SAVOR THE FLAVORS

Register Today!

Register now for the Academy of General Dentistry (AGD) 2010 Annual Meeting & Exhibits, July 8 to 11, and the AGD House of Delegates, July 6 to 8, and prepare to savor the flavors of New Orleans! Visit ***www.agd.org/neworleans*** and click on "Register Now" to sign up today. The registration brochure is available for download exclusively on the AGD 2010 Annual Meeting & Exhibits Web site. This registration program is simply too hot to mail!

For your convenience, registration is available at *www.agd.org/neworleans*.

Participants can register online on our Web site or by downloading the registration brochure and faxing the registration form with their credit card information to 312.440.0513 or by mail to Academy of General Dentistry, Annual Meeting, 38943 Eagle Way, Chicago, Illinois 60678-1389. On-site registration will be available as well. See you in New Orleans!

Advisory Board

Dental Materials
Steve Carstensen, DDS, FAGD, is in general practice in Bellevue, Washington. He is a visiting faculty member of the Pankey Institute and the Pride Institute and is a Diplomate of the American Board of Dental Sleep Medicine.

Dental Public Health
Larry Williams, DDS, ABGD, MAGD, is a Captain in the United States Navy Dental Corps, currently stationed at the Great Lakes Naval Training Center as a member of the Great Lakes Naval Health Clinic. CAPT Williams is the Public Health Emergency Officer for the 16 states of the Navy Region MidWest and for the Naval Health Clinic. He also serves as the Co-Chair of the Navy's Tobacco Cessation Action Team and as a member of the Department of Defense Alcohol and Tobacco Advisory Council. He also teaches for the Dental Hygiene program at the College of Lake County and as an assistant clinical professor for the Rosalind Franklin University for Medicine and Science.

Esthetic Dentistry
Wynn H. Okuda, DMD, is Past National President (2002–03) and a board-accredited member of the American Academy of Cosmetic Dentistry (AACD). He also is on the Advisory Board of Best Dentists in America and on the Executive Council of the International Federation of Esthetic Dentistry (IFED). He practices cosmetic, implant, and restorative dentistry at the Dental Day Spa of Hawaii in Honolulu.

Endodontics
Stephen Cohen, DDS, is one of the foremost endodontic clinicians in the country and lectures worldwide on endodontics. A board-certified endodontist, Dr. Cohen specializes exclusively in the diagnosis and treatment of endodontic infections.

Geriatric Dentistry
Lea Erickson, DDS, MSPH, is Chief, Dental Service, at VA Salt Lake City Health Care System and Clinical Assistant Professor, University of Utah in Salt Lake City.

Implantology
Wesley Blakeslee, DMD, FAGD, is a general dentist who practices in New Jersey. He is a Diplomate of both the American Board of Oral Implantology/Implant Dentistry and the International Congress of Oral Implantologists, and an Associate Fellow of the American Academy of Implant Dentistry.

Oral and Maxillofacial Pathology
John Svirsky, DDS, MEd, is a board-certified oral and maxillofacial pathologist at Virginia Commonwealth University in Richmond. He currently is a professor of oral and maxillofacial pathology and maintains a private practice in oral medicine and oral pathology.

Oral and Maxillofacial Radiology
Kavas Thunthy, BDS, MS, MEd, has been a professor of oral and maxillofacial radiology in the Department of Oral Diagnosis, Medicine, Radiology, at the Louisiana State University School of Dentistry in New Orleans since 1975. He was named a Fellow in the American Academy of Oral and Maxillofacial Radiology in 1978 and was board certified by the American Board of Oral and Maxillofacial Radiology in 1981.

Oral and Maxillofacial Surgery
Karl Koerner, DDS, FAGD, is a general dentist in Utah who performs oral surgery exclusively. He lectures extensively on oral surgery in general practice and has made articles, books, and video presentations available to general practitioners.

Oral Medicine
Sook-Bin Woo, DMD, MMSc, is assistant professor of Oral Medicine, Infection and Immunity at Harvard School of Dental Medicine. She is board certified in Oral and Maxillofacial Pathology and Oral Medicine and practices both specialities in the Boston/Cambridge area in Massachusetts.

Orthodontics
Yosh Jefferson, DMD, FAGD, is Past President, International Association for Orthodontics; a Fellow of the American Academy of Craniofacial Pain; and a member of the American Academy of Dental Sleep Medicine. He maintains a general practice in Mt. Holly, New Jersey.

Pain Management
Henry A. Gremillion, DDS, MAGD, is dean of the Louisiana State University School of Dentistry and a professor in the Department of Orthodontics at LSUSD.

Pediatrics
Jane Soxman, DDS, is a Diplomate of the American Board of Pediatric Dentistry, has authored numerous articles in the dental literature, and has been recognized as a leader in continuing education. She maintains a private practice in Allison Park, Pennsylvania.

Periodontics
Sebastian Ciancio, DDS, is Distinguished Service Professor and Chair, Department of Periodontics and Endodontics, Adjunct Professor of Pharmacology, and Director of the Center for Dental Studies at the University at Buffalo, State University of New York.

Pharmacology
Daniel E. Myers, DDS, MS, is a member of the Oral Diagnosis Department, Dental Associates of Wisconsin, Ltd. in Wauwatosa.

Prosthodontics
Joseph Massad, DDS, is currently the Director of Removable Prosthodontics at the Scottsdale Center for Dentistry in Arizona. He is adjunct faculty at Tufts University School of Dental Medicine in Boston and the University of Texas Dental School at San Antonio.

Jack Piermatti, DMD, is a Diplomate of the American Board of Prosthodontics, the American Board of Oral Implantology, and the International Congress of Oral Implantologists. He is a board-certified prosthodontist in private practice in Voorhees, New Jersey.

Life's challenges

Most of life's lessons are learned the hard way, and I make this statement from personal experience. All of us seek to combine happiness with self-esteem, and our life experiences shape that pursuit every day. The key to being happy is balancing the internal scale that measures positive and negative feedback and reactions. Every dentist wants to lead a full life, complete with loving relationships, satisfying work, and an overall sense of happiness. With our world in an increasingly violent, sad, stressful, and fast-paced state, happiness is often hard-won and can be even harder to hold onto. We need to find a way to deal with the triumphs, tragedies, stress, and changes in our lives.

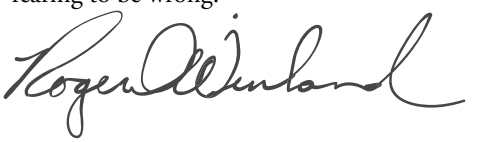
The most important internal coping skill we can develop is our own self-esteem. We are all born without judgment; however, as we grow, the world tends to shuttle us into categories, grouping us based on what we look like and where we come from, and telling us what we can and cannot do. With a solid, positive sense of self-esteem, we can accept who we are and what we do, and not waste energy wondering why we are not someone else or feeling sorry for ourselves for being what we are. We can boost our self-esteem by using the most powerful tool we have—our thoughts. To say this aloud might sound like boasting, but the fact is that there is no one like you and no one who can do what you can do. It's no crime to know that—or to remind yourself of it when you need to.

While your work is clearly valued by patients and colleagues, none of us are completely free from criticism. Allowing those barbs to get under our skin, however, is another matter, as I learned from two experiences that took place during my time in the military.

During my internship, an oral surgeon berated those around him to make his points. He used criticism as a teaching tool. Conversely, at my first duty station, the colonel (an oral surgeon to whom I directly reported) would tell me to try a surgical procedure; if I ran into difficulty, he would be there to help. Now whose name do you think I remember some 40 years later? Which one do you think I still respect and admire? All of us know that we are better than those whose only way to elevate themselves is to put others down. Those people are more to be pitied than censured.

We can build up an immunity to the criticisms of others by silencing the critic within ourselves. We should keep track of our accomplishments to keep self-criticism to a minimum. We must remember all of the dental procedures that went well, rather than dwelling on the one case that turned out less than perfect. Ours is not the only profession that fails to score a triumph every single time.

Years ago, Franklin D. Roosevelt proclaimed to a frightened people that "the only thing we have to fear is fear itself." Our fears are usually rooted in low self-esteem—the fear that we will fail at what must be done, and thus shouldn't even attempt it. To overcome these fears, I recommend trying new things—by seeking new experiences and facing new challenges, you'll develop a wide range of skills, talents, and qualities. What's more, you'll demystify the monster known as Failure. Confidence comes not from always being right, but from not fearing to be wrong.



Roger D. Winland, DDS, MS, MAGD
Editor

Cardioprotective aspirin—Update on three previous special alerts

Richard L. Wynn, PhD

Through its antiplatelet action, low-dose aspirin can prevent arterial thrombosis in both high-risk patients with known occlusive vascular disease and in low-risk healthy patients with no known history of vascular disease.[1]

Among patients with a 4–8% annual risk of serious vascular events, aspirin prevents at least 10–20 fatal and nonfatal vascular events for every 1,000 patients who take the drug for one year.[1] In addition, it is estimated that aspirin (and possibly other platelet-inhibiting drugs as well) reduces the risk of nonfatal myocardial infarction (MI), nonfatal stroke, or death from vascular causes by approximately 25%.[2] Studies suggest that daily doses of aspirin (75–100 mg) are optimal for the long-term prevention of serious vascular events in high-risk patients.[2,3]

Studies suggest that daily doses of aspirin (75–100 mg) are optimal for the long-term prevention of serious vascular events in high-risk patients.

Among every 100 patients at a lower annual risk of vascular events (<4%), aspirin reduces the risk of MI by about 30%.[4] However, it probably has no significant effect on the risk of stroke, as the literature reported a similar number of strokes among those using aspirin and those who did not.[4]

This column will discuss three special alerts of clinical importance that relate to aspirin patients.

Sudden aspirin discontinuation may elevate the risk of MI

It was reported in 2004 that patients with acute coronary syndrome (ACS) who discontinued aspirin therapy had worse short-term outcomes than individuals not previously on aspirin therapy.[5] That same year, Fischer *et al* reported similar findings and suggested that daily aspirin users who discontinue aspirin use may increase the risk of MI.[6] In 2005, a *Harvard Health Letter* stated that quitting aspirin "cold turkey" could be dangerous and that aspirin withdrawal has been linked to heart attacks.[7]

According to Fischer *et al*, patients who stopped taking NSAIDs (including aspirin) were at greater risk for acute myocardial infarction (AMI) over a 29-day period compared to non-users. The risk of AMI was highest in subjects with rheumatoid arthritis or systemic lupus erythematosus. Current or past NSAID use (*past* meaning discontinued therapy 60 days or more prior to evaluation) was not associated with any increased risk of AMI. The authors concluded that the risk of AMI increases during the first several weeks after cessation of NSAID or aspirin therapy.[6]

Collett *et al* reported that temporary withdrawal of aspirin is common and an acute rebound effect with coronary thrombosis may result. This 2004 study examined a cohort of 1,358 patients admitted for suspected ACS: 930 nonusers, 355 prior users, and 73 recent withdrawers. *Nonusers* were defined as patients who had not taken any oral antiplatelet agents for the six months prior to admission and had no history of vascular disease. *Prior users* were patients who took either aspirin (97%) or another oral antiplatelet agent as chronic therapy to prevent acute vascular events without cessation during the three weeks prior to admission. *Recent withdrawers* were patients who had stopped taking oral antiplatelet agents during the three weeks before admission.[5]

At 30 days, there was no statistical difference between nonusers and prior users in terms of the incidence of death or MI (10.3% for nonusers compared to 12.4% for users). The withdrawers had higher 30-day rates of death or MI (21.9% vs. 12.4%) and bleedings (13.7% vs. 5.9%) than prior users. Five percent of the 73 patients admitted with ACS had withdrawn oral antiplatelet agents during the three weeks before admission.

Oral antiplatelet agents were found to be an independent predictor of both mortality and bleedings at 30 days. It was concluded that prior users of oral antiplatelet agents and patients who had recently interrupted oral antiplatelet agent use displayed worse clinical outcomes than nonusers.[5]

Update

Warnings against the premature discontinuation of aspirin remain valid. A 2009 literature review updated the risks associated with discontinuing aspirin antiplatelet therapy and the bleeding risks associated with continuing aspirin during surgical procedures.[8] The authors confirmed the possibility of a pharmacological rebound phenomenon that could lead to adverse ischemic events, and supported previously issued warnings against premature discontinuation of aspirin.[5,6,8]

In an analysis of data obtained from 50,279 patients, Biondi-Zoccai *et al* reported that the patients who withdrew or did not adhere to aspirin therapy had a threefold risk of major adverse cardiac events compared to those who used aspirin. The risk was amplified by a factor of 89 among patients who had undergone stenting.[9]

A 2005 study by Burger *et al* reported that as many as 10.2% of ACS cases follow interruption of aspirin therapy by a mean delay of 8.5 days; this delay is consistent with rebound platelet activity. The delay was longer for a cerebrovascular event (approximately 14.3 days) and for peripheral arterial syndromes (approximately 25.8 days). The authors also reported that acute thrombotic complications are not immediate and usually follow interruption of aspirin therapy after a mean delay of 8–25 days, a time lapse consistent with normal platelet turnover required to replace the platelet pool in circulation and one that suggests a rebound phenomenon.[10]

Ibuprofen may interfere with aspirin's cardioprotection

In a statement released on September 8, 2006, the FDA notified consumers and health care professionals that administering ibuprofen as a pain reliever may interfere with aspirin's cardiovascular benefits. The report stated that ibuprofen can interfere with the antiplatelet effect of low-dose aspirin (81 mg daily), which could diminish the effectiveness of aspirin used for cardioprotection and stroke prevention. The FDA added that although ibuprofen and aspirin can be taken together, patients should talk with their health care providers for additional information concerning the effectiveness of such a regimen.[11]

In addressing situations where these drugs would be used concomitantly, the FDA indicated that patients who use immediate-release aspirin (non-enteric-coated aspirin) and take a single 400 mg dose of ibuprofen should wait at least 30 minutes after taking aspirin before taking ibuprofen, or take the ibuprofen more than eight hours before aspirin ingestion to avoid attenuating the effect of aspirin.[11]

Although available data did not allow the FDA to issue recommendations about the timing of a 400 mg dose of ibuprofen for patients taking enteric-coated low-dose aspirin, one study showed that the antiplatelet effect of enteric-coated low-dose aspirin was attenuated when ibuprofen 400 mg was taken 2, 7, or 12 hours after aspirin.[12] With occasional use of ibuprofen, there was likely to be minimal risk from any attenuation of the antiplatelet effect of low-dose aspirin, due to aspirin's long-lasting effect on platelets.[12]

At present, there are no clear data regarding if or how the antiplatelet effect of aspirin would be affected by chronic ibuprofen dosing of more than 400 mg; however, according to Catella-Lawson *et al*, acetaminophen does not appear to interfere with the antiplatelet effect of low-dose aspirin.[12]

Other OTC NSAIDs (that is, naproxen sodium) should be considered capable of interfering with the antiplatelet effect of low-dose aspirin until proven otherwise. A 2005 study by Capone *et al* suggested that naproxen may interfere with aspirin's antiplatelet activity when the two are co-administered; however, 500 mg of naproxen administered two hours before or after 100 mg of aspirin did not interfere with aspirin's antiplatelet effect.[13]

Update

According to recent studies, other NSAIDs may be involved in blunting the antiplatelet effects of aspirin. A 2008 study by Gladding *et al* compared the *ex vivo* antiplatelet effects of six NSAIDs (300 mg tiaprofenic acid, 400 mg ibuprofen, 25 mg indomethacin, 550 mg naproxen, 200 mg sulindac, and 200 mg celecoxib) to determine whether these agents antagonize the effects of aspirin. Platelet function was measured 12 hours after the administration of each NSAID. The NSAID was administered again two hours before aspirin (300 mg) and platelet function was reassessed 24 hours after aspirin.[14] Platelet function was assessed by Platelet Function Analyzer 100 closure time in normal subjects in a randomized, blinded, multiple crossover study.

The Platelet Function Analyzer 100 closure time is an *in vitro* test that simulates the conditions of platelet aggregation at a vascular wall injured site. Whole blood is aspirated from a reservoir through a capillary and a biologically active membrane. As blood flows through

the aperture, platelets begin to adhere and aggregate; the *closure time* refers to the time required before the platelet thrombus occludes the aperture completely; as the length of closure time increases, so does the antiplatelet effect.

Closure time was significantly prolonged 12 hours after the administration of naproxen, while the other NSAIDs did not cause significant prolongations. Compared with placebo plus aspirin, closure time was significantly reduced when ibuprofen, indomethacin, naproxen, or tiaprofenic acid were given before aspirin. The authors concluded that ibuprofen, indomethacin, and naproxen all block the antiplatelet effect of aspirin. Sulindac and celecoxib did not demonstrate any significant antiplatelet effect or reduce aspirin's antiplaletlet actions. Based on these results, it was suggested that sulindac and celecoxib may be the NSAIDs of choice for patients who must take aspirin and NSAIDs concomitantly.[14]

A 2008 study by Gengo *et al* measured the magnitude and duration of inhibition of platelet aggregation in a group of healthy volunteers following doses of aspirin or ibuprofen taken alone or in combination.[15] Ten subjects underwent three randomized treatment sessions: aspirin (325 mg) alone, ibuprofen (400 mg) alone, and finally ibuprofen (400 mg) followed two hours later by aspirin (325 mg). Ibuprofen given prior to aspirin resulted in a significant reduction in both the magnitude and the duration of aspirin's inhibitory effect on platelet aggregation.[15]

The same authors performed a confirmatory study over 27 months, as patients treated with aspirin (325 mg daily) for secondary stroke prophylaxis while taking an NSAID were identified.[15] None of the 18 patients who were taking either ibuprofen (200–800 mg per dose) or naproxen (220–500 mg per dose) with aspirin demonstrated inhibited platelet aggregation; however, all 18 showed such inhibition after discontinuing the NSAID and 13 experienced a recurrent ischemic episode while taking an NSAID and aspirin concomitantly. The authors concluded that ibuprofen and naproxen prevent aspirin's irreversible inhibition of platelet aggregation, which is needed for secondary stroke prophylaxis. This interaction can have clinical consequences for patients taking aspirin.[15]

A strong advisory warning against the discontinuation of dual aspirin/clopidogrel antiplatelet therapy in patients with coronary artery stents

For coronary patients, aspirin and clopidogrel (Plavix, Bristol-Myers Squibb) in combination is the primary prevention strategy against stent thrombosis after the placement of a drug-eluting metal stent.[16] According to a 2007 advisory issued by the American Heart Association (AHA), discontinuing this drug combination prematurely increases the risk of a catastrophic event of stent thrombosis, which can lead to MI and/or death.[16] To prevent thrombosis at the site of a drug-eluting stent, the advisory stresses a 12-month combination therapy of aspirin and clopidogrel after placement and recommends educating both the patient and the health care provider about the hazards of premature antiplatelet-drug discontinuation. Any elective surgery should be postponed for one year after stent implantation. If surgery must be performed on high-risk patients with drug-eluting stents, the practitioner should consider continuing the antiplatelet therapy during the perioperative period.[16]

The advisory panel was concerned that antiplatelet therapy sometimes is prematurely discontinued within a year after stent implantation, either by the patient or by a health care provider who may not realize the consequences of discontinuing the antiplatelet combination. According to the panel, the leading adverse event resulting from discontinuation is stent thrombosis, which can result in AMI or death.[16]

Update

A 2008 report by Chhatriwalla and Bhatt recommended extending dual antiplatelet therapy with aspirin and clopidogrel for more than one year (perhaps indefinitely) in all patients receiving drug-eluting stents. This recommendation was based on a current body of randomized and observational evidence which indicated that extending antiplatelet therapy improved cardiovascular outcomes for patients with ACS, a prior history of ischemic events, or percutaneous coronary intervention with bare metal stents or drug-eluting stents.[17]

More recently, a literature review by Eisenberg *et al* sought to examine the safety of short-term discontinuation of antiplatelet therapy. Of 161 cases of late stent thrombosis found in the literature, 19 occurred in patients who were receiving dual antiplatelet therapy (aspirin and Plavix) at the time of the event. If patients stopped both drugs, the median time to late stent thrombosis was seven days. Among patients who stopped Plavix with no ill effect and subsequently stopped aspirin, the median time to event was seven days from the time of aspirin cessation. By comparison, the median time to event was 122 days when Plavix was stopped but aspirin was maintained.[18]

Among the 48 patients who stopped both agents, 36 cases of late stent thrombosis (75%) occurred within 10 days. By comparison, of the 95 patients who discontinued Plavix but continued aspirin, only six cases (6%)

occurred within 10 days. The authors concluded that short-term discontinuation of Plavix may be relatively safe in patients with drug-eluting stents, provided that aspirin therapy is maintained.[18]

Intracoronal cast gold restorations

Bruce W. Small, DMD, MAGD

Cast gold has been used as a dental restorative material for more than 100 years. Taggart is generally credited with being the first to perform the dental gold casting technique.[1] Cast gold that is cast and finished properly displays wear very similar to that of natural teeth.[2] A 2004 article by Donovan *et al* reported that intra- and extracoronal cast gold restorations had an overall survival rate of 95.4% after 52 years.[3] In many cases, intracoronal cast gold restorations can be constructed for both functional and esthetic purposes (Fig. 1–3)—which begs the question: Why do so relatively few restorative dentists place intracoronal cast gold restorations? This column attempts to answer that question while also describing the technique for the preparation of a Class II cast gold inlay.

Intracoronal gold—Why not?

The technique for casting intracoronal cast gold restorations does not get sufficient attention from most dental schools, especially now that the construction of a cast restoration is no longer included in licensing examinations within the U.S. Since the demand for cast gold restorations has diminished, qualified cast gold technicians have retired and new ones are not being trained. Consequently, many teeth that could be restored using a conservative intracoronal restoration are being prepared for ceramic inlays or full coverage of some kind.

In the 1970s, porcelain-fused-to-metal (PFM) crowns were introduced, as were direct and indirect tooth-colored restorations. All three contributed to the shift from cast gold to materials with a shorter lifespan.

In addition to the paucity of opportunities to learn about cast gold restorations, some dental insurance companies have declined to cover such procedures, which affects a dentist's treatment plan options when a tooth needs to be restored.

Class II inlay technique

Most intracoronal cast gold restorations begin with a Class II inlay. The following paragraphs will describe the clinical procedure for a Class II inlay.

Removal of existing restoration and caries

After anesthesia is administered and a rubber dam is placed, the old restoration and/or caries is removed (Fig. 4). If the caries is on a virgin tooth and this is the initial entry into that tooth, one might consider a direct gold foil or other type of restoration. Do not remove any healthy tooth structure at this time, even if the excavation creates an undercut. The tooth should be examined very closely for any fracture lines or wear facets, particularly internal cracks seen on the pulpal floor. If there are fracture lines on the pulpal floor but no clinical signs of pain or discomfort, it may be possible to complete the preparation and place a long-lasting inlay. The patient

Fig. 2. A maxillary occlusal view of the patient in Figure 1.

Fig. 3. A mandibular occlusal view of the patient in Figure 1.

Fig. 4. An ill-fitting all-ceramic restoration prior to removal.

Fig. 5. Preparation of maxillary premolar for a disto-occlusal cast gold inlay.

should be informed as to the prognosis and an onlay or other restoration that will help to hold the tooth together should be considered.

Placement of blockout and preparation

After removing the old restoration and any caries, place a blockout or a build-up material in the cavity. The blockout is utilized to fill in any undercuts, thus allowing the operator to create an ideal preparation with the proper depth, draw, and flare of the proximal walls while conserving as much tooth structure as possible. The blockout should have a draw of approximately 6 degrees on each wall (including the axial wall), with the proximal walls flared enough to break contact, thus allowing the dentist to finish the margins with sandpaper disks (Fig. 5). The occlusal portion of the preparation should be at least 2 mm deep, with an axial depth of approximately 1.5 mm.

The preparation (particularly the cavosurface margins) can be refined using hand instruments and a 7404 finishing bur with a pear-shaped head. Using hand instruments, place an external bevel of 60 degrees on the cavosurface of any proximal box and add a 30 degree internal acuteness to two surface restorations on premolars without a definitive keyway. The internal acuteness aids in seating and draws the casting close to the axial wall.

Impression and laboratory construction

After the final refinement of the preparation, a very precise impression should be taken. The rubber dam septum should be cut and a retraction cord placed. Following the appropriate amount of time (usually three to five minutes), remove the rubber dam and place a cotton roll holder (if operating on the mandibular arch) and possibly a dri-angle (if working on the maxillary arch). Controlling moisture is mandatory.

Fig. 6. An occlusal view of a completed disto-occlusal cast gold inlay.

Fig. 7. The lingual view of completed disto-occlusal cast gold inlay.

The impression should be poured as soon as possible to prevent any dimensional change in the impression material. The wax-up is completed and the inlay cast is finished and polished to the operator's specifications. A Type 2 gold is recommended for constructing the casting.

Seating, finishing, and polishing

After placing the rubber dam, try-in the inlay and adjust the contact, if necessary. If the preparation was designed to provide sufficient retention and it fits properly, zinc phosphate is the cement of choice, as it allows the operator to adjust the working time of the cement mix. Other, more adhesive cements are available, but most will harden too quickly, making it difficult to remove excess material.

Finish the inlay using paper-backed sandpaper disks. Rotating carefully from gold to tooth, the disks are used to level the gold with the tooth in three planes. Three grits of sandpaper disks are recommended for finishing: medium garnet, fine sand, and fine cuttle used on a straight mandrel at slow speeds.

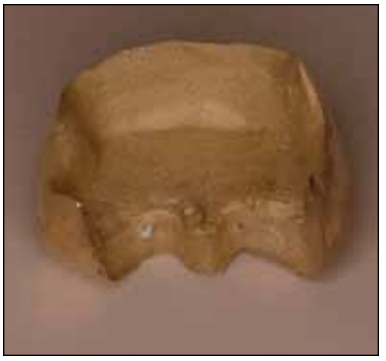

Fig. 8. A gold casting showing an integral pin.

Fig. 9. An example of a cast gold onlay with a Tucker pin in the center of casting.

Fig. 10. An example of a two-surface cast gold restoration with an integral pin in the restoration.

Fig. 11. An example of a two-surface cast gold restoration with a large lingual bale.

Finally, any scratches made on the inlay by the disks should be removed and the polishing procedure completed. This step is accomplished by using three powders (a wet No. 4 flour of pumice, a wet 15 µ aluminum oxide powder, and a dry 1 µ aluminum oxide powder) in webbed rubber prophy cups. The end result should be highly polished and have no reflective margins (Fig. 6 and 7).

Additional retention techniques

After the completion of a surface preparation, an operator may determine that extra retention is necessary. In the author's experience, it is common to use additional retention in large, wide open preparations or clinically short teeth. Clinical experience is the best guide for deciding the most appropriate treatment plan for any particular case. The most common methods are adding integral pins (Fig. 8 and 9), slots (Fig. 10), or bales (Fig. 11).

Summary

Cast gold is by far the longest lasting dental material available.[3] However, cast gold has been used less frequently for intracoronal restorations since the "esthetic revolution" of the early 1970s. As a result, more direct composites and tooth-colored inlays, onlays, and crowns are being placed, with each having problems of sensitivity, secondary caries, fracture, and increased wear. The author recommends that dentists obtain some exposure to intracoronal cast gold techniques so that they can determine which type of restoration is most appropriate for their patients.

Impression materials—Are there any *really* new ones?

Michael B. Miller, DDS, FAGD

Polyethers (PEs) and vinyl polysiloxane (VPS) materials are the most popular classifications of impression materials for precision restorations such as inlays, onlays, crowns, and bridges. But you might be amazed to know that PEs were first introduced by ESPE (before the company was purchased by 3M) in 1965—yes, Impregum (3M ESPE) has been around that long! Dentsply Caulk led the way with VPS materials by bringing Reprosil to the market back in 1982. A quick check shows that there have been no other major category advancements in the material side of impression-taking for 28 years!

A quick check shows that there have been no other major category advancements in the material side of impression-taking for 28 years!

So what has changed—and which of these changes really affect your chances of taking the perfect impression the first time?

Hydrophilicity

One of the main advantages PEs have over VPS products is their inherent hydrophilicity. Hydrocolloid, which still has a very small segment of the impression material market, is the epitome of this type of material. It is generally considered that the greater a material's hydrophilicity, the less likely that fluid in the sulcus or really anywhere else on the preparation will distort the impression; the hydrophilic material will merely absorb the fluid and continue with its mission of registering an accurate and detailed impression. This property also goes hand-in-hand with the ability of the impression material to "wet out" on the preparation and capture better detail. This latter property has enhanced my own experience taking impressions over the years with PEs, especially Permadyne (3M ESPE), which has long been one of my favorite materials.

Dentsply Caulk trumped the market again with the first "hydrophilic" VPS material (Aquasil) in 1997. Since that time, there has been a race among manufacturers to be the first to create VPS materials with as much hydrophilicity as PE materials. Note that hydrophilic properties in VPS products need to be additives, since, unlike PEs, these materials are not inherently hydrophilic. This race escalated recently when several manufacturers released marketing videos to illustrate what happens when you place a drop of water on a set or even an unset mix of impression material. Presumably, the material is not hydrophilic if it beads up like water on a freshly waxed car; however, if it flattens out, it will do the same on a preparation in the mouth, showing that it has enhanced hydrophilicity and wetting out ability.

The REALITY Research Lab (RRL) has developed a more clinically relevant (albeit more labor-intensive) test, in which an acrylic model with prepped and intact extracted teeth is impressed with different materials after the teeth have been dried, coated with a glistening layer of water, or coated with a rather thick film of freshly captured saliva. Not only are the impressions and models examined closely, but full-cast crowns are fabricated and marginal gaps are measured under a stereomicroscope at 50x. A recent RRL product comparison showed virtually no differences between two popular materials, Flexitime (Heraeus Kulzer, Inc.) and Aquasil Ultra (Dentsply Caulk).

On the other hand, one VPS material bucking the hydrophilicity trend is Precision (Discus Dental), which is marketed as "hydrokinetic" (which simply means "moving water"). Well, you can't move water if you also have an affinity for it, which is the essence of the meaning of "hydrophilic." Therefore, another way of

describing "hydrokinetic" would be "hydrophobic." In other words, this product essentially returns to the early days when all VPS materials were hydrophobic. The RRL also tested this product, but the manufacturer did not specify another product as a control. This makes it more difficult to interpret the data, although there were virtually no differences between the experimental groups, indicating that this product will perform as the manufacturer claims it will.

Does any of this matter when you are trying to take an accurate impression? Well, if the sulcus is filled with fluid (including blood), thus obscuring your margin, it could definitely make a difference. If you are using a supremely hydrophilic material, you hope that the product will literally soak up the fluid similar to a sponge and, at the same time, register the impression.

On the other hand, if the material is hydrokinetic, the aim is to move the fluid out of the sulcus first and then capture the margin. Is this a better strategy? The answer is probably yes, since there is less chance that the fluid will distort the material, which could happen if the fluid is absorbed.

But if this strategy is preferred, why have virtually all manufacturers opted for the hydrophilic route? One reason could be the mob mentality: If it works for one company, then other companies will produce the same item with some slight tweaks. Another reason is that the hydrokinetic concept flies in the face of the trend. Hydrophilic is the *in* concept, from bonding agents to cements to sealants. Why should impression materials be any different? Hydrophilic PEs followed in the successful footprints of hydrophilic hydrocolloid. Finally, only one company thought of using the hydrokinetic approach.

So should you switch to a hydrokinetic impression material? Not necessarily. There are numerous other factors to consider, such as working and setting times, flow, availability in different delivery systems, and so forth. All of these criteria may be as important or even more so than hydrophilicity.

Of course, none of this matters at all if you use proper soft tissue management before you even lay a diamond on the tooth. I obsess over tissue management, so I believe that preventing a bloody sulcus is much more effective than having to deal with it after the fact. As admirable as this goal may be, though, it doesn't always happen. Therefore, an impression material that will work in less than optimal conditions has significant value, which is why PEs continue to garner kudos from their devotees: These products tend to be less sensitive to moisture and have a terrific ability to wet out the preparation under adverse conditions.

Viscosity and flow

This issue depends on how you prefer to take an impression. Personally, I prefer a very light body/heavy body combination: I look for a light body material that syringes easily and flows well without being too runny, and a heavy body tray material that will push the syringe material firmly against the preparation and, at the same time, not allow it to run down the patient's throat, which materials with very low viscosity have a tendency to do. Less popular is a monophase material for both the syringe and tray.

The combination of very low viscosity syringe materials and heavy body tray materials is not new, although the RRL tests on flow using the Shark Fin device developed by 3M ESPE have found more recently introduced materials with high flow. So, if you're like me, you no longer have to stick with one or two brands to get better flow in your syringe material.

Hardness/stiffness

With the increasing popularity of closed mouth impressions (especially with sideless trays), a more rigid or stiff material should work better by providing lateral support, although to my knowledge, this theory has never been proven in a clinical comparison. Nevertheless, using a digital durometer, the RRL has found a few materials that are, indeed, stiffer than the rest. Just don't be tempted to use a very rigid material for a full-arch impression, especially if you are using a well-fitting custom tray—you may need a "knee-on-chest" maneuver to remove it from the patient's mouth!

Dispensing options

Another area that has undergone some significant changes is the mixing/dispensing of materials. The hand-mixing required for tube-based products has been largely replaced with cartridge-based products that are mixed and dispensed using a ubiquitous automix gun. However, these guns are not exactly cutting-edge any longer; they look like you bought them in a home improvement store, and can make filling a full-arch tray a real challenge for an auxiliary due to the hand and forearm strength required for heavy body materials.

To overcome the disadvantages of guns, ESPE introduced the first electronic mixer in 1995. There have been tweaks and speed improvements in these machines, which have been cloned by a handful of competitors over the ensuing 15 years, but the overall design is largely the same as that of the original version.

For syringe materials, at least two VPS products have unidose versions. While I like unidose packaging, it

doesn't seem to have caught on with impression materials and has not been a significant factor in product selection.

Intraoral working time

Our thirst for speed has resulted in the availability of a number of very fast-setting materials, which can be a real time-saver when you impress one or two teeth. However, when you try to stretch the use of fast-set materials for more than the aforementioned one or two teeth, the intraoral working time of these materials becomes a major issue.

Unfortunately, the working times provided by manufacturers are typically determined at room temperature. While this provides some comparison between products, it doesn't really give you much indication about how much time you have between starting to syringe the material around your preparation and when you need to seat the tray. For example, if you are taking a 10-unit impression, how much time do you have from when you syringe material around the first preparation and when you need to seat the tray? This is critical to know because the material syringed around the first of the 10 preparations is already starting to set before you've reached the last preparation; this setting is accelerated by the heat and moisture of the mouth. If it sets too fast, the tray material will not bond adequately to the syringe material and you'll most likely end up with wrinkles or other types of distortion.

To my knowledge, there are only two extended working time VPS materials on the market—Aquasil Ultra Xtra (Dentsply Caulk) and Multi-Prep (Clinician's Choice)—both of which have been introduced in recent years. For large cases, it would be prudent to consider using one of them.

Tear strength

If you have ever removed an impression from a patient's mouth and found that it has torn on a critical marginal area, you know how important this property is. I recently took an impression for 10 veneers in a patient who had open gingival embrasures. Normally, I would block out these embrasures from the lingual to prevent the impression material from locking into them and tearing when it is removed from the mouth. But I was using an "improved" formula of a well-known material (Take 1 Advanced, Kerr Dental) that had claims of high tear strength. Therefore, on this case, I decided to go for it and dispense with the block out procedure. Sure enough, the impression tore. I took a second impression and it also tore.

The guru of tear strength testing, in my opinion, is Dr. Alan Boghosian, a member of the REALITY Editorial Team. Dr. Boghosian and his colleague recently completed a test of eight impression materials for the RRL. The material I used that tore in the mouth scored in the middle of the pack, meaning it did not quite match the strength forecast by the manufacturer. To be fair, even though the impressions I took did indeed tear, the margins were still captured and the veneers seated beautifully.

Nevertheless, since a torn impression can ruin an otherwise perfect effort, it would be wise not to tempt fate. Block out areas that could cause tears, such as the aforementioned open embrasures—assuming, of course, that these areas don't need to be captured.

What to use?

Many aspects of taking an impression are personal. For example, you get to select the material that meets your flow and set time requirements. Beyond that, don't get too caught up with pseudo-categories like "vinyl polyether silicone" or marketing slogans such as "polyeasier." There are still only two real classes of impression material, the same as there have been for the past 28 years. And remember, no impression material can do it all. To get the best of all worlds, you probably need to stock two or three different types of material to cover all clinical situations as efficiently and productively as possible.

Asymptomatic carotid artery calcifications discovered on panoramic radiography

Mohammad Ali Dolatabadi, DDS ▪ Mohammad Hosein Kalantar Motamedi, DDS ▪ Eshagh Lassemi, DDS
Yousef Janbaz, DDS

This article presents the case of a 50-year-old asymptomatic man whose panoramic radiograph revealed calcium deposits within the left internal carotid bifurcation region. Subsequent duplex ultrasonic examination indicated unilateral low-grade carotid arterial stenosis, a condition associated with a significant risk of stroke, which had not been identified previously. The findings on the panoramic radiograph prompted appropriate and potentially lifesaving treatment. Dentists who are well-versed in diagnosing calcified plaques on panoramic radiographs can play a major role in the early referral and treatment of undiagnosed asymptomatic patients.

Received: November 21, 2008
Accepted: February 6, 2009

The most common manifestations of atherosclerosis are coronary artery disease, peripheral vascular disease, and cerebrovascular accidents (strokes).[1] A 2009 article reported that carotid artery calcification is responsible for an estimated 5% of ischemic strokes.[2] Stroke survivors face lifelong disabilities such as loss of mobility, aphasia, and depression.[3] Atheroma-related formations of thrombi and emboli in the carotid artery are the most frequent causes of stroke.[2] Early detection of carotid atherosclerosis not only can save lives but also may reduce medical expenditures.

Friedlander and Lande reported that panoramic radiology could aid in detecting patients at risk of stroke.[4] Calcified atherosclerotic lesions in the carotid bifurcation can be detected in the lower corners of the panoramic radiograph, adjacent to the cervical spine and hyoid bone; such lesions may appear as a nodular radiopaque mass or as double radiopaque vertical lines within the neck. These calcifications are found on panoramic radiographs inferior-posterior to the angle of the mandible, at the lower margin of the third cervical vertebra and the entirety of the fourth cervical vertebra; such lesions are approximately 1.5–4.5 mm in size (Fig. 1).[5]

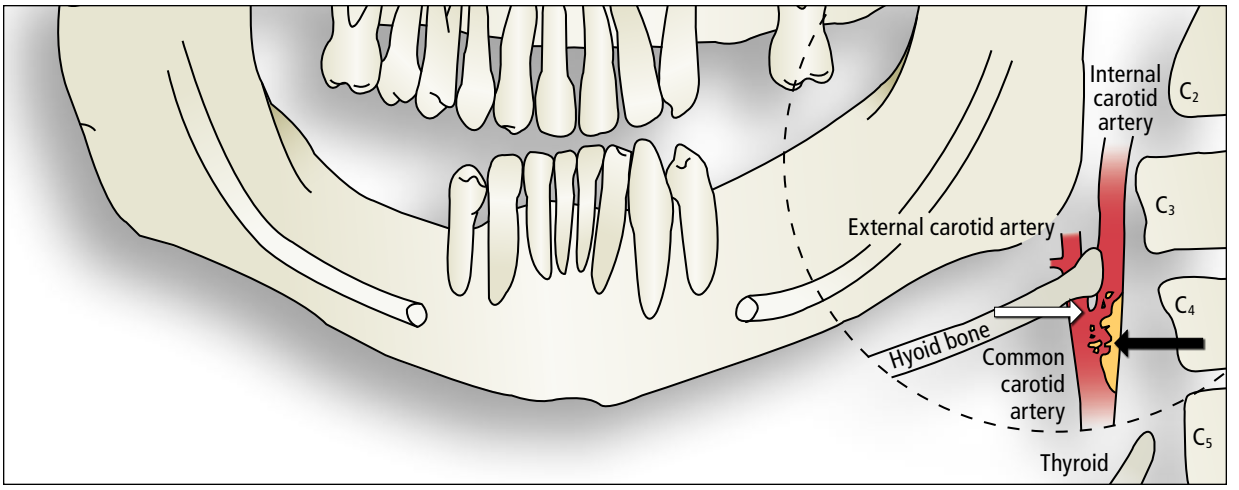

Fig. 1. A schematic illustration of the relationship of the common carotid artery, the internal carotid artery, the external carotid artery, and the structures usually seen on a panoramic radiograph. Note the process of embolization of atherosclerotic debris (black arrow) at the carotid bifurcation (white arrow).

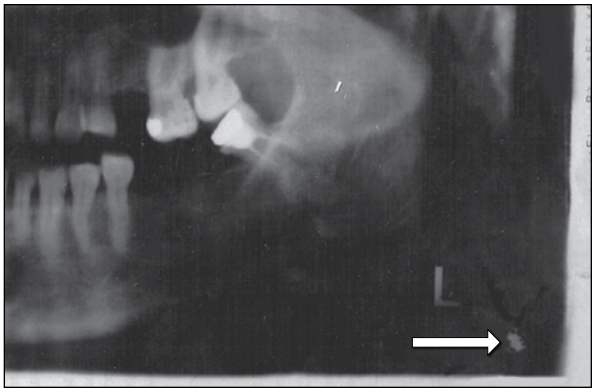

Fig. 2. The calcifications (arrow) appeared as heterogeneous radiopacities overlying the carotid bifurcation near the tip of the greater horn of the hyoid bone, approximately 2.5 cm posterior and 2.5 cm inferior to the cortical rim of the midpoint of the mandibular angle.

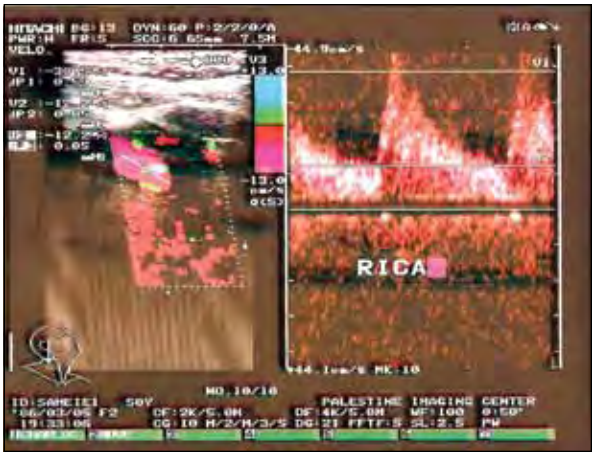

Fig. 3. A color-flow duplex sonography image of the left internal carotid artery confirming the presence of atheroma.

Case report

A 50-year-old man came to the dental office for comprehensive dental care. His medical history revealed non-insulin-dependent diabetes mellitus, hyperlipidemia (controlled with oral medication), and tobacco use (which he had ceased one year earlier). The patient had no history of medical problems, and his primary care physician had not diagnosed any other illness during his last examination. A panoramic radiograph taken during his dental treatment revealed the presence of single, irregular, non-homogenous radiopacities lying over the left carotid bifurcations. The calcifications were located inferior to the angle of the mandible and the tip of the hyoid bone and superior to the tip of the thyroid cartilage and the C3, C4, and C5 vertebrae (Fig. 2).

