pt. 2

I Introduction

As was explained in the introduction and in the section of "Material investigated" of Part I, the present report deals with the investigation conducted on the specimens, which had been ~~number~~ collected by research vessels, ~~and~~ and which had been forwarded by the Fisheries Agency, on frozen fish, which had been sent from the U. S. A., and on specimens, which had been collected by the author in Hokkaido and Aomori-Ken. In comparison to the list of known parasites in salmonoid fishes, which was mentioned in V of Part I, the number of parasites, which the author has been able to observe, is extremely meagre--consisting merely of two species of Trematoda, approximately 5 species of Cestoda, approximately 6 species of Nematoda, 2 species of Acanthocephala, and 1 species of Copepoda. Further, they consist solely of known species, and there is no need to specially describe

them. However, the present report is not written for specialists in parasites. The report is written partly to meet the request for a report on the investigations by the Fisheries Agency and partly to aid persons who are not specialists.

The author has had some knowledge concerning Trematoda and Acanthocephala, but had no knowledge concerning other species. During the present investigation, the author had to research; however, he feels that there is a possibility for errors as well as inadequacy. The author appreciates if these can be pointed out to him by other scholars.

There is a considerable duplication in the present article with Part I; further, references are included in the present article. This was done in consideration of the fact that there may be persons who will read only Part II and will not be interested in Part I.

The author takes this opportunity to express his appreciation, in addition to persons mentioned in Part I, to members of the Department of Physiology of Yokohama Civic University, Dr. Takashi Fujii of the Faculty of Science, Tokyo University, Miss Satsuko Hamada and Dr. Takeichiro Yafuku of the Research Station, Fisheries Agency, Prof. Manabu Sasa of the Institute of Epidemiology, and to Mr. Megumu Tsukida of the Department of Medical Physiology, Tokyo University, for assisting the author in the compilation of references. A report will be made later concerning specimens, which were

offshore of  
 obtained at Kanazaki, Hokkaido and sent to the author by Mr. Akio  
 Ishida, and fries, which were sent to the Fisheries Agency from the  
 U. S. A.

## II Method of Investigation

No special method of investigation was adopted; the traditional methods have been used. Thus, the author feels that there is no need to mention it specially. However, for the benefit of non-specialists, this paragraph is added.

All the ~~specimens~~ specimens of <sup>Trematoda</sup> ~~Acanthocephala~~ were treated by "total preparation". They were stained with DELAFIELD haematoxylin, and sealed with balsum. Some were sealed with "neocygararl" (?) without staining. There is no difficulty in identification even with the latter ~~method~~ procedure.

Some specimens of Cestoda were sealed in "neocygararl"; others were stained <sup>with carmine</sup> darkly and cut <sup>horizontally</sup> to the thickness of <sup>approximately</sup> 15  $\mu$ . Sections were paraffin sections.

Some specimens of Nematoda and Acanthocephala were sealed in "neocygararl"; others were made transparent with lacto-phenol solution and observed.

Specimens of Copepoda were observed as they were or sealed in "neocygararl".

## III Trematoda

The first reference ~~to~~ to Trematoda, which is parasitic on ~~salmonoid~~ salmonoid fishes, in Japan seems to be the article by

Parahemiurus sp., and Aponurus sp.. <sup>mentioned</sup> ~~mentioned~~ <sup>The</sup> 1956 report by Margolis mentioned, in addition to the ~~same~~ above, Tetraonchus alaskensis, ~~the~~ Bucephaloides sp., Bacciger sp., Podocotyle shawi, Tetra-cotyle sp., Genolinea oncorhynchi, and Syncaelium katuwo. ~~Among~~ <sup>Among</sup> Axmepob's report mentioned Eucephalopsis basargini, Crepidostomum farionis, Hemiurus levinseni, Brachyphallus amuriensis, Sterrhurus sp., ~~Acithas-~~ ter gibbosus, Derogenes varicosus~~, and~~ and Azygia robusta.

As was explained above, species of Trematoda, which had been found in salmonoid fishes, are considerable, and a tentative list of these <sup>is</sup> ~~same~~ as follows:

Monogenea.

Gyrodactylidae

- 1. Gyrodactyloides strelkowi

Dactylogyridae

- 2. Tetraonchus alaskensis PRICE, 1937

Discocotylidae

- 3. Discocotyle salmonis SHAFFER, 1916 (D. sagittata (LEUCKART, 1842) DIESING, 1850) <sup>Synonym for</sup>

Digenea.

Bucephalidae

- 4. Bucephaloides sp.
- 5. Eucephalopsis basargini LAYMAN, 1930.

Fellodistomatidae

- 6. Bacciger sp. (B. harengulae YAMAGUTI, 1938?)

Allocreadiidae

- 7. Allocreadium oncorhynchi EGUCHI, 1933.
- 8. A. shawi (MCINTOSH, 1939)
- 9. Crepidostomum farionis O. F. MÜLLER, 1784 (= C. baicalensis LAYMAN, 1933)
- 10. C. salmonis FUJITA, 1921.

(? in original manuscript)

Tsunenobu Fujita ~~mentioned~~, which he ~~mentioned~~ contributed in 1916 to Vol. 28 of Dobutsu-Gaku Zasshi, concerning a specie of Crepidostomum, obtained from ~~fries~~<sup>y</sup> of Oncorhynchus keta in ~~some~~<sup>a</sup> small stream in the compound of Sapporo University. Next, he has ~~an~~<sup>an</sup> article in ~~the~~<sup>Vol. 30 of</sup> the same periodical in 1918 on a new specie, Azygia perryi which he ~~mentioned~~ had obtained in ~~Hucho~~<sup>Hucho</sup> perryi in Hokkaido. A further article by him ~~appears~~ appears in Vol. 32 of the same periodical concerning a new specie, Crepidostomum uchimii, which ~~he~~ he had obtained in Salmo ~~macrocystoma~~<sup>macrostoma</sup>. Another article by him ~~was~~ on a new specie, ~~a~~ Crepidostomum salmonis, appeared in 1921 in Vol. 33 of the same publication. Some ~~the~~ time elapsed before an article by Sueo Eguchi appeared in Vol. 1 of the Journal of Osaka Medical College on Allocreadium oncorhynchi n. sp. which he had obtained in ~~Salmo milletschitsch (WILBAUM)~~<sup>Oncorhynchus rhodurus JORDAN et MCGREGOR</sup> in Nagara river.

Beginning in 1934, Sanaka Yamaguchi published expansive reports in several publications concerning Trematoda in fish; he mentioned Brachycephallus crenatus in Oncorhynchus masou, Lecithaster salmonis n. sp. from Oncorhynchus keta. In 1935 Misao Kobayashi mentioned these Trematoda in his book published in 1935. Fish Pathology by Tsunenobu Fujita, published in 1937, mentioned, in addition to the above, Misco-cotyle salmonis, Crepidostomum farionis, Lecithaster gibbosus, L. <sup>and</sup> bothryophorus, Derogenes varicus. Publications of the U. S. A. and Canada mentioned, in the text and in tables, Diplostomulum sp., Hemirurus levinseni, Lecithaster gibbosus, Brachyphallus sp., Gyrodactylodes strelkowi, ~~a~~ Derogenes varicus, Tubulovesicula lindbergi,

11. C. uchimai FUJITA, 1921.

12. Podocotyle shawi

Azygiidae

13. Azygia <sup>FUJITA</sup> perryi, 1918

14. A. robusta ODHNER, 1911.

Hemiuridae

15. Aponurus sp.

16. Brachyphallus amuriensis BABASKIN, 1928.

17. B. crenatus (RUDOLPHI, 1802)

18. Derog<sup>e</sup>nes varicus (MÜLLER, 1784) LOOSS, 1901.

19. Genolinea oncorhynchi

20. Hemiurus levinseni ODHNER, 1905.

Lecithaster

21. ~~HEMIPHYSALIDAE~~ gibbosus (RUDOLPHI, 1802) LÜHE, 1901 = L. both-  
ryophorus (OLSSON)

22. L. salmonis YAMAGUTI, 1934.

23. Parahemiurus sp. (P. anchoviae VAZ et PBREIRA, 1930?) ? in original  
manuscript

24. Sterrhurus sp.

25. Tubulovesicula lindbergi (LAYMAN, 1930)

Syncoeliidae

26. Syncoelium katuwo YAMAGUTI, 1938.

Diplostomatidae

27. Diplostomulum sp. larvae.

Strigeidae

28. Tetracotyle sp. Larvae

The list consists of 28 species in 22 genera; there will be some changes in the list, since it includes larvae and species not yet identified. An attempt<sup>was made</sup> at constructing a ~~summary~~ reference table which is shown below:

Table of reference of eye:

- (Development is direct. Mainly <sup>externally</sup> parasitic on aquatic animals--Monogenea)
- (Development through transformation. Hosts are changed. <sup>Parasitic</sup>)
- (internally on Vertebrata--Digenea.)

Table of refer<sup>e</sup>nce of families of Monogenea.

- (4 pairs of specialized ~~unusual~~ anchor device in adhesive disc locate
- (in the posterior end of the body ----Discocotylidae
- (No such device -----2

- 2 (pair of cerebral sense organs(?). Pair of large hooks ~~in adhesive disc~~
  - { and
  - { ~~15-16~~ 15-16 peripheral hooks in adhesive disc. Viviparous--
  - { --Gyrodactylidae.
  - { (2 pairs or more of cerebral sense organs; cerebral gland(?) pre-
  - { sent; 1-2 pairs of large hooks in adhesive disc; generally 14
  - { pairs of peripheral hooks. Oviparous-----Dactylogyridae

Table of reference of families of Digenea

- 1 (Mouth located near the centre of ventral side of the body--
  - { (--Bucephalidae.
  - { ((Gasterostomata)
  - { (Mouth located in the anterior end of the body---(Prosostomata) 2
- 2 (Anterior half of the body widens and forms adhesive disc;
  - { posterior half is cone-shaped, cylindrically-shaped and large.
  - { ~~Genital~~ Genital opening opens in the posterior end of the body-
  - { ----- 3
  - { (Body is not as described above. Genital opening located in
  - { the front-----4
- 3 (In some, the front half of the body is flat and the sides pro-
  - { truded like ears-----Diplostomatidae
  - { (The front half of the body is shaped like a cup or a spoon.
  - { (The sucker is extremely poor -----Strigeidae
- 4 (Testiculus is divided into many parts; or it is tubular with
  - { ~~nodes~~
  - { (nodes-----Synnema Cyncoeliidae
  - { (Generally, testiculus is ~~spherical~~ spherical or leaf-like-----5
- 5 (Body is long and cylindrical; genital opening is near oral
  - { sucker; vitelline gland is located at the back of ovary and
  - { (is leaf-shaped or tubular;generally lacks cirrus sac. In some
  - { (the posterior portion of the body is telescope-shaped---
  - { (Hemiuridae
  - { (Not in such condition ----- 6
- 6 (Bristles are found on integument---Fellodistomatidae(=Steringo-
  - { phoridae)
  - { (No bristles on integument-----7

- 7 (Vitelline gm gland spreads mainly sideways on both sides<sup>of the body</sup>--
- (--Allocreadiidae... ..)
- (Vitelline gland spreads mainly towards the back<sup>of the body</sup>--Azygidae

The author realizes that ~~thummbobndumda~~ that the construction of such a table is almost impossible; he does not believe that the table is too useful after Syncoeliidae. The reason is that it is impossible to find singular characteristics. Simple listing of characteristics of each genus follows:

- (1) Gyrodactyloides. It is impossible to list the characteristics of the present genus as the author has no reference books. He believes it to resemble Gyrodactylus NORDMANN, 1832 closely. Therefore, the characteristics of the latter will be listed. The anterior end of the body divides into two leaves with cerebral sense organ in each leaf. The adhesive disc is plate-shaped with a pair of large hooks and 16 small peripheral hooks. It is parasitic on fish and Amphibia.
- (2) Tetraonchus. There are ~~two~~ two or several pairs of cerebral sense organs; cerebral glands ~~opens~~ open to the surfaces. Adhesive organs can be distinguished from the trunk of the body fairly readily. There is a pair of large hooks supported by a rod of cuticle. There are 16 peripheral hooks. Intestine consists of a single tract and does not branch out. There are eyes. Reproductive gland is located in the centre of the body. No vagina. There are two known species.
- (3) Discocotyle. The body is long. The oral sucker is well developed. There are 4 pairs of specialized anchor devices in the adhesive

parasite parasite parasite

disc. They are located on the periphery. <sup>of the side</sup> Unguis of cuticle in <sup>ese</sup> these anchor devices is uniform and all its parts face inward.

The vagina opens on the lateral periphery and is located in the front third of the body. They are parasitic on fishes in sea as well as fresh water.

(4) Bucephaloides. They are found in intestine of Oncorhynchus gorguscha in sea; ~~the~~ the original reference is not available; thus, it is impossible to list its characteristics. The author believes that the genus resembles Bucephalopsis mentioned below.

(5) Bucephalopsis. The body is cone-shaped or cylindrical. The lip is shaped ~~w~~ like a sucker. There is no <sup>e</sup> ~~t~~antacle-like appendage. Intestine is short. Testiculus is located at the back of the body from the centre and located from front to the back or slanted. Ovarium is located to the front or at the same height as the <sup>s</sup> ~~t~~esticulus. Vitelline gland divides itself to right and left on front of the ovarium. ~~The~~ The genus is parasitic on salt water or fresh water fishes ~~and~~ and occasionally on ~~amphibia~~ amphibia. Sanaka Yamaguchi reports that the genus has been obtained in Verasper ~~moseri~~ <sup>the</sup> moseri JORDAN et GILBERT in <sup>the</sup> Japan Sea.

(6) Bacciger. The body is flat and egg-shaped. Small bristles. The length of the digestive tract is 2-3 times that of pharynx. Intestine is ~~short~~ short and reaches testiculus. Ventral sucker is buried under the flesh up to approximately <sup>the</sup> ~~the~~ middle of the body. Testiculus is located immediately behind on both sides of the

Ventral  
 sucker. Reproductive opening is located in the middle in front of the ventral sucker. Ovarium is located immediately behind the ventral sucker and between the testiculus. The vitelline gland is located in front of the ventral sucker on the ~~margin~~ outside of the intestine. The genus is parasitic of salt water fish (in the intestine). Margolis reports that the genus resembles *B. harengulae* however, the species is a new one (obtained in *Harengula zunasi* (BLEEKER) in ~~Hamana~~ Lake Hamana by Yamaguti.)

