Abstract—*Solanum medians* is a widely distributed species of wild potato (*Solanum* sect. *Petota*), growing along the coastal lomas and up the western slopes of the Andes Mountains from central Peru and northern Chile, from 200–3800 m elevation. Fertile diploid and sterile triploid cytotypes are common, are believed to be associated with morphological variants, and are formally named as subspecies. A morphometric study based on principal components and canonical discriminant analyses of characters obtained from herbarium specimens tests the circumscription of these subspecies and other currently recognized species that are very similar to *S. medians*. The results show so much overlap of these taxa that it is impractical to use morphology to define species or to provide reliable keys or identifications. We synonymize ten names under *S. medians*: *S. medians* var. *angustifolium*, *S. medians* var. *majorifrons* subvar. *majorifrons*, *S. medians* var. *majorifrons* subvar. *protohypoleucum*, *S. medians* var. *autumnale*, *S. sandemannii*, *S. tacnaense*, *S. weberbaueri* var. *decurrentialatum*, *S. tacnaense* f. *decurrentialatum*, *S. weberbaueri* var. *poscoanum*. We also treat *S. neoweberbaueri* as a closely related species to *S. medians*. We consider the synonymy in *S. medians* to be part of a much larger need for reduction of names in sect. *Petota*.

Keywords—biodiversity, lomas, potato, *Solanum medians*, *Solanum* section *Petota*.

Solanum sect. *Petota*, which includes the potato and its wild relatives, is by any standard taxonomically difficult. As a widespread and economically important group, it has been the subject of various and conflicting taxonomic treatments. Taxonomy in sect. *Petota* is complicated by the weedy nature of many of its species, ease of hybridization among some morphologically distinct species, and apparent allopolyploidy (Spooner and van den Berg 1992; Spooner and Salas 2006). Hawkes (1990) recognized 21 series and 232 species in sect. *Petota*, but series *Etuberosa* Juz. and *Juglandifolia* (Rydb.) Hawkes have been placed in other sections and many names within sect. *Petota* have been reduced to synonymy (Spooner and Salas 2006).

The *Solanum medians* complex is a term used here to describe a group of species distributed along the coast and western slopes of the Andes Mountains from central Peru to northern Chile. Plants of this complex have coarse erect pubescence, articulation distal to the middle of the pedicel, and dark blue to violet corollas typically with a green central star. The relationships and difficult species boundaries of many of its members were first recognized by Correll (1962, p. 514):

"The plants described as *S. Weberbaueri*, *S. medians*, *S. neoweberbaueri*, *S. tacnaense* and *S. Sandemannii* unquestionably represent "specific" separations by degrees rather than by lines of demarcation...While all the above have some common characteristics, such as high articulation of the pedicels, densely pilose calyx and rather coarse-appearing pilose-denticulate leaves, each has at least one characteristic whereby it may be distinguished from the others. It must be admitted, however, that some of these differences are somewhat recondite, and it is quite possible that these entities should be further united." Hawkes (1990) and Ochoa (1999) likewise indicated close relationships of some of these species. Figure 1 summarizes differing taxonomic treatments of Hawkes (1990), Ochoa (1999), and our new treatment described below.

Hawkes (1990) placed *S. medians* and other species examined here in ser. *Tuberosa*, containing over 90 species. Spooner and Castillo (1997) showed *S. medians* to be a member of plastid clade 4 of sect. *Petota* that contains most of the South American species and the polyploid species from North and

Central America. Beyond these studies, the relationship of *S. medians* is unresolved, and is the subject of continuing molecular studies.

The purpose of the present study is to reevaluate the species status of members of the *S. medians* complex through examination of herbarium specimens from throughout the range of the group, as part of a comprehensive treatment of *Solanum* sect. *Petota* in "PBI *Solanum*: a worldwide treatment" (<http://www.nhm.ac.uk/research-curation/projects/solanaceaesource/>).

