1 Materials and Methods

1.1 Taxon sampling and sequencing

To generate sequencing data from specimens that were not preserved in ideal conditions and/or are more than five years post-collection (including a large library of previously sequenced chiton specimens from the personal collections of D.J. Eernisse as part of ongoing systematic revisions), we generated a suite of target capture loci. We designed target capture baits to predicted exon regions following a similar approach to Hugall et al. (52). We identified a set of 891 orthologs from 19 chiton transcriptomes and three reference molluscan genomes (*Octopus bimaculoides*, *Lottia gigantea*, and *Crassostrea gigas*) using the phylogenomics pipeline from Kocot et al. (53). We identified conserved exons from the three mollusc genomes using EnsemblMetazoa and predicted intron-exon boundaries in the chiton sequences with a custom script using tBLASTx. From this, we compiled a set of predicted chiton exons from 355 genes that had at least four representative chiton sequences from our transcriptome dataset. Arbor Biosciences synthesized 19,980 biotinylated DNA baits that target these regions. The baits have a length of 120 bp and a GC content between 35-55

We used the MYbaits Custom DNA-Seq kit v. 3.02 (Arbor Biosciences, Ann Arbor, Michigan, USA) according to manufacturer's instructions. We applied our target capture baits to DNA extracted from chiton specimens preserved in ethanol. We extracted total DNA from 87 specimens of preserved chitons with a phenol-chloroform extraction. We then produced Illumina sequencing libraries with unique barcodes using the NEBNext® Ultra™ II FS Library Prep Kit (New England Biolabs, Ipswich, Massachusetts, USA) with a 25 minute incubation at the fragmentation step. We used the TapeStation (Agilent, Santa Clara, California, USA) automated electrophoresis to confirm that the libraries had an average fragment size of 250 bp with adapters and that adapter dimers were absent. We incubated these libraries with biotinylated DNA baits via the MYbaits Custom DNA-Seq kit, and we pulled down the baits that hybridized with the Illumina library fragments with a streptavidin-coated magnetic bead binding process before washing away the uncaptured library fragments. We amplified the captured fragments with the KAPA HiFi Library Amp Kit (Roche Molecular Systems, Inc., Wilmington, Massachusetts, USA.) After the amplification, we confirmed that the libraries maintained an average fragment size of 250 bp and that adapter dimers were absent. We pooled enriched sequencing libraries and sequenced them on either an Illumina MiSeq (11 species) or NextSeq (68 species).

We trimmed Illumina adapters and low-quality sequences (quality score of ≥ 20) using TrimGalore v0.4.1 (54). We used HybPiper (55) to map reads to reference sequences. To expand our taxon sampling further, we combined target capture data with chiton transcriptomes from recent phylogenies of chitons that included chitons with only aesthete, chitons with eyespots, and chitons with shell eyes (56). We also included transcriptomes of several aplacophoran molluscs and a few conchiferan molluscs to root the phylogeny (Accession numbers in Supplementary Material, Outgroup and Available Sequences). To recover our target capture loci from chiton transcriptomes, we aligned the sequencing results from each target capture locus across chitons and determined the consensus DNA sequence for each. Then, we created a local blast database of each new chiton transcriptome and used each consensus DNA sequence from a target-capture locus as a query to locate the corresponding sequence within the new transcriptome. For each gene that we included, we retrieved only a single hit at E-value threshold $1e-4$, so we are confident in matching gene sequences.

*Most taxa follow MolluscaBase; all differences are intentional and reflect ongoing systematic revisions by DJE

**Note to reviewers: The 'xxxx' placeholders in this column will be updated in a subsequent version of this manuscript when museum catalog numbers become available.

1.2 Phylogeny

To generate a robust phylogeny of chitons, we compared coalescence and concatenation-based approaches using Maximum Likelihood, and Bayesian approaches. We first aligned all loci with MAFFT v7.305 (58) to produce a single data matrix of 103 chitons that could be partitioned by locus. We produced a maximum likelihood tree in IQ-TREE2 (57), partitioning by gene and using ModelFinder to determine the best model for each locus. We also calculated gene concordance factors in IQ-TREE2. Separately, we produced a maximum-likelihood phylogeny for each gene individually with IQ-TREE2, again using ModelFinder, and input these trees into ASTRAL-Pro (41), which estimates a species tree from multiple gene trees via the multispecies coalescence (MSC) model and a quartet-based approach.

The placement of *Schizochiton* has been uncertain across studies of chitons, and our study is limited by the inclusion of only a single representative of the genus *Schizochiton*, *Schizochiton incisus*. Specimens of the only other accepted congeneric species, *S. jousseaumei* (Dupuis, 1917) were not available, and this is the only genus in the superfamily, Schizochitonoidea. Some morphological characters, most notably pectinated insertion plates and adanal gills, suggest an affinity of *Schizochiton* with Chitonidae. However, differences of opinion persist as to whether these traits are useful apomorphies. For example, the insertion plates of *Schizochiton* were once termed “obsoletely pectinated” (59) although they have strong pectination comparable to members of Chitonidae (DJE, pers. observation). Additionally, the caudal sinus is absent in Chitonidae but present in *Schizochiton* (65). However, caudal sinuses evolved multiple times across chitons, so the presence or absence of a sinus may not be a useful morphological character. *Schizochiton* has been recovered as sister to the remaining Chitonina, but with weak support (36). Our placement of *Schizochiton* requires that pectinated insertion plates evolved convergently in *Schizochiton* and Chitonidae. To further investigate the placement of *Schizochiton* in our phylogeny, we used an iterative pruning method to verify that *Schizochiton* was not an unstable branch (90) and determined that *Schizochiton* did not have any indicators of being a long branch or a highly unstable branch (Supplemental Data, RogueNaRok).

