

## REVISION OF *IPOMOEA* SERIES *TYRIANTHINAE* (CONVOLVULACEAE)

J. Andrew McDonald

Plant Resources Center and Section of Integrative Biology, The University of Texas, Austin, Texas 78712

**Abstract:** *Ipomoea* series *Tyrianthinae* (House) D.F. Austin is revised in light of recent systematic surveys of New World morning glories. The group includes two species of vines and three highly derived shrubs. Four varieties of *I. orizabensis* (Ledeb.) Pelletan are recognized for the first time; two are new to science, *I. orizabensis* vars. *austromexicana* and *novogaliciana*, and one requires a new combination, *I. orizabensis* var. *collina* (House) J.A. McDonald. Molecular studies indicate that *Ipomoea* ser. *Tyrianthinae* shares close phylogenetic affinities with *Ipomoea* sects. *Calonyction* and *Tricolores*, yet few morphological features support this arrangement. It is assumed, therefore, that highly derived elements of the tyrianthina complex have undergone rapid morphological change in the arid environments of central and northern Mexico.

**Keywords:** Convolvulaceae, *Ipomoea*, *Tyrianthinae*.

House (1908) first defined *Ipomoea* subsection *Tyrianthinae* House on the basis of two combined floral features: 'herbaceous sepals' (i.e., green and foliaceous) and 2-locular capsules. He placed the group in *Ipomoea* section *Pharbitis* (Choisy) Griseb. with subsections *Cephalanthae* Choisy, *Heterophyliae* House, *Hederaceae* House and *Cissoides* House (= *Merremia pro parte*), and distinguished the latter four groupings collectively on the basis of their 3-locular capsules. Subsequent studies have dealt with *Pharbitis* groupings in various ways (Matuda 1963, 1964, 1965, McPherson 1979, McDonald 1991, McDonald & Mabry 1992, Austin & Huaman 1996, Wilkin 1999), the most comprehensive of which (Austin & Huaman 1996) recognizes three of House's subsections at the series level [i.e., *Ipomoea* sers. *Tyrianthinae* (House) D.F. Austin, *Heterophyliae* (House) D.F. Austin and *Pharbitis* (Choisy) D.F. Austin].

House initially included nine species within series *Tyrianthinae*, but most original members have since been transferred to other infrageneric groups or lumped under a broadened concept of *I. orizabensis* (Pelletan) Ledeb. ex Steud. [i.e., *I. tyrianthina* House and *I. longepedunculata* M. Martens & Galeotti *pro syn.* (McDonald 1994; Austin

& Huaman 1996)]. Former subsectional associates such as *I. portoricensis* (Spreng.) G. Don [= *I. indica* (Burm.) Merr.] and *I. venusta* (M. Martens & Galeotti) Hemsl. (= *I. marietii* Choisy) are now known to have 3-locular capsules, and therefore key to *Ipomoea* sers. *Hederaceae* and *Pharbitis*, respectively (Austin & Huaman 1996). Chloroplast-DNA studies (McDonald & Mabry 1992) indicate that *I. variabilis* and *I. isostemma* [= *I. meyeri* (H.B.K.) G. Don] are nested within *Ipomoea* sect. *Exogonium* (Choisy) Griseb., while *I. silvicola* House is now associated with *I. crinicalyx* S. Moore and *I. pedicularis* Benth. (*Ipomoea* subg. *Eriospermum*) on the basis of its setaceous sepals and tomentose seeds (McDonald 1991, Austin & Huaman 1996).

The idiosyncratic treatments of Matuda (1963, 1964, 1965) abandoned most of House's taxonomic constructs, but provide few legitimate taxonomic alternatives due to the author's adoption of informal groupings. Matuda's inordinate reliance on the *a priori* weighting of sepal characters tends to reduce the significance of his contributions, but useful insights can still be gleaned from his comprehensive consideration of most known Mexican species. Matuda allied, for example, two vining xerophytes, namely *I.*

*collina* House [= *I. tyrianthina* var. *collina* (House) J. A. McDonald] and *I. jacalana* Matuda, with the widespread mesophyte, *I. orizabensis* (*s. str.*), thereby forming the core of his 'ampli-tomentosi-sepalas group.' The present treatment adopts this scheme, but rejects Matuda's inclusion of other disparate elements which have since been relegated to a wide variety of subgeneric groupings: i.e., *I. igualensis* House [*Ipomoea* ser. *Pharbitis* (Choisy) D.F. Austin], *I. suaveolens* [*Ipomoea* ser. *Eriospermum* (Hallier f.) D.F. Austin], *I. suffulta* [*Ipomoea* sect. *Exogonium* (Choisy) Griseb.], and *I. leonensis* House [*Ipomoea* sect. *Jalapae* (House) D.F. Austin; McDonald 1991, Austin & Huaman 1996].

McPherson (1979) later adopted Matuda's perspective in part, but recognized two highly derived shrubs, *Ipomoea sescossiana* Baill. and *I. stans* Cav., as close relatives of *I. orizabensis* (*s. str.*) and *I. collina*, based primarily on their shared floral features (see below). While most of McPherson's groups, like those of Matuda, were adopted on an informal basis, his interpretations set an important taxonomic precedent by recognizing that erect growth habits have multiple origins in the genus. Prior to McPherson's study, all self-supporting shrubs were lumped with arborescent elements of the genus [i.e., *I. arborescens* (H.B.K.) G. Don, *I. murucoides* Roem. & Schultz and allies; Don 1838; Choisy 1845], resulting in an unwieldy group that included a heterogenous array of flower and fruit types. McPherson's (1979) novel refinements were later supported by anatomical and DNA studies of Mexican *Ipomoea* (McDonald 1992; McDonald & Mabry 1992; Miller & McDonald, in prep).

