14

15 **ABSTRACT** *Russula griseocarnosa*, an ectomycorrhizal (ECM) fungus, is a
16 species of precious wild edible mushrooms with very high market value in southern
17 China. Its yield is affected by many factors including the tree species and
18 environmental conditions such as soil microbiome, humidity. How the microbiome
19 promotes the ECM fungus symbiosis with Fagaceae plants and
20 sporocarp-producing has never been studied. In this study, we collected rhizosphere
21 samples from Fujian province, the microbiota in the root and mycorrhizal
22 rhizosphere were identified by Illumina MiSeq high-throughput sequencing. First,
23 we compared three types of fungal communities: root tips infected with ECM
24 *Russula* (type 1), tips with *Russula* sporocarp (type 2) and tips without ECM (type
25 3). Our results showed that the fungal richness was negatively correlated with
26 *Russula*. *Russula*, *Tomentella* and *Lactarius* were common in Fagaceae ECM roots.
27 As to the mycorrhizal interactions, *Boletus* may be considered as an indicator
28 species for sporocarp-producing *Russula*, and *Acremonium*, *Cladophialophora* were
29 associated with *Russula* symbiosis. Second, we analyzed the fungal and bacterial

30 communities in rhizosphere soils from the corresponding to previously three types
31 (type 1, 2, 3). *Dacryobolus* and *Acidocella* may be considered as an indicator
32 species for sporocarp-producing *Russula*. Fungi *Tomentella*, *Saitozyma*,
33 *Elaphomyces* and bacteria *Acidicaldus*, *Bryobacter*, *Sorangium* and *Acidobacterium*
34 occurred more frequently in the ECM *Russula* rhizosphere. Furthermore, the
35 indicators *Elaphomyces*, *Tomentella*, *Sorangium* had a positive correlation with
36 *Russula* symbiosis by network analyses. Overall, our results suggest a relationship
37 between micro-community and ECM *Russula* formation and *Russula* sporocarp,
38 which may provide new strategies for improving *Russula* symbiosis rate and
39 sporocarp production.

40 **KEYWORDS** micro-Community, *Russula*, ectomycorrhizae, Fagaceae

41 **IMPORTANCE** *Russula* (Russulaceae, Russulales, Agaricomycetes,
42 Basidiomycota) species are ectomycorrhizal (ECM) fungi that form symbiotic
43 associations with host roots. Approximately 750 *Russula* species have been reported
44 in worldwide (1). *Russula* taxa showed high diversity, strong habitat preference and
45 some preference for soil horizons (2)(Jo'zsef Geml 2010). Li M(3)(2010)identified
46 that *Russula* emerge at least three divergent lineages based on the genetic diversity
47 and geographic differentiation in southern China , and *R. griseocarnosa* belongs to
48 one of the lineages. *R. griseocarnosa* is described from southern China, including
49 Guangdong, Yunnan, and Fujian Provinces (4). *R. griseocarnosa* sporocarp,
50 which is popularly commercially as food and medicine, is uncultivable and
51 collected from the natural habitat. To date, there is little knowledge about the
52 controlled production of *Russula* and its micro-community.

53 Several biotic factors affect ectomycorrhizal fungal communities: plant host species
54 (5, 6) , plantation age (7), asymptomatic ectomycorrhiza endophytes (8),
55 ectomycorrhizal propagules in the soil(9) and the traits of the dispersal propagules
56 of ECM fungi (10). The common ectomycorrhizal *Russula* sp. was associated with
57 seven host genera: *Pleioblastus chino*, *Quercus serrata*, *Symplocos prunifolia*, *Ilex*
58 *pedunculosa*, *Prunus jamasakura*, *Gamblea innovans*, and *Lyonia ovalifolia*(11, 12).
59 *R. griseocarnosa* grows in forests with Fagaceae in southern China (13). ECM

60 fungal communities strongly vary during long-term ecosystem development, even
61 within the same hosts (14). Some *Russula* spp. was reported to be dominant
62 colonizers of mature roots of pines (15)(Horton & Bruns, 2001) but did not
63 colonize bioassay seedlings (16). ‘Early stage’ and ‘late stage’ mycorrhizal fungi of
64 birch appeared distinction (7). Gebhardt also found that Ectomycorrhiza
65 communities of *Quercus rubra* of different age performed specificity with low
66 similarity between the chronosequence stands site (17) . Some fungal root
67 endophytes prefer ECM formed by particular species of ectomycorrhizal fungi (8,
68 18), potentially representing a second level of root endophyte selection. Dark
69 septate endophytes are considered to be ubiquitous, colonizing mycorrhizal(19).
70 ECM propagule communities in soil may diverge from those root-colonizing ECM
71 communities and affect persistence of symbiotic relationship between mycorrhiza
72 and available host roots by competitive networks(20). ECM propagules in soil are
73 less frequent and diverse in early primary succession and become more frequent
74 and diverse along forest development, due mainly to the accumulation of dormant
75 spores of *Rhizopogon* spp. and sclerotia of *Cenococcum* spp(20). Simultaneously
76 dispersal ability across ECM species correlated well with the composition of
77 communities associated with host (21). *Russula* naturally propagate by
78 short-distance spore dispersal rather than vegetative growth of dikaryophytic
79 mycelia or long-distance spore dispersal(22). In all, the *Russula* ECM community
80 may be affected by symbiotic structures and root endophytes in the roots,
81 mycorrhizal extraradical mycelia, spores in the soil , as well as its dispersal ability.

82

83 Mycorrhizal interactions are usually classified on the basis of the features of the
84 symbiotic interfaces(23). The ECM community colonizing root tips was strongly
85 structured by competitive interactions or ecological processes generating a similar
86 spatial pattern, rather than neutral processes. The ECM *Cortinari* sp. and
87 *Lactarius rufus* competed for root tips(24). Both *Cenococcum geophilum* and
88 *Clavulina cinerea* as mycorrhizas and as extramatrical mycelium (EMM) in a *Pinus*
89 *resinosa* plantation showed a negative correlation(25). Hortal suggests that

90 interspecific competition between *Lactarius deliciosus* (inoculated fungi) and
91 *Rhizopogon roseolus* (indigenous fungi) occurs in the root system for
92 ectomycorrhiza formation in available roots, rather than in the extramatrical
93 mycelium phase (26). However, associations among *Suillus bovinus* and
94 *Gomphidius roseus* occur within ectomycorrhizal roots (27). There are also a
95 number of notable examples of associations between sporocarps of different species,
96 such as between *Boletus parasiticus* and *S. citrinum*, *Asterophora parasitica* and
97 *Lactarius*, and between *Claudopus parasiticus* and *Cantharellus cibarius* (28),
98 However, mycorrhizal interaction studies of *Russula* are limited in the literature.