MATERIALS AND METHODS

We collected data from 13 characters that distinguish the species of the *S. medians* complex in keys or descriptions of these taxa (Table 1) from 118 herbarium specimens from throughout the range of the group. The measured specimens are designated by an asterisk in Representative Specimens Examined (below). We used data from all of these specimens for character state distributions, but due to some missing data, we used only 104 specimens for principal components analysis (PCA) and canonical discriminant analysis (CDA). We assessed 53 specimens of *S. medians* var. *medians* for character state distributions and 49 for PCA and CDA, 34, 30 for *S. medians* var. *autumnale*, 17, 14 for *S. sandemannii*, and 12, 11 for *S. tacnaense* including its form *decurrentialatum*. We identified accessions to taxa based on identifications in Ochoa (1999), or for the few records not listed there, we identified collections based on their published ranges in Ochoa (1999). Based on Ochoa (1999) we labeled the few accessions identified as *S. weberbaueri* by Hawkes as *S. medians* var. *autumnale*. These specimens represent the entire geographic distributions of the *S. medians* complex. We also included *S. neoweberbaueri* because Correll (1962) suggested this taxon was part of this complex. Our results include observations from personal herbarium collections and field observations in Peru (Spooner et al. 1999; Salas et al. 2001).

PCA was calculated from the correlation matrix of the variance-covariance matrix. All analyses were done in SAS ver. 9.1 (SAS Institute Inc. 2004).

RESULTS

Means, ranges, and standard deviations for 12 of the 13 characters are presented in Fig. 2. For convenient space considerations we do not graph character 12 of Table 1 but it showed widely overlapping traits as described below. The characters overlapped so much with others that reliance on any of them would lead to unstable identifications of poorly defined species. PCA (Fig. 3) shows almost total intermixture of these accessions, and CDA (Fig. 4) shows only trends that

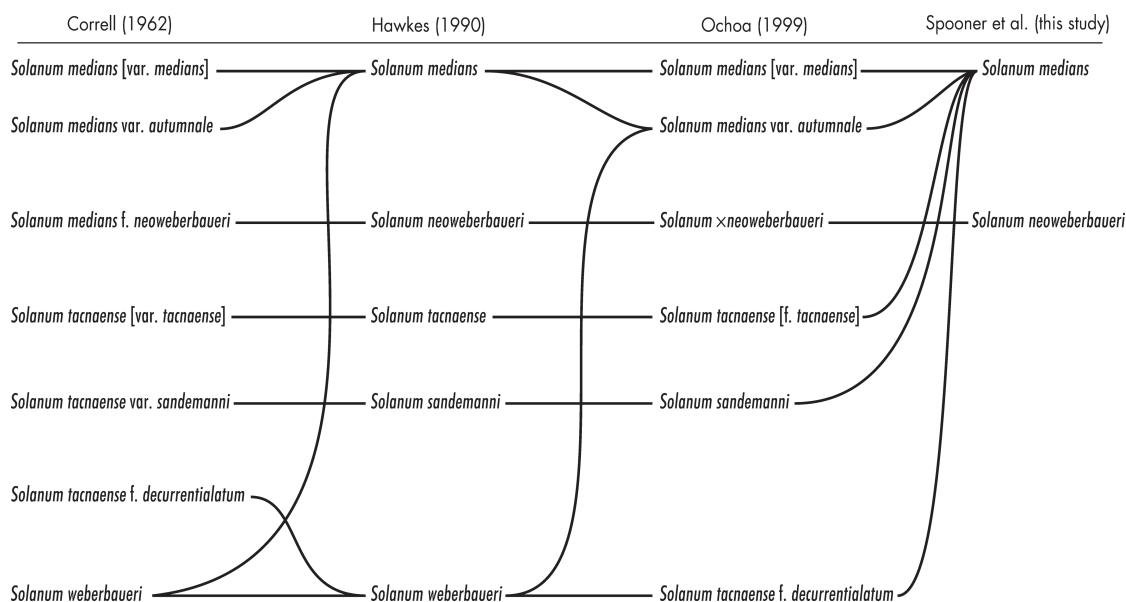

FIG. 1. Chronological flow chart of hypotheses of species boundaries of members of the *Solanum medians* complex according to Correll (1962), Hawkes (1990), Ochoa (1999), and our present study.

TABLE 1. Characters used in the phenetic analysis of the *Solanum medians* complex. The character state distributions of these characters (except character 11) are graphed in Fig. 2.

