long shoots to four or five buds.

**PROPAGATING VARIEGATED PELARGONIUM (Idem).**—It is much better to take cuttings of the gold and silver-leaved kinds now than to wait till later in the season. We prefer taking up old plants and striking cuttings from them in a gentle heat in spring. Cuttings of the scarlets may be taken from this time to the middle of September, the earlier the better.

**CLUB (T. D.).**—We would recommend a dressing of gas lime at the rate of twelve bushels an acre as the most likely remedy for this disease, which, as you are doubtless aware, is of frequent occurrence in all old garden ground.

**CLEMATIS JACKMANNI (Hortensis).**—This will grow in any good garden soil, and any situation. It is readily propagated by cuttings in a cool frame.

**PROPAGATING CENTAUREA RAGUSINA (Idem).**—If plants are taken up, and divided in July or August, or even cuttings are taken off at that time, every bit will strike, if ordinary care be taken to prevent damping; and one of these little bits struck will have a better chance to pass through the winter than old plants taken out of the ground, however carefully managed. Small bits will also strike freely in spring in a little drishy heat. It is a good plan where there are some old plants to top them in February, and then in March they will throw out a lot of shoots 2 or 3 inches long, which strike freely round the sides of a pot. The great secret of success is to divide or strike early, so as to have the plants well rooted and established before winter. Young plants do best for edgings. If kept drishy they will stand plenty of air and cold in winter, if frost be excluded.

**STRAWBERRY DR. HOGG (J. T. S.).**—This will prove one of the most valuable Strawberries in cultivation. It is a British Queen as late as the Elton and Frogmore Late Pine, but it is a far more robust grower than the British Queen, and the fruit colours perfectly, while it possesses the true Queen flavour. This variety, therefore, prolongs the Queen race to the latest period of the season.

**CLIMBERS FOR A CONSERVATORY (G. H. C.).**—We would do as you propose. For climbers in front, and to go up the roof, we would have *Mandevilla suaveolens*, *Bignonia chirera*, *Passiiflora carulea*, and *Habrothamnus elegans*, and these we would plant in elegant boxes some 18 inches square. On the floor we would have from three to five largish vases, with their pediment resting on a wooden one, painted and sanded to resemble stone, with an opening on one side from which to remove a tin vessel that would catch all the water from waterings. Such vases filled with flowers, and with little creepers hanging over the sides, would look very nice, and if there were more room smaller vases or tazzas might be used. In such a drawing-room conservatory we would not have a single red clay pot.

**MAKING MUSHROOM SPAWN (Amateur).**—If you have had a small gathering in seven weeks that by no means shows that the spawn has been bad. There may yet be plentiful gatherings; but it is just possible there may not, even though your beds have been well managed. You will find minute directions for making Mushroom spawn at page 203, Vol. IX., New Series, or No. 233, September 12, 1865, which may be thus summarised in answer to your queries. No better time for making the spawn can be fixed on than the end of August and the month of September. Take, as materials, a barrow-load of cowdung, rather stiff, and two barrow-loads of horse-droppings, with a little short straw with them, and half a barrow-load of fibry loam. Mix these up into a stiff mortar-like substance until it is pretty well incorporated and looks like grouting-clay. Then make a frame either of iron or wood, say half-inch boards at the latter, and in four pieces—that is, two sides and two ends, enclosing a space of 9 inches long, 4½ inches wide, and 1½ inch deep. Then obtain a flat clean board, and a bucket of water, dip the frame in the water, place it on your board, fill it with the prepared dung, strike level with a spade or trowel, and turn out the brick on boards, to dry on its flat side. In a couple of days make two holes in the brick, but not going through it—say three-quarters of an inch in diameter, turn the bricks until they are tolerably dry, then into each hole push a piece of good spawn, and draw a little cowdung or clay over it to prevent its falling out. Next make up a slight bed of litter, on which build these bricks in open honeycomb or pigeon-hole fashion, and cover over with litter, so that these spawned bricks shall have a temperature of from 50° to 85°, and not more. As the spawn runs, the bricks must be examined, and, as soon as they are filled with the gossamer-like white spawn threads, removed, and kept in a dry place until wanted for use. Some bricks or pieces will be ready to remove before others.

**HEATING A VINERY (J. H. Bilston).**—Your arrangements will keep you safe, but you will not be able to keep up a high temperature in very cold weather. In your forcing part adding another flow pipe would be economy in the end, and we would be inclined to say the same of the cooler house. A flow and return would prevent the necessity of having the pipes too hot, and you will save fuel by having more piping. Some £3 or so saved now will insure a future loss. The saddle boiler we would recommend would be 24 inches long, 19 inches wide, and 16 or 17 inches in height.

**THUJOPSIS DOLABRATA, RETINOSPORA OBUSA, AND LIBOCEDRUS CHIL-  
ENSIS IN YORKSHIRE (P. W.).**—We fear that the last-named will succumb  
to very severe winters like that of 1860-61, which we know it has done in  
more favoured parts of England; still we would try it. *Retinospora*  
*obusa* we believe to be hardier, and it seems to grow very freely in places  
where it has been tried. *Thujaopsis dolabrata* is less free in growth, but  
may, nevertheless, be quite hardy. We would expect the *Retinospora* to  
be the best of the three, and the one most likely to become a fine tree.  
A dry soil, inducing an early ripening of the wood, has much to do with  
the success of the plant. Some Conifers, such as the *Wellingtonia*, con-  
tinue their growth very late in the season, and when suddenly caught  
with cold weather they suffer in consequence. We would be disposed to  
try the species which you mention, sheltering them a little the first  
winter, as it often happens newly planted trees or shrubs do not then  
mature the growth of that season, although they may do so afterwards.

**LILIUM AURATUM (R. B.).**—Your *Lilium auratum* is going to rest  
Cease watering it, and keep it in a dry cool frame.

**MORONELLA MAGNIFICA CULTURE (W. H. W.).**—We would support the  
head of bloom on such a young subject to be grown as a specimen plant,  
and so that it would incline gracefully; but we would not keep it long, but

cut it off, that the buds from the axils of the leaves might burst into  
shoots and be encouraged. Stop when 2 or 3 inches long, and let the  
plant receive plenty of heat and moisture to encourage growth. More  
light, air, and less moisture next summer will cause the flower-shoots to  
show, and they would do so sooner if the growing influences were not kept  
up. It flourishes in peat and loam, and may have occasional manure  
waterings, and especially when the bloom shows.

**NAME OF FRUIT (John M. Miller).**—Your Grape is *Rod Chasselas*. We  
had 8d. to pay for carriage, which please remit.

**NAMES OF PLANTS (A. R. C.).**—*Tenerium fruticosum*; *Stachys lanata*.  
(A. T. S.).—Specimens very bad. 1, *Blechnum occidentale* (?); 2, *Drodia*  
*caudata*; 3, insufficient for identification; 4, *Platyloma hastata* (?); 5, *Pol-*  
*ypedium phymatodes*; 6, *Polystichum* sp.; 7, *Cheilanthes hirta*. (M. D.).  
—1 and 2, *Athyrium Filix-foemina* var.; 3, *Pteris aquilina*; 4, *Pteris longi-*  
*folia* var. *scrabata*. (E. J.).—*Hypericum montanum*. (Edney).—*Pteris*  
*cretica*; *Adiantum pedatum*. (E. T. W.).—*Oncoclea senariilis*; *Indigofera*  
*decora*. (J. P. G.).—*Statice limonium*. (A Reader).—From the small  
portion you have sent, your plant appears to be a white variety of  
*Myosotis palustris*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 11th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

VULTURE HOCK IN BRAHMAS.

BEING one of those curious people who desire to know the  
reason "why," I am now anxious to know why the vulture  
hock is objected to in Brahmans. There must be, I suppose,  
some ground beyond the mere fancy of the period against it,  
and as the season advances it becomes important to know  
what is the objection; for without some real ground for op-  
posing it, it seems hard to make it a disadvantage, and, perhaps,  
cause the whole class to suffer in the long run.

I believe it is right to say, that there is no cause without its  
effect, and I presume, therefore, the simple converse to be also  
true. What is the cause, then, of the vulture hock? Is it a  
sign of impure breeding anywhere? If so, why are vulture-  
hocked birds even admitted at exhibitions? Cochins are suffer-  
ing now, I believe, under the same ban; but if it can be  
alleged to come from them, it may surely with equal right be  
argued that the Cochins have taken it from the Brahmans, as  
the actual source cannot be discovered, and that it is, there-  
fore, perhaps a legitimate appendage (I speak, of course, as  
an amateur in search of knowledge, rather than laying down  
facts). Again, If it is a sign of cross-breeding, why does not  
the plumage otherwise suffer? and I think it will be admitted  
to be quite as correct in marking, &c., as the plumage of birds  
without the brand. Some of our best breeders prefer vulture  
hocks, I believe, so they can hardly be a sign of degeneracy.  
Why, then, are vulture-hocked birds to be at a disadvantage  
in exhibitions? If they are admitted, supposing no valid  
argument can be brought against them, surely they ought to  
be on an equal footing with the rest; or else, some real ground  
of objection being proved, let them be absolutely forbidden, and  
breeders will then know what they are about. In another  
year, as it stands at present, perhaps nothing else may be  
approved of!

As I may be taken to be interested in the advancement of  
the vulture hock, I can candidly say, beyond wishing to know,  
as I said before, "the reason why" it does not matter to me in  
the least. The subject, however, appears to me to deserve a  
thorough investigation—that is, if poultry breeding is im-  
portant, which far be it from me to deny. I tremble at the  
crushing my presumption may bring upon me, but if you  
deem this letter worthy of publication, I hope I shall do  
Brahmas and Brahma fanciers a good turn.—A QUESTIONING  
BRAHMA.

[The above was sent to a well-known poultry Judge, and this

is his reply:—"The birds originally imported had no vulture  
hocks, and those that have the appendage are a later introduc-  
tion. The same is true of Cochins. There was an attempt  
at the second London show to admit the vulture hocks, and  
the question you ask about the Brahmans was put by all those  
who had vulture-hocked birds. Evidence was at once collected  
from all those who were the first importers and the largest  
breeders, and in no instance were the vulture hocks imported  
or bred from imported birds. That which is intended for ex-  
hibition should come as nearly as possible to the admitted  
standard of the breed, and I think that, in all breeds, has  
been safe in the hands of the gentlemen who for many years  
have awarded the principal prizes. The proof of it is, there  
has been little or no alteration in their requirements in any  
breed. If the objection to the vulture hocks were new, or only  
just published, then those who possess vulture-hocked birds  
might justly complain, and ask why they were excluded from  
competition; but they have always been excluded. Doubtless  
they arose from the freak of some amateur, or they were the  
result of a distant cross, and the unhappy owner of it, instead  
of 'stamping it out,' perpetuated it. I have tried to explain  
why they are disqualified, I want to ask, Why they were ever  
produced?"]

SOME months have elapsed since any article upon this sub-  
ject appeared in the pages of "our Journal;" and as the  
points involved in the late controversy affect a large number of  
breeders besides myself, I feel urged to resume the subject,  
especially as the season has now arrived when a selection of  
young birds for future exhibitions must be judiciously made.  
When "Y. B. A. Z.," in the commencement of last spring,  
challenged "one of our most able judges," (whose name I do  
not happen to know), to justify his objection to the vulture-  
hock covering upon our birds, it was hoped that the challenge  
would be accepted; but it was not, so that at present we are  
all at sea upon the matter. And I would respectfully inquire  
whether the awkward position in which we are thereby placed  
ought not to receive the considerate attention of the Judge who  
first opened the controversy by affirming, what has since been  
palpably disproved—that the vulture hock is a recent intro-  
duction. The silence he has thought proper to maintain may  
be regarded as a tacit admission that he was in error; or it  
may signify something else, and which we hope is not intended,  
as it would tend to irritate rather than appease. Between  
exhibitors and the judges there ought to exist the most friendly  
feeling upon poultry matters; but if there is secret distrust  
entertained on the one hand, and an erratic if not arbitrary  
judgment displayed on the other, the result must sooner or

later prove extremely prejudicial to the interests of our poultry shows. In sending our pens for competition we should possess the firmest persuasion that the standard by which they will be tried is that which has been set up in former years—that which is recognised and fully approved of by exhibitors themselves, and that no deviation from it will in any wise be made. If defeated, we can then patiently endure it, because we know that the rules of judging have been strictly and impartially carried out. If, however, on a sudden a judge shall be pleased to make such alterations in the standard as shall strike at some of the finest characteristics of a class, convert that which was formerly deemed essential and ornamental into a glaring defect, and sweep from the proud and high position it has long held that very type of perfection in a class which till late never contested for a prize but to win it, and which never appeared at an exhibition but to be most admired;—what remains for exhibitors but to protest against such an abuse of delegated power, and to take effectual steps to prevent the recurrence of such a prodigious wrong? If what is accepted as perfection in a class one year may, through fickleness and caprice, be reprobated the next, what reliance can breeders possibly repose even upon the most promising specimens they are rearing? and what faith can they have in the judges themselves when their opinions are so fiftful and contradictory?

By allowing the question to remain an open one nothing but confusion and mischief must ensue. It is highly detrimental to the whole class of Brahma fowls; it creates suspicion where it did not exist, and feeds the flame where it has been already kindled; it unsettles breeders; it disheartens many; it misleads persons who are providing themselves with stock; it makes a wrong impression abroad, and works injuriously every way. If not brought to a speedy termination, it will require no prophet's eye to foresee the consequences that will spring out of it in a considerable diminution of entries for our annual shows. If we are at the expense and hazard of sending a few pens to an exhibition, we ought certainly to know beforehand what specimens should be sent; and if objections are taken to any particular marking which have not heretofore been taken, and which are not taken by other judges of equal ability in judging, are we not entitled to inquire upon what ground those objections are raised? and does not common courtesy demand that an explanatory answer should be given?

I have been at the trouble of writing to several eminent breeders of Brahmas upon the subject of the vulture hocks, and I find that most of them are decidedly in favour of it, not merely on account of the feathering itself, which they consider ornamental, but because the birds thus marked almost invariably carry the heaviest fluff, and have the shortest, best-feathered legs. The feathering we are contending for is not a long, stiffly set mass of feathers, reaching nearly to the ground, which may be deemed unsightly, and which I have never observed in birds of the larger growth, but a moderately curved furl, from 1 to 1½ inch round the joint, of soft and flexible texture, and this, a popular writer on Brahmas affirms, "should appear." To the inquiries I have made only one gentleman has objected; and when I pressed him for his reason, to my great surprise and infinite amusement he sincerely remarked, that "the vulture hock was a sign of weakness in the leg joint, and therefore it was a defect." A greater blunder was never made. Birds of stouter frame, of larger limb, with bones stronger, thicker, more firmly set, and knit together with more powerful joints, are not to be found among the Brahma species; and if our opponents have no better reason for supporting their opposition than this, I would advise them at once to give up the contest, or for ever hold their peace. This was, however, the only person that I have found object to our specimens. Among those who approve is a lady, whose treatise on poultry many have read and admired. She remarks, "It is hard upon us, this change of fashion in Brahmas. To be abundantly feathered there must be a tendency to vulture hocks."

So strong and general a predilection existing in favour of our birds, is it not much to be deplored that any gentleman holding the office of a judge should come down with a pouncing veto upon them at the annual shows? It is, however, a satisfaction to know that other judges are unbiassed by the prejudice we are combating, as was evident from their award of prizes at the last West of England Show to birds that were more or less vulture-hocked. But Birmingham is looming in the distance, and whether a broad line of demarcation between the covered and uncovered hock joint will be drawn at Bingley Hall, is a question in which all exhibitors, like myself, are concerned. We insist that it should not be drawn for the abun-

dant reasons which have been brought forward in the course of this controversy; but if arbitrary rule should be allowed to over-ride popular opinion and calm remonstrance, we have no alternative but to keep our pens at home. I sincerely trust that the grievance which has so frequently been complained of, will, upon sober reflection, be speedily removed. It is in the power of the unknown but able Judge to do it.

The breeding season is now over: thousands of beautiful Brahma chickens, full of young life, are heard at early morn, chirping their cheerful notes as they rapidly and eagerly snatch up the grain scattered over their green runs; and when we visit the older broods at noonday—pretty creatures! there they are, stretching their fine large limbs on sunny bank, or beneath the shady covering of the hawthorn bush. Day by day they are gaining size, and strength, and plumage; their good points are coming more and more prominently into view, amply repaying us in promises for the future for all the expense, care, and anxiety we have sustained in rearing them; and now from this and that goodly group the most admired and likeliest to win many a laurel in the hard-fought battle are about to be selected, and all that we demand for them is fair play and nothing more. Let them be permitted to enter the lists without any distinction being made between the vultured and naked hock, and our end is gained, our ambition is gratified. The pen of controversy will then be allowed to return to its resting-place; our confidence in the decision of judges will be restored; our co-operation with existing poultry committees will be heartily rendered; the aloof of contention will be exchanged for the olive branch of peace; a good understanding will exist; a fresh stimulus to friendly and honourable emulation will be imparted; and, forgetting the past, we shall rejoice in the harmony which has been established, and render all honour to the judge, the sentence from whose lips has conferred such a boon upon a large number of the proscribed and oppressed offspring of the Brahma tribe.—*JUSTITIA*.

[We have always admired the vulture-hocked Cochins, and we know that some of the earliest bred by Mr. Sturgeon were so feathered. We also know, from our own experience, that some of the finest birds are vulture-hocked. "*JUSTITIA*" says the same of Brahma Pootras. Such being the case, why not have separate classes—vulture-hocked, and not-vulture-hocked?—*Ens.*]

#### EVIL DOINGS OF THE SUFFOLK OR WOODBRIDGE POULTRY SOCIETY.

THE above Association, under the presidency of the Right Hon. Lord Rendlesham, and under the patronage of Lord Henniker, Sir Fitzroy Kelly, and a large number of the clergy and gentry of Suffolk, is earning a notoriety which is not to be desired. Although the Show was held on the 24th of May last, the prize money and silver cups have not yet been delivered, and every application by letter, of which there have been a vast number, is left unanswered. In one instance, and probably in many others, a pen of birds has not been returned to the owner, and he is not able to obtain any answer to his applications as to what has become of his property. In my own case I can neither obtain my prize money nor an answer to my letters.

Were there any difficulty or failure in the results of the Show, in a money point of view, no one would have been more ready than myself to meet the Committee, either by a total abandonment of my claims, or by receiving a composition; but when the letters of gentlemen are left unanswered, and the names of others who patronise the Show are indirectly involved in the evil doings of the officials, any consideration of the kind, even if needed, is entirely out of the question.

I do not suppose that these remarks will be very intelligible to those for whom they are intended; but there is a method of addressing these people which is not beyond their comprehension, and which I shall adopt—namely, by process in the County Court.—*EGOMET*.

#### PRESERVING EGGS.

IN the Number for July 24th, some hints are given as to a mode of preserving eggs in lime. The plan is undoubtedly very good, and I have myself practised it successfully for several years, but I found some difficulty in taking the eggs out of the lime without breaking them. For the last two years I have adopted another plan. I take a deep earthenware jar, slake the lime in it, and as soon as the lime has settled, I sink

the top of an old hamper, to rest on the sediment. I then drop the eggs into the clear lime water above, the top of the hamper preventing them from sinking into the lime. I found that this plan answered just as well as that which is described at page 76, and I had only two bad eggs in five hundred.—A NEW SUBSCRIBER.

### GOOLE POULTRY SHOW.

This was held on August 2nd, and for a first meeting was patronised by a large company, for, although the weather was very unfavourable, there could not have been fewer than two thousand persons present in the afternoon.

There was a good show of birds, but, as is often the case at this season, many of the lots were out of feather from moulting, which tended to lessen the richness of their appearance. *Spanish* headed the list, and the prize for this class was won by a superior pen of Mr. Beldon's, a well-known exhibitor. The *Dorking* class which came next under the Judge's notice was very moderate, and also the *Cochins*, and the prizes were generally won by medium birds. The pen which won the *Game* prize (a cup, value £3 3s.), was one of the great attractions of the Show, and the spectators by hundreds loitered about the pens as if loth to leave them to gaze upon inferior birds. The three classes of *Hamburghs* were all of great merit, and called forth the praises of the Judge. The *Poland* class was also first-rate. The *Bantams* were only moderately good, and scarcely received a notice from the visitors.

The *Pigeons* were all of superior merit and attracted much attention. The following are the awards of the Judge, Geo. Hatfield, Esq., Braithwaite Hall, Doncaster:—

**SPANISH.**—First, H. Beldon, Goitstock, Bingley. Second, J. Hatfield, Cottingham.

**DORKINGS.**—First, J. Hatfield. Second, W. Dawson, Hopton, Mirfield. **GAME (Black-breasted and other Reds.)**—First, H. Beldon. Second, F. Sales, Crowle.

**GAME (Duckwings and any other variety.)**—First, T. Chantry, Goole. Second, F. Sales.

**GAME (Any variety.)**—Silver cup, F. Sales. **HAMBURGH (Golden-spangled.)**—First, J. W. Cannan, Bradford. Second, H. Beldon.

**HAMBURGH (Silver-spangled.)**—First and Second, H. Beldon. **HAMBURGH (Golden-pencilled.)**—First, S. Smith, Northwram. Second, H. Beldon.

**HAMBURGH (Silver-pencilled.)**—First and Second, H. Beldon. **POLISH (Any variety.)**—First and Second, H. Beldon.

**ANY OTHER PURE OR DISTINCT BRED NOT PREVIOUSLY CLASSED.**—First, H. Beldon. Second, W. Glentworth, Goole. Extra Second, H. Beldon. **GAME BANTAMS.**—First, W. Clayton, Howden. Second, W. Chester, Old Goole.

**BANTAMS (Any other variety.)**—First, J. R. Jessop, Hull. Second, J. W. Cannan.

**ANY VARIETY.**—First, H. Beldon. Second, R. Newbitt, Epworth. **GAME BANTAMS (Any variety.)**—Prize, J. W. Cannan.

**GEESE.**—Prize, O. A. Young, Driffield.

**TURKEYS.**—Prize, F. W. Porter, Goole.

**GUINEA FOWLS.**—Prize, O. A. Young.

**DUCKS.**—First, E. P. Porter. Second, J. R. Jessop.

**PIGEONS.—Carriers.**—First, S. Robson, Brotherton, South Milford. Second, J. Thackray, York. **Croppers.**—First, J. Thackray. Second, S. Smelt, Beverley. **Tumblers.**—First, G. Snelling, Hull. Second, Messrs. Grant & Tomlinson, Thorne. **Barbs.**—First, Messrs. Grant & Tomlinson, Second, C. Cussons, Hull. **Jacobins.**—First, H. Beldon. Second, C. Haycroft, Thorne. **Trumpeters.**—First, J. Thackray. Second, H. Beldon. **Turbits.**—First, H. Beldon. Second, S. Smelt. **Fantails.**—First, J. Thackray. Second, C. Cussons. **Any other variety.**—First, S. Robson. Second, J. Thackray (Swallows).

### CLITHEROE POULTRY SHOW.

This Exhibition was held in connection with the annual meeting of the Agricultural Association, on Saturday, August 4th, and the result, both in the number and quality of the birds exhibited, has far exceeded the expectations of the Committee when they issued their amended and more liberal prize list. In the twenty classes into which the schedule was divided, 254 pens were entered, and most of them contained first-rate birds from different exhibitors in all parts of the kingdom. Both Judge and exhibitors expressed their entire satisfaction with the arrangements, both for their convenience and for the well-being of the specimens. The condition of the birds was excellent, and far beyond what could be expected at this advanced season, more particularly as poultry-breeders generally have found that the moulting season has begun fully a month earlier than usual. Had the Show been held at a more favourable time, the number of entries would, no doubt, have been considerably larger.

The *Game* fowls were very good. The cup for the best pen of *Game* in the Exhibition was awarded to Brown Reds belonging to Mr. Brierley, of Middleton. To this gentleman were allotted also the cup and second prize in the Single *Game* Cock class, the first-prize bird, a Black Red, being considered by the Judge, Mr. Teebay, the best Black Red he ever saw. Messrs. Fletcher, Julian, Westall, and Fell exhibited very fine specimens. The cup for coloured *Dorkings* went to Mr. Lingwood, of Barking. The cock, a very handsome bird, was not mated equally. The class generally was very good, and besides the three prizes, five pens were highly commended. In

this class, as in the Spanish, the third prize was awarded to a very fine pen of *Chickeus*. *Cochins* were moderate, but much out of condition. The cup was awarded to a pen of Partridge-coloured belonging to Mr. James, Kirby-Lonsdale, which were claimed at the price put upon them, £10 10s., directly the Show opened. Some splendid specimens of White *Cochins* were sent by Mr. Zurhorst, of Dublin, and this class was the best in the *Cochin* variety. *Brahmas* were very good. The cup was given to the well-known pen so long exhibited by Mr. Boyle, now the property of Mr. Pickles, of Tolmorden. The *Spanish* class was one of the best in the Exhibition. The cup went to Messrs. Burch & Boulter. The cock is one of the best we have seen lately, and had he been accompanied by the hen in the second-prize pen, a pen would have been made which could scarcely have been surpassed, if equalled. A very good pen of *Chickeus* received the third prize. Very good pens were exhibited by Messrs. Thresh and Beldon. The hen in Mr. Thresh's pen attracting the attention of all Spanish admirers by the extreme beauty and quality of her face. *Hamburghs* formed a very good class. The cup was given to a pen of Golden-spangled, belonging to Mr. Newton, of Silsden, near Leeds. Very excellent pens were sent by Messrs. Wood, Walker, Smith, Beldon, and Pickles. The gem of the Exhibition was the "Any other variety class." Mr. Teebay assured the Committee that he had never judged so good a "variety class" in his life. On referring to the prize list the names of many pens which have been prizetakers elsewhere, will be noticed. *Game Bantams* were very poor, and several pens were empty. The Any other variety of *Bantams* were first-rate. The cup for *Bantams* was awarded to Mr. E. Hutton, of Pudsey, whose pen of Black *Bantams* was much admired.

*Turkeys, Geese, and Ducks* were very good, Mrs. Seamons, of Aylesbury, as usual taking the cup for the best pen of *Ducks*, with very fine specimens of Aylesbury.

**GAME (Black and other Reds.)**—Cup, C. W. Brierley, Middleton. Second, W. Westall, Baxenden (Brown). Third, J. Fletcher, Stoneclough, Manchester (Black). Highly Commended, J. Robinson, Garstang (Black). Commended, W. James, Bolton Gatehead, Cumberland (Black); M. W. Stobart, Middleton-one-row, Darlington (Black).

**GAME (Any other variety.)**—First, J. Fletcher (Duckwing). Second, H. M. Julian, White Friargate, Hull (Duckwing). Third, J. Fell, Adwalton, Leeds (Duckwing).

**DORKINGS (Coloured.)**—Cup, H. Lingwood, Barking, Needham Market. Second, J. Hill, Burton-on-Trent. Third, D. Parsons, Cuedon, Preston. Highly Commended, J. Robinson; W. Moorhouse, Reed, near Whalley; D. Parsons; W. Whittaker.

**COCHINS (Cinnamon and Buff.)**—First, E. Smith, Middleton. Second, J. Cunningham, Blackburn, (Cinnamon). Third, J. Nelson, Heaton Mersey, Manchester (Buff). Highly Commended, Messrs. Bowman and Fearon, Whitehaven (Buff). Commended, W. J. Mellor, Colwick Rectory, Nottingham (Buff).

**COCHINS (Brown and Partridge.)**—Cup, W. A. G. James, Kirby Lonsdale (Partridge). Second and Third, J. Wood, Woodbank, Heywood (Partridge).

**COCHINS (White.)**—First and Third, F. W. Zurhorst, Donsybrook, Dublin. Second, W. Dawson, Hopton, Mirfield. Highly Commended, E. Smith.

**BRAMA POULTRY.**—Cup and Second, J. H. Pickles, Bridgeroyde, Tolmorden (Dark). Third, T. Pomfret, Houghton Lane, Preston (Dark). Highly Commended, G. H. Roberts, Penwortham, Preston, (Dark); W. Hargreaves, Bacup (Dark). Commended, G. H. Roberts (Dark).

**SPANISH (Black.)**—Cup, Messrs. Burch & Boulter, Sheffield. Second, E. Jones, Clifton, Bristol. Third, J. Newton, Silsden, Leeds. Highly Commended, H. Beldon, Goitstock, Bingley; J. Thresh, Bradford. Commended, E. Draper, Northampton.

**HAMBURGHS (Golden-pencilled.)**—First, A. K. Wood, Burneside, Kendal. Second, S. Smith, Northwram, Halifax. Third, H. Beldon. Highly Commended, W. Bee, Goosnargh. Commended, J. Bowe, Carlisle; T. Wareing, Preston.

**HAMBURGHS (Silver-pencilled.)**—First, H. Beldon. Second, J. Walker, Hay-a-park, Knaresborough. Third, H. Pickles, jun., Early, Skipton.

**HAMBURGHS (Golden-spangled.)**—Cup, J. Newton, Silsden, Leeds. Second, J. Walker. Third, A. K. Wood. Highly Commended, J. W. Cannan, Bradford; R. Tate, Leeds. Commended, T. Wareing, Preston; A. K. Wood.

**HAMBURGHS (Silver-spangled.)**—First and Second, A. K. Wood. Third, J. Altham, Baxenden. Highly Commended, H. Beldon. Commended, A. K. Wood.

**GAME BANTAMS.**—First J. W. Cannan, Bradford. Second, J. Walker, Third, R. & E. Toder, Little Carlton, Newark (Black Reds). Highly Commended, H. Smalley, Stanhill, Accrington.

**BANTAMS (Any other variety.)**—Cup, E. Hutton, Pudsey, Leeds (Black). Second, F. L. Roy, jun., Newthorne, Kelso. Third, J. W. Cannan (Black). Highly Commended, Captain Dwyer, Burnley (White); F. L. Roy, jun., (Sbright).

**ANY OTHER VARIETY.**—First, H. Beldon (Polands). Second, National Poultry Company, Bromley, Kent (La Flèche). Third, Mrs. A. Whittaker, Vicarage, Whalley. Highly Commended, H. Carter, Upperthong, Holmfirth (Black Polands); F. W. Zurhorst (Sultans and La Flèche); M. Leno, fifth (Black Polands); National Poultry Company (Houdan and Crève Dunaible (Houdan)); National Poultry Company. Commended, H. Beldon (Polands); J. Robinson (Black Hamburghs). Commended, H. Beldon (Polands); H. Savile, Ruford Abbey, Ollerton (White Japanese Silkies).

**TURKEYS.**—First, J. Cunningham, Blackburn. Second, S. H. Stott, Rochdale. Highly Commended, E. Leech, Rochdale; J. Wilson, Wood-horne, Morpeth.

**GEESE.**—First, Mrs. M. Seamons, Aylesbury. Second, S. H. Stott (Toulouse). Highly Commended, E. Leech; H. Savile (Sébastopol White); C. W. Brierley; E. Hutton (Egyptian). Commended, B. Baxter, Skipton (Grey Toulouse).

**DUCKS (Aylesbury.)**—Cup and Third, Mrs. M. Seamons. Second, E. Leech.

**DUCKS (Ronen.)**—First, J. Nelson, Heaton Mersey, Manchester. Second, T. Wareing, Preston. Third, J. Robinson. Commended, C. P. Ackers, Bickershaw, Wigan.

**DUCKS (Any other variety.)**—First, T. C. Harrison, Hull (Pintail).

Second, E. Hutton (Brown Call). Third, T. Wakefield, Newton-le-Willows (Brown Call). Highly Commended, R. Tate (Grey Call); D. Parsons, Cuerden (Call).

SINGLE COCKS.

GAME.—Cup and Second, C. W. Brierley (Black Red). Third, N. Grimshaw, High Field, Burnley. Highly Commended, J. S. Butler, Poulton-le-Fylde; J. Fletcher (Black Red). Commended, R. Greuell, junr., Ribchester.

GAME BANTAMS.—First, H. Smalley, Accrington (Black Red). Second, T. Wareing, Third, C. W. Brierley. Commended, S. H. Scott (Duckwing); J. Percival, Birmingham (Pile).

UTTOXETER POULTRY SHOW.

THIS took place on Friday last. The following is the prize list:—

SPANISH.—First, S. Mills, jun., Walsall. Second, A. O. Worthington, Burton-on-Trent. Highly Commended, W. Tams, Hilderstone, near Stone.

DORKING (Any variety).—First, Mrs. F. S. Arkwright, Derby. Second, Lady Bagot, Blithfield. Highly Commended, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, Rotherham. Chickens.—First, Mrs. F. S. Arkwright. Second, Lady Bagot (Silver-Grey).

COCHIN-CHINA.—First, S. Mills. Second, E. Daniel, Cheadle. Commended, Mrs. P. Wolferston, Tamworth. Chickens.—First, W. S. Bagshaw, Uttoxeter. Second, F. E. Richardson, Bramshall. Highly Commended, Mrs. P. Wolferston. Commended, S. C. Hamerton, Warwick.

GAME (Black or Brown-breasted Reds).—Prize, G. Bagnall, Cheadle. GAME (Any other variety).—Prize, G. Bagnall. Chickens.—First, —Beck, Uttoxeter. Second, G. Bagnall.

HAMBURGH (Golden-pencilled).—First, Hon. H. W. Fitzwilliam. Second, A. K. Wood, Burnside, Kendal. Chickens.—First, A. O. Worthington. Second, F. D. Mort, Moss Pit House, near Stafford. Highly Commended, E. Bell.

HAMBURGH (Golden-spangled).—First, E. Fynney, Leek. Second, H. Bagshaw. Highly Commended, J. Atkins, jun., Walsall; A. K. Wood. Commended, W. Tatton, Leek. Chickens.—Prize, T. May.

HAMBURGH (Silver-pencilled).—First, A. K. Wood. Second, E. Bell, Burton-on-Trent. Highly Commended, H. Richardson, Roycrofts.

HAMBURGH (Silver-spangled).—Prize, A. K. Wood. BRAMA POOTRA.—First, A. O. Worthington. Second, T. Greatrex, Walsall. Highly Commended, Mrs. P. Wolferston.

BANTAMS (Any variety).—First and Second, R. Charlesworth, Manchester. DUCKS (Aylesbury).—Prize, H. Chawner, jun., Houndhill.

DUCKS (Rouen).—First, C. Whitaker, Uttoxeter. Second, H. Chawner, jun. GESE.—First, F. E. Richardson. Second, G. Walker, Sandon. Highly Commended, W. A. Rawlins, Uttoxeter. Commended, Mrs. P. Wolferston.

TURKEYS (Cambridge).—First, F. E. Richardson. Second, W. Bagnall. Highly Commended, F. E. Richardson.

GUINEA FOWLS.—First, H. Chawner, jun. Second, W. A. Rawlins. EXTRA CLASS.—First, E. S. Wolferston, Tamworth. Highly Commended, F. E. Richardson (Black East Indian Ducks).

SWEEPSTAKES FOR SINGLE COCKS.

SPANISH.—Prize, E. T. Holden, Walsall. COCHIN-CHINA (Buff).—Prize, F. E. Richardson.

INCUBATORS.

It would be a great service to the poultry world if, through your Journal, any one having used artificial incubators during this season would give an impartial account of the results thereby obtained, and especially as to the strength of the chickens, and how many reared artificially; also the cost of the heat, and the difficulty or otherwise of keeping up the proper temperature.

I keep Spanish fowls, and this year bought several sittings of eggs from noted breeders, and I found, as I anticipated, that the hens broke far too many eggs. If artificial incubation is a real success this would be avoided.

My idea is to hatch artificially, and then place the chickens when pretty strong under hens which have been sitting—say on pot eggs.

I, like many more, would certainly use an incubator if I were satisfied that with a fair share of care the results would be satisfactory; but before purchasing I should very much like to have, through your Journal, some of the results from gentlemen who have tried the various inventions.—A SPANISH BREEDER.

LONG SUTTON POULTRY SHOW.—It will be seen from our advertising columns that this is to take place on the 10th of October. The prizes are liberal, and include eight silver cups of the value of £5 each.

GAPES IN CHICKENS.—I have seen this disease treated as follows by American housewives. The horny tip or scale at the end of the tongue is plucked off by the thumb-nail, and a wing feather, pulled from the chicken, is thrust as a seton through the skin of the neck, and so remains until it wears off.—D. J.

COCK PHEASANT SITTING.

A FRIEND of mine has a cock Silver Pheasant two years old, and one Silver hen one year old; they have been running with some Game fowls, and a nest was made in the shrubbery, and seven eggs laid, which were scattered about several feet from the nest for fourteen or twenty days in the hot sun. To his great surprise one day he saw the cock Pheasant collecting the eggs to the nest. The cock bird sat on them, and on Wednesday, July 25th, brought off three chickens, all doing well. No doubt more eggs would have been hatched, had they not been exposed so long in the sun. The father is as proud as any father of a family. Is this a common occurrence with Silver Pheasants?—AFFECTION.

[Your account is most interesting. We once met with a similar case. For a long time it was denied that a Silver hen would lay good eggs the first season, but two of ours did so last year.]

LIGURIAN BEES.

“Is the Ligurian really more prolific than the common bee?” Such is the inquiry of one of your correspondents in a recent Number. The question is fair and natural, and I have no doubt is often reiterated by many of your readers. That the Ligurian bee is said to possess this and other qualities which render it superior to the common species, is evident from the reported results of its cultivation by scientific apiarians both in Germany and England. Admitting this, however, the question still recurs, Can the deductions of scientific observers be depended upon by those who aim chiefly at practical results, and keep bees only for profit? Undoubtedly so, or science and empiricism would become synonymous. True science takes cognisance of all circumstances, and investigates without prejudice or partiality. The establishment of a theory is one thing, that of fact and proof another. In theories it is very easy for a man to impose upon himself; in comparative experiments, fairly and honestly conducted, with the exercise of ordinary observing and reasoning faculties, conclusions in time become irresistible, and proof rests upon an irrefragable basis.

The experiments alluded to in my former letter were undertaken neither to disparage our old friend the black bee, nor to exalt the asserted superior qualities of the Ligurian, but simply to ascertain for myself, and in my own way, whether there is any difference between them, and if so, in what that difference consists. My experiments were conducted on the *cateris paribus* principle (without which I should not have been satisfied with results), and I made them as fairly and as fully comparative as I could. I was influenced by no prejudice, and my aim was simply the satisfactory establishment or disproof of an asserted fact. With the results, as given in a former Number of this Journal, your readers are already acquainted. I will briefly recapitulate my statistics of progress, and append one or two additional facts of an interesting character, which place in a still stronger light the fecundity of the Ligurian bee.

I began the season with six stocks, two of them so light at midwinter that I never expected them to survive until the floral season. However, I watched them carefully, and when the increase of temperature awoke them into activity, I gave them a liberal supply of strong syrup slightly salted. Under this treatment they rallied, but their numbers had diminished to such an extent that I never expected them to swarm; each of these, however, has thrown off three swarms. For brevity's sake I will call my six stock hives A B C D E F.

Date of First Swarm.	Second Swarm.	Third Swarm.
A. May 27th, A A ..	June 8th.....	I suspect that the third swarms from these hives, which were both strong, took flight very early in the morning and were lost.
B. June 3rd.....	June 15th ....	
C. June 3rd, C C ..	June 19th ...	June 21st.
D. June 8th .....	June 19th ...	June 21st.
E. June 9th .....	June 20th ...	June 22nd.
F. June 23rd .....	June 30th ...	July 7th.

MAIDEN SWARMS.

C C June 23rd .....	July 9th.....	July 10th.
A A June 25th .....	July 8th.....	

The results, then, are these:—My six stocks have yielded me, without taking into account the two third swarms which I am fully convinced were lost, twenty-one swarms, and leave me in possession at the end of the season of twenty-seven stocks altogether. I have occasionally, although rarely, had from first-rate stocks of the common bee three swarms, and a

maiden one from the first of these; but maiden second and third swarms are entirely new to me. So far as I can judge, and I endeavour to observe as accurately as I can, what in this respect seems exceptional in the case of common bees, is normal in the case of Ligurians.

I may observe, in passing, that I had kept the black species for many years, and last season my hives yielded me about 5 cwt. of honey. I have a gardener who can hive the bees and attend to the apiary during my absence, but, as a rule, they are under my sole management, and I mostly manage to be at home in the busy season. I like to work as well as to observe; but, alas! "The rector's bees," as my poor people say, "generally swarm on a Sabbath," and twice on the same Sunday (immediately before and after morning service), have I experienced what I should call, on other days, the pleasurable excitement of hiving two large swarms. However, I have never lost a single swarm from the unsabbatical habits of my little busy workers, and, with the exercise of a little watchfulness, hope I never shall. Some of my neighbours are less fortunate, for twice during the last month have my services been interrupted, and my congregation perturbed, by the intrusion of a swarm of bees just before morning prayer. Fortunately, however, beyond the droning which was very distinctly sustained during the whole service, and a nervous movement occasionally amongst the occupants of one or two seats near the window, through which the imprisoned bees were vainly struggling to escape, when some stray intruders threatened too dangerous a proximity, our quiet village worship was conducted the same as usual. These swarms effected their entrance into the roof of the north aisle through a small opening, which could only have been discovered by a previous reconnoitre. I am convinced by this, and several other analogous facts which have come under my observation during the last three or four years, that swarming is nothing more than a general muster of emigrants previous to their departure in one compact phalanx, to a new habitation fixed upon, and made ready, when necessary, at least some days before their leaving the old hive.

One remark on the letter of your correspondent from Kildare. There is something so unusual in the size of his third swarm, which came out on the 8th of June, that I am inclined to ask him whether he is quite sure that no considerable portion of this returned to the parent hive during the process of swarming? This, with me, has not unfrequently happened, both with second and third swarms, and on two occasions this summer I have had the latter leave their hive and return to it no fewer than three times in one day.

I daresay many of your readers are aware that after-swarms are sometimes, perhaps more frequently than not, headed by three or four queens. With my Ligurians this has been almost invariably the case this summer, and the knowledge of this fact has enabled me to capture several queens, and to place them at the head of swarms of the purity of which I might have been in some doubt. Sometimes I have had three or four clusters enclosing as many queens, and in this case nothing is easier than to treat them as the heads of distinct establishments, and hive them separately. As a rule, however, there is but one cluster, and around this an experienced eye will detect, often—for instance, on the leaves of the tree on which the swarm may have alighted—thirty or forty bees congregated together, indisposed, apparently, to increase their numbers, and yet disinclined to separate and join the main body. Careful examination of these little nuclei will almost invariably disclose a queen, and nothing is easier than, with the aid of a wine-glass and a piece of stiff card-board, to capture her and her body-guard. It requires very little dexterity to accomplish this feat, and in this simple manner I one morning secured three queens. One of these, of remarkable size and beauty, I utilised in this way, keeping her and about a dozen of her companions on the red currant leaf on which they settled, for three or four days in a wine-glass with a piece of honeycomb, until the opportunity arrived.

At last this was presented by the departure of a third swarm, the largest I ever saw, from a hive in a rather exposed situation. The morning was windy and occasionally showery, and altogether most unpropitious. The bees no sooner took wing than they were scattered on the ground and trees around, on an area of some three or four hundred square yards. The queen, as I expected, did not accompany them, and now was the time for my experiment. I waited until the scattered bees began to grow impatient and unsettled, and some few of them attempted to take flight homewards. I placed my imprisoned queen and her companions on a kind of extemporised stand

made of small branches of currant tree, in the upper part of a common straw hive; held it immediately over some trees on which the greater portion of the bees had alighted, and, one by one, shook these sharply so as to induce the bees to take wing. They did so, and in rising at once discovered the queen. Then arose the call-hum which the anxious apiarian under such circumstances is delighted to hear, and the whole swarm rose up, one by one, acknowledging the sovereignty of their alien queen. I was determined to increase their numbers as I knew that the hive was populous, and the whole of the bees that could well be spared had not come out. So as soon as the swarm had quietly settled in its new abode, I removed the old stock from the stand and replaced it with the new swarm, taking the former into a room lighted with only one small window which was closed; on gently tapping the hive, still attached to its bottom board, the bees became irate, and immediately rushed out of the hive to the narrow light. Repeating this operation at intervals of two or three minutes, and opening the window to set its bewildered occupants at liberty before resuming the tapping process, I managed to collect in the new hive one of the largest swarms I ever possessed, the liberated bees at once returning to the old familiar spot. I kept the new hive where I had placed it, and removed the other to a station at a considerable distance. Both hives are doing well, and with their present teeming population bid fair to make first-rate stocks.

I must conclude this discursive paper with an account of a calamity which happened to one of my heaviest hives last Sunday morning (July 29th). Just as I had entered my dressing-room, word was sent up to me by my gardener that one of my hives had fallen over in consequence of the ground being saturated with rain, and that the combs were all broken, and the honey and bees mixed together in one homogeneous mass? What was to be done? And all this on a Sunday morning too! I remembered that one of my hives had been placed near a new wall, erected in the dry weather, and that the earth had not been well rammed around the foundations. One of the legs of my stand had sunk in this, and the "centre of gravity" soon found its way over "the base." To save the stock was impossible, and to approach it, dangerous. And now came the question, How can I take the honey? The thought struck me in a moment, that the only immediately available plan was to pick up the hive and plunge it and the whole of its contents into a vessel of water, deep enough to cover all, and to leave things *in statu quo* until my clerical duties were completed. The idea proved eminently practical, and after breaking up the combs and washing them in the water, the débris of these and their constructors were separated from the syrup by means of a strainer, leaving me to ascertain the value of this by means of a saccharometer. It happened fortunately, that we were just on the point of commencing our annual brewing of elder-flower wine; the required quantities of sugar and water were duly added, and the wine is now made and on the point of being stored away in the barrel for winter use.—WILLIAM LAW, *Marston Trussell Rectory.*

In my communication at page 115, there is a mistake in the date of the first swarming from the two stocks, which, if uncorrected, would lead to the erroneous notion that the queens of two united swarms could remain peaceably together for more than a week. Both the swarms alluded to took place on the 7th of June (not 1st), their union to the original Ligurian stock being effected that night, and the huge swarm coming out again on the 9th, at 11 A.M., so that these two queens were in the same hive only thirty-six hours. It was, doubtless, their proximity to one another becoming known then that occasioned the second issue.

I can also fully bear my testimony as to the greater fecundity of the Ligurian queen to that of the common bee. The bees of the only Ligurian stock I possess still (8th of August), keep up their numbers, and maintain their activity to a much greater extent than any of the best of my other stocks, and during the last three weeks of very indifferent weather have worked vigorously, although I am afraid to little purpose, so far as honey-collecting is concerned; but the number of foragers returning with pellets of farina on their legs is still most remarkable.

My advice to all owners of hives this year is, Be cautious in depriving them of honey, for the season has been scarcely an average, or you will lose them during the ensuing winter.—A BLACKHEATH'AN.

### A DETHRONED QUEEN.

The old queen in my six-frame observatory hive has been quietly dethroned, and a youthful sovereign welcomed as her successor; and as the proceedings were carried on of the bees' own free will, without any intermeddling on my part, I will narrate what came under my observation; and when I state that for nine days the aged and youthful queens, without any manifestations of antipathy, paced the combs, I think even close observers may find somewhat to interest them in the details.

I observed on the 14th of July a sealed queen cell in the above-mentioned hive; it struck me at the time as a rather singular circumstance, no swarms being contemplated, as a large amount of space in the hive remained unoccupied by comb or bees. As the royal brood approached maturity I looked for symptoms of antipathy on the part of the queen, but no excitement was manifested either by her or her attendants. On the 21st the cell was opened, and as I watched the queen performing the functions of the hive, and an examination of the exterior of the hive failing to reveal a discarded princess, I presumed the effort to raise another queen had been abortive. On the 22nd, however, I was surprised to see a beautiful young queen attended by a delighted and attentive circle, and upon the same comb my old queen also surrounded by a portion of her subjects. This state of affairs of course afforded a fine opportunity in installing a youthful sovereign in lieu of the three-years-old queen, but as the interest in watching the hive would be diminished I left them entirely to their own devices. Affairs remained in much the same position during the next two or three days, when marked inattention was evident towards the old queen, indeed one or two discontented bees even pulled her by a leg or wing; and this soon was followed by an entire disregard of her presence as she wandered uncasily from place to place, not on the comb so much as over and through the clustering bees; at the same time an increased, nay, energetic attention was paid the youthful queen, who, I had reasons to believe, had made a trip and safely returned to her hive. This was verified on the 29th, as she was then laying. I need not say how anxiously I looked for a battle royal, but in this was disappointed, for although I saw the two queens in close proximity they manifested no enmity towards one another. Upon the 29th the old queen was brought out, but whether she had been encased, or whether the two had met in deadly embrace I cannot say. These two queens having lived together for nine days, and the remarkable instinct and forethought in the bees in raising a young queen to take the place of the old one, and then quietly disposing of her, has been, perhaps, as interesting a circumstance in the economy of the bee as ever came under my observation during a period of bee-keeping of about twenty-three years.—*GEORGE FOX, Kingsbridge.*

### TRANSFERRING BEES.

Four years ago a swarm of bees settled on a fence in my garden. I was wholly unprepared for such an unexpected visit, and had to put them in a large box 17 inches in length, 12 inches in height, by 10 in width. They have swarmed but twice in the four years, and they are now so numerous that they cannot find room in the box, and, after filling a glass super, have taken possession of a space between the top of the box and a sack suspended 6 inches above it for the purpose of shade and to prevent the dashing rains beating into the entrance.

I know very little about bees, but enough to be aware that some better accommodation ought to be afforded. I have, therefore, had a new box hive made for them, but am wholly ignorant as to how and when I ought to set about getting them into it. I have two acres of clover just coming into flower close to the hive, and were they in their new quarters, this, I think, would enable them to make some provision for the winter.—*H. S.*

[It is too late in the season for bees to make provision for the winter if left unassisted in an empty hive, although it is quite possible to transfer them to a new domicile filled with either bars or frames, one or the other of which, however, is indispensable. Should you determine on doing this, our replies to "G. J." and John J. Smith, in pages 113 and 115, may perhaps sufficiently enlighten you. If not, write us again, stating upon what points you require information, and we will endeavour to supply it.]

THE HONEY HARVEST IN OXFORDSHIRE.—A correspondent, who writes from the neighbourhood of Banbury, informs us

that "It has been an unusually favourable summer for bees in Oxfordshire—a more abundant blossom of Dutch clover in the pastures than has been known for many years. Many hives have attained heavy weights."

HIVING BEES SETTLED IN A FLUE.—Your correspondent "W. P." (page 95), will find the bees which have settled in the chimney may be hived as follows. Place a prepared hive securely at the top of the flue, and surround it with a thick blanket, so as to close every aperture, then fix a bell at the bottom of the flue (all this must be done at night when the bees are resting within), and set it ringing. The bees will wake up with the din, and rise gradually into the hive. This will be traced by the buzzing. When they have all risen, stop the bell, and they will settle in the hive. After giving them time to become comfortable, the hive may be carefully removed to its stand, which should be as remote as possible from the flue.—*D. J.*

### OUR LETTER BOX.

EGGS NOT HATCHING—DORKING'S TOES (*Eboracum*).—You are singularly unfortunate, but the same might not happen again in twenty years. We can give no guess at the cause of failure in hatching, but we know four-clawed chickens will sometimes come; not, however, so frequently as formerly. You are right in thinking the five toes indispensable. The birds you have hatched are useless for stock or exhibition, unless you use them only for the table. It is more than likely these four-toed birds would breed five-toed chickens; but it is running a risk to use them.

CROSS-BRED COCHINS (*Ilem*).—The crosses of Cochins are legion in number, and curious in description. Thus, the cross between the White and Buff is said to have produced the Blacks that were in vogue some years ago; but although the pullets were black the cocks had white feathers, and the under feathers were all white. We ourselves, from good and apparently pure Buffs, have bred the Emu fowls, covered with buff hair instead of feathers. Many of the Buffs are heavily crossed with the original Silver Cinnamon Cochins of Dorsetshire. They sported sometimes, and produced white birds with yellow stripes and spots. This would account for the White. The pencillings of the hackle and the dark tail would easily come from the Dorking. The first is common, almost general, in Dorking hens, and the last a desideratum in the cocks. Both are imperative in the Silver-Grey class. Dorkings are so mixed in colour, that any can be had from them, and indeed may be expected.

HAMBURGS RUNNING WITH A GAME COCK (*Silver-spangled*).—If you take away the cock you will breed pure chickens.

PREVENTION OF DISEASE IN PIGEONS (*Hemipife*).—We have heard of no disease among Pigeons. Have the lofts or houses thoroughly cleaned and lime-whited. Let the birds have pure water frequently changed, and rock salt always within reach. Change their food.

FEEDING CHICKENS (*P. H. G.*).—For the first fortnight chickens are best kept upon alternate feedings of Indian meal, bread-crumbs, and eggs boiled hard, chopped fine, and mixed with a little crushed hempseed. The Indian meal should be only so far moistened as still to remain crumbly. After the first fortnight, and until large enough to feed with the older fowls, give them daily, in addition, a feed or two of either bruised wheat, or bruised grits. From the very first days of their life continue, without fail, to give them daily fresh green food. Cabbage and lettuce leaves, and mowings of grass are best. Remember, above all things, that a little food given often—every two hours is not too frequently—is the chief rule for chicken-rearing.

BEE HIVE (*G. Sinclair*).—The identical hive is figured, and its management (also identical), described in the third, fourth, fifth, and sixth editions of Taylor's Manual, under the name of the "Improved White's Hive." So also is the mode of working two common hives side by side in the exact manner figured and described by you, with the exception of a slight point of detail, in which we think Mr. Taylor has the advantage. This latter is also figured and described in "A Short and Simple Letter to Cottagers, from a Bee-preserved," (by the Rev. W. C. Cotton), which is published at a cheap rate by the Society for Promoting Christian Knowledge, and which we should fancy would meet your views with regard to a cottager's bee-book. The practical objections to the "transposing system" are the instinct which leads the queen to deposit her eggs near the entrance, causing the added box to become the main if not the only seat of breeding; so that if it be taken away the whole, or nearly the whole, of the brood is destroyed, and comparatively little honey obtained, and that much contaminated by pollen, &c.; whilst if the original hive be removed it is filled with old comb, the contents of which are of little value, and the remaining box or hive is liable to contain so large a proportion of drone-comb that the colony can never again become prosperous.

CANARY MULES BREEDING.—We have a communication for "W. B. H.," which we will forward if he will send his address.

### POULTRY MARKET.—August 13.

TRADE is almost extinct, and there is not sale for all the poultry that comes to market.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 72.1°; and its night temperature 49.0°. The greatest heat was 80°, on the 25th, 1859; and the lowest cold 31°, on the 26th, 1861. The greatest fall of rain was 1.32 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

CULTURE OF ROSES IN POTS.

FORMERLY, and that not many years ago, the cultivation of Roses in pots was considered difficult, and the results obtained were uncertain; but since the accession

of varieties of more tractable and free-blooming habit, Roses at a season when their beauties cannot be enjoyed out of doors have ceased to be the greatest of floral luxuries. They are no longer confined to large gardens, but are also successfully produced in small establishments, and in some of these from want of space, as well as for other reasons, large numbers of Roses are grown in pots to be bloomed either with or without artificial heat. A few hints on the cultivation of Roses in pots having been requested by some correspondents, I venture to offer the following remarks on the subject, based on my own experience, and arranged under three heads—viz., 1st, Forcing; 2nd, Roses for the greenhouse; 3rd, Roses in pots out of doors.

1st, Forcing.—The best Roses for this purpose are those which have been established a year in pots, particularly if required to bloom early—say in January. I shall presume that the plants for early bloom have been obtained in May. They should, after they have recovered from the journey, be shifted from the small pots in which they are usually received into pots 6 inches in diameter, draining these to one-fourth their depth with broken pots, with a little of the rougher parts of the compost over the drainage. I have found no better compost for pot Roses than that formed of turf from a pasture, the soil of which is rather strong hazel or yellow loam. The turf having been pared off 2 inches thick, and laid up in alternate layers with sheep-droppings, or where the latter cannot be procured, with horse-droppings instead, should be allowed to lie six months and then be turned, and in three more again turned. At the end of twelve months an excellent compost will be the result. Previous to use it should be chopped with a spade, and made somewhat fine, but not sifted. When the turf is of a light nature it is well to mix it with cowdung in preference to horse-manure, and with neither till it is a year old at least, using equal quantities of loam and thoroughly-rotted manure of whatever kind. About one-sixth of sharp sand may be added to make the soil porous. To keep worms out of the pots a little soot may be sprinkled over the pieces of turf placed on the drainage.

In potting, turn the plants out of the small pots, pick away the drainage carefully, press the balls gently so as to loosen them, and place the plant with its stem in the centre of the pot; then fill in the compost (which should be in a medium condition as regards moisture), round the ball, and so that the roots may be covered about an inch. Press

it well, give a good watering, and set the pots on slates or a concrete floor in an open and sunny situation, filling the intervals between the pots with tan or sawdust up to the rims.

In this situation the plants are to remain through the summer, being well supplied with water, and frequently sprinkled overhead or syringed. The very weak shoots should be removed, and any showing for bloom are to have the buds pinched out. The very long shoots must be cut back to eight joints if they make more than twelve, otherwise let them alone. Stopping the shoots should not be practised until the middle of August. The pots should be occasionally examined to see that the roots do not make their way through the holes at the bottom; the object of placing the pots on slates is to prevent this as much as possible.

Early in September, if all has gone well, the plants will be strong, and have filled their pots with roots. This being the case, shift them at once into eight-inch pots in the same compost as before, adding, however, one-sixth charcoal, with the dust sifted out, in pieces from the size of a pea to that of a hazel nut, and this with the sand may form one-fourth of the compost. Drain the pots well, and press the soil gently round the ball, which should be loosened a little so as to disentangle the roots. If loam from rotted turves cannot be procured, then the compost may be formed of two-thirds loam and one-third leaf mould, or well-rotted manure, adding about one-fourth of river or sharp sand and pieces of charcoal. After potting, give a good watering, and place the pots on the slates, filling in the spaces between them with sawdust or spent tan.

In a month after potting the pots will have become full of roots: the plants having the strongest and best-matured wood should then be cut in to from four to six eyes, more or less according to their strength. It should be borne in mind that the weak are to be cut in most, and the strongest shoots the least. The weak shoots may be cut in to two or three eyes, those of medium strength to four eyes, and the strong to from four to six eyes. Now, if possible, protect the shoots from wet by placing them in an open shed, and keep them rather dry for a fortnight or three weeks. If pruned in the second week in October they may be thus rested until the first week in November, then they will soon break well if the pots be plunged to the rim in a bed of tan or other fermenting material, with a heat of not more than 70°, in a house with a night temperature of 45°. Here they should be sprinkled through a syringe with water morning and evening.

When the eyes have broken, and the shoots are an inch or so in length, the night temperature may be raised to 50°, and that is as high as it need be for forcing Roses until the buds show colour, then it may be increased to 55°. When in bloom a temperature of 50° from fire heat is sufficiently high. The plants should be kept near the glass, and the roof must not be shaded by creepers or otherwise. Avoid a high temperature from fire heat by night; in fact, it would be well to let the fire go out at night in mild weather, lighting it in the morning, and

working on so that the highest temperature may be attained by one or two o'clock in the afternoon. On the temperatures above named allow a rise of 5° on dull days, of 10° on those which are cloudy with clear intervals, and of 15° on sunny days. The art of forcing Roses is to afford them abundance of air and plenty of heat by day, and a comparatively low night temperature, shutting up in good time after admitting air early, so as to let in, catch, and retain as much sun heat and fresh air as possible. By day the temperature from fire heat should not exceed 70°. The sprinkling overhead may take place from 9 to 10 A.M., and again at the time of shutting up the house; but in dull, foggy weather only the morning syringing will be necessary.

Keep the plants as far from the heating apparatus as possible, and above all avoid cold currents of air. Let the waterings be copious after growth has become active; but, on the one hand, do not over-water, and on the other afford a supply as soon as the state of the soil shows that water is necessary; at the same time the soil should never be allowed to become so dry as to affect the foliage. When the buds are formed the pots should be gradually withdrawn from the hotbed, partly to prevent the roots striking into the fermenting materials, and partly to avoid a check when the bloom is nearer expansion. They may after this be set on a hard bottom, as flags, boards, or slates, and have liquid manure once or twice a-week; but not strong. It may consist of 1 lb. of guano dissolved in twenty gallons of soft water.

When the blooms are about half expanded, or hardly so much, the plants should be removed to a cooler house, from 45° to 50° by night. I have never observed any check result from doing this, and the colour of the flowers is rendered deeper and brighter, and their perfume more powerful, whilst the blooming period is likewise prolonged. When the buds are far advanced towards expansion syringing should be discontinued, and the paths sprinkled instead; also afford the plants ample room, abundance of air when the weather permits, and all the light possible. After blooming they should be gradually hardened off, and not placed out of doors until danger from frost is past.

To keep up a succession of bloom a number of plants should be prepared a month later than the first lot, say the first in the first week in October, the second in November, and the third in December, introducing them into the forcing-house in November, December, and January respectively, and onwards up to March; but of these successions I shall say more hereafter, as I propose to treat of them as not established a year in pots, though they are as well if not better in that way, either for early or later-forced bloom.

The most suitable classes for early forcing are the Provence, which I value most of all, probably from having commenced forcing Roses with it, the Hybrid Perpetuals, and the Teas.—G. ABBEY.

To be continued.

### LAXTON'S EARLY PROLIFIC PEA.

I PERCEIVE in your Journal for August 14th, page 120, that I am not the only one who is disappointed in this Pea. Some time before ordering my seeds I received a very flattering account of it, so much so, that I determined to try a quart, notwithstanding the high price at which it was sold; and I obtained it, with other sorts named below, from Messrs. Veitch, of Chelsea. There can be no mistake about its being the right sort, as it was under Messrs. Carter's seal. I was very much disappointed with it, for my other sorts have been extra good. These were Sutton's Ringleader, first crop June 1st; second crop, Eley's Essex Rival, a very fine Pea; third, Dickson's Favourite, an enormous cropper, many of the pods having eleven and twelve fine peas in the pod; fourth, Veitch's Perfection, which was perfection indeed both in crop and flavour; in fact, all points considered, it was the best Pea grown here this season, which is saying much, as I have tried about fifteen sorts this year. Laxton's Early was sown to come in after Dickson's Favourite—namely, in the last week in June, and the first in July, a season at which I think all sorts of Peas ought to do well, having the month of May to grow in, and June to bloom and fill out their pods. When fit to gather it was not equal to Princess Royal growing by its side, and one or two others which came in soon afterwards, so that I think it better to leave these high-priced articles alone, and keep to others which are cheaper, and equally good. The soil here is a

clay loam resting on brick clay; in lighter soils the result might be very different, as I have found many varieties which succeed well in one kind of soil do very badly in another. The late Peas here this season are very inferior, on account of dry weather, and the very rough winds which we have had, along with great changes in the temperature.—J. MAX.

### IVY.

Ivy is a truly British plant, and seems interwoven with our history from its earliest periods. Less honoured than the Oak, and less gloomy in its associations than the Yew, it is more immediately connected with our homes than either of these. Its adaptability to all situations and to the climate of all parts of the country is likewise a great recommendation to favour. In one place we see it covering the ground with a dense carpet, in another ascending the loftiest tree, and in both maintaining itself against all intruders; it frequently mantles our dwellings, and, by the natural armour which it affords, those no longer tenanted are to a great extent preserved from the attacks of time. To it the venerable appearance of many a ruin is as much due as to the masonry; to it many a rocky eminence owes much of its beauty; and an old tree acquires a new interest when its trunk and limbs become clothed in the evergreen drapery of the ivy. I must now proceed to the details of its culture and uses, and endeavour to name a few of the many purposes for which it may be employed.

As regards culture, the Ivy is by no means particular, for it will live—nay, thrive, in situations unfavourable to most plants, and differing widely from each other; but in general it succeeds best in a dry soil containing plenty of stones. I may here observe, by way of parenthesis, that the utility of stones in land is not sufficiently recognised. Ivy thrives amongst such materials, but it is often enough found growing freely on clayey soils; and, in fact, it is common to plant it in any situation where it is wanted without any preparation whatever. Shade, however, seems to encourage its growth, and it will usually do better against the north than the south side of a house. Moist shady woods also not unfrequently abound in Ivy. I believe that it is likewise plentiful in soils containing a good proportion of calcareous matter. It will, however, do well in some soils of an opposite nature; and, indeed, it is so obedient to the requirements of the cultivator that it may be made to succeed almost anywhere, and that with a very small space for its roots to run in. It will, in fact, struggle for a living in ground closely matted with the roots of plants.

The propagation of the Ivy is exceedingly easy and rapid. Seed is abundantly produced, and it germinates freely enough—too much so in some cases. Plants may also be raised in abundance from cuttings, or rather slips, put into the ground almost at any time, but certainly the autumn is the best period for doing so; while if valuable kinds be trained over the ground and pegged down, roots will be emitted at each joint. In this case, if the shoots be cut through some time before the plants are removed, the latter will be much improved in strength. These modes will generally be sufficient to increase this plant to any reasonable extent. Autumn I believe to be the best time to plant Ivy, but I have met with good success by planting in May, while March is perhaps the worst period; but plants in pots may be turned out at any time, and where only a few are to be planted it is best to obtain such, as they become more speedily established, and commence growing sooner.

The variegated Ivies would be the better of fresh accessions, for those which we now have certainly fall short of what I expect we shall hereafter possess. The best gold, silver-edged, or blotched Ivy, does not come up to varieties of the Holly similarly variegated, there being a want of clearness in the colouring of all that I have seen yet, which places them much below the standard, or what ought to be the standard. I hope that when we shall have Ivies as good in colour as the Hollies referred to, our Golden and Silver Chain Geraniums will be less wanted in the parterre. There are, besides, other forms of Ivy, differing considerably from the common or wild variety; one with heart-shaped leaves is much admired, though not more so than that called *Hedera helix maculata*. There are many other varieties, some having almost a Willow leaf, while others with palmate foliage vary much in the obtuseness or acuteness of the leaf. Sturdiness of growth is another feature not common in every variety, and some kinds seem to lose the creeping character entirely, and form evergreen

bushes of great beauty; one plant not far from where I am now writing is upwards of twenty years old, healthy, and vigorous, and although it has scarcely ever been touched with the knife, is now not more than 4 feet high, but as much through. The Ivies, however, are naturally climbers, and as such they are generally planted. The varieties are often the result of sports, and have a strong tendency to return to the normal state, especially some of the variegated kinds. Nearly all the variations in size of leaf and habit of growth may often be seen in woods where the common wild Ivy, with small leaves of a grey colour, having shining veins of white, may be met with along with others of larger and greener foliage in every gradation up to the robust Irish Ivy, which, I may remark, is the most useful kind we have, and that most generally cultivated. I am not positive that it is the best climber, but its rapid growth, and its property of forming fresh leaves when cut-in, render it suitable to most places where it is subjected to some degree of management. Even this Ivy presents a difference in its foliage, leaves broadly palmate being met with at one time, while others almost lanceolate or ovate are formed higher up the plant, and the climbing shoot becomes a short, dense, bushy-headed one when it can find nothing to cling to, or where the plant is stunted in its growth, as may be seen where an aged tree is covered with Ivy, and the laterals thrown out can find nowhere else to travel. The Ivies form picturesque, I may almost say grotesque objects, where they cover a curious-headed pollard, and the most symmetrically-trained pyramidal or conical Azalea has more than its equal in some large Fir trees that I have seen covered with this plant.

With regard to trimming the Ivy, I by no means agree with some instructions lately given in this paper as to the proper time for doing so in the south and more favoured parts of England, though the case may be different in the north, where the plant is less robust. The plan we adopt here is to cut-in closely the Ivy covering dwelling-houses in the beginning of August, very often scarcely leaving a leaf, and yet the whole plant is again densely covered with foliage five or six weeks afterwards; and the season being then too far gone, the growth is confined to leaves, which, with us, become firm and established before winter, so as to sustain no injury from frosts. Thus the Ivy looks trim and neat up to the following June, when the summer shoots begin to elongate. It will be seen that there is with this plan a period of fully eight or nine months in which the plant looks as trim and uniform as the wall against which it clings, while the remainder of the time may be divided about equally between the period of the shoots growing in early summer and that of the formation of foliage in the latter part of the season. Now, let us see what are the effects of cutting Ivy in March. The formation of fresh foliage or shoots will then take about the same time as in the former case, while the period during which the Ivy forms a close carpet is very short indeed. Shoots of some length are formed, and these, remaining unshortened until the following March, are often in the way when a trim and symmetrical appearance ought to prevail. Observe, I by no means advise the trimming of Ivy in August when there is a danger of the leaves not being produced sufficiently early to withstand the autumn and winter frosts; but when the operation can be performed at that time with safety, let it be done then.

As to the propriety of covering a dwelling-house with Ivy, there are various opinions, many contending that appearance is the only recommendation it has; but to trees it is very injurious; many an Oak has been strangled in its embraces, and Pinuses suffer still more. Within a very few yards of where I write, a Spruce Fir upwards of 70 feet high has been for some years struggling for an existence, which is gradually drawing to a close. A few small patches of green on the tips of some of its branches are all the signs of life which it exhibits. The tree may survive one more year, while the mantle of Ivy triumphantly takes possession of the whole of the trunk; the Ivy branches, dense as Box, protrude in all directions, forming an elongated cone of greater symmetry than ever the Spruce did in its best days. The Ivy has not taken possession of any of the dead branches, although many of them are from 4 to 6 inches in diameter at their base; but the creeper apparently disdains to trust them as supports, and confines itself to the trunk. This support, however, will also have an end, for we have lost several trees, which had become quite denuded of branches, and only presented a beautifully tapering Ivy-covered spire. The trunk of the tree, when deprived of its vitality, can no longer resist decay, and when it becomes too weak to

withstand a high wind, its load brings the whole down. Even Spruce and Larch trees containing from 50 to 100 or more cubic feet of timber, are not proof against the elements, and the downfall of the structure is only a matter of time. Sometimes such pillars will be blown down by the root, and sometimes broken off in the middle. One which suffered in the latter way was about 18 inches in diameter at the place where broken, and was not far advanced in decay. Such casualties cannot well be prevented except by bracing up the dead stem, like the mast of a ship, but doing so would mar the effect.—J. ROSSON.

THE ROSES OF 1865.

I AM sure Mr. Kent is a kind-hearted man. I but once had the pleasure of meeting him, and so he seemed—just the sort of man one would like to see governor of a gaol or director of a reformatory. You would be quite certain that the people would be well looked after, their little foibles overlooked, and every extenuating circumstance possible brought forward in their favour; for so he seems to have acted in his opinions of the new Roses of 1865. He has passed over defects which will be fatal to some and damaging to others. He has kept others which may linger for a year or two in the lists, and then will disappear, save in the collections of those who care more for variety of sorts than for quality; and he has exhibited that amiability which rather inclines one to say a good word on behalf of what is really good but not super-excellent. "Ah, poor thing! he (or she) has his faults, but with all that he is a good fellow!" Now, on the other hand, a critic must be of sterner stuff, something between a relieving officer and a Yankee skipper—two of the hardest and corniest specimens of human nature I know. He must be on the lookout for defects, and not for beauties. He must have a large stock of "bats" in his vocabulary, and he must be prepared to use them. It is the misfortune of such that they miss much pleasure; although, perhaps, their appreciation of excellence is more enjoyable to them than to others, yet is their enjoyment continually marred by seeing what others see not, and by having magnifying-glasses on for every defect. One goes into raptures over a new flower, and while he is having his enjoyment, you, alas! see a wrongness of shape, a deficiency of colour which has escaped the other. I have said all this, inasmuch as my judgment on the Roses of 1866 differs materially from that of Mr. Kent; and I hope he will pardon me for saying I think he is too lenient. I may be the opposite, but I shall endeavour to clear myself from such a charge by giving my reasons.

There were sent out by the French raisers in 1865 (I purposely omit English Roses), or rather in the autumn of 1864, nine Bourbons, two Teas, seventy-five Hybrid Perpetuals, two Hybrid Noisettes, and four Perpetual Moss—in all ninety-two! Of these Mr. Kent has selected twenty-one, but this selection must be, I think, still further reduced. First, however, let us see what each raiser contributed. I pass by the Bourbons, not one of which has made, I fancy, any permanent claim on our sympathy. The same may be said of the Perpetual Mosses; while one of the Teas, glorious *Maréchal Niel*, has established himself *facile princeps* of all the Roses of the last three years—the greatest acquisition we have had since Charles Lefebvre. Of the Hybrid Perpetuals I therefore speak, and the following is, I believe, a correct statement of the numbers sent out by each raiser.

Charles Verdier.....	2	Portemer.....	2
Eugène Verdier.....	7	Touvais.....	3
Margottin.....	2	Trouillard.....	5
Marest.....	1	Oger.....	3
Levêque.....	2	Bucher.....	3
Lacharme.....	2	Moreau.....	4
Guillot pere.....	4	Fontaine.....	4
Guillot fils.....	3	Dumazin.....	2
Gonod.....	3	Pernet.....	3
Guinot-seau.....	1	Baumann.....	1
Defaux.....	1	Jamain.....	1
Liabaud.....	1		

There are besides some thirteen or fourteen from growers whose names sometimes are not given, and others are unknown to us. Taking Mr. Kent's list I find he has selected of Guillot fils, 1; Gonod, 2; Oger, 1; Margottin, 2; Portemer, 2; Eugène Verdier, 4; Charles Verdier, 2; Levêque, 1; Jamain, 1; Lacharme, 2; Pernet, 1; and on referring to my critique on these when the catalogue appeared, I named the following as likely to be the favourites:—Rush-ton Radelyffe (Eugène Verdier), Souvenir de Wm. Wood (Eugène Verdier), Duc de

Wellington (Charles Verdier), Duchesse de Caylus (Charles Verdier), Duchesse de Medina Celi (Marest), Madame Charles Verdier (Lacharme), Marguerite de St. Amand (Jamain), Jean Rosenkrantz (Portemer), Triomphe de la Terre des Roses (Guillot père), Xavier Olibo (Lacharme), Madame Moreau (Gonod), Charles Wood (Portemer), and Souvenir de Bernardin St. Pierre (Guillet fils), and I believe that the best varieties of the year are now, after we have had the opportunity of testing them, with one or two exceptions, to be found in this list, which was drawn up partly from observation, and partly from supposition; for the following I believe to be the best of the list:—Duchesse de Caylus, Dr. Andry, Marguerite de St. Amand, and, perhaps, Duc de Wellington; in the second rank, some treading very closely on these, I would place Rushton Radclyffe, Madame Moreau, Madame Amélie Halphen, M. Boncenne, and Xavier Olibo; all the others are pretty good in some sort of way, but not coming up to my ideas of acquisitions. There are several of them which I dare say will be prized by exhibitors for some time to come, but judging them by the standard of excellence that I would set up as that to which I would have all raisers aspire, I will now give my reasons for discarding them, and also why I place those I have named.

*Duchesse de Caylus* is the premier H.P. of the year, lovely in colour, a beautiful soft carmine rose, and, as Mr. Kent justly says, perfect in form.

*Marguerite de St. Amand*.—Any one who had the opportunity of seeing Mr. Cant's stand of this at the National Rose Show, can have no doubt as to the position in which I have placed it. It is a light rose-coloured flower of large size, and good shape, nothing coarse about it.

*Duc de Wellington*.—Brilliant in colour, splendid in petal, but I have noticed that it has not been much shown. Whether this implies any delicacy of constitution I know not, as I have never had it.

It will thus be seen that Charles Verdier has two of the 11 varieties (and as he only sent out two, this says much), Eugène Verdier one, and Jamain one.

Of those which I have placed in the second rank,

*Dr. Andry* is a fine flower of good shape and brilliant in colour. A friend to whom I gave a plant says he thinks it and Charles Lefebvre the best two Roses he ever had. I do not go quite so far as this, but think it a fine Rose.

*Rushton Radclyffe* is a fine full Rose, of the François Lacharme and Madame Furtado type. It was said by some to be delicate, but Mr. Radclyffe says no, and I have seen it very vigorous; but I fear it will not do everywhere, and so I put it as second rate.

*Madame Moreau*.—Undoubtedly a fine showy Rose, as Mr. Keynes's stand of it testified, but it is one of those flat, saucer-like flowers which we do not want.

*Madame Amélie Halphen*.—A very delicately-coloured pretty flower, but I fancy not quite full enough. Too apt to show the eye.

*Monsieur Boncenne*.—A very dark and good-shaped Rose, in colour something like Prince Camille de Rohan, but a better-shaped flower. I should have put it in the first class if I were quite sure that it was full enough, a fact I rather doubt.

*Xavier Olibo*.—Very near being one of the best. The petal is large and thick, the colour glorious, but it has an ugly cleft-way of opening its bud, and the consequence is that few of the flowers open well.

Abbé Berzé is pretty, and would be admired by some. Belle Normande is too washy in colour. Charles Wood is a fine dark colour, but we have many like it; the same may be said of Général d'Hautpoul. Jean Rosenkrantz is a good colour, but not remarkable. Madame Charles Verdier is not good in shape. Madame Elise Vilmorin is brilliant enough in colour, but rough. Charles Margottin is a very showy Rose, but it wants form. Semiramis and Triomphe des Français are good enough, but we have others quite "as good as they."

And so our list is pruned. Ah! what patience and disappointment our English Rose-growers must experience, to propagate a lot of worthless varieties, and then to have to throw them away! and unless more attention is paid to the antecedents of raisers, and less to high-flown descriptions, it will always be so. I know what it is from seeing my friend and neighbour Mr. Banks over his seedling Fuchsias; he consigns to destruction literally thousands every year, of which many persons would consider a large number quite good enough to send out. He, however, has a high standard, and where another would overlook a trifling defect of shape, or colour, or habit, or incertainty, he ruthlessly consigns them to destruction. Some of the French

raisers act thus; but others send out their flowers, and leave us to discover that while in many points the description held good, there was one little point omitted which altered the whole character.—D., Deal.

## ORCHARD-HOUSE CULTURE.

Two or three weeks ago a letter appeared in your Journal from a correspondent who described himself as the parson of a parish, in which he gave your readers the benefit of his experience as regards orchard-house culture. His letter was interesting to me, partly I suppose on the principle that "birds of a feather flock together" (for I, also, am a country parson), and also because the system which he described so nearly resembled that which I have myself pursued, that I felt I could endorse nearly all his statements. Now, as my orchard-house is pronounced a decided success in this part of the country, perhaps a few words from me may be acceptable to some of your readers, and I shall be glad indeed if any observations of mine prove useful to those who have lately invested their money in orchard-houses. First of all, let me just say that I attribute my success to the implicit obedience which I have paid to the directions furnished by those *Arcades ambo*, Mr. Rivers and the Rev. T. Bréhaut, and I most strongly urge others to do the same, as I am quite sure that the reason why some of my neighbours have met with comparative failure, is because they have not paid sufficient attention to the valuable information contained in such books as "The Orchard-House," and "Cordon-Training of Fruit Trees;" but have left their trees to the tender mercies of their gardeners, the ignorance of some of whom is often the measure of their prejudice and presumption.

It is now four years since I built a cheap orchard-house, over ground which I had carefully prepared for the purpose. Spade in hand I set to work, employing myself during my leisure hours in excavating a trench 45 feet long, 14 feet broad, and 4 feet deep, placing all the good soil outside, and barrowing that which was bad or indifferent to fill up a hollow in my field. It was splendid exercise—perhaps I should say hard work—this digging, *sine otio* (as Mr. Bréhaut has it), but not so hard as I remember it was tugging at the end of an oar in the University race between Westminster Bridge and Putney—dear me! I do not like to think how many years ago. It was with no little pleasure I assure you that I at length surveyed the result of my labour—a tidy hole as some one called it; but it would not do to stand long gazing on vacancy, so I soon commenced the work of paving the bottom with large pieces of clunch stones, bricksbats, and anything else that would serve as drainage, overlaying these with a quantity of cinder ashes, which I rammed down hard and smooth. I then threw in all the old faggots I could find, plenty of leaves and garden refuse, and next shovelled in the good soil, mixing it with bones and dung, giving it also a copious drenching with the contents of a tank, which is the receptacle of the liquor which is drained from my scullery—capital stuff for Strawberries, I may mention, but likely, I should think, to stink in the nostrils of inspectors of nuisances. My friends the farmers were very good to me, carting in, free of expense, I know not how many loads of splendid virgin fibrous mould.

Against the back wall of my house are trained Peach and Nectarine trees on the triple cordon plan invented by the Rev. T. Bréhaut, which I beg highly to recommend, as elegant, productive, and having the advantage of making available every inch of the wall. A foot and a half from the wall is a path 2½ feet wide, having an ornamental edging. The remaining space is filled with pyramidal trees in pots, Apricots, Peaches, and Nectarines, all paragons of perfection, as in consequence of regular syringing, the application of Gishurst compound in the winter, and early fumigation in the spring, I have not been in the least degree troubled with either aphides or red spider. Beneath each rafter and round each pillar is trained a Grape Vine, each having on the average eight large well-thinned bunches of either Muscat or Black Hamburgh Grapes, which alone would repay me for the original expense of my house. Half the number of my potted trees (which were retained under glass until June), are planted outside; from them I have already gathered ripe fruit of exquisite flavour and colour. I have a pump inside my house, supplied by the rainfall from the glass, and which, although I have drawn rather heavily upon its resources, has not yet failed me. I have twenty zinc pails arranged on one side of the path, in which the water is

exposed to the heat of the sun before I use it for either watering or syringing. I believe this to be an excellent plan. I will not add to the length of this communication by obtruding any hints of mine on the subject of orchard-house culture. Suffice it to say, that I go by book as closely as I can. I must frankly own, indeed, that my trees will not invariably grow in such a manner as to square with Mr. Bréhaüt's theory, where he lays down that each spur should be furnished with two shoots, one for wood and one for fruit, yet I regard that formula as the embodiment of a very important principle, and I follow it as nearly as my judgment enables me and Nature seems to permit.

There are two mistakes against which I should like just to warn beginners, and say, *crede experto*,—do not ram the earth into your pots when it is at all wet, especially if it be of a clayey nature; and, secondly, do not be in too great a hurry to pinch-in your young shoots. Experience has taught me to rectify these two radical errors, and I can only say, but not in a vaunting spirit, that success has crowned my efforts. Patience and observation have enabled me to overcome many difficulties, and I can thankfully add that my orchard-house has been to me a source of unmixed happiness, giving me delightful occupation during my leisure moments all the year round, and affording me a never-failing source of interest and pleasure. I feel my mind refreshed as I walk along my orchard-house and view my thriving cordon trees, my graceful pyramids, my splendid bunches of Grapes, my luscious Figs, and I think of that scriptural picture which is presented to us of almost perfect human happiness and contentment, where we read that Judah and Israel dwelt safely, every man under his Vine and under his Fig tree, all the days of Solomon. Once I was one of Izaak Walton's enthusiastic disciples; but, alas! streams are polluted now, and I care not to issue forth, rod in hand, when so many common sewers are permitted to disgorge their unsavoury contents into every noble river and babbling brook; but I have that at home which makes ample compensation for the loss of piscatory pleasures, and am inclined to think that if any relics of primæval Paradise still linger upon this much-abused earth of ours, they are still to be found within the precincts of a garden—in the simple cultivation of fruit and flowers—still to be traced in the glory of the gaily ornamented parterre, in the perfume of the sweetly-scented conservatory, and in the beauty of the spring blossoms and autumnal produce, even of the more humble, but no less enjoyable, orchard-house.—A CONSTANT READER.