Carotid duplex ultrasonography revealed a left unilateral carotid stenosis (Fig. 3). Small calcified plaque (4 x 2 mm) was seen in the left internal carotid artery but did not display any hemodynamic symptoms. The patient was referred to his specialist for further management.

Discussion

According to Khosropanah *et al,* panoramic radiographs have a sensitivity of 66.6% and a positive predictive value of 45%, indicating that they cannot be considered accurate or reliable for detecting carotid artery calcifications.[2] However, dentists who review oral panoramic radiographs should look for incidental calcifications lying over the carotid bifurcation region. The patient in the present case had no signs or symptoms of carotid artery disease and may not have been evaluated or screened for atherosclerotic disease had these calcified carotid plaques not appeared on the panoramic radiograph. He had unilateral low-grade stenosis and he needed follow-up for changes in plaque size and form, which could cause symptoms requiring surgical removal.

Diagnosis

Stenosis is best determined by using duplex ultrasonography, which is inexpensive, easily available, accurate, and noninvasive. Duplex ultrasonography measures the increase in blood velocity produced by a focal stenosis (a process known as the *Bernoulli Effect*), thus indirectly yielding information concerning the severity of stenosis. Similar calcifications are found in the coronary arteries of individuals with ischemic heart disease.[6]

Differential diagnosis

Atherosclerosis is not the only cause of soft tissue calcifications seen anterior to the cervical vertebrae on panoramic radiographs; in fact, carotid calcifications must be differentiated from calcified triticeous/thyroid cartilage, calcified lymph nodes, and non-carotid phleboliths (sclerosing hemangiomata).[7] When an anterior-posterior radiograph of the neck uses soft tissue exposure settings, calcifications within the carotid arteries will appear lateral to the spine; by contrast, calcifications in the thyroid gland, thyroid cartilage, triticeous cartilage, or epiglottis will appear in the midline, superimposed over the spine. Phleboliths (sclerosing hemangiomata) and calcified acne or lymph nodes are other calcifications that may be

superimposed over the same part of the panoramic film. By contrast, the stylohyoid and calcified stylomandibular ligaments are situated posterior to the mandibular ramus.

Treatment

Carotid endarterectomy, which consists of using a variety of techniques for local removal of the atherosclerotic plaque, has been conclusively shown to reduce the risk of stroke among symptomatic and asymptomatic patients who have significant plaque lesions (that is, a stenosis of 60% or more).[8,9] Duplex ultrasonography—the most accurate screening method short of angiography—is noninvasive and relatively inexpensive; however, screening all patients is impractical and not cost-effective. High-risk groups for whom ultrasonic screening might be cost-effective include those with bruits or atherosclerosis in other parts of the body.

Audible cervical bruits may be caused by turbulent blood flow, tortuousity, high flow rates through otherwise normal vessels, a cardiac problem, or carotid artery stenosis. Although the presence of a bruit does not necessarily indicate carotid artery stenosis, most physicians believe that their presence increases the patient's risk of developing carotid artery stenosis and that they are an indication for ultrasonic evaluation.[10,11] In addition, because atherosclerosis tends to be a systemic problem, 10–12% of patients with lower extremity and coronary atherosclerosis also have significant carotid artery stenosis.[12,13] Dentists should refer these patients to a physician for a cardiovascular evaluation to receive proper and timely medical treatment.

Occlusive disease in either location (extremity or coronary) has become a *de facto* indication for carotid ultrasonography. To date, however, there are no universally accepted screening criteria, and the decision to refer a patient for ultrasonic evaluation remains that of the individual physician.

Summary

Although panoramic radiographs do not have a 100% sensitivity or positive predictive value for detecting carotid artery calcifications, dentists should make a point of examining them for incidental calcifications over the carotid bifurcation region. When that is the case, dentists can refer their patients to a physician for a cardiovascular evaluation to receive proper and timely medical treatment.

Medication use in geriatric populations: Dental implications of frequently prescribed medications

Mary A. Aubertin, DMD ▪ Carlton Horbelt, DDS ▪ Waletha Wasson, DDS ▪ Marjorie Woods, DDS

Anticipated demographic changes in the U.S. during the next 20 years will bring increasing numbers of geriatric patients into dental practices. It is expected that these patients will have multiple co-morbid medical conditions and will have to take multiple medications as a result. Dental practitioners must stay informed concerning newly marketed drugs and those commonly prescribed to geriatric patients, and the potential dental implications of those drugs. Specialized training in geriatric dentistry, continuing education, and consultation with medical and pharmacy practitioners can provide valuable tools for managing this special patient population.

Received: May 20, 2009
Accepted: August 18, 2009

The demographic changes anticipated in the next 20 years are expected to lead to an increased interest in the health concerns of older adults.[1] The prevalence of medical conditions is high among geriatric patients, and the concomitant incidence of medication use increases with age.[2-6] Geriatric patients may be at high risk medically due to cumulative illnesses, and their treatments require specialized dental skills, medical monitoring, and careful pharmacological management.[4] The medications commonly used to treat disease states associated with aging may have notable side effects and drug interactions; these effects may be exacerbated in geriatric patients. In a recent study of dental school patients, Miller *et al* reported that approximately 57% of all drugs taken had the potential to affect dental care adversely and to create life-threatening drug interactions.[4] Today's dentists must be able to assess complex medical conditions, multiple and complex medication regimens, and how each of these affects the patient's oral and overall health and the provision of dental care.

Common medical disorders among geriatric patients include cardiovascular disease, hypertension, dislipidemia, diabetes mellitus and other endocrine disorders, respiratory diseases, musculoskeletal disorders, neurological disorders, and chronic pain.[2-4,7] Cardiovascular drugs are the most common group of drugs used by geriatric patients and elicit dentally significant adverse effects.[2,3,6-8] More often than not, however, geriatric patients are taking multiple medications. The most frequently prescribed medications that may impact dental management of older patients include cardiovascular drugs, NSAIDs, gastrointestinal agents, psychotropic agents, and endocrine agents.[8]

Not only do dentists need to be familiar with their patients' medical disorders, they also must carefully analyze their patients' medications.[2,9] Increased knowledge of pharmacology as it pertains to geriatric patients and advanced dental management of this special patient population are essential.[4] When patients provide incomplete or vague medical or medication histories, medical consultation, pharmacist consultation, or family member clarification should be performed before any dental treatment begins. Many of these chronic complex medical conditions and their drug therapies, combined with the frequent use of OTC drugs, place the patient at risk for adverse outcomes during dental therapies.[4,5] To compound matters, at least 40% of geriatric patients receive drugs from two or more physicians and 12% of older patients either take medications prescribed for someone else or take their own medications incorrectly.[6]

Geriatric patients often have chronic and sometimes complex health problems and consume more medication than any other age group.[2,5] The use of multiple drugs (from multiple drug categories) increases with age.[2] Independent elders take at least one to four medications daily, while elders in long-term care take an average of 5–14 medications daily.[1-4,6,9] Polypharmacy, multiple co-morbid medical conditions, and physiological changes in terms of the absorption, distribution, metabolism, and excretion of drugs affect geriatric patients' responses to medications,

placing them at a higher risk of side effects and adverse effects.[6,7,9,10]

Physiological changes that result during normal aging are in large part due to increases in total body fat, circulatory changes, decreased organ function, and decreases in total body water and lean body muscle mass.[6,9] As a result, lower doses of medications are often necessary to reach therapeutic concentrations in older patients, and these doses may remain in body tissues for longer periods of time. Poor nutritional status and drug interactions also enhance adverse or toxic reactions.[11]

Adverse effects are considered to be unwanted, unintended, preventable, or toxic injuries caused by a drug; they may appear as physical or oral manifestations.[2] Important adverse reactions include side effects, drug allergy, and toxic reactions.[1] Known risk factors for adverse drug interactions include administration to geriatric patients, administration to medically compromised patients, use of drugs with small margins of safety, and chronic drug therapies which utilize drugs that are excreted slowly.[5,11] Adverse drug effects are common in geriatric patients, affecting approximately 25% of older patients and accounting for 10–17% of hospitalizations of geriatric patients.[6,9]

As patients take increasing numbers of prescription and non-prescription drugs, several factors can increase the likelihood of adverse reactions and potential mortality in geriatric patients, including drug interactions, errors in taking medications, prescriptions from multiple physicians, and the physiologic states produced by each drug. The mortality rate associated with adverse drug reactions and the average hospital stay due to drug reaction increases exponentially with the number of drugs taken.[6]

Adverse drug reactions occur most commonly in connection with drugs used to treat congestive heart failure, arthritis, hypertension, diabetes, respiratory tract infections, and prostatic hypertrophy.[6] In addition, the drugs dentists administer and prescribe to geriatric patients may interact adversely with medications prescribed by their physicians. As the number of geriatric patients increases, dentists must be familiar with currently prescribed medications taken by geriatric patients, the diseases for which they are taking these medications, self-administered OTC drugs, potential interactions with dentally prescribed drugs, and adverse drug effects.[6]

This article lists medications commonly prescribed to geriatric patients and adverse effects associated with those drugs.[12-16] Dentists should have a working knowledge of how these drugs act, potential drug interactions, dosing restrictions, and how the body handles these drugs. Because new drugs and new drug combinations are prescribed frequently, unreported drug interactions should be considered.[5]

Adverse interactions with drugs prescribed in dentistry

ACE inhibitors

No dentally significant effects or complications have been reported with quinapril (Accupril, Pfizer Inc.) or benazepril (Lotensin, Novartis Pharmaceuticals). Lisinopril (Prinivil, Merck & Co.) is associated with orthostatic hypotension. Enalapril (Vasotec, Merck & Co.) is associated with orthostatic hypotension and abnormal taste.

In patients with compromised renal function, prescribing NSAIDs may result in further deterioration of renal function. Quinapril may reduce the absorption of quinolone and tetracycline antibiotics. High-dose aspirin, NSAIDs, and salicylates may reduce the therapeutic effects of ACE inhibitors. Lisinopril may increase the toxicity of adverse events from azathioprine, cyclosporine, or NSAIDs.[13]

Aldosterone antagonists

No dentally significant effects or complications of using this drug group have been reported. Prescribing salicylates and NSAIDs (indomethacin) may decrease the natriuretic effect of spironolactone (Aldactone, Pfizer Inc.).[13]

Vasodilators

No dentally significant effects or complications have been reported with hydralazine (Apresoline, Novartis Pharmaceuticals). Nitroglycerin is associated with xerostomia, although normal salivary flow returns once the drug is discontinued.[13] Prescribing NSAIDs may decrease hydralazine's hemodynamic effects.

Calcium channel blockers

Diltiazem (Cardizem, Abbott Laboratories) has been reported to cause a greater than 10% incidence of gingival hyperplasia, which usually disappears once the drug is discontinued.[13] There have been few reports of gingival hyperplasia with amlodipine (Norvasc, Pfizer Inc.).

The blood levels/physiologic effects of diltiazem and amlodipine may be increased by systemic azole antifungals, clarithromycin, diclofenac, doxycycline, and erythromycin. Diltiazem may increase the levels/effects of selected benzodiazepines and cyclosporine.[13]

Anti-arrhythmics

When patients are taking medications that prolong the QT interval (specifically amiodarone), dentists should consult with the patient's physician prior to administering a

vasoconstrictor. Use epinephrine and levonordefrin with caution. Amiodarone is associated with abnormal salivation and taste.[13]

Azithromycin (Zithromax, Pfizer Inc.) may prolong the effect of amiodarone. Cimetidine (Tagamet, GlaxoSmithKline) may decrease the metabolism of amiodarone, which may in turn diminish the therapeutic effect of codeine and decrease the metabolism of cyclosporine and lidocaine.[13]

Anti-adrenergic agents/Beta adrenergic blockers

Carvedilol (Coreg, GlaxoSmithKline) has been associated with postural hypotension and periodontitis. Using NSAIDs (such as ibuprofen and indomethacin) for three weeks or longer may reduce the hypotensive effect of beta blockers; no special precautions are needed for short-term use.[13] Propranolol and nadolol (nonselective beta blockers) enhance the pressor response to epinephrine, resulting in hypertension and bradycardia. Local anesthetic with vasoconstrictor can be used safely on patients taking atenolol (Tenormin, AstraZeneca) or metoprolol.[13,17]

Barbiturates may decrease the serum concentration of beta blockers. Cimetidine may decrease the metabolism of carvedilol. Carvedilol may increase the serum concentration of cyclosporine. Beta blockers may decrease the metabolism of lidocaine. Propoxyphene may decrease the metabolism of beta blockers. Ampicillin may decrease the bioavailability of atenolol. NSAIDs may diminish the antihypertensive effect of beta blockers.[13]

Anti-arrhythmics/Nonselective beta adrenergic blockers

Epinephrine has interacted with nonselective beta blockers such as sotalol to cause an initial hypertensive episode followed by bradycardia.[13] Sotalol is one of the drugs that is known to prolong the QT interval and could result in *torsade de pointes,* a ventricular tachycardia in which the heart rate can range from 150–250 beats per minute.[18] It is not known what effect vasoconstrictors in local anesthetic will have on patients with a known history of congenital prolonged QT interval or on patients taking drugs that prolong the QT interval. Until more information is obtained and reported in the medical literature, it is suggested that dentists consult with the patient's physician prior to the use of a vasoconstrictor and that the vasoconstrictor be used with caution due to the potential for hypertensive episodes.[13]

Angiotensin II inhibitors with or without diuretic

Orthostatic hypotension has been reported with angiotensin II inhibitors.[13] Systemic antifungal azole derivatives may decrease the metabolism of losartan (Cozaar, Merck & Co.). NSAIDs may diminish the therapeutic effect of angiotensin II receptor blockers (ARBs), and NSAIDs used in combination with ARBs may significantly decrease glomerular filtration and renal function.[13]

Loop diuretics

Xerostomia and oral irritations have been reported with loop diuretics such as furosemide (Lasix, Sanofi-Aventis).[16] Systemic corticosteroids may enhance the hypokalemic effect of loop diuretics, while NSAIDs may diminish the diuretic effect.[13]

Thiazide diuretics

Xerostomia, orthostatic hypotension, and hypotension have been reported with thiazide diuretics such as hydrochlorothiazide (Microzide, Watson Pharmaceuticals). Systemic corticosteroids may enhance the hypokalemic effect of thiazide diuretics, while NSAIDs may diminish the diuretic and antihypertensive effects.[13,16]

Anti-anginal agents

Isosorbide dinitrate may cause xerostomia and affect salivation. Normal salivary flow resumes once the drug is discontinued. No significant effects have been noted with isosorbide mononitrate (Imdur, AstraZeneca). There are no reported drug interactions with dentally prescribed drugs.

Potassium replacements

No dentally significant effects, complications, or drug interactions between potassium chloride and dentally prescribed drugs have been reported.

Cardiac glycosides

Vasoconstrictors should be used with caution due to risk of cardiac arrhythmias with digoxin. Digoxin has been reported to cause a sensitive gag reflex, which could affect taking a dental impression.[13]

Systemic antifungal azole derivatives may increase the serum concentration of cardiac glycosides, with the exception of miconazole. Cyclosporine may decrease the metabolism of cardiac glycosides, while kaolin may decrease their absorption.[13]

Osteoporosis treatments

Osteonecrosis of the jaw (ONJ)—a condition generally associated with local infection and/or tooth extraction and delayed healing—has been reported in patients taking bisphosphonates.[13] Symptoms include a nonhealing extraction socket or an exposed jawbone. Most reported cases of bisphosphonate-associated osteonecrosis have been in cancer

patients treated with intravenous bisphosphonates; however, it has also been reported in patients taking oral bisphosphonates for postmenopausal osteoporosis.[13] For patients requiring dental procedures, there are no data available to suggest whether discontinuation of bisphosphonate treatment reduces the risk of ONJ. NSAIDs may enhance the adverse/toxic effect of bisphosphonate derivatives.[19]

Antidiabetic agents

Patients with Type 2 diabetes who are taking glimepiride (Amaryl, Sanofi-Aventis), glyburide, rosiglitazone (Avandia, GlaxoSmithKline), metformin (Glucophage, Bristol-Myers Squibb), or glipizide (Glucotrol, Pfizer Inc.) should undergo dental treatment in the morning to minimize the chance of stress-induced hypoglycemia. Metformin has been associated with taste disorder.[13]

Systemic corticosteroids may diminish the hypoglycemic effect of antidiabetic agents. Adrenal suppression may lead to acute adrenal crisis, which may manifest as enhanced hypoglycemia. Sulfonylureas may increase the serum concentration of cyclosporine. Fluconazole may increase the serum concentration of sulfonylureas. Sulfonamide derivatives and trimethoprim may enhance the hypoglycemic effect of sulfonylureas.[13]

Anxiolytics, sedatives, hypnotics

Zolpidem (Ambien, Sanofi-Aventis), lorazepam, and alprazolam are associated with xerostomia. Normal salivary flow resumes when the drug is discontinued.[13]

Azole derivative antifungal agents (with the exception of miconazole) may decrease the metabolism of zolpidem and decrease the metabolism of benzodiazepines. Zithromax also may decrease the metabolism of benzodiazepines.[13]

Anti-anxiety medications/ antihistamines

Hydroxyzine is associated with xerostomia, although normal salivary flow resumes when the drug is discontinued.[13] No drug interactions have been reported with dentally prescribed drugs.

Anti-dizziness medications

Slight to moderate drowsiness, thickening of bronchial secretions, and significant xerostomia have been reported with meclizine; normal salivary flow resumes when the drug is discontinued.[13] No drug interactions with dentally prescribed drugs have been reported.

Anti-Alzheimer's medications

No dentally significant effects, complications, or drug interactions with dentally prescribed drugs have been reported with drugs such as donepezil (Aricept, Pfizer Inc.).

Respiratory agents

Xerostomia and changes in salivation and dry mucous membranes are associated with ipratropium (Atrovent and Atrovent HFA, Boehringer Ingelheim Pharmaceuticals). Taking ipratropium and albuterol in combination may enhance the adverse/toxic effects of other anticholinergic and sympathomimetic drugs.

Anti-inflammatory medications/analgesics

Celecoxib (Celebrex, Pfizer Inc.) is associated with stomatitis, abnormal taste, xerostomia (normal salivary flow resumes when the drug is discontinued), and unspecified tooth disorder.[13] Nonselective NSAIDs are known to reversibly decrease platelet aggregation via mechanisms different than those observed with aspirin.[20] Celebrex taken at single doses of up to 800 mg or in multiple doses (600 mg twice daily) have no reported effect on platelet aggregation or bleeding time. Meloxicam (Mobic, Boehringer Ingelheim Pharmaceuticals) has been associated with abnormal taste, ulcerative stomatitis, and xerostomia (normal salivary flow resumes when the drug is discontinued).[13]

Systemic corticosteroids may enhance the adverse/toxic effects of COX-2 inhibitors. NSAIDs may enhance the nephrotoxic effect of cyclosporine and increase its serum concentration; they may also enhance the adverse/toxic effects of other NSAIDs and may decrease the excretion of vancomycin.[13]

Antidepressants

No interactions have been reported between vasoconstrictors and citalopram (Celexa, Forest Pharmaceuticals), paroxetine, trazadone (Desyrel, Bristol-Myers Squibb), or sertraline (Zoloft, Pfizer Inc.). However, citalopram and sertraline have been associated with xerostomia and citalopram has been associated with abnormal taste.[13] Xerostomia and changes in salivation, postural hypotension, and abnormal taste have been reported with paroxetine.[13] Problems such as bruxism have been reported with selective serotonin reuptake inhibitors (SSRIs) and may preclude their use.[13] Clinicians attempting to evaluate any patient with bruxism or involuntary muscle movement who is simultaneously being treated with an SSRI should be aware of the potential association. Prolonged use of antidepressants may decrease or inhibit salivary flow.[13]

For patients taking drugs that block the uptake of norepinephrine, vasoconstrictors should be used in limited amounts due to the potential for exacerbation of

hypertension.[13] Dentists should monitor the vital signs of patients who are taking antidepressants that affect norepinephrine, especially venlafaxine (Effexor, Wyeth Pharmaceuticals) and mirtazapine (Remeron, Schering-Plough), which may produce a sustained increase in diastolic blood pressure and heart rate.[13] Significant xerostomia with venlafaxine, mirtazapine, and trazadone may contribute to oral discomfort, especially in the elderly; these drugs are also associated with abnormal taste.[13] No interactions have been reported between vasoconstrictors and escitalopram (Lexapro, Forest Pharmaceuticals), although the drug is associated with xerostomia and toothache.[13]

Amitriptyline prolongs the QT interval and can put a patient at risk for *torsade de pointes*.[13] Dentists should consult with the patient's physician prior to administering a vasoconstrictor to a patient taking amitriptyline. Amitriptyline has been associated with xerostomia and changes in salivation, orthostatic hypotension, stomatitis, peculiar taste, and black tongue. Long-term treatment with tricyclic antidepressants (TCAs) (such as amitriptyline) increases the risk of caries by reducing salivation and the salivary buffer capacity.[13]

SSRIs have several other significant drug interactions of note relevant to dentistry. Opioid analgesics and tramadol (Ultram, Ortho-McNeil Pharmaceutical, Inc.) may enhance the serotonergic effect of SSRIs, resulting in serotonin syndrome. Conversely, SSRIs may enhance tramadol's neuroexcitatory effect and/or potential to cause seizures.[13] Macrolide antibiotics (with the exception of azithromycin) may decrease the metabolism of SSRIs.

SSRIs also interact with common medications to alter bleeding hemostasis. SSRIs may enhance the antiplatelet effects of aspirin and COX-2 inhibitors, while SSRIs taken with TCAs may enhance the antiplatelet effect of nonselective NSAIDs.

Significant interaction between antidepressants and other drugs may affect their toxicity, metabolism, and potency. Paroxetine may enhance the adverse/toxic effect of other central nervous system (CNS) depressants. Barbiturates may increase the metabolism of TCAs. Propoxyphene may enhance the CNS depressant effect of TCAs, while SSRIs may decrease their metabolism. Trazadone may diminish the therapeutic effect of codeine and tramadol.[13]

Non-sedating antihistamines

Xerostomia and stomatitis in children have been reported in connection with loratadine; however, no drug interactions with dentally prescribed drugs have been reported.[13]

Anticoagulants/antithrombotics

Systemic corticosteroids and tetracycline derivatives may enhance the anticoagulant effect of warfarin. Mouth ulcers and abnormal taste have been reported with warfarin; bleeding gingival tissue has been associated with the first signs of warfarin overdose.[13] If temporary reduction or discontinuation of the medication is warranted prior to surgery, consultation with the patient's prescribing physician is advisable.

Patients who take more than 1.3 g of acetaminophen daily for more than one week are likely to enhance the anticoagulant effect of coumarin derivatives.[13] Systemic azole antifungal derivatives (including fluconazole), macrolide antibiotics, metronidazole, and propoxyphene may decrease the metabolism of coumarin derivatives, while barbiturates may increase their metabolism. Azathioprine may diminish the anticoagulant effect of coumarin derivatives, while NSAIDs and tricyclic antidepressants may enhance it. Cephalosporins (with the exception of cephalexin) and fluorouracil may enhance the anticoagulant effect of coumarin derivatives.[13]

Anti-platelet medications

Premature discontinuation of aspirin and clopidogrel antiplatelet therapy strongly increases the risk of a catastrophic event of stent thrombosis, leading to myocardial infarction and/or death.[13] Any elective surgery should be postponed for one year after stent implantation; if surgery must be performed, dentists should consider continuing the antiplatelet therapy during the perioperative period in high-risk patients.

Macrolide antibiotics (except for azithromycin) may diminish the therapeutic effect of clopidogrel (Plavix, Bristol-Myers Squibb). NSAIDs may enhance the adverse/toxic effect of antiplatelet agents and increase the risk of bleeding.[13]

Analgesics/narcotics

No significant effects or complications have been reported. Hepatotoxicity caused by acetaminophen is potentiated by chronic ethanol consumption. Patients who use acetominophen (even in therapeutic doses) and consume ethanol at the same time are at risk of developing hepatotoxicity. Xerostomia, nausea, sedation, and constipation have been reported with oxycodone and acetaminophen use.[13] Barbiturates may increase the metabolism of acetaminophen, diminishing its effect and increasing the risk of liver damage.

Anticonvulsant drugs

Valproic acid (and its derivatives) is associated with periodontal abscess,

taste perversion, stomatitis, and xerostomia. Gingival hyperplasia is common during the first six months of phenytoin therapy.[13] To minimize the severity and growth of gingival tissue, the patient should begin a program of professional cleaning and at-home plaque control within 10 days of the start of anticonvulsant therapy.

Some adverse effects have been reported in connection with anticonvulsant drugs: Xerostomia, dry throat, and dental abnormalities have been reported with gabapentin (Neurontin, Pfizer Inc.).[13] Valproic acid may decrease the metabolism of barbiturates and lorazepam (barbiturates, in turn, may decrease the serum concentration of valproic acid) and may increase the serum concentration of TCAs. Anticonvulsants may increase the metabolism of acetaminophen, thus diminishing its effect and increasing the risk of liver damage. Phenytoin may increase the metabolism of systemic azole derivative antifungal agents, doxycycline, and cyclosporine. Benzodiazepines may increase the serum concentration of phenytoin. Fluconazole may decrease the metabolism of phenytoin.[13]

Peripherally acting anti-adrenergic blockers

Orthostatic hypotension and tooth disorder have been reported with tamsulosin (Flomax, Boehringer Ingelheim Pharmaceuticals). No drug interactions with dentally prescribed drugs have been reported.

Anti-psychotic drugs

Ziprasidone (Geodon, Pfizer Inc.) and quetiapine (Seroquel, AstraZeneca) prolong the QT interval, which could lead to *torsade de pointes.*[13] Hypotension and tachycardia may result among patients who take vasoconstrictors with anti-psychotic drugs.[16] Local anesthetics that contain vasoconstrictors should be used with caution and the patient's physician should be consulted to determine the risk.[13]

Xerostomia and changes in salivation, orthostatic hypotension, tongue edema, dysphagia, and unspecified tooth disorder have been reported with ziprasidone. Significant xerostomia and toothache have been reported with risperidone.[13] No significant effects or complications have been reported with olanzapine (Zyprexa, Eli Lilly and Company).

Anti-estrogen and estrogen replacement drugs

No significant effects, complications, or drug interactions between raloxifene (Evista, Eli Lilly and Company) or conjugated estrogen and dentally prescribed drugs have been reported in the literature.

Lipid-lowering agents

Few reports of gingival hyperplasia with atorvastatin (Lipitor, Pfizer Inc.) have been reported in the literature.[13] In the event of hyperplasia, consultation with the patient's physician is suggested. No significant effects or complications have been reported in connection with lovastatin, pravastatin (Pravachol, Bristol-Myers Squibb), simvistatin (Zocor, Merck & Co.), or ezetimibe with simvistatin (Vytorin, Merck & Co.).

Systemic azole derivative antifungal agents may decrease the metabolism of atorvastatin, lovastatin, pravastatin, and simvistatin, while cyclosporine may increase the serum concentration of atorvastatin, pravastatin, and simvistatin. Macrolide antibiotics (with the exception of azithromycin) may decrease the metabolism of atorvastatin, pravastatin, and simvistatin. Atorvastatin may increase the serum concentration of midazolam.[13]

Quinolone antibiotics

Before giving a vasoconstrictor to patients taking levofloxacin, dentists should consult with the patient's physician, as this drug prolongs the QT interval and puts patients at risk for *torsade de pointes*. However, the risk of drug-induced *torsade de pointes* is extremely low when a single QT interval-prolonging drug is prescribed. Quinolone antibiotics may enhance the adverse/toxic effect of systemic corticosteroids and the risk of tendon-related side effects, including tendonitis and rupture. NSAIDs may enhance quinolone antibiotics' potential for neuroexcitatory effects and/or seizures.

Sulfonamide antibiotic combinations

Sulfonamide derivatives may enhance the nephrotoxic effect of cyclosporine and decrease its serum concentration. Glossitis and stomatitis have been reported with trimethoprim/sulfamethoxazole.[13]

Macrolide antibiotics

No significant effects, complications, or drug interactions have been reported between dentally prescribed drugs and azithromycin.

Antidiarrheal drugs

Significant xerostomia has been reported with diphenoxylate and atropine.[13] No drug interactions between these antidiarrheal drugs and dentally prescribed drugs have been reported.

Gastrointestinal agents

No significant effects or complications from lansoprazole (Prevacid, Takeda Pharmaceuticals) or pantoprazole (Protonix, Wyeth Pharmaceuticals) have been reported; however, taste perversion, dry mouth, esophageal candidiasis, and mucosal atrophy of the tongue

have been reported in connection with omeprazole (Prilosec, AstraZeneca). Xerostomia has been reported in connection with metoclopramide use.[13]

Proton pump inhibitors may decrease the absorption of systemic azole derivative antifungal agents (with the exception of miconazole). Omeprazole may increase the serum concentration of benzodiazepines. No dental drug interactions have been reported with metoclopramide.

Anti-Parkinson's drugs

Anti-Parkinson's agents have been associated with orthostatic hypotension; however, no drug interactions between carbidopa-levodopa (Sinemet, Merck & Co.) and dentally prescribed drugs have been reported.[13]

Glucocorticoids/steroids

No dentally significant effects or complications have been reported with systemic steroid use.

Systemic corticosteroids may enhance the hypokalemic effect of amphotericin B and the adverse/toxic effects of both COX-2 inhibitors and nonselective NSAIDs. Systemic azole derivative antifungal agents (such as fluconazole) and macrolide antibiotics (with the exception of azithromycin) may decrease the metabolism of corticosteroids. Barbiturates may increase the metabolism of systemic corticosteroids; in turn, systemic corticosteroids may increase the serum concentration of cyclosporine.[13]

Synthetic thyroid agents

No significant effects or complications have been reported. No precautions with vasoconstrictor are necessary if a patient's thyroid disease is well-controlled with levothyroxine.[13]

Glaucoma treatments

No dentally significant adverse effects or drug interactions have been reported between latanoprost (Xalatan, Pfizer Inc.) and dentally prescribed drugs.

Anti-gout medications

No dentally significant effects or complications or drug interactions have been reported between allopurinol and dentally prescribed drugs.

Impact on patient care

Treating more elderly, medically complex dental patients will challenge dentists' technical and cognitive skills. These patients will require a greater knowledge of medicine and more thorough evaluation.[3] As newer drugs are prescribed on a frequent basis to treat complex medical problems, dentists should keep abreast of new regimens their patients may be taking (including OTC medications) and update the medical history as needed at each patient visit. Each new drug brings with it the possibility of a side effect or adverse effect that could impact the patient's dental treatment.

When evaluating a patient's medication regimen, dentists should recognize the drug category or class and each drug's potential for complicating dental treatment, compromising treatment outcomes, and producing oral side effects.[5]

Dentists should be ready to advise patients or change dental management plans based on the latest drug information; consultation with the patient's physician may be advisable as well. Before prescribing or administering any dental drug, dentists should evaluate the potential for adverse drug interactions with the patient's existing medication(s) or medical conditions, the efficiency with which the dental drugs are metabolized or eliminated, the possibility of emergency situations, and how the patient's health dictates what is considered a safe dosage.[5] Continuing education via literature, courses, or specialized training in geriatric dentistry can provide updated and current drug information concerning this special patient population.

Summary

Increasing numbers of geriatric patients in dental practices challenge dental professionals to continually update their knowledge of common medical conditions, the new medications used to treat those conditions, and the unique medical concerns of geriatric patients. Complex medical conditions that require complex medication regimens increase the risk when providing dental care to these patients. Many of the commonly prescribed drugs have significant drug interactions with dentally administered or prescribed drugs. Thorough collection and evaluation of each patient's medical and medication history, with physician consultation when prudent, will help to ensure appropriate dental management. Advanced education in geriatric dentistry as well as continuing education in oral medicine and pharmacology offer immeasurable aid in the comprehensive care of these patients.

Author information

Dr. Aubertin is an associate professor, Department of Biologic and Diagnostic Sciences, University of Tennessee College of Dentistry in Memphis, where Dr. Wasson is an associate professor, Department of Endodontics and Operative Dentistry; Dr. Woods is a professor, Department of Biologic and Diagnostic Sciences; and Dr. Horbelt was a professor, Department of

Pediatric Dentistry and Community Oral Health, prior to his death in November 2009.

Self-Instruction 255

Geriatric Dentistry

Subject code: 752

The 15 questions for this exercise are based on the article: "Medication use in geriatric populations: Dental implications of frequently prescribed medications" on pages 100-107. This exercise was developed by Daniel S. Geare, DMD, in association with the *General Dentistry* Self-Instruction Committee.

Reading this article and successfully completing the exercises will enable you to understand:

- medical conditions that might afflict elderly patients in dental practices;
- which medications are used to treat medical conditions in elderly patients;
- the implications of the medical pharmaceuticals in dental practice; and
- the interactions between medications and how they may impact dental treatment.

1. Which of the following frequently prescribed medications affects dental management of patients?
   - A. Cardiovascular drugs and NSAIDs
   - B. Topical corticosteroids
   - C. Estrogen replacement medications
   - D. Erectile dysfunction medications

2. Why are therapeutic concentrations of medications in the elderly important?
   - A. Lower doses can produce the desired effects.
   - B. Elders often forget how much medication they have taken.
   - C. Higher dosing is required due to lower metabolic activity.
   - D. Less-active elderly patients take more medications.

3. Adverse drug reactions are least likely to occur with drugs that treat
   - A. congestive heart failure.
   - B. diabetes.
   - C. high cholesterol.
   - D. respiratory tract conditions.

4. Risk factors for adverse drug interactions in elderly patients include all but which of the following?
   - A. Medically compromised patients
   - B. Drugs with a small margin of safety
   - C. Chronic drug therapies with slowly excreted drugs
   - D. Drugs with a short half-life

5. Why is deteriorated renal function a concern for dental practices?
   - A. High doses of anesthetics can deteriorate the renal function further.
   - B. NSAIDs can contribute to further deterioration of renal function.
   - C. Heavy metals in restorations can damage kidney function.
   - D. Diltiazem can damage a compromised renal system.

6. Why should anesthetics with epinephrine be used with caution?
   - A. Epinephrine can cause hypertension in patients taking beta blockers.
   - B. Epinephrine can interact with NSAIDs to cause hypertension.
   - C. Epinephrine can interact with anti-anginals to cause hypertension.
   - D. Epinephrine can cause myocardial infarction.

7. Thiazide diuretics have been associated with all but which of the following?
   - A. Orthostatic hypotension
   - B. Xerostomia
   - C. Hypotension
   - D. Hyperkalemic effects

8. Bisphosphonate treatment for osteoporosis is important in dentistry for all but which of the following reasons?
   - A. Healing after dental surgical procedures can be disrupted.
   - B. Implant placement can be compromised in patients taking bisphophanates.
   - C. Bisphosphonates can cause xerostomia.
   - D. Long-term bisphosphonate use can accelerate bone loss in periodontal patients.

9. Which of the following is true about *torsades de pointes*?
   A. It is a ventricular tachycardia.
   B. It causes a prolonged QT interval.
   C. It can be caused by vasoconstrictors.
   D. It is an arrhythmia caused by medications decreasing the QT interval.

10. What is the significance of anti-anxiety agents to dental treatment?
   A. Caution should be used with lorazapam because of induced bruxism.
   B. Alprazolam has been associated with xerostomia.
   C. Trazadone is an effective anti-anxiety medication.
   D. Local anesthetics are more effective with patients taking anti-anxiety medications.

11. Amitriptyline is associated with all but which of the following?
   A. Xerostomia
   B. Orthostatic hypotension
   C. Stomatitis
   D. Tardive dyskinesia

12. Anticoagulant coumarin derivatives are
   A. less effective with cephalosporins.
   B. reduced in effect with acetominohen products.
   C. decreased in metabolism with propoxyphene.
   D. are less effective with NSAIDs and antidepressants.

13. Adverse drug effects occur in what percentage of elderly patients?
   A. 15
   B. 25
   C. 50
   D. 65

14. Which of the following is true concerning adverse drug reactions in elderly dental patients?
   A. OTC pain medications can increase the therapeutic effects of ACE inhibitors.
   B. Bisphosphonates increase the risk of success for dental procedures.
   C. Hypoglycemia is difficult to control in a diabetic patient.
   D. Medications containing digoxin increase the risk of arrhythmias when used with vasoconstrictors.

15. Medications that affect dental treatment include all but which of the following?
   A. Cardiovascular drugs
   B. Diabetes medications
   C. Alzheimer's medications
   D. OTC anti-inflammatories

Methods for analyzing saliva proteins for systemic disease detection

Tara Luther, BA, MS ▪ Carlos F. Carrion, BS, MS ▪ Nicholas Cobb, BS ▪ Giao Le, BS ▪ Cynthia Edwards, BS
Stephen Schwartz, DDS, MS ▪ Charles Streckfus, DDS, MA

New technological developments, coupled with the limitations of existing methodologies for the detection of disease, are propelling the field of salivary diagnostics forward at unprecedented rates. Advancements in proteomics and nanotechnology are paving the way for diagnostic tests that will be capable of rapid multi-analyte detection in both laboratory and nonlaboratory settings. Technological advancements have also benefited biomarker research to the point where saliva is now recognized as an excellent diagnostic medium that can be collected simply and noninvasively. This article reviews the varying nanotechnological platforms and how they will utilize saliva as the diagnostic medium.

Early detection of cancer is vital to providing timely treatment and producing a favorable outcome. An inexpensive, minimally invasive, convenient, and accurate method for detecting cancer (one that can be employed in a clinical/private practice environment) would be enormously beneficial to both dentists and patients. This article reviews the literature concerning the current biotechnologies that can be used to analyze saliva and identify specific proteins that would indicate cancer.[1,2]

Salivary diagnostic methods

Any technology that is to be used for saliva screenings must be inexpensive, accurate (that is, with minimal false positives and negatives), self-contained, easy to use, and capable of handling a low volume sample.[3] Saliva has a measured concentration of 10^{-12} picograms of protein, which is considered a low concentration compared to other fluids in the body. Any measuring device should be able to analyze multiple varieties of proteins and compare the ratio of one protein to another.

Using the aforementioned criteria, this article evaluated the strengths and weaknesses of three different technologies.

Lateral flow immunochromatographic test

The most easily recognizable example of this technology is the OTC pregnancy test. This type of rapid diagnostic test contains a base membrane (typically consisting of nitrocellulose and detector reagents) (Fig. 1). The detector reagent complex (that is, an antigen/antibody indicator specific to the protein analyte that is to be analyzed) is inserted at one end of the

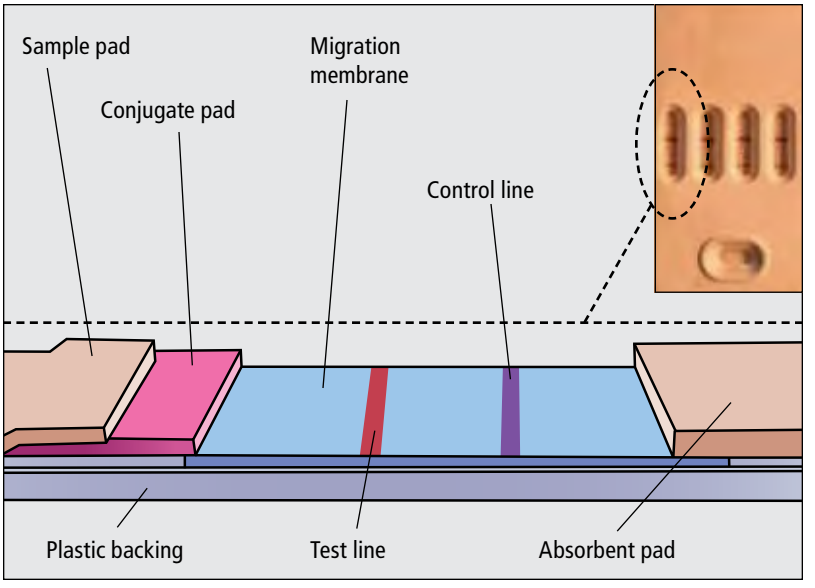

Fig. 1. The lateral flow immunochromatography platform.

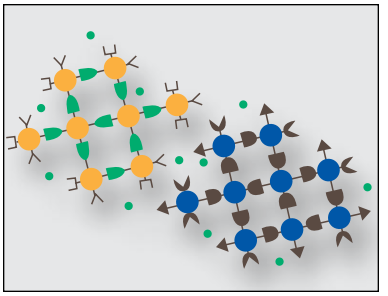

Fig. 3. An illustration of the introduction of the biological sample.

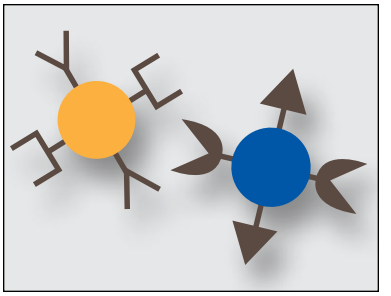

Fig. 4. Quantum dots are surface-functionalized with polyclonal antibodies.

membrane, and a special reagent used to capture the analyte is coated on the test region of the membrane. When the analyte is added to the test pad, the fluid flows quickly through the membrane and binds to the detector antigen/antibody when the substance of interest is present. As the specimen moves down the test lane, it reaches the capture reagent and immobilizes the detector-reagent complex; at that point, a band proportional to the amount of analyte present in the sample develops when dyed reagent in the test lane binds with the tested molecules in the analyte.[4] This band serves as a visual signal to the test reader to indicate whether the tested analyte was detected.

The lateral flow immunochromatographic test detects the presence of entities that normally are not found in healthy individuals and makes it possible to quantitatively determine the presence of multiple analytes.[5-7] The testing strip would be lightweight and just as small as a pregnancy test in order to be transported easily.

One problem foreseen when utilizing such technologies for saliva analysis is the extremely small amount of protein in the saliva sample. This test is not as accurate as an in-house laboratory analysis test; however, the lateral flow immunochromatographic test platform has proven to be a rapid and useful test for diagnosing specific viruses and can be extrapolated to detect the presence of specific proteins in saliva.[8] It is unclear as to whether the saliva will have to be manipulated (centrifuged) to enhance its accuracy. Nevertheless, from a field use standpoint, minimal pre-test manipulation is expected, making it acceptable to use this test in the field.

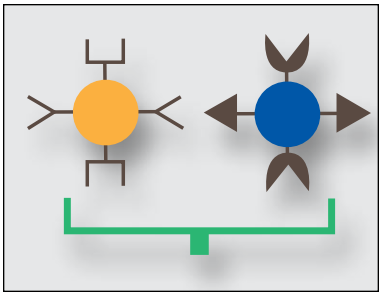

Fig. 5. The conjugates are placed into a sample well.

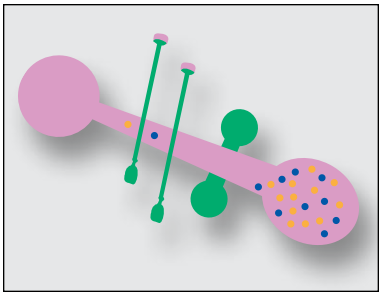

Fig. 6. Flow cytometry is used to detect the agglomerates.

Protein microarray

Historically, two types of technologies have been used for scanning microarrays: laser confocal excitation and charged coupled device (CCD) imaging.[9] Laser confocal excitation uses a photo multiplier tube. The analytic process for the photo multiplier tube begins with the aggregation of the tested particles (Fig. 2), which allows the particles to be characterized by scattered light and fluorescence. The biological sample is introduced and the proteins bind to the polyclonal antibodies to form two-body quantum dot agglomerates (Fig. 3). The quantum dots (Fig. 4) are bound with polyclonal antibodies in response to a variety of proteins in the laser confocal excitation process. The conjugates and groups of particles are then placed into a sample well (Fig. 5) and tested using flow cytometry (Fig. 6). This method offers high resolution and sensitivity, but is very time-consuming, as each point must be scanned individually.