1.3 Ancestral state reconstruction and morphospace determination

To determine how many times distributed visual systems evolved across the chiton phylogeny, we performed ancestral state reconstruction using RayDISC and corHMM in R, which take a tree file and a corresponding character matrix for a given trait and estimates transition rates and ancestral states for binary or multistate traits (Beaulieu and O’Meara 2014). We used the consensus tree file from our Mr-Bayes dated phylogeny run with 15 loci from sortadate as our input tree, and inferred ancestral states for shell eyes, eyespots, and the maximum number of insertion slits on the anteriormost shell plate. We gathered information on slit number from volumes of Kaas’s monographs (60-64). We took the highest recorded slit number for the anterior valve to account for the impact of animal size on slit number, where slit number can increase across growth.

To estimate the density of aesthetes on a given shell plate, we used Fiji (Schindelin et al. 2012) to simplify SEM images of chiton plates by applying filters for cell counting from various sources (67-80). We then manually took a series of 10 estimates of shell eye, eyespot, and/or aesthete density (aesthetes/mm², including both microaesthetes + macroaesthetes) per animal (Supplemental Data, Aesthete Quantifications).

1.4 Molecular dating analyses:

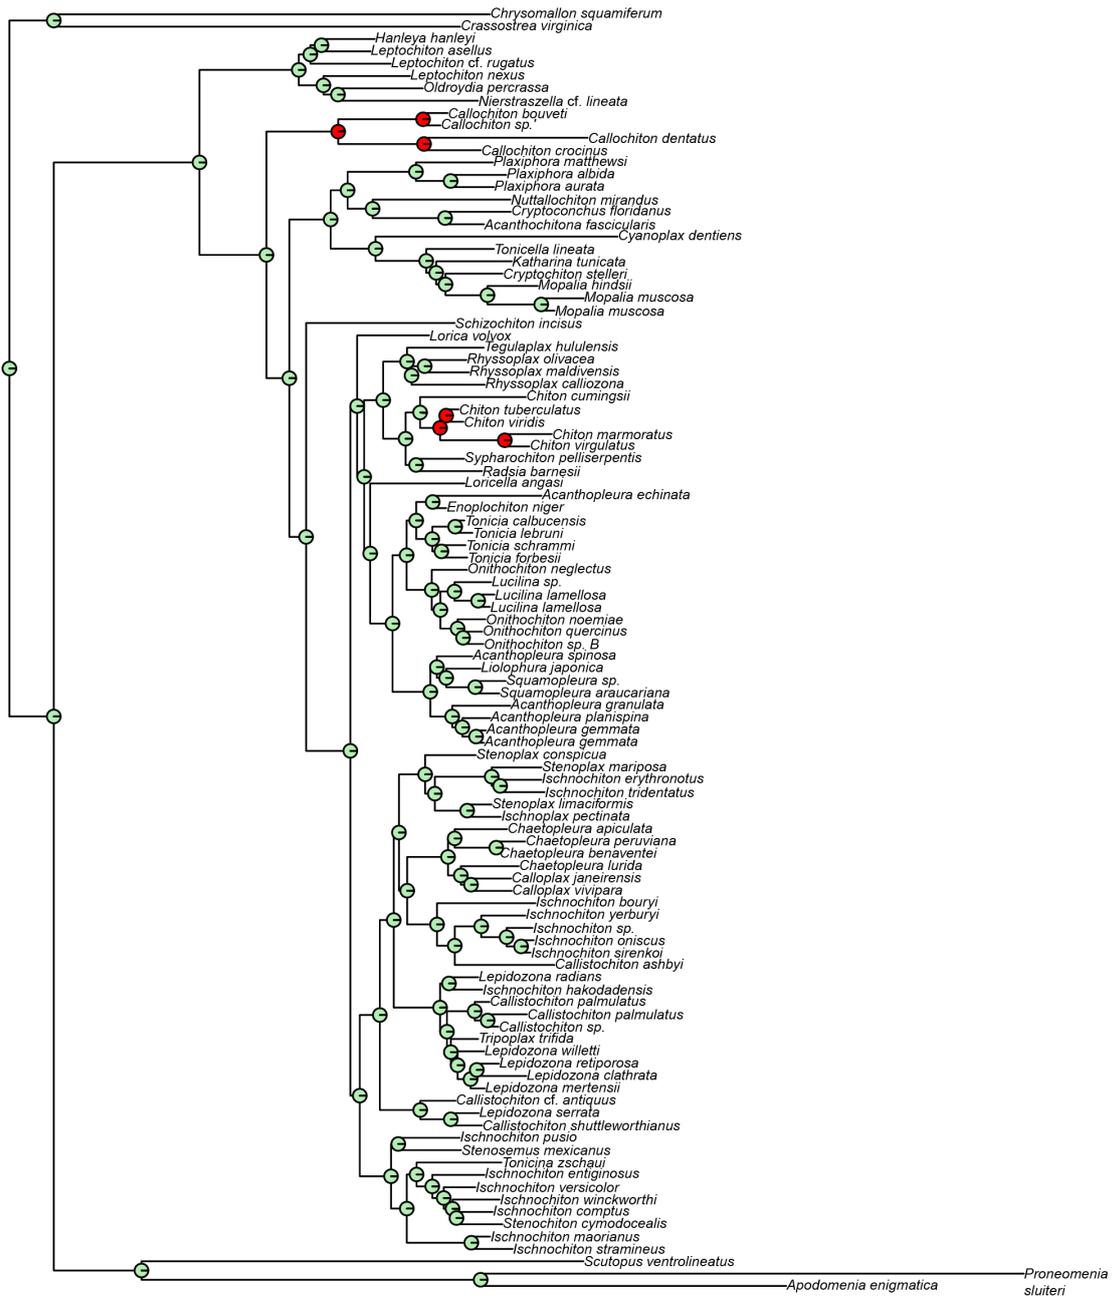

Following guidelines by Wolfe et al. for fossil calibrations across deep phylogenies, we selected fossil calibration points that span the depth of the phylogeny and are supported by multiple dating methods (82-83). There is a known bias in the chiton fossil record because members of Chitonida have thicker plates than Lepidopleurida (84), so there are more available calibration points for shallower nodes in the tree, and recent fossils are more easily identified (48,37). We set a hard maximum date for the entire phylogeny, including the outgroup *Crassostrea virginica*, of 549 million years ago, based on the Ediacaran deposits of the Nama group, a marine community with many of the earliest marine animal remains (including calcareous algae), but no remains of molluscs (39, 48). We assigned a soft maximum date of 359 million years to Neoloricata as a clade, based on the earliest fossils with a recognizable articulamentum (the inner layer of a shell plate) and thus the earliest likely emergence of Neoloricata (73, 