## Introduction

Freshwater crayfish reach their greatest diversity in the southeastern United States, totaling more than 375 species with new species being described each year (Taylor et al. 2007, Crandall and Buhay 2008). Crayfish serve important functions in aquatic systems as processors of energy (Nystrom et al. 1996), as a keystone species in community structure (Usio and Townsend 2004), as prey organisms (Correia 2001) as well as support a viable bait and human food industry (Huner 2002). In the United States crayfish have a higher percentage of vulnerable species than amphibians, freshwater fish, reptiles, mammals, and birds (Primack 1998). Despite their diversity, function and overall imperilment, surprisingly little is known about most crayfish species (Schuster 1997).

Current records indicate 37 native species of crayfish are found in South Carolina, of which 24 species are considered ‘priority conservation species’ in the state (A. Smith, SC DNR, personal communication). Species range, one of the five criteria used by the AFS Endangered Species Committee to assess crayfish species imperilment (Taylor et al. 2007), information is seriously lacking for South Carolina species. Since a state-wide survey of South Carolina crayfish has not been done, distribution information needs to be gathered from historic records and existing collections.

South Carolina Department of Natural Resources (SC DNR) collected crayfish as a by-catch of water and stream sampling programs for eventual identification and convergence with existing crayfish distribution records. The

objectives of this project were: 1. to enumerate, sexual stage and identify to the greatest extent possible 407 unidentified crayfish samples; 2. once identified add the data to the State's spread sheet database; 3. to construct crayfish distribution maps with the available data; and 4. to return the samples to SC DNR.

## Methods and Materials

The alcohol preservative in sample jars were decanted, specimens were separated according to subgenera then individuals were identified using Bouchard (1978), Hobbs (1981), Cooper (2001, 2004a, b), Eversole and Jones (2004), and Cooper and Price (2010). Specimens were identified to species if possible, while a genus or "cf." species epithet was used for those individuals not identified to species.

Samples that proved difficult were re-evaluated a second and on some occasions a third time. Named individuals were sexed, staged and recorded before returning to collection jars. The number of form I males, form II males, adult females, ovigerous females, juvenile males, juvenile females and unsexed juveniles were recorded for each taxa. Each taxa in a collection was provided an unique spread sheet entry (row) per collection event (number).

Collection events with crayfish identified to species and geo-located collection sites were merged to existing crayfish distribution data (A. Eversole and J. Foltz, unpublished data). Species distribution maps were generated using ArcGIS 10 software program and stored in jpeg files.

## Results and Discussion

Crayfish were collected from all 46 South Carolina counties and one site in North Carolina. Data from North Carolina collection is not summarized in this report. Collections were not evenly distributed across the state, some counties are

represented with a disproportionate number of samples (e.g., Aiken, Bamberg, Colleton, Greenville, Laurens, and Orangeburg counties) while other counties were poorly represented in the overall collection (e.g., Beaufort, McCormick, Union, and Williamsburg counties). Selected watercourses also appear to have been sampled more frequently than other water courses (e.g., Salkehatchie and Little Salkehatchie rivers). Eversole and Foltz (2012) spatial analysis of the historic crayfish collection records indicate that collections are clumped in those counties adjacent to research institutions and survey localities (e.g., Francis Marion National Forest). The uneven survey effort underscores the need for a state-wide crayfish survey.

A total of 2,883 crayfish specimens were contained in the 406 collection jars (Table 1). Nearly all the collections were made in wadeable waterways; the exceptions include specimens from a burrow, two fish stomachs and an aquaculture facility. The collections varied considerably in specimen composition and condition, in some cases limiting species identification. Crayfish identification to species for some taxa relied on collecting adult (large) specimens, particularly mature (form I) males (Hobbs 1981). Unfortunately adult crayfish comprised only 40.5% of the samples of which only 9.5% were form I males. The other adults in the collection were form II males (11.0%), and females (20.0%). A small percentage of the adult females (3.6%) were ovigerous or had attached early instars. Small crayfish classified as juveniles (59.5%) were frequently too small using existing diagnostic characters to identify beyond genus. A higher percentage of specimen species identifications have resulted if a selective sampling protocol for larger mature individuals was used.

Three of the five genera known to occur in South Carolina were encountered in the collection. Specimens in *Procambarus*, *Cambarus* and *Fallicambarus* accounted for 52.8%, 47.1% and < 0.1% of the samples, respectively. *Faxonella*

and none of the four species of *Distocambarus* were collected. The distocambarids, the most terrestrial of our crayfish species (Welch and Eversole 2006), are unlikely to be collected while electrofishing wadeable streams (Welch and Eversole 2006). Also the probability of collecting *Faxonella* and any *Distocambarus* species is less because of their restricted distributions (Welch and Eversole 2006, Eversole and Welch 2010, Eversole and Foltz 2012).