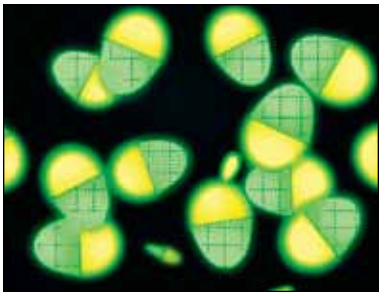

Fig. 7. An example of fluorescent microarray probes.

CCD imaging analyzes the entire array at once by illuminating the sample uniformly. While this method reduces the required reading time, it also results in reduced sensitivity due to background interference, such as instrument noise.[9]

Research concerning microarray analysis has focused primarily on identifying the target proteins and reducing the complexity of the measuring device. A 2008 article reported on a method for targeting the proteins by conjugating commercial quantum dots (with emission wavelengths of 525, 585, and 705 nm), using a streptavidin-biotin interaction.[10] This attachment with the antibodies leads to self-agglomeration around the target proteins; at that point, the results are obtained with flow cytometry using a microplate reader. A device that analyzes light scatter was used to determine if the particles detected were free quantum dots or agglomerated to the target proteins. This method made it possible to detect protein concentrations as small as 0.5 picamoles.[10]

Researchers at Massachusetts Institute of Technology have analyzed microarrays for various proteins simultaneously, thus reducing the analysis time.[11] This procedure allows for increased sensitivity because the probe becomes porous, allowing the target molecules to diffuse into the material. The probes are created from two monomers (hydrogel polymer and polyethylene glycol) that flow side-by-side through a microfluidic device and are exposed to ultraviolet light, which initiates a chemical reaction that causes the fluids to change into a solid. A filter is placed over the ultraviolet light to determine the shape and size of the created probe. The probe consists of a fluorescent chemical group (chromofore) attached to a molecule (protein) that is matched specifically to the target protein and fluoresces when it detects a target (Fig. 7). The unique barcode allows for the use of multiple probes with a single sample, thus allowing the quantification of many different proteins.[11]

The microarray is analyzed by using flow cytometry while the fluorescent bar codes are scanned with a standard microscope. The probes can be created inexpensively due to the simplicity of the manufacturing process and analyzed using relatively inexpensive (but typically nonportable) scanning devices.[11] Studies that have used this method identified DNA oligomers in concentrations as low as 500 attomoles.[12]

The array itself is inexpensive due to the private companies that can custom-load microarrays; however, the technology required to scan the microarray is not as affordable. Advances in these technologies are helping to reduce the prices. The equipment required to analyze a microarray requires special training. Newer technologies are attempting to make the analysis easier.

Lab on a chip

The lab-on-a-chip (LOC) is based on microtechnology, which itself is derived from lithography-based processing steps on semiconductor substrate. LOC actually is a compilation of miniature reservoirs, pumps, valves, and channels that handle the flow of sample and reagents in volumes as minute as nanoliters; LOC also employs advances in nanotechnology based on the miniaturization of mechanical systems through precision engineering.[13] For convenience, the reagents can be manufactured onto the chips and used in the field without any additional support.

LOC is an example of efficient biotechnology, as it can consolidate several laboratory steps on a single device. Some of the upstream sample preparation steps that LOC can perform include cracking cells to extract intracellular proteins and DNA; separating proteins and DNA by chromatography, gel electrophoresis, and capillary electrophoresis; and real-time polymerase chain reaction to amplify the DNA content of a sample. LOC can be utilized to perform assay antigen-antibody reactions on multiple samples and multiple reagent combinations in a single step.[14,15]

Researchers are still working to combine all of the functions that can possibly be performed on the LOC; however, many problems have to be solved before a one-chip test can be utilized to treat any complex medical condition. Research is underway to generate an LOC test for HIV to replace the traditional flow cytometry method of counting CD4 cells.[13]

Because the LOC would replace individual laboratory methods with a mass-produced device, the cost is not a significant factor compared to doing these steps individually; in addition, its compact size would allow it to be transported easily. The degree of sensitivity is currently being improved; however, it can handle

specimens in extremely small volumes. The accuracy depends on the methods used with this technology.

Summary

Each of the technologies discussed in this article should be critically analyzed and tested in terms of its specific ability to detect cancers. Researchers also should conduct more specific cost-versus-benefit investigations for each of these technologies in medical settings such as clinics and outreach programs, where medical professionals can diagnose cancer properly. More research needs to be performed to determine how commercially feasible and cost-effective the newer microarray technologies are or must become.

Dentistry's wonder drugs: Local anesthetics and vasoconstrictors

Michael J. Wahl, DDS ▪ Ronald S. Brown, DDS, MS

This article reviews recent developments concerning local anesthetics, including the amount of pain resulting from injection, which drugs achieve anesthesia most effectively, proper dosing for anesthetizing children and adults, the maximum recommended doses of lidocaine 2% with epinephrine for cardiac patients, and which drugs can be used for patients taking monoamine oxidase (MAO) inhibitors, tricyclic antidepressants, or nonselective beta blockers. Dentists should be familiar with all aspects of local anesthetics, especially anesthetic toxicity and maximum recommended doses.

Received: July 7, 2009
Accepted: September 21, 2009

It is essential that dentists understand all aspects of local anesthetics and vasoconstrictors. This article outlines the properties of and techniques used with local anesthetics and vasoconstrictors, including injection pain, efficacy, toxicity, maximum dosages, duration, and drug interactions.

Injection pain

The paradox of using local anesthetics in dentistry is that while they lead to decreased pain for dental procedures, they usually are administered via injection. These injections can cause pain, due to the necessity of a needle puncture, the pressure of the solution entering the area to be anesthetized, and/or the pH of the anesthetic solution. Dentists have used various techniques to reduce the pain of anesthetic injection. This article examines the factors involved in the injection of anesthetics and explores which injection techniques affect pain.

Prilocaine vs. lidocaine

Some practicing dentists consider prilocaine 4% plain to be less painful on injection than other anesthetics.[1] Some dentists use a two-injection technique to achieve a painless or near-painless injection. This technique begins by injecting only enough prilocaine to anesthetize the soft tissue, followed with the normal dose of lidocaine 2% with epinephrine for the full anesthetic effect. Studies have shown that injections with prilocaine 4% plain may be perceived as less painful than injections with lidocaine with epinephrine, but only slightly. In a 2001 study, 334 injections were administered to 310 patients and the average pain response was recorded using a six-point scale (with 0 = no pain and 5 = severe pain). The average pain response was 0.63 for prilocaine injections and 0.71 for lidocaine injections, a difference that was not statistically significant.[2]

By contrast, other studies have reported a statistically significant decrease in pain perception with prilocaine compared to lidocaine.[3,4] In a 2006 study involving 1,391 patients, articaine with 1:100,000 epinephrine, lidocaine with 1:100,000 epinephrine, and mepivacaine plain were perceived to be approximately equal in terms of injection pain; however, each produced significantly more injection pain than prilocaine plain.[4] Patients estimated injection pain using a 10-point scale, with 1 being no pain and 10 being severe pain. There was a decrease in perceived pain rating from lidocaine (3.24 on average) to prilocaine (2.63 on average). But since the vast majority of injections were rated as no pain or very mild pain, the slight difference in perceived pain between lidocaine with epinephrine and prilocaine plain may not be clinically significant for the majority of patients.[2,4]

Bupivacaine 0.5% with 1:200,000 epinephrine is perceived by patients to be significantly more painful than prilocaine 4% plain. In a 2002 study by Wahl *et al,* 153 patients receiving nonpalatal injections of bupivacaine 0.5% with 1:200,000 epinephrine reported a mean pain rating of 1.63 (using the same six-point scale cited earlier) compared to a mean pain rating of 0.64 for 139 patients receiving nonpalatal injections of prilocaine plain, a decrease that was statistically significant.[2,5] Out of a total of 300 patients receiving bupivacaine injections, only 53.3% reported no pain or mild pain (as opposed to moderate pain or worse), compared to 85.9% of 291 patients receiving lidocaine with epinephrine.[5]

This difference between bupivacaine with epinephrine and prilocaine plain may be clinically important. A 2002 study reported that when a dentist injected 100 patients with bupivacaine with 1:200,000 epinephrine, 46 patients experienced a moderately painful or worse injection compared to 14 of 100 patients injected with lidocaine with 1:100,000 epinephrine. In other words, more than three times as many patients would experience a moderately painful or worse injection with bupivacaine than with lidocaine.[5]

Prilocaine's relative painlessness may or may not be related to its pH, which is relatively neutral (6.0–7.0) when compared with other anesthetics (see Table 1).[6-10] Typically, manufacturers of local anesthetic solutions with vasoconstrictors make the pH more acidic to prevent oxidation of the vasoconstrictor; sodium metabisulfite is an antioxidant preservative that is added to anesthetic solutions containing vasoconstrictors, thus lowering pH levels of the solution even more.[11] Clinical pH measurements of solutions have been shown to be lower than those taken by manufacturers, possibly because of degradation of the ingredients of the solutions over time.[11]

There are several potential problems concerning the two-injection technique, which utilizes both a plain anesthetic (for example, prilocaine 4% plain) and lidocaine with epinephrine. There may be slightly more postoperative pain at the site of both injections, even if there is less intraoperative pain with the conventional one-injection technique. There are no known studies concerning postoperative pain from the two-injection technique. Four percent solutions like prilocaine plain are more likely to be associated with postinjection paresthesia. Although paresthesia is rare, the benefit of slightly reduced injection pain may not be worth the corresponding risk.

Table 1. pH measurements of local anesthetics.[4,6-10]

	Clinical measurement	Manufacturers' measurement
Articaine with 1:100,000 epinephrine	3.5–4.5	5.0
Bupivacaine with 1:200,000 epinephrine	N/A	3.4–4.5
Lidocaine with 1:100,000 epinephrine	4.0–4.5	5.0
Mepivacaine plain	4.5–5.5	4.5–6.8
Prilocaine plain	5.5–6.5	6.0–7.0

If an entire cartridge of anesthetic is used, the patient may lose the ability to detect nerve impingement during the second injection, removing a possible clue for the dentist not to inject local anesthetic there. Furthermore, since local anesthetic toxicity is additive, doubling the dose of local anesthetic administered leads to a significant increase in the amount administered, which could be problematic for patients who receive large volumes of anesthetic for full-mouth treatment.

Needle gauge

To decrease injection pain, dentists have also utilized smaller gauge needles for injections, based on the idea that the these needles produce less pain than larger gauge needles. Although it makes intuitive sense that smaller mucosal punctures would produce less pain, clinical studies have shown repeatedly that there is no difference in perceived pain between smaller gauge (27- and 30-gauge) and larger gauge needles (25-gauge).[12-16] In other words, the old adage "size doesn't matter" is true when it comes to needle gauge and injection pain; as a result, dentists may wish to choose larger gauge needles for injections, as they are less likely to break during injection. By contrast, smaller gauge needles may be more likely to deflect during injection, resulting in an inaccurate injection.[17]

Larger gauge needles also may produce more accurate aspiration than smaller gauge needles, although the literature has noted that this hypothesis has not been confirmed.[18,19] Malamed points out that more pressure is required for aspiration with smaller gauge needles than with larger gauge needles, meaning that the harpoon is more likely to dislodge during aspiration.[17]

On the other hand, smaller gauge needles require more pressure to inject than larger gauge needles, which could force the operator to inject more slowly. Slower injections cause less pain than faster injections, since the anesthetic solution can dissipate from the area without causing excess pressure in the tissues (provided the injection is performed slowly enough).[20] Injecting with smaller gauge needles creates a fast-moving stream of anesthetic, which might cause some hydrostatic damage when an injection is performed rapidly and could result in more pain than would result from a larger gauge needle injecting a greater volume of anesthetic.

Table 2. Maximum recommended doses of local anesthetics for dental infiltration/block injections.[73]

Anesthetic	Maximum dose	Dose/cartridge	Maximum cartridges for 154-lb adult	Maximum cartridges for 50-lb child
Articaine 4% with 1:100,000 or 1:200,000 epinephrine	500 mg (3.2 mg/lb)	68 mg/1.7 mL cartridge	7.4	2.4
Lidocaine 2% with 1:100,000 epinephrine	500 mg (3.2 mg/lb)	36 mg/1.8 mL cartridge	13.9	4.4
Mepivacaine 3% plain	400 mg (3.0 mg/lb)	54 mg/1.8 mL cartridge	7.4	2.8
Prilocaine 4% plain	600 mg (8.0 mg/lb for adults; 7.0 mg/lb for children, not to exceed 150 mg)	72 mg/1.8 mL cartridge	8.3	2.1

Because of its stiffness and strength, the larger gauge needle may cause more pain if the periosteum is struck tangentially (for example, when the lingual is hit during an inferior alveolar nerve block injection). If the dentist applies heavy pressure during the injection, the larger gauge needle may be stiff enough to penetrate and tear the periosteum, whereas a smaller gauge needle may simply bend in the soft tissues. The authors are unaware of any studies concerning this phenomenon.

Anesthetic efficacy

Articaine vs. lidocaine

Many dentists use articaine 4% with epinephrine, presumably because they believe it is more effective than lidocaine 2% with 1:100,000 epinephrine. In fact, articaine 4% has been shown to be more effective for anesthesia than lidocaine 2% when used at similar volumes; however, the difference has been slight, and in most studies was not statistically significant.[21-27]

A prospective, randomized, double-blind clinical study of 1,129 patients in 2007 showed that when similar volumes of solution were used, articaine 4% with epinephrine was slightly more effective than lidocaine 2% with epinephrine for first-dose anesthesia during 128 crown preparations, 360 extractions or implant placements, 574 fillings, and/or 67 root canal treatments; overall, the difference was statistically significant (but not for every parameter, such as tooth location and the operator conducting the injection).[28] Overall, articaine's first-dose efficacy was 68.7% compared to 60.1% for lidocaine; in other words, slightly more than six of 10 injections with lidocaine 2% with 1:100,000 epinephrine produced adequate local anesthesia, compared to slightly less than seven of 10 injections that used articaine 4% with 1:100,000 epinephrine.[28]

A 2008 study of 73 patients showed that inferior alveolar nerve anesthesia was significantly more successful with articaine than with lidocaine.[29] In other studies using similar volumes of solution, articaine 4% with epinephrine has been shown to be more effective than lidocaine 2% with epinephrine for buccal infiltration injections (to achieve mandibular molar anesthesia) and for maxillary lateral incisor injections.[30,31] For maxillary molar injections, articaine 4% with epinephrine was slightly more effective than lidocaine 2% with epinephrine, although the difference was not statistically significant.[31]

Anesthetic toxicity

Anesthetic toxicity is probably the most important factor to consider in choosing a local anesthetic. Unfortunately there are reported cases of dental patients who have died after receiving large doses of local anesthetics, especially children, who weigh less than adults and thus can receive fewer cartridges of anesthetic before reaching the maximum recommended dose.[32-36] Articaine's slightly greater efficacy compared to lidocaine must be weighed against certain disadvantages.

Articaine and lidocaine have the same maximum recommended dose (3.2 mg/lb; up to 500 mg maximum).[37,38] Articaine is available in a 4% solution (compared to lidocaine's 2% solution); as a result, a 154-lb adult may receive only 7.4 cartridges (1.7 mL) of articaine 4% with 1:100,000 epinephrine compared to 13.9 cartridges (1.8 mL) of lidocaine 2% with 1:100,000 epinephrine before reaching the maximum recommended dose. Similarly, one may use significantly fewer cartridges of mepivacaine 3% plain and prilocaine 4% plain

before reaching the maximum recommended dose.[10,39] Lidocaine 2% with epinephrine has the widest margin of safety per cartridge of all commercially available injectable local anesthetic formulations, since more lidocaine 2% cartridges can be administered before reaching the maximum recommended doses (see Table 2). In addition, each cartridge of lidocaine 2% with epinephrine is approximately half as toxic as mepivacine 3% plain.

Although articaine's 4% solution allows dentists to safely administer approximately half as many cartridges as can be administered when using lidocaine 2%, articaine's shorter elimination half-life (~44 minutes for articaine vs. 1.5–2.0 hours for lidocaine) may permit dentists to administer additional cartridges of articaine during a long procedure.[38,40,41] In addition, articaine with epinephrine and prilocaine plain (both 4% solutions) have been associated with a somewhat higher rate of paresthesia after anesthesia compared with other anesthetics.[42] Gaffen and Haas reported that over a two-year period, prilocaine (1:332,000) and articaine (1:410,000) demonstrated higher incidences of paresthesia compared to lidocaine (1:2,580,000) and mepivicaine (1:839,000).[43]

In a 1995 study, Haas and Lennon studied 143 reported cases of paresthesia after the administration of local anesthetic (not associated with surgery) over a 21-year period. Of the 102 cases where the anesthetic agent was known, 50 (49.0%) received articaine, while 43 (42.2%) received prilocaine, 5 (4.9%) received lidocaine, and 4 (3.9%) received mepivacaine, with no reports of bupivacaine use.[44] Based on the total of all cartridges of local anesthetic administered in Ontario in 1993, the probability of paresthesia occurring from a local anesthetic injection for a nonsurgical dental procedure was estimated at 2.27 per million injections of articaine and 1.7 per million injections of prilocaine, compared to an overall probability of approximately 1:785,000.[44]

Paresthesia is associated almost exclusively with inferior alveolar block injections and is clearly very rare, regardless of the anesthetic used. It was estimated that more than 11 million local anesthetic injections were performed in Ontario in 1993 alone. Over the 21-year period, therefore, there probably were more than 100 million local anesthetic injections but only 143 cases of paresthesia after nonsurgical procedures.[44] In any case, dentists must determine whether articaine's slightly improved efficacy outweighs its dosing limitations and the relatively rare reports of paresthesia associated with this drug.

Plain anesthetics and lip mutilation in children

It is believed that anesthetics containing vasoconstrictors prolong the anesthetic effect; as a result, many dentists prefer to use plain anesthetics for young children instead of lidocaine 2% with epinephrine. A plain anesthetic, it is alleged, is less likely to be associated with prolonged lip anesthesia; therefore, young children would be less likely to bite their lips after the procedure.

Unfortunately, plain anesthetics have higher drug concentrations than lidocaine 2% with epinephrine and significantly fewer cartridges can be administered before the maximum recommended dose is reached. For example, a maximum of 13.9 cartridges of lidocaine 2% with epinephrine can be administered to a 154-lb adult, compared to only 7.4 cartridges of mepivacaine 3% plain or 8.3 cartridges of prilocaine 4% plain. For a 50-lb child, a maximum of 4.4 cartridges of lidocaine 2% can be administered, compared to only 2.8 cartridges of mepivacaine 3% plain or 2.1 cartridges of prilocaine 4% plain.

Although adding vasoconstrictors to anesthetics may produce more profound and longer-lasting pulpal anesthesia, lidocaine 2% with epinephrine and mepivacaine 3% plain produce a similar duration of lip anesthesia; as a result, there is no less likelihood of lip mutilation when one of these anesthetics is chosen over the other.[45]

Cases involving small children who have died or gone into convulsions after overdoses of mepivacaine 3% plain or prilocaine 4% plain have been reported.[32-36] Some of these children may have survived had they received a similar number of cartridges containing lidocaine 2% with epinephrine instead. A 1992 article by Moore reported the case of a 50-lb, 8-year-old girl who had been sedated for multiple extractions and died after receiving six cartridges of mepivicaine 3% plain, even though the maximum number of cartridges permitted was only 2.8.[32] By contrast, up to 4.4 cartridges of lidocaine 2% with epinephrine can be administered (although the six cartridges administered in this case would still exceed the maximum number of cartridges allowed); for this reason, lidocaine 2% with epinephrine should be the preferred anesthetic in children (although at no time should the maximum recommended dosages for any local anesthetic be exceeded).

It is imperative for clinicians to stay within maximum recommended dosages for local anesthetics, especially in small children, and to maintain the patient airway if

signs of overdose reactions occur. Exceeding maximum recommended dosages with both local anesthetics and sedatives and failing to maintain a patient airway when symptoms of overdosage occur have been cited as major causes of mishaps among child patients.[34]

Recent studies have documented that submucosal injections of the alpha-1 blocking agent phentolamine mesylate significantly reduce the duration of soft tissue anesthesia from combined local anesthesia and vasoconstrictor injections.[46,47] This pharmacologic agent can decrease the negative effects of continued soft tissue anesthesia for both adults and children after dental procedures with local anesthesia and vasoconstriction have been completed.

In 2008, Hersh *et al* reported that when phentolamine was injected, the median recovery time of the lower lip was reduced from 155 minutes to 85 minutes, suggesting that phentolamine is able to accelerate the systemic absorption of the local anesthetic from the oral tissues into the systemic circulation.[46] Unfortunately, phentolamine is not recommended for children under the age of six years—the very patients who are most likely to suffer lip mutilation while numb.[48]

Intraosseous injections

Intraosseous injections have gained popularity, especially as a supplemental injection when conventional injections have failed. Intraosseous injections can be more effective and have a faster onset than conventional infiltration/block injections. According to the manufacturer of the Stabident intraosseous injection system (Fairfax Dental), dentists should never administer more than two cartridges of any anesthetic per visit.[49] According to Jastak *et al,* dentists can intravenously administer two to three times the amount of lidocaine in a single anesthetic cartridge in a two-minute period for most patients without incident; however, injecting the drug more rapidly may cause convulsions.[50]

These recommendations may be overly cautious. The lidocaine manufacturers' maximum recommended dose for intravenous injection is 4 mg/kg (1.8 mg/lb), as opposed to 7 mg/kg (3.2 mg/lb) for infiltration/block injections.[8] Therefore, a maximum recommended dose of up to 7.7 cartridges of lidocaine 2% can be administered intravenously in a 154-lb adult. In terms of speed and the quantity of anesthetic that enters the bloodstream, intraosseous injections are probably somewhere between infiltration/block injections and intravenous injections; therefore, the maximum recommended dose of lidocaine 2% for intraosseous injections is probably somewhere between 7.7 cartridges for intravenous injections and 13.9 cartridges for infiltration/block injections.

Still, it would be prudent for dentists not to exceed 7.7 cartridges of lidocaine 2% for intraosseous injections, as these maximum recommended doses are additive between infiltration/block injections and intraosseous injections. Fortunately, since intraosseous injections are usually very effective in very small doses, clinical situations in which a dentist would need to administer anything close to 7.7 anesthetic cartridges intraosseously are unlikely.

Vasoconstrictors in local anesthetics

In 1955, the New York Heart Association recommended no more than 0.2 mg (200 µg) of epinephrine in one session for patients with heart disease.[51] This amount of epinephrine would require slightly more than 11 cartridges of lidocaine 2% with 1:100,000 epinephrine—an amount close to the maximum recommended dose of 13.9 cartridges of lidocaine 2% for 154-lb patients. Since epinephrine has a half-life of approximately one to two minutes, virtually all exogenous epinephrine would be eliminated within 30 minutes.[52-57] It is unlikely that more than 11 cartridges of anesthetic would be administered in a 30-minute period in a typical clinical setting. As long as the cartridges are administered over a period longer than 30 minutes, the maximum recommended dose of lidocaine 2% (500 mg or 3.2 mg/lb) is clinically more significant than the maximum recommended dose of the epinephrine within the cartridges.

Due to the relatively short half-life of epinephrine, toxicity issues are limited. With a 30-second half-life, 50% of the drug is metabolized by monoamine oxidase (MAO) and/or catechol O-methyltransferase (COMT) within one minute and 75% of the drug is metabolized at two minutes. Using two minutes as the half-life, half of the drug is metabolized in two minutes, and three-fourths is metabolized in four minutes. Utilizing Malamed's atraumatic local anesthesia slow injection technique, an injection of a single 1.8 mL local anesthetic cartridge should be administered in approximately two minutes.[58] Malamed noted that many clinicians inject anesthetic much faster than the suggested two-minute approach.[58] However, since secondary injections require unloading and reloading anesthetic cartridges and relocating the injection site, the two-minute time frame is probably reasonable.

A 1:50,000 epinephrine local anesthesia formulation contains 36 µg for each 1.8 mL anesthetic cartridge. Utilizing the model of a two-minute half-life, the seventh

injection with a 1:50,000 epinephrine local anesthetic solution would add less than 36 µg of epinephrine total, for a total of less than 72 µg of epinephrine—well below the recommended dosage of 200 µg for patients with heart disease (see Table 3). Furthermore, additional injections would not result in any significant increase of serum epinephrine. Even if 14 cartridges of lidocaine with 1:50,000 epinephrine were administered (slightly more than the maximum of 13.9 cartridges of lidocaine 2% permitted for a 154-lb adult), the patient would still receive less than 72 µg of serum epinephrine, assuming a two-minute injection time per cartridge.

When 1:100,000 epinephrine is used with this protocol, the total amount of serum epinephrine from 14 cartridges would be less than 36 µg. Of course, if the cartridges are administered faster than the recommended two minutes each, significantly more serum epinephrine would accumulate. Although the biotransformation of epinephrine occurs once it enters the serum, epinephrine as a vasoconstrictor injected intramuscularly for a dental procedure gradually leaches out of the injection area and into the serum, resulting in a rate of epinephrine biotransformation that is slower than what would be expected from half-life dynamics alone.

Certainly, epinephrine toxicity from overdose is and should be a serious consideration, but it does not appear that vasoconstriction utilization within dentistry presents any viable epinephrine toxicity risk. The same cannot be said for other vasoconstrictors like levonordefrin, which have a poor β1:β2 ratio and thus tend to increase blood pressure reactivity. Conversely, the β1 and β2 activity is approximately equal for epinephrine.[59-63]

Table 3. Serum epinephrine levels after consecutive injections of lidocaine with 1:50,000 epinephrine every two minutes.

Cartridges	Minutes	µg of epinephrine for each cartridge	Total µg
1	2	36	36
2	4	18	54
3	6	9	63
4	8	4.5	67.5
5	10	2.25	69.75

14	28	0.00439453	71.9956054
	Total after 14 cartridges		<72 µg

A 1987 study by Troullos *et al* reported that the mean arterial pressure (MAP) increased in 10 subjects who received eight local anesthetic cartridges of 2% lidocaine with 1:100,000 epinephrine, compared to five subjects who each received six anesthetic cartridges of mepivacaine without vasoconstrictor.[64] Compared to the group that received mepivicaine without vasoconstrictor, the systolic blood pressure for those receiving lidocaine with 1:100,000 epinephrine was approximately 20 mmHg higher (to approximately 150 mmHg) while the diastolic blood pressure essentially stayed unchanged or dropped only slightly. It was not noted how quickly the anesthetic cartridges were administered.[64]

Two years later, Troullos *et al* compared 15 patients who each received seven cartridges of 2% lidocaine with 1:100,000 epinephrine with 15 patients who each received six cartridges of mepivacaine without vasoconstrictor and noted an increase in systolic blood pressure of only 10 mmHg (to approximately 130 mmHg) in the group receiving 2% lidocaine.[65] Again, it was not noted how quickly the anesthetic cartridges were administered, and it is possible that the rise in blood pressure in both of these studies could be attributed to the clinicians injecting the epinephrine-containing cartridges one after the other in quick succession. Future clinical studies are necessary to evaluate the cardiovascular dynamics of increased local anesthesia vasoconstriction dosages and to establish the dose-response curve.

In a 2007 study involving patients with cardiovascular disease undergoing restorative dentistry, one group was administered either one or two cartridges of lidocaine 2% with

1:100,000 epinephrine (0.018 mg or 0.036 mg of epinephrine), while another group received one or two cartridges of lidocaine 2% without epinephrine. There was no difference in blood pressure or heart rate between the two groups, leading to the conclusion that epinephrine was safe to use among these patients.[66]

In a similar study, 24 patients received up to two cartridges of mepivacaine 2% with 1:100,000 epinephrine (≤0.036 mg of epinephrine), while three patients received more than two cartridges (>0.036 mg of epinephrine) and 27 patients received mepivacaine 3% cartridges without epinephrine. There were no additional ischemic risks among coronary patients undergoing dental extraction with local anesthetic, regardless of whether it contained epinephrine.[67] These results confirm earlier studies which stated that local anesthetics with epinephrine are relatively safe in cardiac patients and in hypertensive patients.[59,68] Dental patients with hypertension and cardiovascular disease appear to tolerate two to three local anesthetic cartridges of 2% lidocaine with 1:100,000 epinephrine.[60,69]

Drug interactions and misconceptions concerning local anesthetics and vasoconstrictors

Adding vasoconstrictors to local anesthetic solutions generally increases the depth and duration of anesthesia and may indirectly decrease anesthetic toxicity, as less anesthetic is necessary to achieve the same anesthetic effect as anesthetic used alone.[60,61] It has been alleged that vasoconstrictors added to local anesthetics may interact with MAO inhibitors, tricyclic antidepressants (TCAs), nonselective beta blockers, and cocaine, and that they can potentially cause hypertensive crises.[70] A hypertensive crisis may result from stress, a single drug effect, or the interactions of two or more drugs, causing an increase in blood pressure that may produce a cardiovascular and/or cerebral vascular accident.[63,71-73] Some of these allegations are still published on product inserts of local anesthetics that contain vasoconstrictors.

MAO inhibitors and vasoconstrictors

Both animal and human studies have failed to show an interaction between local anesthetics containing vasoconstrictors and MAO inhibitors.[74-76] All anesthetics containing vasoconstrictors can be used without special reservation for patients taking MAO inhibitors.[77,78]

Drug interactions with epinephrine and other vasoconstrictors

There are significant differences between the actions of epinephrine and other vasoconstrictors. The failure to appreciate these differences has led to misconceptions regarding epinephrine vasoconstrictor pharmacology and drug interactions with TCAs, nonselective beta blockers, and cocaine. Brown and Rhodus noted that there are very few if any articles showing any interaction at all between the epinephrine vasoconstrictor within local anesthetics and other drugs.[60]

Epinephrine has relatively equal β1 and β2 adrenergic agonist actions, while norepinephrine and levonordefrin possess considerably greater β1 receptor potency compared to β2 receptor potency. Since β1 activity increases blood pressure and β2 activity decreases it, using norepinephrine and levonordefrin as vasoconstrictors tends to increase MAP; by contrast, using epinephrine as a vasoconstrictor does not have a significant effect on MAP.[59,61,62]

It appears that norepinephrine and levnordefrin's unfavorable β1:β2 ratio increases the risk of hypertensive crisis. Hypertension and negative cardiac effects secondary to the utilization of norepinephrine and levonordefrin vasoconstriction have been documented in the literature.[63,71,72] By contrast, epinephrine vasoconstriction does not appear to be a causative agent of hypertension. Many dentists have believed that the supposed hemodynamic action of epinephrine vasoconstriction is due to epinephrine's alpha adrenergic potency.[60] However, alpha adrenergic vasoconstriction is equalized because dental anesthetic formulations with less adrenergic potency are provided in increased concentrations; for example, levonordefrin is provided in a 1:20,000 formulation compared to the more potent epinephrine, which typically is provided in 1:100,000 formulations.[60]

TCAs and vasoconstrictors

The possibility of a problematic interaction between TCAs and epinephrine vasoconstriction has been a source of controversy.[60,70,73-75,79-83] In three studies that alleged such an interaction, the authors failed to explain the mechanism of the pharmacologic antidepressant drug action.[74,75,79] These authors were privy to the initial catecholamine reuptake blockade within the neurotransmitter synapse, the initial action of the antidepressant drug which would be expected to initially increase the agonist activity of catecholamines. However, the long-term neurotransmitter/drug action is downregulation of both alpha-1 receptors and serotonin (5HT) receptors; receptor downregulation takes approximately two to three weeks.[84-88]

These studies used either naive human subjects or animal models (and none of these subjects received the drugs for the two weeks necessary for alpha-1 downregulation); as a result, these studies reported the initial increase in blood pressure reactivity (due to the initial drug action of re-uptake synaptic blockade) and failed to evaluate the reality of the clinical utilization of these drugs in terms of long-term alpha-1 downregulation.[60,74,75,79] The authors have not found a single reported case of such an interaction (concerning drugs that have been utilized for millions of patients) in the medical or dental literature, suggesting that there is no clinical interaction between epinephrine vasoconstriction and TCAs within clinical practice.[60]

Nonselective beta blockers and vasoconstrictors

Brown and Rhodus made a similar conclusion about the alleged interaction between epinephrine in local anesthetics and nonselective beta blockers that produces hypertension.[60] The authors could find no reported cases of local anesthetic and epinephrine formulations utilized in dental treatment and nonselective beta blocker drug interaction in the literature.

Interaction between beta blockers and a local anesthetic with epinephrine vasoconstrictor may be possible, but it is extremely unlikely and may be related to a vasoconstrictor other than epinephrine, as the only reported dental clinical case report actually involved the vasoconstrictor levonordefrin.[89] There have been reports of hypertensive crises secondary to the vasoconstrictor norepinephrine.[63,71,90,91] As with levonordefrin, norepinephrine has an unfavorable β1:β2 ratio.[72] Norepinephrine is no longer used in the U.S.; however, levonordefrin is added to some formulations of mepivacaine. As a result, although there is no interaction between local anesthetics with levonordefrin and MAO inhibitors or TCAs, it may be prudent for patients taking nonselective beta blockers to avoid local anesthetics with levonordefrin vasonstrictors and instead use an alternate local anesthetic formulation.

Cocaine and vasoconstrictors

Although an interaction between epinephrine vasoconstriction and cocaine has been alleged, the real problem is additive, not interactive—in other words, there is a potential additive toxicity between cocaine and the dental local anesthetic used.[70,80]

Local anesthetics (including cocaine, mepivicaine, and lidocaine) all have cardiac toxicity potential. There is a danger that a dental patient using cocaine will be exposed to quantities of a dental local anesthetic that could add significantly to the total local anesthetic level of cardiotoxicity. However, the fact that cocaine is the only local anesthetic with significant vasoconstrictive properties suggests that adding a vasoconstrictor local anesthesia formulation (such as epinephrine) would also create another additive toxicity situation.[60] The vasoconstrictor tends to limit local anesthetics into the systemic circulation and thus may help to decrease local anesthesia toxicity.[60]

Malignant hyperthermia and local anesthetics

In the past, amide local anesthetics (for example, articaine, bupivacaine, etidocaine, lidocaine, mepivacaine, and prilocaine) were alleged to cause malignant hyperthermic reactions in patients susceptible to malignant hyperthermia; ester local anesthetics (for example, procaine) were advised for such patients.[1] However, according to the literature, animals that were susceptible to malignant hyperthermia showed no reaction to large doses of amide local anesthetics.[92,93] In addition, amide local anesthetics have been used safely in humans who were susceptible to malignant hyperthermia.[94,95] All local anesthetics are considered safe for these patients.[96-98]

Summary

There are no more important drugs in dentistry than local anesthetics and vasoconstrictors. Dentists should have an intimate knowledge of the properties of and techniques used with local anesthetics and vasoconstrictors, including injection pain, efficacy, toxicity, maximum dosages, duration, and drug interactions. Used properly, local anesthetics and vasoconstrictors are extremely safe and effective.

Author information

Dr. Wahl is in private practice in Wilmington, Delaware. Dr. Brown is a professor, Department of Oral Diagnostic Services, Howard University College of Dentistry in Washington, DC, and a clinical associate professor, Department of Otolaryngology, Georgetown University Medical Center in Washington, DC.

Exercise No. 256

Anesthesia & Pain Control

Subject code 132

The 15 questions for this exercise are based on the article, "Dentistry's wonder drugs: Local anesthetics and vasoconstrictors" on pages 114-123. This exercise was developed by Thomas C. Johnson, DMD, MAGD, in association with the *General Dentistry* Self-Instruction Committee.

Reading the article and successfully completing the exercise will enable you to:

- evaluate the factors that affect the pain from an anesthetic injection;
- understand the significance of the relative efficacy of lidocaine and articaine;
- understand the factors affecting the toxicity of local anesthetics and epinephrine; and
- review potential drug interactions with local anesthetics and vasoconstrictors.

1. Which of the following is true regarding the different anesthetics used?
   - A. Bupivacaine is more painful than prilocaine.
   - B. Prilocaine is more painful than lidocaine.
   - C. Lidocaine is more painful than mepivacaine.
   - D. Mepivacaine is more painful than articaine.

2. What is the most important factor in choosing a local anesthetic?
   - A. Efficacy
   - B. Concentration of epinephrine
   - C. Toxicity
   - D. pH

3. Compared to lidocaine 2% with epinephrine, which of the following is true about anesthetic without a vasoconstrictor?
   - A. Less likelihood of lip mutilation
   - B. A shorter duration of pulpal anesthesia
   - C. A lower concentration of anesthetic
   - D. Both have the same maximum recommended dose

4. What is the maximum recommended dose of lidocaine (in mg) for a 154-lb adult?
   - A. 300
   - B. 400
   - C. 500
   - D. 600

5. What is the maximum number of 1.8 cc cartridges of mepivacaine that should be used for a 50-lb child?
   - A. 2.1
   - B. 2.8
   - C. 2.4
   - D. 3.0

6. Which of the following is true about the administration of phentolamine mesylate?
   - A. It reduces the chances of lip mutilation for children of all ages.
   - B. It accelerates the systemic absorption of the local anesthetic from the injection site.
   - C. It blocks the beta-one receptor, thus complementing the action of the vasoconstrictor.
   - D. It is recommended when signs of anesthetic overdose are observed.

7. Which of the following is true about intraosseous injections?
   - A. They commonly elicit convulsions.
   - B. They require a larger volume of anesthetic than conventional injections.
   - C. They demonstrate slower absorption into the bloodstream than infiltration/block injections.
   - D. They can be more effective and have a faster onset than conventional injections.

8. What is the half-life of epinephrine?
   - A. Less than one minute
   - B. One to two minutes
   - C. Three to four minutes
   - D. More than four minutes

9. Which of the following is not true regarding the biotransformation or metabolism of epinephrine?
    A. Biotransformation is increased indirectly by its vasoconstrictor effects.
    B. Biotransformation occurs at a predictable rate once it enters the serum.
    C. Methylation is catalyzed by Catechol O-methyltransferase (COMT).
    D. Oxidation is catalyzed by monoamine oxidase (MAO).

10. What is the maximum dose (in mg) of epinephrine recommended for patients with heart disease?
    A. 0.2
    B. 0.4
    C. 0.6
    D. 0.8

11. How many mg of epinephrine are in an anesthetic cartridge containing 1.8 cc of lidocaine 2% with 1:50,000 epinephrine?
    A. 0.018
    B. 0.028
    C. 0.036
    D. 0.050

12. The maximum recommended dose of lidocaine 2% is clinically more significant than the maximum recommended dose of epinephrine. The utilization of two to three local anesthetic cartridges of 2% lidocaine with 1:100,000 epinephrine appears to be well-tolerated in dental patients with hypertension and cardiovascular disease.
    A. Both statements are true.
    B. The first statement is true; the second statement is false.
    C. The first statement is false; the second statement is true.
    D. Both statements are false.

13. Which of the following is true regarding anesthetic selection and dosage for a 50-lb child?
    A. An anesthetic without epinephrine provides a wider margin of safety to avoid overdose.
    B. Dentists can administer 6.5 cartridges of lidocaine with epinephrine before reaching the maximum recommended dose.
    C. Dentists can administer 2.4 cartridges of articaine with epinephrine before reaching the maximum recommended dose.
    D. The recommended dose for intraosseous injections usually is the same as that for infiltration/block injections.

14. What is the approximate pH of prilocaine plain?
    A. 3.5
    B. 4.5
    C. 5.5
    D. 6.5

15. An atraumatic injection technique should take approximately two minutes per cartridge. If the maximum number of cartridges is administered more quickly than two minutes each, significant serum epinephrine can accumulate.
    A. Both statements are true.
    B. The first statement is true; the second statement is false.
    C. The first statement is false; the second statement is true.
    D. Both statements are false.

Answer form and Instructions are on pages 159-160.

A novel, minimally invasive approach to managing mild epithelial dysplasia

Kevin D. Huff, DDS, MAGD ▪ Kurt C. Garren, MD ▪ Marlene S. Huff, RN, MSN, PhD

Conventional oral cancer screening examinations can be enhanced by direct tissue fluorescence visualization. Early dysplastic lesions detected during screening examinations often are monitored for progression or changes in appearance. Aggressive surgical intervention usually is contraindicated for mild epithelial dysplasia. As epithelial dysplasia progresses from mild to severe, the likelihood of it developing into carcinoma increases. Minimally invasive tissue management procedures should be considered as a possible method of early intervention to reduce the occurrence of oral cancer. This case report describes a novel approach to managing mild epithelial dysplasia when therapy is indicated (due to a high risk for oral cancer) but aggressive surgical management is contraindicated (due to a potential loss of function and increased morbidity).

Received: March 2, 2009
Accepted: May 5, 2009

Classically, epithelial dysplasia appears as subtle tissue changes that may be erythroplakic, leukoplakic, or erythroleukoplakic.[1] However, pre-neoplastic lesions may be undetectable when conventional oral cancer screening is performed under white lighting. It has been reported that adding direct tissue fluorescence visualization technology (VELscope, LED Dental Inc.) to a conventional oral cancer screening protocol is useful in identifying lesions that had not been detected on the same patients by conventional screening alone. In a 2009 study, 83% of those lesions detected with adjunctive technology were dysplastic, although they were occult.[2]

Twelve percent of dysplasias will become carcinoma *in situ* within five years, and 73% of those will likely progress to metastatic carcinoma. Mild dysplasia may take 58 months to convert to carcinoma, while severe dysplasias can become cancer within one year.[3] Unfortunately, there is no documented correlation between the clinical appearance and the grade of dysplasia; for such cases, a surgical biopsy is required for a definitive diagnosis.[4] Clearly, overall survival and patient morbidity is improved following early diagnosis and appropriate intervention and treatment.[5]

There is controversy as to whether mild epithelial dysplasia should be treated or monitored. The argument for observation without surgical intervention is based on the fact that the majority of dysplasias do not become cancer and that surgical intervention may cause unnecessary tissue injury and potential dysfunction.[3] The argument for surgical intervention may be that high-risk lesions should be radically excised to minimize the risk of carcinogenesis. As with all aspects of health care, there are multiple approaches to the management of any given situation, and the choice of care should be driven by a professional code of ethics.[6]

Early dysplasia in cervical tissues has been treated conservatively by using cryotherapy with liquid nitrogen.[7] Since the histological compositions of cervical tissues and oral mucosa are similar, it is plausable that cryotherapy may be useful for conservatively managing early dysplasias or pre-neoplastic lesions intraorally. The following case report illustrates how a case of mild epithelial dysplasia in a high-risk site was managed via cryotherapy.[1]

Case report

A 67-year-old man sought treatment for a broken mandibular right first molar. He was healthy and ambulatory with no significant medical history; specifically, he had no history of intraoral or extraoral cancer. He denied the use of alcohol, but he reported that he previously had a long-term habit (approximately 40 years) of chewing long tobacco. He claimed to have stopped chewing tobacco several years earlier.