McPherson included yet other morphologically discordant elements in his 'Tyrianthinae group,' such as *I. longifolia* Benth. and *I. simulans* D. Hanb., but these have since been transferred to alternative subgeneric groups. The former species is now associated with *I. leptophylla* Torr. [*Ipomoea* ser. *Jalapae* (Austin 1978, 1986; Mill-

er et al. 1999)] on the basis of its sprawling shrubby habit, narrowly elliptic, glabrous leaves, and subdehiscent fruits, whereas *I. simulans* is allied with *I. caudata* Fernald of *Ipomoea* sect. *Exogonium* (McDonald 1987). Due to these newly proposed associations, *Ipomoea* series *Tyrianthinae* is left with a mere five species. The type species of this complex, *I. orizabensis*, is presently divided into four geographically defined varieties.

The tyrianthinas as a whole are endemic to Mexico and Guatemala, and usually prefer high altitudinal regions and seasonally arid environments. Vining habits in the group are generally considered to be plesiomorphic, and shrubby habits as apomorphic (McDonald & Mabry 1992). Although recent authors (McPherson 1979, Austin & Huaman 1996) have aligned shrubs such as *I. durangensis* House, *I. lenis* House, *I. petrophila* House and *I. ciervensis* Painter ex House with the self-supporting elements of series *Tyrianthinae* (i.e., *I. an-cisa* House, *I. stans* Cav. and *I. sescossiana* Baill.), I consider the former species complex to be phylogenetically distant due to their densely sericeous foliage and comose seeds. The erect growth habits of these distantly related congeners must therefore be interpreted as analogous. Indeed, preliminary cpDNA evidence confirms that the hairy-seeded shrubs fall within *Ipomoea* subgen. *Eriospermum* (unpubl. data), and consequently far removed from *Ipomoea* sers. *Tyrianthinae* of subgenus *Quamoclit* (McDonald 1991; Miller et al. 1999).

In light of the above interpretations, it seems probable that Mexican *Ipomoea* have lost their twining habits on at least six different occasions, as exemplified by the following species: *I. capillacea* (*Ipomoea* ser. *Leptocallis*), *I. leptophylla* (*Ipomoea* ser. *Jalapae*), *I. stans* (*Ipomoea* ser. *Tyrianthinae*), *I. arborescens* (*Ipomoea* ser. *Arborescentes*), *I. lenis* (ser. undetermined), and *I. carnea* (ser. undetermined). This same trend has been recognized in various shrubby species complexes that have arisen independently in arid terrains of South America, Africa

and Australia. One may surmise that erect growth habits have arisen in Mexico during episodic periods of drought since the Eocene, for all these species prosper in deserts and sparsely vegetated dry-monsoon forests, where the adaptive behavior of clinging to tall plants confers few advantages.

## MORPHOLOGY

Growth habits are variable and highly diagnostic at the species level in *Ipomoea* ser. *Tyrianthinae*. *Ipomoea orizabensis* s. lat. and *I. jacalana* are typical morning glory vines, as they climb by slender stems that twine at their supple tips. This growth habit contrasts remarkably, however, with the shrubby growth habits of *I. ancisa*, *I. sescessiana* and *I. stans*, whose stems are straight, comparatively short in stature (1–2 m long), ascendent, and only sparingly ramified. The stalks of these shrubs arise in fascicles from large (1–50 cm diam.), woody, resinous roots, growing rapidly during the onset of the rainy season (Jun–Dec) and dying back to the ground level during the onset of the dry season (Jan–May).

Leaf size and shape in *Ipomoea* ser. *Tyrianthinae* are equally variable and diagnostic at the species level, each specific type generally correlating with a particular growth habit. Vines such as *I. orizabensis* vars. *orizabensis*, *austromexicana* and *novogallicana* usually have cordiform leaf blades (Figs. 1A; 4A,B), while the leaves of the vining xerophyte, *I. orizabensis* var. *collina*, are either 3-, 5- or 7-lobate (Fig. 1B). The highly derived laminae of *I. jacalana* and *I. stans* resemble holly leaves in their presentation of elliptic blades with strongly developed teeth (Fig. 1C), whereas leaves of *I. ancisa* and *I. sescessiana* are further derived, exhibiting pseudo-compound blades that are pinnatifid or irregularly dissected (Figs. 1D,E). Their leaf segments are either linear or filiform. Although various distantly related *Ipomoea* of Mexico exhibit dissected leaves of similar type, such as *I. quamoclit* [sect. *Mina* (Cerv.) Griseb.] and members

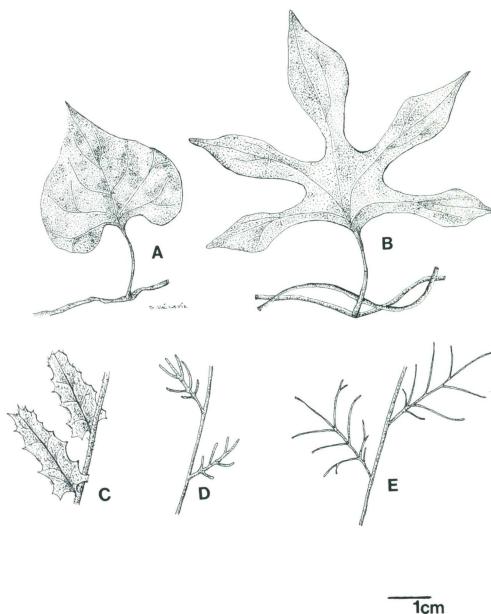

FIG. 1. Leaf variation in *Ipomoea* ser. *Tyrianthinae*. A. Leaf of *I. orizabensis* var. *orizabensis*. B. Leaf of *I. orizabensis* var. *collina*. C. Leaf of *I. stans*. D. Leaf of *I. sescessiana*. E. Leaf of *I. ancisa*.

of *Ipomoea* section *Leptocallis* (G. Don) J.A. McDonald (McDonald 1995), their distinctive blades are apparently of independent origin, as noted early on by Asa Gray (1887). As interpreted here, linear leaf segments of *I. ancisa* (Fig. 1E) and *I. sescessiana* (Fig. 1D) are thought to be homologous with the laminar teeth of *I. jacalana* and *I. stans* (Fig. 1C). And it is assumed that the serial reduction in leaf surface area resulted as an adaptive response to arid environments.

