26 **Abstract**

27 Neuropeptides are a diverse class of intercellular signaling molecules that mediate neuronal
28 regulation of many physiological and behavioural processes. Recent advances in
29 genome/transcriptome sequencing are enabling identification of neuropeptide precursor
30 proteins in species from a growing variety of animal taxa, providing new insights into the
31 evolution of neuropeptide signaling. Here detailed analysis of transcriptome sequence data
32 from three brittle star species, *Ophionotus victoriae*, *Amphiura filiformis* and *Ophiopsila*
33 *aranaea*, has enabled the first comprehensive identification of neuropeptide precursors in the
34 class Ophiuroidea of the phylum Echinodermata. Representatives of over thirty bilaterian
35 neuropeptide precursor families were identified, some of which occur as paralogs.
36 Furthermore, homologs of endothelin/CCHamide, eclosion hormone, neuropeptide-F/Y and
37 nucleobinin/nesfatin were discovered here in a deuterostome/echinoderm for the first time.
38 The majority of ophiuroid neuropeptide precursors contain a single copy of a neuropeptide,
39 but several precursors comprise multiple copies of identical or non-identical, but structurally-
40 related, neuropeptides. Here we performed an unprecedented investigation of the evolution of
41 neuropeptide copy-number over a period of ~270 million years by analysing sequence data
42 from over fifty ophiuroid species, with reference to a robust phylogeny. Our analysis
43 indicates that the composition of neuropeptide “cocktails” is functionally important, but with
44 plasticity over long evolutionary time scales.

45

48 neuropeptide-Y

49

50 **Introduction**

51 The nervous systems of animals utilize a wide variety of chemicals for neuronal
52 communication. These include amino acids (*e.g.* glutamate), biogenic amines (*e.g.* serotonin),
53 and neuropeptides (*e.g.* vasopressin) amongst others. Neuropeptides are by far the most-
54 diverse and they control many physiological/behavioural processes, including feeding,
55 reproduction and locomotion [1-3]. Recent advances in genome/transcriptome sequencing are
56 enabling identification of neuropeptide precursor proteins in species from a growing variety
57 of animal taxa, providing new insights into the evolution of neuropeptide signaling [4-8]. The
58 echinoderms are notable in this regard because as deuterostomian invertebrates they occupy
59 an “intermediate” phylogenetic position with respect to the vertebrates and intensely studied
60 protostomian invertebrates such as insects (*e.g.* *Drosophila melanogaster*) and nematodes
61 (*e.g.* *Caenorhabditis elegans*). Accordingly, characterisation of neuropeptide signaling
62 systems in echinoderms has recently provided key “missing links” for determination of
63 neuropeptide relationships and reconstruction of neuropeptide evolution [8-10].

64 The phylum Echinodermata comprises five extant classes: Echinoidea (sea urchins
65 and sand dollars), Holothuroidea (sea cucumbers), Asteroidea (starfish), Ophiuroidea (brittle
66 stars and basket stars) and Crinoidea (sea lilies and feather stars). Recent molecular
67 phylogenetic studies support the hypothesis that Echinoidea and Holothuroidea are sister
68 groups (Echinozoa) and Asteroidea and Ophiuroidea are sister groups (Asterozoa), with the
69 Crinoidea basal to the Echinozoa + Asterozoa clade (Eleutherozoa) [11, 12]. Echinoderms
70 are marine organisms that have several unique features including pentaradial symmetry as
71 adults, a remarkable ability to autotomise and regenerate body parts, and neurally-controlled
72 mutable collagenous tissue [13, 14]. Previous transcriptomic analyses have identified
73 neuropeptide precursor complements in *Strongylocentrotus purpuratus* (purple sea urchin),
74 *Apostichopus japonicus* (Japanese sea cucumber) and *Asterias rubens* (common European
75 starfish) [8, 15, 16]. Furthermore, the identification of neuropeptides in these species has

76 facilitated investigation of the evolution and physiological roles of various neuropeptide
77 signaling systems [8-10, 17-21].

78 The recent progress in transcriptomic/genomic characterization of echinoderm
79 neuropeptide systems has hitherto not been extended to ophiuroids or crinoids. The
80 Ophiuroidea constitutes the largest class among extant echinoderms [22] with a long
81 evolutionary history that extends back to the early Ordovician (around 480 million years ago)
82 [23], whilst extant families date from the mid-Permian (~ 270 million years ago) [12].
83 Available molecular data for ophiuroids has increased significantly in recent years with the
84 emergence of numerous transcriptomic studies [20, 24-29]. Here, we utilize transcriptome
85 sequence data from three brittle star species, *Ophionotus victoriae*, *Amphiura filiformis* and
86 *Ophiopsila aranea* to perform the first comprehensive identification of neuropeptide
87 precursors in ophiuroids. We identify representatives of over thirty neuropeptide families
88 including homologs of endothelin/CCHamide, eclosion hormone (EH), neuropeptide-F/Y
89 (NPF/NPY) and nucleobinin (NUCB)/nesfatin, which are the first to be discovered in a
90 deuterostome/echinoderm.

91

92 Transcriptomes have also been employed to investigate the phylogenetic relationships
93 of the ophiuroids, utilising data from fifty-two species [12]. In this the most comprehensive
94 molecular analysis of ophiuroid phylogeny to date, previous morphology-based classification
95 schemes [30] were rejected in favour of a new phylogeny comprising three primary ophiuroid
96 clades [12, 31, 32]. This landmark study and the associated large dataset has provided a
97 unique opportunity to investigate the conservation and diversification of neuropeptide
98 precursor structure over a period of ~270 million years of ophiuroid evolution. Our analysis
99 reveals that the majority of ophiuroid neuropeptide precursors contain a single copy of a
100 neuropeptide, but several precursors comprise multiple copies of identical or non-identical,
101 but structurally-related, neuropeptides. Interestingly, the number of neuropeptide copies in
102 the majority of precursors is constant across all the ophiuroid species examined, but examples

103 of clade-specific losses/gains of neuropeptides are also observed. This remarkable
104 conservation in neuropeptide copy number across ~270 million years of ophiuroid evolution
105 indicates that the composition of neuropeptide “cocktails” is functionally important, but with
106 plasticity over long evolutionary time scales.

107 **Results and discussion**

108 Here, we have utilized transcriptome sequence data for the first comprehensive identification
109 of neuropeptide precursors in ophiuroids (**Figure 1**). Representatives of over thirty bilaterian
110 neuropeptide precursor families were identified. Identification of ophiuroid representatives of
111 these neuropeptide precursor types has in some cases provided new insights into neuropeptide
112 precursor structure and evolution, as discussed in more detail below. First, however, we will
113 highlight representatives of bilaterian neuropeptide precursor families that have been
114 identified here for the first time in an echinoderm species.

115

116 ***Discovery of the first echinoderm representatives of bilaterian neuropeptide families***

117 Comprehensive analysis of transcriptome sequence data from three ophiuroid species,
118 *O. victoriae*, *A. filiformis* and *O. aranea*, has enabled the discovery of the first echinoderm
119 representatives of four bilaterian neuropeptide families. Specifically, we have discovered the
120 first deuterostomian homologs of eclosion hormone (**Figure 2**), the first ambulacrarian
121 homolog of CCHamide/endothelin-type peptides (**Figure 3A**), and the first echinoderm
122 homologs of neuropeptide-Y/neuropeptide-F (**Figure 3B**) and NUCB/nesfatin (**Figure S1**),
123 as discussed in detail below.