As part of a comprehensive oral evaluation, a conventional oral cancer screening examination was conducted according to standard technique.[8] In addition, direct tissue fluorescence visualization imaging with the VELscope was employed as an adjunctive visual screening tool. An expansive loss of fluorescence did not blanch when blunt pressure was applied with the side of a periodontal probe, which indicated increased metabolic activity of epithelial cells (Fig. 1 and 2). The

Fig. 1. A conventional oral cancer examination indicates trauma from the fractured mandibular molar to the buccal mucosa.

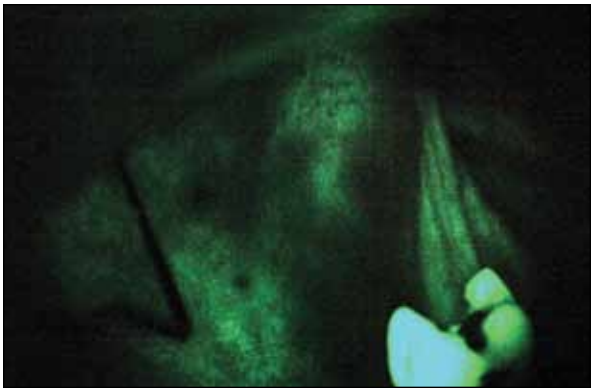

Fig. 2. Direct tissue fluorescence imaging reveals an expansive loss of fluorescence distal to the mandibular molar and extending distobuccally and distolingually around the retromolar pad.

Fig. 3. An incisional biopsy was taken at the center of the lesion, which is outlined in indelible ink.

Fig. 4. Liquid nitrogen was applied to the lesion using the dip-stick application method.

patient was informed that a suspicious lesion had been discovered that required re-evaluation in two weeks, and the fractured tooth was restored to eliminate the obvious source of potential trauma.

After two weeks, the lesion was still present. Liquid-based cytology was utilized as a secondary screening measure to confirm that the questionable area discovered during the initial examination was, in fact, abnormal tissue. A tissue sample was collected using a brushing technique and the entire sample (including the brush) was placed into SurePath solution (BD Diagnostics) and processed according to SurePath protocol. A board-certified oral pathologist reported that the sample was "suspicious for mild epithelial dysplasia" and recommended conducting a surgical biopsy of any persistent lesion.

Immediately following receipt of the positive cytology report, an incisional biopsy was performed. Following adequate local anesthesia using lidocaine with 1:100,000 epinephrine, a tissue sample was collected surgically from the center of the questionable area (Fig. 3) identified by the VELscope according to accepted protocol.[4,9] The biopsy specimen was placed in formalin and submitted for processing and diagnosis by a board-certified oral pathologist, who reported a diagnosis of mild epithelial dysplasia and recommended excising any persistent lesion.

The VELscope was used to help identify the margins of the lesion as described by Poh *et al.*[9] Liquid nitrogen was applied to the lesion and approximately 5 mm beyond the margin using the dip-stick applicator method described by Orengo and Salasche (Fig. 4).[10]

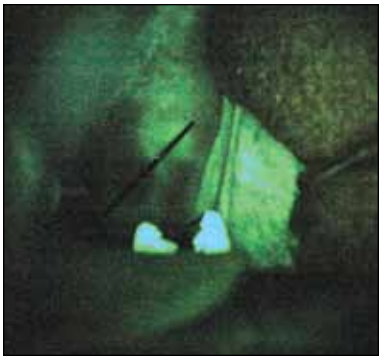

Fig. 5. The patient three months post-treatment, demonstrating a generalized loss of fluorescence that blanches with diascopic pressure, which is indicative of inflammation and tissue maturation.

Fig. 6. The tissues appear healthy one year after treatment.

Fig. 7. Normal fluorescence indicates that the dysplastic tissue in the right retromolar and retromylohyoid areas has resolved completely.

The patient returned for follow-up appointments and re-evaluation (consisting of oral cancer screening examination and direct tissue fluorescence visualization with the VELscope) every three months for one year (Fig. 5 and 6); during that time, tissue healing occurred uneventfully. At one year, direct tissue fluorescence imaging indicated no loss of fluorescence, suggesting that the tissues were healthy (Fig. 7). Throughout the course of therapy, the patient reported no pain, paresthesia, or morbidity.

Discussion

This case represents an example of utilizing minimally invasive ablation for the management of mild epithelial dysplasia. Conventional radical excision in the retromylohyoid region carries an elevated risk of injury to the lingual nerve that may result in permanent paresthesia and loss of taste. Scar tissue formation may lower the quality of life by complicating the swallowing and agglutination functions of the tongue. Therefore, avoiding surgical insult was desirable and in the patient's best interest. Laser ablation was considered; however, the authors anticipated a higher degree of postoperative discomfort following laser ablation. The patient reported no postoperative pain following cryotherapy, although he did complain that the tissues felt "leathery" for approximately one week.

Cryotherapy has not been documented for intraoral use as of this writing, and the patient was advised that this therapy was unconventional. He agreed to follow-up visits on a three-month basis. The tissues appeared to be normal after one year of close observation; at that time, the patient opted for semi-annual re-evaluation. Cytology was not repeated because a surgical biopsy was the only way to definitively confirm the presence of healthy or dysplastic tissues at follow-up visits. The authors and the patient felt that additional biopsies would be an unnecessary surgical insult to a site that appears to have responded favorably to treatment.

However, the patient has been faithful with regular re-evaluation since the initial submission of this report, with no apparent change in the healthy appearance of the treated tissues.

Summary

Since survival rates for oral cancer patients have not changed significantly over the past 30 years, proactive measures are indicated to improve the prognosis of oral cancer.[3] Minimally invasive measures that can manage early, potentially premalignant oral lesions should be seriously considered. Based on the results of the present case, cryotherapy is a novel and effective approach to appropriately managing mild epithelial dysplasia.

Resistance of composite and amalgam core foundations retained with and without pins and bonding agents

Terence A. Imbery, DDS ▪ Ryan Swigert ▪ Brian Richman ▪ Vincent Sawicki, DDS, PhD ▪ Lauren Pace
Peter C. Moon, PhD

To compare the resistance of different amalgam and composite core foundations retained by pins, bonding agents, or both, 100 molars were mounted in acrylic resin and their occlusal surfaces were reduced to expose dentin. Pins were inserted at the four line angles of the teeth and matrices were placed. Bonding agents were applied according to the manufacturers' instructions. Amalgam was hand-condensed and composite was incrementally added and photocured. Restorations were adjusted to produce specimens ($n = 10$) 5 mm in height with a 1 mm bevel at the axial-occlusal surface. After immersion in deionized water for 24 hours, specimens were loaded at a 45 degree angle on their beveled surfaces in a Universal Testing Machine at a crosshead speed of 0.02 in./minute. ANOVA and Tukey's tests indicated that FluoroCore 2 (with or without pins) was statistically stronger than all other combinations ($p < 0.05$).

Received: May 15, 2009
Accepted: July 24, 2009

A well-retained core foundation is a prerequisite for cast gold, porcelain-fused-to-metal (PFM), and ceramic crowns. Both amalgam alloy and composite resin may be used for core foundations.[1] Amalgam has the advantage of having proven its effectiveness for nearly 100 years. Historically, amalgam core foundations have been retained with pins; however, pin-retained amalgam core foundations present several disadvantages, including crazing of dentin, pulpal inflammation, decreased physical strength of the amalgam, and pin placement errors that may lead to periodontal or pulpal perforation.[2-5] In addition, unless a fast-setting, high-strength amalgam is used, the majority of amalgam core foundations and crown preparations must be completed and placed at separate appointments.[1]

Today, dentin bonding agents are able to bond amalgam to tooth structure. Several *in vitro* studies have demonstrated that amalgam core foundations retained with only an amalgam bonding agent are as retentive as foundations retained by pins.[6-8] An additive effect is obtained when pins are combined with amalgam bonding agents.[9] A six-year clinical study by Summitt *et al* reported that pin retention and amalgam bonding were equally effective for retaining extension amalgam restorations.[10] A recent *in vitro* study demonstrated that Scotchbond Multi-Purpose Plus (3M ESPE) provided more retention and resistance for flat, nonretentive preparations than four TMS Link Plus Regular pins (Coltene/Whaledent, Inc.), and that PQ Amalgam (Ultradent Products, Inc.) was the most cost-effective (with the fewest procedural steps) and was as effective as four TMS Regular pins.[8]

Composite resins are the most widely used core foundation material in private practice.[1] The main advantage of resins is that they allow dentists to prepare crowns at the same appointment. In addition, composites can match tooth shades very closely, allowing for a better shade match when an all-ceramic crown is planned. However, this advantage becomes a disadvantage if the shade match makes it difficult to discern the composite-tooth junction during crown preparation. Another disadvantage is that self-etch and total etch bonding agents containing acidic primers may cause incomplete polymerization; the basic tertiary amine activator in the dual-cured resin becomes inactive (through an acid-base reaction) with acidic monomers contained in the self-etch and total etch bonding agents.[11-15] To compensate for possible incomplete polymerization of the dual-cured resin, a bond enhancer or coupling agent must be applied to the cured dentin bonding agent. The use of a bond enhancer such as BondLink (Den-Mat Corporation) has been shown to improve the bonding of dual-cured resins to dentin bonding agents utilizing self-etching primers.[16]

CompCore AF (Premier Dental Products) and FluoroCore 2 (Dentsply Caulk) are dual-cured, fluoride-releasing resin composites with a viscosity that allows them to be stacked, while Tytin (Kerr

	Fumed silica
BondLink	2 Propanone
	Benzene sulfinic acid
CompCore AF	Catalyst (Bis-GMA and triethylene glycol dimethacrylates (TEGMA), benzoyl peroxide, barium silicate, fumed silica)
	Base (Bis-GMA and TEGMA, co-initiator, photoinitiator, barium silicate, fumed silica)
FluoroCore 2	Catalyst (urethane dimethacrylate (UDMA), aluminum oxide (Al_2O_3), benzoyl peroxide, barium boron fluoro alumino silicate glass)
	Base (UDMA, barium boron fluoro alumino silicate glass, camphoroquinone, photoinitiators, and accelerators)
Valiant Ph.D.	Admixed high copper alloy (52.5% silver, 29.7% tin, 17.5% copper, 0.3% palladium, 47% mercury)
Tytin	Spherical high copper alloy (59% silver, 28% tin, 13% copper, 42% mercury)

Dental) and Valiant Ph.D. (Ivoclar Vivadent) are two high-copper amalgam alloys. Tytin is a spherical, fast-setting alloy and Valiant Ph.D. is an admixed, slower-setting alloy. Adequate proximal contacts are easier to obtain via admixed alloys such as Valiant Ph.D.[17]

When Haller *et al* compared the retention of pin-retained amalgam and composite cores, the composite cores demonstrated only 56% the strength of amalgam cores.[18] Conversely, Tjan *et al* found composite cores to be more retentive than amalgam cores.[19] The present study sought to compare the retention of Valiant Ph.D., Tytin, CompCore AF, and FluoroCore 2 foundations when using pins, bonding agents, or a combination of the two. This study also evaluated how pin size, type of amalgam bonding agent, and type of core material affected retention. The chemical composition of each material used in the study is listed in Table 1.

Materials and methods

One hundred caries-free third molars of a similar size were cleaned of debris and disinfected for 30 minutes in a 0.5% solution of sodium hypochlorite and sterile water. The teeth were embedded in Orthodontic Resin (Dentsply Caulk), 2 mm apical to their cementoenamel junction (CEJ) (Fig. 1). The teeth were assigned randomly to one of 10 groups (n = 10): Tytin retained by four TMS Regular pins (Group A); Tytin retained by Scotchbond Multi-Purpose Plus (Group B); Tytin retained by four TMS Minim pins and Scotchbond Multi-Purpose Plus (Group C); Valiant Ph.D. retained by four TMS Minim pins (Group D); Valiant Ph.D. retained by PQ Amalgam (Group E); Valiant Ph.D. retained by PQ Amalgam and four TMS

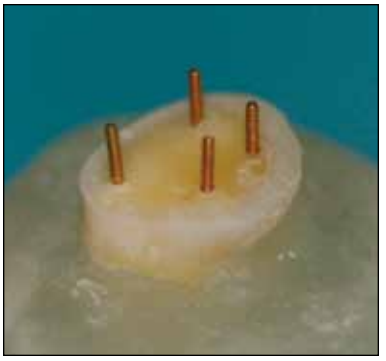

Fig. 2. A specimen with four TMS Link Plus Regular pins.

Fig. 3. A copper band matrix reinforced with dental impression compound.

Fig. 4. A specimen from Group J, following the application of FluoroCore 2.

Fig. 5. A Tytin specimen with a 1 mm bevel at the axial-occlusal line angle.

Regular pins (Group F); CompCore AF retained by Optibond Solo Plus and BondLink (Group G); CompCore AF retained by four TMS Minim pins, Optibond Solo Plus, and BondLink (Group H); FluoroCore 2 retained by four TMS Regular pins, Optibond Solo Plus, and BondLink (Group I); and FluoroCore 2 retained by only Optibond Solo Plus and BondLink (Group J).

The occulsal surface of each tooth was reduced to within 2 mm of its CEJ junction by using an Isomet saw (Buehler Ltd.) to essentially produce a flat, nonretentive surface. Using a 2 mm self-limiting twist drill (Coltene/Whaledent, Inc.) in a slow-speed handpiece (A-Dec), the teeth receiving four TMS Link Plus Regular or Minim pins had pin channels prepared at the four line angles of the tooth, within 1 mm of their dentin-enamel junctions. The pins were placed manually until the shoulder of each pin contacted dentin (Fig. 2).

Copper band matrices (Moyco Technologies) were adapted to the prepared teeth and supported with Impression Compound (Kerr Dental) (Fig. 3). All specimens restored with CompCore AF or FluoroCore 2 (Groups G–J) were etched for 15 seconds with an etchant (Scotchbond Etchant, 3M ESPE) containing 35% phosphoric acid, rinsed for 20 seconds with an air/water aerosol, and blotted dry. Optibond Solo Plus was applied by rubbing it gently onto the dentin surface for 15 seconds and gently air-thinning for five seconds to evaporate the ethanol solvent. This step was repeated and the bonding agent was photocured for 20 seconds (L.E.Demetron II, Kerr Dental). BondLink was applied by gently rubbing for 15 seconds and air-drying gently for five seconds. CompCore AF and FluoroCore 2 were applied in 2 mm increments, both of which were photocured for 60 seconds (Fig. 4).

The dentin surfaces of the Scotchbond Multi-Purpose Plus samples (Groups B and C) were treated with Scotchbond Etchant for 15 seconds and rinsed with an air/water aerosol for 30 seconds. The dentin surface was dried carefully to remove excess water while remaining slightly moist. Scotchbond Multi-Purpose Plus was applied according to manufacturer's instructions.

The dentin surfaces for the PQ Amalgam specimens (Groups E and F) were etched with Ultra-Etch (Ultradent) for 15 seconds and rinsed with an air/water aerosol for 30 seconds. A uniform layer of PQ Amalgam was applied according to manufacturer's instructions.

For specimens restored with amalgam, Tytin or Valiant Ph.D. was triturated in a Touch Pad amalgamator (Henry Schein, Inc.) for eight seconds and hand-condensed. For all groups, the copper band matrices were removed 10 minutes after the restorations were completed. Specimens were adjusted using a high-speed handpiece (A-Dec) to produce restorations 5 mm in height with a 1 mm bevel at the axial-occulsal surface (Fig. 5). All groups were stored in deionized water for 24 hours at 37°C; at that point, specimens were

Table 2. Mean fracture resistance. Groups with the same superscript letters are statistically similar ($p < 0.05$).

Group	Mean (SD)	Fractures
A	1,345 N (204)[a]	1

Fig. 7. Root fracture of a FluoroCore 2 specimen retained by pins and Optibond Solo Plus with BondLink. The core foundation remained intact.

placed in a universal testing machine (TTC, Instron Corp.) at a 45 degree angle and loaded in compression on their beveled surface until failure (Fig. 6). The load required for failure was recorded in Newtons. The parametric data were analyzed with an ANOVA and significant differences among the means were determined by Tukey's test at a confidence level of $p = 0.05$. In addition, linear contrasts were used to ascertain the effect of pin size, bonding agent, and core material.

Results

The mean fracture resistance, standard deviations (SD), and number of nonrestorable tooth fractures are listed in Table 2. The means ranged from a low of 1,345 N for Group A to a high of 3,035 N for Group J. Amalgam alloys and both resin cores retained by only the bonding agents (Groups B, E, G, and J) were statistically equivalent to their pin-retained counterparts. FluoroCore 2 specimens with and without pins (Groups I and J) were statistically stronger than all other groups. Of the 20 FluoroCore 2 specimens, 15 had nonrestorable tooth fractures; three of these were the result of the roots fracturing within the acrylic base without the core fracturing (Fig. 7). In general, as the resistance to fracture increased, so did the number of nonrestorable tooth fractures. The effect of pin size was not statistically significant ($p = 0.3172$). Similarly, the load required for failure in specimens retained by pins or an amalgam bonding agent was not statistically significant ($p = 0.0596$).

There was no statistical difference between the Scotchbond Multi-Purpose Plus used in Groups B and C and the PQ Amalgam used in Groups E and F ($p = 0.5299$), nor was there any difference between Valiant Ph.D. and Tytin ($p = 0.9559$). However, there was a significant difference among the four restorative materials, with FluoroCore 2 proving significantly stronger than Tytin, Valiant Ph.D., and CompCore AF ($p = 0.00001$). Together, the composite core materials were stronger than the amalgam alloys ($p = 0.0001$), with FluoroCore 2 being stronger than CompCore AF ($p = 0.0001$). Table 3 illustrates how pins, bonding agents, and restorative materials affected retention.

Fig. 8. Debonding of the entire amalgam core.

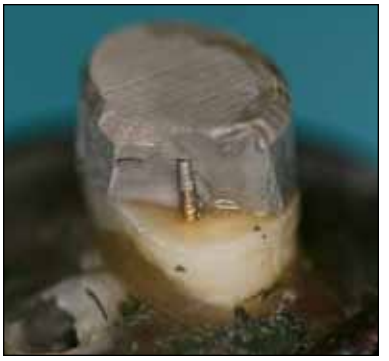

Fig. 9. A fracture within the amalgam at the pin/amalgam interface.

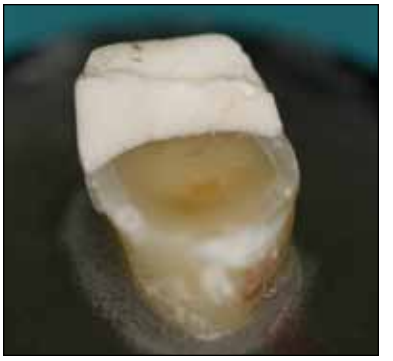

Fig. 10. A partial fracture within a CompCore AF specimen without pins.

Discussion

The results from Group A (1,345 N) are nearly identical to prior studies that used Tytin with four TMS Link Plus Regular pins (1,325 N) and Valiant Ph.D. with four TMS Link Plus Regular pins (1,340 N).[8,20] Smaller pins are recommended whenever possible, primarily because the smaller Minim pin has proven to be clinically successful while causing less dentin crazing.[1,2] Furthermore, if a Minim pin fails to insert adequately, it can be removed and the pin channel prepared for the larger Regular pin.

It was once suggested that the composite-to-dentin bond alone does not provide the required bond strength to resist crown rotation and dislodgement.[21] However, in the present study, CompCore AF retained by only Optibond Solo Plus (Group G) had the weakest composite core (1,930 N), which was statistically equivalent to all amalgam core foundations that used pins or a combination of pins and amalgam bonding agents. This result suggests that the strength of the composite-to-dentin bond can resist intraoral forces as well as pin-retained or bonded amalgam restorations.

Using an amalgam bonding agent as the only source of retention and resistance is not recommended.[1,17,22,23] However, Summitt *et al* used specimens similar to those used in the present study and demonstrated that bonded amalgam restorations were as successful as pin-retained restorations in terms of retention, pulpal vitality, recurrent caries, and additional tooth fracture.[10] As in the present study, several of the specimens restored by Summitt *et al* were essentially flat without any additional retention or resistance features such as grooves or pins, but they did not de-bond; any failures in that study were due to root fractures and recurrent caries rather than a loss of retention.[10]

A dentin bonding agent is not recommended as the only method of retention and resistance for composite core foundations.[1] Yet Group J samples (FluoroCore 2 retained by only Optibond Solo Plus with BondLink) demonstrated more than twice the strength of Group A samples (Tytin retained by pins only) (3,035 N to 1,345 N).

Fracture resistance of amalgam foundations increased when pins and bonding agents were utilized together, in keeping with previous laboratory studies that evaluated amalgam bonding in conjunction with pin retention.[7,9,24,25] Generally, filled resins provide greater bond strength than unfilled resins and spherical alloys provide greater bond strength compared to admixed alloys.[26] Mixing and matching the different types of alloys with amalgam bonding agents produced varying results. The bond between the spherical alloy and an unfilled resin (Group B) was slightly stronger (1,990 N) than the bond between an admixed alloy and a filled bonding agent (Group E) (1,880 N).

Four common failure patterns were evident. The first involved shearing off the entire core foundation at the dentin/core interface (Fig. 8), which occurred most often when amalgam was used with bonding agents only, suggesting that the bond between amalgam and dentin can be improved.

Failures also occurred within the core material, especially when pins were used without bonding agents (Fig. 9). This failure occurred more commonly in amalgam specimens than composite core specimens and always occurred at the pin/core interface, confirming that the

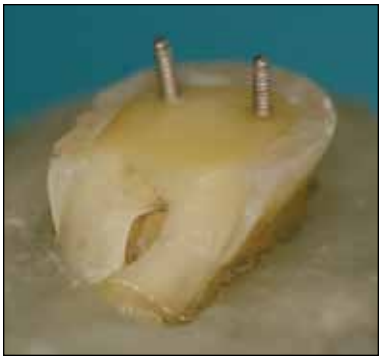

Fig. 11. A nonrestorable specimen with four TMS Link Plus pins, after fracture and pulp exposure.

Fig. 12. A nonrestorable partial fracture within a specimen of CompCore AF without pins.

Fig. 13. A specimen of CompCore AF, with pins bending away from the applied force.

presence of pins weakens the physical properties of amalgam.

The third type of failure was a partial loss of the core material, in which a portion of the core remained intact on the tooth (Fig. 10); this phenomenon occurred most commonly with composite core materials and suggests that the bonding configuration to dentin was nearly equal to the physical strength of the core material.

The fourth type of failure was a catastrophic root fracture, in which the roots embedded in the acrylic base fractured without the core foundation failing; this failure was observed in three FluoroCore 2 specimens and one CompCore AF specimen.

As the mean fracture resistance of the core foundations increased, so did the number of nonrestorable tooth fractures. Teeth were considered nonrestorable if failure resulted in a pulpal exposure or occurred 2 mm or more beyond the CEJ (Fig. 11 and 12). Most of the FluoroCore 2 specimens were nonrestorable, while amalgam foundations exhibited the fewest nonrestorable failures. This should not be a clinical concern because the reported maximum biting force in the molar region is approximately 800 N, far less than the mean fracture resistance measurement of all core foundations in the present study.[27,28]

It was noted that pins in the composite core materials tended to bend prior to the core's failure; however, pins in the amalgam cores remained upright or were directly sheared off at the level of the dentin, which could result from the stiff elastic nature of amalgam compared to the more viscoelastic nature of composite. The pins in the composite cores tended to bend away from the applied force, whereas pins in amalgam simply fractured (Fig. 13).

Historically, pin-retained amalgam restorations have been accepted as the clinical standard for a core foundation. Eight experimental groups in this study exceeded this standard, with some displaying more than twice the resistance strength, indicating that the restoration that had been considered the standard is actually the weakest among the groups tested.

One disadvantage of a pin-retained foundation is that the pin must be confined within the core after crown preparation. A PFM crown requires at least 1.5 mm of occlusal and axial reduction for maximum strength and esthetics; as a result, it may be necessary to extend a core preparation axially toward the pulp to ensure that pins are confined within the final crown preparation. This extension is especially difficult for premolars, which have smaller mesial-distal and buccal-lingual dimensions than molars.

The results of the present study indicate that it may be possible to rely on bonding a composite core in lieu of placing pins and risking pulpal exposure. There is a general decrease in the fracture resistance of cores following crown preparation; this decrease is significantly greater for amalgam than for composite.[29]

Compared to amalgam, composite core foundations can result in an increase in water absorption, less dimensional stability, weaker physical properties, and less caries inhibition.[1] The delayed water absorption may cause the crown to bind along the axial walls of the preparation, resulting in incomplete seating; however, this condition may be alleviated by sufficient application of die spacer.[30,31]

Another disadvantage of a dual-cured composite core is the potential incompatibility between the enamel/dental adhesive and the core material. A clinician may use

an enamel/dental adhesive from one manufacturer for routine operative procedures and a dual-cured composite core material from a different manufacturer, only to learn later that they are incompatible. Possible incompatibility between the bonding agent and dual-cured composite core materials can be prevented by using a bond enhancer such as BondLink.[16] The manufacturer of a core material may list compatible enamel/dental adhesives and bond enhancers.

An optimal composite-to-dentin bond cannot be formed if the smear layer is not completely removed. The conditioners/primers of many self-etching enamel/dentin adhesives do not contain a low enough pH to remove the smear layer completely. For that reason, the authors used Optibond Solo Plus, a two-step total-etch system that removes the smear layer completely and etches uncut enamel.

When choosing a core material, the core's physical properties are important. The compressive strengths of CompCore AF (40,600 psi) and FluoroCore 2 (44,092 psi) reported by the products' manufacturers are considerably lower than those of their amalgam counterparts, Tytin (65,000 psi) and Valiant Ph.D. (76,900 psi). However, the present study reported that the fracture resistance of the foundations of Groups H–J were approximately twice that of amalgam cores (Groups A and D), indicating that the effectiveness of the core's bonding configuration may be just as important as the core's physical properties. The presence of a ferrule may be even more important than physical properties, retention, and resistance form. *In vitro* studies have demonstrated that when crown preparations are located on sound tooth structure and extend at least 2 mm apically beyond the core foundation, there is no statistical difference among the different types of core materials (or even in the absence of a core material) in terms of the amount of force necessary to dislodge the crown.[32,33]

Conclusion

Amalgam and dual-cured resins both provided adequate core foundations. Pins and bonding agents were equally effective at providing retention form. Clinicians must understand the functional requirements of the core, as well as the advantages and disadvantages of various core materials and bonding agents and their compatibility with dual-cured resins. Dentists also must understand principles of retention and resistance and know the risks of pin placement and how it affects the physical properties of the core material. The ultimate choice of core material and retentive features may come down to personal preference, based on factors such as handling characteristics.

Exercise No. 257

Operative Dentistry

Subject code 250

The 15 questions for this exercise are based on the article "Resistance of composite and amalgam core foundations retained with and without pins and bonding agents," on pages 130-137. This exercise was developed by William U. Wax, DDS, FAGD, in association with the *General Dentistry* Self-Instruction Committee.

Reading the article and successfully completing the exercises will enable you to:

- determine the best method for placing cores;
- understand the testing procedures involved in determining core resistance to displacement;
- determine the best material to use in core formation; and
- be aware of problems that can arise when using different types of cores.

1. Which of the following is not a disadvantage of a pin-retained amalgam core?
   - A. Pulpal inflammation
   - B. Dentin crazing
   - C. Need for bonding agent
   - D. Periodontal perforation

2. Amalgam bonding is equal to the use of pins to retain a core restoration. Combining pins with a bonding agent has a deleterious effect on core retention.
   - A. Both statements are true.
   - B. The first statement is true; the second statement is false.
   - C. The first statement is false; the second statement is true.
   - D. Both statements are false.

3. The groups containing which of the following were statistically stronger than all of the others?
   - A. Valiant
   - B. CompCore AF
   - C. FluoroCore 2
   - D. Multi-Purpose Plus

4. The strength of the FluoroCore 2 samples was _____ times that of the Tytin group.
   - A. two
   - B. three
   - C. four
   - D. five

5. Amalgam's physical properties are weakened by which of the following?
   - A. Bonding agents
   - B. Smooth particle alloy
   - C. Using an admixed alloy
   - D. Retentive pins

6. Which of the following was not a common failure pattern seen in this study?
   - A. Complete core loss
   - B. Intracore fracture
   - C. Pin evulsion
   - D. Root fracture

7. The stronger the core foundation, the greater the possibility of unrestorable tooth fracture. In the present study, maximum molar biting force was greater than the mean fracture resistance.
   - A. Both statements are true.
   - B. The first statement is true; the second statement is false.
   - C. The first statement is false; the second statement is true.
   - D. Both statements are false.

8. Which of the following conclusions can be drawn from this study?
   - A. Pinned amalgam cores may be the ideal restoration foundation.
   - B. Bonded composite cores may be the ideal restoration foundation.
   - C. There is no risk in using pins in a premolar.
   - D. Fracture resistance increases following crown preparation.

9. Which core material had the greatest compressive strength?
    A. CompCore AF
    B. Tytin
    C. FluoroCore 2
    D. Valiant Ph.D.

10. Which of the following contributes most to the prevention of crown dislodgement?
    A. A 2 mm ferrule
    B. The core material's physical properties
    C. The core material's adhesive properties
    D. Absence of a smear layer

11. What type of cores are used most widely in private practice?
    A. Bonded amalgam
    B. Pinned amalgam
    C. Composite resin
    D. Pinned composite

12. When inserted properly, what do Minim pins minimize?
    A. Amalgam expansion
    B. Dentin crazing
    C. Composite failure
    D. Oral fluid leakage

13. The composite-to-dentin bond is strong enough to resist intraoral forces. Recurrent caries may be a factor in core loss.
    A. Both statements are true.
    B. The first statement is true; the second statement is false.
    C. The first statement is false; the second statement is true.
    D. Both statements are false.

14. Historically, which of the following have been accepted as the standard for cores?
    A. Pin-retained composites
    B. Bonded composites
    C. Bonded amalgams
    D. Pin-retained amalgams

15. Cured composite cores resist water absorption. Should core expansion occur due to water absorption, the problem can be solved by using a die spacer.
    A. Both statements are true.
    B. The first statement is true; the second statement is false.
    C. The first statement is false; the second statement is true.
    D. Both statements are false.

Immediate provisional restoration fabrication for immediate implant loading using a modified technique: A clinical report

M. Erhan Comlekoglu, DDS, PhD ▪ A. Yucel Parlar, DDS ▪ Bulent Gokce, DDS, PhD ▪ Mine Dundar, DDS, PhD
Erdem Kaya, DDS ▪ Tayfun Gunbay, DDS, PhD

This article describes the immediate fabrication and placement of a provisional restoration, using a modified method for impression-making. An impression was made before surgery and provisional acrylic temporary restorations with composite resin frameworks were prepared on the solid-screw implant abutments. This article demonstrates this simple method and discusses the benefits of immediate provisionalization after surgery.

Received: December 30, 2008
Accepted: March 20, 2009

Implant treatment can produce considerable anxiety, discomfort, and inconvenience for patients. *Immediate loading of an implant* refers to placing an implant-supported restoration into occlusal loading within 48 hours after implant placement.[1] Implants placed using the standard loading protocol include a healing period of three to six months, followed by an osseointegration period of another three to six months, resulting in up to one year of stress and discomfort.[2] Immediate placement and loading of implants has been utilized to reduce these inconveniences, especially through the introduction of objective implant primary (initial) stability measurements.[3-5]

To maintain the primary stability of implants that are intended to be loaded immediately, stabilizing splinting (using rigid, precisely fitted superstructures) has been recommended to decrease the risk of overloading the implants and to place them in favorable cross-arch positions.[6,7] Splinting the implants distributes the occlusal forces over a greater surface area, offering a biomechanical advantage.[6,7] Regardless of the implant design, splinted prostheses have demonstrated a higher success rate (94.7%) than implants restored with single crowns (88.4%).[8]

Temporary metal-supported acrylic prostheses are used most commonly for splinting.[9] However, making an impression immediately after surgery can cause more discomfort for an already tired patient. Placing the impression caps on the abutments at the fresh surgical site (that is, the site of the finished surgical procedure) requires a meticulous procedure and sutures should be maintained without the risk of disturbing the impression material.[9-11] This article describes a simple method for taking an immediate impression for immediate loading of mandibular posterior solid-screw implants.

Case report

A 55-year-old man was considering implant treatment due to severe periodontal problems. Radiographic and clinical examinations revealed a loss of alveolar height and gingival tissue at the mandibular implant sites. His opposing maxillary dentition consisted of an implant-supported full-mouth metal-ceramic fixed partial denture (FPD), which had been placed one year earlier by two of the authors (TG and EK) without any advanced surgical techniques or grafting. The patient had worn a mandibular removable partial denture (RPD) until maxillary treatment was completed. Since his maxillary implants (SLActive, Straumann) were immediately loaded at that time, and his definitive FPDs were fabricated six months after surgery, he was acquainted with immediate loading treatment procedures. The patient was offered treatment options (including a mandibular RPD or implant-supported crowns) but accepted implant therapy because he did not want to wear a removable denture.

To determine the patient's eligibility for immediate loading, the quality and quantity of the hard and soft tissue in the implant site were examined; in addition, radiographic and computed tomography (CT) examinations were performed. The patient had slightly decreased levels of hard and soft tissues at the site of the mandibular left implant but did not have any

Fig. 2. The solid-screw implants are placed.

Fig. 3. Composite resin cores are placed on the implants.

Fig. 4. An autopolymerizing acrylic pattern resin was applied to the buccal flanges of the modified template to connect the composite cores to the template.

Fig. 5. Composite resin cores are attached to the acrylic template.

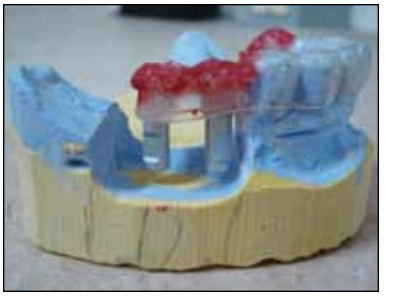

Fig. 6. The template is placed on the master cast.

parafunctional habits and was willing to receive immediately loaded provisional cemented crowns. The patient had no systemic disorders to contraindicate implant surgery.

One week before the surgery, preliminary impressions of both arches were made with an irreversible hydrocolloid (CA37, Cavex Dental) and immediately poured with a Type IV dental stone (Glastone, Dentsply Trubyte). Composite resin caps for solid-screw implants (Straumann) were prepared on solid-screw implant analogues to serve as cores (frameworks) for the acrylic crown superstructures. An acrylic surgical template was prepared (Fig. 1). The distal extensions of the template were removed, leaving the bilateral buccal acrylic template supports (flanges) to connect the resin core caps with the template. The template was tried in the mouth for adaptation and stability before surgery.

The surgery was performed under local anesthesia and the 4.1 mm solid-screw implants were placed as guided by the acrylic surgical template (Fig. 2). Implants were placed to provide at least 1.5 mm from the adjacent dentition. Primary stability was optimized by selecting the 12 mm implants and by the resulting resonance frequency analysis measurements, using the Osstell Mentor (Osstell) with a minimum Implant Stability Quotient (ISQ) of 65. The final insertion torque was 45 Ncm. The prepared composite resin frameworks were placed on the abutments. The disinfected template was placed in the mouth; at that point, using a mini-brush, an autopolymerizing acrylic resin (Pattern Resin, GC America Inc.) was applied meticulously to the composite cores and the buccal supports of the template (Fig. 3 and 4). After the resin set, the template-composite core assembly was removed from the mouth (Fig. 5) and the flap was closed.

At that point, the implant sites on the master cast were carved and the solid-screw implant analogues were mounted on the template-composite core assembly (Fig. 6). Type IV dental stone was poured into the created cavities on the master cast (Fig. 7) and ceramic polymer provisional crowns (Solidex, Shofu Dental Corporation) were fabricated on the composite resin cores (Fig. 8).

Fig. 7. Type IV dental stone is poured into the cavities.

Fig. 8. Acrylic crowns are prepared on the composite cores on the cast and finished.

Fig. 9. The patient after composite resin was progressively added to the occlusal surfaces.

Fig. 10. A panoramic radiograph of the patient one week after surgery.

On the day of surgery, the crowns were cemented temporarily (Temp-Bond Cement, Kerr Dental) (Fig. 9). Occlusion was checked, posterior disclusion with anterior group functioning was maintained, and the occluding surfaces were brought into contact from a single point. Since excess cement could lead to peri-implantary tissue infection over time, periapical radiographs were taken to observe the excess cement and/or any adaptation problem.

After surgery, the patient was given ibuprofen (1.2 g per day for five days) and instructed to rinse with 0.2% chlorhexidine gluconate for at least one minute twice a day for two weeks. During the immediate loading period, the patient was given instructions for a specific soft diet. Restorative composite resin (Filtek Z250, 3M ESPE) was applied to the occlusal surfaces incrementally for progressive loading. The resin was applied monthly onto the occlusal surfaces to gradually bring the surfaces into full contact. Definitive crown fabrication was performed four months after surgery (Fig. 10) after resonance frequency analysis results reported an ISQ value of approximately 82.

The patient was scheduled for follow-up evaluations at 1, 3, 6, and 12 months postsurgery and annually thereafter. At each follow-up visit, periapical radiographs were taken using a paralleling technique to evaluate peri-implant crestal bone-level changes over time. No complaints were reported for two years postsurgery.

Discussion

Immediate loading of dental implants requires a nonsubmerged, one-stage surgery technique, in addition to loading the recently placed fixtures with a provisional or definitive prosthetic restoration. Immediate implant restoration with functional loading provides better patient comfort and allows quick chewing function and esthetics (when the implants are placed in the anterior region) while eliminating the need for additional surgery to place transepithelial abutments.[7,10] Immediate implant restoration often leads to early soft tissue healing and early stabilization of the peri-implant mucosa, ensuring a higher implant survival rate.[7]

The immediate loading performed in the present case eliminated the need to take any painful postsurgical impressions. Metal-reinforced acrylic is the recommended FPD design for immediate loading protocols; however, since this case required a crown rather than an FPD, it was decided to prepare the crowns by taking an impression before surgery. Although esthetics was not a major concern in the present case, the acrylic/restorative composite resin materials provided good esthetics, indicating that this method could be easily applied for

immediate implant-crown fabrication in the anterior, where esthetics is very important.

Since the implants were placed in the posterior region, one-point contact—followed by progressive loading with anterior group functioning occlusion—was applied to improve mastication. Restorative composite resin was applied incrementally on the occlusal surfaces of the restorations to gradually bring the crowns into full contact without the need for crown removal and restoration fabrication procedures in the dental laboratory.

Stereolithography is a technique that uses computer-generated templates with a rapid prototyping technology. This method transfers the implant position intraoperatively from a three-dimensional computer model to one-stage surgery.[12] However, this technique requires individual surgical template fabrication, which costs more and is used only during the surgical stage of implant treatment.

In the present case, an acrylic surgical template was used for implant placement. Although an acrylic template does not provide three-dimensional implant placement, the surgeons were experienced enough to position the implant correctly once the location of the implants was indicated by the holes in the template. The abutments in the present case were solid and not angulated, suggesting that this method could not be applied for angulated abutments, since composite resin cores can be fabricated easily on solid analogues. Since fewer implants were placed, implant-supported provisional crowns were fabricated with composite cores. When multi-unit implant-supported FPDs are made for full-mouth reconstructions, frameworks should be prepared using metal instead of resin to guarantee the mechanical strength of the restorations.[7,8]

Summary

Immediate implant placement and loading provides many advantages for the patient. However, impression-making after surgery and dental laboratory procedures present difficulties for both the clinician and the patient. This case report defined a simple and cost-effective method of immediate loading by using composite resin cores and acrylic without the need for making an impression after surgery.

Criteria for performing extraction in the treatment of certain malocclusions

Farhad Moshiri, DMD, MS

This article identifies variables that should be assessed in patients with certain dental malocclusions that may require extraction. In addition, by presenting criteria for performing the more popular types of extraction, the article facilitates treatment decision-making. Pre- and post-treatment illustrations demonstrate the desired patient outcomes.

Received: November 18, 2008
Final revisions: April 30, 2009
Accepted: May 15, 2009

In the past, orthodontists have vacillated radically about the need to extract. Many cephalometric analyses have relied heavily on the angulation of the mandibular incisors.[1-4] Consequently, many practitioners would accept only an ideal relationship of the mandibular incisors to bone, discounting the wide range of variability existing in normal, stable dentition.

Today, as a result of the efforts of many orthodontic researchers and clinicians, there is information about the importance of soft tissue changes (secondary to skeletal modifications) and dental movement.[5-11] There also is research regarding soft tissue remodeling as it relates to aging and gender differences.[6,7] This information has provided an important context for treatment decisions and has strengthened practitioners' skill in projecting the long-term stability of treatment outcomes.

Increasingly, dentists have employed a combination of hard and soft tissue parameters, early interceptive treatment, reducing enamel from the interproximal areas of the dentition in borderline cases, orthognathic surgery, and temporary anchorage devices (TADs); as a result, many have been able to treat their patients without performing extractions.[7,8,10,12-14] In fact, to some extent, the number of extractions has decreased. As reflected in the literature, this trend has arisen in part in response to concerns about whether extraction contributes to a more retrusive, or dished-in, profile.[7] Numerous studies have examined the alleged differences produced by the two types of treatment, and most conclude that, if a thorough diagnostic assessment has occurred—with particular attention to the extent of pretreatment crowding—there is no detrimental effect on the face as a function of extraction and, indeed, the stability of treatment outcomes may be improved.[11,13,15]

In any case, it is clear that the extraction of teeth should be regarded as the treatment method of choice for certain types of malocclusion. The question of which teeth to extract may be addressed by considering the patient's profile or facial balance; the amount of arch length discrepancy/crowding; the inclination of the mandibular incisors; the discrepancy in tooth size; the mandibular plane angle (paying particular attention to projected growth); the health of the patient's gingiva, bone, root structure, and temporomandibular joints; the patient's age and gender; and the etiology of the malocclusion (that is, whether it is skeletal and/or dental in origin).

The following classification system offers criteria for performing what are probably the most common types of extraction currently used by most orthodontists in the United States.[11,13,15-22] Cases illustrating each method are included.

Extraction of the maxillary and mandibular first premolars

This type of extraction is utilized for patients with bimaxillary protrusion (that is, dentoalveolar protrusion that causes the teeth to thrust forward beyond the normal position on the basal bone), anterior crowding of 5 mm or more, and Class I or Class II occlusion (with the potential for additional growth). Prior to such an extraction, the dentist should determine the need to preserve anchorage (that is, keeping the molars close to their original position).

Figure 1 shows a 12-year-old girl with facial convexity, a lack of chin prominence, a constricted maxilla, and crowded dental arches. Extraction of her four first premolars helped to correct her arch forms and midlines, provide a detailed occlusion, and improve facial balance (Fig. 2).

Figure 3 shows the pretreatment views of a 12-year-old girl who had a functional occlusion but also had bimaxillary protrusion,

Fig. 1. Extra- and intraoral pretreatment views of a 12-year-old girl with facial convexity.

Fig. 2. Extra- and intraoral post-treatment views of the patient in Figure 1.

Fig. 3. Extra- and intraoral pretreatment views of a 12-year-old girl with bimaxillary protrusion and a constricted maxilla.

