

# Continuous invasion of exotic thrips: their damage in horticulture and biological control implications

BIOCONTROL  
CONFERENCE

*Tuesday 22 November, 2022*

Angelos Mouratidis, Sophie Le Hesran, Ada Leman & Gerben Messelink.

# Thrips (Thysanoptera)

- About 6.000 extant species, occupying different ecological niches.
- Average size  $\sim 2$  mm.

Fungal feeders ( $\sim 50\%$ )

*Idolothrips* spp.

Plant feeders ( $\sim 40\%$ )

*Frankliniella* spp.  
*Thrips* spp.

Obligatory Predators

*Scolothrips* spp.  
*Franklinothrips* spp.

# Thrips as crop pests

- Phytophagous thrips may be further distinguished based on the plant tissue they prefer to feed upon.

True flower thrips

*Frankliniella* spp.  
*Thrips* spp.

Immature foliage thrips

*Scirtothrips* spp.

Mature foliage thrips

*Heliethrips haemorrhoidalis*  
*Echinothrips americanus*

# Thrips as invasive pests

- Several aspects of the biology of thrips predisposes them to be successful when introduced in new regions
  - Abundant in the region of origin
  - Cryptic behaviour
  - Polyphagous
  - Multivoltine
  - Parthenogenetic
  - Rapid development of insecticide resistance

# Thrips as crop pests in Europe

- *Thrips tabaci* the main pest in European horticulture in the 19<sup>th</sup> century
  - Mostly affects *Allium* spp. but is damaging also several horticultural crops
  - Nowadays spread worldwide through trade, but originates from the Mediterranean region

# The arrival of *Frankliniella occidentalis*

- One of the most important invasive pests worldwide is introduced in the Netherlands in 1983, and then quickly spreads around the globe

Almeria (Spain) 1988

- Insecticide resistance
- Vector of TSWV
- Pressure from the market for low residues

- Research on BC in the Netherlands and Spain

Success of Biological control programmes starts in 1980s, based initially on *Amblyseius* predators and later on *Orius*

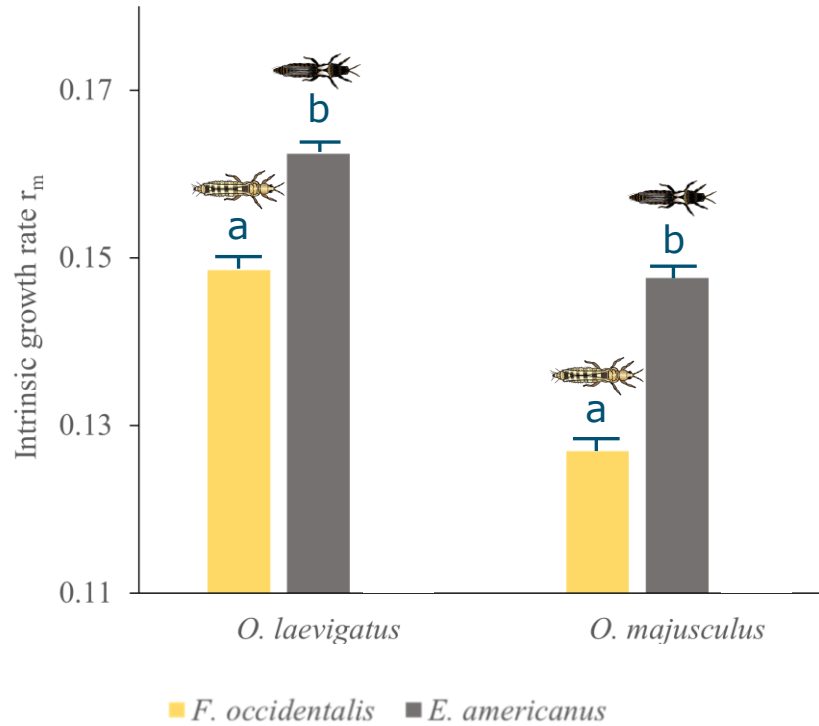

# *Echinothrips americanus*

- A leaf-feeding thrips is introduced in the Netherlands in 1993 from the US
- This thrips feeds mature leaves and often co-exists with *F. occidentalis* in many crops (sweet pepper, gerbera, roses, etc.)