1. Number of lateral leaflet pairs. 2. Number of interjected leaflets. 3. Second most distal lateral leaflet length (cm). 4. Second most distal lateral leaflet width (cm). 5. Second most distal lateral leaflet decurrency 3 mm down from the petiole (mm). 6. Most distal lateral leaflet length (cm). 7. Most distal lateral leaflet width (cm). 8. Most distal lateral leaflet decurrency 3 mm down from the petiole (mm). 9. Terminal leaflet length (cm). 10. Terminal leaflet width (cm). 11. Length from the widest point of the terminal leaflet to the base of its petiolule (cm). 12. Pedicel length (cm). 13. Ratio: distance from base of pedicel to the articulation (cm)/pedicel length (cm).

support *S. sandemanii*, but again with so much overlap with other taxa that it is impractical to use morphology to define species or to provide reliable keys or identifications.

DISCUSSION

Species Boundaries—Our results provide the first morphological study of members of the *S. medians* complex. They support only a single, highly variable species, united by its coarsely pilose stems, leaves, and calyces (Fig. 5F); pedicels typically articulate distal to the middle; and pentagonal to rotate corollas colored dark blue to violet and typically with a green star above and below. We chose the name *S. medians* for this species over *S. weberbaueri*, published at the same time, as it is the more common name in the literature.

Hawkes (1990) accepted 225 wild species in sect. *Petota*, but ten new species have been described in the section since 1990, raising the total to 235 wild species. Recent morphological and molecular studies have reduced this number, and Spooner and Salas (2006) summarized this reduced list with 187 wild species. Our study synonymizes two more names from that list (*S. sandemanii* and *S. tacnaense*), and Spooner et al. (2007) synonymized two others (*S. litusinum* Ochoa and *S. tarijense* Hawkes as *S. berthaultii*), reducing the current number of wild species in sect. *Petota* to 183. We predict that continued reductions will be forthcoming in this section, as

suggested by van den Berg et al. (1998), Miller and Spooner (1999), and Spooner et al. (2005) in the *Solanum brevicaule* complex, and Fajardo et al. (2008) for members of ser. *Conicibaccata*.

TAXONOMIC TREATMENT

SOLANUM MEDIANIS Bitter, Repert. Spec. Nov. Regni Veg. 11: 366. 1912.—TYPE: PERU. Lima: hills of Mongomarca, loma formation, [Cerro de Amancaes], 500–600 m, 14 Aug 1910, A. Weberbauer 5683 (Seler 260) (holotype: B, destroyed, photos: F 647974! G! MO 1691266! NY! Plants 0.2–0.6 m tall, herbaceous, terrestrial, erect. Stems 3–5 mm in diameter at base of plant, coarsely pilose with typically whitish non-glandular erect trichomes, dark green

and sometimes tinged with purple. Pseudostipules minute to 12 mm long, lunate. Leaves 8–15 cm long, 5–15 cm wide, odd-pinnate, pubescent (like the stems), medium to dark green and sometimes tinged with purple underneath; petioles 0.7–3.0 cm long; lateral leaflet pairs 1–4, greatly subequal and rapidly decreasing in size to the base; most distal lateral leaflets (1.5-) 2.0–8.0 (-10) cm long, (0.4-) 1–4 (-8) cm wide, narrowly to broadly ovate to more rarely orbicular, the apex typically acute to acuminate to more rarely rounded and apiculate, the base typically sessile and short to widely decurrent on the basiscopic side to more rarely short petiolulate; terminal leaflet 3–11 (-14) cm long, 1–6 (-8) cm wide, narrowly to broadly ovate to more rarely orbicular, the apex typically acute to acuminate to more rarely rounded and apiculate, the base attenuate; interjected leaflets 0–2 (-7), sessile to short petiolulate, ovate to orbicular. Inflorescences generally in distal half of plant; peduncle 1.3–8.0 cm long. Flowers 5–15; pedicels (1.5-) 2–6 (-8) mm long, articulate typically