- (7) *Allocreadium*. The body is long; two ends are not pointed. No bristles. Sucker and pharynx are well developed. The intestine ~~is~~ is long and reaches the posterior end of the body. The ventral sucker is located in the anterior half of the body. The testiculus is ~~in~~ located in the middle of the posterior half of the body and runs front to back. The cirrus sac is well developed and contains winding ~~vasicula seminalis~~ seminal vesicle, prostate gland, and penis and is located in front of the ventral sucker ~~in~~ and on the dorsal side, and occasionally at the back. The reproductive opening is located at the dividing point of the intestine. The ovarium is located between the ventral sucker and the ~~margin~~ anterior testiculus somewhat on the side. The ~~margin~~ seminal receptacle and the Laurer's tube are present. The vitelline gland is located mainly in the posterior half of the body. The genus is parasitic ~~on~~ in the intestine of sea or fresh water fishes. As parasitic on salmonoid fishes, *A. oncorhynchi* EGUCHI, 1933 and *A. shawi* (MCINTOSH, 1939) are recorded.

(8) Crepidostomum. The body is elongated egg shape or cylindrical; there are no bristles. There are 6 protrusions in at the back of frontal periphery of the oral sucker. Frontal pharynx is present. The digestive tract is short; the intestine nearly reaches the posterior end of the body. The ventral sucker is located in the anterior half of the body. The testiculus is located in the posterior half of the body and aligned from front to back. The cirrus sac is long-stick shape and reaches the ventral sucker. The reproductive opening is located in the centre in front of the ventral sucker. The ovarium is located approximately in the middle between the ventral sucker and the frontal testiculus. The seminal receptacle and the Laurer's tube are present. The vitelline gland spreads on the outside of the intestine practically on the whole side of the body. The genus is parasitic on the intestine of fresh water fish and Mammalia. Three species of the present genus have been recorded as having been found in salmonoid fish -- *C. farionis* (O. F. MULLER, 1984), *C. salmonis* FUJITA, 1921, and *C. uchimii* FUJITA, 1921. The differences are shown in tabular form:

-----  
Headings of the table shown on page 8.

Second column - heading	Length of body
Entries	2 - 6 x 1.5 mm
	1.42 x 0.41
	1 x 0.5
Third columnar heading - Testiculus	
Entries -	Front to back
	A little slanted; front to back
	Front to back

## Fourth columnar heading - Reproductive opening

Entries - At the height of pharynx  
 Division point of intestine  
 At the height of pharynx

## Fifth columnar heading - Sucker

Entries - Ventral sucker large  
 Both somewhat intermediate  
 Both large

## Sixth columnar heading - Egg

Entries - 65 - 85 x 40---44  
 80 x 70  
 80 x 40

- (9) Podocotyle. The body is long; no <sup>spine</sup> bristle. The ventral sucker is located <sup>in the front</sup> in the anterior half of the ~~main~~ body and is occasionally equipped with a short <sup>stalk</sup> handle. Further, there may be folds in the <sup>skin</sup> handle. Both the oral sucker and the pharynx are well developed. The intestine reaches near the posterior end of the body. The testis is located in the posterior ~~part~~ portion of the posterior half of the body and is aligned from front to back. The cirrus sac is long, or thin and long, and is rod-shaped. It <sup>extends</sup> ~~is~~ in some from the ventral sucker ~~to~~ backwards. The reproductive opening is at the height of the digestive tract or the division point of the intestine and opens to the left of the central line. The ovarium is ~~is~~ located ~~in the front~~ in the front of the testis on the right side of the central line. The seminal receptacle and the Laurer's tube are present. The ~~ventral~~ gland spreads

from both sides of the body backwards. The genus is parasitic in the intestine of fresh or <sup>salt</sup> sea water fish. Only one specie, *P. shawi*, of the present genus is recorded <sup>in</sup> from *Uncorhynchus masou* <sup>nick</sup> from <sup>the</sup> Columbia River.

- (10) *Azygia*. The body is very long; <sup>and muscular</sup> there are no ~~muscles~~ nor bristles. The pharynx is somewhat elongated. The esophagus is very short. The intestine winds somewhat and reaches the posterior end of the body. The ventral sucker is not large, and is located in the middle of the ~~post~~ anterior third of the body. The testiculus is located near the anterior end of the posterior third of the body and aligned either front to back or ~~diagonally~~ obliquely. The cirrus sac is spherical or pear shaped and located immediately to the front of the ventral sucker or lies on top of it. The reproductive opening is in front of the ventral sucker. The ovarium is located immediately in front of the cirrus sac. The vitelline glands are located on ~~the~~ both sides of the body in the back and reaches the posterior end of the body. The genus is <sup>the stomach or intestine of</sup> parasitic <sup>on</sup> fresh or <sup>salt</sup> sea water fish. In the present genus, *A. perryi* FUJITA, 1918 and *A. robusta* ODHNER, 1911 are recorded. The comparison of the description of the two makes one wonder if they are identical; however, there is a considerable difference in the size of eggs. It is 58 x 33  $\mu$  in *A. perryi* and 45 x 23  $\mu$  in *A. robusta*. Further, The Trematoda (page 251) by B. DAWES treats <sup>*A. robusta*</sup> ~~them~~ as being synonymous with *A. lucii* (MÜLLER, 1776) LÜHE, 1909.

(11) *Aponurus*. The body is either stick- or cone-shaped. There is no tail portion. Occasionally prostomium is found in oral sucker. The pharynx is round. The esophagus is short. The intestine reaches near the posterior end of the body. The ventral sucker is larger than the oral sucker. It is located ~~mm~~ at the posterior end of the anterior third of the body. The testiculus is located at the centre of the ~~mm~~ body and aligned obliquely from front to back.. The seminal vesicle is ~~m~~ spherical or elongated egg shape, and is located in front of the ventral sucker or lies ~~mmmmmmmmmm~~ on top of it. ~~mmmm~~ The prostate gland is tubular. The hermaphroditic tube is tubular, ~~m~~ and enclosed by hermaphroditic sac which is elongated pear shape ~~x~~ or egg shape. The reproductive opening is located at the height of oral sucker, pharynx, or intestinal division point. The ovarium is located at the back of the testiculus approximately in the centre. The vitelline gland is located at the back of the ovarium and consists of 7 round leaves. The seminal receptacle at times is quite large. The genus is parasitic ~~mm~~ in the stomach of ~~m~~ salt water fish. The only record of the present genus is ~~is~~ in ~~the~~ Margolis' report in which it is recorded as *A. sp.*

(12) *Brachyphellus*. The body is long. The tail portion is present. At times there is a depression between the ventral sucker and the reproductive opening. The oral sucker is relatively large; the pharynx is spherical; the esophagus is short; and the intestine reaches near the posterior end of the body. The ventral sucker is located

near the centre in the anterior third of the body. The testiculus is located at the back of the ventral sucker ~~and is~~ aligned ~~obliquely~~ obliquely. The seminal vesicle is constricted(?) ~~and~~, is divided into two portions, and is located in the front of the ventral sucker. The prostate gland is short and poor. The hermaphroditic tube is short. The reproductive opening is located at the height of ~~the~~ pharynx or ~~the~~ esophagus. The ovarium is separate from the testiculus and is located near the centre ~~of~~ in the ~~middle~~ <sup>posterior portion</sup> of the body. The vitelline gland is divided into two parts with lobation or ~~into~~ into two ~~part~~ leaf-like parts. The genus is parasitic on fresh or salt water fish. Two species of the present genus, *B. amuriensis* BABASKIN, 1928 and *B. crenatus* (RUDOLPHI, 1802), are known. They are somewhat similar. However, in *B. amuriensis*, horizontal folds are found only in ~~around~~ the central portion of the body, the tail is approximately one quarter of the body, the ~~vitelline~~ vitelline gland is large and occupies a wide area in the centre of the body. Among the material, which the author had collected, a few specimens were found in *Oncorhynchus gorbuscha*, and identified as *B. crenatus*.

- (13) *Derogenes*. The body is small with no tail portion. The oral sucker is equipped with prostomium. The pharynx is spherical; the esophagus is short; and the intestine reaches the posterior end ~~of~~ of the body. The ventral sucker is larger than the oral sucker, and is located near the centre of the body. The testiculus

to  
 is at the back and is aligned ~~to~~ left ~~and~~ right or obliquely. The seminal vesicle is a single sac-like structure or tubular, and is located in front of the ventral sucker. The prostate gland is tubular and long. <sup>a</sup> <sup>o</sup> The hermaphroditic gland is wrapped in a muscular sac and protrudes into the genital atrium in cone-shaped prominence. The reproductive opening opens at the height of <sup>the</sup> pharynx. The ovarium is ~~now~~ located near the centre at the back of the testiculus; the seminal receptacle is present. The Laurer's tube is absent. The vitelline gland is divided into two leaves and is located on both sides of the body at the back of the ovarium. The genus is parasitic in the esophagus, stomach, and the gall bladder of salt water fish. Only <sup>(MULLER, 1784) LOOSS, 1901</sup> *D. varicus* has been ~~mentioned~~ recorded in the present genus. The afore-mentioned parasite is parasitic on various salt water fishes; approximately 25 ~~genera~~ genera of fish have been mentioned as hosts.

- (14) Genolinea. The size ranges from small to <sup>medium</sup> ~~large~~ ~~small~~ scales, <sup>and is approximately</sup> ~~cylindrical~~ <sup>cylindrical</sup>.
- There is no tail portion. The pharynx is spherical. The esophagus is short. The width of the intestine is wide; its wall is somewhat crooked and reaches the posterior end of the body. The ventral sucker is larger than the oral sucker, and is located at the ~~posterior~~ posterior end of the anterior third of the body. The testiculus is located ~~a~~ a little to the back of the centre of the body and is aligned obliquely from front to back. The seminal vesicle is tubular, crooked, and located on the dorsal side in front of the

ventral sucker. The prostate gland is short. The hermaphroditic tube is ~~when~~ crooked and ends in a pear shaped hermaphroditic sac. The reproductive opening opens at the ~~the~~ height of intestinal ~~division~~ point. The ovarium is located in the posterior half of the body. The seminal receptacle is at times large. The vitelline gland consists of ~~a~~ two dense leaves, and is aligned obliquely from front to back, and is located ~~at~~ the back of the ovarium. The genus is parasitic ~~in~~ the stomach of salt water fish. Only a single specie of the present genus, *G. oncorhynchi* has been reported by Margolis; ~~however~~ it has been reported that ~~the~~ <sup>was</sup> the specie ~~is~~ rare and had been observed only twice.

- (15) *Hemiurus*. The size range from small to medium; there is a tail portion. There are tooth-like protrusions on the cuticle. The esophagus is short. The intestine gets ~~in~~ into the tail portion. The ventral sucker is located near the ~~an~~ anterior end of the body; ~~it~~ <sup>or smaller than</sup> is larger ~~than~~ the oral sucker. The testiculus is located ~~a~~ <sup>^</sup> considerably behind the ventral sucker ~~and~~ <sup>is</sup> and is aligned obliquely. The seminal vesicle is located in front of the testiculus, is constricted into two parts: its frontal portion is covered by a somewhat thick muscle layer. The prostate gland is long and crooked. The hermaphroditic tube is thin. The reproductive opening is ~~located~~ located at the height of the <sup>oral</sup> sucker or the pharynx. The ovarium is located at the back of the testiculus behind the ovary. The vitelline gland is divided into two dense leaves and

is located immediately behind the ovarium. Eggs are small; there is no polar filament. The genus is parasitic ~~in~~ in the stomach of salt water fish. Only one specie of the present genus, *L. levinsoni*, <sup>ODNER, 1905</sup> appears in the reports by ~~Mangaham~~ MARGOLIS or AXMEPOB. It appears that in *Uncorhynchus nerka* they are prevalent in the western part of the ~~the~~ Pacific.

(16) *Lecithaster*. The size of the body ~~is~~ <sup>small</sup> ~~medium~~. ~~The~~ The body is cone-shaped, smooth; there is no tail portion. The esophagus is short. The intestine does not reach the posterior end of the body. The ventral sucker is larger than the oral sucker, and is located at the posterior end of the front third of ~~the~~ the body. The testis is located near the back of the ventral sucker, and is aligned obliquely from front to back or from left to right. The seminal vesicle is in the shape of a sac, and is located ~~in~~ in the dorsal side of the ventral sucker ~~at~~ <sup>its</sup> ~~the~~ ~~back~~ ~~at~~ ~~the~~ ~~back~~. ~~The~~ The prostate gland is tubular. The hermaphroditic tube is ~~egg-shaped~~ ~~located~~ <sup>in</sup> ~~the~~ ~~the~~ ~~hermaphroditic~~ ~~sac~~. The reproductive opening is located ~~at~~ <sup>at</sup> the height of pharynx or the intestinal division point. The ovarium is divided into ~~in~~ 4-5 leaves, and is located in the posterior half of the body. The seminal vesicle is at times remarkable. The ~~glands number~~ <sup>glands number</sup> ~~vetilline~~ ~~glands~~ ~~number~~ ~~seven~~, and ~~number~~ form flower-crest-like or rod-like leaves. The genus is parasitic in the intestine of salt water fish. Two ~~p~~ species of the present genus, *L. gibbosus* (RUDOLPHI, 1802) LÜHE, 1901 and *L. salmonis* YAMAGUTI, 1934 have

has been recorded. Examination of the report by Yamaguti on *L. salmonis* (Dobutsu-Gaku <sup>Shu</sup> ~~Ruiho~~, Vol. 5, page 466, 1934) shows that the egg is remarkably large; in this respect the species resembles closely *L. gibbosus*. However, according to ODHNER, the size of egg in this species is 25-27x 13  $\mu$  and the seminal vesicle does not reach the back of the ventral sucker. However, <sup>in</sup> *L. salmonis* of Yamaguti the size of egg is 23.7x 15.8  $\mu$  or 22-24x 14-16  $\mu$  (Dobutsu-Gaku <sup>Shu</sup> ~~Ruiho~~, Vol. 9, page 97, 1940), and there is hardly any difference in comparison to that of *L. gibbosus*. The distinguishing feature <sup>seminal</sup> whether the ~~seminal~~ vesicle reaches the back of the ~~seminal~~ seems to be ~~how far the seminal vesicle reaches the back of the~~ ~~ventral sucker.~~ It is not possible now for the author ~~to see the original manuscript of ODHNER.~~ However, a comparison of the description of *L. gibbosus* on page 269 of the Trematoda by B. DAWES and the original description of *L. salmonis* by Yamaguti does not enable one to distinguish the two. Even with respect to the position of the seminal vesicle, Yamaguti himself writes, ~~at the point where he mentions variations,~~ that it is located at times on the <sup>dorsal</sup> ~~ventral~~ side in front of the ventral sucker. Thus, it appears as though the two species are identical and that *L. salmonis* and *L. gibbosus* are synonymous. The author observed many in *Oncorhynchus keta* in Hokkaido.