# Life tables & predation success

- Observation = 1 h
- % Success =  $\frac{N^{\circ} \text{ thrips predated}}{N^{\circ} \text{ encountered}}$

Successful catch rate  
*O. laevigatus*

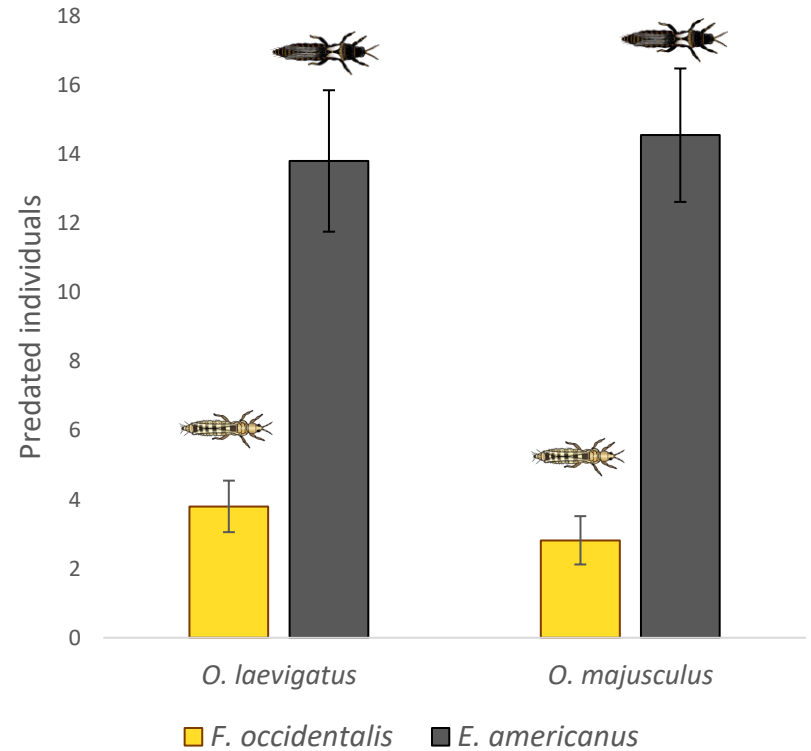

Successful catch rate  
*O. majusculus*

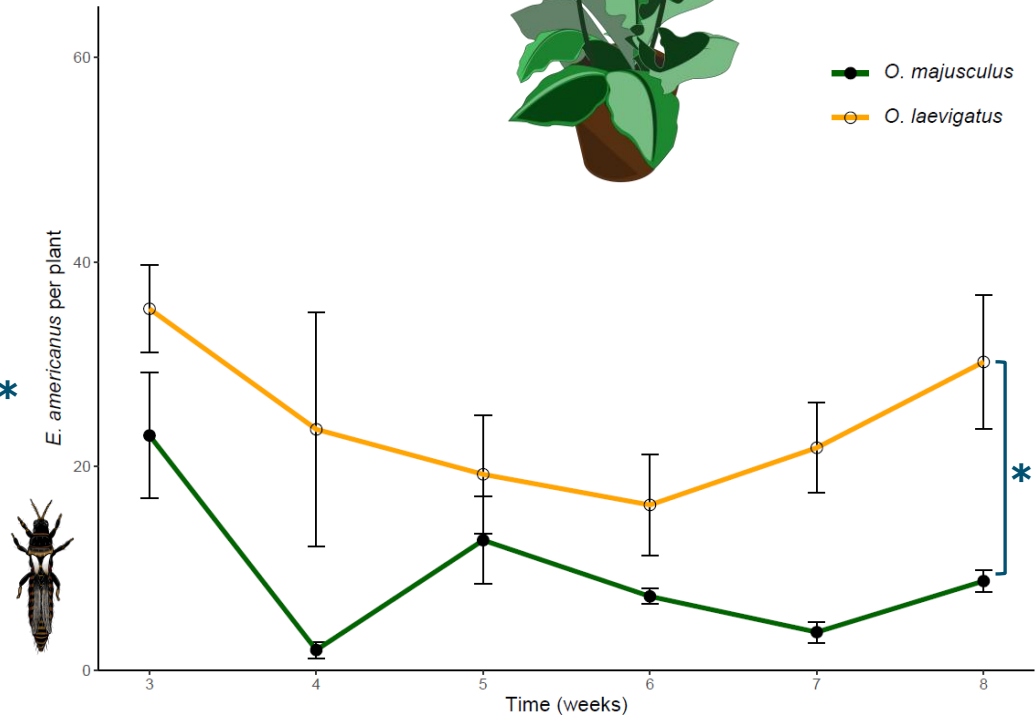

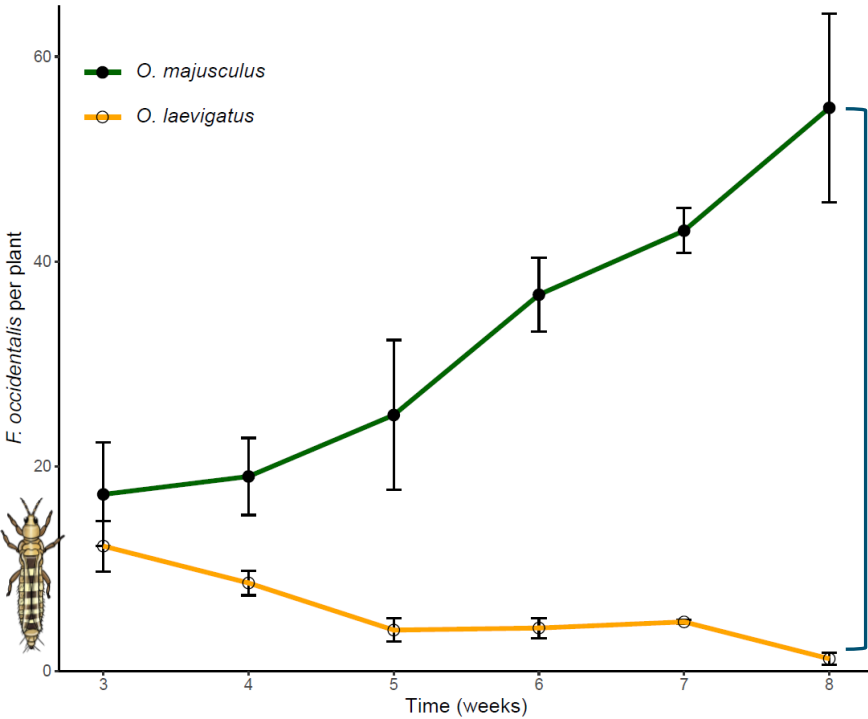

# Prey preference in the lab

- 30 thrips of both species offered to 1 predator for 8 hours

# Control of *E. americanus* and *F. occidentalis*

*Orius* predators have distinct habitat preferences

# *Thrips setosus*

- Originally from Japan and detected in the Netherlands in 2014.
- Leaf-feeding thrips that causes problems in ornamentals in the Netherlands (Hortensia, Lillie, Hosta etc..)
- Biological control options at the moment lacking due to unfavourable plant characteristics for the BCAs.

# *Dichromothrips corbetti*

- First record in the Netherlands in 1988. Native to the Malaysian Region.
- Stenophagous thrips, pest of Orchidaceae
- In recent years causing increasing damage in *Phalenopsis*

# *Thrips parvispinus*

- First finding in 2019 on Ficus and gerbera in the Netherlands
- This species quickly adapted to the greenhouse crops in Europe and is now an emerging pest in anthurium (Netherlands) and sweet pepper (Spain)
- Feeds on both leaf tissue and flower resources (like *F. occidentalis*).

# *Chaetanaphothrips orchidii*

- Widespread in South East Asia and Central Americas
- Pest of orchids, citrus, bananas, anthurium etc.
- Currently causing problem in anthurium and monstera in the Netherlands, and citrus in Spain (2016)

# *Scirtothrips*

- Species of this genus are key pests for many crops
- In recent years these thrips are repeatedly intercepted in mainland Europe and efforts to prevent their establishment are crucial

*S. inermis*, Canary islands

*S. aurantii*, Spain 2020

*S. dorsalis*, Spain 2016

# Orthotospovirus vectors

## Areas of Origin

# Wageningen UR Research on thrips

- Species identification is crucial
- Our team has developed a card that helps professionals identify thrips in European horticultural crops