99

100 Similar to the rhizosphere, mycorrhizosphere is the feet of fruiting bodies or the
101 root of ectomycorrhizal fungi . Mycorrhizosphere may constitute a hot spot(29), in
102 which microorganisms were affected(30-32).The mycosphere effect was prominent ,
103 though previous studies have failed to demonstrate significant differences between
104 bacterial communities associated with roots colonized by *Suillus variegatus* and *T.*
105 *submollis*, *Lactarius* sp. and *Tomentella* sp.(33) or by *C. geophilum* and *Russula* sp.
106 (34). It has also been established that mycorrhizal networks have different
107 microbial communities compared with bulk soil by stimulating some families such
108 as *Bradyrhizobiaceae*, *Burkholderiaceae*, and *Pseudomonadaceae* (35). Bacterial
109 activity is stimulated by the provision of easily available nutrition such as
110 carbonaceous compounds (30).The mycosphere effect might exert strong influences
111 on the bacterial community of soil(36), in which bacterial activity is stimulated by
112 trehalose, which is degraded by hyphosphere and derived from fungi (37, 38).
113 Andersson(39)(2003)., who used phospholipid fatty acid profiles to characterize
114 bacterial communities, has demonstrated that basidiomycete wood-decomposing
115 fungi are able to influence bacterial community structure. Bacteria adapted to the
116 mycospheres of three or more or just one fungal species was defined as specific
117 selective bacterial(40). The specific members of the Sphingomonadaceae family
118 selected were at the bases of the fruiting bodies of the ectomycorrhizal fungi
119 *Laccaria proxima* and *Russula exalbicans* in comparison to the adjacent bulk soil,

120 major of which did not cluster with known bacteria from the database (36, 41). On
121 the other hand, some mycorrhiza-associated bacteria have been shown to produce
122 compounds that are antagonistic to plant pathogens (42). Meanwhile, “mycorrhiza
123 helper bacteria” (MHB) appeared to positively influence the development and
124 function of ectomycorrhiza (43), but the effects varied with different species
125 combinations (44, 45). *Ralstonia* sp. and *Bacillus subtilis* can promote *Suillus*
126 *granulatus*-infected *Pinus thunbergii* (34). *Bacillus subtilis* helped the growth of
127 *Cenococcum geophilum* Fr and promoted *Suillus granulatus* infection (34) but
128 inhibited *Rhizopogon* sp. infection (45). Apart from bacterial , ectomycorrhizal
129 symbionts strong also selected ascomycete communities and other ECMs(31)
130 (32).Högberg (2002)(46) demonstrated that the EMM is at least 30% of the
131 microbial biomass in boreal forest soils. ECM fungi competed with saprotrophic
132 fungi in soil by the EMM(47). *Tuber rufum* and some members of *Boletales* are
133 typically restricted to productive truffle plots. On the other hand, *Hebeloma*,
134 *Laccaria* and *Russula* species are mostly associated with unproductive truffle plots,
135 Ectomycorrhizae belonging to *Thelephoraceae* are frequently found in mature
136 truffle orchards but do not seem to affect sporocarp production (32). Ascomycetes
137 associated with ectomycorrhizas: molecular diversity and ecology with particular
138 reference to the Helotiales had been reported (48).However, the rhizosphere,
139 mycosphere effect of *Russula griseocarnosa* has not been recorded in the literature.

140

141 Regarding the relationship between the amount of soil EMM with ectomycorrhizae
142 and sporocarps, different mycorrhizas have different conclusions . Zampieri et
143 al.(2010)(49) showed that the mycelium of *Tuber magnatum* was more widespread
144 than was inferred from the distribution of its fruiting bodies and ectomycorrhizae.
145 Zhou et al. (2001) (50)demonstrated that the development of *Suillus grevillei*
146 sporocarps is correlated with amount of EMM and ectomycorrhizae of *S. grevillei*
147 in a narrow area. The *Tuber melanosporum* EMM biomass detected in the soil from
148 the natural truffle ground was significantly greater than that of other plant orchards
149 analyzed, and the lowest amount of *T. melanosporum* mycelium maintained a

150 sporocarp production in plant orchards (51). However, Some ECMs are consistent
151 in ectomycorrhizae but inconsistent in sporocarps. De la Varga et al. (52)(2012)
152 quantified *B. edulis* extraradical mycelium in a Scots pine forest and found a
153 positive correlation between the amount of mycelia and the presence of *Boletus*
154 *edulis* mycorrhizae, but not with the productivity of fruiting bodies. However, the
155 relationship between the amount of *Russula* with ectomycorrhizae and sporocarps is
156 scarce in the literature.

157 The relation between the productivity of fruiting bodies and ECM symbiosis is still
158 unclear. Some ectomycorrhizal species produce abundant ectomycorrhizal root tips
159 but few or no fruiting bodies, while other ectomycorrhizal fungi form abundant
160 fruiting bodies but a low number of ectomycorrhizal root tips. Guidot et al.
161 (53)(2001) found a spatial congruence of above- and belowground distribution for
162 *H. cylindrosporium* . However, De la Varga et al.(52) (2012) found that the presence
163 of mycorrhizae of the *B. edulis* symbiotic rate was not consistent with the
164 production of fruiting bodies. There are also *Russula* species difference between the
165 above-ground *Russula* sporocarp and underground *Russula* mycorrhizal(2) .
166 Geml(2010) (2)observed that 15 and 45 of the 50 *Russula* phylogroups species were
167 found in sporocarp and soil clone sequences, respectively. Given the long delay
168 between the establishment of the plantation and the formation of sporocarps, short-
169 and medium-term control of the survival and persistence of fungal symbionts in
170 plantations have to still be evaluated by the assessment of vegetative structures as
171 the ectomycorrhizas or extraradical mycelium.

