Prize Lectures and Biographical Notes

European Journal of Endocrinology Prize Winner

The *European Journal of Endocrinology* Prize is awarded to a candidate who has contributed significantly to the advancement of knowledge in the field of endocrinology through publication. This year's recipient is Dr Miguel Lopez who will receive his prize and deliver his lecture as part of the ECE 2017 Opening Ceremony on Saturday 20 May 2017. Further information on the prize can be found at http://www.ese-hormones.org/prizes/.

Dr. Miguel López received his PhD in Molecular Biology (2002) from the University of Santiago de Compostela (USC, Spain) and made his postdoctoral training (2002–2006) in the Department of Clinical Biochemistry in the University of Cambridge (UK). Currently, Dr. Miguel López is Associate Professor in Department of Physiology at the School of Medicine and the Research Centre of Molecular Medicine and Chronic Diseases (CIMUS) of USC. Since the beginning of his PhD, he has focussed his research on the regulation of energy balance and obesity, with his current interest on hypothalamic energy sensors in the modulation of energy balance and metabolism. He has published around 150 peer-reviewed papers. He currently serves on the editorial board of *Endocronology, Journal of Molecular Endocrinology, Molecular Metabolism, Journal of Endocrinology*, several *Frontiers journals* and *PLoS ONE*, and as a reviewer for several international biomedical journals and funding agencies. For his work in this area, Dr. López received the awards for Basic Research in Obesity from *Spanish Endocrinology and Nutrition Society* (*SEEN*, 2006 and 2009) and the *Spanish Society for the Study of Obesity* (*SEEDO*, 2009), *Spanish Award on Neuroendocrinology* (2012), as well as the *European Association for the Study of Obesity* (*EASO*) Young Investigator Award for Basic Science (2008; first Spanish citizen to be awarded with that price) and the *European Journal of Endocrinology Prize* for the *European Society of Endocrinology* (2017). He has been PI of 12 national and international grants, among them an *ERC Starting Grant*. He teaches Endocrinology in the Schools of Medicine and Pharmacy of USC. He has supervised 14 Master Thesis and 10 PhD Thesis.

EJE1

Hypothalmic AMPK: a golden target against obesity?

Miguel López
Spain.

AMP-activated protein kinase (AMPK) is a cellular gauge that is activated under conditions of low energy, increasing energy production and reducing energy waste. Centrally, the AMPK pathway is a canonical route regulating energy homeostasis, by integrating peripheral signals, such as hormones and metabolites, with neuronal networks. Current evidence links hypothalamic AMPK with feeding, brown adipose tissue (BAT) thermogenesis and browning of white adipose tissue (WAT), as well as muscle metabolism, hepatic function and glucose homeostasis. The relevance of these data is interesting from a therapeutic point of view since several agents with potential anti-obesity and/or antidiabetic effects, some currently in clinical use, such as nicotine, metformin and liraglutide are known to act through AMPK, either peripherally or centrally. Furthermore, the orexigenic and weight-gaining effects of the worldwide use of antipsychotic drugs, such as olanzapine, are also mediated by hypothalamic AMPK. Overall, this evidence makes hypothalamic AMPK signaling an interesting target for drug development, with its potential for controlling both sides of the energy balance equation, namely feeding and energy expenditure via defined metabolic pathways.

Geoffrey Harris Prize Winner

The prestigious Geoffrey Harris Prize is awarded to an established researcher in the field of neuroendocrinology and is the first of its kind in Europe. This years recipient is Professor Matthias Tschöp who will receive his prize and deliver his lecture as part of the ECE 2017 Opening Ceremony on Saturday 20 May 2017. Further information on the prize can be found at http://www.ese-hormones.org/prizes/.

Professor Matthias H. Tschöp received his M.D. from Ludwig-Maximilians Universität in Munich, where he also trained as a physician in internal medicine. In 1998 he accepted an invitation for a postdoctoral fellowship at the Eli Lilly Research Laboratories in Indianapolis, USA before returning to Europe in 2002 to establish his independent research laboratory at the German Institute of Human Nutrition (DIfE) Potsdam. He later returned to the United States where he joined the University of Cincinnati to ultimately serve as the Director of the Diabetes and Obesity Center of Excellence and Arthur Russell Morgan Endowed Chair of Medicine. In 2011 Prof. Tschöp accepted the position as Scientific Director of the Helmholtz Diabetes Center at Helmholtz Center München and was named Chair of the Division of Metabolic Diseases at Technische Universität München. Prof. Tschöp is the first German physician to receive the prestigious Alexander-von-Humboldt Professorship (2012). He was elected into the German National Academy of Science (Leopoldina) in 2013 and one year later was named adjunct Professor at Yale University, USA. He started the peer-reviewed open access journal Molecular Metabolism, which he leads as the Editor-in-Chief (first impact factor 2016: 5.4). In 2016 Matthias Tschöp received an honorary doctorate of the University of Leipzig and was named Director for Biomedicine of the Helmholtz Pioneer Campus in Munich, which he co-founded.

The Geoffrey Harris Prize Lecture

GH1

Toward hormone-based precision medicines for metabolic diseases

Matthias Tschöp
Germany.

After decades of research unraveling complex metabolic control networks, medicines capable of a safe reversal of morbid human obesity and type 2 diabetes are still not available. Historically, complex diseases have repeatedly proven to be defiant to the best mono-therapeutic approaches. Several examples of combination therapies have largely overcome such challenges, notably for the treatment of severe hypertension and tuberculosis. Obesity and its consequences, such as type 2 diabetes, have proven to be equally resistant to therapeutic approaches based on single medicines. Appropriate management of type 2 diabetes often requires adjunctive medications, and the recent registration of a few compound mixtures has set the precedent for combinatorial treatment of obesity. On the other hand, double or triple therapeutic combinations are more difficult to advance to regulatory approval. Following an improved understanding of the molecular basis for metabolic benefits following bariatric surgery interventions, several classes of novel unimolecular or independent combination therapeutics were discovered. These new classes of drug candidates are based on gastrointestinal hormones, offer efficacy superior to currently prescribed options and seem to have potential to fully reverse human obesity and type 2 diabetes. Moreover, gut peptide-based cell-specific targeted delivery of small molecules offer additional potential for novel metabolic precision medicines and reduced systemic side effects. In this presentation the discovery, pre-clinical validation and first clinical test of peptide hormone poly-agonist drug candidates as well as of combinatorial single molecule therapeutic candidates will be summarized, including previously unpublished observations.

European Hormone Medal Lecture

The European Hormone Medal is awarded to an international scientist who has made significant contributions to the field of basic or clinical endocrinology. This year's recipient is Professor Evi Diamanti-Kandarakis who will receive her prize and give her lecture as part of the European Congress of Endocrinology (ECE), beginning on the 20th May. Further information on the prize can be found at http://www.ese-hormones.org/prizes/.

Dr. Evanthia Diamanti-Kandarakis is professor of Internal Medicine-Endocrinology & Metabolism and Chairman of the Endocrine Department of Euroclinic Athens. She received her MD from Medical School of Athens and her PhD in experimental Endocrinology on the effects of androgens in hypophysectomised rats, from the same University. She was trained in Internal Medicine in England (1974–1980), and in Endocrinology-Diabetes, Metabolism & Obesity in USA (1980–1986). Her research interests have focused for the last 25 years on clinical, molecular and environmental aspects of metabolic & hormonal abnormalities in obesity Diabetes and Polycystic ovarian syndrome. This work has generated 181 publications and more than 12000 citations, classifying her among the 27 worldwide best Greek scientists and the first Greek woman endocrinologist with the greatest international contribution. In 2016 she has received the award of the best teacher in endocrinology in Greece. Dr. Diamanti-Kandarakis has been invited by the international academic community as a speaker and Tutor and has given more than 250 lectures, in Europe, Asia, Africa, North & South America.

European Hormone Medal Lecture

EHM1

Endocrine disruptors: Is it all Greek to us?

Evi Diamanti-Kandarakis

The main achievement at present, on Endocrine-Disruptors (EDCs) effects on human health and disease development, is that it becomes a less ≪of a foreign language≫ issue. The widespread distribution of environmental chemicals in the atmosphere and the detection of these substances within human body, converge to the concept that humans are continually exposed to EDCs. This presentation will focus on the possible role of the most common and studied environmental toxins in female reproductive disorders and especially in PCOS. Exposure to endocrine disrupting chemicals (EDCs) such as plasticizers, bisphenol A (BPA) or phthalates, and food toxins like advanced glycation end products (AGEs), which may affect women's health in everyday, industrialized life, will be discussed. Acute or prolonged exposure to EDCs and AGEs may result in destabilization of the hormonal and metabolic homeostasis and lead to disruption of reproductive functions in females. Strategies and strong recommendations should be considered to protect present and future generations from their adverse health effects. Understandably, Rachel Carson, said in an international language: 'In nature nothing exists alone.'

DOI: 10.1530/endoabs.49.EHM1

Clinical Endocrinology Trust Lecture

The Clinical Endocrinology Trust (CET) Award is given for clinical research that addresses aspects of endocrinology at the forefront of clinical practice. This year's recipient is Professor Renato Pasquali who will receive his prize and give his lecture as part of the European Congress of Endocrinology (ECE), beginning on the 20th May. The award is sponsored by the Clinical Endocrinology Trust and further information can be found at http://www.ese-hormones.org/prizes/.

Renato Pasquali is full professor of Endocrinology at of University Alma Mater Studiorum of Bologna (UNIBO), Italy. In the 90's In 2000 he established the division of Endocrinology in the S. Orsola-Malpighi Hospital of Bologna (who was not present before), and served for a long period of time as Director. In addition, he was director of the School of Specialization in Endocrinology and Metabolism of UNIBO for fifteen years. Its clinical activity has covered over the years, all the major areas of Endocrinology and Metabolic diseases. He is a member of numerous national and international scientific societies and of the editorial boards of international journals. His scientific work was dedicated, in particular, to (i) the pathophysiology and treatment of the polycystic ovary syndrome, and (ii) the endocrinology of obesity (sex hormones, the hypothalamic-pituitary-adrenal axis, and the endocannabinoid system). He has authored 285 original papers and review articles published in international journals (PubMed) (HI 51) and 18 chapters in international textbooks. In particular, he participated as co-author, to the writing group of Clinical Guidelines in "Position" and "Consensus" statements.

Clinical Endocrinology Trust Lecture

CET1

Prospects for a new assessment of polycystic ovarian syndrome

Renato Pasquali
Italy.

PCOS is the most common hyperandrogenic disorder, with a high prevalence of metabolic comorbidities, including obesity and central fat distribution, insulin resistance and the metabolic syndrome. With this background, it should be accepted that androgen excess must be present in all women with PCOS. Thanks to the advance in measuring blood androgen levels by LC-MS/MS, it has become clear that almost all typical cases of PCOS have a variable pattern of androgen excess. An androgen profile including all major androgens should therefore be used for research purposes and clinical practice. The phenotype characterized by menses abnormalities and polycystic ovarian morphology but without androgen excess should be regarded as a separate entity. The presence of a dysmetabolic profile should also be used in the characterization of PCOS, specifically insulin resistance, which is commonly present in obese PCOS women but can also be detected in their normal-weight counterpart. In fact, there is evidence that androgen excess may play a crucial role in disrupting the metabolic pathway, in favouring aberrant visceral fat morphology and function, in favouring the development of insulin resistance and in increasing the susceptibility to develop glucose intolerance states and type 2 diabetes. Hirsutism is common in PCOS, however its correlation with blood androgen levels is weak or absent. Apart from the opportunity to use more objective methodologies to define it, much more research is needed on the potential role of cutaneous androgens. Finally, due to the relevant impact of obesity on PCOS and the fact that in many developed countries most PCOS women are obese, it can be suggested that a secondary form of PCOS related to obesity may exist. The concept of secondary PCOS can be extended to other pathological entities, particularly to the severe insulin resistant states, but also to other endocrinopathies and, finally, to specific drugs (particularly antiepileptics). As with other endocrine syndromes, we should therefore consider that PCOS, precisely because it is a ‘syndrome’, may include many different phenotypes, ranging from the classic to milder forms, and that a secondary PCOS may occur. Additional mild phenotypes without well defined androgen excess may have different pathophysiological mechanisms.

Redefining neuroendocrinology: stress, sex and cognitive and emotional regulation

Bruce McEwan
USA.

Abstract unavailable.

Plenary Lectures

The Fantastical World of Hormones

P1

The fantastical world of hormones

John Wass
USA.

We all know that endocrinology is the most amazing specialty. However although some of the discoveries in the last 3–400 years have been amazing, some of the wrong turns have exhibited opportunism and quackery. Perhaps we should start with testosterone and the effects of castration. We know that removal of the testes before puberty has irreversible affects and that in 16th and 17th centuries these were exploited for music. Popes did not come out of this covered in glory and the last papal castrato was singing in the Sistine Chapel choir in the early 1900s. In the late 1840s Berthold a German physiologist in Göttingen experimented on capons showing that if he removed their testes and transplanted them into the abdomen, where they regained their blood supply, the effects of castration were not seen. He did not recognize the importance of his observation. Later in the late 1880s Brown-Séquard, the famous French neurologist, reported at the French Royal Society injecting himself with a mixture of the bloods from the testes of dogs and guinea pigs. His reported marked improvement in strength and stamina was a placebo effect because of the shorter half-life of testosterone. Thyroxine from sheep given to patients with hypothyroidism, again in the late 1880s had a remarkable effect in women with hypothyroidism because of the longer half-life of thyroxine. In the late 1880s the ovary was thought to be part of the nervous system. Oophorectomy at that time was used to treat conditions in women including hysteria and anorexia and anxiety and even nymphomania. Ernest Starling was the first person to coin the term 'hormone' and 'Ormao' is the Greek word to 'excite or stir up'. This was the founding of endocrinology. We have then gone from strength to strength with the discovery of insulin and more recent leptin, pioneered amongst others by Steve O'Rahilly and Sadaf Farooqi in Cambridge.

DOI: 10.1530/endoabs.49.P1

The Secret Life of FGF21

P2

The secret life of FGF21

David Mangelsdorf
USA.

Fibroblast growth factor 21 (FGF21) is an endocrine and paracrine factor that is produced in many tissues in response to metabolic stress, including several nutrient and dietary conditions. In addition to its physiologic role in regulating the adaptive response to these conditions, pharmacologic administration of FGF21 to obese animals causes weight loss and improves insulin sensitivity. The diverse actions of FGF21 are mediated through a unique receptor complex that is composed of a classic FGF receptor and the novel co-receptor, βeta-Klotho. Investigation of the tissue-specificity of this FGF21 signaling pathway has revealed the existence of a complex peripheral and neural endocrine circuit that regulates metabolism, nutrient preference, and reward behaviors. We have also found an unexpected role for FGF21 in the exocrine pancreas as a secretagogue that protects acinar cells from proteotoxicity.

DOI: 10.1530/endoabs.49.P2

Update on Regulation of Steroidogenesis by Aberrant Hormone Receptors

P3

Update on regulation of steroidogenesis by aberrant hormone receptors

Andre Lacroix
Canada.

The mechanisms regulating cortisol production when ACTH of pituitary origin is suppressed in primary adrenal causes of Cushing's syndrome (CS) include diverse genetic and molecular mechanisms. These can lead either to constitutive activation of the cAMP system and steroidogenesis or to its regulation exerted by the aberrant adrenal expression of several hormone receptors, particularly G-protein coupled hormone receptors (GPCR) and their ligands. Screening for aberrant expression of GPCR in bilateral macronodular adrenal hyperplasia (BMAH) and unilateral adrenal adenomas of patients with overt or subclinical CS demonstrates the frequent co-expression of several aberrant receptors. In addition, the aberrant GPCR can also exert their activity by regulating the paracrine secretion of ACTH or other ligands for those receptors in BMAH or unilateral tumors. The molecular mechanisms underlying the abnormal tissue-specific expression of the aberrant GPCR remains unclear but may be secondary to dedifferentiation of progenitor cells at the origin of hyperplasia or tumors or to specific genetic alterations. The aberrant expression of hormone receptors is not limited to primary adrenal CS but can be implicated in other endocrine tumors including primary aldosteronism (aldosteronoma or bilateral idiopathic hyperaldosteronism) and Cushing's disease. Targeted therapies to block the aberrant receptors or their ligands have been effective in selected limited cases to date, but development of novel specific antagonists could become useful in the future.

The role of brain insulin resistance for the development of prediabetic phenotypes

Hans-Ulrich Häring
Germany.

Abstract Unavailable

Browning of Adipose Tissue and Metabolic Regulation

P5

Browning of adipose tissue and metabolic regulation

Jan Nedergaard
Sweden.

In most countries in the world, an increasing number of people suffer from the metabolic syndrome, normally defined as obesity, high blood sugar, high blood fats and high blood pressure. The new understanding that adult humans possess active brown adipose tissue has led to hope that a (re)activation of this tissue (browning) may be helpful in ameliorating the metabolic syndrome. Brown adipose tissue has the ability to combust (extra) food intake in a direct way, due to the unique presence in this tissue of the UnCoupling-Protein-1 (UCP1). Thus, if activated – normally through the release of norepinephrine from the sympathetic nervous system – the tissue will burn away food energy, leaving only heat, water and CO_2. Thus, it protects against the development of obesity. When the tissue is chronically activated, the stored lipid reserves in the tissue will not suffice for continued heat production, and the tissue will take up large amounts of sugar from the circulation, through a unique adrenergic mechanism, leading to lowering of blood sugar levels through a large glucose disposal. It will similarly activate the synthesis of lipoprotein lipase, leading in parallel to a large increase in lipid uptake from the circulation, diminishing blood triglyceride levels. During prolonged stimulation, the constant burning of food in the tissue will lead to the mobilization of the body's lipid reserves (the white adipose tissue) that will be broken down and the released fatty acids will be transported to the brown adipose tissue for combustion, i.e. the brown adipose tissue is slimming (and all these effects together will likely also result in lowering of blood pressure). Although the acute activity of the tissue is determined by norepinephrine, it would seem that sex hormones (positively) and glucocorticoids (negatively) can affect the tissue. The tendency to a worsening of the metabolic syndrome with age could then partly be explained by a diminished sex hormone stimulation and an unaltered but increasingly dominating negative effect of glucocorticoids, together leading to brown adipose tissue inactivity, and thus to obesity.

DOI: 10.1530/endoabs.49.P5

Thyroid Oncology in the Crossroads of Precision and Narrative Medicine

P6

Thyroid oncology in the crossroads of precision and narrative medicine

Manuel Sobrinho Simões
Portugal.

Thyroid cancers are the solid tumours of mankind with the lowest mutational load. This holds particularly true for papillary carcinomas (PTC) whose pathogenesis appears to be understandable by a limited number of genetic alterations (That is why they are so frequently multifocal). The utilization of NGS allowed the establishment of three molecular subtypes of well differentiated thyroid carcinomas: BRAF-life (Conventional and tall cell PTC, mainly), RAS-like (Follicular variant PTC and follicular carcinoma) and No BRAF/No RAS. Precision medicine is playing a major role in thyroid oncology but its shortcomings are becoming evident. Somatic copy number alterations play also a role in some tumour subtypes and, furthermore, one is progressively aware of the important role played by host factors: Stromal reaction (including extracellular matrix characteristics, subsets of fibroblasts and degree of desmoplasia), 'social' RNAs, immune cells, hormones, growth factors. The data brought in by the latter narrative medicine approach is turning easier the diagnosis and treatment of thyroid cancer patients.

Symposia

Clinical Updates in Hypoparathyroidism

S1.1

Congenital hypoparathyroidism

Agnes Linglart
France.

The most common causes of hypoparathyroidism in children are the lack of or the impaired development of the parathyroid glands due to genetic/chromosomal alterations and the abnormal signaling of the $Ca(^{2+})$-sensing receptor (CaSR). The latter refers to autosomal dominant hypocalcemia (ADH) mainly caused by heterozygous activating mutations in CASR encoding CaSR (ADH type 1), and exceptionally caused by activating mutations of GNA11 encoding the Gq/11 protein (ADH type 2). Hypoparathyroidism can also be caused by an autoimmune process, mainly in the context of AIRE mutations. However, in many children, the origin of the hypoparathyroidism remains undiscovered. In a recent national French survey gathering 142 children affected with hypoparathyroidism performed by MAC, 43% of the patients were diagnosed before the age of 1 year. The main causes of the PTH insufficiency were 22q1.1 deletion (31%), ADH1 (13%), AIRE mutations (10%) and cervical surgery (7%). The etiology is still unknown in 23% of the children. Due to the high calcium needs of the skeleton during infancy and childhood, hypoparathyroidism in children is often symptomatic and is diagnosed because of the clinical symptoms of hypocalcemia (muscle spasms, laryngospasm, seizures). Children may present with unspecific features such as cognitive and or motor delay, slowness, ungueal, dental and skin anomalies. In addition, clinical characteristics due to the disease itself causing the hypoparathyroidism may be present such as candidosis, conotruncal cardiac defect, renal and/or uterine malformation. Once hypoparathyroidism has been diagnosed in a child, a comprehensive work-up should be performed to identify the disease-causing defect. The investigations depends on the age of the child (neonate, child, adolescent), and on the clinical features associated with the hypocalcemia. The diagnosis is of importance for the management of follow-up and treatment. The management of hypoparathyroidism in children relies upon calcium supplements and vitamin D analogs. Following the initial period of profound hypocalcemia which may require IV infusion of calcium and high doses of vitamin D analogs (up to 4 μg/day of alfacalcidol), the conventional therapy should aim at absence of clinical symptoms, low-normal level of serum calcium (2–2.2 mmol/l), avoiding hyperphosphatemia and having normal urinary calcium excretion. In some children, this may be a challenging management requiring the use of thiazide diuretics, phosphate binders, calcium supplements and in refractory cases, recombinant PTH. It has become obvious in the past ten years that we need to i- obtain more data on the long-term evolution of children affected with hypoparathyroidism, ii- adjust our decision rules for the identification of the cause of hypoparathyroidism in the context of next generation sequencing and gene panels or whole exome sequencing, and iii- develop guidelines for the management of hypoparathyroidism in children including the specificity of ADH.

DOI: 10.1530/endoabs.49.S1.1

S1.2

Acquired hypoparathyroidism

Fadil Hannan
Uk.

Hypoparathyroidism is characterized by absent or low circulating concentrations of parathyroid hormone (PTH), which results in hypocalcaemia, hyperphosphataemia and impaired renal reabsorption of calcium. Hypoparathyroidism has a prevalence of ~20–40 cases per 100 000 individuals, and anterior neck surgery accounts for around 75% of cases. Postsurgical hypoparathyroidism may arise in patients undergoing total thyroidectomy, radical neck dissection for head and neck malignancies, and after total parathyroidectomy. Hypoparathyroidism following surgery is caused by intraoperative trauma, and inadvertent gland removal or devascularisation. Transient postsurgical hypoparathyroidism, defined as lasting <6 months, affects 25–30% of patients following total thyroidectomy; whilst permanent postsurgical hypoparathyroidism, defined as lasting >6 months, affects up to 3% of patients after total thyroidectomy. Decreases in pre-operative serum calcium and 25-hydroxyvitamin D concentrations, reduced intraoperative PTH concentrations, and longer duration of surgery represent independent predictors of transient hypoparathyroidism. Permanent hypoparathyroidism following thyroid surgery is associated with: inability to identify ≥ 2 parathyroid glands during surgery; hypocalcaemia at 24-h post-surgery; and reoperation for bleeding. Occasionally, postsurgical hypoparathyroidism may have a delayed-onset and present several years after neck surgery. Autoimmune-mediated destruction of the parathyroids represents the next most common cause of acquired hypoparathyroidism and is considered in patients with a personal or family history of autoimmune diseases. Autoimmune acquired hypoparathyroidism may be associated with the presence of anti-parathyroid gland antibodies, and some patients harbor antibodies against the calcium-sensing receptor (CaSR). Acquired hypoparathyroidism may also be caused by hypomagnesaemia, which impairs PTH secretion; and can rarely be due to exposure to ionizing radiation, or result from infiltrative diseases affecting the parathyroids such as metastases or iron/copper overload.

Clinical updates in hypoparathyroisism

Erik Fink Eriksen
Norway.

The spectrum of symptoms associated with hypoparathyroidism span from virtually none to severely debilitating fatigue, memory loss, muscle cramps, and paresthesia. Until recently disease management has focused on securing stable serum calcium values at the lower end of the reference range using potent active vitamin D analogues like Etalpha and Rocaltrol, together with calcium supplementation. Recently maintenance of adequate levels of 25(OH)D have also been mentioned as being important. Adequate intracellular magnesium levels seem to be pivotal for PTH secretion and action at the receptor level, and should therefore be kept at the upper end of the normal range if possible. It is one few endocrine diseases where supplementation of missing hormone was impossible about 10 years ago. Now we have access to recombinant PTH(1-34) and PTH(1-84), and I will review the potential use of and differences between these analogues in the treatment of hypoparathyroidism. In terms of symptomatic relief the results of controlled studies using these analogues as sc. injections have been disappointing. A more physiological pattern can be achieved with continuous subcutaneous infusion using insulin pumps, and I will review the results obtained with this technique so far.

Evolving Diagnostics in Adrenal and Neuroendocrine Tumours

S2.1

Role of genetic and biomarker tests for diagnosis of neuroendocrine tumours (NETs)

Raj Thakker
UK.

Neuroendocrine tumours (NETs) are a heterogeneous group of neoplasms that occur in different organs and give rise to tumours including carcinoids, pancreatic tumours (PNETs), pituitary adenomas, medullary thyroid carcinoma, and phaeochromocytomas. NETs usually occur as isolated non-familial tumours, but can also occur as hereditary and syndromic disorders, such as multiple endocrine neoplasia (MEN types 1–4), Von Hippel Lindau (VHL) and phaeochromocytoma/paraganglioma. Patients with NETs such as PNETs that do not secrete hormones (referred to as non-secreting or non-functioning PNETs) are often asymptomatic, and this may result in late diagnosis and presentation with metastases. Thus, there is an unmet need for new, reliable and specific biomarkers for early diagnosis that would improve patient survival and quality of life. Biomarkers, which are defined by the World Health Organisation as a substance, structure or process that can be measured in the body or its products and influence or predict the incidence of outcome or disease, for non-secreting NETs include pancreatic polypeptide, chromogranins, carcinoembryonic antigen, α-foetoprotein, neuron specific enolase and synaptophysin. However, these current biomarkers have poor sensitivity and specificity for non-secreting NETs thereby limiting their use for clinical decision making. Recently, detection of germline mutations of the *MEN1* and *VHL* genes have been established as useful predictive biomarkers for the development of PNETs in families with these disorders. However, such familial mutations account for only approximately 3% of NETs. Additional biomarker development has also focussed on studying altered expression of the epigenome, transcriptome, proteinome and metabolome, as well as circulating DNA, microRNAs and tumour cells that can be released from tumours into the vasculature. These advances will be reviewed. Dr Kate E Lines, Dr Mark Stevenson & Professor Rajesh V Thakker.

Current status in morphological imaging in adrenal and gastrointestinal neuroendocrine tumours

Sundin Anders
Sweden.

Computed Tomography (CT) constitutes the basic technique for imaging of adrenal tumours and neuroendocrine tumours (NETs). The major work-load in adrenal imaging is characterisation of adrenal incidentalomas, i.e. adrenal tumours diagnosed on imaging performed for other reasons than adrenal disease. Myelolipomas, which have a typical appearance with areas of macroscopic fat, and simple cysts are easy to characterize and require no follow-up. Morphologically benign adrenal tumours (rounded, sharply delineated, homogenous internal structure) with an attenuation of $\leq$10HU in the native CT images are characterized as benign adrenocortical adenomas and require no additional imaging. With an attenuation $\geq$10HU, follow-up of tumour size is recommended for 6 months. In young ($<$40 years) patients this should preferably be performed by MRI. Calculation of contrast medium wash-out is no longer applied. For tumours $>$4 cm surgical resection is recommended unless in cases of a typical myelolipoma or cyst. CT is for NETs used for the initial localization of the primary tumour, for staging of the disease, detection of recurrence and for monitoring of therapy. It is also used in hybrid imaging in conjunction with PET (PET/CT) and SPECT (SPECT/CT). MRI is superior for imaging of liver, pancreas, brain and bone. In metastatic NETs, 68Ga-DOTA-somatostatin analogue PET/CT generally shows several additional lesions as compared to CT/MRI and small lesions such as lymph nodes may be characterized as metastatic/not metastatic lesions. Contrast-enhanced US is excellent for diagnosis and characterization of liver lesions and to guide the biopsy needle for the histopathological NET diagnosis. Endoscopic US is the best method for detection of pancreatic NETs.

From the Pituitary to the Periphery

S3.1

Implication of the prolactin receptor in humans

Nadine Binart
France.

While prolactin (PRL) is known as the pituitary hormone of lactation, accumulating evidence shows that PRL acts on many tissues and in many pathophysiological conditions. The major isoform, 23 kDa PRL, acts via a membrane receptor, the prolactin receptor (PRL-R), a member of the hematopoietic cytokine superfamily, and for which the mechanism of activation has been elucidated. The aim of this symposium is to present and discuss data supporting actions of PRL in hyperprolactinemia in the context of gonadotropic deficiency. High levels of PRL in humans may interfere with reproductive function mainly by actions at the hypothalamus. Our data suggest that Kisspeptin neurons appear to be the missing link between hyperprolactinemia and GnRH deficiency. Otherwise, germline *PRLR* mutations have been suspected to be a specific genetic cause of prolactinoma in humans. This will be discussed in light of our recent results.

Somatostatin receptors: news in the pituitary, lessons for the periphery

Justo Pastor Castaño
Spain.

The pituitary has been classically considered the 'Master Gland', owing to its ability to regulate the function of the other endocrine glands of the body. However, the hypophysis also served over the years as a master, guiding example to enlighten multiple fields of experimental biology and medicine, from classic physiology to modern cell biology, biochemistry and molecular biology. Somatostatin and its receptors (sst1-5) comprise a classic regulatory system, initially discovered and characterized at the hypothalamo-pituitary interface, which subsequently expanded to influence multiple bodily functions, from neurotransmission to digestive function and metabolic homeostasis, and also tumour biology. In this scenario, our group discovered an aberrantly spliced variant of sst5, sst5TMD4, which lacks 3 of the typical 7 transmembrane domains of GPCRs, but retains unique functional abilities and tisular and subcellular distribution. Initial studies revealed sst5TMD4 overexpression in pituitary tumors, particularly in acromegaly, where its presence is associated to a reduced response to somatostatin analogues, both *in vitro* and *in vivo*, and is linked to enhanced aggressiveness features, such as cell proliferation *in vitro* and tumor invasion *in vivo*. These findings led us to explore the possible presence and activity of sst5TMD4 in other hormone-related tumors. Interestingly, a series of collaborative studies demonstrated that this truncated receptor is overexpressed in multiple tumors and cancers, including, so far, breast cancer, pancreatic neuroendocrine tumors, poorly differentiated thyroid cancer, medullary thyroid carcinoma, and prostate cancer. In these pathologies, studies on patient samples and clinical features, an on tumor-derived primary cells or model cell lines have demonstrated that sst5TMD4 presence is directly linked to enhanced aggressiveness features, such as increased cell proliferation, migration and invasion, hormonal secretion, etc. Further analysis on the molecular underpinnings of these observed features have revealed a number of activated oncogenic or inactivated tumor-suppressing pathways and molecular players, some of which seem to be shared by most tumor types studied, whereas others seem to be unique for a given type of tumor/cancer. These results, coupled to our observation that other misspliced variants related to pituitary pathophysiology (namely, In1-grelin and GHS-R1b) are also present in the same tumors prompted us to study the splicing machinery. Of note, ongoing studies have revealed that the splicing machinery is dysregulated in these pathologies. Thus, the pituitary served, once again, to pave the way to scientific discovery for the periphery.

2nd Joint Global Symposium on Obesity – The Many Dimensions of the Childhood Obesity Problem

S4.1

Efficacy and effectiveness of physical activity and nutrition interventions in childhood obesity treatment

Hollie Raynor
USA.

While several organizations have recommended that multicomponent, behavioral family-based programs delivered at a moderate- to high-intensity contact frequency have a moderate to high rating of efficacy for improving weight status in children, these types of programs are difficult to translate into many practice-based settings. This presentation will review areas that have been identified within childhood obesity treatment programs that may assist with translation to practice-based settings, and discuss research that has been conducted that examine these factors. An example of a current randomized trial translating a multi-component,

behavioral family-based program into an integrated primary care setting in the USA will be provided.

S4.3

Can we prevent childhood obesity?

Tim Lobstein
UK.

Childhood obesity prevalence continues at a high level in most developed economies and is rising strongly in emerging middle-income countries. This rise in prevalence shows strong links to the exposure of populations to mass-marketed foods and beverages and the use of motorised transport. In Europe the prevalence tends to be higher, and rising faster, among children from lower-income households. The prevention of obesity is essential but clearly we are not doing very well – no country in Europe has successfully and sustainably reduced childhood obesity prevalence. We need to ask: What are the major social, commercial and political barriers which need to be overcome? What steps can we take to overcome these barriers and create a truly health-promoting society?

Effects of maternal thyroid function on infant neurodevelopment

Tim Korevaar
The Netherlands.

In this talk I aim to provide a helicopter view of clinical studies on maternal thyroid function and child neurodevelopment and use this to pinpoint out how different viewpoints on the results can help to interpret the clinical relevance of the currently available data and provide handles to make personal but informed clinical decisions. It is well-established that thyroid hormone plays an important role during early stages of fetal brain development. Thyroid hormone-dependent stages of brain development occur from the 5th week of pregnancy onwards while the fetal thyroid is not functionally matured until week 18–20. This implicates that adequate maternal thyroid hormone concentrations are important for achieving optimal early fetal brain development. After the initial link between iodine deficiency and cretinism was first identified, a wide range of experimental studies further established underlying (patho)physiological mechanisms. Subsequently, clinical studies were set-up to translate these findings and quantify the extent of effects in humans. During this presentation I aim take the audience through a brief timeline of clinical studies published since the late 1990s until this year. The interpretation of clinical outcomes used to study the hypothesis that maternal thyroid hormones are important for fetal brain development, such as child IQ, will be discussed. The timeline of clinical studies together with the interpretation of the results of recent studies, including clinical trials, could help to weigh the potential clinical benefits and harms, and make for a better informed decision making.

Vitamin D and rickets in African children

Vickie Braithwaite
UK.

Rickets is the most common non-communicable disease in low and middle income countries and is re-emerging in countries such as the UK where it was once thought to be eradicated. Rickets is a bone disease which affects growing children and is caused by the undermineralisaton of the growth plate of long bones. Rickets can lead to osteomalacia, disabling bone deformities of the lower-limbs, stunting, increased fracture risk and in severe cases circulating bone mineral disturbances can result in hypocalcaemic seizures and death. The majority of nutritional rickets worldwide is thought to be driven by vitamin D deficiency due to inadequate skin exposure to UVB-containing sunshine. In many countries in Africa however, 25-hydroxyvitamin D concentrations (the status marker for vitamin D) are above those generally associated with vitamin D deficiency thus indicating alternative causes of rickets. This presentation will explore some of our work on the role of the vitamin D-calcium-phosphate axis on nutritional rickets in a selection of African countries; highlighting the potential roles of calcium and iron deficiency. This presentation will also explore whether aetiology may differ depending on setting i.e. urban vs rural and the various treatment methods for rickets including surgical correction of bone deformities, nutritional supplementation and prophylactic treatment strategies for rickets prevention.

Carbohydrate metabolism in patients with Cushing disease: a glance at the incretin system

Lubov Matchekhina
Russia.

The relevance of carbohydrate metabolism studying in patients with Cushing disease (CD) and acromegaly can be explained by frequent occurrence of glucose metabolism disturbances on the one hand, and difficulties in glucose-lowering therapy in these patients on the other. The effectiveness of hyperglycaemia treatment may be reduced due to difficulties in remission/cure of the underlying disease, as well as to the use of specific drug-therapy, leading to hyperglycaemia. There is a growing interest in research aimed at studying the role of incretin system in the pathogenesis of secondary hyperglycemia associated with neuroendocrine diseases recently.

Aim of the study

To analyze the rhythm and levels of incretins and neuropeptides secretion in patients with CD and acromegaly and therefore to specify the pathogenesis of carbohydrate metabolism disturbances.

Methods

42 patients with Cushing disease and acromegaly were included; the mean age was 37.5 years. All of the patients were newly diagnosed with Cushing disease (using urinary free cortisol levels, evening saliva cortisol levels and low-dose dexamethasone suppression test) and acromegaly (in absence of GH suppression during OGTT and high IGF1 levels); none of them had a history of previous drug therapy, radiotherapy or pituitary surgery. All patients underwent OGTT, during which glucose, glucagon, GLP1, GLP2, GIP, ghrelin were measured at 0, 30 and 120 min respectively.

Results

During OGTT glucose levels were not significantly different in all groups. The mean HbA1c level was 5.8% (5.3–6.2). However the relevance of prediabetes was higher in CD patients. In CD patients glucagon levels were significantly higher at all cut off points compared to controls ($P=0.001$). In acromegaly patients, no significant differences were found. GIP secretion was slightly lower in CD patients; in acromegaly patients, no differences were found. Acromegaly group was characterized by inverse rhythm of GIP secretion, with no peak level at 30': GIP 0 min – 194.2 pg/ml, GIP 30 min – 178.8 pg/ml. GLP-1 levels were significantly higher in CD patients ($P=0.047$). In acromegaly group, no significant differences in GLP-1 secretion were found. GLP-2 levels were significantly higher in CD patients compared to acromegaly and controls ($P=0.001$). Ghrelin levels were significantly higher in CD ($P=0.013$) and acromegaly ($P=0.023$) patients.

Conclusion

More pleotropic actions of glucocorticoids can possibly explain higher relevance of carbohydrate metabolism disturbances in CD patients. This can be also explained by higher levels of glucagon secretion, which does not depend on type

of carbohydrate metabolism disorder and is stimulated by a direct action of glucocorticoids on glucagon receptor. GIP and GLP-1 secretion in CD and acromegaly patients are characterized by inverse rhythm with no peak levels which means that these hormones are not playing the crucial role in carbohydrate disturbances development in these patients. On the contrary, GLP-2 and ghrelin seem to influence and potentially regulate glucose homeostasis in CD and acromegaly patients.

What is the clinical relevance of deiodinase polymorphisms?

Antonio Bianco
USA.

Abstract unavailable.

S6.2

T4/T3 combination therapy: is there a true effect?

Wilmar Wiersinga
The Netherlands.

L-T4 monotherapy remains the standard treatment of hypothyroidism, as RCTs comparing T4 and T4 + T3 did not indicate superiority of the combination therapy. However, the issue is far from settled, as these RCTs can be criticized and 5–10% of patients on T4 have persistent complaints.
i) Has T4 + T3 therapy a true effect on serum thyroid hormones? Under T4 monotherapy serum FT4 is higher and serum FT3 is lower than in healthy subjects, giving rise to abnormal T3/T4 ratio's in 29% of patients. T4 + T3 therapy produces lower FT4 and higher FT3 values, and thereby T3/T4 ratio's are closer to normal values. There is conflicting data whether T3/T4 ratio's are related to SNPs (e.g. in DIO2) and to persistent complaints.
ii) Has T4 + T3 therapy a true effect on thyroid-hormone dependent actions? There is emerging but weak evidence that markers of thyroid hormone action (such as LDL-cholesterol, SHBG, bone alkaline phosphatase) are closer to normal under T4 + T3 therapy than under T4 monotherapy.
iii) Has T4 + T3 therapy a true effect on the clinical condition? Patients were asked for their preference in 4 RCTs. Preference for T4 was 25% and for T4 + T3 48%; no preference was expressed by 27%. Preference has been related to loss of body weight and to combined SNPs in MCT10 and DIO2.
iv) Has T4 + T3 therapy a true effect on clinical practice? Yes, absolutely. Many patients demand T4 + T3 therapy, sometimes in a aggressive manner. Prescription of T3 tablets have increased, and pharmacy has discovered the potentially big market for T3, among others resulting in a steep price increase of T3 tablets but also in availability of 5 microgram T3 tablets. Only the ETA published detailed guidelines how to start the still experimental T4 + T3 regimen (Eur Thyroid J 2012;1:55). The many unresolved issues call for many more clinical trials.of different designs.

Crosstalk between Bone & Other Organ(ism)s

S7.1

Immune system

Patrizia D'Amelio
Italy.

The immune system has been recognized as one of the most important regulators of bone turnover and its de-regulation is implicated in several bone diseases as post-menopausal osteoporosis and inflammatory bone loss. The study of the relationship between immune system and bone metabolism is generally indicated under the term 'osteoimmunology', the vast majority of these studies have been performed in animal models, however several data have been confirmed also in humans. Post-menopausal osteoporosis (PMO) is the most frequent metabolic skeletal disease, it is characterized by reduced bone mineral density and micro architectural deterioration of bone with increased fracture risk. In PMO the uncoupling between osteoblast (OB)-mediated bone formation and osteoclast (OC)-mediated bone resorption results in bone loss. Estrogen deficiency is the main driver of post-menopausal bone loss: during estrogen depletion OCs formation and activity are increased, this increase is partially mediated trough the effect of estrogen deficiency on immune system. Estrogen deficiency influences immune response, in particular T cells, become more active and able to produce inflammatory and pro-osteoclastogenic cytokines as TNFα and RANKL. Despite of some inverse reports, the main body of literature firmly supports the essential role of activated T cells in regulating bone loss induced by estrogen deficiency, both in animal models and in humans. We recently demonstrated that immune system, and in particular T cells mediate the effect of PTH on bone turnover, in particular we demonstrated that during treatment with teriparatide for PMO T cells mediates osteoblastogenesis trough the production of Wnt10b, whereas primary hyperparathyroidism do not increase this molecule. Moreover we demonstrated that, both in mice and humans, continuous infusion of PTH and primary hyperparathyroidism increases the differentiation of T helper (TH) cells in TH17. These cells are responsible for increased OCs formation and activity both in inflammatory diseases and in PMO. In conclusion The interactions between immune system and bone are complex and play significant role in both health and disease, nevertheless not all the pathways discovered in animal models have been fully demonstrated in humans, and several challenging questions remains unsolved.

Osteocalcin signaling in myofibers is necessary and sufficient to increase exercise capacity

Gerard Karsenty
USA.

The observation that circulating osteocalcin levels double during exercise in young mice suggests that this hormone might be a long sought after endocrine regulator of exercise capacity. We addressed this question by analyzing mice lacking either osteocalcin or its receptor in myofibers only. This analysis showed that osteocalcin signaling in myofibers enhances adaptation to exercise because it increases uptake and utilization of glucose into the tricarboxylic acid cycle and promotes fatty Osteocalcin signaling in myofibers favors adaptation to exercise through a second mechanism. Indeed it up-regulates the expression of Interleukin-6 a myokine that favors adaptation to exercise in part by signaling in bone to promote the production of bioactive osteocalcin. Acids utilization. In the course of these studies we noticed that circulating osteocalcin levels decline sharply before mid-life and do not increase during exercise in older mice. This observation raised the prospect that osteocalcin may also be sufficient to correct the age-related decline in muscle function. In support of this hypothesis, our experiments show that exogenous osteocalcin increases the exercise capacity of young wilt-type mice and confers to 15 month-old mice the exercise capacity of 3 month-old mice. This study uncovers an osteocalcin-interleukin-6 axis that increases muscle function during exercise and can reverse the age-induced decline in exercise capacity.

Gut microbiota and bone metabolism

Klara Sjögren
Sweden.

The gut microbiota (GM), the commensal bacteria living in our intestine, performs numerous useful functions, including modulating host metabolism and immune status. Our recent studies demonstrate that the GM is also a regulator of bone mass and we propose that the effect of the GM on bone mass is mediated via effects on the immune system, which in turn regulates osteoclastogenesis. A role of the GM in bone metabolism is further supported by studies demonstrating that antibiotic, probiotic, and prebiotic treatments that impact GM composition regulate bone metabolism. Collectively, these studies suggest that the GM may be a novel therapeutic target for osteoporosis. Treatment with probiotics has already been shown to improve bone mass in rodent models of bone loss, but future randomized clinical trials are required to determine the possible effect of probiotics and other novel therapies modulating the GM composition on bone mass and fracture risk in patients with osteoporosis. Access to cheaper sequencing and improved bioinformatics tools will allow metagenomic sequencing for the analysis of the GM composition in large prospective clinical cohort studies. This can be used to evaluate the predictive value of the GM composition as a biomarker for low bone mass and fracture risk. In addition, metatranscriptomics and metaproteomics will most likely be used to identify the microbial genes and proteins that have an impact on bone mass and fracture risk. We propose a new cross-disciplinary GM–bone research field called 'osteo-microbiology', bridging the gaps between bone physiology, gastroenterology, immunology, and microbiology. Future studies are clearly warranted in this new research field to determine if the GM composition might be used as a biomarker for fracture risk prediction and to validate the GM as a possible novel therapeutic target for osteoporosis.

S8.2

MRI predictors of therapeutic response in GH-secreting pituitary tumours

Jean Francois Bonneville
Belgium.

The T2-weighted characteristics of GH-secreting pituitary adenomas have recently received particular attention from the research community. It now appears that somatotropinomas can be divided into groups with different behavior according to their T2-weighted signal. T2-hypointense adenomas are generally smaller, invade the cavernous sinus less frequently and are responsible for higher levels of GH-hypersecretion (Fig. 1). Treatment with somatostatin analogues, both before and after surgery, leads to different responses of T2-hypointense adenomas versus non-hypointense tumours. The T2-hypointense adenomas have higher GH and IGF1 decreases and more important tumour shrinkage rates (1). It is therefore interesting to have high quality T2-weighted MRI images at the diagnosis of acromegaly, as it allows to estimate disease evolution and to orient the management strategy.

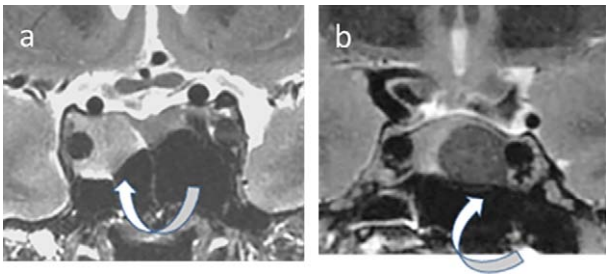

Figure 1 Hyperintense (a) and hypointense (b) GH-secreting adenomas on T2 W MRI.

Predictors of therapeutic response in functioning pituitary tumours

Marek Bolanowski
Poland.

Therapeutic response for medical therapy in hormonally functioning pituitary tumours is different in various types of tumours. While majority of prolactinomas respond well for medical therapy using dopamine agonists, in other tumours like somatotropinoma or corticotropinoma their response is significantly lower. In some case therapy resistance can occur. There are various factors determining the efficacy of medical therapy in patients harboring functioning pituitary adenomas. They are different for certain type of tumour. Among clinical aspects, gender, age and extent of hormonal hypersecretion are important factors. In general, response for the therapy in acromegaly is poor in younger male patients with larger tumours and greater GH hypersecretion. Pituitary imaging using MRI can show tumour size and invasiveness, together with T2 intensity. Histological and molecular analyses assess granulation pattern, somatostatin and dopamine receptors number and expression, Ki-67 index, mitotic activity, p53 immunoreactivity, AIP expression, genetic mutations and polymorphisms. The knowledge of possible factors influencing therapeutic response is important and may be helpful in the choice of optimal individualized therapy.

Novel Type 2 Diabetes Treatment: Beyond Glycaemic Control

S9.1

Experimental models

Jens Holst
Denmark.

One of the most surprising and inspiring experimental models for type 2 diabetes therapy is gastric bypass surgery. Recent 5-year results have demonstrated massive improvements in glycaemic control and body weight, lipids and quality of life after surgery compared to intensive medical therapy (the Stampede trial). Therefore, it is imperative to identify the responsible factors with a view to utilize this knowledge for future therapy without surgery. Substantial evidence suggests that increased secretion of gut hormones plays an important role for both weight loss (inhibition of appetite + food intake) and glucose metabolism (by stimulating glucose-induced insulin secretion). The appetite inhibition seems to involve hypersecretion of PYY, GLP-1 and perhaps CCK, oxyntomodulin, and neurotensin. Decreased secretion of ghrelin may also play a role. The improved glycaemic control is due to a combination of (i) dramatically improved insulin sensitivity (initially improved hepatic sensitivity in parallel with reduction in steatosis) and secondly peripheral sensitivity in parallel with general weight loss – and (ii) improved postprandial insulin secretion due to improved beta cell glucose sensitivity as well as a stronger glycaemic stimulus caused by accelerated glucose absorption. The latter is also the major driving force for postprandial release of the insulinotropic hormone GLP-1, whereas lipids (bile salts) may explain neurotensin secretion while protein derivatives drive CCK secretion. Further experiments using isolated primary gut cells and perfused gut preparations have identified certain bile salts to potently stimulate secretion while amino acids transporters including Pept-1 and basolateral calcium-sensing receptors are important for protein-induced secretioin. The most important lesson so far is that stimulated secretion predominantly depends on absorption of nutritional elements. Some of these elements may form the basis for new therapeutic approaches.

S9.2

Clinical studies on GLP1 - cardiovascular outcomes

Baptist Gallwitz
Germany.

The incretin hormone Glucagon-like peptide-1 (GLP-1) has various non-glycaemic properties. Among those, cardiovascular effects have been described in animal studies and in clinical studies in patients with type 2 diabetes that have been treated with GLP-1 receptor agonists (GLP-1RA). In animal studies, GLP-1 and GLP-1RA have lead to a decrease in ischaemic areas in artificial myocardial infarct models. Additionally, in some clinical studies, an improvement in left ventricular function was observed as well as a decrease for catecholamine requirement in post-surgical patients after coronary bypass graft surgery. The pathophysiological explanations for these effects are a possible improvement in substrate utilization of the myocardium as well as vascular effects mediated by the activation of cardiovascular GLP-1 receptors and a consecutive amelioration of hypertension. In recent years, randomized, prospective cardiovascular safety trials have been initiated or performed with GLP-1RA in patients with type 2 diabetes and concomitant cardiovascular disease or cardiovascular risk factors. Results from three of these studies have been published so far. In the ELIXA-trial, the short acting GLP-1RA lixisenatide was given as add on to a standard antidiabetic therapy in patients after an acute cardiovascular event. In comparison to an established diabetes therapy, lixisenatide demonstrated non-inferiority and cardiovascular safety. The LEADER-study performed with liraglutide in patients with type 2 diabetes and concomitant cardiovascular risk or disease showed a highly significant 13% relative risk reduction in the 3-point MACE (MACE = multiple adverse cardiovascular events; combined endpoint of cardiovascular death, non-fatal myocardial infarction and non-fatal stroke) after 54 months. This result was primarily driven by a significant reduction of cardiovascular death by 22%. Semaglutide, a long-acting GLP-1RA for once weekly injection that is not approved yet, lead to a significant 26% relative risk reduction in the 3-point MACE in its clinical phase III study programme. From these data, the hypothesis that the activation of the GLP-1 receptor has beneficial cardiovascular effects, is strongly supported and it has now been demonstrated in two studies, that patients with type 2 diabetes and cardiovascular disease may profit from a therapy with GLP-1RA regarding their cardiovascular outcomes.

The Challenges of Male Fertility

S10.1

Manipulating testicular androgen production to promote lifelong male health

Lee Smith
UK.

Abstract unavailable.

S10.2

Fertility preservation in pre-pubertal and young males

Ans van Pelt
The Netherlands.

Survival rates for patients with cancer have continuously increased over the past decade as a result of more advanced cancer treatment. As a consequence, adverse side effects of cancer therapy becomes an important health issue for these cancer survivors. Male sterility is a relative common side effect of cancer treatment. This adverse fertility effect is caused by gonadotoxic effects as the cancer treatments not only effectively kill cancer cells but also destroy the progenitors of sperm. Spermatogenesis is the process of sperm production starting from spermatogonial stem cells that are extremely sensitive to treatments with alkylating agents or irradiation. Damage to these stem cells results in temporary or permanent sterility depending on the doses. For this reason, adult men diagnosed with cancer are offered cryopreservation of semen before starting cancer treatment. However, for pre-pubertal and young boys, this is not an option as sperm is not yet produced in these boys. As spermatogonial stem cells are already present in the testis, these cells are a source for fertility preservation. A potential future clinical application to preserve fertility in these boys with cancer is to cryopreserve a small testis biopsy prior to cancer treatment for later isolation and propagation of spermatogonial stem cells from this biopsy and transplantation of these cells back after cure of cancer. Studies in animal models have provided evidence that this method indeed restores fertility. It is shown that spermatogonial stem cells can be transplanted to the testis, where they migrate to their niche and colonize the testis, giving full spermatogenesis of which sperm was able of fertilizing eggs and producing offspring. Using this transplantation as readout, spermatogonial stem cell characteristics could be studied in more detail, resulting in the establishment of a long term *in vitro* propagation system for mouse spermatogonial stem cells that upon transplantation could produce sperm to generate offspring. This presentation will give an overview on the state of art of the translation of these techniques to the human situation to establish a clinical application for fertility preservation in young boys suffering from cancer.

Pubertal induction and hormone replacement in young males

Nelly Pitteloud

Congenital gonadotropin-releasing hormone deficiency is a rare disorder characterized by incomplete or absent puberty and infertility. This condition is both clinically and genetically heterogeneous and presents with a broad spectrum of phenotypes ranging from mild to severe. This presentation will provide a review of hypogonadotropic hypogonadism, including the clinical presentation of HH, a rational approach to evaluating HH patients, and an update on treatment options. In particular, the speaker will focus on the choice of the most appropriate treatment in hypogonadotropic hypogonadism based on clinical presentation including the use of rFSH to enhance treatment outcome.

New Roles for Nuclear Receptors

S11.1

Identification of nuclear receptors network in male fertility

David Volle
France.

Male fertility is controlled by complex interactions among the hypothalamus, pituitary, and testis. The major functions of the testis include production of spermatozoa (male gametes) and synthesis of testosterone. Testosterone is produced by the testicular Leydig cells and is responsible for the development of gonad, the attainment of puberty, and the maintenance of secondary sexual characteristics. It is also involved in the maintenance of of spermatogenesis and thus ensuring male fertility. Many studies have highlighted the complexity of the regulations of testicular homeostasis at both tissue and cellular levels. Among the involved molecular mechanisms, several nuclear receptors (NRs) have been identified as key regulators of testicular physiology. NRs are a family of transcription factors with a conserved structure that within testis control steroidogenesis and germ cell differentiation. Since several years, using both genetic and pharmacologic strategies, we have been implicated in the identification of the multiple roles of particular members of the NR superfamily. Here we will give an overview of our research highlighting the identification of a complex network showing the interactions of these NRs in the regulation of the exocrine and endocrine functions of the testis.

Crosstalk between estrogen signalling and DNA damage repair

Simak Ali
UK.

Estrogen receptors (ER) are expressed in the majority of breast cancers, are key drivers of breast cancer development and progression and hence therapies to inhibit their activities are a mainstay of treatment for breast cancer. A large proportion of patients develop resistance to these therapies, so determining the mechanisms of ER action is important for improving patient management and for identifying new therapies. In defining the mechanisms by which ER regulates gene expression, we and others find that proteins involved in DNA damage recognition and repair (DDR), including components of base excision repair (BER) and non-homologous end-joining (NHEJ) are central to the promotion of gene expression by ER. Most recently, we have demonstrated that the cytosine deaminase APOBEC3B (A3B) is recruited to the regulatory regions of estrogen-responsive genes in an ER-dependent manner. We have shown that A3B recruitment promotes transient C-to-U changes at ER/A3B binding regions, repaired by BER/NHEJ pathways, with the cytosine deamination and its repair facilitating chromatin remodeling that aids expression of ER target genes. Importantly, we have now extended these studies to demonstrate an important role for A3B in transcription regulation in ER-negative, as well as ER-positive breast cancer cell lines, indicating that A3B has a general role in regulating gene expression in human cells. These findings highlight the therapeutic potential of A3B inhibitors for the treatment of ER+ and ER-negative breast cancer. Recent reports have implicated A3B as the enzyme responsible for acquisition of mutations and tumour evolution in diverse cancer types, highlighting the inherent dangers associated with the cellular role of DNA damage and repair in the regulation of gene expression. These findings also raise the question of whether targeting of A3B to gene regulatory regions might promote non-coding mutations that modify gene enhancer function and provide further impetus for the development of A3B inhibitors for cancer.

New Development in Graves' Orbitopathy

S12.1

The orbital fibroblast: a key player and target for therapy in graves' orbitopathy

Wim Dik
The Netherlands.

Graves' orbitopathy (GO) is characterized by orbital tissue inflammation, expansion, remodelling and fibrosis. Although the initiating trigger of GO is still indistinct, excessive orbital fibroblast activity is at the heart of its pathogenesis. Orbital fibroblasts are activated by cellular interactions with immune cells and the soluble factors they secrete as well as autoantibodies (e.g. TSH-receptor autoantibodies). Activated orbital fibroblasts produce inflammatory mediators thereby contributing to the inflammatory process in GO. Moreover, orbital fibroblasts exhibit robust proliferative activity and extracellular matrix (especially hyaluronan) synthesizing capacity and can differentiate into adipocytes and myofibroblasts with disease progression, thereby contributing to tissue expansion/remodelling and fibrosis in GO. Orbital fibroblasts, especially those from GO patients, exhibit a hyper-responsive phenotype when compared to fibroblasts from other anatomical regions, which may further contribute to GO pathogenesis. This presentation will address our current view on the role that orbital fibroblasts fulfil in GO pathogenesis as well as the potential of direct targeting of the orbital fibroblast in the treatment of GO.

Management of Graves orbitopathy

Luigi Bartalena
Italy.

Management of Graves' orbitopathy (GO) depends on the severity and activity of the disease. Guidelines for the management of GO have recently been published by EUGOGO (European Group on Graves' Orbitopathy) (*European Thyroid Journal* 2016 **5** 9–26). Assessment of GO by standardized criteria is fundamental to determine the type of intervention. General measures for all patients with GO, irrespective of the degree of severity and activity, include restoration and stable maintenance of euthyroidism, refrain from smoking, use of local measures (e.g. artificial tears, ocular gels). All GO patients, except for the mildest cases, should be referred to specialists. Mild GO is not treated actively, except for a 6-month course of selenium supplementation, shown in a randomized clinical trial (RCT) to be more effective than placebo also in terms of prevention of progression to more severe forms of GO. Sight-threatening GO, due to dysthyroid optic neuropathy and/or corneal breakdown, is an endocrine emergency and should be treated immediately with very high doses of intravenous glucocorticoids (ivGCs) and measures to protect the corneal surface. If, however, response is absent or poor within 2 weeks, the patient should be promptly submitted to orbital decompression. Treatment of moderate-to-severe GO depends on disease activity. If GO is stably inactive, there is no place for medical treatment, and rehabilitative surgery (orbital decompression, squint surgery, eyelid surgery) can be performed, as needed. For moderate-to-severe AND active GO, ivGCs represent, for the time being, the first-line treatment. ivGCs are given as 12 weekly, slow infusions of methylprednisolone (MP). Most commonly, the cumulative dose of MP is 4.5 g, but the dose should be tailored to the patient conditions, avoiding a cumulative dose >8 g and a single dose >0.75 g, to minimize the risk of toxicity. If response is not satisfactory in terms of regression and inactivation of GO, second-line therapies include a second course of ivGCs, a course of oral glucocorticoids combined with either orbital radiotherapy or cyclosporine, treatment with rituximab. The choice of second-line treatments should be part of a shared decision-making process with the informed patient. In addition to rituximab, the effectivess and safety of which should be confirmed in larger RCTs, ongoing studies are investigating the effectiveness and safety of other biologics, including teprotumumab and tolicizumab. Results of these studies are not available yet.

S12.3

How to predict progression in Graves orbitopathy?

Petros Perros
UK.

Graves' orbitopathy (GO) is a relatively rare condition, but can cause significant morbidity, poor quality of life, socioeconomic cost and occasionally impaired vision. Some studies indicate that nearly all patients with Graves' hyperthyroidism, even those without overt GO, have subclinical eye disease. It is becoming increasingly evident that early recognition of GO and early interventions can affect the long-term outcome favourably. Predicting which patients will develop clinical manifestations of GO is therefore important. Clinical tools for early recognition of GO in a population of patients with Graves' hyperthyroidism attending endocrine clinics have been developed and are being further validated. A number of clinical and biochemical parameters have been shown to be associated with progression of GO and can be used clinically to identify such cases. They include age, gender smoking status, severity of thyrotoxicosis, dysthyroid status, use of radioiodine and the level of TSH receptor antibodies.

DOI: 10.1530/endoabs.49.S12.3

Challenging Pituitary Diseases

S13.1

Hypophysitis

Niki Karavitaki
UK.

Hypophysitis is a rare inflammatory condition of the pituitary gland. Its pathogenesis is poorly understood and new variants have been recently described. It can be primary (isolated inflammation of the gland, not related with medications, systemic inflammatory disorders, infections, or other diseases), or secondary (associated with systemic inflammatory processes (as sarcoidosis, Wegener's granulomatosis, Crohn's disease, Takayasu's arteritis, Cogan's syndrome), inflammatory cell proliferative disorders (Langerhans cell histiocytosis, Erdheim-Chester disease), infections (as tuberculosis, syphilis), tumour-associated inflammatory infiltrate (as in germinoma), immunotherapy (as medications targeting cytotoxic T-lymphocyte antigen-4 (CTLA-4) or programmed cell death 1 (PD-1)), rupture of sellar cysts (Rathke's cleft cysts and craniopharyngiomas)). The histological subtypes are lymphocytic, granulomatous, xanthomatous, and plasmacytic (also termed IgG4-related hypophysitis which is often a manifestation of systemic disease). The inflammation may involve the anterior pituitary gland (adenohypophysitis), posterior gland and stalk (infundibulo-neurohypophystis), or entire gland (pan-hypophysitis). Patients with hypophysitis present with manifestations related to mass effect from the gland enlargement and hypothalamo-pituitary dysfunction. The severity of hormone deficiencies may be out of proportion to imaging findings. Radiological findings include homogenous enhancement of the pituitary, diffuse symmetric gland enlargement, midline stalk thickening, and absence of a posterior pituitary bright spot. The diagnosis is established by biopsy and pathological examination. There are no prospective controlled studies on the optimal management of hypophysitis and treatment remains controversial; potential options include surgery (if visual deterioration), glucocorticoids (at variable dosages and duration), immunosuppressive agents and radiotherapy. Spontaneous resolution of pituitary enlargement has been observed in a number of cases and improvement of pituitary hormone deficits may occur after the resolution of hypophysitis.

S13.2

Empty sella

Laura De Marinis
Italy.

Empty Sella (ES) represents a heterogeneous syndrome, with a completely unknown pathogenesis. Defects in the organogenesis or hypoplasia of the sellar diaphragm (associated with stable or intermittent variation of intracranial pressure and/or with pituitary volume variation) can facile the herniation of the arachnoid space into pituitary fossa and the consequently pituitary compression. ES can be the sequel of necrosis of pituitary adenomas, of hypophysitis or of brain/head trauma. In these condition, ES is defined secondary. In cases with unknown aetiology ES is defined Primary. However, actually, obesity, systemic hypertension, multiple pregnancies, diabetes mellitus and *pseudotumor cerebri* are considerate factor risks for the occurrence of primary ES (PES). In 50% of cases with PES a coexistent intracranial hypertension is associated, with the occurrence of neurological signs and symptoms. The clinical manifestation of PES can be insidious, with subclinical or severe symptoms, as headache or papilledema, as visual disturbance or diplopia or optic neuritis, as partial or complete hypopituitarism, also associated to hyper-prolactinemia. Pituitary Magnetic Resonance is crucial for the diagnosis and allow to distinguish between partial or complete empty sella. A complete pituitary function clinical and laboratory evaluation is required to identify and diagnose hypopituitarism condition, with basal and, if necessary, dynamic test. Moreover, measurement of intracranial pressure is suggested, though direct or indirect test, as lumbar puncture or optical nerve ultrasound to evaluate the thickness of the optic nerves. In ES affected patients, hormonal replacement therapy is required for the management of hypopituitarism. Moreover, treatment of intracranial hypertension is strongly suggested, though diuretic drugs, as acetazolamide. In cases of drug-resistant intracranial hypertension or in cases of neurological emergencies, intracranial hypertension neurosurgery treatment, as ventricular shunt placement, is recommended. A semestral or at least annual follow-up is suggested in these patients, with endocrinological, ophthalmological and neurosurgical clinical, laboratory and morphological evaluation. ES, in fact, represents a complex syndrome which requires a multidisciplinary and dedicated team, as to ensure integrated therapy charge and as to prevent the occurrence of the severe disease complications.

S13.3

Imaging of sellar masses

Michael Buchfelder
Germany.

To date, magnetic resonance tomography is generally considered the imaging method of choice for its premium resolution of lesions and surrounding anatomic structures. This is mainly due to the improved soft tissue contrast this method offers. Other advantages are the possibility of direct multiplanar imaging in sagittal, coronal, and axial orientations and the avoidance of ionizing radiation. The goal of all imaging studies in this region is to indicate precisely the location, extent, and size of a sella region tumor. These features, along with signal characteristics, frequently not only allow us to determine the presence of a lesion but also indicate the nature of the lesion. For this purpose, its extension in relation to the various surrounding structures, its structure, and its enhancement pattern must be recognized in order to help in differential diagnosis and in treatment planning. A proper set of images is required. A stepwise analysis of the images is suggested. For various types of lesions, typical examples are shown. In this context, monitoring of treatment effects is shown by using repeat imaging with comparable data acquisitions. The common artifacts are discussed as well as enhancement of depiction of minute tumours. Of course, the common features that allow differential diagnosis, are presented.

DOI: 10.1530/endoabs.49.S13.3

Searching for the Cause and Approach in Ectopic Hormone Syndromes

S14.1

Rare Cushing's

Stephen Petersenn
Germany.

Ectopic ACTH syndrome accounts for approximately 20% of all cases of ACTH-dependent Cushing's syndrome. The most common causes are oat cell carcinomas, bronchial and foregut carcinoid tumors, pancreatic islet cell tumors and pheochromocytomas. Rarely, ectopic CRH-secretion occurs by peripheral tumors, especially carcinoids. Whereas the screening for hypercortisolism followed by analysis of ACTH is well established, the distinction between pituitary adenomas and ectopic sources in ACTH-dependent Cushing's syndrome is more challenging. Ectopic tumors producing ACTH with already suppressed pituitary ACTH levels do generally not respond even to high doses of glucocorticoids. Measuring response to CRH or vasopressin may also be useful in the differential diagnosis. Inferior petrosal sinus venous sampling allows definite identification of a pituitary source of ACTH, especially in combination with a CRH-test administered during catheterization. Localization of the source of ectopic ACTH secretion may be especially difficult. In addition to CT, MRI and endoscopic ultrasound, nuclear medicine techniques can help greatly in identifying the source of ectopic ACTH production. Treatment often requires a combination of different approaches, including surgery, medical therapies to control hypercortisolism and/or proliferation, local ablation techniques, and PRRT. As hypercortisolism may cause more clinical problems than the underlying tumor itself, bilateral adrenalectomy is performed in selected cases.

Searching for the cause and approach in ectopic hormone syndromes: rare acromegaly

Françoise Borson-Chazot
France.

Acromegaly secondary to ectopic growth hormone-releasing hormone (GHRH) is rare accounting for less than 1% of cases of acromegaly. Less than 100 cases have been reported in the literature mainly as case reports, except for a nationwide French series of 21 cases. Ectopic acromegaly occurs more frequently in women who represent 2/3 of cases. Median age at diagnosis is 41 years but ranges from adolescence to elderly. GHRH secreting neuroendocrine tumors are usually well differentiated, originating in 90% of cases from pancreas or lung. Pheochromocytomas or paragangliomas have been reported in a small proportion of cases. Positive immunoexpression for GHRH is found in most tumors. Clinical and hormonal features of ectopic acromegaly are very similar to that of somatotropic adenomas and differentiating between both may be challenging. Pituitary may be normal or enlarged at MRI which may be difficult to interpret especially in MEN1 patients where the association of a microprolactinoma to a pancreatic tumor secreting GHRH may be misleading. GHRH plasmatic measurement has an excellent specificity for the diagnosis. Tumors are usually large and easy to localize by conventional imaging or somatostatin receptor scintigraphy. Prognosis is usually favorable, even in metastatic forms which represent 50% of cases. Surgical approach is recommended and, when a complete tumoral resection is feasible, results, in most patients, in long-lasting remission. In such cases, GHRH concentration is normalized and its increase is an accurate indicator of recurrence. In uncured patients, somatostatin analogs control GH secretion but inhibit, only partially, GHRH secretion. MEN1 mutation should be systematically investigated in patients with a pancreatic tumor.

The role of bile in metabolic surgery

Gilles Mithieux
France.

Gastric bypass surgery (GBP) promotes early benefits in energy homeostasis in obese diabetic patients, including decreased hunger and improved glucose control. A suggested mechanism associates a decrease in hepatic glucose production (HGP) with an enhanced intestinal gluconeogenesis (IGN), the latter promoting metabolic benefits in energy homeostasis. In addition, bile acids (BA) have emerged as key metabolic regulators, which might account for several anti-diabetic effects. Moreover, plasma bile acids are elevated after GBP and are known to inhibit gluconeogenesis. Bile diversions mimicking GBP in lean rats (re-insertion of bile in the mid-jejunum or the mid-ileum) promote an increase in plasma bile acids and a marked improvement in glucose control. Bile bioavailability modification is causal since a bile acid sequestrant suppresses the beneficial effects of bile diversions on glucose control. In agreement with the inhibitory role of bile acids on gluconeogenesis, bile diversions promote a blunting in HGP, whereas IGN is increased in the gut segments devoid of bile. In obese rats fed a high fat-high sucrose diet, bile diversions improve glucose control and dramatically decrease food intake. This is due to an acquired disinterest for fatty food, leading the animals to prefer starch-enriched diet. These data suggest a key role of bile and of gluconeogenesis in the favorable outcomes of metabolic surgery.

Clinical implications of SDHx mutations

Anne-Paule Gimenez-Roqueplo
France.

Paragangliomas and pheochromocytomas (PPGL) are neuroendocrine tumors with a very strong genetic component. A germline mutation in one of the different susceptibility genes identified so far explains about 40% of all cases. Genetic testing is recommended in every affected patient and next-generation sequencing (NGS) is the ideal technology to screen the high number of PPGL susceptibility genes (1). The interpretation of genetic variants identified by NGS can be guided by the clinical presentation as well as by the secretory phenotype and by the immunohistochemical analysis of tumors (2). The diagnosis of an inherited form drives clinical management and tumor surveillance of the patient and relatives (1). While whole-exome sequencing studies showed that PPGL is characterized by a low mutation rate of 0.3 mutations per megabase similar to other neural crest-derived tumors, the first integrative genomic analysis of a large collection of 202 PPGL, carried out by the French COMETE network, demonstrated that mutation status in PPGL susceptibility genes is strongly correlated with multi-omics data and revealed the crucial role of predisposing mutations as being the main drivers of PPGL (3). PPGL subtypes can be defined by a set of unique genomic alterations that represent different molecular entities. Transcriptomic studies identified two main molecular pathways, activating either the hypoxic pathway (cluster C1) or the MAPkinase/mTOR signalling (cluster C2). This comprehensive analysis illustrated the functional interdependence between genomic and epigenomic dysregulations. Indeed, DNA methylation profiling uncovered a hypermethylator phenotype specific to the tumors related to a mutation in one of the PPGL susceptibility genes encoding for a protein of the tricarboxylic cycle. Besides, we demonstrated that succinate is acting as an oncometabolite, inhibiting 2-oxoglutarate-dependent dioxygenases, such as HIF prolyl-hydroxylases and histone/DNA demethylases, explaining noradrenergic secretory and metastatic phenotypes of PPGL classified in cluster 1A (4). A recently published novel comprehensive multi-platform analysis of 173 PPGLs led by TCGA has confirmed the COMETE data and identified recurrent fusions genes by RNA sequencing. Altogether those data suggested new therapeutic targets for patients with a metastatic PPGL as well as novel diagnostic and prognostic biomarkers. New 'omics'-based tests for PPGL are likely to be transferred from research laboratories to clinical practice in order to give the access to a precise molecular classification of every PPGL, after surgery, to practicing clinicians with the goal of establishing a personalized medical management.

Will genomics help to finally classify NET's?

Jean Yves Scoazec
France.

The genetic landscape of neuroendocrine tumors (NETs) is being rapidly uncovered. It has long been known that, like other endocrine tumors, NETs might occur in the context of familial predisposition syndromes, involving genes like *MEN1*, *VHL*, *TSC1/TSC2*, *NF1* and *CDKN1B*. Recently, several seminal papers have described the main molecular abnormalities underlying sporadic or apparently sporadic NETs. The results confirm that: (a) well differentiated NETs from various sites are genetically distinct; (b) well differentiated and poorly differentiated neuroendocrine neoplasms are genetically distinct and likely correspond to different entities. Pancreatic and lung well differentiated NETs are mainly associated with abnormalities in genes encoding proteins involved in chromatin regulation and telomere control (such as *MEN1, DAXX* and *ATRX* in pancreatic NETs, *MEN1* again and a number of genes of the SWI/SNF pathway in lung NETs); in addition, recent results have revealed the occurence of fusion transcripts involving *EWSR* in pancreatic NETs, uncovering a new perspective in the molecular mechanisms underlying pancreatic and perhaps other NETs. In contrast, in well differentiated small intestinal NETs, the molecular landscape appears to be heterogeneous, with a high frequency of chromosomal changes and a wide spectrum of mutations involving various signalling pathways (mTOR, SMAD). Taken together, these results suggest that in well differentiated NETs, several oncogenic mechanisms might be involved: epigenetic dysregulations due to chromosomal and genomic instability, alterations in intracellular signalling pathways, and production of oncogenic proteins. As regards the neoplasms morphologically classified as poorly differentiated neuroendocrine carcinomas, concurrent results show that they might be associated with three different molecular signatures: (a) typical 'high grade neuroendocrine' signatures, characterized by mutations in *TP53* and *Rb*, and corresponding to 'true' neuroendocrine carcinomas; (b) 'adenocarcinoma-like' signatures, corresponding to aggressive carcinomas maskerading as neuroendocrine neoplasms, (c) 'well differentiated NET' signatures, corresponding to highly proliferative well differentiated neuroendocrine neoplasms with an aggressive behavior. The molecular tools now available will clearly help to refine the classification of aggressive, high grade neuroendocrine malignancies, but their clinical and therapeutic impact remains to be evaluated. As for low grade neuroendocrine malignancies, the main interest of molecular profiling will probably be prognostic and predictive.

Hyperandrogenism: Challenges in Clinical Management

S18.1

Hyperandrogenic states: pitfalls in diagnostic approach

Michel Pugeat
France.

Measuring total testosterone level is the first line approach to assess androgen excess in women. Most laboratories in Europe use direct testosterone immunoassay without prior extraction. In the near future, liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) will be commonly used for measuring testosterone, providing the best accuracy with low limit of detection. In all cases, testosterone norms must be standardized for normal premenopausal women values. Where testosterone is twice the upper limit of normal, it is recommended that DHEAS assay be performed. DHEAS is primarily of adrenal origin in women. Thus, a DHEAS level of over 600 µg/dl indicates a diagnosis of androgen-secreting adrenal carcinoma (often associated with hypercorticism). In this case, abdominal scan must be performed rapidly. Where testosterone is just above the normal upper limit, the most likely diagnosis is polycystic ovary syndrome (PCOS). However, screening should be performed for the nonclassic form of 21-hydroxylase deficiency (assay of 17OH-progesterone) and depending on the clinical setting, Cushing disease must be ruled. Normal testosterone levels in patients with clear clinical symptoms of hyperandrogenism must be interpreted with care. Indeed, T circulates in the blood tightly bound to sex-hormone binding-globulin (SHBG). Low SHBG is typically observed in overweight PCOS patients, in association to inflammatory state and metabolic syndrome, and contributes to lower total testosterone by increasing its clearance from the blood. Therefore, it is recommended, to measure SHBG for correct interpretation of total testosterone by calculating free testosterone index, awaiting direct free-T assay that is still not available. Δ4-androstenedione (A) has been studied comparatively with testosterone, and dissociations exist, with isolated elevation of A but no elevation of testosterone, particularly in the incident of reduced SHBG. In unusual circumstances, dexamethasone test to suppress androgens arising from a functional adrenal source and gonadotropin-releasing hormone (GnRH) agonist in identifying ovarian androgen secreting tumor and hyperthecosis, could be helpful. All these pitfalls should not discourage endocrinologist to challenge the diagnosis of hyperandrogenic states. Decision trees for evaluating the origin of androgen excess will be suggested and discussed during the session.

DOI: 10.1530/endoabs.49.S18.1

S18.2

Metabolic perspectives for the non-classical CAH (NCAH)

Fahrettin Kelestimur
Turkey.

Congenital adrenal hyperplasia (CAH) is one of the most common autosomal recessive inherited endocrine diseases and is characterized by complete or partial impairment of adrenal steroidogenesis. 21-hydroxylase deficiency and 11β-hydroxylase deficiency account for 90% and 6–8% of cases of CAH, respectively. NCAH is the mild form of CAH and occurs in approximately 0.1–0.2% in the general population. The worldwide prevalence of NCAH among hyperandrogenic women is approximately 4.0%. Adrenal androgen secretion and its response to ACTH is increased in these cases. Patients with NCAH generally present with manifestations due to high androgen levels including hirsutism, acne and alopecia. Ovulatory and menstrual dysfunction are seen in more than 30–50% of

patients with NCAH. Polycystic ovarian morphology is recorded in at least 25% of the patients. The data regarding insulin resistance, diabetes, obesity and abdominal visceral adiposity in NCAH patients is scarce. Chronic androgen excess around puberty may favor abdominal visceral adiposity, insulin resistance and its metabolic consequences. Hyperinsulinemia and insulin insensitivity associated with high androgen levels were reported in untreated newly diagnosed patients with NCAH. Chronic glucocorticoid administration in a limited number of patients may also favor metabolic abnormalities. The frequency of type 2 diabetes was reported to be increased in NCAH patients. It seems that NCAH is associated with increased cardiovascular and metabolic morbidity. Therefore, screening metabolic abnormalities may be required in patients with NCAH.

DOI: 10.1530/endoabs.49.S18.2

S18.3

Hyperandrogenism and cardiometabolic risk

Marija Pfeifer
Slovenia.

Hyperandrogenism is the main characteristic of PCOS therefore hyperandrogenism in women is best addressed when studying this highly prevalent syndrome. Besides the clinical features of oligomenorrhea, hirsutism and infertility, PCOS patients are often insulin resistant (IR), obese, they have arterial hypertension, dyslipidemia, an increased pro-thrombotic state, impaired glucose tolerance or frank type 2 diabetes (T2D). The prevalence of metabolic syndrome is doubled as compared to non-PCOS population. Obesity, particularly of visceral origin, plays a crucial role in both the development and maintenance of PCOS and significantly influences the severity of cardiovascular risk profile. At least 30% of women with PCOS are obese, and in some series, up to 75% are obese. About 50–60% of women with PCOS have central body fat distribution. Metabolic disease in PCOS should be considered as a continuous variable, with metabolic dysfunction worsening with severity of androgen excess. Increasing androgen burden is associated with an adverse metabolic phenotype. Androstenedione (A) has been shown to be in better correlation with IR than testosterone (T) in PCOS women. Recent data suggest that biochemical androgen excess poses a higher risk of liver disease, IR, and subclinical atherosclerosis in PCOS compared with those women with anovulation and polycystic ovaries alone. Serum A is a more sensitive indicator of PCOS-related androgen excess than serum total T concentrations. Concurrent measurement of both A and T discovers a PCOS cohort that appears to be at the highest metabolic risk. The analysis of 2543 pre- and perimenopausal women in their 40s originally included in the SWAN study indicated that hyperandrogenemia but not oligomenorrrhoea was independently associated with the risk of prevalent metabolic syndrome. High prevalence of cardiovascular risk factors in PCOS is assumed to be associated with accelerated cardiovascular disease (CVD). However, clear data from large end point trials about cardiovascular morbidity and mortality in PCOS is currently lacking. Though, there is plenty of data on early occurrence of subclinical, potentially reversible atherosclerosis in women with PCOS. Endothelial dysfunction is associated with higher levels of androgens and with insulin resistance. This was observed even at very early ages, and with a trend of deterioration of endothelial function from lean to overweight and obese PCOS women. Recent systematic review has confirmed that carotid intima-media thickness was thicker in women with PCOS in comparison to controls. PCOS women have a greater prevalence and extent of coronary artery calcification, and that is independent of age and BMI.

How to Incorporate the New Guidelines for Thyroid Cancer in my Clinical Practice

S19.1

Thyroid microcarcinoma: to treat or not to treat?

Paolo Vitti
Italy.

In the last 20 years, the incidence of thyroid cancer (TC) has more than doubled. Since 50% of the increase is related to papillary microcarcinomas (mPTC, <1 cm), it appears that an increased detection, due to the wide use of neck ultrasound (US), is the major factor driving this dramatic rise. Autoptic and histological studies after thyroidectomy (TX) show that 10 to 30% of adults harbor an undiagnosed mPTC. The disease-specific mortality of patients treated by surgery for mPTC is <1% and loco-regional and distant recurrence rates are 2–6 and 1–2%, respectively. Furthermore, 2 Japanese prospective clinical trials demonstrated a good outcome in more than 1,300 patients with biopsy-proven mPTC who were not submitted to TX. Thus, since only a minority of mPTC progress to a clinically overt disease, it is critical to re-evaluate the current management strategy that indiscriminately recommends thyroid surgery that is, although infrequently, burdened by complications. We retrospectively evaluated clinical data of 293 consecutive patients with mPTC, surgically treated at our Department. After 6 years of follow-up no patient had evidence of structural disease. This prompted us to obtain the approval by the ethical committee to offer patients an active surveillance instead of immediate surgery, when they had an intrathyroid nodule with a Thy4 or a Thy5 cytology, less than 1.3 cm of diameter, with no evidence at US of extrathyroid extension and cervical lymphnodes suspicious for metastasis. Out of 163 patients who choose active surveillance, 97 (59.5%) did not satisfied the inclusion criteria and 66 (40.5%) were enrolled in the protocol. With a median follow-up of 12 months (6–28) only 3/66 (4.5%) were addressed to surgery for the appearance of neck metastatic lymphnodes or an enlargement of the nodule. 7/66 (10.6%) patients withdrew from the study. In conclusion, the results of prospective studies will provide more precise data to build up a patient tailored approach for the management of mPTC.

When and how should we perform extensive surgery?

Electron Kebebew
USA.

Thyroid cancer is one of the most rapidly increasing cancer diagnoses worldwide. Thyroid cancers exhibit the full range of cancer behavior from the relatively indolent occult papillary thyroid cancer to the uniformly aggressive and lethal undifferentiated thyroid cancers. Surgical resection is the principal treatment for thyroid cancer and there are several important areas of controversy in the surgical management of thyroid cancer. Some of these controversies have arisen due to the increasing incidence of thyroid cancer, the variable biologic behavior of low-risk differentiated thyroid cancer, and because of the improved detection of persistent/recurrent disease. International Surgical and Medical Societies and Association have proposed guidelines to the surgical management of thyroid cancer and the level of evidence for these guidelines will be reviewed. Three critical areas in the surgical management of differentiated thyroid cancer remain controversial: the extent of thyroidectomy for differentiated thyroid cancer, need for prophylactic central neck lymph node dissection in patients with papillary thyroid cancer, and the need for completion thyroidectomy in patients who initially undergo hemithyroidectomy. A clinical, pathologic and molecular based approach to address these three controversial areas in the surgical management of differentiated thyroid cancer will be proposed to personalize surgical management decisions in patients with differentiated thyroid cancer.

DOI: 10.1530/endoabs.49.S19.2

S19.3

Dynamic risk stratification in low-risk vs high-risk patients

Miguel Melo
Portugal.

In recent years, an increasing interest in an individualized approach for the care of patients with differentiated thyroid cancer has occurred. The cornerstone of individualized treatment is the existence of a proper risk stratification system that supports physicians' options regarding the treatment and follow-up of patients. Considering that the initial risk stratification systems account for only about 15–20% of the variability in the outcome they are trying to predict, it is now well recognized that risk stratification is a dynamic process. The input of clinical, biochemical and imaging data collected during follow-up, notably the response to the initial treatment, can dramatically change risk estimation and significantly improve its accuracy in predicting long-term outcomes. The use of this approach faces different problems in patients with low/intermediate risk and in patients with high risk of recurrence. Regarding the low/intermediate risk group, dynamic risk stratification was based in the assessment of response to an initial treatment that consisted in total thyroidectomy followed by radioiodine (RAI) treatment. However, lobectomy is now considered a reasonable approach for some low risk patients and the role of postsurgical RAI in the low/intermediate risk group is currently under debate. As a consequence, there are no well-established thyroglobulin (Tg) cut-off points to define categories (e.g. excellent response, biochemical incomplete response) in patients treated with lobectomy or total thyroidectomy without postsurgical RAI treatment. Nonetheless, different

thresholds for patients submitted to lobectomy or total thyroidectomy without RAI treatment have been included in clinical recommendations and recently validated in the low risk group. Apart from static Tg levels, the trend of both Tg and Tg-antibodies levels over time, with similar TSH values, has proven to be an effective way of assessing response to treatment. An increase of 20% seems to accurately predict structural disease recurrence. High-risk patients require a very individualized follow-up because most of the patients are expected to have persistent disease after the initial treatment. For these patients, the initial follow-up is mainly aimed at identifying those with progressive disease despite initial treatment. Nonetheless, most impact of dynamic risk stratification in this group occurs when an excellent response is found, precluding patients from an unnecessary aggressive follow-up strategy. In this session, different ways of implementing and refining dynamic risk stratification will be discussed, addressing the low, intermediate and high risk groups.

Beta Cell Replacement and Plasticity (*Endorsed by Endocrine Connections*)

S20.1

Stem cells for β cell replacement in type 1 diabetes

Valeria Sordi
Italy.

Pluripotent stem cells (PSC), both embryonic and induced (iPSC), are the most promising cell sources for replacement therapies. In particular for a disease like type 1 diabetes (T1D), caused by the loss of a single specific cell type that does not need to be transplanted back in its originating site to perform its function, a stem cell-based cell replacement therapy seems to be the ideal cure. At present, however, a successful strategy for the use of PSC in patients with diabetes has still to overcome several important hurdles, including i) the development of *in vitro* differentiation protocol for β cell generation, efficient and reproducible in different cell lines in different labs, ii) the possible tumorigenicity of PSC-derived β cells, iii) the risk of allo- and auto-immune rejection upon transplantation into a subject with T1D and iv) the regulatory/economic issues associated to the use of iPSC in humans, starting from production of GMP iPSC lines. At present, the major challenge is how to avoid immune-rejection of stem cell-derived β cells. To overcome the risk of an alloimmune response we could (i) use autologous iPSC, but personalized cell therapy has big economic and safety limits or (ii) iPSC from a cell bank with a limited number of highly selected cell donors with homozygous HLA types, to enable HLA matching for a majority of potential recipients. These strategies, however, would not eliminate the recurrence of autoimmunity after a new exposure to β cell antigens of the immune system of the T1D recipient. The only possible solution consists into trying to 'hide' the transplanted cells from the immune system: we and others are exploring the possibility to achieve this goal through i) the setup of a new immunosuppressive regimen for PSC-derived β cells, able to contrast autoimmune response; ii) the microencapsulation of cells into inert biomaterials, iii) the macroencapsulation of cells into specific devices able to protect them from allo- and auto-immune response while allowing oxygen, nutrients, and insulin exchange and iv) the genetic manipulation of the cells to escape immune recognition. If the limit of immune rejection is solved, a successful translation to the clinical practice of stem cell therapy for diabetes will be closer.

Induction of pancreatic beta-like cell neogenesis

Patrick Collombat
France.

The recent discovery that genetically-modified α-cells can regenerate and convert into β-like cells *in vivo* holds great promise for diabetes research. However, to eventually translate these findings to human, it is crucial to discover compounds with similar activities. Herein, we report the identification of GABA as an inducer of α-to-β-like cell conversion *in vivo*. This conversion induces α-cell replacement mechanisms through the mobilization of duct-lining precursor cells that adopt an α-cell identity prior to being converted into β-like cells, solely upon sustained GABA exposure. Importantly, these neo-generated β-like cells are functional and can repeatedly reverse chemically-induced diabetes *in vivo*. Similarly, the treatment of transplanted human islets with GABA results in a loss of α-cells and a concomitant increase in β-like cell counts, suggestive of α-to-β-like cell conversion processes also in humans. This newly discovered GABA-induced α-cell-mediated β-like cell neogenesis could therefore represent an unprecedented hope towards improved therapies for diabetes.

Environmental Influences on Endocrine Systems

S21.1

Lifestyle and environmental factors in metabolic diseases; endocrine disruptors: new diabetogens?

Patrick Fenichel
France.

The prevalence of metabolic syndrome, obesity and type 2 diabetes has dramatically increased worldwide during the last few decades and exceeds World Health Organisation's predictions. It is not possible anymore to explain this real pandemic only by genetic predisposition and/or by classical lifestyle changes such as sedentary lifestyle or energy-dense diet. There is increasing experimental and epidemiological evidence suggesting that exposure to environmental factors such as noxy foods, dysbiosis or endocrine disrupting chemicals (EDCs) may also contribute to the prevalence of DT2. EDCs are natural or synthetic chemical compounds, present in the everyday domestic environment, interfering with hormonal regulation systems critical for energy homeostasis. Many are present in the food chain and after absorption are sequestred in adipose tissue. They may represent after low-doses exposure during sensitive windows or via chronic exposure to cumulative doses, one aspect of the genetic/environment interface, involved in the pathophysiology of DT2. In humans, some epidemiologic reports suggested a strong link between exposure to some persistent EDCs (pesticides, polychorinated biphenyls, bisphenol A, phthalates, dioxins, polycyclic aromatic hydrocarbons) and DT2, especially after acute and accidental releases of EDCs (Seveso plant explosion, Vietnam war veterans). Other cross-sectional studies around the world reported suggestive to strong association between diabetes and obesity and EDCs exposure, especially for persistent organic pollutants, which should be considered as insulin-resistance risk factors. In rodents, exposure to bisphenol A is responsible for modifications of insulin synthesis and secretion in pancreatic beta cells but also for modifications of insulin signaling in liver, skeletal muscle and adipose tissue, which both lead to insulin-resistanc. *In vivo* and *in vitro* experimental studies have shown that EDCs may act through nuclear receptors (ERs, AhR, PPARγ, ERRγ) involved in metabolic control and are able to induce in specific windows of exposure (fetal, perinatal, pre-pubertal periods) epigenetic changes (DNA methylation, histone modifications, miRNA dysregulation) programming later obesity, insulin resistance, and/or β cell failure. It is still necessary to better understand the involved molecular mechanisms, to develop additional human prospective, longitudinal case/control epidemiological studies, and to identify early biomarkers of exposure, in order to improve assessment of chronic exposure to mixture of EEDs in order to determine the real implication of EEDs in DT2 highly susceptible patients.

Evidence on reproductive disorders through endocrine disruption in-utero

Jorma Toppari
Finland.

Differentiation of male reproductive system is guided by testicular hormones and growth factors secreted during fetal development under gonadotropin control. Disruption of testicular hormone production or action leads to gonadal dysgenesis and maldevelopment of external genitalia. Cryptorchidism and hypospadias are the most common birth defects in boys, and both conditions can arise as a consequence of anti-androgenic disturbance during development. Both of them are also associated with poor semen quality and testicular cancer, suggestion similar pathogenetic pathways. Animal experiments show robust evidence that inhibition of androgen synthesis or action causes abnormalities in testicular and genital development. Chemicals with different mechanisms of action towards declined androgen activity work in an additive fashion. Therefore even small amounts of anti-androgens can add a critical dose to the total anti-androgenic load. While this is well documented in experimental animals, there is limited evidence on human harm. This is due to challenges in epidemiology to demonstrate causal relationships, albeit there are many examples of associations of chemical exposures with reproductive disorders.

Euthyroid: towards a euthyroid Europe

Henry Volzke
Germany.

Despite the fact that iodine deficiency (ID) can easily be prevented by iodine fortification of table salt, industrial salt and cattle food, Europe belongs to the worst regions in terms of access to iodized salt and is seriously iodine deficient, resulting in the perpetuation of the single most important, preventable cause of brain damage. Up to an estimated 360 million European citizens are exposed to ID, which is not only due to variable iodine provision, it is also rooted in significant heterogeneity of prevention and monitoring activities, leading to inappropriate interventions, health inequalities and increased disease burden with substantial impact on health-care costs. A major concern remains the large number of pregnant women exposed to ID, which results in a measurable decrease in cognitive potential of their children. The effects of ID in total cause significant, preventable costs in health-care systems of affected regions. More than 30 countries contribute to the EUthyroid consortium, which is funded by the EC Horizon2020 programme. The overall aims of EUthyroid are to evaluate IDD prevention programmes in European countries, to initiate capacity building for integrated activities in Europe. Coordinated measures at national and EU level are a long-term goal, which will be worked towards by targeted communication activities of project results. EUthyroid has established a meta-platform for collaborative data collection and use. National and regional registry data are collected to gain an overview over prevalent and incident thyroid diseases and treatments in European nations. In parallel, EUthyroid improves the data quality of ID monitoring studies by providing infrastructures for training and standardization of interviews, laboratory measurements and thyroid ultrasound. All data will be used to provide a European map of iodine status and subclinical disorders and to relate the iodine status of populations to thyroid-related outcomes for the evaluation of ID prevention programmes. In addition, thyroglobulin, a novel and promising biomarker for the iodine status will be evaluated using biomaterials collected in ID monitoring studies and three mother-child cohorts from regions with different iodine status. The latter cohorts will investigate the important association between the iodine status in pregnant women and the neurocognitive function in their children. Combining findings from all studies, health-economic analyses will be conducted to investigate benefits and harms as well as cost-effectiveness of IDD prevention. Potential barriers against harmonized IDD prevention and monitoring programmes will be explored by collecting information from national and European ministries.

Rare Bone Diseases (*Endorsed by the European Journal of Endocrinology*)

S22.1

Approach for clinicians

Maria-Luisa Brandi
Italy.

Rare skeletal metabolic diseases comprise a group of diseases commonly associated with severe clinical consequences. In recent years, the description of the clinical phenotypes and radiographic features of several genetic bone disorders was paralleled by the discovery of key molecular pathways involved in the regulation of bone and mineral metabolism. Including this information in the description and classification of rare skeletal diseases may improve the recognition and management of affected patients. In a recent effort to recognize the rare skeletal diseases based on their metabolic pathogenesis 116 OMIM phenotypes with 86 affected genes related to bone and mineral homeostasis were recognized. The diseases were divided into four major groups, namely, disorders due to altered osteoclast, osteoblast, or osteocyte activity; disorders due to altered bone matrix proteins; disorders due to altered bone microenvironmental regulators; and disorders due to deranged calciotropic hormonal activity. This publication provides the first comprehensive taxonomy of rare metabolic skeletal diseases based on deranged metabolic activity. This classification will help in the development of common and shared diagnostic and therapeutic pathways for these patients and also in the creation of international registries of rare skeletal diseases, the first step for the development of genetic tests based on next generation sequencing and for performing large intervention trials to assess efficacy of orphan drugs. For their metabolic nature, the interest of endocrinologists towards this disorders is very high. The clinical management of these diseases from a metabolic point of view will be illustrated during the presentation.

Fibrous dysplasia of bone/McCune-Albright syndrome

Roland Chapurlat
France.

Fibrous dysplasia of bone/McCune-Albright syndrome (FD/MAS) is due to a somatic activating GNAS mutation. Patients may be asymptomatic in monostotic forms, which represent two thirds of cases. In those forms, the diagnosis is often incidental. But these monostotic FD may also be revealed by bone pain, bone deformity or fracture. The diagnosis is generally made in childhood or in young adults. Polyostotic FD is often more severe, with a higher incidence of fragility fracture. It is also commonly associated with renal phosphate wasting. About 5% of patients with FD also suffer from endocrine complications, including precocious peripheral puberty, growth hormone excess and hyperthyroidism. These endocrine conditions have to be treated as early as possible. For example, the precocious puberty generally responds well to an aromatase inhibitor, letrozole. Bisphosphonates have been used to treat bone pain and reduce bone turnover for more than two decades with satisfactory outcomes in most patients. This treatment can often be tapered after 2–3 years. Preventive surgery is often advised in children to avoid fracture and deformity of lower limbs. This kind of approach is also warranted in adults. A multidisciplinary management is necessary, involving specialists of bone diseases, endocrinologists, orthopedic surgeons, and sometimes cranio-facial surgeons along with neurosurgeons, both in children and adults. New therapies e.g., denosumab and tocilizumab are currently being studied to improve bone pain in those patients who do not adequately respond to bisphosphonates. An international collaboration is currently developing a framework that would be applicable around the world to improve the care of this rare disease, in particular to avoid delays in treatment.

Prolactin regulation of prostate stem cells: potential implications in prostate cancer

Vincent Goffin
France.

Prostate stem cells have been proposed to participate in prostate cancer initiation. Furthermore, based on their androgen-independence, they are suspected to trigger prostate cancer recurrence when the tumor is no longer responsive to anti-androgens. Therefore better understanding the regulation of this particular cell pool may have important therapeutic relevance. In the human prostate, expression of prolactin (PRL) and activation of its major downstream signaling effector Stat5, have been correlated to prostate cancer progression and relapse. To understand these effects, we use the probasin (Pb)-PRL transgenic mouse model which involves prostate-specific expression of PRL. Pb-PRL mice recapitulate many pre-neoplastic features of the human prostate including focal areas of epithelial dysplasia, prostate intra-epithelial neoplasia and moderate inflammation ('reactive stroma'), together with hypertrophy and ductal dilatation of all prostate lobes. Using various cell lineage-specific markers coupled to immunohistochemistry and cell sorting (FACS), we showed some years ago that the p63+ basal/stem cell compartment (which contains 'tumor-initiating' cells) was highly enriched in Pb-PRL prostate tumors (Rouet et al, PNAS 2010). Subsequent studies revealed enrichment of another cell population that we discovered and named 'LSCmed' based on its FACS profile (Sackmann Sala et al, Am. J. Pathol 2014). LSCmed are luminal progenitors that exhibit stem-like properties *in vitro* (prostasphere assay, gland formation in transplantation assays) and importantly, resistance to androgen deprivation *in vivo*. Transcriptomic profiling showed that LSCmed is a distinct cell entity that differs from the well-known basal and luminal cell populations and that can be identified using a specific gene expression signature. LSCmed are rare in the normal prostate and their amplification in Pb-PRL prostate tumors more likely results from paracrine signals downstream of PRLR/Stat5 signaling than from a direct PRL effect. Strikingly LSCmed represent the major cell component of aggressive, castration-resistant prostate tumors driven by Pten loss, both before and after castration. This is particularly relevant since loss of PTEN is frequently observed in the human prostate oncogenome. In summary, LSCmed represent a newly-identified prostatic cell population that is a strong candidate for mediating cell resistance to androgen-deprivation therapy. Ongoing studies aim to elucidate the mechanisms that that regulate these luminal progenitors and to identify LSCmed(-like) cells in the human prostate.

Is GH a cancer growth factor?

Shlomo Melmed
USA.

Acromegaly is associated with increased soft tissue neoplasms, while GH deficient patients are protected from cancer development. Both environmental and age-related signals lead to cellular senescence and cell cycle dysregulation. We have shown that DNA damage-induced cellular senescence increases GH by inducing p53. GH, in turn, suppresses tumor suppressor proteins in both pituitary and nonpituitary cells.These observations led us to propose that intracellular epithelial GH in the mucosal microenvironment may enable neoplastic growth. Mechanisms underlying pro-neoplastic GH actions include: knockdown or suppressing either *GH* or *GHR* mRNA induces p53; GH suppresses p53 by inhibiting PTEN,a p53 acetylator, which protects p53 from ubiquitination, and up-regulates TRIM29, which also destabilizes p53. Thus, p53 ubiquitination and altered acetylation underlie suppression of p53 mediated by GH. GH also induces mTOR, EMT transcription factors and enhanced cell motility. *In vivo* epithelial p53 is markedly induced in GH-deficient $Prop1^{-/-}$, and in GH receptor deficient $GHR^{-/-}$ mice, and in mutant GH receptor (Laron syndrome) fibroblasts. In nutlin-treated mice with DNA damage, GH is induced in colon epithelial cells. Doubly mutant $Prop1^{-/-}$ (GH-deficient) and $Apc^{min+/-}$ (develop intestinal tumors) mice exhibit high colon p53 and markedly decreased intestinal tumor number and size compared to single mutant APC min+/− mice.GHR blockade induced by pegvisomant treatment of acromegaly patients leads to increased colon mucosal p53 and its transcriptional target p21. Overexpressing intracellular GH, or re-introducing WT GHR to mutant human fibroblasts, suppresses p53 thereby evading cellular senescence.

Conclusions
We hypothesize that GH leads to a pro-neoplastic environment and that high intracellular GH is a component of the field change enabling colon mucosal proliferation. GH-mediated senescence evasion may explain why GH deficiency is protective for cancer.

Obesity: Pharmacological Solutions

S24.1

MSH analogs

Peter Kühnen
Germany.

The leptin-melanocortin signaling pathway plays a pivotal role in the regulation of body weight within the hypothalamus. Leptin, secreted by the adipose tissue, activates the leptin receptor at the arcuate nucleus, which in turn leads to the production of proopiomelanocortin (POMC) derived peptides as melanocyte stimulating hormone (MSH). MSH activates the melanocortin 4 receptor (MC4R), regulating thereby satiety and energy expenditure. Mutations within this pathway are leading to severe early onset obesity based on severe hyperphagia. After the discovery of MSH, different approaches have been made to generate MC4R agonists. Unfortunately, most of the studies were not successful either due to ineffectiveness of the drug to reduce body-weight or due to severe side-effects as e.g. increased blood pressure. However, recently the development of new MC4R agonists as setmelanotide (RM-493), which is leading to severe weight loss in POMC deficient patients, has open new perspectives for the treatment of monogenic obesity forms. Future studies will elucidate whether this new compounds will be of advantage and a new treatment option for obesity in these rare diseases.

S24.2

The future drugs to come

Gema Frühbeck
Spain.

A complex interaction between environmental and genetic/epigenetic factors is driving the escalating obesity and diabetes epidemics together with a multitude of associated comorbidities. In the past decades the role of gastrointestinal signals in energy homeostasis and glucose control has made tangible progress mainly due to the findings derived from bariatric/metabolic surgery. In particular, incretin-based approaches in relation with glucagon-like peptide 1 and amylin have fostered the emergence of new treatment avenues. Interestingly, one of the most challenging obstacles in obesity treatment is maintaining a lower body weight after weight loss. It can be argued that weight loss and its maintenance may be uncoupled

biological processes that require different pharmacological approaches. Thus, the reduction in metabolic rate triggered by a high calorie-restriction-induced weight loss, contributes to powerful counter-regulatory 'homeostatic' mechanisms leading to weight regain. Therefore, innovative strategies aimed at effectively minimizing these compensatory adaptations with combinations of drugs (combos) using different mechanisms of action may prove useful. Consequently, targeting of food hedonics in combination with the archetypical anorectic and thermogenic pathways will probably provide unparalleled pharmacological efficacy to combat obesity and prevent weight regain. Glucagon has reemerged in weight loss polypharmacy relevantly complementing thermogenic agents. Fibroblast growth factors (FGFs) are undoubtedly among a plethora of newly identified metabolic macromolecules. Evidence that brown adipose tissue exists in adult humans and is activated after cold exposure has opened the interest in the potential browning of adipose tissue and the quantitative contribution of BAT induction/activation towards energy expenditure in obesity. Novel insights that facilitate the design of refined polypharmacy that relevantly targets food hedonics at the same time as stimulates energy expenditure without severe off-target effects that are currently frequently linked to behavioral pharmacology are being pursued.

HPA Axis Regulation During a Woman's Life: Impact on Metabolic Outcomes

S25.1

HPA axis regulation during a woman's life: impact on metabolic outcomes

Svetozar Damjanovic
Serbia.

Aging in both men and women is linked with a decline in diurnal variations in cortisol secretion. Cortisol secretion is increased during circadian nadir and possibly in total through the day. Reduced suppressibility of cortisol after dexamethasone (DEX) administration and increased ACTH secretion with aging are well documented. It appears that aging associates with the decrease in cortisol negative feedback efficacy on HPA axis due to underexpression of mineralocorticoid receptors (MRs) and imbalance of MRs to glucocorticoid receptors (GRs) in hippocampus (HC). Chronically elevated glucocorticoids (GCs) in mice, but not in the other species, lead to neuronal cell loss in the HC. In contrast to these results, an age-related decline in peripheral cortisol values from 30 to 60 years of age within the obese subjects has been observed. This may be explained by emotional eating which reduce HPA axis activity by CRF suppression. No such correlation was found in healthy individuals with normal body-mass-index (BMI). It seems that 'healthy' aging does not lead to enhanced HPA axis activity and peripheral cortisol levels rather decline with aging. Parental regulation of hippocampal GR expression as well as the priming effect of high GC concentrations on the future responses to stressors imprint life history through epigenetic changes within HC. Additionally, men and women tend to react differently with stress–both psychologically and biologically. Clinical significance of reduced adrenal androgen production (DHEA and DHEAS) with aging is not well established. Aldosterone secretion appears to be slightly reduced in elderly whereas sympathetic tone vary from organ to organ. Altogether aging associated changes in HPA activity only in a part depends on genetic background. Individual differences in stress reactivity might be important risk factor for gender-specific health problems in men and women.

HPA axis, insulin resistance and adipocytokines in the fetal-maternal unit

George Mastorakos
Greece.

'Stress' is defined as a state of disharmony or threatened homeostasis. Pregnancy is a transient period of relative hypercortisolism. Chronic or acute stressors influence maternal and fetal Hypothalamus-Pituitary-Adrenal Axes (HPA) during pregnancy. Insulin sensitivity is a feature of normal pregnancy, possibly reflecting an adaptive phenomenon aiming at diverting maternal glucose towards fetal needs. We investigated the effect of maternal stress into maternal insulin sensitivity during pregnancy by employing state-trait anxiety inventory (STAI) trait and state questionnaires for stress assessment and we found that in normal pregnant women, enhanced long-term stress is associated with decreased insulin sensitivity. Both long- and short- term stress are associated with enhanced maternal HPA axis and increased placental CRH secretion. Furthermore the decrease in insulin sensitivity during pregnancy is paralleled by the progressive increase of maternal adipose tissue deposition. Throughout pregnancy maternal adipose tissue is metabolically active, producing adipocytokines involved in the process of insulin resistance. Visfatin concentrations in the 1st trimester positively predict insulin sensitivity during the 2nd trimester. Body fat mass during 1st trimester of pregnancy is negatively associated with insulin sensitivity during the 2nd trimester and should be kept under control. Furthermore, first trimester maternal BMI and serum visfatin seem to be strongly associated with fetal insulin secretion and final birth weight, respectively, suggesting a role of early-pregnancy maternal adipose tissue in the pregnancy metabolic environment. Interestingly, during pregnancy, maternal GLP1 might be involved in mechanisms that compensate for the pregnancy-related increase in glycemia and insulin resistance, suggesting a role of this peptide in maternal metabolism and weight and fetal growth. In conclusion, both maternal adipose tissue and stress-induced HPA activation influence directly and/or indirectly the development of insulin resistance during pregnancy.

11β-hydroxysteroid dehydrogenase activity, androgen excess, and metabolic outcomes in woman

Jeremy Tomlinson
UK.

Steroid hormones have potent metabolic effects. Glucocorticoid excess is characterized by central adiposity, insulin resistance, type 2 diabetes and increased cardiovascular risk. Whilst endogenous glucocorticoid excess is rare, local tissue-specific availability of glucocorticoid is controlled by a series of enzymes that are, at a pre-receptor level, able to regulate cortisol's ability to bind and activate the glucocorticoid receptor. 11β-hydroxysteroid dehydrogenase type 1 (11β-HSD1) converts inactive cortisone to active cortisol, and therefore amplifies local glucocorticoid action. It is highly expressed in key metabolic target tissues including liver, fat and muscle and is dysregulated in metabolic disease including polycystic ovarian syndrome. It has been a target for therapeutic intervention and selective 11β-HSD1 inhibitors provide modest metabolic improvements in patients with type 2 diabetes. In parallel, the A-ring reductases, (5α- and 5β-reductase), inactivate glucocorticoids, but importantly, the isoforms of 5α-reductase convert testosterone to the more potent androgen, dihydrotestosterone. 5α-reductase activity is increased in patients with PCOS and may contribute significantly to the androgen excess observed in these patients and fuel their adverse metabolic phenotype. In addition, adipose tissue is able to generate androgens through the activity of 17β-hydroxysteroid dehydrogenase type 5 (AKR1C3), and activity and expression are increased in patients with obesity and PCOS. *In vitro* data suggest that AKR1C3 may drive lipid accumulation locally within adipocytes through enhanced androgen generation. In conclusion, pre-receptor steroid hormone metabolism has a powerful role to play in the regulation of metabolic phenotype in patients with PCOS and offers significant potential as a target for therapeutic intervention.

Tissue Specific Defects in Thyroid Hormone Action

S26.1

Mouse models to study tissue specific hypothyroidism

Heike Heuer
Germany.

Thyroid hormone (TH) actions and metabolism are intracellular events that require the transport of TH across the plasma membrane in target cells. Consequently, impaired uptake of TH can lead to tissue- specific TH deprivation independent of the TH concentrations in the circulation. A prominent example for such a scenario represents the Allan-Herndon-Dudley syndrome (AHDS). This syndrome is caused by inactivating mutations in the X-linked Slc16a2 gene encoding the monocarboxylate transporter MCT8, a highly specific TH transporter widely expressed in CNS and peripheral tissues. Patients with inactive MCT8 display severe neurological symptoms and signs of brain hypothyroidism despite highly elevated serum T3 concentrations. Likewise, Mct8 ko mice exhibit abnormal TH serum values together with complex tissue-specific changes in the TH status ranging from hypothyroidism (brain, pituitary) to hyperthyroidism (liver, kidney, skeletal muscle). In order to define the tissue-specific function of Mct8 we recently started to generate mouse mutants that lack Mct8 in defined cell types only. In my presentation, I will report on our studies demonstrating pronounced cell-specific alterations in the TH status upon deletion of Mct8 at the blood-brain barrier (BBB), in hypothalamic tanycytes as well as in thyrocytes while absence of Mct8 in forebrain neurons or hepatocytes did not compromise proper tissue-specific TH action. Overall, our data clearly underscore the importance of Mct8 and other TH transporters in mediating TH transport thereby influencing tissue-specific TH homeostasis.

S26.2

Syndromes of decreased sensitivity to thyroid hormone

Nadia Schoenmakers
UK.

Disorders of thyroid hormone action are classified broadly, to encompass conditions with defective cellular uptake, metabolism or nuclear action of thyroid hormones. Genomic thyroid hormone action is mediated via receptor subtypes (TRalpha, TRbeta) with differing tissue distributions. TRbeta-mediated Resistance to Thyroid Hormone (RTH) is characterised by elevated thyroid hormones, raised metabolic rate and cardiac hyperthyroidism but hepatic resistance (dyslipidaemia, steatosis). In contrast, TRalpha1-mediated RTH patients exhibit growth retardation, skeletal dysplasia and constipation together with reduced metabolic rate and cardiac hypothyroidism, with near-normal thyroid hormone levels. The contrasting phenotypes of TRalpha1 and beta- mediated RTH exemplify the differing importance of receptor subtypes in tissues, providing a rational basis for receptor-specific drug development. Mutations in *SECISBP2* and *TRU-TCA1-1* cause a multisystem disorder of defective selenoprotein synthesis, with features attributable both to tissue-specific selenoprotein deficiencies (e.g. male infertility, muscular dystrophy) and raised cellular reactive oxygen species due to lack of antioxidant selenoenzymes (e.g. photosensitivity, increased adipose mass and function). Additionally, patients have a characteristic biochemical signature resulting from impaired conversion of T4 to T3 via selenium-containing deiodinases. This presentation will describe clinical features of these conditions, which increase our understanding of thyroid hormone action and inform potential future therapeutic developments.

Restoring TH action in patients with transporter defects: the triac trial

Stefan Groeneweg
The Netherlands.

Mutations in the thyroid hormone (TH) transporter MCT8 result in the Allan–Herndon–Dudley syndrome (AHDS), which is characterized by severe intellectual and motor disability and high serum T3 levels inducing thyrotoxicity in peripheral organs. At present, no effective treatment is available. Preclinical studies suggest that the T3 analogue Triac is a promising candidate to i) normalize serum T3 levels and thus alleviate the thyrotoxicosis and ii) restore TH signaling in the brain.

Methods

We conduct a world-wide prospective interventional trial in which about 45 AHDS patients receive 1 year Triac treatment. The primary end-point is the reduction of serum T3 levels, and secondary end-points include normalization of heart rate (HR), improvement of body weight (BW) and serum parameters that reflect TH action in peripheral tissues. Neuro(psycho)logical functioning is assessed before and after 1 year of Triac treatment.

Results

Currently, 41 patients (age: 1–66 years) have been enrolled (median (IQR) follow-up time: 8 (3–12) months) of whom 18 have completed 1 year of follow-up. Triac treatment effectively suppressed serum TSH levels (2.3 (1.6–3.9) to 0.9 (0.2–1.9) mU/l; $P<0.001$), resulting in a strong reduction of T3 levels (5.0 (3.9–6.5) to 1.7 (1.4–2.2) nmol/l; $P<0.001$). Importantly, BMI, serum HDL cholesterol, creatinine and CK levels significantly increased, whereas basal heart rate and serum SHBG levels significantly decreased.

Discussion

Triac treatment effectively normalizes serum T3 levels. This interim analysis suggests that Triac treatment has beneficial effects on the peripheral phenotype of AHDS, which will be further substantiated upon completion of the follow-up period by the other participants.

Vitamin D Beyond Bone (*Endorsed by Endocrine Connections*)

S27.1

Heart & Vessels

Klaus Witte
UK.

Vitamin D is a recognised important factor in bone health but in recent years is receiving much attention for its role in multiple other systems. The enthusiasm with which it is embraced as an elixir vitae especially in cancer, cardiovascular disease and neurodegenerative diseases is overwhelming and matched only by the skepticism from other quarters, since solid evidence is largely lacking. I will review the pleiotropic effects of vitamin D and how they may be of relevance to the specific syndrome represented by chronic heart failure and the evidence generated to date by, amongst others, the VINDICATE program at Leeds.

DOI: 10.1530/endoabs.49.S27.1

S27.2

Fertility

Elisabeth Lerchbaum
Austria.

Accumulating evidence from animal and human studies suggests that vitamin D is involved in many functions of the reproductive system in both genders. In women, vitamin D status has been associated with *in vitro* fertilization (IVF) outcome, features of polycystic ovarian syndrome (PCOS), endometriosis, and sex hormone steroidogenesis. In detail, cross-sectional data suggest a regulatory role of vitamin D in PCOS-related aspects such as ovulatory dysfunction, insulin resistance as well as hyperandrogenism. Moreover, results from randomized controlled trials (RCTs) suggest that vitamin D supplementation may be beneficial for follicular development and menstrual cycle regulation in PCOS women. Although several data converge towards a beneficial effect of vitamin D supplementation in metabolic disturbances in women with PCOS, this remains to be demonstrated in high-quality RCTs. Regarding assisted reproductive techniques, recent studies suggest that vitamin D supplementation might be beneficial for couples undergoing IVF. In men, vitamin D status has been associated with semen quality and sperm count, motility and morphology as well as with androgen levels in both fertile and infertile men. Further, there is evidence for a favourable effect of vitamin D supplementation on semen quality, fertility outcomes as well as on testosterone concentrations. In summary, vitamin D deficiency may be a risk factor for adverse fertility outcomes, there is, however, insufficient evidence to establish causality. High quality RCTs are needed to further evaluate the effects of vitamin D supplementation on fertility and sex hormone steroidogenesis in women as well as in men.

DOI: 10.1530/endoabs.49.S27.2

S27.3

Muscles

Roger Bouillon
Belgium.

The vitamin D endocrine system (D-endo) is essential for calcium and bone homeostasis. The vitamin D receptor, VDR, is ubiquitously expressed and about 3% of the mouse or human genome is regulated by D-endo. VDR knock-out mice show impaired striated muscle maturation and selective VDR deficiency in heart muscle cause cardiomyopathy. Muscle weakness may be severe in patients with severe chronic renal failure combined with vitamin D deficiency or in subjects with congenital CYP27B1 deficiency. Muscle strength and function may be impaired in elderly vitamin D deficient elderly subjects and result in increased risks of falls. The final proof of causality is hotly debated but meta-analyses of supplementation studies suggest a modest reduction in falls in elderly subjects with severe vitamin D deficiency. All cells of the immune system express VDR. A large number of immune-related genes are coherently controlled by $1,25(OH)_2D$. The native immune system is stimulated by $1,25(OH)_2D$. A low vitamin D status is associated with an increased risk for all types of infections. Human intervention studies however are equivocal. The acquired immune system is suppressed by D-endo. In animal models vitamin D deficiency leads to increased sensitivity to autoimmune diseases such as inflammatory bowel disease or autoimmune diabetes after exposure to predisposing factors. In man, epidemiological studies confirm such associations, but intervention studies till now fail to show preventive effects. The antiproliferative effect of 1,25(OH)2D on cancer cells has been confirmed in most cells with inhibition of the cell cycle. VDR deficient mice are more prone to cancer when exposed to predisposing factors. The association between a low vitamin D status and colon cancer is fairly consistent in several meta-analyses. A few RCTs however have so far not confirmed beneficial effects on caner. In conclusion, serum 25OHD levels above 20 ng/ml may convey some global health benefits beyond bone but ongoing studies will allow confirming or correcting this conclusion.

Sleep, Love and Reproduction (*Endorsed by Endocrine Connections*)

S28.1

Candidate mechanisms underlying the association between poor sleep and obesity

Christian Benedict
Sweden.

An increasing proportion of people living in our 24/7 culture complain about insomnia symptoms, i.e., they experience problems to fall and/or stay asleep. As demonstrated by epidemiological studies, chronic sleep loss is correlated with weight gain. To investigate whether sleep loss would alter energy metabolism in favour of weight gain, my lab therefore performed a series of sleep loss experiments in metabolically healthy normal-weight subjects. These studies demonstrated that acute sleep loss alters circulating levels of appetite-modulatory metabolites (e.g. higher levels of the hunger-promoting hormone ghrelin), impairs the ability to control food impulses, and increases metabolic efficiency. In the setting of chronically insufficient sleep, such behavioral and metabolic effects may predispose normal-weight individuals to gain weight.

S28.2

Oxytocin: from biology to love

Susana Guerreiro
Portugal.

Oxytocin was discovered by Henry Dale in 1906 and synthesized in the early 50's by Vincent du Vigneaud and coworkers. It is secreted by axonal terminals in the neurohypophysis emanating from the neurosecretory neurons of the supraoptic and paraventricular nuclei of the hypothalamus. This hormone similarly to others is secreted in a pulsatile way and, classically, in relation to labor (uterine contractility), lactation and to the maternal behaviour. After the initial identification of its role in labor induction and lactation it became clear that Oxytocin plays other very important roles in human life namely in the creation of bonds which gave this hormone the title of social hormone. First it became clear that it was responsible for the strong bonds between mother and child but in the recent years it was investigated in relation to other types of pair bonding, the development of monogamous relations, and even the relation between different species like between humans and dogs. It's role in sexual orgasm was also recognized. Its secretion can be influenced by a hug or a simple conversation when feelings of trust are present. Indeed, Oxytocin could be responsible for social behaviour as it facilitates the development of trust and empathy between individuals, strengthening relationships. This neuropeptide seems to facilitate security in human relations thus being supportive of positive social interactions. For all of these discoveries it became known as the love hormone. However other roles have also been attributed to Oxytocin: decreasing levels of stress, fear and pain, and also a sort of selective influence on memory (allowing the individual to keep some memories while eliminating others). The therapeutically potential of oxytocin has already started to be studied in diseases like autism spectrum disorder, schizophrenia and depression. Lab tools like measurements of oxytocin in plasma, brain imaging (f-MRI/PET) and genetic/epigenetic assays bring new opportunities to explore the oxytocin pathway and will continue to help us to understand how to live a healthy life in a love ambience.

Kisspeptin and neurokinin B – novel reproductive hormones with therapeutic potential

Waljit Dhillo
UK.

Kisspeptin and neurokinin B are 2 novel key hypothalamic hormones which are vital in normal reproductive function. Inactivating mutations for the gene or the receptor for either of these peptides will cause a failure of puberty due to hypogonadtotrophic hypogondaism. In this talk I will present evidence to suggest that kisspeptin is important in sexual and emotional processing in humans (1). In addition I will present evidence which suggests that NK3R (the receptor for NKB in humans) is important as a mediator of menopausal flushing and this has potentially practice changing therapeutic potential (2).

Novel Predictors of Diabetes

S29.1

Novel predictors of type 1 diabetes

Mikae Knip
Finland.

Islet autoantibodies are strong predictors of type 1 diabetes (T1D), as positivity for multiple, i.e.is two or more, autoantibodies is associated with a risk of around 70% of progression to clinical disease over the next 10 years. Autoantibodies do not, however, predict when T1D will present clinically. We have assessed the utility of signs of dysglycemia for the prediction of the time of disease manifestation and observed that an increase in HbA1c of 10% over 3–12 months provides a 50% likelihood of disease presentation within 1.1 year after the observed increase. When the HbA1c value was 5.9% (41 mmol/mol) in two consecutive samples, the median time to diagnosis was 0.9 years. The median time to diagnosis after the detection of impaired glucose tolerance on OGTT was 0.7 years. After the detection of an increased random plasma glucose ($\geq$7.8 mmol/l) the median time to diagnosis was 1.0 years. The omics technologies have raised the issue, whether there is a possibility to identify high risk individuals before the appearance of the first autoantibodies. We have looked at markers generated by transcriptomics. We observed that genes and pathways related to innate immunity functions, such as the type 1 interferon (IFN) response, were active, and IFN response factors were identified as central mediators of the IFN-related transcriptional changes. In a proteomics study we found that when including the total observation time from birth to diagnosis we were able to classify the participants into disease progressors and non-progressors

with a success rate of 91%. The classifica-tion was based on the combination of the relative levels of APOC4 (decreased) and afamin (AFAM, increased). Lipidomics and metabolomics analyses showed that individuals who developed T1D had reduced serum levels of succinic acid and phosphatidylcholine (PC) at birth, reduced levels of triglycerides and antioxidant ether phospholipids throughout the follow up, and increased levels of proinflammatory lysoPCs several months before seroconversion to autoantibody positivity. The appearance of insulin and glutamic acid decarboxylase autoantibodies was preceded by diminished ketoleucine and elevated glutamic acid. Another study focusing on the lipidome/metabolome in cord blood revealed that those children, who progressed quickly to clinical T1D, were characterized by a distinct cord blood lipidomic profile that includes reduced major choline containing phospholipids, including sphingomyelins and phosphatidylcholines. Risk children, who progress to clinical T1D are characterized by a decreased microbial diversity, an increased abundance of potentially pathogenic bacteria and a reduced functional gene content in their intestinal microbiome. These changes, can however, not be seen before seroconversion to autoantibody positivity. To summarize, metabolic markers help in the estimation of time to diagnosis in prediabetic individuals. The potential predictive markers generated by omics technologies have to be validated.

Clinical and genetic indicators for diabetes prediction

Valeriya Lyssenko
Denmark.

Worldwide diabetes epidemic leads to exponential increase in incidence and prevalence of associated co-morbidities and mortality. During the last 10 years we have devoted to investigate how clinical and genetic biomarkers can be used to facilitate prediction of these life-threatening hazards. Accumulating evidence from our large prospective studies indicate that decline in insulin secretion adjusted for the degree of insulin sensitivity is the key factor contributing to overt type 2 diabetes. Furthermore, genetic data indicate that risk alleles in genetic loci for type 2 diabetes influenced changes in pancreatic beta-cell function over time, while having no effect on changes in body mass index. Presently, genetic information has insufficient power to predict common type 2 diabetes. However, our follow-up studies on variants in *TCF7L2, MTNR1B, GIPR, GRB10* genes unravelled multiple and pleiotropic mechanisms of genetic loci which significantly contributed to our understanding of pathogenesis of type 2 diabetes including effects on insular-incretin axis (GIP/GLP-1 and glucagon) and hepatic glucose production in the liver. We and others have also reported α-hydroxybutyrate, linoleoyl glycerophosphocholine, and copeptin as novel biomarkers to be associated with increased risk of type 2 diabetes. However, these new biomarkers require a systematic evaluation and validation across different studies and populations before their actual diagnostic and prognostic value is confirmed.

Moving Away from Old-fashioned Steroidogenesis: What Are the Clinical Implications?

S30.1

Clinical relevance of alternative synthesis of androgens

Hans Hofland
The Netherlands.

Recent years have seen many exciting developments in the field of steroidogenesis. These include improved diagnostics through mass spectrometry, novel clinical relevance attributed to steroids previously deemed irrelevant and successful implementation of new anti-cancer treatments. Prostate cancer is a prime example of the latter with the recent confirmation that castration-resistant disease is still androgen-dependent and susceptible to hormonal manipulation with next generation steroidogenic enzyme inhibitors and anti-androgens. In advanced stages of prostate cancer hormonal treatment leads to complex and incompletely understood changes in circulating steroid hormones levels. CYP17 inhibitors like abiraterone acetate lead to accumulation of mineralocorticoid precursors and progesterone metabolites. This ensues a steroid flux into the alternative pathway to 5α-dihydrotestosterone (DHT) with intermediates such as allopregnanolone and androstanediol. Our data in parental and abiraterone-resistant prostate cancer cells show a functional block at the level of CYP17 in prostate cancer cells, preventing *de novo* steroid synthesis and local activation of CYP17 precursors. However, accumulation of other steroid hormones intratumorally could affect nuclear receptor activation. Concurrently, interaction with supplemented glucocorticoids leads to a complex interaction between wild type, mutant and splice variants of nuclear receptors and DNA regulatory elements. Further research into pre-receptor regulation of steroid hormones combined with innovative genome-wide receptor-DNA binding analyses will pave the way towards comprehensive understanding of their effects. In turn, this could secure efficient targeting of the detrimental sequelae of steroid hormones in prostate cancer and other endocrine diseases.

S30.2

Clinical relevance of steroid precursors in adrenocortical tumors

Vasileios Chortis

Adrenal incidentalomas represent an increasingly common diagnostic problem facing clinical Endocrinologists. Swift and accurate differentiation of benign from malignant disease is essential, but the diagnostic performance of current imaging modalities is sub-optimal and often leads to ill-advised management decisions. Urinary steroid profiling by modern mass spectrometry-based techniques can provide a comprehensive profile of steroidogenesis, quantifying both precursor molecules and end products. Adrenocortical carcinomas display a premature pattern of steroidogenesis, dominated by precursor hormone synthesis, which can be captured in the urinary profile. Emerging evidence highlights the unique diagnostic opportunities presented by this feature. The combination of high-sensitivity biochemical analysis and computational data processing is expected to transform the management of adrenal tumours, from the diagnostics of adrenal incidentalomas to the post-operative surveillance of adrenocortical carcinomas.

S30.3

Glucocorticoid production in primary aldosteronism – from mechanisms to clinical implications

Felix Beuschlein
Germany.

Adrenal aldosterone excess is the most common cause of secondary hypertension and is associated with increased cardiovascular morbidity and mortality. However, adverse metabolic risk in primary aldosteronism extends beyond hypertension, with increased rates of insulin resistance, type 2 diabetes, and osteoporosis, which cannot be easily explained by aldosterone excess but would rather be associated with oversecretion of glucocorticoids. Over the last years, exome sequencing has provided new insights into the genetic set-up of adrenal adenomas highlighting the concept of calcium dependent signalling being the main driver for aldosterone secretion while the cAMP/PKA pathway can be considered of particular importance for cortisol production. In rare examples somatic mutations in genes involved in cAMP signalling could be identified. However, in the majority of cases the contribution of glucocorticoid oversecretion in patients with primary aldosteronism has remained uncertain. Recently, we have performed mass spectrometry-based steroid metabolome profiling in 24-h urines from consecutively recruited patients with primary aldosteronism. Comparisons were made with healthy controls, patients with endocrine inactive adrenal adenoma, and patients with mild subclinical and clinically overt adrenal cortisol excess. Based on these measurements, patients with primary aldosteronism had significantly increased cortisol and total glucocorticoid metabolite excretion, only exceeded by glucocorticoid output in patients with clinically overt adrenal Cushing syndrome. Several surrogate parameters of metabolic risk correlated

significantly with glucocorticoid but not mineralocorticoid output. We analysed the expression of cortisol-producing CYP11B1 and aldosterone-producing CYP11B2 enzymes in adrenal adenoma tissue from patients with primary aldosteronism, employing immunohistochemistry with digital image analysis. Intra-tumoral expression of CYP11B1 correlated significantly with glucocorticoid excretion, whereas CYP11B2 expression correlated with aldosterone output. Unilateral adrenalectomy for adenoma removal resolved both mineralocorticoid and glucocorticoid excess. Postoperative evidence of adrenal insufficiency was found in roughly one third of tested patients. These data show that glucocorticoid co-secretion is a prevalent feature in primary aldosteronism and significantly contributes to associated metabolic risk. Mineralocorticoid receptor antagonist therapy alone may not be sufficient to counteract adverse metabolic risk in medically treated patients with primary aldosteronism.

New international clinical practice guidelines for the care of girls and women with turner syndrome

Claus H Gravholt
Denmark.

Turner syndrome (TS) affects 25–50 per 100 000 females and can involve multiple organs through all stages of life, necessitating a multidisciplinary approach to care. Previous guidelines have highlighted this, but numerous important advances have been noted since their publication. These advances cover all specialty fields involved in the care of girls and women with TS. This new international guideline is based on an international effort that started with exploratory meetings in 2014 in both Europe and the USA, and culminated with a Consensus Meeting held in Cincinnati, Ohio, USA in July 2016. Prior to this meeting, five groups each addressed important areas in TS care: i) diagnostic and genetic issues, ii) growth and development during childhood and adolescence, iii) congenital and acquired cardiovascular disease, iv) transition and adult care, and 5) other comorbidities and neurocognitive issues. These groups produced proposals for the new guidelines. Additionally, four pertinent questions were submitted for formal GRADE (Grading of Recommendations, Assessment, Development and Evaluation) evaluation with a separate systematic review of the literature. These four questions related to the efficacy and most optimal treatment of short stature, infertility, hypertension, and hormonal replacement therapy. These guidelines were initiated and developed by the European Society of Endocrinology (ESE) in Europe, and by the Pediatric Endocrine Society (PES) in USA, with important contributions from the European Society of Human Reproduction and Embryology (ESHRE), the Endocrine Society (ES), the European Society for Cardiology (ESC), the American Heart Association (AHA), and the European Society for Pediatric Endocrinology (ESPE). Several delegates from other societies also participated. Advocacy groups appointed representatives who participated in pre-meeting discussions and in the consensus meeting. Here, we will present the most important new advances in the care of Turner syndrome.

GS1.3

Adult aspects of turner syndrome

Janielle Alfen-van der Velden

In this session, the adult aspects of Turner syndrome are addressed following the new Clinical Practice Guidelines for Turner syndrome. The presentation includes both theoretical backgrounds and practical recommendations. Fertility preservation is discussed and the results of our GRADE evaluation according to the outcome of oocyte donation is presented. New insights in health surveillance for co-morbidities are highlighted. Practical tools for transition from pediatric to adult care are provided. In addition, a toolbox for neuropsychological and psychological assessment of women with Turner syndrome is presented and possible options for intervention are discussed.

DOI: 10.1530/endoabs.49.GS1.3

GS1.4

Cardiovascular health issues in turner syndrome

Philippe Backeljauw

Individuals with Turner syndrome (TS) have an increased risk for congenital and acquired cardiovascular disease (23–50%). This results in increased morbidity and mortality throughout the TS lifespan. There is an increased prevalence of bicuspid aortic valve malformation, coarctatio of the aorta, elongation of the transverse aortic arch, and partial anomalous venous return. In addition, TS females may develop aortopathy that may result in clinically significant aortic dilatation, which occasionally leads to dissection or rupture. Other cardiovascular conditions such as hypertension, coronary heart disease, and cerebrovascular disease (stroke) further reduce the lifespan of TS individuals. Because of this high prevalence of cardiovascular disease, any care provider should have some familiarity with the non-invasive cardiac imaging techniques required for diagnosis and management. Imaging modalities include transthoracic echocardiography and cardiac magnetic resonance imaging. Echocardiography is useful in the diagnosis of a bicuspid aortic valve and other congenital heart diseases, and can be used for surveillance of aortic dilatation. Some abnormalities, such as elongation of the transverse aortic arch and partially anomalous pulmonary venous return, are not as readily ascertained by ultrasound however, and cardiac magnetic resonance imaging is now commonly used as a screening and surveillance tool, especially in adult TS patients. The newly developed clinical care guidelines for girls and women with TS include very specific recommendations on which aortic dimensions may warrant consideration for close monitoring and possible operative intervention. They also provide guidance in decision-making regarding participation in various sports disciplines, and greatly clarify when more frequent cardiovascular health monitoring may be beneficial. It is important that both pediatric and adult endocrinologists, as well as reproductive endocrinologists, are familiar with the updated recommendations for cardiovascular health management in TS, in order to coordinate care with the cardiologists and to facilitate over health maintenance of girls and women with TS.

New Scientific Approaches

NSA1

Identifying molecular signatures for cancer patient stratification via metabolomics and integrative bioinformatics

Hector Keun
UK.

Altered metabolism in tumor cells is required for rapid proliferation but also can influence other phenotypes that affect clinical outcomes such as metastasis and sensitivity to chemotherapy. Integration of metabolome and transcriptome data for the NCI-60 panel of cancer cells lines allowed us to identify ecto-5′-nucleotidase (NT5E or CD73) and miRNA-22 as a major determinants of metabolic phenotypes in cancer cells. NT5E expression and associated metabolome variations were also correlated with sensitivity to several chemotherapeutics including platinum-based treatment. We observed that tumor NT5E levels were prognostic for outcomes in ovarian cancer and were elevated after treatment with platinum, supporting the translational relevance of our findings. The cancer-associated and cardioprotective miR-22 was shown to repress fatty acid synthesis and elongation in tumour cells by targeting ATP citrate lyase and fatty acid elongase 6, as well as impairing mitochondrial one-carbon metabolism by suppression of methylene tetrahydrofolate dehydrogenase/cyclohydrolase (MTHFD2). Importantly, a beneficial effect of miR-22 on clinical outcomes in breast cancer was shown to depend on the expression levels of the identified target genes, demonstrating the relevance of miRNA/mRNA interactions to disease progression *in vivo*. These studies illustrate one route towards patient stratification based the rational combination of different types of molecular biomarkers for metabolic processes.

Exosome profiling: potential in cancer diagnosis and stratification

Juan Falcon-Perez
Spain.

In the last decade, cell-secreted extracellular vesicles (EVs) have been isolated from most of the fluids of the body. There are many different types of EVs that include different subpopulations of exosomes, microvesicles and apoptotic bodies, all of them varying in size, composition and intracellular origin. Many laboratories around the world have shown that its composition of lipids, proteins, messenger and micro RNAs is cell-type specific, and subject to changes in pathological scenarios, consequently these vesicles are being actively studied as a source to identify disease biomarkers. Metabolic syndrome is a clinical condition affecting up to 25% of all adults worldwide. It influences many cellular systems including adipose tissue, macrophages and hepatocytes compromising most of the time the hepatic function that is essential for homeostasis of the organism. Apart of metabolic syndrome, liver injury ranging from mild infection to life-threatening liver failure constitute by itself a serious worldwide health issue. Consequently, a major goal in liver pathology is the identification of molecular markers for its early detection, i.e. before clinical manifestations are produced. In this context, by applying metabolomics, proteomics and transcriptomics technologies as well as specific biochemical tools, our group is studying the physiological role of extracellular vesicles in the hepatic function in normal and pathological conditions to identify novel low-invasive markers for liver injury. During last years, our group has demonstrated that hepatocytes are able to secrete exosomes-like vesicles enriched in metabolic enzymes. Now, we are currently achieving a thorough qualitative and quantitative analysis by proteomics, transcriptomics and metabolomics of extracellular vesicles secreted by hepatocytes obtained from experimental models of drug-induced liver injury and metabolic syndrome. Our work provides a repertoire of low invasive candidate markers to evaluate hepatic function in a low invasive manner. Furthermore, our results also support a physiological role of hepatic exosomes in different patho-physiological processes.

CRISPR/cas9 cas9-generated mouse models of resistance to thyroid hormone due to THRA mutations

Frederic Flamant
France.

Resistance to thyroid hormone due to THRA mutations (RTHα) is a recently discovered genetic disease with high variability in its clinical presentation. This variability may result from the fact that patients bear different types of mutations, which may impact in different ways the functionality of thyroid hormone receptor α1 (TRα1). Our aim was to understand the relationship between specific THRA mutations and symptoms, using mouse models. CRISPR/Cas9 genome editing was used to generate five new models of RTHα, the human genetic disease caused by mutations in THRA. Like human patients, the mutant mice displayed a hypothyroid-like phenotype, with altered post-natal development. Phenotype severity varied over a broad range between models, mainly depending on the ability of the mutant receptor to interact with the NcoR transcription corepressor in the presence of thyroid hormone. These data illustrate the outstanding possibilities offered by CRISPR/Cas9 genome editing which allows to rapidly produce mouse models of human genetic disease, and even to model individual sporadic cases of the disease.

Small molecule agonists and antagonists as potential new therapeutics targeting the TSH receptor

Susanne Neumann
USA.

Thyroid-stimulating hormone (TSH, thyrotropin) is an activator of the TSH receptor (TSHR) in the hypothalamic-pituitary-thyroid axis leading to biosynthesis and secretion of thyroid hormones. We have developed an orally available small molecule, allosteric TSHR agonist, E2, for follow up diagnosis of patients with thyroid cancer. This ligand could replace recombinant human TSH (rhTSH, Thyrogen) which is currently used in the clinic. In a mouse model, oral administration of E2 is as efficacious as intraperitoneal injections of rhTSH. Therefore, E2 represents a next step in the pre-clinical development of an oral drug to stimulate radioiodine uptake and/or serum thyroglobulin levels in patients with thyroid cancer. Graves' disease (GD) is caused by persistent, unregulated stimulation of thyroid cells by thyroid-stimulating antibodies (TSAbs) that activate the TSHR. We identified the first small molecule TSHR antagonist (ANTAG3) which inhibits TSH- and TSAb-stimulated signaling. ANTAG3 is selective for TSHR because it does not inhibit activation of LH or FSH receptors, the receptors with the highest homology to TSHR within the seven transmembrane domain in which ANTAG3 binds, and it inhibits TSHR activation in the thyroid gland of mice *in vivo*. These findings suggested that ANTAG3 could be able to inhibit TSHR signaling in extra-thyroidal tissues that express TSHRs including orbital fibroblasts, which play a role in the pathogenesis of Graves' ophthalmopathy (GO), a disease of the eye that is associated with GD. None of the treatment regimens for GD and GO used today are directed at the pathogenesis of these diseases. In an ideal case the same drug would treat Graves' hyperthyroidism and GO. ANTAG3, directly acting at the TSHR, reduced TSH- and TSAb-stimulated hyaluronan (HA) production, a major component of GO, by Graves' orbital fibroblasts. Crosstalk between the TSHR and the insulin-like growth factor 1 (IGF-1) receptor (IGF-1R) initiated by activation of TSHR may play a prominent role in the development GO. We have

shown that TSHR activation alone is sufficient to stimulate HA secretion, through both IGF-1R-dependent and -independent pathways. ANTAG3 inhibited both IGF-1R-dependent and -independent pathways at all doses of the monoclonal stimulating antibody M22; whereas IGF-1R antagonist linsitinib (a small molecule kinase inhibitor) and 1H7 (inhibitory antibody) lost efficacy at high M22 doses. We propose that combination therapy targeting TSHR and IGF-1R may be an effective treatment strategy, especially for GO. We suggest that small molecule TSHR antagonists are leads for the development of orally active drugs to treat patients with Graves' hyperthyroidism and GO.

Mitochondrial epigenetics in obesity and its co-diseases

Ana Belén Crujeiras

The biological regulatory system through which the organism responds to environmental pressures is mediated by epigenetic modifications of the genome without altering the DNA sequence. Among the epigenetic processes, DNA methylation is perhaps the best understood epigenetic adaption and most common DNA modification. This mechanism plays an important role in regulating the gene expression of many biological processes and has wide-ranging effects on health. Aberrant epigenetic regulation has been described in many human diseases. Concretely, there is growing body of evidence that shows a relevant role of epigenetic marks with obesity and its co-disease susceptibility. However, while nuclear DNA methylation is a well stablished feature, very little attention has been devoted to mitochondrial epigenetics. Obesity is often associated with a state of mild chronic inflammation characterized by an abnormal production of proinflammatory and prooxidant mediators. This proinflammatory condition has been linked to a mitochondrial dysfuncion. In fact, an energy restriction therapy devised to lose weight induces an increase in the intracellular ATP content and mitochondrial-related gene expression, concomitantly with a decrease oxidative stress and inflammatory markers. Mitochondrial dysfunction and the increment of mitochondrial Reactive Oxygen Species (ROS) production are important benchmarks of the aging and metabolic disturbances development. Therefore, the mitochondrial dysfunction might be critically involved in the pathogenesis of obesity. However, the molecular mechanisms leading to mitochondrial dysfunction in metabolic diseases are still unknown. In this context, mitochondrial epigenetics is a novel mechanism to understand the pathobiology of diseases with a mitochondrial dysfunction involvement. Epigenetic regulation of mtDNA has received increasing attention in the last years due to its implication in clinically relevant disease. Variations in mtDNA methylation were associated with exposure to pollutants and Nonalcoholic fatty liver disease (NAFLD) and were proposed to have a role in mitochondrial gene expression regulation. mtDNA methylation was reported to be induced by hyperglycaemia in retinal endothelial cells and to negatively regulate mitochondrial gene expression. Moreover, mitochondrial epigenetic can modulate nuclear DNA and nuclear DNA epigenetic may affect mtDNA. Hence, abnormal mtDNA methylation is attracting increasing attention as potential biomarker and might have therapeutic potential for metabolic diseases management.

Is There a Role for Medical Therapy for Non- Functioning Pituitary Adenomas?

D1.1

Is there a role for medical therapy for non- functioning pituitary adenomas? - FOR

Yona Greenman
Israel.

In this debate I will make an overview of outcomes of NFPA patients with post-operative remnants, who were treated conservatively after surgery. In view of the high rates of tumor progression with consequent need for repeated surgery and radiation therapy, we propose the use of dopamine agonists in these patients. Recent data showing that preventive treatment with dopamine agonists significantly reduces the rate of tumor progression and the need for radiation therapy or additional surgical interventions will be reviewed.

DOI: 10.1530/endoabs.49.D1.1

D1.2

Is there a role for medical therapy for non- functioning pituitary adenomas? - AGAINST

Stylianos Tsagarakis
Greece.

Non-functioning pituitary adenomas (NFPA) are the second most common variant of pituitary tumors. They are presented by compression symptoms, hypopituitarism and in rec as incidental findings during brain imaging. When symptomatic, primary therapy for NFPAs is surgery most commonly by the trans-sphenoidal (TSS) approach. Medical therapy is not generally recommended in this setting, particularly when immediate decompression of the optic chiasm is needed. Despite the debulking efficacy of TSS, in many occasions only partial tumor resection is achieved. Recurrence rates are high in partially resected tumors. Although less frequently, even completely resected tumors may also recur. Therefore, there is a need for post-surgical surveillance and intervention in order to prevent recurrence. The current practice in most centers is to follow-up the pituitary lesion by MRI-imaging and offer additional therapy, usually in the form of radiotherapy (RT), in case of recurrence. RT, either conventional or stereotactic, is effective in controlling further tumor growth but its use is compromised by significant side effects. Based on findings that many NFPAs demonstrate expression of dopamine and somatostatin receptors, medical therapy with dopamine agonists (DA) and somatostatin analogues (SSA) have been used after surgery in order to prevent recurrence. So far, DAs have been more widely tested showing some promise in several small-scale case series. In a recent larger study, introduction of DA immediately after surgery led to a lower number of recurrences compared to a control group that did not receive DA therapy. However, since not all patients will recur, such a strategy exposes a substantial number of patients to unnecessary long-term DA therapy. Unfortunately there are no robust predictors for tumor recurrence. In fact, the best predictor of tumor growth is growth itself. However, DA therapy was less effective when introduced later in patients that already demonstrated a tendency for tumor regrowth. Surprisingly the beneficial effect of DA therapy does not correlate with dopamine receptor expression. This finding raises concerns about the pathophysiological background of the observed DA benefit. Moreover, there are no solid data on hard end points e.g. prevention of visual fields defects and avoidance of second surgery. Although early initiation of treatment may be preferable, dosage and duration of treatment are largely empirical. The need for higher doses and long treatment periods raises some safety concerns. Definitely a well-designed randomized control trial will resolve many of these issues. However, the lack of industrial interest and the long time-length required to obtain valid data, limits the feasibility of such a perspective. To summarize, the promise of most medications is limited by imprecisions regarding the final outcome and uncertainties on dosing and duration of preventive therapy. So far, effective medications have rendered prolactinomas and acromegaly well manageable disorders. For NFPAs such a possibility still remains elusive.

Incidentally Discovered Nonfunctioning Pancreatic NETs: Surgery or Not? (*Endorsed by the European Journal of Endocrinology*)

D2.1

Incidentally discovered nonfunctioning pancreatic NETs: Surgery or not? - FOR

Ulrich Knigge
Denmark.

Pancreatic incidentalomas are defined as asymptomatic pancreatic lesions, discovered incidentally by imaging for an unrelated indication. A significant proportion of these tumors may be malignant or have a malignant potential. As the use of improved cross sectional imaging increases incidentalomas are becoming more common. In the ENETS guidelines it is proposed that selected patients with incidentally found sporadic, asymptomatic, non-functioning (NF) pancreatic neuroendocrine neoplasms (pNEN) less than 2 cm in size may be followed with repeated imaging instead of resected. However, this conclusion is based on limited data as only few and retrospective studies with a heterogeneous design have investigated the safety of active surveillance. Only few patients had histological or cytological diagnosis and the Ki67 proliferation index, which is the most powerful prognostic marker in NF pNEN, was only determined in 10% of the patients. Up to 20% (in a single study 50%) of the patients had significant tumor growth although regional lymph node metastases developed in few patients. In a recent study, 38% of pNEN <2 cm displayed malignant features. Hence, it cannot be predicted which patients will progress during observation. Accordingly, active surveillance is a doubtful approach and resection should be offered patients with small NF pNEN, if not contraindicated by age, severe co-morbidity and poor performance status. Surgical procedures for small NF pNEN are safe when performed in high-volume centers. In contrast, in MEN-1 patients NF pNEN $\leq$ 2 cm are generally indolent tumors with low malignant features and surgical treatment is rarely indicated.

Is Cardiovascular Risk Increased in Women with PCOS?

D4.1

Is cardiovascular risk increased in women with PCOS? - FOR

Harpal Randeva
UK.

Polycystic ovary syndrome (PCOS) is the most common endocrine disorder amongst women of reproductive age and is associated with various cardiometabolic perturbations, in addition to chronic anovulation and factors related to androgen excess. Indeed androgen excess has been associated with increased cardiovascular risk in women; serum testosterone correlates with indices of subclinical atherosclerosis and cardiovascular disease (CVD). Moreover, women with PCOS, as compared with age- and body mass index-matched women without the syndrome, appear to have a higher risk of insulin resistance, hyperinsulinemia, glucose intolerance, dyslipidemia, and an increased prothrombotic state, possibly resulting in a higher rate of type 2 diabetes mellitus, fatty liver disease, subclinical atherosclerosis, vascular dysfunction, and potentially cardiovascular disease and mortality. Obesity, an independent risk factor for CVD, is also more prevalent in PCOS women as compared to age-matched controls, and is aggravated by androgen excess and has an detrimental android pattern of distribution. Further alterations in PCOS include an increased prevalence of sleep apnoea, as well as various changes in the secretion and/or function of adipokines and adipose tissue-derived pro-inflammatory factors, all of them with direct or indirect influences on the complex signaling network that regulates metabolism, insulin sensitivity, and energy homeostasis. The literature is full of conflicting data and this is partly due to the definition(s) used to identify women with PCOS and also the phenotypic variability of PCOS, which in itself generates significant influence on the cardiometabolic risks.

DOI: 10.1530/endoabs.49.D4.1

D4.2

Is cardiovascular risk increased in women with PCOS? – AGAINST

Enrico Carmina
Italy.

Young women with PCOS presents a severe risk of developing type II diabetes, cardiovascular diseases, chronic liver disease and endometrial cancer. However, in term of events, there is proven evidence only for type II diabetes and for endometrial cancer. In particular, it is still unclear whether CV events are increased in women with PCOS. Completely different data have been published and the quality of many studies is relatively low. Some recent evidence suggests a larger number of cardiovascular events (4 fold) in young population with PCOS. However, studies at this age present an inherent difficulty linked to the low number of CV events in young population. In addition, these data are based on hospitalized population and this approach may have some biases because it may exclude the less affected population. In our large follow up of unselected PCOS patients, no increase of CV events was noted. In aged PCOS patients the data are also contrasting with some studies showing a slight increase of CV diseases and others reporting normal prevalence of CV events. Large follow up studies are missing and are urgently needed to solve this important issue. However, it is clear that the number of events in aged women, who had PCOS during their reproductive age, is much lower than that expected on the basis of risk calculation during young adult age. The mechanisms of the discrepancy between CV risk and late events in PCOS are unclear but a progressive normalization of CV risk during late reproductive age may have a main role.

Should We Still Ablate all Patients Undergoing Total Thyroidectomy for Thyroid Cancer?

D5.1

Should we still ablate all patients undergoing total thyroidectomy for thyroid cancer? - FOR

Markus Luster
Germany.

Abstract Unavailable.

D5.2

Should we still ablate all patients undergoing total thyroidectomy for thyroid cancer? - AGAINST

Sophie Leboulleux
France.

Regarding the debate about whether we should still ablate all patients undergoing total thyroidectomy, the answer is no. Most thyroid cancer patients have an excellent prognosis with a normal life expectancy and among them most of them have a low risk of recurrence. The absence of ablation in patients with thyroid cancer of 1 centimeter or less (pT1a) is already widely applied, so, we are used not to ablate all thyroid cancer patients treated with total thyroidectomy. The question, indeed, is whether the group of patients not undergoing systemic ablation can be extended beyond pT1aN0/x patients. The selection of patients to be spared from ablation can indeed be based on pathology examination, on tumour size, on lymph node involvement and since some of these patients are now recognized as low risk patients. The selection can also be based on postoperative thyroglobulin level because of its excellent negative predictive, whether measured after TSH stimulation or measured under levothyroxine treatment with ultrasensitive method, and on neck ultrasonography. However, prospective randomized trials are needed in order to answer this question of ablation. This will allow reinforcing the strength of recommendation that can be done.

Is It Time for Initial Combination in Type 2 Diabetes?

D6.1

Is it time for initial combination in type 2 diabetes? - FOR

Stefano Del Prato
Italy.

Abstract Unavailable.

D6.2

Is it time for initial combination in type 2 diabetes? - AGAINST

Didac Mauricio
Spain.

Type 2 diabetes mellitus is a heterogeneous disease with multiple pathophysiological pathways contributing to hyperglycemia, and also resulting in a variable clinical picture. Thus, individualization of hypoglycemic therapy is a mainstay of current clinical guidelines. Several factors should be considered for a given treatment choice. These include the characteristics related to a given medication (efficacy, hypoglycemia, effect on weight, other safety issues, the mechanism of action), and other factors, like costs related to each treatment, convenience for the patient, etc. Initial combination therapy may be considered as a suitable choice for some patients/circumstances. However, the evidence favoring this combinatory initial option has not been clearly established. Different issues concerning the convenience of using either initial combination therapy vs sequential addition of hypoglycemic drugs will be addressed during the discussion. The following aspects will be dealt with: long term efficacy of combination therapy vs sequential titration/addition of hypoglycemic agents; durability; overall cost and cost-effectiveness; safety issues, including hypoglycemia and weight changes; advantages/disadvantages in terms of treatment adherence; effects on patient-oriented outcomes, including long-term morbidity and mortality; effect on clinical inertia; what is the best combination of hypoglycemic agents; individualization vs combination for every patient. To conclude, the question about the implementation of initial combination therapy as a strategy in usual clinical practice is still open.

How to manage diabetes in the elderly?

Leocadio Rodriguez-Manas
Spain.

The prevalence of diabetes and glucose intolerance is close to 50% in people older than 65. At the same time, near 50% of people with type 2 diabetes are $\geq$ 65 years old. But being these figures relevant enough to raise a special consideration about how to manage diabetes in this population, there are other reasons supporting the need of that a special consideration. These other needs are not quantitative but qualitative ones, making older people with diabetes a particular group of patents with different characteristics, different aims and, as a consequence, different management compared to adult non-older patients with type 2 patient and, of course, younger patients with both type 1 and type 2 diabetes. These differences range from differences in the pathophysiology of diabetes, that although stemming from insulin resistance have a different origin of this insulin resistance, to the mechanisms underlying the development of vascular and other complications of diabetes, the impact of the disease in the several classical target organs (in people older than 80 diabetes does not increase the risk of blindness), the clinical manifestations of the disease, the diagnostic approach or the general management of the patient. Among all of those, and some others, differences, perhaps the most relevant is the focus on function. While in younger populations, the focus is usually centered in preventing or treating vascular disease (both micro- and macroangiopathy) and other complications of diabetes, when people is older the main focus is to avoid, delay or, if possible, reverse functional (both physical and cognitive) impairment. It is quite clear that diabetes increases less significantly the risk of death in this population, reaching relative risks as low as 1.2 in people older than 80 years. old. However, diabetes is one of the chronic diseases increasing the risk of mobility disability, dependency for instrumental or basic activities of daily living, falls and cognitive impairment/dementia in more than twice. In addition, the role of functional status in conditioning the prognosis (both functional and vital, plus other outcomes like hospitalization) is increasingly higher as patient is getting older, substituting the classical role of the comorbidities (both those related and those non-related to diabetes). Finally, the functional impact of the disease is also the main factor explaining the costs of the disease, reaching figures of 78% of the costs. As a consequence, the management of diabetes in older people should be based in functional status as the main factor in the decision-making process, but also as the main therapeutic target. This change in the focus is crucial to get the best benefits when facing older people with diabetes.

Diagnosis and management of GH deficiency - from childhood to adulthood

Jens Jorgensen
Denmark.

Pituitary dwarfism has been known for many decades, originally as a component of organic panhypopituitarism. GH for clinical use was purified by Maurice Raben from human cadaveric pituitaries and tested for the first time and with success in 1957 in a patient with childhood onset disease. Moreover, pivotal short term studies on the metabolic effects were performed in both healthy and hypopituitary adults. The concomitant introduction of imunnoassays for GH led to the introduction of GH stim tests and recognition of isolated and idiopathic GHD. But the scarcity of GH for clinical use was a major limitation until the 1980s when biosynthetic GH became available. This opened the possibility of novel indications including GHD in adults (GHDA). The two first placebo-controlled studies in 1989 reported positive effects in both childhood- and adult-onset GHDA in terms of body composition and exercise capacity. This has since been corroborated in numerous trials, and it is also documented that discontinuation of GH in the transition from child to adulthood is unfavorable. Finally, there is indirect evidence to suggest that GH replacement in adults may reduce mortality and does not associate with increased cancer risk. Still, GH therapy in adults is by no means a fountain of youth, and there is no evidence to suggest that it is of any meaningful use in either normal or frail aging. This MTE will discuss this exiting journey from a personal point of view.

Hormone-secreting adrenal tumours in pregnancy

Catherine Williamson
UK.

Hormone-secreting adrenal tumours are rare occurrences in women or reproductive age. The commonest is phaeochromocytoma, followed by primary aldosteronism and Cushing's syndrome. The shared maternal phenotypic feature of these tumours in marked hypertension. They may be difficult to diagnose as many of the clinical features are mimicked by pregnancy, e.g. flushing, weight gain, palpitations. Furthermore hypertensive disease occurs in approximately 5% of pregnant women. However, there are specific clinical features associated with each tumour type that aid diagnosis; the hypertension in phaeochromocytoma may be paroxysmal; primary aldosteronism is often accompanied by hypokalaemia and the striae in Cushing's syndrome are usually more purple and marked than in normal pregnancy. It is important to know the normal ranges for the specific endocrine tests used to diagnose each hormone-producing tumour, and once a diagnosis has been made a multidisciplinary team should be involved with clinical management. This should include endocrinologists with an understanding of gestational disease, obstetricians, specialist anaesthetists, midwives and neonatologists. Individualised decisions should be made with regard to treatment with surgery or drugs. All hormone-secreting adrenal tumours are associated with increased rates of adverse pregnancy outcome, including preterm labour and stillbirth. This talk will summarise current knowledge about the management of these rare, and potentially life-threatening tumours in pregnant women and will consider the merits of prospective population cohorts to improve our understanding of the optimal management strategies to improve maternal and offspring outcomes.

Treatment of congenital hypothyroidism

Heiko Krude
Germany.

Treatment for congenital hypothyroidism (CH), based on thyroid extracts, was introduced more than 100 years ago and resulted in a compelling improvement of impaired growth, obesity, depression and severe delay of motor development. However, severe mental retardation remained despite treatment. It was only after the implementation of neonatal screening for CH in 1970s that intellectual outcomes improved to an average normal IQ. However, whether complete normalization of cognitive outcome is possible remains controversial, since some studies have found significant gaps compared to control populations including healthy siblings. Furthermore, there is some evidence that quality of life (QoL) scores are lower compared to the general population. To further improve the outcome, higher starting doses of more than 10 μg/kg and commencement of treatment within the first two weeks of life were recommended. The most recent outcome study from New Zealand, reporting patients treated according to a regimen consistent with these recommendations, documented IQ at age 10 years that was no longer different from sibling control subjects. Nevertheless treatment with higher starting doses has raised concerns regarding adverse effects of supraphysiological T4 levels, with studies in rodents and patients with neonatal hyperthyroidism suggesting abnormal CNS development. In addition, it has been repeatedly shown that the recommended high LT4 dose of $>$10 μg/kg results in fT4 levels in newborns and infants with CH that exceed the reference ranges in this age group. However, after decades of neonatal screening and recent confusion about an "unfavourable" outcome with a high dose LT4 treatment, we now provide strong evidence –based on a recent IQoutcome study- that the present recommendations of a high initial dose above 10 μg/kg is necessary, efficient and safe to achieve optimal cognitive development in all CH patients including those who are severely affected.

Modern spectrum of bone turnover markers – are they clinically useful?

Richard Eastell
UK.

Bone turnover markers reflect the work of the osteoblast and the osteoclast. They can be measured in blood or urine and allow for an inexpensive and non-invasive way to study bone metabolism. They have been evaluated for their use in

predicting risk of fracture, accelerated bone loss or the presence of secondary osteoporosis, but for all these uses they are not yet established. They are useful in monitoring the response to treatment of osteoporosis, especially with drugs such as oral bisphosphonates. One study focused on the clinical utility of modern spectrum of bone turnover markers for monitoring oral bisphosphonate therapy (alendronate, ibandronate, risedronate) in women with postmenopausal osteoporosis. The study concluded that two approaches could be used to identify response, namely a change beyond the least significant change or a change to below the mean value of bone turnover in healthy young women (1). This approach identified about 90% of women from the study as responding by 12 weeks on treatment. The International Osteoporosis Foundation and European Calcified Tissue Society proposed that a bone marker measurement made after 12 weeks was a good way to identify patients who are not adhering to therapy, as non-adherence is the commonest reason for non-response (2). The meet-the-expert session will examine the evidence for the use of bone turnover markers in treatment monitoring and give case examples of this approach in practice.

How best to utilise technology in diabetes?

Hans DeVries
The Netherlands.

More and more devices are becoming available for people with diabetes. Should you advise your patients to use a pedometer? How can insulin pumps be of help? An insulin pump is the best way to accommodate the changing insulin needs over the 24 hours of the day and gives one the opportunity to temporarily stop insulin administration in case of unanticipated exercise, which is impossible when using injection therapy. Trials have mainly been done in Type 1 diabetes, but a recent trial also shows beneficial effects in a selected group of people with Type 2 diabetes. The evidence for Continuous Glucose Monitors Continuous has recently been brought to higher level, both for insulin pump and injection therapy users. Both a lower HbA1c and less severe hypoglycemia have now convincingly been shown in people with Type 1 diabetes. The role of continuous glucose monitoring in diabetic pregnancy on the other hand is unclear. The newest kid on the block is Flash Glucose Monitoring, for which the evidence is mixed and scarce, but it does herald the end of finger pricks. And how are we going to implement the holy grail of diabetes technology, the artificial pancreas or closed loop? A first generation closed loop is now on the market in the US, EU to follow early 2018. What can it do and what not? Together we will cover a number of the above questions in an interactive way.

When and which treatment to use in Graves disease?

Tomasz Bednarczuk
Poland.

Graves' disease (GD) is a heterogeneous autoimmune disorder affecting, with varying degrees of severity, the thyroid, eyes and skin. GD is the most common cause of hyperthyroidism. The incidence peaks between 30 and 50 years of age, but people may be affected at any age. Hyperthyroidism is caused by autoantibodies stimulating the TSH receptor on thyroid cells. The severity of thyrotoxicosis in GD is variable and the response to anti-thyroid drugs is difficult to predict. Graves' orbitopathy (GO) is the most common and serious extrathyroidal manifestation of GD, significantly impairing the quality of life of affected patients. Clinically apparent orbitopathy occurs in 25%–50% of patients. Pretibial myxedema and acropachy are much less common, occurring in less than 2% of patients. The reasons for this variation in the clinical presentation of GD are largely unclear. There are three treatment options for Graves' hyperthyroidism: (1) blocking of hormone synthesis by antithyroid drugs (ATD), (2) destruction of the thyroid by radioactive iodine (RAI) and (3) partial or total surgical ablation of the thyroid. Additionally, patients can take β blockers for symptomatic relief. Although all three options are effective, no treatment is ideal and thus indicated in all patients with GD. Selection of therapy depends on multiple considerations, including: patient's age, severity of thyrotoxicosis, presence of goiter, orbitopathy, pregnancy, comorbidities. The treatment selection must also take into account the patient's preference. Before deciding on a treatment plan, the treating physician and patient should discuss each of the treatment options, including the logistics, local availability, advantages, disadvantages, potential side effects and costs.

How best to manage neuroendocrine tumours? - Towards a new algorithm

Alicja Hubalewska-Dydejczyk
Poland.

During the last couple of years an essential increase of newly diagnosed NENs has been observed, however it should be underlined that many cases represent new challenges for the medical staff. Development of personalized approach to NEN patients on the basis of knowledge rapidly coming from genetic/molecular research, improvement of biochemical/imaging diagnostic methods and availability of more efficient therapeutic options, means that existing guidelines are still being changed. However, the questions: 'what of the future hold for NEN?' and 'how will future achievements influence the new algorithm?' remain open. In the majority of patients the overall prognosis depends on the grade (G) and stage (TNM) of the tumour. Recently proposed classification of NENs divides additionally G3 NENs into NET G3a and G3b neuroendocrine cancers. Ki-67 is currently the main prognostic index which drives the management of all NENs, nevertheless it should be stressed that very often patient outcomes are difficult to foresee and the lack of response to therapeutic treatment regiments remains unpredictable so the identification of other prognostic factors would be of great help and it would make diagnostic and therapeutic decisions more appropriate. At present chromogranin A, urinary 5-HIAA and tumour specific hormones in secreting NENs are widely used as biomarkers. One should bear in mind that surgery is the only possible curative method in NENs however, half of the patients have metastases at presentation and unknown primary focus can also be challenging. Therefore, the development of fast and accurate imaging procedures (endoscopies, USG, CT/MRI and the implementation of the different radiolabelled compounds targeting various membrane/intracellular receptors/metabolic pathways (PET/SPECT-CT/MRI) is necessary. Antiproliferative therapy with SSA, TKI, PRRT and cytotoxic therapy should be given rather as sequential monotherapy than a combination one. Based on clinical cases of patients with NENs in different locations and at a different stage of the disease the different diagnostic/therapeutic options will be discussed during the Meeting.

What can new insulins provide for management of diabetes?

Jean François Gautier
France.

The major abnormality in type 1 diabetes is insulin deficiency. Type 2 diabetes is also characterized by an insulin secretory defect so that many patients are on insulin therapy. Methods of replacing insulin have improved throughout the decades, but there are still limiting factors that prevent the achievement of a better HbA1c levels such as hypoglycaemic events and glycaemic variability, weight gain and fatty liver. Additionally, most patients wish to do less insulin injections and less blood glucose self-monitoring! New insulins and newer delivery systems are being developed that can improve some of the limitations of current insulins or make the delivery of insulins more acceptable for some patients. Extending the duration of action of basal insulins (glargine U300, Insulin degludec, PEGylated insulin Lispro) may have advantages in reducing risk of hypoglycemia (and especially nocturnal hypoglycemia) and weight gain. PEGylated insulin Lispro is no more in development for safety reasons (high triglycerides and liver enzymes) and there is still no head-to-head comparison between glargine 300 U/ml and degludec. Shortening the peak of fast-acting insulins in order to mimic the physiological first phase insulin secretion (bioD-090, rHuPH20, Ultra-fast-acting insulin aspart, BioChaperone lyspro) may also have advantages. However, peer-reviewed evidence to date remains scarce. Biosimilars are developed to minimize insulin cost but do not bring something new for the patients. Combination of new long acting insulins with a short acting insulin or with a GLP-1 analogue are available in some countries. These combinations reduce the number of injections. Different delivery systems may make insulin more acceptable to patients. Whether these innovations permit a better glycemic control will be discussed. Lastly, we will see whether 'smart' insulin, that is glucose-responsive insulin, the Holy Grail promise, will be available in the next future.

Thyroid carcinoma: complicated cases

Valeriano Leite
Portugal.

Thyroid neoplasias show a wide range of biological behaviours from indolent to highly aggressive, invasive and metastatic cancers. The great majority of thyroid carcinomas are successfully treated with surgery, radioactive iodine and TSH suppressive therapy. However, a subset of tumors can behave aggressively, with distant metastasis and/or local invasion. These patients have a poor prognosis and a shorter survival, remaining a challenging task in treatment options. Cytotoxic chemotherapy has only limited effect, without clear evidence that benefit outweighs risk of toxicity. Radiotherapy is an option for surgically unresectable neck recurrences and for bone and brain metastases. Recently, interest rose on tyrosine kinase inhibitors (TKI) and, currently, there are several TKIs that have been approved for advanced thyroid cancers either from follicular or parafollicular origin. A judicious use of different treatment modalities in advanced thyroid carcinoma may improve patients' outcome and prolong survival. Illustrative cases of some advanced thyroid cancer patients will be presented and discussed in this MTE session.

DOI: 10.1530/endoabs.49.MTE14

MTE15

Gaucher disease: interdisciplinary management

Milan Patakov
Serbia.

Gaucher disease (GD) is a rare, genetic, autosomal recessive lysosomal storage disease with multi-system manifestations caused by a deficiency of the lysosomal enzyme glucocerebrosidase, which leads to an accumulation of its substrate glucosylceramide (glucocerebroside) in macrophages of various tissues with an inflammatory response and a release of cytokines. In general population its incidence is approximately 1/40 000 to 1/60 000, rising to 1/800 in Ashkenazi Jews. Clinical features comprise cytopenias, splenomegaly, hepatomegaly, and bone lesions. Non-neuronopathic type-1 Gaucher disease, which affects the majority of patients (90% in Europe and USA), is characterized by visceral effects, whereas neuronopathic types 2 and 3 are dominantly associated with neurological impairment. The diagnosis of GD can be confirmed by the deficient acid glucocerebrosidase activity in peripheral blood leukocytes. Patients with type 1 GD, and even carriers of one gene mutation have predisposition to develop Parkinson's disease, and there is increased risk of some neoplasia in GD patients. Disease-specific treatment of type 1 GD consists of intravenous enzyme replacement therapy (ERT) with one of the available enzymes (imiglucerase, velaglucerase, or taliglucerase) or oraly administered substrate reduction therapy (SRT) with inhibitors of glucosylceramide biosynthesis (miglustat or eliglustat). Currently there is no treatment for type 2 disease which is lethal early in the life.

New treatment approaches in dyslipidemia

Luis Masana

The introduction of PCSK9 inhibitors has changed the paradigm of dyslipidemia treatment. These monoclonal antibodies produce an incremental LDL reduction of about 60% add-on current therapy. Achieving LDL concentrations below 40 mg/dl is usual. The recent publication on the effect of very low LDL concentrations on atherosclerotic plaque burden (Glagov study) and on cardiovascular outcomes (Fourier and Spire) show the impact of this therapy in cardiovascular prevention. In the other hand these treatments seem to be pretty safe. Ebbinhouse study has demonstrated no impact on neurocognitive function. Price of therapy is the main limiting factors and several scientific societies have issued recommendation for use. The aim of this meeting is discussing about the new approaches of dyslipidemia therapy.

MTNE1

A paediatric perspective of endocrine late complications following childhood cancer

Tanya Urquhart
UK.

Dramatic improvements in cancer survival over the past four decades means that greater than 80% of children diagnosed with cancer can expect to survive for more than five years. For some cancers, such as acute lymphoblastic leukaemia and Hodgkin's disease, cure rates exceed 90%. Currently, there are over 26000 young adults living in the UK, 600 000 across France, Italy, Switzerland, Netherlands and the Nordic countries and 363 000 in the US, who are survivors of childhood cancer (CCS). A late effect (LE) is the term used to describe any physical, psychological or social consequence of the disease itself or the disease treatment. The consequence of cytotoxic effects on maturing tissues may only become apparent many years following completion of treatment and with subsequent development, hence the term LE. Treatment for childhood cancer

usually involves chemotherapy, radiotherapy (including radiosurgery) and surgery. These treatments can occur in isolation or in any combination, and can affect almost any system in the body. The most common effect of these treatments is on growth, endocrine function, fertility, neuropsychology and the cardiac systems. Two-thirds of childhood cancer survivors will experience at least one LE and the endocrine system is commonly involved. Another third of patients will develop two or more LE which may be severe or life threatening. Therefore this session will explore the endocrinopathies associated with the treatment for cancer in childhood using case studies to provide examples from practice. Knowledge of oncology and endocrinology are paramount for nurse specialists working with this patient cohort to ensure accurate education for young people about their past treatment and its implications for their future health. Transition will also be considered as these young people grow, develop and require continuing care from adult healthcare professionals.

DOI: 10.1530/endoabs.49.MTNE1

MTNE2

Providing nursing care for the adult patient with endocrine late effects of cancer treatment

Cecilia Follin
Sweden.

Survival rates of childhood cancer have improved markedly and today more than 80% of those diagnosed with a pediatric malignancy will become 5-year survivors. Nevertheless, survivors exposed to cranial radiotherapy (CRT) are at particularly high risk for long-term morbidity, such as endocrine insufficiencies, metabolic complications and cardiovascular morbidity. Deficiencies of one or more anterior pituitary hormones have been described following therapeutic CRT for primary brain tumours, nasopharyngeal tumours, and following prophylactic CRT for childhood acute lymphoblastic leukemia (ALL). Studies have consistently shown a strong correlation between the total radiation dose and the development of pituitary deficits. Further, age at treatment and also time since treatment has strong implications on pituitary hormone deficiencies. Studies have shown that childhood cancer survivors (CCS) need information regarding psychosocial support and social advocacy. Thus, the challenge is to guide the survivors through the potential late complications and offer care designed to meet their specific needs in order to optimise their quality of life. Information about late complications is essential in order to achieve an independent life and to engage in healthy behaviour, such as regular physical activity. Thus, having a holistic approach, tailored to their specific needs is crucial for their future well-being and quality of life.

Regulation and dysregulation of appetite and satiety

Patricia Iozzo
Italy.

The modulation of appetite, satiation and food intake stems from the interplay of central mechanisms of homeostasis, hedonism and cognitive control, receiving and integrating information on energy balance and feeding status of the body from peripheral organs, including dietary and gut-related signals. Obesity is a phenotype, likely resulting from the dysregulation of one or more of the above mechanisms. Different mechanisms may prevail in different people, though leading to a similar phenotype. The recognition of such diversity would offer opportunities for personalized treatment. This lecture will present data from a study conducted in well characterized overweight women, undergoing brain imaging of glucose metabolism to detect cerebral reactions to sensory food stimuli. The study suggests that women with food addictive behavior have a specific pattern of activation, which implicates cognitive control and diet-related factors (hormones, substrates, and possibly microbiota) in their food seeking behavior. This hypothesis is supported by the characterization of feeding behavior and brain and brown adipose tissue (BAT) metabolism in mice models of neurodegenerative disease and/or high-fat feeding, also in combination with intranasal insulin therapy. In order to better define the sequence of events linking brain function and feeding behavior, studies in the offspring of obese mothers are addressed, since maternal obesity represents a preventable condition, in which the factors above are affected since early life in the offspring. Results in humans, and animal models will be presented. Cumulatively, our studies suggest that a hypermetabolic brain, deriving from metabolic disturbances or high-fat dietary exposure may be an early detrimental factor, and a hypometabolic brain reflecting neuronal loss may enhance food intake, but also BAT browning. Substrates, hormones and gut microbes can promote a vicious cycle.

Clinical practice overlap and seamless care – diagnosis and management of hypothyroidism in patients with diabetes mellitus

Elena Shelestova

Today diabetes (DM) is one of the largest global health emergencies. Each year a large number people live with this condition. Currently there are more than 422 mln people with DM worldwide. DM is one of the major public health problems in Georgia. Number of people with DM is on the rise, though no exact statistical data for Georgia exist. Diabetes Atlas (International Diabetes Federation, 2015) gives diabetes prevalence for Georgia of 7.9%, though these data are extrapolated from other countries. On the other hand, hypothyroidism (HOT) is believed to be a common health issue worldwide. The prevalence of HOT in the developed world is about 4–5%, and the prevalence of subclinical HOT is about 4–15%. Both HOT and subclinical HOT are thought to be risk factors for T2DM development. In our patients approximately 30% of women and 15% of men have both conditions. Prevalence of both conditions increases with the age of the patients (age 35–74 years, prevalence range 7–5%).

Materials and methods

Herein, 2 clinical cases (coexisting T2DM and HOT) are discussed. Both patients (pt) were diagnosed and are managed at the National Centre for Diabetes Research. Case #1 – pt. E.G., 49 years old, female. T2DM since 2008, HOT – since 2015. Pt. was treated with oral hypoglycaemic agents (OHAs) – SU and Metformin (Met), in 2017 pt. was transferred to DPP-4 and Met. DM control is satisfactory. In 2015 pt addressed the Centre with typical signs and symptoms – weight gain, dyspeptic symptoms, cognitive impairment, constipation. Ultrasound examination was performed and thyroid hormones (TSH, F_4, anti-TPO) were tested. L-thyroxine therapy was initiated (50 mg, then elevated to 100 mg). Since treatment initiation pt. condition is satisfactory, clinical and laboratory tests have improved. Pt is control every 3 months. Prescribed treatment is continued, Case # – pt. K.N., 65 years old, female, HOT and goiter with thyroid nodules (no biopsy performed) were diagnosed in 2010. Treatment with L-thyroxine was initiated. No follow-up was carried out though the drug (50 mg) was used regularly. In 2017 pt. came to our Centre for the 1-st time. Ultrasound of the thyroid gland and hormone tests was performed that revealed thyroid nodules (TSH was within the *n* range). Nodule biopsy was carried out, colloid goiter was diagnosed. Pt had following DM risk factors – family history of DM, obesity, arterial hypertension, HOT. Thus, she was screened for DM. HbA1c was 7.0% indicating to T2DM. Met. (500 mg) was initiate. Treatment with L-thyroxine at selected dose is continued. Diet and physical activity recommendations were selected individually. At present both pts are regularly followed-up (every 3 months). Doses and treatment are adjusted based on the results achieved.

Conclusion

Combination of the conditions is globally widely spread, it needs serious attention, knowledge and experience to manage. Proper management permits pts to live long and productive life and avoid complications caused by the conditions.

Clinical practice overlap and seamless care – links between hypogonadism, the metabolic syndrome and type 2 diabetes

Andrew Dwyer
Switzerland.

There is a bi-directional relationship between hypogonadism and type 2 diabetes and the metabolic syndrome (T2DM/MetS). Studies show that up to 50% of men with MetS/T2DM have testosterone deficiency. Moreover, both hypogonadism and MetS confer increased health risk for morbidity and mortality. Men with MetS are twice as likely to develop cardiovascular disease and have a fivefold higher risk for developing T2DM. Notably, the inverse relationship between testosterone and MetS is consistently observed across racial and ethnic groups. Therefore, in the setting of ever increasing obesity rates, the relationship between the reproductive endocrine axis and metabolism warrants renewed attention. Using a case-based approach, this presentation will provide an overview of the pathophysiologic basis for the relationship between hypogonadism and MetS/T2DM. Male patients may be trapped in the vicious cycle of hypogonadism-obesity-insulin resistance. We will review an evidence-based approach to the patient including the appropriate evaluation and treatment based on existing guidelines and recommendations. This presentation will have a particular focus on the role of the endocrine nurse in managing patients who present with this confluence of endocrine disorders. Current challenges in the field will be highlighted and we will touch on some yet unanswered questions as well as envisioned future directions. At the conclusion of this session participants will be able to:

- describe the interrelationship between hypogonadism and MetS/T2DM
- identify those patients who warrant screening for androgen deficiency
- recognize barriers to providing integrated care for these patients
- examine how their nursing care for these patients may be improved

Clinical practice overlap and seamless care – at risk of two endocrine emergencies: the patient with type 1 diabetes and Addison's disease

Sofia Sjöberg
Sweden.

Patients diagnosed with Addison's disease and diabetes mellitus type1, has a rare combination of two autoimmune conditions. Two diagnosis that requires a great deal of self-care. Patients have a potential risk to induce endocrine emergencies such as diabetic hypoglycemia, adrenal crisis and diabetic ketoacidosis. The lack of lifesaving hormones can put the patient in potential life threatening situations. I'll share my experience in meeting these patients. Brief physiology how the lack of hormones affects the glucose metabolism and what aid the patient need to handle the two disorders in daily life.

Nurses professional development and networking session – obstructive sleep apnea and comorbidities in patients with pituitary adenomas

Christine Yedinak
USA.

Short sleep duration and insomnia have been linked to higher risk of cardiovascular disease and CVD related mortality. Likewise, obstructive sleep apnea has been shown to confer a higher cardiovascular risk and is reported to be associated with 52-70% of acute myocardial infarctions and strokes. Hypertension (HTN), diabetes (DM), weight gain, sleepiness, fatigue and depression have all been correlated with obstructive sleep apnea (OSA). Patients with pituitary adenomas (PA), particularly those with Cushing's disease and acromegaly, often present with reported sleep dysfunction, fatigue and metabolic risk factors, diabetes, hypertension and cardiovascular disease and depression. The prevalence of sleep apnea in patients with pituitary hypersecretion at diagnosis has not been clearly quantified in patients as it may not be recognized and may go undiagnosed at the time of presentation. Additionally, the correlation with diabetes and other cardiovascular risk factors is not clear in these disorders. There is little data regarding the impact of treatment and disease remission on both OSA and persistent risk factors. The aim of this presentation is to explore the prevalence and correlation between sleep disturbance (SD), depression, BMI, HTN, diabetes

Mellitus (DM), pituitary deficiencies (PD), tumor size, diagnosis and risk of OSA for patients with PA pre and post treatment remission. Data from one institution will be presented.

Nurses professional development and networking session – utilising the competence framework to develop the role of endocrine nurses in adrenal insufficiency

Janina Kirchner
Germany.

The competence of endocrine nurse in the treatment of adrenal insufficiency (AI) is defined by the competence framework. Here is distinguished into Competent, proficient and expert. In these points, the nurse's knowledge is presented and gives a good overview of already acquired knowledge and things to be learned. With the acquired knowledge the endocrine nurse is intended to treat, train and support patients with AI as far as possible. Due to differences in the health systems of the countries in Europe, not all approaches are possible. Here the example of Germany is shown how patients with AI are provided with a national training program and the competence framework is also applied.

Nurses professional development and networking session – hybrid training of nurses in/for the endocrinology; train the trainer with help of e-learning modules

Johan Beun
The Netherlands.

Adrenal insufficiency is a rare adrenal disorder that can be made more complicated by an adrenal crisis even to a life-threatening situation. An adrenal crisis occurs when the body has a shortage of the hormone cortisol. If the patient does not receive the correct treatment an adrenal crisis can be fatal. This can be avoided by correctly and carefully following the 'stress instructions' (also known as 'sick day rules'). A significant percentage of patients have insufficient knowledge of these stress instructions or are not able to put them into practice themselves. In addition, it has become evident that the stress instructions vary between the different hospitals. For that reason, AdrenalNET has drawn up uniform stress instructions. These form part of the Quality of Care Standard for Adrenal Disorders, which sets out quality criteria (as applicable in the Netherlands) for the care of patients with adrenal insufficiency. One important quality criterion for the proper care of patients with adrenal insufficiency is that the hospital must have a nurse who has successfully completed this training course.
Objective
The objective of this training course is to offer nurses the essential theoretical and practical knowledge that they need if they are to provide adrenal patients with optimum care and instruct them how to apply the stress instructions for themselves. Indirectly, this will also help to promote the principle of co-management when patients with adrenal insufficiency find themselves in stressful situations. We are, in fact, training the trainers first via e-learning modules (4×) later one day at the university incl. a test at the end.

Update on diet and lifestyle throughout lifespan to improve health – prevalance and treatment of vitamin D deficieny in children

Pauline Musson
UK.

A number of factors have been associated with the apparent increase in children with vitamin D deficiency (VDD) in developed countries: increased awareness, increased migration, children living with chronic illness or disabilities, effects of medication (e.g. glucocorticoids, anticonvulsants), use of sunscreen, changes in lifestyles and a rise in childhood obesity. The clinical features of VDD vary with age and degree of deficiency and importantly, calcium deficiency is now recognized as a key factor in symptomatic VDD. At presentation, children may be asymptomatic or, have musculoskeletal pain; and in severe cases hypocalcaemic seizures, rickets and life threatening cardiomyopathy may occur. Evaluation of children should include careful assessment of dietary intake, previous medical history, medication review (including use of complementary alternative medicines), growth and puberty, and systemic enquiry of symptoms suggestive of malabsorption. Biochemical investigations are merited in symptomatic cases and there are important rare diagnoses that should be considered when interpreting results. There are a variety of treatment regimens for VDD. Typically treatment is with cholecalciferol, administered in daily, weekly, monthly or 12 weekly doses. Oral doses are considered as effective as intramuscular injections in children with normal intestinal absorption. Potential side effects from treatment should be communicated to the family and are rare. Calcium supplements should be considered in those with inadequate dietary intake. The family should be made aware of the reasons for intervening, the differences between treatment versus supplement doses of vitamin D, and how to optimize diet and adverse lifestyle factors. Some licensed products are not palatable for children and achieving adherence can be challenging. Poor medicine adherence may be further aggravated by confusion regarding the doses required and inconsistent information given to families by health care professionals. I will review the contemporary multidisciplinary approach to the child presenting with vitamin D deficiency with illustrative clinical cases.

Update on diet and lifestyle throughout lifespan to improve health – sexual hormones and bone, a close link throughout lifespan

Georgios Papadakis
Switzerland.

Bone health is increasingly recognized as a crucial factor for quality of life. Osteoporosis, defined as bone impairment leading to an increased risk of fracture, is an important source of morbidity and even mortality in later life. Both male and female achieve the peak bone mass at around the age of 25 years. This peak is significantly lower in case of puberty and/or growth disorders, thus increasing the risk of osteoporosis later in life.
Discussion
Our Reproductive Division of Endocrinology in Lausanne University Hospital specializes in Congenital Hypogonadotropic Hypogonadism (CHH), a disorder characterized by absent puberty and infertility due to complete or partial deficiency of GnRH, the hypothalamic hormone that initiates the reproductive cascade. When CHH is accompanied by anosmia, it is called Kallmann syndrome (KS). In our cohort of KS and CHH patients, there is an important decrease of bone density, which is more significant when the disease was diagnosed late in life, resulting in long periods without hormonal replacement. On the contrary, as our clinical cases illustrate, when diagnosis of these rare disorders is performed promptly and adequate treatment is followed, the patients maintain a near-normal bone density and avoid fractures later in life. In a different approach to the relation between bone and sexual hormones, using data from the OsteoLaus population-based study, a large cohort of post-menopausal women, we recently showed that menopausal hormone treatment (MHT) is associated with enhanced bone density and structure. Interestingly, the bone benefit seems to persist for at least 2 years after its withdrawal. These results corroborate other studies outlining that in young postmenopausal women aged 50 to 60 years old the ratio benefit/risk is clearly in favor of the benefits in terms of bone health, cardiovascular outcomes and even mortality. We should reconsider MHT for recently postmenopausal women with menopausal symptoms such as hot flushes and/or increased risk of fractures. In new unpublished data, we detected that MHT users have significantly lower visceral fat mass, an important element with potential bone and systemic implications.

Conclusion
Sexual hormone deficiency throughout lifespan severely impairs bone quantity and quality leading to bone fragility. Increased awareness of the link between bone and gonadal function is mandatory among endocrine physicians and nurses in order to promote early diagnosis and avoid lack of treatment. The risk of bone morbidity later in life can be an important argument to increase patient's adherence to therapy.

Update on diet and lifestyle throughout lifespan to improve health – osteoporosis and prevention of fractures: nurses can a play key role

Marsha Van Ooswaard
The Netherlands

Treatment of osteoporosis is all about prevention of fractures. It relies on a combination of approaches, including adjustments to the patient's diet and lifestyle, pharmacological therapy, and patient education. Changes to the patient's diet and lifestyle typically involve: optimizing calcium and vitamin D intake and exercise levels, cessation of smoking and reducing alcohol consumption. Pharmacological therapies used to treat osteoporosis by reducing the fracture risk include bisphosphonates or the RANK ligand inhibitor denosumab. Nurses have an important role in educating patients about fracture risk, the benefits of lifestyle modifications for maintaining bone health and the treatment options available, including side effects and the importance of adherence. In the current Dutch osteoporosis guidelines, it is recommended that hospitals appoint a specialised fracture nurse for the organisation and coordination of osteoporosis care. These specialised nurses provide care relating to case finding, risk evaluation, prevention, diagnosis, treatment and follow up. Each of these steps is essential and an insufficient implementation can result in suboptimal fracture prevention. Their main area of expertise is the recognition of risk factors. These risk factors can be related to the bone itself, a fall or the patient's lifestyle. Some of these factors can be influenced, some cannot. Patients need to have a good understanding of their diagnosis and fracture risk to make informed choices with regard to pharmacological treatment and/or lifestyle change.

High resolution tissue mass spectrometry imaging: a new tool for identification of prognostic markers in adrenocortical carcinoma

Thomas Kunzke[1], Na Sun[1], Silviu Sbiera[2,3], Vanessa Wild[3], Michaela Aichler[1], Cristina Ronchi[2], Nicolas Schlegel[2], Andreas Rosenwald[3], Martin Fassnacht[2,3], Axel Walch[1] & Matthias Kroiss[2,3]
[1]Helmholtz-Center Munich, Munich, Germany; [2]University Hospital Würzburg, Würzburg, Germany; [3]University of Würzburg, Würzburg, Germany.

Adrenocortical carcinoma (ACC) is an orphan tumor entity the pathogenesis of which is poorly understood. In advanced tumour stages, prognosis is unfavorable, but biomarkers for early diagnosis are lacking. MALDI-Mass Spectrometry Imaging (MALDI-MSI) enables semi-quantitative detection of a broad spectrum of analytes including endogenous cell metabolites in tissue sections. MALDI-MSI was used as a discovery approach to analyse tissue specimens of 72 ACC patients in FFPE tissue arranged in tissue microarrays to identify pathways of pathophysiological relevance and histologic markers related to patient prognosis. We focused on steroid hormones and their metabolites which might also serve as tumour-derived blood biomarkers in the future. 3843 individual endogenous *m/z* species were obtained of which five were identified as known components of steroid hormone synthesis and metabolism. 2/5 steroid hormone metabolites showed differential abundance between ACC samples. Their low abundance in 5 and 6 of the 72 ACC samples was associated with poor overall survival in Kaplan-Meier analyses (Log rank $P = 0.0030$ and 0.0045, respectively). Based on the type of the steroid hormone modification present, mass spectra were screened for related *m/z* species. An unusual steroid hormone metabolite (M) was identified and validated by tandem mass spectrometry. After multivariable adjustment for age, tumor stage and sex by using the Cox proportional hazards model, presence of M was associated with poor overall survival (HR 4.54, 95%CI 1.56–13.22; $P = 0.0056$). By using immunohistochemistry we analysed protein expression of two related enzymes which was correlated with metabolites abundance. In conclusion, we demonstrated the utility of MALDI-MSI in detecting and identifying small molecule markers in FFPE tissue samples of ACC. A limited number of compounds related to steroidogenesis with strong prognostic value could be detected. One steroid hormone metabolite and related enzymes were of outstanding prognostic value. The potential of these metabolites as blood biomarkers remains to be investigated.

EZH2: a master regulator of adrenal cortex homeostasis and zonation

Mickael Mathieu[1], Coralie Drelon[2], Houda Tabbal[1], Stéphanie Rodriguez[1], Amandine Septier[1], Annabel Berthon[3], David Sainte-Catherine[1], David Breault[4] & Antoine Martinez[1]
[1]Laboratoire GReD, Clermont-Ferrand, France; [2]Albert Einstein College of Medicine, Bronx, New York, USA; [3]National Institutes of Health, Bethesda, Maryland, USA; [4]Harvard Stem Cell Institute, Boston, Massachusetts, USA.

In adult mice the adrenal cortex is divided, in two distinct functional zones, outermost zona glomerulosa (ZG) and innermost zona fasciculata (ZF), encapsulated by a thin layer of mesenchymal cells (capsule). The adrenal cortex undergoes constant centripetal cell renewal, reliying on recruitment of progenitors located within an outer cortex niche. Progenitors initially differentiate as ZG cells and undergo lineage conversion to ZF as they move within the cortex. This relies on a subtle balance and trans-inhibition between WNT and PKA signalling pathways. Epigenetic histone modifiers are prototypical factors that play essential roles from embryonic development to carcinogenesis. We have recently shown that the histone methyl-transferase EZH2 is overexpressed in adrenal cortex carcinomas where is it associated with poor prognosis and tumour aggressiveness. In order to understand EZH2 function in adrenal physiology, we have developed a mouse model of EZH2 inactivation relying on a floxed allele of EZH2 and the Sf1:Cre driver (EZH2KO). Our analyses show adrenal hypoplasia and primary corticosterone insufficiency, associated with expansion of ZG at the expense of ZF and aberrant mixed ZG/ZF differentiation. Consistent with the role of PKA and WNT signalling in establishment and maintenance of zonation, WNT pathway is increased whereas PKA activity is decreased in EZH2KO adrenals. In addition to zonation defects, EZH2KO present abnormal accumulation of 'stress progenitors'. Recruitment of these particular progenitors is under control of WT1 and GATA4. Our *in vivo* ChIP and expression data show that these two transcription factors are direct targets of the inhibitory action of EZH2 in the adrenal. Altogether, these data suggest completely unanticipated functions of EZH2 in the control of stress progenitors homeostasis through WT1 and GATA4 and adrenal cortex zonation, which rely on a novel interaction between EZH2 and PKA signalling pathway.

Steroid metabolomics for accurate and rapid diagnosis of inborn steroidogenic disorders

Elizabeth Baranowski[1,2], Kerstin Bunte[3,4], Cedric H L Shackleton[1], Angela E Taylor[1,2], Beverley A Hughes[1], Michael Biehl[3], Peter Tino[1,4], Tulay Guran[5] & Wiebke Arlt[1,2]
[1]Institute of Metabolism and Systems Research, University of Birmingham, Birmingham, UK; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; [3]Johann Bernoulli Institute for Mathematics and Computer Science, University of Groningen, Groningen, The Netherlands; [4]School of Computer Science, University of Birmingham, Birmingham, UK; [5]Department of Pediatric Endocrinology and Diabetes, Marmara University, Istanbul, Turkey.

Background
Urinary steroid metabolite profiling is an accurate reflection of adrenal and gonadal steroid output and metabolism in peripheral target cells of steroid action. Measurement of steroid metabolite excretion by gas chromatography-–mass spectrometry (GC–MS) is considered reference standard for biochemical diagnosis of steroidogenic disorders. However, performance of GC–MS analysis and interpretation of the resulting data requires significant expertise and age- and sex-specific reference ranges. Here we developed novel computational approaches for rapid interpretation of GC–MS data for diagnosis of inborn steroidogenic disorders
Methods
We analysed the urinary steroid metabolome by GC–MS in 829 healthy controls (302 neonates and infants, 167 children and 360 adults) and 118 untreated patients with genetically confirmed inborn disorders (21-hydroxylase deficiency, 17-hydroxylase deficiency, POR deficiency, 11β-hydroxylase deficiency, 3β-HSD2 deficiency, 17β-HSD3 deficiency, 5α-reductase type 2 deficiency, cytochrome b5 deficiency). We calculated age-related normative values for established metabolite ratios representing distinct enzymatic functions. We developed a novel interpretable machine learning technique, Angle Learning Vector Quantisation (ALVQ), which looks at all possible metabolite ratios, computationally reduces these to the most relevant for discrimination, and differentiates disease states by comparison to a representative prototype. The method runs independent of sex and age information, units of measurement and method of urine collection.
Results
Conventional biochemical ratios had 100% sensitivity but only very poor specificity. By contrast, ALVQ predicted 'affected urine' vs 'healthy urine' with 100% sensitivity and 97% specificity. For our three most prevalent conditions (PORD, SRD5A2 and CYP21A2), the specific condition was identified correctly in 96% of cases.
Conclusion
We developed a novel Steroid Metabolomics approach to automatically diagnose inborn steroidogenic disorders with very high sensitivity and specificity, superior to current methods, and with high potential for implementation in routine clinical care.

The epidemiology of pheochromocytoma: increasing incidence and changing clinical presentation. A population-based retrospective study 1977–2015

Andreas Ladefoged Ebbehoj[1,2], Esben Sondergaard[1], Christian Trolle[1], Kirstine Stochholm[1] & Per Logstrup Poulsen[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Medicine, Aarhus University, Aarhus, Denmark.

Pheochromocytoma is a rare disease but frequently poses a diagnostic dilemma due to the unspecific symptoms and its potentially life-threatening nature. There is a perception of an increase in the incidence of pheocromocytomas in recent years, but no data on time trends exist. We obtained data from The Danish National Registry of Patients, The Danish Registry of Causes of Death, and The National

Pathology Registry for all persons registered with pheochromocytoma in 1977–2015. Health records were reviewed to validate the diagnosis for all patients in the Northern and Central Regions of Denmark (population 1.75 million). Incidence rates were calculated using Poisson regression and time trends were analysed with year as a continuous explanatory variable. As incidence increased significantly in 2007–2015, we compared the clinical characteristics of patients diagnosed in this time interval with patients diagnosed in 1977–2006 in a secondary analysis using the Wilcoxon–Mann–Whitney test. We identified 183 confirmed cases of pheochromocytoma. A significant increasing trend ($P<0.001$) was observed in incidence rates from 2.06 (CI95% 1.68–2.49) per million person-years 1977–2006 to 4.65 (CI95% 3.72–5.82) 2007–2015. In 1977–2006 paroxysmal symptoms and secondary hypertension were the primary causes leading to the diagnosis (34 and 21%, respectively), while incidentalomas were the leading cause of diagnosis 2007–2015 (57%). Patients diagnosed 2007–2015 were older ($P<0.001$), less symptomatic ($P=0.003$) and had smaller tumours ($P=0.033$), compared to 1977–2006. No changes were observed in duration of symptoms or level of catecholamines. The incidence of pheochromocytoma has increased significantly in recent years, presumably due to increased use of imaging studies. It is unlikely that earlier diagnosis or lead-time bias accounts for the increasing incidence since patients are getting older. Therefore, these incidentaloma patients appear to represent a new group of pheochromocytomas not previously diagnosed. Whether surgical treatment provides a health benefit in this group remains unknown.

Diagnostic accuracy of three confirmatory tests for primary aldosteronism: a prospective study and systematic review

Qifu Li, Ying Song, Shumin Yang & Aipin Zhang
Department of Endocrinology, Chongqing, China.

Background
Confirmatory tests, including saline infusion test (SIT), captopril challenge test (CCT) and fludrocortisone suppression test (FST) are commonly used for diagnosis of primary aldosteronism (PA). Each test has its advantages and disadvantages, but which one should be preferentially performed is controversial. We aimed to evaluate the diagnostic accuracy of three tests in a prospective study.
Methods
Five hundred and thirty-one hypertensive patients with high risk of PA were enrolled. Plasma aldosterone-renin ratio (ARR) was used for screening. Hypertensive patients tested positive at PA screening (ARR $\geq$ 3.7 ng/dl per μIU/ml), one in every three consecutive patient tested negative (ARR $<$ 3.7 ng/dl per μIU/ml) and patients who tested negative but PA was strongly suspected proceeded to three confirmatory tests. Area under receiver operator characteristics curve (AUC), sensitivity and specificity were calculated. A systematic review and meta-analysis of relevant studies were performed to place our results in context.
Findings
Finally, 132 patients diagnosed as PA and 104 diagnosed as essential hypertension completed three tests. AUC of CCT, SIT and FST were 0.97 (95% CI 0.95–0.99), 0.97 (0.95–0.99) and 0.98 (0.97–0.99), respectively, when post-test plasma aldosterone concentration (PAC) was used to confirm PA. But AUC of CCT significantly decreased to 0.76 (0.69–0.82) if PAC suppression ratio was used to confirm PA. When PAC cutoffs of SIT and FST was set at 8 ng/dl, and CCT at 11 ng/dl, the sensitivity were 87.9%, 93.2%, 92.4% and specificity were 93.3%, 90.4%, 90.4% respectively. No significant difference of synthetic AUC, pooled sensitivity or specificity between SIT and CCT was found in the meta-analysis. Only one study of FST fulfilling the criteria of the systematic review was included, reporting a sensitivity of 0.87 and a specificity of 0.95.
Interpretation
CCT, SIT and FST has comparable diagnostic accuracy. Based on their pros and cons, it is reasonable to recommend CCT as the first choice to confirm PA in clinical practice. When interpreting the results of CCT, PAC post-CCT is recommended.

microRNA expression profile in plasma from patients with type 1 diabetes: a case–control study and bioinformatics analysis

Tais Silveira Assmann[1,2], Mariana Recamonde-Mendoza[4], Marcia Punales[3], Balduino Tschiedel[3], Luis Henrique Canani[1,2] & Daisy Crispim[1,2]

[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Postgraduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Instituto da Criança com Diabetes, Porto Alegre, Brazil; [4]Institute of Informatics, Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Context
Since the exact cause of type 1 diabetes mellitus (T1DM) remains unclear, the detection of novel biomarkers is necessary to complement the information obtained from the presence of autoantibodies together with genetic and environmental risk factors. MicroRNAs (miRNAs) are a class of small noncoding RNA molecules that negatively regulate gene expression. Changes in their expression were described in several pathological conditions, including autoimmune diseases. Circulating miRNAs are attractive biomarker candidates as they can be easily collected, are stable under different storage conditions and can be measured using specific assays.
Objective
To investigate a miRNA expression profile in plasma from patients with T1DM and nondiabetic controls and suggest their targets using bioinformatics analysis.
Design
Expressions of 48 miRNAs were investigated in the plasma from 33 T1DM patients and 26 age-and-gender-matched controls using Stem-loop RT-PreAmp Real-time PCR and TaqMan Low Density Array cards (Thermo Scientific Inc). Five dysregulated miRNAs were chosen for validation using RT-qPCR in an independent sample (27 T1DM patients and 14 age-and-gender-matched controls).
Results
Nine miRNAs were differentially expressed between controls and T1DM patients with <5 years of diagnosis: 1 miRNA was downregulated (has-miR-146a-5p) while 8 miRNAs were upregulated (hsa-miR-101-3p, hsa-miR-103a-3p, hsa-miR-1275, hsa-miR-146a-5p, hsa-miR-148b-3p, hsa-miR-155-5p, hsa-miR-200a-3p, hsa-miR-210-5p and hsa-miR-21-5p) in patients with <5 years of T1DM diagnosis compared to controls. In contrast, no differences were detected between controls and T1DM patients with >5 years of diagnosis. Bioinformatics analysis evidenced that hsa-miR-103a-3p, hsa-miR-146a-5p, hsa-miR-155-5p, hsa-miR-200a-3p and hsa-miR-210-3p participate in pathways associated with T1DM pathogenesis, such as apoptosis, insulin and immune system.
Conclusions
Our data demonstrate that 9 miRNAs are differentially expressed in T1DM patients in the first years of the diagnosis. Our study also provided novel information about biological pathways implicated in T1DM. Ongoing studies will further explore the role of these miRNAs as possible novel biomarkers for T1DM prediction.

OC2.2

Effectiveness of complex therapy in patients with comorbidity of type 2 diabetes and essential hypertension depending on genetic polymorphism PPARγ2

Anna Shalimova, Oleksandr Bilovol & Lesya Bobronnikova
Kharkiv National Medical University, Kharkiv, Ukraine.

The aim
To evaluate effectiveness of complex therapy in patients with comorbidity of type 2 diabetes (DM2) and essential hypertension (EH) depending on genetic polymorphism peroxisome proliferator-activating receptor-γ2 (PPARγ2). Before and after 3 months of treatment we examined 145 patients with EH stage II, grade and DM2 moderate, subcompensated aged 45–60 years: group 1 (71 patients) received standart therapy (telmisartan, indapamide, metformin, gliclazide, atorvastatin, acetylsalicylic acid) and group 2 (74 patients) additionally received α-lipoic acid (α-LA). Both groups were matched for age, sex, EH stage and grade, the degree of compensation DM2. Methods: biochemical blood analysis, echocardiography evaluation of mitral diastolic blood flow and tissue Doppler spectral modes, reactive hyperemia, color Doppler mapping, enzyme immunoassay. We conducted genotyping of Pro12Ala polymorphism of PPARγ2.
Results
Patients with genotype Pro/Pro of PPARγ2 had significantly higher levels of total cholesterol, LDL, proinflammatory cytokines (TNF-α and IL-6), the values of intima-media thickness and significantly lower degree of endothelium-dependent vasodilatation as compared to genotype Pro12Ala/Ala12Ala. After standart therapy in patients with EH and concomitant DM2 (in all PPARγ2 genotypes) metabolic and hemodynamic parameters were improved. More pronounced dynamics was in patients with genotype Pro12Ala/Ala12Ala. Additional appointment of α-LA impacted more to vascular remodeling and levels of

proinflammatory cytokines as compared to standard therapy. Decrease HbA1c and triglyceride levels in patients with additional appointment of α-LA was significantly more pronounced as compared to standard therapy only in genotype Pro12Ala/Ala12Ala.
Conclusions
Effectiveness of complex therapy in comorbidity of DM2 and EH depends on PPARγ2 genotype. Dynamics of metabolic and hemodynamic parameters was more pronounced in additional appointment of α-LA, especially in genotype Pro12Ala/Ala12Ala.

GLP-1 based multi-agonists-induced signaling includes profound TRP channel involvement in insulin secretion

Noushafarin Khajavi[1], Brian Finan[2], Oliver Kluth[3,4], Stefan Mergler[5], Timo Müller[2], Gunnar Kleinau[1], Annette Schürmann[3,4], Matthias H Tschöp[2], Richard DiMarchi[6], Heiko Krude[1] & Heike Biebermann[1]
[1]Institute for Experimental Pediatric Endocrinology, Charite, University-Medicine Berlin, Berlin, Germany; [2]Institute for Diabetes and Obesity, Helmholtz Center Munich, German Research Center for Environmental Health (GmbH) and Technical University Munich, Munich, Germany; [3]Department of Experimental Diabetology, German Institute of Human Nutrition Potsdam-Rehbruecke, Nuthetal, Germany; [4]German Center for Diabetes Research, Neuherberg, Germany; [5]Department of Ophthalmology, Charite, University-Medicine Berlin, Berlin, Germany; [6]Department of Chemistry, Indiana University, Bloomington, Indiana, USA.

Promiscuous multi-agonists that simultaneously activate two or three key receptors (incretin- and/or glucagon receptor) were recently shown to improve glycemic control in mice. Here we investigated the underlying mechanisms of multi-agonists to enhance insulin secretion in murine islets and human pancreatic β-cells. These mixed agonists display a greater potency in cAMP signaling as compared to the native incretins. However, pharmacological blockade of cAMP signaling only partially inhibited the increases in insulin secretion. Therefore, additional mechanisms independent from Gs signaling-coupled Ca^{2+} influx appear to mediate insulin secretion. Here, we showed multi-agonists evoked significant increases in Ca^{2+} influx through activation of both voltage-dependent Ca^{2+} channels (VDCCs) and transient receptor potential channels (TRPs). These responses were more rapid and larger after multi-agonist stimulation than those after mono-agonists. Pharmacological blockade of TRP channels suppressed Ca^{2+} transients induced by multi-agonists to a greater degree than exposure to VDCC blocker. TRP blockers also blunted cAMP accumulation and abolished increases in whole-cell currents that are evoked with multi-agonists. These observations argue for a direct TRP channel activation by ligand-engaged incretin receptors. Collectively, direct activation of adenylyl cyclase through GPCR/channel constellations and concomitant rapid Ca^{2+} influx likely contribute to the increases in insulin secretion induced by multi-agonists.

Effect of alive probiotic on insulin resistance in type 2 diabetes patients: randomized clinical trial

Nazarii Kobyliak[1], Kateryna Kondratiuk[1], Dmytro Kyriienko[2] & Galyna Mykhalchyshyn[1]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Kyiv City Endocrinology Center, Kyiv, Ukraine.

Background
Probiotics have beneficial effect on obesity related disorders in animal models. Despite a large number of animal data, randomized placebo-controlled trials (RCT) concluded that probiotics have a moderate effect on glycemic control-related parameters. However, effect of probiotics on insulin resistance are inconsistent.
Aim
In a double-blind single center RCT, effect of alive multistrain probiotic vs placebo on insulin resistance in type 2 diabetes patient were assessed.
Methods
A total of 53 patients met the criteria for inclusion. They were randomly assigned to receive multiprobiotic 'Symbiter' (concentrated biomass of 14 probiotic bacteria genera Bifidobacterium, Lactobacillus, Lactococcus, Propionibacterium) or placebo for 8-weeks administered as a sachet formulation in double-blind treatment. The primary main outcome was the change HOMA-IR (homeostasis model assessment-estimated insulin resistance) which calculated using Matthews *et al.*'s equation. Secondary outcomes were the changes in glycemic control-related parameters, anthropomorphic variables and cytokines (TNF-α, IL-1β, IL-6, IL-8, INF-γ) levels. ANCOVA was used to assess the difference between groups.
Results
Supplementation with alive multiprobiotic for 8 weeks was associated with significant reduction of HOMA-IR from 6.85 ± 0.76 to 5.13 ± 0.49 ($P = 0.047$), but remained static in the placebo group (7.24 ± 0.74 to 7.95 ± 1.01; $P = 0.573$). With respect to our secondary outcomes, HbA1c insignificant decreased by 0.09% ($P = 0.383$) and 0.24% ($P = 0.068$) respectively in placebo and probiotics groups. However, in probiotic responders ($n = 22$, patient with decrease in HOMA-IR) after supplementation a significant reduction in HbA1c by 0.39% ($P = 0.022$) as compared to non-responders was observed. In addition, from markers of chronic systemic inflammatory state only TNF-α (15.8%, $P < 0.001$), and IL-1β (14.4%, $P = 0.001$) and IL-6 (22.1%, $P = 0.027$) changes significantly after treatment with probiotics.
Conclusion
Probiotic therapies modestly improved insulin resistance in patients with type 2 diabetes. Modulation of the gut microbiota represents a new treatment for diabetes and should be tested in larger studies.

OC2.5

Urinary peptidomics for the detection of diabetic kidney disease

Leticia A Brondani, Ariana A Soares, Angelica D'Allagnol, Joíza L Camargo, Karina Monteiro & Sandra P Silveiro
Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil.

Background
Diabetic kidney disease (DKD) is the main cause of end-stage renal disease It is defined by glomerular filtration rate (GFR) impairment and/or presence of increased urinary albumin excretion (UAE). However, these parameters are nonspecific and somewhat delayed manifestations of renal damage. Thus, earlier DKD new biomarkers are strongly warranted.
Objective
To investigate the urinary peptidomics profile of type 2 diabetes mellitus (DM) patients with different stages of DKD.
Methods
Casual urine samples were collected from 66 type 2 DM patients matched by age, gender and time of diabetes duration. Urine natural occurring peptides were purified by ultrafiltration under denaturing conditions and analyzed by LC–MS/MS. UAE was assessed by immunoturbidimetry and GFR was estimated by CKD-EPI equation. Kruskall–wallis, Mann–Whitney and $\chi 2$ tests were performed when appropriate; Perseus software was used to perform hierarchical clustering of significantly up- and down-regulated proteins.
Results
Type 2 DM patients (mean age $= -61.5 \pm 9.7$ years; males $= 47.1\%$) were stratified by the levels of albuminuria (normal ($n = 27$), moderately increased (MI, $n = 18$) and severely increased (SI, $n = 21$)). A total of 116 urinary proteins were detected by LC/-MS/MS. A distinct proteomic profile was identified in patients with SI albuminuria, represented by 11 proteins. When GFR values were analyzed, we observed that 13 urinary proteins differed significantly in the 9 patients with GFR < 60 ml/min per 1.73 m^2 when compared to 57 patients with GFR ≥ 60 ml/min per 1.73 m^2. Among the most remarkably different urinary protein profile, alpha-1 type I collagen was around 10% less expressed in SI patients, while alpha-1 antitrypsin, plasma protease C1 inhibitor and apolipoprotein-1 were ~twofold increased in these patients.
Conclusions
LC–MS/MS analysis revealed that at least 11 urinary proteins were differentially expressed in type 2 DM patients according to DKD severity. This study confirms the previously described findings in other populations and also detected novel proteins commonly altered in patients with GFR impairment and increased albuminuria.

Epigenetic regulation of aldosterone synthase gene, CYP11B2 by potassium

Yoshiyu Takeda, Masashi Demura, Takashi Yoneda, Yoshimichi Takeda, Mitsuhiro Kometani, Seigo Konishi & Toshitaka Sawamura
Kanazawa University, Kanazawa, Japan.

Purpose
We found the hypomethylation status of CYP11B2 gene in the aldosterone-producing adenomas compared with normal adrenal glands or non-functioning adrenal adenomas and reported that the methylation of promoter region of this gene influenced the mRNA expression in the adrenal cells. Angiotensin II or potassium regulates CYP11B2 gene expression in the adrenal cells. In order to clarify the acute effect of potassium on the methylation status of CYP11B2 gene, Human adrenal cells rats were treated with potassium and the methylation status of CYP11B2 gene in the adrenal cells was examined.
Methods
H295R cells were treated with potassium for 28 days. The gene expression of CYP11B2 was measured by real time quantitative PCR in the adrenal cells. ChiP assay and methylation activity were measured. Isolated DNAs from adrenal cells were treated with bisulfite and amplified using primers specific for the human CYP11B2 promoter regions.
Results
CYP11B2 mRNA levels were increased from 4th day to 7th day by the treatment with potassium. The methylation ratio was decreased from 4th day. The expression of CREB1 and NR4A1 were increased from 4th day. The methylation activity was increased from 7th day. The chromatin accessibility was increased from 4th day to 7th day
Conclusions
Aldosterone biosynthesis may be reversibly regulated by the epigenetic mechanism.

DOI: 10.1530/endoabs.49.OC3.1

OC3.2

Elucidating the role of Liver X receptors (LXRs) in the testis using lipid systems biology

Sheba Jarvis[1], Lee Gethings[2], Raffaella Gadaleta[3,1], Lord Robert Winston[1], Catherine Williamson[4] & Charlotte Bevan[1]
[1]Department of Surgery and Cancer, Imperial College London, Hammersmith Hospital, London, UK; [2]Waters Corporation, Wilmslow, UK; [3]Dipartimento Interdisciplinare di Medicina, University of Bari, Bari, Italy; [4]Womens Health Clinical Academic Group, Kings College London, Guys Campus, London, UK.

Introduction
The importance of the liver-X receptors (LXRs) in the maintenance of cholesterol homeostasis within the testis has yet to be fully characterised. By 7 months of age, Lxrα/β double knockout male mouse (Lxrα/β DKO) develops sterility with aberrations in testosterone production and lipid homeostasis. However, the underlying testicular LXR-regulated pathways are not well understood.
Aim
The aim of this study was to further understand the importance of LXRs in the testis by investigating disruption of candidate genes and networks of cellular lipids and steroid metabolites in Lxrα/β DKO mice.
Methods
We used RNA-seq and quantitative mass spectrometry to study whole testicular tissues from 6-month old Lxrα/β DKO mice alongside age-matched littermate controls. cDNA libraries were prepared followed by sequencing using NextSeq-500. Lipid extracts from mouse testis were prepared for LC-MS analysis using SONAR acquisition, based on an m/z isolation range of the quadrupole. Results were analysed using LipidMaps and Progenesis QI for normalized quantitation.
Results
Histological assessment of testicular tissues from Lxrα/β DKO mice confirmed abnormal seminiferous tubules, germ-cell loss and lipid deposition. Quantitative lipidomic analysis confirmed statistically significant differences in 53 lipid species including triglycerides and cholesterol esters (notably 20:4 cholesteryl ester) in the Lxrα/β DKO mice. Sphingolipid species (e.g. ceramide t18:0/20:0) were also altered. The retrieved curated targets were mapped onto KEGG pathway analysis, identifying key changes in steroid hormone biosynthesis and sphingomyelin metabolism. RNA-seq analysis revealed 1161 differentially expressed genes (log2 fold change in gene expression of -3.49 to $+2.17$, $P<0.01$) in Lxrα/β DKO. Androgen biosynthesis genes (Cyp17a1, Hsd3β2, Hsd17β3), triglyceride synthesis (Acsl, Acot7) as well as genes involved in sphingolipid metabolism were altered correlating with lipidomic data.
Discussion
Our integrative approach using lipidomic analysis with mRNA transcript studies provides novel data, implicating LXRs in pathways such as sphingolipid metabolism, critical for successful spermatogenesis.

DOI: 10.1530/endoabs.49.OC3.2

AKR1C3-mediated adipose androgen generation drives lipotoxicity in polycystic ovary syndrome

Michael O'Reilly[1], Punith Kempegowda[1], Mark Walsh[3], Angela Taylor[1], Konstantinos Manolopoulos[1], William Allwood[1], Robert Semple[4], Daniel Hebenstreit[3], Warwick Dunn[1], Jeremy Tomlinson[2] & Wiebke Arlt[1]
[1]University of Birmingham, Birmingham, UK; [2]University of Oxford, Oxford, UK; [3]University of Warwick, Coventry, UK; [4]University of Cambridge, Cambridge, UK.

Polycystic ovary syndrome (PCOS) is prevalent metabolic disorder in women, associated with androgen excess and insulin resistance. These two major features are closely correlated, but the direction of causality remains unclear. Aldoketoreductase type 1C3 (AKR1C3) converts the androgen precursor androstenendione to testosterone (T), and is highly expressed in subcutaneous (SC) adipose tissue. We hypothesised that adipose tissue represents an important site linking androgen activation and metabolic dysfunction in PCOS. We undertook metabolic phenotyping in 10 PCOS women and 10 age- and BMI-matched controls. Participants underwent an oral challenge with the androgen precursor DHEA, alongside adipose tissue microdialysis, with measurement of metabolic markers and adipose androgens in microdialysate fluid. Non-targeted serum metabolome analysis was performed before and after androgen exposure. SC adipose tissue biopsies were collected for RNA-sequencing. Complementary *in vitro* experiments in primary SC adipocytes and a preadipocyte cell line were performed to examine the effects of insulin and androgens on AKR1C3 expression and de novo lipogenesis, respectively. PCOS women had higher adipose T ($P<0.0006$) and dihydrotestosterone (DHT, $P=0.01$) than controls as measured by liquid chromatography-tandem mass spectrometry. Non-targeted serum metabolomics and adipose microdialysis revealed pro-lipogenic effects of androgens at baseline and after DHEA in PCOS. AKR1C3 mRNA expression was increased in PCOS SC adipose tissue ($P=0.04$). Transcriptional profiling revealed dysregulation of mitochondrial and inflammatory pathways in PCOS SC adipose tissue. *In vitro* studies showed that insulin upregulates adipose AKR1C3 expression and activity, and androgens enhance adipose de novo lipogenesis. Pharmacological inhibition of AKR1C3 decreased adipose tissue androgen generation and androgen-mediated de novo lipogenesis. Complementary *in vivo* and *in vitro* studies highlight that AKR1C3-mediated intra-adipose androgen activation drives lipotoxicity and adverse metabolic risk in PCOS, fuelling a vicious circle of androgen generation and insulin resistance. Selective inhibition of AKR1C3 holds promise as a novel therapeutic approach in PCOS.

Treatment with thyroid hormone metabolite 3,5-T2 alters cholesterol and sex steroid metabolism in mouse liver

Julika Lietzow[1], Janine Golchert[2], Georg Homuth[2], Wenke Jonas[3], Claes Ohlsson[4], Andreas Landin[4], Matti Poutanen[5] & Josef Köhrle[1]
[1]Institute of Experimental Endocrinology, Charité Universitätsmedizin Berlin, Berlin, Germany; [2]Interfaculty Institute for Genetics and Functional Genomics, Ernst-Moritz-Arndt-University Greifswald, Greifswald, Germany; [3]Department of Experimental Diabetology, German Institute of Human Nutrition, Nuthetal, Germany; [4]Institute of Medicine, The Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden; [5]Department of Physiology, Institute of Biomedicine, University of Turku, Turku, Finland.

Recent findings revealed 3,5-diiodo-L-thyronine (3,5-T2) as a metabolically active iodothyronine affecting hepatic energy and lipid metabolism. Therefore, 3,5-T2 has been proposed as a potential hypolipidemic agent for treatment of obesity and its hepatic aftermath. So far only limited data exists relating to the effects of 3,5-T2 on metabolism in euthyroid mammals maintained on high-fat

diet from the day of weaning onwards. Therefore, we performed a study in which 20-week old diet-induced obese male mice in comparison to lean animals received either 3,5-T2 (2.5 µg/g body weight) or saline over a four-week period. To identify new target genes and signaling mechanisms of 3,5-T2 which are distinct from established hepatic T3 action we performed microarray-based transcriptome analyses of liver tissue. The transcriptome as well as qPCR data demonstrated higher hepatic expression of genes involved in cholesterol biosynthesis (e.g. Sqle 4.8-fold, Cyp51 2.8-fold, Hsd17b7 1.8-fold) and bile acid formation (Cyp7a1 2.0-fold, Cyp39a1 2.9-fold) in obese but not in lean mice treated with 3,5-T2. In contrast to the elevation of hepatic cholesterol biosynthesis, serum cholesterol concentration was reduced by up to 57% with 3,5-T2 administration. In addition, 3,5-T2 modulated expression of genes important for sex steroid biosynthesis and inactivation (e.g. Cyp17a1 3.5-fold, Hsd17b6 -7.8-fold). GC MS/MS analysis of the hepatic sex steroid hormone profile indicated higher progesterone and androstenedione content in livers of obese mice treated with 3,5-T2, whereas no such changes were observed in 3,5-T2-treated lean mice. These results suggest a diet-dependent role of 3,5-T2 in modulating local cholesterol as well as sex steroid biosynthesis and androgen homeostasis in mouse liver. Such actions of thyroid hormone metabolites have not been reported elsewhere up to date and might help to explain liver-targeting effects of T3-receptor beta-selective ligands.

Accurate staging of non-alcoholic fatty liver disease through analysis of the urinary steroid metabolome

Ahmad Moolla[1], Amin Amin[2], Beverly Hughes[2], Wiebke Arlt[2], Zaki Hassan-Smith[2], Lorna Gilligan[2], Matt Armstrong[3], Philip Newsome[3], Tahir Shah[3], Luc Van Gaal[4], An Verrijken[4], Sven Francque[4], Jane Grove[5], Neil Guha[5], Guruprasad Aithal[5], Ellie Barnes[6], Michael Biehl[7] & Jeremy Tomlinson[1]

[1]Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; [2]Centre for Endocrinology, Diabetes & Metabolism, University of Birmingham, Birmingham, UK; [3]Centre for Liver Research, University of Birmingham, Birmingham, UK; [4]University of Antwerp, Antwerp, Belgium; [5]NIHR Nottingham Digestive Diseases Biomedical Research Unit, Nottingham University Hospitals NHS Trust and University of Nottingham, Nottingham, UK; [6]Translational Gastroenterology Unit, University of Oxford, Oxford, UK; [7]University of Groningen, Groningen, The Netherlands.

Introduction

Non-alcoholic fatty liver disease (NAFLD) is associated with dysregulated glucocorticoid metabolism. Advanced stages of NAFLD are associated with adverse outcome and current strategies to stage disease severity are still reliant upon liver biopsy. We have previously described changes to enzymatic pathways that regulate cortisol bioavailability; 11β-hydroxysteroid dehydrogenase type-1 (11β-HSD1) regenerates cortisol from inactive cortisone, and A-ring reductases, 5α- and 5β-reductase (5αR/5βR), inactivate cortisol to tetrahydrocortisol metabolites (THF/5αTHF). Changes to these pathways are apparent across the NAFLD spectrum (simple steatosis, steatohepatitis (NASH), fibrosis and cirrhosis). Here we have further validated these observations in a large cohort of patients with NAFLD and compared these to healthy controls and to patients with alcoholic cirrhosis.

Methods

Using gas chromatography / mass spectrometry, we analysed steroid metabolites in spot urine samples (corrected for creatinine) in patients with biopsy proven NASH ($n=65$), NAFLD cirrhosis ($n=51$), alcoholic cirrhosis (n=48) and in healthy controls ($n=58$). Additionally, we used machine learning-based analysis to investigate changes across 32 steroid metabolites.

Results

Cortisol regeneration (11β-HSD1 activity: THF+5αTHF/THE ratio), was significantly increased in NAFLD cirrhosis ($P=0.0004$), and alcoholic cirrhosis ($P<0.0001$), compared to controls. Cortisol inactivation (A-ring reductase activity: THF/5αTHF ratio) was significantly reduced in NAFLD cirrhosis compared to controls ($P=0.0004$), but not between controls and alcoholic cirrhosis ($P>0.99$) nor NASH ($P=0.332$). Machine learning-based analysis by generalised matrix-learning vector quantisation (GMLVQ) achieved excellent separation of control and NASH groups (AUC-ROC=0.87). Furthermore, there was near perfect separation of controls from NAFLD cirrhosis (AUC-ROC=0.99) and controls from alcoholic cirrhosis (AUC-ROC=0.98).

Conclusion

This data is consistent with our previous findings that identified differentially regulated steroid metabolic pathways across the spectrum of NAFLD. Furthermore, unbiased GMLVQ analysis of the urinary steroid metabolome appears robust in differentiating healthy controls from cirrhosis and warrants further exploration as a novel non-invasive biomarker tool to assess the severity of NAFLD.

Hypothyroidism in pregnancy is associated with twin pregnancies and with adverse obstetric outcome: Analysis of 142,277 deliveries data from a single center

Orit Barenholz-Goultschin[1,2], Rivka Farkash[1,2], Arnon Samueloff[1,2] & Gabriel Munter[1,2]

[1]Shaare Zedek Medical Center, Jerusalem, Israel; [2]Hebrew University, Jerusalem, Israel.

Introduction

Many studies have examined maternal and fetal complication rates in treated and untreated overt and subclinical hypothyroidism. Maternal hypothyroidism may adversely affect the development of the fetal pituitary–thyroid axis. It has also been reported to be closely related to adverse pregnancy outcome.

Aim

To study the prevalence and outcome of hypothyroidism in pregnancy during the last decade in a high volume obstetric center in Jerusalem.

Methods

A retrospective study of the obstetric database between August 2005 and December 2015 in Shaare Zedek Medical Center, Jerusalem.