124

125 **Eclosion hormone**

126 Eclosion hormone (EH) was first isolated and sequenced in the insects *Manduca sexta*
127 (tobacco hornworm) and *Bombyx mori* (silk moth) and shown to alter the timing of adult
128 emergence [33, 34]. EH is one of the main peptide/protein hormones involved in control of
129 ecdysis (*i.e.* shedding of the cuticle) behavior in arthropods [35, 36]. It binds to and activates
130 a receptor guanylyl cyclase that is expressed in epitracheal Inka cells and causes the
131 secondary release of ecdysis-triggering hormone (ETH) that is also expressed in Inka cells
132 [37, 38]. In *Drosophila*, EH is important for ecdysis but whether this hormone is essential for

133 ecdysis is not yet clear [39, 40]. EH null mutant flies show defects in ecdysis and are unable
134 to reach adulthood yet some flies in which EH-producing neurons have been genetically
135 ablated (a more extreme manipulation) are able to survive till adulthood. Arthropod EHs have
136 six conserved cysteine residues that form three disulfide bridges [37]. EHs have not been
137 discovered previously outside of arthropods. Interestingly, four EH-like precursors were
138 identified in *A. filiformis* and *O. aranea* and two in *O. victoriae* (**Figure S2-S4**, GenBank;
139 MF155236; MF155237). The ophiuroid EH-like precursors are orthologous to neuropeptide
140 precursors previously identified in the sea-urchin *S. purpuratus* (Spnp11 and Spnp15, which
141 we now rename as Spur EH1 and Spur EH2, respectively) [16] and the starfish *A. rubens*
142 (Arnp11, Arnp15 and Arnp15b renamed as Arub EH1, Arub EH2a and Arub EH2b,
143 respectively) [8]. The positions of cysteine residues are conserved across all echinoderm and
144 insect EHs, but aside from this there is little sequence conservation (**Figure 2A**). The
145 echinoderm EH-like precursor sequences were also analysed using a sequence-similarity-
146 based clustering approach based on BLASTp e-values using CLANS software [41]. The
147 analysis shows that echinoderm EH-like precursors (i) cluster in two compact subgroups
148 (echinoderm EH-like precursor 1 and EH-like precursor 2 and (ii) have strong positive
149 BLAST results with arthropod EHs and, to a lesser extent, with arthropod ion transport
150 peptide (ITP) and vertebrate atrial natriuretic peptide (ANP) (**Figure 2B**). ITP precursors also
151 possess six cysteine residues; however, the position of these residues is not conserved with
152 cysteine residues found in echinoderm EH-like precursors (not shown).

153 To obtain further evidence for the presence of an EH-like signaling system in
154 echinoderms, we performed a phylogenetic analysis of EH-type receptors. Insect EHs
155 mediate their effects by binding to membrane guanylyl cyclase receptors [38]. EH receptors
156 are closely related to vertebrate ANP receptors and various orphan receptors [42]. Specific
157 BLAST searches enabled identification of transcripts in *O. victoriae*, *A. filiformis* and *O.*
158 *aranea* that encode proteins similar to arthropod EH receptors. Maximum likelihood and
159 Bayesian phylogenetic analyses confirmed that these sequences group with the receptor

160 cluster containing EH receptors (**Figure 2C**). The discovery of the first deuterostomian EHs
161 suggests an ancient bilaterian origin of EHs and indicates that these hormones may have other
162 functions in invertebrates aside from their role in ecdysis.

163

164 CCHamide

165 CCHamides are neuropeptides that were discovered relatively recently in the
166 silkworm *Bombyx mori* [43]. Later, it was found that insects have two CCHamide genes,
167 CCHamide-1 and CCHamide-2, each encoding a single copy of the mature peptide [44].
168 These peptides are referred to as CCHamides because they contain two cysteine residues and
169 a characteristic histidine-amide C-terminal motif. There are two CCHamide receptors in
170 insects: CCHamide-1 specifically activates one receptor and CCHamide-2 specifically
171 activates the second receptor [44, 45]. CCHamide-1 has a physiological role in starvation-
172 induced olfactory modifications [46] whereas CCHamide-2 regulates feeding, growth and
173 developmental timing in flies [45, 47]. Recent studies examining the evolution of
174 neuropeptides in the Bilateria have shown that protostomian CCHamides are related to
175 elevenin (another protostomian neuropeptide originally discovered from the mollusc *Aplysia*
176 *californica* L11 neuron), lophotrochozoan GGNG peptides, endothelins and gastrin-releasing
177 peptides (GRPs) [6, 7, 48, 49]. The latter two are neuropeptide types that have not been found
178 outside chordates. Furthermore, the degree of sequence/structural conservation varies across
179 these different peptide families. Hence, CCHamides are amidated and have a disulphide
180 bridge, elevenins and endothelins have a disulphide bridge but are non-amidated and GRPs
181 are amidated but lack the disulphide bridge. Furthermore, CCHamide-1 is located
182 immediately after the signal peptide whereas there is a dibasic cleavage site separating the
183 signal peptide and CCHamide-2 [44].

184 Here we have identified two neuropeptide precursors in brittle stars whose sequence
185 and precursor structure resembles those of lophotrochozoan GGNG peptides and insect
186 CCHamide-1 (**Figure 3A**). The CCHamide-like precursor 1 (GenBank; MF155229)

187 identified in *O. victoriae* is orthologous to an uncharacterized neuropeptide precursor
188 (Arnp25) identified previously in the starfish *A. rubens* [8], whereas the CCHamide-like
189 precursor 2 (GenBank; MF155230) was only found in brittle stars. Both CCHamide-like
190 precursors in *O. victoriae* comprise a single copy of a putative cyclic amidated peptide that is
191 flanked by a signal peptide at the N-terminus and a dibasic cleavage site at the C-terminus.
192 Interestingly, both of these peptides lack a penultimate histidine residue, just like the
193 lophotrochozoan GGNG peptides (**Figure 3A**) [48, 49].

194

195 Neuropeptide-Y/Neuropeptide-F

196 Neuropeptide-Y (NPY) was first isolated and sequenced from the porcine
197 hypothalamus in 1982 [50, 51]. Although the NPY/NPF family of peptides are pleiotropic in
198 nature [52], they are mainly known for their roles in regulation of feeding and stress [3, 53,
199 54]. The discovery of Neuropeptide-F (NPF) in the tapeworm *Moniezia expansa* in 1991
200 demonstrated for the first time the occurrence of NPY homologs in invertebrates [55]. Here,
201 we have identified the first echinoderm representatives of the NPY/NPF family in brittle stars
202 and starfish (**Figure 3B, Figure S12**). The brittle star precursors contain a peptide with a C-
203 terminal RYamide, in common with NPY in vertebrates and an ortholog in the starfish
204 *Patiria miniata*. In contrast, an ortholog in the starfish *A. rubens* has a C-terminal RFamide, a
205 feature that it shares with NPY/NPF-type peptides in the hemichordate *S. kowalevskii* and in
206 protostomes. Thus, our findings have revealed that NPY/NPF-type peptides with a C-terminal
207 Yamide motif are not restricted to vertebrates, as has been shown previously in some insects
208 [52]. Echinoderm NPY/NPF-type peptides are located immediately after the signal peptide in
209 the precursor proteins, as is the case in other bilaterian species. Surprisingly, we did not find
210 NPY/NPF-type precursors in the sea urchin *S. purpuratus* or the sea cucumber *A. japonicus*.
211 However, we suspect that this may reflect sequence divergence rather than gene loss because
212 a gene encoding a NPY/NPF-type receptor can be found in the *S. purpuratus* genome [56].