Like most *Ipomoea* groups, the sepals of *Ipomoea* ser. *Tyrianthinae* are highly diagnostic, generally exhibiting either a foliaceous condition, as observed in calices of *Ipomoea orizabensis* vars. *orizabensis* and *collina* (Figs. 4C,D), or a coriaceous, two-toned aspect (best observed on the inner sepals). The latter condition derives from the exaggerated development of a fleshy midrib and broad hyaline margins (Figs.

4E,F). The two-toned sepals of the tyrianthinas are somewhat reminiscent of sepals in *Ipomoea* sect. *Tricolores*, as exemplified by those of *I. tricolor* and *I. cardiophylla*. Sepals of the latter species are, however, relatively small (< 6 mm long) and deltate in shape, whereas those of *Ipomoea* ser. *Tyrianthinae* are broadly to narrowly elliptical shapes and generally larger in size [(4–) 6–17 mm long, 3–9 mm wide].

#### KEY TO *IPOMOEA* SECTS. *CALONYCTION*, *TRICOLORES* AND SERIES *TYRIANTHINAE*

1. Corollas white, crepuscular, usually salverform, the outer sepals often bearing a singular, subterminal, carnosé appendage *Ipomoea* sect. *Calonyction*
1. Corollas red, blue or purple-pigmented, always diurnal, infundibular; the sepals lacking carnosé appendages.
  2. Plants vining; leaf blades always cordiform; inner sepals <6 mm long, deltate or broadly elliptic; inner base of corolla tube yellow . . . . . *Ipomoea* sect. *Tricolores*
  2. Vines or suffrutescent shrubs; leaf blades variable, cordate, 5,7-lobed, elliptic, or pinnatifid; inner sepals > 6 mm long, elliptic, broadly or narrowly elliptic to lanceolate; corollas lacking yellow pigmentation . . . . . *Ipomoea* ser. *Tyrianthinae*

*IPOMOEA* ser. *TYRIANTHINAE* (House) D.F. Austin. TYPE: *Ipomoea tyrianthina* Lindl. [= *I. orizabensis* (Pelletan) Ledeb. ex Steud. var. *orizabensis*]. *Ipomoea* subsect. *Tyrianthinae* House, 1908, Ann. New York Acad. Sci. 18:206.

Perennial VINES and suffrutescent SHRUBS; stems slender and twining or straight, ascendent, herbaceous or lignescent; roots tuberous, lignescent, starchy and resinous; LEAVES variable, cordiform, broadly or narrowly elliptic, pinnatifid or irregularly dissected, margins entire or large-dentate; INFLORESCENCE a simple or compound cyme or reduced to a single flower, the peduncles variable in length (1–25 cm); sepals variable, herbaceous or green-fleshy along midrib with hyaline

margins, broadly or narrowly elliptic, rarely ovate, apex acute or acuminate; corollas infundibular, the limb broadly developed, bluish, magenta, pale pink or white; FRUIT a 2-locular, subovate capsule, the seeds ob-elliptic, short-pubescent or rarely glabrous.

DISTRIBUTION: Northern Mexico to Guatemala.

#### KEY TO *IPOMOEA* SECTION *TYRIANTHINAE*

1. Vines, stems twining and contorted.
2. Leaf blade margin dentate-crenulate. . . . . 2. *I. jacalana*
2. Leaf blade margin entire.
  3. Leaves always ovate; sepals ovate or broadly elliptic, <1.5 times as long as wide, 4–10 mm long, apex of inner sepals usually obtuse or broadly emarginate; corollas 3–6 cm long . . . 3d. *I. orizabensis* var. *novogaliciana*
  3. Leaves ovate or 3,5,7-lobate; sepals narrowly elliptic or lanceolate, 1.5–3 times as long as broad, (7–) 9–14 mm long, apex of inner sepals usually acute; corollas 5–8.5 cm long.
  4. Xerophytes, leaves always 5- or 7-lobed, the middle lobe elliptic, the apex and base of leaf segments attenuate . . . . . 3c. *I. orizabensis* var. *collina*
  4. Mesophytes, leaves usually ovate, or if rarely 3–5-sublobed, then middle segment ovate-elongate to lanceolate, but generally not narrowed at base.
  5. Stems conspicuously pubescent; leaves pubescent; sepals herbaceous, lanceolate or narrowly elliptic, ca. 3 times as long as broad, 9–18 mm long, usually conspicuously pubescent . . . . . 3a. *I. orizabensis* var. *orizabensis*
  5. Stems glabrous or sparingly pubescent; leaves glabrous; sepals narrowly elliptic, 1.5–2 times as long as broad, (7–) 9–11 mm long, glabrous or sparingly puberulent at base . . . . . 3b. *I. orizabensis* var. *austromexicana*
  1. Suffruticose shrubs, stems erect, self-supporting, ascendent or decumbent, not twining.
    6. Leaves elliptic, usually puberulent below, the margins crenulate-dentate . . . . . 5. *I. stans*
    6. Leaves pinnatisect, glabrous below, the margins entire.
      7. Plants 1–1.5 m tall, leaf segments 10–60 mm long; peduncles 3–12 cm long during anthesis; corolla limb white or pale lavender . . . . . 1. *I. ancisa*

7. Plants to 1 m tall, leaf segments 3–25 mm long; peduncles 0.8–3.5 (–8) cm long; corolla limb dark blue . . . . . 4. *I. sescossiana*

1. *IPOMOEA ANCISA* House, Ann. New York Acad. Sci. 18:187. 1908. TYPE: MEXICO. Chihuahua: between Colonia García and Pratt's Ranch below Pacheco, 1899, Nelson 6276 (HOLOTYPE NY!; ISOTYPE GH!).

