INTRODUCTION

Microalgae are primary producers in the ocean where millions of species are distributed. This extensive biological resource produce 20 billion tons of organic matter annually. Thus, related studies have a long historical background. Early microalgae work was limited to basic studies on the natural science related to the ecosystem. However, studies on artificial culture started in Europe beginning in the mid-19th century. Small-scale culture was started by Cohn (1850) in a German laboratory and developed into outdoor mass cultures for the purpose of industrial applications in the mid-20th century. Microalgae are now widely used as study subjects in marine basic science, as educational resources for students, and as diverse industrial materials.

Microalgae culture has a long history as live food for shellfish farming (Allen and Nelson 1910, Loosanoff and Davis 1963). However, full-scale commercial culture was developed mostly as mass culture to utilize algae as a functional food material (e.g., mass culture of *Chlorella vulgaris* as a dietary supplement in Japan and Taiwan in the 1960s, mass culture of *Spirulina platensis*, *Dunaliella salina*, and *Haematococcus pluvialis* for pigment and β-carotene (astaxanthin) production in USA, Israel, Australia, China, and Thailand after the 1980s, and commercial mass culture of heterotrophic algae (*Cryptothecodinium cohnii*) to produce eicosapentaenoic acid, which is a highly unsaturated fatty acid, after the 1990s (Borowitzka 2014).

However, microalgae are now widely used in diverse industries such as neutraceuticals, cosmetics, the environment, and bioenergy. Moreover, microalgae exhibit promising potential to be converted into high value medicines and pharmaceutical products. Thus, studies on microalgae are ongoing with tremendous expectations by scientists (Borowitzka and Borowitzka 1988, Becker 1994, Cohen 1999, Richmond 2004). Although mass cultures of microalgae remain expensive and have not been industrialized, commercialization of a number of higher value-added biological industries is expected in the near future.

Microalgae culture collections became an important study project when many countries competed to collect useful biological resources after conclusion of the UN Convention on Biological Diversity in 1992. The first microalgae culture collection in the world was established by Chodat (1928) in Geneva, Switzerland and by Pringsheim (1928) at German University in Prague, Czech Republic. Since then, Pringsheim founded the large Culture Center of Algae and Protozoa (CCAP) at Cambridge University in England and Sammlung von Algenkulturen (SAG) at Göttingen University, Germany with the same strains in 1953 (Tompkins et al. 1995, Preisig and Anderson 2005). CCAP is now operated by the Scottish Association for Marine Science at Oban. The Culture Collection of Algae at the University of Texas at Austin (UTEX) in USA (Starr and

Zeikus 1993) and Provasoli-Guillard National Center for Culture of Marine Phytoplankton (CCMP) were established and developed in the USA (Andersen et al. 1997). The Culture Collection established at Indiana University, Bloomington in 1953 moved to UTEX in 1976 (Starr 1964). CCMP started at Woods Hole Oceanographic Institution but was transferred to Biglow Laboratory for Ocean Sciences, Maine in 1981 and was renamed the Provasoli-Guillard National Center for Marine Algae and Microbiota in 2011. Studies on *Chlorella* culture in Japan were conducted actively in the early 1950s, Tamiya (1956, 1966) developed synchronous culture to advance experiments in algal physiology. In addition, the National Institute for Environmental Studies (NIES) has been actively culturing microalgae since the 1980s (Kasai et al. 2009). Large and small microalgae collections in many countries, such as the Freshwater Algae Culture Collection at the Institute of Hydrobiology (FACHB) in Wuhan, China and the CSIRO Microalgae Culture Collection (CSIRO 1996) in Australia are being operated.

History of microalgae culture in Korea

Studies on microalgae culture in Korea began at the end of the 1960s to utilize algae as live food in aquaculture. Some microalgal species such as *Chaetoceros calcitrans*, *Cyclotella nana*, *Phaeodactylum tricornutum*, *Isochrysis galbana*, and *Pavlova lutheri* were obtained from Japanese institutions and tested for bivalve larvae culture in the laboratory (Yoo 1968, 1969, 1970). Isolation of microalgae from Korean coastal waters began in 1983

at the Department of Marine Bio-materials and Aquaculture, Pukyong National University. The initial purpose of this work was to collect microalgae for larval culture in a hatchery. Subsequently, a culture collection of 117 marine microalgal strains was reported (Hur 1992).

