ABSTRACT

The aim of this present research was to explore the floristic analysis and species diversity of the Family Fabaceae depending on species which are represented by voucher specimens and deposited at the National herbarium depending on the data provided from the Flora of Libya series. 7 species *Pisum syriacum*, *Coronilla emerus*, *Astragalus massiliensis*, *Vicia sericocarpa*, *Vicia hirsuta*, *Retama monosperma*, and *Sesbania sesban* were added as a new record to the family Fabaceae in Libya. Results disclosed that the family Fabaceae in Libya is composed of 198 species belonging to 42 genera. The largest genera in the family Fabaceae in the flora of Libya are *Astragalus* which includes 26 species, followed by *Trifolium* with 21 species. Simpson's Diversity index indicated that the Family Fabaceae has high diversity. The life forms and chorological spectra of plant species were analyzed. There are few trees and

shrubs species in our data; this can be referred to as the difficulties for most species to grow in a dry habitat. It appears that annual and perennial life forms are the preferable strategy in the temperate deserts of Libya. Therophytes displayed the greatest number of species (69.19%), followed by Hemicryptophytes (14.65%), Nanophanerophytes (7.57%), Therophytes / Hemicryptophytes (5.55%), Chaemephytes (2.02%) and Phanerophytes (1.01%). Based on the results obtained from the geographical distribution of the species showed that the highest percentage is (58.1%) for the Mediterranean region, followed by (8.6 %) Mediterranean / Irano-Turanian regions. The results obviously showed that the majority of species distribution of the family Fabaceae is located within the Mediterranean region.

Keywords: Flora of Libya, Fabaceae, Species Diversity, Floristic Analysis, Life Forms, Chorotype.

1. INTRODUCTION

The legume family (Fabaceae) is the most diverse plant family in the world (Beech *et al.*, 2017). It is a family with about 770 genera and 19,500 species; it is widely distributed and is the third-largest land plant family of angiosperms in species numbers after Asteraceae and Orchidaceae in the global context (LPWG, 2017). The family has economic importance in supplying food crops that provide highly nutritious sources of protein and micronutrients for man and his animals (Graham, 2003; Yahara *et al.*, 2013; Okeke *et al.*, 2019). Some plants in this family are important agricultural and food plants, including *Pisum sativum* (pea), *Phaseolus* (beans), *Medicago sativa* (alfalfa), *Cicer arietinum* (chickpeas), *Arachis hypogaea* (peanut) and *Glycyrrhiza glabra* (liquorice) (Rahman, & Parvin, 2014). A number of these plants have great importance in medicinal purposes and also used to produce a large range of natural products including flavors, dyes, poison (Patel & Shah, 2014; Ahmad *et al.*, 2016). Ciotir *et al.*, 2019 said that in the family Fabaceae many species were identified as toxic, include 15 species with known human toxicity, 118 species with animal toxicity, 26 species with animal toxicity in laboratory studies, and 80 species with predicted toxicity based on reported information from the Perennial Agriculture Project Global Inventory (PAPGI). Ali *et al.*, (2019) said that the family Fabaceae in Libya has many traditional uses, including 37 species used in medicinal, and 33 species have harmful effects and considered poisonous plants, and ornamental represented by 9 species. Fabaceae plant habits are trees, shrubs, and herbaceous plant perennials or annuals (Rahman, & Parvin, 2014, Heuzé *et al.*, 2018). The widespread and largest genus in this family is *Astragalus* that over 2,400 species, followed by *Crotalaria* and *Indigofera* about 700 species of each, which contain about 9.4% of all flowering plant species (Magalion & Sanderson, 2001, Rahman & Parvin, 2014).

Figure 1. Map of Libya. (Via <https://www.google.co.uk/map of Libya>)

Libya is a country in the region of North African. It lies along the southern coast of the Mediterranean between latitude 32° 56' 08" North and longitude 25° 08' 51" East (Figure 1) and has an area of about 1, 759, 540 square kilometers (El-Mokasabi, 2017), except the coastal belt, Jabal Nafousa, and Al Jabal El-Akhdar regions more than 90% of the Libya area is desert ((El-Darier & El-Mogaspi, 2009). Boulous (1972) said that the coastal strip is about 5.2% of the whole country which extends from the Egyptian to the

Tunisian borders. This area receives an adequate amount of rainfall in winter and quite fertile, specifically in the east and west; therefore a great part of this belt shows the typical flora. Four Biogeographical regions are recognized in Libya, which are the Mediterranean region, Mauritanian steppe of Irano-Turanian region, the Saharo- Arabian region and the Sudanian region (Qaiser & El-Gadi, 1984). The climate characterized by the cool, rainy winter season and hot dry summer, it's typical of the Mediterranean climate. The climate is moderated along the coastal littoral by the Mediterranean Sea, but it is over most of the country is that of the hot, arid Sahara (Sharashy, 2016). This study is based on the analysis of the Family Fabaceae depending on legume species which are represented by voucher specimens and deposited at the National herbarium by (Jafri, 1980) in Flora of Libya series.