48). We used this same soft maximum for all calibration points within Neoloricata. We assigned the Lepidopleurida a uniform calibration of 359 to 201.3 mya based on fossils from the Jurassic (67,74). We selected 66 mya as a minimum for Chitonida in agreement with Irisarri 2014 and Puchalski 2008 that earlier fossils are ambiguous and not plentiful enough to constrain the divergence of Chitonida from other chitons, so we used a fossil from the Upper Cretaceous as the more recent but definitive calibration point (74, 37, 85, 48). We set the minimum for Acanthochitonina at 33.9 mya based on fossils of *Plaxiphora* (which we in turn calibrated at a minimum of 23.03 mya) and *Mopalia* (which we calibrated at 15 to 359 mya) according to assessments and comparisons of multiple fossils by Puchalski (48). We set the genus *Tonicia* at 33.9 mya based on the fossils that bracket the divergence of Toniciinae from Acanthopleurina (48). This suite of fossils spans the expected phylogeny without constraining any of our clades of interest for the evolution of chiton visual systems.

To estimate divergence times across chiton evolution, we used a Bayesian relaxed molecular clock in MrBayes (83). Bayesian analyses are time-intensive (83), so we selected 15 loci with sortadata (87), a program that selects a subset of loci for analysis based first on congruence with a phylogeny (in this case, our maximum likelihood phylogeny from ASTRAL-Pro), and second based on how well each locus adheres to a clock-like accumulation of changes across a phylogeny. To ensure that using a subset of genes did not change the resulting dates of the phylogeny in a way that changed our interpretation of visual system evolution in chitons, we re-ran a Bayesian dating tree using sets of 15, 25, and 30 genes from sortadata. Though chains did not converge in a reasonable time with 30 genes (standard deviation of split frequencies between two concurrent chains did not drop below 0.05), tree topologies and age estimates remained consistent. We used a fixed amino acid substitution model of GTR across our 15 (or 25/30) partitions, and we applied the IGR model with a preset prior of $\exp(10)$ and a preset clock rate prior of $\text{lognorm}(-7, 0.6)$. We set the branch lengths prior based on the fossilization clock, and ran each analysis a minimum of one million generations, extending as needed to reach a standard deviation of split frequencies ≤ 0.05 .