The culture industry of marine invertebrates and fish has developed in Korea since the 1980s. Therefore, many studies on the development of live food for artificial seedling production in hatcheries have been conducted. Chlorophyceae (*Chlorella* and *Nannochloris*), Prasinophyceae (*Tetraselmis*), and Eustigmatophyceae (*Nannochloropsis*) have been used mostly for rotifer mass cultures in marine fish larval rearing (Lee and Hur 2009, Bae and Hur 2011, Kim and Hur 2013). Haptophyceae (*Isochrysis* and *Pavlova*), non-adhesive Bacillariophyceae (*Chaetoceros*, *Thalassiosira*, and *Phaeodactylum*), and Chlorophyceae (*Dunaliella*) have been used for shellfish farming (Hur et al. 2005, Youn and Hur 2009), and adhesive Bacillariophyceae (*Navicula*, *Nitzschia*, *Caloneis*, *Rhaponies*, and *Amphora*) have been developed for abalone farming (Ko and Hur 2011, Kim et al. 2013). Daesang Co., Ltd has cultivated freshwater heterotrophic *C. vulgaris* since 1999 and sold dietary supplements. In addition, concentrated marine *Nannochloropsis oceanica* was developed as a rotifer mass culture (Park and Hur 1996), and freshwater concentrated *Chlorella* produced by Daesang Co., Ltd. has been used extensively. After the 1990s, harmful red tide algae, such as *Cochlodinium polykrikoides* and *Heterosigma akashiwo*, bloomed on a large scale on the Korean coast, and studies on toxic Dinophyceae and Raphidophyceae became active (Jeong et al. 2013, Lee et al. 2013).

KMMCC, Korea Marine Microalgae Culture Center.

In 1995, the Korea Marine Microalgae Culture Center (KMMCC) was established with financial support from the National Research Foundation of Korea in the Department of Marine Bio-materials and Aquaculture, Pukyung National University (at the Institute of Fisheries Sciences located at Dongbacksum in Busan). The microalgae strain collection has been increasing continuously since 1995 and reached about 1,200 strains in 2004. The KMMCC moved from Dongbacksum to the Daeyun Campus of the university in September 2004. The KMMCC microalgal collection was first published in 2008, with about 1,400 strains since establishment of the KMMCC in 1995 (Hur 2008). In 2008, the another culture collection (the Culture Collection of Useful Marine Plankton, CCUMP) was established in the same laboratory with financial support from the Korea Institute of Marine Science & Technology Promotion (KIMST), Ministry of Oceans and Fisheries, and useful zooplankton have also been collected for studies. Useful zooplankton including Ciliata, Rotifera, Branchiopoda, Cladocera, and Copepoda, which are widely used as live animal food for fish larval culture or as test organisms in ecotoxicology, are cultivated.

Information of the KMMCC strains

The KMMCC is currently cultivating 2,219 microalgae strains of 690 species, 233 genera, and eight phyla (Table 1). About 80% of the strains are marine and 4% and 16% are brackish water and freshwater microalgae, respectively. Among all microalgae at the KMMCC, the proportion of species collected in foreign seas and obtained from foreign culture collections are 5% and 4%, respectively. These include Bacillariophyceae (53%), Chlorophyceae (18%), Dinophyceae (8%), Cyanophyceae (6%), Prasinophyceae (4%), Eustigmatophyceae (3%), Haptophyceae (2%), Cryptophyceae (2%), Raphidophyceae (1%), Euglenophyceae (1%), Chrysophyceae (1%), and Rhodophyceae (1%). Approximately 54% of all strains are classified at the species level, and 4% of the strains are classified at the class level. The phylogenetic positions of very small or not clearly classified strains is investigated through DNA base sequence (generally 18S rRNA, *rbcL*, or internal transcribed spacer [ITS]) analysis to confirm taxonomic position. Base sequences of 42% of the microalgae have been analyzed and are used as taxonomic reference data. Although assigning the correct taxonomical position to the strains has always been our primary concern, many difficulties exist in identifying them. The numbers of axenic and cryopreserved strains are about 48% and 49%, respectively, of all strains in the collection.