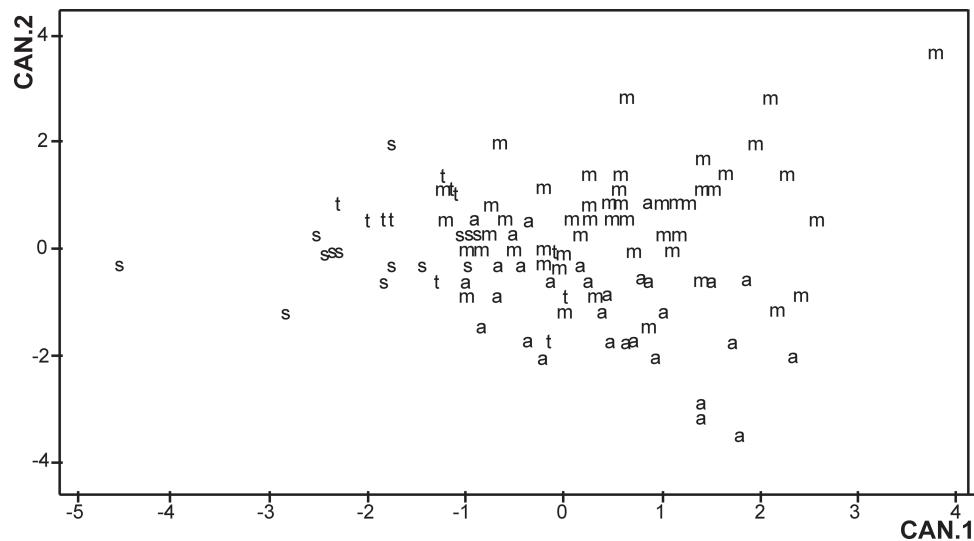

FIG. 4. Canonical discriminate analysis based on 13 morphological characters (Table 1). The accessions examined and taxon codes are the same as in Fig. 3.