213

214 NUCB

215 Nucleobindins (NUCB1 and NUCB2) are multidomain Ca^{2+} and DNA binding
216 proteins. NUCB1 was first discovered in 1992 and thought to play a role in apoptosis and
217 autoimmunity [57]. Interestingly, the NUCB1 precursor has both a signal peptide and a
218 leucine zipper structure suggesting that it can bind DNA and act as an endocrine factor [58].
219 NUCB2 is a homolog of NUCB1 and was named based on high sequence similarity between
220 the two precursors [59]. In 2006, an 82 amino acid peptide located in the N-terminal region of
221 NUCB2 was reported. This peptide, Nesfatin-1 (Nucleobindin-2-Encoded Satiety and FAT-
222 Influencing protein-1), was discovered as a satiety inducing factor in the rat hypothalamus
223 [60]. Its role in inhibiting food intake in vertebrates is now well-established [59, 61].
224 Moreover, this pleiotropic peptide also modulates other processes including glucose and lipid
225 metabolism, and cardiovascular and reproductive functions. Recently, nesfatin-1-like peptide
226 derived from NUCB1 was shown to be anorexigenic in goldfish [62]. Surprisingly, the
227 presence of NUCBs in invertebrates other than *Drosophila* has not been reported until now
228 [63]. Here, we show that NUCB-type precursors are present in echinoderms (**Figure S1A**).
229 Phylogenetic analysis of NUCB precursors reveals that a single copy of the NUCB precursor
230 is found in invertebrate species and gene duplication in the vertebrate lineage gave rise to
231 NUCB1 and NUCB2 (**Figure S1B**). In chordates, the NUCB precursors are predicted to
232 generate three peptides (Nesfatin-1, 2 and 3); however, no biological role has been attributed
233 specifically to nesfatin-2 and nesfatin-3. Interestingly, the prohormone convertase cleavage
234 sites expected to generate Nesfatin-1, 2 and 3 are conserved between echinoderm and
235 chordate NUCBs. Moreover, the *O. victoriae* precursor (Genbank; MF155235) has an
236 additional predicted cleavage site within the Nesfatin-1 containing region, which is not
237 present in other species (except for *Drosophila melanogaster*). However, it remains to be
238 determined whether or not this cleavage site in the *O. victoriae* precursor is functional.

239

240 *First comprehensive identification of neuropeptide precursors in ophiuroids*

241 We have identified neuropeptide precursors belonging to 32 families, which
242 represents the first comprehensive analysis of neuropeptide precursors in ophiuroids (**Figure**
243 **4; Figure S2-S4**). Several of these neuropeptide families have been identified previously in
244 echinoderms and include homologs of AN peptides, bursicon (α and β) (GenBank;
245 MF155260; MF155227), calcitonin (GenBank; MF155228), cholecystokinin (CCK)
246 (GenBank; MF155231; MF155232) [15], corazonin (GenBank; MF155233) [10],
247 corticotropin-releasing hormone (CRH) (GenBank; MF155234; MF155235, MF155261,
248 MF155262), glycoprotein hormones ($\alpha 2$ and $\beta 5$) (GenBank; MF155238; MF155239;
249 MF155240) [64], gonadotropin-releasing hormone (GnRH) (GenBank; MF155263) [10],
250 insulin-like peptide (ILP) (GenBank; MF155264) [64], kisspeptin (KP) (GenBank;
251 MF155241) [8], luqin (GenBank; MF155242) [7], melanin-concentrating hormone (MCH)
252 (GenBank; MF155243) [8], NG peptides (neuropeptide-S) (GenBank; MF155244) [9, 65],
253 orexin (GenBank; MF155245; MF155246) [6, 8], pedal peptides (GenBank; MF155247;
254 MF155266; MF155267) [16], pigment-dispersing factor (PDF) (GenBank; MF155248) [8],
255 relaxin-like peptide (GenBank; MF155249) [66], SALMFamides (L-type and F-type)
256 (GenBank; MF155250; MF155268) [19, 20, 67], somatostatin (GenBank; MF155252;
257 MF155253) [8], tachykinin (GenBank; MF155254) [8], thyrotropin-releasing hormone
258 (TRH) (GenBank; MF155255; MF155256) [16] and vasopressin/oxytocin (GenBank;
259 MF155257) [64, 65] (**Figures 5-7 and S5-S10**). With the exception of MCH (which may be
260 unique to deuterostomes) [6, 8], AN peptides and SALMFamides (which thus far have only
261 been identified in echinoderms), the origins of all of the neuropeptide precursors identified
262 here in ophiuroids predate the divergence of protostomes and deuterostomes [6, 7]. Of the
263 three species examined here, the neuropeptide precursor complement of *O. victoriae* was the
264 most complete (**Figure 4**) and therefore this species is used as a representative ophiuroid for
265 sequence alignments, except in a few cases where a neuropeptide precursor was not found in

266 *O. victoriae*. Below we highlight several interesting and/or unusual features of ophiuroid
267 neuropeptides and neuropeptide precursors.

268

269 ***Neuropeptide precursors that occur in multiple forms in O. victoriae***

270

271 Thyrotropin-releasing hormone (TRH)-type precursors

272 TRH (also known as thyrotropin-releasing factor or thyroliberin) was first isolated and
273 sequenced in the 1960s [68-70]. In mammals, TRH is produced in the hypothalamus and
274 stimulates the release of thyroid-stimulating hormone (TSH) and prolactin from the anterior
275 pituitary [71, 72]. The recent discovery of a TRH receptor in the annelid *Platynereis*
276 *dumerilii* indicates that the evolutionary origin of this neuropeptide signaling system predates
277 the divergence of protostomes and deuterostomes [73].

278 The human TRH precursor contains six copies of the tripeptide pQHPamide [74].
279 Precursor proteins comprising multiple copies of TRH-like peptides have been identified
280 previously in the sea urchin *S. purpuratus*, the sea cucumber *A. japonicus* and the starfish *A.*
281 *rubens* [8, 15, 16], with a single TRH-type precursor found in each of these species.
282 Interestingly, here we identified two TRH-type precursors (OvTRHP1 and OvTRHP2) in *O.*
283 *victoriae* (**Figure S2 and 6A**). OvTRHP1 comprises 21 copies of putative TRH-like
284 tetrapeptides with the motif pQXXXamide (where X is variable). OvTRHP2, on the other
285 hand, comprises two copies of the putative tetrapeptide pQGPRamide and two longer
286 peptides that also have a C-terminal GPRamide motif but lack the N-terminal pyroglutamate.

287

288 Cholecystokinin (CCK)-type precursors

289 A CCK-type peptide (formerly pancreozymin) was first sequenced in the 1960s [75].
290 CCK-type peptides play numerous roles in feeding and digestion related physiology. CCK
291 mediates satiety, stimulates the release of digestive enzymes and gall bladder contractions
292 [76-78]. CCK-type peptides are involved in mechanisms of learning and memory, and

293 analgesia [79]. A neuropeptide precursor comprising two CCK-like peptides was recently
294 identified in the starfish *A. rubens* [8]. Here we have identified two CCK-type precursors in
295 *O. victoriae* (OvCCKP1 and OvCCKP2) and orthologs of both of these precursors were also
296 identified in the sea urchin *S. purpuratus* (Figure S2) [16]. The CCK-type precursor 1
297 comprises three CCK-like peptides in both *O. victoriae* and *S. purpuratus* and this precursor
298 is similar to the *A. rubens* CCK-type precursor, which comprises two CCK-like peptides. In
299 contrast, the CCK-type precursor 2 comprises a single CCK-like peptide in both *O. victoriae*
300 and *S. purpuratus*. Interestingly, the sequence of the *S. purpuratus* CCK-type precursor 2 was
301 reported previously as part of a genome-wide search for neuropeptides [80], but the authors
302 of this study did not identify it as a CCK-type precursor. However, based on the presence of a
303 conserved tyrosine residue and a C-terminal F-amide motif in the predicted neuropeptide
304 derived from this protein, it is evident that it belongs to the family of CCK-type precursors
305 (Figure 6B). A search of a preliminary genome assembly of the starfish *Patiria miniata*
306 (<http://www.echinobase.org>) [81] did not reveal a gene encoding a CCK-type precursor 2.
307 Therefore, it appears that this neuropeptide precursor type may have been lost in the
308 Asteroidea; nevertheless, further analysis of a wider range of starfish species will be required
309 to draw definitive conclusions. With a broader evolutionary perspective, CCK-type peptides
310 in deuterostomes are orthologs of sulfakinin (SK)-type neuropeptides found in insects [6, 7].
311 Interestingly, insects have a single SK precursor, which comprises two neuropeptides, SK-1
312 and SK-2 [82], and this may reflect the ancestral condition in the common ancestor of
313 protostomes and deuterostomes. Thus, the occurrence of two CCK-type peptides on a single
314 precursor in *A. rubens* and insects may be an ancestral characteristic and the occurrence of
315 two CCK-type precursors that comprise one and three CCK-type peptides appears to be a
316 derived characteristic.