Results

During the study period there were 142,277 deliveries of singleton or twin pregnancies (1.9% twin deliveries). The medical files of 4042 (2.8%) deliveries (group A) included a diagnosis of maternal hypothyroidism. Women giving birth with the diagnosis of hypothyroidism were older (31.1±6 years 28.8±5.6 y. $P<0.0001$). Gestational diabetes was more prevalent (7.3% vs 3.3%, $P<0.0001$) in group A as were hypertensive disorders (3.7% vs 2.3%, $P<0.0001$). Higher rate of assisted reproduction techniques were used in group A (8.5% vs 3.7%, $P<0.0001$). Although not previously reported, the incidence of twin pregnancies was higher in group A (3.8% vs 1.8% $P<0.0001$) and this association remained significant in a multivariate analysis with IVF as a co-variate (OR 1.43 95%CI[1.20–1.71], $P<0.001$). Obstetric complications including preterm deliveries (7.8% vs 5.2%, $P>0.0001$), cesarean sections (20.6% vs 11.4%, $P>0.0001$), any obstetric hemorrhage and prolonged hospitalization were more frequent in group A. The incidence of adverse neonatal outcome including low birth weight (7.3% vs 5.4%, $P>0.0001$) and NICU admission (5.1% vs 3.6%, $P>0.0001$) was higher in group A but there was no difference in fetal macrosomia and apgar scores.

Conclusions

In this large database, hypothyroidism is associated with adverse obstetric outcome. This is the first study to describe a higher incidence of hypothyroidism in twin pregnancies. TSH screening should be considered in twin pregnancies.

Inducible thyrocyte-specific Gs alpha-deficient mice as a novel model for hypothyroidism

Konrad Patyra[1], Holger Jaeschke[1], Henriette Undeutsch[1], Christoffer Löf[1], Suvi Ruohonen[1], Meeri Jännäri[1], Min Chen[2], Lee S. Weinstein[2], Ralf Paschke[3], Jorma Toppari[1] & Jukka Kero[1]

[1]Institute of Biomedicine, Turku, Finland; [2]Metabolic Diseases Branch, National Institute of Diabetes, Digestive and Kidney Diseases, National Institutes of Health, Bethesda, MD, USA; [3]Division of Endocrinology and Metabolism, Departments of Medicine and Oncology and Arnie Charbonneau Cancer Institute, Cummings School of Medicine, University of Calgary, Calgary, Canada.

The thyroid gland produces thyroid hormones, which are essential regulators of growth, development and metabolism of the body and is mainly regulated by the thyroid stimulating hormone (TSH)/TSH receptor (TSHR) interplay. The TSHR couples to all four G protein families *in vitro* but only for the Gs and Gq signaling cascade a role has been identified in vivo. To gain further insights into the complex signaling networks mediated by G proteins in the thyroid, we generated

a thyrocyte-specific tamoxifen-inducible Gs deficient mouse line (iTGsKO). Mice were injected with tamoxifen at P28 and phenotypic characterization was carried out by performing thyroid function tests at different ages. iTGsKO mice showed hypothyroidism at P56, four weeks after induction with tamoxifen. Furthermore, a decrease in thyroid weight and an increased pituitary weight support the conclusion of hypothyroidism in these mice. Morphometric analysis of the thyroid histology of iTGsKO mice with an age of 6 months (P168) showed that the thyrocyte layers between adjacent follicles and the follicle areas were significantly reduced when compared with controls. Interestingly, despite of an identical thyroid hormone status we observed a clear sex difference. In iTGsKO males, the body weight was significantly decreased at P70 when compared with control males but no weight difference was seen in females over the investigated time period of 6 months (P168). The lower body weight in iTGsKO males was associated with reduced fat mass. In summary, we show that iTGsKO mice are a useful tool for understanding the role of G-protein signaling in the thyroid as well as investigating the metabolic consequences in hypothyroidism.

A novel variant in the SERPINA7 gene causing partial TBG deficiency in a women and two male siblings: molecular and protein structural analysis

Cristiane Lima[1], Andressa Maciel[1], Sarah Caixeta Cardoso[1], Matheus Andrade[1], Vinicius Cunha[1], Lucas Bleicher[2], Juliana mazzeu[3] & Adriana Lofrano-Porto[1]
[1]University of Brasília, Faculty of Health Sciences, Molecular Pharmacology Laboratory, Brasilia, DF, Brazil; [2]Federal University of Minas Gerais, Department of Bichemistry and Imunology, Belo Horizonte, MG, Brazil; [3]Univeristy of Brasilia, Faculty of Medicine, Medical Genetics Laboratory, Brasilia, DF, Brazil.

Background
Thyroxine-binding globulin (TBG) is the major human thyroid hormone transport protein. It is encoded by the SERPINA7 gene, located on the long arm of the X chromosome (Xq22.2). Inherited TBG abnormalities result in complete (TBG-CD) or partial (TBG-PD) TBG deficiency. We performed a comprehensive molecular analysis of the SERPINA7 gene in a Brazilian family with TBG-PD.
Methods
Genomic DNA was extracted from the female proband, her father, dizygotic twin sister and two brothers, and the coding region of the SERPINA7 gene was sequenced. The proband's X-chromosome inactivation pattern was evaluated by methylation analysis using the human androgen receptor (AR) gene, located next to SERPINA7 (Xq11.2). Structural analysis of the Serpin protein family was performed using PFSTATS, and was also used to map equivalent positions in all human homologs. Molecular modeling was done as described by Feyfant et al.
Results and Discussion
A novel missense mutation in the SERPINA7 gene (p.R35W; c.163C>T) was found in heterozygosity in the proband and in hemizygosity in her brothers. They presented low serum levels of total T4, total T3 and TBG, compatible with TBG-PD. The proband expressed an X-chromosome inactivation ratio of 20:80. The substitution of an arginine by a tryptophan is predicted to disrupt the protein surface and main electrostatic interactions. The conservation and correlation patterns showed that tryptophans are extremely rare (0.1%) in this position, and there is no significant ($P<10\text{-}10$) pairwise.
Conclusion
We report a new variant of the SERPINA7 gene associated with TBG-PD in three siblings. The proband's X-chromosome inactivation pattern may have accounted for the rare phenotypic expression in a heterozygous woman. The hydrophobic nature of the mutant is predicted to create an apolar patch at the protein surface, which would be significantly exposed to the solvent, and result in protein aggregation and/or misfolding with consequent thyroxin transport defect.

The TSH receptor reaches the trans-Golgi network to induce PKA activation and trigger gene transcription

Amod Godbole[1,2], Sandra Lyga[1,2], Martina Leo[1,2] & Davide Calebiro[1,2]
[1]Institute of Pharmacology and Toxicology, University of Würzburg, Würzburg, Germany; [2]Bio-Imaging Center/Rudolf Virchow Center, University of Würzburg, Würzburg, Germany.

Whereas G-protein coupled receptors (GPCRs) have long been believed to signal via cyclic AMP (cAMP) exclusively at the cell surface, our group has shown that GPCRs also stimulate cAMP production from the cell interior once internalized together with their ligands. This phenomenon, which we originally described for the thyroid stimulating hormone receptor (TSHR) in thyroid follicles, has now also been shown for several other GPCRs. However, the involved subcellular compartment(s) and the mechanisms linking signalling by internalized GPCRs to downstream biological effects are largely unknown. The aim of this study was to follow the trafficking of internalized TSHRs and involved signalling proteins in living primary thyroid cells by highly inclined thin illumination (HILO) microscopy as well as to monitor cAMP production and protein kinase A (PKA) activation by real-time fluorescence resonance energy transfer (FRET) microscopy. Importantly, using a biosensor nanobody that is specific for the active Gs-protein, we were able to directly demonstrate that the internalized TSHR activates an endogenous pool of Gs-protein located on membranes of the Trans Golgi Network (TGN). Direct monitoring of PKA activation with a Golgi-localized FRET sensor (AKAR2) showed a delayed PKA activation (approx. 10 min) after TSH stimulation, which is compatible with the time required for TSH/TSHR complexes to reach the Golgi/TGN. Moreover, our results also indicate that Gs-protein mediated signalling by internalized receptors at the TGN and the resulting PKA activation at a critical position near the nucleus are required for the efficient induction of CREB phosphorylation and gene transcription. These findings provide a mechanism to explain the biological relevance of GPCR signalling at intracellular sites, which might help explaining the pathogenesis of endocrine disorders such as Graves' disease and might pave the way to innovative pharmacological therapies.

Levothyroxine replacement therapy: once treatment is started, should it last indefinitely?

Sarantis Livadas[1], Christina Bothou[1], Ioannis Androulakis[1], Anastasios Boniakos[1], Nicholas Angelopoulos[1] & Leonidas Duntas[2]
[1]Endocrine Unit, Metropolitan Hospital, Athens, Greece; [2]Unit of Endocrinology, Diabetes and Metabolism, Evgenideion Hospital, University of Athens, Athens, Greece.

Background
Levothyroxine (LT4) is one of the most prescribed drugs worldwide. Once started, about 90% of patients continue LT4 treatment long-term.
Aim of the study
To evaluate the necessity of long-term thyroxine supplementation and to determine the prognostic factors that could identify which patients may discontinue LT4 treatment.
Design and methods
LT4 replacement therapy was paused for at least six weeks in all patients consecutively visiting our department, excluding those who have a definite need for L-thyroxine use (replacement after total thyroidectomy), those on thyroid-altering medication, women wishing to conceive and those who gave birth last year. 231 individuals were assessed (84% females), aged 48 years (SD = 16.5), who were categorized into the following categories: a) unknown reason for thyroxine supplementation ($n=62$), b) presence of thyroid nodules ($n=90$), normal TSH before thyroxine administration ($n=44$), over 10 years' use ($n=10$), therapy initiated post-pregnancy ($n=20$). Thyroid function was evaluated before and after the thyroxine pause. A value of TSH $\geq$4.5 IU/ml post treatment discontinuation was considered as 'relapse' and LT4 was reinstituted in those individuals. The potential prognostic factors analyzed were family history of thyroid dysfunction, sex, age, dose per BMI and dose per kg, thyroid volume, thyroid ultrasound characteristics, positivity of thyroid autoantibodies, basal TSH values and reason for the initial treatment indication.
Results
25.54% (83% females) of the studied subjects relapsed. Of the above-described factors, only diffuse inhomogeneous echogenicity was tentatively identified as the only predictive factor for relapse (71% vs 57%, *P*:001). The age (47.27 $\pm$ 15.45 vs 48.17 $\pm$ 16.98 years, *P*:0.72), the positivity of TPOAb (69%% vs 54%, *P*:0.064) and basal TSH values (1.51 $\pm$ 0.96 ΩΣ. 1.57 $\pm$ 0.84, *P*:0,81) did not differ significantly among the two groups.
Conclusions
One out of four individuals evaluated required thyroxine treatment. The need for a patient-centered approach regarding L-thyroxine supplementation and for a thorough review of patient history was evident.

Polarized epithelial cells release exosomes loaded with miRNAs capable of interacting with HSD11B2 and MR genes

Eric Barros[1], David Ortiz[1], Carmen Campino[1], Carolina Valdivia[1], Alejandra Tapia-Castillo[1,2], Jaime Lizama[1], Fidel Allende[1], Sandra Solari[1], José Vicente Gonzalez[1], Alejandro Martínez-Aguayo[1], Andrea Vecchiola[1], Gabriela Repetto[1,2], Marlene Aglony[1], Rene Baudrand[1], Carlos F Salomon[1,3], Carlos E Fardella[1] & Cristian Carvajal[1]
[1]Pontificia Universidad Católica de Chile, Santiago, Chile; [2]Universidad del Desarrollo, Santiago, Chile; [3]University of Queensland, Brisbane, Australia.

Arterial hypertension is a major health problem affecting 1.13 billion people worldwide, of which 10% could be due to endocrine pathologies related to the mineralocorticoid receptor (MR) (i.e. primary aldosteronism, 11β-hydroxysteroid dehydrogenase type 2 enzyme (HSD11B2) deficiency). The MR pathway is expressed mainly in placenta, kidney and colon epithelial cells. Current research highlights potential epigenetic regulatory mechanisms for the MR pathway. Here, specific miRNAs are being studied as epigenetic regulators, either present in cells or exosomes (nanovesicles of 40–150 nm diameter) carrying miRNA, RNA, lipids and proteins. Those miRNAs could dynamically influence the onset and progression of the mineralocorticoid arterial hypertension (AH).

Aim

To isolate exosomes from polarized epithelial cells and to identify in their cargo miRNAs affecting HSD11B2 and MR gene expression.

Methods

The bioinformatic tool mirWalk2.0 was used to determine miRNAs capable to interact with HSD11B2 and MR RNAs. The cell line derived from colon epithelia (Caco-2) cells was cultured and polarized in Transwells. MR pathway genes and miRNAs targeting the MR and HDS11B2 were measured by qPCR. Exosomes from apical and basolateral culture medium were isolated at 24 h of incubation in basal conditions, quantified with NanoSight-NS300 and their specific miRNA content was determined.

Results

We identified bioinformatically that miRNA 135b, 644a and miRNA 488, 1205 could interact with the MR and HSD11B2, respectively. Caco-2 cells polarize after 21 days of culture (trans-epithelial resistance (TEER): 114.18 cm^2), expressing polarization genes (SLC11A2, SLGT1, ALPI), genes associated to MR pathway (NR3C2, HSD11B2, SCNN1A, SLC12A2, SGK1, ATP1A1) and pre-miRNAs (135b, 644a, 488, 1205). We identified that Caco-2 release $21\times109\pm0.69\times109$ (apical) and $4.1\times109\pm0.0029\times109$ (basolateral) extracellular vesicles per ml of which a 36.8 and 38.5% are exosomes with a modal range in 124–125 nm diameter respectively. Preliminary results show expression of miRNA 135b, 644a, 488 and 1205 in apical and basolateral exosomes.

Conclusion

Caco-2 cells release five-times more exosomes in the apical than basolateral side, both carrying miRNAs that could interact HSD11B2 and MR gene.

Association of PPAR gamma gene expression with dietary intake of fat and oil among non-diabetic subjects

Emad Yuzbashian[1,2], Maryam Zarkesh[3], Golaleh Asghari[1], Azita Zadeh-Vakili[3], Behnaz Mahmoodi[1], Mehdi Hedayati[3], Parvin Mirmiran[1] & Alireza Khalaj[4]
[1]Nutrition and Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [2]Student Research Committee, Biochemistry of Nutrition Research Center, School of Medicine, Mashhad University of Medical Sciences, Mashhad, Iran; [3]Cellular and Molecular Endocrine Research Center, Research Institute for Endocrine Sciences, Shahid Beheshti University of Medical Sciences, Tehran, Iran; [4]Obesity Treatment Center, Department of Surgery, Shahed University, Tehran, Iran.

Background and Objective

Several animal studies showed the expression of peroxisome proliferator activated receptor-gamma (PPAR gamma) in adipocytes among rats fed with high-fat diet was higher than those fed with normal diet. However, there are no human studies to support this. The objective of the present study was to investigate the association between the PPAR gamma expression in adipose tissue and intake of hydrogenated and non-hydrogenated vegetable oils and butter.

Materials and methods

Visceral and subcutaneous adipose tissues were obtained from 97 non-diabetic subjects (41 non-obese, 18 obese, and 38 morbid obese), who underwent open abdominal surgery with minimal impact on dietary intake. Intake of hydrogenated and non-hydrogenated vegetable oils and butter was collected using a valid and reliable food frequency questionnaire. The gene expressions of PPAR-gamma in visceral and subcutaneous adipose tissue were assessed by Real-Time PCR.

Findings

After adjustment for total energy intake and age, visceral adipose tissue PPAR-gamma gene expression was correlated with total fat and oil intake ($\beta=-0.531$, $P=0.014$) in total population. Among non-obese subjects, visceral adipose tissue PPAR-gamma gene expression was correlated with non-hydrogenated oil ($\beta=0.621$, $P=0.017$). PPAR-gamma gene expression in subcutaneous adipose tissue was correlated with non-hydrogenated oil ($\beta=0.481$, $P=0.026$) among obese subjects. Moreover, among morbid obese subjects we found significant correlations between visceral adipose tissue PPAR-gamma expression and total fat and oil intake ($\beta=0.417$, $P=0.020$).

Conclusions

Expression of adipose tissue PPAR-gamma mRNA negatively correlates with total fat and oil intake mostly in visceral fat. In addition, non-hydrogenated oil positively correlates with PPAR-gamma expression.

Pitié Salpêtrière, F-75651 Paris Cedex 13, France; [5]Saint-Antoine Research Center, Institute of Cardiometabolism and Nutrition, INSERM UMR, Pierre-and-Marie Curie University, Université Paris, Sorbonne Universités, Paris, France; [6]Departments of Molecular Biology and Endocrinology, Assistance Publique-Hopitaux de Paris, Hôpital Saint-Antoine, Paris, France; [7]Equipe INSERM 1190 Prise en charge translationnelle du diabète Institut EGID (European Genomic Institute for Diabetes), Lille, France.

Background

Lamin A/C mutations show heterogeneous phenotypes expanding from cardiopathies to lipodystrophies. LMNA-related heart disease has recently been shown to be associated with a high incidence of phenotypic progression and adverse arrhythmic and non-arrhythmic events. Anticipatory planning to prevent sudden death has been recommended in a multicentric cardiologic recruitment. Nevertheless the specific cardiac prognosis of R482-LMNA mutated patients, the hot-spot for partial lipodystrophic syndromes, has not been well studied.

Objectives

To compare the cardio-metabolic complications of R482-LMNA mutated patients, and carriers of other LMNA mutations.

Methods

This retrospective study included 29 R482-LMNA mutated patients and 29 carriers of another lamin A/C mutation (non-R482 group) followed at a single university hospital for a median of 5.5 years. The cardiac and metabolic phenotypes were compared between the two groups.

Results

The non-R482 carriers showed more electrocardiographic anomalies and wore more cardiac devices than the R482-carriers ($P<0.001$). The ultrasound cardiac examinations of non-R482 patients showed a higher frequency of left auricular dilatations ($P<0.05$) and a lower mean left ventricular ejection fraction ($P<0.01$) than in R482-carriers. A family history of medical devices ($P<0.001$) or sudden death ($P<0.01$) was more frequent in non-R482 than in R482-carriers. The prevalence of diabetes ($P<0.01$) and hypertriglyceridemia ($P<0.05$) and coronaropathy was higher in R482 than in non-R482 carriers. The R482 carriers had a lower leptin ($P<0.01$) and BMI ($P<0.05$) level than the non-R482.

Conclusion
The non-R482 presented more arrhythmias than the R482-carriers, who were twice more often diabetic with more coronaropathies. The frequency of diabetes reached, however 40% in non-R482 mutations. The follow-up of laminopathies should be adjusted to the genotype. Arrythmias, especially associated to diabetes or medical device family history should lead to LMNA genetic testing.

DOI: 10.1530/endoabs.49.OC5.3

Food history characterization of Portuguese centenarians, nutritional biomarkers and cardiovascular risk: case control study

Alda Pereira da Silva[1,2], Catarina Chaves[3], Andreia Matos[1,5], Angela Gil[1,5], Carolina Santos[1,5], Ana Valente[4], Manuel Bicho[1,5] & João Gorjão Clara[2]
[1]Genetics Laboratory, Environmental Health Institute – ISAMB, Faculty of Medicine, University of Lisbon, Lisbon, Portugal; [2]Geriatric Universitary Unit of Faculty of Medicine, University of Lisbon, Lisbon, Portugal; [3]Centro Hospitalar de Lisboa Central, Lisbon, Portugal; [4]Department of Nutritional Science, Atlantica University, Barcarena, Portugal; [5]Instituto de Investigação Científica Bento da Rocha Cabral, Lisbon, Portugal.

Introduction
Eating habits may contribute to longevity. Consumption of red meat, source of saturated fatty acids and cholesterol may be associated with increased risks of diabetes, cardiovascular disease (CVD), and mortality risk.
Methods
We studied 521 subjects, both genders, 253 centenarians (CENT) (100.26 ± 1.98 age) and 268 controls (67.51 ± 3.25 age), both low (LCR) and high cardiovascular risk (HCR), calculated based on QRISK®2-2016. Anthropometric and body composition analysis were evaluated by bioimpedance. The abdominal obesity (cm), BMI (kg/m^2) and the cut-off for fat mass (FM) by gender, defined according WHO. Sarcopenia defined by muscle-mass index cut-off $\leq$ 16.7 kg/m^2. Statistical methods were chi-square test, ANOVA and binary logistic regression.
Results
There were differences in the distribution of food frequency history between centenarians and controls concerning food groups except oilseeds. The daily intake of red meat, adjusted for age and gender, was a protective factor for sarcopenia (OR = 0.25, CI 95% = 0.096–0.670, P = 0.006), but contributes for FM excess (OR = 4.946, CI 95% = 1.471–16.626, P = 0.01), overweight and obesity (OR = 4.804, CI 95% = 1.666–13.851, P = 0.004). Only 2% of the centenarians reported this eating habit unlike the 64.3% of the HCR group. The frequency history of red meat intake was associated with higher cardiovascular risk (χ2 = 239,807; df = 8, P < 0.0001), as well as canned food intake (χ2 = 225.321; df = 8, P < 0.0001). Basal metabolism (Kcal) was lower in centenarians and higher in HCR group (CENT = 1176.78 ± 201.98; LCR = 1356.54 ± 170.65; HCR = 1561.33 ± 267.85; P < 0.0001), in the same way as BMI (CENT = 21,06 ± 3.68; LCR = 28.49 ± 4.69; HCR = 29.56 ± 5.26; P < 0.0001), waist circumference (CENT = 85.29 ± 10.83; LCR = 96.02 ± 11.71; HCR = 104.50 ± 11.84; P < 0.0001) and hip-waist ratio (CENT = 0.88 ± 0.07; LCR = 0.92 ± 0.08; HCR = 1.01 ± 0.08; P < 0.0001).
Conclusions
Centenarians have different food history than the control population. Frequent consumption of red meat may contribute to obesity and increased cardiovascular risk, since the hemic iron of red meat may catalyze oxidations leading to disease processes. The low frequency of this consumption, observed in centenarians, although associated with sarcopenia, may be one of the keys to longevity.

DOI: 10.1530/endoabs.49.OC5.4

Sex dimorphism of renal corticosteroid signaling during development and long term consequence on blood pressure

Laurence Dumeige[1], Caroline Storey[1,2], Lyvianne Decourtye[3], Mélanie Nehlich[1,4], Christophe Lhadj[1,4], Say Viengchareun[1], Laurent Kappeler[3], Marc Lombès[1] & Laëtitia Martinerie[1,2]
[1]INSERM 1185, Le Kremlin Bicetre, France; [2]Service d'endocrinologie pédiatrique, hôpital Robert Debré, APHP, Paris, France; [3]INSERM UMR-S 938, Paris, France; [4]Prem Up foundation, Paris, France.

Sex differences have been demonstrated in various biological processes such as arterial blood pressure. However, the potential sex dimorphism of the renin-angiotensin-aldosterone system and, by extension, the mineralocorticoid receptor (MR) signaling pathway, major regulators of blood pressure, has only been poorly studied, notably in the kidney. Basal systolic blood pressure (SBP) and heart rate (HR) were measured in adult male and female mice. Renal gene expression studies of major players of MR signaling were performed at different developmental stages in male and female mice using RT-qPCR, and were compared to that of the same genes in the lung, another mineralocorticoid epithelial target tissue. The potential role of sex hormones in the regulation of these genes was also investigated in differentiated KC3AC1 renal cells. Additionally, renal expression of the 11βHSD2 protein, a regulator of mineralocorticoid specificity, was measured by immunoblotting and its activity was indirectly assessed in the plasma using LC-MSMS method. SBP (91.7 ± 1.1 vs 99.2 ± 1.0 mmHg, P < 0.0001) and HR (662 ± 3 vs 687 ± 4 bpm, P < 0.0001) were significantly lower in females compared to males. This was accompanied by a sex and tissue-specific expression of MR signaling pathway from fetal stage (E18) to adulthood, most notably for GR (Nr3c1) and Gilz renal mRNA expression which was twofold-lower in adult females mice compared to males (P < 0.01). Moreover, 11βHSD2 mRNA and protein expression was found significantly increased in females (P < 0.05), with a statistically different ratio of corticosterone/dehydrocorticosterone between both sexes (P = 0.012). Finally, the implication of sex hormones in this sex-specific expression profile was confirmed in vitro, most notably for Gilz mRNA expression. We demonstrate a tissue-specific, sex-dependent and developmentally-regulated pattern of expression of MR signaling that could have important implications in physiology and pathology, particularly in the development of essential hypertension in men.

A passe-PAR2 for β-cell regeneration and protection

Ron Piran[1] & Fred Levine[2]
[1]Bar Ilan University's Faculty of Medicine, Safed, Israel; [2]Sanford Children's Health Research Center, Sanford Burnham Prebys Medical Discovery Institute, La Jolla, California, USA.

Cell and tissue damage, particularly to pancreatic β-cells, is an essential characteristic of diabetes mellitus, triggered by autoimmune destruction of β-cells in type-1 (T1D) and by obesity associated factors or insulin resistance in type 2. Thus, stimulating β-cell regeneration has long been a most important goal of diabetes research. Recently, we have shown that pancreatic injury consisting of acinar cell inflammation and β-cell destruction led to islet cell transdifferentiation. In this work, we report that the molecular mechanism for this process requires the activation of the protease-activated receptor-2 (PAR2), a G-protein-coupled receptor. PAR2 modulation was sufficient to induce islet cell transdifferentiation in the β-cells ablated animals as PAR2 Knock out mice and mice injected with PAR2 pharmacological activator showed that it was necessary and sufficient for the induction of islet cell transdifferentiation in the settings of β-cell ablation. PAR2 expression was modified in an islet cell type-specific manner in murine and human T1D. In addition to transdifferentiation, PAR2 regulated β-cell apoptosis in caerulein-mediated pancreatitis, demonstrating that PAR2 was required for β-cell survival and protection during inflammation.

Insulin-mimetic effects of short-term Rapamycin in type 1 diabetic patients prior islet transplantation

Federica Ermetici[1], Silvia Briganti[1], Stefano Benedini[1,2], Roberto Codella[2], Paola Maffi[3], Rossana Caldara[3], Antonio Secchi[3], Lorenzo Piemonti[3], Rodolfo Alejandro[4], Camillo Ricordi[4] & Livio Luzi[1,2]
[1]Endocrinology and Metabolism, IRCCS Policlinico San Donato, San Donato Milanese, Italy; [2]Department of Biomedical Sciences for Health, Università degli Studi di Milano, Milano, Italy; [3]Department of Internal Medicine, Transplant Medicine Unit, San Raffaele Scientific Institute, Milano, Italy; [4]Diabetes Research Institute, University of Miami Miller School of Medicine, Miami, Florida, USA.

It has been suggested that the selective m-TOR inhibitor, Rapamycin, has been improved the success pancreatic islet allotransplantation (ITx) in type 1 diabetic patients (T1DM). Forty-one ITx were studied. Thirteen T1DM in poor glycemic control underwent a 45-days Rapamycin before ITx followed by standard Edmonton Protocol (EP, group 1, Milan), and they were compared to 28 T1DM patients undergoing EP (group 2, Miami). Outcome measures were daily insulin requirement (DIR), HbA1c, C-peptide and the SUITO index of beta-cell function before and 1 year after ITx. Four patients from group 1 underwent euglycemic-hyperinsulinemic clamp with 6,6-d2-glucose infusion before and after ITx. We found a significant reduction in DIR after Rapamycin pre-treatment (-8 ± 6 U/day, mean $\pm$ S.D., $P < 0.001$). Nine patients from group 1 fulfilled follow-up. One year after ITx, DIR significantly decreased (-37 ± 15 U/day, $P < 0.001$) and six patients became insulin independent. We observed greater DIR reduction in group 1 as compared to group 2 at 1-year follow-up (-37 ± 15 vs -19 ± 13 U/day, $P = 0.005$), which remained significant after adjusting for gender, age, glucose and baseline HbA1c (beta coefficient of multivariate regression analysis $\pm$ S.E. 18.2 ± 5.9, $P = 0.006$). In patients from group 1, HbA1c significantly decreased 1 year after ITx ($-2.1 \pm 1.4\%$, $P = 0.002$), while C-peptide ($+1.5 \pm 0.9$, $P = 0.002$), and SUITO index increased ($+57.4 \pm 39.7$, $P = 0.016$). We did not observe differences in change between group 1 and 2 as far as HbA1c, C-peptide and SUITO index are concerned before and after ITx. Hepatic glucose production during the insulin clamp decreased after Rapamycin pre-treatment (-1.1 ± 1.1 mg/kg per min, $P = 0.04$) and after ITx (-1.6 ± 0.6 mg/kg per min, $P = 0.015$), while no changes in peripheral glucose disposal were observed during Rapamycin treatment. In conclusion, Rapamycin contributes to improve metabolic control also enhancing hepatic insulin sensitivity after ITx. Rapamycin pre-treatment may improve ITx success rate by reduction of pre-transplant DIR and increase of hepatic insulin sensitivity.

Alterations in DNA methylation from peripheral blood cells in humans threated with metformin

Janis Klovins[1], Ilze Elbere[1], Raitis Peculis[1], Ineta Kalnina[1], Linda Zaharenko[1], Ilze Konrade[3] & Valdis Pirags[1,2]
[1]Latvian Biomedical Research and Study Centre, Riga, Latvia; [2]Department of Endocrinology, Pauls Stradins Clinical University Hospital, Riga, Latvia, [3]Riga Stradins University, Riga, Latvia.

Metformin is a biguanide class agent widely used as a first-line treatment for type 2 diabetes, however the detailed mode of action and exact pharmacodynamics has not been clarified. Moreover there is no studies in humans displaying the effect of metformin on DNA methylation. We therefore performed a clinical study involving twelve healthy nondiabetic individuals who were subjected to the 1 week of metformin ($2\times$ 850 mg/day) treatment. Peripheral blood for DNA isolation was drawn at three time points during metformin treatment: i) right before metformin treatment, ii) 10 hours after the first metformin dose and iii) after a week-long metformin administration. DNA methylation was estimated using genome-wide Illumina Infinium HumanMethylation450 BeadChip (Illumina), which allows interrogation of 485 512 CpG dinucleotides. Analysis global methylation data displayed predominance of demethylated CpGs over the methylated as the result of metformin treatment. In order to identify differentially methylated gene promoter regions we filtered all CpGs located in 2000 pb proximity of the transcription start site and having median methylation change across all samples larger than 3% with Bonferroni corrected P values. This stringent approach resulted total in 35 genes with differentially methylated CpG regions near the promoters. Five genes, considered most likely biologically relevant to have impact in diabetes were those involved in processing of energy molecules, differentiation and formation of adipocytes and exhibiting GTF-ase activities. Eighteen regions included genes with known specific functions that are not directly linkable to influencing diabetic phenotype. Finally 12 genes where either pseudogenes or had unknown function. In conclusion this is the first study that shows influence of metformin in altering DNA methylation in humans and identified markers may prove to be valuable biomarkers for the understanding of the molecular basis of metformin action and may lead to the identification of new drug targets.

Copeptin and its association to cardiovascular dysfunction in type 2 diabetes

Simona Ioana Chisalita[1], Lee Ti Chong[2], Fredrik Nyström[1], Carl Johan Östgren[3] & Toste Länne[4]
[1]Department of Endocrinology and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden; [2]Department of Emergency and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden; [3]Department of Medical and Health Sciences (IMH)/Division of Community, Linköping, Sweden; [4]Department of Thoracic and Vascular Surgery, and Department of Medicine and Health Sciences, Linköping University, Linköping, Sweden.

Background
We aim to test whether plasma copeptin (copeptin), the C-terminal fragment of vasopressin, has predictive value of cardiovascular events in patients with type 2 diabetes without previous cardiovascular disease who were treated in primary care.
Methods
We measured copeptin in 697 patients who participated in the epidemiological study CARDIPP (Cardiovascular Risk Factors in Patients with Diabetes – a Prospective Study in Primary Care; ClinicalTrials.gov identifier NCT01049737) and who did not have previously known myocardial infarction or stroke. The outcome variable was a composite endpoint consisting of cardiovascular mortality, hospitalization for myocardial infarction and hospitalization for stroke.
Results
During a median follow-up time of almost 7 years, the unadjusted HR per each increment of Copeptin by 1 pmol/l was 3.5 (95% CI 1.7–7.1, $P < 0.001$) for the primary endpoint. Following adjustments for age, sex, HbA1c, arterial stiffness (PWW) as well as atherosclerosis plaque the adjusted hazard ratio was 2.4 (95% CI 1.1–5.2, $P = 0.03$).
Conclusions
In primary preventive patients with type 2 diabetes treated in primary care, copeptin predicted a composite outcome of incident cardiovascular events independently of age, sex, HbA1c, arterial stiffness as well as atherosclerosis plaque.

Activation of the Renin-Angiotensin II-Aldosterone-System leads to increases in extracellular protein disulfide isomerase: role in insulin resistance

Ricardo Perez-Fuentes[4], Patricia Pulido[1,4], Joshua Cazares[1,2], Yaritza Inostroza-Nieves[1], Enrique Torres-Rasgado[1,4], Akira Nishiyama[3], Alicia Rivera[1], Rudy Ortiz[2] & Jose Romero[1]
[1]Division of Endocrinology, Diabetes and Hypertension, Department of Medicine, Brigham and Women's Hospital, and Harvard Medical School, Boston, Massachusetts, USA; [2]Department of Molecular and Cellular Biology, University of California, Merced, California, USA; [3]Department of Pharmacology, Kagawa Medical University, Kagawa 761-0793, Japan; [4]Universidad Autonoma de Puebla/Instituto Mexicano Seguro Social, Puebla, Mexico.

Insulin resistance and type II diabetes (T2D) are associated with activation of the Renin-Angiotensin-Aldosterone-System (RAAS) in part via regulation of its principal effector molecule, Angiotensin II (AngII). Endothelial cell activation leads to, among other factors, increased

extracellular protein disulfide isomerase (PDI), a multifunctional protein that is critical to thrombus formation and regulation of reactive oxygen species. However, the effects of RAAS on PDI are unknown. We studied the *in vitro* effects of AngII on EA.hy926 human endothelial cells and measured PDI activity. Our results show that AngII (10 nM), dose- and time-dependently, increased PDI activity ($P<0.05$, $n=6$); an event that was blocked by pre-incubation with 0.5 μM losartan, an AngII Type I receptor antagonist (ARB). Western blot analyses showed increased PDI following AngII that was likewise reduced by losartan. In normal in Sprague–Dawley rats, we studied the *in vivo* effects of exogenous AngII infusion and observed significant increases in plasma PDI levels ($P<0.05$, $n>5$) that were blunted by ARB treatment. We then studied the obese Otsuka Long Evans Tokushima Fatty (OLETF) ($n=6$/group) rats, a model of naturally increased AngII and RAAS-mediated insulin resistance and hypertension. Our results show that OLETF rats had increased insulin resistance and greater circulating PDI activity than lean control rats ($P<0.05$) and was reduced by ARB treatment to baseline levels ($P<0.05$). To assess the clinical relevance of our findings, we measured circulating PDI in subjects with and without T2D. PDI activity correlated with measures of insulin resistance in our cohort (HOMA2-IR, Spearman $P=0.496$, $P<0.001$, $n=134$) and was significantly greater in T2D patients than healthy controls ($P<0.01$, $n=56$ vs 78, respectively). Our data in human and animal models suggest that RAAS activation represents a novel mechanism for PDI secretion. Thus we posit that PDI may contribute to the deleterious effects of RAAS-mediated vascular disease.

Prepubertally gonadectomized (GDX) wild-type DBA/2J mice develop adrenocortical neoplasms presenting with small spindle-shaped non steroidogenic A-cells and large lipid-laden, steroidogenic and mitotically active B-cells. Neoplastic B-cells overexpress estrogen receptor α (ERα, Ers1) and β (ERβ, Ers2), aromatase (CYP19a1) and produce sex-steroids, resembling gonadal rest tissue. To test the role of estrogen-ER system in adrenocortical tumor progression, GDX 12 months-old DBA/2J females were treated with selective estrogen receptor modulator tamoxifen (TMX, 0.4 mg/kg/24 h) and aromatase inhibitor letrozole (LET, 2 mg/kg/24 h) for 21 days. Both TMX and LET treatments significantly reduced the adrenal weights, with stronger effect of the latter. Both treatments decreased the expression of proliferation marker MKI67 and induced apoptosis predominantly in the tumorous B-cells. TMX and LET treatments decreased plasma estradiol (E2) levels significantly decreasing sensitivity of the negative feedback on luteinizing hormone (LH) secretion. Gene expression profiling showed that TMX and LET downregulated gonadal-like markers Ers2, LH receptor (Lhcgr) and transcription factor Gata4, but upregulated a negative regulator of steroidogenesis Nr0b1. Additionally, LET significantly decreased expression of Esr1, Cyp19a1 and Cyp17a1. Control GDX mouse uteri displayed endometrial hyperplasia without cellular atypia. TMX- and LET-treated mice uteri were significantly smaller and showed cystically dilated endometrial glands and signs of mild chronic inflammation. In summary, we showed that adrenal estrogens promote progression of GDX-induced adrenocortical tumors. Our findings also support the rationale for TMX- and LET-based therapeutic strategies in treating ERs-positive/estrogen responsive adrenocortical carcinomas in human.

Background

Adrenocortical cancer (ACC) is an aggressive tumour with heterogeneous prognosis. Recently integrated genomics reported distinct genomic alterations: transcriptome "C1A" (high expression of proliferation/cell cycle-related genes) vs "C1B", "CIMP" (CpG islands hypermethylation) vs "non-CIMP", chromosome alterations "Noisy" (numerous and anarchic alterations) vs "Chromosomal" (extended patterns of loss of heterozygosity) and "Quiet" (limited alterations), and recurrent somatic mutations in 20 genes. These alterations converge into a single three-groups classification, correlating with outcome. The aim was to develop and validate targeted molecular markers reflecting these genomic groups.

Patients and methods

Two hundred and forty five ACC were included from 21 ENSAT (European network for the Study of Adrenal Tumors) centers. Tumor RNA was assessed by RT-qPCR for BUB1B-PINK1 expression ($n=135$). Tumor DNA was studied by SNP array for chromosomal alterations ($n=238$), targeted NGS for mutations of 20 driver genes ($n=251$), and MS-MLPA for CpG islands methylation of four genes -PAX5, GSTP1, PYCARD, PAX6- ($n=221$).

Results

Gene expression levels identified "C1A", "C1B" and "undetermined" ACC in 50, 38 and 12% of cases respectively. Methylation assay identified "CIMP" and "non CIMP" ACC in 44 and 56% of cases respectively. Chromosomal alteration profiles identified "chromosomal", "noisy" and "quiet" ACC in 55, 32 and 13% of cases respectively. Recurrent mutations or deletions were found in ZNFR3, CDKN2A, TP53 and CTNNB1 in 21, 17, 15 and 11% of cases respectively, in agreement with previous exome studies. All molecular statuses were available for 107 tumors. 87/107 (81%) concordantly recapitulated the 3 main ACC subgroups previously identified by genomic classifications: 37 were "C1A/CIMP", 18 were "C1A/non-CIMP", and 32 were "C1B/non-CIMP". Death events occurred in 34/37, 7/18 and 1/32 patients respectively (Fisher exact $P<10–15$).

Conclusion

Targeted molecular measures can recapitulate the genomic classification of ACC, giving original and useful prognostication information for patient management.

High Total 68Ga-DOTATATE-Avid Tumor Volume (TV) is associated with low progression-free survival and high disease-specific mortality rate in patients with neuroendocrine tumors

Amit Tirosh[1,2], Georgios Z. Papadakis[1,3], Corina Millo[1], Samira M. Sadowski[4], Peter Herscovitch[1], Karel Pacak[1], Stephen J. Marx[1], Lily Yang[5], Pavel Nockel[5], Jasmine Shell[5], Patience Green[5], Xavier M. Keutgen[6], Dhaval Patel[5], Naris Nilubol[5] & Electron Kebebew[5]

[1]National Institutes of Health, Bethesda, MD, USA; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Institute of Computer Science (ICS), Foundation for Research and Technology Hellas (FORTH), Crete, Greece; [4]Endocrine and Thoracic Surgery, University Hospitals of Geneva, Geneva, Switzerland; [5]Endocrine Oncology Branch, National Cancer Institute, National Institutes of Health, Bethesda, MD, USA; [6]Department of Surgery, Rush University Medical Center, Chicago, IL, USA.

Background
Patients with neuroendocrine tumors (NETs) have divergent survival, even when having the same site of primary tumor, and tumor stage and grade. 68Gallium (68Ga)-DOTATATE positron emission tomography (PET)/computed tomography (CT) is a sensitive imaging modality for detecting NETs. The purpose of this study was to determine whether 68Ga-DOTATATE PET/CT imaging has any prognostic utility in patients with NETs.
Methods
One hundred and eighty-four patients with NETs were enrolled in a prospective study of 68Ga-DOTATATE PET/CT imaging and comprehensive biochemical analysis. Total 68Ga-DOTATATE-Avid Tumor Volume (68Ga-DOTATATE TV) was measured in all participants. The primary outcome measures were progression-free survival (PFS) and disease-specific mortality (DSM). PFS and DSM rates were compared according to 68Ga-DOTATATE TV quartiles of the current cohort. Then, specific 68Ga-DOTATATE TV cut-offs were set using a receiver operating characteristic (ROC) curve analysis, and the risks for DSM and PFS were validated with Kaplan-Meyer and Cox regression analyses.
Results
Patients were followed for a median of 18 months (range 4–35 months). 68Ga-DOTATATE TV quartiles had inverse correlation with PFS ($P=0.001$) and survival rates ($P=0.002$). Using cut-offs derived from ROC curve analysis, 68Ga-DOTATATE TV $\geq$7.0 was associated with a lower PFS (HR = 2.0, $P=0.03$), and 68Ga-DOTATATE TV $\geq$35.8 ml was associated with increased (HR = 10.7) disease-specific mortality in multivariate analysis ($P=0.03$), as well as in subgroup analysis of patients with pancreatic NETs.
Conclusions
We show for the first time the prognostic utility of 68Ga-DOTATATE TV in a large cohort of patients with NETs, enabling clinicians to determine the need for intervention using this non-invasive tool.

A novel insight into the anticancer mechanism of metformin in Pancreatic Neuroendocrine Tumor cells

Eleonora Vitali[1], Sara Piccinini[1], Ilena Boemi[1], Alberto Tresoldi[1], Alessandro Zerbi[2], Carlo Carnaghi[3], Anna Spada[4] & Andrea Lania[1,5]
[1]Laboratory of Cellular and Molecular Endocrinology, IRCCS Humanitas Research Hospital, Rozzano, Italy; [2]Pancreas Surgery Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [3]Oncology Unit, IRCCS Humanitas Research Hospital, Rozzano, Italy; [4]Endocrinology and Diabetology Unit, IRCCS Ospedale Maggiore Policlinico, Milano, Italy; [5]Department of Biomedical Sciences, Humanitas University, Rozzano, Italy.

Metformin (1.1-dimethylbiguanide hydrochloride), a widely used antidiabetic drug, has been reported to display potent anticancer properties in various types of cancers, including neuroendocrine tumors. Recently, a potential synergistic activity between metformin and octreotide (SSA) in Pancreatic Neuroendocrine Tumors (P-NETs) has been proposed. AIP (aryl hydrocarbon receptor-interacting protein) acts as tumor suppressor gene in neuroendocrine tumors at pituitary level and it is up-regulated by SSA. We investigated the effects of metformin on P-NETs cell proliferation, apoptosis and colony formation, the potential synergistic effect between metformin and octreotide and the possible role of AIP pathway in mediating these effects. We found that in QGP-1 cells metformin significantly inhibited cell proliferation ($-37\pm2\%$ $P<0.001$ vs basal at 10 mM). We showed no additive effect between Metformin and Octreotide on P-NETs cell proliferation. Moreover, metformin incubation reduced colony formation, cells amount after 7 days ($-66\pm6\%$ $P<0.001$ vs basal) and it promoted apoptosis ($+150\pm8\%$ $P<0.05$ vs basal). As expected, octreotide induced AIP up-regulation ($+60\pm11\%$ $P<0.05$ vs basal), and surprisingly, AIP expression levels were also increased by metformin ($+90\pm13\%$ $P<0.05$ vs basal). In addition, AIP silencing abolished the antiproliferative and proapoptotic effects of metformin, confirming its involvement in mediating metformin effects. Interestingly, metformin decreased HSP70 expression, increased Zac1 and AhR expression levels. These effects were totally abolished in QGP-1 cells lacking AIP. In conclusion, metformin acts as anticancer agent in P-NET cells, its activity is mediated by AIP and its interacting proteins, HSP70, AHR and Zac1. These findings provide a novel insight into the antitumorigenic mechanism of metformin.

Regulation of steroid receptor signalling by tumor suppressor INPP4B

Manqi Zhang[1], Egla Suarez[1], Lubov Nathanson[2], Michael Ittmann[3], Nancy Weigel[2] & Irina Agoulnik[1,3]
[1]Florida International University, Miami, FL, USA; [2]Nova Southeastern University, Ft. Lauderdale, FL, USA; [3]Baylor College of Medicine, Houston, TX, USA.

Androgen receptor (AR) signaling is the main driver for prostate cancer progression and androgen ablation is the treatment of choice for tumors that spread beyond the prostate. Efficient at first, androgen ablation fails due in part to altered cell signaling and expression of AR spice variants. Cell signaling in prostate cancer is regulated by dual specificity phosphatases and tumor suppressors INPP4B and PTEN that are lost with prostate cancer progression. Loss of PTEN destabilizes AR and alters AR transcriptional output. We investigated how loss of INPP4B affects AR signaling. We have previously shown that AR induces expression of INPP4B in prostate cancer. Intriguingly, AR splice variant AR-V7, which also contributes to ADT resistance, was unable to induce INPP4B expression. We performed microarray analysis of changes in gene expression caused by INPP4B knockdown. Gene expression clustering and GSEA analysis revealed that the INPP4B loss significantly altered AR transcriptional activity. Using immunofluorescent labeling with 3D rendering we determined that INPP4B localizes to cellular and endoplasmic membranes. We and others have shown that INPP4B suppresses PI3K/Akt and PKC pathways. We show that INPP4B specifically inhibits PKCζ and βII in multiple prostate cancer cells. The analysis of PI3K, Akt and PKC specific inhibitors, LY294002, AZD5363, and BIM-I, showed that Akt and PKC signaling did contribute to the changes in AR signaling. We investigated INPP4B functions in prostates of Inpp4b$^{-/-}$ mice. AR expression in mouse prostate was not affected by the loss of INPP4B. Remarkably, expression of several direct AR target genes like Msmb, Apof, and Nkx3.1 was significantly reduced in Inpp4b$^{-/-}$ prostates. We compared Akt and PKC signaling in the anterior (AP), dorsal/lateral (DLP) and ventral (VP) prostate lobes of the wild-type and Inpp4b$^{-/-}$ mice. Loss of INPP4B increased Akt signaling in DLP and VP and PKC ζ and β II pathways in AP and DLP. We determined that levels of PTEN protein were unchanged in Inpp4b$^{-/-}$ mouse prostates suggesting that Akt signaling was elevated exclusively due to Inpp4b loss. Taken together, full length AR, but not AR-V7 induce INPP4B expression. INPP4B reciprocally modulates AR transcriptional activity without altering AR protein level in both normal prostate and prostate cancer cells and suppresses Akt and PKCζ and β II signaling and the suppression is required for optimal AR transcriptional activity.

Elucidating the molecular mechanisms underlying AIP dependent tumorigenesis

Eva-Maria Bogner[1], Adrian F. Daly[2], Albert Beckers[2], Michael J. Atkinson[3] & Natalia S. Pellegata[1]
[1]Institute for Diabetes and Cancer, Helmholtz Center Munich, Munich, Germany; [2]Department of Endocrinology, Centre Hospitalier Universitaire de Liège, University of Liège, Liège, Belgium; [3]Institute for Radiation Biology, Helmholtz Center Munich, Munich, Germany.

Pituitary adenomas (PAs) are benign neoplasms that comprise 10–20% of all intracranial tumors. Mutations in the aryl hydrocarbon receptor interacting protein (AIP) have been identified to cause a small subset of hereditary PAs. To study the mechanisms of tumor formation in patients with AIP-mutated PAs we conducted a miRNA array analysis comparing AIP-mutated PAs with AIP-wild type PAs. We found a novel and specific set of miRNAs differentially expressed between the two groups of PAs. We selected several candidate miRNAs and validated them in the patient tissues. To characterize the candidate miRNAs *in vitro* and clarify their role in AIP dependent tumorigenesis we performed

functional studies using mouse embryonic fibroblasts (MEFs) derived from Aip knockout (AIP-KO) mice and a rat somatotroph tumor cell line (GH3). In the AIP-KO MEFs we saw that transfection of mutant AIP altered the expression of two of the candidate miRNAs according to the changes observed in the miRNA array. Additionally, cell viability and cell migration were increased after transfection of mutant AIP. Since deregulation of cAMP levels is a common feature of PAs we also checked cAMP levels upon transfection of mutant AIP. We could observe that mutant AIP increased cAMP levels in AIP-KO MEFs. Overexpression of the candidate miRNAs in GH3 cells increased cell migration and cAMP levels while apoptosis was decreased. To further clarify the role of the selected miRNAs in tumor development we identified their predicted targets and focused on those involved in cAMP signalling. We plan to validate the role of these predicted targets in PAs in the future. In conclusion, we identified novel miRNAs in AIP-mutated PAs and were able to show that these miRNAs promote a tumor-like behaviour in several functional assays in AIP-KO MEFs and GH3 somatotroph cells.

Knocking down/out the prokineticin pathway during zebrafish development results in the GnRH neurons axons misguiding

Ivan Bassi[1], Federica Marelli[1], Valeria Vezzoli[2], Luca Persani[1,2], Yoav Gothilf[3] & Marco Bonomi[1,2]
[1]Laboratory of Experimental Endocrinology, Istituto Auxologico Italiano IRCCS, Milan, Italy; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Department of Neurobiology, The George S. Wise Faculty of Life Sciences and Sagol School of Neuroscience, Tel-Aviv, Israel.

Studies conducted using knockout mouse model revealed that defects of PROKR2 affect the correct ontogeny of GnRH neurons and, by consequence, neuroendocrine control of reproduction. Nevertheless its exact role during these processes and in the pathogenesis of congenital hypogonadotropic hypogonadism (CHH) remains elusive due to the phenotypic differences observed between mouse and human. Zebrafish (ZF) has emerged in the last ten years as a reliable model organism for studying the GnRH neuronal development and the neuroendocrinology of reproduction. Previous results obtained in our lab identified two well-conserved loci in the ZF genome, on chr1 and chr13, respectively named prokr1a and prokr1b. Whole mount *in situ* hybridization (WISH) and qRT-PCR experiments conducted at different developmental stages of ZF revealed distinct patterns of expression for prok-receptors suggesting prokr1b as the potential candidate involved in the GnRH-secreting neurons migration process from olfactory placode to their final hypothalamic destination. To verify these indications and better elucidate the function of both prokineticins receptors we recently conducted knockdown experiments using morpholino oligonucleotides sequences. Our results display an alteration of the GnRH fibers network architecture at 48 hours post fertilization (hpf) after downregulation of prokr1b that appeared misguided and reduced in numbers especially at level of pallium commissure and optic chiasm. Moreover, we also generated in ZF the prokr1b knockout model and our preliminary data are confirming the knockdown model observations. On the contrary, the downregulation of prokr1a does not affect GnRH fibers architecture. Taken together these results confirm the role of prokr1b during GnRH neurons migration establishing it as the ZF orthologous of human PROKR2. A deeper characterization of ZF prokr1b KO model could provide new information regarding the early establishment of the forebrain GnRH system, the factors controlling this complex developmental event, and its functional significance.

Background
Non-functioning pituitary adenomas (NFPAs) necessitate prolonged clinical, biochemical and radiological observation, constituting a significant burden in terms of medical resources and societal costs. Reliable biomarkers associated with aggressiveness and recurrence of NFPAs are lacking. As the growth of tumor remnants is highly variable, molecular markers that can predict growth potential and tumor behavior are necessary.
Aim
To identify target genes in fast- and slow- growing NFPAs estimated by postoperative initial tumor volume doubling time (TVDT), and to find reliable biomarkers predicting the growth potential of the remnant tumor, focusing on the specific role of epithelial-mesenchymal transition (EMT) process.
Material and methods
RNA sequencing was performed in gonadotroph NFPAs with short TVDT (median <30.05 months, fast group, $n=4$) and long TVDT (median >30.05 months, slow group, $n=4$). Data was analyzed by tophat2 and cufflinks/cummeRbund pipeline. Furthermore, genes ($n=40$) were selected based on significance, fold of change and pathway analysis for validation with RT-qPCR in a larger cohort of gonadotroph NFPAs ($n=20$, 13 male).
Results
RNA sequencing identified 350 genes significantly differentially expressed, between the two groups (285 genes up- and 65 down- regulated in the fast group, P adjusted <0.05). Of the 40 genes chosen for further validation by RT-qPCR, 11 showed significant correlations with TVDT ($-0.669 \leq R \geq -0.466$, $P<0.05$). These were six genes involved in EMT (PCDH18, SPAG9, SKIL, MTDH, HOOK1 and CNOT6L), and also UNC5D, EMCN, MYO1B, GPM6A and PRKACB.
Conclusions
Fast- and slow- growing NFPAs show different gene expression profiles. Genes known as related to EMT have higher expression in fast-growing tumors, suggesting a pathogenic role in tumor growth. The identified genes and their products could represent useful markers for predicting tumor aggressiveness and recurrence, and may be potential targets for drug therapy.

Cerebrovascular stroke incidence in GH-treated adults: experience from KIMS (Pfizer International Metabolic Database)

Cecilia Camacho-Hubner[1], Jose Cara[1] & Anders Mattsson[2]
[1]Endocrine Care, Pfizer Inc, New York, NY, USA; [2]Endocrine Care, Pfizer Health AB, Sollentuna, Sweden.

Background and aim
Patients with GH deficiency (GHD) have increased risk of cerebrovascular events. The aim of this study was to evaluate the rate and factors associated with the occurrence of stroke, a major cause of death and disability, in adults with GHD.
Patients and methods
Data from 15,188 GHD patients treated with GH replacement therapy (GHRT) enrolled in KIMS were analyzed. Stroke incidence rates were compared to rates from the Oxford Vascular Study (Lancet_2004; 363:1925–33) by standardized incidence ratios (SIRs). Age at first radiotherapy (RT) corrected for attained age and sex, was analyzed with Poisson regression.
Results
Causes of GHD comprised pituitary adenoma 42.9%, craniopharyngioma 10.8% and idiopathic GHD 15.6%. Mean age at KIMS entry was 43.7 (range 17–75) years. Mean GH dose was 0.42 mg/day and number of patient treatment-years was 81,086. Mean age at first radiotherapy (RT) was 34.5 (range 3–72) yrs. First-ever stroke was reported in 155/7667 (M) and 123/7521 (F) patients. The crude incidence was 377 (M) and 308 (F) per 100,000 patient- years and overall SIR was 2.51 (95% CI: 2.22–2.82). SIR ranged between causes of GHD from 1.02 (0.41–2.1) in patients with Idiopathic GHD and unexposed to RT to 19.3 (11.6–30.1) in patients with GHD secondary to a malignant cranial tumor. RT was reported in 3866 patients and 146 reported a stroke (SIR: 3.96; 3.35–4.66). Rates were increased in all ages at first exposure ($P<0.01$), especially in younger patients

(RR = 2.2 (1.05–4.63) for <18 vs ≥18 years of age). Among 11,322 patients who did not receive RT, 132 cases were reported, SIR 1.78 (1.49–2.11).
Conclusion
GHD patients have a significantly increased rate of strokes with considerable variability between causes of GHD. Rates were positively associated with RT in all studied ages, with younger patients at first RT showing a higher risk.

Ephrin-B2 is required for pituitary development

Fernando Jimenez, Angelica Gualtieri, Valeria Scagliotti & Carles Gaston-Massuet
WHRI, Queen Mary University of London, London, UK.

The pituitary progenitors are responsible for generating a fully functional endocrine organ during embryonic development. They also preserve potency, to maintain the homoeostasis in the adult pituitary, being able to respond to endocrine challenges, such as pregnancy or obesity. But the main players of this complex process remain elusive. Eph-Ephrins have been implicated in an increasing number of physiological functions such as axon-guidance, eye field segregation from neural plate, tissue boundary formation, cell migration, angiogenesis and more recently stem cell maintenance and differentiation in the colon and mammary gland. However, the EprhinB:EphB signalling pathway in hypothalamic-pituitary function is not known. Using a transgenic line that expresses GFP under the EphrinB2 (Efnb2) genetic locus we observed that cells expressing Efnb2 are localised in the pituitary progenitor of the anterior pituitary. We found Efnb2 co-expressed with known PPSCs markers Sox2/Sox9 during embryogenesis and this expression continues in adulthood, suggesting a role in adult pituitary homoeostasis. Conditional genetic removal of Efnb2 in the undifferentiated precursor using a Cre-pituitary line, results in significant pituitary abnormalities, comprising multiple bifurcations hyperplasia of the anterior pituitary gland. These data suggest for the first time, that Efnb2 is a critical regulator of pituitary development and could have an effect on hypothalamic-pituitary body endocrine regulations. Interestingly a proportion of Efnb2 Knock-out animals exhibit features of congenital hypopituitarism, such as dwarfism and eye abnormalities suggesting that, in this physiological context, Efnb2 could be a candidate gene for rare unknown conditions such Septo-Optic Dysplasia.

Thyroid function and metabolic syndrome: results from the population-based LifeLines Cohort study

Bruce Wolffenbuttel, Hanneke Wouters, Sandra Slagter, Robert van Waateringe, Jana van Vliet-Ostaptchouk, Thera Links & Melanie van der Klauw
University of Medical Center Groningen, Groningen, The Netherlands.

Background
The metabolic syndrome (MetS) is a combination of unfavourable health factors including abdominal obesity, dyslipidaemia, hypertension and impaired fasting glucose. Several small-scale studies have reported a relationship between thyroid function and some MetS components or suggested that serum FT3 levels within the normal range were independently associated with insulin resistance. We assessed how thyroid function relates to the prevalence of MetS in a large population-based study.
Methods
Data of 26,719 western European participants aged 18-80 years from the Dutch LifeLines Cohort study, all with normal TSH, FT4 and FT3 levels (electrochemiluminescent immunoassay, Roche Modular E170 Analyzer), were available. MetS was defined with the revised NCEP ATP III criteria. We calculated prevalence of all MetS components according to FT4 and FT3 quartiles.
Results
At similar TSH levels and age (mean 45 yrs), men had significantly higher levels of FT4, FT3, blood pressure (BP), heart rate, total and LDL-cholesterol, triglycerides (TG), and creatinine, but lower HDL-cholesterol compared to women (all $P<0.001$). In total, 9.1% of women and 10.2% of men were treated with BP-lowering agents. In men, lower FT4 levels were associated with higher prevalence of all MetS components. The lowest FT4 quartile was associated with the highest prevalence of elevated BP (60%), elevated glucose (22.7%), waist circumference (33.4%) and TG (30.2%), low HDL-cholesterol (26.5%), and MetS (27.7%). In women, the lowest FT4 quartile was only associated with elevated TG (11.2%), waist circumference (47.4%), and MetS (13.8%). In contrast, higher FT3 levels were associated only with low HDL-cholesterol in both sexes, and with a higher percentage of participants with ≥3 MetS components (21.6% in men, 12.4% in women).
Conclusions
Levels of FT4, but not FT3, were inversely associated with all components of the metabolic syndrome in men, and with elevated TG, waist, and overall MetS in women.

Effect of restoration of euthyroidism in patients with hypothyroidism on cold induced thermogenesis

Claudia Maushart, Rahel Loeliger, Cemile Bathelt, Nina Hutter, Mirjam Christ-Crain & Matthias Betz
Department of Endocrinology, Diabetes and Metabolism, University Hospital Basel, Basel, Switzerland.

Background
Thyroid hormones have been shown to be necessary for proper function of brown adipose tissue (BAT) and cold induced thermogenesis (CIT) in rodent models. In humans hyperthyroidism has been demonstrated to activate BAT and increase thermogenesis. However, the data on CIT in humans in the hypothyroid vs. the euthyroid state are limited and conflicting.
Methods
This was a prospective observational study. We recruited 40 patients presenting to a University hospital out-patient endocrine clinic with subclinical or overt hypothyroidism, and in whom thyroid hormone replacement was planned. Currently, 24 patients completed the study. Thermogenesis was measured by indirect calorimetry during warm conditions and after a mild cold stimulus of 90 min, both during the hypothyroid state and after at least 3 months of sufficient thyroid hormone replacement. CIT was determined as the difference between resting energy expenditure (REE) during cold (REEcold) and warm (REEwarm) conditions. Additionally, skin temperature was measured using wireless probes in one-minute intervals in the supraclavicular region adjacent to the major human BAT depot. The primary endpoint was CIT in the hypothyroid vs euthyroid state. Data were analysed by non-parametric tests and are given as mean ± S.D.
Results
CIT increased from 73(±103) kcal/d during the hypothyroid state (CIThypo) to 160 (±143) kcal/d in the euthyroid state (CITeu), $P=0.0007$. REEwarm was 1324 (±120) kcal/d during hypothyroidism and rose slightly to 1395(±140) kcal/d, $P=0.0137$. REEcold rose profoundly from 1396(±157) kcal/d to 1555(±178) kcal/d, $P=0.0001$. While the inter-individual variability of CIT was large, the correlation between CIThypo and CITeu was moderate, $r=0.657$, $P=0.001$. The change in supraclavicular skin temperature during cold exposure correlated with CIT in the euthyroid ($r=0.389$, $P=0.067$), but not in the hypothyroid state ($r=0.041$, $P=0.853$).
Conclusion
Cold induced thermogenesis is blunted in hypothyroid patients and increases markedly after restoration of euthyroidism. The difference in CIT is larger than the difference in resting energy expenditure during warm conditions.

How much of the genetic predisposition to Hashimoto's thyroiditis can be explained by genes commonly associated with the disease?

Anna Skalniak[1,2], Agata Jabrocka-Hybel[1,2], Jakub Piętkowski[2], Renata Turek-Jabrocka[1,2], Dorota Pach[1,2], Agnieszka Ludwig-Gałęzowska[3], Julita Machlowska[3], Przemysław Kapusta[3], Paweł Wołkow[3] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Endocrinology Department, University Hospital in Krakow, Krakow, Poland; [3]Center for Medical Genomics OMICRON, Jagiellonian University Medical College, Krakow, Poland.

Background
Hashimoto's thyroiditis (HT) is a common autoimmune disorder of the thyroid (AITD) which affects about 1–2% of the European population. The disease often

clusters in families, which is why many attempts have been undertaken to find the genetic background that would underly the predisposition to HT. In contrast to another AITD - Graves' disease, results of genetic analyses have been ambiguous and have failed to find a major genetic locus that would be essential for HT development.

Aim

To assess the joined impact of disease loci associated in the literature with HT predisposition.

Methods

One hundred and forty seven HT fully-symptomatic patients and 147 healthy controls (matched for age, gender, incomes, education, marital status and place of descent), unrelated to each other, were genotyped for 40 polymorphisms (Illumina GoldenGate, custom panel), which were located in genes most often tested in literature for association with AITD, or typed out by genome-wide association studies. All polymorphisms were confirmed to be in Hardy-Weinberg equilibrium in the control group ($P > 0.05$). Variations in the HLA-DRB1 gene were analyzed by Sanger sequencing. A genetic model for HT predisposition was obtained with use of stepwise logistic regression. Biostatistical analyses were performed with the programs Statistica v12, Plink v1.9, and GCTA v1.02.

Results

The model which best explained the predisposition to HT contained seven polymorphisms in the genes PTPN22, IFIH1, CTLA4, RGS6, TNMD, NOX1, and the promoter region of FAM155A. The model was able to classify correctly 67% of all cases, similarly for both groups. Such a model explained only 5.12% of the between-group variance. This value is in agreement with a model published lately for another autoimmune disorder.

Discussion

Our data confirm that there seem to be no genes that are per se crucial for HT development. Future analyses on HT predisposition should focus on the joined influence of many polymorphisms in different genetic regions.

Thyroid dysfunction during the use of PD-1/PD-L1 blockade predicts its therapeutic response in the patients with advanced non-small cell lung cancer

Hye In Kim[1], Tae Hyuk Kim[1], Hye Won Jang[2], Young Nam Kim[1], Hosu Kim[1], So Young Park[1], Sun Wook Kim[1] & Jae Hoon Chung[1]
[1]Samsung Medical Center, Seoul, Republic of Korea; [2]Sungkyunkwan University School of Medicine, Seoul, Republic of Korea.

Background

PD-1/PD-L1 blockade is one of the promising drugs in the treatment of advanced non-small cell lung cancer (NSCLC). and predicting drug effect is important due to unique pattern of response. Immune-related adverse event (IRAE) might be associated with favorable clinical outcome. Thyroiditis is the most common IRAE which can be easily detected with the measurement of thyroid hormone levels. However, the relationship between thyroid dysfunction during the use of PD-1/PD-L1 blockade and its therapeutic response has not been well demonstrated in advanced NSCLC patients.

Methods

A total 53 patients with stage IV NSCLC treated with PD-1/PD-L1 blockade were enrolled. Patients were categorized into thyroid dysfunction and euthyroid group. Overall survival (OS) and progression free survival (PFS) of two groups were compared. Hazard ratio (HR) adjusting patients, tumor, and drug factors were analyzed using Cox proportional hazard model. Response rate (RR) and durable RR were assessed according to thyroid dysfunction and its severity.

Results

OS (mean 148.5 ± 82.6 vs 82.0 ± 65.1, log-rank $P = 0.003$) and PFS (143.2 ± 88.2 vs 68.0 ± 50.0, log-rank $P = 0.001$) were significantly longer in the thyroid dysfunction group. After adjustment for age, sex, smoking status, tumor stage, and drug type, adjusted HR (95% CI) for overall death and progression disease were 0.08 (0.01–0.65) and 0.29 (0.12–0.69) compared with euthyroid group. RR (36.0 vs 10.7%, $P = 0.028$) and durable RR (28.0 vs 0%, $P = 0.003$) were more frequent in the thyroid dysfunction group. Severity of thyroid dysfunction was also associated with RR (P for trend $= 0.018$) and durable RR (P for trend $= 0.001$).

Conclusions

Thyroid dysfunction during the use of PD-1/PD-L1 blockade and its severity predict its favorable disease outcome in NSCLC patients. Therefore, regular measurement of thyroid hormone levels during the use of PD-1/PD-L1 blockade could be the good biomarker of immune monitoring.

Selenium supplementation in the management of thyroid autoimmunity during pregnancy: results of the 'Serena Study' a randomized, double-blind, placebo-controlled trial

Carla Di Dato[1], Giovanna Mantovani[2], Costanzo Moretti[3], Ermanno Greco[4], Marco Bonomi[5], Antongiulio Faggiano[6], Stefania Di Sante[1], Vincenzo Giannetta[1], Luisa Petrone[7], Angela Fumarola[1], Annamaria Colao[8], Andrea Lenzi[1], Andrea M. Isidori[1] & Elisa Giannetta[1]
[1]Department of Experimental Medicine - Sapienza University of Rome, Rome, Italy; [2]Endocrine Unit, Department of Clinical Sciences and Community Health, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, University of Milan, Milan, Italy; [3]Unit of Endocrinology, Section of Reproductive Endocrinology, Department of Systems' Medicine, University of Rome Tor Vergata, Rome, Italy; [4]Centre for Reproductive Medicine, European Hospital, Rome, Italy; [5]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [6]Thyroid and Parathyroid Surgery Unit, Istituto Nazionale per lo Studio e la Cura dei Tumori-IRCCS, Fondazione G. Pascale", Naples, Italy; [7]Endocrinology Unit, Careggi Hospital and University of Florence, Florence, Italy; [8]Endocrinology Unit, Department of Clinical Medicine and Surgery, University of Naples Federico II, Naples, Italy.

Autoimmune thyroiditis and related complications represent a growing concern during pregnancy. Selenium is frequently present in nutraceuticals recommended for thyroiditis and pregnancy, given its advocated role in immunity, fertility and thyroid function. However, most evidences come from non-controlled studies.

Materials and Methods

We designed a multicenter, randomized, double-blind, placebo-controlled trial (Serena Study: NCT01465867) to evaluate the effects of L-selenomethionine (Se) supplementation on antibodies title in euthyroid women with positive anti-thyroid antibodies that are pregnant or undergoing *in-vitro* fertilization. Secondary outcomes included: implantation rates, pregnancy rate, delivery, obstetrical, fetal and neonatal complications. Ten endocrinology and gynecology Italian referral centers participated. The study was promoted and supported by EnGioI Club (Italian Young Endocrinology).

Results

56 women were randomly assigned to placebo (PLB) or Se 83 mcg/die. Thyroid hormones, TgAb, TPOAb, selenium concentration were measured during pregnancy and after labor (months 3° to 6°). All analysis were centralized. Of the enrolled women, 45 (80.3%) were pregnant and 11 (19.6%) embryo transferred. A significant reduction of TgAb was observed in Se-treated women after labor: treatment effect $d = 108.67$ (95%CI: -1.3, 218.6; $P = 0.03$). The change in antibodies was paralleled by a significant increase in selenium serum concentration measured already at 36 ± 2 weeks: (PLB: -11 ± 23.76, Se: $+30.5 \pm 17.63$; treatment effect $d = 35.57$ 95% CI:14.9, 62.3; $P = 0.004$) and confirmed after labor: treatment effect $d = 17.56$ (95% CI: 3.9, 31.2; $P = 0.014$). Post-labor rebound in antibodies' title of PLB treated, as compared to Se-treated women was paralleled by a trend toward TSH rise (PLB: $+3.96 \pm 12.56$ vs Se: $+1.69 \pm 6.00$). Safety analysis showed no discontinuation in the Se-treated subjects. Two miscarriage occurred in PLB vs 0 in Se-treated. No differences were found in fetal and maternal complications. The pregnancy rate after embryo transfer was 3/5 (60%) in Se-treated vs 1/6 (16.6%) in PLB.

Conclusion

SERENA Study demonstrated a beneficial effect on the title of TgAb with a safety profile. Larger studies are needed to confirm the trends observed on post-partum thyroiditis recurrence and hypothyroidism, miscarriage and pregnancy rate in *in vitro*-fertilization.

Bone & Calcium Homeostasis

OC10.1

Treatment of 711 patients with hypoparathyroidism: a retrospective study in 3 German endocrine centres

Martin Grussendorf[1], Bettina Stamm[2], Niklas Stamm[3,4] & Heide Siggelkow[4,5]
[1]Endocrine Centre, Stuttgart, Germany; [2]MVZ Endokrinologikum, Saarbrücken, Germany; [3]Endocrinology and Metabolism, University Medicine, Mainz, Germany; [4]Clinic of Gastroenterology and Gastrointestinal Oncology, University Medical Center, Göttingen, Germany; [5]MVZ Endokrinologikum, Göttingen, Germany.

Care of patients (pts.) with hypoparathyroidism (HypoPT) is a challenge, because pts. are usually not treated with the absent hormone, but with several forms of vitamine D. We retrospectively evaluated the data of pts. with HypoPT in three endocrine centres in Germany.

Methods

Records of 711 pts. with HypoPT (Centre 1 (C1): $n=381$, C2: $n=253$, C3: $n=77$) were reviewed (female: 592, male: 119). The following data under treatment (time range 2–199 months) were evaluated: medication, Calcium (Ca) – values, tingling sensations (paresthesia), and cramps.

Results

Of these 711 pts. 29 had idiopathic HypoPT, 10 HypoPT after parathyroidectomy, 669 after thyroid operation (Tx): subtotal Tx: 471, HemiTx: 12, totalTx: 186 pts. Age of pts. at first visit (V1): 49.85 years (mean), time between Tx and V1: 76.85 months (mean, range 0–733 months). Mean values of Ca (mmol/l), PO4 (mg/dl) in serum, Ca in urine (Ca U; mmol/24 h); % of patients with paresthesia (par.) and cramps under different therapies (mean daily dose in brackets) as follows:

Medication	Ca	PO4	Ca U	par. %	cramps %
Calcium (1462 mg/d)	2.08	1.49	1.67	90	63
Vitamine D (11,442 U/d), Ca (1245)	2.12	1.46	2.88	51	43
1-Alphacalcidol (2.41 ug/d), Ca (1321)	2.19	1.26	2.65	32	26
1-Alphac.(1.26), Vit.D (15,949),Ca (1005)	2.19	1.44	2.65	38	38
Calcitriol (0.64 ug/d), Ca (1354)	2.19	1.43	2.52	57	35
Calcitr.(0.60), Vit.D (9845), Ca (1133)	2.18	1.34	3.27	48	31
Tachysterin (0.73 mg/d)	2.29	1.35	2.52	36	34
Tachysterin (0.77), Ca (1292)	2.22	1.43	2.75	67	48

Conclusion

As expected monotherapy with high doses of calcium was not sufficient. The combination of 1-Alphacalcidol and Calcium was the best regimen for treating HypoPT and improving complaints. Further correlations between different treatment regimen and parameters of renal and bone metabolism will be calculated.

DOI: 10.1530/endoabs.49.OC10.1

OC10.2

Evaluation of bone quality, measured by trabecular bone score (TBS) in patients with primary hyperparathyroidism (PHH) with and without surgery

Isabel Huguet, Miguel Sampedro-Núñez, Jose Luis Muñoz De Nova, Ana Ramos-Levi, Sandra Campos, Eugenio Escolano & Mónica Marazuela
Hospital La Princesa, Madrid, Spain.

Evaluation of bone quality represents a challenge since the analysis by bone mineral density (BMD), provides useful but incomplete information. New tools are arising, and amog them, TBS is emerging as a new surrogate marker of bone texture and microarchitecture which may be useful to potentially evaluate the risk of bone fracture and can be obtained from already existing BMD scans. Retrospective study of 23 patients with PHH. Clinical, analytical and BMD data were collected form clinical records. TBS was calculated by reevaluating the already existing BMD images. Patients were classified into two different groups according to their treatment: 1) 13 patients who underwent surgery, in whom TBS was evaluated before surgery (B-S) and one year after surgery (A-S), and 2) 10 patients who received standard medical treatment, in whom TBS was evaluated with a time-lapse of 1 year. Basal age, body mass index (BMI), serum calcium, vitamin 25-OH-D levels and *T*-Scores were not significantly different between the two groups. Only PTH levels (82 vs 110 pg/ml, $P=0.04$) presented differences. We observed a significant improvement of TBS one year after surgery in the first group ($1.244\pm$ 0.11 vs 1.311 ± 0.1 $P=0.08$). A subtle deterioration on TBS was observed one year after standard treatment in the second group ($1{,}249\pm0.06$ vs 1.223 ± 0.07 $P=0.124$). Overall, surgical patients experienced a TBS increase 5.8% whilst a decrease of -2.04% was observed in the second group ($P=0.02$). In the multivariate correlation analysis, the percentage of variance in TBS was negatively correlated with the level of PTH and calcium at the moment of the second BMD (0.04 and 0.03 respectively). Bone microarchitecture, measured by TBS, improves after surgery in patients with PHH and has shown to be sensitive to changes developed during only one year time-lapse in bone. This parameter is a promising tool in the evaluation of bone status in PHH.

DOI: 10.1530/endoabs.49.OC10.2

OC10.3

High prevalence of radiological vertebral fractures in patients with differentiated thyroid carcinoma undergoing L-thyroxine TSH-suppressive therapy

Anna Maria Formenti[1], Gherardo Mazziotti[2], Stefano Frara[3], Filippo Maffezzoni[1], Mauro Doga[3], Francesco Bertagna[4], Roberto Maroldi[5], Maurizio Memo[1], Raffaele Giubbini[4] & Andrea Giustina[3]
[1]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [2]Department of Internal Medicine, Mantua Hospital, Mantua, Italy; [3]Chair of Endocrinology, Vita-Salute San Raffaele University, Milan, Italy; [4]Chair of Nuclear Medicine, University of Brescia, Brescia, Italy; [5]Chair of Radiology, University of Brescia, Brescia, Italy.

Thyroid hormones play a central role in the regulation of bone turnover and thyrotoxicosis is an established cause of secondary osteoporosis. Increased prevalence of reduced bone mineral density (BMD) has been reported even in patients with subclinical thyrotoxicosis such as those with differentiated thyroid carcinoma undergoing long-term L-thyroxine (L-T4) TSH-suppressive therapy. Morphometric vertebral fractures (VFs) are an early and clinically crucial marker of bone fragility but they have never been investigated so far in this setting. In this cross-sectional study, we evaluated the VF prevalence (DXA quantitative morphometry) and BMD (DXA Hologic 4500 W, at lumbar spine, total hip and femoral neck) in 53 consecutive patients with differentiated thyroid carcinoma (two males, 51 females; median age 61 years, range: 42–82; 45 with papillary carcinoma and eight with follicular carcinoma; median duration of therapy 5 years, range: 1–45) and 75 control subjects (72 females and three males; median age 62 years, range: 42–83) with normal thyroid function attending an outpatient bone clinic. VFs were significantly more prevalent in patients with thyroid carcinoma as compared to the control subjects (30.2 vs 9.3%; $P=0.002$) without significant ($P=0.21$) differences in BMD at either skeletal sites. BMD was not significantly different between fractured and non-fractured TSH suppressed patients at either skeletal site. Prevalence of VFs was not significantly ($P=0.29$) different among patients with normal BMD (11.1%), osteopenia (39.1%) and osteoporosis (28.6%). In patients under TSH-suppressive therapy, VFs were significantly associated with age (OR 1.1, C.I.95% 1.01–1.12; $P=0.03$) but not with duration of L-T4 therapy (OR 1.03; C.I.95% 0.96–1.11; $P=0.34$). This is the first study showing high prevalence of VFs in patients with thyroid carcinoma undergoing L-T4 TSH-suppressive therapy likely due to an impairment in bone quality. Vertebral morphometry should be performed at baseline and during follow-up of TSH-suppressed patients to assess their skeletal health.

The effect of denosumab or bisphosphonates in women with severe postmenopausal osteoporosis after completion of teriparatide treatment

Tomaz Kocjan[1], Antonela Sabati Rajic[1], Mojca Jensterle Sever[1], Gaj Vidmar[2], Barbara Ostanek[3], Janja Marc[3], Nina Orehek[3] & Marija Pfeifer[1]

[1]University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]University Rehabilitation Institute, Ljubljana, Slovenia; [3]Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia.

The ideal antiresorptive agent to preserve or further increase bone mineral density (BMD) following teriparatide treatment is not known. We aimed to compare BMD changes after one year of therapy with denosumab or bisphosphonates in osteoporotic patients who had completed treatment with teriparatide. We retrospectively analyzed 140 women (age 74 years, 26 years from menopause, BMI 27 kg/m^2 on average) with severe postmenopausal osteoporosis who had been treated between 2006 and 2014 with teriparatide for 18–24 months at our outpatient clinic. After stopping teriparatide, they continued with a bisphosphonate (alendronate, risedronate, ibandronate or zoledronic acid) or with denosumab in standard doses per physician's and/or patient's preference. All patients were prescribed with vitamin D3 1000 IU daily and were instructed to ingest 1200 mg of calcium daily. BMD was measured at lumbar spine (LS), total hip (TH) and femoral neck (FN) by DXA when teriparatide was stopped and after 12 months of further treatment. The data were analyzed using multiple linear regression to adjust the comparison between groups for age, BMD, 25-hydroxyvitamin D, serum urate, procollagen type 1 N-terminal propeptide (P1NP) at baseline and BMD gain on teriparatide. Seventy patients continued treatment with a bisphosphonate and 70 received denosumab. The results indicate a lower BMD increase (especially at LS) in patients on bisphosphonates when compared to denosumab; a lower BMD increase at FN and LS in patients who had a larger BMD increase on teriparatide (i.e. regression to the mean); a lower BMD increase at FN and a higher BMD increase at LS in patients with higher baseline P1NP; and a higher BMD increase at FN in patients with higher baseline serum urate. Twelve months after stopping teriparatide, sequential osteoporosis treatment with denosumab yields higher additional BMD gain as compared to a bisphosphonate. The effect is more pronounced at LS.

OC10.5

Gα11-Phe220Ser loss-of-function mutation causes familial hypocalciuric hypercalcemia type-2 (FHH2) by disrupting a hydrophobic cluster critical for G-protein signaling

Caroline M. Gorvin[1], Treena Cranston[2], Fadil M. Hannan[1,3], Helena Valta[4], Outi Makitie[4], Camilla Schalin-Jantti[5] & Rajesh V. Thakker[1]
[1]Academic Endocrine Unit, Radcliffe Department of Medicine, Oxford Centre for Diabetes, Endocrinology and Metabolism, University of Oxford, Oxford, UK; [2]Oxford Molecular Genetics Laboratory, Churchill Hospital, Oxford, UK; [3]Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; [4]Children's Hospital, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [5]Division of Endocrinology, Abdominal Center, University of Helsinki, Helsinki, Finland.

Mutations of the calcium-sensing receptor (CaSR), G-protein alpha-11 subunit (Gα11), and adaptor protein-2 sigma subunit (AP2σ) resulting in a loss-of-function, cause familial hypocalciuric hypercalcemia types 1-3 (FHH1-3), respectively. We investigated a family with FHH (four affected and two unaffected members) for CaSR, Gα11 and AP2σ mutations, and identified a heterozygous Gα11 missense mutation, Phe220Ser, which is predicted to disrupt a cluster of hydrophobic residues that are important for G-protein/G-protein coupled receptor interactions. Gα11, which acts downstream of the CaSR, activates phospholipase C (PLC) leading to two predominant signal outputs: intracellular calcium (Ca2+i) release; and activation of the extracellular-signal regulated kinase (ERK) mitogen-activated protein kinase (MAPK) pathway. We assessed the effects of the Gα11 mutation on signalling by expressing Gα11-wild-type Phe220, and three Gα11-mutants: Ser220, detected in the FHH2 kindred; and engineered mutants, Ala220 (a hydrophobic residue); and, Glu220 (a non-hydrophobic residue), in HEK293 cells stably expressing CaSR. Ca2+i responses to extracellular calcium (Ca2+e) were assessed using a Fluo-4 fluorescent assay and an NFAT-response element-containing luciferase reporter that measures Ca2+i–induced gene expression; and MAPK responses assessed using a phospho-ERK (pERK) AlphaScreen assay and a serum-response element (SRE)-containing luciferase reporter that measures ERK-induced gene expression. Mutation of Phe220 to the non-hydrophobic Ser220 and Glu220 residues, but not the hydrophobic residue, Ala220, significantly impaired Gα11 signalling via PLC-Ca2+i and ERK/MAPK pathways. Thus, Ser220 and Glu220, when compared to wild-type (Phe220) and Ala220 led to: a rightward shift of the dose-response curves of Ca2+i responses to Ca2+e with increased mean half-maximal concentration (EC50) values; reductions in NFAT reporter responses; impaired pERK responses; and reductions in SRE reporter activity. Thus, we have identified a novel Gα11 mutation, Phe220Ser, causing FHH2, and have demonstrated the importance of the hydrophobic Phe220 residue, which forms part of a cluster, for G-protein signaling via PLC-Ca2+i and ERK/MAPK pathways.

Role of Extracellular vesicles in the crosstalk between adipocytes and pancreatic beta-cells

Iacopo Gesmundo[1], Eleonora Gargantini[1], Enrica Favaro[2], Lorenzo Piemonti[3], Giovanni Camussi[2] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Torino, Torino, Italy; [2]Department of Medical Sciences, Torino, Italy; [3]San Raffaele Diabetes Research Institute, IRCCS San Raffaele Scientific Institute, Milano, Italy.

Obesity is characterized by insulin resistance and pancreatic β-cell dysfunction; moreover, secretion of adipokines from adipocytes may affect metabolic functions in several tissues, including pancreatic β-cells. Extracellular vesicles (EVs), released by cells as exosomes or shedding vesicles, play a key role in cell-to-cell communication, modifying the phenotype and function of recipient cells by delivering proteins, RNAs and microRNAs. The crosstalk between adipocytes and β-cells in the regulation of glucose and lipid metabolism is still unclear. We hypothesized that EVs derived from adipocytes are able to influence the survival and function of β-cells in pathophysiological conditions. In this study, the role of EVs released by murine 3T3-L1 adipocytes was evaluated on cell viability and proliferation, apoptosis and function of rat INS-1E β-cells and human pancreatic islets. INS-1E β-cells and human pancreatic islets were treated for 24 and 72 hours, respectively, with EVs in either presence or absence of CKs or palmitic acid and high glucose (P/G). Our results show that EVs derived from untreated adipocytes promote cell survival and proliferation, inhibit apoptosis in β-cells and pancreatic islets treated with CKs and P/G, and stimulate glucose-induced insulin secretion. Conversely, EVs derived from adipocytes treated with CKs enhanced the detrimental effects of CKs and P/G. These results suggest a functional crosstalk between adipose tissue and β-cells/pancreatic islets. Furthermore, the protective effects of EVs derived from adipocytes on survival and function of β-cells exposed to stress, such as inflammatory CKs or glucolipotoxicity, suggest possible therapeutic implications in pathological conditions like diabetes and obesity.

Three year prospective study in morbidly obese patients between longitudinal gastrectomy and gastric bypass based on a composite outcome combining weight loss efficacy and surgery related complications (PHRC SLEEVE K060213 / IDRCB2007-A00373-50)

Jean Marc Catheline[1], Marinos Fysekidis[2], Yasmina Bendacha[1], Najib Bdeoui[1], Vidhya Raghavan[3], Sophie Gérard[3], Jean Jacques Portal[3], Rami Dbouk[1], Jean Michel Fabre[4], Gilles Fourtanier[5], Jean Gugenheim[6], Noël Huten[7], Maxime Sodji[8], Simon Msika[9], Michel Scotté[10], Eric Vicaut[3] & Regis Cohen[1]
[1]Centre coordinateur du PHRC, Centre Hospitalier de Saint-Denis, Saint-Denis, France; [2]CHU Bobigny, Bobigny, France; [3]Unité de Recherche Clinique Lariboisière-St Louis Hôpital Fernand Widal, Paris, France; [4]CHU de Montpellier, Montpellier, France; [5]CHU Toulouse, Toulouse, France; [6]CHU Nice, Nice, France; [7]CHU Tours, Tours, France; [8]Clinique Emailleurs, Limoge, France; [9]Hôpital Louis Mourier « APHP », Colombes, France; [10]CHU Rouen, Rouen, France.

Since its first description in 2000, Longitudinal Gastrectomy (LG) has become the first surgical procedure in the treatment of morbid obesity in the world, exceeding in numbers Gastric Bypass (GB). GB is considered to have better results regarding long-term weight loss and improvement in co-morbidities. We aimed to demonstrate that LG is non inferior to GB for a composite end point that included more than 50% excess weight loss from the baseline and surgery related complications after a mean follow-up of 36 months. This is a prospective study in

morbidly obese patients that tested a two hypotheses composite outcome: the first hypothesis was that after 36 months LG was non-inferior to GB regarding EWL (the predefined margin of non-inferiority was ±15%), and the second hypothesis was the presence of significant difference in post-operative morbidity and mortality. From February 2008 to March 2015 we included 277 patients (91 GB vs 186 LG). The mean age was 41.1 years, 19.2% had a previous bariatric operation, 85.9% were women and the average pre-intervention BMI was 45.3 kg/m^2. At baseline there were no significant differences between the GB and LG for age, sex and BMI. The % of patients with EWL > 50% was at 18 months for 82.1% (GB) vs 84.5% (LG), and 79.1 vs. 79.5% respectively at 36 months. The estimated difference in EWL was [−10.5% to 9.8%], confirming the non-inferiority of LG compared to BP. Finally there was a significant less morbidity and mortality for the LG group (GB vs LG, 12.1 vs. 4.8%, one death for LG, $P=0.01$). This is the first prospective study demonstrating that LG is not inferior to GB for an estimated 10% difference in EWL but with less surgical complications. These results reinforce the choice of LG as surgical procedure for obesity.

OC11.3

Interleukin-1 antagonism decreases cortisol levels in obese individuals

Sandrine Urwyler[1], Philipp Schütz[2], Fahim Ebrahimi[1], Marc Y. Donath[1] & Mirjam Christ-Crain[1]
[1]University Hospital Basel, Basel, Switzerland; [2]Kantonsspital Aarau, Aarau, Switzerland.

Background
Increased cortisol levels in obesity may contribute to the associated metabolic syndrome. In obesity, the activated innate immune system leads to increased interleukin (IL)-1β, which is known to stimulate the release of adrenocorticotropin hormone (ACTH). We therefore hypothesised that in obesity IL-1 antagonism would result in downregulation of the hypothalamo-pituitary-adrenal (HPA) axis, leading to decreased cortisol levels.
Methods
In this prospective intervention study we included 73 patients with obesity (BMI >30 kg/m^2) and at least one additional feature of the metabolic syndrome. The primary endpoint was change in morning cortisol from baseline to after the administration of the IL-1 receptor antagonist (anakinra/Kineret®, total dose 3×100 mg). Secondary endpoints were effects on salivary cortisol and ACTH.
Results
Median morning serum cortisol levels (nmol/l) decreased significantly after IL-1-antagonism (from baseline 452 to 423, absolute difference −38.7, 95%CI −64 to −13.4, $P=0.0019$). Similar effects were found for salivary cortisol levels (−2.8, 95%CI −4.4 to −1.3, $P=0.0007$), ACTH levels (−2.2, 95%CI −4.2 to −0.1, $P=0.038$), systolic blood pressure (−5.2, 95%CI −8.5 to −1.8, $P=0.0006$) and heart rate (−2.9, 95%CI −4.7 to −1.0, $P=0.0029$).
Conclusion
IL-1 antagonism in obese individuals with features of the metabolic syndrome leads to a decrease in serum cortisol, salivary cortisol and ACTH-levels along with a reduction in systolic blood pressure and heart rate. IL-1 antagonism could thus be a novel treatment option to improve cortisol levels and associated comorbidities in obesity.

OC11.4

Comparing effects of weight loss by liraglutide with intensive lifestyle modification on hepatic steatosis, inflammation and stiffness, and insulin resistance in obese Asians with non-alcoholic fatty liver disease (NAFLD)

Joan Khoo, Ngai-Moh Law, John Hsiang, Jessica Tan & Tiing-Leong Ang
Changi General Hospital, Singapore, Singapore.

Background and Aims
Non-alcoholic fatty liver disease (NAFLD), a leading cause of cirrhosis and liver cancer, is increasing worldwide due to rising obesity rates, particularly in Asia. Weight loss induced with diet and exercise decreases hepatic steatosis and inflammation, but requires greater efforts to sustain compared to medication. We therefore aimed to compare the effects of liraglutide, a glucagon-like peptide-1 agonist which induces weight loss, on hepatic steatosis and inflammation in obese Asian adults with NAFLD with intensive lifestyle modification.
Methods
22 abdominally obese Asian (mean BMI 33.6±3.9 kg/m^2, mean waist circumference WC 108.5±10.6 cm) non-diabetic normotensive adults with NAFLD, as diagnosed by a hepatologist based on elevated serum alanine transaminase (ALT) and aspartate transaminase (AST) levels and liver fat fraction >5% using magnetic resonance imaging (MRI) in the absence of other causes of hepatic steatosis and transaminitis, were randomized to supervised dieting (restriction by 400 kcal/day) plus moderate-intensity exercise (200 minutes/week) to induce ≥5% weight loss (DE group, $n=11$) or liraglutide 3 mg daily (LI group, $n=11$) for 26 weeks. Insulin resistance was estimated by homeostasis model assessment (HOMA-IR) and liver shear stiffness with MRI elastography.
Results
At 26 weeks, both DE and LI groups had significant ($P<0.01$) and similar reductions in weight (−3.1±2.9 vs −3.6±2.4 kg), WC (−4.4±3.2 vs −5.7±3.9 cm), liver fat (−9.5±13.8 vs −7.7±7.3%), liver stiffness (−0.22±0.20 vs −0.32±0.25 kPa), ALT (−42±34 vs −43±39 U/l), AST (−21±16 vs −26±25 U/l) and HOMA-IR (−2.87±2.67 vs −3.12±2.40).
Conclusion
Once-daily liraglutide is as effective as intensive lifestyle modification for decreasing hepatic steatosis, inflammation and stiffness in obese Asian adults with NAFLD.

Differentiating constitutional thinness from anorexia nervosa in DSM 5 era

Bruno Estour[1,2], Nesrine Marouani[1], Torrance Sigaud[2,3], Francois Lang[2,3], Eric Fakra[2,3], Aurelie Diamonde[2], Bogdan Galusca[1,2] & Natacha Germain[1,2]
[1]Endocrinology Department, University Hospital of Saint Etienne, Saint Etienne, France; [2]EA 7423, Jean Monnet University of Saint Etienne, Saint Etienne, France; [3]Psychiatry Department, University Hospital of Saint Etienne, Saint Etienne, France.

Introduction
Constitutional thinness (CT) is an underweight state characterized by normal menstruations and no change in feeding behaviour. Thinness is the only resemblance between Anorexia Nervosa (AN) and CT. Removal of amenorrhea in the new DSM 5 definition of AN might lead to misdiagnosis between these two populations. The objective of this study was to compare CT, AN and Control subjects in terms of biological, anthropometric, and psychological markers in order to better distinguish AN from CT subjects.
Patients and method
This retrospective study conducted from 2000 to 2015 included three groups of young women: fifty-six CT, forty restrictive-type AN and fifty-four control subjects were included in the study. Basal evaluation was made in all groups with any intervention. Body composition, nutritional markers, pituitary hormones, bone markers and psychological scores were evaluated in three groups. For every markers, a receiver Operator Characteristics (ROC) curve was calculated to evaluate the accuracy of differentiation between AN and CT groups.
Results
For the majority of the studied parameters, CT subjects were similar to controls but dramatically different from AN subjects. According to ROC data, while psychological scores were unsuccessful to differentiate AN from CT, except for DEBQ Restrained Eating item, free-T3 and Leptin were strong tools for AN and CT distinction as they displayed high sensitivities and specificities with low P values (<0.0001).
Conclusions
Taking AN and CT distinction as a major objective, the exclusive use of psychological criteria is not sufficient and should be completed by at least a free T3 determination, which is a cheap and an accessible laboratory testing for general practitioners. The final goal is to avoid social stigmatization and excessive useless therapies for CT women.

T2-Weighted signal intensity of functional pituitary adenomas: correlation with clinicopathological findings and response to treatment

Sema Ciftci Dogansen[1], Seher Tanrikulu[1], Gulsah Yenidunya Yalin[1], Sakin Tekin[1], Nihan Nizam[1], Bilge Bilgic[2] & Sema Yarman[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey; [2]Department of Pathology, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey.

Purpose
Somatotrophinomas have been shown to demonstrate T2-weighted signal intensity (WSI) on MRI that is correlated with clinicopathological findings and response to treatment. Therefore, we aimed to investigate these correlations in functional pituitary adenomas, including prolactinoma and corticotrophinoma.
Material and Methods
Patients with somatotrophinoma ($n=87$), prolactinoma ($n=78$) and corticotrophinoma ($n=33$) were involved in this study. The initial T2-WSI findings (grouped into hypo-, iso- and hyperintense) were compared with hormon levels, tumor diameter, granulation patterns and treatment response.
Results
While most of somatotrophinomas were hypointense, most of prolactinomas and corticotrophinomas were hyperintense. Tumor diameter was significantly larger in hyperintense somatotrophinomas than in hypointense group ($P=0.007$), but the tumor diameter in the isointense group did not show any difference when compared to the others. IGF-1% ULN (upper limit of normal) was higher in hypointense somatotrophinomas than the other two groups ($P=0.02$). Sparsely granulation pattern in hyperintense somatotrophinomas and densely granulation pattern in hypointense somatotrophinomas are more frequent ($P=0.035$), whereas the granulation pattern distribution in isointense group did not differ from the other two groups. The hormonal response to somatostatin analogs (SSA) treatment (percentage of IGF-1 reduction) was higher in the hypointense group than in the other two groups ($P=0.04$). The tumor diameter was smaller in the hyperintense prolactinomas than in the other groups ($P=0.039$), but the basal PRL levels were not different between the groups. The response to dopamine agonist (DA) treatment of iso- and hyperintense prolactinomas is much better than the hypointense group ($P<0.001$). Tumor diameter was larger in hyperintense corticotrophinomas than the other two groups ($P=0.012$), but there was no difference between the baseline cortisol and ACTH levels of the groups. Sparsely granulation pattern was higher in hyperintense corticotrophinomas and densely granulation patern in hypointense corticotrophinomas ($P=0.029$), whereas granulation pattern distribution in isointense group was not different from the other two groups. There was no difference between the groups in terms of remissions and recurrences.
Conclusion
Hyperintense somatotrophinomas support literature knowledge with increased tumor diameter, sparsely granulation pattern and less responsiveness to SSA treatment. The response to DA treatment of iso- and hyperintense prolactinomas is much better, but there was no difference between the groups in terms of remissions and recurrences in corticortophinomas. Our results in prolactinomas and corticotrophinomas should be supported by further studies.

Use of temozolomide in a large cohort of patients with aggressive pituitary tumours and pituitary carcinomas: Results from a European Society of Endocrinology (ESE) survey

Ann McCormack, Olaf M Dekkers, Stephan Petersenn, Vera Popovic, Jacqueline Trouillas, Gerald Raverot & Pia Burman
[1]Garvan Institute, Darlinghurst, Australia; [2]Leiden University Medical Centre, Leiden, The Netherlands; [3]ENDOC Center for Endocrine Tumors, Hamburg, Germany; [4]Medical Faculty, University Belgrade, Belgrade, Serbia; [5]Faculté de Médecine Lyon-Est, Lyon, France; [6]Universite de Lyon, Lyon, France; [7]Medical Faculty, University of Lund, Malmö, Sweden.

Objective
To collect clinical and treatment outcome data in a large patient cohort, and specifically to report experience with temozolomide (TMZ).
Design
Cohort study based on an electronic survey open for participation to ESE members Dec 2015-Nov 2016.
Results
Reports on 167 patients, 40 pituitary carcinomas, and 127 aggressive pituitary tumours were obtained. Median age at diagnosis was 43 (range 4–79) years. 59% of tumours were clinically functioning at presentation, and the most frequent were corticotroph tumours. TMZ was the first line chemotherapy in 157 patients. At the end of TMZ treatment (mean 9.92 cycles) radiological evaluation showed complete response in 6%, partial response in 31%, stable disease in 33% and progressive disease in 30%. Progression occurred more often in pituitary carcinomas (40%) than in aggressive adenomas (26%), $P=0.05$. Clinically silent tumours showed less regression compared with secreting tumours, 17 vs 45%, $P=0.01$ (overall χ^2 test). Median follow-up after TMZ treatment was 21 months. Of patients with complete response, partial response and stable disease 22, 34 and 40% respectively showed progression during further follow-up. Twenty five patients received a second course of TMZ, 3 had a partial response. Overall mortality was 33%, and highest in patients with progression after TMZ treatment (54%).
Conclusion
TMZ was accompanied by tumour regression in 37% of patients, documenting its value in the management of these aggressive tumours. The high recurrence rate following TMZ cessation highlights the need to identify additional effective therapies.

DOI: 10.1530/endoabs.49.OC12.2

OC12.3

Recombinant Growth Hormone added to physical therapy in GH-deficient adults with complete (ASIA A) Spine Injury (EudraCT 2011-005377-23)

Guillem Cuatrecasas[1], Hatice Kumru[2,3], M°Josep Coves[1], Ioana Patrascioiu[1] & Josep Vidal[2,3]
[1]Department of Endocrinology, Hospital Quiron-Teknon, Barcelona, Spain; [2]Fundación Institut Guttmann, Badalona, Spain; [3]Institut Universitari de Neurorehabilitació (UAB), Badalona, Spain.

Introduction
Although *in-vitro* models suggest GH-induced differentiation, migration and survival of astrocytes and oligodendrocytes, no studies had been published in-vivo. We want to evaluate the efficacy and safety of GH associated with physical therapy compared to placebo in patients with complete spine injury (SI) and associated GH deficiency (GHD).
Methods
Eighteen Patients with complete SI were screened for GHD (glucagon test). 12 severe (GH < 3 ng/ml) or partial (< 10 ng/ml) GHD were randomized in a double-blind placebo-controlled study. Motor and sensory ASIA scale, SCIM-III (spinal cord injury independence measure), Ashworth (spasticity), Neuropathic Pain Scale and Quantitative Sensory tests were assessed. Patients received subcutaneous injections of placebo or GH (Nutropin®) 6 days/week IGF1-adjusted, in addition to intensive physical therapy 2 h/day, for 6 months. Both groups were similar according to age, sex, BMI, waist circumference.
Results
Significant ($P=0.05$) improvement was observed in SCIM-III score at 3 months: 55.6 (14.4 s.d.) vs 74 (2.8 s.d.) and 6 months: 55.4 (14.2 s.d.) vs 73.5 (2.1 s.d.), comparing GH-treated group with placebo. A significant improvement in the electrical perception threshold from the 1st up to the 5th metamera below the SI site was observed on both sides after 6 months of treatment in the GH, but not in the placebo group. These differences were observed intra-individually ($P=0.04$ Friedman's test) and between groups (5th left level ($P=0.023$) and 5th right level ($P=0.031$), mixed linear model). No correlations with IGF1 were observed. No GH-related adverse events were reported.
Conclusions
Not studied so far, GHD seems very prevalent in SI. This is the first trial with complete SI and concomitant GHD. GH added to intense physical rehabilitation improved functional parameters (SCIM) and changes in sensory quantification up to 5 levels below SI. Larger studies should be performed to confirm a GH beneficial effect on sensitive pathways in SI.

OC12.4

Subclinical cardiovascular system dysfunction in the patients with Cushing's disease

Przemyslaw Witek[1], Beata Uzieblo-Zyczkowska[2], Pawel Krzesinski[2], Agnieszka Jurek[2], Grzegorz Zielinski[3], Andrzej Skrobowski[3] & Grzegorz Gielerak[3]
[1]Department of Endocrinology and Isotope Therapy, Military Institute of Medicine, Warsaw, Poland; [2]Department of Cardiology and Internal Medicine, Military Institute of Medicine, Warsaw, Poland; [3]Department of Neurosurgery, Military Institute of Medicine, Warsaw, Poland.

Background
Hypercortisolism in Cushing's disease (CD) is associated with high cardiovascular risk. Hemodynamic disturbances, especially excessive vasoconstriction and elevated blood pressure (BP), may contribute to accelerated myocardial remodeling. Early identification of subclinical left ventricular (LV) dysfunction may be crucial for optimizing treatment and reducing mortality in patients with CD.
Purpose
The aim of this study was to assess the hemodynamic function of cardiovascular system in three groups of patients: 1/ with CD (CD), 2/ with essential arterial hypertension (AH) and healthy volunteers (HV).
Methods
In 171 subjects (CD – 22, AH – 114, HV – 35), without any symptoms of heart failure, the echocardiographic assessment of LV systolic and diastolic function and non-invasive hemodynamic assessment by impedance cardiography (ICG) were performed. Statistical comparison included separate analysis for women and men.
Results
CD revealed good BP control (82% below 140/90 mmHg). However, in comparison to AH and HV they presented: 1) significantly lower LV contractility expressed by global longitudinal strain (GLS: −17.7% vs −19.2 vs −20.0; $P=0.004$); 2) higher prevalence of LV diastolic function (45.0% vs 14.2% vs 0.0%; $P<0.00001$); 3) lower impedance indices of LV performance: stroke index (SI: 39.8 vs 52.2 vs 49.9 ml/m^2; $P<0.00001$) cardiac index (CI: 2.86 vs 3.54 vs 3.27 l/min/m^2; $P<0.0001$) and 4) higher afterload: systemic vascular resistance index (SVRI: 2560 vs 1901 vs 1907 dyn*s*m^2/cm^5; $P<0.0001$). Men with CD distinguished with lower CI ($P<0.00001$) and SVRI ($P<0.0001$), as though worse LV diastolic function (e': $P=0.0002$; GLS: $P=0.052$). In women hypercortisolism was more related to impaired LV systolic function (GLS: $P=0.010$; e': NS).
Conclusions
Cushing's disease, even with well-controlled BP, is associated with LV systolic and diastolic dysfunction and pronounced vasoconstriction which individual presentation depends on sex. These hemodynamic alterations can be detected by modern non-invasive diagnostic tools and became potential therapeutic objectives.

Effects of pegvisomant and somatostatin receptor ligands on risk of vertebral fractures in patients with Acromegaly

Sabrina Chiloiro[1], Gherardo Mazziotti[3], Antonella Giampietro[1], Anna Maria Formenti[2], Antonio Bianchi[1], Marilda Mormando[1], Alfredo Pontecorvi[1], Andrea Giustina[4] & Laura De Marinis[1]
[1]Pituitary Unit, Catholic University of the Sacred Heart, Rome, Italy; [2]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [3]Department of Internal Medicine, Mantua Hospital, Mantua, Italy; [4]Chair of Endocrinology, Vita-Salute San Raffaele University, Milan, Italy.

Acromegalic osteopathy is an emerging complication of chronic GH excess characterized by increase in bone turnover, deterioration in bone microarchitecture and high risk of vertebral fractures (VFs). Medical therapies may exert direct effects on peripheral targets leading to improvement of clinical outcomes regardless of biochemical control of acromegaly. In this longitudinal study, we compared the effects pegvisomant (PegV) and somatostatin receptor ligands (SRLs) on VF risk in 80 acromegaly patients (47 females, 33 males; mean age 53 years, range 24–86 years) who were prospectively evaluated by quantitative vertebral x-ray morphometric approach. During the 30 month study period, 39 patients (48.8%) were treated with PegV, 33 (41.2%) with SRLs and 8 (10%) showed a controlled disease after neurosurgery. At follow-up, 23 patients (28.8%) experienced incident VFs which were significantly correlated with persistently active disease (OR .49, C.I.95% 1.75–17.22; $P=0.003$) and preexisting VFs (OR 2.79, C.I. 95%1.03–7.61; $P=004$). By contrast, no significant differences in incident VFs were found between patients receiving PegV and those treated with SRLs alone, either when disease was persistently active (58.3% vs 60.0; $P=0.94$) or when disease was controlled by treatment (20.0 vs 27.0%; $P=0.67$). In conclusion, this longitudinal study showed that PegV and SRLs had comparable effects on VF risk in acromegaly. Biochemical control as well as early diagnosis of the disease are the main endpoints for fracture prevention in acromegaly.

Thyroid peroxidase antibodies do not predict outcome in 900 women with recurrent pregnancy loss

Sofie Bliddal[1], Henriette Svarre Nielsen[2], Aase Krogh-Rasmussen[1], Astrid Marie Kolte[2], Ole Bjarne Christiansen[2], Claus Henrik Nielsen[3] & Ulla Feldt-Rasmussen[1]
[1]Department of Medical Endocrinology, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark; [2]Recurrent Pregnancy Loss Unit, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark; [3]Institute of Inflammatory Research, Copenhagen University Hospital (Rigshospitalet), Copenhagen, Denmark.

Introduction
Thyroid autoimmunity has been associated with pregnancy loss. A possible mechanism is an overactive maternal immune system leading to rejection of the fetal allograft. In women with recurrent pregnancy losses (RPL), we investigated the association of thyroid peroxidase antibodies (TPOAbs) with number of losses and outcome of first pregnancy after referral.
Methods
Prospective study of women with RPL (≥ 3) followed at the RPL Unit, Copenhagen University Hospital, from 2011 to 2016. Upon first visit, all women were screened for TSH (Roche Modular E170 electrochemiluminescense immunoassays) and TPOAbs (automated Kryptor immunoflourescent assay). TPOAb-positivity >60 kU/l. We performed test for trends by chi-square or independent *t*-tests as appropriate, and adjusted regression analyses with covariates: maternal age, TSH (logtransformed), number of losses, immunotherapy, thyroxine replacement therapy. The National Data Protection Agency approved the project.
Results
We included 5219 pregnancies (76.6% spontaneous) in 900 women; 119 (13.2%) women were TPOAb-positive. TPOAb-positivity was neither associated with number of losses ($P=0.87$, aOR 0.004 (-0.3-0.3), $P=0.98$), nor number of pregnancies ($P=0.62$, aOR 1.02 (0.92-1-11) $P=0.76$). Among TPOAb-positive women, TPOAb-concentration was not associated with number of losses (B = 0.75 (-0.12-0.27), $P=0.45$). In women with a registered first pregnancy after referral, TPOAb-positivity (72 of 557 (12.9%)) was not associated with live birth rate (54.4 vs 60.6%, $P=0.35$, aOR 0.78 (0.42-1.43) $P=0.38$). However, live birth rate was significantly associated with total number of losses (aOR 0.53 (0.45-0.61) $P=0.000$). TSH-levels were positively associated with TPOAb-positivity ($P=0.00$), but not with any investigated outcome. Immunoglobulin therapy or thyroxine replacement did not alter results.
Conclusion
In a large cohort of women with RPL, we found no association between TPOAbs and pregnancy outcome. TSH-levels were significantly increased in TPOAb-positive women and screening according to guidelines should be performed. However, if RPL is caused by an immunological reaction, thyroid autoimmunity does not seem to be a sensitive marker hereof.

Sertoli cell expressed hydroxysteroid (17beta) dehydrogenase 1 is required for male fertility

Janne Hakkarainen[1], Heli Jokela[1], Fuping Zhang[1], Noora Kotaja[1], Petra Sipilä[1] & Matti Poutanen[1,2]
[1]Department of Physiology and Turku Center for Disease Modeling, Institute of Biomedicine, University of Turku, Turku, Finland; [2]Institute of Medicine, Sahlgrenska Academy, Gothenburg University, Gothenburg, Sweden.

Hydroxysteroid (17beta) dehydrogenase 1 (Hsd17b1) is a steroidogenic enzyme catalyzing the conversion of estrone (E1) to estradiol (E2), and androstenedione (A-dione) to testosterone (T). We have shown that the deletion of Hsd17b1 gene in mice resulted in the failure of ovarian estrogen production and subfertility. In this study, we clarified the role of Hsd17b1 in male reproduction. The data revealed that in mice Hsd17b1 mRNA is highly expressed in the Sertoli cells at the fetal age. The Sertoli cell function is critical for normal spermatogenesis, and their action is dependent on the pituitary gonadotropins and testosterone. The breeding tests revealed that the Hsd17b1 knockout male mice (HSD17B1KO) were infertile. Because the Hsd17b1 is part of the steroid synthesis machinery, we analyzed the *in vivo* biomarkers for androgen action, while no changes were observed in fetal masculinization or in onset of puberty. Furthermore, the weights of androgen-dependent tissues in HSD17B1KO were neither affected. Also, the serum gonadotropin levels and the steroid concentrations in the testis, were close to normal in the HSD17B1KO males, with minor changes in the E1/E2 and A-dione/T ratios. Interestingly, several steroidogenic genes, Hsd17b3, Star, Cyp11a1 and Hsd3b1, were significantly upregulated in HSD17B1KO testes, suggesting a functional compensation due to the lack of Hsd17b1 activity. Although no marked changes were observed in the hormonal environment, histological analysis of HSD17B1KO testis revealed defects in the organization of differentiating germ cells in the seminiferous epithelium, and major defects in the haploid germ cell differentiation, particularly in the head shaping of elongating spermatids. Consequently, the epididymal sperm count was dramatically reduced in the HSD17B1KO males, and the remaining spermatozoa were morphologically abnormal. These results revealed a novel role for Hsd17b1 in the control of spermatogenesis and male fertility, and suggest that Hsd17b1 is required for a proper function of Sertoli cells.

Diabetes mellitus: a new cause of male infertility

Rosita Angela Condorelli, Sandro La Vignera, Rossella Cannarella, Laura Maria Mongioì & Aldo Eugenio Calogero
Unit of Andrology and Endocrinology, Department of Clinical and Experimental Medicine, Catania, Sicily, Italy.

Introduction
Diabetes mellitus (DM) may cause male infertility acting with pre-testicular, testicular and post-testicular mechanism.
Aim
To evaluate the presence of male infertility and the mechanisms of sperm damage in diabetic patients in childbearing age.
Patients and methods
Thirty-four patients with DM1, 55 with DM2 and 100 healthy fertile men (controls) were enrolled. Diabetic patients were further divided into three groups based on their glycometabolic status and illness duration. Conventional and biofunctional sperm parameters were evaluated by standard semen analysis and flow cytometry. This latter included sperm DNA fragmentation, vitality, early and late apoptosis, chromatin condensation, mitochondrial membrane potential (MMP), leukocyte subpopulations, lipid peroxidation (PL) and sperm mitochondrial superoxide. In addition, all patients and controls underwent testicular ultrasound sca and serum LH and testosterone measurements.
Results
Diabetic patients had lower sperm concentration, progressive motility and morphology vs controls ($P<0.05$). The ejaculate volume is significantly lower in patients with DM1 vs controls ($P<0.05$). Leukocyte concentrations were higher in patients with DM2 ($P<0.05$), showing a statistically significant reduction in the percentage of T helper cells and an increase of the suppressor T lymphocytes compared to controls ($P<0.05$). The analysis of the biofunctional sperm parameters showed worsening MMP in diabetic patients ($P<0.05$). Patients with DM2 showed a significant decrease in the degree of sperm vitality and increased spermatozoa in late apoptosis vs Controls and of the DNA fragmentation compared to the other two groups ($P<0.05$). Moreover, patients with DM1 had a lower progressive motility when the disease duration was >10 years vs the other two groups, and lower MMP after 5 years of disease ($P<0.05$). The degree of PL was higher in DM2 patients compared to the other two groups ($P<0.05$), while the concentrations of mitochondrial superoxide were greater in DM2 patients compared to DM1 and control group ($P<0.05$). The ultrasound data showed that the diameter of the epididymal head and tail after ejaculation were greater in patients with DM1 long term than those of short duration compared to controls ($P<0.05$). Testosterone levels were lower in DM2 patients vs controls ($P<0.05$).
Conclusion
Patients with DM1 have low ejaculate volume for an altered epididymal emptying and a mitochondrial damage that anticipates the later decline of sperm motility. DM2 is instead characterized by an inflammatory condition with increased leukocyte and oxidative stress and elevated levels of sperm DNA fragmentation and decreased sperm vitality.

Urinary cadmium excretion is associated with increased synthesis of cortico- and sex steroids in a family-based Swiss population study

Murielle Bochud[1], Judith Jenny-Burri[2], Menno Pruijm[3], Belen Ponte[4], Idris Guessous[1], Georg Ehret[5], Dusan Petrovic[1], Vincent Dudler[2], Max Haldimann[2], Geneviève Escher[7], Bernhard Dick[7], Markus Mohaupt[7], Fred Paccaud[1], Michel Burnier[3], Antoinette Péchère-Bertschi[6], Pierre-Yves Martin[4], Bruno Vogt[7] & Daniel Ackermann[7]
[1]Institute of Social and Preventive Medicine (IUMSP), Lausanne, Switzerland; [2]Federal Food Safety and Veterinary Office, Bern, Switzerland; [3]Service of Nephrology, Lausanne, Switzerland; [4]Service of Nephrology, Geneva, Switzerland; [5]Cardiology, Department of Specialities of Internal Medicine, Geneva, Switzerland; [6]Endocrinology, Department of Specialities of Internal Medicine, Geneva, Switzerland; [7]University Clinic for Nephrology and Hypertension, Bern, Switzerland.

Background
Cadmium (Cd) is considered as a human carcinogen. A potential intermediate mechanism could be hormone-related by disturbing steroidogenesis in gonads and adrenal glands. We tested whether urinary Cd excretion, as a marker of long-term exposure, is associated with the urinary steroid profile in the general adult population.
Methods and Findings
The Swiss Kidney Project on Genes in Hypertension (SKIPOGH) is a multicentric family-based population study with a response rate of 25.6%. We measured 24-h urinary excretions of Cd and steroid hormone metabolites by gas chromatography and mass spectrometry in 1000 participants (473 men, 527 women), with separate day and night collections. Mixed linear models were used to analyse the associations of each steroid metabolite with Cd excretion.
Cd and testosterone excretions were positively associated in men (β[SE, *P*]: 1.378[0.242, <0.00001] and 1.440[0.333, 0.00002] for day and night, respectively), but not in women (0.333[0.257, 0.2] and 0.674[0.361, 0.06]). There was a strong positive association of the urinary excretion of Cd and cortisol (0.475[0.157, 0.0025] and 0.877[0.194, 0.00001], for day and 0.875[0.253, 0.00053] and 1.183[0.277, 0.00002] for night, respectively). Cd excretion was not associated with the excretion of tetrahydroaldosterone, the major metabolite of aldosterone, but with other mineralocorticoid metabolites ($P<0.01$ in men and women). Further adjustment revealed an independent effect between the synthesis of sex hormones and corticosteroids and an interdependent effect of Cd on gluco- and mineralcorticoid synthesis.
Conclusions
Our findings provide evidence for a global stimulating effect of low-dose Cd exposure on sex and corticosteroid synthesis in the general adult population. Further studies are needed to explore the health consequences of chronic low-dose exposure to Cd on selected diseases such as steroid-sensitive cancers or metabolic disorders.

Anti-Mullerian hormone (AMH) in pre-menopausal females after ablative radioiodine (RAI) treatment for differentiated thyroid cancer (DTC): single-center study

Miranda Mittica[1], Paola Comite[2], Claudia Campana[1], Stefano Gay[1], Michele Mussap[2] & Massimo Giusti[1]
[1]UO Clinica Endocrinologica, Azienda Ospedaliera Universitaria San Martino – IST, Genoa, Italy; [2]UO Laboratorio Analisi, Azienda Ospedaliera Universitaria San Martino – IST, Genoa, Italy.

Background
It is generally reported that female fertility is not affected by high-dose RAI treatment. AMH has been considered a reliable and accurate index of ovarian reserve. There are few data on AMH values in thyroid diseases. Recently, in DTC women who had undergone RAI ablation treatment, Acibucu *et al*. (2016) reported low AMH levels without significant impairment of fertility.
Aim
The aim of this single-center study was to evaluate AMH levels in association with the characteristics of spontaneous menstrual cycles and the levels of pituitary–gonadal hormones in our cohort of pre-menopausal women with a history of low-risk DTC.
Subjects
From a group of 68 women, 39 who were not on oral contraceptive therapy were enrolled. All hormone evaluations were performed on chemiluminescence assays. AMH, FSH, 17B-estradiol (E2) were assayed on day 2 and PRL and progesterone (P) levels on day 21–24 of the same menstrual cycle. Twenty-seven women (aged 40 ± 6 years) were studied 7 ± 4 years after primary DTC treatment, which included at least one RAI treatment (median activity 80 mCi). As a control group, 12 female DTC patients (aged 40 ± 8 years) who had undergone only thyroidectomy were used.
Results
All women were free from DTC. Pregnancy (study group 62%; control group 50%) and abortion rates (17 and 33%) were similar. TSH and f-T4 were similar in both groups. Hyperprolactinemia was found only in one patient, while FSH >30 mU/l was found in 2 (1 study, 1 control). Regular (28 ± 2 days) menses were reported in 33% of both groups. A high incidence of polymenorrhea was reported in the study group (33%), while a high incidence of oligomenorrhea was noted in the control group (50%). Ovulatory cycles ($P>4$ ng/ml) were noted in 72 and 60% of study and control women, respectively. AMH levels were found to be negatively correlated with age ($P=0.002$), but not with E2, FSH, TSH or f-T4 levels. AMH levels were 2.0 ± 0.4 ng/ml and 2.3 ± 1.5 ng/ml in the study and control groups, respectively.
Limitations
These data are preliminary, as data collection is still ongoing.
Conclusions
AMH should replace FSH in the evaluation of gonadal reserve in pre-menopausal DTC women. At present, age is the only predictor of AMH levels. About one out of two women with a history of DTC suffers from menstrual dysregulation, but infertility must be considered a low risk.

Suppression of heme oxygenase-1 inhibits growth and invasion of thyroid cancer

Shih-Ping Cheng[1,2], Jie-Jen Lee[1,2], Ming-Jen Chen[1,2], Chien-Liang Liu[1,2], Po-Sheng Yang[1,2] & Yi-Chiung Hsu[3]
[1]MacKay Memorial Hospital, Taipei, Taiwan; [2]Mackay Medical College, Taipei, Taiwan; [3]National Central University, Taoyuan City, Taiwan.

Oxidative stress generated in the process of iodide metabolism and thyroid hormone synthesis may play a role in thyroid tumorigenesis and progression of thyroid cancer. The transcription factor Nrf2 is the most important regulator of antioxidant responses. It has been shown that Nrf2 expression is upregulated in papillary thyroid cancer. In response to oxidative stress, nuclear Nrf2 activates antioxidant-responsive elements and induces the expression of stress-responsive genes, including heme oxygenase-1 (HO-1). Previously we have demonstrated that HO-1 overexpression was associated with advanced tumor stage in thyroid cancer. Therefore, we hypothesize that HO-1 may represent a potential target for cancer therapy. HO-1 inhibitors have been clinically used in patients with hyperbilirubinemia and hereditary porphyria. In the present study, thyroid cancer cells were treated with two different classes of HO-1 inhibitors: metalloporphyrin and imidazole–dioxolane compound. We found that treatment with HO-1 inhibitors suppressed cell growth, colony formation, cell migration, and invasion of thyroid cancer cells in a dose-dependent manner. Cell cycle analysis by flow cytometry revealed that growth arrest in the G0/G1 phase. However, there was no synergistic effect of HO-1 inhibitors in combination with doxorubicin or sorafenib. Our results suggest a modest susceptibility of thyroid cancer cells to HO-1 inhibitors. Nonetheless, HO-1 inhibition may not act as a sensitizer to chemotherapy in thyroid cancer.

João, Porto, Portugal; [12]Department of Pathology and Oncology, Medical Faculty, University of Porto, Porto, Portugal.

Context
Little is known about the frequency of key mutations in thyroid cancer metastases and its relationship with the primary tumor genotype.
Objectives
To evaluate the frequency of TERT promoter (TERTp), BRAF and NRAS mutations in metastatic thyroid carcinomas, analyzing primary thyroid tumors, lymph node metastases (LNM) and distant metastases.
Material and Methods
Mutation analysis was performed in 437 tissue samples from 204 patients, mainly with papillary thyroid carcinomas (PTC) ($n=180$), including 196 LNM and 56 distant metastases. All the distant metastases included corresponded to radio-iodine-refractory metastatic tissue.
Results
We found the following mutation frequency in primary thyroid tumors, LNM and distant metastases, respectively: TERTp- 15.9, 10.8, and 52.4%; BRAF (PTC-only)- 44.6, 41.7, and 23.8%; NRAS- 1.7, 1.3, and 11.9%. In the subgroup of patients with PTC, the TERTp mutation frequency in primary tumors, LNM and distant metastases was 12.9, 10.5, and 52.4%, respectively. There was a significant concordance between the primary tumor genotype and the corresponding LNM, in particular for BRAF-mutated PTC. The overall concordance between primary tumors and respective distant metastases was low. In the group of patients with PTC, we found a high frequency of TERTp mutations and a low frequency of BRAF mutations in distant metastases, in comparison to the paired primary tumors.
Conclusions
The frequency of BRAF, NRAS and TERTp mutations is similar in primary tumors and matched LNM, whereas distant metastases show an enrichment in TERTp mutations and a decrease in BRAF mutations. TERTp mutations seem to play an important role in distant metastases.

OC14.4

Inverse relation between thyroid cancer incidence and threshold for thyroid surgery: a national population-based retrospective study

Brigitte Decallonne[1], Van den Bruel Annick[3], Elaut Nathalie[1] & De Schutter Harlinde[2]
[1]KU Leuven, Leuven, Belgium; [2]Belgian Cancer Registry, Brussels, Belgium; [3]General Hospital Sint Jan, Bruges, Belgium.

Background
In Belgium, lower thyroid cancer incidence – most pronounced for microcancers (T1a) – is present in the North compared to the South. This variation is paralleled by differences in clinical practice: in the North less thyroid surgery is performed, more surgery is preceded by fine needle aspiration (FNA), and more patients with a final cancer diagnosis (2004–2006) underwent a presurgical FNA or a lymph node dissection (LND) at fist surgery.
Aim
To study 1/ the evolution in the use of FNA and LND, and 2/ the weight of T1a non-thyrotoxic thyroid glands in a recent thyroid cancer cohort.
Methodology
Population-based retrospective study, using data from the Belgian Cancer Registry (including case-by-case study of pathology protocols) and Belgian Healthcare Insurance database for differentiated thyroid cancer (DTC) cases diagnosed between 2009 and 2011 ($n=2659$).
Results
Linkage of both databases resulted in 2557 DTC cases (96%). In the North a higher proportion of DTC cases underwent FNA before surgery: 62.3%[95%CI 58.3;66.3] compared to 33.6%[95%CI 29.3;39.9] in the South ($P<0.0001$), confirming geographical differences. A positive trend for FNA was observed in the period 2004–2012, at national and regional level, especially in the South. The execution of LND during first thyroid surgery was proportionally higher in the North (24.3%[95%CI 20.6;28.0]) compared to the South (15.3%[95%CI 12.0;18.7], $P<0.0001$), without temporal trend. Finally, in the subgroup of T1a DTC cases – considered to be mainly incidental findings – the mean thyroid weight was 57.7 ± 52.1 g in the North, compared to 37.99 ± 29.1 g in the South ($P<0.0001$).
Conclusion
In the present cohort, more FNA precedes thyroid cancer diagnosis, according to international guidelines. However, geographical differences clearly persist. A lower thyroid weight is present in DTC T1a in the South. These findings support the alignment of a higher thyroid cancer incidence with a lower threshold for thyroid surgery in case of nodular disease, strongly suggesting overdiagnosis.

DOI: 10.1530/endoabs.49.OC14.4

OC14.5

Dose aggressive variants of papillary thyroid carcinoma have worse clinical outcome than classical papillary carcinoma?

Eyun Song[1], Min Ji Jeon[1], Hyemi Kwon[1], Suyeon Park[1], Hye-Seon Oh[1], Jin-Sook Ryu[1], Dong Eun Song[1], Eui Young Kim[2], Tae Yong Kim[1], Young Kee Shong[1], Won Bae Kim[1] & Won Gu Kim[1]
[1]Asan Medical Center, Seoul, Republic of Korea; [2]Dongnam Institute of Radiological & Medical Sciences Cancer Center, Busan, Republic of Korea.

Background
Unlike excellent prognosis of classical papillary thyroid carcinoma (cPTC), certain pathological subtypes of aggressive variants of PTC (AV-PTC) are considered to have poor clinical outcome. However, the evidence of unfavorable outcome of AV-PTC is not clear because previous studies did not control other confounding factors contributed to clinical outcomes.
Methods
This retrospective cohort study initially included 4339 patients with cPTC and 121 patients with AV-PTC including tall cell, columnar, hobnail, solid and diffuse sclerosing variants. Dynamic risk stratification (DRS) and recurrence free survival (RFS) between the two groups were compared after two-to-one individual risk factor matching by age, sex, tumor size, and initial surgical extent.
Outcome
AV-PTC was associated with larger tumor size ($P<0.001$) and higher rates of cervical lymph node (LN) metastasis ($P<0.001$) compared to cPTC. A total of 121 patients with AV-PTC and 242 patients with cPTC were evaluated after individual risk factor matching. There were no significant differences in the tumor size and cervical LN metastasis between the two groups after mating. When we compared the proportion of patients according to the DRS, there was no significant difference between patients with cPTC and those with AV-PTC ($P=0.14$). There was also no significant difference in RFS (hazard ratio [HR] 1.93, 95% confidence interval [CI] 0.68-5.47, $P=0.23$) between the two groups. In subgroup analysis including patients with tall cell, columnar, and hobnail variants of PTC, there were no significant differences in DRS ($P=0.68$) and RFS (HR 2.04, 95% CI 0.56-7.41, $P=0.29$) compared with matched patients with cPTC.
Conclusion
The clinical outcome of patients with AV-PTC was not different with those with cPTC when their other clinicopathological risk factors were similar. Therapeutic and follow-up strategies for PTC might not need to be modified according to presence of AV-PTCs.

PRKACA mutations in adrenal Cushing can alter substrate specificity

Kerstin Bathon[1,2], Isabel Weigand[3], Jens T Vanselow[4], Cristina L Ronchi[3,5], Guido Di Dalmazi[6,7], Felix Beuschlein[6], Silviu Sbiera[3], Andreas Schlosser[4], Martin Fassnacht[3,5] & Davide Calebiro[1,2]
[1]Institute of Pharmacology and Toxicology, University of Würzburg, Würzburg, Germany; [2]Bioimaging Center, University of Würzburg, Würzburg, Germany; [3]Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital, Würzburg, Germany; [4]Rudolf Virchow Center, University of Würzburg, Würzburg, Germany; [5]Comprehensive Cancer Center Mainfranken, University of Würzburg, Würzburg, Germany; [6]Medizinische Klinik and Poliklinik IV, Ludwig-Maximilians University, München, Germany; [7]Division of Endocrinology, Department of Medical and Surgical Sciences, University of Bologna, Bologna, Italy.

Previously, we identified seven mutations in the main catalytic subunit of protein kinase A (PKA Cα) to be responsible for cortisol-secreting adrenocortical adenomas (CPAs): L206R, L199_C200_insW, S213R_L212_K214insIILR, C200_GlyinsV, W197R, del244-248+E249Q, E32V. Here we performed a functional characterization of these mutants. Specifically, we evaluated the association between PKA regulatory and catalytic subunits using co-immunoprecipitation and PKA activity using a kemptide assay and a western blot analysis. Our results show that four mutations (L206R, L199_C200_insW, W197R, del244-248+E249Q) cause increased basal PKA activity. Interestingly, the measured activity varied considerably among mutants depending on the assay used, suggesting changes in substrate specificity. Binding to RIα and RIIβ subunits was lost for three and two mutants respectively. One mutant (E32V) showed no differences with the wild type. The S213R_L212_K214insIILR mutant was associated with a loss of PKA activity, but showed a strong accumulation in the nucleus. The C200_G201insV mutant was associated with a loss of activity in the kemptide assay but showed normal behavior in the western blot and nuclear translocation. For all mutants we performed an in silico analysis to predict the effect of the mutation on substrate specificity. The analysis suggested changes in substrate specificity for five mutants. Based on this, we performed phosphoproteomic experiments, which directly compare the phosphorylation of a large number of PKA substrates. The results directly demonstrated altered substrate specificity for three mutants (L206R, del244-248+E249Q, C200_G201insV). Taken together, these findings suggest that the PKA Cα mutations found in CPAs alter substrate specificity and that interference with the formation of a stable PKA holoenzyme is probably just one of the mechanisms through which these mutations affect PKA signaling, ultimately leading to increased cortisol production and cell proliferation. The results of the phosphoproteomics analysis might lead to the identification of new PKA targets involved in the pathogenesis of CPAs.

Recurrent somatic mutations in *KCNJ5, CACNA1D, ATP1A1* and *ATP2B3* have been identified in aldosterone producing adenoma (APA). Although the role of these mutations in regulating aldosterone biosynthesis has been clearly established, the mechanisms involved in proliferation and APA formation still remain to be elucidated. The aim of our study was to identify pathways involved in adrenal cortex nodulation and APA formation.

Transcriptomic analysis from 123 APA and 11 control adrenal and correlations of gene expression with genetic, morphological and functional characteristics of the tumors allowed us to identify retinoic acid receptor (RAR) signalling as a central molecular network involved in APA formation independently of the mutation status. Treatment of H295R cells with all-trans retinoic acid and 9-cis retinoic acid reduced cell viability in a time and dose dependent manner. This effect was due to decreased cell proliferation and increased cell apoptosis. In contrast to the effects observed in vitro, 9-cis retinoic acid did not modify tumor progression in a mouse xenograft model.

Investigation of the adrenal phenotype of rar$\alpha^{-/-}$ mice demonstrated that in young (12 weeks) and old (52 weeks) rar$\alpha^{-/-}$ mice the characteristic cellular arrangement of the adrenal cortex was replaced by an enlarged zona glomerulosa and a disorganized zona fasciculata. This is also associated to dilatation and disorganisation of vessels and increased capsule thickness. Furthermore, young rar$\alpha^{-/-}$ mice displayed lower plasma aldosterone concentration and decreased expression of steroidogenic enzymes. Interestingly, this was associated with the inhibition of WNT/β-catenin pathway.

Our results suggest that RAR signaling contributes to normal adrenal morphology and functional zonation through modulation of WNT/β-catenin pathway and that its disruption could contribute to abnormal cell proliferation in the adrenal cortex, creating a propitious environment for the emergence of specific driver mutations in APA.

Background

Extracellular vesicles (exosomes, microvesicles) shed from tumor cells containing microRNAs can be exploited as markers of malignancy. The preoperative diagnosis of adrenocortical malignancy is difficult and microRNAs have proved useful in the diagnosis of many tumors, including adrenocortical cancer (ACC), but there have no studies to date on extracellular vesicle associated microRNAs in ACC.

Aim

To evaluate the diagnostic potential of extracellular vesicle-associated (exosomal) microRNAs in human adrenocortical tumors.

Methods

The isolation of extracellular vesicles (EV) was performed either by differential centrifugation/ultracentrifugation or by applying Total Exosome Isolation Kit. EV preparations were also assessed by transmission electron microscopy and flow cytometry. 6 adrenocortical adenomas (ACA) and 6 histologically verified ACC samples were profiled by Taqman Human Microarray A-cards in the discovery cohort. The significantly differentially expressed microRNAs were validated in 13 ACAs and 12 ACCs by targeted quantitative real-time PCR.

Results

Significant overexpression of EV-associated hsa-miR-101 and hsa-miR-483-5p was measured in ACC vs ACA samples in the microRNA profiling. We could confirm the overexpression of these microRNAs in the validation cohort, too. dCThsa-miR-483-5p normalized to cel-mir-39 showed the highest area under curve (AUC) value (0.96), with 91.67 sensitivity and 92.33 specificity.

Conclusions

Extracellular vesicle-associated (exosomal) hsa-miR-483-5p might be a promising minimally invasive biomarker in the preoperative diagnosis of ACC.

Androgen receptor signalling is essential for regression of the adrenal x-zone and regulation of the adrenal cortex in the male mouse

Anne-Louise Gannon, Laura O'Hara, Rod Mitchell, Ian Mason & Lee Smith
University of Edinburgh, Edinburgh, UK.

Introduction
Androgens have long been known to play an important role in health and wellbeing. A range of clinical disorders in males and females can arise due to disruption to production and action of androgens. Androgen receptor (AR) is widely expressed throughout the adrenal cortex, yet the wider role for androgen signalling in the adrenal remains underexplored due to the lack of suitable animal models.
Methods
An adrenal-specific androgen receptor knockout mouse model was created by targeting GFP-Cre-GC to the mouse *Cyp11a1* locus to drive Cre Recombinase expression in steroidogenic cells. Males were then mated to C57BL/6 female homozygous $AR^{fl/fl}$ mice. C57BL/6 mice were also used to investigate normal adrenal function. Tissue was analysed through qRT-PCR and statistical analysis by one way ANOVA. Immunohistochemistry was used to determine changes in protein localisation.
Results
Results highlight that androgens signalling through AR is essential for the regression of the foetal 'X-zone' during puberty in male mice. Loss of androgens (through castration) or AR results in significant morphological differences in the adrenal cortex and X-Zone cells. However, interestingly, loss of androgens or AR impact cortex structure, gene expression and protein localisation differently.
Conclusions
We show that androgen signalling through AR is essential for removal of X-zone cells during puberty. We also demonstrate that androgens can act independently of AR to modulate cortex function. Additionally, the loss of androgen signalling results in a decrease in apoptotic cells, suggesting the adrenal has become more resistant to cell death. Improper removal of cortical cells and loss of apoptosis could have serious implications for adrenal function and disease progression. The impacts of this are undergoing further investigation.

Protein Kinase A signaling saves regulatory subunit IIβ from PRKACA mutation-mediated degradation

Isabel Weigand[1], Kerstin Bathon[2], Cristina Ronchi[1], Marthe Rizk-Rabin[3], Guido Di Dalmazi[4], Vanessa Wild[5], Beatrice Rubin[6], Jens T Vanselow[7], Andreas Schlosser[7], Davide Calebiro[2], Felix Beuschlein[4], Jérôme Bertherat[3], Martin Fassnacht[1] & Silviu Sbiera[1]
[1]Division of Endocrinology and Diabetes, University Hospital Wuerzburg, Wuerzburg, Germany; [2]Institute of Pharmacology and Toxicology, Bioimaging Centre, University of Wuerzburg, Wuerzburg, Germany; [3]Institut Cochin, Department of Endocrinology, Hôpital Cochin, Paris, France; [4]Medizinische Klinik and Poliklinik IV, Ludwig-Maximilians University, Munich, Germany; [5]Institute of Pathology, University of Wuerzburg, Wuerzburg, Germany; [6]Department of Medicine, University of Padua, Padua, Italy; [7]Rudolf Virchow Center for Experimental Biomedicine, University of Wuerzburg, Wuerzburg, Germany.

Protein Kinase A (PKA) consists of two catalytic and two regulatory subunits with several isoforms (Cα,β,γ, RIα,IIα,Iβ,IIβ). In 30–40% of cortisol-producing adrenocortical adenomas (CPA) heterozygous activating somatic mutations in the catalytic subunit α (Cα) of PKA have been found. Previous reports found strikingly reduced levels of RIIβ in CPA compared to other adrenocortical tumors. Here, we investigated the correlation between Cα mutational status, RIIβ expression levels and the underlying regulation mechanisms in CPA and the adrenal cell line NCI-H295R. RIIβ expression was strongly reduced in Cα-mutated CPAs, especially in tumors harboring the frequent L206R mutation (34 Cα-WT and 23 Cα-mutated CPA) by both immunohistochemistry (mean expression: 1.5 ± 0.7 vs 0.4 ± 0.5, $P<0.05$) and WB. Similar results were observed for RIα (1.8 ± 0.9 vs 2.6 ± 0.6, $P<0.05$) but not for the other regulatory subunits. Notably, mRNA expression of all subunits was unchanged in Cα-WT compared to Cα-mutated CPA. In NCI-H295R cells co-transfected with RIIβ and Cα-WT or different Cα mutants, only the L206R mutation led to a full degradation of RIIβ and this degradation could not be abolished by proteasome and lysosome inhibition but, surprisingly, by stimulating PKA signaling. Same co-transfections with RIα did not lead to its degradation. By performing RIIβ co-IP experiments in the presence of Cα-WT or Cα-L206R, followed by nanoLC-MS/MS analysis, we could identify possible novel RIIβ interaction partners mediating RIIβ stability in NCI-H295R cells. In conclusion, our data demonstrate that mutations in PKA Cα lead to post-transcriptional downregulation of the main regulatory subunit in CPA. In NCI-H295R cells, transfection with the L206R mutant led to full degradation of RIIβ, which could not be rescued by different degradation mechanisms, suggesting another mechanism that can be abrogated by stimulating PKA signaling. LC-MS/MS revealed putative RIIβ interaction partners affecting its stability in the presence of Cα L206R only after stimulation of PKA signaling.

Involvement of ARMC5 in proliferation and cell cycle control of human cell cultures from adrenal nodules of primary macronodular adrenocortical hyperplasia (PMAH)

Isadora Cavalcante[1], Mirian Nishi[2], Maria Claudia Zerbini[4], José Luiz Chambo[3], Madson Almeida[2,5], Claudimara Lotfi[1] & Maria Candida Fragoso[2,5]
[1]Institute of Biomedical Sciences, São Paulo, Brazil; [2]Laboratory de Medical Investigation LIM 42, São Paulo, Brazil; [3]Department of Urology, São Paulo, Brazil; [4]Department of Pathology, São Paulo, Brazil; [5]Adrenal Unit, São Paulo, Brazil.

Background
The mechanisms causing hypercortisolism in primary macronodular adrenocortical hyperplasia (PMAH) are not fully clarified. The participation of ectopic receptors and autocrine/paracrine regulation of intra-adrenal ACTH in hyperplastic tissue have been considered. Additionally, germline *ARMC5* mutations have been described as main cause of PMAH. So far, the functional study that analyzed the role of ARMC5 used the adrenocortical carcinoma cell line, H295R. Therefore, we propose a more suitable model in cell cultures obtained from nodules of PMAH.
Aim
To investigate the role of ARMC5 related to PMAH.
Methods
Cell cultures obtained from nodules of 13 unrelated patients with PMAH *ARMC5* mutated or not were analyzed for: i) Morphological and functional characterization; ii) *ARMC5* sequencing; iii) ARMC5 silencing through shRNA in non-mutated PMAH cells for steroidogenic and proliferative functional studies; iv) ARMC5 overexpression through transient transfection in mutated PMAH cells and viability analyses.
Results
i) The cell cultures demonstrating presence of steroidogenic cells, ectopic/aberrant receptors and functional intra-adrenal ACTH. ii) *ARMC5* mutations were located mostly in exons 1, 2 and 3, responsible for protein-protein interactions of ARM repeat family; *ARMC5* germline mutations identified in seven samples were associated or not to somatic mutations or LOH. In six samples, ARMC5 mutation was not identified; iii) ARMC5 silencing in non-mutated PMAH cell cultures decreased *StAR, CYP17A1*, *CYP11A1*, *NR5A1* and *MC2R,* increased *CCNE1* mRNA expression and its proliferative capacity, but without interference in cell viability. iv) ARMC5 overexpression induced apoptosis and necrosis after 8h in PMAH mutated cell cultures, decreasing cell viability.
Conclusions
We confirm the role of ARMC5 as a pro-apoptotic protein and its importance in the steroidogenesis related to PMAH, as previously described in H295R cells. We also report for the first time the involvement of ARMC5 in proliferation control and cell cycle regulation of PMAH cell cultures, which needs to be further explored.

Identification of a new glucocorticoid receptor mutation underscores the substantial prevalence of genetic *NR3C1* alterations in adrenal hyperplasia: the French National Research Program MUTA-GR

Géraldine Vitellius[1], Brigitte Delemer[2], Philippe Caron[3], Antoine Bennet[3], Jerome Bouligand[1,4], Anne Guiochon-Mantel[1], Say Viengchareun[1], Christian Dani[6], Severine Trabado[1,4] & Marc Lombes[1,5]
[1]Inserm UMR S 1185, Kremlin Bicetre, France; [2]Service d'Endocrinologie, Hopital Robert Debré, CHU de Reims, REIMS, France; [3]Service d'endocrinologie, maladies métabolique et nutrition,CHU Larrey, TOULOUSE, France; [4]Service de Génétique moléculaire, pharmacogénétique et hormonologie, KREMLIN BICETRE, France; [5]Service d'Endocrinologie et des Maladies de la Reproduction, KREMLIN BICETRE, France; [6]Université Côte d'Azur, CNRS, Inserm, iBV, NICE, France.

Primary generalized glucocorticoid resistance is characterized by glucocorticoid excess without any Cushing syndrome. Patients exhibit variable clinical presentation including arterial hypertension, hirsutism or adrenal hyperplasia. Although glucocorticoid resistance has been associated with glucocorticoid receptor (GR) mutations (encoded by *NR3C1* gene), only 23 mutations have been reported so far. We have conducted a French National Research Program, referred to as MUTA-GR that aims at determining the prevalence of *NR3C1* genetic alterations in patients with adrenal masses associating by glucocorticoid resistance. In this context, we have recently identified a novel GR stop mutation in a 43-year-old man presenting with glucocorticoid resistance, bilateral adrenal hyperplasia and biological hypercortisolism (1.5 to 3-fold increased in 24 h urinary free cortisol, negative response to dexamethasone suppression test and normal plasma ACTH concentrations). Alteration of GR signaling is currently validated by transient transfection assays, binding studies, subcellular trafficking, Chromatin Imunoprecipitation experiments, stability investigation, three-dimensional modeling and gene expression studies.

More than 120 patients have been enrolled and five original GR heterozygous mutations (two missense and three false sense including R469X, R477S, Y478C, L672P) were discovered. Each original mutation impaired a different step of GR intracellular signaling. Ex vivo experiments performed on patients' fibroblasts demonstrated that some mutations (R469X, R477S) led to an haploinsufficiency phenotype with a decreased response in glucocorticoid-dependent target gene expression (*FKBP5, SGK1*).

Interestingly, all mutated patients present with metabolic disorders (high BMI, metabolic syndrome, …), supporting the essential role played by glucocorticoid signaling in adipocyte physiology that we are currently exploring. Altogether, GR mutations are not such an uncommon event given that 5% of our patients carried *NR3C1* alterations. Collectively, GR defects are not a rare cause of glucocorticoid resistance, an incidence initially minimized. We propose that genetic screening of the *NR3C1* gene should be conducted in patients with adrenal incidentalomas and subclinical hypercorticism.

Clinical and translational relevance of circulating miR483 in adrenocortical cancer

Letizia Canu[1], Francesca Salvianti[1], Giada Poli[1], Roberta Armignacco[1], Giulia Cantini[1], Alessandra Di Franco[1], Stefania Gelmini[1], Tonino Ercolino[1], Massimo Terzolo[2], Gabriella Nesi[1], Pamela Pinzani[1], Massimo Mannelli[1] & Michaela Luconi[1]
[1]University of Florence, Florence, Italy; [2]University of Turin, San Luigi Gonzaga Hospital, Orbassano, Turin, Italy.

Adrenocortical cancer (ACC) is a rare aggressive malignancy, with poor prognosis when metastaic at diagnosis. Recent ACC pan-genomics analysis contributed to redefine the risk groups on molecular bases, including tumor micro RNA (miR), which can be detectable not only in the primary lesion but also in the bloodstream.

We develop a quantitative real-time assay for the measurement of absolute levels in plasma samples of miR483 and its mature miR483-5p form. miR483/miR483-5p levels were evaluated in plasma samples of 27 patients with ACC before surgery and at follow up, and in an independent validation cohort of 21 metastatic ACC. Statistically significant difference in miR483-5p and miR483 levels of pre-surgery and post-surgery samples was found between low (stage 1/2) and high (stage 3/4) risk groups. Moreover the mean levels of both miRs were significantly higher in plasma of patients belonging to the high stage risk group compared to subjects with the benign form (ACA) and healthy subjects. ROC curves analysis of miR483–5p levels resulted in predicting the risk stage (accuracy 0.917 ± 0.084). The best ROC cut-off value for miR483-5p (0.221 ng/ml) significantly predicted overall and recurrence-free survival. miR483-5p was the only variable that significantly predicts recurrence, but not overall survival, in a multivariate Cox analysis (HR 16.2, 95%CV[1.39–188.6, $P < 0.026$]). In addition, miR483 and 483-5p levels significantly correlated with the number of circulating tumor cells in the same blood samples, independently of the timing of sampling. Analysis of an independent cohort of metastatic ACC ($n = 21$) revealed that miR483 negatively correlated with mitotane levels.

In conclusion, we demonstrated that miR483 and miR483-5p absolute plasma levels in ACC patients are powerful molecular markers that may help to follow patients after surgery and chemotherapy, and contribute to better classify and predict tumor evolution.

Background

It is still undetermined whether patients with Cushing's disease (CD) in remission have an increased mortality. Most previous studies are limited by small numbers of patients and/or short follow-up time.

Objective

To study mortality in a nation-wide cohort of patients with CD during long-term follow-up.

Methods

Patients with ICD codes for Cushing's syndrome and/or CD, between 1987 and 2013, were identified in the Swedish National Patient Registry. Medical records of the patients were reviewed (clinical, biochemical, imaging and histopathological data) to verify the diagnosis, and to determine remission status. All other forms of Cushing's syndrome than CD were excluded from the study. Standardized mortality ratios (SMRs) with 95% confidence intervals were calculated using the Swedish general population as reference.

Results

Out of 1252 identified patients, 502 (387 women (77%)) had a confirmed CD diagnosis. Of these, 411 (82%) were in biochemical remission. The mean $\pm$ s.d. age at diagnosis was 46 ± 16 years. The median (interquartile range) follow-up time was 13 (6–23) years, resulting in 7165 patient-years of follow-up. Of the 502 patients, 364 (73%) had been treated with pituitary surgery, 129 (26%) with radiotherapy and 102 (20%) with bilateral adrenalectomy. The observed number of deaths was 133 vs 54 expected, resulting in an overall SMR of 2.46 (95% CI 2.06–2.91). SMR in patients not in remission ($n = 91$) was markedly increased, SMR 8.23 (95% CI 5.42–12.0). Mortality in patients in biochemical remission was lower ($P < 0.0001$), but increased compared to the general population, SMR 1.80 (95% CI 1.44–2.23).

Conclusion

This large nation-wide study demonstrates that patients with CD have an excess mortality, irrespective of remission status. The findings emphasize the importance of curative treatment as well as continued active surveillance after remission has been achieved.

Expression of GATA transcription factors and their role in the aetiology of Testicular Adrenal Rest Tumours

Manon Engels[1,2], Paul Span[3], Monica Marijnissen-van Zanten[4], Teun van Herwaarden[2], Christina Hulsbergen-van de Kaa[4], Rod Mitchell[6], Lee Smith[6], Nike Stikkelbroeck[5], Fred Sweep[2] & Hedi Claahsen-van der Grinten[1]

[1]Department of Pediatrics, Radboud University Medical Center, Nijmegen, The Netherlands; [2]Department of Laboratory Medicine, Radboud University Medical Center, Nijmegen, The Netherlands; [3]Department of Radiation Oncology, Radboud University Medical Center, Nijmegen, The Netherlands; [4]Department of Pathology, Radboud University Medical Center, Nijmegen, The Netherlands; [5]Department of Internal Medicine, Radboud University Medical Center, Nijmegen, The Netherlands; [6]Medical Research Council Centre for Reproductive Health, University of Edinburgh, Edinburgh, UK.

Background

Recently, GATA transcription factors have been linked to the development of Testicular Adrenal Rest Tumours (TART), benign adrenal-like testicular tumours that frequently occur in male patients with congenital adrenal hyperplasia (CAH). The objective of this study is to determine GATA expression in TART and other steroidogenic tissues, examining their discriminative potential and their possible role in the aetiology of TART.

Methods

GATA1-6 expression was determined in TART, Leydig cell tumour (LCT), adult testis, adult adrenal, foetal testis, and foetal adrenal tissues. In addition, GATA expression was measured in Hs181.tes cells after induction with dibutyryl cAMP (dbcAMP).

Results

In TART, testis-like *GATA4* gene expression, but higher compared to adult adrenal, was found. In contrast, *GATA3* and *GATA6* expression in TART is similar to adrenal, but higher compared to adult testis or LCT. *GATA3* and *GATA6* could discriminate between TART and testis (AUC of 0.982 and 0.920, respectively). ACTH is a potential stimulator of TART differentiation in CAH. Stimulation of the Hs181.tes cell line with 0.1 mM dbcAMP for 4 hours increased gene expression of both *GATA3* and *GATA6*.

Conclusion

Gene expression of GATA transcription factors in TART shows both testicular and adrenal characteristics. Additionally, *GATA3* and *GATA6* mRNA levels can help discriminate TART from LCT. Furthermore, we found that dbcAMP can induce GATA3 and GATA6 gene expression, which might indicate that ACTH can stimulate testis cells to become more adrenal like and eventually TART cells. To confirm this, we are pending on the results of stimulation experiments with dbcAMP or ACTH in ACTH-responsive H295RA cells.

A country comparison of glucocorticoid replacement therapy in patients with primary and secondary adrenal insufficiency: data from the EU-AIR

Bertil Ekman[1], Marcus Quinkler[2], Pinggao Zhang[3], Pierre Zelissen[4] & Robert D. Murray[5]

[1]Linköping University, Linköping, Sweden; [2]Endocrinology in Charlottenburg, Berlin, Germany; [3]Shire, Lexington, Kentucky, USA; [4]University Medical Center Utrecht, Utrecht, The Netherlands; [5]St James's University Hospital, Leeds, UK.

Introduction

The daily maintenance dose of conventional hydrocortisone currently recommended by international guidelines for the management of primary adrenal insufficiency (PAI) or secondary adrenal insufficiency (SAI) is 15−25 mg/day, in 2−3 divided doses. The aim of this analysis was to investigate inter-country differences in glucocorticoid replacement doses in patients with PAI and SAI.

Design

EU-AIR (ClinicalTrials.gov identifier: NCT01661387) with 20 contributing centres across Germany, the Netherlands, Sweden and the UK started enrolling patients with AI in August 2012. Baseline clinical and biochemical data from patients in the four countries were compared. 1798 patients (626 PAI, 1172 SAI) were included in the current analysis of data collated until November 2016. Patients with congenital adrenal hyperplasia or tertiary AI were excluded.

Results

No major differences between countries were seen in disease duration, BMI, blood pressure or blood lipids in patients with PAI and SAI. However, BMI was generally higher in patients with SAI than PAI. Most patients were treated with conventional hydrocortisone, with similar mean doses administered in Germany, the Netherlands, Sweden and the UK (PAI: 24.7±8.4 mg/day, 22.2±5.7 mg/day, 21.5±10.0 mg/day, 21.0±9.3 mg/day; SAI: 20.0±6.4 mg/day, 20.8±6.1 mg/day, 21.6±9.4 mg/day, 18.9±5.2 mg/day). Cortisone acetate was most commonly used in the Netherlands (PAI, 23%; SAI, 27%). No difference was observed in fludrocortisone dosing in patients with PAI between countries (0.1±0.07 mg/day, 0.1±0.04 mg/day, 0.1±0.05 mg/day, 0.1±0.12 mg/day). Patients with PAI treated with dual-release hydrocortisone (DRHC) were treated with lower doses in Germany 21.3±2.3 compared with those in Sweden 28.0±6.0 mg/day.

Conclusions

The maintenance doses of hydrocortisone observed in this study are in line with international guidelines in all four countries. The country difference in maintenance doses in DRHC is consistent with data showing that mean daily doses of hydrocortisone tend to be higher in Sweden than in other countries.

Activation of the cAMP/PKA transduction system triggers abnormal expression of the serotonin signaling pathway in human adrenocortical cells

Julie Le Mestre[1], Céline Duparc[1], Zakariae Bram[1], Yves Reznik[2], Jérôme Bertherat[3], Philippe Touraine[4], Jacques Young[5], Olivier Chabre[6], Constantine A. Stratakis[7], Hervé Lefebvre[1,8] & Estelle Louiset[1]

[1]Normandie University, UNIROUEN, INSERM, U1239, Rouen, France; [2]Department of Endocrinology-Diabetology, Caen University Hospital, Caen, France; [3]Department of Endocrinology and Metabolic Diseases, Assistance Publique des Hôpitaux de Paris, Hôpital Cochin, Paris, France; [4]Department of Endocrinology and Reproductive Medicine, Assistance Publique-Hôpitaux de Paris, Hôpital Pitié Salpêtrière, Paris, France; [5]Department of Endocrinology, Assistance Publique-Hôpitaux de Paris, Hôpital Bicêtre, Kremlin-Bicêtre, France; [6]Department of Endocrinology, CHU de Grenoble, Grenoble, France; [7]Section of Endocrinology and Genetics, PDEGEN, NICHD, Bethesda, Maryland, USA; [8]Department of Endocrinology, Rouen University Hospital, Rouen, France.

In human adrenals, serotonin (5-HT), released by subcapsular mast cells, increases aldosterone secretion through activation of type 4 serotonin receptors (5-HT_4R) but only exerts a modest control on cortisol production. Interestingly, illicit synthesis of 5-HT in adrenocortical cells as well as overexpression of the 5-HT_4R and ectopic expression of the type 7 receptor (5-HT_7R) have been observed in bilateral macronodular adrenal hyperplasia responsible for hypercortisolism. In this study, we have investigated the expression of the key enzyme of 5-HT synthesis tryptophan hydroxylase (Tph) and 5-HT_4R, 5-HT_6R, 5-HT_7R in the adrenal samples removed from patients suffering from diseases associated with activation of the cAMP/PKA pathway in adrenocortical cells, such as primary pigmented nodular adrenocortical disease (PPNAD), Cushing's disease (CD), ectopic secretion of ACTH, and 21-hydroxylase deficiency (21-OHD), in comparison with normal adrenals. In PPNAD cells, we observed upregulation of Tph together with 5-HT_4R, 5-HT_6R and 5-HT_7R. Overexpression of the 5-HT signaling pathway appeared to be the consequence of the activation of PKA by *PRKAR1A* gene mutations which cause the disease. 5-HT strongly stimulated cortisol production and inhibition of Tph reduced corticosteroidogenesis in cultured PPNAD cells. High expression of Tph and 5-HTRs was also detected in adrenal tissues exposed to high plasma ACTH levels, including CD, 21-OHD and ectopic Cushing's syndrome. Our results indicate that activation of the cAMP/PKA pathway in adrenocortical cells resulting either from *PRKAR1A* mutations or activation of the MC2R by sustained increase in plasma ACTH levels induces an aberrant serotonergic stimulatory loop in zona fasciculata. They also suggest that the intraadrenal 5-HT signaling pathway may participate in the pathophysiology of PPNAD-associated and ACTH-dependent hypercortisolisms and could represent an adaptive mechanism to increase glucocorticoid synthesis in 21-hydroxylase deficiency.

GP13

PRKARIA (Carney complex gene) is a major regulator of the tight link between cell cycle phases and steroidogenesis in the adrenocortical tumor cells H295R

Marthe Rizk-Rabin[1], Bruno Ragazzon[1] & Jerôme Bertherat[1,2]
[1]INSERM U1016, CNRS UMR8104 Paris Descartes University, Paris, France; [2]Center for Rare Adrenal Diseases, Department of Endocrinology, Hôpital Cochin, Paris, France.

The cyclic AMP/PKA signalling cascade is involved in the pathogenesis of cortisol-secreting adrenocortical tumors (ACT). Defects in cell cycle checkpoints play a major role in oncogenesis. The PKA regulatory subunits *PRKARIA and PRKARIIb* are involved in cell survival and steroidogenesis in the adrenocortical carcinoma H295R cell line. We have previously shown that their inactivation enhances the accumulation of cells in the G2 phase and activates PKA and MAPkinases pathways.
This study investigates the correlation between the cell cycle phases and the adrenal steroid secretion, as well as their control by PKA.
Methods
Using pharmacologic drugs, H295R cells were synchronized at specific cell cycle check point (G1 phase), (S phase) and (G2 phase). The cell cycle distribution (Cytometry), the expression of cyclins, PKA subunits, cell signalling pathways, StAR and steroidogenic enzymes were analysed. The effect of PKA activation either by the different PKA subunits, or cAMP, PKA inactivation by H89 and PKI along the cell cycle synchronization were studied.
Results
Cells synchronized at G2 phase increased the expression of the steroidogenic enzymes and steroid secretion. Arresting H295R in G1 phase decreased the steroidogenic enzymes expression and cortisol secretion. PKA subunits distribution and PKA activity modulation were cell cycle dependent. PKA activation by *PRKARIA* inactivation counteracted specifically the decrease of steroidogenesis in cells arrested in G1 phase: StAR/luc reporter gene activity and cell progression in G2 phase were stimulated. *PRKARIIb* inactivation and *PRKACA* overexpression or cAMP increased the StAR/luc reporter gene activity, independently of the cell cycle check point arrest. The H89 and PKI differentially reduced StAR/luc reporter gene activity, and both reversed the cell cycle in the G2 arrested cells.
Conclusion
Inactivation of the Carney complex gene stimulates steroidogensis in the low steroidogenic G1 phase arrested cells. This study shows a link between the cell cycle check points and the regulation of steroidogenesis, in which the *PRKARIA* subunit is a key regulator of both cell cycle and steroidogenesis.

Simultaneous assays of aldosterone and renin concentrations in just ten minutes could change the clinical assessment for the diagnosis of primary aldosteronism

Fumitoshi Satoh[1,2], Morimoto Ryo[2], Yoshikiyo Ono[2], Yuta Tezuka[1,2], Kei Omata[1,2], Masahiro Nezu[2], Yoshitsugu Iwakura[2], Yoshuhiro Igarashi[2], Masataka Kudo[2] & Sadayoshi Ito[2]
[1]Tohoku University Graduate School of Medicine – Division of Clinical Hypertension, Endocrinology and Metabolism, Sendai, Japan; [2]Tohoku University Hospital – Division of Nephrology, Endocrinology and Vascular Medicine, Sendai, Japan.

Measurement of plasma aldosterone and renin concentration, or activity, is useful for selecting antihypertensive agents as well as detecting hyperaldosteronism in hypertensive patients. However, it takes several days to get results when measured by radioimmunoassay and development of more rapid assays has been long expected. We have developed chemiluminescent enzyme immunoassays enabling the simultaneous measurement of both aldosterone and renin concentrations in ten-minutes by a fully automated assay using antibody-immobilized magnetic particles with quick aggregation and dispersion. We performed clinical validation of diagnostic ability of this newly developed assay-based screening of 125 patients with primary aldosteronism from 97 patients with essential hypertension. Results of this novel assay significantly correlated with the results of radioimmunoassay (aldosterone, active renin concentration and renin activity) and liquid chromatography-tandem mass spectrometry (aldosterone). The analytical sensitivity of this particularly novel active renin assay was 0.1 pg/ml, which was better than that of radioimmunoassay (2.0 pg/ml). Using Bland-Altman plots with the mass-spectrometry values, both bias and limits of agreement with 95% confidence interval of the automated aldosterone assay were smaller than those of the radioimmunoassay, indicating smaller systemic errors in the novel measurement. The ratio of aldosterone-over-renin concentrations of 11.2 (ng/dl per pg/ml) provided 80.8% sensitivity and 94.9% specificity as a cut-off for differentiating primary aldosteronism from essential hypertension. This novel measurement is expected to be a clinically reliable alternative for conventional radioimmunoassay and to provide better throughput and cost-effectiveness in diagnosis of hyperaldosteronism from larger numbers of hypertensive patients in clinical settings.

Integrated genomic and phenomic analysis reveals key molecular pathways of aldosterone producing adenoma

Fabio Fernandes-Rosa[1,2], Sheerazed Boulkroun[1], Felipe Golib Dzib[3], Georgios Daniil[1], Laurence Amar[1,4], Bastien Rance[5], Benoit Samson-Couterie[1], Xavier Jeunemaitre[1,2], Tchao Meatchi[1,6], Arndt Benecke[7,8], Tim Strom[9,10] & Maria-Christina Zennaro[1,2]
[1]INSERM, UMRS_970, Paris Cardiovascular Research Center, Université Paris Descartes, Sorbonne Paris Cité, Paris, France; [2]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service de Génétique, Paris, France; [3]Institut des Hautes Etudes Scientifiques, Bures sur Yvette, France; [4]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Unité Hypertension artérielle, Paris, France; [5]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Département d'Informatique Hospitalière, Paris, France; [6]Assistance Publique-Hôpitaux de Paris, Hôpital Européen Georges Pompidou, Service d'Anatomie Pathologique, Paris, France; [7]Université Pierre et Marie Curie, Paris, France; [8]CNRS UMR 7224, Paris, France; [9]Institute of Human Genetics, Helmholtz Zentrum München, Neuherberg, Germany; [10]Institute of Human Genetics, Technische Universität München, Munich, Germany.

Primary aldosteronism is the most common form of secondary hypertension. Somatic mutations in *KCNJ5*, *ATP1A1*, *ATP2B3* and *CACNA1D* have been described in 50% of aldosterone producing adenomas (APA). To identify genetic alterations in new genes, we performed whole exome sequencing in 23 patients with APA negative for recurrent mutations in known driver genes. A low number of somatic variations were identified per patient, ranging from 1 to 22. No somatic variations were identified in two patients. Somatic mutations in *KCNJ5* and *CACNA1D* were identified in 12 APA. These mutations were not observed or were present at very low levels on previous Sanger sequencing, indicating tumor heterogeneity. Two patients harbored mutations in genes involved in the Wnt/β-catenin pathway, which represents, together with the membrane ion transporter activity, the two significantly overrepresented pathways in gene ontology analysis. Sequencing of *CTNNB1* in somatic DNA from 150 subjects with APA identified additional variants in 13 subjects, including 2 APA harboring also a *KCNJ5* mutation. Transcriptome data obtained from 123 APA and 11 control adrenals did not show differences on the expression levels of Wnt4, an activator of the Wnt/β-catenin pathway, and *LEF1* and Axin2, two β-catenin target genes, as a function of the mutation status. Hierarchical clustering of transcriptional profiles at a genome-wide scale was not associated to the APA mutation status, supporting a model whereby all recurrent mutations converge upon activation of calcium signaling and increased aldosterone production. In addition, β-catenin activation was observed by immunohistochemical analysis in two thirds of APA independently of *CTNNB1* mutations, suggesting the involvement of additional mechanisms promoting cell proliferation. Using transcriptome affinity-propagation-based analysis we identified 15 different clusters of APA. These clusters are not associated with demographic or clinical data, highlighting additional molecular pathways underlying APA development and identifying subgroups to be targeted for gene discovery.

Cardiovascular features of autonomous cortisol secretion in patients with adrenal incidentalomas

Emilia Sbardella[1], Marianna Minnetti[1], Laura Rizza[1], Maria Rosaria Di Giorgio[1], Valeria Hasenmajer[1], Denise D'Aluisio[2], Sergio Morelli[2], Andrea Lenzi[1] & Andrea M Isidori[1]
[1]Department of Experimental Medicine, Sapienza University of Rome, Rome, Italy; [2]Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome, Italy.

Background
Possible Autonomous Cortisol Secretion (pACS) is a condition found in 1–29% of patients with adrenal incidentalomas. The diagnosis of pACS has been variably associated with an increased risk of cardiovascular events and mortality. However, dedicated studies describing the morphologic and functional cardiac alterations in these patients are lacking.
Aim
To compare the cardiovascular features of patients with pACS to those with nonfunctioning (NF) adrenal masses.
Materials and methods
Fifty-eight patients with adrenal incidentaloma without the classic signs or symptoms of overt hypercortisolism were prospectively enrolled. Anthropometric, metabolic and hormonal parameters, adrenal magnetic resonance, echocardiography B-mode ultrasound and arterial stiffness calculated with oscillatory method were assessed in all patients. We diagnosed patient with pACS after 1-mg overnight dexamethasone suppression test (1 mg-DST), confirmed by traditional 48-h Liddle tests, if post-test serum cortisol felt between 51 and 138 nmol/l.
Results
Overall 30 patients had pACS and 28 NF adrenal masses. No differences in gender, smoke habits, hypertension, obesity and diabetes prevalence were observed between pACS and NF patients. Mean left ventricular (LV) mass index was increased in the pACS compared to the NF group (112.6 ± 29.2 vs 94.8 ± 31 g/m^2 $P=0.032$). We also detected a significantly higher prevalence of LV hypertrophy in PACS than NF group (35.7% vs 14.3% $P=0.007$). Furthermore, there was a negative correlation between the post-dexamethasone cortisol levels and ejection fraction ($r=-0.26$; $P=0.041$). The assessment of arterial stiffness showed a higher pulse wave velocity in pACS compared with the NF group (11.3 ± 1.4 vs 10.2 ± 0.6 m/s; $P=0.048$).
Conclusions
Autonomous Cortisol Secretion (pACS) can lead to early cardiac and vascular dysfunction even in apparently asymptomatic patients. These results underline the need for further studies, including second line cardiovascular assessment, to correctly define the management of pACS and allow early recognition of possible complications.

Hypercortisolism is prevalent in newly diagnosed type 2 diabetes: a prospective study of 384 consecutive patients

Charlotte Steffensen[1], Olaf M Dekkers[2,3], Johanne Lyhne[1], Per L Poulsen[1], Jørgen Rungby[4], Henrik T Sørensen[2] & Jens Otto L Jørgensen[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Clinical Epidemiology, Aarhus University Hospital, Aarhus, Denmark; [3]Department of Epidemiology, Leiden University Hospital, Leiden, The Netherlands; [4]Department of Clinical Pharmacology, Aarhus University, Aarhus, Denmark.

Background
Cross-sectional studies in small and selected populations indicate a relatively high prevalence of incipient and/or subclinical Cushing's syndrome (CS) in patients with type 2 diabetes (T2D), which could have therapeutic implications.
Aim
To estimate the prevalence of CS in a large, unselected cohort of recently diagnosed T2D patients.
Methods
A total of 384 consecutive out – patients with T2D diagnosed after 1 January 2009 were investigated by means of an overnight dexamethasone (1 mg) suppression test (DST). Patients who failed to suppress to ≤ 50 nmol/l after the DST were further examined with 48 h low dose dexamethasone suppression test (LDDST) and 24-h urinary free cortisol collection (UFC). Patients with elevated cortisol levels according to LDDST or UFC underwent ACTH measurements and imaging.
Results
85 (22%) patients had elevated cortisol after DST of whom 20 (5%) failed to suppress after LDDST and/or had elevated UFC. No significant difference in age, BMI, HbA1c, T-score, Total Body Fat or blood pressure were recorded between the two groups. Among the 20 patients with biochemical CS subsequent imaging with either pituitary MR or abdominal CT, according to suppressed ($n=10$) or unsuppressed ($n=10$) ACTH levels, revealed adrenal adenoma(s) in nine cases and a pituitary macroadenoma in one case.
Conclusion
i) The prevalence of hypercortisolism is high in T2D, also in unselected newly diagnosed patients, ii) Hypercortisolism was not associated with a persuasive phenotype, iii) The clinical implications remain uncertain but continued interest is justified, preferably in terms of randomized intervention trials.

GP18

Effects of two mineralocorticoid receptor antagonists on the morphology of the adrenal cortex

Sofia S Pereira[1,2], Madalena M Costa[1], Ângela Moreira[1], Liliana Carvalho[3], Mariana Monteiro[1], Gavin Vinson[4] & Duarte Pignatelli[2,5]
[1]Department of Anatomy and UMIB (Unit for Multidisciplinary Biomedical Research) of ICBAS, University of Porto, Porto, Portugal; [2]IPATIMUP/I3S, Porto, Portugal; [3]Departament of Experimental Biology, Faculdade de Medicina, University of Porto, Porto, Portugal; [4]The School of Biological and Chemical Sciences Queen Mary University of London, London, UK; [5]Department of Endocrinology, Hospital S.João, Porto, Portugal.

Arterial hypertension usually results from the deregulation and hyperactivity of the renin angiotensin-aldosterone system. One of the available therapeutic approaches for its treatment is the use of mineralocorticoid receptor (MR) antagonists, thus blocking aldosterone action.
The aim of this study was to characterize the effects of spironolactone and eplerenone, on the morphology of the adrenal gland of spontaneously hypertensive (SHR) and normotensive (Wistar-Kyoto) rats.
SHR ($n=18$) and Wistar-Kyoto ($n=18$) rats were exposed, for 1 month, to spironolactone (100 mg/kg per day, $n=6$), eplerenone (50 mg/kg per day, $n=6$) or not exposed to either drug ($n=6$) and at the end of this period their adrenal glands were collected and we evaluated the percentage of the stained area (%SA) of CyP11B1, CyP11B2, the adrenal inner zone antibody (IZAb), a proliferation marker (ki-67), β-catenin and finally the percentage of cellular area occupied by lipid droplets as well as the capsular width.
SHR Hypertensive rats presented higher area of lipid droplets in all layers of the adrenal cortex, an effect that was even further increased by the exposure to eplerenone, in the fasciculata and reticularis zones. In the normotensive rats it was only spironolactone that elicited this effect, being significant only in zona reticularis. Both drugs also increased Ki-67 expression in the hypertensive rats, but only eplerenone increased it on normotensive rats. Finally, spironolactone decreased the capsular size but only in the normotensive rats. No significant differences were found for the % SA of CyP11B1, CyP11B2, IZAb or β-catenin.
In conclusion, we have found that, morphologically the adrenal glands of normotensive and SHR only differed in number of lipid droplets. Exposure to the MR antagonists had significant consequences on the capsular size, lipidic depots and on the cellular proliferation of both normotensive and SHR adrenal glands.

Plasma cortisol and aldosterone responses to insulin tolerance test and sodium depletion in women with non classic 21-hydroxylase deficiency caused by bi-allelic CYP21A2 mutations (NC-CAH)

Peter Kamenicky[1,2], Anne Blanchard[3], Antonin Lamaziere[4], Bruno Donadille[4], Lise Duranteau[1], Sylvie Salenave[1], Laurence Pietri[5], Marie Laure Raffin-Sanson[6], Jean-François Gautier[7], Philippe Chanson[1,2], Sophie Christin Maitre[4], Veronique Tardy[8], Yves Le Bouc[4], Sylvie Brailly-Tabard[1] & Jacques Young[1,2]
[1]APHP Hôpital Bicêtre, Paris, France; [2]University Paris Sud- Reproductive Endocrinology, Paris, France; [3]APHP Hôpital Georges Pompidou, Paris, France; [4]APHP-UPMC Hôpital Saint-Antoine, Paris, France; [5]Hôpital Saint Joseph, Paris, France; [6]APHP Hôpital Ambroise Paré, Paris, France; [7]APHP Hôpital Lariboisière, Paris, France; [8]Hôpital Nord-Hôpitaux Civils de Lyon, Lyon, France.

NC-CAH is diagnosed in pubertal/post-pubertal women because of androgen excess however, the risk of potential adrenal insufficiency is not known, and indication of systematic glucocorticoid replacement therapy is controversial.
Aim
To evaluate cortisol and aldosterone secretions in response to challenges tests.
Design
Prospective controlled clinical study in a tertiary referral center. 20 women with NC-CAH (serum stimulated 17-OHP >10 ng/ml/250 µg, Synacthen) comparatively to matched healthy women, were included if they had not receive glucocorticoid treatment >1 year and estrogen-based oral contraception stopped >3 months. Each participant underwent sequentially two tests separated by a 2 to 7-days: insulin tolerance gold standard test (ITT) and a sodium depletion test (oral 40 mg furosemide under low sodium diet) to stimulate both endogenous active renin (AR) and aldosterone. Steroid levels measured by LC-MSMS.
Results
NC-CAH had lower pic plasma cortisol concentrations during ITT than healthy women: 17.2 µg/dl (13.1–22.8) vs 21.2 µg/dl (17.1–33.5), $P=0.0002$. A peak plasma cortisol above 17.0 µg/dl was obtained in all controls but only in 60% NC-CAH women. NC-CAH had higher baseline ACTH and AR levels. 24-h after sodium depletion, mean plasma aldosterone levels were comparable between the two groups, but NC-CAH women had higher ($P=0.003$) stimulated AR levels than healthy women: 67 mUI/l (15–156) vs 39 mUI/l (6–87).
Conclusions
Forty percent women with NC-CAH have subnormal glucocorticoid adrenal function. Their aldosterone secretion was maintained normal by increased AR levels. Besides androgen excess therapy, clinical management of NC-CAH women should include assessment of their cortisol and aldosterone secretion; systematic chronic replacement therapy is still an open question, but transient glucocorticoid supplementation and rehydration during periods of stress should be considered.

Which are the factors and causes of death in patients with adrenal insufficiency? Mortality data from EU-AIR

Marcus Quinkler[1], Bertil Ekman[2], Pinggao Zhang[3], Pierre Zelissen[4] & Robert D Murray[5]
[1]Endocrinology in Charlottenburg, Berlin, Germany; [2]Linköping University, Linköping, Sweden; [3]Shire, Lexington, Kentucky, USA; [4]University Medical Center Utrecht, Utrecht, The Netherlands; [5]St James's University Hospital, Leeds, UK.

Introduction
If untreated, adrenal insufficiency (AI) leads to premature death. Hospital record data suggest mortality associated with primary (PAI) and secondary AI (SAI) to be 2–3-fold higher than in the general population. Major causes of death include cardiovascular disease, Addisonian crises, brain tumours and infections; however, there is little further characterization of patients who died.
Design
We analysed real-world data from the European Adrenal Insufficiency Registry (EU-AIR; NCT01661387) with centres across Germany, the Netherlands, Sweden and the UK. Clinical and biochemical data at enrolment were compared for patients who had died and those alive for each AI subset. Patients with congenital adrenal hyperplasia or tertiary AI were excluded. 1798 patients were included (626 PAI, 1172 SAI) in the current analysis.
Results
To November 2016, 21 deaths had occurred (7 PAI, 14 SAI). Causes of death were cardiovascular ($n=8$), infection ($n=3$), unclear ($n=3$), Addisonian crisis ($n=1$), suicide ($n=2$), renal failure, drug-induced hepatitis, cachexia and brain tumour (each $n=1$). Patients who died were significantly older at enrolment than those alive (PAI, 63.4 ± 13.4 vs 50.0 ± 15.8 years, $P=0.0253$; SAI, 64.0 ± 16.6 vs 54.3 ± 16.2 years, $P=0.0250$). Interestingly, duration of AI was shorter in patients with PAI who died versus alive patients (6.5 ± 5.7 vs 16.3 ± 13.1 years, $P=0.0035$), whereas the reverse was true for SAI (20.4 ± 13.2 vs 13.7 ± 11.1 years, $P=0.0257$). There were no significant differences in sex, BMI, blood pressure, triglycerides, LDL-cholesterol, cholesterol or HbA1c between the deceased and alive cohorts. Patients who died were generally more likely to have hypertension (PAI, 85.7% vs 21.8%, $P=0.0007$; SAI, 71.4% vs 33.9%, $P=0.0076$) and diabetes mellitus (PAI, 57.1% vs 14.4%, $P=0.0112$; SAI, 28.6% vs 11.5%, ns) at study inclusion.
Conclusions
This is the first study providing detailed characteristics of AI patients who died. Hypertension and diabetes, as well as infectious diseases, appear to play a major role in mortality.

Is diabetes mellitus associated with catecholamine-secreting tumours always a secondary diabetes?

Mara Baetu[1], Ana Maria Stefanescu[1], Simona Jercalau[1], Victor Tomulescu[2], Anna-Maria Tinu[3] & Corin Badiu[1,4]
[1]'C.I. Parhon' National Institute of Endocrinology, Bucharest, Romania; [2]'Fundeni' Clinical Institute, Bucharest, Romania; [3]'N.C. Paulescu' National Institute of Diabetes, Nutrition and Metabolic Diseases, Bucharest, Romania; [4]'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Hyperglycaemia occurs frequently in catecholamine-secreting tumours due to insulin suppression or induced insulin resistance. These changes can be reversible postoperatory (postOp).
Objective
Our study aims to establish the impact of surgery in patients with catecholamine-secreting tumours upon glucose metabolism disorders, as well as the predictive factors for postOp diabetes-free patients.
Methods
We retrospectively analysed 72 patients (46 women-26 men), mean age 48 years (9–82), median body mass index 24.5 kg/m^2 (16–36.19), 66 with pheochromocytoma, 6 with paraganglioma, 3 malignant, 12 known with genetic syndromes. We evaluated their glycaemic status preoperatory (preOp), and for 64 of them postOp, with a median follow-up of 4.17 years. Glucose metabolism disorders were diagnosed according to World Health Organization criteria.
Results
We found preOp diabetes mellitus (DM) in 32 patients (44.44%). We identified significant glycaemic changes in older patients, with longer hypertensive period, higher frequency of metabolic syndrome, adrenal tumours rather than ectopic, and a higher level of ChromograninA ($P<0.05$). PostOp, 66.6% of patients were free of DM, 30% of them starting from week one postOp. We found significantly more cases of remnant DM in patients with longer duration of preOp DM ($P=0.0004$, 110-vs-10 months) and in those requiring insulin preOp ($P=0.005$). Patients with or without postOp DM did not differ in presence of metabolic syndrome (but all patients with remnant DM had metabolic syndrome), history of familial DM, tumour characteristics, clinical or laboratory findings.
Conclusions
Our study found that DM is associated frequently with catecholamine-secreting tumours and 2 thirds disappear postOp. Remnant DM suggests that DM associated with catecholamine-secreting tumours is not always a secondary DM. A longer duration of preOp DM and the fact that the glycaemic control is obtained with insulin upon tumour diagnosis are predictive factors for remnant DM.

Epithelial to mesenchymal transition in adrenocortical tumours: focus on FGF-FGFR pathway and c-MET

Iuliu Sbiera[1], Barbara Altieri[1,2], Annette Feuchtinger[3], Kerstin Höfner[1], Axel Walch[3], Martin Fassnacht[1,4], Cristina L Ronchi[1], Matthias Kroiss[1,5] & Silviu Sbiera[1,4]
[1]Division of Endocrinology and Diabetes, University Hospital, University of Würzburg, Wuerzburg, Germany; [2]Division of Endocrinology and Metabolic Diseases, Catholic University of the Sacred Heart, Rome, Italy; [3]Research Unit Analytical Pathology, Helmholtz Zentrum München, Oberschleissheim, Germany; [4]Comprehenssive Cancer Center Mainfranken, University of Würzburg, Wuerzburg, Germany; [5]Clinical Chemistry and Laboratory Medicine, University Hospital, University of Würzburg, Wuerzburg, Germany.

Ad Adrenocortical carcinoma (ACC) is an aggressive tumour and treatment remains unsatisfactory in advanced disease. Activation of epithelial to mesenchymal transition (EMT) is considered causative for metastatic spread in a variety of human cancers. Accordingly, new drugs were developed specifically targeting EMT with a focus on hepatocyte growth factor (HGF)/HGF receptor (c-MET) and fibroblast growth factor (FGF)/FGF receptor (FGFR) signalling.
We here asked whether EMT is relevant to ACC progression to evaluate the therapeutic potential of small molecule drugs targeting EMT.
Expression of FGFR family members and c-MET was analysed in 20 normal adrenal glands (NAG), 23 adrenocortical adenomas(ACA) and 27 ACC at mRNA and protein level. Expression of FGFR1-4 was quantified in FFPE tumour tissue using RNAscope mRNA *in situ* hybridization technique. c-MET mRNA was quantified by qRT-PCR. In a subset of 40 samples we quantified expression of 92 different genes involved in FGF-FGFR pathway signalling.
FGFR2 mRNA was lower in ACC compared to ACA (3.1 ± 2.1 vs 6.5 ± 2.3 mRNA copies/cell, $P=0.0005$) whereas FGFR1 (7.5 ± 5.3 vs 4.5 ± 2.9, $P=0.09$) and FGFR4 (5.1 ± 2.3 vs 2.6 ± 1.3, $P=0.002$) were higher in ACC. FGFR4 expression was higher in advanced vs localized ACC (6.2 ± 1.6 vs 3.9 ± 2.7, $P=0.03$). Pan-FGF-FGFR pathway qRT-PCR confirmed differential FGFR expression and revealed decreased expression of FGF7, FGF17 and mitogen associated protein kinases in tumours compared with NAG. In advanced ACC protein kinase c PRKCA was decreased but PRKCQ increased.
c-MET mRNA expression was significantly higher in ACC compared to ACA and NAG (0.03 ± 0.05 vs 0.01 ± 0.03 and 0.01 ± 0.02, respectively, $P=0.02$). Considering median expression as a cut-off, high c-MET expression in ACC was associated with decreased overall survival (HR = 8.8, $P=0.02$).
In conclusion, EMT appears to be relevant for adrenocortical tumourigenesis and progression. PRKCQ may be involved in EMT signalling in advanced ACC. EMT-related kinases such as c-MET and FGFR4 may be suitable treatment targets in advanced ACC.

Clinical features and treatment outcomes in a group of SDHx-related pheochromocytoma/paraganglioma patients

Helder Simoes, Pedro Antunes, Ana Pinto, Sara Donato, Valeriano Leite & Branca Cavaco
Portuguese Oncology Institute, Lisbon Centre, Lisbon, Portugal.

Introduction
Germline mutations in succinate dehydrogenase complex (SDHx) are a risk factor for developing Pheochromocytoma (Pheo) and/or Paragangliomas (PGL) (named together PPGL), being responsible for approximately 30% of cases. The precise genotype-phenotype correlations and best management strategies are still uncertain.
Objective
To characterize the clinical features and genotype-phenotype associations in a group of SDHx-mutated PPGL patients.
Methods
Retrospective analysis of all germline SDHx-mutated PPGL cases followed in a reference centre.
Results
Total PPGL patients with SDHx-mutation: 30 (16 female). SDHB-related: 18(60%); SDHD-related: 9(30%); SDHC-related: 3(10%). Mean age at diagnosis: $36,8\pm15,4$ years. Median follow-up: 94,8 months. Twenty nine patients had symptoms at diagnosis. Cathecholamine secretion was detected in 9(30%). Nine cases (30%) were malignant. Anatomical distribution: SDHB: 9 head and neck PGL (HNPGL), 5 Pheo and 5 thoraco-abdominal PGL (TAPGL) cases; SDHD: 9 HNPGL, 1 Pheo and 1 TAPGL cases. All SDHC were single non-metastatic HNPGL. Malignancy: SDHB = 44,4%; SDHD = 11,1%. Multiple PPGL: SDHB = 16,7%; SDHD = 55,6%. Family history of SDHx-related PPGL was present in 20%. Deletions in SDHB exon-1 were the most frequent genetic defect. Complete resection was achieved in 7(33,3%) and pre-surgery vascular embolization was performed in 10(47,6%) of HNPGL patients. Radiotherapy was used in 12(40%) patients (mainly unresectable HNPGL) achieving partial response/stabilization. 177Lu-DOTATOC or 131I-MIBG were used in 4. Overall, remission was observed in 33,3%, stable disease in 53% and progression in 13,3% of patients. Related morbidity was observed in 66,6% of patients, and one death occurred.
Conclusion
SDHC and SDHD patients are prone to develop single and multiple HNPGL, respectively, and SDHB patients carry increased risk of malignancy, as suggested in other studies. SDHB patients and HNPGL had the worse prognosis, the former related to malignancy, and the last to cranial nerve deficits, unresectable disease and multimodality interventions. Radiotherapy represented a good alternative in unresectable HNPGL.

Increased exosomes in endogeneous Cushing syndrome

Gloria Aranda[1], Gemma Xifra[2], Jose Manuel Fernandez-Real[2], Guillermo Garcia-Eguren[1], Gregori Casals[3], Adriana Pane[1], Mireia Mora[1], Irene Halperin[1] & Felicia A Hanzu[1]
[1]Group of Endocrine Disorders, Department of Endocrinology Hospital Clinic Barcelona, IDIBAPS, CIBERDEM, Barcelona, Spain; [2]Department of Endocrinology, Hospital de Girona 'Dr Josep Trueta'; IdIBGi Girona, CIBERobn, Girona, Spain; [3]Biochemistry and Molecular Genetics, Hospital Clinic Barcelona, Barcelona, Spain.

Exosomes are nano-sized vesicles secreted by the cells in the exatracellular fluids representing a novel way of intracellular communication. Exosomes secreted from blood cells like monocytes and platetes have been reported to be checkpoints involved in haemostatic and thrombotic response. Glucocorticoids are inducing a profound alteration of blood cells homeostasis with atherothrombotic, bleeding and immune response alterations. Hereby we quantified for the first time circulating exosomes in overt Cushing syndrome (CS) patients.
Methods
Cross sectional study in CS patients and controls. Diagnosis of CS was performed following ECE and Endo guidelines. Blood samples from active, drug naive CS patients ($n=20$) and age and sex matched controls ($n=20$) were obtained after overnight fast. Peripheral blood cells, biochemical and hormonal parameters were analyzed using standard methods. Circulatory exosomes were quantified in plasma by a sandwich enzyme-linked-immuno-sorbent assay (ExoTEST) employing a monoclonal antihuman CD9 antibody. Further exosome phenotyping and analysis is ongoing.
Results
CS patients present as compared to controls a significant increased number of CD9 positive exosomes (2.35×10^{10} vs 7.74×10^{9}/100 µl; $P=0.005$**). Absolute monocytes (MN) number and 24 h urinary free cortisol (UFC) level correlates with the number of exosomes, respectively $P=0.022$* with r:0.391 for MN and $P=0.005$** with an r:0.467 for UFC.
Conclusion
Circulatory exosomes are increased in the hypercortisolemic state of Cushing syndrome.

Tumor microenvironment increases migration/invasion of murine pheochromocytoma SDHB silenced spheroids

Vanessa D'Antongiovanni[1], Serena Martinelli[1], Susan Richter[3,4], Letizia Canu[1], Daniele Guasti[2], Paolo Romagnoli[2], Karel Pacak[5], Graeme Eisenhofer[3,4], Massimo Mannelli[1] & Elena Rapizzi[2]
[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [3]Institute of Clinical Chemistry & Laboratory Medicine, Dresden, Germany; [4]Department of Medicine III, Technische Universitat Dresden, Dresden, Germany; [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, USA.

Pheochromocytomas (PHEOs) and paragangliomas (PGLs) are rare neuroendocrine tumors. About 30-40% of Pheo/PGLs are due to a germ-line mutation in one

of the 13 main susceptibility genes which include the genes encoding the four subunits of the succinate dehydrogenase (SDH - mitochondrial complex II). In PHEO/PGL due to SDHB mutations up to 80% of affected patients develop metastatic disease and no successful cure is at present available. To obtain an experimental model resembling the *in vivo* conditions of the SDHB-mutated PHEO, we used multicellular tumor spheroids (3D culture) of a murine cell line cultured alone or in co-culture with mouse primary fibroblasts, evaluating the effects of SDHB silencing and microenvironment on invasion and migration processes. The growth of spheroids is linear with clear edges. When the spheroids are treated with conditioned medium of cancer-associated fibroblasts (CAFs), we observe an evident detachment of clusters of viable cells in the surrounding space. SDHB silenced cells show a greater migratory capability than negative control (NC) cells. In particular, SDHB silenced cells invade the surrounding space moving collectively, unlike the NC spheroids where cells tend to move individually. This difference was even more evident when spheroids were co-cultured directly with mouse primary fibroblasts. Using electronic microscopy on spheroids, we observed that SDHB silenced cells show swollen mitochondria and, alterations of mitochondrial crests (similarly to mitochondria of patients with SDHB mutations) while SDHB mutated spheroids show borders that are more fraying than those of NC spheroids. In conclusion, SDHB silencing strongly increased the invasion/migration capabilities, and these changes are more evident in SDHB spheroids co-cultured directly with primary fibroblasts. Further studies on these mechanisms may suggest new therapeutic targets.

Metformin reduces viability and proliferation of pheochromocytoma cells in vitro

Cinthia Meireles, Francisco Neves, Luiz Simeoni & Adriana Lofrano-Porto
University of Brasilia, Brasilia, Brazil.

Background
Pheochromocytomas (PHEO) are rare neuroendocrine tumors derived from chromaffin cells of the adrenal medulla. Catecholamins' secretion is associated with a high risk of cardiovascular complications. Malignancy is rare, but still demands effective treatment. Metformin has been shown to have antiproliferative properties in several cancer cell lines, possibly related to its ability to inhibit cell proliferation pathways. Accordingly, we aimed to evaluate the effects of metformin in the survival and proliferation of PHEO cells.
Methods
Cell viability was evaluated by MTT and TRIPAN assays using the PC12-Adh PHEO cell line treated with metformin in increasing concentrations (0–30 mM). A lipid peroxidation assay and determination of O_2 consumption using a respirometer were performed to evaluate cellular stress. The effects of metformin on cell proliferation markers were analyzed by western blot.
Results and Discussion
Metformin at 20 mM induced an inhibition of 60% of cell viability after 48 h treatment, as compared to untreated controls, and increased cellular lipid peroxidation, while decreased O_2 consumption in PC12-Adh PHEO cells. Moreover, metformin treatment reduced the activation of proteins of the AMPK/PTEN/AKT/mTOR pathway, which suggests growth and cell proliferation impairment. We then performed a primary culture of a PHEO from a 10-year-old boy with VHL disease to test wheter metformin exerts its antiproliferative effects *ex vivo*. Our results suggest that metformin has a moderate inhibitory effect on the viability of PC12-Adh PHEO cells. This effect is associated with enhanced lipid peroxidation and decreased O_2 consumption by those cells, which are both suggestive of increased cellular stress. Moreover, metformin treatment induced a positive modulation of the AMPK/PTEN/AKT/mTOR signaling pathway. Altogether our results corroborate the hypothesis of an inhibitory effect of metformin on PHEO cellular proliferation *in vitro*.

The role of in vivo metabolomics using H-MRS in SDH deficient disease

Ruth Casey[1,3], Mary McLean[1,2], Madhu Bassetti[2], Ben Challis[3], Helen Simpson[3], Mark Gurnell[1,3], Ramesh Bulusu[3], Alison Marker[3], Olivier Giger[1,3], Kieran Allinson[3], Krishna Chatterjee[1,3], Eamonn Maher[1,3] & Ferdia Gallagher[1,3]
[1]Cambridge University, Cambidge, UK; [2]Cancer Research UK, Cambridge, UK; [3]Cambridge University Hospital NHS Foundation Trust, Cambridge, UK.

Tumours caused by mutations in the SDH enzyme complex have a unique tumour metabolome due to a truncated citric acid cycle. The accumulation of the onco-metabolite succinate is believed to drive tumourigenesis. The aim was to investigate the role of MRI spectroscopy (H-MRS) to detect *in vivo* succinate elevations in suspected SDH deficient tumours including GIST, phaeochromocytoma/paraganglioma (PPGL) and pituitary adenomas (PA). Suitable patients were identified based on *SDH* germline status, clinical phenotype and or tumour SDHB immunonegativity. A minimum tumour size of 1.5 cm was applied. H-MRS was performed on a 3T MRI scanner and spectra with and without water suppression, was obtained. Succinate when detected, was visible on the spectra at a frequency of 2.4 ppm and a succinate to choline ratio of >0.1 was deemed confirmatory of succinate detection. H-MRS was performed on nine patients to date including four patients with GIST, 4 with PPGL and 1 with a PA. A succinate peak was detected in 7/9 patients and correlated with the immunohistochemistry (IH) and or germline status in all seven cases. H-MRS of a PA in a patient with a germline mutation in *SDHB* demonstrated no succinate peak and this correlated with the tumour SDHB immunopositivity. H-MRS successfully detected a succinate peak in a patient with a metastatic GIST and a somatic mutation in *SDHC*. This is the first study to investigate the use of in *vivo* metabolomics in SDH deficient GIST and pituitary adenomas and has proven efficacy as a non-invasive test for the identification of *in vivo* succinate peaks and detection of SDH deficient tumours. It may be particularly useful for the detection of somatic *SDH* mutations and to clarify the role of *SDH* mutations in newly identified phenotypes. Future application includes the use of *in vivo* succinate detection as a biomarker for therapeutic response.

A PRKACB somatic mutation in a cortisol producing adenoma: a new example of protein kinase A activation leading to adrenal Cushing syndrome

Stéphanie Espiard[1,4], Matthias Knape[2], Kerstin Bathon[3], Guillaume Assié[1], Daniel Abid[2], Simon Faillot[1], Davide Calebiro[3], Friedrich Herberg[2], Constantine Stratakis[4] & Jérôme Bertherat[1]
[1]Team Endocrine Tumors and Signaling, Cochin Institute, Paris Descartes University, Paris, France; [2]Department of Biochemistry, Kassel University, Kassel, Germany; [3]Institute of Pharmacology and Toxicology and Bio-Imaging Center/Rudolf Virchow Center, University of Würzburg, Würzburg, Germany; [4]Program on Developmental Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, France.

Introduction
Alterations of the cAMP signaling pathway are described in adrenal tumors causing Cushing syndrome, specifically mutations in the gene coding for the protein kinase A (PKA) catalytic subunit alpha (PRAKCA) in cortisol producing adenomas (CPA) with overt Cushing syndrome.
Materiel and Methods
Eight CPAs without PRKACA mutations were analyzed by whole exome sequencing. Direct sequencing of PRAKCB encoding for the catalytic subunit beta (Cβ) of the PKA was performed in 21 others. Interaction of WT or mutant Cβ with the PKA-regulatory subunits was studied by bioluminescence resonance energy transfer and surface plasmon resonance analysis. To study the PKA activity, phosphorylation of the synthetic PKA-substrat Kemptide was analyzed in cellulae in HEK293 cells transfected with a combination of RIα and Cβ and *in vitro* with purified proteins.
Results
A PRKACB somatic mutation p.S54L was found in one CPA, from a 41-year-old patient presenting with a severe form of Cushing syndrome. Direct sequencing of PRKACB did not show any other mutations in additional samples. Functional studies demonstrated loss of interaction between the mutant Cβ and the regulatory subunit type 1 (RIα, RIβ). After stimulation by cAMP or forskolin, dissociation of Cβ and RIα was faster and stronger with the mutant than with the WT Cβ. In addition, basal PKA activity was higher for the mutant catalytic than the wild-type while the maximal activity after stimulation was lower.
Conclusions
PRKACB is a new gene responsible for at least one CPA, mutated in the somatic state. This finding suggests that the Cβ subunit of the PKA, too, may have specific functions in the adrenal cortex. Particularly, the role of the residue Ser54 (as was previously suggested) may be very important for PKA function in the adrenal cortex.

Familial case of SDHB mutation presenting as a macroprolactinoma

Edouard Mills, Pratibha Machenahalli, Ali Naqvi & Jeannie Todd
Imperial Centre for Endocrinology, Imperial College Healthcare NHS Trust, London, UK.

Germline mutations in the succinate dehydrogenase subunit-B gene (SDHB) are well recognised for predisposing to head and neck paraganglioma, sympathetic paraganglioma, phaeochromocytoma and renal cell carcinoma. The co-existence with pituitary adenomas remains uncommon.

We report a 31-year-old female who presented at age 29 years old with 9 months of secondary amenorrhoea. Prolactin was 3000 mIU/l and a 1.7-cm macroprolactinoma revealed on MR pituitary. Taking prolactin-lowering therapy, she achieved normal menses and subsequent MRI imaging demonstrated reduction in the size of this macroprolactinoma. At age 30 years, she was found to have a paraganglioma in the aortic–pelvic region. On reflection, she had noticed anxiety, sweating, palpitations and extreme exercise intolerance for the 2 years preceding diagnosis, which resolved following surgical resection. She was screened for familial paragangliomas, which revealed she was a carrier of the SDHB mutation. Interval screening MRI neck to pelvis has since demonstrated no evidence of recurrent or new disease. Plasma metanephrines have subsequently remained normal.

Her father, aged 64 years old, was referred for genetic counselling and testing. He too is an SDHB mutation carrier. His plasma metanephrines are normal and MRI neck to pelvis has not revealed a paraganglioma or phaeochromocytoma. Both the index case and father will remain under lifelong specialist care in a Neuroendocrine Tumours Clinic. Family members have been advised to seek genetic counselling.

Although uncommon, increasing incidence of pituitary adenomas in carriers of SDH mutations are being reported. These pituitary adenomas tend to be larger with macroprolactinomas commoner than other pituitary adenomas. Screening programmes vary widely for carriers of SDH mutations and tend not to involve pituitary imaging. However, given the association with pituitary lesions, screening imaging might need to include the pituitary. At present, however, it is thought that this is likely to be a low-yield strategy.

Diffuse idiopathic pulmonary neuroendocrine cell hyperplasia with cyclical ectopic adrenocorticotrophic hormone secretion

Pratibha Machenahalli, E Mills, N Ali & JF Todd
Imperial College Hospitals NHS Trust, London, UK.

DIPNECH is pre-invasive precursor to carcinoid tumors and tmorlets, most of which present with pulmonary symptoms. We present a case of ectopic cyclical ACTH producing DIPNECH.

33-year lady presented with a short history of weight gain, abdominal striae, proximal myopathy and secondary amenorrhoea. She reported a previous episode with similar symptoms one year earlier which resolved spontaneously after a few weeks. Random cortisol 4000 nmol/l, ACTH 98 ng/l. LDDST failure to suppress cortisol levels. IPSS showed no central:peripheral ACTH gradient, representing ectopic ACTH source. CT chest showed multiple pulmonary nodules, a dominant RLL nodule larger since 2006. 68-Gallium DOTATATE PET/CT scan was normal. Metyrapone was commenced. One week later, Metyrapone was stopped due to low cortisol levels. Off Metyrapone, cortisol levels remained low with concomitant reduction of ACTH levels, indicating another spontaneous remission of Cushing's syndrome. Histology from an excision biopsy of the RLL nodule revealed tumourlets with a typical carcinoid appearance and a background of DIPNECH. Post-operatively, she was treated with hydrocortisone replacement for a couple of weeks. After a few months later symptoms of Cushing's recurred and repeat imaging of the chest has not shown any progression of the lung nodules. Repeat LDDST confirmed the biochemical excess of cortisol. She is currently awaiting bilateral adrenalectomy.

As per the literature review, DIPNECH is common in female. There is only one case presented with ACTH secretion. It is relatively a stable disease with only 26% of the patients deteriorates clinically and radiologically. Octreotide has not shown to improve the prognosis.

Long-term treatment of acute ectopic ACTH syndrome with Etomidate

Zydrune Visockiene[1,2], Vilija Guntaite[3], Vigantas Dunauskas[2], Donatas Vajauskas[1,2], Gintautas Kekstas[1,2] & Giedre Vasyliene[4]
[1]Vilnius Univesity Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Clinics, Vilnius, Lithuania; [3]Republican Siauliai Hospital, Siauliai, Lithuania; [4]Republican Panevezys Hospital, Panevezys, Lithuania.

Case description

A 25-year-old male was admitted to the Intensive Care Unit due to progressive muscle weakness, difficulty walking, weight loss, headache, chest discomfort, type 1 diabetes for few months. He was confused and irritated, with "moon" face, facial plethora, acne, and hyperpigmentation of the skin, few obscure red-bluish striae and significant wasting of proximal and distal muscles of lower limbs. Cortisol hypersecretion due to ectopic ACTH production was confirmed by plasma ACTH (> 1250 ng/l) and cortisol (1120–2145 nmol/l), 24-h urinary free cortisol (14 726 nmol/24 h), failure to supress cortisol on a high dose intravenous and 16 mg oral 2 days dexamethasone suppression tests. Severe hypercortisolemia resulted in critical fluid and electrolyte imbalance, deterioration in physical and mental state. Daily Etomidate infusion 20–60 mg for 14 days stabilized condition and later was used for treatment on alternate days in the dose of 20–40 mg for 10 months in day care clinic. Alternative treatment with Ketoconazole induced hepatic injury, Octreotide was ineffective, Metyrapone was not available. Following Etomidate infusions, plasma cortisol decreased to 280–560 nmol/l, potasium – 3.7–4.3 mmol/l with oral supplementation of KCl 3 g/day and Spironolactone 50 mg, glucose became normal without insulin. In 10 months Metyrapone became available and 1 g/day was used to achieve control. Patient refused from adrenalectomy.

Pituitary MRI, chest and abdomen CT, somatostatin receptor scintigraphy, bronchoscopy, esophagogastroduodenoscopy, colonoscopy revealed no potential source of ectopic ACTH production. Further assessment by whole body 18F-FDG PET-CT and 68Ga-DOTATOTE PET-CT scans, selective sinus petrosus inferior sampling and enteroscopy failed to detect the source of ACTH. Thorax CT and colonoscopy was performed three times, abdominal CT and pituitary MRI – twice during 16 months. Primary tumour was not detected.

Conclusion

Etomidate infusion could be used for long term treatment of ectopic ACTH syndrome when other options are ineffective or unavailable.

Multiple pathologic fractures as the presenting manifestation of Cushing's syndrome in patients with vitamin D receptor FokI gene polymorphism

Vasiliki Daraki[1], Paraskevi Floroskoufi[1], Theodoros Liarigkovinos[1], Maria Chrysoulaki[1], Vasilios Tsamadias[2], Emmanuel Economou[2] & Stathis Papavasiliou[1]
[1]Department of Endocrinology Diabetes and Metabolic Diseases, University Hospital of Crete, Heraklion, Greece; [2]Laboratory of therapeutic individualization, University of Athens, Aretaieio University Hospital, Athens, Greece.

Rare cases of Cushing's syndrome have been diagnosed only based upon bone manifestations. Fracture risk is related to individual susceptibility to glucocorticoids that is genetically determined by several factors, including VDR gene polymorphism.

We report three patients with VDR FokI gene polymorphism and multiple non-traumatic pathologic fractures as the presenting manifestation of Cushing's syndrome.

Case reports

The first case is a 55-year-old man who presented with pain in the right hip. CT scan revealed fracture in the right femur. Additionally bone scintigraphy revealed non-traumatic micro-fractures in ribs and pelvis.

The second case is a 44-year-old woman who presented with pain in the left hip. She reported weight gain (25 kg) in the last 6 years, depression, fatigue, and muscle weakness. MRI revealed fracture in the left hip, while bone scintigraphy showed multiple non-traumatic micro-fractures in ribs and right femur.

The third case is a 64-year-old woman presented with recurrent rib and low extremities fractures the last 10 years. She also suffered from depression and hypercholesterolemia.

Dual-energy X-ray absorptiometry (DXA) revealed severe osteoporosis in all patients. Additionally laboratory tests and imaging techniques confirmed the diagnosis of Cushing's syndrome due to an adrenal mass. Further investigation for FokI and Bsm polymorphism of VDR gene by polymerase chain reaction and restriction fragment length polymorphism (PCR-RFLP) analysis showed that all patients had the ff genotype of the VDR FokI gene.
Discussion
VDR FokI gene polymorphism correlates significantly with an increased rate of bone loss in ff postmenopausal women. However data of its functional significance on glucorticoid-induced osteoporotic fractures is lacking so far. We report for the first time an association between the ff genotype and multiple non-traumatic fractures as the predominant manifestation of Cushing's syndrome. Our findings suggest that VDR FokI gene polymorphism may increase fracture risk in ff subjects with endogenous hypercortisolism.

The aim of the present study was to evaluate the phenotype of PHPT, the adherence to International Guidelines and the rate of surgical cure of PHPT in Italy. From January 2014–January 2016, we conducted a prospective, multicenter ($n=29$ endocrine tertiary referral centers) study on patients with PHPT, recording clinical and biochemical data, parathyroid imaging and therapy choice at baseline and at last follow-up. The study group included 604 patients with PHPT, with a mean age of 61 ± 14 yrs (F:M = 5:1). Most patients had sporadic PHPT ($n=566$ (93.7%), mean age 63 ± 13 yrs); the remaining 38 (6.3%, mean age 41 ± 17 yrs) were familial forms. Follow up data were available in 345 patients: 158 (45.8%) with symptomatic and 187 (54.2%) with asymptomatic PHPT. Eighty-six patients (54.4%) of the former group underwent PTx, mainly for symptomatic nephrolithiasis ($n=71$, 82.6%). One hundred twenty-one asymptomatic patients (64.7%) met at least one criterion for PTx according to the 2008 International guidelines for parathyroidectomy and 65 patients (53.7%) underwent surgery. Criteria for PTX were: serum calcium levels 1 mg above the upper normal limit ($n=37$, 56.9%), osteoporosis ($n=35$, 53.8%) and age <50 yrs ($n=14$, 21.5%). Surgery was not performed in the remaining patients ($n=56$, 46.3%) despite the presence of serum calcium levels 1 mg above the upper normal limit ($n=12$, 21.4%), osteoporosis ($n=44$, 78.6%) and age <50 yrs ($n=11$, 19.6%). Surgery was also performed in 16 of the 66 (25.7%) patients who did not meet the criteria for surgery. A total of 168 patients underwent PTX. The histological diagnosis was single adenoma in 89% of cases, hyperplasia in 9%, atypical adenoma in 1%, and carcinoma in 1%. The large majority ($n=158$, 94%) of patients were cured. Persistence of PHPT was observed in the remaining 10 patients, who were apparently sporadic. Patients followed without surgery showed a stable clinical and biochemical disease, after one year of follow-up. This is the first multicenter Italian study with the specific aim of evaluating PHPT phenotype and therapeutic approach. International guidelines recommendations for surgery were observed in half of cases, either for symptomatic or asymptomatic patients.

Fat mass distribution and resistin are independent predictors of bone mass in postmenopausal, but not premenopausal women.

Stefana Catalina Bilha[1,2], Maria-Christina Ungureanu[1,2], Petru Cianga[3,4], Catalin Buzduga[1,2], Adrian Aancute[1], Valentin Zaharia[1], Daniela Constantinescu[3,4], Ecaterina Anisie[3], Adrian Covic[5,6] & Dumitru Branisteanu[1,2]

Popa" University of Medicine and Pharmacy, Iasi, Romania; [3]Laboratory of Immunology and Genetics, "Sf. Spiridon" Hospital, Iasi, Romania; [4]Immunology Department, "Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania; [5]Nephrology Clinic, "Dr. C.I. Parhon" University Hospital, Iasi, Romania; [6]Nephrology Department, "Gr. T. Popa" University of Medicine and Pharmacy, Iasi, Romania.

Introduction
Body weight and lean mass (LM) are classic bone mass determinants. However, the association between total fat mass (FM), regional FM and bone remains controversial, especially as fat is a source of adipocytokines, with both positive and negative bone consequences.
Materials and methods
Anthropometric, bone mass (assessed by Dual X-Ray Absorptiometry; DXA) and body composition parameters (assessed by DXA) and also serum adipocytokine (leptin, adiponectin, resistin) levels were determined from 93 female volunteers (38 premenopausal and 55 postmenopausal women). Correlation analysis was performed in order to assess the association between body mass index (BMI), body composition parameters, adipocytokines and bone mass. Multivariable and hierarchical regression models were used to determine which of the above factors are independent predictors of bone mass.
Results
In correlation analysis, BMI, total LM, total FM and regional FM (trunk FM and lower limbs FM) were positively associated with bone mass in both groups. Correlations between adipocytokines and bone were found only in the postmenopausal group. In multivariable regression analysis, only LM remained an independent predictor of bone mass in premenopausal women, explaining 38.1% ($P<0.001$) of femoral neck, 24.5% ($P=0.002$) of total hip and 20% ($P=0.005$) of whole-body bone mineral density (BMD) variance; in postmenopausal women, LM, trunk-to-lower limbs FM ratio (together explaining 30.9% of the variance of total hip BMD, $P<0.001$) and resistin (adipokine known to regulate bone cell proliferation and bone turnover) remained independent positive predictors of bone mass. Hierarchical regression showed no additional effect of BMI or of total FM to that of total LM in predicting bone mass in both groups.
Conclusions
LM independently predicts bone mass in premenopause, while after menopause FM distribution becomes an important factor in regulating bone mass together with total LM and resistin. These parameters may find their place for fine tuning the evaluation of fracture risk.

Aldosterone and parathyroid hormone – is there a connection?

Mara Ventura, Miguel Melo, Diana Oliveira, Diana Martins, Adriana Lages, Nelson Cunha & Francisco Carrilho
University and Hospital Center of Coimbra, Coimbra, Portugal.

Introduction
Recent studies seem to support a bidirectional positive interaction between aldosterone and parathyroid hormone (PTH). Understanding the normal physiological relationship between renin-angiotensin-aldosterone system (RAAS) and PTH is of clinical interest because their inappropriate activity may negatively impact cardiovascular and skeletal health.
Objective
To evaluate the presence of an interaction between aldosterone and PTH in a cohort of patients assessed for suspicious hyperaldosteronism or hyperparathyroidism.
Material and Methods
We retrospectively evaluated consecutive patients followed in our Endocrinology Department between January 2014 and December 2016. We collected data about renin-angiotensin-aldosterone system and calcium metabolism from clinical and laboratorial records and selected patients whenever both data were available.

Results
We identified 97 patients evaluated for suspicious hyperaldosteronism or hyperparathyroidism. 51 patients were excluded due to insufficient data. From the 46 patients included, 8(17%) had confirmed primary hyperparathyroidism and one had confirmed primary hyperaldosteronism; 74% ($n=34$) were women, mean age of 60.0 ± 13.2 years and mean BMI of 27.8 ± 4.1 Kg/m^2. This group had a mean aldosterone level of 141.9 ± 74.6 pg/ml (reference range: 40–310), PTH level of 87.3 ± 48.0 pg/ml (reference range: 9–72), 25(OH) vitamin D level of 26.5 ± 10.2 ng/ml and plasma calcium level of 9.6 ± 1.1 mg/dl (reference range: 8.8–10.6). PTH and aldosterone levels presented a moderate correlation in our cohort (rho$=0.474$, $P<0.01$). After exclusion of the patients with confirmed disease, PTH and aldosterone levels presented a week correlation, though still statistically significant (rho$=0.377$, $P=0.021$).
Conclusion
Aldosterone levels were positively correlated to PTH levels in our sample. This interaction may be one of the mechanisms responsible for hypertension and increased cardiovascular risk in patients with hyperparathyroidism. On the other hand, hyperaldosteronism may indirectly impair calcium metabolism and bone health.

Relationship between circulating microRNAs and bone mineral density in patients with active acromegaly

Elena Valassi[1], Natalia García-Giralt[2], Jorge Malouf[3], Iris Crespo[1] & Susan M. Webb[1]
[1]Endocrinology/Medicine Department, Hospital Sant Pau, Centro de Investigación Biomédica en Red de Enfermedades Raras (CIBERER 747), II-B Sant Pau, ISCIII, Universitat Autònoma de Barcelona (UAB), Barcelona, Spain; [2]URFOA, IMIM (Institut Hospital del Mar d'Investigacions Mèdiques), Universitat Autònoma de Barcelona, Barcelona, Spain; [3]Mineral Metabolism Unit, Medicine Department, Hospital Sant Pau, Barcelona, Spain.

Objective
Acromegaly (ACRO) is associated with abnormal bone remodeling and reduced volumetric bone mineral density (vBMD) at the lumbar spine and proximal femur. Circulating microRNAs (miRNAs) modulate the activity of osteoblasts and osteoclasts, and are currently being investigated as potential biomarkers of osteoporosis. The aims of our study were: 1) To identify differentially expressed miRNAs in the serum of five patients with active ACRO vs. healthy controls, and 2) To correlate selected miRNAs concentrations with altered bone parameters in 11 ACRO patients.
Patients and methods
Eleven patients with active ACRO (six females; mean age, 47.5 ± 6.7 years; BMI, 27.2 ± 3.8 kg/m^2) and 11 age-, gender-, and BMI-matched controls were recruited. Analysis of differential expression of miRs was performed in 5 of them (5 males; mean age, 44.3 ± 4.3; BMI, 26.2 ± 2.8). Areal BMD (aBMD) at lumbar spine and femur was assessed through dual energy X-ray- absorptiometry (DXA); vBMD was measured by quantitative computed tomography (QCT). Serum miRNA levels were assessed by qPCR. Osteocalcin (OC), type 1 amino-terminal propeptide (P1NP) and carboxy-terminal collagen crosslinks (CTx) were measured using electrochemiluminescent immunoassay.
Results
Expression of miR-885-5p, miR-99a-5p, and miR-29a-3p was significantly higher, while that of miR-7-1-3p and miR-335-3p was significantly lower in the ACRO patients. Both miR-885-5p and miR-7-1-3p were inversely associated with femoral aBMD ($r=-0.64$, $P=0.034$ and $r=-0.73$, $P=0.009$, respectively), and trocantheric vBMD ($r=-0.66$; $\rho=0.038$ and $\rho=0.67$; $P=0.023$) in ACRO but not in the controls. They were also positively associated with P1NP ($r=0.82$, $P=0.002$ and $r=0.79$, $P=0.004$, respectively) and CTx ($r=0.73$, $P=0.010$ and $r=0.68$, $P=0.019$) in ACRO. MiR-99a-5p was inversely associated with femoral aBMD ($r=-0.66$, $P=0.26$) and positively associated with P1NP ($r=0.83$; $P=0.001$) and CTx ($r=0.88$, $P<0.001$) in ACRO only. The relationship between femoral aBMD and miR-99a-5p remained significant after adjusting for age and IGF-SDS ($\beta=-0.52$, $P=0.012$).
Conclusions
Circulating miRNAs may be one of the mechanisms whereby BMD is impaired, mainly at the femoral level. Further larger studies are needed to confirm these preliminary data.

Effects of BCR-ABL targeted tyrosine kinase inhibitors on the whole transcriptome pattern of cultured murine osteoblasts

Bernadett Balla[1], Gyöngyi Kirschner[1], Péter Horváth[1], Gergely Lakatos[2], János Kósa[1] & Péter Lakatos[1]
[1]First Department of Internal Medicine, Semmelweis University, Budapest, Hungary; [2]Second Department of Internal Medicine, Semmelweis University, Budapest, Hungary.

Breakpoint cluster region abelson fusion oncoprotein (BCR-ABL) targeted tyrosine kinase inhibitors (TKIs) are widely used in long-term medications of hematological malignancies. Numerous clinical observations confirmed that these drugs significantly modify the physiology of bone tissue as a side effect. Currently, there are numerous contradictory results regarding the complex effects of TKIs on bone metabolism, as well as there is no clear evidence to explain them, either in the level of basic or clinical research.
The aim of the present study was to analyze the whole transcriptome differences of cultured murine osteoblasts (MC3T3E1) after imatinib or nilotinib treatment using SOLiD next generation RNA sequencing technique. Based on the cell viability test, 1 μM drug concentration and 6-day incubation period had the greatest effects on the expression profile of osteoblastic cells.
The results showed only three common up-regulated genes in the TKI-treated groups with almost the same expression activity compared to the control one. Ingenuity Pathway Analysis was applied to reveal the cellular response for the two drugs. Six and five top canonical pathways were identified from the whole transcriptome sequencing data in case of imatinib and nilotinib, respectively. GABA receptor cascade was found among the markedly upregulated signaling pathways in both of the treated groups. During the bone remodeling process, this signal transduction network is deeply involved in bone cell proliferation, differentiation and development.
In conclusion, this was the first study to observe the complete mRNA pattern of osteoblasts after selective TKI administration. These preliminary transcriptional results indicate various mechanisms of action of the examined TKIs on osteoblast function that might be due to their different chemical profiles and non-kinase target spectrum. Therefore, further investigation is required to verify the detected expression changes of the reported genes as well as to validate the biologically significant targets.

Decreased trabecular bone score but not bone mineral density in patients with acromegaly and concurrent hypogonadism: cross-sectional study with healthy controls

Martin Kužma[1], Dušan Pavai[2], Ivana Ságová[3], Zdenko Killinger[1], Peter Jackuliak[1], Anton Vaňuga[2], Peter Vaňuga[2] & Juraj Payer[1]
[1]Comenius University Faculty of Medicine, Fifth Department of Internal Medicine, University Hospital Bratislava, Bratislava, Slovakia; [2]National Institute of Endocrinology and Diabetology, Lubochna, Slovakia; [3]Comenius University Jessenius Faculty of Medicine, First Department of Internal Medicine, University Hospital, Martin, Slovakia.

Introduction
Acromegaly is associated with higher prevalence of vertebral fractures (VFx) and bone microarchitecture potentially play a role in fracture development. Trabecular bone score (TBS), a novel indicator of bone microstructure could provide additional information.
Objectives
Assessment of BMD, TBS and bone turnover markers (BTM) in acromegaly patients in comparison to healthy controls with regard to gender, hypogonadism and disease activity.
Patients and methods
A cross-sectional study of acromegaly patients with age-, gender- and BMI-matched healthy controls was conducted. Study group consisted from all acromegaly patients (regardless age, gender, disease duration or activity) which came for follow-up visit during period 6/2016 – 12/2016 and the control group consisted of healthy subjects. In all subjects a single measurements of all pituitary axis hormones levels, BTM, BMD of total hip (TH) and lumbar spine (LS) and TBS was performed. N-terminal type 1 procollagen (P1NP) - marker of bone formation and C-terminal telopeptide (CTx) –marker of bone resorption were analyzed.

Results
Thirty Seven acromegaly patients (12 males/25 females with mean age 56.7 years, mean BMI 29.8 kg/m^2) and 27 of control group subjects (seven males/20 females with mean age 59.5 years, mean BMI 30.9 kg/m^2) were included. TBS was significantly lower in patients in comparison to controls (1.16 vs 1.22; $P<0.05$), but no BMD and BTM difference was observed. Hypogonadal patients had lower TBS in comparison to patients without hypogonadism (TBS 1.13 vs 1.20; $P<0.05$) and no BMD difference. BTM were increased in hypogonadal patients (CTx 0.67 vs 0.38 ng/ml; P1NP 75.5 vs 47.5 ng/ml; both $P<0.05$). No difference in TBS, LS BMD and BTM with regard to gender was observed.
Conclusion
This study indicates that patients with acromegaly, especially those with hypogonadism, despite unchanged BMD, may have impaired trabecular bone microstructure, which can lead to increased prevalence of fractures.

Association of changes in serum urate level and bone mineral density during treatment with teriparatide: a retrospective observational study

Tomaz Kocjan[1], Gaj Vidmar[2], Antonela Sabati Rajic[1], Mojca Jensterle Sever[1], Marija Pfeifer[1], Janja Marc[3], Nina Orehek[3] & Barbara Ostanek[3]
[1]University Medical Centre Ljubljana, Ljubljana, Slovenia; [2]University Rehabilitation Institute, Ljubljana, Slovenia; [3]Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia.

Serum urate level has recently been associated with increased bone mineral density (BMD). Teriparatide, an osteoanabolic medication for osteoporosis, is associated with increased incidence of hyperuricemia. Hence, we hypothesized that changes in serum urate are associated with changes in BMD and procollagen type 1 N-terminal propeptide (P1NP) during treatment with teriparatide.
We collected data from 151 women (mean age 72 years, mean BMI 26.6 kg/m^2) with severe postmenopausal osteoporosis who had been treated with teriparatide for 2 years at our outpatient clinic. They were prescribed with vitamin D3 1000 IU daily and were instructed to ingest 1200 mg of calcium daily. BMD was measured at the three standard sites by DXA at baseline, after 12 and 24 months of treatment. Routine laboratory parameters (including serum urate), 25-hydroxyvitamin D and P1NP were measured at the same time-points. Estimated glomerular filtration rate (eGFR) was calculated. The associations were assessed using univariate correlations and multiple linear regression models (each fitted using casewise deletion of records with missing data as well as missing data imputation). Repeated-measures analysis of variance was used to verify the increase in serum urate level and stability of eGFR.
During the 2-year treatment with teriparatide, we observed no notable univariate association between change of serum urate level and change of BMD. When adjusting for basal eGFR, vitamin D sufficiency, previous bisphosphonate treatment, change of serum and of urinary calcium during the same period, we observed a weak positive association of serum urate level change with change of BMD at lumbar spine. Conversely, change of serum urate level tended to be weakly positively univariately associated with change of P1NP, but the association vanished when adjusting for the confounders listed above.
Our results may indicate that the effect of teriparatide on bone might be partly mediated by changes in serum urate level.

Coexistence of primary hyperparathyroidism with papillary thyroid carcinoma: a case series

Panagiotis Anagnostis[1], Athanasios Panagiotou[1], Fotini Adamidou[1], Savvas Rafailidis[2] & Marina Kita[1]
[1]Department of Endocrinology and Diabetes, Hippokration Hospital of Thessaloniki, Thessaloniki, Greece; [2]Euromedica Kyanous Stavros, Thessaloniki, Greece.

Introduction
Primary hyperparathyroidism (PHPT) may rarely coexist with non-medullary thyroid carcinoma (NMTC). We report the clinical manifestation and management of nine cases of synchronous PH and NMTC.
Cases
Eight women and one man were included (mean age at diagnosis: 64 ± 6.6 years). In all cases, PH was the initial diagnosis, whereas NMTC was detected incidentally, after ultrasound assessment for PH. The histological diagnosis of NMTC was classical papillary thyroid carcinoma (PTC) in all cases, with follicular subtype in four cases. In one patient, medullary carcinoma was also detected and a diagnosis of multiple-endocrine neoplasia type 2B syndrome was set. In three cases (33.3%), NMTC was multifocal. Extrathyroidal extension was detected in one case, but without metastatic disease. In seven cases (78%), maximum NMTC diameter was <10 mm (mean diameter: 7.6 ± 4.4 mm). Thyroid autoimmunity was positive in two cases.
The histological diagnosis of PHPT was single parathyroid adenoma (mean diameter: 15.4 ± 19.3 mm, in six cases on the right side) in all cases. In one case, the adenoma was intrathyroidal. Nephrolithiasis was diagnosed in one case, hypercalciuria in two, whereas low bone mass in eight patients. Preoperative mean parathyroid hormone (PTH) and total calcium concentrations were 133.5 ± 43.9 and 11.3 ± 0.8 mg/dl (corrected calcium: 11 ± 0.78 mg/dl), respectively. Cardiovascular risk factors, such as arterial hypertension, dyslipidemia and/or hyperglycemia were diagnosed in six cases (66.7%).
PH and NMTC were successfully managed with parathyroidectomy and total thyroidectomy (mean post-operative PTH concentrations: 33.3 ± 24.7 pg/ml). No case developed post-operative hypocalcemia. Prophylactic central lymph node resection was performed in one patient. No recurrence of either PH or NMTC has been reported (mean follow-up time: 3.8 ± 5.1 years).
Conclusions
NMTC may rarely be incidentally detected in patients with PH. It is usually unifocal microcarcinoma of classical PTC subtype, without extrathyroidal extension. The pathogenetic mechanisms linking these two endocrine entities are currently unknown.

Follow-up of patients with surgical hypoparathyroidism: unknown cause of renal function decline?

Tess van de Meerhaeghe, Sergei Bukowski, Elien Coudenys, David Unuane, Brigitte Velkeniers & Bert Bravenboer
UZ Brussels, Brussels, Belgium.