(17) Parahemiurus. The body is long and has <sup>a</sup> the tail portion. There are tooth-like protrusions of cuticle. The esophagus is short. There are specimens in which the intestine enters into the tail

portion. The ventral sucker is located near the anterior end of the body. The testiculus is located somewhat at the back of the ventral sucker near the posterior end of the front third of the body, and is aligned front to back a little obliquely. The seminal vesicle is a single-sac-like structure with a considerably thick wall, and is located in front of the testiculus. The prostate gland is long, and spreads and winds between the seminal vesicle and the ventral sucker. The hermaphroditic tube is thin; the reproductive opening is located at the height of the oral sucker. The ovarium is located near the centre of the body; the space between the testiculus is occupied by <sup>part of the uterus</sup> ~~the ovary~~. The genus is parasitic in the stomach and the intestine of salt water fish. Only one specie of the present genus appears in MARGOLIS' report as *P. sp.*; it was observed only once in *Oncorhynchus nerka* in the coast. It is said <sup>that it is believed to</sup> ~~to~~ be *P. anchoviae*.

- (18) *Sterrhurus*. The body is cone shaped. There is a tail portion which is wholly or partially depressed. There is prostomium in the oral sucker. The esophagus is short. At times the intestine ~~enters~~ enters into the tail portion. The ventral sucker is located near approximately the posterior end in the front third of the body; it is larger than the oral sucker. The testiculus is located immediately behind the ventral sucker, and is aligned from left to right somewhat obliquely. The seminal vesicle is twisted, and is located on the dorsal side in front of the ventral sucker. The anterior end of

the prostate gland enters into the hermaphroditic sac. The hermaphroditic sac contains the hermaphroditic tube, the anterior end of <sup>the</sup> vagina, and the ejaculatory sac. The reproductive opening opens in the ventral side of the pharynx or at its back. The ovarium is located near the centre of the body. The ~~vitelline~~ vitelline gland consists of seven round or finger-like leaves. The ~~genus~~ genus is parasitic in the stomach of salt water fish. Only one specie of the present genus appears in AXMEPOB's report as S. sp.

- (19) Tubulovesicula. The body is cone shaped. There is a tail portion. There is prostomium in the oral sucker. The esophagus is extremely short. The intestine reaches the posterior end of ~~the~~ the body. The ventral sucker is larger than the oral sucker and is located near the anterior end of the body. The testiculus is located at the back of the ventral sucker somewhat obliquely from left to right. The seminal vesicle is located in front of the testiculus, is tubular and somewhat crooked. The prostate gland is long. The base of the hermaphroditic tube fills out, and is enclosed in a muscular sac. The reproductive opening is located at the height of the pharynx. The ovarium is located immediately behind the testiculus near the centre of the body. The seminal vesicle is present. The Laurer's tube is absent. The vitelline gland consists of seven tubular leaves. The genus is parasitic in the stomach of salt water fish. Only one specie of the present genus, *T. lindbergi* (LAYMAN, 1930) is mentioned in MARGOLIS's report.

It is also known in <sup>the</sup> Japan Sea.

(20) Syncoelium. The body is considerably large. The anterior portion is thin; the posterior portion is either tubular or flat and cone shaped. The cuticle is either smooth or uneven with protrusions. The esophagus is short. At times the intestine is observed to be crooked and meets ~~near~~ near the posterior end of the body. The ventral sucker has a handle and is located approximately near the centre of the body. ~~The testiculus is~~ ~~vesicular and divides into~~ many parts. In many cases, it is found in two ~~mm~~ vertical rows between the handle of the ventral sucker and the ovarium. The seminal vesicle is tubular, long, and somewhat crooked. In some ~~them~~ the prostate gland is seen well developed behind the division point of the intestine. The hermaphroditic tube is ~~seen~~ found inside or outside of a sac. The reproductive opening is located at the height of the oral sucker. The ovarium is located immediately behind the testiculus and is divided into few round or somewhat long leaves. The vitelline gland consists of few dense small leaves, and is located ~~at~~ between the posterior ends of the ovarium and the intestine. The genus is parasitic in the branchial chamber of salt water fish. With respect to the present genus, ~~the~~ Margolis's report mentioned the collection of *S. katuwo* YAMAGUTI, 1938 once in *Oncorhynchus nerka*. In 1936, L. C. LYOYD and J. E. GUBERLET ~~mentioned~~ obtained *Syncoelium filliferum* (SARS) and reported findings (trans. Amer. Micr.

Shu

Vol. 55, p. 44-48). According to Yamaguti (Dobutsu-Gaku Zasshi, Vol. 8, page 70), they resemble each other but differ in the size of eggs.

(21) Diplostomulum. This generic name refers to the late stage larvae

of so-called Strigeata LA RUE, as does the Tetracotyle mentioned next, whose front half of the body is flat, and which has a type of sucker near the centre. The adult parasite is parasitic on birds and Mammalia. The parasites of the present genus are parasitic in eyes, brain, or spinal cord of fish or Amphibia; there is no tunica; the parasites move freely through the structures of the host. With respect to salmonoid fish, MARGOLIS states in his report that they are prevalent in eyes of Oncorhynchus nerka.

(22) Tetracotyle. As is the case with the previous genus, the present genus is the larvae of Strigeata LA RUE; unlike the former, the genus is in tunica, and is parasitic on Hirudinea, Mollusca, or Vertebrata. There is a reference to this genus also in MARGOLIS' report in which he states that it is observed sporadically in pericardial cavity or mesentery in fry of Oncorhynchus nerka.

The meagre data on Trematoda, which the author possesses are extremely meagre. They consist of two species, Lecithaster gibbosus in Oncorhynchus keta and Brachyphallus crenatus in Oncorhynchus gorbuscha, which the author collected in Hokkaido.

IV Cestoda

As was noted on page 73 (617) of Part I, Cestoda, which are found in salmonoid fishes number 17 species in 11 genera; however, there are species in which <sup>the</sup> adult parasite ~~has~~ has not been recognized, or species, which have been defined later as synonym. Thus, the actual number will be less.

So far as the author has been able to ascertain, the first reference to the genus appears ~~to~~ <sup>in</sup> the thesis entitled "The source of *Bothriocephalus* ~~latus~~ *latus* in Japan", by Takashi Iiyama, which he published in 1889 in Vol. 2 pp. 49-56 of Tokyo Teikoku Daigaku Rika Daigaku Kiyō (Tokyo Imperial University Science Bulletin). In the thesis he established experimentally using his own body that *Dibothriocephalus latus*, which was parasitic on human, was communicated from *Oncorhynchus masou*. In 1922, Tsunenobu Fujita contributed a thesis, entitled "Parasites in Fish", to *Dobutsu-Gaku Zasshi*; ~~on~~ on p. 579, Vol. 34, in this thesis, he makes reference to two species, *Phyllobothrium salmoni* n. sp. and *Plerocercoides* sp. Both are larvae. The former is parasitic in the digestive tract, the latter in ~~the~~ the gall bladder. In the same year, Sueo Eguchi published an article on *Dibothriocephalus latus*, which was parasitic on *Oncorhynchus keta* in Jintsu River, in Vol. 29 of *Aichi Igaku Senmon Gakko Zasshi* (Aichi Medical College Publication); later in 1924, 1926 and 1929 he published his studies on the cestoda on p. 518, vol. 14, p. 563, Vol. 15, p. 253, Vol. 16, and p. 567,

Vol. 19 of *Eyorigaku Kyoan* (日本病理学会雑誌) Nihon Eyorigaku-Kai Shi (Journal of Japan Pathological Society), Qn p. 1; Vol. 3 of *Eyorigaku Kiyo* (Pathological Bulletin). During 1934-1935, Sanaka Yamaguti published a series of articles, Studies on the Helminth Fauna of Japan, in *Dobutsugaku Zasshi* (Zoological Bulletin); in these articles, he made reference to <sup>larvae of</sup> *Pelichnibothrium*, which he had obtained from *Oncorhynchus keta* and *Oncorhynchus masoni*. The book by Hisao Kobayashi, Fresh water fish and their parasites in Japan, which was published in 1935, mentioned *Diphyllobothrium latum* (larvae); in 1936, he added *Pelichnibothrium* (larvae) in Vol. 8 of *Sake-Masu Ruiho* (Salmon Trout Bulletin). <sup>by Tsubenobu Fujita</sup> *Fish Pathology*, which was published in 1937, mentioned *Diphyllobothrium latum* (larvae) in muscle, *Schistocephalus gasterostei* (Europe), *S. solidus* (Europe), <sup>and</sup> *Tetrarhynchus quadrirostris* (Atlantic) in the abdominal cavity, *Triaenophorus tricuspidatus* (Europe, Canada), *Diplocotyle olrikii* (U. S. A.), *Cyathocephalus truncatus* (Europe, U. S. A., Canada), *Eubothrium crassum* (Europe, U. S. A.), *E. oncorhynchi* (U. S. A.), *E. salvelini* (Europe, U. S. A.), *Phyllobothrium salmonis* (Japan), *Proteocephalus longicollis* (Europe), *P. torulosa* (U. S. A.), *P. salvelini* (U. S. A.), *P. arcticus* (U. S. A.), *P. coregoni* (U. S. A.), and *P. laruei* (U. S. A.) in the digestive tract, and *Taenia longicollis* (Europe) in the liver. Reports by U. S. A. and Canada mention *Diphyllobothrium* sp., *Phyllobothrium caudatum*, *Triaenophorus crassus*, *Proteocephalus*, *Eubothrium salvelini*, *E. oncorhynchi*, *E. sp.*, *Diplocotyle* sp.,

and Nybelinia surmenicola; AXMEPOB's report mentioned Labothrium crassum, E. salvelini, Nybelinia sp., Calliobothrium fillicolle(larvae), Proteocephalus exiguus, and Diphyllobothrium sp. (larvae).

From ~~the~~ as a reference, the author attempted a construction of a Table of Reference of eye of species of Cestoda mentioned above:

1. { There are four thin "hook-lips" with ~~movable~~ <sup>retroverse</sup> bristles, which freely go in and out, at the tip of the head. Trypanorhyncha(= Tetrahynchidea).  
 { No "hook-lip" at the tip of the head -----2
2. { There are four phyllidia at the tip of the head. Tetrephyllidea.  
 { No phyllidium -----3
3. { There are 4 single-cup-like suckers at the tip of the head. Proteocephala.  
 { No sucker -----4
4. { There are sucking grooves at the tip of the head, <sup>or</sup> the back and the abdomen. Pseudophyllidea  
 { No true sucking groove or sucker. Spathebothridea.

~~the~~ Notes on the above-mentioned genera, which belong to each ~~and~~ order will be given next:

Trypanorhyncha. Nybelinia surmenicola OKADA, 1929, whose specific name was mentioned in Part I, was mentioned by MARGOLIS in his 1956 report; the one mentioned as N. sp. was mentioned by AXMEPOB in his 1957 report; the one mentioned as Tetrarhynchus quadrirostris (GOEZE) is quoted on page 84 of Fish Pathology by Tsunenobu Fujita as having been found by ZSCHOKKE KM and HEITZE in Oncorhynchus tshawytscha in

parasite parasite  
Kamchatka. The generic name, Tetrarhynchus is used for larvae of different genera; thus, it is not recognized today as an independent genus.

Tetraphyllidea.

~~Onchobothriidae~~ Of the above-mentioned genera, ones belonging to the present order are the following two:

- { Possesses only four phyllidium.      Pnyllobothriidae  
A pair of hooks each on the tips of four phyllidium.  
Onchobothriidae

Phyllobothrium caudatum is mentioned in AXMEPOB's report: it is reported as the late stage larvae of Calliobothrium filicolle & ZSCHOKKE. It also appears in MARGOLIS' report as larvae under the same name. Ph. salmonis FUJITA is mentioned on page 168 of Fish Pathology. Pelichnibothrium, which belongs to the same order, is mentioned in AXEMPOB's report as the larval name of the above-mentioned Calliobothrium filicolle. Calliobothrium licole ZSCHOKKE, which should be included in Onchobothriidae, is in AXMEPOB's report. There is some confusion here.

Proteocephala. Proteocephalus is the only one which belongs to this order. It is mentioned as P. spp. in ~~MARGOLIS' report;~~ MARGOLIS' report; it is reported that the adult is P. salmonicida. P. exiguus LA LUE is in AXMEPOB's report.

PSEUDOPHYLLIDEA. Two genera, Diphylobothrium and Triaenophorus, can be mentioned as belonging to this order. It is a well known fact that plerocercoid, the larvae of Diphylobothrium latum, lurks in muscle of fishes of this family and infect human beings. The parasite is

lives (upon) mainly ~~in~~ fishes caught in fresh water. This fact is mentioned in reports by MARGOLIS KMM and AXMEPOB referred to in Part

I. Plerocercoid, which was ~~found~~ obtained by AXMEPOB, is reported not to be parasitic ~~on humans but to be the~~

larvae of *D. strictum*, which is parasitic on sea gulls in Lake Baikal.

The specimens obtained by MARGOLIS <sup>are</sup> is reported to be the larvae of *D. ursi*, which is parasitic on bears. There ~~is~~ seems to be considerable confusion between this genus and the traditional genus *Dibothriocephalus*. It appears that there are a few adult types of plerocercoid which is parasitic on salmonoid fishes. Three species of *Eubothrium*, *E. crassum* BLOCH, *E. oncorhynchi* WARDLE, and *E. salvelini* SCHRANK, are mentioned. The three species are ~~all~~ mentioned on page 168 of *Fish Pathology* by Tsubenobu Fujita; the ~~characteristic~~ distinguishing features are given as follows:

<i>E. crassum</i>	Length 300 mm:	width 3.5 mm.	Size of egg 54x41 <sup>u</sup> <del>u</del>
<i>E. oncorhynchi</i>	600 mm:	5 mm.	40x30 "
<i>E. salvelini</i>	150 mm		60x30 "

MARGOLIS' report mentions *E. salvelini*, *E. oncorhynchi*, and *E. sp.*: ~~in~~  
 AXMEPOB's report mentions *E. crassum* and *E. salvelini*. According to *The Zoology of Tapeworms* by R. A. WARDLE and J. A. MCLEOD, there are eight species of *Eubothrium*; of these, the species parasitic on salmonoid fishes are the above-mentioned three. <sup>comparison of</sup> The descriptions of each species brings about differences noted below:

The examination of the above table shows that *E. crassum* (parasitic on *Salmo salar* in the Atlantic and *Salmo trutta* in Europe and Canada) and *E. oncorhynchi* (parasitic on *Oncorhynchus* in the Pacific) are very closely related. The specimen, which the author has, is identified as *E. crassum* mentioned above. In *Triacnophorus*, *T. tricuspидatus*, *T. nodulosus*, and *T. robustus* are mentioned in on page 169 of *Fish Pathology* by Tsunenobu Fujita; it is stated that they were recognized as identical species. In MARGOLIS' report, it is stated that larvae of *T. crassus* had been obtained from fry of *Oncorhynchus nerka*. The above-mentioned book by WARDLE and MCLEOD mentions three species, *T. nodulosus*, *T. crassus*, and *T. stizostedionis*, and states that *T. tricuspидatus* and *T. robustus* are synonymous to *T. crassus*. Larvae infect salmonoid fishes.