### ENCROACHING TREES.

THE trees (Elm and Ash), of a neighbour's plantation are placed so close to my garden as to do me great mischief by overhanging, and the roots running under the fence into my borders. As I believe this grievance is not an uncommon one, I address you, in the hope that you will say what remedy I may legally have in my power to adopt. The overhanging branches were pruned at my request three or four years ago, when I was asked to lop off any offending branch thenceforth; but the trees have now grown so large and overhanging from the very top that no pruning, and, I believe, nothing short of removal, can be of any permanent advantage.—A SUBSCRIBER.

[We do not think that you could compel your neighbour to remove the trees, and even if he were willing to do so, perhaps you would hesitate from urging him to take that course, if they are ornamental, or shelter his grounds. The remedy, however, is in your own hands, for you have permission to remove the offending branches; and such permission is much better than compelling the owner to lop them off, which he could be compelled to do, for no branches have a right to hang beyond the boundary of their owner's ground. As to the invading roots, they may be effectually repelled. Close to your boundary have a trench dug 2 feet wide and sufficiently deep to be below the roots, cutting through all that penetrate your soil. Fill the trench with stones rammed in hard without any earth admixed, and the roots will not attempt to trespass again.]

THE SAWBRIDGEWORTH ORCHARD-HOUSES.—Those of our readers who are interested in orchard-house cultivation should seize an opportunity to visit Messrs. Rivers's extensive establishment at Sawbridgeworth, which now offers great attractions, particularly to such as are fond of fruit-tree culture. The new Peaches and Nectarines which Mr. Rivers has succeeded in raising, and which will supersede all the old varieties,

are of themselves a study; and the profusion of fruit with which they and the Apricots in pots are laden cannot fail to astonish even those who have no practical knowledge of the subject.

### ROSES AND STRAWBERRIES AT SEEND, WILTS.

THE Rose is not only an Englishman's national emblem, but also his favourite flower; he is proud of it as he sees it entwined with the Thistle and the Shamrock, and he thinks that the best portion of the device is his; he grudges not the Scotchman his Thistle, nor the Irishman his Shamrock; and as to the Welshman's national vegetable—well, he would rather have nothing to do with that. But the Englishman is not only proud of the Rose, he loves it. Watch the crowd in Cheapside, and men of business though they be, they have their favourite flower, and that flower is the Rose; and dear, round-faced, smock-frocked Hodge—smock-frocked at church on Good Friday and Ash Wednesday, but in good broadcloth (black usually, with an eye to a good appearance at burials), on a Sunday—well, does not he cram his button-hole with Cabbage Roses? (Fancy a Scotchman with a Thistle in his coat!) And, more than that, does he not tell his Mary, as he pours bucket after bucket of milk into her cheese-tub, "that her cheeks be like two full-blown Roses?" Well, of course he does, the Rose being his ideal of beauty. We all love the Rose. In babyhood we did, when with chubby plucking fingers we littered our little carriage floor with petals of Damask and China Roses. Childhood succeeded babyhood; still we loved the Rose, and prized most of all that Maiden's Blush in our little garden. Youth next. Ah! then we gathered carefully the choicest half-opened buds, and gave them with such a look and meaning to our —. But no more; these reflections will not do. Ah!

"That was the time of Roses,  
We plucked them as we passed."

But putting aside the poetry of life connected with the Rose, it is certain that each year the love of Roses is on the increase. This we owe to raisers of Hybrid Perpetuals. Blessings on the man who brings out a good Rose which will bloom from June to December. That is the Rose for popularity. It needs no wrapping up in lavender in the winter, no potting and repotting, no taking up, &c. No, there all winter long it stands in the garden uninjured, and for half the year is an object of beauty.

One miserable, rainy day last February I received a hearty word-of-mouth invitation from Mr. Ambrose Awdey, the head of one of our oldest, happily most numerous, and most respected Wiltshire families, to be present at his annual Rose and Strawberry gathering, held on his ancestral acres at Seend. Now, knowing Mr. Awdey to be one of our best and most enthusiastic rosarians, and that his Strawberries made people open their eyes and their mouths too, I accepted the invitation readily and gladly. I often thought about the treat in store, laid my head back in my study chair on windy days—my horror—and said I shall enjoy myself then. I sniffed at the treat at a distance, as an alderman may be supposed to sniff at turtle soup when a mile off. I longed for the time to come, intending to give myself up to enjoyment like a very child. At long-last the Rose time came round, and with it a note fixing the day of the Rose and Strawberry festival. There had been a good deal of rain those first four days of July, but why should it be wet on the 5th? Besides, the word Seend means sand, so the roads will not be very bad if there be rain.

On reaching Seend by rail, I ascend from the station, and climb a steep hill and soon enter the village, seeing a break before me full of ladies (flowers on their way to the flowers). Then I enter the village street; a pretty clean-looking village it is, with a sufficient number of good houses near enough together to make a charming band of country neighbours—ladies who would drop in to tea with each other after an afternoon's walk, and have pleasant parochial chats about the school and the poor, "how nervous the governess is about the coming of that terrible government inspector, and they intend to give her an hour's help each day;" and then the poor, "how Martha Smith needs beef tea, and Molly Hull wants an outfit for her daughter, who is going to her first place of service." In fact, I liked the look of Seend, and almost coveted the parson's place.

Having reached my host's house we had a light lunch, only a standing lunch—cake, and wine, and biscuits, and Straw-

berries, for we are to dine at half-past three. Luncheon over, we formed little parties and started out whither I knew not, for I was an utter stranger. As usual, the young folks managed to get together—the old story over again; and the married ladies they got together, doubtless talking about their children's colds, measles, and education. Then the husbands they got together, save the very young ones or the hen-pecked, and felt almost bachelors again.

Led by my host, who welcomed me as warmly as he had invited me, I saunter up the village a little way, and enter a walled garden about half an acre in extent. On the left hand I inspect a well-built orchard-house, full of healthy little trees, and vines, and larger wall trees. This pretty house is on what was a mere garden wall three years ago. "This house," said Mr. Awdey, "I owe to THE JOURNAL OF HORTICULTURE." Passing on I come to a ground viney; "This, too," said Mr. A., "I owe to THE JOURNAL OF HORTICULTURE." Looking round me I noticed the thorough cultivation of the garden. There is a great difference between half gardening and whole gardening—the soil made to produce something, or the soil made to produce as much as possible, and grow everything as well as possible. I said, "What a soil you have!" "Ah, yes; but I carted six and thirty loads of maiden mould here a little time back," was the reply. Perhaps being in the fruit garden is the place to speak of the Strawberries cultivated by Mr. Awdey, although, as I shall presently state, they are grown chiefly with the Roses. The varieties Mr. Awdey cultivates are Eclipse, Oscar, Sir Harry, Sir C. Napier, Carolina Superba, and Eleanor; but of their size and flavour by-and-by. Walking around the walled garden I observed that net frames were fastened in front of the fruit trees; this is a neater and better plan than mere nets of string.

Coming out into a lane we reached the church, crossed the churchyard, dipped down the grassy slope, now and then looking at the fine view before us, and took a path across the fields to the right. Well, where are we going? I had imagined a house, shrubberies and Rose garden adjoining; but I was now leaving all human habitations behind me, and going among the rich pastures in the valley below the Wiltshire Downs. Further on I find in a field Roses surrounding a piece of grass used for croquet, just outside a boarded enclosure. Here I prepare to stop, but no; I am told that these Roses are but a few, chiefly transplanted dormant buds of last year's budding. I am led to the corner of the wooden enclosure, a suspiciously little door is opened, and my breath is almost gone; for slightly to alter the words of Kirke White—

"Such a sight as I saw there, I ne'er had seen before;  
But such a sight as I saw there, I hope to see once more."

Now, good reader, just imagine a two-acre field right out in the country, boarded in with 10-foot high boards, precluding, therefore, all sight of what was inside while you were on the level ground. A door opens and you enter, and behold *Felicité Perpetue* Roses, those darling cream white flowers, covering or rather lining the whole inside of the boards, thus giving a frame of pearly whiteness to the picture. Then within, beds of Roses some 16 yards square, in each bed Roses of the same height, and each row of the same colour. Imagine wide borders all round, separated by paths of the original turf of the field, for this Rose garden was a few years since but a field where cows grazed; then grass paths between each bed; while overhead arches, Rose-covered, united border with bed, and beds with each other. Then at your feet on each side of you were marvellously-grown Strawberries in vast abundance. I walked up the middle path to the other end of this Rose field, then turning round I surveyed the scene. Before me at that end lay a carpet of dwarf Roses, grown on the *Manetti*, then beds of half-standards, then higher; but I was struck with the rich colour of the scene before me, begirt in such good taste with a belt of white. No flower was there but the Rose; but what a bedding plant it makes in good hands and good soil! The Roses in the beds were sometimes in lines, at other times planted *quincunx*, and the rich brown pasture mould looked not unsightly between the stems. Now, to say what Roses were there would be simply to write out the first good Rose catalogue that came to hand. Mr. Awdey had within and outside the enclosure about four thousand plants. Inside none but the best *Perpetuals*; outside were groups of the best of the old summer Roses, and extensive young plantations of the novelties of the Rose world, which having successfully passed their novitiate outside, will be hereafter admitted to the Rose garden proper. Every known beautiful Rose suited for out-door

growth was before me. Hundreds of Charles Lefebvres, and *Senateur Vaisses*, and *Comtesse de Chabrilants*, the three unrivalled ones; bold *Eugène Appert*, its leaf almost a flower, so beautiful is it; delicate *Auguste Mié*; more delicate *Made-moiselle de Bonnaire*; *Madame Boll*, that fine woman; that gorgeous velvety monarch, *Louis XIV.*; *John Hopper*, the best of recent English (Rose) gentlemen. "But how can I mention the dukes and duchesses, the generals and lords, the madames, princes, and emperors, the tender souvenirs?—why, all were there! Hybrid—no, *high-bred Perpetuals*, princes of the Bourbon line, Chinese mandarins, and ladies very fine indeed, and smelling, as of course they ought, of tea. Hundreds of the best, dozens of the second best, all varieties of colour, all varieties of leaf, and habit, and growth—truly it was a fair scene.

Then came the attack upon the Strawberries, though we were warned not to judge of their size, as the best had been gathered for dinner.

Round and round I go—outside to see the novelties, or to look at the old favourite summer Roses. In the middle of the garden I had noticed something that seemed a combination of skeleton pump without a handle and a camera, the whole made of wood and painted green; but where was the photographer? Why was the camera always looking straight at the summer house? By the way, how indifferent to appearance must a photographer be. See one with his head under his velvet focussing his picture: behold the human form greatly degraded—a sort of two-legged head-wrapped-up animal, given to inelegant postures. But, to return. I asked what the green machine might be, and was told that it was a revolving gun, which went by clockwork, had a pendulum, and when loaded and wound up fired every half hour during the four-and-twenty, and that it was invented by a Wiltshire man. Now, query, Do not the blackbirds become used to the firing at stated intervals? For instance, Do they not enjoy twenty-five minutes' thieving of the Strawberries, fly over the wall, and then, the firing over, enjoy twenty-five minutes more, and so on? Wandering among the Roses, Mr. Awdey attracted my attention to his favourites, and remarked, "He not only read, but looked for the papers of 'D., Deal.'"

A bell sounded on the hill, and we strolled up to a tent where dinner was provided, and sat down—forty happy souls, to refresh our bodies. A capital dinner *à la Russe*, and, oh, the dishes of Strawberries! Mr. Awdey stated, "that during the whole season the fruit on all his six varieties had been remarkably fine, many of the berries weighing an ounce each." I wandered from Oscar to Sir Harry, which I think I liked best; then to Sir Charles Napier, until Eleanor's charms attracted me; nor could I think of passing by *Carolina Superba*, nor wholly neglect *Eclipse*. Certainly the old rule, the larger the berry the poorer the flavour, no longer holds good. I have not yet tasted *The Lady*; but what can beat Sir Harry? We had a pleasant merry dinner under the tent, laughing at rain, for though one shower fell, who cared a bit about it?

After dinner we went back to the Roses, and soon Mr. Awdey gave the word "Gather bouquets for the ladies!" Then out came knives and scissors, and the ladies were most civil and fascinating to those who gathered for them. They were—who would not be?—greedy for Roses; they opened their parasols, yea, and umbrellas, which, inverted, became Rose-baskets of large dimensions, while our host looked on laughing, and bade them take more. A walk back to the tent followed, where we sipped our tea, looking down upon the beautiful Rose garden, which shone like a rich-coloured gem among the green fields, and no one could imagine a single Rose had been gathered.

Send possesses a lovely view; there it lay before us, the rich broad valley, then the rising woods of Earlstoke, backed by the Downs; to the right, far away, was Rood Ashton, to the left, but distant, Roundaway Down. A wide, wide view filled our eyes.

After tea there came the gradual dropping-off of guests; timid ladies eyed their boot soles, fearing damp; loving fathers hastened away their daughters; the most determined croquet players had to give up; the party grew smaller and smaller in spite of our host's hospitable entreaties, for many of his guests had far to go to reach their homes.

I must add, in conclusion, that Mr. Awdey had budded the greater number of his Roses with his own hand, and, like all Rose-lovers, he loved them more and more. He afforded us all a great treat; his love of Roses was no selfish love, for he

made it the means of making a large party happy. May he for many, many years have all the success and all the pleasure which he so richly deserves.—WILTSHIRE RECTOR.

## BEDDING PLANTS.

(Continued from page 98.)

**VERBENAS.**—In August take cuttings from the strongest and shortest-jointed shoots, such as start from near the collar, and do not appear disposed to flower. They should be from 2 to 3 inches in length, and have two, or at most three, good joints, in addition to the growing point. The cutting is to be taken off below the lowest joint, and not too closely, as at or a little beneath the joint there may be a root or roots in course of being protruded, and such may be distinguished upon close examination. To cut off this portion of the stem is to jeopardise the rooting of the cutting, though the latter may strike if cut quite up to the joint, and cutting off the lower part of the shoot midway between the joints is to leave a portion of stem likely to rot; therefore, take off the cutting from the point beneath the joint at which it begins to swell upwards. Trim off the leaves from the lowest joint, and from the one next above it if that part is required for insertion in the soil. The cutting should be of such a length that, when inserted, two-thirds of it shall be in the soil.

I shall now suppose that the cuttings are ready for insertion either in pans or in the frame, there to remain permanently during the winter, but the adoption of either system in preference to the other is a question which those for whom these notes are written must determine for themselves. If the means are limited to a two-light frame, then I would recommend the division of the frame into two parts by a partition of wood immediately under the bar on which the lights are supported and slide. This division will, of course, be of three-quarter-inch Baltic timber, or red deal boards, tongued and grooved, and fitting exactly in the manner of an end with this difference, that it is to fit within the frame. A strip of wood, three-quarter-inch by half-inch, nailed to the sides back and front vertically under the sliding bar, will allow of the division being secured there. The two-light box being thus divided into two parts, either can be opened or shut independently of the other. The half of this frame I propose to fill with Verbena and Gazania cuttings, and I would choose for it a warm, sheltered, dry situation, open to the south, but protected from the north and east. The soil where it is to stand is to be taken out to the depth of a foot, and 1 foot 6 inches wider than the frame every way, giving the bottom an inclination from the centre to the sides. In the place thus dug out spread brickbats or rubble to the depth of 9 inches, then an inch or two of gravel or of the rubble made finer, and on this set the frame so as to face the south. A couple of inches of the siftings of the compost may now be spread over the gravel or fine rubble, then 3 inches of turfy light loam two-thirds, and leaf mould one-third, the whole chopped and made fine with a spade, and finally sifted through a riddle with half-inch meshes. On the surface place an inch of river sand, and, after making it level, gently pat it down with the back of a spade.

The cuttings may now be inserted in lines  $1\frac{1}{2}$  inch apart, and the same distance asunder in the row, putting them in with a dibble just up to the lowest leaves, and pressing the sand gently around them. Two-thirds of the light may in this way be occupied with Verbenas, and the remaining one-third with Gazanias, the cuttings of which are to be taken in the same manner, preferring those which come from the collar, and, instead of cutting, slip them from the plant. They are best when 3 inches long. Cut them transversely below the lowest joint, which may only need a little trimming, remove the leaf from that and the joint next above it, and if the cutting have no more than another joint and the growing point it is a good specimen of the proper kind. These are to be inserted in lines 2 inches apart and 3 from the Verbenas, allowing  $1\frac{1}{2}$  inch from cutting to cutting in the lines. Put them in in precisely the same manner as the Verbenas—that is, up to the leaves, and close the sand about them. The cuttings having been inserted, give the whole a good watering, but only to settle the sand about them, put on the light, and cover with a mat if the day be sunny.

The cuttings will never flag, or if they do they will recover by the next morning. They should then be shaded from sun, and kept close during the day, admitting a little air at night

by tilting the frame or light half an inch or so at back. So long as the sand remains moist do not water, but if it show signs of dryness sprinkle the plants overhead in the morning through the rose of a watering-pot. Continue the shading, and, when the cuttings exhibit signs of growth, gradually reduce the shade, and admit air during the day as well as at night by tilting the light at back; but if the cuttings flag diminish the amount of air, and continue to shade until they become well rooted, which will be in three weeks. They are then to have air day and night, and, after they have been thus gradually hardened off, at the end of a month the light may be drawn down, and only replaced during heavy rains, remembering that the object of doing so is to keep the wet from the soil, and not to deprive the cuttings of air, which must in this case be given by tilting the glass at back. Afford all the air possible, using the light for no other purpose than protection from wet and frost. A gentle shower will be of advantage at times, but anything tending to make the soil wet, or causing it to become green, is to be avoided, at the same time it must be kept sufficiently moist.

When the weather becomes foggy, and the ground wet, do not scruple to give air, but keep on the light, admitting air day and night all the same, and this until absolutely obliged to close the frame on account of frost. The other light, respecting which I have as yet been silent, is intended for *Calceolarias*, which I shall treat of in due time. When frosts occur, the sides of the frame are to be banked up with coal ashes, commencing about a yard from the frame, and carrying the ashes up to the top of the sides so that the lights may just slide up and down. This may be done early in November, and will not only tend to prevent the frost penetrating by the sides of the frame, but will keep the ground from being frozen so near it as would otherwise be the case, and thus give the plants the benefit of the heat of the earth.

During frost protect the frame with a single thickness of mats thrown over the lights, with two thicknesses if the weather become more severe; and if the frost is very sharp, in addition to the mats cover with dry short straw or litter, not only the lights, but the ground for a distance of 2 or 3 feet from the frame. This covering may be from 6 to 9 inches in thickness, and need not be removed so long as the ground remains frozen, nor then until a thaw commences. The covering, with the exception of a single mat, which may remain on a day or so, should then be removed, and air admitted by tilting the lights at back, gradually increasing the amount, and also exposing to light, so that the plants may bear full exposure to both in the course of a week or so. (I here employ the word lights, for these remarks on protection relate to the whole frame, Verbenas and *Calceolarias* requiring the same treatment as regards protection from frost in winter, and exposure to light and air after a continuance of frosty weather.) If the frost at night thaws during the day, the covering is to be removed daily, and air afforded, taking care that it shall not be frosty; put on the covering at night, and remove it in the morning after it has thawed, not otherwise. Whilst the weather is so cold that the plants cannot make growth, the covering may remain, for the want of air and light will not harm them; but when the weather becomes mild the plants if left uncovered will grow though in darkness, and the shoots so made are more susceptible of injury than those formed with light and air. It is, therefore, necessary to remove the covering as soon after frost as consistent with the safety of the plants, and that is when the covering becomes thawed. This is the best guide I know. To sum up, give air whenever the weather is mild, protect from wet as well as from frost, admit air in wet weather, and have protecting materials always in readiness to throw over the lights when necessary, and I may add that the drier the plants are kept the better they will resist frost.

Beyond protection and giving air, the plants will not require any further attention until April, excepting stirring the sand between them, and picking off any mouldy or decayed leaves. Early in April a bed may be made of the litter used for protection, mixed with tree leaves and a little fresh litter; raise the bed to a height of 2 feet or so, and cover it with 3 or 4 inches of turfy loam and leaf mould, two parts of the former to one of the latter. When the bed becomes warmed through take up the Verbenas and Gazanias from the frame, plant them in the bed 3 inches apart every way, and give a gentle watering. An excellent protection may be formed of four 11-inch boards 1 inch thick—*i.e.*, two for the ends and two for the sides, nailed to a piece of wood (2 inches square) at the corner, and a few slater's laths (3 inches by half an inch), placed like the rafters of

a roof at 1 foot apart, and tacked to the edges of the boards. A covering of one thickness of mats should be put on by day for a few days, and of two or more thicknesses at night, as the weather may prove frosty; but after the plants have become thoroughly established expose them in all mild weather, merely protecting at night from frost. Due attention should be paid to watering, never supplying more than is sufficient to keep the soil moist, and when water is given in the morning, a sprinkling now and then overhead will do good.

The plants having been stopped for cuttings in April, or if these are not wanted then, merely stopped if they seem disposed to become lanky (and this may be done from the middle of March up to the middle or end of April), they will by the middle of May be strong and bushy, and will lift with good balls. The first showery weather after this they are to be planted out finally in the beds or borders. These should be prepared for the reception of the plants by being deeply dug, and have a liberal dressing of leaf mould, or well-rotted manure worked in.

As to dealing with the pit and frame of "A YOUNG AMATEUR," what to do in the matter of wintering Verbenas is not clear. For my part I should elect to retain the frame for *Calceolarias*, and divide the pit into two by a 4½-inch brick wall, carrying it up to the rafter, or bar supporting the lights. One half, or two lights, I would fill to within 15 inches of the glass with any kind of rubble, and then place 3 or 4 inches of the rougher portion of the soil, and an inch of sand over all, preparing and putting in the cuttings as in the former case, and treating them in precisely the same manner. The only objection to this plan is that the rubble renders the bed a permanency, whereas it may be desirable after the bedding plants are cleared out to make up a bed for Cucumbers or Melons, or for forwarding half-hardy annuals and other plants for bedding-out. In that case the *Verbena* and *Gazania* cuttings may be inserted in well-drained pots, with an inch of the siftings of the compost placed over the drainage, and the pots filled to within an inch of the rim with a compost of two-thirds light turfy loam, and one-third leaf mould; afterwards fill to the rim with sand. A six-inch pot will hold a dozen cuttings. After the cuttings have been put in set the pots on coal ashes in a cold frame, watering gently to settle the sand about the cuttings. Keep close, and shaded from bright sun, and sprinkle the cuttings overhead occasionally in the morning, admitting a little air at night. The sand in which the cuttings are inserted should be kept moist, but never very wet, avoiding extremes as much as possible, and in this manner proceed until they show signs of rooting, which may be known by their commencing to grow, and withstanding sun without flagging. Give all the air practicable after that, protecting only from heavy rains, and keep the soil sufficiently moist.

Although I have detailed the treatment of *Verbena* and *Gazania* cuttings in pots, I would recommend them to be struck without pots in beds. I would devote two lights to them, and the other two to bedding *Pelargoniums*, which I presume to be struck either in pots or boxes, and wintered in these in the pit. Of their management there I shall treat when I come to the wintering of old plants.

Of *Verbenas*, I may state that *Géant des Batailles*, crimson, with a dark centre; *Defiance*, scarlet; and *Boule de Neige*, white, winter well. *Purple King*; *Lord Raglan*, cerise scarlet, lemon eye; *Ariosto Improved*, mulberry; and *Blue King*, do fairly; but none excel *Impératrice Elizabeth*, and *Velvet Cushion*, magenta. *Cherry Ripe*, a charming rosy pink, likewise does well. Of *Gazanias* I care for none except *G. splendens*.

Should thrips or green fly make their appearance, cover the frame or pit with mats, and on a calm evening, when the foliage of the plants is dry, fill the frame with tobacco smoke, and on the next night but one repeat the fumigation. Whenever mildew is discovered, dust the leaves and shoots with flowers of sulphur.—G. ARBEY.

(To be continued.)

ST. JULIEN STRAWBERRY.—For the sake of Strawberry lovers, I wish you would recommend a seedling sent out by Messrs. Rivers, of Sawbridgeworth, named *St. Julien*. It is a very fine, beautifully-formed, dark-coloured fruit, most prolific, and for flavour one of the best I ever tasted. I have had a wonderful crop this year off beds made last March, and I intend to recommend it strongly to my friends.—A SUBSCRIBER.

## CULTURE OF TRACHELIUM CÆRULEUM.

I HAVE just now a good plant of the somewhat-neglected *Trachelium cæruleum*. When a year or two ago I saw it growing in a window of a friend's house in London, I was so much struck with it that I begged some seed, and have grown a plant or two every season since, as it has now become not only with myself but with my employers an established favourite.

The seed should be sown in June. This will admit of having good strong plants in 48-pots to stand the winter. In spring give them a good shift into 24 or 16-sized pots, keep them as cool and as near the glass as possible, and pinch back constantly till the end of May, by which time the plants will have two or three dozen blooming stems. As it is properly an autumn-flowering plant, the plants would be better plunged in ashes out of doors till the bloom is about to expand, when they may be carefully tied out, and removed to the conservatory, verandah, or any sheltered nook where they are not exposed to the rain. The large masses of cerulean blue, often 6 inches across, which each stem will produce, will make each plant a handsome specimen, and will well repay the small amount of labour they have cost.—A. D., *Maybush* (in *Fleurist and Pomologist*).

## VARIEGATED MAIZE.

IN answer to "A YORKSHIRE CLERGYMAN" respecting the Variegated Maize, I am sorry to say that I have been equally disappointed. My employer obtained from a respectable London house a shilling packet of seed, which contained only four seeds; only one grew, and the plant is now about 4 feet high, but in just same state as "YORKSHIRE CLERGYMAN" describes, the bottom leaves being dead and the tips of the others dying. I also obtained a shilling packet of seed from Messrs. Carter and Co.; it contained eight seeds. These produced six plants, which grew rapidly, but one has since died; they are not so forward as the plant first referred to, but I find they are going in the same way.

I may mention that my plants are in some large ornamental pots, and have leaves about 30 inches long, from 2 to 2½ inches wide, and beautifully variegated. If anything could be done to preserve the leaves, by placing three plants so as to form a triangle in a pot or in a clump in the borders, this Maize would be a great ornament to our gardens and conservatories. The soil which I used was loam, leaf mould, and a little drift sand. The plants have never been allowed to suffer for want of water or pot room. The plant raised from the first packet is under glass, the rest out of doors. I hope others will report their experience.—S. TAYLOR, *Barbourn Terrace, Worcester*.

## NOTE ON BORDER-HEATING.

[The following paper by the Rev. W. Kingsley, of South Kilvington, appeared in the third Number of the "Journal of the Royal Horticultural Society," recently published. This contains, besides, a continuation of Professor Schultz-Schultzenstein's dissertation on the nutritive constituents of water; a note on the cultivation of *Amherstia nobilis*, by Mr. Taplin; a report on Peach and Nectarine trees at Chatsworth, by Mr. R. Thompson; articles on a disease in Celery, on two species of *Rudgea*, and on *Asplenium ebenoides*, a supposed hybrid Fern from Philadelphia, by the Rev. M. J. Berkeley; observations on certain species and varieties of *Cratægus* and *Pyrus* as ornamental plants, by Mr. T. K. Short; hints on hybridising fruits, by Mr. Standish; and a short note on the horticulture of Hungary, by Miles Berkeley, Esq. Both of the two last papers have already appeared as extracts in our pages.]

The border which I have the means of heating is about 120 feet long and 10 feet wide, and is at the foot of a south wall 12 feet high, with a cross wall at each end. Four pipes run the entire length, and are in the midst of a mass of drain-tiles, which are at right angles to these hot-water pipes, and lie in lines sloping upwards towards the wall, with rise enough to secure the flow of the water, and the circulation of the hot air; upon the drain-tiles there is a layer of coke. The result gives me a temperature about that of a very gentle hotbed. I do not think I should construct the bed in the same way again; but I had been doing a good deal of draining, and the defective tiles were good enough for this purpose. My fruit-trees are in pots, some as large as 2 feet across, but most of them 15 inches. The pots stand upon the coke, or very little above it. In winter they are covered with earth and dry litter, so as to keep the frost off completely; but in the mild weather they are little

more than half buried, and in the heat of summer are raised to the surface to let the sun give them as much heat as possible, and at the same time to allow the roots during the summer months to pass out of the bottoms of the pots into the ground.

The way in which I have applied the heat is, as far as I can, to encourage the growth of roots in winter, and to give a temperature to them, when the fruit is setting, above what we get from the sun in this climate, and then again, when the heat begins to fail in early autumn, to give warmth to ripen the wood and get the trees put to rest early, by their having heat and no water. Perhaps it will be best to state how the trees are heated throughout one year. During the sharp frosts of winter the hot water is kept going night and day, and I have heat enough to thaw any snow that falls, but I do not raise the temperature of the ground so high as this, but only enough to prevent the roots being so much checked in their growth as to destroy the young spongioles. Whenever the weather is mild the fire is not lighted; and by the end of February there is rarely any occasion for artificial heat. As soon, however, as the trees are in full blossom, the fire is again lighted and the heat steadily increased, and kept up till the sun warms the ground thoroughly; at this period the fire is lighted early in the morning and allowed to go out at night, and so gradually till artificial heat ceases about the middle of June, or later if the season be cold; and if a few cold days come, I give heat again during the day. During the blossoming-season the trees have a wide piece of netting over them. The trees now will have got a very great advance upon those in the open ground so far as the ripening of the fruit is concerned, but they do not open their blossoms more than a very few days before them.

Then again about the end of August I give heat during the day, and, according to the nature of the fruit, give water or withhold it, as I would encourage growth or ripen the wood. In the latter case it is necessary to cover the pots with slates or wood, to keep the rain off. My rule is to withhold water and give heat as soon as ever the fruit is ripe. When the terminal buds are fully developed, the pots are lifted and the protruding roots cut off; the soil taken out halfway down, and the roots so far cut within a few inches of the stem; fresh soil is put in, a little water given to the tree, which is placed on the hot border again for about a couple of weeks, and then kept dry till the leaves fall and for some time after. The root-pruning is going on from the end of September to the end of October (I believe it should always be performed before the leaves fall); and by giving water and heat the trees do not flag for more than a day, and heal their wounds at once. No doubt much has to be learned here, and it will require many seasons to find out the best treatment. My object is to get the trees to cast their leaves very soon after the wood is mature, and to stop the long herbaceous growth that our damp autumns produce. I need hardly mention that close summer pinching is practised, so that very little winter pruning is needed. The dry heat soon sends the leaves off, and a long rest is given to the trees during the autumn. Some are placed under glass to ripen their fruit; and all would be, if I had sufficient extent of it; for as the trees are merely resting, a small space accommodates a great number, as they may be packed close together, and, the pots being dry, no mildew need be feared, as they have at this time plenty of air. Finally, as soon as the rains of autumn are over and the cold weather sets in, the hardy trees are again put into the hot border.

As may be expected, the flavour of the fruit is first-rate, and the additional length given to our summers allows many kinds to come to perfection that otherwise we cannot ripen. A month or six weeks is certainly thus added. We have plenty of light from our long days in summer; but, excepting for July and part of August, we have no heat in the ground, and during our long cold and wet autumns the rootlets of our trees rot and die, and they have to grow again before the trees have strength to swell their fruit. I tried three trees of Beurré Superfin last year, all grafted at the same time and equal in vigour—one in the open ground, one in the orchard-house, and one with root heat and no glass. The Pears from the open border were about the size of Walnuts, those from the orchard-house fair-sized and good, but those from the hot border were larger and finer than I have ever seen in the south of England; and it must be remembered that the season was one especially favourable for the open border, the trees in which had not been disturbed for three years, and were kept well mulched during the hot weather.

I first began the system of bottom heat by plunging Strawberry plants in an open hotbed and planting them out after

giving them a rest in the autumn; and the result induced me to try the plan on a larger scale with very various kinds of fruit. One very useful application of the hot border is for grafting young trees: the stocks potted early in the autumn and treated like the other trees during the autumn and winter and early spring are quite vigorous enough then for grafting, and they push strongly and get no checks, and so there is no trouble in keeping back the scions till the stocks are ready.

Last year I put a row of Potatoes just over one of the hot-water pipes, at the same time that the ordinary crop was planted. Some time afterwards my man (who is not learned in gardening, though thoroughly trustworthy and interested in his work), came to me and said, "The tatoes on the hot pipes are not thriving like those in the grund." I asked him what made him think so; and then it came out that he was judging by the tops. However, in a few days more the ground over those in heat swelled and broke up like mole-hills, and we had in the beginning of June the best Potatoes I have had at any time since I came here six years ago.

I am now making preparations for giving bottom heat with glass overhead, and I shall be very glad to work out any systematic experiments on the use of heat without glass, glass without heat, and heat and glass united; but I am sure that unless our experiments are based upon some principle to begin with, they will never be of value for making correct inductions; and so I shall be glad to give some time to experiments of a scientific kind in order to obtain results that, as an individual, I should never live long enough to see, but which by the united efforts of many may be arrived at in a very few seasons. So please do not think that in the account I am giving you, I suppose my system to be anything more than an experiment, or that I should consider it otherwise than a hasty induction to declare from it that the principles which for the sake of clearness I have stated, are in anywise proved to be correct.

## CELERY CULTURE.

EIGHT-AND-TWENTY years ago my father grew the best Celery in the county. For nearly twenty years it was grown on the same spot. His system had something peculiar in it, and to a great extent had to be adopted through the force of circumstances. The soil of his garden was a uniform depth of 3 feet of light sandy loam, where Pears were either cracked or gritty, Cauliflowers always clubbed, Carrots worm-eaten, and the main crop of these was always grown on some distant part of the home farm; but Apples were healthy, fruitful, and their skins shining and glossy. We never since saw such Hawthorn-dens, Oslins, or Golden Pippins; and the Raspberry quarter, in a moist rather shady corner, was a perfect labyrinth of tall strong canes. Below the 3 feet of soil lay a fine clear yellow sand, upon which we used to speculate in our budding geological fancy whether it reached through to the other side of the earth; but our convictions on that point are now a little more matured. Just outside the wall stood a green rocky eminence commanding a view of the whole garden, on the top of which used to stand two venerable umbrella-looking Scotch Firs. That will ever be a green spot in our memory, recalling reminiscences of struggles then unfelt, of a large family on scanty fare, scanty clothing, on a gardener's very scanty wages.

It was a very dry hungry soil, and for its depth, readily became parched. In summer the Celery required great quantities of water, often repeated, and far to carry; and being scarce of both water and labour, my father economised both by adopting the following system:—The Melon ground stood in an open part of the garden, on a declivity to the south, with the river Doveron running near the lower end. Large quantities of stable manure were annually used for Melon, Cucumber, and other beds, in ranges running from east to west. The Celery trench, about 5 feet wide and 18 inches deep, lay parallel to the dung-beds at the lower side. The surrounding ground was quite hard from long treading, so were the bottom and sides of the trench. The Celery trench was part and parcel of the Melon ground, and was annually in the spring cleared out; the soil which was used for earthing-up was laid to one side; the wasted manure in which the Celery had grown the previous year was wheeled away, and the trench was recharged with a quantity of the old dung from the Melon-beds.

The Celery, raised in boxes in one of the frames, was pricked out at once in rows across the trench, where it had to remain, the earliest being for some time protected and encouraged by having a few sashes from the frames laid across the trench;

the Celery, therefore, did not suffer from the usual check of removal at a later period of its growth; the later plantings had no protection at all save a little shading for a day or two. The Melon and Cucumber-beds stood on a basement slightly hollowed out of the surface of the ground, in order to have a level bottom to build upon, and to keep the surrounding ground clean and dry. Quantities of liquor, assisted by rains drained from the beds in spring and summer, and were conducted in underground channels to tanks sunk in the ground by the side of the Celery trench, and the overflow from them was directed into the trench itself. From these tanks the Celery was often watered throughout the summer, and this was a great auxiliary to the dung in the trench as a cool liquid manure, and saved carrying so much water from a distance.

The Celery was gradually earthed-up throughout the summer and autumn as it grew. This process was not left until late in the season, and the plants then earthed-up at twice or thrice as is often done, the fine clean sandy soil offering no resistance to its growth and swelling. It lay close and soft about the heads, and the Celery consequently dug out clean and perfectly blanched, and never suffered from slug and worms, as is usual and almost unavoidable in heavy clay soils. It, moreover, kept exceedingly well in winter, the soil from its texture never becoming saturated with wet. It will thus be seen that the manure the first season did service as a heating material, the second it grew the Celery, and the third was removed to the quarters much diminished in bulk. The Seakale, Rhubarb, and Asparagus plots were also adjoining the Melon-ground for convenience of the manure, and occupied the same ground as long as the Celery did the trench.

My father still grows Celery by deputy, but very far from the old spot. Since then we have seen it grown in many ways, in many different soils, in places widely distant. The largest Celery we ever had a hand in growing, though not the best flavoured, was grown on the moist west coast, in a soil 80 per cent. peat. Plenty of pure cowdung not at all rotten was mixed in the peat soil, and the Celery otherwise grown on the so-called Scotch system. The loose dry peat was excellent for earthing-up, and the operation could be done with the greatest facility. Under this treatment we were convinced that any variety whatever would become transformed into a "Giant," a "Mammoth," "Champion," "Leviathan," "Defiance," or "Nonsuch." It has never since been our fortune to have to deal with soil so accommodating as the two kinds mentioned. Alas! a gardener has always something to learn or unlearn with every change of place and circumstances.

Among all the varied items of advice so liberally dealt to young gardeners, we have never seen recommended the advantage of serving part of his novitiate in gardens of which the soils are of the most opposite nature. A gardener reared upon a warm sandy soil would find his dates sadly wily of the mark when coming to deal with a cold retentive clay. Celery on the clay is a difficulty, especially in the earthing-up, aggravated if the garden is new. In Lancashire I have seen it wrapped in straw ropes before earthing, which met the end in view very well, but was a tedious and untidy process. I have also seen a drain-tile slipped down over each plant after the first or second earthing, when the finer soil was used up, and nothing but the stiff lumps of clay was available to finish the process; this is also a lame resource; an improvement might be made on it by having the tiles cut longitudinally, and bringing them together round the stalks of the Celery. We have also seen pieces of thin old turf placed round the Celery, but no substitute approaches the peat or the sandy loam.

For some years we have had to deal with a stiff retentive clay, but on the drier east coast still there is the difficulty of rotting in winter to be overcome, as well as the mechanical difficulty of earthing-up. We have tried various plans and found single lines the best; the ground is trenched if possible, but always ridged high in winter. In spring we throw out the Celery ridges, 5 feet apart. These ridges are not more than 8 or 9 inches deep and 11 inches broad, which are filled up with the rotten dung, and a sprinkling of the firm soil thrown over it, so that when the Celery is planted out it is about level with the surface. The Celery having been prepared by being pricked out in rotten dung on a hard surface, is lifted and drawn asunder with good balls. The roots are spread on the surface of the dung in the ridges, and finally covered over with leaf mould, and well watered, and earthed-up in the usual way; but long before the final earthing the excavation between the rows has become much deeper than the roots of the Celery, and the ridge of soil has assumed a high sharp wedge-shape,

tapering to a point, to shoot off the rain which the clay does effectually, the only drawback being that the soil falls a good deal after hard frosts.

When we have grown Celery in deep ridges, either singly or on the wide-ridge plan, we never found it grow kindly early in the season, and it was always long in making a start, and patches of plants would provokingly lag behind, causing a sad bungle in the casting-up. We are satisfied this was caused by the coldness of the clay bottom, communicated by the manure in the trench. Since we have adopted the surface-planting, it grows to perfection; strong and equal, even though it might be supposed to require more water, which it does not. It is remarkable that we have had a considerable deal more Celery "run" in cold wet seasons than in dry ones. Notwithstanding the heat and drought of the last two years, we have scarcely had a "run" head of Celery, and it has grown amazingly, though not so liberally supplied with water as could have been wished. We think that worms at the root of Celery, especially that early planted, so as to encourage healthy, quick growth, is the most effectual preventive of "running," and surface-planting best secures that condition. We advise all whose soil is cold or stiff to plant high; the extra labour spent in autumn on earthing-up is saved in busy spring.—(*Scottish Gardener.*)

### A USEFUL GARDEN CART.

Among the numerous implements and machines in use in gardens of considerable extent, there is none, perhaps, more in request at the present season than a garden cart. Of this requisite there are many forms, and yet few, if any, fully answer the purpose for which they are intended; but, that improvement is not difficult, I think I shall be able to prove, by laying before the readers of this Journal a drawing and description of a cart which I have in use here.

In the construction of a cart of this kind, due regard must be paid to the width of the paths, doorways, and gates of the establishment, and wheels are entirely dispensed with, an iron garden roller being substituted. To this roller shafts are attached, having iron supports made fast by an iron spindle passing through the centre of the roller, and kept in their places by a nut screwed on each side, as at *a*. The body of the cart is made fast to the shafts by a spindle passing through an iron eye at the end of each shaft and corresponding eyes on

the body, at *b*. On each side, as at *c*, there is a fastening, which admits of the body being tilted. It is necessary to remark that the size of the body must be regulated according to the size of the roller used, for if made too large it will be liable to over-balance itself when loaded; the diameter of the roller in this instance is 1 foot 6 inches, carrying a body 2 feet 6 inches wide by 3 feet 6 inches long at the bottom, and 3 feet 6 inches wide, by 4 feet 6 inches in length at the top. The end, *d*, is made to take out, and by taking out the keys at *e*, the body can be tilted, and so unloaded with ease.

The qualities that recommend this cart are its simplicity of construction and neatness, and from having a roller instead of wheels it can be taken to any part of the garden or lawn without doing damage. When the cart is not required, the body can be easily taken off, and the rest used as an ordinary garden roller.—THOMAS RECON, *Gardener to Lieut.-Col. Loyd.*

### LORD PALMERSTON PELARGONIUM.

As a pot plant this is one of the best with which I am acquainted, and I can with the greatest confidence recommend it to any one who has vases under cover to fill. For greenhouse decoration, as a specimen, it is a telling plant, being dwarf in habit, a very free bloomer, and having very large trusses of  $\alpha$

bright crimson colour. I have in a six-inch pot a plant with twenty good trusses of bloom on it, several of which are from 4 to 5 inches in diameter. On looking down upon it the foliage is almost totally excluded from view by the bloom. As a bedder it is also good, but like most of its kindred race the Nosegays, it requires a sheltered place, as its large heads of bloom are not capable of withstanding such rough weather as we have experienced this summer. As a suitable companion to the

above, I may name Magenta Queen, which though not such a telling pot plant as Lord Palmerston, is deserving a place in every flower garden, on account of its colour combined with a good truss of bloom. Out of some fifty varieties grown here these two stand first for pot culture.

I quite agree with Mr. Robson, that there is plenty of room for improvement in many varieties of bedding Pelargoniums, particularly in those of the Ivy-leaved section.—J. MAY.

AMONG THE SCOTTISH BRAES, LOCHS, AND MOUNTAINS.—No. 2.

“OVER the Border!” What a cluster of romantic associations in all past times are summoned up by those three words! Fendal affrays, raids, moss troopers, romantic marriages—all, happily, now civilised away. “Gretna Green,” the first railway station, has ceased to be a refuge for impetuous lovers, the law has rendered it no longer Hymen’s Zoar; but had law left it unnoticed, the electric telegraph would have outstripped the fugitives. The hand pauses over naming that power which now is rendering the world neighbours. I was at Inellan the other day, a seedling watering-place scarcely known except by those on and about the Clyde, yet the electric telegraph has extended its wires thither. The Glasgow citizens have gardened villas there, and on the day the Atlantic cable brought America’s reply to England’s congratulation, the Inellan wire conveyed an order from Glasgow for the despatch of Carrots and other “garden stuff!”

That “garden stuff,” from Kale up to Roses, is of the best our islands produce. The thorough Englishman of our southern counties, and who never travelled north of the Humber, thinks that Scotland’s climate is too inclement for any cultivated plant to thrive in if less robust than Scotch Curlies and Oats. No conclusion is more erroneous. Let that southerner be landed on Dunoon Pier—let him walk along the shore eastward for two miles until he reaches the extreme end of Holy Loch; let him walk westward for four miles until he reaches Inellan, and I will undertake to guarantee that he will confess he never before looked upon such a six-miles unbroken succession of handsome well-gardened villas. Not only are the gardens good, but the gardening such as might be expected from attentive readers of THE JOURNAL OF HORTICULTURE.

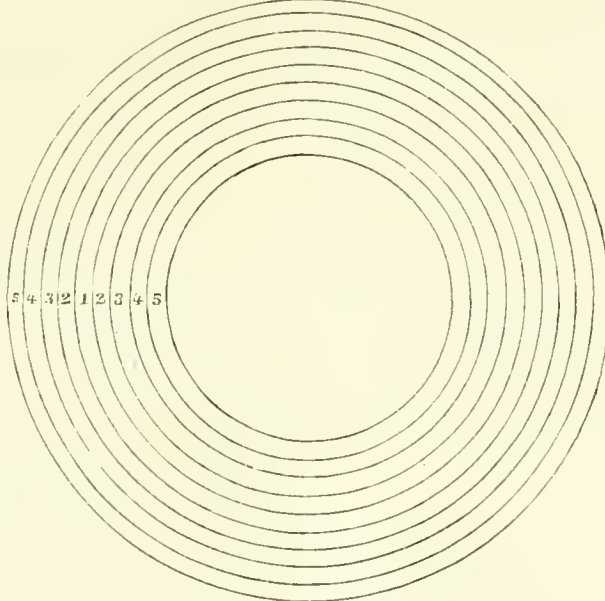

In those gardens a few days since I saw fine specimens of *Araucaria imbricata*, large bushes of *Fuchsia Riccartonii*, and *Hydrangeas* that have endured many winters unprotected and uninjured. *Dahlias*, some of the finest I ever saw, were in full vigour and full bloom on the 3rd inst.

The villas and their gardens towards Inellan are at the base of a mountain whose side is deeply wooded, and good taste has made good use of this natural advantage, by the introduction of paths up the wooded ascent, and the display of the

falls of the mountain streams. The gardens before the villas are mostly lawns well garnished by flower-beds, though one gentleman preferring the useful to the ornamental, has converted his front garden into one large Potato-bed! This stern utilitarian, however, is alone in his stoicism, for all the other gardens evince, more or less, a just appreciation of the beautiful.

I had seen near London one central bed which to me was novel, and as here I saw its counterpart its introduction may be now permitted. The effect is excellent. Here it is surrounded by turf, but near London by gravel; and the gravel, I think, was the best contrasting surrounding.

At the foot of the first mountain on the Inellan Road is a combination, forming a little district, of what is comfortable and beautiful both in nature and art rarely to be met with. There is there a cluster of villas looking from the mountain side over the west bay of Dunoon; there is a mountain stream dashing over the rocks, and winding its course among the well-arranged, well-attended gardens; a lofty one-arched bridge takes you over that stream, among the villas, and to the foot of a road winding up higher through the garden of “the parsonage.” In that garden—and from it “God’s acre” is not separated—stands a small church, its walls trimly clad with Ivy and Cotoneaster. All is so beautiful: there is such a union between the house of God and the houses of men—it seems to so look down over them all, and they so seem to look up to it—that the words uttered on another mound seemed to be evoked as I stood by that sanctuary, “It is good for us to be here.” Everything was in such exquisite keeping—not a weed, not a faded flower, not a thing to offend the eye—I recall it all, and there’s not a repulsive remembrance. There three brothers lie; and I feel that to pass to their side, and to have “In memoriam” inscribed as it is to them, would be like passing from one home to another. My old landlady, one of the Covenanter Hamiltons, told me—but erroneously—“It is a Puseyite place, and one Perry is minister.” Without urging them to change their doctrines or their ritual, I heartily wish the disciples of Knox in Mr. Perry’s vicinity would emulate his good taste and neatness both in externals and internals.—G.

- 1, Purple Orach, 1 foot high.
- 2, 2, Golden-edged Geranium, 9 ins.
- 3, 3, Yellow Calceolaria, 6 inches.
- 4, 4, Lobelia speciosa, 4 inches.

- 5, 5, Cineraria maritima, 2 inches.
- Centre, turf, 8 feet in diameter.
- Each circle about 6 inches broad.

THE SELECTION OF VERBENA CUTTINGS.

As the store plants of Verbenas turned out a failure last winter with many, I venture to urge the importance of having them well established in the store pots before winter. Here (in the west of Scotland), I find that the 1st of September is the latest period to which we can safely delay putting in the cuttings. I generally begin to do so about the middle of

August, by which time cuttings may be obtained without in the least disturbing the beds. I select shoots at least 3 inches in length, without flower-buds, if possible, and with prominent eyes at every joint; for without eyes they never make good plants, and to this cause I attribute the failures which occur in many cases. On examining the shoots previous to taking them

from the plants, many will be found eyeless, or blind, and such should be carefully avoided.

Four-inch pots are the most suitable size for store plants; crock in the usual way, half fill them with rotten dung, and then with about three parts finely sifted leaf mould to two parts river sand. Plunge the pots to the rims in leaf mould on an old hotbed, water sparingly through a fine rose, and afford a little shade in bright sunny weather. I find that *Verbena* cuttings thus treated strike freely, and can be kept satisfactorily through the winter.—JAMES REID.

### LORD CLYDE STRAWBERRY.

I AM quite willing to have Lord Clyde Strawberry tested against the Old Chinese, but I must decline accepting the test from plants of Lord Clyde sent by Mr. Gloede. I will either send plants, or have plants sent from some other source, with a guarantee that they are the true Lord Clyde.

I have been intimately acquainted with Strawberries for nearly thirty years, and, therefore, think I have spent about "half a lifetime" amongst them, as Mr. Gloede says he has.—WILLIAM DEAN, *Shipley*.

### WORK FOR THE WEEK.

#### KITCHEN GARDEN.

CONTINUE to plant out winter and spring vegetables wherever there is room. The culture of growing crops should be attended to when the state of the ground and weather will permit. *Broccoli*, the principal spring crop of Walcheren and of *Cauliflowers* should be sown. Sow thinly in an open place, and not in too rich soil, otherwise the plants will become gross, and less capable of withstanding the winter. *Cabbage*, another sowing of the different kinds may be made for spring planting, and likewise of the hardy *Cos* and *Cabbage Lettuces*, selecting a similar spot for the seed-beds to that recommended for *Cauliflower*. *Celery*, plant out. *Onions*, the main crops must now be pulled up and the roots exposed to the sun; this is the more necessary, because as soon as the bulbs have attained their full growth they will in a very short time begin to decay at the root or else strike root again into the earth, which is injurious to their keeping. *Potatoes*, taking up must now be vigorously prosecuted as fast as they become ready. *Parsley*, thin out and cut down a portion of the spring-sown, that a fresh growth may be made before winter; a part of the thinnings should be potted in 12-inch pots for removing to frames in winter. *Mushrooms*, as soon as a sufficient quantity of droppings is ready proceed to make a bed, if not already done. *Tomatoes*, to be kept thinned out, the shoots fastened to the wall, and the fruit well exposed. *Turnips*, it is not yet too late to sow for winter and spring use, for which purpose the ground where *Potatoes* have been growing is very suitable. *Shallots*, take up, and also *Garlic* for drying.

#### FRUIT GARDEN.

The value of the Strawberry as a summer fruit renders its successful cultivation a matter of some importance, the more especially as it comes within the reach of the humblest possessor of a garden. The present is the best season for making new beds. Strawberries thrive best in a deep rich loam and in an open situation. The land should have been previously trenched 2 feet deep and well manured, for Strawberry roots penetrate to a great depth. Select runners which have been layered into small pots for the purpose, or the strongest which have taken root from the older beds. If large fruit is an object a good space should be allowed them, say 2½ or 3 feet between the rows for the large-leaved kinds, and 18 inches between the plants. A somewhat less distance between the rows will suffice for the dwarf-growing kinds; and where economy of space is an object see that an open situation is selected, for Strawberries never do well in close confined places, though there is a general opinion that they will grow anywhere. Water them during dry weather till they become well established. Pears and Apples, both on walls and espaliers, will now require to have the second growth spurred in, and the leaders nailed or tied in, as they require it. Keep the lateral growth of Vines removed, and the shoots spread out as openly as possible; they will need all the influence of the sun to attain anything like maturity. Figs must have the principal shoots nailed in, and the remainder taken off; suckers of the same must be constantly removed. All stone fruits should be gathered as

soon as perfectly ripe, as they seldom improve much by being allowed to become too ripe, and they will keep a day or two longer in a cool place than on the walls.

#### FLOWER GARDEN.

Cuttings of choice herbaceous plants, Carnations, Picotees, &c., put in early should be pricked out or potted immediately they are struck, to become established. Early-struck Pansies may be planted for autumn blooming. Young seedling Wall-flowers, Brompton Stocks, Sweet Williams, and other biennials should either be planted out into reserve-beds or where they are to flower. This year's beauty should assist to suggest next year's improvement in the distribution of the masses in the flower garden. Attention should be given to the effect, duration of bloom, habit, and colour of the different plants, and another arrangement planned for a future season. The propagation of scarlet Pelargoniums, Verbenas for stock plants, and Calceolarias should commence. China Roses should be put in, and budded Roses examined, bandages removed, and failures replaced. Mark the best Hollyhocks for seed. We are glad to see that this magnificent flower is meeting with the attention its beauty well entitles it to. At this season many florists divide and repot their Auriculas and Polyanthus. We consider it a good time for the operation, so that both young and old plants may become established before winter. Hollyhocks, Dahlias, and herbaceous plants must be made safe from the effects of high winds by securely fastening them to their supports. The like attention should be paid to climbing plants against walls and trellises, standard Roses, &c. Plants blown about by the wind give an appearance of negligence, which should by all means be avoided. Remove daily dead leaves, decaying blooms, and litter of all sorts, and frequently sweep and mow grass, that all may look clean and well-kept. Gravel walks should be frequently rolled during heavy rains to keep them firm. The general pruning of evergreen shrubs should now take place, reducing straggling growths within proper limits, but to avoid giving them anything of a formal character. The object is to assist, not deform nature. By this the general characteristics of each plant will be as much as possible preserved.

#### GREENHOUSE AND CONSERVATORY.

Should heavy rains continue to fall it will be necessary to remove to glass shelters of some kind the more delicate-rooted plants, and unless the weather be fine all the more valuable greenhouse plants out of doors will require housing. In our last calendar we advised shading of all kinds to be reduced in order to afford assistance in ripening the summer growth by an increased amount of light. We need scarcely point out that an abundance of air night and day should accompany the above; and, as an additional means of effecting a slow but progressive and effectual ripening of the summer wood, the atmospheric moisture of plant-houses should be gradually reduced as heat and the length of the days decline, so that an increasing dryness of the atmosphere may coincide with the ripening of the wood. We wish to lay particular stress at this season on the importance of well-matured wood to plants intended to bloom in perfection; while they will be found to bear the vicissitudes of winter with impunity compared with plants whose wood is soft and imperfectly ripened. The supply of water will much depend on the state of growth and habit of the plant. It should, however, be remembered that many plants are now actively forming roots, and will require water liberally, especially when subjected to a somewhat drier medium to grow in. The stock of hardy shrubs in pots for next season's forcing, if the growth is perfected, may be laid on their sides facing south, this will assist to ripen their wood and prevent their making autumn shoots. After a short time remove them to the shade of a north wall for the winter. No time should be lost in completing any repairs that may be required by houses devoted to the growth of plants. Continue to keep the conservatory gay with plants in bloom. Carefully tie-out the different varieties of *Lilium lancifolium* before they come into flower; two other good autumn-flowering plants should likewise have similar attention—viz., *Crowea saligna* and *Plumbago capensis*, these are invaluable at this season. Attend to the proper regulation of climbers, and give weak liquid manure to plants in bloom, to maintain them in vigorous health, and to assist the late flower-buds to open. Finish the potting of *Chrysanthemums*, and stake them securely as they advance. The stock of autumn and winter-flowering plants should not be stopped after this, but have every encouragement to ripen their wood early, that no difficulty may arise in

inducing them to bloom at the time wanted. Daphnes, Oranges of different kinds, Myrtles, and Gardenias intended for forcing, should be removed to a cool airy house to rest.

## STOVE.

Many of the hardwooded spring-flowering specimens when kept growing late in the autumn, when there is not sufficient sunshine to properly ripen the wood, seldom flower strongly; therefore give every encouragement to such as have not made their growth, and use the shading very sparingly after this time. The twiners here will now be in their glory; keep them well supplied with water at the root, and give frequent attention to regulating the shoots and disposing the blooms in the most effective manner. The Allamandas are fine plants for pot-culture, but to have them in perfection they must be planted out in the border of the stove, and trained to the pillars or back wall, where they flower magnificently during a great part of the year. The brilliant *Clerodendron splendens*, the *Combretums*, *Echites splendens*, and *Stephanotis floribunda*, do splendidly when treated in the same manner, and trained near the glass.—W. KEANE.

## DOINGS OF THE LAST WEEK.

## KITCHEN GARDEN.

For the sake of the harvest we hope that a slowly rising barometer will be attended with more settled weather. The extreme changes from slight frosts in the morning to a close moist atmosphere almost resembling that of tropical climes will soon tell on the corn crops, and has already affected Potatoes unfavourably in many places. Had we plenty of ground to devote to Potatoes we would have a fresh field every year; and either plant on raised beds, as in many parts of Ireland, or in rows far enough apart and sufficiently raised for the water not to lodge about them. Most raised beds will be moist enough from the absorption of moisture from beneath, and then there would be a better chance of escape from the heavy autumn rains. In crowded gardens the only security will be found in planting early kinds and taking them up before the autumn rains come. As alluded to last week, we find that some fine samples of ours, clear and without a spot, are showing some specks of the disease after being housed dry and in the best order. This is most unaccountable.

Sowed more Cabbage seed, and Cauliflower for the main crop next season. In the case of those who have early light soil it will be time enough to make this sowing in the first week in September, or later. It is also a good time to sow a little Savoy seed and *Scotch Kale*, or Borecole, if these are wanted early next season. In England Scotch Kales are little used until they have been a little frosted; but in many parts in the north they are sown largely about the middle of August, and planted out and kept in beds like young Cabbages; and then in the spring, long before the Cabbages come in, the larger leaves are cut half in two, taking away the more tender part, and they boil beautifully tender either in broths or soups, or as a separate dish. We attain much the same object in England by sowing in spring and not cutting before winter, and all through the next spring we obtain a large quantity of nice stubby side shoots, so that the plants may well be called "cut and come again." The Tall Curled Scotch Borecole is the best for this continuous supply. The Scotch Cabbaging and a variety sent out by Mr. Veitch are the best dwarfs, yielding amazingly, and affording very late gatherings before they begin to run to seed. We instanced the other week the simple but important fact, that if a Cabbage plant runs to flower-stalk instead of forming a head, cut how you may, all the young shoots are almost sure to run to flower-stalks; and the converse of this holds so equally true that when we first grew the Cabbaging Colewort we thought so much of it, and were so doubtful of obtaining it true from seed, that we grew it several years by slipping off the side shoots in spring before they began to show signs of starting for bloom, and planting them; and though they looked a little wilted at first, they soon rooted and made excellent plants. The same will hold good in all the Cabbage tribe we have tried, but it must be done before the flowering or fruiting tendency has been regularly developed. When that has taken place it requires an extra amount of trouble and care to make a plant out of a flowering shoot. Hence in making cuttings of flowering plants we avoid the flower-stalks, and select firm side shoots, that we may first lay the foundation of the necessary amount of growth to carry the flowering process to completion.

Sowed also more Lettuces and Onions, the latter we will sow again in about a fortnight, and they will be generally the best for transplanting in spring; also sowed the first crop of Winter Spinach, to be followed by another sowing in a week or a fortnight.

Planted out more Cauliflower on a raised bank, young Coleworts on a tree border, under shade, not so good as in an open place; also Lettuces and Endive. Made up beds of *Parsley* where there were some blanks. Make a point of always having fresh ground for this, as otherwise it is apt to go off. It is difficult to account for failures at times; we sowed two pieces of ground in rows, each piece being as much alike as possible, and only a walk between them, and both pieces were treated exactly alike, as far as we could see, receiving about the same amount of seed out of the same packet, and yet one piece will bear almost any amount of thinning, and the other will require to be helped. We have a small row in an orchard-house, just coming through the ground, which will be found invaluable in bad weather in winter. Those who have no such convenience should now place some good plants in large pots or boxes, so as to afford protection in winter. To be without Parsley in winter is rather more uncomfortable than being without Mint in the height of the Pea season. Forward Parsley should now be cut well down to make it bushy before winter.

*Celery*.—We stated lately that some of the beds were acquiring a lighter hue in the foliage than we liked, and we may here note that the dusting of soot all over them, which has now been mostly cleared off by the rains, has made the foliage of a black green again. We would like to give them a good soaking, even after these showers, with strong house-sewage, as it generally does wonders, when the plants are thoroughly established, but at present we are afraid to have anything to do with it, in case the men should be injuriously affected in this muggy weather, and with the dread enemy Cholera hovering around us. As respects this sewage, two things are required from our scientific friends—a cheap disinfectant, and safe for a common labourer to apply; and, secondly, an assurance that when the odour is removed, the danger of affecting the human system will also be removed when the sewage is used.

*Sow Thistle*.—This has been a troublesome visitant to us this year, and generally in this neighbourhood, and is mostly confined to the variety of *Sonchus oleraceus*, having plain leaves serrated at the edge. In some places it looks as if it had been sown, but we know too well what even a single plant will do if left undisturbed to mature its seeds, and to scatter them by the wind, the fine down giving to each seed the wings with which it can fly. We have noticed that in the present season, this and the common field Thistle, far more difficult to extirpate, are more prevalent than usual by the sides of some highways. It would be a wise act if our Legislature were to compel the surveyor of highways, or those holding lands adjoining, to at least cut every Thistle before it bloomed, if not take it up by the roots, in the case of the common Thistle. Even in the case of the Sow Thistle, if a single flower-head should have changed its yellow blossom for the head of down, it would be wise policy to go and pick all these heads off before attempting to cut up or pull up the plant, as the very act of pulling or cutting, will be sure to spread the seeds, and the first brisk wind will do so without our aid. As to pulling up this Sow Thistle, it is next to impossible in most soils, the stems are so brittle, and the roots are so strong; and as to cutting the plants over at the surface of the ground, or a little below it, that is only a temporary relief, as they will send up numerous shoots from the collar; but if cut 1 or 2 inches below the surface there will be little more trouble, as from the annual character of the plant, the fleshy roots will soon decay, if there is no reciprocal action from leaves and stems above ground. If the annual character of the plant is kept in mind, there will be no necessity for grubbing up the roots with a fork or mattock, as in the case of the common Thistle. But however cut or grubbed, just as in the case of the common Groundsel, it is never advisable to leave large plants on the ground when so cut up, or to remove them to that general receptacle, called the rubbish-heap, but which may be made one of the best adjuncts to the garden, as then from the juice contained in the succulent stems, the seeds will often be perfected and scattered. It is better in every way to remove such plants to the burning or charring heap, where the excessive heat will destroy all seeds even when imperfectly formed.

Upon the *cut bono*, what-good? principle, a very favourite topic with our utilitarian philosophers, but which may be carried too far when everything is ignored for which in their

wisdom they can perceive no utility, a great deal cannot be said for the Sow Thistle; and yet there may be something advanced in its favour. On the principle that observing and working are in themselves blessings to mankind, then for keeping the eye of the cultivator open and his hands active, the weed has its use; and besides that, swine like it, and other domestic animals, and rabbits are especially fond of it; also, when its young shoots and leaves are nicely boiled it forms, in our estimation, a better substitute for garden greens than even the blood-cooling shoots of young Nettles. Then there may be circumstances in which a piece of this ugly weed might be useful, could we by canvas or fine wire protection prevent its seeds being dispersed over the neighbourhood, just as if we had a large collection of the feathered race, we would most likely appropriate a piece of our garden thus duly enclosed to prevent the egress of the winged seeds, to growing Groundsel for the sole delectation of our birds. All such fancies, however, should ever be kept subordinate to the general advantage. The good considerate man would not, and the inconsiderate man should not, be allowed to ride a favourite hobby so as to injure his neighbours or do mischief to the whole community. The man who carried and sowed the seed of the common Thistle in Australia, where it had never previously been seen, might have had plenty of enthusiasm for the rugged emblem of old Scotland, but he could have formed little idea of the extra toil and labour he was securing for all future cultivators in that land.

*Calyptegia, or Convolvulus, sepium.*—Having said thus much on the Sow Thistle, we may notice that this plant, the Bindweed or Bearbind of our gardens—producing now where it only partly had its own way its luxuriant twining shoots and green foliage, and its large milk-white flowers—is one of the worst weeds that can find its way into any garden where the soil is at all stiff and moist, as in these circumstances it especially delights. We can see its pretty flowers where we do not want to see them, and this result has been assisted by the rapid growth during the moist weather, when the hoe was apt to be let alone. The long white roots, which if let alone would soon net a piece of ground, are meddled with by but few animals, except pigs, and are difficult to eradicate, as almost every inch will send up a shoot, and that will soon be followed by the extension of the roots and numerous other shoots. Digging out these roots at every change of cropping is all very well, only it is difficult to take all out and not leave a little bit behind. The simplest plan of eradicating this beautiful but dreadful pest, is a continuous use of the hoe, and cutting up every shoot before it attains more than 2 or 3 inches in length. Where the labour power will permit of that being regularly done, the plants will die out, as even the long, white, fleshy roots will decay, if no shoots from them are allowed to be seen above ground. When permitted to grow so as to show a single flower, it would require continual cutting-in a future year to paralyse the energy of the roots.

The *Small Bindweed* (*Convolvulus arvensis*), which produces according to the variety its white or pinkish flowers on the small trailing shoots, may have its roots destroyed in the same way, or by cutting off the crowns and placing a good pinch of salt upon them. The roots of this, like the Bearbind, are difficult to eradicate, as the smallest piece left in the ground will grow; but, as in the former case, if no shoots are allowed in summer, the roots having no outlet for their juices, and no fresh matter added, will at length die of starvation. There are few plants that would not be killed in time by a similar process, but the action must be continuous.

FRUIT GARDEN.

Regulated trees as previously described. Went on with potting Strawberries in the manner stated the other week, the wet intervals giving a good opportunity for washing pots well previously to using them, for we have less faith in a dirty pot than in almost any other dirty thing; and one reason why some of our window gardeners fail is that they use the same pot over and over again before thoroughly scrubbing it inside and outside. Sometimes in the spring, when pots are used frequently, being filled as soon as emptied, we content ourselves with washing the inside merely; but in all cases where the plants are to remain some time in the pots, these pots should be well washed inside and outside, and be well dried before using.

Went over the orchard-houses, exposing the fruit more to the light, and even lessening the number of those most crowded, as it is better to do this late than never. As the fruit would come in too soon for us, we have shaded one part of a house a

little, though aware that it will not improve the colour or the flavour; but we most likely will have the glass exposed enough before the fruit ripens. We find that as a general rule in these cold, merely glass-covered houses, there is always a danger of leaving too much fruit, as it generally sets so thickly. As soon as we can find time, we will plant out a good many runners of *Strawberries* rather thickly—say from 4 to 6 inches apart, and these will come in well for forcing late, and making fresh plantations in spring, if it be desirable to do so. As soon after this as possible, we will clear away the runners from all Strawberry plants we intend to remain, and dig, or rather trench down all those we intend to remove, filling the space with winter stuff, late Celery, &c., so as to secure the advantages of a rotation of crops. We will also break up where there are a few blanks, a border of Cuthill's Black Prince, and plant some more, as though its dark colour when thoroughly ripe may be a drawback in the estimation of some, its great bearing qualities, and the firmness of its substance, render it one of the best for preserving-purposes we know. This we are given to understand, that many who make much jam, will have no other sort so long as Black Prince is to be had. In our opinion it is far before the old Scarlet, Grove End, &c.; but every one to his fancy.

In our rather stiff soil we thus generally manage plantations of Strawberries. Trench the ground well, incorporating with the lower 12 or 18 inches about 3 or 4 inches, or more, of what we can lay hold of in the way of manure. When the ground is dryish on the top, we point-in a layer of 2 or 3 inches of rotten hotbed manure, generally consisting of leaves and litter at first. We then turn out plants in rows 2 feet apart, and, according to kinds, from 12 to 15 or 18 inches apart in the row, making the ground firm about the plants, and then to prevent cracking, either pointing the surface somewhat roughly with the point of a fork, or throwing a little rotten dung over it. From that time, besides clearing the plants, merely breaking the surface of the soil, and placing a little manure between the rows in winter, allowing all the leaves to remain on during that season, and dressing them a little in the spring, the plants have no more of the spade until, two or three years after planting, they are transferred to the bottom of a trench. Except plants that have been forced, we plant none in the summer or autumn, as from scarcity of ground that would deprive us of a winter crop; but we plant early in spring, lifting with good balls those runners that we prick out now. Of course, to save labour, we would rather plant out in the autumn. By planting in spring we can make more sure of every plant being fruitful, and after all that has been said and done, we think it worth while to select young plants as much as possible from fruitful parents. At any rate, we once had a patch of fine-looking Keens' Seedling that in three succeeding years never showed a bloom, and the runners from them were equally barren. We wish now that some experiments had been made to render these fine-looking barren plants fruitful.

If the ground is light and sandy, it would be well after trenching for Strawberries, to roll it well before planting in a dry day, and then give a mulching of rotten dung. The only way to make light soil support a Strawberry crop equal to one with more loam and consistence in it, is to make it as firm as possible, but so that the surface may not be cracked or fissured.

ORNAMENTAL DEPARTMENT.

Of this more anon. Much the same as to keeping lawns and walks right, looking over flower-beds, regulating them when necessary, preparing for cuttings, planting Violets, potting and attending to greenhouse plants, regulating climbers, so that the sun may have more free access to the plants as the days become shorter, &c.—R. F.

TRADE CATALOGUE RECEIVED.

W. Dillistone, Munro Nursery, Sible Hedingham, Essex.—Catalogue of Choice New Plants of 1866.

TO CORRESPONDENTS.

We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

We also request that correspondents will not mix up on the same sheet questions relating to Gardening and those on Poultry and Bee subjects, if they expect to get them answered promptly and conveniently, but write them on separate communications. Also never to send more than two or three questions at once.

N.B.—Many questions must remain unanswered until next week.

AZALEAS (A. A. H.).—Your Azaleas are attacked by a grub which is eating the young tips. Syringe them with Gishurst compound.

BOOKS (A Constant Reader).—We think that the "Vine Manual," which may be obtained at our office for 2s. 6d., or free by post for 2s. 8d., and "Vine Culture under Glass," by Mr. Pearson, 1s., or free by post for thirteen penny stamps, would suit your requirements. (F. J.).—Hogg's "Fruit Manual," price 5s., or free by post 5s. 4d. (A Young Gardener).—You can obtain "The Modern Peach Pruner" at our office for 3s. 6d., or free by post by enclosing forty-four postage stamps with your address.

EGG PLANT (A Foot).—The plant was introduced into this country in 1597. The fruit is cut in slices, and fried with lard; or, after cutting it in half, parboiling it, and scooping out the seeds, it may be stuffed with various herbs and bread-crumbs, and fried or baked until brown, adding various seasonings according to taste.

GERANIUM LEAVES EATEN (A Subscriber).—We have had to encounter the same enemy in our greenhouse. The pest is a green fleshy grub, about 1 or 1½ inch long, which you may detect by examining the under surface of the leaves of your Pelargoniums. The only remedy is to hunt closely after them and destroy them. They do burrow in the earth; but you go to into the chrysalis state.

BLANCHING CARDOONS (F. N. S.).—The Cardoons, now 18 inches high, may have the leaves tied closely and regularly together with strips of matting, and have a little earth placed around them, as in earthing-up Celery. By the middle of September they will have grown amazingly, and will need final earthing-up for blanching. This you will best do by means of a hayband; gathering the leaves regularly together and beginning at the bottom, wrap the hayband round the plants to within a few inches of their tops, and lay up soil, broken fine, about them as high up as they are tied. If the haybands cannot be procured, then tie up the leaves with matting and place straw or dry litter about them, tying that up with matting, and earthing-up as before directed. The plants earthing-up from the middle of September to the end of that month, will be fit for use in the end of October and onwards to December, earthing-up again if necessary, and protecting in frosty weather with a covering of dry litter. In gathering, the plants are taken up like Celery, and the outer leaves removed until the blanched heart is reached. This has the same appearance when dressed as an immense stick of Celery, is stewed like it, and used in soups.

GARDEN WALL (Allerton).—The thickness of "single brick," with which you intend to raise your wall, supported by piers at 4 feet distance, will answer perfectly. The only difference will be, that you will not secure such an amount of radiation from the 4½ that you would from the 9-inch work. The contrivance for a coping is very ingenious, and will, no doubt, be effective; but why do you give it an upward direction? We should prefer it inclining downwards, as it will more readily prevent the free ascent of warm air passing off from the wall. We should have these copings of nine-inch boards, to be screwed on the brackets and removed after the spring frosts have gone; they are always unsightly. We cannot advise you on the price of the masonry, as that varies very widely in different parts.

PLANTING ANEMONES (G. C.).—The tubers are best kept on a shelf in a cool dry shed, and covered with an inch or so of dry sand. The best time to plant them for early blooming is October. In January go over the bed and stop up any holes made by worms, or the leaves protruding, and topdress with an inch of half-decayed leaves. Choose a rich light loamy soil, and an open situation. Plant 2 inches deep, and from 7 to 9 inches apart, with a gentle pressure only, as the tubers are fragile, employing a little care in placing them so as to set the right end upwards, and let the ground be dry rather than wet.

TONACCO DRYING (Nicotiana).—The leaves are to be gathered when they assume a yellow tint, tied in small bunches, and hung up in some shady airy place to dry. When crisp watch for the first humid state of the atmosphere, when they will become soft, and pack them evenly in a box with the ends or butts all one way; press moderately, and a slight heat will be generated. Whilst warm take out the bunches, shake in the air to let of the heat, repack lightly, and, when thoroughly dry and cool, store tightly in a barrel, and keep there for use. The leaves which turn black and smell disagreeably will not be spoiled if you dry them, but if fungus attack them they will lose their virtue.

PRUNING GOOSEBERRY AND CURRANT TREES (Gregory).—You must now wait until the leaves fall, and then thin out the main branches so as to leave them from 6 to 9 inches apart, keeping the centre of the bushes open. The shoots of the current year are to be cut in to within an inch of the branches whence they take their rise, leaving untouched any short shoots having the buds very close together, as these spurs and the buds set closely together at the base of this year's shoots produce fruit in the following year. The upper shoot of this year on the main branches may be cut back to four or six buds according as the bushes are required to be larger or kept to their present size. Any old branch destitute of spurs may be cut out, and a well-disposed young shoot retained to replace it.

PRUNING PLUM AND APRICOT TREES (Idem).—The forelight and all shoots not required to train in at 9 inches apart should now be shortened to four leaves, leaving the shoots necessary to cover the wall regularly at 9 inches apart, and the leading shoots at their full length. Nail these loosely to the wall.

MANURING FRUIT TREE BORDERS (Idem).—You may dress them in autumn with 1½ or 2 inches thick of stable or hotbed manure, leaving it on the surface, and pointing it in in February or early in March, but not so deeply as to injure the roots. The rains will wash the manure into the soil.

MANURING A VINE BORDER (Idem).—You may cover the border in November with 6 inches of litter or half-reduced manure, and allow it to remain until March; then remove the straw portion, and fork the short dung in without going so deep as to affect the roots. In April you may give a surface-dressing of bone dust, leaving it to be washed in by rains.

BED FOR TULIPS (Idem).—After the Geraniums are removed, dig the bed a foot or 18 inches deep, work in a dressing of rotten manure 3 inches thick, or leaf mould. Plant in November, or early in December.

LAWN MOWINGS (Idem).—These are of no use for the formation of leaf mould; that and garden refuse generally form, when rotten, a good manure for kitchen garden crops.

EXCRESCENCES ON THE STEMS AND BRANCHES OF VINES (A Subscriber).—The warts, we apprehend, are caused by the roots having gone down into cold bad soil, and to a considerable depth below the surface. The Vines, consequently, having lost most of their fibres are seeking to furnish themselves with surface roots, and the excrescences are the parts from which such roots would be emitted under suitable conditions. Your only remedy is to have the roots brought nearer the surface.

ROSES FOR A WIRE FENCE (Ambleside).—The best Roses for either a low or high wire fence are the climbing Ayrshire Roses;—Duodece Rambler, Ruga, Queen of the Belgians, Myrrh-scented or Splendens, Thoresbyana, and Alice Gray; Rosa multiflora vars., Purpurea, Kusselliana, and Laure Davoust; and of the Evergreen kinds, Brunoni, Rampante, Felicit-Perpetua, and Myrianthes. On a fence 4 feet high these should be planted from 9 to 12 feet apart.

RED SPIDER IN MELON-FRAME (Cypher).—Your only plan is to syringe the plants on a sunny day about 2 P.M., and, whilst wet, to dust over them powders of sulphur; then close the frame, cover the lights with a thin mat, and keep the plants well supplied with water at the root. Syringe overhead every alternate day early in the afternoon, and close the frame, throwing a mat over the lights if the afternoon be clear, removing it at 4 P.M. In a week dust again with sulphur on a clear day, having previously sprinkled the foliage with water, close the frame, and cover up.

STRAWBERRIES FOR FORCING (Idem).—Take pots 4½ inches in diameter for the Black Prince, and six-inch pots for Keen's Seedling; place a piece of crock over the hole, over that an inch of the rougher parts of the compost, and then sprinkle over the latter a pinch of soot; fill the pots to the rim with a compost of two-thirds turfy loam from rotted turves, and one-third well-rotted manure, making it very firm in the pots. Having prepared the pots, take them to the beds, and place in the centre of each a good runner, keeping it in its place by a stone set on the side next the old plant. If well supplied with water, the runners will by the middle of September be strong, and may be detached from the parent by cutting, and removed to a sunny open situation, where they should be well supplied with water up to the middle of October, after which the soil is only to be kept moist. After November pinage the pots in coal ashes to protect the roots from frost. In February set them on a shelf in the vinery about 15 inches from the glass, the shelf having previously been covered with turves 1½ inch thick, placed grass downwards. Keep the soil moist, but not very wet, until the plants come into bloom, when they should be very liberally supplied with water and air, admitting a little at night. With abundance of air, a moderate temperature, and a light situation, we think your plants would please you. Give them liquid manure after the fruit is set.

PROLIFEROUS ROSE (A. R., Bromley).—Yours is not a singular case of morphology. It arises from an elongation of the axis beyond the point where it is usually arrested in the normal form of the Rose.

INSECTS ON PEAR LEAVES (W. Berry).—The insects were slimy grubs, the larvae of Selandria aethiops, which are of common occurrence in July, August, and September. Dust with lime.

INSECTS (S. B.).—We do not know what the insects are, but they are quite harmless, and are certainly not thrips.

**RED SPIDER ON ORCHARD-HOUSE PEACH TREES—APRICOTS LATE IN RIPENING (A. B. C.).**—You must continue to syringe your Peach trees in the morning; the flavour of the fruit may suffer a little, but better that than allow the trees to be weakened by red spider. Your ventilation must be deficient, or perhaps your orchard-house is in a confined position, for our trees treated as detailed in page 87 are perfectly free. You may safely syringe the trees after the fruit is gathered with the decoction of guassia chips, 4 ozs. to the gallon, boiled ten minutes, adding to it while cooling 4 ozs. of soft soap. This will injure neither leaves nor buds. You should have kept that part of your house in which are the Apricot trees warm as soon as the fruit commenced to swell towards ripening. The trees would have remained healthy, and the fruit would have ripened early. Apricots are easily retarded by abundant ventilation, while Peaches and Nectarines often ripen freely with it in sunny weather. All the ventilators may be open in October and November, except in stormy weather, when the entrance of a violent gale may do mischief.

**VICTORIA NECTARINE (J. W. G.).**—Your own surmise is a correct one. There is no doubt but that the ungenial weather of the present summer has been unfavourable to the ripening of all fruits that prefer and require a warm and bright season; and the Victoria Nectarine is one of those.

**DRYING FERNS (E. B.).**—Gather the fronds when they are perfectly dry, and spread them out neatly on sheets of paper—old newspapers will do very well; pile them one over the other, and cover with a piece of board, on which put as much weight as will keep them perfectly flat. Change the papers, or dry them once a-day, and in a few days the fronds will be quite dry.

**NAMES OF PLANTS (Lachenalia).**—We cannot do anything with the plants unless you attach numbers to them. Thanks for the returns of rainfall, but we must decline them till the end of the year, when we shall be pleased to publish the observations for the year. The two Numbers which you name will be sent free by post for eight penny stamps. (*Rodolph*).—1, *Stachys sylvatica*; 2, *Epilobium hirsutum*; 3, *Verbascum nigrum*; 4, *Senecio sylvaticus*. (*Erica*).—1, *Erica cinerea*; 2, *Erica cinerea* covered with *Cuscuta europæa*; 3, *Calluna vulgaris*; 5, *Erica vagans*. (*J. B.*).—1, *Adiantum capillus-Veneris*; 2, *Adiantum cucullatum*; 3, *Pellæa adiantifolia*; 4, *Platyloma rotundifolia*; 5, *Nothochlæna rufo*; 6, *Pleopeltis nuda* (?); 7, *Onychium japonicum*; 9, *Pellæa ternifolia*; 10, *Aspidium molle*; 11, *Davallia elegans*; 13, *Platyterium alciornæ*. (*H. T. W.*).—1, *Lysimachia vulgaris*; 2, *Kerria japonica* fl. pleno. (*S. A. N.*).—Probably *Lastrea punctulata*. (*Hypericum*).—The Violet, *V. cornuta*, is not a native plant.

**POULTRY, BEE, and HOUSEHOLD CHRONICLE.**

**VULTURE HOCK IN COCHINS AND BRAHMAS.**

"A QUESTIONING BRAHMA" has again mooted this point, and the reply is, "Why were they ever produced?" This is, in fact, the question asked, and I suppose I must take it and the context as the reply to my challenge, of which "JUSTITIA" speaks, given so many months ago, to which, in truth, I felt confident that "silence had given consent." Is it worth while to open up all this question again? I am certain the "Judge" will never convert me; and as far as I can make out, there is only one judge who holds the opinion that moderate vulture hock is not a necessary qualification of a thoroughly good Brahma. I have been led to this belief by the career of my old cock, "Champion." In his long life he has made acquaintance with a great number, and some variety, too, of judges. I may say that with the great majority of them he has been on most friendly terms, and they have constantly expressed their good opinion of him. Once, and once only, did Mr. Hewitt, allowed by all to be the most able judge we have, ever omit to notice him. It was in a very large class, and I am quite convinced it was an oversight, and "Champion" forgave him, as he never bore malice, and within a fortnight, in a severe competition, Mr. Hewitt awarded him first prize. Since then the gentleman to whom Mr. Hewitt awarded the first prize at the exhibition where "Champion" was unnoticed, wrote to me for birds, saying he had remarked my pen at the show, and he considered them "perfect," though somewhat smaller than his own. This gentleman knows as well as the "able Judge" what a good bird is, and whenever he exhibits, which is not often, his specimens are always near the top, if not quite there. "Against this I place the other fact, that at the only shows other than that mentioned, where Champion has remained unnoticed, the same judge, whom I fancy (rightly or wrongly, I cannot say), to be the "Judge" replying in "our Journal," is the awardee of honours. Now does not this appear like an isolated opinion against the moderate vulture hock and a host in favour of it? Against it we have the "able Judge's" unsupported opinion, for I trust I am not mis-stating the case; no single exhibitor has given in his adhesion against the hock, at least to my knowledge. What have we in favour of it?—all the judges whom old "Champion" has had the pleasure to meet; the majority of breeders; the "Standard of Excellence;" Mr. B. P. Brent, no light authority; our Editors; the "Poultry Book," brought out at the time of the Cochin fever and before

Brahmas were scarcely known; and, lastly, that which I before advanced, and which no words of the "Judge" can possibly refute—the fact that the drawings of these birds, as in their earliest days they were presented to Her Majesty, are unmistakeably vulture-hocked birds.