317

318 Somatostatin-type precursors

319 Somatostatin was first isolated and sequenced from sheep hypothalamus in 1973 [83].
320 This peptide inhibits the release of pituitary hormones such as growth hormone, prolactin and
321 thyroid-stimulating hormone [84]. Moreover, it also inhibits the release of gastrointestinal
322 (cholecystokinin and gastrin amongst others) and pancreatic (insulin and glucagon) hormones
323 [85-87]. Aside from its effects on release of hormones, somatostatin also has central actions
324 that influence motor activity [85]. Here, we have identified two somatostatin-type precursors
325 (OvSSP-1 and OvSSP-2) in *O. victoriae*. (**Figure S2 and 6C**). Homologs of both of these
326 precursors are present in the sea urchin *S. purpuratus* (**Figure S2 and 6C**), one of which was
327 previously referred to as Spnp16 [16]. By comparison, only a single somatostatin-type
328 precursor has been found in the starfish *A. rubens*, which is an ortholog of OvSSP-1 [8]. All
329 somatostatin-type precursors comprise a single copy of the bioactive neuropeptide, which is
330 located in the C-terminal region of the precursor [88, 89]. Interestingly, the type-1
331 somatostatins in echinoderms have a phenylalanine residue located in the middle part of the
332 peptide and this conserved feature is found in human somatostatin. Conversely, type-2
333 somatostatins in echinoderms lack the phenylalanine residue but have a neighbouring
334 tryptophan-lysine (WK) motif that is also conserved in human and *B. floridae* somatostatins
335 (**Figure 6C**). The deuterostomian somatostatins are orthologous to the allatostatin-C
336 neuropeptide family in arthropods [7]. This family of peptides comprises three precursor-
337 types: allatostatin-C, allatostatin-CC and the recently discovered allatostatin-CCC [89, 90].
338 Both allatostatin-C and allatostatin-CC are non-amidated, like somatostatins; however,
339 allatostatin-CCC has a C-terminal amide. Hence, non-amidated peptides may be
340 representative of the ancestral condition in the common ancestor of protostomes and
341 deuterostomes, with the amidated allatostatin-CCC probably having evolved only within the
342 arthropod lineage [90]. It remains to be determined whether or not the duplication of
343 somatostatin-type precursors in echinoderms and the duplication of allatostatin C (to give rise
344 to allatostatin-CC) represent independent duplications. Further insights into this issue may be
345 obtained if the receptors for somatostatin-type peptides in echinoderms are deorphanised.

346

347 Corticotropin-releasing hormone (CRH)-type precursors

348 CRH-type peptides are a family of related neuropeptides that include CRH, urocortins
349 and urotensin-I in chordates, egg-laying hormone (ELH) in lophotrochozoans and diuretic
350 hormone 44 (DH₄₄) in arthropods [6, 7]. Arthropods usually have a single DH₄₄ precursor,
351 which comprises a single copy of the mature peptide. In some insects, such as *Tribolium*
352 *castaneum* and *Bombyx mori*, alternative splicing of DH₄₄ transcripts results in multiple
353 mature peptide isoforms of varying lengths [43, 91]. The situation in lophotrochozoans is
354 more complex, with several species having multiple precursors and some of these precursors
355 comprising multiple ELH mature peptides [4, 92]. A single CRH-type precursor was found
356 previously in the starfish *A. rubens*, whereas here we have identified four CRH-type
357 precursors in *O. victoriae* (**Figure S2 and 6D**). Thus, expanded families of CRH-type
358 peptides and receptors appear to have evolved independently in multiple animal lineages,
359 including chordates and ophiuroid echinoderms [93, 94].

360

361 *Diversity in neuropeptide precursor structure: new insights from ophiuroids*

362

363 Tachykinins

364 The mammalian neuropeptide substance P was the first tachykinin-type peptide to be
365 isolated and sequenced [95-97]. Subsequently, tachykinin-type peptides were discovered in
366 other animals including tunicates [98], insects [99, 100], annelids [101] and molluscs [102].
367 Tachykinin-type peptides regulate various physiological processes including muscle
368 contractility [103], nociception [104] and stress responses [105] amongst others [106].
369 Analysis of genomic/transcriptomic sequence data from the sea urchin *S. purpuratus* and the
370 sea cucumber *A. japonicus* did not identify candidate tachykinin-type precursors [6, 7, 15,
371 16]. However, recently a putative tachykinin-type precursor was discovered in the starfish *A.*
372 *rubens* (ArTKP), indicating that this signaling system does occur in some echinoderms [8].

373 Here we have identified orthologs of ArTKP in *O. victoriae* and other ophiuroids (**Figure 4**
374 **and 7A**). Collectively, these findings indicate that this signaling system has been retained in
375 the Asterozoa but lost in the Echinozoa. Comparison of the structure of the asterozoan
376 tachykinin-type precursors reveals that the *A. rubens* precursor (ArTKP) comprises two
377 putative mature peptides, whereas the *O. victoriae* precursor comprises four mature peptides
378 (**Figure 7B**). It remains to be determined, however, which of these two conditions represents
379 the ancestral state in the common ancestor of the Asterozoa. Further insights into this issue
380 may be obtained if sequence data from a variety of starfish species are analysed.

381

382 Kisspeptins (KP)

383 Kisspeptin (formerly known as metastin) is encoded by the *KiSS1* gene in humans.
384 *KiSS1* was originally discovered as a gene that may suppress the metastatic potential of
385 malignant melanoma cells [107]. Subsequently, it was found to play a vital role in regulating
386 the onset of puberty. Thus, in vertebrates kisspeptin binds to its receptor GPR54 to stimulate
387 pituitary release of gonadotropin-releasing hormone (GnRH) [108]. The first KP-type
388 precursors to be identified in non-chordates were discovered recently in ambulacrarians - the
389 echinoderms *A. rubens* and *S. purpuratus* and the hemichordate *S. kowalevskii* [8].
390 Accordingly, here we have identified KP-type precursors in *O. victoriae* and other
391 ophiuroids. All of the ambulacrarian precursor proteins comprise two KP-type peptides and
392 the first putative neuropeptide in the echinoderm precursors has two cysteine residues at the
393 N-terminus, which could form an N-terminal disulphide bridge similar that of calcitonin-type
394 peptides (see below). In contrast, the second putative neuropeptide does not contain any
395 cysteine residues and is typically shorter than the first peptide (**Figure 7C and D**).
396 Interestingly, comparison of the sequences of the first (long) and second (short) KP-type
397 peptides in echinoderms reveals that the long and short peptides share less sequence
398 similarity with each other within a species than they do with respective peptides in other
399 species (**Figure 7C**). This indicates that the duplication event that gave rise to the occurrence

400 of the long and short peptides occurred before the divergence of the Asterozoa and
401 Echinozoa. Interestingly, previous studies have revealed that there has been an expansion of
402 KP-type receptors in ambulacraria (*S. purpuratus* and *S. kowalevskii*) and in the
403 cephalochordate, *Branchiostoma floridae*, with 16 KP receptors present in the latter [6, 56].
404 Further studies are now needed to identify the proteins that act as receptors for the KP-type
405 peptides identified here in ophiuroids and previously in other echinoderms [8].