The microalgae of 223 genera of the KMMCC strains are shown on Figs 1-9 in alphabetical order.

The initial direction of the KMMCC focused on finding microalgae species that had a good dietary value for aquacultured larvae. However, recent work has shifted to collecting a wider range of diverse microalgae that are taxonomically different, screening useful microalgae strains, and effectively managing the strains. The demand for strains in research fields has been expanding from the aquaculture industry to neutraceutical, environmental, chemical, and biological engineering. Annual domestic orders for algae from educational, academic, and industrial organizations have increased to nearly 300 requests for as many as 400 strains. Information on each strain includes sampling information (date, location, habitat, sampling method, sampler, temperature, salinity, and depth), registration information (isolator, isolation method, date, and identifier), culture information (media, axenic or xeric, temperature, salinity illumination intensity, photoperiod, cryopreservation, and subculture interval), biological and chemical information (image, size, DNA sequence, nutritional composition), and other information (deposit, purchase, patent strains, specific characteristics, references, etc). This information is available to researchers.

Deposition

Making a deposit of a newly isolated microalgae strain in the KMMCC is always possible if the depositor agrees to distribute the strain to other researchers. The KMMCC accepts strains that are valuable additions. The strain should be free from any legal limitations and in a clonal or unicellular state (axenic strains are preferable). The deposition should include information regarding sampling, identification, culture, and other information that may be of value. All deposited strains will be given a KMMCC registration number and will be available to the public. The final decision of which strains are deposited belongs to the KMMCC. The KMMCC bears no responsibility for any loss or inevitable change during maintenance. Contact the KMMCC through our website (<http://www.kmmcc.re.kr>) to deposit a strain.

Information for ordering and service

KMMCC cultures are available to any individual or academic or commercial organizations in Korea. Orders for cultures are accepted by e-mail, fax, through the website, or in person. Purchasers are welcome to search the

The cost per culture is 30,000 Korean won for non-profit organizations (universities and governmental institutions), whereas commercial organizations such as aquaculture farms and private companies are charged 60,000 Korean won. If the strain is contaminated with another species or has died, the purchaser can request a

new order. The KMMCC can supply autoclaved medium for culture, gDNA, and detailed database information. If the purchaser requires a mass culture >15 mL, an axenic strain on agar, or a cryopreserved strain, the KMMCC requires 2-4 weeks before parcelling out the strain. The KMMCC provides several special services when time allows, including teaching culture techniques, consulting, mass culture, and cell harvesting. Detailed information on ordering and special services is self-explanatory at the web site (<http://www.kmmcc.re.kr>).

CULTURE TECHNIQUES

Isolation, purification, and registration

Microalgae species sampled from nature are isolated to a single cell using single or multiple techniques of capillary pipette, agar streak, serial dilutions, or photo-taxis. Monospecific algae are usually purified by successive sonication, washing, and streaking on agar combined with antibiotic treatment. The kind and concentration of antibiotic treatment are different for different algal strains. There are three strain types, including, a type unable to adhere, a type able to weakly adhere, and a type able to adhere well to agar medium and grow (see Fig. 10A-C). The types unable to adhere, such as *Chaetoceros*, *Thalassiosira*, and *Skeletonema* of Central Bacillariophyceae, require aseptic culture in liquid medium, and 500-2,000 ppm penicillin or penicillin + streptomycin + chloramphenicol is effective. Less adhesive Haptophyceae, such as *Isochrysis* and *Pavlova*, and most Dinophyceae, such as *Amphidinium*, *Gymnodinium*, and *Scripsilla*, are aseptically treated in liquid medium and then mixed with agar medium in a 1 : 1 ratio for culture. Thus, an axenic culture can be kept for a long time. Antibiotic treatment in liquid medium is 500-2,000 ppm neomycin, gentamicin, or dihydrostreptomycin used alone.