2. FLORISTIC

This paper represents an overview of the Family Fabaceae depending on the analysis legume species which are represented by voucher specimens, and deposited at the National herbarium, Faculty of Science, University of Tripoli [ULT], with life form patterns, distribution of species and chorotype. Taxa, which are not represented by voucher specimens excluded from this study. According to Jafri, & Ali, (1976), Klopper *et al.*, (2007) and Mahklouf, & Etayeb (2019) there are 2088 species belonging to 844 genera and 145 families in the flora of Libya as angiosperms. The third dominant family in the flora of Libya is Fabaceae (El-Mokasabi, 2017) with 200 species of 42 genera (Jafri, 1980). When excluded the species without voucher specimens at the National herbarium the present study includes 42 genera and 191 species with 7 new records (Table 1). The Family Fabaceae in Libya became 198 species belonging to 42 genera (Appendix). The largest genera in the Family Fabaceae in the flora of Libya are *Astragalus* which includes 26 species, followed by *Trifolium* with 21 species, *Medicago* (19 species), *Vicia* (15 species), Lotus (14 species), Lathyrus and Ononis (12 species each), Hippocrepis and Trigonella (8 species each), the rest genera less than 8 species for each genus (Table 2).

Table 1. List of new records to the family Fabaceae for Flora of Libya

New records	Specimen plant collector
<i>Pisum syriacum</i> (Berg.) E. Lehm.	El- Gadi <i>et al.</i> ,1987
<i>Coronilla emerus</i> L. subsp. <i>emeroides</i> (Boiss. & Sprun.) Hayek	El- Gadi <i>et al.</i> ,1987
<i>Astragalus massiliensis</i> (Mill.) Lam.	Sherif <i>et al.</i> , 1990
<i>Vicia sericocarpa</i> Fenzl	Sherif <i>et al.</i> ,1990
<i>Vicia hirsuta</i> (L.) Gray	Alhabony, 1999
<i>Retama monosperma</i> (L.) Boiss. subsp. <i>bovei</i> (Spach) Maire	El-Mokassbi, 2014
<i>Sesbania sesban</i> (L.) Merr.	Erteeb and Sharashi, 2015

3. SPECIES DIVERSITY

One of the most important indices which are used for the evaluation of ecosystems at different scales is species diversity (Ardakani, 2004). Typical biodiversity measurement focuses on the species level and local diversity can be studied with various indices (Eshaghi, 2009); such as Simpson's index or species richness which are commonly used to assess different trends in plant diversity. Diversity values of Simpson's index are a range between 0 and 1; when the value closer to 1 it is more diverse and when it closer to 0 it is less diverse (Reich *et al.*, 2001; Ket, 2012). In this study, Simpson's diversity index calculates a diversity score for the family Fabaceae; it is based on both the number of different species of each genus and the number of individuals present for each of those species (Table 2).

The formula for calculating Simpson's index is:

$$\text{Simpson's Diversity Index (D)} = 1 - \frac{\sum n_i(n_i - 1)}{N(N - 1)}$$

Where N = the total number of all species in the family Fabaceae.

n_i = the numbers of species of each genus.

$$\begin{aligned} \sum n_i (n_i - 1) &= 650 + 420 + 342 + 210 + 182 + (132 \times 2) + (56 \times 2) + 32 + (12 \times 3) + (6 \times 3) + \\ &(6 \times 13) + (2 \times 9) \\ &= 2284 \end{aligned}$$

$$N(N-1) = 198(198-1) = 39006$$

$$\begin{aligned} \text{Simpson's Diversity Index} &= 1 - (2284/39006) \\ &= 1 - 0.058 \\ &= 0.942 \end{aligned}$$

Table 2. Shows the number of species depending on the genus in the Family Fabaceae

Genus	number of species (n_i)	($n_i - 1$)	$n_i(n_i - 1)$
<i>Astragalus</i>	26	25	650
<i>Trifolium</i>	21	20	420
<i>Medicago</i>	19	18	342
<i>Vicia</i>	15	14	210
<i>Lotus</i>	14	13	182
<i>Lathyrus</i>	12	11	132
<i>Ononis</i>	12	11	132
<i>Trigonella</i>	8	7	56
<i>Hippocrepis</i>	8	7	56
<i>Melilotus</i>	6	5	32
<i>Anthyllis</i>	4	3	12
<i>Crotalaria</i>	4	3	12
<i>Lupinus</i>	4	3	12
<i>Coronilla</i>	3	2	6
<i>Hedysarum</i>	3	2	6
<i>Pisum</i>	3	2	6
<i>Argyrobium</i>	2	1	2
<i>Calicotome</i>	2	1	2
<i>Dorycnium</i>	2	1	2
<i>Ebenus</i>	2	1	2
<i>Genista</i>	2	1	2
<i>Indigofera</i>	2	1	2
<i>Onobrychis</i>	2	1	2
<i>Psoralea</i>	2	1	2
<i>Retama</i>	2	1	2
Other 18 genera	1	0	0