Erect, suffrutescent, glabrous SHRUBS, 1–1.5 m tall; stems erect, straight, terete, occasionally moderately striate, hollow, deciduous, to 2 m long, 2–15 mm in diam.; internodes 1–6 cm long. LEAVES pinnatisect or irregularly dissected, 3.5–11 cm long, 2–5 cm wide; petiolate, petioles terete 7–15 mm long, 1–2 mm in diam., green, smooth, glabrous; leaf lobes 6–9, filiform, 1–6 cm long, 1–2 mm wide, green, smooth, glabrous. INFLORESCENCE bearing solitary flowers; peduncle terete, 3–12 cm long, 1–2 mm in diam. during anthesis, extending to 16 cm long and 4 mm in diam. in fruit, green, glabrous, smooth or minutely striate, secondary peduncles similar, to 2 cm long; pedicel terete or slightly angled, erect, 10–15 mm long, 2–3 mm in diam. during anthesis, recurved and to 27 mm long, 4 mm in diam. in fruition, green, smooth, glabrous; sepals unequal, broadly elliptic to ovate, 6–10 mm long, 4–8 mm wide, the outer somewhat shorter and more coriaceous than the inner, smooth, glabrous, the midrib green and coriaceous, the margins conspicuously hyaline, the apex obtuse or truncate, rarely acute; corolla infundibular, glabrous, white or pale lavender, 5–7 cm long, the basal tube 1–2 cm long, 4–7 mm in diam., the throat and limb expanding gradually, the limb 7–8 cm wide during anthesis; stamens subequal, white, 4–5 cm long, the filaments basally glandular-pubescent; style white, surpassing the stamens, 5–6.5 cm long, glabrous. FRUIT a pyriform capsule, 2-locular, 1.5–1.8 cm long, 1.1–1.7 cm wide at base, tan or pink, glabrous, the pericarp with observable reticulate ven-

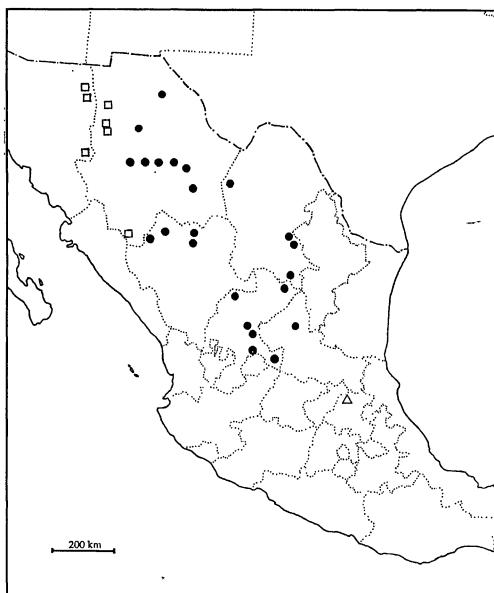

FIG. 2. Natural distributions of *Ipomoea ancisa* (open squares), *I. jacalana* (open triangle) and *I. sescossiana* (closed circles).

tion, the style base often persistent and ca. 5 mm long; seeds 4, ellipsoid, 3-angled, 7–10 mm long, 5–7 mm wide, gray-brown, puberulent.

COMMON NAME: Romería de la Sierra.

DISTRIBUTION (Fig. 2) AND HABITAT: A narrow endemic of juniper-oak forests that interface the northeastern slopes of the Sierra Madre Occidental and the arid altiplano of Mexico.

FLOWERING AND FRUITING: July to September.

REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Chihuahua: La Cienegita, Río Mayo, 10 Sep 1936, Gentry 2648 (CAS,F,GH,MEXU,US); Río Gavilán, 7 mi SW of Pacheco, ca. 2000 m, 26 Jul 1948, Leopold 136 (CAS); Chuhuichupa, Aug–Sep 1936, Le Sueur 850 (CAS,F,GH,MEXU, TEX); Río Negro, 1 Sep 1937, Le Sueur s.n. (CAS); NW of Yepomera on hwy 180 between San Jose and Bavicora, 2100 m, 31 Aug 1989, Mayfield et al. 275 (TEX); Madera, 2150–2200 m, 25 Sep 1934, Pennell

19251 (GH,US); Río Negro, 22 Jul 1964, Walker ELS-15 (NY); Mpio. de Janos, Cartetas, border of Chihuahua and Sonora, 2320 m, 26–28 Aug 1939, White 2552 (GH,MEXU,US), 2578 (GH,MEXU), 2598 (GH,MEXU). **Sonora:** Arroyo Agua Caliente, 8 km S of Maycoba on road to Moris, 1500 m, Van Devender & Reina 97-1263 26 Sep 1997 (TEX); Rio de Bavispe, Baburia, N of Aribabi, Cañón de Hueparí, 1500 m, 2–3 Sep 1939, White 2691 (GH,MEXU); 2692 (GH,MEXU); Río de Bavispe, Piedra Parada, 2–3 Sep 1940, White 3672 (GH,MEXU).

*Ipomoea ancisa* is distinguished by its relatively tall stature (to 1.5 m tall), filiform leaf segments to 6 cm long (Fig. 1E), white or pinkish corollas, and long peduncles (3–12 cm). *Ipomoea ancisa* is probably reproductively isolated from its sister species, *I. sescossiana*, since it exhibits nocturnal anthesis (Van Devender 97-1263). In contrast, flowers of *I. sescossiana* open during early daylight hours. *Ipomoea ancisa* generally undergoes rapid growth during the onset of rains, and quickly develops fruits before the rapid onset of the dry season from July to September.

2. **IPOMOEA JACALANA** Matuda, Anales Inst. Biol. Univ. Nac. Autón. México, Bot. 35:58. 1964. TYPE: MEXICO. **Hidalgo:** Cumbre de Jacala, 18 Sep 1962, Matuda 37288 (HOLOTYPE MEXU!).