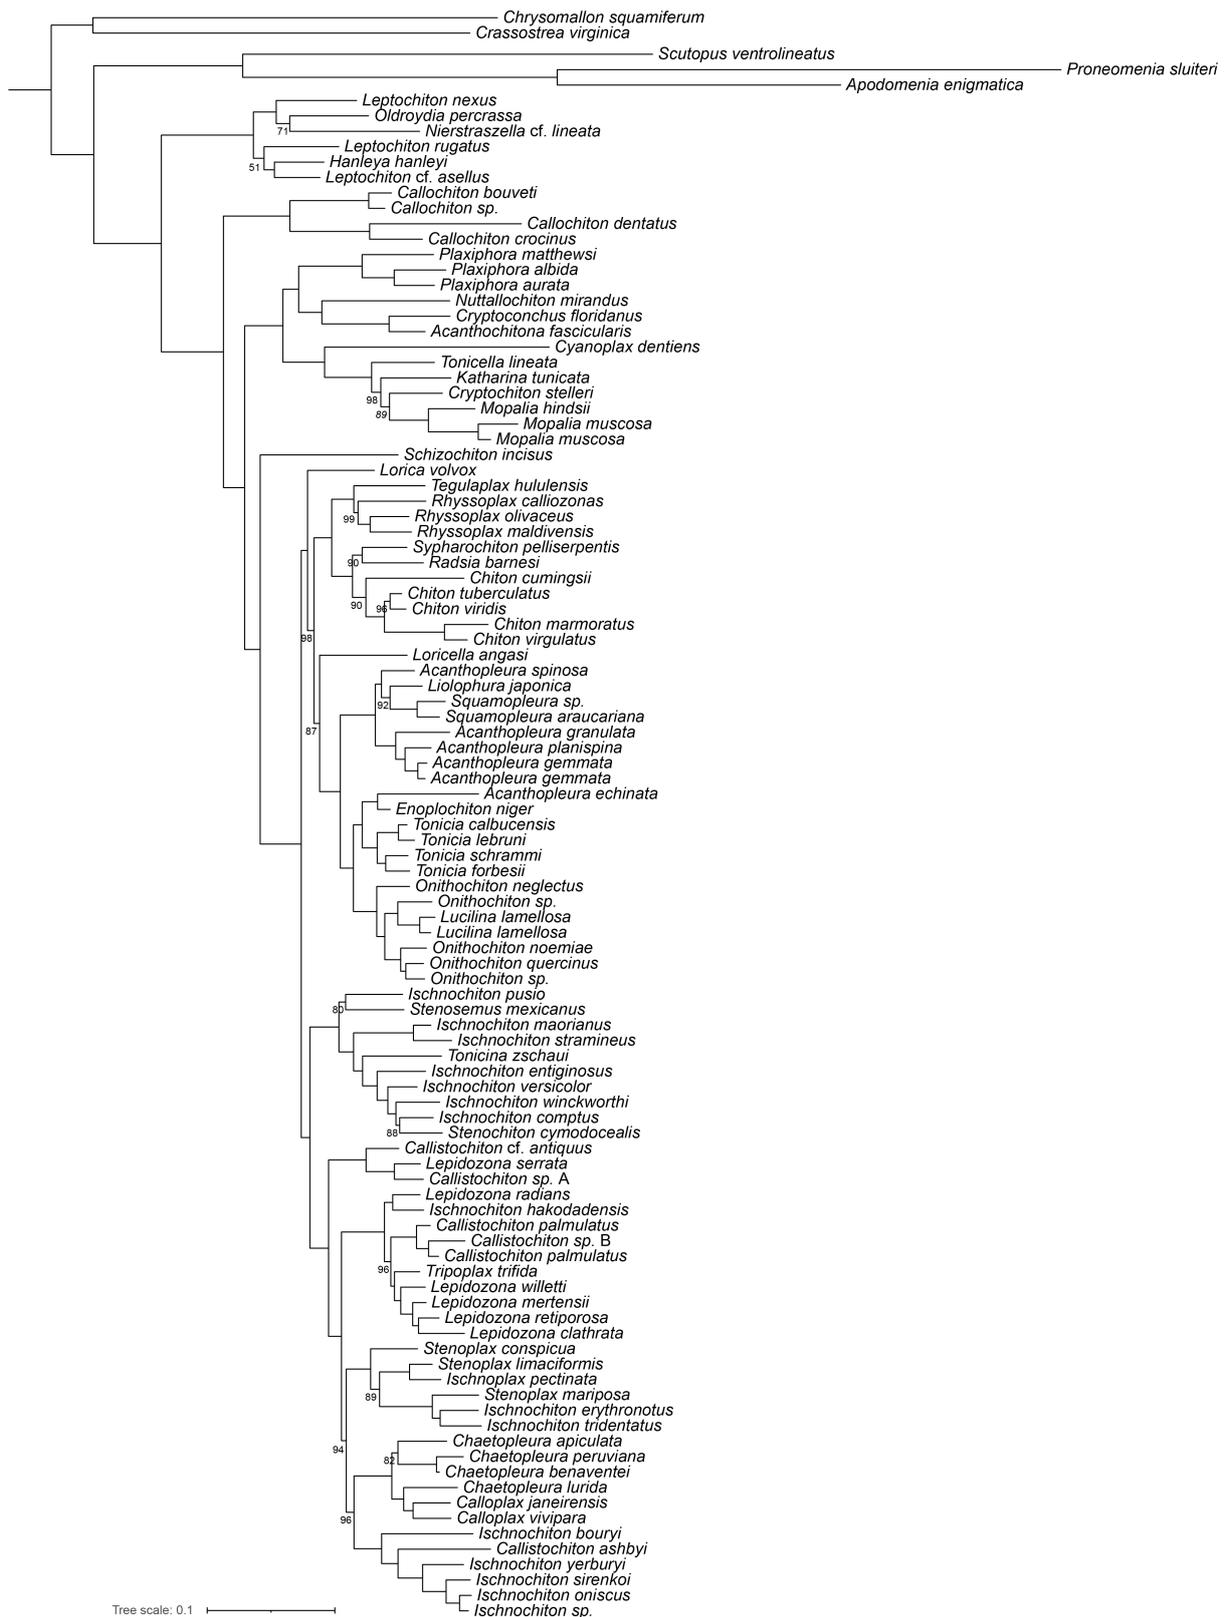

2 Supplementary Figures and Tables

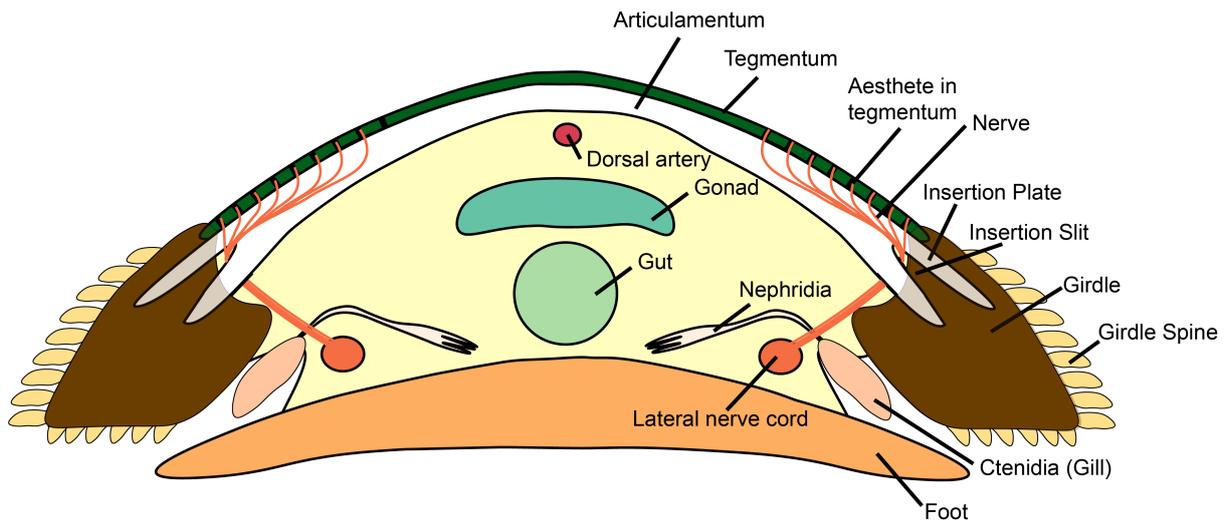

Supplementary Fig. 1: Ancestral state reconstruction of shell eyes shows $\geq 95\%$ proportional marginal likelihood for two independent origins of shell eyes, one within the Chitonidae and one in *Schizochiton incisus* (not visible because *S. incisus* is a monotypic branch). Blue circles indicate the presence of eyespots, green the absence of eyespots.

Supplementary Fig. 2: Ancestral state reconstruction of eyespots show $\geq 95\%$ proportional marginal likelihood for two independent origins of eyespots, once in Callochitonida and once in Chitoninae. Red circles indicate the presence of eyespots, green the absence of eyespots.

Supplementary Fig. 3: Maximum likelihood phylogeny of chitons based on the full matrix of all target capture loci generated in the present study. Tree made with IQTree2; all support values not shown are 100.

Supplementary Fig. 4: An axial cross section through a chiton with labeled parts, showing how nerves (orange) run through the tegmentum (green) and across the shell plate (white) to pass through an insertion slit between insertion plates to join the nerve cord below (orange). Insertion plates extend into the mantle (brown) to hold shell plates in place.

4 Other Sample and Laboratory Details

The majority of samples available were plugs of foot tissue (muscle) preserved in ethanol. As such, we excluded from the analysis any samples for which the providence was not absolutely certain and/or the identification was unclear.