172 Microbial community affected mycorrhizal fungal function (for example, symbiosis
173 establishment capacity, sporocarp production), and the reciprocal effects are vice
174 versa. The microorganisms associated with mycorrhizal fungi may either have
175 positive or negative impacts on fungal spore germination, growth, nutrient
176 acquisition and plant colonization (43, 54). *Tuber indicum* altered the
177 ectomycorrhizosphere and endoectomycosphere microbiome and metabolic profiles
178 of the host tree *Quercus aliena* (55). *Tuber borchii* shapes the
179 ectomycorrhizosphere microbial communities of *Corylus avellana*(56). Therefore,

180 we speculate that detecting the communities of *Russula* can tracked ECM
181 persistence throughout the entire biological cycle, which will help to control
182 ectomycorrhiza formation and sporocarp production. In this study, to understand the
183 communities of the targeted *Russula griseocarnosa* and to find the possible
184 indicator microbes of successful *Russula griseocarnosa* plantations, we identified
185 the *Russula* ectomycorrhizal fungal communities inhabiting different life cycle
186 stages based on MiSeq sequencing of ribosomal internal transcribed spacer (ITS)
187 sequences of root DNA and mycosphere communities based on MiSeq sequencing
188 of the 16S V3-V4 as well as ribosomal internal transcribed spacer (ITS) sequences
189 of mycosphere soil DNA.

190

191 This study is the first attempt to analyze ectomycorrhizal communities of *Russula*
192 using MiSeq sequencing metagenomics DNA of *Russula* root and the Mycorrhizal
193 rhizosphere soil in *Russula* at different stages. We think that *Russula* shapes the
194 ectomycorrhizosphere microbial communities of Fagaceae (*Quercus glauca* and
195 *Castanopsis hainanensis*).

196

197 **RESULTS**

198 **Comparing microbiomes among types of the ECM fungus *Russula*.** ECM
199 *Russula* was first identified by combining morph typing with Sanger sequencing
200 DNA sequences . We analyzed internal transcribed spacer (ITS) rDNA sequences of
201 ECM root tips and ECM rhizosphere soil samples using phylogenetic methods,
202 operational taxonomic unit (OTU) delimitations and ordinations to compare species
203 composition in various types of ECM *Russula*.

204 In the ECM metagenome, we found a positive correlation between the
205 concentration of *Russula* DNA and the presence of *Russula* mycorrhizae in the
206 mycorrhizal rhizosphere and ECM root (Tab 1). To analyze whether distinctive
207 communities are selected by *Russula* ectomycorrhizal fungi, the fungi of ECM root
208 microbiomes were compared and divided into three types. *Russula* that could be
209 detected by Sanger sequencing with a DNA concentration above 10% of total ECM

210 genomic DNA, as determined by MiSeq sequencing, were classified as type 1.
 211 *Russula* sporocarps that could be collected from the ground and the extended
 212 hyphae of which could be connected between roots of the host and sporocarp within
 213 50 cm, with *Russula* detected by Sanger sequencing, were classified as type 2.
 214 *Russula* that were not detected by Sanger sequencing or with a DNA concentration
 215 below 5% of the total ECM genomic DNA, as determined by MiSeq sequencing,
 216 were classified as type 3. Therefore, the samples of ECM tip and rhizosphere
 217 samplings were divided into three types: *Russula*-infected (type 1),
 218 sporocarp-producing *Russula* (type 2), and *Russula*-uninfected (type 3) (Tab 1).
 219 Relative *Russula* OUT abundance is significant difference in ECM *Russula*
 220 symbiosis root and in ECM *Russula* rhizosphere, respectively (Tab 1, Fig. 1A). Type
 221 2 is the most abundant, type 1 is the second, and type 3 is the least. Interestingly, in
 222 type 3, the amount of *Russula* in the soil is higher than in the root. This may
 223 indicate that in the natural growth area of *Russula*, there are a large number of
 224 *Russula* propagules in the soil.

225 **TABLE 1** Relative *Russula* OUT abundance in three types and Alpha diversity

230 3 repeats.

231 2. Analysis of variance by one-way analysis of variance In each column: different
232 words indicate differences, uppercase letters indicate extremely significant
233 differences (P <0.01); and lowercase letters indicate significant differences (P
234 <0.05)

235 **Fungal diversity analysis and analysis of indicator species associated with**
236 **ECM *Russula* roots.** In total, 1346 fungal operational taxonomic units (OTUs)
237 were distinguished in roots. Among the three types, the Chao1 diversity index and
238 Shannon diversity index decreased in sporocarp-producing *Russula* type (type 2)

239 and *Russula*-infected type (type 1) compared to the *Russula*-uninfected (type 3)
240 (Tab 1). The result shows that species richness shifted in the composition of the
241 ECM community associated with *Russula*. The fungal community composition and
242 the abundance of the main fungi (over 0.05% fungi in roots genome) were different
243 in the three *Russula* types roots (Fig. 1A, Tab 1). The result shows that *Russula* is
244 dominates in fruiting bodies (type 2) and infected samples (type 1) though *Russula*
245 in three type samples.

246 Based on the top 20 fungi of each sample, we first obtained the common species of
247 three types after intersecting each type with the Venny mapping tool: 14 species
248 were in type 2, 5 in type 2 and 3 in type 3 (Tab S1). Then, we intersected the
249 common types of three types with the Venny mapping tool. At the genus level, the
250 three types shared 3 common genera: *Russula*, *Tomentella* and *Lactarius* (Tab S2,
251 Fig. 1B). These results showed that these are common fungi in Fagaceae ECM roots.
252 Types 1 and 2 shared 2 common genera: *Acremonium* and *Cladophialophora* , in
253 addition to the abovementioned three common ECM (Tab S2, Fig. 1B). Second, We
254 take a collection of three types genera respectively, subsequently we intersected the
255 collection of three types by the Venny mapping tool (Fig. 1C): 24 species in type 2,
256 46 in type 1 and 41 in type 3, and 5 genera were exclusively in type 2 collection.
257 We take the intersection of the unique collection (9 genera) and union (5 genera) in
258 type 2, and found only one species *Boletus* (Fig. 1D , Tab. 2). Analyze fungi
259 composition differences of three types roots by PCoA based on the top 20 fungal
260 genera , we found that the control (type 3) belonged to quadrant IV, type 1 belonged
261 to quadrant I or II, and type 2 belonged to quadrant III (Fig. 1F). The results show
262 that the fungal community of sporocarp- producing *Russula* was completely
263 different from that of *Russula*-uninfected . The *Russula*-infected type was in the
264 transitional phase. We suggest the *Russula* infection contributed 31.3% and others
265 elements host contributed 20.5% of the differences, respectively. *Boletus* was the
266 only ECM with the emergence of *Russula* fruit bodies. In all, *Boletus* may be
267 considered an indicator species in the *Russula* sporocarp-producing fungal
268 community, and *Acremonium* and *Cladophialophora* may be considered indicator

269 species in *Russula* symbiosis fungal communities (Tab. 2). Analyze the different
270 effects of ECM species by PCoA based on the top 20 fungal genera, we found
271 *Tomentella*, *Xylogone*, and *Lactarius* belonged to I, II, while others belonged to
272 quadrant III, V (Fig. 1E). The *Russula* infection contributed 55% and others
273 elements contributed 24% of the differences, respectively. Combining these two
274 factors, it shows *Russula* and *Elaphomyces* can be divided into one categories,
275 while *Xylogone* can be divided into another category functionally. So we assume
276 that *Elaphomyces* are benefit for *Russula* symbiosis while
277 *Tomentella*, *Xylogone*, and *Lactarius* has the function of competing hosts.