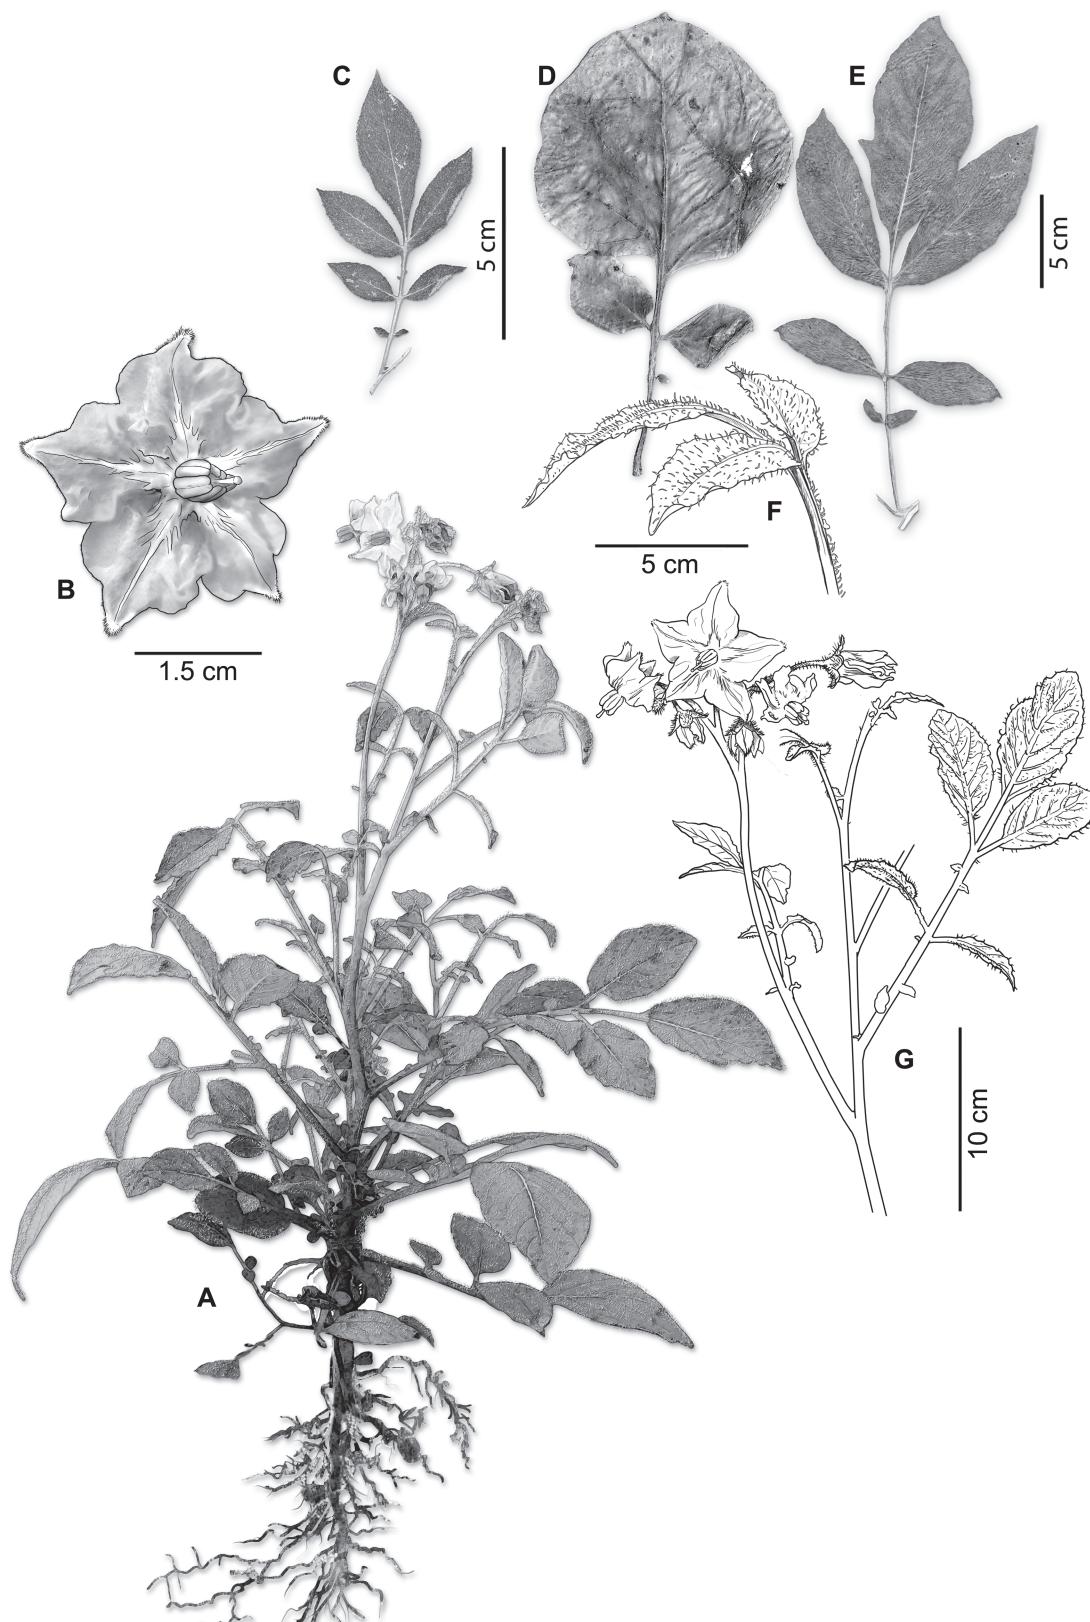

FIG. 5. *Solanum medians*. A. Habit. B. Flower. C-E. Adaxial surface of leaf showing differences in leaflet shape with C typical of the narrow-leaflet morphotype characteristic of *S. sandemannii*, D a rarer type with orbicular leaflets, and E the more common morphotype. F. Oblique view of adaxial surface of leaf showing trichomes typical of stems, leaves, and calyces. G. Upper part of plant including inflorescence. (Based on A, B, F, G, Salas et al. 7314, from a living plant vouchered at CIP and PTIS; C, Ochoa 5057, US; D, Ferreyra 17742, USM; E, Ochoa and Salas 14900 US).

above the middle; calyx 6–11 mm long, the lobes linear to long-attenuate, the acumens 2–4 mm long; corolla 2.8–3.5 cm in diameter, pentagonal to rotate, the acumens 1.0–1.5 mm long, edges of corolla flat, not folded dorsally, dark blue to violet and typically with a green star above and below; anthers 4–7 mm long, connate; style 8–9 mm long, exceeding stamens by 2–4 mm, straight, stigma clavate to capitate. Fruits 1.5 cm long, globose to slightly ovoid, medium to deep green, often with scattered white dots. Seeds from living specimens green-white throughout. Chromosome number and EBN $2n = 2x = 24$ (2EBN) and $2n = 3x = 36$ (Spooner & Salas 2006; Hijmans et al. 2007). Figure 5.