4.1 Deconcatenating Initial Chiton Data

To pull out individual genes from additional transcriptomes, first partitioned data had to be de-concatenated using a custom script `decat.py`:

```
#decat.py Rebecca M Varney 2021
#First separating the names of the loci from the numeric range of each locus
loci=[]
names=[]
with open ("partitions.txt") as p:
    for line in p:
        line = line.strip ('LG, ')
        line = line.split (" = ")
        loci.append (line [1])
        names.append (line [0])

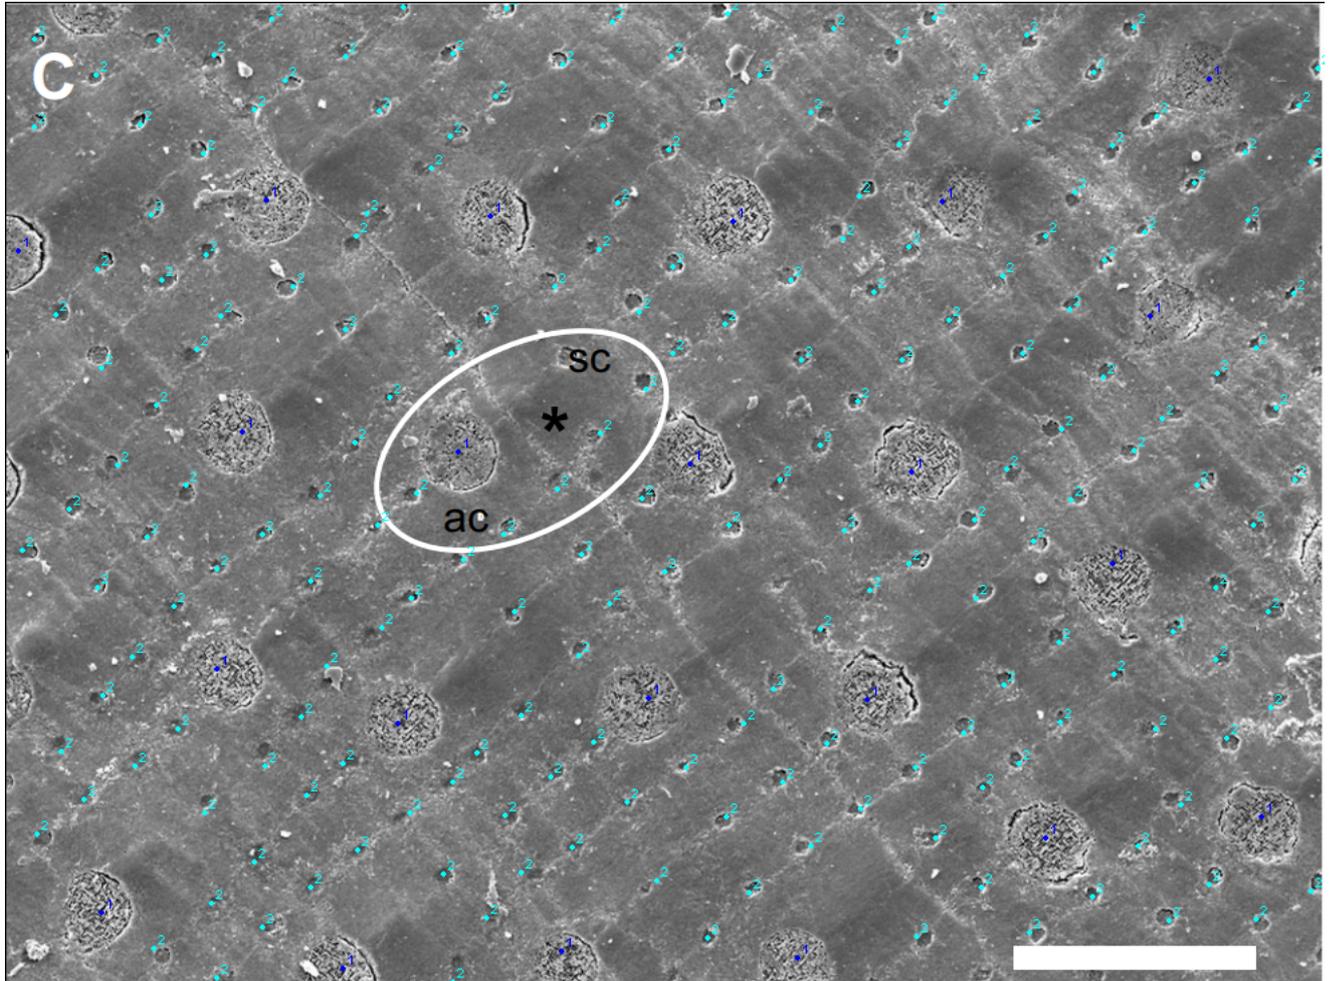

#Change the hyphens to colons
num_loci=[]
for string in loci:
    numloci = int(string.split("-")[0])-1 #Save the first number as an integer
    num_loci.append(numloci) # Add to list

# Open concatenated file
file = open("concatenated.fas")
c = "" # Empty string to save into
for line in file:
    c += line
file.close()
data = c.splitlines() # Save a data into a list broken up by lines

# Loop over loci names
for i in range(len(names)):
    # Create empty string to save data into for each loci
    sout = ""
    # Loop over data
    for line in data:
        if line[0] == ">":
            # Write name
            sout += line + "\n"
        else:
            if i == len(names)-1: # Need to do something special for the last loci to get the
                end of the string
                sout += line[num_loci[i]:] + "\n"
            else:
                sout += line[num_loci[i]:num_loci[i+1]] + "\n"
    #break
    ofile = open(names[i]+".fas",'w')
    ofile.write(sout)
    ofile.close()
```

4.2 Aesthete Quantifications

To determine aesthete densities, we used available SEM images from as many species as we could find reliably. We used the cell counter function in FIJI (Image J) to determine the number of complete aesthetes (and eyespots and shell eyes) visible within a frame. Below is a midway example, with macroaesthetes and microaesthetes counted:

(example image from (14))

From these counts, we could calculate density in aesthetes/mm² for each chiton by calibrating the image with the scale bar. We were limited by the availability of SEM images of sufficient magnification. The resulting aesthete data is:

5 Maximum Likelihood Analyses

5.1 Maximum Likelihood Tree

We made our initial phylogenetic tree in IQ-TREE 2 (57), using the model MFP+MERGE to implement Lanfear clustering to reduce a fully-partitioned model down to a best-fitting merged set of models and partitions.

```

source /home/.bash_profile

iqtree -s FcC_supermatrix.fas -spp *.nex -bb 1000 -ntmax 16 -nt AUTO -m MFP+MERGE -rcluster 10
-pre <date>
```

5.2 Coalescence-based approach

To assess the impact of a coalescence based approach, we also used ASTRAL-Pro (Zhang et al. 2020) which assumes the multi-species coalescent to estimate a species tree from a high number of gene trees. We first generated individual gene trees for all loci with IQTree2:

```
# IQTree2 individual gene trees loop:
for i in *.tre; do
    iqtree -m -B 1000
done
```

```
#!/bin/bash -l

```

5.3 RogueNaRok Leaf Instability Testing

To assess whether specific branches were unstable relative to the rest of the tree, we used RogueNaRok's leaf instability index (88). Investigating *Schizochiton*, the leaf stability was not lower for this taxon than for the majority of the tree. However, leaf stability and branch length indices did indicate that the sample of *Callochiton septemvalis* comprised a very long branch and very low stability, indicating that this taxon may be misidentified and/or responsible for errors in topology. Further testing, including

BLAST analyses, caused us to doubt the identity of *C. septemvalis*. Due to these concerns, and with plenty of remaining representatives of *Callochiton*, we removed this sample from subsequent analyses.

6 Bayesian Inference Analyses/Divergence Time Estimation

6.1 Dating Overview

We dated our phylogeny in MrBayes following (Zhang and Wang 2019) and (Zhang 2017) <https://arxiv.org/pdf/1603.05707.pdf>.