Of the 26 species encountered 14 species were *Procambarus*, 11 species *Cambarus*, and one species a *Fallicambarus*. The most frequently identified species *P. troglodytes*, *P. hirsutus*, *P. echinatus*, *C. latimanus*, and *C. acuminatus* occurred in 21.8%, 16.9%, 6.8%, 8.8%, and 7.9% of the samples, respectively. The exotic *P. clarkii* was encountered in three samples. Eleven South Carolina crayfish species were not represented in the collections. In addition to the five species in *Distocambarus* and *Faxonella* genera, representatives of *P. barbatus*, *P. pearsei*, *C. nodosus*, *C. carolinus*, *C. diogenes*, and *C. reduncus* were not collected. Seven of these species are primary burrowers therefore are less likely to be collected sampling fish in wadeable streams (Welch and Eversole 2006, Eversole and Welch 2010). The distocambarids and some of these other species have restricted distributions, e.g., *D. youngineri* occurs only in a few locations in one county (Eversole and Welch 2010). The probability of a random encounter of limited range species is less than those species found across broader landscape patches and another reason why a fish survey failed to collect representatives of the state's crayfish.

Spatial distribution of 4000<sup>+</sup> South Carolina crayfish museum and collection records is displayed in Figure 1. Crayfish identified to species collected at geo-referenced locations in this study added 6.8% to the total state-wide distribution records. Maps of all 38 described species in the state are displayed in Figures 2 – 39. The crayfish found in the state include seven endemic species, all the

distocambarid species, *P. echinatus*, *P. hirsutus*, and *P. lepidodactylus* (Figs. 17-20, 30, 31, 35) and one introduced species, *P. clarkii* (Fig. 39). *Cambarus latimanus* and *P. troglodytes* were the two widest distributed species while the four *Distocambarus* species have the narrowest distributions (Figs. 4, 17-20, 38). Most of the records of *Cambarus* were from above the fall line whereas *Procambarus* records occurred mostly below the fall line; the exceptions include the primary burrowers *C. diogenes* and *C. reflexus* (Figs. 5, 11), and the stream dwelling *P. raneyi* and *P. spiculifer* (Figs. 36, 37 ). Crayfish species restricted to single river systems or watershed units were *C. chaugaensis*, *C. nodosus*, *C. spicatus*, and *P. echinatus* (Figs. 10, 13, 14, 35).

The recent updated Comprehensive Wildlife Conservation Strategy of South Carolina (A. Smith, SC DNR, personal communication) indicates seven species listed as “highest priority” and three species as “high priority” conservation species. These two conservation categories include all four of the *Distocambarus* species (Figs. 17-20), four *Cambarus* species (Figs. 5, 9, 13, 14) and two *Procambarus* species (Figs. 27, 35). In addition to having limited ranges, these priority conservation species occupy specific habitats - e.g., *P. chaugaensis* occur in high gradient good water streams in the Blue Ridge ecological zone, and *D. youngineri* burrows in those soils with a seasonal perched water table within the species’ range (Eversole and Welch 2010). Species with more specialized habitat requirements and narrower ranges are at more risk and buffered less than those widely distributed generalist species. The conservation status of the newly described *C. hobbsorum* and *C. aldermanorum* has yet to be determined; however, recent distribution records suggest that a priority ranking may be necessary (Figs. 15, 16).

## Recommendations

It is clear from the work on this project many research opportunities exist for crayfish identification and distribution in the state. Historic distribution records indicate disproportionate sampling of the state crayfish fauna, both across the landscape and taxonomic groups which a state-wide survey would help remedy. Furthermore, a state-wide survey would provide an opportunity to examine the distributional limits of conservation priority species and those species with disjunct distribution patterns (e.g., Fig. 22). A state crayfish survey would help flush out the distribution records necessary for the conservation status assessment of the newly described species. A survey targeted for crayfish would also increase the probability of collecting specimens living in specialized habitat (e.g., terrestrial burrows) and increase the number of collected mature crayfish. Recommended are survey records that include detailed descriptions of specimen color and precise site locations for improved species identification and the spatial coverage of the state's crayfish fauna.

In addition to a comprehensive crayfish survey, there is a need to address several taxonomic issues – e.g., the occurrence of two species complexes and at least one species undescribed species in the state (Jones 2012). Also there are two newly described species found in the state and a species resembling the description for *C. howardi* by Hobbs (1981) and species "A" by Cooper (2004a). Although species descriptions and clarification of species complexes are long term research objectives, an immediate need is a workable key for South Carolina crayfish fauna. The recommended initial step is revision of Eversole and Jones (2014) key with updated species content and distribution ranges. Alternative recommendation instead of a comprehensive state-wide key is a series of river drainage based keys which are more user friendly for the casual crayfish

enthusiast. In either case, the content of SC DNR crayfish web site should also be considered at this time, new information added and expanded to include interactive features (e.g., links from species to distribution maps).

### Acknowledgments

My thanks go to Cathy Marion and Jeremy Pike for their help with the ArcGIS program, to John Crane for geo-locating some missing collection localities and to Jim Bulak for securing project funding. Finally, of course, my sincere thanks are extended to Jeff Foltz and all those undergraduates involved in the development of the first version of South Carolina crayfish maps.