406

407 Calcitonin

408 Calcitonin was first discovered in 1962 by Copp and Cheney [109]. The sequencing of
409 the porcine calcitonin in 1968 revealed that this polypeptide is composed of 32 amino acids
410 [110]. In vertebrates, calcitonin is produced by the thyroid gland [111] and regulates calcium
411 (Ca^{2+}) levels in the blood, antagonizing the effects of parathyroid hormone [112, 113]. The
412 evolutionary antiquity of calcitonin-related peptides was first revealed with the discovery that
413 a diuretic hormone in insects (DH_{31}) is a calcitonin-like peptide [114]. However, DH_{31} shares
414 modest sequence similarity with vertebrate calcitonins and lacks the N-terminal disulphide
415 bridge that is characteristic of calcitonin-type peptides in vertebrates. More recently, it has
416 been discovered that both DH_{31} -type and vertebrate calcitonin-type neuropeptides occur in
417 some protostomian invertebrates, including the annelid *Platynereis dumerilii* and the insect
418 *Locusta migratoria* [4, 115]. Hence, it is proposed that an ancestral-type calcitonin precursor
419 gene duplicated in the common ancestor of protostomes to give rise to DH_{31} -type and
420 calcitonin-type peptides, but with subsequent loss of calcitonin-type peptides in some
421 protostomes. Consistent with this hypothesis, calcitonin-type precursors but not DH_{31} -type
422 precursors have been identified in deuterostomian invertebrates, including echinoderms [8,
423 15, 16, 116].

424 An interesting feature of calcitonin/ DH_{31} precursors is the occurrence of multiple
425 splice variants. In vertebrates, alternative splicing of the calcitonin gene results in two
426 transcripts: one transcript encodes calcitonin and the other transcript encodes calcitonin gene-

427 related peptide [117]. Furthermore, a complex interplay of receptors and accessory proteins
428 determines the pharmacological profile of these peptides [118, 119]. Alternative splicing of
429 DH₃₁ and calcitonin precursors in insects has also been previously reported [115, 120, 121].
430 Interestingly, alternative splicing of insect calcitonin genes also generates variants that give
431 rise to different mature peptides [115]. However, unlike the calcitonin gene, DH₃₁ splice
432 variants all produce an identical mature peptide [120, 121].

433 Our analysis of the ophiuroid transcriptomes also identified two transcript variants for
434 calcitonin (**Figure 7E and F**). Based on our analysis of transcript sequences, ophiuroid
435 calcitonin genes comprise at least three putative coding regions or ‘exons’. It is unclear if
436 these three coding regions represent three or more exons due to the lack of genomic data, but
437 for the sake of simplicity, we refer to them here as ‘exons’. Transcript variant 1 comprises
438 ‘exons’ 1 and 3 but lacks ‘exon’ 2 whereas transcript variant 2 contains all 3 ‘exons’.
439 Interestingly, ‘exons’ 2 and 3 both encode a calcitonin-type peptide. Hence, transcript variant
440 1 encodes a precursor that produces one calcitonin-type peptide and transcript variant 2
441 encodes two non-identical calcitonin-type peptides. These alternatively spliced transcripts
442 were found in several brittle star species (**Figure 8**) and thus this may represent an ancient
443 and conserved feature, although transcript variant 1 was not found in *O. victoriae*.

444 Previous studies have identified precursors comprising a single calcitonin-type
445 peptide in the starfish *A. rubens* and the sea urchin *S. purpuratus* [8, 16], and a precursor
446 comprising two calcitonin-type peptides in the sea cucumber *A. japonicus* [15]. Informed by
447 the identification here of two transcript types in ophiuroids (transcript variant 1 and 2), we
448 have now discovered that two transcript types also occur in *A. japonicus* transcriptome.
449 Hence, alternative splicing of calcitonin-type precursor genes can be traced back in the
450 echinoderm lineage to the common ancestor of the Asterozoa and Echinozoa, but with
451 subsequent loss of this characteristic in some lineages.

452

453 GPA2 and GPB5

454 The vertebrate glycoprotein hormone family comprises luteinizing hormone (LH)
455 follicle-stimulating hormone (FSH), chorionic gonadotropin (CG), thyroid-stimulating
456 hormone (TSH) and the recently discovered thyrostimulin (TS) [122, 123]. Thyrostimulin is a
457 heterodimer composed of two subunits, glycoprotein alpha 2 (GPA2) and glycoprotein beta 5
458 (GPB5). Orthologs of GPA2 and GPB5 have been identified and characterized in the insect
459 *Drosophila melanogaster* [124] and in other invertebrates, including echinoderms [125].
460 Insect GPA2 and GPB5 both contain 10 conserved cysteine residues that are important in
461 forming a heterodimeric cysteine-knot structure. Surprisingly, *A. japonicus* GPA2 contains
462 only 7 cysteine residues (having lost residues 7, 8 and 9) while *O. victoriae* GPB5.1, *A.*
463 *rubens* GPB5.1 and *S. purpuratus* GPB5 all contain 8 cysteine residues (having lost the final
464 two cysteine residues) (**Figure S5**). It is difficult to predict the structural differences that may
465 arise in the heterodimer due to this variability in the number of cysteine residues. The
466 possibility of GPA2 and/or GPB5 monomers or homodimers exerting their own biological
467 functions has not been ruled out [126]. Additional investigations are needed to investigate if
468 GPA2 and GPB5 are co-localized in echinoderms and if the monomers and dimers (both
469 homo and hetero) exert different effects.

470

471 *Uncharacterized neuropeptides*

472 In addition to the neuropeptides discussed above, we have also identified three
473 neuropeptide precursors that could not be classified into any known neuropeptide families.
474 These include *O. victoriae* neuropeptide precursor (Ovnp) 18 (*O. victoriae* ortholog of
475 Spnp18 in *S. purpuratus*) [16], Ovnp26 and Ovnp27, with the latter two identified for the first
476 time in echinoderms. The choice of nomenclature for Ovnp26 and Ovnp27 is based on a
477 previously used numerical nomenclature in *S. purpuratus* and/or *A. rubens*, which goes up to
478 Arnp25 in *A. rubens*.

479

480 Ovnp18

481 Ovnp18 comprises four copies of a predicted mature peptide with the sequence
482 LFWVD and the C-terminal region of the precursor (partial sequence) contains at least four
483 cysteine residues (**Figure 5F**, GenBank; MF155258). Interestingly, this precursor type only
484 comprises a single mature peptide in *A. rubens*, *S. purpuratus* and *A. japonicus* and the C-
485 terminal region contains 9, 8 and 8 cysteine residues, respectively (data not shown) [[8](#), [15](#),
486 [16](#)].

487

488 Ovnp26

489 Ovnp26 was identified following an analysis of *O. victoriae* transcriptome sequence
490 using NpSearch [[8](#)]. Orthologs of Ovnp26 (GenBank; MF155259) were identified in other
491 brittle stars but not in other echinoderms (**Figure S2-S4**). Ovnp26 comprises seven copies of
492 peptides with a conserved C-terminal GW motif, whereas orthologs in *O. aranea* and *A.*
493 *filiformis* are predicted to generate eight copies of the mature peptide. Some of the mature
494 peptides have a C-terminal SGW motif, which is similar to the C-terminus of predicted
495 mature peptides derived from *O. victoriae* pedal peptide precursor 3 (**Figure S7**). However,
496 the lack of sequence similarity in other parts of the peptide suggests that the C-terminal
497 similarity may reflect convergence rather than homology.