I might rest the case here, I think; but before I close, I will, however, further glance at the reply attached to "A QUESTIONING BRAHMA'S" letter, "There was an attempt at the *second London Show* (the italics are mine) to admit the vulture hock." Is this allowed? Then, I ask, wherever did it spring from, if not from the birds themselves? Thus early the vulture hock intrudes itself. The "Judge" supposes some freak or cross, but he does not explain how this was possible. Ptar-migans, Serai Taook fowls, if I recollect rightly, were not then introduced, and the old booted Bantam alone enjoyed the appendage; but it is impossible that Cochins and Brahmas derived it from this source. Whence, then? The Gwynne Cochins and the Sturgeon Cochins, I know personally, never patronised the naked hock that disfigures many Brahmas and Cochins now-a-days. "Evidence was at once collected, &c.," he continues, but where is this evidence to be found? Nobody knows. Surely, the "Poultry Book," written in the very height of the Cochin fever, would not have committed itself to the opposite opinion, or, at least, would have noticed this evidence. Possibly, too, there is another reason why the first imported birds should have been *naked-hocked*: I say this, taking it for granted they were so, but unable to credit it. It is quite possible that the natives valuing the moderate vulture hock, would not part with these birds until the prices rose to the fabulous amounts all of us who recollect the period can remember.

But he continues—"If the objection to the vulture hock were new, or only just published, then those who possess vulture-hocked birds might justly complain, and ask why they were excluded from competition; but they have always been excluded." I pass over my own personal experience of Brahmas, fairly successful. I have kept them a dozen years, and always more or less vulture-hocked, and I ask, What can our "Judge" mean by "exclusion from competition?" Is his memory so short that he cannot recollect the grand show at the Agricultural Hall, Islington, two years or so ago? In the largest class of Brahmas that had ever been seen, and in a most severe competition, a vulture-hocked pen was awarded first prize, and though on all hands it was allowed that the second-prize pen ought to have been first, I never heard that any objection would have been raised to this pen receiving second prize; and if "always excluded," how is it that my old "Champion"

should never have been excluded from the prize list, except at the two or three shows I mention?

Many years ago, in my early Brahma days, I asked the judge of an exhibition why he had not awarded a prize in a single cock Brahma class, where a friend of mine and I were the only exhibitors. He replied, the one bird was poorly feathered, and the other (mine) had a peacomb, which he considered incorrect. Where is that judge's opinion now? Does any one hold it? Is the hock a parallel case?

Our Editors' note to "JURISTIA'S" letter, which appears in the same Number, I cannot quite pass over. No one can accuse me of slighting my favourite breed; through the bygone years of evil repute and scandal that attached to their origin, their good qualities made them my favourites; I will not desert them now, when I so constantly read that at such an exhibition the Brahma class, which I have lived to see added to almost every meeting of importance, was without exception the class of the show. With the greatest deference to our Editors' opinion, I do not see how Brahmas can expect two classes (according to hock feathers). Funds would not permit it, and at many exhibitions they are already divided into dark and light. If granted to Brahmas, why not to Cochins? Rather, I would say, let the "Judge" give up his opinion; he may still hold it, but there is no reason that he should judge by it. Let him award the prizes irrespective of moderate vulture hock, and I am quite sure our covered-hock birds will beat their naked brethren out of the field.

One more word to my brother exhibitors. I am one of those who think that with the general run of honourable judges that we have, exhibitors should know who are to be the judges of the exhibition to which they send their specimens. It would then rest with them to decide whether they would send their specimens to be certainly defeated, thus throwing away their entrance money, increasing railway revenue, but receiving no kind feeling in return, and injuring their specimens. By watching the names of the judges where they show, they will find out the fancies of each and act accordingly. They can enter their specimens with the reservation that the entrance is only to be paid if Mr. So-and-So do not award the honours.—Y. B. A. Z.

As the originator of the discussion on the vulture hock in Cochins and Brahmas, which was carried on in your Journal last spring, may I be permitted to make a few remarks on the same subject on the occasion of its revival? I wrote in the first instance as an inquirer, not prepared to find that opinions so diametrically opposed to one another existed on a question which surely ought to be decided either one way or the other. Consequently, I was prepared to give the subject an impartial consideration. I will now venture to lay before you, with all deference to those more experienced breeders and exhibitors, who have far more right to be heard than I can claim, the results at which I arrived. I will endeavour to state these as briefly as possible. They may be summed up as follows:—

1st, A want of agreement among Judges.

2nd, The want of a better understanding between Judges and exhibitors, for which the former are to blame.

3rd, A want of a clear and unmistakable definition of the "vulture hock."

Respecting the first of these, I have gathered from the correspondence that it exists. I need say no more. Respecting the second, I say advisedly, that "the former are to blame." No impartial critic, weighing well the correspondence in your pages, could arrive at any other conclusion than that, while on the part of breeders and exhibitors there was every wish to state not merely their opinions, but also their reasons, at once as distinctly and as courteously as possible, on the part of judges no corresponding courtesy was shown. If I remember rightly, a few brief words of reply from one judge, based, as was shown by succeeding correspondents, on a mistake, but, nevertheless, repeated, apparently by the same judge, in your last week's impression, formed the only notice taken by that body of the discussion. This treatment speaks for itself, and, therefore, on my second conclusion also I need say no more, but will at once go on to make a few remarks on my third conclusion—viz., that we need a clear and unmistakable definition of the vulture hock. Here, too, I feel sure that judges and exhibitors ought to be agreed, though from the silence of the former we might almost argue that they are of a different opinion. Is it possible, that for the sake of exercising a little arbitrary power, with the love of which one has been accustomed to associate a certain amount of narrow-mindedness, those judges (for, of

course, I allude only to them), who are sworn enemies of the vulture hock, keep us in the dark as to which birds they consider and which they do not consider to be thus disqualified?

It appears to me that this question would be best settled by a certain amount of compromise. I have gathered that exhibitors are agreed that there are at all events two different developments which go by the name of the vulture hock. These are—1st, the *vulture hock proper*, where stiff, straight quill feathers project from the hock; 2nd, the *vulture hock simulative* (if I may be allowed the expression), where the soft fluffy feathers of the leg—which I hope we are all agreed cannot be too abundant—owing to their very luxuriance project a little beyond the hock, sometimes curving towards it, sometimes assuming a more pointed appearance. Now, the compromise which I have to suggest is as follows: Let judges give us some assurance that they will restrict their definition of the vulture hock to the first of these—the vulture hock proper; and I feel sure that breeders in general would be willing for them to go even beyond the dictum of the Poultry Club, and consider it not only an objection, but also an absolute disqualification, on the distinct understanding that what I have termed the vulture hock simulative be regarded not only as no disqualification, but on the contrary as an exuberance of beauty.

I could not but regret to find that one whom you describe as an able judge bases his condemnation on the fact that the originally imported Cochins were not vulture-hocked. Have the imported birds been always the best specimens of their kind? On the contrary, have not careful breeding and matching developed in almost every imported breed qualities nascent only in the originals? Does not the case of wild flowers under cultivation, in their tendency to become double, form a fair parallel? If so, why should we in our greenhouses and gardens rejoice over it, but in our poultry yards condemn it?

I will now, lest you should think that I have exceeded all bounds in the length of these remarks, leave the suggestions which I have thrown out for the consideration of others; venturing only in conclusion most respectfully to invite the judges of poultry to declare their opinions on the subject, as well as to seek to arrive among themselves at some consistent and unanimous opinion, thereby securing at once the increased confidence and the sincere gratitude of every breeder and exhibitor.—CLERICUS.

## CRAVEN AGRICULTURAL SOCIETY'S POULTRY SHOW.

The twelfth annual meeting of this Society was held at Skipton on Friday the 17th inst.

The display of poultry was good, and the number of entries large, but from the advanced state of moulting in which the adult birds at present are, these were extremely difficult to judge. The great attraction of the Show was the chickens of this year, in almost every class of which there were some most beautiful specimens. The Pigeons were also numerous, and of excellent quality. The following prizes were awarded:—

**DORRING (Any colour).—**First, H. Beldon, Goitstock, Bingley. Second, J. Pinder, Clitheroe. Commended, T. Drilen, Earby. **Chickens.**—First, A. Fenton, Rochdale. Second, J. Stott, Healey, near Rochdale. Commended, H. Beldon.

**SPANISH (Black).—**First, H. Beldon. Second, J. Thresh, Bradford. Commended, J. Newton, Silsden. **Chickens.**—First, J. Pinder. Second, J. Newton. Commended, H. Beldon; H. Pickles, jun., Earby.

**GAME.—**First, H. Beldon. Second, J. D. Newsome, Batley. **Chickens.**—First, J. Carlisle, Earby. Second, W. Turner, Earby. Commended, J. D. Newsome.

**COCHIN-CHINA.—**First, H. Beldon. Second, C. Sidgwick, Keighley. **Chickens.**—First, A. Fenton. Second, C. Sidgwick. Commended, J. Stott.

**HAMBURGH (Golden-pencilled).—**First, H. Pickles, jun. Second, S. Smith, Northwram, Halifax. Commended, H. Beldon. **Chickens.**—First, S. Smith. Second, H. Beldon.

**HAMBURGH ON CHITTEPRATT (Silver-pencilled).—**First, H. Pickles, jun. Second, H. Beldon. **Chickens.**—First, H. Beldon. Second, W. Baisrow, Fearn Cliffe, Bingley. Commended, H. Pickles, jun.

**HAMBURGH (Golden-spangled).—**First, W. Throup, Silsden. Second, J. W. Cannan, Bradford. Commended, H. Pickles, jun. **Chickens.**—First, J. W. Cannan. Second, W. Throup.

**HAMBURGH (Silver-spangled).—**First, H. Pickles, jun. Second, H. Beldon. **Chickens.**—First, H. Beldon. Second, J. Preston, Allerton, Bradford. Commended, H. Pickles, jun.

**HAMBURGH (Black).—**First, H. Beldon. Second, C. Sidgwick. **Chickens.**—First and Second, C. Sidgwick. Commended, H. Beldon.

**POLAND.—**First and Second, H. Beldon. **Chickens.**—First, H. Beldon. Second, P. Unsworth, Lewton, near Golborne, Lancashire.

**GAME BANTAM.—**First and Second, J. W. Cannan. **Chickens.**—First, J. D. Newsome. Second, J. W. Cannan.

**BANTAM (Any colour).—**First, E. Hutton, Pudsey. Second, J. W. Cannan. **Chickens.**—First, H. Beldon. Second, E. Hutton.

**ANY OTHER VARIETY.—**First, H. Beldon. Second, W. Culshaw, Skipton.

ton. *Chickens*.—First, E. Leech, Rochdale. Second, J. Hargreaves, Skipton.  
*GEES* (White).—First, B. Baxter, Elslack Hall. Second, P. Rhodes, Bingley. Commended, J. Tattersall, Embsay.  
*GESE* (Grey Toulouse).—First, W. E. Musson. Second, B. Baxter. Commended, E. Leech.  
*DUCKS* (Aylesbury).—First and Second, E. Leech.  
*DUCKS* (Rouen).—First, H. Beldon. Second, E. Leech.  
*DUCKS* (Any other variety).—First, E. Hutton. Second, J. Hargreaves.  
*TURKEYS*.—First, E. Leech. Second, P. Rhodes. Commended, J. B. Eeckwith, Winterburn Wood.

## PIGEONS.

*CARRIER*.—Cock.—First and Second, E. Horner, Harewood, Leeds. Commended, C. Cole, Bowling. *HEN*.—First, H. Smith, Skipton. Second, E. Horner.

*POWTER*.—Cock.—First, J. Thompson, Bingley. Second, C. Cole. *HEN*.—First, E. Horner. Second, J. Thompson. Commended, C. Cole; H. Beldon.

*TUMBLERS* (Almond).—First, J. Fielding, jun., Rochdale. Second, J. Thompson.

*OWLS*.—First and Second, J. Fielding, jun.

*EARES*.—First, J. Fielding, jun. Second, J. Thompson.

*JACOBINS*.—First, J. Hawley, Bingley. Second, E. Horner. Commended, J. Thompson.

*TUMBLERS* (Mottled).—First and Second, E. Horner.

*BALD PATES*.—First, J. Fielding, jun. Second, A. & C. Smith, Silsden.

*FANTAILS*.—First, E. Horner. Second, F. Horner, jun.

*DRAGONS*.—First and Second, J. Parker.

*ANTWERPS*.—First, E. Hutton. Second, H. Fishwick, Gargrave. Commended, J. Whittam, Carlton.

*ANY OTHER VARIETY*.—First, J. Thompson (Nuns). Second, J. Fielding, jun. Third, E. Horner. Commended, H. Beldon.

*JUDGES*.—Mr. James Heywood, Bow Lee, Middleton, Manchester; and Mr. R. Teebay, Fullwood, Preston.

## ALLERTON POULTRY SHOW.

The second annual Show of the Allerton (near Bradford) Agricultural Society took place on the 14th inst. The weather was exceedingly favourable, and the Show was well attended.

In poultry there were about 160 pens, and some of them were very good. Through an oversight on the part of exhibitors generally, the class in which the best prizes were offered—viz., Single Game Cocks, was overlooked, and there were but sufficient entries to carry off the prizes. Some very good *Spanish* were shown, and one of the best *Buff Cochins* cocks that has been seen during the present season. *Hamburgs* were very shabby in moult, but *Game* were shown in much better feather and condition. Black, with the exception of the first-prize pen, consisting of handsome birds, were not good. In chickens there were some excellent *Hamburgs*. *Game chickens* were good in quality, but wanting in feather.

Of *Ducks*, there were some very large well-matched pens of Rouen, and very diminutive Brown Call and Black East Indians divided the honours in the "other variety" class.

The cup for the best pen was awarded to an excellent pen of Golden *Polands*.

The *Pigeons* were good throughout, especially the *Powers*, *Owls*, and *Dragons*.

*SINGLE GAME COCK*.—First, J. Settle, Manningham. Second, L. Robertshaw, Allerton. Third, R. Bottomley, Shelf.

*SPANISH* (Black).—First and Second, H. Beldon, Goitstock, Bingley. Commended, J. Thresh, Bradford. *CHICKENS*.—First, J. Thresh. Second, H. Beldon.

*COCHIN-CHINA*.—First, H. Beldon. Second, W. Bentley, Green Side, Allerton. Commended, H. Beldon. *CHICKENS*.—First, C. Sidgwick. Second, H. Beldon. Commended, H. W. Illingworth, Idle.

*HAMBURGS* (Silver-pencilled).—First, H. Beldon. Second, J. Preston, Allerton. *CHICKENS*.—First, H. Beldon. Second, R. Longbottom, Bingley.

*HAMBURGS* (Golden-pheasant).—First, H. Beldon. Second, J. Preston. *CHICKENS*.—First, H. Carter, Holmfirth. Second, J. Preston.

*HAMBURGS* (Golden-pencilled).—First, H. Beldon. Second, J. Preston. *CHICKENS*.—First, F. Hollings, Horton. Second, H. Beldon.

*HAMBURGS* (Silver-pheasant).—First and Second, H. Beldon. *CHICKENS*.—First, H. Beldon. Second, J. Preston. Commended, J. Preston.

*GAME* (Black Pheasant).—First, H. Beldon. Second, C. Sidgwick, Keighley. *CHICKENS*.—First, C. Sidgwick. Second, J. Preston.

*POLAND* (Any variety).—First, H. Beldon. Second, H. Carter, Upper Thong, Holmfirth. Commended, H. Beldon. *CHICKENS*.—First, H. Beldon. Second, H. Bowker, Keighley.

*DORKING*.—First, H. Beldon. Second, B. Wilkinson, Bradford. *CHICKENS*.—First, H. Beldon. Second, C. Sidgwick.

*GAME* (Red).—First, J. Spencer, Queensbury. Second, H. Beldon. *CHICKENS*.—First, W. Bentley, Allerton. Second, G. Hargreaves, Shipley.

*GAME* (Any variety).—First, H. Snowden, Horton. Second, H. Beldon. *CHICKENS*.—First, W. Spence, Haworth. Second, W. Bentley.

*BANTAMS* (Any variety).—First, E. Hutton, Pudsey, near Leeds. Second, J. Leach, Allerton. Commended, J. Blamires, Horton. *CHICKENS*.—First, J. Blamires. Second, J. Preston.

*ANY VARIETY NOT PREVIOUSLY MENTIONED*.—First, H. Beldon. Second, W. Spence.

*DUCKS* (Rouen).—First, W. Bentley. Second, H. Beldon. Commended, T. Shackleton, Bradford; E. Leech, Rochdale; W. Bentley.

*DUCKS* (Aylesbury).—First, E. Leech. Second, J. Preston.

*DUCKS* (Any variety).—First, E. Hutton. Second, H. Beldon. Commended, W. Greetham, Allerton; W. Bentley.

*GESE* (Any variety).—First, E. Leech. Second, A. Booth, Allerton.

*PIGEONS*.—*Croppers*.—First, H. Beldon. Second, H. Snowden. *Tumblers* (Short-faced).—First, H. Beldon. Second, J. Thompson, Bingley. *Owls*.—First, S. & J. Wade, Ovenden. Second, J. Thompson. *Turbits*.—First,

S. & H. Wade. Second, H. Mitchell, Denholme. Commended, J. Booth. *Fantails*.—First and Second, R. Dodge, Sheffield. Commended, S. Dottomley, Allerton. *Barbs*.—First, A. Verr, Gillington. Second, J. Thompson. *Dragons*.—First, J. Parker. Second, J. Thompson. Commended, H. Beldon. *Carriers*.—First, R. Dodge. Second, H. Stanhope, Eccleshill. *Any Variety*.—First, R. Dodge. Second, H. Beldon.

*RABBITS* (Common).—First, J. Moor. Second, W. A. Booth.

*JUDGE*.—Mr. R. Teebay, Fullwood, Preston.

## IDLE POULTRY SHOW.

THIS took place on Saturday the 11th inst., and the weather being fine there was a large attendance of visitors. The entries for poultry were not very numerous, but some good specimens were sent by Messrs. Jowett and Illingworth, who were the principal exhibitors. The former gentleman won the extra prize, a silver medal, for the best pen in the field.

There were also some good *Pigeons* shown.

The following are the awards:—

*GAME*.—First, Second, Third, and Medal, — Jowett. *CHICKENS*.—First and Second, — Jowett. Third, — Illingworth.

*SPANISH*.—Prize, — Jowett. *CHICKENS*.—First and Third, — Johnson. Second, — Scott.

*DORKINGS*.—Prize, W. Westwood. *CHICKENS*.—Prize, W. Westwood.

*COCHINS*.—First, — Wilson. Second, — Halliday. Third, J. Ward. *CHICKENS*.—First, — Illingworth. Second, — Brotherton. Third, — Halliday.

*HAMBURGS* (Silver-spangled).—*CHICKENS*.—First and Second, — Wright. Third, — Jowett.

*HAMBURGS* (Golden-spangled).—*CHICKENS*.—First, Second, and Third, — Illingworth.

*HAMBURGS* (Silver-pencilled).—First, H. Plekles. Second, W. Sugden. *CHICKENS*.—First, — Garnet. Second, W. Sugden. Third, — Scott.

*HAMBURGS* (Golden-pencilled).—First, — Westwood. Second, — Jowett. *CHICKENS*.—Prize, — Johnson.

*BANTAMS* (Any variety).—First and Second, — Jowett. *CHICKENS*.—First, — Baxter. Second, — Watkinson. Third, — Woodhead.

*ANY OTHER VARIETY*.—First, J. Cordingley. Second, — Watkinson.

*DUCKS*.—First and Second, — Jowett. *Ducklings*.—First and Second, — Jowett.

The Judges who officiated were, Mr. Thos. Dodd, Wakefield, and Mr. R. Tate, Leeds.

## RAILWAY CHARGES.

It is impossible to give, as I promised, the statement of expenses incurred in this matter for a few weeks. I am sorry, however, to be obliged to add, that so far our efforts have been perfectly fruitless, railway directors considering that the matter does not need alteration. I do not say that this is altogether final, as I trust we may yet do something. Meanwhile, it seems absolutely necessary that exhibitions themselves should individually bring the subject before the directors, and that they should lessen the weight as much as possible by making the pens complete with a single hen instead of two.—Y. B. A. Z.

## INCUBATORS.

As the inventor and introducer of an incubator, I should like to make a few remarks in reply to "A SPANISH BREEDER" in last week's Journal, as to the success of incubators and the management of the chicks when out of the shell. That a good incubator is of very great value to a poultry-breeder none will dispute; but it is a source of great annoyance if at the end of the three weeks he cannot bring any chicks out of the shell. That artificial incubation is a real success there is no doubt; but it is a question whether with us in England it has ever been a source of much profit in a commercial point of view. An incubator never was, and I question much whether one ever can be, made that will answer as well as the natural mode of hatching. The time at which the value of a good incubator shows itself is when eggs cannot be hatched by the natural means. Incubators are invaluable when, poultry being required for exhibition, it is important that the eggs should be hatched as early in the year as possible; and perhaps no breeder would at such a time mind sacrificing 40 or 50 per cent. of the eggs if he could hatch and bring up the remainder.

I am quite willing to work my incubator against any introduced, and shall have no objection to sending "A SPANISH BREEDER" one for trial and report of success in your Journal. Incubators require very nice attention, and to be successful with them the eggs must be kept at a heat of 103° (range 98° to 105°); if lower than 98°, development is not going on; if higher than 105°, there is danger of the chicks being killed. I have not been able to determine what low temperature will perish

eggs whilst hatching; but I have found that from 110° to 112° for a short time will kill at least 75 per cent. of them.

With regard to the keeping up of the proper temperature, I may say there is little difficulty in this. I recommend gas to be used where it can be had, as a small flame the size of an ordinary candle is sufficient to keep my incubator at work, and if the flame be kept clear of the bottom of the boiler, there is no dirt attending its use. I have used gas for the last few months, and with the burner I employ have not found it necessary to touch the tap of the gas during the whole time, and my result has been most satisfactory. Oil is more trouble and expense; but if the right temperature is maintained the result is of course the same.

With regard to the strength of the chickens hatched and reared artificially, I can assure "A SPANISH BREEDER" they are equally strong and healthy as those hatched and reared naturally, and there is no reason why they should not be so; indeed, I find they thrive better and grow faster without a mother if they are locked after, well fed, and kept warm. The reason of this is obvious; they have not to wander about with the old hen, but being confined to a small space can go about and rest at will, and on wet and the colder days can be kept in the artificial mother. There is no difficulty in bringing up chickens without a hen, as some people suppose. I find it a good plan to hatch some Ducks, to come out at the same time as the chicks, and these teach them to peck, and in a week they are able to take care of and cater for themselves.—JOHN BRINDLEY.

### PRICE OF LIGURIAN BEES.

I OBSERVE that some correspondents complain that the price of these bees is high, not taking into consideration the cost of importing them from either Italy or Switzerland. I imported four hives; two only survived the journey, and the whole cost of carriage consequently fell on these hives. Some queens which I obtained from Mr. Hermann cost me nearly 40s. each. As many of these bees, however, are sold along with their hives, the price is not so much higher than that of the common black bees. In this county (Durham), they ask from 35s. to 40s. for a common skep hive of black bees, and from 25s. to 30s. for a swarm.

I am glad to find that "A DEVONSHIRE BEE-KEEPER" has the Egyptian bees, and hope he will be successful with them.—J. H. A.

### THE EGYPTIAN BEE.—PART IV.

HOW I OBTAINED AND INTRODUCED IT INTO MY APIARY.

(Continued from page 115.)

As soon as I had ascertained the fact that the Egyptian bee had actually reached Germany, I lost no time in putting myself in communication with Herr Vogel, to whom the Berlin Acclimatisation Society had deputed the task of multiplying and disseminating these interesting strangers, and in due course received the following two letters from him, the first being dated the 2nd July, 1865:—

"MR. WOODBURY,—I am very much honoured by the charge given me of sending you a fertile aegyptian queen bee.

"It may be permitted to me to inform you previously that I will despatch a very fine queen bee with its necessary companions on the 15th of July.

"The transport will be the happiest if the queen bee has only few companions. Therefore, having received this letter, I propose to you depriving a few populous bee-hive of its mother bee, and destroying after nine days all mother-cells. This bee-hive resting, deprived of its mother bee, you may make use of it to strengthen the new comers.

"You wish being informed if the aegyptian bee (*Apis fasciata*) coupled itself with the northern and Italian! *Apis fasciata* is a constant stereotype variety of *Apis mellifica*. Its temper is very lively, and its voice higher than that of *Apis mellifica*. Therefore the virgin queen bees of the aegyptian race flying out choose regularly aegyptian males. It will be also easier to keep this race genuine than the Italian bee (*Apis ligustica*).—Your affectionate, addicted bee-friend—F. W. VOGEL."

The second letter was dated the 15th July, but did not reach me until the 28th, and an examination of the Prussian post-mark showed that it was not posted in Germany until the 25th. It heralded the approach of an Egyptian queen in the following terms:—

"MR. WOODBURY!—You receive adjoined a fertile aegyptian

mother bee. The aegyptian are covered with fair hair, and have a yellowish shield on the breast-plate.

"Is winter coming on, I advise to put the aegyptian bee-hive into a quite dark room where they cannot freeze to death; in such room the bee-races winter generally the best.

"If the queen bee arrives dead, against all my expectations, it may be permitted to me to send you another which is not to be paid.—Your affectionate, devoted bee-friend—F. W. VOGEL."

The result of this correspondence was, that on the 30th of July I received a somewhat weighty deal box, 12 inches long by 9½ wide, and 8½ inches deep, which, in addition to my address, was ornamented with sundry printed labels, one of which declared it to be "aus Zechin," and another "par Ostende." There was also in one corner a rough pen-and-ink sketch of a drinking-glass, meant, I suppose, to convey the intimation to railway porters and all whom it might concern, that the contents of the box were of a like brittle character, and under this cartoon, for the edification of German as well as of English readers, appeared in three lines, thus—

"MIT SORGFALT!

"WITH CARES!

"ÆGYPTIAN BEE!"

The two first lines being likewise repeated on the three remaining sides of the rather large label which concealed fully two-thirds of the box cover.

On applying my ear to the wire cloth which covered an aperture for ventilation, I was somewhat concerned at finding all within as still as death, nor could I by tapping the sides of the box elicit the slightest response from the little prisoners, whose answering hum is usually so prompt and ready under such circumstances. It was therefore with no little trepidation and misgiving that I sought for tools and set to work to prise off the well-secured cover, which, like the box itself, was made of wood nearly an inch in thickness, the latter being dovetailed together, and of such strength as might well have fitted it for the conveyance of bullion from the Antipodes, instead of merely the safe custody of a few hundred bees. On raising the lid a small cluster adhered to it, having apparently removed themselves as far as possible from a large square piece of dark-coloured honeycomb, out of all proportion to their wants, a portion of the contents of which having escaped had so clogged and soiled the unfortunate little prisoners, that few indeed were able to use their wings. On separating and carefully examining this cluster, I found it to consist of worker bees so similar to Ligurians that I could not at that time detect the slightest difference, two or three small but very handsome drones, the whole being in a sad plight, and what seemed to me to be a diminutive Ligurian queen in nearly as bad a case as the rest. This certainly appeared extremely small change for my outlay, and it was with no very pleasant feelings or agreeable anticipations that I proceeded to make the necessary attempt at placing my forlorn Semiramis at the head of a small lot of Italians, which having themselves failed in the attempt to raise a queen, appeared more likely than any others to tender their allegiance to an alien monarch. I, of course, took the precaution of presenting to them this aspirant to the vacant throne in a queen-cage, through the bars of which her future subjects were at liberty to make her acquaintance, and well was it that I did so, for dire was the onslaught made upon her bedraggled attendants which I added to the Ligurians at the same time. "Italian Unity!" or whatever may be its apian equivalent, was at once vociferously buzzed forth, and perseveringly and relentlessly reiterated, as one by one the unhappy Egyptians were dragged out, until their expulsion was at last as absolutely complete as that of their fellow-Africans, the Moors, from Spain by the warlike Ferdinand and Isabella of Castile.

This was in truth an unpromising commencement, but I could do nothing to calm the strife which continued nearly until the sun went down, and it was with gloomy forebodings that I witnessed the massacre—contest it could not be called—and beheld the ground in front of the hive strewn with dead and dying bees. Still I hoped that the animosity of the vindictive Italians might be satiated with the slaughter of her worker attendants, and that they might yet tender their allegiance to the captive Semiramis, whose dynasty might by their means be perpetuated in Great Britain: nor were my favourable anticipations entirely vain. On examining the interior of the hive the next morning, I found the hostile demonstrations of the fiery Italians so far moderated and subdued as to induce

me to set the imprisoned monarch at liberty. Remaining unmolested, and being followed only by admiring and caressing antennae in this her first royal progress in her new domain, I was encouraged to hope for the best, and successive examinations during the same and following days proving to my satisfaction that she indeed reigned in the affections of her alien though adopted children, I set myself by the careful selection and gradual addition of ripe brood-combs, so to increase the population of the hive as to admit of the propagation of *Apis fasciata* before the season, already so far advanced as to make success improbable, should be so far passed away as to render it entirely hopeless.—A DEVONSHIRE BEE-KEEPER.

(To be continued.)

TAKING HONEY FROM SIDE BOXES AND SUPERS.

On the 11th of this month it appeared to me that the bees in a Nutt's hive were abstracting the honey out of a side box, which never had been quite filled, though the comb was quite finished. I took it, and found no honey in it; none has been taken from it this year. The stock has thrown out one if not two swarms (possibly even three), in spite of all precautions. How am I to know when to take the side boxes in future? When should I have taken this? I have two or three stocks in straw hives which must be taken. They are reasonably heavy, but the bees are still busy bringing in pollen. Of what is this a proof? Ought I to leave the stock as long as the bees seem to work, or, honey being my object, ought I to take them at once?—HAMPSHIRE RECTOR.

[It is very probable that the bees commenced breaking in upon the contents of the side box when the first swarm issued, and that they have been diminishing ever since. We can, however, lay down no positive rule as to the proper time for taking either side boxes or supers. Of course, when once completely filled they are best removed as soon as possible; but you must endeavour to form your own opinion as to the time at which the weight of a partially-filled box reaches its probable maximum, when it should at once be appropriated. Bees bringing in pollen freely is a sign of prosperity and of the existence of brood, but it does not show that the store of honey is increasing. Weigh your stocks towards autumn, and take them when they reach the culminating point. We find that the honey harvest is over in our locality whenever the fine weather breaks up in July.]

B. & W.'s APIARY IN 1866.

In a communication to "our Journal" in January last I mentioned that I had received in the autumn a young Italian queen from my friend Mr. Woodbury, who had suspicions, as well as myself, that I had hitherto been unfortunate in possessing only a hybrid queen of that race. With much care, but little difficulty, after uniting the populations of two stocks and destroying their queens, the young stranger was successfully introduced to the united bees, and located in my bee-house in place of A. By careful feeding this united stock survived the winter in good health; but the queen not breeding till late in the spring, the population, which had been large, became so reduced in number that I despaired, even so late as April, of its recovery. However, the queen proved to be all I could desire, and not only filled the box (one of the largest in my apiary), which was only one-third full of comb when the queen was put into it in autumn, but the bees also worked in a super, giving me about 6 lbs. of pure honeycomb.

Being absent from home during July, and this stock (A), being too backward to operate upon before, it was left to its own devices till the 3rd of August, when the queen and entire population were driven and shifted into D's box, whose queen and population had been previously driven into an empty hive.

A's box was subsequently given to the bees of D after the destruction of their queen, the bees of both hives remaining in their former places, but having exchanged hives. I have some doubts, however, whether the bees in D will manage to rear a queen, as there was no brood apparently in the hive, except such as was quite recently hatched. I shall be quite content if I can rear one queen to head this stock this autumn. Mr. Woodbury will be glad to learn that the bees are beautifully marked, and the queen a first-rate breeder. Another

year, if all is well, I shall hope to multiply my Italian stock from her brood more largely.

It is time I should give some account of this year's proceedings in my apiary, so I will make a beginning by stating how many stocks survived the winter. This will be seen by the following schedule of stock hives, corrected from page 81 in your former volume. It represents the condition of my apiary in April last:—

It will thus be seen that I began the year with twelve stocks. I have to add that I discovered I was in error in stating that the queen of F had become degenerate. Most of the bees have been fairly-marked Italians. I am still puzzled to account for the bees in P in the fowl-house, having degenerated, as I remarked at page 80, last volume. No doubt, however, the queen must have died in the course of the summer. I am the more inclined to believe this, as the actual queen of that stock has not proved a good breeder this year, as her predecessor had shown herself to be last year.—B. & W.

(To be continued.)

HOG CHOLERA—COAL FOR CURE.

A WESTERN farmer is convinced that bituminous coal is a preventive of hog cholera. He has four hogs that will average 300 lbs. live weight each, and now about seven months old; some three months since he began to feed them daily with coal, and, to determine the amount consumed, weighed it. For the first twenty days they consumed 1½ lb. each; during the past month he has resumed weighing again, and finds that they eat 2 lbs. each. He thinks this daily feeding keeps them in a more healthy condition. They have no desire to root like other hogs, as this coal supplies what they would get from the soil. He also contends that the cutting of the snouts to prevent rooting is barbarous—positive destruction of the health of the porker. The hog does not root simply for the fun of it, but to supply a want, and as coal answers the purpose, he ceases to root, and lies down in lazy quiet. When the coal has been omitted for two or three weeks the propensity to root returns.—(Boston Cultivator)

OUR LETTER BOX.

COST OF REARING DUCKS AND CHICKENS FOR TABLE (T. H. F.).—At what age do you consider your Ducks and chickens fit for table? In the London markets some are sold very young. They generally realise the best prices because they are earliest in the season. We must also ask at what time of year you want them reared? It is worth twice as much to rear in the winter as the spring. In the summer you should give 6d. per month per head, and you must contribute part of the food. We are assuming that the fowls are reared by cottagers, where, being no farm-yard, there is no run or scratch where food may be found. Geese are easily reared where there is a common, and cost little more than chickens. Turkeys are troublesome, and you would have to pay 1s. per month. The feathers will almost pay for plucking. Ordinary prices are 1d. per head for fowls and Ducks, 4d. for Geese and Turkeys without feathers. These are for practised hands.

UNITING SWARMS (C. L.).—We should prefer driving the bees in the first place into an empty hive, and uniting them afterwards in the manner recommended in page 59 of the fifth edition of "Bee-keeping for the Many." The use of a little smoke, and sprinkling both swarms of bees with peppermint-scented syrup at the time of uniting them, may also be advisable.

WEEKLY CALENDAR.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 71.4°; and its night temperature 47.9°. The greatest heat was 85°, on the 1st, 1843; and the lowest cold 32°, on the 29th, 1850. The greatest fall of rain was 1.50 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

ZONALE AND NOSEGAY PELARGONIUMS.

THE articles which have recently appeared in the Journal on "Zonale and Nosegay Pelargoniums" I have read with interest, and while agreeing generally with the views of the respective writers, it has struck me that there is yet a great deal left unsaid which might be said of these beautiful plants.

With regard to the Pelargonium, I confess myself a disciple of the late Mr. Beaton: the mere florist's view would never have made me a cultivator; it is as a decorative plant that I look at and value it. I would as soon buy a horse from the shape of its head alone as a Pelargonium from the shape of its flower: as the one might have a head of perfect shape, and be a thorough "screw;" so the other might have a most symmetrical flower, and be utterly worthless for decorative purposes.

The seedling Nosegay and Zonale Pelargoniums of the last three years have been so numerous and so varied that we now look in vain for any plant that even rivals them for decorative purposes, either in or out of doors. With all deference I submit that the old and familiar term "Scarlet Geranium" should now be dropped; for, however much we may love things and names that are old and familiar, it would be rather "Irish" to speak of a "white scarlet," a "pink scarlet," or a "purple scarlet" Geranium. Well, thanks to the industry, perseverance, and skill of the late Mr. Beaton and other cultivators, we have not only these colours but numerous intermediate shades—bicolors, tricolors, &c., and promises of even greater variations in the future. The aspect of the numerous recent seedlings is indeed so diverse that a new arrangement must be made at no distant date to enable those who have to deal with them to understand each other. In the matter of leaves, there are the plain-leaved, the zone-leaved, the variegated-leaved, with their numerous shades and combinations of silver, gold, black, and crimson; as to the truss, there are the true zonale and the nosegay; and as to the habit, there are the ordinary, the dwarf, and the giant.

Leaving this aspect of the question thus briefly dwelt on, because it appears to me that the time for a satisfactory generalisation has hardly yet arrived—assuming that we had better delay this work till the new paths recently opened are pushed a little further into the unknown beyond—I shall confine myself in the present paper to two broad and distinct lines of thought—1, Nosegay and Hybrid Nosegay Pelargoniums; 2, Zonale Pelargoniums.

1, The "Nosegay" and "Hybrid Nosegay" Pelargoniums are in my view pre-eminent for bedding purposes and for general out-of-door decoration, because they flower

so continuously and for such a lengthened period. I have one truss of Sir J. Paxton, bright orange, now before me 15 inches in circumference, and another of St. George, chestnut, shaded with black, with 120 flowers on it! While Verbenas and Calceolarias are beautiful now and then, these Pelargoniums are always in condition. Perhaps it required a wet and windy August, such as we have just experienced, to demonstrate this. There are here nearly three hundred varieties of Zonale and other Pelargoniums gathered from all parts of England and abroad, and planted out side by side in order to test their powers of battling with sun, wind, and rain, and never was the pre-eminence of the "Nosegays" for out-of-door work more clearly established. Even the seedlings, of which there are several thousands, "Zonales," "Hybrid Nosegays," and "Nosegays," the latter furnish fresh evidence in favour of that conclusion. Your Dr. Lindleys, Beauté de Suresnes, Floras, Madame Barrés, and others, beautiful as they are viewed from the point of form and under glass, will not stand comparison out of doors with the Amy Hoggs, the Salmon, Peach, and Orange Nosegays, the St. Georges, and Stellas. Fine drawing-room and conservatory gentlemen are the former, but hardly suited for the rough-and-ready work of out-of-door life: hence when I see the florist judging a Pelargonium, whose chief value is for decorative purposes out of doors, by a truss or a single flower, and condemning it *in toto* because the flower does not realise his idea of form, I set him down as a man of "one idea," and wish I could induce him to look without prejudice on the glorious masses of Nosegays and Hybrid Nosegays of all hues on which I am now looking, and which gladden me while I write. It does not, in my judgment, require much foresight to predict that these Pelargoniums have a glorious career before them. Fashion, which has been against them, is fast coming round, and this once established, "interests" and "prejudice" must change or stand aside.

Of the Nosegay and Hybrid Nosegay Pelargoniums which I have seen, I believe the following to be the best:—*Alexandra*.—Bluish purple; large flower; dwarf and compact; free-flowering; leaves slightly zonate. Distinct, and very beautiful.

*Amy Hogg*.—Purplish rose; trusses large and abundant, standing well above the foliage; leaves slightly zonate.

*Archbishop*.—Rich scarlet crimson; large compact truss; petals large and broad; leaves zonate, of a beautiful pale green. Habit good.

*Banneret*.—Crimson scarlet and purple; beautifully shaded; trusses abundant; leaves plain.

*Bicolor*.—Bluish rose, orange blotch in upper petals, quite new in colours; leaves plain.

*Crimson Queen*.—Intense crimson, the darkest of Nosegays; trusses abundant; leaves zonate.

*Cybister*.—Very bright orange scarlet; trusses large and plentiful; leaves zonate.

*Duchess of Sutherland*.—Cerulean scarlet; trusses very large and numerous; leaves slightly zonate.

*Dr. Hogg*.—Deep rosy pink, much darker in colour and broader in the petal than Amy Hogg; truss fair size and abundant, very bright and beautiful; leaves zonate.

*Enchantress*.—Purple and crimson shaded, scarlet blotch on upper petals, very smooth and glowing; trusses plentiful, and thrown well above the foliage; habit fine; leaves plain.

*Fairy Queen*.—Rosy red; trusses fair size, and abundant; flowers large and smooth; leaves slightly zonate.

*Glory of Waltham*.—Intense scarlet, trusses large and compact, resting immediately on the top of the foliage; leaves plain, pale green. The finest of Nosegay Pelargoniums.

*Indian Yellow*.—Orange scarlet, with a strong glow of yellow; trusses fair size, and very abundant; leaves darkly zonate.

*Le Grand*.—Crimson scarlet, shaded with purple; of large size and great substance.

*Lilacium*.—Lilac; trusses large and compact, and rising well above the foliage; leaves plain; habit dwarf and close.

*Madame Barré*.—Bright rosy pink, white eye; leaves plain.

*Naiad*.—Purple, crimson blotch; leaves plain. Very distinct and beautiful.

*Orange Nosegay*.—Bright orange; trusses fair size, and very abundant; leaves plain. Very effective.

*Purple Queen*.—Reddish purple; trusses very abundant; leaves slightly zonate; habit very dwarf. Suited for edgings.

*Saint George*.—Chestnut, shaded with blackish scarlet; trusses very large and compact; flower-stalks stiff, and rising nicely above the foliage; leaves plain. One of the best.

*Salmon Nosegay*.—Salmon; trusses and flowers large, smooth, and abundant; leaves plain. One of the best and most effective.

*Stella*.—Bright crimson; trusses large and abundant; leaves zonate.

*Sir Joseph Paxton*.—Bright orange; trusses large and abundant; leaves zonate. Very effective.

*Village Maid*.—Bright deep pink, with a large white blotch on upper petals, the colours clearly defined, not running into each other; habit dwarf and compact; leaves darkly zonate. Very beautiful.

*Waltham Nosegay*.—Carmine and scarlet shaded; trusses and flowers large, smooth, and compact, rising well above the foliage; leaves plain; habit first-rate. One of the most effective.

*Waltham Seedling*.—Dark crimson; trusses large and abundant; leaves zonate. Very effective.

*Wood Nymph*.—Pale reddish pink; leaves pale green, slightly zonate. Distinct and pleasing.

2. I now come to speak of the "Zonales," which are generally best under glass; and although the Noseguys are alike beautiful, and sometimes more beautiful under glass, we cannot say that the Zonales as a rule are equally beautiful in the open ground. These Zonales, like the Noseguys and their allies, possess one great advantage over the fancy, French, and other Pelargoniums, which it will be well to bear in mind—namely, that they may be had in bloom at any season, or, indeed, all the year round, if kept under glass; whereas the others are only a month, or at most six weeks, in condition. And here I am glad to find that I am in unison with the "one-idea" men. I acknowledge form as one important and desirable quality, and only object to it when it is used to ignore other qualities equally, and for special purposes more, important than itself.

Of varieties best suited for decoration under glass, the following are the best according to my judgment:—

*Beauté de Suresne*.—Deep rosy pink, white eye; trusses large; form fine; leaves zonate.

*Blue Bell*.—Very soft, bluish lilac; colour new, and lovely; truss large; form fine; leaves zonate.

*Bride*.—White, with large crimson eye; of fine shape, and great substance; leaves zonate. One of the best of the light-coloured varieties for out of doors.

*Cardinal*.—Full scarlet; truss large; form fine; leaves plain.

*Charles Rouillard*.—White, shaded with salmon; flowers good shape; truss compact; leaves darkly zonate. Good out of doors.

*Cipper*.—Scarlet; flowers very large; form fine; habit good; leaves zonate. One of the best.

*Dame Blanche*.—White, slightly tinged with pink; leaves darkly zonate. Very pretty and distinct.

*Dr. Lindley*.—Scarlet; truss and form fine; habit good. One of the best for in-doors, forming a beautiful round-headed standard.

*Duchess*.—Reddish cerise; truss very large and fine; habit close and compact; leaves slightly zonate. One of the best.

*Firefly*.—Scarlet, shaded with blackish crimson; trusses fair

size, and abundant; habit good; leaves zonate. Good also out of doors.

*Governor*.—Scarlet; flowers large; good shape and truss; leaves plain.

*Lord Chancellor*.—Reddish salmon; trusses good size, very abundant; leaves darkly zonate, contrasting well with the flowers. Quite first-rate, both in and out of doors.

*Lucius*.—Yellowish orange; flowers large, splendid truss; leaves zonate. One of the best.

*Ma Gloire*.—White, centre red; leaves darkly zonate.

*Madame Werte*.—Flowers white, centre red, colours clearly defined; flowers large; good shape; leaves zonate.

*Madeline*.—Salmon red; flowers large; leaves darkly zonate.

*Merrimac*.—Rosy salmon; leaves zonate. Good either in or out of doors.

*Model*.—Deep orange scarlet; perfect shape; trusses fair size; leaves plain. The finest of all orange scarlets.

*Mr. G. Natchet*.—Light scarlet; leaves darkly zonate. One of the best.

*Mrs. Wm. Paul*.—Soft rosy peach; flowers very large; form fine; habit dwarf and compact; leaves slightly zonate. One of the best.

*Ninrod*.—Orange; fine form; truss large and fine; leaves zonate. One of the best for either in or out of doors.

*Nora*.—Salmon rose; flowers large; good shape; leaves zonate.

*Princess Lichtenstein*.—Salmon pink; perfect shape; good both in and out of doors; leaves darkly zonate.

*Rebecca*.—Cherry colour; fine form and habit; blooms abundantly. One of the best for either in or out of doors.

*Striking*.—Salmon shaded with orange; flowers large and of good form; leaves darkly zonate.

*Virgo Marie*.—Pure white; flowers good shape, the best of the whites; leaves zonate.

Of the double-flowering kinds, I have found *Ranunculiflora plenissima* and *Gloire de Nancy* the best, but cannot recommend either for out of doors.

I have purposely avoided entering on the cultivation of this plant, as it is so simple and so generally understood, that I feared trespassing needlessly on your valuable space. I may just remark, however, that a light soil, not too rich, appears to me the most suitable, and when grown in pots the plants should have plenty of pot room.—WILLIAM PAUL, *Paul's Nurseries, Waltham Cross, N.*

#### COCOA-NUT FIBRE REFUSE.

OUR late lamented friend Mr. Beaton, when he brought the various uses to which the cocoa-nut fibre refuse could be successfully applied into public notice, conferred a great boon on the lovers of floriculture and horticulture, and no doubt at the same time was the means of placing a good round sum to the credit of the Patent Cocoa-nut Fibre Company; for that which was fast becoming a nuisance to them was made a fruitful source of income by his so strongly recommending its application for the various purposes of plant and fruit-growing. Many readers of the Journal can remember with gratitude the good effects it brought about in connection with plant-growing. Now that we have lost him, it is pleasant sometimes to refer back through the long files of Journals that have since been published. Those who had the pleasure of knowing him personally can almost fancy he is present with them whilst they are perusing his practical articles, which are written so clearly that those who run may read; and amongst the numerous suggestions conceived by his fertile brain even the most learned of the present day may find assistance, which will help to unravel many a knotty subject, and relieve and help them out of many difficulties which may beset them.

It will be remembered that Mr. Beaton strongly recommended the use of the cocoa-nut refuse for plunging plants in. I have used it with great success for Pine-growing this season. It is much superior to spent bark for plunging Pines in, for the following reasons:—

1st, It does not breed any fungus.

2nd, Where there are sufficient pipes for bottom heat it will always retain a regular and uniform temperature about the roots of the plants. This is a most important point. One of the greatest evils the Pine-grower has to contend with in using tan for his plunging material is the sudden check to which the plants are subjected when the beds are renewed. The roots have perhaps for some time been growing in a tem-

perature of 80°; when the bed is renewed the temperature will be perhaps as low as 65° for a week or ten days, then all at once there is a rapid rise, and it frequently happens that the roots are subjected to a scorching temperature of 95° or more. These sudden changes must be very injurious to the growth of the plant, and are often the cause of its fruiting prematurely.

Another valuable property which the cocoa-nut refuse possesses is its durability. Plants may be potted into their fruiting pots, and there will be no necessity for removing them again till after the fruit has been cut. This saves the leaves from being broken, and preserves the plant from many dangers to which it is often subjected by removal, especially where proper care is not taken in performing the operation. My Pine-pits were prepared as follows: After the hot-water pipes were fixed some clay was put in layers 6 inches thick, each layer being carefully rammed down. The whole of the space below the pipes was filled up in this way; then 1 foot of broken bricks, stones, &c., was put in around and above the pipes. In putting in this brick rubbish care was taken to place it so that the heat from the pipes might be regularly distributed over the bottom of the bed. The refuse was then sifted, and the fibre was placed over the drainage to prevent the finer refuse from trickling through; 2½ feet of the refuse was put in, and the plants nicely plunged. They are now full of health and beauty, and have the appearance of enjoying themselves to the fullest extent.

As the refuse will last several years, it will in the end be found cheaper than tan, even to those who like myself had to send to London for it, for there is in the first instance a great saving of labour, and it often happens that the spent bark has to be brought from a long distance, in which case the cartage amounts to a considerable item. Then, again, the plants look so neat and comfortable, and there is not that rough unsightly appearance which is produced by the tan.

The following quantities of piping should be placed in the bottom of the pits for bottom heat, as no heat is generated by the refuse itself. For a pit 5 feet wide, two four-inch pipes, and for a pit 10 or 12 feet wide four pipes should be used. These should be placed at equal distances over the bottom. If the pit is 12 feet wide let the pipes be put 3 feet apart, and instead of having two flows and two returns, let there be only one flow and one return, this will cause the heat to be more evenly distributed.

The prices of the cocoa-nut refuse delivered at any of the railway stations or booking-offices in London, bags included, are as follows:—Ten bags for 14s.; twenty for 27s.; thirty for 40s.; forty for 50s.; fifty for 60s.; sixty for 70s., and so on. The larger the quantity taken, the lower the price in proportion. I received sixty bags, the railway charge was about £3 10s., so that I obtained for about £6 10s. nearly three tons of the refuse, enough to fill three large pits, several frames, and for plunging plants in, besides a reserve for mixing with soil for plant-growing, &c. I have been particular in naming quantities, price, &c., so that any one wishing to try it for the purpose of Pine-growing, may know the quantity to apply for.—J. WILLS.

#### THE ROSES OF 1866.

As a natural sequence to my notes on the Roses of 1865 I wish to say a few words on those of the present year, but before doing so must allude to a "mull" made in my former paper. The description of Dr. Andry should have followed immediately on that of Duc de Wellington, and then the paper would have read correctly. As it is, there is a discrepancy between the statement in a former paragraph, that I considered Dr. Andry a first-class Rose, and this arrangement, which makes it a second-class one. With regard to the Roses of the present season, I do not think that one is as yet capable of speaking very decidedly on them all. Some have unmistakably held good their claim on the attention and kind offices of all rosarians; others have as unmistakably proved their worthlessness, and of these few only would I speak in very decided terms. I had the opportunity last season of seeing some of them abroad, and gave my judgment then—a judgment which I am glad to say has been confirmed by Rose-growers at home and abroad. Others I spoke well of on the strength of the raiser's character; but here I have been disappointed, so that there is no infallible rule.

For these reasons it will be obvious that I cannot give so complete a *résumé* as of those of 1865, and must claim for

myself the privilege of altering my opinion when the blooming season next year shall have given me a greater opportunity of seeing them.

*Alba Mutabilis* (Eugène Verdier).—A very pleasing tender tint of rose, changing to a deeper colour when expanded. I am inclined to think this will be a useful Rose.

*Alfred Colomb* (Lacharme).—A magnificent high-coloured flower, very full and well formed, certainly *AI*.

*Exposition de Brie* (Granger).—I have seen this very fine, and it is likely to be among the first, or, if not, at the top of the second class.

*Mademoiselle Marguerite Dombrain* (Eugène Verdier).—Another first-class Rose, large, globular, lively colour, and distinct. How Mr. Heale could have said it was too like *La Reine* I know not. In colour it is intermediate between it and *Comte de Nanteuil*.

*Prince de Porcia* (Eugène Verdier).—A very beautiful flower. I saw it at Mr. Fraser's, and it was certainly very fine.

*Frédéric Biboret* (Damaizin).—I have only seen this once, but it was then very beautiful and well shaped.

*Hippolyte Flandrin* (Damaizin).—A beautiful flower, exquisite in shape, and lively in colour. I think this will be a first-class Rose if its constitution is good.

*Jean Cherpin* (Liabaud).—I have seen this in one or two places, and in very beautiful condition; the colour very brilliant, and the flowers large, but not coarse.

*Joséphine de Beauharnais* (Guillot fils).—Unquestionably a good Rose. I should say decidedly *AI*, were I quite sure that it is sufficiently distinct from its parent *Louise Peyronny*. I think it is, but wait for further acquaintance with it.

*Madame Fillon* (Gonod).—I saw this at Lyons very pretty, but have not to the best of my recollection seen it here.

*Gloire de Ducher* (Ducher).—Not a flower that will be a favourite one here; its colour is against it.

*Pine* (Guillot fils).—A coarse flower, rough in outline, and not distinct in colour. Will be discarded.

*Prudence Besson* (Lacharme).—A huge flaunting flower, far more like a *Paeony* than a *Rose*, with immense petals of a bright rosy pink colour, but so few in number that the flower is worthless.

*Souvenir de Dr. Jamain* (Lacharme).—This has the very opposite fault to the preceding one—it is too small. The colour is admirable, but it will never make a show Rose.

*President Mas* (Guillot fils).—A coarse flower, and somewhat dingy in colour, not unlike *Boula de Nanteuil*, but not so good.

In addition to these I have heard Fisher Holmes and Jean Lambert highly spoken of; but at present my judgment goes thus far—*Alfred Colomb*, *Marguerite Dombrain*, and *Hippolyte Flandrin* are first-class Roses; *Alba Mutabilis*, *Exposition de Brie*, *Prince de Porcia*, *Frédéric Biboret*, *Joséphine de Beauharnais*, and *Jean Cherpin* come next, and some of them have a good chance of getting promotion; while there are some others whose fate, as far as my opinion goes, is as yet undecided.—D., *Deal*.

#### AMONG THE SCOTTISH BRAES, LOCHS, AND MOUNTAINS.—No 3.

DUNOON CASTLE crowns the summit of a grass-clad conical hill, still justifying its Gaelic designation, compounded of *Dun*, an eminence, and *ainc*, green. Small are the fragments of the castle now remaining, and as I rested upon them the thought recurred which had often arisen before when visiting similar ruins of similar residences of the olden times—how effectually they forbade a dependance upon vegetables for sustenance. At first, this may seem a trivial reflection—but if the reflection be pursued it explains and illustrates some of the manners of the feudal ages. The animal diet—the flesh and fish constituting the prominent dishes of every meal—were forced upon the residents of such fortified dwellings. They dared not depend upon provisions to be grown without the walls, and to have included a sufficient space within the walls would have rendered these far too extended for defence by the lord's ordinary retainers—and to increase the garrison would be to increase the difficulty of provisioning it. Corn and preserved meats sufficient for many months could be stored in a castle's vaults, hence those foods of necessity were adopted as the prevailing diet. It would have been inconvenient and risking additional privation to foster a taste for food so liable

to be cut off as that produced by a garden, and hence gardening was among the neglected arts of the feudal ages—the ages of perpetually recurring wars—not merely the wars of nation against nation, but of baron against baron. Dunoon had its full share of these internecine broils. In 1333 John Balliol drove from it its rightful lords—the Lamonts; and his garrison, in its turn, was soon massacred by the aid of Colin Campbell, of Lochawe, founder of the Argyll family, but this stronghold was not restored to the Lamonts. In due course, the Earl of Argyll, two centuries later, was expelled from it by the Earl of Lennox. However, it was restored to the Argylls, and their atrocious hatred of the Lamonts culminated in 1646. They waged a war of extermination against the Lamonts, and nearly two hundred of them, their followers, and their children, are known to have been massacred. The Lamonts who held the strongholds of Toward and Escay, near Dunoon, were captured and brought hither, and thirty-six gentlemen of the clan were hung upon one tree. The Marquis of Argyll was indicted for the crime, and there is scarcely ground for doubting that he was cognizant of the intended slaughter. Some of the concluding sentences of this head of the indictment are as follows:—

“The Lord from Heaven did declare his wrath against the same by striking the tree whereon the said Lamonts were hanged in the month of June; it being a level fresh-growing Ash-tree at the kirk-yard of Dunoon, among many other free-growing trees with leaves. The Lord struck the tree immediately thereafter, so the whole leaves fell from it, and the tree withered.”

It is recorded that the Argylls never afterwards inhabited the castle, and it gradually was deserted and allowed to become a ruin.\*

I could linger over other passages in this castle's history, and could detail some of the doings of Mary Queen of Scots when, in 1563, visiting here her sister, Lady Jane Stewart; but I pass on, cross the mountain at the back of Bullwood—rich in bog plants, follow the mountain stream, the banks of which are clothed with many Ferns, ramble on to Sandbank, where, for a time, Sir William Hooker resided while Professor at Glasgow University, and, homing by the shore of the East Bay, will now jot down a few notes about the plants found in this vicinity.

The neighbouring sea and the comparatively small elevation of the mountains here banish from them the rarer alpine plants which are found within a few miles on the more inland and loftier mountains, yet there are some plants of not common occurrence. The Bitter Cress (*Cardamine impatiens*), is found in the neighbouring glens; Scurvy Grass (*Cochlearia officinalis*), on the beach; that gem of native plants, the Sundew (*Drosera anglica*), in the bogs of the mountains; the Horned Poppy (*Glaucium luteum*), on the higher portion of the beach between the West Bay and Toward Point; and in the same locality grows the Oyster Plant (*Mertensia maritima*), deriving its popular name from the flavour of its leaves when eaten whilst fresh.

In the boggy localities is also found the Sweet Gale or Bog Myrtle (*Myrica gale*), distinguishable even by the non-botanical by the spicy fragrance of its leaves when bruised. This and the elasticity of its spray cause it to be selected for many a highland bed. It abounds in districts once exclusively peopled by the Campbells, and hence it was adopted as the badge of their clan.

On the drier soils, resting on the rock, are several of the Orchidaceæ—the Early Purple (*Orchis mascula*), the Spotted (*Orchis maculata*), the Butterfly (*Habenaria bifolia*); and in the boggy places may be detected the Marsh Orchis (*Malaxis paludosa*).

In the boggy localities, also, is found the Portuguese Butterwort (*Pinguicula lusitanica*), so called because first discovered in Portugal, but since found native in places on our western coasts, though not, I believe, either on our eastern coasts or inland.

The Yellow Mountain Saxifrage (*Saxifraga aizoides*), is found here; and the Great Bilberry (*Vaccinium uliginosum*), the large fruit of which is eatable, and its leaves mingled with the Alpine Club Moss are used for dying woollens yellow by the Icelanders. Lastly, I may mention that all of the Grasses the

Sea Wrack (*Zostera marina*), used for stuffing the skins of birds in the Hebrides and Orkneys. It is not uncommon near the shore here.—G.

## THE CONIFERS AT WOODLANDS, REDHILL, SURREY.

THERE are two chief points in connection with the Coniferous tribe that are obviously distinct, but not necessarily antagonistic. These are, utility in an economic sense, and the various appliances of their timber, fruit, secretions, and, in a horticultural sense, their ornamental qualities and effective appearance in the landscape, whether singly or in groups. Of the first it is not my object to take especial cognizance further than to remark, that excepting in the case of a few well-known kinds, a correct appreciation of the real value of the timber furnished by many of them is as yet confined to comparatively few, and that many years must elapse before the valuable timber of some of the Conifers, now rarely planted for any other purpose than for improving the appearance of parks and kept grounds, or, as we should say, for specimens, will be brought into more general use.

This is at present naturally the case. Commercially speaking, it would not answer to send for timber many thousands of miles away, where labour is also scarce, even if it were known to be superior, when a substitute could be obtained at a comparatively trifling cost although inferior in quality. There are two well-known instances of this, the Douglas Fir (*Abies Douglasii*), and the Himalayan Cedar (*Cedrus deodara*). The durability of the latter under certain circumstances is shown by unimpeachable testimony, and important applications of the latter have been the subject of frequent remark, and it is not many years since some interesting and conclusive experiments by Mr. Wilson Saunders, showed the comparative strength of these and other woods to surpass those hitherto in general use. Both species have been in England several years; they are found to adapt themselves to the climate and soil perfectly; and both have begun to produce seed annually, but whether of sufficient maturity to produce seedling plants has not yet come to my knowledge. Evidence on this point would be useful. In the case of the Douglas Fir it is certainly much to be hoped that the seed may germinate, as the enormous distance and the situation of its native home (North California, British Columbia, and the north-west of North America generally, now in the course of being colonised), must offer almost insurmountable obstacles to its importation in quantity. There is no reason, then, why the Douglas Fir and Deodar should not be extensively planted in this country, and good service is being rendered by several of our most eminent nurserymen in raising large quantities of both from imported seed.

In their relation to horticulture, the selection and planting of Conifers for ornamental purposes is one of the most important considerations in laying out new grounds and the improvement of others. The diversity of form, foliage, habit, and adaptability to situation is so extensive that no garden of any pretension can be without some kinds, and even in the smallest, if we do not find some specimens of compact or fastigate growth we feel that there is something wanted to render it complete, however well it may be managed in other respects. Like other subjects, the planting and selection of Conifers is often carried to an injudicious extent, either from deficiency of knowledge of their habits and requirements or from the pardonable desire to possess specimens. Thus we occasionally find them too much crowded, a vigorous and large-growing tree put where a smaller or more compact kind would be suitable, or the contrast of foliage not sufficiently studied to produce striking or pleasing effect, but something indescribably jarring to our sense of the beautiful which we should wish to see altered. Notwithstanding that much has already been written about Conifers, practical suggestions for planting and arranging specimens might form the subject of more than one useful and interesting article.

At Woodlands all the requisite conditions for securing good specimens combined with good effect have on the whole been satisfactorily complied with. The soil is light, with a large proportion of sand. The situation is favourable, and partially sheltered by high deciduous trees, which materially assist in breaking the force of high winds. The specimens from their size would at first sight appear a little too close together, but they are sufficiently far apart to admit a free circulation of air—an indispensable requisite to secure good and healthy plants.

\* I am indebted for this extract to a local guide about to be published by Mr. John Colegate, Bookseller, Dunoon, of some of the proofs of which he allowed me to have the perusal. Mr. Colegate is also agent for the letting of lodgings—that is, he is what is termed north of the Tweed a “House Factor;” and I advise his aid to be obtained by those about to visit Dunoon.

Contact will always produce some deformity, or render the part that suffers it more or less unsightly. The specimens named beneath may be ranked among the best, certainly in the county of Surrey, as regards their thriving and beautiful appearance, and inferior to few that have ever come under my notice. By the kindness of Mr. Singleton, the gardener, I am enabled to give the dimensions of the plants from actual measurement.

*Wellingtonia gigantea*.—Height, 18 feet. Spread of branches, 45 feet in circumference. Trunk at base, 5 feet; at 4 feet from the ground, 3½ feet. Age, about 12 years. A perfect specimen, symmetrical and compact.

*Picea (Abies) pinsapo*.—Height, 21½ feet. Spread of branches, 60 feet in circumference. Trunk at base, 2½ feet; at 4 feet from the ground, 2 feet 2 inches.

*Thuja aurea*.—Height, 4 feet 9 inches. Circumference, 16½ feet.

*Cupressus torulosa*.—Height, 22½ feet. Spread of branches, 27 feet in circumference. Trunk at base, 3 feet 9 inches; at 4 feet from the ground, 2 feet 3 inches.

*Thuja borealis*.—Height, 8½ feet. Spread of branches, 16½ feet in circumference.

*Picea (Abies) cephalonica*.—Height, 23½ feet. Spread of branches, 40 feet in circumference. Trunk at base, 2½ feet; at 4 feet from the ground, 1 foot 9 inches.

*Cupressus macrocarpa*.—Height, 35 feet. Spread of branches, 64 feet in circumference. Trunk at base, 4½ feet.

*Cedrus deodara*.—Height, 28 feet. Spread of branches, 60 feet in circumference. Trunk at base, 4½ feet; at 4 feet from the ground, 2 feet 9 inches.

*Thuja gigantea*.—Height, 17 feet. Spread of branches, 18 feet in circumference. Trunk at base, 2 feet.

*Abies Douglasii*.—Height, 35 feet. Spread of branches, 60 to 64 feet in circumference. Trunk at base, 2 feet 9 inches; at 4 feet from the ground, 2½ feet. This tree has produced abundance of cones.

*Picea (Abies) Nordmanniana*.—Height, 10½ feet. Spread of branches, 22 feet in circumference. Trunk at base, 1 foot; at 4 feet from the ground, 9 inches.

*Picea (Abies) nobilis*.—Height, 9 feet. Spread of branches, 18 feet in circumference. Trunk at base, 1 foot.

*Pinus excelsa*.—Height, 28 feet. Spread of branches, 38 feet in circumference. Trunk at base, 3 feet; at 4 feet from the ground, 2 feet.

*Pinus insignis*.—Height, 30 feet. Spread of branches, 66 feet in circumference. Trunk at base, 3 feet; at 4 feet from the ground, 2 feet 2 inches.

*Cupressus Uhdiana*.—Height, 24 feet. Spread of branches, 37 feet in circumference.

*Cryptomeria japonica*.—Height, 21 feet. Spread of branches, 54 feet in circumference. Trunk at base, 3 feet; at 4 feet from the ground, 2 feet 2 inches. A truly magnificent specimen of this noble tree.

*Abies morinda*.—Height, 32 feet. Spread of branches, 36 feet in circumference. Trunk at base, 1½ feet; at 4 feet from the ground, 1½ feet.

The above details of these fine Conifers will give a much more correct idea of what they really are than any particular description of each, which would exhaust my vocabulary of euphonious adjectives. They were planted by the late W. Headland, Esq., whose taste for Conifers and Roses was well known in the horticultural world. They are now the property of F. W. Costar, Esq. Occasional notice of some of them has been made in these pages and elsewhere by anonymous correspondents in a very indistinct manner, and without reference to Mr. Singleton, the gardener, under whose care they have been for many years, and of whom it is not too much to say that he is one of those earnest, intelligent, hard-working gardeners whom we are always glad to meet. The grounds at Woodlands are fully in keeping with the beautiful trees that adorn them. The rosery, flower garden, and the various houses, all bear testimony to the excellent management under which they are placed.

While writing of Conifers, I have to record a remarkable sport which has occurred in the nursery of Mr. Cattell, at Westerham, whose general stock of these plants is scarcely surpassed anywhere. It is from a plant of the diminutive *Abies Clanbrasiliana*, whose leader has grown with a vigour quite contrary to the habit of it, and which proves to be the common Spruce (*Abies excelsa*), thus showing that *A. excelsa* and *A. Clanbrasiliana* are not separate species, but simply varieties of the same.—ANOLRUS H. KENT.

## NOTTINGHAM FLORAL FÊTE.

CONTEMPORANEOUSLY with the meeting of the British Association for the Advancement of Science, a floral fete was held on Thursday last, at Nottingham, and continued open till Saturday night. The spot chosen for the Exhibition was a field in the Park Valley, about six acres in extent, along the sides of which numerous tents, some of them of very considerable dimensions, were erected, whilst the central area was left open to the promenaders and the military bands. Of these there were several in attendance, including that of the Grenadier Guards from London. In a horticultural point of view the gathering was most successful, for not only were the subjects exhibited extremely numerous, but they were also very creditable to the growers; the attendance of visitors was also very large, amounting on the first day, we believe, to about 5000, and the weather having been fine throughout, there seems to be no reason to doubt that the results of the Fête in a pecuniary point of view will be most gratifying to the promoters.

Stove and greenhouse plants constituted a leading feature, though it is rather late in the season to see flowering specimens of these in the same perfection as we are accustomed to meet with them at the metropolitan summer shows; but fine-foliaged plants were both numerous and in excellent condition. In a collection of sixteen, from Mr. B. S. Williams, of Holloway, to whom was awarded a first prize in its class, were very good specimens of *Allamanda Schottii*, *Bougainvillea glabra*, *Statice Holfordii*, *Diplazenia splendens*, and *Vallota purpurea*, together with variegated *Yuccas*, *Croton angustifolium*, *Alocasia macrorhiza variegata*, variegated New Zealand Flax, and *Gymnostachyum Verschaffeltii*. A similar award was made to Lord Middleton for a like collection, containing among other plants a very good *Anthurium magnificum* and *Alocasia zebrina*, *Caladium argyrites*, *Cissus discolor*, and *Cyperus alternifolius variegatus*. Capt. Farmer had *Achimenes*, *Lantanas*, flowering *Begonias*, *Fuchsias*, *Lilium lancifolium*, a good specimen of the variegated *Cobea scandens*, which is not so much grown as it deserves to be, being very useful as a conservatory climber, and as a pyramidally-trained variegated pot plant; and W. C. Boden, Esq., Ruddington Hall, had *Lantanas*, the pale blue *Plumbago capensis*, good *Achimenes*, *Vinea rosea*, *Stephanotis floribunda*, *Asclepias curassavica* and *Allamanda Schottii*. Of this last there was a single specimen with magnificent blooms, from Mr. Williams, of Holloway, who also had a first prize for *Erica Maroccanica* in fine bloom.

Of plants shown exclusively for their foliage many fine collections were exhibited, those from Mr. Williams, Lord Middleton, Lord Belper, E. J. Lowe, Esq., J. W. Taylor, Esq., Stoke Newington, and Mr. Bullen, gardener to A. Turner, Esq., Leicester, being especially worthy of note. Among such plants were several fine specimens of *Cyanophyllum magnificum*, variegated *Crotons*, *Pandanus utilis* and *Javanicus variegatus*, *Caladiums*, *Anthurium magnificum*, *Alocasia metallica*, *Lowii*, and *zebrina*, one or two handsome plants of *Spharogyne latifolia*; also, *Cissus discolor*, variegated *Ananassa sativa*, *Colens Verschaffeltii* and *nigricans*, *Cordylone indivisa*, *Dracenas*, *Marantas*, *Rhopalax*, *Theophrasta imperialis*, *Cycas revoluta*, *Pothos argyrea*; *Livistonia Jenkinssii*, *Lantana borbonica*, and other Palms, together with several fine specimens of tree Ferns. Good collections of smaller plants came from Messrs. Small, of Ilkeston, and Messrs. Wood & Ingram, of Hantington. Among single specimens we remarked a noble plant of *Livistonia Jenkinssii*, from Mr. Williams, a fine example of *Cissus discolor* from the same, *Caladium Chantini* from Lord Middleton, and *Alocasia metallica* from Mr. Bullen. Of *Caladiums*, Messrs. Cooling, of Milo Ash Nurseries, Derby, Messrs. Small & Son, and Lord Middleton exhibited well-grown plants of *Wightii*, *Chantini*, *precile*, *bicolor splendens*, and *mirabile*.

The central group in the large tent, in which the flowering and fine-foliaged plants were chiefly shown, comprised a fine specimen of *Dicksonia antarctica* from Mr. Williams, a large *Caladium esculentum* from Lord Belper, Kingston Hall, and other tall plants with ornamental foliage, and was surrounded with well-grown fine-leaved *Begonias* shown by Capt. Smith, Lord Middleton, Mr. Boden, Mr. Wildman, and Capt. Mudell; there were also some very good exotic Ferns from the first-named, and Mr. Boden, including excellent examples of *Adiantum cuneatum* and *formosum*, *Blechnum corcovadense*, and *occidentale*, &c.

Orchids were poorly represented as regards numbers. Mr. Williams, Holloway, and Mr. Bullen, gardener to A. Turner, Esq., of Bow Bridge, Leicester, were the principal exhibitors, and their names are sufficient guarantee that the specimens shown were of no mean excellence. Mr. Williams, who was first for twelve, had *Miltonia spectabilis* with fourteen fine blooms, *Odontoglossum grande* with about a dozen large flowers, *Saccolabium Blumei majus* with a fine spike, *Acrides suavisimum*, *Vanda suavis*, a very good *Phalaenopsis rosea*, *Cattleya crispata*, and *Lælia elegans* in very good bloom, *Calanthe maculosa*, *Dendrobium formosum*, and the showy *Epidendrum vitellinum*. Mr. Bullen had the next best collection, the star of which was a magnificent *Cattleya crispata* literally a mass of bloom, Rollisson's variety of the same, *C. Acklandiae*, *Dendrobium filiforme* with several of its pedulous greenish yellow racemes; *Miltonia Regnelli*, *Saccolabium Blumei majus*, and *Acrides suavisimum* in good bloom, and *Epidendrum cochleatum majus*, the last, however, not a very effective plant in a collection owing to the dusky colour of its blooms. Mr. Williams took the first prize for a specimen Orchid with *Saccolabium Blumei majus* having a beautiful spike of bloom nearly 2 feet in length, Mr.

Bullen being second with *Cattleya crispa superba*, and in all the other classes Mr. Williams was the only exhibitor, showing, besides plants already mentioned, good examples of *Vanda tricolor*, *Afrides nobile*, *Saccolabium Dayii*, *Lycaste Skinneri*, and *Cattleya Harrisonia*.

Ferns, both British and Exotic, have rarely, if ever, been brought together in such numbers. The main body of them was placed in two tents extending altogether nearly 300 feet in length, and however fine they were, we cannot but think they would have excited much greater interest had they been broken up by masses of other plants; as it was, the eye became weary of them, and that this was the effect on most of the visitors, the fact that the Fern-tent was less crowded than the other parts of the Exhibition may be taken as a proof. In addition to the long tent, there was another of good size wholly filled with a most extensive and remarkably fine collection contributed by the Rev. C. Padley, of Beaufield, Plymouth. This excited much interest, and, apart from its merit as a collection, the way in which it was arranged and labelled was worthy of all commendation, for not only could every plant be seen with ease, but each was distinctly named. For this purpose cards specially printed in gold and colours were employed; and the stages of the tent, it may be added, were covered with crimson cloth. Messrs. Edwards & Son, of the Moss Spring Nursery, Nathall, Mr. Cooling, Messrs. Small, and E. J. Lowe, Esq., had also excellent collections of British Ferns, comprising numerous varieties. Messrs. Edwards took a first prize for their collection.

Among Exotic Ferns Mr. Williams, of Holloway, had several fine examples of *Marattia elegans*, *Thamnopteris australasica*, *Cyathea medullaris*, *Toodea africana*, *Nothochloa sinuata* with fronds 2 feet in length, *Platynerium grande*, and *Cibotiums*. Lord Belper had, besides a large plant of *Gymnogramma ochracea* and *Nephrolepis exaltata* and *davallioides*, a remarkably fine specimen of *Adiantum tenerum*, and Mr. Lowe a beautiful example of *Adiantum cucurbitatum* about 4 feet across; *A. formosum*, *Lygodium scandens*, and some others were also very good. J. W. Taylor, Esq., of Stoke Newington, also exhibited fine examples of exotic species, of which we remarked *Alsophila Cooperi*, *Gleichenia dicarpa* and *spelunca*; *Cibotium princeps*, *Cyathea*, and other true Ferns. From the same gentleman came also several very fine pans of *Lycopods*.

Small collections of medicinal and economic plants came from Mr. Williams and Lord Middleton, and comprised the plants affording Cotton, Indian-rubber, Ginger, Teas, Loquat, Cinnamon, Camphor, the Date Palm, the Croton Oil plant, Sage Palm, *Marsilea macropus*, &c. Mr. Barron, of the Elvaston Nurseries, near Derby, filled a circular tent 66 feet in diameter with a fine collection of evergreens, conspicuous among which were *Picea Nordmanniana* showing the silvery character of its foliage, handsome specimens of *Cupressus nutkatensis*, *Torreya nuceifera*, *Abies Alcockiana*, *Enryas*, *Enonymus*, *Elaagnus*, Holly-leaved *Osmantbus*, and various other Japanese plants. Mr. Barron also exhibited *Retinosporas* and other Conifers in great numbers, and a remarkably fine Golden Holly, and a large *Picea pinsapo*, in two of his transplanting machines, showing the mode in which plants are slung in these and transported in safety and good condition to a distance. Mr. Frettingham, Stapleford Nursery, exhibited a similar collection, in which were several remarkably fine variegated Hollies; *Cryptomeria japonica*, *Thuja aurea*, and various other Conifers in fine condition. These plants filled a tent adjoining that occupied by Mr. Barron, and their *ensemble* from the number of the variegated Hollies was much more lively than that usually presented by collections of shrubs.

Fuchsias were in considerable force, and were generally in good bloom, though, as a rule, those grown in the pyramidal form were too tall as compared to their breadth at base, and were not so well furnished as those seen at the London shows. Mr. R. J. Beard was first for eight; Mr. H. Farmer for four; Capt. Mundell, Messrs. Wood and Ingram, Capt. Smith, and others also exhibited plants in good bloom. Among the best were *Rose of Castile*, *Little Bo-peep*, *Conspicua*, *Sensation*, *Schiller*, *Excellent*, *British Sailor*, and *Guiding Star*.

Of Pelargoniums the Duke of Newcastle, Clumber, exhibited large plants in iron vases of *Stella*, *Cybetha*, and *Minimum Nosegay*, in fine bloom; and of Mrs. Pollock, Cloth of Gold, Bijon, and Flower of the Day among variegated kinds. From Messrs. Small, Ilkeston, who had a first prize, we noticed good plants of *Amelina Griseau*, *Clipper*, and *Eleanor*. Messrs. Wood & Ingram, Messrs. Smith of Dulwich, and Mr. Jabez Chater, Gonville Nurseries, Cambridge, exhibited interesting collections of tricolor and variegated kinds.

Among other flowering plants were *Verbenas*, *Petunias*, and *Balsams* in good bloom, the last shown by Lord Middleton, *Lilium lancifolium* from Mr. Williams and Messrs. Small, and some other subjects.

Cut flowers comprised stands of beautiful cut *Roses* from the Rev. S. Reynolds Hole, and the Rev. Mr. Pochin. Messrs. Paul & Son, of Cheshunt, also exhibited a numerous collection, besides taking first prizes for twenty-four and twelve blooms. A number of good bouquets were also shown. *Hollyhocks* from Mr. W. Chater, of Safron Walden, and Mr. Jabez Chater, of Cambridge, comprised many fine spikes as well as blooms; among which were examples of Rev. J. Dix, Rev. E. Hawke, Mrs. B. Cochrane, Annie Chater, *Attraction*, and several seedlings. Dahlias were also well represented in stands from Mr. Draycott, Messrs. Wood & Ingram, Rev. B. Pochin, and Mr. T. Paget, and included fine blooms of *Charlotte Dörking*, *Charles Turner*, *Bob Bidley*, *Lord Derby*, *Lord Palmerston*, *George Wheeler*, *Volunteer*,

*Lilac Queen*, *Leah*, &c. Several fine stands of *Gladioli* were exhibited by Messrs. Paul & Son and Mr. Johnson; and there were numerous exhibitions of German *Asters*, and some good *Zinnias* from Mr. Chater, of Cambridge.

A pretty floral monogram by P. Jeffcock, Esq., attracted much attention; and the first prize for dinner-table decorations was awarded to Capt. Farmer for a looking-glass set round with *Scarlet Geraniums* and *Ferns*, on which was set a silver epergne with *Grapes* and *Vine leaves* at the base, and *Ferns*, *Orchids*, and *Liliums* in the top dish. The second prize went to Capt. Smith for a tasteful arrangement in one of March's stands.

Fruit was not nearly so well represented in quantity as could have been anticipated, but some of it was above the average in point of quality. The first-prize collection came from Mr. Westland, Lord Belper's gardener, and comprised several kinds of *Grapes*, *Pines*, *Melons*, *Peaches*, *Nectarines*, *Apricots*, *Figs*, *Cherries*, *Apples*, *Pears*, *Gooseberries*, *Currants*, and *Alpine Strawberries*. Mr. Dixon, who took the second prize, had fine bunches of *Black Prince* and *Trentham Black Grapes*, very good *Chasselas Musqué*, *Brown Sugarloaf* and *Ripley Queen Pines*, two *Melons*, *Peaches*, *Apricots*, *Cherries*, *Gooseberries*, *Mullberries*, and *Pears*. A collection from the Duke of Newcastle's garden was third. *Grapes* comprised very good well-ripened bunches of *Black Hamburgh* from Lord Belper, Messrs. Dixon, Gregory, and Paget, those from the first-named being by far the finest. Mr. Paget had *Muscate of Alexandria* very good, the Duke of Newcastle *White Frontignan*; Mr. Newton, *Royal Muscadine*; and among other kinds we noticed good bunches of *Red* and *White Frontignan*, *Trebiano*, and *Muscate Hamburgh*. Several good *Pines*, consisting of *Providences*, *Queens*, *Cayenne*, and *Enviles*, were shown; some fine *Peaches* and *Nectarines* came from Mr. Tillyer, Welbeck; and there were also good dishes of *Apples*, *Plums*, *Currants*, and other fruits. There were, besides, some very fine fruiting orchard-house trees; but so crowded was the tent in which these and the rest of the fruit were, that after sundry ineffectual efforts, the attempt to get near them had to be given up.

There was also a small show of vegetables, of which the *Potatoes* were particularly good; the other articles were of fair quality.

The span-roofed glass house in which the *Orchids* were exhibited was erected by Mr. Messenger, of Loughborough, and was efficiently ventilated by a contrivance opening the whole of the upright sashes upwards and outwards. He also exhibited a groundinery, and his tubular boilers and valves. From Messrs. Barr & Sngden, came a number of elegant *Fern-cases*, *drawing-room plant-stands*, *flower-vases*, &c.; and Messrs. Edwards had some very good samples of similar articles.

## ROYAL HORTICULTURAL SOCIETY.

AUGUST 21st.

FLORAL COMMITTEE.—Mr. A. Bartleman exhibited a seedling *Nosegay Pelargonium*, with large, bright pink trusses; a very promising flower, but being a yearling plant no award could be made. Mr. Thos. Cripps, Tunbridge Wells, brought several very interesting plants. Among them were seven varieties of seedling *Clematis*, hybrids from *C. lanuginosa*, which have the great recommendation of continuing some weeks in flower. These seedlings were very beautiful. Two of them received first-class certificates—viz., *Lady Caroline Nevill*, a delicate lavender with dark stripe; and *tunbridgensis*, reddish purple, with a blue stripe in the centre of each petal. The other flowers were very good, and will find a place in every collection. First-class certificates were also awarded to Mr. Cripps for *Forsythia viridissima variegata*, *Pteris serrulata polyactyla*, a very distinct form; and a second-class certificate for *Hydrangea japonica elegantissima variegata*, with golden variegation. Among other plants were *Euonymus japonicus latifolius*, *Aucuba japonica maculata femina*, and *Griselinia macrophylla* from New Zealand. Messrs. E. G. Henderson exhibited *Verberna Blue Shade* and *King of the Scarlet*, bedding varieties—their merits must be tested when planted out; *Verbena Harlequin*; a hybrid *Fuchsia*, *Day Dream*, one of the *Globe* section, having small compact flowers; *Fuchsia Vainqueur de Puebla*, a double white free-flowering sort, but with ragged flowers; *Coleus aureus marginatus*, not sufficiently distinct; and *Petunia Joseph Andreux*, with variegated foliage. Mr. Wm. Paul sent a collection of variegated shrubs, many of which had been seen before, and had received awards—*Weigela rosea marginata* var., *Sedum atropurpureum*, *Ligustrum japonicum maculatum* or *ovalifolium*, *Euonymus japonicus arcevariegatus*, *Euonymus macrophyllus*; also a nice collection of some of his best *Nosegay Pelargoniums*, among which the great favourite *Amy Hogg*, *Dr. Hogg*, and *St. George* were very much admired. A special certificate was awarded for the whole collection of plants and *Nosegay Pelargoniums*. To Mr. James Keeler, gardener to T. Todd, Esq., Dulwich, a first-class certificate was awarded for seedling *Zonale Pelargonium Sambo*, a very bright scarlet, with large and compact trusses of flowers; and Mr. Bull received a first-class certificate for *Dioscorea discolor vittata*, *Adiantum velutinum*, and *Yucca hystrix*; and a second-class certificate for *Pentstemon Sceptre*, a purplish crimson, the lower lobe of the flower marked with large, distinct, dark spots.