Microalgae that grow well in agar are classified into a clear colony type and a widespread spreading colony type (see Fig. 10D & E). The colony type is classified into a round shape, a mucous round shape, and an irregular shape. Pennales Bacillariophyceae, such as *Phaeodactylum* and *Nitzschia*, and Chlorophyceae, such as *Chlorella* and *Nannochloris*, have a typical round shape. In this case, 500-2,000 ppm penicillin is added to liquid medium followed by centrifugation (about 8,000 rpm, 5-10 min) before streaking on agar medium. This results in a clean colony suitable for axenic culture. Chlorophyceae, such as *Botryococcus*, *Synechococcus*, and *Chlamydomonas*, form a round shape colony with mucilage. In this case, penicillin, streptomycin, and chloramphenicol are mixed at 500-2,000 ppm and centrifugation (5,000 rpm, 5 min) is performed. Then, it is streaked on antibiotic-supplemented agar medium prepared by the same method resulting in a relatively uncontaminated colony. In addition, Bacillariophyceae, such as *Achnanthes*, and Cyanophyceae, such as *Trichodesmium*, form an irregular shaped colony. In this case, 500-2,000 ppm penicillin is added to liquid medium and streaked on agar medium resulting in an uncontaminated irregular shape colony.

The widespread spreading colony type, which is not

clearly divided, is classified into a thin shape, a filamentous shape, and a corrugated wave shape. The thin shape includes highly adhesive Pennales Bacillariophyceae, such as *Amphora* and *Navicula*, and 500-2,000 ppm penicillin is added to agar medium. The filamentous shape typically includes spiral Cyanophyceae, such as *Oscillatoria* and *Spirulina*. In this case, 500-2,000 ppm chloramphenicol is used before streaking on agar medium. The wave shape includes Pennales Bacillariophyceae, such as *Cylindrotheca*, and penicillin, streptomycin, and chloramphenicol are mixed at 500-2,000 ppm and added to agar medium just before streaking to obtain an aseptic colony.

An axenic culture can be easily set-up for Chlorophyceae, Cyanophyceae, and adhesive Bacillariophyceae but these cultures are difficult with Dinophyceae and Central Bacillariophyceae. Penicillin, streptomycin, and chloramphenicol are appropriate for Chlorophyceae and Cyanophyceae. Mixed antibiotics are not used for Dinophyceae, and streptomycin or chloramphenicol alone is also not suitable. Penicillin, streptomycin, and chloramphenicol are appropriate for Bacillariophyceae. In general, axenic treatment with antibiotics is more effective in Pennales compared to that in Central Bacillariophyceae. A freshwater microalgae axenic culture is easier to prepare than that of seawater, whereas an axenic culture of non-mucous microalgae with thick cell walls and a smooth surface is much easier. An axenic culture is generally confirmed by microbiological methods. Organic matter, which help bacteria grow, such as broth, yeast extract, peptone and tryptone, are added alone or together to culture media at a concentration of 1-2% (w/v). Then, the culture is incubated in an optimal environment to confirm whether the axenic culture is successful or not.

Unialgal strains are maintained in liquid medium. A newly isolated strain would be subcultured in a 100 mL of Erlenmeyer flask for several months so a monospecific state can be confirmed. The strain is identified through morphology and DNA sequencing (18s rRNA and then *rbcL* and ITS). A taxonomist is used occasionally for a more detailed identification. If the identification is uncertain, it is classified into the unidentified group. Then, the unialgal or axenic strain is registered on a culture list with sampling, culture, and other information. Optimal growth conditions for culturing each strain are maintained by incubators.