6.2 SortaDate

SortaDate is an algorithm that ranks a set of gene trees by three factors: 1) consistency with the species tree, in our case the tree inferred from all genes in ASTRAL-Pro, called "bipartition"; 2) consistent root-to-tip branch lengths across the phylogeny, called "treelength", and; 3) the "clock-like" nature of each gene, called "root-to-tip". This allowed us to selected a recommended 15 loci to use for divergence time estimation. To test the impact of removing data by using only a subsection of genes, we repeated the analysis with 20 and 25 genes selected as well, but no large differences resulted in the dates generated for our phylogeny. We implemented SortaDate as follows:

First we created single-gene trees for each locus. Note that SortaDate requires a SINGLE TAXON as the root of the phylogeny, so for these analyses we removed *C. virginica* from all alignments:

```
#IQTree won't permit sequences that are empty (all Xs) so these must be removed first:
#linearize sequences
for file in *.fas; do
    awk '/^>/ {printf("%s%s\n", (N>0?"\n:":""), $0); N++; next;} {printf("%s", $0);} END
    {printf("\n");}' $file > $file.lin
done
#delete any lines that contain an X
for file in *.fas.lin; do
    sed '/X/d' $file > $file.sed
done
#remove resulting blank headers
for file in *.sed; do
    awk 'BEGIN {RS = ">" ; FS = "\n" ; ORS = ""} {if ($2) print ">"$0}' $file > $file.awk
done
```

Switching to HPC:

```
#!/bin/bash -l

#SBATCH --job-name=iqtree_loop
#SBATCH --nodes=1
#SBATCH --cpus-per-task=16
#SBATCH --mem=96G
#SBATCH --time=72:00:00
#SBATCH --mail-type=ALL
#SBATCH --mail-user=user@ucsb.edu

source /home/user/.bash_profile

for file in *.fas; do
    iqtree -s $file -bb 1000 -ntmax 16 -nt AUTO -m MFP -pre $file
done
```

Note: SortaDate requires library Armadillo; just install the version provided within the SortaDate binary, as other methods are not recognized. Next, we ran SortaDate:

```
for file in *.contree; do nw_reroot $file Csqua > $file.newick; done
python /home/user/SortaDate/src/get_var_length.py /home/user/Desktop/2021.08.23_SortaDate
--flend .contree.newick --outf result1.txt --outg Csqua
python /home/user/SortaDate/src/get_bp_genetrees.py /home/user/Desktop/2021.08.23_SortaDate
concat.tre --flend .contree.newick --outf result2.txt
```

```
python /home/user/SortaDate/src/combine_results.py
/home/user/Desktop/2021.08.23_SortaDate/result1.txt
/home/user/Desktop/2021.08.23_SortaDate/result2.txt --outf result3.txt
python /home/user/SortaDate/src/get_good_genes.py
/home/user/Desktop/2021.08.23_SortaDate/result3.txt --max 15 --order 3,1,2 --outf
result4.txt
```

The gene list, prioritized by the recommendations in the SortaDate manual, is:

```
00347.fas 01031.fas 02057.fas 03411.fas 03880.fas 04012.fas 04284.fas 04817.fas 05071.fas 05072.fas
05395.fas 05809.fas 06126.fas 09237.fas 09678.fas
```

6.3 Fossil Constraints

Chiton fossils pose many problems, both because it is rare to find intact shell valves and also because of biases in fossilization across caldes (84). Thus, we used fossil calibrations as minimum values that allowed for uniform distributions of probabilities from the minimum to the maximum, we which define for all clades as the base of Polyplacophora itself (359 mya). Many chiton fossils are assigned to species, but these identification are often optimistic and based on morphological features that are known to vary in extant chiton groups. Thus, we applied calibrations to the best-supported taxonomic level of each fossil based on the description of characters available (e.g. a fossil identified to species may instead be used to calibrate a genus or family as 'at least X my old').

Clade	Date Range	Citation(s)
Polyplacophora	Max 359 mya	((6), (13))
Lepidopleurida	201.3 - 359	((13), (5))
Chitonida	66 - 359	((2), (7), (1), (4))
Acanthochitonida	33.9 - 359	((7), (10), (3))
Plaxiphora	23.03 - 359	((7), (3))
Mopalialia	15 - 359	((7), (3))
Tonicia	33.9 - 359	((7))

6.4 MrBayes Dating

Using the fossil constraints above, we ran MrBayes to date our phylogeny of chitons as follows. We stopped the run when chain discordance dropped below 0.25, higher due to the larger phylogeny. Run time was approximately 2.5 weeks.

```
#New constraints with NAMES
```

```

7.2 Ancestral State Reconstruction

For BINARY traits (eyespot and shell eyes):

We used RayDISC, a component of corHMM ((12)) in R.

```
#### RayDISC ASR w/ Rooted tree
library(ape)
library(phytools)
library(corHMM)
library(castor)
library(plyr)
library(versitree)

#DECLARE TREE FILE NAME
treefile= "renamedconcat.contree.newick"
#READ IN TREE
chitontree <- ape::read.tree(treefile);phytools::read.newick(treefile)
#GET LIST OF TAXA
chitontree$tip.label

#DATA
filename = "ML_ASR.txt"
chitondata <- read.table("BigChitonTree_STATESslitseyespoteye.csv", header = TRUE, sep = ",",
  as.is = FALSE)

#rename your nodes in the tree; allows for annotation later in iTOL
prefix<-"node"
suffix<-seq(1:104)
chitontree$node.label[chitontree$node.label=="OROOT"]<-""
chitontree$node.label[chitontree$node.label==""]<-paste(prefix, suffix, sep= "")
#Remove NAs from node.length; causes issues in rayDISC ASR
chitontree$edge.length[is.na(chitontree$edge.length)] <- 0
write.tree(chitontree, file="bigchitontree_nodelabel")