Messrs. Low sent plants of *Oncidium cruentum*, which it was requested should be sent again. From Mr. J. Collier, Bethnal Green,

came Zonale seedling Pelargonium Bob, a good flower, but too much like many others; and from Mr. R. Hopkins, Brentford, seedling Dahlias Lord Enfield, Ariel, and Anna. Mr. Standish's seedling Gladioli were much admired, and were very beautiful; many of them had received awards. Two seedlings were selected for first-class certificates—viz., Dr. Hogg, a splendid fiery crimson, with a purple flame, and Basil, a large well-formed white and pink striped flower, one of the finest seedlings yet raised. A special certificate was awarded for the collection. Mr. Todman sent a seedling Verbena, King of the Bidders, a dark crimson; two boxes of the cut blooms of this seedling were also sent. A second-class certificate was awarded it as a useful bedding variety. Mr. Green, gardener to W. W. Saunders, Esq., received a special certificate for a collection of Peperomins. To Mr. Anderson gardener to T. Dawson, Esq., a special certificate was awarded for a collection of cut spikes of beautiful Orchids. Mr. Simms, gardener to E. Dance, Esq., brought a very pretty seedling Zonale Pelargonium Salmon King; being a yearling plant no award was made. Mr. George Rawlins had a very dark seedling Dahlia called John Sladden, which received a second-class certificate. From Mr. Tillery, Welbeck, came seedling Gladiolus Fanny. Messrs. Veitch sent two beautiful Orchids, to one of which, Cattleya Manglesii, a beautiful hybrid between C. Harrisonii and C. Mossii, a first-class certificate was awarded Mr. John Stevens, gardener to F. E. Williams, Esq., Solihull, sent three seedling Gladioli—Mrs. Williams, Wyley Williams, and Exhibitor; to the latter, a dark red with a white throat, a second-class certificate was awarded. Mr. Eckford, Colehill, again brought a fine collection of seedling Verbenas; two of them, Earl of Radnor, a light scarlet, pale lemon centre, and Fanny Martin, received second-class certificates. Mr. Keynes, of Salisbury, exhibited among seedling Dahlias a Fancy named Butterfly, of a dark brownish hue, which was awarded a first-class certificate; and Clara Simon, a light flower tipped with purple, which received a first-class certificate. We may expect many of the seedlings exhibited on this occasion to be sent again, for it is early to decide on the merits of seedling Dahlias; they may and will produce much better flowers than at present.

**FRUIT COMMITTEE.**—A special certificate was awarded to Mr. Bell, gardener to the Duke of Wellington, Strathfieldsaye, for a fruit of Charlotte Rothschild Pine Apple of peculiarly excellent flavour. Mr. Bell also exhibited Anson's Pine, a variety of inferior merit. A Ripley Queen weighing 6 lbs. 6 ozs., was likewise shown by Mr. Holliday, gardener to W. B. Walsley, Esq., The Elms, Acton; it was, however, almost destitute of a crown, a circumstance which detracted much from its appearance. Several seedling Grapes were shown by Mr. James, gardener to the Earl of Dartmouth, Patshull; one of them was the result of a cross between the Black Prince and Black Frontignan, and another between Morocco and Chasselas Musqué. The Committee, however, did not consider them worthy of an award. From Messrs. Osborn, Fulham, came fruit of Podophyllum emodi and Gaultheria shallon; and from the Rev. A. Rawson, of Bromley, the Lawton Blackberry, very juicy, but not equal in flavour to the common Blackberry.

**FORTNIGHTLY MEETING.**—G. F. Wilson, Esq., F.R.S., in the chair. After the election of members and the announcement of the awards, the Rev. M. J. Berkeley directed attention to a Bramble shown at the previous meeting by Mr. Bateman. This, he said, was nearly allied to the common Raspberry (*Rubus idæus*), and evidently a form of *R. strigosus*. Other nearly related species were *R. occidentalis* and *cuneifolius*, having the under sides of their leaves white. Referring then to the Lawton Blackberry, he said the fruit was large, and held in high repute in Canada and the United States; and though to our taste its flavour is somewhat rapid, it is there, owing to the heat of the summer, very acceptable from its juiciness. He might mention, in connection with the Blackberry, that the jelly had been prescribed for gout by a physician in Northamptonshire, and it doubtless owed its efficacy to the circumstance of its containing a small quantity of citrate of potash, which is used as a remedy for that painful disorder. Mr. Rivers, it was added, had been making some experiments with the view of improving the fruit of the Blackberry, and Mr. Berkeley hoped that the produce of some of the cross-bred plants would be shown at the next meeting. *Rubus girardinianus* raised from seeds imported from the Amoor River, and shown at a recent meeting, proved to be the *R. reflexus* of Kor, figured in the "Botanical Register" in 1820; and this fact would serve to show how cautious we ought to be in adopting trade names. Mr. Berkeley then remarked that, though not before the meeting, male catkins of *Picea pinsapo* had been produced at the Marquis of Huntly's, Orton Longville, near Peterborough. Orchids then came under review, and attention was especially directed to an unnamed *Oncidium*, of which a magnificent branch was furnished by Mr. Anderson, gardener to T. Dawson, Esq., Meadow Bank, near Glasgow, from whom there also came a portion of a spike of *Oncidium leucochilum* bearing no fewer than 242 blossoms. *Lelia Wallisii*, and the facility with which *Cattleyas hybridæ*, were then remarked upon, as also *Adiantum velutinum*, from Mr. Ball. With regard to *Podophyllum emodi*, Mr. Berkeley expressed his surprise that the large red fruit should have proved perfectly insipid, seeing that the May Apple or Wild Lemon of the Americans (*P. peltatum*), is one of the most intensely acid fruits known. Among economic plants of interest, there was *Moranta arundinacea*, from the tubers of which the Arrowroot of commerce is obtained, but there are several other plants which

afford a starch to which that name is applied. Thus the Portland Arrowroot is obtained from our common *Arum*, which is very poisonous, but by repeated washings is rendered innocuous. It might also be mentioned that in 1823, when there was a great scarcity of food in the West of Scotland, a great number of people lived on the fecula of the roots of *Typha latifolia*. The Rice-plant, Venus's Flytrap (*Dionæa muscipula*), and *Apoeynum androsaminifolium*, also came under notice, as well as the Dahlia Fanny Sturt, which was exhibited in three forms—viz., in its normal condition, or tipped with white; half tipped with white, and half crimson; and lastly, crimson entirely.

The Middlesborough and the Glamorganshire Horticultural Societies were admitted into union.

**WEEKLY SHOW, August 25th.**—On this occasion prizes were offered for the best collection of vegetables; and Mr. Eartley, gardener to F. Pryor, Esq., Digswell, and Mr. Hill, Angel Row, Highgate, were placed equal first; the former also received an extra prize for a basket of flowers, and a first-class certificate for a neatly arranged hand bouquet. To Mrs. Hooke, Morville Lodge, Fulham, were awarded first-class certificates for three specimens of *Lilium auratum* and for six *Fuchsias*, also a second-class one for *Gladiolus*. Mr. Standish received an extra prize for a collection of *Gladiolus*; and a similar award was made to Mr. Bartlett, of Hammersmith, for *Lilium auratum* and *Asters*.

### ENTOMOLOGICAL SOCIETY'S MEETING.

THE August meeting of this Society was held on the 6th inst., Professor Westwood, Vice-President, being in the chair. On the motion of Mr. Pascoe, seconded by Mr. Stevens, a vote of thanks was unanimously passed to W. W. Saunders, Esq., for the kind and liberal entertainment given by him to the members of the Society at Reigate, as already recorded in our pages.

Mr. Samuel Stevens exhibited portions of two collections of insects recently sent by Mr. Edwin Reed from Bahia in Brazil, and by Mr. Gerrard from Madagascar. Amongst the former were some interesting Cicindelidæ and Carabidæ; and among the latter a new and handsome *Buprestis*, and several species of the very rare genus *Pogonostoma* (*Psilocera*, Gory), also specimens of a new *Cetonia* from Sierra Leone.

Mr. MacLachlan exhibited a remarkable specimen of *Cabera pasaria*, a white Moth, but which had the wings entirely of a slaty colour—it had been captured by Mr. D'Orville; also an extensive series of the cases formed by the larvæ of different species of Caddis Flies (*Trichoptera*), which he had received from Bavaria and the neighbourhood of Basle, one of which was remarkable for being formed of tubular vegetable stems fastened together longitudinally, the insect residing in the central tube; another was formed entirely of minute particles of sand; also specimens of the galls formed by Aphides of the genus *Eriosoma* on Elm trees, within which the Flies are developed in considerable numbers, but some of the galls were observed to be partly filled with fluid. He also noticed the capture of *Sisyra Daliæ*, a very rare species of Hemerobiidæ, at Reigate.

Mr. Bond exhibited several rare British Moths, including *Scopula basistrigalis*, a new species recently described by Dr. Knaggs; also *Sericoris Euphorbiana* and *Catoptria microgrammana*, taken at Folkestone by Mr. Meek.

Mr. Jansen exhibited various rare Beetles collected in the New Forest by Mr. C. Turner, including *Vellerius dilatatus* found in the burrows made by the caterpillars of the Goat Moth. Professor Westwood stated that the late Professor Henslow had reared this rare *Staphylinus* from Hornets' nests, in which its larva is parasitic. He also made some remarks on the structure of the singular blind Ant Beetle from Australia, *Ectrephes formicarium*, described at the last meeting of the Society by Mr. Pascoe; and on the rearing of the new Chinese Silkworm, *Bombyx Cynthia*.

A communication was also read on the recent plague of Locusts in Algeria.

### HORTICULTURE ON THE CONTINENT.

OUR neighbours are occupied with their approaching Exhibition in 1867, and the horticultural journals give us details respecting the *annexé* to the building devoted to plants and fruits. The Show will last from the 1st of April to the 31st of October. A garden of more than 50,000 square yards, in the Champ de Mars, is specially devoted to horticultural objects. There will be fourteen sections. No object exhibited can be withdrawn during the fortnight destined to its section. Expenses to be paid by exhibitors; but the railways reduce the ordinary tariff by one-half. Applications to indicate clearly the objects and their condition, also the space required, &c. In France one cannot be too minute, let it be remembered by intending exhibitors. The following is a sketch of the sections:—

First section, open 1st of April, 1867:—Camellias, Conifers, vegetables, Ericas, forced fruits, and vegetables.

Second section, open 15th of April:—*Rhododendron arborescens*, forced fruits, Hyacinths, and greenhouse plants.

Third section, open 1st of May:—Orchids, Azalea indica, Tulips, ornamental plants.

Fourth section, open 15th of May:—Azaleas indica and pentica, Rhododendrons, Orchids.

Fifth section, open 1st of June:—Orchids, Roses, Pelargoniums, &c.

Sixth section, open 15th of June:—Pelargoniums, Roses, Orchids, fruit in season.

Seventh section, open 1st of July:—Palms, hothouse plants, fruits.

Eighth section, open 15th of July:—Aroidæ, fruits.

Ninth section, open 1st of August:—Plants with coloured foliage, Gladioli, Fuchsias, fruits.

Tenth section, open 15th of August:—Plants, Ferns, and fruits.

Eleventh section, open 1st of September:—Dahlias, plants, and fruits.

Twelfth section, open 15th of September:—Dahlias, plants, and fruits.

Thirteenth section, open 1st of October:—Fruits and plants (open).

Fourteenth section, open 15th of October:—Fruit trees trained (open).

Exotic plants will be placed for the first two days of their sections in the interior of the "Crystal Palace" in the central portion. They will afterwards be replaced in the houses specially devoted to them. There will be a mixed jury, composed of twenty-four members. The prizes will be classed as first, second, third, and honourable mention. Prizes to the value of 250,000 francs (£10,000), will be given; 100 golden medals, each valued at 1000 francs (£40); 1000 silver medals; 3000 medals of bronze; 5000 "mentions honorables." This is the present intention of the Committee of Management.

An important show of Roses at Brie-Comte-Robert has been held. Roses are too well described in this Journal to be decanted on here; but, as one review says, *à tout seigneur tout honneur*, let us not omit to "mention honourably" the Rose raised by M. Desmazes, and called the Countess of Jancourt, which was that most approved of at the show. It is a Rose of a full size, opening well, and of a tender *rose-corné*, and belonging to the *hybrides remontantes*, which we translate, rather unhappily, "Hybrid Perpetuals." Is not the French term far more explicit?

M. André Leroy, the well-known nurseryman at Angers, writes that he has obtained a second series of summer blooms from the *Wistaria chinensis*. "The *Wistaria*," he says, "sometimes at Angers shows a few summer blooms, but these do not form, strictly speaking, a second series. Let us treat it as a *plante remontante*, and, to obtain the desired result, we must develop those portions of the plant which give summer flowers—that is, those short spray-like shoots whose eyes, closely placed, are surrounded with leaves. Generally under those shoots which have flowered there springs a vigorous shoot, sometimes several yards in length, which only produces leaves. These useless shoots should be suppressed, unless required for training. By closely pinching in these gross shoots (would not we imagine that Peach shoots were here spoken of?) the sap will be concentrated at the base of the leaves, modifying the eyes, which generally become transformed into flowers. We thus obtain a second show of blooms during the summer months." M. Leroy always had in his gardens showy plants of the *Erythrina crista-galli*, but the severity of the winter destroyed them. The same thing occurs in the Channel Islands, except in some peculiar cases. In France, generally, this plant is cultivated in the orangeries. M. Leroy recommends, as insuring success, the planting it out in a warm and very well-drained border, and, early in November, to cut it down, and cover it over with a hand-glass well piled round with sand, the upper portion being left exposed. During the severe frosts (he is speaking of the climate of mid-France), of December, January, and February, the glass is completely covered over with stable-litter. Whenever the sun shines this is partially removed, but afterwards replaced. In March the litter is taken away, the sand alone remaining, and in April or May, when the young shoots appear, the other defences are removed. The shoots soon reach 6 feet, and in the course of five or six years each plant readily bears twenty-five or thirty shoots. 1200 to 1500 flowers may be looked for on these, lasting all July and August.

M. Rivière, head gardener of the Luxembourg at Paris, highly recommends the following simple plan of propagating the common Fig. In December some of the branches of the tree were

buried under 18 inches of earth. They remained thus till early in May, when they were dug up, and the extremities were cut into portions of 6 or 8 inches long, and were then inserted in a prepared border. These portions, placed at intervals of 10 inches, were then completely covered over by a layer of earth of about 2 inches, and slightly watered. Early in June the buds broke, and pushed so freely that in four months they were 3 feet high and well rooted. These young trees withstood any amount of drought.

At a meeting of the Committee of the Imperial Horticultural Society, during the examination of a fine collection of Scotch Hollyhocks, shown by M. Loise, of Paris, an animated discussion ensued as to the origin of the name, which in French is *Rose trémière*. Marshal Vaillant, of strategical memory, and the energetic defender of the canine race, when lately menaced in France—"What! will you kill the dog of the regiment?"—hazarded the guess that *Rose trémière* was derived from *Rose d'outre mer*, they having been thought to have come from Damascus (like the Plum), in some horticultural crusader's baggage. M. Brongniart (a difficult word in English indeed), thinks, on the contrary, that the word is derived from *Rose de trois mois*. Both of these suppositions are, doubtless, ingenious. M. Margottin is surprised that English cultivators change the names of French plants into English ones. M. Loise replies, that we are perfectly justified in so doing, as our cultivation and our numerous seedlings create quite new races. A box of locusts, from Algeria, is pronounced to be *Aceridium migratorium* and *peregrinum*. They are supposed to be identical with those which ravaged Egypt in the days of Moses, and they are certainly the same as do so much mischief in Provence.

If it be any consolation to our horticulturists, our neighbours complain as feelingly of the plague of insects this year as we do, and the remedies suggested are equally numerous. Of these, your correspondent, having seriously injured his own trees in experimenting with salt and soft soap, thinks that petroleum might form a component part of some remedy.—T. C. BRÉNAUT.

#### LOBELIA SNOWFLAKE.

ALTHOUGH this was sent out last spring, no opinion has as yet been given of it. Hearing such flattering accounts of it, and emanating from such a respectable firm as Messrs. Lee, I bought a sealed packet, but unlike many of your correspondents who could not make it grow, to use Mr. Lee's own words, it came up "as thick as the hair on a cat's back." It received great care and attention as regards pricking-out, &c., as it was destined to make a row in a ribbon-border; but I would congratulate those correspondents who failed in raising plants, for it has proved a total failure here. In habit it is upright, it produces a few dirty white blooms, and half the plants are dead and dying. I hope some of your correspondents will give their experience of it.—THOMAS DRABBLE, *Winthorpe, Newark*.

#### LAXTON'S PROLIFIC EARLY LONG-POD PEA.

AFTER having grown the above valuable addition to our second early Peas, we have formed a different opinion of its merits altogether from that expressed by "AN AMATEUR" and Mr. J. Marsland at page 120. With us it has fully sustained the high character given to it at the time it was sent out. The pods are remarkably large and well filled, and of a very dark green colour; it is also a very abundant bearer. The flavour is equal to any other Pea coming in at the same time. What we have grown was from a sealed packet, and there was no mixture of Early Frame or any other variety among them.—JOSEPH E. OLIVER, *Eslington Park Gardens*.

THE above Pea was sown at the same time as Maclean's Advancer, and was ready for gathering about a week after that fine sort, and notwithstanding the very flattering account I heard of it, I must say it very far exceeded my expectation, and was the admiration of all who saw it. Its height was 5 feet, and it was one mass of pods from bottom to top, the pods containing on an average from nine to twelve Peas. The soil here is gravelly, resting on gravel.—T. DRABBLE, *Winthorpe, Newark*.

THE letters of an "AMATEUR" and Mr. J. Marsland, in THE JOURNAL OF HORTICULTURE for August 14th, respecting "Laxton's Prolific Early Long-pod Pea," rather astonish us, as our own trials and those of numbers of our correspondents,

who have sent us testimonials in its favour, give very different results. We have ourselves Laxton's Prolific Long-pod Pea growing on our seed farms in Essex, raised from seed reserved from the same bulk as supplied to all our customers last season, and we are in a position to prove, that not only were there very few regens in the whole crop, but that the Pea is in every respect equal to our advertised statements of last season—viz., that "for a second early Pea, and a Pea for early sowing in autumn, there is no Pea of a similar class in cultivation to equal it." We cannot but think that "AMAREVA" is not what he signs himself, and that he was not in a position to continually inspect the Pea for himself, as we have done at our farms, otherwise we feel sure his opinion of Laxton's Prolific Early Long-pod Pea would be different. We may add, orders are coming in so fast that we are afraid the demand will be, as last year, far in excess of our stock.—JAMES CARTER & Co.

### CUPRESSUS MACROCARPA.

The great Californian Cypress is one of the most ornamental trees we possess, and although only introduced about twenty years ago, it is already quite a tree in this country.

Since the introduction of the Silver Fir there is no hardy tree to compare with this Cypress in giving such a decided change to park adornment, and to warm the winter landscape. Over the United Kingdom this tree is perfectly hardy, of rapid growth, noble aspect, and robust constitution. Hartweg, by whom it was introduced to Chiswick, says it formed one of the noblest trees he had ever seen. Hartweg had for seven years previous to that date travelled over the great Conifere regions of South and North America, had seen the lofty elegant *Picea religiosa*, and many equally beautiful trees, and when he gave such decided merit to *C. macrocarpa* it was believed that it would be a rare acquisition. The magnificent trees to be seen over the country confirm Mr. Hartweg's first impression.

About the name of the above tree there is some confusion. Some who pretend to know insist that there is a proper distinction between *C. macrocarpa* and *C. Lambertiana*. I may as well say at once that I do not know the difference, if any. I have grown the tree under the respective names, and the trees were purchased from a nursery at the top of the list for extent and correct knowledge of such plants, but I failed to discover any tangible difference. Plants grown from seed and from cuttings of the same tree show a marked difference in a young state, but this apparent difference disappears after the growth of a few years. In this way nothing could be more distinct than the Funereal Cypress.

In regard to *C. macrocarpa*, there seems no reason why a synonyme should be retained, as the tree is botanically described under the above name, and Hartweg does not refer to any other variety; and he knew well what trees grew in Upper California.

Of the first plants distributed by the Horticultural Society of London two are growing at Woodstock, and are both very fine specimens; both plants were removed and transplanted five years ago; the height of the best specimen is now over 40 feet: the stem at 1 foot from the ground is 4½ feet in circumference. It would be impossible to imagine anything more perfect as a tree. Its cheerful green seems to warm the landscape as far as the eye can see it.

The Cypress tribe have not hitherto occupied much attention in landscape or park planting. Although the Cypress figures in the history of Rome and Greece, this family have only found a place in small gardens and dressed grounds, where trees proper are not admissible. The species of Cypress of which I write will rank with large trees, and it should be planted everywhere in masses where dense habit and cheerful green are desirable. What glorious picture and grouping will arise from the judicious planting of *Cupressus Urdana*, *C. macrocarpa*, and the upright Cypress. After this style I have planted the margin of a wood, which in a few years will add a new feature to the picturesque wood of this fine park.

On limestone gravel *C. macrocarpa* is the only Conifer that I have seen thriving well. It is complained by some planters that this tree will not stand on exposed situations. This is true, and it is the last tree that I would think of planting on very exposed ground, nor will it succeed on very dry ground; but there is no ornamental tree that I find more accommodating in soils suited for tree planting.

Mr. Cramb has told in the "Scottish Gardener" that *Pinus insignis* must be cut off the list of hardy trees in most parts

of England; I would recommend the large-fruited Cypress where the *Pinus insignis* has succumbed.—CHARLES McDONALD (in *Scottish Gardener*).

### CULTIVATION OF THE MELON.

(Concluded from Vol. VIII., page 68.)

The accompanying figure is the section of a house that may be built at a small cost, and there is no horticultural purpose for which it might not be employed with advantage. It has no front lights, yet the glass comes so low as to give light to every part. A house of this description would cost very little more than an ordinary pit with brick walls, and could be converted into a greenhouse or store-house for bedding plants in winter, or a forcing-house for flowering plants or vegetables. A very good use for such a house would be to fill it with Vines in pots, starting them in the beginning of December, so as to ripen the Grapes in May, and the house might then be planted with Melons, to fruit in September and October. The house is represented with four four-inch hot-water pipes for top heat, and two for bottom heat, so that it might be used as a forcing-house in winter; but if for plants merely requiring protection from frost, two of the top pipes might be dispensed with—namely, those situated in the path (under which there is a drain), and if it were not desirable to have Melons at an early season, those under the beds, for bottom heat, would not be required. The house would then be exceedingly well adapted for preserving bedding plants, and very useful for Melons, after being cleared of its winter occupants.

The house having been cleared by the last week in May, it is prepared for the reception of the Melons, which I shall presume to have been raised elsewhere, and to consist of two descriptions of plants—viz., one stopped and trained with a single stem to run on a rafter and wires 9 inches from the glass, and others stopped at the second rough leaf, and trained to run over the surface of the beds. The border, if it consists of strong rich loam approaching clay, could not be better suited for the Melon, and it will only be necessary to dig out a hole 10 inches deep under the centre of each light, or 3 feet from centre to centre, and exactly in the centre of the beds, and fill it with rich turfy loam. Beneath each of the rafters, which are wired the same as for Vines, a pit is likewise made, and filled with rich soil forming a cone with a flattened top on which the Melons are to be planted, one plant in each pit so prepared, and watered well at the time. Should the soil be light and poor, that of the beds should be wholly taken out, and replaced with 10 or 12 inches of strong, rich loam. The stronger the soil the more abundant and finer will be the fruit.

After planting the house should be kept close, admitting no air until the thermometer indicates a temperature of 80°, then only a little, and if the temperature rise to 90° all the better; only shut up by the time the temperature sinks to 85°. The atmosphere should be kept moist by syringing, between 4 and 5 p.m., and not later than 6 p.m., every available surface except the foliage, with liquid manure, which will cause the atmosphere to be sensibly charged with ammonia. Unless the operator is experienced in applying manure water, soot water is a more safe liquid. A peck of soot will make thirty gallons of the most deadly poison to red spider, and a fertiliser having but few equals, and so will guano water made at the strength of 1 oz. of guano to four gallons of water. The plants should also be kept well watered, taking care not to saturate the soil, and may be supplied with liquid manure after the fruit is set and swelling. The atmosphere should be kept rather drier when the flowers are setting, and the quantity both of atmospheric moisture, and water at the root, should be reduced as the fruit approaches maturity. The labour involved in frequent waterings may be lessened by mulching the surface with short littery manure or cocoa-nut refuse, so as not to render the operation necessary oftener than once a week.

There will be a plant to each rafter at 3 feet apart, one between each of these in the centre of the bed, also at 3 feet apart; and these producing three and four fruit, averaging 2 lbs. weight each, the produce will far exceed that obtained in the ordinary mode of culture. The plants on the rafters should be confined to a foot wide—that is, 6 inches on each side of the centre wire, and this is ample for a Melon plant trained with one stem. If allowed to sprawl over the whole of the roof it is of little use expecting fruit from the plants in the beds, as they will be deprived of light to such an extent that they cannot do much good. On the other hand, the plants on

the rafters will afford those beneath them an agreeable shade and the latter will produce larger fruit, though not so well flavoured. In certain cold seasons the heat of the sun may not be sufficient to maintain a proper temperature within the house, a little artificial heat must then be given, and in certain cold districts a little of such heat may at all times be required; but in most seasons and localities Melons of good size and flavour may be obtained in unheated houses, by husbanding the sun heat, and providing a structure having a large surface of glass as compared with that of the wood.

My attention was first directed to the cultivation of the Melon in unheated houses from finding a plant spring up almost spontaneously in a frame used for an early crop. It had no heat whatever beyond that of the sun, and very little attention, yet it grew so as to fill two lights, and produced four fruits weighing upwards of 2 lbs. each. The kind was the Egyptian, which when well grown may be taken as a standard of excellence for a green-fleshed Melon. Since then I have grown Melons in cool structures heated by catching the sun's rays, and I do not hesitate to say that Melons can be grown in cold frames if the plants are strong and planted out in good time. Let the fruit be set in July, or by the middle of August, and then a crop quite equal if not superior to such as are obtained in heated structures will be the result. Abercrombie speaks of growing Melons in paper frames, and I know them to have been grown in England with the simple protection of a hand-glass; but though the climate of England is no colder than it was formerly, it is certain that we now grow kinds totally unsuited for such treatment. To grow Melons successfully, with certainty, and to the highest degree of perfection, they require artificial heat, except in the hot summer months, and then care must be taken to husband the sun heat as much as practicable.

The properties of a Melon I think should be—1st, it should not weigh less than 1 lb. 2nd, it should be netted regularly all over, and the more so the better. 3rd, the rind should be free from furrows, or be perfectly spherical or elliptical without any indentations, though flattened at the two ends. 4th, the flesh should be thick, and be eatable quite to the rind, and be melting, sweet, and piquant. 5th, the core should be small, and easily divided from the flesh. 6th, the seeds should be few, and not mingled with the flesh. In constitution the plant should be hardy, vigorous, and productive. In judging a Melon the points may be—flavour six, appearance two, thickness of flesh two, core small and seeds not mingling with the flesh two, or twelve points to constitute a good Melon. No fruit under 1½ lb. to be eligible for a prize, nor size above that to be taken into consideration, unless the fruits be equal as regards flavour, when, of course, all points being equal, preference would be given to a large Melon. It is very rarely, indeed, that a large Melon is equal in flavour to one not half the size.

**VARIETIES.**—I have found the following the best of the scarlet-fleshed class:—

*Scarlet Gem.*—A standard of excellence, being of a fair size, finely netted, spherical in shape, and of the finest flavour. It is early and prolific. Plant hardy, and though small in foliage a free grower.

*Cantaloupe.*—Of this the variety known as the Early Royal is the best. Lawrence's variety is very fine. These are chiefly

desirable on account of their earliness. The fruit is spherical and much ribbed, too much so to be handsome.

*Bignell's Scarlet Flesh.*—The fruit is elliptical, much ribbed, very prolific. The plant is of slender growth, though by no means tender. It is a fine variety for preserving, and very good for dessert.

*Princess Alice.*—Much resembling Scarlet Gem, spherical finely netted, flesh thick, and not so firm as that of Scarlet Gem, melting and excellent.

*Prince Imperial.*—Simply a red-fleshed Beechwood, elliptical.

*Queen Victoria.*—A scarlet-fleshed Bromham Hall, fine, spherical.

*Lady Sefton.*—Fine.

*Empress Eugénie.*—Finely netted, and good flavoured, spherical.

*Scarlet Perfection.*—Large and much ribbed, juicy and rich, but would be finer without the ribs.

*Mousden's Moreton Hall.*—Of fine flavour, and good shape. I have not grown this variety, but I think it very desirable.

Of green-fleshed kinds:—

*Golden Perfection.*—Elliptical, beautifully netted, and very handsome, flavour good.

*Egyptian.*—Spherical, ribbed, netted, and fine flavoured. One of the best in that respect.

*Bromham Hall.*—Fruit handsome, and most excellent.

*Trentham Hybrid.*—Egg-shaped, smooth skin, delicious flavour.

*Meredith's Hybrid Cashmere.*—Handsome, and of the most delicious flavour. To my thinking the finest Melon in cultivation.

*Orion.*—Early and fine, large fruit.

*Beechwood.*—An old, but excellent-flavoured Melon.

*Trentham Cocoa-nut.*—Fine.

I have had experience with upwards of a hundred varieties of Melons, but have not found any to equal those named.

**DISEASES.**—The plant going off at the collar is the most serious. It is occasioned by the collar not being sufficiently high to cause the water to drain from, not to it, by wetting that part in watering, and by keeping it covered with leaves, and, therefore, deprived of light and air. The preventives are to plant on a cone so that the water may drain from the collar, to keep the stem clear of side branches and foliage for a space of at least 6 inches from the root-stem, and not to wet that part in watering. When once this disease has commenced there is no remedy, it is a disease that cannot be arrested, though it may be kept partly in check by clearing the leaves away that shade the part, and rubbing it with quicklime until it becomes dry. Quicklime may then be placed against the stem so as to cover the part affected, removing the lime every four or five days, and, after rubbing the decayed part away until it becomes dry, placing fresh lime around it. This will keep in check the fungus which accompanies the decay, but beyond this it is certain that no application can arrest for any considerable period a decay which has taken firm hold of an annual plant, though by adopting remedial measures it may be retarded long enough for the fruit to arrive at perfection.

Melons are also liable to a kind of gangrene or gout. It consists of an exudation from the stems, and is of a bright brown colour, for though white at first it afterwards changes colour just as the juices of a cut branch turn brown or red on exposure to the atmosphere. This disease is chiefly brought on by growing the plants in very rich soil, and after allowing a large expansion of foliage reducing it all at once very much. This causes the stems to be gorged with the food absorbed by the roots, which the leaves are unable to elaborate, hence the vessels become ruptured and the sap bursts through the skin of the stem, occasionally splitting it open between the joints. This disease never, to my knowledge, attacks plants grown in moderately rich soil, when the head is kept in due proportion to the root, and all prunings are confined to stopping the shoots by pinching out their points, and thinning out the shoots proportionately with their increase in another part. When grown in rich soil it is not unusual to find the plants gangrened along the stems, for then the amount of nutriment taken up by the roots being more than the plant can assimilate it finds a way of escape through the stems. The fruit formed is generally large if the plant lives to perfect it (the plant frequently dies when the fruit is about three-parts swelled), the flesh is hard, the flavour poor, and most of the seeds abortive. To avoid gangrene grow the plants on a more natural principle, do not use the same soil twice, and encourage no more growths than are necessary for obtaining and perfecting a crop of fruit.

Cracking of the fruit is a very common occurrence, and arises from the atmosphere not being kept sufficiently moist whilst the fruit is swelling. The fruit is most liable to crack in kinds which have the juices highly concentrated, as in the case of all highly-flavoured Melons—Scarlet Gem for instance. It is hardly possible to grow fruit of that kind to any considerable size if the swelling take place during very bright weather, without a slight shade to break the force of the sun's rays from 10 A.M. to 3 P.M. The shading also diminishes the amount of evaporation, and prevents the concentration of the juices of the plant in the fruit being carried to such an extent as to cause the rind to become hard and incapable of expansion. Without a moist atmosphere, and slight shade during intense sun heat, the rind of some Melons becomes quite hard, and the fruit would, indeed, be perfect sweetmeats did not our climate change suddenly from a dry hot state to one of moisture and cloud. As it is, however, after a Melon has been acted on for three weeks or a month by a powerful sun and dry atmosphere its rind becomes quite firm; then the weather changes from being extremely dry to extremely wet, from a state tending to the maturity of fruit to one of growth; the plant starts into fresh growth, and more sap is impelled into the fruit, but the rind is incapable of expansion, and the sap so fills the interior of the fruit as to cause the rind to crack. I know of no mode of preventing this result except by swelling the fruit in a moist atmosphere, and after the full size has been attained to maintain the soil and air in a dry state.—G. ABBEY.

### GRASSES FOR LAWNS.

(Continued from page 126.)

*CYNOSURUS CRISTATUS* (Crested Dog's-tail Grass).—This Grass, of which the accompanying is representation, is thus described in a former volume. "The roots are tufted, with long unbranched fibres. Stems several, varying in height from 12 to

18 inches, unbranched, very stiff, hard, round, smooth, with three or four joints, most leafy in the lower part, remaining brown, withered, and wiry with their dry, empty spikes through the latter part of summer. Leaves bright green, short, narrow,

flat, smooth on both sides, edge scarcely rough, with long, smooth, streaked sheaths. Abrupt or ragged-ended and rather short stipules. The head, or spike of flowers, about 2 inches long, erect, stiff, straight and narrow, green; florets all turning to one side, sometimes purple, with a wavy rough stalk (rachis). Floral leaves divided deeply into awl-shaped segments. Husks or glumes usually containing three florets. Smaller valve of the blossom ending in two points; larger valve ending in a short awn. Anthers prominent, pendulous, purple. Stigmas white, feathered. Seed longish, oval, pointed, reddish yellow, covered with the valves of the corolla."

The Crested Dog's-tail Grass is a perennial, and succeeds well on dry gravelly soils and in hilly situations. It is valuable for parks and lawns on account of its dwarf slender growth; and is likewise admirably adapted for bowling-greens, for it bears treading well, and is not liable to become brown in summer. It is one of the best of all Grasses for resisting dry weather.—G. ABBEY.

(To be continued.)

### GLEANINGS.

The Council of the Royal Horticultural Society have arranged that Mr. Eyles, the Superintendent of the garden at South Kensington, shall give to Fellows of the Society his advice and assistance in the laying out and management of their gardens, at the rate of one guinea per visit, with travelling expenses. Such a boon as this is will, we have no doubt, be greatly valued by the Fellows, who will now have an opportunity, at a trifling cost, of securing the services of one who has for many years had unexampled opportunities of carrying out some of the most extensive horticultural works in this country. We believe Mr. Eyles was a pupil of Sir Joseph Paxton at Chatsworth, and accompanied him to the Crystal Palace at Sydenham, whence, after several years' engagement, he was appointed to carry out the works of the South Kensington Garden, according to the design of Mr. Nesfield.

It has been determined that the Royal Horticultural Society shall hold an annual autumnal Show in the provinces, in co-operation with the Royal Agricultural Society, and that the attempt will be made next year at Bury St. Edmunds, provided the necessary encouragement from the district can be held out to the Society. We have always been of opinion that the Society should be to a certain extent migratory, and exercise the same national influence in horticulture as the Royal Agricultural does in agriculture. There is no reason at all why, with a twelvemonth's previous intimation, the Society should not be able to make as large and as good an exhibition in the provinces as is made in London; and there are many classes of subjects which could be exhibited in fine condition at these autumnal shows which are never seen at the metropolitan exhibitions. We have had of late years metropolitan exhibitions *ad nauseam*; let us see if we cannot vary the order of things, and encourage the cultivation of a large number of plants which have hitherto been left to themselves, but which, if taken in hand, and the same care bestowed on them as has been given to the earlier-flowering kinds, will amply repay any attention that has been given them. We might instance the Zonale Pelargoniums, which have now become exhibition plants. The metropolitan shows are all too early to see them in perfection; and were they grown as we know some of our best gardeners can grow them, what a gorgeous exhibition they would make!

It is intended to make a complete collection of all the known varieties of Strawberries in the Royal Horticultural Society's garden at Chiswick this autumn. There are already nearly all the old varieties in the existing collection; and the Council would be obliged if the raisers or possessors of new varieties would be so good as to forward a few plants of each, so that a correct comparison of their various merits may be made.

OUT-DOOR GRAPE IN CANTERBURY, NEW ZEALAND.—The hardy varieties of wine Grapes are beginning to thrive and bear fruit with us now that we are beginning to get more shelter for them in our gardens. The two varieties which I have fruited this season in my garden are first, the Black Cluster or Black Burgundy. It is a first-rate wine Grape; succeeds on the open wall in England, and out of doors here. I consider it a very excellent out-door Grape for this climate on account of its hardiness; it is also with us a very excellent cropper. The

leaves become of a beautiful bright scarlet every autumn before they fall off, and in Australia are sometimes used for colouring white wines. The second variety is the White Muscadine or White Grape from Teneriffe. This is at no time a high-flavoured Grape. It ripens very early in England out of doors, and may be said to do the same here. It is in consequence of its hardiness, productiveness, and certainty of a crop, more grown than any other Grape.—W. SWALE.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

THE clearance of all crops as soon as they are exhausted, and the destruction of weeds, conduce not only to improve the appearance of a garden, but are actually, with reference to the soil, a work of economical importance. In regard to prescribed periods of sowing, it is advisable to study both the soil and locality of a garden, that its advantages and inconveniences may be understood. There are localities where it is necessary to deviate considerably from ordinary practice to meet their peculiarities. *Cabbage*, it is a good time to sow for spring use, also the *Deptford Onion* and *Cauliflower*. *Endive*, the late planting must be made forthwith; this planting will be eligible to move with balls of earth into frames in November, the soil must be very rich. *Green Kale*, let a good breadth of this and *Coleworts* be got out on well-prepared ground, also the residue of the stock of *Brussels Sprouts* and *Savoys* may be usefully employed to fill up vacancies. *Lettuce*, a rich border should now be made ready, and planted with *Bath* or *Brown Cos*, these will furnish a supply in the open ground until Christmas, provided they are protected. This is also an excellent time to make a sowing of the *Brown* or *Bath Cos* and *Hammersmith*, to remain where sown through the winter. The beds should be elevated considerably, the higher the better, and the seed scattered broadcast rather thinly. *Tomatoes*, if they are over-luxuriant, cut away a portion of the roots. *Turnips*, the sowing must not be neglected.

### FRUIT GARDEN.

The preservation of wall fruit from birds and insects should occupy attention. The beestalk earwig-traps should be frequently examined. Worsted or other small-mesh netting may be employed with advantage to protect *Green Gage* or other *Plums*, the scarcity of which fruit this season invites such precautions. Look carefully over *Peach* and *Nectarine* trees, and remove nails that are too close to the swelling fruit. In stopping and arranging the wood let only as much as can conveniently be laid in be allowed to remain, and let that convenience be qualified by due consideration for the perfection of the fruit and the proper ripening of the wood, which only the influences of sun and air can accomplish. It is also an error in another respect to retain a large amount of wood, to be removed inevitably in the winter pruning; an undue excitement and extension is given to the roots, which, by a superabundant supply of sap, induce in the spring the growth of rank and unmanageable wood. The only effectual method of curing a gross habit of growth is root-pruning, or keeping the roots within proper limits by means of shallow, well-drained borders. Should it be found that the shoots after stopping incline to start into growth, it will be advisable as soon as the fruit is gathered to open a trench at a moderate distance from the stem of the tree, cutting the stronger roots. This will be of the greatest service in checking growth, and will probably do more towards securing ripe wood than anything else that could be adopted. Get *Strawberry* plantations intended to stand for next season trimmed as soon as convenient, cutting off and clearing away the runners, so as to afford the leaves plenty of room. Look carefully over varieties of *Pears* ripening, and gather those that are fit, for if allowed to hang after they are ripe birds are sure to find and attack the fruit before it is fit for gathering, so that the crop will probably be spoiled unless it can be netted up. Where *Currant* trees are covered with mats, which, by the by, are very inferior to close nets for this purpose and much more expensive, the trees should be uncovered occasionally on fine, dry days, so as to expose the fruit thoroughly to the air in order to prevent its being injured by damp, &c.

### FLOWER GARDEN.

Mowing will not be so frequently required as heretofore, once a fortnight or three weeks will be sufficient. Sweeping will now be in greater requisition, as the sere and yellow leaf *és* beginning to fall from the trees and shrubs; the lawn and walks should be gone over every morning. The roller, too,

should not be forgotten. Attend to the destruction of weeds, by hoeing and hand-picking. Tie up climbers, dress the edges of beds by pegging and tying; if encircled with basket-work, pay the greater attention to order and good keeping. The propagation of stock for next year's decoration must be actively proceeded with. Large evergreens intended for autumn removal should now be prepared for the purpose. A trench should be dug round the tree nearly to the depth of the lowest roots; the advantages attending an early preparation of this kind are manifest. Decay of some of the earlier flowers will now begin to leave blanks, which will not be easily filled up unless a stock of large plants in pots has been provided. In mixed beds some of the late kinds of *Phloxes*, *Asters*, &c., may occasionally be untied and made to occupy three or more sticks in order to fill the blanks. *Petunias* and other plants of gross habit should have a pruning betimes to keep them within bounds. A few *Crocuses*, *Snowdrops*, &c., may be planted soon to obtain an early bloom.

### GREENHOUSE AND CONSERVATORY.

The usual quantity for a season's supply of the kinds of soil used in potting should be laid in as soon as convenient, and before the ground is sodden with the autumn rains, for even turfy soil should not be carted and stacked-up when saturated with water. The soil should be neatly put up in narrow ridges, so as to be safe from wet, and exposed as much as possible to the action of the air; and as success in plant-growing very much depends upon having suitable soil for potting, no trouble or expense that may be necessary to procure this should be spared where well-grown specimens are expected. Loam of moderately good quality may be obtained in most neighbourhoods; but good peat is not to be had in many localities. This is absolutely necessary, however, for the growth of choice hardwooded plants, and should be procured at the proper season, so as to have it in a fit state for use when wanted. Stove plants flowering in the conservatory will require attention to prevent their being injured by damp, especially *Achimenes* and *Clerodendrons*, which should be gone over every day in cloudy weather, carefully picking off decayed flowers, &c. *Camellias* may be grafted; the operation may be performed with the greatest success by pursuing the French method, which is merely inserting that portion of wood which includes a bud and leaf, cut longitudinally, into a corresponding cleft in the stock. The grafted subjects should be plunged in bottom heat, and kept covered with hand-glasses for at least a month. The tender *Rhododendrons* may be increased in the same way. *Pelargoniums* which have been cut down and have commenced to grow, may be shaken out of their pots and repotted in others of smaller size. Give attention to the Chinese *Primulas*, and sow *Mignonette* for blooming late in the season. Shift *Chrysanthemums*, and regularly attend to stopping and watering, a little manure water will be found useful. Prick out and pot seedling *Cinerarias* for early blooming.

### STOVE.

Continue former directions in this house as to heat and moisture; and by giving plenty of air endeavour to get your *Ixoras* and similar plants to make strong luxuriant shoots, which, if properly ripened, are sure to produce fine heads of bloom. Successions of *Brugmansias*, *Clerodendrons*, *Euphorbias*, *Poinsettias*, &c., should receive a last shift, in order that they may produce a rich display in the conservatory. A batch of such plants as *Thunbergias*, *Ipomœas*, *Jasmines*, *Stephanotis*, *Passifloras*, &c., should be trained up ornamental trellises without delay.

### COLD PITS.

Young stock intended to flower next season should be exposed to the midday sun in order to ripen the wood, taking care not to do this so rashly as to injure the foliage. This, however, will only be proper in the case of such things as have already made plenty of young wood; but it is advisable after this season to be anticipating the approach of winter, and to use every possible means to forward the growth of valuable hardwooded plants, in order to have it somewhat firm and able to resist damp, &c., as soon as possible, and this is especially necessary where the plants have to be wintered in these structures.—W. KEANE.

## DOINGS OF THE LAST WEEK.

### KITCHEN GARDEN.

*Calery*.—Earthed up a piece of the earliest to be fit for use in a fortnight or three weeks. The general crops though healthy and of a dark green after the slight dusting with soot,

have not mounted up as we would wish, and on close examination we found that all the rains we have had were not quite sufficient for it, and therefore ventured on a good soaking of house sewage, which we have no doubt will make the plants larger, for at present they are thick and stocky enough. The beauty of the White Incomparable is that so little earthing up is necessary, for if the plants are from 15 to 18 inches in height you can have from 12 to 15 inches fit for table, and Celery seldom appears there more than a foot in length, if plants of tall sorts should be banked up a couple of feet or more.

**Peas.**—Ran the fork slightly along the sides of rows of late Peas, and gave them likewise a soaking of sewage water. The more luxuriant the tops the drier were they at bottom, as the stems and foliage throw the water past them, and no more fruitful source of mildew is to be found than a moist dripping atmosphere, as we have lately had, with anything like extra dryness at the roots. Treated the latest Broad Beans in the same way. The later Kidney Beans were growing too strong to need such help, but gave a watering to Scarlet Runners bearing heavily.

**Cabbages.**—Gave a watering with sewage to the first Coleworts, just beginning to heart nicely, also to succession crops, and planted out more in rather a shady place, which will be useful after Christmas, if the weather is at all mild. We would have given a soaking to an old piece of spring Cabbages if we could, as it is now a thicket of young Cabbages, which will be very useful. Threw some wood ashes and a little soot among the Cabbages sown for the first crop next spring, as having come up rather thickly the continuous drizzle threatens to cause some of them to lose their legs. Will prick out as soon as they are a little larger. Sowed also for a succession crop, and covered with net a foot above the ground, alike to keep birds and rabbits from the seed and young plants.

**Cauliflower.**—Sowed for the main crop, the first for hand-lights is just above the ground. Planted out a good space on sloping banks with young plants, which will come in well with a little protection if the weather be favourable, and a few may be lifted and protected in sheds and under glass. Gave a good sewage watering to a piece just beginning to show their heads. All Cauliflowers for pickling should be had before this time, as henceforth they are apt to come more open and with scarcely such a bright white colour, though the crop in general may be very good.

Watered, also, the late-planted Broccoli, Greens, &c., and as soon as we can get at them, will plant a few Greens between Gooseberry bushes, &c., where they often come in serviceable in spring.

**Weeds.**—Of all seasons, this is No. 1. Even such things as Chickweed, which in the kitchen garden we had scarcely noticed for years, seemed to threaten to overrun borders of Strawberries, and quarters of Greens, growing with a rapidity quite unexampled. There is nothing for it but a free use of the Dutch hoe, before the weeds grow large, as when weeding must be resorted to, there is no end to the labour. We hear similar complaints from all quarters. We shall only be relieved from this extra labour by a course of fine, dry, bright weather, which we have every hope we shall have before long. We have heard of a kitchen garden being left to itself for one year, allowed, in fact, not to lie fallow, but to be untouched—left to produce and perfect just what it pleased—and been told that thirty years of extra labour would not mend the mischief. We have this season seen one large cottage garden that was passing its second season in a state of nature, and the masses of Chickweed, Groundsel, and Thistles, were in themselves a sight. Enough of seed would there get imbedded in the ground to give work for at least one generation of occupiers, and to furnish a supply of all the winged kinds for miles round. We can thus have plenty of weeds from the winds, and our own neglect.

**Mushrooms.**—We have not yet been able to make any spawn; but no better time than the present can be selected, as we may expect, however made, that the spawn will now dry quickly. Directions and references were given the other week to a correspondent. It may simplify matters to say that we have often made spawn of horse-droppings alone, with just enough of water and soil, to get it wrought into a stiff dough-heap. We have oftener made it of horse-droppings and enough of fresh cowdung to enable all to be beaten into a tough heap. Road drift, soil, cut straw, &c., may be added at pleasure, only it may be noticed that the spawn runs rather more quickly when the material is not so very compact. We have never had it better

than when made solely of fresh horse-droppings, and fresh cowdung.

Our first piece or bed in the open shed has been producing nicely for some time past. The part in the shed made last, in the previous autumn, gave us a fine return in summer, after beds in the Mushroom-house, from the heat, gave over bearing. We have several times before had a supply from these beds in the shed, after we thought they had done bearing, partly owing, no doubt, to the beds standing on the cool ground. These beds in the shed have always been shallow, not more than about 15 inches thick, and were formed of no finer materials than stubble, litter, &c., with 2 or 3 inches mostly of droppings on the surface, in which the spawn is inserted. Of course, we like droppings, with a little litter best, but in these shed-beds they seem to produce longer in proportion to the lower portion of the bed being of a more open, less rich material. We have never done so well in summer with beds made on the ground in the Mushroom-house, as in this open shed, partly owing to the attacks of woodlice in the house in summer, and partly owing to the air that is given coming more in draughts than in the open shed, which is open to the front all the way, and the force of the wind, and the afternoon sun, broken by hurdles set along, with branches or a little straw in them, and the shade of trees near at hand. There is plenty of air, therefore, over the bed, and yet little or no keen draught.

A second larger piece has been spawned and earthed-down, and as soon as we can, we will remove the piece that has produced late, and have a third larger piece in the thatched shed. We have seen none out of doors in the pastures this season, and it is best to be independent of them.

As soon as we can get all the old beds cleared out of the Mushroom-house we will shut it up, and smoke it with burning sulphur, and a little turpentine probably, to kill everything in it that we possibly can, merely as a preventive to being troubled with woodlice, snails, slugs, &c.; but this will not prevent us taking in these pests with the manure which we use for the beds. Hence we seldom are much troubled with these gentry in winter, but do what we will, trap, kill, and slay, we never are quite free of them after the warm spring months in the house, whilst they trouble us little in summer in our outside shed-beds.

Of late so much of the details of Mushroom culture have been given that we have let it alone, so as not to be wearisome; but as some correspondents complain that still they do not succeed, we would again mention the simple elements of success. 1st, The spawn must be good, which you will know from the smell, and being well filled with whitish threads not much larger than the finest cotton or gossamer. 2nd, The material of the bed should be in a medium between wet and dry, rather inclining to dry. If rather dry, a moist coating may be put over the bed before the earth is put on. If the dung is so wet that by hard squeezing you could make the least juice exude, and you cannot make it drier, then each piece of spawn should be wrapped in a handful of short dry litter. 3rd, The heat of the bed when the spawn is inserted should never be greater than that of new milk, and never warmer afterwards. The bed may range from 75° to 85°. The atmosphere round it, of the house, &c., should not be higher than from 55° to 62°, if under 60° all the better. If we are rather afraid of the bed getting hot we insert the spawn near the surface. By doing so when the heat declines all right, this enables us to place an inch more of good material over the bed before placing the earth on. 4th, We have used all kinds of earths, light and stiff, and with good results; but we prefer stiffish loam put on rather wet than dry, beaten well down with a mallet, and the surface made smooth, then watered, and a clean spade drawn over it lightly, so as to leave a smooth hard surface. The hard surface is chiefly useful for enabling us to sweep the surface of the bed with a hair broom. The thickness of our soil when beaten ranges from 1 to 1½ inch. We put on the soil as soon as the heat of the bed begins gradually to fall after spawning, as, from the compactness of the soil, there is no chance of the temperature rising afterwards, except by the healthy increase of heat promoted by the working of the spawn, which as it works will always raise the temperature.

In most old works there are very definite directions given as to boring holes in Mushroom-beds to make them cool enough before spawning them. In shallow beds, as our's have necessarily been, ranging from 12 inches in-doors to 15 or 18 outside, we looked upon the boring as a waste of material, as the air so promoted decomposition. We prefer using layers at different times, and dispensing with holes by making the sur-

face firm so as to exclude the air as much as possible, and thus save our material. It requires a little time to get an assistant to believe that a bed thus firmly made will cool sooner so as to be fit for spawn, and also keep a more regular heat than a bed left looser, or with holes left in it for the air and its oxygen to increase heat in the first place by a more rapid decomposition.

And lastly, for a continuous supply and with limited material, we like small shallow beds in succession, and to be earthed-up as soon after spawning, as watching the trial sticks makes it out to be safe. The closeness of the earth will prevent extra heating afterwards. By this succession-plan, the spawn works in the bed for support, and works upwards through the soil at the same time. In our young days we helped to make some fine beds, and with such fine prepared material as we have since sighed for in vain, and we have since attributed the small success afterwards partly to the dryness of the place, the dryness of the material, and to the fact, that in order to have all the beds made before autumn, several of them would be spawned for months before they were earthed-up. We have known cases of beds being full of spawn in such cases, and yet from dryness the spawn had no power to come through the soil in the shape of Mushrooms. We have for many years been forced to spawn and earth-up as we go, and the necessity of thus making the spawn work down in the bed and up in the earth has had no bad result, so far as securing regular crops is concerned. In houses where a generally moist atmosphere can be maintained in winter, it is of little consequence whether the beds are covered with a little hay, or not, though the Mushrooms will come rather quicker with such a sprinkling; but earlier and later in the house, and in summer in sheds out of doors, such a covering is most useful, not only for securing a more uniform temperature, but also with the help of a slight syringing at times, securing that muggy rather close atmosphere, without keen draughts, in which all the fungus family so much delight.

FRUIT GARDEN.

Very much the same as last week. Strawberries should now be cleaned as soon as possible, and plants for forcing potted without delay. Many Apples threaten to be so much smaller than usual, that if we had time we would water dwarf standards; but for most sorts there will yet be a couple of months good swelling time. Gave a good watering to trees in orchard-house where the fruit are swelling fast and ripening. Were forced to fork over the surface to let the moisture go deep enough. The dropping off of fruit before they are ripe is more owing to dryness at the roots than is generally imagined. Where mulching is not resorted to, heavy waterings will be wanted after stoning for stone fruit in-doors, but too much must not be given at one time, or the extra stimulus will throw the fruit off. Removed a good portion of the laterals from Vines, and stopped and regulated late Melons. Watered Figs in-doors and out of doors.

ORNAMENTAL DEPARTMENT.

Much time has been taken up securing Hollyhocks, Dahlias, and tall herbaceous plants, among which some high winds had revelled. Grouped flower-beds have suffered but little from the winds owing to being bushed with twigs, but their lustre was rather dimmed by the continuous rains. Even Calceolarias have had only a promise of waterings this season. If the hoped-for dry weather come, we should like to mulch them with spent Mushroom dung. As yet they have done well. We have put in a portion of cuttings for next year's supply, but we have so entered into the minutiae, and other friends are now giving the results of their experience, that an article on the subject would be next to superfluous just now. Fancies, and many other herbaceous plants may still be propagated by cuttings in a shady place, and more especially if hand-lights can be used, with air left on at night. All the China, Perpetual, and Noisette Roses may also be struck in a cool, close place, and a little heat given as soon as the base is swelled. Planted out and divided lots of single and double Violets, and regulated Neapolitan in a pit for free winter blooming. A little sulphur is no bad thing for keeping mildew at a distance. Potted Cinerarias; pricked off and repotted Chinese Primulas. We will not trouble with Calceolaria cuttings until the end of October, if no frost threaten. Azaleas and Camellias set out of doors must have the pots defended from fierce sun. All the large Cactus tribe set out of doors, to have the stems well ripened by roasting against a fence, should have the pots pro-

tected from heavy rains. Lilacs, Deutzias, Prunus, Roses, &c., intended for forcing should now have all the sun possible, and water be gradually withheld, so that the tops may not suffer. Sweet Gardenias should now be kept rather dry and cool under glass, and then when set to work after the shortest day, or before it in moist heat, they will quickly swell and open their sweet blossoms. All the more tender greenhouse plants, as Croweas, Epacris, and even Heaths, should now, if not under glass, be protected from heavy rains, and also from frequent drizzling showers, as that helps much to bring on mildew. In fact, where room is abundant, Camellias, Azaleas, and such as the above in pots, will do better if always sheltered by glass in houses or pits, and shade, air, &c., given according to the requirements of the plants. Pelargoniums should now be pruned-in, cuttings inserted, and the first pruned back shaken out of their pots and repotted. Seeds of Pelargoniums may now be sown. In potting fancy Pelargoniums, the soil should be lighter, and the pots smaller, than for the larger florists' kinds. In both cases the pots should be thoroughly cleaned and well dried before using them, and the soil should be mellow, neither wet nor dry. Looked over climbers in the greenhouse, lessening their bulk, to give more light to the plants below, and but for expected bright weather would lessen the whitening shading, which saves watering, and enables a moist atmosphere to be kept up with greater ease. Did the same as respects the stove, thinned out the Passifloras, &c., considerably, and soaked Stanhopcias in baskets, in bloom, and out of bloom and coming into bloom. Potted and top-dressed Gesneras; Balsams, and many other softwooded plants now coming into bloom will be better of rich top-dressings of rotten dung. The roots are thus kept more equal as respects moisture and temperature, and that is a great means for keeping off spider and green fly.—R. F.

COVENT GARDEN MARKET.—AUGUST 25.

THE market is tolerably well supplied with both fruit and vegetables, there being plenty of Peaches from Jersey, and these keep the price of English fruit down. Green Gage and other Plums are scarce and command good prices. Pears consist of Beurré d'Amanlis, Bon Chrétien, and Jargonelle.

## TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to *The Editors of the Journal of Horticulture, &c.*, 171, Fleet Street, London, E.C.

**LATE STRAWBERRIES (P. J. Newton).**—The best late Strawberries are Frogmore Late Pine, Elton, and the new one called Dr. Hogg; the last is as late as either of the former, and has the favour of British Queen. The Hop will grow in any common garden soil. It likes manure. There is no better evergreen covering for the roof of your fernery than Ivy, and it grows as fast as any evergreen climber.

**ORCHARD-HOUSE TREES (C. P.).**—As soon as the fruit is gathered, cut off the roots that have penetrated into the border, but not before.

**VINE MILDEW (Rev. W. Gibbens).**—Your Vine is attacked with the Oidium. Lose no time in dusting every leaf and bunch of fruit with flowers of sulphur. Even now it may be too late.

**STAMORE LEAVES SPOTTED (K. K.).**—The spots are not the effect of a fungus, but the puncture of an insect. We have examined them carefully by the microscope, and there is no fungoid appearance.

**COMTE DE ZYANS STRAWBERRY.**—We have received several letters asking where the above variety may be obtained, and we beg to refer the writers to our advertising columns.

**MELONS (Malloic).**—In addition to Bromham Hall, Trentham Hybrid, and Scarlet Gem, you might have Orion and Scarlet Perfection. If you can give no things to your Melon-pit, it is not easy to give a regular heat to it by a dung-bed inside; but much may be done by using for the bottom of the bed dung hot and working, but not sweet or much decayed, and for the upper half dung well sweetened and wrought, and therefore more decomposed. The lower half will, therefore, naturally get rather dry. About half-way down the upper or sweet layer set some small drain-pipes standing upright above the soil, and as the heat lessens pour some warm water through them, which will thus gain access to the less reduced manure at the bottom, and cause it to ferment afresh. As to the soil sinking too far from the glass on such a bed, this can be guarded by training the plants over a simple trellis formed of wood, and wire, or even cord strained tight, trailing the Melon at first to one stem, and fastening that with such full play to the trellis that the sinking of the earth will do no harm. More anon.

**STRAWBERRIES (A Dull to be Laughed at).**—We never dig among our Strawberries. See last week's Journal. In your case we would trench the whole of your Strawberries down, and get young plants from a place where you know good crops are produced. That would be the quickest way for your securing a crop, for it is just possible, and likely even, that you have a barren lot that might with difficulty be rendered fruitful. Even then, with new plants, do not manure too highly.

**ASTERS DISEASED (Harry).**—We can assign no reason for the Aster leaves being so affected, unless they have been watered overhead with strong manure, sewage, or other water that might silt the roots, but will not suit the foliage.

**VIOLA CORNUTA (Devonensis).**—Your specimen of *Viola cornuta* was so much crushed that it was impossible to tell whether it was the right variety or not. Send a specimen in a small box, I shall then be able to decide.—J. WILLS.

**ONIONS AND SHALLOTS (Strasburg).**—We have no knowledge of the prices that are given to growers, and these depend very much on the quality. Ascertain the name of some salesman in the metropolitan markets, and write to him. You may apply to Mr. John Black, of Covent Garden.

**LABURNUM SEEDS (J. K. Currie).**—They are decidedly poisonous, being violently purgative and emetic, and should never be left within the reach of children or cattle.

**PROPAGATION OF EVERGREENS (Al Fresco).**—Cryptomerias, Thujsopsis, Thujas, and Wellingtonias are propagated freely by cuttings. Now is the time to take them off. Put them in pans or pots of silver sand, and place them in a cool frame, shading them well. Let them remain all the winter, protected from frost, and in spring plunge them in a gentle hot-bed, when they will very soon strike root. We shall see about the Vines for you and send over cuttings. Can you send a sucker of the Ailanthus? We should much like to see it. Judging from the leaf it will be a pretty thing. We have no recollection of ever seeing the former letter you allude to.

**ON THE VARIATION AND CROSSING OF PELARGONIUMS.**—I am exceedingly pleased with the remarks your correspondent, "C.," has made on the above subject. He has so well and so kindly handled the subject, that it is quite evident his only object is to bring out the opinions of others who may have noticed different facts which may help to elucidate this mysterious phenomenon. I shall again refer to the subject in a future paper; in the meantime I beg "C." to accept my thanks for the kind and able way in which he has taken my paper in hand, and shall be glad if he will favour me with his name and address.—J. WILLS.

**EVERGREEN SHRUBS UNDER AN OAK TREE (Felixstow).**—The following would answer well—*Berberis Darwinii*, *repens*, and *aquifolium*. *Cotoneaster microphylla* would also do, likewise *Aucuba*, which, however, may grow too tall. *Skimmia japonica* would probably succeed; and no plants would be better than the Periwinkles, or *Vincas*, and small-leaved Vines with plain and variegated leaves.

**PEACHES FOR SPAN-ROOFED HOUSE (A Subscriber).**—We would recommend you to get some of those new sorts raised by Mr. Rivers, which are infinitely superior in flavour to the old sorts. *Peaches*—Early Albert, Early Silver, and Nobless. *Nectarines*—Balgowan and Victoria.

**SELECT ROSES (S. A.).**—See "D." of Deal's paper in this Number.

**REPOTTING AN OLEANDER (C. M. Major).**—This plant does all the better when the roots reach the sides of the pot, and unless your plants in tubs are in bad health, we advise you to take away as much soil as you can around the sides, and replace it with fresh. The best time to shift them is in April and May, or just before they begin to grow.

**LILACS IN POTS (Ipswich).**—After the leaves have fallen choose the most dwarf and best furnished plants having a number of flower-buds, which may be distinguished by their being larger and more prominent than the wood-buds. Take the plants up with good balls of earth, and place them in pots of sufficient size to contain them, but not larger than is necessary to admit a tolerable ball. A pot 12 or 15 inches in diameter will in most cases be sufficient. The pots should be efficiently drained, and the soil may be any moderately light rich loam. After potting give a good watering, and plunge the pots in coal ash in a warm sheltered situation. The plants may be placed in your greenhouse shortly after Christmas, and if well exposed to the light they will flower in due season; but as you want them to bloom early, you may in the middle of November place them for a fortnight in a house with a temperature of from 45 to 50°, and then transfer them to a heat of 55°; if sprinkled overhead morning and evening, and properly supplied with water, they will come into fine bloom in about six weeks.

**PROTECTING PEACHES FROM WASPS (M. S. B.).**—The best safeguard against these is to cover the trees with hexagon netting. We are at a loss to know how you are to destroy or prevent woodlice eating the fruit, without at the same time having recourse to means that would injure the trees and crop at this season; but under similar circumstances we have scooped out the inside of Potatoes, and placed them in the forks of the branches with the holes next the wall. The woodlice find their way into the hollows of the Potatoes, and may be picked out with a pointed stick and thrown into a pail of boiling water. This considerably thins their ranks and saves the fruit, as they are equally, if not more, partial to the Potatoes as to the Peaches.

**RELAYING A LAWN (S. J.).**—You should now dig up the tap-rooted and other perennial weeds, as Dandelion, Plantain, Cock's-foot Grass, Bents, and Ranunculus, but if you cannot do this without destroying the lawn, we should take up as many as we possibly could without making it unsightly. Be content with the largest, and in February have the ground trenched deeply without bringing up too much of the subsoil, and if the surface is uneven take advantage of the opportunity to level it. The ground should lie until the first dry weather in April, and should then be well raked or harrowed if possible, making it very fine, and freeing it of stones. As soon afterwards as there is a prospect of rain, sow whilst the ground is dry, lightly rake the seeds in, and roll well the same day, and do not roll again until the seedlings are fairly above ground. If you were to have the ground dug now you might sow the seeds up to the middle of September, omitting the Clovers, and it would become green before winter, but unless your situation is favourable, many of the better kinds of Grasses would perish in winter. No one would think of sowing Grass seeds in February. The beginning of April is sufficiently early. If your lawn consists of little else but weeds, then we would recommend you to dig up the whole in autumn, fork out the worst Grasses and tap-rooted weeds, and, after placing them in a heap, to sprinkle over them one bushel of salt and a like quantity of lime to every cartload. At the end of a year, if turned once or twice, they will, when mixed with an equal quantity of manure, form an excellent compost for dressing the lawn in the autumn after sowing. During the autumn the ground may be forked over, and all weeds picked out, and in December it may be trenched, in which condition it may remain until the first dry weather in March. It may then be levelled, and treated as above directed. Allow the Grass to grow until the end of June or beginning of July, afterwards cut it every three weeks until the middle of September, then give a top-dressing of rich compost, and roll well, as you will do after the Grass is first cut.

**STOPPING THE SHOOTS OF PEACH AND PLUM TREES (Aynes).**—Stop those of the Peach at the third leaf, and those of the Plum at the fourth, and then at every leaf afterwards throughout the season, except the leaders, which are required to cover the wall, and should be trained in at their full length. The side shoots or laterals upon the Peach leaders are to be kept closely stopped to one joint. Upon the shoots of both trees you will find a number of short stabby shoots that do not grow more than 1 or at most 3 inches; these are to be left entire, but if they grow longer stop them.

**CUTTING-BACK PELARGONIUMS (Idem).**—Your plants which are now in full bloom may, when the bloom is going off, have a diminished supply of water, be kept dry for a fortnight or three weeks, and then be cut back. They will not flower so early as plants cut-in sooner, but they will, nevertheless, bloom well in June. The young plants, of which the wood is very soft and tender, should be rested for a time by keeping them dry at the roots, and should then be cut back. They will break strongly and make fine plants for summer bloom.

**STOPPING GERANIUMS (Idem).**—The cuttings put in now may be pinched back when they have struck to three joints, and when they have made three joints again they may have the point taken out, and this process may be repeated until the middle of April, when it should be discontinued. It does not interfere with the summer's bloom.

**CERASTIUM TOMENTOSUM CHOKED WITH WEEDS (Idem).**—We would advise your leaving the border of this *Cerastium* until autumn, and then taking up the best and best from weeds (which from what you state, we think must be of a perennial nature), plant it with the ball adhering in some sheltered situation, and in light dry soil. This will set the border at liberty so that it may be cleared of the weeds, and in the end of March or early in April it may be replanted with the *Cerastium*. Put in small pieces of the latter in lines 6 inches apart, and 3 inches from plant to plant. It will cover the ground by the middle of June, but will not flower to any extent, though, as a silvery-foliaged plant of low growth, it will be very ornamental.

**VARIEGATED GERANIUMS NOT BLOOMING (Idem).**—They do not usually flower so freely as the plain-leaved varieties, and the circumstance of yours having only a flower at the top is due to there being no side shoots. You may remedy this by stopping the plants in spring so as to make them bushy when planted out. Flower of the Day is not a shy bloomer, but as regards its foliage it is inferior to most of the kinds now in cultivation.

**SPOT ON ORCHIDS (Constant Reader).**—The spot on the leaf of *Isoetes odoratum* is caused in the first instance by some parasite, which is becoming very general in collections. We are unable to suggest a remedy, and should feel obliged if those having knowledge of the evil would favour us with their experience. Williams's "Orchid Guide" would suit you; that and Appleby's "Orchid Manual" are the best. You can have the latter, post free, from our office for thirty-two postage stamps.

**ROSE MILDEW** (*An Original Subscriber*).—To rid your trees of this pest, dissolve Gishurst compound in the proportion of 2 ozs. to the gallon of water, and apply it with a syringe.

**MELONS CRACKING** (*W. H. B.*).—The cause of this is the rind becoming hard before the growth has been completed, and generally from a deficiency of water whilst the fruit is swelling; then the soil or atmosphere becoming moister the fruit swells, and the rind being incapable of resisting the internal pressure cracks to make way for the increased growth of the fruit. We know of no remedy except keeping the soil well supplied with water and the atmosphere moist, affording also slight shade from bright sun from the time when the fruit is fairly set and swelling until it has attained its full size and become netted over, when the supply of water should be lessened, and the atmosphere kept as dry as possible until the fruit is ripe. If you allow the soil and atmosphere to become so dry as to check the growth of the fruit, and after the rind has become hard give moisture, some kinds of Melons crack. Melons require as much water when swelling as a Cucumber, and when ripening a very dry atmosphere.

**GLADIOLUS FAILURE** (*J. G.*).—We conclude that your plants go off in that mysterious manner which has caused dismay to most cultivators of Gladioli, and is now familiarly known as "rust." Your mode of culture is good, and we do not know in what way it can be improved on.

**HEATING SMALL GREENHOUSE** (*T. L. M.*).—The sanitary piping will answer the purpose equally as well as a fire, and we should by all means recommend you to use one large nine-inch in preference to two smaller ones, as it will be less liable to foul and be easier cleaned.

**VINES FOR A PIT** (*A Two-years Subscriber*).—In your pit you may plant two Vines as you propose, and train one 2 feet from the bottom across

the lights, and the other half way between that and the top. You may make a border for them outside, and at one end of the pit only; and if you could so contrive it that the Vines could have an inside as well as an outside border all the better; plant them inside. For one Vine we would recommend Black Hamburg, and for the other White Frontignan. Plant next March. It is not desirable, nor indeed prudent, to turn out the Vines, for we apprehend that you will not heat your pit more than will be sufficient to keep out frost, and that will not injure the Vines; but if you maintain a higher temperature than 40° it is well to turn them out, and in that case you must plant them outside.

**NAMES OF FRUIT** (*H. J. C.*).—No. 1, Royal George Peach; 2, Galande; 3, Grosse Mignonne. You should always send leaves with Peaches and Nectarines. The piece of a tree is Liquidambar styraciflua. The seedling Apple is worth keeping for the present. Send it again when ripe.

**NAMES OF PLANTS** (*Anglicus*).—Your Fern is *Asplenium trichomanes incisum*. Be good enough to inform us where you found the plant (*Shanbally*)—*Francoa ramosa*, (*D. Davis*).—1 and 2, Varieties of *Scopolendrium officinarum*; 3, *Phymatodes*, too imperfect; 4, *Nephrodium molle*; 5, *Campyloneuron lanceolatum* (?); 6, *Polystichum aculeatum*. (*R. T. M.*)—*Francoa sonchifolia*, (*Archeaple*).—*Adiantum formosum*. (*Miss E. Jarret*).—The whole of your specimens were unnumbered—*Adiantum concinnum*, *A. macrophyllum*, *A. diaphanum*; others incomplete. (*R. H. A.*)—1, *Blechnum* sp. (?); 2, *Adiantum formosum*; 3, *A. cuneatum*; 4, *Pteris longifolia* var. *serotula*; 5, *Polypodium vulgare* var. *cambriacum*; 6, *Lastræa decurrens*; 7, *Phymatodes vulgaris*; 8, *Doodia media*; 9, *Asplenium obtusum*; 10, *Pellaea edentifolia*; 11, *Davallia emarginata*; 12, *Scopolendrium officinarum*; 13, *Asplenium bulbiferum*; 14, *Thamnopteris australis*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending August 25th.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.
	Max.	Min.	Air.		Earth.				
			Max.	Min.	1 ft. dp.	2 ft. dp.			
Sun... 19	29.829	29.769	77	54	60	58½	S.W.	.08	Fine; very fine; rain, fine; warm at night.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

EXHIBITION POULTRY.

As unless the fowls possess the necessary merit and the qualifications that are likely to insure success, no amount of training or preparation will supply these, it is most important to impress on exhibitors that every bird intended for competition should undergo a strict examination. Pinstaking tends only to develop good points, no amount of condition will supply a want or conceal a defect. The good points in question are so well known that it would seem more than unnecessary to dwell upon them, but even old exhibitors sometimes make mistakes which are so grave that a little mention by way of illustration may not be out of place. Thus, in Dorkings, well-defined five claws, and cock's spurs in their right places; in Poland's, neither spikes nor gills; in Hamburgs, good white deaf ears; in Spanish, the cock's comb upright, the hen's drooping over, and perfectly white faces; in Game cocks perfectly straight breast bones; in Cochins, straight combs. Such remarks might be multiplied to almost any extent, but we have mentioned enough to show the strict examination that is necessary.

Although perfection may be impossible, all try to approach as nearly to it as may be, and it is often a matter of wonder, that among so many capital birds there should be so few that will meet all the requirements of their owners. Where the run is a good one and not overstocked, we are great advocates for allowing fowls their full liberty. They maintain a freshness of plumage, and a brightness of condition that have great charms in an exhibition pen. If four birds are wanted, twelve should be selected some time before they have to be shown. This guards against accidents, and gives a good choice at the last. Where two pens have to be shown in the same class, it is most important that every effort should be made to make the first pen perfect. Many prizes are lost by those who have good birds, and who, showing two pens in one class, give themselves worlds of trouble to make them even, which means two high commendations, whereas if the best birds of the two pens were put together, they would probably be among the prize-takers, perhaps the first. It is a mistake to hold antagonists

cheap, or in these matters to be satisfied with mediocrity. It is also well to recollect, that where the competition is very close, a mere trifle will decide—one of those things that are often declared to be of no importance whatever. It is a matter of great importance to exhibit fowls that agree. To ascertain this point they must be shut up together at times. Fowls will agree running about, that will fight to the death in confinement, and there is no prize for fighting birds; the beaten hen or pullet spoils the pen. A first-prize pen must not only be free from defects that disqualify, it must possess the characteristics that insure success: thus, no perfection of plumage or shape in a Dorking will compensate for lack of size; no stature, carriage, or condition in a Spanish cock will wipe out a red spot over the eye.

It is a mistake in the treatment of exhibition fowls to endeavour to do all in the last few days before competition. Half the food that is wasted in the last week in the vain endeavour to get weight by overfeeding, would, if given a little at a time and spread over some weeks, realise all that can be reasonably expected. Fat is not condition; overfeeding produces fat, and spoils plumage by making it soft and hollow. Where weight is required we advise a little increase in food for fourteen weeks before exhibition, and it is also well to vary it as much as possible. It is the real hard flesh that weighs, and which tells in a judge's hands. We know no food that does better than ground oats, slaked at times with milk, kitchen and table scraps, good barley, and plenty of green food. Damaged bread and ship-biscuit are excellent food, with now and then a meal of tallow-chandler's greaves.

We believe that almost all birds should be at liberty till they are wanted for showing. There are, however, exceptions; Spanish require to be in confinement several days before they are shown and they should be kept in semi-darkness. The less light they have the whiter their faces become. It was a tradition very many years ago that white peas made the faces white. Peas are given to Game cocks to harden feather. Some of the feather birds require to be washed; Hamburgs, Poland's, and the like often need such assistance. The plumage is washed with a sponge dipped in cold water, with a little soap; it does not need much washing, and it is only that part which is in contact with the atmosphere that is dirty. After being washed the bird should be put in a basket with some soft oat straw,

and placed near a fire till dry. It must not be at liberty any more till after the show. We have known Poland exhibitors who for days before a competition confined all top-knots with indian-rubber bands in order to keep them clean. Fowls should be sent to shows with clean legs. They should be liberally fed on soft food before they start, and should be packed in round baskets that will allow them to stand upright without injury or inconvenience to their combs. Many Spanish cocks have lost prizes by being put in baskets that would not allow the bird to stand up without pressing the comb down. The bottoms of all baskets should be covered with straw, and if it can be arranged, fowls should travel by night. On this latter point we are of opinion that where fowls are received during the whole day previous to an exhibition, those which are sent by a night train, and arrive early in the morning, are tenfold gainers by their few hours of extra confinement, owing to the care and comfort bestowed on their unpacking and feeding while there are few birds to attend to compared to the hurry of the evening, when all arrive *en masse*.

### VULTURE HOCK IN COCHINS AND BRAHMAS.

HAVING a slight remembrance of some conversation with a friend about vulture-hocked Brahmans, I take the blame, if any exist, of answering the charge (which seems to have impressed itself so strongly upon the mind of your correspondent "JUSTITIA," "that the vulture hock was a sign of weakness in the leg-joint." "JUSTITIA" is troubled with a bad memory, or he would remember some other points in the statements he only partially announces. The reply I gave was not definite, and the point alluded to was a portion of a question put, to which I received no reply—viz., as "to whether vulture hocks, like a cat-hocked horse, were not a sign of, or resulting from, weakness in the leg-joints." As my words have been so far misconstrued, I will venture to give my own opinion upon the subject, and reply to "JUSTITIA" at the same time.

"JUSTITIA" alludes to the so-called challenge of "Y. B. A. Z." not being replied to. I considered the subject discussed and proved against the vulture hock, and that it was actually of recent introduction. I have not observed judges make alteration in the acknowledged standard of excellence in poultry; they could not do so. The question is not "an open one," it has been definitively settled: it, therefore, should not "unsettle breeders;" if it do so it is their own fault, as the consequences are known beforehand. I never met with breeders who admired vulture hocks. The lady alluded to truly says, "There must be a tendency to vulture hocks." This is a long way from actually being so. It is not one judge but all who exclaim against them. The Birmingham judges will, I have no doubt, act according to the acknowledged standard, and not merely to suit the few who happen to breed vulture hocks, and have thereby become attached to them. The rule to disallow them is old, to allow them would be new. If by agitation the rule could be set aside, then birds of both kinds might be shown, but for my part I do not see any good reason for doing so.

In conclusion, I beg to say I have a friend who has kept Brahmans from the earliest importation, and he quite agrees with the remarks made by the judge who replies to "JUSTITIA," that vulture hocks are a new introduction. As far as my own experience is concerned, I have always found vulture hocks most frequent amongst leggy birds, and whether you look at them sideways or in front, they appear knock-kneed and weak, and continually desiring to sit down.

It is well known that Dorkings have been crossed with Cochins to give them stamina, and birds have actually been exhibited with feather stubs still peeping through the scales of the legs—perhaps our friend "JUSTITIA" would have awarded such birds a high premium; I should not, because they are evidently a fresh importation, and should be treated only as a cross deserves.

I think it would be much more correct to make a fresh class for White Brahmans than for vulture-hocked, since most of last year's winning birds were without any pencilling in the neck hackles, and the preference was given invariably to size, and not to markings, as it should be according to rules.—F. C.

Why should one judge rule against all fanciers? Why do not the Brahma fanciers demand a poll? I do not quite agree with "CLEMENS," for I think exhibitors are most to blame, and while they are content to have their just complaints set down

as the grumblings of "disappointed exhibitors," how can they expect any redress? Though I am not at present a breeder of either Cochins or Brahmans, yet my opinion would lead me to advocate the whole vulture hock.—B. P. BRENT.

### KINGSWOOD POULTRY SHOW.

My only association, until yesterday, August 22nd, with Kingswood, near Bristol, was the preaching of Whitefield to the colliers, some of whom came with brickbats and fool's cap to injure and insult the preacher, but stayed with tears on their blackened cheeks beseeching his forgiveness, and praying his further instruction. I shall now, in addition, connect Kingswood with the sight of a very pretty flower show, and a spirited first attempt at a poultry show. Kingswood is not an easy place to reach from Wiltshire, at least now that railways have made most places so easy of access, and we have come to think a few miles of hilly road terrible to face. I determined to go on to Bristol rather than stop at Keynsham, being afraid of not obtaining a conveyance there.

Entering Bristol station I noticed amid the smoke, dirt, and blackness, a bright little garden amid the great breadth of railway lines crossing and recrossing each other. It belonged to a pointsman, who had also decorated his black sentry-box with creepers. The garden was a perfect little gem, though only a few feet square. Pointing out this specimen of gardening under difficulties to a surgeon, *my vis-à-vis* in the carriage, I said, "That's a good sign." "Yes," he replied, "I never knew a drunkard who took pains with his garden." I found that Kingswood was four miles from Bristol, and "four such miles!" said the cabman. Once started, I thread the narrowest and dirtiest of streets, the abodes of the lowest class—streets ripe and ready for the cholera—the adults begrimed, the little children like half-washed chimney-sweeps. Onwards and always upwards we go. I was early and quite alone on the road. After the thickly crowded streets are passed, blackened cottages succeed, everything has a collier look. Whitefield, a great orator, but no organiser, had left no enduring mark upon Kingswood. Not so quiet John Wesley; Wesleyan chapels and "Wesley Buildings" are there. Still upwards I climb and reach Kingswood village, which had put out its flags for a gala day. Small flags peep out at bedroom windows, larger ones float over our heads, little collier boys cheer me—no, my horse, as I pass along. Turning down a lane I at length get into the pure country, and stopping at a gate enter a park in which the Show is held. It proves to be the park of Mr. Budgett, the son, I believe, of the Mr. Budgett whose memoirs under the title "The Successful Merchant," have found their way into many homes. He was one who rose to wealth by industry, and better still, set a good example by his princely liberality and Christian kindness.

I arrived early, imagining that the Show would be opened at twelve o'clock, but it was not so. However, no one barred the way to "WILTSHIRE RECTOR;" he walks in, the attendant policemen doing him reverence, and no question, and not even a ticket asked for. Possibly the "WILTSHIRE RECTOR" was taken for some Canon, or even—who knows?—for the Dean of Bristol—some one so great that no ticket was required of him. The Judges are at their work, so I find a seat out in the open, and watch and enjoy the proceedings. I note the bustle and eager desire to have everything proper on the part of the officials. I listen to the marvellous Gloucestershire dialect of the workmen who are busy around me. I enjoy the pretty views, and half-doing look-on at the bedding plants in the garden a little way off. At length one o'clock comes, and with it a band enters, then a second band, and the Show is open.