Fig. 2 Diversity analysis of fungi of three types *Russula* mycorrhizal rhizosphere in natural *Russula* growth areas

A: The top 20 fungi genus composition and abundance in type2 *Russula* symbiosis mycorrhizal rhizosphere and the corresponding genus are in the other two types in at Fujian, China

In the sample name, the first letter S indicates mycorrhizal root soil ; first second F stands for fungi; the third letter different treatment :S indicates sporocarp, E indicates ECM ectomycorrhizal , K indicates control respectively; the fourth number indicates the different biological repetitions of different treatment .

B: The Venny mapping of the common genus of the top 20 fungi genus in three types *Russula* symbiosis Mycorrhizal rhizosphere

C: The Venny mapping of the collection genus of the top 20 fungi genus in three types *Russula* symbiosis Mycorrhizal rhizosphere

D: The Venny mapping of the common genus and the collection genus of the top 20 fungi genus in type2 *Russula* symbiosis Mycorrhizal rhizosphere

E : Analysis of ECM role difference of three types *Russula* symbiosis mycorrhizal rhizosphere on top 20 fungi genus of ECM *Russula* by PCoA

F : Analysis of composition difference of three types *Russula* symbiosis mycorrhizal rhizosphere on top 20 fungi genus of ECM *Russula* by PCoA

In E and F: the scales of the horizontal and vertical axes are relative distances and have no practical significance. The contribution rate is the degree of interpretation,

419 and the hypothetical factors can be evaluated and verified.

420 the abundance of the main fungi (over 0.05% fungi in soil genome)were different
421 in the three *Russula* types rhizosphere soil (Fig. 1A,Tab 1).Compared to the
422 root ,The result shows that *Russula* is also dominates in fruiting bodies (type 2) and
423 infected samples(type 1) though *Russula* in three type samples(Fig. 1A,Fig. 2A).
424 However,compared to the root ,the genera variety increased (Fig. 1A,Fig. 2A).

425 The community composition of the top 20 fungi in the three *Russula* rhizosphere
426 soil types was analyzed (Tab. S2). We first obtained the common species of three
427 types after intersecting each type using the Venny mapping tool: 12 species in type
428 2, 7 species in type 1 and 7 species in type 3 (Fig. 2B). Then, we intersected the
429 common types of the three types with the Venny mapping tool. At the genus level,
430 the three types shared 4 common genera: *Russula*, *Mortierella*, *Penicillium* and
431 *Trichoderma*; and *Russula* also had a large frequency in types 1 and 2 (Fig. 2B).
432 This showed that 4 genera are common fungi in Fagaceae-dominant rhizosphere
433 soil. Types 1 and 2 shared 3 common genera: *Elaphomyces*, *Tomentella* and
434 *Saitozyma* ,in addition to the abovementioned 4 common genera(Fig. 2B). Second,
435 we take a collection of three types genera respectively, subsequently intersected the
436 collection of three types by the Venny mapping tool (Fig. 2C): 26 species in type 2,
437 40 in type 1 and 36 in type 3; 4 genera were included exclusively in the type 2
438 collection. We take the intersection of the unique collection (4 genera) and union (4
439 genera) in type 2, and found *Dacryobolus* unique belonged to type 2 (Fig. 2D, Tab.
440 2). The top 20 fungal genera in the sporocarp-producing *Russula* root rhizosphere
441 with types 3 or types 1 were compared. The result shows that *Russula* EMM is
442 dominates in fruiting bodies (type 2) and infected samples (type 1) though *Russula*
443 in three type samples. *Elaphomyces* also dominated in types 1 and 2, but nearly did
444 not exist in the control, type 3 (Fig. 2D). In all, *Dacryobolus* may be considered an
445 indicator species of sporocarp-producing *Russula* in the *Russula* rhizosphere.
446 *Elaphomyces*, and *Tomentella* may be considered indicator species for *Russula*
447 symbiosis in the rhizosphere (Tab. 2). Analyze three types of fungi composition
448 differences of top 20 genera by PCoA in *Russula* rhizosphere soil based on the top

449 20 fungal genera, we found that type 2 belonged to quadrant II and type 1 belonged
450 to quadrants I, III and IV, while type 3 belonged to quadrants III and IV, down the
451 horizontal axis (Fig. 2E). The host and *Russula*-infection contributed 29.3% and
452 25.0%, respectively. Furthermore, analyzing the different effects of fungi species by
453 PCoA, we found *Russula* and *Elaphomyces* belonged to quadrant IV, *Mortierella*
454 and *Tomentella* belonged to quadrant I, *Trichoderma*, *Penicillium*, *Geminibasidium*
455 and *Saitozyma* belonged to quadrant II, while others belonged to quadrant III (Fig.
456 2E). The *Russula* infection contributed 49.4% and others elements host contributed
457 19.4% of the differences, respectively. Combining these two factors, we assume
458 that *Elaphomyces* in soil are benefit for *Russula* symbiosis.

459

460 **Bacterial diversity analysis and analysis of indicator species associated with**
461 **ECM *Russula* rhizosphere soil.** In total, 1494 bacterial operational taxonomic
462 units (OTUs) were distinguished in this study. Compared to type 3, the Chao1
463 diversity index decreased in types 1 and 2 (Tab. 1). There were significant
464 differences between type 3 and the other two types. However, there were no
465 significant differences between types 1 and 2. The Shannon diversity index showed
466 the same tendency as the Chao1 diversity index (Tab. 1). The bacterial community
467 composition and the abundance of the main bacterial (the over 0.05% bacteria in
468 soil genome) were analyzed (Fig. 3A). About 40-60% of the species in the sample
469 cannot be identified by Illumina MiSeq high-throughput sequencing and the
470 remaining bacterial genera in the sporocarp-producing *Russula* root rhizosphere soil
471 were showed for the three types (Fig. 3A). Compared to the fungi of the root and
472 rhizosphere soil, the bacterial genera variety still increased (Fig. 1A, 2A, 3A).