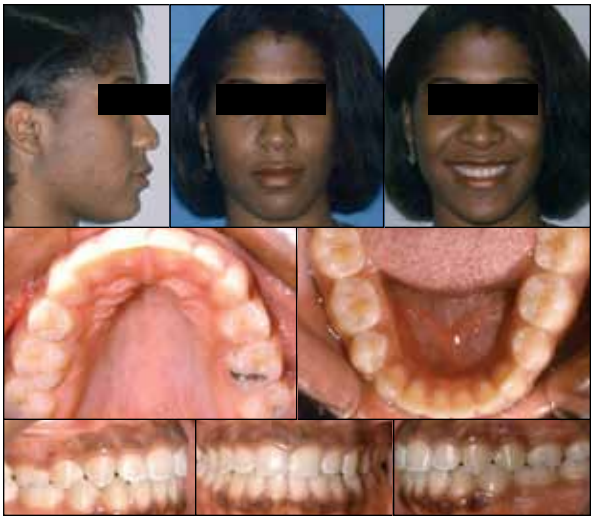

Fig. 4. Extra- and intraoral post-treatment views of the patient in Fig. 3.

a constricted maxilla, and a lack of chin prominence. Despite a lack of crowding, evaluation of hard and soft tissue parameters dictated extraction of the four first premolars. This course of treatment resulted in improved facial balance and fine tuning of the occlusion (Fig. 4).

Extraction of the maxillary and mandibular second premolars

Extraction of the maxillary and mandibular second premolars should be considered for patients who have a balanced facial profile with moderate crowding and good axial inclination of the mandibular incisors. Preserving anchorage is not critical for these patients, so molars can move mesially. This type of extraction is warranted for a patient whose first premolars are already in good alignment, but who would require extensive orthodontic movement to bring the second premolars into a satisfactory position. These

Fig. 5. Extra- and intraoral pretreatment views of a 12-year-old girl with Class I occlusion and two missing mandibular second premolars.

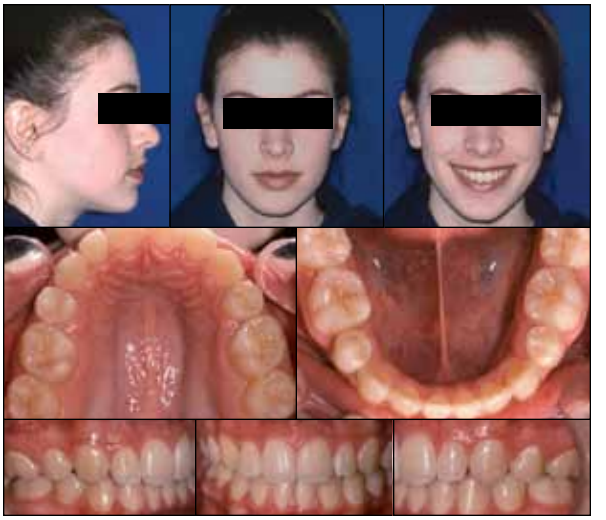

Fig. 6. Extra- and intraoral post-treatment views of the patient in Fig. 5.

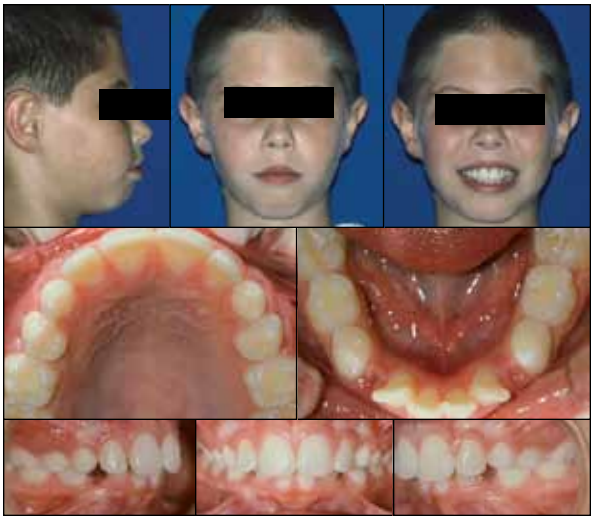

Fig. 7. Extra- and intraoral pretreatment views of a 9-year-old boy with severe facial convexity.

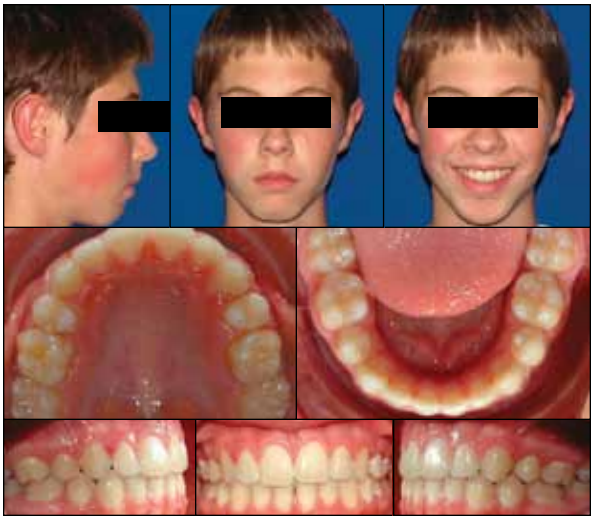

Fig. 8. Extra- and intraoral post-treatment views of the patient in Fig. 7.

patients may also present with evidence of caries or other unsound dental conditions (that is, compromised occlusion or the loss of one or more second premolars).

Figure 5 shows the pretreatment views of a 12-year-old girl who had a reasonably balanced face, a Class I occlusion, and two missing mandibular second premolars. Two maxillary second premolars were extracted, which helped to improve facial balance, correct arch forms, and provide a detailed occlusion. This method of treatment also avoided the need for any future prosthodontic rehabilitation (Fig. 6).

Extraction of the maxillary first and mandibular second premolars

This type of extraction is appropriate for patients who exhibit Class II occlusion with increased overjet, and should be performed when facial growth is completed or nearly complete. Additionally,

Fig. 9. Extra- and intraoral pretreatment views of a 10-year-old girl with Class III malocclusion and reduced overjet.

Fig. 10. Extra- and intraoral post-treatment views of the patient in Fig. 9.

Fig. 11. Extra- and intraoral pretreatment views of a 33-year-old man with Class III malocclusion, a severe arch length discrepancy, and an anterior crossbite.

Fig. 12. Extra- and intraoral post-treatment views of the patient in Fig. 11.

these patients may experience moderate crowding of the mandibular arch but will have good axial inclination of the mandibular incisors.

Figure 7 shows a young boy (9 years, 6 months) who had severe facial convexity and lack of chin prominence. Extraction of his maxillary first premolars and mandibular second premolars helped to improve facial balance, correct arch forms, and provide a detailed occlusion (Fig. 8).

Extraction of the maxillary second and mandibular first premolars

Extracting these premolars can provide a successful treatment option for patients who have Class III malocclusion with reasonable alignment of the maxillary teeth. Patients for whom this procedure is appropriate also will exhibit crowded or proclined mandibular incisors in addition to an anterior edge-to-edge or an anterior crossbite occlusion.

Figure 9 is a pretreatment view of a 10-year-old girl with a Class III dental malocclusion and reduced overjet. Extraction of the maxillary second premolars and mandibular first premolars led to a corrected occlusion (Fig. 10).

Figure 11 presents a pretreatment view of a 33-year-old man with a Class III dental malocclusion, a severe arch length discrepancy, and an anterior crossbite. His maxillary second premolars and mandibular first premolars were extracted,

Fig. 13. Extra- and intraoral pretreatment views of a 52-year-old woman with misaligned mandibular molars.

Fig. 14. Extra- and intraoral post-treatment views of the patient in Figure 13.

which led to a corrected dental relationship, showing that extraction can be performed easily despite completion of growth (Fig. 12).

Extraction of maxillary first premolars only

According to the literature, extraction of maxillary first premolars is indicated for patients who have minimum growth potential, maxillary protrusion (with the mandibular teeth in good alignment), good buccal occlusion with a Class II relationship (or a half-cusp Class II finishing to a solid Class II), and a slight open bite tendency.[19] In the author's experience, some patients experience orofacial pain as a result of this type of extraction.

Extraction of one mandibular incisor

This procedure can help patients who have an anterior edge-to-edge occlusion with minimal mandibular crowding (that is, 5 mm or less—approximately the width of a mandibular central incisor). This procedure is appropriate for patients with complete exclusion of the incisor from the dental arch, the presence of tooth size discrepancy, and good buccal occlusion.[18]

Figure 13 shows a 52-year-old woman who expressed concern about the misalignment of her mandibular incisors. Extraction of one mandibular incisor resulted in corrected arch forms and a fine-tuned occlusion (Fig. 14). Based on the literature and the author's clinical experience, this method of treatment is effective for many adult patients.[18]

Bilaterally dissimilar extraction of premolars

Guided by the above criteria regarding appropriate candidates for this treatment, dentists can use bilaterally dissimilar extraction of premolars to correct midline discrepancies or asymmetrical classification of dentoskeletal conditions (for example, one side Class II and the other side Class I). Figure 15 shows the pretreatment views of a 14-year-old boy who had a reasonably balanced face but also had moderate crowding of his maxillary and mandibular arches and a midline discrepancy. After extracting the maxillary right second premolar, the maxillary left first premolar, and the mandibular right and left second premolars, the patient's arch forms and midlines were corrected; he also demonstrated detailing of his occlusion (Fig. 16).

Summary

The debate over whether to extract teeth has existed in orthodontics for decades and is likely to continue *ad infinitum*. While many patients have been successfully treated without extraction, failure to extract and an over-reliance on alternative methods of space management could lead to a compromised profile, long-term instability, and the risk of periodontal problems.[4,5,8,9,12]

This article does not seek to compare the efficacy of extraction versus nonextraction; rather, it emphasizes the complexity of the treatment planning process and the

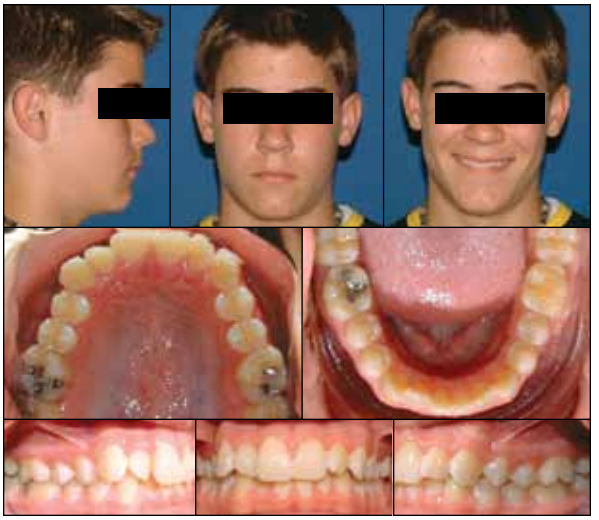

Fig. 15. Extra- and intraoral pretreatment views of a 14-year-old boy with midline discrepancy and moderate crowding of his maxillary and mandibular arches.

Fig. 16. Extra- and intraoral post-treatment views of the patient in Figure 15.

need to arrive at treatment decisions that are informed by thorough assessment and careful diagnosis. By applying the criteria provided, together with detailed clinical examination and proper hard and soft tissue analyses, dentists can feel confident in choosing extraction as a treatment option and performing it in a manner that ensures the best outcome for each patient.

Persistent tongue ulcer

Nikolaos G. Nikitakis, DDS, PhD
John K. Brooks, DDS

A 60-year-old man was referred by his general dentist for evaluation of a tongue ulcer of a few weeks' duration. The patient did not recall biting or burning the area; however, for approximately a year, he had noticed the frequent occurrence of white-to-yellow lesions on the lateral border of the tongue in the area of the current ulcer. The patient indicated that the ulcer was painful during eating or when it rubbed against his teeth. The patient's medical history was significant for chronic obstructive pulmonary disease (for which he was receiving oxygen therapy and theophylline, as well as fluticasone, salbutamol, budesonide, and formoterol inhalers); in addition, he was receiving antihypertensive diuretics (amiloride and hydrochlorothiazide) and omeprazole for gastric ulcer protection. He had smoked four packs of cigarettes a day for 40 years (a habit he discontinued four years earlier) and was a social drinker.

Clinical examination revealed a 1 cm x 1 cm ulcer on the left lateral border of the tongue (Fig. 1), which was making contact with a sharp-edged retained root of the mandibular left first molar. The root fragment was extracted; however, a two-week follow-up assessment revealed no clinical signs of improvement in the ulceration. An incisional biopsy was undertaken for histopathologic assessment (Fig. 2).

Which of the following is the most appropriate diagnosis?

A. Squamous cell carcinoma
B. Atypical histiocytic granuloma
C. Chancre
D. Mucormycosis
E. Eosinophilic ulceration

Diagnosis is on page 153.

Fig. 1. Ulcer surrounded by a white halo on the left lateral border of the tongue.

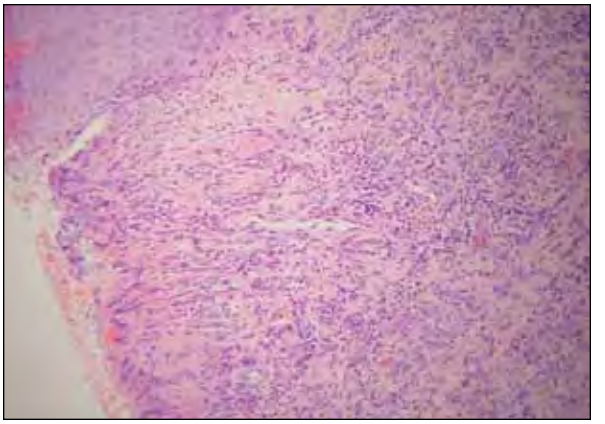

Fig. 2. Mucosal ulceration covered by a fibrinopurulent membrane; the ulcer bed consists of granulation tissue diffusely infiltrated by chronic inflammatory cells with numerous eosinophils (H&E stain, magnification 100x).

Diffuse oral mucosal pigmentations

Nikolaos G. Nikitakis, DDS, PhD
John K. Brooks, DDS

A 54-year-old woman was evaluated for numerous brownish lesions that were affecting her mouth. She had discovered the lesions incidentally one month earlier, although she was unsure when they first appeared. The lesions were asymptomatic and had not changed perceptibly in appearance since their onset. No similar hyperpigmentations were apparent on the skin or other mucosal surfaces. The patient had smoked 5–10 cigarettes per day for approximately 30 years. The medical history was significant only for a nodular goiter, which had been regulated by levothyroxine for the last 10 years. In addition, the patient had experienced an eruption of urticaria that had been managed with levocetirizine for approximately three years; however, this medication had been discontinued for at least six months.

Clinical examination revealed diffuse brown macules with irregular borders, affecting the buccal mucosa bilaterally and the upper and lower labial mucosa (Fig. 1). An incisional biopsy was performed (Fig. 2). After the patient discontinued her smoking habit, the lesions demonstrated a slow progressive reduction in terms of size and color intensity.

Which of the following is the most appropriate diagnosis?

A. Malignant melanoma
B. Intramucosal nevus
C. Smoker's melanosis
D. Amalgam tattoo
E. Addison's disease

Diagnosis is on page 153.

Fig. 1. Diffuse brown pigmented lesions on the right buccal mucosa.

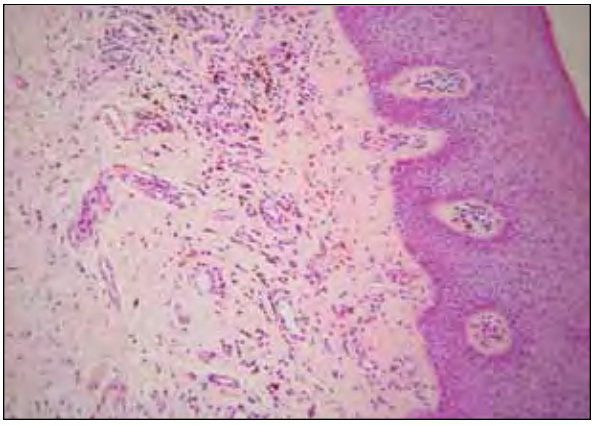

Fig. 2. Diffuse melanin pigmentation, free and within melanophages, in the superficial connective tissue and occasionally within the epithelial basal cell layer (H&E stain, magnification 100x).

Author information
Dr. Nikitakis is an assistant professor, Department of Oral Pathology and Oral Medicine, School of Dentistry, National and Kapodistrian University of Athens, Athens, Greece.
Dr. Brooks is a clinical professor, Department of Oncology and Diagnostic Sciences, Dental School, University of Maryland, Baltimore.

Quiz No. 166

Differential diagnosis of orofacial pain

1. Which of the following central nervous system (CNS) structures is involved in the trigeminal nociceptive mechanism?
   A. Subnucleus interpolaris
   B. Subnucleus oralis
   C. Main sensory nucleus
   D. Subnucleus caudalis

2. Patients sometimes have difficulty localizing pulpal pain due to convergence of neurons in the
   A. thalamus.
   B. cerebral cortex.
   C. trigeminal spinal tract nucleus.
   D. dorsal horn of the spinal cord.

3. Nociceptive signals along the trigeminal pain pathway are perceived as pain when the signals reach the
   A. subnucleus caudalis.
   B. posterior parietal cortex.
   C. thalamus.
   D. motor cortex.

4. Which of the following is not caused by central sensitization?
   A. Secondary hyperalgesia
   B. Primary hyperalgesia
   C. Referred pain
   D. Muscle co-contraction and myofascial trigger points

5. Which of the following represents deep somatic pain?
   A. Mucogingival pain
   B. Traumatic neuralgia
   C. Musculoskeletal pain
   D. Atypical odontalgia

6. Which of the following is an example of neuropathic pain?
   A. Myofascial pain
   B. Fibromyalgia
   C. Postherpetic neuralgia
   D. Cervical pain

7. Which of the following statements is true of psychogenic pain?
   A. It is caused by noxious stimuli.
   B. It is caused by an abnormality of the nervous system.
   C. It has a predictable pattern of pain location.
   D. There is no relationship between symptoms and an organic basis for pain.

8. Which of the following should be considered first when making a differential diagnosis of orofacial pain?
   A. Heterotropic pain
   B. Intracranial pain disorder
   C. Migraine
   D. Myofascial trigger point pain

9. Which of the following causes a reproducible pattern of referred pain?
   A. Myofascial pain
   B. Pain of pulpal origin
   C. Pain of periodontal origin
   D. Cluster headache

10. Which of the following neurovascular pain disorders is referred to as a *suicide headache*?
    A. Classic migraine
    B. Tension-type headache
    C. Cluster headache
    D. Chronic daily headache

This quiz was written by Chikka M. Raju, DMD, MAGD, ABGD, in cooperation with the other Self-Assessment Committee members.

Answers are on pages 154–156.

Oral Diagnosis

Persistent tongue ulcer

Diagnosis:

E. Eosinophilic ulceration

Traumatic ulcerations of the oral mucosa are commonly encountered. They are caused by a variety of stimuli, including accidental biting, sharp teeth or restorations, prosthetic appliances, aggressive tooth brushing or flossing, and foodstuffs. Traumatic mucosal ulcers can be classified as acute or chronic, depending on their duration. Chronic ulcers may result from persistent injury (for example, a fractured tooth that continuously irritates the mucosa), although they may remain even after the traumatic etiology is removed. Eosinophilic ulceration (traumatic ulcerative granuloma with stromal eosinophilia) is a special subtype of chronic traumatic ulceration, characterized by a more protracted course and the microscopic presence of eosinophils. Similar lesions on the ventral and (less often) dorsal surface of the tongue in infants are attributed to nursing-associated trauma from anterior natal or neonatal teeth, referred to as *Riga-Fede disease.*

Clinically, chronic traumatic ulcers (including eosinophilic ulcerations) appear as well-defined lesions, usually covered by a yellowish pseudomembrane and surrounded by a white raised border. Induration of the margins may be discerned on palpation. Although lesions may occur anywhere in the oral mucosa, they typically occur at sites that are easily exposed to injury, such as the buccal mucosa, lips, and tongue. Lesions are often minimally symptomatic. Eosinophilic ulcerations sometimes appear raised, due to granulation tissue overproduction.

On microscopic examination, chronic traumatic ulcerations are covered by a fibrinopurulent membrane and exhibit granulation tissue with a mixed inflammatory infiltrate. The surrounding epithelium may show regenerative changes and appear hyperplastic. In addition, eosinophilic ulceration features deeper extension of the inflammatory response into the connective tissue, with a conspicuous population of eosinophils and sometimes an exuberant granulation tissue reaction. This lesion needs to be distinguished from atypical eosinophilic ulceration (a monoclonal process characterized by cellular proliferation of large cells of T-lymphocytic lineage), which shows a potential for frequent recurrence and dissemination.

Lesions that are clinically compatible with chronic traumatic ulcers or eosinophilic ulcerations that do not heal within two weeks after removal of the purported traumatic stimulus must be biopsied to rule out other possibilities, most notably squamous cell carcinoma or ulcers of infectious etiology (tuberculosis, syphilis, deep mycoses). Incisional biopsies frequently promote healing. In persistent cases, topical or intralesional application of corticosteroids, in combination with mucosal barriers, may induce or accelerate healing.

Diffuse oral mucosal pigmentations

Diagnosis:

C. Smoker's melanosis

Oral pigmentation due to smoking is a relatively common finding and is associated with the degree and duration of usage. Melanin production increases in response to smoke substances and has been suggested to serve a protective role against cellular damage. Women are affected more frequently than men, presumably because of the synergistic effect of the female sex hormones.

The most commonly affected site associated with smoker's melanosis is the anterior facial gingiva; however, any oral mucosal surface may be involved. Smoker's melanosis may be seen in the gingiva of children, ostensibly due to secondhand smoke exposure. Lesions may be quite diffuse and appear brown, with varying intensity of color. They must be distinguished from racial pigmentation and other diffuse pigmented lesions of various causes, including drug-induced pigmentations, post-traumatic pigmentation, heavy metal poisoning, and systemic diseases such as Addison's disease, neurofibromatosis, hemochromatosis, McCune-Albright syndrome, and Peutz-Jeghers syndrome. Malignant melanoma, which is rare in the oral mucosa, also may appear as diffuse pigmentation.

A biopsy of a suspected smoker's melanosis lesion is indicated when there are atypical clinical findings, such as irregular borders, heterogenous pigmentation, surface elevation of texture, pigmentary changes, and abrupt onset. Microscopic examination reveals increased melanin deposition in the basal cell layer of the

epithelium and/or dispersed free or within melanophages in the superficial connective tissue. Cessation of smoking usually promotes a slow, progressive improvement in the clinical appearance of the lesions.

Self-Assessment Quiz No. 166

1. Answer: D

The pain sensation is carried to the central nervous system (CNS) by a complex arrangement of neurons, interneurons, and synaptic connections that together are referred to as the *trigeminal system.* Primary afferent neurons carry sensory information from the face and mouth (except proprioception) to synapse with second order neurons in the trigeminal brain stem complex. This complex can be separated into the trigeminal main sensory nucleus and the trigeminal spinal tract nucleus. The trigeminal spinal tract nucleus is divided into three separate nuclei. From a superior (rostral) to inferior (caudal) direction, they are called the *subnucleus oralis,* the *subnucleus interpolaris,* and the *subnucleus caudalis* (the latter of which is involved in the nociceptive mechanism of the trigeminal nerve).

1. Conti PC, Pertes RA, Heir GA, Nasri C, Cohen HV, Araujo C. Orofacial pain: Basic mechanisms and implication for successful management. J Appl Oral Sci 2003;11(1):1-7.
2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:13-42.

2. Answer: C

The trigeminal spinal tract nucleus primarily receives afferent input from the trigeminal nerve and also from the facial, glossopharyngeal, vagus, and upper cervical (C2, C3) nerves. This convergence of neurons from different areas may synapse on another neuron, resulting in the brain being unable to interpret the exact location of the original pain source. For example, in early pulpal pain, the brain may appreciate that there is a toothache somewhere but cannot localize it.

1. Conti PC, Pertes RA, Heir GA, Nasri C, Cohen HV, Araujo C. Orofacial pain: Basic mechanisms and implication for successful management. J Appl Oral Sci 2003;11(1):1-7.
2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:13-42.

3. Answer: B

After first order neurons synapse with second order neurons in the subnucleus caudalis, nociceptive signals are carried to the thalamus. From the thalamus, signals reach different parts of the somatosensory cortex through third order neurons. Incoming nociceptive signals from the subnucleus caudalis and ascending nociceptive signals on their way to the thalamus can be modified by descending nerve fibers from higher levels of the CNS or through various drugs. This process is called *pain modulation,* which is the inherent ability of the nervous system to alter the intensity of nociceptive signals and reduce pain intensity. After transmission and modulation, the nociceptive signals are perceived as pain in the posterior parietal cortex of the brain.

1. Conti PC, Pertes RA, Heir GA, Nasri C, Cohen HV, Araujo C. Orofacial pain: Basic mechanisms and implication for successful management. J Appl Oral Sci 2003;11(1):1-7.
2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:13-42.

4. Answer: B

Following tissue injury, a continuous barrage of noxious afferent input results in the spontaneous firing of afferent fibers and the sensitization of nociceptors at the site of injury (primary hyperalgesia). When a second order neuron receives these prolonged nociceptive inputs, it may also become sensitized, causing hyperexcitability of CNS interneurons. This phenomenon is referred to as *central sensitization.* The central excitatory effects produce changes in afferent sensory neurons (secondary hyperalgesia and referred pain), efferent motor

neurons (muscle co-contraction and myofascial trigger points) and the autonomic nervous system (injection of the conjunctiva, lacrimation, nasal secretion, nasal congestion).

1. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:64-73.
2. Cohen S, Burns R. Pathways of the pulp, ed. 9. St. Louis: Mosby;2006:62-64.

5. Answer: C

Somatic pain is caused by the noxious stimulation of normal neural structures of the affected area. When the external surface of the body is involved, the pain is called *superficial somatic pain* (for example, cutaneous pain and mucogingival pain) and is characterized by a bright, stimulating quality. The pain can be localized, is anatomically accurate, and is proportionate to direct stimulation. Topical anesthetic at the site will temporarily arrest the pain.

In contrast, if the pain originates from a deep body structure, it is called *deep somatic pain* (for example, musculoskeletal pain and visceral pain); it is characterized by a dull, depressing quality. The pain may not be localized, is anatomically less accurate, and may not be proportional to the stimulus. Application of a topical anesthetic usually does not arrest the pain except in the visceral mucosa. Deep somatic pain also frequently generates effects secondary to CNS sensitization. These effects may include referred pain, localized autonomic effects, secondary hyperalgesia, and muscle co-contraction. Atypical odontolgia is a continuous neuropathic pain disorder, characterized by the absence of dental pathology.

2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:103-133.
3. Balasubramaniam R, Klasser GD. Orofacial pain and dysfunction. Oral Maxillofac Surg Clin North Am 2008;20(2):ix-x.

6. Answer: C

Neuropathic pain results from a structural abnormality of the nervous system itself, characterized by the absence of any obvious noxious stimulation. It is out of proportion to the degree of stimulation (that is, light touch can cause intense pain), may present paresthesia along the nerve distribution, and is relatively unresponsive to low doses of narcotic analgesics. Neuropathic pain is usually described as being bright, intense, stimulating, and burning, and can be divided into episodic (for example, trigeminal, glossopharyngeal, superior laryngeal, and geniculate and intermedius neuralgias) and continuous disorders (for example, peripheral neuritis, herpes zoster, postherpetic neuralgia, traumatic neuralgia, and atypical odontolgia).

1. Pertes RA. Differential diagnosis of orofacial pain. Mt Sinai J Med 1998;65(5-6):348-354.
2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:103-133.
3. Balasubramaniam R, Klasser GD. Orofacial pain and dysfunction. Oral Maxillofac Surg Clin North Am 2008;20(2):ix-x.

7. Answer: D

Psychogenic pain is not caused by noxious stimuli or any abnormality of the nervous system; it is characterized by the history of definite emotional or personality disorders, and the absence of any anatomical relationship between the site and source of pain. There is no relationship between physical symptoms and any organic basis for the pain. Psychogenic pain may be felt in many areas and locations. The degree of pain is often exaggerated and the treatment outcome usually is inconsistent. Examples of psychogenic pain include depressive disorders, bipolar disorders, and post-traumatic stress disorders.

1. Pertes RA. Differential diagnosis of orofacial pain. Mt Sinai J Med 1998;65(5-6):348-354.
2. Okeson JP. Bell's orofacial pains, ed. 5. Chicago: Quintessence Publishing Co., Inc.;1995:103-133.
3. Balasubramaniam R, Klasser GD. Orofacial pain and dysfunction. Oral Maxillofac Surg Clin North Am 2008;20(2):ix-x.

8. Answer: B

Intracranial pain disorders (for example, neoplasm, aneurism, abscess, hematoma, and edema) must be considered first in the differential diagnosis because of life-threatening consequences. The characteristics of pain from an intracranial source include an abrupt onset, progressively more severe pain, interruption of sleep, weight loss, ataxia, weakness, fever, neurologic signs, and the pain precipitated by exertion or positional change (for example, coughing and sneezing).

1. Okeson JP, ed. Orofacial pain: Guidelines for assessment, diagnosis and management, ed. 4. Carol Stream, IL: Quintessence Publishing Co.;2008:55.
2. Pertes RA. Differential diagnosis of orofacial pain. Mt Sinai J Med 1998;65(5-6):348-354.

9. Answer: A

Myofascial pain is the most common form of musculoskeletal pain, affecting the head, neck, and face. It is characterized by a localized area of tight, palpable, tender bands of muscle called *myofascial trigger points* (TPs). When provoked or palpated, TPs refer pain in reproducible patterns to areas distant from the site of TPs (known as the *zone of reference*). The key to diagnosing myofacial pain is to identify TPs and "a reproducible pattern of referred pain."

1. Conti PC, Pertes RA, Heir GA, Nasri C, Cohen HV, Araujo C. Orofacial pain: Basic

mechanisms and implication for successful management. J Appl Oral Sci 2003;11(1):1-7.
2. Pertes RA. Differential diagnosis of orofacial pain. Mt Sinai J Med 1998;65(5-6):348-354.

10. Answer: C

Neurovascular pain disorders (also known as *primary headache disorders*) are a vascular response to a neurologic mechanism. The cluster headache (CH) is also referred to as a *suicide headache* and is one of the most severe forms of headache and facial pain. It is relatively uncommon. CH manifests as sharp, throbbing, or boring pain of severe intensity that can be associated with lacrimation, conjunctival injection, rhinorrhea, nasal congestion, miosis, ptosis, or eyelid edema and facial sweating. These headaches are unilateral, usually side-fixed throughout the lifetime of the patient, and may last from 15 minutes to three hours.

Migraine headache usually manifests as unilateral pain, has a pulsating quality, is moderate to severe in intensity, is aggravated by physical activity, and is accompanied by nausea, vomiting, photophobia, or phonophobia. The attack usually lasts 4–72 hours.

Tension-type headache often manifests as bilateral dull pain, is non-pulsating, has a mild to moderate intensity, is not aggravated by physical activity, and is not accompanied by nausea or vomiting. The attack may last from 30 minutes to seven days.

Chronic daily headache has a similar presentation to tension-type headache with superimposed episodes of migraine.

Correction

In the September-October 2009 issue, the abstract for the October Case Study, "Chondrosarcoma of the mandible: Case report and literature review" (p. 467) should have read as follows:

Chondrosarcoma is a malignant cartilaginous tumor that rarely occurs in the maxillofacial bones. A 44-year-old woman complained about swelling and mild pain during mastication in the right parasymphysis region. Clinical and radiographic examinations revealed characteristics of osteosarcoma. A microscopic examination revealed an abundant proliferation of malignant neoplastic cartilage cells of varying sizes arranged as immature tissue and the absence of an osteoid matrix. This article presents a case of chondrosarcoma of the jaw and discusses the differences between osteosarcoma and chondrosarcoma.

Correction

In the November/December 2009 issue of *General Dentistry,* the Dental Materials column (pp. 550-551) included an incorrectly cited reference. The paragraph in question should read:

With self-etch products being introduced on almost a weekly basis, you would think that the gold standard had shifted away from total-etch. But even the owner of one of the most prolific manufacturers of both types of adhesives was quoted recently as stating that he still considers "fourth generation, total-etch adhesives" as the pinnacle.[2] In addition, the only bonding agent to receive a five-star rating (the highest possible rating based on clinical and laboratory testing) in the 2009 Annual Edition of REALITY happens to be a fourth generation, total-etch product. Furthermore, the bonding agent that created the so-called seventh generation (that is, an all-in-one self-etch material) has recently undergone brand extension with the introduction of a total-etch sibling.

2009 Reviewers

CE credits from a source you can trust

self CDE CREDIT instruction

For more than 15 years, the Self-Instruction program has offered informative articles, challenging exercises, and low-priced, high-quality continuing dental education. If you have yet to take advantage of the opportunity to participate in this exciting PACE-approved program, sign up below or visit us on the Web at *www.agd.org/publications/gd/selfinstruct* to find out what you've been missing.

Whether you're looking for continuing education credits for state license renewal, your AGD membership maintenance requirement, or the AGD Fellowship or Mastership award, or if you're simply seeking to expand your knowledge, the Self-Instruction program has exactly what you need.

The program

Now it's easier than ever to record and submit exercises and earn CE credit! An exercise-specific answer form for submitting your Self-Instruction exercises is located on the back side of this page. Please use this form if you submit your Self-Instruction exercises via regular mail or fax.

The form is easy to use: Simply tear it out or make a copy of it, record your answers for the Self-Instruction exercises in this issue, and fax or mail the form to us. For AGD members, credit will be entered on your transcript immediately once the form is graded.

For participants, the Self-Instruction program offers convenience, simplicity, and faster accreditation—what could be better? If you have any questions regarding this answer form, call toll-free 888.243.3368, ext. 4353.

FAQs

Academy of General Dentistry™
PACE Program Approval for Continuing Education

Approved PACE Program Provider
FAGD/MAGD Credit
Approval does not imply acceptance by a state or provincial board of dentistry or AGD endorsement (06/01/2006) to (05/31/2010)

How do I register?
Simply submit the form below. A letter confirming your enrollment will be sent within two weeks of registration. Exercises may be submitted upon receipt of registration.

How long do I have to submit my exercises?
All exercises must be submitted within 12 months of enrollment.

How do I submit answers?
Fill out the exercise-specific answer form on the back side of this page and mail or fax it as indicated on the form. Answer forms must be completed as directed in the instructions; otherwise, they will not be processed.

When are answers due?
Answers for the exercises in this issue (No. 255–257) must be received by February 28, 2011. Credit will not be awarded for exercises postmarked after the deadline.

How much credit is earned?
Participants must answer at least 12 of the 15 questions correctly (80%) to earn two CE credits.

How is credit registered?
AGD members
The results are entered directly into your CDE record, which is maintained by the AGD. You may request a printout of your CDE record at any time during the year, or you can view it on the AGD's Web site at *www.agd.org/education/transcript.*

Nonmembers
You will receive a letter acknowledging successful completion of an exercise. These letters may be submitted to the appropriate state board or agency for licensure purposes.

What if I don't pass?
A letter will be sent to all participants who score below 80%.

Please direct all other questions to Cassandra Bannon, either via phone (toll-free) at 888.AGD.DENT (888.243.3368), ext. 4353 or via e-mail at *self-instruction@agd.org.*

Sign up today!

6 exercises (12 credits)
❑ $100 (AGD member rate)

Evaluation of shear bond strength between self-etching adhesive systems and dentin and analysis of the resin-dentin interface

Cleonice Silveira Teixeira, DDS, MSc, PhD ▪ Marcelo Carvalho Chain, DDS, MSc, PhD

This study evaluated the shear bond strength between dentin and four self-etching adhesive systems: Clearfil SE Bond (Group 1), Optibond Solo Plus SE (Group 2), Adper Prompt SE (Group 3), and Tyrian SPE (Group 4). A single-bottle adhesive system (Optibond Solo Plus) was used as the control (Group 5). The resin-dentin interface was analyzed by using scanning electron microscopy (SEM). The facial and lingual surfaces of 40 human molars were wet-ground flat; the teeth then were assigned randomly to one of five groups. Each adhesive system was applied to the dentin and the respective resin was applied using a Teflon mold. After 24 hours, the specimens were sheared at a crosshead speed of 1 mm/minute. Five additional teeth were prepared for SEM.

Mean scores (±SD) in MPa were highest for Group 1 (33.23 ± 12.67), followed by Group 2 (32.41 ± 9.90), Group 5 (30.68 ± 4.08), Group 4 (21.37 ± 5.87), and Group 3 (17.50 ± 4.24). The statistical analysis by Kruskal-Wallis and Wilcoxon Rank-Sum tests revealed no significant difference ($p > 0.05$) between Groups 1, 2, and 5. Groups 3 and 4 were different from the others and from each other ($p < 0.05$). The fracture modes were mostly interfacial/adhesive and cohesive in the resin. SEM analysis of the resin-dentin interface showed a homogeneous gap-free hybrid layer for all groups.

Received: March 9, 2008
Accepted: May 9, 2008

Esthetic dentistry has developed considerably in recent decades. The majority of modern adhesive systems utilize a preliminary acid-etching step, which is applied over the enamel and dentin. Dentin etching is necessary to remove the smear layer and to expose the collagen fibrils.[1]

Problems have been associated with the adhesive systems that use acid preconditioning, related to the adhesive's capacity for infiltrating into the demineralized collagen. Some articles have stressed that the adhesive does not always penetrate into the dentin as deeply as the acid does during the preconditioning, leaving an unprotected basal portion of collagen that is not embedded in the resin.[2-4] Collagen fibrils that are unprotected and incompletely coated with resin are more easily affected by hydrolysis, enzymatic attack, and functional and thermal stress, eventually resulting in the degradation of the bond.[5] This weakened zone would be susceptible to hydrolysis from oral and dentinal fluids, jeopardize the bonding strength and durability, and cause microleakage and its consequences.[5]

Systems that act as a conditioner and primer at the same time may be used to avoid this type of problem, since the dentin will be demineralized and infiltrated simultaneously by the monomers.[6,7] At present, self-etching adhesives are used widely, mainly because of their ease of use, their low technique-sensitivity, and their adequate performance in Class V clinical trials.[8-10] One-step self-etching systems mix hydrophobic and hydrophilic monomers together with a large amount of solvent. This adhesive strategy is based on the dissolution and fixation of the smear layer, through the infiltration of mildly acidic hydrophilic monomers.[6,7] Most self-etching systems are methacrylate-based and contain highly acidic monomers, with a pH of approximately 1.5–2.5.[6,7,11]

Various studies have questioned the capacity of these adhesive systems to demineralize the dentin sufficiently to form the hybrid layer.[10] This layer may have a limited thickness or may be absent in some areas of the dentin/restoration interface, resulting in a decreased bond strength and loss of adhesion.[4,10] Some studies have indicated that adhesives which use the total etching technique result in a better performance.[2,11] Other studies have reported better performance from self-etching adhesives, indicating a need for additional research to resolve this question and verify the bond strength of current self-etching primer systems.[8,9]

This study sought to determine the *in vitro* shear bond strength of four self-etching adhesive systems: Clearfil SE Bond (J. Morita USA, Inc.) (Group 1), Optibond Solo

Table 1. Materials, batch numbers, composition, and application procedures as used in the present study.

Material (batch number)	Composition	Application steps
Clearfil SE Bond (00151 B)	Primer: MDP, HEMA, CQ, N,N-diethanol p-toluidine, hydrophilic dimethacrylate, and water (pH 2)	a (20 seconds), b (3 seconds)
	Bond: MDP, Bis-GMA, HEMA, hydrophobic dimethacrylate, CQ, N,N-diethanol p-toluidine, and silanated colloidal silica	c, b, d (10 seconds each)
Clearfil AP-X (00384B)	Silanated barium glass; silanated silica; silanated colloidal silica; bisphenol A diglycidylmethacrylate; triethyleneglycol dimethacrylate; d,1-camphorquinone.	e, d (40 seconds)
Optibond Solo Plus SE (205187)	Ethyl alcohol; alkyl dimethacrylate resins; stabilizers and activators; water	a (15 seconds), b
Optibond Solo Plus (206171)	Ethyl alcohol; alkyl dimethacrylate resins; barium alumino borosilicate glass; fumed silica (silicon dioxide); sodium hexafluorosilicate	c (15 seconds), c (15 seconds again), b, d (20 seconds)
Point 4 (212194)	Uncured methacrylate ester monomers; inert mineral fillers; activators; stabilizers	e, d (40 seconds)
Adper Prompt (Liquid A: 131438; Liquid B: 127613)	Liquid A (red blister): Methacrylated phosphoric esters, Bis-GMA, initiators based on camphorquinone, stabilizers; Liquid B (yellow blister): Water, HEMA, polyalkenoic acid, stabilizers	Mix Liquid A and Liquid B (5 seconds), a (15 seconds), b, d (10 seconds)
Filtek Z250 (2 TT)	Uncured methacrylate ester monomers; inert mineral fillers; activators; stabilizers	e and d (40 seconds)
Tyrian SPE (0200002694)	2-acrylamido-2-methyl propanesulfonic acid; bis (2-(methacryloyloxy) ethyl) phosphate; ethanol	Activation (10 seconds), a (30 seconds), f
One Step Plus (0200003755)	Bi-phenyl dimethacrylate; HEMA; acetone; glass filler	c, b, d (20 seconds)
Pyramid (0200003588)	Bisphenol A diglycidylmethacrylate; ethoxylated bisphenol A dimethacrylate; triethyleneglycol dimethacrylate; glass filler	e, d (40 seconds)
Magic acid (00302) (Vigodent Ltd.)	37.0% phosphoric acid; water; silica gel; dye colorant	g (15 seconds), h (30 seconds), f
Optibond Solo Plus (206171)	Ethyl alcohol; alkyl dimethacrylate resins; barium alumino borosilicate glass; fumed silica (silicon dioxide); sodium hexafluorosilicate	c (15 seconds), c (15 seconds), b, d (20 seconds)

a — application of self-etching primer
b — air spray
c — adhesive application
d — photocuring
e — composite resin application (1.5 mm thickness increments)
f — removal of excess with cotton pellet
g — acid application
h — rinsing in tap water

Plus SE (Kerr Dental) (Group 2), Adper Prompt SE (3M ESPE) (Group 3), and Tyrian SPE combined with One Step Plus (Bisco Inc.) (Group 4). A one-step total-etching adhesive system (Optibond Solo Plus, Kerr Dental) (Group 5) was used as a control. In addition, scanning electron microscopy (SEM) was used to verify the formation of the hybrid layer on the tooth/restoration interface that resulted from the use of each adhesive system. The null hypothesis tested was that there are no differences between the different types of self-etching systems (either one- or two-step) regarding bond strength and formation of the resin-dentin interface.

Materials and methods

This study utilized 45 extracted caries-free maxillary and mandibular human molars. The teeth were stored in 0.1% thymol and 0.9% saline solution (pH = 7) for three to six months; 40 teeth were used for the shear bond testing and five were used for SEM analysis.