Spathelothridea. Among the genus, *Diplocotyle*, belongs to this order.

*D. olrikii* is shown on page 166 of *Fish Pathology* by Tsunenobu Fujita. (2 in original manuscript)  
MARGOLIS reports *D. sp.* and *D. olrikii?* as common among *Oncorhynchus gorbuscha* near Attu Island. Only one species, *D. olrikii* KRABBE, 1874 is mentioned in the book by WARDLE and MCLEOD.

The above sections were written as a ~~summary~~ reference concerning Cestoda which is parasitic on salmonoid fishes.

As was explained in Part I, the specimens, which the first author obtained, were collected from *Oncorhynchus nerka*, *Oncorhynchus keta*, and *Oncorhynchus gorbuscha*, which had been caught in the North Pacific and Bering Sea by the research ships of the Fisheries Agency; further they were

had been damaged heavily. However, the author was able to distinguish and report

four species --Diphyllbothrium sp. (larvae), Phyllobothrium salmonis (larvae), Proteocephalus sp. (larvae), and Schistocephalus solidus? (<sup>? in original manuscript</sup>)

Of these, the last was erroneously identified by the author. At

the request of MARGOLIS, the author sent the specimen to him. It

was identified as Eubothrium sp. There was only one species S. solidus

of Schistocephalus. The adult is found in water fowls, proceroid

in small crustaceans such as Cyclops, and plerocercoid in the coeloma

of fresh water fishes. ~~On the~~ In the fresh water fishes, Salvelinus fontinalis

included. ~~is~~ The reasons for the mis-identification on <sup>the</sup> part of the author were lack of knowledge concerning Cestoda and the lack of references.

The collection on board a ship is ~~inconvenient~~ inconvenient. Further, there is a possibility ~~that~~ that small species will be missed. Thus, the

author has visited on two occasions fisheries in Hokkaido and related operations in Aomori-Ken, and collected parasites from fresh fish,

and <sup>as</sup> were able to collect several species from Oncorhynchus keta and

Oncorhynchus gorbuscha. ~~Only~~ Not too many fishes were dissected.

However, the author was surprised to find <sup>the</sup> in each fish larvae of

Cestoda ~~thickly~~ thickly as <sup>pile</sup> ~~hair~~ on carpet. Further, the

author observed a large number of Eubothrium although they were not

as large as those collected on board the ship. <sup>A</sup> ~~The~~ report on these

will follow.

(1) Diphyllbothrium larva

parasite parasite parasite  
The specimens, which were collected on board ~~Mamma~~Mama Daichi  
Tsukiyama-Maru, ~~mama~~ the research vessel of <sup>the</sup> Fisheries Agency in the  
North Pacific and the Bering Sea in 1955 and forwarded to the author,  
were very poorly preserved as has <sup>already</sup> been described. Cestoda consisted  
solely of ~~sub~~bothrium sp. The specimens, which were collected in  
1956 by the research vessels, Takuyo-Maru, Etsuyama-Maru, and Eiko-  
Maru in the same areas and forwarded to the author, were much better  
preserved in comparison to the former specimens. In one *Oncorhynchus*  
*nerka* and four *Oncorhynchus keta*, the author found specimens which  
appeared to be larvae of *Diphyllobothrium*: this was so reported.  
*Plerocercoid* of *D. latum* has been discovered in ~~muscle~~ muscle of *Oncor-*  
*hynchus masou* in fresh water; Margolis collected many larvae of this  
species from fish which had been caught in salt water. However, the  
majority is from fresh water. Again, the specimens, which ~~AXMEPOB~~  
obtained from Kamchatka River, is stated to be larvae of *Diphyllo-*  
*bothrium*. However, both <sup>Presume</sup> ~~interpret~~ it not to be parasitic on humans  
and to become adult in bears and sea gulls. As was stated in Part I,  
the author made visits to Hokkaido in Nov. 1957 and Sept. 1958. The  
first visit was to Hatano, Abashiri, Gosen and Juyonsen of Wakahyotsu,  
Morouchi of Tokachi, and Makubetsu ~~and~~. Mainly parasites from  
stomach and intestine of *Oncorhynchus keta* were collected. The second  
visit was to Wakubetsu and Shari. Again, parasites in stomach and  
intestine from *Oncorhynchus gorbuscha* and *Oncorhynchus masou*, <sup>were collected</sup> The  
purpose was to collect small species, which were missed <sup>being</sup> ~~during~~ coll-

ected on board ship, and to supplement the collection by research ~~vessels~~ vessels. In this collection, the author found specimens which appeared to be larvae of Diphylobothrium; however, later examination cast doubt on this conclusion. These larvae, i. e., plerocercoid, <sup>are</sup> ~~is~~ known to lie dormant in ~~muscle~~ <sup>was</sup> muscle; however, this ~~is~~ <sup>was</sup> also found in the digestive tract. Those, that the author recognized as ~~Diphylobothrium~~ <sup>this</sup> ~~Gastrea~~, included larvae of other Cestoda, which had been cut. When a larva is cut, the central portion contracts and the ~~tip~~ <sup>end</sup> end becomes Y-shaped. There were occasions when this was mistaken for plerocercoid. Further, in these cases, there are specimens in which the injury can be recognized; however, in ~~some~~ <sup>others</sup> the tip becomes round, and the injury cannot be ~~seen~~ <sup>at a glance</sup> observed and the specimens appears to be plerocercoid. However, it is ~~clearly~~ clearly different from the plerocercoid of *D. latum*.

## (2) Phyllobothrium larva and Pelichnibothrium ~~is~~ larva.

As has already been explained, ~~salmonoid~~ <sup>salmonoid</sup> fishes, which the author examined, consisted of a small number of *Oncorhynchus keta*, *Oncorhynchus m. gorbuscha*, and *Oncorhynchus masou*. However, the author <sup>that</sup> observed ~~in~~ these were very heavily ~~infected~~ <sup>by larvae of genus Phyllobothrium.</sup> infected. If the author may exaggerate, in extreme cases, they looked like pile on a carpet. The locale of infection was that part of the intestine which extends to the stomach. Tsunenobu Fujita, in his ~~series~~ series of articles, entitled "Parasites in Fish", which he ~~contributed~~ contributed to Vol. 34 of *Dobutsugaku Zasshi*, published <sup>on p. 577</sup> *Phyllobothrium salmonis* nov. sp.

parasite parasite parasite

34.34.34.34.34.34.34.

It is reported that the  
and Plerocercoid sp. among Cestoda. ~~Uma~~ latter is extremely young  
larvae, which he found in the gall bladder of *Oncorhynchus keta*, and  
that the ~~latter~~ <sup>former</sup> he found in ~~abundant~~ large numbers in the intestine and  
appendix pylorica of *Oncorhynchus keta* and *Oncorhynchus masou*, which  
were going up-stream in Tone, Jintsu, Sanmen, Ishikari, and Nijibetsu  
Rivers. There is no doubt that the <sup>author's</sup> specimens are this species. The  
author realized that the parasites were larvae and that the reproductive  
organs had not been formed. He felt that there had not been previous  
mention of such a specimen and that the specimens <sup>were</sup> ~~were~~ unique for Japan.  
Thus, he published ~~them~~ <sup>them</sup> as a new species on the basis of the stalk  
in phyllidium, the presence of auxiliary sucker, and the presence of  
neck portion.

However, Sanaka Yamaguti reported on larvae, which he  
had obtained in *Oncorhynchus keta*, as *Pelichnibothrium* larvae on page  
84 of the article, "Studies on the Helminth Fauna of Japan, Part 4.  
Cestodes of Fishes", which appeared in Vol. 6 No. 1 of <sup>the</sup> Japanese Journal  
of Zoology in 1934. There he wrote that the new species of Tsunenobu  
*Pelichnibothrium caudatum* of  
Fujita along with ZCHOKKE and Heltz should be considered as a synonym  
for *Pelichnibothrium speciosum* MONTICELLI, 1839. However, Tsunenobu  
Fujita wrote *Phyllobothrium salmonis* FUJITA in his Fish Pathology  
(page 168) published in 1937. In investigations of U. S. A. and Canada  
since 1955, ~~man~~ MARGOLIS and others wrote as *Phyllobothrium caudatum*  
and added it to be late stage larvae. They stated the rate of infection  
to be high reaching 100% in many places. The maximum average number

of parasites quoted was 408. AXMEPOB regards *Phyllobothrium caudatum*

to be the late stage larvae of *Calliobothrium filicolle* ZSCHÖYKE.

There is no doubt that this *Phyllobothrium caudatum* is identical with the specimen which the author obtained. The author examined the specimen, which had been brought back by the research vessels of <sup>the</sup> Fisheries Agency on its second expedition, identified it as *Phyllobothrium salomonis* of Tsunenobu Fujita, and so reported. The reference to the afore-mentioned *The Zoology of Tapeworms* (1952) of WARDLE and MCLEOD shows: that phyllidium of *Phyllobothrium* BENEDEN, 1849 is with or without stalk; that the adhesive surface <sup>is</sup> ~~was~~ simple, ~~a~~ <sup>is</sup> ~~is~~ bent in a complicated fashion, or ~~is~~ <sup>is</sup> bent; that its ~~margin~~ <sup>margin</sup> line is smooth, forms complicated folds, or has minute sucker-like objects; that the auxiliary sucker is generally present in each phyllidium; that it is lacking in some; ~~is~~ <sup>is</sup> and that the neck portion is either present or absent.

*Pelichnibothrium MONTICELLI*, 1889. There are a single top sucker and four auxiliary suckers which are located on the ~~anterior~~ anterior periphery of each phyllidium. Each phyllidium has a wide base. There is a pair on the dorsal side and a pair on the ventral side. The proglottid forms from immediately behind the sucker. The space between the ~~in~~ proglottids is strongly constricted ~~and~~ and is euapolytic. (Euapolytic means that a mature proglottid separates itself from the parent body, continues <sup>growth</sup>, ~~has~~ <sup>has</sup> power of locomotion, and in some cases, forms <sup>pseudo-sucker</sup>, and undergoes transformation).

The "internal vertical muscle bundle" is well developed in the first ~~segment~~ proglottid and the tail portion; however, this is not present in a mature proglottid. The neural tube is located on both sides inside the vitelline gland zone. The testiculus is extremely numerous, and is located inside the marrow on the side. The deference duct is found coiled up in front of the ~~ovary~~<sup>uterus</sup>; the cirrus sac is long with a thin wall, located obliquely ~~among~~<sup>with respect to</sup> the longitudinal axis of the body, and opens into outside immediately at the back of the vagina. The genital atrium is present on ~~either~~<sup>the right</sup> or the left side irregularly. The ovarium consists of two leaves and ~~is~~<sup>is</sup> dense. The uterine tube opens into the uterus in the anterior end. The uterus is of a long oval shape and is located in the centre of the body. The seminal receptacle is present. The vitelline glands are ~~numerous~~<sup>numerous</sup>, and located between the cortex ~~and~~<sup>side</sup> and the marrow layer. It is present on ~~both~~<sup>both</sup> sides in mature proglottids; however, in those in ~~which~~<sup>which</sup> eggs are ~~present~~<sup>present</sup>, it is absent starting with its anterior end. The author reports in detail that the ~~adult~~<sup>adult</sup> parasites live on Elasmobranchii, and that the larvae have ~~a~~<sup>a</sup> tail and live on Teleostei or on Cephalopoda. Further, the author mentions the fact ~~that~~<sup>of</sup> ~~Sagami~~<sup>n k</sup> Yamaguti's identification and of his creating a new sub-family. However, it does not appear that the author recognizes the new sub-family, Pelichnibothriinae. Judging from the description above, the points of difference between Phyllobothrium and Pelichnibothrium in the case of the specimens of the author of this

the place where the uterus is located. It is noted that the adult  
 infect~~ed~~  
~~inhabits~~ fresh water fish and at times amphibia. Over 62 species  
 are mentioned. Of these, five species, all ~~adult~~ mature parasites,  
 P. arcticus, P. salmonis-umblae, P. pusillus, P. longicollis,  
 and P. salvelini, are parasitic on salmonoid fish. <sup>1</sup> The specimens,  
 which the author had, were larvae; thus, the identification was  
 impossible. The specimens, which had been collected in Hokkaido  
 later, also included similar material.

(4) Eubothrium.

This is a considerably large tapeworm. Since this is  
 most noticeable, ~~there~~ in the collection on board the research ships  
 of the Fisheries Agency, a large number was obtained from *Oncorhynchus*  
*keta* in the first expedition. <sup>An</sup> ~~a~~ overwhelmingly large number of this  
 parasites ~~were~~ was also collected in the ~~the~~ second expedition. <sup>from *Oncorhynchus keta*</sup> Reference  
 to the past literature in Japan finds ~~three~~ three species mentioned  
 as parasitic on salmonoid fishes in Fish Pathology (page 168) of  
 Tsunenobu Fujita--*Eubothrium crassum* (BLOCH) (~~is~~ parasitic on *Oncor-*  
*hynchus keta* and *Salvelinus pluvius* in Europe and U. S. A.; reaches  
 300 mm in length), <sup>1</sup> *E. oncorhynchus* WARDLE (parasitic on *Oncorhynchus*  
*masou*, *Oncorhynchus keta*, and *Oncorhynchus kisutch* in the west coast  
 of ~~the~~ U. S. A.; reaches <sup>6</sup> 200 mm in length), and *E. salvelini* (SCHRANK)  
 (parasitic on *Salvelinus pluvius* and *Oncorhynchus nerka* in Europe  
 and U. S. A.). Reports published in U. S. A. and Canada since 1955  
 often mention *Eubothrium*; MARGOLIS' report mentions three species--

parasitic parasitic parasitic  
E. salvelini (fry of *Oncorhynchus nerka*; fresh water; few), *E. oncorhynchi* (*Oncorhynchus nerka*, *Oncorhynchus gorbuscha*; salt water; rare in the western Pacific, observed ~~many~~ twice in *Oncorhynchus nerka*; seen in *Oncorhynchus gorbuscha* in the east), *E. sp.* (fry of *Oncorhynchus nerka*; fresh water; *E. salvelini*?). In his investigations in the Kamchatka River, AXMEPOB reports finding *E. crassum* in <sup>the intestine of</sup> *Oncorhynchus keta*, *Oncorhynchus tschawytscha*, and *Oncorhynchus kisutch* ~~which were caught in salt water~~; *E. salvelini* in *Salvelinus leucomaenis*, <sup>1</sup> *Salvelinus maxma*, *Salmo mykiss*, and *E. thymallus* which were also caught in salt water.