498

499 Ovnp27

500 Ovnp27 (GenBank; MF155251) was identified following a HMM-based search for
501 SIFamide-type peptides [[127](#), [128](#)], albeit with a high E-value. This neuropeptide precursor
502 comprises two putative amidated mature peptides that are located immediately after the signal
503 peptide (**Figure S2-S4**), as seen in SIFamide precursors [[129](#)]. The first peptide of the *O.*
504 *victoriae* precursor has a C-terminal IFamide motif just like in insect SIFamides (**Figure S9**).
505 However, there is no sequence similarity with SIFamides in the rest of the peptide. This
506 coupled with the fact that SIFamide-type receptors have not been identified in echinoderms

507 [6] suggests that the sequence similarity that peptides derived from Ovnp27-type precursors
508 share with SIFamides may reflect convergence rather than homology.

509

510 *Neuropeptide precursors not found in brittle stars*

511 Our analysis of ophiuroid transcriptome sequence data did not reveal orthologs of the
512 Spnp9 precursor from *S. purpuratus* or the Arnp21, Arnp22, Arnp23 and Arnp24 precursors
513 from *A. rubens* [8, 16]. An Spnp9 ortholog is found in *A. japonicus* but not in *A. rubens* [15]
514 and therefore this neuropeptide precursor type may be restricted to the Echinozoa. Orthologs
515 of Arnp21-24 have not been found in *O. victoriae*, *S. purpuratus* or *A. japonicus*, which
516 suggests that these may be Asteroidea-specific precursors.

517 Previous studies have shown that receptors for leucokinin, ecdysis-triggering
518 hormone, QRFP, parathyroid hormone, galanin/allatostatins-A and Neuromedin-U/CAPA are
519 present in ambulacraria [6, 7, 15]. The presence of these receptors suggests that their cognate
520 ligands should also be present in ambulacraria. However, our search approaches failed to
521 identify any proteins in ophiuroids that resemble precursors of these neuropeptides.

522

523 *Evolutionary conservation and variation of neuropeptide copy number in the Ophiuroidea*

524 Many neuropeptide precursors comprise several structurally similar but non-identical
525 bioactive peptides – i.e. the precursor protein gives rise to a neuropeptide “cocktail”. This
526 feature of neuropeptide precursors occurs throughout metazoans. But how do these
527 “cocktails” of neuropeptides evolve and what is their functional significance? Are the copies
528 of mature peptides functionally redundant or do they have their own specific functions?
529 These are important questions in neuroendocrinology for which answers remain elusive.

530 Evidence that neuropeptide copy number may be functionally important has been
531 obtained from comparison of the sequences of neuropeptide precursors in twelve *Drosophila*
532 species, the common ancestor of which dates back ~50 million years [130]. The number of
533 peptide copies in each neuropeptide precursor was found to be identical (except for the

534 FMRFamide precursor) when compared between the twelve species, suggesting that
535 stabilising selection has acted to conserve neuropeptide “cocktails” in the *Drosophila* lineage.

536 Here, a comparison of *O. victoriae*, *A. filiformis* and *O. aranea* neuropeptide
537 precursors and their putative mature peptides revealed that fourteen neuropeptide precursors
538 comprised multiple neuropeptide copies. In certain cases, the number of the mature peptides
539 derived from a particular precursor varied across species, whereas in other cases the numbers
540 remained constant (**Figure 4**). Interestingly, these three species belong to two of the three
541 major clades of brittle stars that evolved ~270 million years ago [12]. While *O. victoriae*
542 belongs to the Chilophiurina infraorder (clade A), *A. filiformis* and *O. aranea* belong to the
543 Gnathophiurina infraorder (clade C). Hence, this prompted us to examine the evolution of
544 neuropeptides and neuropeptide copy number variation at a higher level of phylogenetic
545 resolution. To do this, we utilized a unique dataset comprising 52 ophiuroid transcriptomes.
546 These transcriptomes were recently used as part of a phylotranscriptomic approach to
547 reconstruct the phylogeny of ophiuroids, generating a robust phylogenetic tree that comprises
548 three major clades [12]. Hence, this dataset allowed us to explore the evolution of
549 neuropeptide precursors in the context of an established phylogenetic framework spanning
550 over an unprecedented timescale of ~270 million years.

551 We selected for analysis neuropeptide precursors comprising more than a one putative
552 mature neuropeptide, which include AN peptide, calcitonin, cholecystokinin 1, kisspeptin,
553 np18, np26, np27, NG peptide, PDF, SALMFamide (L-type and F-type), tachykinin and TRH
554 (1 and 2). Pedal peptide precursors (1, 2 and 3) were excluded from the analysis because
555 orthology relationships between these precursors could not be established with confidence
556 across all species (data not shown). We used *O. victoriae* representatives of these
557 neuropeptide precursor families and the *A. filiformis* AN peptide precursor to mine 52
558 ophiuroid transcriptomes using BLAST. Multiple sequence alignments were generated based
559 on the search hits (**Figure S11**) and the number of predicted mature peptides were compared
560 (**Figure 8**). Interestingly, the number of peptides within the majority of precursors remained

561 constant across all the species examined, which share a common ancestor estimated to date
562 from ~270 million years ago [12].

563 Some studies that have investigated the physiological significance of neuropeptide
564 “cocktails” indicate that neuropeptides derived from the same precursor protein are
565 functionally redundant. For example, this was found for myomodulin neuropeptides in the
566 mollusk *Aplysia californica* using the accessory radula closer muscle preparation as a
567 bioassay [131] and for FMRFamide-related neuropeptides in *Drosophila melanogaster* when
568 analysing effects on nerve-stimulated contraction of larval body-wall muscles [132].
569 However, the authors of the latter study cautiously highlighted the need to “search for
570 additional functions or processes in which these peptides may act differentially”. Importantly,
571 studies employing use of multiple bioassays have obtained data indicating that neuropeptides
572 derived from a single precursor protein are not functionally redundant. For example, when
573 the actions of fourteen structurally related neuropeptides derived from a precursor of *Mytilus*
574 Inhibitory Peptide-related peptides in *Aplysia* were tested on three organ preparations
575 (oesophagus, penis retractor, body wall) it was found that the rank order of potency for the
576 peptides differed between preparations [133]. Similarly, when assaying the effects of
577 allatostatin neuropeptides in cockroaches, tissue-specific differences in potency were
578 observed [134]. The conservation of peptide copy number across a timescale of ~270 million
579 years in the Ophiuroidea supports the idea that the occurrence of multiple copies of identical
580 or structurally related neuropeptides is functionally important.

581 For those neuropeptide precursors that did exhibit variation in neuropeptide copy
582 number, TRH-type precursors exhibited the highest variation, with numbers ranging from 16
583 to 20 copies (**Figure 9**). F-type SALMFamide precursors also showed variation in copy
584 numbers (**Figure 10**) but loss of peptides was more frequent in F-type SALMFamide
585 precursors than in TRH-type precursors. Furthermore, detailed analysis of sequence
586 alignments for these precursors revealed that loss of neuropeptide copies is usually a
587 consequence of non-synonymous mutations in codons for residues that form dibasic cleavage

588 sites or for glycine residues that are substrates for the C-terminal amidation. This is not
589 surprising since the C-terminal amide in smaller-sized peptides is usually important for
590 receptor binding and activation. What is unclear at the moment is how the peptide copy
591 number increases within a given precursor. Perhaps the increase in peptide copy number
592 occurs as a result of unequal crossing-over during recombination [130].

593 The number of peptides within the F-type SALMFamide precursors appear to be clade
594 specific. Thus, the average/median number of F-type SALMFamides in precursors from clade
595 A is 13, clade B is 12 and clade C is 11, with a few exceptions (**Figure 8**). Similarly, the
596 number of peptides within NP26-type precursors also appears to be clade specific. Hence the
597 number of peptides is highly stable at 7 peptides within clades A and B but a high variation in
598 peptide copy number is observed in clade C. When examining peptide copy number within
599 clades, there are a few cases where the number of peptides within a given precursor for
600 certain species appears to be an exception/outlier. For instance, 16 copies of the mature
601 peptide in *Ophioplax lamellosa* TRH-1 precursor is distinctly different to the 19 copies found
602 in other species within that clade (clade C). Likewise, *Ophiactis savignyi* only has 3 copies of
603 kisspeptin-type peptides compared to 4 copies found in other species of that clade (**Figure 8**).