Subculture

When new microalgae strains are isolated and regis-

tered on the culture list, they are maintained by continuous subculture. All strains in stable culture after registration are placed in a constant temperature and humidity controlled room. Species are preserved in liquid culture, solid agar culture, and by cryopreservation. To prepare a subculture, 100 mL of fresh medium is decanted into a 250 mL Erlenmeyer flask. The inocula for a subculture is approximately 5-10% depending on culture cell density, and cultivation is performed at constant temperature (15°C, 18°C, 20°C or 23°C) and humidity (45%). Photosynthetic photon flux density (PPFD) is 20-100 μmol photons m⁻² s⁻¹, depending on the microalgae and the light : dark (LD) cycle is 10 L : 14 D. Adhesive Bacillariophyceae are cultivated under low intensity illumination and Chlorophyceae is cultured under high intensity illumination. Microalgae in a standing culture are shaken once per week, and their growth state is monitored visually. The subculture cycle is generally 6 months for Chlorophyceae, 3 months for adhesive Bacillariophyceae, 2 months for non-adhesive Bacillariophyceae, 1 month for Dinophyceae, and 2-3 months for other species. A subculture is performed once every 1-6 months depending on the species; 60 mL of fresh medium is added to 90 mL of the remaining original culture after a subculture and stored in another constant temperature (15°C) and humidity (45%) room with illumination intensity of 5-10 PPFD and a 10 L : 14 D LD cycle. The objective is to be able to prepare a newly inoculated culture strain that dies during subculture and to supply vendors. After three subcultures, the oldest subculture strain stored in the 15°C room is discarded.

Agar medium alone or agar medium with liquid medium is used for agar cultures. Agar medium alone is used for the strongly adhesive Bacillariophyceae, Chlorophyceae, and Cyanophyceae. The same volume of liquid medium is added to agar medium for the slightly adhesive Dinophyceae and Haptophyceae. Ten milliliters of agar medium or 5 mL agar medium plus 5 mL liquid medium is placed in a 20 mL test tube for agar culture. It is incubated in the constant temperature (20°C) and humidity (45%) room with an illumination intensity of 20-60 PPFD, and an LD cycle of 10 L : 14 D. Agar cultures are subcultured every 4-6 months depending on the strain. Two agar cultures are subcultured for each strain. After inoculation in an agar subculture, the original agar culture is transferred to and stored in a room with 10-20 PPFD illumination intensity. When three subcultures have been performed, the oldest culture strain is destroyed by sterilization.

Low temperature incubators are used when cultures must be kept at <15 or >23°C. Light intensity and photoperiod are controlled in temperature-fixed rooms to

maintain the subculture long as possible. Illumination intensity may differ depending on the location in the same culture room. In general, Chlorophyceae and Cyanophyceae do well under high intensity illumination and are placed on the upper shelf, whereas adhesive Bacillariophyceae are safe in lower intensity and are placed on the lower shelf, which is somewhat dark. Dinophyceae, which require higher intensity illumination, are cultured separately in a brighter location. The subculture cycle of each strain is entered into a computer and the inoculation strain list for that month is printed out on the first week of every month to prevent subculture errors. Different media are tested at the initial isolation, and a suitable medium is chosen for the strain. However, we prefer a simple medium for preparation such as Erdschreiber, f/2, Jaworski's medium (JM), soil agar, or LDM medium to maintain a culture stock. New liquid medium is added to an old agar culture for subcultures.

Cryopreservation

Cryopreservation of microalgae in liquid nitrogen (N₂ gas, -192°C) facilitates long-term storage of living cells without genetic transformation and can economically and safely store many species for a long time. In particular, the greatest advantage of cryopreservation is that cells can be safely preserved in liquid nitrogen even in time of emergency, such as a blackout when temperature cannot be controlled. However, it cannot be applied to all microalgal species because of low viability during cryopreservation due to vitrification inside the cell during freezing, toxicity of the cryoprotective agent added to prevent vitrification, and destruction of essential cell nutrients. Optimal cryopreservation conditions differ highly depending on the species. However, small microalgae with a thick cell wall and a simple external shape (e.g., Chlorophyceae, such as *Chlorella* and *Nannochloropsis*; Eustigmatophyceae, such as *Nannochloropsis*; and Cyanophyceae, such as *Synechococcus* and *Oscillatoria*) have higher viability after thawing, whereas physiologically sensitive Dinophyceae, large microalgae with high water content, and microalgae with a complicated shape and thin cell walls have much lower viability after thawing. In addition, freshwater and brackish microalgae have higher viability, whereas marine microalgae, particularly open-sea microalgae, tend to have lower viability (Youn and Hur 2009).