As was mentioned above, in the specimens of the author, the genus is included in a large number both in the material collected on the research vessels and the ones collected by the author in Hokkaido. The specimens collected in the high sea ~~which~~ are markedly larger.

According to WARDLE ~~and~~ and MCLEOD,

Eubothrium Nybelin, 1922: phyllidium is simple, the proglottid is generally ~~a~~ distinct. Vertical grooves are observed in the centre surface of the dorsal and the ventral sides of the body. The testis <sup>is</sup> ~~are~~ located completely between the two neural tubes. The cirrus sac is not remarkably large; it is not muscular. The vagina is S-shaped and opens outside into the genital atrium, which is narrow and deep, in front of the cirrus sac. The seminal receptacle is not present; however, the vagina ~~is~~ widens at this point. The "mature-egg-cavity" is located on the dorsal side. The vitelline

gland is located as a half-moon shaped side zone in the cortex.

The uterus opening is located on the ventral side.

Species mentioned are eight ~~mm~~ which are all parasitic on fish. Of these, those parasitic on salmonoid fishes are *E. crassum* BLOCH, 1779 (length 120-699 mm), *E. salvelini* SCHRANK, 1790 (length reaches 280 mm in length), and *E. oncorhynchi* WARDLE (reaches 600 mm in length). The differences are points mentioned above; however, *E. crassum* and *E. oncorhynchi* are very closely related; the author wonders if they should be regarded as identical.

The author investigated the above-mentioned material as a section, and identified it as *E. crassum* on the basis of the condition of the vitelline gland and other factors. The specimens, which the author had collected in Hokkaido, were larvae, in which the reproductive organ had not been formed, when they were examined as a section.

#### V. Nematoda

In part I of the present report ~~parasites~~ 33 species of parasites of Nematoda are reported as known those which are known to be parasitic in salmonoid fishes; however, there may be some, which cannot be identified because the specimens are larvae, and there may be others which are synonymous. Thus, as in the cases of Trematoda and Cestoda, the number will decrease. The classification of the above mentioned parasites shows that they belong to the following 4 super-families--Ascaroidea, Spiruroidea, Trichuroidea, and Dracunculoidea.

For convenience, ~~unpublished~~ <sup>a</sup> table of reference, which <sup>is</sup> are based on the most readily distinguishable features of the four super families, is given:

- 1 { The anterior part of the body is <sup>generally</sup> thin and long-----Trichuroidea
  - Not as above.-----2
- 2 { Lips ~~present~~ <sup>absent</sup>-----Dracunculoidea
  - Lips present-----3
- 3 { 3 lips, and no oral cavity -----<sup>ca</sup>Ascaroidea
  - 2 lips, or 4-6 small lips. Oral cavity present.
    - At times, teeth present -----Spiruroidea

Of the above, the one, which belongs to Trichuroidea, is Capillaria of Trichuridae; 6 species of Philometridae belongs to Dracunculoidea; Anisakidae and Goeziidae to Ascaroidea; ~~To~~ the former belongs 3 species of Anisakis(?), 8 species of Contracaecum, and 2 species of Terranova (=Porrocaecum); to the latter belong one species of Goezia. 3 families, Cucullanidae, Rhabdochonidae, and Thelazidae belong to Spiruroidea; of these one species, Dacnitis, belongs to the first family, 5 species of Cystidicola ~~manthemacondrafamily~~, 2 species of Metabronema, and 5 species of Rhabdochona belong to the second family; and 2 species of Ascarophis belong to the third family.

Tabular representation is as follows:

Trichuroidea	-----	Trichuridae	-----	Capillaria	1	specie
				Philometra	1	"
Dracunculoidea	-----	Philometridae	-----	Philonema	6	"
				Anisakis	3	" <sup>(in original)</sup> (?)
		Anisakidae		Contracaecum	8	"
Ascaroidea				Terranova (Porrocaecum)	2	" <sup>(in original)</sup> (?)
		Goeziidae		Goezia	1	"

		1		
Spiruroidea	{	Cucullanidae	Dacnatis	1 specie
		{	Cystidicola	5 "
			Metabronema	2 "
			Rhabdochona	5 "
Thelaziidae	Ascarophis	2 "		

(1) Capillaria.

The one, which belongs to this genus, appears only once in MARGOLIS' report (1956) as C. sp. It is noted that they were obtained from the intestine of fry of *Oncorhynchus nerka* and that they are rare. The ones belonging to this genus are parasitic mainly on birds and mammalia. They are not known to be parasitic on amphibians and fish. There was none in the author's specimens.

(2) *Philonema*.

The first mention of this genus parasites belonging to this genus seems to be two simple diagrams and explanations on *Ph. oncorhynchi* KUITUNEN-EKBAUM, 1933 and *Ph. ochotense* FUJITA on page 87 of Fish Pathology by Tsunenobu Fujita in 1937. Next, he published three species, *Ph. kondai* n. sp., *Ph. salvelini* and *Ph. tenuicauda* n. sp. on pages 260 et seq. of Vol. 42 of Hokkaido Teikoku Daigaku Nogaku-Bu Kiyo (Hokkaido Imperial University, Faculty of Agriculture Bulletin); further in 1940, he published *Ph. elongata* n. sp. on page 390 of Vol. 3 of *Dobutsugaku Zasshi*. Reference is made to *Ph. oncorhynchi* in U. S. and Canadian reports; <sup>Shu</sup> MARGOLIS <sup>Reference</sup> MEE found many of these in <sup>the coeloma of</sup> *Oncorhynchus nerka* in fresh water; further, he found many specimens, which appeared to be the larvae, in fry of

parasite parasite parasite

43.43.43.43.43.

Oncorhynchus nerka. AXMEPOB obtained the genus from the protrusions  
 in the pylorus of Oncorhynchus nerka, Oncorhynchus keta, and Sal-  
 velinus leucomaenis, which had been caught in salt water, and identified  
 it as Ph. oncorhynchi; he stated that Ph. gubernaculum SIMON is et  
 Simon as synonymous with Ph. elongata FUJITA. Be that as it may,  
 the above-mentioned species ~~mentioned~~ <sup>when</sup> listed become the following six  
 species:

- Ph. Oncorhynchi KUITUNEN-EKBAUM, 1933
- Ph. ochotense, FUJITA
- Ph. kondai FUJITA, 1939
- Ph. salvelini FUJITA, 1939
- Ph. tenuicauda FUJITA, 1939
- Ph. elongata FUJITA, 1940

The main points of difference between the species ~~are~~ are  
 tabulated below. In the ~~lack~~ lack of original literature, ~~information~~ <sup>information</sup>  
 on the first two ~~species~~ species was taken from Fish Pathology; ~~information~~ <sup>information</sup>  
 on others was taken from the original works.

Few, indistinct

Indistinct

The examination of the above table shows that there is a difference in size; however, since this depends on the development of parasites, it cannot be relied on too much. The other charac

parasite parasite parasite

45.45.45.45.45.45.45.

teristics are similar. However, the difference in the length of anterior and posterior portion of esophagus, and the position and the number of the genital protrusions, though there are variations, seem to supply fairly distinct bases for the identification of species.

The parasites of this genus <sup>are</sup> ~~is~~ extremely thin and thread-like; thus, ~~but~~ they are easily observed when the host is opened up. Hence, a fairly large number of parasites was included in the collection of the first and the second expeditions. However, perhaps ~~because~~ because the body is soft, they were very badly damaged. Thus, though they <sup>could</sup> ~~can~~ be ~~identified~~ recognized as belonging to this ~~genus~~ genus on the basis of eggs, further identification was difficult. In his <sup>1956</sup> report to the Fisheries Agency ~~in~~, the author identified them as Ph. ochotense and Ph. oncorhynchum <sup>1</sup> on the basis of size and so reported. However, he has his doubts.

### (3) Anisakis.

The parasites of this genus, which are found in salmonoid fishes, are all larvae. The rate of infection is extremely high. The fact probably is known; but, ~~among~~ among the <sup>Japanese</sup> ~~references~~ references quoted in Part I, the author feels that the mention of Anisakis salaris (GMELIN, 1790) by Sanaka Yamaguti (1935) ~~is~~ on page 338 of ~~the~~ Vol. 6 of Dobutsugaku <sup>Shu</sup> ~~and~~ who is the first. The larva of this species has been known as Ascaris capsularia RUDOLPHI, 1802. Before this, the name, ~~the~~ Capsularia salaris (~~the~~ GMELIN, 1790) ZEDER, 1800, was given. However, the generic name Capsularia was ~~taken~~ first <sup>by</sup> a genus of

Hydrozoa by CUVIER. <sup>in 1798</sup> Since Anisakis of DUJARDIN resembled this closely, Yamaguti proposed the name Anisakis salaris, a combination of the two. Since there is no doubt that Ascaris simplex RUDOLPHI, 1804<sub>x</sub> is a mature form of this larvae, Yamaguti states this specie synonymous with Anisakis salaris. Without commenting on the propriety of this argument, the author for the time being at any rate reported as Anisakis salaris. The larvae are ~~mainly~~ parasitic mainly on species of fish ~~in~~ in the ocean; Yamaguti mentions 33 species of fish.

Anisakis sp. larva is mentioned in 1956 reports of U. S. A. and Canada; the rate of infection is shown as 95-100%, and the average number per fish is reported as 5 - 28. On the basis of the rate of infection of Anisakis and others, J. R. UZMANN of U. S. A. argues that the distribution border of salmon between the eastern and the western portion of the Pacific is between 170° E to 180°. The larvae of this specie are found in tunica in a circinate tunica in muscle, <sup>such places as</sup> mesentery, surface of the internal organs, and the methothelium, and <sup>is</sup> easily detected. Later, Uzmann and others used protein-digestive-enzyme to decompose the fish body in order not to miss them. ~~In~~ ~~АХМЕПОВ~~'s report adopted the name, Anisakis simplex RUDOLPHI, 1819, <sup>states</sup> and regards A. salaris of Yamaguti as synonym, and ~~expresses~~ that they are parasitic on Oncorhynchus nerka, Salvelinus malma, Salvelinus leucomaenis, Oncorhynchus keta, Oncorhynchus gorbuscha, Oncorhynchus <sup>and</sup> tschawytscha, Oncorhynchus kisutch, Salmo mykiss.

The material of the author includes the ones which appeared

parasite parasite parasite

47.47.47.47.47.47.

~~to have been~~ <sup>were</sup> parasitic on *Oncorhynchus nerka* in the second collection, which was sent to him from the Fisheries Agency. He also found, <sup>them</sup> though in a small number, in the frozen ~~and~~ fish which was sent from the U. S.

A. ~~Ammoniummattsted~~ On his trip to Hokkaido, he did not pay any ~~particular~~ particular attention; <sup>to them</sup> thus, his collection of the species is few. It appears as though ~~the same~~ <sup>it</sup> is prevalent in the Pacific, <sup>as stated in Uzmann's report</sup> The material of the author includes specimens, in which the back of the esophagus is clearly seen, and those in which this is not distinct; however, since the structure of the head ~~and~~ and the tail is identical, it ~~may~~ probably is not a different species. The size, measurements of nine parasites, is 23-38 x 0,3-0.6 mm.

(4) *Contracaecum*.

<sup>species of</sup>  
The number of this genus, which ~~are~~ are parasitic in salmonoid fishes, are considerable. Tsunenobu Fujita mentions in his Fish Pathology, *C. ochotense* Fujita, *C. benimusu* Fujita as being parasitic in the ventral cavity, *C. adunca* (RUDOLPHI) and *C. clavata* (RUDOLPHI) as being parasitic in the digestive tract. Next, he published *C. hypomesi* FUJITA, *C. crassicaudatum* n. sp., *C. elongatum* n. sp., *C. unidentatum* n. sp. (illustrative diagram refers to *C. monodentatum*), and *C. robustum* on pages 248 - 252 of ~~the~~ Vol. 42 of 1939 Hokkaido Teikoku Daigaku Nogakubu Kiyo; further, in his article entitled "Further notes on nematodes of salmonoid fishes in Japan" in ~~the~~ Vol. 8 (1940) of <sup>Shu</sup> *Dobutsugaku Zasshi*, he published four new species, *C. okadai*, *C. salvelini*, *C. longicaeculum* and *C. oshocensis*.

parasite parasite parasite

48.48.48.48.48.48.

In reports of U. S. A. <sup>and</sup> Canada, the genus is found as

*Contracaecum* sp. in a ~~many~~ considerable number. Larvae are obtained in the coeloma. The rate of infection seems to be higher in the eastern Pacific. ~~Amur~~ ~~NI~~ AXMEPOB notes ~~many~~ one specie, *C. adunca*; he reports finding mature parasites in *Salvelinus leucomaenis*, ~~Amur~~ ~~NI~~ *Oncorhynchus nerka*, *Oncorhynchus gorbuscha*, *Salmo mykiss*, <sup>*Salmo thymallus*,</sup> and immature parasites in *Oncorhynchus keta* and *Salvelinus malma*. Locales of infection are shown as ~~many~~ ~~NI~~ ~~AXMEPOB~~ the esophagus, the stomach, the intestine, and the coeloma.

Both the first and the second material, which were sent to the author by the Fisheries Agency, included this genus; however, a complete identification was not made. <sup>specimens belonging to</sup> The ~~many~~ specimens from the first collection was reported as merely *Contracaecum* sp., and those from the second collection as *C. adunca*? and *C. benimasu*. <sup>(? in original manuscript)</sup> ~~(translator's note the question mark is in the original manuscript)~~. The material from Hokkaido ~~was~~ also included a few specimens.

On the ~~many~~ basis of the literature, the species of this genus, which have been found in salmonoid fishes, are the following

13:

- Contracaecum adunca* (RUDOLPHI), 1809
- C. benimasu* FUJITA, 1932(?) (? in original manuscript)
- C. crassicaudatum* FUJITA, 1939
- C. elongatum* FUJITA, 1938
- C. hypomasi* FUJITA, 1932(?) (in original manuscript)
- C. longispiculum* FUJITA, 1940
- C. ochotense* FUJITA, 1922(?) (? in original manuscript)

parasite parasite parasite

49.49.49.49.49.49.