604 It could be argued that misalignments during transcriptome assembly may have
605 influenced the number of predicted peptides found in a given precursor. However, it is
606 unlikely that misalignments have affected the predicted sequences of neuropeptide precursors
607 comprising multiple copies of peptides that are similar but non-identical, which applies to the
608 majority of the precursor proteins analysed here in ophiuroids. The only exception to this are
609 the TRH-type precursors, where the encoded peptide sequences are short and often identical,
610 even at the nucleotide level (data not shown), Another limitation of using transcriptome data
611 is that the sequences of neuropeptide precursors may be partial or unknown for some species
612 and where this applies a peptide copy number is not shown in Fig. 8. An extreme example of
613 this is the AN peptide precursor, where complete precursors sequences were only obtained
614 from the three reference species and three other species. However, for the majority of

615 precursor types, sequence data was obtained from a variety of species from each of the three
616 clades of ophiuroids. For example, complete F-type SALMFamide precursor sequences were
617 found in most of the investigated species (39 species + 3 reference species).

618

619 **Conclusion**

620 Here we report the first detailed analysis of the neuropeptide precursor complement of
621 ophiuroids and the most comprehensive identification of echinoderm neuropeptide precursors
622 to date. We have identified novel representatives of several bilaterian neuropeptide families
623 in echinoderms for the first time, which include orthologs of endothelin/CCHamide, eclosion
624 hormone, neuropeptide-F/Y and nucleobinin/nesfatin. Furthermore, analysis of precursor
625 proteins comprising multiple copies of identical or related neuropeptides across ~270 million
626 years of ophiuroid evolution indicates that the precise composition of neuropeptide
627 “cocktails” is functionally important as evident from the conservation of neuropeptide copy
628 number for multiple precursors.

629

630 **Methods**

631 ***Sequencing and assembly of transcriptomes***

632 Ophiuroid transcriptomes used in this study were sequenced and assembled as
633 reported previously [[12](#), [20](#), [24](#)].

634

635 ***Identification of neuropeptide precursors in ophiuroids***

636 In order to identify neuropeptide precursors in *O. victoriae*, *A. filiformis* and *O.*
637 *aranea*, sequences of neuropeptide precursors identified previously in other echinoderms
638 (including the starfish, *A. rubens*, the sea urchin *S. purpuratus* and the sea cucumber, *A.*
639 *japonicus*) were used as queries for tBLASTn analysis of a transcriptome database, using an e
640 value of 1000. Sequences identified as potential neuropeptide precursors by BLAST were
641 translated using the ExpASY Translate tool (<http://web.expasy.org/translate/>) and then

642 analysed for features of neuropeptide precursors. Specifically, sequences were evaluated
643 based on 1) the presence of an N-terminal signal peptide (using Signal P v 4.1 with the
644 sensitive cut-off of 0.34) and 2) the presence of monobasic or dibasic cleavage sites flanking
645 the putative bioactive peptide(s).

646 To identify novel neuropeptide precursors or highly-divergent precursors with low
647 sequence similarity to known precursors, we utilized two additional approaches. In the first
648 approach, we used NpSearch [8], software that identifies putative neuropeptide precursors
649 based on various characteristics (presence of signal peptide and dibasic cleavage sites
650 amongst others). In the second approach, NpHMMer (<http://nphmmmer.sbcs.qmul.ac.uk/>), a
651 Hidden Markov Models (HMM) based software was used to identify neuropeptides not found
652 using the above approaches.

653 Neuropeptide precursors identified in *O. victoriae* (which represented a more
654 comprehensive neuropeptide precursor repertoire compared to *A. filiformis* and *O. aranea*)
655 were then submitted as queries for BLAST analysis of sequence data from 52 Ophiuroidea
656 species, using an E-value of 1e-06. BLAST hits were then further analysed using an
657 automated ruby script (available at https://github.com/IsmailM/ophiuroid_neuropeptidome).
658 Each BLAST hit was translated using BioRuby and the open reading frame (ORF) containing
659 the BLAST high-scoring segment pair was extracted. These ORFs were then examined for
660 the presence of a signal peptide using Signal P 4.1 using a sensitive cut-off of 0.34. All
661 sequences were then aligned using MAFFT, with the number of maximum iterations set to
662 1000 to ensure an optimal alignment. These alignments were then further optimized by
663 manually adjusting the location of the bioactive peptide and cleavage sites. Finally, the
664 alignments were annotated using different colours for the signal peptide (blue), the bioactive
665 peptide(s) (red) and cleavage sites (green).

666

667 ***Phylogenetic and clustering analyses of sequence data***

668 Phylogenetic analysis of membrane guanylyl cyclase receptors and nucleobindins was
669 performed using maximum likelihood and Bayesian methods. Prior to these analyses,
670 corresponding multiple alignments were trimmed using BMGE [135] with the following
671 options: BLOSUM30, max $-h = 1$, $-b = 1$, as described previously [10, 94]. The maximum
672 likelihood method was implemented in the PhyML program (v3.1/3.0 aLRT). The WAG
673 substitution model was selected assuming an estimated proportion of invariant sites (of
674 0.112) and 4 gamma-distributed rate categories to account for rate heterogeneity across sites.
675 The gamma shape parameter was estimated directly from the data. Reliability for internal
676 branch was assessed using the bootstrapping method (500 bootstrap replicates). The Bayesian
677 inference method was implemented in the MrBayes program (v3.2.3). The number of
678 substitution types was fixed to 6. The poisson model was used for substitution, while rates
679 variation across sites was fixed to "invgamma". Four Markov Chain Monte Carlo (MCMC)
680 chains were run for 100000 generations, sampling every 100 generations, with the first 500
681 sampled trees discarded as "burn-in". Finally, a 50% majority rule consensus tree was
682 constructed.

683 CLANS analysis was performed on echinoderm EH-like, arthropod EH, arthropod
684 ITP and vertebrates ANP precursors based on all-against-all sequence similarity (BLAST
685 searches) using BLOSUM 45 matrix (<https://toolkit.tuebingen.mpg.de/clans/>) [41] and the
686 significant high-scoring segment pairs (HSPs). Neuropeptide precursors were clustered in a
687 three-dimensional graph represented here in two dimensions.

688

689 **Data accessibility**

690 Raw sequence data used to assemble the transcriptomes have been deposited in the NCBI
691 Sequence Read Archive (SRA) under the accession number SRP107914
692 (<https://www.ncbi.nlm.nih.gov/sra/?term=SRP107914>) and in the NCBI BioProject under the
693 accession number PRJNA311384 (<https://www.ncbi.nlm.nih.gov/bioproject/311384>).

694

695 **Competing interests**

696 The authors declare that no competing interests exist.

1113 **Figure captions**

1114 **Figure 1:** Bilaterian animal phylogeny. The diagram shows i). the phylogenetic position of
1115 the phylum Echinodermata in the ambulacrarian clade of the deuterostomes and ii)
1116 relationships between the five extant classes of echinoderms, which include the focal class for
1117 this study – the Ophiuroidea (e.g. *Ophionotus victoriae*).