I walk straight to the poultry tent. It is of the "Classes open to all England," that I shall speak. It must be borne in mind that this was the first poultry show at Kingswood, and that the time of year is against showing birds. Indeed, I was surprised to see so many in good plumage. The great desire of the Committee was to bring together, by offering liberal prizes, at any rate a few good birds, and this wish was realised.

In Spanish Mr. Parsley, of Bristol, took the first prize with birds which were very superior. Mr. T. Bamfield, of Clifton, was second. In Dorkings and in Buff Cochins Miss Milward was first. Mr. Rodbard was first and second in Partridge Cochins, all his birds in this class being of great merit. The Game was the largest class. It is wonderful how all over England the Game fowl is beloved. Mr. Dupe, of Everecreech, was first with a pen of Brown Game, which were to my thinking the gems of the Show. Mr. Dupe took second with Duckwings—indeed he carried off all the honours: his three pens were a pleasure to look at as they stood side by side. Brahmans were more numerous than Cochins. The best pen was Mr. Boyle's. Rev. C. L. Crawley had his usual place with Sebright *La-stams*, and Mr. Rodbard carried off the second Bantam prize with a pen of very good coloured Duckwings. The special prizes for the best cockerels of any variety, offered by Mr. Rodbard, fell to a good Spanish cockerel belonging to Mr. Parsley: the second to a bird belonging to Mr. Roberts, while Mr. Cornwall's Dorking was commended. The Rev. Mr. Hodson, of North Petherton, acted as poultry Judge.

While looking at the poultry a number of "Reformatory" boys passed through—very little boys they were. I was delighted to see

the little fellows at the Show; such a sight would not, I am sure, hinder their reformation.

Besides the poultry tent there was a large one for flowers; another of equal dimensions for cottagers' flowers, fruits, and vegetables; and a third in which were table decorations, principally flower-vases, in which the flowers were very tastefully arranged by fair fingers, though I fear I saw nothing very new.

At three o'clock I left the Show, and met visitors pouring in as fast as possible, admitted through Mr. Budgett's pretty garden, through which also I made my exit, and reached with difficulty my cab; for now the village street was crowded with carriages, and people on foot, and a pleasure fair was in its full glory.

One final word. I would strongly recommend the poultry Show to be in future held in Bristol; it would be easy of access, and certain to be large and well attended. Let my good friends at Kingswood and the fowl-loving Bristolians lay their managing heads together.—WILTSHIRE RECTOR.

## ALDBOROUGH (BOROUGHBRIDGE) POULTRY SHOW.

THE sixth annual Show was held in the park adjoining Aldborough Manor on Thursday the 17th inst. The day was rather unfavourable, rain falling very heavily during the forenoon, which prevented many visitors from attending. The entries were not numerous, but some good specimens were exhibited. The following are the awards:—

**DORKINGS** (Coloured).—First, O. A. Young, Driffield. Second, J. Bell, Thornton-le-Moor. *Chickens*.—First, T. Mason. Second, J. Bell.

**SPANISH** (Black).—First, O. A. Young. Second, M. & R. Gray, Borough-bridge.

**GAME** (White and Pile).—First, W. Calvert. Second, O. A. Young. *Chickens*.—Prize, W. Calvert.

**GAME** (Black-breasted and other Reds).—Prize, W. Bearpark, Ainderby Steeple. *Chickens*.—First, J. Bell. Second, Mrs. Ward.

**COCHIN-CHINA**.—Prize, J. Walker. *Chickens*.—Prize, J. G. Milner.

**HAMBURGS** (Golden-spangled).—First, J. Topham, Boroughbridge. Second, J. Walker. *Chickens*.—Prize, J. Gatenby.

**HAMBURGS** (Golden-pencilled).—First, O. A. Young. Second, J. Walker.

**HAMBURGS** (Silver-spangled).—First, O. A. Young. Second, J. Walker.

**HAMBURGS** (Silver-pencilled).—First, J. Walker. Second, H. S. Hardcastle, Hunsingore.

**POLANDS**.—First, O. A. Young. Second, W. Lonsdale.

**BRAMA**.—Prize, E. Graham. *Chickens*.—Prize, E. Graham.

**BANTAMS** (White).—Prize, O. A. Young. *Chickens*.—Prize, C. P. Andrews, Aldborough.

**BANTAMS** (Game).—First, O. A. Young. Second, M. & R. Gray.

**ANY OTHER DISTINCT BREED**.—Prize, O. A. Young.

**FARMYARD CROSS**.—First, S. Robson. Second, W. Bickerdike.

**EXTRA STOCK**.—Prize, Miss Norfolk.

**TURKEYS**.—Prize, L. Moorey, Mulwith. *Poult.*—First, Mrs. Maynard. Second, L. Moorey.

**GEESE**.—First, O. A. Young. Second, I. Moorey. *Goslings*.—First, Hattersley & Wilson, Thirsk. Second, I. Moorey.

**DUCKS** (Aylesbury).—First, O. A. Young. Second, J. Cuthbertson.

**DUCKS** (Rouen).—First, E. Graham. Second, Miss Lawson. *Ducklings*.—First, W. Bearpark. Second, Miss Lawson.

**DUCKS** (Any other variety).—First, J. G. Milner. Second, S. Robson.

**GUINEA FOWLS**.—First, O. A. Young. Second, I. Moorey.

**PIGEONS**.—*Croppers*.—Prize, Hattersley & Wilson. *Carriers*.—Prize, G. Sadler. *Trumpeters*.—Prize, G. Sadler. *Jacobins*.—Prize, Lofthouse and Eglin. *Fantails* (White).—Prize, Lofthouse & Eglin. *Tumblers*.—Prize, G. Sadler. *Dragons*.—Prize, Hattersley & Wilson. *Barbs*.—Prize, Lofthouse & Eglin. *Nuns*.—Prize, Hattersley & Wilson. *Turbits*.—Prize, G. Sadler. *Any other variety*.—Prize, Hattersley & Wilson.

**SELLING CLASS** (Any variety).—Prize, G. Sadler.

**RABBITS** (Fancy).—First, O. A. Young. Second, Mrs. Slade.

The Judges were Mr. Jolly and Mr. Hunter.

## DRIFHLINGTON AND ADWALTON POULTRY SHOW.

(From a Correspondent.)

THE eleventh annual Show of the Drifhlington (near Leeds) Agricultural Society was held on Saturday the 18th inst. The show of poultry was scarcely equal to that at previous exhibitions. Except the class in which a cup was offered for the best pen of any breed the Show was well judged; but in this class the cup was given to a pen of Black Red Game which could not have won in its own class, being, to say the least, exceeding poor, while a magnificent pen of Gold Poland and an excellent pen of Spanish were passed over. The cock in the cup pen was in the worst condition and feather, and very much duck-footed; while the hen was more like a Dorking in shape, and altogether out of condition.

(From another Correspondent.)

THE prize for Black Spanish went to Mr. Thresh, whose birds were good, more especially the hen. The second-prize birds of Mr. Beldon's were of average merit. The *Dorkings* were not first-class. The *Cochins* were rather inferior to what we have seen. In Black-breasted and other Reds some good birds were shown. Mr. Nolle showed excellent Black Game. In the *Hamburg* classes Mr. Beldon as usual showed good birds. His Silver and Golden *Polands* were also much admired.

In *Game Bantams* Mr. Noble, who took the first prize, had a good pen. In the class for any variety of *Bantam* Mr. Hutton was first with a very superior pen of Blacks. The second-prize pen was also good. The class for the best cock of any breed brought together some excellent birds, Mr. Beldon taking the first prize with a splendid Buff Cochin; indeed had this bird been shown in the cup class with a hen of equal merit, no doubt he would have taken the first position. The second prize went to a very good Black Red Game cock, the property of Mr. Nolle. Mr. Thresh taking third with a very fair specimen of Black Spanish. For the best pen of poultry Mr. Fell took the cup with Black Red Game. The entry in this class was small, but the birds were of average merit. The classes for *Pigeons* were not well filled.

**SPANISH**.—First, J. Thresh, Bradford. Second, T. Greenwood, Dewsbury.

**DORKING**.—First and Second, H. Beldon, Goitstock, Bingley.

**COCHIN**.—First and Second, H. Beldon.

**GAME** (Black-breasted or other Red).—First, H. Beanland (Black-breasted). Second, H. Beldon.

**GAME** (Duckwing or other Grey or Blue).—Prize, J. Fell & Sons, Adwalton (Duckwing).

**GAME** (White or Pile).—First, W. Walker, Gomersal. Second, G. Hartley (Pile).

**GAME** (Black or Brassy-winged).—First, G. Noble, Staincliffe (Black). Second, G. Hartley (Black).

**HAMBURGH** (Golden-spangled).—First and Second, H. Beldon.

**HAMBURGH** (Silver-spangled).—First and Second, H. Beldon.

**HAMBURGH** (Golden-pencilled).—First and Second, H. Beldon.

**HAMBURGH** (Silver-pencilled).—First and Second, H. Beldon.

**POLISH**.—First and Second, H. Beldon.

**ANY DISTINCT BREED NOT MENTIONED IN THE ABOVE CLASSES**.—First and Second, H. Beldon.

**GAME BANTAMS**.—First, G. Noble. Second, S. Schofield, Heckmondwike.

**BANTAM** (Any other variety).—First, E. Hutton, Pudsey. Second, S. Schofield.

**GUINEA FOWLS**.—Prize, H. Beldon.

**GEESE** (Any breed).—Prize, J. Ward, Drighlington.

**DUCKS** (Aylesbury).—First, J. Garforth, Drighlington. Second, B. Bentley, Birstal.

**DUCKS** (Rouen).—First and Second, J. Ward.

**ANY BREED**.—First, H. Beldon. Second, G. Noble. Third, J. Thresh (Black Spanish). Fourth, J. Fell & Sons. Fifth, J. Gott, Adwalton.

Sixth, H. Beanland.

A SILVER CUP GIVEN FOR THE BEST PEN OF POULTRY.—Cup, J. Fell and Sons.

**PIGEONS**.—*Posters*.—Prize, J. Thompson, Bingley. *Carriers*.—Prize, E. Peel, Birkenshaw (White). *Dragons*.—Prize, J. Thompson. *Antweps*.—Prize, E. Hutton. *Barbs*.—Prize, J. Thompson. *Owls*.—First, J. Thompson. Second, J. Clayton, Drighlington. *Turbits*.—Prize, J. Thompson. *Archangels*.—Prize, J. Thompson. *Any other variety*.—First, J. Thompson. Second, J. Oxley (Balpates).

The Judges were Stephen Barrett, Esq., Harewood, and J. W. Thompson, Esq., Southwram, Halifax.

## HALIFAX AND CALDER-VALE POULTRY SHOW.—AUGUST 25TH.

THE following are the awards made on this occasion:—

**SPANISH**.—First, Messrs. Burch & Boulter, Sheffield. Second, J. Thresh, Bradford. Third, H. Beldon, Bingley. *Chickens*.—First, J. Pindar, Clitheroe. Second and Third, H. Pickles, jun., Earby, near Skipton.

**DORKINGS**.—First, D. White, Driffield. Second, J. Pindar. Third, Hon. H. W. Fitzwilliam, Wentworth Woodhouse, Rotherham. *Chickens*.—First, Hon. H. W. Fitzwilliam. Second, Rev. J. F. Newton, Kirby-in-Cleveland. Third, F. Key, Beverley. Commended, H. Savile, Ollerton, Notts; H. Beldon.

**COCHIN-CHINA** (Cinnamon, Buff, or Lemon).—First, W. Harvey, Sheffield. Second, T. Stretch, Ormskirk. Third, W. Wood, Wadley, Sheffield. *Chickens*.—First, C. Spencer, Attleborough, Norfolk. Second, C. W. Brierley, Middleton. Third, J. Stott, Rochdale.

**COCHIN-CHINA** (Partridge).—First, C. W. Brierley. Second, T. Stretch. Third, W. Gamon, Thornton-le-Moors. *Chickens*.—Prize, T. Stretch.

**COCHIN-CHINA** (Black, White, or any other variety).—*Chickens*.—Second, G. E. Farnell, Queensbury. Third, Mrs. Dale, Scarborough.

**BRAMAH POOTRA** (Light).—Second, E. Pigeon, Lympstone near Exeter. Third, F. Crook, Forest Hill, Kent. *Chickens*.—First, E. Pigeon. Second, F. Crook. Third, H. Savile, Ollerton, Notts.

**BRAMAH POOTRA** (Dark).—First, G. H. Roberts, Penwortham, Preston. Second and Third, J. H. Pickles. *Chickens*.—First, R. W. Boyle, Bray, Co. Wicklow, Ireland. Second, G. H. Roberts. Third, J. H. Pickles. Commended, J. H. Pickles.

**SINGLE GAME COCK** (Any colour).—Cup and First, C. W. Brierley. Second, J. Fletcher, Stoucclogh, Manchester. Third, J. Mason, Worcester.

**SINGLE GAME HEN** (Any colour).—First, R. Pashley, Worksop. Second, C. W. Brierley. Third, Hon. H. W. Fitzwilliam. Commended, T. West, Eccleston, St. Helens.

**GAME** (Black-breasted Red).—First, J. Firth, Dewsbury. Second, T. Bottomley, Shelf. Third, W. Gamon. *Chickens*.—First, J. Hudson, Bradford. Second, J. Firth. Third, G. Noble.

**GAME** (Brown-breasted and other Red).—First, J. Firth. Second, W. Gamon. Third, J. Spencer, Queensbury. *Chickens*.—Cup and First, J. Firth. Second, J. Wood. Third, H. Beldon.

**GAME** (Duckwing Grey and Blue).—First, J. Fletcher. Second, W. Boyes. Third, W. Gamon. Commended, J. Firth. *Chickens*.—First, A. Hodgson. Second, J. Firth. Third, W. Whiteley.

**GAME** (White and Piles).—First, W. Gamon. Second, W. Charter, Driffield. *Chickens*.—First and Second, R. Pashley. Third, G. Hartley.

**GAME** (Black or any other).—First, J. Fletcher. Second, G. Noble, Dewsbury. Third, J. Ibbetson, Leeds. *Chickens*.—First, G. Hartley. Second, J. Ibbetson.

**SINGLE GAME COCKEREL** (Any colour).—First, J. Fell, Leeds. Second, G. Noble. Third, T. Bottomley.

**SINGLE GAME PULLET** (Any colour).—First and Second, H. Crossley, Halifax. Third, G. Noble. Commended, R. Pashley.

**POLANOS**.—First and Second, H. Beldon. Third, S. Shaw. *Chickens*.—First, H. Beldon. Second, H. Bowker, Keighley. Third, J. Bowker.

**HAMBURGS** (Golden-pencilled).—First, R. Hemingway, Shelf. Second, H. Beldon. Third, S. Smith. *Chickens*.—First, H. Beldon. Second, S. Smith. Third, F. Hollings, Bradford. Commended, W. Stansfield, jun., Todmorden.

**HAMBURGS** (Silver-pencilled).—First and Second, H. Beldon. Third, J. F. Powers, Biggleswade Beds. *Chickens*.—First and Second, H. Beldon. Third, W. Bastow.

**HAMBURGS** (Golden-spangled).—First, H. Beldon. Second, W. Throup, Shibden. Third, J. W. Cannan, Bradford. *Chickens*.—First, J. Roe, Hatfield near Manchester. Second, H. Beldon. Third, J. W. Cannan.

**HAMBURGS** (Silver-spangled).—First and Second, A. K. Wood, Burnside, Kendal. Third, H. Beldon. Commended, A. Woods, Liverpool. *Chickens*.—Cup and First, H. Beldon. Second, J. Fielding, Manchester. Third, J. Walker, Knarborough.

**HAMBURGS** (Black, White, or any other variety).—First, C. Sidgwick, Keighley. Second, H. Beldon. Third, S. Shaw. *Chickens*.—First and Second, C. Sidgwick. Third, S. Shaw.

**ANY OTHER DISTINCT BREED, EXCEPT BANTAMS**.—First, Hon. H. W. Fitzwilliam. Second and Third, National Poultry Company (La Fleche, Houdan). Commended, E. Pizon; G. Viney, Halifax. *Chickens*.—First, Second, and Third, National Poultry Company.

**SINGLE GAME BANTAM COCK**.—First, J. Rhodes, Wakefield. Second, W. Beutley, Scholes, Cleckheaton. Third, G. Manning, Essex.

**GAME BANTAMS**.—First, G. Noble. Second, C. W. Brierley. Third, J. Walker.

**BANTAMS** (Gold or Silver-laced Sebright).—First and Second, F. L. Roy, Kelso. Third, S. & R. Ashton, Manchester. Commended, T. E. Harriod, Kendal.

**BANTAMS** (Any other variety).—First, S. Rhodes (Black). Second, W. Harvey (Japanese). Third, J. W. Cannan (Black). Commended, Enoch Hutton, Leeds; E. Cambridge, Bristol.

**DUCKS** (Aylesbury).—First and Third, Mrs. Seamons, Aylesbury. Second, E. Leech. Commended, E. Leech.

**DUCKS** (Rouen).—First and Third, S. Shaw, Stainland. Second, W. Bentley.

**DUCKS** (Any other variety).—First, H. Savile. Second, Sir H. Edwards, Bart., M.P., Halifax. Third, S. Shaw.

**GESE**.—First, E. Leech. Second, C. W. Brierley. Third, O. A. Young, Driffield. *Goslings*.—First, W. Gamon. Second, Mrs. M. Seamons. Third, S. H. Stott.

**TURKEYS**.—First, S. H. Stott. Second, E. Leech, Rochdale. Third, Mrs. Dale. *Poults*.—First, Mrs. Dale. Second, J. Clegg, Gentland. Third, E. Leech.

**SELLING CLASS** (Any Breed).—First, H. Beldon (Spanish). Second, T. Pomfret, Preston (Drahmas). Third, C. W. Brierley.

**EXTRA STOCK** (Poultry).—First, Sir H. Edwards, Bart., M.P., Halifax (Black Swans). Second, H. Savile (Dorking Pullets).

**EXTRA STOCK** (Rabbits).—Commended, Master H. Adams, Halifax (Angora); J. Fleming, Halifax (Spanish); W. Wright, Halifax (Spanish).

**PIGEONS.**

**POWTERS OR CROPPERS**.—First, R. Fulton, London. Second, W. Harvey, Sheffield. Highly Commended, R. Fulton; H. Beldon. *Hen*.—First, J. Thackray, York. Second, W. Harvey. Highly Commended, R. Fulton; E. E. M. Roys, Rochdale.

**CARRIERS**.—First and Cup, T. Colley, Sheffield. Second, M. Hedley, Surrey. Highly Commended, H. Hedley; E. E. M. Roys. *Hen*.—First, M. Hedley. Second, R. H. Artindale. Highly Commended, J. R. Robinson, Sunderland.

**TUMBLERS** (Almond).—First, R. Fulton. Second, F. Crossley, Elland.

**TUMBLERS** (Mottled).—First, E. E. M. Roys. Second, S. Shaw.

**BALDS OR BEARDS**.—First, J. Fielding, Rochdale. Second, E. E. M. Roys.

**OWLS**.—First, J. R. Robinson. Second, J. Fielding, jun.

**TURBITS**.—First, J. Wade, Ovenden. Second, J. Holden, Bradford. Highly Commended, J. Percivall, London.

**JACOINS**.—First, F. Key, Beverley. Second, S. Shaw.

**FANTAILS**.—First, J. Thackray. Second, H. Yardley. Highly Commended, H. Yardley; J. R. Robinson; S. Shaw.

**BARNS**.—First, J. Thackray. Second, J. Firth, jun., Halifax. Very Highly Commended, S. Shaw. Highly Commended, J. R. Robinson.

**DRAGONS**.—First, J. Percivall. Second, F. Crossley. Highly Commended and Commended, H. Yardley.

**TRUMPETERS**.—First and Second, S. Shaw. Very Highly Commended, J. R. Robinson.

**MAGPIES**.—First, S. Shaw. Second, J. Thackray.

**ANY OTHER BREED**.—First, J. J. H. Stockall, Liverpool. Second, National Poultry Company.

**SELLING CLASS**.—First and Second, J. Fielding, jun. Highly Commended, F. Broemel, Kent.

**EXTRA STOCK**.—First, T. Colley. Second, J. Fielding.

**JUNGES**.—*Poultry*: Mr. R. Teebay, Fulwood, Preston; Mr. M. Hedley, Redhill, Surrey; and Mr. J. Douglas, Clumber. *Pigeons*: Mr. Harrison Weir, Peckham, London.

**MOTTRAM POULTRY SHOW.**

THE second annual Show of the Mottram Society took place on Monday the 20th of August. In number of entries and quality of stock the Exhibition was much better than its predecessor. There were upwards of two hundred pens of poultry and Pigeons. Among *Dorkings*, *Spanish*, and *Cochins* there were some excellent pens, especially those from Messrs. Burch & Boulter and Mrs. Sugden. *Game* were worthy of notice, though not well matched in leg; but among the young *Reds* some very good pens were shown. *Gold* and *Silver Pencils* were altogether bad, but the *Spangles* of both varieties were better, though the cockerels of the *Silvers* were not good; but among

the *Golden* were some of the best pens seen this season. The *Poland* and *Variety* classes were not good. The *Game Bantams* contained some perfect pens; but the *Black* and *White Bantams* were not good. Some very good *Gold-laced Bantams* won, but the *Silvers* were out of condition. *Rouen Ducks* were a most excellent class, scarcely any pen of which was left unnoticed. Some pretty little *Teal* were first in the *Variety* class, and *Domesticated Wild* were second. *Turkeys* and *Geese* were very large, and shown in excellent feather. In *Pigeons* the most noticeable pens were the *Kites*, *Owls*, and *Barbs* sent by Mr. Fielding, and the *Almonds* exhibited by Messrs. Roys. The extra prize for the best pen in the Show was awarded to a splendid pen of *Golden-spangled chickens* of this year, though very closely run by the pen of old *Spanish* from Messrs. Burch & Boulter and a capital pen of *Grouse Cochins* from Mrs. Sugden.

**DONKINGS** (Any variety).—First, Messrs. S. & R. Ashton, Mottram. Second, W. Parr, Manchester. *Chickens*.—First, E. Leech, Rochdale. Second, Messrs. S. & R. Ashton.

**SPANISH**.—First, Messrs. Burch & Boulter, Sheffield. Second, T. Walker, jun., Denton, near Manchester. *Chickens*.—First and Second, Messrs. Burch & Boulter.

**COCHINS** (Any variety).—First, W. A. Taylor, Manchester. Second, J. Nelson, Manchester. Highly Commended, T. Hardcar, Manchester; H. B. Whittaker, Alkington. Commended, T. Maxwell, Salford. *Chickens*.—First and Second, The Hon. Mrs. Sugden, Cheshire. Highly Commended, W. Bamford; D. Bamford; T. Wrigley, jun. Commended, J. Thorneley, Hatfield.

**GAME** (Black-breasted and other Reds).—First, W. Gamon, Chester. Second, J. Jackson, Lancashire. Highly Commended, E. B. Sugden, Nantwich. Commended, J. Hilton, Booths Town Bridge. *Chickens*.—First, W. Gamon, Chester. Second, E. B. Sugden.

**GAME** (Any other variety).—First, W. Gamon. Second, S. and R. Ashton, Mottram. *Chickens*.—First, C. Shepley, Mottram. Second, J. Shepley, Mottram.

**HAMBURGS** (Gold-pencilled).—First, T. Wrigley, jun., Middleton. Second, Messrs. S. & R. Ashton. *Chickens*.—First, W. Parr, Patrierott. Second, T. Wrigley. Highly Commended, G. Geast, Chadderton near Middleton. Commended, T. Wrigley, jun.

**HAMBURGS** (Silver-pencilled).—First and Second, Messrs. S. & R. Ashton. *Chickens*.—First, W. Parr. Second, Messrs. S. & R. Ashton.

**HAMBURGS** (Gold-spangled).—First, J. Buckley, Taunton, Ashton-under-Lyne. Second, Messrs. S. & R. Ashton. Highly Commended, J. Andrews, Ashton-under-Lyne. Commended, W. Parr. *Chickens*.—First and Premium Prize, Messrs. S. & R. Ashton. Second, A. Ludlam, Mottram. Highly Commended, J. Andrews, Ashton-under-Lyne.

**HAMBURGS** (Silver-spangled).—First, Messrs. Ashton & Booth. Second, A. Woods, Sefton. Commended, A. Ludlam. *Chickens*.—First, J. Jackson, Bury. Second, T. Wrigley, jun. Highly Commended, A. Ludlam.

**POLANDS** (Any variety).—First, G. Heathcote, Macclesfield (Silver-spangled). Second, Messrs. S. & R. Ashton (Black). *Chickens*.—Prize, Messrs. S. & R. Ashton.

**ANY OTHER VARIETY**.—First, Messrs. Ashton & Booth. Second, Messrs. S. & R. Ashton (Houdans). *Chickens*.—First, W. A. Taylor. Second, Messrs. Ashton & Booth. Commended, T. Wrigley, jun.

**BANTAMS** (Game).—First, W. Travis, Ashton-under-Lyne. Second, T. Walker, jun., Denton. Highly Commended, E. Toder, Little Carlton, near Newark; J. Rhodes, Staleybridge; H. Shaw, Heyrod.

**BANTAMS** (Black or White).—First, Messrs. S. & R. Ashton. Second, G. Heathcote, Macclesfield.

**BANTAMS** (Any other variety).—First, T. C. Harrison, Hull. Second, Messrs. S. & R. Ashton (Silver-laced).

**DUCKS** (Aylesbury).—First, E. Leech, Rochdale. Second, Messrs. S. & R. Ashton.

**DUCKS** (Rouen).—First and Second, J. Nelson, Manchester. Highly Commended, E. Leech; W. Parr. Commended, T. Hardcar; S. H. Stott, Rochdale.

**DUCKS** (Any other variety).—First, T. C. Harrison. Second, T. Walker, jun.

**GESE**.—First, S. H. Stott. Second, E. Leech. Highly Commended, S. & R. Ashton.

**TURKEYS**.—First, E. Leech. Second, S. H. Stott.

**SELLING CLASS**.—First, Mrs. Bamford, Harpurley (Buff Cochins). Second, Messrs. Burch & Boulter (Spanish). Highly Commended, Messrs. Ashton & Booth. Commended, T. Wrigley, jun. (Gold-pencilled Hamburgs); Mrs. Bamford (Buff Cochins).

**PIGEONS.**

**CARRIERS**.—First, C. and E. Roys, Green Hill, Rochdale. Second, N. Tinker, Broadbottom.

**POWTERS**.—First, C. and E. Roys. Second, J. Ashton, Mottram.

**DRAGONS**.—First, J. Withinshaw, jun., Nantwich. Second, J. Lomax, Hollingworth.

**JACOINS**.—First, T. Newell, Portland Street, Ashton. Second, J. Withinshaw, jun.

**FANTAILS**.—First, C. and E. Roys. Second, J. Withinshaw, jun.

**NUNS**.—First, H. B. Whittaker, Alkington. Second, S. and R. Ashton, Roe Cross.

**TUMBLERS** (Any variety).—First, J. Fielding, jun., Rochdale. Second, C. and E. Roys. Highly Commended, J. Fielding, jun. Commended, J. Lomax; N. Tinker.

**OWLS**.—First and Second, J. Fielding, jun. Highly Commended, C. and E. Roys. Commended, J. Rhodes, Staleybridge; T. Newell, Ashton.

**TRUMPETERS**.—First, C. and E. Roys. Second, S. and R. Ashton.

**BARNS**.—First, J. Fielding, jun. Second, N. Tinker. Highly Commended, T. Newell. Commended, J. Lomax.

**TURBITS**.—First, H. B. Whittaker. Second, J. Withinshaw. Commended, J. Midwood.

**NEW OR ANY OTHER DISTINCT VARIETY**.—First, J. Withinshaw. Second, S. W. Sidebottom, Mottram (Archangels).

**SELLING CLASS**.—First and Second, J. Fielding, jun. Highly Commended, C. and E. Roys; J. Withinshaw; H. B. Whittaker; S. and R. Ashton. Commended, S. and R. Ashton.

The Judges were Messrs. J. Dixon, Bradford, and E. Hutton, Padsey.

## WOODBIDGE POULTRY SHOW—A POULTRY PROTECTION SOCIETY WANTED.

Your correspondent "EGOMET" (page 132), has done well in making public through your columns the uncourteous, and, indeed, unjust, conduct of those who had the management of the Woodbridge Poultry Show last May. I am one who has suffered in the way he describes, not only receiving no account of birds sent, but failing to obtain a reply to letters of inquiry. I have received letters from others, too, who are in the same case.

I want to know whether gentlemen and amateurs who have no doubt been repeatedly imposed upon, if not positively robbed, as in my case, cannot form themselves into some sort of protection association, and by the payment of an annual subscription raise a fund for defraying the expenses of the process which "EGOMET" very delicately, though rightly, suggests as the best. I had personally good cause to complain of some very suspicious dealing on the part of a well-known name about two years ago, and the same person has, I find, been acting with other amateurs in a manner that is the reverse of straightforward. Will some of the readers of "our Journal" give me the benefit of their opinion on the subject of a Mutual Protection Society against thieves, unfair dealers, and poultry sharpers?—ESOMET.

As one of the Committee in connection with the above-named Show I beg to state that the Secretary has been applied to many times to call a meeting to have all matters settled up, and to know the reason the money-prizes and cups have not been sent to those who are justly entitled to them. In a financial point of view the Show was successful. The Secretary has had all monies paid over to him; if all the subscriptions are not in hand it is his fault; and now I leave you to think who the party is that ought to have paid up all demands upon the Society.—ONE OF THE COMMITTEE.

[If the Secretary neglects his duty the Committee themselves should take steps to satisfy those whose birds were either prizetakers or sold.—EDS.]

## APPEARANCE OF LIGURIANS IN AN APIARY.

Will you kindly tell me what you think of the accompanying bees? They were taken from a stock hive which three or four years ago I only discovered their presence last night, not having had the most distant idea that any such bees were in my apiary, which consists of fifteen stocks; but I have examined them this morning, and find that there are great numbers in the hive referred to.

I quite believe there are no Ligurians within a distance of three or four miles, and I refer to those kept by the writer of the very interesting contributions to "our Journal" who signs himself "BLACKHEATH'AN," and whose apiary I should much like to see, and would, if he would honour me with a call, show him mine, and this stock which contains the favours for which I think I am indebted to him through the medium of his drones.—EDWD. FAIRBROTHER, 94, Wellington Street, Woolwich.

[The bees are well-marked Ligurians, and doubtless owe their existence to the fact of the young queen of the stock to which they belong having mated with an Italian drone, an event which we have known to occur before at quite as great a distance. We doubt not that "A BLACKHEATH'AN" will be happy to exchange apiarian visits with you.]

## WINTER PROTECTION FOR HIVES.

One of the disputed points among bee-keepers is as to the utility of bee-houses. On the one side it is asserted that these structures are simply nests for vermin, that they prevent the free circulation of air, and so contribute to produce that damp which is fatal to bees. On the other hand, there are experienced apiarians who consider that houses are essential to the well-being of bees, that they shelter the hives from the scorching rays of the sun, and from the cold blasts of winter, and help the bees to maintain an equable temperature in their dwellings. Probably the truth may, as usual, be found in the *via media*. A roof of some kind is certainly advantageous, as it keeps hives dry, and shades them from the sun; and I think that an open shed, in the shape of a steep gable, to accommodate two hives, will probably be found the most desirable kind

of bee-house. A pair of light doors might be fixed with hinges to the two front posts of the shed, so as to form a screen in front of the hives during snow or severe weather.

Of course ordinary straw hives contained in a house of the above description will need some further protection from the weather, and it is upon this point that I am desirous of eliciting the opinion of your experienced apiarian readers. A coating of cement has been recommended, and would certainly be an effectual preservative from cold, but the effect would not be pleasing, and the cement would add very considerably to the weight of the hives for manipulation. Straw covers, again, are liable to the objection that they harbour vermin.

The neatest and best straw cover I have ever seen is one which was recommended to me by a clever and successful Lancashire bee-master. I do not know whether it may be as novel to your readers, as it was to me, but here it is. Take an iron hoop of about the same diameter as the hive. Place it on the top of the hive, and having procured some long wheat straw, take a handful, and draw it through the hoop, until you have an equal length above and below the hoop; then double the straw back upon the hoop. Continue this process until you have surrounded the hive with a double covering of straw. Then take a hoop of larger diameter than that formerly used, and push it down from the top over the other hoop and the straw. Cut off the latter with a sharp knife just below the floor-board of the hive, cut out an opening in the cover opposite the mouth of the hive, and push the outer hoop as low down as you can without bringing it over this opening. Place an earthen bowl over the top of the hive and the straw, and you have then a cover which will defy the most severe weather, and, withal, will not disfigure your apiary. You can feed your bees at any time at the top of the hive by removing the bowl.—F., Westmoreland.

## OUR LETTER BOX.

COCHINS' FACES SWOLLEN (*Martyn*).—We know not the cause of the disease you mention, but should not attribute much importance to it, as Cochins are subject to very few diseases. Your treatment was right; but we believe in such cases castor oil is the best medicine. Either Spanish, Cochins, or Brahmas will suit you; Dorkings will not.

BUFF COCHINS' TAIL AND FLIGHT FEATHERS (*Buff Cochins*).—The black flight is more objectionable than the black tail; neither are to be desired.

BLACK FOWLS PRODUCING WHITE FEATHERS (*Game Bantam*).—If it is only after moulting and in your old birds that the spot appears, it is the effect of age. If it appears in chickens you must breed it out with a strain as good as yours evidently is. We advise the formation of two walks, one made up of the best of your own birds; the other, some of your perfect hens with the best cock you can obtain, and a pure black. By this means you will probably breed your cross; but if it should fail you will have your old strain unmixed to fall back upon. In birds of this class it is often necessary to renew colour or points by means of birds that have only these to recommend them. You are then obliged to breed in and breed out. It is a certain process, and not difficult; but it is slow.

BLACK SPANISH AND COCHINS (*A. L. B.*).—From one to two years old is the best age to breed fine strong chickens from.

SHOWING TURBITS AND CARRIERS (*Martyn*).—Turbit Pigeons may be either *mouth-headed* or *turned-crowned*; but for exhibition the pairs should match. Likewise the Black and Dun Carriers if shown separately would be eligible for prizes, but if shown as a pair must both be of the same colour. I do not know the value of Rosalies.—B. P. BRENT.

DRAGON PIGEON ROTTEN-FEATHERED (*H. L. T.*).—I fear little can be done for your cock Dragon. Let him bathe freely; rub the bare places with sulphur ointment, reduce his condition, and give him pills of I grain calomel; but if the complaint is constitutional, I fear it will break out again.—B. P. BRENT.

TAMING A LINNET (*Mrs. C.*).—Your young pied Linnet may be tamed for exhibition by placing it in a cage with wooden hack, top, and sides, and hanging the cage low where persons are constantly moving about. If, however, the bird knock himself about too much at first, paste a piece of thin paper over the front of the cage, and tear it away by degrees.—B. P. BRENT.

STRAIGHTENING COMBS (*C. F. R.*).—Leave the bees as they are until the end of April, when, in the middle of a fine day, they should be driven into an empty hive, and their own hive being conveyed in-doors, all the combs which are found to have been built irregularly must be cut out, straightened if necessary, and refitted into the frames, where they should be kept in their places by such temporary support as may be most convenient. Return the bees to their own hive when this is effected, and two days afterwards lift out the combs and remove all the temporary appliances by which these have been kept in their places.

SMOKING BEES (*Gilbert Tweedie*).—The honey will do excellently for feeding your weak swarms.

TAKING HONEY (*Omega*).—Try driving the bees out of your supers exactly in the manner described in page 59 of the fifth edition of "Bee-keeping for the Many." We should cut out the best of the combs from the partially-filled box, and put it on again for a few days to give the bees the opportunity of emptying the remaining combs. If they will not do so, take it off, bees and all, and leave it exposed in the midst of the apiary. In the evening, when all the honey is cleared, and the bees departed, convey it in-doors, tie it up, and put it away carefully until the spring.

WEEKLY CALENDAR.

Day of Month	Day of Week.	SEPTEMBER 4—10, 1866.	Average Temperature near London.			Rain in last 39 years.	Sun Rises.	Sun Sets.	Moon Rises.	Moon Sets.	Moon's Age.	Clock after Sun.	Day of Year.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 69.7°; and its night temperature 46.9°. The greatest heat was 83°, on the 5th, 1848; and the lowest cold 28°, on the 7th, 1855. The greatest fall of rain was 1.27 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

HYACINTHS.

GAIN the time has come round when those who wish to secure good bulbs of this charming winter and spring-flowering plant should be on the alert, as the best

bulbs are usually those first imported.

The exhibitions of last spring clearly established two very important points—

1, That judging by the size and beauty of colouring of the specimens then exhibited, this plant had previously had but scant justice done to it as regards cultivation.

2, That notwithstanding this superior cultivation, many of the old favourites must stand aside to make way for the newer kinds, so greatly are the latter in advance in the important points of form, size, and colour.

Having devoted much time and thought to the cultivation of this plant during the last seven years, and having taken the largest share of the premier prizes at the London exhibitions, I may, perhaps, be pardoned for venturing to offer a few brief remarks on their cultivation, and the varieties best suited for various purposes.

First, as to growing for exhibition. He who intends to exhibit must make up his mind to buy the best bulbs that can be obtained, for our present exhibitors do this, and unless this be done there is little chance of standing in the foremost rank. The next step is to pot the bulbs early, that they may lose nothing of their strength by being exposed and overdried in the various seed-shops to which the growers from Holland usually consign them about this season of the year. In our large thoroughfares the temptation to expose the finest bulbs is so great that I believe they suffer more from this cause than the sorts of ordinary merit. Pot them, say late in October, one bulb in each pot of the size known as No. 32, two-thirds of the bulb only beneath the soil, placing an inverted thumb-pot over the crown of the bulb before plunging, to keep the ashes or whatever may be used to plunge them in from soiling the bulb. The soil may be composed of two parts turfy loam, chopped fine but not sifted, one-third well-decayed cowdung, and one-third silver or river sand. When potted place them on the hard level ground under a north wall or fence out of doors if convenient, packing the spaces between the pots tightly with cinder ashes or cocoa-nut fibre. This done, give them one good soaking of water, and cover the tops 6 inches deep with the same plunging material. All is now safe till the month of January, when they should be uncovered and removed to cold pits, covering the glass for a few days with a mat that the rising crowns may be gradually inured to the light, and covering by night with double mats or straw to

insure their protection from frost. During the day, unless very frosty, air should be given plentifully to prevent too rapid a development of the leaves, and water should also be given abundantly. Watering with weak liquid manure from the time the leaves begin to grow until the flowers arrive at maturity proves an excellent stimulant. If required to bloom in March, the bulbs should be removed from the pits in February to a house where there is a command of heat, and placed as closely as possible to the glass, giving plenty of air, and using only such an amount of heat as may be required to bring them to perfection at a given date. No definite instructions on these points can be given. The judgment of the cultivator, having due regard to the state of the weather, must determine the exact amount of air and heat. When the flower-spikes are about 3 inches long, prepare for tying. Small rods, made of iron wire, bent as annexed, are my favourite plan, as the roots, and consequently the flowers, are liable to be injured by placing a stick sufficiently close to the bulb to secure the spike in an upright position. So soon as the first flowers expand a slight shade should be drawn over the glass for a few hours in the middle of sunny days, that the early flowers may be preserved from fading, and the colour of the spike kept uniform throughout.

The kinds I recommend for exhibition are—

SINGLE RED.

*Cavaignac*.—Beautiful pink, with deep rose stripes; very fine bells and spike.

*Garibaldi*.—Shining dark reddish crimson; good bells, and well-formed spike. Very effective.

*Macaulay*.—Rose colour, with dark red stripes; close and handsome spike.

*Princess Clothilde*.—Rose colour, striped with carmine; good bells, and handsome spike.

*Solfaterre*.—Fine orange red, with light centre, changing to deep red. Very distinct and fine.

*Von Schiller*.—Salmon pink, with crimson stripes; large and exquisitely-arranged spike.

SINGLE WHITE.

*Alba Maxima*.—Pure white; splendid bells, and extra large spike.

*Grandeur à Merveille*.—Very pale blush; large bells; broad and handsome spike.

*Mirandoline*.—Pure white; closely-arranged bells; long spike.

*Mont Blanc*.—Snow white; splendid bells; long spike.

*Snowball*.—Beautiful pure white; extra large and handsome bells; close spike.

SINGLE BLUE.

*Charles Dickens*.—Light blue and lilac shaded; extra fine spike.

*Feruck Khan*.—Very dark, almost black; splendid bells, and long spike.

*Grand Lilas*.—Beautiful pale porcelain; large and handsome spike.

*King of the Blues*.—Rich dark blue; large spike, exquisitely arranged.

*Marie*.—Very dark shaded blue; large bells; close and handsome spike.

*General Havelock*.—Blackish purple; large bells, and good spike.

*Haydn*.—Lilac mauve; large and well-formed spike. Very distinct.

## SINGLE YELLOW.

*Ma*.—Beautiful clear primrose; large bells and spike. The best in its class.

## DOUBLE RED.

*Koh-i-noor*.—Pale salmon red; very long and perfect-shaped spike.

*Lord Wellington*.—Delicate pale rose; extra large bells, and handsome spike.

## DOUBLE BLUE.

*Garrick*.—Lilac blue, shaded; large bells, and well-formed spike.

*Lawrens Koster*.—Dark blue; good bells; very close and handsome spike.

*Ven Speyk*.—Light blue, shaded with lilac; largest bells, and close spike.

With regard to Hyacinths grown for the purposes of general decoration, the culture must differ nothing from the above, except that less time, attention, and labour are sufficient to secure the ends in view. Under this head we recommend placing three bulbs of a kind in a pot; or even groups of the cheaper kinds in pans and ornamental vases produce an effect at once massive and beautiful. A mass of red, a mass of white, a mass of blue; also red or blue centres, bordered with white, &c., are very desirable, in the latter cases taking care to secure for the centres kinds which are of a shade taller growth, and of colours that are well contrasted. For masses of red take Robert Steiger, Norma, Madame Hodgson, and Amy; for masses of blue, Baron Von Tuyl, Charles Dickens, Mimosa, and William I.; for masses of white, Grand Vainqueur, Grandeur à Merveille, Queen of the Netherlands, and Tubiflora. Mimosa (dark blue), bordered with Diebitz Sabalkansky (red); Queen Victoria (white), bordered with Mars (red); Victoria Alexandrina (red), bordered with Madame Talleyrand (white); Bloksberg (double blue), bordered with Lord Wellington (double bluish), and the like form beautiful masses.

As to the period of blooming, even Hyacinths may be had in bloom for six months, from November to April, if that is deemed desirable. The earliest kind is the beautiful little Roman Hyacinth, the best of all for early forcing, and which should be grown in the most limited collection of plants for forcing; the flowers are snowy white, so clean, so beautiful, and so sweet. Next in order come L'Ami du Cœur, Herstelde Vrede, and Norma (reds); L'Ami du Cœur, Charles Dickens, and Prince Albert (blues); Groot Vorst (bluish).

The Roman Hyacinth should be potted in August or September to bloom in November, and the early kinds of other Hyacinths in September to bloom in December. Whatever the amount of heat given, which will depend on the time at which they will be wanted in flower, a regular temperature should be maintained, and plenty of water given. I often think that even practical men are scarcely alive to the fact—or at least do not regulate their practice by it—that the only nutriment plants imbibe through the root is water. The forcing of Hyacinths has been long practised, and is generally well understood: not so the process of retarding; but it is as easy to have Hyacinths in bloom in April, and even in May, as in November and December, only the process of cultivation is different. Those who saw the groups of Lily of the Valley exhibited at the International Horticultural Show last spring will not be disposed to question this, for these plants bloom naturally at the same season. Hyacinths for late blooming should be kept in a cold place from the time the roots are imported till the first week in December, then potted in rather dry soil, plunged, and covered up under a north wall, as previously recommended, but not watered. It is by the agency of cold and drought that we retard, as by heat and moisture we accelerate the period of blooming, and the practical man need not be cautioned against freezing and withering on the one hand, or burning and rotting on the other. Hyacinths potted in December to bloom in April and May should be kept plunged as long as possible; it will be well, however, to examine them occasionally from the middle of January onwards, as they must be uncovered and removed to a north pit as soon as the growth becomes very active. When in their

new situation all possible air should be given; in fact, they should be brought as nearly as possible to their out-of-door condition, merely using the lights of the pit to protect them from frost and rough weather. A regular but moderate supply of water should be given, and shading must be resorted to if there is much sun. By this means not only is the season of flowering retarded but also considerably prolonged.

All the kinds recommended for exhibition are also good for general decoration; but as some of them are unnecessarily expensive for the latter purpose, I shall offer here a fresh list of less costly kinds.

*Single Red*.—Amy, Gigantca, Madame Hodgson, Mdlle. Rachel, Norma, Robert Steiger, Victoria Alexandrina.

*Single White*.—Grand Vainqueur, Grandeur à Merveille, Madame Talleyrand, Queen of the Netherlands, Seraphine, Tubiflora, Voltaire.

*Single Blue*.—Baron Von Tuyl, Charles Dickens, Emicus, Leonidas, Mimosa, Prince Albert.

*Single Yellow*.—Alida Jacobs, Heroine, William III.

There are, perhaps, no in-door flowers more easily managed than Hyacinths in glasses, and there is no reason why they should not be used to adorn the parlour of the cottage as well as the ball and drawing-room of the mansion. Place them in the glasses late in October or early in November, the roots in the first instance not quite in contact with the water. Rain or pond-water should be used, and only changed should it become offensive. For the first month they are best placed where excluded from the light, to which they should afterwards be gradually inured. As the water decreases by evaporation and the feeding of the plant, the glasses should be filled up. If some be placed in a warm room and others in a cool one, there will be a difference of days or weeks in the period of flowering according to the difference of temperature. Then, as before, care must be taken to protect them from frost, which, if not likely to be severe enough to injure the plants, may break the glasses. Supports must be used for the leaves and flowers, and these may be purchased for a small sum at the seed-shops. It is well to remember that Hyacinths in rooms should, during the growing and flowering season, be placed where they obtain as much light and air as possible. The best kinds for this purpose are:—

## SINGLE RED.

*Emmeline*.—Rose colour; fine bells and spike.

*La Dame du Lac*.—Pale rose colour, with deep rose stripe; large bells, and well-formed spike.

*Madame Hodgson*.—Fine pale pink, close and good spike.

*Norma*.—Beautiful waxy pink; very large bells. Extra fine and early.

*Ornement de la Nature*.—Beautiful clear waxy bluish, with pink stripes; fine bells and spike.

*Robert Steiger*.—Medium red; fine bells and spike.

*Sultan's Favourite*.—Bluish, with rose stripes; lovely colour.

## SINGLE WHITE.

*Alba Maxima*.—Pure white; large and effective spike.

*Grandeur à Merveille*.—Very pale bluish; large bells; broad and handsome spike.

*Kroon Princess*.—Pure white; compact and good.

*Madame Van der Hoop*.—Purest white, and finest bells; good spike.

*Queen of the Whites*.—Snowy white; extra fine bells, and good spike.

*Seraphine*.—Very pale creamy white; good bells, and long spike.

## SINGLE BLUE.

*Baron Von Tuyl*.—Bright dark blue; very long and handsome spike.

*Conning*.—Lilac, blue shaded; good spike.

*Charles Dickens*.—Light blue, and lilac shaded; extra fine spike.

*Coucoune de Celle*.—Beautiful azure blue; fine bells, and good spike.

*Mimosa*.—Dark purple; fine and distinct.

*William I*.—Dark purple; good spike.

## SINGLE YELLOW.

*Anna Carolina*.—Clear yellow; large bells, and good spike.

## DOUBLE RED.

*Groot Vorst*.—Delicate bluish; fine spike. Early.

*Lord Wellington*.—Delicate pale rose; extra large bells, and good spike.

## DOUBLE WHITE.

*Prince of Waterloo*.—Pure white; large and handsome spike.

## DOUBLE BLUE.

*Bloksberg*.—Beautiful porcelain; large bells, and good spike.

This brings us to the last part of our subject—namely, Hyacinths for beds and borders. October and November are also the best months for planting out of doors: A light sandy loam, with a plentiful admixture of decayed cowdung, is the soil in which they appear generally to succeed best; but they thrive in almost any common garden soil. Place the crown of the bulb 3 or 4 inches below the surface, adding to the top 2 or 3 inches of cocoa-nut fibre or decayed manure as a protection against frost. The latter may be removed, or partly removed, if it be ascertained that the leaves and spikes experience any difficulty in pushing through. By the use of those and other spring-flowering bulbs and plants the garden may be made as gay in March and April as at any season of the year, and they may be readily removed to make way for the "bedding" plants used for summer and autumn decoration. The best kinds for bedding on account of their hardness and cheapness are—

*Single Red*.—Amy, Herstede Vrede, D'Ami du Cœur, L'Honneur de Sassenheim, Madame Hodgson.

*Single White and Yellow*.—Grand Vainqueur, Madame Turc, Voltaire, Heroïne.

*Single Blue*.—Baron Von Tuyll, Charles Dickens, Emicus, L'Ami du Cœur, Orondates.

*Double*.—Anna Maria, white; La Virginité, white; Bouquet Royal, rose; Groot Vorst, blue; Panorama, red; Waterloo, red; König Asinganus, porcelain blue; Lord Wellington, blue; Prince of Saxe Weimar, blue.—WILLIAM PAUL, Paul's Nurseries, Waltham Cross, N.

## GRAFTING ROSES.

I regret that I have not had an earlier opportunity of supplying the information requested by "M. D." respecting my mode of grafting Roses. The process, as I stated in my former letter, is so very simple that I thought a minute description of it unnecessary, presuming at the time I wrote that most, if not all, of your readers who would feel interested in the invention would understand grafting as it is generally practised, which would at once enable them to comprehend it. The only difference between my system and others is in the binding material, which, being perfectly air-tight, requires no covering. As the various modes of grafting are fully explained in the "Cottage Gardeners' Dictionary" and other works on the subject, it would be occupying space unnecessarily to give a description of them here; I will, therefore, confine myself to the questions asked by "M. D."

First, then, the Manetti stocks were taken out of the ground previously to being grafted, their roots trimmed, and their heads cut back. I also gave them a good washing before taking them in-doors in order to keep all clean and tidy, my better half being a little particular in this respect. The indian-rubber bands used were such as are commonly sold for the purpose of holding papers together, and may be had at any stationer's; the length and breadth depend altogether on the size of the stocks; those I grafted being small, I found a ring a little over 2½ inches in diameter and not quite half an inch broad in the band sufficient for two. The operation is performed in this way:—Take the stock in your left hand, and place the thumb, with one end of the band under it; on the lower end of the scion when you have it properly fitted, pressing it firmly to keep it in its place; then, with the band considerably stretched, bind upwards to half an inch or so on the graft and return, taking care in binding backwards to close every opening in order to prevent the admission of air, which, on account of the elastic nature of the material employed, can be done most effectually. At the bottom—that is, a little below the junction, fasten the end with a piece of soft thread or bast to prevent it springing back. This finishes the operation.

In planting out, it is not necessary to slacken or remove the binding; the bast or thread being under the surface of the soil will soon rot, and set the indian-rubber free, which will unwind itself or expand as the stock increases in size.

Many amateur rosarians—fair ones especially—have been deterred hitherto from propagating their favourites by grafting simply on account of the operation being rendered both difficult and disagreeable by the materials required to be used in the process; these obstacles I think I have succeeded in removing, and have shown a way by which the operation can be both easily and pleasantly performed. I may be a little too sanguine; perhaps; but I have an idea that for the smaller

kinds of plants at least, the day is not far distant when wax and clay for grafting purposes will be looked upon as things of the past. Should the discovery be considered of sufficient importance, I would be happy to forward to the office of this Journal a plant from which the indian-rubber has not been removed; it would, perhaps, be more satisfactory than any thing I have written on the subject.

The stock to which I have alluded in former letters is the old Maiden's Blush. I would recommend amateurs to give it a trial; it produces fine growth, is very hardy, and gives no trouble whatever with suckers. With regard to its propagation as a stock, I regret to say that I am not in a position to impart much information; I have been in expectation for some time past of leaving this place, and have not paid that attention to it that I would otherwise have done. It is just possible that it might not succeed so well in other localities, but in these days when Rose stocks are occupying a good deal of attention it is certainly, I think, worth trying.—LOCH NESS.

## NOTES ON THE FORMATION OF NEW GROUNDS AND LAWNS.

WHATEVER differences of opinion may exist as to the merits of continental and British gardening of an ornamental character, there appears to be only one conclusion with respect to the position in which we stand as possessing one of the most important features of embellishment in a higher degree of excellence than our neighbours across the water; that feature being a well-kept lawn. Whether we have to attribute this to climate, or to good management, or to both combined, it is not necessary here to inquire, suffice it to say that the general superiority of English over continental turf admits of no dispute. In isolated instances, however, the case may be reversed, and a few notes will, perhaps, be of service to "AN INQUIRER," who asks for instruction how to renovate a lawn which is not so satisfactory as he could wish; at the same time I disclaim all intention of attacking the systems of other writers in this Journal who advocate means more costly than can be adopted by those having an unpromising piece of ground to cover with a green sward; and whose means are limited. Such cases are of everyday occurrence, and though the adoption of a cheap way of obtaining a good velvet turf may not always be attended with such good results as a more expensive and careful mode of going to work, yet it often serves the end in view, and leaves a good balance in the expenditure that may be applied to other purposes. Good useful turf is always acceptable, and in all cases it is desirable to obtain it at a reasonable cost. As some of the best lawns in the country had only a very commonplace beginning, let us not despise them because the constituent parts of their herbage were not allotted in the exact scale prescribed by some who assume to be authorities in such matters, the sward having merely arrived at its present good condition in consequence of being kept duly mown and rolled. Nature, an assistant to whom, alas, we are not sufficiently grateful, doing the rest.

Let us now see in what way an unpromising piece of land can be made to assume the dressed character of a lawn at the least possible expense. Assuming, therefore, that a plot of ground surrounding a residence which has only recently passed out of the builder's hands has to be operated upon (and there are many such plots); a cursory survey will at once show that its surface—originally grass, perhaps—is now as free of it in places as the footpaths in the London parks, while in others tufts of grass and weeds make an effort to conceal with their foliage the many stones, brickbats, pieces of wood; and other rubbish scattered over the ground. Here and there a large bare spot will be seen on which mortar has, perhaps, been made, and which with other parts of the ground is intended to be laid out in some ornamental or useful way. Notwithstanding all this no unnecessary expenditure has to be incurred in laying out the ground; and when such a plot falls into the hands of the operator it has frequently to be put in order regardless of the time of year, whether favourable or not for such work. Fortunately, however, most kinds of ground work can be executed at all seasons, but planting shrubs and laying turf cannot always be carried out so successfully, yet as they are expected to be done let us see what are the best means to adopt in such a case.

In the first place I shall suppose that a plan has been decided upon, and if it is of an ornamental character most likely there will be some walks and beds, perhaps shrubby borders, plots

for single specimens, or other features. All these being determined, and the position of each roughly marked out before the spade is put in, it will be necessary to consider how the materials on the spot can be worked in to the best advantage. The best soil must be appropriated to the beds and borders, or for specimen trees, while all rough useless stones, brick-bats, pieces of dried mortar, chippings of slate, &c., may be used in making the walks, and the remainder levelled for the turf; and as it often happens that such work has to be done at a season unfavourable for obtaining a good lawn from seed, or without waiting so long for it, and there may be some difficulty in procuring the necessary quantity of old turf to lay down, some homely expedient has to be resorted to in order to obtain the requisite sward. Some of the means which I have been at times obliged to adopt are homely enough, and likely to be derided by the advocates of exact mixtures of certain grass seeds, very careful preparation of the ground, and other niceties in the operation which make a lawn a costly affair. Assuming, therefore, that it is midwinter when such work is in hand, and that there is a little turfy grass on the spot, this, however long, coarse, and neglected, I would take care of, and turn to account. If it be long and ragged at top, mow it first and then pare it up, and pick out docks, dandelions, and other very coarse weeds; lay the patches so obtained in a heap on some spot not likely to be interfered with until the last, and the stones and other rubbish being placed contiguous to where the walks are to be, let the surface soil be removed from the intended walk to whatever depth will receive all the rubbish which is to be disposed of, and lay such soil on some place where wanted, so contriving the work as to have as little of the materials as possible to move twice. Some forethought, with a knowledge of what is ultimately intended, will enable the operator to do this with less difficulty than is imagined, by beginning at the right place, and avoiding as far as possible confusion. No directions can be of much service in assisting the beginner in this matter, as the requirements of places differ so much, and without being on the spot it is impossible to say where the first barrowful of material should be taken to. Generally, however, it is customary to trench or dig plots intended for beds, borders, or shrubberies, and such useless material as may be found there may be removed to where a less valuable soil is wanted, and the stones to the site of the intended walks, but do not by any means remove all the stones from such borders, for be assured they are of great use where they are. The removal, however, of any portion of the material will necessitate additions being made at some places, and to replace it the good soil from the walks may be made available at once. Perhaps some beds or borders want raising into mound-like forms; if so, this may be done at once, and, if necessary, the transplanting of any large shrub or tree may be accomplished before the rest of the ground work, which I expect to be laying down in grass, is proceeded with.

Progress thus far having been made, and the sites for all beds and borders prepared with the necessary materials, then arrange about the walks, the site for which is supposed to have been excavated some 6 or 8 inches or more as material to fill it up may happen to be plentiful or otherwise, but I would not advise less than 6 inches, although I have as a matter of necessity made many walks only half that thickness. Here it is necessary to remark that if the subsoil be wet, a drain may be necessary—in fact it ought to have been mentioned at the commencement of this article, that draining the ground in a proper manner ought to be the first of all operations if it is required; but expecting that to have been already done, I may say that a drain along the centre of each walk will be of service, supposing the substratum to be a sound hard clay. Let the part excavated for the walk be made smooth at the bottom and slightly falling to the centre, where a drain a foot or more deep may be cut, and ordinary drain-tiles leading to some suitable outlet put in. Let the top of the pipes be carefully covered over with stones, as well as the whole of the excavated portion, taking care that no large ones project upwards so as to be within 1 or 2 inches of the surface of the walk. In filling in this foundation reserve all the finer materials to go on the top, and if such cannot be had, a little more care in placing them will much assist in giving the bed of the walk a finish, which may be still farther improved by breaking with a hammer all stones that show too large at top, and finally a good rolling or ramming down will be required before the finer material is put on. This, however, is a subject more especially appertaining to walk-making, while here we are only advising how the materials at hand can be best disposed of.

The next duty is to arrange for the edgings of the walks, and assuming these to be grass, some old turf ought to be obtained to lay the edge with, even if only as much as to cover a space of 6 inches wide; try and obtain that, although a foot in width is not too much. Level the edge for this turf, and be sure to sink it deep enough, so that in the after-levelling of the ground the upper edge of the turf may be no higher, but even a trifle lower, than the surface of the ground to be operated on. Do not depend on forcing the turf edging down by beating it as has often enough been attempted, such beating only results in its springing up again after heavy rain or frosts, but lay it rather under the flush level as it is called, and when the whole becomes of one piece it will not stand up as it often does when laid down by unpractised hands. The edgings of beds and borders may be treated in like manner, taking care in laying such turf both here and by the sides of walks that a little of it overlap the bed or walk, so as to allow of its being cut more exactly when fairly established. To make this plain I shall suppose a walk 10 feet wide to be wanted, therefore in laying down the turf let the two edgings be 2 inches less than this width apart, so that when the turf shall have fairly taken hold of the soil a clean-cut edge may be made by taking off 1 inch from each side; the same plan may be adopted in the beds or borders, or wherever there is a margin of grass. Attention to this is more important in the dry spring months if the turf be laid at such a time, as it is more likely to shrink at that period than in midwinter, and, consequently, will not extend to the place wanted to cut to.

Presuming the work above mentioned to be done, the next operation is that of preparing the remainder of the ground for plain turf. As it is desirable to do the work with as much economy as possible, it is expected that a few sorts not mentioned in the usual lists of mixtures for lawn grasses may be excused (for, in fact, they or some other will be sure to force themselves among those in the more select list), and as we have advised whatever semblance there might be of turf on the ground before operations commenced to be saved, it may now be brought into use. First of all, let the ground be dug over and properly levelled, taking care as far as possible to have the surface soil as nearly of one kind as may be, and although stones in moderate quantity are no detriment to the shrubby border, or even the flower-beds, all above the size of a marble ought to be removed from the surface as the work proceeds. Raking, however, need not be adopted unless the soil be a sandy one and it is easily done.

A moderately level surface having been obtained by using all the material at hand, and contriving to make it do, the next proceeding is to obtain a sward. In order to accomplish this object, sow in the first place a little grass seed over the ground, but only very little, then take the reserved turf or grassy sods that were taken off the ground at first, and tear them into pieces as small as you like—observe, pulling in pieces is better than cutting them—and the pieces may either be 3 inches across, or only 1 inch. When large they ought to be laid carefully over the ground with the right side up, when very small they may be scattered over the plot as in spreading manure; and although many of the pieces will be in any position but that in which they were before, yet if it be moist weather, which may be expected in winter, they will in most cases attach themselves to the ground and grow. When the growing season arrives a tolerably well-covered surface will be the result, certainly not so good as when good old turf is laid down all over the ground, but sufficient with a little patience, and the use of a little Clover and Grass seed, to make a good sward in a reasonable time, and that from materials anything but promising. Later in the season, or when it is dry, it would be better only to tear up the turf into larger pieces, and carefully lay these pieces with their proper side upwards all over the ground, more or less thickly as they are plentiful or otherwise, but assuming them to be about 3 inches wide then they might be 9 inches from centre to centre; take care to press each well into the soft ground, which is best done by only walking on the part planted instead of on the naked ground. Of course, seeds must be sown as well, and the whole well rolled, or otherwise smoothed, which rolling must be repeated on favourable occasions afterwards, especially after the patches begin to grow, or after rain, if the ground will allow of its being done at that time.

In recommending the above simple plan, I by no means assert that it is so good as using good sound turf from an old lawn or pasture; but as such is not always to be had, and there being some uncertainty with seeds, it is worth trying. We

have often covered with turf large breadths of ground in this manner, and if the soil is good, it is speedily covered. All stones, however, should be picked out, as the rain is sure to bring them to the surface if they are near it. Of course, a free use of the roller and scythe helps to improve the sward, or what is better, the mowing machine may be used when it becomes established, and this improves turf more than most people are aware of.

I may be permitted here to observe, that although I have had as much experience as most people with new lawns, I have never been very successful with those sown with grass seeds in the spring, and it is seldom, I believe, that the seeds sown at that time on ground fully exposed to the sun do prosper. The failure, with other observations, has led me to think that the seeds of grass require, while in the course of germinating, a certain amount of shade, and when we consider the mode in which Nature effects the sowing of grass seeds, both the season of year and the amount of shade are at variance with the method which we adopt. The most successful case which I ever knew of raising a good sward from seed, was when it was sown early in September. This was a near approach to the natural time, and the young plants are then encouraged by the long nights and heavy dews, instead of having to encounter the scorching sun of early summer—in fact, so necessary is shade for the well-being of newly-sown grass seeds, that it is good practice to give them some artificial shading. For sowings on a small scale, boughs of trees, mats, or other coverings may be used, and a plan better adapted for an extensive plot is to sow some robust-growing plant along with the grass to effect that object. Sometimes a thin seeding of Barley is sown with the grass seed, or some rapid-growing plant of the Brassica tribe—as Mustard or Coleseed. No inconvenience is experienced afterwards from any of these plants, as by the first cutting with the scythe they are annihilated. Shade, therefore, should be provided in early summer, but for seed sown in autumn none is necessary, as the plant at that time is so much encouraged by the long nights, and, consequently, shorter periods of sunshine.

Of the grasses suitable for forming the best lawns, I do not offer any opinion, but if a sward be cut from an old pasture, it will most likely be found to consist of the kinds best adapted to that soil and situation, and if removed to similar conditions would flourish there also. That many weeds find their way into our lawns cannot be denied, but the most careful selection of grass seeds will not prevent this, and Daisies, Clovers, Milfoil, Plantain, and Dandelion will in greater or less number be present. These plants if naturalised to the soil are not easily eradicated, but Clover is often used in grass mixtures, and some persons have no objection to Moss, but all coarse weeds are objectionable. I am not, however, so fastidious in this respect as some, and I have more than once on visiting a lawn belonging to those who take an immense amount of pains with it, been surprised at finding late in the autumn, when the weather has been mild, the whole surface covered with wormcasts in such a way as to collect to the feet and look badly when viewed either close at hand or from a distance. A little more roughness would have obviated this, and the presence of such plants as Yarrow or Milfoil effectually conceals wormcasts, so that after all this plant has its uses. It also possesses another not less valuable property, its deep-descending roots furnish it with juices sufficient to keep it in luxuriant growth in hot weather when the grass is burnt up, so that notwithstanding its being an intruder, perhaps in a lawn it is not altogether useless.—J. ROBSON.

#### MANURE FOR ROSES.

I HAVE a lot of wood ashes and old lime rubbish which I purpose mixing up with a quantity of loam and dung for planting Roses in at the end of the year. Will you say if the wood ashes and lime rubbish are at all likely to be hurtful to the roots of Roses?

If it would be of any use to your readers I would with pleasure send you a list of those varieties which I find do well in a cold and late climate, as also a list of those found to be tender or bad openers.—SUNSET.

[We consulted the Rev. W. F. Radclyffe on the application of the wood ashes, and this is his reply:—"Mix the lime, soil, and decayed dung, if used, together, and then plant, but on no account put fresh wood ashes; the lye from them is highly caustic; moreover they keep the ground cold by retaining mois-

ture. Spread the wood ashes on the surface over the radius of the roots in November, and they will do good. If applied to land wood ashes and guano should both, or either, be sown on a stale fallow."

We shall be obliged by your sending the lists you offer.]

#### ELM TREE DISEASED.

A GENTLEMAN residing in Kent has an Elm tree in his garden which is suddenly showing symptoms of disease, the leaves turning yellow and falling off, and the tree is infested with hornets. It is asserted that the attack of the hornets on the tree is destroying it. On the other hand this is disputed, the opponents giving it as their opinion that the tree is perishing from other causes, and the hornets are attracted to the parts which have already begun to decay.—H. M.

[Several years ago some of the trees in the London parks suffered severely from the attacks of an insect (*Scolytus destructor*), burrowing under the bark. The same insect had previously been equally destructive amongst the trees in the Paris parks and gardens, and great fears were entertained that its ravages might extend in this country; but it appears not to have done so to the extent apprehended, and we have not made its acquaintance yet, so cannot give any advice respecting it. Elms are, however, subject to what we might call paralytic affections, as large limbs will break off in calm fine weather without the least warning and from no apparent cause. Aged trees are very liable to this, and thus become more or less disfigured; but we cannot account for the tree you mention falling so suddenly into ill health, unless something has happened to the roots. Perhaps they have been cut severely; or has any deleterious matter suddenly come in contact with them? The attack of hornets is evidently a result, and not the cause. We have always regarded the Elm as a healthy free-growing tree, but not destined to arrive at so great an age as the Oak, Beech, and Yew. It is a faster grower than any of these, and also arrives at a greater size. If we can hear of any similar case to yours, which is likely to throw any light upon it, we will record it. In the meantime it would be advisable to examine the roots; and though it is impossible to stop the bleeding, you may, nevertheless, try the effect of cutting off one or two of the branches most affected, and sear the wound over with a hot iron. We hold out no hopes of much success by adopting this plan, but it may do good.]

#### MANURING FOR AND PLANTING STRAWBERRIES.

ARE Strawberries likely to suffer from over-manuring? Some persons say it will make them run more to leaf than to fruit. I propose after trenching the ground two spits deep to plant them as Cauliflowers are planted—that is, to make a trench not so deep, and lay manure in it. Do you approve of this?—AGNES.

[You may over-manure as well as under-manure. It is a matter of judgment, depending on the quality, and on the soil. We do not approve of the planting in trenches, but always plant on the flat ground. Buy the varieties called Dr. Hogg and Mr. Radclyffe, they are very superior in every possible respect: fine constitutions, sure setters, beautiful plants, and hardy. Cockscomb is also a very good late heavy-cropping Strawberry, and so are Wonderful and Frogmore Pine. Mr. Radclyffe and Dr. Hogg colour well all over; Cockscomb and Wonderful do not colour so well to the points.]

#### ORCHARD-HOUSE CULTURE.

YOUR paper often contains accounts of remarkable successes in orchard-house culture; but "CONSTANT READER," page 140, seems the most fortunate of all. Not only do his Vine roots thrive among faggots and old wood, which usually breed fungus, but he ripens off Muscat Grapes, which in other places require artificial heat. His Vine-clad rafters produce no shade which is detrimental to the Peaches beneath them. His potted trees are "all paragons of perfection;" and what is still more remarkable, those which were put out into the open air in June had already, when his letter was written, produced "ripe fruit of exquisite flavour and colour." As he names only Apricots, Peaches, and Nectarines, and the word "colour" probably

refers to the last two fruits, his success has indeed been great. He does not mention in what part of the world this "relic of primæval Paradise" is situated. I, whose lot is cast in the south of England, have had so little sun to ripen off my fruit, that Peaches exposed to full light under glass, and thinned so severely that six are the maximum in an 11-inch pot, and nine in a 13-inch one, have in general been poor in flavour, and sadly deficient in sweetness. French Galande is as usual the most satisfactory; Nectarines sweeter than Peaches; Apricots better than either; and indeed any one who has never tasted a Peach Apricot from an orchard-house can scarcely be said to have tasted one at all.

"CONSTANT READER" must not be offended at the freedom with which I have handled his communication, for in all probability our tastes may differ as to what "exquisite flavour" really is. I confess myself in the matter of ripe Peaches somewhat hypercritical and exacting.—S. B.

### THE ROYAL HORTICULTURAL SOCIETY'S GARDEN, CHISWICK.

A CONSIDERABLE period has elapsed since the Chiswick garden has received more than a passing notice in these pages; but at the present time it offers many features of interest to the practical horticulturist, and others which would recommend it to the mere sight-seer as well. Thus the Vines in the conservatory are alone worth a journey to Chiswick to see; then there are the bedding plants on each side of the broad walk leading from that structure to the iron tent, and constituting a beautiful spectacle, as well as an admirable means of comparing the merits of rival varieties. Then, again, at right angles to the walk just referred to, there is another, having on each side beds of plants used in sub-tropical gardening, and terminating in the old main walk, between which and the northern boundary wall a new pinetum has been planted. We have thus described three sides of a square, the interior of which is principally occupied by the arboretum, where there is a valuable collection of ornamental trees, which, so long as they shall be clothed in their leafy dress, are a study of themselves, and many of them when touched with the mellow tints of autumn, are even more beautiful than now. Yes, there is a beauty in autumn leaves; they are often dearer to us in their old age than in their pride of youth, and though the feelings which they conjure up may not be untinged with melancholy, we have the knowledge that when spring returns the leafless branches will be clothed with fresh verdure, and that nature has but rested. But to return to the garden; there is still one more feature which renders it attractive at this time of year, and that is the extensive collection of fruit trees, which, notwithstanding the adverse season, are in good bearing.

Entering by the gate opposite Turnham Green Church, and passing along the walk leading past the office, or council-room as it is still called, and which completes the fourth side of the square before alluded to, on each side is a ribbon border, 90 or 100 yards in length, which until the late rains was very effective, but now the plants in some of the lines have grown rather tall and leafy as compared with others, and have, therefore, somewhat spoilt its regularity. It is thus planted—1st row next the walk, *Cerastium tomentosum*; 2nd, *Tropæolum Lobbianum*, orange; 3rd, Purple King Verbena; 4th, Mrs. Pollock Pelargonium; 5th, Rose Queen; 6th, Stella, on one side of the walk, Punch on the other; 7th, *Calceolaria viscosissima*. Beyond this ribbon border on the side next the arboretum is a collection of Phloxes, many of which are very beautiful. Here, too, used as an edging, was a pretty seedling Lobelia, raised by Mr. Bowie, gardener to Earl Tankerville, at Chillingham Castle, and which is in the way of Paxtoni, but more compact in habit, and with a greater proportion of white in the flowers. Having reached the end of this walk, we turn to the left and enter the conservatory, which now offers a spectacle which is probably to be met with nowhere else in this country. It is completely clothed with Vines from the bottom to the top of the lofty curvilinear roof, and they are loaded with fine bunches of black, red, and white Grapes, in various stages of ripeness. The Frankenthal, the most robust and healthy of the Black Hamburg varieties, is the most numerous planted, and the bunches are remarkably fine, especially those near the young wood; on Aramon, received here under the name of Burchard's Prince, there are noble bunches with large jet black berries densely covered with bloom. It comes in in succession to the Frankenthal, and requires a longer period to

ripen. It is of excellent flavour, and one of the best varieties for hanging late, but as yet is scarcely known in this country. There are splendid bunches of Barbarossa, which when ripe will probably weigh 7 lbs. each, remarkably fine bunches of Muscat Hamburg, and a good crop as well; Black Prince, very good, but not yet ripe; Black Monukka, remarkable for being seedless; and Jura Black Muscat, larger in bunch than the Black Frontignan, and quite as early. Of white Grapes, there are very fine bunches of Chasselas Musqué, Muscat of Alexandria, advancing towards ripening, and Chasselas Vibert, earlier than the Royal Muscadine, and a good variety for pot culture in a cool vinery. A Frankenthal Vine trained on the east end is worthy of remark, on account of its extraordinary production of fine bunches.

The curvilinear vinery, where a collection of Muscat Vines was planted some five years ago for comparison—an experiment which ended in all but two or three being found identical, is a model of productiveness, the Vines being loaded with a very heavy crop of large bunches. Besides the Muscat of Alexandria, to which the reputed varieties have been referred, the Canon Hall is very fine, and Trovère Frontignan is bearing good-sized bunches. In the lean-to adjoining is a collection of dwarf standard Fig trees in 10 and 12-inch pots in fine bearing, and a number of plants of the Rat-tailed Radish, with pods which for length are fully equal to those exhibited at recent meetings. A Vine-pit contains a numerous collection of Chasselas Grapes in pots for fruiting next season, so that they may be compared under similar circumstances; and in the long narrow house into which the glass wall was converted some years ago there are about 150 varieties, chiefly for trial, whilst in front are cordon-trained Peach trees.

The orchard-house reflects great credit on Mr. Barron's management; it is a model of neatness and careful culture, and the time occupied in examining the well-trained trees and their excellent crops of Apples, Pears, and Plums was spent as pleasantly, if not more so, than among what are usually considered the more ornamental subjects of the garden; but in reality what can be more ornamental than a well-fruited orchard-house tree? Of Apricots there were still a few, although the most of the crop had been gathered, but it had been, we believe, a fair one. In a Cucumber-pit, where there is a heavy crop of different varieties, there was one called Huntingdonian, a very handsome white-spined sort, with fruit from 20 inches to 2 feet in length, and an excellent bearer.

Near the vineries a quarter of pyramid Pears, presented some years ago by Dr. Hogg, were in fine bearing; and it may also be here stated that the Pear trees on the walls, which have always been well managed and very productive, as well as the dwarf espalier trees, are also bearing good crops. Though Peaches and Nectarines have this year suffered severely in most places from spring frosts, the crop here is tolerably good—a circumstance which must be ascribed to the care taken in protecting the blossom, for few places near London are exposed to greater vicissitudes of temperature than Chiswick, which in severe frost is almost invariably some degrees colder at night than the higher ground at Acton and Ealing, whilst in summer the heat is also greater than is generally registered in these localities. Spring frosts are very destructive at Chiswick, for a body of cold air seems to, and no doubt actually does, plunge by its superior gravity downwards into the valley, and destroys the blossoms, whilst on the higher ground these remain safe.

The plant-houses, which some years ago were almost denuded of their valuable contents, are again, it is most pleasing to state, gradually being replenished, and additional structures are being put up; thus, advantage has been taken of part of the old north wall as a back to a lean-to now in progress, 86 feet long by about 10 feet wide. This will prove a very inexpensive house, and it will be of great utility for growing Pelargoniums and other plants for the Society's meetings and for general purposes of decoration. Another span-roofed house, we believe, is also about to be commenced.

In a curvilinear-roofed stove, besides a number of well-grown Palms, Zamias, Musas, Crotons, and a nice bank of Ferns at the back, we observed about thirty varieties of Lantanas, the best and most showy of which were M. Rougère and Conqueror; likewise *Torenia asiatica*, which, though introduced upwards of twenty years ago, is even now not so much grown as it deserves to be. Another house, a lean-to, contains a large number of *Dracænas*, many of the individuals having the foliage very finely coloured, and a similar house is devoted to a collection of Azaleas, of course presenting nothing to

interest at this season. A small span-roofed stove is chiefly devoted to plants of recent introduction and others not yet generally cultivated, such as *Anthurium Scherzerianum* and *magnificum*, *Begonia Pearcei*, *Bertolonia guttata* and *pubescens*, *Palicourea discolor*, *Peperomia arifolia*, *Dieffenbachia Baraguiniana*, new *Marantas*, &c. We also noticed handsome young plants of *Spharogyne latifolia*, *Stevensonia grandifolia*, and a good collection of other Palms, many of which well deserve a more extended culture in this country; on the Continent they are very popular for a variety of decorative purposes, constituting quite an important branch of nursery commerce, and they are beginning to make their way into favour here.

In the propagating-house there is a very useful case which is employed in the multiplication of large plants, such as *Marantas*, *Dieffenbachias*, *Caladiums*, &c., and among the contents of other parts of the house are different Conifers in considerable numbers for distribution among the Fellows, various Japanese plants, *Poinsettias*, *Peperomias*, *Palicourea discolor*, and a number of *Cattleyas* sent home by Mr. Bowman, an intelligent young man who was formerly one of the foremen, but now a plant-collector in Brazil. The span-roofed propagating-pit is temporarily filled with *Bouvardias*, variegated *Hydrangeas*, *Potunias*, and a lot of Indian-rubber and other plants, which will soon have to make room for fresh occupants. In other pits we noticed a fine stock of *Roses* in 43-sized pots, Chinese *Primulas*, a considerable number of half-standard plants of *Solanum pseudo-capsicum* in one, and of fruiting *Aucubas* in others. One of these plants was a handsome bush quite 4 feet high, and other two were fine standards about 3 feet in height, and it is expected that the fruit of the whole will be in full beauty about Christmas. Several other pits contained miscellaneous decorative plants, and in one there were *Geraniums* with sweet-scented leaves, offering a great variety of form, and about eighteen different scents. That of *Odoratissimum* resembles a combination of the lemon with the apple scent; *Lady Scarborough* again has a very powerful odour, resembling that of the well-known Sweet-scented *Verbena* as it is commonly called, or more properly *Aloysia citriodora*. *Odoratissimum lobatum* has a powerful scent of peppermint, and *Citriodorum majus* also possesses a most agreeable fragrance.

The Rose-house at present is filled with *Nosegay* and *Zonale Pelargoniums* in pots. There are now many beautiful varieties which are, strictly speaking, only adapted for this mode of culture, whilst others are good either under glass or out of doors. The most striking for their beauty and profusion of bloom were *Dr. Lindley*, *Clipper*, *Monsieur Martin*, *Rev. J. Dix*, a very free-flowering scarlet with a white eye; *Eleanor*, *Lucius*, *Provost*, *Amy Hogg*, *Monsieur G. Natchet*, *Beauté de Suresnes*, *Rose Rondatler*, *White Perfection*, and *Virgo Marie*.

It seems a natural transition to pass from these glass-sheltered *Pelargoniums* to those bedded-out on each side of the conservatory walk, and which constitute a beautiful sight as well as a most interesting study. There, each in a small circular bed, a multitude of varieties are arranged as nearly as possible according to class and colour for trial by the Floral Committee, and though utility, not ornament, has been the leading idea in carrying out the arrangement, the effect of the whole, notwithstanding the great diversity of the materials, is excellent. It is also worthy of remark that every variety is distinctly labelled, which is a great advantage to those who are desirous of making notes on the kinds grown. The following are those which, at the time of our visit, appeared the best and most distinct:—

*Scarlet*.—*Clipper*, *Garibaldi*, *Eleanor*, *Punch*, *Glow* (Smith), *Commissioner*, and *Rev. J. Dix*. *Red Riding Hood*, bright scarlet, with a white eye, is conspicuous by its very dark zone.

*Rosy Scarlet and Rose*.—*Provost*, *Forester*, *Bonnie Dundee* (light cerise), *Excellent* (G. Smith).

*Rose Pink*.—*Christino*, *Wiltshire Lass*, and *Beauté de Suresnes*.

*Salmon*.—*Souvenir de 8 Juin*, *Fanty*, and *Eugénie Mezard*.  
*White*.—*White Perfection* and *Purity*.

*Nosegays*.—*Stella*, *Cybister*, *Amy Hogg*, *Orange Nosegay*, *Le Grand*, *Waltham Seedling*.

*Silver-variegated*.—*Flower of Spring*, good habit; *Queen of Queens* for flowering, *Mrs. Lennox* for the purest white, and *Silver Chain* for its good habit and flowers.

*Golden-leaved*.—*Golden Chain*, *General Longstreet*, *Circlet*, deep bronzed zone, fine trusses of scarlet flowers; *Glowworm*, narrow zone, of fine habit; *Beauty of Oulton*; *Little Pet*, very compact.

*Tricolor*.—*Mrs. Pollock*.

Among the *Verbena*s are several beds of Mr. Willa's seedlings, which are quite a new race, and some very pretty Italian-striped varieties. *Melindres superba* (Willa), is remarkable for carpeting the ground so closely, and *Oberon*, from the same raiser, is a very effective deep rosy crimson. *Crimson King* and *King of Scarlets* are likewise most effective.

Turning into the walk, on each side of which the sub-tropical plants are growing, well sheltered on the one side by the arboretum and on the other by the tall Lime trees forming the Duke of Devonshire's avenue, we find *Cannas*, *Wigandias*, *Castor Oil* and *Indian-rubber* plants, *Polymnia grandis*, *Nicotianas*, *Solanums*, *Dracenas*, and other tender plants. We noticed *Cyanotia vittata* in a bed, with *Solanum auriculatum* for the centre, growing as luxuriantly as it usually does in a stove, variegated *Pampas Grass*, variegated *Bamboo*, and variegated *Maize*, here beautifully striped. Another effective ornamental *Graas*, though not variegated, is *Panicum sulcatum*. *Coleus Gibsoni* also formed a compact bed, which, from the dwarf habit of the plant and the blackish hue of the foliage, was effective, and so was a bed of the variegated *Coltsfoot*. *Iresine Herbatii*, as bedded-out here, presents a very good appearance, not so, however, the new *Alternantheras*; but position or other circumstances may have had some influence in this result. Of other plants *Canna peruviana* was in fine bloom, and so were *Solanum laciniatum* and *robustum*. A better position as regards shelter for a sub-tropical garden could hardly be found, and the planting of this eastern part of the garden with subjects such as those indicated above, has effected a great improvement on its former aspect.