- C. okadae FUJITA, 1940
- C. oshoroensis FUJITA, 1940
- C. robustum FUJITA, 1939
- C. salvelini FUJITA, 1940
- C. tridentatum FUJITA, 1939
- C. unidentatum FUJITA, 1939 (=C. monodentatum FUJITA).

The author made a comparison of the characteristics of these species with respect to several parts; he is doubtful if there are this many different species. Those, which were published by Fujita as new species, contained a considerable number of larvae. In some, genital organs could not be recognized. In some specimens consisted of a single sex. It is doubtful if their characteristics remain the same until maturity. There was a specimen with no lip (C. robustum). There are considerable degrees of differences between those, whose vagina open in the centre or in front of the centre of the body, and those, in which the vagina opens at the rectum. It is doubtful whether the specie with the genital nipples should be included in the same Contracaecum with the specie without one. Since the esophageal "closed sac" and the intestinal "closed-sac" are present in every specie, it is recognized to be the most marked characteristics of the present genus. However, the author feels that the further examination is necessary. Fujita used the expression, C. unidentatum, in his report, and used the designation, C. monodentatum in the explanation of the diagram. The author adopted C. unidentatum and treated the latter as a synonym.

The following table of reference on the basis of characteristics, ~~characters~~ which are most easily recognized by anyone, is shown below:

- 1 { Lips ~~present~~ absent ----- C. robustum
- 1 { Lips present ----- 2
- 2 { Protrusion <sup>facina forward</sup> ~~in the opposite direction~~  
in front of lips ----- 3
- 2 { No such protrusion ----- 4
- 3 { Only one protrusion on dorsal lip ----- C. unidentatum
- 3 { Three protrusions in each lip ----- C. tridentatum
- 4 { Genital nipples present ----- 5
- 4 { Genital nipples absent ----- 9
- 5 { Genital nipples located only in front of the anus ----- 6
- 5 { Genital nipples located both in the front and the back  
of anus ----- 8
- 6 { Genital nipples consist of 20-25 pairs --- ~~characters~~ 7
- 6 { Genital nipples consist of 28-34 pairs --- ~~characters~~ C. salvolini
- 7 { The vagina opens at the base of the <sup>rectum</sup> ~~small intestine~~ ----- C. okadae
- 7 { The vagina opens in the centre of the front 1/3 of the  
body ----- C. hypomesi
- 8 { Genital nipples - 30 pairs in front of the anus and  
3 pairs at the back. Length of the body 12.5-21 mm  
----- C. longipiculum
- 8 { Genital nipples - 27 pairs ~~at~~ in the front of anus  
and 3 pairs at the back. Length of body 30-65 mm  
----- C. adunca
- 9 { The vagina opens near the centre of the body ----- 10
- 9 { The vagina opens into the rectum ----- 11
- 10 { The esophageal "closed-sac" is longer than the intestinal  
"closed-sac" ----- C. crassicaudatum
- 10 { The esophageal "closed-sac" is shorter than the  
intestinal "closed-sac". ----- C. elongatum

- 12 { Single protrusion at the end of the tail -----C. oshoroensis
- 11 { Many small bristles at the end of the tail -----12
- 12 { The esophageal "closed-sac" is ~~shorter~~ longer than the intestinal "closed-sac" -----C. benimasu
- 12 { The esophageal "closed-sac" is shorter than the intestinal "closed-sac" -----C. ochotense

This table of reference is merely for convenience; there are species in which only the male or the female is known. Further, if the specimens to be examined consists only of one sex, there are cases when the search cannot be made. Further, as was explained previously, there are cases, in which the original report deals only with larvae. Further examination may introduce a change. AXMEPOB stated (1955) that C. okadai, C. longispiculum, C. salvelini, and C. oshoroensis should be regarded as synonymous with C. adunca.

The specimens, which the author has, consist of those which were sent by the Fisheries Agency, and those which the author collected from *Oncorhynchus gorbuscha* caught at Ajigazawa in Aomori-Ken. However, since they appear to be of the same specie, they were identified as C. adunca.

(5) Terranova (=Porrocaecum?). The present genus appears in MARGOLIS's report and is referred to as (=Porrocaecum). It is stated that it is found <sup>the</sup> in inner part of ~~the~~ muscles of *Oncorhynchus nerka* and *Oncorhynchus gorbuscha* in salt water in a small number. It is said that the genus is larvae of T. (=P.) decipiens. According to MARGOLIS' report, Parasitic Helminths and Arthropods from Pinnipedia of the Canadian

Pacific Coast, 1956<sup>x</sup>", this genus, Terranova, which we are not accus-  
tomed to hear, was established ~~with~~ by ATKINSON and LEIPER in 1914

which ~~was~~ had been obtained from sharks in  
with T. antarctica, ~~was~~ New Zealand, as a specimen

and  
specie; the point of ~~the~~ difference from Porrocaecum is the lack of

interlabia . Porrocaecum is parasitic on birds with interlabia; ~~with~~

Terranova is parasitic on Elasmobranchii, Teleostei, and Mammalia <sup>ia.</sup> and  
has no interlabia..

It is reported that T. decipiens ~~is~~ parasitic on Pinnipedia. This  
is also lacking in the author's material.

(6) Goezia. In ~~the~~ literature of Japan ~~the~~ the genus seems to have  
been mentioned first by Tsunenobu Fujita when he published a new specie,

Goezia onchorhynchi, on page 384 <sup>in</sup> ~~the~~ Vol. 8 of Dobutsugaku <sup>Shu</sup> ~~Buho~~.

The genus is the only one which belongs to Goeziidae. The character-

istics of the genus is the presence of <sup>a</sup> thorny ring, of ventricular

caecum, which ~~is~~ faces the back, and the presence of the intestinal

caecum, which faces the front. However, <sup>in the</sup> description by Fujita ~~the~~

~~the~~ horizontal folds ~~is~~ are present but the thorny rings are absent.

What appears to ~~be~~ <sup>the</sup> correspond to ventricular caecum, he defines as

~~the~~ the esophageal gland. Further, ~~the~~ the genital organs are not

~~the~~ well developed. Thus, ~~the~~ <sup>the specimens</sup> appear to be larvae. Although ~~the~~

no mention was made in Part I, R. PH. DOLLFUS obtained G. ascaroides

(GOEZE) from Salmo irideus var shasta and reported ~~(Bull. Soc. Zool. France)~~

Bulletin de la Société Zoologique de France, Tome IX, 1935). This

was also absent from the material of the author.

(7) Dacnitis. MARGOLIS' report states that D. truttae of the present

parasite parasite

53.53.53.353.53.

genus was obtained from the intestine of *Oncorhynchus nerka* in fresh water and that the parasites are not numerous. AXMEPOB'S report states that *D. truttae* DUJARDIN was obtained in a large number from *Salvelinus leucomaenis* and *Salmo mykiss* in fresh water, that only one *Oncorhynchus nerka* harboured the specie, and that this could have been accidental. It is further reported that the specie is <sup>found</sup> ~~was~~ in *Salmo leveratus*, *Salmo nelma*, and *Salmo taimen* in the Lena River(?), the Enisei River(?), The Anadovill River (?) and the Obi(?) and Iltwish(?) water basins. (question marks by the translator). The genus was absent in the author's material.

(8) *Cystidicola*. With respect to the present genus, in 1911 Higeyoshi Ishii published *Ancyracanthus salmonicola*, which is parasitic in the air bladder of *Oncorhynchus masou*, as a new specie; this was later transferred to ~~the~~ the present genus. ~~XXXXXXXXXXXXXXXXXXXX~~ In the article, "Parasites in Fish", which Tsunenobu Fujita published during 1920-1922, references are made to ~~XXXXXXXXXX~~ transferred to *C. oncorhynchi* (later *Rhabdochona*), which was obtained from the intestine of fry of *Oncorhynchus keta*, *C. fujii* (same as above), which was obtained from the intestine of *Oncorhynchus JORDAN adonis* ~~XXXXXXXXXX~~ et MCGREGOR and *Oncorhynchus rhodurus* JORDAN Et et MCGREGOR, and *Spiroptera salvelini*, which was obtained from the intestine of the same hosts, as new species. The last-mentioned specie was later included in the present genus. These are all parasitic in the intestine. Again, the same author published articles entitled "Vermes Parasitic in Fishes in the Lake Biwa" during 1926-

parasite parasite parasite ... 54.54.54.54.54.

1928; he obtained *C. salvelini* from *Salvelinus pluvius*; at the same

time he obtained *C. iwana* from the coeloma and identified this as

a new specie. During 1934 - 1935 Sanaka Yamaguchi published additional observations

concerning *C. salvelini*, and obtained *C. salmonicola* from *Oncorhynchus*

*rhodurus* JORDAN et MCGREGOR. In 1935 Isamu Okada reported on ecology

and pathology of *C. salmonicola* in an article entitled "On Nematodes

Parasitic in Air-Bladders of Salmonoid Fishes". Hisao Kobayashi refers

to the above-mentioned three species in his article "Species of Fresh

water Fish in Japan and Its Parasites". Tsunenobu Fujita mentions

*C. salvelini*, *C. salmonicola*, *C. farionis*, and *C. impar* in his Fish

Pathology. Further, he reported on a new specie, *C. brevicauda*, which

he obtained from *Salvelinus malma*, on page 259 of 1939 Hokkaido Tei-

roku Daigaku Nogakubu Kiyo; and in 1940, he published *C. chitosensis*

as a new specie, which he had obtained in the air-bladder of

*Oncorhynchus keta*, in Vol. 8 of *Dobutsugaku Zasshi*. In his 1955

report AXMEPOB reports of finding *C. farionis* in *Salvelinus leuco-*

*maenis* and *Salmo mykiss*. Thus, the parasites, which belong to the

present genus, number nine:

*Cystidicola brevicauda* FUJITA, 1939

*C. chitosensis* FUJITA, 1940

*C. farionis* FISCHER

*C. Fujii* FUJITA. 1921 → *Rhabdochona fujii*

(*Dobutsugaku Zasshi* - 1926-1928, p. 309)

*C. impar* SCHNEIDER

*C. iwana* FUJITA, 1928 → *Metabronema iwana*

(*Fish Pathology*, p. 86)

*C. oncorhynchi* FUJITA, 1921 → *Rhabdochona*

Oncorhynchi (Dobutsugaku Zasshi, 1926-1928, p. 309)

C. salmonicola (ISHII, -1911)

C. salvelini (FUJITA, 1922)

The table of reference, which excludes *Rhabdochona* and the three species, which were transferred to *Metabronema*, and *O. brevicauda*, in which male is not known, is as follows:

- |   |   |   |
|---|---|---|
| 1 | { | Genital nipples not present behind anus -----C. chitosensis         |
|   |   | Genital nipples present behind anus -----2                          |
| 2 | { | Four pairs of single genital nipple in front of anus;               |
|   |   | four or five pairs behind anus -----C. salvelini                    |
|   |   | Even number of genital nipples in front of anus -----3              |
| 3 | { | Seven pairs in front of anus; five pairs behind anus--C. impar      |
|   |   | Ten pairs in front of anus; four pairs behind anus--C. farionis     |
|   |   | 10-11 pairs in front of anus; 3-4 pairs behind anus--C. salmonicola |

The above table is based <sup>only</sup> on the genital nipple; <sup>therefore</sup> thus, it cannot be used in the case of female <sup>only</sup>. The last two species can hardly be distinguished by other points; however, since there is no original description, the author leaves the table as it is.

The author obtained many specimens from the g air-bladder and the coeloma of fry of *Oncorhynchus keta*, which he had collected in Aomori-Ken. Some differences were observed in the number of the genital nipples; however, the author felt that the differences were variation between specimens. Thus, they were identified as *C. salmonicola*.

(9) *Metabronema* (= *Cystidicoloides*). The first appearance of the present genus in the literature of this country probably is *M. iwana* on page 86 of *Fish Pathology* by Tsunenobu Fujita. The specie was first

parasite parasite parasite

56.56.56.56.56.

published by the same author as *Cystidicola iwana* n. sp. in *Dobutsugaku*

*Zasshi*; here the specie is transferred to the present genus. Further,

he published five new species in 1939 in Vol. 42 of *Hokkaido Teikoku*

*Daigaku Nogaku-Bu Kiyo* -- *M. oncorhynchi* ~~was described~~ from

and *M. amemasu*

*Oncorhynchus masou*, *M. kosugii* from *Salvelinus leucomaenis*, *M. salve-*

*lini* from *Oncorhynchus keta* and *Salvelinus leucomaenis*, and *M. lati-*

*cauda* from *Oncorhynchus nerka*. Further, in 1935 ~~Dr.~~ BAYLIS contri-

buted an article entitled "Four new species of nematodes" in Vol. 16,

Ser. 10 of *Ann. Mag. Nat. Hist.*; in this article he published *M.*

*truttæ* as a new specie. However, in his opinion *Cystidicola* =

*Metabronema* and he states ~~that~~ *C. salvelini* to be *M. salvelini*.

However, this *salvelini* is different from the above-mentioned *M.*

*salvelini*. The name of the present genus does not appear in U. S.,

Canadian, or ~~Soviet~~ <sup>AXMEPOB'S</sup> reports.

in the first collection

Among the specimens of the author, which had been sent

to him by the Fisheries Agency, what appears to ~~be~~ belong to the

present genus was found in *Oncorhynchus nerka*. However, the specimens

~~was~~ consisted solely of females and the author was unable to identify

them. He reported them as *M. sp.* The size ~~was~~ <sup>approximately</sup> 29-36 x 0.7-0.8 mm ;

there ~~are~~ <sup>were</sup> two or three very long strands of thread-like-object coming out of one

end of the egg. The size of the egg ~~is~~ <sup>was</sup> approximately 40 x 20  $\mu$ ;

the egg ~~and~~ contained larva. Thus, in the end six species can be counted to

belong to this genus. They are, *M. iwana*, *M. oncorhynchi*, *M. kosugii*,

*M. amemasu*, *M. salvelini*, and *M. laticauda*. The table of reference

ears are  
 is shown below. It appears as though the distinctions are somewhat clearer in comparison with *Contracaecum* or *Cystidicola*. However, in which only female is known. Variations must also be considered. Thus, the table is not sufficient.