Shear bond test

Using double-faced flexible diamond discs (KG 7020, KG Sorensen Ind. Com. Ltda.) at low speed, the teeth were cut in a mesiodistal direction to enable the use of the buccal and lingual surfaces. The selected faces were ground with diamond points (No. 1956, KG Sorensen Ind. Com. Ltda.) at high speed under irrigation until a smooth dentin surface was

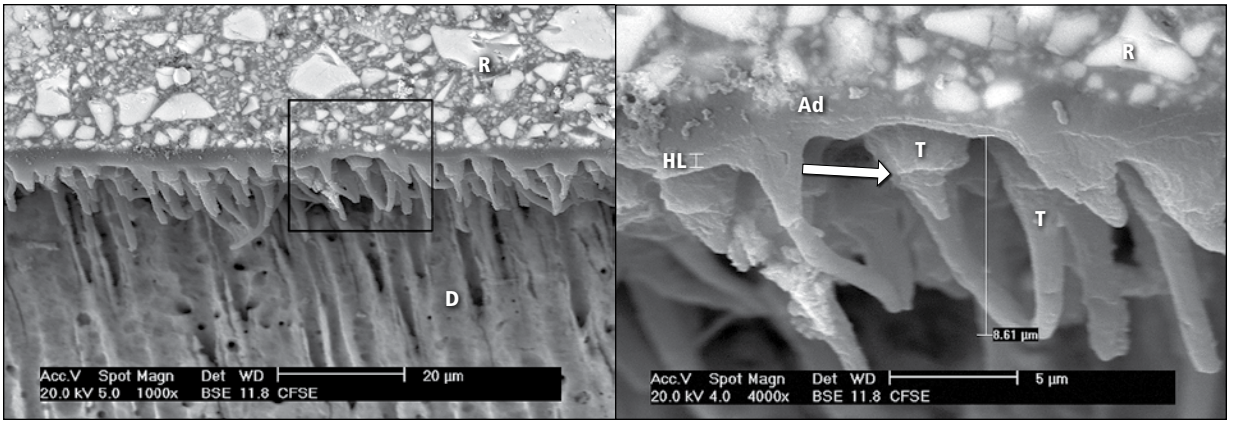

Fig. 1. *Left*: A micrograph of the adhesive interface from a slice of occlusal dentin treated with the Clearfil SE Bond adhesive system and restored with Clearfil APX composite resin (magnification 1,000x). *Right*: A micrograph of the central portion of this specimen (magnification 4,000x). Ad = adhesive; HL = hybrid layer; D = dentin; R = resin; T = tag.

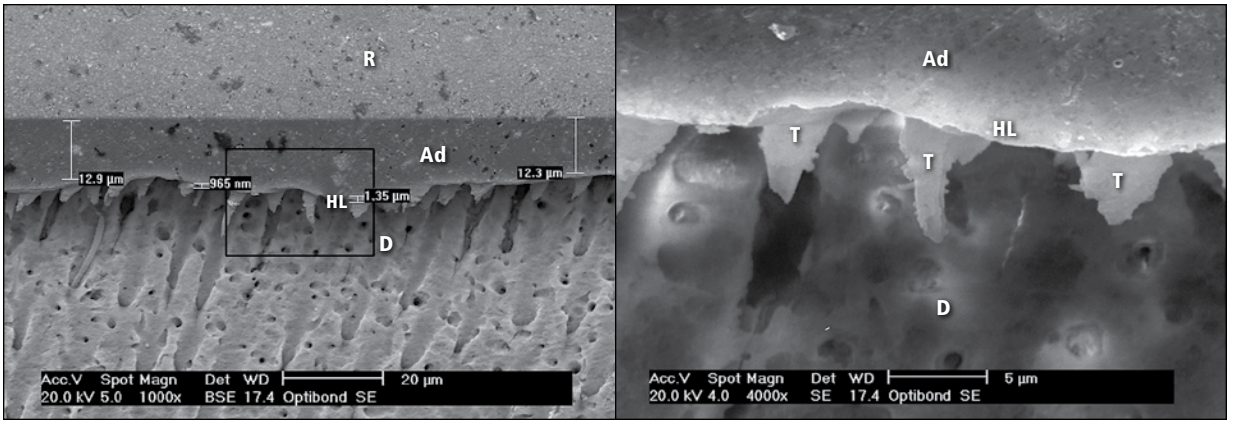

Fig. 2. *Left*: A micrograph of the adhesive interface from a specimen treated with the Optibond Solo Plus SE system and restored with Point 4 composite resin (magnification 1,000x). *Right*: A micrograph of the central portion of this specimen (magnification 4,000x) reveals the anatomy of the extremely irregular, short tags. Ad = adhesive; HL = hybrid layer; D = dentin; R = resin; T = tag.

exposed. After the roots had been sectioned at the cemento-enamel junction, each specimen was embedded in self-curing acrylic resin (Dencrilon, Dencril) inside plastic cylinders (2.0 cm tall and 0.75 in. diameter) with the abraded surface facing upward and parallel to the surface of the cylinder. Each specimen was smoothed under irrigation, with wet silicon carbide paper of decreasing abrasiveness (up to 1200 grit), to create a homogeneous smear layer.

All 80 specimens were rinsed in tap water, dried with oil-free compressed air, and randomly divided into five groups, with 15 specimens in each group; the remaining five specimens were discarded. Each group was treated with one adhesive system, following the manufacturer's recommendations. The information regarding the materials, manufacturers, composition, and application steps for each group is listed in Table 1.

After the adhesive was cured with a photocuring unit (L.E.Demetron I, Kerr Dental) for the recommended time, a bonding jig (Ultradent Products, Inc.) with a cylindrical Teflon mold (2.2 mm in diameter) was placed securely on the adhesive-covered dentin surface. Using a condenser (Tactile Tone, Thompson Dental Mfg.), the respective composite resin for each group was placed in two increments of 1.5 mm each. Each increment was photocured for 40 seconds. The curing

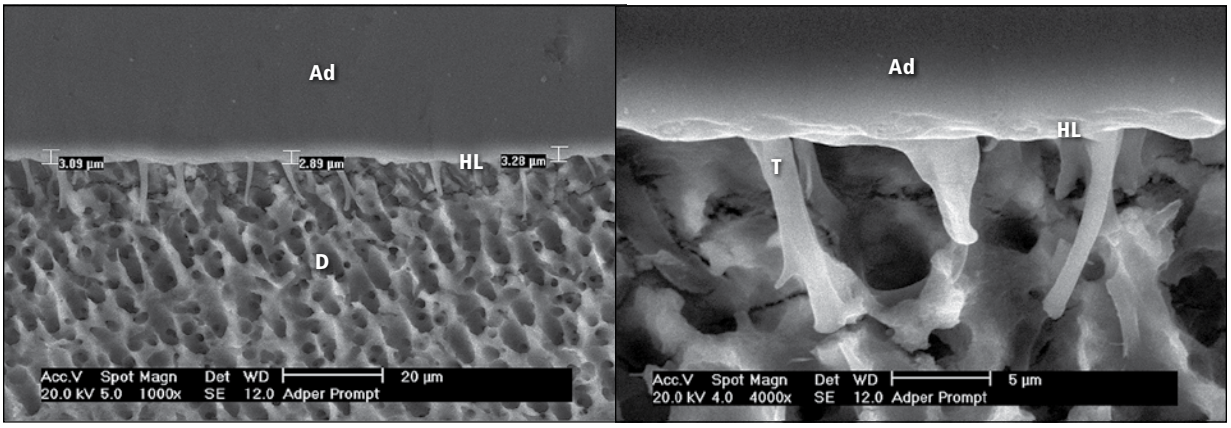

Fig. 3. *Left*: A micrograph of the adhesive interface of occlusal dentin from a specimen treated with the Adper Prompt adhesive system and restored with Filtek Z250 composite resin in a dentin slice of the occlusal surface (magnification 1,000x). The dentinal tubules can be seen perpendicular to the restoration. *Right*: The central area of the sample (magnification 4,000x) indicates short, irregular tags can be observed. HL = hybrid layer; T = tag; Ad = adhesive; D = dentin.

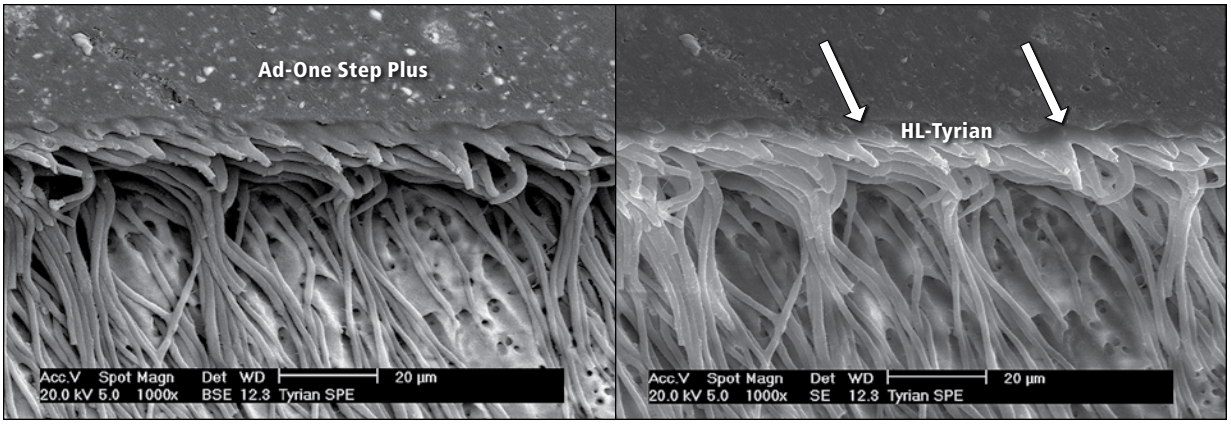

Fig. 4. *Left*: A micrograph of the adhesive interface of occlusal dentin from a specimen treated with Tyrian SPE and One Step Plus adhesives and restored with Pyramid composite resin (BSE mode, magnification 1,000x). The dentinal tubules can be seen positioned slightly oblique to the restoration. *Right*: The same image in the SE mode (magnification 4,000x) reveals the separation between the two adhesives (arrows) and the predominance of Tyrian in the structure of the hybrid layer and the resin tags. Ad = adhesive; HL = hybrid layer.

power was checked initially using a curing radiometer (Kerr-Demetron) and again after every four irradiations to ensure that the light output exceeded 400 mW/cm^2.

After storage in distilled water for 24 hours at 37°C, the specimens were subjected to the shear strength test, using a Universal Testing Machine (Instron 4444, Instron Corp.) with a cross-head speed of 1.0 mm/minute. A notched blade was used flush against the dentin surface to contour the specimen. The shear bond strength was calculated by dividing the failure load by the area and the resulting values were expressed in MPa. After this test, the specimens were analyzed by stereomicroscopy (10x magnification) to determine type of failure at the resin-dentin interface.

All specimens were categorized into one of three types of failure: when more than 5% of the dentin surface was covered by composite resin, the failure was considered to be cohesive in resin; when the dentin fractured, the failure was determined to be cohesive in dentin; and when there were almost no resin remnants on the dentin but only adhesive or exposed dentin, the failure was labeled interfacial or adhesive. Based on these criteria, cohesive failure in

HL = hybrid layer; T = tag.

Table 2. Mean values for shear bond strength for the different experimental groups. The same superscript letter indicates statistical similarity (Kruskal-Wallis and Wilcoxon Rank-Sum tests, $\alpha = 0.05$, $p > 0.05$).

Group	Adhesive system	Shear bond strength (in MPa) (±SD)	*n*
1	Clearfil SE Bond	33.23 (12.67) [A]	15
2	Optibond SE Solo Plus	32.41 (9.90) [A]	15
3	Adper Prompt	17.50 (4.24) [C]	15
4	Tyrian SE + One Step Plus	21.37 (5.87) [B]	15
5	Optibond Solo Plus	30.68 (4.08) [A]	15

the adhesive was also considered interfacial/adhesive.

The results were analyzed using ANOVA. The results revealed a normal distribution but a lack of homogeneity of variance (as shown by the Levene test). Non-parametric Kruskal-Wallis and Wilcoxon Rank-Sum tests were applied ($\alpha = 0.05$).

Preparation for SEM

The five remaining teeth were prepared for observation of the dentin-resin interfaces under SEM. A slice of the dentin was selected from the occlusal surface of each adhesive. These specimens received applications of the adhesive systems as described for each group (see Table 1) and were restored with a layer of composite resin (1.5 mm thick) from the same manufacturer.

Each dentin disk was cut in half in a mesiodistal orientation, fixed in 2.5% glutaraldehyde solution, and dehydrated in ascending grades of ethanol (25%, 50%, 75%, and 95%) for 20 minutes per solution, followed by one minute in 100% alcohol. At that point, all samples were transferred to hexamethyldisilizane (HMDS, Ted Pella, Inc.) for 10 minutes and embedded in epoxy resin (Epo-Thin, Buehler Ltd.) to expose the adhesive interfaces at the center of the tooth surface. The exposed interfaces were polished with wet silicon carbide paper of decreasing abrasiveness (up to 1200 grit) and with 1.0 and 0.3 µm alumina polishing pastes. The specimens were sonicated with 100% alcohol for five minutes, subjected to demineralization using 6 mol/L hydrochloric acid (for 30 seconds), and deproteinized with 2% sodium hypochlorite solution for 10 minutes.

All of the specimens were dried, mounted in aluminum stubs (Ted Pella, Inc.), placed in a vacuum chamber, and sputter-coated with a 300 Å gold layer (Bal-Tec SCD 005, Bal-Tec Co.). The analysis was performed with a scanning electron microscope (SEM XL30, FEI Company) operating between 15 kV and 20 kV.

To illustrate the results from the tested adhesive systems, photomicrographs were taken of areas that represented interaction between the adhesive systems and the conditioned dentin and formation of the hybrid layer at the dentin-resin interface (Fig. 1–5).

Results

Shear bond strength test

Table 2 shows the results of the dentin shear bond strength test for the experimental groups. A

statistical analysis of the shear bond strength data was performed using SPSS 14.0 for Windows (SPSS, Inc.). The confidence level was set at 95%. The analysis of data (Kruskal-Wallis and Wilcoxon Rank-Sum tests) showed that Groups 1 and 2 demonstrated statistically similar results ($p > 0.05$) to the control group (see Table 3). Conversely, Groups 3 and 4 differed from the other groups and from each other ($p < 0.05$); in addition, Group 3 specimens demonstrated a lower mean bond strength (see Table 2).

Each group was examined with stereoscopic magnification glasses (10x) to determine the types of failures that occurred (see Table 4). The experimental groups with the lowest mean shear bond strength (Groups 3 and 4) exhibited predominantly interfacial/adhesive failure, while the predominant failure for the remaining samples was cohesive in resin.

Table 3. Statistical analysis of shear bond strength values using the Wilcoxon Rank-Sum test for the different groups ($n = 15$). The same superscript letter indicates statistical similarity ($p > 0.05$).

Group	Sum of scores	Expected under null hypothesis	SD < null hypothesis	Mean score
1	743.00	570.00	75.49	49.53[A]
2	747.00	570.00	75.49	49.80[A]
3	218.00	570.00	75.49	14.53[C]
4	390.00	570.00	75.49	26.03[B]
5	751.50	570.00	75.49	50.10[A]

SEM analysis of the adhesive interface

Using SEM, the adhesive interface was analyzed for the following characteristics: formation and uniformity of the hybrid layer, adhesive layer and hybrid layer thickness, morphology of the resin tags and their relationship with the intratubular dentin, and resin/adhesive interface.

In general, the SEM analysis revealed that the hybrid layer formation was uniform for all self-etching adhesive systems, despite the fact that self-etching primer systems typically produce thin hybrid layers (that is, a width of less than 1 µm). Group 1 specimens displayed regular resin tags, ranging in size from 5–15 µm); tags were also observed along the entire extension of the adhesive layer. A thin but uniform hybrid layer also was observed (Fig. 1). Group 2 specimens displayed short, irregular tags and a thin, uniform hybrid layer (1.0–1.35 µm). The adhesive layer was relatively thick (12.3–12.9 µm) and appeared to be well-bonded to both the composite resin and the hybrid layer (Fig. 2). Group 3 specimens displayed a uniform hybrid layer (mean thickness of 2–4 µm) and new resin tags (Fig. 3). A micrograph of Group 4 specimens revealed formation of a continuous and uniform adhesive layer, with a large number of tags (Fig. 4). In specimens from Group 5, the adhesive interfaces revealed a hybrid layer approximately 5–7 µm thick (Fig. 5).

Discussion

The main objective of this *in vitro* study was to verify the shear bond strength between self-etching adhesive systems and dentin.

The dentin surface was exposed by grinding the buccal and lingual surfaces of each tooth, making it possible to use the two faces. According to Konishi *et al*, there are no differences between the shear bond strengths of these sites.[12] The grinding was carried out using cylindrical diamond points to approximately 0.5–1.0 mm below the dentin-enamel junction. At this depth, the dentin is apparently more resistant to shear tensions than it is at deeper sites.[12] In addition, a larger amount of intertubular dentin is present, the amount and diameter of the tubules are smaller, and the dentin is less moist.[13] These factors may have contributed to the higher values for shear bond strength, compared with the adhesion observed in dentin closer to the pulp.

In the present study, the area of adhesion of the adhesive resin/composite system was precisely delimited using a bonding jig (2.2 mm in diameter), ensuring a total area of contact with the dentin of approximately 3.8 mm^2. This area is relatively small compared with those reported in most shear bond strength studies.[14-16] In addition, the notched blade of the bonding jig that was used to apply the compressive force adapts flush with the specimen and acts more uniformly, distributing the force over a large area and reducing the concentration of stresses adjacent to the interface. This may have led to higher shear bond strength values than might be achieved with a knife-edged blade, which applies a higher stress concentration over a small area, decreasing the stress required for bond failure.[16]

This study tested four self-etching adhesive systems (Clearfil SE Bond, Optibond Solo Plus SE, Adper Prompt, and Tyrian SPE) and compared the results to those of a

total-etch fifth-generation adhesive system (Optibond Solo Plus).

The Kruskal-Wallis test showed a statistical difference between the groups ($P < 0.0001$). According to the Wilcoxon Rank-Sum test, the paired comparison of the groups showed that Clearfil SE Bond, Optibond Solo Plus SE, and Optibond Solo Plus obtained similar results, all of which were superior to the Tyrian SPE and Adper Prompt systems. The latter two systems were also significantly different from each other, with Adper Prompt exhibiting the lowest bond strength results.

Self-etching adhesives are used in clinical practice with increasing frequency, as they have shown less technique sensitivity than adhesive systems that require a separate etching step.[17-19] Schulze *et al* tested the shear bond strength of the Clearfil SE system bonding to dry, over-wet, and moist dentin and discovered no significant differences in bonding among these three dentin conditions.[17] The dispersion of the mean bond strength values was approximately twice as much for over-wet and moist dentin compared to dry dentin, although dry dentin displayed higher shear bond strength values. The Clearfil SE system was considered less sensitive to the technique used compared to the conventional one-bottle system Single Bond, for which the bond strength results depend on the moisture condition.[17]

Clearfil SE Bond can be classified as a two-step adhesive because the primer is applied separately from the adhesive resin. Similarly, Optibond Solo Plus SE is used prior to the application of Optibond Solo Plus and acts as a primer. In the present study, the Optibond Solo Plus SE system produced very good bond strength results compared with both Clearfil SE Bond and Optibond Solo Plus. Optibond Solo Plus SE is relatively easy to use, although it is more time-consuming to apply (see Table 1). The two-step application may have contributed to better bond strengths from these systems. The one-step self-etching adhesive systems were shown to be less effective than the multiple-step systems.[20-22]

In the present study, Adper Prompt demonstrated the lowest shear bond strength values (see Table 2). Adper Prompt can actually be considered a one-step adhesive system, because it carries out conditioning, priming, and bonding in a single step. Tay *et al* considered the one-step adhesive systems as semi-permeable membranes that leave the moisture of the underlying dentin intact to diffuse through the composite resin interface.[23] This type of moisture diffusion results in blisters and droplets (also known as *water trees*) forming at the adhesive interface when the composite resin is placed on the previously activated adhesive system and not cured immediately. Although the formation of water trees was not verified in the present study, this condition can result in a weakening of the adhesion.[23]

For all-in-one self-etching adhesive systems, high amounts of solvents (water, acetone, or ethanol) or hydrophilic monomers like 2-hydroxyethyl methacrylate (HEMA) are added to their formulations to facilitate diffusion of the resins inside the dental substrates. Water is an essential component because it provides hydrogen ions that are necessary for demineralization. However, these components raise the hydrophilicity of the adhesive, which in turn may increase the risk of water uptake into the matrix and decrease the resins' polymerization rate.[7,22,24]

Tyrian SPE is a self-etching primer that is available as two separate bottles of solutions that must be mixed correctly. In the present study, the active application of Tyrian SPE was followed by removing the excess with a cotton pellet. The solution changed in color from purple to transparent, indicating that the acidic solution was buffered by the dentin substrate. According to the literature, the effect of the self-etching primers is self-limiting due to the release of calcium and phosphate ions during the demineralization process.[6,25] Increasing the concentration of these ions tends to limit the depth of dissolution of the underlying intact dentin by buffering the acid present in the primer.[6] Applying One-Step Plus after Tyrian SPE is intended to provide a bond strength similar to that of the conventional systems, due to the additional layer covering the Tyrian adhesive.

The Optibond Solo Plus system was selected as the control because its efficiency has been proven in earlier experiments and because it was possible to compare the product with its self-etching version (Optibond Solo Plus SE). The results obtained were as expected and demonstrated the system's ability to adhere to the dentin substrate.

To observe the type of failure, each specimen was individually examined under a magnification stereoscopic glass (magnification 10x) without knowing the strength value that had been obtained in the shear bond strength test.

The majority of the experiments produced adhesive and mixed bonding failures.[26,27] In the present study, it was decided to determine criteria to facilitate the observation and categorization of the failure that occurred. It was preferable to classify adhesive failures and cohesive failures in the adhesive as interfacial/adhesive

failures, since the tested adhesive systems reach high bond strength values, form hybrid layers, and do not debond completely from the dentin. With adhesive failures, the failure usually occurs in the middle or at the top of the hybrid layer and partly in the body of the adhesive, which is a cohesive failure of the adhesive. Representative specimens of all groups were selected and observed under SEM.

The experimental groups that produced the lowest mean shear bond strength (Adper Prompt and Tyrian SPE) had primarily interfacial/adhesive failures, while the rest of the failures were predominantly cohesive in resin (see Table 4).

Table 4. Type of failure observed after shear tests for each of the experimental groups.

	Type of failure (by %)		
Group	Interfacial/adhesive	Cohesive/resin	Cohesive/dentin
1	20	80	0
2	20	53	27
3	80	20	0
4	53	47	0
5	0	67	33

Among the self-etching systems, cohesive failure in dentin was observed in only four of the specimens in Group 2. Cohesive failure in resin or in dentin occurred only in the control group (Optibond Solo Plus). As Optibond Solo Plus is a total-etching adhesive, it demineralizes the underlying dentin more deeply than the self-etching systems; as a result, the level of adhesive infiltration may not reach the deepest limit of the demineralization, which results in a weakened area of surface dentin that is more susceptible to fracture.[26]

The resin/dentin interface of the occlusal dentin was easily observed under SEM, making it possible to analyze and measure the hybrid and adhesive layers and note the formation of the resin tags and other important features. The Clearfil SE Bond adhesive system made it possible to observe the formation of a uniform gap-free adhesive layer; while the layer was thin, it appeared to be well-integrated with the composite resin and the hybrid layer. A large number of funnel-shaped, short, wide resin tags were formed. The shape and shortness of the tags can be explained by the chemical composition of Clearfil SE Bond; its primer is not considered to be very aggressive (pH = 2.0) and it has a low ionic dissociation potential, with a relatively low demineralization potential that is rapidly buffered by the dental substrate.

The apparent hybridization of the resin tags may be due to the infiltration capacity of Clearfil SE Bond, because of the presence of HEMA in both the primer and the bonding agent. HEMA is found in most adhesive resins because of its wettability and affinity for dentin, which makes the dentin acid-resistant after impregnation.[6,28] When used in combination with dentin adhesives, HEMA optimizes the wettability and hydrophilicity, which in turn increases the adhesive resin's bond strength to the tooth.[12] The hybrid layer was only 1.0–1.5 µm thick; by contrast, the layer usually obtained from conventional adhesive systems has a thickness of up to 5 µm.[20] The Clearfil SE Bond system obtained the highest mean shear bond strength value in this study.

According to the literature, there appears to be no correlation between the thickness of the hybrid layer and bond strength values, which suggests that the bond strength is more closely related to the presence and quality of the impregnated dentin layer than to its thickness.[29-33]

The use of the self-etching primer Optibond Solo Plus SE resulted in the formation of a thin hybrid layer that was well-integrated with the adhesive layer and the underlying dentin. Although the tags that formed were short and irregular, they were well-bonded to the hybrid layer. This system resulted in shear bond strength values equal to those of Clearfil SE Bond and the control Optibond Solo Plus.

A thick adhesive layer was observed when Adper Prompt was used, probably because two layers of the adhesive were applied to most of the specimens. However, despite the formation of a uniform hybrid layer, the tags that formed were short, irregular, thin, and sparse.

Conversely, the Tyrian SPE adhesive resulted in the formation of a thick adhesive layer and a great quantity of long, thin resin tags. This system has a pH of less than 1.0, with a higher demineralization capacity than the other self-etching systems tested in the present study, which may explain why Tyrian SPE dissolves the smear layer well and opens the dentinal tubules. In addition, the presence of P-phenyl in Tyrian SPE and HEMA in One-Step Plus may have increased the wettability capacity and the diffusion of the monomers in the tubules.[6,28]

For Group 5 samples, conventional Optibond Solo Plus resulted in the formation of a uniform hybrid layer and funnel-shaped, wide-based resin tags. In this system, as with One-Step Plus, the manufacturers included nanoparticles in the composition to reduce polymerization shrinkage and improve the mechanical properties. Studies have shown that such particles can occupy the microscopic spaces in the hybrid layer, penetrate the dentinal tubules, and contribute to the formation of the tags.[34] However, it was not possible to confirm these findings in the present study.

The analysis of the interface for all of the adhesive systems used in the present study contributed to understanding their relationship with the dentin substrate and the restorative material. It does not appear that the thickness of the hybrid layer influenced the shear bond strength results. Although the Optibond Solo Plus system resulted in a thicker hybrid layer (between 5 µm and 7 µm), its bond strength values were equivalent to those of the Clearfil SE Bond and Optibond Solo Plus SE systems, which resulted in hybrid layers of approximately 1–1.5 µm mean thickness.

Since different bonding systems have different chemical compositions, the results obtained in the present study cannot be related to other materials. Following this rationale, these results cannot be extrapolated directly into daily practice, although they suggest great promise in terms of the durability of the tooth resin restorations, especially for Clearfil SE Bond and Optibond Solo Plus SE.

Conclusion

Within the limitations of this *in vitro* study, the results meant that the null hypothesis could not be accepted completely. There were significant differences between the *in vitro* dentin shear bond strengths of the self-etching adhesive materials tested, with Clearfil SE Bond and Optibond Solo Plus SE demonstrating the highest bond strength values. The adhesive failure was predominant in the experimental groups with the lower mean shear bond strengths (Adper Prompt and Tyrian SPE); among the other groups, cohesive failure in resin predominated. Furthermore, for all of the adhesive systems analyzed, it was possible to observe the formation of a uniform gap-free hybrid layer, despite the differences in their thickness.

Elusive dental pain

Stanley Markman, DDS, FAGD ▪ Junad Khan, BDS ▪ Jennifer Howard, RDH

The dental profession is devoted to treating and preventing dental pain. Such pain can be referred from teeth in one jaw to teeth in the opposing jaw, and the origin of the pain a patient describes may not be the same as the source of that pain. As a result, dental procedures often produce no relief for the patient. This article discusses the neural mechanisms involved in referred pain from one tooth to another and from muscles to teeth.

Received: November 18, 2008
Accepted: February 6, 2009

Dentists sometimes find it difficult to determine which tooth is causing a patient's pain. Too often, the patient can identify the side but not whether the pain is coming from a maxillary or mandibular tooth. Periodically, a patient will report dental pain but the clinical and diagnostic findings do not provide a specific dental-related reason for the pain. As a result, well-intentioned dentists sometimes overtreat.

What is dental pain? For that matter, what is pain? The International Association for the Study of Pain defines pain as "an unpleasant sensory emotional experience associated with actual or potential tissue damage or described in terms of such damage."[1] According to Sessle, pain in the face, head, mouth, and throat areas are the most common pains in the body.[2] Noxious, mechanical, heat, cold, chemical, and inflammatory stimuli can activate sensory pathways and lead to responses that are interpreted as pain.[3]

Nocioceptors are preferentially selective to noxious stimuli or to a stimulus that would be noxious if prolonged. Nocioceptors are free nerve endings that are activated by different noxious stimuli according to their functional properties.[4] Mechanical nocioceptors are activated by mechanical stimuli; thermal and mechanical-thermal receptors are activated by stimuli that cause slow, burning pain; and thermal receptors are activated by temperature.[5]

Pain in dentistry creates the need for both tooth removal and endodontic therapy. After root canal therapy is completed, restorative dentistry is required to avoid fracturing the remaining coronal tooth structure and to re-establish form and function.

Periodically, a patient has tooth pain with a more elusive point of origin; for example, maxillary molar or premolar pain due to a sinus infection. An elusive variety of dental pain may occur when a patient has a pain in a maxillary tooth. When a radiographic review provides no confirmation of pathology, the general dentist is likely to refer the patient to an endodontist who generally is more familiar with referred pain. The endodontist reports to the referring dentist that the pain is not coming from a tooth in the maxilla but rather from a tooth in the mandible. How does that happen?

Neuroanatomy

Figure 1 shows a schematic of the side view of the head, with particular emphasis on the brain

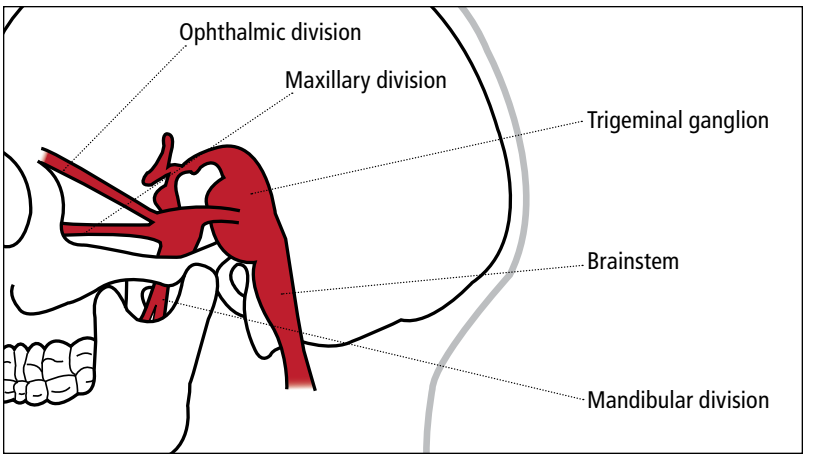

Fig. 1. A schematic illustration of the side view of the head.

stem (the midbrain, the pons, and the medulla). The area of interest to dentists is the trigeminal nucleus located within the brain stem (Fig. 2). The trigeminal nucleus is the pathway for sensory and motor functions of the trigeminal nerve. The trigeminal nerve enters the brain stem at the level of the pons.

In terms of pain sensation, the direction of pain impulses come from the branches of the fifth cranial nerve and are directed into the brain stem. A part of the trigeminal nucleus is the spinal nucleus of V, the structure into which sensory and nocioceptive (primary) neurons enter. A synapse with a second-order neuron takes place and the nerve impulse begins its ascent to the thalamus.[6,7] Neurons from the fifth, seventh, ninth, and tenth cranial nerves (including neurons from adjacent ascending spinal nerves) enter there also (Fig. 3).

Structurally, the spinal nucleus of V is further divided into functionally separate segments (subnucleus oralis, subnucleus interpolaris, and subnucleus caudalis), although there is some overlapping in terms of the segments' functions.[8] Figure 3 presents a schematic rendition of these nuclei.

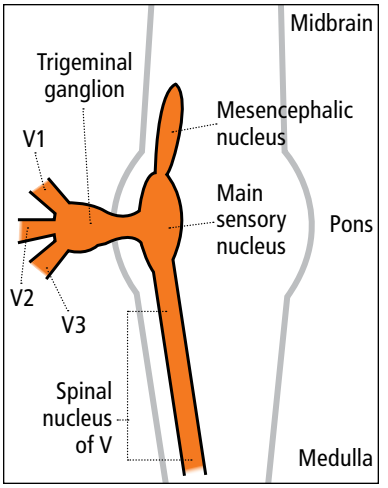

Fig. 2. A schematic illustration of a trigeminal nucleus.

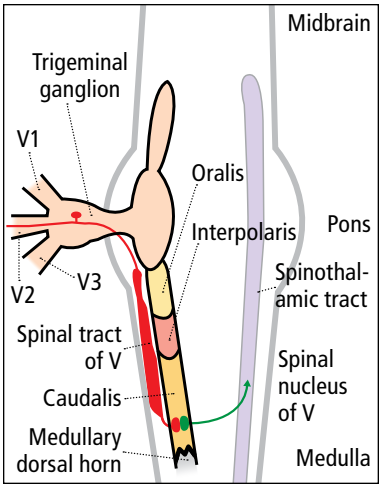

Fig. 3. A schematic illustration of the spinal nucleus of V.

The neuroanatomy of referred pain

The subnucleus caudalis is the structural area of the spinal nucleus of V that needs to be understood relative to referred pain. The caudalis has been described as the gateway for the distribution of head, face, and neck pain.[9] It is considered the main brain stem site responsible for processing and relaying nocioceptive inputs from the craniofacial area.[10]

A 1990 study confirmed that the caudalis of rats has a unique lamellar structure, similar to those found in cats and monkeys. By stimulating a specific neuron, researchers have located the response of that stimulus from a specific segment of the caudalis; that is, when the pulp of a rat's tooth was stimulated, the terminus of that stimulation was found in a specific lamellar area of the caudalis.[11,12]

The structure of the caudalis is similar to that of the spinal cord in that both are segmented. The caudalis has fewer segments than the spinal cord; however, the former is sometimes referred to as the *medullary dorsal horn* because its termination melds into the spinal cord. There is no intrinsic anatomical architecture that demarcates where the spinal nucleus ends and the gray matter of the spinal cord begins.[13]

Neuronal convergence

When a pain impulse arises from one of the three sensory divisions of the trigeminal nerve, it enters into the brain stem, as it follows the neuron (whose cell body is located in the trigeminal ganglion) and turns down caudally via a bundle of common neurons called the *spinal tract of V* (Fig. 3).[14] The axonal portion of the neuron enters into the caudalis, where it synapses with a second-order neuron. The quantity of first-order neurons exceeds that of second-order neurons. It is in the structure of the caudalis that neuronal convergence can affect the brain's perception or location of pain, thus confusing the patient and resulting in referred pain.

Dostrovsky reported that it is difficult to localize the origin of pain to a single tooth, which is consistent with clinical studies which have reported that human patients also find localization difficult, a fact that is common knowledge among dentists.[15] The convergence of deep inputs (also known as *visceral sensory neurons*) upon the majority of cutaneous nocioceptive neurons has led to the suggestion that this is why people often have poor discriminatory ability when it comes to locating pain precisely.[16] For instance, when patients with abdominal pain can't determine if the pain is coming from the gall bladder or the pancreas, it's because synapses with

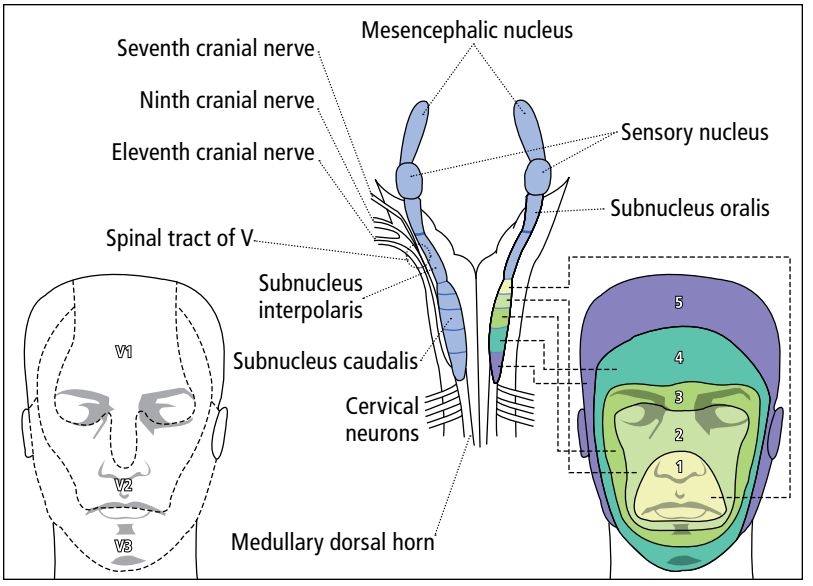

Fig. 4. Divisions of the nucleus caudalis. The numbered icon on the right indicates the facial segmentations that are likely to correspond to the lamellar layers of the caudalis.

a second-order neuron allow the neuron to connect to one of two visceral afferents. The second-order neuron cannot distinguish between the two afferents.

Typically, a number of primary nocioceptor neurons make a synaptic transmission with a secondary neuron; this convergence reduces the acuity of stimulus location.[17] The extensive convergent afferent input patterns that are characteristic of temporomandibular joint (TMJ)- or myofascial-activated neurons in the subnucleus caudalis may explain the poor localization of deep pain, as well as contribute to the spread and referral of pain typical of deep pain involving the TMJ and associated musculature.

Pain of unremitting intensity can induce temporal summation. When temporal summation occurs in the caudalis, excitatory neurons produce excessive excitatory neurotransmitters, which spread into adjacent segments of the caudalis, exciting more neurons. As more segments of the caudalis become involved, the sensation of pain spreads to other areas. If this process continues, the pain that initiated elsewhere is imprinted in the brain stem where the caudalis is located (a process known as *central sensitization*). Eventually, the central sensitization becomes chronic pain.[18] The localization and frequent occurrence of pain referral in most toothaches and headaches can also be explained by analogous convergent patterns from tooth pulps and cervicovascular afferents.

Once the synapse occurs, the pain impulse flows to a second-order neuron. Subsequently, third-order neurons (whose cell bodies are in the thalamus) synapse with second-order neurons. Another synapse occurs in the thalamus, moving the pain impulse to the parietal lobe of the cerebellum, where it is perceived as pain. Until the pain impulse reaches that area, there is no pain perception.

Referred pain

Referred pain describes pain that is felt from a different location than its initial point of origin. Understanding referred pain also requires understanding the mechanism of convergence.[19,20] Neural convergence occurs when multiple primary neurons compete to connect to a secondary neuron.[21] At the same time, primary pain afferents compete to find a secondary connecting neuron. As early as 1984, animal researchers reported that fewer secondary neurons receive pulp afferents exclusively from one tooth.[15] Extensive convergence is characteristic of pulp-activated neurons. Spatial discrimination of tooth pulp stimuli occurs with difficulty in the caudalis because of the discrepancy between the number of secondary neurons and the number of primary neurons. The occurrences listed above, particularly the convergence of closely located primary nocioceptors with a smaller number of secondary neurons, are known to occur in animals and are likely to occur in humans, which could account for a patient's inability to localize pain. In addition, muscle pain also can be diffuse, referred, and difficult to localize.

The concept of segmentation

When discussing the pain referral mechanism, one must consider the importance of the microanatomy of the trigeminal nerve nucleus, which has been the subject of animal studies but has rarely been studied in humans. It is known that the caudalis is divided into at least five segments or lamellar layers; each one corresponds to a segment of the face. These caudalis segments have been referred to as the *onion skin effect*.[22] Figure 4 shows the division of the dermatomes as they correspond to the divisions of

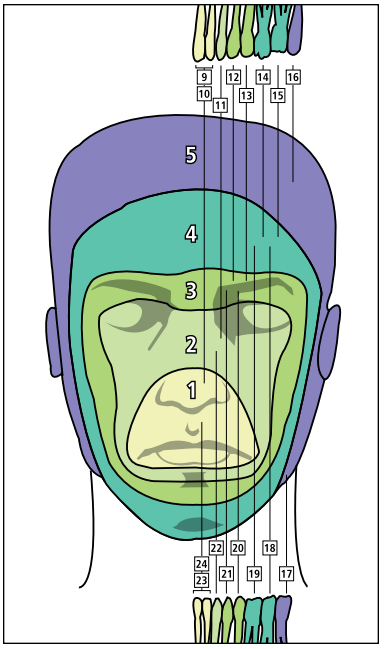

Fig. 5. A schematic illustration of facial segmentation as it relates to teeth.

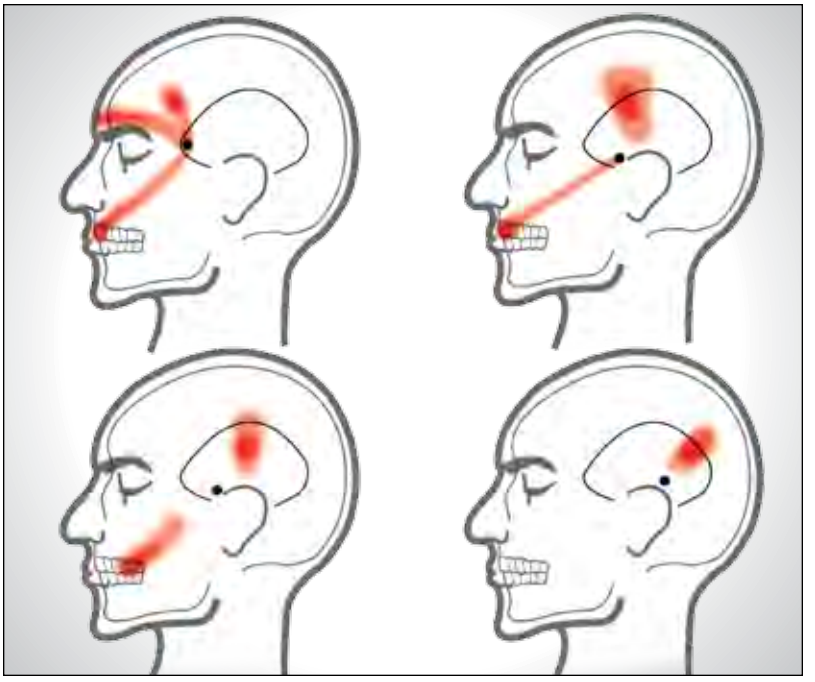

Fig. 6. A schematic illustration of temporal muscles and pain referral patterns.

the trigeminal nerve and the phenomenon known as *segmentation*. According to the literature, as many as 10 segmented lamellar layers can be found in the dorsal horn of the spinal cord.[23]

Figure 5 demonstrates segmentation as it relates to tooth nocioceptors. Segment sharing and neuronal convergence explain why a patient may report pain in the maxillary premolar when the source of the pain is actually in the mandibular premolar, because the maxillary and mandibular premolars share the same segment within the caudalis. It is likely that nocioceptive neurons from the TMJ and the mandibular third molar share a synaptic communicating neuron with a second-order neuron, resulting in perceived molar pain and perceived TMJ pain. Based on the authors' experience, patients often explain TMJ pain as ear pain; also, a patient with pain in a mandibular molar may also report pain in the TMJ on the same side.

Myofascial pain

In certain instances, a patient may complain of tooth pain that cannot be corroborated clinically or radiographically. When examination rules out tooth-to-tooth referred pain, the dentist might consider an alternative diagnosis of myofascial pain.

