

## Supplementary material

Appendix S1. Description of the forest types examined (adapted from Veloso et al. 1991). Veloso's classification is hierarchical. Accordingly, each of the four coarse-level forest types can have two or more fine-level forest types. A general description of the four widely recognized coarse level forest types is given in the first paragraph of the description column. The subsequent paragraphs describe the twelve fine-level forest used in our study.

Coarse-level forest type	Description
Seasonally semi-deciduous forest	<p>A vegetation type comprised of macro- and mesophanerophytes, as well as lianas and epiphytes, Characterized by a tropical dry season when the forest becomes 20–50% deciduous. Within Amazonia this is a climatic transition between rain forest and savanna. Four structural/environmental subtypes are recognized based on altitude: floodplain, lowland, submontane and montane.</p> <p><b>Fine-level forest type adopted:</b>            Seasonally dry submontane semideciduous forest (Fs): in tropical areas, typically dominated by mesophanerophytes on dystrophic soils derived from sandstone; in sub-tropical (non-Amazonian) climate, macrophanerophytes dominate on eutrophic soils derived from basalts.</p>
Vegetation on white sand	<p>Vegetation type found only in Amazonia, predominantly in the middle and upper Negro River Basin. Disjunct patches are found to the north of this area along the Branco River, and to the west in the upper reaches of the Japura, Solimões and Juruá Rivers, penetrating into Colombia and Venezuela. Woody vegetation has a spindly aspect [in the more open subtypes], with the edaphic climax being shrubby woodland or an open mixture of grassy and woody elements. Commonly found in low-lying waterlogged areas with hydromorphic podzols or hydromorphic quartz sand. Includes several endemic genera. Confined to a single climate type which is hot and extremely humid. Average temperature is 25°C and annual precipitation exceeds 3000 mm.</p> <p><b>Fine-level forest type adopted:</b>            Forest on white sand (LO): Subgroup of the white-sand formation; found on seasonally and partially inundated peniplains; locally known as tall campinarana or campina forest; resembles riparian forest on white sand; usually has characteristic dominant tree genera with thin trunks and light-colored bark forming dense stands of about 15 m height mixed with a few trees of up to 20 m; leaves evergreen and mostly sclerophyllous.</p>