Among other improvements, it may be mentioned that a large number of *Roses* have been planted in the new Rose garden, that walks have been mown through the grass of the arboretum, and, which is of still more importance, a pinetum, as already stated, has been formed on a slip on the north side of the arboretum. All the specimens are young and legibly named, and as they advance in growth from year to year they will also greatly increase in interest. All the kept parts of the garden are in excellent order, and Mr. Barron, the Superintendent, deserves all the more credit for this, inasmuch as there are heavy demands on his own time and that of his men, such as do not occur in private gardens.

## SOWING GERMAN AND INTERMEDIATE STOCKS—ALYSSUM CUTTINGS.

It was mentioned a week or two since that this was a good time for sowing German and Intermediate Stocks; tell me whether they will stand in the open borders, or if they should be protected from frost until the spring.

I was very unsuccessful in striking cuttings of the Variegated *Alyssum* last spring; state if they take more easily in the autumn, and whether they should be struck in heat or in a cold frame?—E. S.

[The Stocks may be sown anywhere now in pots, and then kept in a cold frame or pit all the winter, plenty of air being given.]

The Variegated *Alyssum* will strike freely now under a hand-light or in a frame, where it will be kept rather close and shaded from the sun. It will strike in a third of the time in spring if the cuttings are afforded a little heat.]

## LILIUM AURATUM.

I FORWARD to you my yearly account of the progress of *Lilium auratum* here, as from the numerous letters I receive from many parts of Great Britain and the Continent it would appear to be of some public interest. The bulb is now in a 15-inch pot, with three stems; the largest two are each 9 feet 6 inches high from the surface of the soil, one with fourteen flowers, the other with thirteen; the smallest stem is 2 feet high, with one flower, making a total of twenty-eight. The largest of the flowers are about 1 foot in diameter—not so large in proportion to the strength of the plant as in previous years; but, perhaps, this may be accounted for by the fact that I was anxious to bring the plant into flower, and subjected it to the temperature of the East Indian-house (Orchid-house), from the time the buds were half-matured until several of them were expanded. In this way I had it in flower in less than half the

time I should in an ordinary greenhouse. The girth of the largest stem near the bottom is  $3\frac{1}{2}$ , that of the other  $3\frac{1}{4}$  inches.—ROBERT BULLEN, *Gardener to A. Turner, Esq., Bow Bridge, Leicester.*

### LIST OF ROSES.

LAST year Mr. Radclyffe was so good as to give you, at page 209, Volume IX., a list of thirty-six of the best Roses; would he revise that list by this year's experience, and add to it so as to increase it to fifty Roses? With respect to the thirty-six, I can say that, excepting Duchess of Norfolk and Duc de Cazes, which did not succeed very well, and Eugène Verdier, Achille Gonod, and Triomphe de Paris, which I did not plant, all the rest made and are still making an admirable display.—P. C.

[I have had little or no experience of Roses of any kind this year, but last year these were very, very good: Duchesse de Caylus A1, Rushton Radclyffe, Duc de Wellington; I think they are three grand Roses. I have just ordered of Mr. Rivers twelve Duchesse de Caylus, twelve Marguerite de St. Amand, twelve Rushton Radclyffe. M. Boncenne was the best crimson Rose at the International, and Marguerite de St. Amand was A1 in light colour in every box at the National—a fine Rose. I have only seen my Roses three times this season. They were most glorious, but the novelties had bloomed out when I went to Rushton, twelve miles off, so I am much in the dark. Maréchal Niel is glorious colour, but I fancy it will not stand well out of doors; my Briar and Manetti plants of it (gift of Verdier and Turner), have been signal failures.—W. F. RADCLYFFE.]

### HOYA CARNOSA NEGLECTED.

I FOUND in the greenhouse of a house to which I have lately moved, a plant of *Hoya carnosa* in a nine-inch pot. It appears to have been neglected for years, but the leaves look healthy. As I made alterations in the greenhouse, I put the pot out under a south wall, where it has been all the summer, attended to as to watering.

The only place I have for it is on the ground in a warm greenhouse, trained against the end of the stage. If needful, what soil should it be repotted in? and should it be cut back or not?—THORN.

[Shift the *Hoya carnosa* into a pot 12 or 15 inches in diameter, remove a portion of the surface soil, and fill up with a mixture of equal parts of rotten dung, loam, lime rubbish, and sand. Do not prune the plant at all, but leave it as you propose at the end of your stage in a warm house; and if you can give it plenty of sun, plenty of water in summer, and little in winter, you will be rewarded with a profusion of flowers. It is one of the finest of our old plants, and your house is the place for it, but it must have light.]

### LAXTON'S PROLIFIC EARLY LONG-POD PEA.

As the raiser of this Pea, my object in writing to you is not to combat the opinions expressed in letters from "AN AMATEUR" and others in your Numbers of the 14th and 21st of August, as I am content to let the Pea stand or fall by the voice of public judgment alone; but that the condemnations contained in the letters alluded to are not universal, I have proof abundant in flattering reports of the successes of other growers who have volunteered their opinions. "AN AMATEUR" appears to have assumed that it has been announced as the best Pea in cultivation, and to have condemned it as not answering that description; he may have been disappointed as many others must be who look for improvements in all points in a new Pea or plant.

Had Messrs. Carter announced it as such they could hardly have been liable to a charge of deception; but they have in their description of it, I think, been singularly moderate and faithful.

My object, however, in troubling you is to explain what I believe to be the origin of the three so-called varieties in the seed alluded to by "AN AMATEUR." The variety in question is the result of a cross between Beck's Prizetaker (true), and Sangster's No. 1; and although the appearance of the seed as evinced in my own sample would lead one to suppose there were three varieties, yet the produce in the growing state will show but one character with very slight variations, and this is not the only Pea which exhibits such a tendency. Dickson's

Favourite has been likened by high authority to the variety in question, and has probably originated from crossing two Peas of a similar class. Dickson's partakes of a like mixed character of seed, and the variations in the growing produce are also insignificant. It is a characteristic of many crossed Peas to show in their produce after the second generation seeds like both parents and intermediate, and possibly this may explain the appearances alluded to.—THOMAS LAXTON.

IN February last I purchased a quart of this Pea raised by Mr. Laxton and sent out by Messrs. Carter. With me I find it is a very good second early variety, certainly much larger in the pod than the other Peas of its class, quite equal to them in flavour, and ripening about the same time. I have now growing three rows of 12 yards in length, and each row is loaded with fine long pods. I intend to cultivate this variety largely next season.—W. WOOLLEY, *Seedsman, Bunbury.*

### VIOLA CORNUTA.

WITH reference to your reply in No. 281 to "M. K., Bristol," I beg to say, that towards the end of last May I bought six little plants in pots, and turned them out into lightish soil. They grew very fast. I soon began to take cuttings, and have now more than 350 rooted plants, while the originals have spread so as to cover more than a square foot of ground each, and are in beautiful bloom.

I never made cuttings of anything which rooted more easily. I inserted them in light sandy stuff, about twenty under a six-inch bell-glass. I think every one grew. They are all out now, some in their places, some in a reserve-bed, nice stocky little plants. Mine appear to have one fault, they bloom towards the outside of the plant, the centres being void of blossoms. I take it for granted that I have the true sort, as I bought them of Messrs. James Carter & Co.—THORN.

### MILDEWED GRAPES.

I HAVE been a successful Grape-grower for many years; but this year my crop of Black Hamburgs, though excellent in size of bunches and berry, is completely ruined by mildew. The leaves of the Vines are perfectly healthy, but not one of the bunches will be fit for use. My Vines never had the slightest attack of mildew before, and I am not aware that their treatment this season has been different from that of former years. What ought to be done? Would it be well to cut off the bunches immediately? and what precautions should be taken to avoid this pest for the future? I have a crop of Muscats very slightly attacked, and the disease does not seem to increase. The orchard-houses as usual are full of fruit.—W. C.

["Completely ruined," though a very strong epithet, is not so definite as to enable us to judge whether some of the berries might not be saved for table use. If they are not burst we should have a dish full of flowers of sulphur held under each bunch, so that the bunch rested in the sulphur; and we would rub each berry between the fingers and thumb, so as to have it thoroughly covered with sulphur. This ought to have been done when the mildew was first seen on the berries. We have seen some very severely attacked by the mildew saved by the treatment we have specified. If the berries are all burst cut off all the bunches and burn them. Sprinkle sulphur over the borders at once, and when the leaves have fallen from the Vines paint the stems with a creamy mixture of soft soap, flowers of sulphur, and water.]

### NOTES AND GLEANINGS.

WE are informed that Lady Dorothy Nevill has determined on parting with her collection of tropical fruits, which is perhaps the finest both in regard to extent and condition in the country. Here is an opportunity for any one who is disposed to begin or extend this interesting branch of culture to possess himself of true specimens of the best exotic fruit trees. The Mangoes are remarkably fine, and flower abundantly every year.

—MR. RIVERS has raised another seedling Nectarine from the seed of a Peach. It is not yet named, nor will it be for a

year or two, till Mr. Rivers has, as he always does in such cases, proved the constancy of its good qualities.

— THE works at the Alexandra Park and Palace are now in full operation, not less than two thousand men being employed on the building and the grounds, both of which are fast advancing towards completion. The Park, under the able direction of Mr. McKenzie, is being carried out in a splendid style according to his own plans; and from that portion which is already completed one can now form an idea of what the future of this charming estate, with its fine picturesque scenery, is likely to be.

— WE have before us the third edition of that admirable little work by Mr. William Paul, "Observations on the Cultivation of Roses in Pots; including the Autobiography of a Pot Rose." The mere fact of this being a third edition, and that the author on such a subject is Mr. William Paul, supercedes the necessity of any further observation.

— MONDAY last being the day on which the Royal Horticultural Society's gardens at South Kensington were thrown open to the public in commemoration of the birthday of the late Prince Consort, it is estimated that no fewer than 150,000 persons took advantage of the privilege. Several bands gave their services gratuitously on the occasion. We are also authorised to state that to enable the public to inspect the plants and grounds in greater quiet than on such a day, the Council have determined to open the gardens free on every Wednesday during the months of September and October.

— At the meeting of the Floral Committee at South Kensington this day, we are informed that Mr. Bull will exhibit a plant of *Amaryllis Josephinae*, with upwards of fifty flowers.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

KEEP the hoe and fork constantly at work amongst all advancing late crops. *Celery*, proceed with the earthing-up in proportion to the demand; some of the very latest crops may also be planted in rows to stand through the winter. The haulm of Peas laid by now in a dry place is a good material for covering *Celery* during severe frost. *Cabbage*, the seedling plants intended to stand through the winter, must now be pricked out into nursery-beds of light soil at 5 inches apart, this will be found of great advantage, by inducing a stocky, hardy growth. *Endive*, continue to make successional plantations, some of the first planted out will now be in a good condition for tying up for blanching. A few only at a time should be tied, and these loosely, to allow the heads to swell out large. *Lettuce*, a small patch of Bath Cos sown now will, if the autumn prove mild, be more valuable than those sown earlier. *Mushrooms*, now is the last time to make beds out of doors. The various methods of growing them both in-doors and out, were last week ably set forth by Mr. Fish. *Onions*, no time should be lost in storing the crops fully dry. As the ground from which they are taken is generally used for *Cabbage*, it should be immediately trenched up; if manure is necessary let it be laid on the top of the trenched soil, and fork it in; if, however, the ground was well manured for the *Onions*, it ought to carry the *Cabbages* through, and they will always be the better, because if too much manure comes in contact with the roots in the autumn, it induces a succulent luxuriant growth, which renders them far more liable to injury from alternations of frost and thaw in the winter. *Radishes* may still be sown.

### FRUIT GARDEN.

Apples and Pears require constant attention now. Gather the various sorts as they ripen, and let the operation be performed with as much gentleness as if they were eggs, for wherever an Apple or Pear is bruised there is laid the foundation of premature decay. Peaches and Nectarines must be looked over daily, and gathered as they ripen, as a fall, even when nets are suspended to relieve them, is fatal to their flavour and appearance if they have to be kept a day.

### FLOWER GARDEN.

Besides keeping every part of this department in the neatest order, the propagation of the stock for supplying next season's demand will engross all the time and attention that can be spared. In all cases, the number of plants which it will be necessary to provide should be noted down, allowing a wide margin for contingencies and losses. The earlier-struck cuttings must be potted off, and after they become established,

placed out of doors in an open situation, bearing in mind that all the more delicate bedding *Geraniums* should well fill their pots with roots before winter, or many will be lost. While propagation is being proceeded with, attention must be turned to the amount of winter accommodation, which, whether in the shape of frames, pits, or larger structures, should be put in readiness to receive the plants before bad weather sets in. Though more expensive in the first place, a series of brick pits from 5 to 6 feet wide, will be the cheapest in the end, and if heated by running a four-inch pipe round them, mats may be dispensed with; besides, pits of this class would be valuable during the summer for a variety of purposes. The late heavy rains have caused considerable derangement amongst the flowers. Immediate attention should be given, and all deficiencies from such injuries at once replaced. Attention must be paid to the layers of *Carnations* and *Picotees*. It sometimes happens that the wireworms (young ones almost as thin as hairs), have insidiously introduced themselves into the pith of the layers, to their certain destruction. When one is destroyed, it is advisable to lift the pegs which hold down the others, and closely examine them; if at the section of the stem a bran-like appearance is visible the enemy is not far off, and it must be carefully sought and destroyed. Continue to plant out links as they strike root, bearing in mind that those which are put out now in the places where they are to flower next season, generally lace much better than those planted in the spring. Plant offsets of *Tulips*, and commence arranging the best bed for planting.

### GREENHOUSE AND CONSERVATORY.

Any inmates of these structures which have been placed out of doors will still be much benefited by being out, even for two or three weeks more, especially all those which appear long-jointed or somewhat pale. If drenching rains occur, any tender plants which are likely to suffer damage should be taken in-doors again; there is no occasion to house the whole stock at once. Plants impatient of moisture should not be kept out too late, the nights are becoming long, the solar heat will soon be much diminished, and, of course, evaporation will proceed at a slower pace. When *Camellias*, *Chinese Azaleas*, and the hybrid *Indian Rhododendrons* were not potted in the spring and require shifting, the present will be the most favourable time, as the young wood is now becoming somewhat firm and the flower-buds are perceptible. As this class of plants require water very liberally during one period of their growth, drain the pots well, and use very turfy peat and sand, adding an equal portion of fibrous loam for the *Camellia*. Most of the class of bulbs known as Cape bulbs, if obtained now, might by the aid of a little extra heat be had in flower at various periods throughout the winter and early spring. Any of the free-growing species of *Ixias*, such as *flexuosa*, *viridiflora*, *comica*, &c., would be suitable, as also would the varieties of *Sparaxis* tricolor. *Amaryllis vittata*, *Johnsoni*, and the innumerable allied mules, are splendid, and might be bloomed by gentle forcing. *Lachenalia pendula*, tricolor, and *luteola*, with many species of *Oxalis*, would serve to increase the variety, and are all handsome individually; of *Oxalises* perhaps *versicolor*, *hirtella*, and *cernua* would be as easily procured as any, but many others are equally good. *Ornithogalum aureum*, a fine orange-coloured species, and some of the white ones, as *lacteam* and *revolutum*, are desirable plants. *Cyclamen coum*, *vernum*, and *persicum* ought not to be omitted.

### STOVE.

Plenty of moisture in the atmosphere and plenty of air are still essentials, increasing the ventilation progressively as the plants approach towards the next period, and inuring them to much more sunlight in a similar ratio, at least those which have made a strong and early growth. Shading will of course be dispensed with, except in the case of bright sunshine and during the middle of the day. Pay every attention to such superior stove plants as *Allamandas*, *Dipladenias*, *Stephanotis*, *Echites*, *Euphorbia*, and *Luculia*. A considerable number of *Orchids* may now be selected from the general stock, which, having done growing, require a temperature gradually declining, accompanied with a drier atmosphere, and, for some kinds, a pretty free exposure to the sun and light. Where different structures are devoted to this family no difficulty exists in affording to each section a suitable temperature both in the seasons of active growth and repose, and in those transitions from one state to the other during which, perhaps, plants require the greatest care. On the contrary, where one house is made to contain a class of plants which vary nearly as much in constitution as they do in form, contrivances of all

sorts must be had recourse to for accommodating them during some months of the year. Pineries, vineries, a warm greenhouse, and spare pits present themselves as affording room where a greater or less number of this interesting family may pass their vacation when the more active duties of the season are over. The thinning out of the principal house will permit of the remaining plants having more room, and enable such kinds as are coming into bloom to be brought forward to meet the eye.—W. KRANE.

### DOINGS OF THE LAST WEEK.

Had nearly a day's watering on Tuesday, the 28th ult. Chiefly applied the water to Peach-tree borders out of doors, and such strong growing plants as Salvias in the flower garden, using principally house-sewage water. We felt confident that we should have rain before long, but we made allowance for that in using the sewage, as that always seems to tell more wonderfully when a moderate rain and a cloudy sky follow the watering. Had we known that there was to have been such a drenching rain as that which fell on Tuesday evening and Wednesday morning, we might have saved ourselves the labour and finished some other work. We are sure that the sewage watering will tell as expected, still it would not have been so urgent a work, if the heavy rain had been a certainty beforehand. The change in the weather, though a drawback as regards the harvest, has helped us in another way, as it will retard the fruit a little in the orchard-houses, which with all the air possible, and a little shade, is ripening faster than we want it. We could have easily kept it later by leaving air on in summer instead of shutting up. In fact, by a little attention in the management, fruit may be obtained in orchard-houses unheated, considerably earlier, or considerably later, than on the open wall.

#### KITCHEN GARDEN.

The chief work here besides hosing to keep down all incipient weeds, has been sowing Lettuces and Turnips, planting out Endive, Lettuces, and a border of American Red-topped Stone Turnips, which the rains will make all right. These were planted in rows 15 inches apart, and about 7 inches apart in the rows, as that, after this season, will give plenty of room for nice useful tubers, more especially if the most forward be taken up first. From 3 to 4 inches across is quite large enough for such tubers to be used at the parlour table. At that size they will be crisp and white at the root end, instead of brown, hard, and stringy. This border will come in in succession to that from which the thinnings were taken for planting, and will be several weeks earlier than a fresh sowing. One of our best gardeners told us the other day, that Turnips were a perfect plague to him. Do what he would he had his borders and quarters cleared off by the fly. He perceived at once that by sowing under some kind of protection, and planting out after the plants had made several strong rough leaves, he could beat his enemy. The drawback is, that in sunny weather the plants would require frequent slight waterings until they had taken hold, when they would look after themselves. In dripping, or cloudy weather, there is no difficulty whatever. The plants very soon make themselves independent, and the labour is not much more in planting than in sowing, protecting from birds, and thinning to the requisite distance.

It has not been generally considered that such Turnips may be transplanted as successfully as Swedes. The chief point is that whilst fixing the root, the collar of the plant should not be buried. Even in this little matter, less care is needed than in transplanting an Onion which we wish to bulb well. Well-aired soil, enriched with rotten dung or leaf mould, is the best preparation for a sweet, crisp young Turnip. When weight of tuber is the object, the manure may be used less decomposed, and plenty of it, and if assisted with the stimulus of artificial manure, such as guano, superphosphate, broken half-inch bones, or droppings from sheep fed on trellised boards in winter, all the better.

*Dissolving Bones.*—A gentleman told us the other day that a farmer effected this process in a very simple economical way without the help of sulphuric or any other acid. A heap of damp pig and other dung was thrown together, so as to produce a good heat, the bones were well wetted with strong water from the manure tank, placed on the hotbed, and covered all over for a foot or so in thickness with the same materials, and the steam and the heat caused the bones to fall down in powdery

flakes, when the whole was mixed together. The plan may be well known, though we have no recollection of meeting with it. We have slowly dissolved, or rather broken down, a small heap of bones by frequently wetting them with strong urine drainage from houses, and then covering well up with litter.

*Tomatoes,* however grown—against walls, fences, or on the ground—will now want regulating, removing many of the larger leaves, and exposing the fruit to the sun. This plant, unless the roots are much confined, is sure to grow rampant in such a season as the present, and one of the best means of keeping it fruitful and within bounds is to stop the shoots repeatedly after they show their bunches of bloom, and remove when too luxuriant a good portion of the larger leaves. So treated, the plants will need little water after the plants are fairly established. Few people in this country, as yet, adopt the American system of using the Tomatoes when in a young green state as a constituent of salads.

*Potatoes.*—During the heavy rains of Wednesday looked over the Potatoes, and was sorry to find as pretty a sample as could be seen—when housed not a speck or mark of disease upon them—now very much infected, which we regret all the more, as most of them were intended for seed Potatoes. For several years we have seen little of the disease until after the Potatoes were housed for some time, in shallow bins, too, and in an airy place. This is one of the most puzzling facts connected with this still little-understood disease. We have advocated fresh soil and an open situation, instead of the old soil and close situation of a kitchen garden; but we have since learned that a market gardener who makes a large profit generally by securing fine samples of all the earlier kinds for selling for planting, will have few if any to dispose of next spring, as, though his stock was harvested in excellent order and from an open situation, the Potatoes are going very fast now. It is to be hoped that this will not be at all general. The weather has been such as we might expect the disease among late kinds in moist sheltered places, but there was but little of such weather before the early kinds were taken up, and we can assign no reason why such crops, taken up early, and housed in a sound condition, should begin to go all wrong a month or so afterwards. It also seems doubtful if such samples could be perfectly healthy to use when they showed no signs of disease, as the germs of that disease must have been in them before they were housed.

*Mushrooms.*—See last week. We again allude to this subject because an "OLD CULTIVATOR" who used to be troubled in summer with maggots, thin Mushrooms, and these going off and crumbling up in his house with platforms in the usual way, examined our little bed, producing nice Mushrooms in our shed, thatched at top, open in front, and shaded by trees. The depth of the old bed at the end of that being cleared out, he found to be rather less than we stated—namely, 14 inches at back and 12 in front, earth and altogether, and on poking with his stick he satisfied himself that fully half that depth was chiefly rather long litter, with shorter litter and droppings at the top. Of course we would have preferred that for that depth all, or nearly the chief part, had been droppings. We have had Mushrooms good all the summer in a large house, the bed on the floor, with means of wetting the floor and syringing the walls, but in a small narrow house, and furnished with platforms, we have not been so successful in the hot summer months. We have also succeeded very well in a sort of underground cellar, where the temperature and moisture of the air were very uniform. We have helped to make beds in an underground Mushroom-house, and where they did well in summer, and well, too, in winter, only requiring a covering over the beds at the latter season. The ground was cleared out as for the cellar of a house, a wall of old bricks and stones built all round, and piers on each side in the centre, with room left for a path between the beds. Stout flat iron rods went across from wall to wall, resting also on the piers, these rods being 18 inches below the ground level. On these slates and flagstones were placed, which were again covered with earth rammed down, averaging 18 inches in thickness, and slightly in the ridge form, highest in the centre. On this was rolled about 1 inch of fine gravel and tar, extending a yard beyond the side walls so as to take off the damp, this concrete top being only a few inches above the surrounding ground. There was a stair, with a door at the end, covered with a flap-door to keep the wet out. This house answered well all the time we knew it. It was cool in summer and warm in winter, but all the material had to be carried in baskets to the beds, which greatly increased the labour. For summer work we have found

nothing better than a shady thatched shed, where you can regulate the force of a breeze pretty well at pleasure. Before we used it, and having no large house that could have been kept cool, and no underground in place, we used to have much difficulty with Mushrooms in June, July, and part of August, if the weather was very hot. That might have been surmounted by more thorough but equal ventilation in a narrow house, but even then it is advisable to have the Mushroom-house unoccupied for a few months in summer, so that it may have a good cleaning, smoking, &c.

*Cucumbers.*—Petted off some for winter work, if wanted. Regulated others in beds. Both Cucumbers and Melons in frames will be the better of some linings, as litter and grass, round the boxes now, so that they may not receive any check.

Gathered *Vegetable Marrows* before they became too old. For some years we have dispensed with the usual hotbed beneath these vegetables, but where early gatherings are desirable it is well to give the plants a rough hotbed below the soil, and a hand-light when first planted out. They then grow with such vigour, and root into the dung, as it decomposes, so freely as to give little more trouble for the season than gathering the young fruit, which in the long kinds should scarcely be more than  $1\frac{1}{2}$  inch in diameter. After trying many sorts we must say that we like the old long-shaped *Vegetable Marrow*, which turns to a bright yellow when ripe, the best of all. That is no reason why others may not prefer the *Custard* and other choice-named kinds.

#### FRUIT GARDEN.

Can do nothing now to clear away runners of *Strawberries*, until dry weather sets in. In stiff, strong soil, where the leaves keep pretty compact and close to the ground, would not move a leaf from the plants further than might be necessary to give light and air to those left; but on light rich ground, where the foliage is nearly up to one's knee, and becoming brownish by this time, there would be no harm if a good portion of the tallest were pruned off soon after the fruit was gathered, as then there would be time for the buds to mature themselves, and the plants would be more compact and fresh all the winter. Circumstances may thus alter practice, but as a general rule, in good *Strawberry* soil, it is well not to touch any of the leaves until they are browned by the winter's frost, and they are, therefore, trimmed a little in spring as the young leaves expand. These old leaves act as a protection to the plant in winter. On the other hand, on light rich soils, where the old leaves are removed early, the young leaves formed by this time, are seldom injured by frost. In a word, if the soil will keep the leaves of *Strawberries* green until the end of autumn, that is a plain sign that there at least the cutting or removing the leaves would be wrong. When the foliage becomes brown and withered, as in some places it is often seen in August, then such foliage can be of no use further than as a mere protection to the buds, and the buds would have been better with the young stiff foliage around them instead of the old.

Gathered some of the riper Apples, as the birds began to peck them. We shall have few Pears or Plums this season, except where the buds have escaped the destructive bills of the birds. They so nearly killed outright some nice dwarf Plum trees, that we were obliged to allow these to throw out from the elder wood strong shoots, to be stopped and treated so as to produce masses of fruit-buds. These trees were so prolific of fruit-buds as to require previously but little trouble, except to syringe them for a little fly, and gather the fruit. Two or three fine Thorn trees were so completely cleared of flower-buds and wood-buds as only to maintain their vitality by breaking pretty freely all over the elder wood. Cherries and Apples were little touched by the birds this season, as respects the buds, and they have produced their usual crops. The birds seemed to take themselves off for a short time as the buds of Apples and Cherries were swelling. Some birds suffered for attacking the Cherries under nets, but on the whole as respects the Cherries, the "black mail" demanded was pretty well earned by good service in other respects. We are anxious to keep a good crop of the *Florence Cherry* as late as possible, and had it, therefore, double-netted and lost but few by the birds. The ants were a smaller but more difficult enemy to dislodge. We could syringe the tree heavily to bring them down, and then throw some quicklime on the ground, which they abominate. A good plan would have been to have placed a few saucers on the ground supplied with honey, or sugar and arsenic, with a saucer over it, and openings large enough for the ants to enter. A band of tar along the bottom of the wall will also keep them down so long as it is damp, and not longer.

Even then they are not easily conquered, being as famed for perseverance as even the spider itself. We have watched a detachment of them going along fully 50 yards at the foot of a wall, going up where it was clean, and marching back again on the wall to reach the coveted plunder.

A new enemy has appeared within a few days in the shape of wasps, which have troubled us but little this season. A nest has been found near at hand, and treated in the usual way, but use what means you will, you will never catch all the industrious wasps at home, and the finest decoys in the shape of sunk bottles with enticing fluids, will fail to tempt them all to enter; and deprived of the stimulus of having a home to care for and young wasps to feed there, the marauders will give themselves up to feats of gluttony, eat, rest, sleep, and eat again without greatly shifting their quarters. In these circumstances, such a rain as we have had, if a little colder, generally settles, at least for a time, all these gorged, swelled-out, muzzy, yellow-coated plunderers—not but that suspended bottles of saccharine matter, and double hand-lights, with a hole at the top of the lower one, are not good traps for catching all such interlopers, but a few days' rain will often do much to set them adrift, and if their wings are wet they are easily caught.

An amateur lately directed our attention to a sort of scavenging employment for which he had found wasps very useful. He had a house with Vines trained up the rafters, and Peaches against the back wall. These Peach trees were very much infested with fat scale, that was making sad havoc of his trees. A colony of wasps were in turn making havoc among the scale insects and their sweetish excretions, and not a berry of the Grapes was touched; but when they had worked their sweet will with the attractive scale insect, we should be a little surprised if, of their own accord, they left the tempting vicinity of the ripening Grapes. Some years ago we saw a Peach-house a perfect nest of wasps, though the fruit had been cleared out more than a month, and here, too, the scale which had been allowed to have its own way was the great attraction.

Out of doors on walls and inside in orchard-houses, &c., earwigs and woodlice have begun to nibble the fruit, and it is annoying to find fine fruit with just a little hole in it that makes it unfit to go to table. The elder and the opener the seams in a wall the more will woodlice choose such places for their best living and breeding quarters. Before the fruit begins to become soft it is a good plan to lash the wall and trees either with clear water or clear soot water, or clear water with as much quassia water added as to make it a little bitter. This repeated several times before the leaves become dry will send most of the woodlice to the bottom of the wall for shelter, under clods, &c., and many may be destroyed by beating heavily along the side of the wall with a clean spade. Then if a band 4 inches wide is painted along the bottom of the wall in tar and oil the woodlouse will not cross it so long as it is wet. This may be done as respects any wall out of doors, but it would be dangerous to do it in a house, under glass. There small pots, with a bit of boiled Potato in them, covered with dry moss or hay, may be laid down and examined every morning, and the hidiers treated according to the whim or taste of the trapper.

Similar means will also entice the earwig, and keep the wingless ones from ascending, but it likes a hollow tube to hide in during light better than all these; and of all tubes is fonder of none than a hollow beanstalk—say a foot in length, stuck among the branches of the tree. Examine these tubes every morning, and, putting an end close to your mouth, give a brisk blow which will send the earwigs, if there, out without ceremony at the other end, into a pot of water or any other contrivance considered more suitable. We have counted twenty blown out of a single beanstalk 9 inches in length.

*Preserving Morello Cherries and Currants on the Trees.*—We have had both good after Christmas—the Morello merely by matting or Nottingham fine netting, kept at a distance from the tree; and the Currants by using mats, straw ropes, or netting. However done, there is generally great loss from those decayed, and the trees are more or less injured, so that in general, but for having the fruit fresh gathered, it would be better to gather and bottle when the fruit was at its best. The best method we have noticed for preserving Currants, Gooseberries, &c., on the bush, we saw from twenty to thirty years ago, at Tingrith, and we believe the same plan is adopted there still. A light iron frame was made, about  $3\frac{1}{2}$  feet in diameter, and as much in height, having a rim for resting its bottomless base on the

ground, and a rim at top over which projected a light tin lid, painted. The lower and upper rim were connected by upright bars, and round these bars was stretched and fastened Nottingham-lace netting. The lid threw aside the rains, the small holes of the netting allowed air to enter freely, and a good amount of subdued light, but kept out the smallest of our winged insects, not to speak of birds and larger enemies.

ORNAMENTAL DEPARTMENT.

This has been one of the most troublesome seasons we have known as respects lawn-keeping; it has been mow or machine continually. Some lawns have been allowed to become rather rough. Even that most in sight would scarcely be presentable if not gone over three times in a fortnight. At longer intervals we have had to use the machine twice on the same ground, or mow with the scythe, and in either case there was so much to take away that we found delay, though it could not be helped at times, was anything but an advantage. After these rains a fine opportunity will be given for eradicating large Plantains on lawns, weeding walks, and rolling walks and lawns, and that rolling will help to keep worms longer from disfiguring the surface of either.

Worms seldom show in walks that have been dressed with salt, but ours are already too smooth to put salt on them. The roughest walk on the surface will ere long become smooth enough if well salted on the top. Walks at all smooth, if salted, will retain moisture so much as to be almost impassable in winter. But for these after-effects there is no plan so economical for keeping walks bright in summer as throwing a coating of salt over them on a sunny day, and when you may expect some days of bright weather. There is only one way in which we could use salt for smooth-surfaced walks, and that is by covering the salt with a slight sprinkling of fine gravel from which the mere dust was excluded. This, rolled in after wet, would give a nice walk for the season, as the fresh material would prevent all softening and liting, and the salt beneath would keep the weeds from growing.

Went on regulating plants and houses; potting Cinerarias, Primulae, &c.; cutting down Pelargoniums; put in cuttings of bedding stuff, much as detailed last week. Now is a good time to top-dress Roses for forcing. Took up and potted firmly such shrubs as coloured Ribes, Lilacs, Syringae, and Rhododendrons. These should be plunged in the ground in a sunny spot, and the tops syringed or shaded for a short time to prevent flagging. A little bottom heat in a bed, with the tops fully exposed, helps to fill the pots with roots, and that is the chief element of success.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 1.

THERE has been a tolerably good supply of wall fruit during the past week, with the exception of Green Gage Plums, which are now almost over. Apples are plentiful; and Pears consist of Beurre d'Ananlis, Louise Bonne de Jersey (both from Jersey), Bon Chretien, and Jargonelle.

TRADE CATALOGUES RECEIVED.

Charles Turner, Royal Nurseries, Slough.—Catalogue of Bulbous Flower Roots and Tulips.

R. Parker, Exotic Nursery, Tooting, S.—Catalogue of Stove, Greenhouse, and Hardy Plants, Fruit Trees, Hyacinths, &c.

Sutton & Sons, Reading.—Catalogue of Bulbous Flower Roots, Geraniums, Fuchsias, and other Plants, Fruit Trees, &c.

TO CORRESPONDENTS.

•• We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

"COTTAGE GARDENERS' DICTIONARY" (R. S. F.).—It is true that the name of "G. W. Johnson" appears on the title page, but he is not responsible for any edition beyond the earliest. The copyright belongs to the publisher, and over it Mr. Johnson has no control; he regrets, as you do, that "the old edition of 1852 is as good and as far advanced as that of 1865."

LABOUR REQUIRED FOR A GARDEN (A Reader).—You will require a gardener and a young man or active labourer to keep in good order a conservatory 24 feet by 22, two vineries 18 feet by 18, Peach-house 31 feet by 14, stove 22 feet by 9, frame 30 feet by 8, kitchen garden 32 yards square and flower garden 40 yards square, which last takes three thousand bedding plants annually, all propagated.

IMPROVING A LAWN TREATED WITH COAL ASHES (A Subscriber from the Beginning).—Unless a lawn was hopelessly overgrown with moss we would not recommend coal ashes for it; but as you say they are in the way, it would be better to scratch them up with a garden rake and sweep them off. Then sift a little fine mould, and mix it with proper grass and Clover seeds, say one part seeds to ten or twenty of soil, and sow this over the ground. After sowing roll the seed in, and if birds are likely to pick them out sow some soot over all. There is no better time than the present for sowing grass seeds, and most likely your lawn will be much improved by this simple process.

THIN-ENDED CUCUMBERS (A. R. L.).—The thin ends of your Cucumbers are not caused by your mode of heating. We think that the Cucumbers wanted more water or more rich top-dressings. Why not have planted them in the bed instead of in the boxes? The boxes would do well enough, only you must give richer soil and top-dress frequently. We presume you have means for letting up the heat into the atmosphere of the house from the flue. You might make a tank at the side of the flue or over it. For your other pit we think a small tank covered with slate would be the cheapest, with reversed turf laid on the slate before you place your soil on; or, better still, place 4 inches of rubble on the slate below the turf. We are sure, however, you may succeed with your flue. Make the trough 2 feet wide, and 6 inches deep.

HEATING A VINERY (J. B.).—The two four-inch pipes along the front of a house 190, by 14, by 7½ feet, will keep it safe, but it will not help you to force the Vines much. We have tried most boilers, and if well set and well managed we do not think there is much difference in them as to total results. In such a large house, 190 feet long, there is not much gained by having the boiler inside, unless you shut it off from the house. Tubular and cylindrical boilers are best fed at the top, though they can be fed from below the same as a saddle boiler. Take care that the top of your boiler is lower than the lowest pipe in the house. We cannot say what would be the price of a tubular boiler to suit you; but in case you should want more heat we would recommend a cast-iron cylinder boiler 28 inches in height and 22 or 23 inches in diameter, which will cost about £6 10s.; or a cast-iron saddle-back, 30 inches long, 24 inches wide, and 22 inches high, which will cost about £1 less. Good piping will cost about 3s. 6d. per yard. You could place the boiler at one end as you propose, but we would prefer having it in the middle and a glass partition, so that you could have three pipes in one half, and heat it independent of the other.

RIDDELL'S BOILER (A. B.).—We have no doubt Riddell's boiler will suit you, and so would a small cast-iron saddle-back for about £2 10s. We would make the small Vine-border inside, plait there, and make a border outside at our leisure. Your proposed piping of one four-inch pipe round a house 14 feet by 8, will keep up a heat of from 40° to 45° in all except the most severe weather.

HEATING A SMALL PIT (Ardent Lover of Flowers).—Your single flue will be sufficient for your purpose, but then you must make a fresh chimney at the end of the pit. Even then you should have openings to let the heat up into the house. This, as far as we recollect, was alluded to in the last volume, and is very easily done.

FUCHSIA FLOWER-BUDS DROPPING (R. H. S.).—What is puzzling is, that Camellias bloom so well, and Fuchsia blooms drop. Are you sure the plants are damp enough? Before we altered the glass we would dab it all over with thin whitening, made of whitening and milk, and see what that would effect. Put it on outside during a bright day. That will help to let you know if the dark-fluted glass occasions the mischief.

GRAPES IN MUSLIN BAGS (F. G.).—Your gardener is quite right in putting muslin bags over the bunches of ripe Grapes. It prevents wasps and flies injuring the berries.

COMTE DE ZYANS STRAWBERRY.—"I beg to state that Comte de Zyans Strawberry can be had true to name from Mrs. Nicholson, Eaglescliffe, Yarm (widow of the late Mr. J. W. Nicholson), and I can fully corroborate all that Mr. Leurenson has said in its praise.—ROBERT DOWKIN."

NAMES OF FLOWERS (Poor Man).—The petals of the Geraniums had all fallen off, but if they had remained on no judgment could have been formed of them from such scraps. The Calceolarias seem both alike, and of the commonest yellow variety, Aurea floribunda.

**GRAPES SMALL (A Cambrian).**—The cause of the berries being no larger than Currants is their not having set. They will, consequently, be stoneless. To make sure of the Mill Hill Hamburgh and Sweetwater setting well in a cool house, it is necessary to run the hand lightly over the bunches whilst in flower. You are doing right to give air at night; but it would be well to discontinue fire at night, and employ it by day only.

**SAVING MIGNONETTE SEED (Presbyter).**—You must pick the pods as they become ripe, going over the plants frequently on dry days for the purpose, and place them thinly on paper in a dry place, rubbing out the seeds when the pods are thoroughly dry.

**LAURELS DYING OFF UNDER TREES (H. D.).**—We have some in the same state, the old branches dying off and fresh ones coming from the bottom. It is from the dryness and poorness of the ground. You could not improve them by destroying the trees which overshadow them, and we would advise you to replace them with Aucubas. We have done so, and find these grow well where Laurels will not succeed.

**STEPHANOTIS FRUITING (W. H. B.).**—It is rather unusual for the *Stephanotis floribunda* to fruit, but some places where it has done so you will find referred to in Vol. V. New Series, pages 372, 410, 448, and 469. We have seen plants from seed sowed in this country; they had the midribs of the leaves red, and flowered when six years old, but were not different from the parent, with one exception, in which the plant was of less vigorous habit, and had flowers of a bluish colour. You would by sowing the seed have a chance of obtaining something deviating from the species either in habit or bloom. You will bloom the seedlings much sooner by grafting them on stocks of the old plant, otherwise you may wait years for their flowers.

**DESTROYING WEEDS ON WALKS (J. H.).**—Choose a dry period, and water the walks with the following solution—2 lbs. powdered arsenic dissolved in six gallons of cold water, boil, and keep stirring until well mixed; then add twelve more gallons of water, and 4 lbs. crushed soda, stirring well until it boils. Apply to the walks by a watering-pot with a rather fine rose. Care should be taken to keep the hot liquid from the grass or Box edging, by placing an inclined board to throw the water off on to the walk. The quantity above named is sufficient for 50 square yards of walk. If applied during dry weather from March to May it will keep the weeds under the greater part of the season.

**TROPEOLUM SEEDLING (G. G.).**—Your *Tropeolum* is bright in colour, but very deficient in form. We have seen much better seedlings this season—very superior to those enclosed.

**RENOVATING A MULBERRY TREE (A. K.).**—We apprehend the fruit would neither fall nor be small if you were to give in autumn a top-dressing under the tree of 3 inches thick of half-decayed manure, extending from the stem to the outside of the branches. Let it remain until March, and then point it in. During dry weather in summer give a thorough soaking of liquid manure.

**PROTECTING A VINE-BORDER (Willing to Learn).**—The cheapest plan is to procure some spars 3 inches by 2½, and three-quarter-inch deal boards. The spars should be a foot or more longer than the width of the border, and the boards 11 inches wide. These should be well coated with boiling coal or gas tar, which will greatly add to their durability. The border should be covered with litter or dry leaves, and to a greater depth next the house than in front, so that the surface may slope towards the front of the border. The spars should be put with one end on the wall, and the lower side level with the front wall plate, and nailed to maintain them in their places, the lower end resting on a brick. They should be placed 3 feet apart, narrow side upwards, and on them the boards should be laid. Commence at the bottom, and let each overlap that below it to the extent of three-quarters of an inch. A nail at both ends of the boards will maintain them in their places. If they are sound and have a sufficient incline they will render the border waterproof. All you need besides is a spout in front to carry off the water. The boards will last a dozen years and still be sound, if coated every third year with gas tar.

**PLUMS, PEARS, AND CHERRIES FOR A NORTH-WEST ASPECT (S.).**—You may have of *Plums*—Pond's Seedling, Victoria, Green Gage, Yellow Imperatrice, July Green Gage, Orleans, Vincennes, Drap d'Or, Coe's Late Red, and Blue Imperatrice. Of *Pears*—Alexandra Lambré, Baurré de Capriaumont, Colmar d'Été, Flemish Beauty, Knight's Monarch, Prince Albert, Thompson's, and Vicar of Winkfield. Of *Cherries*, besides Morello, Belle Magnifique, Belle de Choisy, Empress Eugénie, Coe's Late Carnation, Kentish, Royal Duke, May Duke, and Ohio Beauty.

**PEACHES AND NECTARINES ON A SOUTH-EAST ASPECT (Idem).**—Your situation being dry, warm, and sheltered, we think Peaches and Nectarines would grow and do fairly on a south-east aspect.

**SULPHUR AND LIME WASH (C. P.).**—It should be applied in the evening, the water being heated to a temperature of 120°, or it may be applied cold, but it is more efficacious hot.

**CURRANT SHOOTS BLACK INSIDE (J. H.).**—The shoots having the centre black are all right if the leaves are healthy.

**NAMES OF PLANTS (J. T. B., Sligo).**—It is impossible to name a *Geranium*—there are hundreds nearly alike—from such a scrap. The other morsel you sent seems to be a tip of the Club Moss, *Lycopodium clavatum*. (*J. T. B.*)—The tree of which you enclosed leaves is the *Salisbury adiantifolia*, or Maiden-hair-leaved. It is not very uncommon. There is a good specimen in the Chelsea Botanic Garden. (*A. B.*)—*Celastrus arcturus*. (*G. S.*)—Your plant is one of the *Asclepiadeæ*, *Oxyptelum Banksii* (?) If you can spare the room, we would advise you to keep it, and when it flowers send it to us again. (*Beginner*)—1, *Pellea adiantifolia*; 2, *Pteris cretica albobacata*; 3, *Pteris tricolor*; 4, *Scolopendrium officinarum*; 6, *Adiantum cuneatum*; 7, *Isoplepis gracilis*; 8, *Selaginella hortensis*; 9, *Begonia spatulata*; 10, *Begonia*, insufficient for determination.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending September 1st.

DATE.	BAROMETER.		THERMOMETER.				Wind.	Rain in inches.	GENERAL REMARKS.

POULTRY, BEE, and HOUSEHOLD CHRONICLE.

VULTURE HOCKS.

SURELY "F. C." must have seen many cockerels weak at the hock joint, that never had any tendency to vulture hocks. Weakness in this joint could never produce vulture-hock feathers, so that I would say to the question, whether, "vulture hocks, like a cat-hocked horse, were not a sign of, or resulting from, weakness in the leg-joints?"—Most decidedly not.

On the day of hatching I could tell "F. C." whether a Brahma or Cochin chick would be vulture-hocked or the reverse. Weak joints, at any rate at the hock, depend very much on a want of strength adapted to the increasing weight. If the legs once begin to give at the knees, and the bird should at the same time lay on flesh rapidly, nothing can save the knees becoming weak; but when this has occurred in a naked-hocked bird, no person has ever seen vulture hock "result" from it.

The most marked case of vulture hock I ever saw, I picked up accidentally just twelve years ago last month—viz., July, 1854. Now, as Cochins were unknown in this country in 1845, at least we may presume so, as at the show in May, 1845, none appeared in the class for Asiatic breeds, we have, if I may so term it, a Cochin life of twenty-one years, or at the furthest twenty-two years in this country. Yet twelve years ago—more

than half the age—is to be considered "recent introduction." So, also, the attempt at the second London show, I presume, must be considered "recent." However, if we are to have a poll, as Mr. B. P. Brent suggests, the "judge" has obtained a vote in "F. C."

I may here correct an error in my former letter, either my own or the printer's. I am made to say the "Gwynne Cochins and Sturgeon Cochins," instead the "Gwynne Brahmas," &c. I possessed birds of each of these gentlemen, and this I can aver, that they were not naked-hocked.—Y. B. A. Z.

WOODBIDGE POULTRY SHOW, AND A POULTRY PROTECTION SOCIETY.

It is all very well for "ONE OF THE COMMITTEE" of this Show to say that the Secretary has been applied to many times to call a meeting to have all matters "settled up." It is the duty of the Committee themselves, as you say, to satisfy those whose birds were either prizetakers or sold. Pray who is the person dignified in the schedule with the title of Chairman of the Committee? Surely this fixed office implies some authority. Let the Chairman of the Committee, or the Committee themselves, publish some satisfactory account of their proceedings, and pay their just debts. Until this is done, they will all stand in the same disrepute. I can tell them that some, and probably all, of the Patrons of the Show are as much

annoyed that their names have been printed in connection with this Committee as the subscribers and exhibitors are disgusted with the manner in which their money and their birds have been neglected. Without some explanation, both patrons and exhibitors will be difficult to obtain another year.

Your correspondent "Esoner" in reference to a Poultry Protection Society, remarks "I had personally good cause to complain of some very suspicious dealing on the part of a well-known name about two years ago, and the same person has, I find, been acting with other amateurs in a manner the reverse of straightforward." He does not tell us in what direction he points this remark. I should not be surprised if one, or more, of these persons have not tried some tricks upon me, as I have had one or two narrow escapes. I shall, therefore, be very glad to subscribe to any Poultry Protection Society that may be formed. My object is to do right and to expose wrong.—**RIGHT AND WRONG.**

I SHALL be glad to subscribe to get up a Mutual Protection Society if it can be done, for I am sure it is needed. In the spring I wrote to a Game-Bantam fancier, who lives not a hundred miles from Leeds, for a sitting of eggs; the result was they were all bad. My firm opinion is that they were boiled. I wrote and told him, and he never answered my note.

At the same time a gentleman from Halifax sent me a sitting; most of these were bad. I wrote and told him; he expressed his regret, and most handsomely gave me another sitting, which were all good. I expect I shall meet my Leeds friend some day ere long, and then he will hear my opinion of him.—**HOWARTH ASHTON, Polefield, Prestwick.**

P.S.—My poultry man says the first individual wants his "tête" punching.

### MEIGLE POULTRY SHOW.—AUGUST 29TH.

LAST year was a most successful commencement for a provincial show of poultry. There were many specimens equal to or surpassing those at most of the great exhibitions of the day, and therefore it was much to the credit and encouragement of the Association to find that the list of entries for this year was even in advance of the numbers on the previous occasion. These, too, included specimens from competitors far and near, as will be sufficiently seen from the prize list; and not only was there such a generality, but the names were those well known in this department as breeders of first-class birds. The advancement was very noticeable in several classes, especially in that for the young *Dorkings* and young *Game*, where the first places were held by Mr. P. W. Ogilvy, and also in *Game Bantams*. A new and additional attraction to the Show were the prizes for the best pens of six chickens for table use, and in this class some fine lots were shown. There was also much individual excellence in young *Spanish*, but unfortunately the superior individual birds were not found in the same pens. The *Geese* were as good as last year. As to single pens, it will be seen that the silver challenge cup presented last year to the Society by Admiral Popham for old birds, and that presented since then by the Hon. Mrs. Arbuthnot for young birds, were both carried off by pens of *Dorkings*. The former cup was again won by the Hon. Mrs. Arbuthnot, whose *Dorkings* were very fine, though of course bearing indifferent plumage at this season of the year. The cup presented by that lady was, however, won by Mr. P. W. Ogilvy, for his young *Dorkings*, and in that pen the pullets were very fine indeed, and the cockerel promised to be very superior—although the pullets in the second-prize pen were not inferior. The Judges of the Poultry were—Mr. Redpath, Edinburgh, and Mr. Brown, Perth, and these gentlemen made the following awards:—

**GAME.**—First, Hon. Mrs. Arbuthnot, Inchmartine. Second, R. Swift, Notts. *Chickens*.—First, P. W. Ogilvy. Second, J. M'Nab, Barrhead. Third, P. W. Ogilvy.

**DORKINGS.**—First and Challenge Cup, Hon. Mrs. Arbuthnot. Second, P. W. Ogilvy. Third, Hon. Mrs. Arbuthnot. *Chickens*.—First and Challenge Cup, P. W. Ogilvy. Second, Hon. Mrs. Arbuthnot. Third, P. W. Ogilvy.

**COCHIN-CHINA.**—First, Hon. Mrs. Arbuthnot (Buff). Second, H. Yardley Third, A. Crosbie, Melrose. *Chickens*.—First, W. Henry, Aberdeen. Second, Hon. Mrs. Arbuthnot (Buff). Third, Miss Soutar, Airth.

**SPANISH.**—First, J. Kair, Scone. Second, A. Cochrane, Perth. Third, Hon. Mrs. Arbuthnot. *Chickens*.—First, Mrs. Anderson, Meigle. Second, Mrs. Robertson, Belmont.

**HAMBURGH.**—First, J. Whitton, Ruthven. Second, J. Wilkie, Cortachy. *Chickens*.—First, Duke of Newcastle. Second, G. Edwards, Aberdeen. **BANTAMS.**—*Chickens*.—First and Second, P. W. Ogilvy. Third, R. M'Gregor, Perth.

**ANY OTHER VARIETY.**—*Chickens*.—First, Mrs. White (Crève Cœur). Second, Hon. Mrs. Arbuthnot (Dark Brahmas). Third, D. Gellatly (Houdan).

**DUCKS.**—First, Hon. Mrs. Arbuthnot (Rouen). Second, R. Forsyth (Aylesbury). Third, P. W. Ogilvy. *Ducklings*.—First, P. W. Ogilvy. Second and Third, Hon. Mrs. Arbuthnot (Rouen, Aylesbury).

**GEESE.**—First and Second, Hon. Mrs. Arbuthnot (Toulouse, Normandy). Third, Mrs. Davidson.

**TURKEYS.**—First, P. W. Ogilvy. Second, Hon. Mrs. Arbuthnot (Improved Cambridge). Third, Mrs. Kidd, Balmachrean

**ANY BREED.**—First, Mrs. Robertson (Spanish). Second, D. Gellatly (Game). Third, Mrs. White, Whins (Duckwing Game Bantams).

**ANY BREED.**—First and Second, D. Gellatly (Cochin-China). Third, W. Simpson, Cardean (Dorkings).

**ANY BREED.**—First, P. W. Ogilvy. Second, Mrs. Kidd, Balmachrean. Third, Mrs. Robertson.

**ANY BREED.**—First, P. W. Ogilvy. Second, Mrs. Barclay, Simprun. Third, Mrs. Tait, Meigle.—(Dundee Advertiser).

### DEWSBURY POULTRY SHOW.

THIS took place on the 29th ult., at Savile Town, near Dewsbury, and had it not been that the weather was extremely unfavourable it would have proved the most successful meeting ever held here. The entries were more numerous than on any previous occasion, in almost all classes, and the competition keener.

**Cup (best pen in Exhibition), J. Threshy, Bradford, COCHIN-CHINA.**—First, C. W. Brierley, Middleton. Second, H. Beldon, Bingley. *Chickens*.—First, C. Sedgwick, Keighley. Second, T. Vickerman, Chickensley.

**SPANISH.**—First, J. Thresh, Bradford. Second, H. Beldon. *Chickens*.—First, J. Newton, Silsden. Second, T. Greenwood, Dewsbury.

**DORKING.**—First, J. Tyrell, Beaumont, Huddersfield. Second, H. Beldon. *Chickens*.—First, E. Leach, Rochdale. Second, H. Beldon.

**BRAMA POOTRA.**—First, J. H. Pickles, Bridgeroyd. Second, G. H. Roberts, Preston. *Chickens*.—First, R. W. Boyle, Ireland. Second, J. H. Pickles.

**GAME (Black Reds).**—First, H. Beldon. Second, G. Noble, Staincliffe. *Chickens*.—First, W. Fell, Adwalton. Second, G. Noble.

**GAME (Brown Reds).**—First, H. Beldon. Second, J. Byrom, Lancashire. *Chickens*.—First, J. Ineson, Staincliffe. Second, H. Beldon.

**GAME (Duckwing and other Greys and Blues).**—First, W. Fell. Second, H. Beldon. *Chickens*.—First, W. Fell. Second, — Spedding & Senior, Chickensley.

**GAME (White and Piles).**—*Chickens*.—Prize, H. Beldon. **GAME (Black and Brassy-winged, except Greys).**—First G. Noble. Second, J. Ineson. *Chickens*.—Prize J. Ibberson, Great Gomersak.

**HAMBURGH (Golden-spangled).**—First, J. Walker, Knarsborough. Second, H. Beldon.

**HAMBURGH (Silver-spangled).**—Prize, H. Beldon. **HAMBURGH (Golden-pencilled).**—First, Mrs. Holmes, Halifax. Second, A. K. Wood, Kendal.

**HAMBURGH (Silver-pencilled).**—First, J. Walker. Second, H. Beldon. **HAMBURGH (Black).**—First, C. Sedgwick. Second, H. Beldon.

**POLANDS (Gold and Silver-spangled).**—First and Second, H. Beldon. *Chickens*.—First, H. Beldon. Second, T. E. Kell, Wetherby.

**POLANDS (Any other variety).**—Prize, H. Carter, Holmfirth. **BANTAMS (Black).**—First, Miss G. Ridgway, Dewsbury. Second, S. Schofield.

**BANTAMS (White).**—First, S. Schofield. Second, E. Hutton, Pudsey. **GAME BANTAMS.**—First, G. Noble. Second, W. Newsome, Leeds.

**GAME COCK (Any variety).**—First, J. Mason, Worcester. Second, J. Hodgson, Bradford. **Hen.**—First, G. Noble. Second, T. Dyson, Halifax.

**DUCKS (White).**—First, E. Leach. Second, J. K. Fowler, Aylesbury. **DUCKS (Rouen).**—First, W. Newsome. Second, F. Horsfall, M.D., Pontefract.

**DUCKS (Any other variety).**—First, E. Hutton, Pudsey. Second, J. K. Fowler.

**RABBITS (Lop-eared).**—*Buck.*—First, F. Mosey, Leeds. Second, E. Brooke, jun., Huddersfield. *Doa.*—First, F. Mosey. Second, W. Newsome, Pair far colour. First, F. Horsfall. Second, E. Brooke, jun. *Weight.*—First, E. Brooke, jun. Second, J. E. Crowther, Dewsbury.

**PIGEONS.**

**POWER.**—*Cock.*—First, E. E. M. Roys, Rochdale. Second, J. Thackray, York. *Hen.*—First, J. Thackray. Second, E. Horner, Harewood.

**CARRIER.**—*Cock.*—First, E. Horner. Second, J. Firth, jun., Dewsbury. *Hen.*—First, E. E. M. Roys. Second, E. Horner.

**TUMBLERS (Almond).**—First, E. E. M. Roys. Second, J. Thackray. **TUMBLERS (Any other variety).**—First, C. Cowburn, Leeds. Second, E. E. M. Roys.

**TURBITS.**—First, J. Thackray. Second, E. Horner. **JACOBS.**—First and Second, E. Horner.

**TRUMPETERS.**—First, J. Thompson, Bingley. Second, E. Horner. **OWLS.**—First, J. H. Pickles, Bridgeroyd. Second, J. Fielding, jun., Rochdale.

**BARBS.**—First, J. Firth, jun. Second, J. Thompson. **FANTAILS.**—First, J. Thackray. Second, C. Cowburn.

**NUNS.**—First, J. Thackray. Second, J. Thompson. **PIGEONS (Common).**—First, T. Watson, Thornhill. Second, J. Vickerman.

**ANY OTHER VARIETY.**—First, J. Thackray. Second, H. Yardley, Birmingham.

### SWANSEA POULTRY, PIGEON, RABBIT, AND BIRD SHOW.

THE Exhibition was held in a yard adjoining the Music Hall, on Thursday, the 23rd ult., in connection with a Fruit and Flower Show. The entries were not numerous, but some good specimens were exhibited. The following are the awards:—

**DORKINGS.**—First and Second, G. Lewis, Carmarthen. **SPANISH (Black).**—First and Special, T. Ace, Ystalyfera. Second, J. Butler.

**COCHINS.**—First, T. Ace. Second, G. Lewis. **HAMBURGHES.**—First, withheld. Second, — Milroy.

**GAME.**—First and Second, G. Lewis. **BANTAMS.**—First, J. Butler. Second, W. Crapper. Highly Commended, W. Nettle.

**FOR THE BEST PEN OF PULLETS.**—First and Extra, T. Ace (Spanish and Buff Cochines).

**DUCKS (Aylesbury).**—First, W. E. Walcup, Rheola. Second, Sergeant Green, Swansea.

**DUCKS (Rouen).**—Prize, E. M. Savours, Briton Ferry Road.  
**PORONS.—Carriers.**—Prize, J. Butler. *Pointers.*—Prize, J. Butler. Highly Commended, J. Pugsley. *Jacobins.*—First, W. Crapper. Special and Highly Commended, J. Butler. *Tumblers (Almond).*—First, D. Evans. Special, T. Evans. *Fansails.*—Prize, W. Phillips, Swansea.  
**RABBITS (Lop-eared).**—First, Sergeant Green. Second, W. Crapper.  
**RABBITS (Common).**—Prize, —Harding.  
**CANARIES.**—First, J. Griffiths. Second, Sergeant Green.  
**GREY PARROT.**—Prize, J. Harris.  
**GREEN PARROT.**—Prize, W. Crapper.

The Judges were Mr. J. Savours and Mr. Woolley.

**COTTINGHAM POULTRY SHOW.**

(From a Correspondent.)

THE annual Exhibition of Poultry and Pigeons was held on the 29th August, and, as regards numbers of entries, far exceeded those of former years, while in many of the classes it was a matter of great difficulty for the Judges to decide upon the respective merits of the various pens: so much so, that in several cases they placed two pens on an equality, and awarded an "equal" first, or an "equal" second; but, as the authorities would have us to understand it, they bestowed these extra favours to the specimens thus honoured with a very niggardly hand, as instead of either competitor receiving the full value of the prize, it was to be divided equally between the two!—which is certainly a new idea, and it is very doubtful whether either one or both of the successful parties cannot legally claim the amount offered in the schedule for those classes. However this may be, another year, it will be well to avoid such a cause of dispute, and one way of doing so will be to restore the class for Rouen Ducks, and not to leave these and a host of other Ducks to compete together for the prizes.

F. Ferguson, Esq., of Risby Park, and Mr. D. Pickering, of Hull, officiated as Judges. The following is believed to be a list of their awards; but no catalogues being printed it was difficult for even the Secretary to find to whom the birds belonged.

**SPANISH.**—First, G. Hoyle, Hessele. Second, M. Robinson. *Chickens.*—First and Second, J. H. Rea.  
**DORKINGS.**—First, W. Watson, Bishop Burton. Second, G. Holmes. *Chickens.*—First, —Mankin. Second, W. Watson.  
**COCHINS (Any variety).**—First, J. Hatfield. Second, T. C. Trotter, Sutton. *Chickens.*—First, H. Taylor, Newland. Second, W. Charter, Driffield.  
**GAME (Black-breasted and other Reds).**—First, W. Naylor. Second, G. Holmes. *Chickens.*—First, O. A. Young, Driffield. Second, G. Holmes.  
**GAME (Any other variety).**—First, J. Hodgkinson, Hull. Second, W. Charter. *Chickens.*—First, J. Hodgkinson. Second, O. A. Young.  
**POLARDS.**—First, J. W. Proctor (White-crested Black). Equal Second, J. Berooff and O. A. Young. *Chickens.*—First, J. M. Proctor. Second, J. Cross.  
**HAMBURGERS (Golden-spangled).**—First, J. M. Blanchard. Second, G. Holmes. *Chickens.*—First, J. Blanchard. Second, G. Holmes.  
**HAMBURGERS (Golden-pencilled).**—First, A. Hume. Second, R. Robson. *Chickens.*—Second, G. Holmes.  
**HAMBURGERS (Silver-spangled).**—First, J. Blanchard. Second, O. A. Young. *Chickens.*—First, J. Jennings. Second, R. Cooke.  
**HAMBURGERS (Silver-pebbled).**—First, R. Robson. Second, G. Holmes. *Chickens.*—First and Second, S. Holmes.  
**BANTAMS (Gold-laced).**—First, T. C. Harrison, Hull. Second, J. Marshall. *Chickens.*—First, R. Smith, Malton. Second, O. A. Young.  
**BANTAMS (Game).**—First, E. Voakes. Second, T. Holmes. *Chickens.*—First, J. Blanchard. Second, R. Smith.  
**BANTAMS (Any other variety).**—First, J. R. Jessop (Black). Second, T. C. Harrison (Silver-laced). *Chickens.*—First and Second, J. R. Jessop (White and Black).  
**ANY OTHER DISTINCT VARIETY.**—First, R. Loft, Woodmansey (Sultans). Second, J. Hodgkinson. *Chickens.*—First and Second, R. Loft.  
**FARMYARD CROSS.**—First, R. Loft. Second, J. Robinson. *Chickens.*—First, J. Coverdale. Second, Mrs. Robinson.  
**SELLING CLASS.**—First and Second, E. Loft.  
**GEES.**—First, O. A. Young. Second, Mrs. Nicholson.  
**DOES (Aylesbury).**—First, O. A. Young. Second, F. Ker, Beverley.  
**DOES (Any other variety).**—Equal First, T. C. Harrison and O. A. Young (Mandarin and Rouen). Equal Second, Mrs. Morris and J. E. Jessop (Rouens and Summer Teal).

**SINGLE-COCK CLASS.**

**SPANISH.**—First, T. C. and E. Newbill. Second, G. Holmes.  
**DORKINGS.**—First, J. Hatfield, Cottingham. Second, G. Holmes.  
**COCHINS (Any variety).**—First, T. C. Trotter. Second, J. Hall.  
**GAME (Black-breasted and other Reds).**—First, J. Hatfield. Second, J. Hanson.  
**GAME (Any other variety).**—First, W. Drewry. Second, W. Charter.  
**POLARDS.**—First, J. M. Proctor.  
**HAMBROKS (Golden-spangled).**—First, O. A. Young. Second, G. Holmes.  
**HAMBURGERS (Golden-pencilled).**—First, G. Holmes. Second, J. Hall.  
**HAMBURGERS (Silver-spangled).**—First, G. Holmes.  
**HAMBURGERS (Silver-pencilled).**—First, S. Holmes. Second, R. Voakes.  
**BANTAMS (Gold-laced).**—First, T. C. Harrison. Second, J. Marshall.  
**BANTAMS (Game).**—First, W. Scott. Second, T. C. Harrison.  
**BANTAMS (Any other variety).**—First, J. R. Jessop (Black). Second, Miss Bright (White).  
**ANY OTHER DISTINCT VARIETY.**—First, R. Loft. Second, T. C. Trotter.  
**FARMYARD CROSS.**—First, O. Robinson. Second, W. Charter.  
**SELLING CLASS.**—First, R. Carling. Second, R. Loft.

**PIGEONS.**

**CRUMPERS.**—First, H. Yardley, Birmingham. Second, W. Watson, Beverley.  
**CARRIERS.**—First, H. Yardley. Second, W. Barratt, Hull.

**TURBETS.**—First, B. Lesson, Driffield. Second, G. H. Pickering, Driffield.  
**TRUMPETERS.**—First and Second, F. Key.  
**JACOBINS.**—First, T. Ellington, Woodmansey. Second, T. C. & E. Newbill.  
**FANTAILS.**—First, T. Ellington. Second, C. Cousins, Hull.  
**DRAGONS.**—First, H. Yardley. Second, W. Beccroft.  
**TOMBLES.**—First, C. N. Lythe, Cottingham. Second, J. R. Jessop.  
**BARBS.**—First, H. Yardley. Second, W. Barratt.  
**NUNS.**—First, C. N. Lythe. Second, B. Lesson.  
**ANY OTHER VARIETY.**—First, T. Statters (Frillbacks). Second, J. R. Jessop (Runts).  
**SPECIAL PRIZES (by W. Boulton, Esq., for best Carrier Hen).**—Prize, R. Bellsmy, Leven.  
**TOMBLES (Mottled).**—Prize, C. N. Lythe.  
**RABBITS (Any variety).**—First, O. A. Young.

**HASTINGS, ST. LEONARDS, AND EAST SUSSEX POULTRY EXHIBITION.**

(From a Correspondent.)

THE first Show of the Hastings, St. Leonards, and East Sussex Poultry Society, was held in Warrior Square, August 29th and 30th, in conjunction with the annual Flower Show.

The Show was entirely for birds of the year, and 123 pens of poultry were exhibited. These were shown in Turner's pens. In *Dorkings*, the silver cup was awarded to the Duke of Newcastle, Mr. Lingwood's beautiful pen of White Dorkings being second, Dr. Campbell taking third with Greys. *Cochin Chinas* came next, Mr. Rodbard taking the cup with a splendid pen of Grouse-coloured; Mr. Lingwood second with Buffs, and Mr. Rush, third. In *Game*, Mr. S. Mathews took the cup with Black-breasted Reds; Mr. Jenkins being second and third. One pen was disqualified owing to the sickly state of the birds. *Spanish* were not in such good feather as the other varieties. Mr. Rowe took the cup. Of *Brahmas* there was a strong entry both of Dark and Light. Mr. Lane was first with Dark, and Mr. Edc second with Light. In *Spangled Hamburgs* Mr. Preston was first, and Miss Barter second. In *Pencilled Hamburgs*, Mr. Havers was first, and Mr. Preston second. In the *Variety* class, the National Poultry Company had it all their own way, taking first and second with very excellent *Hondas* and *Crève Coeurs*, and third with *La Flèche*. In *Game Bantams*, Mr. Manning was first with Piles, and second with Black-breasted Reds. In the any other *Bantam* class, Mr. E. Hutton was awarded a prize for a very deserving pair of Whites. No other entry. In *Aylesbury Ducks*, the first and third prizes fell to Mr. Fowler, the second prize to Mr. Winham. For other *Ducks*, the first prize was awarded to Mr. Oliver, for *Rouens*; second to Mr. Hutton, for *White Call*; and third to Mr. Fowler, for *Black East Indian*. *Geese*, first to Mr. Wells, for *Pied*; second, withheld. In the sweepstakes for *Game* cockerels, Mr. Pope was first with a *Black-breasted Red*; the Duke of Newcastle second with a *Brown Red*, and Mr. Mathews third with a *Black-breasted Red*. Mr. Munsters had a *Black-breasted Red*, and a *Pile* very highly commended; and Mr. Jenkin's was also commended, the whole being a very good class. A very fine *Malay* cockerel was here shown out of place. Of the Cottagers' poultry, to which it was desired to hold on as much encouragement as possible, there were two pens of *Dorkings*, one was awarded a second prize, the other being a mongrel breed. In the Cottagers' *Variety* class, *Silver Polands* were first; *Brahmas*, second; *Cochins*, third; *Game*, fourth. Of Cottagers' *Ducks*, the first were *Rouens*; second, third, and fourth, *Aylesbury*.

The Judges were Mr. Nicholson, Mr. Price, and Mr. Brent.

**WAKEFIELD POULTRY SHOW.**

THE second annual Exhibition of the great West Riding Agricultural and Horticultural Society was held at Wakefield on Saturday, the 1st inst. The poultry, although not numerous, was very choice.

For the best pen of *Game*, the silver cup was carried off by Sir St. George Gore, Bart., with a first-class pen of *Brown Reds*. In the classes for *Reds* and *Duckwings*, the first prizes were awarded to chickens, and in any other variety of *Game*, *Blacks* and *Piles* took the prizes. *Hamburgs* were good. Mr. Beldon obtained most of the prizes with capital birds. *Game Bantams* were one of the best classes, the competition being very keen between Messrs. Newsome and Crossland. The first-prize pen from the former contained a very fine-shaped cockerel, deficient in colour; while the pullet in Mr. Crossland's pen was perhaps one of the best we ever saw.

There was a fine show of *Ducks*, but many pens were indifferently matched. The following is the prize list:—

**GAME (Any colour).**—Cup, Sir St. G. Gore, Bart., Hopton Hall, Wkirkworth, Derbyshire. Second, C. W. Brierley, Rhodes House, Middleton, Manchester. Highly Commended, Sir St. G. Gore, Bart.  
**GAME (Black-breasted or other Red).**—First, J. D. Newsome, Batley. Second, Sir St. G. Gore, Bart.  
**GAME (Duckwing).**—First, J. Bradford, Bradford. Second, Sir St. G. Gore, Bart.  
**GAME (Any other variety).**—First, J. D. Newsome. Second, Sir St. G. Gore, Bart.  
**GAME (Any colour).**—*Pullets.*—First, H. Crosley, Bloomfield, Halifax.

Second, E. H. Woodcock, Thornhill, Wigan. Highly Commended, H. Beldon, Goitstock, Bingley. Commended, Sir St. G. Gore, Bart.

DORRING.—First, H. Beldon. Second, J. T. Beaumont, Greenhead House, Huddersfield.

SPANISH.—First, H. Beldon. Second, J. Thresh, Manchester Road, Bradford.

COCHIN-CHINA (Any colour).—First and Second, C. W. Brierley (Partridge and Buff). Highly Commended, H. A. Child, Wakefield.

BRAHMA POOTRA (Any colour).—First and Second, J. Pickles, Bridge-road, Todmorden.

POLANDS (Any colour).—First and Second, H. Beldon (Golden and Silver).

HAMBURGH (Golden-pencilled).—First, Sir St. G. Gore, Bart. Second, S. Smith, Northwram, Halifax. Commended, H. Beldon.

HAMBURGH (Silver-pencilled).—First, H. Beldon. Second, A. K. Wood, Burnside, Kendal.

HAMBURGH (Golden-spangled).—First, H. Beldon. Second, Sir St. G. Gore, Bart.

HAMBURGH (Silver-spangled).—First, H. Beldon. Second, Sir St. G. Gore, Bart.

ANY OTHER DISTINCT BREED.—First and Second, National Poultry Co., Bromley, Kent (La Flèche and Houdan). Highly Commended, H. Beldon (Black Hamburgs).

BANTAMS (Game).—First, J. D. Newsome. Second, Master J. Crosland, Wakefield. Highly Commended, H. A. Child, Wakefield.

BANTAMS (Any other variety).—First, F. L. Roy, jun., Nenthorn, Kelso, N.B. (Silver-faced Sebrights). Second, E. Hutton, Pudsey, Leeds (Black).

DUCKS (Aylesbury).—First, E. Leech, Graves House, Rochdale. Second, O. A. Young, Driffield.

DUCKS (Rouen).—First, J. White, Whitley, Netherton. Second, J. and J. Charlesworth, Dircar, Wakefield. Highly Commended, Sir St. G. Gore, Bart.

DUCKS (Any other variety).—First, Sir St. G. Gore, Bart. Second, J. R. Jessop, Beverley Road, Hull.

EXTRA STOCK.—First, Mrs. Bnrrill, Sharlestone (Duck with three legs). Second, S. Burton, Dircar (Bantams).

The Judges were Mr. Richard Woods, Osberton, Worksop, and Mr. Wm. Cannon, Bradford.

### GAME BANTAMS:

POSTANS' AND RAYNOR'S STRAINS.

MR. POSTANS in his advertisement, contained in your paper of last week, quotes Mr. Crosland's opinion of the cockerels bred by him last year, and states that "all the Black Red Bantams shown with such eminent success last year by the Rev. George Raynor, were bred from birds had direct from Mr. Postans or were their descendants of the previous year." As the purchaser of this celebrated strain of Mr. Raynor's, I beg to state that Mr. Crosland has within the last fortnight seen my stock, and remarked that Mr. Raynor's birds were superior to what he produced last year. With the same amount of pride which naturally moves Mr. Postans, I must say that Mr. Raynor in a great measure attributes his success this year to two hens of my strain, with which he took the cup at the last Manchester show, as well as to eggs of my strain which he had from a friend of mine, a clergyman in Hertfordshire; and I am bound to say that my strain was from the original and pure blood of Mr. Crosland's stock. I am sorry to see that Mr. Postans is giving up a class of birds which have been of such credit to the county of Essex, but I hope with Mr. Raynor's stock and my own to maintain at the next Birmingham show the place occupied last year by Mr. Raynor, and to keep in the county one at least of two very celebrated strains.—GEORGE MANNING, Springfield, Essex.

### PIGEONS' SELLING CLASS AT HALIFAX.

AT Halifax an exhibitor entered two pens of valuable Pigeons in the selling class, which required that the price should not exceed £1 Is. Now, that exhibitor would not take five times that amount for the birds he showed; but they were claimed through himself previously to the Exhibition, and by this dishonest procedure he took first and second prizes.

Unless the secretaries of shows decline allowing the exhibitor or any one else to claim the birds previous to the judge concluding his awards, whereby the public, one and all, would have a fair chance of claiming anything, or unless something be done to put a stop to this disgraceful proceeding, the selling class will soon dwindle out of sight.—AN EXHIBITOR.

### BEE-WRITING EXTRAORDINARY.

THE example of Dr. Cumming, who, with a mere smattering of apian knowledge, first aspired to instruct the world in bee-culture through the columns of the *Times*, and then ran a ruck against every one who ventured to point out and correct any of his very numerous mistakes, seems to have encouraged

magazine writers generally to take up the subject; and we find accordingly that nearly every periodical has recently had one or more articles, in which the changes are rung on bees, beehives, and bee-keeping, with greater or less success, according to the assiduity with which the compiler has "read up" his subject, and the amount of information which he has been able to glean in other ways. Of course, under these circumstances we must expect to find most of the old facts and fallacies furnished up, and presenting themselves in their new guise with as much complacency as if they now for the first time saw the light. Accordingly the traditional snail is again discovered, glued either to the window or to one of the sides of the hive; once more is slain that celebrated mouse or huge slug (whichever you please, my little dears!), and again with infinite labour and sagacity do the industrious little insects render its putrescent carcase inoffensive by enshrouding it in a thick covering of propolis; whilst once more, alarmed and terror-stricken, yet standing erect and motionless, Thorley's immortal maid-servant is presented to our view in the unenviable predicament of being made use of as a resting-place by an eccentric swarm of bees. To all these, and such as these, do I bow, smile, and pass on; but when, as in a recent Number of "Chambers's Journal," I meet with an article written by a gentleman so ardent in the pursuit of apian knowledge, that, as he informs us, he has "often sat up all night" to watch the bees' manœuvres by lamp-light, I make a far lower obeisance than usual, and peruse his lucubrations with the most wrapt attention, in the hope of benefiting at second-hand from the reflected light produced by such an expenditure of the midnight oil. Nor are my expectations disappointed. Here are new facts and discoveries sufficient to set us all thinking, and as I have no wish to be selfish, I invite all the readers of the bee department of "our Journal," to share with me this intellectual banquet.

First, then, I observe, that this illustrious contributor, whom, as he maintains a strict incognito, we may, for convenience, venture to denominate "The Chamber Bee-master," almost invariably speaks of the bee in the masculine gender. It is true he gives us no reason for this; but shall we presume to ask for chapter and verse from such a Gamaliel? No, rather let us sit humbly at his feet and drink in unquestioningly the words of wisdom that flow from his pen. Away, then, with all unworthy doubts; tell me not of the investigations and discoveries of mere bee-keepers and naturalists, from Huber and Mademoiselle Jurine downwards; is not the masculine very ungallantly assumed to be the most worthy gender? and shall I on such slender authority venture to doubt the infallibility of my new-found guide?

Commencing, then, with Samson's swarm, "The Chamber Bee-master" cites divers unsavoury receptacles as having been at different times selected as a habitation by "Master Bee." Among these are a baby's coffin deposited in a vault, a horse's head, the belly of a dead ass, and the vault of a common sewer! But, we are told, that "in spite of" these facts "the bee delights in all kinds of perfumes; and one of the means of coaxing a stray swarm into a hive is to rub the inside of it with balm, and suspend it within reach of their olfactory nerves." But here let me pause to make candid confession of my ignorance, smite my breast, and cry "*Mea culpa!*" Sinner that I am, I never knew until now that bees affected "all kinds of perfumes." Heretic that I was, I never believed that they could be attracted to a hive by the smell of balm! Nay, worse than this, so little do I know of the herb that I am deeply grateful to Webster's dictionary for informing me that it is "an aromatic plant of the genus *Melissa*." It is true that during more than a quarter of a century I have never lost a swarm, yet what risks may I not have unconsciously run through my want of faith! But is there not balm in Pedlington? Yea, let us hope so, and trust that Mr. Roots will be able to supply such a bundle of plants, or such a packet of seeds, as may absolve me from encountering such desperate hazards for the future.

"Among the rustics of France and England bees are accommodated with very poor habitations . . . furnished with only one entrance." Can I then venture to whisper the humiliating confession that my hives also have "only one entrance," and that here my Mentor leaves me in most distressing doubt? A single entrance is evidently condemned, but the right number is not stated. It may be two only, or one may possibly be required for the separate use of every inhabitant of the hive, those for the queen and drones being, of course, of extra size, or it may be any intermediate number

between these two extremes. Where, then, is the *Œdipus* who can expound this riddle for me?

We all know that Dr. Cumming asserted that bees never worked after four o'clock in the afternoon; but our "Chamber Bee-master" discovered that on very fine nights in June they never lost a moment in sleep, but in double columns kept marching out and in, and that they always "kept their neighbours on the sword-hand, reversing the fashion which prevailed in London when men were weapons." As it would be impossible, however, for the bee "to persevere in such a course, it occasionally takes a nap in the bells of flowers, where, if particularly weary, it nestles all night, and one of its favourite resting-places is the hollow of the scented geranium, or the spotted cranesbill!"

Seeking publicity in an Edinburgh magazine, and writing professedly on the subject of "Bee-hives," these manufactured at Stewarten, and which have achieved so extensive a reputation, are not only passed over in silence by our "Chamber Bee-master," but we are told that, on the contrary, "people are beginning, through attention to analogy, to prefer the hexagonal shape, which is that of the cells of the comb." Now, it may be remembered that Dr. Cumming declared Stewarten hives to be hexagonal, and after stating that he had found them to "answer best of any," drew from this fact the inference "that the bees, who construct their cells in the form of hexagons, prefer the house in which they work to be of the same shape." On its being pointed out to him that these hives had eight sides instead of six, he was unable to deny the fact, but, willing to retract as little as possible, he still upheld the hexagon as the best shape, although he could give no reason whatever for this opinion beyond the purely imaginary one of a fancied analogy. This, therefore, is the history of these hexagonal hives, which having thus achieved notoriety only by a "fluke," we are now told "people are beginning to prefer," and which must perforce rapidly supersede the well-made and successful Stewartens, when these latter are thus pointedly ignored in a Scottish periodical by so unfailing an oracle.

It seems, also, that we were far too hasty in rejecting the Italian story of bees feeding on oil-cake, since it is here reproduced, and, of course, under such sponsorship none can any longer refuse to receive it.

I have reserved to the last the inestimable suggestions of "The Chamber Bee-master," which, if carefully and consistently carried out, will doubtless raise apiculture to the highest pitch of which it is capable. The first is, that cheap hives should be made "with two storeys divided by a sliding roof," so that "the bees might be admitted into the upper storey by removing the slide as soon as they had filled the lower." The second is, that bee-keepers should dislodge the bees from their habitations without sacrificing the lives of any of the inmates. "This," we are told, "might be done by placing new hives at a short distance from the old ones, and then introducing a pipe into the latter, by means of which they might easily be smoked out." The third is, that hives should be kept in niches formed in walls "to hold twelve, twenty-four, or thirty-six hives, in one, two, or three stages of twelve in each."

I am aware that hard-headed and cold-blooded practical men may urge that there is a plentiful lack of novelty about the first suggestion, this being in some sort admitted and apologised for by the illustrious writer himself; that the second is impracticable as he describes it, and unadvisable if accomplished by any other means; that the mode of keeping bees recommended in the third is so clumsy and inconvenient as to have become almost obsolete even in Devonshire itself; and that the entire contents of the paper are such as to prove that its author possesses only the most superficial knowledge of his subject. A plague on all such strictures! say I. Having probed and investigated narrowly to the uttermost all the known facts, do we not now want novelties in the natural history of the bee? and have we not here got them, in company with ancient stories turned inside-out and vamped up, until, like the Jew's second-hand garments, they look almost "bettersh dan new?"—AN OLD BEE-KEEPER.

#### LIGURIANISED BEES—PLURALITY OF EGGS.

This fine day I observe that many young bees leave the hive, but very few indeed, comparatively, marked like those I sent you, and differing in no respect that I can see from the common bee. Is it possible that the queen breeds both kinds?

In the spring of this year, I frequently examined the combs

of a weak stock and always found a plurality of eggs in the cells most irregularly laid. There were cells with one egg certainly, but all about these there were others with two and three eggs in them. What could have been the cause of this? This stock has much improved of late. The queen is one year old.—EDW. FAIRBROTHER.

[A common queen having had intercourse with Ligurians produces a mixed progeny, some nearly as handsome as pure Italians, many of the ordinary kind, and some intermediate between the two. A prolific queen at the head of a weak stock frequently, or we might even say generally, lays a plurality of eggs in many of the cells, an abnormal condition of things which ceases as soon as the colony becomes prosperous and extends its combs sufficiently to admit of its deriving the full advantage from her marvellous reproductive powers.]

#### UNITING AND FEEDING BEES.

I wish to take away all the honey of seven hives, and to unite four swarms together, and three swarms together. Will you state the process, the best time of day, and in what place, as fully as time and space will admit? If I keep the troughs of the hives always full of sugar, are the bees likely to survive the winter? and what quantity of beer or water should be mixed with 1 lb. of sugar, and ought it to be boiled? If the bees have not made enough honey from the supply of sugar by the time the cold weather sets in, would it influence their working to keep them in a greenhouse at a temperature of from 50° to 60°? Will the bees interfere with you while performing the operation? What is the best site for bees in winter?—W. BRADLEY, Bromley Road, Beckenham, Kent.