Different cryoprotective agents are used depending on the type of microalgae. A 5-15% proportion of cryoprotective agent such as dimethylsulfoxide (DMSO),

methanol, or glycerol are generally added. Slow freezing using a machine that controls freezing rate (controlled-rate freezer) results in higher viability after thawing, compared to rapid freezing. The cryoprotective agent is added for slow freezing, and then cells are slowly frozen at -1°C per min up to -40°C before being stored in liquid nitrogen (-196°C). A lower rate (-0.5°C min⁻¹) may improve viability but is time-consuming; therefore, -1°C per min is applied first. Frozen microalgae are thawed and inoculated in liquid medium. The microalgae is fully cultured in an optimal culture environment to confirm viability. The amount stored in liquid nitrogen is small; therefore, the inocula are also small after thawing. The cultures have a long lag phase and take time to enter the log phase of growth. In addition, there is high possibility of contamination or death during that period; therefore, the optimal culture environment is well maintained.

Cryopreservation methods at the KMMCC (see Fig. 10F-H) involve 1.8 mL cultured cells in the log phase contained in a 2 mL cryotube and 5-10% DMSO, methanol, or glycerol as a cryoprotective agent added to the culture medium, depending on the species. The cells are stored at room temperature for 10 min and then slowly frozen in a controlled-rate freezer (SY-LAB, Vienna, Austria) from 20°C to -40°C at -1°C min⁻¹ before being immediately stored in a liquid nitrogen container (-196°C). Ten samples per strain are cryopreserved; five are used for permanent preservation and the other five are used or tested for supply to vendors. Cryopreserved microalgae (1.8 mL) are thawed in a water bath at 35°C and inoculated into 10 mL culture medium in a 20 mL test tube. They are cultured under optimal conditions, and cell density is measured to confirm growth. The growth rate differs according to the species; therefore, slowly growing species are cultured for about 4 weeks before confirming viability. The freezing rate of species that fail to survive under cryopreservation is adjusted to -0.5°C min⁻¹, and the type and concentration of cryoprotective agent are altered for retesting.

About 49% of the microalgae at the KMMCC are cryopreserved, including freshwater microalgae (9%), brackish microalgae (2%), and marine microalgae (38%). With regard to taxonomic division, Bacillariophyceae (19%), Chlorophyceae (15.7%), Cyanophyceae (4.5%), Prasinophyceae (4.5%), Haptophyceae (0.3%), Dinophyceae (0.2%), and others (4.7%) are cryopreserved. The type and concentration of optimal cryoprotective agent, freezing rate, and thawing method according to species with low viability is investigated by reducing water content and by drying cells before freezing to develop an appropriate freezing method for each species.

Management of strains in 2D barcode system

When the number of strains stored in the bank is small, it is easy to manage. However, if the number increases, an accurate management system is required because strains require different culture conditions and a diverse database of sampling, registration, deposition, subculture, distribution, and other references related to each strain must be well managed. Therefore, a database of all strains stored in the bank requires a barcode system to protect information and to manage it systematically. Information related to each strain at the KMMCC is systematically managed by a 2D bar code system and updated regularly (see Fig. 10I).

CULTURE MEDIA

Preparation of media

Media are classified into marine, freshwater, and estuarine according to salinity. Seawater sampling is performed by the Institute of Fisheries Sciences, Pukyong National University in front of the coast at Dongbaek-ri, Ilgwang-myeon, Gijang-gun, Busan, Korea for the marine media. This seawater is usually 32-33 psu despite differences depending on season. Seawater is collected through an intake pump and is filtered by a sand filter. The seawater for microalgae cultures is first filtered and transferred to a 300 L plastic container with a plastic bag installed. This container is closed with a lid and stored in cool, dark underground storage. This seawater is used all year round. The water is re-filtered through a µm cartridge, filter screen, or filter paper before preparing the media. Seawater is not sampled in summer due to high water temperature and red tides. Seawater filtered through the sand filter is occasionally stored after passing it through an ultraviolet sterilizer.