Dense rain forest	<p>Vegetation type of northern Brazil comprised mostly of macro and mesophanerophytes, as well as lianas and epiphytes; climate is hot and humid, a biologically dry season nearly absent; annual precipitation exceeds 2300 mm and average annual temperature is 22–25°C. In Amazonia these forest types cover the vast Northern Depression, a large part of the Amazonas-Orinoco High Plateau north of Roraima and almost all of the Central Amazon Depression, including most of the states of Pará, Amazonas and Roraima. Physiognomy varies with altitude and lithology, being divided into four main phytophysiognomies (floodplain, lowland, submontane and montane) and two floristic formations, based on the presence or absence of emergent trees.</p> <p><b>Fine-level forest types adopted:</b></p> <p>Dense rain forest on river floodplains with emergent trees (Dae): a forest formation found on recently deposited fine sediments of alluvial plains and terraces along rivers. In the Amazon two local types are called várzea forest (seasonally flooded) and igapó forest (permanently flooded). [In other classification systems várzea forest is seasonally inundated by muddy rivers and igapó is seasonally inundated by clear- and black-water rivers.] Fast-growing tree species predominate [in várzea forests], bark is smooth and many trunks have stilt-roots or buttresses. Large emergent trees could be observed in this forest.</p> <p>Dense rain forest on river floodplains without emergent trees (Dau): as same as Dae, but without emergent trees.</p> <p>Lowland dense rain forest with emergent trees (Dbe): a formation which is found mainly on the [clay-rich] plio-pleistocene sediments of the Barreiras Group, forming low plateaus of up to 100 m a.s.l. This is the typical lush rain forest of Amazonia with many large emergent trees.</p> <p>Submontane dense rain forest with emergent trees (Dse): a formation found on the piedmonts of highlands and mountains, ca 100–600 m a.s.l. Trees of more uniform height, rarely exceeding 30 m, sometimes with a few emergents and with few nanophanerophytes or chamaephytes. Large emergent trees could be observed in this forest.</p> <p>Submontane dense rain forest without emergent trees (Ds): as same as Dse, but without emergent trees.</p>
Open rain forest	<p>A vegetation type still located in the rainy portion of Amazonia, but having a brief dry season (2–3 months) and dominated by either large palms, scandent bamboos, lianas or the giant herb <i>Phenakospermum</i>. Located south of the main Amazon valley in a transition zone, between dense rain forest and seasonally semi-deciduous forest. To the north this forest type is found in a mosaic of small scattered inclusions within the dense forest, for example, between the Trombetas and Jari Rivers or in the southwest portion of Roraima State. Previously this was called a “climatic transition zone”. Forest structure varies with altitude and lithology, having five main divisions (floodplain, lowland, submontane, montane and high-montane).</p> <p><b>Fine-level forest types adopted:</b></p> <p>Open rain forest on floodplains with palms (Aap): forests found on recently deposited fine sediments of alluvial plains and terraces along rivers. Seasonally or permanently flooded versions are respectively várzea or igapó forests [but see alternative definitions of these two terms above]. Patches with high density of palms are common.</p> <p>Open lowland rain forest with palms (Abp): a formation found on well drained [clay-rich] sediments of terraces, plains or low plateaus, ca 5–100 m a.s.l., with subtypes dominated by large palms.</p> <p>Open lowland rain forest with bamboos (Abb): a formation found on well drained [clay-rich] sediments of terraces, plains or low plateaus, ca 5–100 m a.s.l., with subtypes dominated by bamboos.</p> <p>Open submontane rain forest with palms (Asp): located ca 100–600 m a.s.l. and dominated by large palms.</p> <p>Open submontane rain forest with vines (Asc): located ca 100–600 m a.s.l. and dominated by lianas.</p>

Appendix S2. Families, common-name equivalents of included morpho-species, relative abundance and frequency of presence of the 272 large-tree genera found in the 1,184 RADAMBRASIL inventories.

Family	Genus	Common names	Included morpho-species	Relative abundance (% of all trees)	Frequency of presence (% of all inventories)
Anacardiaceae	<i>Anacardium</i>	caju, caju-açu, caju-açu-da-folha-miúda, cajuí, cajuí-da-folha-miúda, cajuí-da-terra-firme, caju-do-campo, cajutim, tauari, uixirana, guariuva, sucupirana-brava, fava-folha-fina	17	0.447	50.7

Appendix S3. Geographic distribution of the twelve forest types in the Brazilian Amazon. See Table 1 for full names. Within-type beta diversity is the number of half-changes:  $\beta_d = (\log(1 - \text{average internal dissimilarity})/\log 0.5)$ . Colors show overall floristic change across all 1196 inventories from all twelve types, using a single-axis ordination (as in Fig. 2A). This one map was then “clipped” to the extent of each forest type.

Appendix S4. Relation between number of samples for each of the 66 pairwise combinations of forest types and the floristic separation between the two types (see Fig. 4 for separation details). Widespread forest types had more samples and showed poor floristic separation. About half of forest-type pairs exceed  $R^2$  value of 0.09, considered to be floristically well separated (see text). For most of these pairs, one or both forest types were geographically restricted, thus had few inventories. Each letter represents one of twelve forest types compared. A = Aap; B = Abb; C = Abp; D = Asc; E = Asp; F = Dae; G = Dau; H = Dbe; I = Dse; J = Dsu; K = LO; L = Fs. See Table 1 and Appendix S2 for forest type codes and descriptions.

Appendix S5. Floristic similarity between sample pairs within each forest type, as a function of geographic distance. Tick marks on the x-axis are 500 km intervals. The coefficient “ $b$ ” refers to inclination of regression lines. See Table 1 and Appendix S2 for forest type codes and descriptions.

Appendix S6. Floristic trend of large canopy trees (interpolated scores of the 296 samples in a single-axis NMDS ordination) in Brazilian Amazon. For details see the full article.