- 1 { Width of tail is mm wide and is approximately equal to the length and is rectangular in shape -----*M. laticauda*  
 The tail becomes smaller towards the end -----2
- 2 { Eggs are large: 90 x 40  $\mu$  -----*M. amemasu*  
 Eggs are smaller -----3
- 3 { Genital nipples are single -----4  
 Genital nipples in front of anus are in groups of two -----5
- 4 { Genital nipples: 8 pairs in front of anus and 2 pairs at the back of anus -----*M. kosugii*  
 Genital nipples: 10 pairs in front of anus and 3 pairs at the back of anus -----*M. salvelini*
- 5 { Genital nipples: in front of the anus in one part groups of two; however, counting singly 16 pairs: 2 pairs at the back of anus -----*M. iwana*  
 Genital nipples: 13 pairs in front of anus, 3 pairs at the back of anus -----*M. oncorhynchi*

(10) *Rhabdochona*. There are 10 - 12 high ridges running longitudinally along the inner wall of the oral cavity in the present genus. The ends of the ridges become teeth. The first reference to this genus appears in the literature in this country to be the publication of a species as *Cystidicola oncorhynchi* and *C. fujii* by Tsunenobu Fujita in 1922; these were later transferred to the present genus. Next, he published a specimen as *Rh. salvelini* sp. on page 172 Vol. 1 of 1927 *Dobutsugaku Zasshi*; the same item was also

parasite parasite parasite

58.58.58.58.58.58.58.

published in Dobutsugaku Zasshi. Following this, Sanaka Yamaguti ~~published~~  
published Rh. amago n. sp. on page 372 Vol. 6 of Dobutsugaku ~~Zasshi~~<sup>Shu</sup>.

The above-mentioned three species are mentioned in "Fresh Water Fish  
of Japan and Their Parasites " by Hisao Kobayashi; Fish Pathology  
by Tsunenobu Fujita also mentions these. . In 1940 the same author

published Rh. oncorhynchi n. sp. ~~in~~<sup>on</sup> page 388 , Vol. 8 of Dobutsugaku  
~~Zasshi~~<sup>Shu</sup>. ~~MAN~~ MARGOLIS states in his report that ~~he~~ he obtained Rh.

sp.(?) (translator's note: question mark is ~~in~~ in the original manus-  
cript) in the intestine of fry of Oncorhynchus nerka and that they are

a rare. \* The above accounts indicate that the species of the present  
genus found in salmonoid fishes are two in Rh. oncorhynchi--Rh. fujii

and Rh. salvelini-- and Rh. amago. A comparison was ~~made~~ made of  
these by tabulating distinguishable characteristics. However, Rh.

oncorhynchi, which was published by Fujita in 1940 Dobutsugaku ~~Zasshi~~<sup>Shu</sup>,  
was described in terms of female only, and can hardly be distinguished

from the specie, which was published as Cystidicola (~~Cystidicola~~  
~~the~~ translator's note: Cystidicola?) oncorhynchi and later transferred

to the present genus. The description of high ridges in the oral cavity  
is not sufficient and the identification is difficult. However, the

author feels that they are identical. The table of reference, const-  
ructed with this excluded, is as follows:

- 1 { no high ridges of chitinous substance in the oral cavity
- 2 { -----Rh. amago
- 3 { six high ridges consisting of 2 closely located ridges in the  
oral cavity-----2

- 2 { Copulatory wing is distinct and well developed ---Rh. fujii  
 Copulatory wing is absent <sup>or</sup> can hardly be recognized -----3
- 3 { Genital nipples: 8-9 pairs in front of anus, and 5 pairs at the back of anus. Egg size: 43 x 24  $\mu$  -----Rh. oncorhynchi  
 Genital nipples: 10-12 pairs in front of anus, and 5 pairs at the back of anus. Egg size: 58 x 32 -----Rh. salvelini

Among the specimens of the author, what appears to be of the present genus was included in the first collection which had been forwarded to the author <sup>by the Fisheries Agency</sup>; he reported them as Rh. sp. Later, he obtained Rh. oncorhynchi from the intestine of fry of Oncorhynchus keta 54 mm which he had obtained from the Prefectural Hatchery in Aisaka, Towada-Shi, Aomori-Ken. There was a small variation in the number of  $m\bar{u}$  genital nipples; however, they appear to be of the present specie.

(11) Ascarophis. There does not appear to be any mention of the present genus in the literature in this country. MARGOLIS' report mentions that A. skrjabini was  $m$  collected from the stomach and the intestine of Oncorhynchus gorbuscha in salt water. AKMEPOB's report ~~also~~ mentions that A. malmae ACHMEROW was obtained from the intestine of fry of Salvelinus malma in fresh water. It was not seen in the author's material.

VI ACANTHOCEPHALIA

The known parasites of Acanthocephala, which is parasitic on salmonoid fishes, as was noted  $\bar{u}$  on page 81 (page 624) of Part I, number 15 species in 7 genera. However, there are cases where the

parasite parasite parasite parasite

60.60.60.60.60.60.60.

specific names are not known. There are cases which <sup>were</sup> ~~was~~ taken as synonyms for others. Thus, the actual number ~~is~~ probably is less.

For convenience, the following table of reference is constructed:

Table of reference of eye

- 1. Cement glands. The oral hooks are collectively located. Hosts are land animals -----1. Archiacanthocephala
- 6 cement glands in general. Oral hooks aligned in radial fashion alternately. Hosts are mainly aquatic animals -----2. Palaeacanthocephala
- Cement glands are multinuclear cells; the "storage-sac" is present. Oral hooks are aligned in radial fashion. Hosts are aquatic animals -----3. Eoacanthocephala.

The first order is not related. The above-mentioned parasites belong to the second and the third order.

Palaeacanthocephala. Those belonging to this order have the oral hooks drawn up in ~~a~~ small cubes; main "groove-tubes" are on the side; in a female, the single "ligament sac" breaks. In a male, there usually are six cement glands; there is no protonephridium. The main families are Rhadinorhynchidae, Gorgorhynchidae, Polymorphidae, and Echinorhynchidae. The species mentioned above belong to the three families excluding the ~~second~~ Eoacanthocephala. In this order the oral hooks are ~~aligned~~ aligned in ~~radial~~ a radial fashion; there is no protonephridium; the cement glands are multinuclear cells with a large nucleus; the secretion ~~is~~ pours into the "storage-sac". The main families are Palliseridae, Quadrigyridae, Neoechinorhynchidae, and Hebesomidae, and others. The one related here is Neoechinorhynchidae only.

The first record of ~~the genus~~

is parasitic on salmonoid fishes (In the literature of Japan) was in the article by Tsunenobu Fujita on *Acanthocephalus* entitled "Vermes Parasitic On Fry of ~~Some~~ Salmonoid Fishes" in 1916 in Vol. 28 of *Dobutsugaku Zasshi*; the specie was not identified. The same author wrote on *Echinorhynchus gadi* MÜLL (= *E. acus* RUD.) and a new specie *Acanthocephalus echigoensis* in Vol. 32 of *Dobutsugaku Zasshi* in 1920; the next year, in 1921, he reported on *A. oncorhynchi* n. sp. in Vol. 33 of *Dobutsugaku Zasshi*. In 1931 VAN CLEAVE published *Acanthocephalus aculeatus* n. sp. which is parasitic on *Oncorhynchus nerka*, and *A. acerbus* n. sp., which is parasitic on *Salmo irideus* Gibbons, in Vol. 13 of *Dobutsugaku Ruiho*. In 1935 Isokichi Harada discussed marked variations in the number of hooks, the number of rows of hooks, or the size of eggs in Vol. 14 of *Taihoku Teikoku Daigaku Rinogaku-Bu Kiyo* (*Taihoku Imperial University Science and Agriculture Faculty Bulletin*), and stated that the above four species of *Acanthocephalus* should be all identified as *A. echigoensis*. In 1936 the author and Tetsuo Morishita made a report on one male and one female specimens of *Acanthocephalus echigoensis*, which had been obtained by Mifusa Kurozawa in *Salmo macrostoma* from Sano River in Yamanashima<sup>-Ken</sup>, in on page 761 of Vol. 48 of *Dobutsugaku Zasshi*. *Fish Pathology* ~~by Mifusa~~ (1937) by Tsunenobu Fujita mentions, in addition to the above-mentioned species, *Acanthocephalus angullae* (MÜLL), which is parasitic on *Oncorhynchus masou*; of *Echinorhynchus*, the publication mentions *E. salmonis*

and *E. truttae* SCHIRANK  
 MÜLLER, which is parasitic on *Oncorhynchus keta* and *Nippon spinosus* in  
 Europe, ~~EMMENTHEIM~~ *Bolbosoma @ caeniforme* (HEITZE), which is  
 parasitic on *Oncorhynchus nerka* in Kamchatka, and *B. heteracanthae*  
 (HEITZE) in *Oncorhynchus keta* in Europe. In 1937 the author and Tetsuo  
 Morishita published *Rhadinorhynchoides miyagawai* n. g., n. sp., which  
 had been obtained from *Salvelinus pluvius* from Taguchi River in Niigata-  
 Ken, in Vol. 21 of *Jikken Igaku Zasshi* (~~EXPERIMENTAL MEDICINE~~ Journal  
 of Experimental Medicine). Further, in the same year in the same pub-  
 lication, Tetsuo Morishita published *Neoechinorhynchus tsintaensis*  
 n. sp., which he had obtained from *Oncorhynchus masou* in Tsingtau.

Reports of U. S. A. and Canada mention at the beginning  
*Echinorhynchus* sp. and *Bolbosoma* sp.; however, the former is *E. gadi*  
 and among the collection, which ~~was~~ <sup>was</sup> made in rivers and lakes  
 during Apr. - May, 1955, the name of *Neoechinorhynchus rutili* appears.  
 In the collection, which was made in ~~in~~ <sup>in</sup> July-Sept., 1955, *Echinorhyn-*  
*chus* and *Bolbosoma* are noted; the fact that the former may be useful  
 in <sup>d</sup>etermining the borderline of fish distribution is also indicated.  
 MARGOLIS's 1956 report shows *Echinorhynchus gadi*, *Nipporhynchus* sp.,  
*Corynosoma strumosum* later period larvae, *Corynosoma* spp. late period  
 larvae, *Bolbosoma* sp. late period larvae, and *Neoechinorhynchus rutili*.  
 Of these, the genus, *Nipporhynchus*, was established by A. C. CHANDLER  
 in 1934 in his thesis, "A revision of the genus *Rhadinorhynchus* with  
 the descriptions of new genera and species", which was published on  
 p. 355 of *PARASITOLOGY*, Vol. 26 No. 3. However, <sup>in 1935</sup> Sanaka Yamaguti ~~in~~ at

the end of his supplementary article on a new species, Rhadinorhynchus katsuwonis, of Harada and notes that there is not sufficient evidence to regard it as a new genus. AXMEPOB's report mentions six species-- Echinorhynchus gadi, E. salmonis, Corynosoma strumosum, Bolbosoma caenoforme, Neoechinorhynchus crassus, and N. cristatus. The listing of the above is as follows:

Palaeacanthocephala order

Echinorhynchidae family

- Acanthocephalus acerbus VANCELEAVE, 1931
- A. aculeatus VANCELEAVE, 1931
- A. echigoensis FUJITA, 1920
- A. oncorhynchi FUJITA, 1921
- Echinorhynchus gadi ZOEGER in MÜLLER, 1776
- E. salmonis MÜLLER
- E. sp.
- E. truttae SCHRANK

Rhadinorhynchidae family

- Nipporhynchus sp.
- Rhadinorhynchoides miyagawai FUKUI et MORISHITA, 1937

Polymorphidae family

- Bolbosoma caenoforme (HEITZE)
- B. sp.
- Corynosoma strumosum HEITZE
- C. spp.

← Eoacanthocephala order

Neoechinorhynchidae family

- Neoechinorhynchus crassus VANCELEAVE
- N. cristatus LYNCH
- N. rutili (MÜLLER)
- N. tsintaoensis MORISHITA, 1937

Of the above Acanthocephalus becomes a species of A. echigoensis, if we agree with Harada's theory. For reference, the

characteristic of several parts are listed from the original publication.

Consideration of such factors as the ~~development~~ growth of the specimens, the state of preservation of the material, original variations leads one to the belief that these four species are identical as was shown by Harada. The author examined and compared the reproductive organs with ~~them~~ respect to ~~the~~ the original description and the diagram; he failed to find differences sufficient to identify them <sup>as</sup> <sup>o</sup> separate species. The comparisons were not made with type specimens; therefore, nothing definite can be ~~made~~ stated. However, the author is inclined to accept Harada's theory.

(2) Echinorhynchus. E. gadi is found parasitic on <sup>in</sup> salt water fishes; Sanaka Yamaguti reports, in his 1935 report, finding it in

"kinguchi" (golden mouth), Cyclogaster owstoni (JORDAN et SNYDER),  
 Stereolepis ishinagi (HILGENDORF), ~~Hexagrammos~~ Hapalogenys nigripimis  
 TEMMINCK  
 (~~Hexagrammos~~ et SCHLEGEL), Arctoscopus japonicus (STEINDACHNER), Hexa-  
 grammos otakii JORDAN et STARKS~~X~~, and Linanda punctatissima (STEIN-  
 DACHNER), and others. As the specific name indicates, it is ~~found~~  
 prevalent in cod. The author has obtained it in a red snapper in  
 Hokuriku. ~~Hexagrammos~~ E. salmonis cannot be compared since ~~the~~ the author  
 has not seen the ~~original~~ original description. Numerical information in Fish Patho-  
 logy by Fujita differs considerably from E. gadi; thus, it appears  
 that it is a different specie.

(3) Nipporhynchus. This genus was published as a new specie by A. C.  
 CHANDLER in ~~an~~ his article, "A revision of the genus Rhadinorhynchus  
 with descriptions of new genera and species", on page 355 of Vol. 26,  
 Parasitology in 1934. The name was given ~~to~~ the parasite, which  
 Isokichi Harada published as Rhadinorhynchus katsuwonis, which is  
 parasitic on bonito, in his article, "A new species of Acanthocephala  
 from the Japanese Bonito, Euthynnus", published on p. 10 Vol. 2 of  
~~Shu~~ <sup>Shu</sup> ~~Robutsugaku~~ <sup>Robutsugaku</sup> ~~Ruiho~~. Its marked characteristics ~~are~~ <sup>are</sup> four long and  
 thin cement glands. However, even the reference to Chandler's original  
 article, as Yamaguti states, does not reveal sufficient differences  
 to define as a new specie. MARGOLIS' report mentions Nipporhynchus sp.;  
 however, it probably is Rhadinorhynchus katsuwonis. The author collected  
 specimens which ~~appear~~ appear to belong to the present species. However, there are some  
 points of ~~the~~ difference; therefore, the report on it will be made ~~in~~ <sup>later</sup> in

(4) Rhadinorhyncoides. This genus was defined as a new genus by the author and Tetsuo Morishita in 1937 as was stated above. <sup>A</sup> brief ~~outline~~ <sup>outline</sup> of its characteristics are as follows: the <sup>lip</sup> is cylindrical; the oral hooks in the front <sup>are</sup> smaller than those at the back and those on the ventral side are larger than those on the dorsal side; there are no hooks on the body, which is cylindrical in shape, and on the head; the "lip-sheath" is cylindrical; the walls are double; the brain is located in the middle of the "lip-sheath"; the lemniscus is a little shorter than the "lip-sheath" and is "finger-shaped"; the <sup>S</sup>teticulus is ~~is~~ aligned vertically ~~and~~ adjacent to one another and is located in the anterior portion of the posterior half of the body; there are four cement glands which are arranged parallel to one another in a group of two; the ovarium is circular; the uterus and the uterine bell are short; mature eggs fill the coeloma; the "middle shell" has elongated terminals; the inner shell is distinct. The present genus resembles Leptorhyncoides KOSTYLEV, 1914 or Tenuisentis VANCELEAVE. However, it ~~differs~~ differs completely in the number of cement glands, ~~shape~~ shape, or "<sup>lip</sup>lip-sheath".