Background
Hypoparathyroidism is a rare endocrine disease with low calcium and insufficient parathyroid hormone levels. In most cases it is caused by thyroid surgery. The objective of this retrospective cohort study was to evaluate if the typical therapy regimens of postsurgical hypoparathyroidism with calcitriol have a negative effect on renal function.
Methods
We performed a chart analysis of patients that were seen in a tertiary care hospital in Brussels, Belgium. A total of 101 patients were identified as patients with permanent post-surgical hypoparathyroidism, based on the hospital records of patients who underwent a total thyroidectomy between 1996 and 2016, while still being treated with calcitriol. Patients with pre-existing renal insufficiency and/or active malignancy were excluded. The cohort was predominantly female of Caucasian origin. Kidney function was evaluated before and after surgery (with a maximum follow-up of 12 years), using the CKD-EPI equation.
Results
A multivariate linear regression model was used to correlate kidney function decline with the duration of calcitriol therapy, while accounting for the mean calcium-phosphate product and age. We found a statistically significant ($P=0.027$) relation between the duration of calcitriol treatment and renal function decline at a rate of 1.06 ml/min/1.73 m^2 per year of calcitriol therapy.
Conclusions
Renal abnormalities are frequent finding in patients with hypoparathyroidism. Our study, although being retrospective, is the first one to demonstrate a relationship between the duration of calcitriol therapy and progressive renal insufficiency.

Expression of hypoxia-inducible factor-1α in Calbindin-D_{9k} Knockout mice

Song Ai Kang, Seon Young Park, Jin Yong An & Eui-Bae Jeung
Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Introduction
Hypoxia-inducible factors (HIF) are the key transcription factor induced by hypoxic condition, which regulate expression of specific target genes including angiogenic factors, erythropoietin, glucose transporters, and glycolytic enzymes. Recently, many studies connected to intracellular calcium levels and regulation of HIF-1α protein level. Calbindin-D_{9k} is a cytosolic calcium-binding protein and compensate with other calcium transporter protein for maintenance of cellular calcium level. It is expressed in primarily duodenum for absorption of calcium and in kidney for resorption of calcium. The objective of this study is to investigate interaction between HIF-1α and calbindin-D_{9k}.
Materials and methods
8–10 weeks old C57BL/6 mice and calbindin-D_{9K} knockout mice were exposed to hypoxia (12±2% O2) for 3 weeks in closed polycarbonate chamber with nitrogen supply to remove the oxygen vs the normoxic groups. Calbindin-D_{9k}-transfected ACHN cells were cultured in normobaric hypoxia (1% O2), with match control in normoxic conditions. Expression of HIF-1α and glucose transporter 1 (GLUT1, a downstream gene of HIF-1α) were analyzed in mRNA or protein level.
Results
Protein level of HIF-1α was increased in calbindin-D_{9K} knockout mice compared with that of control in normoxic condition. However, increased protein level of HIF-1α of calbindin-D_{9k} knockout mice was reduced in hypoxic condition. mRNA levels of GLUT1 showed similar pattern with HIF-1α expression. In comparison to in vivo experiment, expression of HIF-1α and GLUT1 in mRNA and protein levels corresponded to that of Calbindin-D_{9k} knockout mice.
Conclusions
These results suggest that calbindin-D_{9k} can regulate expression of HIF-1α in protein level.

Chromosome 2q37 microdeletions in two cases of sporadic PHP-1B with broad GNAS imprinting defects

Arianna Pirelli[1], Francesca Marta Elli[1], Paolo Bordogna[2], Luisa de Sanctis[3], Daniele Terraris[3], Maura Arosio[1,2] & Giovanna Mantovani[1,2]
[1]Department of Clinical Sciences and Community Health, Endocrinology and Metabolic Sciences, University of Milan, Milan, Italy; [2]Endocrinology and Metabolic Diseases Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [3]Department of Public Health and Pediatrics, University of Turin, Regina Margherita Children's Hospital, Turin, Italy.

Pseudohypoparathyroidism type 1B (PHP-1B) is a rare, familial or sporadic, imprinting disorder due to the epigenetic dysregulation of the GNAS locus, whose main product is the α subunit of the stimulatory G protein (Gsα). Sporadic PHP-1B cases (spor-PHP-1B) display broad methylation abnormalities at multiple GNAS DMRs, but the underlying molecular mechanism is still unknown.
Classically, PHP-1B patients show PTH and TSH resistance, but, in the past years, also physical features of Albright hereditary osteodystrophy (AHO) were described, suggesting the existence of an overlap among PHP subtypes. Moreover, mutations in *PRKAR1A* and *PDE4D* genes, and deletions of 2q37 were reported in small subsets of clinically diagnosed PHP patients with no detectable GNAS defects, highlighting the clinical overlap with diseases in differential diagnosis. Brachydactyly-mental retardation syndrome (BDMR), associated with 2q37 deletions, may present a spectrum of clinical features, including intellectual disabilities, developmental delays, behavioural abnormalities and skeletal abnormalities, among which brachydactyly type E.
In the present study, we screened our series of spor-PHP-1B pts with ($n=21$) or without AHO ($n=33$) for BDMR-associated deletions to find modifier genes possibly involved in the phenotypic heterogeneity observed in PHP-1B, and we detected 2 different deletions (ranging from ~2.83-Mb up to ~4.5-Mb) in 2 unrelated pts with AHO. Additional analysis confirmed rearrangements and allowed to roughly delineate the genetic defects extension.
Deletions overlapped with previously described rearrangements and included several genes already proposed as causative for BDMR. Interestingly, our mutated patients displayed molecular (GNAS loss of imprinting) and endocrine characteristics (overt PTH resistance) usually absent in BDMR, although so far only one BDMR patient with raised PTH levels was described (Power et al. 1997 J Med Genet). These preliminary results prompt us to confirm the causative role of found genetic variants, and to clarify their role in the pathogenesis of specific and unexpected clinical manifestations.

Investigation of total and free 25OHD vitamin levels in patients with chronic renal failure on different dose of cholecalciferol

Erzsébet Toldy[1,2], László Kovács[3,4], Réka Németh[2], Gyuláné Szakács[4], Imre Kulcsár[3,4] & Zoltán Locsei[3]
[1]Institute of Diagnostics Faculty of Health Science, University of Pécs, Pécs, Hungary; [2]Central Laboratory, Markusovszky University Teaching Hospital, Szombathely, Hungary; [3]Department of General Internal Medicine of Markusovszky University Teaching Hospital, Szombathely, Hungary; [4]B. Braun Avitum 6th Dialysis Centre, Szombathely, Hungary.

The total 25-hydroxy-vitamin-D (t-25OHD) level reflects the vitamin-D supply, but it is also influenced by the levels of vitamin-D-binding-proteins (DBP) and albumin. The type of dialysis influences the levels of serum proteins. The 'free-hormone hypothesis' states that only the free molecules (f25OHD) can diffuse intracellular. Our aim was to evaluate the total, calculated (c-f25OHD) and direct measured (dm-f25OHD) 25OHD levels in patients with chronic renal disease on cholecalciferol.
Methods
100 patients [45 men; 55 women; 69±14 years: 40 on haemodialysis (HD), 26 chronic renal failure (CRF) both on 1000 IUD_3/day; 34 on peritoneal dialysis (PD) on 3000 IUD_3/day] were investigated. Their sera were analysed for DBP (Dako), albumin, Ca, PTHi, t-25OHD (Roche), dm-f25OHD (DIAsource).
Results
Albumin levels were significantly lower (PD:38±5 HD:40±5; CRF:43±3 g/l; $P<0{,}001$) and DBP concentrations higher (390±55 CRF:352±42; HD:323±61 mg/l; $P<0{,}001$) were in PD group. The t-25OHD and c-f25OHD were the lowest in PD (t-25OHD: 65±30; CRF:78±38; HD:79±45 nmol/l, c-f25OHD: 14±7; CRF:18±9; HD:20±11 pmol/l, $P<0.05$). There were no significant differences among dm-f25OHD levels (PD:16±5; CRF:16±6; HD:15±6 pmol/l). The highest incidence of suboptimal vitamin D supply was found in PD patients on the bases of t-25OHD (PD:65%; CRF:42%; HD:43%) and also in c-f25OHD levels. These incidences decreased significantly into 15%–23%, when dm-f25OHD was taken into consideration. Out of the three 25OHD fractions only dm-f25OHD levels gave the opportunity to prove significant relationship between PTHi/Ca and 25OHD level ($OR=3.8_{CI:1.024\text{-}14.4}$; $P=0.036$).
Conclusions
t-25OHD and c-f25OHD values underestimate the vitamin D supply particularly in PD patients. Patients on PD need much higher doses of cholecalciferol, without any differences from other two groups in dm-f25OHD levels either. Patients, who have higher dm-f25OHD level have 3.8 times higher chance for normal Ca/PTHi levels. In case of dm-f25OHD there was a significant relationship proven between 25OHD level and related biomarkers. The dm-f25OHD seems to be a reliable marker for estimation of vitaminD supply in patients with chronic renal disease.

Methylation patterns at the novel DMR of GNAS (GNAS-AS2) in pseudohypoparathyroidism 1B (PHP1B or iPPSD3) subtypes

Patrick Hanna[1], Anne Rochtus[2], Harald Jueppner[3], Deborah Mackay[4], Bruno Francou[5], Jérôme Bouligand[5], Anne Mantel[5], Elli Anagnostou[6], Dominique Gaillard[7] & Agnès Linglart[1,8]
[1]INSERM U1169, Bicetre Paris Sud, France; [2]University of Leuven, Leuven, Belgium; [3]Massachusetts General Hospital and Harvard Medical School, Boston, USA; [4]University of Southampton, Southampton, UK; [5]APHP, Pharmacogenetics and Hormonology, Bicetre Paris Sud, France; [6]Obstetrics and Gynecology, Alexandra Hospital, Athens, Greece; [7]Génétique et Biologie de la Reproduction, Centre Hospitalier Universitaire, Reims, France; [8]APHP, CMR Calcium-Phosphore, Bicêtre Paris Sud, France.

PHP1B -iPPSD3 per the new proposed classification- is a rare disorder characterized in most patients by proximal tubular resistance to PTH resulting in hypocalcemia, hyperphosphatemia and elevated PTH. Loss-of-methylation (LOM) at the Differentially Methylated Region (DMR) at *GNAS* exon A/B occurs in all PHP1B patients, but methylation changes at other DMRs within GNAS

occur in some familial and most sporadic PHP1B cases. All patients with autosomal dominant PHP1B (AD-PHP1B) due to a maternal deletion that comprises the STX16 region (del*STX16*+) present with LOM restricted to the GNAS-A/B DMR, while sporadic cases (sporPHP1B) present with broad *GNAS* methylation defects, including LOM at a novel, recently identified DMR within the *GNAS* locus referred to as antisense DMR2 (GNAS-AS2).
Objectives and patients
Characterize the methylation pattern at the GNAS-AS2 DMR in AD-PHP1B del*STX16*+ ($n=9$) and del*STX16*- ($n=5$) patients; furthermore, sporPHP1B ($n=10$) and healthy controls ($n=10$) were investigated. *STX16* and *GNAS* deletions were excluded in the del*STX16*- patients by MLPA, genomic multiplex and quantitative PCR of the *GNAS* and *STX16* regions.
Results

1. The mean methylation index at the GNAS-AS2-DMR was significantly higher in delSTX16- patients (32±14%) than in controls (24±6%), del*STX16*+ (5±2%) and sporPHP1B patients (3+1%) ($P<0.0001$).
2. Bisulfite-treated DNA of PHP1B patients with del*STX16*- was PCR amplified across the GNAS-AS2-DMR and products were cloned into pcDNA3.1. First, we identified 2 CG-rich subdomains (SD1 and SD2) within the GNAS-AS2 DMR that are separated by 184 bp. Second, in del*STX16*- patients we observed a unique pattern of methylation including an gain of methylation at SD1 and a methylation pattern at SD2 similar to that of controls, whereas both del*STX16*+ and sporPHP1B patients displayed full LOM at SD1 and SD2.

Conclusion
We have further refined the GNAS-AS2-DMR and identified a subgroup of PHP1B patients with a specific pattern of methylation at the GNAS-AS2-DMR. Our findings reinforce the hypothesis that del*STX16*- patients carry a defect in an element that controls the methylation both at the GNAS-A/B DMR and at the GNAS-AS2 DMR.

GP46

Vitamin D correction elevates apolipoprotein levels in a sex-specific manner

Nasser Al-Daghri[1], Spiros Garbis[2], George Chrousos[3], Shaun Sabico[1], Naji Aljohani[4] & Yousef Al-Saleh[5]
[1]King Saud University, Riyadh, Saudi Arabia; [2]University of Southampton, Southampton, UK; [3]University of Athens, Athens, Greece; [4]King Fahad Medical City, Riyadh, Saudi Arabia; [5]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

Numerous studies have identified several extra-skeletal health outcomes to be associated with vitamin D deficiency, yet a definitive causal link is yet to be discovered. Our recent 3D LC-nESI-FTMS proteomic analysis among normal and overweight but apparently healthy adult Saudis identified apolipoproteins, a known independent cardiovascular risk factor, as one of the serological molecular signatures that modulate vitamin D levels. The present interventional study aims to compare and validate the identified apolipoproteins among vitamin D deficient subjects that have achieved full vitamin D status correction. 199 Saudi adults [89 males, mean age 42.0±10.4; BMI 28.6±4.4 kg/m^2; 110 females, mean age 39.1±12.0; BMI 30.7±5.3] (with vitamin D deficiency [25(OH)D <50 nmol/l] were recruited and given 50 000 IU cholecalciferol (VitaD50000®) weekly for 2 months, then twice a month for 2 months, followed by daily 1000 IU (VitaD1000®) until month 6. Blood samples were taken at baseline and after 6 months. Serum 25(OH)D was measured using electrochemiluminescence and apolipoproteins (AI, AII, B, CI, CII, CIII and E) using commercially available kits. In all subjects, serum 25(OH)D increased significantly from baseline and after 6 months (32.6±11.1 vs 63.4±16.4 nmol/l; $P<0.001$). In parallel, a significant increase in apolipoproteins B, CI, CII, CIII and E (P-values <0.05) after 6 months compared to baseline was observed. After stratification according to sex, only apolipoproteins CII and CIII were significantly increased in males (P-values <0.001), and only apolipoprotein CI was significantly increased in females ($P<0.001$), showing sexual dimorphism in the effects of vitamin D with regards to apolipoprotein levels. The rest of the apolipoproteins were not significantly different pre- and post-vitamin D correction. The present study partially explains the effects of vitamin D correction in the reduction of cardiovascular risk through significant modification of apolipoproteins, particularly the apolipoprotein C class. These effects differ according to sex.

Recombinant human parathyroid hormone (rhPTH[1-84], parathyroid hormone rDNA) improves hypercalciuria in patients with hypoparathyroidism: 3-year analysis from RACE study

Bart L Clarke[1], Tamara J Vokes[2], John P Bilezikian[3], Henry G Bone[4], Douglas S Denham[5], Hak-Myung Lee[6], Michael A Levine[7], Michael Mannstadt[8], Munro Peacock[9], Jeffrey G Rothman[10], Dolores M Shoback[11], Mark L Warren[12], Nelson B Watts[13] & Alan Krasner[6]
[1]Mayo Clinic, Rochester, Minnesota, USA; [2]University of Chicago Medicine, Chicago, Illinois, USA; [3]College of Physicians and Surgeons, Columbia University, New York, New York, USA; [4]Michigan Bone and Mineral Clinic, PC, Detroit, Michigan, USA; [5]Clinical Trials of Texas, Inc., San Antonio, Texas, USA; [6]Shire Human Genetic Therapies, Inc., Lexington, Massachusetts, USA; [7]Children's Hospital of Philadelphia, Philadelphia, Pennsylvania, USA; [8]Massachusetts General Hospital and Harvard Medical School, Boston, Massachusetts, USA; [9]Indiana University School of Medicine, Indianapolis, Indiana, USA; [10]Staten Island University Hospital, Staten Island, New York, USA; [11]Endocrine Research Unit, Department of Veterans Affairs Medical Center, Department of Medicine, University of California, San Francisco, California, USA; [12]Physicians East, PA, Greenville, North Carolina, USA; [13]Mercy Health, Cincinnati, Ohio, USA.

Hypoparathyroidism (HPT) is characterised by hypocalcaemia and impaired renal phosphate excretion and calcium conservation. Oral calcium supplements and calcitriol can improve serum calcium levels but lack the physiologic effects of PTH on renal reabsorption of calcium. RACE is an ongoing open-label study evaluating the long-term safety of recombinant human parathyroid hormone 1-84 (rhPTH[1-84], parathyroid hormone rDNA) in adults with HPT (NCT01297309). In this interim analysis, we report the 3-year treatment effect with 25–100 µg/day rhPTH(1-84) on 24-h urinary calcium levels, with or without thiazide diuretics. All data are presented as mean (SD). The study cohort comprised 49 patients enrolled at 12 USA centres; 38 (78%) completed 36 months of rhPTH(1-84) treatment. Baseline demographics were as follows: 82% women, age 48 (9.8) years, HPT duration of 16 (12.5) years, 100% taking prescribed calcium supplements and calcitriol. In response to rhPTH(1-84), albumin-corrected serum calcium remained within the target range over the 3 years; 2.1 (0.17) mmol/l at baseline (i.e., start of rhPTH[1-84], $n=49$) and Month 36 ($n=36$). Treatment with rhPTH(1-84) also led to a reduction in urinary calcium, from baseline 8.9 (5.0) mmol/24 h to 6.5 (2.8) mmol/24 h ($n=35$; $P<0.05$). Urinary calcium excretion at Month 36 was similar for men compared with women, and in patients taking or not taking thiazide diuretics. Overall, 71% of rhPTH(1-84)−treated patients with baseline hypercalciuria had normal 24-h urinary calcium excretion at Month 36 ($n=12/17$). Treatment with rhPTH(1-84) improved calcium–phosphate product from baseline 3.4 (0.5) mmol^2/l^2 ($n=49$) to 2.9 (0.5) mmol^2/l^2 ($n=36$) ($P<0.0001$). eGFR was baseline 108.2 (36.4) ml/min ($n=41$) and 115.7 (47.3) ml/min ($n=36$) at Month 36 ($P<0.0772$). Over 3 years, rhPTH(1-84) maintained target levels of serum calcium and reduced urinary calcium to normal levels in HPT patients. More information is needed to understand the timing of the beneficial effect on urinary calcium excretion.

GP48

Vitamin D levels after 4 weeks of very low calorie diet (VLCD)

M[a]Ángeles Bennasar Remolar, Ignacio Pérez Catalán & María Guinot Soler
Hospital General Universitario, Castellón, Spain.

Introduction
Vitamin D is a liposoluble molecule which takes part in calcium–phosphorous homeostasis of the human body. Its optimum levels according to SEIOMM range between 30 and 75 ng/ml. Being liposoluble substances they require the presence of biliar salts for their absorption; 80% is absorbed in the yeyune and in a lesser extent in the duodene. The correct concentration of vitamin D is of key significance in obesity, particularly its visceral type. An excessive body weight is thought to represent a significant determinant of a reduced vitamin D concentration in serum. Due to its high metabolic activity, visceral adipose tissue promotes sequestration and alterations in turnover of the vitamin-resembling hormone. Care for elimination of the factors which promote deficiencies is particularly essential in obese persons in whom degree of adiposity correlates with reduced concentrations of this vitamin in blood. Given the

importance of this vitamin in the body we have analysed its levels in obese patients which were going to follow a VLCD (600 kcal) before undergoing bariatric surgery. The patients followed a VLCD during 4 weeks before the surgery. The values of vitamin D were analysed at two different moments: before beginning the diet and after the diet, 4 weeks later.
Method
We have designed a prospective observational study; 18 patients were analysed with IMC >35 kg/m^2 with associated comorbility or IMC >40 kg/m^2, between 18 and 60 years old, candidate for bariatric surgery with laparoscopic gastric by-pass. Vitamin D concentrations were monitored at two different moments: 1 month before surgery and at the moment of surgery, 4 weeks after the VLCD.
Objective
To establish whether there are statistically significant variations in the values of vitamin D before and after following a VLCD.
Results
We obtain an average level of vitamin 25 (OH) D of 16,31 ng/ml in the analytical evaluation 1 month before surgery and 21,32 ng/ml at the time of the surgery, which takes place at the end of the VLCD. Statistically significant differences are observed between the levels of vitamin 25 (OH) D 1 month before surgery and at the time of the chirurgical act.
Conclusions
According to the results, patients that follow a 4-week VLCD significantly improve the levels of vitamin 25 (OH)D in blood. Those levels do not reach a normal level after the diet, however it is evident the benefit of the recommended process, and it would be interesting to evaluate in the long term if such a tendency remains.

Introduction
Upper gastrointestinal (UGI) symptoms are frequently encountered in patients with primary hyperparathyroidism (PHPT). Some of these symptoms may improve after PHPT treatment, while hypercalcemic state may also cause permanent effects. We aimed to evaluate UGI symptoms, UGI endoscopic and pathologic features and determine the relationship between these features with serum chromogranin A (CgA) and gastrin in PHPT patients.
Methods
Seventy-one patients diagnosed with PHPT were included in the study after exclusion of patients who refused UGI endoscopy, had an UGI surgery or used drugs that affect serum chromogranin A or gastrin. Patients were questioned regarding UGI symptoms. Serum CgA and gastrin were measured. Endoscopy was performed and gastric biopsy specimens were taken to evaluate atrophic gastritis.
Results
There were 60 females and 11 males, and median age was 52 years. Mean serum CgA and gastrin levels were 134.10 ± 19.43 ng/ml (28-620) and 219.39 ± 48.6 pg/ml (14-2255), respectively. Dyspepsia, epigastric pain and weight loss were the most common symptoms and presented in 61, 51.7 and 46.6% of patients, respectively. *Endoscopy* was *normal* in 25(35.2%) patients. Erosive antral gastritis, atrophic gastritis, gastric ulcers, duedonal ulcers, reflux gastritis and nodular gastritis were present in 14 (19.7%), 12 (16.9%), 6 (8.5%), 5 (7%), 4 (5.6%) and 4 (5.6%) patients, respectively. Intestinal metaplasia, gastric atrophy, gastric neuroendocrine tumor and Helicobacter pylori infection were detected in 29.2, 20, 1.4 and 66.2% of patients, respectively. Serum CgA was similar in patients with and without atrophic gastritis, while serum gastrin was higher in patients with atrophic gastritis ($P=0.024$). Presence of intestinal metaplasia and Helicobacter pylori infection did not affect serum CgA and gastrin levels.
Conclusion
Dyspeptic symptoms are common in patients with PHPT. The frequencies of atrophic gastritis and peptic ulcers are increased. We think that patients with PHPT should be questioned for UGI symptoms and evaluated with UGI endoscopy when needed.

Localisation of parathyroid adenomas using ^{11}C-methionine-PET/CT when conventional imaging methods are negative

Lassi Nelimarkka[1,7], Aapo Ounaslehto[7], Eija Eloranta[4], Leena Moilanen[5], Saija Hurme[3], Marko Seppänen[2,6] & Pirjo Nuutila[1,2]
[1]Turku University Hospital, Department of Medicine, Division of Endocrinology, Turku, Finland; [2]Turku PET Centre, Turku University Hospital, Turku, Finland; [3]Department of Biostatistics, University of Turku, Turku, Finland; [4]Department of Medicine, Division of Medicine and Pulmonary Diseases, Oulu University Hospital, Oulu, Finland; [5]Division of Endocrinology, Department of Medicine, Kuopio University Hospital, Kuopio, Finland; [6]Department of Nuclear Medicine, Turku University Hospital, Turku, Finland; [7]Department of Medicine, University of Turku, Turku, Finland.

In primary hyperparathyroidism (pHPT) an exact localization of the pathological parathyroid gland(s) is essential before minimally invasive parathyroidectomy. We have previously shown in a small group of pHPT patients, that ^{11}C-methionine-PET/CT provides additional information if ^{123}I/^{99m} Tc-sestamibi (MIBI) scan remains negative. The aim of the present study was to evaluate the clinical value of ^{11}C-Met-PET/CT in a larger pHPT patient cohort.
Methods
Totally 89 patients with pHPT (66 females, 23 males, age 18-81 years) and negative or inconclusive localisation findings with ^{123}I/^{99m}Tc- MIBI-SPECT/CT (78,7%) or ^{99m}Tc-MIBI-SPECT/CT (21.3%) were studied with ^{11}C-Met-PET/CT. Most of the patients (87.6%) were surgical treatment naive and the rest of them (12.4%) were previously operated 1–2 times.
Results
^{11}C-Met-PET/CT revealed the pathologic parathyroid gland in 48 (60.8%) of the 79 surgically treated patients. Totally 26 patients (32.9%) had a negative ^{11}C-Met-PET/CT finding and 16 of them had further explorative surgery, whereas 10 of these Met-PET negative patients were not operated, but treated conservatively instead. In five cases (6.3%) Met-PET detected a false-positive finding, i.e. the pathological parathyroid gland was found in another location. On a per-lesion level PET results were 48 true positive (60.8%) and 21 false negative (26.6%). The lesion-based sensitivity was 75.4% (positive predictive value 94.6%) and specificity 40.0% (negative predictive value 10.5%). The diagnostic accuracy of ^{11}C-Met-PET/CT in this study was 73%. Based on the histological examinations 67 adenomas (84.8%) and six hyperplastic (7.6%) parathyroid glands were found. In five cases the finding was normal parathyroid tissue or unspecified. Ten patients (12.7%) had more than one pathological parathyroid glands. There were no parathyroid carcinomas detected in this study. Totally 79 patients had parathyroid surgery and 55 (69.6%) of them were biochemically cured, but in 16 patients (20.3%) pHPT persisted and in eight patients (10.1%) the postoperative status remained unknown.
Conclusion
^{11}C-methionine-PET/CT offers an additional noninvasive imaging method to localize hyperfunctiong parathyroid glands in a situation when conventional imaging methods ^{99m}Tc or ^{123}I/^{99m}Tc-sestamibi SPECT/CT fail or are equivocal.

Calcium to phosphorous ratio (Ca/P) as helpful index to recognize primary hyperparathyroidism, but not primary hypoparathyroidism: a big-data approach

Sara De Vincentis[1,2], Daniele Santi[1,2], Vincenzo Rochira[1,2], Monica Setti[3], Simonetta Tagliavini[4], Manuela Varani[4], Tommaso Trenti[4], Manuela Simoni[1,2] & Bruno Madeo[1,2]
[1]Unit of Endocrinology, Department of Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Endocrinology, Department of Medicine, Endocrinology, Metabolism and Geriatrics, Azienda OU of Modena, Modena, Italy; [3]Service of Clinical Engineering, Azienda USL of Modena, Modena, Italy; [4]Department of Laboratory Medicine and Pathological Anatomy, Azienda USL of Modena, Modena, Italy.

Background
Primary hyperparathyroidism (HyperPT) and primary hypoparathyroidism (HypoPT) are often underdiagnosed. Several strategies have been investigated in the past in order to identify diagnostic parameters, although the diagnosis of both HyperPT and HypoPT remains challenging so far, especially in asymptomatic patients. Calcium (Ca) and phosphorus (P) are inversely related together, thus the Ca/P ratio could be an useful tool to define these conditions. Recently, we proposed for the first time a cut-off of 3.5 for Ca/P ratio for the diagnosis of HyperPT.
Aim
To evaluate the diagnostic value of the Ca/P ratio for HyperPT and HypoPT through a big-data approach.
Methodology
A retrospective, observational, case-control study on big-data was carried out. All examinations of parathyroid hormone (PTH), Ca and P performed at the laboratory of Modena Hospital from 2010 to 2016 were consecutively included. We considered only patients between 18 and 90 years of age. Laboratory ranges of normality for both PTH and Ca were used to divide records in HyperPT, HypoPT and controls.
Statistical analysis
The diagnostic accuracy of Ca/P ratio was investigated using receiver operator characteristics (ROC) curves in order to define cut-off points, which show higher sensitivity and specificity for the identification of affected patients.
Results
46 597 records were considered. 576 HyperPT (1.2%), 323 HypoPT (0.7%) and 45 698 controls (98.1%) were found. Ca/P ratio was significantly different among groups ($P<0.001$). In particular, Ca/P ratio was significantly higher in HyperPT than controls ($P<0.001$). For the diagnosis of HyperPT, the threshold of 3.17 for Ca/P ratio was obtained by means of the ROC curve analysis, with 85% of both sensitivity and specificity. HypoPT showed lower Ca/P ratio compared to controls ($P<0.001$), although no useful threshold for the diagnosis was found at ROC curve because of the low sensitivity.
Conclusions
We confirm the high sensitivity and specificity of Ca/P ratio for the diagnosis of HyperPT using the largest cohort of patients available so far in the literature. On the contrary, Ca/P ratio does not contribute to identify patients with HypoPT and further researches are needed to better describe this condition. In conclusion, Ca/P ratio is a simple and inexpensive diagnostic tool to recognize HyperPT.

Liraglutide prevents right ventricle hypertrophy by avoiding ACE1 & ACE2 reduction in an experimental model of idiopathic pulmonary fibrosis

Juan Fandiño, Laura Toba, Hugo Ogando, Yolanda Diz, Lucas González & Federico Mallo
Biomedical Research Centre (CINBIO, Vigo, Galicia, Spain.

The Glucagon-like peptide-1 (GLP-1) receptor is expressed in the lung having a very important role in the modulation of the Angiotensin Converting Enzymes (ACEs). ACE1 cleaves angiotensin-I into angiotensin-II, which is converted by ACE2 to Ang(1-7). Ang(1-7) has vasodilating effects. The Idiopathic Pulmonary Fibrosis (IPF) is characterized by excessive extracellular matrix deposition disrupting the alveolar architecture and physiology. IPF develops by a sequence of inflammation multifocal process that leads to a fibrotic response. IPF presents pulmonary hypertension and right ventricle hypertrophy.
The aim of this study is to elucidate the effect of precocious treatment with LIR during the inflammatory phase of IPF in ACE1 & ACE2 in the late fibrotic phase in an experimental model of IPF.
IPF was induced in rats by a single intra-tracheal instillation of Bleomycin (BLM, 2.5 mg/kg) on day 0 (D0). From day −1 to day 6, animals were treated with Liraglutide (LIR, 100 μg/kg/12h subcutaneous). On D21 rats were sacrificed. Heart ventricles and lungs were isolated, weighted and frozen. Histology of lungs confirmed interstitial lung fibrosis in all BLM-treated rats.
The real time-PCR levels of ACE-1 & ACE-2 were lower in lungs of BLM-IPF than in controls (40% and 48% reduction, respectively). Right ventricle weight was markedly increased in BLM-IPF rats (+66%). The treatment with LIR at the beginning of the inflammatory phase completely restored the levels ACEs at the fibrotic phase (21D), and prevented the right ventricle hypertrophy.
In conclusion BLM instillation causes local injury with inflammation and alteration of lung vasculature with pulmonary hypertension reflected by right ventricle hypertrophy and related to a reduction in the expression levels of ACEs in the lung, especially ACE2. The precocious LIR treatment in the inflammatory phase prevented all these pathogenic alterations.

Clinical, laboratory and cardiac parameters in overt primary hypothyroidism versus overt central hypothyroidism

Melania Balas[1], Florina Parv[2], Mihaela Vlad[1], Ioana Golu[1], Daniela Amzar[1] & Ioana Zosin[1]
[1]Department of Endocrinology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; [2]Department of Cardiology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background
Hypothyroidism affects cardiac function, leading to cardiomyopathy, pericarditis, lower left ventricular performance, etc. The present study investigates different parameters (clinical, hormonal, biochemical, echocardiographic) in overt primary hypothyroidism (OPHypo) and overt central hypothyroidism (OCHypo).
Material and methods
The study included 33 untreated patients with OCHypo (5 with empty sella, 3 with idiopathic hypopituitarism, 7 with Sheehan's syndrome, 18 with different types of pituitary macroadenomas, before or after surgery) and 67 cases with OPHypo, respectively with chronic autoimmune thyroiditis. Among the patients with OCHypo, 4 presented partial pituitary insufficiency (2 cases on gonadotropins and TSH secretion and 2 cases on growth hormone and TSH secretion), the rest of the cases showing global pituitary insufficiency. Patients with acromegaly and Cushing's disease were excluded.
Results
The clinical picture was more severe in OPHypo as in OCHypo (dominated by fatigue, edema, dry skin, neurological alterations). The values of serum thyroxin were significantly lower in OPHypo ($P<0.0001$). 40% of OPHypo patients presented pericarditis, as compared to OCHypo (2 cases, $P=0.0003$). No statistical differences were noted between the two groups, regarding heart rate, systolic and diastolic blood pressure values, isovolumic contraction time. Nonetheless, the isovolumic relaxation time was significantly higher in OPHypo group (91.8 ± 8.5 ms), as in OCHypo (80.2 ± 9.9 ms, $P<0.0001$). Coronary artery disease was more common in OPHypo group (21 cases, 31.3%), as compared to OCHypo (5 cases, 15.1%, $P=0.095$). Hyponatremia was recorded in 4 patients with OPHypo and in 3 cases with OCHypo ($P=0.68$). The values of serum total cholesterol, LDL-cholesterol, glycemia, creatin-kinase, transaminases, creatinine were significantly higher in OPHypo group, correlated to lower values of serum thyroxin. The incidence of anemia was similar in both groups (18 cases in OPHypo group, 6 cases in OCHypo group, $P=0.456$).
Conclusion
The metabolic and cardiac parameters were more profound altered in primary hypothyroidism, as compared to central hypothyroidism.

Correlation between triglyceride glucose index (TyG) and coronary artery calcification in Korean adults

Jihong You, Kahui Park, Jung Hye Kim, Sang Bae Lee, Yusik Kim, Ji sun Nam, Jong Suk Park & Chul Woo Ahn
Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective
Triglyceride glucose (TyG) index is considered a surrogate marker of insulin resistance, and insulin resistance is known risk factor of cardiovascular disease. Until now, few studies have investigated the relationship between TyG index and coronary artery calcification (CAC), thus we investigated the correlation between TyG index and CAC in healthy Korean Adults.
Methods
A total of 4,463 participants underwent cardiac computed tomography in health promotion center were enrolled. TyG index was calculates as ln[fasting triglycerides(mg/dl) X fasting glucose(mg/dl)/2]. Multi-detector CT was used to measure coronary artery calcium score (CACS) and CACS > 0 was defined as the presence of CAC.

Results
There were significant differences in cardiovascular parameters among the groups and the prevalence of CAC significantly increased with TyG index levels. In the logistic regression analysis after adjusted for multiple risk factors, the odds ratios (95% CI) for the prevalence of CAC were 1.0, 1.03 (0.72–1.45), 1.23 (0.85–1.74), 1.68 (1.15–2.44) for increasing TyG index level ($P<0.05$).
Conclusion
There was a significant association between TyG index and prevalence of CAC. TyG index, a simple measure reflecting insulin resistance, might be useful to the indicator of atherosclerosis. TyG index is even simple to calculate and seems a useful marker of atherosclerosis, and reflect cardiovascular risk.

Both oral and vaginal combined hormonal contraceptives induce unbeneficial metabolic effects in women with PCOS: a randomized study

Maria-Elina Mosorin[1,2], Terhi Piltonen[1,2], Juha Tapanainen[3,4] & Laure Morin-Papunen[1,2]
[1]Department of Obstetrics and GynecologyOulu University Hospital, Oulu, Finland; [2]Department of Obstetrics and Gynecology, PEDEGO, MRC, University of Oulu, Oulu, Finland; [3]Department of Obstetrics and Gynecology, University of Helsinki, Helsinki, Finland; [4]Department of Obstetrics and Gynecology, Helsnki University, Helsinki, Finland.

Oral combined hormonal contraceptives (CHCs) have been suggested to induce more unbeneficial metabolic effects than vaginal CHCs. CHCs are used routinely to treat the clinical symptoms of polycystic ovary syndrome (PCOS), but there are no studies investigating whether the vaginal route is safer in women with known metabolic risks.
Twenty-five women with PCOS defined according to the Rotterdam criteria were randomized to use either oral contraceptive pills (desogestrel-ethinylestradiol) ($n=14$) or contraceptive vaginal rings (etonogestrel-ethinylestradiol) ($n=11$) continuously for 9 weeks. Blood samples were drawn and OGTT performed at baseline and at 9 weeks.
Serum levels of SHBG increased and consequently the free androgen index (FAI) decreased in both study groups from baseline to 9 weeks of treatment [oral: 3.2 (95% confidence interval, CI: 2.2; 4.3) to 0.7 (0.5; 1.0); vaginal: 3.8 (1.8; 5.8) to 0.6 (0.5; 0.8), $P\leq0.003$ in both groups]. Insulin sensitivity was reduced at 9 weeks according to the Matsuda index [oral: 2.5 (0.1; 4.8) to 0.2 (0.2; 0.3), $P=0.035$]; vaginal: 3.0 (0.4; 4.4) to 0.2 (0.1; 0.2), $P=0.366$]. Serum levels of triglycerides [oral 0.9 (0.7; 1.2) to 1.3 (0.8; 1.8) mmol/l, $P=0.132$; vaginal 0.8 (0.6; 1.0) to 1.3 (0.9; 1.7) mmol/l, $P=0.003$] hs-CRP ($P=0.034$) and the AUCglucose during the OGTT ($P=0.017$) rose significantly only in the vaginal group. The AUCinsulin (oral: $P=0.36$, vaginal: $P=0.16$) increased non-significantly from baseline to 9 weeks in both treatment groups. There were no differences in serum levels of glucose, insulin, hs-CRP, lipids or testosterone between the treatment groups at baseline or after 9 weeks.
Against our hypothesis, vaginal CHCs were not metabolically safer than oral CHCs. These results emphasize the importance of monitoring glucose metabolism during CHC use regardless of the route of administration, especially in PCOS women displaying typically risks of type 2 diabetes or cardiovascular diseases.

GP56

PCSK9 in relation to coronary damage severity in patients with cardiovascular disease

Nan Hee Cho, Kwi Hyun Bae, Gwon Soo Jung, Mi Jin Kim, Yeon Kyung Choi, Jung Beom Seo & Keun Gyu Park
Kyungpook National University Hospital, Dae Gu City, Republic of Korea.

Proprotein convertase subtilisin/kexin type 9 (PCSK9), a circulating protein that promotes degradation of the low density lipoprotein (LDL) receptor, has been emerged as a novel therapeutic target for the dyslipidemia. It is well known that the pathogenesis of cardiovascular disease (CVD) involves lipid metabolism alteration, but the predictive value of circulating PCSK9 level concerning coronary disease severity is largely unknown. The main objective of this study is to determine whether circulating PCSK9 concentration is linked to coronary damage severity in patients with acute coronary syndrome (ACS). We studied 137 patients with ACS who underwent coronary angiography. The study population was divided into two groups depending on the presence of coronary artery lesion (lesion (+): $n=112$, lesion (−): $n=25$). Baseline characteristics and PCSK9 levels were measured and coronary lesions were evaluated using the SYNTAX scoring system. After adjustment for established CVD risk factors including age, body mass index (BMI), total cholesterol and low-density lipoprotein-cholesterol (LDL), ACS patients with coronary artery lesion have significantly higher PCSK9 levels than patients without lesion (178.26 ± 63.9 ng/ml vs. 223.0 ± 76.1 ng/ml, $P=0.026$). Spearman's correlations revealed that PCSK9 was positively associated with the number of involved coronary artery (Pearson coefficient, 0.034; $P=0.01$) and the global registry of acute coronary events (GRACE) risk score which is a risk prediction tool applicable for ACS patients (Pearson coefficient, 0.209; $P=0.015$). Furthermore, we found that plasma PCSK9 level was positively correlated with SYNTAX score (Spearman's $R=0.115$, $P=0.048$). In the present study, we show that Serum PCSK9 concentration is associated with angiographic severity of ACS and GRACE score after adjustments for established CVD risk factors. Further studies are needed to confirm this observation.

DOI: 10.1530/endoabs.49.GP56

Clinical significance and hormonal relationships of visceral adiposity index (VAI) in independently living old subjects

Mireia Mora[1,2], Elisabet Palomera[3], Mateu Serra-Prat[3] & Manel Puig-Domingo[4]
[1]Department of Endocrinology and Nutrition1, Hospital Clínic i Universitari of Barcelona, Barcelona/, Spain; [2]Group of Endocrine Disorders, IDIBAPS, Barcelona, Spain; [3]Research Unit and Ciberhep, Hospital de Mataró, Mataró, Spain; [4]Department of Endocrinology and Nutrition, Hospital Universitari Germans Trias i Pujol, Badalona, Spain.

Introduction
The Visceral Adiposity Index (VAI) has been proven to be an indicator of adipose distribution and function that indirectly expresses cardiometabolic risk, in particular in specific populations such as women with polycystic ovary syndrome, acromegaly or type 2 diabetes. Little information is known about its usefulness in the definition of cardiometabolic risk in ageing population.
Objective
To study VAI in relation to metabolic and hormonal data, frailty and mortality in non-institutionalized people more than 70 years old of the Mataró Ageing Study.
Methods/Design
289 participants (142 men/147 women) were included. Individuals were characterized by anthropometric variables, metabolic syndrome (MS) parameters by IDF and ATP-III as well as hormonal factors (TSH, free-T4, growth hormone, IGF-I, ghrelin, cortisol, dehidroepiandrosterone –DHEA-, DHEAs, testosterone, SHBG, estradiol, estrone, cortisol/DHEA and cortisol/DHEAs), grip strength, Barthel and assessment of cognitive impairment (MiniCognoscitive Examination -MCE- Spanish version) and frailty by Fried criteria. VAI was calculated according to Amato et al.
Results
The whole cohort showed a statistically significant association of the individual components the MS with VAI. In women but not in men, a lineal trend association was observed between the prevalence of diabetes and VAI categorized in quartiles. However, VAI showed no association in our sample population with the presence of cardio or cerebrovascular disease. The multiple regression analysis showed that ghrelin ($B=-0.240$, $P=0.005$) and SHBG ($B=-0.199$, $P=0.034$) were the only hormonal variables independently associated to VAI in women, while no associations were found in men. After a prospective follow-up of two years, those individuals with higher VAI at basal time point were associated to frailty condition at two years (media (SD): 2.47 (2.19) in frail vs 1.71 (0.97) in non-frail, $P=0.064$). No significant association was found between VAI and mortality 2 and 8 years follow-up.
Conclusions
VAI does not provide additional information to MS criteria in ageing individuals in relation to cardiovascular risk or mortality in our population. However, VAI was associated to frailty in the whole cohort, and in women, with diabetes and ghrelin.

Circulating levels of miR24-1 cluster microRNAs are increased in primary aldosteronism

Josie van Kralingen[1], Cali Anderson[1], E. Marie Freel[1], John M. Connell[2], Scott M. MacKenzie[1] & Eleanor Davies[1]
[1]University of Glasgow, Glasgow, UK; [2]University of Dundee, Dundee, UK.

Introduction
Measurement of microRNA (miRNA) in aldosterone-producing adenoma (APA) tissue from primary aldosteronism (PA) patients show levels of the miR24-1 cluster miRNAs (i.e. miRNAs 24-1, 27b and 23b) are significantly reduced relative to normal adrenal tissue. Our previous studies also show that miRNA-24 directly targets *CYP11B2* (aldosterone synthase) gene expression. Circulating miRNAs released into the bloodstream may be diagnostic biomarkers or signalling molecules. Here, we assessed whether circulating levels of miR24-1 cluster miRNAs differ significantly between PA patients and essential hypertensives, and whether they correlate with relevant phenotypic traits.
Methods
Patients with essential hypertension patients ($n=18$) were drawn from the British Genetics of Hypertension (BRIGHT) study and matched with 18 confirmed PA patients for age, gender and systolic blood pressure. Circulating miRNA was isolated from 200 μL EDTA plasma and analysed using quantitative realtime assays for miRNAs 24, 27b and 23b.
Results
PA patients had significantly increased circulating levels of miRNAs 24 ($P<0.05$) and 23b ($P<0.0001$) relative to primary hypertensive patients; there were also trends towards higher miRNA-27b but this was not significant. MiRNA-23b negatively correlated with diastolic pressure ($P<0.05$), left ventricular mass ($P<0.01$) and age ($P<0.05$). MiRNAs 27b and 23b positively correlated with BMI ($P<0.05$).
Conclusions
We have identified and validated increased circulating miR24-1 cluster miRNA levels in PA patients. These contrast with the significantly reduced levels of these miRNAs observed in APA tissue. Interestingly, miR-24 has been proposed to act as a feedback signal, repressing *CYP11B2* expression when aldosterone levels are high. Therefore, increased secretion of these miRNAs into the circulation may be the result of high aldosterone levels and be intended to suppress its release. Future studies will examine the role of these miRNAs in the aetiology and pathology of PA.

Body composition and testosterone determined VO2max in 780 young men – results from the Odense Androgen Study

Louise Lehmann Christensen, Torben Leo Nielsen, Pernille Hermann, Dorte Glintborg & Marianne Andersen
Odense University Hospital, Odense C, Denmark.

Background
Cardiorespiratory fitness is a measure for physical activity and a prognostic health indicator. However, measurement of maximal oxygen consumption (VO2max) is not possible in clinical practice.
Aim
We hypothesized that body composition and testosterone levels could be used as possible determinants of VO2max in young men.
Participants and design
The Odense Androgen Study, a population-based, observational study including 780 men aged 20–30 years. VO2max (ml/min/kg 0.73) was indirectly measured by a mechanically braked cycle ergometer. Fat mass (%) and lean body mass (%) were assessed by whole-body DXA scans. Total testosterone levels (nmol/l) were measured (RIA using extraction and chromatography). SHBG levels (nmol/l) were determined by immunoluminometric assay. Bioavailable and free testosterone were calculated.
Results
Descriptive data of the subjects were BMI 24.4 kg/m^2 (22.4–26.6), waist 88 cm (82–94), percentage lean body mass 79.1% (75.6–82.5), percentage fat mass 17.2% (18.8–21.1), total testosterone 20.7 nmol/l (17.0–25.4), SHBG 27 nmol/l (21–34) and VO2max 160.3 ml/min/kg 0.73 (143.3–177.6) (median (interquartile range). In bivariate analysis, lean body mass (%) ($r=0.62$), SHBG ($r=0.26$), total testosterone ($r=0.24$), and free testosterone ($r=0.13$) were positively associated with VO2max, whereas fat mass (%) ($r=-0.63$) and waist ($r=-0.47$) were negatively associated with VO2max (all $P<0.001$). Fat mass (%) and lean body mass (%) were closely associated ($r=-0.998$, $P<0.001$). In multivariate regression analysis, models with VO2max as the dependent variable and lean body mass (%) or fat mass (%) as independent variables were the best predictors of VO2max (both models $R2=0.47$), whereas the models including testosterone (total, free or bioavailable testosterone) or SHBG as independent variables had lower R2 values ($R2=0.09$–0.13). All models were adjusted for age and smoking.
Conclusion
Body composition measures were the best predictors of VO2max in young men. VO2max was more closely associated with waist than testosterone or SHBG.

Probiotics and nutraceuticals as a new frontier in obesity prevention and management

Nazarii Kobyliak[1], Tetyana Falalyeyeva[2], Petro Bodnar[1] & Tetyana Beregova[2]
[1]Bogomolets National Medical University, Kyiv, Ukraine; [2]Taras Shevchenko National University of Kyiv, Kyiv, Ukraine.

Introduction
The beneficial interaction between the microbiota and humans is the way how bacteria contained within the gut 'talk' to the immune system. Into this landscape probiotics and nutraceuticals play a major role. The study **aims** to determine whether probiotics plus nutraceuticals such as smectite or omega-3 are superior to probiotic alone on the monosodium glutamate (MSG) induced obesity model in rats.
Methods
Totally 75 rats divided into five groups were included ($n=15$, in each). Rats of group I were intact. Newborns rats of groups II-V were injected with MSG. The III (Symbiter) group received 2.5 ml/kg of multiprobiotic "Symbiter" containing concentrated biomass of 14 probiotic bacteria genera. The IV (Symbiter-Omega) and V (Symbiter + Smectite) groups received combination of probiotic biomass supplemented with flax and wheat germ oil (250 mg of each, concentration of omega-3 fatty acids 1–5%) or smectite gel (250 mg) respectively. Anthropometric, biochemical parameters of lipid and carbohydrate metabolism, and level of proinflammatory cytokines (IL)-1β, IL-12Bp40, INF-γ) and anti-inflammatory cytokines (IL-4, IL-10, TGF-β) were measured.
Results
In all interventional groups significant reduction of total body and VAT weight as compared to MSG-obesity were observed. However, the lowest prevalence of obesity was noted for Symbiter-Omega (20% vs 33.3% as compared to other interventional groups). Moreover, supplementation of probiotics with omega-3 lead to more pronounced decreasing of HOMA-IR (2.31 ± 0.13 vs 4.02 ± 0.33, $P<0.001$) and elevation of adiponectin level (5.67 ± 0.39 vs 2.61 ± 0.27, $P<0.001$) as compared to obesity group. Both nutraceuticals combination with probiotic and probiotic alone equally attenuated inflammation that was confirmed by the decrease of the pro-inflammatory and the activation of anti-inflammatory system.
Conclusion
Probiotics and nutraceuticals led to a significantly lower prevalence of obesity, reduction of insulin resistance, total and VAT weight. Our study demonstrated that supplementation of probiotics with omega-3 may have most beneficial antiobesity properties.

Constructing a long-acting leptin analogue

Suleyman Nahit Sendur[1], Ian R Wilkinson[2] & Richard J Ross[2]
[1]Hacettepe University Department of Endocrinology and Metabolism, Ankara, Turkey; [2]University of Sheffield Department of Oncology and Metabolism, Sheffield, UK.

Introduction
Leptin is a 16-kDa peptide hormone secreted by adipose tissue and acts as a sensor for energy stores. It feedsback at the hypothalamic arcuate nucleus to suppress appetite. Leptin treatment has been highly effective in suppressing appetite in the rare cases of leptin-deficient obesity and improving the metabolic profile in congenital generalised lipodystrophy. These patients require 2.5–10 mg once daily recombinant leptin treatment. We hypothesised that prolonged constant exposure to leptin with a long acting leptin may have a more potent metabolic action and appetite supression and therefore we designed a long acting leptin molecule.
Aim
To construct, express, purify and test for bioactivity a long acting leptin.
Methods
We have previously demonstrated that a fusion of growth hormone to growth hormone binding protein (GHBP) generated a long acting GH. In this project we utilise GHBP as a fusion partner with leptin the concept being that linking a fusion protein to the C-terminus will decrease clearance through reduced proteolysis and renal clearance. We further modified this molecule by introducing a W104A (Tryptophan-Alanine amino acid substitution) in the GHBP to prevent GHBP binding to GH in the circulation.
Results
GHBP(W104A)-leptin fusion was cloned in to a modified invitrogen pSecTag plasmid with the secretion sequence for leptin. This plasmid was transfected into CHO Flp-In cells by reagent-mediated transfection. Protein was expressed in CHO cells grown in roller bottles in the presence of valproic acid at a set temperature of 31 °C and purified by antibody affinity chromatography. *In vitro* bioactivity was assessed by luciferase expression induced by leptin. Approximately two times fold induction was achieved.
Conclusion
We have demonstrated it is possible to generate a fusion of leptin to GHBP and that this fusion retains bioactivity. Future studies will assess pharmacodynamic and pharmacokinetic properties of this molecule.

Effects of prenatal dexamethasone on fetal rat ovary

Natasa Ristic[1], Lazo Pendovski[2], Milica Manojlovic-Stojanoski[1], Dragana Miljic[3], Marko Miler[1], Vladimir Ajdzanovic[1], Svetlana Trifunovic[1], Natasa Nestorovic[1] & Verica Milosevic[1]
[1]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia; [2]Faculty of Veterinary Medicine, Ss. Cyril and Methodius University in Skopje, Skopje, Macedonia; [3]Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Glucocorticoids affect the growth and maturation of fetal organ systems, but overexposure to exogenous glucocorticoids retard fetal growth and may alter developmental process in sensitive tissues. On the other hand, fetal ovary is not characterized by definitive follicular structure, but the clusters of germinative cells are predominant. Germ cells may be in meiotic prophase or with sign of degeneration.
The aim of this study was to determine whether prenatal exposure to dexamethasone (Dx) altered normal structure and development of ovary in 19 day old rat fetuses. Pregnant females in the experimental group received subcutaneous injections of 1.0, 0.5 and 0.5 mg Dx /kg body weight on days 16–18 of pregnancy. Control mothers were injected with the same amount of saline. On day 19 of pregnancy, the dams and their fetuses were sacrificed under ether anesthesia and the fetuses were referred to as 19-day-old fetuses. Fetal ovaries were prepared for further stereological examination.
The volume of the fetal ovary estimated using Cavalieri's principle was significantly reduced after exposure to Dx by 22% ($P<0.05$) in comparison with control ovary. Using a fractionator-physical disector method, a reduction in total number of germ cells in meiotic prophase by 43% ($P<0.05$) was observed, while total number of germ cells with sign of degeneration increased by 54% ($P<0.05$), when compared with control values.
Overexposure to dexamethasone during fetal development intensifies the process of degeneration of germ cells in the ovary, contributing thus the reduction of reproductive potential for the individual.

Does the loss of RAD52 in PC contribute to resistance to antiandrogen therapy?

Mahmoud A. Alfaqih[1,2], Ching yi Chang[2], John Norris[2] & Donald P. McDonnell[2]
[1]Jordan University of Science and Technology, Irbid, Jordan; [2]Duke University Medical Center, Durham, NC, USA.

Recent statistics indicate that prostate cancer (PC) is the most frequent cancer in men worldwide and is the leading cause of cancer death in men above 50 years of age. The Androgen receptor (AR), a member of the superfamily of nuclear hormone receptors, plays a well-established role in the development and progression of the disease. PC localized to the prostate is commonly treated with surgical removal of the gland and is often associated with a favorable outcome. However, metastatic PC requires more aggressive treatment modalities often consisting of gonadotropin releasing hormone (GnRH) agonists and/or an AR antagonist (ex: bicalutamide). Although initially successful in alleviating symptoms, the disease progresses to a castrate resistant state, where drugs targeting the AR axis have limited clinical utility. Several mechanisms were suggested to explain resistance to antiandrogen treatment including AR mutations, AR amplification and/or local production of androgens. Additionally, some studies also suggest that deregulation of AR cofactor expression may permit weak androgens or even antiandrogens to function as full AR agonists and fuel tumor growth, a mechanism that contributes to the castrate resistance phenotype. This puts into context our observation that RAD52, a protein involved in DNA repair machinery also functions as an AR cofactor whose deregulation affects PC response to antiandrogens. Herein, using PC cell models, we found that knockdown of RAD52 increases AR protein levels and enhances AR transcriptional activity in the presence of low levels of androgens. More importantly, we found that RAD52 knockdown converts the AR antagonist bicalutamide into a full agonist in cell reporter assays and on AR target genes; an activity associated with enhanced recruitment of AR to target gene promoters. Taken together, our results suggest that deregulation of RAD52 expression may mediate PC resistance to antiandrogen therapy.

Thyroid hormone protects hepatocytes from HBx-induced carcinogenesis by enhancing mitochondrial turnover

Hsiang-Cheng Chi & Kwang-Huei Lin
Chang-Gung University, Taoyuan, Taiwan.

Infection by hepatitis B virus (HBV) accounts for 50∼80% of hepatocellular carcinoma (HCC) development worldwide, in which the HBV encoded X protein (HBx) plays critical role in the induction of carcinogenesis. Several studies have shown that thyroid hormone (TH) suppresses HCC development and protects hepatocytes from HBx induced damage, thus it is of interest to examine whether TH can protect hepatocytes from HBx-induced carcinogenesis. By treating HBx-transgenic mice with or without TH, we confirmed the protective effects of TH on HBx-induced hepatocarcinogenesis, which was achieved via reduction of ROS inflicted DNA damage. We further found that TH induced biogenesis of mitochondria (MITO) and autophagy of HBx-targeted mitochondria simultaneously, consequently leading to suppression of HBx-promoted ROS and carcinogenesis. Using microarray data analysis, this protective effect of TH was found to be mediated via activation of PTEN-induced kinase 1 (PINK1) in hepatocytes. PINK1, in turn, activated and recruited Parkin, an E3 ligase, to ubiquitinate MITO-associated HBx protein and trigger selective mitophagy. The pathological significance of the TH/PINK1 pathway in liver protection was confirmed by the concomitant decrease in expression of both TR and PINK1 in matched HCC tumor tissues and negatively correlated with aggressive progression of cancer and poor prognosis. Our data indicates that TH/PINK1/-Parkin pathway plays a critical role in protecting hepatocytes from HBx-induced carcinogenesis. Notably, several liver-targeting therapeutic derivatives of thyroid hormone facilitating prevention or therapy of steatosis have been identified. Furthermore, our proof-of-concept experiments suggest that application of T3 constitutes an effective novel therapeutic or preventive option for HCC. Thus, the

utilization of the agonists of TRs could be the meaningful strategy in liver relative diseases, ranging from simple hepatic steatosis to HCC.

3-year safety and efficacy Update of the VERTICAL & VISTA trials of somavaratan (VRS-317), a long-acting rhGH, in children with Growth Hormone Deficiency (GHD)

Bradley S. Miller[1], Wayne V. Moore[2,3], Patricia Y. Fechner[4,5], Quentin L. Van Meter[6], John S. Fuqua[7], David Ng[8], Eric Humphriss[9], R. William Charlton[9] & George M. Bright[9]
[1]University of Minnesota Masonic Children's Hospital, Minneapolis, MN, USA; [2]Children's Mercy Hospital, Kansas City, MO, USA; [3]University of Missouri-Kansas City, Kansas City, MO, USA; [4]Seattle Children's Hospital, Seattle, WA, USA; [5]University of Washington, Seattle, Seattle, WA, USA; [6]Van Meter Pediatric Endocrinology, P.C., Atlanta, GA, USA; [7]Indiana University School of Medicine, Indianapolis, IN, USA; [8]ResearchPoint Global, Inc., Austin, TX, USA; [9]Versartis, Inc., Menlo Park, CA, USA.

Requirement for daily rhGH injections is a treatment burden that can compromise adherence and efficacy in patients with GHD. Somavaratan is a novel long-acting rhGH fusion protein in clinical development for pediatric and adult GHD. In a multicenter, randomized Phase 1b/2a study, somavaratan significantly improved height velocity (HV) and IGF-I in pre-pubertal children with GHD. Preliminary efficacy and safety in subjects who have completed 3 years of somavaratan treatment are presented. Of 64 subjects randomized in the Phase 2a VERTICAL study to receive 5.0 mg/kg/month (weekly/twice-monthly/monthly dosing) for 6 months, 60 elected to continue treatment in the long-term safety study, VISTA. Initial IGF-I response supported a dose increase, and all subjects transitioned to somavaratan 3.5 mg/kg twice-monthly by the 2nd treatment year. Data cutoff was December 8, 2016. Of 48 subjects (24 males, 24 females), the mean ± SD age was 7.6 ± 2.4 years, and mean IGF-I SDS was −1.6 ± 0.8 at baseline. In Year 3, IGF-I SDS increased to 1.2 ± 1.7 at peak (3–5 days post-injection) and −0.3 ± 1.0 at trough (end of dosing cycle). Mean HV remained consistent during Years 1, 2, and 3, at 8.4 ± 2.0, 8.3 ± 1.6, and 7.8 ± 1.6 cm/year, and height (HT)-SDS continued to increase from −2.6 ± 0.6 at baseline to −2.1 ± 0.6, −1.6 ± 0.7, and −1.2 ± 0.8; delay in bone age (years) was −1.48 ± 0.81 at baseline, −1.34 ± 0.89 (Year 1, $n=48$), −1.09 ± 1.02 (Year 2, $n=47$), and −0.66 ± 0.82 (Year 3, $n=25$). Treatment-related AEs were generally transient and mild. Overall, IGF-I, HV, HT-SDS, and bone age showed continued improvement through 3 years of somavaratan treatment in pre-pubertal children with GHD. Dose increase to somavaratan 3.5 mg/kg twice-monthly resulted in consistent growth rates through 3 years of treatment, and overall Year 3 growth was consistent with daily rhGH from US registries. A Phase 3 study of somavaratan 3.5 mg/kg twice-monthly in treatment-naïve GHD children is ongoing.

GP66

Achievement of a suitable basis of comparison in phase 2 and 3 clinical trials (VERTICAL/VISTA, and VELOCITY) comparing somavaratan vs daily rhGH for pediatric GH deficiency

Philippe Backeljauw[1], Bradley S Miller[2], Nancy Wright[3], Aristides Maniatis[4], Michael Stalvey[5], Eric Humphriss[6], R William Charlton[6] & George M Bright[6]
[1]Cincinnati Children's Hospital Medical Center, Cincinnati, OH, USA; [2]University of Minnesota Masonic Children's Hospital, Minneapolis, MN, USA; [3]Nancy Wright MD p.a., Tallahassee, FL, USA; [4]Rocky Mountain Pediatric Endocrinology, Centennial, CO, USA; [5]University of Alabama at Birmingham, Birmingham, AL, USA; [6]Versartis, Inc., Menlo Park, CA, USA.

Efficacy of rhGH for treatment of pediatric GH deficiency (PGHD) may depend on several variables at treatment initiation (age, body weight, height velocity (HV), IGF-I SDS, skeletal maturation, GHmax), but may be compromised by poor adherence to required daily injections. Somavaratan is a novel, long-acting rhGH fusion protein that demonstrated clinically meaningful improvements in HV and IGF-I concentration in PGHD patients. Over 200 pre-pubertal GHD subjects have enrolled in somavaratan trials to date, including 137 in the Phase 3 noninferiority VELOCITY trial comparing somavaratan vs daily rhGH. In the randomized Phase 1b/2a VERTICAL study in pre-pubertal children with GHD, primary determinants of Year 1 HV included age at treatment initiation and GHD severity. To achieve a valid basis of comparison of efficacy outcomes across trials (VELOCITY, VERTICAL, VISTA (long-term safety)), distribution of clinical characteristics known to affect HV should be similar between treatment arms (somavaratan vs daily rhGH) and between trials. The same primary efficacy endpoint (HV) and similar eligibility criteria were used across trials. Stratification for Phase 3 randomization (somavaratan vs daily rhGH) was based on region, expected age, and expected baseline IGF-I SDS. In VELOCITY ($n=104$ somavaratan; $n=32$ daily rhGH), mean ± S.D. baseline ages were 7.07 ± 2.0 vs 7.03 ± 2.4 years, respectively, mean GHmax 5.77 ± 2.6 vs 5.87 ± 2.5 ng/ml, mean height-SDS −2.76 ± 0.7 vs −2.64 ± 0.7, mean IGF-I SDS -1.72 ± 0.7 vs −1.87 ± 0.9, and mean bone ages 5.28 ± 1.9 vs 5.29 ± 2.2 years. In VERTICAL (N = 64), mean age was 7.8 ± 2.4 years, mean height-SDS −2.6 ± 0.6, mean IGF-I SDS −1.7 ± 0.8, and mean bone age 6.4 ± 2.4 years. No clinically meaningful differences in baseline characteristics were noted between trials, or between VELOCITY treatment arms. Collectively, similar populations were achieved between trials by use of consistent eligibility and stratification procedures. This allowed balanced treatment arms for clinical characteristics that may influence the primary efficacy outcome, thereby achieving a valid basis of comparison between trial populations.

Karyotype and mid-childhood gonadotropin concentrations in prediction of spontaneous puberty in Turner syndrome patients

Aneta Gawlik[1], Magdalena Hankus[2], Kamil Soltysik[3], Kamila Szeliga[2] & Ewa Malecka-Tendera[1]
[1]Department of Pediatrics and Pediatric Endocrinology, School of Medicine in Katowice, Medical University of Silesia, Katowice, Poland; [2]Department of Pediatrics and Pediatric Endocrinology, Upper-Silesian Pediatric Health Center, Katowice, Poland; [3]Department of Anatomy and Molecular Cell Biology, Nagoya University Graduate School of Medicine, Nagoya, Japan.

Gonadotropin levels in all Turner syndrome (TS) patients present a diphasic pattern: highest in early childhood, declining at 6–10 years of age, and then increasing again. Here, we have investigated whether karyotype or FSH&LH can be used as indicators of spontaneous puberty in TS. From a consecutive group of 139 TS girls treated at one clinical center (1996–2015) the clinical & biochemical data were finally analyzed in 110 TS patients (1268 visits). The study population was divided into two subsets based on karyotype (type A- 45X, 54%; type B- others excluding 45X/46XY). The mean diagnosis age and duration of follow-up were 10.7 ± 4.0 and 5.9 years, resp. The average number of visits was 10.4. Spontaneous puberty was confirmed in 48.2% and menarche in 20%, both less common in group A than B (31.1% and 9.8.% vs 69.4% and 32.6%, resp., $P<0.05$). The mean age of Tanner B2 and menarche in all girls were 13.7 ± 2.4 and 14.2 years, no difference between the groups (13.5 ± 2.5 and 13.2 ± 1.0 years (A) vs 13.8 ± 2.3 and 14.6 ± 1.7 years (B), $P>0.05$). The median FSH and LH values in all patients at the age of 6–10 were 8.16 and 0.35 IU/l resp., significantly lower comparing to younger (44.6 and 0.76 IU/l) and older (93.0 and 16.1 IU/l) age ($P<0.0001$). LH were similar in both groups, whereas in group B FSH values were significantly higher only in the older age. At the age of 6–10 FSH and LH levels ≥than 6.7 and 0.2 resp. decrease the chance of spontaneous menarche (33.3% vs 13.9% and 28.6% vs 11.8%). Conclusion: Nearly half of our TS patients showed spontaneous puberty symptoms and every fifth had spontaneous menarche with higher frequency in non-45,X girls. The diphasic pattern of FSH&LH was confirmed, however using their cut-off values one can predict the chance for spontaneous menarche.

Assessment of reports of behaviour by patients and their parents in paediatric Cushing disease

Margaret Keil, Elena Belyavskaya, Charalampos Lyssikatos, Maya Lodish & Constantine Stratakis
NIH, NICHD, Bethesda, MD, USA.

Context
Prior studies of children with endogenous Cushing syndrome (CS) have identified cognitive decline despite reversal of brain atrophy after remission as well as residual impairment of quality of life measures. Although parental observations support personality changes with CS, significant psychopathology has not been described. We investigated the feasibility of using paediatric Patient-reported

outcomes (PROMIS) using a computer interface to assess patient perception of burden of illness and correlation with parent proxy report using Child Health Questionnaire (CHQ).
Setting
Subjects were enrolled in a clinical protocol at the National Institutes of Health Clinical Center in Bethesda, MD, USA.
Method
We report 9 children (6F, 12±3.5 years) diagnosed with Cushing disease (CD). Prior to surgical treatment, subjects completed paediatric PROMIS measures and parents completed CHQ using an online secure website.
Results
PROMIS measures scores (mean±S.D.): anxiety (54±9), depression (55±11) anger (50±9), and emotional support (52±10) (higher scores indicate more of the concept being measured); CHQ total Psychosocial score (mean±S.D.) (43±10) (lower values are associated with a greater deficit in functioning). A significant correlation was found between Psychosocial summary score of CHQ and paediatric PROMIS measures of anxiety ($r=-70.5$; $P<0.03$) and depression ($r=-0.9$; $P<0.002$). No correlation was found between urinary free cortisol level or midnight serum cortisol and PROMIS measures.
Conclusion
Prior to treatment for CS, a significant correlation was found between children's endorsement of anxiety and depression symptoms and parental proxy report of psychosocial function. Our findings support that paediatric PROMIS measures represent feasible and potentially valuable instruments for future studies to assess behavioural symptoms in children diagnosed with CS prior to and after treatment.

5β-reductase (AKR1D1) is a potent regulator of carbohydrate and lipid metabolism and inflammation in human liver
Nikolaos Nikolaou[1], Laura Gathercole[3], Charlotte Green[1], Catriona McNeil[1], Wiebke Arlt[2], Leanne Hodson[1] & Jeremy Tomlinson[1]
[1]University of Oxford, Oxford, UK; [2]University of Birmingham, Birmingham, UK; [3]Oxford Brookes University, Oxford, UK.

Non-alcoholic fatty liver disease (NAFLD) is the hepatic manifestation of metabolic disease. 5β-reductase (AKR1D1) is highly expressed in human liver where it inactivates steroid hormones and catalyzes a fundamental step in bile acid synthesis. Steroid hormones, including glucocorticoids, as well as bile acids are established regulators of metabolic phenotype. We hypothesized that AKR1D1 plays a crucial regulatory role in hepatic metabolic homeostasis. Genetic manipulation of AKR1D1 (over-expression, siRNA knockdown) was performed in human liver HepG2 and Huh7 cells. Gene expression changes were confirmed by qPCR. Functional activity, assessed using gas chromatography mass spectrometry to measure cortisone clearance and tetrahydrocortisone generation was paralleled by the anticipated changes in glucocorticoid receptor activation measured by luciferase reporter assays. AKR1D1 knockdown in HepG2 cells increased glucose transporter mRNA expression and extracellular glucose concentrations in the cell media decreased (15.3±1.5 vs 12.1±0.9 μmol/mg, $P<0.05$) while intracellular glycogen levels were increased (18.9±0.3 vs 22.7±0.3 μg/ml, $P<0.05$). AKR1D1 knockdown increased Fatty Acid Synthase and Acetyl CoA Carboxylase 1 expression, the rate-limiting step in *de novo* lipogenesis, DNL) (0.52±0.06 vs 0.89±0.04, $P<0.01$), and increased intracellular triglyceride (54.3±12.7 vs 73.3±11.0 nmol/mg, $P<0.01$). Furthermore, 3-hydroxybutyrate levels in the cell media were reduced, indicative of impaired fatty acid oxidation (18.7±2.3 vs 11.4±2.7 nmol/mg, $P<0.01$). Mass spectrometry analysis of lipid composition demonstrated increased palmitic and palmitoleic acid production consistent with increased DNL and fatty acid saturation. In addition, bile acid composition was altered with a significant increase in chenodeoxycholic acid levels. Conversely, pharmacological manipulation of the bile acid receptors FXR and LXR using the FXR agonist GW4064 and LXR antagonist 22-S-Hydroxycholesterol rescued HepG2 cells from metabolic dysfunction by reducing the expression of lipogenic genes. Furthermore, AKR1D1 knockdown increased proinflammatory cytokine IL-1, IL-6 and IL-8 mRNA expression; changes were confirmed by elevated cell media IL-8 levels (4.68±0.70 vs 13.39±2.28 ng/ml, $P<0.05$), increased IκBα degradation and induced IRE-1α protein expression, indicative of inflammation and cellular ER stress. In conclusion, AKR1D1 activity regulates steroid hormone and bile availability, potently modulating hepatic carbohydrate and lipid metabolism in addition to an inflammatory phenotype suggesting a crucial role in the pathophysiology of NAFLD.
DOI: 10.1530/endoabs.49.GP69

GP70

The adverse effects of prescribed glucocorticoids are worsened by co-administration of 5α-reductase inhibitors
Tom Marjot, Nantia Othonos, Conor Woods, Jonathan Hazlehurst, Ahmad Moola, Leanne Hodson & Jeremy Tomlinson
Oxford Centre for Diabetes, Endocrinology and Metabolism, NIHR Biomedical Research Centre, Churchill hospital, University of Oxford, Oxford, UK.

Introduction
Glucocorticoids (GC) are prescribed to 2–3% of the population of the UK and USA. Their use is associated with a significant side effect profile that includes the development of central obesity, insulin resistance and type 2 diabetes. 5α-reductase (5αR) inhibitors (Finasteride and Dutasteride) are also commonly prescribed in the context of prostate disease, where they inhibit the conversion of testosterone to dihydrotestosterone. Additionally, they have a role to inactivate and clear GC. We have therefore hypothesised that 5αR inhibitors have the potential to exacerbate the adverse metabolic effects of GC.
Methods
We conducted a prospective, randomised, study in 19 healthy male volunteers (age; 45±8.5 years, BMI; 27.1±3.1 kg/m^2). Participants underwent detailed metabolic assessments including a 2-step hyperinsulinaemic euglycaemic clamp incorporating stable isotopes, adipose tissue microdialysis and biopsy. They were then randomised to receive either prednisolone (10 mg OD) or prednisolone (10 mg OD) and a 5αR inhibitor (finasteride 5 mg OD or dutasteride 0.5 mg OD) for 7 days, metabolic assessments were then repeated.
Results
We have previously shown that high dose parenteral GC administration decreases glucose utilization (M value; 3.1±0.4 vs 1.6±0.1 mg/kg per min, $P=0.001$) and 5αR inhibitors alone are without effect (M value; 3.5±0.4 vs 3.3±0.4 mg/kg per min, $P=0.42$). In this study, prednisolone only did not alter glucose utilization (M-value; 3.2±1.3 vs 2.8±1.6 mg/kg per min, $P=0.37$), however, co-administration of prednisolone and 5αR inhibitors significantly decreased it (M-value; 4.0±2.0 vs 2.6±1.3 mg/kg per min, $P=0.02$). Similarly, high dose GC, but not 5αR inhibitors alone, impair insulin-mediated suppression of circulating non-esterified fatty acids (NEFA). Prednisolone 10mg OD did not alter insulin-mediated suppression of NEFA (0.15±0.27 vs 0.13±0.13, $P=0.88$), however, co-administration with 5αR inhibitors impaired the ability of insulin to suppress NEFA (0.15±0.1 vs 0.29±0.18, $P=0.01$).
Conclusion
5αR inhibitors exacerbate the adverse metabolic effects of prescribed GCs. This has significant translational implications, not only with regards to the need to consider steroid dose reductions, but also the necessity for increased vigilance for the development of adverse effects.

Carbohydrates metabolism and H. pylori: case-control study
Isabel Ma Cornejo-Pareja[1], M Mar Roca-Rodríguez[2], Leticia Coín-Aragüez[3], Araceli Muñoz-Garach[1], María Molina-Vega[1], Cristina Díaz-Perdigones[1], Carmen Hernández-García[1], Juan Alcaide-Torres[3], Carlos Clu-Fernández[1], Laura Viñuela-González[4], Laura Mora-Navas[4], Isabel Mancha-Doblas[1] & Francisco J Tinahones-Madueño[1]
[1]Endocrinology and Nutrition Department. Virgen de la Victoria Hospital, Málaga, Spain; [2]Endocrinology and Nutrition Department Puerta del Mar Hospital, Cádiz, Spain; [3]Research Laboratory IBIMA, Málaga, Spain; [4]Microbiology Department, Virgen de la Victoria Hospital, Málaga, Spain.

Introduction
H. pylori infection has been related with extragastric diseases such as type 2 diabetes.
Aim
to evaluate changes in carbohydrate metabolism induced by 75g oral glucose tolerance test (OGTT), before and after antibiotic eradication treatment in patients colonized by H. pylori compared to healthy controls.
Materials and methods
A prospective case-control study. Biochemical parameters, carbohydrate profile, ghrelin and GLP1 levels before and after antibiotic eradication treatment were analyzed.

Results
We studied 40 cases and 21 controls (60% and 57.1% women, respectively). Mean age: 46,95±2,02 vs 44,52±2,73 years, family history of digestive disorders: 70% vs 57.1% and clinical history of gastrointestinal disease: 57,5% vs 42.9%, respectively. After antibiotic treatment, significant improvements in HbA1c ($P=0,014$), glucose levels post OGTT at 60′ and 120′ ($P=0,018$ and $P=0,019$, respectively) and HDL Cholesterol ($P=0,021$) were observed. Significant changes in basal ghrelin levels ($P=0,05$) were found, but C peptide levels did not change. We observed differences between infected population by H. pylori and healthy people: lower post OGTT insulin levels at 30′ and 60′ ($P=0.042$ and $P=0.03$, respectively) in infected patients. Those differences disappeared after treating the infection. In cases and controls, we found significant positive correlations in carbohydrate metabolism, and significant negative correlations in controls between ghrelin with basal insulin and C peptide. No significant correlations respect to GLP1 were found. 90% of patients completed correctly the treatment, 31,6% needed ranitidine and 97,5% eradicated H. pylori after conventional antibiotic treatment.
Conclusion
1) H. pylori eradication improved carbohydrate metabolism. 2) Significant positive correlations in carbohydrate metabolism in cases and controls were found. 3) Negative correlations between ghrelin and pancreatic reserve were observed in cases. 4) Carbohydrate metabolism differences between healthy and infected people disappeared after eradication treatment. 5) More than 95% of patients achieved H. pylori eradication with conventional antibiotic treatment.

Specific plasma amino acids alternations associated with metabolic syndrome
Marta Siomkajło[1], Jacek Rybka[3], Andrzej Gamian[2,3], Joanna Stankiewicz-Olczyk[1], Marek Bolanowski[1] & Jacek Daroszewski[1]
[1]Department of Endocrinology, Diabetes and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; [2]Department of Medical Biochemistry, Wroclaw Medical University, Wroclaw, Poland; [3]Ludwik Hirszfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wroclaw, Poland.

Objectives
Amino acids (AA) plasma profile is associated with cardiometabolic diseases (CMD), predicts diabetes mellitus type 2 (DM2) and cardiovascular diseases (CVD) many years in advance. Metabolic syndrome (MS) defines the area of metabolic disturbances that precede DM2 and CVD development. The primary objective of the study was to examine the association between BCAA (branched chain amino acids), AAA (aromatic amino acids) profile and MS's phenotype and to evaluate its clinical utility for MS diagnosis.
Methods
263 healthy, professionally active men, with and without MS (MS+, $n=165$; MS−, $n=98$) were included into the study. Anthropometrical, biochemical and AA measurements were performed. AA were tested for the ability to discriminate subjects with MS and insulin resistance irrespectively. Based on logistic discrimination multivariate early MS diagnostic model was built and its discrimination properties were evaluated.
Results
2 functionally independent AA clusters were identified. BCAA and phenylalanine differed strongly between MS+ and MS- participants ($p=0.003$), appeared as significant indicator of MS+ individuals (AUC 0.66; 95%CI: 0.5757–0.7469) and correlated with cardiometabolic factors. No statistical significant differences in AAs concentrations between IR+ and IR− groups were noted and none of the AA group appeared as meaningful IR+ indicator. Proposed MS multivariate diagnostic model consisted of phenylalanine, insulin, leptin, adiponectin and had good discrimination properties – AUC 0,79; (95% CI: 0.7239–0.8646).
Conclusions
MS is associated with selective hiperaminoacydemia that could be a part of CMD pathogenesis. Present study suggests that AA disturbances do not derive directly from insulin sensitivity impairment nor obesity or muscle mass. AA utility for MS diagnosis needs further evaluation. The original outcome of the study became MS diagnostic model creation – MS screen test, with good discrimination properties and that could be validated in the next coming studies.

Permanent neonatal diabetes in a 24 year old Spanish patient
Milagros Sierra, Elena Garcia, David Males, Juan Carlos Romero, Carlos Silva, Gonzalo Allo & Guillermo Martinez
12 De Octubre University Hospital Endocrinology and Nutrition Department, Madrid, Spain.

Introduction
Neonatal diabetes mellitus is a rare form of diabetes, diagnosed within the first six months of life. We report a case of a 24-year-old patient with permanent neonatal diabetes.
Case Report
The patient had no relevant family history. Her mother had no gestational diabetes. Personal history included: Normal birth weight, polycystic ovarian syndrome and ovarian teratomas. She was diagnosed of diabetes at 3 months of age, starting immediately with insulin treatment. Glucose control had always been optimal (HbA1c l $<6.7\%$). Acute diabetic complications included: symptomatic hypoglycemias every 3 days, usually after dinner and, less frequently nighttime hypoglycemias. No hyperglycemias that required in hospital management. No chronic metabolic complications. The patient came to our clinic to continue follow up. We completed her work up doing islet antibodies detection (anti GAD65, anti tyrosine phosphatase IA2, anti insulin and anti zinc transporter), and as expected the results were negative. Considering the age of the diagnosis, genetic testing for monogenic forms of diabetes was performed, discovering a heterozygous mutation c.323Ag (pY108C) in INS gene. Family genetic mutation are still pending.
Discussion
Neonatal diabetes mellitus have an incidence of 1 in 500000 live births. Most common genes are KLF 11, ABCC8 and less frequently INS gene (30%, 19% and 14% respectively). Depending on the severity of the mutations insulin bioactivity will be affected, ranging from a decreased biosynthesis to altered transcription. Clinical implications include transient requirement of insulin, later switching to sulfonylureas or even completely stopping hypoglycemic treatment; and permanent insulin treatment. In the latter, the risk of ketoacidosis also depends and the recessive or dominant inheritance.
Conclusions
Monogenic forms of diabetes are uncommon, however it is important to consider them in the differential diagnosis of particular cases. Genetic mutation study is important to assess future treatment options and the risk of ketoacidosis.

Rescue study of trapped AVPR2 mutants with chemicals
Beril Erdem, Emel Saglar, Tugce Karaduman, Merve Ozcan, Dilara Sahin & Hatice Mergen
Department of Biology, Faculty of Science, Hacettepe University, Ankara, Turkey.

Diabetes insipidus (DI) is a disorder that characterized by producing large volume of urine for daily due to the problems at the arginine vasopressin (AVP-NPII), aquaporin 2 (AQP2) and arginine vasopressin receptor 2 (AVPR2) genes. These problems can be inherited or acquired. Among these genes, AVPR2 is a G protein coupled receptor and most of the inherited type of DI are caused by mutations in AVPR2 gene. Mutations can cause improper folding of the receptor protein and this situation causes to retention of the protein in cellular compartments such as endoplasmic reticulum (ER) or Golgi apparatus. For treatment strategies, researchers try to use chemicals to rescue of mutant proteins from the control mechanisms to make them at least functional. In this study, we aimed to do pre-research for the rescuing mutant receptors (R68W, V162A, T273M, R67_G69del/G107W, V88M, R106C, G12E). We performed functional characterization of these mutant receptors in our previous study and they were observed as trapped in the ER or Golgi apparatus. In the present study, COS-7 cells were transfected with mutant and wild type AVPR2s. 48 hours after the transfection, different concentrations of DMSO and glycerol were performed to the cells. 16–18 hours after the treatment of DMSO and glycerol, cell surface ELISA were performed to understand cell surface expression of the mutant proteins when they were treated with different concentrations of DMSO and glycerol. According to the ELISA results, mutant receptors showed different rescue profile compared to the wild type receptor. As a result, we can say that rescuing trapped mutant receptors from ER or Golgi apparatus control mechanisms using with chemicals could be a forward step for the treatment of DI. Receptors that have mutations which cause retention in ER or Golgi apparatus may be functional if they are rescued by chemicals. For further studies, instead of chemicals, pharmacochaperons could be use. We can conclude that, rescue

studies of mutated proteins by using chemicals or pharmacochaperons shed light to the treatment strategies of DI. This work was supported by The Scientific and Technological Research Council of Turkey (Project Numbers: 216S304 and 112S513).

GLP-1 acutely regulates carbohydrate and lipid metabolic routes in the liver

Laura Toba, Yolanda Diz-Chaves, Juan Fandiño, Hugo Ogando, Lucas González-Matías & Federico Mallo
University of Vigo, Vigo, Spain.

The Glucagon-like peptide-1 receptor is widely expressed in diverse tissues including the liver. GLP-1 contributes itself to the regulation of glucose homeostasis and has important effects in lipid metabolism even preventing liver steatosis induced by high fat diets.
The aim of this study was to analyse the short-term effects of liraglutide on key enzymes of the hepatic energy metabolism.
Thirty-six Sprague-Dawley young adult male rats were studied (weight range 350–400 g). Control rats were fed *ad libitum*, while the fast group (F) were deprived of food for 48 hours, and treated with liraglutide (100 µg/Kg/12 h; CT/LIR; F/LIR) or vehicle (CT/VEH; F/VEH) for 48 hours. Rat body weight was measured at 0, 24 and 48 hours. At 48 h, rats were sacrificed and liver samples were collected and stored at −80 °C until analysis. mRNA expression of G6P, PCK-1, DGAT-1, GPAT4, CPT1A and ACACA in the liver were assessed by real time PCR.
CT/LIR rats gained less body weight (−6.4 g/100 g, $P<0.0001$) than CT/VEH at 24 h and still less at 48 h (−2.9 g/100 g, $P<0.0001$). The expression levels of G6P and PCK-1, key enzymes in gluconeogenesis, decreases in rats treated with liraglutide by a 58% ($P<0.05$) and 75% ($P<0.01$) respectively. On the other hand, DGAT-1 and GPAT4 levels, involved in synthesis of triacylglycerol, were not modified by LIR. In addition, CPT1a and ACACA, enzymes implicated in the synthesis & metabolism of fatty acids, yielded no significant differences. Fasting just increased CPT1 levels (271% F/VEH vs CT/VEH, $P<0.01$), and LIR treatment reduced them (92% F/LIR, $P<0.01$ vs F/VEH).
In conclusion, Liraglutide modifies the metabolism of energy substrates in the liver reducing glucose production in normal feeding and CPT1a specially in fasting, limiting lipid access to mitochondria. These metabolic changes may underlie the prevention of liver steatosis attributed to GLP-1 analogues.

Increased risk of diabetes and hyperglycaemia associated with treatment with statins, beta-blockers and diuretics: the PPP-Botnia study

Liisa Hakaste[1,2], Teo Helkkula[2], Bo Isomaa[2], Marja-Riitta Taskinen[3,4], Leif Groop[5,6] & Tiinamaija Tuomi[1,2]
[1]Endocrinology, Helsinki University Hospital, Helsinki, Finland; [2]Folkhalsan Research Center; Diabetes and Obesity Research Program, University of Helsinki, Helsinki, Finland; [3]Research programs Unit, Diabetes and Obesity, University of Helsinki, Helsinki, Finland; [4]Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland; [5]Lund University Diabetes Center, Malmo, Sweden; [6]Finnish Institute for Molecular Medicine, University of Helsinki, Helsinki, Finland.

Background
Statin medication is commonly used in prevention of cardiovascular diseases. Pooled evidence shows that statin therapy is associated with increased risk of incident diabetes, but studies vary in results and there is no consensus of the diabetogenic mechanism of statins. Beta blockers and diuretics are commonly used antihypertensive agents that also have been shown to increase the risk of incident diabetes. Our objective was to examine the effects of statins, beta blockers and diuretics on glucose metabolism and the risk of incident diabetes.
Methods
5208 subjects from western Finland identified through the Population registry participated in the baseline PPP-Botnia Study, and 3,614 subjects participated in the follow-up study after a mean time of 6.7 years. Participants underwent oral glucose tolerance tests (OGTT) and gave information about their use of medication. Insulinogenic index (IGI) and corrected insulin response (CIR) were calculated from the glucose and insulin response during OGTT.
Results
After controlling for confounding factors, the group treated with statins during the entire follow-up had a, nominally significant, 79% (95% CI 1.16, 2.76 $P=0.008$) increased risk of developing incident diabetes, compared to the group without statins, and statin use was significantly associated with higher levels of fasting plasma glucose (FPG) and 2 hour plasma glucose (2hPG). Statin therapy was associated with a reduced CIR30, but not IGI30. Beta blocker therapy was associated with a nominally significant 63% increased risk of developing incident diabetes.
Conclusion
Statin treatment is associated with an increased risk of incident diabetes, higher levels of FPG and 2hPG, and reduced insulin secretion. Beta blocker therapy is associated with an increased risk of incident diabetes.

Susceptibility to type 2 diabetes may be modulated by haplotypes in G6PC2, a target of positive selection

Mario Clerici[1], Nasser Al-Daghri[2], C Pontremolli[1], R Cagliani[1], Diego Forni[1], Majed Alokail[2], Omar Al-Attas[2], Shaun Sabico[2], S Riva[1] & M Sironi[1]
[1]University of Milano, Milan, Italy; [2]King Saud University, Riyadh, Saudi Arabia.

Introduction
The endoplasmic reticulum enzyme glucose-6-phosphatase catalyzes the common terminal reaction in the gluconeogenic and glycogenolytic pathways and plays a central role in glucose homeostasis. In most mammals, different G6PC subunits are encoded by three paralogous genes (G6PC, G6PC2, and G6PC3). Mutations in G6PC and G6PC3 are responsible for human Mendelian diseases, whereas variants in G6PC2 are associated with fasting glucose (FG) levels.
Methods
We analyzed the evolutionary history of G6Pase genes in mammals. Results indicated that negative selection was the major force shaping diversity at these genes. Nonetheless, site-wise estimation of evolutionary rates at corresponding sites revealed weak correlations, suggesting that G6Pases have evolved different structural features over time. We also detected pervasive positive selection at mammalian G6PC2 genes. Most selected residues are located in the C-terminal protein region, where several human variants associated with FG levels also map. This region was thus re-sequenced in a cohort of ∼560 subjects from Saudi Arabia, 185 of whom suffering from type 2 diabetes (T2D).
Results
The frequency of rare missense and nonsense variants was not significantly different in T2D and controls. Association analysis with two common missense variants (V219L and S342C) revealed a weak but significant association for both SNPs when analyses where conditioned on rs560887, previously identified in a GWAS for FG. Two haplotypes were significantly associated with T2D with an opposite effect direction.
Conclusion
These results, although preliminary, suggest that distinct haplotypes at the G6PC2 locus modulate susceptibility to T2D.

Contribution of genetic predisposition and lifestyle to gestational diabetes risk

Polina Popova[1,2], Alexandra Tkachuk[1], Yana Bolotko[1], Andrey Gerasimov[1], Alexandra Klyushina[1], Anna Kostareva[1] & Elena Grineva[1,2]
[1]Almazov Federal North-West Medical Research Centre, Saint-Petersburg, Russia; [2]St Petersburg Pavlov State Medical University, Saint-Petersburg, Russia.

Aim
The aim of our study was to assess the contribution of genetic variation in some previously reported gestational diabetes mellitus (GDM) susceptibility loci and lifestyle parameters to GDM risk.

Methods
We performed a case-control study of 278 GDM cases and 179 controls who had filled up special questionnaires concerning their lifestyle habits during the oral glucose tolerance test (OGTT) on the 24–32 week of gestation. The questionnaire consisted of the following sections, stratified in a semi-quantitative manner: the consumption of major food groups and drinks, the amount of physical activity and smoking before and during pregnancy. GDM was diagnosed according to the IADPSG criteria. Maternal blood was sampled for further genotyping of single nuclear polymorphisms (SNPs) in MTNR1B (rs10830963 and rs1387153), GCK (rs1799884), KCNJ11 (rs5219), IGF2BP2 (rs4402960), TCF7L2 (rs7903146), CDKAL1 (rs7754840) and IRS1 (rs1801278). Binary logistic regression (forward conditional) was accomplished to identify the contribution of «classical» risk factors for GDM (advanced maternal age, higher body mass index (BMI), history of GDM, impaired glucose tolerance, arterial hypertension, family history of diabetes), lifestyle parameters and the above mentioned SNPs to the assessment of GDM risk.
Results
After automatic lineal modeling the following factors proved to be associated with the increased GDM risk: age (OR = 1.11, 95% CI = 1.06–1.16, $P < 0.001$), BMI (OR = 1.09, 95% CI = 1.05–1.14, $P < 0.001$), the presence of G allele of rs10830963 (OR = 2.1, 95%CI = 1.4–3.1, $P = 0.001$), T allele of rs1799884 (OR = 2.1, 95%CI = 1.3–3.4, $P = 0.003$) and consumption of sausage > 3 times a week (OR = 2.55, 95%CI = 1.36–4.78, $P = 0.004$) compared to less consumption. Legumes consumption 1–2 times a week was associated with the decreased risk of GDM, when compared to less consumption (OR = 0.59, 95%CI = 0.36–0.97, $P = 0.036$).
Conclusion
MTNR1B and GCK variants, some eating habits along with an increment in maternal age and BMI were associated with the increased risk of GDM.

The rs2292239 polymorphism in the *ERBB3* gene is associated with risk for type 1 diabetes mellitus

Daisy Crispim[1,2], Cristine Dieter[1,2], Natalia Lemos[1,2], Tais Assmann[1,2], Guilherme Duarte[1,2], Luiza Dorfman[3] & Andrea Bauer[1,2]
[1]Endocrine Division, Hospital de Clinicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; [2]Post-graduation Program in Medical Sciences: Endocrinology, Faculdade de Medicina, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; [3]Universidade do Vale do Rio dos Sinos - UNISINOS, Sao Leopoldo, Rio Grande do Sul, Brazil.

Background and Aim
Type 1 diabetes mellitus (T1DM) is an autoimmune disease resulting from the complex interaction among multiple genes, environmental factors and the immune system. Genome-wide association studies identified *ERBB3* (Erb-b2 receptor tyrosine kinase 3) gene as a main susceptibility locus for T1DM. This gene encodes a member of the family of intracellular receptors of protein tyrosine kinases, which activates multiple signaling pathways including PI3K-Akt and MAPK; thus, regulating cell survival and proliferation. Moreover, ERBB3 seems to contribute to T1DM pathogenesis by modulating antigen-presenting cell function and autoimmunity as well as beta-cell apoptosis and insulin production. Therefore, the aim of this study was to investigate the association of the rs2292239 (C/A) polymorphism in the *ERBB3* gene with susceptibility to T1DM in a Brazilian population from Southern-Brazil.
Methods
Frequencies of the rs2292239 polymorphism were analyzed in 461 T1DM patients (cases) and 570 non-diabetic subjects (controls). Genotyping was performed using Real-Time PCR and TaqMan MGB probes (Thermo Scientific).
Results
Genotype distributions of the *ERBB3* rs2292239 polymorphism were in agreement with those predicted by the Hardy-Weinberg Equilibrium in the control group ($P \geq 0.05$), with the A/A genotype being more frequent in T1DM patients compared with non-diabetic subjects ($P = 0.007$). The A allele frequency was 39.7% in the T1DM group and 32.8% in the control group ($P = 0.008$). Moreover, the A allele was significantly associated with T1DM risk when taking into account additive (OR = 1.67, 95% CI 1.07 – 2.61; $P = 0.023$) and recessive (OR = 1.58, 95% CI 1.04 – 2.40; $P = 0.031$) inheritance models, adjusting for T1DM high-risk *HLA- DR/DQ* haplotypes. In conclusion, our data confirms the association between the *ERBB3* rs2292239 and risk for T1DM in a population from Southern-Brazil.

Trace elements as an oxidative stress marker in women with gestational diabetes and their neonates

Georgios Boutzios[1], Eleni Koukoulioti[1], Ioannis Papoutsis[2], Sotirios Athanaselis[2], Gerasimos Tsourouflis[1] & Evangelia Zapanti[3]
[1]Endocrine Unit, Department of Pathophysiology, Laiko University Hospital, Medical School, University of Athens, Athens, Greece; [2]Department of Toxicology, Medical School, University of Athens, Athens, Greece; [3]Endocrine Unit, Alexandra Maternity Hospital, Athens, Greece.

Background and aims
Gestational diabetes (GD) is closely related to unbalanced zinc (Zn) and cooper (Cu) serum levels. The aim of this study was to investigate serum zinc and cooper levels in relation to the metabolic profile, and the impact on fetal development in a cohort of gestational diabetes GD(N) neonates and their mothers GD(M) compared to normal pregnancies.
Material and Methods
Prospective controlled study in a tertiary Academic medical center. The study population included 101 mother/neonate pairs; 50 control group (C) and 51 GD group. Intervention: Diet and/or insulin administration in GD(M). Anthropometric, metabolic parameters, and trace elements serum levels were assessed.
Results
Age and body weight change during pregnancy (ΔBW) were similar in both groups. HbA1c was comparable between C and GD group (5.37 ± 0.34 and 5.39 ± 0.48%, for C and GD respectively, $P = 0.844$). Mean serum Cu levels were (150.1 ± 45.85, 32.16 ± 43.37)μg/dl in C and (203.53 ± 65.63, 23.62 ± 13.42) μg/dl in GD, mean Zn levels (87.8 ± 17.48, 120.47 ± 37.16)μg/dl in C and (88.1 ± 27.1, 113.76 ± 36.77)μg/dl in GD, for mothers and neonates, respectively. Neonates had statistically significantly lower serum Cu levels but higher Zn levels compared to their mothers ($P < 0.0001$, $P < 0.0001$). Serum cooper levels in mothers (Cu(M) levels were statistically significantly higher in GD(M) compared to C(M) ($P < 0.0001$). There was a negative correlation between Zn(M) and insulin levels(M) in C ($r = -0.284$, $P = 0.045$), between Zn(M) and insulin(N) in GD ($r = -0.372$, $P = 0.012$), and between Zn(N) and head circumference in C group ($r = -0.423$, $P = 0.013$). There was a positive correlation between Cu(N) and insulin(N) in GD ($r = 0.365$, $P = 0.019$), and between Cu (M) and birth weight in C ($r = 0.304$, $P = 0.042$).
Conclusions
Serum cooper levels are higher in women with gestational diabetes and independently of diabetes control. Both serum trace element levels in neonates seem to correlate with neonatal head circumference and birth weight only in control group.

Reduced level of soluble TLR2 in type 2 diabetes despite increased TLR2 monocyte expression

Emanuela Zaharieva[1], Tsvetelina Velikova[2], Elena Vikentieva[3], Dora Popova[3], Adelina Tsakova[4] & Zdravko Kamenov[1]
[1]Medical University Sofia, Alexandrovska University Hospital, Clinic of Endocrinology, Sofia, Bulgaria; [2]Medical University Sofia, St Ivan Rilski University Hospital, Laboratory of Clinical Immunology, Sofia, Bulgaria; [3]Military Medical Academy, Department of Clinical Laboratory and Immunology, Sofia, Bulgaria; [4]Medical University Sofia, Alexandrovska University Hospital, Central Clinical Laboratory, Sofia, Bulgaria.

Background
Chronic low-grade inflammation is a major factor in the pathogenesis of type 2 diabetes. One way for promoting inflammatory cytokines secretion is through activation of toll-like receptors (TLR). Their overexpression on monocytes has been demonstrated in insulin resistance and type 2 diabetes. Soluble forms of toll-like receptors (sTLR) are considered a regulatory mechanisms of their activation. Their role has been described in modulation of bacteria-induced infective diseases but has not been analysed in diabetes. The aim of the study was to evaluate the place of sTLR2 in type 2 diabetes and compare it with monocyte expression.
Subjects and methods
We performed a cross-sectional study that included 63 patients with type 2 diabetes and 25 controls. All were assayed for soluble forms of TLR2 through Enzyme-Linked Immunosorbent Assay. We evaluated monocyte expression of TLR2 in 28 diabetic patients and 14 control subjects through direct immunofluorescence with conjugated monoclonal antibodies. All participants were assayed for Interleukin 6 (IL-6) through Electro-Chemiluminescence Immunoassay and high sensitivity C-reactive protein (hs-CRP) through Particle Enhanced Immunoturbidimetric Assay.
Results
TLR2 expression in patients with type 2 diabetes was higher compared to controls ($89.85 \pm 9.66\%$ vs. $50.20 \pm 36.91\%$ for CD14++CD16+ monocytes, $P=0.003$ and $34.54 \pm 12.38\%$ vs. $17.12 \pm 15.39\%$, $P=0.011$ for CD14+CD16++ monocytes) but sTLR2 was significantly lower in diabetic subjects (1.15 ± 0.65 ng/ml vs 1.44 ± 0.60 ng/ml, $P=0.019$). Inflammatory status between groups was confirmed significantly different concerning hs-CRP (2.79 ± 2.89 mg/l vs. 0.70 ± 0.89 mg/l, $P=0.000$) and IL6 (2.65 ± 2.46 ng/ml vs 1.44 ± 0.22 ng/ml, $P=0.005$) with higher values in diabetic group, although correlations with TLR2 expression were not established ($P>0.05$).
Conclusion
Type 2 diabetes-associated chronic inflammatory state is characterised by elevated monocyte expression of TLR2 but decreased serum sTLR2 level. This poses the question about presence of an impaired immunomodulation of TLRs' activation in diabetes.

Vitamin D metabolites and IL1β RS16944 polymorphism in type 2 diabetes patients: evidence for functional interaction

Nojan Nejatian, Marissa Penna-Martinez & Klaus Badenhoop
Division of Endocrinology, Diabetes and Metabolism, University Hospital Frankfurt, Frankfurt am Main, Hessen, Germany.

We investigated the SNP rs16944 in German type 2 diabetes (T2D) patients and healthy controls (HC) and correlated the findings with concentrations of VD metabolites.
Methods
504 T2D patients and 447 HC were genotyped by a Taqman assay. Additionally $25(OH)D_3$ and $1,25(OH)_2D_3$ plasma levels of 76 T2D patients and 267 HC were measured by radioimmunoassay.
Results
The AA genotype was significantly less frequent in T2D compared to HC whereas GG and AG genotypes were more frequent in T2D (AA: 48.5 vs 37.95%; AG 40vs 49.7%; GG: 11.4 vs 12.4%; $P=0.003$). Furthermore the allele A was less (68.6 vs 62.7% OR = 0.77; 95% CI: 0.64–0.93) and allele G was more frequent (31.4 vs 37.3% OR = 1.3 95% CI: 1.07–1.57, $P=0.008$) in T2D patients compared to HC. Both T2D patients and HC with IL1β genotypes AA and AG did not differ for the VD metabolites. However T2D patients with the GG genotype showed significantly lower levels of $25(OH)D_3$ (median 34.95 vs 13.7 ng/ml $P=9\times10^{-6}$) and $1,25(OH)_2D_3$ (median 59.05 vs 41.15 pg/ml $P=0.006$) compared to HC with the same genotype.
Conclusion
We describe an association of the IL1β with T2D in German patients. Significantly lower $25(OH)D_3$ and $1,25(OH)_2D_3$ levels were observed in T2D patients with the GG genotype. Whereas the major allele A appears to be protective, the minor allele G is may predispose to T2D in combination with a vitamin D deficiency. Our results suggest that VD deficiency enhances the genetic risk for T2D conferred by the genotype GG of IL1β SNP rs16944. Whether and how vitamin D interacts with IL1β through this polymorphism is subject to further studies.

IMIM (Hospital del Mar Research Institute). Autonomous University of Barcelona, Barcelona, Spain; [7]Cooperative Research Network on Aging and Fragility (Spanish acronym: RETICEF). Carlos III Institute of Health, Madrid, Spain.

Background
Patients with type 2 diabetes mellitus (T2DM) have an increased risk of fragility fractures. Anti-diabetic oral agents and insulin may also impact on fracture risk. There is however scarce data available on the effect of such therapies combined as usually prescribed in real-life practice conditions.
Objectives
The objective of this study was to compare the risk of fracture among T2DM patients who are users of different antidiabetic treatments.
Methods
A nested case-control study was conducted using incident T2DM patients registered in computerised primary care records in the Sistema d'Informació per al Desenvolupament de la Investigació en Atenció Primària (SIDIAP) between 2006–2012, with follow-up available until end/2013. Each case (incident fractures of the hip, spine, wrist, or proximal humerus in 2006–2013) was risk-set matched with five controls of the same gender, calendar year of T2DM diagnosis and age at index date (± 10 years). Study exposure included metformin mono-therapy (reference category) and other antidiabetic medications (alone or in combination as prescribed in actual practice) in the 180 days before the index date. Conditional logistic regression analysis was used to estimate odds ratios and 95% confidence interval adjusting for the following confounders: age, gender, HbA1c level, body mass index, history of fracture, co-morbidities, and concomitant medication use.
Results
Data on 12,277 T2DM patients (2,049 cases and 10,2280 controls) was analysed. Insulin use was associated with increased fracture risk (adj OR 1.63 [95%CI 1.30–2.04]), as was the combination of metformin + sulphonylureas (adj OR 1.29 [1.07–1.56]). No significant association was found with other antidiabetic medications and/or combinations.
Discussion
Insulin and sulphonylureas use appear to be associated with an increased fracture risk when compared to metformin amongst recently diagnosed T2DM patients. Residual confounding cannot be ruled out, and more studies are needed to confirm these findings. Given their impact, risk of fracture should be taken into account in the management of T2DM patients.

Increased incidence of diabetes mellitus 30 years after the radiation impact in persons exposed to ionizing radiation during the Chernobyl NPP accident

Oleksii Kaminskyi, Dmitrii Afanasyev, Olga Kopilova, Irina Chikalova, Irina Muravyova, Olena Tepla, Oleksii Pronin, Irina Kiselova, Natalia Dombrovska & Dimitrii Bazyka
National Research Center for Radiation Medicine of NAMS of Ukraine, Kiev, Ukraine.

Several million people in Ukraine and other countries had been exposed to ionizing radiation during the Chernobyl nuclear power plant accident (ChNPPA) on April 26, 1986. The ChNPPA clean-up personnel involved in emergency and recovery works in the 30-kilometer exclusion zone of power plant in the nearest days or months and/or for a long time had received the highest radiation doses due to external gamma-exposure and from incorporated radioactive isotopes with high affinity to endocrine organs, including the thyroid, pancreas, and cerebral endocrine structures. Consequently a dramatic elevation in non-cancer endocrine morbidity emerged due to thyroid disease, pre-diabetes, diabetes mellitus, and obesity. Despite pancreas was previously considered resistant to ionizing radiation the recent research however suggests high sensitivity of endocrine cells, particularly pancreatic beta cells to radiation exposure. It just explains a high prevalence of diabetes mellitus (up to 23%) in the ChNPPA survivors, whilst the respective value for population of Ukraine is much lower, i.e. from 3 to 7% depending on data source. According to retrospective review of endocrine system data from the ChNPPA clean-up workers ($n = 13{,}158$) the prevalence of pre-diabetes and diabetes mellitus had increased dramatically 10 years upon the accident and continues to increase 30 years later. Now it is in average $\sim$16% and $\sim$12% respectively. At that not only a radiation dose but also the duration of moderately intensive gamma-exposure, namely 0.082 ± 0.01 Gy, is critical for the onset of type 2 diabetes mellitus. Persons involved in recovery operations for more than 4–6 months are of concern here. Survey results in the ChNPPA emergency workers demonstrate an increased incidence of latent autoimmune diabetes in adults (LADA).

Baicalin lowers glucose intolerance by controlling pancreatic hormone in high fat-induced obese diabetic rats

Kahui Park, Jung Hye Kim, Sang Bae Lee, Ji Hong You, Yusik Kim, Ji sun Nam, Jong Suk Park & Chul Woo Ahn
Gangnam Severance Hospital, Seoul, Republic of Korea.

Objective
Bacalin was known as an allosteric modulator of the benzodiazepine sites of the γ-aminobutyric acid A receptor ($GABA_AR$), which produce anxiolytic effects in mice without myorelaxant or sedative effects. Baicalin occur flavonoid found in naturally in the genus Scutellaria. It has been recently shown to exert metabolic effects by attenuating hyperglycemia-induced mitochondrial damage in β-cells in diabetic rats, high-fat diet- (HFD-) induced body weight gain, and lipid deposits in the liver and systemic inflammation in mice. This study investigated the effects of baicalin on islet functions and diabetic status in HFD-induced obese diabetic mice.
Methods
C57BL/6 mice were grouped into normal control, HF control, HF sham, and 4 different baicalin dose-administered groups (25, 50, 100, and 150 mg/kg). HFD containing 60% fat and water were fed *ad libitum* for 24 weeks. Designated doses of baicalin or 0.9% saline were administered intraperitoneally 5d/wk. Body weight (BW) and conventional glucose homeostasis parameters (FPG, FPI, AUC-glucose, AUC-insulin, and etc.) were monitored; in addition, *ex vivo* glucose-stimulated insulin secretion (GSIS) and glucagon secretion (GSGS) with isolated islets were performed.
Results
Insulin secretion in response to high glucose stimulation (16.7 mM) was significantly higher in islets isolated from the groups administered 50, 100, 150 mg/kg baicalin compared to HF control; glucagon secretion was significantly suppressed by high glucose stimulation in islets from the same groups.
Conclusion
This study showed that baicalin had positive effects on glycemic control by regulating secretion of insulin and glucagon, possibly through $GABA_AR$ mediation.

Effect of insulin on neurotrophins' levels in the muscular wall of mice intestine and colon

Mohammad Alqudah, Ayman Mustafa, Mohammad Allouh, Othman Alshboul & Ahmad AlDwairi
Jordan University of Science and Technology, Irbid, Jordan.

Background
Neurotrophins are implicated in the physiology and pathophysiology of the mature gastrointestinal tract (GIT) such as motility and inflammatory bowel disease. Moreover, GIT disturbances has been attributed to hyperinsuliemia. Insulin-neurotrophins interactions in the (GIT) have not been investigated yet.
Aim
To test the effect of Insulin on the expression of neurotrophins in the muscular wall of mice intestine and colon.
Methods
Total protein extracts from intestinal and colonic muscular wall treated for 24 hours with insulin were subjected to ELISA assays specific for different neurotrophins and data were analyzed using suitable statistical test with graph pad.
Results
Insulin treatment resulted in significant reduction of neurotrophin-3 (NT-3) protein levels in the muscular wall of both mice intestine and colon. Moreover, neurotrophin-4 (NT-4) levels were significantly reduced in response to insulin treatment in muscular tissue from both intestine and clone as well. Interestingly the effect of insulin was more profound in the colon on NT-3 and NT-4.
Conclusion
These results indicate that changes in GIT structure and function seen in hyperinsulinemia might be due to the effect of insulin on neurotrophins expression levels. However, functional studies are needed to elucidate the exact interactions between insulin and neurotrophins in the GIT.

Clinical assessment of trabecular bone microstructure in type 2 diabetes mellitus with Trabecular Bone Score (TBS)

María Dolores Avilés Pérez, Antonia García Martín, Cristina Novo Rodríguez, Rafael Nieto Serrano, Elena Torres Vela & Manuel Muñoz Torres
Hospital Campus de la Salud, Granada, Spain.

Introduction
Type 2 diabetes mellitus (T2DM) is a risk factor for osteoporotic fractures although bone mineral density is increased. As such, there is a need for improved approaches to estimate fracture risk in such individuals. The Trabecular Bone Score (TBS) is a new technique to determine the trabecular bone micro-architecture.
Objective
Our aim was to evaluate evaluate the usefulness of TBS in T2DM patients.
Methods
We compared TBS values in T2DM group (n: 31) and control group (n: 25) and we analized its relationship with bone mineral density (BMD), history of prior fractures and glycemic control. BMD was evaluated by conventional bone densitometry (DXA) and 3D (3D-DXA).TBS values were determined using TBS InSight® software.

Results
T2DM patients had lower TBS than controls (1.14±0,17 vs 1.25±0,16, $P=0.013$). However, there were no differences in the densitometric or volumetric parameters measured by conventional DXA and 3D-DXA. In T2DM group, TBS at the lumbar spine showed degraded microarchitecture (TBS $\leq$ 1.2) in 16 patients (51.6%); 13 patients (41.9%) had partially degraded structure (TBS $>$ 1.20 & $<$ 1.35); and only 2 patients (6.5%) had normal TBS values (TBS $\geq$ 1.35). TBS results differed between groups close to statistical significance (Default 1). We did not find diferences in TBS values according densitometric diagnosis of osteoporosis (Tscore $\leq$ 2.5 S.D.) or history of prior fracture in either group. We found a significant correlation of TBS with age, body mass index and lumbar spine BMN both in diabetic patients and controls ($P < 0.05$). Finally, we did not observe relationship with glycemic control or duration of diabetes in T2DM group.
Conclusion
TBS is shown as a promising method in the clinical assessment of trabecular bone microstructure in T2DM.

The G allele of the *BDKRB1* rs12050217 polymorphism is associated with protection for diabetic retinopathy

Leticia A. Brondani[1,2], Julia Pisco[1], Jorge A. Guimarães[1,2], Daisy Crispim[1,2] & Markus Berger[1]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil.

Background
Diabetic retinopathy (DR) is a chronic diabetic complication occurring in most diabetic patients after 20 years of disease. Progression of DR to its sight threatening stages is usually associated with worsening of underlying retinal vascular dysfunction and disease. The plasma kallikrein kinin system is activated during vascular injury, mediating important functions in inflammation, blood flow, and coagulation. Bradykinin B1 receptor (B1R) is expressed in human retina, and retinal B1R levels are increased in murine models of diabetes. Furthermore, experimental studies reveal that B1R antagonists ameliorate retinal functional abnormalities caused by diabetes in rodents. Thus, B1R gene (BDKRB1) is a candidate gene for DR.
Objective
To investigate the association between rs12050217A/G polymorphism in the BDKRB1 gene and DR in patients with type 2 diabetes mellitus (T2DM).
Methods
We analyzed 1129 T2DM patients and 416 non-diabetic subjects. T2DM patients were categorized by the presence of non-proliferative DR (NPDR, $n=476$), proliferative DR (PDR, $n=275$) and absence of DR ($n=200$). The local ethic committee approved the study, and all subjects signed a consent form. The BDKRB1 rs12050217A/G polymorphism was genotyped by Real-Time PCR using TaqMan MGB probes.
Results
The genotype frequencies of the BDKRB1 rs12050217A/G polymorphism are in Hardy-Weinberg equilibrium, and did not differ between T2DM patients and normoglycemic subjects ($P>0.05$). The presence of the minor G allele of the rs12050217 polymorphism was less frequent mainly in patients with PDR when compared to patients with NPDR and without DR (31.5, 41.8 and 41.2%, $P=0.034$; respectively). Interestingly, we observed that the presence of the G allele was associated with protection for PDR, which was confirmed after correction for the presence of hypertension, ethnicity, diabetes duration and age ((95% CI) $=0.580$ (0.398–0.843); $P=0.004$).
Conclusions
The BDKRB1 rs12050217 G allele is associated with protection for the advanced stage of DR in T2DM patients.

Dipeptidyl peptidase-4 inhibitor therapy and risk of diabetic retinopathy: a population based study

Nam Hoon Kim[1], Hye Suk Kim[2], Hye Jin Yoo[1], Ji A Seo[1], Nan Hee Kim[1], Kyung Mook Choi[1], Sei Hyun Baik[1], Juneyoung Lee[1], Jung Hyun Noh[3] & Sin Gon Kim[1]
[1]Korea University College of Meidicine, Seoul, Republic of Korea; [2]Anyang SAM Hospital, Anyang, Republic of Korea; [3]Inje University College of Medicien, Ilsan, Republic of Korea.

Background
Given the possible association between dipeptidyl peptidase-4 (DPP-4) inhibitor and risk of diabetic retinopathy (DR), we examined whether DPP-4 inhibitors are beneficial or harmful for DR compared with other glucose-lowering agents.
Methods
From a Korean population-based cohort, we identified 67,743 adults with type 2 diabetes treated with oral glucose-lowering agents between 2008 and 2013. Matching (1:1) was done for comparative groups: ever-used (case) and never-used (control) DPP-4 inhibitors ($n=14,522$ each group). Cox regression analyses assessed the risk of DR events: vitreous hemorrhage, vitrectomy or photocoagulation, intravitreal agent use, and blindness.
Results
During a median follow-up of 28·4 (14.0–45.2) months, there were 305 (control group) and 342 (case group) composite DR events, respectively. Use of DPP-4 inhibitors was not associated with overall risk of composite DR events (adjusted hazard ratio [HR] 1.08, 95% CI 0.93–1.26). Each DR events including vitreous hemorrhage, vitrectomy or photocoagulation, use of intravitreal agents, and blindness were also not increased with DPP-4 inhibitor therapy. The results were consistent according to baseline retinopathy. However, in the analyses by duration of treatment, a DPP-4 inhibitor treatment duration of <12 months was associated with increased risk of composite DR events (adjusted HR 1.95, 95% CI 1.61–2.36).
Conclusion
DPP-4 inhibitor treatment did not increase the overall risk of DR compared with other oral glucose-lowering agents. Given that short-term DPP-4 inhibitor use was associated with increased risk of DR, the need to assess the aggravation of retinopathy in the early phase of DPP-4 inhibitor use is warranted.

Non-genetic rat model of nephropathy in type 2 diabetes with attenuated streptozotocin-induced tubular alteration

Valentina Bayrasheva[1,2], Alina Babenko[1,2], Ivan Pchelin[3], Anna Arefjeva[2], Svetlana Chefu[1,2], Ivan Shatalov[4], Yurii Dmitriev[1], Alexandra Ivanova[3,5], Pavel Andoskin[1], Parvis Aliev[2] & Elena Grineva[1,2]
[1]Federal Almazov North-West Medical Research Centre, Saint Petersburg, Russia; [2]Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russia; [3]Saint Petersburg State University, Saint Petersburg, Russia; [4]Saint Petersburg National Research University of Information, Technologies, Mechanics and Optics, Saint Petersburg, Russia; [5]Komarov Botanical Institute of the Russian Academy of Sciences, Saint Petersburg, Russia.

Non-genetic animal models of diabetic nephropathy (DN) are most commonly reproduced by using streptozotocin (STZ) which preferentially gets into β-cells via GLUT2 transporters. However, STZ administration results in nephrotoxic effects as well, due to expression of GLUT2 by renal tubular epithelial cells. We hypothesized that nicotinamide (NA), which is considered to attenuate the severity of STZ-induced β-cell damage, could also prevent tubular alteration. Starting at 3 weeks after unilateral nephrectomy, thirty adult male Wistar rats were fed the high-fat diet for 5 weeks and then successively received either NA (230 mg/kg) and STZ (65 mg/kg, NA-STZ-group) or STZ in a low dose (40 mg/kg, LD-STZ-group) intraperitoneally in 15-min interval. Control nondiabetic uninephrectomized rats received vehicle and were fed normal chow (C-group). At weeks 10, 20, and 30 (the end of the study), metabolic parameters, creatinine clearance, albuminuria, and urinary tubular injury markers (NGAL, KIM-1) were evaluated as well as renal ultrastructural and light microscopic changes at weeks 20 and 30. NA-STZ-group showed higher reproducibility and stability of metabolic parameters. By week 10, NA-STZ-injected rats showed overweight (328.9±22.7 g (NA-STZ) vs 285.4±20.5 g (C)), mild hyperglycemia (HbA1c 5.39±0.24% vs 3.6±0.29%), significant increase in insulin resistance (HOMA-IR 3.2±0.39 vs 1.93±0.29),and

dyslipidemia (total cholesterol 2.89 ± 0.25 mmol/l vs 1.55 ± 0.35; triglycerides 1.05 ± 0.18 mmol/l vs 0.57 ± 0.1), $P < 0.05$ each, that were observed until the end of the study. At 20 weeks, development of early stage of DN was confirmed by glomerular basement membrane thickness, gradual decline in creatinine clearance, and mild albuminuric status (478.4 ± 63.3 μ/24 h vs 35.8 ± 3.6 μ/24 h), with progression by week 30, when light microscopic features of DN were observed. Morphofunctional renal changes in NA-STZ appeared to be more pronounced than those in LD-STZ despite lower levels of KIM-1 and NGAL (2535.8 ± 303.9 ng/24 h (LD-STZ) at week 30) vs 1704.4 ± 444.7 ng/24 h in NA-STZ, $P = 0.037$. We have described a model of type 2 diabetes and DN with attenuated STZ-induced tubular alteration in rats that is characterized by stable metabolic disorders and renal morphofunctional changes similar to relatively early stages of human DN.

microRNA expression profile in plasma from patients with diabetic kidney disease

Tais Silveira Assmann[1,2], Marcia Punales[3], Balduino Tschiedel[3], Luis Henrique Canani[1,2], Andrea Carla Bauer[1,2] & Daisy Crispim[1,2]
[1]Hospital de Clínicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil; [2]Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil; [3]Instituto da Criança com Diabetes, Porto Alegre, Brazil.

Introduction
Diabetic kidney disease (DKD) is the major cause of end-stage renal disease; however, the pathogenesis of this disease is not fully understood. Currently available therapies are not totally efficacious in the treatment and prognosis of DKD, suggesting that further understanding of the molecular mechanisms underlying the pathogenesis of this disease is necessary to improve its management. Recently, research on microRNAs (miRNAs) has become a hotspot because of their critical role in regulating posttranscriptional levels of protein-coding genes. Several miRNAs were found to participate in DKD pathogenesis; nevertheless, results are still inconclusive. Therefore, the identification of miRNAs involved in DKD may help in the diagnosis and treatment of this disease.
Objective
To identify a miRNA expression profile associated with DKD in plasma from patients with type 1 diabetes mellitus (T1DM) with different degrees of this diabetic complication.
Design
Expressions of 48 miRNAs were investigated in the plasma from 46 T1DM patients: 24 patients in group 1 [patients with T1DM for more than 10 years, with urinary excretion of albumin (UEA) < 30mg/g and estimated glomerular filtration rate (eGFR) ≥ 60 ml/min/1.73 m^2)], 11 in group 2 (patients with T1DM with UEA 30–300mg/g or eGFR 45-59 ml/min/1.73 m^2) and 11 in group 3 (patients with T1DM with UEA > 300 mg/g or eGFR 15-29 ml/min/1.73 m^2), using Stem-loop RT-PreAmp Real-time PCR and TaqMan Low Density Array cards (Thermo Scientific Inc).
Results
Eighteen miRNAs were differently expressed between T1DM patients without DKD (controls) and T1DM patients with different levels of DKD (cases). Seventeen miRNAs were downregulated (miR-126, miR-146a, miR-155, miR-192, miR-200a, miR-200b, miR-204, miR-216a, let-7b, miR-29c, miR-200a, miR-20b, miR-216a, miR-25, miR-320, miR-92a and miR-638) and one miRNA was upregulated (miR-124) in cases compared to controls. In addition, miRNAs let-7b, miR-155, miR-200a, miR-20b, miR-216a, miR-25, miR-29c, miR-320 and miR-92a were downregulated in T1DM patients with severe DKD (group 3) compared to controls.
Conclusion
Our preliminary results show that some circulating miRNAs are differentially expressed between T1DM patients with and without DKD.

The A allele of the -866G/A polymorphism in *UCP2* gene decreases high glucose-induced *UCP2* expression in HUVECs

Tais Assmann[1,2], Daisy Crispim[1,2], Michelle Rodrigues[2], Liana Silva[2], Ana Paula Bouças[1,2], Rodrigo Carlessi[2], Leticia Brondani[1,2], Luis Henrique Canani[1,2] & Bianca Souza[1,2]
[1]Postgraduate Program in Medical Sciences: Endocrinology, Universidade Federal do Rio Grande do Sul, Porto Alegre, Rio Grande do Sul, Brazil; [2]Endocrine Division, Hospital de Clinicas de Porto Alegre, Porto Alegre, Rio Grande do Sul, Brazil.

Uncoupling protein 2 (UCP2) is a mitochondrial protein located in the mitochondrial inner membrane, and it uncouples substrate oxidation from ATP synthesis, thereby dissipating the membrane potential energy and consequently decreasing reactive oxygen species (ROS) formation by mitochondrial respiratory chain. ROS overproduction is related to diabetic retinopathy (DR), a chronic complication of diabetes mellitus (DM). Recently, our group reported that the -866A/55Val/Ins haplotype (-866G/A, Ala55Val and Ins/Del polymorphisms) of the *UCP2* was associated with risk for proliferative DR in both type 1 and type 2 diabetic patients. Additionally, this haplotype influenced *UCP2* expression in human retina samples. Indeed, some studies suggest that the -866G/A polymorphism directly affect *UCP2* expression; however, its effect on endothelial cells under different glucose concentrations is not well defined.
Objective
To investigate the effect of -866G/A polymorphism on *UCP2* expression in an endothelial cell line under different glucose concentrations.
Methods
HUVECs cells were transfected with pGL3 plasmids containing the promoter region of *UCP2* gene and the coding sequence of firefly luciferase, using LTX Lipofectamine (Life Technologies). The test conditions were: 1) transfection with the wild-type allele-containing plasmid (pGL3-UCP2-G); and 2) transfection with the mutated allele (pGL3-UCP2-A), under conditions of normoglycemia (4 mM) or hyperglycemia (25 mM) after 24 h and 48 h. Plasmid pCMV encoding renin luciferase and pEGFP were co-transfected as internal control and transfection control, respectively. Luciferase levels were measured with Luminescent Dual-luciferase Assay (Promega).
Results
HUVECs cells transfected for 24 h and 48 h with the plasmid containing the -866A allele under normal glucose conditions had 47% and 37% decrease in *UCP2* expression than cells transfected with the plasmid containing the G allele ($P = 0.011$ and $P = 0.0001$; $n = 3$). Interestingly, under high glucose conditions, cells containing the A allele had a more drastic decrease in *UCP2* expression (70% and 54%) compared to cells with the G allele ($P = 0.0001$ and $P = 0.028$; $n = 3$) after 24 and 48 h.
Conclusion
Our preliminary results demonstrate that the UCP2 -866A allele decreases *UCP2* expression in HUVEC cells, which is exacerbated under high glucose conditions. The -866G/A polymorphism of the *UCP2* gene is associated with increased UCP2 protein concentrations in human retina, which may explain the previous reported association between the -866A/55Val/Ins haplotype and risk for DR.

GP95

The relation between PON-1 activity and 25-OH hydroxyvitamin D3 levels and other biochemical parameters in diabetic patients with respect to obesity and diabetic complications

Pinar Karakaya[1], Meral Mert[1], Hamide Karagöz[1] & Bahar Ozdemir[2]
[1]Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey; [2]Department of Internal Medicine, Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey.

Objective
To evaluate the relation of mean platelet volume (MPV) levels with serum paraoxonase-1 activity in diabetic patients with respect to obesity and diabetic complications.
Methods
A total of 201 diabetic patients grouped with respect to obesity obese ($n = 89$) and non-obese ($n = 112$) and diabetic complications with ($n = 50$) or without ($n = 150$) microvascular complications and with ($n = 91$) or without ($n = 108$) macro-vascular complications groups were included. Data on demographic and lifestyle characteristics of patients, anthropometric measurements, diabetes related microvascular and macrovascular complications, Correlation of MPV values to paraoxonase and arylesterase activities.

Results
Mean(SD) paraoxonase and arylesterase values were 119.8±37.5 U/l and 149.0±39.9 U/l, respectively in the overall population, with no significant difference with respect to obesity and macrovascular diabetic complications, whereas significantly lower values for paraoxonase 107.5±30.7 vs. 123.9± 38.8 U/l, ($P=0.007$) and arylesterase 132.1±30.2 vs. 154.±41.2 U/l ($P=0.001$) were noted in patients with than without diabetic microvascular complications. Mean(SD) MPV values were 9.10±0.87 fL in the overall population, with no significant difference with respect to obesity and diabetic complications. No significant correlation of MPV values to paraoxonase and arylesterase activities. A significant positive correlation was determined with plasma 25-(OH) hydroxyvitamin D3 levels ($r=0.398$, $P=0.001$ and $r=0.484$, respectively $P=0.001$). HOMA-IR exhibited a significant negative correlation with PON and arylesterase in the groups.
Conclusion
In conclusion, our findings revealed a significant decrease I PON-1 activity in diabetic patients with microvascular rather than macrovascular complications, whereas regardless of obesity and diabetic complications, no increase in thrombogenic activity and no relation of thrombogenic activity with PON-1 activity. PON-1 activity exhibited a significant negative correlation, independent of obesity, sex and age, with plasma glucose, HbA1c and HOMA-IR values in all patients and a significant positive correlation with 25-OH vitamin D3 values. Low PON-1 activity and 25 OH vitamin D3 levels may be a marker of inadequate glycemic control independent of obesity in diabetic patients They may play an important role for early atherosclerosis who had only in obese diabetic especially microvascular diabetic complications well glysemic control of the most factor that it prevents diabetic complications and also well glysemic control and apropiate vitamin D levels have good affect on diabetic complications.

DOI: 10.1530/endoabs.49.GP95

High prevalence of lower extremity peripheral artery disease in type 2 diabetes patients with diabetic nephropathy and the role of netrin-1 levels

Ahmet Kor, Suleyman Baldane, Suleyman Hilmi Ipekci, Kamile Marakoglu, Ali Altinok, Ali Unlu, Fatih Colkesen, Bahadir Ozturk, Cem Onur Kirac & Levent Kebapcilar
Selcuk University, konya, Turkey.

Background
Netrin-1 is an early biomarker of acute kidney injury. Besides, recent studies have showed that netrin-1 promotes angiogenesis; but its usefulness for peripheral artery disease (PAD) in type 2 diabetes patients is unknown.This study aimed at investigating whether netrin-1 levelsare increased in peripheral artery disease among patients with type 2 diabetes and also investigating possible associationsbetween diabetic nephropathy (DN) and PAD.
Material and Methods
This was a cross-sectional observational clinical study. This study involved a total of 84 adults with type 2 DM, who underwent ABI (low ankle-brachial index) measurement in an outpatient clinic. PAD was defined as ABI <0.9 in either leg. ABI of 42 patients with PAD were compared with 42non-PADpatients. Diabetic nephropathy was evaluated by estimated glomerular filtration rate and urinary albumin-creatinine ratio (ACR).
Results
Compared with control group, the levels of Netrin-1 levels and diabetic nephropathy subjects were significantly increased in the PAD group. As regards similar GFR values, patients with higher urinary albumin-creatinine ratio (ACR) values had significantly lower ABI parameters than the patients without albuminuria.(Right: 0.96±0.1 vs 1.05±0.01, Left: 0.94±0.1 1.04±0.01vs $P<0.01$).Binary logisticregression analysis revealed that diabetic nephropathy (vs non-DN) was associated with PAD (OR =2.94, 95%CI: 1.2–7.1; $P=0.017$) .In multivariate models, adjusted additionally for the mean duration of diabetes, gender, BMI, HbA1c, hyperlipidemia and hypertension, theassociations with netrin-1and PAD persisted (beta: 0.238, $P=0.042$).
Conclusion
Our study in patients with type 2 DM demonstrated that PAD was associated with diabetic nephropathy and netrin-1 levels. In conclusion, changes in netrin-1 levels are likely to be used as a biomarker for monitoring the risk of PAD in patients with Type 2 diabetes.

Comparison of current perception threshold measured by Neurometer in patients with type 2 diabetes mellitus to a group of normal individuals

Chin-Hsiao Tseng[1,2]
[1]National Taiwan University College of Medicine, Taipei, Taiwan;
[2]National Taiwan University Hospital, Taipei, Taiwan.

Purpose
To determine the proportion of abnormal current perception threshold (CPT) in patients with type 2 diabetes mellitus.
Methods
A total of 1360 patients with type 2 diabetes mellitus involved in an epidemiological study received an examination of CPT measured by Neurometer® CPT/C (Neurotron, Inc., Baltimore, Maryland, USA) on a supine position. The measurement was taken for three frequencies, i.e., 5, 250 and 2000 Hz at three sites: the preauricular area (trigeminal nerve), the index finger (median nerve) and the great toe (superficial peroneal nerve) on both sides. The three frequencies measure small unmyelinated C fiber (5 Hz), small myelinated Aδ fiber (250 Hz), and large myelinated Aβ fiber (2000 Hz), respectively. The normative data from 75 normal individuals were used as control and an "abnormal CPT" was defined as a value greater than the normal mean plus 3 standard deviations derived from the normal individuals. Age, sex, body height and body weight were treated as potential confounders. Student's t test, Chi-square test, correlation coefficient and stepwise regression were used for statistical analyses and a P value <0.05 was considered as statistically significant.
Results
Accept for a significantly older age in the diabetes group, the distribution of sex, body height and body weight were not different significantly. CPT measurements on the right and left sides correlated significantly with correlation coefficients mostly >0.7 ($P<0.0001$) in the diabetes patients. The trigeminal nerve had the most commonly reported "abnormal CPT" that involved approximately 60% of the diabetes patients, followed by the superficial peroneal nerve (50%) and the median nerve. The median nerve showed frequency-dependent abnormality with higher proportion of "abnormal CPT" involving lower frequency. For the frequency of 2000, 250 and 5 Hz, "abnormal CPT" was observed in 15–20, 30–33 and 56–59%, respectively. In stepwise regression analyses, diabetes and age were consistently predictive for CPT.
Conclusions
Patient with type 2 diabetes mellitus have higher CPT values than normal individuals in all anatomical sites. The application of Neurometer® for screening of diabetes neuropathy awaits further confirmation.

Gestacional diabetes mellitus: the new screening criteria and its outcomes

Pedro Gouveia, Maritza Sá, Eduarda Resende, Margarida Ferreira & Silvestre Abreu
Centro Hospitalar do Funchal, Funchal, Portugal.

Background
Gestational Diabetes Mellitus (GDM) is one of the most common illness of pregnancy. Despite its frequency, there's no worldwide accepted screening criteria for GDM. In 2011, Carpenter and Coustan (CC) screening (50-g glucose challenge test (GCT) followed by 100-g glucose tolerance test (OGTT) if GCT screen was positive) was abandoned and began the implementation of the screening of the International Association of Diabetes and Pregnancy Study Group (IADPSG) 2010 (75-g OGTT).
Aims
Asses and compare perinatal outcomes of these two screening criteria.
Materials and methods
We undertook a retrospective study, of gestacional diabetes followed on Endocrinology department. Two groups were constituted: CC (followed in 2009 and 2010) and IADPSG (followed in 2014 and 2015). All patients were treated with nutrition and exercise. When target glucose levels were not met, insulin was initiated, no oral antidiabetic agents were used. Analysed data included birthweight, premature delivery, macrosomia, mode of delivery, maternal parity, body mass index (BMI) and insulin treatment.
Results
In 2009 and 2010, of 4705 childbirths in the hospital, 259 (5.5%) women met the CC criteria, of which 134 were included in this study. In 2014 and 2015, of 3496 childbirths in the hospital, 348 (9.9%) women met the IADPSG criteria, of which 221 were included in this study. Those with GDM per IADPSG criteria had more

insulin treatment (46.6 vs 23.1%; $P<0.0001$), fewer large for gestacional age fetus (3.6 vs 9.0%, $P=0.038$) and less premature delivery (1.4 vs 5.2%, $P=0.033$).
Conclusions
Although the application of the IADPSG criteria increased the number of women diagnosed with GDM, there was an increase in insulin treatment, and an overall better newborn outcomes. This could mean that the IADPSG criteria identified a group of women with a increased risk of perinatal outcomes that were not recognized by the CC screening.

Higher levels of adiponectin might contribute to lower bone mass observed in patients with type 1 diabetes, through alterations in osteocalcin energy circuit signaling of bone cells.

Charalampos Tsentidis[1], Dimitrios Gourgiotis[2], Lydia Kossiva[1], Artemis Doulgeraki[3], Antonios Marmarinos[2] & Kyriaki Karavanaki[1]
[1]Diabetes Clinic, Second Pediatric Department, University of Athens, "P&A Kyriakou" Children's Hospital, Athens, Greece; [2]Biochemistry Laboratory, Second Pediatric Department, University of Athens, "P&A Kyriakou" Children's Hospital, Athens, Greece; [3]Department of Bone and Mineral Metabolism, Institute of Child Health, "Aghia Sophia" Children's Hospital, Athens, Greece.

Introduction
Recent advances in energy homeostasis revealed a significant interconnection between bone and adipose tissue through osteocalcin. Reduced bone mass documented in type 1 diabetes mellitus (T1D) could be related to disregulation of adipokine signaling on bone.
Materials and Methods
We evaluated 40 children and adolescents with T1D (mean $\pm$ s.d. age 13.04 $\pm$ 3.53 years, mean $\pm$ s.d. T1D duration 5.15 $\pm$ 3.33years) and 40 healthy age- and gender-matched controls (mean $\pm$ s.d. age 12.99 $\pm$ 3.3years). Adiponectin, leptin and bone metabolism markers were measured, while lumbar spine (LS) and total body (TB) Bone Mineral Density (BMD) were evaluated with dual energy X-ray absorptiometry (DXA).
Results
Lower BMD values have already been documented in patients, as well as lower osteocalcin (log(osteocalcin) 3.44 $\pm$ 0.5 vs 3.6 $\pm$ 0.51). Patients had higher levels of adiponectin (18078 $\pm$ 8645 vs 13536 $\pm$ 6703 ng/ml, $P=0.007$) while leptin levels were comparable between groups (8.85 $\pm$ 8.73 vs 10.03 $\pm$ 8.75 pg/ml, $P=0.13$). Both adipokines were associated with Body Mass Index (BMI) in both groups. Adiponectin was positively associated with osteocalcin only in controls (Rho $=0.31$, $P=0.05$) possibly indicating altered energy signaling in bone of T1DM patients, whereas in patients it was negatively associated with IGF1 (Rho $=-0.30$, $P=0.05$) and positively associated with HbA1c (Rho $=0.38$, $P=0.01$) and i-phosphorus (Rho $=0.39$, $P=0.01$). No associations of leptin with bone markers were observed.
Conclusion
Increased adiponectin might contribute to lower bone mass observed in young T1D patients with altered interconnection of energy signaling in bone cells, through osteocalcin circuit.

Type 1 diabetes and hearing loss: a meta-analysis

Mario Mujica-Mota & Neel Patel
Montreal, Québec, Canada.

Objective
Evidence shows type 1 diabetes leads to vascular damage and neuropathy. The purpose of this study was to perform a systematic review and a meta-analysis to asses the evidence of the effects of type 1 diabetes on hearing function.
Methods
Three different electronic databases were used to identify eligible studies including a manual searching of references. The articles obtained were independently reviewed by two authors using predefined inclusion criteria to identify eligible studies. Meta-analysis was performed on pooled data of hearing loss incidence, PTA thresholds and ABR wave latencies.
Results
Fifteen articles fulfilled the inclusion criteria and passed the quality control evaluation. In most studies, hearing loss (HL) was defined as pure tone greater than 25 dB in the worse ear of at least one frequency. The incidence of HL ranged between 0 and 48% for diabetics, which was higher than in controls (OR $=12.43$ 95% CI 3.09–49.95). The tendency of mean PTA (pure tone audiometry) thresholds were greater in diabetics than in controls for higher frequencies, however the results were not significant. Auditory brainstem response (ABR) latencies were longer in diabetic patients compared to controls. Statistical significance was obtained in wave III and V ($Z=3.18$, $P=0.001$ $I^2=82\%$; $Z=2.55$, $P=0.01$, $I^2=89\%$ respectively).
Conclusions
Patients with type 1 diabetes have a significantly greater incidence of HL compared to the control group. However, hearing thresholds seems to be not significantly different from control subjects. Mean PTA thresholds were greater at 6000 and 8000 Hz. Despite a trend of higher threshold difference at higher frequencies tested, the mean differences between groups at any frequency were not statistically significant. A significant prolonged ABR of waves III and V latencies in the diabetic group suggest a retro-cochlear involvement in hearing damage in type 1 diabetes.

Comparison of the effects of combinations of different antihypertensive therapies on microalbuminuria and renal functions in type 2 diabetic patients

Muge Erek[1], Alparslan Ersoy[1] & Canan Ersoy[2]
[1]Uludag University Medical Faculty, Department of Nephrology, Bursa, Turkey; [2]Uludag University Medical Faculty, Department of Endocrinology and Metabolism, Bursa, Turkey.

Renin angiotensin system blockers are currently used in the treatment of diabetic nephropathy. Carvedilol, 3. generation beta-blockers, may provide additional benefits in diabetic patients. Its antiproteinuric activity is not investigated in patients with diabetic nephropathy. We aimed to compare short-term additive effects of losartan with cilazapril or carvedilol combination on blood pressure, proteinuria and renal functions in microalbuminuric patients with type 2 diabetes mellitus and hypertension.
Methods
Thirty patients with type 2 diabetes, stage 1 hypertension and albuminuria of 30–300 mg/day, were enrolled in the study. After the 2 week follow-up period, all patients were started on losartan 50 mg/day for 6 weeks. Then, they were randomized to three groups for 6 weeks: 1st group (n:10) on losartan 100 mg/day, 2nd group (n:10) on carvedilol 25 mg/day + losartan 50 mg/day and 3rd group (n:10) on cilazapril 5 mg/day + losartan 50 mg/day treatment.
Results
Characteristics of groups were similar. In all groups, systolic and diastolic blood pressures (BP) were significantly decreased. Greatest decrease in systolic (16.5 $\pm$ 7.4 mmHg) and diastolic (10.5 $\pm$ 2.8 mmHg) BPs were seen in group 3 and smallest decreases were seen in group 1 (systolic BP: 9 $\pm$ 6.1 mmHg, diastolic BP: 3 $\pm$ 4.8 mmHg). Microalbuminuria levels in all groups decreased significantly when compared to the period of 50 mg losartan alone ($P<0.05$). Renal functions of the groups did not change significantly. But creatinine clearances significantly increased in all groups after the randomization, although there was no significant difference between groups.
Conclusion
We observed that the combination of carvedilol in hypertensive type 2 diabetics patients with microalbuminuria safely controlled blood pressure more effectively without additional benefit in reducing microalbuminuria

Non-stimulated c-peptide is independently associated with requirement at 1 year for insulin therapy in patients with diabetes: a retrospective cohort study of 872 patients

Emma Leighton[1], Karen Smith[2], Christopher Sainsbury[1] & Gregory Jones
[1]Gartnavel General Hospital, Glasgow, UK; [2]Glasgow Royal Infirmary, Glasgow, UK.

Introduction
C-peptide is frequently used in clinical practice to estimate insulin secretion, and guide need for future insulin treatment. Present practice is based on studies with small patient numbers.
Aim
To explore the association between non-stimulated c-peptide and progression to insulin therapy in patients with diabetes.
Patients and Methods
1971 patients with c-peptide measurements were identified (February 2007–December 2016) within a single health board. 940 individuals also appeared on national diabetes database. 872 individuals within this dataset have a defined diabetes diagnosis and were analysed. The date of first encashed insulin prescription for each individual was extracted from the national diabetes dataset. Insulin-free survival (time to first insulin prescription or end of follow-up) in individuals who were insulin-naive at the time of c-peptide measurement was investigated using survival analysis. Individuals with c-peptide values below median were compared with those above median value. Time to insulin prescription was analysed using cox proportional hazard model with age and BMI as covariables. The positive predictive value (PPV) of c-peptide for predicting insulin use at 1 year was calculated in 0.2 nmol/l increments.
Results
458 individuals had BMI data available, and were insulin-naive at the time of c-peptide measurement. In this cohort a c-peptide in the lower half of the range of observed values (<0.76 nmol/l) is associated with a significantly decreased insulin-free survival time ($P<0.001$, HR 3.0). PPV for initial c-peptide(nmol/l) increments were: c-peptide 0.01-0.2 PPV = 0.95, 0.2–0.4 PPV = 0.67, 0.4–0.6 PPV = 0.6, 0.6–0.8 PPV = 0.43, 0.8–1.0 PPV = 0.3.
Conclusion
Unstimulated c-peptide is independently associated with increased probability of requiring insulin at 1 year. This is a simple test which offers potentially useful information allowing patients to plan for future treatment.

Ceramide synthase 6 inhibition as a novel therapeutic approach for obesity and type 2 diabetes

Maximilian Bielohuby[1], Surya Prakash[1], Bodo Brunner[1], Anja Pfenninger[1], Ulrich Werner[1], Sarah Turpin-Nolan[2], Jens Brüning[2] & Norbert Tennagels[1]
[1]Sanofi-Aventis Deutschland GmbH, R&D Diabetes Division, Industriepark Höchst, Frankfurt am Main, Germany; [2]Max Planck Institute for Metabolic Research, Cologne, Germany.

Excess consumption of saturated fatty acids may lead to an increased production of ceramides that contribute to development of insulin resistance and type 2 diabetes. Substantial research demonstrated that inhibition of ceramide biosynthesis ameliorates atherosclerosis, hepatic steatosis, insulin resistance and obesity. However, as ceramides and their sphingolipid products are involved in multiple fundamental cellular processes, concerns exist about possible risks or adverse effects resulting from overall inhibition of sphingolipid synthesis for treatment of chronic diseases. Therefore, the inhibition of specific ceramide species represents a new strategy for pharmaceutical intervention. Recent research demonstrated that specifically CerS6 mediated C16 ceramide synthesis plays a key role in the development of obesity mediated insulin resistance.
In the current study, we investigated the effects of specifically knocking-down CerS6 in ob/ob mice using CerS6 anti-sense oligonucleotides (ASO). In this animal model, CerS6 expression is significantly higher vs. lean control mice ($\sim$2 fold in the liver and BAT) which correlates with a 4-fold increase of C16 ceramide in the plasma and a 2-fold increase in the liver. CerS6 ASO treatment led to selective and significant $\sim$80% knockdown of the CerS6 expression in the liver and correlated with a significant 50% reduction of C16 ceramide in the liver and plasma compared to control ASO-treated ob/ob mice. CerS6 knockdown protected against body weight gain and was associated with a significant reduction in fat mass and blood glucose levels. Moreover, insulin resistance was significantly improved by ASO treatment as evidenced by oral glucose tolerance and insulin tolerance tests ($\sim$50% reduction in AUC during oGTT).
In conclusion, CerS6 dependent C16 ceramide synthesis represents a distinct sphingolipid species, which contributes to the development of obesity and insulin resistance and therefore may represent a unique and attractive novel target to treat obesity and type 2 diabetes.

Outcomes of integrating personal continuous glucose monitors with insulin pumps in a University Diabetes Unit

Ali Rizvi & Kyoka Smith
University of South Carolina School of Medicine, Columbia, SC, USA.

Objective
Personal continuous glucose monitoring (pCGM) with interstitial fluid glucose sensing is rapidly becoming the standard of care for real-time, intensive insulin therapy of diabetes. We report our experience of glycemic control in patients in an academic setting using minimally invasive pCGM with continuous s.c. insulin infusion (CSII, or insulin pump) vs CSII alone.
Methods
Over a two-year period, we reviewed all patients treated with insulin pumps at the Diabetes Unit of the Palmetto Health-University of South Carolina Medical Group. Group A (CSII alone) used only meters to self-monitor blood glucose, and while Group B additionally used pCGM integrated with CSII to adjust pump settings, including basal rate and/or short-acting bolus insulin doses, and change insulin-to-carbohydrate ratio and supplemental factor. The data was analyzed with respect to age, gender, glucose control as assessed by glycosylated hemoglobin (HbA1c), and severe hypoglycemia.
Results
There were 54 patients in group A and 59 in group B. They were comparable in mean age and gender breakdown (47.3 vs 45.2 years, and 66.8% vs 62.7% females, respectively). The average glycosylated hemoglobin (HbA1c) changed from 8.8% to 8.2% and from 8.2% to 7.3% from baseline to the end of one year in the two groups respectively. The number of severe hypoglycemic episodes per patient during the one year was 0.2 and 0.07 respectively.
Discussion
CSII patients who used pCGM were similar in demographics to those who used insulin pumps alone, but had a lower baseline A1c, exhibited a larger decrease in A1c at one year (0.9% vs 0.6%), and had fewer severe hypoglycemic events.
Conclusions
The better outcomes with pCGM-integrated pump therapy may be explained by a higher motivation ability for self-monitoring and care, and by the pCGM being a valuable informational tool in assessing glucose trends when used in properly chosen insulin pump patients who are managed by qualified experts.

Specific Oct1 gene variants are associated with changes in the risk of cardiovascular death in metformin users

Natascha Schweighofer[1,7], Bernd Genser[2,3], Winfried März[4,5], Marcus E Kleber[6], Thomas R Pieber[1,7] & Barbara Obermayer-Pietsch[1,7]
[1]Division of Endocrinology and Diabetology, Department of Internal Medicine, Medical University Graz, Graz, Austria; [2]BG Statistical Consulting, Vienna, Austria; [3]Institute of Public Health, Social and Preventive Medicine, Medical Faculty of Mannheim, University of Heidelberg, Mannheim, Germany; [4]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University Graz, Graz, Austria; [5]Synlab Center of Laboratory Diagnostics, Heidelberg, Germany; [6]Vth Department of Medicine (Nephrology, Hypertensiology, Endocrinology, Diabetology, Rheumatology), Medical Faculty Mannheim, Heidelberg University and Competence Cluster of Nutrition and Cardiovascul, Heidelberg/Halle-Jena-Leipzig, Germany; [7]CBmed GmbH, Center for Biomarker Research in Medicine, Graz, Austria.

Aim
Increased cardiovascular incidents and a high risk for microvascular complications are associated with type 2 diabetes. Worldwide, metformin is the most commonly prescribed antidiabetic drug. Polymorphisms in the *Oct1* gene can alter the function or activity of organic cation transporter 1 (Oct1), thus changing metformin efficacy (Oct1 acting as its main transporter) as well as influencing the actions of Oct1 physiological substrates. In the past, polymorphisms in *Oct1* were associated with cardiovascular risk factors, thus they might contribute to cardiovascular risk development.
We investigated, whether the Oct1 polymorphism rs3777392 is associated with increased risk for cardiovascular death in a cohort of patients with and without type 2 diabetes (T2DM) on various therapies.
Methods
Data from the LURIC study ($n=3316$), a prospective cohort study of Caucasians scheduled for coronary angiography were analysed. We identified 1820 non-diabetics, 1220 T2DM patients, including 73 metformin users (Met), 154 sulfonylurea users (SF) and 967 T2DM individuals without medication. Cardiovascular mortality was assessed in all groups according to Oct1 rs3777392 genotypes using Cox proportional hazard models and associations with cardiovascular biomarkers were investigated.
Results
Cardiovascular mortality risk for each minor allele copy was HR 2.08 (95% CI: 1.01, 4.28) only in metformin users. Variants of rs3777392 were associated with BMI, baseline insulin values and triglyceride levels in all T2DM patients ($P=0.016$, $P=0.048$ and $P=0.007$, respectively), patients without medication ($P=0.006$, $P=0.041$, $P=0.008$, respectively) and non-diabetics ($P=0.021$, $P=0.074$, $P=0.125$, respectively) but not in the Met and SF groups.
Conclusion
In our study, the minor allele of rs3777392 in the Oct1 gene was associated with an increased cardiovascular mortality risk in T2DM patients on metformin therapy, which might be due to loss of association with cardiovascular parameters. Besides very positive effects in the majority of metformin users, some individuals may profit from a pre-treatment genotyping and careful monitoring.

DOI: 10.1530/endoabs.49.GP107

Liraglutide improves carotid intima-media thickness in pre-elderly and elderly patients with type-2 diabetes: an 18-month prospective, real life study

Ali Rizvi[1], Angelo Maria Patti[2], Giuseppa Castellino[2], Carlo Mannina[2], Dragana Nikolic[2], Rosaria Vincenza Giglio[2], Roberta Chianetta[2], Giuseppe Montalto[2] & Manfredi Rizzo[1,2]
[1]University of South Carolina School of Medicine, Columbia, SC, USA; [2]University of Palermo, Palermo, Sicily, Italy.

Introduction
Liraglutide exerts cardio-protective effects beyond of those on glucose metabolism, affecting several cardio-metabolic parameters, such as subclinical atherosclerosis. However, it is not known if those effects differ in the long-term between pre-elderly and elderly subjects with type-2 diabetes (T2DM).
Methods
We included 135 subjects with T2DM divided in 2 groups: i) 71 pre-elderly subjects (46 men and 25 women, 55 ± 7 years), and ii) 64 elderly subjects (33 men and 31 women, 70 ± 5 years). All subjects were naïve to incretin-based therapies and treated with liraglutide as add-on to metformin, 0.6 mg/day for two weeks, followed by a dose of 1.2 mg/day. At baseline and every 6 months fasting samples were taken for laboratory analyses and carotid-intima media thickness (cIMT) was assessed by B-mode ultrasound. Statistical analysis was performed by ANOVA and the Spearman correlation method.
Results
After18 months of liraglutide therapy HbA1creduced significantly in both groups (from 9.02 ± 1.06 to 6.93 ± 1.25 and from 8.50 ± 0.71 to 6.74 ± 0.90%, respectively) as well as fasting glycemia (from 9.57 ± 3.33 to 7.16 ± 2.83 mmol/l; and from 9.14 ± 3.71 to 7.28 ± 2.29 mmol/l, $P<0.0001$ for all. Anthropometric parameters changed although not significantly. Lipids, with the exception of HDL-cholesterol, reduced significantly only in pre-elderly subjects (triglycerides from 1.94 ± 1.48 to 1.57 ± 0.80 mmol/l, $P=0.0458$; total cholesterol from 4.90 ± 1.57 to 4.27 ± 1.04 mmol/l, $P=0.0025$; LDL-cholesterol from 2.92 ± 1.44 to 2.34 ± 0.91 mmol/l, $P=0.0054$. cIMT significantly decreased in both groups (from 0.96 ± 0.18 to 0.78 ± 0.20 mm; and from 0.98 ± 0.17 to 0.79 ± 0.20 mm, respectively; $P<0.0001$ for both). Changes in cIMT were positively associated only with changes in triglycerides in both pre-elderly ($r=0.245$, $P=0.0398$) and elderly ($r=0.566$, $P<0.0001$) groups.
Conclusion
Liraglutide significantly reduced cIMT in both pre-elderly and elderly subjects with T2DM, beyond glycemic control.

Treatment of diabetic ketoacidosis at type 1 diabetes mellitus presentation: 13 year experience from a tertiary centre (2004–2016)

Joana Serra-Caetano[1], Lia Gata[1], Alexandra Dinis[1], Rita Cardoso[1], Isabel Dinis[1], Miguel Patrício[2] & Alice Mirante[1]
[1]Pediatric Hospital, Coimbra Universitary Hospital Centre (CHUC), Coimbra, Portugal; [2]Laboratory of Biostatistics and Medical Informatics and IBILI, Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Introduction
Diabetic ketoacidosis (DKA) is an endocrine emergency and the leading cause of morbi-mortality in children with type 1 diabetes mellitus (1DM). DKA treatment is still controverse, mainly regarding hydroelectrolytic replacement and insulin dose.
Aims
To evaluate efectiveness and safety of our tertiary centre protocol in DKA treatment, which included initial volume expansion with isotonic saline in the first two hours followed by 0.45% sodium chloride with 5% glucose and insulin infusion (0.1 U/kg per h). Potassium replacement with potassium phosphate in the first 12 h.
Methods
Retrospective study of all children with moderate and severe DKA 1DM presented from 2004 to 2016. Data collected: insulin infusion dose, glycemia, pH. Osmolarity, corrected sodium, potassium and phosphate along the first 12 h of treatment. Statistic analysis with SPSS21 ($P<0,05$).
Results
179 new cases of 1DM were admitted and 45 (25%) had DKA at presentation (15 severe, 12 moderate and 18 mild DKA). Within moderate and severe DKA (N=27), 18(67%) were female and mean age at diagnosis was 8.5 ± 3.8 years. Means at admission were: 528 ± 138 mg/dl glycemia, 310 ± 12 mosm/kg osmolarity, 146 ± 5 mmol/l corrected sodium, 4.5 ± 0.73 mmol/l potassium and 1.5 ± 0.5 mmol/l phosphate. Mean insulin infusion dose at treatment start was 0.08 ± 0.03 U/kg per h. Along the first 12 h mean replacement doses were 4.3 ± 1.3 gr/U per h of glucose, 0.13 ± 0.04 mmol/kg per h of potassium, 0.33 ± 0.1 mmol/kg per h of sodium and 0.06 ± 0.02 mmol/kg per h of phosphate. There were 12(45%) cases of hypokalemia and 10(37%) of hypophosphatemia. There was no hypocalcemia nor cerebral edema. There was statistical significance in variation regarding glucose, pH, corrected sodium and osmolarity along the 12 h ($P<0.0001$). Sodium decreased in the first 8 h. Potassium decreased along the first 4 h and rose from 8 h forwards.
Conclusions
Our protocol allowed a safe treatment of DKA at 1DM presentation, with gradual correction of dehydration and acidosis. However, sodium and potassium replacement should be adjusted, leading to our actual protocol.

DOI: 10.1530/endoabs.49.GP109

The method of reporting hypoglycemia in Randomized Control Trials (RCTs): a systematic review on RCTs conducted for SGLT-2 inhibitors

Noor Kassir[1], Sarah Medeiros[2] & Pendar Farahani[3]
[1]National University of Ireland, Galway, Ireland; [2]University of Western Ontario, London, Ontario, Canada; [3]McMaster University, Hamilton, Ontario, Canada.

Background
Hypoglycemia is an important side effect in pharmacotherapy of patients with diabetes mellitus. Medical organizations have tried to define hypoglycemia in clinical practice and RCTs with scientific statements and guidelines.
Objective
To explore the method of reporting hypoglycemia conducted on SGLT-2 inhibitor RCTs.
Methods
A systematic review using PubMed to find data on RCTs conducted for SGLT-2 inhibitors, limited to English language.
Results
Of 155 RCTs, 95(61.3) (n(%)) were found to have defined and reported hypoglycemia. The results showed that 8(5.2) RCTs were reported as event/arm, 15(9.7) as event/combined all arms, 69(44.5) as event/patient/arm and 3(1.9) RCTs reported as both event/arm and event/combined all arms. Additionally, 3(1.9) RCTs defined hypoglycemia but did not report it. Hypoglycemia was neither defined nor reported in 57(36.8) of the RCTs. In addition, 41(26.5) RCTs had hypoglycemic episodes that were confirmed, by glucose threshold, whereas only 24(15.5) RCTs had episodes that were reported as symptoms from patients. Hypoglycemic episodes were reported and confirmed in 5(3.2) of the RCTs and 27(17.4) showed that the episodes were reported or confirmed.
Conclusion
This study illustrates that around 40% of RCTs on SGLT-2 inhibitors did not define and report hypoglycemia. The method of reporting hypoglycemia was variable among the RCTs. Almost half the RCTs reported as event/patient/ arm. Additionally, a quarter of RCTs only reported hypoglycemic episodes with confirmation of glucose threshold. Future RCTs should unify the reporting of hypoglycemia for safety assessment of diabetic medication.

Hepatic effects of GLP-1 receptor agonist Liraglutide in patients with type 2 diabetes

Maria Hayon[1], Marta Fernandez[1], Silvia Maraver[2], Teresa Muros[1], Daniel Cepero[3], Martin Lopez[1], Miguel Quesada[1], Joaquin Pechuan[4] & Gonzalo Piedrola[1]
[1]Complejo Hospitalario Universitario de Granada, Granada, Spain; [2]Clínico Virgen de la Victoria Hospital, Malaga, Spain; [3]Torrecardenas Hospital, Almeria, Spain; [4]Endocrinology Private Office, Granada, Spain.

Introduction
The aim of this study was to analyze the effects of Liraglutide in hepatic steatosis as well as clinical and biochemical data before and after 6 months.
Methods
We have retrospectively analysed epidemiological, anthropometric and laboratory data of 83 type 2 diabetic patients treated with Liraglutide and followed at different endocrinology units across east Andalusia. We have evaluated nonalcoholic fatty liver disease using liver enzymes and hepatic steatosis index (HSI). HSI > 36 reflects fatty liver, < 30 absence, and intermediate values are considered indeterminated.
Results
Of the 83 cases evaluated, 54.2% were male, mean age 56.76 ± 9.87 years, time from diagnosis 9.46 ± 5.46 years. Prior to treatment, patients had BMI 37.68 ± 6.82 kg/m^2, blood pressure 138.80/82.87 mmHg, fasting glucose 187.33 ± 55.11 mg/dl, glycated hemoglobin (HbA1C) 8.62 ± 1.3%, total cholesterol 178.1 ± 35.74 mg/dl (c-LDL 97.66 ± 32.16 mg/dl, c-HDL 44.54 ± 13.78 mg/dl), triglycerides 197.64 ± 24.19 mg/dl, AST 29 ± 20.311 U/l, ALT 39.88 ± 31.69 U/l and HSI 46.44 ± 6.48.
Clinical and biochemical figures at 6 months were: BMI 36.08 ± 6.32 kg/m^2, blood pressure 132.76/77.41 mmHg, fasting glucose 165.16 ± 56 mg/dl, HbA1C 7.73 ± 1.33%, total cholesterol 170.6 ± 39.19 mg/dl (c-HDL 46.25 ± 15.03 mg/dl, c-LDL 87.74 ± 30.5 mg/dl), triglycerides 198.29 ± 22.29 mg/dl, AST 24.97 ± 12.49 U/l, ALT 32.76 ± 18.24 U/l, and HSI 43.98 ± 6.38.
Statistically significant differences were found regarding several variables, such as BMI, HbA1C, fasting glucose, blood pressure and c- LDL, as well as in ALT and HSI, showing an amelioration in hepatic steatosis. No differences were found in total cholesterol, c-HDL, triglycerides and AST.
Conclusion
In our study, six- month therapy with Liraglutide improves, not only risk factors for cardiovascular disease, but also hepatic steatosis as shown by a decrease in HSI index and ALT.

GP112

Exenatide treatment causes suppression of serum fasting ghrelin levels in patients with type 2 diabetes Mellitus

Metin Guclu[1], Sinem Kiyici[1], Zulfiye Gul[2] & Sinan Cavun[2]
[1]Department of Endocrinology and Metabolism, Health Sciences University, Bursa Yuksek Ihtisas Education and Training Hospital, Bursa, Turkey; [2]Uludag University Medical Faculty, Department of Pharmacology, Bursa, Turkey.

Aim
Ghrelin plays an important role in the stimulation of food intake and long-term regulation of body weight. In present study we investigate the long term effect of exenatide treatment on serum fasting ghrelin levels in patients with type 2 diabetes mellitus.
Methods
Type 2 diabetic patients who were using metformin with and without the other oral antihiperglycemic drugs on a stable dose for at least 3 months were enrolled in the study. Body mass index (BMI) > 35 kg/m^2 and hemoglobin A1c (HbA1c) > 7.0% were the additional inclusion criteria. Oral antihyperglycemic drugs other than metformin were stopped and metformin treatment was continued at 2000 mg per day. Exenatide treatment was initiated at 5 mcg per dose sc twice daily and after one month the dose of exenatide was increased to 10 mcg twice daily. Changes in anthropometric variables, glycemic control, lipid parameters, and total ghrelin levels were evaluated at baseline and following 12 weeks of treatment.
Results
Thirty-eight patients (male/female = 7/31) with type 2 diabetes mellitus entered to the study. Mean age of patients was 50.5 ± 8.8 years with mean diabetes duration of 8.5 ± 4.9 years. Mean BMI was 41.6 ± 6.3 kg/m^2 and mean HbA1c of patients was 8.9 ± 1.4%. Percentage change in weight of patients was −5.2 ± 3.7% following 12 weeks of treatment. BMI and HbA1c levels of patients were decreased significantly ($P < 0.001$ and $P < 0.001$; respectively) while there was no change in lipid parameters. Serum fasting ghrelin levels were suppressed significantly after 12 weeks of exenatide treatment compared with baseline values (328.4 ± 166.8 vs 245.3 ± 164.8 pg/ml) ($P = 0.024$).
Conclusion
These results suggest that the effect of exenatide on weight loss may be related with the suppression of serum fasting ghrelin levels, which is an orexigenic peptide.

Impact of the socio-economic level on the management in type 2 diabetes

Boulbaba Kolsi[1], Mouna Elleuch[1], Rihab Ben Abdallah[2], Feten Haj Kacem[1], Fatma Mnif[1] & Mohamed Abid[1]
[1]Hedi Chaker Hospital, Sfax, Tunisia; [2]Faculty of Sciences of sfax, Sfax, Tunisia.

Diabetes is a chronic disease whose associated comorbidities are largely influenced not only by pathology but also by socio-economic conditions. The aim of this study is to investigate the influence of social conditions on the evolution of diabetes. A retrospective, comparative study of 111 patients with type 2 diabetes Follow-up in the Endocrinology-Diabetology department in hospital Hedi Chaker of Sfax. Patients were divided into two groups with unfavorable (G1) and good (G2) socio-economic conditions, both groups had 58 and 53 patients, respectively. The average age of our patients was 54 in G1 and 49 in G2 ($P = 0.7$). A female predominance was noted in the G 1/64% while the male sex was predominant in the G 2: 80%. The age of diabetes was comparable between the two groups (12.5 years vs 11 years, $P = 0.09$). Fasting glucose was significantly higher in G 1 (15 mmol / l) versus 9 mmol / l in G2 ($P < 0.0001$). The number of hospitalizations was higher in G1: 2.8 versus 1.3 in G2 ($P = 0.005$). The food investigation showed a higher caloric intake in G2 estimated at

2615 Kcal/d versus 2184 Kcal/d for the G1. Infectious complications and amputation were significantly more frequent in G 1 compared to G2. Similarly, microangiopathic complications were more frequent in G1 patients. This imbalance was related to management difficulties, so no patient of G1 group was placed under insulin analogs versus 23% of G2 patients. Socioeconomic status seems to play a crucial role in the glycemic balance and the occurrence of chronic complications of diabetes. This is mainly due to the restriction of access to health care structures and therapeutic, sometimes expensive, and the level of instruction of these disadvantaged classes.

Outcomes of a nurse-led thyroid clinic at a tertiary-care endocrine centre

Violet Fazal-Sanderson[1], Niki Karavitaki[2], Ashley Grossman[3] & Atul Kalhan[4]
[1]Royal Berkshire Hospital, Reading, UK; [2]Queen Elizabeth Hospital, Birmingham, UK; [3]Oxford University Hospitals NHS Foundation Trust, Oxford, UK; [4]Royal Glamorgan Hospital, Wales, UK.

Introduction
A Nurse-led Thyroid Clinic (NLTC) in a tertiary-care Endocrinology centre (EC) in Oxford was set up in 2005. The patients were managed by an Endocrine Advanced Nurse Practitioner.
Aims
To evaluate standard of clinical care (SOCC) quality of service provision (QOSP) and cost effectiveness (CE) of the NLTC.
Methods
Three aspects of service were assessed:

a) *SOCC*: Data were collected for patients managed over 12 months between 1/2014 and 1/2015. Diagnosis, investigations and management plans for individual patients were compared against accepted regional and national guidelines.
b) *QOSP* was evaluated from standardised patient feedback questionnaires (PFQ) that were anonymised for confidentially
c) *CE* was analysed through collection of retrospective data of filed patients clinic lists between 1/2014 and 1/2015. A new patient (NP) tariffed at £120, follow-up, at £90 per visit according to finance department protocol. Annual data recorded of non-face-to-face-telecommunication (NFTFT) costed at £30 per call.

Results

a) *SOCC*: 214 patient appointments for 134 patients were reviewed; 112 patients had Graves' disease, 10 subacute thyroiditis,10 toxic nodular diseases and two subclinical thyrotoxicosis. Patients were managed with a departmental protocol based on British Thyroid Association guidelines 2006.
b) *QOSP:* 50 out of 60 PFQ were returned (34 women/16 men, median age 52.3 years, range 21–85). Majority of the patients expressed high satisfaction with the quality of services provided, with 86% "Extremely Likely" to recommend the TNLC to friends and family.
c) *CE*: New and follow-up patients generated an annual income of £20,490. NFTFT calls (908 patients) generated an income of £27,240. 41 empty NP clinic slots, 22 follow up cancellations and 19 patients who failed to attend the clinic, amounted to a loss of £8610.

Conclusions
The audit supports the value of NLTCs in EC's with a significant thyroid-dysfunction workload. These clinics can provide high quality of clinical care and potentially be cost-effective.

GP115

Education, patient empowerment and admission avoidance

Anna Hawkins, Edel Casey & Khash Nikookam
Barking, Havering & Redbridge University NHS Trust, ESSEX, UK.

It is paramount to educate our patients, thereby empowering them to manage their chronic conditions. This is an evidence based fact. As healthcare professionals our challenge is to provide and ensure patients have been well informed in order to understand and manage their condition successfully on a daily basis.
In today's healthcare service patient education has become a casualty of the reduced resources; there are ever increasing restrictions on both the length and frequency of consultations.
Endocrine teams and in particular the specialist nurses role involves teaching patients with new diagnosis as well as building on information they have gained from their consultations etc. We wanted to see how many patients with pituitary/adrenal failure have gaps in the understanding of their condition, particularly in relation to their sick day rules.
We surveyed 18 patients on hydrocortisone replacement who completed a questionnaire assessing their knowledge and understanding of their condition. When asked what action they would take if they had flu and a high temperature, nine would double their steroid dose, three would triple it. This leaves six patients at potential risk of admission. When asked about vomiting and/or diarrhoea, six said they would double their dose, one would triple it and one would take their emergency hydrocortisone injection, potentially leaving ten patients at risk of an Addisonian crisis. Within this group of patients seven had been given intra muscular hydrocortisone, but only four had been shown how to use it.
The national annual admission rate for patients with Addison's disease/syndrome is 8%. Within this sample group the admission rate was 27.7%.
We need more resources to build on our initial and ongoing education/teaching programme to work on patient awareness of their condition as a whole, including sick day rules.

Recovery of the hypothalamus-pituitary-adrenal axis after transsphenoidal surgery for pituitary adenomas

J P van Eck, S J C M M Neggers, J A M J L Janssen, Y B de Rijke, A H G Dallenga, A P Nagtegaal, A J van der Lely & R A Feelders
Erasmus Medical Center, Rotterdam, The Netherlands.

Purpose
Hypopituitarism is frequently associated with lifelong replacement therapy. However, it has been suggested that recovery from hypopituitarism after transsphenoidal surgery (TSS) for pituitary adenomas may occur during follow up. The aim of this study was to assess the frequency of hypothalamus-pituitary-adrenal (HPA) axis recovery after TSS in patients with non-functioning pituitary adenomas and acromegaly.
Methods
Over the 3-year observational study-period, 146 patients underwent transsphenoidal pituitary surgery. The metyrapone test was used to assess the HPA-integrity after 1 week and after 3–12 months after TSS. The pituitary-thyroid, -gonadal and growth hormone axis were measured one week after TSS.
Results
Patients with Cushing's disease and panhypopituitarism were excluded from the study. 44 subjects had a sufficient HPA-axis one week after surgery. 14 subjects with an insufficient HPA-axis were excluded, as the 11-deoxycortisol after metyrapone was <100 nmol/l. Eighteen patients were eligible to re-assess the HPA-integrity. In 10 out of 18 patients, insufficiency of the HPA-axis appeared to be reversible. Eight patients had persistent secondary adrenal insufficiency. The number of other pituitary hormone insufficiencies one week after TSS was associated with recovery of the HPA-axis after TSS.
Conclusion
After TSS, recovery of the HPA-axis over time does occur in a proportion of subjects. Therefore it is recommended to re-assess the HPA-integrity during follow up to prevent unnecessary glucocorticoid replacement therapy. Pituitary adenoma, reversible hypopituitarism, recovery HPA-axis, pituitary surgery, adrenal insufficiency.
Key words
Pituitary adenoma, reversible hypopituitarism, recovery HPA-axis, pituitary surgery, adrenal insufficiency.

The Swedish Pituitary Register Nursing Group (SPRNG) Projects and Experiences

Maria Forsgren[1], Caroline Alkebro[2], Margareta Lindgren[3], Helena Wik[4], Maria Wärn[5] & Christina Dahlgren[6]
[1]Uppsala University Hospital, Uppsala, Sweden; [2]Örebro University Hospital, Örebro, Sweden; [3]Norrland University Hospital, Umeå, Sweden; [4]Sahlgrenska University Hospital, Gothenburg, Sweden; [5]Karolinska University Hospital, Stockholm, Sweden; [6]Linköping University Hospital, Linköping, Sweden.

Background
The Swedish Pituitary Register (SPR) is a national quality register founded in 1991 by the Swedish Pituitary Group and it provides important data in the

continuous quality assessment and improvement work within the Swedish health care system.
The Swedish Pituitary Register Nursing Group (SPRNG) was formed by nurses at the University Hospitals, working with the register, in 2011.
Purpose
To increase the coverage rate and improve the data quality in the register.
To strengthen the endocrine nurse role and encourage and promote the nurses to own register projects.
Methods
The SPRNG, consisting of endocrine nurses, one responsible for the register at each University Hospital. Meetings are performed 1–2 times /year. The SPRNG is working for the same routines considering the register and is actively working with projects in the SPR.
Results
Since the SPRNG was started the coverage rate and the reporting speed in the SPR have increased. Several nurse projects during 2016. Implement PREM and disease-specific PROM variables. User Survey in the register. Register data template for the hospitals operations managers and for the public to increase the knowledge of this patient group.
A study 'Time from first symptoms to diagnosis', where approximately 600 patients with pituitary tumours (Acromegaly, Mb Cushing, NFPA and Prolactinomas) are included, will be compiled 2017. The purpose of this study is to find these patients earlier and to identify how we can do that.
The SPRNG have been active at international conferences with several abstracts. Meeting and sharing experiences of the register with finish endocrine nurses.
Conclusion
The SPRNG has contributed to increase the data quality and coverage rates in the SPR.
The SPRNG is a good example of how nurses can be supported by each other and share experiences, skills and knowledge but also operate their own project.

Luteinizing hormone receptor mediated GATA4 induction promotes adrenocortical tumorigenesis in gonadectomized mice

Milena Doroszko[1], Marcin Chrusciel[1], Joanna Stelmaszewska[2], Tomasz Slezak[3], Adolfo Rivero-Muller[4,5], Artur Padzik[4], Slawomir Anisimowicz[6], Slawomir Wolczynski[2], Ilpo Huhtaniemi[1,7], Jorma Toppari[1,8] & Nafis Rahman[1,2]
[1]Department of Physiology, Institute of Biomedicine, Turku, Finland; [2]Department of Reproduction and Gynecological Endocrinology, Medical University of Bialystok, Bialystok, Poland; [3]Department of Biochemistry and Molecular Biology, University of Chicago, Chicago, Illinois, USA; [4]Turku Center for Biotechnology, Åbo Akademi and University of Turku, Turku, Finland; [5]Department of Biochemistry and Molecular Biology, Medical University of Lublin, Lublin, Poland; [6]Center of Gynecology and Reproductive Endocrinology Artemida, Bialystok, Poland; [7]Institute of Reproductive and Developmental Biology, Imperial College London, London, UK; [8]Department of Pediatrics, Turku University Hospital, Turku, Finland.

The role of luteinizing hormone (LH) and its receptor (LHCGR) signaling in the adrenal gland remains unknown. Gonadectomy-induced chronically elevated LH levels trigger neoplastic transformation in genetically susceptible mouse strains (DBA/2J) or transgenic mice expressing the Simian Virus 40 T antigen (SV40Tag) oncogene under inhibin-α promoter (inhα/Tag). In order to study the functional role of LHR and GATA4 in the onset and progression of adrenocortical tumors in ovariectomized (OVX) inhα/Tag females *in vivo* and *in vitro*, we crossbred the inhα/Tag with *LHR* knockout (LuRKO) mice. Additionally we knocked out *Lhr* (*Lgr*–ko) and *Gata4* (*Gata4*-ko) in the Cα1 cell line derived from an adrenal tumor of inhα/Tag mice. In inhα/Tag mice, we identified two distinct types of SV40Tag expressing neoplastic cells. The first type, subcapsular non-steroidogenic spindle-shaped A-like cells, which never developed to tumors, were found in both intact and OVX inhα/Tag females. The second type, parenchymal tumor cells in the topmost layer of zona fasciculata, later forming tumor foci, were found only in OVX inhα/Tag mice. Lack of LHR in OVX inhα/Tag/LuRKO mice adrenals prevented tumor formation. Histological and immunohistochemical analyses revealed the presence of hyperplastic cells expressing SV40Tag in parenchyma. These cells were devoid of GATA4 and showed signs of apoptosis. *In vitro*, a complete inactivation of *Gata4* significantly decreased cell proliferation, expression of tumor markers (*Inha*, *SV40Tag*, *Lhcgr* and *Esr1*) and gonadal-like steroidogenic phenotype of Cα1 cells. Our results suggest that at first, the tumor formation was LH-dependent, but later on became LH-independent. GATA4 is responsible for the *Inha/SV40Tag* expression, gonadal steroidogenic phenotype and possibly pro-survival pathways. Identifying GATA4 downstream targets in the adrenocortical tumors in both, inhα/Tag and human could be of importance to find potential therapeutic targets for human adrenocortical tumors.

Targeted molecular analysis in adrenocortical carcinomas: a way towards personalized medicine

Cristina L Ronchi[1], Juliane Lippert[2], Silke Appenzeller[3], Silviu Sbiera[1], Sonja Steinhauer[1], Raimunde Liang[1], Andrea Gehrig[2], Matthias Kroiss[1], Simone Rost[2], Andreas Rosenwald[4], Clemens Müller-Reible[2] & Martin Fassnacht[1]
[1]Division of Endocrinology and Diabetes, University Hospital of Wuerzburg, Wuerzburg, Germany; [2]Institute of Human Genetic, University of Wuerzburg, Wuerzburg, Germany; [3]Core Unit Bioinformatics, Comprehensive Cancer Center Mainfranken, University Hospital of Wuerzburg, Wuerzburg, Germany; [4]Department of Pathology, University of Wuerzburg, Wuerzburg, Germany.

Adrenocortical carcinoma (ACC) is a rare tumor with heterogeneous outcome and no available targeted therapy. The aim of the study is to identify prognostic molecular markers and novel potential drug targets.
A total of 43 FFPE tumor samples were retrospectively investigated for somatic mutations and copy number variations (CNV) by next-generation sequencing (160 cancer-related genes, Qiagen). Gene expression was evaluated by quantitative RT-PCR in a subgroup of 25 ACC samples (84 cancer drug targets, Qiagen). The major clinical endpoint was progression free survival (PFS).
We observed 123 protein-altering mutations in 47 genes (median 2 per sample), with the most frequent known to be ACC-related: TP53 (28% of samples), *CTNNB1* (26%), *ZNRF3* (19%), *NF1* (16%) and *GNAS* (14%). Notably, we also detected recurrent mutations in genes previously not clearly associated with ACC (i.e. *ABL1*, *KDM6A*, *TSC1*, *FBXW7*, *DNMT3A*, *BRCA1*, *BRCA2*). Some focal CNV were found in >30% samples (i.e. gains of *CDK4*, *MDM2*, *IL7R*, and losses of *TNFRSF14*). A noisy pattern was associated to a shorter median PFS than chromosomal or quiet pattern (4.5 vs 7 vs 14 months, respectively, $P=0.07$). Most affected genes were involved in p53/Rb or Wnt/β-catenin pathway or chromatin remodeling, but also in immune response or DNA repair mechanisms. Patients with alterations in DNA repair genes had longer PFS than others ($P=0.067$, HR = 1.78). At mRNA level, most frequently overexpressed genes (> 2.5 fold change) were *IGF2* (92%), *TOP2A* (92%), *CDK1* (72%) and *PLK1* (60%). Tumors with increased *BUB1B-PINK1* (>5.9) were associated with a trend to worst PFS ($P=0.16$, HR = 1.98).
This pilot study demonstrates the feasibility of molecular analysis in FFPE samples. We identified some genetic variants previously not associated with ACC and new potential drug target genes. These results will be validated in a larger series in order to path the way to a personalized medicine in ACC.

Introduction
The Carney Complex is a multiple endocrine and non endocrine neoplasia mostly due to PRKAR1A mutations. Spectrum of manifestations and genotype-phenotype correlations have been previously described by retrospective studies. A prospective study evaluating the occurrence of the different manifestations was needed to precise the optimum follow-up.
Methods
Multi-center national prospective study (Clinical Trials NCT00668291) including 70 patients mutated or wild-type for PRKAR1A followed prospectively during 3years with screening of the different manifestations by annual clinical, biological and radiological evaluation.
Results
The cohort was compound of 50 females and 20 males with a mean age at 35.4years +/−16.7. Prevalence of cardiac myxomas at the end of the follow-up was 22.9% with newly diagnosis during the study period for 3 patients. Forty-four% of patients with myxomas had related stroke attack and 56% had recurrences. Median delay between recurrences was 3.8years (minimum-maximum: 0.8–24). Primary pigmented adrenal nodular disease was diagnosed in 57.1%. Skin manifestations, abnormal somatotroph hormonal tests and thyroid tumors were observed respectively in 58.6, 21.4 and 12.9%. Four% had melanotic shwannomas confirmed by histology. Spinal magnetic resonance imagery revealed lesions for 8.6%. Characteristic multiples calcified tumors on testicular ultrasonography were present in 35% of male patients. Ten% of female patients had surgery for breast myxoma or adenofibroma. Forty% had lesions classified ACR2-3 at mammography. Interestingly, four patients (8%) had breast adenocarcinomas (11.1% of female older than 30years). Eighty-three% of patients had PRKAR1A mutations. Patients carrying the mutation c.709-7del6 (34% of the cohort) had no manifestation or phenotype restricted to adrenal, lentigines and abnormal somatotroph test.
Conclusion
The penetrance of the disease is high after screening except for patient carrying the c.709-7del6 mutation. This study highlights the importance of an annual follow-up, with especially annual cardiac imaging for patients with history of cardiac myxomas and earlier and regular senologic evaluation.

Immunity in adrenocortical carcinoma patients – interplay between anti-cancer immunity and steroid hormones

Silviu Sbiera[1,2], Thomas Dexneit[1,3], Iuliu Sbiera[1], Jochen Schreiner[1], Cristina L. Ronchi[1], Matthias Kroiss[1,2] & Martin Fassnacht[1,4]
[1]Division of Endocrinology and Diabetes, University Hospital, University of Würzburg, Wuerzburg, Germany; [2]Comprehenssive Cancer Center Main-franken, University of Würzburg, Wuerzburg, Germany; [3]Department of Neurosurgery, University Hospital, University of Würzburg, Wuerzburg, Germany; [4]Clinical Chemistry and Laboratory Medicine, University Hospital, University of Würzburg, Wuerzburg, Germany.

Adrenocortical carcinoma (ACC) is one of the most aggressive endocrine malignancies. By applying a 'multiple omics' approach, we recently identified two distinct subgroups of ACC patients, a good prognosis "immune" and bad prognosis "steroid" phenotype.
We hypothesized that the steroid phenotype is associated with glucocorticoid-induced suppression that can be 'rescued' by reactivating the immune system using immune checkpoint inhibitors and inhibitors of steroidogenesis.
To assess changes induced by ACC on circulating immune cells we isolated PBMCs from blood of 19 healthy controls = HC and 163 ACC patients (41: tumour free = TF, 82: tumour present without cortisol excess = TP and 40: tumour present and cortisol excess = CE) and performed FACS analyses to quantify T-cells (CD3 + CD4 + and CD3 + CD8 +), B-cells (CD19), monocytes (CD14) and regulatory T-cells (T-reg) as a sign of immune suppression (CD4 + $CD25^{high}FOXP3+$). Using immunofluorescence, we analysed the presence of tumour infiltrating T-cells, Tregs, B-cells, dendritic cells (CD209 +) in full FFPE from 58 primary ACC tumours. Furthermore, expression of immune checkpoint-markers programmed death 1 (PD1) and its ligand PDL1 was analysed by IHC. From the peripheral cells the percentage of Treg in the circulating T-cell population correlated significantly with tumoural and steroid secretion status (4.4 ± 1.2 in HC, 7.9 ± 6.1 in TF, 9.0 ± 7.9 in TP and 11.0 ± 7.8 in CE, $P < 0.01$). Using median as cut-off, patients with increased percentage of peripheral Treg had a lower survival rate (HR = 1.8, 95%CI 1.0-3.1, $P = 0.02$). Most tumours presented a tumour infiltrate (T-cells: 80%, 37 ± 65 cells/HPF, cytotoxic T-cells: 72%, 24.9 ± 53.0, T-helper: 57%, 19.3 ± 16.9 cells/HPF, Treg: 48%, 3.8 ± 3.8, dendritic cells: 73%, 5.8 ± 3.7, B-cells: 0%, PD1: 36%, 14.7 ± 30.1, PDL-1: 83%, 34.6 ± 81.6). The only tumour infiltrating cells associated overall survival were the CD4 + T-helper cells (HR for death: 0.34, 95%CI 0.12–0.95, $P = 0.005$).
In conclusion, ACC patients are characterized by increased circulating immune inhibitory Tregs and tumour infiltrating CD4 + T-helper cells have a positive influence on patient survival.

Background
Adrenal masses are discovered in 5% of abdominal imaging scans. Work-up aims at exclusion of malignancy and hormone excess. However, estimates of these risks derive from retrospective studies only, mostly small and with significant selection bias.
Methods
Prospective multi-centre study (2011–2016) in 14 centres (11 countries) of the European Network for the Study of Adrenal Tumours (ENSAT) with prospective consecutive enrolment of patients with newly diagnosed adrenal mass. Extra-adrenal malignancy and phaeochromocytoma were exclusion criteria. Diagnosis was confirmed by histology or imaging follow-up.
Results
We enrolled 1994 patients, 1746 (87.6%) with a benign adrenocortical adenoma (ACA), 83 (4%) with other benign masses (e.g. adrenomyelolipoma, cyst), 106 (5.3%) with adrenocortical carcinoma (ACC) and 59 (3%) with other malignant masses (e.g. metastases, sarcoma). Risk of ACC was highest in young patients (< 40yrs:13%; 40–60yrs:6%; > 60yrs:3%, $P < 0.0001$) and in large masses (> 4 cm:21%, < 4 cm:0.4%, $P < 0.0001$). Of 1746 patients with ACA, imaging for exclusion of malignancy included unenhanced CT in 1301 patients, with tumour density < 10HU indicative of a benign tumour in 69%, with 16% borderline (10–20HU) and 15% suspicious (> 20HU) results. MRI with chemical shift results in 271 ACA patients were indicative of a benign lesion in 79%. In 829/1746 (47%) ACA patients, two or more imaging studies were performed; 19% underwent three or more. Upon re-imaging after ≥ 6 months, the adrenal mass appeared stable in size 601 of 629 ACA patients (96%). Mild autonomous cortisol excess (MACE) was detected in 547/1316 (42%) patients with ACA. Adrenalectomy was performed in 21% (370/1746) of ACA patients. Of those, 222 (60%) had overt hormone excess and 64 (17%) had MACE (70; 18%); the remaining 84 patients (23%) had non-functioning ACA.
Conclusions
Overall risk of ACC is 5.3% and is highest in young patients with adrenal mass size > 4 cm. ACAs are frequently misclassified as malignant by routine imaging, resulting in a high rate of interval imaging and unnecessary adrenalectomies.

Background
Adjuvant mitotane therapy is frequently used in Europe following surgery for adrenocortical carcinoma (ACC). Management of adjuvant mitotane is mainly empirical and a major open question is the optimal duration of therapy, because no study has ever addressed this issue.
Objective
We aimed to assess the outcome of ACC patients who were treated with adjuvant mitotane for at least one year following surgery and then discontinued therapy for other reasons than ACC recurrence.
Design
We did a retrospective analysis of 132 patients (91 F, 41 M; median age 44 years) with histologically confirmed ACC who were treated at 9 European centres and 1 centre in Canada since 1999.
Results
Tumour stage was ENSAT I, 11%; ENSAT II, 79%; ENSAT III, 20%; hormone secretion was present in 44% and resection status was R0, 83% and Rx, 17%. Median Ki-67 was 10% and Weiss 6. Duration of adjuvant mitotane therapy was 34 months (12–141). Median duration of follow-up was 79 months (31–280), including 34 months after discontinuation (1-263). Seventeen patients (13%) recurred after treatment discontinuation with a recurrence-free survival from surgery of 74 months (31–277) and tumour-free survival after mitotane discontinuation of 32 months (1–263). The only difference in prognostic characteristics between patients with recurrent ACC and the remainders was a higher number of secreting tumours. Interestingly, no recurrence was observed among the 41 patients (31%) treated for >48 months; such patients had similar prognostic characteristics and follow-up duration after mitotane discontinuation than the remainders.
Conclusions
These first results suggest that a prolonged duration of adjuvant mitotane therapy may be associated with better recurrence-free survival.

VHL Genotype and risk stratification of pancreatic neuroendocrine tumors in patients with von hippel-lindau disease

Amit Tirosh[1,2], Jasmine Shell[3], Patience Green[3], Xavier M. Keutgen[4], Samira M. Sadowski[5], Mustapha el Lakis[3], Pavel Nockel[3], Dhaval Patel[3], Naris Nilubol[3] & Electron Kebebew[3]
[1]National Institutes of Health, Bethesda, MD, USA; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Endocrine Oncology Branch, National Cancer Institute, Bethesda, MD, USA; [4]Department of Surgery, Rush University Medical Center, Chicago, IL, USA; [5]Endocrine and Thoracic Surgery, University Hospitals of Geneva, Geneva, Switzerland.

Background
About 8–20% of patients with von Hippel-Lindau disease (vHLd) develop pancreatic neuroendocrine tumors (PNETs). However, prognostic markers for these tumors are lacking. The VHL gene mutation type is associated with the clinical phenotype of vHLd. Hence, we aimed to determine whether VHL mutation characteristics may be associated with PNETs phenotype in patients with vHLd.
Methods
A prospective study of patients with vHLd and PNETs with follow-up imaging. *VHL* mutation type and position were defined using Sanger sequencing of germline DNA.
Results
182 patients (476 PNETs) were followed for a median of 52 months (range 3–84). The *VHL* gene was sequenced in 154 patients: 75 patients (48.7%) had a missense mutation [MisM], 51 (33.1%) - deletion, 12 (7.8%) - nonsense, one (0.6%) - rearrangement, and 15 (9.7%) had frameshift mutations. Patients with a largest lesion diameter <1.2 cm had a lower risk for metastases (Log-Rank test, $P=0.006$) compared with larger diameters, whereas those with diameter >3 cm had higher risk for metastases compared with other patients (Log Rank test, $P=0.007$). Patients with MisM had a higher risk of requiring an intervention (Log-Rank test $P=0.01$) and for developing metastases during follow-up ($P=0.007$) compared to those with other mutation types. Among patients with a largest lesion diameter between 1.2 and 3 cm, those with MisM had higher risk for metastases (Log-Rank test, $P=0.048$) compared to other mutation types, and patients with mutation positioned in exon 3 of the *VHL* gene had higher risk for requiring intervention both in univariate ($P=0.03$) and multivariate analysis (Hazard ratio 2.9, 95% confidence interval 1.2–7.2, $P=0.02$).
Conclusion
Lesion diameter should be the pivot factor in directing PNETs management in vHLd. Among patients with a largest PNET diameter >1.2 and <3 cm, *VHL* genotyping may be useful for risk stratification.

GPER-stimulation increases proliferation in colorectal cancer via the Hippo signalling pathway

Anastasia Arvaniti, Karthik Basker, Ali Gondal, Habibur Rahman, Lorna Gilligan & Paul Foster
University of Birmingham, Birmingham, West Midlands, UK.

Colorectal cancer (CRC) is the 2nd most commonly diagnosed cancer in Europe. Previously, we have shown steroid sulphatase (STS), the enzyme that converts conjugated oestrogens to their active forms, is significantly upregulated in human CRC tissue. Furthermore, increased STS activity substantiates greater CRC tumour burden in mouse models. Here we demonstrate that this oestrogen-induced increase of CRC proliferation is mediated by G-protein coupled oestrogen receptor (GPER) via Hippo pathway signalling through the yes-associated protein 1 (YAP1), transcriptional coactivator with PDZ-binding motif (TAZ), and connective tissue growth factor (CTGF).
To examine how GPER effects CRC proliferation we employed *in vitro* BrdU proliferation assays and in vivo mouse models of CRC treated with G1, a GPER agonist, oestrogens and G15, a GPER antagonist. To investigate whether YAP1, its target gene CTGF, and its transcriptional co-activator TAZ, were altered by oestrogen-induced GPER signalling, we used immunoblotting and immunohistochemistry. YAP1 knockdown cells were also examined by treating them with G1, oestrogens and verteporfin, a YAP1 inhibitor, to assess the role of YAP1 on proliferation.
GPER-stimulation by G1 and oestrogen increased CRC proliferation in a dose-dependent manner, with this effect inhibited by G15 *in vitro* and *in vivo* CRC xenografts. YAP1 mediated this pro-proliferative response in CRC cells in contrast to colon adenoma cells. These findings were underpinned by increased phosphorylation of YAP1 and increased protein expression of TAZ and CTGF after oestrogen and G1 treatment. Intriguingly, CTGF up-regulation correlated with elevated GPER in human CRC tissue. In line with the above results, pharmacological inhibition of YAP1 and YAP1 knockdown blocked G1-induced cellular proliferation supporting the functional pro-proliferative role of YAP1 in CRC.
Taken together, our results propose a new oestrogen-driven pro-proliferative GPER-stimulated pathway through Hippo signalling in CRC. Further studies are required to establish whether this early metabolic response translates into increased cellular viability and cancer development.

Inhibition of hRAS and CDK4/6 leads to an antiproliferative activity, blocks cell cycle and induces cell death in anaplastic thyroid cancer cell lines

Marta Pojo[1], Sara Lopes-Ventura[1], Ana Matias[1], Valeriano Leite[1,2] & Branca Cavaco[1]
[1]Unidade de Investigação em Patobiologia Molecular (UIPM), Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal; [2]Serviço de Endocrinologia, Instituto Português de Oncologia de Lisboa Francisco Gentil E.P.E., Lisbon, Portugal; [3]Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal.

The unresponsiveness of anaplastic thyroid carcinomas (ATCs) to multimodal therapy represents the major challenge in thyroid cancer treatment. Our group previously showed that genes involved in cell cycle are differentially expressed in ATCs compared to normal thyroid, and that the most common mutations found in

these tumours are related with proliferation and cell cycle genes, namely *TP53*, *RAS*, *CDKN2A* and *CDKN2B*. Therefore, these genes are promising new targets in ATCs.
Here, we investigated if the inhibition of HRAS by Tipifarnib (TIP) and CDK4/6 by Palbociclib (PD) could be an option in ATC treatment. Different ATCs cell lines with distinct mutational patterns for *RAS, CDKN2A* and *CDKN2B* were used to evaluate the cytotoxic effects of these drugs. The IC50 for TIP and PD were determined, and the effects of these compounds in cell cycle, cell death and cell proliferation were analysed.
Cell culture studies demonstrated that low doses of TIP, at 48 h, induced cell cycle arrest in G2/M phase (50%, $P<0.01$), cell death (20%), and inhibition of cell viability ($P<0.001$), only in the *HRAS* mutated cell line. PD at low concentration increased significantly cell cycle arrest on G0/G1 phase (80%, $P<0.05$), only in cell lines with deletion/mutation in *CDKN2A* or *CDKN2B* genes, however only higher doses induced more than 50% of cell death. The inhibition of cell viability was more pronounced in cell lines with deletion/mutation in *CDKN2A* or *CDKN2B* genes than in wild type thyroid cancer cell lines or in normal thyroid cells ($P<0.05$).
In conclusion, this study suggests that TIP and PD, which are currently in clinical trials for other types of cancer, could play a relevant role in inhibiting the progression of ATC, depending on the specific molecular profile of the tumour.

Benign prostatic hyperplasia is associatied with liver inflammation: it's time for prevention?

Giorgio Ivan Russo[2], Aldo E. Calogero[1], Giuseppe Morgia[2], Rosita Angela Condorelli[1] & Sandro La Vignera[2]
[1]Andrology Center of Catania University, Catania, Italy; [2]Urology Center of Catania University, Catania, Italy.

Metabolic Syndrome (MetS) has been frequently associated with an overall inflammation status, called "metaflammation", including atherosclerosis and non-alcholic steatohepatitis (NASH), In this study we aimed to evaluate the relationship between intra-prostatic inflammation and NASH in a cohort of patients affected by BPH. Between January 2012 and January 2016, 132 consecutive patients with BPH-related lower urinary tract symptoms (LUTS) who underwent transurethral resection of the prostate were prospectively enrolled. The presence of NASH was evaluated using the NASH score: 1.18*MetS (yes = 1) + 0.45*Diabetes (yes = 2) + 0.15*fasting serum insulin + 0.04*serum AST − 0.94*(AST/ALT) − 2.89. A cut-off of 1.05 was set to predict NASH (AUC: 0.82). Prostate samples were anlaysized for the evaluation of inflammation and this was classified accordindg to Irani score (score from 0 to 6). Patients with viral hepatitis or alcohol steatohepatitis were excluded. A final cohort of 132 patients were included. The median age was 70.8 (interquartile range (IQR) 64.65–73.97), the median IPSS was 24.0 (IQR; 20.0–25.75) and the median prostate volume was 50.5 (IQR: 40.0–72.25). The prevalence of patients affected by MetS alone was 56.8% (76/132), by NASH in 56.8% (76/132) and by severe intraprostatic inflammation (Irani ≥ 4) in while by the both disease in 27.3% (36/132). When considering patients with Irani score ≥ 4, we observed significant increase of NASH score (-0.45 vs -1.01; $P<0.01$). The age-adjusted linear regression analysis demonstrated that waist circumference ($r=0.35$; $P<0.01$), fasting glucose ($r=0.32$; $P<0.01$), LDL ($r=0.15$; $P<0.05$), tryglycerides ($r=0.42$; $P<0.01$) and Irani score ($r=0.12$; $P<0.05$) were associated with increase in NASH score. The age adjuested logistic regression analysis revealed that Irani score ≥ 4 (OR: 3.06; $P<0.05$) was an independent risk factor of NASH. Further, the combination between MetS and NASH was significantly associated with severe intra-prostatic inflammation (OR: 10.8; $P<0.01$) while vs MetS as single alteration. Patients with BPH are more frequently associated with a parallel liver inflammation. These findings can be explained by the metaflammation condition, associated with metabolic aberration. Further studies should be conducted with the scope to revert or prevent prostate related inflammation.

Peptides derived from the sst5TMD4 extracellular domain increase malignancy of endocrine-related cancer cells

Manuel D Gahete, Mercedes del Rio-Moreno, Emilia Alors-Perez, Patricia Borges de Souza, Maria E Prados-Gonzalez, Justo P Castaño & Raul M Luque
Maimonides Institute of Biomedical Research of Cordoba; Reina Sofía University Hospital; Department of Cell Biology, Physiology and Immunology, University of Cordoba; CIBER Physiopathology of Obesity, Cordoba, Spain.

A growing number of studies suggest that extracellular fragments derived from plasma membrane receptors can play relevant functional roles in the development and progression of certain tumoral pathologies which might, therefore, serve as novel tools in the diagnostic and prognostic of such pathologies. In this scenario, the truncated somatostatin receptor sst5TMD4, which is overexpressed in various endocrine-related cancers (i.e. breast, prostate, neuroendocrine, liver and pituitary), is an aberrant splicing variant with only 4 transmembrane domains, wherein its C-terminal tail is exposed towards the extracellular matrix and could, therefore, be the substrate for proteolytic enzymes. Thus, to explore the plausible generation of soluble peptides derived from the sst5TMD4 extracellular domain and their potential patho-physiological implications, in silico and *in vitro* approaches were implemented using several cancer-derived cell lines (i.e. breast, prostate, neuroendocrine and liver). Firstly, in silico analysis predicted the existence of two cleavage sites for metalloproteases (MMP) 2, 9, 14 and/or 16, which could generate the release of three possibly soluble peptides. We, then, chemically synthetized these sst5TMD4-derived peptides and demonstrated that they were able to enhance malignancy features (proliferation, migration and dedifferentiation processes) in all the tumoral cell lines tested, probably acting through PI3K/Akt and/or MEK/ERK signalling pathways. Moreover, treatment with sst5TMD4-derived peptides altered the expression pattern of several genes involved in cancer development and progression (e.g. certain MMPs, Ki67, ARP2/3 or CD24/44). Therefore, based on these results, it is possible that sst5TMD4-derived peptides could be linked to the pathological role of sst5TMD4 previously observed in these tumoral pathologies. Altogether, these studies provide new information about the patho-physiological role of this truncated variant of sst5 and suggest that sst5TMD4-derived peptides could be potential candidates for future studies aimed to identify novel diagnostic, prognostic and/or therapeutic targets in certain endocrine-related cancers.

Androgen receptor activation inhibits endothelial cell proliferation through an extra-nuclear signaling pathway

Yen-Nien Huo[1], Shauh-Der Yeh[2], Chih-Ming Chou[3] & Wen-Sen Lee[4]
[1]Graduate Institute of Medical Sciences, Medical College, Taipei Medical University, Taipei 110, Taiwan; [2]Departments of Urology, Taipei 110, Taiwan; [3]Departments of Biochemistry and Molecular Cell Biology, Taipei 110, Taiwan; [4]Departments of Physiology, School of Medicine, Medical College, Taipei Medical University, Taipei 110, Taiwan.

The effect of androgen on angiogenesis has been documented. However, its molecular mechanisms underlying has not been well illustrated. Here, we show that treatment with an androgen receptor (AR) agonist, metribolone (R1881) at a range of concentrations (0.05–5 nM) or dihydrotestosterone (DHT) at a range of concentrations (0.4–40 nM) caused concentration-dependent inhibition of proliferation in human umbilical venous endothelial cells (HUVEC). The R1881-induced proliferation inhibition was also observed in human dermal microvascular endothelial cells (HDMVE). Blockade of the AR activity by pre-treatment with HF (5 nM), an AR antagonist, or knockdown of AR expression using the shRNA technique abolished the R1881-induced proliferation inhibition in HUVEC, suggesting that AR receptor activation can inhibit endothelial cell proliferation. To further delineate the signaling pathway involved in the AR activation-induced proliferation inhibition, our data indicate that R1881 inhibited proliferation in vascular endothelial cells through activating the AR/cSrc/AKT/-p38/ERK/NFκB signaling pathway, which in turn up-regulated the expression of p53, p21 and p27 protein, and finally reduced endothelial cell proliferation. Using the zebrafish model, we also demonstrate that R1881 inhibited angiogenesis through the AR-mediated pathway *in vivo*. The findings of the present study highlight the molecular mechanisms underlying AR activation-induced proliferation inhibition in vascular endothelial cells.

Long non-coding RNA expression profiles in human parathyroid tumors

Annamaria Morotti[1], Irene Forno[1], Valentina Andrè[2], Andrea Terrasi[1], Chiara Verdelli[2], Vito Guarnieri[3], Alfredo Scillitani[4], Leonardo Vicentini[5], Edoardo Beretta[6], Valentina Vaira[1,7] & Sabrina Corbetta[8]
[1]Division of Pathology, Department of Pathophysiology and Transplantation, University of Milan, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [2]Laboratory of Experimental Endocrinology, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy; [3]Genetic Medicine, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy; [4]Endocrinology Unit, IRCCS Casa Sollievo della Sofferenza, San Giovanni Rotondo (FG), Italy; [5]Endocrine Surgery, IRCCS Fondazione Ca' Granda Ospedale Maggiore Policlinico, Milan, Italy; [6]Endocrine Surgery, IRCCS Ospedale San Raffaele, Milan, Italy; [7]Istituto Nazionale Genetica Molecolare "Romeo ed Enrica Invernizzi" (INGM), Milan, Italy; [8]Endocrinology Unit, Department of Biomedical Sciences for Health, University of Milan, IRCCS Istituto Ortopedico Galeazzi, Milan, Italy.

Aberrant epigenetic signatures have been preliminary detected in parathyroid tumors, in terms of microRNAs (miRNAs) and methylome deregulation. In this study, we profiled the expression of 90 long non-coding (Lnc) RNAs in 4 parathyroid carcinomas (PCas), 12 parathyroid adenomas (PAds) and 2 parathyroid glands from normocalcemic patients (PaNs). Matched miRNA profiles were available for a subset of cases. Unsupervised clustering distributes samples in two groups clearly distinguishing PCas from PaNs. Further analyses identified 9 LncRNAs significantly deregulated between PCas and PaNs, 12 LncRNAs between PAds and PaNs, and 23 LncRNAs between PAds and PCas. Five LncRNAs with a fold change > 2.0, namely *MEG3*, *SGNH6* and *KCNQ1OT1* downregulated in PCas, *NEAT1* and *HAR1B* upregulated in PAds, were validated by qPCR in an independent series of 3 PCas, 4 atypical PAds, 22 PAds and 2 PaNs. PCas and atypical PAds showed similar expression levels of the 5 LncRNAs, whereas PAds were distinguished in two clusters with 10 PAds similar to PaNs. Clinically, PAds with the LncRNA profile similar to normal glands had lower mean serum calcium and ionized calcium than PAds with the LncRNA profile similar to PCas and PAds with intermediate profile (10.2 ± 0.5 vs 12.1 ± 0.2 vs 11.5 ± 0.8 mg/dl; $P = 0.006$ and 1.36 ± 0.06 vs 1.81 ± 0.11 vs 1.51 ± 0.08 mmol/l; $P = 0.0001$). Correlating LncRNA and miRNA profiles, we detected an association between the 5 deregulated LncRNAs and a set of miRNAs, including miR-296-5p, previously identified signifcantly downregulated in PCas. Finally, 10 PAds were characterized for the *MEN1* gene expression level: PAds with lower nuclear menin expression had decreased expression of two LncRNAs mapping on chromosome 11: *KCNQ1OT1* on 11p15.5 and *NEAT1* on 11q13.1. In conclusion, LncRNAs are deregulated in parathyroid tumors and identify 3 clusters of parathyroid tumors with different clinical activity. Moreover, LncRNAs deregulation in PAds may be modulated by the genetic background, while they may be involved in miRNAs deregulation.

Neurokinin 3 receptor antagonism as a novel treatment for menopausal hot flushes: a phase 2, randomised, double-blind, placebo-controlled trial

Julia Prague[1], Rachel Roberts[1], Alexander Comninos[1], Sophie Clarke[1], Channa Jayasena[1], Zachary Nash[1], Chedie Doyle[1], Deborah Papadopoulou[1], Stephen Bloom[1], Pharis Mohideen[2], Nicholas Panay[3,4], Myra Hunter[5], Johannes Veldhuis[6], Lorraine Webber[7], Les Huson[8] & Waljit Dhillo[1]
[1]Department of Investigative Medicine, Imperial College, London, UK; [2]Millendo Therapeutics, Inc., Michigan, USA; [3]Department of Gynaecology, Queen Charlotte's & Chelsea Hospital and Chelsea & Westminster Hospital, London, UK; [4]Institute of Reproductive and Developmental Biology, Imperial College London, London, UK; [5]Institute of Psychiatry, Psychology and Neuroscience, King's College, London, UK; [6]Mayo Clinic, Minnesota, USA; [7]Scientific Partnering & Alliances, Innovative Medicines & Early Developmental Biotech Unit, Astrazeneca, Melbourn, UK; [8]Division of Experimental Medicine, Imperial College, London, UK.

Background
Hot flushes affect 70% of menopausal women, can be long-lasting, and often severely impact on physical, psychosocial, sexual, and overall wellbeing. Hormone replacement therapy is effective but not without risk. Neurokinin B is an important mediator of hot flushes in rodents and elevated hypothalamic expression occurs in menopausal women. Neurokinin B acts via the neurokinin 3 receptor. We therefore hypothesised that neurokinin 3 receptor antagonism could be a novel treatment for menopausal hot flushes.
Methods
This phase 2, randomised, double-blind, placebo-controlled, crossover trial assessed the effectiveness of an oral neurokinin 3 receptor antagonist (MLE4901) on menopausal hot flushes in an ambulatory setting (Clinicaltrials.gov NCT02668185). Sixty-eight women were screened between February and October 2016 in a single-centre, of which 37 were randomised and included in an ITT analysis. Twenty-eight participants (aged 49–62yrs, experiencing >7 hot flushes/24 h some of which were reported as bothersome or severe), completed the trial, and were included in a Per-Protocol analysis. They received 4 weeks of MLE4901 and placebo in random order separated by a washout period. Randomisation was completed by a central computer, and participants were allocated to treatment number in numerical order. Primary outcome was total number of hot flushes during the final week of both treatment periods.
Findings
MLE4901 significantly reduced the total weekly number of hot flushes by 45% compared to placebo (adjusted means: placebo 49.01 (CI: 40.81–58.56), MLE4901 19·35 (CI: 15.99–23.42), $P < 0.0001$) (ITT). MLE4901 also significantly reduced weekly hot flush severity, bother, and interference compared to placebo by 41% ($P < 0.0001$), 45% ($P < 0.0001$), and 58% ($P < 0.0001$) respectively. Treatment was well tolerated.
Interpretation
Treatment with a neurokinin 3 receptor antagonist (MLE4901) could be practice changing as it safely and effectively relieves hot flush symptoms without the need for oestrogen exposure. Larger scale studies of longer duration are now indicated.

Testosterone administration decreases insulin sensitivity (IS) in adult female sheep born to testosterone treated mothers

Albert Carrasco[1], Monica P Recabarren[1], Daniel Sandoval[1], Teresa Sir-Petermann[2] & Sergio E Recabarren[1]
[1]Laboratory of Animal Physiology and Endocrinology, Faculty of Veterinary Sciences, Universidad de Concepcion, Faculty of Veterinary Medicine, Chillan, Region del BioBio, Chile; [2]Laboratory of Endocrinology and Metabolism, Western School of Medicine, Universidad de Chile Western School of Medicine, Santiago, Chile.

Different animal models have been used to study the postnatal effect of a prenatal exposure to an androgen excess on the female offspring. We have established a sheep model to test the hypothesis that the intrauterine environment of the PCOS mother may play a role in the etiology of the PCOS. In this regard, our sheep model for the study of PCOS has the advantage that provides mainly an androgenized milieu to the fetus in comparison to pregnant PCOS women who offers a hyperandrogenic and hyperinsulinemic intrauterine environment to the fetus. Previous results from our laboratory have demonstrated that female sheep born to mothers receiving testosterone (T) during part of their pregnancy exhibit features from early postnatal life until adulthood resembling those of PCOS women. In the present work the programming effect of prenatal T on the IS was explored in adult females born to T treated mothers (T-females), and born to untreated mothers (C-females). Our aim was to establish if exogenous T may exacerbate the insulin resistance due to programming effect of prenatal exposure to T. Both groups were injected with T, twice weekly (40 mg per dose), for 8 weeks, beginning at 30 weeks of age. Females were estrous synchronized with prostaglandin and 48 hours after the last T dose, an IVGTT was carried out. On the day of the IVGTT, there was no difference in plasma concentration of estradiol, progesterone and T between groups. IS indexes were calculated with the plasma insulin and glucose concentrations during the IVGTT. Plasma levels of glucose were not different during the IVGTT but T-females secreted more insulin ($P < 0.05$) than C-females. The ratio insulin/glucose before the IVGTT tended to be higher in T-females ($P = 0.054$) and the IS Index-C tended to be lower in T-females compared to C-females ($P = 0.054$). Results show that T administration to T-females amplifies the effect of a glucose challenge on the insulin secretion compared to C-females, suggesting an exacerbation of the insulin resistance induced by fetal programming.

Influence of BMI on AMH levels in non-PCOS women

Joana Simões-Pereira[1], Joaquim Nunes[2], Ana Aguiar[2], Sandra Sousa[2], Cátia Rodrigues[2], J Sampaio Matias[3] & Carlos Calhaz-Jorge[2]
[1]Endocrinology Department, Instituto Português de Oncologia de Lisboa, Francisco Gentil, Lisbon, Portugal; [2]Reproductive Medicine Unit, CHLN-Hospital de Santa Maria, Lisbon, Portugal; [3]Clinic Pathology, CHLN-Hospital de Santa Maria, Lisbon, Portugal.

Introduction
Anti-Müllerian Hormone (AMH) is a useful marker of ovarian reserve (OR), since it remains stable inter/intra-cycles and presents a good correlation with ultrasonographic antral follicular count. Obesity/overweight are increasing and may affect the reproductive health. However, previous studies regarding the effect of body mass index (BMI) on AMH levels are discordant. Our main goal was to evaluate the influence of BMI in AMH levels in women with infertility.
Methods
Revision of medical records of 995 women who performed AMH determinations as part of their fertility workup, between 2011–2016. Women diagnosed with polycystic ovarian syndrome (Rotterdam criteria) were excluded. We analysed the influence of BMI, age, ethnicity, smoking and previous ovarian surgery on AMH levels.
Results
Median AMH concentration was 1.75(0–26)ng/dL and median age at AMH determination was 35(19–40)years. These women evidenced a median BMI of 23(15–39) kg/m^2 and had been struggling with infertility for 60(7–432) months. The majority [700(70.4%)] presented primary infertility. Caucasian women were more represented [889(89.3%)]. Smoking habits (present/past) were present in 359(36.1%), and 147(14.8%) harboured a history of ovarian surgery. On univariable analysis AMH was not correlated with BMI ($r=0.52/P=0.10$); the only factors influencing AMH were age ($P<0.001$), ethnicity ($P=0.005$) and previous surgery ($P<0.001$). On multivariable analysis, age was the only variable significantly associated with AMH, evidencing a reduction of 6.2% for each additional year ($P<0.0001$). Furthermore, we verified a trend suggesting an AMH reduction of 22% ($P=0.08$) in melanodermic patients comparing with the caucasian ones, when controlling for the other variables.
Conclusion
We report one of the largest series evaluating the influence of BMI on AMH levels and, consequently, on OR. BMI does not seem to affect AMH levels. The reported concerns on infertility in overweight/obese women may be related to follicular development/endometrial disorders, rather than decreased OR.

Relugolix, an oral gonadotropin-releasing hormone (GnRH) receptor antagonist, in women with endometriosis (EM)-associated pain: Phase 2 safety and efficacy 24-week results

Yutaka Osuga[1], Yoshifumi Seki[2], Masataka Tanimoto[2], Takeru Kusumoto[2], Kentarou Kudou[2] & Naoki Terakawa[3]
[1]The University of Tokyo, Tokyo, Japan; [2]Takeda Pharmaceutical Company Limited, Osaka, Japan; [3]Tottori University Faculty of Medicine, Yonago, Japan.

Objective
The objective of this Phase 2 study was to evaluate the safety of relugolix when administered for 24 weeks in women with EM-associated pain. Efficacy was exploratory assessed using leuprorelin as a reference.
Design
This was an open-label extension study evaluating safety of 3 doses (10 mg, 20 mg, and 40 mg) of relugolix administered orally once daily for a total of 24 weeks in women with EM-associated pain, who had participated in a preceding 12-week study.
Materials and methods
Premenopausal women with EM-associated pain who completed a preceding 12-week study and were eligible to continue for an additional 12-week treatment were enrolled. The primary endpoint was the safety including assessment of change in bone mineral density using dual energy x-ray absorptiometry. Analysis sets were defined as all patients who were administered the study drug.
Results
Among the randomized patients in the preceding study (N=487), 397 were enrolled in this extension study; 77 to placebo, 78 to 89 to relugolix groups, and 69 to leuprorelin. Baseline characteristics were similar between randomized patients and all patients who entered the extension study. The incidences of adverse events including metrorrhagia, menorrhagia, and hot flush in the relugolix 40 mg group were similar to those in the leuprorelin group. Dose-dependent bone density loss was observed with relugolix treatment, with the relugolix 40 mg result consistent with the leuprorelin result. The change from baseline in mean visual analogue scale score for pelvic pain (in mm) during the last 4 weeks of treatment period was −3.222 in the placebo group, −6.849, −9.032, and −11.924 in relugolix 10 mg, 20 mg and 40 mg groups, respectively, and −12.552 in the leuprorelin group. Estradiol levels decreased with increasing dose of relugolix and were maintained below the postmenopausal levels throughout the 24-week relugolix 40 mg treatment period.
Conclusion
Treatment with relugolix for 24 weeks was generally well tolerated and demonstrated similar pelvic pain reduction as leuprorelin in women with EM. Relugolix, a once-daily oral nonpeptide GnRH receptor antagonist, demonstrated similar benefit to injectable leuprorelin in this Phase 2 study.

Brown adipose tissue thermogenesis in women with polycystic ovary syndrome

Soulmaz Shorakae[1,2], Eveline Jona[1], Barbora de Courten[1,2], Gavin Lambert[3,4], Elisabeth Lambert[3], Sarah Phillips[3], Iain Clarke[5], Helena Teede[1,2] & Belinda Henry[6]
[1]Monash Centre for Health Research and Implementation, Monash University, Melbourne, Australia; [2]Diabetes and Vascular Medicine Unit, Monash Health, Melbourne, Australia; [3]Human Neurotransmitters Laboratory, Baker IDI Heart & Diabetes Institute, Melbourne, Australia; [4]Department of Physiology, Monash University, Melbourne, Australia; [5]Neuroscience Program, Monash Biomedicine Discovery Institute, Department of Physiology, Melbourne, Australia; [6]Metabolic Disease and Obesity Program, Monash Biomedicine Discovery Institute, Department of Physiology, Melbourne, Australia.

Polycystic ovary syndrome (PCOS) is the most common endocrinopathy of reproductive age women and is characterized by reproductive, metabolic and psychological features exacerbated by weight gain. Weight management in PCOS is challenged by propensity to weight gain and lack of sustainable dietary interventions. Body weight is regulated by calorie intake and the rate of energy expenditure. Metabolically active brown adipose tissue (BAT), contributing to energy dissipation, has been described in humans. The thermogenic activity of BAT is controlled by the sympathetic nervous system (SNS). Sex hormones also play role in modulating BAT. Human studies confirm association of supraclavicular skin temperature, where most human BAT is located, with BAT activity. This observational study aimed to explore BAT thermogenesis and its associations, for the first time, in PCOS. Cutaneous wireless temperature probes (2 cm diameter, 0.5 depths) were taped to supraclavicular (BAT) and upper arm (muscle) regions of 49 premenopausal women with PCOS, over 96 hours, (mean age: 29.85±5.93, mean BMI: 29.02±5.43), recruited from community. Multiunit muscle SNS activity (by microneurography) and plasma noradrenaline levels were measured as markers of SNS activity. Fasting lipids, serum androgens, markers of insulin resistance and inflammation were measured. Recorded temperature data from both regions were available in 41 participants. Supraclavicular temperature was significantly higher than arm temperature (33.87±0.65 vs 32.23±0.85, $P < 0.0001$). Supraclavicular temperature correlated with testosterone ($r=-0.410$, $P=0.011$), noradrenaline ($r=-0.488$, $P=0.005$) and triglycerides ($r=-0.393$, $P=0.015$) which remained significant after adjustment for BMI. Arm temperature did not correlate with testosterone, noradrenaline and triglycerides. This is the first study of BAT thermogenesis in PCOS using cutaneous temperature probes. The negative correlation of BAT temperature with noradrenaline levels could implicate a maladaptive thermogenic response to chronic SNS activation in PCOS. Chronic sympathoexcitation and hyperandrogenism play potential roles in modulation of BAT thermogenesis in PCOS.

Dipeptidyl peptidase-4 (DPP-4) inhibitor sitagliptin improved beta cell function and prevented a conversion rate to MTG and DM2 in metformin intolerant PCOS with high metabolic risk

Andrej Janez, Simona Ferjan & Mojca Jensterle
University Medical Center Ljubljana, Ljubljana, Slovenia.

Objective
Metformin is the first-line therapy for PCOS with high metabolic risk, yet a large proportion of patients cannot tolerate it due to associated gastrointestinal adverse events. The alternative pharmacological strategy when metformin cannot be tolerated is not well established in this population. Our aim was to evaluate whether sitagliptin (SITA) preserves metabolic profile in metformin (MET) intolerant PCOS with high metabolic risk.
Design and methods
A 12-week prospective randomized open-label study was conducted with 30 obese MET intolerant women with PCOS (aged 35.0±7,2 years, BMI 36,9±5.5 kg/m^2). They were randomized to lifestyle intervention and SITA 100mg QD or lifestyle intervention alone as controls (CON). All participants underwent standard anthropometric, endocrine measurements and OGTT. Model derived indexes of insulin resistance (IR) and β-cell function were calculated.
Results
SITA improved beta cell function as assessed by HOMA beta for 45,9±35,8 (P=0,001), modified beta cell function index (MBCI=I0XG0/(G120+G60-7)) for 7,9±7 (P=0,002) and QUICKI for −0,03±0,03 (P=0,002) and increased IR as assessed by HOMA-IR and insulin action index (IAI=1/G0XI0) for 1,8±1,7 (P=0,002) and −0,01±0,01(P=0,003). By contrast, beta cell function decreased in CON arm. The between group differences were significant for HOMA-beta (P=0,000), MBCI (P=0,010) and QUICKI (P=0,025). The conversion rate from normal glucose tolerance to impaired glucose tolerance (IGT) or T2DM was prevented in SITA (3/15 of subjects with MTG before and after the study). In CON 4 women had IGT at the beginning. After 12 weeks IGT was observed in 2 and T2DM in 3 subjects.
Conclusion
SITA improved beta cell function and prevented a conversion rate to IGT and T2DM in metformin intolerant PCOS with high metabolic risk when compared to lifestyle alone.

Genetic susceptibility for adrenal hyperandrogenism in polycystic ovary syndrome

Nicoleta Baculescu[1,2], Sarah Haydar[3], Monica Livia Gheorghiu[1,2], Serban Radian[1,2], Corinne Lautier[3], Catalina Poiana[1,2], Michel Pugeat[4] & Florin Grigorescu[3]
[1]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [2]C.I. Parhon Institute of Endocrinology, Bucharest, Romania; [3]IURC, UMR-204 NUTRIPASS, University of Montpellier, Montpellier, France; [4]Fédération d'Endocrinologie, Hopital Neuro-Cardio, University of Lyon, Lyon, France.

Background
Hyperandrogenism is a main feature of the polycystic ovary syndrome (PCOS). Although its ovarian origin is well recognized, laboratory investigation suggested the contribution of adrenal gland, albeit of unknown mechanism.
Aim
To understand the contribution of genetic factors in adrenal hyperandrogenism (AH) we investigated genome wide SNPs in subgroups of PCOS patients stratified as function of DHEAS levels in two ethnic populations (Romanians and French).
Subjects and methods
Patients recruited during European MEDIGENE program (FP7-279171) with PCOS (n=307) of 18–42 years old were stratified in two groups as function of DHEAS level greater than 95th percentiles in age-matched controls. Genotyping was performed with customized MEDISCOPE microarray chip with 759 000 SNP. Influential SNPs were determined by correlation trend (CT) test and then by genetic association in two subgroups of patients.
Results
Despite no difference in total-testosterone levels, in PCOS with AH (n=58, 18.9%) the SHBG (27.6±3.6 vs 44.5±3.3 nmol/L, P< 0.0002) was lower and FAI (14.0±2.2 vs 8.7±0.7, P< 0.002), 2-h insulin in OGTT (111.2±26.0 vs 77.3±6.9 mUI/L, P<0.044) and systolic BP (123.7±4.26 vs 114.4±1.8 mmHg, P<0.045) were higher than in PCOS without AH. SNPs corresponding to at least 15 genes were positive in CT test with DHEAS levels. Among them, INSR and CDH13 were the most significant with numerous SNPs having a P value < 1.0×10-5 after Bonferroni correction. In genetic association by logistic regression between two groups, other genes were also confirmed, the most influential being IL2RA, PTER, SORCS1, LGR4 and KSR2. For instance, LGR4 (Chr 11) was associated with P< 0.005, OR 5.6, 95%CI [1.6–19].
Conclusion
These data indicated that, in PCOS patients, AH may be in part explained by genetic susceptibility. Despite a full array of genes involved, the insulin-resistance appears as potential actor of AH in PCOS.

Turner's syndrome and abnormal liver chemistry: relationship with karyotype in a large dedicated clinic

Matilde Calanchini[1,3], Ahmad Moolla[1], Jeremy W Tomlinson[1], Jeremy Cobbold[2], Andrea Fabbri[3], Ashley Grossman[1] & Helen Turner[1]
[1]Oxford Centre for Diabetes, Endocrinology and Metabolism – Churchill Hospital, University of Oxford, Oxford, UK; [2]Department of Hepatology, John Radcliffe Hospital, Oxford, UK; [3]Department of Endocrinology, CTO Alesini & S. Eugenio, University of Rome Tor Vergata, Rome, Italy.

Introduction
Abnormal liver function tests (↑LFTs) are frequently observed in Turner's syndrome (TS), although the aetiology is unclear. Obesity is reported as one of the causes; recently an increased prevalence of elevated GGT was found in TS patients with a ring X karyotype.
Aim
To analyse the association between abnormal LFTs and TS-related conditions, and in particular their relationship with the different TS-karyotypes.
Methods
Data on adult TS-patients were collected. ↑LFTs was defined as elevated aminotransferases ± GGT and ALP, for more than 6 months. TS-karyotypes were classified in eight groups.
Results
109 TS women were studied: mean age 36(±13.1)y, BMI 28.3(±6.9)Kg/m^2. 45,X was found in 47 patients (46.1%), mosaicism 45,X/46,XX or 45,X/47,XXX in 15 (15.7%), 4 (3.9%) del(X)(p), 1 (1%) del(X)(q), 10 (9.8%) isochromosome(X)(q), 10 (9.8%) ring X, presence of Y in 4 (3.9%) and 10 (9.8%) other TS-karyotypes.
38/109 (35%) presented with ↑LFTs, most frequently a ↑GGT. Differences between the normal-LFTs-group versus the ↑LFTs-group were found for age (33.8 vs 41y, P=0.008), Tot-Chol (4.9 vs 5.5 mmol/L, P=0.005), LDL-Chol (2.7 vs 3.2 mmol/L, P=0.006), and triglycerides (1.1 vs 1.5 mmol/L, P=0.02). No differences were noted analysing anthropometric values, HbA1c, history of diabetes, hypertension or autoimmunity.
The prevalence of ↑LFTs was significantly higher in the isochromosome(X)(q)-group (P=0.0003); the mosaicism-group had a decreased prevalence of ↑LFTs (P=0.0092). Using the stringent ALT cut-off of 19UI/L, this was commoner only in the i(X)(q)-group (P=0.0134). The i(X)(q)-group showed a similar clinical phenotype compared to 45,X and no increased prevalence of autoimmune disease.
Conclusions
This study shows 1) ↑LFTs are common in TS; 2) the prevalence of ↑LFTs increases with age and is associated with increased cholesterol and triglycerides; 3) for the first time, a relationship between ↑LFTs and karyotype was found, suggesting that liver biochemical abnormalities could be triggered by over-expression of Xq genes escaping inactivation.