Climbing woody VINES; stems twining, contorted, angled, 4–5 mm in diam., puberulent, hollow, with internodes ca. 2.2 cm long. LEAVES simple, petiolate; petioles terete, 2–5 cm long, ca. 1.5 mm in diam., puberulent; leaf blades ovate, 4–9 cm long, 2.5–7 cm wide, membranous, green on both surfaces, the undersurface venation prominent, with primary and secondary veins pubescent, the margins dentate-crenulate, the teeth ca. 1 mm long and wide, the apex obtuse and mucronate, the base acute or moderately auriculate. INFLORESCENCE a simple, monochasial, 2-flowered

cyme; peduncle terete, ca. 10 cm long, 2 mm in diam., first ramification subtended by 2 foliar bracts, these ca. 4 cm long, 2.5 cm wide; secondary peduncles ca. 7 cm long, 1 mm in diam.; pedicels terete, gradually expanding into receptacles, 14–20 mm long, 1–2 mm in diam., striate, puberulent, subtended by foliar bracts, these 1–1.5 cm long, 4–13 mm wide, the margins dentate-crenulate; sepals imbricate, subequal, narrowly elliptical, 1.5–1.7 cm long, ca. 6 mm wide, glabrescent, green and coriaceous along midrib, the margins entire, hyaline, the apex apiculate or caudate, occasionally foliaceous and expanded; corolla infundibular, ca. 6 cm long, the tube ca. 1.5 cm wide at base, ca. 2 cm wide at throat, the limb convolute-duplicate during aestivation, glabrous, the limb red-purple, ca. 6 cm wide; stamens unequal, 2.5–3 cm long; style ca. 3 cm long. FRUIT not seen.

DISTRIBUTION (Fig. 2) AND HABITAT: Known only from the type locality in Hidalgo.

FLOWERING: September to October.

*Ipomoea jacalana* is morphologically intermediate between *I. stans* and *I. orizabensis*, and perhaps of hybrid origin. The species retains the vining habit of *I. orizabensis* but produces a highly derived leaf blade with crenulate-dentate margins.

1. **IPOMOEA ORIZABENSIS** (Pelletan) Ledeb. ex Steud.

Twining VINES from woody, resinous roots; stems climbing or occasionally re-pand, herbaceous or lignescens, terete, ribbed or irregularly angled, 1–5 m long, 2–6 mm in diam., branching, smooth or rough, the new growth green, the old growth stramineous, pilose, hirsute, glabrescent or glabrous. LEAVES variable, simple, lobed or not, deciduous, petiolate; petioles green, 2.8–7 cm long, 1–2 mm in diam.; leaf blades ovate, ovate-elongate, occasionally 3-, 5- or 7-lobed, 3–15 cm long, 2.5–12 cm wide, green, membranous, striate, puberulent or glabrous, the margins entire, the apices acute, acuminate, the base

cordate, basal lobes 0.4–2.3 cm long, 1.5–5.5 cm wide; venation palmi-pinnate. INFLORESCENCES of mono- or dichasial cymes, flowers 1–5; peduncles usually surpassing leaves, terete, 2–24.5 cm long, 1–2.5 mm in diam., stramineous, strigose, puberulent or glabrous; secondary peduncles reduced, to 7 mm long, subtended by 2 opposite, lanceolate or ovate herbaceous bracts, 3–20 mm long, 1–8 mm wide; pedicels erect during anthesis, recurved in fruit, terete, 1.3–1.6 cm long, 1–2 mm in diam., pilose or hirsute; sepals variable, subequal or unequal, imbricate, dark green along midrib, stramineous or hyaline margins, ovate, ovate-elongate, elliptic or broadly deltoid, 4–18 mm long, 3–7 mm wide, the exterior herbaceous-coriaceous or coriaceous, pubescent or glabrous, the interior ones more membranous, glabrous or pubescent along midrib, the margins entire, scarious, the tips acute, attenuate, obtuse or emarginate; corolla infundibular, 3–8.5 cm long, the tube ca. 8 mm in diam. at base, ca. 15 mm in diam. at throat, the limb subentire, scantly 10-lobate, magenta-purple, glabrous, aestivation convolute-duplicate, 4–6 cm wide during anthesis; stamens subequal, included, 1.8–2.5 cm long, the filaments white, the base glandular-pubescent; style white, surpassing stamens, 2.3–3.2 cm long, glabrous, the stigma white, glabrous. FRUIT a globose capsule, brown, 1–1.3 cm in diam., dehiscent, chartaceous, glabrous; seeds 4, black, subglobose, 3-angled, ca. 5 mm in diam., puberulent or glabrous.

Four regionally distinctive morphotypes of *I. orizabensis* s. lat. are encountered in the tropical and temperate mountains of Mexico; these are hereby recognized as varieties. The type variety of the species is common and widespread, ranging from the northern extensions of the Sierra Madres Occidental and Oriental to the Sierra Soconusco of Chiapas and Guatemala (Fig. 3). This variety is readily distinguished by its pubescent foliage and calices, and by relatively long (9–18 mm), foliose sepals (Fig. 4C). The Chihuahuan Desert endemic, *I. or-*

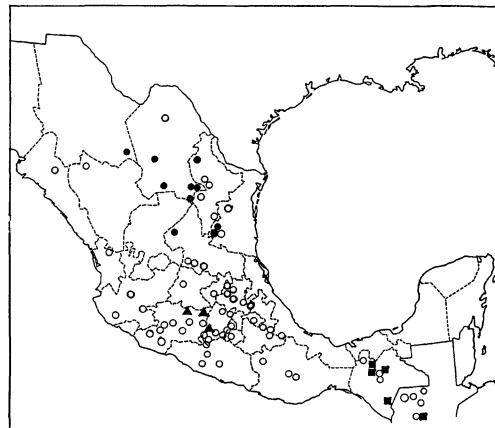

FIG. 3. Natural distributions of *Ipomoea orizabensis* vars. *orizabensis* (open circles), *austromexicana* (closed squares), *collina* (closed circles), and *novogaliciana* (closed triangles).

*izabenis* var. *collina* House, is distinguished by deeply lobed leaf blades (Fig. 1B), whereas two newly described varieties, *I. orizabensis* vars. *austromexicana* and *novogaliciana*, exhibit glabrous foliage and calices, and relatively small sepals (usually <8 mm long). Since the latter characteristics may vary somewhat within each variety, and occasionally intergrade between sympatric varieties, they are regarded as racial attributes of a polymorphic species.

*Ipomoea longepedunculata* (M. Martens & Galeotti) Hemsl., Biol. Centr. Amer. Bot. 2:289. 1882.

COMMON NAMES: Mechoacan, Tlaxcan, Correhuela, Rompeplatos.

DISTRIBUTION (Fig. 3) AND HABITAT: Throughout Mexico and Guatemala, preferring wet or dry montane habitats from 800–2000 m.