[If you intend putting your expelled bees into frame hives the operation is easy and success nearly certain. Drive the bees during the forenoon of a fine day into common hives, in the manner described in page 59 of the fifth edition of "Bee-keeping for the Many," and it may be as well to drive the first four into four different hives, which should for the time be put in their places on the old stands. The deserted hives should be conveyed in-doors, one by one, as soon as their inhabitants are expelled, the combs cut out, and any stragglers that remain be returned to their brethren. When all four have been operated on, the combs should be carefully dissected, every piece of brood or pollen-laden comb being cut out in a square or other available form, matched together, and fitted into frames, wherein they must be temporarily fastened by means of zinc or tin clips, wire, slips of wood and tacks, or any other means which may occur to you. There will probably be quite sufficient of what would otherwise be waste comb to fill a complete set of frames, which should be put into a hive, and this hive should be surmounted by an empty one of the same size, from which the frames and top board have been removed, placed between it and the crown-board. Convey the whole to its stand in the apiary (which should be as nearly as possible in the centre of the space previously occupied by the four hives), and knock the clusters of bees out of these one after the other as rapidly as possible into the upper hive and on the top of the frames of the lower one, which must be exposed by removing the crown-board. Replace this latter the instant the last lot of bees is knocked out, and leave them to settle matters until the next day but one, when the top hive and all, or nearly all, the artificial supports to the combs may be removed. If any of the latter appear unsafe, their supports should be left until the day following, when all are pretty sure to be safe. This operation may be repeated in a day or two with the remaining three hives. We have framed these instructions on the hypothesis that the bees are your own, and on your own premises. If they are at a distance you may drive them one day, tie them up in cloths and take them home with the brood-combs (which are of course nearly valueless to their owners, but for which you had better make a trifling money payment rather than ferege them), in the evening, placing these latter in a warm room (say the kitchen), for the night, and complete the operation next morning. If you manage matters properly there is no danger whatever from the bees.

Use no feeding-trough, but an inverted pickle-bottle for each of your newly-formed stocks, which fill every evening until they have stored sufficient food to last them through winter, during which season no feeding should be attempted. We use no beer, but lump sugar and water, in the proportion of 3 lbs. of the former to 2 lbs. of the latter, and boiled a minute or

two. This mixture is so well adapted for the purpose that it really leaves nothing to be desired.

We have had no experience of wintering bees in a greenhouse; but, although we do not think very favourably of it, should, nevertheless, like to see the experiment tried. We prefer their summer-stands as the best site for bees in winter, although aware that they will do well in a dry cellar or dark room adapted to the purpose. If your hives are fitted neither with bars nor frames, the expelled bees should be inducted into them in the manner recommended in the same page of "Bee-keeping for the Many," to which we have already referred, and fed by means of an inverted bottle until they have built combs and stored them sufficiently to last the winter.]

A SORROWFUL TALE OF BEE-KEEPING.

In the spring of 1865 I lost my old gardener, who had an affection for bees. Three old stocks were then reduced to one old and one new. My new gardener cared nothing for bees, and I had no time to go into college on their behalf, or to attend to them. The summer passed, and in September, lamenting the lost harvest, I had the curiosity to examine my two hives. The new one is Mr. Neighbour's improved arrangement for depriving, with three apertures and slides, and upper-storey skep to cover them. I attempted to lift this, and finding it very heavy, proceeded to take off the upper skep, which was, however, fast. With a knife I prised it up, and found it entirely full of new honey. One of the zinc slides had been displaced in fixing it on the lower chamber, and the bees now had free access to the whole area. This I took then as my harvest; it weighed 33 lbs., and when taken out the prime honey in the comb weighed 22 lbs.

The old skep had a small straw cap on the top, merely placed there to be out of the way, and having no communication with the hive. On turning my attention to that, I observed that wasps were passing into the cap, and, lifting it, found it filled with a wasp's nest; accordingly after sundown I brought a bucket of boiling water to this hive, and lifting the cap transferred it to the bucket. A few stray wasps were easily killed. The winter passed but the bees were not fed, as I had no keeper, and supposed the new hive was well stored before the upper compartment was filled, and that the old hive was stored, as I had not deprived it.

This summer there has been very little "business" going on in either hive, and we have no honey; also, the hives are very light. My impression is, therefore, that I deprived one hive, and the wasps deprived the other of all, or nearly all, the stores they had for winter use in 1865-6, and that winter being very mild they needed the more, and so have been reduced in population by starvation. Well, then, on Saturday last there was a great commotion in both hives, which culminated in a pitched battle, and ended in a "great slaughter on both sides;" but whether either has "knuckled down," I do not know. I send you a few of the slain, as taken from the battle field before the camp of each of the belligerents, as I think you may thus be enabled better to judge the nature of the conflict. Since the battle wasps are observed to pass in and out of both hives. What does that mean? Are they rifling the slain, or pillaging both hosts?

Pray console and give the best advice to one who loves to see bees and see them thrive.—CHARLES ELLIS.

[You may possibly have deprived the Neighbour's hive of an undue proportion of its stores, but we should be more inclined to fancy that the honey-harvest has been a failure this season in your locality. We are confirmed in this opinion by both your stocks being in the same condition, as we doubt if the wasp's nest did much harm. The weakest colony has probably "gone to the wall" ere this, but as "dead bees tell no tales," especially after being subjected to the manipulations of the post-office officials, those which you enclosed do not enable us to assign a reason for, or to judge of the nature of, this inter-tenne conflict. Whenever an autumnal scramble of this kind takes place, the wasps never fail to take advantage of it by pilfering one or both belligerents, acting apparently on the conviction, that "when bees fall out, wasps come by what is not their own." The best mode of averting the probable ruinous consequences of a combat between two hives, is to shut up one of them in the evening of the first day on which serious fighting is observed, and convey it to a distance of not less than a mile and a half, there to remain a few weeks until the quarrel is forgotten on both sides.]

**GREENFINCH MULE BREEDING.**—In the Number of the 7th ult. "W. B. H." says he has five young ones from a "Greenfinch hen mule" and a cock canary, and the hen is again sitting. Such an occurrence is so rare that it would be well worth authenticating; and if "W. B. H." will give his name and address, also state how and by whom the greenfinch mule hen was bred, he will greatly oblige; for many persons not naturalists not unfrequently call a green or pied canary a mule bird; consequently his statement requires more explanation ere it can be received as fact. I have no wish to disparage "W. B. H.'s" statement, but would be glad to have it in an authentic form.—B. P. BRENT.

OUR LETTER BOX.

[N.B.—Replies to many correspondents are unavoidably postponed till next week.]

**CRÈVE CŒUR AND HOUDAN HENS (Mrs. Brent).**—Mr. Baily, Mount Street, Grosvenor Square, can give the information you seek for.

**CHICKENS DECLINING (Fancy Fowl).**—You do not describe the malady from which your fowls are suffering. The loose ruffled feathers are the result and sign of the disease; they are not the disease itself. Purge with castor oil, and feed on bread and ale.

**FOOD FOR FOWLS TO BE EXHIBITED (W.).**—Ground oats slaked alternately with milk and water, bread or damaged ship biscuit, table and kitchen scraps, given three times per day. Birds to be kept very clean and running at liberty. All the best poultry is fed on ground oats mixed with milk. As these can only be had in Sussex, oat or barley meal must be substituted where they are unattainable. The finer the meal is ground and the less bran there is taken from it the better it is for the birds. In Sussex, the fowl-feeding county *par excellence*, some millers have stones dressed for the purpose, by means of which they grind the whole of the oat so fine that it mixes smoothly, although nothing whatever is taken from it. It is this fact that makes ground oats so nutritious.

**SPANISH CHICKENS (R. G.).**—The eggs were quite right. Not only do Spanish chickens show a great deal of white, but the flight feathers often remain white till after the first moulting.

**IRISH POULTRY SOCIETY.**—Having received many inquiries from exhibitors at a distance asking if we have any connection with the Suffolk or Woodbridge Poultry Society, we beg on behalf of the Committee to state that our Society is perfectly distinct from, and in no way connected with, that of Woodbridge.—W. E. JEFFRIES, G. W. BALES, Hon. Secs.

**COTTINGHAM POULTRY SHOW (F. Key).**—It is very difficult to distinguish an early pullet that has laid from a young hen; and from your statement and your offer to submit the bird to other arbitrators, we conclude that the Judge was wrong in disqualifying her. You should appeal to the Committee, and if they afford you no redress we fear you must submit to the injury.

**HALIFAX POULTRY SHOW.**—"I find my name down as having won a number of prizes in the Game classes, including the silver cup for a pair of Game chickens. I also find in the Pigeon department, 'Barbs, second prize, J. Firth, jun., Halifax.' The addresses want reversing, as I do not show poultry; but I did win the second prize for Barbs, and Mr. Firth, of Halifax, won the Game prizes mentioned.—J. FIRTH, JUN., Webster Hill, Dewsbury."

**Book (W. B. Woolley).**—"The Poultry-Keeper's Manual," published at our office, price 7s. 6d.

**WHITE DORKING CHICKENS (Maud).**—We have received the MS., and wish we saw the eggs hand-writing oftener. It will be published next week.

**WRY-BEAKED ALMOND TUMBLER (F. W.).**—I know of no cure for the distortion known as wry-beaked or Parrot-beaked. It sometimes arises from the birds being reared under Pigeons with longer bills, but I think it is as often constitutional.—B. P. B.

**GREY PARROT UNWELL (Susannah).**—As worms have come from your Parrot, I recommend area out in powder as the best vermifuge. If all food were taken from the Parrot overnight, and a little of the powder mixed with its food for breakfast, I have little doubt it would expel the worms, and then the bird probably will regain its health. If at first it refuses to eat the food mixed with the powder let it fast a little longer and try again, always mixing fresh food. If the powder is exposed long it becomes bitter.—B. P. B.

**BEES UNPRODUCTIVE (Winchfield).**—As you do not state the dimension of the stock hive we can offer no opinion as to its size. Your swarm not being particularly early, the season may not have permitted them to do more than fill their stock hive, which, nevertheless, may not be too large. We should have made an artificial swarm, had one been desired, from a stock the bees of which were often hanging out. We can assign no reason for their not swarming naturally, but it is certain that the fact of two casts having united together can have had nothing whatever to do with it.

**PEAS FOR PIGS (R. G.).**—The common gray pea is that usually given to pigs. You can obtain the seed from any corn-dealer.

POULTRY MARKET.—SEPTEMBER 3.

We are hardly able to give any quotation for poultry. There is little or no demand for it. The supply of Grouse diminishes a little, and they have sold better the last few days.

From observations taken near London during the last thirty-nine years, the average day temperature of the week is 63.0°; and its night temperature 46.0°. The greatest heat was 86°, on the 12th, 1858; and the lowest cold 23°, on the 12th, 1860. The greatest fall of rain was 0.90 inch. N.B.—The Calendar contains the names of plants flowering in the greenhouse.

VIOLA LUTEA AND MONTANA.

OR bedding-purposes these,

like *Viola cornuta*, will be found invaluable. *Viola lutea* has a bright yellow flower, and the plant is of a very neat dwarf habit. It is quite

as free as *Viola cornuta*, and will become a valuable addition to the flower garden. *Viola montana* is rather stronger in habit, and grows taller than either *V. cornuta* or *V. lutea*. It possesses a pleasing grey shade of colour. This season some large beds of *Viola montana* var., dotted with *Pelargonium Boule de Feu*, in the Liverpool Botanic Gardens, are very fine: some small beds of *V. lutea* were also very effective. I consider both Mr. Tyerman's *Violas* valuable additions to the flower garden, and have much pleasure in calling public attention to them. These, like Mr. Tyerman's beautiful *Dactylis glomerata*, will become general favourites for flower-garden decoration. Mr. Tyerman thinks some of the *Campanulas* may be used with good effect as summer bedding plants. He suggests the following arrangement, which, I have no doubt, would have a very pleasing effect as a ribbon-border:—1st row next the grass, *Viola lutea* (var. Tyerman); 2nd row, *Viola cornuta*; 3rd row, any scarlet *Verbena* possessing a good dwarf habit; 4th row, *Campanula carpatia alba*; 5th row, *Campanula carpatia* (blue); 6th row, *Pelargonium Beauty of Oulton*.

It will be seen that four out of the six plants to be used in the above arrangement are perfectly hardy, and very easily propagated. This will save much trouble and expense in labour and material for covering up and sheltering tender bedding plants from the early spring frosts whilst the ordinary bedding plants are undergoing the process of hardening-off, and will give much extra space for other purposes; and if the *Campanulas* prove after trial to be as useful as *Viola cornuta*, *lutea*, and *montana*, I shall consider it a step in the right direction. All who cultivate bedding plants extensively well know what a very large amount of time and space they require during the spring months, whilst plants of the description named above will be growing in their nursery-beds, where they have been all winter, and at the proper time will only want carefully planting out where they are to gladden the eye with their varied array of pleasing colours during the summer. They can be planted in their proper places early in March, if the weather is open and suitable, and will very much assist their more delicate companions when these are planted out in May or June by sheltering them from the cold winds, &c.; for by this time they will have firm hold of the soil, and by planting the intermediate rows rather thickly an immediate effect will be produced, which

will continue throughout the summer and autumn. The spaces between the rows should, however, be frequently stirred with the hoe in April and May, so that the soil may be in good condition for receiving the summer bedding plants, and if the ground is not rich enough, a slight sprinkling of guano should be sown over it. The plants will be greatly benefited by this soon after they are planted out.

The ground in which bedding-out plants are too frequently planted is often very poor; but however poor it is, some persons expect the plant to grow and produce the desired effect, and when it fails to do so it is often condemned, and said to be useless for the purpose for which it has been recommended. No plant has been more unjustly abused than the *Iresine Herbistii*, solely because the soil in which it has been planted was too poor for it, and because the plants were not in good condition when they were planted out. Plant the *Iresine* in a good rich soil, and if the weather be dry after it is planted, supply it once or twice a-week with manure water, and I will guarantee that it shall answer the most sanguine expectations. In a letter which I received from a nobleman in the early part of last month, speaking of the *Iresine*, he says, "The *Iresine* was just coming to its best, and was very effective. It is absurd to compare this with *Amaranthus*, to the discredit or merit of either. Both are valuable, and *Iresine* takes up the effect just when *Amaranthus* is growing rather worse. *Coleus* beats both in climates where it will grow."

I have seen beds of *Iresine Herbistii* far surpassing the *Coleus* when dressed in its best garb. Let all who have condemned the *Iresine* try it once more in rich deep soil, and I venture to predict a very decided reversion of feeling and opinion. Plant two beds of Mrs. Pollock *Pelargonium* side by side, let the soil in one be composed of one-half, or more, well-decomposed manure, and the soil of the other bed contain very little or no manure, and see what the effect will be. The plants in the poor soil will be scarcely fit to look upon, whilst those growing in the rich compost will be models of health and beauty. The difference in the appearance of the plants in the two beds will be so great that they will scarcely be recognised as the same variety; but water the plants in the poor bed three or four times a-week with moderately strong guano water, and each time the bed is watered let it be well soaked through, and in a fortnight or three weeks, if the weather be warm and forcing, it will be equal in its appearance to the bed that so much surpassed it only a short time before.

I saw Mrs. Pollock *Pelargonium* in great beauty with Mr. Tyerman the other day; in fact it looked better with him than any bed of it which I have ever seen. It was one of a very pleasing group of beds which had been formed on what originally was a rubbish corner. The beds in this group are formed in a sunk panel, and, being raised about 10 inches above the bottom of the panel, they were, therefore, surrounded by a beautiful carpet of green grass. Behind this beautiful group of beds there is a fine background of evergreens. The spaces between the beds

appeared to be about 30 inches wide. The bed of Mrs. Pollock had a simple edging of *Lobelia Paxtoniana*. On a raised terrace, between the panel and a broad gravel walk, was a very neat series of chain beds. The smaller beds in the chain were planted with *Viola lutea* and *Lobelia Blue King*, mixed; these had a very charming effect. The larger beds in the chain, I think, were planted with *Centaurea candidissima*, *Perilla*, and *Verbena venosa*. The whole group of beds was so beautiful, and the arrangement of the colours in them so perfect, that it struck me as being one of the most successful groups I had ever seen. Another irregular chain which I saw was very successfully planted with a centre of *Pelargonium Rubens Improved*; 2nd row, *Flower of the Day*; 3rd row, *Verbena Purple King*, with an edging of *Cerastium tomentosum*. This arrangement looked exceedingly beautiful. Altogether I considered the bedding-out at the Liverpool Botanic Gardens much superior to anything I had seen in the neighbourhood of London this season.

Mr. Tyerman had a fine bed of a dark-leaved plant which I think is likely to prove useful. It is *Plantago purpurea major*. This is also a perfectly hardy plant, and may be used with good advantage with the *Violas*. It seeds very freely, and is easily propagated by offsets.

A large bed of *Geranium anemonæfolium* produced a fine effect. This plant would look well in a sub-tropical arrangement.

In one of the large greenhouses containing a miscellaneous collection of plants, the whole of the roof was covered with *Fuchsias*. They were planted just inside the front wall, and trained up the rafters. The effect on looking from either end was exceedingly pretty. The Liverpool Botanic Gardens and the Denbies are the only places where I have seen *Fuchsias* show off to such advantage.—J. WILLS.

#### MR. HARLOCK'S ORCHARD-HOUSE AT ELY.

HEARING of the success of this mode of culture at Ely, I was induced on the 30th of last month to pay a visit to that city, and with the kind permission of Mr. Harlock I saw all that I wished to see.

The house is span-roofed, 100 feet long and 25 feet wide, ventilated on each side, and at the apex of the roof. The trees are from five to six years old, and all, or nearly all, open pyramids from 6 to 8 feet in height. Mr. Grix, the gardener, who is a self-taught orchard-house cultivator, not having practised summer pinching, has hitherto satisfied himself with winter pruning, which he has done well; but, owing to the shoots not having been shortened, the luxuriant growth of the trees this season gives a crowded appearance to the house which summer pruning would have obviated.

In no place have I seen orchard-house culture more thoroughly carried out. The trees are all in 18-inch pots, are top-dressed in autumn and surface-dressed in summer, the pots stand on concreted borders, and, owing to their large size, and the rich surface-dressings given, the trees are all in the most vigorous health—not a trace of red spider or mildew to be seen. A large portion of the crop had been gathered—a most abundant one, most of the Peach and Nectarine trees having borne from six to nine dozen each; the Apricots had borne a crop equally good, one and a half bushel having been gathered. I saw only the later kinds of Peaches, such as the Walburton Admirable, the Boudin, and others; the fruit abundant and very large. At the time of my visit 115 fine luxuriant trees of Peaches, Nectarines, and Apricots, and a few Plums, were in the house, forming a group exhibiting the most perfect culture I ever witnessed.

To illustrate how perfectly Mr. Harlock has carried out the orchard-house system, I may mention that in the garden, arranged in rows, were 120 fine pyramids of Pears and Plums, all in 18-inch pots, and nearly all full of fine fruit; from those not so the fruit had been gathered. These trees had been wintered in the orchard-house with the Peach and other trees, and removed to the open air early in June, when the danger from spring frosts was over. On many of the Pear trees were from five to six dozen of fruit, and the Plums were equally abundant. On trees of Guthrie's Late Green, Reine Claude de Bavay, and Belle de Septembre, were fine crops, and the flavour of the two first, the fruit quite ripe, was remarkably rich. A Diamond Plum tree was pointed out from which the fruit had been gathered; this was described as having been the most beautiful object ever seen, the fruit very large, and out-

numbering the leaves. Mr. Harlock stated that many of the pyramidal Pear trees on Quince stocks which had been planted out in the garden for some years and had not borne any fruit, were now under pot-culture the most prolific. I noticed particularly Winter Nelis, Glou Moreeau, Joséphine de Malines, Zephirin Grégoire, and Bourré Sterckmans bearing most abundant crops. The latter sort, which often ripens badly when cultivated in the open ground, is in common with other late Pears so forwarded by its early blossoming, and setting its fruit under glass, that it ripens in December, and is always good. This may be a hint to those who live in places where late Pears ripen with uncertainty. As far as I could judge, Mr. Harlock's Pear trees seemed to be in most robust health, and so fertile as to lead one to think this method of cultivating our fine sorts of Pears far preferable to planting them in the open borders, the blossoms being always safe from spring frosts, and the fruit being large and ripening perfectly. Some Louise Bonne were the largest I have ever seen. I have only to add that Mr. Harlock is an enthusiastic amateur, and derives much pleasure from his fruit culture. His vineries, 200 or 300 feet in length, are crowded with Grapes.—VIATOR.

#### THE THEORY OF SILVER SAND.

WE have long been in the habit of using the silver sand of Surrey when striking cuttings, but we do not comprehend very clearly the reason for its beneficial action. Can any of your readers help us to an explanation? We mix it with the ordinary garden mould in varying proportions. There is surely something in the sand which operates chemically, and not merely mechanically?

We have noticed, also, that in removing many of the very old timber trees in this neighbourhood that a small collection of flint stones is commonly to be found under the bole of the tree. Did our forefathers place these stones there for a reason similar to that which leads us gardeners to use silver sand?—*SILICA, Croydon.*

[We have no doubt that silver sand when mixed with the soil in potting acts a little chemically on other constituents of the soil, but to a great extent the action is mechanical. In using it for striking cuttings it is chiefly valued for its purity—its freedom from iron and other minerals, and clay, earth, and calcareous matters, which are often the accompaniments of other pit and river sands. The nearest to silver sand in usefulness we have found to be that collected on public roads, after heavy rains, which sand, when well washed, is about as pure silex as silver sand. What in practice makes it such a good covering for pots of cuttings is its freedom from other substances, its porosity, which allows the water freely to pass without lodging about and rotting the cuttings, and, notwithstanding this porosity, the closeness with which it clings round the cuttings, preventing the access of air to their base, which, if permitted to any extent, would rob them of their juices and vitality.]

We should suppose that the heaps of flints beneath old timber trees, if placed there at all by our ancestors, must have been used for the purpose of drainage, but we have some doubts about the matter, as we recollect that when a number of Scotch Fir trees were blown down in a storm, and the winds brought along with the torn-up roots a mass of earth almost as large as the end of a cottage, it was noticed that there were lots of stones at the bottom of the excavations thus made; and great were the divisions of opinion among us young rustics how they came there, some contending that they were placed there as a suitable foundation for the trees to stand upon, and this opinion was considered an utterance of wisdom until the sceptics by mattock and shovel demonstrated that at a similar depth in the locality plenty of stones were found where there were no trees growing. This simple matter might lead our learned inquirer to give his valuable opinion as to the collecting of stones, we will not say growing, as some people maintain.

We are sorry we should be accused "of never giving a reason for what we do," as to give reasons for operations is rather a general habit with us, and if the practice is not more universal it is because we are not wise enough to know the reason why, or, as in the case of the upturned trees, we have come to see that some things that we once looked upon in the relation of cause and consequence have turned out to be a mere fortuitous coincidence. If this does make us a little chary in assigning reasons where all does not appear quite transparent, it places us just in the right position of learners; and we presume that

few could elucidate the "why" of all our simple operations so well as our learned inquirer "SILICA," and from no one would we more gratefully receive instruction.]

### VINERY CONSTRUCTION.

I AM about to build a vinery for the purpose of ripening Black Hamburgh Grapes in April, when, I suppose, I should reap the greatest profit from their sale.

I propose to build a lean-to house, 100 feet long by 18 feet wide. I have strong reasons for not building a very high wall if I can avoid it, and I also want to reduce the cost as much as possible.

I have read all the works on the subject which I have heard of, and I read the Journal regularly, and have some gardening experience; but I need some counsel on certain points at starting, and it is most important that I should commit no errors at first which cannot afterwards be rectified. It will be of great service to me if you will kindly advise me on the following points, as I wish to commence at once:—

1. The aspect available is south-west. Will this answer my purpose?

2. What is the lowest wall I may have at back for the width of 18 feet?

3. What is the height recommended for the front wall?

4. What is the lowest quality and weight of the glass to be used consistent with satisfactory results?

5. I propose to have the Vines planted inside the house, and bearing in mind that I want to force early, where should the roots be? Kept inside, or allowed 12 feet of border outside, as well as some border inside to spread in? In the latter case I should have the front wall on arches. I propose to plant 2 feet apart, should I then have an arch for each Vine, or for every two Vines? If it is necessary to keep the roots inside the house, what width of border should I have there?

6. In either case, how many four-inch pipes must I have, and what position should they occupy?

7. What is the best time for planting the Vines? Mr. Thomson, in the Journal of Feb. 20th, 1866, page 140, says "when they have burst their buds about a quarter of an inch," and he gives good reasons; in "Sanders on the Vine," I find at page 5, "in the autumn;" "Pearson on Vine culture" is silent on this point.

8. What boiler would suit my purpose best?

It is my intention to build large houses for the growth of fruit, and to experiment on hybridising.

In the Journal for July 24th, 1866, page 170, I see recommendations as to preserving fruit. I have experimented on this subject, and succeed in preserving fruit perfectly fresh without sugar. For some winters past I have never been without a good supply of bottled fruit, perfect in flavour and bright in colour. If you would like the details I will send them.—H. W.

[You scarcely give us sufficient data to enable us to decide; but taking your width of an early vinery to be 18 feet, and your disinclination to have a high wall at the back, economy being the great object, then, instead of a thorough lean-to, we would advise a hipped roof. For early Grapes you should either have a steep roof or plenty of upright glass. To have a roof at 45° you would require a wall as high as the width of the roof, and the roof to slope to the wall plate. If you had 2 feet of a front wall that would make the roof all the more flat, but still suitable for Grapes in April and May, not but that early Grapes may be grown in a house with a flat roof, but not so well as in one with a steeper roof, so as to have all the help possible from the sun in winter and spring. A fine house would be obtained by having the wall 18 feet at back, and from 1½ to 2 feet high in front. Keeping economy in bricks in view, a good house would be formed by having a back wall 10 feet in height, a hip of 5 feet meeting the front roof at 4 feet or so from the wall, at a height of 13 feet from the floor, which, with a front wall of 2 feet, would give a front sash of about 17 feet. You can judge for yourself by pencilling these dimensions in lines. You will perceive that with a 10-foot wall and no hip, your roof will be more suitable for July, August, &c., than for April.

But for the protection of the back wall, the most economical plan for covering 18 feet of ground, would be a span roof with side walls about 18 inches in height, with ventilation in them, and a double ridge with ventilators between them, and the Vines trained up each side; height to ridge about 13 feet. All such roofs could be fixed.

With these general remarks, and bearing in mind that the roof is to be less or more of a lean-to, we reply—

1. That the aspect will answer very well, though direct south would have been better, as securing more early sun.

2. Even with a hip the lowest wall would be about 10 feet above the ground line.

3. For convenience, the wall in front should not be less than 2 feet, and in that the front ventilators.

4. The lowest priced glass suitable, is what is called fourths, and 16 ozs. to the foot, which will generally range from 13 ozs. to a little over 15 ozs., and according to the size of the squares will cost from 1½d. to 2d. per foot. If at all afraid of hail, it would be best to use 21-oz. glass, which will cost from 2½d. to 3d. per foot, for fourths. If you obtain a better quality, as thirds or seconds, you will pay more in proportion.

5. In an 18-foot-wide house, you may have the border for the Vines inside the house entirely for early forcing. At any rate, we would plant inside. If the roots are to be kept entirely there, we would plant in the middle of the house, and train both ways; if in such a hip-roof as alluded to, and you resolve on also having an outside border, then we would plant 3 feet or so from the front. In that case were we doing the work we would dispense with arches, build piers some 4 feet apart, and on these place a stout oak or, rather, an iron sill, and the roots could go out and in as they liked. To make the most of such a house early, we would plant within 2 feet of the front, and also along the back wall, or have something else there. For early forcing, we would make all the inside into a border, and keep the roots mainly there.

6. For early forcing we would have at least five four-inch pipes, four flows and one return, and as far as pipes would interfere with nothing, we would have them all on the same level, just above the level of the floor, placed over it as most convenient.

7. It does not matter when you plant the Vines, if treated rightly afterwards. If in a state of rest, the roots must be protected and encouraged to move as soon as or before the tops. If the buds are moving before planting, they must have no check afterwards. Many plant in May or June. There is less trouble if the Vines are planted when at rest. If the roots are planted outside in autumn, they should be protected from frost, snow, and cold rains.

8. The cheapest boiler, and a very good one, would be a saddle-back, 36 inches long, 25 inches wide, and 22 inches high, which if cast iron will cost about £7 10s. Cylinders will cost a little more, and tubular more still. Monro's cannon boiler will be about the same in cost as a saddle-back. The tubular boilers if fed from the top are, perhaps, the easiest managed, but we have done well with saddle-backs, and after trying many, some of the greatest gardeners in the largest establishments are going back to them. Wrought-iron saddle-backs cost a little more, and, on the whole, our opinion is, that they do not last so long.

Even if you mean to have a border outside, you need not make it the first year, and a piece at a time will be better than making it all at once.

We shall be much pleased to receive an account of your mode of preserving fruit, so as to have it perfect in flavour, and bright in colour in bottles in winter, and without sugar. It would be generally useful and valuable.]

### ROYAL HORTICULTURAL SOCIETY.

SEPTEMBER 4TH.

At this meeting there was an excellent display of plants, both ornamental-foliaged and flowering. Of the former Messrs. Downie, Laird, and Laing contributed a numerous collection of those employed in sub-tropical gardening, for which they received a special certificate. Among them were *Wigandia caracasana* and *urens*, *Alternanthera*, *Polymnia grandis*, variegated Maize, *Eucalyptus globulus*, *Undea bipinnatifida*, *Ferula nodiflora* with much-divided foliage, and several fine *Solanums*. Of the last, *Solanum robustum* was particularly noticeable by the fine reddish cinnamon of the upper sides of the leaves, and among other very ornamental plants of the same genus were *S. pyracantha* and *decurrans*, both with reddish orange spines, and the latter with white flowers; *S. laciniatum elegans*, with deeply cut foliage and large violet flowers; *S. arniculatum*; *S. marginatum argentum*, with whitish foliage; and *S. amazonicum atropurpureum*, with deep green leaves, which, as well as the stem, were set with numerous formidable spines. Messrs. Veitch, Chelsea, had likewise a special certificate for a collection in which were some beautiful ornamental-foliaged plants, such as *Marantas Lindenii* (first-class certificate), *roseo-picta*, and *Veitchii*,

*Dieffenbachia Veirii*, *Herrania palmata*, *Ananassa Porteana*, *Coleus Gibsoni*, *Euonymus macrophyllus* with broad, shining, dark green leaves, a pretty variegated *Abutilon striatum*, and the golden variety of *Retinospora obtusa*, the last very beautiful. From Mr. Bull, Chelsea, came three plants of the old *Amaryllis Josephinae*, now seldom seen, the largest of which had a thick stem about 2½ feet high, bearing a very large head of flowers, like a much-branched candelabrum, and numbering nearly fifty. For this a well-deserved special certificate was awarded to Mr. Bull, and for *Polystichum angulare* *Holeanum* he received a first-class certificate. The same exhibitor likewise contributed *Philodendron crispipes*, with deeply-lobed, shining, pea green leaves, *Tacca picturata*, with a dark stem marbled with white, *Dioscorea discolor variegata*, shown at the previous meeting under the erroneous name of *D. vittata*, a variety with beautifully mottled and striped leaves, and *Caladiums Sanspareil* and *Annihilator*, the latter with crimson veins and white blotches. Mr. Cripps, Tunbridge Wells, again exhibited a collection similar to that which he produced at the previous meeting, and which comprised handsome *Aucubas* and other Japanese plants, *Alternantheras*, *Teleianthera ficoides* variegated, and *Desmodium penduliflorum*, a hardy Japanese shrub with purplish pea-like flowers. Ivy-leaved *Geranium L'Elegance* from Mr. Cunningham, The Forge, Burton-on-Trent, the leaves neatly edged with creamy white, a very desirable variety of compact habit, was awarded a first-class certificate. Messrs. Carter & Co. contributed several *Lobelias* of the fulgens section, as did likewise Mr. Kinghorn, of the Sheen Nursery, Richmond, who received second-class certificates for *Crimson King* and *Rose Queen*, the former a deep crimson and the latter a rosy crimson. Messrs. E. G. Henderson were awarded a first-class certificate for *Pelargonium Sophia Domaresque*, one of the tricolor class and very showy, having a finely coloured zone. From the same firm came also *Agalmis staminea*, a plant of creeping habit, with fine bright red flowers, *Coleus aureo-marginatus* having the foliage dined and blotched with yellow, and *Coleus marmoratus*. Messrs. Veitch exhibited a fine collection of *Asters*, comprising examples of the various sections, such as the *Crown*, *Peony-flowered*, *Emperor*, *Hedgehog*, *Chrysanthemum-flowered*, &c., together with the unimproved *China Aster*, to show the advance made on the original. A special certificate was given for the collection. First-class certificates were likewise awarded to Messrs. Osborn, Fulham, for *Statice Frostii*, a fine deep-coloured variety, and to Mr. R. Hartland, Lough Nurseries, Cork, for a golden-variegated form of *Wellingtonia gigantea*. From Mr. R. Parker, of Tooting, came a dark variety of *Laha elegans*, and from Mr. Ferguson, Whitton Nursery, several *Zonale Pelargoniums*, but to none of these subjects was any award made. A certificate of the first-class was awarded to Mr. Mann, of Brentwood, for tricolor *Pelargonium Melona*, and one of the second-class for *Mimas*, bright scarlet, in the way of Dr. Lindley. Mr. Smith, gardener to S. H. Norris, Esq., Altrincham, contributed a good spike of *Renanthera coccinea*, and Mr. Standish, Ascot, a fine collection of choice *Gladioli*, for which a special certificate was awarded. Mr. Eckford, Colchill, had a first-class certificate for an orange-scarlet *Verbena* called *Colchill*, and a second-class one for *Dahlia Lady Jane Ellice* tipped with purplish rose; and second-class certificates were also given to Mr. Keynes, of Salisbury, for *Gazelle*, shaded salmon, tinged with violet at the tips, and for *Harriet Tetterell*, a light ground, heavily tipped with rosy purple. *Paradise Williams*, deep maroon crimson, a fine variety, also from Mr. Keynes, received a first-class certificate, as did also *Tropæolum King of Scarlets*, a free-flowering scarlet variety shown by Mr. George, of Stamford Hill, who likewise exhibited *Luteum Improved*, a yellow kind spotted with crimson. Mr. Cannell, Woolwich, sent two seedling *Fuchsias*, and Messrs. Stuart & Mein, of Kelson, Hollybuck blooms, but owing to the journey, not in good condition.

**FRUIT COMMITTEE.**—With the exception of some fruit sent to name very little was submitted to the Committee at this meeting. Mr. Comins, Royston, sent a seedling Plum called *Black Prince*, but it proved to be inferior in flavour to existing varieties; and from Mr. C. Dixon came *White Beechwood Melon*, raised between the *Beechwood* and *Bromham Hall*, but its flavour was likewise not good; also a double *Cucumber* united by the sides, a monstrosity, however, which is not of uncommon occurrence with *Cucurbitaceæ*. Mr. Craddock, gardener to Lord Willoughby de Broke, Compton Verney, sent *Alston Kidney Potato*, a clean-skinned, fine-looking variety, and *Melbourne Seedling*, both of which were referred to Dr. Hogg to report upon when cooked. Messrs. Veitch exhibited a collection of well-grown *Onions*, comprising among others the *Trebons*, *Danvers Yellow*, *Nuneham Park*, *White Spanish*, and *Reading*. The last three were decided to be absolutely the same. A special certificate was awarded to Messrs. Veitch for the collection.

**WEEKLY SHOW, September 8th.**—Mr. Young, Highgate, received a first prize for a collection of fruit, consisting of seventeen dishes, and very excellent in quality; and Mr. Earley, Digswell, had a third prize for one consisting of five dishes. Mr. Earley and Mr. Young likewise received first and second prizes for collections of vegetables, and an extra prize was awarded to Mr. Young for a collection of nineteen varieties of well-grown *Onions*. Messrs. Cuthbush, Highgate, received a first-class certificate for very fine specimens of what is called the *Nuneham Park Onion*, noticed in another page, and a similar award for

twelve handsome spikes of *Gladiolus Brencleyensis*. Prizes were offered on this occasion for collections of six miscellaneous plants. Mr. Bartlett, Hammersmith, was first, and Mr. Young second; and an extra prize was likewise awarded to the former for a good collection of miscellaneous plants and Ferns.

## KEEPING WASPS AND FLIES FROM WALL FRUIT.

At page 171 I observe a remark about protecting Peaches from wasps and woodlice. Last year I lost a large portion of my crop, both inside and outside my house, by woodlice and bluebottle fly. In the spring of this year I procured from the gasworks some of the refuse lime through which the gas had been purified, mixed it as I would common lime for whitewash, and put a good coat over my walls, the effect has been I have not seen a single wasp or bluebottle there this year.—JAMES PIER.

## CRYSTAL PALACE SHOW.

THE autumn Show took place on Wednesday and Thursday last, when there was an excellent display of fruit and cut flowers, though scarcely so extensive as in former years. Considering the somewhat unfavourable character of the weather, there was a good attendance of visitors.

Fruit, to which one side of the nave was devoted, was not so well represented as usual, both as regards quantity and size; but deficiency in the latter respect is pretty general this season. Only two collections were shown: that from Mr. T. Dawson, gardener to Earl Cowper, Panshanger, to which the first prize was awarded, consisted of a *Black Prince Pine Apple*, good bunches of *Barbarossa* and *Muscat Grapes*, a green-fleshed *Melon*, fine *Violette Hative Peaches*, *Elruge Nectarines*, and *Florence Cherries*. Mr. Donald, gardener to J. G. Barclay, Esq., Leyton, was second with a *Queen Pine*, *Black Hamburg* and *Muscat Grapes*, *Scarlet Perfection Melon*, *Peaches*, *Nectarines*, *Cherries*, and *Pears*.

**PINE APPLES** were not numerous nor remarkable for quality; there were, however, a few good Queens. For three fruits, Mr. Dawson was first with *Smooth-leaved Cayenne*, *Providence*, and *Black Prince*; and Mr. Chilman, gardener to the Earl of Normanton, Ringwood, second with a *Queen* and two *Smooth-leaved Cayennes*. Mr. Page, gardener to W. Leaf, Esq., Streatham, exhibited two of the latter, weighing 5 lbs. each, and *Charlotte Rothschild*, 4 lbs.; and Mr. Walls, gardener to J. Dixon, Esq., Astle Park, Providence, Enville, and *Brown Sugar-loaf*. A well-ripened *Queen* from Mr. R. Smees, gardener to W. H. Stone, Esq., M.P., Dulwich, was first in the class for that variety. Mr. Elstone, gardener to S. Lawrence, Esq., Clapham Park, being second with a fruit of 4 lbs. 6 oz.; and Mr. R. Craik, gardener to G. Soames, Esq., was third. In the class for any variety Mr. J. Douglas, gardener to F. Whitbourne, Esq., Ilford, was first, and Mr. Page second, with *Smooth-leaved Cayenne*, and Mr. Douglas also took the third prize with *Charlotte Rothschild*, weight 5 lbs.

**GRAPES.**—There was not nearly so fine an exhibition of these as might have been expected, though several very excellent bunches were shown. The *Black Hamburgs* from Mr. Meredith, of Garston, which took the first prize in the class for *Black kinds*, were, as usual, remarkably fine, the bunches being very large, and the berries large and finely coloured. Mr. Osborne, Kay's Nursery, Finchley, who was second, had also very fine bunches, though not so even as Mr. Meredith's in the size of the berries. Equal third prizes were awarded to Mr. R. Norris, gardener to A. Bosanquet, Esq., Southgate, for *Black Hamburg*, and to Mr. Devenish Rodwell, Weymouth, for fine but somewhat loose bunches of the *Muscat Hamburg*, weighing 10 lb. 1 oz. These were all three on the same rod, and it was a matter of surprise that three such bunches should have been produced within so short a distance of each other. Of other kinds good bunches of *Black Prince* came from Messrs. Lane & Son, of Lady Downe's from J. Hollingworth, Esq., Maidstone, and Mr. Morris, gardener to R. Bright, Esq., Tring, and of *Black Alicante* (?) from Mr. Irving, gardener to the Duke of Hamilton, Easton Park, Suffolk, the last being ripened in a Peach-house without fire heat. Of *White Grapes* the best were beautifully ripened *Canon Hall Muscats* from J. Hollingworth, Esq., Mr. Irving, gardener to the Duke of Hamilton, was second with good well-ripened bunches of *Buckland Sweetwater*; and Mr. Osborne, Finchley, and Mr. Bailey, gardener to T. T. Drake, Esq., Shardeloes, were equal third for *Muscats*. The heaviest bunch of any kind was a very fine one (weight not stated), of *Black Hamburg*, not, however, quite perfect as regards colour, shown by Mr. Osborne; and a bunch of the same kind, weighing upwards of 4 lbs., from Mr. Irving, was second. There were several good baskets of 12 lbs. and upwards, mostly consisting of *Black Hamburg*. Mr. R. Norris, gardener to A. Bosanquet, Esq., was first, and Mr. Osborne, Finchley, second with that kind, and equal third prizes were awarded to Mr. W. Toomer, gardener to J. Perrett, Esq., Herne Hill, for *Muscats*, small in berry but well ripened, and to Mr. T. Frost, Maidstone, for *Black Hamburg*.

**PEACHES AND NECTARINES** were all rather small though well coloured. The former chiefly consisted of *Grosse Mignonne*, *Royal*

George, Royal Charlotte, Noblesse, Barrington, Violette Hâtive, and Bellegarde. Mr. Thornycroft, Floore, Weedon, was first; Mr. Crane, gardener to the Rev. L. Deedes, second, with Royal Charlotte; and Mr. Hazell, Denmark Hill, third, with Grosse Mignonne. Some good fruit of Royal George, grown in pots in an unheated orchard-house, came from Mr. Douglas, gardener to P. Whitbourne, Esq. For Nectarines: Mr. King, gardener to G. Roder, Esq., Slougham, was first with a good dish of Violette Hâtive; Mr. Sutherland, gardener to Mrs. Jamieson, Fulham, second with the same variety; and Mr. Dawson, third, with Downton. Some finely-coloured fruit of Rivers's Orange, from orchard-house trees, were shown by G. F. Wilson, Esq., Weybridge. Elrage, Roman, Pitmaston Orange, Murray, and one or two other varieties were also fairly represented.

MELONS were shown to the number of three score. The best Green-fleshed was Preston Hall Hybrid, from Mr. Frost, Maidstone; Mr. Samuel, Broom Park, Betchworth, was second; and Mr. Chilman, third. Of the Scarlet-fleshed varieties, Scarlet Gem had the pre-eminence, Mr. Stacey, gardener to E. Raymont, Esq., Norwood, being first with it; Mr. Bailey, second; and Dr. Cooper, Slough, third.

FIGS were not numerously shown, but very good. The best were very fine Brunswick and Brown Turkey, from Mr. Dennis, gardener to H. Hayward, Esq., Fellington; next came Black Ischia and Brunswick, from Mr. Samuel, Betchworth. Mr. Turcor, of Slough, was third; Mr. Lacey, gardener to C. S. Mortimore, Esq., Morden Park, fourth.

CHERRIES.—Morello, as might be expected at this late season, was the variety most shown, and Florence was also well represented. The first prize was awarded to Mr. Marchan, gardener to E. Oates, Esq., Ilanwell, for fine dishes of Morello and Kentish; the second to Mr. Bailey, for Morello and Bigarreau; and equal third prizes to Mr. Sage, gardener to Earl Brownlow, Ashridge, for Morello and Florence, and to Mr. Dawson for the latter and Belle Magnifique.

PLUMS were tolerably numerous, but scarcely so good as in former years. R. Webb, Esq., of Reading, was first with excellent dishes of White Magnum Bonum, Goliath, and Coe's Golden Drop. Mr. Bailey was second with Victoria, Washington, and Prince of Wales; and Mr. Shoebridge, gardener to E. C. Goad, Esq., Carshalton, third, with Goliath, Jefferson, and Washington. Mr. Gilbert, Stoke, Slough, had a fourth prize for the first and last, and Pond's Seedling. Excellent orchard-house fruit of Transparent Gage, Coe's Golden Drop, and Reine Claude de Baray, came from Mr. Wilson, Weybridge.

APPLES.—Of dessert kinds the best four dishes were Red Pearmain, Red Astrachan, Colonel Vaughan, and Reimette du Laak, from Messrs. Lane, St. Mary's Cray; Mr. Gilbert, Stoke, was second with Bishop's Pippin, Devonshire Quarrenden, Cox's Orange Pippin, and a red-streaked seedling; Mr. Webb, Reading, third, with Red Astrachan, Scarlet Nonpareil, Ribston and Cox's Orange Pippins; and Mr. Beester, Gorring, Sussex, fourth, with Pearn's Pippin, Red Astrachan, Bull's Golden Reimette, and Cellini. Among other kinds we noticed Early Strawberry, pretty, but not of much value as regards flavour, Kerry Pippin, Ashmead's Kernel, (misnamed Colonel), King of the Pippins, Pearson's Plate, Early Red Margaret, and Irish Pench. The first prize for kitchen Apples was taken by Mr. Willmore, Hoyle Place, with good examples of Alexander, Red Astrachan, Blenheim and Stone's Pippins. Mr. Mortimore was second with a kind called Putt's Patting, Cellini, Lord Derby, and Lord Suffield. Messrs. Lane, St. Mary's Cray, were third, and Messrs. Gadd, Dorking, fourth. Afriston, Dumelow's Seedling, Northern Greening, Gloria Mundi, Hollandbury, and Kentish Fill-basket were among the other kinds exhibited.

PEARS.—The best three dishes were exhibited by Mr. Gilbert, of Stoke, Slough, who had good examples of Williams's Bon Chrétien, Louise Bonne of Jersey, and Duchesse d'Angoulême. Mr. Harrison, Outlands Palace Gardens had fine dishes of the two last-named kinds and Beurré Clairgeau, and Mr. Richbell, gardener to — Heathcote, Esq., Epsom, was third with good Beurré Diel and Beurré Clairgeau. A third prize was awarded to Mr. Bonner, gardener to the Rev. J. Cooper, Woking, for Gansel's Bergamot, Duchesse d'Angoulême, and Marie Louise. The prize for the heaviest dish of twelve was awarded to Mr. Gadd, gardener to J. Jaffray, Esq., for Uvedale's St. Germain, weighing 10 lbs. 4 ozs. G. F. Wilson, Esq., was second with one of Marchal de la Cour, weighing 8 lbs. 4 ozs., and Mr. O. Goldsmith third. Pears shown for flavour consisted almost exclusively of Williams's Bon Chrétien and Jargonelle. The second and third prizes were awarded to the former kind shown by Mr. Grover, of Hammer-smith, and Mr. Fraser, of Lea Bridge, whilst the first went to a variety unnamed, exhibited by Mr. Thornycroft.

FRUIT TREES IN POTS.—Mr. Toomer, gardener to J. Perrett, Esq., Herne Hill, exhibited a Black Hamburgh Vine, bearing splendid bunches. Messrs. Lane & Sons and Mr. Hope, gardener to W. Murrell, Esq., also exhibited beautifully fruited specimens, and some good pot Vines, though of smaller size, came from Mr. Geirs, Norwood. Vines, Pear, Apple, and Plum trees in pots, were shown by Mr. Fraser, together with excellent dishes of ripe fruit from pot trees; and pot Plum and Peach trees came also from Mr. Vertigan, Clapham Common.

MISCELLANEOUS.—Mr. Webb, of Reading, furnished twenty kinds of Filberts, among which were several of his own raising; Mr. Preece, gardener to E. Wood, Esq., Ealing, a good dish of Mulberries; Mr.

Salama, Hampton, Tomatoes and fruit of what was called the Golden Bash Squash, used as a Vegetable Marrow; and Mr. Kemp, gardener to E. Bentall, Esq., a cluster of Musa Cavendishii, on a stem upwards of a foot in diameter, which had been an unrooted sucker but fourteen months ago. Mr. Sage, gardener to Earl Brownlow, likewise exhibited a cluster of the same Banana. A good dish of Victoria Red Currant came from Mr. Vertigan, Clapham, also one of Sir Charles Napier Strawberry. In the vegetable department, Mr. Levell, Clapton, exhibited good fruit of Butcher's Black Spine Cucumber; and Mr. Porter, gardener to the Hon. A. Ashley, Copt Hall, Essex, Essex Champion, a spineless variety, said to be a wonderful cropper and of good flavour. From Messrs. Barr & Sugden came a collection of Onions; and from Messrs. Cutbush, very fine bulbs of the Nuneham Park Onion, all of which were said to weigh at least 1 lb. each, and one as much as 2½ ozs. The same firm also contributed dishes of their Giant Kidney Bean, which, though the pods were large, was crisp and succulent.

#### FLOWERS.

In the floral department of the Show there was an evident flatness from its being almost exclusively confined to cut blooms, and another year it might be well to consider whether a judicious introduction of plants in pots along the centre of the tables would not be an improvement.

DAHLIAS.—The stands of these were numerous, and the blooms for the most part excellent. In the class for forty-eight, Mr. Keynes, of Salisbury, was first with fine blooms of Golden Admirer, King of Sweden, Matilda, Queen of Primroses, Delicata, Edward Spary, Baron Taunton, Lord Shaftesbury, Chairman, James Backhouse, Miss Henshaw, Flossy Girl, George White, Leah, Paradise Williams, Mrs. Wyndham, Andrew Dodds, Umpire, John Wyatt, Charlotte Dorling, Annie Austin, Disraeli, Anna Keynes, British Triumph, Lady of the Lake, Freemason, Lady Mary Wyld, George Wheeler, Miss Herbert, Bob Ridley, Lady Palmerston, Criterion, Stella Colas, Hugh Miller, Ellen Potter, Lilac Perfection, Lady Gladys Herbert, Lord Derby, Princess, Norfolk Hero, Lilac Queen, Sam Bartlett, Peri, Earl of Pembroke, Fanny Purchase, Vice-Chairman, Golden Gem, and Jenny Austin. Mr. Walker, of Thame, was second with stands in which we noticed fine examples of Chairman, Lord Derby, Imperial, Madge Wildfire, and Peri; the third prize going to Mr. Kimberley, of Coventry, and the fourth to Mr. Morse, of Epsom.

For twenty-four blooms Mr. Keynes was again first with excellent examples of Queen of Primroses, Lady of the Lake, Chairman, James Backhouse, Lord Derby, Charlotte Dorling, Lady Gladys Herbert, Golden Admirer, Bob Ridley, Norfolk Hero, Earl of Pembroke, Anna Keynes, George Wheeler, Mrs. Wyndham, Queen of Lilacs, George White, Lady Palmerston, Edward Spary, Vice-President, Miss Henshaw, Delicata, Harriet Tetterell, Leah, and Miss Herbert. Mr. Draycott, Hamberstone, Leicester, was second with Alexandra, Charles Turner, Lottie Atkins, Imperial, Marquis of Bowmont, George Brown, Lady G. Herbert, Prince of Prussia, Foxhunter, Lord Derby, Miss Henshaw, Juno, Anna Keynes, Norfolk Hero, Fanny Purchase, Lilac Queen, Champion, Model, Charlotte Dorling, Leah, Donald Beaton, Triomphe de Pequ, Annie Austin, and Lady Maude Herbert, all of which were very good. Mr. Legge, Edmonton, was third; Mr. Walker, Thame, fourth; and Mr. C. Kimberley, fifth.

In the Amateurs' class for the same number, Mr. C. J. Perry, Castle Bromwich, was first with fine blooms of Chairman, Arthur, Phidias, Anna Keynes, Andrew Dodds, Master of Arts, Bob Ridley, a pink seedling, Model, Leah, Delicata, Donald Beaton, Miss Henshaw, Messenger, Lady G. Herbert, Lord Derby, Alexandra, Hugh Miller, George Brown, British Triumph, Juno, Criterion, Charlotte Dorling, and Pauline. Mr. Thornycroft, Floore, Weedon, was second; Mr. Hopkins, Brentford, third; Mr. Hedge, Colchester, fourth; Mr. Glascock, Bishop Stortford, fifth; and Mr. Cottis, Newhall, Chelmsford, sixth.

In the class for twelve blooms, the best stand came from Mr. Thornycroft, the varieties being Lord Palmerston, Volunteer, Fanny Purchase, seedling, Lord Derby, Model, International, Willie Austin, Juno, Miss Henshaw, British Triumph, and Matilda Keynes. Mr. Glascock was second with Goldfinger, Chancellor, Andrew Dodds, Jenny Austin, British Triumph, Garibaldi, Lord Palmerston, Fanny Purchase, Bird of Passage, Delicata, Lord Derby, and Mrs. Belton. Mr. Lukins, Shooters Hill, was third; Mr. Hopkins, fourth; Mr. Hedge, fifth; and Mr. C. J. Perry, sixth.

Of the Fancy varieties the stands were not very numerous. The best twelve blooms in the Nurserymen's class came from Mr. Keynes, and consisted of Chang, Formidable, Regularity, Lightning, Octoroon, President Lincoln, Remarkable, Lord Warden, Messenger, Butterfly, John Salter, and Ebor. In the corresponding class for amateurs Mr. Perry occupied a similar position with John Bann, Sam Bartlett, Queen Mab, Octoroon, Pauline, Queen of Sports, Harlequin, Garibaldi; a yellow seedling streaked with crimson, Triomphe de Roubaix, Regularity, and Artemus Ward. Mr. Thornycroft was second, and Mr. Petfield, gardener to G. Thornhill, Esq., Duddington, third.

A good number of seedlings were exhibited. First-class certificates were awarded to Mr. Keynes for Paradise Williams, and for Princess of Wales, delicate lilac with a white centre, tipped with violet; Vice-President, golden yellow, and Butterfly, reddish orange, received second-class certificates. Mr. Petfield had a similar award for a pleasing flower, white, tipped with purplish lilac; also Mr. Pope, of

Chelsea, for Pope's Gem, a white and purplish crimson Fancy. Mr. Burgess had likewise a second-class certificate for Mrs. Burgess, violet crimson, tipped with brighter crimson. Vanguard and Bijou from Mr. Wheeler, of Warminster, the former purplish maroon, the latter salmon tinged with lilac, were also awarded second-class certificates.

**ASTERS.**—The best stands both of German and French came from Mr. Stanford, gardener to T. Thomasset, Esq., Walthamstow, and contained blooms of remarkable size and beauty. In the former class Mr. Benham, Newbury, was second, and in the latter Mr. Hedge; Mr. Jennings, Shipston-on-Stour, and Mr. Minchin, Hook-Norton, being respectively third.

**MISCELLANEOUS.**—Besides twelve boxes of beautiful cut blooms of Roses, furnished by Mr. William Paul, wonderfully fine for the season, he exhibited fine specimens of Amy Hogg and other Nosegay Pelargoniums, as well as dwarf standard plants of Mrs. Pollock, and some other variegated kinds. A collection of variegated shrubs and Ivies, likewise from the Waltham Cross Nurseries, attracted considerable attention. Mr. Turner, Slough, received first-class certificates for Nosegay Pelargoniums Duchess of Sutherland and Lady Constance Grosvenor, a fine orange scarlet, and Mr. C. J. Perry, one of the second-class for Shirley Hibberd, rosy scarlet. Messrs. Downie, Laird & Laing reproduced their collection of sub-tropical plants exhibited the previous day at Kensington, Mr. Cunningham his pretty Ivy-leaved Pelargonium L'Elegante; and from Messrs. Barr and Sagden and Carter & Co. came plant-cases, flower-baskets, &c. Those from the latter were interspersed with fine-foliaged and flowering plants, forming altogether a very pretty stand. Among other articles of utility was a window box of zinc, with the front enamelled to resemble porcelain, over which it has the advantage of not being so liable to breakage.

THERE is a large class of persons to whom the Crystal Palace Autumn Show presents more features of interest than the great Show in May. There may not be the grand masses of greenhouse and stove plants, and Orchids, Geraniums and Azaleas are of course absent; and these have, comparatively speaking, a small circle, if not of admirers, at any rate of cultivators; but the Rose, the Aster, the Dahlia, the Gladioli, and the Hollyhock are flowers which the humble cultivator can manage, and often does manage, as well or better than his more aristocratic neighbour, and hence the multitude know more of them and care more for them than those already named. It might have been supposed that the extremely unfavorable season would have seriously militated against this Exhibition, but it was not so. Dahlias were never better, Roses certainly more in character than I have seen them at the autumn show, the Gladioli excellent, although one missed the fine collection of Mr. Standish, Asters were good, and the Exhibition as a whole only presented a great falling off in fruit, which, especially in the out-door department, was scarce, and not up to the quality of former years.

**ROSES.**—In the class for twenty-four single blooms Mr. Keynes was first with Charles Lefebvre, Louise Peyronny, General Washington, Souvenir de la Malmaison, Vicomte Vigier, Madame Vigneron, Anna de Diesbach, Mlle. Amélie Halphen, Gloire de Vitry, Gabriel de Peyronny, Gloire de Dijon, Maurice Bernardin, Madame Charles Wood, François Lachurme, Maréchal Niel, John Hopper, Madame Rivers, Centifolia Rosea, Baron P. de Kinkelin, Belle Normande, Duc de Wellington, Madame Rousset, Baron Gonella, and Senateur Vaisse. Messrs. Paul & Son were second with Madame C. Wood, Duchesse d'Orleans, Maurice Bernardin, Vicomte Vigier, Charles Lefebvre, Gloire de Dijon, Jean Touvais, Madame Rousset, Pierre Notting, Lord Herbert, Souvenir d'Elise, Maréchal Niel, Beauty of Waltham, Souvenir d'un Ami, Madame V. Verdier, Madame Caillat, Dr. Spitzer, Olivier Delhomme, Madame Emain, Baronne Gonella, and Senateur Vaisse.

In the class for thirty-six, Messrs. Paul & Son were first with Colonel de Rongemont, Charles Lefebvre, Duchesse d'Orleans, Anna Alexieff, Céline Forestier, John Hopper, Madame C. Wood, Lælia, M. Victor Verdier, Maréchal Niel, Senateur Vaisse, Souvenir d'Elise, Pierre Notting, Emotion, Beauty of Waltham, Princess Mary of Cambridge, Duchesse de Medina Coli, Baron Gonella, Queen Victoria, Maurice Bernardin. Mr. Keynes was second.

In the class for eighteen blooms, Mr. Hollingworth, of Maidstone, was first. His flowers were Souvenir de 8 Mai, Senateur Vaisse, Bouger, Pierre Notting, Gloire de Dijon, Pauline Lanzezeur, Madame Boutin, Devoniensis, Madame Caillat, Souvenir de la Malmaison, Olivier Delhomme, Madame Masson, Gloire de Santenay, Madame Villermez, La Reine, Comte de Paris, Beauty of Waltham, Adam, and Triomphe de Rennes. Mr. Hedge was second with Madame Charles Wood, Triomphe de Rennes, Madame Boll, Prince Léon, Pauline Lanzezeur, Beauty of Waltham, Gloire de Dijon, Lord Raglan, Reine Victoria, Pierre Notting, Louise Peyronny, Olivier Delhomme, Eugène Desgaches, George Prince, Souvenir d'Elise, Charles Lefebvre, and John Hopper. Before leaving Roses one must not omit the magnificent box of Maréchal Niel contributed by Mr. Keynes, and a smaller though more highly coloured one by Messrs. Paul & Son. That this is a magnificent and free-blooming Rose does not now admit of a doubt. Mr. Wm. Paul had also twelve fine boxes not for competition.

**GLADIOLI.**—Some fine Gladioli were exhibited by Messrs. Kelway, of Langport, Messrs. G. Paul & Son, and Mr. Prince. Mr. Kelway had first prize, and amongst his collection were—Ceres, Ophir,

Raphael, M. Rabourdin, James Carter, Calypso, MacMahon, Le Poussin, and Belle Gabrielle. In Messrs. Paul's collection, there were newer kinds, although the spikes were not so long, this included Meyerbeer, Madame de Sévigné, Eurydice, James Veitch, Charles Dickens, Madame Fortado, and other well-known and fine varieties. Mr. Ingle was the only contributor amongst amateurs, while Messrs. Kelway exhibited a large collection, which formed a trophy, that required only a lining of green to have heightened its effect, and been very fine; it contained a large number of excellent spikes. Mr. Brown, of Sudbury, also contributed a smaller collection.

**HOLLYHOCKS.**—The Rev. E. Hawke, Willingham Rectory, was as usual first, his flowers both in twenty-four and twelve, were remarkably fine, and comprised Charmer, Acme, Hercules, Invincible, George Young, George Keith, Lilac Perfection, Orange Perfection, Mr. J. B. Ullett, Willingham Defiance, W. Dean, Senior Wrangler, Fair Ellen, Prince, Countess of Craven, Amber Queen, and a number of seedlings. The incessant rain must have been very much against these flowers, but they were shown remarkably clear and good.

**VERBENAS.**—Mr. Perry was the only exhibitor whose flowers were worth looking at; they were Aimé, Magnifica, Géant des Batailles, Lilac King, King of Verbenas, Premier, Fairy, Admiral of the Blue, Lord Leigh, Rose Imperial, Wonderful, Snowball, Foxhunter, Charles Turner, Ruby King, Sylph, Mr. Dean, Black Prince, Annie, and some seedlings. He sustained his usual high character as the prince of cultivators in this class of flowers.

The day was tolerably fine, and the whole of the arrangements bore witness to the care, attention, and courtesy which always mark the Crystal Palace Shows, thanks to the untiring energy of Mr. Wilkinson, and his staff of assistants.—D., Deal.

## ROYAL CALEDONIAN HORTICULTURAL SOCIETY.

THE great autumn competition of this Society took place, the plants being in the Music Hall, and the fruit in the adjoining Assembly Room, in George Street, Edinburgh, on the 5th and 6th inst. It was expected that as the prize schedule was not on so liberal a scale as last year, when a special effort was made, that there would be a great falling off in the extent and quality of the subjects exhibited. The former expectation was realised to some extent, but not the latter. There was a falling off as regards Pears and Apples, and not quite so many Grapes were exhibited. There were 100 entries this season against 130 last year. Pines were much more numerous and of much higher quality; Peaches and Nectarines not so numerous, but, on the whole, the room looked much better than last year, when every corner had to be crowded, so that fruit did not appear to such good advantage as this year. We have said the Grapes were not so abundant as last year, but they made up in quality for what they lacked in quantity.

In the collection of eight sorts of Grapes, Mr. Fowler, of Castle Kennedy, was the only exhibitor. His sorts were Black Hamburgh, 1½ lb. weight; Golden Hamburgh, 1½ lb.; Black Morocco, 2 lbs.; Trebbiano, 4 lbs.; Black Muscat, 4 lbs.; Muscat of Alexandria, 3 lbs.; Black Prince, 3½ lbs.; and Duchesse of Buccleuch, 3½ lbs. This was a splendid collection of Grapes. In the four sorts of Grapes there were five competitors, Mr. Meredith, of Garston, being placed first with finely finished bunches of Black Hamburgh, Trebbiano, Barchard's Prince, and Muscat of Alexandria. For the heaviest three bunches, Mr. Fowler was first with White Nice, 10 lbs.; Black Muscat, 6 lbs.; and Trebbiano, 6 lbs. For the heaviest bunch of White, Mr. Fowler was first with White Nice, 10½ lbs. For the best two bunches of Black Hamburgh, Mr. Meredith was first with noble examples of that Grape; and Mr. Hill, Keele Hall, second. We have often seen larger bunches, and there were plenty such in the room, but never finer berries or more perfectly finished bunches. In the collection of the various sorts of Black Hamburgh, Mr. Meredith was first; Mr. Mitchell, second. In collections of White Muscats, Mr. Fowler was first with Tynningham Muscat, Bowwood Muscat, Muscat of Alexandria, Eschalata Muscat, and Canon Hall Muscat.

For the chief prize of the day, the collection of twenty sorts of fruit, there were three competitors, Mr. Thomson, Dalkeith, being first; Mr. Murray, of Taymouth Castle, second; and Mr. Mitchell, of Hamilton, third. In the class for sixteen sorts of fruit, excluding Pines, Mr. Temple, gardener, Balbirnie, was first. In this class there were seven competitors. Prizes being offered for the best White and the best Black seedling Grapes, Mr. Fowler exhibited for the former, and Mr. Melville, of Dalmeny Park, for the latter, and got the prizes offered. We think it would be much better to withhold prizes for seedlings unless they possessed some very evident superiority over existing varieties, which in the instances referred to was not the case. Mr. Webster, gardener to the Duke of Richmond, at Gordon Castle, exhibited a box of seedling Plums, one of which was considered of first-rate quality, and was named Webster's Gage. We tasted it, and can endorse the finding of the Judges in this case.

Though this Show is chiefly famous for the display of fruit which it calls forth, it was also a fine Exhibition, for the season of the year, of fine-foliaged plants, and plants in bloom. The Heaths and ornamental-foliaged plants were greatly admired for the excellence of their culture. Messrs. Downie, Laird, & Laing were almost alone in their glory in the Nurserymen's classes for Hollyhocks, Dahlias, and

Gladioli. Of Hollyhocks, they exhibited and had certificates for three splendid seedlings, one named Mr. Hastie, one William Thomson, and the third James Anderson. These were very large fine-formed flowers, remarkable for substance and symmetry. Mr. Richard Hartland, Lough Nurseries, Cork, exhibited a variety of *Wellingtonia gigantea* with variegated foliage and branches, the variegation being of a beautiful golden colour. This plant was very much admired. Had it been entered before the Judges made their awards, there is no doubt a certificate would have been given to it.

On the evening of the first day of the Exhibition the members of the Society and the Judges dined together in the Waterloo Hotel, James Smith, Esq., W.S., in the chair, Professor Douglas McLaggan, croupier, when a variety of appropriate toasts were given, and the evening was spent in a way that gave great satisfaction to all present.

Subjoined is a list of the prizes awarded on the occasion:—

**PINE APPLES:** Two Queens.—First, R. Fowles, Fordell. Second, J. Paddock, Castle-Bydies, Dumfries. Third, W. Thomson, Dalkeith. Two Smooth Cayenne.—Prize, J. Munro, Liverpool.

**GRAPES:** Eight varieties, one bunch of each.—Prize, A. Fowler, Castle Kennedy. Four varieties, one bunch.—First, J. Meredith, Garston. Second, J. Turner, Riddell, Selkirk. Third, J. Temple, Balbirnie. Three heaviest bunches.—Prize, A. Fowler, Black Hamburg, Two bunches.—First, J. Meredith. Second, W. Hill, Keelo Hall, Staffordshire. Third, A. Fowler, Muscat of Alexandria, Two bunches.—First, J. Maconochie, Cameron House. Second, A. Fowler. Third, Rev. — Bushby, Dalkeith. Muscat Hamburg, Two bunches.—First, J. Turner, Riddell, Selkirk. Second, D. Morrison, Inchmartine. Third, A. Fowler, True Tokay, Bunch.—First, J. Meredith. Second, D. Mathieson, Tulliallan. Black Hamburg, Bunch.—First, J. Meredith. Second, W. Hill, Staffordshire. Third, J. Temple, Balbirnie. Muscat of Alexandria, Bunch.—First, A. Anderson, Torwoodlee. Second, A. Fowler. Third, J. Maconochie, Black Alicante, Bunch.—Prize, G. Young, Westland House, Dalkeith. Black Heaviest Bunch.—Prize, A. Fowler, White, Heaviest bunch.—First, A. Fowler. Second, J. Laing, Pitcairnie. Equal Second, J. Mackay, Keithick. White, Finest-flavoured bunch.—First, N. Black, Dalhousie. Second, D. Mitchell, Hamilton Palace. Third, A. Anderson, Black, Finest-flavoured bunch.—First, J. Laing. Second, D. Morrison. Third, A. Fowler, Black, Bunch with finest bloom.—First, G. Young, Westland House. Second, J. Meredith. Third, J. Turner, Black Hamburg, Collection of Varieties.—First, J. Meredith. Second, D. Mitchell. White Muscat, Collection of Varieties.—First, A. Fowler. Second, D. Mitchell. Grape, Bunch of any, not named in the schedule.—First, A. Fowler. Second, D. Morrison. Third, D. Mitchell. White Seedling, Two bunches of any, not yet offered to the public.—Prize, A. Fowler. Black Seedling, Two bunches of any, not yet offered to the public.—Prize, W. Melville, Dalmeny.

Collections of twenty sorts of Fruits; not more than four sorts of Grapes, two of Pines, and two of Melons.—First, W. Thomson, Dalkeith Park. Second, P. Murray, Taymouth Castle. Third, D. Mitchell, Hamilton Palace. Collection of sixteen sorts of Fruits, exclusive of Pines.—First, J. Temple, Balbirnie. Second, J. Mitchell, Newbyth. Third, J. Mackay, Keithick.

Pot-grown Vines in Fruit, Black.—First, J. Gordon, Niddrie House. Second, J. Laing, Bowerhouse. White.—Prize, J. Gordon.

Thirty sorts of Fruit by Fruit Merchants.—First, W. Brown, Fruiterer, Edinburgh. Second, Carstairs & Sons, Edinburgh.

Melon Green Fleshed.—First, J. Mathieson, Barnton. Second, J. Laing, Scarlet Fleshed.—First, J. Colburn, Gorgie. Second, T. Shannon, Redhall.

Twelve Figs, three sorts.—Prize, D. Mathieson, Tulliallan Castle. Twelve Peaches, two sorts.—First, D. Ross, St. Martin's Abbey, Perth. Second, J. Laing.

Twelve Nectarines, two sorts.—First, R. B. Annandale, Seaton House, Arbroath. Second, J. Laing.

Twelve Apricots, two sorts.—First, J. Cumming, Newbyth. Second, J. Mitchell, Amisfield.

Twelve Plums, in four sorts.—First, R. Ramsay, Mountsuarth, Rothesay. Second, J. Temple, Balbirnie.

Six Peaches, any sort.—First, A. Heath, Eildon Hall; Second, J. Turner, Riddell.

Six Nectarines, any sort.—First, R. B. Annandale, Seaton House. Second, J. Laing.

Six Jargonelle Pears, fit for table.—First, R. Ramsay, Mountsuarth. Second, J. Fowler, Mavisbank.

Twelve sorts Pears, three of each, ripe or unripe.—First, R. Ramsay, Mountsuarth. Second, D. Ross, St. Martin's Gardens. Third, J. McMillan, Erskine.

Twelve sorts Dessert Apples, three of each, ripe, or unripe.—Prize, R. Ramsay.

Twelve sorts Baking Apples, three of each, ripe or unripe.—First, R. Ramsay. Second, J. Fowles. Third, A. Kerr, Saughton Hall.

Six Dessert Apples, two sorts, fit for table.—First, R. Ramsay. Second, A. Kerr.

Pint of Gooseberries.—First, G. Smith, Clerminton. Second, R. Ramsay. Pint of Red Currants.—First, R. Ramsay. Second, A. Thomson, Woodburn, Dalkeith.

#### OPEN TO GARDENERS AND AMATEURS.

Six Stove and Greenhouse Plants in flower, exclusive of Fuchsias, Calceolarias, and Geraniums.—First, W. Thomson, Dalkeith. Second, J. Fowler, Mavisbank. Third, N. Black, Dalhousie.

Three Cape Heaths, of sorts.—First, W. Thomson. Second, J. Currie, Salisbury Green.

Six Plants with fine Foliage, of sorts.—First, W. Thomson. Second, J. Currie.

Six Ferns, of sorts.—First, W. Thomson. Second, J. Currie.

Two Fuchsias, of sorts.—First, — Gilchrist, Duddingston House. Second, J. Mathieson, Barnton.

Three Pots of Achimenes, of sorts.—First, W. Thomson. Second, J. Gordon, Niddrie House.

Four Zonale or Bedding Geraniums, of sorts.—First, W. Laird, Kinnellan. Second, J. Gordon.

Four Variegated Geraniums, of sorts.—First, W. Laird. Second, T. McGuigan, Woolmet.

Three Liliums, in pots, of sorts.—Prize, J. Gordon.

Twelve Cdt Roses, of sorts.—First, G. Barrie, Corstorphine Hill. Second, D. Campbell, Alloa.

Twenty-four Gladioli, of sorts.—First, J. Taylor, Inveresk. Second, W. Reid, Newhailes.

Twelve Quilled Asters, of sorts.—First, J. Taylor. Second, D. Campbell.

Twelve Chrysanthemum-flowered Asters, of sorts.—First, J. Jones, Banghona Bower. Second, D. Campbell.

Six Phloxes, of sorts.—First, G. Smith, Corstorphine. Second, J. Gordon.

Nine Spikes Hollyhocks, of sorts.—First, J. Allan, Belehester. Second, J. Thompson, Preston Tower, Northumberland. Five spikes Hollyhocks, of sorts.—First, J. Allan. Second, J. Thompson. Twelve Hollyhock Blooms, of sorts.—First, A. Kerr, Saughton Hall. Second, T. Shannon, Redhall.

Eighteen Dahlia Blooms, of sorts, exclusive of Fancies.—First, A. Kerr. Second, A. Glen, Rosehall.

Twelve Dahlia Blooms, of sorts, exclusive of Fancies.—First, W. Vair, Pittferan. Second, — Buchanan, Kincardine. Third, — Mercer.

Twelve Fancy Dahlias, of sorts.—First, W. Vair. Second, A. Kerr. Third, A. Glen.

#### FOR NURSERYMEN ONLY.

Eleven spikes Hollyhocks, of sorts.—Prize, Messrs. Downie, Laird, and Laing, Edinburgh.

Twenty-four Dahlia Blooms, of sorts.—Prize, Messrs. Downie, Laird and Laing.

Twelve Blooms Fancy Dahlias, of sorts.—Prize, Messrs. Downie, Laird, and Laing.

Fifty Gladioli, not more than two of a sort.—Prize, Messrs. Downie, Laird, and Laing.

#### OPEN TO GARDENERS AND AMATEURS.

Two Cuenubers.—First, J. Allan, Belchester. Second, J. Shannon.

Caniflowers.—First, J. Brydon. Second, J. Fowler.

Beetroot.—First, J. Pow, Hanley, Corstorphine. Second, J. Jones, Banghona Bower.

Six Leeks.—First, J. Mathieson. Second, A. Thompson.

Twelve Onions.—First, W. Vair. Second, W. Gray, Craig Park.

Collection of Salads.—First, D. Mathieson. Second, J. McMillan, Erskine.

Twelve sorts of Vegetables.—First, D. Mathieson. Second, J. Shannon.

#### AMATEURS ONLY.

Basket eight sorts of Vegetables.—First, T. Fairley, Henderson Row, Edinburgh. Second, T. Chisholm, Dalhousie.

Six Gladioli.—First, T. Fairley. Second, T. Chisholm.

Six Rose Blooms.—First, J. Hay. Second, T. Chisholm.

Six Dahlias, of sorts.—First, R. Buchanan. Second, T. Fairley.

Six Phloxes, varieties.—Prize, T. Fairley.

*Special awards for articles not specified in the prize schedule:—*

Pimms.—Prize, J. Laing, gardener to P. Dalmahoy, W.S.

Yellow Foliaged Bicolor Zonale Geranium.—First-class Certificate, W. Young, Assistant-Secretary.

Verbenas—"Blondin" and "Cherry Ripe," the first bright scarlet and white eye, and the second rosy peach, with a very light white eye, a very promising flower.—First-class Certificates to Mr. Fowles, of Fordell.

Hollyhocks—"William Thomson," deep rose and crimson;—"Mr. Hastie," light rosy peach;—"James Anderson," bright rose and lilac.—First-class Certificates to Messrs. Downie, Laird, & Laing.

#### EXHIBITING KITCHEN-GARDEN PRODUCE.

At a recent horticultural show which was held at Northleach, the greater portion of the vegetables, such as Potatoes, Turnips, Carrots, Parsnips, and Onions, were cleansed by washing. This practice was much condemned by some of the judges, who are all professional gentlemen, but not by the others; and at a previous exhibition one of them said that if the articles were dirty he should not touch them. This difference of opinion among the judges makes exhibitors uncertain which course to pursue. Will you give us the benefit of your opinion? or inform us how these matters are conducted at large shows?—GEORGE CHILDE.

[At all the leading exhibitions the tubers and bulbs are washed; and this is desirable not only for the sake of appearance, but because it facilitates the determination whether they are diseased.—EDS.]

#### GROWING GRAPES, PEACHES, AND NECTARINES IN THE SAME HOUSE.

This is the second year I have accomplished the above satisfactorily, and my trees being planted in the border have not the same chance as if in pots, still the fruit on all the trees is abundant, and of good flavour, and excepting where the trees were moved last autumn, it is also large. The circumference of some of the trees is 30 feet, and the stems are 4 inches in diameter.

I manage the Vines thus: They are planted 5 feet apart—thirty Vines in all—the stems are trained from 18 to 20 inches from the glass, and the laterals are drawn up to a wire on each side nailed to the plate and ridge. I have thus 3 feet of light

between each Vine. I do not recollect that a single lateral was broken in the tying.

Supposing the trees were planted in pots, and taken out of the house to ripen their fruit, we should then have a secured crop with the highest flavour. A Quickset hedge, planted on purpose, with the ends returning a few feet, would probably answer as well as anything. As all my water has from 30 to 50 feet of pressure I have no difficulty in watering a large space of fruit trees if necessary. In pot-culture we are able to move the trees on all sides to the light, and thus obtain a high flavour in every part of the fruit.—A CONSTANT READER.

### BROWN TURKEY FIG.

I HAVE long been convinced that two distinct Figs are cultivated under the same name, and I send you a specimen of each. They are taken from two potted plants growing side by side. Possibly a comparison of these two solitary specimens will hardly convey an adequate impression of their difference; but this difference was shown very strikingly at the Crystal Palace on the 5th of September, where the dish exhibited by Mr. Turner was of the sort marked No. 1, and Mr. Dennis's prize dish of No. 2. The latter is the Fig which is imported from the Channel Islands into the London market, and which forms the staple of the Fig gardens at Taring. It is much longer than the other, and more juicy, to my taste decidedly superior. Its colour is between purple and green, and upon cutting it open the flesh, particularly near the eye, is dark purple. No. 1 is flatter at the apex, and brown or reddish brown both inside and out. Its consistence is fleshy; but when highly ripened, which I fear the accompanying specimen is not, it is very saccharine. I would suggest that the name Brown Turkey be confined to No. 1, while No. 2 might be called the Common Purple. The latter name would be at least descriptive, for it is the only Fig in England both purple and common. I imagine that old Miller was well aware of the difference, for although he does not name the Brown Turkey, I conceive that he describes it as his No. 7, and calls it Murrey or Brown Naples. The blue or purple Fig he mentions by name. The Castle Kennedy Fig, again, is his No. 1, and called by him Large Brown Ischia.

Having alluded to the Crystal Palace Show, I would add that the two dishes furnished by Mr. Dennis, one of Brown Turkey and the other of Brunswick, were the finest I ever saw either in this or any other country. Their intense colouring in this unseasoned season was remarkable. Among the other exhibitors there were several instances of misnomers; the two varieties correctly named by Mr. Dennis doing duty elsewhere as White Genoa, Black Turkey, &c.—G. S.

[The two Figs are doubtless quite distinct. That marked No. 1, and which was exhibited by Mr. Turner, appears to us to be either l'Archipel, or St. Ursule d'Avignon. We should rather incline, in absence of the foliage, to the supposition that it is the former.]

### THE BEST ROSES.

THE colours can be seen in any catalogue.

*Bourbons*.—Acidalie, Souvenir de la Malmaison, and Baronne Genella.

*Tea-scented Noisettes*.—Solfaterre, Triomphe de Rennes, Celine Forestier, and Gloire de Dijon.

*Hybrid Perpetuals*.—Charles Lefebvre, Senateur Vaisse, Professor Koch, Prince Camille de Rohan, Sœur des Anges, Pierre Notting, Madame Victor Verdier, La Ville de St. Denis, Cecile de Chabillant, Maurice Bernardin, Duc de Cazes, Duc de Rohan, Duchesse d'Orleans, Jules Margottin, Maréchal Vaillant, Madame Boutin, Carohne de Sansal, Madame Boll, Alfred de Rougemont, Souvenir de Comte Cavour, Baronne Provost, Comte de Nanteuil, W. Griffiths, Monsieur de Montigny, Lord Clyde, Lord Macaulay, Madame Knorr, Victor Verdier, Madame Clemence Joigneaux, Souvenir de la Reine d'Angleterre, Baronne Pelletan de Kinkelin, Madame C. Crapelet, General Washington, Leopold Premier, George Prince, Duchesse de Caylus, Rushton Radcliffe, Duc de Wellington, Mademoiselle Amélie Halphen, Glory of Waltham, and Madame Moreau.

From sight only I recommend Marguerite de St. Amand, Monsieur Boncenne, Rosea alba, and Alba mutabilis. The last two are Tea Roses, and were very good in pots at the International.

I do but little in *Tea Roses*. Sombrenil is a very hardy excellent white Rose. These appear to be the *élite* of such as

I know: Devoniensis, Madame Willermoz, Souvenir d'Elise; Souvenir d'un Ami, Adam, La Beule d'Or, and Rubens.

At the National Rose Show Mr. Hedge's L'Enfant Trouvé, and Souvenir d'Elise, and Mr. Moffat's globular specimen of Gloire de Dijon, were masterpieces. Tea Roses may be grown out of doors under certain conditions, but their proper place is under glass, for which purpose they are the best of all Roses. It is a pity that there are not among them any full-sized high-coloured Roses.

The Bourbons, Tea-scented Noisettes, and Hybrid Perpetuals, recommended above, are all excellent, and of good growth, constitution, and habit. Washington does not always open freely, but it is a grand Rose, a huge red turban. All the rest are free and constant bloomers.—W. F. RADCLIFFE, *Okeford Fitzpaine*.

P.S.—I saw at Rushton two plants each of Glory of Waltham, and Madame Moreau, in splendid bloom.

### GERANIUM PRATENSE AND SYLVATICUM. VIOLA CORNUTA.

As the subject of carrying improvement as far as possible into the class of Geraniums used for bedding purposes is now receiving much attention, would it not be worth while to call in the aid of species hitherto despised or not cared for, and ascertain if something could not be obtained from them? Hitherto improvement has run in one course, or nearly so, and it must be admitted that the alteration is so great that the original can scarcely be recognised; still, further advance seems to be the order of the day, and the industry of hybridisers is now and then rewarded by something fresh. The introduction of Flower of the Day formed a feature, which, followed by Osborn's Brilliant, led the way to many other improvements; and here I would ask, Is there any Geranium of the present day more prolific than the old Brilliant? I do not know of any. Golden-leaved varieties have also multiplied, and seem likely to do so, and I suppose that by-and-by the zonale marking on the foliage of Geraniums will have to conform to a clearly-defined line, with no jags or running, but accord with strict rule, like prize Tulips thirty or forty years ago.

Be this as it may, assuredly there is still room for exploration in fresh directions—some openings for a wide departure from the route taken by the generality of hybridisers. I have already pointed out the Ivy-leaved section as deserving notice; also the small-leaved class represented by Shrubland Pet, in which scent as well as beauty forms an important point; but I am now anxious to direct attention to a member of the Geranium family still further removed from the brotherhood of ornamental objects, in fact, I am disposed to ask these having the means and the opportunity to call in the aid of one of our British species—a common weed, and ask them to experiment with it, and who knows whether something very ornamental may not be produced? The Pansy and Carnation, I believe, both owe their present degree of perfection to the long-continued exercise of skill and care on the part of cultivators, both being of British origin, and why not a Geranium? Our moist meadows and woods contain members of this family, possessing a colour which none of our cultivated ones has yet approached. Geranium sylvaticum and G. pratense, both British plants, have flowers of a pretty bluish purple hue, just that which is wanted among our bedding plants; and to convert the thinly-clad spike of flower into the compact corymb of the cultivated varieties, presents difficulties no doubt, but the colour is worth the attempt, and if either of these wild species could in any way be made to assist in the production of a Zonale Geranium, having flowers of the same hue as itself, a great boon would be conferred on the public.