Sensitivity of hypothalamo-pituitary-adrenal axis in women with PCOS

Djuro Macut[1], Ivana Bozic-Antic[1], Jelica Bjekic-Macut[2], Dusan Ilic[1], Danijela Vojnovic-Milutinovic[3], Olivera Stanojlovic[4], Tamara Bogavac[1], Bojana Popovic[1], Tatjana Isailovic[1], Valentina Elezovic[1] & Sanja Ognjanovic[1]

[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]CHC Bezanijska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]IBISS, University of Belgrade, Belgrade, Serbia; [4]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

Increased adrenal androgen production is present in 20–60% of women with polycistic ovary syndrome (PCOS). Possible mechanism is not clarified yet and could be related to altered hypothalamic-pituitary-adrenal-axis (HPA) activity or a consequence of adrencortical steroidogenic abnormalities. The aim of the study was to assess HPA sensitivity in PCOS women using different doses of dexamethasone.

Methods

We analyzed 359 women with PCOS diagnosed using ESHRE/ASRM criteria (age: 25.6±5.3 years, BMI: 25.1±6.4 kg/m^2), and 58 BMI-matched healthy controls (age 28.79±6.1 years, BMI 23.7±6.1 kg/m^2). In all subjects serum ACTH, morning serum cortisol (SC), and DHEAS were measured, and SC and DHEAS determined after overnight dexamethasone test with 0.5 mg ($Dex_{0.5mg}$) and 1 mg (Dex_{1mg}), and marked as $SC_{dex0.5}$, SC_{dex1}, $DHEAS_{dex0.5}$ and $DHEAS_{dex1}$, respectively. Differences between groups were age adjusted and data are presented as ANCOVA-mean (95%CI).

Results

SC was borderline higher [437.9(421.6–454.3) vs. 395.7(356.7–437.8)nmol/l, $P=0.052$] and DHEAS significantly higher [7.7(7.3–8.2) vs. 5.6(4.6–6.7)nmol/l, $P<0.001$] in PCOS than in controls. There was no difference in ACTH among groups. After dexamethasone tests, both groups significantly lowered SC and DHEAS in comparison to basal analyses. In comparison to controls, PCOS had borderline higher $SC_{dex0.5}$ [49.9 (22.9–76.9) vs. 78.5(67.8–89.1)nmol/l, $P=0.055$] but similar percentage of SC suppression [86.5 (80.6–92.3) vs. 82.8(80.4–85.3)%, $P=0.26$]. PCOS had lower SC_{dex1} [26.8 (23.5–30.2) vs. 22.9(21.6–24.2)nmol/l, $P=0.055$] and suppressed SC more than controls [92.5(91.6–93.5) vs. 94.5(94.1–94.9)%, $P<0.001$]. There were no differences in $DHEAS_{dex0.5}$ and $DHEAS_{dex1}$ between groups. Suppression of DHEAS was similar after $Dex_{0.5mg}$ ($P=0.92$), but PCOS suppressed DHEAS after Dex_{1mg} less than controls [32.1 (25.9–38.3) vs. 47.7(34.0–61.4)%, $P=0.04$].

Conclusions

Our women with PCOS, in comparison to BMI-matched controls have increased age-adjusted HPA axis sensitivity to 1 mg but not to 0.5 mg of dexamethasone. DHEAS production in PCOS seems to be more independent of ACTH than in controls.

Nonalcoholic fatty liver disease liver fat score (NAFLD-LFS) could be used for the assessment of NAFLD in women with PCOS

Jelica Bjekic-Macut[1], Ivana Bozic-Antic[2], Konstantinos Tziomalos[3], Dusan Ilic[2], Danijela Vojnovic-Milutinovic[4], Olivera Stanojlovic[5] & Djuro Macut[2]

[1]CHC Bezanijska kosa, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [2]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Department of Medicine, University of Thessaloniki, Thessaloniki, Greece; [4]IBISS, University of Belgrade, Belgrade, Serbia; [5]Institute of Physiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia.

Introduction

A relation between polycystic ovary syndrome (PCOS) and nonalcoholic fatty liver disease (NAFLD) was demonstrated recently. Both NAFLD and PCOS are associated with increased risk for type 2 diabetes and cardiovascular disease. NAFLD liver fat score (NAFLD-LFS) has been implicated as a non-invasive surrogate marker for NAFLD. The aim of this study was to identify the prevalence of NAFLD in different PCOS phenotypes using NAFLD-LFS.

Methods

We evaluated 489 obese PCOS women (PCOS: 33.2±5.7 kg/m^2; 25.6±6.2 years) diagnosed using ESHRE/ASRM criteria and 97 BMI-matched obese healthy women (controls: 32.5±5.5 kg/m^2; 31.7±5.1 years). PCOS group was divided into 4 phenotypes: A [anovulation (ANOV), hyperandrogenism (HA), polycystic ovary morphology (PCOM)], B (ANOV,HA), C (HA,PCOM) and D (ANOV,PCOM). NAFLD was assessed using NAFLD liver fat score (NAFLD-LFS) cutoff > -0.640. Differences between groups were age adjusted.

Results

NAFLD was more prevalent in PCOS in comparison to controls (59.7 vs 44.4%, $P=0.009$). Our PCOS group consisted of 268 women with phenotype A, 129 with phenotype B, 47 with phenotype C and 35 with phenotype D. Prevalence of NAFLD in phenotypes were: A: 59%, B:61%, C:53% and D:66%. There were significant differences in the prevalence of NAFLD between controls and phenotype A ($P=0.015$), phenotype B ($P=0.015$) and phenotype D ($P=0.028$). There were no significant differences between phenotypes.

Conclusions

NAFLD is more prevalent in obese PCOS women than in obese BMI-matched controls. All four phenotypes have the same risk for NAFLD which confirms susceptibility of PCOS as a whole to develop metabolic derangements.

Effects of central sympathoinhibition with moxonidine on the elevated sympathetic nervous activity and downstream metabolic abnormalities observed in polycystic ovary syndrome

Soulmaz Shorakae[1,2], Elisabeth Lambert[3,4], Eveline Jona[1], Carolina Ika Sari[3], Barbora de Courten[1,2], Gavin Lambert[3,4] & Helena Teede[1,2]

[1]Monash Centre for Health Research and Implementation, Monash University, Melbourne, Australia; [2]Diabetes and Vascular Medicine Unit, Monash Health, Melbourne, Australia; [3]Human Neurotransmitters Laboratory, Baker IDI Heart & Diabetes Institute, Melbourne, Australia; [4]Department of Physiology, Monash University, Melbourne, Australia.

The role of the sympathetic nervous system (SNS) in the pathophysiology of PCOS and associated cardiometabolic risks is emerging. Previous studies support increased SNS activity in PCOS, potentially contributing to metabolic features via multiple mechanisms including insulin resistance. Moxonidine is a second-generation imidazoline I_1 agonist, acting centrally, inhibiting sympathetic outflow at the level of rostral ventrolateral medulla with known beneficial effects on hypertension, insulin sensitivity, dyslipidemia and inflammation. This study aimed to explore pharmacological modification of SNS activity, for the first time, in women with PCOS, using moxonidine. 51 premenopausal women (mean age: 29.8±5.9 years, mean BMI: 29.0±5.4 kg/m^2) with PCOS were recruited, from a community setting, in a double blind placebo controlled clinical trial. 48 women were weaned off any interacting medication for 3 months then randomized to moxonidine (0.2mg daily initially, up titrated to 0.4mg daily in 2 weeks) ($n=23$) or placebo ($n=25$) for 3 months. Multiunit muscle SNS activity (MSNA by microneurography), heart rate variability (HRV) and endothelial function (ischaemic reactive hyperaemia index (RHI)) were examined. Fasting lipids, serum androgens, markers of insulin resistance and inflammatory markers were measured prior to and following intervention. 45 women completed the trial (19 moxonidine and 23 placebo). Change in MSNA (−3.23±6.71 vs −2.81±8.2 bursts per minute, P=NS), HRV (5.26±13.56 vs 2.95±15.37 nu in low frequency component, P=NS) and endothelial function (0.10±0.70 vs 0.06±0.67 in RHI, P=NS) did not differ significantly with moxonidine compared to the placebo. Mean changes in BP, fasting lipids, HOMA-IR, hs-CRP and androgens were similar in both groups. In women on moxonidine, change in BMI correlated positively with change in MSNA ($r^2=0.593$, $P=0.03$). Central sympathoinhibition with moxonidine does not modify higher SNS activity and downstream metabolic abnormalities in PCOS. Sympathoexcitation in PCOS may be driven peripherally or from other brain regions with further research needed.

Steroid receptors involvement in enamel hypomineralization resulting from exposure to low-dose DEHP and bisphenol A

Bui Ai Thu[1,2], Sophia Houari[1,2], Sophia Loiodice[1,2], Katia Jedeon[1,2], Ariane Berdal[1,2] & Sylvie Babajko[1,2]

[1]University Paris Diderot, Paris, France; [2]INSERM, Paris, France.

The environment has become increasingly contaminated by various pollutants including endocrine disrupting chemicals (EDCs). This has led to an increase in the incidence and gravity of known pathologies and the emergence of new ones, including dental pathologies as the Molar Incisor Hypomineralization (MIH). Among the thousands of EDCs, bisphenol A (BPA) and phthalates (DEHP) are widely used by the plastic industry and responsible to frequent contaminations.

We previously showed a link between experimental exposures to low-dose BPA and enamel defects similar to MIH (1). The characterization of enamel defects may be helpful to propose them as early markers of exposure to EDCs thanks to enamel unique properties.
The aims of the present work are 1) to compare mouse enamel defects resulting from exposure to low-dose BPA and/or DEHP and, 2) to approach the mechanism, of action of both EDCs during amelogenesis.
The study was carried out on mice exposed to 5 and 50 mg/kg per day DEHP with or without 5 μg/kg per day BPA. Exposed animals present enamel defects on their incisors with similar characteristics than those of MIH affected teeth. In addition, 11% of DEHP mice presented enamel breakdown suggesting a weak enamel structure. As both EDCs act through steroid receptors, their presence and expression levels were investigated in ameloblasts by immunofluorescent assays and RT-qPCR respectively. We found that dental epithelium express a specific combinatory of steroid receptors (AR, ERs, ERRs, RARα/RXRα, VDR, GR, MR and PGR) depending on their stage of differentiation. These data suggest that depending on their nature and the time of exposure, phthalates and BPA could affect enamel quality (through AR) and/or quantity (through ERRγ and ERα). Studies are currently driven to decipher the functional role of AR in the mechanism of action of both EDCs in ameloblasts.

In vitro effects of Bisphenol A on two metabolic receptors signaling: MC4R and FFAR1

Mathilde Munier[1,4], Mathilde Louvigné[5], Hélène Rudelle[4], Louis Gourdin[1,3], Claire Briet[4,3], Daniel Henrion[1,2], Marie Chabbert[1,2], Régis Coutant[3,5] & Patrice Rodien[3,4]
[1]UMR CNRS6015-INSERM1083, Angers, France; [2]MITOVASC Institute, Angers, France; [3]Reference Center for Rare Diseases of Hormonal Receptivity, Angers, France; [4]Department of Endocrinology, Angers, France; [5]Department of Pediatric Endocrinology, Angers, France.

Metabolic diseases (type 2 diabetes (T2D) and obesity) prevalence is increasing in the world. This is partly related to a change in lifestyle with an increase of caloric intake and a decrease of physical activity. Environmental causes are also involved among them exposure to bisphenol A (BPA). The mode of action of the latter is unknown. Beyond a suggesting effect relayed by nuclear receptors, we propose that BPA can act by modulating the functionality of G protein-coupled receptors involved in the pathophysiology of metabolic disorders. In order to test this hypothesis, we analyzed the effect of BPA on the activity of MC4R and fatty acid receptor FFAR1 (GPR40). MC4R is involved in obesity by regulating dietary intake and energy balance. There are two ligands of MC4R: αMSH (agonist) and AgRP (inverse agonist). FFAR1 increases the glucose-dependent insulin secretion. It is a new therapeutic target in T2D.
Each receptor is transiently expressed in HEK293, and its activity is assessed by measuring cyclic AMP (cAMP) for MC4R, using a biosensor kit, or calcium for FFAR1, using a fluorimetric calcium sensor.
At a concentration of 10 nM, BPA increased by up to 30% the cAMP production induced by αMSH and reduced by half the inhibition induced by AgRP, without modifying the basal activity. These effects are specific for MC4R as BPA did not change the activity of the downstream effectors of cAMP pathway (adenylate cyclase, G protein or phosphodiesterases) or one of endogenous adenosine receptor (negative control).
In addition, 10 pM BPA decreased by one-third the calcium mobilization stimulated by GW9508 (a synthetic agonist of FFAR1).
We show here new effects of BPA with a disruption of G protein-coupled receptors activity, which may be worth to take into account when addressing the question of the link between endocrine disruptor and metabolic diseases.

Altered protein expression of cell cycle- and EMT-associated genes by bisphenol compounds in MCF-7 CV human breast cancer cells via estrogen receptor dependent pathway

Ana Patricia Ayala-Cuellar, Kyung-A Hwang & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Bisphenol-A (BPA) has been considered as an endocrine disrupting chemical (EDC) because it can exert estrogenic properties. For bisphenol-S (BPS) and bisphenol-F (BPF) that are BPA analogs and substitutes, their risk to estrogen-dependent cancer has been reported rarely compared with the numerous cases of BPA. In this study, we examined whether BPA, BPS, and BPF can lead to the proliferation, migration, and epithelial mesenchymal transition (EMT) of MCF-7 clonal variant (MCF-7 CV) breast cancer cells expressing estrogen receptors (ERs). In a cell viability assay, BPA, BPS, and BPF significantly increased proliferation of MCF-7 CV cells compared to control (DMSO) as did 17β-estradiol (E2). In Western blot assay, BPA, BPS, and BPF enhanced the protein expression of cell cycle progression genes such as cyclin D1 and E1. In addition, MCF-7 CV cells lost cell to cell contacts and acquired fibroblast-like morphology by the treatment of BPA, BPS, or BPF for 24 h. In cell migration assay, BPA, BPS, and BPF accelerated the migration capability of MCF-7 CV cells as did E2. In relation with the EMT process, BPA, BPS, and BPF increased the protein expression of N-cadherin, while they decreased the protein expression of E-cadherin. When BPA, BPS, and BPF were co-treated with ICI 182,780, an ER antagonist, proliferation effects were reversed, the expression of cyclin D1 and cyclin E1 was down-regulated, and the altered cell migration and expression of N-cadherin and E-cadherin by BPA, BPS, and BPF were restored to the control level. Thus, these results imply that BPS and BPF also have the risk of breast cancer progression as much as BPA in the induction of proliferation and migration of MCF-7 CV cells by regulating the protein expression of cell cycle-related genes and EMT markers via ER-dependent pathway. Reproductive toxicity of low dose nonylphenol in mice: a two-generation study

Sung-Ho Lee, Yong Bin Kim & Hee Su Kim
Sangmyung University, Seoul, Republic of Korea.

Nonylphenol (NP), a member of alkylphenol family, has been widely used in both industry and household. NP is classified as an endocrine-disrupting chemical and is known to act as an agonist of the GPER (GPR30). The aim of this study was to address the two-generational effects of para-nonylphenol (NP) on the body weights, reproductive organ weights and histopathologies of ICR mice. We also test the potential reproductive toxicity of octylglucuronide (OG), a substitute candidate for NP. The testing drugs were administered as drinking water (50 and 500 ug/l) throughout the pre-mating period of P0 animals and lactation of F2 animals. Significant decreases were found in the weights of testis, prostate and seminal vesicle in the F1 NP500 group, in the weights of testis and epididymis in F2 NP50 and NP500 groups. There was no weight change in the OG-treated groups. In female, significant decreases in the weights of ovary and uterus in F1 NP50 group, uterus of F1 NP500 group, and F2 NP500 group were found. The weights of ovary in F1 OG50 and OG500 were also significantly decreased. Histopathological studies revealed that the numbers of Leydig cells were reduced in the testes of F1 and F2 NP50 groups. There were no changes in the Leydig cell numbers of OG groups. In F1 NP500 mice, the increased numbers of primary and secondary follicles and decreased number of corpora lutea were observed. There was no change in OG-treated group gonad. Finally, vaginal opening was delayed in F1 NP50 and NP500, and F2 NP50 animals. Present study demonstrated that the potential reproductive toxicity in animals long-term exposed to low dose NP (approximately 15–150 ng of daily intake). Our study also show that OG seems to be a promising alternative to NP, and further studies are warranted. This work was supported by the National Research Foundation of Korea Grant funded by the Korean Government (NRF-2016904200).

Psychological rather than organic and/or relational components are involved in sexual dysfunction in Young/Middle aged human immunodeficiency virus (HIV)-Infected Men

Maria Chiara Decaroli[1], Sara De Vincentis[1], Chiara Diazzi[1], Stefano Zona[2], Giovanni Guaraldi[2], Daniele Santi[1] & Vincenzo Rochira[1]
[1]Unit of Endocrinology, University of Modena and Reggio Emilia, Modena, Italy; [2]Unit of Infectious Diseases, University of Modena and Reggio Emilia, Modena, Italy.

Background
HIV-infection is associated to an increased prevalence of erectile dysfunction (ED). In HIV-infected men ED seems to be less related to serum Testosterone (T), depending from other factors.
Aim
To investigate the role of different components (organic, relational, psychological) of erectile function by using validate questionnaires in HIV-infected men with normal serum T.
Methodology
Prospective, cross-sectional, observational study on eugonadal HIV-infected male patients with ongoing Highly Active Antiretroviral Therapy (HAART) attending the Clinic of Infectious Diseases. The International Index of Erectile Function (IIEF)-15, IIEF-5 and Structured Interview for Erectile Dysfunction (SIEDY) were used to assess sexual function. Sexual desire was further evaluated through a direct question during the visit. LC-MS/MS was used to assess gonadal status.
Results
225 HIV-infected patients were enrolled (mean age 45.19 ± 5.36 years). SIEDY scores at appendix and scale 3 were significantly higher in patients with ED at IIEF-15 ($n=136$, 60.4%) compared with those without ED ($P<0.001$ and $P=0.015$, respectively). Conversely, scale 1 ($P=0.448$) and 2 ($P=0.503$) of SIEDY did not differ between patients with or without ED, suggesting a predominance of the psychological basis of ED in our cohort. The erectile function domain at IIEF-15 was directly correlated with IIEF-5 score (0.778, $P<0.001$). Similarly, the score at SIEDY appendix was significantly different among ED degrees at IIEF-15 ($P<0.001$). In particular, lower score was found in HIV-infected men without ED compared to those with mild, moderate and severe ED ($P<0.001$, $P=0.001$, and $P<0.001$, respectively), confirming the reliability of these tools. Sexual desire was impaired in 73 patients (31.33%) at interview with a good correlation with the specific item of IIEF-15 ($P<0.001$).
Conclusions
The psychological component impacts in a significant manner on ED in HIV-infection context. Despite the high prevalence of comorbidities in these patients, the organic component does not affect erectile function. All the three validated questionnaires seem to be trustworthy in the diagnosis of ED in this setting.

Effects of physical exercise or metformin on testosterone deficiency and erectile dysfunction associated to metabolic syndrome

Linda Vignozzi[2,3], Sandra Filippi[1], Paolo Comeglio[2], Ilaria Cellai[2], Francesca Corcetto[2], Chiara Corno[2] & Mario Maggi[2,3]
[1]Interdepartmental Laboratory of Functional and Cellular Pharmacology of Reproduction, Department of Neuroscience, Phychology, Drug Research and Child Care, University of Florence, Florence, Italy; [2]Sexual Medicine and Andrology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [3]INBB, Rome, Italy.

Metabolic Syndrome (MetS) is a cluster of clinical conditions, associated to an increased cardiovascular and metabolic risk, to hypogonadism and erectile dysfunction (ED). Lifestyle modification (including physical exercise, PhyEx) and metformin (MET) are well-known treatments for the condition. We established an animal model of MetS that recapitulates the human phenotype, including andrologic derangements.
The aim of this study was to investigate in experimental MetS the effect of PhyEx or MET on penile erection and on hormonal and metabolic parameters.
Control (RD) and MetS rabbits were treated with MET (the last 18 days) or exercise-trained to run on a treadmill for 12 weeks. Penile tissue was collected for *in vitro* contractility study or gene expression.
MET, but not PhyEx, induced a reduction in visceral adiposity, blood pressure, triglycerides, glucose level and tolerance. MET increased testosterone (T), whereas PhyEx completely restored it. Ach-induced relaxation, hampered in MetS rabbits, was significantly ameliorated by MET and completely normalized by PhyEx. HFD determined a net reduction of electrical field (EF)-vasorelaxation in CC. The relaxant response to sildenafil, abolished in HFD rabbit CC, was restored by PhyEx. PhyEx normalized sodium nitroprusside (SNP)-induced relaxation, that was enhanced in MetS rabbits. Genes related to NO signaling were up-regulated by PhyEx, but not by MET. Similar results were obtained for smooth muscle-related genes. PDE5 expression was decreased in MetS rabbits and completely restored by PhyEx. Accordingly, sildenafil-induced increase in SNP relaxation was completely normalized by PhyEx.
In conclusion, PhyEx more than metformin, completely restored T levels and responsiveness to Ach and sildenafil in experimental MetS, even though it was less effective than metformin in reducing metabolic abnormalities. The effect of exercise training is most probably related to an improved NO signaling, including PDE5. Hence, PhyEx can be considered a new strategy to treat hypogonadism and ED related to MetS.

Impacts of a single ablative dose of radio iodine therapy for differentiated thyroid carcinoma on testicular function: results from the SAPIRA study

Nathalie Bourcigaux[1], Carole Rubino[2], Isabelle Berthaut[3], Bruno Donadille[2], Marie Elisabeth Toubert[4], Laurence Leenhardt[5], Catherine Corone[6], Isabelle Petrot-Keller[1], Sylvie Brailly-Tabard[7], Julie Beaufaron[10], Tabassome Simon[1], Jean-Pierre Siffroi[8], Florent De Vathaire[2], Martin Sclumberger[2], Philippe Bouchard[9] & Sophie Christin-Maitre[1]
[1]Hôpital St Antoine, Greater Paris University Hospitals, Paris, France; [2]Institut Gustave Roussy, Villejuif, France; [3]Hôpital Tenon, Greater University Paris Hospitals, Paris, France; [4]Hôpital St Louis, Greater Paris University Hospitals, Paris, France; [5]Hôpital Pitié Salpétrière, Greater Paris University Hospitals, Paris, France; [6]Centre René Huguenin, St Cloud, France; [7]Hôpital Le Kremlin-Bicêtre, Greater Paris University Hospitals, Le Kremlin-Bicêtre, France; [8]Hôpital Armand Trousseau, Greater Paris University Hospitals, Paris, France; [9]Hôpital Foch, Suresnes, France; [10]Cabinet Médical, Nouméa, New Caledonia.

Background
Radioactive iodine therapy (RAI) is a classical therapeutic approach in patients with differentiated thyroid carcinoma (DCT). Few data are currently available on RAI's potential impacts on testicular function.
Design
A longitudinal prospective multi-center study (PHRC N°P040419) included male patients before a single radioiodine dose of 3.7 GBq of I^{131} (V0), at 3 months (V3) and 13 months (V13) post treatment.
Method and Patients
Hormonal assessments (FSH, LH, Testosterone, inhibin B) as well as sperm parameters (number, mobility and morphology), DNA fragmentation and sperm FISH analysis in order to detect chromosomal abnormalities were performed at V0, V3 and V13.
Results
Thirty six patients were included in the study. At V0, all patients had normal gonadal function. At V3, FSH median levels were significantly increased as compared to V0, respectively 9 UI/l ± 4.8 (*N*: 3–7 UI/l) versus 4 UI/l ± 3 ($P<0.0001$). Between V3 and V13, FSH levels decreased but remained higher than baseline levels. Inhibin B median levels decreased significantly at V3 ($P<0.0001$) and returned to V0 levels at V13. LH and T levels were not modified at V3 or V13.
Median sperm concentration significantly decreased at V3 as compared to V0 (20 vs 48 million/ml; $P<0.0001$) and returned to V0 levels at V13. In parallel, a statistically significant decrease in sperm morphology was observed at V3. Sperm mobility and DNA fragmentation were not modified after RAI. However sperm chromosomal abnormalities were increased at V3 ($P<0.0005$) and V13 ($P<0.01$), as compared to V0.
Conclusion
In this prospective study, RAI transiently altered FSH, inhibin B and sperm number. Furthermore, chromosomal abnormalities observed at V3 were found to persist 13 months after RAI. Therefore, our study illustrates that counseling about fertility could be interesting in male patients with DCT treated by a single dose of radioiodine.

Presentation, clinical features and long-term follow-up of Leydig cell tumours of the testis: 77 cases from a single center experience

Andrea M. Isidori, Vincenzo Giannetta, Daniele Gianfrilli, Rosa Lauretta, Maria Grazia Tarsitano, Giorgio Fattorini, Riccardo Pofi, Carlotta Pozza & Andrea Lenzi

Introduction
With the improved imaging techniques, Leydig cell tumours (LCTs) are frequently found, accounting up to 22% of testicular tumours. The natural history of LCTs is relatively unknown, because of the small size and heterogeneity of available studies. Since LCTs are often removed, long-term follow-up is missing. The aim of this study was to report the experience with a large cohort of prospectively collected LCTs.
Materials and methods
Patients with LCTs were enrolled from 2005 to 2016. Clinical and biochemical features of LCTs were compared with two matched cohorts: patients with seminomas and patients without testicular lesions (noL) randomly selected among patients referred in the same period.
Results
77 patients had LCTs, 90 had seminomas, and 1420 had no lesion (noL). Groups were matched for age and BMI. Infertility was the reason for referral in more than half of LCTs. Testicular volumes ($P=0.002$), sperm concentration ($P=0.001$) and morphology ($P<0.001$) were significantly lower in LCTs compared to noL; gonadotropins were higher ($P<0.001$) and testosterone was lower ($P=0.008$) in LCTs vs noL. No differences were found in gonadal steroid after hCG test, between groups. When compared to seminomas, LCTs did not show differences in hormonal status except for higher SHBG levels ($P=0.028$), LH/Te ratio ($P<0.001$), and lower sperm concentration ($P=0.04$). LCTs lesions were smaller compared to Sem ($P<0.001$). Cryptorchidism ($\chi^2=45.658$ $P<0.001$) and gynecomastia ($\chi^2=54.923$, $P<0.001$) were associated with a higher risk of LCTs. After a median follow-up of 32.5 months, no metastases have been detected. Non-operated LCTs developed subclinical hypogonadism ($P=0.018$) compared to surgically removed LCTs.
Conclusions
LCTs have a good prognosis when correctly recognized. Based on the largest existing series, we showed that infertility, gynecomastia,low testicular volume, and cryptorchidism are frequently associated with LCTs, supporting the hypothesis that testicular dysgenesis syndrome could play a role. Active surveillance, as an alternative to surgical removal, appears to be a safe option, but monitoring of Leydig cell failure remains necessary.

Semen quality in patients with adult-onset hypogonadotropic hypogonadism

Mikkel Andreassen[1], Anders Juul[2], Ulla Feldt-Rasmussen[1] & Niels Jørgensen[2]
[1]Department of Endocrinology, Rigshospitalet, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark; [2]Department of Growth and Reproduction Rigshospitalet, Faculty of Health Science, University of Copenhagen, Copenhagen, Denmark.

Introduction
Gonadotropins from the pituitary gland are essential for testosterone production and spermatogenesis. However, little is known about semen quality in patients with adult onset gonadotropin insufficiency.
Aim
To investigate semen quality in men with adult onset hypogonadotropic hypogonadism requiring testosterone replacement therapy.
Patients and method
A single center study comprising all hypogonadal men with pituitary disease (year 2003–2016, $n=28$, (median(IQR) 30 (27–37) years), who accepted cryopreservation of semen before initiation of testosterone therapy. On the day semen samples were cryopreserved, reproductive hormone levels were measured. Semen parameters, hormone levels and size of testicles were compared to those of young men ($n=340$, 19 (18–20) years) from the general population.
Results
Patients vs controls had lower serum testosterone 5.6 (3.5–7.8) vs 19.7 (15.5–24.5) nmol/l ($P<0.001$), free testosterone index 33.3 (18.1–55.1) vs 73.7 (57.8–91.7) ($P<0.001$), luteinizing hormone 1.5 (1.1–2.1) vs 3.1 (2.3–4.0) U/l ($P<0.001$), and inhibin-B 142 (126–187) vs 229 (176–285) ng/l ($P<0.001$). Levels of follicle stimulating hormone were unchanged 2.3 (1.4–4.4) vs 2.2 (1.5–3.3) U/l ($P=0.47$). There were no differences on semen volume 3.0 (1.5–5.0) vs 3.2 (2.3–4.3) ml ($P=0.33$), sperm concentration 35 (6–62) vs 43 (22–73) mill/ml ($P=0.1$), or total sperm counts 102 (8–236) vs 136 (65–235) mill ($P=0.09$). Forty-seven percent of patients and 77% of controls had normal semen quality, WHO criteria (volume >1.5 ml, concentration >15 mill/ml and AB-motile sperm $>42\%$) ($P=0.001$). Three had azoospermia. Testicular size was unchanged 18 (13–25) vs 20 (19–25) ml ($P=0.46$).
Conclusion
Patients with acquired pituitary insufficiency had reduced semen quality, supporting the need for early cryopreservation of semen in this group of patients. However, despite severe Leydig cell insufficiency almost half of patients had normal semen quality based on determination of three variables. This finding is in contrast to men with hypergonadotrpic hypogonadism where spermatogenesis is often severely compromised before Leydig cell insufficiency occurs.

Growth hormone-releasing hormone (GHRH) antagonists, MIA-602 and MIA-690, inhibit survival and proliferation of human pleural mesothelioma cells

Tania Villanova[1], Iacopo Gesmundo[1], Marina Taliano[1], Ezio Ghigo[1], Andrew V Schally[2,3] & Riccarda Granata[1]
[1]Division of Endocrinology, Diabetology and Metabolism, Department of Medical Sciences, University of Torino, Torino, Italy; [2]Endocrine, Polypeptide, and Cancer Institute, Veterans Affairs Medical Center, Miami, Florida, USA; [3]Department of Pathology and Department of Medicine, Divisions of Hematology, Oncology and Endocrinology, University of Miami Miller School of Medicine, Miami, Florida, USA.

Human malignant pleural mesothelioma (MPM) is a rare but aggressive neoplasm, arising from pleural mesothelial cells, generally due to asbestos exposure. Different growth factors are involved in the pathogenesis of MPM and in resistance to therapy; moreover, chemotherapy with cisplatin and antifolates, like pemetrexed (PEM), is the first-line treatment for inoperable MPM. Growth hormone-releasing hormone (GHRH), apart from stimulating GH secretion in the pituitary, exerts many extrapituitary functions, including stimulation of cell proliferation and survival. GHRH and GHRH receptor (GHRH-R) are expressed in different cancer cell types, where they modulate their proliferative effects. Moreover, GHRH-R antagonists were found to inhibit the proliferation of different cancer cells *in vitro* and *in vivo*; however, the role of GHRH antagonists in MPM remains unknown. Thus, in the present study, we investigated the effects of the GHRH antagonists MIA-602 and MIA-690 on survival, proliferation and apoptosis of human MPM cells. Our results show that MIA-602 and MIA-690 reduce survival and proliferation of MSTO-211H (biphasic) and REN (epithelioid) MPM cells, but have no effect in MeT-5A (human non-malignant mesothelial cells). Moreover, MIA-602 and MIA-690 promoted apoptosis and reduced the expression of the antiapoptotic protein Bcl-2 in MSTO-211H and REN cells. Cell cycle analysis of REN cells treated with GHRH antagonists showed an increase in the Sub-G1 apoptotic phase and a decrease in the G2 pre-mitotic phase. Furthermore, MIA-602 and MIA-690 inhibited cell migration in REN cells and increased the cytotoxic action of PEM in both MPM cell lines. These results suggest a novel therapeutic role for GHRH antagonists in the treatment of MPM, alone or in combination with standard therapies, by reducing the chemotherapy doses and their associated side effects.

Somapacitan expected to provide IGF-I levels suitable for once-weekly dosing in children

Rasmus Juul, Michael Rasmussen, Henrik Agersø & Rune Overgaard
Novo Nordisk A/S, Bagsvaerd, Copenhagen, Denmark.

Somapacitan is a long-acting growth hormone (GH) intended for once-weekly subcutaneous administration. As for GH, the mechanism of action of somapacitan is either directly or indirectly via insulin-like growth factor I (IGF-I). A PK/PD model of somapacitan was developed from the pharmacokinetics (PK) and IGF-I levels from three phase 1 trials data: a single dose/multiple dose trial (0.02–0.24 mg/kg per week) in healthy adults, a multiple dose trial in adults with growth

hormone deficiency [GHD] (0.02–0.12 mg/kg perweek) and a single dose trial in children with GHD (0.02–0.16 mg/kg). Somapacitan exposure-response was described with a non-linear relationship between dose and exposure and a delay in response observed between C_{max} PK and C_{max} IGF-I. Somapacitan PK levels and IGF-I response was found to correlate to body weight bridging exposure and response between children and adults. The PK/PD model was based on goodness of fit judged adequate to describe somapacitan exposure and IGF-I levels and simulate the expected IGF-I profiles after multiple doses in children. Descriptive IGF-I exposure-response analysis of single dose data in GHD paediatric patients indicated that the dose range 0.04–0.16 mg/kg provided change in IGF-I comparable to daily hGH. Based on the PK/PD model of somapacitan, once-weekly dosing of 0.04 mg/kg per week are expected to provide C_{max} IGF-I levels that match the average daily human GH (hGH) treatment; 0.08 mg/kg per week are expected to provide C_{avg} IGF-I levels that match the average daily hGH treatment; and 0.16 mg/kg per week are expected to provide higher IGF-I levels than with daily hGH, with average concentrations not exceeding +2 SDS. In conclusion, the PK/PD of somapacitan is well characterised in adults and children in GHD in support of once-weekly dosing.

Evaluating CHARGE syndrome in CHD7-positive CHH patients: clinical implications

Cheng Xu[1], Daniele Cassatella[1], Almer van der Sloot[2], Michael Hauschild[1], Richard Quinton[3], Christian De Geyter[4], Christa Flück[5], Katrin Feller[5], Deborah Bartholdi[5], Attila Nemeth[6], Irene Halperin[7], Sandra Pekic Djurdjevic[8], Georgios Papadakis[1], Andrew Dwyer[9], Laura Marino[1], Duarte Pignatelli[10], Carol Huang[11], Nicolas Niederländer[1], James Acierno[1] & Nelly Pitteloud[1]

[1]Lausanne University Hospital, Lausanne, Switzerland; [2]Institute for Research in Immunology and Cancer, Quebec, Montreal, Canada; [3]Institute for Genetic Medicine, University of Newcastle-on-Tyne, Newcastle-on Tyne, UK; [4]University Hospital, University of Basel, Basel, Switzerland; [5]Inselspital, Bern, Switzerland; [6]St John's Hospital, Budapest, Hungary; [7]Hospital Clínic, Universitat de Barcelona, Barcelona, Spain; [8]Institute of Endocrinology, University Clinical Center, Belgrade, Serbia; [9]University of Lausanne, Lausanne, Switzerland; [10]Faculty of Medicine of the University of Porto, Porto, Portugal; [11]Alberta Children's Hospital, Calgary, Canada.

Context

Congenital hypogonadotropic hypogonadism (CHH) and CHARGE syndrome are clinically and genetically overlapping syndromes, with mutations in the *CHD7* gene presenting in both disorders. However systematic evaluation of CHARGE features in *CHD7*-positive CHH patients is seldom performed.

Objective

This study aims to systematically evaluate CHARGE features in CHD7-positive patients and explore the phenotype-genotype correlation.

Design

Whole exome sequencing was performed on 130 CHH probands to identify mutations in 24 CHH genes, including *CHD7*. Putative mutations were defined as rare sequence variants (RSVs, minor allele frequency <1%) that were either protein-truncating variants (PTVs) or missense variants predicted to be deleterious by SIFT and/or PolyPhen2. Missense mutations were also evaluated using Bergman criteria, integrating computational algorithms, population and segregation data (Bergman, Human Mutation, 2012). CHD7-positive CHH patients were evaluated for CHARGE features.

Results

We identified 16 CHH patients harboring heterozygous mutations (two PTVs and 14 missense), of whom 14 were available for re-evaluation. After detailed phenotyping, three probands (one PTV and two missense) were re-classified as CHARGE syndrome. Four probands with missense mutations present additional CHARGE features, while the remaining seven probands exhibit no additional CHARGE feature (one PTV and six missense). Both the missense mutations underlying CHARGE syndrome were categorized as pathogenic using Bergman criteria, while the other missense mutations were classified as either benign or of unknown significance. Of note, 3/4 CHH patients with additional CHARGE features also had mutations in other CHH genes, contributing to the variable expressivity.

Conclusions

50% of *CHD7*-positive CHH patients exhibit additional CHARGE features, with 21% meeting the clinical diagnosis of CHARGE syndrome. While the Bergman criteria accurately predict the most severe mutations resulting in CHARGE syndrome, it is unable to distinguish isolated CHH from CHH with additional CHARGE features. The results of this study have diagnostic and genetic counseling implications for *CHD7*-positive CHH patients.

The effect of chronic hypothalamic-pituitary-adrenal axis activation on hypothalamic glucagon-like peptide-1 action in an animal model of depression and *in vitro* studies

Jan Detka, Anna Kurek, Mateusz Kucharczyk, Joanna Slusarczyk, Katarzyna Glombik, Wladyslaw Lason & Boguslawa Budziszewska
Department of Experimental Neuroendocrinology, Institute of Pharmacology, Polish Academy of Sciences, 12 Smętna Street, 31-343, Cracow, Poland.

Hypersensitivity of hypothalamic–pituitary–adrenal (HPA) axis is considered to be an important factor in the pathogenesis of depression. Interestingly, glucagon-like peptide-1 (GLP-1) – an incretin hormone involved in the maintenance of glucose homeostasis in the periphery is known to activate HPA axis. The aim of the present study was to investigate whether prenatal stress (an animal model of depression) may influence levels of GLP-1 and GLP-1 receptor (GLP-1R) in the hypothalamus. Since prenatal stress may not change the level of the investigated factors in basal conditions, but may change the response to adverse factors in the adulthood, our studies were also conducted on animals subjected to acute stress and oral glucose administration (1 g/kg). In parallel in order to study the direct influence of GLP-1 receptor agonists on the activity of corticotropin-releasing hormone (CRH) promoter gene, a hypothalamic cell line mHypoA-2/12 was stably transfected with plasmid DNA containing the sequence (from −663 to +124 bp) of human CRH promoter gene conjugated with luciferase reporter gene. The cells were treated with GLP-1 and exendin-4 (20 and 200 nM) for 6, 24 and 48 h. The amount of GLP-1 in the hypothalamus was not altered by prenatal stress in basal conditions, however it was significantly lower in a group subjected to acute stress. Prenatal stress and glucose loading significantly decreased the concentration of GLP-1R in the hypothalamus. Obtained results suggest that attenuated central incretin hormone signaling may contribute to metabolic disturbances, evident in depression. In contrast, transfected mHypoA-2/12 cells treated with selected GLP-1R agonists displayed no significant differences in reporter gene activity, which may suggest that GLP-1R activation does not stimulate CRH expression in this experimental model.

A novel purified polyclonal antibody towards T-Pit is a reliable marker of corticotroph cell differentiation

Evelina Sjöstedt[1], Jens Bollerslev[3,4], Fredrik Pontén[1,2] & Olivera Casar-Borota[1,2]

[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [2]Department of Clinical Pathology, Uppsala University Hospital, Uppsala, Sweden; [3]Department of Specialized Endocrinology, Rikshospitalet, Oslo University Hospital, Oslo, Norway; [4]Faculty of Medicine, University of Oslo, Oslo, Norway.

Classification of pituitary neuroendocrine tumours (NETs) or pituitary adenomas is based on the expression of the anterior lobe pituitary hormones (FSH, LH, GH, Prolactin, TSH, ACTH and alpha-subunit of the glycoprotein hormones). Assessment of the transcription factors SF-1, Pit-1 and T-Pit has been a complement to the classification. Tumours negative for both pituitary hormones and transcription factors have been designated as null-cell adenomas. However, lack of sensitive and specific antibodies towards T-Pit has presented difficulties for the inclusion of these transcription factors into the classification system of pituitary endocrine tumours. Here, we present a novel purified polyclonal antibody (HPA072686) towards T-Pit and demonstrate its high sensitivity and specificity for immunohistochemistry-based identification of the cells with corticotroph differentiation. In an immunohistochemical study of a large cohort of pituitary adenomas of different types from 246 patients, a distinct nuclear expression of T-Pit was demonstrated in all ACTH-immunolabelled tumours, silent and clinically functioning, as well as in a proportion of tumours previously diagnosed as null-cell adenomas. None of the tumours that were immunoreactive for Pit-1, SF-1 or pituitary hormones, other than ACTH, expressed T-Pit. We expect that the availability of a reliable T-Pit antibody as a marker of corticotroph cell differentiation will contribute to: i) more precise classification of pituitary neuroendocrine tumours, particularly, those with sparse or no hormone expression, ii) better identification of silent corticotroph tumours that may have more aggressive clinical behaviour than silent gonadotroph tumours, and which are at the moment difficult to identify in cases with sparse or no ACTH

expression, iii) more cost effective immunohistochemical screening of pituitary tumours based primarily on the use of the three transcription factors and iv) identification of potential corticotroph cell differentiation in non-pituitary NETs.

Liraglutide treatment prevented the increased expression of proinflammatory cytokines in the hippocampus of male pups in a perinatal stress model of food restriction

Yolanda Diz-Chaves[1], Laura Toba[1], Juan Fandiño[1], Lucas González-Matías[1], Luis Miguel Garcia-Segura[2] & Federico Mallo[1]
[1]University of Vigo, CINBIO, Vigo, Spain; [2]CSIC, Instituto Cajal, Madrid, Spain.

Adverse events during gestation in rodents, results in an enhancement of immune function, including elevated levels of inflammatory cytokines in the brain. Liraglutide is a GLP-1 receptor agonists known to exert neuroprotective effects in brain. The aim of this study was to elucidate if liraglutide given to food restricted (FR) pregnant rats may prevent the deleterious effects of FR in the hippocampal inflammatory status of male and female pups at 21 days of age (D21). 20 Sprague-Dawley pregnant rats were included. Controls (CT) were fed ad libitum, whereas dams in restricted group were fed with 50% (50FR) daily intake of control dams. Pregnant rats were treated with liraglutide (100 μg/kg per 12 h; 50FR/LIR, CT/LIR) or vehicle (50FR/VEH, CT/VEH) from gestational day 14 to 21. During lactation FR was increased to 30%. At D21 and before weaning, pups were sacrificed. The hippocampi were obtained and stored at −80 °C until analysis. mRNA expression levels of IL1β, IL6,NFKβ,IL 10 and Arginase1 in the hippocampus were assessed by RT-PCR. Immunohistochemistry analysis for Iba1 (marker of microglia) was performed in dentate gyrus (DG). The FR-mothers model promoted a proinflammatory state in the hippocampus just in male but not in female pups. 50FR male rats displayed increased mRNA expression of IL1β, IL6 and NFKβ compared to control males. LIR treatment decreased the expression of these cytokines and increased IL6 in control males. Furthermore, LIRA treatment increased the anti-inflammatory cytokine IL10 in 50FR male and CT female rats and the mRNA expression of the arginase1 (marker of microglia M2-like phenotype) in 50FR male rats. The number of IBA1 immunopositive cells were increased in the DG of 50FR males compared to controls, and were reduced by the treatment with LIRA. In conclusion, LIRA prevents the proinflammatory status induced by FR of the mother in male pups and enhanced anti-inflammatory markers.

Predictors of permanent, transient and three-phase postoperative diabetes insipidus

Daria Mikhaylova, Larisa Dzeranova, Ekaterina Pigarova, Ludmila Rozhinskaya, Andrey Grigoriev, Vilen Azizyan & Oksana Ivashenko
Endocrinology Research Centre, Moscow, Russia.

Objectives
To evaluate predictors of permanent, transient and three-phase diabetes insipidus (DI) in patients undergoing endoscopic endonasal transsphenoidal surgery.
Patients and methods
The study included 154 patients undergoing endoscopic endonasal transsphenoidal surgery (122 women and 32 men) age from 18 to 65 years (median 40 (31;52)). 73 patients with Cushing disease, 66 patients with acromegaly, four patients with prolactinomas, nine patients with non-functioning pituitary adenomas, one patient with thyrotropinoma, one patient with Nelson's syndrome and three patients with multihormonal secreting adenomas we examined. Patients were monitored for hormones, balance of fluids, serum electrolytes, plasma and urine osmolality.
Results
Postoperative permanent DI occurred in 27 patients, among them four as three-phased disturbances. Transient DI occurred in 42 patients, among them nine as three-phased disturbances. Onset arised on the 1th day–2nd month after surgery (median 1 day (1;5)) for the permanent DI's and on the 1th day–4th month for transient DI's (median 1 day (1;5)). Duration for transient DI was 1 day–1 year and 3 month (median 2 (1;30)), in 38% patients transient DI occurred as single polyuria-polydipsia episode. Adrenal insufficiency incrised risk of transient and three-phased DI development (RR 0.516 (0.287; 0.927), $P=0.02$, RR 0.056 (0.008; 0.42), $P=0.0003$, respectively), panhypopituitarism increased permanent DI onset risk (RR 0.264 (0.132; 0.53), $P=0.02$). Patients with corticotropinomas and somatotropinomas had higher risk of transient and three-phased DI (RR 0.212 (0.061; 0.734), $P=0.02$, RR 0.459 (0.311; 0.677), $P=0.04$, for corticotropinomas, respectively; RR 4.559 (1.049; 19.813), $P=0.03$, RR 1.977 (1.033; 3.783), $P=0.07$ for somatotropinomas, respectively). Macroadenoma also increased risk of transient and three-phased DI (RR 5.739 (1.32; 24.962), $P=0.01$, RR 2.593 (1.357; 4.955), $P=0.02$, respectively).
Conclusions
ACTH- and GH-secreting adenomas, macroadeomas and postoperative adrenal insufficiency can be considered as predictors of transient and three-phased diabetes insipidus. Panhypopituitarism can be considered as predictor of permanent diabetes insipidus.

The effect of chronic tianeptine administration on NLRP3 inflammasome pathway – study in an animal model of depression

Ewa Trojan, Anna Kurek, Katarzyna Chamera, Joanna Slusarczyk, Katarzyna Glombik & Agnieszka Basta-Kaim
Department of Experimental Neuroendocrinology, Institute of Pharmacology PAS, Cracow, Poland.

Introduction
Recently, the immune hypothesis of depression has gained a new dimension because of inflammasomes. NLRP3 inflammasome is a protein complex and its activation leads to stimulation of the enzyme caspase 1 responsible for generation of active form of pro-inflammatory cytokines: IL-1 β and IL-18. Recently postulated 'inflammasome theory of depression' assumes that depression is based on a disturbance of the mechanisms regulating NLRP3 complexes and uncontrolled synthesis of IL-1β.
Aim
The aim of present study was to examine whether prenatal stress influence the inflammasome NLRP3 system (subunits: NLR, ASC, protease caspase-1) in the frontal cortex and hippocampus of adult rats offspring. Furthermore the impact of chronic antidepressant drug – tianeptine administration on the above-mentioned parameters were evaluated.
Methods
Pregnant rats were subjected to restraint stress. At 3 months of age, control and prenatally stressed rats were tested for behavioural changes in forced swimming test. After that male offspring were administered i.p. for 14 days with tianeptine or vehicle. The animals' behaviour were tested again and rats were sacrificed. The protein level of all NLRP3 inflammasome subunits was determined by Western blot analyses.
Result
Prenatal stress procedure cause long-lasting behavioral alterations expressed as an increase in immobility and a decrease in swimming and climbing time measured in the forced swim test. Chronic treatment of tianeptine normalized all above-mentioned changes in prenatally stressed offspring. Prenatal stress procedure increased concentration of all NLRP3 subunits in frontal cortex. In hippocampus prenatal stress affected caspase-1 levels but had no effect on the other NLRP3 inflammasome subunits. Chronic tianeptine treatment attenuated all evoked by stress changes.
Conclusion
Prenatal stress procedure leads not only to persistent behavioral disturbances but also malfunction in brain NLRP3 inflammasone pathway. NLRP3 pathway can be indicate as an potential attractive target for antidepressant drug action.

Pituitary androgen receptor signalling is a novel negative regulator of prolactin production

Laura O'Hara, Paul Le Tissier & Lee Smith
University of Edinburgh, Edinburgh, UK.

The classical paradigm of lactotroph prolactin production and release is based around tonic inhibition by hypothalamic dopamine and stimulation by factors such as estrogen. We have recently shown that conditional ablation of pituitary androgen receptor (Foxg1-Cre ARKO) surprisingly does not change the concentration of circulating gonadotrophins but increases circulating prolactin

in male mice; highlighting androgen signalling as a novel negative regulator of prolactin production. We aimed to refine our knowledge of the site and mechanism of action of this control by performing further genetic, pharmacological and surgical experiments to ablate the production and/or action of prolactin and/or androgens. Male mice with a genetic ablation of AR in neurons (Nestin-Cre ARKO) do not have an increase in circulating prolactin, confirming that the increase in prolactin seen in the Foxg1-Cre ARKO mouse is not due to loss of hypothalamic AR, but specifically pituitary AR. However, Foxg1-Cre ARKO mice treated with the dopamine agonist bromocriptine show a decrease in circulating prolactin levels suggesting that the mechanism of prolactin increase originates with the hypothalamic dopamine system that normally controls prolactin. Male mice with postnatal AR ablation in ~50% lactotrophs (Prolactin-Cre ARKO) do not show an increase in circulating prolactin, suggesting that either the mechanism is not lactotroph-specific or that ablation of AR needs to occur earlier or in a greater number of lactotrophs to result in an increase in circulating prolactin. Mice castrated in adulthood do not show an increase in circulating prolactin which suggests that the control mechanism is not an acute response to changes in androgens but is programmed during the pre-adult development of the pituitary. Further experiments are currently being undertaken to ablate AR in other pituitary cell populations and at earlier time points with the aim of pinpointing the spatio-temporal mechanism of control of prolactin production by androgen receptor signalling.

Recent studies have reported a high prevalence of *USP8* mutations in corticotroph adenomas causing Cushing's disease. Nelson's syndrome is a potentially life-threatening complication of bilateral adrenalectomy in patients with refractory Cushing's disease that is caused by the development of an ACTH-secreting tumor in the pituitary gland. Whether *USP8* alterations are also present in Nelson's tumors has not been studied in detail so far.

Methods

We have screened for mutations in the exon 14 of *USP8* in tumors from 32 patients who were diagnosed with Nelson's syndrome (28 females, four males). Genomic DNA was extracted from fresh-frozen or FFPE adenomas. The presence of mutations was analyzed by Sanger sequencing. Mutational status was correlated to clinical data.

Results

In our cohort, 15/32 tumors presented a mutation in the exon 14 of *USP8*, a prevalence similar to that reported in Cushing's disease, with c.2159C>A (p.Pro720Gln) being the most frequent (8/32), followed by c.2155_2157delTCC (p.Ser718del, 4/32) and c.2152T>C (p.Ser718Pro, 3/32). Two *USP8* WT cases were categorized as atypical pituitary tumors and excluded from subsequent analyses. Mutations were found exclusively in females (15/27, 55%; vs 0/3 males). Other variables, such as age at diagnosis of Nelson's syndrome, BMI, hyperpigmentation, visual field defects, adenoma size or mortality did not significantly differ between patients with WT and mutant tumors. Regarding the hormonal status, patients with mutant tumors tended to exhibit higher levels of plasma ACTH at time of Nelson's diagnosis (median WT 1335 pg/ml vs mutant 1668 pg/ml; $P=0.098$; $n=25$) and significant changes after surgery (median 131 vs 639, $P=0.043$; $n=22$). Postoperative normalization of plasma ACTH was reached more frequently in patients with WT tumors (4/12, 33% vs 1/10, 10%) but without statistical significance ($P=0.323$). No differences were observed in tumor control after surgery.

Conclusion

Somatic mutations in the *USP8* gene are common in Nelson's syndrome and may be related to a more severe hormonal phenotype.

The association between olfaction and taste functions with serum ghrelin and leptin levels in obese women

Burçin Uygun[1], Sinem Kiyici[1], Suay Ozmen[2], Zulfiye Gul[3], Deniz Sigirli[4] & Sinan Cavun[3]
[1]University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Otorhinolaryngology, Bursa, Turkey; [3]Uludag University Medical Faculty, Department of Pharmacology, Bursa, Turkey; [4]Uludag University Medical Faculty, Department of Bio-statistics, Bursa, Turkey.

Aim

Olfaction and gustation have great importance on feeding behavior and food preferences. Recent published data suggests that olfaction and taste functions are modulated in response to changing levels of various molecules such as ghrelin and leptin which are play important roles on feeding and energy balance. We aimed to investigate the olfaction and taste functions in obese female patients and the association between serum ghrelin and leptin levels compared with healthy controls.

Methods

Fifty two obese women who have body mass index >30 kg/m^2 and 15 healthy women were included in to the study. After 8 h of fasting, blood samples were taken for serum biochemical parameters, ghrelin and leptin levels measurement. For the quantitative assessment of olfactory function, all participants underwent on N-butanol threshold test and odor identification test by using 12 Sniffin' Sticks ready-made fragrance sticks. The gustatory function was tested by administering a whole-mouth above-threshold test using sucrose solutions.

Results

The sucrose taste threshold score in obese women was significantly higher than the controls ($P=0.004$). N-butanol smell threshold was not significantly different between the two groups ($P=0.149$) while the Sniffin' Sticks smell test scores were significantly lower in obese women compared with the controls ($P=0.007$). Serum leptin levels were also significantly higher in obese women ($P<0.001$) although there was no significant difference in serum ghrelin levels between the two groups ($P=0.768$).

Conclusion

No significant association was observed between olfaction and taste functions and serum ghrelin levels of obese individuals. It was found that serum leptin levels were increased while taste and smell functions were decreased in obese women. These results might suggest that leptin, which is an anorexigenic peptide, may have a negative effect on taste and smell functions.

Sarcopenic obesity and associated factors in older adults with diabetes: the 2009–2010 Korean National Health and Nutrition Examination Survey

Jin Hwa Kim[1], Hee Jung Ahn[1], Tae Young Yang[2] & Sang Yong Kim[1]
[1]Chosun University Hospital, Gwangju, Republic of Korea; [2]Teayoung21 Hospital, Gwangju, Republic of Korea.

Objective

Sarcopenic obesity is a double burden for older people because it carries the cumulative risk of functional abnormality, metabolic, cardiovascular risk, and mortality compared to either sarcopenia or obesity alone. Diabetes is related to an increase in visceral adiposity and is associated with the risk of sarcopenia. The objective was to explore the association between sarcopenic obesity and diabetes and determine the associated factors with sarcopenic obesity in older people with diabetes.

Research design and methods

This study was based on data from the Korean National Health and Nutrition Examination Survey (KNHANES), conducted by the Korean Ministry of Health and Welfare, from 2009 to 2010. Out of 19,491 participants, the analysis included data for 3,206 older people. Multivariate logistic regression analyses were used to identify

independent associated factors with sarcopenic obesity. The complex sample analysis was used for the KNHANES data for weighting all values following the guidance of statistics form the Korea Centers for Disease Control and Prevention.
Results
The Prevalence of nonsarcopenic nonobesity, nonsarcopenic obesity, sarcopenic nonobesity, and sarcopenic obesity were 43.2, 7.7, 23.5 and 25.6%, respectively, in all subjects. The prevalence of sarcopenic obesity in older people with diabetes was significantly higher than those without diabetes (33.9% vs. 23.4%, P-value <0.001). Diabetes was an independent associated factor with sarcopenic obesity after fully adjusting for confounding factors, including chronic disease, sociodemographic influences, and lifestyle. Among the older people with diabetes, undiagnosed diabetes, diabetes duration with more than 10 years, elevated diastolic blood pressure, known hypertension, increased intake of protein, and number of comorbidity were independent associated factors with higher risk of sarcopenic obesity. History of stroke and increased vitamin D level were independently associated with a lower risk of sarcopenic obesity.
Conclusion
Diabetes influenced the risk of sarcopenic obesity in older people. Undiagnosed diabetes, diabetes duration with more than 10 years, elevated diastolic blood pressure, known hypertension, increased intake of protein, number of comorbidity, history of stroke, and vitamin D level were independently associated with sarcopenic obesity in older people with diabetes.

Resistance training reduces skeletal muscle inflammation even after 4-week detraining in obese rats

Patricia Seraphim[1], Marcelo Freitas[1], Marcos Teixeira[1], Giovana Teixeira[1], Maria Tereza Nunes[2] & José Carlos Camargo Filho[1]
[1]School of Sciences and Technology – Sao Paulo State University/UNESP, Presidente Prudente/SP, Brazil; [2]Institute of Biomedical Sciences – University of Sao Paulo, Sao Paulo/SP, Brazil.

The ingestion of high-fat diet has been considered a crucial factor in the genesis of subclinical systemic inflammation and insulin resistance. The resistance training (RTr) can be an effective tool for the prevention and treatment of immune-metabolic disorders through physiological and morphological adaptations. The purpose of the present study was to analyze the effects of RTr and cessation of training on muscle inflammation and expression of genes related to glucose metabolism in obese rats. Thirty male Wistar rats aged 2 months were subdivided into three groups: High-Fat Diet (DH), Trained High-fat Diet (DHT) and Detrained High-fat Diet (DHD). RTr was performed for 12 weeks (wk), 3×/wk, three sets of 12 repetitions per session. In the 8th wk, DHD group interrupted training for 4 wk. RT-PCR was performed to analyze genes code TNFα, AMPK, GLUT4 and MEF2A, and Western blotting was assayed to analyze the expression of TNFα in the soleus muscle. Additionally we analyzed the insulin sensitivity by ITT, and muscle fiber area by HE staining. The results showed that RTr (DH vs. DHT) caused increase of muscle fiber area ($P<0.05$), and insulin sensitivity by 34% ($P<0.05$), increased AMPK gene levels by 23% ($P<0.05$), GLUT4 by 24% ($P<0.05$) and MEF2A by 20% ($P<0.05$), and reduced protein and gene levels by 51 and 28% of TNFα ($P<0.05$), respectively. Detraining (DHD vs DHT) increased body weight ($P<0.05$), and provoked reduction of muscle fiber area ($P<0.05$). However, TNFα expression remained reduced even after cessation of training. We conclude that RTr exerts positive effects on reduction of the local inflammation, and improves the expression of genes related to glucose metabolism in the oxidative skeletal muscle. These adaptations are maintained even after 4-week detraining.

miR-26b is decreased in obesity and is associated with insulin resistance and visfatin levels

Mitra Nourbakhsh[1], Atieh Hosnieh Farahan[4], Farideh Yaghmaei[4], Saeedeh Moradgholi[4], Fatemeh Ahmadpour[1] & Maryam Razzaghy-Azar[2,3]
[1]Department of Biochemistry, Faculty of Medicine, Iran University of Meical Sciences, Tehran, Iran; [2]Metabolic Disorders Research Center, Endocrinology and Metabolism Molecular-Cellular Sciences Institute, Tehran University of Medical Sciences, Tehran, Iran; [3]H.Aliasghar Hospital, Iran University of Medical Sciences, Tehran, Iran; [4]Department of Biology, Science and Research Branch, Islamic Azad University, Tehran, Iran.

Obesity is one of the major causes of morbidity and mortality worldwide and is considered a risk factor for metabolic syndrome, type 2 diabetes and cardiovascular disease (CVD). miRNAs are epigenetic regulators of several aspects of metabolism and energy homeostasis and are involved in obesity and regulation of insulin sensitivity. miR 26b is among the obesity-related micoRNAs and is differentially expressed in preadipocytes and mature adipocytes in humans and is upregulated during adipocyte maturation. Visfatin which is implicated in insulin resistance and metabolic syndrome is a target of miR-26b. The aim of this study was to investigate the levels of miR-26b levels in obesity and its association with insulin resistance and metabolic parameters.
Methods
Seventy children and adolescents (35 controls; 35 obese), between the ages of 8 and 18 years, were selected and clinically evaluated. The expression of miR-26b was measured after microRNA extraction from plasma samples. The extracted microRNAs were elongated using poly A polymerase reaction followed by cDNA synthesis. Real-time PCR was performed using SYBR green and delta Ct was calculated by the formula: Ct (reference gene)-Ct (target gene). miR-16 was used as the reference gene. Insulin and visfatin levels were measured using ELISA, and insulin resistance was calculated by the homeostasis model of assessment of insulin resistance (HOMA-IR). Fasting plasma glucose, triglyceride, total cholesterol, LDL-C and HDL-C were also measured colorimetrically.
Results
miR-26b expression were significantly lower in obese subjects compared with control group and were also lower in subjects with insulin resistance compared to those without insulin resistance. miR-26b was significantly correlated with insulin levels and HOMA-IR. It also showed a significant negative correlation with visfatin which was higher in obese subjects compared with control subjects.
Conclusion
Decreased miR-26b expression in obese children and adolescents may be involved in insulin resistance and increased visfatin levels.

The effect of FTO polymorphism rs 9939609 on obesity and metabolic disturbances in Polish people from Lower Silesia

Aleksandra Zdrojowy-Welna[1], Katarzyna Kolackov[1], Katarzyna Zatonska[2], Malgorzata Tupikowska-Marzec[3], Marek Bolanowski[1] & Grazyna Bednarek-Tupikowska[1]
[1]Department of Endocrinology, Diabetology and Isotope Therapy, Wroclaw Medical University, Wroclaw, Poland; [2]Department of Social Medicine, Wroclaw Medical University, Wroclaw, Poland; [3]Department of Dermatology, Venerology and Allergology, Wroclaw Medical University, Wroclaw, Poland.

Background
The association between fat mass and obesity-associated gene (FTO) polymorphism rs 9939609 and obesity was found in some European countries. However, the data concerning Polish population is insufficient. The relationship between FTO and metabolic disorders remains unclear.
Methods
The study group consisted of 686 women and 418 men from Lower Silesia in Poland, aged 30–80 years (mean age 54.2±9.26 years). The examination included anthropometric measurements, blood pressure, lipid profile and fasting blood glucose analysis. The group was genotyped for *FTO* rs9939609 polymorphism.
Results
Mean BMI was 28.2±5.0 kg/m^2 and was slightly higher in men. Prevalence of obesity (BMI >30 kg/m^2) was around 31% with no sex differences. Minor allele frequency was 0.44. In whole study group, mean BMI was higher in risk allele carriers (AA, AT) than TT homozygotes (AA – 28.45 kg/m^2, AT – 28.41 kg/m^2 vs TT – 27.8 kg/m^2), but the difference was not statistically significant. The association between *FTO* polymorphism and obesity traits were stronger in men than in women (p-values, respectively: for body weight 0.0005 vs >0.1, for BMI <0.01 vs >0.1, for waist circumference 0.0005 vs >0.1 in co-dominant model). We did not observe any association between *FTO* polymorphism and dyslipidaemia, hypertension or higher blood glucose concentration.
Conclusions
FTO polymorphism is one of many factors influencing body mass in Polish population. The effect on other metabolic disturbances is not significant. The reasons why the association between *FTO* and obesity were more pronounced in men than women remain unclear. Probably age, degree of obesity or other hormonal factors modify the clinical presentation of genetic predisposition.

Role of Elovl6 in brown and beige adipose tissue during β3-adrenergic receptor activation

Rahul Sharma[1], Takashi Matsuzaka[1], Zao Hui[1], Hiroshi Ohno[1], Yoshinori Takeuchi[1], kaori Motomura[1], Naoya Yahagi[1], Motohiro Sekiya[1], Yoshimi Nakagawa[1], Masafumi Muratani[2] & Hitoshi Shimano[1]
[1]Department of Internal Medicine, Endocrinology and Metabolism, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan; [2]Department of Genome Biology, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan.

Anti-obesity therapeutics based on increasing the amount of brown fat have received more attention from industry as the biology and regulation of brown fat are better understood than that of beige fat. Cold exposure and treatment with β3 adrenergic receptor agonist are known to activate brown/beige adipose tissue. Many transcriptional pathways regulating brown/beige adipose tissue have been identified, the role of lipid biosynthetic enzymes in brown/beige adipose tissue has been less investigated. In this study, we investigated the role of Elovl6, the enzyme responsible for converting C16 non-essential fatty acids (FAs) into C18 species, in brown/beige adipose tissue. We have observed upregulation of Elovl3, 4, 6 and 7 in BAT and inguinal WAT of mice treated with β3-adrenergic receptor agonist CL-316243 as well as cold-expose. These elongases are responsible for the conversion of C16 FAs into C30 saturated FAs, indicating the relevance of very long chain FAs in the activation process of brown/beige adipose tissue. It was reported that Elovl6 KO mice have impaired mitochondrial function and hence impaired thermogenic capacity of BAT when exposed to cold temperature (Cell Rep. 13:2039, 2015). When exposed to chronic CL-316243 treatment we observed that Elovl6 KO mice compensate its impaired BAT function by increased development of functional beige fat contributing to its increased energy expenditure. Interestingly, these metabolic changes are appearing to be mediated by increased type-2 cytokine signalling and macrophage polarization in the inguinal WAT of Elovl6 KO mice, as per our preliminary results. We have observed increased expressions of markers for cell proliferation (Ki67), macrophage (F4/80, CD68, Itgax-1, Arg-1, Clec-10) in the beige fat of Elovl6 KO mice compared to WT mice stimulated with CL-316243. These results suggest that Elovl6-regulated FA chain length is important for beiging and M2 macrophages are playing a mediator role in beige adipogenesis.

A link between sex hormones, obesity and gut microbiota

Gabriela Martínez-Chacón[1,2], Eveliina Munukka[2], Himanshu Kumar[1], Sami Pietilä[4,5], Niina Saarinen[2,3], Raine Toivonen[2], Seppo Salminen[1], Arno Hänninen[2], Leena Strauss[2,3] & Sari Mäkelä[1,2]
[1]Functional Foods Forum, University of Turku, Turku, Finland; [2]Institute of Biomedicine, University of Turku, Turku, Finland; [3]Turku Center for Disease Modeling, Univesity of Turku, Turku, Finland; [4]Turku Centre for Biotechnology, University of Turku, Turku, Finland; [5]Åbo Akademi, Turku, Finland.

Sex steroids are involved in the development of obesity and metabolic disorders. The interrelationship between sex steroid balance and metabolism is complex, and the underlying mechanisms are still unclear. The impact of gut microbiota in development of obesity, inflammation and metabolic dysregulation has been suggested in humans and demonstrated in mouse models. Less is known about the interactions between sex steroids and gut microbiota. Based on available evidence, it is, however, pertinent to ask if sex steroids participate in the regulation of the composition or function of gut microbiota, or if gut microbes regulate sex steroid balance. The aim of the present study was to define the interplay between sex steroid balance and gut microbiota, in the context of obesity and metabolic dysregulation. First, we showed that non-obese human aromatase expressing (AROM+) male mice, with increased circulating estradiol to testosterone ratio and impaired liver lipid metabolism, have a female-type intestinal microbiota and higher ratio of *Firmicutes* to *Bacteroidetes*. Treatment with aromatase inhibitor restored estradiol/testosterone levels, followed by a slight improvement in their microbiota ecology. Second, in a mouse model reporting the expression of human aromatase (*CYP19A1*) gene (hARO-Luc mouse), ovariectomy-induced obesity, accompanied with elevated *Firmicutes* to *Bacteroidetes* ratio, altered gut homeostasis and increased aromatase reporter gene expression in the mammary adipose tissue. In conclusion, by applying two gene-modified mouse models, we showed that changes in sex steroid balance are linked to altered gut microbiota composition, and on the other hand, sex steroid – related obesity is linked to increased expression of human aromatase gene reporter. Further experiments, such as fecal transplantation from mice with altered sex steroid balance to WT mice, are needed to confirm the causality between sex steroids, gut microbiota and metabolic disorders.

Effects of short sleep duration on energy metabolism and energy balance in subjects with overweight and obesity

Eleonora Poggiogalle, Lorenzo Donini, Lucio Gnessi, Stefania Mariani, Marianna Calabretto, Federica Luisi, Andrea Lenzi & Carla Lubrano

Introduction
The chronic reduction of sleep duration is associated to an increased risk of weight gain, but mechanistic aspects remain to be fully elucidated. The aim of our study was to examine the relationship between short sleep duration and energy metabolism, fuel selection and energy balance in overweight and obesity. Methods: Inclusion criteria were: age 18–65 years, BMI $\geq$25 kg/m^2. Use of any CNS medications, any psychiatric disorders and night shift work were considered as exclusion criteria. Body composition was evaluated by DXA. All participants underwent indirect calorimetry. The respiratory quotient (RQ) was calculated from gas exchanges. The equations by Weir and by Frayn were used to calculate the resting energy expenditure (REE), and carbohydrate and fat oxidation, respectively. Sleep duration, total daily energy expenditure (TDEE) and the level of physical activity (METs/day) were objectively assessed (Sensewear Armband). A 3-day dietary record was administered. Participants were divided into two groups, "regular sleep" (RS): >300 min/day or "short sleep"(SS): $\leq$300 min/day. Results: 88 women and 30 men were included (age:49.6$\pm$12.1 years), of whom 30.5% exhibited a short sleep duration. BMI (39.7$\pm$7.1 vs. 36.2$\pm$5.0 kg/m^2, $P=0.03$) and truncal body fat (18.7$\pm$6.2 vs. 16.1$\pm$4.6 kg, $P=0.04$) were higher in the SS group than the RS group. Subjects with short sleep had a lower RQ (0.71$\pm$0.12 vs. 0.76$\pm$0.12, $P=0.004$) and oxidized more fat (113$\pm$55 vs. 95$\pm$56 g/min, $P=0.006$) than regular sleepers. The METs/day were higher in the SS group compared to the RS group (1.56$\pm$0.55 vs. 1.35$\pm$1.24, $P=0.04$). RQ was positively associated to sleep duration ($P=0.04$, adj. for age, sex, and body fat). No difference emerged in TDEE or energy intake (SS group: 23$\pm$10 vs. RS group: 25$\pm$6 kcal/kg/day, $P>0.05$).
Conclusion
Short sleep affects energy substrate metabolism and adiposity distribution in overweight and obese subjects.

Blood mercury concentration in relation to overweight or obese among Korean children and adolescents: KNHANES 2009–2013

Kyung Hee Park[1] & Jeong-Hyeon Kim[2]
[1]Hallym University Sacred Heart Hospital, Anyang, Republic of Korea; [2]Chuncheon Sacred Heart Hospital, Chuncheon, Republic of Korea.

Background
Harmful effects of mercury on cardiovascular disease have been suggested in many epidemiologic studies. However, reports on harmful effect of mercury in relation to overweight or obesity have shown inconsistent findings.
Methods
A total of 1577 children and adolescents (10–18 years of age) from the Korean National Health and Nutrition Examination Survey (KNHANES) 2009–2013. Overweight or obese group was defined as over the 85th percentile of the age- and sex-specific BMI norms or BMI over 25. Subjects were categorized into three groups by age and gender specific blood cadmium, lead, and mercury concentration. Multivariate logistic regression stratified by gender was performed to estimate the odd ratio (OR) and 95% confidence interval (CI) for investigate the association.
Results
Compared to non-obese group, blood mercury concentration of was higher in obese group. Blood levels of cadmium and lead were not significantly different according to obese status. After adjustment for confounders, subjects in the highest tertile group of blood mercury levels were more likely to have overweight or obesity (OR 2.65, 95%CI 1.13–6.26) compared to subjects in the lowest tertile group in girls. No significant association was found in boys.
Conclusions
Blood mercury concentration is positively associated with overweight or obesity among Korean children and adolescents. Further longitudinal studies will be needed to confirm the causality.

Association of the FTO gene rs9939609 polymorphism with obesity in the Republic of Tatarstan

Kamilya Khasanova[1], Tatyana Kiseleva[1], Sabina Bogdanova[1], Elena Valeeva[1], Svetlana Gubaidullina[2], Ildus Ahmetov[1] & Farida Valeeva[1]
[1]Kazan State Medical University, Kazan/Republic of Tatarstan, Russia; [2]Volga Region Academy of Physical Culture, Sport and Tourism, Kazan/Republic of Tatarstan, Russia.

Aim
To investigate the possible association of the rs9939609 polymorphism in the FTO gene with obesity in the Republic of Tatarstan (RT).
Materials and methods
The study involved 63 adult patients (21 men and 42 women; 38–77 years old) with overweight or obesity and 515 healthy young people (157 men and 358 women; 16–35 years old) with normal weight. We assessed clinical and biochemical parameters (blood lipid profile). The analysis of the rs9939609 T/A polymorphism of the FTO gene in buccal cells was performed using Sintol kits (Russia) for RT-PCR. All the patients were tested by bioelectrical impedance analysis.
Results
The distribution of genotypes of the FTO gene polymorphism (TT – 11%, TA – 65% AA – 24%) and alleles (T – 44% A – 56%) in the group of patients with overweight and obesity was significantly different from those of the control group (TT – 42,9%, TA – 45,4%, AA – 11,7%; T – 65,6%, A – 34,4%; OR = 2.43, $P < 0.0001$), confirming that the A allele is a risk factor for obesity. In the group of obese patients we found an additive effect of the A allele on the increase of the average waist-hip ratio (lowest value in TT carriers, maximum value in AA carriers). We found that the number of patients with arterial hypertension and dyslipidemia was higher in the group with AA and TA genotypes compared with group with TT genotype.
Conclusion
We found a significant association of the T/A polymorphism of the FTO gene with the obesity. Obese patients with the risk allele of the rs9939609 FTO gene polymorphism have significantly higher values of absolute and relative body fat mass and BMI, total cholesterol, low-density lipoprotein, and triglycerides.

Effect of bariatric surgery on sexual function and sex hormone levels in obese patients: a meta-analysis

Junping Wen[1,2], Lingying Wen[2], Wei Lin[1,2], Liantao Li[1,2], Jixing Liang[1,2], Huibin Huang[1,2] & Gang Chen[1,2]
[1]Fujian Provincial Hospital, Fuzhou, China; [2]Fujian Medical University, Fuzhou, China.

Objective
The aim of this meta-analysis is to evaluate the effect of bariatric surgery on sexual function and sex hormone levels in obese patients.
Methods
Two independent investigators conducted a literature search of PubMed, Medline and Cochrane databases using the terms *bariatric surgery*, *sexual function and sex hormone* to identify appropriate human studies published in English about the effect of bariatric surgery on sexual function and sex hormone levels in obese patients. The search was restricted to data from January 1, 1990 to December 1, 2016. Bibliographies of recent review articles and systematic reviews were searched to identify any additional trials. Two investigators according to the inclusion and exclusion criteria independently select literature, extract data and evaluate quality, then using RevMan 5.3.5 software for Meta analysis.
Results
In all, 31 studies met all criteria, including 1150 patients. The types of bariatric surgery performed included laparoscopic Roux-en-Y gastric bypass, laparoscopic gastric banding surgery, laparoscopic adjustable gastric banding, laparoscopic sleeve gastrectomy, Roux-en-Y gastric bypass, sleeve gastrectomy, adjustable gastric banding, vertical gastric banding, biliopancreatic diversion. The time to follow-up after surgery varied from 1 months to 115 months. Of the 31 studies, 5 reported the IIEF in obese men in 154 of 1150 patients (MD = 4.84, 95%CI (2.92, 6.75), $P < 0.00001$); 7 studies reported the FSFI in obese women in 369 of 1150 patients (MD = 4.10, 95%CI (−0.28, 8.48), $P = 0.07$). The changes of sex hormone levels in obese male patients before and after bariatric surgery as following: total testosterone (MD = 8.55, 95%CI (6.59, 10.52), $P < 0.00001$); free testosterone (MD = 6.52, 95%CI (3.09, 9.94), $P = 0.0002$); estradiol (MD = −7.03, 95%CI (−11.05, −3.01), $P = 0.0006$); luteinizing hormone (MD = 0.92, 95%CI (0.64, 1.20), $P < 0.00001$); follicle-stimulating hormone (MD = 1.29, 95%CI (0.65, 1.94), $P < 0.0001$); sex hormone-binding globulin (MD = 23.85, 95%CI (18.44, 29.26), $P < 0.00001$). The changes of sex hormone levels in obese female patients before and after bariatric surgery as following: total testosterone (MD = −0.78, 95%CI (−0.84, −0.71), $P < 0.00001$); free testosterone (MD = −5.53, 95%CI (−10.47, −0.59), $P = 0.03$); estradiol (MD = −25.10, 95%CI (−36.92, −13.27), $P < 0.0001$); luteinizing hormone (MD = 4.50, 95%CI (−1.04, 10.05), $P = 0.11$); follicle-stimulating hormone (MD = 1.68, 95%CI (0.50, 2.86), $P = 0.005$); sex hormone-binding globulin (MD = 34.79, 95%CI (22.63, 46.96), $P < 0.00001$).
Conclusion
This meta-analysis indicates that bariatric surgery has a significant improvement on the sexual function in both genders.

Lipolytic effects of endogenous 3-iodothyronamine (T1AM) and synthetic analog SG-2 *in vivo* and in cultured adipocytes

Martina Sabatini[1], Michael P Rogowski[2], Ebru S Selen Alpergin[3], Fariba Assadi-Porter[3], Riccardo Zucchi[1] & Grazia Chiellini[1]
[1]Department of Pathology, University of Pisa, Pisa, Italy; [2]UAB School of Medicine-Cardiovascular Disease, Birmingham, AL, USA; [3]Department of Zoology, University of Wisconsin-Madison, Madison, WI, USA.

3-Iodothyronamine (T1AM) is a hormone like molecule structurally similar to TH, that has been reported to modulate energy metabolism by favoring lipid over glucose catabolism. To better understand the role played by T1AM on the regulation of lipid metabolism, in the present study we administered spontaneously obese mice with T1AM at two different dosages (10 and 25 mg/kg per day) for 7 days and the effects on body weight (BW) and lipid profiles were examined. In addition a fluoro-labeled version of T1AM (FL-T1AM) was synthesized and utilized to assess T1AM intracellular localization in 3T3-L1 mouse adipocytes.
Administration of 10 or 25 mg/kg per day T1AM showed a BW loss of 10% or 18% of initial BW by day 7 of treatment. T1AM treatment at both dosages produced a significant increase in total plasma triglycerides ($P < 0.05$) and a significant decrease in plasma cholesterol ($P < 0.05$), without any significant change in glycaemia. At present, the specific mechanism of T1AM entry into the cell, as well as its internal targets remains unknown. Cellular imaging revealed rapid intercellular uptake of FL-T1AM without localization to the lipid droplet or nucleus of mature adipocytes. This rapid rate of uptake was further evaluated via flow cytometry, with peak detection of FL-T1AM steadily rising until reaching peak signal and equilibrium at ∼20 min. We also observed that when 3T3-L1 adipocytes were treated with T1AM or its synthetic halogen free analog SG-2 (1–10 μM), both compounds decreased lipid accumulation in mature adipocytes, with SG-2 showing a potency significantly higher than T1AM ($IC50_{SG\text{-}2} = 5$ μM; $IC50_{T1AM} = 20$ μM).
In conclusion T1AM and its synthetic analog show a significant lipolytic activity, both in cultured adipocytes and *in vivo*.

A comparison of single-dose effects of short acting somatostatin analogs: octreotide vs pasireotide in patients with active acromegaly after surgical debulking

Agnieszka Majos, Maria Stelmachowska-Banas, Izabella Czajka-Oraniec & Wojciech Zgliczynski
Department of Endocrinology, Centre of Postgraduate Medical Education, Bielanski Hospital, Warsaw, Poland.

Acromegaly is a rare endocrine disorder caused by growth hormone (GH) secreting pituitary adenoma. The treatment of choice is transsphenoidal surgery. In patients with persistent disease after surgery medical therapy is recommended.

First-line medical treatment include first generation long-acting somatostatin analogs: octreotide LAR and lanreotide autogel. Recently, pasireotide – a second generation somatostatin analog has been investigated in patients with acromegaly. The aim of this study was to compare the effectiveness of the single-dose of short-acting somatostatin analogs: octreotide vs pasireotide in patients with active acromegaly after surgical debulking who were resistant to first generation long-acting somatostatin analogs.

Eighteen patients after debulking surgery without biochemical control of acromegaly on medical therapy were enrolled in the study. All patients had short-acting octreotide and pasireotide administered on different days. GH concentration was measured before and 60, 120 and 180 min after drug administration. Nadir GH concentrations and decreases in GH concentrations were compared.

Nadir GH values in octreotide test were reached 60 min after drug administration, while in pasireotide test – 180 min after drug administration. The median nadir GH concentration was 2.765 μg/l (IQR: 1,885–4.07) vs 1.51 μg/l (IQR: 0.95–2.555) respectively, $P<0.001$. The decrease in GH concentration was more significant after pasireotide administration compared to octreotide administration ($P<0.001$). The median decrease in GH concentration in octreotide test was 1.255 μg/l (IQR: 0.918–1.75) vs 2.805 μg/l (IQR: 1.523–5.043) after pasireotide administration. Octreotide was generally better tolerated than pasireotide.

Short-acting pasireotide is more effective than short-acting octreotide in GH supression in patients with uncontrolled acromegaly. Pasireotide may be a promising alternative for patients resistant to first-generation somatostatin analogs.

GP174

Efficacy and safety of switching to pasireotide LAR alone or in combination with pegvisomant in acromegaly patients controlled with combination treatment of first-generation somatostatin analogues and weekly pegvisomant (PAPE study): a prospective open-label 48 week study, preliminary results 24 weeks

Ammar Muhammad, Aart Jan van der Lely, Joop Janssen & Sebastian Neggers
Erasmus MC, Rotterdam, The Netherlands.

Background

Efficacy and safety of combination treatment of pasireotide LAR with pegvisomant (PEGV) has not been studied yet. Switching to Pasireotide LAR in patients previously controlled with long-acting somatostatin analogues (LA-SSAs) and PEGV could reduce the required PEGV dose to normalize serum IGF1 levels, while the effect on glucose metabolism is unknown.

Methods

We enrolled 60 acromegaly patients >18 years with acromegaly who had normal IGF1 levels ($\leq 1.2\times$Upper Limit of Normal (ULN)) using combination treatment of high dose LA-SSAs and weekly PEGV for ≥ 6 months. After enrollment LA-SSA treatment was continued, and the PEGV dose was reduced by 50% for 12 weeks. If IGF1 levels remained normal after 12 weeks, patients were switched to pasireotide LAR 60 mg monotherapy, every 4 weeks. If IGF1 levels $>1.2\times$ULN patients were switched to pasireotide LAR 60 mg and continued with the 50% reduced PEGV dose. The primary endpoint was the percentage of patients achieving normal IGF1 levels at 24 weeks. The key secondary endpoint was the frequency diabetes at 24 weeks.

Results

At baseline, median IGF1 was $0.94\times$ULN with a median PEGV dose of 80 mg/week, and 30.6% of patients had pre-existing diabetes. After the 50% dose reduction of PEGV, median IGF1 levels increased to 1.43 ULN, while IGF1 remained normal in 33% of patients. At 24 weeks, 73% of patients achieved normal IGF1 levels with a median IGF1 $0.98\times$ULN. Cumulative PEGV dose reduction between baseline and 24 weeks was 66%. At 24 weeks, IGF1 levels were normal in 88% of patients on pasireotide LAR monotherapy, and 68% of patients on combination treatment. Pasireotide LAR was well tolerated. At 24 weeks, the most common adverse event was diabetes which occurred in 70.2% of patients. Two patients withdrew prematurely due to hyperglycemia requiring insulin treatment.

Conclusion

Pasireotide LAR alone or in combination with pegvisomant controls IGF1 in 73% of patients after 66% reduction in cumulative dose of weekly pegvisomant. The frequency of diabetes was 70.2% and is in line with previous studies.

Resistance to somatostatin analogues is associated with GSTP1 gene methylation and AHR rs2066853 variant in acromegaly patients

Francesco Ferraù[1], Petronilla Daniela Romeo[1], Soraya Puglisi[1], Marta Ragonese[1], Federica Spagnolo[1], Riccardo Ientile[2], Isa Anna Maria Picerno[2], Monica Currò[2], Giuseppa Visalli[2], Angela Alibrandi[3] & Salvatore Cannavò[4]
[1]Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [2]Department of Biomedical Sciences, Dental Sciences and Morpho-functional Imaging, Messina, Italy; [3]Department of Economics, Messina, Italy; [4]Department of Human Pathology of Adulthood and Childhood, Messina, Italy.

Evidences suggest that environmental contaminants exposure and/or the impairment of intracellular xenobiotic metabolizing system could affect pituitary pathophysiology. Glutathione-S-transferase-P1 (GSTP1) gene encodes for an enzyme that is involved in cellular detoxification mechanisms. GSTP1 altered activity or expression has been reported in some tumours.

We aimed to assess the GSTP1 gene promoter methylation status in acromegaly patients and its contribution to their clinical features.

Seventy-seven WT AIP gene acromegaly patients (50 women) have been screened for germline AHR rs2066853 variant and GSTP1 promoter methylation. Epidemiologic, clinical, biochemical and radiological parameters at diagnosis have been compared after patients' stratification according to GSTP1 methylation status and the presence of AHR rs2066853 variant. We also evaluated the response to somatostatin analogues (SSA) administered either before or after surgery in 71 cases.

Seventeen patients were found to carry AHR rs2066853 variant and 26 methylated GSTP1 (GSTP1met). GSTP1met patients showed a higher prevalence of diabetes mellitus ($P=0.01$), colonic polyps ($P=0.05$), and were more resistant to SSA ($P=0.02$) as compared to GSTP1 unmethylated patients (GSTP1unmet).

On the basis of GSTP1 methylation status and the presence of AHR rs2066853 variant, we identified four groups: group 1, 40 patients GSTP1unmet and AHR WT; group 2, 20 patients only GSTP1met; group 3, 12 patients carrying only AHR rs2066853 variant; group 4, five patients with both GSTP1 methylation and AHR rs2066853 variant. Group 1 patients were more sensitive to SSA than other groups ($P=0.02$). Patients of group 4 were more resistant to SSA ($P=0.02$) and showed higher GH ($P=0.03$) and IGF1 ($P=0.04$) levels and lower percentage of GH decrease ($P=0.04$) after SSA than other groups.

In conclusion, GSTP1 methylation and AHR rs2066853 variant associate with resistance to SSA in acromegaly patients.

Minimally Invasive Diagnosis and Direct Transnasal Surgery: a single centre series of 100 children with Cushing's Disease with long term follow-up

Patricia Crock[1,2], Dieter K Lüdecke[3], Ulrich Knappe[4], Joerg Flitsch[3] & Wolfgang Saeger[5]
[1]Paediatric Endocrinology, John Hunter Children's Hospital, Newcastle, NSW, Australia; [2]University of Newcastle, Newcastle, NSW, Australia; [3]Department Neurosurgery, University Hospital Eppendorf, Hamburg, Germany; [4]Neurosurgical Clinic, Minden, Germany; [5]Department Neuropathology, University Clinic Eppendorf, Hamburg, Germany.

Introduction

Trans-sphenoidal surgery (TSS) with minimally invasive techniques is the first choice in the treatment of paediatric Cushing's disease (CD). The question is how can high remission rates be achieved with less invasive investigations and TSS. The developments in our centre treating 100 pediatric Cushing patients with long-term follow-up may add some helpful ideas.

Material and methods

Data from our first series 1 ($n=55$) will be compared with new data from the recent series 2 ($n=45$) until 2009. All patients were operated by one surgeon by direct transnasal microsurgery (TNS). Special diagnostic methods such as inferior petrosal sinus sampling (IPSS) were replaced by ACTH measurement from the cavernous sinus (CSS) restricted to unclear cases without increase of salivary cortisol in the CRH-test, difficult sella anatomy and/or negative MRI. Multiple direct micro-cytology, micro-doppler and adequate visualization will be described.

Results

In our first series of 55 cases, IPSS was performed in 13 (24%) of whom 46% had false adenoma lateralization. All adenomas could be removed with extensive pituitary exploration and all had intraoperative pathology. Two patients had early successful re-surgery. Recurrence rate 15%. In the second series with more

refined MRI and endocrinology: easy repeat CRH saliva tests and CSS sampling used in only 7 patients (15%), all micro-adenomas were initially detected. Early repeat-TNS was necessary and successful in three. Recurrence rate 11%. Side effects of TNS were minimal, as such, children and parents readily accepted re-TNS. Thus, including re-TNS in recurrences, 98 of 100 patients had long-term remission. TNS in recurrences had a better outcome in the last series with less pituitary dysfunction using more intraoperative minute biopsies.
Conclusions
Invasive pre-surgical investigations could be reduced. 98% remission rate could be achieved with advanced investigations, refined TNS, early re-TNS and re-TNS in recurrences. Only two children (2%) were irradiated – only one was indicated by the senior surgeon.

Octreotide subcutaneous (s.c.) depot, a novel ready-to-use formulation, provides higher exposure and maintains response in patients with acromegaly and functioning neuroendocrine tumours (NETs) previously treated with long-acting octreotide: Results from a phase 2, open-label, multicentre, randomized study

Diego Ferone[1], Françoise Borson-Chazot[2], Anne Cailleux[3], Dieter Hörsch[4], Harald lahner[5], Rosario Pivonello[6], Libuse Tauchmanova[7], Christelle Darstein[7], Håkan Olsson[8], Fredrik Tiberg[8,9] & Marianne Pavel[10]

Innere Medizin, Essen, Germany; [6]Dipartimento di Medicina Clinica e Chirurgia, Università Federico II di Napoli, Naples, Italy; [7]Novartis Pharma AG, Basel, Switzerland; [8]Camurus AB, Lund, Sweden; [9]Physical Chemistry, Lund University, Lund, Sweden; [10]Charité Universitätsmedizin Berlin, Campus Virchow-Klinikum, Berlin, Germany.

Background
Octreotide s.c. depot is a novel, ready-to-use formulation administered via a thin needle, which may allow self-administration. In a phase 1 study in healthy volunteers, octreotide s.c. depot provided greater bioavailability with faster onset and greater IGF1 suppression than long-acting octreotide. Here, we present data from a phase 2 study evaluating pharmacokinetics (PK), efficacy, safety, and tolerability of octreotide s.c. depot in patients with acromegaly and neuroendocrine tumours (NETs).
Methods
Adult patients with acromegaly or functioning, well-differentiated NETs treated with long-acting octreotide 10 mg/20 mg/30 mg every 4 weeks (q4w) for $\geq$2 months received the last dose of long-acting octreotide in period 0 (P0). Patients were randomized 28 days later to receive octreotide s.c. depot 10 mg q2w or 20 mg q4w for 3 months (period 1 [P1]).
Results
Twelve patients were randomized to receive octreotide s.c. depot 10 mg q2w (acromegaly, n=3; NET, n=1) or 20 mg q4w (acromegaly, n=4; NET, n=4). Acromegaly: steady state (SS) PK (for octreotide s.c. depot 10 mg, 20 mg vs long-acting octreotide 10 mg, 30 mg, respectively) – $AUC_{0\text{-}28d}$(day*ng/l): 95.6, 78.5 vs 6.23, 24.1; C_{max}(ng/ml): 10.6, 11.3 vs 0.35, 1.41. NETs: SS PK (for octreotide s.c. depot 10 mg, 20 mg vs long-acting octreotide 20 mg, 30 mg, respectively) – $AUC_{0\text{-}28d}$(day*ng/l): 83.3, 135.0 vs 27.8, 39.9; C_{max}(ng/ml): 5.61, 15.7 vs 1.68, 2.48. In acromegaly, control of IGF-1 and GH levels was maintained or improved in P1 vs P0. In NETs, symptoms of carcinoid syndrome were similar or improved in P1 vs P0; symptoms disappeared in two patients in 20 mg group. Adverse events (all grade 1-2) were reported in six and eight patients during P0 and P1, respectively; most common in P1 were GI disorders.
Conclusions
Octreotide s.c. depot provided higher exposure than long-acting octreotide, maintained biochemical control in patients with acromegaly and symptom control in patients with functioning NETs, and was well tolerated with a safety profile consistent with long-acting octreotide.

Sleep patterns in patients with non-functional GHRH receptor

Francielle T Oliveira[1], Roberto Salvatori[2], José Marcondes[3], Larissa B Macena[1], Alecia A Oliveira-Santos[1], Augusto C N Faro[1], Viviane C Campos[1], Carla R P Oliveira[1], Ursula M M Costa[1] & Manuel H Aguiar-Oliveira[1]
[1]Federal University of Sergipe, Aracaju/Sergipe, Brazil; [2]The Johns Hopkins University School of Medicine, Baltimore, MD, USA; [3]Instituto do Sono e Medicina Integrada, Aracaju/Sergipe, Brazil.

Hypothalamic GH releasing hormone (GHRH) has hypnotic actions by increasing slow wave sleep (SWS) (non-rapid eye movement sleep, non-REM), which account for about 75% of sleep. Conversely, GH may stimulate the rapid eye movement sleep (REM). Patients with GH deficiency (GHD) often exhibit sleep problems leading to daytime fatigue and reduced quality of life (QoL). We have described a cohort of patients with isolated GHD (IGHD) due to GHRH resistance caused by a homozygous null mutation (c.57+1G>A) in the GHRH receptor gene. They have normal QoL and no obvious complaints of chronic tiredness. The aim of this study was to determine objectively and subjectively the sleep quality in these subjects, who have never received GH therapy. A cross sectional study was carried out on 21 adult IGHD subjects, and 21 matched controls. Objective sleep assessment included polygraphic records of the stages wake (W), non-REM: N1 (drowsiness), N2 and N3 (already sleeping) and R (REM). Subjective evaluation included the Pittsburgh Sleep Quality Index, Insomnia Severity Index, and Epworth Sleepiness Scale. Compared to controls, IGHD subjects exhibited lower sleep efficiency (77.7 (27.5) vs 87.5 (10.1) %, $P=0.007$), total sleep time (330.0 (127.5) vs 385.5 (56.0) min, $P=0.028$) and higher percentage of the non-REM 1 stage (14.6 (18.9) vs 7.3 (8.1) %, $P=0.022$). There was no difference between the groups in REM sleep and in quality questionnaires. These data show an extension of the drowsiness period, with a reduction in the total sleep time, suggesting a preponderant role of GHRH resistance over GHD in the sleep quality of these IGHD subjects. The objective reduction in the sleep efficiency and total sleep time seem have minimal subjective consequences, as it was not reflected in differences of quality sleep questionnaires.

Correction of sustained hyponatremia secondary to SIAD by the use of chronic tolvaptan therapy is associated with a reduction in Emergency Room visits, hospital admissions and days of hospitalization over a 3-year period

Martín Cuesta Hernández[1], Irene Crespo Hernández[1], Pablo Amich Alemany[1], Emilia Gómez Hoyos[2], Nancy Sánchez Gómez[3], Alejandro Santiago[1], Paz De Miguel Novoa[1], Alfonso Luis Calle-Pascual[1] & Isabelle Runkle de la Vega[1]
[1]Hospital Universitario Clínico San Carlos, Madrid, Spain; [2]Hospital Universitario Clínico Universitario de Valladolid, Valladolid, Spain; [3]Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain.

Introduction
Hyponatremia (HN) is associated with worse clinical outcomes, and longer hospital lengths-of-stay than seen in eunatremic patients. The Syndrome of Inappropriate Antidiuresis (SIAD) is the most common cause of hyponatremia in hospitalization. We studied the relationship between correction of sustained SIAD-induced hyponatremia and visits to the Emergency Room (ERv) as well as hospital admissions (HA) in a case series.
Methods
Retrospective, cross-sectional study of patients whose HN was corrected with chronic tolvaptan therapy (CTV) for a minimum of 3 years. Serum Sodium levels(SNa) in mmol/l. Descriptive statistics expressed as median (IQR). SPSS 15, non-parametric tests (Wilcoxon for paired data), univariate analysis.
Results
16/25(64%) patients fulfilled inclusion criteria. Nine patients not completing 1 year of follow-up were excluded. Median age: 82 (74–87). Women: 11/16(69%) . HN was first detected a median of 51 months (IQR 29–56) prior to initiation of therapy. SIAD etiology: 9/16(56%) idiopathic, 3/16 (19%) drug-induced (19%), 2/16 (3%) respiratory, 1/16 (6%) abdominal, 1/16 (6%) cancer. The year before HN correction, Nadir SNa:120(115–125) mmol/l, with a median of 2(1–4) ERv/patient, HA:1(1–2) with 18(10–32) days of hospitalization (DH). During year 1 of CTV, Nadir SNa rose to 136(133–137) mmol/l ($P=0.001$), ERv dropped to 1(0-3)($P=0.03$), HA to 0(0-0)($P=0.003$), DH to 0(0,0)($P<0.001$). The benefits were sustained when comparing the second and third years to the year prior to HN correction. Second year: ERv: 0(0-1)($P=0.004$), HA: 0(0-1)($P=0.001$), DH: 0(0-1)($P<0.001$). Third year: ERv: 1(0-2)($P=0.05$), HA: 0(0-1)($P=0.009$), DH:

0(0-4)($P=0.01$). Three years before start of therapy vs 3 years post: Total median ERv/patient: 3(1-5), HA: 2(1-4), DH 18(10-34) vs total ERv: 2(1-4) ($P=0.03$), HA: 1(0-2)($P=0.006$), DH 0(0-4)($P=0.006$). No patient developed hypernatremia. Tolvaptan doses were lowered if thirst developed or SNa reached 141 mmol/l. Final weekly TV dose was 34 mg (23–105).
Conclusions
Correction of sustained hyponatremia secondary to SIADH with chronic TV therapy was safe, and associated with a significant and sustained reduction in ER visits, hospital admissions, and days of hospitalization.

Outcome of non-functioning pituitary adenomas that regrow after primary treatment: a study from two large specialist UK centers

Metaxia Tampourlou[1,2], Georgia Ntali[3], Shahzada Ahmed[4], Wiebke Arlt[1,2], John Ayuk[2], James Byrne[5], Swarupsinh Chavda[6], Simon Cudlip[7], Neil Gittoes[1,2], Ashley Grossman[3], Rosalind Mitchell[8], Michael O'Reilly[1,2], Alessandro Paluzzi[8], Andrew Toogood[2], John Wass[3] & Niki Karavitaki[1,2]
[1]Institute of Metabolism and Systems Research, College of Medical and Dental Sciences, University of Birmingham, Birmingham, UK; [2]Centre for Endocrinology, Diabetes and Metabolism, Birmingham Health Partners, Birmingham, UK; [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, Churchill Hospital, Oxford, UK; [4]Department of Ear, Nose and Throat, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [5]Department of Neuroradiology, John Radcliffe Hospital, Oxford, UK; [6]Department of Radiology, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK; [7]Department of Neurosurgery, John Radcliffe Hospital, Oxford, UK; [8]Department of Neurosurgery, Queen Elizabeth Hospital, University Hospitals Birmingham NHS Foundation Trust, Birmingham, UK.

Introduction
Despite the significant risk of regrowth of non-functioning pituitary adenomas (NFAs) after primary treatment, systematic data on the probability of further tumour progression and the effectiveness of management approaches are lacking.
Aims
Assess the probability of further regrowth(s), predictive factors and outcomes of management approaches in patients with NFA diagnosed with adenoma regrowth after primary treatment (surgery combined or not with radiotherapy) in two UK referral centers.
Methods
The records of the patients with NFA who during their follow-up had adenoma regrowth were reviewed. The period covered for the primary NFA surgery was between 1/1963 and 12/2011 and the follow-up period ended in 6/2016.
Results
We identified 237 patients (median follow-up after 1st regrowth of 5.9 years (range 0.4–37.7)). The 5-year 2nd regrowth rate was 35.3% (36.2% after surgery; 12.5% after radiotherapy; 12.7% after surgery combined with radiotherapy; 63.4% with monitoring). Of those managed by monitoring, 34.8% eventually were offered intervention. Type of management and sex were risk factors for 2nd NFA regrowth, whereas age at diagnosis of primary NFA and type of adenoma immunostaining were not. Amongst those with 2nd adenoma regrowth, the 5-year 3rd regrowth rate was 26.4% (24.4% after surgery; 0.0% after radiotherapy; 0.0% after surgery combined with radiotherapy; 48.3% with monitoring). Overall, patients with a NFA regrowth had probability of a 3rd regrowth 4.4% at 5 years, and 10.0% at 10 years, and the type of management of the 1st regrowth was the only risk factor. Malignant transformation was diagnosed in two of 237 patients (one gonadotroph and one silent ACTH adenoma).
Conclusions
Patients with regrown NFA after primary treatment continue to carry considerable risk of tumour progression necessitating long-term follow-up. Management approach of the regrowth is the major factor determining this risk; monitoring alone is associated with high progression rates and a substantial number of patients will ultimately require intervention.

Targeting either GH or IGF-I levels during somatostatin analogue treatment in patients with acromegaly: A randomized, investigator-initiated multicenter study

Jakob Dal[1], Marianne Klose[5], Ansgar Heck[6], Marianne Andersen[3], Caroline Kistorp[4], Eigil Husted Nielsen[2], Jens Bollerslev[6], Ulla Feldt-Rasmussen[5] & Jens Otto Lunde Jørgensen[1]
[1]Aarhus University Hospital, Aarhus, Denmark; [2]Aalborg University Hospital, Aalborg, Denmark; [3]Odense University Hospital, Odense, Denmark; [4]Herlev Hospital, Herlev, Denmark; [5]National University Hospital, Copenhagen, Denmark; [6]Oslo University Hospital and Faculty of Medicine, Oslo, Norway.

Context
Assessment of disease control in acromegaly depends on GH and IGF-I, but discordant values frequently occur. Further, the role of OGTT-suppressed GH (GH_{nadir}) in somatostatin analogue (SA) treated patients is debated.
Objective
To evaluate the effect of targeting either IGF-I or GH during SA treatment.
Design
A randomized, investigator-initiated, multicentre trial.
Patients and methods
84 patients controlled with either SA ($n=61$) or surgery-only ($n=23$) underwent a 3 h GH profile including a 2 h OGTT at baseline, after 6 months (SA treated patients only) and after 12 months together with IGF-I. SA patients were randomized to be monitored by either IGF-I ($n=33$) or GH_{nadir} ($n=28$). SA dose increase were allowed at baseline and after 6 months. Symptoms and quality of life (QoL) were assessed by disease-specific questionnaires (PAQ12 and AcroQoL).
Main outcome measures
GH and IGF-I at baseline and 12 months, symptoms and QoL, and SA dose increases.
Results
IGF-I and fasting GH levels at baseline were comparable between the two groups, whereas GH_{nadir} (μg/l) was lower in the surgery group (GH_{nadir} 0.7 ± 0.1 (SA) vs 0.3 ± 0.1 (surgery), $P<0.01$). At baseline, 31% of SA patients had concordant controlled GH and IGF-I, 43% had elevated GH and 3% elevated IGF-I. Significantly more patients in the surgery group had concordant controlled values (65%), $P<0.01$. SA dose increase was performed in 20 patients in the GH target group as compared to eight patients in IGF-I target group ($P=0.02$) and resulted in a higher proportion of controlled patients ($P=0.01$). SA patients had suppressed insulin levels and elevated glucose and FFA levels during the OGTT compared to surgery. QoL was only mildly affected at baseline and did not change consistently.
Conclusions
i) Discordance between GH and IGF-I is more prevalent during SA treatment as compared to surgery, mainly due to elevated GH_{nadir} levels, ii) targeting discordant GH or IGF-I levels in SA patients translates into SA dose increase and a higher degree of concordance, iii) Our data suggest that a sizable proportion of SA patients are undertreated.

Brain white matter damage and volumes of hippocampus and hypothalamus correlates to cognitive function in craniopharyngioma

Sigridur Fjalldal[1], Daniel Svärd[2], Cecilia Follin[1], Danielle Van Westen[2], Sanaz Gabery[3], Åsa Petersén[3], Magdalena Jansson[4], Pia Maly Sundgren[2,5], Isabella Björkman-Burtscher[2,5], Jimmy Lätt[5], Peter Mannfolk[5], Carl-Henrik Nordström[7], Lars Rylander[8], Bertil Ekman[9], Aki Johansson[4] & Eva-Marie Erfurth[1]
[1]Department of Endocrinology, Skåne University Hospital, Lund, Sweden; [2]Department of Diagnostic Radiology, Clinical Sciences, Lund University, Lund, Sweden; [3]Translational Neuroendocrine Research Unit, Department of Experimental Medical Science, Lund University, Lund, Sweden; [4]Department of Psychology and Psychiatry, Skåne University Hospital, Lund, Sweden; [5]Department of Medical Imaging and Physiology, Skåne University Hospital, Lund, Sweden; [6]Lund University BioImaging Center, Lund University, Lund, Sweden; [7]Department of Neurosurgery, Skåne University Hospital, Sweden, Lund, Sweden; [8]Division of Occupational and Environmental Medicine, Lund University, Lund, Sweden; [9]Department of Endocrinology and Medical and Health Sciences, Linköping University, Linköping, Sweden.

Introduction
Adult patients with craniopharyngioma (CP) and hypothalamic (HT) damage have impaired cognitive function. The white matter (WM) changes behind these findings remain to be elucidated. Diffusion tensor imaging (DTI) is a MRI technique that quantifies microstructural damage in the WM. This is the first study of DTI, hippocampal (HC) and HT volume in relation to cognition in CP patients.
Methods
A cross-sectional study of childhood onset CP was performed at median 22 years after first operation. After exclusions, 36 patients and 31 controls remained in the MRI study. Main outcome measures were comparison of cognitive tests, volume measurements of HC and HT and the DTI parameters median diffusivity (MD) and fractional anisotropy (FA) between patients and controls.
Results
CP patients have WM damage in the left dorsal cingulum and right uncinate fasciculus. No significant difference was found on DTI measurements of the HC. Correlations were found between DTI results from the right uncinated fasciculus (MD, $P=0.035$ and FA, $P=0.005$) and the left HC (MD, $P=0.035$ and FA, $P=0.001$) with long term memory reflecting general knowledge. DTI in the cingulum correlated with visual memory (MD, $P\leq0.04$ and FA, $P\leq0.04$) and short term memory (MD, $P=0.004$). DTI in the HC correlated with long term memory (MD, $P=0.03$ and FA, $P\leq0.046$) and short term memory (FA, $P=0.02$). HT volume correlated negatively with MD of right uncinate fasciculus ($P=0.015$). The CP patients had a smaller HC volume which correlated with long term memory ($P=0.016$).
Conclusions
A structure to function relationship is established between cognition and WM damage detected with DTI in CP. CP patients have a smaller HC compared to controls. Whether the cognitive deficits are a direct consequence of HT damage or an indirect effect on frontotemporal network remains to be elucidated.

Copeptin – a sensitive marker of an altered CRH-axis in pituitary disease

Krzysztof Lewandowski[1], Andrzej Lewinski[1], Elzbieta Skowronska-Jozwiak[1], Katarzyna Malicka[1], Wojciech Horzelski[2] & Georg Brabant[3]
[1]Department of Endocrinology and Metabolic Diseases, "Polish Mother" Memorial Research Institute and The Medical University of Lodz, Lodz, Poland; [2]Faculty of Mathematics and Computer Science, University of Lodz, Lodz, Poland; [3]Experimental and Clinical Endocrinology Med Clinic I, University of Luebeck, Lübeck, Germany.

Background
Copeptin (pre-proAVP) secreted in equimolar amounts with vasopressin (AVP) closely reflects AVP release. Previously it was shown that copeptin is stimulated in standard pituitary function tests acting through hypothalamic centres. Furthermore, copeptin has been shown to subtly mirror stress potentially mediated via CRH. To further test a potential direct interaction of CRH with copeptin release which could augment AVP effects on pituitary function, we investigated copeptin response in a standard CRH test, both in healthy controls and patients with pituitary disease.
Patients and methods
18 healthy controls and 29 subjects with history of pituitary disease were subjected to a standard CRH test and in addition to ACTH and cortisol we measured copeptin by standard assays (ThermoFisher).
Results
Patients with previous pituitary disease were subdivided in a group passing the test (P1) and failing (P2). The latter group included five patients with diabetes insipidus. The overall copeptin response was higher in controls than in subjects with pituitary disease (area under the curve, $P=0.04$ for P1 + P2) with a maximum increase in controls from 3.84 ± 2.86 pmol/l, to 12.65 ± 24.87 pmol/l, $P=0.04$, at 30 min). In contrast, both groups of pituitary patients lacked a significant CRH response. The mean increase in P2 was from 1.93 ± 1.44 pmol/l to 3.37 ± 3.49 pmol/l, at 30 min, $P=$ns, and even in P1 where ACTH concentrations increased four-fold (mean 21.48 vs. 91.53 pg/ml, $P<0.01$) copeptin did not respond (e.g. 4.35 ± 5.81 pmol/l vs. 5.36 ± 6.79 pmol/l, at 30 min, $P=$ns).
Conclusions
CRH is able to stimulate copeptin release in healthy controls suggesting a direct interaction of CRH and AVP/vasopressin. Interestingly, this relation is altered already in the group of pituitary patients who pass the standard CRH test indicating i) that the CRH-ACTH-cortisol response is largely independent from the AVP system, but ii) the CRH-AVP interaction reflected by copeptin may be much more sensitive to reveal subtle alterations in the regulation of pituitary function.

Hormonal and metabolic effects of long-term cabergoline withdrawal in patients with hyperprolactinemia

Renata Simona Auriemma, Chiara Blasio, Ludovica Francesca Stella Grasso, Mariano Galdiero, Mariarosaria Negri, Claudia Pivonello, Luciana Granieri, Annamaria Colao & Rosario Pivonello
Dipartimento di Medicina Clinica e Chirurgia, Sezione di Endocrinologia, Università Federico II di Napoli, Naples, Italy.

Hyperprolactinemia is associated with abnormalities in glucose and lipid profile with development of insulin resistance and metabolic syndrome (MetS), which have been found to be improved by treatment with cabergoline (CAB). The current study aimed at investigating hormonal and metabolic effects of long-term CAB withdrawal in patients with prolactinomas. In 46 patients (37 F, 9 M, aged 34.5 ± 11.5 yrs, 36 microadenomas and 10 macroadenomas) anthropometric (weight, BMI, waist circumference (WC)) and metabolic (fasting glucose (FG) and insulin (FI), total (TCHO), HDL and LDL cholesterol, triglycerides (TG), HOMA-IR, HOMA-β, ISI0, VAI, and prevalence of MetS) parameters, and PRL levels were evaluated at baseline, at CAB withdrawal (TWD), and 12 (T12) and 60 (T60) months after CAB discontinuation. CAB treatment (median duration = 72 months) induced PRL normalization in all patients, and a significant improvement of BMI ($P<0.0001$), WC ($P<0.0001$), FI ($P=0.007$), HDL ($P<0.001$), LDL ($P<0.001$), HOMA-IR ($P=0.012$) and ISI0 ($P=0.05$) compared to baseline. CAB withdrawal resulted in prolonged and sustained normoprolactinemia, with only 8 (17.4%) patients requiring treatment restarting within 12 months. In 38 patients permanently discontinuing CAB, compared to TWD BMI ($P<0.0001$), WC ($P<0.0001$), TCHO ($P<0.001$) and VAI ($P<0.0001$) significantly impaired at T12, and similarly BMI ($P<0.0001$), WC ($P<0.0001$), TCHO ($P<0.05$) and VAI ($P<0.0001$) at T60. Compared to TWD no further changes were seen in FI, HOMA-IR, HOMA-β, ISI0. MetS prevalence significantly increases from T0 (23.9%) to T60 (41.3%, $P<0.0001$), with 8 patients (17.4%) developing MetS after CAB withdrawal. In conclusion, CAB discontinuation significantly worsens lipid profile and MetS prevalence in patients with prolactinomas.

Localization of benign insulinomas using glucagon-like peptide-1 receptor (GLP1-R) SPECT/CT and PET/CT and MRI in a prospective clinical study

Kwadwo Antwi[1], Melpomeni Fani[1], Tobias Heye[1], Guillaume Nicolas[1], Elmar Merkle[1], Jean Claude Reubi[2], Beat Gloor[3], Damian Wild[1] & Emanuel Christ[1,4]
[1]Clinic of Radiology and Nuclear Medicine, University of Basel Hospital, Basel, Switzerland; [2]Division of Experimental Pathology, Department of Pathology, University of Bern, Bern, Switzerland; [3]Department of Visceral Surgery, University Hospital of Bern, Inselspital, Bern, Switzerland; [4]Division of Endocrinology, Diabetology and Clinical Nutrition, University Hospital of Bern, Inselspital, Bern, Switzerland.

Purpose
We aim at prospectively comparing the detection rate of GLP1-R PET/CT vs GLP1-R SPECT/CT vs standardized contrast enhanced 3T-MRI in patients with suspected insulinoma.
Methods
40 patients with neuroglycopenic symptoms due to endogenous hyperinsulinemic hypoglycemia were enrolled.
3T-MRI was performed. Afterwards patients received SPECT/CT after injection of ^{111}In-DOTA-exendin-4 and PET/CT after injection of ^{68}Ga-DOTA-exendin-4 in a randomized order. Three blinded nuclear medicine physicians and three blinded radiologists reviewed the scans.
Standard of comparison was the histological diagnosis after surgery.
Results
Previously performed cross-sectional imaging was negative or inconclusive in 27/40 patients. So far 29 patients have been operated. The histological diagnosis of a benign insulinoma was confirmed in 25 patients, one patient had a nesidioblastosis. In one patient no lesion could be found intraoperatively. In two patient symptoms of endogenous hypoglycemia ceased postoperative but histological diagnosis did not confirm a benign insulinoma or nesidioblastosis. These two patients were excluded from evaluation as the final diagnosis remained unclear. Two patients refused surgery. Three patients are awaiting surgery. In five patients all performed imaging modalities did not find any suspicious lesion and were thus not operated up to date. One patient showed signs of malignancy in MRI, thus did not meet the inclusion criteria and was excluded. In this interim

analysis of 27 operated patients PET/CT showed an overall pooled sensitivity of 92%, SPECT/CT at 72 h a sensitivity of 71% and 3T-MRI a sensitivity of 76%.
Conclusion
1) These preliminary data suggest that PET/CT performs better as standardized MRI imaging and SPECT/CT at lower irradiation dose and much shorter investigation time than the latter.
2) GLP-1R PET/CT will be a useful diagnostic tool in patients where CT/MRI fails to localize the insulinoma.

24 hour urinary 5-hydroxyindoleacetic acid (5-HIAA) doubling-time (DT) is associated with disease-specific mortality (DSM) and progression-free survival (PFS) in patients with neuroendocrine tumors (NETs)

Amit Tirosh[1,2], Naris Nilubol[3], Dhaval Patel[3] & Electron Kebebew[3]
[1]National Institutes of Health, Bethesda, Maryland, USA; [2]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [3]Endocrine Oncology Branch, National Cancer Institute, Bethesda, Maryland, USA.

Background
Biochemical biomarker DT is used clinically for prognosis prediction in several solid malignancies. The aim of the current analysis was to determine whether biomarker DT has any prognostic utility in patients with NETs.
Methods
Patients with NETs ($n=184$) were enrolled in a prospective study with comprehensive biochemical analysis. The current analysis included subjects with increasing 5-HIAA levels in at least two consecutive measurements. DTs for each biomarker were calculated using the formula DT = $[\log_{10}(2)$*(time interval between tests)]/$[\log_{10}(2^{nd}$ value)–$\log_{10}(1^{st}$ value)]. Log-rank test was used to assess differences in DSM or PFS risk by DT. The *c*-statistic of 5-HIAA predictive utility for DSM was calculated using receiver operating characteristic (ROC) curve analysis. DSM and PFS were compared by 5-HIAA DT using Kaplan-Meier survival analysis and multivariate analysis was performed using Cox regression.
Results
91 patients had increasing 5-HIAA levels. Four patients died during a median follow-up of 8 months (interquartile range, 12). The c-statistic for DSM prediction by 5-HIAA was 0.76 (95% CI 0.62–0.90), and 5-HIAA DT <434 days had positive and negative predictive values for DSM of 75 and 76%, respectively. Patients with a 5-HIAA DT <434 days had higher risk for DSM during follow-up (Log-Rank test, $P=0.02$). In sub-group analysis this difference was found only among patients with a non-pancreatic NET ($P=0.002$). In the entire cohort, PFS were comparable between patients with 5-HIAA DT longer vs. shorter than 434 days. However, patients with small-intestine NET with 5-HIAA DT $<$ 434 days had a higher risk for progression ($P=0.006$), also in multivariate analysis (Hazard Ratio 15.3, 95% CI 1.01–232.6, $P=0.049$).
Conclusions
Short 5-HIAA DT is associated with increased DSM and lower PFS in patients with NET, and specifically among those with SINET, and can be used as a prognostic measure in NET patients.

Pasireotide alone or in combination with cabergoline effectively controls urinary free cortisol levels: results from a prospective study in patients with Cushing's disease (CAPACITY)

Rosario Pivonello[1], Pritam Kadioglu[2], Marie Bex[3], Deyanira González Devia[4], Cesar Boguszewski[5], Dilek Gogas Yavuz[6], Heather Patino[7], Federico Campigotto[7], Alberto Pedroncelli[8], Maria Fleseriu[9], Beverly M K Biller[10] & Richard Feelders[11]
[1]Università Federico II di Napoli, Naples, Italy; [2]Istanbul University, Istanbul, Turkey; [3]University Hospitals Leuven, Leuven, Belgium; [4]Hospital Universitario Fundación Santa Fé de Bogotá, Bogota, Colombia; [5]Federal University of Paraná, Curitiba, Brazil; [6]Marmara University Medical School, Istanbul, Turkey; [7]Novartis Pharmaceuticals Corporation, East Hanover, New Jersey, USA; [8]Novartis Pharma AG, Basel, Switzerland; [9]Oregon Health and Science University, Portland, Oregon, USA; [10]Massachusetts General Hospital, Boston, Massachusetts, USA; [11]Erasmus Medical Center, Rotterdam, The Netherlands.

Background
Pasireotide is a multireceptor-targeted somatostatin analogue that predominantly binds to somatostatin receptor subtype 5 (SSTR5) and provides sustained control of urinary free cortisol (UFC) levels in some patients with Cushing's disease (CD). Cabergoline is a dopamine D2 receptor agonist with efficacy in some patients with CD. Most corticotropinomas co-express SSTR5 and D2, providing rationale for combination treatment with pasireotide and cabergoline. Results are reported from a Phase II study of pasireotide alone or combined with cabergoline in patients with CD.
Methods
Open-label, multicentre, non-comparative study. Patients with persistent/recurrent or *de novo* (if not surgical candidates) CD who were pasireotide-untreated at screening were enrolled. Patients initiated treatment with pasireotide (subcutaneous) 0.6 mg bid. If mean UFC (mUFC; from two consecutive 24h collections) remained $>$ULN after 8 weeks, the pasireotide dose was increased, if tolerated, to 0.9 mg bid for 8 weeks. If mUFC remained elevated, cabergoline 0.5mg qd was added for 8 weeks, increasing to 1.0mg qd for another 8 weeks if mUFC$>$ULN. Primary endpoint: proportion of patients with mUFC$\leq$ULN at week 35.
Results
Sixty-six patients (median 40.5 years; 59 females) were enrolled. Twenty-seven patients received pasireotide monotherapy; 39 received combination therapy. At week 35, mUFC$\leq$ULN was achieved in 25 patients (37.9%, 95%CI 26.2–50.7), 13 of whom received pasireotide monotherapy, with a further 12 achieving the primary endpoint after cabergoline addition. The most common ($>20\%$) AEs were hyperglycaemia (51.5%), nausea (47.0%), diarrhoea (45.5%), headache (28.8%), dizziness (24.2%) and cholelithiasis (24.2%). Sixteen (24.2%) patients discontinued before week 35 (10 on pasireotide monotherapy); seven (10.6%) because of AEs (five on pasireotide monotherapy). Two on-treatment deaths occurred, both unrelated to study treatment.
Conclusions
Pasireotide alone or combined with cabergoline effectively controlled mUFC. Results suggest that addition of cabergoline in patients with persistently elevated mUFC is an effective strategy to enhance the control of CD.

Vertebral fractures are prevalent among patients with acromegaly in spite of normal bone mineral density reflecting overall duration of disease regardless of biochemical control or cure

Marko Stojanovic[1,2], Dragana Miljic[1,2], Sandra Pekic[1,2], Mirjana Doknic[1,2], Marina Nikolic Djurovic[1,2], Zvezdana Jemuovic[1], Vera Popovic[2] & Milan Petakov[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]University of Belgrade, School of Medicine, Belgrade, Serbia.

Introduction
Skeletal complications of acromegaly are among its most persistent and invalidating impacts. Dual-X-ray absorptiometry (DXA) alone might be insufficient or even misleading for bone health assessment in acromegaly.
Patients and methods
Patients with acromegaly ($N=170$) were classified as active ($N=104$), operatively cured ($N=34$) or medically controlled ($N=32$). 57 males and 113 females were included, 52.8 (22.0–78.5) years old. Bone mineral density (BMD) was assesed at L1-L4 and Femoral neck (FN) using DXA Hologic Discovery-W-QDR. BMD results were expressed as Z score, accounting for age and gender. Vertebral fracture assessment (VFA) on Th4-L4 was performed in 71 patients (24 male, 47 female) to identify number, type, location and degree of severity of vertebral fractures (VFs).
Results
L1-L4 BMD was normal in all patients and not significantly different in active (Zsc: 0.61 ± 0.13) cured (Zsc: 0.32 ± 0.25) or controlled acromegaly (Zsc: 0.17 ± 0.32). FN BMD was normal in all and not significantly different in active (Zsc: 0.61 ± 0.11) cured (Zsc: 0.59 ± 0.19) or controlled acromegaly (Zsc: 0.49 ± 0.22). VFs were identified in 23.9% (17/71) of patients. Prevalence in males was significantly higher than in females (33.3% vs. 19.2%; $P<0.01$). Patients with and without VFs did not differ in BMD L1-L4 Zsc (0.98 ± 0.06 vs. 1.04 ± 0.02) or FN Zsc (0.83 ± 0.05 vs. 0.86 ± 0.02). Duration of the disease in patients with VFs was significantly longer (14.1 ± 1.9 vs. 9.6 ± 1.2yrs) then in those without VFs ($P<0.05$). Prevalence of VFs was significantly higher in controlled (62.5%) and cured (40.0%) compared to active (17.8%) acromegaly ($P<0.01$).
Conclusion
Considerable prevalence of vertebral fractures (24%) was identified in a large cohort of patients with acromegaly, irrespective of normal bone mineral density. Duration of the disease was the main determinator of VFs prevalence, regardless of the biochemical control or cure. VFs are important, persistent and invalidating yet often under-recognized complication of acromegaly.

Evaluation of pituitary toxicity after radiotherapy for cerebral chondrosarcomas in adult patients

Suzanne Laroche[1], Loïc Feuvret[3,5], Alain Beauchet[2], Rémi Dendale[3], Philippe Chanson[4], Eric Bruckert[1] & Christel Jublanc[1]
[1]Endocrinologie, Hôpital Pitié Salpêtrière, APHP, Paris, France; [2]Unité de Recherche Clinique, Département de Santé Publique, Hôpital Ambroise Paré, APHP, Paris, France; [3]Centre de Protonthérapie d'Orsay, Institut Curie, Orsay, France; [4]Endocrinologie, Hôpital Bicêtre, APHP, Le Kremlin Bicêtre, France; [5]Radiothérapie, Hôpital Pitié Salpêtrière, APHP, Paris, France.

Pituitary dysfunction can be a consequence of cranial radiotherapy. It usually occurs years after the treatment. However little is known on risk factors for pituitary dysfunction. The object of this study was to evaluate radiation induced pituitary toxicity of proton beam therapy in a cohort of adult chondrosarcoma patients.
The files of 113 patients were reviewed. Mean age at the beginning of radiotherapy was 43 years old (18–76). Mean dose delivered to the tumor was 67 Gy and mean dose delivered to the pituitary gland was 59 Gy. Mean post-radiotherapy follow-up time was 7 years (4–17). Pituitary dysfunction was observed in 78 patients, within the delay of 4 years after radiotherapy. The prevalence of hyperprolactinemia was of 40%, thyrotrophic insufficiency was 36%, corticotropic insufficiency 31%, and gonadotropic insufficiency 25%. No significant differences were shown in the delay of dysfunction between the pituitary axes. In multivariate analysis, risk factors known to increase the risk of vascular side-effects of radiation (sex, age, smoking, high blood pressure, dyslipidemia and diabetes mellitus) were not associated with an increase of pituitary dysfunction.
Conclusions
Pituitary toxicity of radiotherapy is frequent after 4 years. The high prevalence of hyperprolactinemia pinpoints a possible hypothalamic origin of post radiotherapy pituitary insufficiency. A prospective follow up is necessary to complete these observations and propose relevant guidelines. Our study analyses the largest cohort of patients with chondrosarcomas after proton beam therapy. Our results emphasize the importance of careful and long term endocrine follow-up of these patients.

[1]Aarhus University Hospital, Aarhus, Denmark; [2]University of Belgrade, Belgrade, Serbia; [3]Novo Nordisk Health Care AG, Zurich, Switzerland; [4]Novo Nordisk A/S, Søborg, Denmark; [5]Charité Universitätsmedizin Berlin, Berlin, Germany.

Background
Long-term safety data (1998 to mid-2016) are reported for adult patients with GHD treated with GH (Norditropin® (somatropin), Novo Nordisk) as prescribed by treating physicians in the real-life clinical setting and enrolled in NordiNet® International Outcome Study (IOS) (NCT00960128), a non-interventional, multicentre study.
Objective and hypotheses
To describe and report safety data and incidence rates (IRs) (events/1000 patient-years) of adverse drug reactions (ADRs), serious adverse events (SAEs) and serious ADRs (SADRs).
Method
Events were classified by MedDRA Preferred Term/System Organ Class (SOC). IRs during GH treatment were calculated.
Results
Data for 2438 patients (adult-onset, 90.1%; female 44.0%; mean (S.D.) age at treatment start, 43.3 (17.8) years; duration of follow-up, 5.8 (4.7) years; GH dose, 0.41 (0.32) mg/day) were analysed. Overall, 197 adverse events (AEs) were reported in 150 patients. Among these patients, mean (S.D.) treatment duration to first AE was 4.7 (4.1) years and GH dose at AE onset was 0.36 (0.31) mg/day. After the first AE, GH dose was unchanged in 55.3%, discontinued in 26.4% and decreased in 7.6% of patients (not reported/other for 10.7%). IRs were 11.91 for SAEs, 1.89 for SADRs and 5.52 for ADRs. Most frequently reported ($n \geq 10$) AEs by SOC (n, %) were nervous system disorders ($n=43$, 21.8%), neoplasms (benign, malignant and unspecified) ($n=35$, 17.8%), musculoskeletal and connective tissue disorders ($n=20$; 10.2%); general disorders and administration-site conditions or infections and infestations (each $n=15$, 7.6%); and cardiac disorders ($n=14$, 7.1%). Type 2 diabetes was reported as an AE in four patients. Twelve deaths (one possibly related) were reported.
Conclusions
IRs of SAEs, ADRs and SADRs were low. Data from NordiNet® IOS revealed no new safety signals, further supporting the favourable safety profile of GH replacement in adults with GHD.

GH and IGF-1 levels at 12 weeks predict long-term responses to lanreotide Autogel in treatment-naïve acromegalic patients: *post-hoc* analyses from the PRIMARYS study

Philippe Caron[1], Stephan Petersenn[2], Aude Houchard[3], Caroline Sert[3] & John S Bevan[4]
[1]Department of Endocrinology, CHU Larrey, Toulouse, France; [2]ENDOC Center for Endocrine Tumors, Hamburg, Germany; [3]Ipsen Pharma, Boulogne-Billancourt, France; [4]Department of Endocrinology, Aberdeen Royal Infirmary, Aberdeen, UK.

Background
In PRIMARYS, lanreotide Autogel (LAN) 120 mg/28 days reduced tumour volume (TV), and GH/IGF-1 levels in patients with GH-secreting macroadenomas. In *post-hoc* analyses, we investigated predictive factors for treatment responses.
Methods
PRIMARYS, a 48-week, international, open-label study, involved 90 treatment-naïve patients with GH-secreting macroadenomas receiving LAN. Factors predictive for hormonal control (HC; GH ≤ 2.5 μg/L + normal IGF-1) at last post-baseline value available (LVA) or $\geq 20\%$ TV reduction (TVR) at week 48/LVA were investigated using univariate logistic regression. Week-12 GH, IGF-1 and TV cut-off values for predicting responses were obtained from ROC curves, maximising the Youden index. Analyses used intention-to-treat populations and $P<0.05$ as significant.
Results
From univariate analyses, HC was more likely in women (odds ratio: 2.9 times higher for women vs. men), and older patients (2.2 times higher for each 10-year higher age), and with lower baseline IGF-1 (1.1 times higher for each 10% lower IGF-1 level [% upper limit of normal, ULN]), but no association with GH levels was shown. HC was determined by week-12 hormonal response: optimal cut-offs were 1.19 μg/L for GH (sensitivity, 0.79; specificity, 0.89; area-under-the-curve [AUC] value, 0.87) and 110% ULN for IGF-1 (0.89, 0.85 and 0.93, respectively). Univariate analyses revealed no baseline factors influencing TVR. TVR was, however, determined by changes from baseline to week 12 in GH, IGF-1 and TV: optimal cut-offs were -69% for GH (sensitivity, 0.74; specificity, 0.67; AUC, 0.74), -61% for IGF-1 (0.58, 0.80, 0.75), and -21% for TV (0.81, 0.97, 0.93).
Conclusions
Based on *post-hoc* PRIMARYS data, treatment-naïve patients with GH-secreting macroadenomas are more likely to achieve long-term hormonal control with LAN 120 mg/28 days if GH levels are <1.2 μg/L and IGF-1 levels $<110\%$ ULN at 12 weeks, and more likely to achieve clinically significant long-term reductions in TV with $>60\%$ reductions in GH/IGF-1 levels by week 12.

Long-term treatment with pegvisomant (Somavert®): Observations from 2090 acromegaly patients followed in ACROSTUDY

Aart Jan vanderLely[1], Beverly Biller[2], Thierry Brue[3], Michael Buchfelder[5], Ezio Ghigo[4], kaijie Pan[8], Peter Jonsson[9], Joanne Lavenberg[8], Christian J. Strasburger[6], Susan Webb[7], Cecilia Camacho-Hubner[8] & Judith Hey-Hadavi[8]
[1]Erasmus University Medical Center, Rotterdam, The Netherlands; [2]Massachusetts General Hospital, Boston, MA, USA; [3]Universite de la Mediterranee, Marseille, France; [4]Universita de Torino, Torino, Turin, Italy; [5]University of Erlangen-Nurnberg, Erlangen, Germany; [6]Charite-Universitatsmedizin, Berlin, Germany; [7]Universitat Autonoma de Barcelona, Barcelona, Spain; [8]Pfizer Inc Endocrine Care, New York-Collegeville, USA; [9]Pfizer Inc ACROSTUDY Endocrine care, Sollentuna, Sweden.

Introduction
Pegvisomant (PEGV) is approved for the treatment of acromegaly since 2003. This is the second interim analysis of data from ACROSTUDY, with the majority of patients treated for at least five years (yrs).
Methods/design
ACROSTUDY is an international, open-label, prospective, non-interventional, post-marketing surveillance study monitoring the long-term safety and efficacy of PEGV. Patients were enrolled in the study on an ongoing basis.
Results
As of May 31, 2016, data from 2090 patients (51% men) from 15 countries were available. Mean treatment duration was 7.6 yrs (median 8.1 range: 0.0–19.1 yrs). Patients were followed in ACROSTUDY for a mean of 6.3 yrs (median 6.8, range 0.1–12.1). At ACROSTUDY start, there were 12 patients in the 0–18 yrs category and 203 patients in the >70 yrs category. At PEGV start, pituitary insufficiencies were observed for gonadotrophins (37.9%), TSH (29.1%) and ACTH (28.3%). 54.4% of patients experienced adverse events (AEs) with most common AE being IGF-I increased (10.5% of patients), headache(4.9%), vitamin D deficiency(4.6%) and arthralgia(3.7%). SAEs were experienced in 22% of patients (2.3% were treatment related, while 7.0% of patients discontinued treatment due to the SAE). A total of 78 deaths were reported (all non-treatment related). Locally assessed MRIs showed that most patients (72.2%) had no change in tumour size relative to last exam; 16.8% had decrease in tumour size, 6.8% had an increase, and 4.3% had both increase and decrease. Shift analysis demonstrated that of the 1245 with reported normal LFTs (AST/ALT) at baseline, 3% developed elevations > 3xULN. Administration site reactions were reported for 3.4% of patients.
Conclusions
This second interim analysis of long-term follow up showed that PEGV is an effective and safe treatment in patients with acromegaly. Data indicate low occurrence of reported pituitary tumor changes, liver test elevations and site administration reactions.

Amenorrhea without vasomotor symptoms in women over 40: A sign of pathological hyperprolactinemia?

Irena Ilovayskaya, Alexader Dreval & Yulia Krivosheeva
Moscow Regional Research & Clinical Institute, Moscow, Russia.

Background
Hyperprolactinemia is often seen in women of reproductive age (20–35 years), most often due to microprolactinoma. However, prolactinomas do occur in older women.
Objective
To analyze clinical features of hyperprolactinemia in women >40 years
Material and methods
Clinical and biochemical data of 185 women with pathological hyperprolactinemia were analyzed.
Results
Seventy (37.8%) patients had microprolactinomas (MI), 57 (30.8%) – macroprolactinomas (MA), and 58 (31.4%) – non-tumoral hyperprolactinemia (NT). Among them, 26(36.1% of corresponding subgroup) with MI, 27(46.6%) with NT and 37(64.9%) with MA were >40 years of age. Menstrual disturbances and infertility issues are key factors for prolactin measurement but among these women, it was a reason to visit doctor only in few cases. In most cases with onset of hyperprolactinemia within 40–50 years of age, women themselves or their gynecologists considered amenorrhea as a natural postmenopause, missing the correct diagnosis. It was characteristic for hyperprolactinemic women that they did not experience vasomotor climacteric symptoms. Weight gain was common (68% women) but was also considered as climacteric and result of ageing. Headache and visual impairment were common causes for referral later on, and hyperprolactinemia was found due to hormonal investigation after MR-visualization of pituitary tumor. In some cases with prolactin levels 1300–1900 mMU/l, differential diagnosis was required between hyperprolactinemia due to pituitary stalk compression and prolactinomas with moderate secreting activity ("hook" phenomena was excluded). However, significant tumor shrinkage and (in some cases) restoration of regular menstrual cycle after 3–6 months of cabergoline treatment confirmed prolactinoma.
Conclusion
If a woman over 40 has menstrual irregularity or amenorrhea and does not experience any vasomotor symptom, it is a reason to prove a natural menopause by measuring high FSH levels (>25 MU/l). In cases of lower FSH levels it is reasonable to consider pathological hyperprolactinemia.

Serotonin, ATRX and DAXX as differential diagnostic markers of neuroendocrine tumours (NETs) in the sellar region. An immunohistochemical study in a large series of pituitary adenomas and in a non-pituitary NET

Olivera Casar-Borota[1,2], Johan Botling[1,2], Dan Granberg[3], Johan Wikström[4], Fredrik Pontén[1,2] & Jacqueline Trouillas[5,6]
[1]Department of Immunology, Genetics and Pathology, Uppsala University, Uppsala, Sweden; [2]Department of Clinical Pathology, Uppsala University Hospital, Uppsala, Sweden; [3]Department of Medical Sciences, Uppsala University, Uppsala, Sweden; [4]Department of Surgical Sciences, Uppsala University, Uppsala, Sweden; [5]Faculté de Médecine Lyon-Est, Université Lyon 1, Lyon, France; [6]Centre de Pathologie et de Biologie Est, Groupement Hospitalier Est, Hospices Civils de Lyon, Bron, Lyon, France.

We present a case of a patient with a locally invasive, serotonin- and ACTH-reactive tumour in the sellar region, filling the sphenoid sinus and expanding into the epipharynx. Clinical examination completed by 68-Gallium-DOTA-TOC PET revealed tracer uptake in the sellar tumour as well as in a 7 mm lesion in the pancreatic tail. A differential diagnosis between silent corticotroph adenoma and another primary or secondary neuroendocrine tumour (NET) with ACTH-expression was difficult.
As serotonin was strongly positive in the tumour cells and its expression in pituitary endocrine tumours has not been systematically studied, we performed immunohistochemical analysis of serotonin in a large series of pituitary adenomas of different hormonal types from 246 patients. In addition, ATRX and DAXX, which mutations are associated with a subset of pancreatic NETs have been studied by using immunohistochemistry in the same cohort of pituitary tumours. None of the examined pituitary tumours expressed serotonin. There was normal expression of ATRX and DAXX corresponding to a lack of ATRX/DAXX mutations in the pituitary tumours.
Thus, serotonin-immunolabelling tumours in the sellar region most probably represent primary or secondary neuroendocrine tumours of non-pituitary origin. ATRX and DAXX do not seem to be involved in the pathogenesis of pituitary adenomas. Demonstration of ATRX or DAXX mutations in a neuroendocrine tumour of the sellar region excludes pituitary adenoma and suggests a non-pituitary NET, probably of pancreatic origin.

Long-term follow-up of a family with a large *AIP* gene deletion: variable phenotypes and challenges in the management

Pedro Marques[1], Mary Dang[1], Arla Ogilvie[2], Helen Storr[3], Michael Powell[4], Joan Grieve[4], Jane Evason[5], Ajith Kumar[6] & Marta Korbonits[1]
[1]Centre for Endocrinology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London, London, UK; [2]West Hertfordshire Hospitals NHS Trust, Watford, UK; [3]Department of Paediatric Endocrinology, Royal London Hospital, Barts Health NHS Trust, London, UK; [4]The National Hospital for Neurology and Neurosurgery, London, UK; [5]Department of Radiology Barts Health NHS Trust, London, UK; [6]North East Thames Regional Genetics Service, Great Ormond Street Hospital, London, UK.

Introduction
Germline aryl hydrocarbon receptor-interacting protein (*AIP*) mutations are responsible for 15–30% of familial isolated pituitary adenomas (FIPA). We report

a 4-generation FIPA kindred with a heterozygous *AIP* gene deletion in exon 2, highlighting the benefits of genetic screening and management challenges in affected subjects and asymptomatic carriers.

Patients

A 45y woman died of a spinal ependymoma (obligate carrier). Her 18y son showed lethargy over the following months attributed to grief. However, investigations due to headache revealed hypopituitarism and a clinically non-functioning PA was diagnosed. Two years later, his 185 cm 18y-brother was diagnosed with a sparsely-granulated PA co-expressing PRL&GH. Fourteen-years after operation his IGF-1 was repeatedly raised with small increase in his tumour remnant. Lanreotide treatment was started and surgery is planned. A Rathke's cyst was detected in a bulky gland in their eupituitary 17y mutation carrier sister when she was first screened, which is now regressed. However, after 8y follow-up a 4 mm-microadenoma became visible, with normal PRL, IGF-1 and OGTT-GH nadir 0.38 µg/l. Their 27y second-cousin presented amenorrhoea after cessation of oral contraceptive, hyperprolactinaemia and 2xULN IGF-1. Her MRI showed 2 pituitary microadenomas, corresponding to a 6 mm-somato-tropinoma on the right and a 4 mm-prolactinoma on the left, confirmed histologically.

Discussion

Of 14 subjects with *AIP* mutations, 4 have PA, 1 ependymoma and 7 are asymptomatic (penetrance 29%). Ependymomas were described with loss of genetic material at 11q13-locus, but has not been described in patients with *AIP* mutations. The slow regrowth of the tumor in the brother suggests that long-term follow-up is needed. Bulky pituitary and not fully suppressed GH on OGTT can represent challenges in *AIP* mutation carrier teenager females. Multiple PAs with different secretory profiles may arise in the pituitary of these patients. Genetic screening and baseline review with follow-up of younger subjects is recommended in *AIP* mutation-positive families.

Diagnosis of acromegaly: Sex and BMI are the major determinants of growth hormone suppression during oral glucose tolerance test (OGTT)

Katharina Schilbach, Shiva Sophia Nicolay, Michael Haenelt, Andreas Lechner, Christina Gar, Jochen Schopohl, Sylvère Störmann, Rita Schwaiger & Martin Bidlingmaier
Medizinische Klinik und Poliklinik IV, Klinikum der Universität München, Munich, Germany.

GH suppression during OGTT is the gold-standard test in diagnosis and monitoring of acromegaly. However, discrepancies between GH nadir and IGF-I have been described and have triggered search for factors modifying the extent of GH suppression. Cut-offs at 1.0 or 0.4 ng/ml are currently recommended with modern, highly sensitive GH assays. To establish assay specific GH nadir cutoffs for the 22kD GH specific IDS-iSYS assay, we examined 381 subjects (319 females, 62 males) with normal pituitary function. We analyzed the impact of age, body mass index (BMI), menstrual cycle and hormonal contraceptive therapy.

In 96% of all subjects the GH nadir was <0.4 ng/ml (92% <0.3 ng/ml, 81% <0.2 ng/ml and 56% <0.1 ng/ml). In all sex- and age-groups BMI was the major determinant, with lower GH nadirs in subjects with higher BMI. In 4 different BMI groups (A: <20 kg/m^2, $n=30$, B: 20–25 kg/m^2, $n=174$, C: 25–30 kg/m^2, $n=99$ and D: >30 kg/m^2, $n=77$) mean GH nadirs were as follows: A: 0.29 ng/ml, B: 0.15 ng/ml, C: 0.10 ng/ml and D: 0.07 ng/ml with significant differences between all groups except group C vs. D (A vs. B: $P=0.0043$, A vs. C, A vs. D, B vs. C, B vs. D: $P<0.0001$, C vs D: $P=0.057$). While age had no impact, men exhibited significantly lower mean GH nadirs compared to women (0.09 vs 0.14 ng/ml, $P<0.0001$). Premenopausal women on estrogen containing oral contraception (OC) ($n=20$) had significantly higher mean GH nadirs (0.36 ng/ml) compared to women not taking estrogen containing OC ($n=272$, 0.13 ng/ml, $P<0.044$), while the phase of the menstrual cycle had no impact.

Our findings confirm the need for lower cutoffs for the GH nadir if new sensitive GH assays are used, but also suggest adjustment to sex- and BMI can improve diagnostic sensitivity and specificity.

Cognitive functions in primary hypothyroidism on selenium supplementation

Marina Nikolic-Djurovic[1], Alberto Pereira[2], Johannes Smit[3], Olga Vasovic[4], Zvezdana Jemuovic[1], Svetozar Damjanovic[1], Milika Asanin[5], Dragan Pavlovic[6], Dragana Jankovic[1], Sandra Pekic[1], Dragana Miljic[1], Marko Stojanovic[1] & Milan Petakov[1]
[1]Clinic for Endocrinology, Diabetes and Diseases of Metabolism, Clinical Centre of Serbia, University of Belgrade, Belgrade, Serbia; [2]Department of Endocrinology and Metabolic Diseases Leiden University Medical Center, Leiden, The Netherlands; [3]Division of Endocrinology, Department of Internal Medicine, Radboud University Medical Centre, Nijmegen, The Netherlands; [4]Institute for Gerontology and Palliative Care, Belgrade, Serbia; [5]Clinic for Cardiology, Clinical Centre of Serbia, University of Belgrade, Belgrade, Serbia; [6]Faculty of Philosophy, University of Belgrade, Belgrade, Serbia.

Introduction

Selenium (Se) is a trace element that plays key roles in thyroid pathology. In patients with Hashimoto thyroiditis (HT), Se supplementation might reduce antibody levels and may provide additional beneficial effects, such as on cognition.

Aim

To evaluate cognitive function (cognitive decline) in patients on long-term levothyroxine replacement for primary hypothyroidism with and without selenium supplementation.

Design

Cross-sectional, case-control study.

Patients and methods

Sixty nine patients with HT (mean age 43.52 ± 14.33 yrs) on long-term levothyroxine replacement and 57 euthyroid healthy controls, matched for age, sex, and educational level, were included. HT patients were divided into 2 groups, 25pts with (Se+) and 44pts without selenium supplementation(Se-). Neuropsychological evaluation assessed general cognitive function(cognitive screening: MMSE, Visual- and Digit Span), attention span in visual and verbal modality (Numbers from WAIS and Visual span from WMS-R), conceptual tracking (TMT A and B), verbal divergent thinking (Phonemic fluency test, Listing of animals from BDEA, TMT B, Verbal fluency test).

Results

Selenium levels were within the normal range in all groups, but significantly higher in HT(Se+)vs controls (94.88 ± 20.63 vs 86.95 ± 14.95 mcg/l, $P<0.05$). TSH concentrations were higher in patients (both HT(Se+) and HT(Se-)) when compared to controls: (3.01 ± 1.66 and 3.01 ± 1.90 vs 1.77 ± 0.88 mU/l, $P<0.000$), but FT4 concentrations were not different: (12.81 ± 4.01 vs 12.46 ± 2.64 vs 12.93 ± 2.88 ng/l, $P>0.05$). TPOab concentrations were different, both between HT(Se+) and HT(Se-), as well as between patients and controls (1399.25 ± 1968.30 *vs* 4290.96 ± 3177.13 *vs* 20.48 ± 30.73 U/ml, $P<0.001$). Global cognitive function (MMSE) was not different between groups (29.16 ± 1.31 vs 29.16 ± 1.61 vs 29.54 ± 0.93, $P>0.05$), but conceptual tracking and verbal divergent thinking was different between all groups (TMTA:36.40 ± 12.85 vs 40.89 ± 21.89 vs 29.81 ± 11.57, $P<0.001$, TMTB:89.00 ± 27.88 vs 103.93 ± 48.81 vs 73.02 ± 24.10, $P<0.001$, KF:21.88 ± 5.61 vs 19.07 ± 5.65 vs 21.44 ± 5.11, $P<0.05$, FF:11.28 ± 3.37 vs 9.22 ± 3.69 vs 11.05 ± 3.44, $P<0.05$).

Conclusion

Patients treated for primary hypothyroidism according to routine clinical care guidelines show persistent impairments in cognitive functioning which were, in certain domains, improved with selenium supplementation. Future studies are still needed in order to provide reliable evidence to support selenium supplementation in a clinical practice.

Which is the best tool to use when initiating the differential diagnosis of a thyrotoxic patient? A challenge to current guideline recommendations

Carolina Perdomo[1], Elisa Gil Ramos[1], Gala Gutiérrez Buey[1], María Llavero[1], Javier Gargallo[1], Javier Arbizu[2], Magdalena de la Higuera[1] & Juan C Galofré[1]
[1]Department of Endocrinology. University of Navarra, Pamplona, Spain; [2]Department of Nuclear Medicine. University of Navarra, Pamplona, Spain.

Aim

Differential diagnosis (DD) of thyrotoxicosis is critical as the treatment of the three main causes of this condition (Graves' disease [GD], Toxic Multinodular

Goitre [TMG], and Thyroiditis [TS]) differs substantially. Recently published diagnostic algorithms investigating hyperthyroidism embrace the presence of thyrotropin receptor (TSH-R) antibodies (TRab) as the first and most cruicial diagnostic step. Although TRab measurement has important limitations (some can block or be neutral to TSH-R, or pass undetected by the assay), Guidelines recommend thyroid radionuclide scan (TRS) when TRab are absent. Our objective was to compare the TRab vs. TRS values in the DD of hyperthyroidism. We sought to analyse limitations of the current diagnostic Guidelines which could lead to misdiagnosis and improper treatment of thyrotoxicosis.
Methods
We conducted a retrospective study of 235 outpatients attended at our Centre from 2006 to 2016. Inclusion criteria were patients with overt or subclinical hyperthyroidism from whom TRab and TRS levels were taken at the time of diagnosis. SPSS 20.0 was used for statistical analysis. Pearson's correlation was applied to quantify the relationship between the two diagnostic tools.
Results
We grouped the sample in Gr. A: 89 (37.8%) those with positive TRab; Gr. B: 102 (43.4%) those with diffuse TRS uptake; and Gr. C: 146 (62.2%) those with negative TRab. All groups were partially overlapped. In Gr. A, the TRS reported a diffuse increase uptake (consistent with GD) in 63 (70.8%), heterogeneous uptake consistent with TMG in 21 (3.6%), and absent or low uptake consistent with TRS in 5 (5.6%). In Gr. B, only 63 (61.8%) had positive TRab. In Gr. C, up to 39 (26.7%) of individuals had a diffuse increased uptake in TRS. Pearson's r analysis between positive TRab and diffuse increased uptake was: 0.431 ($P = <0.001$).
Conclusions
Provided that a high diffuse uptake by TRS can only be associated with GD, our study suggests that the DD of thyrotoxicosis should not rely initially on TRab, as this approach may leave a third (29%) of patients misdiagnosed, and consequently, improperly treated. Our results support the value of thyroid scintigraphy as the first step in the DD of thyrotoxicosis.

Cardiovascular risk factors in patients with autoimmune thyroiditis

João Sérgio Neves[2], Catarina Cunha[1], Celestino Neves[2], Sofia Castro Oliveira[2], Oksana Sokhatska[3], Camila Dias[4], César Esteves[2], Miguel Pereira[2], José Luís Medina[1], Luís Delgado[3] & Davide Carvalho[1,5]
[1]Faculty of Medicine, University of Porto, Porto, Portugal; [2]Endocrinology Service, São João Hospital, Faculty of Medicine, University of Porto, Porto, Portugal; [3]Immunology Department, São João Hospital, Faculty of Medicine, University of Porto, Porto, Portugal; [4]Department of Biostatistics and Medical Informatics, Faculty of Medicine, São João Hospital, University of Porto, Porto, Portugal; [5]Instituto de Investigação e Inovação em Saúde, Faculty of Medicine, University of Porto, Porto, Portugal.

Background
Overt thyroid dysfunction is associated with an increased cardiovascular risk. The impact of subclinical hypothyroidism and autoimmunity in the increased cardiovascular risk remains controversial. Aim: To evaluate the interrelations between thyroid function, thyroid autoimmunity and cardiovascular risk factors, in patients with autoimmune thyroiditis (AIT).
Methods
353 subjects with AIT were evaluated. We defined three groups based on TSH levels: TSH < 2.5 μUI/ml, TSH 2.5–5.0 μUI/ml and TSH > 5.0 μUI/ml. We recorded thyroid function tests, thyroid autoimmunity, insulin resistance markers including Homeostasis Model Assessment for Insulin Resistance (HOMA-IR), lipid profile, homocysteine, C-reactive protein (CRP) and vitamin B12 levels. Statistical analysis was performed using Kruskal-Wallis test and Spearman correlations.
Results
Our sample comprised 94% females with a mean age of 47 ± 16.3 years. The group TSH > 5.0 μUI/ml presented higher levels of HOMA-IR when compared to the other two groups [2.96(1.76–4.59) in TSH > 5.0 μUI/ml vs 1.86(0.97–2.56) in TSH 2.5–5.0 μUI/ml and 1.58(1.06–2.46) in TSH < 2.5 μUI/ml, $P = 0.002$]. In the total group we observed positive correlations between free T3 (FT3) and both HDL ($r = 0.118$, $P = 0.028$) and ApoA1 ($r = 0.129$, $P = 0.024$); TSH was positively correlated with HOMA-IR ($r = 0.146$, $P = 0.018$) while free T4 (FT4) was negatively correlated with homocysteine ($r = -0.119$, $P = 0.041$). In the group TSH < 2.5 μUI/ml, positive correlations were found between TSH and both HDL ($r = 0.136$, $P = 0.031$) and homocysteine ($r = 0.147$, $P = 0.028$), FT4 and CRP ($r = 0.136$, $P = 0.037$) and also anti-thyroglobulin and ApoB ($r = 0.165$, $P = 0.013$); anti-thyroglobulin was negatively correlated with homocysteine ($r = -0.186$, $P = 0.006$). Negative correlations between anti-thyroglobulin, total cholesterol ($r = 0.371$, $P = 0.004$), LDL ($r = -0.325$, $P = 0.011$), ApoB ($r = -0.342$, $P = 0.022$) and lipoprotein(a) ($r = -0.470$, $P = 0.001$) were revealed in the group TSH 2.5–5.0μUI/ml. Regarding the group TSH > 5.0 μUI/ml, we found positive correlations between FT3 and HDL ($r = 0.358$, $P = 0.030$), vitamin B12 ($r = 0.398$, $P = 0.024$) and HOMA-IR ($r = 0{,}424$, $P = 0{,}031$); and between anti-thyroglobulin and homocysteine ($r = 0.383$, $P = 0.033$).
Conclusion
We observed significant correlations between thyroid function, thyroid autoimmunity, insulin resistance, lipid profile and homocysteine that may contribute to an increased cardiovascular risk in AIT.

Evaluation of the effectiveness of personalized radioiodine treatment in Graves' disease

Ana Fernandes[1], Teresa Faria[1], Ana Oliveira[1], Jorge Pereira[1] & Pedro Coelho[2]
[1]Centro Hospitalar são João, Porto, Portugal; [2]Universidade Fernando Pessoa, Porto, Portugal.

Aim
Radioiodine activities for the treatment of Graves' disease hyperthyroidism are still subject to discussion, as is the use of a fixed approach over a dosimetric one. We aimed to evaluate our success rate using a personalized dosimetric approach: instead of the "(MBq I-131 × g gland mass × 100)/(percentage uptake at 24 h)" activity calculation, we further adjusted for factors such as gender, age, diagnosis, 2 h and 4 h radioiodine uptake, previous medication, and clinical history.
Materials and methods
We reviewed data from all patients treated with radioiodine therapy (RIT) for hyperthyroidism at our department ($n = 179$), from January 2008 to January 2016, selected those with Graves' disease ($n = 118$), and excluded the ones without follow-up ($n = 11$). RIT was considered successful if either euthyroidism or hypothyroidism were achieved. We evaluated success rates differences between lower and higher activities. All statistical analyses were carried out using IBM SPSS version 21.0 for Mac. A type I error 0.05 was considered.
Results
107 patients were included (44.346 ± 13.07 years; 89 female). RIT was successful in 91.6% ($n = 98$), while 8.4% ($n = 9$) remained hyperthyroid. If we consider the success after the first RIT, 72.0% ($n = 77$) succeeded, while 28.0% ($n = 30$) remained hyperthyroid. 87 (81.3%) were submitted to a single therapy whereas 20 (18.7%) were submitted to multiple RIT. There were no significant outcome differences between the lower and higher activities used ($P = 0.061$).
The used activities ranged between 148 MBq and 703 MBq (335.92 ± 101.60 MBq).
Conclusion
Our results confirm RIT effectiveness in Graves' disease hyperthyroidism treatment. Although using inferior activities to those generally prescribed (200–800 MBq), we achieved higher success rates – comparable to the best reposted in the literature. There were no statistically significant outcome differences between the lower and higher activities used, highlighting the importance of tailored treatment approaches to warrant the best therapeutic outcome and while avoiding unnecessary exposure.

Citrus flavanones naringenin and hesperetin induced mild functional alteration in thyroids of old-aged Wistar rats

Marko Miler[1], Vladimir Ajdzanovic[1], Natasa Ristic[1], Branko Filipovic[1], Gordana Uscebrka[2], Dragana Miljic[3], Verica Milosevic[1] & Branka Sosic-Jurjevic[1]
[1]Institute for Biological Research "Sinisa Stankovic", University of Belgrade, Belgrade, Serbia; [2]Department of Veterinary Medicine, Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia; [3]Department of Neuroendocrinology, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Aging is a complex process characterized by a progressive decline in cellular function, alterations of the endocrine system and the increased incidence of thyroid diseases. Citrus flavanones naringenin (NAR) and hesperetin (HES) may contribute to maintenance of health at old age however they may also affect thyroid hormone economy. The aim of this study was to test weather NAR or HES administration alter thyroid functioning. NAR or HES were administrated orally (15 mg/kg) to male 24-month-old Wistar rats during 4 weeks. Control groups received vehicle, sunflower oil. Immunohistochemical staining of thyroglobulin (Tg), thyroxine (T_4) bound to Tg (T_4-Tg) and sodium iodide sysmporter (NIS) were performed. Immunopositivity of Tg or T_4-Tg in thyroid follicles were measured as intensity of optical density (OD) or relative intensity of fluorescence (RIF). Thyroid stimulating hormone (TSH) and total T_4 concentrations were measured in serum. After citrus flavanones treatments, thyroids showed Tg and T_4-Tg immunopositivity mainly in the colloid of the follicles. The obtained results showed increased ($P < 0.05$) intensity of OD for Tg and T_4-Tg RIF after both flavanones treatments, while NIS expression did not change. Serum TSH increased ($P < 0.05$) only after NAR, although T_4 remained unchanged after both treatments. In conclusion, citrus flavanones induced stronger expression of thyroid-specific proteins in gland of old-aged males. However, only NAR elevated serum TSH, being more potent than HES. This alteration is in line with preserved capacity of the thyroid to compensate the mild interference of flavanones treatments with thyroid hormone production in old-aged males.

The oxford multidisciplinary thyroid eye disease (TED) clinic; can short waiting times and use of steroid sparing agents (SSA) reduce total steroid dose and requirement for surgery/radiotherapy?

Helen Turner[1], Joel David[2] & Jonathan Norris[3]
[1]Department of Endocrinology, Churchill Hospital, Oxford, UK; [2]Department of Rheumatology, Nuffield Orthopaedic Hospital, Oxford, UK; [3]Oxford Eye Hospital, Oxford, UK.

Introduction
The Oxford multidisciplinary thyroid eye disease (TED) clinic comprising an oculoplastic surgeon, rheumatologist and endocrinologist with access to orthoptics, neuroradiology and radiotherapy was established in 2013. The aim was to facilitate rapid referral and treatment in a specialist centre in keeping with Amsterdam Declaration. Early use of steroid sparing agents (SSA) and recently rituximab forms part of the treatment regimen.
Methods
A retrospective, 4-year, single-centre, consecutive case series of patients with TED audited both outcomes (in terms of severity and activity) derived from the VISA classification and treatment modalities, at presentation and 1 year follow-up.
Results
104 patient records were analysed. Mean wait from referral to first review was 1 month with 42% of referrals originating from endocrinology departments. Mean age was 51.2 years. 26.0% ($n=27$) of patients were male and 35% were current/ex-smokers. Where thyroid biochemistry was available at referral ($n=80$): 51% were euthyroid, 45% hyperthyroid and 4% hypothyroid. TSHRAb was positive in 85% of patients checked compared to 62% of TPO Ab. Presenting signs included: ocular surface disease (68%), exophthalmos (53%), diplopia (45%), eyelid retraction (38%) and reduced vision (7%). Presenting activity was mild (VISA $\leq$3/10) in 69% and severe in 16% ($\geq$7); severity mild in 47.1% and severe in 20.2%. 1 year data ($n=36$) showed mild activity at 1 year in 95% (38.9% at referral) and 0% severe disease (33% at referral).
Intravenous methylprednisolone was administered to 30 patients; 47% required $\leq$1.5 g total with use of SSAs: methotrexate ($n=30$), azathioprine ($n=6$), ciclosporin ($n=10$) and Rituximab ($n=8$). Orbital decompression surgery was performed in 12.5% ($n=13$), squint surgery 12.5%, eyelid surgery 22% and orbital radiotherapy 8%.
Conclusion
Early use of SSAs has significantly reduced the overall steroid load in patients when compared to established European guidance (EUGOGO). This regimen confers a low orbital decompression and orbital radiotherapy rate.

GP204

24-month efficacy of a single radiofrequency ablation on autonomously functioning thyroid nodules

Stella Bernardi[1,2], Fulvio Stacul[2], Andrea Michelli[1], Veronica Calabrò[2], Fabiola Giudici[1], Chiara Dobrinja[2] & Bruno Fabris[1,2]
[1]Università degli Studi di Trieste, Trieste, Italy; [2]ASUITS, Trieste, Italy.

Background
Radiofrequency ablation has been advocated as an alternative to radioiodine and/or surgery for the treatment of autonomously functioning benign thyroid nodules. However, only a few studies have measured radiofrequency ablation efficacy on autonomously functioning benign thyroid nodules. The aim of this work was to evaluate the 24-month efficacy of a single session of radiofrequency ablation (performed with the moving shot technique) on solitary autonomously functioning benign thyroid nodules.
Methods
Thirty patients with a single, benign autonomously functioning thyroid nodule, who were either unwilling or ineligible to undergo surgery and radioiodine, were treated with radiofrequency ablation between April 2012 and May 2015. All the patients underwent a single radiofrequency ablation, performed with the 18-gauge needle and the moving shot technique. Clinical, laboratory, and ultrasound evaluations were scheduled at baseline, and after 1, 3, 6, 12, and 24 months from the procedure.
Results
A single radiofrequency ablation reduced thyroid nodule volume by 51, 63, 69, 75%, and 76% after 1, 3, 6,12, and 24 months, respectively. This was associated with a significant improvement of local cervical discomfort and cosmetic score. As for thyroid function, 33% of the patients went into remission after 3 months, 43% after 6 months, 50% after 12 months, and 70% after 24 months from the procedure. This study demonstrates that a single radiofrequency ablation allowed us to withdraw anti-thyroid medication in the majority of patients, who remained euthyroid afterwards.
Conclusions
This study shows that a single radiofrequency ablation was effective in 70% of patients with autonomously functioning benign thyroid nodules. Most importantly, patients responded gradually to the treatment, such that it is possible that longer follow-up studies might show greater response rates.

Association of vitamin D levels with thyroid function and autoimmunity

Luis Raposo[1,2], Sandra Martins[3,4], Daniela Ferreira[5], João Tiago Guimarães[4,5] & Ana Cristina Santos[2,5]
[1]Grupo de Estudo da Insulino-Resistência da Sociedade Portuguesa de Endocrinologia, Diabetes e Metabolismo, Portugal, Portugal; [2]Instituto de Saúde Pública da Universidade do Porto - EPIUnit, Universidade do Porto, Porto, Portugal; [3]Serviço de Patologia Clínica, Centro Hospitalar de S. João, Porto, Portugal; [4]Departamento de Biomedicina, Faculdade de Medicina, Universidade do Porto, Porto, Portugal; [5]Departamento de Epidemiologia Clínica, Medicina Preditiva e Saúde Pública, Faculdade de Medicina, Universidade do Porto, Porto, Portugal.

Introduction
Vitamin D is a hormone that acts through the Vitamin D receptor (VDR) not only on the skeletal system but on a great number of target tissues, including thyroid gland. In recent years the association of vitamin D with autoimmune thyroid diseases (AITD), has been suggested.
VDR gene polymorphisms had been associated with an increased risk of AITD. In addition a recent meta-analysis showed that AITD patients had lower level of 25-hydroxyvitamin D. However some studies have not confirmed the association between vitamin D levels and AITD. Furthermore, data on the effects of vitamin D in thyroid hormones and TSH serum levels are very poor.
The aim of our study was to evaluate the association of vitamin D levels with thyroid function and positivity for thyroid antibodies.
Material and methods
PORMETS is a nationwide, cross-sectional study in Portugal comprising a sample of 4095 adults. Five hundred participants were randomly selected to be included in the present study. A fasting venous sample was collected and serum calcium, PTH, 25-hydroxyvitamin D [25(OH)D], TSH, FT_4, FT_3 and thyroid antibodies were measured.
Results
Our study included 286 women and 214 men with a mean age of 53.4 years.
Free thyroxine (FT_4), free triiodothyronine (FT_3), TSH and thyroid antibody levels did not present any significant linear correlation with 25(OH)D levels.
After adjustment for sex and age, TSH, FT_4 and FT_3 levels did not present any significant association with 25(OH)D levels or with low vitamin D status.
Logistic regression analysis did not show any significant association of low vitamin D status with thyroid antibodies positivity, even after adjustment for several possible confounding variables.
Conclusion
Our results do not confirm the association of vitamin D levels with thyroid function and positivity for thyroid antibodies.

Early use of steroid-sparing agents in treatment of moderate-to-severely active thyroid eye disease

Zuzana Sipkova[1], Joel David[2], Helen Turner[3] & Jonathan Norris[1]
[1]Oxford Eye Hospital, Oxford, UK; [2]Nuffield Orthopaedic Centre, Oxford, UK; [3]Oxford Centre for Diabetes, Endocrinology and Metabolism, Oxford, UK.

Introduction
The management of active thyroid eye disease (TED) remains controversial. High dose intravenous methylprednisolone (IVMP) is the current recommended first-line treatment based on EUGOGO guidance. Such therapy has the potential for serious adverse effects. We present the outcomes of an alternative approach in the management of moderate-to-severely active TED, using steroid-sparing agents (SSAs) in conjunction with IVMP. Methotrexate is used as the first-line SSA alongside ciclosporin and rituximab depending on activity score.
Methods
Presented is a retrospective, 4-year, single-centre, consecutive case series of patients with moderate-to-severe TED treated using the Oxford protocol. Treatment modality, disease activity (derived from the VISA classification) and adverse effects are reported at initial presentation, 6- and 12-month follow-up.
Results
104 consecutive case notes were reviewed of TED patients treated by the TED MDT. 24 patients with moderate-to-severely active disease were identified (mean age 46.8 years; 12 female) with a mean pre-treatment VISA activity score of 5.5/10 (S.D. = 1.98; range 1–9). IVMP and an SSA was commenced in all patients. Mean total steroid dose was 2.72 g (S.D. = 1.4; 1.0–6.9). 38% of patients ($n = 9$) received 1.5 g of IVMP or less. Only two patients required >4.5 g of IVMP equating to the EUGOGO treatment protocol dose for this patient group. There was significant improvement in VISA activity score both at the intermediate review (mean score 2.7; S.D. = 2.8; $P < 0.001$; mean follow up 25.2 weeks) and at one year or last follow up (mean score 1.4; S.D. = 1.5; $P < 0.001$; mean follow up 48.0 weeks). Three patients stopped methotrexate due to a non-specific chronic cough, deranged liver function or nausea. No serious or long-term adverse effects were reported.
Conclusion
Based on our experience and outcomes, the initiation of an SSA with limited adjuvant IVMP is as an effective and safe therapy for moderate-to-severely active TED. This approach results in a significant reduction in disease activity with reduced total steroid load.

Prediction of response to methimazole based on clinical symptoms in new onset graves' patients, using neural networks

Hoon Sung Choi[1] & Won Sang Yoo[2]
[1]Kangwon National University Hospital, Chuncheon-si, Republic of Korea; [2]Dankook University Hospital, Cheonan-si, Republic of Korea.

Introduction
Anti-thyroidal drug (ATD) therapy is a treatment of choice for Graves' disease because of its effectiveness and low rate of adverse effect. Response to ATD or remission rate varies among individuals, although there were few useful clues for prediction of treatment response. We applied neural network model to predict response to methimazole, based on clinical symptoms at initial clinical symptoms.
Methods & Design
We reviewed 20 new onset Graves' patients and used their symptoms at initial diagnosis. A total of 12 symptoms were classified into 5 categories (general, cardiac, neuromuscular, psychologic, and gastrointestinal). In each category, the number of positive symptoms was considered the score of the category. Response to methimazole was defined as whether serum TSH normalized within 3 months. A total of six variables, 5 symptom categories and sex, were used for a 2-layer neural network model. Among 20 subjects, 15 subjects used in training set, and the other 5 subjects were use in model validation.
Results
The mean age of subjects was 49.3 ± 12.2 years and male subjects were 6 (30%). Our neural network model with 15 subjects as a training set showed sensitivity of 1.0 and specificity of 0.545 with AUC of 0.75 to predict normalization of serum TSH within 3 months. With same model, the estimated scores of the other 5 subjects corresponded to their actual outcomes.
Conclusion
Despite the limitation of small sample size, our neural network model showed promising performance to predict response to methimazole with patients' clinical symptoms in new onset Graves' patients.

Serum Interleukin-37 (IL-37) levels were increased and correlated with oxidative stress parameters in Hashimoto's Thyroiditis (HT) patients

Rosaria Maddalena Ruggeri[1], Teresa Manuela Vicchio[1], Angela Alibrandi[2], Salvatore Giovinazzo[1], Rosaria Certo[1], Giuseppe Giuffrida[1], Francesco Trimarchi[3], Sebastiano Gangemi[4] & Mariateresa Cristani[5]
[1]Division of Endocrinology, Department of Clinical-Experimental Medicine and Pharmacology, University of Messina, Messina, Italy; [2]Department of Economy, University of Messina, Messina, Italy; [3]University of Messina, Accademia Peloritana dei Pericolanti, Messina, Italy; [4]Division of Clinical Immunology and Allergology, Department of Human Pathology, University of Messina, Messina, Italy; [5]Department of Pharmaceutical Sciences and Health Products (SCIFAR), University of Messina, Messina, Italy.

Background
IL-37, member of the IL-1 family, is a natural suppressor of immune and inflammatory responses. Increased serum IL-37 levels were observed in several autoimmune diseases, including Graves' disease. No data on TH are available from the literature.
Materials and methods
We enrolled 45 euthyroid HT patients (5 M e 40 F, mean age 38.5 ± 12.6) and 50 age- and sex-matched healthy controls. None was on LT-4 therapy. Smokers, subjects with kidney failure, history of cancer or autoimmune, inflammatory and infection comorbidities were excluded. Serum IL-37 levels were measured by ELISA (kit IL-37 DuoSet Elisa, R&D System, Minneapolis, USA; minimum detectable dose 10 pg/ml). Specific serum tests, such as d-ROMs (derived Reactive Oxygen Metabolites) test and BAP (Biological Antioxidant Potential) test (Diacron International, Italy), were performed in all

subjects to investigate the changes in oxidative balance, and AGEs (Advanced Glycation End Products) were determined as a specific marker of oxidative stress.
Results
IL-37 levels were significantly higher in TH (mean ± s.d.: 999.59 ± 1064.93 pg/ml) than in controls (448.02 ± 498.96 pg/ml; $P=0.018$). In both groups, these values correlated negatively with age (TH, RS = −0.377 $P=0.016$; controls, RS = −0.404; $P=0.06$) and were tendentially higher in men than in women ($P=0.063$). Furthermore, there was a positive correlation between serum IL-37 levels and TSH, statistically significant in TH (RS = 0.412 $P=0.008$; in controls, RS = 0.418; $P=0.053$). The regression analysis showed a significant positive association between IL-37 and d-ROMs ($P=0.029$) and AGEs ($P=0.014$): if serum d-ROMs and AGEs levels increased, serum IL-37 levels also increased. A significant direct correlation between serum IL-37 levels and AGEs was also observed (RS = 0.578; $P=0.006$).
Conclusion
Serum IL-37 levels were significantly increased in TH patients and correlated with oxidative stress parameters. Given the anti-inflammatory properties, IL-37 could be an innovative research strategy for TH pathogenesis and therapy.

DOI: 10.1530/endoabs.49.GP208

GP209

The increased immunohistochemical expression of IL-23 in Hashimoto's thyroiditis but not in Graves' disease patients

Tatjana Zake[1,3], Sandra Skuja[3], Ieva Kalere[2], Ilze Konrade[1,2] & Valerija Groma[3]
[1]Riga East University Hospital, Riga, Latvia; [2]Department of Internal Medicine, Riga Stradins University, Riga, Latvia; [3]Institute of Anatomy and Anthropology, Riga Stradins University, Riga, Latvia.

Introduction
Recently, Th17 cells and their cytokines were identified to play an important role in the pathogenesis of thyroid autoimmunity. IL-23, produced by antigen presenting cells, is required for survival and differentiation of Th17 cells, and is known to guide T cells toward the Th17 phenotype. Its serum levels are increased in several autoimmune diseases, including Hashimoto's thyroiditis (HT), however, the expression level of IL-23 within thyroid tissue assessed by immunohistochemistry has not been addressed thoroughly before. The aim of our study was to estimate the levels of immunoexpression and distribution of IL-23 within thyroid tissue of patients with HT and Graves' disease (GD) and compare them with controls.
Materials and Methods
Forty seven adult patients presenting 21 cases of HT, 8 of GD, and 18 cases of ordinary colloidal goiter without autoimmune component, which served as control group, were enrolled in this study. Immunostaining was performed using an anti-IL-23 antibody (Santa Cruz Biotechnology, CA, dilution 1:50). Levels of immunopositivity for IL-23 were defined semiquantitatively.
Results
In HT patients the expression of IL-23 was detected both in the abundant inflammatory lymphocytic infiltrates characteristic of HT and follicular epithelial cells, whereas tissues obtained from GD patients demonstrated the weak thyrocytic expression predominantly. Majority of patients in controls showed negative or occasional expression of IL-23. The highest IL-23 immunopositivity was observed in HT patients, furthermore, it was significantly higher compared to the control group and GD ($P<0.001$; $P=0.043$, respectively). No difference was found between the expression of IL-23 in GD patients and the control group ($P=0.324$). Additionally, weak expression of IL-23 was observed in connective tissue septae and blood vessels in most HT patients.
Conclusion
Overexpression of IL-23 might play a role in the pathogenesis of HT, guiding T cells towards the Th17 phenotype and promoting the autoimmune inflammation of the thyroid gland.

GP210

Laser ablation of benign thyroid nodules without anesthesia: clinical tolerance, hazards and complications

Pablo Vidal-Ríos, Teresa Jiménez, Antonio Rodríguez, Laura Villas & Sebastian Vidal-Ríos
Coruna Endocrinology Center, La Coruna, Spain.

Laser ablation of thyroid nodules has been used for the last two decads (Pacella et al, 2000). Surprisingly, complications are less frequent in patients treated without anesthesia, probably because eventual pain is an useful alarm symptom, leading the operator to repositioning the fiber during the procedure (Pacella et al., 2015).
Material and methods
A total of 32 patients were included, without using local anesthesia. Nodules were solid, 5–72 ml volume, age 36–84 years, gender female (84%). Procedure included three phases: (1) Preparation 30 min (informed consent and final decision about anatomic approach); (2) Laser ablation 30 min (usually 3–8 paths, 3–5 illuminations each and total energy of 50–500 joules/cc); and (3) Observation 60 min (with ice collar and vital constants monitoring). A 1064 nm Nd-YAG laser from an EchoLaser generator (Elesta, Florencia-Italy) was used. Triple thyroid image (Ultrasound, Doppler and Elastography) was monitored using an Acusson 2000 Hellix platform (Siemens, Forchheim-Germany).
Results
30 of 32 patients (93.75%) would accept another ablation if necessary. Pain was refered as 1–6 of 10 (arithmetic mean 3.5; median 2). Difficulties were: cervical discomfort (4), excessive time of manipulation because short neck (1), transient mild hypertension (1), mild vasovagal reaction (1), small intra-thyroid hematoma (1) and a partial and transient Horner syndrome (1) resolved 3 months later.
Discussion
Clinical tolerance in general was spectacular. Major complaints were postural. Complications were mild and transient, although potentially risky. No cases of severe pain, voice change, fever, skin burn or cough were observed. In the future, preventive specific strategies (like careful identification of risky patients, laser cauterization of large feeding vessels or protective hydrodissection to protect vital organs) will be considered before laser ablation.
Conclusions
Clinical tolerance was very good. Complications were few, mild and transient, but potentially risky. This highlights the importance of identifying properly risky patients as well as the need of including preventive strategies.

Orbital ectopic thyroid mistaken for mestastases

Greta Jagucianskaite[1,2], Agne Petrenaite[1,2], Rasa Ziukaite[2] & Zydrune Visockiene[1,2]
[1]Vilnius University Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Klinikos, Centre of Endocrinology, Vilnius, Lithuania.

Introduction
Ectopic benign thyroid tissue outside the normal migration path of the thyroid is an extremely rare condition that, to our knowledge, has never been described in the orbit.
Clinical case
75-year-old woman with nodular thyroid was referred to Vilnius University Hospital Santariskiu Klinikos for fine needle aspiration biopsy. Her complaints were palpitations, difficulty swallowing, diplopia, *exophthalmos* with medial and –superior dislocation. Symptoms were progressing for 2 years, although laboratory testing always showed euthyreosis. Her thyroid-stimulating hormone (TSH) was 1.04 mU/l (normal 0.4–4.1 mU/l), anti-TPO antibodies – 1.9 kU/l (<5.61 kU/l) on admission. Fine needle aspiration biopsy and histological examination suggested diagnosis of Hurthle cell carcinoma and subject was referred to surgery.
Management and Outcome
After thyroidectomy histology revealed nodular thyroid hyperplasia and follicular adenoma. To exlude orbital malignancy head MRI was performed. Imaging

showed 18×14 mm in size, non-homogenic, contrast accumulating mass with well-defined margins in the inferior –lateral part of the orbit. Orbital tumor excision was performed and histological examination revealed tumor composed of micro-/macrofolicules with colloid. Folicular epithelium had no atypical changes, as confirmed by three independed pathologists. These criteria supported diagnosis of ectopic thyroid tissue. Due to patients noncompliance further postoperative period is unknown. A 5-year follow-up showed normal TSH levels of 3.07 mU/l, with 75 mcg/day levothyroxin therapy, anti-TPO antibodies – 0.2 kU/l, thyroglobulin 0.91 mgk/l (normal 0.83–55 mgk/l). Once no primary or secondary tumors were detected we concluded that the thyroid tissue in the orbit of our patient was ectopic.

Conclusion

Ussualy ectopic benign thyroid tissue could be found in the normal migration path of the thyroid. However, we are presenting the extremely rare case of benign thyroid tissue located in the orbit, suggesting the extensive diagnostic approach in unclear cases.

Association of the Period3 clock gene polymorphism with autoimmune thyroid diseases

Nafiye Helvaci[1], Seda Oguz[1], Serkan Kabacam[2], Erdem Karabulut[3], Filiz Akbiyik[4], Mehmet Alikasifoglu[2] & Alper Gurlek[1]

[1]Division of Endocrinology and Metabolism, Hacettepe University Faculty of Medicine, Ankara, Turkey; [2]Department of Medical Genetics, Hacettepe University Faculty of Medicine, Ankara, Turkey; [3]Department of Biostatistics, Hacettepe University Faculty of Medicine, Ankara, Turkey; [4]Department of Medical Biochemistry, Hacettepe University Faculty of Medicine, Ankara, Turkey.

Background

Circadian rhythmicity is generated by a set of genes including Period3. Changes in the expression of Period3 and other clock genes have been linked with regulation of the immune system. Period3 polymorphisms have been associated with circadian disruption and so immune system dysregulation and altered secretion of several cytokines, which can lead to inflammatory and autoimmune disorders.

Aim

To investigate the influence of a polymorphism in Period3 gene on susceptibility and severity of autoimmune thyroid diseases (AITD).

Methods

A total of 125 unrelated patients (mean age 35.94±9.9 years) with AITD (GD, 69; HT, 56) and 115 unrelated healthy controls (mean age 31.3±8.7 years) were included. Serum levels of IL-6 (pg/ml) and TNF-α (pg/ml) were determined by ELISA method. Period3 gene polymorphism rs2797685 was identified by PCR-RFLP.

Results

Subjects expressing the GA+AA genotype of the selected polymorphism in Period3 gene demonstrated a significantly higher risk of AITD compared to the population expressing the GG genotype (OR = 1.83, CI: 1.04-3.20; $P = 0.033$). No significant associations of genotypes were detected with the age of onset of disease, presence and severity of orbitopathy in GD and thyroid function status at diagnosis and daily dose of thyroxine per kg body weight in HT. AITD and control groups were similar in terms of mean IL-6 levels, but mean serum IL-6 level was significantly lower in the group with GA genotype than in the group with GG genotype in GD ($P = 0.013$). Mean level of TNF-α was significantly higher in patients with AITD compared with controls ($P < 0.001$) but TNF-α levels were not significantly different in the groups of different genotypes of the selected polymorphism of the Period3 gene.

Conclusion

This study provides the first evidence for a genetic association between AITD and the Period3 gene, highlighting the possible relevance of polymorphisms in clock genes in the etiopathogenesis of AITD.

IgG4-related fibrous variant of Hashimoto thyroiditis in a non-Asian woman

Sónia do Vale[1,2], Ana Filipa Martins[1], Cristiana Costa[1], Lucas Batista[3] & Margarida Mendes de Almeida[4]

[1]Endocrinology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; [2]Endocrinology Department, Lisbon Medical School, Lisbon, Portugal; [3]Surgery Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal; [4]Pathology Department, Santa Maria Hospital, North Lisbon Hospital Center, Lisbon, Portugal.

Introduction

First described in 2009, IgG4-related thyroid disease includes several subcategories: Riedel's thyroiditis, fibrous variant of Hashimoto thyroiditis (FVHT), IgG4-related Hashimoto thyroiditis (HT) and Graves' disease with elevated IgG4. It is rare, with most cases described in Japan and characterized by increased IgG4 plasma cells at immunostaining.

Case Report

A 59-year-old Caucasian women, without known Asian ancestry, was observed at the endocrinology department due to neck swelling over the previous 4 months. She reported dyspnea at some neck positions, fatigue and constipation. She presented a diffusely enlarged very hard thyroid, with some nodules and reduced mobility. Laboratory evaluation revealed primary hypothyroidism, very elevated titles of anti-thyroglobulin and anti-peroxidase antibodies, elevated erythrocyte sedimentation rate and G immunoglobulins (3400 mg/dl, reference range, RR: 751–1560), elevated IgG4 (267 mg/dl, RR: 4–86) and κ-dominant light chains. There was no monoclonal band; IgA and serum calcium levels were normal. Ultrasound confirmed an enlarged heterogeneous thyroid, with nodules and small calcifications. Cytology was compatible with lymphocytic thyroiditis. The CT scan additionally revealed multiple latero-cervical ganglia, esophageal diversion, airway impression and reduction of the nasopharynx lumen. There was no evidence of malignancy, infection, other autoimmune disorders or non-neck involvement. Euthyroid state was obtained with levothyroxine reposition and total thyroidectomy was performed. Histology revealed a FVHT with elevated IgG4-positive plasma cells and IgG4/IgG ratio. After surgery, serum IgG levels decreased and IgG4 levels became normal.

Discussion

The very hard rapidly enlarging thyroid, short disease duration, high antibody titers, hypothyroidism, diffuse thyroid involvement, no evident extrathyroidal invasion, increased inflammatory parameters, IgG and k dominant profile and elevated IgG4 that normalized after surgery, suggested a fibrous IgG4-HT. Histology and immunostaining confirmed an IgG4-related FVHT. Although very rare in non-Asian countries, it is important to suspect and confirm an IgG4-related thyroid disease, allowing an adequate diagnosis, treatment and follow-up.

Thyroid hormones deficiencies and poor outcome in chronic heart failure outpatients

Vincenzo Triggiani[1], Brunella Licchelli[1], P Terlizzese[2], D Grande[2], C Rizzo[2], MS Lattarulo[2], T Leopizzi[2], I Gioia[2], Vito Angelo Giagulli[1], Edoardo Guastamacchia[1] & Massimo Iacoviello[3]
[1]Endocrinology and Metabolic Diseases Unit, Interdisciplinary Medicine Department, University of Bari, Bari, Italy; [2]School of Cardiology, University of Bari, Bari, Italy; [3]Cardiology Unit, Cardiothoracic Department, Polyclinic Hospital of Bari, Bari, Italy.

Background
Hypothyroidism and low T3 syndrome frequently occur in HF patients.
Aim of the study
To evaluate in a large sample of CHF patients the association between thyroid hormone deficiencies and poor outcome.
Methods and results
From 2006 to 2015, we screened 712 consecutive CHF outpatients (551 males, 64 ± 14 years, left ventricular ejection fraction (LVEF) 33 ± 10%, NYHA class 2.3 ± 0.6, NTproBNP 2153 ± 4696 pg/ml, GFR-EPI 71 ± 25 ml/min*1.73 m^2) in stable clinical conditions (> 1 month) and in conventional therapy. All patients underwent assessment of thyroid function. A total of 34 patients were excluded for hyperthyroidism; among the remaining 678, 58 (9%) showed a TSH level above the upper normal limit, but below 10 microU/ml, 23 (3%) a TSH value above 10 microU/mL, and 20 patients (3%) low fT3 (LT3) levels without changes in TSH levels. During a mean follow-up of 38 months, 122 patients died (101 for cardiovascular causes) and 202 experienced at least one admission for acute decompensated heart failure. TSH > 10 microU/mL (HR:2.96; 95%CI: 1.54–5.68; *P*: 0.001) and LT3 (HR: 3.79; 95%CI: 1.91–7.54; *P* < 0.001), but not high TSH < 10 microU/mL (HR: 1.59; 95%CI: 0.871–2.91; *P*: 0.13), were associated with an increased risk of death at univariate analysis. At multivariate Cox regression analysis, after correction for the presence of NYHA class 3, LVEF < 35%, NTproBNP > 1000, systolic arterial pressure < 100 mm Hg and GFR-EPI < 60 ml/min, only LT3 remained significantly associated with events (HR: 2.75; 95%CI:1.38–5.49; *P*: 0.004). When the occurrence of heart failure hospitalization was considered, high TSH levels with a value < 10 microU/ml (HR 1.82; 95% CI: 1.18–2.83; *P* < 0.01), TSH > 10 microU/ml (HR 2.84; 95%CI:1.61–5.01; *P* < 0.001) and LT3 (HR: 3.33; 95%CI: 1.89–5.88; *P* < 0.0001) were all associated with events at univariate regression analysis. At multivariate regression analysis TSH > 10 microU/ml (HR: 1.91; 95%CI:1.06–3.46; *P*:0.03) and LT3 (HR: 2.39; 95%CI: 1.36–4.24; *P*:0.002), but not high TSH with value < 10 microU/ml, remained associated with HF hospitalization.
Conclusions
In this observational study on a large cohort of CHF outpatients, we found that impaired thyroid function, particularly when high levels of TSH (> 10 microUI/ml) and low T3 levels are considered, has an independent adverse impact on CHF events.

Hypothyroidism and heart failure outcome: a study with a long-term follow-up

V Triggiani[1], B Licchelli[1], C Rizzo[2], D Grande[2], P Terlizzese[2], T Leopizzi[2], I Gioia[2], VA Giagulli[1], E Guastamacchia[1] & M Iacoviello[3]
[1]Endocrinology and Metabolic Diseases Unit, Interdisciplinary Medicine Department, University of Bari, Bari, Italy; [2]School of Cardiology, University of Bari, Bari, Italy; [3]Cardiology Unit, Cardiothoracic Department, Polyclinic Hospital of Bari, Bari, Italy.

Background
Hypothyroidism (HT) has been demonstrated to be associated to heart failure (HF) progression.
Aim of the study
To evaluate the impact of HT on the progression of HF during a long-term follow-up.
Methods
From 2006 to 2015, we evaluated 675 consecutive CHF outpatients (523 males, 64 ± 13 years) in stable clinical conditions (> 1 month) and in conventional therapy. They underwent a clinical evaluation, 12-lead ECG, echocardiogram, blood pressure measurement and a routine chemistry. They have been carefully evaluated for the presence of thyroid diseases. The follow-up was extended on a median value of 47 months, for a maximum of 123 months. Thyroid function has been evaluated every 4 months, more frequent (every 6 weeks) for patients receiving levothyroxine. The onset of HT during follow-up was defined as detection of TSH values above the upper limit. When HT was detected, thyroid replacement therapy was started according to guidelines. During follow-up were also evaluated hospitalizations related to exacerbation of HF and death.
Results
Four hundred and fifty-five patients (67.7%) were euthyroid at the enrolment and showed a normal thyroid function during the follow-up; in 80 patients (11.8%) there was a previous diagnosis of HT; in 40 patients (5.9%) the HT was detected at the time of enrolment; 52 patients (7.7%) developed HT during the follow-up. To avoid confounding factors, we compared patients in euthyroid status at the enrolment and during follow-up and patients with HT at the enrolment. At univariate Cox regression analysis, a significant association between HT and the events, i.e. mortality for all causes (HR: 1.60; 95% CI: 1.08–2.38; *P*:0.019) and hospitalization for HF worsening (HR: 2.13; 95% CI: 1.54–2.96; *P*: < 0.001) was found. At multivariate Cox regression analyses, HT remained associated only with HF hospitalization (HR: 1.58; 95% CI: 1.09–2.29; *P*:0.015), but not with mortality (HR: 1.05;95% CI:0.67–1.65; *P*:0.819), after correction to LVEF < 35%, GFR < 60 ml/min/m^2, NTproBNP > 1000 pg/ml, NYHAIII, PA 95 mmHg.
Conclusion
In a long-term follow-up, HT is independently associated with hospitalization due to HF worsening, but not with mortality. We hypothesise that HT is able to induce hemodynamic instability leading to hospitalization, but, probably, its correction with thyroid hormone therapy could in part blunt its impact on patients' survival.

GP216

The correction of TSH with thyroid replacement therapy is associated with a better outcome in chronic heart failure patients

V Triggiani[1], B Licchelli[1], D Grande[2], C Rizzo[2], P Terlizzese[2], VA Giagulli[1], M.S Lattarulo[2], T Leopizzi[2], I Gioia[2], E Guastamacchia[1] & M Iacoviello[3]
[1]Endocrinology and Metabolic Diseases Unit, Interdisciplinary Medicine Department, University of Bari, Bari, Italy; [2]School of Cardiology, University of Bari, Bari, Italy; [3]Cardiology Unit, Cardiothoracic Department, Polyclinic Hospital of Bari, Bari, Italy.

Background
It has been previously demonstrated that thyroid hormone deficiency is associated with a worse outcome in patients affected by chronic heart failure (CHF). However, few data are available about the effects of thyroid replacement therapy on the prognosis of patients.
Aim of the study
The aim of the study was to evaluate the relationship among thyroid replacement therapy, correction of thyroid stimulating hormone (TSH) serum levels and outcome of a series of CHF outpatients.
Methods
We screened CHF outpatients in stable clinical conditions (> 1 month) and in conventional therapy. All patients underwent a baseline clinical evaluation, a 12-lead ECG, an echocardiogram and routine blood tests. Thyroid hormones were assessed at the enrolment and routinely during follow-up (every 3–4 months or every 6–8 weeks if TSH level was altered at the previous control). All patients with history or newly diagnosed hypothyroidism were managed by endocrinologists. We considered hypothyroidism corrected when TSH serum levels were normalized by thyroid replacement therapy (levothyroxine).
Results
Hypothyroidism was diagnosed in 180 patients (121 males, 67 ± 12 years, left ventricular ejection fraction, LVEF, 33 ± 10%, NYHA class 2.5 ± 0.5, NTproBNP 2125 ± 2975 pg/ml, GFR-EPI 64 ± 22 ml/min*1.73 m^2) out of 712 patients. Twenty-four patients were excluded because they were lost at follow-up or died within the first 3 months or because endocrinologists did not prescribe

levothyroxine for TSH values not high enough. Among the remaining 156 patients in which levothyroxine was prescribed, in 111 patients a normal TSH value was obtained. During a mean follow-up of 38 months, 29 patients died (25 for cardiovascular causes) and 62 experienced at least one admission for acute decompensated heart failure. The failure in TSH correction was associated with an increased risk of all cause of death (HR: 3.31; 95% CI: 1.59–6.86; *P*: 0.001) and of heart failure hospitalization (HR: 2.27; 95% CI: 1.36–3.79; *P*: 0.002). At Cox multivariate analysis the failure in TSH correction remained associated with all cause mortality (HR: 2.57; 95% CI: 1.20–5.51; *P*: 0.002) and with heart failure hospitalization (HR: 1.78; 95% CI: 1.05–3.01; *P*: 0.03) after correction for NYHA class 3, LVEF $<$ 35%, NTproBNP $>$ 1000, systolic blood pressure $<$ 100 mmHg and GFR-EPI $<$ 60.

Conclusion

Our results support the possibility that hypothyroidism correction could improve the prognosis of CHF patients, although randomized controlled trials should be designed in order to demonstrate this hypothesis.

Thyroid function in heart failure with preserved ejection fraction (HFpEF) – evaluation of serum and myocardial thyroid hormones in an animal model of HFpEF

João Sérgio Neves[1,2], Catarina Vale[2], João Almeida-Coelho[2], Soledad Bárez-López[3,4], Maria Jesus Obregon[3], Ana Isabel Oliveira[1], André Lourenço[2], Inês Falcão-Pires[2], Davide Carvalho[1,5] & Adelino Leite-Moreira[2]

[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]Departamento de Cirurgia e Fisiologia, Unidade de Investigação Cardiovascular, Faculdade de Medicina, Universidade do Porto, Porto, Portugal; [3]Department of Endocrine and Nervous System Pathophysiology, Instituto de Investigaciones Biomédicas Alberto Sols, Consejo Superior de Investigaciones Científicas (CSIC)-Universidad Autónoma de Madrid, Madrid, Spain; [4]Department of Endocrine, U-708, Center for Biomedical Research on Rare Diseases (Ciberer), Instituto de Salud Carlos III, Madrid, Spain; [5]Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Faculdade de Medicina, Universidade do Porto, Porto, Portugal.

Introduction

Thyroid hormones play a central role in the regulation of the cardiovascular system. Heart failure with preserved ejection fraction (HFpEF) is responsible for more than 50% of all heart failure cases and its main pathophysiological alteration is diastolic dysfunction. Diminished thyroid function is known to predominantly impair diastolic function, however the thyroid hormone status in HFpEF remains largely unknown.

Methods

We evaluated an animal model of HFpEF, ZSF1 Obese rats (ZSF1-Ob, $n=13$), and their control group, ZSF1 Lean rats (ZSF1-Ln, $n=11$), with serial echocardiography followed by invasive hemodynamic recordings and tissue collections at 20 weeks. Serum TSH was quantified by ELISA. Thyroxine (T4) and triiodothyronine (T3) were quantified in serum, left ventricle and visceral adipose tissue by radioimmunoassay (RIA).

Results

At 20 weeks of age, ZSF1-Ob group developed HF with diastolic dysfunction, as shown by an increased E/E' on echocardiography, a prolonged time constant of isovolumetric relaxation, an elevated end-diastolic pressure and upward shifted end-diastolic pressure-volume relationship on invasive hemodynamic evaluation. Serum levels of thyroid hormones were significantly decreased in ZSF1-Ob rats (T3: 5.96 ± 4.65 vs 35.85 ± 9.39 ng/dL in ZSF1-Ln, $P<0.001$; T4: 1.51 ± 0.64 vs 3.49 ± 1.35 µg/dl in ZSF1-Ln, $P<0.001$), while the levels of serum TSH were not significantly different between the two groups (0.65 ± 0.38 ng/ml in ZSF1-Ln vs 0.79 ± 0.57 ng/ml in ZSF1-Ob, $P=0.531$). Left ventricle levels of thyroid hormones were significantly decreased in ZSF1-Ob rats (T3: 3.87 ± 0.85 vs 10.51 ± 7.91 ng/g in ZSF1-Ln, $P=0.012$; T4: 0.99 ± 0.43 vs 2.02 ± 0.60 ng/g in ZSF1-Ln, $P=0.016$). The levels of T3 and T4 in visceral adipose tissue were not significantly different between the two groups.

Conclusion

We observed a decrease in serum and myocardial thyroid hormone levels in an animal model of HFpEF. This may contribute to impaired diastolic function and, therefore, may constitute an interesting therapeutic target in HFpEF.

STAT6 deficiency ameliorates Graves' disease severity by suppressing thyroid epithelial cell hyperplasia

Bingbing Zha

Department of Endocrinology, Fifth People's Hospital of Shanghai Fudan University, Shanghai, China.

Signal transducer and activator of transcription 6(STAT6) is involved in epithelial cell growth. However, little is known regarding the STAT6 phosphorylation status in Graves' disease (GD) and its role in thyroid epithelial cells (TECs). In this study, we found that STAT6 phosphorylation (p-STAT6) was significantly increased in TECs from both GD patients and experimental autoimmune Graves' disease mice and that STAT6 deficiency ameliorated GD symptoms. Autocrine IL-4 signalling in TECs activated the phosphorylation of STAT6 via IL-4R engagement, and the downstream targets of STAT6 were Bcl-xL and cyclin D1. Thus, the IL-4-STAT6-Bcl-xL/cyclin D1 pathway is crucial for TEC hyperplasia, which aggravates GD. More importantly, *in vitro* and *in vivo* experiments demonstrated that STAT6 phosphorylation inhibited by AS1517499 decreased TEC hyperplasia, thereby reducing serum T3 and T4 and ameliorating GD. Thus, our study reveals that in addition to the traditional pathogenesis of GD, in which autoantibody TRAb stimulates thyroid-stimulating hormone receptors and consequently produces T3, T4, TRAb could also trigger TECs producing IL-4, and IL-4 then acts in an autocrine manner to activate p-STAT6 signalling and stimulate unrestricted cell growth, thus aggravating GD. These findings suggest that STAT6 inhibitors could be potent therapeutics for treating GD.

Delayed TSH recovery after dose adjustment during TSH-suppressive levothyroxine therapy in patients with differentiated thyroid cancer

Hye In Kim, Tae Hyuk Kim, Young Nam Kim, Hosu Kim, So Young Park, Yun Jae Chung, Jae Hoon Chung & Sun Wook Kim

[1]Samsung Medical Center, Seoul, Republic of Korea; [2]Chung-Ang University Hospital, Seoul, Republic of Korea.

Background

Delayed thyroid-stimulating hormone (TSH) recovery during treatment of Graves' disease is caused by long-term excessive thyroid hormone, which results in down-regulation of pituitary thyrotropic cells. However, it is unknown whether delayed TSH recovery exists after levothyroxine (LT4) dose adjustment in patients with differentiated thyroid cancer (DTC) who are taking a suppressive dose of LT4.

Methods

We retrospectively reviewed 97 DTC patients who had a reduced LT4 dose while receiving excessive LT4 for TSH suppression. TSH levels at baseline (point 1), 6 months (point 2), and 12-18 months (point 3) after LT4 dose adjustment were compared with each other. A delayed TSH recovery group whose TSH levels exceeded target TSH levels (according to recent guidelines) between points 2 and 3 was identified.

Results

In patients with LT4 reduction, the median TSH level at point 3 was significantly higher than that at point 2 [0.17 vs 0.09 µIU/ml; $P<0.001$). The delayed TSH recovery group (44.3%, 43 of 97 patients) showed increased body weight during follow-up (60.84–62.73 kg; $P=0.01$), although TSH levels remained in the target range. A lower LT4 dose per body weight (LT4 dose/weight) after reduction [HR (95% CI), 0.01 (0.00–0.54); $P=0.03$], greater changes in the LT4 dose/weight [1.10 (1.00–1.22); $P=0.04$], and higher BMI before surgery [1.19 (1.03–1.38); $P=0.01$] predicted the occurrence of delayed TSH recovery.

Conclusions

Delayed TSH recovery was commonly observed after LT4 dose adjustment was performed as recommended by dynamic risk stratification. Six months may not be enough time to evaluate real thyroid hormone status by TSH levels.

Analysis of a large cohort of subjects with thyroid hemiagenesis (THA) reveals random seasonality in the dates of birth

Ewelina Szczepanek-Parulska[1], Ariadna Zybek-Kocik[1], Marek Niedziela[2], Agata Czarnywojtek[1] & Marek Ruchala[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of Paediatric Endocrinology and Rheumatology, Poznan University of Medical Sciences, Poznan, Poland.

Introduction
In the etiology of thyroid dysgenesis (TD) an interplay between genetic and environmental factors is thought to play a crucial role. Data from previous studies on association between the season of birth and the incidence of TD causing congenital hypothyroidism (mainly agenesis and ectopy) are conflicting. To date, seasonality of births have not been analysed yet in regard to congenital absence of one thyroid lobe (thyroid hemiagenesis, THA).
Patients and Methods
Dates of birth of 102 patients diagnosed with THA were analysed and compared to 102 control subjects with no thyroid pathology matched for age and gender. Both groups were subdivided according to the month of birth (I-XII), season of birth (spring, summer, autumn, winter) and quarter (1–4) of the year. The differences were analysed statistically.
Results
Distribution of the months of birth in the group of patients with THA was asymmetric; smaller number of patients were born in the 4th (X-XII) quarter of the year (19 patients) vs 1st (28 patients), 2nd (29 patients) and 3rd (26 patients). Similarly, smaller number of patients were born in autumn (IX-XI) – 19 patients if compared to other seasons of the year (winter – 27 patients, spring – 27 patients, summer – 29 patients). However, if the studied group was compared to the control group, the difference in the distribution of the months of birth was at the border of statistical significance ($P < 0.0923$). Furthermore, if the studied and control group were subdivided into four quarters or seasons, and then compared, the difference was definitely not statistically significant.
Conclusions
An analysis of the largest so far reported cohort of patients with THA indicate that environmental factors including intrauterine exposure to maternal seasonal viral infections or variable vitamin D availability seem not to play a significant role in pathogenesis of THA.

Thyroid hormone T3 protects mice from fasting induced skeletal muscle atrophy by counteracting autophagy

Sarassunta Ucci[1], Valentina Russi[1], Maria Giulia Santaguida[2], Marco Centanni[2], Viviana Moresi[3] & Cecilia Verga Falzacappa[1,2]
[1]Pasteur Institute, Rome, Italy; [2]Sapienza, University of Rome, Medical Surgical Sciences and Biotechnologies Department, Rome, Italy; [3]Sapienza, University of Rome, Department of Anatomy, Histology, Forensic Medicine and Orthopedic, Section of Histology, Rome, Italy.

Purpose
Skeletal muscle has been recognized as a thyroid hormones (THs) target for contractile function, regeneration, metabolism and glucose disposal. Despite a role in regulating muscle development has been described, little is known about the role of THs in regulating muscle homeostasis in a pathological state such as food deprivation induced atrophy. The purpose of this study is to evaluate whether thyroid hormones may hamper the fasting induced skeletal muscle atrophy and to investigate the mechanisms involved.
Methods
Preliminary data on C2C12 myotubes have suggested that T3 could counteract the starvation induced atrophy *in vitro.* Based on these results, BALB/C male mice (8–10 weeks) were used for *in vivo* experiments. Animals were food-deprived (STV) for 24 and 48 hours to induce muscle atrophy and daily injected intraperitoneally with T3 (100 ug/kgBW) or vehicle (NaCl 0,95%) as controls. Tibialis anteriors were taken at the end of the experiments. Morphological analyses were performed on hematoxylin/eosin stained sections. ATG7-Mrna was evaluated by Sybr-Green qRT-PCR and LC3II/Lc3I was evaluated by western blot.
Results and conclusions
As a sign of skeletal muscle atrophy, the STV group showed a significant ($P < 0.001$) reduction in the Cross-Sectional-Area of the myofibers, compared to the control group; on the contrary the T3 treated group (STVT3) ensures the maintenance of the fiber size. Protein degradation in skeletal muscle cells is mediated by the autophagic/lysosomal pathway. The core autophagic machinery is composed of ATG (autophagy-related) proteins. One ATG family member, Atg7, activates enzyme facilitating microtubule-associated protein-light-chain3 (LC3)-phosphatidylethanolamine conjugation. The presence of T3 was able to significantly reduce ATG7 mRNA expression, moreover the hormone significantly reduces LC3II/LC3I protein expression, when compared to STV mice ($P < 0,05$). On the whole our results suggest that T3 treatment can reduce fasting induced skeletal muscle atrophy by counteracting the autophagic process.

Will it be useful to measure PTH at 4 hours post thyroidectomy to decide for calcium replacement? 1st result of a prospective study

Sílvia Silva[1], Ana Rafael[1], Ricardo Marques[1], Luisa Moniz[1], Carlos Costa[1], Ricardo Capitão[2], Catarina Saraiva[2], Clotilde Limbert[2], Luis Fernandes[1] & Rogério Matias[1]
[1]Surgery, Egas Moniz Hospital, Lisboa, Portugal; [2]Endocrinology, Egas Moniz Hospital, Lisboa, Portugal.

Introduction
Calcium replacement after Thyroid surgery has been changing along times. The aim for this replacement is to avoid hypocalcaemia effects after thyroid surgery but not all the patients seem to need it. Parathyroid hormone (PTH) has a short half-life after its release into the bloodstream, making it a good marker of calcium metabolism in short time after surgery.
Method
Prospective study of Endocrine Surgery Multidisciplinary group of one Centre between March and December of 2016. Calcium replacement was done according to a protocol defined by multidisciplinary group after PTH measurement. PTH values were considered normal above 15 pg/ml. Data were analyzed using SPSS.
Results
96 patients underwent total thyroidectomy vs totalization of thyroidectomy. 5 were excluded since they were admitted at ICU and protocol was not implemented. PTH was measured 4 hours after surgery.
From the 91 patients, 74 had normal PTH levels. The remaining patients (17) started calcium replacement according to established protocol and showed no symptoms of hypocalcaemia.
Considering group with normal PTH, at day one after surgery, 41 had normal calcium levels (*P* 0,01 on correlation analysis) and 33 had low levels. This last group started the protocol of calcium replacement and at day two after surgery were observed higher calcium levels (*P* 0,001 at linear analysis) and didn't refer hypocalcaemia symptoms.
Our Sample has a significance of 0.05 in the non-parametric, Q-square and Kolmogorov-Smirnov test.
Conclusion
Measuring PTH 4 hours after surgery is helpful to decide which patients should start calcium replacement, using PTH value cut-off of 15 pg/ml.

Endogenous TH metabolite 3-iodothyronamine (T1AM) and synthetic thyronamine-like analogues SG-1 and SG-2 induce autophagy in human glioblastoma cells (U-87MG)

Lorenza Bellusci[1], Martina Sabatini[1], Giulia Nesi[2], Simona Rapposelli[2], Leonardo Rossi[3], Paola Lenzi[4], Francesco Fornai[4], Riccardo Zucchi[1] & Grazia Chiellini[1]
[1]Department of Pathology, University of Pisa, Pisa, Italy; [2]Department of Pharmacy, Pisa, Italy; [3]Department of Clinical & Experimental Medicine, Pisa, Italy; [4]Department of Translational Research and New Technologies in Medicine and Surgery, Pisa, Italy.

Endogenous TH metabolite 3-iodothyronamine (T1AM) and recently developed thyronamine-like synthetic analogues SG1 and SG2 have emerged as neuroprotective agents. Autophagy has proved to be an effective therapeutic approach for neurodegenerative diseases. Therefore we investigated whether these compounds can induce autophagy in human glioblastoma cells (U-87MG). Cultured U-87MG cells were initially treated with 1 μM T1AM, SG-1, SG-2 or vehicle for 30', 4, 8 and 24 h and autophagy was monitored morphologically by assessing the presence of autophagic vacuoles and LC3-II puncta formation with transmission electron microscopy (TEM) and immunofluorescence (IF) microscopy, respectively. In addition, cellular lysates were subjected to western

blotting to assess the accumulation of microtubule-associated protein 1 light chain 3 (LC3). This protein is widely used as a marker for autophagy because it is a structural protein vital in autophagosome formation. TEM and IF microscopy showed a significant time dependent increase of autophagy-like vacuoles density and LC3 punta formation in U-87MG cells exposed to the treatment with test compounds, with T1AM and SG-1 being the most effective. Along with extensive cytoplasmic vacuolization, western blotting analysis revealed significant up regulation of LC3-II expression ($P<0.01$). Finally, we extended our analysis to examine the role played by our test compounds on the PI3K–AKT–mTOR pathway that has been suggested to play an important role in the regulation of autophagy in mammalian cells. We carried out WB for Akt, phosphorylated Akt (pAkt) and we calculated the ratio pAkt/Akt in vehicle-treated cells following test compounds administration. We found that 1 μM T1AM, SG-1 and SG-2 decreased such a ratio after 30' and 4 h treatment, suggesting that they might induce autophagy through the modulation of pAkt level. In conclusion, T1AM and synthetic analogues induce autophagy in a glioblastoma cell line. The potential pathophysiological and/or therapeutic implications of this finding remain to be determined.

Impact of chronic high fat diet consumption on the expression of organic nutrients carriers in the small intestine of mice: role of thyroid hormones in these processes

Mariana Losacco Cerqueira, Carolina Fernanda Theodora Almeida, Paula Bargi-Souza, Maria Tereza Nunes, Patricia Gama & Francemilson Goulart-Silva
Institute of Biomedical Sciences – University of São Paulo, São Paulo-SP, Brazil.

Products of carbohydrates, proteins and lipids hydrolysis are absorbed by specific carriers located at the enterocytes apical membrane, but little is known about the mechanisms related to their regulation by own nutrients, especially considering the high consumption of fats. Carbohydrates are transported by SGLT1, GLUT5 and GLUT2 and peptides are transported by PEPT1. Cholesterol is transported by NPC1L1 and long chain fatty acids occur through FAT-CD36 and FATP4. Thyroid hormones have important effects on organic nutrients metabolism, but little is known about their role on the intestine, which led us to evaluate thyroid hormone effects on intestine organic nutrients carriers of mice fed high fat diet (HFD) or standard diet. C57BL/6 mice were fed standard diet (control) or high fat diet (HFD) for 12 weeks. Afterwards, both mice were treated with saline, PTU (antithyroid drug) or T3 for 30 days. They were killed and the jejunum was removed for histological analysis or inverted for intestinal epithelium separation from the mucosa for protein analysis by Western blotting technique. FAT-CD36, NPC1L1 and GLUT2 protein contents reduced in mice fed HFD compared to control mice. SGLT1, PEPT1 and FATP4 remained unchanged among experimental groups. On the other hand, NHE3 protein content, which is important for sodium and peptides absorption, increased significantly in the small intestine of mice fed HFD. PTU or T3 treatment did not affect these parameters. High fat compared to standard diet did not show any alteration of the villus length, but mice fed standard diet and treated with PTU or T3 showed an increased villus length compared to treated-vehicle mice, however this finding have no association with the changes of nutrient carriers described above. Thus, we can infer that HFD affects the expression of some organic nutrient carriers in the small intestine, independently of thyroid hormones treatment.

Prognostic factors for intrathyroidal papillary carcinomas – a multivariate analysis

Nada Santrac[1], Ivan Markovic[1,2], Merima Goran[1], Marko Buta[1,2], Igor Djurisic[1] & Radan Dzodic[1,2]
[1]Surgical Oncology Clinic, Institute for Oncology and Radiology of Serbia, Belgrade, Serbia; [2]Medical Faculty, University of Belgrade, Belgrade, Serbia.

Introduction
The aim of this study was to examine prognostic significance of patient-related, tumor-related and treatment-related factors for intrathyroidal papillary thyroid carcinomas (PTC), via multivariate analysis.
Materials and methods
This study included 153 patients with intrathyroidal PTCs (pT1/pT2/pT3) surgically treated in our Institution during two-decade period. Patients with locally invasive tumors (pT4) and initial distant metastases (M1) were excluded. Parameters of interest were: gender (male; female), age (≤ 45; >45 years), tumor size (pTNM classification WHO 1984), multifocality (no; yes), histological type of PTC (pure; microcarcinoma; follicular; poorly differentiated), presence of lymphonodal metastases (pN1a; ipsilateral-pN1b; contralateral-pN1b; total), surgery extent (total thyroidectomy; total thyroidectomy with lymphonodal dissections). Univariate and multivariate analysis of all parameters was performed in order to distinguish factors of significance for disease-free (DFS) and cancer-specific overall survival (cs-OS).
Results
In the follow-up, 10% of patients had locoregional or distant relapse, while 5.2% died due to PTC. Univariate analysis distinguished older age, male gender, tumors over 4 cm in diameter, multifocality and poorly differentiated PTC-types as unfavorable prognostic factors for cs-OS. DFS was significantly shorter in males vs. females, as well as in patients with multifocal vs. solitary PTC. Tumor multifocality was unfavorable prognostic factor for both DFS and cs-OS. Independent prognostic factors for intrathyroidal PTCs, based on Cox multivariate analysis, were multifocality and gender for DFS, and multifocality and age at diagnosis for cs-OS.
Conclusion
Prognostic factors define risk groups within population of differentiated PTCs providing timely, adequate treatment and opportunity for longer quality life of patients with PTCs.

Malignancy Rate in Thyroid Nodules: Cytology versus Histology in challenging categories

Catarina Silvestre, Rita Luís, Maria João Bugalho, Margarida Mendes de Almeida & Raquel Carvalho
Santa Maria Hospital, Lisbon, Portugal.

Background
To stratify the risk of malignancy, thyroid fine-needle aspiration cytology (FNAC) is an important and cost-effective method to evaluate nodules. The Bethesda System for Reporting Thyroid Cytopathology III, IV and V categories are diagnostic challenges, falling between benign and malignant.
Objective
Determinate the malignancy rates of thyroid nodules classified as Bethesda Categories III-V.
Methods
Retrospective study of patients' records with thyroid nodules classified as III-V by the Bethesda system, between January 2014-June 2016.
Results
Of a total of 2791 cytologies, 176 (6%) were classified as III-V, with the following distribution: 93 (3%) atypia of undetermined significance (AUS, III); 50 (1,8%) suspicious for follicular neoplasm (SFN, IV) and 33 (1%) suspicious for malignancy (SM, V). Malignancy rates for IV and V FNAC diagnostic groups were 27% (10/37) and 85% (22/26), respectively. Among patients in group III, 27 patients underwent surgery after a single AUS report (final diagnosis of malignancy – 33%), 39 repeated the FNAC and the remaining are under surveillance. The second cytology report was as follows: 24 benign, 9 AUS, 4 SM, 1 SFN and 1 unsatisfactory; surgery was performed in 9 patients (5AUS + 1SFN + 3SM) and the final diagnosis of malignancy was 44%. The malignancy rate based on histology was not statistically different between patients with one or two cytologies ($P=0{,}693$).
Conclusions
Incidences of III-V diagnostic categories in our study resemble the predicted by the Bethesda System. The malignancy rate for the AUS category was higher than expected and similar to the one found in SFN. Repeating the FNAC in the former group offered minimal additional benefit.

Fine needle aspiration biopsy in pediatric patients with thyroid nodules

Maria Manuel Costa[1,3], Rita Santos Silva[2,4], Cintia Castro-Correia[2,4], Maria Bom Sucesso[2,4], Tiago Henriques Coelho[2,4], Helena Barroca[6] & Manuel Fontoura[2,4]
[1]Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Instituto de Investigação e Inovação da Saúde da Universidade do Porto, Porto, Portugal; [4]Department of Pediatrics of Centro Hospitalar de São João, Porto, Portugal; [5]Department of Pediatric Surgery of Centro Hospitalar de São João, Porto, Portugal; [6]Department of Pathology, Centro Hospitalar de São João, Porto, Portugal.

Introduction
Although thyroid nodules (TN) are less common in children than in adults, the risk of malignancy is much higher in pediatric age and therefore representing greater concern in this age group.
Objective
Evaluate a cohort of pediatric patients with TN and search differences between subjects with malignant and benign TN regarding sex, age, compressive symptoms, cervical ultrasound characteristics, family history of differentiated thyroid cancer (FHDTC), radiation exposure and previous/coexisting thyroid disease.
Methods
Retrospective review of patients under 18 years of age with the diagnosis of TN submitted to fine needle aspiration biopsy (FNAB) from 2010 to 2016.
Results
Seventy-three patients [21% males; mean age 13.8(3.2) years] were included. 46.6% had palpable nodules. 84.9% were euthyroid and 12.3% had hypothyroidism. 31.5% of the patients had positive anti-thyroid antibodies. Ultrasound showed that TN had a diameter range of 15.9 ± 9.8 mm, 47.9% patients had a solitary nodule, 31.5% TN were hypoechoic, 5.5% had increased intranodular flow, 10.9% had microcalcifications and 5.5% had irregular margins. We found that 5.5% of patients had undergone previous cervical irradiation and 12.3% had FHDTC. 84.9% of the patients had a conclusive FNAB at first: benign in 39 (colloid ($n=25$), chronic lymphocytic thyroiditis ($n=12$), granulomatous thyroiditis ($n=1$), thymus tissue ($n=1$)), FLUS in 4, suspected follicular neoplasia in 3, suspected malignancy in 1 and papilar carcinoma in 15 patients. Thyroidectomy was performed in 43.8% of the patients. In histology, 71.9% were diagnosed as malignant. One patient developed permanent hypoparathyroidism after surgery. We verified that the FHDTC was more frequently present in the malignant nodules (26% vs 6%, $P=0.024$), while for the other factors mentioned above there were no statistically significant differences.
Conclusion
In most patients a conclusive diagnosis was achieved with FNAB. The high prevalence of malignancy was similar to that described in the literature. FHDTC was the only factor found associated with an increased risk of malignancy.

GP228

Differentiated thyroid cancer – comparison between patients with and without remission

Ana Amado[1], Patrícia Gouveia[2], Teresa Alves Pereira[1], Rosa Castro[2], António Moreira da Costa[3], André Carvalho[1], Cláudia Freitas[1] & Fátima Borges[1]
[1]Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Nuclear Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; [3]Surgery Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Differentiated thyroid cancer (DTC) is one of the most frequent forms of malignancy. Because of its favourable outcome and low mortality rates, identifying prognostic factors has been a challenge. Several risk stratification systems have been developed. Most of them include demographic and tumour specific features, as well as extrathyroidal extension. Our objective was to compare clinical characteristics between DTC patients with and without remission.
Methods
Data from patients followed for DTC between 1956 and 2016 was retrieved. Patients with less than 2 years of follow up, those submitted to subtotal thyroidectomy or with positive antithyroglobulin antibodies were excluded. They were divided in two groups, according to the presence or absence of remission criteria (undetectable TSH-suppressed thyroglobulin levels and no evidence of structural disease). Groups were compared for age at diagnosis, nodule dimensions, multicentricity, capsule presence and extrathyroidal involvement as well as the presence of node or distant metastasis.
Results
A total of 814 patients was included, 82.9% of which were female. The median age at diagnosis was 47 years old (min. 11; max. 89). Five hundred patients had criteria for remission (Group 1) and 314 didn't (Group 2 [36 with cancer related death, 55 with persistent or recurrent disease and 223 with indeterminate response]). Median follow up was 10 years (min. 3; max. 50) in Group 1and 9 years (min. 3; max. 57) in Group 2. Patients in group 1 were significantly younger (median 44.5 vs 49.5; $P<0.001$) had more multicentricity (45,7% vs 37.7%; $P=0,041$) and less local (22.7 vs 30.6%; $P=0,016$) and distant metastasis (0.4% vs 5.7%; $P<0,001$). No differences were found in nodule dimensions, capsule presence or extrathyroidal involvement.
Conclusion
Among patients with differentiated thyroid cancer, the older ones, with unicentric tumours, local or distant metastasis at presentation seem to have worst outcome.

Trends in papillary microcarcinoma prevalence in North of Portugal

Teresa Alves Pereira[1], Ana Amado[1], Patrícia Gouveia[2], Rosa Castro[2], António Moreira da Costa[3], André Couto de Carvalho[1], Cláudia Freitas[1] & Fátima Borges[1]
[1]Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Nuclear Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; [3]Surgery Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction and Objectives
The incidence of thyroid cancer has increased worldwide. This increase has been attributed to more diagnosed papillary thyroid microcarcinomas. The purpose of this study was to analyse the growing trend of first appointments in our Thyroid Cancer Unit, namely patients with papillary microcarcinomas.
Methods
We performed a retrospective study based on the patients diagnosed with thyroid cancer between 1960 and 2016. We divided these patients into groups, based on the year of first surgical treatment: 1960 to 1996, 1997 to 2001, 2002 to 2006, 2007 to 2011 and 2012 to 2016. We calculated the relative frequency of papillary microcarcinomas comparing to the total cancer diagnostics in each group.
Results
The total count of patients with registered thyroid cancer dimensions was 1146. The mean age was 48.2 ± 15.3 years old. 81.9% were female. We have found that papillary microcarcinoma frequency increased steeply from 11.2% [35/313, 95% confidence interval (CI) 8.2–15.2%] in 1960–1996 to 30.9% (42/136, 95% CI 23.7–39.1%) in 1997–2001. From that time onwards it stabilised around 1/3 of thyroid cancer cases evaluated – 34.0% (54/159, 95% CI 27.1–41.6) in 2002–2006; 34,6% (93/269, 95% CI 29.1–40.4%) in 2007–2011 and 30.5% (82/269, 95% CI 25.3–36.2%) in 2012–2016.
Conclusions
The prevalence of papillary microcarcinomas has increased until the end of the last century. After 2002 our data showed a somewhat stabilised rate of 1/3 of all diagnosed thyroid cancers.

Radioiodine (RAI) refractory differentiated thyroid cancer (DTC): outcome and prognostic factors for DISEASE progression

Katerina Saltiki, George Simeakis, Elli Anagnostou, Michalis Apostolakis, Evangelia Zapanti, Eleni Anastasiou & Maria Alevizaki
Endocrine Unit, Department Medical Therapeutics, Alexandra Hospital, Athens University School of Medicine, Athens, Greece.

Introduction
Patients diagnosed with DTC have excellent prognosis. A small percentage of patients with disease persistence do not respond to treatment with RAI (RAI-refractory DTC) and have low median survival (3.5 years). We investigated the prognostic factors and the disease course in patients with RAI-refractory DTC.
Methods
Of all DTC patients (n = 1160) followed-up in our department in recent years, 800 received RAI treatment and were classified in 2 groups: RAI-refractory DTC

(5.8%) and RAI responsive DTC (94.2%). Clinical and histological characteristics were compared between the 2 groups.
Results
The incidence of RAI-refractory DTC was higher in patients ≥45yrs and particularly in those ≥65yrs (3% vs 7.4% vs 17.4%, $P=0.001$). Men had RAI-refractory DTC more frequently than women ($P=0.02$). RAI-refractory DTC patients presented higher incidence of capsular, lymph node and extra-thyroid invasion ($P<0.004$), larger size ($P<0.001$), worse histological type (high risk papillary: 34.9% vs 12% and features of poor differentiation: 14%vs0.6% respectively, $P<0.001$,). They presented more frequently distant metastases at follow-up (73.3% vs 1.5%, $P<0.001$). 12 RAI-refractory patients had local persistence. 5/12 had no distant metastasis; all underwent multiple surgeries and 3 locoregional external radiation therapy. The 10-year probability of lack of progression of disease was 27.9% vs 98.8% ($x^2=297$, $P<0.001$). In Cox proportional hazard analysis, the only predictor for disease progression was resistance to RAI (HR 0.032, 95% CI 0.007–0.146, $P<0.001$). Within the RAI-refractory DTC subgroup, when age at diagnosis, gender, tumor size, histological type, lymph node, capsular and tissue invasion were taken into account, the only predictor for disease progression and occurrence of distant metastases was tumor size ($P=0.008$ and $P=0.015$ respectively).
Conclusions
Patients with RAI-refractory DTC present disease progression at high percentage (72.7%). In these patients, tumor size is the most important unfavorable factor predicting disease progression and occurrence of distant metastases. These data may be useful in designing treatment strategy.

Maria Nuova A.O. Reggio Emilia, Reggio Emilia, Italy; [12]Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy; [13]Department of Medicine and Surgery, University of Salerno, Salerno, Italy; [14]Institute of Biostructure and Bioimaging of the National Research Council of Italy – CNR, Naples, Italy; [15]Nuclear Medicine, Catholic University of Rome, Italy, Rome, Italy; [16]Endocrinology, San Raffaele Vita-Salute University, Milan, Italy.

Although differentiated thyroid cancer (DTC) has the third highest propensity to spread to the bone after breast and prostate cancer, there is a paucity of data concerning the treatment of bone metastasis (BM) in this setting. The MOSCATI (Metastasi OSsee da Carcinoma TIroideo) was a multicenter, retrospective study investigating the real-life outcome and management of BM in 143 patients (80 F, 63 M; median age 60 years) with DTC involving 10 specialized centers in Italy. One or more skeletal related events (SREs) were diagnosed in 58% of patients in significant association with more aggressive tumor histotype (OR 5.39), higher number of BM (OR 1.36), localization of BM to thoracic spine (OR 2.7), cervical spine (OR 7.47) or skull (OR 2.28), and lack of radio-iodine (RAI) uptake (OR 6.03). RAI treatment was performed in 93% of patients. Bone active drugs were used in 32 patients with SRE (22.4%; zoledronate in 31 and denosumab in one). Bone active drugs were used more frequently in patients with more aggressive histotype of DTC ($P<0.001$), with RAI-refractory BM ($P<0.001$) who did not receive RAI therapy ($P<0.001$) and/or in those with multiple BM ($P=0.006$), malignant hypercalcemia ($P=0.001$), pathological fractures ($P=0.02$) and in those undergoing radiotherapy ($P<0.001$). After treatment, 13.5% of patients developed new SREs and 39 patients (27.3%) died. RAI treatment significantly prevented the second SRE (HR 0.01) and decreased mortality (HR 0.12) as compared to patients treated with anti-resorptive drugs alone. Patients treated with RAI plus anti-resoptive drugs showed less efficacy in preventing second SRE and decreasing mortality as compared to treatment with RAI alone. In conclusion, in the real life, the use of bone active drugs is currently limited to zoledronate in patients with pre-existing SREs. In this specific clinical setting, RAI therapy, but not zoledronate, prevented progression of SREs and mortality. Future studies are needed to clarify the effectiveness of anti-resorptive drugs in primary prevention of SREs and possible advantages of denosumab versus zoledronate in the treatment of BM from DTC.