Phenology—Flowering and fruiting along the coast from May to October, and in the higher Andes from November to April.

Distribution (Fig. 6)—Central Peru (Department of Ancash) south to northern Chile in Regions I (Tarapacá) and II (Antofagasta), along the western slopes of the Andes; growing in a variety of sunny habitats along the dry coastal lomas to high frigid areas near snow fields and among *Stipa ichu* grasses in the puna. The most frequently mentioned habitat characteristics are apparently poor soils in rocky and sandy areas, but it has been collected along field margins and streambeds; 200–3800 m.

Solanum medians is morphologically very similar to some populations of *S. oplocense* Hawkes, an inland species ranging from central Bolivia to northern Argentina. Correll (1962, pg. 512) identified some collections from Bolivia as *S. tacnaense* var. *sandemanii* that we examined and identify as *S. oplocense*. Both species share similar pubescence, leaf shape, and corolla

morphology. *Solanum oplocense*, however, generally has pedicel articulation at or below the middle, and *S. medians* is distinct based on AFLP data (Spooner et al. 2005).

No herbarium was designated for the type of *S. weberbaueri* var. *poscoanum*. The label states *Herbarium Vargasianum, Universidad del Cuzco*, and Correll's labels distributed with his photos of these plants state the specimen was at herbarium CUZ, but the only specimen we found was at K. Ochoa (1999) lists specimens in CPC (Commonwealth Potato Collection at Dundee Scotland) and his personal herbarium. The CPC has

FIG. 7. *Solanum neoweberbaueri*. (Based on Ochoa 14860, US).

distributed all of its specimens, and Ochoa has distributed his herbarium widely, but mostly to CUZ. We found no isolectotype at CUZ on our visits in 2006 and 2007.

Hawkes (1954) designated *F. W. Pennell* 13196 at K as holotype for *S. sandemanii*. We have not located this specimen but have seen photos of it as listed above. Ochoa (1999) invalidly designated a specimen of *F. W. Pennell* 13196 at F as lectotype of *S. sandemanii*.

SOLANUM NEOWEBERBAUERI Wittm., Bot. Jahrb. Syst. 50 (Suppl.) 540, Figs. 1–2. 1914. *Solanum medians* f. *neoweberbaueri* (Wittm.) Correll, Wrightia 2: 191. 1961.—TYPE: PERU. Lima: Morro Salar, near Chorrillos, 250 m, in rocky places in a formation called loma, 21 Aug 1910, Weberbauer 5689 (holotype: B, destroyed, photo and fragment, Fl, photos of B holotype: G! MO! NY!; lectotype, designated by Ochoa, 1999, pg. 840: Fl, photos [Correll neg. 724]: LL! NY! UC!, isolectotypes: GH! US 144889! US 1444890!, photo of GH isolectotype [Correll neg. 725]: F! GH! MO! NY! UC!, photo of US 1444889 isolectotype [Correll neg. 723]: LL! MO! NY! UC!, photo of US 1444890 isolectotype [Correll neg. 721]: LL! NY! PTIS! UC!).