1118

1119 **Figure 2:** Eclosion hormone (EH)-type peptides and receptors in echinoderms A) Partial
1120 multiple sequence alignment of eclosion hormone-type precursor sequences, excluding the N-
1121 terminal signal peptide; B) Cluster analysis of arthropod EH precursors, echinoderm EH-like
1122 precursors, arthropod ion transport peptides (ITPs) and vertebrate atrial natriuretic peptides
1123 shows that echinoderm EH-like precursors are more closely related to arthropod EH than ITP
1124 C) Maximum likelihood and Bayesian phylogenetic analyses of membrane guanylate cyclase
1125 receptors shows that EH-like receptors are found in echinoderms but are absent in vertebrates
1126 as seen for the EH-like precursors. OGC1, 2, 3 and 4 are orphan guanylate cyclase receptors
1127 found in arthropods [42]. Echinoderm EH-like receptors are clustered with arthropod EH
1128 receptors, neuropeptide-like peptide 1-VQQ receptors (NPLP1-VQQ) and OGC1 receptors.
1129 The inset shows the alternate topology obtained following Bayesian analysis. Species
1130 names: *Ophionotus victoriae* (Ovic), *Asterias rubens* (Arub), *Strongylocentrotus*
1131 *purpuratus* (Spur), *Drosophila melanogaster* (Dmel), *Bombyx mori* (Bmor) and *Pediculus*
1132 *humanus corporis* (Pcor).

1133

1134 **Figure 3:** Multiple sequence alignments of A) CCHamide-type and B) Neuropeptide-F/Y-
1135 type peptides. Species names: *Ophionotus victoriae* (Ovic), *Asterias rubens* (Arub),
1136 *Apostichopus japonicus* (Ajap), *Drosophila melanogaster* (Dmel), *Apis mellifera* (Amel),
1137 *Lottia gigantea* (Lgig), *Aplysia californica* (Acal), *Homo sapiens* (Hsap), *Ophiopsila aranea*
1138 (Oara), *Amphiura filiformis* (Afil), *Patiria miniata* (Pmin), *Saccoglossus kowalevskii* (Skow),
1139 *Branchiostoma floridae* (Bflo) and *Daphnia pulex* (Dpul).

1140

1141 **Figure 4:** Summary of neuropeptide precursors identified in *Ophionotus victoriae*, *Amphiura*
1142 *filiformis* and *Ophiopsila aranea*. Neuropeptide precursors are classified based on the type of
1143 G-protein coupled receptor (GPCR) their constituent peptides are predicted to activate (see
1144 Mirabeau and Joly, 2013). Some peptides bind to receptors other than GPCRs and these are
1145 grouped with peptides where the receptor is unknown. Ophiuroids have neuropeptide
1146 precursors from up to 32 families. The number of putative mature peptides derived from each
1147 precursor has been indicated along with the presence of amidation and pyroglutamation.

1148

1149 **Figure 5:** Multiple sequence alignments of mature peptides belonging to selected
1150 neuropeptide families. A) corazonin alignment; B) gonadotropin-releasing hormone (GnRH)
1151 alignment; C) orexin alignment; D) luqin alignment; E) vasopressin/oxytocin (VP/OT)
1152 alignment; F) Ovnp18 alignment; G) melanin-concentrating hormone (MCH) alignment; H)
1153 NP peptide alignment; I) pigment dispersing factor (PDF) alignment (see Figure S10 for a
1154 multiple sequence alignment of PDF-type precursors). Species names: *Ophionotus victoriae*
1155 (*Ovic*), *Asterias rubens* (*Arub*), *Strongylocentrotus purpuratus* (*Spur*), *Apostichopus*
1156 *japonicus* (*Ajap*), *Saccoglossus kowalevskii* (*Skow*), *Branchiostoma floridae* (*Bflo*),
1157 *Anopheles gambiae* (*Agam*), *Daphnia pulex* (*Dpul*), *Strigamia maritima* (*Smar*), *Lottia*
1158 *gigantea* (*Lgig*) and *Homo sapiens* (*Hsap*).

1159

1160 **Figure 6:** Alignments of neuropeptides derived from precursors that exist in multiple forms
1161 in ophiuroids. A) thyrotropin-releasing hormone (TRH) alignment; B) cholecystokinin
1162 alignment; C) somatostatin alignment; D) corticotropin-releasing hormone (CRH) alignment.
1163 Species names: *Ophionotus victoriae* (*Ovic*), *Asterias rubens* (*Arub*), *Strongylocentrotus*
1164 *purpuratus* (*Spur*), *Apostichopus japonicus* (*Ajap*), *Branchiostoma floridae* (*Bflo*), *Homo*
1165 *sapiens* (*Hsap*), *Drosophila melanogaster* (*Dmel*) and *Lottia gigantea* (*Lgig*).

1166

1167 **Figure 7:** Comparative analysis of ophiuroid tachykinin, kisspeptin and calcitonin-type
1168 precursors and neuropeptides. A) Alignment of tachykinin-type peptides in *O. victoriae*
1169 (Ophiuroidea) and *A. rubens* (Asteroidea); B) Schematic diagrams of the *O. victoriae* and *A.*
1170 *rubens* tachykinin precursors showing the location of the signal peptide (SP) and predicted
1171 neuropeptides (labelled 1 to 4); C) Alignments of the long and short forms of kisspeptin-type
1172 neuropeptides in *O. victoriae*, *A. rubens* and *S. purpuratus* (Echinoidea) D) Schematic
1173 diagrams of the *O. victoriae* and *A. rubens* kisspeptin precursors showing the locations of the
1174 SP, short and long orthocopies and cysteine (C) residues; E) Alignment of calcitonin-type
1175 peptides from *O. victoriae*, *A. rubens*, *S. purpuratus* and *A. japonicus* (Holothuroidea); F)
1176 Predicted alternative splicing of the calcitonin gene in ophiuroids, with the location of the SP
1177 and neuropeptides (CT1 and CT2) labelled. Species names: *Ophionotus victoriae* (Ovic),
1178 *Asterias rubens* (Arub), *Strongylocentrotus purpuratus* (Spur) and *Apostichopus japonicus*
1179 (Ajap).

1180

1181 **Figure 8:** Comparison of neuropeptide copy numbers across the Ophiuroidea for precursors
1182 comprising multiple copies of neuropeptides. Neuropeptide precursors were mined from 52
1183 ophiuroid transcriptomes, with the phylogeny adapted from O'Hara et al. (2014) [12].

1204

1205 **Figure 9:** A partial multiple sequence alignment of ophiuroid thyrotropin-releasing hormone
1206 (TRH) precursors showing clade-specific gain/loss of neuropeptide copies. Mono- and di-
1207 basic cleavage sites are highlighted in green, mature peptides in red with the glycine residue
1208 for amidation in pink. Species have been grouped and coloured (clade A in purple, clade B in
1209 blue and clade C in orange) based on the phylogeny determined by O'Hara et al. (2014) [12].

1210

1211 **Figure 10:** A partial multiple sequence alignment of ophiuroid F-type SALMFamide
1212 precursors showing clade-specific gain/loss of neuropeptide copies. Di-basic cleavage sites
1213 are highlighted in green, mature peptides in red with the glycine residue for amidation in
1214 pink. Species have been grouped and coloured (clade A in purple, clade B in blue and clade C
1215 in orange) based on the phylogeny determined by O'Hara et al. (2014) [12].

1216

1217 Supplementary files

1218 **Figure S1:** Alignment and phylogenetic analysis of nucleobindins (NUCB). A) Partial
1219 sequence alignment (excludes the signal peptide) of NUCB precursors. The locations of

1220 *Homo sapiens* nesfatin-1, 2 and 3 are indicated. A dibasic cleavage site in *O. victoriae*
1221 nesfatin-1 is marked in red. B) Phylogenetic analysis of NUCB precursors. Species names:
1222 *Ophionotus victoriae* (Ovic), *Amphiura filiformis* (Afil), *Ophiopsila aranea* (Oara),
1223 *Apostichopus japonicus* (Ajap), *Strongylocentrotus purpuratus* (Spur), *Homo sapiens* (Hsap),
1224 *Mus musculus* (Mmus) and *Drosophila melanogaster* (Dmel).

1225