GP232

Germ-line mutations in RET-790 and RET-791 codons (exon 13) among subjects with sporadic medullary thyroid cancer

Darko Katalinic[1], Miljenko Solter[2] & Nora Nikolac[2]
[1]Department of Internal Medicine, Faculty of Medicine, Josip Juraj Strossmayer University of Osijek, Osijek, Croatia; [2]UHC Sisters of Charity, Faculty of Medicine, University of Zagreb, Zagreb, Croatia.

Background
Medullary thyroid carcinoma (MTC) is a rare calcitonin producing neuroendocrine tumour that originates from parafollicular C-cells of the thyroid gland. RET proto-oncogene germline mutations are crucial for the onset and the progression of MTC, and the occurrence of single nucleotide polymorphisms could predispose the clinical course of disease. The objective of this study was to evaluate possible differences in clinical presentation among patients with/without RET codon 790 and codon 791 (exon 13) mutations.
Methods
A non-isotopic polymerase chain reaction based single strand confirmation polymorphism analysis and heteroduplex gel electrophoresis method was used to screen tumour DNA extracted from 132 formaldehyde fixed and paraffin embedded MTC specimens. We analysed clinical data from 69 patients harbouring RET codon 790 and codon 791 mutations (exon 13) (group A) compared with 63 patients with "wild-type" genotype (group B). The study was conducted according to the Declaration of Helsinki, the protocol was reviewed and approved by the institutional independent ethics committee. All patients were provided with written informed consent.
Results
Mean age for the group A was 56.2 ± 11.4 years (range, 44.8–67.6) vrs. 49.4 ± 9.7 (range 39.7–59.1) for the group B. Lymph node metastases were found in all patients (group A, $n=46$ vrs. group B, $n=31$; $P<0.001$), and distant metastases in 11 patients (group A, $n=7$ vrs. group B, $n=4$; $P>0.001$). Postoperatively, 62% of patients in group A vrs. 78% of patients in group B were biochemically cure ($P<0.001$). In the group A, pT-category was: T_0, $n=21$; T_1, $n=16$; and T_2, $n=9$. In the group B, pT-category was: T_0, $n=22$; T_1, $n=7$; and T_2, $n=2$ ($P<0.001$).
Conclusions
Patients with RET codon 790/791 (exon13) mutations have a more aggressive clinical course and lower biochemic cure rate in comparison with patients with 'wild-type' genotype. This information should be considered by genetic counseling or by operative therapy and could have clinical importance when specific targeted therapy is discussed.

GP233

Comparison of clinicopathological features in patients with familial and sporadic papillary thyroid cancer

Fatma Dilek Dellal[1], Didem Ozdemir[1,2], Cevdet Aydin[1,2], Berna Ogmen[1], Aydan Kilicarslan[1,2], Mehmet Kilic[1,2], Reyhan Ersoy[1,2] & Bekir Cakir[1,2]
[1]Ataturk Training and Research Hospital, Ankara, Turkey; [2]Yildirim Beyazit University, Ankara, Turkey.

Introduction
Although, familial medullary thyroid cancer is a known condition, familial papillary thyroid cancer (PTC) is a rare and less well described clinical entity. While some studies suggest more aggressive features in familial PTC, some do not support these findings. We aimed to compare ultrasonographical, cytopathological and histopathological results of patients with familial and sporadic PTC.
Methods
Data of 194 patients diagnosed with PTC histopathologically between 2007–2016 were retrospectively reviewed. PTC in ≥2 members of the family was defined as familial PTC. Thyroid functions, ultrasonography features, cytological and histopathological findings were compared in familial and sporadic PTC.

Results
There were 35 tumor foci in 20 familial and 253 foci in 174 sporadic PTC patients. Gender, thyroid functions, thyroid autoantibody positivity, mean nodule number, thyroidectomy indications and surgical approach were similar in two groups. Preoperative ultrasonography features were available in 20 familial and 112 sporadic nodules. There was not any difference in mean nodule diameter, echogenity, texture, microcalcification, macrocalcification, presence of hypoechoic halo, taller than wide shape, margin irregularity and vascularization pattern. Cytological results were distributed similarly in two groups ($P=0.433$). In histopathological examination, mean tumor number was 1.79 ± 0.98 in familial and 1.46 ± 0.77 in sporadic patients ($P=0.09$). Mean tumor diameters were 6.26 ± 4.10 mm and 9.87 ± 11.62 mm in familial and sporadic tumors, respectively ($P=0.074$). Multifocality, microcarcinoma rate, variants of PTC, vascular invasion and extracapsular extension were similar ($P=0.155$, $P=0.239$, $P=0.094$, $P=0.617$ and $P=0.743$, respectively). Capsular invasion was significantly increased in sporadic group (19.8% vs 5.9%, $P=0.049$).
Conclusion
Whether familial PTC is more aggressive than the sporadic form of the disease is controversial. Clinical, ultrasonographical, cytological and most of the histopathological features of familial and sporadic PTC were identical in our study. Early detection of cases other than index patients might cause diagnosis at an earlier stage of the disease in familial form.

GP234

Lobectomy as a treatment option for well differentiated thyroid cancer (WDTC) between 1–4 cm: which results should we expect?

Ana Fareleira, Patrícia Andrea Ferreira, L Matos Lima & J Costa Maia
Centro Hospitalar S. João, E.P.E., Porto, Portugal.

Introduction
The ATA guidelines 2015 suggests lobectomy as an option for low risk thyroid tumors between 1–4 cm, although there remains some controversy once some characteristics become apparent only on pathologic examination.
Objective/methods
Retrospective analysis of patients who underwent thyroid surgery in 2014 and 2015, with a histologic diagnosis of WDTC 1–4 cm in size and revision of the proportion of patients eligible for lobectomy with indication for completion thyroidectomy according to the ATA guidelines 2015.
Results
Three hundred and eighty eight patients who underwent thyroidectomy were analysed. Of these, 85 (21,9%) were include for final analysis. Exclusion criteria: history of cervical radiation, tumors <1 and >4 cm, macroscopic extrathyroidal extension (ETE), cN+, and bilateral thyroid nodules.
The mean age of the cohort was 49 years**,** 83,5% are females, none had an aggressive histology, 12 (14,1%) had vascular invasion, 5 (5,9%) had microscopic ETE, 3 (3,5%) had positive margins and 1 (1,2%) patient had positive lymph node metastasis.
Conclusion
(20%) of the patients with apparently 'low risk' WDTC who are eligible for lobectomy would have indication for completion total thyroidectomy according to the ATA guidelines 2015.

Clinical Utility of response to therapy in combination with BRAF in risk assessment of thyroid cancer

Laura Pérez Fernández[1], Antonio De la Vieja Escolar[2], Carles Zafón[3], Juan Carlos Galofré[4], Garcilaso Riesco-Eizaguirre[5] & Spanish Task Force for the study of BRAF SEEN[4,5]
[1]Hospital del Tajo, Aranjuez, Madrid, Spain; [2]Instituto de Salud Carlos III, Majadahonda, Madrid, Spain; [3]Hospital Universitari Vall d'Hebron, Barcelona, Cataluña, Spain; [4]Clinica Universitaria de Navarra, Pamplona, Navarra, Spain; [5]Hospital Universitario de Móstoles, Móstoles, Madrid, Spain.

Response to therapy re-stratification approach has been recently included in the 2015 ATA guidelines as a risk-adapted approach to management of thyroid cancer. Our aim was to investigate the clinical utility of response to therapy variables obtained during early follow-up in combination with BRAF, a prominent oncogene in thyroid cancer with prognostic value. This was a retrospective multicenter study of 871 patients at 11 centers in Spain with papillary thyroid cancer followed after total thyroidectomy and radioactive iodine remnant ablation. 685 patients were re-stratified during the first year of follow-up based on response to therapy: excellent (73% of the patients), indeterminate (8%), biochemical incomplete (6%) and structural incomplete (13%). Clinical outcomes were obtained in each group and no evidence of disease (NED) was seen in 95%, 47%, 32% and 24% respectively for a median follow-up of 57 months. BRAF mutation prevalence was 51% and was significantly associated with patients who had no excellent response (31.4% vs 22.9%; HR 1.53 (95% CI, 1.080 a 2.188)). This association remained significant with biochemical incomplete response but not with structural incomplete response. Moreover, BRAF positive tumors were less likely to have distant metastasis compared with BRAF negative tumors. Patients with excellent response and BRAF negative tumors, almost 100% had NED at the end of follow-up. Patients with indeterminate and biochemical incomplete response and BRAF positive tumors, were less likely to have NED compared with BRAF negative, although the difference was not significant due to the small number of patients in each group. Our data show that indeterminate and biochemical incomplete response may not have such favourable clinical outcome as previously shown. In addition, BRAF status informs about the way papillary carcinomas disseminate (locoregional vs distant metastasis) and may help to better assess risk estimates that change over time based on response to therapy.

A rare case of medullary thyroid cancer, mesothelioma and meningioma, due to APC and RASAL1 mutations

Charalampos Lyssikatos[1], Martha M Quezado[2], Fabio R Faucz[3], Anna Angelousi[1,4], Narjes Nasiri-Ansari[5], Constantine A Stratakis[1] & Eva Kassi[5,6]
[1]Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development (NICHD), National Institutes of Health (NIH), Bethesda, MD, USA; [2]Laboratory of Pathology, National Cancer Institute, Bethesda, MD, USA; [3]Section on Endocrinology & Genetics, NICHD, National Institute of Health, Bethesda, MD, USA; [4]Department of Pathophysiology, Unit of Endocrinology, Kapodistrian University of Athens, Athens, Greece; [5]Laboratory of Biochemistry, National and Kapodistrian University of Athens, Athens, Greece; [6]Endocrine Unit of Clinical and Translational Research, National and Kapodistrian University of Athens, School of Medicine, Athens, Greece.

Introduction
Patients with "mixed" phenotypes are common among patients with multiple endocrine and non-endocrine neoplasias. Their diagnoses do not fit a given pattern making ge netic counseling difficult and testing impossible to guide. Most of these patients end up getting genome-wide studies for the identification of any predisposing genetic defect. We present a rare case of a 57 year old female who presented clinically with medullary thyroid cancer (MTC), mesothelioma and meningioma. As part of our diagnostic work-up for this category of patients, we performed a SNP microarray (comparative genomic hybridization; CGH) and whole exome sequencing (WES). CGH did not reveal any abnormalities; WES revealed two variants of unknown significance (VUS) in two separate genes, namely APC and RASAL1.
Case presentation
The patient, a 57 year old female patient, was diagnosed with AML at 41y old, peritoneal mesothelioma at 43y old, meningioma at 53y old and medullary thyroid cancer with lymph node metastasis at 53y old. She also suffers from autoimmune atrophic gastritis, alopecia universalis and relapsing perichondritis of the ear.
Results
WES was performed by DNA extracted from blood and revealed two specific VUS, in the APC gene: p.R1103W, c.3307 A>T and in the RASAL1 gene: p.R538H, c.1613 G>A. The APC gene (OMIM #17500) is a tumor suppressor gene involved in Wnt / β catenin signaling pathway; mutations have been reported in Familial Adenomatous Polyposis (FAP), brain tumors and Turcot syndrome. Mutations in the RASAL1 gene (OMIM#604118) have been found in thyroid cancer (both papillary and medullary) and Cowden syndrome. The above two variants found in this patient have not been reported previously as pathogenic. The mutations in the APC and RASAL1 genes are probably involved in thyroid cancer development. In addition, the mesothelioma and meningioma are likely related to mutations in the APC gene. This unique clinical presentation has not been reported before and is being proven by additional immunostaining and molecular studies.
Conclusion
Patients with unique phenotypes may present with a list of clinical manife stations that do not fit any given diagnosis. These patients deserve genome-wide testing

that is often rewarding but also complex. In our patient with MTC, mesothelioma and meningioma two new gene defects were identified that are probable responsible for the phenotype.

Thyrotoxic Periodic Paralysis due to Graves' disease: a mandatory differential diagnosis in Asian patients presenting with paralysis and hypokalemia

David Barbosa[1], Carolina Faria[1], Ana Sofia Osório[1], Ema Nobre[1], Ana Paula Vilas[2] & Maria João Bugalho[1]
[1]CHLN – Hospital de Santa Maria, Endocrinology, Diabetes and Metabolism Department, Lisbon, Portugal; [2]CHLN – Hospital de Santa Maria, Medicina 2B, Lisbon, Portugal.

Introduction
Thyrotoxic periodic paralysis (TPP) is a potentially life-threatening complication of hyperthyroidism that is underdiagnosed and frequently missed. It is relatively common in Asian men with Graves' disease. TPP attacks are frequently associated with hypokalemia.
Case presentation
We describe a 26-year-old Asian male with an unremarkable past medical history who was admitted following sudden onset of flaccid paralysis of the lower extremities. Signs and symptoms such as weight loss, diaphoresis, palpitations and mild diffuse goitre were present. The electrocardiogram showed a sinus tachycardia and the laboratory evaluation revealed markedly low potassium and phosphorus levels (K^+ 1.5 mmol/l; PO_4^{3-} 1.8 mg/dl). The patient was managed with intravenous potassium chloride with markedly improvement of the neurological deficits, despite a rebound hyperkalemia shortly after replacement. A thyroid profile was taken due to the suspicion of TPP in the context of Graves' disease, and the diagnosis was made (TSH 0.01 μU/ml; free T4 5.21 ng/dl; free T3 15,64 pg/ml; TRABs 37,64 U/l). The patient then started on oral propranolol and tiamazol, with complete remission of the symptoms and sustained normalization of serum potassium.
Conclusion
TPP is an alarming and potentially lethal complication of hyperthyroidism characterized by muscle paralysis and hypokalemia due to a massive shift of potassium into cells. This condition mainly affects male patients of Asian descent. With increasing population mobility and admixture, TPP as the presenting feature of hyperthyroidism is now more common in Western countries. Early diagnosis not only aids in definitive management with nonselective beta-blockers and correction of hyperthyroidism, but also prevents the risk of rebound hyperkalemia due to excessive potassium replacement. We report this case to emphasize the importance of recognizing TPP to avoid missing a treatable and curable condition.

A fatal case of fetal goiter: autoimmunity is the key

Irene Berges-Raso[1], Lara Albert[1], Assumpta Caixàs[1], Ismael Capel[1], Albert Cano[1], Isabel Mazarico[1], Laura Serra[2], Manuel Corona[2], Cesar Martín Martínez[3] & Mercedes Rigla[1]
[1]Endocrinology and Nutrition Department. Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona., Sabadell, Barcelona, Spain; [2]Obstetrics and Gynecology Department. Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona., Sabadell, Barcelona, Spain; [3]SDI-UDIAT. Parc Taulí Hospital Universitari. Institut d'Investigació i Innovació Parc Taulí I3PT. Universitat Autònoma de Barcelona, Sabadell, Barcelona, Spain.

Introduction
Fetal goiter is an infrequent and potentially life-threating condition derived from either fetal hypothyroidism or hyperthyroidism. TSH-receptor stimulating antibodies (TSH-R-ABs) can cross the placenta and induce fetal hyperthyroidism and goiter. We describe a rare case of TSH-R-ABs-induced hyperthyroidism in a woman with autoimmune hypothyroidism (AH) without previous hyperthyroidism.
Case Report
A 28 years old pregnant woman under treatment with Levothyroxine (LT4) for 6 years because of AH was referred during pregnancy. She had history of 2 miscarriages: fetal death at 28th gestational week (GW) two years before and fetal loss in 2015 because of corioamnionitis. Blood tests at 12th GW showed undertreated AH (TSH 31.4 μU/mL, fT4L 0.97 ng/dL) and Levothyroxine dose was increased. At 24th GW, blood tests showed a mild hyperthyroidism (TSH 0.05 μU/mL, fT4 1.53 ng/dL) and LT4 dose was reduced. Fetal ultrasound (US) at 25th GW showed a male fetus with bilateral cerebral ventriculomegaly without other alterations. TORCH serologies were negative, amniocentesis revealed a normal karyotype and fetal MRI showed bilateral cerebral ventriculomegaly and fetal goiter.
To study the fetal thyroid function a blood sample by cordocentesis was obtained and a maternal blood test to examine TSH-R-ABs levels was performed. Meanwhile, fetal US at 26th GW showed tachycardia, mild pericardial effusion, hydrothorax, cardiomegaly, hepatomegaly and splenomegaly. Fetal blood sample showed fetal hyperthyroidism (TSH $<$ 0.008, fT4 4.03, fT3 9.92) while maternal TSH-R-ABs were elevated ($>$ 40 mUI/mL). Unfortunately, fetal death occurred before knowing the results and antithyroid drugs could not be started. As far as we know, this is the second reported case of TSH-R-ABs-induced fetal thyrotoxicosis in an AH woman.
Conclusion
TSH-R-ABs plasma determination should be mandatory in pregnant women with any previous autoimmune thyroid disease and fetal goiter or thyrotoxicosis. Antithyroid drugs should be started as soon as fetal hyperthyroidism is suspected.

GP239

Renal cell carcinoma metastasis to thyroid tumor: a case report

Carolina Faria, David Barbosa, Ana Sofia Osório, Ema Nobre & Maria João Bugalho
Hospital de Santa Maria, Lisboa, Portugal.

Introduction
Subacute thyroiditis (SAT) association with papillary thyroid carcinoma (PTC) has been rarely reported in the literature. Metastatic neoplasms to the thyroid are rare in clinical practice. Renal cell carcinomas (RCC) are the most frequent site of origin of thyroid metastases (12 to 34%). Tumor-to-tumor metastases, in which a thyroid neoplasm is the recipient of a metastasis, are exceedingly rare. Tuberous sclerosis (TS) is associated with several renal manifestations (80–85% of the patients) including angiomyolipomas (AMLs) (80%), renal cysts (30%) and RCC (2–4%)
Case report
A 19-year-old male, with personal history of TS, presented in the emergency department complaining of edema, jitteriness and pain in cervical region. SAT diagnosis was established based on complaints, physical examination and laboratory results. After the resolution of SAT, thyroid ultrasonography (US) revealed 2 suspicious nodules. The major nodule was submitted to fine needle aspiration cytology and the report was suspected of malignancy. Total thyroidectomy was performed. Postsurgical pathology evaluation showed a bilateral PTC/follicular variant (pT3N0). Within the PTC were a few nests of a morphologically distinct neoplasm. Immunoperoxidase stains of these cells were positive for CK8/18 and CK7 and were negative for thyroglobulin, calcitonin, vimentin, CK20, CD10 and racemase thus suggesting metastases of RCC. The body CT showed bilateral renal lesions likely to be angiolipomas without distinctive criteria. Suspicious lesions in the liver, lungs and bones were also reported without uptake in a 18F-FDG PET-CT.
Conclusion
This case illustrates an extremely rare occurrence of tumor-to-tumor metastasis where the recipient was a PTC and the donor likely to be an occult RCC.

Giant goiter with intrathyroid arteriovenous fistula as a cause of severe pulmonary hypertension

Elena Márquez Mesa, Estefanía González Melo, Cristina Lorenzo González, Pilar Olvera Márquez, Ricardo Darias Garzón, María Teresa Herrera Arranz, Bruno Francisco García Bray, Yolanda Zambrano Huerta & Enrique Palacio Abizanda
Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain.

Introduction
Hyperthyroidism has been described as a rare cause of pulmonary hypertension (PH) as well as systemic arteriovenous fistulas. However, we describe a case of pulmonary hypertension secondary to an intrathyroid arteriovenous fistula, not previously described in the literature.

Case report
A 56 year old woman followed in our consultations with multinodular goiter and a long standing hyperthyroidism, secondary to Graves Basedow disease with difficult management. She required methimazole and low doses of levothyroxine simultaneously to achieve hormonal control, needing multiple admissions for heart failure (HF). In her last admission to Cardiology, she had right HF stage III-IV of NYHA, and physical examination revealed grade III goiter with murmur auscultation and thrill palpation. The blood tests revealed that she was euthyroid. The echocardiogram showed dilatation of both ventricles, ejection fraction 57%, moderate-severe biauricular dilatation, moderate mitral and tricuspid insufficiency, PAPs 73 mmHg. Cervical thoracic CT evidenced large multinodular goiter with intrathoracic extension and tracheal compression, multiple hypervascular nodules and cervico-vascular venous congestion. Right cardiac catheterization showed moderate precapillary PH with high saturations in the venous territory explored and cardiac output 8.1 l/m. These findings were consistent with the diagnosis of PH secondary to intrathyroid arteriovenous fistula. Definitive treatment was made by performing total thyroidectomy. The pathologic study of the piece was reported as multinodular thyroid goiter ($12 \times 13 \times 5$ centimeters and 140 grams) with signs of diffuse hyperplasia and arteriovenous fistula. Two months after surgery the patient had improved her functional class and the PAPs had decreased to 30 mmHg.
Conclusions
This is the first case described in which pulmonary hypertension is secondary to an arteriovenous fistula in a giant goiter. Surgery was a successful treatment, and one year after, the patient has a disease free survival.

DOI: 10.1530/endoabs.49.GP240

Thyroid-related adverse events in patients treated with Nivolumab

I Peiró[1], L San Martín[2], A Simó-Servat[2], J Otero[2], JC Ruffinelli[3], E Nadal[3], P Iglesias[4], JJ Díez[4] & C Villabona[2]
[1]Clinical Nutrition Unit, Institut Català d'Oncologia (ICO), Hospitalet de Llobregat, Spain; [2]Department of Endocrinology, Hospital Universitari de Bellvitge, Hospitalet de Llobregat, Spain; [3]Department of Oncology, ICO, Hospitalet de Llobregat, Spain; [4]Department of Endocrinology, Hospital Ramón y Cajal, Madrid, Spain.

Introduction
Nivolumab is an antibody that binds to and blocks the activation of programmed-death-receptor 1(PD-1), promoting the activation of T-cells against tumor cells. Thyroid dysfunction (TD) is one of the most common immuno-related adverse events, with incidence up to 10% in patients treated with PD-1/PD-L1 blockade.
Objective
To report our experience of Nivolumab-TD in patients with advanced cancer.
Methods
All patients diagnosed of nivolumab-induced TD during 2016 were included. Data from thyroid function tests, autoimmunity and imaging study before and during nivolumab therapy were recorded.
Results
Twelve cancer patients (5 lung, 4 melanoma, 3 Hodgkin lymphoma) were evaluated. 75% women, mean age: 56.7 year (19–77). Ten patients were treated with nivolumab 3 mg/kg (with or without chemotherapy) every 15 days, 2 patients received combined immunotherapy (nivolumab 1 mg/kg plus ipilimumab 3 mg/kg). Three patients had previously well-controlled thyroid disease (1 overt primary hypothyroidism, 2 subclinical hypothyroidism). Baseline serum TSH and free thyroxine were evaluated in eleven patients, being normal in ten whereas one showed minimal subclinical hypothyroidism. During follow-up, 7 patients (58.3%) developed hyperthyroidism (4 overt and 3 subclinical). Six of them after cycle(C) 2, and 1 after C3. Thyroid antibodies were positive in 3 patients. One overt hyperthyroidism was treated with high dose steroids (prednisone 0.8 mg/kg per day) and nivolumab was temporarily withdrawn. Four of seven hyperthyroid patients became hypothyroid later, needing levothyroxine. Primary hypothyroidism occurred in 5 patients (41.7%) (3 overt and 2 subclinical), between C4-C7. Autoimmunity was positive in 3 hypothyroid patients. No patient discontinued nivolumab due to hypothyroidism.
Conclusions
In our series, hyperthyroidism is more frequent and appears earlier than hypothyroidism. A pattern consistent with a transient thyroiditis followed by hypothyroidism is seen in one-third of patients. Monitoring thyroid function at baseline and before each therapeutic cycle is warranted to detect and treat TD promptly.

GP242

False negative fine needle aspiration thyroid cytology: an institutional experience

Anabela Martins, Evelina Mendonça, António Garrão, Hugo Marques, Maria Cid, Francisco Rosário, Ricardo Veiga & Ana Catarino
Hospital da Luz, Lisbon, Portugal.

Introduction
Fine needle aspiration cytology (FNA) is the most accurate diagnostic method for thyroid malignant nodule diagnosis. According to the literature, the percentage of false negative results (FN-FNA) is less than 1.5%, in tertiary health care centers. In this study we describe the cases reported in this Hospital, between 2014 and 2016, of benign cytology, histologically characterized as malignant. All pathologic specimens were reviewed.
Results
From a total of 299 benign FNA cases submitted to surgery, 6 cases with malignant histopathology were detected (2.0%). FN-FNA was identified in 5 males and 2 females, with ages ranging from 42 to 72 years old. The nodules size varied between 41 to 95 mm.
The ultrasound malignancy risk was between 5 and 20% (ATA 2015 Risk Stratification System).
The benign FNA were described as hyperplasic nodule in 3 cases, cystic hyperplasic nodule in 1 case, cystic colloid nodule in 1 case and colloid nodule in the remaining.
In all the cases the histological diagnosis was of follicular variant of papillary carcinoma, with macrofollicular areas, either predominant or focally, and with a heterogeneous distribution of the distinctive nuclear features of papillary carcinoma.
Four patients were recommended for radioiodine therapy. One of these patients was diagnosed with pulmonary and bone metastases.
Four patients were available for follow-up (mean time = 1.5 years; 9–24 months). There is no imaging evidence of disease in any of the patients.
Conclusions
In our institution, the percentage of FN-FNA was 2.0%, in accordance with that described in the literature.
The ultrasound risk assessment did not significantly change the risk assessed by FNA.
In all the cases the histological diagnosis was follicular variant of papillary carcinoma. The presence of macrofollicular areas, cystic areas and a heterogeneous expression of the typical nuclear features of papillary carcinoma may explain the occurrence of FN-FNA.

Risk factors associated with malignancy in thyroid nodules classified as Bethesda category IV (follicular neoplasm/suspicious for follicular neoplasm)

Bekir Kuru & Mehmet Kefeli
Ondokuz Mayis University School of Medicine, Samsun, Turkey.

Background
Thyroid nodules diagnosed as Bethesda category IV (follicular neoplasm/suspicious for follicular neoplasm (FN/SFN)) are recommended for surgery. However, only 25% of these nodules turn to be malignant on histopathology. Therefore, selection of nodules for surgery diagnosed as Bethesda category IV is important. We aimed at to define the predictive factors for malignancy and predictive risk indices for selection of surgery.
Method
The records of all patients with nodules that underwent fine needle aspiration biopsy (FNA) and classified by Bethesda reporting system as FN/SFN between 2011 and 2017 at our institution were reviewed. Univariate and multivariate analysis were performed to select independent factors associated with thyroid cancer. Using independent risk factors for malignancy predictive indices were created.
Results
Among 6,217 nodules which underwent FNA, 163 (2.6%) were diagnosed as FN/SFN. Of the 163 patients classified as FN/SFN, 126 underwent surgery with an associated malignancy rate of 36% (45/126). Age under 45, solid structure, microcalcification, hypoechogenicity and increased vascularization were found to be significant and independent risk factors associated for malignancy. The risk

indices were created by classifying nodules with 0, 1, 2, 3, and ≥4 risk factors as risk indices 0, 1, 2, 3, and 4. There were 17 (14%), 41 (33%), 27 (21%), 22 (17%), and 19 (15%) patients in risk indices 0, 1, 2, 3, and 4, respectively. The estimated malignancy risk in patients with 0, 1, 2, 3, and 4 risk indices were 0% (0/17), 12% (5/41), 26% (7/27), 64% (14/22), and 100% (19/19), respectively.
Conclusions
Using predictive factors for malignancy in Bethesda IV category a small, but important proportion of patients 14% who had nodules without any risk factors could be spared unnecessary surgery. Predictive indices should be considered for informing the patients about the malignancy risk and for selection of surgery in Bethesda IV category.

Expressions of miRNAs and BRAF^{V600E} mutation detection in papillary thyroid carcinoma

Vaida Simanaviciene[1], Aiste Kondrotiene[2], Daina Pamedytyte[1], Valdas Sarauskas[3], Dalia Dauksiene[4], Albertas Dauksa[5], Aurelija Zvirbliene[1] & Birute Zilaitiene[1]
[1]Institute of Biotechnology, Vilnius University, Vilnius, Lithuania; [2]Lithuanian University of Health Sciences, Medical Academy, Kaunas, Lithuania; [3]Department of Pathological Anatomy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [4]Institute of Endocrinology, Medical Academy, Lithuanian University of Health Sciences, Kaunas, Lithuania; [5]Institute of Digestive Research, Medical Academy, Faculty of Medicine, Lithuanian University of Health Sciences, Kaunas, Lithuania.

Introduction
Papillary thyroid carcinoma (PTC) is the most common type of thyroid malignancy. For the majority of patients with PTC, the prognosis is very good; however, up to 20% of patients suffer disease recurrence. Currently, the risk stratification for PTC recurrence is based on clinicopathological features which have limited prognostic value. Identification of molecular biomarkers of PTC recurrence such as protooncogene BRAF and miRNAs may help to improve risk-stratified patient management.
Objective
The aim of this study was to detect BRAFV600E mutation and identify miRNA biomarkers for PTC recurrence.
Methods
We selected 3 miRNA (miRNA- 146b, -222 and -21) and measured the expresion levels of these miRNAs in patients with recurrent PTC (Rc-PTC) and without recurrence (NRc-PTC). 106 NR-PTC and 60 Rc-PTC FFPE samples were analysed for selected miRNAs. 114 FFPE PTC samples (31 Rc-PTC and 83 NR-PTC) were analysed for BRAF^{V600E} mutation.
Results
The expression levels of all three miRNAs were significantly increased in PTC when compared to healthy thyroid tissue. miRNA-146b expresion was extremely elevated with 55.6-fold over-expression in PTC ($P<0.001$). miRNA-222 and -21 were over-expressed 13.8-fold and 3.7-fold, respectively ($P=0.001$ and $P=0.16$). In Rc-PTC and NRc-PTC groups miRNA-21, -146b and -222 were significantly differently expressed with 1.4- fold ($P=0.006$), 1.8-fold ($P=0.007$) and 2.1-fold ($P<0.001$) higher expresion in NRc-PTC compared with Rc-PTC tissues. 114 FFPE PTC samples were analysed for BRAF^{V600E} mutation and 66 of them (57.9%) were shown to be positive. Subsequently, DNA samples from Rc-PTC and NR-PTC groups were analysed for BRAF^{V600E} mutation and this mutation was found in 54.8% (17/31) of Rc-PTC samples and 59.0% (49/83) of NR-PTC samples. There was no signifficant difference between these groups ($P=0.686$).
Conclusion
These results suggest that miRNA-21, miRNA-222, miRNA-146b might be potential biomarkers for PTC recurrence. BRAF mutation is not associated with PTC recurrence.

DOI: 10.1530/endoabs.49.GP244

A statistical, in silico model predicts polygenic thyroid cancer risk

Livio Casarini[1,2], Marco Marino[1,2], Federico Nuzzo[1], Manuela Simoni[1,3] & Giulia Brigante[1,3]
[1]Unit of Endocrinology, Department Biomedical, Metabolic and Neural Sciences, University of Modena and Reggio Emilia, Modena, Italy; [2]Center for the Genomic Research, University of Modena and Reggio Emilia, Modena, Italy; [3]Azienda Ospedaliero-Universitaria di Modena, Modena, Italy.

Introduction
The detection of a unique genetic marker is not possible for multifactorial diseases, such as thyroid cancer (TC), where the pathological phenotype is given by the contribution of multiple genes, environmental factors and lifestyle. We found a mathematical model for inferring the risk of thyroid cancer, an example of multifactorial disease.
Methods
Genetic data represented by 184 SNPs associated to thyroid tumors were used for Bayesian clustering of 2504 individuals from the 1000 Genomes database, by STRUCTURE software. Numerical values representing the inferred genetic structure of each individual is provided in the output file of the software and were matched with environmental and lifestyle parameters associated to thyroid functions, i.e. iodine exposure and obesity, by principal component analysis (PCA). Data analysis was performed using labels such as geographic origin of individuals, population, sex and thyroid cancer incidence.
Results
We found that seven thyroid tumor-related genetic clusters are differently represented among human populations. The matching of genotype, iodine and obesity data resulted in individuals' gradient distribution by thyroid cancer incidence, revealing that all these components are required to infer the disease risk. Genetic background and, to a lesser extent, environmental factors and lifestyle, are not related per se to a specific range value of cancer risk. An exception is provided by individuals from Tuscany, Italy, which deviates from the overall distribution, preserving high cancer risk independently from obesity or iodine. This could result from a peculiar genetic setting or from the exposure to environmental factors not considered in the analysis.
Discussion
We demonstrated that TC risk may be detected a priori by applying polygenic model to specific population or individuals.
Conclusion
This study provides a novel mathematical approach to infer the polygenic disease risk, as a promising diagnostic tool for personalized medicine.

Confirmatory tests for diagnosis of primary aldosteronism among Chinese hypertensives

Minchun Jiang[1], Dujuan Ma[2], Hailun Lin[1], Ying Lin[1], Yajuan Deng[3], Juying Tang[1], Shaoling Zhang[1] & Ying Guo[1]
[1]Department of Endocrinology and Metabolism, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou, China; [2]Department of Endocrinology and Metabolism, Guangzhou Panyu Central Hospital, Guangzhou, China; [3]Shenzhen Hospital of Southern Medical University, Shenzhen, China.

Objective
Primary aldosteronism (PA) has emerged as the most frequent form of secondary hypertension. For the diagnosis of PA, confirmatory testing is indispensable and different tests are recommended by guidelines, including captopril challenge test (CCT) and saline infusion test (SIT). However, there are sparse studies evaluating and comparing CCT and SIT in Chinese population. Hence, we investigate the diagnostic efficiency of CCT and SIT for PA in Chinese hypertensives in our study.
Methods
In total, 183 patients with essential hypertension and 105 patients with PA were recruited in the study, and their clinical data were analyzed by constructing the receiver operating characteristics (ROC) curve to compare the accuracy of CCT and SIT.
Results
(1) A total of 277 patients underwent CCT. The AUC of post-CCT aldosterone, aldosterone suppression rate and post-CCT aldosterone/renin ratio (ARR) were 0.877 (95% CI 0.833 to 0.921, $P<0.001$), 0.683 (95% CI 0.617 to 0.748, $P<0.001$) and 0.929 (95% CI 0.896 to 0.963, $P<0.001$), and accuracy of ARR post-CCT is highest ($P<0.001$). For post-CCT ARR, at the optimal cut-off value of 30 ng•dl-1/ng•ml-1•h-1, the sensitivity and specificity were 67.6% and 96.2% respectively. (2) The SIT was performed in 116 patients. The AUC of post-SIT aldosterone and post-SIT ARR were 0.829 (95% CI 0.731 to 0.928, $P<0.001$) and 0.923 (95%CI 0.860 to 0.985, $P<0.001$), and post-SIT ARR has higher accuracy ($P<0.05$). The best cut-off value of post-SIT ARR for identifying PA was 60 ng•dl-1/ng•ml-1•h-1, with sensitivity and specificity of 81.8% and 95.2%, respectively. (3) 110 patients underwent both CCT and SIT. In the consistency check of CCT and SIT, kappa value was 0.714, $P<0.001$. The AUC of post-CCT ARR, post-SIT ARR, serial test of post-CCT ARR and post-SIT ARR were 0.937 (95% CI 0.885 to 0.990, $P<0.001$), 0.921 (95% CI 0.858 to 0.984, $P<0.001$) and 0.939 (95% CI 0.881 to 0.881, $P<0.001$), there is no statistical difference among the three indices.
Conclusions
With a good consistency, CCT and SIT are both efficient confirmatory tests for PA, and applying ARR post-CCT or ARR post-SIT make it feasible to diagnose PA more accurately. However, combining two tests fails to further improve the accuracy for diagnosis of PA.

The correlation of salivary cortisol values with serum cortisol values

Blertina Dyrmishi[1], Taulant Olldashi[1], Ema Lumi[3], Entela Puca[4], Emirvina Kolici[4], Dorina Ylli[2] & Thanas Fureraj[2]
[1]Hygeia Hospital Tirana, Tirana, Albania; [2]UHC Mother Teresa, Tirana, Albania; [3]Regional Hospital Korca, Korca, Albania; [4]Neo Style Clinic, Tirana, Albania.

Aim
The aim of the study was to evaluate the correlation between salivary and serum cortisol values to the healthy people and patients with Cushing's syndrome.
Methods
33 cases: 21 healthy people aged 22 to 53 years old; 12 patients with Cushing's syndrome values were included to our study. All the participants of control group were healthy without known disease. Two samples of salivary and serum cortisol was taken to all the participants of the study in the morning and in the midnight. All the subject respect the rolls of salivary collected samples.
Results
The mean age of the healthy subjects was 31 ± 4.8 years old. Basal salivary cortisol was significantly correlated with serum salivary cortisol in the morning and at the midnight; $P<0.05$ in the morning and $P=0.052$ at the midnight. Pearson coefficients were 0.45 in the morning and 0.42 at the midnight (2300 h). The sensitivity of salivary cortisol values in diagnoses of Cushing's syndrome was 100% for cut off values 2.18 ng/dl and for cut off values 3.14 ng/dl the sensitivity was 100% and specificity 83%. ACU 0.97.
Conclusions
In our study we found a correlation between salivary and serum cortisol values in both samples, at the morning and at the midnight to all participants; in healthy people, patients with Cushing's disease.

Keywords: salivary cortisol; serum cortisol; correlation

Adrenocortical virilizing tumor in an adult woman in remission after surgical therapy performed more than 12 years ago

Terroba Larumbe, Crespo Soto, Citores Pascual, Benito Fernandez, Calero Aguilar, Anacabe Goyogana, Urbon Lopez De Linares, Ventosa Viña, Cuellar Olmedo & Palacio Mures
Hospital Universitario Rio Hortega, Valladolid, Spain.

Introduction
Adrenocortical carcinomas (ACCs) are rare, frequently aggressive tumors. Pure virilizing carcinomas are infrequent, constituting 5 to 10% in most series.
Clinical case
A 36-year-old female consults for 5 years evolution of amenorrhea associated with hirsutism attributed to polycistic ovary syndrome (PCOS) and treated with oral contraceptives during the previous 2 years. There was no other data on virilization, changes in body weight, hypertension or gastrointestinal symptoms. In the biochemical exam the following were observed: total testosterone 405 ng/dl (15–110), free testosterone 26.9 pmol/l (0.19–8.9), DHEA-sulphate 1000 µg/dl (35–430), FSH 2.9 mU/ml and LH 11.4 mU/ml. Basal and urinary cortisol, prolactin, beta-estradiol, 17-OH-progesterone, thyroid, hepatic and renal function, ions, were normal. The response to LHRH and ACTH and ovarian ultrasound were compatible with PCOS and ruled out late onset congenital adrenal hyperplasia. The imaging tests showed a solid adrenal mass in the left $10\times13\times14$ cm, with prominent vascular structures inside it, which were embolized prior to surgical excision performed by bilateral subcostal laparotomy. The histological diagnosis of the tumor which weighed 1.152 kg and measured $20\times12.5\times8.5$ cm, proved to be an adrenocortical tumor of low degree malignancy, without invasion of the capsule or adjacent tissues. Menstruation, hormonal tests and ovarian ultrasound became normal after surgery. The patient did not receive any therapy and the follow-up has not shown recurrence.
Discussion
Overall, survival is poor for ACC. Five-year survival is approximately 45–60% for early stage disease, and 10–25% for advanced stage disease. For patients with stage I to III disease, complete surgical resection as initial therapy is the only potentially curative treatment and open surgery remains the standard approach. Despite the large tumor size, the patient had a good prognosis based on the absence of invasion of the surrounding tissues, the histological grade of differentiation and the complete tumor resection. The interest of her case is due not only to the prolonged survival with an optimal quality of life, but also is a representative example of PCOS secondary to hyperandrogenism that disappears from the functional and morphological point of view after the suppression of its cause.

Investigation of atrophic adrenal glands in Cushing's syndrome model rats induced by the administration of dexamethasone

Toshiro Seki[1], Atsushi Yasuda[1], Natsumi Kitajima[1], Masami Seki[2], Masayuki Oki[1], Atsushi Takagi[1] & Masafumi Fukagawa[1]
[1]Tokai University School of Medicine, Isehara-shi, Kanagawa, Japan; [2]Seirei Numazu Hospital, Numazu-shi, Shizuoka, Japan.

Cushing's syndrome is a disease caused by excessive glucocorticoids from adrenocortical tumors. In most cases, impaired adrenocortical function is likely caused by atrophy of the normal adrenal tissue as a result of chronic suppression by the low ACTH levels in the hypercortisolism state. Secondary adrenal insufficiency causes with surgical resection of cortisol-secreting tumors. Therefore, we thought that it was necessary to prepare Cushing's syndrome model rats for establishment of a new treatment method to promote improvement of the function of the remaining adrenal glands after adrenalectomy. Cushing's syndrome model rats have already been published and they describe changes in blood pressure and body weight. Regarding atrophy of tissues, it is considered that the atrophy of cells and the appearance of apoptosis are observed in such tissues. However, the weight and histological changes of the adrenal glands are not

described. In this study, we investigate ACTH, the ratio of adrenal cortex to medulla and number of apoptotic cells as evaluation of atrophic adrenal glands in dexamethasone-treated rats ($n=5$) compared to control rats ($n=5$). In the group treated with dexamethasone, an increase in blood pressure (135 ± 24 mmHg), suppression of plasma ACTH (20 ± 12 pg/ml) and the low serum corticosterone levels (7.5 ± 1.1 ng/ml) were observed as compared with the control group. In addition, adrenal gland weight decreased (13.6 ± 1.2 mg), and the low ratio of adrenal cortex to medulla and an increase of apoptotic cells were observed. Compared with control rats, dexamethasone-treated rats showed a significant decrease in hormonal secretory ability both endocrinologically and histologically. Our group is currently conducting experiments to investigate the levels of mRNAs for c-fos in adrenal glands as assessment of the recovery of adrenal atrophy.

Long-term assessment of AddiQoL and patient diaries may identify Addison patients at high risk for adrenal crises

Maike Koch[1], Klaus Badenhoop[1], Eva Herrmann[2] & Gesine Meyer[1]
[1]Department of Internal Medicine 1, Endocrinology, Goethe-University Hospital, Frankfurt, Germany, [2]Institute for Biostatistics, Goethe-University Hospital, Frankfurt, Germany.

Introduction
Several studies have shown a reduced quality of life (QoL) in patients with Addison's disease (AD). However, by now there are no data investigating the changes of QoL over a long-term course. Adrenal crises (AC) are frequent and potentially life-threatening complications in patients with AD. Since no reliable laboratory indicator can predict impending crises it is difficult to detect patients at increased risk. The purpose of this study was to test whether the repeated use of questionnaires for self-assessment over longer periods can detect possible prodromal periods of an AC.
Methods
137 patients with AD were included. They were asked to complete the disease specific-quality of life questionnaire AddiQoL once monthly over a period of ten months. In addition they also completed a short questionnaire about adverse events during the last month. AC was defined if at least two of the following symptoms were reported: a) hypotension, b) nausea or vomiting, c) severe fatigue, d) documented hyponatremia, hyperkalemia, or hypoglycemia, and subsequent parenteral glucocorticoid administration was carried out.
Results
110 patients completed the study by fulfilling at least 9 of the 10 required sets of questionnaires and not exceeding a time-lag over more than three months. Seven patients suffered an AC, resulting in 7.6 crises/100 patient years. AddiQoL scores in patients with adrenal crises showed a trend ($P=0.058$) to a wider fluctuation over the ten months. 19 Patients reported about severe adverse events not fulfilling the named criteria of AC. In these patients we found a significantly lower median ($P=0.017$) of the AddiQoL scores compared to patients not suffering a pre-crisis.
Conclusions
These are the first data showing the course of QoL during a period of ten months in patients with AD. Prevalence of AC lay by 7.6 per 100 patient years, in accordance with previous data. Our data show, that relevant medical adverse events in patients with AD are associated with a lower QoL. Furthermore, such events affect intraindividual AddiQol-scores over time with a trend to a stronger fluctuation. Long-term assessment of AddiQol and assessment of adverse events, e.g. via patient diaries, may be applied as an additional clinical tool to identify patients at risk for critical events.

Impact of Cortrosyn treatment on weight and adrenal structure in the wistar rat

Samira Akdader-Oudahmane, Zohra Hamouli-Said &
Fatma Hadj-Bekkouche
University of Algiers, Algiers, Algeria.

The corticotropic hormone (ACTH) mainly secreted by the anterior lobe of the pituitary gland which, following a physiological or psychological stress situation, stimulates the adrenal gland and induces the release of glucocorticoids. Many studies have shown their effects on several physiological functions such as immunity, inflammation as well as the cardiovascular system whose action is controlled by ACTH. For this purpose, the study carried out in the wistar rat revealed the effects of a treatment with Cortrosyn (ACTH of synthesis) on the weight and the adrenal structure in the wistar rat. The work was carried out on a lot of rat wistar divided into two lots: one batch of control rat (T) and one batch of treated rat (S) receiving a daily intramuscular injection of Cortrosyn at the rate of 0.01 mg/100 g of weight Body for 20 days. After sacrifice of the animals, the adrenals are taken, weighed and immediately immersed in the fixing liquid in order to carry out the histological techniques. The results show that the intramuscular injection of Cortrosyn resulted in a very significant increase in absolute and relative adrenal weights in treated rats as compared to controls as well as an increase in the number of cells (hyperplasia), a different cell distribution and The appearance of optically empty space. These results to be investigated and could explain why the activation of the adrenal cortex during 20 days by the Cortrosyn would be in favor of an important structural and functional modification of the adrenal gland whose indirect trophic effect of this hormone could be regulated by several factors.

Keywords: Cortosyn; adrenal; ACTH

Molecular variability determines subtle adrenal biosynthetic defect in non-classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency

Livia Mermejo[1], Fernanda Coeli-Lacchini[1], Wendy Turatti[1], Marcia Elamid[2], Renata Parente[2], Carlos Martinelli[2], Sonir Antonini[2], Margaret Castro[1] & Ayrton Moreira[1]
[1]Department of Internal Medicine Ribeirao Preto Medical School, University of Sao Paulo, Brazil, Ribeirao Preto/SP, Brazil; [2]Department of Pediatrics Ribeirao Preto Medical School, University of Sao Paulo, Brazil, Ribeirao Preto/SP, Brazil.

There is a clinical spectrum of non-classical congenital adrenal hyperplasia due to 21-hydroxylase deficiency (NC-CAH). In addition, *CYP21A2* gene mutations analysis present in homozygosis or as compound heterozygosis.
Objectives
To evaluate the relationship between the genotype and biochemical profiles and also compare with clinical severity in NC-CAH.
Patients and methods
Clinical, hormonal and molecular data of 57 patients (47 female,10 male; 47 children,10 adults) with NC-CAH were retrospectively analyzed.
Results
The majority of children (76%) presented with premature pubarche at the diagnosis and 12% showed clitoromegaly. Among adult patients, hirsutism (90%) and menstrual abnormalities (66%) were observed at diagnosis. The basal and ACTH-stimulated 17OHP mean levels were 1115 ± 919 (97–4125) and 4245 ± 2059 (1115–10648) ng/dl. The most frequent mutation was p.V281L (68% of alleles) being 42% in homozygosis and 39% of the patients were compound heterozygotes for one classic and one non-classical mutation (C/NC).The severe mutations were p.I172N, IVS2-13A/C>G, Δ8, CL6, p.Q318X, p.R356W and LGC. Basal and ACTH-stimulated 17OHP values were higher in patients carrying the C/NC genotype group compared to NC/NC genotype (1549 ± 250 vs 806 ± 162; $P=0.01$ and 4740 ± 577 vs 3355 ± 345 ng/dl; $P=0.04$, respectively). Moreover, ROC curve analyses showed that the basal and ACTH-stimulated 17OHP levels of 610 and 3,913 ng/dl were the best cutoffs to identify NC-CAH patients carrying compound heterozygosis with severe mutations. We observed a higher DHEAS (182 ± 150 vs 85 ± 69 µg/dl, $P=0.03$) and a bone age advancement trend ($P=0.05$) in C/NC genotype group compared to NC/NC. There were no differences in age, height, weight, androstenedione and testosterone levels at diagnosis.
Conclusion
Although no phenotype difference was observed between NC/NC and C/NC genotypes, the present study showed graded severities of adrenal biosynthetic defect reflecting the molecular variability in NC-CAH.

Corticoids-therapy related complications in patients with primary adrenal insufficiency

Juan Carlos Romero Rodríguez, María Calatayud Gutiérrez, Laura Mola Reyes, Carlos Silva Vaca, Sonsoles Guadalix Iglesias & Guillermo Martínez Díaz-Guerra
Hospital Universitario 12 de Octubre, Madrid, Madrid, Spain.

Introduction
Patients with primary adrenal insufficiency (PAI) require lifelong corticoids replacement and they are at risk of therapy-related osteoporosis and cardiovascular complications.
Objectives
Determine the prevalence of cardiovascular risk factors, osteoporosis, and other toxicities related with corticoids treatment.
Material and methods
Retrospective, descriptive study in patients with PAI follow up in our service during the last 30 years. Information was collected from clinical histories.
Results
Identified 30 patients with PAI. *Clinical characteristics:* 21 were women, mean age at diagnosis of 36.72 ± 5.3 years and mean time since diagnosis 263.8 ± 57.5 months. Etiology: 15 (50%) autoimmune disease; 7 (23.3%) post-surgery; 5 (16.6%) congenital adrenal hyperplasia; 2 (6.7%) tuberculosis and 1 (3.3%) metastatic disease.
Steroid replacement: 26 (86.7%) used hidrocortisone (HC), 3 (10%) dexametasone, 1 (3.3%) prednisone. 25 patients were on treatment with fludrocortisone. Mean glucocorticoid dose (HC or equivalent): 20.58 ± 1.5 mg/day, mean fludrocortisone dose 0.066 ± 0.008 mg/day.
Possible therapy-related complications: 23(76.7%) patients developed at least 1complication during follow-up: osteoporosis 11(36.7%), dyslipidemia 10 (33.3%), prediabetes 8(26.6%), hypertension 7(23.3%), type 2 diabetes 6(20%), 1(3.3%) cardiovascular event. 88% patients with osteoporosis, 78.6% with diabetes or prediabetes, 85.7% hypertension and 70% with dyslipidemia used HC dose ≥ 20 mg/d.
Conclusions
Osteoporosis and cardiovascular complications are frequents in patients with PAI. Patients on treatment with higher corticoid dose are at risk of development therapy-related complication. Adjustment in corticoid to minimal necessary dose could prevent these complications.

Severe hypertriglyceridemia in relation to toxic levels of mitotane in a patient with stage IV adrenocortical carcinoma (ACC)

Terroba Larumbe, Crespo Soto, Anacabe Goyogana, Urbon López De Linares, Amon Sesmero, Ventosa Viña, Cuellar Olmedo, Marcos García, Otero Roussel & Almendros Muñoz
H. U. Rio Hortega, Valladolid, Spain.

Introduction
The use of mitotane as ACC therapy is associated with multiple adverse effects including hypercholesterolemia due to increased levels of LDL cholesterol. There are no reported cases of severe hypertriglyceridemia (HTG).
Clinical case
A 59-year-old male with a personal history of dyslipidemia phenotype IV and pulmonary emphysema, former smoker and drinker was diagnosed with non-functioning left-sided ACC. Left adrenalectomy + left nephrectomy and subsequently right adrenalectomy and atypical segmentectomy of the upper right lung lobe due to the presence of metastases was performed. One month later, low-dose (2 g/day) mitotane therapy was initiated in combination with hydrocortisone and oral fludrocortisone replacement therapy. In the first post-mitotane control, triglycerides (TG) level which previously was 325 mg/dl increased to 953 mg/dl, coinciding with serum mitotane of 13.8 mg/l. Other factors that could increase it were overruled. Fenofibrate 145 mg/day was prescribed but in the following control TG were 880 mg/dl with serum mitotane of 14.3 mg/l. The dose of mitotane was then reduced to 1 g/day, its level dropped to 10.5 mg/l and TG were 939 mg/dl. Consequently ezetimibe 10 mg/day was added to the therapy and the mitotane dose was increased to 1.5 g/day and subsequently to 2 g/day because the level was very low and a 4.5 cm unresectable metastatic adenopathy that received radiotherapy appeared in the mediastinum. Coinciding with a mitotane level of 33.8 mg/l, the patient presented severe asthenia attributable to mitotane toxicity and TG of 1,528 mg/dl, without data of pancreatitis, what required a drastic decrease in the dose of drug. In the last review, the mitotane level was 6.7 mg/l, TG were 344 mg/dl, the symptoms disappeared and the mitotane dose was again raised while those of fenofibrate, ezetimibe, hydrocortisone and fludrocortisone remained the same.
Discussion
The presence and type of hyperlipemia prior to therapy is likely to affect the adverse effects of mitotane on lipids and in this patient, TG levels have varied according to mitotane doses and levels despite lipid-lowering therapy. On the other hand, dyslipidemia may induce an overestimation of plasma mitotane measurements, so it is necessary to closely monitor the lipid profile in all patients treated with this drug.

Addison's disease presenting as severe hypoglycaemia and cachexia

Ana Cláudia Martins, Paula Bogalho & Ana Agapito
Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Addison's disease (AD), also known as primary adrenal insufficiency, is caused by destruction or dysfunction of the adrenal cortex, resulting in hypocortisolism. The usual clinical features of chronic AD are non-specific and include fatigue, nausea, vomiting and hyperpigmentation. We describe the case of a 58-year-old African black male with AD presenting with recurring severe hypoglycaemia. The patient was admitted several times to the emergency department with hypoglycaemia (blood glucose between 26 and 50 mg/dl) and loss of consciousness, managed with intravenous dextrose. These episodes were associated with anorexia, dizziness, fatigue and progressive weight loss over two years prior to presentation. His past history was significant for pulmonary tuberculosis, and there was no family history of note. Physical examination revealed a cachectic habitus, depressed mood and hyperpigmentation of palmar creases and oral mucosa. He had a body mass index of 14.9, blood pressure 98/57 mmHg and regular pulse of 64 bpm, with no other remarks on systemic examination. Biochemical analysis revealed Hb 11 g/dl, mild hyponatremia (134 meq/l), normokalemia (4.1 meq/l), hypoalbuminemia (32.4 g/l), and normal renal and hepatic function tests. Morning serum cortisol level was 2.3 μg/dl and ACTH 52.2 pg/ml, with normal levels of other pituitary hormones. ACTH stimulation test was performed and confirmed adrenal insufficiency. Computerised tomography scan of the abdomen showed normal shaped and sized adrenal glands. HIV screening was negative and there were no clinical or radiological signs of active tuberculosis. He started treatment with hydrocortisone and fludrocortisone, and his symptoms readily improved. This case illustrates an unusual presentation of Addison's disease and points out the need for a high index of suspicion so that morbidity and mortality can be decreased by a prompt diagnosis.

Posterior reversible encephalopathy syndrome (PRES) in a patient with primary aldosteronism

Julia Silva-Fernández[1], Florentino Del Val-Zaballos[1], Francisco Javier Gómez-Alfonso[1], Paloma González-Lázaro[1], Belvís Torres-Arroyo[1], Rafael García-Ruiz[2], Álvaro García-Manzanares Vázquez de Agredos[1], María López-Iglesias[1] & Inés Gómez-García[1]
[1]Endocrinology Service, Hospital La Mancha Centro, Alcázar de San Juan, Spain; [2]Neurology Service, Hospital La Mancha Centro, Alcázar de San Juan, Spain.

Posterior reversible encephalopathy syndrome (PRES) is a neurological disorder characterized by varied neurological symptoms. There are two leading theories regarding the pathophysiology: hypertension crisis and endothelial dysfunction.
Case report
We report the case of a 42-year-old patient with history of hypertension. She presented to the emergency department with headache and bilateral loss of vision. She described one previous episode of witnessed generalised tonic-clonic seizure at home. She was found to have an elevated blood pressure (BP) of 210/105 mm Hg. An ocular examination revealed a diminished vision and perception of hand movement on both eyes. Laboratory findings were within normal range except for potassium, which was 2.7 mEq/l (normal range 3.5–5). Brain MRI showed bilateral posterior parietooccipital hyper densities in the cortex and subcortical white matter consistent with PRES. Antihypertensive therapy was started. The patient's headache rapidly resolved and her vision improved. The patient was discharged symptom-free on potassium supplements and antihypertensive therapy. After discharge the patient was referred to the Endocrinology service. Aldosterone concentration/plasma renin activity ratio was positive and the saline

infusion test confirmed the diagnosis of hyperaldosteronism. Abdominal MRI revealed a two-centimetre adenoma of the left adrenal gland. The patient underwent surgery to remove the adenoma. After surgery, hypokalemia and hypertension resolved.
Conclusions
Although primary aldosteronism (PA) is not included among the reported causes of PRES, it is important to consider its existence in PRES patients, particularly in those with hypokalemia. The occurrence of PRES in patients with PA might be independent of hypertension since the direct action of aldosterone on the mineralocorticoid receptor may cause endothelial dysfunction.

Evaluation of cardiovascular risk in patients with adrenal incidentaloma

Goknur Yorulmaz[1], Aysen Akalin[1] & Burcu Yagiz[2]
[1]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [2]Uludag University School of Medicine, Bursa, Turkey.

Introduction
Recent studies indicate that patients diagnosed with adrenal incidentaloma may present with cardiovascular disease. The aim of this study was to investigate markers of subclinical cardiovascular disease in patients with adrenal incidentaloma and healthy control group.
Methods
This study included 50 patients with non-functional adrenal adenoma and 30 healthy controls. BMI and waist circumference of the patients were measured. The lipid parameters, glucose, insulin, C-peptide, erythrocyte sedimentation rate, fibrinogen, homocysteine, hsCRP levels and carotid intima media thickness were measured. HOMA levels of the patients were calculated.
Results
Patients with non-functional adrenal adenomas were compared with obese and non-obese control groups. Carotid intima media thickness and erythrocyte sedimentation rate levels of the patients with adrenal incidentaloma were significantly higher than the healthy controls. There was not statistically significant difference between lipid parameters, glucose, insulin, C-peptide, fibrinogen, homocysteine, hsCRP levels of the patients and control group.
Conclusion
In patients with nonfunctional adrenal adenomas the carotid intima media thickness, which is a cardiovascular risk indicator, was found to be thicker than the normal population. At the same time, erythrocyte sedimentation rate, another indicator of cardiovascular risk, was also higher in the adrenal incidentaloma group. These findings suggest that patients with adrenal adenomas have a higher risk for subclinical cardiovascular disease and close follow-up may be necessary.

Hair cortisol in patients with primary aldosteronism

Aaron Hodes[1,3], Maya Lodish[1], Amit Tirosh[1,3], Jerrold Meyer[5], Elena Belyavskaya[1], Charalampos Lyssikatos[1], Kendra Rosenberg[5], Andrew Demidowich[1], Jeremy Swan[1], Nichole Jonas[1], Constantine Stratakis[1] & Mihail Zilbermint[1,2]
[1]Section on Endocrinology and Genetics, Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, Maryland, USA; [2]Johns Hopkins University School of Medicine, Division of Endocrinology, Diabetes, and Metabolism, Baltimore, Maryland, USA; [3]Sackler Faculty of Medicine, Tel Aviv University, Tel Aviv, Israel; [4]Albert Einstein College of Medicine, Department of Radiology, Jacobi Medical Center, Bronx, New York, USA; [5]Department of Psychological and Brain Sciences, University of Massachusetts, Amherst, Massachusetts, USA.

Context
Primary aldosteronism (PA) is a common cause of secondary hypertension, and some PA adrenal tumors co-secrete glucocorticoids, causing subclinical or overt Cushing syndrome (CS). We recently reported correlations between hair cortisol concentration (HCC) and serum and urinary levels of cortisol in patients with CS.
Objective
To determine correlations of segmental hair cortisol and biochemical markers of a referred cohort of patients for the evaluation of PA and to compare to patients with normal cortisol secretion. This pilot study was conducted at the National Institutes of Health Clinical Center.
Methods
Hair samples were collected from 12 study subjects (four with PA, two with PA and cortisol co-secretion, and six controls), with mean age 40.1 ± 21.4 years, mean BMI 28.1 ± 5.3 kg/m^2. Diurnal serum cortisol and ACTH measurements, 24-h-urinary free cortisol corrected by body surface area (UFC/BSA) and 17-hydroxysteroids, corrected for creatinine (17OHS/Cr) were measured. Patients underwent step-wise diagnosis, with measurement of serum aldosterone and plasma renin activity followed by saline suppression and/or oral salt loading tests. Patients without PA or CS were excluded as controls, if midnight serum cortisol >1.8 μg/dl. Segmental hair samples from each patient were processed and analysed for cortisol according to the methods described by Meyer *et al*. (2014).
Results
Age, blood pressure, urinary and midnight cortisol levels were higher ($P<0.05$) in the PA group compared to the controls. Average hair cortisol values in the groups with PA and controls were 30.0 ± 31.0 pg cortisol/mg hair (median: 16.3 pg/mg; interquartile range: 12.6–37.4 pg/mg) and 22.9 ± 27.6 pg cortisol/mg hair (median: 11.3 pg/mg; interquartile range 7.9–26.6 pg/mg), respectively ($P>0.05$). No correlation between hair cortisol and serum and urinary markers of hypercortisolemia was seen in the six patients with PA.
Discussion
We found that no statistically significant difference in hair cortisol between groups and no significant correlation of hair cortisol with urinary or serum cortisol evaluations. We speculate that the lack of correlation may be due to insufficient power. More research is needed on the use of hair cortisol in patients with PA.

Salivary steroid levels during diagnostic tests for adrenal insufficiency

Michaela Dušková[1], Kateřina Šimůnková[1,2], Jana Vítků[1], Lucie Kolátorová[1], Hana Jandíková[1], Hana Pospíšilová[1], Monika Šrámková[1], Mikuláš Kosák[2] & Luboslav Stárka[1]
[1]Institute of Endocrinology, Praha, Czech Republic; [2]Third Department of Medicine, General University Hospital and First Faculty of Medicine, Charles University, Praha, Czech Republic.

Diagnostic tests of the hypothalamic–pituitary–adrenal axis (HPA axis), measuring of free cortisol and use of other adrenal steroids are the subject of debate. We investigated 15 healthy men with mean/median age 27.4/26 (± 4.8) years, and mean/median BMI 25.38/24.82 (± 3.2) kg/m^2. All subjects underwent four dynamic tests of the HPA axis, specifically 1, 10, and 250 μg synacthen tests and an insulin tolerance test (ITT). Salivary cortisol, cortisone, pregnenolone, and DHEA were analysed using liquid chromatography-tandem mass spectrometry.
During the ITT maximum salivary cortisol levels of over 12.5 nmol/l were found at 60 min. Maximum cortisol levels in all of the Synacthen tests were higher than stimulation in the ITT. Cortisone reacted similarly as cortisol, i.e. we did not find any change in the ratio of cortisol to cortisone. Pregnenolone and DHEA were higher during the ITT, and their peaks preceded the cortisol peak. There was no increase of pregnenolone or DHEA in any of the Synacthen tests.
Our results indicate that a 10 μg Synacthen dose is a safe and cost-effective choice.
This study was supported by the project MZCR for conceptual development of research organization 00023761 Institute of Endocrinology and grant 17-28692A.

Assessment of quality of life of patients with Cushing's syndrome depending on the disease course

Gulchekhra Narimova, Zamira Yusupovna, Ravshan Fayzullaev & Iskandar Arifjanov
Republican Specialized Scientific and Practical Medical Center of Endocrinology Uzbekistan, Tashkent, Uzbekistan.

Aim of the study
To evaluate effectiveness of pituitary transsphenoidal surgery (TSS) in patients with ACTH-dependent Cushing's syndrome (ACTH-DCS) in Republic of Uzbekistan (RUZ).
Materials and methods
Patients who included in CS register monitored in 2015. All data from 2000 to 2015 analyzed including outpatient, inpatient examines, tests and treatment. To present, 158 patients with ACTH-DCS registered and monitored. Of these 158 patients, 41 males (26%) and 117 females (74%). Mean age of patient varied from 12 to 38 years old. Mean age was 26.38 ± 3.4 and 27.58 ± 3.4 years old for males

and females respectively. Duration of the condition varied from 4 months to 25 years. 73 patients who had TSS were evaluated in 1, 3, 6 and 12 months period of time and the every 3 months for the follow-up period. TSS was performed initially in 73 patients and in ten patients it was carried out after medical treatment.
Results
Of 158 patients, 86 patients (54%) had surgery including 73 cases who underwent TSS. Pituitary surgery performed as a monotherapy in 32 patients (44%) and in 41 cases (56%) patients received combination therapy. Of 73 patients who underwent TSS, in 60 cases (82%) patients had cured, while repeat surgery performed in ten cases (13.7%). After repeat surgery all ten patients (13.7%) had remission, however, four of them relapsed in 15 months in average. After TSS remission was achieved in 82% of patients who included 62 patients with microadenomas (84.9%) and 12 cases with macroadenimas (16.6%). After 3 years of follow-up five patients (6.8%) who had total hypophisisectomy procedure developed no relapse, whereas of 62 patients (84.9%) with selective adenomectomy and of six patients (6.8%) who had hemihypophysisectomy recurrent disease observed in 5 (8.1%) and 1 (16.7%) cases respectively while remission has not developed in 6 (9.7%) and 1 (16.7%) respectively ($P=0.03$).
Conclusion
Of 73 patients with CS who had pituitary surgery, remission observed in 60 patients (82%), whereas six patients (8.2%) relapsed and in seven cases (9.6%) remission has not developed. TSS remains as first treatment choice in CS and contributes to a steady remission in 82% according to our results.

Paraneoplastic Cushing's syndrome and nephrotic syndrome in a patient with bronchial carcinoid

Daniel Grigorie[1,2], Andra Caragheorghopol[2], Carmen Iordachescu[2], Dan Hortopan[2], Ionela Pascanu[3], Livia Hara[4], Iulian Brezean[1], Nicolae Galie[1], Florina Vasilescu[5], Eugen Mandache[6] & Alina Sucaliuc[1,2]
[1]Carol Davila University of Medicine, Bucharest, Romania; [2]National Institute of Endocrinology, Bucharest, Romania; [3]University of Medicine, Targu Mures, Romania; [4]Matei Bals Hospital, Bucharest, Romania; [5]Central Military Hospital, Bucharest, Romania; [6]Carol Davila Nephrology Hospital, Bucharest, Romania.

Introduction
We report a case of Cushing's syndrome association with nephrotic syndrome in a patient with occult ectopic ACTH (EAS) secretion by a bronchial carcinoid and resolution of both disorders after bilateral adrenalectomy.
Case report
A 42-year-old man was admitted to our department with the suspicion of EAS. He was in a very good health until several months ago when he developed suddenly nephrotic syndrome, severe hypertension, severe hypokalemia, hyperglicemia and rapidly progressive the full blown picture of severe hypercortisolism: severe mental changes, muscle weakness, bruising, pigmented moon facies, no striae, distal muscular atrophy and weight loss. A renal biopsy showed podocyte foot process effacement and no inflammation/sclerosis; renal function was normal. Serum cortisol was frankly elevated and variable (21–97 μg/dl), because of the heavy and variable proteinuria (1.7–7.5 g/24 h), urinary free cortisol 37.071 nmol/24 h. Serum cortisol did not supress with both low -dose and high-dose dexamethasone and serum ACTH was high (238 pg/ml). A pituitary MRI was normal. Chest CT scan revealed a round subpleural nodule 8–9 mm in the right lung. SRS (111-indium-pentetreotide) and 18-FDG-PET CT scans were negative. Bilateral laparoscopic adrenalectomy was performed. Postoperative course was marked by sepsis and he was treated with antibiotics for three months. All the sign and symptoms of hypercortisolism gradually disappeared but the pigmentation remained; surprisingly the resolution of the nephrotic syndrome was noted. One year later he was in good clinical condition with adrenal replacement therapy. Chest CT scan confirmed the presence of a stable pulmonary nodule and he underwent thoracic surgery. A bronchial typical carcinoid tumour with positive immunostaining for ACTH was diagnosed. Postoperative course was uneventful.
Conclusion
This is a rare case of the association of severe occult EAS with nephrotic syndrome, which has been cured by the resolution of the severe hypercortisolism.

Frequancy of diabetes and prediabetes in patients with adrenal incidentaloma without hormonal activity

Elzbieta Bandurska-Stankiewicz, Katarzyna Myszka-Podgórska, Joanna Rutkowska & Wojciech Matuszewski
Endocrinology, Diabetology and Internal Diseases Clinic, University of Warmia and Mazury in Olsztyn, Olsztyn, Poland.

Aim of the study
Estimation of the frequancy of diabetes and prediabetes in patients with adrenal incidentaloma (AI) without hormonal activity.
Material and methods
The study comprised patients with AI without hormonal activity, verified by CT. The hormonal function of adrenal glands was determined according to the circadian rhythm of cortisol and/or dexametasone suppression test, ACTH, aldosterone, plasma renin activity, DHEAS, androstenedione, 17hydroxy progesterone, metanephrines in urine.
Physical examination included: the BMI, the waist circumference (norm <80 cm women, <94 cm men), blood pressure. The biochemical assays: fasting glycemia, OGTT (excluded patients with diabetes), fasting insulin and lipids level (total, HDL and LDL cholesterol, triglycerides).
Results
125 patients were examined, aged 61.3 ± 8.8 years, 72 (57.6%) women. Size of tumors were 27.6 mm ±15 mm. Carbohydrates disorders were observed in 62 (49.6%) persons aged 62.9 ± 7.5 years, including 32 (25.6%) women. Abdominal obesity was diagnosed in 87 (69.6%), 56 (44.8%) women and 31 (24.8%) men. Diabetes was regonised in 16 (13%) patients, IFG in 24 (19.2%), IGT in 34 (27.6%). The concentration of fasting insulin was $8.9+/-5.5$ μU/ml, higher in men then in women ($9.16+/-5.65$ vs $8.71+/-4.70$; $P>0.01$). The concentration of total cholesterol was 218 ± 49.7 mg/dl, HDL-cholesterol 59 ± 21.1 mg/dl, LDL cholesterol 134 ± 44.1 mg/dl, triglycerides 116 ± 60 mg/dl; 83 (66.6%) of the patients had been diagnosed positive for dyslipidemia or were administered hypolipemic medications. Additionaly arterial hypertension was diagnosed in 99 (79.2%) patients, with the arterial systolic BP 131 ± 15 mmHg, diastolic BP 80 ± 9 mmHg.
Conclusions
1) Diabetes was observed more often in patients with AI without hormonal activity then in the entire Polish population.
Patients with AI without hormonal activity are a risk group of prediabetes and diabetes.

To big to work! Lymphoma presenting with primary adrenal insufficiency

Joel Capraro, Hanna Giessen & Beat Müller
Division of Endocrinology, Diabetes and Metabolism, Kantonsspital Aarau, Aarau, Switzerland.

Background
Primary adrenal lymphoma (PAL) is a rare cause of primary adrenal insufficiency (PAI). Most often patients present with unspecific symptoms. Bilateral adrenal enlargement with signs and symptoms of PAI are clues, percutaneous biopsy after having excluded pheochromocytoma in a situation of high suspicion is diagnostic. Most of PAL are highly malignant B-cell lymphomas with a bad prognosis.
Case
A 71-year-old patient was sent for endocrine workup because of a 2-month history of intermittent dyspnea, thoracic discomfort, weight loss and abdominal pain. An ambulant CT scan to exclude pulmonary embolism showed bilateral adrenal enlargement (right $77\times31\times55$ mm, left $63\times38\times41$ mm, native 25-29HE), which were new compared to a CT scan done one year earlier. On clinical examination, the patient was orthostatic and in an im-paired general condition. He had hyperpigmented hand lines. Laboratory evaluation showed a slight hyponatremia (131 mmol/), potassium in the upper normal range (4.2 mmol/l), pathologic ACTH-stimulation test (peak cortisol level: 153 nmol/l) and elevated ACTH levels (231 ng/l, normal range <46 ng/l). Antibodies for 21-hydroxylase were negative, as well as free metanephrines in plasma, aldosterone-renin ratio was decreased (aldosterone 122 pmol/l, renin 39 mU/l). 17-hydroxyprogesterone was low (3.3 nmol/l, normal range 1.9–6.5 nmol/l). Quantiferon test was negative, and the CT scan did not raise suspicion for tuberculosis. We diagnosed PAI and started substitution with hydrocortisone (initial dose 50 mg/d) and

fludrocortisone (0.1 mg/d). Histology of a CT-guided needle biopsy revealed infiltration of a highly malignant B-cell lymphoma. The patient was sent for oncological evaluation and start of chemotherapy with rituximab, cyclophosphamide, doxorubicin, vincristine and prednisone (R-CHOP).

Discussion

PAL is a rare manifestation of primary extranodal lymphomas (1/3 of all lymph node neoplasms, PAL < 1% of all extranodal lymphomas). Only about 100 cases are published in the literature worldwide. Conversely, secondary spreading of a lymphoma to the adrenals is quite common (in autopsy studies up to 25%). Other reasons for bilateral adrenal enlargement are adrenal hyperplasia (any cause), metastasis of lung, breast and stomach (>50% of metastasis), bilateral pheochromocytoma, adrenal hemorrhage, adrenal involvement with granulomatous diseases, histicytosis and primary pigmented nodular adrenal dysplasia (PPNAD). Symptoms of PAL are unspecific (asthenia, weight loss, vague abdominal pain, fever). Diagnosis is made by percutaneous biopsy. In nearly 70% of cases PAL are bilateral, causing primary adrenal insufficiency. Average age of affected patients is around 70 years. Most of PAL are diffuse large B-cell lymphomas with BCL6 gene rearrangement and poor prognosis, as in our case. Therapy consists of R-CHOP.

Conclusion

Patients with bilateral adrenal enlargement and PAI need immediate replacement of glucocorticoid (including instructions about dosing in stressful situations) and mineralocorticoid hormones. While PAL is rare, it has a poor prognosis, thus rapid induction of treatment is necessary.

Specificity of the posture test for subtyping of primary aldosteronism, a 10 year nationwide summary in Iceland

Hrafnhildur Gunnarsdottir[1], Gudbjorg Jonsdottir[1,2], Jon Gudmundsson[3], Gudjon Birgisson[4] & Helga Sigurjonsdottir[1,5]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Department of Internal Medicine, University of Iowa Hospitals and Clinics, Iowa City, Iowa, USA; [3]Department of Radiology, Landspitali University Hospital, Reykjavik, Iceland; [4]Department of Surgery, Landspitali University Hospital, Reykjavik, Iceland; [5]Department of Endocrinology, Landspitali University Hospital, Reykjavik, Iceland.

Introduction

The posture test (PT), developed to distinguish idiopathic adrenal hyperplasia (IAH) from aldosterone producing adenoma (APA), has been postulated as inaccurate. In 2007, standardized diagnostic methods, including PT for subclassification, were introduced in Landspitali University Hospital (LUH), housing the only endocrine department in Iceland. The aim of this study is to review the results of PT performed in LUH in 2007–2016.

Methods

Charts for all patients ≥18 years old, diagnosed with primary aldosteronism (PA) during 2007–2016 in LUH, were retrospectively reviewed. After screening, verification of PA was made with saline infusion test. During PT, s-aldosterone, s-renin and s-potassium were measured after a 10-h bed-rest and again after subsequent 4-h upright-position. If s-aldosterone increased by >50%, the test was considered positive. Thereafter, patients underwent a CT-scan and adrenal venous sampling (AVS). Adrenalectomy was offered if PA was found unilateral by AVS.

Results

Out of 49 PA-patients undergoing PT during the period, 22 had unilateral disease and 27 bilateral. The unilateral group (UG) consisted of 14 patients with APA and 4 with IAH. Three are awaiting surgery and one histopathological examination was inconclusive. Average increase of s-aldosterone during PT in the bilateral group (BG) was 217±127%, significantly higher than 88±26% in the UG ($P=0.008$). A greater proportion of the BG had a positive PT, 81% (22/27) versus 55% (12/22) of the UG, $P=0.04$. Positive predictive value of the PT with regards to bilateral disease was 0.65 (22/34), sensitivity 0.81 (22/27) and specificity 0.45 (10/22).

Conclusions

In this nationwide study we found the PT to have fairly high sensitivity but low specificity in subclassifying PA, supporting previous reports of inaccuracy. Although the PT is not conclusive, it could be informative in addition to CT-scan for treatment decision if a patient is unable to undergo AVS for practical reasons.

Cofilin is a cAMP effector in mediating actin cytoskeleton reorganization and steroidogenesis in mouse and human adrenocortical tumor cells

Rosa Catalano[1,2], Erika Peverelli[1,2], Elena Giardino[1,2], Donatella Treppiedi[1,2], Valentina Morelli[1,2], Iacopo Chiodini[1,2], Lorenzo Marcon[1,2], Cristina L Ronchi[3], Jérôme Bertherat[4], Felix Beuschlein[5], Maura Arosio[1,2], Anna Spada[1,2] & Giovanna Mantovani.
[1]Endocrine Unit, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico; [2]Department of Clinical Sciences and Community Health, University of Milan, Milan, Italy; [3]Department of Internal Medicine I, Division of Endocrinology and Diabetes, University Hospital, University of Wuerzburg, Wuerzburg, Germany; [4]Institut Cochin, Inserm U1016, CNRS UMR8104, Descartes University, Department of Endocrinology, Reference Center for Rare Adrenal Diseases, Hôpital Cochin, Paris, France; [5]Medizinische Klinik und Poliklinik IV, Endocrine Research Unit, Klinikum der Universität München, LMU, Munich, Germany.

The cAMP signaling pathway plays a major role in the pathogenesis of cortisol-producing adrenocortical adenomas (CPA). In adrenocortical cells cAMP induces dramatic changes in cell morphology accompanied by actin cytoskeleton rearrangements that precede steroidogenesis, the causal relationship between these events being still undefined. In this study we investigated cAMP effects on cytoskeleton rearrangements and steroidogenic response in mouse (Y1) and human adrenocortical tumor cells, focusing on the role of the actin-severing protein cofilin, whose inactivation is regulated by phosphorylation on Ser3. Moreover, we tested possible alterations in cofilin phosphorylation status and expression in human CPA vs endocrine inactive adrenocortical adenomas (EIA). We demonstrated that forskolin induced cell rounding and reduced phosphorylated (P)-cofilin/total cofilin ratio in Y1 (−52±16%, $P<0.001$) and primary human CPA cells (−53±18%, $P<0.05$). Cofilin silencing in Y1 cells reduced both forskolin-induced morphological changes (37±8% rounded cells vs 63±7% in control cells, $P<0.05$) and progesterone production (1.3-fold increase in silenced cells vs 1.8-fold in control cells, $P<0.05$), whereas transfection of wild type or S3A (active) cofilin, but not S3D (inactive) cofilin, potentiated forskolin effects on cell rounding (80±6% and 85±14% rounded cells, respectively, vs 69±6% in control cells) and increased about threefold progesterone synthesis with respect to control cells ($P<0.05$). Furthermore, cofilin dephosphorylation by Y27632, a selective inhibitor of ROCK, the kinase that phosphorylates cofilin, potentiated forskolin induced cell rounding (about 90% rounded cells) and steroidogenesis (about twofold increase vs forskolin alone).

Finally, western blot analysis showed a reduced P-cofilin/total cofilin ratio and an increased total cofilin expression in CPA vs EIA (P-cofilin/total cofilin ratio 0.76 and 2.44 respectively, $P<0.05$, total cofilin/GAPDH 1.20 and 0.54, respectively, $P<0.01$).

Overall, these data identified cofilin as a mediator of cAMP effects on both morphological changes and steroidogenesis in mouse and human adrenocortical tumor cells.

Primary Aldosteronism in Iceland, nationwide results from 2012–2016

Hrafnhildur Gunnarsdottir[1], Jon Gudmundsson[2], Gudjon Birgisson[3] & Helga Sigurjonsdottir[1,4]
[1]Faculty of Medicine, University of Iceland, Reykjavik, Iceland; [2]Department of Radiology, Landspitali University Hospital, Reykjavik, Iceland; [3]Department of Surgery, Landspitali University Hospital, Reykjavik, Iceland; [4]Department of Endocrinology, Landspitali University Hospital, Reykjavik, Iceland.

Introduction

Primary aldosteronism (PA) is an important, potentially curable cause of hypertension (HT) with higher risk of cardiovascular events than essential HT. In 2007, a standardized PA work-up protocol was introduced in Landspitali University Hospital (LUH), housing the only endocrine department in Iceland. The aim of this study is to review characteristics, test results and histopathology for patients diagnosed with PA in 2012-2016 in LUH.

Methods

Charts for PA-patients aged ≥18, diagnosed in 2012–2016 in LUH, were retrospectively reviewed. Screening was considered positive if s-aldosterone and/or 24-h urinary aldosterone excretion was increased and s-renin decreased. Diagnosis was confirmed if s-aldosterone increased by >140 pmol/l on saline

infusion test (SIT) performed by a 4-hour intravenous infusion of isotonic saline, 500 ml/h. Thereafter, patients underwent a CT-scan and adrenal venous sampling (AVS) for distinguishing unilateral (UD) from bilateral disease (BD). Adrenalectomy was offered if UD was diagnosed.

Results

Thirty-six patients were diagnosed with PA during the period; 19 males and 17 females. All had s-aldosterone >300 pmol/l on morning screening and 12 had an elevated 24-h urinary aldosterone ($n=23$). Median (range) s-aldosterone after SIT was 311 pmol/l (202-1715). By the end of 2016, 10 had a confirmed UD (32%), 21 BD (68%) and 5 were awaiting AVS. Six out of 10 UD underwent adrenalectomy by the end of 2016 and all had a cortical adenoma on histopathological examination. CT-scan showed unilateral adrenal nodule in 15 patients, 8 of whom had UD by AVS on that same side (positive predictive value 0.53).

Conclusions

This study indicates that PA is an important cause of HT in Iceland with equal gender distribution. Bilateral hyperplasia proved to be a more frequent cause than cortical adenoma which is consistent with prior Icelandic results from 2007–2011. Interestingly, no-one was diagnosed with unilateral hyperplasia during the study period.

Cardiovascular risk factors do not play a role in the risk factor profile of adrenal crisis

Marcus Quinkler[1], Robert D. Murray[2], Pinggao Zhang[3], Pierre Zelissen[4] & Bertil Ekman[5]
[1]Endocrinology in Charlottenburg, Berlin, Germany; [2]St James's University Hospital, Leeds, UK; [3]Shire, Lexington, MA, USA; [4]University Medical Center Utrecht, Utrecht, The Netherlands; [5]Linköping University, Linköping, Sweden.

Introduction

Adrenal crises (ACs) are life-threatening events in patients with primary (PAI) or secondary (SAI) adrenal insufficiency, occurring ~4–10 times per 100 patient-years. Major causes of ACs are infections, especially gastroenteritis and tonsillitis/laryngitis. Risk factors for ACs remain ill defined, but could include concomitant endocrine diseases (diabetes mellitus, premature ovarian failure) in PAI, diabetes insipidus in SAI, and concomitant non-endocrine diseases (obesity, asthma, cancer, and cardiac and neurological diseases) in both groups.

Design

We analysed data from the European Adrenal Insufficiency Registry (EU-AIR; NCT01661387) with centres across Germany, the Netherlands, Sweden and the UK. Clinical and biochemical data at enrolment were compared for patients with frequent ($n\geq2$) and infrequent ACs ($n<2$) in each AI subset; 1969 patients were included (727 PAI, 1172 SAI) in the current analysis. Patients with congenital adrenal hyperplasia or tertiary AI were excluded.

Results

To November 2016, 27 patients with frequent ACs were identified (19 PAI, 8 SAI). The number of adverse events/patient was significantly higher in the frequent than the infrequent AC group in both subsets (PAI, 15.3 ± 14.0 vs 3.9 ± 6.5; SAI, 19.6 ± 18.5 vs 2.2 ± 4.3, respectively; $P=0.0024$). Patients with frequent ACs were more likely to be female (PAI, 78.9% vs 65.1%; SAI, 75.0% vs 47.9%), and less likely to have hypertension (PAI, 5.3% vs 21.0%; SAI, 25.0% vs 34.4%), with a lower BMI (PAI, 24.2 ± 4.7 vs 26.2 ± 4.9 kg/m^2; SAI, 26.0 ± 5.7 vs 28.7 ± 5.1 kg/m^2). There were no differences in daily glucocorticoid dose, frequency of diabetes mellitus, HbA1c levels, lipid profiles or use of statins. Interestingly, disease duration was shorter in patients with frequent compared with infrequent ACs in PAI (12.8 ± 13.2 vs 18.9 ± 14.5 years), whereas the opposite was true in SAI (15.6 ± 12.3 vs 13.8 ± 11.2 years).

Conclusions

Data suggest that known cardiovascular risk factors appear not to feature in the AC risk profile.

Bilateral adrenal incidentaloma: a diagnostical and therapeutical challenge

Ines Bilic-Curcic[1,2], Tatjana Bacun[1,2], Marija Tripolski[2] & Biljana Zulj[2]
[1]Faculty of Medicine, University J.J. Strossmayer, Osijek, Croatia; [2]Clinical Hospital Center, Osijek, Croatia.

Incidentally discovered adrenal masses (incidentalomas) present challenges both in diagnosis and management. The bilateral adrenal mass carries a risk of hormone hypersecretion, but it could also present a metastasis from another primary carcinoma or be a part of genetic syndrome.

We report a 68 year old patient with bilateral adrenal incidentalomas (revealed accidentally on US, confirmed by abdominal CT in 2015.) left 29 mm, right 33 mm in diameter, radiological characteristics indicating adenoma. Initial diagnostical work up showed subclinical Cushing syndrome with osteoporosis and arterial hypertension as part of clinical presentation. One year later, abdominal CT showed significant enlargement of both adrenal masses (left 50 mm, right 45 mm), still adenomas according to CT characteristics, but post contrast imaging could not be performed due to chronic renal impairment. Her laboratory results were still consistent with subclinical Cushing syndrome, now presenting with osteoporosis, hypertension and glucose impairment with no signs of other excessive hormone secretion but now her chest x-Ray revealed a lesion in her left lung 27 mm in diameter of unknown etiology (although she mentioned lung tuberculosis in her youth). As she did not have any signs of metastatic disease and her tumor markers were normal we decided to perform left adrenalectomy to provide definite diagnosis. Histological finding confirmed adrenal adenoma and hormone reevaluation showed possible excessive cortisol secretion with osteoporosis, but now blood glucose was normal, and anti-hypertensive agents were discontinued due to normal blood pressure. There was no change in the size of the lung lesion on her chest X ray (6 months after) and no signs of metastatic lesions. Thoracic CT and bronchoscopy are planned.

While the initial diagnostic approach is similar to the unilateral incidentaloma, additional testing should be considered in the case of the bilateral adrenal mass and as oppose to unilateral incindentalomas surgery remains the mainstay of treatment in most cases.

DOI: 10.1530/endoabs.49.EP23

EP24

Are we missing patients with primary aldosteronism (PA) if we require both elevated aldosterone: renin ratio (ARR) and elevated aldosterone levels?

Troy Puar, Joan Khoo & Meifen Zhang
Changi General Hospital, Singapore, Singapore.

Introduction

Although the Endocrine Society guidelines recommend using aldosterone: renin ratio (ARR) to screen patients for primary aldosteronism (PA), whether to include a cut-off for aldosterone levels remains controversial. In Singapore, most centres require both an ARR >550 (ng/dl)/(ng/ml per h) and aldosterone ≥15 ng/dl. However, it has been shown that patients with PA may have aldosterone levels <15 ng/dl, and also respond well to mineralocorticoid antagonists. We examined the prevalence of Asian patients with high ARR, and influence of including patients with unsuppressed aldosterone levels >5 ng/dl.

Methods

We determined the prevalence of patients with high ARR >550 (aldosterone, ng/dl; plasma renin activity, ng/ml per hr) in a multi-ethnic Asian population with hypertension being screened for PA in a single tertiary centre, and stratified them by aldosterone levels.

Results

A total of 786 patients were screened for PA from 2015–2016, with 219 of 786 (27.8%) patients having a high ARR. Amongst these 219 patients with a high ARR, 68 of 219 (31.1%) had an aldosterone levels ≥15 ng/dl, 51 (23.3%) had aldosterone levels 10-14.9 ng/dl, 60 (27.4%) had an aldosterone levels 5–9.9 ng/dl, and 40 (18.3%) had aldosterone levels <5 ng/dl. When both ARR> 550 and aldosterone ≥15 ng/dl are required, only 68 of 786 (8.6%) patients will proceed for confirmatory tests as per current practice. However, if all patients with ARR>550 and unsuppressed aldosterone levels ≥5 ng/dl are included, then 179 of 786 (22.8%) of patients should be considered for the diagnosis of PA.

Conclusion

Current practice of requiring a high aldosterone level in addition to a high ARR may underdiagnose patients with PA. However, potential benefit of working-up all patients with a high ARR has to be weighed against increased cost. A possible alternative would be a trial of mineralocorticoid therapy in these patients.

DOI: 10.1530/endoabs.49.EP24

EP25

Severe hypoglycaemic ketoacidosis in a patient with adrenal crisis

Azmi Mohammed, Giridhar Tarigopula, Paul Peter, Praveen Partha & Shafie Kamaruddin
Darlington Memorial Hospital, Darlington, UK.

We present a case of a 26 years old female who was rushed to hospital with 4 days history of abdominal pain, vomiting and dizziness. She also had one episode of diarrhoea. Further history revealed that she had lost 32 kilograms of weight over the last 18 months through diet and exercise. There were no signs suggestive of an eating disorder.

On examination she was peripherally cold, tachycardic (117/min), hypotensive (86/50 mmHg) and sweaty. Her Glasgow Coma Scale was 15. Her chest was clear and she had mild epigastric tenderness. She was fluid resuscitated with 0.9% sodium chloride. Blood test results: pH 7.01, pCO2 (3.2), pO2 (14.6), blood glucose (2.1 mmol/l), HCO3 (12), Na (126), K (5.6), ketones (7.6 mmol/l), urea 15.1 mmol/l and creatinine (79) and CRP (76). 10% Dextrose infusion was started. An adrenal crisis was suspected and she was commenced on IV hydrocortisone. A possible trigger was thought to be gastroenteritis. Her serum cortisol was 13 mmol/l, no baseline ACTH was checked. She remained hypotensive despite aggressive fluids and was subsequently transferred to ITU. Over the next 24 hours her blood pressure was maintained on inotropes however her acidosis was refractory to treatment (pH $<$ 7.2 after 8 hours). She was started on sodium bicarbonate 1.26%; however, the effect was not sustained as her pH continued to drop. Her ketones also remained high (5–6 mmol/l) despite a normal glucose (4–7 mmol/l). She was subsequently commenced on 5%Dextrose infusion to halt ketogenesis. Her HbA1c was 35 mmol/mol. Following 5% Dextrose infusions, her acidosis started to improve with normalisation of ketones. Learning points:

1. Adrenal crisis should be treated promptly
2. Euglycaemic or hypoglycemic ketosis can complicate prolonged starvation, vomiting and eating disorders, so detailed and collateral history is important
3. Although very rare, type 1 diabetes can be masked by adrenal insufficiency and present with euglycemic ketoacidosis. It should be considered in similar scenarios.

Assessment of the hypothalamic pituitary adrenal axis in patients receiving adjuvant mitotane treatment after radical resection of adrenocortical carcinoma

Giuseppe Reimondo[1], Soraya Puglisi[2], Barbara Zaggia[1], Vittoria Basile[1], Laura Saba[1], Paola Perotti[1], Silvia De Francia[3], Maria Chiara Zatelli[4], Salvatore Cannavo[2] & Massimo Terzolo[1]
[1]Internal Medicine 1, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; [2]Endocrinology Unit, Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy; [3]Pharmacology, Department of Clinical and Biological Sciences, University of Turin, Orbassano, Italy; [4]Section of Endocrinology and Internal Medicine, Department of Medical Sciences, University of Ferrara, Ferrara, Italy.

Mitotane, used in the treatment of adrenocortical cancer (ACC), is able to inhibit multiple enzymatic steps of adrenocortical steroid biosynthesis, potentially causing adrenal insufficiency (AI). Recent studies *in vitro* have also documented a direct inhibitory effect of mitotane at the pituitary level.

The aim of the study was to assess the hypothalamic pituitary adrenal (HPA) axis in patients receiving mitotane as adjuvant treatment after radical resection of ACC getting insights on how mitotane affects the HPA axis and looking for markers to assessing AI.

We prospectively enrolled 16 patients on adjuvant treatment with mitotane after radical surgical removal of ACC, who were on stable mitotane dose and cortisol replacement therapy for at least 6 months and were disease free at the time of evaluation. Patients underwent standard hormone evaluation and stimulation test with h-CRH. A group of 10 patients with Addison's disease served as controls for the h-CRH test.

At the time of the study, six patients had mitotane levels within the therapeutic range, one had levels $>$20 mg/l, while nine had levels $<$14 mg/l. The median dose of cortisone acetate was 62.5 mg daily. Basal serum cortisol was reduced in 14 patients, being undetectable in 7 of them, and in the normal range in only two patients (12.5%); one of them had low mitotane concentrations. Only a non-significant trend between mitotane dose and either serum or salivary cortisol was evident. We demonstrated a close correlation between CBG levels and plasma mitotane levels ($P=0.003$) and between serum cortisol levels and salivary cortisol levels ($P=0.005$), while ACTH levels were inversely correlated with the daily dose of cortone acetate ($P=0.006$). ACTH levels were significantly higher in the Addison group than in ACC patients, both in baseline conditions ($P=0.036$) than following CRH ($P=0.041$).

In conclusion, measurement of salivary cortisol did not add useful information for assessing AI in mitotane-treated ACC patients. Assessment of ACTH levels may be of some aid, since levels that are not frankly elevated may herald over-replacement. The observation of lower ACTH levels in ACC patients than in patients with Addison, both in basal conditions and after CRH stimulation, suggests that mitotane may play an inhibitory effect on ACTH secretion at the pituitary level. However, an effect of high-dose cortisol replacement should not be ruled out.

EP27

Extra-gastrointestinal stromal tumor in the retroperitomeum which had difficulty in differential diagnosis with adrenal cancer

Naotetsu Kanamoto, Makiko Nagatsuji, Keiko Yamagami, Shinya Tokunaga & Masayuki Hosoi
Osaka City General Hospital, Osaka, Japan.

Extra-gastrointestinal stromal tumors (EGISTs) in the retroperitomeum are extremely rare. A 44-year-old man was referred from a private clinic suspicious of an adrenal tumor that was incidentally detected by abdominal ultrasound. Computed tomography (CT) scan showed a retroperitoneal mass of 12 cm harboring a feeding artery from the left adrenal gland contiguous with the left adrenal gland, which enhanced heterogeneously on post-contrast imaging. By magnetic resonance imaging, the tumor demonstrated heterogeneous low intensity in T_1 weighted images and an extremely heterogeneous lesion composed of high and low signal intensity in T_2 weighted images. PET CT imaging with fluorine-18-fluorodeoxyglucose (^{18}F-FDG) demonstrated ^{18}F-FDG accumulation in the tumor in the early and late phase. Iodine-123-metaiodobenzylguanidine and iodine-131-adosterol scintigram did not detect any accumulation in the tumor. The results of all conducted serum and urinary examinations of adrenocortical hormone and catecholamine were within the normal range. Adrenalectomy was performed. Histopathological diagnosis of the tumor was GIST. Immunohistochemical findings revealed that the neoplastic cells were positive for c-kit and CD34 and negative for S100 protein, alpha-SMA, and desmin. Mitotic activity (2–3/50 high power field) and the labeling index for MIB-1 (about 3.2%) were low. The GIST was diagnosed as a high-risk tumor because its diameter was over 5 cm. We started imatinib 400 mg/day according to the Japan GIST guideline 1 month after operation.

Perceptions of medical practitioners' management of addison's disease across Africa: an on-line survey

Ian Louis Ross[1], Thabiso RP Mofokeng[2], Fazleh Mahomed[2] & Salem Beshyah[3]
[1]University of Cape Town, Cape Town, South Africa; [2]University of the Free State, Bloemfontein, South Africa; [3]Sheikh Khalifa Medical City, Abu Dhabi, United Arab Emirates.

Objectives

Addison's disease diagnostic and management challenges in Africa are not well documented. We aimed to identify the specific needs of patients with established Addison's disease, across Africa.

Methods

An online survey of a large pool of medical practitioners was undertaken. The questionnaire covered patient demographics, aetiology, therapy and limitations of diagnosis and treatment.

Results

Of the 36,203 recipients; 661 responded; 246 completed the questionnaire. 151 were actively treating Addison's disease. The total number of patients identified with Addison's disease in this study was 1134 (530 males; 604 females). The highest number were reported from South Africa (748; 66%). Majority of patients were in the age groups of 16-60 years with a slight excess of females (334 vs 403). Associations were reported with hypothyroidism in 15.3%, type 1 diabetes in 11.6%, pernicious anaemia in 6.5%, premature ovarian insufficiency in 4.6% and Graves' disease in 3.0%. Presentation in crisis was reported in 12.1% of cases, otherwise classical symptoms were seen fairly consistently. Over 60% of patients received hydrocortisone only and the remainder received combination of hydrocortisone and fludrocortisone. Fixed doses of steroid replacement were used by 35.3% of physicians, whereas 57.9% of respondents adjust doses on basis of body weight. Appropriate diagnostic investigations, proved to be the greatest

limitation in making the diagnosis, with 73.2% of responders relying on the combination of clinical grounds and compatible electrolytes alone and only 27.9% having access to an ACTH stimulation test. There were few therapeutic options available to the responders outside of South Africa, with overall, 53% indicating non-availability of medication and 58% not having access to a CT scan.
Conclusions
This first continent-wide survey highlighted some challenges in diagnosis and treatment of Addison's disease. Awareness and resources are required for timely recognition and optimal management of Addison's disease in Africa.

Improved metabolic outcomes for patients with subclinical Cushing's syndrome treated with surgery: Ten year experience in a tertiary centre
Lih Ming Loh, Du Soon Swee, Wei Lin Tay & Peng Chin Kek
Department of Endocrinology, Singapore General Hospital, Singapore, Singapore.

Introduction
Subclinical Cushing's syndrome (SCS) occurs in up to 12% of patients with incidentally found adrenal masses. Optimal management remains controversial. We report our experience of nine patients with SCS managed at our institution from 2007 to 2016.
Methods
All patients were referred for adrenal incidentalomas (AI) and had no discriminatory clinical features of Cushing's syndrome. SCS was defined using cortisol levels $>$ 138 nmol/l after overnight 1-mg dexamethasone suppression test and one additional abnormal biochemical test. ACTH was suppressed in all. Urinary free cortisol measurements were normal in the majority.
Patients and results
The median age of our patients was 53 years (range 36–63) and all but one were female. Mean size of the adenomas was $2.65 + 0.52$ cm. Majority of our patients had metabolic comorbidities of overweight, hypertension, glucose intolerance or diabetes and dyslipidemia. One patient initially followed up as a non-functioning AI developed SCS over 8 years of surveillance as her adenoma grew. Another patient had bilateral adrenal adenomas. All our patients underwent surgical resection. The patient with bilateral nodules underwent bilateral subtotal adrenalectomy. All but one required a period of postoperative corticosteroid support. Following withdrawal of steroids, there was observable median weight loss of 3.85 kg (0.5–10.7) compared to presurgical weight. Four patients had an improvement of their BMI category from overweight to normal. All six patients with hypertension had sustained improvement in their blood pressure: two became normotensive and the remainder had reduction of doses of antihypertensives. However there was no change to glycemic and lipid status.
Conclusions
In our small series of patients with SCS, surgical intervention resulted in improved metabolic outcomes. We therefore suggest that if patients are surgically fit, surgery should be considered for SCS.

Severe hypoaldosteronism after unilateral adrenalectomy for primary hyperaldosteronism
João Ananias Gonçalves[1], Rui Barrros[1], Betânia Ferreira[1] & Cláudia Amaral[1,2]
[1]Hospital da Luz Arrábida, Vila Nova de Gaia, Portugal; [2]Centro Hospitalar do Porto - Hospital de Santo António, Porto, Portugal.

Introduction
Primary hyperaldosteronism is a known cause of arterial hypertension, classically with hypokalaemia. About 30–40% of the cases are caused by unilateral aldosterone-producing adenoma, and the recommended treatment is adrenalectomy. Hypoaldestoronism is an uncommon complication of unilateral adrenalectomy, but it can be life-threatening. We present a case of severe hypoaldosteronism after unilateral adrenalectomy for the treatment of primary aldosteronism.
Case presentation
A 66 years old male with long term hypertension on triple drug therapy, chronic kidney disease and persistent hypokalaemia was diagnosed with primary hyperaldesteronism. He had increased aldosterone – 3426 pg/ml (normal 34.7–275 pg/ml) and low renin – 4 uUI/l (normal 4.4–46.1 uUI/l). An elevated plasma aldosterone to renin ratio was compatible with diagnosis. A CT scan revealed a right adrenal nodule suggestive of adenoma (21×19 mm). He was submitted to laparoscopic unilateral adrenalectomy. Pathology confirmed an adrenal adenoma. At discharge, all anti-hypertensive drugs were suspended.
3 weeks after surgery he complained of asthenia, anorexia and diarrhea. Blood tests showed severe hyperkalaemia (7.8 meq/l), metabolic acidosis and acute renal failure (creatinine 4.2 mg/dl). The serum aldosterone was low (43 ng/dl) and renin (4.7 pg/ml) normal. We assume the diagnosis of hyporeninemic hypoaldosteronism and he was treated with fludrocortisone (0.1 mg id), sodium bicarbonate and fluids, with improvement in serum creatinine and normalization of potassium levels. 3 months after discharge he remained asymptomatic but fludrocortisone dependent, with stable potassium and creatinine levels and mild hypertension.
Conclusion
Despite uncommon, hypoaldosteronism after unilateral adrenalectomy is known to occur. Usually mild and transitory, it can also be severe, persistent and life-threatening. Long term hypertension and impaired renal function, both present in our patient, are associated with persistent disease. A close and regular follow-up is essential for earlier detection, especially in high risk patients.

The role of CYP11B2 polymorphism in the pathogenesis of hypertension in patients with adrenal incidentaloma
Lukasz Zukowski[1,2], Natalia Wawrusiewicz-Kurylonek[1], Janusz Mysliwiec[2] & Maria Gorska[1]
[1]Department of the Endocrinology, Diabetology and Internal Medicine, Medical University of Białystok, Poland; [2]Department of Nuclear Medicine, Medical University of Białystok, Poland.

Background
Significant prevalence of hypertension in the world's population and its consequences tend to an intensive search for pathogenesis and etiology of this disease. Epidemic of hypertension is accompanied by an epidemic of adrenal incidentaloma and grows in direct proportion to patients age. Polymorphism of aldosterone synthase (CYP11B2) in -344th region of promoter seems to have much in common with hypertension and adrenal incidentaloma.
Aim
The aim of this study was to assess what role may play CYP11B2 polymorphism in the phenotype of hypertension with associated adrenal incidentaloma. In this study, the analysis of alleles and genotypes focused on incidence of adrenal tumour and impact on the number of antihypertensive medications required to proper control.
Subjects and methods
Study was performed on 106 hypertensive patients with diagnosed adrenal incidentaloma (HAI), on 44 hypertensive patients without adrenal incidentaloma (HWAI) and on 63 healthy individuals forming control group. Groups matched to each other in terms of age, gender. Related patients and those who suffered from disease that may falsely affect the results were excluded. Severity of hypertension was determined by number of antihypertensive medications used to control. The significance of differences between the groups was evaluated through chi-square and Student's *t*-test.
Results
TT genotype and T allel occurred significantly less frequently in HAI in comparison with Control Group (respectively: $P = 0.049$; $P = 0.04$). Patients with TT genotype needed more medication to control hypertension in comparison with CC genotype (3,080 vs 2,361, $P = 0.0439$). Lack of significant differences between HWAI to the rest groups.
Conclusions

- The presence of the C allele in the region of -344 aldosterone synthase promoter predisposes to adrenal tumour, the TT genotype reduced that risk.
- Hypertension in patients with CC genotype is less severe, regardless of its phenotype.

Primary aldosteronism: more common than once thought: Two clinical cases
Nadine Monteiro, Eduarda Comenda, Joana Costa, Helena Vitorino, Sofia Santos, Filipa Moleiro, Claúdia Jesus, Ana Afonso & Helena Cantante Lusiadas, Lisboa, Portugal.

Introduction
Estimated prevalence of hypertension (HT) in Portugal is 42%. It is a major risk factor for coronary heart disease and cerebrovascular disease, the leading mortality cause in Portugal. Primary aldosteronism (PA) was once recognized as rare cause of secondary hypertension and hypokalemia a condition present in all cases. Nowadays, prevalence of this condition is about 10% in HT patients, being the commonest form of secondary HT. Secondary forms of HT should be excluded in young patients, severe increase in blood pressure, sudden onset or worsening of HT, poor blood pressure response to drugs and organ damage disproportionate to the duration of hypertension.
Case 1
A 69 years old female with a past medical history of HT for the last 20 years, presented with poor blood pressure control on bisoprolol 10 mg *id* perindopril 10 mg *id* and nifedipine 30 mg ER *id* at outpatient department. She had normal electrolytes. Screening tests for PA revealed high plasmatic aldosterone and suppressed renin plasmatic activity with a ratio > 25 ng/ml per h. Diagnosis was confirmed after saline infusion test. CT adrenal scan suggested left adrenal diffuse hyperplasia.
Case 2
A 48 years old female presented at the emergency room complaining of severe headache and four limbs' muscle weakness. There was a past medical history of eclampsia and hypertension diagnosed at the age of 30, and euthyroid multinodular goiter. Labs revealed hypokalemia and she was started on oral KCl 600 mg *bid.* After electrolytes correction, she was screened for PA. High plasmatic aldosterone and low renin plasmatic concentration with a ratio > 3.8 was detected. Diagnosis was confirmed after saline infusion test.
Conclusion
PA is an important cause of secondary hypertension, with a higher cardiovascular event rate than essential hypertension. It is frequently underdiagnosed and a potentially curable form of hypertension.

Rapid reduction in left ventricular mass in primary aldosteronism after treatment; a prospective cardiac MRI study

Marianne Aardal Grytaas[1,2], Kjersti Sellevåg[1], Hrafnkell Baldur Thordarson[1,2], Eystein Sverre Husebye[2,1], Kristian Løvås[1,2] & Terje Hjalmar Larsen[1,2]
[1]Haukeland University Hospital, Bergen, Norway; [2]University of Bergen, Bergen, Norway.

Background
Primary aldosteronism (PA) patients have increased left ventricular mass (LVM) and increased cardiovascular morbidity compared with those with essential hypertension. Echocardiographic studies have demonstrated that adrenalectomy or spironolactone decreases LVM. The aim of the present study was to use MRI to assess both LVM and cardiac function before and during stress testing, at baseline and after treatment with adrenalectomy or spironolactone, compared with healthy subjects (HS).
Material and methods
Fifteen recently diagnosed PA patients and 24 age- and sex-matched HS performed a baseline cardiac MRI with a 3.0 Tesla scanner. Imaging was performed at rest and during stress-testing with adenosine 140 μg/kg per min. Short-axis images were used for quantifications of LVM and left ventricular volumes. A follow-up MRI was performed in 20 of the HS and 14 of the PA patients, at least one year after starting specific treatment.
Results
Nine patients (60%) had unilateral PA, the remaining bilateral ($n = 5$, 33%) or not representative ($n = 1$, 7%) adrenal vein sampling. The PA and HS did not differ in age or sex. PA patients had higher baseline blood pressure (BP) than the HS (median BP 138/90 vs 118/75, $P < 0.001$). At follow-up, 8/14 PA were adrenalectomized (median 18 months). The remaining 6/14 were on spironolactone (median 21 months). LVM at baseline differed significantly between the PA and HS groups (median 145 vs 97 g; $P < 0.001$). At follow-up, the PA group had a significant reduction in LVM (median -18 g, $P < 0.001$), but no difference in cardiac output (CO) response to stress compared with baseline (follow-up PA median stress CO/rest CO 1.4 vs baseline 1.5, $P =$ ns).
Conclusion
Cardiac MRI showed rapid reduction in LVM in PA after treatment with adrenalectomy or spironolactone. CO response to stress remained unchanged after treatment. Our results underline the importance of early diagnosis and treatment of PA.

The treatment with dual release hydrocortisone in patients with adrenal insufficiency: correlation between change of the evening cortisol exposure time profile and change in metabolic profile, depression status and quality of life

Chiara Simeoli, Rosario Ferrigno, Claudia Pivonello, Renata Simona Auriemma, Mariarosaria Negri, Gilda Di Gennaro, Davide Iacuaniello, Maria Cristina De Martino, Annamaria Colao & Rosario Pivonello
Dipartimento Di Medicina Clinica E Chirurgia, Sezione Di Endocrinologia, Università Federico Ii Di Napoli, Naples, Italy.

Conventional glucocorticoids (CGCs) are unable to mimic physiological cortisol rhythm in adrenal insufficiency (AI), resulting in increased metabolic morbidity and impaired quality of life (QoL). Non-physiological cortisol pattern and elevated evening cortisol levels may be responsible for the increased risk of metabolic disorders observed in AI patients under CGCs. Once daily dual-release-hydrocortisone (DR-HC), which better reproduces physiological daily cortisol profile, significantly improves metabolic parameters and QoL in primary AI (PAI) and secondary AI (SAI) patients. The aim of the current study was to evaluate cortisol profile and its impact on metabolism, depression status and QoL in PAI and SAI patients switched from CGCs, including cortisone acetate and immediate-release hydrocortisone, to DR-HC. Fourteen AI patients underwent daily cortisol sampling, at 3 h intervals, at baseline (CGCS treatment) and 12 months after switching to DR-HC. Mean cortisol (24 h, 7-7am) AUC was 15.61% lower with DR-HC than with CGCs. In particular, mean (7am-1pm) and (1-7am) were 15.61% and 2.1% higher whereas mean (1-7pm), (7pm-1am) and (7pm-7am) AUC were 18.8% ($P = 0.057$), 58.39% ($P < 0.001$) and 41.87% ($P = 0.004$) lower with DR-HC than with CGCs, respectively. After 12 months of treatment, DR-HC induced a significant improvement in waist circumference ($P = 0.002$), depression status ($P = 0.05$) and QoL ($P = 0.05$). Moreover, the change (Δ) in cortisol 7pm-1am and 7pm-7am AUC appeared significantly correlated with the change (Δ) in glucose 120' after load ($P < 0.005$), depression score ($P < 0.05$) and QoL score ($P < 0.05$). The change (Δ) in cortisol 7pm-1am AUC appeared also significantly correlated with the change (Δ in fasting insulin ($P = 0.045$) and HOMA index ($P = 0.045$). In conclusion, the switch from CGCs to DR-HC in AI patients induces a significant improvement of waist circumference, depression status and QoL, and a significant decrease of late afternoon, evening and night GC overexposure; this reduction is significantly correlated with the improvement in metabolic profile, depression status and QoL.

Treatment of adrenal insufficiency with hydrocortisone dual-release formulation: glycometabolic profile and health-related quality of life

Laura Maria Mongioì, Rosita Angela Condorelli, Laura Cimino, Sandro La Vignera & Aldo Eugenio Calogero
Unit of Andrology and Endocrinology, Department of Clinical and Experimental Medicine, University of Catania, Catania, Sicily, Italy.

Introduction
Treatment of adrenal insufficiency (AI) in the last years has been object of important changes due to the development of a dual-release preparation of hydrocortisone (Plenadren®). Hydrocortisone dual-release therapy contemplates a once-daily tablet that allows more closely mimicking the physiological circadian rhythm cortisol, thus avoiding overexposure.
Objective
The aim of the study was to value effects of Plenadren administration on the 24-h urinary free cortisol (UFC), the glycometabolic profile and health-related quality of life of patients with AI.
Methods and materials
We enrolled seven adults with secondary AI caused by panhypopituitarism (55.9 ± 3.6 years) and seven adults with primary AI (36 ± 6.2 years). We evaluated BMI, UFC levels, the glycometabolic profile and health-related quality of life (estimated by AddiQol questionnaire) before and 3, 6, 9 and 12 months after Plenadren administration. One patient dropped out the study for personal reasons.
Results
All patients, except one, reported a significant improvement of the quality of life after 3 months of treatment, whereas after 1 year everyone reported individual wellness. After 12 months of treatment, all parameters evaluated improved, though not in statistically significantly manner. The parameters for which there was evidence of a greater improvement were total cholesterol, low-density cholesterol and glycosylated hemoglobin levels.

Conclusions
The once-daily oral hydrocortisone dual-release therapy is a valid option for the treatment of patients with AI. It allows a good glycometabolic balance in the absence of side effects and improving compliance.

Transformation from Addison's disease to adrenocortical carcinoma presented as Cushing's syndrome with androgenisation

Antonela Sabati Rajic, Kristina Groti Resman, Tomaž Kocjan & Marija Pfeifer
Department of Endocrinology, University Medical Centre Ljubljana, Ljubljana, Slovenia.

We present a female patient 56 years old, who was treated at the endocrinology department from the year 2006. The diagnosis of Addison's disease was established and she was properly treated. At the same time primary hypothyroidism was diagnosed, also started treating it properly. She was regularly controlled more often at the first time, than yearly at outpatient clinic. In September 2015 she was in menopause. A few months before she noticed oedematous legs and arms and diffuse bruising. Hypertension was also noticed for the first time and needed therapy. Her voice was different (became deep), she noticed hair loss and hirsutism, as well. She thought it was all in correlation with menopause. At the control examination she had hypokalemia, hypernatremia, hypertension, osteopenia with clear clinical aspect of Cushing. The abdominal ultrasound, CT scan and FDG-PET scan showed huge (13.8 cm in diameter) heterogeneous tumour mass in the right adrenal gland. The tumour infiltrates inferior vena cava and liver. Pelvic bone metastases were diagnosed also. CT angiography showed tumour thrombus and pulmonary embolism. Tumour biopsy showed adrenocortical carcinoma. The hormonal tests showed co-secretion of cortisol and androgens (Cushing's syndrome and androgenisation). Tumour was inoperable so tumour arterial embolisation was performed with idea of debulking. The patient was treated with mitotane in combination with systemic chemotherapy (EDP regiment: etoposide, doxorubicin), antiandrogen therapy per os and metirapon. Because of the important hepatotoxicity mitotane was discontinued soon. She needed also hydrocortisone supplementation transitory, for the short time. The patient died due to the disease progression after one year.

Visinin-Like Protein-1 in the regulation of aldosterone biosynthesis

Celso Gomez-Sanchez[1], Maniselvan Kuppusamy[1], Jeanne Ishimwe[1], Tracy Williams[2], Paolo Mulatero[2] & Elise Gomez-Sanchez[1]
[1]University of Mississippi Med Center, Jackson, MS, USA; [2]University of Turin, Turin, Italy.

Visinin-Like Protein-1 (Vsnl1) is a member of the EF-hand calcium sensor protein family that is expressed in the zona glomerulosa of the rat and human adrenal and upregulated in aldosterone-producing adenomas.
We studied the expression pattern of Vsnl1 and co-localization with the CYP11B2 enzyme and the zona glomerulosa (ZG) marker Dlk1 (ZOG) using double and triple immunofluorescence in the adrenal of rats on a normal, high and low sodium diets. We also studied the role Vsnl1 in aldosterone biosynthesis and calcium in the HAC15 cell.
In the rat adrenal, Vsnl1 was expressed only in cells of the ZG and in cells expressing Dlk1, including undifferentiated cells between the ZG and zona fasciculata. Nearly all of the ZG cells from adrenals of rats on a low sodium diet expressed both Vsnl1 and CYP11B2. However in adrenals of rats on a normal and high sodium diet the staining for Vsnl1 was in many more ZG cells than those expressing CYP11B2. Vsnl1 and Dlk1 immunoreactivity was found not only cells that are steroidogenically active and producing aldosterone, but also in ZG and undifferentiated cells in the rat adrenal subcapsular area.
Human adrenal cortical carcinoma cell line HAC15 was transduced with a lentivirus carrying Vsnl1. Three days after transduction cells were incubated with vehicle, angiotensin II (A-II) 10 nM, Forskolin 10 μM and potassium 16 mM and compared with control cells transduced with an empty lentivirus. Aldosterone and cortisol were measured after 24 h. The basal secretion of aldosterone was not increased, but that of cortisol was. Aldosterone and cortisol secretion were greater after A-II, forskolin and potassium stimulation in cells overexpressing Vsnl1. Proliferation of the HAC15 cells measured by the XXT and crystal violet methods and intracellular calcium, as measured by the Fluo-4 AM dye, were also increased after transduction with Vsnl1.
Transduction of HAC15 cells with shRNA for Vsnl1 that reduced Vsnl1 expression decreased their basal and A-II stimulated aldosterone synthesis. The Vsnl1 has a myristoylation consensus sequence at the N-terminal domain. Site directed mutagenesis of Vsnl1 at the 2 position (G2A) lentivirus transduced in HAC15 cells resulted in a significant decrease in the aldosterone response to A-II. In summary, the Vsnl1 is a zona glomerulosa protein that participates in calcium mobilization and increases the various secretagogue-induced aldosterone synthesis.

EP38

Metabolic syndrome is common among patients with adrenal incidentalomas, but not associated with functional adrenal status

Charalampos Tsentidis, Andreas Bampilis, Vasiliki Ntova, Grigoria Betsi & Georgia Kassi
Department of Endocrinology, Metabolism and Diabetes, Nikaia General Hospital 'Ag. Panteleimon', Athens, Greece.

Background
Adrenal incidentalomas (AI) have an increasing prevalence during last decades, probably due to the extended use of new imaging techniques and longer life expectancy. Adrenal hormonal hypersecretion, even subclinical, is probably related to cardiovascular disease (CVD).
Methods
We evaluated 100 patients with adrenal masses, incidentally discovered in imaging techniques performed for non adrenal disorders (67 Female, 33 Male, mean 58.1 ± 12.9 years, median 60.5y), according to NIH criteria of 2002 and ESE 2016. IDF 2006 criteria were used for metabolic syndrome (MS) definition.
Results
Mean incidentaloma size was 35.5 ± 20 mm. 20% were bilateral, while 41% were located to the right and 39% to the left adrenal. The majority (70%) was found to be non functional and 30% to be functional. Autonomous cortisol secretion (ACS) was found in 15%, pheochromocytoma (Ph) in 7% and hyperaldosteronism (HA) in 8% of all cases. Non functioning lesions were defined as non functioning adenomas (62%), non malignant cysts (2%), myelolipomas (2%), metastases (1%) and bilateral teratoma (1%). MS prevalence was higher in study group compared with general population (65% vs 23%, $P<0.001$). There was no difference in MS prevalence between patients with functional and non functional tumors (63.3% vs 64.7%, $P=0.53$), while no difference was found between functional tumors (ACS60% vs Ph57% vs HA75%, $P=0.78$). Hypertension had the greatest proportion in cases with hyperaldosteronism, while no difference in central obesity, hyperlipidemia and abnormal glucose metabolism was found between functional tumors.
Conclusions
The prevalence of metabolic syndrome was found to be high in patients with AI. A common pathophysiologic pathway (probably hyperinsulinaemia) must be the underlying mechanism between AI and MS, associated with an increased risk for CVD.

DOI: 10.1530/endoabs.49.EP38

The clinical course of patients with adrenal incidentaloma: Başkent University experience

Nazli Gulsoy Kirnap[1], Ozlem Turhan Iyidir[1], Yusuf Bozkus[1], Lala Ramazanova[1], Asli Nar[1], Altug Kut[2] & Neslihan Tutuncu[1]
[1]Department of Endocrinology, Baskent University Hospital, Ankara, Turkey; [2]Department of Family Medicine, Baskent University Hospital, Ankara, Turkey.

The prevalance of incidentally discovered adrenal masses increased in last three decades. The major clinical concern is the risk of malignancy and hormone overproduction but most of them are non-fonctional and benign. Current practices in the management of adrenal incidentalomas reevaluated the follow-up suggestions considering low probability of the transformation of a benign and non-functional adrenal mass to a malignant or functional one. Therefore, in the present study we analysed the clinical course of patients with adrenal incidentaloma. We evaluated 203 consecutive patients (139 females, 64 males:mean age 55.8 ± 0.8 years) who were referred to the Department of Endocrinology, Başkent University Hospital, between January 2007 and 2017. Among the 203 patients examined 171 had unilateral, 32 had bilateral adrenal masses. Mean size of tumors was 22.7 ± 10.8 mm. In 157 (%77.3) patients' adrenal mass was benign and non-functional, 21 (%10.3) had autonomous cortisol

secretion, 9 (%4,4) had Cushing syndrome, 5(%2.5) had pheochromocytoma, 9 (%4,4) had primary hyperaldosteronism and, 2(%1) had adrenocortical carcinoma. Twentyone patients went adrenelectomy. Median follow up time was 3 (1–10) years. During the follow up the change in the size of adrenal mass was non significant ($P=0.12$) and there were no changes either in metanephrines and normetanephrines or in the activity of renin–aldosterone axis. There was a significant correlation between adenom size and cortisol levels after dexamethasone supression test in patients with autonomous cortisol secretion. As a result our study suggests that the risk of an adrenal adenoma initially diagnosed as benign or non-functional becoming malignant or hormonally active is low.

Predictive baseline morning P-cortisol levels for the response to a Synacthen test in prednisolone treated patients

Stina Willemoes Borresen[1], Marianne Klose[1], Henning Locht[3], Toke Laursen[3], Bente Jensen[3], Linda Hilsted[6], Bo Baslund[2], Åse Krogh Rasmussen[1], Lennart Friis-Hansen[7], Annette Hansen[4], Merete Lund Hetland[5] & Ulla Feldt-Rasmussen[1]
[1]Department of Medical Endocrinology, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [2]Center of Rheumatology and Joint Diseases, Copenhagen University Hospital, Rigshospitalet Blegdamsvej, Copenhagen, Denmark; [3]Center of Rheumatology and Joint Diseases, Copenhagen University Hospital, Frederiksberg Hospital, Frederiksberg, Denmark; [4]Center of Rheumatology and Joint Diseases, Copenhagen University Hospital, Gentofte Hospital, Gentofte, Denmark; [5]Center of Rheumatology and Joint Diseases, Copenhagen University Hospital, Rigshospitalet Glostrup, Glostrup, Denmark; [6]Department of Clinical Biochemistry, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [7]Department of Clinical Biochemistry, Copenhagen University Hospital, Nordsjællands Hospital Hillerød, Hillerød, Denmark.

Introduction
Evaluation of glucocorticoid production generally requires a dynamic test. Cut-off levels for baseline cortisol concentrations predicting the outcome of a Synacthen test have been proposed for different cortisol assays. With introduction of the new Roche Elecsys Cortisol II assay, P-cortisol concentrations are expected to decrease by 20%. We have investigated cut-off levels for baseline P-cortisol concentrations measured with the Roche Elecsys Cortisol II assay that could predict the response to a Synacthen test in patients at risk of glucocorticoid-induced adrenal insufficiency.
Methods
In a cross-sectional study, 110 prednisolone treated rheumatologic patients had a 250 µg Synacthen test performed, fasting, in the morning, starting between 0800 and 1030 h, 36–48 h after the last prednisolone dose. P-cortisol was measured before and 30 min after Synacthen injection. The locally validated assay specific cut-off for normal adrenal function was 30 min P-cortisol $\geq$420 nmol/l.
Results
Forty-six patients (42%) had an insufficient response to the Synacthen test. Baseline and 30 min P-cortisol correlated positively ($P<0.0001$, $r=0.86$). Receiver-operator curve analysis showed an area under the curve of 0.94 (95% CI: 0.90–0.98). All patients with baseline P-cortisol $<$139 nmol/l also failed the Synacthen test (positive predictive value$=$100%). All patients with baseline P-cortisol $>$310 nmol/l had a normal response to the Synacthen test (negative predictive value $=$100%). Applying these cut-off values baseline P-cortisol measurements predicted the response to the Synacthen test in 58/110 (53%) of cases; P-cortisol $>$310 nmol/l (33%); P-cortisol $<$139 nmol/l (20%).
Conclusion
We have presented assay specific baseline P-cortisol concentrations that could predict the response to a Synacthen test in half of patients at risk of glucocorticoid-induced adrenal insufficiency and potentially reduce the number of needed Synacthen tests in the worldwide many glucocorticoid treated patients. Baseline morning cortisol measurements might become a valid diagnostic screening tool in the future.

Silent pheochromocitoma – a rare case of adrenal incidentaloma

Ana Filipa Martins[1], Sónia do Vale[1,2] & João Martin Martins[1,2]
[1]Hospital de Santa Maria-CHLN, Lisboa, Portugal; [2]Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction
Pheochromocytomas are rare tumors arising from adrenomedullary chromaffin cells. Pheochromocytomas are a serious clinical condition and undiagnosed cases are associated with increased unexpected cardiovascular mortality.
Case report
A female Caucasian patient aged 52-year-old was referred to the endocrine department of a public central hospital because of an incidental right adrenal mass first found 3 years before during the work out of non specific tiredness. Annual CT CT scans documented significant growth (34, 40 and 62 mm) of a hypodense lesion (less than 10 Housefield units). Presently the patient denied gastrointestinal or abdominal complaints and did not present clinical evidence for hypercortisolism, hyperaldosteronism, hyperandrogenism or for excessive catecolamine production. Past medical history revealed chronic gastritis treated with omeprazole daily. She reported three uneventful pregnancies 25, 20 and 19 years ago. Physical examination was unremarkable, with normal blood pressure and no orthostatic hypotension. Analytic evaluation excluded hypercortisolism and hyperaldosteronism. Urinary metanephrine and normetanephrine were high (12 and 16 times higher than the upper limit of the reference range) and dopamine 1.5 times over the upper limit. Serum calcium and calcitonin were in the reference range. ^{123}I-MIBG scintigraphy presented increased right adrenal uptake. Uneventful laparoscopic right adrenalectomy was performed after preoperative treatment with doxazosin 8 mg, 2 l normal saline ev and propranolol 30 mg daily. Histologic evaluation confirmed a 55 mm pheochromocitoma, with no signs of malignancy. No genetic study was conducted.
Discussion and conclusion
About 7% of adrenal incidentalomas are pheochromocytomas. Although rare, clinically silent pheocromocytomas are recognized. Possible mechanisms may include 1) vasodilator peptides co-secreted by pheochromocytomas such as dopamine; 2) desensitization of target organs due to high catecholamine long-term exposure, 3) low circulatory volume in these patients and 4) malignancy with undifferentiation and minimal catecholamine production. This case highlights the need to exclude catecholamine producing tumors in all adrenal incidentalomas, even if they are asymptomatic.

EP42

LH and adrenal tumor size correlate with insulin resistance in menopausal patients with adrenal incidentalomas and (possible) autonomous cortisol secretion

Ljiljana Marina[1,2], Miomira Ivovic[1,2], Milina Tancic-Gajic[1,2], Zorana Arizanovic[1], Dragana Rakovic[1], Jelena Milin-Lazovic[1,2], Aleksandra Kendereski[1,2], Dragan Micic[1,2], Srdjan Pandurevic[2] & Svetlana Vujovic[1,2]
[1]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]Faculty of Medicine, University of Belgrade, Belgrade, Serbia; [3]Institute of Medical Statistics and Informatics, Belgrade, Serbia.

High prevalence of insulin resistance (IR) has been shown in patients with adrenal incidentalomas (AI) and it has been demonstrated that an increase in IR is related to the adrenal tumor size (ATS). Also, responsive adrenal pathologies are well documented in patients with chronically elevated LH. The aim was to investigate the association between LH and IR and ATS and IR in AI patients. The case-control study was conducted in Clinic for endocrinology, diabetes and metabolic diseases, Belgrade, Serbia. The total studied group consisted of 105 menopausal women: 75 AI patients (mean age 60.13$\pm$7.28 years, mean BMI 27.60$\pm$4.66 kg/m^2, mean menopause duration 10.86$\pm$7.79 years, mean LH 31.82$\pm$14.17 IU/l and mean ATS 31.25$\pm$10.72 mm) and 30 age, BMI, menopause duration and LH matched healthy control (HC) women. Based on level of cortisol after 1 mg-dexamethasone suppression test AI patients were divided in two groups: $<$50 nmol/L, 27 with nonfunctional AI (NAI) and $>$50 mmol/l, 48 with (possible) autonomous cortisol secretion ((P)ACS). To estimate IR we used homeostasis model assessment (HOMA-IR). There was no significant difference between AI subgroups in terms of age, BMI, menopause duration, LH and HOMA-IR. HC subjects had significantly lower HOMA-IR when compared to NAI ($P=0.017$). There was a significant positive correlation between LH and HOMA-IR in AI group ($r=0.230$; $P=0.047$) and in (P)ACS subgroup ($r=0.353$; $P=0.017$), but not in patients with NAI ($r=-0.097$, $P=0.623$). The correlation of ATS and HOMA-IR was significant in AI group ($r=0.341$; $P=0.003$) and both NAI ($P=0.018$, $r=0.445$) and (P)ACS ($P=0.012$, $r=0.362$). After adjusting for age and BMI both LH and ATS were significant predictors of HOMA-IR,

($r^2=0.196$, $P=0.004$). There was no significant correlation between LH and HOMA-IR in HC. Our data suggest that not only insulin, but also the interplay between LH and insulin may contribute to the adrenal tumorigenesis.

A case of recurrent Cushing's disease after total bilateral adrenalectomy

Ivan Vicic[1], Ivan Kruljac[2], Miroslav Cacic[2], Bozidar Peric[2], Maja Filipovic-Grcic[2], Gorana Mirosevic[2], Vatroslav Cerina[3], Leo Pazanin[4] & Milan Vrkljan[2]
[1]University of Zagreb School of Medicine, Zagreb, Croatia; [2]Department of Endocrinology, Diabetes and Metabolic Diseases 'Mladen Sekso', University Hospital Center 'Sestre Milosrdnice', Zagreb, Croatia; [3]Department of Neurosurgery, University Hospital Center 'Sestre Milosrdnice', Zagreb, Croatia; [4]Department of Pathology 'Ljudevit Jurak', University Hospital Center 'Sestre Milosrdnice', Zagreb, Croatia.

Bilateral adrenalectomy usually results in lifelong primary adrenal insufficiency. Evidence exists that up to 34% of patients with Cushing's disease (CD) have some degree of endogenous cortisol secretion after bilateral adrenalectomy due to ACTH driven hyperplasia of residual cortical tissue. We present a case of a patient with atypical corticotropinoma/carcinoma and recurrence of CD after bilateral adrenalectomy.

A 59-year-old man presented with Cushing's disease (CD) in 2010. An MRI revealed intrasellar mass 8×8 mm suggestive of a microadenoma. After the surgery pathohistological evaluation was suggestive of atypical corticotropinoma (Ki-67 proliferation index 7%, positive nuclear staining for p53). CD recurred eight months after the surgery. Total hypophysectomy led to complete remission, followed by recurrence 5 months later. We performed radiosurgical treatment of the remnant tumor mass, along with bilateral two-stage adrenalectomy. Pathohistological evaluation confirmed complete removal of the left adrenal gland, and was inconlusive about the right one. Postoperatively, patient required replacement therapy. Two years after the adrenalectomy patient was diagnosed with Nelson's syndrome due to enlargement of the pituitary mass. Fractionated radiotherapy was performed, after which ACTH slightly decreased, but UFC levels continued to increase, while taking hydrocortisone replacement. Replacement therapy was stopped, but urinary free cortisol increased to 1400 nmol/24 h 3 years after the bilateral adrenalectomy, accompanied by the recurrence of signs and symptoms of CD. Computed tomography showed 4-cm large mass in the left adrenal bed suggestive of an adrenal tissue, along with the multiple liver lesions and without the signs of another primary tumor. Patient died five years after the initial diagnosis and his family refused an autopsy.

This is the first case of a recurrent CD after bilateral adrenalectomy. This report highlights the importance of long-term monitoring of the patient and individual dosing of replacement therapy.

Late-night salivary cortisol: cut-off definition and diagnostic value in Cushing's syndrome

Adriana Lages[1], João Frade[1], Isabel Paiva[1], Patrícia Oliveira[1], Diana Oliveira[1], Diana Martins[1], Mara Ventura[1], Nelson Cunha[1], Alexandre Rebelo-Marques[2], Susana Antunes[1], Fátima Leitão[1] & Francisco Carrilho[1]
[1]Coimbra Hospital and University Center, Coimbra, Portugal; [2]Faculty of Medicine University of Coimbra, Coimbra, Portugal.

Background

The diagnosis of Cushing's syndrome (CS) remains a challenge in clinical endocrinology. Several screening tests have been proposed to establish hypercortisolism. Late-night salivary cortisol (LNSC) is used as screening tool, however, individualized cut-off levels for each population must be defined.

Methods

Three group of subjects were studied: healthy volunteers, suspected CS and proven CS. All patients collected saliva at 23.00 h using a Salivette. Salivary Cortisol was measured using an automated electrochemiluminescence assay – Elecsys 2010-Roche. The functional sensitivity of the assays is 0.018 μg/dl. Diagnostic cut-off level was defined by Receiver operating characteristic (ROC) curve and Youden's J index.

Results

We studied 127 subjects: 57 healthy volunteers, 39 patients with suspected CS and 31 with proven CS (ACTH-dependent: 22 pituitary, two ectopic; ACTH-independent: two adrenal adenoma, five adrenal carcinoma).

The 2.5th–97.5th percentile of the LNSC concentrations in normal subjects was 0.054–0.1827 μg/dl, respectively. The mean ± s.d. LNSC concentration in patients with proven CS (0.6798 ± 0.52 μg/dl) was significantly higher than those in normal subjects (0.0642 ± 0.03 μg/dl; $P<0.0001$) and suspected CS group (0.1803 ± 0.19 μg/dl; $P<0.0001$).

ROC curve analysis showed an AUC of 0.9881 ($P<0.0001$) and a cut-off point of 0.1 μg/dl provides a sensibility (S) of 96.77% (95%CI 83.3-99.92%) and specificity (E) of 91.23% (95%CI 80.7–97.09%).

There were significant correlations between LNSC and late-night serum cortisol (LNSeC) levels ($r=0.6977$; $P<0.0001$) as well as with Urinary Free Cortisol (UFC) levels ($r=0.5404$; P 0.0025) in proven CS group.

Conclusion

Our results give to LNSC an excellent accuracy and reaffirm that can be used as a highly reliable noninvasive screening tool for outpatient assessment. In our population, the LNSC reference cut-off was 0.1 μg/dl with S 96.77% and E 91.23% for CS diagnosis. Given its convenience and diagnostic accuracy, LNSC may profitably be added to traditional screening tests such as LNSeC and UFC.

Adrenal involvement in MEN1 families

Mara Ventura, Miguel Melo, Leonor Gomes, Joana Saraiva, Luisa Barros, Dírcea Rodrigues, Diana Oliveira, Diana Martins, Adriana Lages, Nelson Cunha & Francisco Carrilho
University and Hospital Center of Coimbra, Coimbra, Portugal.

Introduction

MEN1 is a rare autosomal dominant syndrome typically characterized by neoplastic lesions of parathyroid glands, anterior pituitary gland and endocrine pancreas. Several other tumours are associated with this syndrome, including adrenal lesions, but their prevalence and clinical characteristics (endocrine secretion and aggressiveness) are largely unknown.

Objective

To determine the prevalence, clinical characteristics and the possible genotype/phenotype association of adrenal lesions in MEN1 patients, as well as their global impact on patients' outcome.

Material and methods

We retrospectively studied 16 patients belonging to six families of individuals with MEN1. Adrenal involvement was evaluated clinically, biochemically and imagiologically based on clinical records.

Results

Adrenal lesions were identified in 9 of 16 (56.3%) patients. This group comprises seven women and two men with a mean age of 55.6 years. The mean age at diagnosis of MEN1 was 46.3 years (18–68) and adrenal involvement was detected between 0 and 16 years after the syndrome was diagnosed. Among the 16 patients evaluated, a total of nine adrenal nodules were founded, with a median of two nodules per patient. Only three patients had unilateral involvement. The mean adrenal lesion diameter at diagnosis was 17.5 mm (6–30 mm). Hormonal hypersecretion – autonomous cortisol secretion – was founded in one patient. None of the patients was submitted to adrenalectomy. Adrenal lesions were evenly distributed between the different germline mutations.

Conclusion

Adrenal tumours are a common feature of MEN1 that can affect more than half of the patients. Most of the tumours are bilateral non-functional lesions, but hormonal secretion may occur and should be promptly identified in order to reduce the morbidity/mortality of the syndrome. Adrenal evaluation should be considered in patients with MEN1.

Differential effects of aldosterone excess on potassium homeostasis and blood pressure in Asian subjects

Du Soon Swee, Peng Chin Kek & Lih Ming Loh
Department of Endocrinology, Singapore General Hospital, Singapore, Singapore.

Introduction
Hypokalemia is considered as a late manifestation of primary aldosteronism (PA), long preceded by hypertension. However, there have been reports of normotensive PA patients presenting with hypokalemia. This study aims to examine the relationship of hypokalemia and blood pressure in patients with hyperaldosteronism.
Methods
A retrospective review of patients who underwent saline infusion test (SIT) from 2014 to 2016 was conducted. All patients had screening plasma aldosterone concentration (PAC): plasma renin activity (PRA) ratio of >20. Postinfusion PAC level <5 ng/dl (139 pmol/l) indicated normal aldosterone suppression, PAC >10 ng/dl (277 pmol/l) confirmed PA, whereas PAC 5–10 ng/dl (139–277 pmol/l) was regarded as indeterminate. Hypokalemia was defined as serum potassium <3.5 mmol/l.
Results
Over a 3-year period, 52 patients referred for hypokalemia had non-suppressible postinfusion PAC (>5 ng/dl). They comprised of 36 men and 16 women, with a mean age of 58.4 ± 9.1 and 57.3 ± 13.2 years respectively.
In the PA group consisting of 26 men and 11 women, the mean serum potassium were 2.9 ± 0.3 mmol/l and 2.7 ± 0.5 mmol/l respectively. Eighteen (69.2%) men and 10 (90.9%) women were on ≤2 antihypertensive agents, including two women (age 48 and 51) with severe hypokalemia (<2.5 mmol/l) who were normotensive and rendered normokalemic after adrenalectomy and spironolactone treatment separately.
In the indeterminate group comprising of ten men and five women, the mean serum potassium were 3.1 ± 0.2 mmol/l and 3.0 ± 0.2 mmol/l respectively. Five (50%) men and 4 (80%) women were on ≤2 antihypertensive agents.
In all patients with moderate to severe hypokalemia (≤2.9 mmol/l), 7/11 (63.6%) men and 8/9 (88.9%) women were on ≤2 antihypertensive agents.
Conclusion
In our cohort of Asian patients, majority with hypokalemia secondary to autonomous aldosterone production required only 0–2 antihypertensive agents, even in those with more severe degree of hypokalemia. This suggests possible differential effects of aldosterone excess on potassium homeostasis and blood pressure.

Effect of adrenal mass lateralization on diagnostic tests in patients with Cushing

Ozlem Ustay Tarcin, Emre Pehlevan, Eren Imre, Melin Uygur, Oguzhan Deyneli & Dilek Gogas Yavuz
Marmara University Pendik Hospital, Endocrinology and Metabolism, Istanbul, Turkey.

The frequency of adrenal masses is increasing in parallel with the progress of the technology. Most of these masses, which are detected by chance, are not functional, and only a part of them are exposed to an excess of hormone. The most common dysfunction in masses with hormonal activity is hypercortisolism. However, the diagnosis of Cushing's disease is based on more than one test. In this study, we intended to compare the values of screening tests to determine whether the presence of a unilateral mass or bilateral mass would help in the diagnosis.
Materials and methods
Adrenal masses were detected in our clinic and 143 patients who were followed up were evaluated. 112 of these patients have unilateral adrenal mass, 31 have bilateral adrenal masses. Twenty (17.8%) of 112 unilateral adrenal masses and 15 (51.6%) of the patients with bilateral adrenal masses were diagnosed as Cushing. The 1 mg overnight dexametasone suppression test (DST), 2 days 2 mg dexametasone suppression test (Liddle test), and 24-h urine cortisol levels used for diagnosis in these patients were compared. Averages of tests were taken multiple times.
Conclusion
The mean age of the patients with bilateral and unilateral adrenal masses was around 60. When the mean values of 1 mg DST, Liddle test and 24 h urine were compared, no statistically significant difference was found between the two groups.
Comment
In the case of Cushing's syndrome, the adrenal glands on one side or on both adrenal glands are not diagnostic in terms of diagnosis.

Table 1

Cushing's Syndrome	Unilateral mass (*n*:20)	Bilateral Masses (*n*:15)	*P*
Age	58.2 ± 2.4	63.5 ± 2.5	0.7
1 mg DST	5.9 ± 1.6 (median:3.3)	5.8 ± 1.8 (median:3.1)	0.9
Liddle test	4.8 ± 1	4.2 ± 0.7	0.2
24 h urine cortisol	138.2 ± 28.8	184 ± 26.5	0.5

Late night salivary cortisol measurement may help in excluding Cushing's syndrome in patients with chronic kidney disease

Urszula Ambroziak[1], Agnieszka Kondracka[1], Jadwiga Rojek-Trębicka[2], Paweł Gajkowski[1], Agnieszka Stańczyk[1], Malwina Stępor[1] & Tomasz Bednarczuk[1]
[1]Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warsaw, Poland; [2]Department of Internal Medicine and Nephrology, Medical University of Warsaw, Warsaw, Poland.

Objective
The diagnosis of Cushing's syndrome may be challenging, especially in cases of patients with chronic kidney disease (CKD).
Aim
The assessment of late night salivary cortisol concentration, serum and salivary concentration in overnight dexamethasone suppression test in patients with CKD stage III–V and a control group.
Patients and methods
37 patients mean age 66 ± 12 ($M=13$) with CKD stage III–V according to KDIGO and 28 controls mean age 45.3 ± 15 years ($M=6$) were enrolled to the study. Patients were recruited in the nephrology clinic during their routine control visits. Serum and salivary cortisol were measured by Roche ECLIA cortisol test (Cobas E411). Two samples of late night salivary cortisol (LNSC) from each subject were obtained from home. 1 mg dexamethasone suppression test (DST) was done in patients and controls with serum and saliva measurement at 0800 h. Serum creatinine assessment was done no longer than 1 week prior to cortisol measurement. GFR was obtained from the Cockcroft−Gault calculator.
Results
The mean GFR in patients was 33.89 ml/min (8.4–54) while in controls 125 ml/min (73–230) ($P<0.0001$). The mean serum DST cortisol in patients was 2.62 μg/dl (0.46–7.42). In 19 (51.4%) patients serum DST cortisol was >1.8 μg/dl. In all controls serum DST cortisol was <1.8 μg/dl (mean, min–max 0.70, 0.36–1.48). The mean DST salivary cortisol in patients was 0.88 μg/dl (0.11–0.88) while in controls 0.18 μg/dl (0.02–0.69) μg/dl. Although there was a significant difference between controls' and patients' salivary cortisol concentration in DST ($P=0.01$), all but one patient's salivary measurement were within control ranges. The mean LNSC in patients was 0.26 μg/dl (0.10–0.65) while in controls 0.29 μg/dl (0.04–0.80), $P=0.4$. All patients' LNSC measurements were within control ranges. In the patients' group the negative correlation between GFR and DST serum cortisol was detected, $r=-0.6$, $P=0.001$ (the higher cortisol the lower GFR).
Conclusion
LNSC may be helpful in excluding Cushing's syndrome in patients with CKD.

The short Synacthen test revisited – reevaluation of the normal reference range using LCMSMS

Grethe Åstrøm Ueland[1,2], Paal Methlie[1,2], Marianne Øksnes[1,2], Kristian Løvås[1,2], Hrafnkell Thordarson[2] & Eystein Husebye[1,2]
[1]Department of Clinical Science, University of Bergen, Bergen, Norway; [2]Department of Endocrinology, Haukeland University Hospital, Bergen, Norway.

Background
The Synachten test is used to diagnose for adrenal insufficiency (AI) and non-classical congenital adrenal hyperplasia (CAH). The cut-off levels for s-cortisol and s-17-hydroxyprogesterone are derived from immunoassays that were not well standardized and are no longer in use. Introduction of liquid chromatography tandem mass spectrometry (LCMSMS) could resolve the lack of standardization of steroid hormone assays and enable increased diagnostic accuracy.
Aim
Define cut-off values for s-cortisol and s-17OH-progesterone by LCMSMS after intravenous administration of 250 µg tetracosactide acetate (Synachten).
Methods
The Synachten test was performed in healthy individuals ($n=60$) and patients referred for evaluation of adrenocortical function ($n=42$). Steroids were assayed by LCMSMS. Cut-off level for s-cortisol was defined as the 2.5% percentile in healthy subjects not using oral estrogens ($n=55$), and for 17-OH-progesterone as the 97.5% percentile in the healthy women.
Results
Cortisol cut-off levels were 415 and 493 nmol/l at 30 and 60 min, respectively. All controls had higher cortisol at 60 compared to 30 min. Applying the current cut-off of 550 nmol/l, 27 healthy controls would have had a false negative test at 30 min, and six at 60 min. For s-17-OH-progesterone the cut-off levels were 10.5 and 11.1 nmol/l at 30 and 60 min, respectively. Forty-two patients performed the test for suspected AI or non-classic CAH. Applying the new cut-offs, seven who had AI according to old criteria, now scored normal.
Conclusions
Cut-off levels for s-cortisol after Synacthen test are lower than the commonly recommended discriminating levels when cortisol is analyzed by LCMSMS. When applied, a significant proportion of patients can be re-categorized from adrenal insufficiency to healthy. We recommend using the 60 min value as standard, as cortisol increased from 30 to 60 min in all controls.

Cushing's syndrome in pregnant woman

Anastasiia Chekanova, Irina Komerdus, Tatiana Shestakova, Fatima Burumkulova, Timur Britvin & Alexander Dreval
Moscow Regional Research Clinical Institute n.a. M.F.Vladimirsky, Moscow, Russia.

Background
Pregnancy occurs rarely in Cushing's syndrome (CS), slightly over 150 cases have been reported in the literature. The risk of maternal morbidity and a poor fetal outcome is significant when CS coexists with pregnancy. CS may be difficult to detect clinically and laboratory because of the hormonal changes and pathological comorbidities associated with normal pregnancy.
Material and methods
A case of CS that was diagnosed and treated during pregnancy.
Case
Woman Y., 30y.o., since she was 18 had menstrual irregularities and since she was 28 an arterial hypertension, type 2 DM. She was on supervision of therapeutist and take metformin for her DM and hypotensive medication. Unexpected pregnancy occurs in December 2016. She was referred in our clinic in 15 weeks of her pregnancy because of uncontrolled DM and hypertension. Examination revealed increased blood pressure, fatigue, easy bruising, excessive hair growth on the face and body, swelling and rounding of the face, edema of legs and feet. Laboratory evaluation: UFC-1475.0 and 1511.0 nmol/24 h (N 138.0–524.4), serum cortisol – at 0800 h −868 nmol/l (190–650), at 2300 h −995 nmol/l (50–350)), suppressed ACTH level. HbA1c–7.7%. Insulin therapy initiated to treat DM. MRI data: adenoma in left adrenal (32×30 mm). 13.05.16.-unilateral adrenalectomy was done. Adrenal insufficiency developed post-operatively and glucocorticoid therapy was started. She was under close supervision of gynecologist. At 38 weeks gestation surgical delivery performed (boy, 1900 g, 44 cm, 7/8 Apgar score, with three degrees of fetal growth retardation and two degrees of malnutrition). Insulin was cancelled after delivery, and hydrocortisone and antihypertensive therapy cancelled 2 months postpartum.
Conclusion
High clinical suspicion of the CS during pregnancy can help for the diagnosis and leads to better outcomes for the mother and the fetus. Multidisciplinary approach needs for these patients with careful supervision during pregnancy and postpartum.

Education sessions in patients with adrenal insufficiency

Aldora Távora, Ema Lemos, Isaura Duarte, Joaquim Sobral, Catarina Machado, Patrícia Tavares, Gustavo Rocha, Sara Monteiro, Ana Sousa, Pedro Rodrigues & Maria João Oliveira
Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal.

Introduction
Adrenal insufficiency (AI) is a rare and potentially life-threatening disease. The most common causes are primary adrenal insufficiency (Addison's Disease), due to an adrenocortical disease, and secondary insufficiency, due to disorders of the pituitary gland. Chronic glucocorticoid replacement is vital and patients should be educated about how to act in acute stress situations, in order to avoid adrenal crisis. Taking this into account, we organized education sessions, aimed at patients with AI.
Discussion
We realized group sessions of about 90 minutes duration each, with maximum 8 patients with AI; the presence of a family member or caregiver was strongly advised. A multimedia presentation was performed, focusing on basic knowledge on adrenal insufficiency, management of the disease during stress situations and early recognition of signs and symptoms of an adrenal crisis. At the end of each session, patients were given an emergency hydrocortisone kit and taught how and when to use it. In addition, three brochures with written information with general information about the disease, specials situations and how to prepare and administer emergency medication were available to take home. The identification card of disease carrier (European Society of Endocrinology) was also provided to those who didn't have it. Patient adherence was 100% and a second session will be scheduled in order to access the effectiveness of the first session and to reinforce patient education.
Conclusions
AI is a chronic disease with a significant burden in both patients and its partners. A careful and repeated education is the best strategy to avoid life-threatening emergencies.

Characteristics of aldosterone-producing adenomas: a tissue microarray study

Yara Rhayem[1], Annette Feuchtinger[2], Christine Woischke[3], Philippe Ludwig[1], Thomas Kunzke[2], Thomas Schwarzmayr[4], Stefanie Hahner[5], Celso E. Gomez-Sanchez[6], Tim M. Strom[4], Thomas Kirchner[3], Martin Reincke[1], Axel Walch[2] & Felix Beuschlein[1]
[1]Department of Endocrine Research, Klinikum der Universität München, Ludwig-Maximilians University, Munich, Germany; [2]Research Unit of Analytical Pathology, Institute of Pathology, Helmholtz Zentrum München, Neuherberg, Germany; [3]Institute of Pathology, Klinikum der Universität München, Ludwig-Maximilian University, Munich, Germany; [4]Institute of Human Genetics, Helmholtz Zentrum München and Technische Universität München, Munich, Germany; [5]Endocrinology and Diabetes Unit, Department of Medicine I, University Hospital Würzburg and Comprehensive Heart Failure Center, University of Würzburg, Würzburg, Germany; [6]Division of Endocrinology, G.V.(Sonny) Montgomery VA Medical Center and Department of Medicine-Endocrinology, University of Mississippi Medical Center, Jackson, MS, USA.

Background
Sporadic aldosterone-producing adenomas (APA) are relevant cause of endocrine related hypertension in Primary Aldosteronism (PA). Next generation sequencing techniques have identified somatic mutations in APA harbored in KCNJ5, ATP1A1, ATP2B3, CACNA1D, CTNNB1 and PRKACA genes. Yet, a number of APA harbor no mutations in candidate genes (designated as wild type, WT) and little is known about genotype/phenotype correlation.
Objectives
We investigated the tissue-based molecular and histopathological characteristics of 132 APAs after laparoscopic unilateral adrenalectomy in PA-patients and studied genotype/morphometry and histopathology correlation.
Methods
Tumor-DNA was screened for somatic mutations in candidate genes by targeted ($n=84$) or whole-exome ($n=48$) sequencing. Accurate characterization of 179 morphometric parameters and of immunohistochemistry (IHC) results for steroidogenic enzymes CYP11B1, CYP11B2, CYP17, HSD3B1 and HSD3B2 was performed on tumor tissue microarrays from all samples by digital image analysis.

Results
Prevalence of *WT* APA in our cohort was 34% and affected men more frequently. In 8/48 APA, non-recurrent somatic mutations (*NR*) were identified. H&E analysis demonstrated that 6 morphometric parameters correlated negatively with *WT* status whereas those same parameters correlated positively with the presence of *KCNJ5* or *NR* ($P<0.01$). The same reversed pattern between *WT* and *KCNJ5* mutated APA was found in 10 cytoplasmic parameters, including mainly color-based features ($P<0.01$). *KCNJ5* mutation status was negatively correlated with CYP11B1 and HSD3B1 expression ($P<0.01$). On the contrary, *WT*, *CACNA1D* and *NR* APA significantly correlated positively with CYP11B1. *ATP1A1* mutated APA correlated positively with CYP11B2 ($P<0.01$) and not with CYP11B1 or HSD3B2.
Conclusion
Our findings in *NR* APA point towards a *KCNJ5*-like morphometric pattern associated with a *WT*-like steroidogenic enzymes expression pattern. *WT* APA presented an opposed morphometric pattern in comparison to mutated APA, indicating that in absence of detectable somatic mutations APA cells are driven towards a different cellular fate.

Adrenal cushing's syndrome surprisingly unveiling breast cancer

João Sérgio Neves[1,2], Ana Isabel Oliveira[1], Pedro Souteiro[1,3], Sofia Castro Oliveira[1,3], Helena Baldaia[4], Daniel Melo[4], Celestino Neves[1,3], Paula Freitas[1,5] & Davide Carvalho[1,5]
[1]Department of Endocrinology, Diabetes and Metabolism, São João Hospital Center, Porto, Portugal; [2]Departamento de Cirurgia e Fisiologia, Unidade de Investigação Cardiovascular, Faculdade de Medicina, Universidade do Porto, Porto, Portugal; [3]Faculty of Medicine University of Porto, Porto, Portugal; [4]Department of Pathology, São João Hospital Center, Porto, Portugal; [5]Instituto de Investigação e Inovação em Saúde da Universidade do Porto, Porto, Portugal.

Introduction
Cushing's syndrome is an endocrinopathy characterized by glucocorticoids excess. Adrenalectomy is the recommend treatment for unilateral adrenal Cushing's syndrome and is usually associated with resolution of the disease.
Clinical Case
A 54-year old woman with central obesity (BMI 34.3 kg/m^2), diabetes and hypertension had a left adrenal mass of 15 mm and characteristics suggestive of adenoma (Hounsfield unit of <10). On CT reevaluation, five years later, there was evidence of mass growth (28 mm) and the characteristics were suspicious of malignant lesion (Hounsfield unit of 38 and absolute contrast washout of 35%). She was then referred to our department for evaluation. Urinary catecholamines and metanephrines were normal, ACTH level was 4.2 pg/ml and the cortisol following 1 mg overnight dexamethasone suppression test was 11.0 µg/dl. The 24 h urinary-free cortisol, late-night salivary cortisol and two-day low-dose dexamethasone suppression test were consistent with ACTH-independent Cushing's syndrome. A left adrenalectomy was performed. At pathological evaluation, there was a neoplasm of solid pattern, with vascular invasion and a immunohistochemical pattern suggestive of a breast carcinoma metastasis. Mammography revealed a 15 mm nodule with spiculated contours that on breast biopsy revealed a NST (no special type) breast carcinoma. The patient was submitted to neoadjuvant chemotherapy and surgical tumorectomy. Five months after surgery she was admitted in Endocrine department for adrenal insufficiency. Ten months after the adrenalectomy, the patient presents an adrenal insufficiency (compensated with replacement therapy) and maintains follow-up on endocrinology and multidisciplinary breast cancer appointments.
Conclusion
The authors present a case of Cushing's syndrome of adrenal origin, with a concomitant metastasis of a breast carcinoma. The find of a metastasis in an adrenal mass, is consistent with a tumor-to-tumor metastasis, a rare finding in adrenal masses that, in this case, allowed the diagnosis of a previously unknown breast cancer.

Centro Hospitalar Entre Douro e Vouga, Santa Maria da Feira, Portugal.

Introduction
Adrenal tumors are usually detected due to clinical manifestations of hormonal hypersecretion or incidental findings on imaging evaluation. Although most incidentalomas are non-functioning adenomas, it is important to appropriately evaluate such masses to exclude hormonal excess or malignancy.
Case description
An 81-year old male was admitted to our hospital for fever with 15 days of evolution. The patient also presented chills and loss of 3 kg in the last 4 weeks. Regarding past medical history, the patient had type 2 diabetes, hypertension, coronary artery disease, heart failure, cerebrovascular disease (stroke 8 years before), vertebral fractures (3 years before), deep vein thrombosis (3 months before), renal lithiasis and a right adrenal mass (3 cm in the abdominal tomography 16 months before; no functional study available). An elevated C-reactive protein (142 mg/l) was observed, with negative blood and urinary cultures and no other signs of infection. The abdominal ultrasound shown a right adrenal mass of 13 cm. On magnetic resonance, the mass was heterogenous with invasion of inferior vena cava. The patient had no stigmas of Cushing's syndrome. Plasma catecholamines, urinary catecholamines and metanephrines, and renin and aldosterone levels were normal. The midnight salivary cortisol was normal and the plasma cortisol level after 1 mg overnight dexamethasone suppression test was 3.7 µg/dl. Given the risk for a surgical approach, the fast growth of the tumor and the imaging characteristics suggestive of adrenal carcinoma, a decision to preclude biopsy was made. The patient started mitotane and two months later the mass has 15 cm and the patient is still on follow-up in outpatient setting.
Conclusions
The authors present a case of adrenal carcinoma in a patient with previous adrenal mass not completely studied at presentation. Adrenal incidentalomas are frequent. This case highlights the importance of prompt evaluation of adrenal incidentalomas to early recognize rapidly growing adrenal carcinomas.

The relative risk of developing Addison's disease among patients with type 1 diabetes mellitus: a nationwide, matched, observational cohort study

Dimitrios Chantzichristos[1,2], Anders Persson[3], Björn Eliasson[1,2], Mervete Miftaraj[3], Stefan Franzén[3], Ann-Marie Svensson[3] & Gudmundur Johannsson[1,2]
[1]Department of Internal Medicine and Clinical Nutrition, Institute of Medicine at Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden; [2]Department of Endocrinology-Diabetes-Metabolism, Sahlgrenska University Hospital, Gothenburg, Sweden; [3]Department of Medicine, National Diabetes Register, Centre of Registers, University of Gothenburg, Gothenburg, Sweden.

Background
Both prevalence and incidence of type 1 diabetes (T1DM) is increasing. T1DM is associated with other autoimmune diseases, such as Addison's disease (AD). This combination is rare, with estimated prevalence in Norway 20 per million. Having both DM & AD is associated with marked excess mortality.
Objectives
To study prevalence and incidence of AD among patients with and without T1DM.
Methods
Nationwide, observational study cross-referencing the Swedish National Diabetes Register with Inpatient Register in patients with T1DM & AD and matched controls from the general population (matched 1:5 for age, sex and country). Demographics at baseline, group proportions and time to AD diagnosis using a Cox proportional hazards model were assessed.
Results
Prevalence: Between 1987–2012, 105 subjects were diagnosed with AD among 30,685 patients with T1DM, while 32 among 153,918 controls. The odds ratio for AD in T1DM patients vs controls was therefore 16.5 (95% CI 11.1–24.5).

The prevalence of AD in patients with and without T1DM was 3400 and 200 per million, respectively. Incidence: Between 1998-2013, 67 subjects were diagnosed with AD at a mean age of 36.7 years (SD 13.1) among 36,705 patients with T1DM, while 33 were diagnosed with AD at a mean age of 43.1 (SD 15.1) among 184,304 controls. The estimated relative risk increase to develop AD in T1DM patients was therefore 10.7 (95% CI 7.0–16.2). The incidence of AD for a patient with and without T1DM was 195 and 18 per million patient-years, respectively.
Conclusion
This nationwide study shows that prevalence of AD is higher than previously reported and that the incidence of AD for a patient with T1DM is 195 per million patient-years. T1DM patients have a more than 10-fold higher risk of developing AD than matched controls and their AD develops at a younger age.

The frequency of incidental liver and renal masses in patients with adrenal incidentalomas

Narin Nasiroglu Imga, Yasemin Tutuncu, Mustafa Unal, Mazhar Müslüm Tuna, Bercem Aycicek, Serhat Isik, Dilek Berker & Serdar Guler
Department of Endocrinology and Metabolism, Ankara Numune Education and Research Hospital, Ankara, Turkey.

Purpose
Adrenal incidentalomas (AIs) are adrenal masses, which are found on imaging studies not performed related to an adrenal problem. Hepatic incidental masses and renal incidental masses are usually seen in abdominal imaging methods. We aim to investigate the frequency and the kind of hepatic and renal incidental masses in patients with AIs.
Methods
Retrospective evaluation of 381 (245 female and 136 male) AI patients and 285 (168 female and 117 male) controls were done. Adrenal masses were divided into two groups according to Hounsfield Units (HU) ≤ 10 and > 10, also classified as right, left and bilateral sided. The comparisons were made between hepatic and renal and both hepatic and renal incidental masses in AIs patients.
Results
Renal incidental mass and both hepatic and renal mass frequency were found higher in AIs group than controls. InAIs patients who had left sided unilateraladrenal mass HU > 10, the frequency of both hepatic and renal incidental mass was found more than left sided unilateral adrenalHU ≤ 10 group ($P = 0.001$). Also in patients who had bilateral sided adrenal mass HU > 10 the frequency of both hepatic and renal incidental mass was found more than bilateral sided unilateral adrenal HU ≤ 10 group ($P = 0.049$).
Conclusions
Increased incidence of both hepatic and renal incidental masses were detected in AIs patients which adrenal mass HU greater than 10. We consider that the physicians should carefully evaluate these cases. Large studies are needed to define the incidence and follow-up of AIs patients with hepatic and renal incidentalomas.

Primary adrenal insufficiency: a Portuguese multicentre study by the adrenal tumour study group

Lia Ferreira[1], João Silva[2], Ana Martins[3], Carlos Belo[4], Diana Oliveira[5], Hélder Simões[6], Isabel Paiva[5], Joana Guimarães[7], Marta Ferreira[8], Rita Silva[9], Susana Garrido[10], Tiago Silva[11], Vera Fernandes[12] & Maria Lopes Pereira[12]
[1]Centro Hospitalar do Porto, Porto, Portugal; [2]Hospital das Forças Armadas, Lisboa, Portugal; [3]Centro Hospitalar Lisboa Norte, Lisboa, Portugal; [4]Centro Hospitalar Lisboa Ocidental, Lisboa, Portugal; [5]Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; [6]Instituto Português de Oncologia Lisboa, Lisboa, Portugal; [7]Centro Hospitalar do Baixo Vouga, Aveiro, Portugal; [8]Centro Hospitalar Leiria, Leiria, Portugal; [9]Centro Hospitalar São João, Porto, Portugal; [10]Hospital Tâmega e Sousa, Penafiel, Portugal; [11]Hospital Garcia da Orta, Lisboa, Portugal; [T2]Hospital de Braga, Braga, Portugal.

Introduction
Primary adrenal insufficiency (PAI) is a rare but severe and potentially life-threatening condition. There are no studies characterizing portuguese patients with PAI.
Aims
To characterize the clinical presentation, diagnostic workup, treatment and follow-up of patients with confirmed PAI.
Methods
A multicentre retrospective study of PAI patients followed in 12 portuguese hospitals.
Results
We investigated 278 patients with PAI (55.8% were females) with mean age of diagnosis of 33.6 ± 19.3 years, 7.3 years after the beginning of the symptom presentation. The most frequently reported symptoms and signs were asthenia (60.1%), hyperpigmentation (55.0%), weight loss (43.2%), hypotension (42.8%) and hypoglycaemia (8.6%). Hyponatremia was documented in 36.3% of cases and hyperkalaemia in 25.9%; 29.1% of patients were diagnosed in adrenal crisis. In 122 patients the diagnosis was established using morning cortisol < 5 g/dl and plasma ACTH 2-fold the upper limit of the reference range and in 39 cases by the corticotropin stimulation test. The main causes were autoimmune adrenalitis (140 cases), idiopathic (48 cases), congenital adrenal hyperplasia (27 cases) and tuberculosis (17 cases). Concerning associated autoimmune diseases, the most common were autoimmune thyroiditis (81 patients) and type 1 diabetes mellitus (25 patients). Seventy-nine percent were treated with hydrocortisone (mean dose 26.3 ± 8.3 mg/day) in three (57.5%), two (37.4%), one (3.7%) or four (0.5%) daily doses; the remainder with prednisolone (10.1%), dexamethasone (6.2%) and methylprednisolone (0.7%); 66.2% were medicated with fludrocortisone (median dose of 100 μg/day). Since diagnosis 33.5% have been hospitalized due to disease decompensation. At the last consultation, 17.2% of the patients had complaints (7.6% asthenia and 6.5% depression) and 9.7% presented changes in the ionogram.
Conclusion
This is the first multicentre Portuguese study about PAI. As described in international studies a significant number of PAI patients continue to have symptoms of over or under-substitution despite optimal steroid replacement.

Adrenal incidentaloma: a challenging dilemma!

Caoimhe Bonner, Usman Shah, Anna Hawkins, Anthony Pittathankal, Imran Syed, Edel Casey & Khash Nikookam
King George Hospital, London, UK.

The prevalence of adrenal incidentaloma on abdominal Computed Tomography (CT) is around 4.4%. This prevalence is increased in obese, diabetic, hypertensive patients, and could be as high as 10% in older patients. Unilateral adrenal masses larger than 4 cm should be considered for surgical removal to avoid missing adrenal carcinoma, particularly in younger patients.
This is the case of a 67 year old gentleman with Type 2 diabetes mellitus, known to have hypertension, hypercholesterolaemia, ischaemic heart disease with six coronary stents, and iron deficiency anaemia. He was on polypharmacy including aspirin, clopidogrel, bisoprolol, amlodipine, oral hypoglycaemic agents, insulin and iron supplementation. He presented with increased urinary frequency and pain in the right flank. Urinalysis and examination of all systems were unremarkable.
An ultrasound of kidney, ureter, and bladder (KUB) was performed showed a well-defined solid echogenic mass superior to the right kidney measuring $98 \times 76 \times 85$ mm with no vascularity. CT of the adrenals and abdomen revealed a 7 cm right adrenal mass, most likely myelolipoma, multiple bilateral small renal cysts, and an extensively calcified atherosclerotic abdominal aorta. Phaeochromocytoma and Conn's syndrome were ruled out following normal 24 hour urinary metanephrines and normal renin aldosterone ratio. It was rather unlikely for Cushing's in view of normal 24 hour urinary cortisol and lack of the clinical stigmata of excess cortisol.
Conclusion
Is it best to leave it alone, bearing in mind his multiple co morbidities or to operate in view of right flank pain, the size of tumour, and the risk of bleeding in this type of tumour?

Assay of steroids with Liquid chromatography tandem mass spectrometry is superior to immunoassays in monitoring patients with 21-hydroxylase deficiency

Ingrid Nermoen[1,2], Sandra Rinne Dahl[1], Ingeborg Brøndstad[1,3], Eystein S Husebye[3,4], Per M Thorsby[1] & Kristian Løvås[3,4]
[1]Oslo University HospitalHrmone Laboratory, Oslo, Norway; [2]Akershus University Hospital, Lørenskog, Norway; [3]University of Bergen, Bergen, Norway; [4]Haukeland University Hospital University, Bergen, Norway.

Objective
Immunoassays of steroids are still used in the diagnosis and biochemical monitoring of patients with congenital adrenal hyperplasia due to 21-hydroxylase deficiency (21 OHD). However, high levels of steroid intermediates can promote cross-reactivity between steroids giving rise to falsely elevated levels.
Design
Fifty-nine patients with classic 21OHD (38 women) were studied. Blood samples were collected in the morning after overnight medication fasting. Immunoassay and liquid chromatography-tandem mass spectrometry (LC-MS/MS) quantitation of the following steroids were performed: 17OH-progesterone (17OH), 21-deoxycortisol (21DF, an 11-hydroxylated derivative of 17OHP), 11-deoxycortisol, testosterone and androstenedione.
Results
Concentrations of testosterone, androstenedione and 17OHP were lower when measured with LC-MS/MS compared with immunoassays, with exception of testosterone levels in men. Testosterone results differed by 30.0% in females and only a small difference in men (+1.1%). The difference was even larger for androstenedione (31.3%) and 17OHP (57.0%).
The correlation between 21DF and 17OHP was good ($r=0.87$), but three patients did not have measurable 21DF which indicate that 21DF is not superior to 17OHP to monitor replacement therapy. Subjects with no enzyme activity had significantly lower mean 11-deoxycortisol concentrations compared with subjects with severe enzyme failure, analyzed by *LC*-MS/MS. Levels of other steroid hormones did not differ significantly between the genotypes and methods.
Conclusions
LC-MS/MS is superior to immunoassays in monitoring patients with 21-OHD on corticosteroid replacement therapy as they are more specific and can be multiplexed. Immunoassays seems to overestimate high levels of 17OHP and androstenedione considerably.

Treatment of patients with primary and secondary adrenal insufficiency with hydrocortisone modified-release (Plenadren®)

Tania Pilli, Raffaella Forleo, Sandro Cardinale, Valeria Cenci & Furio Pacini
Section of Endocrinology, Department of Clinical&Surgical Sciences and Neurosciences, University of Siena, Siena, Italy.

Introduction
Adrenal insufficiency is a life-threatening disease. Conventional treatment requires multiple daily doses of immediate-release hydrocortisone or cortisone acetate causing non-physiological peaks and nadir of cortisol and it has been also associated with premature mortality, high frequency of infections, reduced quality of life, altered metabolic profile and reduced bone mineral density. A modified-release hydrocortisone (Plenadren®, Shire) by combining a rapid with an extended-release of the hormone can mimic the normal circadian rhythm of cortisol and may be administered as a single daily dose. Plenadren has been also associated with a reduction of body weight and blood pressure and improvement of the glyco-metabolic parameters.
Purpose
The study objectives are: (1) to compare the area underr the curve (AUC) of cortisol under conventional therapy and Plenadren and (2) to evaluate clinical (body weight, body composition, blood pressure), glyco-metabolic (HbA1c)) and bone (T score, BMD, serum bone alkaline phosphatase (BAP) and cross laps) parameters at 3, 6 and 12 months of treatment with Plenadren.
Materals and Methods
Thirteen patients (7 M/6 F; age 53±17 (m± S.D.)) with primary adrenal insufficiency in seven subjects and secondary in six cases were prospectively enrolled in the study.
Results
Daily cortisol profiles were more physiological on Plenadren and body exposure to cortisol, calculated as area under the curve, was not statistically significant between conventional therapy and Plenadren. Currently, the median follow-up is 9 months (range 3–24 months). In one obese and diabetic patient body weight decreased as well as fat mass while lean mass increased and HbA1c improved. In one patient with osteoporosis T score improved and accordingly cross laps decreased and BAP increased. All study parameters did not show significantly changes in the remaining patients.
Conclusions
Treatment with Plenadren provides a more physiological cortisol profile and in some patients shows a beneficial effect on glucose metabolism and bone and body composition without increasing adrenal crisis and/or infections.

Autoimmune Addison disease – data from long-term follow-up of patients from a tertiary hospital's Endocrinology Department

Diana Oliveira, Isabel Paiva, Adriana Lages, Diana Martins, Mara Ventura, Nelson Cunha, Sandra Paiva & Francisco Carrilho
Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction
Autoimmune Addison disease requires lifelong glucocorticoid and mineralocorticoid replacement. Optimal therapy is not standardized and must balance adequate hormone substitution with prevention of treatment-related complications.
Objective
Assessment of patients followed at our department: epidemiology, associated conditions, treatment, cumulative hydrocortisone dose and comorbidities.
Methods
Review of clinical records of patients currently followed at our department, diagnosed from 1975 until 2015. Statistical analysis using SPSS v. 23.0.
Results
A total of 27 records were evaluated, 17 were women, 10 men. Mean age at diagnosis was 32±9.7 years, mean follow-up 19.7±13.8 years. Disease duration was 20 or more years in 55.6%. Mean current age 51±13 years. The most frequently associated immune system disorder was autoimmune thyroiditis (42.3%). Regarding glucocorticoid replacement, 92.6% were treated with hydrocortisone (HC), 2 patients with prednisolone. Mean daily dose of HC 31.2±10.0 mg (range 5.0–47.5 mg). Mineralocorticoid replacement with fludrocortisone, mostly 0.1 mg/d. Osteoporosis/osteopenia was found in 33.3% ($n=9$), hypertension (HT) in 25.9% ($n=7$), diabetes in 14.8% ($n=4$), treatment for depression or anxiety in 40.7% ($n=11$) and dyslipidemia in 51.9% ($n=14$). Mean cumulative HC dose was higher in patients with osteoporosis/osteopenia and in those with HT, dyslipidemia and diabetes, although not reaching statistical significance. Tendency remained when adjusted for age.
Discussion and conclusion
Our sample shows a long follow-up time, associated with lifelong need of Endocrinology assessment. A significant number of patients developed comorbidities possibly related to long-term glucocorticoid therapy (osteoporosis, HT, dyslipidemia and diabetes). All of these were related to higher cumulative HC dose. Absence of statistical significance was likely due to sample size. To reduce the risk of complications, replacement therapy in autoimmune Addison disease should be individually adjusted and overtreatment avoided.

Effect of GH treatment on coagulation and fibrinolysis parameters in prepubertal children with growth hormone deficiency

Feneli Karachaliou[1], Maria Kafetzi[2], Maria Drakopoulou[3], Elpis Vlachopapadopoulou[4], Sofia Leka-Emiris[4], Aspasia Fotinou[2] & Stefanos Michalakos[4]
[1]Pediatric Endocrinology Unit, 3rd Department of Pediatrics, University General Hospital Attikon, Athens, Greece; [2]Biochemistry-Hormonology Department, P & A Kyriakou Children's Hospital, Athens, Greece; [3]Endocrine Unit, Choremis Research Laboratory, A Pediatric Department, Athens University Medical School, Aghia Sophia Children's Hospital, Athens, Greece; [4]Endocrinology Department, 'P. & A. Kyriakou' Children's Hospital, Athens, Greece.

Background
Increased fibrinogen levels have been reported in prepubertal children and adolescents with growth hormone deficiency (GHD), which were reduced after rhGH treatment. rhGH treatment has also been shown to exert a beneficial effect on the amount of aPAI-1 in children with GHD.
Aim
Of the study was to evaluate whether prepubertal GH deficient (GHD) children showed any impairment in coagulation- and fibrinolysis-related parameters and the effect of GH therapy on these parameters.
Patients and methods
Fifteen prepubertal children (10 girls and five boys) of a mean (s.d.) age of 9.8 (0.4) years with GH deficiency were included in this hospital based prospective study. Serum levels of PT, APTT, fibrinogen, VII, VIII, AT, PC, D-dimers, Plg, and PAI-1 were measured before and after 6–12 months of GH treatment.
Results
At baseline all studied parameters were within normal ranges. A significant increase in PT values was noted after a mean (s.d.) interval of 9.3 (0.4) months of treatment: 12.46 (0.2) s vs 12.1(0.15) s, $P=0.045$. A significant decrease in PAI-1 levels (3.04 (0.1) U/ml vs 2.28 (0.3) U/ml, $P=0.018$) was noted at the same time. No significant changes in the rest of parameters were found during the study period.
Conclusion
GH replacement therapy for 6–12 months led to a significant increase in PT values, while fibrinogen levels did not change. Moreover, GH treatment reduced PAI-1 levels in GHD children, suggesting a beneficial effect of GH treatment on possible risk of future atherothrombosis. Further evaluation of the clinical significance of these changes is needed.

Treatment with modified-release hydrocortisone for 6 months: A clinical audit in 15 patients with adrenal insufficiency

Charlotte Steffensen[1], Marianne Andersen[2], Ulla Feldt-Rasmussen[3], Caroline Kistorp[4] & Jens Otto L Jørgensen[1]
[1]Department of Endocrinology and Internal Medicine, Aarhus University Hospital, Aarhus, Denmark; [2]Department of Endocrinology and Internal Medicine, Odense, Denmark; [3]Department of Endocrinology and Metabolism, Rigshospitalet, Copenhagen, Denmark; [4]Deparment of Endocrinology and Internal Medicine, Herlev, Denmark.

Background
Patients with adrenal insufficiency (AI) exhibit increased morbidity, mortality and impaired quality of life (QoL) and conventional hydrocortisone replacement does not mimic the endogenous circadian pattern and may compromise adherence. A modified – release hydrocortisone formulation (Plenadren) for once-daily use is licensed in order to meet these needs.
Objective
To audit the effects of treatment change from HC to Plenadren in an out-patient, daily-life clinical setting.
Patients and methods
Fifteen consecutive patients with AI and problems with adherence and/or QoL were shifted from HC to Plenadren treatment. The effect of treatment was assessed by clinical biochemistry, DEXA scanning and QoL (AddiQol) before and after 6 months.
Results
Fifteen patients (10F/5M) were included in the audit of whom 8 had primary AI with a mean age of 49.5 years. The mean daily HC dose was 21.4 mg and the mean daily plenadren dose was 20 mg. No significant changes were recorded in fasting lipid levels, morning salivary cortisol, serum electrolytes, HbA1c, or CRP before and after plenadren treatment. Likewise, body composition and BMD were unchanged. The AddiQol questionnaire showed a trend towards improved sleep, less muscle pain and better concentration at 6 months. Fourteen of the 15 patients continued on Plenadren after 6 months.
Conclusion
Plenadren treatment for 6 months in patients with AI was well received but did not translate into detectable changes in clinical biochemistry or body composition. Longer treatment duration and a larger patient group are needed to evaluate the long term benefit of plenadren.

Cushing's Syndrome During Pregnancy mimicking preeclampsia – case report

Danijela Radojkovic[1,2], Milan Radojkovic[1,3], Milica Pesic[1,2], Slobodan Antic[1,2], Sonja Kostic[2], Sanja Curkovic[2], Vojislav Ciric[2] & Ivan Ilic[1,4]
[1]Medical Faculty, University of Nis, Nis, Serbia; [2]Clinic of Endocrinology, Diabetes and Metabolic Disorders, Clinical Center Nis, Nis, Serbia; [3]Surgery Clinic, Clinical Center Nis, Nis, Serbia; [4]Pathology Institute, Clinical Center Nis, Nis, Serbia.

Introduction
Physiological changes of pregnancy could be similar with classical presentation and biological confirmation of Cushing's Syndrome (CS). To diagnose CS in pregnancy is very difficult especially in previously healthy women. Since the hypercortisolemia in the pregnancy increase maternal and foetal morbidity it is a concern for endocrinologists, gynaecologists, and paediatricians.
Patient case report
Herein, we present young woman (23 years old) admitted to the Genecology Clinic, with uncontrolled hypertension and gestational diabetes. The pregnancy was terminated with an emergency caesarean section at 28 weeks of gestation due to sever preeclampsia. Five months after delivery hypertension, weight gain, poor glycaemic control, irregular menstrual cycles and cushingoid features persisted. She was admitted to the Endocrinology Clinic for further evaluation. Computed tomography revealed right adrenal adenoma, size 32×41 mm. Endocrine evaluation verified increased cortisol and decreased ACTH. There was no plasma cortisol suppression after low- and high-dose dexamethasone suppression tests. Vanillylmandelic acid in 24 h diuresis, plasma catecholamine and chromogranin serum level, were normal. Potassium was decreased, but other electrolytes (sodium, calcium, phosphorus, magnesium) were in normal range. After adequately preoperative preparation, right adrenalectomy was performed. The procedure and postoperative course were uneventful. The histopathological examination confirmed a benign adrenocortical adenoma.
Conclusion
Even though CS in pregnancy is very rare, it is worthy to be considered when pregnant women develop hypertension and gestational diabetes. Delayed diagnosis and treatment could lead to maternal-foetal complications.

Potentially aggressive adrenal oncocytoma during pregnancy: about one case

Mouna Mezoued[1,2], Maissa Smaili[1] & Djamila Meskine[1,2]
[1]Laboratoire Endocrinologie et Metabolisme, Algiers, Algeria; [2]EPH Bologhine, Algiers, Algeria.

Oncocytary cells adrenal adenoma or adrenal oncocytoma is an extremely rare tumor, mainly composed by oncocytomes. The diagnosis is exclusively confirmed on histological findings. There are about 50 cases published in the scientific reviews, of which only one case described a pregnant woman.
We report an observation about a 31 years old patient, with no personal antecedent, explored in our unit for an adrenal masse, measuring $71\times58\times46$ mm discovered during an abdominal CT scan done for low back pain.
Patient did not present obvious signs of adrenal hypersecrtion at clinical exam, we noticed some sympathic signs associated to an amenorrhea, and a pregnancy of 8 weeks of amenorrhea was then diagnosed. At CT scan the adrenal masse did not match with the characteristics of an adenomatous one, having a spontaneous density of 40 HU, and an absolute washout up to 33%.
Methoxylated drift and hormonal exploration were normal.
Regarding to the size of this mass and its radiological characteristics with a strong suspicion of malignancy, Surgical management was decides, and patient was treated at 12 weeks of amenorrhea with simple post-operative issues. Histological findings concluded to an adrenal adenoma with oncocytary cells presenting malignant potential (according to BISCEGLIA criteria).
Pregnancy was leaded to its term, with birth of a healthy new-born. The patient was followed for more than one year without recurrence.
Treatment of adrenal oncocytoma should always be surgical, with an exert as large as possible.

Primary hyperparathyroidism associated with Cushing syndrome and primary hyperaldosteronism

Fatma Mnif, Hamza Elfekih, Mouna Elleuch, Faten Hadjkacem, Dorra Ghorbel, Nabila Rekik, Mouna Ammar, Mouna Mnif & Mohamed Abid
Hedi-Chaker University Hospital, Sfax, Sfax, Tunisia.

Introduction
The simultaneous occurrence in the same patient of more than one endocrinological condition is rare and was described in the multiple endocrine neoplasia (MEN). Here, we report a patient with an unusual combination of primary-hyperparathyroidism, papillary thyroid microcarcinoma, primary-hyperaldosteronism and ACTH-independent Cushing's syndrome.
Case description
A 54-year-old women with a primary-hyperparathyroidism was admitted to our hospital to undergo a parathyroidectomy for a single adenoma and total thyroidectomy for suspicious nodules in which one of it was confirmed histopathologically to be a 3 mm papillary thyroid microcarcinoma. An exploration of a resistant hypertension associated with hypokalaemia was done and the co-secretion excess of aldosterone (aldosterone-renin ratio >23 ng/ng twice) and cortisol (negative overnight and low-dose Dexamethasone suppression with low ACTH level) was confirmed with an abdominal CT-scan showing a 19 mm left adrenal adenoma. The patient has also multiple lipomas.
Conclusion
The multiple endocrine hypersecretion exists and the MEN1 should be considered since there is a considerable number of atypical MEN1 syndrome thus the DNA testing is scheduled.

Comparison of biochemical and hormonal parameters in patients with primary adrenal insufficiency of autoimmune and no-autoimmune cause

Anna Angelousi, Aggeliki Karapanagioti, Giorgos Nikolopoulos, Panagiotis Moschouris, Marina Tsoli, Vasiliki Mavroeidi, Michalis Kokkinos, Nikolaos Assonitis, Fotini Petychaki, Gregory Kaltsas & Eva Kassi
Kapodistrian University of Athens, Athens, Greece.

Introduction
Primary adrenal insufficiency (PAI) can be of autoimmune origin (AI), non-autoimmune origin (bilateral adrenalectomy, acute hemorrhage, infection) (NAI) or pharmaceutical (mitotane) origin. Studies have shown that these patients develop long-term morbidities and increased mortality due to excessive glucocorticoid tissue exposure. Data about differences concerning hydrocortisone (HC) needs, cortisol hormonal levels and metabolic parameters in these patients are scarce.
Methods
This retrospective analysis included patients with PAI with follow-up more than 5 years (mean follow-up: 9 ± 6.9 years). Patients had two different day curves of cortisol (F) measurements and 24 h urinary cortisol levels (UFC) and were on oral HC replacement treatment (total mg/day).
Results
We included 12 patients with Addison disease (AD), 8 patients under therapeutic mitotane levels (>13 mg/l) and six patients with PAI of other causes (NAI). BMI increases in all groups in the follow up and it is positively correlated with daily HC substitution ($P=0.017$, $r=0.5$). Mitotane group had statistical significant higher BMI at diagnosis compared to the two other groups ($P=0.015$). This difference among groups in the BMI disappears in the follow-up thus probably due to 'Cushing effect'. NAI group had higher HC substitution compared to AD group ($P=0.01$) and higher Hb1Ac and cholesterol levels during follow up compared to AD group ($P=0.02$) and mitotane group ($P=0.05$). As expected HC substitution as well as UFC levels were significant higher in the mitotane group compared to the two other groups ($P=0.0014$, $P=0.05$ respectively). Median F levels were positively correlated with HC substitution ($P=0.027$) (mitotane group was excluded).
Conclusion
Patients with NAI had statistically higher HC substitution as well as Hb1Ac and cholesterol levels in the follow up compared to AD group. Despite the small sample of patients the over-substitution of these patients should be reconsidered regarding the consequences.

The role of dehydroepiandrosterone sulphate (DHEAS) in the evaluation of autonomous cortisol secretion in adrenal incidentalomas

Fotini Adamidou, Thomas Georgiou, Gesthimani Mintziori, Efrosini Tsirou, Panagiotis Anagnostis, Athanasios Panagiotou & Marina Kita
Ippokrateion General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction
Subclinical hypercortisolism (SH) has been reported in 5–20% of patients with adrenal incidentalomas (AIs), with various cardiometabolic consequences. We intended to investigate the contribution of DHEAS to standard testing, as another indicator of autonomous cortisol secretion in AIs.
Materials and methods
Ninety consecutive patients ($n=90$) with AIs were included in a prospective cohort study. SH was diagnosed if ≥ 2 criteria were fulfilled: an overnight dexamethasone suppression test (DST) ≥ 1.8 μg/dl, a 24 h urinary free cortisol (UFC) above the upper limit of normal, midnight/morning serum cortisol ≥ 0.5 and plasma ACTH <10 pg/ml. Age- and sex-specific DHEAS ratios were calculated and a ratio of 1.25 was considered the cut off. Data are expressed as median (interquartile range).
Results
Ten cases of SH were found among the 90 patients (11%), harboring 112 AIs. DHEAS ratio in patients with SH was 1.55 (2.5) and 1.85 (2.67) in non-functional AIs. A DHEAS ratio ≤ 1.25 was not predictive of SH.
Conclusion
DHEAS failed to prove a useful screening tool for SH in patients with AIs in this study. Further study is needed to evaluate its potential as an adjunct to DST.

Adrenocortical carcinoma in pregnancy

Goknur Yorulmaz[1], Nur Kebapci[1], Funda Canaz[2], Betul Aydin Buyruk[1], Sevil Alaguney[1], Bartu Badak[3] & Mahmut Kebapci[4]
[1]Division of Endocrinology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [2]Department of Pathology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [3]Department of General Surgery, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [4]Department of Radiology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey.

Introduction
Adrenocortical carcinoma (ACC) is a very rare tumor. The mean age at onset is between 40 and 50 years. Patients with nonfunctioning ACC report symptoms of abdominal discomfort or back pain due to the large tumor size. Surgery for ACC should be performed by an expert surgeon.
Case
A 29-year-old patient with 25 weeks of pregnancy admitted at our clinic with right side pain. 10×11 cm solid mass on right adrenal gland was detected by ultrasonography. The lactate dehydrogenase level of the patient was 10 times higher than normal ranges. The urinary metabolits were within normal limits. Because of the increase in the size of the mass, the patient underwent operation urgently. The histopathological report indicates an adrenocortical carcinoma and tumor weighting 376 g and measuring $10\times9\times7$ cm. The patient gave birth on the 32nd gestational week. The patient was evaluated after delivery and liver, pulmonary and brain metastases were detected. One week after delivery patient was died in intensive care unit.
Conclusion
Several clinical data shown that the secretion and or proliferation of adrenocortical tumors may have be affected by the hormonal context of pregnancy. Most of patients present with excess steroid hormone or abdominal mass effects. In our patient, a mass was detected in the ultrasonography performed with the cause of side pain. In pregnancy treatment procedure was not still standardized in ACC, but ACC was an aggressive malignant tumor, so our patient

was operated urgently. Because of her pregnancy chemotheraphy was planned after birth. But one week after delivery patient was died.

Abnormal aldosterone/renin ratio is common in patients of African compared to European origin, is associated with hypokalaemia, and left ventricular hypertrophy, but is rarely associated with abnormal adrenal imaging characteristics

KS Ahmed, D Bogdanet, S Heshe, G Boran, LA Behan, M Sherlock & J Gibney
Departments of Endocrinology, Cardiology and Chemical Pathology, The Adelaide and Meath Hospital, Incorporating the National Children's Hospital, Tallaght, Dublin 24, Dublin, Ireland.

Adrenal mineralocorticoid biochemistry differs between people of African and European ancestry. The aldosterone/renin ratio (ARR) is the initial screening test for primary hyperaldosteronism (PHA), but little data exists regarding ethnic variations in this.

Following clinical observation of a high prevalence of abnormal ARR in patients of African origin, we retrospectively reviewed all ARR measurements in a single centre over 10 years. Rates of hypokalaemia and intraventricular septal thickness (IVS, by echocardiography) were studied as end-points of PHA, and adrenal imaging was reviewed. Data were analysed using Student's *t*-test, χ-square test and Mann–Whitney–Wilcoxon test as appropriate.

ARR was available in 1,473 patients, and abnormal in 374 (25.4%). Abnormal ARR occurred in 305/1473 (20.7%) of European and 69/124 (55.6%) of African patients ($P<0.001$). Among those with abnormal ARR, hypokalaemia (<3.5 mmol/l) was documented on at least one occasion in 171/305 (56.1%) European and 43/69 (62.3%) African patients. Median (range) IVS was 1.57(0.78–2.80) cm in African-origin and 1.2 (0.69–2.18) cm in European patients ($P<0.002$). Adrenal adenoma was identified in 2/69 (2.8%) African and 41/305 (13.4%) of European patients ($P<0.005$).

In summary, ARR was abnormal in 55.6% of African-origin patients screened at an Irish hospital, but only 2.8% had demonstrable adrenal pathology. Rates of hypokalaemia were similar between European-origin and African-origin patients, while cardiac hypertrophy was more marked in African-origin patients. These findings have implications for the use of current screening guidelines for ARR in African-origin patients and also for the mechanistic role of aldosterone in hypertensive complications in African-origin patients.

Neutrophil-lymphocyte and platelet-lymphocyte ratios as biomarkers in distinguishing adrenocortical adenomas and carcinomas

Mirsala Solak[1], Ivana Kraljevic[1], Marko Kastelan[1], Luka Kakarigi[1], Tina Dusek[1], Tanja Skoric Polovina[1], Annemarie Balasko[1], Nikola Knezevic[2] & Darko Kastelan[1]
[1]Department of Endocrinology, University Hospital Center Zagreb, Zagreb, Croatia; [2]Department of Urology, University Hospital Center Zagreb, Zagreb, Croatia.

The role of systemic inflammation in promoting tumor progression has been a topic of increasing interest. Neutrophil-lymphocyte ratio (NLR) >5 and platelet-lymphocyte ratio (PLR) >190 used as indicators of inflammation have been reported to have prognostic value in numerous solid tumors. The aim of this retrospective study was to investigate NLR and PLR as biomarkers in distinguishing between adrenocortical adenomas and adrenocortical carcinomas (ACC). Nineteen patients with ACC (mean age 54 years, range 24–75; eight male, 11 female) and 22 patients with adrenal adenomas (mean age 47 years, range 28–71; six male, 16 female) were enrolled in the study. In the ACC group, only one patient presented with functional tumor (excess estradiol), whereas all the others were discovered incidentally. Eleven out of 19 patients with ACC were operated laparoscopically, while the open approach was used in eight of them. In the adenoma group, the first presentation of the disease was hyperandrogenemia in one patient, and in the rest of the group, adenoma was discovered incidentally. Open surgical approach was used in one patient with adenoma and the others were operated laparoscopically. The mean size of adenoma was 5.8 cm while the mean ACC size was 9 cm ($P<0.05$). In the ACC group, NLR>5 was found in 26.3% (5/19) patients which was higher compared to 9% (2/22) of the patients with NLR>5 in the adenoma group. PLR>190 was found in 36.8% (7/19) of ACC patients compared to 18.2% (4/22) in the adenoma group. Mean NLRs in the ACC and in the adenoma group were 3.6 and 3.1, respectively ($P=0.886$) and mean PLRs were 219.1 and 143.3, respectively ($P=0.026$). Our results indicate that in addition to tumor size, PLR might potentially serve as biomarker of malignant tumor behavior.

Adrenal involvement of Non-Hodgkin's lymphoma: a case report

Ozen Oz Gul, Soner Cander, Erdinc Erturk & Canan Ersoy
Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Introduction

The involvement of certain organs such as the adrenal gland is rare in non-Hodgkin's lymphoma (NHL). Although lymphomas can involve virtually all extranodal organs, different organs show different frequency of involvement. Adrenal gland involvement is usually bilateral. We report that a rare case of unilateral adrenal involvement of diffuse large B-cell lymphoma presenting with abdominal pain.

Case

A 64-year-old-man presented with abdominal pain, weakness, weight loss. Abdominal computed tomography (CT) revealed 59×53 mm right adrenal mass, 40×25 mm paraaortic lymphadenopathy, multiple solid mass lesions in the spleen and malignant infiltrating mass lesions in the perineal vascular structures. Surgical lymph node biopsy demonstrated a diffuse large B cell lymphoma. The pathology specimens showed neoplastic infiltration of pleomorphic lymphoid cells with scanty cytoplasm, irregular nuclear contour, large nuclei, with one to three peripherally positioned nucleoli. He was treated with rituximab, cyclophosphamide, doxorubicin and vincristine (R-CHOP). The patient tolerated treatment well without significant side effects. After the six courses chemotherapy, the patient's systemic symptoms were improved.

Conclusion

Extranodal organ involvement is more common in non-Hodgkin's lymphoma than in Hodgkin's lymphoma. Systemic chemotherapy has been regarded as the best therapeutic approach for NHL involving rare extranodal sites. Adrenal involvement of systemic lymphoma should be considered when evaluated the adrenal masses.

Challenges in differential diagnosis of adrenal incidentaloma or clinical case of multiple myeloma

Natalia Volkova[1], Maria Porksheyan[1], Ilya Davidenko[1], Kit Oleg[2] & Dimitriadi Serguey[2]
[1]Rostov Sate Medical University, Rostov On Don, Russia; [2]Rostov Research Institute of Oncology, Rostov On Don, Russia.

Adrenal incidentaloma (AI) in patients with cancer poses diagnostic challenge for doctors. We present clinical case of generalised metastatic bone diseases and adrenal mass.

Male 59 years old asked the second opinion about incidental adrenal mass, which was suspected for adrenal cancer by urologist. His medical anamnesis began in April of 2015 with severe generalised bone pain. The whole body MRI/CT detected multiple bone lesions, adrenal mass (57×45×56 mm, 37 HU) and prostate mass. Urologist studied PSA and carried out prostate biopsy, the results excluded prostate cancer. Basing on size and CT dencity of adrenal mass, the urologist suspected adrenal cancer and prepared to perform adrenal biopsy. First, he decided to get an endocrinologist consultation to exclude pheochromocytoma and ask the second opinion about suspected adrenal cancer. There were excluded pheochromocytoma, subclinical Cushing and adrenal insuficiency. Taking into accout the fact that adrenal cancer metastasis affect liver and lung first, which were abcent in this case, lack of rapid growth of adrenal mass, the suspected diagnosis of adrenal cancer was hardly probable. The suggestion for adrenal

biopsy was refused because of hematologic disturbances and potential hemorrhage. Also there was made an offer to perform the bone lesion biopsy, which is easier and safer to perform. The results were consistent with multiple myeloma. Patient was seen by hematologist, the appropriate treatment assigned. The interesting fact was that the hematologic, bony and urinary signs, which are typical for myeloma, were abcent. Unfortunately, patient died after second cource of chemotherapy.
This case illustrates as diagnostic as administrative issues. First, the urologist did not follow the diagnostic protocol for adrenal incidentalomas, which would have been fatal. Secondly, the management of AI in cancer or suspeceted cancer patients should be absolutely multidisciplinary. Thirdly, untypical signs of the disease requires doctors to be more educated in edjacent specialities.

Iatrogenic Cushing syndrome and suprarenal secondary insufficiency due to interaction between fluticasone and ritonavir

Suarez Gutierrez Lorena[1], Veiguela Blanco Brenda[2], Dieguez Felechosa Lorena[2], Manjon Miguelez Laura[1], Riestra Gonzalez Maria[2], Antuña García Nuria[2], Diaz Fernandez Maria Jesus[2] & Casal Alvarez Florentino[2]
[1]Hospital Universitario Central De Asturias, Oviedo, Spain; [2]Hospital De Cabueñes, Gijon, Spain.

Introduction
The interaction between corticosteroids and protease inhibitors (PIs) is a clearly described drug interaction.
Case report
A 44-year-old woman diagnosed with HIV category B3 diagnosed in 1989; severe lipodystrophy. In addition , HCV genotype IA. Bronchial asthma since 2000. Treatment with fluticasone 1 inh/24 h, salbutamol on demand, darunavir 800 mg/day and ritonavir 100 mg/day. He had known lipodystrophy since 2001 and the abdominal perimeter was monitored, aiming to increase it. Likewise, it presented progressive proximal weakness in lower limbs, with increased hair, hair fragility and alopecia reason why it is referred to Endocrinology. Moderate hirsutism, muscular atrophy and in the analytical study: normal FSH and LH are objectified. Testosterone 0.05 ng/ml (0.1–0.9), ACTH 1.0 pg/ml (7.2–63.3), Cortisol am 0.65 µg/dl (4.30–22.40) urinary free cortisol 3.74 µg/24 h (36–137). A Synacten test is performed: Basal 0.52; 30 min 2.33; 60 min 2.84 with ACTH 1 and was diagnosed as having an independent iatrogenic Cushing ACTH syndrome associated with secondary adrenal insufficiency. With this diagnosis he is referred to the pulmonology department for corticosteroid replacement. Inhaled and substitution treatment was initiated with hydrocortisone and went home with a new antiretroviral regimen (raltegravir, tenofovir and abacavir)
Discussion
Fluticasone is a synthetic steroid that is cleared by the cytochrome P450 CYP3A4 enzyme, which is inhibited or potentiated by a multitude of drugs, including ritonavir. As it is not metabolized, an increase in circulating levels leads to a decrease in the secretion of ACTH and therefore a suppression of the adrenal gland with insufficiency of the same and cushing syndrome.
The options are the substitution of Fluticasone by a non-substrate of CYP3A4 such as beclomethasone and the substitution of ritonavir for another antiretroviral. Most cases resolve in about 9–12 months.

Body composition in women with Cushing's syndrome of different etiology

Dusan Ilic, Djuro Macut, Ivana Bozic Antic, Bojana Popovic, Tamara Bogavac, Tatjana Isailovic, Valentina Elezovic, Sanja Ognjanovic & Svetozar Damjanovic
Clinic of Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia.

Introduction
Cortisol has important roles in the regulation of body composition and hypercortisolaemia have major impact on body fat distribution. The aim of this study was to analyze differences in adipose tissue distribution in women with Cushing's disease and Cushing's syndrome due to adrenal adenoma.
Method
We evaluated 12 women with Cushing's syndrome, six with ACTH secreting pituitary adenomas (Group A) and six with adrenal adenomas (Group B). In all subjects BMI was calculated and body composition assessed by dual energy X-ray absorptiometry. Basal values of serum cortisol, ACTH and DHEA-S were determined at admission to the hospital.
Results
Mean age was comparable between Group A and Group B (44.5 +/− 14.7 years vs. 52.7 +/− 5.6 years, $P=0.23$) while BMI was significantly higher in Group B (32.7 +/− 5.5 kg/m^2 vs. 25.6 +/− 4.3 kg/m^2, $P=0.034$). Group B had significantly higher percent of total body fat (45.4 +/− 4.3% vs. 34.5 +/− 8.4%, $P=0.021$) but borderline difference in trunk fat percentage (Group B 44.3 +/− 6.8% vs. Group A 32.6 +/− 10.7%, $P=0.055$). Main difference in adipose tissue percentage was found on arms and legs, which was higher in Group B (arms 53.6 +/− 8.8% vs. 38.5 +/− 11.9%, $P=0.037$; legs 47.6 +/− 4.4% vs. 39.0 +/− 5.9%, $P=0.022$). There was no significant difference in lean body mass or bone mineral density between these two groups. As expected, ACTH was significantly higher in group A (74.3 +/− 16.4 ng/l vs. 14.7 +/− 7.6 ng/l, $P=0.040$), but with no significant differences in morning cortisol concentrations (Group A 664.2 +/− 210.4 nmol/l vs. Group B 432.8 +/− 146 nmol/l, $P=0.060$), midnight cortisol concentrations (Group A 461.3 +/− 236.2 nmol/l vs. Group B 330.3 +/− 203.6 nmol/l, $P=0.410$) or DHEA-S concentrations (4.9 +/− 5.4 nmol/l vs. 2.8 +/− 3.8 nmol/l, $P=0.564$) between groups.
Conclusion
Our group of women with Cushing's syndrome due to adrenal adenoma had higher BMI and increased total fat adiposity. It was not determined yet if the origin of hypercortisolism, or derangements in other related hormones or metabolic pathways, could possibly influence body composition in those patients.

Clinical course of patients with adrenal incidentaloma: retrospective analysis of a single center

Ana Carolina Ruiz Serrano[1], Ana Megia Colet[1,2], Silvia Näf Cortes[1,2], Joan Vendrell Ortega[1,2], Inmaculada Simon Muela[1,2], Esther Solano Fraile[1] & Theodora Michalopoulou Alevras[1]
[1]Endocrinology and Nutrition Service University Hospital of Tarragona Joan XXIII, Tarragona, Spain; [2]CIBERDEM, Tarragona, Spain.

In the adrenal incidentaloma (AI) it is fundamental to determine functionality and benignity. The aim of this study was to evaluated the clinical, radiological and hormonal evolution of AI and compare the frequency of autonomous cortisol secretion (ACS) between American and European Guidelines.
Methods
Retrospective evaluation of patients with AI referred to our service in the last 5 years.
Results
140 patients were included, 50.9% were men. At diagnostic, the media of age was 66 ± 11.2 years and the median of size was 20 mm. CT detected the 95% of AI and 80% had an adenoma-like appearance (49.3% left). Hormonal evaluation revealed that 54.3% were nonfunctional (NF), 38.6% possible autonomous cortisol secretion (PACS), 5.7% ACS, 5% Cushing's syndrome (CS) and 1.4% pheochromocytoma (PCC). Considering American guidelines: 87.9% were NF, 9.3% subclinical Cushing's syndrome and 0.7% CS. The majority of patients remained stable. None developed overt CS. The 13.6% showed growth, with a median of 6 mm. Median follow-up: 30 months. There were significant statistical differences ($P<0.05$) between the group of NF and PACS/CS in terms of size and between NF and CS in terms of growth. No differences were observed in terms of sex, age or cortisol-related comorbidities. Seven patients underwent surgery: one PACS, three ACS, two PCC and one adrenal carcinoma. The 4.3% died due to unrelated adrenal disease.
Conclusions
The AI's are predominantly small, benign, nonfunctioning; stable in time, tumor size and hormonal production. The use of the diagnostic criteria for ASC according to European guidelines shows an increase in the frequency of PACS/ACS, therefore, ACTH determination should be considered in the diagnosis.

Malignant androgen-secreting adrenocortical carcinoma with adrenal insufficiency: a case report

Fatma Mnif, Mehdi Kalthoum, Mona Elleuch, Saafi Wajdi, Nadia Charfi, Mouna Ammar, Hamza Feki, Mona Mnif & Mohamed Abid
Endocrinology-diabetelogy Departement CHU Hedi Cheker, Sfax Tunisia, Tunisia.

Adrenocortical carcinoma (ACC) is a rare malignancy, accounting for 0.02% of all annual cancer. The majority of these tumors are benign, non-functioning adenomas that are incidentally discovered on abdominal image studies. Others are functional adenomas secreting cortisol, aldosterone, or less commonly androgens or estrogens. Pure androgen-secreting adrenal tumors are very rare.
Case report
A 34-year-old female patient presented with pain in the left upper abdomen. A multiphasique CT scan abdomen was done, which revealed large adrenal mass measuring 18×14×14 mm in dimension with central hemorrage. Patient gave history of amenorrhea since 6 months associated with increased hair growth of chest, lower abdomen, and face. Moreover the patient declare recent weight loss (11 kg in 2 months) with asthenia, anorexia, and melanoderma.
On examination, heart rate was 84/min, blood pressure 120/70 mm of Hg. Hirsutism was evaluated based on Ferriman-Gallwey score (result = 13). Biochemical screening showed a total testosterone = 8 ng/ml (0.06–0.82), DHEA sulfate = 3.27 mg/ml (0.4–2.17 mg/ml), 17-hydroxyprogesterone > 20 ng/ml (0.1–0.8 ng/ml), LH = 0.83 mUI/l and FSH = 0.1 mUI/l. The diagnosis of Addison's disease was confirmed by basal serum ACTH = 125.82 ng/l and serum cortisol = 135 µg/l after ACTH test; serum aldosterone and 24 h urinary VMA were normal. A diagnosis of androgen-secreting adrenocortical cancer with adrenal insufficiency was made.
Patient underwent exploratory laparotomy with excision of large adrenal tumor without any complication. The histopathological examination described a mass 21×18×12 mm with microscopique features of tumor cells sharing mild nuclear atypia and rare mitotic figures: histological and immunohistochmical aspect of adrenocortical carcinoma (Weiss score = 3, Ki67 = 10).
On follow-up after 6 months, patient was comfortable, and no longer had amenorrhea or hursitism. Total testosterone was 0.03 ng/ml (0.06–0.82), DHEA-sulfate was 0.174 µg/ml (0.4–2.17 µg/dl) and CT scan abdomen was normale.

DOI: 10.1530/endoabs.49.EP77

EP78

Hyperaldosteronism screening in Hypertensiologists experience - epidemiological review of over 800 cases

Weronika Korzynska, Anna Jodkowska & Grzegorz Mazur
Department and Clinic of Internal and Occupational Diseases, Hypertension and Clinical Oncology, Wrocław Medical University, Wroclaw, Poland.

Primary aldosteronism (PHA) is one of the most common cause of secondary hypertension. It can possibly concern over 10% of hypertensive patients, but often is being under-recognised. The basic tool of case PHA detection is aldosterone to renin ratio (ARR). Appropriate cutoff value of ARR is still under discussion.
We review occurrence of CT/MRI detectable adrenal gland laesions according to assigned ARR cutoff value. Retrospective data from 833 consecutive hypertensive patients of average age 39.85 (S.D.: +/− 15), 449 men and 384 women was analized. ARR > 20, 30, 40 concerned respectively: 12.7%, 7.6%, 4.7%. CT/MRI was performed respectively in patients with ARR > 20, 30, 40 in 55.7%, 66.7%, 69.2%. Laesions in adrenal glands in groups of ARR > 20, 30, 40 concerned respectively: 47%, 52.4%, 56%. The most common CT/MRI findings were adenomas: respectively: 37.3%, 42.9%, 44.4% in groups of ARR > 20, 30 and 40. Less common was nodular hypertrophia: respectively: 10.2%, 9.5%, 14.8% in groups > 20, 30, and 40. The average potassium level in a group of ARR > 20 was 4.05 (mmol/l) (S.D.: +/− 0.46), > 30 3.94 (S.D.: +/− 0.50), > 40 3.93 (S.D.: +/− 0.55).
Average concentration of urine aldosterone in a group > 20 was 14.36 (µg/24 h) (reference value 2.1–18.0 µg/24 h) (S.D.: +/− 10.88), > 30 15.72 (S.D.: +/− 12.33), > 40 17.71 (S.D.: +/− 14.08).
Adrenal lesions in enlarged ARR group were notably more often than adrenal incidentalomas occurrence reported in population (47% vs 2–3%). Higher cutoff ARR value is more specific and allows to reduce costs of confirmative tests. If the ARR over > 40 group we miss 16.95%, in ARR > 30 group we miss 6.78% in compare to ARR > 20. Can we afford missing them considering its' increased cardiovascular risk?
In everyday PHA diagnostics practice there is still lack of "game changer" bringing the final conclusion for diagnostic and profilactic strategies for the whole hypertensive population.

Clinical, laboratorial and densitometric evaluation of adult women with congenital adrenal hyperplasia

Leilane Vensão, Victoria Borba & Adriane Rodrigues
SEMPR, Curitiba, Paraná, Brazil.

Introduction
There is paucity of data comparing bone densitometry and body composition in adult women with congenital adrenal hyperplasia (CAH) treated with glucocorticoids since childhood and the same parameters in healthy women of the same age and BMI.
Methods
20 women with classical CAH (35% simple virilizing, 65% salt losing), aged 16–45 years, had anthropometric, laboratorial and densitometry exam (DXA) for bone mineral density (BMD) (L1–L4, total femur and femoral neck). Laboratory determinations during follow-up were recorded and expressed as average levels. 18 control women of the same age and BMI as patients realized densitometric evaluation for mineral density and body composition.
Results
BMI ranged from16 to 41 kg/m^2 (average 26.3; 25% overweight and 30% obese), whereas height varied from136 to167 cm (average 151 cm). During follow-up, 35% patients were treated with prednisone as the sole glucocorticoid type, 50% used prednisone and dexamethasone and 15% other combinations. Average daily dose of prednisone was 7.5 mg (hydrocortisone equivalent dose 37 mg/day) and 70% used fludrocortisone (average 0.1 mg/day). Combined oral contraceptives were taken by 65% women. Half of women were not controlled based on average testosterone and androstenedione levels, 40% presented altered glycemic status, 26% elevated LDL cholesterol, 21% elevated triglycerides, 68% low HDL-cholesterol levels. No patient presented low BMD according to Z-score and compared to control group. Fat-free mass was considerably lower in patients than controls (33.726 vs 40.637 kg) and it correlated positively with testosterone levels (R 0.52, *P* 0.027). Women using fludrocortisone had lower body fat mass than women who used only glucocorticoids (34.3 + 12.3% vs 44.9 + 3.8%).
Conclusion
Adult women treated for classical congenital adrenal hyperplasia had important metabolic disturbances and alterations in body composition. Nevertheless bone mass was preserved, possibly because hyperandrogenism was not controlled most of the time.

The effect of subclinical hypercortisolism on bone mineral density in female patients with adrenal incidentalomas

Sanja Ognjanovic, Djuro Macut, Milan Petakov, Valentina Kovacevic Elezovic, Tatjana Isailovic, Ivana Bozic Antic, Dusan Ilic, Bojana Popovic, Tamara Bogavac, Jadranka Antic & Svetozar Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Belgrade, Serbia.

To investigate the prevalence of SH and osteoporosis in female patients with unilateral AIs (UAIs) and bilateral AIs (BAIs).
We enrolled 106 female patients, 68 (64.2%) with UAIs and 47 (35.8%) with BAIs. SH was diagnosed in the presence of serum cortisol levels after 2-day low-dose dexamethasone suppression test (LDDST) > 50 nmol/l with at least one of the following parameter (midnight serum cortisol > 208 nmol/L, 24-h urinary free cortisol > 245 nmol/24 h, or ACTH < 10 ng/l). BMD was measured with dual-energy X-ray absorptiometry at lumbar spine (LS), femoral neck (FN), and total skeleton.
No difference was noted in age, BMI, percent of postmenopausal women and years since menopause. The overall prevalence of SH was 20.2%, and was more prevalent in BAIs than UAIs patients (36.1% vs 11.8%, respectively, $P = 0.003$). The largest tumor diameter was similar in patients with UAI and BAI ($P = 0.254$).

After adjustment for BMI, waist, and presence of BAIs, SH were associated with adrenal mass size (odds ratio (OR) = 1.101, 95% CI 1.041–1.166, $P = 0.001$) and age (OR = 1.086, 95% CI 1.021–1.155, $P = 0.009$). LS-BMD and total-BMD were lower in BAIs than in UAIs patients (0.94 ± 0.13 vs 0.86 ± 0.17, $P = 0.015$, and 1.08 ± 0.18 vs 1.02 ± 0.14, $P = 0.029$). There were no differences in FN-BMD. Patients with BAIs had an increased frequency of osteoporosis (46.41% vs 23.5%, respectively, $P = 0.036$). The presence of osteoporosis was associated with SH (OR = 5.775, 95%CI 1.423–23.426, $P = 0.014$) and lower BMI (OR = 1.226, 95%CI 1.071–1.405, $P = 0.003$), after adjusting for age, menopause and vitamin-D.

This study suggests significantly higher prevalence of SH in patients with BAIs than in patients with UAIs. Tumor mass could be of importance for the amount of autonomous cortisol production. The prevalence of osteoporosis was higher in patients with BAIs due to SH.

Long term follow up of patients with adrenal incidentaloma and 'autonomous cortisol secretion'

Ivana Kraljevic[1], Mirsala Solak[1], Tina Dusek[1,2], Tanja Skoric Polovina[1], Annemarie Balasko[1] & Darko Kastelan[1,2]
[1]University Hospital Center Zagreb, Zagreb, Croatia; [2]ZAgreb University School of Medicine, Zagreb, Croatia.

The aim of this study was to compare the long-term co-morbidities and biochemical data between patients with adrenal incidentaloma and 'autonomous cortisol secretion' who were treated surgically and conservatively.

Methods

The research of the database of the patients with adrenal incidentaloma diagnosed between 2007 and 2014 was performed. Among them, 43 patients with 'autonomous cortisol secretion' were identified and invited for a follow-up visit. Diagnostic criteria for 'autonomous cortisol secretion' were: cortisol- > 83 nmol/l after 1 mg dexamethasone suppression test plus one additional criteria (suppressed ACTH secretion or elevated urinary free cortisol). At follow-up visit the anthropometric as well as biochemical data were collected (blood glucose, lipid panel test, HOMA index, cortisol after 1 mg dexamethasone, urinary free cortisol, and ACTH). All patients were evaluated for hypertension, dyslipidemia, osteoporosis and diabetes mellitus/impaired glucose tolerance.

Results

Of the 43 invited patients, 26 patients performed follow up visit (4 males). Among them, 17 patients were treated surgically and 9 were treated conservatively. Median follow-up was 6 years (range 2–16), median age at follow-up was 62 years (range 41–76). There was no difference in BMI at baseline and at follow up in both groups. In the group of surgically treated patients, during follow-up period one patient was diagnosed with arterial hypertension, 4 with hyperlipidemia, and one with diabetes mellitus. Nevertheless, nine out of 12 patients with hypertension in the surgical group reported improvement/disappearance of arterial hypertension at the follow-up visit. Among conservatively treated patients, six out of nine patients had no difference in co-morbidities, one was newly diagnosed with osteoporosis, one with arterial hypertension and one with renal insufficiency. Conclusion: Patient who underwent surgery for 'autonomous cortisol secretion' experienced improvement in the regulation of hypertension after medium follow-up of 6 years. No other significant differences were found in the prevalence of comorbidities between conservatively versus surgically treated patients.

Adrenocortical carcinoma - casuistic analysis

Catia Ribeiro, Joao Lobo, Ana Mesquita, Pedro C Martins, Mariana Peyroteo, Maria Joao Matos, Pedro Antunes, Cristina Sanches, Augusto Moreira & Joaquim Abreu de Sousa
IPO, Porto, Portugal.

Introduction

Adrenocortical carcinomas are rare neoplasms with an incidence of 0.7 to 1.5 per million/year. Diagnosis often requires a multidisciplinary approach. When the disease is confined to the adrenal gland, absolute criteria defining malignancy, do not exist, however a score of Weiss> or =a 3 is considered diagnosis. The prognosis is usually reserved and conventional chemotherapy is not curative.

Material and Methods

Retrospective analysis of the clinical and demographic characteristics, review of the anatomopathological and therapeutic criteria of patients with adrenocortical carcinoma treated at our Institution between 1999 and 2015.

Results

Twenty-two patients with a mean age of 56 years were evaluated, 50% of cases were male. The majority of patients (63.6%) were symptomatic and pain was the most frequent symptom (57.1%). All patients underwent surgical treatment. Multiorgan resection was performed in 5 cases (22.6%). The surgery was R0 in 72.7%. After histological examination, 72.7% presented Weiss score> 2. Adjuvant therapy was performed in 5 patients (22.6%). Considering the revision of the Weiss score, TNM staging and margins status, 50% of the patients would had indication for adjuvant treatments. In this series, the relapse rate (local or distance) was 38.1% (8 cases) and the overall survival at 5 years was 62%; which compares favorably with that described in the literature.

Conclusions

The rarity of this pathology makes diagnosis and therapeutic orientation difficult. A rigorous and standardized histological evaluation is imperative to ensure the most appropriate adjuvant treatment. The referral of this patients to centers of expertise is essential, with the hope that new target therapies will lead to better results.

A near miss on blaming the heart: a rare case of Adrenocortical carcinoma with thrombus extension into right atrium and Cushing syndrome

Hadeil Morsi[1], Mohamed Eisa[3], Lynsey Goodwin[2], Peter Flegg[2] & Myint Aye[2]
[1]North West Health Education England, Manchester, UK; [2]Blackpool Victoria Hospital Foundation Trust, Blackpool, UK; [3]Wellstar Atlanta Medical Center, Atlanta, GA, USA.

A 39 year old female patient presented with one week history of Shortness of breathing. Over the last four months she noted bilateral leg swelling, which failed to improve on diuretic. Examination revealed no other evidence of fluid overload or heart failure. An element of right heart strain rather than failure was raised on cardiologists review. Subsequently, an echo showed a friable mass extending form inferior vena cava to right atrium into proximal left ventricle. The nature of which was revealed to be a tumor thombus extending from the upper pole of right kidney with resultant pulmonary emboli. To this end, an impression of invasive renal carcinoma was made. Until endocrinology review for erratic hyperglycemia, when the patient reported irritability, 6 weeks amenorrhea, change in weight distribution and facial hirsutism in addition to abdominal striae on examination. Hence,the diagnosis shifted to Adrenocortical carcinoma with Cushing. Tertiary center was consulted. In the meantime, Mitotane was started gradually, alongside Hydrocortison. It was a difficult time for the patient who preferred palliative support at home. Unfortunately, few days after discharge she was readmitted with hypoglycemiia, metabolic acidosis and liver impairment. She was treated as Addison crises, though cortisol levels came normal later. Liver involvement was not confirmed to be Mitotane related toxicity or ischemic injury with progression of malignancy.

Unfortunately, she did not survive his well-known aggressive tumor. ACC are tumors are rare tumors and presentation with such vascular invasion is an additional rarity. As clinician on medical take, there is tendency to overclaim heart failure. Having high index of suspicion for patients with Cushing syndrome is central, although not all tumors are functional. The definitive management of ACC is surgical which is not always feasible, particularly with such vascular extension. Wider scale clinical studies pave the management of ACC and optimize Mitotatne therapy.

Congenital Adrenal Hyperplasia due to 11β-Hydroxilase Deficiency: clinical and molecular studies of two novel families with variable phenotypes

Alessandra Pfeilsticker, Luciana Valadares, Selma Sousa, Sarah Cardoso, Olivia Morais, Renata Santarem & Adriana Lofrano-Porto
University of Brasilia, Molecular Pharmacology Lab, Brasilia DF, Brazil.

11β-hydroxylase deficiency is the second most frequent cause of congenital adrenal hyperplasia (CAH), corresponding to approximately 5% of cases., and caused by inactivating mutations in the *CYP11B1* gene. We aimed to describe four new cases from two different families with a clinical diagnosis of 11β-hydroxylase deficiency. Family 1: Two siblings born from consanguineous parents. A 31-year-old (yo) woman presented at 5 yo with genital ambiguity (Prader II), high blood pressure (HBP) and precocious pubarche (PP). She lost follow and returned after 3 full term normal pregnancies while using prednisone. 4 years after last gestation, she remained normotensive without any treatment. Her 24 yo brother presented at age 7 yo with PP, hypokalemia and HBP, when glucocorticoids and anti-hypertensives were started. He had low treatment adherence and evolved with persistent hypertension and left ventricular hypertrophy. Family 2: A 2.9 yo boy presented with PP and high BP, managed with hydrocortisone and anti-hypertensives. His sister presented at 21 days of life with genital ambiguity and salt wasting, managed with hydrocortisone and oral sodium. A detailed steroid profile was performed in all subjects, which confirmed the diagnosis. The CYP11B1 coding region of the patients' and their parents' was automatically sequenced. In the two siblings from Family 1, a homozygous splice site point mutation, IVS4 ds-1 G>A, was identified in exon 4 (g.3132G> A). In Family 2, both siblings harbored a nonsense mutation in exon 6 (c.1066 C> T), which generates a truncated protein (p.Q356X). The mutations presented herein were associated with a highly variable phenotype, from a mildly virilizing phenotype to a high degree of virilization with hypertension and with salt wasting, which is unexpected. Further studies of variants in other genes associated with hypertension, in compensatory pathways of steroid synthesis and metabolism, or the verification of chimeric CYP11B genes are needed to clarify the phenotypic heterogeneity.

'Record-breaking hyponatraemia' with Addison's disease

Irfan Khan & Elizabeth Cheyne
Southmead Hospital, Bristol, UK.

Addisons disease is a rare but potentially life threatening endocrine disorder. It is well-known for disguising as a variety of presentations before diagnosis. Here we present a case report of Addison's disease presenting with very severe hyponatraemia. A 35 year old lady was admitted with lethargy, low mood, weight loss and feeling generally unwell for the last 3 months. Six weeks prior to her admission, her GP arranged some routine investigations including U&E which were normal with a Na of 137. He later prescribed her Mirtazapine for her low mood and anxiety which she took for 4 days. This made her feel more unwell and triggered the hospital admission. She looked tanned but there was no buccal or palmar pigmentation. She was alert with normal cognition.

Admission blood results showed a plasma Sodium of 94 mmol/l, K 5.7 and normal urea/creatinine. Further investigations showed: Serum Osmolality 252, Urine osmolality 192, Urine Na 27, TSH 3.2 and random cortisol 290. She was monitored on ITU and was given normal saline and IV Hydrocortisone for a presumed diagnosis of Addison's disease. Her Sodium level slowly came up to 114 and then to 118 over the next few days. The short synacthen test showed a flat response with the following Cortisol values: 0 min 240, 30 min 242 and 60 min 260. She denied taking exogenous steroids in any form. Later her ACTH came back very high (>2000) with positive anti-adrenal antibodies confirming primary adrenal insufficiency. The Renin/Aldosterone results are still awaited. She transiently developed behavioral disturbance with strange affect raising the suspicion of osmotic demyelination. Fortunately this resolved with reducing the dose of Hydrocortisone suggesting 'steroid psychosis' as cause of the behavioral symptoms. The sodium level stabilized in the low 120's but increased further slowly with addition of Fludrocortisone.

This case demonstrates the unusual presentation of Addisons disease with very severe hyponatraemia with surprisingly few neurological signs or symptoms. It also highlights theproblem of antidepressants potentially exacerbating hyponatraemia in these patients.

24 hour ambulatory blood pressure levels according to adrenal adenoma size

Alp Atasoy[1], Evrim Cakir[2], Suleyman Ahbab[1], Derya Kayas[1], Esra Ataoglu[1] & Mustafa Yenigun[1]
[1]Internal Medicine Department, Haseki Training and Research Hospital, Istanbul, Turkey; [2]Endocrinology and Metabolic Diseases Department, Haseki Training and Research Hospital, Istanbul, Turkey.

Aim

The etiology and underlying pathology of non-functional adrenal adenoma has not been clearly defined, yet. Blood pressure levels according to adrenal adenoma size has not been evaluated, yet. Therefore, we evaluated 24 hour ambulatory blood pressure levels in patients with non functional adrenal adenoma.

Materials & Methods

We studied thirty newly diagnosed adrenal adenoma patients in a tertiary health-care center. They grouped in two categories according to adenoma size. Cut-off size was taken 23 mm. 24 hour ambulatory blood pressures were evaluated in all participants. Delta blood pressure was found by calculating the difference between maximum and minimum blood pressure values.

Results

There were 17 patients with lower adenomas size, which was smaller than 23 mm, the remaining 13 patient's adenomas size was equal or higher than 23 mm. Patients with higher adenomas size had statistically higher systolic delta levels compared to lower size group (70.84 ± 34.9 to 51.29 ± 18.0, $P=0.004$). Additionally; the maximume systolic (165.6 ± 28.7 to 152.0 ± 23.1) and maximum diastolic blood pressure (115.1 ± 37.8 to 100.2 ± 14.9) were higher and also minimum systolic (94.76 ± 11.05 to 100.70 ± 18.60) and minimum diastolic blood pressure (60.69 ± 9.01 to 62.41 ± 12.62) were lower in this group. However; the differences did not reach statistically significance.

Conclusion

Delta systolic blood pressure has been found toe higher in higher adenomas size group. Further studies are necessary to better clarify the association between blood pressure and non functional adrenal adenoma.

Coexisting Graves's disease and pheochromocytoma

Rim Belaid, Ibtissem Oueslati, Wafa Mimita, Karima Khiari & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction

Although Graves' disease is often accompanied by other autoimmune diseases, only a few cases of Graves' disease accompanied by pheochromocytoma have been described.