FLOWERING AND FRUITING: July–December; a secondary flush occurring in the tropical mountains of Chiapas and perhaps Guatemala from March to June.

REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Chiapas: Mpio. Tenejapa, trail from Tenejapa to Pokolum, 1900 m, 9 Jul 1964, Breedlove 6058A (F,MEXU); Mpio. The long list of synonyms for *I. orizabensis* var. *orizabensis* may be attributed to the polymorphic nature of the variety and to the numerous collections that were distributed throughout Europe during the 19th century. The variety is often identified in the literature and in herbaria as *I. tyrianthina*, a synonym. Populations of *I. orizabensis* var. *orizabensis* are generally distinguished by their pubescent stems, leaves and sepals, and by outer sepals that are foliaceous and either ovate-elongate or narrowly elliptic. They normally present cordiform laminas, although a few aberrant populations in the Sierra de Manantlán of Jalisco exhibit 5- or 7-lobate blades. These leaves are apparently convergent with those of the xerophytic vine, *Ipomoea orizabensis* var. *collina* (Fig. 1B), whose leaf segments invariably taper at the base. The rare leaf-segment bases of *I. orizabensis* var. *orizabensis* generally do not taper.

Resins from the roots of *Ipomoea orizabensis* have been employed as purgatives throughout Mexico since pre-colombian times, and were marketed abroad along with other *Ipomoea* species during the colonial era under the trade names of 'Mechoacan' or 'Jalap' (McDonald 1982).

3b. IPOMOEA ORIZABENSIS (Pelletan) Ledeb. ex Steud. var. AUSTROMEXICANA J. A. McDonald, var. nov. (Figs. 4A,E).

Differet a *I. orizabensis* var. *orizabensis* foliis glabris sepalis coriaceis late ellipticis vel deltoideis.

**TYPE: MEXICO. Chiapas:** Mpio. San Andrés Larraínzar summit of Chuchil Ton, NE of Bochil, 2700 m, 17 Oct 1972, *Breedlove* 29283 (HOLOTYPE: MEXU!).

**DISTRIBUTION (Fig. 3) AND HABITAT:** This variety is endemic to the Sierra Madre del Sur and Sierra Soconusco, extending from the Mayan highlands of central Chiapas to the border of Guatemala.

**FLOWERING AND FRUITING:** October to February (and May).

**REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Chiapas:** Mpio. Tenejapa, barrio of Yashanal, along the river of Chik Ha, 1900 m, 2 Oct 1965, *Breedlove* 12640 (F); Mpio. Amatenango del Valle, ca. Amatenango del Valle 2000 m, 27 Jul 1966, *Breedlove* 14642 (F,LL); Mpio. Sacatepequez,** along Río Guacalate, NW of Antigua, 1620–1710 m, 6 Feb 1939, *Standley* 64686 (F).

*Ipomoea orizabensis* var. *austromexicana* occurs as a narrow endemic in southern Mexico, and is distinguished from the type variety of this species by glabrous foliage and short, glabrous, broadly deltate or elliptical sepals. Outer sepal margins of this variety are only scarcely hyaline (Fig. 4E), and thus contrast markedly with the broadly developed hyaline sepal margins of *I. orizabensis* vars. *orizabensis* and *novogalicana*. Populations of *I. orizabensis* var. *austromexicana* might represent a cryptic species, as they occasionally occur in close proximity to populations of *I. orizabensis* var. *orizabensis* without demonstrating any evidence of hybridization. The co-occurrence of these taxa may be, however, of very recent origin, owing to the ongoing extension of

roadways and opening of agricultural lands in the Mayan highlands of central Chiapas.

3c. **IPOMOEA ORIZABENSIS** (Pelletan) Ledeb. ex Steud. var. **COLLINA** (House) J. A. McDonald comb. nov.

*Ipomoea collina* House, Bot. Gaz. 43:412.

1907. TYPE: MEXICO. Coahuila: San Lorenzo Canyon, 6 mi E of Saltillo, 22–23 Sep 1904, Palmer 396 (HOLOTYPE: US!; ISOTYPES: CAS!, GHI!, NY!, US!, photo F!).

DISTRIBUTION (Fig. 3) AND HABITAT: An endemic of the greater Chihuahuan Desert region, usually occurring in ravines and seasonal washes on rocky mountain slopes.

FLOWERING AND FRUITING: July to September.

REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Coahuila: 14 mi S of Saltillo, 2 Jul 1947, Barkley et al. 7196 (TEX); Sierra de Jimulco, 3 km N of Mina San José, 8 km NE of Estación Otto, 1800–3138 m, Chiang et al. 9551d (LL); NW of Yepomera on hwy 180 between San Jose and Bavicora, 2100 m, 31 Aug 1989, Mayfield et al. 275 (TEX); Sonora: Arroyo Agua Caliente, 8 km S of Maycoba on road to Moris, 1500 m, Van Devender & Reina 97-1263 26 Sep 1997 (TEX); Sierra Mojada, S of Esmeralda, 1600–2463 m, 27 Sep 1972, Chiang et al. 9099A (LL); ca. 12 air mi E of Saltillo along dry river margin W of hwy. 57 in lower portion of Cañon de Chorro, 1900 m, 27 Sep 1980, Henrickson & Bekey 18646 (TEX); Sierra Arteaga, 1800 m, 28 Aug 1949, Hinton et al. 16838 (GH); Sierra de la Madera, ca. La Cueva in Corte Blanco fork of Charretera Canyon, 1430–2160 m, 11–15 Sep 1941, Johnston 8904 (GH, LL); Sierra de Parras, Aug 1910, Purpus 4975 (CAS, F, GH). Chihuahua: Sierra del Diablo, 4 km SSW of Cerro del Gringo, 1800–2050 m, 30 Aug 1972, Chiang et al. 9015 (LL). Nuevo León: Aramberri, 1790 m, Hinton 23668 (TEX); Mpio. Villaldama, summit of Sierra Gomas,

15 Aug 1988, Patterson 6781 (TEX); Chipinque Park, SW of Monterrey, 11 Jun 1978, Poole & Watson 1381 (TEX). Tamaulipas: ca. 46 km WNW of Jaumave, 6.5 road km W of Miquihuana on road to La Perdida, ca. 1850 m, 3 Oct 1982, Henrickson & Hess 19135 (TEX); Gomez Farias, Rancho del Cielo, near Aguacates turnoff, 24 Nov 1968, Richardson 974 (TEX). Zacatecas: 15 air mi NE of Estación Camacho on NW slopes of Pico de Teyra, 2220 m, 23 Sep 1973, Henrickson 13415 (TEX).