The author feels that one Rhadinorhynchus aspinosus FUKUI et MORISHITA (Jikken Igaku Zasshi Vol. 21, No. 1, p. 39), which has been obtained in Teutis fuscescens (HAUTTUYN), should be classified ~~as~~ as belonging to the present genus.

(5) Bolbosoma. The species belonging to the present genus can be easily recognized by its extraordinary shape, ~~where~~ <sup>where</sup> e. e., there is an extremely swollen portion following the neck, followed by a markedly

67.67.67.67.67.67.

parasite parasite parasito

the main trunk of thin portion, which forms the body.

There are many <sup>spines</sup> bristles

in this swollen portion. <sup>spines</sup> The bristles form roughly two bands. The

mature parasite of this genus is parasitic on salt water mammals; those, which infect salmonoid fishes, are larvae. As has been mentioned above, MARGOLIS' and AXMEPOB's reports mention B. caeniforme. However, Fujita (Fish Pathology) states that the identification was made on immature specimens. The author obtained many larvae from Oncorhynchus gorbuscha in Hokkaido; however, since the reproductive organs were not developed sufficiently, the identification was impossible.

(6) Corynosoma. The mature parasite of This genus is also parasitic on sea birds and marine

animals. The anterior portion of the body is extremely thick. The <sup>spines</sup> body bristles are found to the posterior portion of the body. Thus the genus can be recognized easily. There are species which have <sup>spines</sup> bristles around the genital opening located at the posterior end of the body. The species of this genus are not in the author's material.

(7) Neoechinorhynchus. The characteristics of this genus are that

it is small in size generally, and that it has a large nucleus in <sup>cell</sup>

the epidermis. The <sup>lip</sup> lip is short and circular; ~~it~~ it

has few hooks of which the ones located in the anterior end are <sup>extremely</sup> large.

reports mention N. crassus, N. cristatus, N. rutili and N. tsintaoensis;

however, they were <sup>are</sup> caught ~~in~~ (all) in fresh water. There ~~is~~ no specimens

in the author's possession which belong to the present genus.

Copopoda

With reference to Copopoda, which is parasitic on salmonoid

among the Japanese literature fishes, one can cite the reference to 6 species -- *Caligus rapax*, *Lepeophtheirus salmonis*, *L. stromii*, *Lernaeopoda carpionis*, *L. salmonea*, and *L. edwardsii*-- in Fish Pathology by Tsunenobu Fujita in 1937. In each case, it is the introduction of the specie found in Europe.

Following this in 1939, Sanaka Yamaguti published a new specie, *Lepeophtheirus uenoi*, on page 451 of Dr. Sadao Yoshida *Hin Shukuga Kinen-Shi*, Obun-Hen, 2-Kan ( Dr. Sadao Yoshida Congratulatory Commemorative Publication, European Language Volume, Vol. 2). U. S. and Canadian

reports mention *Lepeophtheirus salmonis*, *Ergasilus* sp., and *Salmincola falculata*; AXMEPOB's report mentions four species, *Salmonicola thymalli*, *Salminicola edwardsi*, *S. bicauliculata*, and *Lepeophtheirus salmonis*.

(Note: the references in the author's possession ~~show~~ spell *Salmiricola*, *Salmonicola*, and *Salminicola*. The author feels that ~~these~~ these were errors in printing. Since the author cannot confirm it, they were

~~repeated~~ copied as they appear). In 1954 Riichi Hoshina and Takeshi E Suenaga published *Salminicola yamame* n. sp., which he obtained ~~from~~ from *Salvelinus pluvius* on page 75 of No. 1, Vol. 41 of Jour. Tokyo

Univ. Fisheries. The listing of these species are as follows:

#### Caligidae

1. *Caligus rapax* (M. EDWARDS)
2. *Lepeophtheirus salmonis* KRÖYER
3. *L. stromii* (BAIRD)
4. *L. uenoi* YAMAGUTI, 1939

#### Ergasilidae

5. *Ergasilus* spp.

#### Lernaeopodidae

6. *Lernaeopoda carpionis* KRÖYER

7. L. salmona KRÖYER
8. L. edwardsii OLSSON
9. Salmincola bicauliculata
10. S. edwardsi OLSSON
11. S. falculata (WILSON, 1908) WILSON, 1915
12. S. thymalli KESSLER
13. S. Yamame HOSHINA et SUENAGA, 1954

The author found many specimens of this genus in the two collections, which had been forwarded to him from the Fisheries Agency. The list was shown on pages 628 to 632 of Part I. However, <sup>these</sup> ~~these~~ ~~names~~ agreed completely with <sup>uenoi</sup> Lepeophtheirus. Thus, <sup>the</sup> ~~the~~ author reported them under this name. However, in U. S., Canadian, and Soviet reports <sup>they are</sup> ~~these~~ identified as *L. salmonis*. Thus, the author felt that, if these <sup>were</sup> ~~were~~ an entirely different specie, ~~these~~ they would be useful in establishing a distribution border of fishes. However, the author came to have ~~his~~ doubt on reading MARGOLIS' thesis, "The identity of the Species of *Lepeophtheirus* (Copepoda) parasitic on Pacific Salmon (Genus *Oncorhynchus*) and Atlantic Salmon (*Salmo Solar*)", on p. 889-892 of *Can. J. Zool.* 36 (1958). He made extensive investigations of this genus in salmonoid fishes both in the Pacific and Atlantic, ~~extensively~~ consulted ~~an~~ literatures extensively, and wrote that the identification as a new specie by Yamaguti ~~was~~ was the result of inadequate description by C. B. Wilson and T. and A. Scott whose reports <sup>he</sup> had used as references. The author agrees with this view. Thus, he feels that *L. uenoi* and *L. salmonis* should be regarded as synonymous. <sup>is</sup> ~~This~~ <sup>which</sup> is all the material the author has on this genus.

VIII Protozoa

The author made <sup>almost</sup> no consideration of Protozoa which are parasitic on salmonoid fishes. However, since the present volumes are not for specialists, he will give a general outline as a reference.

The first reference <sup>in the literature of this country</sup> seems to be the report on *Myxidium oncorhynchi* n. sp. (*Oncorhynchus masou*), *Chloromyxum salvelini* n. sp. (*Salvelinus leucomaenis*), *Ch. chitosense* n. sp. (*Oncorhynchus keta*), *Ch. giganteum* n. sp. (*Oncorhynchus gorbuscha*) and *Ch. quadriforme* n. sp. (*Oncorhynchus keta*, *Oncorhynchus gorbuscha*, and *Oncorhynchus masou*) by Tsunenobu Fujita in his article "Studies on Myxosporidia of Japan" in 1923.

In 1935 Muneo Watanabe reported on *Ichthyophthirius multifiliis*; there are other reports on "white spot" disease. Books and reports by Hisao Kobayashi in 1935 and 1936 and Fish Pathology by Tsunenobu Fujita in 1937 mention this. Further, the book by Fujita mentions *Costia* sp. (fry of *Oncorhynchus masou*), *Cyclochaeta domerqueri* (fry of *Oncorhynchus masou*), *Lymphosporidium truttae* (*Salvelinus fontinalis*, U. S. A.), *Lentospora cerebralis* (HOFFER) (*Salmo irideus* GIBBONS<sup>?</sup>, Europe; *Oncorhynchus masou*, the Atlantic Ocean; *Salvelinus Fontinalis*), *Octomitius intestinalis truttae* (MOROFF) (*Salmo irideus* GIBBONS, Europe), *O. salmonis* MOORE (U. S. A.), *Myxidium oviforme* PARISI (*Oncorhynchus masou*, Europe; *Salmo irideus* GIBBONS, U. S. A.), *Chloromyxum truttae* LÉGAR (*Oncorhynchus masou*, France), <sup>and</sup> *Thelohania ovicola* (AUERBACH) (Nippon spinosus, Switzerland). Although there is no mention of it in U. S. and Canadian reports, AXMEPOB's report mentions *Henneguya*

salminicola WARD (Oncorhynchus keta, Oncorhynchus nerka, Oncorhynchus

kisutch, Salmo thymallus). The list of these is as follows:

Flagellata (=Mastigophora)

Tetramitidae

- 1. Costia sp. (Author's note: C. pyriformis DAVIS, 1943?)

(? in original manuscript)

Hexamitidae

- 2. Octomitus intestinalis truttae (MOROFF)
- 3. O. salmonis MOORE

(Author's note: This genus is now Hexamita).

~~Sporezoa~~  
Sporozoa

Chloromyxidae

- 4. Chloromyxum chitosense FUJITA, 1923
- 5. Ch. giganteum FUJITA, 1923
- 6. Ch. quadriforme FUJITA, 1923
- 7. Ch. salvelini FUJITA, 1923

Myxidiidae

- 8. Myxidium oncorhynchi FUJITA, 1923
- 9. M. Oviforme PARISI

Myxosomatidae

- 10. Lentospora cerebri (HOFFER)

(Author's note) This genus is now Myxosoma)

Myxobolidae

- 11. Henneguya salminicola WARD

Nosematidae

- 12. Thelohania ovicola (AUERBACH)

Family unknown

- 13. Lymphosporidium truttae

Ciliata

Holophryidae

- 14. Ichthyophthirius multifiliis FOUQUET

Urceolariidae

- 15. Cyclochaeta domerquei WALLENGREN

The author examined the gall-bladders and the bile of

material which he had collected in Hokkaido. He found nothing which

resembled a spore. Since this ~~had~~ <sup>had</sup> not much relation to the present investigation, the examination was not carried further.

Annelida. Hirudinea.

As one, which is parasitic on salmonoid fishes, <sup>Fish</sup> Pathology by Fujita on page 47 mentions Pontobdella moorei OKA only. <sup>^</sup> There is no other record. It appears that it infects fresh water fish; however, there is no other record.

Acarina.

Some ticks were found in a bottle, which contained Anisakis salaris, which is parasitic on Oncorhynchus keta, in the collection forwarded to the author from the Fisheries Agency, and in a bottle, which contained Philonema, which is parasitic in ~~an~~ Oncorhynchus nerka, and in ~~an~~ a bottle, which contained parasite from Oncorhynchus keta. The latter two were sent from the U. S. A. It is not known whether these ticks had happened to be in the bottles, whether these entered the bottle during collection, or whether these were in the <sup>live</sup> internal organs of fishes. The ~~unsuccessful~~ attempt at an identification is now being made; ~~unsuccessful~~ when it is completed, on the basis of the ecology of the genus <sup>(will <sup>be</sup> answered)</sup> these questions.

## IX Results of the Investigation and Discussion

As the reading of Part I and Part II of the present report will reveal, what the author has done is to identify a very small number of species among the parasites which are parasitic on <sup>a</sup> few main salmonoid fishes. Further, they are all known species. Nothing new

has been gained.

As was stated in Part I, there have been many reports concerning parasite on salmonoid fishes in this county; ~~unpublished~~ Tsunenobu Fujita especially published many new species. However, many of these dealt with ~~the~~ material which ~~was~~ <sup>was</sup> ~~were~~ obtained in fresh water. Only <sup>a</sup> few reports ~~was~~ by Fujita ~~is~~ <sup>are</sup> available concerning material from the sea. The present investigations by the author were conducted mainly on material which had been obtained in the ocean. The author is grateful for having been given this opportunity. ~~Some of the~~ <sup>Some of the</sup> ~~reasons~~ <sup>reasons</sup> for the lack of worthwhile results are as follows:

- (1) The ~~unpublished~~ <sup>of parasites</sup> collection was made by amateurs on board a ship where the ~~unpublished~~ working was difficult.
- (2) The number of fish investigated was few.
- (3) The work was carried by the author in his spare time between his main work and ~~unpublished~~ many other work.
- (4) Number of days was few on account of conferences and other reasons.
- (5) In sufficient literature.

When the author was first asked by the Fisheries Agency, he understood the work to be a mere identification of parasites collected. On this basis he accepted the work. However, the work developed into the area related to ~~the~~ <sup>fisheries</sup> problems between Japan, U. S. A. and Canada, into the problem of distinguishing the American and the Asiatic strains, <sup>on the basis of parasites</sup> or into the problem of border with respect to the distribution of fish

In the north Pacific Ocean. With respect to ~~whammmmm~~ this situation the author has already made several recom<sup>m</sup>endations to the Fisheries Agency. In order to solve the problems of the nature mentioned above, it will be necessary to fullfill at least the ~~whammmmmmmmmmm~~ following conditions:

- (1) It will be necessary to have a specialist in parasites who will devote full time to the investigation.
- (2) <sup>will be</sup> It ~~is~~ necessary to establish a place and employ<sup>a</sup> number of people to investigate many fishes.
- (3) It will be necessary to continue the investigations for at least five or six years.
- (4) Thus, ~~whammmmmmmmmmm~~ a large expenditure will be necessary.

~~whammmmmmmmmmm~~

LEO MARGOLIS made important contributions. The author

feels that the reasons for his success are:

that the work was done in a specialized research institute, that he is a young, and able, and full time worker, and that the work was carried with sufficient funds and with a well-equipped library.

The problem of the investigation of ~~sm~~ parasites in fish <sup>in future</sup> will occur in connection with fisheries problems with U. S. A., Canada, Soviet Union as well as with ~~whammmmm~~ China and other countries in the south. I would ~~whammmmm~~ suggest that the Fisheries Agency set up a specialized agency to carry on research and investigation with able and young parasitologists to accumulate knowledge.

the author  
Finally ~~the~~ apologizes that the investigations, which were

undertaken with ~~much~~ so much effort, did not yield much useful results on important points. At the same time he would express his deepest appreciation for assistance and co-operation to officials of concerns both public and private.