Herein we report a rare case of coexisting Graves' disease and pheochromocytoma.

Observation

A 50-year-old male patient was referred to our department for the evaluation of right adrenal incidentaloma of 80*66 mm. He had a history of coronary disease and he presented with heat intolerance, diaphoresis, palpitations, intense headaches, excessive nervousness, mood disturbances as well as a rapid weight loss of 30 kg during the last one year.

On physical examination, he had a body weight of 53 kg, a body mass index of 16.5 kg/m^2 and a blood pressure (BP) of 120/75 mm Hg in supine position and 95/60 in standing position.

However his blood profile showed paroxysmal hypertension with peaks of 160/110 mm Hg. The pulse rate was 132 beats per minute (bpm). He had neither goiter nor exophthalmos. Electrocardiogram (ECG) showed a regular sinus tachycardia at 138 bpm with signs of left ventricular hypertrophy.

Laboratory tests indicated diabetes mellitus with a fasting blood sugar of 2.86 g/l and a glycated hemoglobin of 7.9%, hyperthyroidism with a low TSH of 0.05 µIU/ml, an elevated free T4 of 1.96 ng/dl and urinary metanephrines and normetanephrines were greater than 20 time normal values. TSH receptors antibodies were positive.

Thyroid scintigraphy showed homogeneous increased uptake involving the whole thyroid gland.

The diagnosis of coexisting Graves' disease and pheochromocytoma was established. Treatment with prazosin, benzylthiouracil and insulin was then initiated. Propranolol was added progressively. The patient was planned for right adrenalectomy after achieving euthyroid state.

Conclusion
Pheochromocytoma and Graves' disease are known by their similar clinical features making their differential diagnosis difficult. In our case, adrenal incidentaloma evaluation had revealed the pheochromocytoma. Otherwise, a meticulous physical examination and detailed laboratory investigations are needed in order to make a precise diagnosis.

Pheochromocytoma in neurofibromatosis type 1

Agustina Pia Marengo[1], Paula García-Sancho[1], Fernando Guerrero[1], Inmaculada Peiró[2], Elisa Santacruz[3], Andrés Ortiz[3], Juan José Diez[3], Pedro Iglesias[3] & Carles Villabona[1]
[1]Hospital Universitari Bellvitge, L'Hospitalet de Llobregat, Barcelona, Spain; [2]Institut Català D'Oncologia, L'Hospitalet de Llobregat, Barcelona, Spain; [3]Hospital Ramón y Cajal, Madrid, Spain.

Background
Individuals with neurofibromatosis type-1 (NF1) carry an increased risk of pheochromocytoma (PHEO). Detection strategy is unknown but most experts recommend screening if hypertension develops.
Objective
Report the characteristics of PHEO in patients with NF1 (NF1 group) and compare them with non-NF1-associated PHEO (non-NF1 group).
Methods
Retrospective cohort study of patients undergoing PHEO resection in two Spanish tertiary hospitals, from 1980–2016.
Results
Of 78 patients undergoing PHEO resection, 5 (6.4%) had NF1. NF1 patients were younger than those with non-NF1 (mean age 41.8 vs 52.5 yr, $P=0.068$). Males comprised 60% versus 40% of the NF-1 group and non-NF1 group, respectively. PHEO was incidentally diagnosed in 3 of 5 (60%) from NF1 group and only in 29 of 73 (39.7%) from non-NF1 group ($P=0.395$). Remaining NF1 cases were diagnosed by screening (hypertension, $n=1$) and compatible adrenergic clinic ($n=1$). Hypertension was present in 2 (40%) NF1 patients and in 33 (45%) non-NF1 patients. Urinary and/or plasma catecholamines were elevated in all NF1 patients and in 55 (88%) of non-NF-1 group. There was no significantly difference ($P=0.207$) in tumor size between both groups of patients (median 4.6 cm vs 5.6 cm in NF1 and non-NF1 patients, respectively).
Conclusion
In our series, age at diagnosis and gender were similar in NF1 and non-NF1 PHEO patients. NF1-associated PHEO is diagnosed incidentally in more than half of the patients. Although all NF1-PHEO tumors were functioning, only two of five patients had hypertension. It is necessary to keep in mind the possibility of developing PHEO in NF1 patients even in those non-hypertensive patients. On the contrary, in all patients with PHEO is advisable to search clinical criteria used to diagnose NF1, and thus confirming an often-delayed diagnosis.

EP89

Should all patients with Neurofibromatosis type 1 undergo biochemical screening for Pheocromocytoma?

Ahmed Al-Sharefi, Suhel Ashraff, Ramesh Vanka & Satyajit Nag
Department of Diabetes and Endocrinology, The James Cook Univeristy Hospital, Middelsbrough, UK.

Pheocromocytomas (PHEO) are catecholamine secreting tumours which can occur sporadically or as part of other hereditary/familial syndromes including Neurofibromotosis 1 (NF-1). Unlike the case with other genetic syndromes, the current neurofibromatosis guidelines do not recommend a routine hormonal screening strategy for PHEO in the absence of hypertension or other symptoms. In this paper we describe 2 asymptomatic and normotensive patients with NF-1 where secretory PHEO were incidentally diagnosed. The first patient is 61- year old female with a history of NF-1 who received a diagnosis of takotsubo cardiomyopathy and was found to have an incidental adrenal mass of 2.4 cm where subsequent investigations confirmed a diagnosis of secretory PHEO.The second patient is a 44 - year old female with also a background of NF-1 who was found to have a $7.8 \times 7.0 \times 5.8$ cm adrenal adenoma where further work up confirmed PHEO. Both patients underwent adrenalectomy and the histology confirmed the diagnosis and their catecholamines level normalised eventually. Undiagnosed PHEO will put patients at unnecessary risk from having an adrenergic crisis and even death. These cases highlight the importance of considering routine biochemical screening for a catecholamine secreting tumour in all patients with NF-1 to prevent the development of catastrophic events in the future.

Pheochromocytoma in pregnancy

Belgin Efe[1,2], Goknur Yorulmaz[1,2], Sevil Alaguney[1,2], Funda Canaz[1,3] & Bartu Badak[1,4]
[1]Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [2]Division of Endocrinology, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [3]Pathology Department, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey; [4]Depertmant of General Surgery, Eskisehir Osmangazi University School of Medicine, Eskisehir, Turkey.

Introduction
Pheochromocytoma is a tumor originating from the chromaffin cells. These tumors secrete catecholamines which act on target organs and cause hypertensive crises. They are rare during pregnancy, and a differential diagnosis must be carried out mainly with pregnancy-induced hypertension.
Case
A 27-year-old patient in week 17 of pregnancy admitted to our clinic with hypertension and 45×55 mm heterogeneous nodular lesion in left surrenal. The hospitalized patient had tachycardia and hypertensive episodes despite the treatment. Urinary catecholamine and metanephrine collections revealed elevated norepinephrine and normetanephrine. Magnetic resonance imaging identified a adrenal adenoma. After subsequent pharmacological treatment with alpha and beta blockers, a left adrenalectomy was performed laparoscopically. The histopathological report indicates pheochromocytoma (Pheochromocytoma of the Adrenal gland Scaled Score: 6) and tumor weighing 70 g and measuring $6.5 \times 5.5 \times 3.5$ cm. After the surgery urinary catecholamine and metanephrine collections was normal. Postoperatively the patient with 24 weeks gestation had no antihypertensive need.
Conclusion
Pheochromocytoma in pregnancy can cause the death of both the fetus and the mother. This issue should be remembered in hypertensive pregnancies. The approach to the biochemical diagnosis is the same as for the nonpregnant patient. MRI (without gadolinium enhancement) is the preferred imaging modality, and ^{123}I-MIBG is contraindicated. Adrenal pheochromocytomas should be removed promptly if diagnosed during the first or second trimester of pregnancy. In our case, its recognized with new onset hypertention and adrenal tumor was removed in the 2nd trimester.

The role of p27 in pheochromocytoma development

Andrea Kügler[1], Enzo Lalli[2], Juan Higareda Almaraz[1], Steffen Sass[3] & Natalia Pellegata[1]
[1]Helmholtzzentrum München, Institute of Diabetes and Cancer, Munich, Germany; [2]University Nice, Institute of Molecular and Cellular Pharmacology, Valbonne, France; [3]Helmholtzzentrum München, Institute of Computational Biology, Munich, Germany.

Defective p27 function predisposes mice and rats to pheochromocytomas (PCC), and reduction of p27 repression is a feature of human PCCs. These findings suggest that p27 plays a role in PCC tumorigenesis. Recently, it was reported that p27 indirectly regulates gene transcription by associating with transcription factors (TF) and inhibiting gene transcription at specific promoters.
We hypothesized that defective p27 promotes tumor formation in adrenomedullary cells because of aberrant gene expression. To address this hypothesis, we used normal adrenomedullary tissue from wild-type rats or human individuals and performed chromatin immunoprecipitation-sequencing (ChIP-Seq). DNA sequences bound by p27-contaning protein complexes were immunoprecipitated from rat and human tissue extracts using an anti-p27 antibody coupled with magnetic beads. DNA sequences were identified by quantitative next generation sequencing (NGS).

We successfully pulled down DNA sequences with the anti-p27 antibody, indicating that p27, together with unknown transcription factors or co-factors binds the chromatin in adrenomedullary cells. DNA sequences bound by the p27-containing complexes were mapped on the rat/human genome and analyzed using both Genomatix and MEME suite software to identify the most enriched TFs and TF binding sites (Tcf19, Tcf4, Znf423, Runx1, Ascl2, Lhx4). The binding between p27 and these selected TFs is being verified by immunoprecipitation. The association of p27-containing complexes to specific promoters of these identified genes is currently being validated. The p27-dependent regulation of the expression of selected target genes will be verified by modulating p27 levels in PCC cell lines. The significance of the p27-dependent gene expression will also be obtained by analyzing the expression of these target genes in normal adrenal medulla and PCC of MENX-affected rats (with loss of functional p27).
In conclusion, the observation that p27 may regulate gene transcription will give insight into the pathomechanisms associated with reduced p27 function specifically in adrenomedullary cells.

Role of microenvironment on metabolic control of murine pheochromocytoma SDHB silenced cells

Vanessa D'Antongiovanni[1], Susan Richter[3,4], Serena Martinelli[1], Letizia Canu[1], Tonino Ercolino[1], Graeme Eisenhofer[3,4], Karel Pacak[5], Elena Rapizzi[2] & Massimo Mannelli[1]
[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [3]Institute of Clinical Chemistry & Laboratory Medicine, Dresden, Germany; [4]Department of Medicine III, Technische Universitat Dresden, Dresden, Germany; [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA.

Pheochromocytomas (PHEOs) and paragangliomas (PGLs) are rare neuroendocrine tumors. About 30–40% of Pheo/PGLs are due to a germ-line mutation in one of the 13 main susceptibility genes which include the genes encoding the four subunits of the succinate dehydrogenase (SDH - mitochondrial complex II). In PHEO/PGL due to SDHB mutations up to 80% of affected patients develop metastatic disease and no successful cure is at present available. Tumor microenvironment plays a pivotal role in modifying the metabolism and the functional characteristics of tumor cells, becoming a potential therapeutic target. To obtain an experimental model resembling the in vivo conditions of the SDHB-mutated PHEO, we evaluated the effects of SDHB silencing and microenvironment on metabolism in the mouse tumor tissue-derived cell line (MTT), cultured alone or in association with mouse primary fibroblasts (here representing the tumor microenvironment). SDHB silenced cells showed a significant increase of both glucose and lactate uptake, and an increase of intracellular lactate compared with control. This increase was even more evident when SDHB silenced cells was co-cultured with mouse primary fibroblasts. The expression levels of monocarboxilase transporter 4 (MCT4), responsible for the transport of lactate from the intracellular to the extracellular space, was found upregulated in fibroblasts in co-culture with tumor cells. Consequently, in co-cultures, primary fibroblasts showed an increase of extracellular lactate. Surprisingly, SDHB silenced cells in co-culture showed a reduction of ATP levels compared to SDHB cultured alone and control cells in co-cultures. Our data demonstrate that SDHB silencing strongly affects tumor metabolism, and these changes are more evident in co-cultures. The comprehension of the mechanisms driving these changes in tumor metabolism may suggest new therapeutic targets.

DOI: 10.1530/endoabs.49.EP92

EP93

Role of microenvironment on proliferation and migration of an SDHB silenced murine Pheochromocytoma cell line

Serena Martinelli[1], Vanessa D'Antongiovanni[1], Susan Richter[3,4], Letizia Canu[1], Tonino Ercolino[1], Graeme Eisenhofer[3,4], Karel Pacak[5], Elena Rapizzi[2] & Massimo Mannelli[1]
[1]Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [2]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; [3]Institute of Clinical Chemistry & Laboratory Medicine, Dresden, Germany; [4]Department of Medicine III, Technische Universitat Dresden, Dresden, Germany; [5]Eunice Kennedy Shriver National Institute of Child Health and Human Development, National Institutes of Health, Bethesda, MD, USA.

Paragangliomas are rare neuroendocrine tumors derived from neural crest cells: if localized in the adrenal medulla they are called Pheocromocytomas (Pheo).The 30–40% of Pheo are mutated in one of the susceptibility genes among which there are genes encoding for the four subunits of the succinate dehydrogenase (SDH). Germ line mutations of SDHB are metastatic in about 80% of the cases. Surgery is the current therapy, but in presence of metastasis there is no effective treatment. Using shRNA, we stably silenced for SDHB a Pheo murine cell line (MTT). The proliferative growth of non-silenced cells (CN) was higher than that of the silenced ones (B-). However, in co-culture with fibroblasts, the proliferation of B-was higher than that of the CN cultivated in the same conditions.
When cultured in fetal-bovine-serum (FBS), B- cells tended to aggregate more than the CN. When FBS was not present, both the cells lines lost this characteristic. When cultured in conditioned medium from activated murine fibroblasts (CAF), the aggregating effect disappeared, the cells assumed a longer shape and started migrating.
To understand whether this change corresponds to an epithelial to mesenchimal transition (EMT), we are evaluating the EMT markers and the expression of metalloproteases either secreted in the medium or expressed on membranes. To understand if the cross talk between fibroblasts and tumor cells was due to a signal mediated by receptors, we evaluated the phosphorylation of mTOR, Akt and ERK in B- and CN cells without detecting any difference.
These preliminary data suggest that the microenvironment, here represented by fibroblasts, affects the behaviour of cancer cells and studies on this interaction are needed to identify new therapeutic targets in SDHB mutated tumors.

Pheochromocytoma: a clinical and pathological study

Elisa Santacruz[1], Agustina Pía Marengo[3], Andrés Ortiz[1], Inma Peiró[3], Héctor Pián[2], Juan José Díez[1], Paula García-Sancho[3], Carles Villabona[3] & Pedro Iglesias[1]
[1]Department of Endocrinology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [2]Department of Pathology, Hospital Universitario Ramón y Cajal, Madrid, Spain; [3]Department of Endocrinology, Hospital de Bellvitge, L' Hospitalet de Llobregat, Barcelona, Spain.

Objective
To assess clinical features, diagnosis, treatment and outcome in patients with pheochromocytoma surgically treated in the past 3 decades in two tertiary referral hospitals.
Methods
A retrospective study on clinical and pathological characteristics, treatment, and outcome in patients with pheochromocytoma followed up in specialized neuroendocrinology units who underwent surgery in the period 1981–2016 was performed.
Results
81 patients (45 women (56%); age 51 ± 15 year (range, 13–76)) were studied. The tumor was sporadic in 68 patients (84%) and familial in 13 patients, more frequently in the context of a MEN type 2 ($n=6$).10% of the pheochromocytoma were bilateral. Most of the patients (66%) were symptomatic. The main complains were the classic triad (27%), and hypertensive crisis (27%). 40% of the pheochromocytoma were incidentally discovered on imaging investigations. 47% of patients were hypertense at diagnosis. 24-h urinary catecholamines excretion was determined in 80% of patients, being elevated in 75% of cases. Fractionated urinary metanephrines were only determined in 23% of patients, and were elevated in 84%. Abdominal CT was the most used imaging technique (87%, $n=68$), followed by ^{123}I-MIBG scintigraphy (54%, $n=42$) which detected 88% of those tumors ($n=37$). MRI was performed in 50% of the patients, 87% of those tumors were hyperintense in T2. 89% ($n=65$) patients had a preoperative alpha-adrenergic blockage. 17 patients (22%) had a complication during surgery, being hypertensive crisis the most common complication (12.5%, $n=10$). Median tumor diameter was 5.9 ± 2.8 cm (range, 1.5–13). 15% of pheochromocytomas had vascular invasion, 15% had capsular invasion and 23% presented necrosis. Only 6% presented ganglionar or distant metastasis. 68 patients were followed in our two centers, 55 patients (81%) were cured, 4 of them (6%) had persistent disease and 9 (13%) had recurrence after surgery.
Conclusion
Pheochromocytoma in our series is generally a large, symptomatic and sporadic tumor. Incidentally discovered pheochromocytoma is common. Abdominal CT is the preferred imaging technique for localization. Surgical complications are common. Despite the high rate of vascular invasion in the histopathological study, ganglionar and distant metastasis are rare. The presence of cases with persistent and recurrent disease after surgery requires a long term follow-up. these tumors.

Biochemical testing for pheochromocytoma

Carolina Faria, David Barbosa, Ana Sofia Osório, Ema Nobre, Joaquim Sampaio & Maria João Bugalho
Hospital de Santa Maria, Lisboa, Portugal.

Introduction
Biochemical testing for Paraganglioma/Pheochromocytoma (PGL/PHEO) is recommended in patients with classical symptoms, in those harbouring an adrenal incidentaloma and in patients who have a hereditary risk for developing a PGL/PHEO. Measurements of plasma free metanephrines and/or urinary fractionated metanephrines provide a highly sensitive test for diagnosis but false-positive results remain a problem.
Aim
Comparative analysis of plasma and urinary metanephrines results in a group of individuals suspected of having PGL/PHEO.
Subjects and methods
Retrospective analysis of tests performed at a tertiary hospital during the year 2015 (January 1st-December 31th) and correlation with imaging studies and clinical data.
Results
686 measurements of urinary and/or plasma metanephrines, ordered by physicians of different medical specialties, were performed. From the analysis of these results, we identified 124 patients with both measurements; they were 77 women and 47 men with a mean age of 47.3 years (range 6–82). The main reason for testing was therapy-resistant or paroxismal hypertension ($n=68$; 54.8%) followed by the presence of an adrenal incidentaloma ($n=13$,10.4%). Abnormal high values were observed in 56 patients: in 44 (45.2%) only abnormal urine values, in 6 (4.8%) both urine and plasma abnormal values and in 6 (4.8%) only abnormal plasma values. 3/6 patients who presented elevation of urinary and plasma metanephrines had histologically proven disease (2 PHEO, 1 abdominal PGL). Among the patients with normal plasma metanephrines and high urinary metanephrines only one (2.3%) had a bilateral pheochromocytoma in the context of a MEN2A syndrome. None of the 6 patients with normal urinary metanephrines and increased plasma metanephrines had disease.
Conclusion
In the present series, all patients with a histologic diagnosis of PGL/PHEO had elevated urinary metanephrines regardless, in one case, normal plasma metanephrines. On the other hand, the frequency of increased urinary metanephrines without a positive imaging was very frequent.

Paraganglioma and Fallot Tetralogy: case report

Ana Filipa Martins[1], João Martin Martins[1,2] & Sónia do Vale[1,2]
[1]Hospital de Santa Maria – CHLN, Lisboa, Portugal; [2]Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction
Catecholamine secreting tumors are rare neoplasias. About 15% are paragangliomas. If untreated, they are almost invariably lethal. Surgery is the only curative therapy.
Case report
A female caucasian patient aged 32 was evaluated in the endocrine department. She had a dramatic medical history: Fallot's Tetralogy was diagnosed soon after birth but was not corrected. Only a Blalock-Taussing shunt was performed after three isquemic strokes due to endocarditis, when patient was 22. She suffered from sequelar right-side hemiparesis and epilepsy. She had also glucose-6-phosphate desidrogenase deficiency. At 32 she was assisted at the emergency department because of recent vomiting, headache and arterial hypertension. She had a recent weight loss with a BMI of 16 kg/m^2. Examination revealed depressed mood, orthostatic hypotension, holosystolic aortic bruit and chronic hypoxia signs. Several hypertensive paroxysms (maximum value: 240/140 mmHg) with diaphoresis were documented. Urinary normetanephrine and metanephrine were very high (227 and 58 times higher than the upper limit of the reference range) with a paradoxal increase in clonidine test. The CT scan revealed a solid hypervascular right paramedian retroperitoneal tumor with 49 mm of diameter at the level of the superior mesenteric artery with strong uptake in I^{123}-MIBG scintigraphy. Surgery was uneventful after careful pre-operatory preparation with α- and β-blockers and volume expansion. Five months later the patient recovered weight and was normotensive without antihypertensive drugs. Succinate dehydrogenase mutations (SDHA, SDHB and SDHC) were not found.
Conclusion
We report a challenging situation, life-threatening without surgical treatment, but with a high surgical risk due to the severe comorbidities. A positive outcome was strongly dependent on the multidisciplinary collaboration of different departments.

Retrospective audit at a UK teaching hospital of phaeochromocytomas and paragangliomas against the 2016 guidelines

Nawal Ibraheem & David Hughes
Derby Teaching Hospitals NHS Trust, Derby, UK.

Introduction
In this audit we explored the treatment and follow up of pre-2016 cases against the 2016 European Society of Endocrinology (ESE) guidelines on PPGL follow-up.
Results
Demographics of the patients revealed 50% were male with median age (45 ± 5), 82% of patients underwent surgery of which 73% were diagnosed with adrenal phaeochromocytomas & 27% with paragangliomas. Only 64% of surgical cases were followed up in clinic in the last year. Of all surgical cases only 73% had evidence of undergoing genetic testing. In the first year post surgery the following appropriate biochemistry screening was performed: Chromogranin A = 36.5%, (27% unknown), Urinary MN or catecholamines = 64% (27% unknown), Calcium = 64% (27% unknown), PTH = 56%, (unknown in 27%), Calcitonin = 46% (27% unknown), CEA = 0% (27% unknown). In the first year post surgery between 9% and 27% of patients underwent USS/CT/MRI/MIBG/PET scan of neck or abdomen appropriately.
Discussion
The recommendations made in these guidelines have been implemented locally and a local registry of cases is in development to improve follow up of cases (see poster for further details).

Pheochromocytoma – surgical outcomes

Pedro Carvalho Martins, Cátia Ribeiro, Mariana Peyroteo, Helena Pereira & Abreu de Sousa
IPO-Porto, Porto, Portugal.

Objective
To retrospectively evaluate the results of the pheochromocytoma surgery in our institution assessing the surgical complications, perioperative hemodynamic instability and oncologic outcomes.
Methods
The medical records of patients admitted for pathologically confirmed pheochromocytoma between 2000 and 2015 were reviewed. Patients with paragangliomas were excluded.
Results
We identified 40 patients with 43 resected pheochromocytomas. The mean age was 47 years with an equal distribution between genders. Twelve cases (30%) had a syndrome known to have an increased incidence of pheochromocytoma. The mean tumor size was 7 cm (range of 1.5–17.2 cm). Most of the lesions were functional (95%) and preoperative alpha-blockade has been instituted in 93% of the patients, with 48% having a beta blocker simultaneously. Fourteen cases (30%) underwent a minimal invasive approach. The mean operative time was 150 min and the median of intraoperative blood loss was 150 ml. More than a half of the patients (54%) had a hypertensive crisis at some point during surgery, almost always associated with manipulation of the lesion. Ten patients (25%) required vasopressor support after adrenal gland removal. Two patients (4.6%) had CTCAE 3/4 complications. There were no cases of mortality and the median length of stay was seven days. Two (5%) cases were defined as malignant: one secondary to metastatic disease to distant organs (recurrence at 30 months of follow-up in the form of multiple lung metastasis) and other to lymph nodes who is alive and disease-free. Three patients were diagnosed with contralateral pheochromocytoma during the follow-up, admitted as a new primary lesion, in context of a known genetic syndrome.

Conclusion
The results of our retrospective study show that adrenalectomy is a safe, effective and a low morbidity procedure. However, the organization of surgical, anesthetic and medical teams experienced in this type of pathology is fundamental for perioperative management.

EP99

Role of urinary fractionated metanephrines and catecholaminas in the diagnosis of pheochromocytoma/paraganglioma

Ma Luisa Martinez-Triguero, Ma Isabel del Olmo, Rosa Cámara del Olmo, Amparo Alba, Francis Fernández, Juan Francisco Merino & Begoña Laiz
Servicio de Análisis Clínicos, Servicio de Endocrinología, Hospital Universitario y Politécnico La Fe, Valencia, Spain.

Introduction
Paragangliomas/pheochromocytomas present frequently with vague symptomatology which makes its diagnosis difficult and challenging. Cuantification of fractionated metanephrines and fractionated catecholamines in 24 h urine sample are used for diagnosis. There are situationes that can produce false positive results such as stress, drugs or smoking that must be taken into account.
Patients and methods
Retrospective study on the requests made for the diagnosis of pheochromocytoma/paraganglioma to the laboratory with the determinations of fractionated catecholamines and metanephrines during 10 months. Determinations were analysed by HPLC with electrochemical detector (Teknochroma®).
Results
During this period 260 determinatios (of 218 patients) were analysed. 10 of these patients were diagnosed of pheochromocytoma, nine of extraadrenal paraganglioma and 199 patients did not present either of the pathologies. Patients with paraganglioma were excluded (Table 1).

Table 1 Sensitivity and specificity of fractionated catecholamines and metanephrines.

	Sensitivity	CI 95%	Specificity	CI 95%
Catecholamines	0.9	0.71–1.09	0.88	0.83–0.92
Metanephrines	0.9	0.71–1.09	0.89	0.85–0.93

Of the patients who did not present pheochromocytoma (199), 35 had elevated catecholamines and/or fractionated metanephrines (18% false positive), 17 were due to antihypertensive or antidepressant drugs, 11 had other adrenal pathologies and seven others.
Conclusions
1. Urinary fractionated metanephrines have a higher specificity than catecholamines. Both of them present the same sensitivity in our patients.
2. The rate of false positive results surpasses those of true positive, especially those produced by drugs, as published in literature.

Lung adenocarcinoma in a 34-year-old female SDHB asynptomatic mutation carrier – case report

Maria João Matos, Claudia Costa, Ana Paula Santos, Manuel Teixeira, Carlos Franco, João Bento, Isabel Azevedo, Susana Dias, Inês Lucena Sampaio, Ana Luísa Cunha & Isabel Torres
Portuguese Oncology Institute of Porto, Porto, Portugal.

Introduction
Patients with germline mutations in one of the succinate dehydrogenase (SDH) genes are at substantially increased risk of developing paragangliomas (PGL) and pheochromocytomas (PCC). Mutations in SDHB are the most commonly found gene mutations in PC/PGL and are associated with younger ages at presentation, higher rates of metastases and poorer prognosis. Although familial PGL syndromes were initially thought to predispose only for PCC and PGL, other tumor types such as gastrointestinal stromal tumors (GISTs), renal cell carcinomas (RCCs), and pituitary adenomas (PAs) have expanded the SDHx-associated tumor spectrum.
Case Report
A 34-year-old female patient, with a history of mild asthma, non-smoker, was referred to the Endocrinology Department as an asymptomatic carrier of a pathogenic heterozygous germline SDHB mutation (c.1-?_72+?del). Her paternal-uncle died from metastatic bladder paraganglioma by the age of …She had also family history of breast cancer (paternal-aunt) and prostate cancer (paternal-grandparent). Twenty-four-hour urinary excretion of fractionated catecholamines and metanephrines were in the normal range. Screening computed tomography (CT) scan showed a 3 cm mass in the lower lobe of the right lung. CT guided transthoracic lung biopsy revealed adenocarcinoma of probable primary lung origin. Staging positron emission tomography with 2-deoxy-2-[fluorine-18]fluoro-D-glucose (^{18}F-FDG PET/CT) showed, besides malignant right lung involvement, moderate left paratracheal FDG uptake. She underwent inferior right lobectomy with mediastinal lymph node ressection and histologic examine confirmed lung adenocarcinoma pT2a N0 M0 R0, stage I B. The patient is under surveillance.
Discussion
Questions still remain unresolved concerning non PCC/PGL tumors in patients with germline pathogenic SDHx mutations with regard to their pathogenesis, clinicopathological phenotype, and possible causal relation to the aforementioned mutations.

Pheochromositoma in childhood

Olcay Evliyaoglu, Oya Ercan, Aydilek Çakır, Duhan Hopurcuoğlu & Betül Çınar
Istanbul University Cerrahpaşa Medical School Pediatric Endocrinology Department, Istanbul, Turkey.

Introduction
Feochromositoma is a rare neuroendocrine tumor derived from chrommaffin cells of adrenal medulla. The most characteristic clinical symptoms are headache, perspiration, palpitation, and paroxysismal hypertension. Childhood feochromositoma is generally genetic while it is mostly sporadic in adults. Here we report three feochromositoma cases in whom two had von Hippel Lindau syndrome (VHLs).
Case 1
10 years old girl with admitted with fever. Her physical examination revealed hyperthermia and hypertension. Urine VMA level was increased and ultrasound examination showed left adrenal mass, diagnosis of pheochromositoma was confirmed after resection. In the second year of her follow-up GA-68 Octreotide scintigraphy determined accumulations in right adrenal and pancreas, pathological diagnosis were feochromositoma and neuroendocrine carcinom respectively after resection. Two disorederes together suggested VHLs and heterozygous p.L129P mutation in VHL gene was detected.
Case 2
11-years-old boy admitted with perspiration and palpitation in whom hypertension was determined. Urine VMA level was increased, and bilateral adrenal mass was determined in ultrasonography. Diagnosis of pheochromositoma was confirmed after resection. In his 5 years of follow-up he admitted with headache. Cranial MRI showed frontal, adrenal ultrasound showed right adrenal masses, after resection hemangioblastoma and pheochromositoma were diagnosed respectively. Associaton of two disorders suggested VHLs and heterozygous p.R161Q mutation in VHL gene was determined.
Case 3
9-years-old boy admitted with perspiratation and palpitation in whom hypertension was determined. His family history was significant with pheochromositoma in his father and grandmother. His urine VMA levels were high and adrenal ultrasound revealed bilateral adrenal masses. Diagnosis of pheochromositoma was confirmed after resection of both masses. No mutation in VHL gene was detected.

Conclusion
Although rare pheochromositoma should be thought in children with hypertension. In children pheochromositoma is mostly genetic in which VHLs is most frequent. Genetic tests should be performed in all children after diagnosis.

EP102

A case of silent pheochromocytoma presenting with clinical and radiological findings suggesting metastatic adrenal lesion

Soner Cander[1], Ozen Oz Gul[1], Pinar Sisman[2] & Canan Ersoy[1]
[1]Uludag University Medical School, Bursa, Turkey; [2]Kars State Hospital, Kars, Turkey.

Case
A 75-year-old male patient was treated for lung adenocarcinoma 12 years ago. During the routine imaging studies of the patient who was followed without treatment after curing, a suspicious, non-adenomatous lesion in the right adrenal gland, 16×9 mm in size was detected by thoracic computed tomography. Serum aldosterone/renin ratio and urine catecholamine tests were normal with no complaints of suspicion for pheochromocytoma. F18FDG PET-CT showed an increase in metabolic activity (SUVmax:4,8) in the right hilar region. The cytological examination was benign with bronchoscopy. Laparoscopic right adrenalectomy was performed because no other lesions were detected. Histopathologic examination revealed non-invasive pheochromocytoma showing positive staining with synaptophysin and chromogranin.
Discussion
Pheochromocytoma is very rare in adrenal incidentalomas, however, can be asymptomatic at rates up to 10%, as they can manifest with attack symptoms or less with persistent hypertension. It is suggested that catecholamine synthesis is defective in these tumors. In some reports it is specified that, this phenomenon may be seen in some mutations in the succinate dehydrogenase gene. In some reports, however, about 10–20% of silent pheochromocytomas were reported to be due to laboratory error. On the other hand, non-adenomatous lesions in the adrenal glands in a patient known as primer malignancy are generally considered as metastases. In our case, the patient was referred to a similar presentation and it was initially thought that the lesion may be a metastatic lesion. However, the fact that the primary malignancy has been in control for more than 10 years has been questioned about metastasis. One of the methods that can be applied in such a case is biopsy but pheochromocytoma should be firstly excluded. In this case report, we have demonstrated that; in non-adenomatous adrenal lesions, the absence of clinical signs and normal catecholamine levels do not exclude pheochromocytoma.

EP103

The storm before the calm: a phaeochromocytoma

Yasmin Nikookam, Caoimhe Bonner, Edward Bettany, Anthony Pittathankal, Ranjan Gunasekara, Edel Casey & Khash Nikookam
King George Hospital, London, UK.

We report a case of a male patient aged 45 years who presented with a history of intermittent back discomfort over a year, but more persistent over the previous 2–3 months. His general practitioner (GP) referred him for an ultrasound of the spine for a possible encapsulated lipoma but the findings were unremarkable. He was then referred to a consultant gastroenterologist for further assessment. He had normal endoscopic examinations, however the MRI had shown a right adrenal lesion which led to a referral to the endocrine team.
On further history he reported episodes of perspiration and bursts of aggression, for the past few years. Investigations revealed a normal cortisol response following overnight dexamethasone suppression and a normal renin aldosterone ratio.
He had elevated 24-h urinary normetanephrines 6360 nmol/24 h and metanephrines 2530 nmol/24 h (normal <2129 and <1622 respectively), in keeping with phaeochromocytoma. Subsequent meta-iodobenzylguanidine (MIBG) scan showed prominent activity in the region of the right adrenal gland. The patient was initially commenced on an alpha blocker doxazosin, and the dose was incremented to the maximum of 16 mg BD. He was subsequently commenced on beta blocker bisoprolol, and his blood pressure dropped from average of 150/100 mmHg (no history of hypertension) to around 110/70 mmHg.
This patient had a right adrenalectomy, made an uneventful recovery and was discharged with no medication. His BP remained at around 130/85 mmHg at his post-operative consultations. Phaeochromocytoma presents with various forms of signs and symptoms. In our case, the history of episodes of intermittent perspiration, back pain and severe aggression were uncommon symptoms emphasising the importance of comprehensive history taking.
Since surgery the patient has no longer experienced any of the above, and he describes himself to be calmer than ever.

EP104

Improvement of insulin secretion and oral glucose tolerance after pheochromocytoma removal: a case report

Zoran Erlic, Kathrin Roost, Oliver Tschopp & Christoph Schmid
Division of Endocrinology and Diabetology, University Hospital Zurich, Zurich, Switzerland.

Introduction/case report
Diabetes mellitus is an important clinical manifestation of catecholamine excess in patients with pheochromocytoma, and glucose control is usually better after tumour removal. Both impaired insulin secretion and increased insulin resistance have been implicated as underlying causes. We describe the case of a 38-year-old male patient diagnosed with left adrenal pheochromocytoma and personal history of diabetes mellitus diagnosed at age 36, under treatment with metformin, saxagliptin and gliclazide, with a preoperative HbA1c of 7.2%. BMI of the patient was 23 kg/m^2. After successful pheochromocytoma removal, the anti-diabetic medication was immediately stopped with remission of diabetes mellitus (HbA1c 3-months-postoperative 5.7%).
Methods
We performed oral glucose (75 g) tolerance tests and measured venous plasma glucose and serum insulin levels at the time of diagnosis and three months after successful surgery, to derive the insulinogenic index (IGI) as proposed by Wareham, and whole body insulin sensitivity index (ISI) as proposed by Matsuda and DeFronzo.
Results
Plasma glucose and serum insulin levels are shown in the table 1.

Table 1

Time (min)	−15	0	30	60	90	120
Preop glucose (mmol/l)	9.8	9.5	10.9	12.7	15.8	16.1
Postop glucose (mmol/l)	5.3	5.3	8.0	10.7	10.9	7.0
Preop insulin (pmol/l)	28	42	104	161	248	181
Postop insulin (pmol/l)	74	47	316	461	613	354

Improved glucose levels were associated with increased insulin levels and an increase in IGI, from a preoperative value of 5.7–33.6 pM/mM, while the ISI remained unchanged.
Conclusion/discussion
Remission of diabetes mellitus in our patient was associated with marked improvement of insulin secretion and oral glucose tolerance after removal of pheochromocytoma. Adrenergic alpha2A receptors on pancreatic beta cells play an important role in mediating inhibitory effects of catecholamines on insulin release, according to recent genetic association and pharmacological intervention studies. In our case, impaired insulin secretion could be corrected by surgery.

DOI: 10.1530/endoabs.49.EP104

Ephedrine/caffeine toxicity masquerading as phaeochromocytoma in a vigorexic male with paroxysmal hypertension and headache

Manuel Nivelo-Rivadeneira[1], Agnieszka Kuzior[1], Sara Quintana-Arroyo[1], Carmen Acosta-Calero[1], Claudia Arnas-Leon[1], Ana Delia Santana-Suarez[1], Alba Lucia Tocino-Hernandez[3] & Francisco Javier Martinez-Martin[2]
[1]Endocrinology Dpartment, Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas de Gran Canaria, Spain; [2]Outpatient Hypertension Clinic, Hospital Universitario de Gran Canaria Dr Negrin, Las Palmas de Gran Canaria, Spain; [3]Primary Care Center, Arucas, Las Palmas de Gran Canaria, Spain.

Clinical case
A 19-year-old male came to the Emergency Department complaining about a holocraneal nonpulsatile headache growing in intensity for the last 3 h, unresponsive to common analgesics. He had been suffering anxiety sleep deprivation, nervousness, tremor and heart palpitations for the last week. Family history was irrelevant, and the patient had no history of hypertension, dyslipidaemia, diabetes or smoking or medication use; he reported moderate alcohol, coffee and energy drink consumption but no cocaine nor amphetamines. He was on a high-protein diet with casein-based supplements, maintained a very high level of physical exercise and lately had been consuming a 'fat-burner' obtained from a local gym, but ignored its composition. The patient was fully conscious and did not have chest pain, fever or dyspnoea. His BP was 219/126 mmHg and HR 129 bpm, with sinus tachycardia in the EKG. He was treated with diazepam and diltiazem, discharged with BP 154/87 and HR 98 and referred to our Endocrinology Clinic for phaeochromocytoma screening. He brought the 'fat-burner' pills containing ephedrine 50, ASA 100 and caffeine 150 mg; he had been taking 1–2 daily during the week before the hypertensive episode. He was asymptomatic, with athletic constitution, weight 87 kg, height 173 cm, BMI 29 kg/m^2, waist 88 cm, impedanciometry 19% fat mass, BP 119/76, HR 75. Physical exam was otherwise unremarkable. Lab tests including metanephrines, aldosterone, PRA, TSH and microalbuminuria; chest X-ray and 24 h. ABPM were normal.
Diagnosis
Paroxysmal hypertensive episode caused by ephedrine/caffeine toxicity, with no target-organ damage. Vigorexia. Phaeochromocytoma/paraganglioma were ruled out.
Commentary
Ephedrine is a sympathomimetic amine with no legitimate medical indications at present, but widely used as doping or to trim subcutaneous fat. Its use has been linked with major cardiovascular and renal events, including ictus and sudden death, and must be discouraged.

DOI: 10.1530/endoabs.49.EP105

EP106

Loss diagnosis of pheochromocytoma in the initial evaluation

Teresa Azevedo, Márcia Alves, Joana Guimarães, Rosa Dantas, Ana Margarida Balsa & Isabel Inácio
Centro Hospitalar Baixo Vouga, Aveiro, Portugal.

Introduction
In most cases, adrenal masses are non-functioning adrenocortical adenomas. On '*Management of adrenal incidentalomas: European Society of Endocrinology Clinical Practice Guideline*' published in 2016, the experts 'suggest against repeated hormonal work-up in patients with a normal hormonal work-up at initial evaluation unless new clinical signs of endocrine activity appear or there is worsening of comorbidities'.
Case report
A 59-year-old male patient was referred to endocrinology with a right adrenal mass of 17 mm compatible with adenoma, discovered in difficult-to-control hypertension study. The patient had no symptoms apart from hypertension, that was controlled with three classes of antihypertensive drugs. Initial hormonal evaluation revealed normal urinary fractionated metanephrines, normal aldosterone/renin ratio (with interfering drugs suspension), intermediate hyperglycaemia and subclinical hypercortisolism (1 mg overnight dexamethasone 2.1 μg/dl). One year later, adrenal mass was stable and hormonal study highlighted elevation of total and fractionated urinary metanephrines (total metanephrines 1921 μg/24 h (329–1263), fractionated metanephrine 956 μg/24 h (64–302) and normetanephrine 636 μg/24 h (162–527) with normal 3-methoxytyramine. The repetition of metanephrines, with adequate preparation, confirmed these results: urinary total metanephrines 2005 μg/24 h (329–1263), urinary fractionated metanephrine 1094 μg/24 h (64–302) and normetanephrine 545 μg/24 h (162–527) with normal 3-methoxytyramine. The patient kept lack of symptoms such as headache, palpitations, diaphoresis or tremors. ^{123}I-MIBG scintigraphy revealed focus of hyperactivity located on projection of the right adrenal gland suggesting the presence of pheochromocytoma. We sent this patient to multidisciplinary expert team. Plasma-free metanephrines were measured with elevated results: 125 pg/ml (<65) and he will undergo unilateral adrenalectomy soon.
Discussion
This case illustrates the possibility of false negative results in hormonal evaluation of adrenal masses. These misleading results can happen, for example, by an inadequate urine sampling. If we had not repeated the measurement of metanephrines, the diagnosis of pheochromocytoma had not be done at this time.

Unexplained resistant hypertension in a young male with recurrent transient ischemic attacks, resembling endocrine hypertension

Ana Delia Santana Suárez[1], Manuel Nivelo-Rivadeneira[1], Agnieszka Kuzior[1], Sara Quintana Arroyo[1], Carmen Acosta Calero[1], Claudia Arnás León[1], Esperanza Perdomo Herrera[2] & Francisco Javier Martínez Martín[3]
[1]Endocrinology Department, University Hospital Dr Negrin, Las Palmas, Spain; [2]Primary Care Center of Escaleritas, Las Palmas, Spain; [3]Outpatient Hypertension Clinic, University Hospital Dr Negrin, Las Palmas, Spain.

A 27-year-old male without relevant familial or personal history had three TIAs in the last year, lasting for about 20 min with partial right palsy and aphasia. By the time he was cared for in the Emergency Department. he had already recovered; his lab tests, chest X-ray and EKG were normal but his BP was high (PAS 170–190 mmHg, PAD 105–120 mmHg). He had no chest pain, headache or neurovegetative symptoms. On discharge the patient was treated with manidipine and ASA and referred to the Neurology Clinic and to our Hypertension Clinic for phaeochromocitoma/paraganglioma screening and diagnostic workup.

Stress cardiomyopathy in pheochromocytoma

Cristina Alexandra Gheorghiu, Simona Jercalau & Corin Badiu
National Institute of Endocrinology 'C.I. Parhon', Bucharest, Romania.

Introduction
Rare cases of pheochromocytoma are associated with stress induced Takotsubo cardiomyopathy explained by high catecholamine exposure causing microvascular spasm and direct myocardial impact.
Case report
A 49-year-old female with a history of poorly controlled hypertension, with paroxysmal elevations in blood pressure and rare supraventricular extrasystoles, lipothymic events, was firstly assessed in the cardiologic department. She presented with resistant hypertension, associated with acute pulmonary oedema and cardiogenic shock. Echocardiography revealed new mid LV segment motion abnormality with apical ballooning, ECG – acute ST-segment elevation in the anterior leads and a rise of cardiac biomarkers. The coronary angiography excluded any coronary artery lesion. Thoraco-abdominal CT imaging revealed an 86/85/68 mm left adrenal mass, suggestive for pheochromocytoma. Laboratory evaluation for 24-h urine and plasma catecholamine metabolites disclosed intermediary-low elevated values (plasmatic MN = 10/11 pg/ml; plasmatic NMN = 59/41 pg/ml, urinary MN = 114/881 μg/24 h; urinary NMN = 632/1121 μg/24 h), despite high cardiac impact of the spells. She was submitted to 12 days of alpha adrenergic blockade followed by beta blockers, during which control of blood pressure and spells was achieved. Improvement of systolic function (EKG and echocardiography) could be noticed. Laparoscopic adrenalectomy was safely performed without hemodynamic events during surgery or immediately afterwards. Metanephrines and normetanephrines levels normalised with good residual adrenal function. Long term systolic function as well as high blood pressure returned to normal.
Conclusions
Takotsubo cardiomyopathy is associated with reversible LV-ballooning. In this observation, we report a case of stress cardiomyopathy caused by

pheochromocytoma; a rare medical condition which is easily confused with acute coronary syndrome due to clinical and biochemical resemblance, especially in our case where plasma and urinary catecholamines were only slightly elevated.

Prolonged zona glomerulosa insuffiency with hyperkalemia in primary hyperaldosteronism after adrenalectomy

Feyza Yener Ozturk, Esra Cil Sen, Rumeysa Selvinaz Erol, Emre Sedar Saygili, Seda Erem Basmaz, Sezin Dogan Cakir, Adnan Batman & Yuksel Altuntas
Sisli Hamidiye Etfal Training and Research Hospital, Istanbul, Turkey.

Introduction
Hyperkalemia due to zona glomerulosa (ZG) insufficiency is generally transient and mild for patients with aldosterone-producing adenoma (APA) after adrenalectomy. We report here a case with prolonged ZG insuffiency requiring long-term mineralocorticoid replacement (MR) therapy.
Case report
A 45-years-old female with hypertension and hypokalemia admitted to outpatient clinic with incidentally detected right adrenal adenoma (3 cm) showing signal loss on opposed-phase images of MRI. Laboratory tests revealed high plasma aldosterone concentration (PAC) (72 ng/dl, *N*: 7–30 ng/dl), supressed plasma direct renin concentrations (DRC) (5.25 ng/l, *N*: 5.41–34.53 ng/l) and high PAC/DRC ratio (13.71). PAC after saline infusion test was 30.7 ng/dl. After confirmation with adrenal venous sampling (AVS), right adrenalectomy was performed laporoscopically. Serum urea, creatinine, sodium, PAC (19.6 ng/dl) and DRC (13.6 ng/l) were in normal limits on postoperative 20th day; but serum potassium was markedly increased (5.9 mmol/l). The causes of pseudohyperkalemia and hyperkalemia were excluded. Because of low suppression index in the contralateral adrenal during AVS, hypoaldosteronism was thought to be the etiology as PAC did not increase while serum potassium level was higher than 5 mmol/l. Patient was followed-up with high-sodium, low-potassium diet on polystyrene sulfonate therapy. On the second month postoperatively, serum potassium was still high (5.6 mmol/l). MR therapy with fludrocortisone 0.1 mg/day was started for persistent hyperkalemia. Treatment continued for eight months until PAC and DRC raised up to 23.27 and 20.8 ng/l, respectively. After then, serum potassium concentration remained at the upper limit of normal range (5 mmol/l) with normal renal function tests, PAC (10.8 ng/dl) and DRC (8.1 ng/l) without replacement.
Conclusion
Suppression of contralateral ZG function by supressed plasma renin level in APA can lead to ZG insufficiency and hypoaldosteronism after adrenalectomy. Hypoaldosteronism cause impairment of renal potassium clearance and hyperkalemia. MR therapy may be essential in case of prolonged hyperkalemia.

Mature ganglioneuroma of the adrenal gland

Betül Aydin Buyruk[1], Medine Nur Kebapci[1], Goknur Yorulmaz[1], Evrim Yilmaz[2] & Enver Ihtiyar[3]
[1]Department of Endocrinology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; [2]Department of Pathology, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey; [3]Department of General Surgery, Eskisehir Osmangazi University Medical Faculty, Eskisehir, Turkey.

Introduction
Ganglioneuroma is an extremely rarely seen tumour in the adrenal gland, which originates from neural crest cells. Clinically, they generally have a silent course and in laboratory tests, the hormone levels expressed from the adrenal gland are within the normal range.
Case
A 46-year old male patient, for whom a mass in the adrenal gland was diagnosed incidentally on abdominal ultrasonography and MRI. The physical examination, laboratory tests and hormonal tests were within normal limits. As the appearance on dynamic adrenal CT was compatible with an adenomatous lesion, a biopsy was applied to the left adrenal gland. In the histopathological examination, findings were determined of neuroblastic tumour and ganglioneuroma, so adrenalectomy was applied and adrenal ganglioneuroma (mature type) was reported in the pathology examination.
Conclusion
Ganglioneuroma is rarely seen in adults and diagnosis is difficult as it is asymptomatic. As the masses are asymptomatic, they are not usually determined before reaching large dimensions. With increased availability of high-resolution tomography and MRI, an increase has been seen in the frequency of these types of masses. In recent years, ganglioneuroma have been separated into two sub-types as mature or maturing ganglioneuroma. In mature ganglioneuroma, the tumour is completely formed of a ganglioneuromatous component. Diagnosis is made histopathologically and it should be kept in mind as a rare tumour in adrenal masses.

Primary adrenal insufficiency and pregnancy – a case report

Slavica Savic[1], Mirjana Stojkovic[1,2], Biljana Nedeljkovic-Beleslin[1,2], Tanja Nisic[1], Milos Stojanovic[1,2], Marija Miletic[1], Jasmina Ciric[1,2], Svetlana Spremovic-Radjenovic[2,3] & Milos Zarkovic[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Centre of Serbia, Belgrade, Serbia; [2]School of Medicine, University of Belgrade, Belgrade, Serbia; [3]Clinic for Gynecology and Obstetrics, Clinical Centre of Serbia, Belgrade, Serbia.

Primary adrenal insufficiency (PAI) is uncommon in pregnancy. Women with PAI have reduced fertility and parity. If unrecognized or untreated during pregnancy PAI increases risk for maternal and foetal morbiditiy and mortality. Majority of women diagnosed before conception and appropriately treated, have uneventful pregnancies, with increased risk of cesarean section (CS) and preterm delivery.
We report a 38-year-old woman with PAI during first spontaneus pregnancy.
The patient was diagnosed with Addison's disease at the age of 17, and hyperthyroidism 14 years later. Her family history revealed hyperthyroidism in mother. She had regular menstrual pattern and no pregnancy during 5 years of marriage. Gynecological investigation was unremarkable, but she had addisonian crisis during hysterosalpingography 6 months before conception. At that time she was taking 30 mg hydrocortisone, 0.1 mg fludrocortisone and 50 mcg levothyroxine/daily. At 8 weeks of pregnancy she started to complain of fatigue, dizziness and palpitations, with no nausea or vomiting. Physical examination was unremarkable, BP 100/70 mmHg, with no orthostasis or discolouration of skin/mucous membranes. Oral progesterone was started because of spotty vaginal bleeding and in 2 weeks she developed mild hyponatraemia. We recommended to split hydrocortisone in four doses, and increased fludrocortisone to 0.125 mg. During second trimester she was stable, plasma electrolytes and thyroid function test were normal, with no foetal or placental abnormalities on ultrasonography. In the middle of the third trimester hydrocortisone and fludrocortisone doses were further ajusted to 35 mg and 0.15 mcg respectively. She underwent CS at the 39th gestational week and a healthy baby girl weighing 3250 g was delivered. During the 15-month follow-up period mother and baby were in good condition.
We presented a case of women with autoimmune polyglandular syndrome (APS 2) and succesful pregnancy outcome. Women with PAI should be monitored by a multidisciplinary team throughout pregnancy to ensure maternal and foetal health.

Paraganglioma (PG) and cyanotic congenital heart disease (CCHD): the role of tisular hypoxia

Amelia Oleaga, Fernando Goñi, Miguel Paja, Estibaliz Ugarte, Cristina Moreno, Natalia Iglesias, Eider Etxeberria, Laura Calles, Maddalen Dublang & Alba Zabalegui
Basurto University Hospital, Bilbao, Vizcaya, Spain.

Introduction
CCHD comprises a number of different congenital heart defects associated with elevated pulmonary artery pressure and pulmonary vascular resistance, resulting in a reversed or bidirectional shunt (Eisenmenger syndrome). These entities develop systemic hypoxia. Pheochromocytoma and paraganglioma (PHEO/PG)

are neuroendocrine tumours. Several inheritance genetic alterations have been reported in PHEO/PG syndromes. A pathogenic association between these entities is proposed.
Case report
A 41-year-old female diagnosed of a CCHD in the new-born period, on stable medical treatment, as surgery was rejected. She presented with symptoms suggesting exacerbation of heart failure. Catecholamine hypersecretion was suspected; 24 hour urine metanephrine: 215 μg/24 h (NV < 341) and normetanephrine (NM): 2491 μg/24 h (NV < 444). Abdominal CT showed a retroperitoneal lesion consistent with a PG. Functional imaging with Iodine^{123}MIBG showed a pathological uptake area at the same localization. No other pathological images were observed. Genetic testing was performed and no mutations in SDHD, SDHC, SDHB, VHL, SDHAF2, MAX and TMEM127 genes were found. She underwent surgery after alpha blockade. Pathological examination confirmed the diagnosis of a PG. NM became normal after surgery and patient symptoms improved.
Discussion
Several hypoxemic phenomenon have been related to be implicated in the pathogenesis of PHEO/PG, as it is known that some of the genetic alterations (SDHx, VHL, HIF2) lead to enhanced production of hypoxia inducible factors, which induce an increase in angiogenic factors leading to the development of tumours. The patient had an evolved heart disease with significant cyanosis. Chronic exposure to hypoxia in patients with CCHD could increase the risk for developing PHEO/PG. In addition, the noradrenergic biochemical phenotype found agrees with that observed in some of the PHEO/PG syndromes. In patients with CCHD the diagnosis of PHEO/PG can be difficult to suspect because symptoms may be confounding, nevertheless catecholamine excess may be dangerous. Therefore we consider that the existence of a PHEO/PG should be ruled out in patients with CCHD and aggravation of the previous heart function.

Von Hippel Lindau disease in two Turkish families with different mutations

Mine Adaş, İlkim Deniz Toprak & Recep Yılmaz Bayraktarli
Istanbul Okmeydani Education and Research Hospital, Istanbul, Şişli, Turkey.

Von Hippel-Lindau (VHL) disease is an inherited, autosomal dominant syndrome manifested by a variety of benign and malignant tumors. Herein we describe, two families who had VHL. A 21-year-old man (index case 1) presented with bilateral adrenal mass, serendipitously discovered by radiologic examination. He had newly diagnosed arterial hypertension. His family history was significant for his mother who had operated for pheochromocytoma, his two uncles who had experienced cerebral tumors and his mother's cousin who had bilateral pheochromocytoma. After the diagnosis of bilateral pheochromocytoma, bilateral adrenalectomy was performed. Histopathological data correlated with pheochromocytoma. A genetic test was carried out. A germline mutation p.R167Q (c.500G > A) was detected in the patient confirming VHL. A further genetic test was prescribed in other family members. His mother had a history of cystic astrocytoma, meningioma, hemangioblastoma and right adrenalectomy for pheochromocytoma. A germline mutation p.R167Q (c.500G > A) was detected, too. Index case 1's brother had a history of arterial hypertension and the germline mutation p.R167Q (c.500G > A) was detected, too. Index case 1's mother's cousin had a 24-year history of hypertension. He had experienced right adrenalectomy 24 years ago and left adrenalectomy 4 years ago with the diagnosis of pheochromocytoma. The germline mutation p.R167Q (c.500G > A) was detected, too. A 43-year-old woman (index case 2) was referred from the cardiology department to our outpatient clinic to examine the etiology of endocrine-induced arterial hypertension (150/90 mmhg). After the diagnosis of pheochromocytoma, the right adrenalectomy was performed. 5 years after the operation she had operated for the pancreatic neuroendocrine tumor and 15 years after the operation she was diagnosed as hemangioblastoma. A genetic test was carried out. A germline mutation p.L118R was detected in the patient. A genetic test was prescribed to the other members of the family. Her two boy's genetic tests were detected the same mutation. All patients with pheochromocytomas should be screened for the genetic syndromes for example MEN 2 and VHL. It is important for averting the further morbidity and mortality in the patients and their families. Family screening is crucial in patients who are diagnosed with the disease.

Large adrenal adenoma presenting as a clinically inapparent Cushing syndrome, a trap diagnosis

Denisa Petrescu[1], Cristina Alina Silaghi[2], Doina Crisan[3], Daniel Tudor Cosma[4], Ionela Lungu[1], Carmen Emanuela Georgescu[2], Romeo Ioan Chira[5] & Horatiu Silaghi[6]
[1]County of Emergency Hospital, Cluj-Napoca, Romania; [2]Department of Endocrinology, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Discipline of Pathology, Department of Morphological Sciences, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Diabetes, Nutrition and Metabolic Diseases Clinical Center, Cluj-Napoca, Romania; [5]Ist Internal Medicine Department, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania; [6]5th Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Adrenal incidentalomas (prevalence between 0.4 and 7%) have become a very common clinical problem, the major concern being the risk of malignancy and hormone overproduction.
A 57-year-old woman was admitted for asthenia and uncontrolled hypertension. The only relevant clinical signs were abdominal obesity (BMI = 31.1 kg/m^2) and hypertension. Abdominal ultrasonography showed a voluminous left adrenal solid mass of 10/9 cm, with well-defined sharp borders, hypoechoic with necrotic areas and hyperechogenic foci of scars and calcifications. The differential diagnosis of an atypical adenoma and pheochromocytoma or adrenocarcinoma was difficult.
Laboratory assays revealed hypercortisolism, indicated by the loss of the circadian rhythm of cortisol secretion: cortisol value at 8 a.m. of 7.84 μg/dl and at midnight of 11.2 μg/dl, elevated free 24 h urinary cortisol of 731.4 μg/24 h (normal range: 50–190 μg/24 h), no suppression at overnight dexamethasone suppression test (cortisol of 5.46 μg/dl), low ACTH level of < 1 pg/ml and decreased cortisol level < 50% at the high dose dexamethasone test. Plasmatic metanephrines, normetanephrines, renine and aldosterone were normal. Abdominal CT scan indicated a tumoral left adrenal mass of 10/8.5/8.5 cm, well defined, inhomogeneous, with microcalcifications, < 10 HU, induced caudal displacement of the left kidney, no lymphadenopathy or other visceral involvement. She underwent left laparoscopic adrenalectomy. The histopathological evaluation indicated Ki67 < 1% and chromogranin, synaptophysin, calretin, protein S100, inhibin were isolated low positive; PanCK, EMA were negative; CD31 showed the capillary network, without emboli; vimentin was positive; suggesting an atypical adenoma and excluding an adrenocarcinoma, a kidney and liver tumor, but also a pheochromocytoma. Two weeks after surgery, a large ischemic vascular attack occurred, with poor prognosis. We should keep in mind that voluminous cortisol-producing adrenal adenomas could have clinically inapparent features, but with hidden vascular damages and increased cardiovascular risk.

NK/T lymphoma adrenal presenting as adrenal insufficiency and cranial nerves neuropathies-a case report

Shalini Sree Dharan, Norazizah Aziz, Shueh Lin Lim & Pavitratha Puspanathan
Penang General Hospital, Penang, Malaysia.

Adrenal Lymphoma is extremely rare with fewer than 200 cases reported. The most common subtype is the diffuse large B cell lymphoma. Malignant lymphoma arising in the endocrine glands represents only 3% of extranodal malignant lymphomas and is usually confined to the thyroid gland. NK/T-cell lymphoma presents primarily in the nasopharynx and sinuses. Although involvement of the adrenal glands can be seen in disseminated disease, primary presentation with adrenal masses and adrenal insufficiency is extremely rare. We report a case of 34 years old gentleman presenting with prolonged fever, constitutional symptoms and symptoms and signs of adrenal insufficiency. He was treated as adrenal crisis in the district hospital with hypotension, hyponatremia, and hyperkalemia. He appeared cachexic, with no hyperpigmentation or palpable lymph nodes. His lactate dehydrogenase enzymes (LDH) was elevated. Cortisol taken during this stressful period was deemed too low. This was confirmed by an inadequate response to the Synacthen test. CT Adrenal was performed and reported as bilateral enlarged adrenal, likely hyperplasia. He developed multiple cranial nerves neuropathies that progressively worsened. CT Brain was normal. Lumbar puncture revealed high opening pressure and CSF biochemistry revealed no cells and negative for tuberculosis. With the possibility of disseminated tuberculosis, empirical anti-tuberculosis medications were started but failed to abate his

symptoms. Laparoscopic left adrenal excision biopsy was performed and histology features are in keeping with high grade NK/T cell lymphoma. His condition deteriorated fast and he succumbed to his illness. This case illustrates the need to include Primary Adrenal Lymphoma in the differential diagnosis of adrenal masses especially when adrenal contour is preserved on imaging, hypoadrenalism and high LDH.

Primary hyperparathyroidism and primary hyperaldosteronism – cause or coincidence in arterial hypertension – case report

Tijana Icin[1,2], Ivana Bajkin[1,2], Dusan Tomic[1], Jovanka Novakovic-Paro[1,2], Bojan Vukovic[1,2], Jovana Prodanovic[1] & Milica Medic-Stojanoska[1,2]
[1]Clinic of Endocrinology, Diabetes and Metabolic Disorders, Clinical Center of Vojvodina, Novi Sad, Serbia; [2]Department of Internal Medicine, Faculty of Medicine, University of Novi Sad, Novi Sad, Serbia.

Introduction
30% of the adult population has high blood pressure. About 6% of the hypertension may be caused by primary aldosteronism and very rare by primary hyperparathyroidism. The combination of these two causes is very rare.
Case report
Our patient is women (age 50) with a 21 year long history of uncontrolled hypertension. Treatment of hypertension consist of a beta-blocker, calcium channel blockers, angiotensin converting enzyme inhibitor, loop diuretics and thiazide diuretics. Laboratory tests confirmed the presence of hypercalcemia (ionized calcium 1.42 mmol/l), and hypokalemia (3.4 mmol/l). After correction of medical therapy results shows elevated levels of parathyroid hormone (221.7 pg/ml) and aldosterone/renin ratio (A/R > 30), normal value of metanephrines and normetanefrine, normal ACTH and cortisol levels and diurnal rithm of secretion. CT of the abdomen showed adenoma like enlargement of left adrenal gland of 2 cm. Scintigraphy and ultrasound confirmed the presence of hyperplasia/adenoma of the lower left parathyroid gland. Bone mineral density indicates osteoporosis and ultrasound of abdomen described nephrolithiasis in the left kidney. Due to hypercalcemia, first we have decided to operate the parathyroid glands. Surgery leads to normalization of calcium. The pressure is regulated without both the diuretics at a reduced dose of a calcium channel blockers. After recovering from surgery, in a hospital setting we discontinued therapy and dynamic testing was conducted (volume loading test and postural stimulation test) that indicate adrenal hyperplasia as a cause of primary hyperaldosteronism. Patient started with spironolactone therapy that even in small doses leads to normalization of potassium and reduce the need for other antihypertensive agents.
Conclusion
More endocrine disorders can simultaneously affect arterial hypertension. Treatment of hyperparathyroidism may lead to better control of hypertension. Despite the existence of left adrenal enlargement that looks like an adenoma, adrenal hyperplasia is a possible cause of primary hyperaldosteronism.

Endocrine masses displayed as incidentalomas in patients with unilateral nephrectomy

Adina Ghemigian[1], Eugenia Petrova[2], Nicoleta Dumitru[2], Andra Buruiana[2], Mara Carsote[1] & Ana Valea[3]
[1]C.Davila UMPh & I.Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Parhon National Institute of Endocrinology, Bucharest, Romania; [3]I.Hatieganu UMPh & Clinical County Hospital, Cluj-Napoca, Romania.

Introduction
Menopausal adrenal tumours may be elements of a complex panel of co-morbidities. Some of these are represented by the presence of a second pathology requiring surgery at the kidney level.
Aim
We aim to introduce a series of two cases involving menopausal women who were referred for specific endocrine assays after they had a unilateral nephrectomy (UN).
Method
This is a cases series observational study. The patients gave their consent. They were followed in different medical and surgical centres from Romania.
Results
A 61-year woman was admitted for a right adrenal and a thyroid incidentaloma after left UN for renal cancer with clear cells, Fuhrman Nuclear Grade of 2 (pT3N0Mx). Post-operatory endocrine panel of investigations were consistent for non-secretor low risk lesion. A fine needle aspiration biopsy at thyroid excluded a second malignancy. A 56-year old female had left UN 14 years ago for a benign condition. One year after surgery a right adrenal tumour of 1.2 cm was discovered at CT (computer tomography) scan. After 13 years, the subject became hypertensive and experienced hot flushes in association with secondary amenorrhea so an endocrine evaluation was considered. Non-secretor adrenal profile and high Follicle Stimulant Hormone consistent for physiological menopause was associated with stationary CT aspects for right adrenal tumor but also a left adrenal tumor of 1.3 cm was identified. Nevertheless, abdominal CT scan performed 1 year later showed similar aspects. Further serial imaging was recommended.
Discussion
Adrenal incidentaloma discovered in menopausal patients with UN requires a complex differential diagnosis including the fact that they need to be differentiated from metastases arising from kidney cancer. Also, serial imaging assessments after kidney removal may lead to the discovery of different solid masses as thyroid incidentaloma or nodules.

DOI: 10.1530/endoabs.49.EP117

EP118

Case with metastatic lung cancer who developed adrenal insufficiency

Buket Yilmaz Bulbul[1], Ece Celik[2], Mehmet Celik[1], Semra Ayturk[1], Funda Ustun[3] & Sibel Guldiken[1]
[1]Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; [2]Department of Chest Diseases, Edirne Sultan 1. Murat State Hospital, Edirne, Turkey; [3]Department of Nuclear Medicine, Medical Faculty, Trakya University, Edirne, Turkey.

Adrenal metastasis is common (35%) among the patients with lung cancer, while less than 3% of the patients develop bilateral adrenal metastasis. Adrenal metastases are generally small and clinically asymptomatic. Adrenal insufficiency is rare despite the presence of adrenal metastasis. Lam et al. reported this ratio as 0.7%. We aimed to present a case with lung cancer and bilateral adrenal metastasis who developed adrenal insufficiency.
A 63-year old male patient was presented with cough. Chest X-ray revealed a mass lesion in the upper zone of left lung. PET/CT examination was performed and demonstrated increased FDG uptake in upper lobe mass lesion of left lung, mediastinal lymph nodes, bilateral surrenal glands (9 mm at the right and 5.5 × 2 cm at the left),liver and bones. Following bronchoscopy, the patient was diagnosed with non-small cell lung cancer. Pathologic examination of surrenal biopsy material revealed surrenal metastasis. The patient had no signs of adrenal insufficiency and electrolyte imbalance at the time of diagnosis. He was scheduled for cisplatin + gemcitabine chemotherapy. Although lung and adrenal gland lesions were stable within 6 months after treatment, the patient developed hypoglycemia, hypovolemia, hyponatremia and hyperkalemia. Laboratory examination revelaed ACTH:1250 pg/ml (normal: 0–46), and cortisol 4.43 µg/dl (n:5–29). The patient was given prednisolone and fludrocortisone treatment with the diagnosis of adrenal insufficiency. Symptoms of the patient were subsided after treatment. Post-treatment laboratory examination revealed Na:138 mEq/l (normal:135–145), K: 4 mEq/L/normal:3.5–5.5) and ACTH:37 pg/ml.
It should be considered that patients with lung cancer and adrenal metastasis may later develop adrenal insufficiency despite the absence of adrenal insufficiency at the time of diagnosis. Although fatigue, nausea, hypotension and hyponatremia may also be seen in the patients with cancer, these may also be the signs of adrenal insufficiency.

DOI: 10.1530/endoabs.49.EP118

EP119

Adrenal haemorrhage: from Urology to Endocrinology

Catarina Silvestre, Ana Gomes, Raquel Carvalho & Maria João Bugalho
Santa Maria Hospital, Lisbon, Portugal.

Background
Bilateral adrenal haemorrhage (Waterhouse–Friderichsen syndrome) is a rare consequence of sepsis (usually a result of meningococcal infection), with an

estimated 15% mortality. Despite the predominant association with meningococcal infection, there are other recognised aetiologies: sepsis resulting from other organisms, and non-infectious causes, such as anticoagulant treatment, trauma and postoperative adrenal haemorrhage.
Case report
A 53-year-old man was admitted in the Urology department, to undergo a retropubic radical prostatectomy (prostatic adenocarcinoma). Other medical history: thromboangiitis obliterans, managed with warfarin and acetylsalicylic acid. No complications on the postoperative period; prophylactic antibiotherapy was started with ceftriaxone. On the 7th postoperative-day, the patient had a lipothymia episode, with a decrease of consciousness level (Glasgow 9), hypotensive and subfebrile condition. Blood evaluation consistent with sepsis: leukopenia, thrombocytopenia, raised transaminases, C-protein reactive and troponin, and severe hyposmolar hyponatremia (113 mEq/l). No anomalies detected on neurologic evaluation or cranial computerized-tomography (CT). Antibiotherapy was changed to Piperacillin-Tazobactam. A random ACTH, cortisol and TSH were performed as workup for hyponatremia: ACTH 141 pg/ml (0–46), cortisol 2.5 ug/dl (4.3–23), normal TSH. Abdominal CT scanning was performed: grossly abnormal adrenal glands bilaterally, with masses compatible with hematomas. On the 8th day he began intravenous hydrocortisone in high doses, with recovery of natremia and consciousness level. Blood and urine cultures results were negative (probably "decapitated"). When discharged, the patient was asymptomatic, with normal blood evaluation, and taking long-term hydrocortisone and fludrocortisone. So far, the patient has been asymptomatic and is being monitored by the Endocrinology department.
Conclusions
This case highlights the importance of awareness for symptoms/signs and electrolyte variation when assessing surgical patients post-operatively. The early recognition of this disease allowed immediate treatment, avoiding a worse outcome and leading to a quick recovery. There are risk factors, as anticoagulation therapy, predisposing the development of this rare, but serious, disease.

EP120

Hemangioma a rare adrenal tumors: report of two cases

Aribi Yamina, Bensaleh Meriem, Brakni Lila, Iabassen Malek & Ould Kablia Samia
Central Hospital of the Army, Algiers, Algeria.

Introduction
Dramatically with increased use of computed tomography (CT) and magnetic resonance imaging (MRI), more and more uncommon adrenal masses have been detected at abdominal examinations. Adrenal cavernous hemangiomas (ACH) are rare vascular tumor. The first case report was published in 195 by Johnson and Jeppesen. Approximately less than 70 cases were reported in the literature to date. ACH are nonfunctioning benign tumors that is often discovered incidentally. They are more frequent in women in the 5th or 7th decade. Their differential diagnosis preoperatively is rather challenging.
These tumors are unilateral lesions in general large and most usually cavernous. All cases reported were treated with surgery.
Case report
We describe two cases of ACH in a 66 years old woman and a 36 years old men. In the first case ACH was discovered as incidentaloma and in the second it was revealed by flank pain.
The diagnostic was performed on ultrasonography. Because of the impossibility of ruling out the presence of malignancy (CT, MRI), surgical adrenalectomy was performed. The patients did well postoperatively. Pathological examination revealed that the adrenal masse corresponded to an ACH.
Discussion
ACH is an uncommon benign vascular tumor. These rare tumors usually localized in the liver and the skin. Adrenal site is extremely rare occurring only in 0.01% of cases and accounts for 63 reported cases in the literature.
ACH are often discovered as incidentalomas either by imaging studies or histologic examination.
The indications for resection of this neoplasm particularly in tumours more than 3 cm in diameter are to relieve the mass-effect-type symptoms, to exclude malignancy, and to treat complications such as haemorrhage, necrosis and thrombosis.

EP121

A rare case: adrenal lymphangioma

Yusuf Durmus[1], Mehmet Celik[2], Buket Yilmaz Bulbul[2], Semra Ayturk[2], Nuray Can[3], Ebru Tastekin[3] & Sibel Guldiken[2]
[1]Department of Internal Medicine, Medical Faculty, Trakya University, Edirne, Turkey; [2]Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; [3]Department of Pathology, Medical Faculty, Trakya University, Edirne, Turkey.

Adrenal lymphangioma is a rare benign tumors of the adrenal gland. Because of the increased use of imaging methods in recent times, the diagnosis is usually made incidentally. It is usually due to malformation between the lymphatic and the venous system. Those with small indiameters are generally asymptomatic and can be evacuated by needlea spiration. However, surgery is recommended for cysts over 6 cm in diameter due to risk of infection, bleeding, compression of neighboring organs, and perforation. A 45-year-old male patient was admitted due to left abdominal pain and swelling for 2 months. There was no chronic disease or drug use in hisstory. Blood pressure: 130/80 mm/hg, pulse rate was 94/min. Ultrasonography revealed a grade II hepatosteatosis in the liver and a 70 mm multilocular cystic lesion in the left suprarenal region. A mass lesion with multilocule cystic components was observed in the abdominal MRI was T_1 hypointense, T_2 hyperintense in the left adrenal gland and 75 mm in diameter. There were no blood pressure attacks, flushing and palpitations. In laboratory tests: sodium 138 mmol/l (n:135–145), potassium 4.3 mmol/l (n:3.5–5.5), ACTH 27.4 pg/ml (n:0–46), basal cortisol 15.83 μg/dl (n:5–29), 1 mg dexamethasone supression test 0.83 μg/dl (<1.8) was detected. Plasma aldosterone-to-renin ratio was <10, metanephrine and normetanephrine were normal in 24 hour urine.
Laparoscopic left surrenalectomy was performed for the hormone inactive mass. Pathologic examination revealed D2.40 positive, CD34 positive, MelanA on cystwall as local positive lymphangioma. The patient was asymptomatic for 8 months. We aimed to present the rare case of adrenal lymphangioma in ourcase.

EP122

A rare case of a patient with MEN 4 phenotype and associated pheochromocytoma

Alexandra Mirica[1], Rodica Petris[1], Radu Mirica[3], Sorin Paun[2,4] & Diana Loreta Paun[1,2]
[1]C.I.Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; [3]Saint John Emergency Hospital, Bucharest, Romania; [4]Floreasca Emergency Hospital, Bucharest, Romania.

Introduction
MEN4 syndrome is a recently described form of MEN in patients with parathyroid and anterior pituitary tumors, which may also develop bronchial, gastric and pancreatic neuroendocrine tumors. In general, the patients present with clinical signs of primary hyperparathyroidism and simptoms caused by pituitary hormones hypersecretion or due to the tumor mass. However, clinical cases with the coexistence of pituitary tumors and pheochromocytoma are very rare described.
Case presentation
We present a young male patient of 44 years old, who presented in our department for endocrinological pre-operative assessment of a pituitary macroadenoma. The brain MRI indicated a macroadenoma (31/30/21 mm) with supra- and para-sellar extension, compressing the optic chiasm, optic tract and the 3rd cranial nerve on the right side. The patient accused acute right blindness starting 2 weeks ago, denying other simptoms. On clinical examination, the patient was obese (BMI = 36 kg/m^2) and hypertensive (BP = 170/100 mmHg). In addition, personal and family medical history were not significant, excepting personal arterial hypertension debut at 36 years old. Endocrinological evaluations showed normal levels of pituitary, thyroid, mineralocorticoid and glucocorticoid hormones. However, there were detected elevated values of parathyroid hormone (110 pg/ml), plasmatic and urinary normetanephrines (250 pg/ml and 900 ug/24 h) and plasmatic chromogranin A (230 ng/ml). Furthermore, abdominal computed tomography have identified a left adrenal nodule of 1.02/1.14 cm with no other lesions. Thus, in the first instance, the patient underwent laparoscopic left adrenalectomy and afterwards transsphenoidal pituitary surgery, after which he regained visual acuity of the right eye and also it was obtained normalized blood pressure values. Adrenal histopathology confirmed the presence of pheochromocytoma. Blood samples were collected for genetic testing.

Conclusion
We present the case of a young patient with pituitary non-functioning macroadenoma and hyperparathyroidism (MEN4syndrome), also associating left pheochromocytoma.
Keywords: MEN 4 phenotype; pheochromocytoma.

The difficulty in predicting aggressive tumour behaviour of phaeochromocytomas
Edouard Mills, Ali Naqvi, Roberto Dina, Fausto Palazzo & Florian Wernig
Imperial Centre for Endocrinology, Imperial College Healthcare NHS Trust, London, UK.

Phaeochromocytoma and paragangliomas (PH/PG) are rare neuroendocrine tumours. Prediction of aggressive tumour behaviour remains a major challenge. The Phaeochromocytoma of the Adrenal gland Scaled Score (PASS) is used to separate benign from malignant lesions with a score $>$ 4 showing potential for biologically aggressive behaviour. Pre-operatively, MIBG together with CT/MRI remain the diagnostic radiological gold standard.
We report a 68-year-old female who was found to have a locally arising colonic adenocarcinoma on biopsies. Staging also identified a 10.7 cm right adrenal lesion and work-up revealed markedly raised urinary metanephrines and positive MIBG imaging. The MDT decision was to first remove the colonic cancer with appropriate alpha blockade. It was felt that a combined laparoscopic approach would not be appropriate given the adrenal lesion size, which might require an open procedure. Histology confirmed a stage III Duke's C tumour and adjuvant chemotherapy commenced. Although adrenal surgery had been planned once she completed chemotherapy, she did not tolerate chemotherapy and it had to be discontinued. An open adrenalectomy was undertaken. Histology was consistent with a phaeochromocytoma with a PASS score of eight. 2 months after adrenal surgery, she reported intermittent tingling and numbness in the left arm with thoracic back pain. An MRI confirmed a soft tissue mass at T_2 extending into the spinal cord. Urinary metanephrines confirmed persistently elevated normeta-drenaline levels. She underwent bilateral laminectomy under alpha-blockade. Histology confirmed a metastatic phaeochromocytoma. She is currently awaiting Ga^{68}-DOTATATE PET-CT imaging to guide further management.
Ga^{68}-DOTATATE PET-CT has been shown to be the most sensitive imaging modality for detection of metastatic PH/PG and would potentially have identified metastatic lesion(s) not seen on MIBG scanning. We therefore propose that Ga^{68}-DOTATATE PET-CT – where available – should be used for initial staging and MIBG should be reserved for those patients only for whom MIBG therapy is being considered.

EP124

An unusual cause of unilateral adrenal haemorrhage
Jayamalee Jayaweera[1], Emily Symington[2] & John Clark[1]
[1]West Suffolk Hospital, Suffolk, UK; [2]Addenbrookes Hospital-Cambridge University Hospitals, Cambridge, UK.

A 24 year old man was admitted by the Surgeons with left sided abdominal pain. He was febrile and tachycardic and found to have raised inflammatory markers. Abdominal CT scan revealed a 6 cm left adrenal haemorrhage with no evidence of an underlying lesion. Initial endocrine investigations were unremarkable for Cushings, Conn's and adrenal insufficiency. Norepinephrine levels were high but settled subsequently. He had a coagulopathy and evidence of reactivation of EB virus. He had a past history of Multiple sclerosis treated eighteen months previously with Alemtuzumab.
He remained febrile and developed acute kidney injury. His symptoms and signs fitted the criteria for haemophagocytic lymphohistiocytosis (HLH), confirmed on bone marrow biopsy. His coagulopathy was due to antibodies to factor VIII (acquired haemophilia) and he developed autoimmune thyroiditis requiring Thyroxine replacement. His HLH was successfully treated with steroids and Rituximab.
We think Alemtuzumab treatment had induced the autoimmune disorders (his coagulopathy and thyroid disease), as well as reactivating EB virus. The combination of coagulopathy and EB viral infection may have caused his adrenal haemorrhage. Endocrinologists should be aware of the wide spectrum of autoimmune disorders that can be precipitated by monoclonal antibody treatment.

Incidentaloma as a first manifestation of lymphoma
Pamela R. Chávez Díaz, Cristina Álvarez Escola, Miriam Zapatero Larrauri, José Tomás Castell Gómez, Alfredo Aguilera Bazán & Lucrecia Herranz de la Morena
Hospital U. La Paz, Madrid, Spain.

Introduction
Incidentally discovered adrenal masses (incidentalomas) are common and in some cases differential diagnosis could be a challenge.
Case report
A 55-years old woman presented with an incidental left adrenal mass of 36mm discovered on an abdominal ultrasound. As sole background she underwent resective surgery of an ovarian serous cyst. She denied symptoms like flushing, headache, diaphoresis or palpitations. Physical examination was irrelevant. BP: 130/76 mmHg; CF:78 bpm.
Fractionated metanephrines and catecholamines in a 24-hour urine specimen, sodium and potassium levels, 24-hour urinary free cortisol, adrenocorticotropic hormone, aldosterone/plasma renin plasma ratio and dehydroepiandrosterone sulfate were normal.
Abdominal computed tomography showed an heterogeneous left adrenal gland and multiple nodes in locations such as subdiaphragmatic region, celiac trunk, gastrohepatic ligament, splenic hilum and retroperitoneal area, most of them with the presence of central necrosis.
Additionally axillary and paratracheal nodes were found, and also lungs nodules less than 5mm in diameter were described. PET F-18 FDG scan identified an hypodense centrum area suggestive of necrosis into the left adrenal. A tomography guided biopsy only detected necrotic cells. Finally a left adrenalectomy was performed and histopathological study revealed a diffuse large B-Cell non-Hodgkin's lymphoma. The patient was started on chemotherapy with a successful response.
Conclusion
Biopsy could be necessary in the differential diagnosis of necrotic adrenal masses even when lymph nodes are present.

EP126

Clinical case of aldosterone-producing adrenocortical carcinoma
Alexey Krivosheev[1], Iya Voronkova[1,2], A Platonova[1] & Timur Britvin[1]
[1]Moscow Regional Research and Clinical Institute, Moscow, Russia; [2]Endocrinology Research Centre, Moscow, Russia.

Aldosterone-secreting adrenocortical carcinoma (ACC) is rare neoplasm, which detected in 2.5% of active ACCs.
Clinical case
A 58 years old female, was admitted to our clinic with complaints of high blood pressure, back pain, weakness, convulsions. Biochemical evaluation confirmed primary hyperaldosteronism (serum aldosterone 1012 pg\ml, serum renin concentration 0.5 mkME\ml, aldosterone-renin ratio 202.4, hypokalemia 1.2 mmol\l). There was no evidence of cortisol co-secretion on standart low-dose dexamethasone test. The level of metanephrine and normetanephrine in urine were in normal range. A CT scan with contrast-enhanced identified right adrenal tumor 8*6*9 cm with heterogeneous structure. Native density of tumor was 38 Hounsfield units (HU). In arterial and venous phase tumor density was 70 HU, delayed - 55 HU. Dynamics of growth was $+5$ cm in 6 months. Surgical treatment was performed: in the right retroperitoneal there was tumor about 15 cm in diameter, comressed the inferior vena cava, right renal artery, and renal veins. Adrenalectomy with a tumor and lymph node dissection was performed. Histological examination revealed adrenocortical cancer. Ki-67 expression was up to 75% in 'hot spots'. Number of Weiss score - 6. A 1.5 month follow-up CT–scan was no evidence of local reccurence. Serum aldosterone level was in normal range.
Although rare, this case demonstrates the ability of this pathology, and therefore requires caution against the ACC at the small size of the tumor. As a method of follow-up screening can be a controlling level of aldosterone and potassium in the blood and monitoring blood pressure. To improve the results of treatment these patients it is necessary to conduct studies with larger numbers of patients, as well as development of new diagnostic and prognostic criteria allowing to improving diagnosis ACC before and after surgery.

The case of adrenal incidentaloma due to unrecognized nonclassic congenital adrenal hyperplasia

Milina Tancic-Gajic, Miomira Ivovic, Ljiljana Marina, Zorana Arizanovic, Zorana Stojanovic, Aleksandra Kendereski & Svetlana Vujovic
Faculty of Medicine, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia.

Introduction
A rare cause of adrenal incidentaloma is congenital adrenal hyperplasia (CAH). Nonclassic CAH is one of the most frequent autosomal recessive disorders. Most cases of nonclassic CAH are never diagnosed due to very mild symptoms.
Case report
A 62-year-old woman admitted at our Department for right adrenal incidentaloma sized 39×34×38 mm confirmed by MRI. She was asymptomatic. Her past medical history included stabile hypertension, euthyroid Hashimoto thyroiditis, uterine leiomyoma, varicose vein surgery and pulmonary embolism. Menarche occured at the age of 18, and the monthly menstrual cycle continued until the menopause at the age of 51. She had a miscarriage and three failed *in vitro* fertilisation attempts. Upon physical examination clitoromegaly was present. Endocrine assessment for excess of cortisol, catecholamine and aldosterone concluded that the adrenal mass was hormonally non-functioning. ACTH level was normal. 17- hydroxyprogesterone, total testosterone, androstenedione and progesterone were elevated: 26 nmol/l, 3.4 nmol/l, 8.5 ng/ml, 16.2 nmol/l, respectively. A 0.25-mg intravenous ACTH-stimulation level of cortisol (341/347/402) and 17- hydroxyprogesterone (29/51) showed partial cortisol insufficiency and nonclasssic CAH. After informed consent molecular genetic study for CAH was conducted. Our patient was found to be a heterozygote with two mutations in the CYP21A2 gene: p.P30L i I2G, that verified the diagnosis of CAH. In order to prevent adrenal insufficiency Hydrocortisone was advised in a case of surgical procedures or illness. During the 2 year follow-ups there were changes in either clinical and biochemical presentations or in repeated abdominal MRI examinations.
Conclusion
Undiagnosed nonclassic CAH is the cause of miscarriage, infertility and adrenal incidentaloma in our patient. 17- hydroxyprogesterone would be determined in all patients with infertility or adrenal incidentaloma.

DOC secreting adrenal adenoma, a rare cause of hypertension

Miguel Paja, Maddalen Dublang, Alba Zabalegui, Cristina Arrizabalaga, Amaia Expósito & Javier Espiga
Hospital Universitario de Basurto, Bilbao, Vizcaya, Spain.

Secondary endocrine hypertension affects around 10% of all hypertensive population, most frequently primary aldosteronism (PA). Less frequent forms of adrenal hypertension include pheochromocytomas and other causes of mineralocorticoid excess than PA, featuring suppressed renin without excess of aldosterone. Featuring. We present a 29-year-old woman with difficult to control hypertension diagnosed two years before and poor response to ACEI and ARA II treatment. She was referred for study and treatment. She had a normal appearance, without Cushing's stigmata, overweight nor clinical suspect of pheochromocytomas. She had not noticed hirsutism and maintained regular menstrual cycles. Biochemical study was normal except for slightly lower potassium (3.48 mmol/l). Hormonal study showed suppressed renin activity (<0.2 ng/ml per h), with normal to low aldosterone (7.3 ng/dl), normal urinary metanephrines and normal plasma ACTH (34.5 pg/ml). Abdominal CT revealed a well-defined heterogeneous and much vascularized right adrenal mass of 6 cm in diameter. Deoxycorticosterone (DOC) measured in previous stored sample was 237.9 ng/dl (normal < 15 ng/dl) with normal deoxycortisol (4.5 ng/ml; NV < 7.2), testosterone, DHEAs and plasmatic and urinary cortisol. Open right adrenalectomy was performed due to the size and suspicion of malignancy. On light microscopic examination, the tumour was an adenoma of 6.5 cm not encapsulated, composed of cells with clear and eosinophilic cytoplasm and large nuclei without mitosis nor necrosis. Weiss's criteria classified it as adrenocortical adenoma. Postoperatively, DOC level fell to 7.1 ng/dl and blood pressure and potassium normalized.
Conclusion
DOCA-producing adrenal neoplasm are exceptionally reported, and they are usually malignant tumours. They should be suspected in the presence of adrenal tumours with supressed renin but inappropriate low aldosterone, not suggesting PA. Early diagnosis can be very important because malignancy is the rule in this peculiar pathology.

Aldosterone-producing adrenocortical carcinoma and alteration of secretion pattern on recurrence: a case report

Joana Lima Ferreira, Ana Paula Marques, Carlos Sottomayor & Vitor Valente
Hospital Pedro Hispano, ULS Matosinhos, Portugal.

Introduction
Adrenocortical carcinoma (ACC) is a rare neoplasm with a variable but overall poor prognosis. The presentation is heterogeneous usually with mass effect and less often with evidence of hormonal secretion. About half of cases the tumors are hormonally active most commonly with cortisol secretion followed by sexual hormones production, being rare the aldosterone secretion.
Case report
A 41-year-old male presented with hypertensive crisis and marked hypokalemia. A primary hyperaldosteronism was diagnosed and Computed Tomography (CT) showed a 9 cm suspicious adrenal mass. The patient started on spironolactone and underwent open adrenalectomy. A total resection was done (R0) and it was a 10 cm adrenal carcinoma, Weiss score 5, Ki67 30% and stage II ENSAT. There was clinical and biochemical normalization and at 9 months CT didn't show any recurrence. Due to high risk carcinoma therapy with mitotane was proposed, however the patient refused and left follow-up. 30 months after surgery, he was admitted to the Emergency Department for adrenal carcinoma relapse and disseminated metastatic disease with simultaneous secretion of aldosterone and cortisol. He started on chemotherapy with EDP-M (etoposide, doxorubicin, cisplatin and mitotane). Despite initial favorable course, the patient got worse with disease progression, culminating in death 44 months after the diagnosis.
Discussion
The management of ACC is challenging. Surgery is crucial for treatment and mitotane is important as an adjuvant therapy, as a chemotherapeutic agent and also to control the hormonal secretion. We report a case of an aldosterone-producing ACC, an extremely rare cause of primary hyperaldosteronism. Even rarer was the change on secretion profile throughout disease evolution with multiple steroid production. The hormonal profile should be carefully investigated in an ACC and the possibility of multiple combined hormonal secretion or the shift of the profile secretion should be considered.

Congenital adrenal hyperplasia: hazards of non-compliance with treatment!

Mazhar Dalvi[1] & Faisal Dalvi[2]
[1]Al Noor Hospital, Abu Dhabi, United Arab Emirates; [2]Aster Medical Centre, Dubai, United Arab Emirates.

A 30-year-old male presented to emergency with history of palpitations for 6 months. At birth he was diagnosed with salt-losing congenital adrenal hyperplasia (female pseudohermaphrodite) and commenced on steroid therapy. He also underwent corrective surgery. He needed both fludrocortisone and hydrocortisone. At age 17, he visited urology because of bilateral testicular enlargement. On examination he had normal secondary sexual features, but his testicles felt hard and four times the normal size. His serum testosterone level was 50.4 nmol/l (10–38 nmol/l), 17-OH-progesterone 142 nmol/l (<13 nmol/l) and ACTH (corticotrophin) of 139 ng/l (0–50 ng/l), clearly indicating non-compliance. He had bilateral orchidectomy. Upon pathologic review, these lesions were most consistent with testicular tumors of the adrenogenital syndrome. Patient continued to default at clinic appointments. At age 26, he presented to the surgeon with increasing abdominal girth and abdominal pain. CT of the abdomen demonstrated very low-density adrenal masses (18×11 cm on the left side and 8×4.5 cm on the right side). Blood work up showed high 17-OH- progesterone indicating inadequate suppression with glucorticoids partly due to non-compliance. As these adenomas was new onset and there was a possibility of adrenocortical cancer the patient underwent laparoscopic bilateral adrenelectomy. The final histology to be consistent with adrenal myelolipomas. Hydrocortisone dose

was doubled and fludrocortisone 100 mcg/day was started. Now at age 30, he presented with history of palpitations and dizziness. He had sinus tachycardia In ECG (HR120/min). Blood work up: Na 130 mmol/l (135–145 mmol/l) K 5.33 mmol/l (3.5–5.1 mmol/l) Plasma renin 100 μIU/ml (<40 μIU/ml). This indicated under replacement. He was clearly tachycardic because of volume depletion. His compliance was enforced. Within 6 weeks his heart rate normalised with normalisation of renin levels. Persons with CAH are at increased risk of developing adrenal myelolipomas, testicular adrenal rest tumours particularly if their CAH is poorly controlled.

EP131

Adrenal insufficiency due to both hemorrhage and thrombosis related with primary antiphospholipid syndrome

Buket Bicer[1], Pinar Sisman[2], Soner Cander[3], Ozen Oz Gul[3] & Canan Ersoy[3]
[1]Uludag University Medical School, Department of Internal Medicine, Bursa, Turkey; [2]Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; [3]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Antiphospholipid syndrome (APS) is characterized by venous or arterial thrombosis and/or an adverse pregnancy outcome in the presence of persistent laboratory evidence of antiphospholipid antibodies. Loss of adrenal function due to bilateral adrenal vein thrombosis, resulting in hemorrhagic infarction, may occur in association with APS.
Case presentation
We present the case of a 45-year-old woman with APS diagnosis since she was 37, with history of multiple thrombotic events (deep vein thrombosis, sigmoid sinus thrombosis, spontaneous abortion, adrenal hematoma and pulmonary embolism). She was hospitalized for adrenal hematoma under anticoagulant therapy with warfarin. The basal adrenal function tests revealed morning serum cortisol 0.7 μg/dl (reference range 3.7–19.4) and ACTH 345 pg/ml (5–46). Abdominal CT showed nodular lesion with 55 HU density (29×27 mm) suggestive of adrenal hematoma in the left adrenal gland; right gland is thickenned. Adrenal insufficiency was associated with both hematoma in the left adrenal gland and thrombosis in the right gland. The patient was discharged under corticosteroid treatment and low molecule weight heparin (LMWH). After being discharged, warfarin was started again and she was admitted in the emergency department with dyspnea and pleuritic chest pain. Initial analytical study revealed INR (2.26), hypoxemia (PO2:64 mm/Hg) and hypocapnia (32 mm/Hg). She was restarted on therapy with LMWH. Further study showed deep vein thrombosis in right lower extremity. The patient was discharged after vena cava filter replacement.
Discussion
The recurrence rate of thrombotic events among patients with APS is highly variable among studies, with an annual recurrent thrombosis risk ranging from 5 to 12%. However adrenal involvement has been reported in 13% of cases of catastrophic APS. In patients with antiphospholipid antibody syndrome, adrenal insufficiency is often seen with bilateral adrenal thrombosis, although rarely in some patients an adrenal gland hemorrhage may occur with other adrenal gland hematomas.

EP132

In spite of long-term symptoms, a pheochromocytoma diagnosed in pregnancy results in fetal loss despite proper approach

Soner Cander, Ozen Oz Gul, Erdinc Erturk & Canan Ersoy
Uludag University Medical School, Bursa, Turkey.

A 27-year-old woman with had sweating flushing attacks for three years prior to pregnancy, but did not follow with any medical examination. At 12th gestational week, hypertension was detected and alpha-methyldopa was started, no abnormal findings were found in the routine examinations, in the 24-h holter study, blood pressure values (using alpha-methyldopa) were found to be higher than 144/99 (general), 147/101 (awake) and 134/92 mmHg (sleep). 24-hour urinary levels of catecholamine and metabolites were significantly higher than normal ranges; noradrenaline was 787.99 μg/24 h, dopamine 3635.43 μg/24 h, normetanephrine 1605.31 μg/24 h. MR imaging revelaed a heterogeneous lesion (49×37 mm) in the left adrenal gland. Because of the early stage of pregnancy laparoscopic surrenalectomy was performed. Histopathologic examination revealed a tumor consistent with pheochromocytoma. In the follow-up, there was no maternal problem except hypotensive state but unfortunately, because of anhydramnios and intrauterine growth retardation, medical abortion was applied at the 27th gestational-week. Pheochromocytoma is a very rare cause of hypertension in pregnancy however, early detection are crucial because of the increased risk of maternal-fetal mortality. Therefore, in cases of high blood pressure which can not be explained by gestational hypertension, it is necessary to carefully evaluate other secondary causes such as pheochromocytoma. The most suitable period for the operation is the second-trimester. Surgical approach was used and no complication related to the operation occurred in our case. However, it was thought that the outcome of fetal loss due to developmental delay was related to the adverse effects of circulatory factors due to long-term illness in the patient. The fact that the patient could not be examined in the pre-pregnancy period and probably the prolongation of the duration of the illness resulted in a negative result. Especially in women of childbearing age, the importance of hypertension in terms of maternal and fetal outcomes is emphasized by this case report.

DOI: 10.1530/endoabs.49.EP132

POEMS: a rare cause of adrenal insufficiency in a young male

Joanna Prokop[1], João Estorninho[1], Sara Marote[2], Teresa Sabino[1], Aida Botelho de Sousa[3], Eduardo Silva[2] & Ana Agapito[1]
[1]Endocrinology Department, Centro Hospitalar de Lisboa Central, Lisbon, Portugal; [2]Internal Medicine Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal; [3]Hemato-Oncology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

POEMS syndrome characterized by polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy and skin changes is a rare disease that usually presents in the 6th decade. We report a case of a young male in whom the presenting manifestations were mandibular mass, adrenal insufficiency and peripheral polyneuropathy. Clinical case: A thirty-three year old man from Guinea-Bissau was admitted to our hospital with asthenia, weight loss, decreased tactile sensibility with pain and muscle weakness in upper and lower limbs. Bedridden for 2 years, after surgery of mandibular mass with nondiagnostic histological examination. Physical examination revealed mandibular deformity, unilateral gynecomastia, bilateral axillary lymphadenopathy, sensorial motor peripherial polyneuropathy, edema of lower limbs. Lab. evaluation: normochromic, normocytic anemia, thrombocytosis, hyperkalemia, normal renal/liver function and protein electrophoresis, immunofixation: monoclonal protein negative, urine: increased kappa/lambda chains, Bence Jones protein neg., morning cortisol 8.3 ug/dl, ACTH 129 pg/ml. Laboratory workup confirmed adrenal insufficiency, subclinical primary hypothyroidism and primary hypogonadism. Thoracic-abdominal CT: hepatosplenomegaly, multiple sclerotic lesions in thoracic vertebras and ribs. Gluco- mineralocorticoid substitution and levothyroxine therapy were started with clinical improvement. Bone marrow biopsy revealed plasma cell dyscrasia and confirmed POEMS syndrome. Axillary lymphadenopathy biopsy: Castleman disease. The patient had several community-acquired, nosocomial pneumonias and an episode of pulmonary edema. Autologous hematopoietic cell transplantation (HCT) was planned, cyclophosphamide induction started. Meanwhile he suffered two ischemic strokes which resulted in motor aphasia and hemiparesis. Cerebral angiography revealed vascular lesions compatible with vasculitis and stenosis of two cerebral arteries. Comments: In this case, although serum immunofixation was negative for monoclonal protein, bone marrow biopsy confirmed POEMS syndrome. There is no standard therapy, however patients with disseminated bone marrow involvement are treated with chemotherapy with or without HCT. In this patient despite the young age, the disease was already advanced and resulted in severe complications, which led to resignation from chemotherapy and HCT complications, which led to resignation from chemotherapy and HCT.

Recurrent phaeochromocytoma – Iatrogenic

Samantha Anandappa, Jeya Navaratnam, David Fish, Brendon Conry, Sithara Perera & Jesse Kumar
Maidstone and Tunbridge Wells NHS Trust, Kent, UK.

Phaeochromocytoma is a common endocrinological diagnosis with an incidence of 1–2 per 10 000 people. Prompt evaluation and treatment leads to an excellent prognosis. Recurrence has been documented rarely (with literature reporting possibility of up to 8 years delay) and causes are generally attributed to inherited mutations, seeding during surgery or malignancy. Malignancy rates have been variable from 10% depending on site and mutations. In addition, the definition of malignant pheochromocytoma/paraganglioma is not always clear as there is no combination of clinical, histopathologic, or biochemical features to reliably predict biologic behaviour. In general; pathologic evaluations provide little prognostic insight to predict risk of recurrences or metastases reliably. We present a case that demonstrates relapse as a result of possible seeding from original laparoscopic adrenalectomy as one of the factors. Thus, pre-operative features that potentially make the tumour a high risk for recurrence should be identified and aid in creating an individualised management plan. Aspects that have been recognised to be directly related to outcome such as the size of tumour, underlying conditions such as MEN 2A/B and neurofibromatosis, the site of the tumour and anatomical ease of surgical intervention. This case highlights the importance of the recognition of such factors & multi-disciplinary team input, to prevent recurrences which have a significant effect on long-term cure and prognosis.

An association of adrenal ganglioneuroma, Addison's disease and Mediterranean fever: a case report

Nabila Rkik, Houcem Mrabet, Mouna Elleuch, Mouna Ammar, Faten Haj Kacem & Mohammed Abid
Department of Endocrinology, Hedi Cheker University Hospital, Sfax, Tunisia.

Introduction
Ganglioneuroma is a rare benign tumour arising from neural crest sympathogonia. It is usually asymptomatic and non functional. An association between ganglioeneuroma and genetic or autoimmune diseases such as Addison's disease or Mediterranean fever has never been described.
Case description
We report the case of a 24-year-old woman presenting with paroxysmal abdominal pain with loss of weight and no fever. Physical examination along with biological and hormonal explorations were normal. CT scan showed a solid tumour of the right adrenal gland, measuring 50×31 mm, with no sign of malignancy and a moderate ascites, so the patient underwent adrenalectomy. Anatomopathological examination of the adrenal gland confirmed the presence of a ganglioneuroma, and the patient presented an adrenal insufficiency 4 days after the surgery. Addison's disease was confirmed with positive anti- adrenal antibodies, with anti-21-hydroxylase at 2866.9 U/ml and she received corticosteroid replacement therapy. The patient continued to have recurrent abdominal pain, fever and ascites. A Mediterranean fever was suspected, and she was put on colchicine 1 mg per day, with improvement of paroxysmal abdominal pain. Genetic confirmation is underway.
Conclusion
We report for the first time an association between ganglioneuroma, Addison's disease and Mediterranean fever whose clinical features can be confused. A possible underlying genetic mechanism can be suspected rather than just a random association.

Adrenal carcinoma after ovariectomy. Report of a case

Eleni Xanthakou[1], Panagiotis Spyropoulos[2], Panagiotis Athanassiou[3] & Ifigenia Kostoglou-Athanassiou[4]
[1]Endocrinologist, Sparti, Greece; [2]Endocrinologist, Athens, Greece; [3]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece; [4]Department of Endocrinology, Red Cross Hospital, Athens, Greece.

Adrenocortical tumorigenesis has been observed in mice. It is speculated to be gonadotropin dependent. In particular LH receptors appear to be found within such adrenal tumors in high density and elevated LH levels may be related to adrenal tumorigenesis. The aim was to describe the case of a patient who after ovariectomy developed a large malignant adrenal tumor. A patient, female, aged 42 presented with uterine leiomyomas. She was treated by surgical excision of the uterus along with ovariectomy. Subsequently, she refused to be treated with estrogens, developing however severe postmenopausal symptoms. At the age of 50 she presented with musculoskeletal symptoms affecting the spine, both knees and the left shoulder. A CT scan of the abdomen was performed showing a large mass originating from the left adrenal gland. An MRI was performed and the patient was treated by left adrenalectomy. The adrenal tumor was malignant, measuring 6×6×5 cm, androgen receptor positive and progesterone receptor positive in some areas. The patient recovered. On follow up 6 months later she was free of any malignant disease. She developed Hashimoto's thyroiditis, antithyroglobulin antibodies being 425 IU/ml (normal values <115 IU/ml) and antimicrosomal antibodies being 213 IU/ml (normal values <34 IU/ml), while TSH was 3.9 IU/L (0.3–4.2 IU/L). In conclusion, the case of a patient is presented who developed a large adrenal tumor following ovariectomy. Adrenal tumorigenesis has been observed in mice following ovariectomy. It is believed to be related to LH stimulation by elevated LH levels, LH receptors having been observed within the adrenal tumors. In mice tumorigenesis may be prevented by the administration of agents lowering gonadotropin levels (Rahman et al, Reprod Biol 2001). It may be that in such cases of premature ovarian failure following surgical ovariectomy, thought should be given to possible treatment aiming at low gonadotropin levels.

ACTH-independent Cushing syndrome with concomitant parathyroid carcinoma

Georgiana Alexandra Smarandoiu[1], Raluca Trifanescu[1,2], Andra Caragheorgheopol[1], Anda Dumitrascu[1], Sorina Schipor[1] & Catalina Poiana[1,2]
[1]C.I. Parhon National Institute of Endocrinology, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
The incidence of parathyroid carcinoma in primary hyperparathyroidism is less than 1% and the association with ACTH-independent Cushing syndrome is very rare.
Case report
A 40-year-old female was admitted for weight gain and reddish-purple striae. One month earlier she had a ¾ parathyroidectomy for primary hyperparathyroidism with histopathological examination showing a parathyroid carcinoma and two parathyroid adenomas. She also had a history of deep vein thrombosis. She had no family history of endocrinopathies. The physical exam revealed a positive Chvostek sign, facio-troncular obesity, reddish-purple striae and grade I hypertension. Biochemical assessment revealed hypocalcaemia (5.75 mg/dl) and diabetes mellitus. Hormonal assessment revealed hypoparathyroidism (PTH = 12.45 pg/ml), no catecholamine excess, normal prolactin level. High levels of urine free cortisol (415.91 µg/dl) and positive long low dose DST(2mg/day×2 days) (12.29 µg/dl) confirmed the clinical suspicion of Cushing syndrome. ACTH levels were suppressed. Chromogranin A levels were normal. We performed a pituitary MRI and a CT of the neck, thorax and abdomen that showed bilateral adrenal macronodular hyperplasia with no other suspicious masses including pituitary adenomas. DXA evaluation showed osteoporosis for which she later received bisphosphonate therapy. A bilateral adrenalectomy was performed and subsequent mineralocorticoid and glucocorticoid replacement therapy was initiated. Genetic test for MEN1 syndrome is pending. The hyperparathyroidism relapsed 18 months after the parathyroidectomy. Calcium levels remained in the high normal range during monitoring with normal renal function and the last scintigraphy and CT scan showed an adenoma of the remaining parathyroid with no sign of local recurrence of the parathyroid carcinoma. Periodic follow-up also revealed a pituitary microadenoma with minimally raised prolactin and a thymic lesion that were stationary over the last 7 years of monitoring.

Conclusion
In patients with primary hyperparathyroidism special attention should be given to signs of other endocrinopathies as hyperparathyroidism could be the first manifestation of a MEN syndrome.

Incidental adrenal cyst: a case report

Aribi Yamina, Bensaleh Meriem, Brakni Lila, Khaldi Hassiba, Sellal Zoubir & Ould Kablia Samia
Central Hospital of the Army, Algiers, Algeria.

Introduction
Cystic adrenal lesions (CAL) are a rare diseases representing 5.4–6.0% of all pathological changes affecting adrenal glands. In about one-third of the cases, lesions are detected incidentally; in the remaining two-thirds cysts lesions are symptomatic, which is typically related to their large size or rapid growth. Although CAL are usually benign, since malignancy is reported in up to 7% of all CAL. Management algorithms for CAL vary and are controversial because of the overall rarity of such lesions.
Case report
We describe a case of a 29-year-old man who presented with abdominal pain. The computed tomography of the upper abdomen revealing the presence of a 4-cm simple cyst originating from the left adrenal. All serological and hormonal secretion tests were negative. So the final diagnosis was a simple left adrenal cyst; 8 months later, abdominal ultrasound follow-up revealed adequate cyst shrinkage down to 2.8×6.9 cm. The patient remains symptom free to date.
Discussion
Surgical excision of adrenal cysts is indicated by the presence of symptoms, suspicion of malignancy, or the detection of a functioning adrenal cyst. Cysts may coexist with primary and metastatic adrenal tumours. Malignancy of the cyst is found in 7% of all affected patients. Adrenocortical and adrenomedullar hyperfunction is accompanied by adrenal cysts in ca. 15% of cases. What is more, adrenal cysts accompany approximately 7% of primary and metastatic cancerous processes, and in 0.5% of cases they are of parasitic origin and their clinical management remains controversial. However, surgical intervention is not recommended for asymptomatic patients with incidental cysts, for the fact that the pathological data of our series revealed no malignant cases. Patients after surgical resection should be followed up closely especially in functional cysts and when histopathology showed cystic tumor.

Gynecomastia in men: A rare case of adrenal feminizing tumors

Vitória Duarte, David Veríssimo, Dolores Passos, Filipa Serra, João Silva, Luís Lopes, J.J. Castro & Mafalda Marcelino
Hospital das Forças Armadas, Lisbon, Portugal.

Estrogen-producing adrenal gland tumors (EPAGT) are extremely rare, accounting for only 1–2% of all adrenal tumors. They are most commonly observed in men or in children, and are unusual in women. They are almost always malignant even if they seem benign at presentation, and most of them have a poor prognosis. We present a case of a 71-year-old man with painful bilateral gynecomastia, without galactorrhea, over 4 months. Markedly elevated plasma estradiol levels were found (161.7 ng/l; normal 15.5–63.3) with low LH and FSH values. All other parameters were within normal range (b-HCG, PRL, TSH, FT4, total testosterone, SHBG, cortisol, ACTH, DHEA SO4, delta-4-androstenedione, 17OHPRG, fractionated metanephrines, cromogranine-A). Echographic images and mammography showed bilateral mammary gland hypertrophy excluding any nodules. CT abdominal scan indicated a large retroperitoneal mass measuring 14×8 cm with posterior and inferior deviation of the left kidney, with heterogeneus contrast uptake. It appeared to be a retroperitoneal tumor independent of any other retroperitoneal organ. To clarify its etiology, a biopsy was performed. The histology suggested an adrenal cortex tumor. It displayed cell proliferation with abnormal nuclei. Immunohystochemistry was positive for melan A, HMB45, INHA and focal AE1/AE3. The Ki-67 was around 15%. While it was impossible to distinguish between adenoma and carcinoma, the images were suggestive of malignancy. Although there were no signs of metastasis in toraco-abdomino-pelvic-CT, a PET-scan is arranged to exclude some other lesions. Gynecomastia in adult males is usually related with drugs and systemic or endocrine diseases. However, it is less often related with rare conditions, such as the testicular tumor of Leydig cells and the rarest adrenal feminizing tumor. Surgery is the main option for EPAGT, nevertheless the prognosis is very poor.

Introduction
Adrenocortical carcinoma (ACC) is a rare and aggressive endocrine malignancy with a poor prognosis. Hormone-secreting ACC appear with manifestations of virilization, feminization or Cushing syndrome.
Case Report
A 63-year-old woman with no pathological history of relief was referred to Endocrinology evaluation with an history of deepening of the voice since 1-year ago, as well as hair loss and facial and abdominal hirsutism with 6-month evolution. The analytical study revealed the following results: total testosterone 6.03 (Normal Range (NR) 0.06–0.82) ng/ml, delta-4 androstenedione >10.00 (NR 0.30–2.99) ng/ml, DHEA-S 545.8 (NR 18.9–205) µg/dl, 17-OH-Progesterone 6.32 ng/ml, SHBG 71.4 (NR 14.1–68.9) nmol/l, FSH 7.96 ng/ml, LH 5.96 ng/ml Estradiol 123.8 pg/ml; normal urinary catecholamines and metanephrines; normal renin and aldosterone values; ACTH 2.1 ng/l (NR <63.3), urinary free cortisol 353.6 (NR 36–137) µg/day, late-night salivary cortisol 0.499 (NR <0.32) µg/dl and plasma cortisol after 1-mg overnight dexamethasone suppression test 13.3 µg/dl (NR<1.8). She performed an abdominal MRI with documentation of a massive solid tumor lesion with heterogeneous contrast uptake, well delimited and measuring about 13.4 cm in diameter, which was admitted to be dependent on the left adrenal gland. Were identified several hepatic and lung nodularities suggestive of secondary lesions. In a multidisciplinary evaluation, it was decided to perform left adrenalectomy by laparotomy. No ascites or signs of peritoneal carcinomatosis were present. The anatomopathological examination revealed an ACC ENSAT stage IV, pT2NxMx, with a modified Weiss score of five and a classic Weiss score of seven. The patient is now proposed for adjuvant chemotherapy with mitotane.
Conclusions
We report a case of an ACC combining hyperandrogenism with Cushing's syndrome. Hormonal hypersecretion, particularly hypercortisolism, is associated with a worst outcome. Complete tumor removal remains the only potentially curative treatment.

The ovarian origin of hiperandrogenism in the postmenopausal woman with the adrenal adenoma – a case report

Marta Kialka[1], Tomasz Milewicz[1], Katarzyna Doroszewska[1], Sandra Mrozinska[2] & Robert Jach[1]
[1]Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland; [2]Department of Metabolic Diseases, Jagiellonian University, Medical College, Cracow, Poland.

Hyperandrogenism is a clinical condition characterized by excessive secretion of male sex hormones. An excess amount of androgens in women is manifested by

symptoms of defeminization and masculinization. Hormonally active adrenal and ovarian tumors and non-tumor causes must be considered in the differential diagnosis. The authors describe the case of a 77-year-old patient who had hirsutism and reduction of the timbre of the voice. At the beginning she was suspected to have adrenal hyperandrogenism because of the tumor in the adrenal gland. Then adrenalectomy was conducted but it did not lead to alleviate symptoms. A MRI of the pelvis revealed a change of appendages projection and the patient underwent the total hysterectomy. The normalization of testosterone levels as well as reduction of the symptoms was observed after the operation. Finally, the ovary etiology of hyperandrogenism was confirmed. This case report is an example of difficulties in recognition the etiology of hyperandrogenism.

Secondary autonomic neuropathy in patient with polyglandular autoimmune syndrome III and type 1 gastric neuroendocrine tumor: a case report

Jekaterina Nagaiceva[1], Natalija Fokina[2], Karina Levina[1], Janis Mednieks[2], Kristine Bernarde[2] & Valdis Pirags[1,2]
[1]Latvian University, Riga, Latvia; [2]Paul Stradins Clinical University Hospital, Riga, Latvia.

The polyglandular autoimmune syndromes (PAS) are rare disorders characterized as multiple autoimmune-mediated organ failure. PAS III includes chronic autoimmune thyroiditis with type 1 diabetes mellitus or pernicious anemia and/or vitiligo or alopecia and many other organ-specific autoimmune diseases, but never involves adrenal cortex. Several patients with PAS III and associated type 1 gastric neuroendocrine tumor (NET) have already been reported. We report probably the first case of PAS III, type 1 gastric NET and concomitant secondary autonomic failure as the main clinical manifestation. A 65-years-old woman with severe postural and postprandial orthostatic hypotension admitted to the hospital. The orthostasis has been debilitating and gradually has worsened in the past year. She has lost about 25 kg due to postprandial sickness and consequent dietary restrictions. The patient has a history of mild type 2 diabetes mellitus. She has been treated with metformin and her HbA1c has been $< 6\%$ during the last 8 years. Diabetes has resolved due to weight loss and the patient has had a good glycemic control without any treatment for the past year. The patient has a history of primary hypothyroidism due to chronic autoimmune thyroiditis. Besides that she has suffered from hair loss with global alopecia over the last decades of life. Initial B12 vitamin deficiency without anemia has been detected. Upper endoscopy was performed, showing multiple gastric polyps. Histological examination revealed chronic atrophic gastritis, hyperplasia of endocrine cells and gastric NET G1, Ki-67 = 1%. Numerous gastric polyps have been removed during endoscopy. The patient has been treated with intramuscular B12 vitamin injections with a gradual positive effect on the autonomic dysfunction. Annual endoscopic follow-up and lanreotide injections are recommended to prevent progression and dissemination of the gastric NET.

MEN 1 Syndrome- a case with recurrence of neuroendocrine tumor and hyperparathyroidism after 9 years of follow up

Bianca Maria Leca[1], Iustina Gherasim[1], Elisabeta Sava[2], Sorina Martin[1,2], Suzana Florea[1] & Simona Fica[1,2]
[1]Elias University Clinical Hospital, Bucharest, Romania; [2]Carol Davila University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
Life expectancy is decreased in MEN1 patients due to multiple tumors that may be larger, more aggressive, resistant to treatment and with a higher risk of recurrence.
Case report
We report a 59-year-old male patient with family history of endocrine tumors (father- pituitary adenoma, son- primary hyperparathyroidism, daughter-microprolactinoma, primary hyperparathyroidism). He was first referred to our Clinic in 2007 after being incidendally diagnosed with well differentiated pancreatic neuroendocrine tumor (CT-scan performed for nephrolithiasis and repeated renal colic revealed a pancreatic mass that was surgically removed). In 2009 the patient was diagnosed with primary hyperparathyroidism and multinodular goiter for which subtotal parathyroidectomy and total thyroidectomy were performed. He also presented MEN1 associated tumors such as non-functioning left adrenal adenoma, bilateral asymmetric lipomastia and multiple subcutaneous lipomas and conditions associated with calcium disorders: nephrolithiasis, nephrocalcinosis, secondary osteoporosis. Regarding these findings, the patient was diagnosed with MEN1 syndrome and started undergoing periodical follow-up. Between 2009 and 2016, at the anual reevaluation, no clinical or paraclinical evidence of tumor recurrence was found. In October 2016 he presented a mild elevation of calcium and PTH levels and the sestamibi parathyroid scan revealed the presence of parathyroid adenoma. The CT-scan showed two pancreatic masses, immunohistochemistry tests from the biopsy supported the diagnosis of neuroendocrine tumor NET G1 and the patient started treatment with somatostatin analogues. Further assessment of the possibility of tumor resection and parathyroidectomy is considered.
Conclusion
Considering the high risk of tumor recurrence in MEN1 patients, regular follow-up is crucial in detecting and treating the relapses. Our patient developed both recurrence of neuroendocrine tumor and hyperparathyroidism.

Insulinoma- from diagnosis to full recovery. Case study

Marcin Lewicki[1,2], Magdalena Urbanczuk[2,3], Agnieszka Zwolak[2,4], Marta Dudzinska[2,4], Monika Lenart-Lipinska[2,5] & Jerzy S. Tarach[2]
[1]Chair and Department of Epidemiology and Clinical Research Methodology of Medical University of Lublin, Lublin, Poland; [2]Department and Clinic of Endocrinology of Medical University of Lublin, Lublin, Poland; [3]Chair and Department of Clinical Pathomorphology of Medical University of Lublin, Lublin, Poland; [4]Department of Internal Medicine and Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland; [5]Department of Laboratory Diagnostics of Medical University of Lublin, Lublin, Poland.

Introduction
Insulinoma is a rare form of a functional neuroendocrine tumor with an estimated incidence at 1–2 new cases per million persons per year. This infrequent endocrinopathy, frequently escaping standard disease course, constitutes a diagnostic challenge for every endocrinologist. Successful surgical resection of the lesion is the only available method that ensures patient's full recovery.
Case study
53 years old patient with complaints about recurring episodes of hypoglycemia, without accompanying adrenergic symptoms though, was admitted to Department and Clinic of Endocrinology, Medical University of Lublin. During diagnostic procedures: low glucose levels (ranging from 1.94–3.56 mmol/l) with corresponding inadequately high insulin levels were observed in a prolonged glucose tolerance test, where glucose and insulin concentrations measurements had been carried out every hour. Afterwards supervised 72-h fast was introduced, only to be terminated after just 24 h, due to symptomatic hypoglycemia (2.28 mmol/l). Insulin levels at the end of fasting remained disproportionately elevated (10.7 mU/l). Based on follow up diagnostic tests we were able to exclude other potential causes of hypoglycemia in the form of adrenal insufficiency and hypothyroidism. Abdomen CT scan didn't reveal any lesions in pancreas whereas abdomen MRI unveiled presence of the tumor, 2 cm in diameter, located in the tail of pancreas. On the 1st of September 2016 patient underwent surgical resection of the pancreas mass. Histologic evaluation confirmed the diagnosis of insulinoma (pNET: G2 insulinoma). Octreoscan and abdomen MRI didn't indicate a diffuse process. Currently all of the symptoms subsided, the patient doesn't require any additional treatment.
Conclusions
Insulinomas are neuroendocrine tumors of rare occurrence. The readily available imaging methods rarely allow for a location confirmed diagnosis because of borderline small size of lesions. Persistent hypoglycemia being the most characteristic symptom facilitates the diagnosis and introduction of proper treatment.

EP145

Insulinoma masquerading as neurologic disease

Catarina Machado, Patrícia Tavares, Sara Monteiro, Gustavo Rocha & Maria João Oliveira
Centro Hospitalar de Vila Nova de Gaia/Espinho, EPE, Vila Nova de Gaia, Portugal.

Introduction
Insulinomas are the most frequent cause of hypoglycemia and the most common functional endocrine pancreatic tumors. Whipple triad is often present and should alert to the diagnosis.
Case report
A 36-year-old male was admitted in the emergency room with loss of consciousness, diaphoresis and blurred vision, and hypoglycemia (50 mg/dl). The patient recalled recurrent symptoms of diaphoresis, tremors and palpitations, sometimes with loss of consciousness and incontinence of urinary sphincters, for the past 4 months, having been diagnosed with epilepsy and medicated with anticonvulsive drugs. This symptoms were associated with weight gain, occurred before meals and were relieved with eating carbon hydrates. He had no family history of endocrine disease. Prolonged supervised fasting test was applied and led to symptomatic hypoglycemia with hyperinsulinemia (blood glucose 40 mg/dl, plasma insulin 68.7 μIU/ml and C-peptide 7.07 ng/ml). Other hormonal studies were normal, rejecting the diagnosis of multiple endocrine neoplasia. He maintained severe hypoglycemia despite glucose fluid administration and nutritional adequate plan, and medical treatment was necessary with octreotide 300 mg/day and diaxozide 900 mg/day. Abdominal magnetic resonance demonstrated a well-defined enhanced lesion in the tail of the pancreas measuring 14 mm. Nodule enucleation was performed by laparoscopy and pathological examination revealed an encapsulated pancreatic mass measuring $17\times14\times15$ mm. Mitotic index was <2 per 10 CGA and proliferation index ki-67 was estimated $<2\%$. Immunohistochemically, tumor cells showed a positive staining for insulin, synaptophysin and cromogranine. Shortly after surgical treatment, glucose level increased to normal range. The patient was discharged without any hypoglycemic symptoms after 7 days.
Conclusion
The diagnosis of insulinoma may be challenging due to its rarity and variable presentation. Other diseases, such as neurologic, may be considered first, but it's important to contemplate the diagnosis since chronic and severe hypoglycemia can be fatal and the surgery is usually curative.

Glucose metabolism abnormalities and insulin resistance are frequent in well diferentiated digestive NETs

Ana P Santos[1,6], Ana C Santos[2,5], Clara Castro[1,2], Luís Raposo[2], Isabel Torres[1], Rui Henrique[6,7], Mariana P Monteiro[3] & M Helena Cardoso[3,4]
[1]IPO Porto, Porto, Portugal; [2]ISPUP/EPI Unit - UP, Porto, Portugal; [3]UMIB/ICBAS - UP, Porto, Portugal; [4]CHP, Porto, Portugal; [5]FMUP - UP, Porto, Portugal; [6]IPO Porto, Research Unit, Porto, Portugal; [7]EPOP, Porto, Portugal.

Introduction
Incidence of Digestive NETs (DNETs) has increased in the last 40 years. Visceral obesity, metabolic syndrome (MetS) and insulin resistance (IR) have been associated with several types of cancer.
Aim
To evaluate possible associations of obesity, hyperinsulinemia and IR with well-differentiated (WD) DNETs through a case control study.
Materials and methods
Ninety-six patients with gastrointestinal (75.0%) and pNET (22.9%) WD DNETs were recruited from Endocrine Tumours Clinic of IPO Porto and cross-matched with a control group ($n=96$) from PORMETS, a nationwide epidemiological study designed to evaluate the MetS prevalence in the general population, pair-matched by age, gender and place of birth. Hyperinsulinemia and IR were defined according to Mattews's classification. WD DNETs were classified according to primary tumour localization, hormonal secretion, TNM stage and WHO grading.
Results
MetS was present in 45.8% of WD DNETs. According to grading, 66.7% were G1 and 27.1% were G2 tumours. The disease was localized in 31.3%, locoregional in 16.7% and disseminated in 43.8%. Both patients and controls had high mean body weight (26.9 vs 27.2 kg/m^2, $P=0.645$). No significant differences were found between the two groups for waist circumference, Fasting Plasma Insulin (FPI) and HOMA-IR ($P=0.236$; $P=0.372$ and $P=0.274$, respectively). Median Fasting Plasma Glucose (FPG) and Impaired Fasting Glucose (IFG) frequency were higher in WD DNETs ($P<0.001$ and $P=0.013$, respectively). FPG $\geq$ 100 mg/dl and HOMA-RI ≥ 5 were associated with a higher risk for WD DNETs (OR 4.3 (95%CI 2.3–8.2, $P<0.001$); OR 4.1 (95%CI 1.2–13.5, $P=0.014$), respectively). When anthropometric and metabolic parameters are compared, there was no difference between somatostatin analogues users and no-users.
Conclusion
Association of glucose metabolism abnormalities and IR with WD DNETs confirmation can open new perspectives for prevention and treatment, through modifying lifestyle and insulin sensitizers use.

Clinical and hormonal characteristics of adrenal incidentalomas

Rym Belaid, Ibtissem Oueslati, Wafa Mimita, Karima Khiari, Nadia Mchirgui & Néjib Ben Abdallah
Department of Endocrinology, Charles Nicolle Hospital, Tunis, Tunisia.

Introduction
Widespread use of abdominal imaging has led to the identification of an increasing number of adrenal incidentalomas (AI) in the last decades. Causes of these adrenal masses are multiple.
Aim
The aim of this study was to investigate the clinical and hormonal characteristics of AI.
Materials and methods
The study was a retrospective monocentric analysis of 44 patients with AI who underwent radiographic and endocrine evaluations.
Results
The mean age was 59.25 ± 10.3 years and the sex ratio (F/M) was 1.3. Arterial hypertension was diagnosed in 27 patients (61.4%), obesity or overweight in 84%, diabetes in 18 patients (40.9%), dyslipidemia in 7 patients (15.9%). Five patients had an extra-adrenal tumor (11.4%). First diagnostic procedure was computed tomography (CT) in 63.6%, abdominal ultrasonography in 31.8% and magnetic resonance imaging in 4.5%. Regarding the location of the masses: 36.4% were in right side, 34.1% were in left side and 29.5% were bilateral. The Cause of radiologic imaging was kidney problems in 50%, liver disorders in 20.4%, epigastralgia in 13.6%, thorax pathology in 6.8%, rheumatologic causes in 6.8% and an inflammatory syndrome in 2.3% of cases. The average diameter of tumors was 26.6 ± 15.9 mm. The mass was single in 65.9%, well limited in 95.5% and homogeneous in 81.8%. Patients with functioning tumors had larger tumor diameters than those with non-functioning tumors ($P<0.05$). Final diagnosis was: non-functioning adenomas in 68.2%, pheochromocytoma in 6.8%, Cushing's syndrome in 6.8%, primary aldosteronism in 4.5%, subclinical Cushing's syndrome associated to phéochromocytoma in 2.3%, hematoma in 2.3%, tuberculosis in 2.3% and metastasis in 6.8%. Patients with functioning tumors had larger tumor diameters than those with non-functioning tumors ($P<0.05$). Two patients were diagnosed with adrenal insufficiency.
Conclusion
Our study showed that AI occurred more frequently in overweight or obese women with diabetes and hypertension. Its most common diagnostic procedure was CT and etiologies were dominated by nonfunctioning adenomas.

Pituitary insufficiency, the beginning of a diagnostic journey

Amalia Ioana Arhire[1], Lumnita Cima[1,2], Simona Petrescu[1,2], Miron Adrian[1,2], Florin Andrei[1] & Carmen Gabriela Barbu[1,2]
[1]Elias Hospital, Bucharest, Romania; [2]"Carol Davila" University of Medicine and Pharmacy, Bucharest, Romania.

Introduction
We report a case of a pituitary insufficiency apparently resistant to treatment.
Case report
A 74 year old patient was admitted through the ER in our department for a recently discovered pituitary macroadenoma. His general condition was poor in spite of the initiation of corticotherapy. Evaluation: Smoker, with no significant medical history, the BP: 100/60 mmHg, no orthostatic hypotension, disoriented, confused, with moderately altered general state and no visual deficit. Biologically: normal ionogram, TSH: 0.076 mcIU/ml, fT_4: 0.767 ng/dl, total T_3 <40 ng/dl, prolactin: 21.5 ng/dl, IGF1: 84.8 ng/ (low). He had leukocytosis, high neutrophils, but normal markers of inflammation. No causes of infection were found, but the clinical condition worsened in the next 2 days despite an i.v. with Hydrocortisone and oral Levothyroxine. Additional imaging studies showed an adenoma of 3.4/2.8/3.8 cm, with a mass effect on the optic chiasm, multiple secondary lesions in the upper and infratentorial regions at the cerebral MRI. During the neck ultrasound we found a multinodular goiter with a large nodule of 1.53/1.33 cm with multiple large pathological laterocervical adenopathies. The thoraco-abdomino-pelvic CT found a large pulmonary mass of 45/49 mm in the left lung, some osteholytic lesions in the right ribs and body of L5, a large cephalic pancreatic lesion of 35/24 mm and bilateral adrenal metastatic lesions. At that moment we thought that the pituitary macroadenoma was highly probable to be a metastatic lesion with multiple options regarding the origin of the primary neoplasia. The biopsy of an excised cervical adenopathy showed an aggressive neuroendocrine tumour as the probable cause, diagnosis which was unfortunately sustained by the lethal outcome of the patient.
Conclusion
The pituitary insufficiency in normally a benign condition which responds to treatment and has a favourable outcome; if this is not the case we must search for additional causes of poor responders.

Thyroid carcinoma in multiple endocrine neoplasia type 1

Khelil Nour El Houda[1,2], Loudjedi Lotfi[2], Meghelli Sidi Med[1,2] & Berber Necib[1,2]
[1]Abou Bekr Belkaid University, Tlemcen, Algeria; [2]University Hospital of Tlemcen, Tlemcen, Algeria.

Introduction
Multiple endocrine neoplasia type 1 (MEN1) is a cancer syndrome characterized by the development of neuroendocrine tumors of the pituitary gland, parathyroid and pancreas, and other neoplasms such as adrenocortical tumors and carcinoid.
Observation
We report the case of a 70-year-old women with acromegaly that diagnosed 15 years ago, in relation with pituitary macroadenoma (30×25 mm) invading the left cavernous sinus and in contact with the third ventricle without endocrine or ophthalmological repercussions. The impact of acromegaly is diabetes mellitus treated with insulin complicated by retinopathy. The visceral assessment revealed a hypertension with cardiomegaly and a multinodular goiter diagnosed 2 years after the discovery of the acromegaly. Refusing pituitary surgery and radio-therapy, the patient remains uncontrolled with maximal dose of somatostatin analogues and dopaminergic agonists, the Gh level is 70 and IGF1 is 638 ng/ml. Exploration of the goiter finds 3 nodules (20 to 30 mm of diameter) benign in fine needle aspiration biopsy, operated 10 years later and the pathological examination finds papillary carcinoma of the thyroid, patient is treated by iodine 131 under recombinant TSH, It is currently in remission, her thyroglobulin level is under 0.20 ng/ml. During evolution, the patient presents bilateral renal lithiasis repeatedly, the balance allowed the discovery of a primary hyperparathyroidism with high serum calcium and PTH around 150 pg/ml due to a right inferior parathyroid adenoma, complicated with osteoporosis for which the patient refused surgery. In this clinical context, the genetic studies to search presence of mutation in *MEN1* gene encoding the menin protein was performed and confirm multiple endocrine neoplasia type1.
Conclusion
The hypersecretion of Gh induces an organomegaly, and the development of multinodular goiter is very frequent but discovery of thyroid carcinoma is rare, the prevalence of this association remains to be determined.

Small pancreatic neuroendocrine incidentalomas: an observational prospective study

C Villabona[1], J Busquets[2], L San Martín[1], A Planas[1], N Peláez[2], J Fabregat[2], A Teulé[3] & I Peiró[4]
[1]Department of Endocrinology, Hospital Universitari de Bellvitge (HUB), l'Hospitalet de Llobregat, Spain; [2]Department of Surgery, HUB, l'Hospitalet de Llobregat, Spain; [3]Department of Oncology, Institut Català d'Oncologia (ICO), l'Hospitalet de Llobregat, Spain; [4]Clinical Nutrition Unit, ICO, l'Hospitalet de Llobregat, Spain.

Background
Diagnosis of small pancreatic neuroendocrine incidentalomas (PNETs-I) is increasing during last years and often their management remains unclear.
Objective
To describe our experience with patients with PNETs-I in our institution.
Methods
Since March 2000, patients with non functioning PNETs-I ≤30 mm were evaluated in our center, prospectively. A descriptive analysis of all patients and a comparative study between observational group (OG) vs resection group (RG) was made.
Results
Forty-six patients were evaluated: 36 in OG and 10 in RG. Median follow up (months) was 35.9 in OG and 76.6 in RG. Most of patients (69.9%) were diagnosed in the last 6 years. Mean age (years): 69.5 in OG and 57 in RG ($P<0.003$). Gender: 56.5% women. Mean tumor size (mm) was 12.5 (11 in OG vs 18.7in RG $P<0.005$). PNETs-I were multiple in 17.4% cases. At diagnosis, all PNETs-I's size were ≤20 mm in OG, without metastases. In RG, 8 patients (80%) had surgery complications, mostly mild to moderate without deaths. Diagnosis was made by imaging procedures in 91.6% of OG. In our series, 82% had a CgA assessment at diagnosis. Median CgA value was 179 µg/l (72–304). At the end of follow up, 88% in OG of patients had no change in tumor size, the rest had tumor growth <20%; In OG no PNETs-I resection were needed, and none of the patients metastasized or died because of PNETs-I in this group.
Conclusions
Non functioning PNETs-I is increasing in incidence in our center. After almost 36 months of follow up, no patients had significant growth, developed metastases and neither of them died from PNETs-I. In OG, active surveillance is safe in selected PNETs-I patients. We need prospective multicentric studies to confirm our results.

Potential inhibitory effect of progesterone on breast cancer metastasis via the regulation on protein expression of apoptosis- and EMT-related genes

Gyu-Sik Kim, So-Ye Jeon & Kyung-Chul Choi
Laboratory of Biochemistry and Immunology, Veterinary Medical Center and College of Veterinary Medicine, Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Breast cancers that are estrogen receptor (ER)/progesterone receptor (PR)-positive are more likely to respond to hormone-related treatments than tumors that are ER/PR-negative. The present study investigated the effect of progesterone (P4) on 17β-estradiol (E2)-induced cell proliferation, apoptosis, EMT, and migratory and invasive features of MCF-7 clonal varient (CV) breast cancer cells that are ER/PR-positive. Preferentially, E2 was verified to induce breast cancer progression by stimulating cell proliferation, EMT, and migration of MCF-7 CV breast cancer cells. On the other hand, P4 reduced E2-induced MCF-7 CV cell proliferation by down-regulating the protein expression of cyclin D1 and E1 and induced apoptosis of MCF-7 CV cells by up-regulating Bax and p53 and by

down-regulating Bcl-2. Also, P4 appeared to inhibit E2-induced EMT process by increasing mRNA and protein expression of E-cadherin, a crucial epithelial marker, as well as by reducing the expression of mesenchymal markers such as N-cadherin and vimentin and EMT-associated transcription factors such as snail and slug. Eventually, E2-induced migration and invasion ability of MCF-7 CV cells and the protein expression of proteolytic enzymes such as MMP-9 and cathepsin B were reduced by P4 treatment. Co-treatment of RU486, a PR inhibitor, restored the inhibited cellular migration and invasion and the reduced expression of proteases by P4 to the control levels, suggesting the involvement of PR in P4-induced inhibition on migration and invasion of MCF-7 CV cells. Taken together, P4 treatment may be suggested as an effective tool for suppression of human breast cancer progression and metastasis. (This work was supported by a grant from the Next-Generation BioGreen 21 Program (no. PJ011355-2015), Rural Development Administration, Republic of Korea.)

Incidental paraganglioma, diagnosis and follow-up – case report

Alice Violante[1], Roberto Lemme[1], Sarah Galvão[1] & Erika Naliato[2]
[1]Federal University of Rio de Janeiro, Rio de Janeiro, Brazil; [2]Ricardo A T Catilho Center of Studies Teresopolis Medical Association, Teresopolis, Brazil.

Paragangliomas and Pheochromocytomas are tumors originated from chromaffin cells (Pheochromocytomas (PHEO): adrenal glands; Paragangliomas (PGL): paravertebral thoracic, abdominal, and/or pelvic sympathetic ganglia, and glossopharyngeal and vagal neck and skull base parasympathetic ganglia). Catecholamine hypersecretion predominates in PHEO, while PGL are oligosymptomatic with compression-related symptoms. The authors report the case of a 33-year-old male with an incidental retroperitoneal PGL, detected during an investigation for urinary lithiasis (abdominal pain that shifted to different location, varying in intensity), without clinical evidence of catecholamine hypersecretion. The abdominal ultrasound identified a well-defined 5.0×4.5 cm hypoechoic nodular area at the right retroperitoneal region, above the renal pelvis, dislocating the renal vein anteriorly. The image was confirmed by CT (a 5.6×4.5×4.1 cm nodular area anterior to the right adrenal gland without a cleavage line with the inferior cava vein), MRA (a 5.4×3.5×4.6 cm nodular area anterior to the right adrenal gland), and PET/TC with FDG (a right retroperitoneal 5.2×3.8 cm mass that dislocated the inferior cava vein at the confluence of the renal veins; SUVmax =29.7). *^{123}I-MIBG* scintigraphy showed a discrete tumoral uptake. Ultrasound-guided biopsy: the patient presented a hypertensive peak during this procedure and was successfully medicated. He did not present arterial hypertension during the follow-up. Histopathology: suggestive of paraganglioma and neuroendocrine tumor.chemical investigation for catecholamines and plasmatic metanephrines hypersecretion: negative. Surgery: anterior laparotomy (without pharmacological preparation, since the tumor was non-secreting) without complications. Histopathology: paraganglioma/neuroendocrine tumor. Post-op follow-up: normal levels of metanephrines/catecholamines. I^{123} MIBG scintigraphy without evidence of the previously described lesion in the right lumbar region. No recurrence or clinical evidence of disease after a 5-year period.

Conclusion

Despite the tumour dimensions, there were no symptomatology previously to the diagnosis and no recurrence at a 5-year follow-up.

Primary hepatic neuroendocrine tumor with multiple liver metastases treated with somatostatin analogues: case report

Ioana Golu[1], Melania Balas[1], Daniela Amzar[1], Marioara Cornianu[2] & Mihaela Vlad[1]
[1]Department of Endocrinology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania; [2]Department of Morphopatology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania.

Introduction

Somatostatin analogues (SSA) have been used as first line treatment to control the symtoms in hormonally active neuroendocrine tumors (NET), for over three decades. Primary hepatic neuroendocrine tumors (PHNETs) are rare neoplasms. Despite increased incidence of PHNETs over time, these tumors remain a rarity. According to the previously reported cases, primary neuroendocrine carcinoma of the liver is usually multicentric, often mimicking liver metastases. The demonstration of the hepatic origin of a neuroendocrine carcinoma is often arduous.

Case presentation

A 59-year-old woman underwent ultrasound examination 3 years ago, that revealed two liver nodular tumors (the largest having approximately 4 cm), with a complex structure. Abdominal IRM images confirmed multiple liver nodular tumors with intense vascularization, suggesting liver metastases. The patient was asymptomatic. In order to determinate the primary site of the tumor, the patient underwent multiple imagistic investigations and endoscopies. Among the blood tests (5-hydroxy **indole acetic acid**, carcinoembryonic antigen, chromogranin A, serotonin), only chromogranin A presented significantly high values. Further, a liver aspiration biopsy was performed. The histopathological examination result completed with the immunohistochemistry techniques suggested a well differentiated neuroendocrine carcinoma of an intermediary stage, with a proliferation marker ki67 of 4%, most likely a metastasis. For a full diagnosis, Octreoscan (11In-pantreotide scintigraphy) was performed. The whole body scintigraphy at 10 minutes completed with the SPECT/CT at 4 hours established a primary liver site with secondary spleen metastases, along with liver and renal adenopathies. Treatment with somatostatin analogues (SANDOSTATIN LAR 30 mg/month), was commenced, with favourable outcome. After 18 months of treatment, serum chromogranin values are still normal, while the volume of the tumors decreased significantly (by repeated MRI).

Conclusion

Despite that the liver represents the common site for metastases from other gastrointestinal neuroendocrine carcinomas or other tumors, primary hepatic neuroendocrine tumors are rare, but can occur. The diagnosis of primary neuroendocrine tumors of the liver is difficult, as radiological appearances on ultrasound, CT scan and MRI can mimic other pathologies.

Keywords: Neuroendocrine tumors; liver metastases.

Development of an everolimus-resistant BON1 cell line with altered cell cycle and c-Met activity

Elke Tatjana Aristizabal Prada, Julian Maurer, Gerald Spöttl, Christoph Auernhammer & Svenja Nölting
Klinikum der Universität München, Munich, Germany.

Introduction

Pancreatic neuroendocrine tumors (panNETs) are often inoperable at diagnosis. The mTORC1 inhibitor everolimus is approved for the treatment of advanced NETs. Unfortunately, the development of resistance against everolimus limits its clinical efficacy.

Aim

Our aim was to establish an everolimus-resistant panNET cell line to find common mechanisms of resistance.

Methods

Pancreatic neuroendocrine tumor cells (BON1) were treated for 24 weeks with 10 nM everolimus (Novartis). Medium supplemented with 10 nM everolimus was changed every 3 days. Two independent everolimus resistant BON1 cell lines were established (RR1 and RR2). Resistance was defined with an at least 2-fold higher IC_{50}, compared to the parental/control cell line.

Results

After 24 weeks of permanent exposure to everolimus both cell lines (RR1 and RR2) showed morphologic changes when compared to the control cell line. The control cell line showed sensitivity to everolimus with cellular survival declining to 54.70% (IC_{50}=34 nM) at 144 h treatment, whereas RR1 and RR2 showed resistance with cellular survival rates of 96.70% (IC_{50}=5200 nM) and 92.30% (IC_{50}=2500 nM), respectively. Western blot analysis showed different adaptive changes of the protein expression level in RR1 and RR2, but two prominent mutual features: The cell cycle component CDK1 (cdc2), which orchestrates the G1-S and G2-M progression was remarkably downregulated and the tyrosine kinase c-Met responsible for tumor cell motility, invasion and metastasis formation was upregulated. Consequently, flow cytometric analysis showed a significant cell cycle shift to G1 phase in RR1 and RR2 cells as well as a higher migration potential than control cells after everolimus treatment.

Conclusion
Everolimus resistance might be acquired by permanently altering the cell cycle and the migration potential. Combinatory treatment approaches to overcome resistance will be subject of further studies.

False positive findings on 6-[18F]fluor-L-3,4-dihydroxyphenylalanine Positron Emission Tomography (^{18}F-FDOPA-PET) performed for imaging of neuroendocrine tumors

MA Berends[1], JW Bolt[1], MN Kerstens[1], TP Links[1], E Korpershoek[2], RR de Krijger[2,3], AME Walenkamp[1], W Noordzij[1], B van Etten[1], G Kats-Urgurlu[1], AH Brouwers[1] & ANA van der Horst-Schrivers[1]
[1]University Medical Center Groningen, Groningen, The Netherlands; [2]Erasmus University Medical Center, Rotterdam, The Netherlands; [3]Reinier de Graaf Hospital, Delft, The Netherlands.

Background/Aim
Neuroendocrine tumors (NETs) are rare tumors arising from neuroendocrine cells throughout the body. Positron Emission Tomography (PET) scanning with 6-[18F]fluor-L-3,4-dihydroxyphenylalanine (^{18}F-FDOPA) has been shown to be a valuable technique for the imaging of NETs. While the sensitivity has been assessed numerously, studies systematically describing false positive results, other than physiological variants, are lacking. Our aim was to systematically examine, in a large series of ^{18}F-FDOPA PET scans, false-positive results and determine which other tumor types have the potential of ^{18}F-FDOPA uptake.
Patients and methods
A single-center study was conducted among patients, aged 18 years or older, who underwent a ^{18}F-FDOPA-PET scan for the clinical suspicion or follow-up of a NET between January 2004 and December 2014. Clinical data were retrieved from medical charts. We compared the original ^{18}F-FDOPA PET scan report with the pathology report of the ^{18}F-FDOPA PET-positive lesion. In case this was inconsistent with the diagnosis of a NET, both the scan and the pathology slides were reassessed. Non- NET tissues were immunohistochemically stained for aromatic-L-aminoacid decarboxylase (AADC), Chromogranin A and Synaptophysin.
Results
1070 ^{18}F-FDOPA PET scans from 705 patients were evaluated. Focal or multiple ^{18}F-FDOPA avid lesions were described in 709 ^{18}F-FDOPA PET scans (66%). Histology of these ^{18}F-FDOPA PET positive lesions was present for 508 (72%) scans. In eight cases the original pathology report and revision was not compatible with a NET but showed a squamous cell carcinoma of the cervix and larynx, a multiple myeloma (in two cases), a hepatocellular carcinoma, a schwannoma, an adrenocortical carcinoma and a skeletal myxoid chondrosarcoma, with positive immunohistochemical staining for AADC in four out of the seven stained tumor tissues.
Conclusions
Pathological uptake of ^{18}F-FDOPA does not always indicate the presence of a NET. The possibilty of ^{18}F-FDOPA uptake by tumor types other than NETs should be considered.

Imaging follow-up of non-functioning adrenal masses at Vilnius University Hospital Santariskiu Klinikos: 2010–2016

Kristina Svaikeviciene[1,2], Milda Girdziute[3] & Zydrune Visockiene[1,2]
[1]Vilnius University Faculty of Medicine, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania; [3]Antakalnis Clinic, Vilnius, Lithuania.

Background
Current guidelines suggest against further imaging follow-up (FU) of patients with non-functioning adrenal masses with clear benign features on imaging studies.
Aim
To analyse the data of patients with non-functioning adrenal masses who had FU at Vilnius University Hospital Santariskiu Klinikos (VUHSK) from 2010 to 2016.
Methods
Cases coded as D35.0; D44.1; C74.1; C74.9; E26.0; E27,8; E24,8 according to ICD-10 classification were retrieved from database. Electronic data capture system was used to extract CT scans and biochemical testing data retrospectively.
Results
There were 714 subjects assessed for adrenal masses from 2010 to 2016 at VUHSK. At least one FU and non-functioning adrenal masses with obvious benign features on CT scan had 216 subjects and thus were included into further analysis. They were 61.6 ± 11.2 years of age (184 female) with tumour size at baseline of 22.8 ± 12.8 mm. Average FU time was 4.1 ± 1.4 years (from 2 to 7), during which tumour size increased in 84 (39%), decreased in 48 (22%), did not change in 84 (39%) cases. Significant increase (by $>$ 20% in addition to at least 5 mm increase in maximum diameter) was observed in 19 (8.8%) cases. Average size of 19 significantly enlarged tumours changed from 19.37 ± 7.60 mm to 30.58 ± 13.68 mm in 2.7 ± 1.4 years. All these tumours were associated with female gender. Despite tumour size enlargement, none of them became functioning during observation time.
Conclusions
Our study showed, that the significant enlargement of non-secreting initially benign adrenal masses during follow up of about 2.7 years occurred in 8.8% of cases and was associated with female gender. Further larger studies with longer follow up are needed to suggest time-frame for imaging follow up in order not to miss the enlargement of the adrenal masses that could require surgery and also to estimate possible enlargement prediction factors.

Medullary thyroid carcinoma and pheochromocytoma in multiple endocrine neoplasia type 2A – a reversed order diagnosis

Ana Coelho Gomes, Catarina Silvestre, José Marçalo, Maria Raquel Carvalho & Maria João Bugalho
Endocrinology, Diabetes and Metabolism Department, Santa Maria Hospital, Lisbon, Portugal.

Introduction
RET germline mutation in codon 634 of exon 11 is one of the most frequent mutations of classical multiple endocrine neoplasia type 2A (MEN2A). Virtually all patients with classical MEN2A develop medullary thyroid carcinoma (MTC), which is often the first manifestation of the disease and usually occurs early in life. Pheochromocytomas (PHEOs) tend to be diagnosed several years later or simultaneously with the MTC.
Case report
The patient, a 45 year-old man, was referred to the Endocrinology outpatient department following a bilateral adrenalectomy, performed 2 months before, (Pheochromocytoma of the Adrenal gland Scaled Score: left $=0$, right $=4$) and the finding of a thyroid micro nodule in a neck ultrasonography. There was no familiar history of MEN2 neither of its components. The physical examination did not disclose particular signs namely skin alterations in the interscapular region. Laboratory tests revealed elevated calcitonin (63.47 pg/ml, $n < 2$). CEA, calcium, phosphorus, parathyroid hormone and plasmatic metanephrines were within the normal range. Thyroid, ultrasound guided, fine needle aspiration cytology of a 7 mm nodule in the left lobe was negative. Genetic testing of the RET proto-oncogene identified the heterozigous pathogenic variant c.1901G$>$A (p.Cys634Tyr) in the exon 11. The patient was submitted to total thyroidectomy with bilateral central neck dissection. The histology revealed multifocal and bilateral MTC (biggest diameter - 10 mm).
Discussion
Although less common the PHEO can be the first manifestation of MEN2A. Moreover, MTC is not always the most aggressive component of the syndrome.

Bilateral pheochromocytomas, asyptomatic medullary thyroid carcinoma associated with left side thyroid hemiagenesis in a patient with MEN2A: diagnostic correlations

Ionela Lungu[1], Carmen Emanuela Georgescu[1,2], Anca Ciurea[3], Carmen Georgiu[4], Denisa Petrescu[1], Daniel Tudor Cosma[5], Horatiu Silaghi[6] & Cristina Alina Silaghi[1,2]

[1]Endocrinology Clinic, County Emergency Hospital, Cluj-Napoca, Romania; [2]Department of Endocrinology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [3]Department of Radiology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [4]Department of Pathology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania; [5]Diabet, Nutrition and Metabolic Diseases Clinical Center, Cluj-Napoca, Romania; [6]5th Department of Surgery, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania.

Multiple endocrine neoplasia 2A (MEN2A), an autosomal dominant genetic syndrome caused by germline mutation in RET proto-oncogene, associates medullary thyroid carcinoma (MTC), pheochromocytoma (PHEO) and primary hyperparathyroidism (HPT). Thyroid hemiagenesis (TH), the absence of one lobe, is a rare congenital abnormality (300 cases are reported in literature). Most cases of TH are diagnosed when patients present a lesion in the functioning lobe. TH was observed among members of the same family and genetic causes have been evoked. The present case is a 35 year-old-female patient with family history of MEN2A (the pedigree was studied). Genetic testing of the patient's cousin and nephew indicated heterozygosity for the same mutation at codon 634. Plasma metanephrines, normethanephrines, parathormone (PTH) and calcitonin (CT) levels were increased. Serum ionized calcium was normal. Abdominal computed tomography provided the bilateral heterogeneous adrenal masses measuring 30×21 mm on the right and 20×16 mm on the left with an intense enhancement after contrast infusion. Neck ultrasound examination described 2 hypo-echoic, heterogeneous thyroid micro-nodules in the right thyroid lobe, with micro-calcifications inside, which measure 78×58, respectively 45×47 mm. In the left side, hemiagenesis of the thyroid lobe was observed. No parathyroid adenoma or lymphadenopathy were found. The patient had underwent a bilateral laparoscopic adrenalectomy for PHEO followed by total right thyroidectomy. Microscopic examinations established the diagnosis of multicentric PHEO and synchronicity of C-cell hyperplasia with medullary thyroid microcarcinoma. Although the identified RET mutation has hight risk, suggesting a possible aggressive evolution, in this case the CMT development was gentle, with a good prognosis (lesion $<$ 1 cm diameter, without distant metastases, preoperative basal calcitonin $<$ 150 pg/ml). In conclusion our patient is a rare case of association of an anatomic thyroid abnormality and MTC in the context of a complex genetic disease.

EP159

Follow-up of adrenal incidentalomas after the initial approach

Ángel Rebollo-Román, Paloma Moreno-Moreno, Inmaculada Prior-Sánchez, Aura-Dulcinea Herrera-Martínez, Ana Barrera-Martín & María-Ángeles Gálvez-Moreno
Endocrinology Service, Hospital Universitario Reina Sofía, Córdoba, Spain.

Aim
To describe the follow-up of adrenal incidentalomas (AI) classified as non-functioning and no suspicious for malignancy in the first approach.
Patients and methods
Observational retrospective study of a cohort of patients who consulted in the Endocrinology service between 2005 and 2015 because of an AI. Statistical analysis performed with SPSS 19th version.
Results
Two hundred and one patients with IA were firstly evaluated. Thirty two of them (15.92%) underwent surgery after the initial evaluation. One hundred and twenty four patients out of the 169 who didn't undergo surgery (73.37%) were followed: 97 unilateral AI and 27 bilateral AI. Age: 58.48±11.84 years. Size: 26.36±14.14 mm. 57.3% Women. Repeated measurement of plasma metanephrines in 26 patients (20.97%): 21 unilateral AI (21.65%) and five bilateral AI (18.52%). No catecholamine production in any AI. Median follow-up: 4.12±3.44 years. Ninety eight patients (79.03%) underwent a 1 mg dexamethasone suppression test to screen the cortisol autonomous production: 76 unilateral AI (78.35%) and 22 (81.48%) bilateral AI. Follow-up: 2.83±2.67 years. 10 patients (10.20%) diagnosed with subclinical Cushing not present in the first evaluation. The rest of them showed no autonomous cortisol production. A follow-up imaging study was performed in 103 patients (83.06%): 80 with unilateral AI (82.47%) and 23 with bilateral AI (85.19%). Median follow-up: 2.77±2.70 years. In four patients (5%) with unilateral AI there was a significant growth (28.85±15.63 mm), so they underwent surgery to remove them. None of them were malignant.
Conclusions
There wasn't any patient with new cathecolamine production in the follow-up. In 10.20% of patients we discovered a subclinical Cushing. Our findings agree with previously published studies. There was a significant AI growth in 5% of the patients so they were operated upon. Pathological diagnosis didn't show malignancy in any case, which is consistent with the available scientific evidence.

A case of silent pancreatic neuroendocrine tumour of carcinoid variety masquerading as an insulinoma

Tarik Elhadd[1], Noor Suleiman[1], Mohamed Bashir[1], Emad Naem[1], Khalid Mohamed[2], Ahmed Elaffandi[2] & Abdul Badie Abou Samra[1]
[1]Qatar Metabolic Institute, Hamad Medical Corporation, Doha, Qatar; [2]Section of Hepato-biliary Surgery, Hamad Medical Corporation, Doha, Qatar.

Objective
To highlight an unusual cause of hyperinsulinaemic hypoglycemia
Methods: Case Report
Results or Case Presentation
A previously healthy and fit 52 year old gentleman of Asian descent presented with recurrent severe neuroglycopenic hyperinsulinemic hypoglycemic symptoms, suggestive of insulinoma. On several occasions he was confirmed to have severe hypoglcaemia with venous blood glucose values ranging between 1.5 and 2.7 mmol/l with inappropriate high level of insulin and C-peptide of 32 mc/unit per ml (N. 2–23) & 4.5 ng/ml (N. 0.78–5.19) respectively. Other hormonal assessment including pituitary hormones, chromogranin A, urinary 5-HIAA, and cortisol were all normal. CT imaging picked up a 4×4 cm well circumscribed lesion in the tail of the pancreas, with no lesion elsewhere. Endoscopic ultrasonography confirmed the mass to be avascular and within the pancreas. He underwent laparoscopic distal pancreatectomy uneventfully in February 2016. Histology of the tumour showed a well differentiated neuroendocrine tumour of a carcinoid variety, grade 2, with positive staining for chromogranin A, and Synaptophysin CK. Following surgery, the patient had no further hypoglycemia and remained symptom free up to 9 month of follow up. Postoperative PET scan and CT scanning of chest, abdomen and pelvis showed no recurrence of the tumour, and no lesion elsewhere.
Discussion
Non-islet cell tumours induced hypoglycemia is generally caused by big IGF-II molecules secretion. Rarely carcinoid tumours were reported to secrete insulin but this is usually in the context of carcinoid syndrome and has been reported to arise from tumours in the lungs, appendix and the liver. For a silent pancreatic carcinoid tumour to cause hyperinsulinaemic hypoglycemia is rather unusual. Plausible mechanisms include processing and secretion of insulin from tumour cells. Alternatively secretion of insulin from adjacent islet cells may have been caused by paracrine effects. The exact mechanism in our case, however, only remains speculative.
Conclusion
Tumours of the pancreas causing hypoglcemia may not necessarily be insulinoma. Silent neuroendocrine tumour of the carcinoid (Argantafinoma) variety may be the culprit.

CYP2W1*6 polymorphism as a potential predictive marker of sensitivity to mitotane treatment in adrenocortical carcinoma.

Barbara Altieri[1,2], Sabine Herterich[3], Silviu Sbiera[1], Marco Volante[4], Matthias Kroiss[1], Silvia Della Casa[2], Alfredo Pontecorvi[2], Massimo Terzolo[5], Martin Fassnacht[1] & Cristina L. Ronchi[1]

[1]Division of Endocrinology and Diabetes, Department of Internal Medicine I, University Hospital of Wuerzburg, Wuerzburg, Germany; [2]Division of Endocrinology and Metabolic Diseases, Catholic University of the Sacred Heart, Rome, Italy; [3]Central Laboratory, University Hospital of Wuerzburg, Wuerzburg, Germany; [4]Department of Oncology, San Luigi Hospital, University of Turin, Turin, Italy; [5]Division of Internal Medicine I, San Luigi Hospital, University of Turin, Turin, Italy.

Mitotane is the only approved drug for the treatment of advanced adrenocortical carcinoma (ACC) and we recently demonstrated that a high expression of cytochrome P450 2W1 (CYP2W1) correlated with response to mitotane. The association between CYP2W1 alleles and a generally increased cancer risk is under debate. Aim of the study was to evaluate the frequency of CYP2W1 polymorphisms and its correlation with the response to mitotane treatment in ACC patients.
Methods
DNA was isolated from whole blood of 108 Caucasian ACC patients (F/M = 68/40) treated with mitotane monotherapy in adjuvant (ns = 66) or palliative (n = 42) setting. Three CYP2W1 polymorphisms were genotyped by PCR and sequenced: CYP2W1*2 (p.A181T), CYP2W1*5 (p.Q482H) and CYP2W1*6 (p.P448L). The response to therapy was evaluated by time to progression (TTP).
Results
The allele frequencies for CYP2W1*2 and CYP2W1*6 were 8 and 18%, respectively, and are comparable to those found in the European population (1000 Genomes Project Phase 3 allele frequencies, ENSEMBLE, 5% for CYP2W1*2 and 17% for CYP2W1*6). For CYP2W1*6 there were slightly more homozygotes than expected (P = 0.1). Both variant alleles were in the Hardy-Weinberg equilibrium. CYP2W1*5, which is only reported in non-Causasian population, was not found. We did not find any correlation between CYP2W1*2 allele and clinical outcomes. Whereas, we observed that patients with advanced disease who have CYP2W1*6 allele have a worse response to therapy (median TTP 3.0 vs 5.5 months, P = 0.03, HR 1.83). Among these patients, 86% who have CYP2W1*6 allele did not reach the therapeutic range of mitotane plasma level (14–20 mg/l) in comparison to 61% of those without CYP2W1*6 allele (P = 0.09, chi-squared = 2.7). No relevant impact of CYP2W1*6 was observed in patients treated with adjuvant mitotane.
Conclusion
This study further suggests that CYP2W1 might be involved on mitotane metabolism and that CYP2W1*6 allele might correlate with a worse sensitivity to mitotane palliative treatment.

Ectopic ACTH-syndrome – 31 consecutive patients from the Helsinki University Hospital

Sanna Toivanen[1], Helena Leijon[2], Timo Sane[1] & Camilla Schalin-Jäntti[1]
[1]Endocrinology, Abdominal Center, University of Helsinki and Helsinki University Hospital, Helsinki, Finland; [2]Department of Pathology, University of Helsinki and Helsinki University Hospital, Helsinki, Finland.

Background
Ectopic ACTH syndrome (EAS) is rare and published series are scarce.
Aim
To increase the understanding of EAS we describe 31 consecutive cases in years 1997–2016.
Results
Of the 31 patients, 65% (20/31) were women and 35% (11/31) men. Median follow-up was 23 months (0–217). Median age at diagnosis was 62 years (21–78), with peak incidences in age groups 30–39 and 60–69 years. Most patients presented with hypokalemia (87%), muscle weakness (77%), ankle edema (74%), hypertension (71%), psychiatric manifestations (58%), changes in body fat distribution (58%), and bruises (51%). Median (range) cortisol, ACTH and 24 h urinary free cortisol were 1467 nmol/l (121–4380), 155 ng/l (16–4700), 8221 nmol/l (568–69038), and median (range) cortisol after 1 mg DST 1103 nmol/l (74–3390), respectively. Thirteen (42%) underwent CRH-testing, which was accurate (< 50% increase in ACTH and < 20% in cortisol) in 9/13 (69%) patients. Underlying tumours: pancreatic NET (n = 6), pulmonary NET (n = 6), pulmonary small cell carcinoma (n = 6), unknown primary (n = 4; no tumour detected n = 2, disseminated disease n = 2), medullary thyroid carcinoma (n = 3), thymic NET (n = 2), and, ileum NET, prostate carcinoma, poorly differentiated pulmonary NEC, poorly differentiated pulmonary LCC (n = 1 for each). Median overall survival was 23 month (0–217). At the end of follow-up, 12/31 (39%) patients were alive. Four patients initially cured recurred at 2, 6, 6 and 10, and 12 years, respectively. Surgery of the primary tumour was possible in 10/31 (32%) patients, nine (90%) of whom were alive at the end of follow-up. Bilateral adrenalectomy was performed in 10/31 (32%) patients, three (30%) of whom were alive at the end of follow-up. Outcome was best in thymic and pulmonary NETs.
Conclusion
EAS affects women in 65% of cases. Incidence peaks in age groups 30–39 and 60–69 years. Recurrences are possible > 10 years later. Overall survival is poor.

Ectopic Cushing's syndrome caused by a pulmonary adrenocorticotropic hormone secreting tumour: a case report

Renata Pauliukiene[1], Edita Prakapiene[1,2], Rasa Koreiviene[1,2], Raimonda Klimaite[1,2], Lina Barsiene[1] & Valdas Sarauskas[3]
[1]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Endocrinology Department, Kaunas, Lithuania; [2]Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Hospital of Lithuanian University of Health Sciences, Kauno Klinikos, Pathological Anatomy Department, Kaunas, Lithuania.

Introduction
Ectopic adrenocorticotropic hormone (ACTH) production by the pulmonary neuroendocrine tumour (p-NET) is rare, and is considered an aggressive variant of carcinoid tumours with poor prognosis.
Case presentation
59-year-old male with fast progressing generalized fatigue, abdominal discomfort, and diarrhea was hospitalized in gastroenterology unit of Hospital of Lithuanian University of Health Sciences, Kauno klinikos (HLUHS KK). Digestive tract diseases were ruled out. Persistent hypokalaemia (up to 2.2 mmol/l) was observed and endocrine pathology changes were considered. Examinations revealed markedly elevated plasma ACTH (44.4 pmol/l) and cortisol (> 1665 nmol/l) levels, diabetes, osteoporosis. No suppression of serum cortisol level with high-dose dexamethasone test was found, confirming ACTH dependent Cushing syndrome. The treatment with Metirapone was started. Pituitary and abdominal magnetic resonance imaging (MRI), abdominal computer tomography (CT) scans were normal. Thoracic CT scan showed nodules in the S2, S3, S6 of the left lung. No cytologic changes were found in repetitive bronchial leachates through endoscopic bronchoscopy. There were two episodes of pneumonia (Pseudomonas aeruginosa) and two episodes of sepsis (Staphylococcus aureus and Enterococcus faecium). Suspected fungal infection, intended antifungal treatment. Single nodule in S3 of the left lung with no changes in size was found in repeated chest CT. ^{99M}Tc-tectrotyd SPECT-CT showed left lung S3 neuroendocrine tumour. The radical surgery (bilobectomia superior sinistri) was performed. Histological result was well-differentiated p-NET (pT1a N0 R0 G1). No radiochemotherapy was suggested. On the follow up visit after three months normal glycaemia, potassium and cortisol were found.
Conclusion
We present ectopic ACTH secreting neuroendocrine lung carcinoma with likely good prognosis. No clearly defined guidelines of follow up exist.

Could alcohol ablation become the standard of care for benign insulinomas?

Isabel Mazarico[1], David Subías[1], Fèlix Junquera[2], Carme Vilardell[3], Ignasi Saigí[4], Albert Cano[1], Laia Casamitjana[1], Olga Giménez-Palop[1], Lara Albert[1], Ismael Capel[1], Assumpta Caixàs[1] & Mercedes Rigla[1]
[1]Endocrinology and Nutrition Department, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; [2]Department of Gastroenterology, Parc Taulí Hospital Universitari, Institut d'Investigació i Innovació Parc Taulí I3PT, Universitat Autònoma de Barcelona, Sabadell, Spain; [3]Endocrinology and Nutrition Department, Althaia Fundation, Manresa, Spain; [4]Internal Medicine Department, Consorci Hospitalari de Vic, Vic, Spain.

Introduction
Surgical resection is currently considered the standard treatment for symptomatic insulinomas; however, its morbidity is high (> 10%) and it is restricted to suitable candidates. In recent years, alternative minimally invasive therapies, such as endoscopic ultrasound (EUS)-guided ethanol ablation (EA), have emerged as new therapeutic options, especially for small lesions or poor surgical candidates. We report two cases of insulinoma ablated with EA.
Cases report
We report two cases of recurrent hypoglycaemia due to benign insulinoma: a 75-year- old man, with a 9 mm hypoechoic lesion in the neck of the pancreas, unfit for surgery because of comorbidities (case 1); and a 71-year- old man with a 19×14 mm hypoechoic lesion in the pancreas head, who refused surgery treatment (case 2). EUS fine needle aspiration (EUS-FNA) confirmed neuroendocrine tumor with a Ki67 <5% in both of them. They were admitted to our department for EA. Insulinomas were punctured under EUS guidance with a 22 G needle. A total volume of 0.8 ml (case 1) and 13 ml (case 2) ethanol 98% was injected. After each injection a whitish halo was observed inside the lesion, and no extravasation of alcohol was detected. There were no perioperative or postoperative complications. In case 1, hypoglycaemia was not reported along the two years follow-up period. Case 2 presented occasional mild hypoglycaemia 1 year after treatment, so we considered repeating EA, but the patient refused it.
Conclusion
EUS-guided ethanol ablation of a single small insulinoma is an effective, minimally invasive, and safe therapeutic modality. Currently, it is considered when surgery cannot be an option. However, this new technique should be applied to a wider range of potential candidates. A multicentric study seems necessary to establish the indications of EA in insulinomas.

Clinical characteristics and survival of patients with paraganglioma: a single center experience

Valentina Elezovic, Djuro Macut, Sanja Ognjanovic, Tatjana Isailovic, Bojana Popovic, Ivana Bozic-Antic, Tamara Bogavac, Dusan Ilic, Jovana Bankovic & Svetozar Damjanovic
Clinic of Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Paragangliomas (PGLs) and pheochromocytomas (PCCs) are rare neuroendocrine tumors that derived from pluripotent neural crest stem cells. PCCs are derived from the adrenal medulla, while PGLs are histologically identical tumors derived from ganglia outside the adrenal gland. Even though the majority of tumors are benign, they are associated with high morbidity rates caused by excessive catecholamine secretion. We retrospectively analyzed 71 patients (36 female and 35 males) with PGLs between January 2002 and December 2016. Twenty three patients were lost to follow up. Kaplan-Meier curve was used as the univariate version of survival analysis. The median age at diagnosis was 47.0 years (11–75) and the mean tumor size was 53 mm (26–170 mm). PGLs in our group were mostly distributed in abdomen (60%), head and neck (26.2%), rarely in spine (9.2%) and chest (4.6%). Hereditary form of disease was present in 22.5% of patients. The most common mutation was in SDHB gene (10/16), hereafter in VHL gene (3/16); two patients had mutation in SDHD gene and one in SDHC. Multiple PGLs were identified in six patients. Hormonally secreting tumors were present in 28%; 16/30 patients had positive finding on I-123 MIBG scintigraphy. Surgical resection was performed in 79% of patients, tumor embolization in 11%. At 22 patients the median proliferation index Ki67 was 1.8% (0.1–18%) and median PASS score 3(1–6). Metastatic disease was present in 18.8% of patient at the time of diagnosis and five patients had acquired metastasis. These patients were treated with PRRT (6/14), chemotherapy (3/14) and sutent (3/14). Median overall survival (OS) was 284 months (95%CI 251–318) with 10-year OS 88%. Mean disease free survival was estimated 20 months (95%CI 8–31). We presented clinical characteristics, genetic profile, treatment options and survival of our patients with PGLs, our experience as single tertiary center.

Corticotroph deficiency in patients with insulinoma

Faten Hadj Kacem[1], Mouna Ammar[1], Mouna Elleuch[1], Dorra ghorbel[1], Rihab Ben Abdallah[2], Nadia Charfi[1], Wajdi Sefi[1], Mouna Mnif[1] & Mohamed Abid[1]
[1]Department of Endocrinology and Diabetes Hedi Chaker, Sfax, Tunisia; [2]Faculty of sciences, Sfax, Tunisia.

Introduction
The metabolic stressor, hypoglycemia, elicits integrated counterregulatory responses, including activation of the hypothalamic–pituitary–adrenal axis. However, it is suggested that recurring insulin-induced hypoglycemia can impair this counter-regulation. Here we report three cases of patients with isulinoma and corticotroph deficiency.
Case reports
The first case, 38-year-old man *was referred* because of recurrent episodes of *hypoglycemia*. Hormonal investigations were in favour of dissociated anterior pituitary failure, with growth hormone and corticotroph deficiency. The hypothalamic-pituitary MRI was normal. The fasting test argued in favour of a hyperinsulinemic hypoglycemia. The abdominal scan and the endoscopic ultrasound showed a mass within the tail of the pancreas. Distal pancreatectomy was performed. Histology disclosed an insulinoma. On follow up, no hypoglycemic episodes recurred and cortisol and GH response to induced hypoglycemia was normal. The second case, 68 years old man referred for investigation of hypoglycemic episodes. He was diagnosed with corticotroph deficiency and hypergonadotropic hypogonadism with negative investigations. The hypothalamic-pituitary MRI was normal. After treatment with glucocorticoids, hypoglycemic episodes were significantly improved. After 6 years, he presented severe hypoglycemia and investigations revealed a 1.5 cm tumor in the head of the pancreas with hepatic and pulmonary metastases. The third case, 38 years old woman with a history of primary hypothyroidism for 6 years, presented with symptomatic hypoglycemia and a history of weight gain. Laboratory investigations argued in favour of a hyperinsulinemic hypoglycemia and the abdominal scan showed a mass within the tail of the pancreas. Furthermore, she was diagnosed with corticotroph deficiency. The hypothalamic-pituitary MRI was normal.
Conclusions
Our clinical cases show that hyperinsulinemia and hypoglycemia in patients with insulinoma can give rise to functional corticotrophin deficiency. The pathophysiological mechanism of this defective counter-regulation remains to be clarified; some studies suggest it could be related to hyperinsulinemia-induced decreased in CRF secretion.

EP168

Hyperinsulinemic hypoglycemia in a 71-year-old patient with a suspected case of β-cells hyperplasia of pancreatic body and tail- case report

Jelena Malinovic Pancic[1,2], Bojana Caric[1,2] & Bojana Popovic[3]
[1]University Clinical Center of Republic of Srpska, Banja Luka, Bosnia and Herzegovina; [2]Medical Faculty Banja Luka, Banja Luka, Bosnia and Herzegovina; [3]Clinical Center of Serbia, Belgrade, Serbia.

B-pancreatic cells are programmed to react to plasma glucose level with insulin secretion. Insulin secretion is precisely regulated and in the physiological conditions fasting glucose levels are maintained in the range 3.5–5.5 mmol/l. In hyperinsulinemic hypoglycemia, a disorder of the regulation of insulin secretion, insulin secretion continues at low concentrations of plasma glucose. In adults hyperinsulinemic hypoglycemia is the cause of 0.5 to 5.0% of hypoglicaemias and are result of eather β-cell tumor (insulinoma), or β-cell hyperplasia. Rapid diagnosis and treatment is essential in the prevention of acute and chronic complications of hypoglycaemia, especially in central nervous system.
We are presenting the 71-year-old patient who had been previously diagnostic evaluated at the primary health care level due to frequent episodes of unconsciousness and weakness periodically in period of 3 years prior to admission. After established refractory hypoglycemia patient was sent to our department where endogenous hyperinsulinism after 72-hour test of hunger was found. After endoscopic ultrasound showed probable β-cells hyperplasia of the body and tail of the pancreas. I-131 ocreotid scintigraphy of somatostatin receptors was negative. Calcium artery stimulation of the pancreas with insulin sampling from vein lienalis showed a clear gradient of insulin and distal pancreatectomy was suggested which patient refused. inhibitor of potassium channels-diazoxide was introduced in the therapy which led to reduction in subjective symptoms and no registered hypoglycaemas.

Respiratory symtoms lead to a diagnosis of pheochromocytoma: An unusual presentation

Luís Teles[1,2], João Sérgio Neves[2], Pedro Souteiro[2], Sofia Castro Oliveira[2], Celestino Neves[2], Paula Freitas[2] & Davide Carvalho[2]
[1]Internal Medicine Department Centro Hospitalar Entre Douro e Vouga, Santa Maria da Feira, Portugal; [2]Endrocrinology Department Centro Hospitalar São João, Porto, Portugal.

Introduction
Pheochromocytoma is one of the major secondary causes of hypertension. The classic triad of pheochromocytoma symptoms of headache, sweating and tachycardia is not present in a high percentage of patients and is sometimes diagnosed as incidentaloma or atypical presentations.
Case report
The authors present a 56-year-old man, with no known diseases, referred to Endocrinology evaluation by incidentaloma of the right adrenal gland, from the Pneumology appoitment, where he was followed by persistent cough, after an episode of bronchospasm. From the complementary study, a 32 mm nodule in the right adrenal gland was observed on thoracic computed tomography and confirmed by MRI. Bronchofibroscopy with bronchoalveolar lavage and functional respiratory tests were also performed, which were normal. Patient didn't refer any symtoms, however, he maintained a sustained hypertension in the ambulatory monitorization. Analytically, there was a significant increase in the urinary normetanephrines (2585 ug/24 h for a reference value <390) and urinary metanephrines (1551 ug/24 h, for a reference value <320), as well as plasma noradrenaline (1107 pg/ml for a reference value <750) and plasma adrenaline (137 pg/ml, for a reference value <110). Remaining study was without alterations, namely renin-angiotensin-aldosterone axis, thyroid function and urinary free cortisol. Patient started alpha-adrenergic blockade with phenoxybenzamine and laparoscopic adrenalectomy was performed 3 weeks later. Pathological anatomy confirmed diagnosis of pheochromocytoma.
Conclusion
Authors present a case of atypical presentation of pheochromocytoma. The respiratory airways are sensitive to the effects of catecholamines. Although they have mainly beta-adrenergic receptors, there are also alpha receptors that may explain the patient's clinical condition (bronchospasm).
Given the existence of multiple presentations, detection of a pheochromocytoma might be difficult but is mandatory, not only for the potential cure of the hypertension but also to avoid the potentially lethal effects of the unrecognized tumor.

A rare cause of secondary endocrine hypertension in a young woman with hypokaliemia and recurrent transient ischemic attacks

Francisco Javier Martinez-Martin[3], Sara Quintana-Arroyo[1], Carmen Acosta-Calero[1], Claudia Arnas-Leon[1], Ana Delia Santana-Suarez[1], Manuel Nivelo-Rivadeneira[1], Agnieszka Kuzior[1] & Elisa Gonzalez-Rodriguez[2]
[1]Endocrinology Department, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Ganaria, Spain; [2]Endocrinology Department, Hospital Vithas Santa Catalina, Las Palmas de Gran Ganaria, Spain; [3]Outpatient Hypertension Clinic, Hospital Universitario de Gran Canaria Dr. Negrin, Las Palmas de Gran Ganaria, Spain.

Clinical Case
A 39-year-old woman was referred to our Hypertension Clinic for workup after three episodes of TIA with SBP >180 mmHg in the last 6 months. Diagnosed and treated of hypertension and hypokaliemia since she was 15 years old, no secondary cause had been searched. She was treated with Telmisartan/Amlodipine/Hydrochlorothiazide 80/10/25 mg plus Carvedilol 12.5 mg BID and potassium supplements. She had no history of diabetes or dyslipidemia and did not smoke. Height was 168 cm, weight 63 kg, IMC 22.3 kg/m^2, office BP 142/88 mmHg, HR 72 bpm. The physical exam was otherwise normal.
Treatment was changed to Diltiazem/Doxazosin for 3 weeks. Lab: normal including TSH and metanephrines, except venous pH 7.51, Cr 1.23 mg/dl, CKD-EPI eGFR 57 ml/min/1.73 m^2, albuminuria 139 mg/g Cr, aldosterone 792 ng/ml, PRA 58 ng/ml per h, normal ratio (13.7).
Funduscopy: stage 2 hypertensive retinopathy, brain RMN: scattered white matter microinfarctions, heart US: normal function, mild LVH (LVMI 92 g/m^2). Chest X-ray and abdominal US: normal.
AngioCT excluded renal artery sclerosis, but showed a 12 mm subcapsular mass in the right kidney. The adrenals were normal.
Renal venous sampling for renin: Peripheral 628 U/l (normal <42), Left renal vein 645 right renal vein 3120 U/l; right/left ratio 4.8. Laparoscopic nodulectomy was performed; a encapsulated 14 mm adenoma with clean margins was obtained. It tested positive for renin.
Diagnosis
Secondary aldosteronism due to reninoma, resistant hypertension and target-organ damage (retinopathy, brain microinfarctions and TIAs, stage IIA CKD with microalbuminuria, LVH). Two months after surgery the patient is normotensive with manidipine 10mg/day: aldosterone, ARP, K^+, venous pH and albuminuria are normal.
Commentary
Reninoma is rare but probably infradiagnosed, and a long diagnostic delay is not unusual. Even with well-controlled BP, it may cause severe organ damage due to hyperaldosteronism. Thus, it should be included in the workup of secondary hypertension.

Atypical symptoms of hypoglycemia, hiding a diagnosis of insulinoma: a case report

Agne Petrenaite[1,2], Greta Jagucianskaite[1,2], Rasa Juskiene[2], Rasa Ziukaite[2] & Zydrune Visockiene[1,2]
[1]Faculty of Medicine, Vilnius University, Vilnius, Lithuania; [2]Vilnius University Hospital Santariskiu Klinikos, Vilnius, Lithuania.

Introduction
Insulinoma is a rare pancreatic tumor, typically sporadic, solitary and benign. However, nonspecific symptoms of hypoglycemia, negative laboratory investigations and small size of these tumors can retard the diagnosis, and symptoms may be misattributed to psychiatric, cardiac, neurological disorders.
Case presentation
A 35-year-old male had history of night time seizures with hallucinations, delirium and spasms, lasting from 10 minutes to 1.5 hours for about 2 years. These seizures were always resolving spontaneously. Due to recurrent seizures he was consulted by phychiatrist and diagnosed with depression and conversion disorder and treated with psychotropic medications. As the spasms remained, he was referred to neurologists. During examination early in the morning while performing electroencephalography typical dyscognitive seizures occured. Plasma glucose analysis was performed for the first time and hypoglycemia of 1.4 mmol/l was found. Symptoms disappeared after intravenous glucose infusion.

Management and outcome
The patient was hospitalized due to suspected insulinoma and supervised 72-hour fast test was performed. Plasma glucose was 3.5 mmol/l, plasma insulin - 49.3 pmol/l (43–210 pmol/l) and C-peptide - 780 pmol/l (260–1730 pmol/l) at the baseline. The test was ended after 16 hours with plasma glucose of 1.7 mmol/l, plasma insulin - 29.7 pmol/l, C-peptide - 521 pmol/l. These results confirmed the diagnosis of insulinoma. Abdominal computed tomography scan with contrast demonstrated a well-defined hypervascular lesion involving the head of pancreas measuring 10×15 mm in diameter, typical of neuroendocrine tumor. The patient underwent laparoscopic extirpation of the pancreatic mass. Histopathological evaluation revealed a pancreatic well-differentiated (G1) neuroendocrine tumor – benign insulinoma. The patient gradually discontinued all psychotropic medications following the operation. Currently he is feeling well, without any seizures and normal plasma glucose for about 1.5 years.
Conclusion
We recommend to check plasma glucose for all patients with seizures of unknown origin, although they are not typical to hypoglycemia.

A nomogram consisted of routine biochemical tests may increase the diagnostic accuracy of chromogranin A in detecting patients with neuroendocrine tumors

Ivan Vurnek[1], Ivan Kruljac[2], Miroslav Ćaćić[2], Božidar Perić[2], Maja Filipović-Grčić[2], Gorana Mirošević[2], Davor Kust[2] & Milan Vrkljan[1,2]
[1]School of Medicine, University of Zagreb, Zagreb, Croatia; [2]University Hospital Center 'Sestre Milosrdnice', Zagreb, Croatia.

Introduction
Falsely elevated serum chromogranin A (CgA) is associated with the use of proton pump inhibitors, the presence of renal impairment and systemic inflammation. We aimed to investigate which laboratory parameters are independently associated with increased CgA and to develop a nomogram, in order to improve the diagnostic accuracy of CgA in detecting patients with neuroendocrine tumors (NET).
Methods
Our retrospective study included 155 subjects (controls) and 55 treatment naïve patients with NET, with available data on CgA, other laboratory tests, medical history and antropomethric parameters. Nomogram was developed in a form of scoring system, based on z-score obtained from receiver operating curve analysis for each parameter that was independently associated with CgA.
Results
CgA was positively associated with erythrocyte sedimentation rate, red cell distribution width, serum creatinin, glucose, urine leukocyte casts and the use of proton pump inhibitors. The combination of all these parameters was associated with increased CgA with an area under the curve of 0.771 ($P<0.001$). Overall, CgA level of 189 had a sensitivity of 56.4% (42.3–69.7) and a specificity of 76.8% (69.3–83.2) in detecting patients with NET (area under the curve 0.656, $P<0.001$). In subjects with a score of <6, CgA level of 150 ng/ml had a sensitivity of 68.2% (45.1–86.1) and specificity of 89.4% (80.8–95.0), (AUC 0.767, $P<0.001$). In subjects with a score ≥ 6, AUC decreased to 0.534 ($P=0.538$).
Conclusion
CgA should not be used as a biomarker for NET in patients with laboratory signs of inflammation and renal impairment. Our study suggests the possibility to adjust CgA in these patients in order to increase its diagnostic accuracy.

Concentration of dehydroepiandrosterone sulphate in 109 males and 54 females with adrenal tumors

Ilona Banisauskaite[1], Paulina Simaityte[1], Milda Sarkinaite[1], Viktorija Bakstyte[1], Juste Baksanskaite[1], Rasa Steponaviciute[2], Astra Vitkauskiene[2], Vaidotas Urbanavicius[3] & Valentinas Matulevicius[1]
[1]Institute of Endocrinology, Lithuanian University of Health Sciences, Kaunas, Lithuania; [2]Department of Clinical Laboratory, Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania; [3]Faculty of Medicine, Vilnius University, Kaunas, Lithuania.

Relation of dehydroepiandrosterone sulphate (DHEAS) concentration and adrenal tumors (AT) has never been investigated systematically. After promising Terzolo group (1995, 1996, 2000) investigations, there was made a recommendation in the last clinical guidelines for adrenal incidentaloma (2016) to assess concentration of DHEAS in special clinical situations. Here we present the first systemic study of DHEAS in adrenal tumors.
The aim was to analyse the clinical and laboratory characteristics (including DHEAS) of 109 males and 54 females with AT.
Methods
During 2014–2016 years concentration of DHEAS was determined in 5133 patients. Out of those case records of 590 females and 450 males were randomly selected for a detailed retrospective analysis. The relation between presence or absence of AT and DHEAS was established. Age and gender adjusted maximal values (R max) and minimal values (R min) of DHEAS concentration were used to express the results.
Results
AT were detected in 109 males and in 54 females. R max ≤ 0.4 was found in 64.81% of females starting from 45 years-old and in 67% of males starting from 60 years-old. R max value >1 was found in 11 cases of females (20.4%) and only in one case of males (0.92%). R min <1 value was detected in 13 cases of males (11.92%) and in two cases (3.7%) of females.
Conclusions
Out of all 163 cases of adrenal tumors, high level of DHEAS was found more frequently in females (7.36%), otherwise, low level of DHEAS was found more frequently in males (7.97%).

Jejunum/ ileum Neuroendocrine Tumours: results of a multicentric retrospective study

Ana Paula Marques[1], Ana Paula Santos[2], Isabel Claro[3], Ana Cristina Sanches[2], Isabel Fernandes[5], José Manuel Lopes[6], John Preto[6], Fernando Rodrigues[7], Ana Luisa Catarino[8], Juan Mellidez[9], Bernardo Pereira[10], Gustavo Rocha[11], Maria João Bugalho[5] & Grupo Estudos Tumores Neuroendócrinos[12]
[1]Hospital Pedro Hispano, Matosinhos, Portugal; [2]Instituto Português Oncologia, Porto, Portugal; [3]Instituto Português Oncologia, Lisboa, Portugal; [4]Instituto Português Oncologia, Porto, Portugal; [5]CHLN, Lisboa, Portugal; [6]CHSJ/IPATIMUP, Porto, Portugal; [7]Instituto Português Oncologia, Coimbra, Portugal; [8]HBA, Loures, Portugal; [9]HSP, Aveiro, Portugal; [10]HGO, Almada, Portugal; [11]CHVNG, Vila Nova de Gaia, Portugal; [12]Portugal, Portugal, Portugal.

Introduction
The Neuroendocrine Tumors Study Group of the Portuguese Endocrine Society (SPEDM) performed the first observational study between November 2012 and July 2014 too assess the profile of Gastroenteropancreatic Neuroendocrine Tumours (GEP-NET) patients (pts) followed at the main Portuguese hospitals. Several demographic and clinical data were collected
Objective
Characterize the clinicopathological features and treatment of patients with NET originating in the jejunum and ileum.
Material and methods
Included 71 pts with ≥ 18 years and a confirmed diagnosis of jejunum /ileum NET based on histopathology/cytology findings.
Results
Mean age was 57.2 (32–83) years, 61% ($n=43$) males. Most tumors 89% ($n=63$) were located at the ileum; two were multifocal. Ki67 was available in 86% of pts, 64% G1. At diagnosis 91% (51/56) had lymph node metastases and 70% (43/61) distant metastases.
The most common symptom, available in 59 pts, was abdominal pain in 49% (29/59). Serum Chromogranin A (Crg A) was available in 65% (46/71) and was $2\times \geq$ upper limit of normal in 61%(28/46). Urinary 5HIAA checked in 61% (43/71) was elevated in 56%(24/43), 86% of these with distant metastases. CT scan was the preferred radiologic procedure in 87% of pts. Nuclear medicine imaging, either octreotide scan or ^{68} Ga-DOTA-NOC Pet Scan was used in 75%(53/71) of pts Tumor size known in 58 pts was 24 ± 14.7 mm. Primary tumor surgery was performed in 90 and 32% did surgery of hepatic metastases. 62% of the pts received somatostatin analogues(SA), two were treated with SA and interferon and two with systemic chemotherapy. 11 cases were submitted to hepatic transarterial embolization. Peptide Receptor Radionuclide Therapy with ^{177}Lu was done in 9%.

Conclusions
This paper reveals important information regarding clinical practice. Most of our pts presented with well differentiated tumors but in an advanced stage. Regarding therapy there was an extensive use of surgery and systemic treatment mainly with SA.

Follow-up in neuroendocrine tumors: is chromogranin A the confounder?

Diana Martins[1], Carla Baptista[1], Ana Velez[2], Fernando Macário[3] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department of Coimbra Hospital and Universitary Centre, Coimbra, Portugal; [2]General Surgery Department of Coimbra Hospital and Universitary Centre, Coimbra, Portugal; [3]Nephrology Department of Coimbra Hospital and University Centre, Coimbra, Portugal.

Introduction
Chromogranin A continues to be one of the most valuable markers for neuroendocrine tumors (NETs) **however,** it has several limitations, including its reduced specificity.
Methods
The authors present the case of a patient diagnosed with a midgut NET, during follow-up.
Results
Male patient, 61 years old, with chronic renal disease (CRD), underwent right hemicolectomy owing to ileo-cecal valve lesion; histological result consistent with NET. Pre-operatory staging: without metastatic disease on thoracic-abdominal CT; octreoscan with elevated expression of somatostatin receptors on ileo-cecal valve topography; CgA 32 nmol/l (<6.0), NSE 14 ng/ml (<15.0). Anatomopathological examination of surgical specimen: well-differentiated G1 NET; mesenteric infiltration and metastization in 1 of 20 lymph nodes (T3N1Mx; AJCC-IIB; R0). After 3 years of stable disease, the patient presented CgA of 1173.8 ng/ml (<85), with impaired CRD (Cr 4.42 mg/dl), on dyalisis. 3 months later: CgA 1619.0 pg/ml and Calcitonin 26 pg/ml (<10). In additional investigation, cervical-thoracic-abdominal CT and 68 Ga-PET rated negative for relapse. Total colonoscopy, including evaluation of ileocolonic anastomosis, didn't demonstrate alterations. The patient maintained follow-up with clinical stability, showing in the last evaluation CgA 272.3 ng/ml, Calcitonin 38 pg/ml, NSE 12 ng/ml (<15) and Cr 6.88 mg/dl.
Conclusions
Evaluation of CgA in end stage renal disease is not reliable. Although it's postulated that higher the degree of renal failure, higher the CgA concentration, it wasn't verified such correlation. In NET patients, renal function should be carefully evaluated and ruled out the potential impact on the concentration of CgA.

Large intestinal metaplasia is a precancerous lesion present in patients with gastric neuroendocrine neoplasms type 1

Georgios Boutzios[1], Krystallenia Alexandraki[1], Vassiliki Mavroeidi[1], Eleni Koukoulioti[2], Ioannis Papanikolaou[2] & Gregory Kaltsas[1]
[1]Endocrine Unit, Department of Pathophysiology, Medical School, National and Kapodistrian University, Laikon University General Hospital, Athens, Greece; [2]Hepatogastroenterology Unit, Second Department of Internal Medicine - Propaedeutic, Research Institute and Diabetes Center, Medical School, National and Kapodistrian University, Attikon University Gen, Athens, Greece.

Background
Intestinal metaplasia (IM) of the gastric mucosa is a relatively frequent precancerous lesion. The aim of the study was to assess the prevalence and the kind of IM and also to find parameters that could predict the presence of IM in gastric neuroendocrine neoplasms type 1 (GNEN1).
Methods
Fifty-nine (45 females) patients with GNEN1 were retrospectively studied. All patients included in the study had positive parietal-cell antibodies. All patients underwent a gastroscopy with multiple biopsies. Chromogranin A, gastrin, vitamin B12, folate and ferritin levels were also assessed.
Results
The mean age and follow up were 54.14±13.62 years and 67.66±48.9 months, respectively. At diagnosis, chromogranin A, gastrin, vitamin B12, folate and ferritin levels were: 277.54±173.54 ng/ml (<98), 896.18±818.98 pg/ml (<110), 395.43±488.18 pg/ml (300–960), 12±11.36 ng/ml (2–20) and 58.02±75.08 ng/ml (20–350), respectively. Intestinal metaplasia appeared in 48 patients (81.35%) with GNEN1; 41 (85.5%) had large IM, 1 (2%) had small and 6 (12.5%) had both small and large IM. In univariate regression analysis, only mean follow-up from the parameters studied (age at diagnosis, gender, biochemical markers) predicted the presence of intestinal metaplasia (OR: 0.979; 95%CI: 0.961–0.997, $P=0.021$).
Conclusion
Our study showed a high prevalence of large IM in GNEN1. Mean follow up predicted IM presence. Further clinical studies are required to determine which parameters predict the presence of IM in patients with GNEN1.

Pancreatic neuroendocrine tumors (PNETs) in patients with MEN1 syndrome

Tatjana Isailovic[1], Djuro Macut[1], Sanja Ognjanovic[1], Milan Petakov[1], Valentina Elezovic[1], Ivana Milicevic[2], Bojana Popovic[1], Ivana Bozic Antic[1], Tamara Bogavac[1], Dusan Ilic[1] & Svetozar Damjanovic[1]
[1]Clinic for Endocrinology, Department for Endocrine Tumors and Heritable Cancer Syndromes, Belgrade, Serbia; [2]Clinic for Endocrinology, Genetic Laboratory, Belgrade, Serbia.

PNETs represent the leading cause of mortality in MEN1 patients. Yet, their characteristics, behaviour, and therefore management, are still uncertain.
The aim of this study was to describe the main clinical characteristics of NETs in MEN1, and to compare them with sporadic NETs.
We investigated 164 patients with PNETs retrospectively, treated in one centre from 2004–2016. We identified 15 (9.1%) patients with MEN1. All patients had germline mutations in *MEN1* gene, except one who had sporadic MEN1. There was no gender difference among the groups. No difference in age at onset between the groups was noted (48±16.1 in MEN1 vs 53.8±13.5 years in sporadic, $P>0.05$). According to WHO classification, well-differentiated tumors were the most frequent in MEN1, in contrast to sporadic PNETs where well-differentiated carcinomas prevailed ($P<0,01$). Functioning PNETs were more frequent in MEN1 group (60 vs 30%, $P<0.05$). Among functioning tumors, insulinoma and gastrinoma were the most frequent in both groups ($P>0.05$). MEN1 patients had multiple tumors more frequently (33.3 vs 5%, $P<0.05$). Metastatic disease as initial presentation had 17% of MEN1, and 26% of sporadic patients ($P>0.05$). Surgery was performed in 70% of MEN1, and 92% of sporadic patients. Tumor size did not correlate with the presence of metastases at surgery in any of the groups. Median OS was 149 months (95%CI 71–226) with no difference between the groups ($X^2=2.049$, $P>0.05$). Mean time to tumor progression (TTP) was estimated to 41 months (95%CI 10–75). However, no difference was found regarding the MEN1 status ($X^2=0.22$, $P>0.05$). TTP negatively correlated to Ki-67, local invasiveness and stage of the disease in all patients, but not to size or functionality. These data suggest that MEN1 PNETs share similar clinical behaviour as sporadic PNETs. Therefore, close tumor surveillance and early surgery are advocated, irrespective of the tumor size or functionality.

Dysregulation of the components of the splicing machinery in neuroendocrine tumors and its association with malignancy and aggressiveness

Sergio Pedraza-Arévalo[1], Emilia Alors-Pérez[1], Aura D. Herrera-Martínez[2], Mercedes del Río-Moreno[1], Rafael Sánchez-Sánchez[3], Rosa Ortega-Salas[3], Raquel Serrano-Blanch[4], María A. Gálvez-Moreno[2], Manuel D. Gahete[1], Raúl M. Luque[1] & Justo P. Castaño[1]

[1]Department of Cell Biology, Physiology and Immunology, Maimonides Institute of Biomedical Research of Cordoba (IMIBIC), Reina Sofia University Hospital (HURS), University of Cordoba (UCO), CIBER Physi, Cordoba, Spain; [2]Service of Endocrinology and Nutrition, HURS/IMIBIC, Cordoba, Spain; [3]Service of Anatomical Pathology, HURS/IMIBIC, Cordoba, Spain; [4]Service of Medical Oncology, HURS/IMIBIC, Cordoba, Spain.

Dysregulation of the splicing machinery is emerging as a novel cancer hallmark due to its association with multiple dysfunctions in tumor cells. An inappropriate function of the components of this machinery (spliceosome) could be primarily linked with the generation of tumor-associated aberrant splicing variants. In line with this, we have previously reported that overexpression of aberrantly spliced variants of somatostatin receptor 5 (sst5TMD4) and ghrelin (In1-ghrelin) is directly associated to malignancy features in gastroenteropancreatic neuroendocrine tumors (GEP-NETs). Therefore, in this study we aimed to characterize, for the first time, the pattern of expression of a selected set of components of the splicing machinery in GEP-NETs samples, compared to adjacent non-tumoral control-tissues, and to determine its relationship with the aggressiveness of these tumors. Accordingly, we designed a PCR-based array to determine the expression levels of components of the major ($n=13$) and minor spliceosome ($n=4$) and associated splicing factors ($n=28$) using a microfluidic technology in 20 pancreatic NET-samples (47% G1, 47% G2 and 6% G3) and control-tissues. The results showed that the expression of several splicing factors and spliceosome components was altered in tumor tissues compared to non-tumoral adjacent tissues. Remarkably, important splicing factors (e.g. CELF4, NOVA1, SNW1, and RAVER1) and components of spliceosome (e.g. PRP8) were clearly overexpressed in NET-samples, wherein they were correlated with some malignancy features. Furthermore, *in vitro* assays using NETs cellular models (i.e. BON-I/QGP-I-cells) demonstrated that CELF4 and NOVA1 overexpression induced an increase on cell-proliferation, while their silencing (using specific siRNAs) caused a marked decrease on cell-proliferation, suggesting a role in the aggressiveness of these tumors and their putative suitability as therapeutic targets in pancreatic NETs. Hence, our results demonstrate an alteration of splicing machinery in pancreatic NETs and unveil its putative relevance in NETs development/progression, where it could provide novel diagnostic biomarkers and therapeutic tools for this pathology.

Serum succinate: investigation of its putative role as a new biomarker in malignant *SDH-x* mutated pheochromocytoma-paraganglioma patients?

Constance Lamy[1], Julien Hadoux[1], Lionel Mercier[1], Dorian Bailleux[1], Ségolène Hescot[1], Angelo Paci[1,2], Eric Baudin[1] & Sophie Broutin[1]
[1]Gustave Roussy, Villejuif, France; [2]Université Paris-Sud, Châtenay-Malabry, France.

Introduction
Malignant paraganglioma/pheochromocytoma (MPP) are very rare neuroendocrine tumors with heterogeneous prognostic and no gold-standard treatment. MPP can be associated with germline mutations at *SDH-x* genes which encode for the succinate dehydrogenase that catalyzes the oxidation of succinate to fumarate. *SDH-x* mutations lead to inactivation of the enzyme and thus accumulation of succinate.
Aim
This project aims to evaluate succinate as a potential early serum biomarker in *SDH-x* MPP patients.
Material & Methods
A fully validated LC-MS/MS method has been developed to quantify succinate serum levels. A prospective collection of MPP patients 'serum has been initiated.
Results
Succinate has been quantified in 108 serum samples collected from 47 MPP patients. Among them 25 presented a *SDH-B* mutation, 4 a *SDH-D* mutation and 15 were *SDH* wild-type (WT). Succinate levels were statistically higher in the *SDH-B* group (mean $=25$ µM, min-max: ~3–106 µM) compared to the WT group (mean $=7$ µM, min-max: 4–11 µM) ($P=0.01$).
Conclusion
These results suggest a role of succinate as serum biomarker in *SDH-x* patients. TNM adjustment is ongoing to determine cut-off value that may differentiate mutated *vs* WT patients. Quantification of serum succinate levels after treatment is in progress and aims to evaluate succinate as a biomarker of response in *SDH-x* MPP patients.

Survival analysis of patients with gastroenteropancreatic neuroendocrine tumors

Miguel Sampedro-Núñez[1,2], Angeles Maillo-Nieto[1], Ana María Ramos-Leví[1,2], Isabel Huguet[1,2], Sandra Campos[1,2], Elena Fernandez[1], Nerea Aguirre[1], Jose Luis Muñoz de Nova[3], Elena Martín[3] & Mónica Marazuela[1,2]
[1]Department of Endocrinology, Hospital Universitario de La Princesa, Madrid, Spain; [2]Instituto de Investigación Princesa, Madrid, Spain; [3]Department of Surgery, Hospital Universitario de La Princesa, Madrid, Spain.

Introduction
One of the main difficulties in the study of gastroenteropancreatic neuroendocrine tumors (GEP-NETs) is their wide heterogeneity and variable outcome. Several potential influencing factors on patient survival have been recently identified. These factors could help predict patients' prognosis.
Objectives
Analysis of long-term survival of our GEP-NETs cohort according to the presence of metastatic disease, tumor grade, age, sex, tumor functionality and tumor origin.
Materials and methods
Ambispective study of patients with GEP-NETs in Hospital Universitario La Princesa (Madrid, Spain) from 1995 to the present. Survival analysis and factors involved were assessed by Kaplan-Meier method and Cox regression analysis using STATA v12.0.
Results
One hundred and four patients were evaluated (55 women, age 61 ± 16 years). Primary origin was pancreatic in 39, intestinal in 69 and unknown in 6 cases. Histological tumor grade was G1 in 51%, G2 in 39% and G3 in 10% of cases. 68% patients had metastatic disease and 33 died during follow-up. Median survival time was 5261 days (CI 3247 to not reached). Grade G3 multiplied the risk of mortality by 26 (CI 6 – 112); metastatic disease doubled the risk (CI 1.3 – 5.1); every 10-year increase in age multiplied the risk by 1.6 (CI 1.2 – 2.2); and if the tumor had unknown primary origin, the risk was multiplied by 2.5 (IC 0.9 – 7.4). Sex and tumor functionality did not significantly affect survival.
Conclusions
Several factors influence the heterogeneity and clinical outcome of patients with NETs. Median survival is reduced in patients with G3, metastasis, and primary tumors of unknown origin. Knowing these factors guides the therapeutic approach of this rare disease.

EP181

Insulinoma – clinical features and outcome of patients diagnosed at a central hospital

Joanna Prokop, Ana Cláudia Martins, Carolina Neves, Teresa Sabino, Paula Bogalho, José Silva Nunes, Fernando Fonseca & Ana Agapito
Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Insulinoma, a rare neuroendocrine tumor (NET), is benign in more than 90% of cases. We present a review of patients diagnosed with insulinoma at our Department.
Methods
Retrospective review of clinical records of patients diagnosed with insulinoma between 2011 and 2016.
Results
Six female patients were diagnosed with insulinoma (age at presentation 30–66, follow-up: 0.25–3.25 years). Episodes of sweating, palpitations, tremor, confusion, visual disturbances and weight gain were present in five patients from 2 months to 5 years before diagnosis. There was no familial history or

clinical findings of hereditary tumor syndromes. The 72-h fast test confirmed endogenous hyperinsulinism at 4–12 h of fast. Abdominal CT: pancreatic lesion in four patients (14–25 mm). Endoscopic ultrasound done in four patients revealed pancreatic nodule; three performed cytology/biopsy compatible with pancreatic neuroendocrine tumor (pNET). Five patients underwent surgery: two tumor enucleation, three central and distal pancreatectomy with left hepatectomy and splenectomy in 1 of these. Histopathology: well differentiated pNET G1(two patients) and G2 (three patients). Two patients had lymph node involvement and one of them liver metastases. Among five surgically treated patients: four did not have recurrence of hypoglycemia and the one with liver metastases was treated with octreotide and deceased 2 years after diagnosis. The sixth patient had undergone central and distal pancreatectomy with splenectomy 5 years earlier due to pNET without diagnosis of insulinoma at that time and presented us with large hepatic metastases and hypoglycemia. Octreotide and peptide receptor radionucleide therapy (DOTA-TATE) were started due to hepatic hyperfixation in PET-68Ga-DOTANOC.

Discussion

In this group there was a high prevalence of malignancy, which is unusual. Time elapsed from onset of symptoms to diagnosis was highly variable. The natural history of malignant insulinoma is difficult to predict, however uncontrolled hypoglycemia, liver tumor burden exceeding 30% of liver volume, morphologic progression and Ki67 $>$10–20% are factors of poor prognosis.

EP182

Effects of ketoconazole on ACTH-producing and non ACTH-producing neuroendocrine tumor cells

Aura D Herrera-Martínez[2,3], Richard Feelders[1], Justo Castaño[2,4], Fadime Dogan[1], Peter van Koetsveld[1] & Leo Hofland[1]
[1]Department of Internal Medicine, Division of Endocrinology Erasmus University Medical Center, Rotterdam, The Netherlands; [2]Maimonides Institute for Biomedical Research of Cordoba (IMIBIC), Córdoba, Spain; [3]Endocrinology and Nutrition Service, Reina Sofia University Hospital, Córdoba, Spain; [4]Department of Cell Biology, Physiology, and Immunology, University of Córdoba, Córdoba, Spain.

Prolonged spontaneous remission of hypercortisolemia in ectopic ACTH syndrome after long-term treatment with steroidogenesis inhibitors has been described. Direct drug effect on the adrenal glands, effects on tumoral ACTH secretion and/or *POMC* gene expression have been suggested. Medical treatment could be used for symptoms, but also for disease control.

Materials and methods

In human BON-1 and DMS-79 cells, we have evaluated the effects of ketoconazole on cell growth, apoptosis, cell cycle, LDH production, POMC/-chromogranin-A mRNA expression and ACTH/serotonin secretion.

Results

In the BON-1 cells, ketoconazole significantly suppressed cell growth in a dose and time-dependent manner. Maximal inhibitory effects by 10 μM ketoconazole were 41 and 95% after 3 and 7 days ($P<0.0001$); the ratio LDH/DNA after 3 days was increased. The IC_{50} value of growth inhibition was 7.8 μM after 7 days of treatment. Ketoconazole also induced a significant G1-phase arrest accompanied by a decrease in S-phase and G2-phase, as well as a significant increase in early and late apoptosis ($P<0,01$), confirmed using an ELISA method. Ketoconazole (up to 10 μM) did not significantly affect the chromogranin-A expression or serotonin secretion (corrected for cell number). DMS-79 cells are less sensitive to ketoconazole, with maximally inhibitory effects by 50 μM ketoconazole of 44 and 94% after 3 and 7 days of treatment ($P<0.0001$). The IC_{50} value of the growth inhibitory effect was 15 μM after 7 days of treatment. The highest ketoconazole concentration (50 μM) tested induced a significant G1-phase arrest ($P<0.001$), increased number of dead cells ($P<0,001$) without significant effect on early/late apoptosis, increased total apoptosis (ELISA; $P<0.0001$), as well as the LDH/DNA ($P<0.001$). Ketoconazole up to 10 μM suppressed ACTH secretion ($P<0.01$). POMC expression did not show significant changes.

Conclusions

These results suggest a potential direct effect of ketoconazole on cell proliferation, apoptosis and cell cycle in ACTH- and non-ACTH producing NET cells. Additional studies are required to confirm and extend these results.

Treatment with (177Lu)-DOTATATE in patients with advanced metastatic somatostatin receptor-positive tumors

Antonio Ballesteros Martín-Portugués, María Isabel Del Olmo García, Pilar Bello Arqués, Ángel Segura Huerta, Rosa Cámara Gómez & Juan Francisco Merino Torres
Hospital la Fe, Valencia, Comunidad Valenciana, Spain.

Introduction

The NETTER 1 trial resulted in markedly longer progression-free survival (PFS), with preliminary evidence of an overall survival benefit. We report the results of PFS and safety of (177Lu)-DOTATATE in patients treated in our hospital between 2014 and 2016.

Methods

Transversal and descriptive study of seven patients with advanced, progressive, somatostatin receptor-positive tumors who had received previous treatments. All of them were treated in progressive disease with (177Lu)-DOTATATE. Results are expressed in average (s.d.) or percentage(%). SPSS version 2.2 was used for statistical analysis.

Results

71.4% (5) were women, with an average age of 46.4 (16.2). Histological classification was: 4 (57%) well-moderate differentiated neuroendocrine tumors (three pancreatic, one ileal), 2 (28.6%) paragangliomas and 1 (14.3%) follicular thyroid carcinoma. At the time of administration of (177Lu)-DOTATATE, all tumors were in metastatic stage. The localization of the metastasis was: bone 85.7% (6), liver 57.1% (4), lymph nodes 42.8% (3) and lungs 14.3% (1). All patients had received previous treatments: two underwent surgery exclusively, five of them several systemic therapies: one with somatostatin analogues (SA) and surgery, two only SA, one surgery, SA, temsirolimus and sunitinib, and one patient with diagnosis of metastatic follicular thyroid carcinoma, received: surgery, radioiodine, sorafenib, sunitinib, everolimus, adryamicine, and SA. 177Lu-DOTATE was infused every eight weeks in four doses, except in two patients who have received only three. At the data-cutoff date PFS was of 20.29 (7.13) months. Two patients had adverse events related to the treatment: one hematologic events (mild-moderate thrombocytopenia and anemia), and one self-limited nausea and vomiting. Death occurred in one patient after 15 months of stable disease.

Conclusions

In real world practice treatment with (177Lu)-DOTATATE not only shows benefit in advanced intestinal NETS but also in other patients with metastatic disease, previous treatments, and positive somatostatin-receptor expression it seems to have favorable results attending to PFS and safety.

Gastroenteropancreatic neuroendocrine tumors (GEP-NETs) followed in the endocrinology and nutrition service's monographic outpatient clinics of neuroendocrine tumors in hospital clínico san carlos (HCSC). Description of its characteristics and evolution

Ines Jimenez-Varas[1], Angela Amengual[1], Rona Penso[1], Anna Ortolá[2], Ane Azkutia[1], Lorea Herraiz[1], Paz de Miguel[1] & Jose Angel Díaz[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Clinico Universitario, Valladolid, Spain.

Introduction

The multidisciplinary approach of the patients with GEP-NETs is very important, having a fundamental role the participation of the endocrinologist.

Methods

Description of cases of GEP-NETs followed in the Service of Endocrinology of the SCCH from 1990 to 2016.

Results

95 patients were included, 53.7% were males, age 61.2 years (IR: 50.5–73.5). The diagnosis was incidental in 53.8%. 27.6% presented clinical secretion, from them the most frequent was carcinoid (13.8%). The median primary tumor size was 3 cm (IR: 2–4). The most frequent location was pancreas (43.2%) followed by small intestine (20%). The initial stage was 49.5% I and 39.6% IV (72% hepatic metastases). Clinic as a cause of diagnosis was significantly associated with staging (Cramer's V (V) 0.72, $P<0.05$). Chromogranin A (CrA) was high in 30% and 5-Hydroxyindolacetic in 18.7% (only 73.7 and 58.4%, respectively) were

studied. 9.4% of the patients had history of familiar syndrome. Degree of differentiation (DD) 1 and 2 (63 and 30.3%) predominated. The follow-up was 6.63 years (IR: 4.6–9.3). During that period, 30.2% of the cases were lost, with mortality rate of 17.9% of the remaining group, due to progression in 83.3% of the patients. The most frequently used treatment was surgery (39.1%). From stage IV patients 20.8% received only somatostatin analogues and 45% received more than one treatment (surgery, chemotherapy, antiangiogenic drugs, somatostatin analogues or everolimus) There was significant association between mortality and stage (V 0.42, *P* 0.04), CrA (V 0.38, *P* 0.012), presence of symptoms at diagnosis (V 0.32, *P* 0.017) and DD (V 0.41, *P* 0.02).

Conclusion

Patients followed in the endocrinology outpatients clinic are more frequently stages I and DD1 and DD2 that have been incidentally diagnosed. More than 50% of the cases were treated only with surgery or somatostatin analogues. One third of the patients had secretion.

DOI: 10.1530/endoabs.49.EP184

EP185

Descriptive and survival study of 142 cases of gastroenteropancreatic neuroendocrine tumor (GEP-NETs) diagnosed at the Hospital Clínico San Carlos (HCSC)

Rona Penso[1], Inés Jiménez-Varas[1], Angela Amengual[1], Lorea Herraiz[1], Ane Azkutia[1], Anna Ortolá[2], Paz de Miguel[1] & José Angel Díaz[1]
[1]Hospital Clinico San Carlos, Madrid, Spain; [2]Hospital Clinico Universitario, Valladolid, Spain.

Introduction

Neuroendocrine tumors (NETs) constitute a very heterogeneous group of rare neoplasms, although their incidence has increased in recent years. We describe its evolution and survival.

Methods

Retrospective study. All patients with histopathological diagnosis of GEP-NETs performed at the HCSC between 2000 and 2016 were selected, data from the medical history were included. Statistical analysis were done with SPSS.

Results

One hundred and forty-two patients, 54.9% male, mean age 60.2 years (s.d. 19.7). The median follow-up time was 3.3 years (IR: 0.78–6.33). The most frequent locations were pancreatic (28.2%) and rectal (16.2%). The tumor stage was: I 47.2%, II 4.9%, III 13.4%, IV 34.5%. The initial stage (IS) presented positive correlation with the degree of differentiation (DD) (Cramer's V 0.46, $P < 0.05$) and with levels of Chromogranin A (Cramer's V 0.37, $P < 0.05$). 12% had progression and 64% died during follow-up (72% due to tumor). Overall survival at 5 years was 69 and 53% at 10 years. There were significant differences in survival according to location, with gallbladder and colon being the lowest (0 and 38% at 5 years, respectively). DD, IS and sex were also associated with survival (at 10 years: G1 95% vs G3 14.3% $P < 0.01$, stage I 91% vs IV 28% $P < 0.01$, median males 7.5 years vs 16.9 in females *P* 0.018). These differences were maintained after multivariate analysis in the case of DD and IS.

In stage IV survival was modified according to surgical treatment (operated median 5.9 years vs non-operated 0.64 years, $P < 0.01$).

Conclusion

In our sample the overall mortality was high, despite having a low rate of progression. DD and IS were determinants of survival. In advanced stages surgical treatment improves survival significantly.

Nonfunctional adrenal incidentaloma affects central blood pressures and arterial stiffness parameters

Tolga Akkan[1], Mustafa Altay[2], Yasemin Aydogan Unsal[1], Murat Dagdeviren[2] & Esin Beyan[1]
[1]Internal Medicine, Keciören Education and Research Hospital, Ankara, Turkey; [2]Endocrinology and Metabolism, Keciören Education and Research Hospital, Ankara, Turkey.

Introduction

In recent years, it is thought that cardiovascular risk is increased in patients with nonfunctional adrenal insidentaloma (NFAI). There are not enough studies in the literature that evaluating this condition in patients with NFAI who don't have traditional cardiovascular risk factors. The aim of our study is to determine peripheral and central blood pressures and arterial stiffness in patients with NFAI who don't have traditional risk factors and autonomous cortisol release with pulse wave analysis (PWA) measurement.

Material and methods

In our cross-sectional study, we evaluated 70 participants (35 patients with NFAI and 35 healthy volunteers) without traditional cardiovascular risk factors. All participants were similar in terms of gender, age and body mass index. Measurements of peripheral and central blood pressures and PWA were made with Mobil-O-Graph PWA/ABPM device (I.E.M. GmBH, Stolberg, Germany). Radiological and biochemical data were obtained retrospectively in the NFAI group.

Results

In the NFAI group, systolic blood pressure (SBP), diastolic blood pressure (DBP), mean arterial pressure (MAP), central SBP, central DBP, peripheral vascular resistance, augmentation pressure (AP), augmentation index that corrected based on pulse rate of 75 bpm (Aix@75) and pulse wave velocity (PWV) were significantly higher than control group. We also found that PWA measurements are affected by age and the time from diagnosis to PWA measurement. There was no significant correlations between biochemical parameters and central blood pressures and arterial stiffness parameters in NFAI group.

Conclusion

In patients without traditional cardiovascular risk factors who have NFAI that known as cardiometabolically innocent, both peripheral and central blood pressures and arterial stiffness parameters are affected negatively. These patients are at risk for cardiovascular diseases.

Landscape of sporadic adrenal tumours from surgical unit – histopathological audit of 101 cases from a single centre in Poland

Anna Jodkowska[1], Maciej Sroczynski[2], Monika Sepek[2], Krzysztof Tupikowski[3] & Grzegorz Mazur[1]
[1]Department and Clinic of Internal and Occupational Diseases, Hypertension and Clinical Oncology, Wroclaw Medical University, Wroclaw, Poland; [2]Department of Minimally Invasive Surgery and Proctology, Wroclaw Medical University, Wroclaw, Poland; [3]Department of Urologic Oncology, Lowersilesan Oncology Centre, Wroclaw, Poland.

Laparoscopic surgery of adrenal tumours is widely used because of its high effectiveness, patients safety and relatively low cost. Current indications to adrenalectomy of oncological and endocrinological origin are highly accepted. However there is still lack of perfect clinical tool identifying malignant lesions. In everyday practice clinicians rely on low specific features, especially considering larger nonsecretory lesions to surgery.

To show the landscape of sporadic adrenal tumours we analysed retrospectively histopathological findings from 101 consecutive adrenalectomies performed in our centre in 71 women and 30 men of average age 57.7 years (s.d. 13.5), between 2009 and 2016 years.

There were 53 (52.47%) adenomas found; 7 (6.93%) of them secreting: 4 (3.96%)-cortisol, 3 (2.97%)-aldosterone. Pheochromocytoma occurrence was notably often-14 cases (13,86%). Adrenal cancer was found in two cases (1.98%), metastatic lesions from lung, kidney and urinary bladder in three cases (2.97%); and 1(0.99%) malignant peripherial nerve seath tumor (MPNST) derived from ganglioneuroma of adrenal gland was found. Thirteen cases (12.87%) of adrenal hyperplasia were found. In 16 cases (15.84%) the histopathological findings were classified as "various" in detail consisting of: 3 myelolipomas, 1 angiomyolipoma, 2 cysts, 6 pseudocysts or secondary posthaemorrhagic/inflammatory lesions, 1 normal adrenal tissue, 1 fatty tissue, 1 mesenteric cyst and 1 teratoma. In two cases benign adrenal lesions coincided with unilateral kidney cancer. Seventeen patients (16,83%) had previous oncological anamnesis positive, while patients with adrenal cancer had negative previous oncological anamnesis.

We observe that adrenalectomy of oncological indications is prevalent: adrenal lesions with positive previous cancer history; lesions suspected of

malignancy because of the CT morphological features. In the audit almost half of them occur benign incydentalomas. Are we overtreating, then? We conclude there is a great need of new specific clinical tools to identify malignancy in adrenal glands in everyday practice.

An elevated chromogranin A: is it always a tumor progression?-case report

Anamaria Bursuc[1], Alina Daniela Belceanu[1], Ioana Armasu[1], Mirela Tirnovan[1], Adina Manolachie[1], Felicia Crumpei[2], Delia Ciobanu[3], Letitia Leustean[1] & Carmen Vulpoi[1]
[1]Department of Endocrinology, 'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [2]Department of Radiology, 'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania; [3]Department of Pathology, 'Gr. T. Popa' University of Medicine and Pharmacy, Iasi, Romania.

Introduction

Pancreatic neuroendocrine tumors (PNET) are rare, with an incidence of 1/100,000/year. Chromogranin A (CgA) is the most valuable marker in the diagnosis and monitoring of PNET. One of the disadvantages is its low specificity and the existence of a number of processes leading to an increase in its concentration, which often results in confusion and diagnostic difficulties.

Case report

We present a 44-years-old female patient with a history of PNET-pT3NxMx-G3 surgically excised in 2007, chemotreated with 6 cycles of Gemcitabine and Capecitabine. In 2009, a left thoracotomy for lung metastasis was performed, followed by 10 cycles of chemotherapy and in 2015 the patient was diagnosed with a recurrence of PNET which required atypical pancreatectomy. Immunohistochemistry revealed intense positive markers: NSE, chromogranin, synaptophysin CD56 and ki67 = 3%. The subsequent evaluations showed normal biological (CgA, serotonin, 5HIAA) and morphological (thoraco-abdominal CT) parameters until 2016, when CgA level was 7-fold higher that the upper normal value (545 ng/ml vs 76 ng/ml) but with normal thorax and abdomino-pelvic CT. As the patient took moderate doses (40 mg/day) of Omeprazole 6 months for gastroesophageal reflux disease, iatrogenic elevation of CgA was suspected. After cessation of proton pump inhibitors (PPIs) therapy for 1 week, serum CgA level rapidly decreased to 66 μg/l ($N < 100$ μg/l).

Conclusions

In this case, the elevated CgA raised the suspicion of a new recurrence which required further investigations. PPIs may cause serious differential diagnostic problems with elevation of serum CgA especially in suspected neuroendocrine tumors. An interesting phenomenon highlighted by this case is the report of rapid normalization of CgA after withdrawal of PPI. Giving particular attention to the use of PPIs as a possible cause for elevated CgA levels might help to prevent the need for further diagnostic procedures.

An unknown giant neuroendocrine tumor

Nabila Rekik, Dorra Ghorbel, Fatma Mnif, Mahdi Kalthoum, Houcem Mrabet, Nadia Charfi, Hamza Elfekih, Mouna Mnif & Mohamed Abid
The Department of Endocrinology and Diabetology of Hedi Chaker Hospital in Sfax, Sfax, Tunisia.

Introduction

Neuroendocrine tumors may develop in almost any organ. These types of tumors may present with giant and asymptomatic mass. We describe a case of a large non functional neuroendocrine tumor reported in the department of endocrinology and diabetology of Hedi Chaker hospital in Sfax-Tunisia in 2016.

Presentation of case

A 28 years old male presented with asthenia, gastric heaviness and epigastric pain. Further computerized tomography, a large mass (20 cm) near the stomach in the coeliomesenteric region has been demonstrated. Magnetic Resonance Imaging has showed the presence of a voluminous encapsulated mass with abundant vascularization and central necroses, measuring 18.5 cm × 14.5 cm compressing the vascular structures. The dosage of methoxylated plasma derivatives was negative. The dosage of NSE was returned positive at 30.5 ng/l. The biopsy of the mass showed a histological and immunohistochemical aspect of a neuroendocrine tumor. The therapeutic decision was to start with exploratory laparotomy and tumor excision if possible. Because of the vascularized character and significant bleeding during the intervention, a surgical abstention was decided. The patient had two chemoembolization sessions with good tumor response. It is being evaluated for possible re-intervention.

Conclusion

The incidence of neuroendocrine tumors has been increasing during the last decade, underscoring the need to improve our understanding of their biology and behavior especially.

A challenging case of metastatic paraganglioma and metastatic melanoma and prolactinoma

Rehmat Karim[1], Kamrudeen Mohammed[1], Najeeb Zaheer Shah[1] & Muhammad Fahad Arshad[2]
[1]Hull Royal Infirmary, Kingston Upon Hull, East Yorkshire, UK; [2]Doncaster Royal Infirmary, Doncaster, South Yorkshire, UK.

Background

Paragangliomas are extremely rare endocrine tumours and can cause diagnostic difficulty, especially with a coexistent metastatic malignancy.

Case

A 78-year-old man with diagnosed metastatic melanoma underwent a PET scan for staging of the malignancy. It showed a left upper quadrant mass with multiple skeletal deposits and a lesion in the pituitary all with intense focal uptake. The mass was unusual for a metastatic lesion from melanoma although other lesions, including pituitary could be explained by metastatic melanoma. A biopsy of the abdominal mass showed histological features of a paraganglioma; 24-h urinary catecholamines showed raised noradrenaline 1474 nmol/24 h (70–550 nmol/24 h), dopamine 6277 nmol/24 h (400–3000 nmol/24 h) and a normal adrenaline < 21 nmol/24 h (0–190 nmol/24 h) confirming a functional paraganglioma. The diagnosis of the skeletal lesions was unclear, and a 123-MIBG scan showed increased activity at the skeletal lesions but no avidity at pituitary confirming skeletal metastases from the paraganglioma with no definite explanation for the pituitary lesion. An MRI pituitary showed diffuse enlargement of pituitary gland with fossa expansion indicating chronicity and suggestive of prolactinoma rather than metastasis as his prolactin was 9400 mU/l and rest of his pituitary function was normal. He had no symptoms of diabetes insipidus. Resection of the paraganglioma was performed after preoperative alpha and beta blockade. His post-operative catecholamines normalised and post operative PET scan has shown stable appearance of skeletal lesions. He was started on Cabergoline for his prolactinoma and referred for chemotherapy for the metastatic skeletal lesions.

Conclusion

Metastatic paragangliomas in patients with a separate existing metastatic malignancy provides a diagnostic and management challenge. With a structured approach to investigation and management the clinical picture can be clarified, which then facilitates appropriate intervention.

Biology and differential diagnosis of calcitonin secreting neuroendocrine tumors

Bojana Popovic, Djuro Macut, Valentina Elezovic Kovacevic, Tatjana Isailovic, Ivana Bozic Antic, Tamara Bogavac, Dusan Ilic, Sanja Ognjanovic, Gordana Rodic, Milan Petakov & Svetozar Damjanovic
Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia.