Natural uncontaminated water is sampled from rivers or reservoir and filtered before use to prepare media for freshwater microalgae. Tap water sits for at least 1 day to remove chlorine before use in subculture media after registration. Tap water is convenient to use and is rarely contaminated but it is not appropriate for difficult to cultivate or sensitive species. In this case, the underground freshwater is used. Marine media and freshwater media are mixed in a 1 : 1 ratio to make estuarine media of about 16 psu, and various salinities can be prepared depending on the ratio. Bay salt is dissolved in distilled water to make brine water and then added to prepare high-salinity me-

dia for species isolated from a salt farm. Media are mostly prepared using a stock solution. The stock solution can be stored and used for about 6 months; therefore, 500-1,000-fold higher concentrations of reagents for each element are added to the media. It is dissolved in distilled water, sterilized, and stored in a refrigerator before use. A brown container is filled with a stock solution and closed with a stopper to prevent evaporation. It is fully shaken before use.

Soil water

Inorganic nutrients alone do not provide for complete growth; therefore, soil water is often added to media (Pringsheim 1912). Soil water is effective to cultivate microalgae for a long time rather than for short-term growth. Therefore, it is suitable for long-term microalgae storage, such as a microalgae bank. Fertile leaf mold, which is uncontaminated with chemical fertilizer, agricultural pesticides, or insecticides, is collected and sieved. Then, 1 L soil is mixed with 1-2 L distilled water and boiled. After sedimentation, the supernatant is filtered. Three g NaOH is added to dissolve the soil organic matter (Droop 1969). After autoclaving the soil water, it is stored in a brown reagent bottle to protect from sunlight and stored in a refrigerator. The soil water is added at up to 5% of media. The prepared soil water can become contaminated with bacteria during preservation; therefore, it is not stored for more than 6 months. Soil water at the KMMCC is used to prepare media such as Erdschreiber (Føyn 1934), MB3N (Brown and Bold 1964), 2X-SW (Rosowski and Parker 1971), soil extract agar (Starr 1978), and SES (Biagini et al. 1998).

Sterilization

Media are autoclaved. Media mixed with nutrient salt reagents are transferred to a culture container, and the container is closed with a stopper before sterilization. A silitop is used for flask cultures and a screw cap is used for test tubes. If a cotton stopper is used, it is wrapped with aluminum foil or parchment paper to protect it from water before sterilization. The aluminum foil or screw cap covers the top loosely to allow steam to escape. Sterilization is performed in an autoclave at 15 lb in⁻² pressure and 121°C for 15-30 min. The autoclaving duration is about 15 min for ≤100 mL culture media in containers and 30 min for ≥2 L culture media. However, reagents (especially, heavy metals) often settle due to the high temperature and pressure of an autoclave. In this case, each reagent

is separately sterilized and aseptically mixed at a clean bench before use. If the microalgae do not grow well in the autoclaved media, the media are boiled in a pressure cooker at 100°C and cooled before being boiled the following day. This process is repeated three times to prepare sterilized media. This method is mostly used when species are first isolated.

List of media

The media to maintain the culture strains are not always the best for optimum growth. To reduce work preparing media, nutritional components and the variety of media used for the collection need to be simplified. An alphabetical list of the culture media and stock solutions used at the KMMCC are presented below.

Agar media

In general, 1.5% agar medium is widely used; 15 g of bactor-agar is dissolved in 1 L of liquid medium, dispensed, and autoclaved in glass tubes as agar slants or autoclaved and dispensed aseptically for Petri dishes.