473 The community composition of the top 20 f bacteria in the three *Russula*
474 rhizosphere soil types was analyzed (Tab. S3). We first obtained the common
475 species of the three types after intersecting each type with the Venny mapping tool:
476 18 species in type 2, 14 in type 1 and 12 in type 3 (Fig. 3B). Then, we intersected
477 the common types of the three types with the Venny mapping tool. At the genus
478 level, the three types shared 10 common genera: *Acidibacter*, *Candidatus*,

479 *Rhizomicrobium*, *Acidothermus*, *Variibacter*, *Burkholderia*, *Roseiarcus*,
480 *Bradyrhizobium*, *Candidatus* and *Granulicella*. (Fig. 3B). This showed that 10
481 genera are common bacteria in Fagaceae-dominant rhizosphere soil. Types 1 and 2
482 shared 4 common genera: *Bryobacter*, *Sorangium*, *Acidicaldus*, and
483 *Acidobacterium* ,in addition to the abovementioned 10 common genera(Fig. 3B).
484 Second, we obtained the collection of the various types: 20 species in type 2, 27 in
485 type 1 and 26 in type 3 (Fig. 3C,Tab S3). Then, the unique genera were analyzed of
486 the unique collection (4 genera) and union (3 genera) in type 2 by the Venny
487 mapping tool, and 2 genera *Acidocella* and *Edaphobacter* were found (Fig. 3D). In
488 all, *Acidocella* ,*Edaphobacter* may be considered indicator species for
489 sporocarp-producing *Russula*, and *Bryobacter*, *Sorangium*, *Acidicaldus*, and
490 *Acidobacterium* can be considered indicator species for *Russula* symbiosis in the
491 bacterial community (Tab. 2). By PCoA based on the top 20 fungal genera, we
492 found that type 2 belonged to quadrant III , left of the vertical axis. Except for one
493 sample, other samples of type 1 belonged to quadrants II or III, left of the vertical
494 axis . Type 3 belonged to the right of the vertical axis (Fig. 3F). We assume that the
495 *Russula* infection and host contributed 47.3% and 21.4%, respectively(Fig. 3F).
496 Analyze the different effects of bacteria species by PCoA , we found *Acidocella*,
497 *Sorangium*, *Haliangium* , *Telmatospirillum* , *Edaphobacter* , *Acidobacterium* ,
498 *Sphingomonas*, *Candidatus_Koribacter* , *Roseiarcus* , *Granulicella* and *Acidicaldus*
499 belonged to quadrant II, III , while the others belonged to quadrant I, IV (Fig. 3E).
500 It shows 11 gengus in quadrant II, III can be divided into one categories by role. All
501 indicator species for sporocarp-producing *Russula* or *Russula* symbiosis in the same
502 categories but *Bryobacter*. We assume that the *Russula* infection contributed
503 80.9% and others elements contributed 10.5% respectively. Combined with
504 indicator species analysis, we assume that 11 bacterial gengus beneficial to the
505 symbiosis of *Russula*.

589 Type2:Russula sporocarp producing; type1 :Russula –infected;
 590 type3 :Russula-no-infected; If one species is with one type and without the other
 591 type, then the species is assumed as the indicator of the type based on the top 20
 592 genus.

593

594 **Interaction of fungi and bacteria with ECM *Russula* root and mycorrhizal**
 595 **rhizosphere**

596 By network net, we analyzed the interaction of the top 20 fungal OTUs of *Russula*
 597 rhizosphere soil and ECM *Russula* root, including 7 *Russula* OTUs(MSFH OTU_1,

598 MSFH OTU_3, MSFH OTU_4, MSFH OTU_16, MSFH OTU_21, MSFH OTU_24
599 and SMFH OTU_1639) (Table S7), five indicator species(MSFH OTU_19
600 *Elaphomyces*, MSFH OTU_9 *Tomentella*_sp, MSFH OTU_655 *Tomentella*_sp,
601 MSFH OTU_6 *Elaphomyces*, and MSFH OTU_5 *Tomentella*_sp).
602 *Russula*, which interacted with other species in positive ways, was the
603 representative and contributed to the main ECM in the community. For example,
604 the interaction result predicted that many fungi had a positive correlation with
605 *Russula* (Fig.4A, Table S4), MSFH OTU_19 (*Elaphomyces*) and MSFH OTU_5
606 (*Tomentella*_sp) with the *Russula rosea*; MSFH OTU_21, MSFH OTU_655
607 (*Tomentella*_sp) and MSFH OTU_5 with *Russula* sp. In all, *Elaphomyces*_sp,
608 *Tomentella*_sp have a positive correlation with *Russula*, combining the previous
609 results that *Elaphomyces* and *Tomentella* were considered indicator species for
610 *Russula* symbiosis in the *Russula* rhizosphere based on the top 20 genera (Tab. 2).
611 Therefore, we further assume that the indicators *Elaphomyces* and *Tomentella* have
612 a positive correlation with *Russula* symbiosis.that

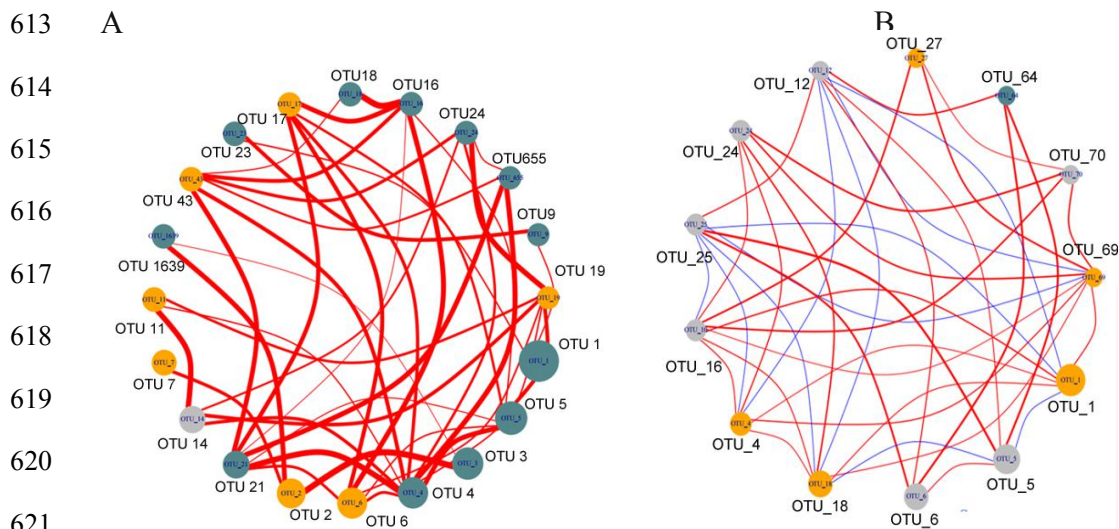

Fig. 4 Interaction of indicator species with the top 20 fungi and bacterial OTUs in