Introduction
Calcitonin secreting neuroendocrine tumors (NET) are rare and not well recognized. Due to many similarities, it is sometimes difficult to differentiate them from medullary thyroid carcinoma (MTC), which can hamper choice of proper therapy. We investigated our group of patients with this type of NET in terms of diagnosis and biology.
Patients and Methods
We analyzed 38 patients with calcitonin secreting NET (5% of all our patients with NET). In addition to standard work up, calcium-stimulation test for calcitonin was performed in 15 of them, and results compared to 34 patients with MTC, and 21 control subjects with elevated calcitonin level and thyroid pathology other than MTC. Statistical analysis was done with SPSS software.
Results
Primary localization of NET was lung (16), pancreas (12), unknown primary (8) and intestine (2), with majority (54.1%) being grade G3, and high majority being metastatic (94.7%). Majority (55.6%) had goiter and 26.3% concomitant TPOAb, while 28.9% co-secreted another hormone (ADH, insulin, serotonin, PTHrP). Patients with NET had significantly higher basal calcitonin levels compared to controls (P(0.01), but with no significant difference compared to patients with MTC ($P=0.427$). Unlike this, patients with NET achieved significantly lower calcitonin levels after calcium stimulation compared to patients with MTC (P(0.01), but no different compared to controls ($P=0.102$). There was no significant correlation between basal calcitonin level and presence of TPOAb ($P=0.816$) or goiter ($P=0.670$) in these patients. Their median overall survival was 24.0 months (95% CI 10.9–37.1).
Conclusion
Patients with calcitonin secreting NET can secrete very high calcitonin levels, but can be differentiated from patients with MTC by absence of significant response to stimulation with calcium. Survival of these patients is poor, but influence of calcitonin on survival is yet to be determined.

EP192

Cancerous neuroendocrine vs endocrine tumours: broad commonalities and differences

Nicola Jervis & Catherine Bouvier
NET Patient Foundation, Leamington Spa, UK.

Endocrine cancers are defined, by European Taskforce on Endocrine Cancer, as malignant tumours arising from endocrine organs including thyroid, adrenal, parathyroid, pituitary, as well as neuroendocrine tumours in general. Cancerous neuroendocrine tumours arise from neuroendocrine cells which can be found within the endocrine system: in the pituitary, pineal, parathyroid and (medulla of the) adrenal gland, or more scantily within the thyroid, pancreas, ovaries and testicles, or more diffusely throughout the body, being present in respiratory, urinary and digestive tracts, as well as breast, skin, prostate and gynaecological structures.
Neuroendocrine and most endocrine cancers are considered both rare and complex.
Commonalities exist in terms of gross classification, that is, designation by site, cell type and whether they are associated with excess hormone/peptide secretion – differences are revealed as this broad definition narrows.
For example: within the adrenal gland:
Endocrine – adrenocorticol carcinoma (ACC) arises within the cortex, and may be associated with excess secretion of steroidal hormones. TNM staging.
Neuroendocrine – pheochromocytoma arises within the medulla, and may be associated with the overproduction of catecholamines. No standardised staging and malignancy designation may be withheld in the absence of metastatic disease, though presentation, family history and proliferation rate will influence treatment planning and follow-up.
Both may be associated with inherited disorders such as multiple endocrine neoplasia, therefore careful history taking and consideration of genetic counselling (Table & diagram of sites, cell type and associated hormone).
Accurate identification of disease site, cell type and associated hormone secretion is paramount in delivering optimal clinical care – evidence based guidelines are available for most neuro/endocrine tumours - but consideration should also be given to meeting the psychosocial and informational needs of the individual diagnosed with one of these rare cancers.

Short-term contralateral recurrence of a Litynski–Conn adenoma

Agnieszka Kuzior[1], Manuel Nivelo-Rivadeneira[1], Ana Delia Santana-Suarez[1], Claudia Arnas-Leon[1], Carmen Acosta-Calero[1], Sara Quintana-Arroyo[1], Marta Martin-Perez[2] & Francisco Javier Martinez-Martin[1]
[1]Division of Endocrinology and Nutrition, Doctor Negrin University Hospital of Las Palmas de Gran Canaria, Las Palmas de Gran Canaria, Spain; [2]Primary Care Center of Guia, Doctor Negrin University Hospital of Gran Canaria, Las Palmas de Gran Canaria, Spain.

Clinical Case
A hypertensive 60-year-old woman with nephroangiosclerotic stage IV chronic renal failure (eGFR 23.44 ml/min/1.73 m^2) was referred to our hypertension clinic after the CT finding of a 26-mm left adrenal mass with adenoma density during hypertension workup, with normal right adrenal. Physical exam was unremarkable except for BP 167/98 mmHg. Plasma aldosterone was 353 ng/ml, PRA 1.3 ng/ml/h, ratio 90.2, K^+ 3.1 mEq/l, and metanephrines were normal. Primary aldosteronism was confirmed by standard captopril test. Adrenal vein sampling showed full left lateralization of aldosterone secretion. The patient underwent laparoscopic adrenectomy, and a 21-g left adrenal -including a 4-cm adenoma with clean margins- was removed. One month after surgery, K^+, aldosterone and ARP were normal, and BP was controlled with manidipine 20 mg.
One year later, BP and plasma K^+ were still controlled but the patient showed again a pattern of primary aldosteronism with aldosterone 747 ng/ml, PRA 0.9 ng/ml/h, ratio 83.0. A new CT showed absent left adrenal, and a 17×11 mm mass in the right adrenal, with adenoma density. Low-dose (12.5 mg) spironolactone was added to the treatment, but surgery was deferred.
Diagnosis
Primary aldosteronism caused by aldosterone-producing adenoma (Litynski–Conn syndrome), with contralateral recurrence after one year. Secondary hypertension with nephroangiosclerotic stage IV chronic renal failure.
Commentary
Contralateral recurrence of an aldosterone-producing adenoma in a previously normal adrenal after a complete surgical removal is exceedingly rare, particularly after such a short follow-up. The differential diagnosis would include familial type II aldosteronism (as types I and III usually cause severe hypertension in the pediatric age and associate normal or bilaterally hyperplastic adrenals but not adenomas, while type II may associate adenomas in adult patients) but as there is no known genetic marker for this condition, confirmation is not possible at this point.

Acinic cell adenocarcinoma of the parotid gland associated with paraneoplastic Cushing's syndrome – a rare clinical case

Sofia Castro Oliveira[1,2], João Sérgio Neves[1,2], Pedro Souteiro[1,2], Sandra Belo[1,2], Ana Isabel Oliveira[1,2], Celestino Neves[1,2], Paula Freitas[1,2] & Davide Carvalho[1,3]
[1]Department of Endocrinology, Diabetes and Metabolism of São João Hospital Center, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal.

Introduction
Primary acinic cell carcinoma (ACC) is an uncommon salivary gland (SG) tumor, making up 1–3% of all SG neoplasms, more frequent in women, at 40–60 year old. The cause is still unknown and the only well-established risk factor is

ionizing radiation. ACC metastasize in 10–15% of the cases, 35% tends to recur and the rate of disease-associated death is about 16%. Surgical resection is the mainstay treatment, but radiation therapy may be used in some cases and, more rarely, chemotherapy in advanced ACC.
Case Report
We describe a case of a 46-year-old man referred by paresthesias, general malaise and hypokalemia of 2.5 mEq/l. The patient had a history of pericentimetric nodule in the left submandibular gland diagnosed 1 year before, hypertension and dyslipidemia diagnosed 4 months before and also new-onset diabetes mellitus (DM) diagnosed in the previous month. Ambulatory analysis showed endogenous hypercortisolism, and he was admitted to the endocrinology department for further investigation. Hormonal study revealed: ACTH 206.8 (<63.3) ng/l, cortisol 30.1(6.2–19.4) μg/dl; cortisoluria, 24-hour salivary cortisol and low-dose dexamethasone suppression test confirmed Cushing's syndrome(CS); high-dose dexamethasone suppression test was compatible with ectopic CS. Initial imaging study found several hepatic nodular lesions, suggestive of secondary lesions by neoplastic process. Investigation was continued, with imaging and cytological documentation of probable primary parotid malignancy with hepatic metastasis. Octreoscan revealed increased uptake in the parotid gland and mild expression in hepatic metastasis. No uptake was observed in PET-Gallium. The patient underwent right parotidectomy, with the histological diagnosis of ACC, pT3NxR1, with no neuroendocrine differentiation, Ki67 70%. Imaging reevaluation revealed disease progression, with pulmonary and bone metastasis, and the patient started chemotherapy. Meanwhile, hypercortisolism was controlled with metyrapone (3 g/day), ketoconazole (400 mg/day) and lanreotide (120 mg/month).
Conclusion
The authors present a very rare case of ACC, with paraneoplastic CS and aggressive behavior, presenting significant diagnostic and management challenges.

EP195

Malignant pheochromocytoma – a challenging diagnosis with nonconsensual management

Sofia Castro Oliveira[1,2], João Sérgio Neves[1,2], Pedro Souteiro[1,2], Eva Lau[1,2], Ana Isabel Oliveira[1,2], Celestino Neves[1,2], Paula Freitas[1,2] & Davide Carvalho[1,3]
[1]Department of Endocrinology, Diabetes and Metabolism of São João Hospital Center, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Instituto de Investigação e Inovação em Saúde, University of Porto, Porto, Portugal.

Introduction
Pheochromocytomas and extra-adrenal paragangliomas are rare neuroendocrine tumors, with a peak incidence between the 3rd–5th decades of life and about 10% are malignant. Although they have the same radiographic and histologic characteristics of their benign counterpart, malignant pheochromocytomas are diagnosed by the presence of local invasion or metastatic tumor in the non-chromaffin tissues, and offer a poorer prognosis. Treatment is typically extirpative surgery, although MIBG-radiotherapy and chemotherapy have been offered in nonsurgical cases.
Case Report
An 83-year-old man with history of diabetes mellitus and hypertension presented abdominal pain, anorexia and weight loss. An abdominal CT revealed a large, hypocaptant and heterogenous neoformative lesion of left adrenal gland, 48× 58 mm, and adjacent metastatic adenomegaly with 18 mm. He was then referred to our Endocrine Department. Imaging study was repeated and revealed an additionally left renal mass, on the posterior face, exophytic, with 40×13× 38 mm, suspected for metastasis. Biochemical diagnosis of pheochromocytoma was established by a marked increase of urinary catecholamines and fractionated metanephrines: norepinephrine 1222 (<97) μg/24 h, epinephrine 106 (<27) μg/24 h and dopamine 1166 (<500) μg/24 h; normetanephrines 3711 (<390) μg/24 h and metanephrines 1226 (<320) μg/24 h; vanillylmandelic acid (VMA) was 29.3 (1.4–6.5) mg/24 h. ^{123}I-MIBG scintigraphy was performed and evidenced left adrenal gland lesion compatible with pheochromocytoma, without uptake on left renal mass. The patient started alpha-adrenergic blockade with phenoxybenzamine (10+10 mg/day) and 6 weeks later underwent exploratory laparotomy surgery, with left adrenalectomy and nefrectomy. Histological examination confirmed malignant pheochromocytoma diagnosis and the patient maintains close surveillance.
Conclusion
Malignant pheochromocytomas present clinicians with three major challenges: scarcity, complexity of characterization, and heterogeneous behavior and prognosis.

Identification of molecular targets of Sunitinib in pancreatic neuroendocrine tumours

Giulia Bresciani[1], Teresa Gagliano[1], Leo J Hofland[2], Erica Gentilin[1], Simona Falletta[1], Eleonora Riva[1] & Maria Chiara Zatelli[1,3]
[1]Section of Endocrinology, Department of Medical Sciences, University of Ferrara, 44121 Ferrara, Italy; [2]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands; [3]Laboratorio in Rete del Tecnopolo Tecnologie delle Terapie Avanzate (LTTA), University of Ferrara, 44121 Ferrara, Italy.

Pancreatic neuroendocrine tumours (pNETs) are rare neoplasms arising from the endocrine pancreas. The fist line treatment is surgery that is often not curative in the presence of metastatic disease. Therefore, there is an increasing need for medical therapy. Sunitinib is a multi-target receptor tyrosine-kinase (RTK) inhibitor, described as having as main target VEGF receptor, with antitumor and antiangiogenic effects, approved for pNETs medical treatment. This study is aimed at evaluating Sunitinib effects in the human pNET cell line, BON1, in order to identify tissue-specific molecular targets that might predict the efficacy of the treatment. We tested BON1 cell viability and proliferation by means of Proliferation Assay and Luminescent Cell Viability Assay after treatment with Sunitinib (0.25–7.5 μM) and found an IC50=5 μM. Western blot analysis confirmed that BON1 cells express VEGF, IGF1 and EGF receptors, therefore we tested the effects of VEGF 50 ng/ml, IGF1 100 nM and EGF 15 nM alone or each in combination with Sunitinib 5 μM. We found that BON1 cell viability is not affected by VEGF and EGF, while it is significantly enhanced by IGF1 (+20%; $P<0.05$), that was capable of blocking the antiproliferative action of Sunitinib, suggesting that the main target of this drug is IGF1 receptor. Therefore, we tested Linsitinib, a specific IGF1 receptor inhibitor, and found that it significantly reduces BON1 cell viability (−25%; $P<0.05$) and blocks the proliferative effects of IGF-1. These data indicate that IGF1 receptor represents the main molecular target of Sunitinib in BON1 cells and that it may play a crucial role in pNET cell proliferation control, suggesting that Linsitinib might be an effective medical treatment.

EP197

Study of different *in vitro* systems for the evalutation of Sunitinib effects in pancreatic neuroendocrine tumour cells

Giulia Bresciani[1], Teresa Gagliano[1], Leo J Hofland[2], Erica Gentilin[1], Simona Falletta[1], Eleonora Riva[1] & Maria Chiara Zatelli[1,3]
[1]Section of Endocrinology, Department of Medical Sciences, University of Ferrara, 44121 Ferrara, Italy; [2]Department of Internal Medicine, Erasmus Medical Center, Rotterdam, The Netherlands; [3]Laboratorio in Rete del Tecnopolo Tecnologie delle Terapie Avanzate (LTTA), University of Ferrara, 44121 Ferrara, Italy.

Finding new preclinical models to study the effects of anticancer drugs is one of the aims of biomedical research. Indeed, testing different *in vitro* systems can lead to a better understanding of the molecular pathways regulating tumor development and growth, and help to find new therapeutic approaches. This is crucial especially in the settings of pancreatic neuroendocrine tumours (pNET), where one of the main drugs approved for medical treatment is Sunitinib, a multi-targeted receptor kinase inhibitor. Clarifying the effects of this drug may be important to develop more effective medical treatment, therefore we tested Sunitinib on the human pNET cell line, BON1, grown in two different *in vitro* systems, monolayer and spheroid, in order to understand the different effects of the drug in 2D and 3D settings.

BON1 cells were grown in monolayer and treated with Sunitinib at increasing concentrations (0.25–5 μM). Cell Proliferation Assay and Luminescent Cell Viability Assay were employed to test Sunitinib antiproliferative effects. We found that Sunitinib 5 μM significantly reduced BON1 cell viability by 30% ($P<0.01$ vs control) after 3 days. Similarly, Sunitinib 5 μM significantly reduced BON1 cell proliferation by 50% ($P<0.05$ vs control) after 3 days and by 90% ($P<0.05$ vs control) after 7 days.
Then, BON1 cells were grown in spheroids with Sunitinib at increasing concentrations (0.25–5 μM). Spheroids size was analyzed with ImageJ software after 3 and 7 days. We found that Sunitinib does not affect spheroid size, but induces spheroid disgregation after 7 days of treatment at 5 μM.
These results indicate that measuring spheroid diameter in a 3D system is not the optimal system to assess the antiproliferative effects of Sunitinib on BON1 cells. On the other hand, the differences observed between the employed models could reflect the variations in drug response depending on cell aggregation state.

Von Hippel–Lindau syndrome: *in vivo* portrait with 68Ga-DOTANOC PET-CT

Ana Paula Moreira[1,2], Gracinda Costa[1,3] & João Pedroso de Lima[1,2]
[1]Centro Hospitalar e Universitário de Coimbra (Nuclear Medicine Department), Coimbra, Portugal; [2]Instituto de Ciências Nucleares Aplicadas à Saúde – Universidade de Coimbra (ICNAS-UC), Coimbra, Portugal; [3]Faculdade de Medicina da Universidade de Coimbra, Coimbra, Portugal.

Introduction
Von Hippel–Lindau syndrome (VHL) is an autosomal dominantly inherited neoplastic disorder with marked phenotypic variability, characterized by a broad spectrum of clinical manifestations in central nervous system (CNS) and viscera. Specific gene mutation can be demonstrated; however imaging plays an important role in diagnosis. 68Ga-labelled somatostatin analog (68Ga-DOTANOC) PET-CT is routinely employed for somatostatin receptor (SSTR) imaging, mainly for neuroendocrine tumors evaluation, but could be an optimal whole body imaging method for screening and follow-up VHL patients.
Purpose
To present 68Ga-DOTANOC-PET-CT findings in three VHL female patients (58, 58 and 65 years old), demonstrating both CNS and visceral tumors.
Material and Methods
68Ga-DOTANOC-PET/CT scan was acquired 45 min after intravenous administration of 100–200MBq 68Ga-DOTANOC in three patients with VHL referred for pancreatic neuroendocrine tumor (PNET) evaluation. Abnormal findings were correlated with histopathology or other imaging modalities (CT, MR, ophthalmoscopy).
Results
68Ga-DOTANOC-PET/CT showed, in all patients, other lesions than PNET, which proved to be related to VHL. Retinal and spinal cord hemangioblastomas were detected in two patients. Endolymphatic sac tumor was demonstrated in one. Lung hemangioblastoma was suspected in one. Liver and lymph node metastasis were present in one patient. Two patients had a pheocromocytoma previously removed by surgery.
Discussion
In VHL diagnosis a multidisciplinary approach is mandatory. Although genetic testing is available, imaging plays a key role in the identification of abnormalities, their follow-up and in the screening of asymptomatic gene carriers. Several analytic and imaging modalities are needed for diagnosis and follow-up. Screening is essential because the lesions in VHL disease are treatable. Early detection enables more conservative therapy and may enhance the patient's length and quality of life. In these three VHL patients, 68Ga-DOTANOC-PET-CT has demonstrated to be a promising whole-body screening high-resolution imaging method for evaluation of the entire picture of this disease.

Gastroenteropancreatic neuroendocrine tumors (GEP-NETs): clinico-pathological characteristics and disease outcome of 110 patients treated at single referral medical center

Shlomit Koren[1], Karen Or[1], Miri Steinschneider[1], Esther Kummer[1], Nirit Yarom[2,6], Haim Shirin[3,6], Ron Lavy[4], Gratiana Gratiana[5,6] & Carlos Benbassat[1,6]
[1]Department of Endocrinology, Asaf Harofe Medical Center, Zeriffin, Israel; [2]Department of Oncology, Asaf Harofe Medical Center, Zeriffin, Israel; [3]Department of Gastroenterology, Asaf Harofe Medical Center, Zeriffin, Israel; [4]Department of Surgery, Asaf Harofe Medical Center, Zeriffin, Israel; [5]Department of Pathology, Asaf Harofe Medical Center, Zeriffin, Israel; [6]Sackler School of Medicine, Tel Aviv University, Tel Aviv, Israel.

Introduction
GEP-NETs incidence increased markedly over the past decades probably due to increased imaging. GEP-NETs are generally indolent but often have unpredictable biological behavior and aggressive clinical course.
Aims
To collect information regarding demographics, presentation, pathology characteristics, treatment and outcome of GEP-NETs.
Methods
Following approval of our institutional ethical board, pathology and clinical records of all GEP-NETs patients diagnosed and treated at our institution during 2005–2015 were reviewed.
Results
We identified 110 patients with GEP-NETs distributed by site as pancreatic 32 (F=45.1%, age 61.2±6.8), gastric 19 (F=50%, age 66.2±11), duodenum 9 (F=33.3%, age 66.3±12), small bowel 13 (F=25%, age 60±12), appendix 34 (F=55.8%, age 36±19) and colorectal 3. The pNETs presented with abdominal pain (45.1%) incidentally (25.8%) or syndromatic (21.8%); including two insulinomas, one gastrinoma and four MEN1 patients. Mean size was 31±23 mm and grading was G1 39.2, G2 42.8, G3 17.8%. Distant metastases (DM) were seen in five patients (M1=3). Surgery was performed in 61.3%, additional treatment given to 32.2% (re-op, somatostatin analogue, TKI, chemotherapy). The gNETs presented mostly during work-up for anemia or GI bleeding (70.6%). Mean size was 15 mm and the majority (82.3%) were GCT1 and there were no DM. The dNETs presented with anemia (43%), abdominal pain (43%) or incidentally. None was syndromatic. Mean size was 11.2 mm, 50% were G1, and 2 had DM at presentation. Surgery was performed in 33.3% patients. The sbNETs presented with bowel obstruction (27%), abdominal pain (36%) or incidentally. None were syndromatic. Only 15% were G1, 6 had DM (M1=5), and 77% had surgery. Excluding aNETs, the overall mortality at last visit was 23.7% (7.9% disease related) at mean follow-up of 34.5 months.
Conclusion
GEP-NETs are associated with significant morbidity and mortality. The primary site of the tumor has clinical implication for disease management.

Insulinoma: diagnostic features and treatment management

Liana Khacimova[1], Tatiana Karonova[1,2], Uliana Tsoy[1], Liubov Ianevskaia[1] & Elena Grineva[1,2]
[1]Federal Almazov North-West Medical Research Centre, Saint-Petersburg, Russia; [2]Pavlov First Saint Petersburg State Medical University, Saint-Petersburg, Russia.

Backgraund
Insulinoma is the most common functional pancreatic neuroendocrine tumor originating from β-cells, with unregulated insulin production and rarely associated with MEN-I syndrome. Diagnosis and treatment of insulinoma are a challenge in the practice of endocrinologist.
Aim
To determine on the basis of retrospective analysis the optimal approaches to the management of patients with organic hyperinsulinism.
Materials and methods
Medical records of 72 patients admitted with suspected organic hyperinsulinism had been screened and medical histories of patients with a confirmed diagnosis of organic hyperinsulinism were included into the analysis. Anamnesis, results of objective, laboratory and instrumental examinations, methods and results of the treatment were analyzed.
Results
The diagnosis of insulinoma was confirmed in thirty two cases. Hypoglycemia was achieved within the first 48 h after the start of the 72-h fasting test in 100% of cases. Study results showed that in 50% of cases the size of the pancreatic neoplasm was more than 1.4 cm. Inverse correlation between tumor size and plasma glucose concentration at the time of hypoglycemia was found ($r=-0.45$,

$P=0.02$). Surgical treatment was carried out in thirty out of 32 patients. Surgical enucleation of insulinoma was performed in 12 (40%) cases, distal pancreatectomy – in 18(60%). Insulinoma was confirmed in 27 cases, while in three patients diagnosis of non-insulinoma pancreatogenous hypoglycemia ('nesidioblastosis') was established according to histological findings. Positive clinical result was achieved after all surgeries. In postoperative period patients were discharged within 11–30 days. Patients without post-operative complications were discharged 13.0 ± 1.4 days after surgery. Twelve (40%) patients developed post-operative complications. The duration of hospital stay in these cases was significantly longer 20.1 ± 1.9 ($P<0.01$).

Conclusions

Obtained data confirmed that comprehensive approach including 72-h fasting test, use of modern imaging techniques and application of high-tech treatment methods, is crucial for successful diagnosis and treatment of insulinoma.

EP201

A rare case: non-islet cell tumor hypoglycemia with adrenal insufficiency

Veysi Asoglu[1], Mehmet Celik[2], Buket Yilmaz Bulbul[2], Semra Ayturk[2], Funda Ustun[3] & Sibel Guldiken[2]
[1]Department of Internal Medicine, Medical Faculty, Trakya University, Edirne, Turkey; [2]Department of Endocrinology and Metabolism, Medical Faculty, Trakya University, Edirne, Turkey; [3]Department of Nuclear Medicine, Medical Faculty, Trakya University, Edirne, Turkey.

Non-islet cell tumor hypoglycemia (NICTH) is a rare paraneoplastic syndrome and is the second most common cause of tumor-related hypoglycemia following insulinoma. Its prevalence is not known and is likely that many cases would go undiagnosed. In here, we describe a patient with PNET who presented with severe hypoglycemia.

A 37-year-old male with known metastatic Pancreatic neuroendocrine tumors (PNET) presented with weight loss, sweating, and tremor, episodic altered sensorium. He had documented blood glucose values below 35 mg/dl during those episodes. He received two cycles of lutetium therapy and was referred to our institute. At blood glucose of 33 mg/dl, he had undetectable plasma insulin ($\leq$0.19 mU/l), low C-peptide 0.159 ng/ml (normal: 0.8–4), cortisol: 5.6 µg/dl (n:5–29), GH: <0.05 ng/ml and low IGF1 <25 ng/ml (normal: 109–284 ng/ml). ACTH: 60 pg/ml (normal: 0–46), Na: 136 mmol/l (normal: 132–146), K: 4.2 mmol/l (normal:3.5–5.5), TSH 1.274 uIU/ml (n: 0.35–4.94), FT_4: 1.47 ng/dl (n:0.7–1.48), FT_3: 2.6 pg/ml (n: 1.71–3.81), prolactin: 8.28 ng/ml (n:2.1–17.7), LH: 5.08 IU/l (1.5–9.3), FSH: 10.22 IU/l (n:1.4–18.1), testosterone: 405.78 ng/dl (n:241–2270). Magnetic resonance imaging of pituitary gland was normal. We were started prednisolone 30 mg/day with which his symptoms abated. After prednisolone treatment, there was no recurrence of hypoglycemia on follow-up. In NICTH patients, the serum levels of insulin, C-peptide, and IGF1 are usually decreased or undetectable; however, the circulating level of total IGF2 as determined by conventional immunometric or receptor assays may be increased, decreased, or normal. In the absence of IGF2 assays, low serum insulin in combination with low IGF1 levels at the time of hypoglycemia is a strong biochemical evidence of NICTH. High-dose glucocorticoid therapy has immediate beneficial effect on symptomatic hypoglycemia.

Late manifestation of a mixed adenoneuroendocrine carcinoma of the cecum

Paraskevi Kazakou, Xakousti Tzamali, Alexis Travlos, Evangelia Vogiatzi, Georgia Ntali, Vasiliki Sarantopoulou & Antonis Polymeris
Department of Endocrinology, Alexandra General Hospital, Athens, Greece.

Introduction

Mixed adenoneuroendocrine carcinoma (MANEC) is a rare tumor of the gastrointestinal tract that consists of a dual adenocarcinomatous and neuroendocrine differentiation. The clinical behavior seems to be influenced by the neuroendocrine component. We report a patient with mixed adenoneuroendocrine carcinoma of cecum who presented 18 years after her initial diagnosis and treatment.

Case report

A 59-year-old woman presented with a 3-month history of episodic hypotension, tachycardia and face and upper trunk flushes. She had a history of cecum tumor resection 18 years ago. It was a poorly differentiated mixed adenoneuroendocrine carcinoma. The tumor extended in the pericolic adipose tissue with perineural and lymphonodular invasion. It was TNM stage IIIB (T3N1M0). Postoperatively, she received interferon and 5-fluoracil chemotherapy for 6 months.

The patient was asymptomatic for 18 years until symptoms of carcinoid syndrome (CS) appeared. Serum chromogranin A and 24-h urine 5-hydroxy-indole-acetic-acid (5-HIAA) were abnormally high. An abdominal magnetic resonance imaging revealed multiple metastatic liver lesions confirmed by biopsy. In111-pentetreotide scintigraphy detected the lesions in the liver and others in the left shoulder and the right sternum-clavicle joint. Bone lesions were also demonstrated by Tc-99m DTP scan. Octreotide LAR 30 mg per month was initiated and resulted in amelioration of symptoms. Chromogranin A and 5-HIAA decreased but remained above normal range. The symptoms of CS reappeared after 2 years and the patient received 9 cycles of targeted radiotherapy (177Lu-Dotatate), which finally resulted in clinical and imaging improvement.

Conclusion

We report a rare case of a patient with a mixed adenoneuroendocrine carcinoma of the cecum who presented with metastatic disease and carcinoid syndrome 18 years postoperatively. Due to the rarity of these tumours and the unknown natural history, lifelong follow up is required.

EP203

Quality of life in patients with neuroendocrine tumors treated with 177Lu-[DOTA^0,Tyr^3]-octreotate: a Single Tertiary Care Portuguese Center Experience

Adriana Lages, Helder Moreira, Gracinda Costa, Patrícia Oliveira, Diana Oliveira, Diana Martins, Mara Ventura, Nelson Cunha & Francisco Carrilho
Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction and purpose

177Lu-[DOTA^0,Tyr^3]octreotate (177Lu-DOTA-TATE) is a radiopharmaceutical frequently used in peptide receptor radionuclide therapy (PRRT), which is a promising treatment modality in patients with metastasized neuroendocrine tumors (NETs). We purpose to evaluate the quality of life (QoL) in patients with somatostatin receptor positive inoperable or metastatic NETs throughout the three cycle's (with three months intervals) protocol used in our hospital.

Patients and methods

We included 24 patients, 16 men and 8 women (age: mean = 67 years; range = 29–81). The majority (13/24 cases; 54.2%) were gastroenteropancreatic NETs. Patients were treated with a mean cumulative 177Lu-DOTA-TATE activity of 614 mCi (range: 303–1177 mCi).

Patients were invited to self-report QoL during PRRT cycles. We analyzed the overall QoL and specific domains of QoL according to the Organization for the Research and Treatment of Cancer Quality of Life Questionnaire C30 (EORTC QLQ-C30) scoring manual.

Results

From 24 patients, 15 completed at least 2 copies of the EORTC QLQ-C30 at different time-points (during the 1st or 2nd cycle and during the 3rd). Twelve patients had progressive disease, eleven had stable disease and one had notable lesions regression during PRRT.

Regardless the treatment outcome, Global Health Status/QoL (GHS/QoL) and all the functional scales (except social status) improved significantly in all group ($P<0.05$). On GHS/QoL, we found an improvement on scores superior to 10 points before vs after therapy ($\Delta +10.56$; $P=0.003$).

Besides GHS and functional scales, we observed also a favorable impact on disease-related symptoms as fatigue ($P=0.00003$), insomnia ($P=0.0003$), appetite loss ($P=0.0003$), constipation ($P=0.033$) and diarrhea ($P=0.014$).

Conclusions

A better health-related QoL in cancer patients with incurable disease is an important outcome of cancer therapy, especially when survival is prolonged. Therapy with 177Lu-DOTA-TATE significantly improved QoL regarding to several functions and had favorable impact on global health status even on those with progressive disease.

Triple tumors in a patient with insulinoma

Urska Ksela & Mitja Krajnc
UKC Maribor, Maribor, Slovenia.

Introduction
Hypoglycemia is a rare clinical problem in patients not being treated for diabetes mellitus and requires further evaluation and management if Whipple's triad is present. Insulinoma commonly presents with fasting hypoglycemia. Insulinoma is rarely associated with type 1 multiple endocrine neoplasia, when tumors are usually multiple and more frequently malignant. The diagnosis of insulinoma is established by demonstrating inappropriately high serum insulin concentrations during a spontaneous or induced episode of hypoglycemia, e.g. 72-h fast.
Patient
46-years old female was referred to our department for evaluation of spontaneous fasting hypoglycemia. She had multiple episodes of temporary probably neurohypoglycemic symptoms (confusion, unusual behaviour) and gained a lot of weight in 2016 (+20 kg). Before the beginning of 72-h fast her serum glucose was 1.8 mmol/l, insulin concentration 20.6 mcU/ml, C-peptide 1.2 nmol/l. Testing was stopped after 6 h due to very low glucose levels (1.5 mmol/l) but without any obvious symptoms of hypoglycemia, insulin was high. After glucagone 1 mg i.v. glucose increased for 1.5 mmol/l. Her serum calcium, iPTH, prolactin and IGF-1 were normal. CT showed 1.8 cm lesion in the pancreatic neck and also unusual lesion in proximal jejunum that appeared to be a neuroendocrine tumor. There was also typical teratoma in left ovary (maximal size 6.6 cm), also seen on US. The patient underwent operation – partial pancreatectomy, proximal jejunal resection with anastomosis and left ovariectomy. Based on patohistology and imaging results benign insulinoma was confirmed, in jejunum there was ectopic pancreatic tissue, and there was mature teratoma of left ovary. We have not performed genetic testing for MEN1 since we thought it was unlikely. After operation, the patient was asymptomatic and normoglycemic.
Conclusions
We found three different tumors, including insulinoma, in a single patient. This combination has not yet been described to coincide and is not due to multiple endocrine neoplasia.

An analysis of R356W and Q318X mutations and 8 bp deletion in 21-hydroxylase gene CYP21A2 in causing pseudo-precocious puberty in patients with congenital adrenal hyperplasia in Pakistani children

Nadiaj Parveen[1], Samar Minallah[1], Muhammad Ismail[2], Qaiser Mansoor[2], Maleeha Akram[1], Zubaria Iqbal[1], Sarwat Jahan[3], Kiran Afshan[3], Gulbin Shahid[4], Faheem Tahir[5], Afzaal Ahmed Naseem[1], Mazhar Qayyum[1] & Syed Shakeel Raza Rizvi[1]
[1]Department of Zoology, Pir Mehr Ali Shah Arid Agriculture University Rawalpindi, Rawalpindi, Punjab, Pakistan; [2]Institute of Biomedical and Genetic Engineering (IBGE), Islamabad, Pakistan; [3]Department of Animal Sciences, Quaid-e-Azam University, Islamabad, Pakistan; [4]The Children's Hospital, Pakistan Institute of Medical Sciences (PIMS), Islamabad, Pakistan; [5]Reproductive Physiology, Public Health Laboratories Division, National Institute of Health, Islamabad, Pakistan.

The first signs of puberty are visible around the age of 8 years in girls and 9 years in boys. If signs of puberty appear before the designated ages in girls and boys, puberty is viewed as precocious. In peripheral precocious puberty, androgens concentrations increase due to testicular tumours or congenital adrenal hyperplasia (CAH). Two mutations, R356W and Q318X, and one 8 bp deletion in CYP21A2 gene, causing CAH type of precocious puberty were examined. Blood samples were obtained from 42 CAH patients (30 boys and 12 girls) exhibiting higher 17-OH progesterone concentrations and 42 normal healthy controls. DNA was extracted, primers of exons of CYP21A2 splice sites were designed and PCR-RFLP method was employed. The PCR product of CYP21A2 digested by enzyme Fnu4HI for R356W mutation gave bands of AA (~106, 110, 229 and 37 bp). The frequency of this genotype was 100% in both groups indicating absence of R356W mutation in both groups. For Q318X, the restriction enzyme, PstI gave bands of 3 different genotypes, GG (161 and 329 bp segments) in 18 patients, GC (490, 329 and 161 bp segments) in 21 patients and CC (segment of 490 bp) in 3 patients (2 boys and 1 girl). For 8 bp deletion, PCR amplification with allele specific primers yielded a segment of ~710 bp; 8 bp deletion was not found in any patient but 3 control subjects were heterozygous for it. The frequency of homozygous wild type (NN) was 1 in patients and 0.85 in controls; the frequency of homozygous mutants (DD) was 0 in both groups, whereas the frequency of heterozygous (DN) was 0 in patients and 0.15 in controls. The frequency of allele D was 0 in patients and 0.075 in controls. The frequency of allele N was 1 and 0.925 in patients and controls respectively.

Congenital adrenal hyperplasia: impact of therapy on growth and sexual maturation – a 5-year retrospective study of a Tertiary Pediatric Endocrinology Center

Camelia Procopiuc, Madalina Vintila, Iuliana Gherlan, Amel Cirla, Andreea Brehar, Andra Caragheorgheopol, Suzana Vladoiu Oana Popa & Cristina Dumitrescu
CI Parhon National Institute of Endocrinology, Bucharest, Romania.

Objective
To evaluate the comparative effects of different glucocorticoid treatments on growth and sexual maturation in patients with congenital adrenal hyperplasia.
Patients and methods
We conducted a retrospective observational cohort study in 78 patients (60 girls, 18 boys) diagnosed with congenital adrenal hyperplasia (CAH), followed-up for a period of 5 years. The majority had 21-hydroxylase deficiency (75 patients), 2 had 11-β hydroxylase deficiency and 1 patient had 3-β hydroxysteroid dehydrogenase deficiency. Patients received either Prednisone (PDN), Hydrocortisone (HC) or Hydrocortisone plus Dexamethasone (DEX). Data on growth, bone maturation, puberty onset, predicted adult height, and parental height were collected. Height gain was calculated as the difference between parentally determined target height and final or predicted height at the last evaluation.
Results
Height gain with therapy was 0.42 S.D. over the initial estimated height deficit. Height gain correlated with the clinical form of CAH, with better outcome in non-classical vs classic forms ($P<0.01$). There were no significantly differences between groups in regard to type of therapy ($P=0.164$). There was no difference in change of body mass index regarding the type of treatment ($P=0.99$). Girls over 12 years of age treated with HC had higher rates of spontaneous menarche versus PDN treated girls ($P=0.006$). Twelve children developed precocious puberty, which correlated with older age at treatment initiation ($P=0.048$).
Conclusions
The type of therapy did not influenced height gain. HC facilitated spontaneous menarche onset in normal age range. Late diagnosis and therapy led to higher rates of precocious puberty in children with CAH.

The risk of hypotension, evaluated by ambulatory blood pressure monitoring, during fasting and outside fasting in patients with adrenal insufficiency

Melika Chihaoui[1], Wafa Grira[1], Meriem Yazidi[1], Ons Rejeb[1], Fatma Chaker[1], Ibtissem Oueslati[1], Jihane Bettaieb[2] & Hedia Slimane[1]
[1]Department of Endocrinology, Faculty of Medicine of Tunis, La Rabta Hospital, University of Tunis El Manar, Tunis, Tunisia; [2]Department of Medical Epidemiology, Faculty of Medicine of Tunis, Pasteur Institute of Tunis, University of Tunis El Manar, Tunis, Tunisia.

The risk of hypotension during Ramadan fasting in patients with adrenal insufficiency is unknown. The aim of our study was to evaluate objectively this risk.
Methods
It is a prospective case-crossover study on 28 patients with known and treated AI. Patients had no hypertension and were regular fasters. All patients underwent a clinical examination and a 24-hours blood pressure monitoring during Ramadan fasting then outside fasting.

Results
There were 23 women. The mean age was 37 ± 14 years. It was a central adrenal insufficiency in 26 patients. The mean duration of the disease was 9 ± 8 years. The mean daily dose of hydrocortisone was 19 ± 3 mg. Systolic hypotension (<90 mmHg) did not occur during fasting and occurred in two cases outside fasting. Diastolic hypotension (<60 mmHg) occurred in 12 cases during fasting and in 13 cases outside fasting without a significant difference. All cases of hypotension were asymptomatic. The levels of systolic and diastolic blood pressure during the 24 h and during the fasting period (from pre dawn to sunset) did not significantly differ between the fasting day and the non-fasting day.
Conclusion
Blood pressure levels during fasting were comparable to those outside fasting and there was not an increased risk of hypotension during fasting.

Steroid metabolome changes in the 1 mg dexamethasone suppression test

Václav Hána jr[1], Mikuláš Kosák[1], Václav Hána[1] & Martin Hill[2]
[1]3rd Department of Internal Medicine, 1st Faculty of Medicine, Charles University and General Teaching Hospital, Prague, Czech Republic; [2]Institute of Endocrinology, Prague, Czech Republic.

Introduction
Dexamethasone induced negative feedback on CRH, ACTH and cortisol secretion is one of the key principles in the diagnostic workup of hypercortisolism. Cortisol secretion has been studied extensively, but changes of other steroids remained apart. Our aim was to establish steroid profile changes in 1 mg dexamethasone test.
Methods
The Steroid profile consisting of 103 steroids and their metabolites from the serum of 9 male and 8 healthy female controls was measured before and in the morning at 0800 hours after 1 mg dexamethasone administered at 1100 hours. Samples were analyzed using GCMS/MS for the measurement of most of the steroids. Only a few were measured by RIA.
Results
Dexamethasone administration suppressed the most the levels of corticosterone (29×), cortisol (20×), 11-OH-androstenedione (12×), 11β-Hydroxy-androsterone (13×), 11β-Hydroxy-etiocholanolone (13×), 11β-Hydroxy-epiandrosterone (6×), 17-Hydroxypregnenolone (5×). Other steroids like DHEA (3×), Androstenedione (2×), Pregnenolone (2×) were suppressed at much lower rate than their 11β-hydroxylated metabolites. As expected, none of the measured steroids increased after dexamethasone.
Conclusions
Inhibition of ACTH secretion leads to a strong suppression of the whole adrenal steroidogenesis including androgen production.
The most prominent changes were observed in corticosterone, cortisol, and interestingly 11-OH-androstenedione and their 5-β/α-reduced metabolites, which all decrease more than 10 times in comparison with the basal levels.
This clearly demonstrates the key role of 11β-hydroxylase being the most influenced enzyme by the adrenocortical axis suppression.

Thyroid Cancer

EP209

Clinical relevance of RET proto-oncogene variants L769L and S836S (exon 11, 13, 14, and 15) in patients with sporadic medullary thyroid carcinoma

Darko Katalinic[1], Miljenko Solter[2] & Nora Nikolac[2]
[1]Department of Internal Medicine, Faculty of Medicine, J.J. Strossmayer University of Osijek, Osijek, Croatia; [2]Faculty of Medicine, UHC Sisters of Charity, University of Zagreb, Zagreb, Croatia.

Background
Medullary thyroid cancer (MTC) makes up to 5–10% of all cases of thyroid malignancies. The clinical course of MTC varies from an extremely indolent tumour to an aggressive variant that is associated with a high mortality rate. RET proto-oncogene germline mutations are crucial for the onset and the progression of MTC. The aim of this study was to evaluate the L769L (subgroup L) and S836S (subgroup S) allele frequencies in patients with sporadic MTC (group A, $n=89$) compared to healthy subjects (group B, $n=83$) and to determine if these polymorphisms have influence the clinical presentation and the course of MTC.
Methods
A non-isotopic polymerase chain reaction based single strand confirmation polymorphism analysis and heteroduplex gel electrophoresis method was used to screen tumour DNA extracted from 89 formaldehyde fixed and paraffin embedded MTC specimens. We also analysed relevant clinical data in the group of patients with MTC. The study was conducted according to the Declaration of Helsinki, the protocol was reviewed and approved by the institutional independent ethics committee. All patients were provided with written informed consent.
Results
Mean age was 51.6 ± 9.2 years for the patients with MTC (range, 42.4–60.8) vs 45.4 ± 7.1 (range 38.3–52.5) for the group of healthy subjects. The allele frequencies showed a similar level of the L769L and S836S variants in both subgroups of examinees (group L, 52.5% vs group S, 47.5%; $P>0.001$). Lymph node metastases were found in all patients with MTC (subgroup L, $n=42$ vs subgroup S, $n=47$; $P>0.001$), and distant metastases in nine patients (subgroup L, $n=5$ vs subgroup S, $n=4$; $P>0.001$). Postoperatively, 52% of patients in subgroup L vs 55% of patients in subgroup S were biochemically cure ($P>0.001$). In the subgroup L, pT-category was: T0, $n=23$; T1, $n=14$; and T2, $n=5$. In the subgroup S, pT-category was: T0, $n=21$; T1, $n=16$; and T2, $n=10$.
Conclusion
We did not find any statistically significant difference in representation of the L769L and S836S gene variants. The RET L769L and S836S (exon 11, 13, 14, and 15) gene variants are not contributing factor in the development of sporadic MTC and are not promoting factor for development of metastatic MTC.

Bisphosphonate related osteonecrosis of the jaw: risk factors: a case report

Pablo Young, Natalia Elias, Noelia Rella, Marcela Moran & Marina Curria
British Hospital, Buenos Aires, Argentina.

Introduction
Bisphosphonates (BP) have been employed for many years and have demonstrated an excellent safety profile. Nevertheless, severe osteonecrosis of the jaw (ONJ) have been described in patients with bone metastases that were treated with BP for many years.
Case
A 72 year old female with breast cancer and bone metastases treated with quadrantectomy, axillary lymph node dissection, radiotherapy, tamoxifen and pamidronate 90 mg/month. Two years later, the patient suffered from pain in the right body of the jaw one month after the extraction of low dental pieces. She had an extended intraoral ulcer, which leaved exposed part of the body of the jaw and loss of dental pieces. The patient had not received radiotherapy in the jaw. X ray revealed osteolysis and CT scan showed lesions in bone and soft parts of the jaw. Biopsy confirmed necrosis. Irrigation with chlorhexidine gluconate 0,12% and extraction of dental pieces were performed. In spite of the conservative treatment, she presented severe pain and suppuration. The right side of the jaw was removed. Pamidronate treatment was discontinued. The patient had cancer progression and died some months later.
Conclusion
The aim of this presentation is to emphasize the importance of taking into account the risk factors of ONJ at the moment of performing an invasive procedure. The estimated incidence of ONJ in patients with malignancy who receive BP seems to range between 1 and 10%. The risk factors of ONJ are related to BP, local, systemic and demographic factors. The use of less traumatic techniques available and adequate antibiotic treatment is mandatory in the presence of risk factors of ONJ. BP treatment should be interrupted after surgery until the wound is fully healed.

Salmon calcitonin affects thyroid endocrine cells and trabecular bone in a rat model of male osteoporosis

Branko Filipović[1], Branka Šošić-Jurjević[1], Jasmina Živanović[1], Milica Manojlović-Stojanoski[1], Nataša Nestorović[1], Svetlana Trifunović[1], Ivana Jarić[1], Gordana Uśćebrka[2] & Verica Milošević[1]
[1]Institute for Biological Research "Siniša Stanković", University of Belgrade, Belgrade, Serbia; [2]Faculty of Agriculture, University of Novi Sad, Novi Sad, Serbia.

Calcitonin (CT) is a hypocalcemic hormone produced by thyroid C-cells that acts as an bone antiresorptive agent. The other endocrine cell population in thyroid, called follicular cells produce thyroid hormones (TH) which also affect bone turnover. In this study, we evaluated the effects of salmon CT administration on structure and function of both CT and TH producing thyroid cells as well as trabecular bone microarchitecture in orchidectomized (Orx) middle-aged rats. Fifteen-month-old male Wistar rats were either Orx or sham-operated (SO). One group of Orx animals were injected subcutaneously with synthetic salmon CT (Orx + CT; 100 IU/kg b.w.) every second day for 6 weeks. The rats from SO and second Orx group received the same volume of vehicle alone by the same schedule. The peroxidase–antiperoxidase method was applied for localization of CT in C-cells. CT-immunopositive thyroid C-cells, thyroid follicular epithelium, interstitium and colloid were evaluated morphometrically. An ImageJ public domain image processing program was used to measure bone histomorphometric parameters of the proximal tibial specimens. Blood serum samples were analyzed for CT, osteocalcin (OC) and thyroxine (T_4), and urine samples fot calcium (Ca^{2+}) concentration. We found a significant decrease in the Vc and Vv of thyroid C-cells after CT treatment compared to both SO and Orx. The Vv of the colloid was higher, while V_V of the follicular epithelium was lower after CT treatment compared to Orx. Analysis of trabecular microarchitecture showed that salmon CT administration significantly increases of cancellous bone area (B.Ar), trabecular thickness (Tb.Th), and trabecular number (Tb.N) whereas trabecular separation (Tb.Sp) was significantly decreased. CT treatment markedly elevated serum CT, but serum OC, T_4 and urinary Ca^{2+} concentrations were lower than in the Orx group. These findings indicate that administration of salmon CT inhibited calcitonin-producing thyroid C-cells and changes the structure of the thyroid gland indicating hypoactivity.

Primary hyperparathyroidism: hormonal profile and risk of complications

Alina-Andreea Gatu[1], Cristian Velicescu[1,2], Cristina Preda[1,2], Voichita Mogos[1,2], Carmen Vulpoi[1,2], Simona Mogos[1,2], Valentin Zaharia[2], Adrian Aancute[2] & Dumitru Branisteanu[1,2]
[1]Gr. T Popa University of Medicine and Pharmacy, Iasi, Romania; [2]St. Spiridon Emergency Hospital, Iasi, Romania.

Background
Vitamin D deficiency is frequently associated with primary hyperparathyroidism, but the impact of this association on disease evolution and complications is ill defined. Aims: to assess the role of vitamin D status on the metabolic profile and spectrum of complications at patients with primary hyperparathyroidism.
Materials and methods
Transversal study involving 42 patients with primary hyperparathyroidism submitted to parathyroidectomy. We evaluated serum calcium, phosphate, serum PTH and 25OHD3, bone mineral density by DXA (Hologic) and anamnestic episodes of bone fractures and kidney lithiasis. Fifteen patients had episodes of kidney lithiasis, whereas 27 patients did not develop this complication. Twenty patients were diagnosed with osteoporosis whereas 22 patients had bone mass in the range of normal or osteopenia. Data between groups were compared using the t test and were considered significant at P values < 0.05.
Results
Twenty-nine of the 42 patients had 25OHD3 in the range of deficiency (lower than 20 ng/ml) and 20 had severe 25OHD3 deficiency (lower than 10 ng/ml). Serum calcium and phosphate were similar irrespective of the presence or absence of complications. No differences were found between mean PTH and 25OHD3 levels of patients with or without osteoporosis. Patients with kidney lithiasis had, however, higher PTH ($390 +/- 90$ pg/ml vs $209 +/- 64$ pg/ml, $P<0.001$) and lower 25OHD3 levels ($12.8 +/- 6$ ng/ml vs $19.2 +/- 7.8$ ng/ml, $P<0.05$) than patients without kidney lithiasis.
Conclusions
D hypovitaminosis accompanies frequently primary hyperparathyroidism. Patients with higher risk of kidney lithiasis seem to have higher PTH and lower 25OHD3 levels.

Efficacy and safety of bisphosphonate discontinuation in postmenopausal osteoporosis: a systematic review

Panagiotis Anagnostis[1], Stavroula Paschou[1], Gesthimani Mintziori[1], Irene Lambrinoudaki[2] & Dimitrios Goulis[1]

[1]Unit of Reproductive Endocrinology, First Department of Obstetrics and Gynecology, Medical School, Aristotle University of Thessaloniki, Thessaloniki, Greece; [2]Second Department of Obstetrics and Gynecology, National and Kapodistrian University of Athens, Athens, Greece.

Introduction
The maximum period of bisphosphonate use has not been determined, as their long-term appliance has been associated with adverse effects, such as osteonecrosis of the jaw (ONJ) and atypical femoral fractures (AFF).
The aim of this study was to systematically present existent data regarding the effect of bisphosphonate discontinuation on fracture risk and bone mineral density (BMD).
Methods/design
MEDLINE, Scopus, EMBASE and Cochrane databases were searched (up to December 2016) for randomized placebo-controlled trials.
Results
Regarding alendronate, five studies fulfilled eligibility criteria ("drug holiday": two-five years). Extending alendronate (5–10 mg/d) use to five years, after continuous treatment for five years, reduced clinical vertebral fracture risk by 55%, without difference in morphometric vertebral or non-vertebral fractures (one study). Lumbar BMD remained higher than pre-treatment levels in the discontinuation group, although lower compared with the extension group. Hip BMD decreased or remained unchanged.
Regarding zoledronic acid, two studies fulfilled eligibility criteria. After three annual infusions (5 mg/y), extending treatment to six years reduced risk of new morphometric vertebral fractures by 49%, without benefit in clinical vertebral or other types of fractures. Lumbar BMD remained above pre-treatment values in the discontinuation group, but reduced in hip sites. Extending treatment to nine years provided no additional benefit.
Regarding risedronate, one study fulfilled eligibility criteria. Discontinuation for one year (after 5 mg/d for three years) did not increase non-vertebral fracture risk, but continued to confer a reduced risk in vertebral fractures (46%). Lumbar BMD remained higher, whereas femoral neck BMD decreased, compared with pretreatment levels. No increased risk of ONJ or AFF was shown in these studies.
Conclusions
A "bisphosphonate holiday" may be considered after five years of treatment with alendronate, three with risedronate and three with zoledronic acid for up to five, one and three years, respectively. However, this decision should be individualized.

Osteopetrosis vs Osteogenesis Imperfecta-is that so hard to distinquish? Case report

Theodor-Eugen Oprea, Mirela Bonea, Suzana Florea & Carmen Barbu
Elias University Emergency Hospital, Endocrinology Clinic, Bucharest, Romania.

Osteopetrosis and O.I. are both bone metabolic disorders with opposite features in terms of the metabolic turnover: while osteopetrozis has a low turnover and increased BMD due to the failure of osteoclasts to resorb bone, O.I. is well known as a high turnover disease with low BMD caused bt mutations in the COL1A1 and col COL1A2 genes that encode type 1 procollagen; yet, both condition, in spite of different mechanism, end up with increased ftracure prevalence. We report the case of a 46 year old women who presented for clinical and biological evaluation with a prior diagnisis of osteopetrosis. The anamnesis revealed that the diagnosis of osteopetrozis was set when the patient was 2 year old based on radiologycal features and multiple nontraumatic fractures suffered in childwhood; last fracture she recalls was at 20 year old and. Also she claims a familial history of osteogenesis imperfecta (maternal grandfather). The clinical examination revealed: Hight-125 cm; Weight-50 kg; BMI-32 kg/sm; blue sclerae, left leg orthosis, with unequal inferior limbs accompanied by difuze joint pain. Lab tests highlighted mild hypercholesterolemia, 25OHVitD insufficiency, low beta-crosslaps level, normal PTH, normal TSH and fT4. Near normal BMD. Dorsal and lombar spine X-ray:rarefaction of trabecular bone structure, suggesting a medium grade of demineralization.
Our O.I. final diagnosis proved to be quite difficult, taking into account the prior one of osteopetrosis, the history of pubertal fractures, familial history of O.I., growth impairment, lack of decreased BMD and increased bone turnover, mild VitD insufficiency. However, the importance of establishing the diagnosis, in our case, consists in choosing the optimal treatment; bisphosfonates are used in O.I. but not indicated in osteopetrosis. Our approach was to treat her with activ vit.D products since her actual fracture risk was not cinsidered increased.

EP216

Osteonecrosis of the jaw and bilateral atypical femoral fracture both occurring during treatment of osteoporosis

Edelissa Payumo, Thelma Crisostomo & Ivan Cudal
Makati Medical Center, Makati, The Philippines.

Background
Osteonecrosis of the jaw (ONJ) and atypical femoral fracture (AFF) are rare potential adverse effects of bisphosphonates and RANK-L inhibitor, occurring in 1 and 2 per 100,000 person-years, respectively. The pathogenic mechanisms of both conditions are known to be independent of each other. Here, we report both conditions sequentially occurring in the same patient.
Clinical case
An 81-year old, obese, diabetic, female was admitted due to hypertensive urgency and persistent jaw pain after tooth extraction. The patient has postmenopausal osteoporosis for fourteen years and was on intermittent unsupervised treatment with alendronate, denosumab and ibandronate. She had suffered sequential fracture of both femurs during the eighth and eleventh year of treatment. Both fractures were transverse, non-comminuted, at the proximal femoral shaft, which occurred after a minor trauma, and were managed with open reduction and internal fixation.
Upon presentation, the patient was noted with tenderness intraorally of tooth number 35 periapical region, no pus, no mandibular swelling. There was peripheral leukocytosis, elevated erythrocyte sedimentation rate, C-reactive protein. Panoramic with periapical view radiograph showed presence of bony sclerosis which represent a sequestrum compatible to chronic osteomyelitis in the molar area of the left hemi-mandible. Antibiotic infusion and excision and debridement of left posterior mandible were done. Necrotic bone with histopathologic finding of acute and chronic osteomyelitis with bacterial colonies was removed consistent with a diagnosis of osteonecrosis of the jaw. The patient was discharged on the fourth post-operative day and was placed on drug holiday.
Conclusion
ONJ and AFF can occur both in the same patient during prolonged treatment with bisphosphonates and RANK-L inhibitor and may suggest a common pathogenic mechanism. This case further emphasized that to avoid these grave consequences, bisphosphonates should be given in a limited period—five years, as recommended by experts.

EP217

Clinical manifestations and treatment approach in osteogenesis imperfecta

Dimitra Tampouratzi[1], Styliani Kalaitzidou[1], Aggeliki Sapera[1], Michalis Kotis[1], Fotini Kanouta[1], Eleni Triantafillou[1], Taxiarchis Kyrimis[1], Georgios Papadakis[2], Anna Drakopoulou[1], Victoria Kaltzidou[1] & Athanasia Tertipi[1]
[1]Endocrinology Department, Metaxa Anticancer Hospital, Piraeus, Athens, Greece; [2]STEPS Stoffwechselzentrum, Biel/Bienne, Switzerland.

Objectives
Osteogenesis imperfecta (OI) is a group of genetic disorders that mainly affects the bones. The underlying mechanism is usually a disorder of connective tissue due to lack of type I collagen. Usually, the disease is due to mutations in the COL1A1 or COL1A2 genes. The disease is inherited in an autosomal dominant manner or occurs via a de novo mutation. There are eight types of the disease. Type I is the most common and the least sever type and is due to mutation in COL1A1 gene. We evaluated the clinical, laboratory and radiological profile of a woman with OI Type I who was treated over a 3-years period in our clinic.

Methods
A 61-year old female patient with family history of OI (son and sister) was treated in our clinic. She had history of multiple repeated fractures since 18 years old, short stature (138 cm), discoloration of the sclera, dental abnormalities, poor muscle tone in arms and legs, triangular face and skeletal deformities such as osteoporosis, spinal canal stenosis and kyphoscoliosis. Bone densitometry found severe osteoporosis. Treatment included zoledronic acid IV, vitamin D and calcium carbonate per os.
Results
After treatment with zoledronic acid the patient reported reduced bone pain and had stable bone mass (0.547 g/cm^2 before treatment and 0.535 g/cm^2 (femoral neck) after treatment) and increased T-score (femoral neck) (-3.3 SD before treatment and -2.88 SD after treatment, 3 years later).
Conclusion
Osteogenesis imperfecta is a heterogeneous disease and may have an indolent course. The diagnosis may be brought forward late in adulthood. The management includes the replacement of a calcium and vitamin D deficit and biphosphonates. Bisphosphonates remain effective and can increase bone mass, reduce bone pain and fractures.

Special features of body composition and bone mineral metabolism in children with primary nephrotic syndrome

Natalia Volkova[1] & Angelika Soltsava[2]
[1]2th City Children's Hospital, Minsk, Belarus; [2]Belarusian State Medical University, Minsk, Belarus.

Objective
To learn characteristics of biochemical markers of bone metabolism, parameters of bone mineral density (BMD) and fat component of body composition for early diagnosis of bone disorders in children with primary nephrotic syndrome (NS).
Material and methods
We compared data of laboratory investigations (phosphorus (P), total calcium (Ca), parathyroid hormone (PTH), and alkaline phosphatase (ALP)), protocols of dual-energy X-ray absorbtiometry of the axial skeleton and total body of 27 children with NS (group 1 – G1, age 9.71 ± 4.23 yrs) and 13 children of control group (G2, age 10.84 ± 3.84 yrs, $P = 0.48$). Group 1 was divided in subgroups G1a (relapse of NS, $n = 12$) and G1b (remission of NS, $n = 15$). Results were processed using SPSS17.
Results
G1 showed significantly lower age-matched z-score of BMD of lumbal spine (L1-4) (-0.71 ± 0.96) compared with G2 (0.08 ± 1.13, P = 0.036). One child of G1 had low bone density of lumbal spine with z-score -2.9. Total BMD was similar in the groups ($0.88 +/- 0.12$ g/cm^2 in G1 vs $0.91 +/- 0.19$ g/cm^2 in G2, $P = 0.39$). Fat component of body composition was increased in G1 ($38.33 \pm 11.30\%$) compared with G2 ($27.52 \pm 6.59\%$, $P = 0.0001$). Android/gynoid fat ratio was higher in G1 (0.90 ± 0.18) than in G2 ($0.70 +/- 0.20$, $P = 0.013$). Children of G1a showed lower level of Ca than control (2.24 ± 0.18 mmol/l vs 2.37 ± 0.07 mmol/l, $P = 0.009$). Concentration of Ca in G1b was similar to G2 ($2.37 \pm 0.07 +/-$ 0.13 vs 2.44 ± 0.15 mmol/l, $P = 0.71$) We didn't reveal significant difference in of PTH, P and ALP levels in the groups ($P > 0.05$).
Conclusions
Most children with NS showed normal BMD of lumbal spine, though it was lower than in healthy controls. Patients with NS had higher fat component of body composition with increased android type of its distribution.

Bone densitometry of type 2 diabetics (about 290 patients)

Samir Ait Abderrahmane, Zahra Kemali, Sihem Hatri, Elmahdi Haffaf, Nacer Sobhi, Lila Brakni & Brahim Oudjit
HCA, Kouba, Algeria.

Introduction
The improvement of the survival of diabetics is accompanied by the emergence of bone fragility which can directly affect, at various levels, the various components of the bone tissue leading to quantitative and qualitative anomalies. The effects of type 2 diabetes on bone are complex because they are associated with the sometimes associated disorders of nutrition, weight and age. Densitometric studies in this context are quite contradictory. We proposed to study the bone status of type 2 diabetics.
Patients and methods
We carried out a cross-sectional study of 290 type 2 diabetics. These patients benefited from a measurement of bone mineral density (BMD) associated with PTH, vitamin D and calcemia.
The results
The average age of our population was 62.5 years. 38% of our patients were treated with insulin with a predominantly mixed regimen (basal insulin combined with oral treatments), with an average HBA1C of 7.05% for an average duration of diabetes of 8 years. Mean calcium in the general population was 2.33 mmol/l, with 2.36 mmol/l in males and 2.27 mmol/l in females, with no significant relationship between the two sexes ($P = 0.1370$).
5 patients had secondary hyperparathyroidism (> 65 pg/ml), the mean PTH in the study population was 46.82 ng/ml, higher in women than in men. 75.6% of patients had normal BMD, 23.3% had osteopenia, 24.3% were women, and 21% were men. The mean concentration of vitamin D is 13.93 ng/ml, with a maximum of 35 ng/ml and a minimum of 3 ng/ml. The mean concentration in males was 15, 14 ng/ml, significantly higher than that of females in the order of 11.91 ng/ml ($P < 0.1 = P = 0.0018$). A negative and significant correlation was found between the serum levels of 25OHD3 and those of PTH. This correlation persisted after adjusting for age and BMI. Our study did not find any significant relationship between PTH levels and BMD scores with ($P = 0.6091$).
Conclusion
According to data from the literature and despite normal BMD in patients with type 2 diabetes, it should be borne in mind that BMD alone is insufficient to assess bone status, management of other factors such as Diet rich in vitamin D and sufficient calcium intake is required.

Effects of acromegaly on bone tissue mRNA levels relevant to bone metabolism

Tatiana Grebennikova[1], Zhanna Belaya[1], Galina Melnichenko[1], Olga Brovkina[2], Alexey Nikitin[2], Ludmila Astaf'eva[3], Andrej Grigoriev[1] & Ivan Dedov[1]
[1]Federal State Institution "The National Research Center for Endocrinology", Moscow, Russia; [2]Federal Research and Clinical Center FMBA, Moscow, Russia; [3]N.N. Burdenko Neurosurgery Institute, Moscow, Russia.

Molecular basis of the bone disorders in patients with acromegaly are largely unknown.
Objective
To investigate gene expression profiles that regulate bone metabolism in bone tissue samples from patients with acromegaly.
Materials and Methods
Patients with clinically evident and biochemically proven active acromegaly and patients with hormonally inactive pituitary adenoma matched by age, sex and BMI were invited to participate. Bone samples were taken during transsphenoidal adenomectomy from the base of the sella-turcica, immediately placed in lysis buffer (QIAzol) and subjected to homogenization. Insulin-like growth factor 1 (IGF-1) was measured by an electrochemiluminescence assay on a Liaison. Total RNA isolation from bone tissue with on-cjlumn digestion of the genomic DNA was carried out with miRNeasy Mini Kit on the automatic station 'QIAcube'. Reverse transcription was carried out using a High-Capacity RNA-to-cDNA Kit. Gene expression analysis was performed by Real-Time PCR on StepOnePlus instrument with Custom TaqMan Array 48 Plus plates, TaqMan Advanced miRNA Assays.
Results
We enrolled 21 subjects (12 patients with acromegaly and 9 with hormonally inactive pituitary adenomas); 13 females and 8 males, the mean age was 38 years (confident interval (CI) 95% 33–43) mean BMI – 28 (CI95% 25–31) kg/m^2. There

were no significant difference within the groups. Mean IGF-1 in subjects with acromegaly – 785 (CI95% 527–1042) ng/ml. The expression of SOST 5,7 (CI95% 1,01–10,44, $P=0.022$), DKK1 7,97 (CI95% 4,4–11,54, $P<0.001$), BGLAP 1,51 (CI95% 0.82–2,19, $P<0.001$) was increased in subjects with acromegaly as compared to inactive pituitary adenoma. miRNA 199a-5p 0,37 (CI95% 0.06–0,68, $P=0.023$) was suppressed.

Conclusion

In spite of increased expression of Wnt signaling antagonist, bone formation is not suppressed in subjects with acromegaly. The suppression of miRNA might explain the predominant differentiation to the cartilage tissue.

Disclosures

This study was supported by the Russian Science Foundation (grant # 15-1530032).

Osteoporosis and fractures in the real world setting

Eleni Pantazi[1], Alexios Travlos[1], Evaggelia Vogiatzi[1] & Ifigenia Kostoglou-Athanassiou[2]

[1]Department of Endocrinology, Alexandra Hospital, Athens, Greece; [2]Department of Endocrinology, Red Cross Hospital, Athens, Greece.

Osteoporosis is a bone disease predisposing to bone fragility. Nowadays, the population is screened for osteoporosis and measures are taken for fracture prevention. Additionally, people are urged to have a diet rich in calcium, are given calcium supplements and are being treated for vitamin D deficiency. Moreover, osteoporosis treatment is administered. Therefore, the relationship between osteoporosis and fractures in the real world setting is very interesting.

The aim was to study the prevalence of fragility fractures in a cohort of patients being followed up and treated for osteoporosis in a center of excellence for the management of osteoporosis in Athens.

A cohort of 91 patients, 82 female and 9 male, aged 69.71 ± 1.09 years, who were followed up and treated as needed for osteoporosis in a center of excellence was studied. Bone mineral density was measured in the spine and the hip. The number of fractures having occurred in the cohort studied was recorded.

Bone mineral density in the spine as assessed by T score was -1.9 ± 0.11 (mean $\pm$ SEM) and in the left hip -2.6 ± 0.11. In the cohort of patients studied 19 patients (20.88%), 15 female and 4 male, suffered a fracture. The fractures recorded were 8 vertebral, 7 distal radius, 2 tarsal joint, 2 rib fractures and 1 fracture of the calcaneus. Within the cohort studied 2 patients had suffered two fractures, a distal radius and a vertebral and a rib and a vertebral fracture, respectively.

It appears that in the modern real world setting despite the measures taken for osteoporosis prevention and management in a cohort of patients being followed up within a center of excellence in Athens, fractures tend to occur especially in the female population. However, interestingly, within the cohort studied many patients with osteoporosis remained free of fracture at the point of time of the study.

EP222

Is osteoporosis a curable disease?

Ifigenia Kostoglou-Athanassiou[1], Eleni Pantazi[2] & Panagiotis Athanassiou[3]

[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Endocrinology, Alexandra Hospital, Athens, Greece; [3]Department of Rheumatology, St. Paul's Hospital, Thessaloniki, Greece.

Osteoporosis may be a disease of unknown etiology, or a degenerative disorder in the context of aging. Nowadays, the availability of multiple forms of effective drug treatment for osteoporosis have raised the hypothesis that osteoporosis may be not only a treatable but moreover a curable disease.

The aim was to describe the case of a patient with osteoporosis who after treatment with alendronate for 6 years had osteopenia and remains in the state of osteopenia for a long period after drug cessation.

A patient, female, aged 65 years, postmenopausal, presented with osteoporosis, T score in the spine being -3.2. Alendronate 70 mg once weekly was administered along with calcium and vitamin D. The patient also had hypothyroidism on treatment with L-thyroxine, TSH levels being within the normal range.

Bone mineral density measurement was performed yearly while the patient was on treatment with alendronate, calcium and vitamin D. Six years later bone mineral density measurement in both the spine and the hip revealed osteopenia, T score being -1.3 and -1.1 in the spine and the hip, respectively. Alendronate was discontinued, while calcium and vitamin D were administered to the patient. The patient is being followed for her osteopenia yearly, T score in the hip being -1.1 five years after treatment cessation.

In the case presented alendronate appears to have had a long lasting beneficial effect on the bone in a patient with osteoporosis. The state of osteopenia appears to be stable in the presented patient. This case of persistent improvement of osteoporosis after long lasting treatment with alendronate raises the question of whether osteoporosis may be a curable disease, not being merely a manifestation of aging. This case raises the hopeful hypothesis that osteoporosis with the emergence of novel effective forms of therapy may be cured.

Fractures at post-partum and lactation: common presentation of different clinical entities

Zoe Efstathiadou, Albana Sykja, Athanasios Panagiotou & Marina Kita "Hippokration" General Hospital of Thessaloniki, Thessaloniki, Greece.

Introduction

Osteoporosis of pregnancy and postpartum is a rare clinical entity, which usually presents with back pain, due to spine fractures. We aimed to describe four different cases presenting with back pain and fractures post-partum, in who, with diverse underlying pathophysiology, recovery time and treatments used.

Case 1

A 32-year-old patient presented with intense back pain and difficulty in standing and walking, 2 weeks after delivery. She had hypercalcaemia, hyperphosphatemia and multiple vertebral fractures. Breast examination and mammography were inconclusive due to lactation. The diagnosis of metastatic breast cancer was made after a bone lesion biopsy. The patient received zolendronic acid and was referred to an oncologist.

Case 2

A 35 year-old patient, several weeks after a singleton pregnancy, presented with acute back pain**.** Imaging studies revealed an L2 fracture and laboratory assessment showed increased bone turnover markers and vitamin D deficiency. She received zolendronic acid and was started on vitamin D3 substitution. Her clinical course was uneventful.

Case 3

A 41 year-old lady was diagnosed with T12 and L3 vertebral fractures, while still breast-feeding. No secondary causes of osteoporosis were found. She received an 18-month course of teriparatide and Vitamin D3 supplementation. Six months after teriparatide discontinuation she presented with urinary tract lithiasis complicated by upper urinary tract infection.

Case 4

A 32-year-old patient presented with lumbar spine bone mineral density Z-score of -2.8, but no fractures, after her first pregnancy. She was treated with intranasal calcitonin and VitD3 supplementation. An improved BMD (Z-score $=-2.1$) was measured after 2 years. Her second pregnancy was uneventful.

Conclusions

Post-partum osteoporosis is a rare cause of bone pain during the puerperium. Fractures should be diagnosed early in order to avoid permanent incapacity. It is mandatory to look for and exclude secondary causes of osteoporosis including breast cancer and vitamin D deficiency.

A multidisciplinary clinic for bone metabolism diseases; descriptive analysis of our experience in quiron salud malaga hospital

Araceli Muñoz-Garach[1], Maria Carmen Ordoñez-Cañizares[2], Ana Nieto-Gonzalez[2], Pablo Manzano Fernández-Amigo[2] & Jose Manuel García-Almeida[1]
[1]Endocrinology and Nutrition Department. Quiron Salud Hospital, Málaga, Spain; [2]Rheumatology Department. Quiron Salud Hospital, Málaga, Spain.

Introduction
A multidisciplinary clinic has been developed to optimize the diagnosis and treatment of bone metabolism diseases. Initiated in March 2013, it is carried out simultaneously, once a week by an Endocrinologist and a Rheumatologist.
Objective
To describe the experience of this unit in the last 12 months.
Material and methods
Cross-sectional observational study. 235 patients were attended from December 2015 to December 2016. In the first visit, we carried out a medical record using a checklist form and impedancemetry. We requested a blood test with bone remodeling markers (CTX-I and P1NP), vitamin D, PTH, sex hormones and 24-hour urine with calciuria and phosphaturia, densitometry and dorsum-lumbar spine x-rays. In the following visit the results were evaluated and the team formed by both specialists agreed the protocol of action. Subsequently we studied treatment tolerance and analytical, radiographic and densitometric changes.
Results
97% were women with a mean age of 60 ± 9.7 years. Weight 66.3 ± 12.7 kg, height 158.2 ± 5.8 cm, BMI 26.6 ± 4.9 kg/m^2. Impedancemetry showed mean lean mass was 43.0 ± 5.9 kg and mean fat mass 23.3 ± 10.1 kg. 36.2% and 20% of the patients had a personal and family history of fracture, respectively. 15.2% patients had taken previous corticoid treatment; 9.5% had more than 2 falls in the last year. 5.7% were active smokers. 87.4% had menopause; early menopause in 13.4% and surgical menopause in 10.7%. 60% practiced more than 3 days of physical activity per week, 78.8% sunbathed more than 10 minutes a day and 36.2% took adequate dairy milk consumption. Among the digestive antecedents, 39% had gastroesophageal reflux and 16.2% hiatus hernia. 17.5% have had a vertebral fracture. In the densitometric data according to T-score they had osteoporosis 55.06%; Osteopenia 42.76% and normal 2.24%. The FRAX index was 4.3% for major fracture and 0.9% for hip fracture. Among the treatments received prior to the first consultation, 29.5% took bisphosphonates, 9.5% denosumab, 2.9% PTH. 37.5% calcium plus vitamin D.
Conclusions
A high percentage of patients received treatment before coming to the clinic. The most used was bisphosphonates. The aggregate management by two specialists in the multidisciplinary clinic is beneficial and improves the quality of care in our patients.

EP225

Spontaneous recovery of BMD after surgical cure of Cushing's syndrome due to an adrenocortical adenoma: a 9-years follow-up

F. Baleanu, L. Iconaru, R. Karmali & J.J. Body
Centre Hospitalier Universitaire Brugmann, Université Libre de Bruxelles, Brussels, Belgium.

A 33-year-old Belgian woman was referred in June 2006 to our Metabolic Bone Diseases Clinic for recent vertebral fractures. X-Rays showed a 3-level severe compression fractures with collapse of the superior endplates of D11, D12 and L1. DXA showed significantly decreased lumbar spine (LS) and femoral neck (FN) Z-scores, at -3.1 and -2.5, respectively.
She was complaining of severe back pain, muscle weakness, cognitive dysfunction, anxiety and irritability. Physical examination revealed moon-shaped face, ecchymosis, purple stretch marks on the breasts, arms, abdomen and thighs. Morning cortisol was normal but ACTH level was suppressed. Urinary free cortisol was elevated. A late-night salivary cortisol also elevated. Standard 2-day 2-mg dexamethasone suppression test showed no cortisol suppression. A loss of diurnal variation in ACTH and cortisol levels was also demonstrated. Cushing's syndrome was confirmed. Abdominal MRI showed a 3 cm left adrenal mass.
Osteoporosis was considered secondary to this endogenous hypercortisolism. Bone turnover markers (BTMs) and 24h urinary calcium excretion were elevated. Successful laparoscopic left adrenalectomy was performed in October 2006. Spontaneous BMD increase (LS Z-score -2.4) was observed already 2 months after surgery. Except for calcium and vitamin D supplementation, no bisphosphonate therapy was prescribed, given this impressive increase of BMD and because she was still premenopausal. X-Rays did not show any new vertebral fracture. BMD continued to increase. 24 months after surgery, densitometry showed 40% absolute increase in LS BMD and 16% in FN BMD, vs baseline. She reached normal BMD values at all sites 3 years following surgery.
After a 9-years follow-up (DXA and BTMs, yearly), complete spontaneous BMD recovery was confirmed (LS T-score $+1.2$ and FN T-score -0.3) with normal and stable BTMs.
Our case suggests no need for any antiresorptive therapy in severe osteoporosis due to cortisol-secreting adrenal adenoma after successful surgery, at least in premenopausal women.

Cinacalcet for control of primary hyperparathyroidism: a single centre experience

Tiago Nunes da Silva, Ana Gonçalves Ferreira, Maria Carlos Cordeiro, Ana Catarina Matos & Jorge Portugal
Endocrinology Department Hospital Garcia de Orta, Almada, Portugal.

Although primary hyperparathyroidism (PHPT) is usually cured by surgery, some individuals are unable to undergo parathyroidectomy and are refractory to standard calcium lowering medical therapy. In such cases, targeted therapy with cinacalcet may be useful.
The aim of this study was to access the short-term efficacy of cinacalcet in lowering calcium (Ca^{2+}) levels in patients with PHPT unable to undergo parathyroidectomy and refractory to standard medical therapy.
Methods
Patients with PHPT refractory to standard medical treatment were treated with cinacalcet. Statistical analysis was carried out using the Wilcoxon test.
Results
Five patients (all female) with a median age of 76 years were included. The known duration of the PHPT was 60 months. The median follow-up of cinacalcet treatment was 12 months. Hypercalcemia related comorbidities were mental changes in 4, osteoporosis in 3 and kidney stones in 2 patients. Before medical treatment, baseline median (quartile 1 (Q1), Q3) serum PTH was 252 (159, 614) pg/ml (reference range 15–65) and serum Ca^{2+} was 11.7 (11.6, 12.65) mg/dl (reference range 8.1–10.2). After standard medical treatment, baseline median (quartile 1 (Q1), Q3) serum PTH was 222 (149, 304) pg/ml and serum Ca^{2+} was 11.9 (11.2, 12.6) mg/dl ($P > 0.05$). After the last stable dose of cinacalcet, median (quartile 1 (Q1), Q3) serum PTH was 190 (139, 361) pg/ml and serum Ca^{2+} was 10.1 (9.7, 12) mg/dl ($P = 0{,}005$). Serum Ca^{2+} normalized in 60% of patients. The median decrease of Ca^{2+} was 15.1% ($P = 0{,}005$) and of PTH was 14.4% ($P = 0{,}174$). Only one patient developed side effects (muscle spasms) without the need to stop cinacalcet.
Conclusions
These results demonstrate the efficacy and safety of cinacalcet in controlling hypercalcemia refractory to standard medical therapy.

Bone remodeling markers predict bone loss in premenopausal women

Gala Gutierrez Buey[1], Sonsoles Botella[1], Patricia Restituto[2], Macarena Rodriguez Fraile[3], Amparo Calleja[1], María Llavero[1], Javier Gargallo[1], Carolina Perdomo[1], Patricia Andrada[1], Nerea Varo[2] & Juan C Galofré[1]
[1]Department of Endocrinology, University of Navarra, Pamplona, Spain; [2]Department of Clinical Chemistry, University of Navarra, Pamplona, Spain; [3]Department of Nuclear Medicine. University of Navarra, Pamplona, Spain.

Aim
Bone turnover markers (BTMs) predict more rapid rates of bone loss. However, most of these studies have been carried out in postmenopausal women. Few prospective studies have examined the degradation marker C-terminal telopeptide of type I collagen (CTX) and the bone formation marker N-aminoterminal propeptide of type I collagen (P1NP) measured during the menopausal transition to predict the subsequent bone loss.
Methods
We performed a prospective cohort study including 72 healthy premenopausal women from de Endocrinology service at the Clinica Universidad de Navarra. Six women were lost in the follow-up and two were excluded because of treatment that affects bone. We measure demographic variables, CTX, P1NP and bone mineral density at baseline and five years later. SPSS 20.0 was used for statistical analysis. Differences between study groups were evaluated by Student's t test for normally and Mann-Whitney-U test for non-normally distributed variables.
Results
Mean age at baseline was 49.2 ± 0.3. After 5 years, there were no significant changes in baseline demographic characteristics (percentage of smokers, coffee intake, sun exposure and physical activity) although there was a significant increase in BMI ($P = 0.027$).
Five years later, 69% became menopausal, 48.4% (31) had normal bone, and 51.6% (33) had pathological bone (below the expected range for age and/or osteoporosis). There was a significant decrease in BMD at 5 years of follow-up compared to baseline (femoral neck 0.92 ± 0.1vs 0.87 ± 0.1 ($P = 0.000$), lumbar spine 1.17 ± 0.19 vs 1.08 ± 0.1 ($P = 0.000$) and a significant increase in BTMs P1NP (ng/ml) 37.22 ± 10 vs 52.23 ± 21 ($P = 0.000$) and CTX (ng/ml) 0.245 ± 0.125 vs 0.441 ± 0.233 ($P = 0.000$). Increased levels of P1NP and s-CTX in the premenopausal group at baseline associated with pathological bone five years later ($P < 0.001$ and $P < 0.001$, respectively).
Conclusion
Our data suggest that measurement of CTX and P1NP in premenopausal women detects those patients who will suffer bone loss five years later.

EP228

Bone mineral density in hospital male physicians over the age of 65

Noa Sylvetsky, Chen Futeran, Meir Frankel & Gabriel Munter
Endocrine Unit-Shaare Zedek Medical Center affiliated with Faculty nof Medicine-Hebrew University, Jerusalem, Israel.

Background
Hospital physicians are indoor workers, with higher prevalence of vitamin D deficiency as compared to community-based physicians. The correlation between vitamin D deficiency and osteoporosis later in life has not been fully studied, and bone mineral density (BMD) in elderly hospital physicians has not been systematically examined.
Methods
A cross-sectional study measuring BMD in hospital male physicians aged 65 and older was carried out. BMD was measured at the hip, spine and distal forearm. FRAX analysis with BMD was performed, using the IOF recommended FRAX cut-offs for treatment (10-year probability of hip fracture ≥3% and 10-year probability of major osteoporotic fracture ≥20%).
Results
51 male physicians, employees and pensioners, participated in our study. The mean age was 71 years (median 69 years; range 65–86), all of them naive to specific treatment for osteoporosis. 14/51(27%) had osteoporosis, 7 of them defined only by distal forearm examination. 29 (56%) had osteopenia, 4 of them defined only by distal forearm examination. According to their FRAX score, 9 of the osteopenic examinees had high risk of major osteoporotic fracture and/or hip fracture.
Conclusion
In elderly hospital-based male physicians, the prevalence of osteoporosis is higher than expected. After adding the FRAX score results, 45% of the physicians would require specific treatment for fracture prevention, according to customary international clinical guidelines. Using only hip and spine BMD, 31% would require treatment. Based on our data we suggest screening elderly physicians for osteoporosis.

DOI: 10.1530/endoabs.49.EP228

Association between bone mineral density and muscle strength in patients with Turner syndrome, after consideration of selected hormonal and metabolic parameters

Elzbieta Sowinska-Przepiera, Monika Koziolek, Lilianna Osowicz-Korolonek, Jakub Poblocki, Martyna Patalong-Nowak & Anhelli Syrenicz
Pomeranian Medical University, Szczecin, Poland.

Turner syndrome (TS), resulting from complete or partial loss of X chromosome, occurs in 1 per 2000-2500 liveborn female neonates. Most patients with TS, especially those untreated with growth hormone, present with osteoporosis or osteopenia, and are at increased risk of bone fractures. Available evidence suggests that depletion of bone mass may be associated with inadequate level of physical activity, and consequently, with too low muscle mass and strength. The aim of the study was to analyse an association between muscle strength and bone mineral density in patients with TS, after consideration of selected hormonal and metabolic factors. The study included 52 subjects (age 28–45 years), among them 32 women with TS (45,X karyotype; Group A) and 20 controls (Group K). The list of analysed variables included body height, body weight, BMI, bone mineral density (BMD L1-4 and BMD Total), total body fat (BF) and visceral adipose tissue (VAT) volumes determined by means of DXA, hand grip strength measured with a manual dynamometer, and laboratory parameters: TSH, FT4, FSH, oestradiol, testosterone, DHEA-SO4, ACTH, cortisol, PTH, vitamin D3 concentrations, lipidogram, levels of glucose and insulin during OGTT. Patients from Group A presented with significantly lower left ($P = 0.001$) and right handgrip strength ($P < 0.000$), lower BMD ($P < 0.000$), lower concentrations of testosterone ($P < 0.000$) and DHEA-SO4 ($P = 0.006$), larger VAT volumes ($P = 0.005$), higher BMI ($P = 0.05$), higher levels of insulin ($P = 0.026$) and FSH ($P = 0.000$). The study groups did not differ in terms of their TSH, fT4, ACTH and cortisol concentrations, and the only significant difference in lipidogram pertained to triglyceride level, higher in Group A ($P = 0.032$). Right handgrip strength in Group A correlated significantly with BMD L1-4 ($r = 0.1318$, $P = 0.0486$), VAT volume ($r = 0.1478$, $P = 0.0360$) and BMD Total ($r = 0.1921$, $P = 0.0154$). These findings suggest that handgrip strength may constitute a predictor of osteoporosis in patients with TS.

Volumes of visceral adipose tissue, gynoid and android fat as predictors of reduced bone mineral density in women with menstrual disorders

Malgorzata Syrenicz, Elzbieta Sowinska-Przepiera, Elzbieta Andrysiak-Mamos & Anhelli Syrenicz
Pomeranian Medical University, Szczecin, Poland.

Disorders of bone mineralization observed in women with ovarian insufficiency are unlikely a simple function of decreased concentration of oestrogens. Published evidence suggests that adipose tissue is a central component within the complex system of metabolic and hormonal interactions responsible for adequate mineralization of the bone. However, to the best of our knowledge, the composite effects of specific substances synthesized within adipose tissue from various anatomical compartments, ovarian hormones and insulin on bone turnover, have not been a subject of a complex analysis in women with menstrual disorders. Therefore, the aim of this retrospective study was to verify if volume and distribution of adipose tissue may predict bone loss in this group. The study included 293 Caucasian women (mean age 26.7 ± 4.4 years) with at least 6-month history of secondary amenorrhea. Based on T-score values for bone mineral density (BMD) in lumbar spine, the study subjects were divided into two groups, with T-scores below −0.5 and at least 0.5. Univariate logistic regression analysis showed that lower bone mineral density (as shown by T-score below −0.5) was associated with larger volumes of gynoid (odds ratio, OR = 7.45), android (OR = 3.03) and visceral adipose tissue (OR = 1.55), as well as with higher values of body mass index (BMI, OR = 1.17), fasting concentration of insulin (OR = 1.08) and body weight (OR = 1.06). However, none of these variables turned out to be an independent predictor of BMD deficiency on multivariate analysis. These findings imply that excessive volume of adipose tissue, irrespective of distribution thereof, is a strong determinant of reduced BMD in women with ovarian insufficiency. The lack of region-specific effects of adipose tissue volume on BMD is probably associated with the influence of ovarian insufficiency on

systemic metabolism and endocrine processes, in particular with the development of insulin resistance.

Effect of chronic atrophic gastritis on bone mineral density of Korean women

CB Lee[1], YC Jeon[1] & KY Lee[2]
[1]Hanyang University Guri Hospital, Guri, Republic of Korea; [2]Incheon Gil Hospital, Incheon, Republic of Korea.

Hydrochloric acid has been demonstrated to be important for the absorption of calcium and the bone loss is often seen in human after total gastrectomy. The aim of our study was to document the change of calcium and bone metabolism in the patients with decreased capacity of gastric acid secretion like chronic atrophic gastritis.

The study sample consisted of chronic atrophic gastritis group and control group. Chronic atrophic gastritis group was 20 post-menopausal females (age: 60.3 ± 5.1 yr) who was confirmed by gastroscopic biopsy, demonstrating atrophic change of gastric mucosal secretory tissue. Control group had 21 healthy females (age: 58.7 ± 6.5 yr) with normal gastroscopic biopsy results. Gastric pH, serum levels of calcium, phosphorus, total alkaline phosphatase, intact PTH, and bone mineral density (Delphi, Hologic, USA) were monitored in all the patients in both group before medication. There were no significant differences of gastric pH (3.9 ± 0.6 vs 3.3 ± 1.0, $P > 0.05$), calcium (8.9 ± 0.9 vs 8.8 ± 1.4 mg/dl, $P > 0.05$), phosphorus (3.2 ± 1.5 vs 3.5 ± 0.9 mg/dl, $P > 0.05$), total alkaline phosphatase (72.5 ± 24.5 vs 60.3 ± 22.4 U/l, $P > 0.05$) and intact PTH (29.3 ± 5.1 vs 27.2 ± 3.8 pg/ml, $P > 0.05$) between chronic atrophic gastritis group and control group. Bone mineral density showed decreased average value in atrophic gastritis group comparing control group (0.78 ± 0.27 vs 0.85 ± 0.31 g/cm^2, $P = 0.09$).

In conclusion, chronic atrophic gastritis which have lower capacity of gastric acid secretion may cause decrease of bone mineral density. And this mechanism may be one of the pathogenesis of senile osteoporosis.

May serotonin metabolism polymorphisms 5HTTVNTR and 5HT$_{2A}$ have a clinical impact in osteoporosis development?

Raquel Simões[1,2], Joana Freitas[1,2], Ana Paula Barbosa[3,4], Rui Mascarenhas[3,4] & Manuel Bicho[1,2]
[1]Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; [2]ISAMB, Genetics Laboratory, Lisbon Medical School, Lisbon, Portugal; [3]Clinic of Endocrinology, Diabetes and Metabolism, Lda., Lisbon, Portugal; [4]Department of Endocrinology, Diabetes and Metabolism, Santa Maria Hospital, Lisbon, Portugal.

Objectives

To study the association of serotonin transporter gene (SLC6A4) polymorphism 5HTTVNTR and serotonin receptor 2A polymorphism 5HT2A_T102C with bone mineral density and metabolic parameters of bone remodelling.

Materials and methods

BMD (g/cm2) was measured by DEXA in 105 post-menopausal women: 35 with normal BMD (age = 58.30 ± 1.33 years; BMI = 28.18 [19.13-39.87] kg/m^2) and 70 with osteoporosis (age = 68.30 ± 1.09 years; BMI = 28.90 [20.78-43.86] kg/m^2). Metabolic bone remodelling parameters were analysed: LDL, HDL, total cholesterol, $HOMA_{IR}$, insulin, glycaemia, alkaline phosphatase, osteocalcin and parathormone. It was determined the platelet and plasma serotonin concentrations by ELISA. 5HTTVNTR was evaluated by PCR and the 5HT$_{2A}$_T102C by PCR-RFLP. Statistical analysis by SPSS 21.0.

Results

In osteoporosis, we found increased osteocalcin ($P = 0.030$) and plasma 5HT concentration ($P = 0.012$) and decreased insulin ($P = 0.023$) and total cholesterol ($P = 0.027$). In women with normal BMD, we found an association between genotype 10/10 of 5HTTVNTR and decreased osteocalcin ($P = 0.035$). and between genotype CC of 5HT$_{2A}$ and decreased HDL ($P = 0.029$). Within this group, we also found inverse correlations between HDL and alkaline phosphatase ($P = 0.030$) and $HOMA_{IR}$ ($P = 0.018$). In women with osteoporosis, we found direct correlations between glycaemia and osteocalcin ($P = 0.017$) and HDL ($P = 0.049$).

Conclusion

In normal BMD, 5HTTVNTR and 5HT2A_T102C polymorphisms appear to modulate directly or indirectly some metabolic parameters associated with bone remodelling. These polymorphisms seem to have no effect in women with osteoporosis suggesting that they may play a relevant role in the susceptibility to osteoporosis development by modulating metabolic bone remodelling parameters.

The effect of mechanical assisted squat exercise on pulmonary function, muscle mass and function with or without sarcopenia

YunKyung Jeon, MyungJun Shin, InJoo Kim, BoHyun Kim & YongBeom Shin
Pusan National University Hospital, Busan, Republic of Korea.

Introduction

Sarcopenia is a geriatric syndrome that causes age-related changes to muscle mass and function. Lung function is reduced in elderly patients with sarcopenia. We explored whether a mechanically assisted squat exercise improved muscle function and mass and pulmonary function in community-dwelling elderly women with or without sarcopenia.

Methods

Participants were recruited via posters or the websites of regional health centers. In total, 76 community-dwelling elderly subjects (aged >60 years) were screened. We finally included 47 subjects in this prospective study. They were randomly assigned to exercise or non-exercise group as a ratio of 2:1. We measured lung function, knee extensor strength, hand grip strength, and the body composition before and after 6 weeks of mechanically assisted squat exercises (3 days a week, 30 min per day).

Results

Subjects with sarcopenia had poor hand grip strength and knee extensor strength. Their lung function parameters [including vital capacity, forced expiratory volume in 1 s (FEV1), and forced vital capacity (FVC)] were lower than those of controls. After 6 weeks of squat exercises, the hand grip strength and knee extensor strength increased significantly in both the sarcopenia and control groups. Appendicular skeletal muscle mass was increased in exercise group only in without sarcopenia group ($P = 0.013$). Leg fat mass was significantly decreased in both sarcopenia and non-sarcopenic group. However, leg lean mass was significantly increased only in non-sarcopenic group after exercise. The FVC (L) and FVC (%) increased significantly only in the sarcopenia group ($P = 0.019$ and $P = 0.041$, respectively), but not in the control group.

Conclusion

Squat exercises improved not only lower extremity functionality, but also upper extremity functionality, including hand grip strength. Muscle mass was significantly increased in without sarcopenia after exercise. The FVC increased in the sarcopenia group. Thus, squat exercises may improve lung function in patients with sarcopenia.

Beta-2 adrenergic receptor (ADRB2) gene polymorphism Arg16Gly as risk factor for osteoporosis

Raquel Simões[1,2], Joana Freitas[1,2], Ana Paula Barbosa[3,4], Mário Mascarenhas[3,4] & Manuel Bicho[3,4]
[1]Institute for Scientific Research Bento Rocha Cabral, Lisbon, Portugal; [2]ISAMB, Genetics Laboratory, Lisbon Medical School, Lisbon, Portugal; [3]Clinic of Endocrinology, Diabetes and Metabolism, Lda., Lisbon, Portugal; [4]Department of Endocrinology, Diabetes and Metabolism, Santa Maria Hospital, Lisbon, Portugal.

Objectives
To study the association of Beta-2 adrenergic receptor (ADRB2) gene polymorphism Arg16Gly with bone mineral density and metabolic parameters of bone remodelling.
Materials and methods
BMD (g/cm^2) was measured by DEXA in 105 post-menopausal women: 35 with normal BMD (age = 58.30 ± 1.33 years; BMI = 28.18 [19.13-39.87] kg/m^2) and 70 with osteoporosis (age = 68.30 ± 1.09 years; BMI = 28.90 [20.78-43.86] kg/m^2). Metabolic bone remodelling parameters were analysed: LDL, HDL, total cholesterol, $HOMA_{IR}$, insulin, glycaemia, alkaline phosphatase, osteocalcin and parathormone. Arg16Gly polymorphism was evaluated by PCR-RFLP. Statistical analysis by SPSS 21.0. Statistical significance for $P < 0.05$.
Results
We found association between Arg16Gly polymorphism and osteoporosis with an increase of homozygous Gly/Gly in women with osteoporosis ($P = 0.009$). They showed a higher risk for the development of osteoporosis (OR = 6.517; CI95% [1.663-25.539]). In osteoporosis, we found increased osteocalcin ($P = 0.030$) and decreased insulin ($P = 0.023$) and total cholesterol ($P = 0.027$). In women with normal BMD, we found an association between genotype carriers of allele Arg (Arg/Arg + Arg/Gly) and decreased total cholesterol ($P = 0.018$). We also found an association between carriers of allele Gly (Arg/Gly + Gly/Gly) and decreased of glycaemia ($P = 0.010$). Within women with normal BMD, we also found inverse correlations between HDL and alkaline phosphatase ($P = 0.030$) and $HOMA_{IR}$ ($P = 0.018$). In women with osteoporosis, we found direct correlations between glycaemia and osteocalcin ($P = 0.017$) and HDL ($P = 0.049$).
Conclusion
Arg6Gly polymorphism of ADRB2 gene is associated with a higher risk for the development of osteoporosis. This polymorphism also appears to modulate directly or indirectly some metabolic parameters associated with bone remodelling.

Bone histomorphometry and bone marrow adipocytes in premenopausal women with type 2 diabetes

Vicente Andrade[1], Victoria Borba[1], Domingos Chula[1], Fellype Barreto[2], Cesar Boguszewski[1] & Carolina Moreira[1,2]
[1]Endocrine Division of Feral/University of Parana – SEMPR, Curitiba, Brazil; [2]LABORATORY PRO, Histomorphometry sivision, Pro Renal Foundation, Curitiba, Brazil.

Few studies have evaluated bone histomorphometry in type 2 diabetic patients (DM2) and none has established if the disease control plays a role on bone morphology and bone marrow adipocytes. The aim of this study is to present preliminary data on bone microstructure, bone formation rate and bone marrow adipocytes in premenopausal women with DM2 with different levels of glucose control. Bone biopsy, followed by tetracycline labelling, was obtained for analysis of static and dynamic parameters of bone histomorphometry and volume of bone marrow adipocytes. To date, 12 bone biopsies and 6 histomorphometry analysis were performed in a group of women with mean age of 40.9 ± 6.0 yrs, mean duration of DM2 of 6.8 ± 2.6 years and median glycosylated haemoglobin of 8,1% (range 6.5–12.3). Initial results have shown a normal bone volume, reduced bone formation and an increase in adipocytes content in comparison to normal premenopausal women values at the literature. Our preliminary results suggest that bone morphology and bone marrow adipocytes content is altered in premenopausal women with DM2.

Differences in bone strength and metabolic parameters according to the presence of hyperadiponectinemia and obesity in Korean adults: The KoGES- ARIRANG study

Jung Soo Lim[1], Eunhee Choi[2], Ji Hye Huh[1], Mi Young Lee[1], Jang Yel Shin[1], Choon Hee Chung[1], Sang Baek Koh[3] & Song Vogue Ahn[3]
[1]Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Republic of Korea; [2]Smith Center for Outcomes Research in Cardiology, Beth Israel Deaconess Medical Center, Boston, MA, USA; [3]Department of Preventive Medicine, Yonsei University Wonju College of Medicine, Wonju, Gangwon, Republic of Korea.

Adiponectin has been thought to exert important influences in energy homeostasis and insulin signalling pathway. Some obese individuals showed paradoxical hyperadiponectine-mia (HA), however, the effect of HA on bone metabolism has not been fully clarified.
This study aimed to evaluate bone strength and metabolic parameters according to the presence of HA and obesity in Korean adults. A total of 9,172 adults (59.4% women) aged 40–70 years assessed in the Korean Genomic Rural Cohort Study from 2005 to 2008 were examined. HA was defined as the levels of higher than or equal to the upper tertile among metabolically healthy subjects with a bone mass index (BMI) less than 23 kg/m^2.
Moreover, obesity was defined as a BMI of more than or equal to 25 kg/m^2. The serum con-centrations of adiponecti-n were measured by radioimmunoassay. In addition, bone status was assessed using the calcaneal quantitative ultrasound method. Obese subjects and those who have HA accounted for 40.3% and 15.7%, respectively; about twenty percent of the non-obese and 9.5% of the obese had HA. Although most of metabolic parameters such as fasting glucose and lipid profiles were significantly better in the HA group compared with the non-HA group, bone stiffness index (BSI) in the former was lower in the latter. In both the non-obese and obese groups, individuals with HA had lower waist circumference and BSI. Moreover, obese subjects without HA showed the highest BSI levels among the group-s, which was especially prominent in women. Our results suggest that bone strength in obese individuals may be more negatively affected by high adiponectin levels. Further studies are necessary to confirm the effects of adiponectin on bone health in subjects with obesity.

Do the surgical outcomes change if the surgeon accompanies the endocrinologist during the preoperative ultrasonography examination?

Ibrahim Kilic[1], Sefika Burcak Polat[2], Sevgul Faki[2], Mehmet Tokac[1], Reyhan Ersoy[2], Mehmet Kilic[3] & Bekir Cakir[2]
[1]Department of Surgery, Ataturk Education and Research Hospital Education and Research Hospital, School of Medicine, Ankara, Turkey; [2]Department of Endocrinology and Metabolism, Yildirim Beyazit University, School of Medicine, Ankara, Turkey; [3]Department of Surgery, Yildirim Beyazit University, School of Medicine, Ankara, Turkey.

Introduction
Parathyroid surgical therapy differs because the glands are small and of variable number and location. Although localization studies have improved greatly, we may not reliably determine the number and location of all diseased glands preoperatively. Ultrasonography (US) is the most widely used imaging method. In this study, we aimed to demonstrate how the surgical outcomes change when the surgeon accompanies the endocrinologist during preoperative ultrasonography examination.
Methods
This prospective study included 50 patients with primary hyperparathyroidism (PHPT) who underwent a minimally invasive parathyroid adenomectomy under local anaesthesia at our institution from January 2014 to December 2015. The patients were divided in two groups. In group A, all patients underwent neck US performed by an experienced endocrinologist and the surgeon on the day of operation and the location of the lesion was specified by the surgeon. Group B patients were operated according to the previous US performed by the endocrinologist only.
Results
There were 25 patients in Group A and 25 patients in Group B. The two groups were similar in regard to demographical features, biochemical and hormonal parameters. Postoperative parathyroid hormone (PTH), calcium and phosphorus levels didn't differ between the groups. In group A operation duration was significantly shorter compared to Group B (25.7 min vs 45 min, $P = 0.00$).

Conclusion
Preoperative detection of hyperactive parathyroid glands is useful for minimizing the extent of surgical intervention, reducing operation time and decreasing the risk of perioperative complication.

Teriparatide discontinuation in a patient with post surgical hypoparathyroidism: a clinical challenge

Alessandro Brancatella, Matteo Apicella, Emilio Fiore, Giovanni Ceccarini, Edda Vignali, Claudio Marcocci, Paolo Vitti & Eleonora Molinaro
Department of Endocrinology and Metabolism, Univesity of Pisa, Pisa, Italy.

Context
Teriparatide may represent a possible treatment for hypoparathyroidism when oral supplementation with calcium and calcitriol fail to maintain adequate serum calcium level (SCL). The switch from teriparitide to oral calcium and calcitriol could be challenging and there is no consensus for clinical management.
Case presentation
A 50-year-old man was admitted at our Department for teriparatide discontinuation. Three years before admission, the patient underwent total thyroidectomy for a multinodular goiter. Three months after thyroidectomy, the patient was admitted to the intensive care unit for the onset of symptomatic hypocalcemia. Laboratory exams were consistent with hypocalcemia related to post-surgical hypoparathyroidism. The patient was discharged with calcium carbonate and calcitriol therapy but in the following months the patient was re-admitted several times to the E.R. for the recurrence of symptomatic hypocalcemia. Therefore in addition to the oral therapy, teriparatide was introduced. After two years of treatment, teriparatide has been discontinued in accordance to the national drug administration (AIFA) authorizing regulations. At the admission, the physical examination was normal. Laboratory exams were notable for low SCL and an elevated serum TSH level despite high dose of Levothyroxine supplementation (250 mcg/d). After teriparatide discontinuation SCL progressively decreased (6,5 mg/dl) with the onset symptoms of hypocalcemia, despite high doses of calcium carbonate and calcitriol. Further investigations revealed an atrophic autoimmune gastritis, confirmed at gastroscopy. It was decided to switch from calcium carbonate to calcium citrate and to modify patient's diet. SCL slowly increased up to 8,6 mg/dl so that the patient could be discharged. In six months, no symptomatic hypocalcemia occurred and the SCL were stable with oral therapy.
Conclusions
Teriparatide discontinuation in patients treated for hypoparathyroidism is challenging and clinically does not differ from "hungry bone syndrome" after parathyroidectomy. Furthermore calcium citrate could be an alternative to calcium carbonate in patients with achlorhydria.

Endocrine disorders in treatment-naïve male patients with HIV infection

Nikolaos Kalogeris[1], Markella Nezi[1], Maria Chini[2], Athina Lioni[2], Vissaria Sakka[2], Nikolaos Mangafas[2], Styliani Kaoustou[2], Marios Lazanas[2] & Andromachi Vryonidou[1]
[1]Department of Endocrinology, Diabetes and Metabolism, Red Cross General Hospital, Athens, Greece; [2]Infectious Diseases Unit, Red Cross General Hospital, Athens, Greece.

Objective
To investigate endocrine disorders concerning bone metabolism, thyroid and gonadal axis in treatment–naïve HIV-infected male patients.
Subjects and methods
We studied 70 male, treatment-naïve patients (stage A = 60, stage B = 10) from the Infectious Diseases Unit of our Hospital. Anthropometric indices were measured and BMI was calculated for each participant. Blood samples were obtained after an overnight fasting for the evaluation of thyroid hormones, 25OHD3, gonadotropins, total testosterone, sex hormone binding globulin (SHBG) levels. Free Androgen Index (FAI) and bioavailable testosterone (BAT) were calculated. Bone mineral density (BMD) in the lumbar spine and adipose tissue percentage (FMR) was measured with DEXA. SPSS 16.0 was used for statistical data processing.
Results
Patients were 33.7 ± 8.9 years old (mean $\pm$ S.D.), BMI was 24.6 ± 5.2 kg/m^2, CD4+ were 475 c/μl (24–1,476) and viral load was 38 600 cp/ml (927–422 000). Four patients (6%) presented with low testosterone levels (hypogonadotropic hypogonadism) and one with newly diagnosed subclinical hypothyroidism requiring therapy. Significant reduction of BMD was observed in 26 patients (37%) from which 22 had osteopenia (Z score -1 to -2.5) and four had osteoporosis (Z score < -2.5). Reduced BMD correlated positively with low BMI ($P < 0.01$), while no correlation was found with viral load, CD4+, smoking, 25OHD3 and gonadal hormones' concentrations ($P > 0.05$).
Conclusion
In treatment – naïve HIV-infected male patients, the most frequently observed endocrine disorder is reduced BMD, which does not seem to correlate with HIV infection markers. In patients with low BMI, measurement of BMD would be helpful for early diagnosis of reduced bone mass and the prevention of further loss by using the most suitable antiretroviral therapy.

Trabecular bone score is negatively associated with bone resorbtion markers in patients with primary hyperparathyroidism

Daniel Grigorie[1,2], Mirela Ivan[2], Andra Caragheorgheopol[2], Diana Paun[2] & Alina Sucaliuc[1,2]
[1]Carol Davila University of Medicine, Bucharest, Romania; [2]National Institute of Endocrinology, Bucharest, Romania.

Objectives
Mean TBS (Trabecular Bone Score) values are generally lower in PHPT (primary hyperparathyroidism) patients than controls. The aim of this study was to assess TBS from spine DXA images in patients with PHPT and look at its correlates.
Methods
This was a cross-sectional study conducted in an osteoporosis referral center. One hundred and thirty six patients with PHPT were selected from our database (2010–2016) if they had a valid LS DXA scan. The patients were both females (20% premenopausal) and males (12%), mean age 59.4 yrs (range 16–83), with both asymptomatic and symptomatic PHPT (mean PTH 226 pg/ml, mean serum calcium 11.3 mg/dl); a third of the patients were severely vitamin D deficient (< 10 ng/ml). TBS indices were derived from LS-DXA images and cutoff points used in term of fracture risk were those previously reported.
Results
Mean TBS values of the group was 1.26 ± 0.12. TBS Z-score was negatively and significantly correlated with serum PTH, serum Calcium, Osteocalcin ($r = -0.275$, $P = 0.005$) and mostly C-telopeptide ($r = -0.314$, $P = 0.001$). Actually TBS values and both T and Z scores correlated negatively and significantly with serum C-telopeptide. TBS was in the partially degraded range but did not differ by vitamin D status, even when compared with severely deficient patients (35 pts, mean TBS 1.25). PTH correlated negatively with 25OHD and TBS correlated strongly ($r = 0.536$) with aBMD.
Conclusion
We observed a good and negative correlation between TBS and serum C-telopeptide which favor the notion that TBS might reflect degraded microarchitecture.

Normocalcemic primary hyperparathyroidism (NPH)

Cristina Corina Pop-Radu[1,2]
[1]University of Medicine and Pharmacy, Tirgu Mures, Transilvania, Romania; [2]Mures Clinic County Hospital, Tirgu Mures, Transilvania, Romania.

Normocalcemic primary hyperparathyroidism (NPH) is characterized by normal total and ionized serum calcium concentrations and consistently elevated PTH levels. These patients have no obvious causes for secondary elevations of PTH, such as renal disease, vitamin D deficiency or malnutrition. The group consisted

of 22 postmenopausal women, six premenopausal women, and two men, aged 58 ± 2 years (range 31–77) investigated between 2011 and 2016.
Results
All subjects had normal renal function and 25-hydroxyvitamin D levels > 20 ng/ml (80% had levels > 30 ng/ml); none used thiazide diuretics or lithium or demonstrated significant hypercalciuria. The reasons for referral included elevated PTH discovered during the evaluation of low bone mass ($n = 22$), recent fragility fracture ($n = 2$), nephrolithiasis ($n = 6$).
At the time of diagnosis, 70% had osteoporosis by BMD (measured at the lumbar spine, hip or distal one-third of the non-dominant radius), 6.6% had documented fragility fractures, and 20% had nephrolithiasis. PTH was elevated, while albumin-corrected serum calcium, serum phosphorus, alkaline phosphatase activity, and urinary calcium, were all in the mid-normal range.
Nine patients with positive localization studies (cervical ultrasonography, technetium 99 m sestamibi scanning) underwent successful parathyroidectomy, with operative findings of a single adenoma or hyperplasia. Twenty one patients who did not undergo surgery were followed for 3.1 ± 0.3 years (annual serum calcium, PTH and bone mineral density determinations). Hypercalcemia developed in 19% of these individuals. Two of the patients who developed hypercalcemia and three additional patients with persistently normal serum calcium levels underwent successful parathyroidectomy. Fourteen patients were without significant change in serum calcium or development of hypercalcemia, PTH continued to remain elevated.

EP242

Secondary hyperparathyroidism and its implication on bone mineral density in patients with different stages of chronic kidney disease

Natalia Karlovich
Minsk City Endocrinology Dispensary, Minsk, Belarus.

Secondary (SHPT) is frequent in patients with chronic kidney disease and can predispose patients to low bone mineral density (BMD). Necessity of BMD assessment in such patients is controversial.
The aim was to analyze BMD and PTH secretion in patients with different stages of chronic kidney disease. We examined 311 patients, 161 f, 150 m; age 49.2 ± 14.4 yrs; 190 patients are on continuous dialysis due to end-stage chronic kidney disease (mean dialysis duration 4.9 ± 3.9 yrs), 121 patients with CKD 1–5 not on dialysis. Serum PTH was measured and BMD was estimated by DEXA in lumbar spine and in proximal part of femur, T score < -2.5 was classified as low BMD. Median PTH level was 314.1 pg/ml (119.2; 770.7) in dialysis patients and 149.0 (65.2; 259.7) in patients with CKD 1–5 not on dialysis ($P < 0.05$). PTH was above upper limit of the reference range in all dialysis patients and in 51.6% of them was 300 pg/ml and higher. SHPT was revealed in all patients with CKD 4–5, in 38.1% of patients with CKD 3; in 25.3% of those with CKD 1–2. In dialysis patients low BMD was revealed in 24.7% of cases, significant implication of PTH level > 300 pg/ml on low BMD development was revealed. In patients with CKD 1–2 there were no cases of low BMD, with CKD 3–19.1%, with CKD 4 and CKD 5–33.3% ($P < 0.05$). Prevalence of low BMD was 10.7% in non-dialysis patients with normal PTH and 29.7% – with SHPT ($P < 0.05$).
We can assume that frequency of low BMD is 25% and higher in patients with CKD 4–5 and secondary hyperparathyroidism significantly implicates on its development. Future investigation is required to evaluate clinical implication of DEXA in patients with SHPT for fracture risk assessment.

Impact of vitamin D on the bone quality assessed by trabecular bone score in men

Mário Rui Mascarenhas[1,2], Ana Paula Barbosa[1,2], Nuno Duarte[2], Ana Wessling[2,3], Ana Raquel Coelho Gomes[3], Carolina Faria[3], Raquel Paixão[3], David Barbosa[3], Catarina Silvestre[3], José Poupino[2], Vânia Gomes[3], Ana Sofia Osório[3], Francisco Sampaio[2], Jacinto Monteiro[2], Didier Hans[4], Manuel Bicho[1] & Maria João Bugalho[2,3]
[1]Endocrinology and Metabolic Diseases, Faculty Medicine of Lisbon, Lisbon, Portugal; [2]Fracturary Osteoporosis Outpatient Clinic – Endocrinology, Diabetes and Metabolism Department, Santa University Maria Hospital-Chln, Epe, Lisbon, Portugal; [3]Endocrinology, Diabetes and Metabolism Department, Santa University Maria Hospital-Chln, Epe, Lisbon, Portugal; [4]Bone Center, Lausanne University Hospital, Lausanne, Switzerland.

Trabecular bone score (TBS) is a recent noninvasive analytical method, based upon DXA images, related to bone microarchitecture or bone quality; together, TBS and DXA may evidence bone strength. Falls and osteoporotic fractures increase with ageing, while both BMD and vitamin D levels slowly decline. Data about the influence of vitamin D on the TBS are scarce.
Aim
To evaluate the influence of the blood vitamin D levels on the TBS in normal men.
Material and methods
The lumbar spine BMD (g/cm^2), and TBS (obtained from DXA scans) were evaluated in a group of normal men more than 40 years old. Fasting blood was collected for osteocalcin, 25(OH)D and iPTH measurements. This group was divided in normal, insufficiency and deficiency vitamin D groups (ES Guidelines) and also in normal BMD, low BMD and osteoporosis groups. Total body fat and lean masses were also assessed by DXA. Adequate statistical tests were used (statistical significance $P < 0.05$).
Results
The mean (± S.D.) BMD and TBS of the vitamin D groups are shown in Table 1. Men of the deficiency vitamin D group were the heaviest and had the lowest TBS. Significant relations were detected between the blood 25(OH)D *vs*. TBS, *vs*. weight and *vs*. total fat mass but not *vs*. BMD.
Conclusions
Blood 25(OH)D levels may play an important role on the bone microarchitecture (by TBS) in vitamin D deficient men, as they have worse bone quality. These data suggest that further studies are needed on larger cohort of men and it might be worth to investigate also elderly men with osteomalacia.

Table 1

Groups Variable	Normal (49.3%)	Insufficiency (37.7%)	Deficiency (13.0%)	*P*
TBS L_1-L_4	1.044 (±0.14)	1.087 (±0.16)	1.079(±0.15)	0.0071
L_1-L_4 BMD g/cm^2	1.294 (±0.12)	1.323 (±0.12)	1.434 (±0.07)	NSD

Neutrophil lymphocyte ratio in 6 month teriparatide therapy of osteoporosis

Bengur Taskiran[1], Goknur Yorulmaz[2], Guven Baris Cansu[1] & Aysen Akalin[2]
[1]Yunus Emre State Hospital, Eskisehir, Turkey; [2]Osmangazi University, Eskisehir, Turkey.

Aim
Low BMD and atherosclerosis may share similar underlying biological mechanisms including higher serum phosphate and inflammation. Neutrophil-lymphocyte ratio (NLR) as a simple marker of inflammation. There are scarce data indicating improved atherosclerosis and cardiovascular events with biphosphonate and teriparatide therapy. We aimed to evaluate NLR before and after 6 months of teriparatide therapy in patients with severe established osteoporosis.
Methods and materials
Electronic data of 53 (49 female, four male) patients with severe osteoporosis and history of fracture of femur neck and/or lumbar spine were evaluated. None of them were previously diagnosed with rheumatoid arthritis, DM, and secondary osteoporosis. Sixteen had with HT and/or other cardiovascular disease.
Results
Mean age was 74 ± 9 years, baseline 25 OH vitamin D level 25.6 ± 17.6 ng/ml, baseline NLR 2.22 ± 0.89, 25 OH vitamin D level at 6th month 27.8 ± 13.4 ng/ml, NLR at 6th month 2.10 ± 0.96.
Mean baseline and 6th month measurements of NLR, 25 OH vitamin D, parathormone, ALP, ESR, and phosphorus were similar in patients with and without cardiovascular disease. NLR did not change significantly after 6 months of teriparatide therapy.
Conclusion
NLR does not change in short term teriparatide therapy and association between osteoporosis and cardiovascular disease cannot be settled in advanced age.

Analysis of DXA scans of males performed in clinical center of vojvodina

Bojan Vukovic[1,2], Jovanka Novakovic Paro[1,2], Tijana Icin[1,2], Ivana Bajkin[1], Djordje Popovic[1,2], Milica Medic Stojanoska[1,2], Radoslav Pejin[1,2] & Edita Stokic[1,2]
[1]Clinical Center of Vojvodina, Clinic for Endocrinology, Diabetes and Metabolic Diseases, Novi Sad, Serbia; [2]Medical Faculty University of Novi Sad, NOvi Sad, Serbia.

The prevalence of osteoporosis among men is not well-documented. The aim of this cross-sectional study is to analyze results of DXA scans preformed in males in Clinical center of Vojvodina between years 2009 and 2016. Form the total of 2006 fist DXA scans performed in 7 years period there was 14.8% of males. DXA scan was indicated by the rheumatologists, internists and endocrinologists predominantly for suspected secondary causes of osteoporosis. We divided male subjects in groups by the age of life. In the group from 20 to 50 years of life there was 68 subjects with average BMI 26.5 ± 6.30 kg/m^2 with average T score in L1–L4 -0.8 ± 1.4 S.D., bone mineral density (BMD) was 1.152 ± 0.184 g/cm^2, and femur neck -0.71 ± 1.2 S.D., BMD 0.959 ± 0.176 g/cm^2, 9 subjects had *Z* score < 2 S.D. In the group form 50 to 70 year of life (average 60.38 ± 4.82, BMI 27.93 ± 5.31 kg/m^2) there was 174 subjects with T score L1–4: -0.82 ± 1.93 S.D., BMD 1.120 ± 0.231 g/cm^2, left femur neck: -1.41 ± 1.36 S.D., BMD 0.887 ± 0.176 g/cm^2. 56 had osteopenia and 49 had osteoporosis. Group above 70 years of life (88 maximum, average 75.6 ± 3.96, BMI 25.17 ± 4.16 kg/m^2) had 55 subjects from whom 22 had osteopenia and 23 osteoporosis and average T score L1–L4 was: -0.85 ± 2.12 S.D., BMD 1.115 ± 0.255 g/cm^2, left femur neck: -1.84 ± 1.25 S.D., BMD 0.829 ± 0.161 g/cm^2. Lower values of *T* score and BMD were measured on left femur neck in older groups. There was very high percentage of osteoporosis and osteopenia in the oldest groups of males although all males referred to DXA scan were suspected to have osteoporosis.

EP246

Biological assessment and causes of secondary osteoporosis

Aicha Bouzid & Djamila Meskine
Dr, Algiers, Algeria.

Secondary osteoporosis accounts for 10–20% of the causes of osteoporosis in menopausal women. The search for a possible etiology should not be neglected before considering the therapeutic management of any osteoporosis. There is no consensus on the first-line biological tests to be prescribed.

Goal

Determine biological abnormalities in postmenopausal women with osteoporosis.

Patients/methods

Postmenopausal women are enrolled, the mean age is 65.5 ± 8.9 years. 305 patients are classified as osteoporotic according to the WHO criteria (*T*-score ≤ 2.5). NFS, VS, CRP, serum calcium, phosphoric acid, 24-hour calcium, total alkaline phosphatase, parathyroid hormone (PTH), serum protein electrophoresis, serum creatinine, liver function test, fasting blood glucose.

Results

6.2% (19/305) patients had an abnormality.

Distribution of anomalies

Monoclonal gammopathy five cases: two myeloma, two MGUS, one unlabeled case

- HPT I: seven cases (two parathyroid adenomas confirmed by the anapath)
- 1 cases rheumatoid arthritis
- diabetes type two unknown: six cases, one case of intolerance to carbohydrates

Discussion/conclusion

In the presence of a low BMD, it is recommended that a diagnostic survey should be carried out, including physical examination, clinical examination and routine biological examinations, in order to eliminate malignant or metabolic osteopathy and to investigate the causes of secondary osteoporosis. In our study targeting a population of postmenopausal osteoporotic women followed in consultation, the discovery by biological examination of a new condition that can lead to bone demineralization is quite common.

Calcium & Vitamin D Metabolism

EP247

Management with Cinacalcet of non-surgical primary hyperparathyroidism in the elderly.

Juan Marti[1], Jose Luis Salsamendi[1], Jon Marti-Ayerdi[2] & LLuis Jordana[1]
[1]Hospital Zumarraga, Zumarraga, Spain; [2]Complejo Hospitalario Navarra, Pamplona, Spain.

Primary hyperparathyroidism (PHPT) is a common condition. The prevalence since the introduction of multichannel analysers is approximately 1:1000, with the older female being the typical patient. PHPT is predominantly a sporadic disorder. Surgery remains the only curative approach to most primary hyperparathyroidism (PHPT), medical treatment with cinacalcet has been proven to be an alternative for patients with hyperparathyroidism.

Objective

Analyze treatment with cinacalcet, in older patient with primary hyperparathyroidism not tributary of surgery.

Material and patients

Between 2011 and 2015, 13 patients with PHPT who were not suitable for surgery were identified. Data collected: age, gender, comorbidities, levels of calcium and PTH and follow-up.

Results

We present 13 patients 8 women and 5 man with a mean of age 80.5 ± 6.59 year-old (range 71–92). Comorbidities, diabetes mellitus 50%, frailty 58%, heart disease 40%, depression 33%, cognitive impairment 17%. Calcium levels previous treatment was 11.85 ± 0.28 mgr/dl and PTH 123 ± 34 pg/ml. T cinacalcet 30 mg. daily was initiated, in 12 patients and 60 mgr. in one. Patients were followed for 1–4 years (2.75 ± 1.21) calcium were adequately controlled (9.98 ± 0.78 mgr/dl), but PTH 112.4 ± 42 pg/ml remains high, renal function was uncharged in all patients. Two patients died during the follow-up, not related with hyperparathyroidism. Adverse events were observed in 1 patient (vomiting) that disappeared to diminishing doses.

Discussion

Geriatricians will readily recognize the clinical conundrum of an incidental finding of PHPT in the older that was unexpected. Retrospective questioning may identify some pertinent symptoms, but none strong enough on their own to have made the diagnosis obvious prior to testing serum calcium. This group of patients is hard to define and hence there is little published guidance on how to manage the increasingly common clinical scenario of the frail, relatively asymptomatic, older patient with PHPT.

Conclusions

Cinacalcet, the first available calcimimetic, increases the sensitivity of the calcium-sensing receptor (CaR) to circulating serum calcium, thereby safely reducing serum calcium and PTH concentrations in patients with mild-to-moderate PHPT, intractable disease, and also parathyroid carcinoma. Cinacalcet in a reasonable and safe alternative to treatment of PHPT not tributary of surgery.

Glucocorticoids regulate expression of lung calbindin-D9k in mouse

Jin Yong An, Jae-Hwan Lee, Seon Yong Park & Eui-Bae Jeung
Chungbuk National University, Cheongju, Chungbuk, Republic of Korea.

Introduction

Calbindin-D9k (CaBP-9k), which is a calcium ion buffering and transporter gene, is known to be regulated by the vitamin D and steroid hormones, and is mainly expressed in mammalian intestine, kidney and uterus. However, CaBP-9k expression in lung has not been studied. Maintaining lung structure using pulmonary surfactant is important for pulmonary gas exchange. Steroids are known to accelerate maturation of the fetal lung and secretion of surfactant. Otherwise the relationship between pulmonary function especially in surfactant secretion and CaBP-9k expression has not been researched. In this study, we investigate the CaBP-9k expression by sex steroid hormones and glucocorticoids in mouse lung.

Materials and methods

To confirm the effect of sex steroid hormones, the immature mice age from 14 days to 16 days were respectively injected of estrogen (E_2) and progesterone (P_4) for 3 days. To confirm the effect of glucocorticoids, the mature mice age from

11 weeks were respectively injected of dexamethasone (Dex). ER antagonist (ICI187,780) and PR, GR antagonist (RU486) were injected 30 min prior to steroid hormones. We compared the changes in the CaBP-9k expression of each group using polymerase chain reaction.
Results
In the estrogen and progesterone treated immature mice lung, the CaBP-9k gene expression had no significant change in mRNA and protein level but significantly increased in Dex treated mice lung. It is suggested that glucocorticoids may play a role in regulation of CaBP-9k expression in lung.
Conclusion
Our results has significance to the regulation of CaBP-9k by Dex. By studying the effects on lung surfactant through the control of CaBP-9k, it may be presented as a basis data of pulmonary surfactant associated disease or research.

Vitamin D intoxication caused hypercalcemia: Case report

Kader Ugur[1], Hakan Artas[2], Mehmet Balin[3], Esra Aykut[4], Selcuk Demircan[4], Bedrettin Orhan[4] & Nevzat Gozel[4]
[1]Firat Univercity Department of Endocrinology, Elazig, Turkey; [2]Firat Univercity Department of Radiology, Elazig, Turkey; [3]Firat Univercity Department of Cardiology, Elazig, Turkey; [4]Firat Univercity Department of Internal Medicine, Elazig, Turkey.

Introduction
Vitamin D is a fat soluble prohormone and can be produced in the body with adequate sunlight exposure or taken up by consumed foods or supplements. Recently vitamin D deficiency has been seen in pandemic. A rare disease, vitamin D intoxication is usually iatrogenic. High levels of 25(OH) vitamin D increases the intestinal calcium absorption and causes severe and refractory hypercalcemia. In this case report we presented a patient with pancreatitis and hypercalcemia secondary to vitamin D intoxication.
Case
79-years-old female patient presented to emergency department with generalized pain, lack of appetite, dry mouth, nausea, vomiting and abdominal pain. Serum calcium level was 13.8 mg/dl. In her medical history she used 12 ampules of vitamin D-3 in the last month. In her physical examination there was abdominal tenderness. Laboratory findings were as follows; 25-OH vitamin D-3: 455 µg/l (20–150), WBC: 19 570 10e3/µl (3.8–8.6), Urea: 60 mg/dl (10–50), Creatinine: 2 mg/dl (0.6–1.2), Ca: 13.8 mg/dl (8.5–10.8), phosphorus: 2.9 mg/dl (2.6–4.5), albumin: 3.7 mg/dl (3.5–5.5), amylase: 132 U/l (28–100), Lipase: 115 U/l (7–60), Parathormone: 28 pg/ml (19.8–74.9). Abdominal CT scan showed interstitial oedematous pancreatitis. In the follow up, patient was hydrated with isotonic saline infusion. To lower the calcium levels, intravenous furosemide infusion was used. Calculated QTc level when serum calcium is 9.1 mg/dl, was 443 msec. According to literature we could see osborn wave in the ECG but we did not.
Discussion
Vitamin D toxicity develops when serum levels of 25 OH vitamin D-3 levels reach 150 ng/ml or above and daily intake should exceed 10.000 IU. In the treatment, cessation of vitamin D intake and controlling of hypercalcemia is mandatory. Limiting daily calcium intake, hydration, loop diuretics, corticosteroids, calcitonin and bisphosphonates can also be used. Dialysis can be performed to those who are refractory to these treatment modalities.
Conclusion
Uncontrolled and over the counter use of vitamin supplements is a common issue worldwide. Patients who need vitamin D supplements should be followed with laboratory and clinically.

Gitelman syndrome and primary hyperparathyroidism – a rare association

Teresa Rego, Fernando Fonseca & Ana Agapito
Endocrinology Department, Centro Hospitalar de Lisboa Central, Lisbon, Portugal.

Gitelman's Syndrome (GS) is a rare autosomal recessive salt-losing tubulopathy of young adults, characterized by secondary hyperaldosteronism, hypokalemia, hypomagnesemia, hypocalciuria and metabolic alkalosis. It is caused by mutations in *SLC12A3* gene. Hypercalcemia due to hypocalciuria in these patients is extremely rare and requires further evaluation.
A 25-year-old normotensive female was referred to Endocrinology clinic for evaluation of persistent hypokalemia. She presented history of malaise, fatigue, myalgias, cramps and paresthesia. She denied diarrhea, recent treatment with diuretics or laxatives. Her physical exam was normal. Laboratory workout revealed: aldosterone 47.1 ng/mL (r.v. 4–31), active renin 374.7 µUI/ml (r.v. 4.4–46.1), K + 2.7 mEq/l (r.v. 3.5–5.1), 24 h urinary K + 84.7 mEq/24 h (r.v. 25–125), Mg2 + 0.71 mg/dl (r.v. 1.6–2.6), 24 h urinary Mg2 + 143.1 mg/24 h (r.v. 73–122), Ca2 + 12 mg/dl (r.v. 8.4–10.2) and 24 h urinary Ca2 + 133 mg/24 h (r.v. 100–300). GS was diagnosed and she was treated with spironolactone, oral K^+ and Mg^{2+} supplementation. Further investigation confirmed hypercalcemia due to primary hyperparathyroidism (parathyroid hormone (PTH) 107.3 pg/ml (r.v. 14.8–83.1)) caused by a large single parathyroid adenoma. Following parathyroidectomy calcium profile normalized. The sequencing of *SLC12A3* gene detected the variant c.602–16G > A and the mutation c.2221G > A (p.Gly741Arg), both in heterozygosity. In this context genetic study of the progenitors was required. The father presents the variant c.602–16G > A and the mother the mutation c.2221G > A (p.Gly741Arg), in *SLC12A3* gene.
The assotiation of hypokalemia, hypomagnesemia and hypercalcemia is uncommon but potentially lethal. Current knowledge favors that hypomagnesemia in GS's patients protects them from hypercalcemia. In this context of multiple electrolyte imbalances, correction of hypomagnesemia is a challenge and should be done carefully. Like in our patient hypercalcemia's etiology should be prompt diagnosed and reversed.

The volume of parathyroid adenoma is related to presurgical PTH and 25OH-D3, but not calcium levels at patients with primary hyperparathyroidism

Cristian Velicescu[1], Cristina Gatu[1], Alexandru Grigorovici[1], Radu Danila[1], Valentin Munteanu[2], Voichita Mogos[1], Carmen Vulpoi[1], Cristina Preda[1], Simona Mogos[1] & Dumitru D Branisteanu[1]
[1]University of Medicine and Pharmacy 'Gr.T.Popa', Iasi, Romania; [2]University of Medicine and Pharmacy 'Iuliu Hatieganu', Cluj, Romania.

Aims
We wanted to evaluate the correlations between the volume of the surgically removed parathyroid adenoma and the presurgical metabolic profile of patients diagnosed with primary hyperparathyroidism.
Materials and methods
Prospective multicentric study, enrolling 52 patients with primary hyperparathyroidism from two medical units, proposed for surgery. Serum calcium and PTH were evaluated in all patients before surgery, and 25OH-D3 was measured only in the 33 patients recruited from one of the two surgery departments. Parathyroid volume was measured immediately after excision, using the formula of a rotating ellypsoid. Data were statistically evaluated by using Pearson correlation analysis. Correlations were considered significant at P values lower than 0.05.
Results
We observed a significant correlation between the volume of parathyroid adenomas and presurgical PTH ($P < 0.001$) but not presurgical calcium levels at patients from the two medical units and in the whole group. Twenty-nine out of the 33 patients diagnosed with primary hyperparathyroidism recruited from the first medical unit had 25OH-D3 levels in the range of vitamin D deficiency or insufficiency. 25OH-D3 was not significantly correlated with PTH or calcium levels, but a significant negative correlation was found between the volume of the parathyroid adenoma and serum 25OH-D3 levels ($P < 0.05$).

Conclusion
The volume of parathyroid adenoma seems to be related to presurgical PTH and 25OH-D3, but not calcium level. D hypovitaminosis is frequently found at patients with primary hyperparathyroidism and may contribute to particular disease profiles. Higher PTH and lower 25OH-D3 levels, as well as larger adenomas may be accompanied by increased disease severity, or by a different spectrum of disease complications.

Pseudohypoparathyroidism type Ib: a case of chronic severe hypocalcaemia and seizures diagnosed in adulthood

Ana Cláudia, Martins, Paula Bogalho & Ana Agapito
Department of Endocrinology, Centro Hospitalar Lisboa Central, Lisbon, Portugal.

Pseudohypoparathyroidism (PHP) is a rare group of genetic disorders characterised by end-organ resistance to parathyroid hormone (PTH). We describe the case of a 34-year-old Caucasian female with severe hypocalcaemia presenting with a first generalised seizure. Her medical history was significant for bilateral cataract. She had three healthy children, and no family history of note. On examination, she had positive Chvostek's sign. Biochemical analysis showed serum calcium 4.5 mg/dl (n.r. 8.4–10.2 mg/dl), phosphorus 5.8 mg/dl (n.r. 2.3–4.7;mg/dl), PTH 94.7 pg/ml (n.r. 14.76–73.1 pg/ml) and vitamin D 19.6 ng/ml (n.r. 30–100 ng/ml), with normal serum albumin and normal alkaline phosphatase. Electrocardiogram demonstrated prolonged corrected QT interval. Brain imaging revealed basal ganglia and cerebellar calcifications, and electroencephalography did not show paroxysmal activity. We excluded a number of causes of secondary hyperparathyroidism based on her medical history and investigations, and concluded that PTH resistance would be the most likely diagnosis. Since she lacked the typical clinical features of Albright hereditary osteodystrophy and did not present with other hormones' resistance, a genetic test was requested and identified abnormal methylation of the 20q13.32 region, confirming the diagnosis of PHP type Ib. The patient is currently medicated with calcium carbonate and calcitriol, maintaining a satisfactory calcium-phosphate homeostasis. This case highlights the importance of PHP as a rare but significant cause of severe hypocalcaemia. The delayed diagnosis, as seen in this case, may result in serious consequences.

A practice review of the use of cinacalcet in primary hyperparathyroidism

Rahat Tauni[1,2], Nida Ali[2] & Ritwik Banerjee[2]
Cambridge University Hospitals, Cambridge, UK; [2]Luton and Dunstable University Hospital, Luton, UK.

Background
The treatment of choice for primary hyperparathyroidism (PHPT) is surgical parathyroidectomy. Cinacalcet is the first calcimimetic approved by European Medicines Agency (EMA) in 2008 for use in patients with PHPT who are not fit for surgery or refuse surgery. British National Formulary (BNF) recommends it for hypercalcaemia in PHPT where parathyroidectomy is inappropriate. The main aim of treatment with cinacalcet is to keep calcium levels at safe levels.

Objectives
To evaluate the efficacy and safety of cinacalcet in patients with PHPT who were unfit for surgery, refused surgery or remain hypercalcaemic post-parathyroidectomy and not amenable to further intervention (complex PHPT).
Methods
We assessed the demographic and clinical characteristics and biochemistry in 12 patients seen in endocrinology and biochemistry clinics with complex PHPT at the commencement of cinacalcet and after approximately 1, 3, 6 and 12 months. We also checked doses, tolerability and side effects of cinacalcet.
Results
Most patients (66.67%) needed small maintenance dose of cinacalcet once a day. Mean baseline adjusted calcium level was 3.36 mmol/l (13.44 mg/dl) with a range of 2.91–5.36 mmol/l (11.64–21.44 mg/dl). There was a significant reduction in adjusted calcium levels at approximately 1 month (10.08%), 3 months (11.93%), 6 months (13.57%) and 12 months (20.17%). Calcium normalised in most patients (83.33%), and one patient developed hypocalcaemia necessitating cinacalcet dose reduction. All patients adhered to the treatment with two people experiencing self-limiting nausea and vomiting.
Conclusion
Our patient cohort indicates that cinacalcet is an effective and safe alternative to surgery in patients with complex PHPT. Cost-effectiveness analyses are needed to allow more widespread use in such patients. Further studies with long-term follow-up are required to assess efficacy in preventing osteoporosis and renal complications related to PHPT.

DOI: 10.1530/endoabs.49.EP254

Is there a threshold of Vitamin D sufficiency that can prevent secondary hyperparathyroidism?

André Amaral[1], Tatiana Nunes[3], João Anselmo[2] & Rui César[2]
[1]Unidade de Saúde Ilha do Faial, Horta, Faial/Açores, Portugal; [2]Hospital Divino Espírito Santo, Ponta Delgada, São Miguel/Açores, Portugal; [3]Unidade de Saúde Ilha de São Miguel, Ponta Delgada, São Miguel, Portugal.

While nonskeletal benefits of vitamin D remain a matter o debate, its importance in bone health is known for decades. Secondary hyperparathyroidism is considered to play a significant role in the pathogenesis of age-related bone loss. In the present study we investigate the association between serum PTH, 25-hydroxyvitamin (25(OH)D) and other clinically related variables in a cross sectional sample of patients followed in an Endocrine consultation during the year 2016. Patients with diseases or medications known to affect calcium metabolism were excluded. 509 participants, 365 female and 145 male, were selected for analysis. Mean age $\pm$S.D. was 52 $\pm$ 16 yrs (2–86); 47% were diabetics; 31% suffered of thyroid disorders and 7% were obese. The mean $\pm$S.D. serum level of 25(OH) D was 20.4 $\pm$ 10.2 ng/ml; 17.8 $\pm$ 8.7 ng/ml in measurements during winter months and 23.4 $\pm$ 10.04 during summer. In 61 patients (12% of the sample) with more than one determination, there was a 51.9% increase in 25(OH) D from a mean level of 16.81 $\pm$ 9.3 ng/ml during winter to 24.94 $\pm$ 11.2 ng/ml during summer months ($P<0.02$). Patients treated with statins presented significantly lower levels of 25(OH)D than non-treated patients, 15.9 $\pm$ 6.7 ng/ml and 26 $\pm$ 10.1 ng/ml, respectively ($P<0.01$).This difference remained statistically significant after adjusting for age, sex and disease.
We found an inverse relationship between 25(OH)D and PTH. The best fitted line was obtained as a logarithmic expression of 25(OH)D ($r=0.65$; $P<0.001$). There was no further significant decrease in PTH for serum levels of 25(OH)D of more than 25 ng/ml. In conclusion, more than half of our patients were Vit D deficient (<20 ng/ml) particularly elderly people treated with statins, but serum levels of 25(OH)D above 25 ng/ml are needed in order to prevent secondary hyperparathyroidism. This value can be considered as the lower limit of Vitamin D sufficiency in the sample studied.

Spontaneous remission of parathyroid adenoma due to parathyroid apoplexy: a case report

Cem Onur Kirac, Suleyman Baldane, Suleyman Ipekci & Levent Kebapcilar
Division of Endocrinology and Metabolism, Selcuk University Faculty of Medicine, Konya, Turkey.

Introduction
Primary hyperparathyroidism (PHPT) is a disease that is characterized by elevated calcium and parathyroid hormone levels. The most common cause of PHPT is the paratiroid adenoma and the first line treatment option is surgical removal of the adenoma. Rarely, the haemorrhage in the lesion may cause the spontaneous remission of the disease.
Case report
A 54-year-old woman patient with fatigue was referred to our department due to calcium level of 11.4 mg/dl (normal range: 8.4–10.2) and PTH level of 76.1 pg/ml (normal range: 15–65). Neck ultrasound examination revealed a 10×5 mm mass lesion in the posterior-inferior region of the left lobe of the thyroid. Sestamibi scan showed activity in the same region with neck ultrasound. Surgical resection of the parathyroid adenoma was planned but the patient refused surgical excision because of personal reasons. One year after the diagnosis of PHPT, her calcium concentration returned into the normal range (9.4 mg/dl), at the same time neck MRI showed a mass with a size of 19×13 mm, which was attached inferiorly to the left lobe of the thyroid. The mass was diagnosed as hemorrhagic parathyroid adenoma because the mass was imaged as a high intensity area by T_2-weighted MRI. At that time the sestamibi scan was negative. Six months after the haemorrhage of the lesion, it was seen that the calcium level rose to 11.1 mg/dl and the PTH level was 89 pg/ml so the PHPT has been recurred.
Conclusion
Parathyroid apoplexy can lead to spontaneous remission of the PHPT but the remission is usually temporary and finally recurrence of the disease could be seen.

EP257

Normocalcemic versus Hypercalcemic Primary Hyperparathyroidism: a comparative study

Natalya Mokrysheva, Svetlana Mirnaya, Anna Eremkina, Julia Krupinova & Elena Kovaleva
Endocrinology Research Centre, Moscow, Russia.

Introduction
Normocalcemic primary hyperparathyroidism (NPHPT) is defined as a condition in which persistently normal serum calcium levels are observed in the presence of high levels of parathyroid hormone (PTH). NPHPT is a new entity which possibly represents a clinically symptomatic disease and which has generated a considerable scientific interest.
Aim
To compare the clinical and laboratory data between the normocalcemic and hypercalcemic forms of PHPT.
Materials and methods
A comparative study of 357 patients with PHPT wich were separated into normocalcemic ($n=56$) and hypercalcemic ($n=301$) subgroups on the basis of their fasting serum total calcium value. Bone mineral density (BMD) and T-scores were evaluated by densitometry of the lumbar spine, femoral neck and total of the radius. Nephrolithiasis and bone fractures were documented by a review of the medical records.
Results
Patients with NPHPT had, on average, a lower serum PTH concentration 150 pg/ml ± 115 (*N* 15–65, Me 114) and a lower serum calcium level 2.44 mmol/l ± 0.08 (*N* 2.15–2.55) vs hypercalcemic PHPT – 408 pg/ml ± 651 (Me 186) and 2.89 mmol/l ± 0.3 respectively. There was no significant difference in urine calcium excretion. The frequency of nephrolithiasis was 27% in normocalcemic patients and 16% in the hypercalcemic ones ($P<0.05$). There were no statistical differences in relation to BMD of the lumbar spine and femoral neck, but BMD significantly differed in the total radius area. BMD in the total radius was 0.423 g/cm^2 (Me 0.415), mean T-score was −2.2 s.d. of the normocalcemic patients, 51.8% had osteoporosis in at least one of the three sites evaluated. In addition, normocalcemic patients differed from hypercalcemic patients by lower values of markers of bone turnover osteocalcin and β-C-telopeptide, $P<0.05$. 20.4% of normocalcemic patients had a previous history of fractures compared to 20.3% of hypercalcemic patients ($P>0.05$).
Conclusion
NPHPT is at present one of the most common reasons for consultation in bone metabolism departments, especially in postmenopausal women. Identifying these patients is important because of the consequences of untreated hyperparathyroidism, which include nephrolithiasis, osteoporosis and atraumatic fractures.

Parathyroid carcinoma: experience of a Portuguese centre

Carlos Tavares Bello[1], Sara Donato[2], Susana Prazeres[2], Helder Simoes[2] & Valeriano Leite[2]
[1]Hospital de Egas Moniz, Lisboa, Portugal; [2]Instituto Portugues de Oncologia Lisboa Francisco Gentil, Lisboa, Portugal.

Introduction
Parathyroid Carcinomas are rare malignant neoplasms, accounting for less than 1% of primary hyperparathyroidism cases. Apart from certain genetic mutations, no additional risk factors are known. Diagnosis is challenging in the absence of metastatic disease since no consensual histological criteria have so far been developed. These neoplasms typically present with severe hypercalcemia and markedly elevated serum PTH levels. Treatment is surgical and despite frequent metastatic disease at diagnosis, clinical course is usually indolent. The authors report the experience of a tertiary reference centre in Portugal regarding parathyroid carcinomas.
Methods
Observational, retrospective study. Patients with diagnosed parathyroid carcinoma from 1999 until 2016 were included. Clinical data was obtained from patient's clinical, laboratory and imaging files. Descriptive statistical methods were used and results are presented as mean and standard deviation.
Results
The sample is composed of ten patients (five females) with a median age of 53 ± 16.9 years at the time of diagnosis. Clinical presentation was heterogeneous. All patients had hyperparathyroidism (mean 1229 ± 642 pg/ml), nine hypercalcemia (13.4 ± 2.2 mmol/l) and four hypophosphatemia (2.1 ± 0.6 mol/l). Histological findings: intratumoral septa (50%), vascular, capsular, perineural invasion (70%, 80%, 10% respectively), extraglandular extension (50%). Mitotic index was evaluated in four patients. CDC73 mutations were present in four patients. Metastases were present in one patient. All patients underwent *en bloc* resection and three received external beam radiotherapy due to recurrent loco-regional disease. After a mean follow up of 9 years, 90% are in remission and no mortality has been documented.
Conclusion
The authors describe a series of ten parathyroid carcinoma patients. Despite the clinical and biochemical severity at the time of diagnosis, most patients achieved sustained remission. Genetic mutations were identified in a significant proportion of patients, having important clinical implications. This series is noteworthy for the good outcome of such an aggressive neoplasm.

Vitamin D prescribing bias in liver transplant referrals

KJ Gan[1], Niamh O'Sullivan[2], Bernadette Hanley[1], Paul Armstrong[1], Mark Kilbane[1], Diarmaid Houlihan[2] & Rachel Crowley[1]
[1]Department of Endocrinology, St Vincents University Hospital, Dublin, Ireland; [2]Department of Hepatology, St Vincents University Hospital, Dublin, Ireland.

Vitamin D (VD) deficiency (25 OHD < 50 nmol/l) is common is chronic liver disease at 64%–92% regardless of aetiology. The only guidelines for routine VD supplementation are for cholestatic (C) liver disease; a population considered being at high risk of low bone mineral density (BMD). BMD decreases further following orthotopic liver transplant (OLT). To assess VD intake in an at risk population, retrospective analysis of intake was performed in OLT patients with C liver disease; this was excellent at 81%. Prospective analysis comparing C with non-cholestatic (NC) patients at time of dietetics referral at OLT assessment was then undertaken ($n=94$, 27% C and 73% NC). Median 25OHD in C patients was 86.7 nmol/l compared to 24.7 nmol/l in NC (P 0.001). 36% of C patients compared to 76% of NC had 25OHD measurement of <50 nmol/l (P <0.0001). 48% of C patients compared to 16% of NC were receiving VD supplementation

before OLT assessment. We have observed a prescription bias at referral to transplant hepatology; VD is prescribed more frequently to C than NC patients with end-stage liver disease, although both populations are at risk of reduced BMD.

How to differentiate primary hyperparathyroidism with D hypovitaminosis from secondary hyperparathyroidism due to D hypovitaminosis?

Alina-Andreea Gatu[1], Cristian Velicescu[1,2], Cristina Preda[1,2], Carmen Vulpoi[1,2], Simona Mogos[1,2], Voichita Mogos[1,2], Valentin Zaharia[2], Adrian Aancute[2] & Dumitru Branisteanu[1,2]
[1]Gr. T Popa University of Medicine and Pharmacy, Iasi, Romania; [2]St. Spiridon Emergency Hospital, Iasi, Romania.

Background
D hypovitaminosis and primary hyperparathyroidism frequently coexist. Secondary hyperparathyroidism reactive to D hypovitaminosis is difficult to be differentiated from primary hyperparthyroidism.
Aims
To differentiate patients with D hypovitaminosis and secondary hyperparathyroidism.
Materials and methods
Prospective study involving 71 patients admitted in our department for 1 year with the initial diagnosis of primary hyperparathyroidism. Serum and urinary calcium and phosphate, PTH and 25OHD3 were evaluated at admission. Patients with vitamin D levels under 30 ng/ml were repleted with 2000 IU/day of 25OHD3 for 1 month and 1000 IU/day for other 5 months. Values between groups were compared using student's t test. Correlations were evaluated by using Pearson correlation analysis.
Results
Forty-eight of the 71 patients had vitamin D deficiency (< 20 ng/ml) and 15 had vitamin D insufficiency (between 20 and 30 ng/ml), only eight having 25OHD3 of over 30 ng/ml. Both 25OHD3 and PTH levels normalized after 6 months of repletion with vitamin D in only 24 of the 63 patients with initial low 25OHD3 levels and they were therefore diagnosed with secondary hyperparathyroidism (group S), whereas in the other 39 patients PTH levels remained elevated despite normalization of 25OHD3 levels, setting the diagnosis of primary hyperparathyroidism associated with D hypovitaminosis (group P). Initial PTH was correlated with serum calcium in both groups, but with serum phosphate only in group P. Initial PTH and serum and urinary calcium were significantly higher, whereas serum phosphate and radius BMD were significantly lower in the patients from group P when compared with patients from the group S ($P < 0.05$).
Conclusions
Patients with secondary hyperparathyroidism reactive to D hypovitaminosis are frequent. Their PTH and electrolyte profile are only mildly modified, with a milder impact on bone mass than in primary hyperparathyroidism. A clear diagnosis could be, however, set only after vitamin D repletion.

Pseudohypoparathyroidism as an etiological cause for epilepsy: a case report

Naile Gokkaya[1], Arzu Bilen[2] & Habib Bilen[1]
[1]Division of Endocrinology and Metabolism, Department of Internal Medicine, Faculty of Medicine, University of Ataturk, Erzurum, Turkey; [2]Department of Internal Medicine, Erzurum Training and Research Hospital, Erzurum, Turkey.

Introduction
Pseudohypoparathroidism (PHP) is a condition mimics hypoparathyroidism biochemically with a hypocalcemia and hyperphosphatemia but differentiates from it an elevated parathyroid hormone (PTH) levels. PHP characterized by targeted organ unresponsiveness to PTH and mainly subdivided two groups. PHP type 1a an autosomal dominant disease related to mutations of GNAS1. This subtype has biochemical findings and characteristic somatic phenotype known as Albright Hereditary Osteodystrophy (AHO). AHO include short stature, round face, brachydactyly, shortened metatarsals, subcutaneous ossifications and reduced intelligence. PHP type 1b has laboratory findings but do not has phenotype of AHO. This disorder caused by methylation defects of GNAS1 regulatory region. We present a patient who was detected PHP while following for epilepsy.
Case report
A 17 years old male patient referred to endocrinology clinic with paresthesias of the hands. He had under treatment due to epilepsy for 3 years. He had normal mental activity and phenotypic features. His family history had no specialty. His laboratory examination revealed hypocalcemia and hyperphosphatemia with a calcium level 7.4 mg/dl (reference range, 8.5–10.5 mg/dl), phosphorus 6.8 mg/dl (reference range, 2.5–4.5 mg/dl), albumin 4.4 g/dl (reference range, 3.5–5.2 g/dl), magnesium 2.06 mg/dl (reference range, 1.8–2.6 mg/dl), 25 hydroxyvitamin D (25 OHD) 64.3 ng/ml (reference range, 30–70 ng/ml) and PTH 115 pg/ml (reference range, 15–65 pg/ml). His rest of the laboratory findings and ophthalmic examination were normal. Brain computed tomography scan showed basal ganglia calcifications. Calcitriol and calcium supplements were started to patient whose biochemical findings support PHP diagnosis. Genetic testing of the patient did not show GNAS coding region mutation and we planned methylation study in terms of methylation abnormality in GNAS regulatory region.
Conclusion
PHP is an uncommon cause of hypocalcemia. Blood electrolytes must be called to mind in case of epilepsy or neurological evidence. Early diagnosis and treatment of PHP prevent complications.

EP262

Long standing primary hyperparathyroidism consequences after parathyroid surgery: fast recovery not only for bone mass

Cristina Stefan[1,2], Amalia Arhire[1], Luminita Cima[1,3] & Carmen Barbu[1,3]
[1]Endocrinology Department, Elias Hospital, Bucharest, Romania; [2]Ghencea Medical Center, Bucharest, Romania; [3]Carol Davila University, Bucharest, Romania.

Background
Primary hyperparathyroidism is usually a long evolving disease before the diagnosis, thus patients who are not diagnosed by routine screening tests may have a lot of complications affecting the bone, kidney, bone marrow.
Aim
Pointing out the possibility of fast recovery not only for bone mass.
Material
We present a case of primary hyperparathyroidism, a female patient 66 years old, sent to emergency room, dehydrated, asthenic, with important hip pain, low back pain. Her Ca = 14.3 mg/dl, PTH > 4000 pg/dl, Hb = 8.5 g/dl, CT: osteolotic lesion, pubis and ischium fracture, two osteolithic lesions on the right acetabulum and the S1 vertebra, bone biopsy: perytrabecullar fibrosis, aspects of bone remodeling and normal medullar celularity, DXA T score: total hip -3, L1-L4 -1.8, forearm -4.4. The complication in the moment of diagnostic were: osteoporosis, spontaneous fragility fractures, medular fibrosis with normocytic normochromic anemia.
Results
Surgery was successful with the normalization of blood calcium and PTH. Questions were raised regarding the high level of PTH(neoplasia was taken into account) and also the impact of medular fibrosis the on the prognosis of the patient. After one year BMD was in age range, DXA T score: total hip -1.2, L1-L4 -0.2, forearm -2, anemia have remitted Hb = 12.5 g/dl, and maintained during 2 years follow up.
Conclusion
In spite of high level of PTH and dangerous medular fibrosis, our case show surgical recovery of bone mass but also of medular complications.

DOI: 10.1530/endoabs.49.EP262

Associations of nitric oxide with vitamin D and other serological factors in healthy adolescents

Nasser Al-Daghri[1], Sobhy Yakout[1], Naji Aljohani[2], Yousef Al-Saleh[2], Omar Al-Attas[1] & Majed Alokail[1]
[1]King Saud University, Riyadh, Saudi Arabia; [2]King Saud bin Abdulaziz University for Health Sciences, Riyadh, Saudi Arabia.

Nitric Oxide (NO) has been considered a very important molecule in the biological system because of its interaction with other molecules for mediating various bio-pathways. Its interaction with vitamin D in particular studied well in animal models, cell lines and patients with various diseases. However, the

relationship between NO and vitamin D has never been studied in healthy adolescents. We aimed to determine the association of NO with vitamin D and other serological factors in healthy Saudi adolescents. We recruited 740 individuals (245 boys and 495 girls) from Riyadh, Saudi Arabia. Socioeconomic status, food habits, BMI and data regarding major medical complications were recoded. Blood samples were performed for estimation of vitamin D, traces of NO and other possible serological parameters. Data revealed that NO has inverse correlation with vitamin D but showed significant and positive association with serum triglycerides and systolic blood pressure. Here, it is suggested that some unknown limiting factors may restrict the relationship of NO and vitamin D in healthy individuals. Therefore, the factors which limit the NO association with vitamin D and other molecules should be investigated *in vitro* and *in vivo*.

Primary hyperparathyroidism in pregnancy

Belgin Efe[1], Goknur Yorulmaz[1], Sevil Alaguney[1] & Bartu Badak[2]
[1]Division of Endocrinology, School of Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey; [2]Department of General Surgery, School of Medicine, Eskisehir Osmangazi University, Eskisehir, Turkey.

Introduction
Primary hyperparathyroidism is the most common cause of hypercalcemia in the general population. Hypercalcemia during pregnancy can result in significant maternal and fetal morbidity and mortality.
Case
A 30-year-old pregnant female primigravida in the 31 weeks of gestation with complaint of obstinate constipation was admitted to our emergency department. In laboratory tests, hypercalcemia was detected. She was a Syrian refugee and was unable to communicate in English and Turkish. The parathyroid hormone (PTH) and albumin-corrected serum calcium levels were high. The results were 203 (12–65) pg/ml and 15.1 (8.5–10.5) mg/dl respectively. Urinary calcium excretion rate was 440 mg/per day. Tubular phosphorus reabsorption rate was 73%, and the chlor/phosphorus ratio was 54.7. In the light of all these data, primary hyperparathyroidism was diagnosed. Ultrasound imaging revealed a parathyroid adenoma ($6\times6\times19$ mm) at the inferior of the left thyroid lobe. In our case we started 3000 cc salin infusion and furosemid treatment but her calcium levels didn't decrease to safe range. Intravenous calcitonin was added to treatment but calcium levels didn't decrease. We started to hemodialysis but still was calcium level >12.5 mg/dl. We followed up the patient in hospital until the baby's lung maturation is completed. When the gestation reached the 35th week, parathyroid adenoma excision and caesarean section were performed concurrently. Post-operative calcium levels decreased. Hypocalcemia improved with medical treatment in the newborn.
Discussion
The main treatment modality of hyperparathyroidism is surgery but if hyperparathyroidism is diagnosed in third trimester surgical approaches have high risk. Because of the high risk, we trained our patient with medical treatment at the hospital until safe birth time. In the postpartum interval to avoid a parathyroid crisis, surgery and cesarean operation were performed simultaneously during the safe period for the baby.

EP265

Eucalcemic parathyroid hormone elevation after parathyroid surgery for sporadic primary hyperparathyroidism

Gulsah Elbuken[1], Sibel Ozkan-Gurdal[2], Makbule Begum Balkan[2] & Sayid Shafi Zuhur[1]
[1]Department of Endocrinology and Metabolism, Namik Kemal University Medical School, Tekirdag, Turkey; [2]Department of General Surgery, Namik Kemal University Medical School, Tekirdag, Turkey.

Introduction
Serum parathormone (PTH) levels may remain elevated in some patients after surgery despite achievement of normal serum Ca levels. The factors contributing to this phenomenon have not been fully elucidated yet. In this study, we retrospectively analysed the data of patients whose serum Ca levels returned to normal after parathyroid surgery in our center.
Patients and methods
Computer records of 35 patients who had undergone parathyroid surgery and achieved normal serum Ca levels were retrospectively analysed. Despite serum Ca values within the normal ranges, patients were divided into two groups according to their PTH values 6 months after surgey (elevated PTH (ePTH) group (PTH $\geq$65 pg/ml) and low PTH (lPTH) group (PTH $<$65 pg/ml)). Fifteen patients were classified as having ePTH and 20 as IPTH. The frequency of ePTH was determined as 42%. The mean pre and postoperative PTH levels in ePTH and IPTH groups were 265 ± 119, 94 ± 32 and 206 ± 136, 39 ± 17 pg/ml, respectively. The mean pre and postoperative 25(OH) vitamin D3 levels in ePTH and IPTH groups were 12 ± 7, 22 ± 11 and 22 ± 14, 32 ± 12 ng/ml, respectively.
Results
Although ePTH group had higher preoperative PTH values as well as lower pre and postoperative 25 (OH) vitamin D3 levels, there was no statistically significant difference between the groups. For the remaining parameters, two groups had similar results.
Discussion
Several hypotheses have been proposed to explain the etiopathogenesis of persistently elevated PTH values despite normal Ca levels following parathyroid surgery. Suggested causes of this phenomenon include 25 (OH) vitamin D3 deficiency, secondary hyperparathyroidism resulting from insufficient renal function, stimulation of PTH secretion induced by relative hypocalcemia postoperatively, and increased bone turnover. However, this condition may also indicate possible recurrence due to multiglandular hyperplasia rather than a single parathyroid adenoma.

Primary hyperparathyroidism mimicking metastatic bone disease

Ali Burkan Akyıldız[1], Seda Sancak[2], Nalan Okuroğlu[1], Kerem Yiğit Abacar[1], Elif Sakcı[1] & Ali Özdemir[1]
[1]Department of Internal Medicine, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey; [2]Division of Endocrinology and Metabolism, Fatih Sultan Mehmet Training and Educational Hospital, Istanbul, Turkey.

We would like to present a case of primary hyperparathyroidism presumably present with clinically large cystic parathyroid adenoma with multiple destructive skeletal lesions, which is of course referred to bone metastases.
Case
A 58-year-old male patient was admitted to the orthopedy polyclinic with left leg pain and on the MR imaging performed here, multiple lytic lesions compatible with metastasis to the tibia and fibula were detected. He was directed to our internal medicine clinic for further investigation. The patient had complaints of widespread bone pain, especially the left leg which lasted for 2 months and was suffering from polydipsia. Biochemical tests showed elevated serum calcium values and increased intact parathyroid hormone (iPTH), low phosphorus, high alkaline phosphatise, compatible with primary hyperparathyroidism. Erosive and brown tumour like lesions were detected in bone x-ray. On PET CT imaging, extensive, lytic and expansile lesions were observed, especially in the kranium and ribs. On the neck ultrasonography, a 50×30 mm sized, septated, irregular contour nodule was detected in the right lobe. Thyroid fine needle aspiration biopsy was performed. Histopathological evaluation was benign and there were no findings indicating parathyroid pathology. Parathyroid scintigraphy showed no lesions compatible with neck or mediastinal adenoma. Due to resistant hypercalcemia, the patient was given bilateral neck exploration. The parathyroid mass was localized and resected intraoperatively in the lower pole of the thyroid nodule extending mediastinum, and histopathological evaluation was compatible with parathyroid adenoma. Biochemical results due to hyperparathyroidism normalized after operation and complaints resolved.
Discussion
It should be considered that primary hyperparathyroidism may have bone lesions that mimic bone metastasis. Especially in cases where the thyroid nodule is visible but there is no evidence of parathyroid adenoma in parathyroid scintigraphy intrathroidal parathyroid adenomas should be considered in the differential diagnosis of cystic neck lesions.

Acute pancreatitis as the first presentation of primary hyperparathyroidism

Alexandra Vieira, Marta Ferreira, Daniela Guelho, Teresa Pereira, Luis Filipe Silva, Estela Ferreira & Ana Inácio
Leiria Hospital Center, Leiria, Portugal.

Background
Hypercalcaemia due to primary hyperparathyroidism is a rare cause of acute pancreatitis, with a reported prevalence of 1.5–8%.
Clinical case
A 25-year-old male patient was referred to the Endocrinology outpatient clinic for hypercalcemia diagnosed in the context of acute pancreatitis. He had medical and surgical pathological antecedents of: clavicle fracture after car accident, cholecystectomy and appendectomy, gastroesophageal reflux disease. Current medications included proton pump inhibitor daily. Laboratory analysis reported serum calcium of 3.46 mmol/l (2.20–2.65), phosphorus of 0.70 mmol/l (0.81–1.45) and intact parathyroid hormone of 569 pg/ml (12–88). Biochemical screening for type 1 and type 2 multiple endocrine neoplasia was performed and was negative. The neck ultrasonography showed a nodular heterogeneity with hyperechogenic contours with cystic areas, and posteriorly and inferiorly to the left lobe an hypoechogenic nodular formation, with 2.4 cm of greater axis, which may correspond to the parathyroid gland with increased dimensions. Bone densitometry showed osteopenia. Sestamibi parathyroid scintigraphy revealed a focus of significant radiopharmaceutical retention on the projection of the lower left lobe pole, alteration compatible with parathyroid adenoma. A lower left parathyroidectomy and left lobectomy of thyroid was performed without complications. The histopathological result confirmed the diagnosis of parathyroid adenoma. At the last visit, he had normal PTH and calcemia values. During the follow-up he had recurrent acute pancreatites episodes.
Conclusions
The authors present this case because of its rarity: hyperparathyroidism in a young patient whose presentation was of acute pancreatitis without the classic clinic manifestations of hypercalcemia.

Gender difference in clinical presentation of primary hyperparathyroidism

Laura Gianotti, Elena Castellano, Francesco Tassone, Claudia Baffoni, Flora Cesario, Gianpaolo Magro, Micaela Pellegrino & Giorgio Borretta
Division of Endocrinology, Diabetology & Metabolism, S.Croce & Carle Hospital, Cuneo, Italy.

Objective
Primary hyperparathyroidism (PHPT) is one of the most common endocrine disorders, with a female to male ratio of 3:1. Currently most patients with PHPT are asymptomatic. However, data about the gender impact on the clinical presentation of PHPT are lacking.
Methods
We evaluated the difference in symptoms and biochemical parameters between men and women with PHPT in a single center series of 417 patients.
Results
Male PHPT patients resulted significantly younger ($P=0.046$) and more frequently symptomatic than women (62.3% vs 47%, $P=0.016$). Furthermore, renal stone incidence was higher in male than in female patients (50.5% vs 33%, $P=0.003$) while no difference was found in the incidence of osteitis fibrosa cystica (21.5% vs 20.7%). Instead, osteoporosis, established as T score < 2.5 at any site, was significantly predominant in women (56.5% vs 39.3%, $P=0.015$) rather than in men. However, no differences were found in classical biochemical disease parameters (i.e. PTH, serum calcium, phosphorus, 24 h-urine for calcium) nor in creatinine and vitamin D levels. Finally, the proportion of patients with surgical indications (symptomatic patients and asymptomatic patients meeting surgical criteria recommended by current guidelines) was similar in male and in female PHPT patients (84,6% vs 84,9%).
Discussion
Gender leads to a different clinical presentation in PHPT patients, male patients being usually younger and more frequently affected by a symptomatic form of the disease. In addition, renal stones are significantly more frequent in men, while in women osteoporosis is prevalent. On the other hand, PHPT biochemical presentation seems not to be influenced by gender. Furthermore, surgical indication is reached equally in male and female PHPT patients.
Conclusions
In male patients PHPT is less frequent but more commonly symptomatic than in female patients. PHPT clinical presentation is influenced by gender, although there are no sex-related differences in its biochemical profile.

Prevalence of hypocalcemia in adults in Minsk, Belarus

Elena Brutskaya-Stempkovskaya[1,2], Alla Shepelkevich[1] & Georg Kostin[1,3]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk City Polyclinic N31, Minsk, Belarus; [3]Minsk Consulting and Diagnostic Centre, Minsk, Belarus.

The prevalence of hypocalcemia among patients non-operated the thyroid and parathyroid glands has increased significantly with the introduction the screening of calcemia. The main reasons for hypocalcemia are hypoproteinemia and hypoparathyroidism.
Objective
To study the prevalence of hypocalcemia in the adult in Minsk.
Materials and methods
We studed 1207 people, average age 53.9 ± 17.25 (892 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein. Hypocalcaemia was detected in total calcium level < 2.2 mmol/l.
Results
Hypocalcaemia was recorded in 40 people (3.3/100 adults), the mean age was 42.9 ± 17.63 years (32 women, men – 8). In the age group up to 30 years hypocalcemia was revealed in 12 cases (8.3%, in women – 10.3%); in the group 30–44 years – five cases (1.3%, in men – 4.7%, in women – 0.3%), 45–59 years – three cases (1.1%, in men – 2.5%, in women – 0.5%); 60–74 years – ten cases (2.5%, in men – 2.6%, in women – 2.4%); >75 years – one case (0.7%, in men – 3.2%). The prevalence of hypocalcemia in the group up to 45 years – 6.6 per 100 adults. The prevalence of hypocalcemia in the group 45 years over – 1.7/100 adults. The results of the study indicate a significant occurrence of hypocalcemia in the age group up to 45 years ($\chi^2=20.34$, $p=0.00001$).
Conclusion
The prevalence of hypocalcemia in the adult population of Minsk-city was 3.3/100 adults (33:1000). The prevalence of hypocalcemia in the age group up to 45 years was 6.6/100 adults, in the age group 45 years over was 1.7 per 100 adults. The results of the study indicate a significant occurrence of hypocalcemia in the age group up to 45 years.

Assessment of changing in the therapeutic attitude in patients with primary hyperparathyrodism in conservative management after the realization of radial densitometry

Jose Alvaro Romero Porcel, Guillermo Martinez De Pinillos Gordillo, Fernando Garcia Perez, Eyvee Arturo Cuellar Lloclla, Jose Ignacio Fernandez Peña, Carmen Carretero Marin, Juan Manuel Garcia De Quiros, Ignacio Fernandez Lopez, Mariana Tome Fernandez-Ladreda & Maria Victoria Cozar Leon
Hospital De Valme, Sevilla, Spain.

Introduction and objectives
In the 4th Workshop on Primary Hyperparathyroidism, it is recommended to perform BMD by DXA of third radius as well as lumbar spine and hip DXA in the initial assessment and follow up of patients with primary hyperparathyroidism. This test is not available in many centers, which means that only *T* Score values of the lumbar spine and hip are used to certify the absence of osteoporosis in asymptomatic patients wich conservative management is performed. Our objective is to evaluate if the recent addition of radius DXA has modified the management of this patients.
Materials and methods
Retrospective study including patients in follow-up by primary asymptomatic hyperparathyroidism in conservative management according to the Fourth Workshop criteria when radial densitometry for the first time in its evolution. Changes after the DXA results were evaluated.
Results
20 patients (65.4 years ± 11.14, 90% women) with a follow-up of 3.95 years ± 1.97 were included. Blood calcium levels 11.05 ± 0.45 mg/dl, mean PTH of 105.46 pg/ml ± 60.9. None presented lumbar and/or femoral *T*-Score scores values lower tan -2.5 DS (lumbar T -0.15 DS ± 2.17, femoral -0.77 DS ± 0.98). The radial *T* Score was -2.67 DS ± 2.45. The radial densitometry results changed the clinical attitude in 70% of the patients, from the recommed conservative management to surgical treatment in those with a *T*-Score lower -2.5 DS in the distal radius and *T*-Score higher than -2.5 DS in the lumbar and/or femoral.
Conclusions
Our study reinforces the importance of performing distal radius densitometry in patients in which conservative management is giving to be performed, as is

recommended as recommended by international criteria. Lack of implementation may lead to conservative management in patients with osteoporosis.

A rare case: intrathymic parathyroid adenoma

Veysi Asoglu[1], Mehmet Celik[2], Buket Yilmaz Bulbul[2], Semra Ayturk[2], Ebru Tastekin[3], Nuray Can[3], Atakan Sezer[4], Funda Ustun[4] & Sibel Guldiken[2]
[1]Trakya University, Medical Faculty, Department of Internal Medicine, Edirne, Turkey; [2]Trakya University, Medical Faculty, Department of Endocrinology and Metabolism, Edirne, Turkey; [3]Trakya University, Medical Faculty, Department of Pathology, Edirne, Turkey; [4]Trakya University, Medical Faculty, Department of Surgery, Edirne, Turkey; [5]Trakya University, Medical Faculty, Department of Nuclear Medicine, Edirne, Turkey.

Primary hyperparathyroidism in the most common cause of hypercalcemia. 87% of the cases present with single adenoma, 9% of them have hyperplasia, while multiple adenomas and parathyroid malignancy are detected in 3 and 1% of the cases, respectively. Although it is rare, parathyroid adenomas may be ectopic. The most common locations for ectopic parathyroid adenomas are thymus, tracheaesophageal cleft, carotis sheet, intrathyroidal and paraesophageal area. In this study, we aimed to present an intrathymic parathyroid adenoma as a rare case.

A 46-year old female patient who received hemodialysis for chronic renal failure secondary to chronic glomerulonephritis for 7 years and then underwent cadaveric renal transplantation in 2010 was presented for routine follow-up visit. Laboratory examination revealed urea:19 mg/dl(*n*:15–43),creatinin:0.8 mg/dl(*n*:0.57–1.11)), calcium:11.5 mg/dl (*n*:8.6–10.2 mg/dl), phosphorus:2.7 mg/dl (*n*:2.4–5.1 mg/dl), albumin:4.2 g/l (*n*:3.2–4.8 g/l), iPTH:340 pg/ml (*n*:15–68), creatinin clerarance in 24-h urine: 82 ml/min, calcium in 24-h urine: 410 mg/day. Neck ultrasonography was performed, which demonstrated 12× 9 mm sized well-circumscribed nodular lesion with heterogeneous echo at inferior part of lower pole of left thyroid gland (thyroid nodule? Parathyroid adenoma?). Femoral neck and L1–L4 vertebra were osteopenic on bone densitometry. Parathyroid scintigraphic examination detected no scintigraphic signs characteristic for parathyroid adenoma in the neck and mediastinum. The patient underwent parathyroidectomy following surgical exploration. Histopathologic examination of parathyroidectomy material revealed intrathymic parathyroid adenoma. The patient was scheduled for outpatientclinic follow-up with post-operative laboratory findings of iPTH: 38 pg/ml, Ca:9.9 mg/dl, P:2.5 mg/dl, Alb:4.3 g/l, kreatinin:0.7 mg/dl.

Annual incidence of primary hyperparathyroidism is 0.27%. Since Primerhiperparatiroidizmin yıllık görülme oranı % 0.27dir. Since both thymus and parathyroid gland embrologically derive from 3rd pharyngeal cleft, ectopic parathyroid adenomas may locate within thymus. It is very important to preoperatively determine the localisation of ectopic parathyroid adenomas to prevent surgical errors.

Audit of emergency hypercalcaemia management in the acute medical unit

Emanuela Bejinariu, Rahat Tauni, Tharanga Rathnayake, Vinit Shah, Shiu-Ching Soo & Ritwik Banerjee
Luton and Dunstable University Hospital, Luton, UK.

Introduction

We conducted a retrospective audit of emergency management of hypercalcaemia presenting to the acute medical team and compared our practice against the Society for Endocrinology guidelines September 2016.

Method

53 adult patients with 59 corresponding medical admissions were identified from tracking all biochemistry samples with corrected calcium (cCa) $\geq$3.0 mmol/l processed between August 2015 and July 2016 trustwide. We conducted a retrospective review of their admissions' case records.

Results

Characteristics: age 40–98 years old (median 79), 60.4% female, median length of stay 7 days, presenting cCa range: 3.04–5.36 mmol/l (median 3.31 mmol/l). 30.5% had severe hypercalcaemia (cCa $\geq$3.50 mmol/l). *Aetiology*: 47.2% malignancy related hypercalcaemia, 15.1% primary hyperparathyroidism, 5.6% secondary or tertiary hyperparathyroidism, 9.4% drug-related, 15.1% unknown. Frailty was documented reason to withdraw further investigations in 62.5% of the latter. Coexistent active prostate cancer and hyperparathyroidism was found in two cases. *Investigations*: PTH was checked in 67.8% cases, Phosphate in 64.4%, ALKP 100%. Of the cases with suppressed PTH, only 72.2% had serum paraproteins checked, 55.5% urinary Bence-Jones proteins and 83.3% imaging for malignancy. Vitamin D was only checked in 22.6%. *Management:* Patients received an average of 3L intravenous fluids in the first 24 h. 62.7% received intravenous bisphosphonates. 13.5% had less than 2L intravenous fluids prior to bisphosphonate. Second line treatment with Cinacalcet, steroids, Furosemide or Calcitonin was used in 20.7% cases. There were no cases of rebound hypocalcaemia.

Conclusions

Compliance with guidelines recommendations was suboptimal in certain areas, not entirely explained by the adoption of a palliative approach with focus on symptom control in cases. Training opportunities will be devised locally to improve practice. Bisphosphonate use in the Emergency department should be controlled for the appropriate circumstances. Vigilance is recommended assigning causality in active malignancy, given that 11.1% of pre-existing malignancy cases were found to have concurrent PTH driven hypercalcaemia, despite only 38.9% of them being investigated with a PTH level.

Higher circulating parathyroid hormone concentration fascilitates preoperative diagnostic imagings for localization in primary hyperparathyroidism

Kentaro Okamoto[1], Yoshihiko Itoh[1], Akiyuki Kawashima[1], Aya Amano[1], Kyoko Okazaki[1], Hiroyuki Murabe[1], Toshihiko Yokota[1], Risa Yoshimoto[2], Akiko Sahara[2], Junko Tomokuni[2] & Keita Hamamatsu[3]
[1]Kurashiki Central Hospital, Department of Endocrinology and Rheumatology, Okayama, Japan; [2]Kurashiki Central Hospital, Department of Laboratory Medicine, Okayama, Japan; [3]Graduate School of Medicine and Faculty of Medicine Kyoto University, Department of Diabetes, Endocrinology and Nutrition, Kyoto, Japan.

Introduction

For minimally invasive surgery of primary hyperparathyroidism (PHPT), the identification of the accurate localization is required. As preoperative diagnostic imagings, we perform ultrasound, technetium 99m-sestamibi scintigraphy and either or both of megnetic resonance imaging or computed tomography in all cases. The aim of the present study is to evaluate the clinical biochemical factors that fascilitate preoperative diagnostic imagings for localization.

Methods

We retrospectively searched the medical records of patients with PHPT who were admitted in our hospital from 2014 to 2016. Fifty-five patients were identified. Four patients with parathyroid carcinoma, multiple endocrine neoplasia type 1, familial hypocalciuric hypercalcemia, and detectable parathyroid hormone-related protein were excluded. Fifty-one patients were included in the study. We defined 36 patients as the 'localized' group, including 30 patients who underwent curative operation and 6 non-operative patients whose suspicious adenoma was consistently identified by two or more of diagnostic imagings. And other 15 patients were defined as the 'non-localized' group. We compared biochemical data including intact parathyroid hormone (iPTH), serum calcium, urine calcium, and tartrate-resistant acid phosphatase 5b.

Results

iPTH was statistically higher in the 'localized' group (146 [103–195] vs. 98 [82–136] pg/ml: $p=0.010$). Multivariate logistic regression analysis demonstrated that the usefulness of preoperative diagnostic imaging was ensured only in higher iPTH ($p=0.014$). When we set the cut-off value of iPTH to 150 pg/ml, sensitivity was 48.6% and specificity was 87.5% (AUC: 0.73 [95% CI 0.59–0.87]). When we used whole parathyroid hormone (wPTH) in place of iPTH, we obtained similar results: the cut-off value 85 pg/ml with sensitivity 57.1% and with specificity 87.5% (AUC: 0.84 [95% CI 0.72–0.96]).

Conclusion

Both iPTH and wPTH as circulating parathyroid hormone concentration are useful to predict whether preoperative diagnostic imagings can identify the acurate localization of the parathyroid adenoma.

Calcifediol is more effective than cholecalciferol in the treatment of severe vitamin D deficiency in a patient submitted to malabsorbitive bariatric surgery: a case report

Alessandro Brancatella, Daniele Cappellani, Edda Vignali, Domenico Canale & Claudio Marcocci
Department of Endocrinology and Metabolism, Univesity of Pisa, Pisa, Italy.

Context
Vitamin D deficiency following malabsorptive bariatric surgery can lead to osteomalacia. We report a patient with severe vitamin D deficiency following malabsorptive bariatric surgery successfully treated with calcifediol but not cholecalciferol.
Case description
A 40-year-old woman, submitted to biliopancreatic diversion 20 years before and chronically treated with 50 000 IU cholecalciferol weekly, was admitted to our Endocrine Unit because of severe low-back pain, muscle weakness, generalized muscular hypotrophy, associated with hypocalcemia and elevated PTH levels. Initial evaluation revealed low albumin-corrected serum calcium (7.4 mg/dl), high serum PTH (240 pg/ml), bone-specific alkaline phosphatase (125 µg/l) and 1,25-dihydroxyvitamin D (112 pg/ml) concentrations, and undetectable serum 25-hydroxyvitamin D (<7 ng/ml). Bone mineral density (BMD) was markedly low. Normocalcemia was initially restored with i.v. albumin and calcium gluconate. Treatment with calcitriol (0.5 µg three times daily) and oral calcium carbonate (1000 mg daily) was simultaneously started and cholecalciferol was replaced with calcifediol (125 µg (5000 UI) daily)). During follow-up the calcifediol dose was progressively tapered to 25 µg (1000 UI) daily and the calcitriol dose progressively reduced and finally withdrawn. Serum biochemistry normalized, BMD significantly increased and the patient's clinical conditions progressively improved, with a substantial recovery of autonomy.
Conclusions
Our data suggest that calcifediol migth be more efficacious than cholecalciferol for prevention and treatment of vitamin D deficiency in patients treated by malabsorptive bariatric surgery.

The effect of $1,25(OH)_2D_3$ on interferon i secretion by human mononuclear cells *in vitro*

Lambros Athanassiou[1], Andrianos Nezos[1], Ifigenia Kostoglou-Athanassiou[2], Clio Mavragani[1], Panagiotis Athanassiou[3] & Michael Koutsilieris[1]
[1]Department of Physiology, Medical School, University of Athens, Athens, Greece; [2]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [3]Department of Rheumatology, St Paul's Hospital, Thessaloniki, Greece.

Vitamin D is a secosteroid hormone known for its skeletal effects. Recently, the extraskeletal effects of vitamin D are under investigation. Vitamin D is thought to exert an immunomodulatory effect, having multiple effects on the immune system. It is known to induce immune tolerance and also to enhance the immune response to bacteria.
The aim was to study the effect of $1,25(OH)_2D_3$ on interferon I secretion by human mononuclear cells *in vitro*.
Human mononuclear cells were separated from whole human blood from healthy female human subjects using the Lymphoprep protocol. Subsequently they were placed in wells 10^6 cells/well and were cultivated for a period of 6 h at a temperature of 37 °C in a humidified environment of 5% CO_2 in the presence or absence of interferon alpha 400 U, $1,25(OH)_2D_3$ 250 pmol, interferon alpha 400 U and $1,25(OH)_2D_3$ 250 pmol. Subsequently the content of the wells was centrifuged and the precipitate was treated with Trizol for RNA extraction of genes known to be stimulated by interferon alpha. Real time PCR was performed for MX1, IFIT1, IFI44 and GAPDH as a control.
Interferon alpha was shown to stimulate genes related to interferon I secretion, i.e. it was found to have a positive feedback on its own secretion. $1,25(OH)_2D_3$ was found to modulate interferon I gene augmentation induced by interferon alpha treatment.
Vitamin D is being investigated for its immunomodulatory properties. In the present study vitamin D was found to modulate the response of human mononuclear cells to interferon alpha treatment.

The changing face of primary hyperparathyroidism

Ifigenia Kostoglou-Athanassiou[1], Alexios Travlos[2], Evaggelia Vogiatzi[2] & Eleni Pantazi[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Endocrinology, Alexandra Hospital, Athens, Greece.

Primary hyperparathyroidism is a disease which nowadays is being diagnosed with increasing frequency. The diagnosis of primary hyperparathyroidism is based on routine calcium measurement, which if detected abnormally elevated leads to the screening of the patient for primary hyperparathyroidism. Therefore, primary hyperparathyroidism is frequently detected early in the course of the disease. Consequently, severe musculoskeletal manifestations may be lacking in the modern world setting in patients with primary hyperparathyroidism.
The aim was to describe musculoskeletal manifestations in patients with primary hyperparathyroidism being followed up in a center of excellence in Athens.
A cohort of 38 patients, 33 female and five male, with primary hyperparathyroidism aged 62.31 ± 1.87 years, being followed up within a center of excellence in Athens was studied. Musculoskeletal manifestations were recorded in the cohort of the patients studied.
Within the cohort of 38 patients with primary hyperparathyroidism being followed up within a center of excellence in Athens, 12 patients (31.58%) had osteoporosis, 2 (5.26%) had osteopenia, 7 (18.42%) had diffuse bone pain, 2 (5.26%) had diffuse myalgia and 1 (2.63%) had suffered a wrist fracture. Within the cohort studied 18 (47.37%) patients did not have any musculoskeletal manifestations.
It appears that primary hyperparathyroidism does not have severe musculoskeletal manifestations, such as osteitis fibrosa cystica, in the real world setting in patients followed up for the disease within a center of excellence in Athens. However, patients with primary hyperparathyroidism appear to have diffuse bone pain as well as osteoporosis, which may be complicated by a fracture in some of the cases. Early detection and diagnosis of the disease seems to have altered the face of primary hyperparathyroidism in the real modern world setting.

Single center experience of intact parathyroid hormone determination in washout samples of suspicious parathyroid adenomas

Mustafa Sahin[1], Asena Gokcay Canpolat[1], Elif Ediboglu[2], Çağlar Keskin[1], Şule Canlar[1], Özgür Demir[1], Sevim Gullu[1], Murat Faik Erdogan[1], Rıfat Emral[1] & Demet Corapcioglu[1]
[1]Ankara University Faculty of Medicine, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University Faculty of Medicine, Department of Internal Medicine, Ankara, Turkey.

Introduction
Minimally invasive surgery is an alternative surgical approach for primary hyperparathyroidism with less surgical trauma and anesthesia complications. Neck ultrasonography and scintigraphy are still the first step tools for localisating parathyroid lesions. Intact parathyroid hormone (PH) determination in washout samples is really very useful when parathyroid lesions can not be easily distinguished from thyroid lesions or sometimes lymph nodes.
Method
In our clinic, we performed ultrasonography guided parathyroid fine needle aspiration procedure for 119 patients diagnosed with primary hyperparathyroidism between January 2005 and January 2016. Intact parathyroid hormone determination was performed in washout samples. 80 of the study group also had a parathyroid scintigraphy. All of the patients underwent parathyroid surgery.
Results
In 106 of the study group had positive parathyroid hormone washout (phw) results according to blood PH levels. Significant difference was achieved in localisation of the lesion (p:0.006), serum calcium levels (p:0.01) and PHW levels ($p<0.001$) between washout negative and positive group. No difference was observed in gender, age, presence of stone, levels of serum phosphorus, creatinin, alkaline phosphatase, parathyroid hormone, vitamin D and 24 h urinary calcium levels. 28 patients in the scintigraphy group had negative scan whereas 47 of them had both scintigraphy and PHW positive. 24 of the patients had positive PHW results but negative scintiscans.
Conclusion
The present study represents that ultrasonography combined with PHW evaluation seems to be more diagnostic according to parathyroid scintigraphy.

Primary hyperparathyroidism due to atypical adenoma: clinical, biochemical and histological features of an Italian cohort

Federica Saponaro[1], Marina Di Giulio[1], Elena Pardi[1], Simona Borsari[1], Gabriele Materazzi[2], Claudio Marcocci[1] & Filomena Cetani[1]
[1]Endocrinology Unit 2, University of Pisa, Pisa, Italy; [2]Endocrine Surgery, University of Pisa, Pisa, Italy.

Primary hyperparathyroidism (PHPT) is mostly due to a benign parathyroid tumor (99%). Some have parathyroid 'atypical adenomas', rare tumors with histological features of parathyroid cancer (PC) (fibrous trabeculae, thick fibrous bands, mitotic figures in parenchymal cells), without local invasion or metastasis. We evaluated 20 patients with histological diagnosis of atypical adenomas. Patients were 13 women and seven males (mean age: 55 ± 13 yrs). Nineteen patients had a sporadic PHPT and one a Familial Isolated PHPT (FIHP). At least one of the following symptoms was present in 8 (40%) patients: nephrolithiasis ($n=8$), clinical fragility fractures ($n=1$), neuropsychiatric symptoms ($n=6$). In the remining patients ($n=12$) PHPT was asymptomatic. Osteoporosis was detected in 8 (40%). Preoperative imaging was positive in 16 (80%) patients. The association with other tumors was recorded: papillary thyroid carcinoma ($n=4$), adrenal bilateral hyperplasia ($n=1$), breast cancer ($n=1$), Morton's neuroma ($n=1$). Biochemical tests at baseline were: albumin adjusted serum calcium 12.4 ± 0.8 mg/dl, PTH 204 (160–277) pg/ml and 25OHD 13.4 ± 7 ng/ml. All patients underwent PTx. The histological diagnosis was of atypical adenoma (mean diameter 24 ± 10.6 mm) with the following features: fibrous trabeculae in two, thick fibrous bands in 13, capsular invasion infiltration in seven and mitotic figures in two. All but one patients were cured after PTx and remained normocalcemic (mean follow-up 5 years). One patient, with apparently sporadic PHPT, had persistent hypercalcemia and he is in follow-up. This study suggests that PHPT due to atypical adenoma is generally asymptomatic at diagnosis, it has a moderate-severe biochemical profile resembling that of PC, it is a sporadic disease and shows a benign prognosis in the majority of cases. We found an association with other tumors, that will be evaluated in further studies.

Medullary vertebral compression in primary hyperparathyroidism

Fedala Saida, Meskine Djamila, Kedad Lamia, Fafa Nadira & Toubal Zakia
Laboratory of Endocrinology and Metabolism (LEM 1), Algiers, Algeria.

We report the case of an ectopic parathyroid adenoma, revealed by a medullary vertebral compression by a brown spinal tumor in a 44-year-old women. Physical examination revealed a lower limb weakness, paresthesia and radicular lower extremity pain. Magnetic resonance imaging (MRI) showed osteolytic vertebral lesions suggesting metastatic localizations. A thoracic CT scan identified a mediastinal mass measuring 6.2 cm in the major axis. Biological evaluation revealed a hypercalcemia (135 mg/l) with very high PTH (1896 pg /ml), parathyroid scintigraphy confirmed the mediastinal ectopic parathyroid. The patient underwent surgical resection of the mediastinal mass that proved to be a parathyroid ectopic adenoma. She showed a remarkable improvement in her clinical condition observed 6 months after parathyroidectomy. Medullary vertebral compression by a brown spinal tumor in primary hyperparathyroidism is rare, surgery of parathyroid adenoma improved clinical condition without resection of the brown tumor, However surgical decompression may be necessary in some cases.

Management of primary hyperparathyroidism: Experience of a large UK teaching hospital

Rebecca Sagar, Amy Longhurst & Afroze Abbas
Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals, Leeds, UK.

Background
Primary hyperparathyroidism (PHPT) is a common cause of hypercalcaemia seen in outpatient endocrinology clinic. Diagnosis is based on biochemistry and exclusion of other conditions, such as familial hypocalciuric hypercalcaemia. Symptomatic patients should usually be referred for parathyroidectomy. For asymptomatic patients there are clear guidelines for surgical referral, based on the Fourth International Workshop (2014) recommendations. This study evaluates current practice for diagnosing and managing primary hyperparathyroidism compared to international guidelines, at a large UK teaching hospital.
Methods
We evaluated all new cases of PHPT seen in outpatient endocrinology clinics between January 2014 and July 2016. Data were collected using a standardised proforma. Data fields included demographics, biochemistry and imaging. Follow-up data on surgical referrals, histology and outcomes were also collected.
Results
Of the 121 patients, at diagnosis, 50.4% were symptomatic. Complete investigation data were available for 117. 59.8% had all relevant investigations performed as recommended per guidelines. Urinary calcium was conducted in 67.5% of patients, of those, 44.3% had inappropriate vitamin D levels at the time of collection. At diagnosis, 30.0% patients had renal complications and 36.3% had osteoporosis. 84% of the 121 met criteria for surgery, although 58.8% were actually referred. The most common reasons for non-referral were patient choice (33.3%) and fitness for surgery (45.5%). On imaging, 74% had a single adenoma, 11.7% had no obvious adenoma. 75% had positive correlation between imaging and surgical findings. 3 months post-operatively, 91% of patients had normal calcium and 68% had normal PTH.
Conclusions
This study shows that the majority of patients with PHPT are diagnosed and investigated as per guidelines. Almost all patients had a normal calcium 3 months post operatively, suggesting surgery was curative. However, urinary calcium estimation was performed without the correction of vitamin D levels in a significant percentage of patients, thereby affecting accuracy of interpretation.

Fahr Syndrome and idiopathic primary hipoparathyroidism – clinical case

Ana Filipa Martins[1], João Martin Martins[1,2] & Sónia do Vale[1]
[1]Hospital de Santa Maria – CHLN, Lisboa, Portugal; [2]Faculdade de Medicina de Lisboa, Lisboa, Portugal.

Introduction
Fahr syndrome (FS) is a neuropsiquiatric condition due to progressive basal ganglia calcification. Although physiopathology is not completely understood, it may be secondary to infectious, metabolic and genetic diseases.
Case report
A 65-year-old male Caucasian was referred to the outpatient endocrine department because of hypocalcaemia. No perioral paresthesia or tingling of the fingers and toes were noticed. He complained of longstanding hand tremor and since one year ago apathy and gait instability were evident. Past medical history revealed High Blood Pressure under treatment. He also referred previous use of anti-convulsivant medication since he was 15 because of diagnosed epilepsy. Drugs were suspended at 20th with no further seizures. No previous cervical surgery or irradiation were done. Her death mother was also diagnosed of epilepsy. Besides slow and rigid movement, physical examination was otherwise normal, with negative Chvosteck and Trouseau. Deafness, visual field defects or dismorphisms were absent. Analytic evaluation confirmed albumin-corrected hypocalcemia, hyperphosphatemia, normal serum magnesium, hypoparathyroidism with sufficient 25OH-vitamin D levels. Slight ferropenia and chronic renal disease grade 2 were diagnosed. Besides Hashimoto thyroiditis, no other endocrinopathy was evident. Ecocardiogram evidenced left auricular dilatation and reduced global systolic function. Cystic renal disease and slight cystic calcifications were documented on kidneys ultrasound and cervical ultrasound evidenced multinodular goiter. Bone densitometry of femur and lumbar spine was normal. craneoencephalic TC identified bilateral simetric parenquimatous calcifications, both supra and infratentorial, with extensive involvement of basal ganglia. I^{123}-SestaMIBI scintigaphy did not fixate in cervical imaging. Anti-NALP5 antibody was negative, as well as CASR activating mutation.
Discussion and conclusion
Parathyroid hormone and calcium abnormalities are the most common metabolic disorders associated to FS. We describe a patient diagnosed of idiopathic hypoparathyroidism. Basal ganglia calcifications support a long-standing

hypocalcemia, and chronic ion disturbance may have contributed to the absence of usual muscular complaints.

Clinical presentations of four patients with familial isolated hyperparathyroidism and hyperparathyroidism-jaw tumor syndrome

Taner Bayraktaroglu[1], Utku Sentosun[1], Dilek Karakaya Arpaci[1], Ali Ugur Emre[2], Mertol Gokce[3], Serkan Uysal[3], Rabiye Uslu Erdemir[4], Burak Bahadir[5] & Guldeniz Karadeniz Cakmak[2]
[1]Bulent Ecevit University, Faculty of Medcine, Department of Internal Medicine, Division of Endocrinology and Metabolism, Zonguldak, Turkey; [2]Bulent Ecevit University, Faculty of Medcine, Department of General Surgery, Zonguldak, Turkey; [3]Bulent Ecevit University, Faculty of Medcine, Department of Chest Surgery, Zonguldak, Turkey; [4]Bulent Ecevit University, Faculty of Medcine, Department of Nuclear Medicine, Zonguldak, Turkey; [5]Bulent Ecevit University, Faculty of Medcine, Department of Medical Pathology, Zonguldak, Turkey.

Introduction
Primary hyperparathyroidism is commonly treated with targeted parathyroidectomy guided by preoperative imaging and intraoperative parathormone monitoring. Despite advanced imaging techniques, failure of parathyroid localization still occurs. Hyperparathyroidism-jaw tumor syndrome and familial isolated hyperparathyroidism are a rare autosomal dominant tumor syndrome characterized by hyperparathyroidism. In this report, we present four patients with familial isolated hyperparathyroidism and hyperparathyroidism-jaw tumor syndrome, below.
Case 1
A 26-year-old man with left maxillary tumoral lesion is referred. He had the elevated serum calcium and parathormon levels, osteoporosis, rena anomalia, nephrolitiasis, Acording to the diagnosis of hyperparathyroidism jaw-tumor syndrome, imaging modalities included neck sonography, scintigraphy, computerized tomography indicaed that a ectopic parathyroidal adenoma, then it was removed by videoscopic assisted medastinoscopy with temporarily hypoparathyroidism.
Case 2
A 43-year-old-man who is a relative of Case 1 is presented with persistent myalgia-arthralgia and nausea due to hypercalcemia caused by increased parathormon levels. Sonographic and scintigraphical evaluations of the neck showed that multiple irregular nodules of thyroid and suspected parathyroid adenomas. Fine neddle aspiration cytology of the nodules and pathological lymphadenopathy revealed a suspect of the low differentiated thyroidal carcinoma with lymphatic invasion. In wash-out sampling from suspected parathyroid adenoma, parathormon levels were increased. Total thyroidectomy with central and lateral neck dissection in addition adenomectomy with hungry bone syndrome.
Case 3
A 600-year-old-man who is in relations with Case 1 and Case 2 is complained with nausea-vomiting and lower back pain with osteoporotic fractures of left femur and left humerus. His serum levels of calcium and parathormon are highly increased. Imaging modalities showed a suspected lesion in the inferior region of the left thyroidal localization. After minimal invasive intervention and selective parathyroid sampling, the second operation included exploration and thyroidectomy with 3.5 paratyhroidectomy and implantation to sternocleidomastoid muscles were performed. Postoperatively, he had hypothyroidism with elevated serum calcium and parathormon levels. Thereafter hybrid nuclear modalities showed a suspected paratrakeal lesion, the case referred to reoperation with radioguided parathyroid surgery.
Case 4
The patient was a 51-year-old man (who is a brother of Case 3) presenting without any symptoms. He had hypercalcemia (12.2 mg/dl) and hyperparathyroidism (247 pg/ml). Parathyroid lesion detected with sonography and scintigraphical evaluations, and it is referred to minimal invasive parathyroid adenomectomy.
Conclusion
Primary hyperparathyroidism is a common clinical problem for which the only definitive management is surgery. Diagnosis of the familial primary hyperparathyroidism caused by CDC73 (formerly known as HRPT2) is based on the biochemical findings of primary hyperparathyroidism, identification of ossifying fibroma(s) of the maxilla and/or mandible on imaging studies, family history, and detection of a heterozygous germline CDC73pathogenic variant on molecular genetic testing. The spectrum of CDC73-related disorders includes hyperparathyroidism-jaw tumor syndrome, familial isolated hyperparathyroidism and parathyroid carcinoma, In familial primary hyperparathyroidism, reoperative parathyroidectomy are challenging entities that require special consideration and expertise.

When is it worthwhile to perform parathyroid SPECT/CT scintigraphy in primary hyperparathyroidism?

Malgorzata Trofimiuk-Muldner[1,2], Anna Skalniak[1,2], Lukasz Kulczynski[1,2], Aleksandra Zapendowska-Dudek[2], Aneta Budek[2], Monika Buziak-Bereza[1,2], Anna Sowa-Staszczak[1,2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Endocrinology Department, University Hospital in Krakow, Krakow, Poland.

Introduction
Observed increasing frequencies of asymptomatic or oligosymptomatic PHP cases may increase the rate of false negative imaging results.
Aim
To determine the level of PTH and calcium at which an enlarged parathyroid gland can be detected by parathyroid SPECT/CT.
Material and methods
A retrospective analysis of 117 patients diagnosed with PHP (100 females and 17 males, aged 16–88 years) was performed. In each patient parathyroid SPECT/CT after administration of 500 MBq of 99mTc-MIBI was conducted (Siemens Symbia T16). Serum calcium and parathormone (PTH) were measured in each patient, serum phosphate was estimated in 109 subjects. Statistical analysis was performed with Statistica 12 Software.
Results
Median serum calcium level was 2.77 mmol/l (LQ and UQ – 2.66 and 2.87 mmol/l, respectively); median serum PTH level was 122.8 pg/ml (97.2 and 191.9 pg/ml); median plasma phosphate was 0.84 pmol/l (0.74 and 0.98 mmol/l). In 70 (59.8%) patients an enlarged parathyroid gland was detected with SPECT/CT. There was a statistically significant difference in PTH levels (median 138.15 and 114.80 pg/ml, respectively; $P=0.02$) and serum calcium levels (median2.74 and 2.67 mmol/l, $P<0.01$) between patients with positive and negative parathyroid SPECT/CT. Serum phosphate levels did not differ significantly ($P=0.19$). Receiver–operator curves (ROCs) were drawn to establish PTH and serum calcium cut-off levels for positive parathyroid SPECT/CT imaging. Sensitivity and specificity of parathyroid scintigraphy were 38 and 89.6%, respectively, for PTH cut-off level of 191.9 pg/ml, and 52 and 79%, respectively, for serum calcium cut-off level of 2.74 mmol/l.
Conclusions
Limiting parathyroid SPECT/CT to patients with significantly increased PTH and/or serum calcium levels, particularly if surgical treatment is not considered, may decrease false negative imaging rates and allow to avoid unnecessary radiation exposure. More precise determination of PTH and calcium cut-off levels requires analysis of larger patients group data.

EP284

Parathormone (PTH) as a marker of vitamin D (VitD) deficiency

Malgorzata Trofimiuk-Muldner[1,2], Anna Skalniak[1,2], Malgorzata Kiec-Klimczak[1,2] & Alicja Hubalewska-Dydejczyk[1,2]
[1]Chair and Department of Endocrinology, Jagiellonian University Medical College, Krakow, Poland; [2]Department of Endocrinology, University Hospital in Krakow, Krakow, Poland.

Introduction
VitD deficiency, the pandemics of which we currently observe, may result in secondary hyperparathyroidism even if not accompanied by hypocalcaemia.
Aim
To assess VitD levels as a cause of secondary hyperparathyroidism.
Material and methods
257 healthy volunteers with normal kidney function (GFR $<$ 60 ml/min) (28.4% males), median age 57 years, were included. In each participant, serum calcium,

phosphates, creatinine, PTH and total VitD levels, as well as urinary calcium in urine morning sample, were measured. Daily calcium intake was estimated with a dietary questionnaire. Statistical analysis was performed with Statistica 12 Software.
Results
Median VitD level in the investigated group was 21.22 ng/ml; PTH – 41.17 pg/ml, serum calcium – 2.39 mmol/l, serum phosphates – 1.12 mmol/l, serum creatinine – 68 μmol/l, and urinary calcium – 2.69 mmol/l. Median daily calcium intake was 689 mg. There was statistically significant negative correlation between VitD and PTH levels ($r=-0.19$, $P=0.0018$), independent of serum creatinine. This relationship was particularly significant for measurements performed during autumn/winter ($r=-0.34$, $P<0.0001$), while losing its significance in study subjects subgroup investigated during spring/summer ($r=-0.06$, $P=0.5153$). Kruskal-Wallis ANOVA analysis showed a statistically significant difference in PTH levels in relation to VitD deficiency severity (predefined ranges: <10; 10–19.9; 20–29.9 and ≥ 30 ng/ml) ($P=0.0078$). A significantly higher PTH level was observed in subjects with severe VitD deficiency (<10 ng/ml) when compared to subgroups with VitD levels of 20–29.9 ng/ml ($P=0.0147$) and ≥ 30 ng/ml ($P=0.0401$). A significant negative correlation was found also between serum PTH and serum calcium ($r=-0.13$, $P=0.0447$).
Conclusions
Lack of significant negative correlation between serum PTH and VitD, seen during spring and summer confirms that appropriate sunlight exposure is sufficient to correct VitD deficiency. Significant increase in PTH levels is seen mostly in subjects with particularly low VitD levels, which may be an argument for redefining the recommended normal range of VitD.

Pathological basal ganglia calcification in isolated idiopathic hypoparathyroidism: a case report

Gordana Pemovska[1], Tose Plaseski[1], Biljana Todorova[1], Nadica Bozhinovska[1], Marija Zivkovic[1] & Radmila Nesovska[2]
[1]University Clinic of Endocrinology, Diabetes and Metabolic Diseases, Skopje, Macedonia; [2]City Hospital September 8th, Skopje, Macedonia.

Introduction
The isolated hyperparathyroidism (IHP) is a metabolism disorder characterized by an absent or low parathormon (PTH) and hypocalcemia. It can be acquired, autoimmune, a result of some syndrome and as a part of a family (FIHP). FIHP is an extremely rear disease which is inherited auto somatic dominant or auto somatic recessive as a result of a mutation of one or several different genes. Pathological calcifications in the cerebrum are a secondary form of calcification in patients with IHP.
Material and methods
We present two patients, a brother and a sister, age 44 and 42. The disease started in both cases, with a series of epileptic attacks, the brother at the adolescent period and the sister at age of 30. The diagnose was established based on a characteristic symptoms: Fatigue, muscle weakness, paresthesis, convulsions, speech and attitude disorder as well as cognitive deficit. The brother has cataract and the sister has hirzutism and acne. Hormone and laboratory diagnostic tests. Radio diagnostic on the kidneys, densitometry and psychological tests.
Results
The brother: PTH = 4.22 pg/ml (15–65), TCa = 1.08 (1.21–2.6), Posf = 2.01 (0.8–1.4 mmol/e), Ca++ = 1.46 (1.3–10) mmol/l, Vit. D 14.35, Mg 0.69 (0.6–1.1 mmol/l). Undergone cataract surgery. The sister: PTH = 1.2 pg/ml, TCa = 1.92, Posf = 1.7. No signs for litiasa and nefrosclerosis. KT scan of the brain: calcification in the cerebellum, basal ganglia, par ventricular and sub cortical – M. Fahr. No signs of nefrocalcinosis. Radiology finding shows osteosclerosis of the cranium, spine, long bones. Both of them have neuropsychological disorder with limited intellectual capacity and light mental retardation.
Conclusion
IPH from an unknown etiology points to a family HypoPTH which needs to be confirmed by a genetic test. The tests were not performed due to financial limitations. Timely diagnose of IPH can prevent calcification in basal ganglia.

Diseases associated with hypercalcemia

Elena Brutskaya-Stempkovskaya[1,2], Alla Shepelkevich[2], Georg Kostin[2,3], Eduard Chertko[2] & Janna Matsiushava[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk City Polyclinic N31, Minsk, Belarus; [3]Minsk Consulting and Diagnostic Centre, Minsk, Belarus.

Introduction
According to modern studies, hypercalcemia is associated with an increased risk of urolithiasis, cholelithiasis, gastritis and peptic ulcer.
Objective
To study the prevalence of urolithiasis, cholelithiasis, gastritis and peptic ulcer in patients with hypercalcemia in Minsk-city.
Materials and methods
we studied 1207 people, average age 53.9 ± 17.25 (892 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein, creatinine, ultrasonography, fibrogastroduodenoscopy, an analysis of morbidity.
Results
Hypercalcemia has been found in 31 people, mean age was 58.39 ± 11.6 years. Urolithiasis was detected in 141 cases (in patients with hypercalcemia – in nine cases) cholelithiasis was detected in 107 cases (in patients with hypercalcemia – in ten cases) gastritis was detected in 397 cases (in patients with hypercalcemia – in 21 cases) peptic ulcer was detected in 102 cases (in patients with hypercalcemia – in nine cases).
Significant differences was detected in the prevalence of urolithiasis ($\chi^2=8.54$, $P=0.0035$), cholelithiasis ($\chi^2=19.33$, $P=0.00001$) gastritis ($\chi^2=16.41$, $P=0.0001$) peptic ulcer ($\chi^2=15.69$, $P=0.0001$) in patients with hypercalcemia compared all studied patients.
Conclusion
The results of the study show an increasing risk of urolithiasis, cholelithiasis, gastritis and peptic ulcer in patients with hypercalcemia. The results may indicate an important role of hypercalcemia in the pathogenesis of these diseases.

PTH levels in vitamin D deficiency

Merve Catak[1], Derya Koseoglu[2], Ozden Ozdemir Baser[1] & Dilek Berker[1]
[1]Numune Education and Research Hospital, Ankara, Turkey; [2]Hitit Univercity Hospital, Corum, Turkey.

Introduction
High level of Parathormone (PTH) impair bone health by increasing the risk of fracture. The aim is to determine the threshold value of PTH elevation to accompany deficiency or failure of Vit D. This may be an important parameter in assessing bone metabolism in clinical practice.
Material and method
931 patients who were referred to the endocrinology clinic were retrospectively studied and 880 patients diagnosed with Vit D deficiency included to the study. Patients were divided into three groups according to their vitamin D levels: <10 ng/dL, 10–19.99 ng/dl, 20–29.99 ng/dl. The mean Ca, P, PTH, Vit D, ALP levels were calculated.
RESULTS
880 patients included in the study, 710 were female and 170 were male.
The mean PTH levels were 68.99, 56.10, 50.92 pg/ml when Vit D levels were <10 ng/dl, 10–20 ng/dl, 20–30 ng/dl and respectively and a statistically significant difference was found between PTH levels ($P<0.0001$).
When ROC analysis was performed, while Vit D level <5 ng/dl; PTH level was >71.25 pg/ml (sensitivity 45%, specificity 78%), while the Vit D level was <10 ng/dl; PTH level was >66.75 pg/ml (sensitivity 50%, specificity 77,4%), while Vit D level <20 ng/dl; PTH level was >61.1 pg/ml (sensitivity 40.3%, specificity 80.9%)
Conclusion
As the Vit D level decreases, the calcium level decreases statistically significantly while the parathormone level increases. Patients with Vit D deficiency have elevated PTH levels but PTH levels are still in the normal reference range. Prospective studies are needed to evaluate the effect of increased but still in a normal range PTH levels on bone with measurement of bone mineral density.

EP288

Renal complications in patients with chronic postoperative hypoparathyroidism treated with oral calcium and active vitamin D metabolites

Filomena Cetani[1], Antonella Meola[2], Edda Vignali[1], Giovanni Guglielmi[3], Irene Donato[4], Antonio Matrone[2], Rossella Elisei[2] & Claudio Marcocci[2]
[1]University Hospital of Pisa, Endocrine Unit, Pisa, Italy; [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [3]University Hospital of Pisa Medicina Preventiva del Lavoro, Pisa, Italy; [4]Department of Traslational Research and New Technologies in Medicine and Surgery, University of Pisa, Pisa, Italy.

Patients with chronic hypoparathyroidism (HypoPT) treated with oral calcium and active vitamin D metabolites are at risk of renal complications, because of the lack of action of PTH at the renal tubule. In the present study we evaluated 90 patients (68 females and 22 males; age: 51.8 ± 14.1 yrs) with chronic postoperative Hypo (PO-HypoPT) diagnosed since at least 3 years. All patients were treated with calcitriol and 35 (39%) with oral calcium two patients were also treated with thiazide diuretics. One-hundred forty-two healthy Hospital employers, matched for age and sex, undergoing routine medical evaluation, were used as control. Mean levels of Alb-Ca and ionized calcium were in the normal range and but 39 (43.3%) patients had values that did not meet the range recommended by the recent guidelines of the European Society of Endocrinology (ESE). Serial measurements of serum calcium prior to the present evaluation were available in 78 patients: only 9 (11.5%) patients had all values within the recommended ESE range, and a large proportion of patients (32, 41.0%) had values greater than the upper recommended value. The mean serum phosphorus and creatinine levels were in the normal range, but 7 (7.7%) patients had elevated values of phosphorus and 22 (24.4%) of creatinine. The serum calcium-phosphate product was normal in all patients. Forty-four (54%) patients showed increased 24-h urinary calcium excretion and 27 (30%) microlithiasis, mostly asymptomatic. Compared to the controls, patients had statistically significant lower mean serum Alb-Ca ($P < 0.0001$) and higher serum creatinine ($P = 0.0008$) and greater prevalence of kidney stones (27/90 vs 7/142, $P < 0.0001$, OR: 8.2 (3.4–19.9)). In conclusion, conventional treatment of chronic PO-HypoPT is suboptimal and associated with an increased risk of renal complications. Careful monitoring of patients, as recommended by the ESE guidelines, should be therefore performed.

EP289

The results of parathormone assay in parathyroid aspirates in preoperative localization of parathyroid adenomas for focused parathyroidectomy in patients with negative or suspicious sestamibi scans

Aysenur Ozderya, Sule Temizkan, Kenan Cetin, Sule Ozugur, Aylin Ege Gul & Kadriye Aydin
Kartal Dr Lutfi Kirdar Training and Research Hospital, Istanbul, Turkey.

Objective
In primary hiperparathyroidism (PHPT), increasing the number of patients treated by focused parathyroidectomy should be the main objective of pre-surgical imaging modalities. Suspicious or negative imaging results do not always mean multiglandular disease, most of the patients may single adenoma and therefore these patients may still benefit from focused parathyroidectomy.
Methods
Retrospectively, we analyzed the data of 65 patients with PHPT with suspicious or negative sestamibi scans who admitted at a tertiary reference center between January 2013 and December 2016. We excluded patients who had history of chronic renal failure, renal transplant and multiple endocrine neoplasia. All patients underwent an endocrinologist operated ultrasonographic examination and parathyroid fine needle aspiration wash-out procedure.
Results
Of the 65 patients, 23 patients had nodular guatr disease. Fifty-four patients had positive parathormone (PTH) wash-out results. A total of 43 patients underwent surgery. Of the 43 patients, four patients had redo-surgery. Of the operated patients, 40 had positive parathormone wash-out results and had successful focused surgery. All of the patients with redo-surgery had positive parathormone wash-out results and successfully re-operated. Three patients with negative PTH wash-out results, two of them had successful bilateral neck exploration, but a patient's operation was not successful although bilateral neck exploration.
Conclusion
Endocrinologist operated US and PTH wash-out increases the number and success of focused surgery. Especially, patients with redo-surgery may benefit from this procedure.

Weight has a weak influence on calcium-phosphorus metabolism in HIV-patients with vitamin d deficiency

Carolina García-Figueras Mateos & Manuel Cayón-Blanco
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
In contrast to general population, clinical consequences related to low levels of 25-hydroxyvitamin D in HIV-infected patients with overweight are not established. The aim of our study was to investigate the influence of weight on clinical parameters and on calcium-phosphorus homeostasis in HIV-patients with vitamin D deficiency.
Methods/design
Prospective study of HIV outpatients treated in our hospital. Vitamin D deficiency (D-DEF) was defined as serum 25-hydroxyvitamin D below 20 ng/ml. Patients were classified as "overweight/obesity" if body mass index (BMI) ≥ 25 Kg/m^2. Their clinical, metabolic and immunological data were compared to HIV-individuals classified as "normal weight" (BMI: 18.5–24.9 Kg/m^2).
Results
One hundred and six HIV-infected individuals (86.8% male, mean age: 46.4 ± 6.5 years) were included. 51.9% were classified as "overweight/obese". Levels of vitamin D were lower in "overweight/obese", but no significant difference was observed between both groups (14.8 ± 4 vs 15.3 ± 1.8 ng/mL; $P = 0.772$). In overweight HIV-patients, although into the normal range, the serum phosphorus levels were higher as compared as those without D-DEF (3.3 ± 0.8 vs 2.9 ± 0.5 mg/dl; $P = 0.04$). Levels of i-PTH were also higher in overweight D-DEF patients (66.1 ± 35.1 vs 48.9 ± 19.8 pg/ml; $P = 0.04$). No others differences were observed between these groups. Analyzing individuals with D-DEF only, there was no difference in calcium, phosphorus or i-PTH levels between patients with or without overweight.
Conclusions
In HIV-infected patients with low levels of 25-hydroxyvitamin D, BMI ≥ 25 Kg/m^2 determines subtle changes on calcium-phosphorus homeostasis which clinical significance remains to be determined. Further follow-up studies to establish potential clinical implications of these findings are needed.

Chronic hypoparathyroidism disease profile from 492 patients in the PARADIGHM™ natural history global registry

Bart L Clarke[1], Steven Ing[2], Aliya Khan[3], Michael Mannstadt[4], Michael McDermott[5], Rebecca Piccolo[6], Michael H. Shanik[7], Tamara J Vokes[8] & John Germak[9]
[1]Mayo Clinic, Rochester, MN, USA; [2]Ohio State University Wexner Medical Center, Columbus, OH, USA; [3]McMaster University, Ontario, Canada; [4]Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA; [5]University of Colorado Hospital, Aurora, CO, USA; [6]Shire Human Genetic Therapies, Inc., Lexington, MA, USA; [7]Endocrine Associates of Long Island, PC, Smithtown, NY, USA; [8]University of Chicago Medicine, Chicago, IL, USA; [9]Shire International GmbH, Zug, Switzerland.

PARADIGHM™ is a global registry (NCT01922440) of patients diagnosed with hypoparathyroidism (HPT) ≥6 months regardless of aetiology and management. Routine medical care data were entered using electronic case report forms; the 36-item Short Form Health Survey was completed by patients. Baseline-recorded data are reported for 492 patients enrolled as of 1 December 2016 from 41 centres. At baseline, 78% were women, mean (s.d.) age was 49 (17) years, and mean (s.d.) BMI was 29.8 (8.6) kg/m^2. Medical histories included mood disorder (29%), arthritis (16%), kidney stones (11%), fractures (8%), chronic renal disease (6%), and hypercalciuria (3%). 93% of patients had baseline symptom data (for the

previous 6 months), all reported ≥1 symptom; the most common were fatigue (40%), paraesthesia (30%), muscle twitching (24%), anxiety (20%), brain fog (17%), muscle weakness (17%), back pain (16%), and headache (16%). HPT management included oral calcium in 91% (calcium carbonate, 59%) and active vitamin D in 84% (calcitriol, 94%) of patients; 7% received recombinant PTH (1–84) in a clinical trial. 62% were taking ≥1 concomitant medication (45% thyroid hormone, 4% hydrochlorothiazide, 1% psycholeptics, <1% magnesium supplements). Key laboratory mean (S.D.) values were PTH 1.5 (1.5) pmol/l, albumin-corrected total serum calcium 2.1 (0.3) mmol/l, phosphate 1.4 (0.3) mmol/l, magnesium 0.8 (0.1) mmol/l, and 24-hour urinary calcium 7.2 (4.6) mmol/day. Among 330 patients who had imaging, calcifications were reported in 40 patients (12%): kidney ($n=12$), brain ($n=9$), cardiovascular ($n=7$), and other sites ($n=12$). In the previous 12 months, 47% of patients had 2−3 doctor visits and 49% had ≥1 emergency room visit owing to HPT. Mean (S.D., range) SF-36v2 summary scores for physical and mental components were 45.6 (10.7; 11.2−64.2) and 48.4 (11.0; 11.9−70.3). These real-world data for 492 patients enrolled in the PARADIGHM™ registry provide valuable insight into disease variability, symptom burden, and HPT treatment approach.

EP292

Prevalence of cardiometabolic risk factors among Saudi Women with vitamin D deficiency

Hanan Al Kadi[1] & Eman Alissa[2]
[1]Physiology Department, Center of Excellence for Osteoporosis Research, King Abdulaziz University, Jeddah, Saudi Arabia; [2]Biochemistry Department, King Abdulaziz University, Jeddah, Saudi Arabia.

Vitamin D deficiency is highly prevalent among Saudi women. The aim of this study was to determine the prevalence of cardiometabolic risk factors in apparently healthy Saudi women with vitamin D deficiency. A Retrospective chart review was conducted in the "Center of Excellence for Osteoporosis Research" (CEOR), King Abdulaziz University, Jeddah, Saudi Arabia. Only healthy women 20–40 years old, with no history of previous illnesses and not on any medications were included. Data on anthropometric measurements as well as blood pressure (BP) were obtained. Body mass index (BMI) was calculated. Laboratory results including fasting blood glucose (FBG), fasting lipid profile, 25-hydroxyvitamin D_3 ($25(OH)D_3$) and parathyroid hormone (PTH) were also obtained. Vitamin D deficiency was defined as $25(OH)D_3$ concentration <50 nmol/l. Modified NCEP:ATPIII criteria were used to define cardiovascular risk factor cutoff points. A total of 305 women were included in the current analysis. Mean (± S.D.) age of the study group was 28.4±6.1 years and median (IQR) $25(OH)D_3$ was 17.8 (11.9–28.2) nmol/l. Almost 97% of the study participants were vitamin D deficient and 70% had values below 25 nmol/l. 25-hydroxyvitamin D was significantly inversely associated with waist circumference, systolic and diastolic BP and PTH ($P=0.011$, <0.0001, <0.0001, <0.0001, respectively). Prevalence of cardiovascular risk factors were higher among subjects who fell in the lowest tertile of $25(OH)D_3$ except total cholesterol and low density lipoprotein cholesterol, however only higher PTH was statistically significant ($P=0.022$). The results of the present study confirm the high prevalence of vitamin D deficiency among otherwise healthy Saudi women. The results also suggest that the prevalence of selected cardiometabolic risk factors is higher among those with low vitamin D status. Prospective studies are needed to determine whether such deficiency will be of clinical significance with advancing age in this population, and whether vitamin D supplementation has beneficial effects.

18F-choline PET/MRI in patients with primary hyperparathyroidism and negative sestamibi SPECT/CT – report of two cases

Michal Krcma
Department of Internal Medicine I, Faculty of Medicine in Pilsen, Charles University, Pilsen, Czech Republic.

Primary hyperparathyroidism is a common disorder which is curable by surgery. Exact localisation of parathyroid adenoma is essential for minimal invasive approach. The gold standard is sestamibi SPECT/CT nowadays - but fails in approximately 10% cases. In last 3 years some case report with 18F-choline PET/CT were published. We describe two cases with SPECT/CT invisible parathyroid adenoma.

First case was 36y/o woman, with osteopenia diagnosed after pregnancy (was attributed to LMWH treatment in pregnancy) and no relevant health problems. Mild hypercalcemia (2.7 mmol/l) was found in 2014 in context with vitamine D deficiency and patient was referred to our department. Primary hyperparathyroidism was clearly stated (serum calcium 2.9 mmol/l; PTH 130 ng/l; 25-OH-D vitamine 69 nmol/l), bone turnover was also slightly elevated. According to age, osteopenia and planned pregnancy we decided for surgery, but ultrasonography and sestamibi SPECT/CT was without any parathyroid adenoma. Patient did not agreed with surgical revision of all four glands and we choosed conservative approach. In 2015, hypercalciuria was appeared, therefore next SPECT/CT and ultrasonography was performed, with still negative results. In 2016 we used PET/MRI with 18F-choline for the first time in our hospital – upper left parathyroid adenoma was found (9×6 mm, SUVmax 5.8). Patient was referred to surgery and histologic examination reveals parathyroid adenoma and patient went normocalcemic, normocalciuric and with normal PTH level, with continuing D vitamine treatment due to osteopenia. No hungry bone syndrome was presented. Second case was 59 y/o man, with primary hyperparathyroidism treated for 3 years by cinacalcet, with twice negative sestamibi SPECT/CT, repeatedly negative ultrasonography. During the treatment was slightly hypercalcemic (2.6 mmol/l), normocalciuric, with non-progressing osteopenia. PET/MRI revealed 8mm left bottom parathyroid adenoma and patient was referred for surgical resection, planned for March 2017.

Despite our limited experiences, 18F-choline PET seems to be a promising diagnostic option. Using MRI instead of CT has some advantages – radiation load, no risk of iodine contrast allergy and slightly better resolution in neck region.

Severe hypocalcemia induced by Denosumab in a patient with Osteroporosis after malabsorptive bariatric surgery

Ana Jiménez Portilla, Guillermo Serra Soler, Juan Ramón Urgeles Planella, María Soledad Gogorza Pérez, Mercedes Noval Font, Honorato García Fernández, Iñaki Argüelles Jiménez & Vicente Pereg Macazaga
Universitary Hospital Son Espases, Palma de Mallorca, Spain.

Introduction

Denosumab is a monoclonal antibody indicated in the treatment of postmenopausal osteoporosis. Hypocalcemia is a rare adverse effect.

Case report

We present the case of a 58-year-old woman with a clinical history of bariatric surgery in 2001 and osteoporosis with multiple vertebral and hip fractures. Under treatment with Zinc sulphate, Vitamin A, 25-OH-vitamin D, calcium and iron. She came to the A&E for general malaise, generalized weakness, paraesthesia, dysarthria and weight loss of some weeks of evolution. She was admitted due to a severe hypocalcemia: calcium 5 mg/dl (8.4–10.2), ionic calcium 2.5 mg/dl (4.64–5.28), phosphate 1.2 mg/dl (2.3–4.7), magnesium 2.35 mg/dl (1.6–2.6), albumin 38.8 g/l (35–50), PTH 284 pg/ml (15–65), 25-OH-vitamin D 22 ng/ml (30–100), alkaline phosphatase 360 U/l (40–150) and normal kidney function. The ECG showed a prolonged QT. The signs for hypocalcaemia were negative. The patient had received treatment with subcutaneous Denosumab 60 mg 22 days before, with prior calcium values of 8.4 mg/dl, phosphorous 3.1 mg/dl, 25-OH-vitamin D 25 ng/ml, PTH 76 pg/ml and Ca-urine 27 mg/24 h. Treatment was started with intravenous calcium for 8 weeks, together with oral calcium, phosphorous and 25-OH-vitamin D. The patient improved symptomatically, with a normalization of the QT and analysis with ionic calcium 4.6 mg/dl, phosphate 3.5 mg/dl, magnesium 2.8 mg/dl, PTH 139 pg/ml, Ca-urine 2.3 mg/dl and 25-OH-vitamin D 39 ng/ml. The treatment to discharge was oral calcium 2.5 g/day and 25-OH-vitamin D 16.000 UI daily.

Conclusions

Hypocalcemia after Denosumab is a rare adverse effect but it can be serious. The patients who have undergone malabsortive bariatric surgery have a greater risk. It is important to monitor the 25-OH-vitamin D and calcium in patients who start treatment with Denosumab and at 15 days in patients who are at the greatest risk, as is the case of this patient.

Performance characteristics of a new Waters MassTrak™ Vitamin D assay

Norma Breen, Leanne Davey, Declan Roche, Philip Lambert, Danielle Cullen & Padhraic Rossiter
Water Technologies Ireland Ltd, Wexford, Ireland.

The Waters MassTrak Vitamin D Kit is designed for the quantitative determination of serum or plasma 25-hydroxyvitamin D3 (25OHD3) and 25-hydroxyvitamin D2 (25OHD2), which in combination provide the total 25-hydroxyvitamin D concentration as an aid in the assessment of vitamin D sufficiency.
The MassTrak Vitamin D Kit is validated for use with the Waters® ACQUITY UPLC® I-Class/Xevo® TQD IVD System and the sample preparation has been validated using the Tecan® Freedom 100/4 EVO® Offline Automated Liquid Handling system. Screening for vitamin D deficiency is recommended by the Endocrine Society Clinical Guidelines- Evaluation, Treatment and Prevention of Vitamin D Deficiency by the Task Force for all individuals at risk for deficiency.
Vitamin D status (Total 25OHD, which is the sum of 25OHD2 and 25OHD3) has been a challenge to measure accurately because the antibodies used in many immunoassays do not have 100% co-specificity for both 25OHD2 and 25OHD3.
Precision, sensitivity, linearity, potential interferents and carryover were all assessed during the development of the MassTrak™ Vitamin D kit and found to meet the performance criteria specified for the kit.
To further assess the accuracy and performance of the MassTrak™ Vitamin D kit assay, Waters enrolled in the CDC Vitamin D Standardisation Certification Program (VDSCP) for 25(OH)D in serum, which assesses bias and precision of assays relative to reference measurement procedures.
The MassTrak™ Vitamin D kit calibrator materials are traceable to NIST SRM2972a via a documented unbroken chain of calibrations. The accuracy of this traceability to NIST SRM2972 has been verified through participation of the Vitamin D Standardisation Certification Program (VDSCP).

Vitamin D intoxication complicated with parathormon treatment in elderly: a case report

S Nur Boysan, Burcu Altunrende, Levent Dalar, M Eren Acik, I Polat Canpolat, C Selcan Akdeniz & M Sait Gonen
Istanbul Bilim University, Istanbul, Turkey.