*Ipomoea orizabensis* var. *collina*, formerly recognized at the species level, is distinguished from *I. orizabensis* sens. lat. by its 3-, 5-, or 7-lobate leaves (Fig. 1B). Leaf primordia exhibit deep sinuses at their inception, suggesting a stabilized genetic condition rather than a phenotypic plasticity to their arid environments. Fresh corollas of *I. orizabensis* var. *collina* also tend to exhibit pale coloration along the plical zones of the limb, but this feature is never apparent on dried herbarium materials. The variety is a narrow endemic of the Chihuahuan Desert (Fig. 3).

3d. **IPOMOEA ORIZABENSIS** (Pelletan) Ledeb. ex Steud. var. **NOVOCALICIANA** J. A. McDonald, var. nov. (Figs. 4B,F).

Different from *I. orizabensis* var. *orizabensis* foliis glabris sepalis ovatis vel late ellipticis 4–10 mm longis apice obtuso vel emarginato sepali.

TYPE: MEXICO. Michoacán: Carretera de Periban a Buenavista, 3 km al SW de Copetiro, 1560 m, 24 Aug 1980, Soto 2451 (HOLOTYPE: MEXU!; ISOTYPE ENCB!).

DISTRIBUTION (Fig. 3) AND HABITAT: A narrow endemic to northern Michoacan and the southwestern district of Temascaltepec in the state of Mexico.

FLOWERING AND FRUITING: July to September.

REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Mexico: Dist. Temascal-

tepec, Ipericones, 23 Jul 1935, *Hinton et al.* 8083 (LL,NY). **Michoacán:** Punguato, 2000 m, 18 Aug 1910, *Arsène* 5467 (MEXU); ca. Rincón, 1950 m, 14 Aug 1910, *Arsene* 5489 (MEXU); ca. Morelia, Loma Santa María, 28 Aug 1910, *Arsène* 5843 (NY); ca. Morelia, N de Zapote, 1950 m, 6 Aug 1910, *Arsène* 5946 (GH,MEXU, NY); Mpio. Tzitzio, 1820 m, El Puerto de Arumbaro, 12 km al S de Temascal, 19 Jul 1982, *Soto & Martínez* 4212 (MEXU).

*Ipomoea orizabensis* var. *novogaliciana* includes populations that are restricted to cool, montane regions of northern Michoacan and vicinity (Fig. 3). Their flowers are relatively small (3–6 cm long), as are their sepals [4–6 (–10)], the latter of which are ovate to broadly elliptic, with a narrow, dark-green midrib and broad scarious margins (Fig. 4F).

4. IPOMOEA SESCOSSIANA Baill., Bull. Soc. Linn. Par. 1:385. 1883. TYPE: Mexico. San Luis Potosí: Charcas, collector and date not indicated. (HOLOTYPE P!; ISOTYPE US!, photo K!).

*Ipomoea pringlei* A. Gray, Proc. Amer. Acad. Arts 22:307. 1887. TYPE: MEXICO. Chihuahua: foothills of Santa Eulalia and Mapula Mountains, 7 Sep 1886, *Pringle* 782 (HOLOTYPE GH!; ISOTYPES F!, LL!, MEXU!, NY!, US!).

Suffrutescent, glabrous SHRUBS to 1 m tall; roots tuberous, woody; stems erect, straight, branching, terete, green, glabrous, deciduous. LEAVES pinnatisect or irregularly dissected, 2–4 cm long, 0.5–2 cm wide, petiolate; petioles terete, 3–15 mm long, ca. 1 mm in diam., green smooth, glabrous; leaf blade lobes 5–9, filiform, 3–25 mm long, 1–2 mm wide, green, glabrous. INFLORESCENCE a 1–2 flowered cyme; peduncles terete, 0.8–3.5 cm long, 2–2.5 mm wide, green, glabrous, secondary peduncles usually lacking, sometimes to 1 cm long, 1 mm in diam.; pedicels terete, 6–15 mm

long, 2–3 mm in diam. during anthesis, extending to 2.5 cm in fruit, green, smooth or moderately striate, glabrous; sepals subequal, outer slightly shorter than inner, ovate or broadly elliptic, 5–9 mm long and wide, glabrous, the midribs green and coriaceous, the margins hyaline, the tips acute or obtuse; corollas infundibular, 5–6 cm long, the basal tube 5–6 mm in diam., white, dilating into a throat 1.5–1.8 cm in diam., the limb purple, glabrous, ca. 6 cm wide; stamens subequal, 3–4 cm long, white, glandular-pubescent at base; style surpassing stamens, 3.5–4.0 cm long, white, glabrous. FRUIT of broadly pyriform capsules, 11–14 mm long, 7–12 mm wide near base, dehiscent, stramineous, glabrous; seeds 4, ellipsoid, 6–8 mm long, ca. 4 mm wide, 3-angled, brown or black, puberulent.

COMMON NAME: Espanta Vaquero.

DISTRIBUTION (Fig. 2) AND HABITAT: Occurring in deserts and arid grasslands of the central and northern Mexican plateau.

FLOWERING AND FRUITING: (June–) July to September.

REPRESENTATIVE SPECIMENS EXAMINED: MEXICO. Durango: Mpio. *Ipomoea sescossiana*, much like its sister species *I. ancisa*, is a perennial shrub with herbaceous stems and pinnatifid leaf blades (Fig. 1D). The species is distinguished from *I. ancisa* by its relatively short leaf segments (-2.5 cm long), short peduncles to 3.5 cm long, and brilliant blue-purple corollas that open during early morning hours.