628 community of *Russula* mycorrhizal

629 A: Interaction of fungi in *Russula* ECM root and *Russula* mycorrhizal rhizosphere

630 B: Interaction of bacterial in *Russula* mycorrhizal rhizosphere

631 In A and B: The size of the dots represents the abundance, the color of the dots
632 represents the phylum (In A : Orange represents p__Ascomycota, blue represents
633 p__Basidiomycota, gray represents p__Mortierellomycota; in B: gray represents
634 p__Proteobacteria, Orange represents p__Acidobacteria, blue represents
635 p__Actinobacteria), the thickness of the lines represents the magnitude of the
636 correlation, and the red line indicates a positive correlation, the blue color indicates
637 a negative correlation.

638 Meanwhile, we analyzed the relationship of the top 20 bacterial OTUs in *Russula*
639 rhizosphere soil by Network net. Only 15 bacterial OTUs were included in the
640 network net (Fig. 4B, Table S5). Among the top 15 bacterial OTUs, there is 1 OTUs
641 SBH OTU_70 *Sorangium* belonging to indicator species. The network net
642 suggested that SBH OTU_70 was positive with SBH OTU_16 (Acidobacteriaceae),
643 24(Caulobacteraceae), 27(Solibacteraceae), 69(Solibacteraceae). Another indicator
644 species *Acidobacterium* was't within network net . Therefore, we further assumed
645 that *Sorangium* and other OTUs (Acidobacteriaceae, Caulobacteraceae,
646 Solibacteraceae) have a positive correlation with *Russula* .

647 **DISCUSSION**

648 The complete exclusion of other species by any single species could be prevented
649 by either fluctuation in the environment, by seasonal root production or by the
650 presence of microbiome competitive networks, the situation in which no single
651 species is competitively superior to all other species. So, we usually obtain 1 ECM
652 species or 2 ECM species by Sanger sequencing of the root sample with
653 basidiomycete-specific primers. The introduction of high-throughput sequencing
654 techniques, metagenomics or environmental genomics has provided new
655 information on ECM fungal communities by 'barcodes' of ITS regions in several
656 biomes/ecosystems, e.g., truffle grounds (57) and ECM roots in the Svalbard(58).
657 In this study, we found that *Russula* cannot successfully infect roots if the amount

658 of *Russula* in the mycorrhizal rhizosphere is less than 10% by MiSeq sequencing
659 (Table 1, part data not shown). Although ECM fungi infection have been detected in
660 nonproductive plots, the amount was not sufficient to shift from vegetative growth
661 to fruit body. *Russula* can form a fruiting body, only when *Russula* infection could
662 be detected by Sanger sequencing of ECM roots, contemporary the relative
663 abundance of its DNA was greater than 60% by MiSeq sequencing. Compared to
664 control, we found significantly more *Russula* DNA in *Russula* sporocarps
665 rhizosphere soil or *Russula* symbiosis rhizosphere soil, above 15% amount of the
666 metagenomics of rhizosphere soil. Zampieri et al.(2012) (49) detected significantly
667 more *T. melanosporum* DNA in truffle productive plots of soil. Zhou et al. (2001)
668 (50) also demonstrated that the development of *S.grevillei* sporocarps is correlated
669 with that of extraradical mycelia, which are distributed in a narrow area. So , we
670 suggest that to the type 2(sporocarps-producing) ,there is congruence of the above-
671 sporocarps and belowground root or mycorrhizospheres soil DNA for *Russula*.
672 However, interestingly, in type 3(uninfected), the amount of *Russula* in the soil is
673 higher than in the root. This may indicate that in the natural growth area of *Russula*,
674 there are a large number of *Russula* propagules in the soil. Whether the *Russula*
675 propagules naturally in the soil of the natural growth area can colonize to the host
676 or not depends on other factors.

677 Fewer species were detected in *Russula* productive root than in nonproductive root,
678 which is consistent with French *truffle* grounds. *T. melanosporum* grounds also
679 have shown a reduced fungal biodiversity, a reduced presence of both ECM
680 Basidiomycota (57). Truffle-colonization reduced the abundance of some fungal
681 genera surrounding the host tree, such as *Acremonium* (55) . *Russula* fruiting body
682 decreased the Chao richness bacterial index and Shannon diversity of bacterial
683 index in rhizosphere soil. Simultaneously, *Russula* fruiting body decreased the
684 Chao richness fungi index but no effect on Shannon diversity of fungi index in
685 rhizosphere soil. Warmin (2009)(40) found bacteria adapted to the mycospheres of
686 three or more or just one ECM fungal species was defined as specific selective
687 bacterial. So, we suggest the diversity decreased phenomenon may be related with

688 the *Russula* sporocarp selection effect, especially to rhizosphere soil bacterial.
689 Temperate forests are generally dominated by Fagaceae, and species in these plant
690 families form mycorrhizae with various phylogenetic clades of ectomycorrhizal
691 fungi(8, 11, 59). Members of the *helotialean* group have recently been identified as
692 the dominant species in the roots of Fagaceae trees in the temperate and subtropical
693 forests of Japan (60, 61). In our study, we found that 3 ECM, *Russula*, *Tomentella*,
694 and *Lactarius*, are the main members in the natural Fagaceae (*Quercus glauca* and
695 *Castanopsis hainanensis*)-dominant *Russula* ground in all the types. This result is
696 consistent with the preference of *Russula* and *Lactarius* for the Fagaceae host. In
697 *Castanopsis*-dominant forest in Japan (62), there are ECM fungi such as *Amanita*
698 (*Amanitaceae*), *Boletus* (*Boletaceae*), *Tylopilus* (*Boletaceae*), *Cortinarius*
699 (*Cortinariaceae*), *Inocybe* (*Inocybaceae*), *Lactarius* (*Russulaceae*), and *Russula*
700 (*Russulaceae*). The dominant ECM lineages of *Quercus liaotungensis* were
701 *Tomentella*, *Thelephora*, *Cenococcum*, *Russula*, *Lactarius* and *Inocybe*(63). The
702 ectomycorrhizal *Russula*, *Lactarius*, *Cortinarius*, *Tomentella*, *Amanita*, *Boletus* and
703 *Cenococcum* were dominant in the *Quercus serrate* plot (11). *R. vinosa* grows in
704 tropical and subtropical evergreen forests in southern China dominated by trees of
705 *Castanopsis* spp., and *R. griseocarnosa* grows in forests with Fagaceae (13). Given
706 commercially harvested truffles can establish ectomycorrhizal relationships with
707 different woody host species, and many different combinations of truffle and host
708 species mycorrhizal seedlings are produced in nurseries (64). Our study shows that
709 *Russula* inoculation may establish satisfactory ectomycorrhizal relationships with
710 two indigenous tree species, *Quercus glauca* and *Castanopsis hainanensis*.