Parathormon treatment for osteoporosis is rarely complicated with hypercalcemia. Vitamin D treatment with high doses frequently can cause asymptomatic intoxication.We present a case with life-threatening hypercalcemia complicated both parathormon and high-dose vitamin D.
A 85-year old woman hospitalized for sudden-onset confusion. In history she had coronary-artery by-pass operation and a serebrovascular accedant. She was treated with teriparatide 20 µr subcuraneously and cholecalciferol 0.25 µ per oral for one year. She had a pulmonary infection one month before admission. Since vitamin D is popular in media for public health, her daughter gave three doses of 300 000 IU vitamin D for infection. She has hallucinations and hypoxia. Her laboratory was; Ca 15.6 mg/dl, P 3.3 mg/dl, PTH 6.88 pg/ml, 25-(OH] vitamin D> 70 ng/dl, $1.25(OH]_2$ vitamin D 86.4 ng/l. She had also increased serum creatinine level. She was followed in intensive care unit fo 2 days. For hypercalcemia she had hydration, forced düresis, calcitonin and glucocorticoid therapy. Thorax CT showed bilaterally lineer atelectatic areas at basal zones. She continued to have nebulisation and oxygen after transmission from intensive care unit. Ejection fraction was 40% on echocardiography. She was discharged after 1 week when serum calcium was 10.2 mg/dl and PTH was 16.37 pg/ml. Vitamin D replacement, in elderly, could be life-threatening in megadoses. In this case, parathormon treatment with vitamin D replacement complicated presentation.

Tc-99m sestamibi uptake by brown tumours in a patient with primary hyperparathyroidism

Daniela Dias, Daniel Macedo, Rita Santos & Valeriano Leite
Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisboa, Portugal.

Tc-99m sestamibi (MIBI) imaging is able to localize parathyroid adenomas/carcinomas in patients with primary hyperparathyroidism. Brown tumours are one of the skeletal manifestations of long standing hyperparathyroidism and its incidence has been reported to be 3%. Radiological features of these tumors may mimic bone metastasis. There are only a few reports showing brown tumours uptake in the whole-body Tc-sestamibi scan.
We report a 72-year-old female with a previous history of right nephrectomy for renal lithiasis at age 49 and a left clavicle mass fracture. A neck and thoracic computed tomography (CT) scan revealed multiple lytic lesions of the skeleton (including in the left clavicle) and a pathological mandibular fracture, suggesting metastatic lesions.
^{18}F-FDG PET scan showed multiple skeletal hypermetabolic lesions and a hypermetabolic nodule close to left lower pole of the thyroid gland. The biopsy of the lesion in the left clavicle revealed histiocytic proliferation with multinucleated osteoclast-type giant cells compatible with a brown tumor. Laboratory data showed an elevated serum calcium of 12.8 mg/dl (8.4–10.2), alkaline phosphatase of 264 UI/l (9–36), and parathyroid hormone of 1056 pg/ml (12–65).
Tc-99m sestamibi scintigraphy showed an uptake in the inferior left pole of the thyroid and in multiple bone lesions. The patient underwent a left inferior parathyroidectomy. Histology revealed a 20 mm parathyroid adenoma.
In this patient with a long standing hyperparathyroidism the intense uptake of brown tumors in both ^{18}F-FDG PET scan and MIBI can mimic a parathyroid carcinoma with bone metastases.

Thyroid supression in patients with primary hyperparathyroidism may improve pre-surgical scintigraphy localisation

Mariana Tomé[1], Guillermo Martínez de Pinillos[2], Eyvée Arturo Cuéllar[2], Juan Manuel García de Quirós[2], Fernando García[2] & Ignacio Fernández[2]
[1]Punta de Europa Hospital, Algeciras, Spain; [2]Valme Hospital, Seville, Spain.

Introduction
The cause of primary hyperparathyroidism (PHPT) is a single adenoma in 85% of cases. Scintigraphy with technetium-sestamibi (MIBI) is the test of choice for localising adenomas in patients with PHPT, allowing minimally invasive surgery in most patients. Some articles recommend thyroid function supression to improve scintigraphy results.
Methods
A prospective study was conducted in which 8 patients were included with diagnosis of PHPT and negative scintigraphy for adenoma localisation. These patients did not have a contraindication for thyroid hormone intake. We started treatment with a dose of 1 mcg/Kg per day with dose titulation until achievement of TSH <0.3 µU/ml. Once the objective was reached, MIBI was repeated with the same technique and interpreted by the same specialist in Nuclear Medicine.
Results
75% of patients were women, mean age 51.9 ± 20.55 years.
De los eight pacientes incluidos en el estudio, 6 eran mujeres (75%), con una edad media de 51.9 ± 20.55 años. Mean preoperative calcium level was 11.49 ± 0.61 mg/dl. Mean preoperative PTH level was 146.26 ± 97.58 ng/l. Mean TSH level before repeating scintygraphy was 0.17 ± 0.08 µU/ml. Thyroxine suppression scan was positive in four of the eight patients (50%). Only two of these four patients underwent surgery for the moment. Minimally invasive surgery was performed in these cases, confirming the existence of a parathyroid adenoma where the MIBI suggested. The level of calcium in these patients normalized after surgery.
Conclusiones
In our study suppression of thyroid function by thyroxine administration improved MIBI sensitivity for parathyroid adenoma localization in our patients with previous negative studies, however, a larger number of patients would be required to confirm these results.

Serum vitamin D in overweight patients with normal and impaired GFR

Stelios Tigas[1], Athanasios Kitsos[2], Evangelia Dounousi[2], Rigas Kalaitzidis[2], Anna Challa[3] & Costas Siamopoulos[2]
[1]Department of Endocrinology, University of Ioannina, Ioannina, Greece; [2]Department of Nephrology, University of Ioannina, Ioannina, Greece; [3]Pediatric Research Laboratory, Child Health Department, Ioannina, Greece.

Introduction
Obesity is a strong risk factor for incident chronic kidney disease (CKD). Furthermore, high body mass index (BMI) is consistently associated with low serum vitamin D in the general population. The aims of the present study were to i) compare vitamin D metabolite levels in overweight/obese versus normal weight individuals with normal to severely impaired renal function and ii) to assess the impact of 25(OH)D on the development of secondary hyperparathyroidism (SHPT).
Methods
Serum 25(OH)D, 1,25$(OH)_2$D, PTH, calcium and phosphate were measured in 104 CKD outpatients with BMI >25 kg/m^2. Participants were categorized according to the eGFR (ml/min/1.73 m^2): G1: ≥ 60 ($n=53$), G2: 30–59 ($n=35$) and G3: 15–29 ($n=16$). Fifty normal-weight subjects with comparable eGFR levels composed the control group (G1-nw – G3-nw).
Results
25(OH)D was lower in overweight/obese G1 patients compared to G1-nw (21.7$\pm$6.5 vs 26.5$\pm$7.0 ng/ml, $P=0.02$) and in G2 versus G2-nw (19.0$\pm$6.0 vs 25.0$\pm$5.2 ng/ml, $P=0.005$), whereas the level did not differ among G3 groups (15.8$\pm$4.7 ng/ml vs 20.3$\pm$4.5 ng/ml, $P=0.49$ in G3 vs G3-nw respectively). Mean 1,25$(OH)_2$D and PTH levels were similar in obese/overweight versus normal-weight individuals in each eGFR category. Multivariate regression analysis in the entire cohort revealed that factors independently associated with low 25(OH)D levels were BMI >25 kg/m^2, eGFR <30 ml/min/1.73 m^2 and female gender whereas low 1,25$(OH)_2$D levels were associated with eGFR <30 ml/min/1.73 m^2, older age and increased serum phosphate. Even though serum 25(OH)D levels were suboptimal (<30 ng/ml) in both overweight and controls and in all eGFR groups, significant SHPT was only observed in the groups with eGFR <30 ml/min/1.73 m^2.
Conclusions
Lower serum 25(OH)D but similar 1,25(OH)2D and PTH levels were observed in overweight/obese compared to normal weight individuals and preserved or moderately impaired renal function. Even though vitamin D insufficiency was a common feature across all eGFR categories, SHPT was only observed in those with severely impaired renal function.

The importance of ultrasound in the preoperative evaluation of patients with primary hyperthyroidism: a case report

José Marçalo, Alexandra Araújo, Ana Wessling, Maria Raquel Carvalho & Maria João Bugalho
Hospital de Santa Maria, Lisbon, Portugal.

Introduction
Primary hyperparathyroidism is the most common cause of hypercalcemia in the outpatient setting, and a single parathyroid adenoma is usually the culprit. Clinical presentation is commonly dictated by hypercalcemia. Symptoms can range from mild non-specific malaise and gastrointestinal disturbances, through bone disease, kidney stones, cardiovascular and neuromuscular dysfunction to, ultimately, coma and death. However, the vast majority of patients are asymptomatic.
Case report
A 46-year-old female with a half-year endocrinology monitoring for type 2 diabetes and obesity, resorted to our hospital after 3 weeks' evolution of persistent nausea and vomiting. Laboratory workup showed increased PTH levels (596 pg/ml), severe hypercalcemia (17.4 mg/dl), mild hypophosphatemia (2.4 mg/dl), acute kidney injury (creatinine clearance 34 ml/min) and hyperuricemia (14.8 mg/dl). A 25-hydroxyvitamin D deficiency was also present (6.5 ng/ml). The first neck ultrasound did not show abnormalities; 99mTc-sestaMIBI scan was negative. Repetition of neck ultrasound revealed a left-postero-inferior nodule likely to correspond to an enlarged parathyroid. The cytological evaluation supported this hypothesis. Pamidronate, antiemetics and volume expansion with isotonic saline reverted the clinico-laboratory condition and served as a bridge to parathyroidectomy. Surgery went uneventful and a 3 cm inferior-left parathyroid was sent to anatomopathological examination. The final diagnosis was parathyroid adenoma. In subsequent postoperative follow-up the patient was asymptomatic and had normal serum calcium levels (9.3 mg/dl) and slightly upper-limit PTH (77.3 pg/ml).
Conclusion
Despite the considerable size of the resected parathyroid, initial ultrasound failed to locate it. Seeking for a topographical diagnosis, a second ultrasound was performed by a different operator in our hospital. This case highlights the importance of carefully selecting experienced centers to address parathyroid preoperative studies. Furthermore, despite the adenoma size, its inferior location, and the associated severe hypercalcemia, the 99mTc-sestaMIBI scan was negative, reminding of potential false-negative results of this method.

Ectopic production of calcitriol by non-hodgkin lymphoma as a cause of hypercalcemia: case report

Elvira Alarcón, Mariana Tomé, Carmen Bautista & Daniel González
Punta de Europa Hospital, Algeciras, Spain.

Introduction
Hypercalcemia of malignancy usually appears in patients with osteolytic metastasis and in those patients with humoral hypercalcemia due to secretion of PTHrp by the tumor. Hypercalcemia due to calcitriol production by the tumor is uncommon ($<1\%$ of cases of hypercalcemia of malignancy). It is the cause of virtually all cases of hypercalcemia in patients with Hodgkin's lymphoma and approximately one third of cases in non-Hodgkin's lymphoma. It has also been described in some cases of ovarian dysgerminoma.
Methods
We describe the case of a patient with MALT Non-Hodgkin lymphoma admitted to our hospital with severe hypercalcemia.
Results
Our patient was admitted to the hospital with calcium levels above 15 mg/dl. After hydration, loop diuretics and zoledronic acid he reached calcium level of 10.5–11 mg/dl but after withdrawal of intravenous hydration he presented recurrence of hypercalcemia up to the initial values. Analytics showed very low levels of PTHi and 25-OH-Vitamin D (5.76 pg/ml, 3 ng/ml respectively). Imaging tests (body CT) did not show osteolytic lesions suggestive of metastases. Given the suspicion of humoral hypercalcemia we initiated treatment with Cinacalcet 60 mg daily and steroids (Prednisone 1 mg/kg per day) without a satisfactory response in reducing calcium levels. Analytical result showed undetectable levels of PTH-related protein (<1.1 pmol/l) and very high calcitriol levels (148 pg/ml, N: 16–56 pg/ml). Our suspicion of calcitriol tumoral production associated with lymphoma is therefore confirmed. In view of the poor response to medical treatment and the need for intense hydration to maintain acceptable calcium levels a splenectomy with cytoreductive objective (19 cm splenomegaly) was performed. After this, calcium levels reached the normal level (9.5–10.2 mg/dl) and remained stable.
Conclusion
Although tumor production of calcitriol is an uncommon cause of hypercalcemia, it is usually related to lymphomas. We must think in this disorder in patiens with lymphoma and hypercalcemia.

Primary hyperparathyroidism: elective parathyroidectomy versus conservative management; results of a retrospective cohort study

Melanie Nana, Holly Morgan, Natasha Shrikrishnapalasuriyar & Atul Kalhan
Royal Glamorgan Hospital, South Glamorgan, UK.

Background
The optimum management strategy for primary hyperparathyroidism remains debatable especially in patients with mild or asymptomatic disease. We aimed to compare the baseline characteristics and long-term outcomes of patients with primary hyperparathyroidism who were either managed conservatively or underwent elective parathyroidectomy.
Methodology
We carried out a retrospective cohort analysis of patients with primary hyperparathyroidism under follow-up at the Royal Glamorgan Hospital, Wales from 1995 to 2016. The baseline characteristics were recorded from case records while the clinical portal was used to collate biochemical and radiological data. The patients were categorised into two main groups based on management approach (conservative treatment vs elective parathyroidectomy group).
Results
Out of a total of 336 patients with confirmed primary hyperparathyroidism, 72 (21.4%) underwent elective parathyroidectomy. Mean duration of follow up was shorter for the surgically treated patients as compared to the ones treated conservatively (3.7 vs 5.2 years). There was no significant difference between mean calcium levels at diagnosis although the mean parathyroid hormone (PTH) level at diagnosis was significantly higher in the surgical group (15.0 vs 11.4, $P=0.038$). Despite age adjustment using binary logistic regression, prevalence of hypertension and ischaemic heart disease was significantly lower in patients undergoing elective parathyroidectomy as compared to the group managed conservatively.
Conclusion
There was a significant difference in prevalence of hypertension and ischaemic heart disease in patients managed conservatively as compared to the group who underwent elective parathyroidectomy despite adjustment for age. The duration of follow up for this group was relatively shorter which can potentially off-set costs associated with surgery. The higher PTH levels at baseline for the elective parathyroidectomy group may also signify a correlation of PTH levels with increased risk of complications. Prospective large randomised controlled trials need to be designed to assess cardiovascular outcomes comparing surgical versus conservative management approach.

Calcium metabolism and autoimmune thyroiditis

Armine Khroyan[1,2], Edvard Toromanyan[1,2], Maria Badalyan[1,2] & Mariam Khachatryan[1,2]
[1]Muracan MC, Yerevan, Armenia; [2]Armenia MC, Yerevan, Armenia.

Objectives
The objective of our – investigation is to find out the role of D3 vitamin deficiency – and calcium in patients with autoimmune thyroiditis and calcified nodules.
Methods
The research has been carried out at "Muratsan" University Hospital and "Armenia" Medical Center, in 2013–2016.
80 patients (ages ±4–0, of which 68 women and 12 men) with autoimmune thyroiditis and calcified nodules have taken part in the clinical research.
They have been tested on TSH, FT4, anti-TPO, vitamin D3, Ca^{2+}, PTH, as well as undergone a thyroid ultrasound, elastography.
Results
TSH – 58%↑, 42% N
FT4 – 60% ↓, 40%N
Anti-TPO – 100%↑
Vitamin D3 – 84%↓, 16%N
Ca^{2+} – 94%N, 6%↓
PTH – 89% ↑, 11%N
Thyroid ultrasound – Calcificates proved to be present in 76% of nodules, which have been formed on the background of autoimmune thyroidits.
Thyroid elastography after 6 month taking vitamin D3 13% 3b elastography is go to 3a. The increased level of PTH hormone and lower vitamin D3 should be taken into consideration, since this can result from secondary hyperparathyroidism and cause formation of calcificates.
Conclusions
Vitamin D3 shout be tested in the first place during the treatment of any kind of calcified nodular goiter, since calcificates can be caused not only by oncologic processes, but also secondary hyperparathyroidism.

Pseudohypoparathyroidism (PHP) and *GNAS* gene mutations – clinical spectrum from PHP type 1a to pseudopseudohypoparathyroidism

Ana Saavedra[1,2], Elisabete Rodrigues[1,2], Filipe Cunha[1,2], Miguel Leão[3] & Davide Carvalho[1,2]
[1]Department of Endocrinology, Diabetes and Metabolism of Centro Hospitalar de São João, Porto, Portugal; [2]Faculty of Medicine, University of Porto, Porto, Portugal; [3]Department of Genetics of Centro Hospitalar de São João, Porto, Portugal.

Introduction
Pseudohypoparathyroidism (PHP) refers to a heterogeneous group of disorders that have in common end-organ unresponsiveness to parathyroid hormone (PTH). The most frequent form, PHP type 1, results from different genetic/epigenetic changes in the *GNAS* gene.
Case 1
Woman, 25 years-old, sent to Endocrinology from Genetics consultation after her daughter had been diagnosed with PHP type 1a (heterozygous pathogenic variant at exon 13 of *GNAS* gene c.1174G>A (p.e392K)). Our patient and her father present some clinical manifestations as observed in the child, suggestive of Albright Hereditary Osteodystrophy (AHO), and both present the same mutation as encountered in index case. We tested phosphocalcic metabolism of our patient and she presented normal serum calcium/phosphorus levels as well PTH levels. Other pituitary hormones were evaluated, with normal results except elevated TSH (18.72 μUI/ml) in context of primary autoimmune hypothyroidism. Patient started treatment with levothyroxine.
Case 2
Male, 31 years-old (case 1 brother). He was sent to Endocrinology in December 2015 for lymphocytic thyroiditis evaluation. During the physical examination, it was recognized a phenotype suggestive of AHO, as was found in his relatives (round facies, brachydactyly and subcutaneous calcifications). Patient's lab tests showed normal serum calcium/phosphorus levels and high PTH in the context of vitamin D deficiency. Other pituitary hormones levels were in normal range. Patient performed genetic test - results ongoing.
Conclusion
Different pathological entities may result from mutations in the *GNAS* gene. PHP type 1a is characterized by the presence of AHO and PTH resistance. However, AHO manifestations may occur in patients without PTH resistance (pseudopseudohypoparathyroidism), as in the two cases presented. This occurs when the mutation is paternally transmitted. These cases somehow demonstrate de complexity of *GNAS* gene mutations, which merited recently a new classification. It is also highlighted that although pseudopseudohypoparathyroidism needs no treatment, genetic counselling should also be recommended.

Hyperparathyroidism and cardiovascular risk

Daniela Amzar[1], Melania Balas[1], Ioana Golu[1], Mihaela Vlad[1], Ramona Sandu[2] & Maria Cornianu[3]
[1]Department of Endocrinology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania; [2]Department of Endocrinology, Emergency County Hospital, Timisoara, Romania; [3]Department of Pathology, Victor Babes University of Medicine and Pharmacy, Timisoara, Romania.

Background
Primary and secondary hyperparathyroidism (HP) are associated with increased risk for cardiovascular complications and high mortality. Risk factors correlated with hypertension in HP are hyperlipidemia, glucose intolerance, insulin resistance, vitamin D deficiency, etc. The aim of the study was to assess the incidence of cardiovascular complications in HP.
Material and methods

The study included 45 patients (15 men, 30 women), with a mean age of 45 years (range 21–65 years). Thirty-two patients were diagnosed with primary HP and 13 with secondary HP due to chronic kidney disease (stages 3 and 4). The patients were evaluated by biochemical, hormonal parameters, imagistic tests, and cardiac sonography.

Results

Vitamin D deficiency was documented in all patients with secondary HP and in 24 patients with primary HP (75%). Other metabolic disturbances and risk factors for cardiovascular diseases were as follows: diabetes mellitus (24.4%), smoking (28.8%), obesity (22.2%), and dyslipidemia (46.6%). The incidence of mitral and/or aortic valvular stenosis (caused by calcifications) was similar in the two groups, affecting 31.1% of the patients. Hypertension prevailed in the group of secondary HP (12 cases), as compared to primary HP (10 cases, $P=0.0002$, Fisher's exact test). Peripheral atherosclerotic manifestations were noted in 11 cases (24.4%). Seven patients (15.5%) experienced an acute coronary event and three patients underwent PTCA procedures with stent implantation. Ten patients showed ventricular hypertrophy (22.2%); the incidence was similar in the two groups (eight patients with primary HP, respectively two with secondary HP).

Conclusion

Our study shows that hyperparathyroidism is associated with higher incidence of severe cardiovascular complications, occurring at younger ages as compared to general populations.

Risk factors associated with osteoporosis in beta-thalassaemia major patients

Elena Mirela Iancu, Alice Ioana Albu & Irina Nicolaescu
Elias University Clinical Hospital, Bucharest, Romania.

Beta-thalssaemia major (BTM) is a rare disease that encompasses a vast range of endocrinological complications, despite of the improvement of treatment protocols. The aim of this study was to identify the clinical and hematological parameters associated with osteoporosis, a frequent complication found in beta-thalassaemia patients.

Patients with BTM were evaluated in the Endocrinology Department of Elias Hospital between February 2004 and March 2016. Only patients who provided written informed consent were included in the study. A complete physical and hormonal evaluation was performed on all patients, and data regarding treatment of hematological disease were collected. The bone density was evaluated using dual energy X-ray absortiometry (DXA).

Forty-nine patients were included in the study (median age 28.37 years; range 12–47). We found that 35 patients (71.4%) had osteoporosis documented using DXA, 16 of them (45.7%) had fragility fractures caused by decreased BMD.

Patients with osteoporosis were older (median age 31.51 vs 20.5 years, $P=0.05$) and started the iron chelation therapy at an older age compared with subjects without this condition (105.72 months vs 63.58 months, $P<0.05$). Although the levels of serum ferritin were higher in patients with osteoporosis (1062 vs 777 ng/ml), the difference did not reached statistical significance. Hypogonadism was significantly more frequently found in patients with osteoporosis (30 pts, 85.7% vs 5 pts, 14.3%) in comparison to patients without osteoporosis ($P=0.014$). The risk of developing osteoporosis was six times greater in hypogonadal study subjects.

Our data show that osteoporosis is a highly prevalent complication among Romanian β-thalasaemia patients, its presence being associated with older age, delayed initiation of iron chelation therapy and the presence of hypogonadism.

Giants walk amongst us

Raj Tanday[1], Bonnie Grant[1], Akin Ojo[2], Edel Casey[1] & Khash Nikookam[1]
[1]Department of Endocrinology, King George Hospital, London, UK; [2]Department of Surgery, King George Hospital, London, UK.

We present the case of a 51-year-old gentleman who had a giant parathyroid adenoma. He has a past medical history of deep vein thrombosis and hypertension. He is taking amlodipine 10 mg od. He is a non-smoker and drinks alcohol in moderation. He was admitted with right leg swelling found to be a new thrombosis. Incidental finding of extreme hypercalcaemia found on bloods with raised PTH (CorrCa 4.23 mmol/l, PTH 83.1 pmol/l.) Patient was completely asymptomatic. CT imaging of chest, abdomen and pelvis demonstrated extensive above knee thrombosis, renal calculi and a large thyroid nodule. However, an ultrasound and Sestamibi confirmed spectacularly this was an enlarged parathyroid. He was anticoagulated with heparin and then oral anticoagulant. He was given aggressive i.v. fluids and bisphosphonate with limited effect so cinacalcet was initiated. We were still unable to control calcium levels and so in patient parathyroidectomy was performed. At operation the gland appeared grossly enlarged and vascular. However, there was no tethering to adjacent tissues and easily removed weighing 43 g. Our patient made a good recovery with normalisation of calcium. Histology showed features in keeping with parathyroid adenoma rather than carcinoma. On review in clinic two months later he remains normocalcemic. A DEXA has shown osteoporosis which we expect to improve in time.

Our case is interesting as there are features of this case in keeping with parathyroid malignancy rather than adenoma and we shall discuss this.

Hungry bone syndrome after treatment of severe primary hyperparathyroidism

El Mghari Ghizlane & El Ansari Nawal
Chu Med6, Marrakech, Morocco.

Introduction

Persistent hypocalcemia after surgery for severe hyperparathyroidism are not uncommon and may be secondary to transient or permanent hypoparathyroidism but may also be due to bone pathology.

Observation

Patient of 44 years old was hospitalized for fractures of the pelvis, and shaft of left femur, spontaneous without trauma turned out. Laboratory tests shows severe hypercalcaemia to 156 mg/l, serum phosphorus at 22 mg/l, elevation of PTH to 1150 pg/ml and proper renal function with a serum creatinine to 8 mg/ml. PAL is increased to 709 U/l.

A spot of médiastinal fixation compatible with ectopic parathyroid adenoma was seen on the MIBI scintigraphy with several brown tumors. Ectopic mediastinal parathyroidectomy was made after medical preoperative treatment with bisphosphonates, vitamin D and active metabolite of vitamin D.

In postoperative period a severe hypocalcemia reaching 65 mg/l at the fifth day was observed, the PTH was (9.9 pg/ml) and PAL are increased to 560 U/l with a lowered serum phosphorus.

The difficulty of standardization of serum calcium despite supplementation of calcium element and 1 alpha and vitamin D, high PAL and the presence of diffuse bone lesions guide to The diagnosis of HBS.

Conclusion

HBS is a heightened greed bones for calcium. It occurs in situations of demineralization and intense bone remodeling.

EP310

Clinical review of nine cases of pseudohypoparathyroidism

David Barbosa[1], Brígida Robalo[2], Carla Pereira[2] & Lurdes Sampaio[2]
[1]CHLN – Hospital de Santa Maria, Endocrinology, Diabetes and Metabolism Department, Lisbon, Portugal; [2]CHLN – Hospital de Santa Maria, Pediatric Endocrinology Unit, Lisbon, Portugal.

Objective

To analyze the clinicopathological features of pseudohypoparathyroidism (PHP), that would help clinicians to consider this rare condition in children.

Methods

A retrospective review of nine patients with PHP (including seven males and three females) admitted to our hospital between 1990 and 2014 was conducted. Clinical and biochemical parameters along with epidemiological data were extracted and analyzed.

Results
The mean age at diagnosis was 61.8 ± 26.1 months, ranging from 4 to 114 months. The most frequent clinical features were: round lunar face and obesity (77.7%), followed by brachydactyly and learning/behavior disabilities (66.7%). Subcutaneous calcifications, although a landmark of PHP, were only present in four patients (44.4%). Afebrile seizures occurred in two cases, despite the majority showed multiple intracranial calcifications on cranial CT scan. Laboratory tests at diagnosis revealed most frequently hypocalcemia (mean 7.4 ± 1.9 mg/dl; 8.6–10.2), hyperphosphatemia (mean 7.9 ± 1.7 mg/dl; 2.7–4.5) and high PTH levels (mean 366.3 ± 218.4 pg/ml; 14–72). Subclinical hypothyroidism was present in eight out of nine patients (88.8%) with a mean TSH of 9.45 ± 4.2 uU/ml (0.35–5.5) and a mean free T4 of 0.95 ± 0.1 ng/dl (0.8–1.9). Vitamin D3, and calcium when needed, were prescribed to all patients to prevent symptomatic hypocalcemia and presumably to stop disease progression by lowering the PTH levels, although it is not clear whether this normalization is beneficial. Genetic testing was performed in six children.
Conclusion
PHP is a rare and heterogeneous genetic disease with a high rate of misdiagnosis and no specific treatment. It should be considered in children presenting with a round face, obesity, brachydactyly, learning/behavior disabilities, subcutaneous calcifications and subclinical hypothyroidism. Laboratory evaluation of blood calcium, phosphorus, PTH and thyroid hormones should be ordered as soon as possible, as well as neuroimaging and a genetic profile for further confirmation.

EP311

Severe hypercalcemia revealing an atypical parathyroid adenoma

El Ansari Nawal & Bouchra Rafiq
Department of Endocrinology, Diabetology Metabolic Diseases and Nutrition Laboratory PCIM, FMPM, Cadi Ayyad University, UHC Mohamed VI, Marrakech, Morocco.

Introduction
Primary hyperparathyroidism is a common cause for hypercalcemia, however severe hypercalcemia remain a rare complication. The atypical parathyroid adenoma is an uncommon cause to severe hypercalcemia. We report a case of a 40-year-old male with very high serum calcium due to a possible atypical parathyroid diagnosed after a spontaneous fracture.
Case report
A 40-year-old male was admitted to the traumatology department for the management of spontaneous fracture of the humerus. The clinical history revealed clinical symptoms of hypercalcemia (abdominal pain, neurologic irritation, asthenia, etc.). The initial blood work up found a severe hypercalcemia (203 mg/l) hypophosphoremia (23 mg/l) and high ALP. Parathyroid hormone level were of 749 pg/ml. The patient underwent a surgical en bloc resection after the localization of a right inferior parathyroid adenoma. Pathology showed a mixed picture consistent with possible atypical adenoma versus parathyroid carcinoma. However, due to the absence of local structures involvement, atypical parathyroid adenoma was more likely. The immunohistochimie: paratyhroidien adenoma atypical. The evolution was marked by the improvement of the clinical signs and calcium normalization.
Conclusion
It can be very difficult to distinguish between atypical parathyroid adenomas and parathyroid carcinomas as in our case and no clear-cut guidelines yet exist to differentiate the two based on histology. Close follow-up is mandatory to detect any local recurrence.

Hypercalcemia and cardiovascular disease

Elena Brutskaya-Stempkovskaya[1,2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Minsk City Polyclinic N31, Minsk, Belarus.

Introduction
According to modern studies, patients with hypercalcemia have an increased cardiovascular risk.
Objective
To study the prevalence of cardiovascular disease in patients with hypercalcemia.
Materials and methods
We studied 1207 people, average age 53.9 ± 17.25 (892 women, 315 men) from 18 to 96 years. Examination: total calcium, total protein, creatinine, cholesterol and triglycerides, HbA1C, ambulatory blood pressure monitoring, ECG, an analysis of morbidity (hypertension, coronary heart disease, cardiovascular events).
Results
Hypercalcemia has been found in 31 people, mean age was 58.39 ± 11.6 years. Arterial hypertension was detected in 677 cases (in patients with hypercalcemia – in 23 patients), coronary heart disease was detected in 599 cases (in patients with hypercalcemia – 21), acute myocardial infarction – in 52 cases (in patients with hypercalcemia – 1), acute cerebrovascular accident – in 39 cases (in patients with hypercalcemia – 1).
Significant differences in the prevalence of arterial hypertension ($\chi^2=4.03$, $P=0.0447$); in the prevalence of coronary heart disease ($\chi^2=3.87$, $P=0.046$) in patients with hypercalcemia were detected. In the same time the differences in the prevalence of acute myocardial infarction ($\chi^2=0.09$, $P=0.8$) and acute cerebrovascular accident ($\chi^2=0$, $P=1$) in patients with hypercalcemia were not revealed.
Conclusion
The results of the study show an increasing risk of arterial hypertension and coronary heart disease in patients with hypercalcaemia. In the same time the risk of acute cardiovascular events is not increased. The results may suggest the influence of hypercalcemia on the development of cardiovascular disease.

Vitamin D levels in obese adults and cardiovascular risk

Andreia Domingues[1], Bruno Oliveira[2,3] & Flora Correia[2,4]
[1]Hospital das Forças Armadas – Polo Lisboa: Unidade de Nutrição e Dietética e Serviço de Endocrinologia e Diabetes, Lisboa, Portugal; [2]Faculdade de Ciências da Nutrição e Alimentação da Universidade do Porto, Porto, Portugal; [3]LIAAD INESC-TEC, Porto, Portugal; [4]Centro Hospitalar de S. João EPE, Porto, Portugal.

Introduction
The prevalence of vitamin D deficiency is high, and yet still little recognized and treated. Cardiovascular diseases are the leading causes of morbidity and mortality worldwide and the emergence of evidence with the link suggesting an association between vitamin D deficiency and cardiovascular risk (CVR), it is pertinent to better understand this association.
Objective
This study aimed to relate the levels of 25 (OH) D in obese patients with the cardiovascular risk.
Methodology
Cross-sectional observational study with a sample of 31 individuals between 40 and 64 years, of both sexes diagnosed with obesity. They evaluated sociodemographic data, solar exposure and use of sunscreen, skin color phototype of skin color, sources of vitamin D, physical activity, anthropometric data, clinical and biochemical and CVR.
Results
The average value of 25(OH) D was 15.6 ng/ml, 71.0 and 22.6% had deficiency and insufficiency, respectively. We observed lower levels of 25(OH) D in smokers, those with less solar exposure time, with a higher waist-to-height ratio and in those with lower levels of DBP. We did not find a statistically significant association between vitamin D and CVR.
Conclusions
We found a high prevalence of vitamin D deficiency in our sample of patients with obesity and a significant association with the waist-to-height ratio. Despite the evidence that suggests that vitamin D deficiency is associated with an increased CVR, we found this association but without statistical significance. The measurement of total 25(OH) D routinely in people with central obesity can help identify those who are at most CVR.
Keywords: vitamin D cardiovascular risk; obesity; SCORE; metabolic syndrome.

Partial gigantism: case report

Munira Karimova & Zamira Khalimova
Center for the Scientific and Clinical Study of Endocrinology, Department of Neuroendocrinoloy, Mirzo Ulugbek str. 56, 100125, Tashkent, Uzbekistan.

The aim
To study case of partial gigantism.
Methods
To evaluate the patient's condition we conducted hormonal and biochemical investigations, as well as total blood and clinical urine analysis; Doppler sonography and multislice computed tomography were performed.
Results
STH – 25.8 mIU/l (normal range: 2.0–20 mIU/l); IGF – 2.9 mg/l (normal range for the age: 13–100 mg/l); ALPase – 160 U/l (normal range: up to 644 U/l); total calcium – 2.08 mmol/l (normal range: 2.5–3.0 mmol/l); phosphorous – 1.42 mmol/l (normal range: 1.3–2.26 mmol/l). Doppler sonographyof left extremity demonstratedpresence of hyperechoic(circular) layer in the projections of the first and second left toes.
Multislice computed tomography (MSCT) of left extremitydemonstrated enlargement of the first and second left toes with the metatarsal involvement. The soft tissues of the area contain multiple poorly demarcated thin-wall cyst-like formations with cystic content density of -120 + 34 HU. Cortical layers of adjacent toe or metatarsal bones demonstrated no disruptions of continuity. Spacing intervals between the first and second toes and metatarsal bones are enlarged. Middle phalanx of the second toe is laterally displaced. Boundaries of bones are well defined; no disruptions of cortical layer or periosteal reaction can be seen. The soft tissues of right extremity have no changes. Total blood and clinical urine analysis, ECG and brain MRI demonstrated no deviations.
Conclusions
Due to few similar cases and limited experience for their managing, it is necessary to:
– choose the wait and see approach. The excessive growth making a patient's movements hard progresses, correcting surgical procedures and appropriate footwear are necessary,
– let the closure of growth zones be accomplished for correcting surgical reconstruction to be performed; the body part disproportionally enlarged should be surgically removed after that, generate a databank to generalize the results, and to develop drug and radiotherapy regimens.

An unique case of celiac disease with hypocoagulation and secondary hyperparathyreodism in elderly patient – a case report

Gocha Barbakadze, Lali Tigishvili, Levan Ramishvili, Nani Tsikarishvili & Koba Burnadze
Enmedic Clinic, Tbilisi, Georgia.

Introduction
Celiac disease (CD) an autoimmune disorder of the small intestine, was considered as a disease of childhood. The symptoms can be obvious. That is the main reason why CD is underdiagnosed in elderly patients.
Aims & Methods
The purpose of our study was to demonstrate a clinical case of CD which was diagnosed in a 41-year-old female patient. The patient attended our clinic with complains of weakness, tenderness, abdominal distension, weight loss. Laboratory tests find severe iron deficiency anemia (HB -9 g/dl, Ery- 3.1×10^{12}/l, serum iron 4 mmol/l) and severe hypocoagolopathy (prothrombine index-48%, INR-2.98, but mild thrombocytopenia 130×10/l). She had suffered with these symptoms for 2 years.
Results
Number of investigations was performed. We also checked parathormone which revealed secondary hyperparathyroidism (parathhormon 187 pg/ml, Ca-1.01 mmol/l). The hemolytic anemia was excluded (haptoglobin was in normal range). Stool examination revealed no pathogens.
It was believed that she has these symptoms due to her anemia. After 2 weeks occurred the oedema of abdomen and diarrhea of 3–4 watery stools daily and night tremor and seizure due to hypoglycaemia (2.3 mmol/l). Ultrasound investigation of abdomen showed very rush peristalsis of small and large intestines, but no ascites, significant meteorism.
CD was suspected. Serologic test for anti-gliadin antibodies was positive. Another examination of the biopsy after the first endoscopy revealed extensive collagen depositions in the lamina propria of the small bowel, giving the diagnosis of CD. Also antibodies against Transglutaminase were positive. After gluten-free diet the above mentioned symptoms disappeared and patient's anemia and blood clot markers as well as parathormone and Ca level were well controlled.
Conclusion
The presence of other immune-related diseases in our case suggests that immunological mechanism plays a crucial role in CD. We recommend active specific screening in older patients belonging to at risk-group like other autoimmune disorders. Disappeared and patient's anemia and blood clot markers as well as parathormone level were well controlled.

Optic neuritis as presenting complaint in primary hypoparathyroidism

Muhammad Fahad Arshad[1], Steven Kang[1], Nauman Arif Jadoon[2] & Rehmat Karim[2]
[1]Doncaster Royal Infirmary, Doncaster, South Yorkshire, UK; [2]Hull Royal Infirmary, Hull, UK.

Background
Papilledema and raised intracranial pressure has been reported frequently in patients with hypoparathyroidism but very rarely optic neuritis (1).
Clinical case
We report a case of 63-year-old male who presented to ophthalmology with right-sided visual loss and a relative afferent pupillary defect. He was diagnosed with optic neuritis and underwent MRI brain which showed bilateral white matter changes with the possibility of demyelination. He was initially diagnosed with relapsing-remitting multiple sclerosis by the neurologist but was later found to have severe hypocalcaemia (adjusted calcium 1.32 mmol/l (2.20–2.60)) and idiopathic primary hypoparathyroidism (PTH < 0.3 pg/ml (1.6–7.2)). Cerebrospinal fluid examination was entirely normal with negative oligoclonal bands. The initial MRI changes were thought to be secondary to severe hypocalcaemia as per neuroradiology MDT and subsequently, the diagnosis of multiple sclerosis was reversed. Although the underlying mechanism is not very clear, we believe there is an association between optic neuritis and primary hypoparathyroidism, especially in the absence of any other underlying cause for optic neuritis.
Conclusion
Although rare, but primary hypoparathyroidism can present as optic neuritis. Therefore, serum calcium should be checked in patients with no clear cause of optic neuritis.

The parathyroid carcinoma in a young adult male

Sevde Nur Firat[1], Anara Karaca[1], Nujen Çolak Bozkurt[1] & Hatice Unverdi[2]
[1]Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Teaching and Research Hospital, Pathology, Ankara, Turkey.

Introduction
Parathyroid carcinoma is a rare malignancy of the parathyroid glands. Parathyroid carcinoma may be suspected, but it usually cannot be confirmed prior to operation.
Case
A 35-year-old male was consulted to Endocrinology department with persistant kidney stones. He was operated five times in 10 years for recurrent kidney stones. His lab results are as follows; Ca:13(8.8–10.6), P:2.2 mg/dl(2.5–4.5), ALP:84U/L(30–120), parathormone:179 pg/ml(14–72), 25(OH)Dvit:8.2 ug/l(10–80). Urine Ca: 1159 mg/24 h(100–300), urine P:134 mmol/24 h(13–42).

Neck USG revealed 17×11×12 mm PTH adenoma with cystic components, but with no pathological cervical lymphodenopathies.
Radionuclide scan confirmed increased parathyroid gland activity on the right inferior of the thyroid gland.
The patient underwent right inferior parathyroidectomy. Postoperative PTH < 6, Ca:8.17,which confirmed successful remove of the pathological parathyroid gland. The histological findings reported marked pleomorphysm in the cells, divided by the typical fibrotic septae and Ki-67: 4–5%. All those findings were consistent with parathyroid carcinoma.
After 4 months his last lab results were as follows; PTH: 57.8 pg/ml, Ca:8.8 mg/dl, P:4.6 mg/dl, urine Ca: 124 mg/24 h.
Conclusion
There is a challenge in the diagnosis of parathyroid carcinoma, because it is commonly confirmed with histological evaluation. Although, parathyroid carcinoma is a rare disease, it should be kept in mind even in young adults.

Clinical case of atypical parathyroid adenoma with severe hypercalcemia and multiple fragility fractures

Anna Eremkina, Natalia Mokrysheva, Julia Krupinova, Svetlana Mirnaya & Iya Voronkova
Endocrinology Research Centre, Moscow, Russia.

Introduction
Atypical parathyroid adenoma (APA) is rarely encountered cause of primary hyperparathyroidism (PHPT). No definite criteria are considered to distinguish preoperatively APA from parathyroid typical adenoma or carcinoma.
The aim
To describe the clinical course of a patient with an atypical parathyroid adenoma with severe hypercalcemia and multiple fragility fractures.
Case presentation
A 61-year-old woman was evaluated for multiple fractures, skeletal deformities, pain in the large joints and bones, tachycardia, oppressive chest pain. She had severe hypercalcemia (calcium level 14.7 mg/dl), hypophosphatemia (serum phosphate 2.1 mg/dl) with an elevated intact parathyroid hormone level of 1871 pg/ml. Ultrasonography revealed a large structure (4.7 cm) of the right parathyroid gland. 99mTc-sestamibi SPECT/CT showed the lesion 43×34×40 mm behind the middle and lower third of the left thyroid lobe. Renal function was impaired, GFR 46 ml/min/1.73 m^2. Whole-body Tc-99m bone scan demonstrated multiple skeletal changes accepted as parathyroid osteodystrophy. As a result of the determination of severe hypercalcemia, heart rhythm disturbances (permanent form of atrial fibrillation), a high risk of hypercalcemic crisis, intravenous hydration was started with no significant effect. Patient received denosumab 60 mg s.c. She underwent a surgical resection of parathyroid adenoma and intra-operative PTH levels fell to 20.9 pg/ml. In the postoperative period serum calcium was decreased to 8.9 mg/dl. On pathological examination, the tumor consisted mainly of chief cells. Capsule invasion, peripherical vascular and perineural invasion of the adjacent tissue, high mitotic activity or large bands of fibrosis were not observed. Ki67 immunostaining was generally positive in about 3% of the tumor. Tumor vessel invasion was detected in the central node part. These changes corroborated the diagnosis of atypical parathyroid adenoma.
Conclusion
APA are rare and have been a challenge for diagnosis. They have some features of carcinoma but lack the indisputable evidence of malignant disease like invasion or metastases. They have unpredictable clinical course, long-term follow up is prudent to assess for local recurrence and metastatic disorder to distinguish between benign and malignant parathyroid disease.

Congenital fibrous dysplasia and Klinefelter syndrome: coincidence or not?

Maria Alexandra Grama[1] & Constantin Dumitrache[1,2]
[1]Institute of Endocrinology IC Parhon, Bucuresti, Romania; [2]University of Medicine and Farmacology Carol Davila, Bucuresti, Romania.

Congenital fibrous dysplasia is a rare disease with a broad spectrum of manifestations, including various endocrinopathies;precocious puberty, hyperthyroidism, excess growth hormone, hypophosphatemia mediated by FGF23.
We present the case of a 33 year old male, who presented in our endocrinology service with infertility and bone pain. He was diagnosed at the age of years old with congenital fibrous dyplasia and suffered multiple surgeries for bone decompression. Blood tests showed vitamin D insufficiency (16,01 ng/ml), very high levels of alkaline phosphatise (919 U/l), normal levels of calcium, phosphorus and parathormone. Bone mineral density was low at the femoral neck: BMD 1.385 g/cm^2, Tscore = −2.4, Zscore = −2.3.
His semen analysis showed a normal aspect, volume and viscosity, but with a low A mobility of spermatozoa and a low percentage of normal form spermatozoa.
His testosterone was within the normal range (3,44 ng/ml), with a TSH of 4,10 microUI/ml. We further performed a karyotype analysis, wich showed the presence of an extra X chromosome in 10% of the studied metaphases, with the diagnosis of mosaic Klinefelter:47XXY(10%)/46 XY (90%).
This is the first description of a case with congenital fibrous dysplasia which associates mosaic karyotype 46XY/47XXY. Although the link between the two conditions is not known, further investigations are necessary to establish a possible correlation between them. It remains to establish if karyotype analysis should be a routine investigation for those diagnosed with fibrous dysplasia.

Parathyroid nodular hyperplasia: when imaging exams fail

Ana Sofia Osório[1], José Rocha[2], Carolina Faria[1], David Barbosa[1], Ema Nobre[1] & Maria João Bugalho[1]
[1]Serviço de Endocrinologia, Diabetes e Metabolismo; Hospital de Santa Maria; Centro Hospitalar de Lisboa Norte, Lisboa, Portugal; [2]Serviço de Cirurgia I; Centro Hospitalar de Lisboa Norte, Lisboa, Portugal.

Introduction
Parathyroid hyperplasia is the second cause of primary hyperparathyroidism (PH), representing 15–20% of all cases. The scintigraphy with Tc-99m-Sestamibi is a preoperative exam used to identify parathyroid adenomas or hyperplasia. It has a sensibility of 50–90%, which increases with larger parathyroid size. The neck ultrasonography (US) has also an important role detecting parathyroid enlarged glands with 70% sensibility. We report a case of parathyroid hyperplasia where the imaging exams fail to detect a 40 mm parathyroid.
Case report
75-year-old woman with osteoporosis, spontaneous bone fracture and osteoarticular pain. Laboratory evaluation showed a parathormone (PTH) of 145 pg/ml (range 14–72), a serum calcium of 12,0 mg/dl (range 8,6–10,2) and a phosphorus of 2,2 mg/dl (range 2,5–4,5). A neck US was performed revealing a 17 mm hypoechogenic vascularised nodule consistent with the inferior left parathyroid, also visible in the Tc-99m-Sestamibi. Patient was submitted to inferior left parathyroidectomy. The intraoperative exploration conducted to the additional finding of an enlarged superior right parathyroid with 40 mm also removed. The final diagnosis was nodular hyperplasia of both glands. Retrospectively, a detailed familial history was taken and considered negative for hyperparathyroidism and/or endocrine tumours. After 2 months post surgery, the patient is under Vitamin D and Calcium and mentioned improvement in symptoms.
Conclusion
Coincidental results of an anatomic exam (US) and a functional one (Tc-99m-Sestamibi), suggesting the involvement of a single gland, do not exclude pluriglandular HP. Vitamin D and Calcium were started considering the bone disease; discontinuation and tapering of therapy will be managed according to calcium and PTH levels.

As clear as mud: an atypical case of primary hyperparathyroidism

Jessica Lai[1,2], Navin Niles[1,3] & Namson Lau[1,4]
[1]Liverpool Hospital, NSW, Australia; [2]South Western Sydney Clinical School, University of New South Wales, NSW, Australia; [3]Macquarie University Hospital, NSW, Australia; [4]LIVE DIAB CRU, Ingham Insitute of Applied Medical Research, NSW, Australia.

Objective
A young woman presented with marked hyperparathyroidism with post-operative course complicated by hungry bone syndrome and diagnostic and management challenges of ongoing hypocalcaemia with hyperparathyroidism.
Method
ML, a 32-year-old Fijian Indian female, was referred with severe hypercalcaemia, following one-year history of migratory debilitating bone pain. Initial labs showed corrected calcium (C.Ca) 3.17 [2.10–2.60 mmol/l], parathyroid hormone (PTH) 305.4 [2.0–6.0 pmol/l] and 25-hydroxyvitamin D (25-VitD) of 22 [40–80 nmol/l]. Acute management included admission for intravenous fluids and bisphosphonates, which normalised C.Ca. A parathyroid SESTAMIBI/CT-SPECT demonstrated a 31×9×33 mm soft tissue mass in anterior superior mediastinum with focal uptake at T3. Further CT neck demonstrated 10×5×5 mm mass between left common carotid and subclavian arteries.
Results
ML's surgical resection of the mediastinal mass was immediately complicated by generalised bony pain, pleural effusions and despite aggressive replacement of calcium, marked hypocalcaemia (Day 1 C.Ca 1.99); consistent with an exaggerated 'hungry bone syndrome'. ML has been followed closely for on-going optimisation of calcium and vitamin D; three-month labs showed elevated PTH (30.7 pmol/l), despite normalisation of 25-VitD (79 nmol/l) and improved C.Ca (2.04 mmol/l). Her pre-operative DEXA scan showed T-scores: lumbar spine −5.1SD and bilateral femoral necks −5.6SD. A MRI cervical spine demonstrated widespread lytic lesions including, a lesion in the C2 spinous process and posterior pedicles, considered consistent with pathological fracture. Histopathology reported a 70×65×51 mm; 41 gm mass with no invasive features. Parafibromin was positive, whilst PGP9.5 was negative; other patterns of staining were normal, making HRPT2/CDC73 mutation unlikely.
Conclusion
This case highlights: 1) the diagnostic challenge of marked hyperparathyroidism with a clinical picture suggestive of malignancy, but histological evidence not supporting invasion; 2) the management issues of moderating post-operative severe hypocalcaemia and *hungry bone* phenomenon; and 3) the on-going diagnostic and management of post-operative hyperparathyroidism with hypocalcaemia. In summary, atypical primary hyperparathyroidism presents unique diagnostic and management challenges.

Familial hypocalciuric hypercalcemia with a new heterozygous missense mutation of CaSR gene and cinacalcet treatment

Sinem Kiyici[1], Burçin Uygun[1] & Orhan Gorukmez[2]
[1]University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Endocrinology and Metabolism, Bursa, Turkey; [2]University of Health Sciences, Bursa Yuksek Ihtisas Education and Training Hospital, Department of Genetics, Bursa, Turkey.

Introduction
Familial hypocalciuric hypercalcemia (FHH) is an autosomal-dominant genetic disease caused by an inactivating mutation in the gene encoding the calcium sensing receptor (CaSR). The loss of function leads to increased circulating level of PTH and subsequent hypercalcemia.
Case report
20-year-old male patient referred to our center with hypercalcemia which was found after the syncope. His serum calcium level was 11.7 mg/dl and the phosphorus was 2.4 mg/dl (normal: 2.5–4.5). The serum PTH was 131 pg/ml (normal: 10–65), 25-hydroxyvitamin D3: 12.2 ng/ml and 24-h urine calcium excretion was below 200 mg/day. His calcium/creatinine clearance ratio was 0.005. After replacement of vitamin D, calcium/creatinine clearance ratio was still < 0.01. The family screening planned for FHH. Both his 49 year-old father and 22 year-old brother had also slightly elevated PTH in spite of moderately increased serum calcium levels. Their calcium/creatinine clearance ratios were <0.01. Patient is tested for mutations in the CaSR gene. The patient was found to have a heterozygous missense mutation (p.Ser182Pro/c.544T $>$C) in the CaSR gene, suggesting the diagnosis of FHH. This mutation has never been reported in literature or in the Human Gene Mutation Database. In the follow up of the patient 30 mg/day cinacalcet treatment was started and increased up to 60 mg/day due to the persistant symptomatic hypercalcemia. Plasma calcium levels were normalized and PTH levels decreased slightly after the treatment.
Conclusions
FHH is a rare disorder, but it is clinically important because it can be confused with asymptomatic primary hyperparathyroidism. FHH is usually asymptomatic but rarely symptoms of fatigue, weakness, and excessive thirst and concentration problems are experienced. Cinacalcet is potentially a useful treatment of patients with intractable hypercalcemia caused by mutations in the CaSR gene.

Parathyroid carcinoma can be misdiagnosis with medullary thyroid cancer: how is that possible?

Natalia Mokrysheva, Julia Krupinova, Ekaterina Pigarova, Nadezhda Platonova, Iya Voronkova & Kirill lanschakov
Endocrinology Research Centre, Moscow, Russia.

Background
Hypercalcemia may stimulate thyroid's C-cells to produce the calcitonin, that could lead to misdiagnosis of medullary thyroid cancer.
Clinical case
A 47-year-old woman suffered from fracture of the left knee. She could not walk and used a wheelchair. CT scan in a public hospital detected multiple bone lytic changes in the ribs and vertebrae (mts?), tumor in the liver (mts?) and node in the thyroid gland 2.6*1.9 cm. Thyroid biopsy showed follicular neoplasia (cancer?). At the same time, blood analysis showed high level of serum calcitonin 190 pg/m (0–5.5). Thus, her state was determined as the medullary thyroid cancer (MTC) with mts in bone and liver and she was sent to our center for surgery of MTC.
Medical examination uncovered primary hyperparathyroidism (PH): total calcium – 3.78 mmol/l (2.10–2.55), PTH −1513 pg/ml (15–65) in combination with 3.7*2.9*2.4 cm tumor behind the thyroid gland showed by the US exam. Osteitis fibrosa cystica was suspected after radionuclide bone imaging. Renal functions were impaired, GFR 10 mL/min/1.73 m^2. Given the fast progress of the disease the parathyroid cancer (PC) was suspected, so "en bloc" removal of the tumor was performed. The diagnosis was confirmed by histological examination. PTH, total serum calcium levels as well as calcitonin were decreased down to the reference level after the surgery. The liver biopsy shows no tumor cells. PET/CT did not observe the abnormal accumulation of 18FDG in the liver and in bones. The patient's condition has significantly improved 4 month after the surgery – she can walk without a wheelchair.
Conclusions
High level of calcitonin caused by hypercalcemia in combination with nodules in the thyroid gland can lead to incorrect diagnosis. It is important to exclude hypercalcemia in case of high levels of calcitonin.

Clinical case of pachydermoperiostosis

Munira Karimova & Zamira Khalimova
Center for the Scientific and Clinical Study of Endocrinology, Department of Neuroendocrinoloy, Republic of Uzbekistan, 100125, Tashkent, Mirzo Ulugbek str. 56.

The aim
To study the case of Pachydermoperiostosisis.
Material and methods
We report a case of a 24-year old male complaining of marked changes in appearance due to the disfiguring thickening and wrinkling of skin, excessive greasiness and perspiration, marked horizontal creases on the forehead, with deep furrows between them, increase in the thickness of eye lids, "senile expression" of the face, thickening of distal parts of extremities, fingers and toes. The patient is unsocial, aloof and focused on his emotions.To evaluate the patient's condition we conducted hormonal and biochemical investigations, as well as total blood and clinical urine analysis; MRI of pituitary and ultrasonography of inner organs were performed.
Results
GH – 2.2 (normal range: 0–20 mIU/l); IGF –114.6 (normal range: 219–644 mg/l); prolactin – 5.3 (normal range: 1–18 ng/ml), TSH – 0.87 (normal range:

0.17–4.05 mIU/l), free T4 – 15.5 (normal range: 11.5–23 pmol/l). The patient was diagnosed with pituitary microadenoma, mastoiditis, ethmoiditis, and sinusitis; US revealed chronic cholecystitis, pancreatitis, and reactive hepatitis. Total blood and clinical urine analysis demonstrated no deviations. The patient presented pachydermia of scalp with moderately painful, rough skin folds in the parietal-occipital region, resembling cerebral gyri, thickening and enlargement of eyelids due to hypertrophy of the cartilage tissue, dystrophic changes of the conjunctiva, atrophy of the tarsal glands with formation of cysts and granulomas in them. The patient is unsocial, aloof and focused on his emotions.
Conclusions
Although the prognosis for patients with pachydermoperiostosis is unfavorable, and there are no specific prevention techniques, they can maintain the ability to work for a long time and live to old age if the appropriate treatment is applied (the latter can be achieved by a thorough medical and genetic counseling of families of patients. Some cases, severe articular syndrome may cause permanent disability.

Vascular dementia in a 57-year old woman with adenoma of parathyroid gland

Mubina Hodzic
Cantonal Hospital, Zenica, Bosnia and Herzegovina.

Dementia describes a set of symptoms such as memory loss, difficulties with thinking, problem solving or language. Vascular dementia is a second most common type of dementia, rare under 65 year old. I report a case of 57- year-old woman with diagnosed dementia vascularis in Neurology department. Beside neurological diagnostic methods(brain scan-CT, MRI, Color Doppler of carotids, she had hypercalcaemia (2.96–3.04 mmol/l; normal range 2.20–2.60) as high calciuresis/24-hour (concentration 6.98 mmol/l). Her parathyroid hormone is elevated (hyperparathyroidism) due to adenoma of right inferior parathyroid gland (PTH is 95 pg/ml). Because of progression on patient's physiological and clinical state, immobility, difficulty to communicate and feeding with nasogastric tube, an operation of adenoma of parathyroid gland was not an option. She ended with stones in her left urether and postsurgery complications.

Keywords: dementia vascular; adenoma of parathyroid gland; hypercalcemia; hyperparathyroidism; parathyroid hormone.

Equivocal preoperative imaging including 18F-fluorocholine PET-CT in primary hyperparathyroidism and nodular thyroid disease – case report

Katerina Zajickova
Institute of Endocrinology, Prague, Czech Republic.

66-year old woman came first for an evaluation of nodular thyroid disease. Primary hyperparathyroidism (PHPT) was incidentally diagnosed during the entrance lab test with total calcium 2.62 mmol/l and PTH 93 ng/l. Serum creatinine was normal and 25 OH vitamin D was 97 nmol/l. Dual-energy X-ray absorptiometry was carried out and revealed osteoporosis at lumbar spine. Moreover, there were two low-trauma fractures in a recent patient history. Although hypercalcemia was mild, the presence of osteoporosis constituted an indication for surgical treatment of PHPT. Neck ultrasound found a hypoechogenic lesion of 0.2 ml behind the cranial third of the left thyroid lobe evocative of a left superior hyperfunctioning parathyroid gland. 99mTc-MIBI double-phase scintigraphy was, however, negative. Due to inconclusive conventional imaging 18F-fluorocholine PET-CT was recommended and localized four abnormal parathyroid foci suggestive of parathyroid hyperplasia and/or multigland parathyroid disease. Basic assessment of hereditary forms of PHPT was, therefore, carried out. Prolactin, IGF1, chromogranin A and calcitonin were normal; calcium/creatinine excretion ratio was 2,2%. No relatives affected with hypercalcemia were found. In a postmenopausal woman with normal renal functions and sufficient vitamin D level a sporadic form of PHPT with a single adenoma would be the most expected. The result of 18F-fluorocholine PET-CT was probably modified by thyroid nodules present in both thyroid lobes. The definitive diagnosis will be made by a surgeon during bilateral cervical exploration. The present case shows how a combination of both false negative and false positive preoperative imaging might influence the extent of preoperative evaluation and the choice of surgical approach in PHPT.

EP327

Parathyroid carcinoma: a report of cases

İlknur Ozturk Unsal, Erman Cakal, Bekir Ucan, Mustafa Calıskan, Esra Tutal, Melia Karakose, Muyesser Sayki Arslan & Mustafa Ozbek
Saglik Bilimleri Universty Diskapi Yildirim Beyazit Traning and Research Hospital, Ankara, Turkey.

Background
Primary hyperparathyroidism (PHPT) is one of the most common endocrine diseases. Parathyroid carcinoma, a rare entity, comprises a small percentage of patients with hyperparathyroidism and represents 0.005% of all cancers and $<1\%$ of cases of PHPT.
Material and methods
Patients was diagnosed at the Endocrinology Department of Diskapi Yildirim Beyazit Training and Research Hospital between 2010 and 2016. Ultrasound and 99mTc-Sestamibi confirmed the suspicion of a parathyroid mass. Parathyroid gland volumes were calculated by multiplication of three diameters and the constant value 0.52. Intraoperative findings and pathology confirmed the diagnosis of parathyroid carcinoma.
Results
Of the patients eight were female and three were male. The patient's ages were between 27–76 years. Parathyroid gland volume of two patients were lower than other cases (respectively 8.92–10.17 ml). Despite small lesion size on ultrasonography, these two patients have moderate-high PTH values. The demographic characteristics and biochemical parameters of the patients.
Conclusion
Pre-operatively, parathyroid carcinoma can be expected based on factors including a larger tumor size, palpable mass, severe primary hyperparathyroidism (PTH 3–15 times the normal upper limit) and hypercalcemia (>14 mg/dl) often with renal and bone involvement by the onset of presentation. Biochemical or ultrasonographic features (lesion size, very high serum calcium and parathyroid hormone levels) may predict aggressive disease, but this is not always the case.

EP328

A rare case of giant parathyroid adenoma: diagnostic and therapeutic aspects

Cristina Alina Silaghi[1], Horatiu Silaghi[2], Gheorghe Cobzac[3], Svetlana Encică[4], Romina Alina Rădi[5], Daniel Tudor Cosma[6], Anca Ciurea[7] & Carmen Emanuela Georgescu[1]
[1]Department of Endocrinology "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania; [2]5th Departament of Surgery, "Iuliu Hatieganu" University of Medicine and Pharmacy Cluj-Napoca, Cluj Napoca, Romania; [3]Clinic of Nuclear Medicine, County Emergency Hospital, Cluj-Napoca, Cluj Napoca, Romania; [4]Department of Pathology, "Niculae Stăncioiu" Heart Institute, Cluj Napoca, Romania; [5]Clinic of Endocrinology, County Emergency Hospital, Cluj-Napoca, Cluj Napoca, Romania; [6]Diabet, Nutrition and Metabolic Diseases Clinical Center Cluj-Napoca, Cluj Napoca, Romania; [7]Department of Radiology "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Cluj Napoca, Romania.

Parathyroid adenomas (85% of cases of primary hyperparathyroidism) are usually small in size (weigh 70 mg – 1 g). Giant parathyroid adenomas (GPTA) weighing more than 3.5 g are very rare, more common in males, in the 6th decade of life, generally affect one parathyroid gland, are oxyphilic and ectopic in 50% of cases. We report the case of a 53-year-old woman presented for asthenia, fatigue, tingling in the arms and legs without other symptoms of hypercalcaemia. Laboratory analysis showed: ionized calcium 6.5 mg/dl (normal: 4.2–5.4 mg/dl), total calcium 13.9 mg/dl (normal: 8.8 to 10.0 mg/dl), hypophosphoremia 2.0 mg/dl (normal: 2.3 to 4.7 mg/dl) and 809 pg/mL intact-parathyroid hormone (normal: 11.0 to 67.0 pg/ml). Calcitonin, thyroxin and thyroid-stimulating hormone levels were normal. Cervical ultrasonography revealed a solid hypoechoic nodule located postero-inferior of the right thyroid lobe with retrosternal extension. An ectopic GPTA localised in para-aortic region of superior mediastinum stretching down to the bifurcation of the trachea was

detected using technetium-99m sestamibi scintigraphy and single photon emission computed tomography/computed tomography (SPECT/CT). GPTA measuring 8.5×4×4.5 cm was removed via cervical approach. Histopathology indicated an atypical GPTA with main cells, oncocytic cells, follicular areas, Ki67 < 5% (rarely, in very small areas Ki67 was up to 10%); chromogranin and cytokeratin AE1/3 were positive; carcinoembryonic antigen, thyroid transcription factor1, and thyroglobuline were negative.
The peculiarities of this case: GPTA but poor symptomatology of hypercalcemia and moderately elevated serum calcium levels; ablation of GPTA by cervical incision although mediastinal expansion; mild hungry bone syndrome postoperatively (not correlated with GPTA volume). In conclusion, GPTA is a very rare condition but their size is not an argument in favour of malignancy. Cervical incision should be considered before sternotomy and thoracic/mediastinal approach.

Autosomal dominant hypocalcemia in a Portuguese family: novel mutation in the calcium-sensing receptor gene

Vânia Gomes, Florbela Ferreira, Catarina Silvestre, Raquel Castro & Maria João Bugalho
Santa Maria Hospital, Lisbon, Portugal.

Introduction
Autosomal dominant hypocalcemia (ADH) is a rare condition, caused by activating mutations in the calcium-sensing receptor (*CASR*) gene. Affected individuals have hypocalcemia with inappropriately low parathyroid hormone (PTH) levels.
Case report
A 50-year-old woman, asymptomatic, was referred to our Endocrinology department for investigation of hypocalcemia detected in routine blood analysis (serum corrected calcium was 7.4 mg/dl – normal: 8.6–10.2). There was also hyperphosphatemia (5.4 mg/dl – normal: 2.4–5.1) and abnormally low PTH (9.9 pg/ml – normal: 14–72).
Her past medical history was irrelevant except for depression in the past. She denied taking any prescription. There was no history of neck surgery/radiation or known family history of hypocalcemia. Thyroid function, morning serum cortisol and 24-h urinary cortisol, fasting glucose, 25-hydroxyvitamin D, renal function, serum magnesium, sodium and potassium were normal. Auto-antibodies against thyroid, parathyroid and adrenal gland were negative. Brain computed tomography identified basal ganglia calcifications. A few first-degree relatives (74-year-old mother, sisters aged 44 and 49, and 30-year-old son) were also screened for hypocalcemia. The mother and the younger sister, both asymptomatic, had hypocalcemia and inappropriately low PTH. The mother also presented basal ganglia calcifications. The son and the older sister had normal calcium levels. Genetic analysis identified a novel heterozygous *CASR* variant: c.2269G>A (p.Glu757Lys) in the proband, her mother and younger sister whereas it was not identified in the son and older sister. Affected individuals started calcium replacement aiming to a low-normal calcium level (8–8.5 mg/dl).
Conclusion
The co-segregation of the novel *CASR* variant with the hypocalcemic phenotype in the family favor its pathogenic role. Clinical investigation and diagnosis of this condition can be challenging, but treatment and long-term monitoring are essential to prevent complications, such as neurological.

A case of intrathyroidal parathyroid adenoma presented with severe 25(OH)D3 deficiency, bone pain and high PTH

Omercan Topaloglu[1], Bahri Evren[1], Ibrahim Sahin[1] & Bulent Unal[2]
[1]Inonu University Medical Faculty, Department of Endocrinology, Malatya, Turkey; [2]Inonu University Medical Faculty, Department of General Surgery, Malatya, Turkey.

The most frequent pathology of primary hyperparathyroidism presented with the findings of hypercalcemia is parathyroid adenoma. Some patients having the signs of primary hyperparathyroidism may have intrathyroidal parathyroid adenoma and it may be overlooked. We present a case of intrathyroidal parathyroid adenoma presented with bone pain.
47-year-old female patient referred to our clinics with bone pain and she had no pruritus, dry mouth, dyspepsia, abdominal pain, nausea, vomiting, polyuria or polydipsia. She did not have any history of hypertension, nephrolithiasis, renal failure or bone fracture; and she was taking risedronate for one week for osteoporosis. On physical examination, vital signs and systemic findings were normal. Blood count revealed mild anemia (hemoglobin:10 gr/dl, MCV:80 fL); and in biochemical analysis, creatinine was 0.65 mg/dl, Ca:12 mg/dl, P:2.2 mg/dl, Mg:2.07 mg/dl, albumin:3.1 gr/dl, ALP:738 U/l. Hormonal parameters showed biochemical primary hyperparathyroidism (PTH:1938 pg/ml, 25(OH)D3: <3 ng/ml). BMD showed severe osteoporosis in lumbar vertebra (T score −4.0). There were osteopenia in bone X-rays and "Brown tumor" in fifth metacarpal bone of right hand. No nephrolithiasis or nephrocalcinosis were found in abdominal sonography. Neck sonography revealed a large (37×24 mm), vascular, heterogenous nodule having both cystic and solid areas in right lobe of the thyroid gland. 99mTc-sestamibi scintigraphy showed MIBI uptake in the nodule, making us to define the nodule as intrathyroidal parathyroid adenoma. Then, the patient underwent to surgery, and right hemithyroidectomy was done; and postoperative pathological examination confirmed the parathyroid adenoma. Postoperative calcium and PTH levels were 7.3 mg/dl and 24.3 pg/ml.
When clinical and biochemical findings point to primary hyperparathyroidism, we should keep in mind that intrathyroidal nodules may be parathyroid adenoma.

EP331

The rare cause of primary hyperparathyroidism: Parathyroid Carcinoma

Nagihan Bestepe[1], Didem Ozdemir[2], Sefika Burcak Polat[2], Berna Evranos[1], Reyhan Ersoy[2] & Bekir Cakir[2]
[1]Ankara Ataturk Training and Research Hospital, Department of Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara Yildirim Beyazit University Medicine Faculty Department of Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Parathyroid carcinoma (PC) is a rare endocrine malignancy which accounts for 0.005% of all cancers and less than 1% of primary hyperparathyroidism cases. This uncommon tumor usually occurs during the fifth decade of life, with equal frequency in both sexes, and has an indolent but progressive course. It's frequently symptomatic and patients may have high values of serum calcium and parathyroid hormone (PTH) with a palpable cervical mass. PC generally occurs as a sporadic disease, and less frequently in the setting of genetic syndromes such as hyperparathyroidism-jaw tumor syndrome and multiple endocrine neoplasia. In this study we present five different PC cases followed in our clinic.
Cases
There were 2 female and 3 male patients with PC. The mean age of the patients was 50.4±13.7(38–65). They had presented with weakness, headache, nausea and vomiting, and widespread bone pain. One of the patients had bone fracture and one other patient had nephrocalcinosis.The mean serum calcium, phosphorus and PTH levels were 15.3±2.7 mg/dl (ranging between 11.6 and 18.9 mg/dl), 2.4±0.8 mg/dl and 869.4±991.9 pg/ml (ranging between 87 pg/ml and 2500 pg/ml), respectively. Histopathologically, mean tumor size was 29.2±11.1 (15–44) mm. Plasma calcium, phosphorus and PTH levels were in the normal range and 36 months after surgery in 2 patients. Local recurrence was observed in 2 patients and reoperation was performed. One other patient withlung and bone metastasis had still high serum Ca and PTH levels despite recurrent surgeries for six times.
Conclusion
PC is usually that of a slowgrowing neoplasm and indicates progressive end-organ damage from disturbed calcium homeostasis. While some patients present with mild increases in serum calcium and PTH levels, some might have very severe hypercalcemia and hyperparathyroidism. Similarly, prognosis varies from cure to life threatening unresectable and metastatic disease depending on the presentation and surgical success.

DOI: 10.1530/endoabs.49.EP331

EP332

A parathyroid adenoma presented with diffuse bone lesions and anemia

Irem Kok, Fatma Dogan, Soner Cander, Ozen Oz Gul, Erdinc Erturk & Canan Ersoy
Uludag University Medical School, Bursa, Turkey.

Primary Hyperparathyroidism is a common endocrine disorder characterized with high parathyroid hormone (PTH) and calcium (Ca) levels. Although most of the patients are asymptomatic, some patients may be presented with renal, gastrointestinal, musculoskeletal, neurologic or cardiovascular signs associated with hypercalcemia or elevated parathyroid hormone related findings such as bone disease, nephrolithiasis, hypophosphatemia increased production of calcitriol, hypomagnesemia, hyperuricemia and anemia. Brown tumor is one of the manifestations of Primary Hyperparathyroidism and is more commonly found in trabecular bone pattern of the mandible, bones of the upper and lower extremities and ribs.

Case

A 54 year-old female with a history of recurrent nephrolithiasis was referred with fragile bones fractures. Biochemical assay revealed an increased value of serum PTH 1570 pg/ml and calcium 13.5 mg/dl. The serum phosphorus level was 3.4 mg/dl, ALP:14 IU/l, 25OH vitamin D: <8 µg/l.

Direct radiographies revealed multipl lesions of the upper and lower extremities, iliac bones, femoral heads, sacrum, sternum, ribs and vertebrae. A complete blood count (CBC) of the patient revealed a low hemoglobin and hematocrit levels (Hg:6.93 g/dl, Htc:20.00%). There was no evidence of neutropenia or leucopenia. After consulting to Hematology department, it was reported that anemia was associated with diffuse bone lesions and it was not possible to make bone marrow biopsy due to diffuse bone lesions. Follow up of anemia for recovery after parathyroidectomy was also suggested. Ultrasound of neck revealed mass of 3 cm associated with parathyroid adenoma. After erythrocytes transfusions, the patient was planned for surgery.

Multipl bone lesions are common in Primary Hyperparathyroidism and Brown tumor may also be a part of this clinical condition. These lesions are usually localized and have a tendency for recovery of the primary disease. It should be in mind that diffuse bone marrow lesions may be seen resulting progenitor cells failure in bone marrow and cytopenia.

DOI: 10.1530/endoabs.49.EP332

EP333

Common bone lesions may be a sign of parathyroid carcinoma in the primary hyperparathyroidism

Soner Cander[1], Ozen Oz Gul[1], Pinar Sisman[2] & Canan Ersoy[1]
[1]Uludag University Medical School, Bursa, Turkey; [2]Kars State Hospital, Kars, Turkey.

A 60-year-old male patient who presented with left hip and knee pain was found to be compatible with primary hyperparathyroidism (PTH:2233 pg/ml, calcium: 15.7 mg/dl, phosphorus: 2.9 mg/dl creatinin:1.99 mg/dl, 25-OH-D:9.7 µg/l, ALP:532 mU/ml). Bone grafts of the patient showed multiple lytic lesions in the pelvis, cranium and long-bones. Neck ultrasonography showed hypoechoic solid nodule with cystic areas, 2×2 cm with size in the left thyroid gland inferior region and delayed wash-out was detected by the parathyroid scintigraphy. Bone scintigraphy was suspicious in terms of metastasis. Left hemi thyroidectomy and left inferior parathyroidectomy was performed. In thorax lytic lesions compatible with multiple metastases in bone structures were observed. Thoracal and lumbar vertebral MR imaging also showed lesions compatible with metastasis. Histopathological examination revealed parathyroid carcinoma with invasion to the thyroid gland.

Primer hyperthyroidism has been increasing in recent years as a laboratory diagnosis the contribution of asymptomatic cases has increased. Frequent routine examinations have also led to the early recognition of the disease, and osteitis fibrosa cystica and bone lesions such as brown tumor, which are among the complications of primary hyperparathyroidism, are increasingly rare. Primer Hyperparathyroidism is often associated with solitary parathyroid adenoma, hyperplasia or multiple adenomas, mostly seen with the genetic syndromes. Parathyroid carcinoma is very rare and is recognized only by the presence of metastases or histopathologically significant invasion findings, such as those present in our case. Clinically, incompatibility in tumor size and serum PTH levels, extremely high PTH levels may be a sign of parathyroid carcinoma. Apart from this, common bony lesions which are rarely seen in primary hyperparathyroidia due to early diagnosis and noisy clinical picture can be considered as malignancy findings as it is in our patient. Therefore, in patients with widespread pain and common bony lesions, the patient should be carefully examined for parathyroid carcinoma and an appropriate approach should be sought.

EP334

Broken bones and blindness- a rare cause of osteoporosis

Rebecca Sagar & Afroze Abbas
Leeds Centre for Diabetes and Endocrinology, Leeds Teaching Hospitals, Leeds, UK.

Case History

A 37 year-old gentlemen was referred to metabolic bone clinic due to recurrent recent fragility fractures. He had several fractures throughout childhood, and these had continued to occur into his adult life. He was blind in his left eye since birth. He felt that this had contributed to his fractures, due to falls. There had been no other previous major health problems. His brother had a similar eye condition. There were no other risk factors for osteoporosis. There was nothing of significance to find on examination.

Investigations & Results

DXA scan- Spine L1-L4 T-score -3.6, Left hip T-score -2.4. CTX 0.24 mcg/L (normal), P1NP 34 mcg/L (normal). Spine X-rays: T11 grade 1 fracture & T4 grade 2 fracture. No other secondary cause of low bone mass identified (normal levels of testosterone, parathyroid hormone, vitamin D, calcium, phosphate and coeliac antibodies)

Discussion

This is a case of a young man with seemingly unexplained fragility fractures and low bone mass. The clue to the aetiology for low bone mass was the gentleman's hereditary eye condition. The eye problems are caused by a condition known as Familial Exudative Vitreoretinopathy (FEVR); a rare genetic disorder affecting retinal angiogenesis that can cause progressive visual loss. FEVR may be mediated by mutation in *LRP5* coding for the LRP5 transmembrane receptor. LRP5 plays a key role, alongside Frizzled protein, in the Wnt signalling pathway, which has effects on cellular proliferation, adhesion and migration. Importantly, Wnt signalling is also known to regulate bone mass. Therefore, it is the defect in this pathway that is the common denominator for this gentleman's blindness and bone problems. We speculate that upcoming new drugs that target Wnt signalling in osteoporosis, such as Romosuzumab (a Sclerostin inhibitor), may be particularly beneficial in patients with low bone mass associated with FEVR.

An usual cause of post operative hypocalcemia

Fatma Mnif, Wajdi Safi, Nabila Rekik, Houcem Mrabet, Hamza Elfekih, Nadia Charfi, Mouna Mnif & Mohammed Abid
Department of Endocrinology, Hedi Chaker University hospital, Sfax, Tunisia.

Introduction

The otorhinolaryngologist can be confronted to multiple surprises after a thyroid surgery

Case description

We report the case of a 48 year-old woman admitted with post operative hypocalcaemia (after thyroidectomy?). The patient has a history of hypothyroidism since 5 years. She then presented a cervical swelling. The ultra-sound confirmed the presence of a suspicious thyroid nodule measuring 4 cm. A thyroidectomy was then conducted. Post operative, the patient presented with symptoms of hypocalcaemia, confirmed by low level of blood calcium at 1.59 mmol/. The anatomopathological examination showed no sign of thyroid tissue, along with the presence of five adenomatous parathyroid nodules. Post operative scintigraphy showed a conserved thyroid tissue, with absence of parathyroid glands. Hungry Bone Syndrome was confirmed led to the prolonged and severe hypocalcaemia, associated to the adenomatous aspect of the parathyroid measuring more than 6 cm. Because of the family history of pituitary prolactinoma, primary hyperparathyroidism and multinodular goitre and the personal history of uterine fibroma and hypothyroidism, Multiple Endocrine Neoplasia 1 (MEN1) was suspected. Genetic confirmation is underway.

Conclusion

This is the case of an asymptomatic hyperparathyroidism discovered by a severe post-thyroidectomy hypocalcaemia. This hyperparathyroidism is due to multiple parathyroid adenomas misdiagnosed as thyroid nodules, and probably falls within a multiple endocrine neoplasia type 1.

Brown tumor in a normocalcemic patient

Pinar Sisman[1], Ozen Oz Gul[2], Soner Cander[2], Erdinc Erturk[2] & Canan Ersoy[2]
[1]Harakani State Hospital, Endocrinology and Metabolism Clinic, Kars, Turkey; [2]Uludag University Medical School, Department of Endocrinology and Metabolism, Bursa, Turkey.

Background
Brown tumor of bone is a non-neoplastic lesion resulting from abnormal bone metabolism in hyperparathyroidism. Brown tumor, as the only and initial symptom of normocalcemic primary hyperparathyroidism is extremely rare.
Case presentation
A 69-year-old female patient was admitted to the hospital with a mass in the right thigh. A mass lesion of the right distal femur with bone and soft tissue infiltration was observed in the lower extremity magnetic resonance imaging (MRI). The size of the mass was measured as approximately $10\times3.7\times4.6$ cm. Apart from this lesion, nodular lesions were detected in various dimensions on the right femur, left femur and left patella. Brown tumor was detected in pathologic evaluation of the mass of the right distal femur. The patient was examined for hyperparathyroidism. Serum parathormone (PTH) level was 2698 pg/mL (reference range 15–68), calcium level was 8.8 mg/dL (8.4–10.2), phosphorus level was 2 mg/dL (2.4–4.4) and 25-OH D level was 10 μg/L. Vitamine D treatment was given to the patient. 24-hour urine calcium could not be assessed because of the patient's low compliance. The total lomber T score was −4.7 and the femur neck T score was −5.5 in the bone mineral density. Localization studies were performed and neck ultrasonography and parathyroid scintigraphy revealed a parathyroid adenoma in the inferior right lobe. Patient underwent parathyroidectomy surgery and in histopathological evaluation solitary parathyroid adenoma was observed. The follow-up of the patient whose postoperative PTH decreased to 161 pg/mL is being continued.
Discussion
Cytologically, it is difficult to separate the brown tumor from any other giant cell lesions. To prevent unnecessary surgical procedures, PTH assay is necessary in any patient with expansive lytic lesion of the bone, even if serum calcium level is normal.

Symptomatic bisphosphonate-induced hypocalcaemia after severe idiopathic hypercalcaemia

Joana Lima Ferreira, Teresa Tavares, Rui Moço & Pedro Melo
Hospital Pedro Hispano, ULS Matosinhos, Portugal.

Introduction
Bisphosphonates, generally considered as safe drugs, are potent inhibitors of bone calcium outflow used to treat osteoporosis and hypercalcemia associated with malignancy. Bisphosphonate-induced hypocalcaemia is an increasingly reported complication, but it has not yet been a subject of comprehensive research.
Case report
A 65-year-old woman had a history of Crohn's disease and ankylosing spondylitis medicated with prednisolone and etanercept. Due to vitamin D deficiency she had been taking calcium and vitamin D supplementation. At a consultation she presented with difficulty in concentration and balance, and blurred vision. Analysis revealed severe hypercalcemia (ionized Ca^{2+}2.18 mmol/l), elevated serum creatinine and normal parathyroid hormone (PTH). She was treated with intravenous fluids and a single intravenous dose of zoledronate, resulting in calcium normalization and clinical remission. Five days later she returned for delirium, tetany, perioral paraesthesia and carpopedal spasm. Chvostek's sign was positive. Hypocalcaemia (ionized Ca^{2+}0.97 mmol/l), vitamin D deficiency, elevated PTH, hypomagnesaemia, hypophosphataemia and hypokalaemia were detected. She required intravenous calcium and long-term oral calcium and vitamin D supplementation with gradual but sustained improvement. Densitometry revealed femur and lumbar spine osteoporosis. Study was negative for neoplasms and despite extensive study, aetiology of hypercalcemia remains unclear.
Discussion
This case illustrates a serious but still poorly recognized complication of hypercalcaemia treatment. Most patients do not develop hypocalcaemia due to compensatory mechanisms that could be affected in this case: vitamin D deficiency, diminished intestinal calcium absorption (corticoids and zoledronate) and lower tubular calcium reabsorption, and decreased excretion of zoledronate due to acute renal failure. Considering the high prevalence of vitamin D deficiency and the sudden nature of hypocalcaemia, these and other risk factors should be considered when using bisphosphonates in order to prevent this potentially fatal complication. Further studies may clarify the overall risk and approach to this situation.

Transient hyperglycemia during the course of primary hypoparathyroidism: Case study

Magdalena Urbanczuk[1,2], Marcin Lewicki[2,3], Agnieszka Zwolak[2,4], Marcin Urbanczuk[5], Joanna Swirska[2,4], Monika Lenart-Lipinska[2,6] & Jerzy S Tarach[2]
[1]Chair and Department of Clinical Pathomorphology of Medical University of Lublin, Lublin, Poland; [2]Department and Clinic of Endocrinology of Medical University of Lublin, Lublin, Poland; [3]Chair and Department of Epidemiology and Clinical Research Methodology of Medical University of Lublin, Lublin, Poland; [4]Department of Internal Medicine and Internal Medicine in Nursing, Medical University of Lublin, Lublin, Poland; [5]Chair and Department of Family Medicine of Medical University of Lublin, Lublin, Poland; [6]Department of Laboratory Diagnostics of Medical University of Lublin, Lublin, Poland.

Introduction
Calcium ions (Ca^{2+}) play an essential role in process of correct β-cell insulin secretion. Hypocalcemia impairs insulin secretion leading to glucose metabolism disorders and insulin resistance.
Case study
62 -year old female patient with 18 years history of type 2 diabetes, treated with insulin, suspected of hypoparathyroidism, was admitted to the Department and Clinic of Endocrinology, Medical University of Lublin because of hypocalcaemia. She was experiencing latent tetany signs like muscle tremors, paresthesia and an unpleasant tingling sensation in her hands, additionally persistent dry cough. Clinical observation and laboratory findings with classic constellation of symptoms (hypocalcemia, hyperphosphatemia, undetectable concentrations of parathyroid hormone (PTH), latent tetany signs, history of nephrolithiasis and of subcortical nuclei calcifications) have confirmed the diagnosis of late onset primary hypoparathyroidism. Significant clinical improvement following introduction of calcium and active form of vitamin D supplementation were achieved. Based on normal blood glucose levels with relatively low daily insulin requirement an attempt at discontinuing insulin therapy was made. In spite of hypoglycemic therapy cessation, patient's glucose levels remained in the normal range. For the purpose of diagnosis verification oral glucose tolerance test (OGTT) was performed, and did not reveal any glucose metabolism disorders. These observations led us to conclude that recognized hyperglycemia was secondary to prolonged hypocalcemia.
Conclusions
The optimal concentrations of organism's cytosolic Ca^{2+} are required for appropriate β-cell insulin release. Hypocalcemia is regarded as a factor implicated in pathogenesis of glucose metabolism disorders thus normalizing serum calcium levels allows for restoration of adequate insulin secretion.

Hyperparathyroidism jaw tumour syndrome (HPT-JT)

KS Ahmed, M Sherlock, L Stassen, C Timon & ML Healy
[1]Department of Endocrinology, St. James Hospital; [2]Department of Endocrinology, Adelaide and Meath Hospital; [3]Department of Maxillofacial Surgery, St. James Hospital; [4]St. James Hospital. Department, Dublin, Ireland.

Hyperparathyroidism jaw tumour syndrome (HPT-JT) is an autosomal dominant disease with variable penetrance. Onset is typically in late adolescence or early adulthood. Primary hyperparathyroidism is typically caused by a single

parathyroid adenoma but parathyroid carcinoma occurs in 10–15%. Ossifying fibroma of the mandible or maxilla occurs in 30–40%, and may be locally aggressive. 15% of patients have renal manifestations which include polycystic kidney disease, Wilms tumour and renal cell carcinoma. In women there is an increased risk of uterine tumours. The gene causing HPT-JT, HRPT2, is located on chromosome 1q31.2a, coding for parafibromin (tumour suppressor gene) found in 50–75%.

We recently identified a patient with HPT-JT which led to detection of a kindred with the CDC73 pathogenic variant. A 54-year-old male presented to the maxillofacial services for surgical removal of a jaw tumour. Histology confirmed an ossifying fibroma of the maxilla. During his admission he was noted to have hypercalcaemia (Ca^{++}3.2 mmol/l, PTH 110 pmol/l).

On review of previous history, he described poor dentition since the age of 20, and he reported that his sister had died at the age of 35 from metastatic parathyroid carcinoma. Diagnosis of primary hyperparathyroidism was established and he underwent parathyroid surgery with normalisation of Ca^{++} and PTH. Histology was consistent with parathyroid adenoma.

His genetic analysis detected a mutation in the CDC73 gene (Exon 7 c.664 C to T leading to protein PArg222Ter). Family members were screened, which confirmed CDC73 mutation in one daughter and one son, and 1 son was mutation negative.

Fahr syndrome revealing a pseudohypoparathyroidism

Imen Sakka, Ibtissem Oueslati, Meriem Yazidi, Malika Chihaoui, Fatma Chaker, Ons Rjeb & Hedia Slimane
Department of Endocrinology, La Rabta Hospital, Tunis, Tunisia.

Introduction

Fahr syndrome is a rare entity characterized by the presence of bilateral intracranial calcifications with predilection for the basal ganglia and dentate nuclei. It is commonly associated with endocrine disorders, particularly parathyroid and Vitamin D disturbances. Herein we report a case of pseudohypoparathyroidism revealed by Fahr syndrome.

Observation

A 29-old-year male was referred to our department for symptomatic hypocalcemia. He showed a decrease in his school performances with memory and concentration impairement. Computed tomography scan of the brain revealed bilateral, symmetric basal ganglia calcifications. Ophthalmic examination showed bilateral cortical cataract.

Physical examination showed positive Chvostek and Trousseau's signs. The rest of clinical examination was normal in particular no typical findings of Albright's hereditary osteodystrophy were observed.

Laboratory investigations revealed severe hypocalcemia of 44 mg/l (normal range: 85-105), hyperphosphatemia of 48 mg/l (normal range: 25-45), elevated parathormone level of 218 pg/ml (normal range: 15–68.3), normal renal function, normal serum albumin and normal 25 OH Vitamin D level (46 µg/l, normal range: 30–80 µg/l). Thyroid function was normal. Urinary cyclic adenosine monophosphate level and Gsα subunit assay were not available Considering laboratory findings, the diagnosis of pseudohypoparathyroidism was established. Patient was put on substitutive therapy.

Conclusion

In the absence of chronic renal failure, the coexisting of hypocalcemia, hyperphosphatemia, elevated PTH and normal vitamin D level is consisting with the diagnosis of pseudohypoparathyroidism.

Parathyroid cyst: the forgotten diagnosis of a neck mass

Esperanza Miranda, Mariana Tomé, Carmen Bautista & Daniel Gonzalez
Punta De Europa Hospital, Algeciras, Spain.

Introduction

The differential diagnosis of cystic cervical masses includes thyroid cyst, thymic cyst, thyroglossal duct cyst, branchial cleft cyst, bronchogenic cyst, lymphangioma and parathyroid cyst (PC). PC is one of the less common causes of the cervical masses.

Methods

We report the case of a 37-year-old man admitted to the hospital with a neck mass of 48 mm.

Results

Our patient presented with neck pain and an hipoechogenic nodule on ultrasound (US) on the left side of the neck adjacent to the lower pole of the left thyroid lobe. An US-guided fine-needle aspiration was performed and follicular cells where described. Measurement of TSH, T4L and AbTPO had a normal result. Given the suspicion of thyroid nodule >4 cm surgical treatment was decided. While waiting for surgery an US was performed and we observed markedly reduction on the size of the nodule (28 mm) and the radiologist suggested the possibility of a parathyroid adenoma. Our patient referred prior episodes of nephrolitisis a few years ago and that he had been told to had high serum calcium levels but did not undergo further studies. We measured PTHi levels and Calcium (100,5 pg/ml; 10 mg/dl) showing a normocalcemic hyperparathyroidism. Left thyroid lobectomy was performed showing a normal left thyroid lobe, a parathyroid cyst and ectopic thymus.

After nodule resection PTHi levels went back to normal and calcium levels remain less than 10 mg/dl.

Conclusion

PCs are rare lesions and often considered as thyroid cysts. Diagnosis is best made by monitoring serum calcium levels and sending cyst fluid for PTH analysis. Therefore, PCs must be included and be remembered within the differential diagnosis of all neck masses.

"Pseudo or not": differential diagnosis of hyperparathyroidism with severe electrolyte imbalance in transgender patient: a challenging case report

Ieva Ruza[1,2] & Linda Kundzina[2]
[1]Riga Eastern Clinical University Hospital, Riga, Latvia; [2]Riga Stradins University, Riga, Latvia.

Introduction

Differential diagnosis between secondary hyperparathyroidism (SHPTH) and possible pseudohypoparathyroidism can be challenging in case of insufficient diagnostic tools and co-existing medical conditions. We report a diagnostic road to final diagnosis.

Case report

A 48-years old white male-to-female transgender patient was admitted to our clinic for evaluation due to mental deterioration, general fatigue, slowly progressing bilateral upper arm and epigastric area cramps over last 2 years, pain in the lumbal area and right hip region leading to reduced mobility. No remarkable history, except crural DVT during estrogen therapy, received from 2004–2015 without any specialist's supervision, not any therapy used in last year. Possible previous delusion episodes since head trauma during teenage years were reported by patient's brother. The patient was severely obese.

Biochemical tests revealed low calcium (1.74 mM/l [2.2–2.55]) and potassium (3.12 mM/l [3.3–5.5]), normal phosphate, creatinine and glucose level. Preliminary suspected Cushing's and Fahr's syndromes were excluded after seeing suppressed cortisol axis and elevated PTH (624.2 pg/ml [12–68]). No substantial changes in other tests. No electrolyte loss with 24 h urine was seen. Thyroid and gonadic axis were unchanged. Head CT scan revealead no basal ganglia calcinosis. No data of paratadenoma. In spite of high normal phosphate level and not characteristic phenotype, our first suspected diagnosis was pseudohypoparathyroidism. Additional tests showed low 25(OH)-vitamin-D ($<$ 7 ng/ml [30–50]) and elevated alkaline phosphatase (320 U/l [44–147]). Pelvic MRI showed left femoral periosteal cyst formation and right hip joint synovitis. Though we were restricted in many diagnostic tools due to multiple factors, no further data strongly supported evidence of pseudohypoparathyroidism.

Based on these findings we suggest the final diagnosis of secondary hyperparathyroidism with severe osteomalacia. Treatment was continued with calcitriol, cholecalciferol, oral calcium. Some improvement of symptoms was seen over the hospitalization course.

Conclusion

We would like to stress the importance of multi-focused investigation for bone-metabolic problems.

Adolescent onset distal renal tubular acidosis presenting with significant growth retardation without rickets

Sagarjyoti Roy, Sandipan Banik, Indira Maisnam, Aniruddha Ray & Apurba Kumar Mukherjee
R G KAR Medical College and Hospital, West Bengal, India.

Introduction
Distal renal tubular acidosis (RTA) can have varied presentation. Onset in infancy is usually severe. However, adolescent onset has variable presentation ranging from hypokalemia to nephrocalcinosis, and rarely with rickets or growth retardation. We describe a girl with distal RTA presenting with hypokalemia and growth retardation.
Case
12 year old girl presented with recurrent episodes of weakness of all four limbs and failure to gain height and weight for last 4 years. There was no sensory or autonomic involvement. She had normal birth history and developmental milestones, no dysmorphism or bony abnormality, no sensorineural deafness and a negative family history. Nutritional status was average. Height and weight were below Indian Academy Of Paediatrics 3rd percentile.
Investigations
$K^+ = 2.9$ mmol/l; Urine K = 30 mmol/24 hr (increased). pH = 7.324, $HCO3^- = 12.4$ meq/l, $pCO_2 = 23.9$ mm-Hg; anion gap = 10 mmol/l Urine pH = 7.0. UAG: Positive (28 meq/l), urine calcium:creatinine ratio = 0.63(N < 0.2) ANA & ENA: negative. Genetic testing not done due to non-availability CBC, LFT, serum 25-OH Vitamin D & iPTH, Ca^{++}, PO_4^{3-}, alkaline phosphatase, FT4/TSH, IGF-1 were all normal. X-ray of wrist: no evidence of rickets. USG Abdomen = Medullary Nephrocalcinosis in both kidneys.
Diagnosis
Growth retardation with hypokalemic periodic paralysis in a case of distal RTA of adolescent onset based on normal anion gap acidosis with high urinary pH with positive urine anion gap.
Treatment
She was managed successfully with intravenous potassium and is on oral sodium bicarbonate 500 mg twice daily. Her clinical response is good.
Conclusion
The take home points are that every child presenting with hypokalemia should be evaluated for RTA. The presentation of distal RTA can be subtle to severe. Even in the absence of bony involvement like rickets children can suffer from significant growth retardation. Growth failure should be actively searched for even in asymptomatic patients.

Differential roles of carboxylated and uncarboxylated Osteocalcin in stage I breast cancer as a diagnostic biomarker

Anara Karaca[1], Nese Ersoz Gulcelik[1], Filiz Bakar[2], Giray Akgul[3], Zeynep Sahiner[1] & Mehmet Ali Gulcelik[3]
[1]Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey; [2]Ankara University, School of Pharmacy, Biochemistry, Ankara, Turkey; [3]Ankara Oncology Teaching and Research Hospital, General Surgery, Ankara, Turkey.

Objective
The finding of new biomarkers is needed to have an early diagnosis of breast cancer. In this study we evaluated serum levels of carboxylated osteocalcin (OC) and uncarboxylated osteocalcin(UcOC), CRP as a diagnostic biomarker for breast cancer.
Design and methods
Blood samples of 39 women with newly diagnosed breast cancer with stage I were obtained before surgery and 39 age and BMI matched health women were selected as controls.
Results
The mean age was 52 ± 7 years ($P = 0.8$). Circulating logOC was significantly lower in breast cancer patients compared to controls (2 ± 1.1 mg/ml vs. 3 ± 1.23 mg/ml, $P < 0.05$), while logCRP levels were significantly higher in breast cancer patients than controls (0.8 vs. -0.6, $P < 0.05$). Serum levels of logUcOC were not different between groups(6.39 ± 0.4 mmol/l vs. 6.39 ± 0.9 mmol/l, $P =$ NS). OC had a positive correlation with ucOC ($r = 0.3$, $P = 0.03$). In contrast, CRP was not correlated with OC and ucOC ($P = 0.2$, $P = 0.3$, respectively).
Conclusion
We conclude that circulating OC has a potential use as a sensitive diagnostic biomarker for early detection of breast cancer.

Gross CDC73 deletions in young patients with primary hyperparathyroidism in Russia

Elizaveta Mamedova, Natalya Mokrysheva, Evgeny Vasilyev, Iya Voronkova, Elizaveta Orlova, Maria Kareva, Zhanna Belaya, Liudmila Rozhinskaya & Anatoly Tiulpakov
Endocrinology Research Center, Moscow, Russia.

Introduction
Hyperparathyroidism-jaw tumour syndrome (HPT-JT) is a rare disorder, which is frequently characterized by the development of parathyroid carcinomas and atypical parathyroid adenomas and, thus, severe course of primary hyperparathyroidism (PHPT).
Case reports
Two patients (*1 male and 1 female, 18 y.o. and 13 y.o. at the time of diagnosis of PHPT, respectively)* among a cohort of young patients (<40 y.o.) with PHPT, underwent next-generation sequencing (NGS) (Ion Torrent™ PGM™, Thermo Fisher Scientific–Life Technologies, USA) using a custom-designed Ion AmpliSeq™ gene panel. NGS did not reveal any pathogenic variants in genes associated with familial PHPT in these two patients, but the analysis of the sequence data by the ExomeDepth program [Plagnol V et al, 2012] allowed us to assume the existence of large deletions in *CDC73* gene. To confirm this observation MLPA (MRC-Holland, the Netherlands) of *CDC73* on ABI 3500xL Genetic Analyzer (Applied Biosystems, USA) was performed. In a male with severe PHPT (serum total calcium 4.49 mmol/l (2.15–2.55), ionized calcium 2.03 mmol/l (1.03–1.29), PTH 1833 pg/ml (15–65), osteitis fibrosa cystica) and histological diagnosis of atypical parathyroid adenoma, a gross deletion including the entire *CDC73* gene and four additional genes (*TROVE2, GLRX2, B3GALT2* and *LINK0103*) was detected. In a female with severe PHPT (serum total calcium 3.57 mmol/l, ionized calcium 1.58 mmol/l, PTH 1550 pg/ml, osteitis fibrosa cystica) and histological diagnosis of parathyroid carcinoma, the deletion of 1–10 exons of *CDC73* gene was detected. The patients' mother also had PHPT due to parathyroid adenoma.
Conclusion
These two cases illustrate that NGS data could be successfully applied for indirect assessment of large gene deletions which could be further confirmed by MLPA. Search for *CDC73* mutations is necessary among patients with parathyroid carcinomas and atypical parathyroid adenomas, which could occur at any age.

Multiple endocrine neoplasia type 1 phenocopies: role of the genes associated with familial primary hyperparathyroidism

Elizaveta Mamedova, Natalya Mokrysheva, Evgeny Vasilyev, Vasily Petrov, Zhanna Belaya, Liudmila Rozhinskaya & Anatoly Tiulpakov
Endocrinology Research Center, Moscow, Russia.

Introduction
The genetic causes of development of multiple endocrine neoplasia type 1 (MEN-1) phenocopies remain largely unknown.
Aim of the study
To evaluate the role of genes associated with familial primary hyperparathyroidism (PHPT) in the development of MEN-1 phenocopies with the combination of PHPT and pituitary adenomas (PA).
Materials and methods
20 patients (19 females and 1 male) were included in the study. All patients had biochemically confirmed PHPT in combination with PA of different types of

secretion: 15 GH-secreting, 3 ACTH-secreting, 1 PRL-secreting, 1 non-functioning PA. Median age at the time of inclusion was 61 years [Q25-Q75;min-max:57–66.5;54–79], median age at the time of PHPT diagnosis was 57 years [Q25-Q75;min-max:54–62;51–72], median age at the time of PA diagnosis was 47 years [Q25-Q75;min-max:40.5–57.5;21–61]. Five patients had mild PHPT, 15 – manifest PHPT (though it was difficult to assess the role of PHPT in osteoporosis development due to concomitant menopause and Cushing disease in some cases). Imaging techniques revealed: in 15 patients – solitary parathyroid tumour, in 2 patients – two parathyroid tumours, in 3 patients parathyroid tumours were not visualized. In the majority ($n=16$) of patients PA was the first manifestation, only in 4 patients PHPT was diagnosed before PA. In all patients no *MEN1* mutations were identified by Sanger sequencing, confirming diagnosis of MEN-1 phenocopy. Next-generation sequencing of a custom-designed Ion AmpliSeq™ panel of genes associated with familial PHPT (*MEN1, CASR, CDC73, CDKN1A, CDKN1B, CDKN1C, CDKN2A, CDKN2C, CDKN2D*) using semiconductor sequencer PGM™ Ion Torrent (Thermo Fisher Scientific, USA) was performed. ANNOVAR was used for variant annotation.
Results
No pathogenic or likely pathogenic variants in the abovementioned genes were identified.
Conclusion
Mutations in the genes associated with familial PHPT are unlikely to have any role in the development of MEN-1 phenocopies with combination of PHPT and PA.

DOI: 10.1530/endoabs.49.EP346

EP347

Recurrent ectopic parathyroid carcinoma

Julia Krupinova, Natalia Mokrysheva, Anna Eremkina, Ekaterina Pigarova & Svetlana Mirnaya
Endocrinology Research Centre, Moscow, Russia.

Background
In most cases of parathyroid carcinoma (PC) only recurrence could be a credible feature of malignancy.
Clinical case
At the age of 19 years a woman was diagnosed with urolithiasis. At the age of 22 years she had a surgical resection of the neck nodule at the right site in the projection of carotid triangle. After the histological study, ectopic parathyroid tumor was misdiagnosis with paraganglioma (material is available for review). At the age of 37 years the patient noted deteriorating state of health: severe weakness, nausea, vomiting (10 times per day), rapid loss of body weight (10 kg in 6 months). She noted the appearance of nodule in the neck to the right in the projection carotid triangle again. A month later she was diagnosed with a primary hyperparathyroidism: total calcium – 3.0 mmol/l (2.19–2.55), PTH-786 pg/ml (15–65). CT-scan showed two tumors sized up to 3.3*1.7 cm; 3.2*1.3 cm between right m. sternocleidomastoideus and the common carotid artery. The next day the hypercalcemic crisis developed (total calcium – 5.33 mmol/l) and therefore, ectopic parathyroid tumors were urgently resected in our center. PC was diagnosed after a histological examination. At the age of 47 years the local recurrence was diagnosed: total calcium – 3.51 mmol/l, PTH-450 pg/ml. PET/CT showed a focus with the pathological accumulation of 18FDG in singles upper jugular lymph node on the right at the level of C3-4, 16,7*19,7 cm. After another surgery, the tumor went through the immunocytochemical analysis which showed a diffuse intensive expression of PTH, Ki-67- 15%.
Conclusions
The diagnosis of PC is challenging due to the lack of credible diagnostic criteria. The treatment of choice in PC is an *en bloc* resection of the mass with total ipsilateral thyroid loboistmectomy and central compartment lymphadenectomy and timely detection and resection of mts.

Exome analysis of a large family with familial isolated primary hyperparathyroidism (FIHP) and multiple cancers

Filomena Cetani[1], Elena Pardi[2], Simona Borsari[2], Federica Saponaro[2], Liborio Torregrossa[3], Chiara Mazzanti[4], Paolo Aretini[4], Marco La Ferla[4], Sara Franceschi[4], Francesca Lessi[4], Prospero Civita[4] & Claudio Marcocci[4]
[1]University Hospital of Pisa, Endocrinology Unit, Pisa, Italy; [2]Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy; [3]Department of Surgical, Medical and Molecular Pathology and Critical Area, University of Pisa, Pisa, Italy; [4]Fondazione Pisana Per La Scienza Onlus, Pisa, Italy.

Familial Isolated Hyperparathyroidism (FIHP) is a hereditary disorder characterized by primary hyperparathyroidism (PHPT) with no evidence of other endocrine disorders. Germline *MEN1, CDC73* and *CASR* mutations have been identified, but the majority of FIHP has still unrecognized causes. The aim of this study was to identify, by whole-exome sequencing, novel gene alterations in a large FIHP kindred. The family's proband, her sister, brother and niece were affected by PHPT. The proband was negative at MEN1, *CDC73* and *CASR* gene mutations by Sanger analysis. The proband, her sister and niece were also affected by papillary thyroid carcinoma, the brother had Non-Hodgkin Lymphoma and bladder cancer. The proband had also a moderate colorectal polyposis and the niece a renal angiomyolipoma. We analyzed the proband, two affected and two healthy family's members with the Illumina NextSeq550 platform. The raw data were converted using Bcl2toFastq tools. Data analysis was performed by the SeqMule pipeline. The three affected individuals, but not the healthy relatives, shared 57 rare genetic variants. A more stringent filter related to genes involved in hereditary cancer detected one missense variant in the *APC* gene (V530A) in the three affected patients, subsequently confirmed by Sanger analysis. Moreover, the other affected relative and 2/15 healthy members carried the variant. The *APC* gene is involved in familial polyposis (FAP), an inherited disease marked by thousands colorectal polyps. The *APC* variant was predicted deleterious by three statistic model. Although the affected individuals don't have classical FAP features, the proband had the excision of two colonic polyps. We might speculate that the presence of non-truncating mutation could lead to a mild colonic phenotype, as showed in the attenuated FAP, characterized by the presence of <100 polyps. FAP tumor spectra is highly various, in about 2% of cases papillary thyroid carcinoma and bladder cancer have been reported.

Parathyroid cancer – clinical presentation, prognostic factors and long-term evolution

Beata Jurecka-Lubieniecka[1], Barbara Michalik[1], Grzegorz Bula[2], Jacek Gawrychowski[2], Dariusz Kajdaniuk[3], Bogdan Marek[3], Andrzej Tukiendorf[4] & Barbara Jarzab[1]
[1]Department of Nuclear Medicine and Endocrine Oncology, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland; [2]Department of General and Endocrinal Surgery, Bytom, Silesian Medical University, Katowice, Poland; [3]Department of Pathophysiology and Endocrinology, Silesian Medical University, Katowice, Poland; [4]Department of Epidemiology and Silesia Cancer Registry, Maria Sklodowska-Curie Memorial Cancer Center and Institute of Oncology, Gliwice, Poland.

Background
Parathyroid carcinoma (PC) is a rare endocrine malignancy affecting 0.5–5% of all patients with primary hyperparathyroidism. Due to the rarity of PC there is still lack of prognostic implications of the disease and clear consensus regarding management. Our purpose was to evaluate prognostic factors and treatment outcomes of patients treated at the Department of Nuclear Medicine and Endocrine Oncology.
Methods
The target group covered 44 patients with parathyroid carcinoma treated in years 1995-2016 at the department of Nuclear Medicine and Endocrine Oncology.
Results
All the patients were treated surgically, 17 of them repeatedly, however, only in 19 patients the en bloc resection was performed, 25 patients underwent only parathyroidectomy. During an average 10-year-observation among all the patients operated non-radically the recurrence of the disease appeared. Deaths occurred only in this group, despite radio- and chemotherapy. An interesting clinical observation are benefits resulting from cinacalcet treatment: taking the medicine for 2–4 years resulted in stabilization and ever remission of the disease in four patients with metastasis. To predict outcome histopathology results, biochemical and clinical features were analyzed. Due to a limited number of patients, a parametric Weibull's regression was adopted. Among the analyzed risk factors

distant metastasis and organ complications, mainly renal failure were statistically crucial in patients survival. Occurrence of distant metastasis increases the risk of early death seven times (HR $=6.82$, $P=0.02$) whereas in renal failure the risk increases nine times (HR $=8.92$, $P=0.008$).
Conclusions
In patients with parathyroid carcinoma, definition of prognostic factors and the role of the radiation, chemotherapy and cinacalcet treatment still has to be elucidated. In our analysis distant metastases and renal failure were critical factors regarding increased risk of death.

A suspicious case of multiple endocrine neoplasia

Teresa Alves Pereira[1], Inês Furtado[2], Ana Amado[1], Lia Ferreira[1], Raquel Almeida[1] & Isabel Palma[1]
[1]Endocrinology Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal; [2]Internal Medicine Department, Centro Hospitalar e Universitário do Porto, Porto, Portugal.

Introduction
Multiple endocrine neoplasia (MEN) syndromes are rare entities characterized by the occurrence of tumors involving two or more endocrine glands in a single patient. These syndromes are classified as type 1 or 2 according to specific phenotypic characteristics. MEN2 encompasses three different subtypes: MEN2A, MEN2B and familial medullary thyroid carcinoma. More recently a syndrome related to mutations in the CDKN1B gene has been described – the syndrome of multiple endocrine neoplasia 4. It is characterized by tumors of the parathyroid and pituitary glands.
The case
A 36-years-old woman was submitted to parathyroidectomy and adrenalectomy in September/2010 due to suspected parathyroid adenoma and pheochromocytoma, both confirmed posteriorly by histology. The patient did not have a positive family history of pheochromocytoma, parathyroid adenomas or thyroid medullary carcinoma and, furthermore, genetic testing for MEN1 and MEN2 was negative. Genetic investigation for MEN 4 is pending. After surgery PTH levels normalized. However, there is a slow increase in PTH levels since 2012 and sestamibi scintigraphy shows signs of right parathyroid adenoma.
Conclusion
This case is highly suggestive of a MEN 2A due to the symbiotic appearance of parathyroid adenoma and pheochromocytoma in the same patient. A negative genetic test, however, raises suspicion for a possible different diagnosis – MEN4 or even another genetic mutation.

Bone mineral density in obese children

Hanna Mikhno[1], Anzhalika Solntsava[1], Olga Zagrebaeva[1] & Natalia Vasilieva[2]
[1]Belarusian State Medical University, Minsk, Belarus; [2]Republican Center of Medical Rehabilitation and Balneotherapy, Minsk, Belarus.

Aim
To evaluate bone mineral density (BMD) and its relationship with calcium (Ca) and phosphorus (P) metabolism in children with obesity.
Methods
We examined 105 children in the University Hospital (Minsk) from 2011 to 2015 yrs. Their anthropometric parameters (height, weight, BMI) were determined. Body composition with evaluating of mineral component were made by dual energy X-ray absorptiometry with the calculation of feet, hands, spine, ribs, hips BMD (g/cm^2), Z-test. The levels of Ca and P, alkaline phosphatase (AlP) were determined. All children were divided into two groups: group one – children with obesity ($n=75$, boys(B)/girls(G) $=47/28$, age 15.34 ± 2.12 yrs, BMI 32.7 ± 5.3 kg/m^2; group 2 – normal-weight control ($n=30$, B/G$=19/11$, 15.08 ± 2.47 yrs ($P=0.3$), 19.4 ± 2.4 kg/m^2 ($P=0.0001$)).
Results
Legs BMD were increased in boys with obesity (0.94 ± 0.11 g/cm^2 vs 1.13 ± 0.17 g/cm^2 ($P=0.03$)) compared to control group without significant differences in G (1.29 ± 0.12 g/cm^2 vs 1.23 ± 0.02 g/cm^2 ($P=0.5$). Ribs BMD were higher in group 1 children compared to group 2 (B 0.72 ± 0.08 g/cm^2 vs 0.59 ± 0.06 g/cm^2 ($P=0.02$); G 0.71 ± 0.05 g/cm^2 vs 0.65 ± 0.06 g/cm^2 ($P=0.05$)). There were no significant differences in hand BMD (G 0.87 ± 0.10 g/cm^2 vs 0.85 ± 0.13 g/cm^2 ($P=0.836$); B 0.93 ± 0.14 g/cm^2 vs 0.85 ± 0.15 g/cm^2 ($P=0.360$)); total (G 1.18 ± 0.09 g/cm^2 vs 1.11 ± 0.13 g/cm^2 ($P=0.29$); B 1.17 ± 0.13 g/cm^2 vs 1.06 ± 0.14 g/cm^2 ($P=0.21$)) in obese children compared to control. A significant increase in Ca levels were in obese B compared to control (2.48 ± 0.07 vs 2.41 ± 0.001 mmol/l ($P=0.001$)) with no differences in G (2.43 ± 0.09 vs 2.41 ± 1.2 mmol/l ($P=0.86$)). There were no differences in P (G 1.23 ± 0.22 vs 0.95 ± 0.64 mmol/l ($P=0.78$); B 1.32 ± 0.27 vs 1.30 ± 0.18 mmol/l ($P=0.85$)), and AlP (G 108.06 ± 26.66 vs 85.13 ± 65.64 IU/l ($P=0.46$); B 217.93 ± 57.24 vs 157.27 ± 26.41 IU/l ($P=0.68$) in two groups.
Conclusions
A significant increase in ribs and legs BMD, Ca levels were found in children with obesity compared to normal weight control.

Progressive osseous heteroplasia in a child with pseudohypoparathyroidism type I

Madalina Vintila, Iuliana Gherlan, Cristina Dumitrescu, Anda Dumitrascu & Camelia Procopiuc
CI Parhon National Institute of Endocrinology, Bucharest, Romania.

Introduction
Progressive osseous heteroplasia (POH) is a rare genetic condition of progressive heterotopic ossification (HO), from skin and subcutaneous tissues into deep skeletal muscles. Most cases are caused by heterozygous inactivating mutations of GNAS gene. Related disorders are Albright hereditary osteodystrophy (AHO), pseudohypoparathyroidism (PHP), and primary osteoma cutis. Distinction from other GNAS-based conditions is made by the extension of HO from superficial to deep tissues in POH.
Case report
We present the case of a 10-year-old girl who came to medical attention at 3-months of age for lumbar and scapular subcutaneous ossifications. The biopsy confirmed osseous metaplasia of the connective tissue. The ossification process progressed in size, depth and area, up to painful swelling and mechanical compression in the shoulder. She underwent surgical resection of the scapular lesion at 3-years of age but the ossification recurred 2 years later. There were no congenital hallux valgus or other skeletal deformities. She had clinical features of AHO: round facies, flat nasal bridge, short neck, brachydactyly, obesity. Lab tests revealed mild elevated TSH (4.98 μU/ml) at 5-years of age and later, at 8-years of age, elevated parathyroid hormone (395.9 pg/ml) with hypocalcemia (Ca$=$ 8.1 mg/dl) and hyperphosphatemia ($P=7.18$ mg/dl). She was diagnosed as having PHP most probably type Ia/c based on the typical clinical findings of AHO phenotype and biochemical profile. She received treatment with calcitriol and levothyroxine. Follow-up examinations revealed moderate progression of the heterotopic ossifications and favourable clinical course with spontaneous puberty and no other hormone resistance identified yet at age of 12.
Conclusions
Overlapping features of POH and PHP type I can be present, as part of the spectrum of the heterogeneous GNAS related disorders. Awareness and distinction of these conditions are important for appropriate management.

Genetic variations in the HSD11B1 gene in patients treated with glucocorticoids show associations with bone mineral density

Heide Siggelkow[1,2], Martina Blaschke[1,2], Gabriele Armbrecht[3], Friederike Thomasius[3], Oliver Bock[3], Mladen Tzvetkov[4], Claus-C Glüer[5] & Dieter Felsenberg[3]

[1]Clinic of Gastroenterology and Gastrointestinal Oncology, University Medical Center, Göttingen, Germany; [2]MVZ Endokrinologikum, Göttingen, Germany; [3]Center for Muscle and Bone Research, Charite, Berlin, Germany; [4]Institute of Clinical Pharmacology, University Medical Center Göttingen, Göttingen, Germany; [5]Section Biomedical Imaging, Department of Radiology and Neuroradiology, MOINCC, Kiel, Germany.

Introduction

Physiological glucocorticoids play an essential role in bone formation but can cause osteoporosis if present in excess. The key enzyme converting inactive cortisone into the active cortisol and *vice versa* is 11-beta-hydroxy-steroid-dehydrogenase (11β-HSD1). We have reported that genetic variations in the HSD11B1 gene correlate with increased cortisol levels in dexamethasone suppression and with changes in bone mineral density (BMD) suggesting individual differences in 11β-HSD1 activity caused by polymorphisms. In this study we investigated the effect of HSD11B1 SNPs on BMD in patients on glucocorticoid therapy.

Methods

In 246 patients treated with different glucocorticoids the HSD11B1 SNPs rs11811440, rs1000283 und rs932335 were determined. Patients received glucocorticoids due to rheumatoid arthritis or asthma (64%), or other rheumatic, gastrointestinal or pulmonary disorders. An equivalent glucocorticoid dose was calculated for the different glucocorticoids used. BMD of the spine or femoral neck, and the number of fractures and falls were correlated to the HSD11B1 SNPs.

Results

BMD, the number of fractures and falls did not show an association with daily or cumulative equivalent dose or type of glucocorticoid. Since the three genetically linked SNPs in intron 5 of the 11β-HSD1 gene – rs11811440, rs1000283, and rs932335 HSD11B1 highly correlated, only rs11811440 was further analyzed. In patients treated with the glucocorticoids prednisolone or methylprednisolone the presence of the A-allele was associated with lower BMD levels.

Discussion

Our results suggest that in patients treated with glucocorticoids the function of 11β-HSD1 is dependent on HSD11B1 polymorphisms. Hence, inactivation of prednisolone or methylprednisolone by 11β-HSD1 would be the crucial step for BMD levels in glucocorticoid-treated individuals.

Metabolic syndrome in digestive neoplasms

Soumaya Mrabet, Nour Elleuch, Aya Hammami, Hanen Jaziri, Aida Ben Slama, Ahlem Braham, Salem Ajmi, Mehdi Ksiaa & Ali Jmaa
Sahloul University Hospital, Sousse, Tunisia.

Introduction
The metabolic syndrome (MS) is a real public health problem on a global scale. People with MS are at increased risk not only for cardiovascular diseases but also for neoplasia. The aim of our study is to determine the prevalence of MS in patients with digestive neoplasia and to study the impact of MS on the epidemiological, clinical profile and prognosis of digestive neoplasms.
Material and methods
This is a retrospective study including patients with digestive neoplasia who were hospitalized in our department between January 2015 and June 2016. For all patients, BMI, waistline, systolic and diastolic blood pressure, HDL cholesterol, triglycerides, and blood glucose levels were determined. A MS was defined according to the criteria of the International Diabetes Federation IDF 2005.
Results
78 patients were included (40 men and 38 women), with an average age of 61.7 years (between 28 and 89 years). The digestive neoplasias found were: colorectal cancer (CRC) ($n=21.27\%$), hepatocellular carcinoma (CHC) on cirrhosis liver ($n=18.23\%$), gastric cancer ($n=13.16.7\%$), Cholangiocarcinoma ($n=10.12.7\%$), pancreatic cancer ($n=9.11.5\%$), oesophageal cancer ($n=3.8\%$), small bowel lymphoma and a Cancer of the gall bladder in two cases each ($n=2.6\%$). The mean tumor size at diagnosis was 6.2 cm (1.5–18 cm). The tumor was metastatic in 26 cases (33.3%). MS was present in 29 cases (37.2%). The analytical study found that MS was more frequently found in female patients (50% versus 25%, $P=0.022$), older patients (68.2 years versus 58 years, $P=0.001$) and having a CRC (57% versus 29%, $P=0.027$). However, the presence of a MS did not influence the average survival of patients (10.3 months versus 8 months, $P=0.138$).
Conclusion
In our study, more than one-third of patients had MS. It was associated with an older age, the female sex and the CRC. However, diagnosis and management of MS remains difficult in these patients because of the malnutrition and weight loss caused by the disease.

Dyslipidemia-associated skin lesions as a short key for etiology unraveling and management of life-threatening acute pancreatitis in young male

Zoran Gluvić[1], Bojan Mitrović[1], Vladimir Samardžić[1], Jelena Tica Jevtić[1], Marina Vujović[1], Vesna Popović-Radinović[1], Aleksandar Stanojević[2] & Esma R. Isenović[3]
[1]Division of Internal Medicine, Department of Endocrinology, Zemun Clinical Hospital, School of Medicine, University of Belgrade, Zemun, Serbia; [2]Division of Internal medicine, Department of Gastroenterology, Zemun Clinical Hospital, School of Medicine, University of Belgrade, Zemun, Serbia; [3]Laboratory for Molecular Endocrinology and Radiobiology, Institute for Nuclear Sciences 'Vinča', University of Belgrade, Belgrade, Serbia.

Background
After the gall bladder stones and alcohol abuse, dyslipidemia is among most frequent causes of acute pancreatitis, especially in youngsters. Some clinical signs can be useful to alleviate either a medical condition diagnosis confirmation or unraveling of its etiology.
Aim
We present a case 30 years old male, presented with nausea, vomiting and diffuse abdominal pain. Three months before hospital admission, patient was unsuccessfully treated for painful, reddish skin lesions 5mm in diameter, dispersed on abdominal wall, arms and legs, interpreted as 'viral papillomata'. Out of mentioned skin lesions-eruptive xanthomata, hypotension, light abdominal tenderness and moderate distention, other physical examination was normal.
Results
Laboratory findings revealed lipemic serum, elevated inflammatory, pancreas and liver necrosis markers, hyperglycemia, hyponatremia and hypocalcaemia. Performed imaging procedures (ultrasound and computed tomography) showed enlarged pancreatic body and tail, and left pleural effusion. Lipemic serum and eruptive xanthomata taken together with other case findings pointed to life-threatening acute pancreatitis caused by mixed dyslipidemia, obviously serious (lipids could not be measured initially). In association with aggressive pancreatitis management, nil-by-mouth treatment with plasmapheresis successfully lowered lipids and enabled their measurement (triglycerides 19.9 mmol/l and cholesterol 10.8 mmol/l). After plasmapheresis, diet and fibrate, triglycerides and cholesterol levels were 4.04 and 3.99 mmol/l, respectively. Patient was referred to lipid clinic, gastroenterologist and surgeon (formed pancreatic cyst).
Conclusions
Adequately interpreted eruptive xanthomata can act as a shortkey for faster confirmation of acute pancreatitis. Treatment of serious pancreatitis and dyslipidaemia is done at the same time. Plasmapheresis, as well lifelong diet and pharmacotherapy later, are the mainstay for management of dyslipidaemia that caused pancreatitis (presumably mixed one).

Metformin and changes in blood pressure and heart rate in lean patients with polycystic ovary syndrome (PCOS)- preliminary study

Marta Kialka[1], Tomasz Milewicz[1], Marek Klocek[2] & Rita Tomczyk[1]
[1]Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland; [2]Department of Cardiology and Hypertension, Jagiellonian University, Medical College, Cracow, Poland.

Introduction
The aim of our study was to assess the value of blood pressure and heart rate using the 24-h blood pressure monitoring (ABPM) before and after treatment with metformin to patients with polycystic ovary syndrome (PCOS) and normal lean.
Material and methods
20 patients received metformin 1500 mg/day in three divided doses. ABPM was performed to each patient with PCOS twice: before and after 6 months of treatment with metformin.
Results
In patients with PCOS and normal lean after treatment with metformin we observed: statistically significant lower systolic blood pressure (120.2 ± 22.33 mmHg vs 113.22 ± 21.43 mm Hg, $P=0.0248$); lower systolic blood pressure of daily measurements (127.1 ± 32.13 mmHg vs 116.1 ± 22.08 mmHg, $P=0.0062$); reduction in average arterial pressure MAP daily measurements (95.52 ± 22.76 mmHg vs 88.36 ± 16.41 mmHg, $P=0.048$); oscillometric pressure reduction (96.27 ± 27.93 mmHg vs 87.82 ± 21.61, $P=0.0004$ mmHg); oscillometric pressure reduction of daily measurements (102.1 ± 27.93 mmHg vs 91.85 ± 21.61 mmHg, $P=0.0032$); oscillometric pressure reduction in the measurement of the night (88.81 ± 24.85 mmHg vs 82.22 ± 20.54 mmHg, $P=0.0089$). In women after treatment with metformin has also been observed higher average heart rate (65.82 ± 13.48/min vs. 70.71 ± 16.04/min; $P<0.01$). The calculations included 500 measurements.
Conclusion
Treatment with metformin in patients with PCOS and normal lean leads to lower blood pressure and increases the frequency of heart rate.

EP358

Screening for type 2 diabetes mellitus as a method of secondary prevention of cardiovascular lesions

Lev Prystupiuk, Liudmyla Naumova, Maksym Prystupiuk, Iuliia Onofriichuk & Marianna Naumova
Bogomolets National Medical University, Kyiv, Ukraine.

In patients with type 2 diabetes mellitus (T2DM), cardiovascular lesions are 3–4 times more often than in non-diabetics. Screening for T2DM in 1564 people from all Ukraine revealed that 12% had HbA1c at 6.1–6.4% and 16% had HbA1c above 6.5%. Those with HbA1c above 6.5% were examined for BMI, glycemia, total cholesterol, HDL-C, non-HDL-C. Dyslipidemia was defined as total cholesterol over 5.20 mmol/l, HDL-C – less than 1.02 mmol/l for males and less than 1.29 mmol/l for females. Total cholesterol averaged 6.41 ± 0.03 mmol/l in screened men and 6.23 ± 0.01 in women. HDL-C was respectively 1.89 ± 0.08 and 1.88 ± 0.07 mmol/l. Whereas non-HDL-C was 4.60 ± 0.02 and 3.38 ± 0.05 mmol/l respectively. As for total cholesterol, objects were divided into the following groups (in mmol/l): 5.2; 5.3–6.5 and over 6.5. Males with these indicators were distributed: 38%, 57%, 5%; females – 28%, 64% and 8% respectively. According to correlation of total cholesterol to fasting glucose, men with glycemia under 6.1 mmol/l had cholesterol 5.70 ± 0.01 mmol/l, those with glycemia 6.2–7.8 mmol/l had cholesterol 5.90 ± 0.05 mmol/l and those with glycemia over 7.8 mmol/l had cholesterol 5.99 ± 0.04 mmol/l. While in women, cholesterol levels were (mmol/l): 4.86 ± 0.03, 6.50 ± 0.03, and 7.50 ± 0.03 in relation to the above mentioned levels of glycemia. In accordance with division of BMI into normal weight, overweight and obesity, cholesterol levels in males were (mmol/l): 5.81 ± 0.06, 6.12 ± 0.04 and 6.10 ± 0.05 respectively, while in females 5.48 ± 0.04, 5.56 ± 0.02 and 5.77 ± 0.01. Consequently, dyslipidemias were found in 70% of our group with T2DM of both sexes. They are induced by increase in non-HDL-C, correlate with degree of compensation of diabetes and with BMI. Therapeutic correction of dyslipidemias in patients with T2DM should be: normalization of glycemia and body weight. Screening for T2DM and its active treatment are most suitable method of secondary prevention of cardiovascular lesions caused by T2DM.

EP359

Soybean phytoestrogens reduce 27-hydroxycholesterol concentration in the liver of middle-aged female rats

Branka Šošić-Jurjević[1], Snežana Janković[2], Dieter Lütjohann[3], Ivana Jarić[1], Marko Miler[1], Branko Filipović[1], Vladimir Ajdžanović[1] & Verica Milošević[1]
[1]Institute for Biological Research 'Siniša Stanković', University of Belgrade, Belgrade, Serbia; [2]Institute for Science Application in Agriculture, University of Belgrade, Belgrade, Serbia; [3]Institut für Klinische Chemie und Klinische Pharmakologie Universitätsklinikum Bonn, Bonn, Germany.

Hypercholesterolemia is associated with athero-thrombotic disease, a leading cause of mortality worldwide. Advances in both dietary and pharmacological interventions contribute to prevention and treatment of modifiable risk factors.Purified soybean phytoestrogens, isoflavones genistein (GEN) and daidzein (DAI), were reported to exert moderate cholesterol-lowering effect. In this research first we studied age-related modifications in hepatic cholesterol metabolism and serum estradiol concentration of acyclic middle-aged (MA) female rats. Then we tested if purified isoflavones may prevent or reverse these changes. Serum and hepatic total cholesterol (TCH), bile acid and cholesterol precursors were determined by comparing data obtained for MA with young adult (YA) intact (IC) females. Effects of subcutaneously administered GEN or DAI (35 mg/kg per daily during four weeks) to MA rats were evaluated vs vehicle (sterile olive oil) – treated MA females. After decapitation, perfused rat livers and serum were used to determine total cholesterol (TCH), its oxidative metabolites (7α-, 27- and 24-hydroxycholesterol) and precursors (lanosterol, desmosterol, dihydro-lano sterol and lathosterol), using gas chromatography/mass spectrometry. Serum estradiol was determined by ECLIA. MA IC females were characterized by: higher ($P < 0.05$) serum TCH, lower ($P < 0.05$) hepatic TCH and its biosynthetic precursors, lower ($P < 0.05$) hepatic7α-hydroxycholesterol but elevated ($P < 0.05$) 27- and 24- hydroxycholesterol in comparison to YA IC. Both GEN and DAI decreased ($P < 0.05$) hepatic 27-hydroxycholesterol, with no effect on any other parameter of cholesterol metabolism. We obtained age-related reduction of serum estradiol, which was reversed by both soybean phytoestrogens. In conclusion, age-related dyslipidemia was associated with reduced 7α-hydroxycholesterol, main intermediate of neutral pathway, and higher 27—hydroxycholesterol, main intermediate of alternative acidic pathway of Chol degradation to bile acid. Both GEN and DAI lowered hepatic 27-hydroxycholesterol, which might be associated with elevated serum estradiol concentrations. Further research is needed to examine this possibility.

Awareness and prevalence of metabolic syndrome among high-risk individuals attending internal medicine clinics across Jordan

Rania Efaishat[1], Rana Abu Farha[2] & Eman Alefishat[3]
[1]Medical Supply Department, Directorate of Royal Medical Services, Amman, Jordan; [2]Department of Clinical Pharmacy and Therapeutics, Faculty of Pharmacy, Applied Science Private University, Amman, Jordan; [3]Department of Biopharmaceutics and Clinical Pharmacy, Faculty of Pharmacy, The University of Jordan, Amman, Jordan.

Purpose
To examine the prevalence and awareness of metabolic syndrome (MetS) in high-risk individuals attending 30 internal medicine clinics in Amman, Jordan, and also to evaluate the various factors associated with increased risk of MetS among them.
Methods
This retrospective cross-sectional study was carried out across Amman, Jordan from October to December 2014. During the study period, 900 high-risk individuals (with hypertension, diabetes, central obesity and/or dyslipidemia) were recruited from thirty internal medicine clinics in Amman, Jordan. Data collection forms were filled based on patient interview and medical case file.
Results
The prevalence of MetS among high-risk individuals was around 40% (361/900), with around 79% (284/361) of MetS patients unaware of their condition. Older age, lower income and family history of premature cardiovascular diseases were associated with a higher prevalence of MetS.
Conclusion
Although MetS was found to be highly prevalent among high-risk individuals in this study, the awareness of the condition in this group is very poor. These findings support the need for educational programs that involve both health care providers and patients. These programs should especially target those at risk of MetS, in order to improve awareness of the concept of MetS.

Nine months of practice in California - self-referrals in endocrinology

Jelena Maletkovic
UCLA, Los Angeles, California, USA.

Objective
A great number of patients are self-referred to endocrinologist. Most of these patients had some research of their symptoms and have a specific diagnosis that they want to investigate.
Methods
A retrospective chart review of 628 new consults conducted in one outpatient endocrine office at University of California, Los Angeles was conducted.

Results
Of the 628 new patients 326 were referred by another physician and were excluded from further review. Of 302 self-referred patients 248 patients had a preexisting endocrine diagnosis and were excluded. The remaining 54 patients were seeing endocrinologist for the first time and these patients were included in further study. Most common complaints were: weight gain (78% of patients), fatigue (72%), cold intolerance (46%), heat intolerance (31%), constipation (24%). Other common complaints observed were hair loss, low libido, erectile dysfunction, anxiety, palpitations, weight loss, hirsutism, acne, muscle weakness, stretch marks, buffalo hump and polydipsia. When asked if they had a specific hormone abnormality in mind most of the patients reported that their main concern is hypothyroidism (69%), high cortisol level (13%), low testosterone (10%), low cortisol (5%), hyperthyroidism (5%), diabetes insipidus (4%), diabetes mellitus (2%). After conducting endocrine studies based on presenting symptoms none of the 54 patients were found to have confirmation of suspected diagnosis. Four patients were found to have elevated TPO antibodies but thyroid functions tests were normal. Six patients were found to have diabetes mellitus that was previously not diagnosed or suspected. Two patients were found to have elevated cholesterol.
Discussion
Common problems lead to online research that offers a number of endocrine conditions as a possible underlying problem. With access to subspecialist care oftentimes unnecessary work-up is done.
Conclusion
A longer period of investigation would add valuable data in determining the impact of self-referrals on subspecialty practices as well as health care in United States in general.

Identifiying underdiagnosed or undertreated patients with familial hypercholesterolemia from the central laboratory registries

Cem Haymana[1], Hamza Berlik[2], Yalcin Gunes[2], Orhan Enes Tuncez[2], Cihat Aytekin[2], Zafer Tapikara[2], Huseyin Guzel[2], Ozlem Ozturk[3], Cem Barcin[4], Taner Ozgurtas[3], Omer Azal[1] & Alper Sonmez[1]
[1]Department of Endocrinology and Metabolism, Gulhane Training and Research Hospital, Ankara, Turkey; [2]Gulhane School of Medicine, Health Sciences University, Ankara, Turkey; [3]Department of Biochemistry, Gulhane Training and Research Hospital, Ankara, Turkey; [4]Department of Cardiology, Gulhane Training and Research Hospital, Ankara, Turkey.

Objective
Familial hypercholesterolemia (FH) is a life-threatening genetic disease associated with elevated low density lipoprotein cholesterol (LDL-C) and premature coronary heart disease that is globally underdiagnosed and undertreated. This study aimed to search for the demographical characteristics, awareness and treatment adherence of underdiagnosed or undertreated FH patients from the records of the central biochemistry laboratory.
Methods
Patients with a central laboratory measurement of LDL-C >250 mg/dl were identified. Patients with older than 18 years without secondary causes of dyslipidemia were called by medical students and interviewed about demographic characteristics, awareness of dyslipidemia and treatment adherence.
Results
A total of 147 patients (mean age 51.7 ± 16.6 years, 59.2% female) were interviewed. The mean LDL-C levels were 292.8 ± 49.9 mg/dl. According to the Dutch Lipid Clinic Network Criteria, the patients with definite, probable and possible FH were 18.4%, 66.0% and 15.6%, respectively. Although the majority of the patients (93.9%) were aware of their high LDL-C levels, only about half of them ($n=75$, 51.0%) were under treatment. Of all the patients who were interviewed, 21% ($n=31$) had never taken, and 28% ($n=41$) had stopped taking lipid-lowering drug.
Conclusion
The results of this pilot study show that, undiagnosed or undertreated FH patients can practically be detected from the high LDL-C registries of the Hospital Laboratories. Nationwide implementation of this method may help us reach and manage these high-risk patients.

The effect of admission hyperglycemia on clinical outcome of ischaemic stroke patients

Vina Yanti Susanti[1], Iswandi Darwis[2] & Fidha Rahmayani[3]
[1]Internal Medicine Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia; [2]Resident on Internal Medicine Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia; [3]Resident on Neurology Department, Universitas Gadjah Mada/Sardjito General Hospital, Yogyakarta, Indonesia.

Background and objective
Hyperglycemia exacerbates multiple deleterious derangements and this process would influence the clinical outcome in diabetic patient. The objective of this study is to know the effect of admission hyperglycemia on clinical outcome of ischamic stroke patients admitted in Sardjito General Hospital.
Method
Observational cohort study over 5 months' period from August 1-2016 to December 31-2016 was done. All patients 18 years old and above, admitted as stroke ischaemic patients in Sardjito General Hospital Yogyakarta were screened. In order to qualify, patient were subjected to initial random blood sugar determination upon admission and monitored to 48–72 h. Capillary blood glucose was monitored using blood glucose monitor device by Bayer. Hyperglicemia status is blood glucose above 200 mg/dl. Clinical outcome was evaluated and recorded using *The National Institutes of Health Stroke Scale* (NIHSS) on day 1 and discharge. Participants who are below 18 years old, previously stroke, or those with acute co-morbid disease like acute myocardial infarction, pneumonia, or critical infection, ketoacidosis diabeticum, hyperglicemia hyperosmolar state were all excluded. All patients managed according to guidelines for stroke and hyperglycemia.
Result
Sixty four eligible subjects admitted at Sardjito General Hospital, 12 (19.35%) were hyperglycemia and 50 (80.65%) normoglycemia. The mean value of blood glucose at admission are $153.45 + 69.09$ mg/dl. Patients who have worsening clinical outcome at dischare are 18 (29.03%) based on NIHSS. Six patients (44.44%) who had hyperglicaemia had worsening clinical outcome and four patients (9.09%) did not have worsening clinical outcome (*P*-value 0.003; OR 8; min 2 001–max 31 988).
Conclutions
Hyperglicaemia at admission have correlate with worsening of clinical outcome ischaemic stroke patients.
Keywords
Hyperglycemia; Ischaemic stroke patients; The National Institutes of Health Stroke Scale.

Deleting genomic region of *Hsd17b1* in mice results into a hypomorphic *Naglu* allele, and consequently to a phenotype mimicking a lysosomal storage disease

Heli Jokela[1], Janne Hakkarainen[1], Pirjo Pakarinen[1,2], Suvi Ruohonen[1], Fuping Zhang[2] & Matti Poutanen[1,2]
[1]University of Turku, Turku, Finland; [2]Turku Center for Disease Modeling, Turku, Finland.

Abstract
Hydroxysteroid 17-beta dehydrogenase 1 (HSD17B1) is an enzyme catalyzing the reduction of estrone (E1) to estradiol (E2), as well as androstenedione (Adione) to testosterone (T). To elucidate the physiological function of HSD17B1, we generated knockout mice with disrupted *Hsd17b1* gene using targeted ES cells (clone 10231) obtained from KOMP repository (www.komp.org). In these ES cells the whole coding region of *Hsd17b1* was replaced with *LacZ/Neo* cassette, expressing the reporter gene. As previously shown by us, the homozygous *Hsd17b1-LacZ/Neo* females were found to be subfertile and have a defect in pseudopregnancy maintenance, likely caused by the imbalance in ovarian steroid synthesis. In addition, the *Hsd17b1-LacZ/Neo* males present with a metabolic phenotype, including reduced adipose mass, increased lean mass and lipid accumulation in the liver. During the characterization of the metabolic phenotype, it became evident that the expression of N-acetyl-alpha-glucosaminidase (*Naglu*) gene, located 8399-739 bp upstream of the *Hsd17b1* transcription start site, was severely reduced (13-40-fold) in all tissues analyzed in *Hsd17b1-LacZ/Neo* mice. Furthermore, similar results were obtained from *Hsd17b1-LacZ* mice after removing the *Neo* cassette or by crossing the *Hsd17b1-LacZ/Neo* mice with transgenic mice constitutively expressing human *HSD17B1*. Deficiency of the *Naglu* gene causes the accumulation of glycosaminglycans (GAGs) in several tissues, and accordingly, GAG accumulation was observed in all the above mentioned mouse models lacking the genomic region coding for *Hsd17b1*. Furthermore, biochemically and morphologically similar metabolic phenotype, mimicking lysosomal storage disease, was observed both in *Naglu* knockout mice (with the presence of active HSD17B1), and all the mouse models lacking 2.3 kb long genomic region of *Hsd17b1* gene. Thus, the data indicate the presence of a strong *Naglu* enhancer inside the *Hsd17b1* gene, and the metabolic phenotype in mice lacking the *Hsd17b1* genomic region is caused by the off target effect.

Salivary lactate levels during anaerobic threshold (AT) training

Hugo Ogando Berea[1], Laura Toba Estevez[1], Juan Fandiño Gómez[1], Yolanda Diz Chaves[1], Jose Luis García Soidán[2], Lucas Gonzalez Matías[1] & Federico Mallo Ferrer[1]
[1]Labendo, Cinbio, Vigo University, Campus Lagoas-Marcosende s/n 36310 Vigo, Spain; [2]Faculty of Educational Sciences and Sports, University of Vigo, Campus a Xunqueira, s/n 36005 Pontevedra, Spain.

Anaerobic threshold (AT) is defined as the point of maximum intensity at which lactate is being produced but does not accumulate in blood during exercise. Training at this intensity is common in athletes. Lactate is currently regard as indicator of effort intensity. It is usually quantified by reflectometry of capillary blood. This procedure although not very invasive, may be annoying during repeated measurements. Saliva is proposed as an alternative sample.
The objective of the present study is to quantify the variation of salivary lactate levels during AT training, in order to prove its usability in this field.
10 male subjects (32 ± 2.96 years) performed a treadmill test recording intensity (watts/min), VO2 and heart rate (HR) to determine AT. After two days resting they performed 6 running series of 1km at AT rhythm with 2 minutes of resting between series. Saliva samples by Salivette system (SARSTEDT, Germany) and HR were taken at pretest, the end of each series, and 3, 6 & 9 min of resting after. Eating, smoking, drinking (except water) or teeth brushing was forbidden in 2 h previous to start.
Salivary lactate concentrations increased significantly from 1st to 3rd series ($P = 0.002$). Afterwards, a plateau of saliva lactate concentration was observed in all subjects up to the end of the series (4th–6th). After a small reduction, an additional increase in saliva lactate was also consistently observed after 6 min of rest. HR hardly changed during the exercise series. Since we can conclude that: The salivary lactate was increased according to the accumulated workload despite exercise was performed at constant intensity (AT). That was confirmed because the heart rate (HR) hardly changed at this constant rate. Since, saliva lactate levels in an AT training are independent of heart rate and mostly of effort intensity.

The effect of tocilizumab – an interleukin-6 receptor antagonist – on lipid levels in rheumatoid arthritis

Ifigenia Kostoglou-Athanassiou[1], Lambros Athanassiou[2], Aikaterini Tzanavari[2], Charoula Katsavouni[2], Markos Kostopoulos[2], Dimitrios Pantelidis[2] & Panagiotis Athanassiou[2]
[1]Department of Endocrinology, Red Cross Hospital, Athens, Greece; [2]Department of Rheumatology, St Paul's Hospital, Thessaloniki, Greece.

Tocilizumab is an interleukin-6 receptor antagonist used in the treatment of rheumatoid arthritis (RA). It is known to induce remission and inhibit radiographic progression in RA. Tocilizumab may be administered either intravenously or subcutaneously. Its effect on lipid levels and the cardiovascular risk has not been fully investigated. The aim was to study the effect of tocilizumab i.v. on disease activity, lipid levels and cardiovascular risk in RA patients.
Tocilizumab was administered i.v. once monthly in 25 patients with RA for a period of 1 year. Inflammation indices, ESR and CRP and lipid levels were measured before and 1 year after tocilizumab administration. The DAS28 disease activity index was also calculated.
Inflammation indices ESR and CRP decreased from 34.3 ± 4.04 mm/h and 2.02 ± 0.34 mg/dl before to 8.3 ± 1.62 mm/h and 0.27 ± 0.07 mg/dl, respectively ($P < 0.001$) after tocilizumab administration. The DAS28 disease activity index decreased from 5.02 ± 0.26 to 2.42 ± 0.26 after tocilizumab ($P < 0.001$). Total cholesterol and HDL cholesterol increased from 207.4 ± 8.53 mg/dl and 57.68 ± 2.65 mg/dl before to 231.08 ± 12.30 mg/dl and 72.51 ± 4.76 mg/dl, respectively ($P < 0.001$) after tocilizumab administration, LDL cholesterol and triglyceride levels increasing from 128.6 ± 7.45 mg/dl and 108.48 ± 7.83 mg/dl before to 136.17 ± 9.39 mg/dl and 130.58 ± 15.82 mg/dl, respectively ($P < 0.001$) after tocilizumab. No acute cardiovascular events were recorded during the study.
Tocilizumab administered i.v. in patients with RA was shown to decrease inflammation indices and disease activity. Lipid levels increased significantly. However, total cholesterol increased in parallel with HDL cholesterol. Cardiovascular events were not observed during the study period. It appears that tocilizumab may be accompanied by lipid level alterations, cardiovascular risk not increasing as the adverse effects of total cholesterol may be counteracted by HDL cholesterol.

Homocystein-significant marker of metabolic syndrome and atherosclerosis risk

Branko Sreckovic[1], Vesna Dimitrijevic-Sreckovic[2,7], Ivan Soldatovic[3,7], Hristina Janeski[4], Nenad Janeski[5], Jasna Gacic[1], Mirjana Sumarac-Dumanovic[2,7] & Igor Mrdovic[6,7]
[1]Clinical Center Bezanijska Kosa, Belgrade, Serbia; [2]Clinic for Endocrinology, Diabetes and Metabolic Diseases, Clinical Center of Serbia, Belgrade, Serbia; [3]Institute for Medical Statistics and Informatics, Belgrade, Serbia; [4]University Children's Hospital, Belgrade, Serbia; [5]Clinical Hospital Center Zemun, Belgrade, Serbia; [6]Clinic for Cardiovascular Diseases, Clincal Center of Serbia, Belgrade, Serbia; [7]Faculty of Medicine, Belgrade University, Belgrade, Serbia.

Background
Obesity is followed by insulin resistance (IR) and low grade inflammation. In patients with metabolic syndrome (MS) and clinicaly evident vascular complications homocystein values are higher. Hyperhomocysteinemia correlates with hyperinsulinemia and IR, resulting in oxidative stress, which causes endothelial lesions and dysfunction, promoting atherosclerosis and hypertension.
Objectives
To examine homocystein levels in patients with and without MS, and find correlation between factors of MS and homocystein values.
Methods
The study included 76 obese individuals (age over 30, BMI > 25 kg/m^2) classified into two groups: I- with MS (35 patients); II- without MS (41 patients). OGTT was used to evaluate the extent of glucoregulation disorder. IDF classification was

applied for diagnosing MS. Si MS risk score by Soldatovic I et all 2016 was used. IR was determined by HOMA IR. Serum CRP was measured by immunometric assay. Microalbuminuria was determined immuno-nephelometrically. Homocistein was determined by immunoassay FPIA-Abbot.
Results
Patients with MS had increased WC:(I-110.6±15.4, II±15.4 cm), BMI:(I-35.3±6.6, II-30.4±7.4 kg/m^2), blood pressure (I-136.4±13.9 /90.5±9.5, II-118.4±12.2/78.1±9.7 mmHg), glycaemia (I-5.4±1.6, II-4.8±0.8 mmol/l), HOMA IR (I-8.8±9.4, II-5.3±3.8 mmol/μU per ml), triglycerides (I-2.17±0.95, II-1.45±0.7 mmol/l), CRP (I-7.0±0.0, II-3.7±3.8 mg/l), microalbuminuria (I-87.4±81, II-56.4±56.9 mg/24 h), homocysteine (I-13.0±3.2, II-11.8±3.7 μmol/l) and decreased HDL (I-1.07±0.2, II-1.35±0.35 mmol/l). Statistical significance between groups was found for WC, BMI, systolic and diastolic pressure, triglycerides, HDL-cholesterol ($P<0.01$) and CRP, Apo B, HOMA IR ($P<0.05$). Correlations: Homocysteine with systolic and diastolic pressure, Apo B and hyperlipoproteinemia ($P<0.05$). Si MS risk score with homocysteine ($P<0.01$), $r=0.263$.
Conclusion
Abdominal obesity, hypertension, hypertriglyceridemia, inflammation factors, IR, homocystein and microalbuminuria as markers of endothelial dysfunction were increased in patients with MS. Correlation of homocystein values with si MS risk score indicates that it is significant co-founding factor of MS. Correlation of homocystein with hypertension and hyperlipoproteinemia indicates importance of homocystein as significant marker for atherosclerosis.

Graft vs host disease and insulin resistance after bone marrow transplantation

Panagiotis Athanassiou[1] & Ifigenia Kostoglou-Athanassiou[2]
[1]Department of Rheumatology, St Paul's Hospital, Thessaloniki, Greece; [2]Department of Endocrinology, Red Cross Hospital, Athens, Greece.

Graft vs host disease is a disorder in which the graft, i.e. bone marrow, attacks the host after bone marrow transplantation. It has various manifestations, one being skin and muscle involvement with cutaneous sclerosis and diffuse muscle pain. The aim was to describe the case of a patient with graft vs host disease complicated by insulin resistance and metabolic syndrome, after bone marrow transplantation for the treatment of acute lymphoblastic leukemia.
A patient, male, aged 2.5 years old, developed acute lymphoblastic leukemia. He was treated and the disease went into remission. At the age of 7 years, the patient had a recurrence. He was found to be compatible with his elder brother and bone marrow transplantation was performed. During the following months the patient developed a skin eruption, diffuse cutaneous sclerotic lesions, muscle edema and pain.
He was treated with thalidomide and cyclosporine and clinical manifestations of graft vs host disease improved. Diffuse skin and muscle involvement improved. The patient developed hypertriglyceridemia and insulin resistance. Metformin and fenofibrate were administered. The patient developed also hypothyroidism. Thyroxine was administered. At the age of 29 the patient developed psoriasis like lesions in the maxilla and the external genital organs.
In conclusion, the case of a patient is described with graft vs host disease after bone marrow transplantation for the management of acute lymphoblastic leukemia. Graft vs host disease may have various clinical manifestations. In the case described skin and muscle involvement, along with insulin resistance and metabolic syndrome were the predominant manifestations.

Coronary artery calcium score in prediabetes – preliminary results

Milica Marjanovic Petkovic[1], Ivana Sasic[3], Miljanka Vuksanovic[1,2] & Teodora Beljic Zivkovic[1,2]
[1]Zvezdara University Medical Center, Belgrade, Serbia; [2]Belgrade University School of Medicine, Belgrade, Serbia; [3]Institute of Cardiovascular Diseases Dedinje, Belgrade, Serbia.

Introduction
Coronary artery calcium (CAC) is examined through multislice CT. Calcifications indicate late-stage subclinical coronary atherosclerosis. An association exists between CAC with coronary vascular disease (CVD), Agatston score being an independent predictor of CVD. Including CAC may improve CV risk prediction in addition to conventional risk factors. The AIM of our study was to assess CAC in subjects with prediabetes (preDM) at the beginning of the long term follow-up for occurrence of cardiovascular disease.
Methods
After diagnosing preDM with oral glucose tolerance test and HbA1c, ECG was performed and subjects were evaluated for CVD risk. Score charts were used to calculate the CVD risk. Thereafter, all subjects were appointed for multislice CT to obtain the CAC.
Results
70 subjects with preDM were screened for CVD. CAC score of 0 was present in 32 subjects. Minimal calcifications with a CAC score of 1–10 AU were present in 12 subjects with pre DM. Moderate calcification of11–100 AU were present in 15 subjects. Nine subjects had significant calcifications with 101–400 AU. Two subjects had a CAC score of 100 AU which meant significant calcifications. Score risk below 2% was present in only 19 subjects, while a score risk of 15% and more was present in 23 subjects. No significant correlation was found between Score charts and CAC. However, a trend of finding more calcifications in those with a 10% and above Score risk was noted.
Conclusion
An approach to risk assessment that combines the traditional risk factor-based paradigm with a more personalized atherosclerosis-imaging model may be appropriate for high risk individuals, such as subjects with pre diabetes.

Cardiometabolic risk and female sexuality: focus on clitoral vascular resistance

Elisa Maseroli[1], Egidia Fanni[1], Sarah Cipriani[1], Irene Scavello[1], Francesca Pampaloni[1], Cesare Battaglia[2], Massimiliano Fambrini[1], Edoardo Mannucci[1], Emmanuele A Jannini[3], Mario Maggi[1,4] & Linda Vignozzi[1,4]
[1]University of Florence, Florence, Italy; [2]University of Bologna, Bologna, Italy; [3]Tor Vergata University of Rome, Rome, Italy; [4]Istituto Nazionale Biostrutture e Biosistemi, Rome, Italy.

The relation between sexual and cardiovascular health in women is not well defined. Clitoral colour Doppler ultrasound (CDU) with assessment of the pulsatility index (PI), reflecting resistance to blood flow, has been proposed as an objective measurement of sexual functioning. We aimed to investigate the associations between clitoral PI and cardiometabolic risk factors. Seventy-one adult heterosexual women attending our clinic for sexual dysfunction were consecutively recruited. Clitoral PI was positively correlated with BMI ($P<0.0001$), waist circumference (WC; $P<0.0001$), glycaemia ($P=0.029$), insulin ($P=0.002$), homeostatic model assessment index ($P=0.005$), triglycerides ($P=0.011$), total cholesterol ($P=0.010$), and LDL-cholesterol ($P=0.016$). All relations, with the exception of glycaemia, retained statistical significance after adjusting for age, smoking habit, and years since menopause ($P<0.0001$ for BMI, WC and triglycerides; $P<0.05$ for all other associations). Analysis of covariance, after adjusting for confounders, showed that women with obesity or metabolic syndrome (MetS) showed significantly higher PI values (obesity: $P=0.001$; MetS: $P=0.019$). In particular, a stepwise increase of PI was found as a function of increasing MetS components ($P=0.007$). Clitoral PI was negatively associated with Female Sexual Function Index arousal ($P=0.014$) and satisfaction ($\beta=-0.289$, $P=0.026$) scores and positively associated with Middlesex Hospital Questionnaire somatized anxiety symptoms, even after adjusting for confounders ($P=0.011$). A positive association also was observed between PI and the Body Uneasiness Test (BUT) positive symptom distress index ($P=0.039$) and BUT for dislike of the womb, genitals, and breast ($P<0.0001$; $P<0.0001$; $P<0.0001$, respectively). After introducing WC as another covariate, the associations between clitoral PI and the BUT positive symptom distress index and BUT dislike of the womb, genitals, and breast retained statistical significance ($P=0.038$ for positive symptom distress index; $P<0.0001$ for dislike of womb, genitals, and breast). Clitoral vascular resistance is positively associated with MetS (in particular insulin resistance), decreased sexual arousal, body image concerns, and increased somatized anxiety symptoms. Further studies are needed to establish whether treatment of metabolic abnormalities might improve clitoral CDU indices and sexual outcomes.

Metformin and changes in serum lipid profile in lean patients with polycystic ovary syndrome (PCOS)

Marta Kialka[1], Tomasz Milewicz[1], Anna Wajda[1], Patrycja Czekanska[1], Barbara Zdzierak[1] & Sandra Mrozinska[2]
[1]Department of Gynecological Endocrinology, Jagiellonian University, Medical College, Cracow, Poland; [2]Department of Metabolic Diseases, Cracow, Poland.

Introduction
The aim of our study was to assess the values of total cholesterol, HDL-C, LDL-C and triglycerides before and after treatment with metformin in patients with polycystic ovary syndrome (PCOS) and normal lean.
Material and methods
32 patients received metformin 1500 mg/day in three divided doses. Lipids measurements were performed to each patient with PCOS twice: before and after 6 months of treatment with metformin.
Results
In patients with PCOS and normal lean after treatment with metformin we observed: statistically significant lower LDL-C levels (4.16 ± 0.79 mmol/l vs 3.4 ± 0.86 mmol/l, $P < 0.05$) and triglycerides levels (1.8 ± 0.53 mmol/l vs 1.12 ± 0.64 mmol/l, $P < 0.05$). We observed an increase in HDL values and a decrease in total cholesterol values, but these changes were not statistically significant (1.5 ± 0.71 mmol/l vs 1.71 ± 0.69 mmol/l, $P = 0.09$; 5.87 ± 0.92 mmol/l vs 5.69 ± 0.97 mmol/l, $P = 0.11$).
Conclusion
Our study showed that treatment of 1500 mg metformin for about 6 months among PCOS women result in improvement in serum lipids. We observed a significant decrease in LDL-C and triglycerides values after metformin treatment.

Prevalence of major cardiovascular risk factors among people living with HIV in a low risk country for cardiovascular disease

Carolina García-Figueras Mateos & Manuel Cayón-Blanco
Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain.

Introduction
It is well known that the prevalence of major cardiovascular risk factors has increased in HIV-infected people since improvement of antiretroviral therapy. Currently, Spain is defined as a 'low risk country' for cardiovascular diseases (CVD) by 2016 European Guidelines on cardiovascular disease prevention. The objective of this study is to assess the prevalence and characteristics of CVD risk factors and risk for CVD in a cohort of HIV-infected adults living in the South of Spain according to current guidelines.
Methods/design
Cross-sectional study. Measurements included anthropometry, blood pressure, fasting lipids and glucose assessment. Demographic, clinical, immunological, and antiretroviral therapy data were obtained from electronic medical records. 10-year risk of heart disease or stroke was calculated using the SCORE- European low risk chart.
Results
218 patients were evaluated. Hypertriglyceridemia was the most prevalent disturbance (44.3%) found, followed by low HDLc levels (41.7%). 8.7% of the cohort had hypertension and 6.9% had type 2 diabetes. 68.5% were current smokers. High risk (10-year risk of fatal CVD $> 10\%$) was found in 13.3% of the cohort. People at higher risk were mostly men (100% vs 81%; $P = 0.005$), had higher BMI (25 ± 2.3 vs 23 ± 2.7 kg/m^2; $P = 0.04$) and had a lower CD4 count (405.5 ± 156.2/mm^3 vs 551.5 ± 211.7/mm^3; $P = 0.035$) and were more likely to receive protease inhibitors (48% vs 30%; $P = 0.04$).
Conclusions
According to our results, the prevalence of major risk factors for CVD is high in HIV-infected patients of our area, especially among those with worse immunity and higher BMI. Physicians should screen their patients for metabolic and cardiovascular risk at the regular visits to reduce CVD risk among people with HIV. Changes in antiretroviral therapy to more metabolic neutral antiretroviral drugs may also be considered.

The role of leptin signalling in the development of cardiovascular diseases in obesity

Stephanie Simonds & Michael Cowley
Monash University, Melbourne, Victoria, Australia.

Cardiovascular diseases are the greatest cause of death globally. Obesity significantly increases the risk for the development of cardiovascular diseases. However research does not under stand the physiological and molecular connections of these diseases. We have identified that the hormone leptin in obesity plays a key role in elevating blood pressure in obesity. However recent findings in humans treated with leptin in the disease state of lipodystrophy, did not result in the elevation of blood pressure. In the research present here we suggest that one reason as to why leptin fails to increase blood pressure in lipodystrophy patients is that plasma leptin concentration in not increasing high enough. For the development of cardiovascular complications in obesity plasma leptin concentration needs to increase significantly to concentrations similar to that of obese animals (ten times the concentration measured in lean animals). In rodents we dose dependently demonstrate the differing effects of concentrations of leptin on changes in body weight, food intake, brown adipose tissue temperature, blood pressure and heart rate. We can demonstrated in obese hypertensive mice that changes to the signaling components of specific neurons within the Dorsomedial Hypothalamic leptin receptor expressing neurons in the brain can substantially change leptin's influence on cardiovascular control. Hence we can control in rodents the development of hypertension in obesity, via manipulating the responsiveness of leptin receptor responsive neurons. We are mapping the connections of this specific subset of neurons and are gaining a true understanding on how the adipose derived hormone leptin plays a key role in the development of cardiovascular diseases.

Influence factors on lipid profile among patients with rheumatoid arthritis

Manuel Cayón-Blanco[1], Carolina García-Figueras Mateos[1], Raúl Menor-Almagro[2] & Mario H Cardiel Ríos[3]
[1]Hospital Jerez de la Frontera, Jerez de la Frontera (Cádiz), Spain; [2]Universitary Hospital Virgen del Rocío, Seville, Spain; [3]Hospital Dr. Miguel Silva, Morelia, Mexico.

Introduction
Patients with rheumatoid arthritis (RA) face an increased risk of developing premature cardiovascular disease and limited ability to modify risk factors such exercise or dietetic habits. Influence of exercise, dietetic habits or treatment on lipid profile has been little studied in patients with RA. Here we aim to determine differences in lipid profile between two cohorts of patients with RA with different habits and patterns of treatment.
Methods/design
Cross-sectional study. Lipid profiles of 50 RA out-patients from South Spain were compared with 50 age and sex matched controls from Central Mexico. Traditional risk factors were analyzed such as overweight or obesity, smoking status and hypertension. Glucose and lipid profiles as well as dietetic habits and physical activity were recorded.
Results
RA patients from Spain were more likely to practice physical activity (66.7% vs 33.3%; $P = 0.001$), had lower BMI (24.9 ± 4.6 kg/m^2 vs 26.7 ± 3.6 kg/m^2; $P = 0.004$). No significant differences in smoking status, prevalence of diabetes (steroid induced diabetes or type 2 diabetes), alcohol consumption or mean dose of steroid treatment were found. Regarding to lipid profile, Mexican patients had lower levels of LDLc (86 ± 31.5 vs 128.7 ± 24.9 mg/dl; $P < 0.001$) In contrast, the European population had lower levels of triglycerides (124.9 ± 14.6 vs 145.3 ± 3.6 mg/dl; $P < 0.001$) and higher HDLc (60.5 ± 12.8 vs 52.1 ± 21.4; $P < 0.005$).
Conclusions
In patients with RA, exercise can modulate lipid profile favourably irrespective of corticoid dose or steroid induced diabetes. More accurate studies focusing on specific nutrients would be useful to confirm our results.

Oxidative stress and metabolic profiles assessment after melatonin and irbesartan co-administration in a novel pharmaceutical formulation

Cristina Manuela Dragoi, Alina Crenguta Nicolae, Daniela Elena Popa, Ion-Bogdan Dumitrescu, Andreea Letitia Arsene, Corina Grigore & Cristina Elena Dinu-Pirvu
University of Medicine and Pharmacy 'Carol Davila', Faculty of Pharmacy, Bucharest, Romania.

The concurrence of glucose intolerance, hypertension, dyslipidemia and obesity has been termed metabolic syndrome. Each component of the metabolic syndrome is an independent risk factor for cardiovascular disease and diabetes type 2, the combination of these risk factors elevating the rates and severity of cardiac pathology.
The therapeutic use of irbesartan, a selective blocker of the AT1 receptors, administered in arterial hypertension, coronary heart disease and diabetic nephropathy, is extremely important due to the presence of these receptors both centrally and in the periphery.
Melatonin is an endogenous indoleamine hormone synthesized by the pineal gland. Melatonin release into the circulation is augmented in darkness and decreased during exposure to light, and facilitates the synchronization of the body's physiologic systems to circadian patterns. Melatonin shows properties of a powerful antioxidant, at sufficiently high concentrations as a direct radical scavenger, but, at lower, near-physiological levels, as a regulator of redox-relevant enzymes, suppressor of prooxidant excitatory and inflammatory processes and as a mitochondrial modulator. Increased oxidative stress has emerged as playing a central role in metabolic syndrome and its component pathologies and may be a unifying factor in the progression of this disease.
In the present study, we evaluated in a hamster experimental model, the influence of irbesartan and melatonin, co-administered in a novel pharmaceutical multiparticulate formulation, on metabolic markers and oxidative profile. Our results depicted blood glucose, serum cholesterol and triglycerides lowering effects, being maximum for the new formulation irbesartan and melatonin, revealing a potentiating effect of the two drugs. On the oxidative status, the new formulation presented a tremendous decreasing effect, due to the simultaneous release in the bloodstream the two medicines, depicting a synergic unique effect, reasoning the use of the two molecules in a single pharmaceutical formulation.

The dual FXR/TGR5 agonist INT-767 counteracts nonalcoholic steatohepatitis and visceral adipose tissue dysfunction in a rabbit model of high fat diet-induced metabolic syndrome

Paolo Comeglio[2], Ilaria Cellai[2], Sandra Filippi[1], Annamaria Morelli[5], Erica Sarchielli[5], Luciano Adorini[4], Mario Maggi[2,3] & Linda Vignozzi[2,3]
[1]Interdepartmental Laboratory of Functional and Cellular Pharmacology of Reproduction, Department of Neuroscience, Phychology, Drug Research and Child Care, University of Florence, Florence, Italy; [2]Sexual Medicine and Andrology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy; [3]I.N.B.B., Rome, Italy; [4]Intercept Pharmaceuticals, New York, USA; [5]Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy.

The nuclear Farnesoid X receptor (FXR) and the G protein-coupled bile acid receptor 1 (TGR5) are bile acids receptors that play a key role in energy metabolism. In an animal model of non-genomic metabolic syndrome (MetS), obtained with a high fat diet (HFD), treatment with the dual FXR/TGR5 agonist INT767 reduced visceral adipose tissue (VAT) accumulation, insulin resistance, hypercholesterolemia and nonalcoholic steatohepatitis (NASH). In liver, INT767 reduced the high macrophage M1 (pro-inflammatory)/M2 (anti-inflammatory) ratio observed in MetS. Furthermore, INT767 increased the expression of: IL10 and FOXP3, markers of M2 macrophage and Treg cell, respectively; PPARα, marker of hepatic fatty acid metabolism; VAMP4 and Syntaxin5, markers of lipid droplet formation; IRS1 and STAMP2, markers of insulin signaling while decreased lipogenesis markers. Moreover histomorphological sign of NASH were significantly improved by INT767.
MetS induced insulin resistance, which shows VAT derangements like adipocytes hypertrophy and reducted GLUT4 translocation to membrane. Treatment with INT767 counteract these VAT alterations and induced the expression of brown adipocytes markers. The analysis of preadipocytes (rPADs) obteined from INT767-treated rabbit and HFD rabbit revealed that INT767 improved insulin sensitivity and mitochondrial ultrastructure and dynamic whereas reduced superoxide production. In rPADs, when compared to HFD, INT767 increased the expression of CIDEA and TMEM (brown fat markers); TFAM and NRF1 (mitochondriogenesis markers); SDHB (membrane respisatory chain marker) and MFN2 and FIS1, (mitochondria fusion/fission markers).
To conclude, INT767 significanlty improves NASH and VAT alterations induced by HFD, restoring insulin sensitivity and inducing the differentiation of rPADs to a metabolically healthy phenotype.

Prevalence of metabolic syndrome and its relation to physical activity and nutrition in Azerbaijan

Afruz Mammadova[1,2], Selen Yilmaz İşikhan[3], Aylin Acikgoz[4] & Okan Bulent Yildiz[1,5]
[1]Department of Internal Medicine, Hacettepe University School of Medicine, Ankara, Turkey; [2]Azerbaijan Medical University Therapeutic Training Clinic, Baku, Azerbaijan; [3]Department of Biostatistics, Hacettepe University School of Medicine, Ankara, Turkey; [4]Department of Nutrition and Dietetics, Faculty of Health Sciences, Hacettepe University, Ankara, Turkey; [5]Division of Endocrinology and Metabolism, Hacettepe University School of Medicine, Ankara, Turkey.

Aim
Metabolic syndrome is a major public health challenge associated with an increased risk for cardiovascular disease and type 2 diabetes. The prevalence of metabolic syndrome in Azerbaijan is unknown. The purpose of this study was to examine the prevalence of metabolic syndrome and its relation to physical activity and nutrition in a representative sample of adult population in Azerbaijan.
Methods
The study population consisted of 288 adults, 20 years of age and over, from Guba, Azerbaijan recruited between January and April of 2016 by random sampling in line with the gender and age distribution.
Revised NCEP/ATP III criteria were used to define metabolic syndrome and prevalence estimates of each individual component were determined. Physical activity and food consumption were assessed with validated questionnaires and their relations with components of metabolic syndrome were evaluated.
Results
The participants were 159 women and 129 men (mean $\pm$s.d. age of 43.1 $\pm$ 15.2 y (range 20–83 y)). Overall prevalence of metabolic syndrome was 28.4%. Abdominal obesity was the most common individual component (49% and 85.4% in whole population and in those with metabolic syndrome respectively). Interestingly, it was also the only component that was more common in women than men ($P<0.05$ for both whole population and patients with metabolic syndrome) whereas the other components did not show a gender difference. The odds ratio for having metabolic syndrome was 0.56 (95% CI, 0.34–0.95) in moderate-high physical activity group compared to low physical activity group suggesting a reduced risk of metabolic syndrome with increased physical activity. Total calorie intake, protein, fat and carbohydrate consumption did not show a significant difference in participants with and without metabolic syndrome.

Conclusions
Metabolic syndrome in Azerbaijan is common and associated with low physical activity. Preventive measures should be taken to address this public health problem and related risk factors in the country.

Isolated low HDL-Cholesterol in patients with type 2 diabetes about 168 cases

El Ansari Nawal, Habra Bahia & El Mghari Ghizlane
Endocrinology, Diabetes and Metabolic Diseases Mohammed the 6th University Hospital, Faculty of Medicine, Cadi Ayyad University, Marrakesh, Morocco.

Introduction
Lipid abnormalities in diabetics both quantitative and qualitative contribute to the increased cardiovascular risk.
Aim
The aim of this study is to determine the prevalence of isolated hyoHDLémie in type 2 diabetics and assess cardiovascular risk in two populations of type 2 diabetes with and without Low HDL-Cholesterol isolated.
Patients and methods
Prospective study started in diabetic patients seen in diabétologic consultation at the University Hospital of Marrakech.
Preliminars Results
One hundred and sixty eight patients were identified, 72% female, The average age of patients was 55 years, average duration of diabetes was 7 years, hyoHDLémie was found in 40.4% of cases (68 patients), the prevalence of isolated hyoHDLémie is estimated at 26.19% (44 cases), with overall cardiovascular risk estimated at more than 20% in the group of patients with isolated Low HDL-Cholesterol.
Discussion
Lipid disturbances are widely studied in diabetic patients, but few studies have examined the Low HDL-Cholesterol isolated. In diabetic patients, current treatment guidelines target low-density lipoprotein cholesterol (LDL-C) with statins. In patients with elevated TGs, non-HDL-C is considered a secondary target of therapy. Despite the use of statin therapy in diabetes, a significant number of fatal and nonfatal coronary heart events still occur, indicating the need to target other modifiable risk factors for coronary heart disease, including Low HDL-Cholesterol. This study shows a high prevalence of isolated diabetics correlated with cardiovascular risk also important that the interests of the target Low HDL-Cholesterol by lipid-lowering therapy to reduce cardiovascular morbidity and mortality in diabetics.

Can hypoglycemic episodes in type 1 diabetics trigger cardiac arrhythmias?

Kelly Regina Lainetti, João Pimenta, Márcio Faleiros Vendramini & José Luiz B. Cassiolato
Hospital do Servidor Público Estadual, São Paulo/SP, Brazil.

Type 1 diabetes mellitus (DM1) accounts for 5 to 10% of DM cases, and can occur both in childhood and adults. Studies show an association between severe hypoglycemia and increased vulnerability to cardiac arrhythmias due to conduction disorders, interval ST-segment changes, and even sudden death. The aim of this study is to evaluate the occurrence of cardiac arrhythmias during episodes of hypoglycemia. A prospective study with DM1 patients under insulin therapy for at least 5 years, aged 18–60 years, of both sexes. Before study initiation, all patients underwent a two-dimensional echocardiogram and laboratory tests, and those who did not present structural heart disease or any hormonal alterations that could cause arrhythmias, were included. The study was approved by the Research Ethics Committee of the Institution and after signed the Informed Consent Forms, the intermittent interstitial glucose reading device (IPro2 - Medtronic/USA) was implanted and simultaneous electrocardiographic recording was performed by the Holter system (Cardios Systems/Brazil). The patients were monitored for hypoglycemia (defined as interstitial glucose value <70 mg/dl according to the International Diabetes Federation without any induction for this occurrence and arrhythmia detection for 24 hours. Twenty-two patients were studied. From these eight patients (36.3%) did not have hypoglycemia: two patients (25%) also had no arrhythmia, while six patients (75%) had arrhythmias interpreted as non-significant. Hypoglycemic events were detected in the other 14 patients (63.7%), corresponding in this scenario from 4% (55 minutes) to 68% (16 hours) of total monitoring time. In this group, seven patients (50%) presented no arrhythmia, while the other seven patients (50%) had some non-significant arrhythmia that is common in non-diabetic subjects, being more prevalent as ventricular and supraventricular extrasystoles, isolated/paired with low frequency and sinus tachycardia. In the evaluated group, we find no relation between episodes of hypoglycemia and clinically relevant cardiac arrhythmia.

Family hypercholesterolemia: about 4 cases

Aicha Bouzid & Djamila Mineesk
Dr, Algiers, Algeria.

Familial hypercholesterolemia (HF) is a rare hereditary dyslipidemia characterized by a major elevation of LDLc, cutaneo-tendinous xanthomas and atheromatous manifestations. This anomaly exposes a high vascular risk, more than 50% for men and 30% for women, occurring early.
Observations
We report four cases of HF from the same family, three girls and one boy and whose parents are affected by hypercholesterolemia. The average age of patients is 11 years. Only the eldest siblings present tendon xanthomas. The mean total cholesterol is 3.45 g/l, the average LDLc is 2.80 g/l, the mean HDLc level is 0.37 g/l, the average triglyceride level is 1.30 g/l. The search for vascular and cardiac repercussions was negative outside aortic narrowing in the elder. For lack of means the genetic diagnosis could not be made.
Discussion
Xanthomas were the main manifestation in this family. The presence of these clinical signs led to the prescription of a biological check-up in search of a lipid perturbation and of early vascular pathologies. Familial hypercholesterolemia results from a lack of binding and internalization of LDL through the LDL receptor. Identification of the mutation should be systematically performed. Genetic diagnosis provides diagnostic certainty and facilitates family screening.

Description of an educational intervention lifestyle program in reducing cardiovascular risk factors

Eduardo Oliveira
Universidade Estadual do Pará, Belém, Pará, Brazil.

Goals
The purpose of this article is to describe an educational program of lifestyle intervention rather successful, taught for 25 groups of customers of a private hospital in Amazon, for a total of 2,215 individuals between 2008 and 2014, 1448 being female and male 767 and briefly assess its results in relation to some of the main risk factors.
Methods
The PVS - Programa Vida Saudável, promotes evaluations and individual and group counselling, consisting of two phases, the first being, with eight meetings of the group with the multidisciplinary team in 12 weeks, followed by the second phase, with monthly meetings during 52 weeks for a total of 15 months. Clinical evaluations occur with individual counselling and laboratory dosages at the beginning and end of each phase, as well as an assessment of reaction to the end of each of the sessions. The goals of the intervention were presented progressively and easy to perform encouraging the adoption of habits and health principles, widely established.

Results
We analyse those who obtained 75% or more of the meetings frequency ($n=1723$) in 15 months and as controls, those who did the assessments and exams, however, did not participate in the educational program ($n=132$). Preliminary results showed a significant evolution in the percentage of each risk factor in patients with blood glucose reduction, improvement in cholesterol, with reduction in LDL-c reduction in triglycerides, reduction in blood pressure and weight reduction.
Conclusion
Based on studies of the data, this program of health education (PVS) presented a good adhesion of the customers and proved to be effective to reduce the risk levels in its active participants.

Role of lactate dehydrogenase-A (LDH-A) in atherosclerosis

Keun Gyu Park, Yeon Kyung Choi, Kwi Hyun Bae & Jung Beom Seo
Kyungpook National University Hospital, Dae Gu City, Republic of Korea.

Pathological proliferation and migration of vascular smooth muscle cells (VSMCs) has been implicated in the pathogenesis of accelerated atherosclerosis in patients with diabetes mellitus. Increased aerobic glycolysis is a key feature of cellular phenotypes including cancer and immune cells. However, it remains largely unknown about the role of aerobic glycolysis in atherogenic phenotype of VSMCs. Here, we investigated the role of lactate dehydrogenase-A (LDH-A), which is a key enzyme for glycolysis, on proliferation and migration of VSMCs. Activation of VSMCs with platelet-derived growth factor (PDGF) or fetal bovine serum (FBS) resulted in cellular proliferation and migration and increased glycolytic activity accompanied by the increased expressions of glucose transporter 1 (GLUT1), hexokinase (HK) 2 and LDH-A in primary rat VSMCs. Through wound healing assay, actin stress fiber staining and transwell migration assay, we observed that both pharmacological inhibition (oxamate) and siRNA-mediated knockdown of LDH-A (siLDH-A) effectively inhibited cellular migration. Oxamate reduced PDGF stimulated glucose uptake, lactate production, ATP production and NAD/ nicotinamide adenine dinucleotide (NADH) ratio. Nicotinamide mononucleotide (NMN), nucleotide precursor of NAD+, partially but significantly recovered oxamate treatment or siLDH-A induced inhibition of VSMC proliferation and migration, suggesting NAD+ involvement in LDH-A mediated VSMC proliferation and migration. Taken together, this study shows that enhanced aerobic glycolysis in PDGF- and FBS-stimulated VSMCs plays an important role in their proliferation and migration and suggests that LDHA can be a potential therapeutic target for the prevention of vessel lumen constriction in the course of atherosclerosis or restenosis.

Prediction of type 1 diabetes in autoimmune polyglandular syndrome type 2

Anara Karaca, Nese Ersoz Gulcelik, Tulay Omma, Isilay Taskaldiran, Sevde Nur Firat & Nujen Bozkurt
Ankara Teaching and Research Hospital, Endocrinology and Metabolism, Ankara, Turkey.

Introduction
Autoimmune Polyglandular Syndrome (APS) is a very rare endocrinopaty, characterized by the coexistence of at least two glandular autoimmune mediated diseases. In this case a patient presented with hyperpigmentation of the whole body, significant weight loss for last 6 months.
Case
A-49 year old male were refered to our deparment with loss of appetite, fatigue, nausea, weight loss and with marked buccal pigmentation. Blood pressure was 80/50 mmHg. Biochemistry revealed fasting glucose:95 mg/dl, Na:127 mmol/l, K:5.35 mmol/l, Hb:16.6. CT abdomen showed normal adrenal gland morphology with no local masses or infectious pathology. Pituitary MRI demonstrated enlarged heterogeneous gland with 9 mm height, probably due to high ACTH levels. All findings were consistent with Addison disease, which was confirmed with morning cortisole of 2.44 mg/dl (normal range 6–22), ACTH: 1250 pg/ml (0–46).
Once Addison's disease had been confirmed, other autoimmune diseases regarding APS were undertaken. Subclinic hypothyroidism with automimmune thyroiditis; TSH:8 (0.4–5.3), fT_4: 0.9 ng/dl (0.6–1.25), anti-TPO:1016 IU/ml (0–9) was detected. Despite his normoglycemia; C-peptit:1.69 ng/ml, fasting insulin:22.3 uIU/ml, A1c:5.6%, he had high anti-GAD and anti-islet cell antibodies, widely used as a diagnostic and predictive tool for type 1 diabetes mellitus, indicating that he may develop type 1 diabetes mellitus in future.
After a week of steroid replacement his physical discomforts were alleviated with improved electrolytes.
Discussion and Conclusion
Herein, we reported an uncommon case, who had complete two-glandular deficiency with third component; predicted type 1 diabetes. This patient is being monitored closely on glycaemic state. Therefore, once an autoimmune disease is identified, the early screening for antibodies against associated disease such as anti-TPO, GADA, ICA, and antibodies to 21-hydroxylase is crucial, which facilitate the diagnosis of further disorder at an early stage.

Insulin autoimmune syndrome (Hirata Disease) triggered by a tyrosine kinase inhibitor drug in a Latin American patient

Susana Mallea Gil, Carolina Ballarino, Daniel Lotero Polesel, Maria Teresa Kleine, Emilio Batagelj & Nicolas Picon
Hospital Militar Central, Buenos Aires, Argentina.

Hirata syndrome is a rare cause of spontaneous hypoglycaemia, more prevalent in Japanese population, very infrequent in Caucasian patients. It has been described that it can be triggered by medication with sulfhydryl compounds or α-lipoic acid. A 73-year-old male patient was sent to the Endocrinology Division in December 2015 because he had been presenting with episodes of sweating, palpitations and feeling hungry for 6 months; these symptoms improved when he ate carbohydrates. In the last 15 days before his visit, the episodes worsened, every 3 hours. The patient had a history of a synchronous bilateral clear cell renal carcinoma, the right kidney was removed in 2007, and the left renal carcinoma was not surgically removed because he presented worsening of a large thoracoabdominal aortic aneurysm and the patient refused to be operated due to the high risk involved in this surgery. He was treated with sunitinib, but this drug was switched to sorafenib because of adverse effects in 2008. In 2013, he presented cancer progression and he began treatment with pazopanib but there was no response and the oncologist decided to switch to axitinib 10 mg/day in 2014. A year later the patient began with endocrine symptoms. Pancreatic CT and MRI were normal. Lab tests: glycaemia 41 mg%, insulin $>$ 1000 uU/ml (N: 0–12) C-peptide: 5.4 ng/ml (N: $<$ 2.6). Insulin antibodies were performed: $>$50 U/ml (N: $<$1) which confirmed the diagnosis of Hirata disease. Axitinib was stopped immediately and fractional eating was indicated. The hypoglycaemic episodes became progressively less frequent and some days there were no episodes. HLA analysis revealed the HLA-DRB1*04:15 allele. As the patient improved, insulin antibodies were repeated but they remained elevated. The patient had renal cancer progression and died a year after.
Conclusions
Episodes of hypoglycaemia with very high levels of insulin in a non-diabetic patient suggest a probable autoimmune origin. This is the first report of Hirata disease triggered by Axitinib, a drug not previously involved in this syndrome. Another novel finding is that HLA phenotype results in HLA-DRB1*04:15 allele, which has not been described before neither in Asian nor in European patients and this may be due to the fact that this patient is Latin American.

Fulminant diabetic ketoacidosis complicating nivolumab immunotherapy

Ploutarchos Tzoulis[1], Justin Stebbing[2], Elly Baker[1], Daniel Heaton[1] & Richard Corbett[1]
[1]Whittington Hospital, London, UK; [2]Imperial College/Imperial Healthcare NHS Trust, London, UK.

A 56-year-old woman, recently commenced on immunotherapy as second-line treatment for advanced non-small cell lung cancer, presented at the hospital critically unwell with severe diabetic ketoacidosis (DKA) (glucose 47 mmol/l, blood ketones 7.5 mmol/l, pH 6.95, bicarbonate 6.6 mmol/l). One week prior to presentation, she was clinically well with random glucose of 6.1 mmol/l. Following admission to Intensive Care Unit, she responded well to standard treatment for DKA and discharged on basal bolus insulin regime. Her anti-GAD antibodies were 12 kU/l (0–5 kU/l), while islet cell antibodies and serum C-peptide were undetectable. Nivolumab has been recommenced without the development of other immune-mediated phenomena to date.

Besides metastatic lung adenocarcinoma diagnosed 3 years ago, she had no personal/family history of diabetes mellitus (DM), while venous glucose had been normal at numerous measurements. She was initially treated with Pemetrexed and Cisplatin followed by Pemetrexed as maintenance chemotherapy which was discontinued due to side-effects two months prior to her emergency presentation. At that stage, Nivolumab every 2 weeks was initiated. She has maintained good radiological and clinical response to treatment.

Nivolumab is an anti-PD-1 monoclonal antibody and as a checkpoint inhibitor acts as an immunomodulatory antibody that augments the anticancer immune response through downregulation of T-cell inhibition. Immunotherapy has a beneficial effect in an increasing number of tumour sites, but is associated with immune-mediated endocrinopathies. Development of new-onset type 1 DM after receiving anti-PD-1 antibodies, especially as single agent, is extremely rare.

This patient developed fulminant type 1 DM leading to severe DKA and remains insulin dependent. Both endocrinologists and oncologists need to recognise this potentially life-threatening complication and to monitor patients for hyperglycaemia prior to and periodically during immunotherapy. Further studies examining the pathophysiology and natural history of immunotherapy-associated diabetes are warranted in order to guide optimal patient monitoring and management.

Dyslipidemia and antiretroviral therapy: a case report

El Meghari Ghizlane, Elbahi Meryam, Rafii Sana & El Ansari Nawal
Faculty of Medecine and Pharmacy, Marrakech, Morocco.

Introduction

The use of highly active antiretroviral therapy in 1996 helped greatly reduce the morbidity and mortality in patients infected by HIV. Very quickly, secondary metabolic complications to this same treatment have been described. Dyslipidemia occupy a large part of these complications and give the patients an atherogenic profile favouring the occurrence of acute coronary events. We report a case that illustrates the lipid abnormalities associated with anti retroviral treatment.

Case report

The subject was 54 years old woman, diabetic for 8 years, without history of hypertension or smoking, BMI was 29 Kg/m^2, diagnosed as HIV infected for 1 year, treated by antiretroviral therapy. Her initial lipid profile reveals a moderate hypertriglyceridemia of 2.5 g/l, total cholesterol was 1.7 g/l and HDL cholesterol was 0.3 g/l. High plasma viral loads persisted after 6 months of antiretroviral therapy, thus the patient was considered to have a treatment failure. The control of her lipid profil, after 2 months of a second-line combination therapy, reveals an aggravation of her previous dyslipidemia with a severe hypertriglyceridemia of 6.36 g/l, an hypercholesterolemia of 2.72 g/l and HDL cholesterol was 0.4 g/l.

Discussion

While the retroviral infection itself, especially at the AIDS stage, is responsible for an increase in triglycerides and a decrease in total cholesterol, antiretroviral therapy exacerbates abnormal lipid metabolism. This is mainly dyslipidemia with predominant hypertriglyceridemia, associated with an increase in total cholesterol and LDL-cholesterol; HDL-cholesterol is either lowered or slightly modified, these abnormalities are partly due to increased hepatic synthesis of large VLDL and decreased purification of remnants rich in triglycerids. The Knowledge of lipid abnormalities induced by antiretroviral treatment is critical for better patient management between infectiologist, biologist and endocrinologist.

Diabetic patient with suppurative thyroiditis caused by *Salmonella enterica* complicated with acute kidney injury

Aleksandra Hernik[1], Ewelina Szczepanek-Parulska[1], Bogusz Falkowski[1], Hanna Komarowska[1], Anna Wejman-Matela[2], Michal Drews[2] & Marek Ruchala[1]
[1]Department of Endocrinology, Metabolism and Internal Medicine, Poznan University of Medical Sciences, Poznan, Poland; [2]Department of General, Endocrine and Gastrointestinal Oncological Surgery, Poznan University of Medical Sciences, Poznan, Poland.

Incidence of acute thyroiditis is about 0.1% of thyroid gland conditions requiring surgical treatment. Main pathogen causing acute thyroiditis is *Staphylococcus aureus* while *Salmonella enterica* is extremely rare.

Herewith we report a 61-year-old obese woman with sore throat and fever. She had chronic atrial fibrillation, hypertension, and well-controlled type 2 diabetes mellitus (HbA1C 5.5%) for 3 years (on metformin and gliclazide). Her medical history was negative for thyroid and renal disorders. Ultrasound examination (US) of the neck demonstrated mixed solid/cystic lesion. Moreover, empirical therapy with clindamycin was introduced (1.2 g/day) and the patient was referred to the endocrinonogy department. On admission she was weakened and dehydrated. Physical examination revealed restricted, swollen, tender and painful lesion in the lower part of the neck. Laboratory tests indicated inflammation, acute kidney injury and hyperthyroidism. Fine-needle aspiration biopsy (FNAB) of the lesion was performed. Cytological diagnosis was consistent with acute thyroiditis, while microbiologically *Salmonella enterica* was identified as pathogenic factor. Blood and stool cultures were negative for *Salmonella*. Neck CT revealed thyroid lesion 6.8 cm in size. Patient received adequate therapy for acute kidney injury (most probably clindamycin-induced). I.v. treatment with ceftazidime according to antibiogram and thiamazole was administered. The patient was qualified for incision and percutaneous drainage. She was discharged after 11 days of hospitalization presenting significant clinical improvement. A year later on US six mixed solid/cystic lesions of size below 1 cm were visualized, benign on FNAB. She remains clinically and biochemically euthyroid. Typical infections with Salmonella concern gastrointestinal tract, while conditions associated with atypical infections are: HIV infection, transplant recipients, diabetes mellitus, thyroid gland disorders (e.g. multinodular goiter, after FNAB), anatomical abnormalities (piriform sinus fistula), corticosteroid therapy, advanced age, neoplastic disease and contact with breeding animals. The only risk factor for acute thyroiditis in our patient was diabetes mellitus, although it was well-controlled.

Improved xanthomas after leptin replacement short therapy in congenital lipodystrophy patient

Antonio F Oliveira-Filho[1], Irla A Dantas[4], Renata N Velloso[3], Sofia N P de Oliveira[2], Diego F F Candido[4] & Adriana Nunes[3]
[1]Paraiba Health State Department, Campina Grande, Brazil; [2]Federal University Campina Grande, Campina Grande, Brazil; [3]Federal University Rio Grande Norte, Natal, Brazil; [4]Faculty of Health Sciences, Joao Pessoa, Brazil.

Berardinelli-Seip syndrome is an autosomal recessive disorder characterized by generalized lipoatrophy, extreme insulin resistance with dyslipidaemia in childhood and development of diabetes and hepatic steatosis in adolescence. The metabolic derangements can be severe and lead to substantial comorbidities, including acute pancreatitis, hepatic cirrhosis, and premature cardiovascular disease. Other manifestations can include polycystic ovarian syndrome, acanthosis nigricans, and eruptive xanthomas. Lipodystrophy syndromes have caught interest because adipose tissue has been found to secrete a variety of cytokines/hormones such as leptin, adiponectin, resistin, and many others. Here we describe a dramatic response to treatment with leptin. A 15-year-old girl was given the diagnosis of Berardinelli-Seip congenital lipodistrophy syndrome (BSCL). She presented generalized lipoatrophy, muscle hypertrophy, xanthomas in elbows legs and soles, umbilical hernia, hirsutism, hyperphagia, acanthosis nigricans and hepatomegaly. Her BMI was 20.67 kg/m^2, body fat was 5.72%, and BMR was 1 440.3 Kcal. Computer tomography revealed hepatic steatosis, one cyst on the right kidney, and absence of subcutaneous and adipose tissues. Patient had difficult to manage metabolic parameters, requiring 300U of insulin and combined therapy. She started a leptin-replacement therapy (1 ml/day). After ten days, her xanthomas became vanished, cholesterol levels decreased from 550 to

196 mg/dl, and triglycerides 5.000 to 840 mg/dl. She observed progressive reduced fasting blood glucose and insulin dose simultaneously with improvement in clinical signs, symptoms and quality of life. In a ten days course, leptin replacement showed to be able to manage metabolic state of the patient and xanthomas.

Resistant hypertension in an obese type 2 diabetic male with obstructive sleep apnea: resolution with CPAP, weight loss and Dulaglutide

Claudia Arnas-Leon[1], Ana Delia Santana-Suarez[1], Alba Rodriguez-Perez[2], Manuel Nivelo-Rivadaneira[1], Agnieszka Kuzior[1], Sara Quintana-Arroyo[1], Carmen Acosta-Calero[1] & Francisco Javier Martinez-Martin[1]
[1]Endocrinology and Nutrition, Hospital Doctor Negrin, Las Palmas de Gran Canaria, Spain; [2]Internal Medicine, Hospital Doctor Negrin, Las Palmas de Gran Canaria, Spain.

A 49-year-old male was referred to our Hypertension Clinic with uncontrolled hypertension, treatment Valsartan/Amlodipine/Hydrochlorothiazide 80/10/25 mg + Doxazosine 4 mg. Mean home BP was 156/103 mmHg. Personal history: dyslipidaemia, central obesity and type 2 diabetes, with mild diabetic retinopathy, persistent microalbuminuria and preserved renal function. Treatment: Metformin/Sitagliptin 1000/50 mg BID; Pravastatin/Fenofibrate 40/160 mg. Height 172 cm, weight 112 kg, BMI 37.8 kg/m^2, waist 126 cm, clinic BP 165/99, HR 77; unremarkable physical exam except abdominal adiposity. Glycemia 132 mg/dl, HbA_{1C} 7.2%, Cr 0.92 mg/dl, GFR (CKD-EPI) 97 ml/min per 1.73 m^2, Cholesterol 166 mg/dL (HDL 38, LDL 96), Triglycerides 161 mg/dl, Albuminuria 126 mg/g Cr; TSH, Metanephrines, Aldosterone, PRA and ratio were normal. Heart US: normal function, mild LVH (PW and IVW 14 and 13 mm). 24 h. ABPM: Awake BP 157/96, Sleeping 146/89, non-dipper.
The treatment changed to Perindopril/Indapamide 8/2.5 mg, Eplerenone 50 mg and Doxazosine 4 mg. Four months later, the patient had lost 2.5 kg with diet/exercise, but BP and HbA_{1C} had not improved. Dulaglutide 1.5 mg/week was substituted for Sitagliptin. The patient's wife reported heavy snoring with apparent pauses, and the patient was referred to polysomnography. A severe OSA was diagnosed, and CPAP was initiated.
Six months later, weight was 98.5 kg (IMC 33.1 kg/m^2); waist 114 cm, and home and office BP were normal. New ABPM: Awake 132/76, sleeping 116/69, dipper. Glycemia was 114 mg/dl, HbA_{1C} 6,7%, Cr 0.91 mg/dl, GFR 98 ml/min per 1.73 m^2, Chol. 153 mg/dl (HDL 43, LDL 79), Trigl. 156 mg/dl, Albuminuria 23 mg/g Cr. New heart US: PW and IVW 11 and 10 mm.
The diagnosis was resistant hypertension with target-organ damage (albuminuria, LVH) associated to OSA, plus type 2 diabetes, central obesity, and dyslipidemia. With CPAP, weight loss and Dulaglutide, BP and glycemic control were achieved and target-organ damage was reversed.

Morgagni-Stewart-Morel Syndrome in a 61-years patient: case report

Mihaela Stanciu
Lucian Blaga University of Sibiu, Sibiu, Romania.

Introduction
Morgagni-Stewart-Morel syndrome is a disorder defined by the presence of internal frontal hyperostosis, variably associated with metabolic disorders, endocrine and neuropsychiatric disorders. Hyperostosis frontalis interna (HFI) is a morphological change of the frontal bone like a single or multiple bilateral nodules on the inner lamina, characteristically sparing the diploë and the midline calvaria.
Case presentation
We present a 61-years old women with hypertension and diabetes mellitus (with oral antidiabetic therapy), obesity, osteoporosis; also the patient was operated in 2005 for a multinodular goiter (total thyroidectomy), treated with L-thyroxin 100 μg per day. She was referred to our department for severe frontal headache which she had suffered for several years, with gradually worsened, failing to respond to nonsteroidal anti-inflammatory drugs in last six months and a history of psychotic disorders. MRI demonstrated the internal hyperostosis frontalis with compression of the cerebral cortex and a small image in the pituitary gland, which is now under observation.
Conclusions
The clinical features of this syndrome was according to those described in the literature. Metabolic and endocrine disorders should not be interpreted as isolated pathology, but as possible pathogenetic factors. We underline the essential role of MRI in detecting the disease correlated with intense headache. The neurological symptoms and psychiatric symptoms were correlated with the severity of internal frontal hyperostosis and cortical atrophy.

Continuous glucose monitoring in glycogen storage disease type Ia – a major improvement for patients

Diana Martins[1], Diana Oliveira[1], Carla Baptista[1], Sandra Paiva[1], Nuno Vicente[1], Luís Cardoso[1], Adriana Lages[1], Mara Ventura[1], Nelson Cunha[1], Sónia Moreira[2], Hugo Clemente[2], Helder Esperto[2] & Francisco Carrilho[1]
[1]Department of Endocrinology, Diabetes and Metabolism of Coimbra Hospital and Universitary Centre, Coimbra, Portugal; [2]Department of Internal Medicine of Coimbra Hospital and Universitary Centre, Coimbra, Portugal.

Introduction
Glycogen storage disease (GSD) type Ia (von Gierke's disease) is an inherited metabolic disorder of glycogen metabolism, caused by defects in the glucose-6-phosphatase complex, with associated risk of severe hypoglycemia within 3–4 h after a meal.
The aim of the present study was to evaluate the efficacy of continuous glucose monitoring (CGM) system in determining the magnitude of hypoglycemia in patients with GSD type Ia.
Methods
We retrospectively analyzed data from three patients with GSD type Ia, who underwent CGM with iProTM2 CGM device (Medtronic, Northridge, CA), over a 7.0 days period, under real life conditions.
Results
A total of 5.520 glucose data points were analysed. Concerning to low glycemic excursions (<70 mg/dl), we identified 15 episodes (three of them below 55 mg/dl and reaching 40 mg/dl in one case). Most of the episodes of hypoglycaemia were asymptomatic and occurred 3 or more hours after meals or during the nocturnal period. The individual CGM analysis revealed a mean area under the curve of blood glucose below 70 mg/dl (AUC<70) respectively of 0.1, 0.5 and 0.8. One patient presented with important glycemic variability: MAGE 3.11 (reference range 0.0–2.8).
Conclusions
The analysis of continuous glucose monitoring data revealed significant periods of asymptomatic hypoglycemia and provided better perception into glycemic variations therefore, it may serve as a safe and useful tool for the long-term management of patients with GSD type Ia. We suggest that CGM can be used as an instrument to detect hypoglycemia, especially in the nocturnal period, helping patients with GSD to modify their nutritional regimens if necessary.

Diabetes mellitus: one train may hide another

Sara Vandewalle[1,2], Nike Van Doninck[1] & Peter Coremans[1]
[1]AZ Nikolaas, Sint-Niklaas, Belgium; [2]Ghent University Hospital, Ghent, Belgium.

A 26-year-old Chinese male with autism spectrum disorder and mental retardation, was referred to start insulin therapy for uncontrolled diabetes mellitus (DM) (HbA1c: 9%; C-peptide: 1.75 ng/ml; anti-GAD AB: negative) treated with oral antidiabetic drugs since 2012.
Clinical examination revealed a tall man with overweight and truncal obesity in light of his ethnicity. We withheld facial dysmorphism with hypertelorism, scarce facial hair, and clinodactyly. He had a true gynaecomastia and acanthosis nigricans. Tanner genital stage was IV, however testicular volume was <4 ml. Blood results showed hypergonadotropic hypogonadism (LH:14.1 U/L, FSH:25.3 U/L, testosterone: 195 ng/dl, free testosterone: 5.71 ng/dl). Additional genetic testing showed 48 XXYY karyotype.

Based on medical questionnaires, DM is described in 18% of 48 XXYY males. Following pathophysiological mechanism is proposed: low tota l and free testosterone levels are associated with truncal obesity leading to metabolic syndrome, insulin resistance and DM. Abdominal obesity and high C-peptide levels in our patient are arguments in favor of insulin resistance as possible etiological factor. Based on the pathophysiology, metformin and testosterone could be considered as therapy. Our patient was initially treated with basal-bolus insulin therapy in combination with metformin to enhance insulin sensitivity. Although in-hospital blood glucose curves were perfect, global metabolic control remained poor (HbA1c: 8.5%) due to compliance problems partially by the complexity of treatment. Therefore therapy was simplified to a combination of basal insulin and metformin. Metabolic control remained however poor. Some data suggest that testosterone treatment might improve metabolic control by increasing skeletal muscle mass and decreasing abdominal obesity. In our patient, there was however no amelioration of metabolic control after start of testosterone. Adequate DM therapy is complicated by mental retardation seen in 48 XXYY making it difficult to use complex insulin schemes. It seems reasonable to use metformin in treatment as insulin resistance seems to play a role in the pathophysiology.

Endocrine manifestations of Woodhouse-Sakati Syndrome – a Portuguese case

Diana Oliveira[1], Sandra Paiva[1], Pedro Louro[2], M Carmo Macário[3], João Durães[3], Diana Martins[1], Mara Ventura[1], Adriana Lages[1], Nelson Cunha[1] & Francisco Carrilho[1]
[1]Endocrinology, Diabetes and Metabolism Department, Coimbra Hospital and University Center, Coimbra, Portugal; [2]Medical Genetics Unit, Coimbra Hospital and University Center, Coimbra, Portugal; [3]Neurology Department, Coimbra Hospital and University Center, Coimbra, Portugal.

Introduction
Woodhouse-Sakati Syndrome (WSS) is a very rare autossomic recessive disorder caused by mutations in *DCAF17* gene that primarily affects the endocrine and the nervous systems. It is associated with hypogonadism, diabetes *mellitus*, hypothyroidism, sensorineural hearing loss, alopecia and extrapyramidal findings. Treatment is symptomatic and managed by multidisciplinary teams. Less than 80 cases are reported to date.
Case report
We describe a 29-year-old woman with dysmorphic facial features, alopecia, mild intellectual disability and sensorineural hearing loss, referred to the Endocrinology department for primary hypothyroidism with negative thyroid autoantibodies, hypergonadotrophic hypogonadism with ovaries not visualized on pelvic ultrasound and diabetes mellitus diagnosed at 19 years of age. She was under treatment with levothyroxine, drospirenone + ethynyl estradiol and oral glucose lowering agents. Worsening of metabolic control led to start of insulin therapy. Week positivity for Islet-cell cytoplasmic autoantibodies and positive glutamic acid decarboxylase autoantibodies were detected. IGF1, GH, prolactin, cortisol and ACTH were normal. Progressive neurologic deficits included dysarthria, dysphagia, lower limb dystonia and spastic tetraparesis. Brain MRI showed generalized leukodystrophy. She was the only child of a consanguineous couple. Common genetic, metabolic and mitochondrial disorders were excluded. WSS was suspected. Sequencing of *DCAF17* gene detected the homozygous variant c.1091 + 2T > C, not previously described in literature. However, since it affects the splice donor site of intron 10 and probably causes exon 10 skipping, it is likely to be pathogenic.
Discussion
When in presence of several endocrine disorders associated with multisystem involvement, it is fundamental to look for genetic disorders. Accurate clinical evaluation allows genetic diagnosis and counseling. A new homozygous variant of the DCAF17 gene was found in this case. The pathogenic mechanisms of the disease are still unclear; diabetes-related autoimmunity is not found in previously described cases. Also unlike other described cases, IGF1 was within normal limits. Endocrine consequences of WSS need frequent follow-up.

EP395

Hypoglycaemia due to hydroxychloroquine in a patient who underwent Roux-en-Y gastric bypass surgery

Kamrudeen Mohammed & Altayeb Abdalaziz
Hull Royal Infirmary, Hull, East riding of Yorkshire, UK.

A 45-year-old female presented with recurrent episodes of neuroglycopaenic symptoms 6 years after Roux-en-Y gastric bypass surgery. Her symptoms occurred during both the fasting and postprandial state. She had a history of Rheumatoid Arthritis. Her symptoms did not response to a complex carbohydrate diet or Acarbose use.
Whipple's triad was demonstrated during a 72 h fast; symptomatic hypoglycaemia (1.8 mmol/l) occurred which resolved with glucose administration. Simultaneous C-peptide, IGF1, IGF2 and insulin samples were requested during the hypoglycaemic episode.
The Insulin level was 10 pmol/l, IGF1 level was 11.6 nmol/l, the IGF2 level was 36.3 nmol/l, IGF2/I ratio was 3.1 (< 10), C-peptide level was < 94 pmol/l, GH was 7.5 μg/l and Sulphonlylurea screen was negative.
Ketones was 'Zero' confirming an insulin independent mechanism for hypoglycaemia. Hydroxcholoroquine for Rheumatoid Arthritis was discontinued which led to complete resolution of her symptoms.
This is the first case of severe hypoglycaemia in a patient who did not have diabetes, who underwent bariatric surgery and developed hypoglycaemia due to hydroxycholoroquine therapy with complete resolution of symptoms on discontinuing hydroxychloroquine.
This case demonstrates the need for a structured approach to the evaluation of hypoglycaemia. Roux-en-Y gastric bypass surgery is associated with subsequent development of hypoglycaemia which can respond to a complex carbohydrate diet or acarbose therapy. The lack of response however should prompt a thorough evaluation. The demonstration of an insulin independent mechanism for hypoglycaemia excluded post gastric bypass hypoglycaemia as a cause and prompted a review of the medication list. Hydroxcholoroquine is associated with the development of hypoglycaemia and cessation resulted in complete resolution of symptoms which were occurring at a frequency of 3–4 times per week resulting in termination of employment and driving.

A case report of insulin autoimmune syndrome in a Caucasian

Jaroslaw Jendrzejewski, Lukasz Obolonczyk, Martina Leczycka & Krzysztof Sworczak
Medical University of Gdansk, Gdansk, Poland.

The Insulin Autoimmune Syndrome (IAS) also called Hirata's disease consists of hypoglycemia, high insulin concentration and presence of anti-insulin antibodies. IAS is the third leading cause of spontaneous hypoglycemia among Japanese population. The syndrome is exceptionally rare among Caucasians, with < 50 cases described in literature.
In this report we showcase a 67 year-old female patient. She presented with paroxysmal sweating, daily fatigue and weakness with no triggering factors for these symptoms. Her blood glucose levels during those episodes were below 50 mg% measured by using a standard home glucometer device. Prolonged 72 h fast test showed extremely high insulin-glucose-ratio with moderate elevation of C-peptide levels. CT scans did not reveal any significant masses in the abdomen. The subsequent laboratory analysis showed high levels of anti-insulin antibodies with low insulin recovery by using polyethylene glycol precipitation method. After treatment with low glycemic index diet and prednisone the average glycemia has increased with the remission of the symptoms. There have been no incidents of hypoglycemia since the establishment of the treatment.
Our report indicates that at IAS should be considered in the differential diagnosis of spontaneous hypoglycemia in Caucasians. The treatment might lead to the remission of the symptoms.

Acquired generalized lipodystrophy associated with latent autoimmune diabetes mellitus in adults: a new metabolic phenotype

Federica Ferrari[1], Marianna Maranghi[2], Giovanni Ceccarini[1], Silvia Magno[1], Caterina Pelosini[1], Margherita Maffei[1], Paolo Vitti[1], Marcello Arca[2] & Feruccio Santini[1]
[1]Obesity and Lipodystrophy Center at the Endocrinology Unit, University Hospital of Pisa, Pisa, Italy; [2]Department of Internal Medicine, Medical Specialties, University La Sapienza, Rome, Italy.

Introduction
Acquired generalized lipodystrophies (AGL) are rare syndromes characterized by complete loss of subcutaneous adipose tissue and very low serum leptin levels.

AGL are complicated by severe insulin resistance, diabetes mellitus, dyslipidemia and fatty liver. In most patients evidence exists of an autoimmune etiology.
Case report
We herein describe the case of a Caucasian woman who was diagnosed with lipodistrophy at 5 years of age, when she began to develop a gradual loss of subcutaneous adipose tissue. At the age of 20 years insulin-resistance, hypertriglyceridemia and fatty liver were evident; diabetes mellitus was diagnosed when she was 28-years old, and 3 years after insulin therapy became necessary in order to improve metabolic control of the disease. Genetic testing were negative for PPARG and LMNA/C mutations, ruling out the principal forms of congenital lipodystrophies. She came to our attention at the age of 35 years. At clinical examination a generalized loss of subcutaneous fat that included the face and the extremities was observed. Laboratory tests showed a poor glicemic control. $HbA1_c$ was 85 mmol/mol on high doses of insulin (150UI/die). Nuclear, PMScl, Gastric Parietal Cell, and high titer Glutamic Acid Decarboxylase autoantibodies were detected.
Discussion
AGL are frequently associated with other autoimmune disorders. The coexistance with type 1 diabetes is very rare, but the association with a latent autoimmune diabetes mellitus in adults (LADA) has never been reported before. This association generates an unusual metabolic pattern characterized by severe insulin-resistance due to ectopic-lipid accumulation and severe diabetes due to an absolute insulinopenia. For these reasons the management of the metabolic syndrome in this case is extremely difficult and the association of insulin with human recombinant leptin therapy seems to be more efficient than conventional drugs. This case shows the need to screen all patients presenting with an AGL for associated autoimmune disorders including type 1/LADA diabetes.

Humalog Mix50® massive overdose for suicidal purpose: a case report

Daniel-Tudor Cosma[1], Cristina Alina Silaghi[2,5], Horatiu Silaghi[4,5], Mihaela Mocan[3,5] & Ioan Andrei Veresiu[1,5]
[1]Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj-Napoca, Cluj County, Romania; [2]Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; [3]1st Internal Medicine Department, Cluj-Napoca, Cluj County, Romania; [4]5th Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; [5]'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Intentional insulin overdose in diabetic patients is a rare critical situation. The severity is due to numerous neurological complications, electrolyte disturbances, liver and lung damage or death.
A 76-years old female, with significant cardiac pathology, diagnosed with type 2 diabetes and treated with Humalog Mix50® 0-0-24 U/day, is admitted to our center via ER (emergency room) after an episode of severe hypoglycemia after administration of 1500U Humalog Mix50. She arrived in the ER one hour after the overdose with a glycemic value of 111 mg/dl after 50 ml of glucose 33% and 500 ml 10% glucose. At admission: altered general status, profuse sweating, multiple injection sites across her abdomen and thighs. Labs exams revealed: hypocalcaemia, hypokalemia, slightly elevated creatinine and BUN, mild normochromic, normocytic anemia, A1c = 6.29%. An infusion of 10% glucose was begun at 1 L/h. The glucose infusion rhythm and concentration was adjusted according to the glycemic profile with a total duration of infusion of 46 h. Besides, multiple boluses of glucose 33% were needed to avoid the hypoglycemic events. Hypocalcaemia and hypokalemia were corrected by intravenous (i.v.) administration of calcium gluconate and potassium chloride. Psychological evaluation diagnosed depression and recommended a psychiatric consult. On day 3 since admission, the patient's general condition worsened significantly with severe hypotension (requiring continuous positive inotropic infusion), liver and renal failure and she was transferred to the ICU. Despite intensive care maneuvers, the patient died of cardiac arrest through electromechanical dissociation.
Insulin overdose requires intensive and prolonged glycemic monitoring to prevent recurrent hypoglycemia. The dose is correlated with a prolonged hypoglycemic risk higher than that deduced from the pharmacokinetics of insulin administered. To our knowledge this case represents the largest overdose with Humalog Mix50® ever reported.

EP399

Extensive venous thrombosis of the upper extremity in a newly diagnosed type 2 diabetic female

Daniel-Tudor Cosma[1], Cristina Alina Silaghi[2,5], Vlad Florin Bontea[3], Calin Homorodean[3,5], Horatiu Silaghi[4] & Ioan Andrei Veresiu[1,5]
[1]Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj-Napoca, Cluj County, Romania; [2]Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; [3]1st Internal Medicine Clinic, Cluj-Napoca, Cluj County, Romania; [4]5th Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; [5]'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Upper extremity deep vein thrombosis (UEDVT) is not infrequent and accounts for approximately 14% of deep vein thrombosis. The risk of pulmonary embolism is lower than in lower extremity DVT and prompt diagnosis is essential to select those patients who deserve anticoagulant treatment. Previous studies indicated that type 2 diabetes (DM) patients carried greater risk of DVT development or recurrence than the general population.
A 49-years old female, with no previous medical history, was admitted to our center via Emergency Room (ER) for optimizing glycemic control. At admission: altered general status, bradylalia, bradypsychia, generalized edema, marked fatigability, BP = 140/90 mmHg, pulse = 96 b/min, holosystolic murmur in the mitral area. Lab findings revealed: BG = 401 mg/dl, glycosuria (1 g/dl), proteinuria (300 mg/dl), low serum iron, mild normochromic and normocytic anemia, high INR and NT proBNP levels, hypocalcaemia, low HDL cholesterol, slightly elevated CRP, cholestasis syndrome and A1c = 14.01% was consistent with a sever glycemic imbalance in the last 3 months. Intravenous insulin infusion and few boluses were needed to correct the hyperglycemic values followed by initiation of a basal regimen with glargine insulin and metformin. On 3rd day since admission, edematous swelling and cyanosis of the right arm with collateral circulation at the shoulder girdle was observed. The echo-Doppler showed a massive thrombosis from brachial to the brachiocephalic and internal jugular vein and the CT pulmonary angiogram thrombi at the level of segmental arteries bilaterally. Treatment with LMWHs was initiated and the patient was transferred to the Cardiology department with a favorable outcome. The screening for thrombophilia emphasized hyperhomocysteinemia and a slightly elevated S protein activity.
Our case illustrates an extensive UEDVT and pulmonary embolism in a newly diagnosed type 2 diabetic patient. The modifications in the thrombophilia screening together with the hypercoagulable state induced by hyperglycemia might have led to the development of this extensive UEDVT.

Early association of three autoimmune disorders in a young male with polyglandular autoimmune syndrome type IIIA

Daniel-Tudor Cosma[1], Cristina Alina Silaghi[2,5], Mihaela Mocan[3,5], Horatiu Silaghi[4] & Ioan Andrei Veresiu[1,5]
[1]Center for Diabetes, Nutrition and Metabolic Diseases Cluj-Napoca, Cluj-Napoca, Cluj County, Romania; [2]Endocrinology Clinic, Cluj-Napoca, Cluj County, Romania; [3]1st Internal Medicine Department, Cluj-Napoca, Cluj County, Romania; [4]5th Department of Surgery, 'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania; [5]'Iuliu Hatieganu' University of Medicine and Pharmacy, Cluj-Napoca, Cluj County, Romania.

Polyglandular autoimmune syndromes (PAS) are a heterogeneous group of rare diseases characterized by autoimmune activity against more than one endocrine organ, although non-endocrine organs can be affected. In PAS III, *autoimmune thyroiditis* occurs with another organ-specific autoimmune disease, but the syndrome cannot be classified as PAS I or II.
A 29-years old man was refer to our center for diagnostic confirmation with the following complaints: xerostomia, polyuria, polydipsia, nocturnal enuresis, 10 kg weight loss in the last 2 months, blurred vision and marked fatigability. One week before admission the lab exams revealed: blood glucose (BG) of 527 mg/dl, severe dyslipidemia, glycosuria, ketonuria and a basal bolus regimen with insulin glargine and lispro was started. Labs findings displayed: BG = 276 mg/dl, moderate hypertriglyceridemia, glycosuria, low sodium and chloride and the A1c = 17.73% was consistent with a sever glycemic imbalance in the last 3 months. The specific antibodies for type 1 diabetes (GAD, ICA, IA_2, anti-insulin) were negative and the C peptide was low. The screening for other autoimmune diseases was positive for thyroiditis (high TPO antibodies) and celiac diseases (high IgA anti-transglutaminase antibodies) and were confirmed by thyroid

ultrasound, gastroscopy (paving stone duodenum) and histopathological examination. In order to improve the glycemic control, the insulin doses were adjusted according to the glycemic values and carbs ingestion. Nutritional education was conducted emphasizing the importance of gluten-free diet and correct estimation of the carbs intake. The lipid profile normalized after normoglycemia was achieved.
Despite the lack of specific antibodies, the patient profile, lab exams and association with other autoimmune diseases support the diagnosis of type 1 diabetes. The zinc transporter-8 (ZnT8) antibodies are not yet available in our country. The evolution in these cases may be unpredictable and requires the concomitant treatment of all the conditions involved in order to achieve the therapeutic success.

Nutritional status in ambulatory patients by Medicine Laboratory

Francisco Javier Merida De La Torre & Nieves Bel Peña
Health Management Area Serrania, Medicine Laboratory, Ronda, Malaga, Spain.

Nutritional status has an important effect on the progression of any disease, not only in hospitalized patients, even more in ambulatory patient of primary care. Although there are many systems of evaluating nutritional status, they are costly and subject to variability amongst individuals. The Medicine Laboratory can correctly perform a nutritional evaluation in a quick an efficient manner.
Objective
Analyze the nutritional status by CONUT nutritional evaluation method performed by the Medicine Laboratory in ambulatory patients of primary care our Health Management Area in 2016.
Materials and methods
The CONUT method for nutritional evaluation was used. This method is based on determining undernutrition according to levels of total lymphocyte count total cholesterol and serum albumin. During the study, the results of rutinary blood tests were used, not additional bllod tests were performed. The focus was a sample size of all patient admitted in primary care centers, $n = 1454$ patients. Statistics data: accepted error 3.5%, C.I. 99%. The frequency of nutritional risk was calculated analysed alongside data on patients' sex, age.
Results
1454 patients were studied, 68.5%were not undernourished, 27,4% were mild undernourished and 4,1% were moderate or severe undernourished. The mean age of patients was 57.9 years, 60.9% were women and 39.1% were men. 6.7% of men were moderate or severely undernourished, only 2.3% of women studied were moderate or severely undernourished. The statistics differences by gender were significatives.
Conclusion
The nutritional evaluation performed by the Medicine Laboratory is an effective tool to evaluate nutritional status and take corrective measures. Although there are many experiences in CONUT nutritional evaluation in hospitalized patients, we think that this method is useful in primary care too.

Satiety, hunger and gastrointestinal hormones after a test meal in patients after gastric bypass surgery: an association with amino acids

Merel van den Broek[1], Loek de Heide[1], Nic Veeger[2,3], Marloes Emous[5] & André van Beek[4]
[1]Department of Internal Medicine, Medical Center Leeuwarden, Leeuwarden, The Netherlands; [2]Department of Epidemiology, University of Groningen, University Medical Center Groningen, Groningen, The Netherlands; [3]Department of Epidemiology, Medical Center Leeuwarden, Leeuwarden, The Netherlands; [4]Department of Endocrinology, University of Groningen, Groningen, The Netherlands; [5]Department of Surgery, Medical Center Leeuwarden, Leeuwarden, The Netherlands.

Background
Nutrition is essential in achieving maximal treatment success after bariatric surgery, and is simultaneously beneficial for avoiding long-term complications. Dietary protein could have an important role, because of its positive effects on preservation of muscle mass and induction of satiety in non-bariatric subjects. Therefore, we investigated the effects of dietary protein, assessed by amino acid composition, on satiety, hunger and gastrointestinal hormones after gastric bypass surgery.
Methods
Participants who previously had undergone primary gastric bypass surgery were studied during an oral Mixed Meal Tolerance Test (MMTT). Satiety and hunger were assessed every 30 min by means of a visual analogue scale. Blood samples were collected at baseline, every 10 min during the first half hour and every 30 min till 210 min after the start. The plasma samples were assessed for 24 amino acids including derivatives and four gastrointestinal hormones.
Results
30 female and 12 male subjects aged 48 ± 11 years, 31–76 months after surgery with total weight loss of $30 \pm 9\%$ completed the MMTT. After ingestion increases in satiety, the hormones PYY, active GLP1, inactive GLP1 and most amino acids were observed, while hunger, ghrelin and citrulline declined. Satiety scores above the median were associated with increased plasma levels of PYY, active and inactive GLP1. Hunger scores below the median (indicating less hunger) were associated with increased levels of PYY and a reduced attenuation in ghrelin. Higher concentrations of several plasma levels of amino acids especially histidine, serine, arginine, glutamine and glycine were observed in subjects experiencing more satiety, higher levels of PYY, active or inactive GLP1. Additional analyses are underway.
Conclusions
Our exploratory analysis shows positive associations between various plasma amino acids in groups with differences in satiety and gastrointestinal hormones. This provides new insights to optimize the outcomes of bariatric surgery.

The fatty acid profile in diabetic children

Cíntia Castro-Correia[1], Sara Sousa[2], Sónia Norberto[3], Cristina Delerue-Matos[4], Valentina Domingues[2], Manuel Fontoura[1] & Conceição Calhau[3,4]
[1]Hospital S João – Unidade Endocrinologia Pediátrica, Porto, Portugal; [2]Requimte/LAQV-GRAQ – Instituto Superior de Engenharia, Instituto Politécnico do Porto, Porto, Portugal; [3]Department of Biochemistry, Faculty of Medicine, University of Porto, Centro de Investigação Médica, Porto, Portugal; [4]CINTESIS – Center for Research in Health Technologies and Information Systems, Porto, Portugal.

Several studies have shown a link between pro-inflammatory activity and the presence or relative deficit of some fatty acids. A low amount of omega 3 fatty acids, appears to promote an inflammatory profile. The omega 6 fatty acids have also the same effect. It is well known that a chronic low-grade inflammation is associated to several diseases, namely, diabetes. The follow-up of children and young people with Type 1 diabetes involves the periodic evaluation of their lipidic profile, however it is not done regularly the evaluation of the profile on the concentration of different types of fatty acids.
Objective
To characterize, and compare, fatty acids profile in children with Type 1 diabetes and healthy children.
The authors observed that the ratio of omega 6/omega 3 fatty acids was higher in the control population. Omega 6 levels were higher in the diabetic children compared to the control group. Several other differences in free fatty acid composition were observed.
Conclusion
Our findings showed higher levels of alpha-linolenic acid, EPA and DHA, as well as mono and polyunsaturated fatty acids in diabetic children. This fact is attributed to pharmacological therapy and nutritional management of these children. These findings reinforce the importance of a precocious nutritional attention and intervention in the diabetic child treatment.

Sitagliptin use may reduce oral cancer risk in patients with type 2 diabetes

Chin-Hsiao Tseng
National Taiwan University Hospital, Taipei, Taiwan.

Background
Whether sitagliptin may affect oral cancer risk has not been investigated.
Methods
The reimbursement database of the National Health Insurance in Taiwan was used. Diabetic patients newly treated with sitagliptin ($n=50033$) or other antidiabetic drugs ($n=277038$) within 1999–2008 were followed for oral cancer until December 31, 2011. The treatment effect was estimated by Cox regression adjusted for propensity score (PS) or using PS weighting by inverse probability of treatment weighting approach.
Results
The overall hazard ratios suggested a 20% lower risk without statistical significance. In tertile analyses, the PS-adjusted hazard ratios for the first (<6.53 months), second (6.53–14.00 months) and third (>14 months) tertile of cumulative duration were 1.382 (0.899, 2.125), 0.908 (0.566, 1.456) and 0.464 (0.272, 0.789), respectively; and were 1.324 (0.864, 2.030), 0.871 (0.545, 1.394) and 0.447 (0.263, 0.760), respectively, for PS-weighted.
Conclusions
Sitagliptin may reduce oral cancer risk when the cumulative duration is >14 months.

Does a first-degree family history of diabetes impact placental vascular circulation and placental inflammatory response?

Jacob Bar
WMC and Tel Aviv University, Tel Aviv, Israel.

Background
Experimental and clinical studies have demonstrated that heritability of diabetes is associated with marked hyperinsulinemia, impaired endothelial function, and inflammatory up-regulation. However, no studies have examined whether a family history of diabetes effects placental maternal and fetal vascular circulation, or placental inflammatory response. The present study was designed to investigate the impact of first-degree family history of diabetes (FHD) on placental vascular circulation and inflammatory lesions.
Methods
402 pregnant women were divided into two groups according to presence of of first-degree FHD: Group 1 included 255 subjects without FHD, Group 2 included 145 subjects with FHD. Placental histology was performed for vascular circulation and inflammation lesions of maternal and fetal origin.
Results
Maternal vascular supply (MVS) abnormalities of the placental bed was significantly higher in subjects with FHD, compared to group 2 (33% vs 52%, $P<0.005$). Fetal vascular supply (FVS) abnormalities as well as maternal and fetal inflammatory lesions (MIR and FIR) did not differed significantly between groups. In the logistic regression analysis, FDH is an independent and significant predictor predictor of maternal vascular supply abnormalities ($P=0.001$) and more than doubles risk of this outcome (OR 2.084, 95% CI 1.337–3.247, $P=0.001$). Gestational diabetes incidence was significantly higher in subjects with FHD.
Conclusion
We demonstrated that first-degree family history of diabetes is associated with an increased rate of maternal vascular malperfusion abnormalities.

Episodes of poorly controlled diabetes in 1486 patients admitted in Orthopedic Surgery and Traumatology

María Molina Vega[1], Pilar Losada Mora[3], Alfonso M Garrido Castro[2], Jose M García Almeida[1], Juan L Carrillo Linares[2], Miguel Damas Fuentes[1], Carmen Rodríguez García[1] & Cristina Díaz Perdigones[1]
[1]Endocrinology, Hospital Virgen de la Victoria, Malaga, Spain; [2]Internal Medicine, Hospital Virgen de la Victoria, Malaga, Spain; [3]Cardiology, Hospital Virgen de la Victoria, Malaga, Spain.

Introduction
Episodes of poorly controlled diabetes (DM) are one of the most frequent medical complications during hospitalization in the elderly population.
Objectives
To analyze the prevalence of episodes of diabetic decompensation in patients admitted in Orthopedic Surgery and Traumatology (OST) area.
Material and methods
Descriptive analysis of patients admitted to OST Service who presented abnormally high or decreased blood glucose levels according to the criterion of the Orthopedic Surgeon who performed the consultation.
Results
From June 2008 to December 2014, 1486 consultations were sent to Internal Medicine, Cardiology or Endocrinology, regarding patients admitted to the OST area who had suffered some type of medical decompensation during admission. Of these patients, 437 (29.4%) had a documented history of DM. The reason for consultation was poorly controlled DM in 124 patients (8.3%), with 111 patients (89.5%) presenting hyperglycemia and 13 (10.5%) presenting hypoglycaemia. However, since the consultations were made by the Orthopedic Surgeon who requested it, after the initial evaluation of all these patients, the diagnosis of poorly controlled DM was only considered in 108 patients (7.4% of the total decompensated patients), since the rest, despite presenting glycemia above 125 on fasting, were considered controlled taking into account their particular clinical situation. This implies an actual decompensation of 24.7% of patients with known DM.
Conclusions
DM is a cause of medical decompensation in 8.3% of patients admitted to OST. One in four known diabetics had abnormal blood glucose levels.
Together with previous studies in which we concluded that approximately one in six known hypertensive patients is decompensated during admission to surgical areas, we suggest that an early evaluation of blood glucose and blood pressure performed by Cardiology, Endocrinology or Internal Medicine could be beneficial in terms of morbidity.