5. **IPOMOEA STANS** Cav., Icon. 3:26. 1795. TYPE: Cultivated in gardens of Madrid (LECTOTYPE MA!; McDonald 1994, Fl. Veracruz 77:115).

*Ipomoea stans* var. *hirsuta* Rob., Proc. Amer. Acad. Arts 29:319. 1892. TYPE: MEXICO. **Jalisco:** ca. Guadalajara plains, 30 Aug 1892, *Pringle* 4488 (LECTOTYPE, here designated, US!; ISOLECTOTYPES CAS!, F!, GH!, US!).

*Ipomoea jaliscana* House, Muhlenbergia 3: 39. 1907. nom. et stat. nov. for *I. stans* var. *hirsuta* Rob.

Suffrutescent SHRUBS to 1 m tall; stems erect, occasionally somewhat decumbent,

deciduous, angled, 0.5–1 m long, 1–5 mm in diam., branching from and above base, smooth, green, puberulent; roots woody, resinous. LEAVES simple, petiolate; petioles terete, to 6 mm long, 0.5–1 mm in diam., puberulent; leaf blades narrowly or broadly elliptic, sub lanceolate, 2.5–7 cm long, 6–30 mm wide, pinnately veined, sub coriaceous, glabrous, scabrous or occasionally puberulent, the margins dentate-sinuate, the tips obtuse, acute, the bases truncate, sub auriculate, the basal lobes to 5 mm long, 1.5 cm wide. INFLORESCENCE of solitary flowers; peduncle erect, terete, 1.5–8.5 cm long, 1–2 mm in diam., puberulent; pedicels terete, 5–12 mm long, accrescent in fruit, puberulent, subtended by 2 opposite bracts; bracts elliptic, 6–10 mm long, 2–4 mm wide, herbaceous, membranous, with sinuate margins, obtuse tips; sepals unequal, imbricate, dark green along midrib, the outer ones elliptic with scarious margins, acute tips, 1–2.3 cm long, 4–4.5 mm wide, coriaceous, pubescent, the interior ones narrowly elliptic, 1.4–2 cm long, 6–7 mm wide, membranous, glabrous or puberulent, with entire and hyaline margins and acute tips; corolla infundibular, 6.5–7.5 cm long, the tube white or pink, 2.8–3.4 cm long, 1–1.6 cm in diam., glabrous, the limb subentire, scantily 10-lobed, aestivation convolute-duplicate, purple, glabrous; stamens unequal, white, included, 2–3 cm long, the filaments glandular-pubescent at base; style white, 2.5–3 cm long, usually as long or longer than longest stamen. FRUIT of broadly pyriform capsules, brown or irregularly purple-pigmented, 1–1.2 cm long and wide at base, dehiscent, glabrous; seeds 4, brown or black, ellipsoid, 3-angled, 6–8 mm long, 4–5 mm wide, pubescent, the hairs short and dark.

COMMON NAMES: Cacatlapa, Correhuela, Espanta Lobo, Limpia tunas, Pega-josa, Tanibata, Tlaxcan, Tumbavaqueros.

DISTRIBUTION (Fig. 5) AND HABITAT: A widespread xerophyte from various semi-desert regions of Mexico, also occurring

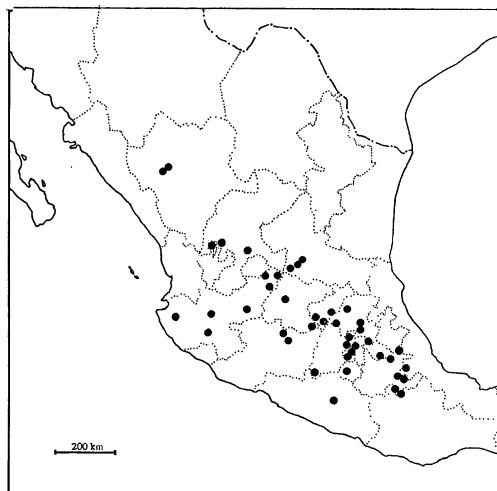

FIG. 5. Natural distribution of *Ipomoea stans*.

among basaltic substrates in the arid zones of South-central Mexico.

FLOWERING AND FRUITING: June to September.

*Ipomoea stans* is unique in its shrubby growth habit and holly-like leaves (i.e., elliptic leaf blades with crenulate-dentate margins; Fig. 1C). Roots of this widespread xerophyte are collected throughout its range for medicinal purposes, being sold in local markets under the name of 'tumba-

vaqueros' as a therapeutic for epilepsy and as a purgative.

## UNCERTAIN SPECIES

*IPOMOEA HARTWEGII* Benth., Pl. Hartw. 15. 1839. TYPE: MEXICO. *Hartweg* 96 (HOLOTYPE K!; ISOTYPES BM!,GH!,P!,NY!).

*Ipomoea hartwegii*, a narrow endemic of Jalisco and Querétaro, is almost indistinguishable from *I. orizabensis* var. *orizabensis* in vegetative and floral features; yet the species is probably phylogenetically distant. *Ipomoea hartwegii* is distinguished by white or occasionally pinkish corollas, relatively small cordiform laminas, and a scandent growth habit. The fruits of the species are particularly distinctive, differing from those of *I. orizabensis* by their narrow-fusiform shape, a hardened, subdehiscent pericarp, and orangish, narrow-ellipsoid seeds that produce long and white hairs along the outer margins. DNA analyses of this species would prove useful in resolving whether or not this plant is convergent with *I. orizabensis* or prototypic to the tyrianthinas as a whole.

## ACKNOWLEDGEMENTS

The curatorial staff at Harvard University (HUH) provided assistance in procuring herbarium loans from AA, CAS, ENCB, F, GH, MEXU, NY and US. Line drawings of the new varieties and leaf-types were provided generously by Ms. Susan Vaclavik, whose budding interests in the botanical arts gave me impetus to complete a manuscript that had been left dormant for years. Many useful comments and opinions on the manuscript were offered Drs. Dan Austin (FAU), James Henrickson (TEX), Tom Wendt (TEX), and an anonymous reviewer.