Myofascial pain refers to pain emanating from skeletal muscle whose internal structure harbors one or more tiny bundles of taut tissue that induce an unpleasant or painful, obviously identifiable sensation by the trigger point's (TP) location (Fig. 6). When a TP is present, the perception of pain is not likely to occur unless some kind of muscular contraction takes place. When a tooth is involved, the locations of the muscle TP and the pain are different. This is an example of heterotrophic pain, where the source of the pain and the location where it is felt are not the same. Movement precipitates pain. According to Imamura *et al*, 10% of the U.S. population has single, multiple acute, or chronic dysfunctioning muscles.[24]

Myofascial pain is a disorder affecting one or more muscle groups, accompanied by local and referred pain, decreased range of motion, weakness, and (frequently) autonomic phenomena. The causative TPs of myofascial pain are excessively sensitive areas of muscle tissue.[25] A TP is defined as a focus of hyperirritability in tissues that is locally tender to percussion. If the TP is sufficiently hypersensitive, referred pain results.[26] Palpated TPs may evoke a twitch response at the site and cause the patient to report pain at the site or elsewhere—possibly

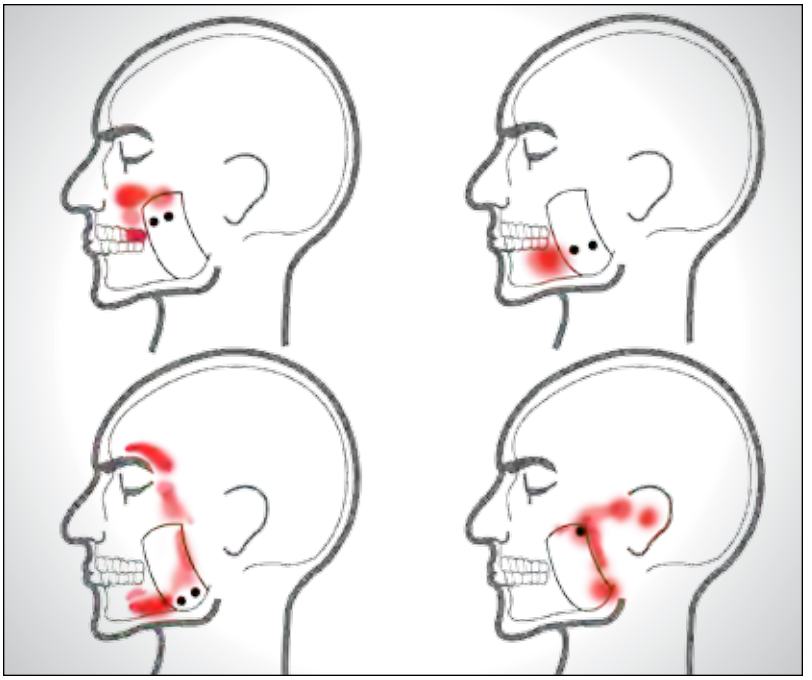

Fig. 7. A schematic illustration of masseter muscles and pain referral patterns.

a significant distance from the source of the pain.[27] When the source of the pain is determined to be a muscle TP, the pain could be alleviated by injecting an anesthetic (without epinephrine) into the TP.[28] Referred pain can also be confirmed by palpating the TP with firm pressure, which will induce the tooth pain. Figures 6 and 7 demonstrate how TPs in the temporalis and masseter muscles can lead to referred pain in teeth.

Myofascial tooth pain is nonpulsatile and aches more constantly than pain of pulpal origin. It is variable over time (that is, it can shut down when muscle activity slows or stops) and may recur over a period of months or years.[29] Pulpal tooth pain is persistent at all times, while myofascial pain can be intermittent and not as acute. Tooth pain increases with vigorous or extended use of the TP muscles, due to the neuronal convergence and segment sharing. Referred pain felt in the teeth may originate from any structure that provides sensory convergence within the caudalis of the trigeminal spinal tract nucleus, including any structure innervated by the trigeminal nerve and the upper cervical nerves.[30]

Pain also can be referred from a more remote location, such as the trapezius or the sternocleidomastoid. The nocioceptor, which innervates the sternocleidomastoid, is from the fourth cervical nerve. This nerve enters the dorsal horn of the cervical spinal cord and, via an interneuron connector, finds its way into a shared segment of the caudalis, which also contains a tooth nocioceptor.

Differential diagnosis

Determining that dental pain is coming from a TP within a muscle involves a step-by-step diagnostic process. A history of dental pain that is not relieved with regular care is an important clue. Such pain often is present for many months, and while the patient may identify a tooth in pain, the surrounding gingiva and alveolar process could be involved.[31]

In one scenario, a patient reports tooth pain but the radiographs and endodontic evaluation are negative. Clearly, referred pain is ruled out. Local anesthesia around the tooth will not relieve the pain. An interligamentary injection may be used to develop a differential diagnosis. The pain is made worse with the patient's jaw (muscular) movements. If a TP can be found, a spray-and-stretch procedure will eliminate the pain, as would a local anesthetic (without epinephrine) injected into the muscle TP. Remember to review the patient's history; most toothaches usually do not stop or disappear for long periods and then return, as TP-induced tooth pain does. A systematic examination of the closing and supporting muscles should be included in the diagnostic process.

Summary

It is not always easy to diagnose dental pain appropriately. There are rational explanations for referred pain to teeth; it may be the result of a muscle problem, and it might be necessary to refrain from treatment when the dental examination and radiographs do not confirm the pain that the patient is experiencing.

Photodynamic therapy in periodontal therapy: Microbiological observations from a private practice

Georgios E. Romanos, DDS, Dr.med.dent, PhD ▪ Birgit Brink, DMD, Dr.med.dent

In recent years, the combination of laser light and photosensitizer known as *photodynamic therapy* (PDT) has been used in periodontal therapy. However, there are not enough clinical studies to fully evaluate the effects of PDT on the periodontal tissues. This microbiological study examined the effects of PDT on the periodontal bacteria in combination with scaling and root planing (SRP) in the same group of patients by randomly selecting PDT or SRP for use in different quadrants of the mouth.

For the present study, PDT was compared with a diode laser (980 nm) and an Nd:YAG laser (1,064 nm). Microbiological samples were examined and evaluated over a period of three months. Significant bacterial reduction has been observed in all cases. The diode laser with SRP presented long-term positive results, while PDT showed a significant bacteria reduction during the entire observation period.

Received: September 29, 2008
Accepted: November 10, 2008

Various clinical guidelines for the treatment of periodontitis have been used successfully in daily practice, and the different methods of therapy and the various recall intervals are well-documented in the literature.[1,2] However, antibiotic therapy is also necessary for subjects who are refractory for treatment or have an aggressive type of periodontitis. Concerns about resistance to and the side effects from antibiotic therapy indicate the need for alternative methods of treatment.

Recent years have seen an increased focus on using laser systems as an adjunct in periodontal therapy.[3-5] Clinicians and researchers have different opinions regarding the results of laser-tissue interactions and the laser wavelengths that are used. Photodynamic therapy (PDT) uses a laser in combination with a dye, thus utilizing the power of light and its resulting antibacterial properties.[6-8] PDT is used primarily as an alternative to chemotherapy or radiotherapy for the treatment of cancer on a routine basis; in addition, PDT has been used effectively to reduce bacteria or viruses in the fields of dermatology, cardiology, ophthalmology, and gastroenterology.[9]

In periodontal disease, the inflamed junctional epithelium at the bottom of the sulcus migrates apically, thus establishing the environment of the periodontal pocket. This migration is caused directly by microorganisms and indirectly by the potentially harmful side effects of the inflammatory response to the accumulation of plaque.[10,11] The inflammatory response to plaque is a fundamental defense mechanism of the organism against microbial infections.[12] However, this defense reaction simultaneously leads to tissue destruction, and the cytokines and prostaglandins can stimulate bone resorption. It appears that changes in the microflora can be very different from person to person as well as from site to site in the same person. In pocket formation, there are periods of disease activity followed by clinical findings, such as bleeding and suppuration.[11] A disease can be prevented not only by a specific kind of treatment against periodontopathogenic microorganisms, but also by influencing the environmental factors that promote changes to equilibrium in the microflora.[12]

One must understand the mechanisms of inflammation and the therapeutic options for controlling the growth of the anaerobic microorganisms. Etiological cofactors like stress, occlusal trauma, and smoking can have a negative effect on tissue response. Changes in the immune system that result from systemic factors (that is, diabetes mellitus and thromboembolic, cardiovascular, and allergic and rheumatic diseases) have been shown to affect the periodontal tissues.[13]

Typical periodontal treatment begins with professional prophylaxis, followed by a manual or mechanical debridement of the diseased root surfaces. In certain situations, surgery may be necessary to access the root surface and thus reduce bacteria and establish periodontal health. Bacteria or their

Fig. 1. A photosensitizer is applied to a sample receiving PDT.

Fig. 2. The pocket is irradiated for a second time using PDT.

Fig. 3. A sample taken six weeks after the start of therapy.

endotoxins may remain even after complete treatment, and recolonization may lead to further loss of attachment.[14]

Laser-assisted therapy, which should lead to a greater reduction in bacteria, is a controversial subject.[3,15,16] The literature has discussed the risk of thermal damage to the surrounding tissues and tooth structures.[17,18] Antimicrobial agents (such as chlorhexidine) or local and systematic antibiotic administration (tetracycline, amoxicillin, or metronidazole) generally are recommended for periodontal therapy.[19] However, the current increase in resistance to antibiotics must be considered and antibiotic therapy should follow bacterial analysis.[13] Possible allergic reactions to mouthrinses must be considered as well.[20]

PDT might also be used to control specific pathogenic microorganisms. According to the literature, periodontopathogenic germs (particularly *Prevotolla intermedia, Porphyromonas gingivalis, Fusobacterium nucleatum*, and *Actinobacillus actinomycetemcomitans*) can be significantly reduced by low-energy laser light if the cells are marked beforehand with photosensitive dyes.[21-26] This study sought to compare the antimicrobial effects of PDT with those of other laser wavelengths during periodontal therapy in a group of patients with periodontitis.

Materials and methods

Ten patients (between 40 and 50 years of age) with active periodontal sites (in a total of 253 teeth) were treated with scaling and root planing (SRP). None of the patients were smokers, had implants, had any significant findings in their medical history, or had received antibiotic therapy within the last six months prior to the start of treatment. At a re-evaluation six weeks after SRP, different laser systems were assigned randomly to the four tooth quadrants.

For Group 1, 62 sites received SRP and irradiation from an Nd:YAG laser (with a wavelength of 1,064 nm). For Group 2, 63 sites received SRP and irradiation from a diode laser (with a wavelength of 980 nm). For Group 3, 63 sites received SRP and PDT using a wavelength of 670 nm. The last quadrant (Group 4; 64 sites) received only SRP and served as the control group.

For Groups 1 and 2, the sulcus was first widened with the laser (using a 400 µm fiber), then scaled and irradiated (at a laser setting of 2 W) for 20 seconds in the periodontal pocket. The sites in Group 3 assigned to receive PDT were scaled before the application of a photosensitizer (Helbo Blue, HELBO Photodynamic Systems) (Fig. 1). At that point, the pocket was irradiated with a low-intensity laser (Minilaser 2075 dent, HELBO Photodynamic Systems) for 20 seconds. The photosensitizer was left in the sulcus for 60 seconds before the residual dye was washed out using saline solution; at that point, the pocket was irradiated again for 20 seconds (Fig. 2). In total, 325 microbiological samples were taken from sites (one or two sites per quadrant), all of which had a pocket depth of more than 5 mm (Fig. 3) six weeks after initial treatment (baseline); samples were collected at three days, seven

Table. Percentage of examined sites that demonstrated complete reduction of bacteria (in %) at examined sites.

	Groups			
	1	2	3	4
A. actinomycetemcomitans	Reduction not complete	Reduction not complete	Reduction not complete	Reduction not complete
Porphyromonas gingivalis	22.22	10.00	27.27	16.67
Prevotolla intermedia	22.22	11.11	25.00	25.00
T. forsythensis	9.09	13.33	14.29	18.75
Peptostroptococeus micros	7.14	11.11	33.33	18.75
F. nucleatum	Reduction not complete	5.56	Reduction not complete	5.88
T. denticola	Reduction not complete	11.76	40.99	16.67

days, one month, and three months after the initial therapy.

The microbiological sample analysis was performed to evaluate the presence of the seven marker germs: *A. actinomycetemcomitans, Porphyromonas gingivalis, Prevotolla intermedia, Treponema forsythensis, Peptostreptococcus micros, F. nucleatum,* and *T. denticola.*

Results

The table indicates the percentage of sites in each quadrant that eliminated bacteria as a result of treatment. Charts 1–4 indicate the bacterial reduction of the individual marker germs at the various sampling times.

Based on the results of the present study, Group 3 achieved the greatest bacterial reduction among all examined individual germs. Three days after treatment, Group 2 showed a 67.72% reduction compared to baseline ($p < 0.05$), Group 4 showed a 64.11% reduction ($p = 0.05$), and Group 3 reported a reduction of 87.57% ($p < 0.05$). Group 1 achieved less reduction compared to baseline (55.31%; $p < 0.05$). The total overall results for all groups improved at seven days.

After one month of treatment, Group 2 reported a 62.20% reduction in bacteria ($p < 0.05$) compared to baseline, compared to 42.7% for Group 1 ($p < 0.05$) and 54.43% for Group 4 ($p < 0.05$). Group 3 produced the greatest reduction in bacteria ($p > 0.05$) after one month (80.11%) and after three months (91.37%). Three months after the start of therapy, Group 1 reported a 48.14% reduction in bacteria ($p < 0.05$), while Group 2 reported a 71.65% reduction and Group 4 reported a 54.22% reduction ($p < 0.05$).

Discussion

The present study showed that PDT was particularly efficient at reducing pocket bacteria compared with the other laser-assisted treatment groups.[23,26] However, the literature indicated that PDT led to a greater reduction of *F. nucleatum* than could be confirmed in the present study.[23,25] In the present study, different therapies each resulted in significant reductions of bacteria.

It is possible that the so-called *biostimulation* using a low-intensity laser will become more popular than the traditional method of treatment.[27,28] The long-term success observed in the present study suggests not only that the mechanism of cell destruction has clinical significance, but also that stimulation of wound-healing mechanisms and alterations in the intra- and extracellular cell areas may play a significant role in healing. Further multicenter and controlled studies (using longer periods of observation) are necessary to uncover the mechanisms of the cellular biological processes after laser irradiation.

Complete elimination of the examined bacteria was not observed in all cases. It should be considered that, in general, antibiotic therapy is not always clinically effective when the pathogenic germs (*A. actinomycetemcomitans, Porphyromonas gingivalis,* and *Prevotolla intermedia*) are present, particularly in cases of aggressive forms of periodontitis. To reduce the risk of resistance, a microbiological sampling should be conducted to determine which germs are present and thus select the correct antibiotic therapy.

Porphyromonas gingivalis is not found in the normal flora of periodontally healthy individuals.[4] *Porphyromonas gingivalis* has a high pathogenic potential.[19] Although *Porphyromonas gingivalis* is an anaerobic germ, most patients can eliminate it from the oral cavity through normal periodontal therapeutic methods. *A. actinomycetemcomitans* is a key germ found in aggressive forms of periodontitis that appears only occasionally in healthy individuals; it is considered responsible for many cases of advanced attachment loss in adults, even among those who have received generalized mechanical debridement.[5] Clinical

Chart 1. Reduction of each type of germ (%) three days after the start of testing.

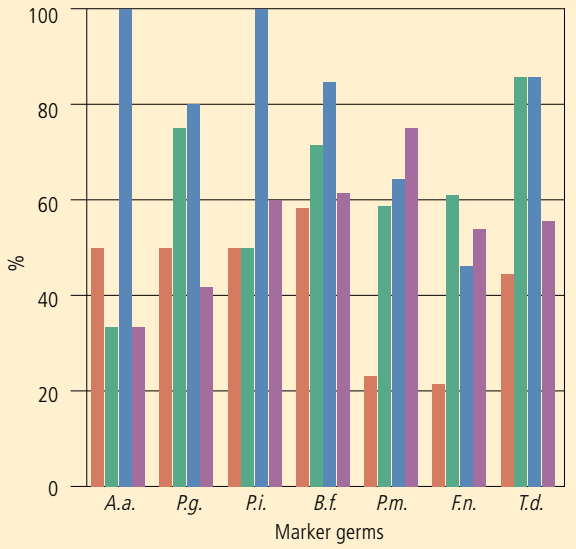

Chart 4. Reduction of each type of germ (%) three months after the start of testing.

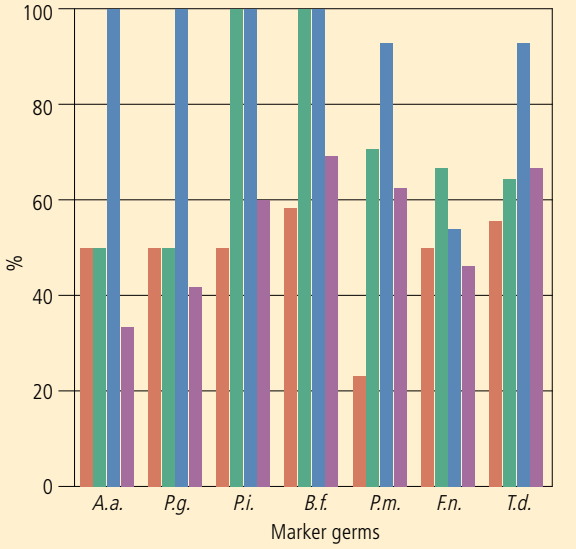

studies have shown a direct association between the complete elimination of *A. actinomycetemcomitans* and the success of therapy in susceptible individuals.[11] *Prevotolla intermedia* is a typical opportunistic inhabitant in the oral cavity; it appears commonly in the general population (even occurring in periodontally healthy individuals) and especially among periodontitis patients.[11] Due to its widespread distribution, it is unrealistic to consider eliminating *Prevotolla intermedia* completely; rather, the goal of treatment should be to reduce this species of bacteria to an acceptable level in the periodontal tissues. Because

these pathogenic species have an additional systemic effect (due to their transmission and ability to penetrate into the bloodstream and the gastrointestinal tract), PDT could be utilized to significantly reduce bacteria and thus improve the clinical outcome.

Unlike other laser wavelengths, PDT does not require dentists to use local anaesthesia; as a result, PDT can be applied during the initial phase of periodontal treatment (as an adjunct to SRP).

PDT may be especially relevant for pregnant women because a high prevalence of *Prevotolla intermedia* is associated within the second trimester, in pregnancy-associated periodontitis, or in patients with a compromised medical history. Based on the authors' experience, antibiotic administration appears to be unnecessary when PDT is used. PDT's bactericidal effects on periodontopathogenic bacteria mean that it also can be used as an adjunct treatment to SRP. A 2007 study by Andersen *et al* used PDT in combination with conventional SRP and reported a significant reduction of pocket depth after 6–12 weeks, which increased the effectiveness of PDT in the treatment of chronic periodontitis.[29]

In general, the photosensitizer dye absorbs photon energy and forms singlet oxygen (O_2), which is capable of reacting with biological systems and destroying them.[9] Specifically, O_2 exerts strong cytotoxic effects, destroying cellular constituents and microorganisms, such as viruses, bacteria, protozoa, and fungi. A higher level of energy may result in the formation of hydroxyl radicals reacting with organic molecules in redox reactions; oxidative destructions of the membrane lipids and enzymes may cause cell destruction. This biochemical effect occurs frequently in the unsaturated fatty acids of the bacterial membranes and infrequently in the membranes of healthy cells, which have a defense mechanism against radicals.[6,30]

Even though PDT has no routine use in daily practice, there are potential benefits for this therapy beyond mechanical debridement. The amount of cementum that must be removed is reduced significantly, which allows for better tissue regeneration without an increased risk of hypersensitivity. Furthermore, PDT's antibacterial effects are advantageous for patients with systemic diseases (such as cardiovascular diseases, diabetes, and immunosuppresion) and for those who display high resistance to antibiotic therapy.[31]

PDT cannot perform the various applications of other lasers during the surgical stage of periodontal therapy (that is, incision, excision, or carbonization), but it may improve both the wound healing mechanisms and the regenerative potential of cells. Additional research is necessary to examine these possibilities.

Conclusion

This study compared PDT's ability to reduce bacteria with that of diode and Nd:YAG lasers. During an observation period of three months, the examined periodontal sites showed significant bacterial reduction when PDT was used as an adjunctive therapy to SRP.

Changes in surface morphology and mineralization level of human enamel following in-office bleaching with 35% hydrogen peroxide and light irradiation

Sandrine Bittencourt Berger, DDS, MSc ▪ Vanessa Cavalli, DDS, MSc, PhD ▪ Glaucia Maria Bovi Ambrosano, PhD
Marcelo Giannini, DDS, MSc, PhD

The objective of this study was to evaluate the alterations on surface morphology and mineral loss of human enamel following in-office bleaching with 35% hydrogen peroxide and light irradiation. Dental enamel samples were obtained from human third molars and randomly divided into 10 groups ($n = 10$). The control group remained untreated. Bleached groups were treated with one of three whitening products. Bleaching was performed in a single session, during which bleaching gel was applied to the enamel surface three times for 10 minutes each time. During treatment, the bleaching agents were either irradiated by a halogen light or an LED/diode laser or were not irradiated at all. Microhardness testing was performed with a Knoop indentor and the surface morphologic observations were carried out by scanning electron microscopy (SEM). Cross-sectional microhardness (CSMH) and polarized light microscopy (PLM) were used to measure the depth of demineralization.

The results revealed a significant decrease in surface microhardness values and changes to the enamel morphology after bleaching. CSMH and PLM showed that bleached enamel presented lower volume percentage of mineral up to 40 µm from the enamel surface and demineralization areas located in the sub-superficial region of enamel, respectively. It was concluded that 35% hydrogen peroxide can alter the surface morphology and the mineralization level of the dental enamel surface and sub-surface regardless of what type of bleaching light is used.

Received: February 2, 2009
Accepted: May 5, 2009

In-office bleaching procedures generally use 35% hydrogen peroxide as a bleaching agent. This agent can be further activated by light to accelerate reduction-oxidation (redox) reactions during the bleaching process. Light that is applied to a whitening product absorbs a small fraction of bleach; this absorption is considered the primary mechanism of action for all light-activated bleaching procedures.[1] A variety of light sources have been developed for use during bleaching procedures; these include halogen curing lights, lasers, light-emitting diodes (LEDs), and plasma arc lamps, which are available in a range of wavelengths and spectral power.[2-7]

In-office bleaching agents contain high concentrations of peroxide (25–38%). The changes on enamel morphology and demineralization seem to be more intense from 35% hydrogen peroxide than with home-applied bleaching, in which patients use a low concentration of peroxide daily for at least two weeks.[8-11]

According to several studies, using 35% hydrogen peroxide for vital bleaching has led to alterations on enamel.[10] There is insufficient information concerning how light-activated bleaching agents affect enamel microhardness and surface alterations. This study used scanning electron microscopy (SEM) to evaluate how light irradiation affected the morphology of human enamel that had been exposed to one of three in-office bleaching agents, each containing 35% hydrogen peroxide. Surface and cross-sectional enamel mineral loss were evaluated through a microhardness test. Demineralization depth promoted by bleaching was evaluated by polarized light microscopy (PLM). The null hypothesis tested was that enamel surface changes and demineralization are not influenced by irradiating the bleaching agents.

Materials and methods

Experimental design and specimen preparation

Sixty-five extracted human third molars were used for this study. The teeth were pumiced and stored in 0.1% thymol solution at 4°C for 30 days. Enamel blocks (4 mm long x 4 mm wide x 3 mm thick) were taken from the buccal and lingual

surfaces. All surfaces of all samples were flattened using 600-grit Al_2O_3 abrasive paper, polished with 1000 and 1200 grit aluminum oxide abrasive papers, and polished (in sequential order) with 6, 3, 0.5, and 0.25 µm grit diamond pastes.

The baseline surface microhardness was determined and enamel blocks with a mean surface hardness of 303.8 (±30.4 SD) Knoop Hardness Number (KHN) units were selected. One hundred specimens of enamel blocks were divided randomly into 10 groups (n = 10), consisting of one control group (with unbleached samples placed in 100% humidity at 37°C) and nine experimental bleaching groups.

Experimental groups and bleaching procedures

In a single session, one of three commercial in-office 35% hydrogen peroxide-based bleaching agents were used: Whiteness HP Maxx (FGM), Pola Office (SDI North America), and Opalescence Xtra (Ultradent Products, Inc.) (see Table 1). The bleaching agents were prepared according to the manufacturers' instructions. Each bleaching agent was applied to 30 samples, as a layer 1 mm thick (±0.05 g) was applied to the enamel surface three times for 10 minutes each time. Each bleaching agent was either irradiated with a halogen curing light (XL 2500, 3M ESPE), irradiated with an LED/diode laser (Ultrablue Laser System, DMC Equipment), or not irradiated at all.

When specimens were irradiated with halogen curing lights (640 mW/cm^2), the bleaching gel was left undisturbed for two minutes and each specimen was irradiated for 30 seconds; this process was repeated three times. For specimens irradiated with an LED (250 to 350 mW/cm^2) and diode laser (wavelength of 810 to 830 nm, with 20 to 30 W of power), the bleaching gel was left undisturbed for one minute and each specimen was irradiated for two minutes; this procedure was repeated three times. After bleaching, the specimens were thoroughly rinsed with deionized water for 10 seconds and stored in 100% humidity.

Table 1. Bleaching agent compositions.

Material	Manufacturer (batch no.)	Composition
Whiteness HP Maxx	FGM (02262005)	35% hydrogen peroxide, distilled water, carbopol, glycol, potassium ions
Pola Office	SDI North America (0567652)	Liquid: 35% hydrogen peroxide, distilled water, stabilizers; Powder: thickener, catalyst, pigments, desensitizers
Opalescence Xtra	Ultradent Products, Inc. (H103)	35% hydrogen peroxide, 1.5% carbopol, glycerin, flavoring

Microhardness, SEM observations, and PLM analysis

Using a microhardness tester with a Knoop indentor (under a 50 g load for five seconds), surface microhardness (SMH) was determined in the enamel blocks before (baseline) and after bleaching. The Knoop indentor made five indentations, spaced 100 µm from each other and from the baseline. Data were analyzed by split-plot two-way ANOVA and Dunnett's and Tukey's tests at a 5% level of significance.

After SMH, all blocks were longitudinally sectioned with a diamond saw (Isomet 1000, Buehler Ltd.) through the center. Half of each block was sputter-coated with gold and representative areas of treated enamel surfaces were photographed using SEM (magnification 5,000x) (JSM-5600, Jeol USA, Inc.) to evaluate the treated enamel.

For the other half of each sample, cross-sectional microhardness (CSMH) was used to determine mineral content; these halves were subsequently subjected to PLM. These surfaces were polished with 1 µm and 0.25 µm-grit diamond pastes (APL-4). Using the same microhardness tester, indentations were made at 20, 40, 60, 80, 100, 120, 140, 160, 180, and 200 µm from the outer enamel surface. CSMH values were converted to volume percentage of mineral.[12] A Knoop indenter (with a 50 g load) was used for five seconds. The values of volume percentage of mineral were analyzed by split-plot ANOVA statistical design, followed by Tukey's test, with bleaching agents, irradiation mode, and depth of microhardness measurements as factors. SAS software (SAS Institute Inc.) was used for statistical analysis, with the significance limit set at 5%.

After CSMH was determined, the specimens were sectioned (100 ± 10 µm thickness), embedded in distilled and deionized water, and mounted on glass slides; at that point, the demineralization depth was analyzed by PLM as previously described. Photomicrographs of a representative area of the enamel were taken (magnification 20x).

Table 2. Mean KHN (± SD) of the enamel surface for each group.

Experimental groups	Baseline	After bleaching
Whiteness HP Maxx with no irradiation	301.7 ± 14.1 A a	284.1 ± 13.5 B a*
Whiteness HP Maxx and halogen light	304.0 ± 11.1 A a	291.7 ± 16.2 B a
Whiteness HP Maxx and LED/diode laser	304.0 ± 17.4 A a	268.7 ± 25.2 B a*
Pola Office with no irradiation	298.6 ± 16.2 A a	268.8 ± 23.9 B a*
Pola Office and halogen light	300.1 ± 17.0 A a	279.1 ± 23.8 B a*
Pola Office and LED/diode laser	317.9 ± 9.6 A a	283.2 ± 22.8 B a*
Opalescence Xtra with no irradiation	297.5 ± 16.3 A a	260.9 ± 17.2 B a*

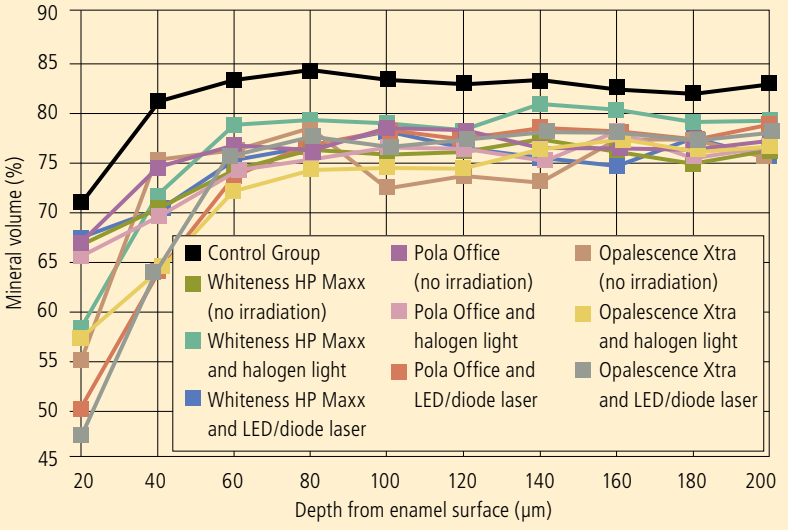
Chart 1. Volume of mineral (in %) as a function of depth from the enamel surface, according to the experimental groups.



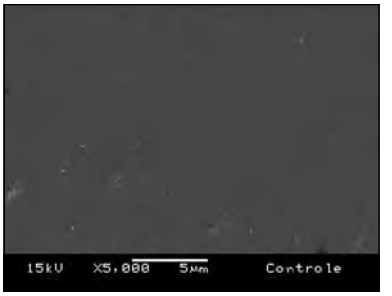


Fig. 1. A micrograph (magnification 5,000x) of enamel surface morphology from an unbleached sample. Note the smooth and unchanged surface is noted.

Results

The mean SMH values for enamel before (baseline) and after bleaching are displayed in Table 2. Tukey's test showed that the initial SMH (baseline) was similar for all groups ($p > 0.05$); however, specimens submitted to bleaching regimens had significantly lower SMH ($p < 0.05$) compared to the control group, but with no differences among the bleached groups. After bleaching, Dunnett's test showed that all groups exhibited lower SMH than the untreated control group. The exception to this was Whiteness HP Maxx irradiated with a halogen light, which had values similar to those of the control group ($p < 0.05$).

A representative photomicrograph of an unbleached enamel surface (control group) is shown in Figure 1. No significant morphologic alterations were detected on unbleached surfaces. Bleached groups showed altered surface smoothness, with similar levels of surface changes and dissolution of some of the enamel superficial areas (Fig. 2–4). The light irradiation did not exacerbate the mineral loss or the morphologic alterations on bleached surfaces.

Chart 1 lists the mean mineral volume (%) at each depth of enamel for all groups. According to the CSMH, all bleached enamel had lower mineral volume percentages at 20 µm and 40 from enamel surface; however, the CSMH did not change significantly at depths of 60–200 µm. PLM analysis did not identify any alterations of mineral content (Fig. 5) in unbleached enamel, while demineralization areas were observed in the superficial and subsuperficial regions of enamel (Fig. 6–8).

Discussion

Studies have indicated that 30–35% hydrogen peroxide can promote superficial enamel alterations and reduce the calcium:phosphorus ratio.[8-11,13-15] However, because 35% hydrogen peroxide is a strong oxidizing agent, it is indicated for professional use only in the dental office.[16,17] SEM images revealed that all bleaching treatments used in the previous study (regardless of whether light irradiation was used) reduced Knoop enamel microhardness and surface morphological alterations, with a lack of enamel smoothness. The changes on the enamel surface produced by the

Fig. 5. A PLM of an unbleached sample (magnification 20x) reveals no areas of demineralization.

Fig. 6. PLM analysis of the Whiteness HP Maxx specimens seen in Figure 2. Asterisks note demineralization areas located at superficial and sub-superficial regions of enamel.

Fig. 7. PLM analysis of the Pola Office samples seen in Figure 3. Asterisks note demineralization areas at the superficial and sub-superficial regions of enamel.

Fig. 8. PLM analysis of the samples in Figure 4. Asterisks note demineralization areas located at superficial and sub-superficial regions of enamel.

oxidizing process of bleaching are related to demineralization on some areas of the surface (Fig. 2–4). The decrease in SMH is associated with the loss of the enamel mineral content and the mineral content's organic matrix.

Although SEM micrographs of the bleached enamel surfaces showed pits, waviness, erosions, and surface roughness, other areas showed no alterations. PLM images showed that demineralization was not uniform along the enamel surface and subsurface. The bleaching agents were applied consecutively three times on the enamel (for 10 minutes each time), which corresponds to one clinical session. Based on these findings, this mode of bleaching product application did not attack or alter the morphology of the entire enamel surface available for analysis.

According to CSMH analysis and PLM images, the bleaching agents produced a demineralization depth of up to 40 µm from the enamel surface (Chart 1). Mineral volume (in %) was reduced at 20 µm and 40 µm from the enamel surface. The enamel was considered sound at depths of 60–200 µm, showing no effect from the bleaching treatment.

Peroxide diffuses through enamel toward the enamel-dentin junction; however, the literature has demonstrated that the effects of peroxides are only superficial and do not involve the entire thickness of human enamel.[18-20] In a 2005 study, Efeoglu *et al* used computerized tomography to examine human enamel specimens that had been treated for 15 days (eight hours a day) with 10% carbamide peroxide and reported significant demineralization in the upper 50 µm.[19] Bizhang *et al* also evaluated bovine enamel after treatments of 10% carbamide peroxide (eight hours a day for two weeks) or 5.3% hydrogen peroxide (one hour a day for two weeks) and found median lesion depths of 4.85 µm and 1.65 µm, respectively.[20] A 2005 study by Attin *et al* showed that the reduction in hardness was confined to the superficial layers.[18]

For products that contain peroxide, the concentration of peroxide and the duration of the products' application are important factors in determining the products' whitening efficacy and adverse effects.[10,21] The bleaching agents in the present study had different compositions and colors, although all of them contained 35% hydrogen peroxide as their main ingredient (see Table 2); as a result, SEM, PLM, and microhardness testing did not reveal any differences among the products. Some colored products used in light-activated bleaching contain pigments (such as carotene, manganese sulphate, and Brazilian urucum) that are said to aid the energy transfer from the light to the peroxide gel.[6,7,22,23]

Because irradiating the bleaching agents did not affect enamel surface changes and demineralization, the null hypothesis tested in this study was accepted. The light source was used to activate peroxide degradation and accelerate the chemical redox reactions of the bleaching process, which could exacerbate

the adverse effects of bleaching agents.[2,3,7] However, such an exacerbation was not observed in the present study. Although some studies have demonstrated the efficacy of light-activated peroxide tooth bleaching systems, the dental literature is controversial and limited regarding the evidence from clinical and *in vitro* studies about the true influence of light irradiation on tooth bleaching.[4,5,6,21] The light sources may be important during bleaching for increasing the peroxide chemical reaction rate and energizing the tooth stain to accelerate the bleaching process; however, the irradiation had no influence on the results in the present study.[21,24]

Conclusion

All bleaching procedures tested in this study reduced enamel microhardness, altered surface morphology, and caused mineral loss for the enamel surface and subsurface. The light irradiation during the bleaching did not exacerbate the effects of 35% hydrogen peroxide.

Clinical importance of the presence of lateral canals in endodontics

Carina Folgearini Silveira, DS ▪ Josue Martos, DDS, PhD ▪ Joao Batista Cesar Neto, DDS, MDS, PhD
Carmen Maria Ferrer-Luque, DDS, MDS, PhD ▪ Luiz Fernando M. Silveira, DDS, MDS, PhD

This article presents a clinical case in which the diagnosis and treatment of a lateral canal was instrumental in the successful completion of endodontic therapy. Endodontic treatment was performed by crown-down shaping and copious irrigation (using 2.5% sodium hypochlorite associated with 17% ethylenediaminetetracetic acid (EDTA)). After 10 months, there were no clinical symptoms of inflammation and radiographs showed periradicular healing.

Received: December 2, 2008
Accepted: March 20, 2009

The anatomical relationship between the pulp and the periodontal structures plays a major role in the etiopathogenesis of the pulp or pulp-periodontal lesions.[1,2] Dentinal tubules, ramifications, lateral canals, or deltas may contribute to the persistence of periapical lesions, even after endodontic treatment is completed.[3,4]

Cleaning the lateral canals mechanically is always a challenge and may favor the perpetuation of a predominantly anaerobic polymicrobial ecosystem that is able to sustain a periradicular lesion.[5,6] Anatomically, a *lateral canal* is defined as a structure that extends from the main canal to the periodontal ligament. Previous studies have used different methods to evaluate the presence of lateral canals and reported such canals in 8.3–19% of the populations evaluated.[4,7,8] Lateral canals are rarely diagnosed; however, this does not mean that they are infrequent.

Ramifications from the main root canal are rarely treated during endodontic preparation and instrumentation; however, they have been discovered during root canal restoration, especially when hybrid-filling techniques are used.[9-12] According to Weine and Buchanan, the presence of lateral canals is not indicative of endodontic failure; however, the presence of bacteria inside these canals can initiate and/or maintain periapical inflammation.[10] Decalcifying solutions, such as citric acid and ethylenediaminetetracetic acid (EDTA), are used to remove the smear layer during canal preparation and to decrease the virulence of bacterial microflora.[13]

Filling a lateral canal denotes that at least part of the bacterial biofilm was chemically affected and that the septic/necrotic content has been partially removed. Finding the right irrigating solution and irrigation technique for such a situation may make the root canal system biocompatible, allowing periradicular healing. In the following case report, these concepts were taken into consideration for the treatment of a tooth that had an extensive lesion and a lateral canal.

Case report

A 26-year-old man reported experiencing moderate pain in the right maxillary region (exacerbated in the dorsal decubitus) during the previous three months, with swelling in the area of the maxillary right first premolar. The thermal test, performed using a tetrafluoroethane spray (Roeko Endo-Frost, Coltene/Whaledent, Inc.), revealed a negative response to cold, confirming the absence of pulp vitality. The intraoral examination showed a gingival swelling with a sinus tract opening on the mucogingival junction. A purulent exudate drainage was observed under digital palpation, but periodontal probing did not reveal a periodontal pocket. The patient also reported discomfort in response to vertical percussion.

Fig. 2. A conductometry radiograph indicates the patient's root canals.

Fig. 3. A radiograph taken immediately after lateral condensation.

Fig. 4. A radiograph taken immediately after root restoration, revealing the presence of a lateral canal.

Fig. 5. A radiograph taken 10 months postoperatively.

Radiographically, a composite restoration was observed in a complex cavity; in addition, an extensive circular radiolucent image (with defined limits) was observed in the interdental alveolar bone, between teeth No. 24 and 25. The radiograph suggested that the lesion was associated with tooth No. 24 and that the alveolar bone crest was intact (Fig. 1). The final diagnosis was a periradicular lesion of pulp origin. A complete buccal examination was performed, during which no other dental/oral pathologies were observed.

Treatment planning focused on the endodontic treatment of tooth No. 24. Radiographically and electronically, it was estimated that both root canals had a working length of 22 mm (Fig. 2). The crown-down instrumentation technique was performed using Gates Glidden burs (No. 2, 3, and 4, in that order), followed by flexofile files (No. 15-40) and K-files (No. 45-80). The irrigant solutions were 2.5% sodium hypochlorite with 17% EDTA (Odontopharma). Calcium hydroxide with paramonochlorophenol (Calen PMCC, S.S. White Technologies Inc.) was used as an intracanal medication for 15 days; at that point, the root canal was restored with an endodontic sealer (Endofill, Dentsply Maillefer) and gutta-percha points.

Radiographs taken after lateral condensation (Fig. 3) and root filling (Fig. 4) revealed a lateral canal that had not been detected initially. A radiograph taken 10 months postoperatively showed that the radiolucent area had healed significantly (Fig. 5).

Discussion

Determining the correct therapeutic approach requires a knowledge of the anatomical structures and the clinical-radiographic characteristics of lesions caused by pulp necrosis and periodontal disease. Periodontitis lesions and lesions of pulpal origin have similar radiographic characteristics, particularly when lateral canals are present. The presence or absence of periodontal pockets and the results of sensitivity tests are key steps to finding the differential diagnosis. The presence of a periodontal pocket suggests the diagnosis of periodontitis, while a healthy periodontium (with an intact dentogingival union of junctional epithelium and supracrestal connective tissue attachment) combined with pulp necrosis strongly suggests endodontic involvement.[1]

In general, periodontal destruction of endodontic origin offers a greater potential for regeneration than lesions that result from periodontal pockets.[14] The destruction of the junctional epithelium and supracrestal connective tissue attachment results in an apical migration of junctional epithelium, which leads to a pocket epithelium. As periodontitis progresses, periodontal ligament and alveolar bone loss will occur.

The present case showed a periodontal lesion of an exclusively pulpal origin. The patient's dentogingival union was intact, which prevented epithelial migration to the healing area. The presence of a bone-cell supply in the surrounding tissues was favorable to tissue regeneration.

An incorrect diagnosis may lead a practitioner to insert periodontal instruments inside the lesion, jeopardizing the potential for regeneration displayed by endodontic lesions. In the present case report, an endodontic lesion located laterally to tooth No. 24 was treated exclusively with a root canal preparation and showed an excellent regenerative response. The presence of an isolated lateral periodontal alteration unrelated to the probing depth suggested the presence of a lateral canal.[2]

According to Zolty, unfilled accessory canals are responsible for a small percentage of endodontic failures; these unfilled canals also may result in persistent lateral bone loss.[2] The continued presence of the lesion may be related to the size and permeability of the lateral canal and the preoperative microbiologic condition.

The anatomical complexity of the root canal system allows viable bacteria to exist inside the infected dentinal tubules and accessory canals.[5,6] It is difficult for endodontic files to access these regions; as a result, dentists must choose the appropriate irrigating solutions to disinfect these accessory canals. According to the literature, sodium hypochlorite (at concentrations ranging from 2.5–5.25%) and decalcifying solutions should be used during the chemomechanical preparation.[13] The irrigant solution will also be responsible for the elimination of the smear layer during endodontic preparation. Although the smear layer is not an obstacle to a sealer's ability to penetrate, maintaining the smear layer may allow the surviving micro-organisms to reorganize and form a biofilm on the walls of the root canal, resulting in treatment failure.[15]

In cases of pulp necrosis, intracanal medications should be utilized between the treatment and retreatment clinical sessions of infected canals. In the present case, calcium hydroxide with paramonochlorophenol was used in response to a predominantly anaerobic polymicrobial ecosystem. The intracanal medication will act primarily in inaccessible areas of the canal system, where bacteria cannot be removed by instruments or irrigation.[13]

A lateral canal can harbor bacteria and remnants of pulp necrotic tissue that could lead to endodontic failure.[9] Although lateral and accessory canals have a clinical pathologic significance, they may be only casually recognized during endodontic treatment.[16] The lateral condensation technique applies a lateral pressure to the wall where the lateral canal is located; however, the hybrid combination of lateral condensation and thermomechanical compaction of gutta-percha results in a more homogenous root canal restoration (that is, one that favors the filling of lateral canals) compared to using the lateral condensation technique alone.[12]

Summary

Radiographically, the presence of a radiolucent area in the lateral portion of a root may indicate pulp necrosis and the presence of a lateral canal. Suspecting and determining the presence of lateral canals may guide the appropriate therapeutic approach, especially in terms of the irrigating solutions used to disinfect the area. The presence of lateral canals may influence the obturation technique selected during endodontic treatment; in addition, it can help to prevent subjecting healthy sites to periodontal treatment due to an incorrect diagnosis.