I think I have stated that most of the colours from white up to scarlet have pretty good representatives, and but little further improvement is wanted, or, shall I say, necessary; but in those classes which may be called a purplish crimson, farther advance is certainly desirable, and if these wild Geraniums of a tolerably good blue can be made serviceable, why, then, perhaps a step towards perfect hardness may also be made.

Geranium pratense and sylvaticum, I have not seen for many years, and I could not find them in the few places where I had a chance to look for them at the time they would be in bloom—namely, early in June; but I hope others know where to look for them. I have seen them flowering beautifully in moist meadows and hedgebanks in the north of England many years ago; but doubtless Mr. Wills may find them out, and by no one is it more likely that their beauties will be turned to account.

Whether he accomplish the object by crossing with some existing garden ornament, or by improving them, must be left to the skill of the operator, subject of course to such natural laws as cannot be overstepped. However, I trust that these Geraniums will in some way be made use of, and I have more hopes of seeing a blue Geranium than a yellow one, although the latter has the start, and already has a representative by name. Perhaps other species of Geranium may also be the subjects of experiment. I think some one ought to take a step out of the beaten track; the breeding-in-and-in system has continued so long that great advances can hardly be looked for; but a new field presents itself in the way here indicated, and I trust that experiments will result in something entirely different from what we now possess.

Apart from the above, but, nevertheless, recommended as a useful auxiliary to the flower garden, is *Viola cornuta*, respecting which Mr. Willis invites opinions. Unfortunately, I cannot on my experience give so decided an opinion as I would like, for having unfortunately planted it in a situation to which rabbits had access, they have eaten off all the flowers, or shoots that would have produced bloom. I can therefore only give my opinion as to its habit, which is all that can be desired, and the plant seems as easy of culture as the *Cerastium*. If it should prove as free a bloomer as it is good in habit, it will be a great boon to the numerous class of flower gardeners, who have already overcharged their means of keeping tender plants during the long winter months, and who will gladly accept a plant that requires so little looking after as this *Viola*. Its flowering capabilities, however, must decide its merits, and for the reasons above given I am, unfortunately, unable to say anything about the plant in that respect.—J. ROBSON.

LOBELIA SNOWFLAKE.

In reply to a letter published in THE JOURNAL OF HORTICULTURE of August 28th, respecting the failure of *Lobelia Snowflake*, I now write to say that it was planted in our garden round *Cerise Unique Pelargonium*, but by its bad form of growth it completely spoiled the look of the border. I should be glad to know of any free-blooming white flower, suitable for an edging in a summer garden, white-leaved and variegated plants not answering the purpose.—L. H. M., *Pole Hill, near Urbridge*.

I HAVE grown the above *Lobelia*, and as far as my experience goes it has proved a failure for bedding-purposes. With me it grows too tall—in many instances 18 inches high, and its flowers being on slender footstalks fall with the first shower, never to rise again. It is not a free bloomer, and the seed-pods are so large as to make it an unsightly object. I have proved it to be a good pot plant. I intend to try it from cuttings if possible, in order to keep it dwarfed and to make it flower more freely. Unlike your correspondent Mr. Drabble, I have not found it liable to die off; on the contrary, it is too free in growth.—THOMAS RECORD, *Hawkhurst, Kent*.

If I recollect aright, this *Lobelia* when first sent out was described as equal to *Lobelia speciosa*, but Mr. Drabble has given its true character. I have tried it this summer, fortunately on a limited scale, and I have seen it in several other places under more or less favourable circumstances, and in every case it has been condemned. It does not approach *Lobelia speciosa* either in habit or bloom. It seems to be of the *Ramosa* race, is of a thin upright habit, a spare bloomer, and when seen at its best has a dirty shabby appearance. Where its colour is an object, I do not think any one will use it in future who can procure either *Alyssum* or *Cerastium*, which are infinitely superior to it as bedders.—J. S. Wortley.

MANURING FOR STRAWBERRIES.

In reply to your correspondent "AGNES," as to whether Strawberries like manure or not, perhaps I may be allowed to give my opinion on the subject. Certainly they do like manure, and plenty of it too, if it only be of the right sort, but formerly it was, I believe, thought a mistake to give them manure at all, for I well remember when I first had to do with Strawberry planting, that the only manuring the land received previous to planting, was a good dressing with some of the strongest clay we could procure, and that was the best way

to obtain a crop of fruit on that land, as it was a very light peaty soil. I have now proved that on any stiff soil (such as I have to deal with), Strawberries will be all the better if the soil is well manured in addition to being very deeply trenched, for the land which I planted last season received a dressing of thoroughly rotten cowdung, such as I never saw laid on, land for any crop. The result was, that the plants this summer produced a crop of fruit far surpassing any I ever saw here or elsewhere, for size, quantity, and quality, and they did not suffer in the least from drought. I have no doubt that this was owing to deep trenching and the good manure. Cow-manure is, I think, far better than horse-manure, as the latter tends to make the ground light, and I am convinced that it cannot be kept too firm and solid, for heavy as my soil is, I always give it a good treading prior to putting in the young plants.

I am glad to notice that Mr. Keane recommends a similar method of planting.—W. LAWRENSEN.

EFFECTUAL THOUGH ECCENTRIC.

"A CORRESPONDENT," probably a schoolmaster, writes to us thus—

"I have no fault to find with the working abilities of a jobbing gardener whom I employ, but I do complain of his orthography, notation, and making a hoe an interjection! For a week's work, some *Lobelias*, and his boy's help, he charged 22s. after this fashion—

"Wan wick .....	51
Lubbeelers .....	5
Sun's obing .....	2
	22 "

We sympathise with our correspondent, but his pain may be assuaged by finding that another gentleman, an American, had his love of the correct still more grossly outraged by the following account being sent to him:—

"aorafada .....	1 50
atacinomimomagiu .....	50
Paed, Josef Javn .....	2 00

"The items of that bill are not apothecaries' articles, as might be supposed; but merely, 'A horse half a day and a taking of him home again.'"

The correspondent we have quoted from, concludes with this backhander to parochial seminaries: "My man was a national school scholar." The only just inference from the facts is, he did not make good use of his advantage. Not so, a co-labourer, who is said to have sent the following to his employer:—

Grantham, October 5.

Mr. W	To W. W	
Five days work at digging Docks,		} s. d.
Pileing Bean stalks into cocks,		
Drawing Leeks and trimming ditto,		
(Easy work that I could sit to),		
Hugging Carrot tops away,		
To be burnt another day,		
Turning manure with a stick up,		
Irish Apricots to pick up,		
Many other trifles also,		
Work that <i>Hand</i> will hardly call so,		
But I think, as I hope to thrive,		
There's <i>quantum suff.</i> for shillings five.		5 9

CULTIVATION OF THE FIG TREE ON OPEN WALLS.

THE cultivation of the Fig has been frequently noticed in these pages, still we often see trees covered with useless spray, having little fruit, and causing the amateur much disappointment.

The Fig will generally bear an abundant crop, which will ripen in September or October if attention be paid in June to the pruning. The top of every spring shoot of a tree with one stem should be pinched off after it has attained three or four leaves. From the pinched shoot two or three short-jointed shoots will be sent forth, each of which will produce two or three Figs in the following year. The Fig which is produced at the base of the midsummer shoot should be removed as soon as it appears, for the ripening of the second crop in the open air is not to be expected; but the third crop, which will be rather larger than Peas in the autumn, will, provided the tree be protected in the winter, become ripe in the July or August of the following year. These, however, are generally

small in number and in size, and unequal in flavour to those which ripen in September. The fruit of the Fig is apt to fall off. The tree requires much water.—J. J. T.

[We prefer pinching the end of the shoot before it has made the leaves.]

### GRASSES FOR LAWNS.

(Continued from page 167.)

*POA NEMORALIS ANGUSTIFOLIA* (Narrow-leaved Wood Meadow Grass).—This is perhaps the most valuable of all grasses to the gardener, as it grows better than any other in shady places, but will also thrive in those which are much exposed; indeed it will succeed almost anywhere, forming a close and beautiful green turf. Its chief value consists in its suitability for shady lawns, for growing under groups of trees in parks, and for woods, in order to encourage game. Its description is as follows:—Root

fibrous, scarcely creeping. Whole plant very slender and delicate, 1½ or 2 feet high. Stems several, erect, slightly flattened, smooth, streaked, leafy, with four or five joints. Leaves almost all on the stem, grass green, long, narrow, flat, with three principal ribs and many intermediate ones; more or less rough, especially the midrib and edges; tapering to a fine slender point; the lowermost smooth at the back. Sheaths hardly so long as the leaves, flattened, nearly smooth. Stipula very short in all the leaves, and inclosed within the sheath, but visibly notched along the margin. Flower-head a panicle, erect, or slightly drooping to one side, very slender, with numerous, half-whorled, angular, rough, wavy, compound branches. Spikelets erect, pale green and white, with a purplish tinge, their general surface shining, and nearly smooth. Calyx of two unequal spear-head shaped, taper-pointed, almost sown valves, each with three ribs; the keel, or central rib, rough; the margin of the larger, or innermost, much swollen and membranous. Florets two or three, rarely four. Outer valve of the corolla-spear-head shaped, acute, with five ribs, of which the two marginal ones and the keel are finely silky at their lower part, the two intermediate ones smooth, and not very conspicuous unless the glume be held against the light; inner valve narrow, rough-edged, cloven at the point. The base of each floret is some-

times, not always, hairy, but there is no complicated web. Stigmas large and tufted. Nectary of two acute cloven scales.'—G. ABBEY.

(To be continued.)

### POT-CULTURE OF PEACH TREES UNDER GLASS.

As everybody is talking of pot Peach cultivation, some approving, some condemning, and some undecided, I am induced to send you a specimen of Royal George, Royal Kensington, Millet's Mignonne, and Noblesse, in order that you may have some idea of their success here (Perthshire).

My experience convinces me that Peaches may thus be grown with as much certainty of crop, as trees covering walls and trellis with root-rambling freedom, provided moderate quantities are taken, the product of the circumference by half the diameter in feet being equal to the very highest number that ought to be left, if good presentable fruit be the object, and if something very fine must be had, that amount must still be moderated. Eighty and one hundred fruit per tree is absurd, as any lady or gentleman will find, should a house be incautiously filled with trees already furnished with fruit to that amount. Consult the Kentish Peach and Apple farmers, as well as those whose interest it is to dispose of their stock.

I find flat-roofed and permanently open-sided houses are not suitable to this part of the country, as some empty, and some full of nothing but what will succeed as well outside as in, will show. If no fire heat is to be used, the houses should be set to the equatorial noonday sunbeams, or even 10° further back (22nd February), and there should be full power to shut out the cold air when necessary. What good is there in raising heat in one part, if only to raise a current in another to carry it off? Objection may be taken to the circumscribed area of flooring in these high pitches, and what is lost in that is more than compensated in the use of the wall, and a more genial and effective heat.

It has been said that pot Peach trees cannot be exhibited in fruit. I took some last year, the distance out and home over highway, rail, and causeway being some 130 miles, without losing one-tenth, and within three weeks of their being ripe. With loading and unloading, they were shifted seven times. They are quite as easily carried as plants in flower.—PERTHSHIRE.

[These were very fine specimens, all of them from 9 to 9½ inches in circumference. Royal George and Millet's Mignonne are the same.]

### NOTES AND GLEANINGS.

In consequence of the failure of the crops at Chiswick this season, the trial of Peas, which was looked forward to with some degree of interest, has not been made. The first crop sown was entirely devoured by grubs and slugs notwithstanding the close vigilance of those under whose care it was placed; and the second sowing was so affected with mildew that no correct observations could be made. Arrangements have been made for another attempt next season, which it is hoped will be more successful; and it is intended that all the early varieties shall be sown in autumn for the purpose of ascertaining which is best adapted for winter sowing. Those who are possessed of new varieties and are desirous that they should be included in the trial, should at once forward a small parcel of each to Mr. Barron, at Chiswick.

— It is with much pleasure we announce, that the great collection of Ferns, as well as phanogamous plants, formed by Mr. John Smith, the late Curator of the Royal Botanic Garden at Kew, has been purchased for the national collection in the British Museum. Such a collection of Ferns as Mr. Smith made during a long and laborious life is, we believe, perfectly unique.

— We regret to have to announce the death of Mr. J. J. Blandy, of Reading, who has long taken a prominent part in horticultural matters in this country. For many years Mr. Blandy was a Member of Council of the Royal Horticultural Society, for which to the last he retained a strong attachment. He was also the deputy chairman of the Committee of the International Horticultural Exhibition. He died at his residence, at Highgrove, on the 2nd inst., aged 72.

— Two physicians, Drs. Sigerson and Divers, state, in a

communication to the *Athenæum*, that the leaflets of the Sensitive Plant do not close if touched by a piece of glass, as they do if touched by the finger or a piece of iron. If further experiments confirm this statement, their conclusion is legitimate that the motion of the leaflets is caused by the passage of electricity between the points of contact.

— OZONE is known only by its effects. There is a peculiar smell elicited when an electric machine is in operation, and that smell is said to arise from ozone; its very name has been derived from that quality—*oze*, I smell—but no one has hitherto succeeded in showing more than its effects. It is never detected except where oxygen is present, and if oxygen be not an elementary body, ozone may be one of its constituents. However, whatever ozone may be, Mr. Glaisher stated at the recent Meeting of the British Association for the Advancement of Science, that “where he found ozone in the atmosphere, there he found health; but where ozone was absent, there he found sickness prevailing.” This observation was made at the conclusion of a lecture delivered by Dr. Daubeny, in which he stated that part, at least, of the ozone present in the atmosphere is derived from plants, their green parts generating ozone when they emit oxygen. He had found this to be so in fifty-seven species of plants belonging to forty-seven different natural families. The ozone was generated by the leaves, and not by the flowers of any of the plants. One inference made by Dr. Daubeny is that plants are the appointed agents not only for restoring the oxygen to the atmosphere, which animals in breathing have withdrawn from it, but also for generating ozone, and by it removing the noxious effusions from the processes of animal life and putrefaction.

## WORK FOR THE WEEK.

### KITCHEN GARDEN.

The long-continued wet weather has favoured the growth of weeds, and rendered their destruction a matter of difficulty. The best way to get rid of them when hoeing and raking are not practicable, is to dig them down, especially the young generation. There is little required this month in the way of sowing, presuming that all the Cabbages, Cauliflowers, Lettuce, and Spinach have been sown in August. *Broccoli*, the advancing winter crops of this and of *Borecole* should be kept frequently hoed, and vacant ground may yet be filled up with the later kinds. The autumn *Broccoli* and Cauliflowers planted in shallow trenches should now have these filled up, for except in very dry situations the autumn rains will keep them moist. *Celery*, in earthing up the greatest care is necessary to prevent any portion of the earth falling into the heart of the plant, which would prevent the upright growth of the inside leaves and spoil its appearance for the table; nor should the earth be pressed too closely round the upper part of the plant, as frequently when such is the case it bulges out below. The best practice is to tie each plant up loosely with matting, having previously removed the suckers and small leaves, and then a little earth can be added every week as the plant increases in height. Another common error arises from earthing *Celery* up too soon. It should be allowed to grow to a moderate size before earthing up is attempted, and be frequently soaked with water; it should never be touched when the plants are at all wet. *Cardoons*, will require similar treatment. The latest of the *Celery* plants may be planted without making ridges for them, using for manure only a little leaf mould and charred earth; they will come in for soup purposes, and keep up the supply till May or June. *Cabbages*, the strongest plants of the early ones may be planted out for late Coleworts; the main crop to stand the winter must be planted by the end of the month in rich manured ground. *Endive*, plant plenty by the side of walls or wooden fences to stand the winter. Gather Chamomile flowers, &c. Basil and Sweet Marjoram should be bunched and packed in a close box to preserve their aromatic flavour. *Leeks* in drills may have the earth drawn up to them by the hoe. Late *Peas* and *Beans* will require close attention to prevent mildew: well supply the former with liquid manure. *Scarlet Runners*, let all the old pods be picked off, except a few of the best for seed, as they exhaust the plants for a succession. *Tomatoes*, as they are likely to be late, the leaves shading the fruit should be removed, and prevent the plants making any further growth by constant stopping.

### FRUIT GARDEN.

Dishud and stop Figs, and stop the points of all strong-growing shoots on Peach and Nectarine trees. Take away all

nails that prevent the fruit swelling, and at the same time remove any very weak or extra strong shoots which will not be wanted for fruiting next season. The remaining shoots, being thinner, will derive more influence from the sun's rays increasing the temperature of the wall. Remove leaves where they prevent the fruit from properly colouring. Continue to tie in and stop Vines against walls, and protect the fruit.

### FLOWER GARDEN.

Unless some precautions are taken to keep the taller plants in the beds of geometric flower gardens within proper limits they will be likely, towards the end of the season, to grow too high, and will destroy the uniform appearance essential to this style of gardening. A constant watch should therefore be kept on plants likely to exceed the standard height, and by frequently pinching back or pegging down endeavour to keep beds of the same pattern at the same height. At this season, with beds of flowering plants, frequent cutting back and trimming will be required to prevent a straggling habit in free-growing plants, which the late rains will help; at the same time allow no dead flowers or seed-pods to remain on the plants. By careful attention to these little matters the season of blooming may be prolonged till the plants are destroyed by frost. The late continuous storms of wind and rain have bruised and injured so much of the foliage of the trees, that, verging as we are on the autumn, the greatest vigilance will be required to insure high keeping. It is important that the lawns should be well rolled now, as the worms will be very troublesome. It will be well that all propagation for beds should be completed as soon as possible. Remove to some shelter tender greenhouse plants which have stood in pots during the summer in the flower garden. Take care to mark the arrangements, and to make memoranda respecting them. The shrubberies may now be cleared of dead wood, and all unnecessary growths controlled.

### GREENHOUSE AND CONSERVATORY.

In arranging plants in their winter quarters on no account allow them to be placed too closely together. It should be borne in mind that very few plants have as yet perfectly matured their wood, and, consequently, as that process is still going on, such will require the air to play freely around them. Plants, too, are now-a-days expected to bear examination on all sides, and it is impossible to obtain bushy, compact plants if they are allowed to touch each other. On flat stages a few may, here and there, be elevated on inverted pots, to give a little relief to the mass of green. As by placing the plants thinner room may not possibly be found for all, a selection of the eldest or worst-formed plants should be set aside to make room for those which are more choice, and as cut flowers are always in request, the above may be found useful to keep for that purpose, and may be wintered in vineries or pits, where they will not interfere with other arrangements. Unless the weather become dry, Orange trees, if at all large, will soon require housing, as the heavy rains have saturated them to excess, and a low temperature will turn the foliage to a sickly yellow, which frequently remains throughout the winter. Before removing them to their winter quarters, any that require additional root-room should have fresh pots or tubs, the present being the most favourable time for the operation. As a compost for the Citrus tribe, French gardeners use a mixture of loam, peat, and rotten dung in the state of black mould; such plants are, however, found to thrive well in yellow turfy loam and thoroughly rotten cowdung, mixing a portion of broken charcoal throughout the mass. One thing, however, should be strictly attended to, and that is drainage, which, if imperfect, will soon produce ruinous results; they will likewise thrive all the better of being rather under than over-potted. Such as do not require a complete shifting should have their drainage examined, and the state of the soil, as regards dryness, noted, that their winter treatment may be regulated accordingly. Directly Japan Lilies, *Gladioli*, and plants of like habit have done blooming, remove them to the foot of a south wall to ripen their growth, water them moderately till their tops show signs of decay, when they may be laid on their sides till pitting-time. The earliest-struck *Pelargoniums* should now be potted off, exposing them on all occasions to the weather, except during heavy rains. To have a late bloom of *Fuchsias*, let a portion of the stock have the young wood cut back about one-half. If these are placed in a little extra heat they will break again and go on blooming till Christmas. Continue shifting *Cinerarias*, Chinese Primroses, *Calceolarias*, *Humeas*, and other seedling plants for next season's blooming.

## ORCHID-HOUSE.

The time has arrived when the following points must be attended to in order to secure success for the coming year. Care must be taken to ripen off fine pseudo-bulbs, strong healthy shoots, &c. To effect this, keep up a sweet growing atmosphere from 65° to 80°, with abundance of air in all favourable weather. Use the shading with caution, and let the plants have more sun, both morning and evening, and shade only when absolutely necessary. Use water more sparingly, except to such plants as are growing freely. All *Lælias*, *Cattleyas*, *Lycaste Skinneri*, and *Odontoglossum grande*, must be kept cool, and nicely syringed occasionally.—W. KEANE.

## DOINGS OF THE LAST WEEK.

With only a couple of dry days up to Wednesday, the 5th, which is very wet, with a falling barometer, the work out of doors was chiefly a repetition of what was alluded to last week, and extra time has been devoted to putting in cuttings of *Geraniums*, &c., and forwarding house work as much as possible, in order that when the rains shall have ceased, more time may be devoted to out-door employment.

## KITCHEN GARDEN.

Here the work has chiefly been confined to banking up Cucumber-frames with grass and litter, planting Coleworts, Lettuces, Endive, making up deficiencies in banks of Cauliflowers, and dusting them and some Turnips and Radishes with lime, soot, and ashes, to keep off slugs and snails, which now threaten to be troublesome.

Walks are almost sure to look unsightly with weeds in such weather, and Strawberry runners from the borders spread over them. If the walks are a little rough on the surface, and the small thread-like weeds are numerous, it may be necessary, to hoe the walks, and rake them, and rake again in the first bright dry day, as in such weather merely cutting up the weeds will not kill them. Where boiling salt water could be thrown over such walks within 9 inches of the Box, that would be the surest means of extinguishing such weeds, and yet leave the surface of the walks untouched. The salting will do little harm to a rough-surfaced walk. Throwing salt over these walks in such wet weather would be of little benefit, as the salt would be so soon washed away beyond even the roots of the multitudinous small weeds. If fine, hot, dry weather can be selected, and the white appearance is no objection for a few days, we think sprinkling the walks with fine salt is the most economical remedy; but, as hinted last week, this must not be done with smooth-surfaced walks, as it will make them soft and retentive of moisture in winter. In many cases in the kitchen garden, when the walks are rather smooth, and the weeds appear chiefly close to the Box edgings, it is a good plan to scrape such weeds and any little moss that may appear, as shallow as possible, with a clean sharp hoe, and then brush all up with a hard broom, drawing it also over the middle parts of the walk, which will disturb all the slimy matters which are apt to accumulate, and give the whole a fresh, clean appearance. Even when labour is scarce, a kitchen garden may always be made to look respectable, if the walks and the borders adjoining them be kept clean. A walk green with weeds makes the whole look neglected, however good the crops.

In pleasure grounds, if the grass anywhere near the walks has been allowed to become long, it is almost certain that there will be a lot of Daisies, and other small weeds appearing at the sides of the walks, and scraping as above in a dry day is a good plan of clearing them off. Salting would be the quickest, but in very smooth walks, salting even the sides prevents the water of autumn and winter escaping so easily as desirable, so as to keep the main part of the walks firm and dry. A firm, smooth walk is a great luxury when dry. Many of our walks have not been broken for many years, and it takes a long-continued drizzle to make them wet, or cause them to lift in frost, and they have served their purpose well; but we begin to think whether instead of such hard-surfaced, unbroken walks, it would not be desirable in many places to have walks like ours rather shallow, a good drain below them, and formed of open, rough material, with the exception of a couple of inches or so of fine sandy matter on the surface, which would let the water pass through easily, and always present a smooth appearance, without the necessity of rolling. There is yet much to be said about walk-making. Even a walk covered with clean-washed gravel or small flints and pebbles, though not very pleasant to walk upon in a hot day with thin-soled hoots,

has this advantage, that you can walk on it in all weathers almost without soiling the sole of a boot, and without leaving a trace of where you have been, which you will be sure to do in moist weather in more solid-crustured walks. Such rough walks may also be easily kept bright by salting, until the salting has dissolved and worn down the pebbles and stones, which it will be sure to do. We have lately met with more corroborative proofs of what we stated some years ago as to the wearing effects of soda and salt, when used in water for clearing flag-stones and pavements from a green slimy covering in shady places. As to the cleaning there can be no doubt; but many stones will suffer in consequence, becoming flowery, and flaking off at the surface in consequence, and just in proportion to their original porousness. We have known stones, after being cleaned with salt and soda, showing a white wasting efflorescence in damp weather for a couple of years, and we have known some cases of fine carved marble chimney-pieces being much injured owing to soda or potash being used in the liquor and brush for cleaning them. We do not know what marble-cutters use for making old dirty carved marble as nice as when new; but we should be doubtful of using either an alkali or an acid, if we wished the fine, bright, clear lines to remain unbroken.

## FRUIT GARDEN.

The wind and the rains have brought down many Apples before they were ripe, and the wet ground has given them anything but the brightest appearance. Had the best gathered and spread out thinly to dry, as when they lie on the ground the idea is suggested that you are wallowing in too great abundance. An Apple pudding would cease to have some of its attractions to many if they thought that Apples were more plentiful than Potatoes. Some people are so constituted that superabundance lessens their enjoyment.

Gathered Peaches and Nectarines, though not fully ripe, that they might escape the ravages of wasps, &c., as they will keep longer than on the tree, and ripen perfectly, and be free from spots. Peaches by themselves, though a hole may be bitten in them, make passable jam, but not nearly so good as Nectarines. Both together do very well, and both are improved by having the scalded kernels broken and placed in the jam a short time before being taken from the fire or oven.

*Vineries*.—Gave fire heat and more air during the day in this muggy weather, and looked after any single moulded berry, as one will soon make half-a-dozen bad, and then the bunch would go. Just now we cannot do what we wish with outside borders to keep off the dreneching rains from late vineries, and from what is intended for early work. As a whole, nothing is more economical for this purpose than wooden shutters or frames covered with asphalt, to be put on and taken off the borders as deemed necessary. These appliances are common in large gardens; but many employers who expect great results would think they were ruined if any such coverings were provided for Vine or Peach-borders. By their help and litter, or nice thatching, the borders can be kept in the right state as respects moisture and dryness, and even to a considerable extent as regards temperature. In many places, especially where there is the least deficiency in drainage, the late heavy rains will so soak the borders that late fruit will be more inclined to rot early, and Vines intended for early forcing will run a risk of many of the fibres decaying, which will be more or less felt when the Vines are started into growth. Hence the number of such covers at such places as Trentham, Keele Hall, Bentley Priory, and Woburn, and hence the drawback where such appliances or glass sashes cannot be used.

*Melons* at this period should be kept pretty free of laterals, and the larger leaves encouraged where room can be found for them. Those in frames will be better of having linings put round them, and thus whilst the heat is maintained inside, a little air may be given at front and back. This, keeping on the swelling, will help to secure the Melons from cracking before they are ripe in this dripping weather. Whilst the roots are supplied with moisture, it will also be well to have the surface soil moderately dry. The fruit should also be elevated on an inverted saucer, &c., so as to be clear of the damp ground. This will sometimes place the fruit too near the glass, and expose it too much to the sun. When not shaded a little by the foliage of the plant, it is a good plan in bright weather to suspend a piece of thin paper a couple of inches or so above the fruit, which will alike prevent scorching and cracking, and keep the fruit warmer at night, when no covering is used for the glass. A day or two before gathering the paper may be removed. When the fruit is 18 inches or

24 inches from the glass, such care will not be necessary; but in frames the fruit is often not half that distance from the glass, and then a slight shade over the fruit, whilst the foliage is exposed, will often be advantageous. We used to like the paper to be suspended, better than laying it on the fruit. In a bed, four little sticks stuck in the soil and their ends through the paper answered admirably.

ORNAMENTAL DEPARTMENT.

Our lawns for a few days have been too wet, either to mow or machine, or roll, but the rapid growth of the grass will give us more work in future. As for the beds, they looked well eight days ago, and after the tremendous rains of Tuesday, Wednesday, and part of Thursday, the 28th, 29th, and 30th ult., they began to look cheery on Saturday and Sunday, but now they look like so many half-drowned miserable mice. They have had no mulching this season as usual, and though a little broken and shaken, and the blooms something dismal, we feel sure that after all this rain, if the weather should clear up, and there should be some sunshine, there will yet be a fine display in September and October.

On the whole, such a season as the present would teach us, if we would be taught, the importance of depending less on large lawns and large flower gardens for our enjoyment, and depending more on those styles of gardening which the weather cannot so easily mar. Who will be the first to give us an acre or two of first-rate flower garden under glass, with means to let in the rain, or shut it out at pleasure?

Proceeded with inserting great numbers of cuttings, and potting and cleaning plants, but for particulars as to bulbs, and greenhouse and stove plants in general, we beg to refer to Mr. Keane's clear directions of the last and present week.—R. F.

COVENT GARDEN MARKET.—SEPTEMBER 8.

Very little alteration in the state of our market. Pears comprise the varieties named last week. Peaches and Nectarines are much more abundant than could have been expected from the reports a month back.

TRADE CATALOGUES RECEIVED.

B. S. Williams, Victoria and Paradise Nurseries, Holloway, London, N.—General Dub and Fruit Tree Catalogue.  
John Scott, Yoevil and Merriott Nurseries, Crewkerne, Somerset.—Catalogue of Flower Roots.

TO CORRESPONDENTS.

\*.\* We request that no one will write privately to the departmental writers of the "Journal of Horticulture, Cottage Gardener, and Country Gentleman." By so doing they are subjected to unjustifiable trouble and expense. All communications should therefore be addressed solely to The Editors of the Journal of Horticulture, &c., 171, Fleet Street, London, E.C.

N.B.—Many questions must remain unanswered until next week.

BLUE GUM TREE (*Blue Gum*).—This is the *Eucalyptus globulus*. The best thing you can do with your plant is to place it with its pot under glass in winter—a cool house will do for it, take some cuttings of it in spring, and then turn the plant out against a wall, or on a hillock in a sheltered place. It will not stand much frost, but the less it grows in summer the harder it will be out of doors. It is not worth room under glass.

VERBENA CULTURE (*E. D. S.*).—You will find the information which you require at page 143, and in papers by Mr. D. Thomson and Mr. Fish in Nos. 123 and 230.

TRANSPLANTING A MAGNOLIA (*Howie Porch*).—Moist weather in the end of September or beginning of October is a good time to transplant an evergreen Magnolia, which we presume yours is as it is now flowering. The end of March and beginning of April are the next best periods. It will be necessary to dig out a trench at least a yard from the stem, if it is of moderate size, varying the distance of course with the size of the tree, so that in any case most of the fibres or a good proportion of them will be preserved along with a good ball. If you dig out a trench around the tree at some distance from the stem, and find only thick roots, and the soil towards the trunk comes away freely, and is not plentifully filled with fibres, then we would recommend you to fill up the trench again, and let the tree remain until that time twelve months; but if the soil from the trench towards the centre of the ball be full of roots, the soil coming away with difficulty, and requiring to be picked out with a fork, then work away any loose soil from amongst the roots, and move the tree at once with a good ball, and after planting spread a little fresh and moderately rich soil under and around the roots, and lay them carefully out. Give a good watering, stake, and tie with rope, interposing a hayband between the rope and the trunk to prevent the former cutting the bark.

DRESSING ASPARAGUS-BEDS (*A Subscriber since March*).—When the stems become yellow they should be cut off close to the ground; the beds may then be covered with from 3 to 6 inches of half-decayed manure, and the soil from the alleys neatly dug out and thrown on the beds. The only good that can result from the stalks being spread over the beds before covering with manure will arise from the berries being left on the beds, and young plants coming up in the following year. Some pick off the berries and scatter them on the beds, covering with manure afterwards, and remove the stalks; others remove the stalks and weeds, and then cover with manure. The one plan is as good as the other.

SHRUBS FOR PLANTING UNDER TREES (*J. S.*).—If very much shaded, and the ground is much occupied by the roots of the trees, we fear that very few shrubs will grow; the best in that case would be *Aucubas* and the *Periwinkles*. If it be possible to dig holes for the shrubs, then the following in addition to those named, which are the very best, would do tolerably well: *Common Laurels*, *Laurustinus*, *common Yew*, *common Holly*, *Box*, *Ivy* in variety, (it and *Periwinkle* being best for surface-covering or near the margin), *Butcher's Broom*, *Alexandrian Laurel*, *Berberis aquifolium*, *B. repens*, and *B. Darwinii*, *Rhododendron ponticum*, and *Privet*.

REMOVING BARK FROM VINES (*H. A.*).—You may strip the loose bark from the vines after the leaves have fallen, not going so deep as to injure the fresh bark, and afterwards dress them with Gishurst compound at the rate of 8 ozs. to the gallon.

APPLYING URINE (*Idem*).—It may be diluted with six times its quantity of water, and then applied to all kitchen-garden crops in the ordinary way of watering, pouring it between the rows of growing crops.

NURSERY GROUND (*China Aster*).—1. Forest trees impoverish the ground more than ordinary farm crops, but not to the extent of rendering it unfit for tillage afterwards. A green crop or two will bring it round. 2. The rent of nursery ground is very variable, ranging from £5 to £20 per acre, locality and quality of ground making all the difference.

BEDS FOR DAHLIAS, PANSIES, AND ASTERS (*Idem*).—To grow these well, it is necessary that the ground should be deeply dug or trenched, and thoroughly exposed to the atmosphere to render it sweet. You cannot, therefore, do this and have the beds gay when not occupied with these plants, for that is the time when the soil should be thrown up roughly to the weather.

ALPINE PLANTS (*M. A. E.*).—Plant *Silene acaulis* in loam and grit on a ledge of rockwork in a sunny exposure; *Linaria alpica* in a sunny chink of rock amongst loam, peat, and grit, which must be kept moist; *Saxifraga aizoon* and *S. aizoides* in moist loam and grit on a ledge or in a crevice of rockwork in the full sun; *Rhododendron ferrugineum* in peat and grit in a sunny fissure, which is to be kept moist; *Erigeron alpinus* and *Crepis aurea* in a sunny opening in sandy loam; *Ranunculus alpestris* in peaty loam and grit in a well-drained fissure, keeping the soil very moist; for *Dryas octopetala*, choose a sunny fissure, and if the rock is not of limestone, place some of that material therein, and plant in peat and grit, keeping moist; plant *Arctia helvetica* in a sunny fissure of rock in grit with a very little peat, kept moist; *Primula viscosa*, in a somewhat sunny opening, among well-drained loam and grit; *Rumex nivialis*, in a sunny opening in sandy loam; *Sedum dasycyllum*, in well-drained sunny fissures, in gravel and sandy-loam. *Hutchinsia alpina* requires a sunny fissure, with limestone, and a compost of loam and grit. The large blue *Gentian* needs a sunny slope of rockwork, and planting in fibrous loam and gravel, with an open exposure; the small *Gentian* a sunny bank, deep rich fibrous loam, gravel, or limestone. The *Alpine Rose* or *Cistus* strikes freely in peat and sand, covered with a hand-glass; select cuttings of the half-ripened wood.

VENTILATING A WALL-CASE (*Rus in urbe*).—We think that with the doors open, and the space above the doors, in hot weather, your 6 inches of ventilation top and bottom will do, as it will be continuous; 3 inches more would have been better, and though left open, with power to close when deemed advisable—a matter of importance in early frosts, and for ripening Grapes in autumn. In addition to Black Hamburg you can have *White Muscadine* and *Buckland Sweetwater*. With the above your arrangements will answer.

CATERPILLAR GNAWING RIPE GRAPES (*R. S.*).—The hairy caterpillar which has gnawed your Black Hamburg Grapes is that of the large *Ermine Moth*, *Bombix (Spilosoma) Menthastris*. It is quite an unusual habit, although the insect is a very general feeder.—W.

**THOMPSON'S GARDENER'S ASSISTANT (Elliott).**—We are informed that the plates are all hand-coloured.

**HOUSE FOR LATE VINES, FRUIT TREES, AND BEDDING PLANTS, AND EARLY VINERY (A Subscriber).**—In such a low house for general purposes, with a hipped roof, and a forcing pit abutting on the front wall, we would have a pathway down the middle, make a border inside all the width of the house, and raised against the back wall a little, and there we would plant the Vines, and train them down the hip and front roof. A latticed path of wood would be best during summer. Fruiting plants as Peaches, Figs, &c., might be set on pans and partly plunged in the floor on both sides, and in winter moveable stages could be let in against the back wall, and a flat one in front of both for bedding plants, which would be better than setting them on the floor. In the smaller or shorter house where you want early Grapes, we would adopt much the same system, only if we did not have pipes underneath the border, we would have an open rubble bottom below it, and upright pipes at back and front communicating with the rough open chamber, which would thus tell on the temperature of the border. To do this more easily you might raise the border at back and front 2½ feet above the ground level, and plant both at back and front; and with a flat-sparred table above each of these borders you could grow Kidney Beans, Strawberries in early spring, dwarf Fig trees, and bring forward lots of cuttings, Gloxinias, Gesnerias, &c.; then when the Grapes were gathered you could have any plants in it that needed glass protection. By this means you would have no outside borders, and a pit in front would be very useful.

**SPERGULA FILIFERA FOR A CHURCHYARD (A. B. C.).**—The *Spergula* may be sown now under protection in a cool place, or in the spring, using sandy soil, and covering the seed slightly. We are doubtful of *Spergula filifera* doing for a permanence, and would use it only in the narrowest parts. We would have more faith as to these narrow parts in *Saxifraga hypnoides*, the smallest bits planted about 6 inches apart would soon make a carpet, but we question if seed could be obtained on a large scale. Will some correspondent oblige "A. B. C." with their experience of *Spergula* for such a purpose?

**DUTIES OF A FOREMAN (A Greenhorn).**—A foreman is the first or chief workman amongst a number or company of other workmen. His "place" is just the position assigned to him by his master, and which he engages to fill. The duties, responsibilities, and privileges, are just as varied as the circumstances of the connection.

**SHELTERING A HOUSE FROM THE NORTH (T. P.).**—The Spruce planted 5 feet apart, and well kept, would answer your purpose, but not nearly so well as Yew at 4 feet apart. Strong plants of the evergreen Privet would soon make a capital protective fence, and be more easily kept to the required height of 12 feet.

**PEAR TREES (P. R. T.).**—If you consider the interest of the tree, you will cut the shoots back, reducing them one-third of their length. Next year you will find the latent buds, of which you now complain, developed, and as these produce shoots you must pinch them back, and induce them to produce fruiting spurs.

**COCOA-NUT FIBRE REFUSE (W. B.).**—You can obtain this for gardening purposes from Messrs. Barsham & Co., Kingston-on-Thames.

**FRUIT TREES AND FRUITS (E. Parrell).**—Fruits vary in quality in different situations and seasons. Dr. Hogg and Mr. Rivers are, no doubt, both right, but you may consider Alexandre Lambre an inferior Pear for this climate, for once it is good it is ten times bad. Kirke's Plum is an excellent bearer, and you may grow it either as a bush or a pyramid. Look to the roots, and see that they have not penetrated into the subsoil. Purple Gage is one of the finest Plums in cultivation. Try watering the trees when the fruit is swelling, and see what effect that will have.

**CONCRETE FOR A VINE BORDER (J. H. W.).**—The surface of your border should be made to slope evenly from the front lights to the front of the border, sufficiently to allow of the water running off. On it place 3 inches of stones broken small, ramming them well down, then run the depth of an inch above the stones with one part of Portland cement, and two parts coarse sand and fine gravel, mixed to a thin gage with water. Before this coating has become thoroughly set, lay upon it a coat of Portland cement, mixed with an equal quantity of sand, and made to the consistency of thin mortar, evenly to the thickness of an inch. This will set very firmly, but it is not a cheap concrete, though the only one we know calculated to throw water off. The surface of the border, however, is not the place for the concrete, it should be at the bottom, immediately under the drainage, to prevent the roots penetrating into bad wet soil, and for this purpose we do not recommend the above concrete, as it is too costly. Concrete on the surface of the border would prevent water and air entering; it would do no great harm to the roots for a time, but ultimately prove their destruction. Your best plan of rendering the border dry would be to adopt a covering of boards, as described at page 183 of the present volume.

**LATE STRAWBERRIES (Idem).**—Elton, Filbert Pine, Frogmore Late Pine, Admiral Dundas, Orange Chili (very late), and Bicton Pine, a good old white, and rather late variety.

**DESTROYING ANTS (A Young Gardener).**—We can only repeat what we have frequently stated before, that arsenic and honey in equal parts, mixed together, and placed in saucers near their haunts, will poison them. Sprinkling guano water over their nests will drive them away, and so will ammoniacal liquor. The flies and wasps may be taken in soda-water bottles half filled with sweetened beer, and suspended by the neck amongst the branches.

**MAKING A VINE BORDER (Idem).**—We would advise keeping the border as much above the level of the surrounding ground as you can, taking out the soil no deeper than 24 feet. The bottom of the border should be made to slope towards the front, where there should be a drain with sufficient fall and outlet. On the bottom of the border place 9 inches of brickbats or stones for drainage, and on this a layer of turves gage side downwards. For soil use the top spit of a pasture, or take off the sods to a depth of 4 or 6 inches, selecting a yellow lightish loam, and if it have a gravelly soil all the better. Form the border of this, chopped a little so as not to be too open, and mixed with one-sixth its bulk of boiled half-inch bones. Make the border 2 feet deep above the drainage, and in a dry period. Not knowing what kind of soil yours is, we are not able to say whether it would be suitable or not.

**MUSHROOM-BEDS (C. P.).**—See "Doings of the Last Week" for the last fortnight. You will see that you may make the bottom of your Mushroom-bed of any rather dry litter, and put the droppings on the top. We have had good beds with from 2 to 3 inches of short dung and droppings. More, mind, if you can obtain them.

**NAMES OF FRUIT (Chivas and Weaver).**—Your Apple is Winter Greening. (J. P. S.).—Revelston Pippin. (E. H.).—I, Cellini; 2, Ashmead's Kernel; 3, Braddick's Nonpareil; 4, Kerry Pippin.

**NAMES OF PLANTS (H. W. E.).**—1, *Polystichum aculeatum*; 2, *Lastrea nigricolor*; 3, *Polystichum angulare*, var.; 4, *P. aculeatum*, var.; 5, *P. angulare*, var. The *Acer* is quite hardy. (W. B. B.).—We are unable to determine from the fragment sent whether your *Pinus* is *P. insignis*. *P. insignis* has usually three leaves in each fascicle, but yours has only two. (C. F. O.).—Specimens too fragmentary. 1 and 5, *Cheilanthes farinosa*; 2, *Gymnogramma*, species uncertain; 3, *G. calomelanos* (?). (B. G.).—1, *Pteris seaberula*; 2, *Adiantum pedatum*; 3, *A. setulosum*; 4, *Pteris longifolia*, var. serrulata; 5, *Pteris cretica*, var. albo-lineata; 6, *Pteris cretica*; 7, *Isolepis gracilis*; 8, *Pilea serpyllifolia*.

METEOROLOGICAL OBSERVATIONS in the Suburbs of London for the Week ending September 8th.

POULTRY, BEE, and HOUSEHOLD CHRONICLE

POULTRY SHOWS WITHOUT PROTECTION.

DURING the last fortnight scarcely a day has passed by in which I have failed to receive two or more letters from various exhibitors complaining of the harsh treatment of their birds by exposing them without any protection whatever during the whole time of exhibition, and requesting me to publicly give my opinion on the practice, as my doing so would most probably have greater weight than any comments of their own. Several pens of both fowls and Pigeons have also been submitted to my inspection, with the double view of asking whether I could suggest any means for their recovery, and also to convince me how seriously they had suffered. The plight in which these unfortunate birds were shown to me was

pitiable beyond the conception of any person who had never been an eye-witness of such injuries; and were further proof wanted of how cruelly these birds have been treated, nothing could be more convincing than the fact that to my personal knowledge more than a dozen valuable specimens have already died, and my own impression is, from what I have seen, that in a few days hence more than double that number will succumb. This has arisen, beyond the possibility of doubt, entirely from the reckless exposure of such specimens to the continuous drenching rains, of late so general.

It might possibly be expected that I should make some remark on the arbitration of show birds when thus thoroughly saturated. I am convinced that under such circumstances, when arbitrators as well as birds are fully exposed to almost a blinding rain, a really correct appointment of the prizes is unattainable, and even a tolerable approximation to it is more than doubtful.

The next question is, What remedial measures can be

adopted so long as some committees wilfully persist in carrying out their shows without tents or similar accommodation? I believe that exhibitors themselves have a power in their own hands so coercive as to enforce better arrangements from the committees of poultry shows for the future, and I know several extensive exhibitors who intend "never to enter a pen at any show in times to come that does not afford necessary shelter to the competing poultry." Such a determination is a very natural one when the fearful losses of a bird in this pen, and perhaps the like in several other well-matched exhibition pens, are considered; but to take the higher ground of the intolerable cruelty of exposing night and day tenderly-reared birds to all the vicissitudes of our changeable climate without any shelter whatever, is, I think, quite sufficient apology for once more reproducing my opinion on the matter, though it must be evident that the subject is far more important to the owners of show poultry than to an arbitrator.—EDWARD HEWITT, *Eden Cottage, Sparkbrook, Birmingham.*

### THE BIRMINGHAM PRIZE LIST.

Your readers will, I have no doubt, hear with deep regret the alterations which the Birmingham Council have decided to make in their prize lists for next Show. The management of the Poultry Committee of this great and important Show has often been criticised in your pages, and frequently these gentlemen have been blamed for the silent manner in which they have listened to the appeal of not only exhibitors, but some of the important members of the Council. Without any appeal to exhibitors, but indirectly opposed to the opinion of some of the leading poultry fanciers in Birmingham, the Committee (although the majority of them know about as much of a poultry show and its management as of a horse show), have decided that the cock and hen classes shall be entirely cut out of the list. Single cocks, hens, and pullets will now form the Birmingham prize list.

Strange to say, although the prize list was decided on two months ago, never has it yet been circulated. Doubtless the object the Committee have in keeping it back is to avoid discussion, to allow as little time as possible for exhibitors to express their opinions and to decide which now is the best show to keep their best birds for. I will only ask, Why is this strange change made? Not to increase the number of entries, for I have always understood that they would rather have less than more. Perhaps it may be that the Committee are so fixed against having different judges, and knowing the incapacities of the old staff, think they may perhaps be able with rather more correctness to award the prizes to single birds, and that the best may then win, instead of the highest honours (as at the last Show) being given to many of the worst pens. The Committee of the Birmingham Show must not forget there are other shows now treading very closely on the heels of Birmingham, and unless a little more judgment be exercised, it will soon occupy a secondary position.—AN OLD EXHIBITOR.

### EXTRA PRIZES TO BUFF COCHINS AT BIRMINGHAM.

THE system of getting up the extra prizes for Buff Cochins at our Birmingham Shows, I regret to say, does not prove satisfactory. The Council object to add these extra prizes to their prize list, unless a guarantee is given for the amount. The prize lists are issued before the amount can be collected. Last year Mr. Boucher and myself guaranteed the amount of the extra prizes suggested by myself—viz., a £5 extra prize in each of the five different classes—£25 in all, Captain Heaton most liberally heading the list with £5; and although I posted circulars to all the principal breeders of Buff Cochins, I am ashamed to say the amount was never subscribed; consequently Mr. Boucher and myself were compelled to make up the deficiency. One noted breeder replied to my circular saying he did not feel disposed to subscribe towards the Captain Heaton cups, but in case he should be fortunate enough to win one he would subscribe—a liberality characteristic of a Yorkshireman. He did win a cup, and there being a deficiency, I applied to him to make good his promise, but he never had the courtesy to reply to any of my letters. This mode of treatment, after putting myself to some trouble and expense in having circulars printed, postage, &c., has quite disgusted me from ever subscribing or obtaining subscriptions towards prizes for general competition. It is

therefore my intention to open sweepstakes of £2 2s., for next Birmingham Show—the amount to be equally divided in an extra prize to each of the Buff Cochin classes—the sweepstakes to be decided by the awards of the Judges. The highest position a subscriber takes gains the sweepstake. If one or more obtain the same position, or should none of the subscribers obtain a position at all, the services of Mr. Hewitt shall be called in to decide the sweepstakes. The individual I have referred to in the early part of my circular, it is my intention not to allow to enter for the sweepstakes, unless he consent to pay up the subscriptions promised last year. The amount shall then be added to these sweepstakes and his name accepted. I need not, I am sure, call your attention to the great importance of these extra prizes; since these have been established Buff Cochins have considerably increased in value, and I think I am quite correct in stating that at the present time they realise much higher prices than any other description of fowls.

The entries for these sweepstakes will close on the 1st of October next; Mr. Lythall, Secretary of the Birmingham Show, will receive all subscriptions.—HENRY TOMLINSON, *Balsall Heath Road, Birmingham.*

[We recommend the foregoing to the attention of all exhibitors of Buff Cochin-Chinas; and at the same time to express our opinion that if this offering of extra prizes were carried into effect at other shows, and for other varieties of fowls, it would add much to their attractions. The Birmingham Exhibition is especially distinguished for the number and excellence of the Buff Cochin-Chinas there exhibited, and this we believe is attributable in no slight degree to the additional premiums to be there contended for.—EDS.]

### VULTURE-HOCKED BRAHMAS.

I HAVE been a large importer, and a very large breeder of Brahma Pootras for many years. I never imported a vulture-hocked bird, nor did I ever breed one, except when I had used birds of other strains for fresh blood. I have always either killed such, or sold them at low prices as mere egg-producers. I have never met with any one who wished to breed this appendage, and the "Standard of Excellence," to which "Y. B. A. Z." refers, says, "Vulture hocks are objectionable, but not a disqualification." If they are correct, they cannot be objectionable. When the Cochin mania was at its height, every ship that sailed for China took out commissions for fowls, and no ship returned without bringing some. These were not all of necessity pure or good specimens of the birds known here as Cochins; but in the anxiety to possess some of the popular breed, every fowl that had any pretension to it, or that possessed some only of the characteristics, was eagerly purchased. The evidence that was collected was from such breeders as Messrs. Sturgeon, Punchard, Andrews, Steggall, and Gilbert. I perfectly recollect the last-named gentleman showing me a Buff pullet, offered to him by a sailor who brought it over, and lamenting that he could not avail himself of the fresh blood because she was vulture-hocked. I knew Mr. Sturgeon's birds from the first, also Messrs. Andrews' and Gilbert's. They were not vulture-hocked. If I were asked to define a vulture hock, I should describe it as composed of stiff feathers, projecting behind and below the knee. The existence of short fluffy feathers that merely curl round the knee joint would hardly be called an offence.

If I were to exhibit Brahmans I should not at all hesitate to do so, leaving the vulture hock out of the question; I believe in almost every case those that have this point are the worst-shaped birds, being stilty and long on the leg. The judges who are blamed by "CLEMENS" must fight their own battles. I may, however, remark that our principal judges have not been considered "arbitrary" or "narrow-minded." What, however, does he mean when he compares vulture-hocked Cochins of the present day and those that were not so in former times, with the fowler that has become double through forcing? In this last case a well-defined object formed the starting point; but no one will pretend that it was ever sought by exhibitors to produce the vulture hock, or that its appearance is the result of more careful breeding or judicious crossing. I believe there is not a breeder who would not gladly get rid of it if he could. I am no partisan, seldom an exhibitor, sometimes act as judge, and have been a close observer all my life of the properties and points of fowls. I have noticed all through the poultry question, that as old leaders withdraw from classes there is often a disposition on the part of their successors rather to bring the

standard down to their birds than to raise them to it. It is said that when Mahomet was guilty of any little "écart," he wrote a chapter of the Koran to justify it; so, I believe, if fowls were produced with Dorking tails on Cochins bodies there would not be wanting those who would honestly believe and support the opinion that they were correct.—BRAHMA N. V. H.

### ECCENTRICITIES OF ENTRIES.

Few exhibitors can have waded through catalogues of poultry exhibitions without being struck by this fact, that the entries in the various classes appear to be devoid of any rule. It is perfectly true that these entries are dependent not only on the will and whim of the exhibitor, but also on the condition of his yards, yet it is difficult to understand the reasons that explain the vast differences that take place. At Birmingham, for instance, Cochins numbered 277 pens, they stood *A1* as payers in entry-money to the coffers of Birmingham; true, there were additional prizes offered, but this was also the case in other classes. At Salisbury there were three classes for Cochins, each with three prizes of £3, £2, and £1, and the entries were respectively: Buff five, Brown and Partridge six, White five; Brahmans mustered seventeen entries in two classes. At Reading Cochins were offered larger prizes; two pens contended for three prizes!—being doubled, in fact, by the Poland entries of all breeds for smaller prizes! At Rochdale, on the contrary, Cochins were far beyond Dorkings and Spanish in number of entries. Birmingham showed Spanish beaten by all the older varieties except Malays and Polands, possibly accounted for by moulting; but still, soon afterwards at Manchester they are the best payers, and this I think was the case two years ago when I examined the catalogue. Again at Salisbury they mustered seventeen pens in one class, as against Cochins in three classes. At Cirencester they assembled six, all told, Cochins amounting to eighteen entries in two classes. At Epping in all the classes save Dorking the entries were simply ridiculous, and I am quite at a loss to account for this, as the prizes are liberal, and the show a one-day exhibition. True, two hens are still required at this show, and this certainly limits entries, but it does not account for the shortcomings of entries both on this occasion at Epping and last year at Brentwood. I regret it, for it discourages the promoters of shows, and I cannot but think that this show is not known as it deserves to be.

At Salisbury, however, a still more extraordinary point in the matter of entries occurred. In 1864 at Bristol three pens of Malays competed for £3, £2, £1 prizes!—so that at last the Bath and West of England that had long remained steadfast to this old breed forsook it, and 1865 saw for the first time for many years no Malay class. Owing to the increased amount offered to poultry (no cattle being exhibited), a Malay class with two prizes only was added in 1866. Well, who can understand the enigma of entries?—the breed that was discarded in 1865 equalled the highest entry for Cochins, which were offered £6 against the £4 to Malays! It surpassed the other classes for Cochins, and (I write from memory), it surpassed some of the classes for Game to the best of my recollection.

I think I have shown by these various quotations that the entries do not depend so much on the amount of prizes offered as on something not very tangible beyond the ken of schedule-framers. What may schedule-framers learn from this? Why, that it is not politic to make extreme distinctions in the amounts offered to various breeds, but rather apportion the amount, especially at the smaller shows, pretty equally to each. They are quite uncertain as to the breed that will in any given show prove the most paying variety. The example set by Darlington does not seem to be followed, yet it is strictly fair, if smaller prizes are offered to certain varieties the entry fee ought to be less.

Then, again, in the Any other variety class there is great need for improvement. Often the right to two prizes is disputed by a motley group of all sorts; many of them are equally deserving, but the fancy of the judge decides. Here it would certainly be a good plan to give an increased number of prizes as was done at Islington, when two first, second, and third prizes were offered. This is better than at Lord Tredegar's Show, where the difficulty has been met by five or six prizes in the class, decreasing in amount. Coupled with this class there is another suggestion I would offer, it is not every exhibition that can afford *Crève Cœur* and *La Flèche* classes, but the generality of shows could afford a class which, now-a-days, I

fancy would pay for "French" fowls. This class would take in Houdans and the two other breeds named, breeds which certainly agree in one respect, they are terribly ferocious-looking! I am a family man and dare not keep them, afraid that some of the juveniles might wander into the yards and be frightened to death by the apparition of one or other of these horrible-looking birds. I had once a *Crève Cœur* hen, every other hen was afraid of her, gave in at once, as though the sight of her were sufficient, and no proof of her prowess necessary.

Another point I would greatly urge on schedule-framers is the adopting one hen instead of two. This will increase the number of entries, lessen the amount of food consumed, lessen the amount of time required for packing, &c., and reduce the present exorbitant and unjust charges for carriage. It is also a wise plan on the part of exhibitors to make the closing day for entries as late as possible; a month may be necessary for Birmingham—I, for one, greatly doubt it, but a week or ten days is ample time for the generality of exhibitions.—Y. B. A. Z.

### WARNING.

I wish to make known my grievance, and ask some of your correspondents to suggest a remedy for the sake of others who may be fellow sufferers. A few weeks since an advertisement appeared in your columns offering a number of chickens of a certain breed, from the strain of a gentleman named, and who took a first prize at Birmingham last year. They were said to be from four to five months old, fit for exhibition, and were offered at 5s. each. I wrote to the party on the same day the paper was published, giving him the name of a respectable and well-known exhibitor in the county in which he resides as reference, and requested him to send me at once on approval six pullets and a cockerel, offering to pay the carriage both ways. I received a reply by return stating that the four and five-months birds were all sold, but there were plenty left at two and three months, but they would not be sent on approval. I then wrote for six three-months-old pullets to be forwarded. More than a week passed and no fowls came, and my letter was unanswered. I then wrote again requesting to know the reason. I received a reply, stating that six pullets, two of them ten weeks the rest sixteen weeks old, were set aside for me, and would be sent on receipt of a post-office order for the amount, at the same time assuring me that several birds had been sold and all had given great satisfaction. I at once forwarded an order made payable in a week. That time had nearly elapsed before I heard anything more, when another letter came stating that only four pullets were left, two at ten weeks, and two at sixteen weeks old, and that two hens of 1865 would be sent if that would suit me. Being quite tired of being trifled with nearly three weeks, I requested them to be sent, and a cockerel into the bargain. I received two moderate hens, the best of which and the cockerel were completely scalped to the bone on the journey by the other hen, which appears to have been a stranger to the rest. The four chickens were the worst specimens of the breed I ever saw, and worth at most 1s. each, or the market value of common barndoor fowls of the size. I at once understood how it was that the birds would not be sent on approval, and why I did not receive them until after the money was payable. From the appearance of the advertisement I had every reason to expect some decent birds, but imagine my disappointment.

What is to be done to protect the public from this species of swindling, and how are buyers and sellers to put faith in each other whilst it continues?—A VICTIM.

[The remedy is obvious. Either do not buy of an unknown seller, or do not part with your money until you have seen the birds.—Eds.]

### POULTRY FANCIERS, AWAKE!

ARE ye asleep or in a torpid state that you allow yourselves to be swindled so continuously? I can truly sympathise with your correspondent Mr. Howarth Ashtou, for I have been similarly victimised, but so very often that it has at last aroused me out of my lethargy; and I would, if possible, arouse my brother fanciers, and unite with them in trying to put down the swindlers that are realising such a nice little fortune out of us.

Last spring I was induced, by seeing an advertisement in THE JOURNAL OF HORTICULTURE representing a very well known

name, and one which has appeared in a great many reports of poultry shows as a successful exhibitor, to pay a very good price (under the circumstances), for a sitting of eggs, and which on a very close examination, after the greatest of care and a little anxiety, *all turned out to be boiled*, even from such a quarter. Again, like "H. A.," the successful swindler is determined that all transactions shall cease after he has sent you the eggs, for he will not condescend to notice any letters written to him.

Now, will you oblige me by answering the following: Cannot I prosecute him for obtaining money under false pretences if I can prove it?—RUSÉ COUPÈRE.

[That you can not only recover the money from the seller of the eggs, but could punish him for the fraud we have no doubt; but the transaction does not come within the legal definition of obtaining money by false pretences. And now a word about a protection society. Let every poultry fancier be his own protector, for nothing is more easy. We adopt these invariable rules: we never buy fowls or eggs except from persons known as honourable, we never part with a fowl or eggs before we have received payment, and we never buy a fowl from a distance unless it has been seen by some one on whose judgment we rely. Abiding by these rules we never have to complain; and we must add that no one has our sympathy who buys of any seller notorious for dishonesty.]

### WOODBIDGE SHOW.

By an oversight I omitted to mention where the "suspicious dealing" of which I spoke in a former letter took place. It was at Woodbridge. And when your correspondent "RIGHT AND WRONG" says his object is to "do Right," I rather suspect he is a bit of a wag, and that he aimed at something like a *double entendre* in choosing that exact phraseology, although his orthography should undergo a slight change. Mr. Howarth Ashton's poultry man is evidently a wag too; and he reminds me of an abominable transaction three or four years ago, in which the same individual to whom Mr. Ashton refers defrauded me in the most deliberate manner. How necessary, then, it is daily becoming to have some means of protection against these rogues. Do not let us only talk about it, but let some one who is able and willing take the trouble to organise and carry on the management of a society of amateurs and gentlemen who either have suffered, or are liable to suffer, from the unprincipled conduct of a set of scamps, whose names as exhibitors or dealers require only to be made public in order to deter any respectable man from having anything to do with them.—ESOICT.

### KEIGHLEY POULTRY SHOW.

THE twenty-fourth annual meeting of the Keighley Agricultural Society, took place on Friday, August 31st. The entries were considerably more numerous than last year, being for poultry 241, for Pigeons 190, for Rabbits 15. The following prizes were awarded:—

**GAME COCK.**—Cup, J. Bradford, Bradford.  
**COCHIN-CHINA.**—First, J. Dixon, Bradford. Second, C. Sidgwick, Riddlesden. *Chickens.*—First, T. Bott, Bury. Second, H. W. Illingworth, Idle. Highly Commended, T. Lambert, Silsden. Commended, C. Sidgwick.  
**SPANISH.**—First, J. Thresh, Bradford. Second, H. Beldon, Goitstock. Highly Commended, E. Brown, Sheffield. *Chickens.*—First, W. Roberts, Halifax. Second, J. Pinder, Clitheroe. Highly Commended, J. Newton.  
**CHITTEPRAT.**—First, H. Beldon. Second, A. K. Wood, Burnside, Kendal. *Chickens.*—First, Second, and Highly Commended, H. Beldon. Commended, T. Fawcett, Baildon, Leeds.  
**PHEASANT (Golden).**—First, H. Beldon. Second, W. Thronp, Silsden. *Chickens.*—First, S. & R. Ashton, Mottram. Second, W. Cannan, Bradford.  
**PHEASANT (Silver).**—First, H. Beldon. Second and Highly Commended, A. K. Wood. *Chickens.*—First, T. Robinson, Baildon. Second, H. Beldon. Commended, J. Clayton, Keighley; S. Butterfield, Keighley.  
**PHEASANT (Black).**—First, C. Sidgwick. Second, J. Hargreaves, Skipton. Commended, H. Beldon. *Chickens.*—First and Second, C. Sidgwick. Commended, H. Beldon; S. Butterfield.  
**HAMBROH (Golden-pencilled).**—First, A. K. Wood. Second, S. Smith, Northwram. Commended, H. Beldon; T. Wrigley, jun., Tongre, Middleton, Manchester. *Chickens.*—First, S. Smith. Second, J. Smith, Bingley. Highly Commended, I. T. C. Fawcett. Commended, H. Beldon; T. Wrigley.  
**POLAND (Golden or Silver Pheasant).**—First and Second, H. Beldon. *Chickens.*—First, H. Beldon. Second, H. Bowker, Keighley.  
**POLAND (White-crested).**—First and Second, J. Smith. *Chickens.*—First and Second, J. Smith.  
**DORKING.**—First, J. Pioder. Second, H. Beldon. *Chickens.*—First, H. Beldon. Second, H. Pickles, jun., Parby. Commended, C. Sidgwick.  
**GAME (Red).**—First, J. Hodgson, Bradford. Second, G. Noble, Sainscliffe. Commended, J. Bradford. *Chickens.*—First, J. Bradford. Second, H. Beldon. Commended, W. Spencer, Haworth; J. Midgley, Haworth; W. H. Robinson, Long Lee; W. Fell, Adwalton.  
**GAME (Any other variety).**—First, W. Fell. Second, J. Bradford. *Chickens.*

—First, A. Hodgson, Illingworth. Second, T. Wilcock. Commended, W. Fell.  
**BANTAM (Black, White, or Game).**—First, E. Hutton. Second, W. Cannan. Commended, Rev. W. J. Mellor, Colwick Rectory; W. News-holme. *Chickens.*—First, G. Noble. Second, W. News-holme. Commended, E. Hutton.  
**ANY OTHER DISTINCT BREED.**—First, H. Beldon. Second, J. Dixon. Commended, H. Bowker. *Chickens.*—First, R. W. Boyle. Second, H. Bowker. Commended, J. Hargreaves.  
**DUCKS (Rouen).**—First and Second, J. Dixon. Commended, F. G. Godwin, Sheffield.  
**DUCKS (Aylesbury).**—First, E. Leech. Second, W. News-holme. Highly Commended, J. Newton.  
**DUCKS (Black Indian).**—First and Second, J. Hargreaves.  
**DUCKINGS.**—First, E. Leech. Second, E. Hutton.  
**GEESE.**—First, E. Leach. Second, B. Baxter.

### PIGEONS.

**POWTER OR CROPPER.**—*Cock.*—First, J. Thompson, Bingley. Second, G. W. Brown, Bradford. Commended, C. Cowburn. *Hen.*—First, E. Horner, Leeds. Second, J. Thackray, York. Commended, C. Cowburn.  
**CARRIER.**—*Cock.*—First and Second, E. Horner. Commended, J. Firth, jun., Dewshury; F. Crossley. *Hen.*—First, F. Crossley. Second, E. E. M. Roys. Commended, E. Horner.  
**TUMBLERS (Almond).**—First, J. Thackray. Second, C. Cowburn. Commended, E. E. M. Roys.  
**TUMBLERS (Mottled).**—First, E. E. M. Roys. Second, J. Percivall. Commended, E. Horner.  
**BALDS OR BEARDS.**—First, J. Lister. Second, J. Fielding.  
**OWLS.**—First, S. Wade, Ovenden. Second and Highly Commended, J. Fielding.  
**TURBITS.**—First and Second, J. & J. Wade.  
**JACOBINS.**—First, J. Thompson. Second, J. & J. Wade.  
**FANTAILS.**—First, J. Thackray. Second, C. Cowburn.  
**BARBS.**—First, J. Firth, jun. Second, H. Yardley.  
**DRAGONS.**—First, F. Crossley. Second, J. Lister.  
**TRUMPETERS.**—First, J. Thompson. Second, J. Thackray.  
**MACPIES.**—First, J. Thackray. Second, H. Yardley.  
**ARCHANGELS.**—First, G. W. Brown. Second, H. Yardley.  
**ANY OTHER BREED.**—First, G. W. Brown. Second, H. Yardley.  
**RABBITS.**—*Long-eared.*—First, F. Mosey, Leeds. Second, W. A. Smith. *Any other Description.*—First, R. Biuns, Bradford. Second, R. Scott, Calversyke Hill.  
**JUDGES.**—*Poultry.* Mr. R. Teebay, Preston. *Pigeons.* Mr. J. W. Thompson, Southwram.

### HALIFAX AND CALDER VALE AGRICULTURAL ASSOCIATION'S POULTRY SHOW.

THE twenty-eighth annual Exhibition of this Society was held in Clare Hall Park, Halifax, on Saturday, the 25th ult., and was extremely successful, financially and otherwise, the arrangements being ably carried out by the Committee and Secretary. The entries numbered 472 pens of poultry, 207 of Pigeons, and 6 of Rabbits.

*Spanish*, as usual, headed the list, but most of the birds were much out of condition. Messrs. Birch & Boulter took first prize in the Adults' class with a pen of very great merit. The Chicken class contained some good pens. Mr. Pindar's first-prize birds were forward. Many very promising pens were exhibited, although rather young for competition. *Dorkings* were an average lot. The Hon. H. W. Fitzwilliam's first-prize chickens were very fine. *Cochins* were fairly represented. In Buffs, Mr. Harvey's first-prize pen contained a magnificent cock, exquisite in colour, and in capital condition. Messrs. Brierley, Spencer, and Stretch each showed good birds. *Brahmas* had four classes—Light and Dark, Adults and Chickens. Mr. Boyle's first-prize Dark chickens stood quite clear of competition. Messrs. Pigeon, Roberts, and Pickles took the other principal prizes. The show of *Game* was large, nearly all the classes being well filled. Mr. Brierley had the cup for a single cock with a Black Red in capital trim, and the cup for chickens went to Mr. Firth's first-prize Brown Reds. Most of the adult *Game* were in deep moult, and the chickens were generally later than usual at this Show, the most noticeable in addition to the above-named being Messrs. Firth and Fell's Black Reds, and Messrs. Fletcher, Boyes, and Hodgson's Ducklings. The single *Game* pullets numbered twenty-four pens, the first and second prizes being awarded to Mr. H. Crossley for very early Grouse-coloured birds. The *Polands* were not numerous, but good. *Hambourghs* were a large and good collection. The cup for the best pen was awarded to Mr. Beldon for Silver-spangled chickens. The pullet in this pen was most unusually good. The prize Silver-pencilled chickens also deserve notice. Mr. Roe's Golden-spangled chickens were remarkably fine, and well merited their position. In *Game Bantams* Messrs. Rhodes, Noble, and Brierley had the principal prizes with good specimens. In *Laced*, Mr. Roy had the first and second prizes with good Silvers. The class for Any other Variety of Bantams was good, Blacks being first, Japanese second, and Blacks third. The latter were deserving of a higher position in the list.

*Ducks, Geese, and Turkeys* formed good classes, Mrs. Seamons, Mrs. Dale, and Messrs. Leech, Gamon, and Stott, dividing the principal positions. In Any other variety of poultry the Hon. H. W. Fitzwilliam and the National Poultry Company showed good specimens, Crève Cœur, Houdan, and La Flèche being well represented.

The *Pigeons* formed a show of themselves, and were placed in a tent adjoining the poultry. The cup for the best pen was awarded to Mr. Colley for a remarkably good Black Carrier cock. Messrs.

Harvey, Thackray, Fulton, and Robinson exhibited first-class Powters. Mr. Hedley's Carriers also deserve mention, and Tumblers were fairly represented in the different classes allotted to them. The Owl class was particularly fine, Mr. Robinson's first-prize pen of Whites containing undoubtedly the best hen ever imported, accompanied by a good cock. It is very seldom the old English Owls are now seen at our exhibitions, the beautiful *petite* foreign variety having now altogether superseded them as show birds. English Owls are, however, much more worthy of a class than many for which prizes are offered, such as Magpies, &c., at this Show, and we hope they will in future be properly classified. The foreigners beat them in competition; but we should very much regret the loss of our old favourites, such birds as fanciers will recollect a few years ago in the Blues of Ridpath, Rake, and Cannan, the Silvers of the latter and Morgan, and the Powder Blues of Harrison Weir and Mewburn. In Barbs, many of the first-class birds known were sent. Yellows were first, Reds second, Blacks very highly commended, and Whites received high commendation; the class also contained some extraordinary Blacks, but they were in rather bad feather. In Trumpeters the recent introductions do not yet show much, but are destined to revolutionise the Trumpeter fancy. The first prize went to capital light-beaked Blacks, the second to Mottles. It is a very remarkable fact that no advance has been made in this breed since Mr. Mewburn's exhibition days, and we believe three out of the four birds in the prize pen were originally from the lofts of that gentleman. The old Mottled hen is lost, and the substitute requires the help of her wonderful old partner, the Mottled cock, shown by Mr. Mewburn seven years ago. We may soon expect to see more of the Russian birds, and then judicious breeding will show the advance. Fantails were good. Many of the other classes do not require special notice.

In the Selling class foreign Blues, Whites and Whites respectively, took the prizes, and were claimed for the owner, thus defeating the object intended—a practice we cannot too strongly reprobate. This means of obtaining prizes has now become very frequent in both poultry and Pigeons, and it is quite time either to discontinue the class or take measures to prevent the recurrence of such practices.

A list of the awards appeared in our Number of the 28th ult.

### DEWSBURY POULTRY SHOW.

THIS, of which we published the prize list last week, would have been a great success had the weather been more favourable. The prizes for poultry have been increased, in addition to the beautiful silver cup, value five guineas, for the best pen in the Show, which was awarded to a capital pen of *Spanish* belonging to Mr. Thresh, of Bradford. The next pens in merit were Mr. Beldon's perfect Golden *Polands* and Mr. Boyle's equally beautiful *Brahma* chickens. In several of the classes the entries were very few, and we feel surprised at this, as the prizes were equal to those offered at any of our local shows, in many of which we often find twelve or fourteen entries, and often more. In the *Cochin* cock class the first-prize bird was remarkably fine, and the two prize pens of adult *Spanish* were both of great merit. In *Dorkings* there was nothing worthy of particular notice. The adult prize *Brahmas* were very good, but Mr. Boyle's chickens were the best in the two classes. The whole of the *Game* classes were well represented; but the entries were very few in all the classes. The *Hamburgh* classes were mostly good in quality, but few in numbers. Mr. Beldon's Silver-spangled were first-class, and Mr. Walker's Gold-spangled cock was about the best we ever saw. There were several pens of good *Bantams*, and among both the *Aylesbury* and *Rouen Ducks* many were really good. Mr. Leech's *Aylesburys* were nearly all that could be wished for, and in the Variety class Mr. Hutton showed a very perfect pen of Grey Call Ducks; Mr. Fowler's East Indian were also very good.

The *Pigeons*, as usual, formed a very attractive feature, and had the day been favourable it would have added materially to their comfort, for they were totally unprotected from the weather. The Committee used every effort to promote the well-being of the birds, and if all go well in future years we believe that, as in the case of the Halifax and Calder Vale Society, a tent will be erected for their special protection. The number of entries amounted to about 162 pens, and there were few of them empty. Unfortunately the Committee had accidentally misplaced one or two pens, and this was not found out until the Judge had made his awards. This was somewhat annoying to the exhibitor, whose birds we think would have taken a good position. The Committee gladly offered to make every reparation in their power for the oversight. The classes opened with that for the best Powder cock, and some excellent birds were shown, Mr. Royds being first with an excellent white, and Mr. Thackray second with a very good bird. In Powder hens Mr. Thackray was first with a Blue hen of great length and well shown, Mr. Horner being second with a Blue hen of nearly equal merit. In the class for Carrier cocks Mr. Horner took the first prize with a very fine Black, Mr. Firth being second with a good bird of the same colour, Mr. Brown and others also showing good birds; indeed, this was a good class. In Carrier hens Mr. Royds was first with a good Black, Mr. Horner being second. This was a good class. In Almond Tumblers Mr. Royds was first and Mr. Thackray second. Some of the birds in this class were in bad condition, and the unfavourable state of the weather did not improve them. In Any other

variety of Tumblers Mr. Cowburn took the first prize and Mr. Royds the second. In Turbits Mr. Thackray was first with good birds and well shown, Mr. Horner closely following him for the second place. There were eleven pens in this class, and of good merit. In Jacobins Mr. Horner was first and second, and in Trumpeters Mr. Jesse Thompson and Mr. Horner occupied the same relative positions. In Owls Mr. Pickles was first with an excellent pen of Whites, which were claimed at ten guineas. In Barbs Mr. Firth took the first prize with good birds, Mr. Thompson being second. In Fantails Mr. Thackray was first, Mr. Cowburn second. In Nuns Mr. Thackray was first and Mr. Thompson second, both pens being of good merit. In the Any variety class some excellent birds were shown, Mr. Thackray taking the first prize and Mr. Yardley the second.

The Judges were:—For *Poultry*, Mr. James Dixon, of Bradford. For *Pigeons*, Mr. J. W. Thompson, Southwain, Halifax.

### WAKEFIELD POULTRY SHOW.

(From a Correspondent.)

THE second annual Exhibition of the above Show, since it was amalgamated with another district show, was held on Saturday the 1st inst. in the Belle Isle Field, on the Sandal Road, within a few minutes' walk of Wakefield Station, and proved one of the most successful ever held both as regards the entries of horses, pigs, poultry, &c., and the attendance of visitors. About eleven o'clock the rain came down freely, and it seemed as though there were no signs of a successful gathering; but after a little thunder and a sharp shower or two the weather cleared up, and visitors thronged the ground until it became a matter of time to obtain a view of almost any of the subjects exhibited.

In the poultry department there were in the first class seven entries for a cup value £4, for the best pen of *Game*, any age or colour. This prize fell to Sir St. George Gore's Brown Reds—a hen of first-class quality, but the cock was a little coarse about the head. He was, however, very hard pressed by a pen shown by Mr. Brierley, containing an adult Black Red cock along with a pullet, and so near were the first and second prize pens that the Judges seemed almost at a loss which to place first. In the class for Black-breasted and other Reds, any age, six pens were exhibited. The first prize fell to a pen of Black Red *Game* chickens, the cockerel being undubbed, and the pullet of first-class quality. Adult Brown Reds, the property of Sir St. George Gore, were second. Next came Duckwings. The first-prize cock was an excellent bird, but the pullet only moderate. The second-prize pen contained a pullet with a very round back, and it must have been the style of the birds which obtained them the position they occupied. The Variety class consisted of three pens, Blacks being first, and Piles second. In the class for *Game* pullets of any colour, the first prize went to a pair of very large strong Brown Reds, but not of first-class quality. *Dorkings* and *Spanish* were only poorly represented as regards numbers. *Cochins* consisted of six pens. The first and second prizes were taken by Mr. Brierley. The former pen contained one of the best cocks the writer has seen for some time, and one that will be difficult to beat. The *Brahma Pootra* class consisted of four entries, and *Polands* of two. The latter belonged to Mr. Beldon, and were much admired. *Hamburghs* were good. The classes for Golden-pencilled, Silver-pencilled, Golden spangled, and Silver-spangled consisted of four, four, eight, and five pens respectively. The winning birds in each were well worthy of their places, the Pencilled ones in particular. In the class for Any other distinct breed the National Poultry Company carried off both first and second prizes with Crève Cœur and Houdan. In *Game Bantams* the first prize fell to Mr. Newsome, the second to Mr. John Crosland. There were eleven entries, but one or two pens were vacant. For *Bantams* of any other variety Mr. F. L. Roy was first with Pencilled, and Mr. Enoch Hutton second with Blacks.

*Aylesbury Ducks* were only very moderate, with the exception of Mr. Leech's first-prize pen; but *Rouens* were good. In the class for any other variety of Ducks I think the Judges made a serious mistake in awarding the first prize, as the birds in the pen of Brown Calls exhibited by Mr. Hutton were very small, and the Duck's beak perfection. The Duck in the first prize pen was black throughout, which, if I mistake not, in *Rouens* is a disqualification. Certainly the Brown Calls should be as good in bill as the *Rouens*, and, if more difficult to obtain, so much more should good ones be encouraged. Mr. Jessop took the second prize with little beauties. The class for extra stock contained a Duck with three legs.

A list of the awards was given last week.

GAME BANTAMS, RAYNOR'S STRAIN.—As Mr. Manning has more than once stated in your columns that he "has purchased the whole of the Rev. G. Raynor's stock," will you kindly allow me to make the following addition to his statement?—"With the exception of the Manchester cup and first-prize pen, and a first-rate pen of chickens, which were purchased by myself."—W. J. MELLOR, Colwick Rectory, Nottingham.

## CHEAP SUPERS.

SOME time ago, being rather at a loss for a super for a common straw hive containing a Ligurian swarm, I placed upon the top of the hive an ordinary flower-pot, having previously filled up the hole at the top with a cork, to which I affixed a small piece of comb. I then placed over all an empty hive, which fitted over the under hive, and rested upon it, protecting the super from wind and weather. The bees immediately began to work in the flower-pot, and I removed it a few days ago filled with honeycomb. The difficulty which is often experienced in driving bees from supers, when taken off, is entirely obviated by this arrangement, for after the flower-pot is removed you have only to place it on a tray and give it one or two sharp blows with a hammer in the line of the combs so as to break the pot, when the sides will fall away, carrying the bees with them, and leaving the combs standing with scarcely any bees upon them. Lift the combs on to a dish, and leave the bees on the tray to find their way back to the hive.—F. Westmoreland.

## BEES AS REGICIDES.

In my last communication which appeared in page 55, I mentioned two instances in which young queens at the heads of swarms which had issued naturally, were found imprisoned in the evening of the day on which they were hived. Observation has led me to believe that the majority of regicides are occasioned by the presence of strange bees, and this seems to offer a solution to the cases referred to.

A prime swarm under an old queen had issued from one of my hives on the preceding day (Sunday), and had remained in the skep in which it was hived until the following morning. I then captured the queen, and sent her off to a distant apiary, allowing the bees to return to their native domicile. As is usual in such cases, many of the bees continued for some hours to hunt after their queen, and some of these in all probability entered the skep in which the swarm under the young queen had been temporarily located, and finding a strange queen had made an attack upon her. I think that a similar state of things would also account for the attack upon the second queen, which I rescued and placed at the head of a queenless nucleus, where she has proved herself the best queen I have yet reared and tested; her progeny being fully equal to that of the old queen.

At times, however, bees do destroy their own queens in a most inexplicable way. A hive sent out a swarm early in July, under an old queen. I caught the queen, and presented her to a neighbouring apiarian, and after removing all the royal cells from the stock, gave them some nearly ripe royal cells reared from the brood of my original queen. In two or three days I found a fine queen at liberty, and all the superfluous royal cells destroyed. In three weeks I again inspected the interior of the hive to see what progress the queen had made in laying, and found brood in two of the central combs, but to my surprise one of them contained six or more royal cells, formed upon the face of the comb, as artificial cells usually are. These I removed, thinking it probable that the queen was still in the hive, and that the removal of these cells would prevent any further attempt at swarming, as the end of July was fast approaching. In two or three days I found a second batch of royal cradles had been almost completed, and a careful examination confirmed my suspicions that the queen herself had disappeared from the hive. These cells were also destroyed, and after a time some more royal cells, raised from the old queen, were presented to the bees, from which I expect a queen will emerge either to-day (August 22nd), or to-morrow.

Two other hives are also now raising queens from the brood of the old queen. A queen which came forth in my unicomb hive upon the 29th of July was not impregnated till Sunday last (August 19th), when twenty-one days old. She has not yet commenced egg-laying.

How very little has been effected by "E. & W." with the queen presented to him by Mr. Woodbury last autumn; her hive might have been strengthened in the spring by brood from other hives, and young queens might then with very little trouble have been raised from her brood to place at the head of all his other stocks. The season has been practically lost, and he will be in a much worse position next year, as the pure queen will then have a poorer chance of proving prolific in 1868, and our friend will not be able to raise any great number of Italian drones before that time.

Although all my hives this spring (eight in number), were headed by moths bred from the pure queen in the preceding year, and have reared a prodigious number of drones, I find that a majority of my queens this summer have mated with black drones. The old queen is, I am glad to say, all right, and will, I hope, enable me to raise a fresh lot of queens next summer.

I find that all her progeny, whether mated with black drones or not, produce very well marked workers; but if their descendants again mate with black drones, the workers then approach very nearly to the colour of their paternal ancestors.

This has been by far the best honey season I have ever experienced. Of four storified hives only one abstained from swarming. In one of them the queen got into the super and laid there a vast quantity of brood. The swarm from this hive was accordingly not returned, as I did not prize the adulterated super.\* In another instance the queen was captured and presented to a neighbour. The native royal cells were excised, and some from brood of the old queen substituted. In the other case I returned the swarm, queen and all, but in about eight days the old queen was ejected—killed no doubt by a young rival, and I was then compelled to remove all the royal cells to prevent the issue of another swarm.

Three of the supers weigh fully 40 lbs. each of pure honey. The fourth, not yet taken, ought to contain from 50 lbs. to 60 lbs. At the same time the stocks themselves are quite overdone with honey, every comb being full of sealed honey or pollen, so that breeding at present is entirely confined to the nadsirs.—J. E. B.

THE HONEY SEASON IN HADDINGTONSHIRE  
FERTILE WORKERS.