4. LIFE FORMS

Depending on Raunkiaer's method (1934) which was modified by Govaerts *et al.*, (2000), the highest proportion was herbs annuals. From the results obtained, the shrubs are representative by 7.57%, while the trees only 1.01% (Table 3). This can be referred to as the difficulties for most species to grow in a dry habitat. Based on the results, figure 2 shows that the highest life form recorded was for the Therophytes which constituted 137 species representing (69.19%) of the total species followed by the Hemicryptophytes with 29 species representing (14.65%), Nanophanerophytes 15 species (7.57%), Therophytes / Hemicryptophytes 11 species (5.55%), Chaemephytes 4 species (2.02%) and Phanerophytes with 2 species (1.01%). Therophytes and Hemicryptophytes are the most frequent life forms which may indicate typical desert spectrum vegetation.

Table 3. Life forms of Fabaceae species

Life forms	No. of species	% of total species
Therophytes (T)	137	69.19
Hemicryptophytes (He)	29	14.65
Therophytes / Hemicryptophytes (T/He)	11	5.55
Chaemephytes (Ch)	4	2.02
Nanophanerophytes (NP)	15	7.57
Phanerophytes (P)	2	1.01

**Figure 2.** Shows the number of species and percentage of Life forms in the Family Fabaceae.

5. GEOGRAPHICAL ELEMENTS OF SPECIES LEVEL (CHOROTYPE)

The results obtained from the geographical distribution of the species showed that 115 species (58.1%) are dominated in the Mediterranean region (Table 4 & Figure 3). 17 species out of the total with a ratio of 8.6 % belong to Mediterranean /Irano-Turanian regions, 8.1% (16 species) belong to Saharo-Arabian region, 6.5% (13 species) belong to Euro - Siberian /Mediterranean/Irano-Turanian regions, Cosmopolitan and Tropical regions representative by 3% with 6 species each, 2% (4 species) belong to Mediterranean / Saharo-Arabian and Euro - Siberian /Mediterranean regions. Figure 4 shows the distribution of Fabaceae species depending on coordinates have been given by the flora of Libya.

Table 4. Geographical distribution (Chorotype) of Fabaceae species

Chorotype	No. of species	% of total species
Med	115	58.1
Sa-Ar	16	8.1
Med/ Sa-Ar	4	2.0
Med - Eu-Si	4	2.0
Med / Ir-Tu / Sa-Ar	1	0.5
Med / Ir-Tu	17	8.6
Ir-Tu	7	3.54
Ir-Tu - Sa-Ar	3	1.5
Sa-Ar/ Su	2	1.01
Eu-Si/ Med / Ir-Tu	13	6.5
Eu-Si	3	1.5

Sud	1	0.5
Trop	6	3.0
Cosmo	6	3.0

Abbreviations: Med = Mediterranean, Sa-Ar = Saharo-Arabain, Ir-Tu = Irano-Turanian, Eu-Si = European Siberia, Cosmo = Cosmopolitan, Sud= Sudanian. Trop= Tropical