Explanatory notes on the information of the strain

The strains are listed in alphabetical order by their scientific names with their synonyms. Strains with the same scientific name are arranged in order of the strain number. Strains that have not been identified are listed by class at the end of the list. In the previous KMMCC culture list, the strain numbers were classified by the taxonomic class and sampling habitat as freshwater or estuary (Hur 2008); however, all strains are now identified using a KMMCC number. The previous number of the strain is also recorded as the original number in the strain data. A detailed example of a strain description is as follows:

3) Scientific name with nomenclator.

4) Synonym(s).

5) KMMCC registration number.

6) Source: Strains from other collections or institutions are presented with the original strain number and deposit or receipt year in parentheses. Acronyms placed before strain numbers refer to the following culture collections and institutions:

CCAP: Culture Collection of Algae and Protozoa, UK

CCMP: The Provasoli-Guillard National Center for Culture of Marine Phytoplankton of the National Center for Marine Algae and Microbiota, USA

KIOST: Korea Institute of Ocean Science and Technology (formerly Korea Ocean Research and Development Institute), Korea

NFRDI: National Fisheries Research and Development Institute, Korea

UTEX: The Culture Collection of Algae, University of

Texas at Austin, USA

- 7) Sampling: Sampling information is categorized by date, locality, habitat, material, water temperature and salinity. Inland sampling locality in the order of place / Korean province. Korean coastal waters are divided into West Sea, South Sea, and East Sea. The official name of the sea is recorded for others. Korean island is written with "do". Longitude and latitude of the sampling location are recorded in parentheses. The sampling area habitat is subcategorized as freshwater, marine and brackish. Fresh water is divided into river, stream, reservoir, lake, pond, or swamp. Marine habitat is divided into salt farm, hatchery, intertidal zone, coast, open sea, high sea, or deep sea. Brackish habitats are mainly estuaries including tidal pools and lagoons. Habitats, except the temperate zone, are also divided into subtropical and tropical. Sampling material is categorized as water, mud, and substratum. The sampling water was mainly surface water (0-20 m in depth). Otherwise, it is further classified as middle water (20-100 m), bottom water (100-300 m), or deep water (>300 m). Water temperature and salinity (psu) at sampling time are also shown.
- 8) Isolator: Isolator's name in the order of family name and first name with the registered date in parenthesis.
- 9) Identifier: The person who determined the scientific name in the order of family name and first name.
- 10) State: The state of the culture strain indicating whether or not they are axenic, and the maintenance method such as liquid, agar, liquid + agar, or cryopreserved. All strains in the list are in a unicellular state.
- 11) Culture: Culture information includes media, temperature, salinity, photosynthetic photon flux density (PPFD, $\mu\text{mol photons m}^{-2} \text{s}^{-1}$), light : dark cycle, and subculture interval in months (M).
- 12) Size (μm): Range of diameters (\varnothing) or length for round, regular square, or triangle forms, and range of length (L) and width (W) for rectangular or elliptical forms. The length of flagella or chaeta was not measured.
- 13) Gene data: Gene names such as 18s rRNA, *rbcL* and ITS with accession numbers in parenthesis, if available.
- 14) Original number: The original strain number is recorded with the initials of sampling habitat and class of species. Strains isolated from estuaries including other brackish water and freshwater are abbreviated with E and F, respectively. A strain without an abbreviation of sampling habitat indicates marine habitat as its place of origin. The strains are also classified into classes such as B (Bacillariophyceae), C (Chlo-

rophyceae), Cr (Cryptophyceae), Ch (Crysophyceae), Cy (Cyanophyceae), D (Dinophyceae), Eu (Euglenophyceae), Eus (Eustigmatophyceae), H (Haptophyceae), P (Prasinophyceae), Ra (Raphidophyceae), Rh (Rhodophyceae), etc.

- 15) References number(s): Publications in which the strain was used as a material. The number corresponds to the publication in the strain reference list.
16) Remarks: Notes for ordering, such as patents, low or high temperature species, salt water, aquaculture, high protein or lipid, EPA, astaxanthin, β -carotene, toxic, etc.