711

712 Healthy ECM can support a wide variety of organisms, including a diverse array of
713 fungi other than the dominant ectomycorrhizal symbiont. Some pathogenic fungi,
714 including *Ilyonectria* and *Podospora*, and other competitive mycorrhizal fungi,
715 such as *Hymenochaete*, had significantly lower abundance in the *T.*
716 *borchii*-inoculated root and *Trechispora* and *Humicola*, which were more abundant
717 in the *T. borchii*-inoculated root. There are some notable examples of associations

718 among *suilloid* fungi and members of the Gomphidiaceae occur within
719 ectomycorrhizal roots (27). Olsson considered *Gomphidius roseus* acted as a
720 parasite of *Suillus bovinus*, the former never occurs without the latter(27) , Based
721 on MiSeq sequencing analysis of the top 20 ectomycorrhizal fungi in *Russula* root,
722 we found *Acremonium*; *Cladophialophora* are associated with ECM
723 *Russula*-Fagaceae roots, and *Boletus* was in association with sporocarp-producing
724 *Russula*. Meanwhile, based on the top 20 genera in *Russula* rhizosphere soil, we
725 found that *Elaphomyces*, and *Tomentella* in association with *Russula* symbiosis;
726 *Dacryobolus* were associated with sporocarp-producing *Russula*. The result will
727 help to find and develop PGPF for *Russula* symbiosis or sporocarp-producing.

728

729 Many studies have addressed the role of soil bacteria in establishing the symbiotic
730 relationship between plants and mycorrhizal fungi (43, 65). We found differences in
731 fungal genus among the three ECM *Russula* types in rhizosphere soil (Table S 3,
732 Table 2).The interactions of bacteria with the dense hyphal network underneath
733 fungal fruiting bodies have also been addressed (44, 66). Differences in bacterial
734 communities associated with the mycorrhizospheres of *Suillus bovinus*- and
735 *Paxillus involutus*-colonized plants were detected early (67, 68). Frey et
736 al.(1997)(69) reported that specific *Pseudomonas fluorescens* prefer *Laccaria*
737 *laccata*. *P.fluorescens* and *Burkholderia terrae* are exclusively found in the
738 mycosphere soil of *Laccaria proxima* (30, 40). Boersma(2009)(36) found that the
739 mycospheres of basidiomycetous fungi indeed exerted a universal selective effect
740 on the *Pseudomonas* community (i.e., *Pseudomonas poae*, *P. lini*, *P. umsongensis*, *P.*
741 *corrugata*, *P. antarctica* and *Rahnella aquatilis*); as well as species-specific
742 selective (i.e. *P. viridiflava* and candidatus *Xiphinematobacter americani*). For the
743 selection of the bacteria family *Sphingomonadaceae* by the mycorrhizal fungi *L.*
744 *proxima* and *R. exalbicans*, the mycosphere effect was most prominent in the latter
745 (36). The mycosphere-isolated bacterium *Burkholderia terrae* has been shown to
746 protect its fungal host *Lyophyllum* sp. from several antifungal agents, such as
747 metabolites produced by *P. fluorescens*, as well as from the antifungal agent

748 cycloheximide (70). Some studies have concentrated on mycorrhization helper
749 bacteria (MHB) in facilitating mycorrhizal colonization of roots in forest nursery
750 environments(43, 71). Rich in bacteria in the mycorrhizal roots, mycorrhizosphere
751 soil and peridium of desert truffles may be used to increase the survival and
752 mycorrhization in the desert truffle plant production system at a semi-industrial
753 scale(72) . The associated bacteria of *Truffle brûlés* are *Pseudomonas* and
754 *Flavobacteriaceae* (73). To achieve successful reforestation, PGPR and MHB were
755 screened to improve the establishment of *Lactarius deliciosus*-*Pinus* sp.
756 symbiosis(74). In our study, *Acidocella* , *Bryobacter*, *Sorangium*, *Acidicaldus*,
757 *Edaphobacter* and *Acidobacterium* were indicator species for *Russula* symbiosis in
758 the bacterial community. we also found ECM universal selective
759 *Sphingomonadaceae* work with *Russula* species-specific selective
760 *Acidocella* ,*Sorangium*, *Acidicaldus*, *Edaphobacter* and *Acidobacterium* in the soil
761 bacterial community of *Russula* symbiosis (Fig. 3E).Further, by network analysis,
762 *Acidobacteriaceae*, *Sorangium* and *Acidobacteria* had a positive correlation with
763 *Russula*. There may be further instruction to provide a wide collection of these
764 bacterial associates of *Russula* and to develop *Russula* MHB or Fagaceae PGPR.

765

766 Only a few edible ectomycorrhizal fungal species, such as black truffles or saffron
767 milk caps, can be produced in manufactured orchards. To date, *Russula* fruit bodies
768 are uncultivable. Five *Russula* were used to inoculate *Shorea parvifolia* seeding
769 successfully (75) , and one *Russula* was used to inoculate *Quercus garryana*
770 seeding successfully(76) . Our results will provide instruction to specifically isolate
771 the fungi or beneficial rhizosphere microbes associated with ECM *Russula* from the
772 root or mycorrhizal rhizosphere. Next , we will further need to isolate and culture
773 the microbial communities of the *Russula* root or mycorrhizospheres soil in three
774 types, which will supplement our research findings. The inoculation of these
775 microbes can stimulate establishment and will help to enhance plant growth and
776 promote a change in infected frequency.