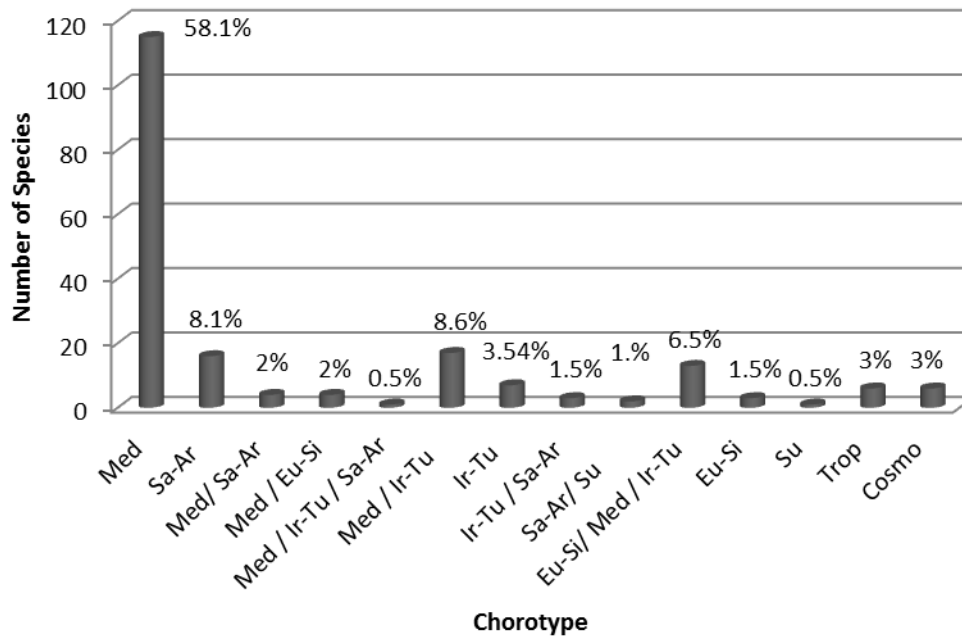

Figure 3. Geographical distribution of species showing number & percentage of species in each chorotype in the Family Fabaceae.

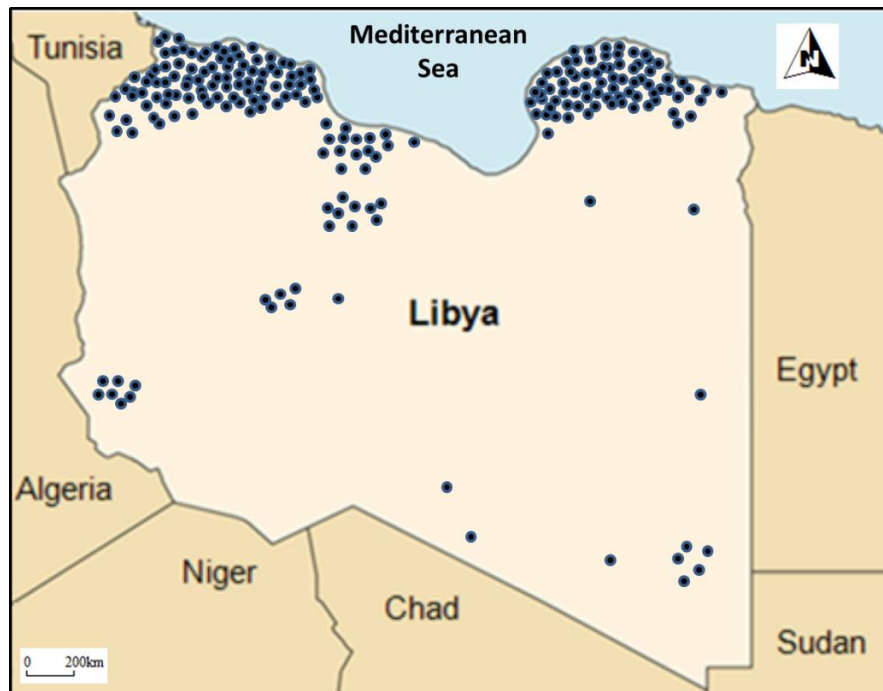

Figure 4. Distribution of Fabaceae species depending on the coordinate's flora of Libya.

6. DISCUSSION

Based on the results obtained from used Raunkiaer's method, the life form classes along the Family Fabaceae showed that the clear dominance of Therophytes (62.2%) followed by the Hemicryptophytes (14.65%). The structure of life forms indicates their compatibility with habitat conditions for the use of environmental resources in the habitat (Pairanj *et al.*, 2011). Therophytes are dominated due to the long dry periods during the year in Libya (El-Mokasabi, 2017). Simpson's Diversity index indicated that the Family Fabaceae has a high diversity. Our finding displayed that chorological characteristics of the Fabaceae species showed that Mediterranean region elements recorded the highest percentage (58.1%) followed by Mediterranean /Irano-Turanian regions elements (8.6%). The map of species distribution clearly shows that the majority of species of the Family Fabaceae are located within the Mediterranean region. It seems that annual and perennial life forms are a better strategy in the temperate deserts of Libya (AL Sghair *et al.*, 2019).

7. CONCLUSION

This research set out to present the first floristic analysis and species diversity of the Family Fabaceae depending on species which are represented by voucher specimens and deposited at the National herbarium. Simpson's Diversity index indicated the Family Fabaceae that has a high diversity. The life forms and chorological spectra of plant species were resolute. There are few trees and shrubs species in our data; this can be referred to as the difficulties for most species to grow in a dry habitat. It seems that annual and perennial life forms are a better strategy in the temperate deserts of Libya. Therophytes displayed the maximum number of species with 69.19%. The map of species distribution clearly shows that the majority of species of the Family Fabaceae are located within the Mediterranean region.