Plants 0.2–0.5 m tall, herbaceous, terrestrial, erect. Stems 2–6 mm in diameter at base of plant, subglabrous to sparsely pubescent, light to dark green and rarely tinged with purple. Pseudostipules minute to 12 mm long, lunate. Leaves 7–16.6 cm long, 4–10 cm wide, odd-pinnate, pubescent as the stems, light green; petioles 1.0–3.0 cm long; lateral leaflet pairs 1–3, slightly to greatly subequal and decreasing in size to the base; most distal lateral leaflets 1.8–6.5 cm long, 0.5–2.8 cm wide, narrowly to broadly ovate, the apex acute to acuminate, the base typically sessile and short decurrent on the basiscopic side to more rarely short petiolulate; terminal leaflet 1.7–8.5 cm long, 0.8–3.5 cm wide, narrowly to broadly ovate, the apex typically acute to acuminate, the base attenuate; interjected leaflets 0–2, sessile to short petiolulate, ovate to orbicular. Inflorescences generally in distal half of plant; peduncle 3–8.5 cm long. Flowers 2–25; pedicels 2–6.5 mm long, articulate typically above the middle; calyx 6–7 mm long, the lobes linear to long-attenuate, the acumens 2–3 mm long; corolla 2.7–4.7 cm in diameter, pentagonal to rotate, the acumens 1.5–2.0 mm long, edges of corolla flat, not folded dorsally, white to blue to lilac with a white star or white and blue mottled above and below; anthers 5–7 mm long, connate; style 8–9 mm long, exceeding stamens by 3–5 mm, straight, stigma clavate to capitate. Ovaries not maturing to fruits. Chromosome number $2n = 3x = 36$ (Spooner & Salas 2006; Hijmans et al. 2007). Figure 7.

Phenology—Flowering and fruiting along the coast in October.

Distribution (Fig. 6)—Central Peru (Department of Lima) in the coastal lomas, growing among rocks, often on slopes, in sandy or rocky soils, 200–750 m. elevation.

Specimens Examined—PERU. Lima: Lomas Manzano, cerca pueblo Pachacamac, al SSE de Lima, 25 Oct 1958, 200–300 m, C. M. Ochoa 1807 (GH, US); 1808 (GH, US); 2163 (K, US); Lima, Lomas de Atosisa, unos 35 km al SSE de Lima y al E del pueblo de Pachacamac, 21 Jul 1971, 300 m, C. M. Ochoa 3035 (US); Lima, San Bartolo, lomas al E de San Bartolo, entrando por el km 58 de la carretera Panamericana Sur, 21 Oct 1976, 350 m, C. M. Ochoa 11248 (GH, US, USM); Cañete, Quilmaná, Lomas de Quilmaná, 10 km al N de Cañete, 26 Oct 1976, 350 m, C. M. Ochoa & A. Salas 11252 (GH, US, USM); Cañete, lomas, cerca de la Mina Condestable, unos 5 km al E de Bujama Baja, entre Mala y Asia, al S de Lima, Oct 1976,

600 m, C. M. Ochoa 11272 (MOL, US); Cañete, lomas, cerca de la Mina Condestable, unos 5 km al E de Bujama Baja, entre Mala y Asia, Oct 1976, 600 m, C. M. Ochoa 11273 (F, GH, MOL, NY, US, USM); Huarochirí, lomas, cerca de la Mina Huarochirí, unos 5 km entrando al pueblo de Lurín, hacia el E, al S de Lima, 22 Oct 1982, 750 m, C. M. Ochoa 14860 (US).

Solanum neoweberbaueri is similar to *S. medians*, but it differs by its subglabrous to sparsely pubescent leaves and calyx; the pedicels, which are typically articulate in the middle or slightly below the middle; and the corollas, which are pure white to white and mottled blue or blue to purple with a white star. All populations are sterile. Ochoa (1999) postulated that *S. neoweberbaueri* is a sterile triploid nothospecies resulting from hybridization of *S. medians* and *S. chancayense*. Ochoa, a sympatric white-flowered species. *Solanum chancayense* is unrelated to *S. medians* as it is a member of plastid clade 3, not clade 4 of Spooner and Castillo (1997). Ochoa (1999) may be correct in the hybrid origin of *S. neoweberbaueri* but we consider its hybrid origin speculative at present and do not designate it as a nothospecies.

ACKNOWLEDGMENTS. We thank the curators of the following herbaria for loans or hosting us to visit their herbaria: C, CIP, COL, CONC, CUZ, F, G, GH, GOET, HAO, K, LL, MA, MO, MOL, NY, OXF, P, PTIS, S, SGO, U, UC, US, USM, and WIS. We thank Andrea Clausen and Associate Editor Gregory Plunkett for a review of this manuscript. This research was supported by the USDA, CIP, and NSF DEB 0316614 to David Spooner entitled “PBI Solanum: a worldwide treatment” (<http://www.nhm.ac.uk/research-curation/projects/solanaceaesource/>//).