777

778 **Conclusion.** The amount of *Russula* DNA is positively correlated with fruiting
779 body and *Russula* mycorrhizae based on the metagenomics of *Russula* root and soil.
780 Fewer fungi species were detected in *Russula*- infected and *Russula* sporocarp root.
781 Fewer bacteria and fungi species were detected in *Russula*- infected and in *Russula*
782 sporocarp rhizosphere soil. *Boletus* is considered as indicator species in
783 *Russula*-Fagaceae root (*Quercus glauca* and *Castanopsis hainanensis*) for
784 sporocarp-producing *Russula*. The *Russula* sporocarp rhizosphere fungi
785 *Dacryobolu* and *Russula* sporocarp rhizosphere bacteria *Acidocella* is considered as
786 indicator species for sporocarp-producing *Russula*. On the other hand, a number of
787 taxa within *Acremonium* and *Cladophialophora* were identified in Fagaceae root in
788 *Russula* symbiosis. The *Russula* mycorrhizal rhizosphere fungi *Tomentella*, and
789 *Elaphomyces* and the *Russula* mycorrhizal rhizosphere bacteria *Acidocella*,
790 *Bryobacter*, *Sorangium* and *Acidobacterium* occurred more frequently in
791 association with the ECM genus *Russula*. Understanding the ectomycorrhizal
792 fungal communities inhabiting natural *Russula* growth areas may give us clues
793 about the dynamics of the targeted *Russula* and the possibility of identifying
794 mycorrhizal fungal species that are good indicators of successful *Russula*
795 semicultivation. This reseach may provide novel targeted strategies to improve the
796 establishment of *Russula*-Fagaceae sp. symbiosis and improve *Russula* ascospore
797 productivity and sustainability.

798 **MATERIALS AND METHODS**

799 **Sampling** . Our study was conducted in areas of *Russula* growth in Jianou, Fujian
800 province, China, in which species of the genus *Russula* are well represented. The
801 dominant trees of the areas are *Quercus glauca* and *Castanopsis hainanensis*. The
802 herb layer is composed of *Podophyllum peltatum*, *Panax stipuleanatus* and
803 *Saxifraga stolonifera*. Fine roots were excavated 2-3 m from the trunk of an adult
804 *Russula* symbiotic tree(Fig. S1A). In addition, another type of fine roots that was
805 clearly connected to *Russula* sporocarp by extraradical mycelia was collected(Fig.
806 S1B,C). We collected three 15-30 cm fine-root segments (containing 100-200 root
807 tips) at a depth of 20 cm (77) . Roots from a single tree were pooled into a single

808 plastic bag. More than 200 cm³ of rhizosphere soil was collected around the root
809 samples for analyses. All root and soil samples were stored in a cooler containing
810 several ice bags and transported to our laboratory within 24 h for subsequent
811 analysis.

812 **DNA extraction, amplification, and sequencing.** The collected root samples were
813 washed carefully with tap water. Root tips were preserved in a plastic centrifuge
814 tube at -20°C before DNA extraction. DNA samples were pulverized using liquid
815 nitrogen. Total genomic DNA was extracted from ECM root tips using a modified
816 cetyltrimethylammonium bromide method, which was modified according to Wang
817 et al. (63)(2017). Total genomic DNA of corresponding rhizosphere soil was
818 extracted using a Fast DNA SPIN Kit (MP Bio) for soil according to the kit
819 operation steps.

820 First, the entire range of fungal ITS sequences was amplified from roots using the
821 ECM Basidiomycetes-specific high-coverage primer polymerase chain reaction
822 (PCR) with the primer pair ITS-1F (CTTGGTCATTTAGACGAAGTAA) and
823 ITS-4B (CAGGAGACTTGTACACGGTCCAG) (M. Gardes, 1993), and
824 traditional Sanger sequencing was performed. The sequences were BLAST against
825 the UNITE database/NCBI database (<http://www.ncbi.nlm.nih.gov>), and taxonomy
826 was assigned to species or genera using sequence similarity criteria of ≥97% for
827 species and 90–97% for genera. Furthermore, DNA of root tips identified as
828 *Russula* and the corresponding *Russula* symbiosis rhizosphere soil were subjected
829 to Illumina MiSeq high-throughput sequencing of ITS sequences to investigate their
830 associated microbiomes, while DNA of root tips with no mycorrhiza was used as a
831 control. The MiSeq sequences were edited, manually corrected in BioEdit 7.0.8 and
832 clustered into species-level operational taxonomic units (OTUs) at 97% sequence
833 similarity for species delimitation using PlutoF (<http://unite.ut.ee>) in UNITE(80). If
834 no match was found in the PlutoF system, any resulting OTU assignments were
835 individually checked by BLAST against the UNITE database/NCBI database
836 (<http://www.ncbi.nlm.nih.gov>).

837 To identify the fungi composition, we analyzed 18S ITS1-ITS4 DNA sequences of

838 ECM rhizosphere root and soil samples using phylogenetic methods, operational
839 taxonomic unit (OTU) delimitations and ordinations to compare species
840 composition in various types of ECM *Russula*. To identify the bacterial
841 composition, we analyzed 16S V3-V4 DNA sequences of ECM rhizosphere soil
842 samples using phylogenetic methods, operational taxonomic unit (OTU)
843 delimitations and ordinations to compare species composition in various types of
844 ECM *Russula*.

845 **Statistical analyses.** Chao1 (species richness index) and Shannon (microbial
846 diversity index) indices were analyzed by 97% OTU similarity. ECM fungal
847 richness and the microbial diversity index of each *Russula* root tip and the
848 corresponding rhizosphere soil of *Russula* symbiosis were calculated using the
849 vegan package and compared by one-way ANOVA. PCoA analyses were based on
850 any distance other than the Euclidean distance using abundance and
851 presence-absence data of the top 20 genera in three types. Differences in
852 community composition among *Russula*-infected samples were visualized by PCoA
853 (79).

854 **Micro-Community diversity analysis and indicator species analysis.** Taxonomic
855 analyses were generated based on the community species abundance (each was
856 above 0.05% of all reads) using Microsoft Excel. The main fungal genus patterns
857 were determined by taxonomic analysis at different ECM *Russula* mycorrhizal
858 roots. The main fungal and bacterial genus patterns were also observed in the
859 *Russula* mycorrhizal rhizosphere. To assess *Russula* preference, aspects indicator
860 species analysis was carried out by comparing the top 20 genera of three types of
861 root micro-communities. Indicator species of the community of the top 20 genera
862 based on the species presence in the *Russula* sample and absence in the no-*Russula*
863 sample were analyzed by Venny drawing tools
864 (<https://bioinfogp.cnb.csic.es/tools/venny/index.html>).

865 **Network analyses.** The relationships of *Russula* and other fungi in the *Russula*
866 community were analyzed by Spearman correlation of the absolute top 20 most
867 abundant in all the samples using the igraph, psych software package. Network nets

868 constructed on the interrelationship result with $P > 0.05$ or $|R| < 0.4$ were filtered. The
869 relationships of bacteria in the *Russula* mycorrhizal rhizosphere were also analyzed
870 by Spearman's correlation.