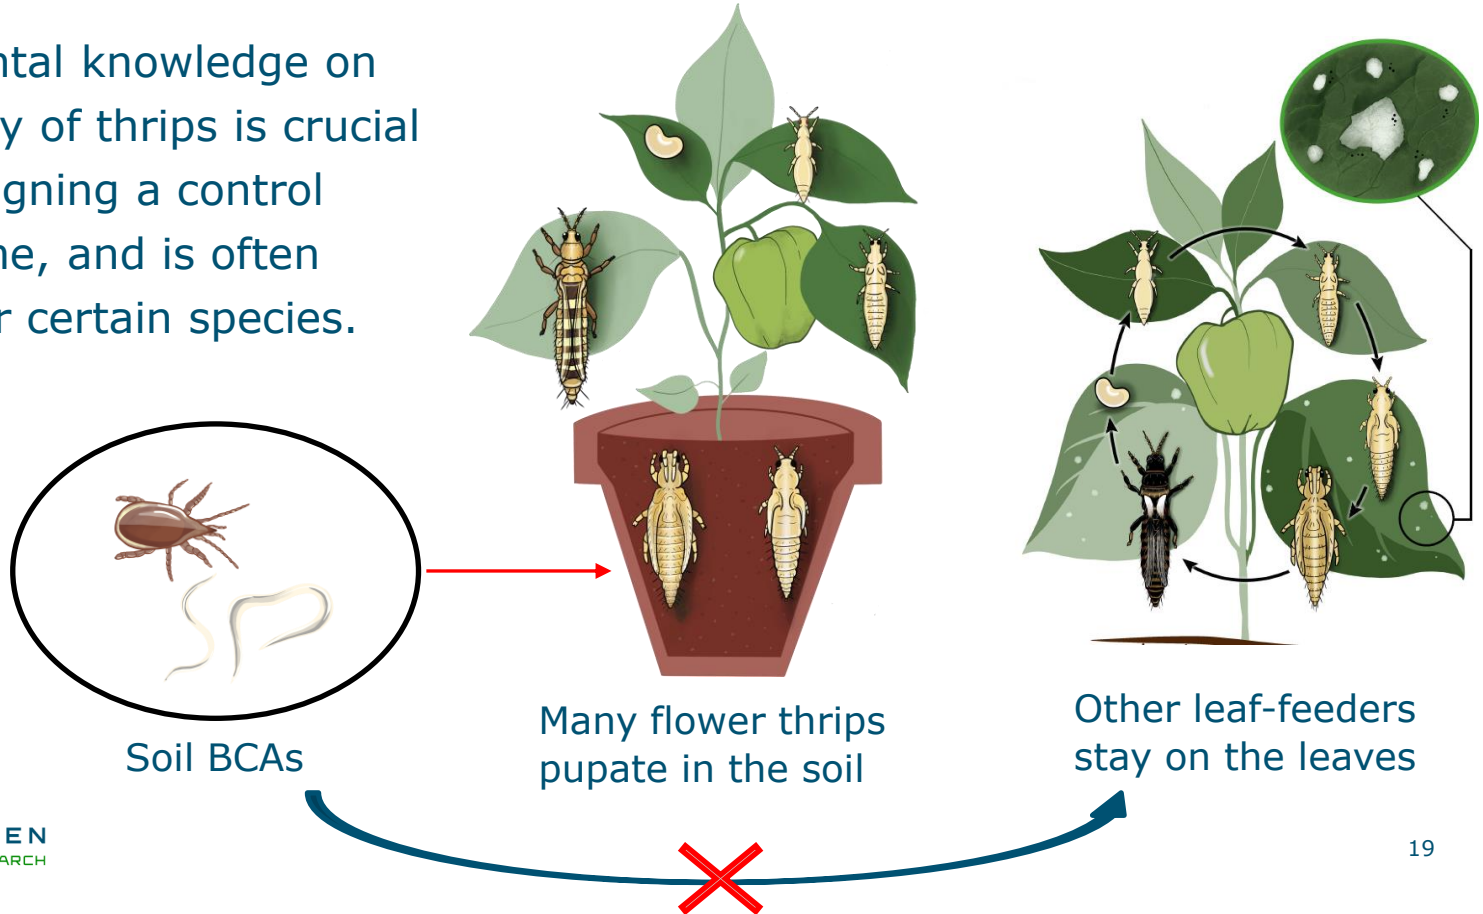

# Thrips diversity around the greenhouse

- Floral diversity increases spontaneous natural enemies around the greenhouse, but also *flower thrips*
- However, most of the thrips we find are endemic and not key crop pests

# Thrips as crop pests

- Fundamental knowledge on the biology of thrips is crucial when designing a control programme, and is often lacking for certain species.

# Thrips omnivory

Several other thrips show this behavior as well

- *Thrips tabaci*
- *Frankliniella schultzei*
- *Frankliniella fusca*
- *Thrips parvispinus?*

# Outlook to the future

- Successful biocontrol of thrips is based on early establishment of generalist predators
- No silver bullet – crop and pest specific strategies are needed
- *Expand our knowledge on recent invasive species*
- *Develop strategies to improve establishment of BCAs*

Banker plants

Supplemental food

New natural enemies