### ASR
## Perform ancestral state estimation, using an asymmetric model of evolution and marginal
## reconstruction of ancestral states

#charnum= column it's graphing
#To decide which model is best
reconbac_ER <- rayDISC(chitontree,chitondata,model="ER", ntraits=1, charnum=1,
  node.states="marginal")
reconbac_ARD <- rayDISC(chitontree,chitondata,model="ARD", ntraits=1, charnum=1,
  node.states="marginal")
reconbac_SYM <- rayDISC(chitontree,chitondata,model="SYM", ntraits=1, charnum=1,
  node.states="marginal")

## Plot reconstructions on tree of a random model
plot <- plotRECON(chitontree,reconbac_ARD$states, title = "Chiton ASR w/ rayDISC ARD model",
  piecolors = c("darkseagreen2", "cyan3"), cex = 0.5, pie.cex = 0.3, height = 60, width =
  10, file = "ChitonASRraydisc.pdf")

write.csv(reconbac_ER$states, file="statesER-slit.csv")
write.csv(reconbac_ARD$states, file="statesARD-slit.csv")
write.csv(reconbac_SYM$states, file="statesSYM-slit.csv")

#writes data into a table so you can input into iTOL to visualize
write.table(reconbac_ER$states, file="chiton_slits_statesER.txt", sep="\t")
```

For MERISTIC traits (maximum slit number), we used phytools:

```

#phytools
library(phytools)

## read tree from file
chiton.tree<-read.tree("treeforASR.newick_underscored_noquotes.tre")

## plot tree
plotTree(chiton.tree,type="fan",ftype="i")
chiton.tree$tip.label

## read data
svl<-read.csv("BigChitonTree_SLITS.csv",row.names=1)
svl<-as.matrix(svl)[,1]
svl

## Must be .tre format; you can just rename the .newick to .tre
## NO SPACES ONLY UNDERSCORES
## Check your tip labels for quotes

fit<-fastAnc(chiton.tree,svl,vars=TRUE,CI=TRUE)
fit

obj<-contMap(chiton.tree,svl,plot=FALSE)
plot(obj,type="phylogram",legend=0.7*max(nodeHeights(chiton.tree)),
      fsize=c(0.7,0.9))

```

7.3 Verifying that the placement of *Schizochiton* does not impact ASR results

To test whether the predictions that chitons evolved visual systems four, separate times held, even if the placement of *Schizochiton* were to change, we artificially constrained our phylogeny to place *Schizochiton* close to genus *Tonicia*, a placement suggested by the highly-pectinated insertion plates.

Schizochiton is consistently drawn to the base of whatever clade it is constrained to within the Chitonina. We therefore concluded that if *Schizochiton* were to appear in the Chitonidae, as supported by the presence of pectinated insertion plates, the overall result that chitons evolved a visual system four distinct times would still hold because ASR indicates separate origins of shell eyes even then.

If we force a topology such that all chitons with shell eyes are monophyletic (a single origin of shell eyes), and perform topology testing in IQTree2 to assess the likelihood of the two trees, we find absolute support for the placement of *Schizochiton* at the base of Chitonina where it appears in our unconstrained tree:

Tree	logL	deltaL	bp-RELL	p-KH	p-SH	p-WKH	p-WSH	c-ELW	p-AU
1	-1591193.439	4336.2	0.0000 -	0.0000 -	0.0000 -	0.0000 -	0.0000 -	0.0000 -	0.00229 -

where

deltaL : logL difference from the maximal logl in the set.

bp-RELL : bootstrap proportion using RELL method (Kishino et al. 1990).

p-KH : p-value of one sided Kishino-Hasegawa test (1989).

p-SH : p-value of Shimodaira-Hasegawa test (2000).

c-ELW : Expected Likelihood Weight (Strimmer and Rambaut 2002).

p-AU : p-value of approximately unbiased (AU) test (Shimodaira, 2002).

and

Tree 1 is constrained, and is compared to our unconstrained best tree.

All topology tests reject the constrained tree because it is significantly worse than the unconstrained tree (indicated by -), so we reject the constrained tree.

The constraint tree used for analysis is: ((de3230, de6119, AGRA, de2429, de3229, de6324, de6128, de8602, IM-2013-14546, de-C17-GK, de7226, ONOE, de3369, de8006, SARA, de-C16-GK, IM-2013-14442,(de7505, de7353, TONI, de8093)), de8294);

8 Phylomorphospace Construction (Figure 2)

To create a phylomorphospace of chitons using slits and aesthetes, we used phytools (90) in R:

```
#This script takes in a treefile in newick format, as well as a data frame of states (slits
  and aesthetes). Note that the phylogeny must contain only taxa with established states.
library(phytools)
#DECLARE TREE FILE NAME
treefile= "FixedSimpleChitonTree.newick"
#READ IN TREE
chitontree <- ape::read.tree(treefile);phytools::read.newick(treefile)
#GET LIST OF TAXA
chitontree$tip.label

statesrownames <- data.frame(StateMatrix_Groups, row.names = 1)
states <- as.matrix(statesrownames)

phylomorphospace(chitontree, states, A=NULL)
```

9 Raw Sequence Data Availability

All data files, alignments, and input/output files are available online at [iFIGSHARE/DRYAD/etc.i](#).