Influence of cavity design and restorative material on the fracture resistance of maxillary premolars

Gloria Beatriz de Azevedo Cubas, DDS ▪ Guilherme Briao Camacho, DDS, MSc, PhD
Tatiana Pereira-Cenci, DDS, MSc, PhD ▪ Tomio Nonaka, DDS, MSc, PhD ▪ Eduardo Luiz Barbin, DDS, MSc, PhD

This study sought to evaluate how the type of cavity preparation and indirect restorative material affected the fracture resistance of maxillary premolars. Teeth were divided into seven groups ($n = 14$) according to the cavity preparation design (inlays, partial onlays with palatal canine coverage, and total onlays with coverage of both canines) and restorative material used. After the teeth were prepared, restorations were manufactured using a ceramic or a composite resin and cemented with a resin-based cement, with the exception of a control group consisting of sound premolars with no preparation. Fracture resistance was assessed using a universal testing machine with a 9 mm steel ball at a speed of 0.5 mm/minute until fracture.

ANOVA results showed significant differences between restorative materials and types of preparations ($p < 0.05$). Cavity design did not affect composite resin restorations, while ceramic restorations with partial and total canine coverage presented the lowest fracture resistance values ($p < 0.05$). Within the limitations of this study, the authors concluded that indirect composite resin restorations offered better performance than ceramic restorations, regardless of the cavity design.

The reconstruction of partially destroyed teeth offers a more conservative approach compared to standard porcelain-fused-to-metal crown preparations, due to the adhesive capacity of esthetic materials; this capacity preserves sound dental structure and reinforces the restored tooth.[1-4] It is important to preserve healthy dental structure, as the loss of dental structure drastically diminishes resistance to tooth fracture compared to sound teeth.[5-7] However, there is little information about how much fracture resistance is restored after the placement of inlays or onlays.[7,8] It is known that catastrophic fractures occur more frequently in restored posterior teeth than in anterior teeth.[6,9-11] The main determinants in posterior tooth fractures are the restorative material, the type of cementing agent, and the extension and conformation of cavity preparation.[1,2,5,6,8,9]

In the past, posterior teeth with occlusal and proximal involvement were restored with amalgam and metallic inlays, a non-adhesive, non-esthetic approach that resulted in a high incidence of fractures over time.[12] These fractures may have occurred because these restorations provided primary mechanical retention without increasing dental structure resistance.[11,13]

Today, more esthetic restorative materials, such as ceramics and composite resins, are being utilized with adhesive techniques.[14-16] Ceramics offer biocompatibility, chemical durability, fluorescence, compression and wear resistance, and a thermal expansion coefficient similar to that of the dental structure.[1,15-17] While composite resins offer improved wear resistance and good esthetic results, they also have certain relevant drawbacks, such as polymerization contraction.[15,18,19] These restorations generate stress at the tooth-restoration interface, which leads to marginal gap formation, marginal discoloration, post-operative sensitivity, and secondary caries.[14,15,20,21]

Indirect or semi-direct techniques have been proposed for minimizing polymerization shrinkage, as the extraoral method of polymerization produces minimal contraction inside the mouth, minimizing shrinkage to the width of the luting agent gap.[15,22] These methods allow for appropriate reproduction of tooth anatomy and proximal contacts, improved surface finish, and greater mechanical resistance.[1,14,23]

This study evaluated how two indirect restorative materials and three types of cavity preparation designs affected fracture resistance in maxillary premolars. Two null hypotheses were tested: The first assumed that there would be no difference in fracture resistance values between the two restorative materials, the other

that there would be no difference in fracture resistance between the different types of cavity preparations.

Materials and methods

This study utilized 98 caries-free sound human premolars that had been extracted for orthodontic reasons. Periodontal soft tissues were removed, and the teeth were immersed in 1% choramin-T for 72 hours.[22] Prior to the study, the teeth were examined (magnification 10x) to find any possible fissures, washed in running water for 24 hours, and stored in distilled water at 37°C for five days. At that time, the teeth were divided randomly into seven groups (n = 14) according to the cavity designs and restorative materials.

Group 1 was the control group, consisting of sound premolars with no restoration. Group 2 consisted of mesio-occlusal-distal (MOD) inlays restored with ceramic material (Vitadur Alpha, Vident); Group 3, partial onlays (that is, palatal canine coverage) restored with Vitadur Alpha; Group 4, total onlays (both canines covered) restored with Vitadur Alpha; Group 5, MOD inlays restored with composite resin (Filtek Z250, 3M ESPE); Group 6, partial onlays with palatal canine coverage restored with Filtek Z250; Group 7, total onlays (with coverage of both canines) restored with Filtek Z250.

Using autopolymerized acrylic resin, the teeth's roots were embedded in a PVC matrix (Artigos Odontologicos, Classico Dental Products) 1 mm below the cementoenamel junction (CEJ) limit (that is, the interface between cementum and enamel). The occlusal preparation was 2 mm deep, with a width of half the interproximal distance. The proximal boxes were prepared at a width that equaled half of the bucco-lingual distance (1.5 mm deep axially), and the cervical wall was 1 mm coronal to the CEJ. The cusps of the protected canines were reduced by 1.5 mm and extended 2 mm in the cervical direction at the buccal surface, while the functional canine was reduced by 2 mm and extended 2 mm in the cervical direction at the lingual surface.[24] Diamond burs (4138, KG Sorensen) were used and discarded after every fourth preparation was performed. To manufacture the indirect and semi-direct restorations, polyvinyl siloxane impressions (Silon 2APS, Dentsply Caulk) were made to produce a hard stone master model for each sample (Fig. 1–3).

Ceramic restorations

The ceramic restorations were manufactured with Vitadur Alpha, using the refractory mold technique, with three burnings at 600–960°C. The restorations were finished and polished (Sof-Lex, 3M ESPE), then glazed at 930°C. At that point, the ceramic restorations were sprayed with glass particles for internal surface cleaning. The ceramic surface was etched using 10% hydrofluoric acid for four minutes and silane was applied with a microbrush. The dental surface was treated with 37% phosphoric acid (Scotchbond Etchant, 3M ESPE), which was applied to enamel for 30 seconds and to dentin for 15 seconds.[22] The dental cavity was washed with water for 15 seconds, and the tooth was dried slightly with absorbing paper. Using a microbrush, the adhesive (Single Bond, 3M ESPE) was applied in two layers, with a light air jet used between the application of the first and second layers. At that time, the adhesive was photocured for 40 seconds (XL 3000, 3M ESPE) at an energy level greater than 450mW/cm^2.

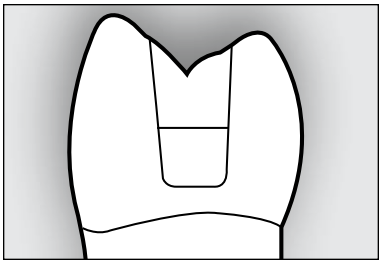

Figure 1. MOD ceramic inlay preparation design.

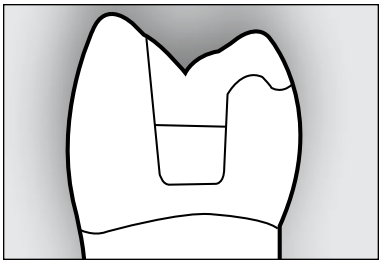

Figure 2. Ceramic onlay preparation design, with lingual canine coverage.

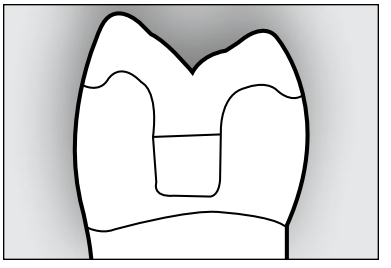

Figure 3. Ceramic onlay preparation design providing coverage to both canines.

Composite resin restorations

The impressions made with the condensation silicone were poured with type IV stone (Durone IV, Dentsply Caulk). Stone dies were covered with a thin layer of separating agent (K-Y Jelly, Johnson & Johnson). The direct microfilled composite resin (Filtek Z250) was added in increments no more than 1 mm thick, and each layer was photocured with a halogen light source (400 mW/cm^2) for 60

Table 1. Mean ± SD fracture resistance (in kgf), according to the cavity design and restorative material.

	Groups			
Materials	Control	Inlays	Partial onlays	Total onlays
Ceramic	178.62 ± 33.91	173.87 ± 12.82Ba	116.54 ± 21.15Bb	104.73 ± 20.40Bb
Composite resin	178.62 ± 33.91	147.75 ± 20.05Aa	150.07 ± 24.51Aa	161.08 ± 34.37Aa

Residual	48	692.739	–	–
Total variation	55	71,693.276	1,303.514	–

seconds at a distance of 10 mm. The internal surfaces of the restorations were abraded with a 50-µm aluminum oxide spray and the dental surface was treated as described prior to cementation.

Cementation of ceramic and composite resin restorations

The ceramic and resin restorations were cemented with a resin-based cement (Rely-X, 3M ESPE), according to the manufacturer's instructions, and the ceramic was positioned over the enamel surface with a 1 kgf load, using a Vicat needle for two minutes to produce standard pressure. Excess cement was removed with scalers. Next, the mesial and distal faces were polymerized for 40 seconds, and all samples were finished and polished using the Sof-Lex system.

The fracture resistance test was performed on the teeth's occlusal surfaces in a universal testing machine (MEM-2000, EMIC Ltd.), using a 9 mm sphere at a speed of 0.5 mm/minute. The sphere was positioned in the center of the occlusal surfaces (with a load of 500 kgf) until specimen fracture.[25] Statistical analysis employed a fixed significance level of 5%. For data analysis, two-way ANOVA followed by Tukey's test was performed.

Results

A significant difference was found among restorative materials and preparation designs ($p < 0.05$). Mean and standard deviation values of the fracture strength obtained in the axial compression test are described in Table 1. Table 2 shows the different performances between the different restorative materials and cavity designs.

Results differed among Groups 2–7 in terms of the different cavity designs. The overall results showed that ceramic restorations (Groups 2–4) offered inferior fracture resistance compared to the composite resin restorations ($p < 0.05$). Among the ceramic restorations, only inlays demonstrated fracture resistance values similar to those of the control group; however, the results among these groups were similar for partial and total onlays ($p > 0.05$).

Composite resin restorations did not differ by the type of cavity design in Groups 5–7; they presented acceptable fracture resistance values even with the more invasive preparations involving one or both cusps. All teeth restored with composite resin demonstrated similar fracture resistance values to sound teeth.

Discussion

Esthetic partial restorations in posterior teeth have increased greatly since the evolution of adhesive systems.[1-4] However, the clinical longevity of these partial esthetic indirect restorations is a concern, with fracture among the main causes of failure.[10,11,18,26,27] It is difficult to determine the ideal restorative material for posterior teeth.[1,14,15,18] Fracture risk becomes critical when extensive cavity preparations in posterior teeth are subjected to masticatory forces.[5,6]

In the present study, composite resin restorations demonstrated higher fracture resistance than ceramic restorations; in addition, the composite resin restorations were not affected by the type of cavity design. All teeth restored with composite resin restorations were capable of developing fracture resistance similar to that of the control group. By comparison, only ceramics with inlays

demonstrated resistance similar to that of the control group.

The composite resin restorations that involved one or two canines demonstrated superior performance in terms of fracture resistance, reinforcing the remaining dental structure. This resistance can be explained by composite resin's elasticity module, which is similar to that of dentin and is capable of absorbing masticatory or compressive loading forces. This elasticity module acts as a resilient substratum that favors more uniform stress transference to the tooth structure; as a result, teeth and restorations tend to act as a single unit.[28-31] In spite of the high elastic modulus materials, ceramics tend to develop high tensile stresses directly below their interface with the resin cement at the loaded area.[28-30]

Fracture can result from crack formation and propagation generated by fatigue, which is significant for ceramic restorations due to their brittleness.[7,17] Using a low modulus restorative material (such as composite resin) for a typical mesio-occluso-distal-lingual (MODL) restoration may result in better biomechanical performance for restorations that involve cuspal replacement.[32] Indirect composite resin inlays also show enhanced stress dissipation and elastic biomechanics similar to that of sound teeth, while glass ceramic inlays may generate higher stress levels at the cusp and transfer stresses to the dental walls or to the resin-cement and adhesive layers.[30] The results of the present study corroborate other studies that showed higher fracture resistance in indirect composite restorations when compared to ceramic or fiber-reinforced restorations.[7,22,31]

It is common knowledge that an indirect restoration is the treatment of choice for a large cavity. Previous studies have recommended reducing canines that have no support, converting inlays to onlays to enhance the restored teeth's resistance to fracture. Converting inlays to onlays with canine involvement is also recommended to eliminate occlusal contacts of the antagonistic tooth when it occurs at the tooth-restoration interface, protecting canines without support.[1,7] Although onlay restorations strengthen teeth, it is important to note that these restorations require removing additional tooth structure.[7,8,29] Indirect restorations are more time-consuming and expensive than direct restorations; however, they may allow for better control during the manufacturing stages, achievement of appropriate anatomy, proper finishing, reconstruction of occlusal and proximal contacts (which may be critical in Class II cavities), and better esthetic results.[1,14,23] Another advantage of indirect restorations is that polymerization contraction is limited to the cement film, reducing marginal gap, marginal staining, and secondary caries.[22,23]

According to the literature, some indirect resin composites have a similar composition to direct resin composites and offer no advantages in terms of mechanical properties.[33,34] Other studies report that the second polymerization procedure (which involves additional polymerization or a furnace or oven for post-curing) does not improve the performance of restorations with composite materials.[34,35] According to Rees and Jacobsen, the curing process prevents the inlays from bonding to the composite luting cement, compromising shear bond strength.[23]

The present study proposed using a semi-direct inlay/onlay technique for indirect inlays. The restorations were not submitted to additional polymerization, which usually occurs when indirect composite restorations are prepared, but still provided the benefits of an indirect technique, as restorations were manufactured outside of the mouth prior to placement.[22,36] Using a direct composite resin for an indirect manufacturing technique presents several advantages, as completing this technique does not necessarily mean depending on a laboratory. Unlike conventional indirect inlays, this technique does not require additional polymerization or a furnace or oven for post-curing. In addition, polymerization shrinkage is restricted to the resin cement, which improves both proximal and occlusal contacts.[22]

This *in vitro* study had its limitations: For example, no thermal or mechanical aging was used and only the effect of preparation design on tooth fracture strength was analyzed. However, this type of fracture strength test indicates the load-bearing capacity of restorations in simulated clinical situations. Additionally, *in vitro* studies are capable of determining probable clinical failures, while clinical trials may be restricted due to the cost of funding and the small number of subjects.[37]

To develop fracture resistance values similar to those of restored teeth, additional studies should be performed, based on load-bearing capacity tests and evaluating different cavity designs and minimum tissue reduction. In the present study, composite resin restorations built with the semi-direct technique presented fracture resistance values similar to those of sound teeth. This was a surprise, as direct resin restorations are not usually recommended for severely destroyed teeth.[14,15,18,23] Indirect or semi-direct techniques may be feasible for extensive Class II cavities with cervical cavity preparation margins in dentin, as indirect restorations minimize polymerization shrinkage, thus favoring the longevity of the restoration.[35]

Conclusion

The composite resin and ceramic restorations performed differently, depending on the cavity design. Overall results showed that ceramic restorations offered less fracture resistance than composite resin restorations, which showed adequate resistance regardless of the type of cavity design. All teeth restored with composite resin as well as ceramic inlays were capable of developing fracture resistance values similar to those of sound teeth.

Prosthetic rehabilitation of hemimandibular hyperplasia: Five-year follow-up

Bulent Gokce, DDS, PhD ▪ Birgul Ozpinar, DDS, PhD, Prof.Dr. ▪ Levent Ozgur, DDS ▪ M. Erhan Comlekoglu, DDS, PhD

Hemimandibular hyperplasia is a rare asymmetrical mandibular malformation, characterized by enlargement of the condyle, the condylar neck, the ramus, and the body of the mandible. This condition results in laterognathia, dental articulation disorders, and functional defects. Therapy largely depends on the patient's age and the desired esthetic and functional results.

This clinical report describes the prosthetic rehabilitation of a 50-year-old woman with hemimandibular hyperplasia. During the diagnostic phase, facial asymmetry was observed, as was the chin midline shifting to the unaffected side and three-dimensional enlargement of one side of the mandible, the condyle, the condylar neck, and the ramus. No biomechanical or functional problems were seen at a five-year follow-up visit, except for physiological wear to the artificial teeth.

Received: January 20, 2009
Accepted: April 20, 2009

Hemimandibular hyperplasia was first reported in 1836 as a complication of rheumatoid arthritis.[1] Obwegeser and Makek were the first authors to classify this disorder; since the anomaly terminates exactly at the symphysis of the affected side, it was referred to as *hemimandibular hyperplasia*.[2] This condition is a rare malformation of non-neoplastic origin, characterized by three-dimensional enlargement of one side of the mandible and enlargement of the condyle, the condylar neck, the ramus, and the body of the mandible.[2]

The incidence of hemimandibular hyperplasia and its hybrid forms is not known; however, according to Baveja *et al,* hyperplasia of the mandibular condyle occurs frequently (and often unilaterally) in women.[3] The etiology of hemimandibular hyperplasia is uncertain; however, the literature has claimed that the condition stems from genetic factors, circulatory problems, hormonal disturbances, traumatic lesions, infections, and arthrosis.[1,4,5]

Clinically, hemimandibular hyperplasia is characterized by facial asymmetry and the midline of the chin shifting to the unaffected side. The unilateral asymmetric increase in facial height usually occurs during the second decade and the rima oris of the mouth becomes shallow; however, mouth opening is not restricted. When hyperplasia occurs before puberty, the downward and forward mandibular growth is followed by maxillary growth. This growth causes the teeth on the affected side to remain at a lower level of occlusion than the teeth on the unaffected side, moving the occlusal plane in the transverse dimension.[2,6,7]

Radiographically, pathognomic findings—including elongation of the ascending ramus, enlargement of the condyle, and elongation and thickening of the condylar neck—are observed. The mandibular border of the affected side is bowed downward and positioned lower than the unaffected side.[1,2] Irregular and thickened bony condylar trabeculae, consisting primarily of trabecular bone whose surfaces are covered in osteoids, are observed.[5]

Histologically, the affected condyle is covered by a broad layer of hypertrophic cartilage; in addition, islands of chondrocytes are present in subcondral trabecular bone. The fibrocartilaginous layer is distributed in a diffuse but regular manner over the entire condylar head.[8,9] Large cells with vesicular cytoplasm and an uninterrupted layer of undifferentiated germinating mesenchymal cells are considered typical.[9]

This case report presents the clinical and radiographic findings and the prosthetic treatment (including a five-year follow-up period) of hemimandibular hyperplasia in a 50-year-old woman. The article also examines the limitations for dental interventions and five-year follow-up.

Case report

A 50-year-old woman with no significant medical problems or any family history of hereditary disease sought treatment for temporomandibular joint (TMJ) problems that required prosthetic treatment. Extraoral examination revealed facial asymmetry of the mandibular facial region with laterognathia

Fig. 1. A 50-year-old woman with lightly sloped rima oris and facial asymmetry.

Fig. 5. The patient's existing dentures mounted on an articulator.

to the right side, resulting in an increase in the lower facial height and rotated facial appearance. Moreover, the rima oris was slightly sloped (Fig. 1 and 2).

A detailed medical history of the patient revealed that laterognathia had been present since puberty (Fig. 3). She was not worried about her facial appearance; rather, her current complaints were pain in the TMJ region and difficulty chewing.

Intraorally, lower and upper clasp-retained partial dentures that had been placed seven years earlier were at cross-bite relation at the anterior and right posterior regions. The occlusal plane was inclined to the left side and deep carious lesions were seen on the mandibular canines (under the clasps). The dentures were severely worn, resulting in decreased occlusal vertical dimension (OVD). The loss of maxillary abutment teeth resulted in a lack of retention in the existing maxillary denture (Fig. 4 and 5). When the dentures were removed, the inter-arch distance on the left side was larger than that on the right side due to a hypertrophic left mandibular bone that did not restrict mouth opening. The remaining teeth were periodontally healthy.

A radiographic examination revealed excessive overgrowths in the condyle, the condylar neck, the ramus, and the body of the mandible (Fig. 6 and 7). The distance between the apex of the left mandibular canine and the lower mandibular border of the mandible was greater than the distance from the mandibular border to the apex of the right canine on the contralateral side.

Before a definitive prosthetic rehabilitation was performed, a treatment plan was formulated that involved endodontic and periodontal therapy for the mandibular canine teeth and increasing the OVD. The current dentures were mounted on a semi-adjustable articulator (Artex CT, Jensen Dental) and acrylic resin (Orthoplast, Vertex Dental) was applied (in 1 mm increments) to the occlusal surface of the existing dentures over a 90-day period to increase the previous OVD by 3 mm (Fig. 8). The patient was asked to wear the dentures for six months; during this period, biweekly recall visits were used to identify discomfort or TMJ-related problems. At each six-month recall visit, the patient's complaints of TMJ discomfort decreased gradually.

After the static and dynamic positions of the jaws had been evaluated on the articulator, a definitive treatment plan was developed. No mandibular surgical corrections were planned, as the prosthetic rehabilitation could be performed without any anatomical limitations from the hypertrophic mandible.

A complete maxillary denture and a mandibular conus crown-retained overdenture were planned. Individual trays were fabricated on casts that had been constructed using irreversible hydrocolloid impression material (CA37, Cavex Dental). The mandibular canines were prepared for conus crowns and the impressions for these crowns were made with a polyvinylsiloxane elastomeric impression material (Affinis, Coltene/Whaledent, Inc.). The border molding was applied to the upper tray and an impression was made using a ZOE product (Cavex Outline, Cavex Dental). The impressions were poured using a low-expansion Type IV dental stone (Glastone, Dentsply International).

Fig. 6. A radiograph reveals excessive overgrowth of the condyle, the condylar neck, the ramus, and the body of the mandible.

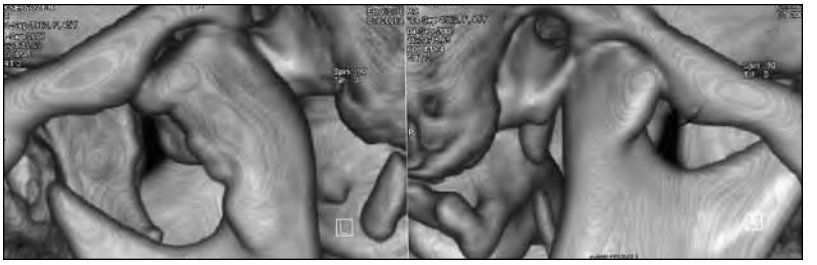

Fig. 7. CT views of the left and right condyles of the mandible.

Fig. 8. The patient's dentures, after the OVD was increased *in situ* by 3 mm.

The maxillo-mandibular relationship was recorded with a facebow and the casts were mounted on the Artex CT.

The conus crowns were prepared by a laboratory and checked in the mouth; at that point, a functional impression was taken for each individual tray, using a polyether impression material (Impregum, 3M ESPE). The denture try-in was performed and the dentures were set to achieve balanced occlusion.

Fig. 9. An anterior view of the final dentures.

Fig. 10. The patient after placement of the final dentures.

Dentures finished in the laboratory (using Orthoplast) were evaluated clinically and OVD, centric relation, excursive movements, esthetics, and phonation were examined. The conus crowns were cemented with a polycarboxylate cement (Poly-F Plus Bondex, Dentsply DeTrey) according to the manufacturer's instructions, and the dentures were delivered to the patient (Fig. 9 and 10).

The patient was satisfied by the esthetic and functional outcome and agreed to return every six months for follow-up. The five-year follow-up period did not reveal any significant changes or any biomechanical, functional, or TMJ pain issues, except for the physiological wear of the artificial teeth.

Discussion

Hemimandibular hyperplasia is a disorder that causes unilateral, excessive mandibular growth, resulting in facial asymmetry.[2,3] Condylar hyperplasia has been classified into three categories: hemimandibular hyperplasia (consisting of enlargement of the condyle, the condylar neck, the ramus, and the body of the mandible, with tilting in the occlusal plane), hemimandibular elongation (condylar neck enlargement accompanied by variable displacement of the ramus and the body of the mandible without tilting the occlusal plane), and condylar hyperplasia.[2]

The patient in the present case had all of the major properties of hemimandibular hyperplasia, including the occlusal plane's movement to the unaffected side and different right and left intermaxilla relations. The patient had no significant medical history and her family history did not include this condition. Radiographs revealed a large volume of trabecular bone; excessive overgrowth of the condyle, the condylar neck, the ramus, and the body of the mandible; and bony surfaces covered in osteoids.[5] Photos revealed that she had suffered from hemimandibular hyperplasia since childhood.

Surgical and orthognathic treatment plans for children and adults affected by hemimandibular hyperplasia have been reported in the literature.[3,6,10-13] However, the authors are unaware of any studies concerning the prosthetic treatment of elderly patients with hemimandibular hyperplasia. Surgical treatments (such as condylectomy, condylar shave, orthognathic surgery, and so forth) have been proposed, depending on the patient's age, the presence of active or inactive condylar growth, and the severity of the patient's facial appearance.[14] Delaire supported an early condylectomy for young patients.[15] In a 2001 article about adults with hyperplasia, Bertolini *et al* recommended a condylectomy with standard orthognatic surgery for active condylar hyperplasia, and orthognatic surgery alone for inactive condylar hyperplasia.[10]

For the patient in the present case, diagnostic cast evaluation indicated that a prosthetic design could be utilized; as a result, no surgery was planned. When noninvasive prosthetic treatment is applicable, the authors believe that conservative treatment modalities should be adopted before surgery in most cases. Proper prosthetic treatment could lead to correct

function, esthetics, and phonation. By contrast, surgical treatment is difficult, more time-consuming, and may result in nerve injury, neurological complications, and postoperative patient discomfort; in addition, it may not correct the asymmetry of the mandibular border.[7,13]

In most cases of hemimandibular hyperplasia, the occlusal plane is inclined, which interferes with antagonistic tooth contacts and interference during excursive movements; as a result, prosthetic treatment in such cases requires careful treatment planning.[16,17] In the present case, function, phonation, comfort, and esthetics were the primary goals of prosthetic treatment. A lower conus crown-retained overdenture and a complete maxillary denture were applied to maintain retention and stability, and occlusion was balanced following the gradual increase of the OVD.

Although many clinical methods for obtaining an appropriate vertical dimension are described in the literature, no instrumentation to obtain this exact craniomandibular position is currently available.[18] The patient's ability to tolerate the proposed increase in OVD was verified by using her existing dentures as a diagnostic treatment prosthesis. The conus crowns prevent excessive lateral loads with sufficient retentive capacity to transmit the occlusal loads along the long axis of the abutments.[19,20] Balanced occlusion is necessary for the even distribution of the masticatory forces and the stability of complete dentures and overdentures.[21,22]

Summary

For the treatment of hemimandibular hyperplasia, case-sensitive treatment modalities should be adopted, depending on the patient's age and demands, while being aware of the possible risks of surgery. Prosthetic rehabilitation should be considered for elderly patients affected by hemimandibular hyperplasia, to maintain function and relieve any discomfort related to TMJ. In the present case, the recalls for maintenance continued every six months for five years; the patient remains satisfied with her final dentures and has no TMJ discomfort.

Factors influencing the microhardness of a microhybrid composite

Marcos Britto Correa, DDS, MS ▪ Sandrina Henn, DDS, MS ▪ Jose Laurindo Machado Marimon, DDS
Sinval Adalberto Rodrigues Jr., DDS, MS, PhD ▪ Flavio Fernando Demarco, DDS, PhD

This study investigated how different photocuring units, exposure times, and ethanol storage affected the depth of cure in a microhybrid composite. Forty composite specimens (each with a depth of 4 mm) were prepared and divided randomly into four groups ($n = 10$) to receive treatment from a quartz-tungsten-halogen (QTH) curing unit (400 mW/cm^2) or a light-emitting-diode (LED) curing unit (180 mW/cm^2). The specimens were photocured for either 20 or 40 seconds and stored in the dark for 24 hours at room temperature. Knoop hardness was measured by making three indentations at each depth interval of 1 mm (up to 4 mm) with a 50 g load for 30 seconds. The specimens were stored in ethanol for 24 hours; at that time, hardness was measured again. Data were submitted to three-way ANOVA, Tukey's test, and Student's *t*-test ($p < 0.05$).

Statistical analysis revealed that hardness was significantly affected by depth, exposure time, and storage in ethanol ($p < 0.001$). No differences were observed between the curing units tested.

Received: April 15, 2008
Accepted: June 16, 2008

The long-term durability of composite restorations depends in large part on the quality of the composites' polymerization. The polymerization process is triggered by exposing these materials to a light that will excite the initiator molecules present in the composite; camphoroquinone is the most common initiator.

Quartz-tungsten-halogen (QTH) photocuring units are the most commonly employed photocuring devices. The curing units produce a white light that must utilize a filtering process to select the wavelength that corresponds to the intensity required to excite the camphoroquinone. Because of this characteristic of the white light, only 20% of the light produced is within the useful band (between 400 nm and 500 nm).[1] Additionally, the filtration process produces heat, which tends to degrade the curing unit over time.

Light-emitting diodes (LEDs) produce a blue light with a narrower light spectrum; their intensity peaks at approximately 460 nm, a level similar to the absorption peak of camphorquinone.[2] LED curing units produce less heat than QTH units and the diodes can last for approximately 10,000 hours. However, most of the first generation LEDs offer a considerably lower light intensity than the QTH curing units, impairing the depth of cure.[3] When comparing the microhardness of composites cured by a QTH unit to those cured by first generation LED units, some studies showed similar hardness results between the two devices, while others reported improved hardness from QTH units, especially at depths of more than 2 mm.[4-6]

In an effort to reduce chairtime, recent composites have been manufactured for the purpose of photocuring them within 20 seconds. However, low exposure time may be especially critical when first generation LED curing units are used.[7] Curing a composite for a short time may not polymerize it completely, especially when the device produces a low light intensity.[8,9] Forty seconds is considered the minimal amount of time necessary to produce adequate hardness for composites photocured with an LED unit.[10]

Microhardness has been used indirectly to evaluate the degree of conversion for composites.[11] The degree of conversion represents the consumption of carbon double bonds after polymerization and depends on the photocuring mode. Dental composites characteristically form dense, cross-linked polymer networks. The cross-link density of the polymer determines many of the polymer's properties (including sorption and swelling).[12] This parameter may be measured by exposing the material to a solvent (usually ethanol) and subjecting it to a microhardness test.[12,13] Differences in cross-link density may be found in composites that display similar degrees of conversion.[13]

This study sought to evaluate the Knoop hardness of composites activated with an LED or QTH curing light, with different exposure times, at different depths of cure, and

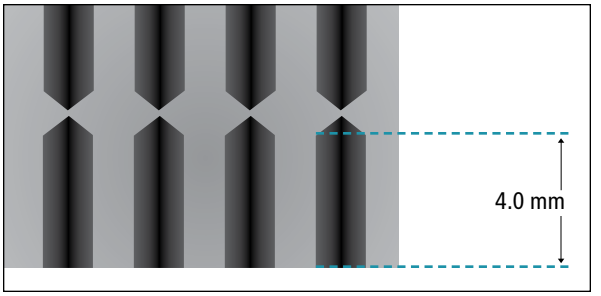

Fig. 2. An upper view of the inferior part of the mold and the length of the grooves (4 mm), which simulates the depth.

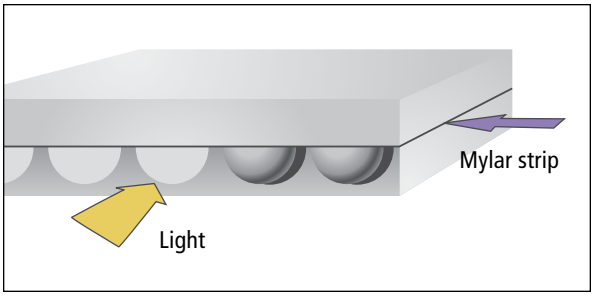

Fig. 3. A view of the insertion of composite, matrix position, and direction of light incidence during the polymerization process.

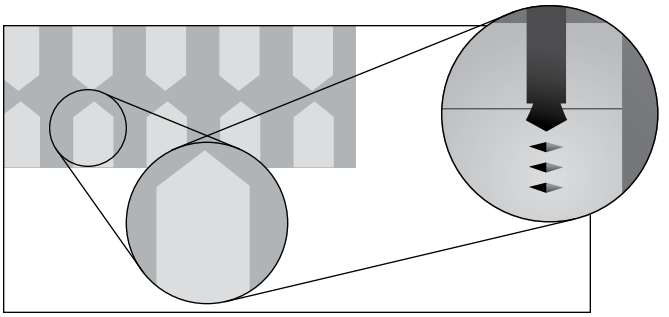

Fig. 4. The specimen is divided for the hardness test. Indentations are made in the upper surface of the specimen, before and after the unit is stored in ethanol.

after ethanol immersion. The null hypotheses tested were that the type of photocuring unit, the exposure time, the depth of cure, and the specimen's immersion in ethanol would have no significant effect on composite microhardness.

Materials and methods

Sample preparation

Forty specimens of a microhybrid composite resin (Filtek Z250, 3M ESPE) were prepared using a rectangular metallic split mold containing 10 grooves 4 mm deep (Fig. 1 and 2). A mylar strip was positioned between the two parts of the mold. The composite was inserted and photocured from the lateral face of the mold, with the light guide as close as possible to the composite surface (Fig. 3). This study used a QTH curing unit (CLK-50, Kondortech Dental Equipment) with a 400 mW/cm^2 light output and an LED curing unit (Ultrablue I, DMC) with a 180 mW/cm^2 light output. The light intensity produced by the curing units was measured constantly, using a radiometer (Model 100, Kerr-Demetron).

Storage and hardness measurement

The specimens were dry-stored for 24 hours in a dark environment at room temperature and submitted to the Knoop hardness test.[7] The upper surface of the specimens was divided with a razor blade into four 1 mm segments (Fig 4). The microhardness test was performed with a miniload hardness tester. Three indentations were made at each 1 mm interval, with a load of 50 g for 30 seconds. The specimens were placed in ethanol (98°C) for 24 hours; following storage, hardness was evaluated again.

Statistical analysis

Data were submitted to three-way ANOVA and Tukey's test ($\alpha < 0.05$) to evaluate the effect of exposure time, depth, and storage condition for each curing unit. Student's *t*-test was used to determine how each curing unit affected hardness in terms of depth, exposure time, and storage condition.

Results

While exposure time, storage in ethanol, and depth were found to significantly influence hardness

Chart 1. Mean hardness values produced with the QTH curing unit.

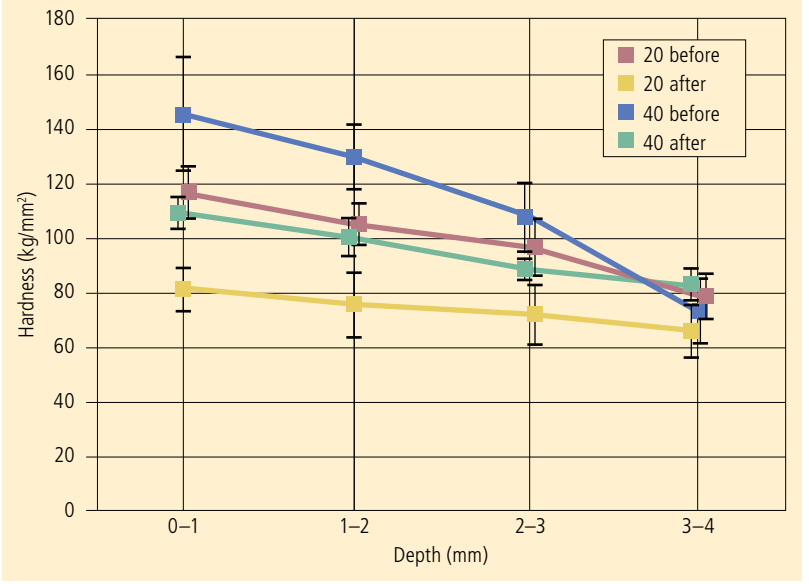

Chart 2. Mean hardness values produced with the LED curing unit.

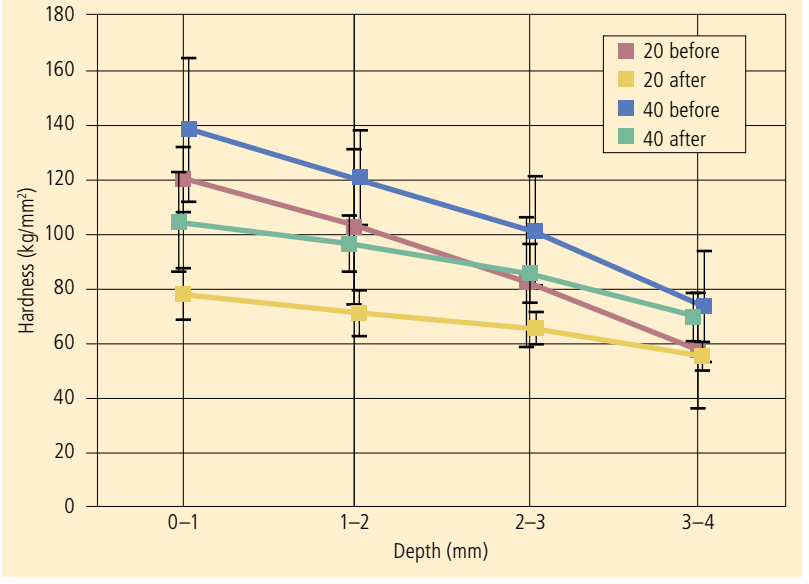

($p < 0.001$), no significant differences were reported between curing units ($p > 0.05$). Chart 1 shows the mean hardness values produced with the QTH curing unit. Hardness was reduced significantly as the depth increased ($p < 0.001$). Generally, specimens photocured for 40 seconds produced higher mean hardness values, while ethanol storage produced significantly lower hardness, especially at depths of 3 mm or less from the surface ($p < 0.001$).

Chart 2 shows the mean hardness values produced with the LED curing unit, indicating that increased depth, shorter exposure time, and ethanol storage decreased hardness significantly ($p < 0.001$).

Discussion

A QTH curing unit must have a power output of more than 300 mW/cm^2 to guarantee an adequate degree of conversion in an increment 2 mm deep.[14] The QTH curing unit used in the present study has a power output of 400 mW/cm^2; however, it was unable to produce greater hardness than specimens cured with the 180 mW/cm^2 LED unit. LEDs produce a narrower light spectrum that is closer to the excitation peak of camphoroquinone. As a consequence, the light emitted by these curing units is more effective at initiating the polymerization process, even when their power density is lower.[15]

Both curing units demonstrated a strong inverse relationship between hardness and depth (Charts 1 and 2), in accordance with the literature.[4,5,8,16,17] The light's ability to penetrate the composite depends on several factors, chiefly, the presence of opaque pigments and filler particles.[16,18,19] The dense polymer network that forms during polymerization also hinders light penetration.[1]

In the present study, both curing units displayed similar hardness within the first 2 mm. According to Rueggeberg *et al,* composite increments should not be thicker than 2 mm to provide homogeneous hardness; they reported in 2000 that the mean hardness ratio for all curing lights exceeded 0.80 (the accepted minimum standard) at a depth of 2 mm.[4] Nevertheless, in some clinical situations (for

example, with proximal boxes of Class II cavities), the distance from the curing tip to the cervical wall is more than 4 mm, making an adequate degree of conversion more difficult; such situations require additional exposure time.[20]

Some composite manufacturers recommend limiting exposure to curing lights to approximately 20 seconds. However, previous studies have reported that photocuring for 40 seconds produces greater hardness than photocuring for 20 seconds.[8,21] Increased exposure time promotes longer exposure to the photons produced by the curing units, which could be especially helpful when working with first generation LED curing units, which have a low power density. However, it is important to highlight that despite its reduced power output, the first generation LED curing unit used in this study matched the hardness produced by the QTH curing unit. At the same time, the LED light did not affect the degree of conversion or the composite's cross-link density, as represented by the hardness measured before and after the specimens' storage in ethanol.

Storing resin-based composites in ethanol has a softening effect and may reveal differences in cross-link densities after the composites are subjected to different types of photocuring.[8,13] In the present study, ethanol significantly reduced the hardness values for both curing units and for the exposure times; however, this effect was reduced as the depth increased. The softening effect was reduced when the specimens were cured for longer periods of time. A longer exposure time contributes to the formation of a cross-linked network, compared to the linear polymer chains formed during shorter exposure times.

Polymerization of a photocured composite is never complete; as a result, a considerable number of monomers (25–55%) fail to react. These remaining monomers act as plasticizers in the polymer matrix, thus reducing the stiffness of the polymer network. Polymer degradation occurs via a chain scission process in which the chains are cleaved into oligomers and even into monomers. This degradation process may be mediated by water or another solvent such as ethanol, which modifies the microstructure of the material, creating pores, releasing the residual monomers and fillers, and weakening the material architecture.[12,22]

Summary

Within the limitations of this *in vitro* study, it was possible to conclude that LED and QTH curing units produce similar hardness values when exposed to similar conditions. Increased depth and storage time in ethanol reduced hardness significantly, while increased exposure time increased hardness. These findings suggest that both LED and QTH curing units can be used safely in daily dental practice to cure composite resins, obtaining satisfactory results in increments up to 2 mm deep.

The AGD Self-Instruction Program

Get 8 exercises for the price of 6. A $50 savings!

Hurry—this offer expires March 31, 2010!

The AGD's Self-Instruction program is a convenient, cost-effective way to earn valuable continuing education (CE) hours in the office, at home, or even on vacation! There is no easier way to earn credits toward relicensure, membership maintenance, or the AGD's Fellowship Award.

Each issue of the AGD's award-winning, peer-reviewed clinical journal, *General Dentistry,* contains three Self-Instruction articles. Simply read the articles and take the "open-book" exercise following each one. Exercises are developed by and for general dentists, ensuring that you're getting CE that will benefit you, your patients, and your practice.

Submit your answers using the form at the end of each issue or via the AGD Web site (*www.agd.org);* we'll score and grade your responses. For every exercise you pass, you'll earn two CE hours—it's that easy! Credits are automatically posted to your AGD transcript, so there is no additional paperwork to submit. And, like all AGD CE offerings, Self-Instruction is PACE-approved!

Academy of General Dentistry™

PACE
Program Approval for Continuing Education

Approved PACE Program Provider
FAGD/MAGD Credit
Approval does not imply acceptance by a state or provincial board of dentistry or AGD endorsement
(06/01/2006) to (05/31/2010)

To enroll in Self-Instruction, contact the AGD Self-Instruction Coordinator via phone at 888.AGD.DENT (888.243.3368), ext. 4353, or via e-mail at *self-instruction@agd.org*. Or, you can enroll online at *www.agd.org/publications/gd/selfinstruct* and start submitting exercises today!
